26.7. Coverings of CW-complexes . . . 672
26.8. Spanning trees of graphs (∗) . . . 676
Exercises for Chapter 26 . . . 679
27. CW-complexes II: Advanced properties . . . 682
27.1. Constructing homotopies on infinite-dimensional CW-complexes (∗) . . . 682
27.2. The Homotopy Extension Theorem . . . 686
27.3. Fundamental groups of CW-complexes . . . 691
27.4. The Cellular Approximation Theorem . . . 697
27.5. Proof of Proposition 27.17 (∗) . . . 702
Exercises for Chapter 27 . . . 707
28. Higher homotopy groups . . . 709
28.1. Definition of the higher homotopy groups . . . 709
28.2. Alternative descriptions of homotopy groups . . . 714
28.3. Properties and basic calculations of higher homotopy groups . . . 717
28.4. Covering spaces and higher homotopy groups . . . 722
28.5. Are there any higher homotopy groups that are non-trivial? . . . 725
28.6. The Poincaré Conjecture . . . 728
Exercises for Chapter 28 . . . 732
29. The homology groups of a topological space . . . 734
29.1. Singular chains . . . 734
29.2. Definition of the homology groups of a topological space . . . 737
29.3. First calculations of homology groups . . . 742
29.4. Algebraic chain complexes . . . 744
29.5. The functoriality of homology groups . . . 746
29.6. Direct products and direct sums (∗) . . . 748
29.7. The homology groups of a direct sum . . . 749
Exercises for Chapter 29 . . . 750
30. Homology and homotopies . . . 752
30.1. Chain homotopies . . . 752
30.2. Homology and homotopic maps . . . 753
Exercises for Chapter 30 . . . 760
31. Long exact sequences and the homology of quotient spaces . . . 761
31.1. Reduced homology groups . . . 761
31.2. Long exact sequences . . . 763

31.3. The homology groups of spheres . . . 765
31.4. Basic homological algebra . . . 769
31.5. Relative homology groups . . . 774
31.6. The Excision Theorem . . . 782
31.7. The proof of the Excision Theorem 31.17: the idea . . . 786
31.8. The proof of the Excision Theorem 31.17: the full details . . . 786
Exercises for Chapter 31 . . . 800
32. Applications of the long exact sequence in homology . . . 804
32.1. Applications to topological manifolds (∗) . . . 804
32.2. Explicit generators of homology groups . . . 811
32.3. Suspensions and homology groups . . . 817
32.4. The degree of a self-map of a sphere . . . 819
32.5. The local degree . . . 826
Exercises for Chapter 32 . . . 834
33. The Mayer–Vietoris sequence and its applications . . . 836
33.1. Split exact sequences . . . 836
33.2. The Mayer–Vietoris sequence . . . 840
33.3. Applications of the Mayer–Vietoris sequence . . . 844
33.4. The Mayer–Vietoris Theorem for manifolds and CW-complexes . . . 846
33.5. The homology groups of the torus and the Klein bottle . . . 848
33.6. The homology groups of a knot complement . . . 853
33.7. The homology groups of a mapping cone (∗) . . . 855
33.8. The homology groups of a mapping torus (∗) . . . 859
Exercises for Chapter 33 . . . 863
34. Homology groups and direct limits . . . 867
34.1. Direct limits and induced maps . . . 867
34.2. The homology groups of a nested sequence of topological spaces . . . 869
34.3. The homology groups of the wedge of topological spaces . . . 871
34.4. Moore spaces (∗) . . . 874
Exercises for Chapter 34 . . . 878
35. Cellular homology . . . 880
35.1. The definition of cellular homology . . . 880
35.2. The relationship between cellular and singular homology . . . 883
35.3. The cellular boundary maps . . . 888
35.4. The homology groups of 2-dimensional manifolds . . . 893
35.5. The homology groups of real projective spaces . . . 897
Exercises for Chapter 35 . . . 899
36. The Jordan Curve Theorem . . . 902
Exercises for Chapter 36 . . . 909
37. Topological robotics . . . 911
37.1. The matrix groups SO(3) and SU(2) . . . 911
37.2. The belt trick . . . 915

37.3. Topological robotics . . . 917
37.4. Linkages . . . 919
38. The first homology group and the fundamental group . . . 922
38.1. The Hurewicz homomorphism . . . 922
38.2. The Hurewicz homomorphism in higher dimensions . . . 931
Exercises for Chapter 38 . . . 934
39. Simplicial complexes and homology groups of manifolds . . . 935
39.1. Simplicial complexes . . . 935
39.2. The top-dimensional homology group of a manifold . . . 938
39.3. The fundamental class of a compact orientable manifold . . . 945
39.4. The homology groups of the connected sum of two manifolds . . . 954
39.5. Representing homology classes by manifolds (∗) . . . 957
39.6. The degree of a map between oriented manifolds . . . 959
Exercises for Chapter 39 . . . 964
40. The Euler characteristic . . . 966
40.1. The Euler characteristic and homology groups . . . 966
40.2. Properties of the Euler characteristic . . . 970
40.3. Groups acting on spheres . . . 976
40.4. Curves on surfaces . . . 977
40.5. Graphs (∗) . . . 980
40.6. The Lefschetz Fixed Point Theorem (∗) . . . 981
Exercises for Chapter 40 . . . 982
41. Applications of the Euler characteristic (∗) . . . 985
41.1. Building a leather football . . . 985
41.2. Platonic solids . . . 986
41.3. Homology spheres . . . 992
41.4. Planar graphs . . . 994
42. Homology with coefficients . . . 1001
42.1. The tensor product of abelian groups . . . 1001
42.2. The homology groups of a topological space with coefficients . . . 1007
42.3. Exact functors . . . 1012
42.4. The G-torsion of an abelian group . . . 1015
42.5. The Universal Coefficient Theorem . . . 1025
42.6. Splittings of the Universal Coefficient Theorem . . . 1031
42.7. Isomorphisms on homology groups induce chain homotopies (∗) . . . 1034
42.8. Homological algebra over an arbitrary commutative ring (∗) . . . 1035
42.9. The Eilenberg-Steenrod axioms for homology (∗) . . . 1037
Exercises for Chapter 42 . . . 1039
43. The Künneth Theorem . . . 1041
43.1. The tensor product of chain complexes . . . 1041
43.2. The Eilenberg-Zilber Theorem . . . 1043
43.3. The Künneth Theorem for chain complexes . . . 1046

43.4. The Künneth Theorem for topological spaces . . . 1049
Exercises for Chapter 43 . . . 1052
44. Applications of homology groups . . . 1053
44.1. Persistent homology (∗) . . . 1053
44.2. Division algebras . . . 1054
44.3. The transfer map . . . 1064
44.4. The Borsuk-Ulam Theorem and the Ham-Sandwich Theorem . . . 1068
Exercises for Chapter 44 . . . 1074
45. Topological manifolds . . . 1075
45.1. Topological manifolds and CW-structures . . . 1075
45.2. The Topological Collar Neighborhood Theorem . . . 1077
45.3. The Euler characteristic of compact topological manifolds . . . 1079
45.4. Variations of the excision theorem . . . 1081
45.5. The double of a (topological) manifold . . . 1085
45.6. The local homology of topological manifolds . . . 1088
45.7. R-Sections on topological manifolds . . . 1095
45.8. Orientations of topological manifolds . . . 1099
45.9. Induced orientations . . . 1105
Exercises for Chapter 45 . . . 1110
46. The fundamental class . . . 1112
46.1. The fundamental class of an oriented topological manifold . . . 1112
46.2. Lifts of sections on manifolds . . . 1121
46.3. Proof of Theorem 46.4 . . . 1127
46.4. Proof of Theorems 46.2 and 46.3 . . . 1129
46.5. Further properties of topological manifolds . . . 1132
46.6. The fundamental class and induced orientations . . . 1135
46.7. Lifts of homology orientations for topological manifolds with boundary (∗) . . . 1141
Exercises for Chapter 46 . . . 1144
47. Chirality . . . 1146
47.1. Chiral objects . . . 1146
47.2. Chiral knots . . . 1147
47.3. Chiral topological manifolds . . . 1149
Exercises for Chapter 47 . . . 1154
48. The cohomology groups of a topological space . . . 1156
48.1. The Hom-functor . . . 1156
48.2. Cochain complexes . . . 1158
48.3. Dual cochain complexes . . . 1161
48.4. The singular cohomology groups of topological spaces . . . 1164
48.5. Basic properties of cohomology groups . . . 1172
48.6. Reduced cohomology groups . . . 1176
Exercises for Chapter 48 . . . 1178
49. Chain complexes with isomorphic homology groups . . . 1180

49.1. Isomorphisms of homology groups are homotopy equivalences . . . 1180
49.2. Proof of Propositions 49.1 and 49.2 . . . 1183
49.3. Singular and cellular chain complexes . . . 1188
Exercises for Chapter 49 . . . 1191
50. Properties of cohomology groups . . . 1192
50.1. Excision theorems for cohomology groups . . . 1192
50.2. Cellular cohomology . . . 1193
50.3. Explicit generators of cohomology groups . . . 1198
50.4. Excisive triads and the Mayer–Vietoris Theorem for cohomology groups . . . 1203
Exercises for Chapter 50 . . . 1210
51. The Universal Coefficient Theorems . . . 1211
51.1. The Ext group . . . 1211
51.2. The Universal Coefficient Theorem for Cohomology Groups . . . 1219
51.3. Proof of Proposition 51.18 (∗) . . . 1229
51.4. Change of coefficients in cohomology (∗) . . . 1231
Exercises for Chapter 51 . . . 1235
52. Cohomology groups and limits . . . 1237
52.1. Direct limits of direct systems . . . 1237
52.2. Inverse limits of inverse systems . . . 1241
52.3. Cohomology groups and inverse limits . . . 1244
52.4. The cohomology group of an ascending sequence of topological spaces . . . 1250
Exercises for Chapter 52 . . . 1253
53. Cohomology with compact support and bounded cohomology . . . 1255
53.1. The definition of cohomology with compact support and basic properties . . . 1255
53.2. Cohomology with compact support and direct limits . . . 1260
53.3. Bounded cohomology (∗) . . . 1265
Exercises for Chapter 53 . . . 1269
54. De Rham cohomology of manifolds . . . 1270
54.1. Alternating forms and the wedge-product . . . 1270
54.2. The de Rham cohomology of a manifold . . . 1272
54.3. Partitions of unity . . . 1276
54.4. The Poincaré Lemma . . . 1277
54.5. Applications of the Poincaré Lemma to classical vector calculus (∗) . . . 1282
54.6. More properties of the de Rham cohomology groups . . . 1283
Exercises for Chapter 54 . . . 1287
55. The relationship between de Rham cohomology and singular cohomology . . . 1289
55.1. Smooth cohomology theories . . . 1289
55.2. Smooth singular cohomology . . . 1293
55.3. The isomorphism between singular and de Rham cohomology . . . 1298
55.4. Realizing cohomology classes by maps to S^1 . . . 1300
55.5. The wedge product of differential forms (∗) . . . 1304
Exercises for Chapter 55 . . . 1307

56. The Eilenberg-Zilber theorem and the cross product . . . 1308
56.1. The Eilenberg-Zilber theorem . . . 1308
56.2. Proof of the Eilenberg-Zilber Theorem 56.1 . . . 1309
56.3. The relative Eilenberg–Zilber map Υ . . . 1314
56.4. The cross product on homology . . . 1316
56.5. Product orientations . . . 1318
56.6. The shuffle product and the proof of Proposition 56.11 $(*)$ . . . 1323
56.7. The Acyclic Model Theorem . . . 1325
57. The cup product . . . 1332
57.1. A first definition of the cup product . . . 1332
57.2. An alternative definition of the cup product . . . 1333
57.3. The cup product of the torus . . . 1346
57.4. The cup product of the surface of genus 2 . . . 1348
57.5. The cup product of the real projective plane $(*)$ . . . 1351
57.6. The cup product and the wedge product $(*)$ . . . 1354
Exercises for Chapter 57 . . . 1355
58. The relative cup product . . . 1356
58.1. Definition of the relative cup product . . . 1356
58.2. Calculations using the relative cup product . . . 1361
58.3. The Lusternik-Schnirelmann category . . . 1365
Exercises for Chapter 58 . . . 1370
59. The cap product . . . 1371
59.1. The definition of the cap product and calculations . . . 1371
59.2. The relative cap product and more properties of the cap product . . . 1376
Exercises for Chapter 59 . . . 1384
60. The Product Theorem and the Künneth Theorem for cohomology . . . 1385
60.1. The Product Theorem . . . 1385
60.2. Proof of the Product Theorem 60.1 . . . 1390
60.3. The Künneth Theorem for cohomology groups . . . 1401
60.4. The cohomology ring of product topological spaces . . . 1406
Exercises for Chapter 60 . . . 1411
61. Poincaré-duality . . . 1413
61.1. The Poincaré Duality Theorem . . . 1413
61.2. Consequences of the Poincaré Duality Theorem 61.1 . . . 1416
61.3. A geometric approach to the Poincaré Duality Theorem 61.1 $(*)$ . . . 1420
61.4. The proof of Poincaré Duality for topological manifolds without boundary . . . 1426
61.5. The proof of Poincaré Duality for topological manifolds with boundary . . . 1440
Exercises for Chapter 61 . . . 1445
62. The cup product of projective spaces . . . 1447
62.1. Non-singular pairings and the cup product . . . 1447
62.2. The cup product of $\mathbb{C}\mathrm{P}^n$ and applications . . . 1452
62.3. The cup product of $\mathbb{R}\mathrm{P}^n$ and applications . . . 1457

62.4. The cup product of quaternionic and octonion projective spaces (∗) 1461
62.5. Division algebras 1462
Exercises for Chapter 62 1466
63. The Hopf invariant 1468
63.1. The Hopf map is not null-homotopic 1468
63.2. The Hopf invariant 1471
63.3. The Hopf invariant and multiplication maps 1479
Exercises for Chapter 63 1486
64. Differential topology II: Regular and Tubular Neighborhoods 1488
64.1. Regular neighborhoods 1488
64.2. The Tubular Neighborhood Theorem II 1492
Exercises for Chapter 64 1501
65. Differential topology III: Whitney Approximation and Whitney Embedding . . 1502
65.1. The Regular Value Theorem II (∗) 1502
65.2. The Whitney Approximation Theorem 1506
65.3. Embeddings of (topological) manifolds into $\mathbb{R}^n$ 1510
65.4. The Whitney Embedding Theorem (∗) 1520
65.5. Neighborhood retracts 1521
65.6. Representing one-dimensional homology classes by submanifolds 1531
Exercises for Chapter 65 1532
66. Alexander Duality 1534
66.1. The basic Alexander Duality Theorem 1534
66.2. Immersions and embeddings of manifolds into $\mathbb{R}^n$ 1540
66.3. The generalized Alexander Duality Theorem 1544
66.4. The square-peg problem 1551
Exercises for Chapter 66 1554
67. The cup product and algebraic intersection numbers 1556
67.1. The Transversality Theorems 1556
67.2. Algebraic intersection numbers of submanifolds 1559
67.3. The cup product and algebraic intersection numbers 1565
67.4. Proof of Theorem 67.10 1569
67.5. Further applications of Theorem 67.10 1580
67.6. Is the algebraic intersection number a complete invariant? 1582
67.7. Higher dimensional analogue of Theorem 67.10 1585
Exercises for Chapter 67 1588
68. Intersections of cycles and the cup product 1590
68.1. Intersections of cycles 1590
68.2. Proof of Theorem 68.5 1596
68.3. Intersections of transverse maps of manifolds 1607
68.4. The algebraic $\mathbb{F}_2$-intersection number (∗) 1608
Exercises for Chapter 68 1610
69. Homology, cohomology and submanifolds 1611

69.1. Codimension one submanifolds . . . 1611
69.2. Representing homology classes by submanifolds . . . 1614
69.3. The basic Thom-Pontryagin Theory . . . 1618
Exercises for Chapter 69 . . . 1622
70. Applications to knot theory . . . 1623
70.1. Curves on 2-dimensional manifolds (∗) . . . 1623
70.2. The longitude of a knot . . . 1625
70.3. Seifert surfaces . . . 1629
70.4. Linking numbers . . . 1634
70.5. Alexander duality and linking numbers (∗) . . . 1644
Exercises for Chapter 70 . . . 1646
71. The intersection form of topological manifolds I: definition and calculations . . . 1649
71.1. (Anti-) symmetric forms . . . 1649
71.2. The definition of the intersection form of topological manifolds . . . 1652
71.3. The intersection form and degree-one maps . . . 1657
71.4. The connected sum of topological manifolds . . . 1658
71.5. The intersection form and the connected sum operation . . . 1660
Exercises for Chapter 71 . . . 1664
72. The intersection form of topological manifolds II: Algebra and 4-dimensional manifolds . . . 1665
72.1. Non-singular anti-symmetric forms . . . 1666
72.2. Interlude: Sphere-packing . . . 1668
72.3. Non-singular symmetric forms over the real numbers . . . 1670
72.4. Non-singular symmetric forms over the integers . . . 1675
72.5. The intersection forms of 4-dimensional (topological) manifolds . . . 1680
72.6. Symmetric forms over $\mathbb{F}_2$ . . . 1687
Exercises for Chapter 72 . . . 1688
73. Handlebodies and Heegaard splittings of 3-dimensional manifolds . . . 1690
73.1. The boundary connected sum operation . . . 1690
73.2. Heegaard splittings of 3-dimensional manifolds . . . 1695
73.3. The mapping class group (∗) . . . 1703
Exercises for Chapter 73 . . . 1710
74. The linking pairing on rational homology spheres . . . 1711
74.1. Rational homology spheres . . . 1711
74.2. The Bockstein homomorphisms . . . 1712
74.3. The cup product and the cap product with coefficients . . . 1714
74.4. The linking pairing on odd-dimensional rational homology spheres . . . 1718
74.5. Proofs of Propositions 74.16 and 74.17 . . . 1721
74.6. Linking forms of lens spaces . . . 1724
74.7. The proof of Proposition 74.20 . . . 1727
74.8. Computing the linking pairing by intersecting singular simplices . . . 1733
74.9. Linking forms and intersection forms (∗) . . . 1734

Exercises for Chapter 74 1742
75. Branched coverings and chiral knots 1743
75.1. Branched coverings 1743
75.2. The hyperelliptic involution and branched coverings of surfaces 1746
75.3. Branched coverings of 3-manifolds 1749
75.4. Branched coverings defined by knots 1752
Exercises for Chapter 75 1757
76. Cobordisms 1759
76.1. The cobordism rings 1759
76.2. The cobordism groups of rational homology spheres $(*)$ 1771
Exercises for Chapter 76 1780
77. Vector bundles and Pontryagin classes 1782
77.1. Vector bundles 1782
77.2. The pullback and the Whitney sum of vector bundles 1789
77.3. Pontryagin classes 1794
77.4. Pontryagin classes as invariants of manifolds 1797
77.5. Pontryagin numbers and the signature 1798
Exercises for Chapter 77 1805
78. Steenrod operations 1806
78.1. The axioms of Steenrod operations 1806
78.2. Steenrod operations and connecting homomorphisms 1810
78.3. Steenrod operations and suspensions 1815
78.4. Proof of Theorem 78.2 I 1820
78.5. Proof of Theorem 78.2 II 1826
Exercises for Chapter 78 1831
79. The Adem relations 1832
79.1. Application of the Adem relations to homotopy groups of spheres 1833
79.2. Decomposing Steenrod operations and the Hopf invariant revisited 1838
79.3. The Steenrod cyclic reduced powers $(*)$ 1844
Exercises for Chapter 79 1846
80. The Hurewicz Theorem in higher dimensions 1847
80.1. The group structure on $\pi_n(X, x_0)$ 1847
80.2. The statement of the Hurewicz Theorem and applications 1851
80.3. The proof of the Hurewicz Theorem 80.5 1856
Exercises for Chapter 80 1867
81. Applications of the Hurewicz Theorem 1869
81.1. Paths acting on homotopy groups 1869
81.2. Group rings 1872
81.3. Homotopy groups of $S^1 \vee S^2$ 1875
81.4. The Connected Sum Decomposition Theorem $(*)$ 1878
Exercises for Chapter 81 1881
82. Relative homotopy groups 1883

82.1. The definition of relative homotopy groups . . . 1883
82.2. The long exact homotopy sequence of a pair . . . 1889
82.3. Paths acting on relative homotopy groups . . . 1893
82.4. Alternative description of relative homotopy groups . . . 1896
82.5. Connected (pairs of) topological spaces . . . 1899
82.6. The relative Hurewicz Theorem . . . 1901
82.7. Excision for relative homotopy groups? . . . 1907
Exercises for Chapter 82 . . . 1909
83. Fibrations . . . 1911
83.1. Definition and examples of fibrations . . . 1911
83.2. The homotopy fiber of a fibration . . . 1915
83.3. The long exact homotopy sequence of a Serre fibration . . . 1921
83.4. Proof of Theorem 83.7 . . . 1924
83.5. The path space fibration . . . 1929
83.6. Every map can be replaced by a fibration . . . 1937
Exercises for Chapter 83 . . . 1942
84. Cofibrations $(*)$ . . . 1945
84.1. Cofibrations: definition and examples . . . 1946
84.2. Properties of cofibrations . . . 1951
84.3. Adjoint functors . . . 1954
Exercises for Chapter 84 . . . 1959
85. Fiber bundles . . . 1960
85.1. The definition of fiber bundles . . . 1960
85.2. Hopf fibrations arising from complex and quaternionic projective spaces . . . 1969
85.3. The Hopf fibration arising from the octonions $(*)$ . . . 1973
Exercises for Chapter 85 . . . 1980
86. Homotopy groups of Lie groups . . . 1982
86.1. Topological groups and Lie groups . . . 1982
86.2. The homotopy groups of $\mathrm{O}(n)$, $\mathrm{U}(n)$ and $\mathrm{Sp}(n)$ . . . 1986
86.3. Spin groups . . . 1992
86.4. The Bott Periodicity Theorem . . . 1996
86.5. H-spaces $(*)$ . . . 2000
Exercises for Chapter 86 . . . 2005
87. The Thom-Pontryagin Theory . . . 2006
87.1. The generalized Thom-Pontryagin construction . . . 2006
87.2. The Thom-Pontryagin construction and homotopy groups . . . 2010
87.3. The fattened cobordism groups and the Thom-Pontryagin Theorem . . . 2016
87.4. The calculation of the fattened cobordism group $\Omega_1^{\mathrm{fat}}(\mathbb{R}^3)$ . . . 2023
87.5. The fattened cobordism group $\Omega_{2n-1}^{\mathrm{fat}}(\mathbb{R}^{4n-1})$ . . . 2028
Exercises for Chapter 87 . . . 2032
88. Thom-Pontryagin Theory II: The Freudenthal Suspension Theorem . . . 2034
88.1. The framed cobordism group . . . 2034

88.2. The Freudenthal Suspension Theorem . . . 2039
88.3. The calculation of the framed cobordism groups $\Omega_1^{\mathrm{fr}}(\mathbb{R}^{n+1})$ for $n \geq 3$ . . . 2045
88.4. Further results obtained using the Thom-Pontryagin approach . . . 2053
Exercises for Chapter 88 . . . 2054
89. Summary of homotopy groups of spheres . . . 2055
Index . . . 2059
Statements and Results . . . 2070
Notation . . . 2073
Calculations . . . 2075

1. Topological spaces

In this chapter we give the definition of topological spaces, we provide many examples and we discuss a long list of basic properties and constructions. Many of these results might well be familiar to the reader. Nonetheless we attempt to give a fairly complete list of basic statements so that later on we have a firm common foundation to work with.

1.1. **The definition of a topological space.**

In this section we give the definition of a topological space and we discuss some very basic definitions and statements. Presumably most readers will have seen this material. Throughout these lecture notes, in the proofs, we strive for giving precise references to earlier results. The main exceptions are the lemmas from this Section 1.1. Usually we use them without referring to them explicitly.

We start out with a basic definition of set theory.

Definition. Let $\{U_i\}_{i\in I}$ be a family of subsets of a given set X. We write

$$\begin{aligned} \bigcup_{i\in I} U_i &= \{x \in X \mid \text{ there exists an } i \in I \text{ with } x \in X_i\} \\ \bigcap_{i\in I} U_i &= \{x \in X \mid \text{ for every } i \in I \text{ we have } x \in X_i\}. \end{aligned}$$

In particular, if $I = \varnothing$, then $\bigcup_{i\in I} U_i = \varnothing$ and $\bigcap_{i\in I} U_i = X$.[1]

We continue with two elementary lemmas from set theory. Even though they are elementary it is helpful to have them on record.

Lemma 1.1. *Let $f\colon X \to Y$ be a map between two sets X and Y.*[2] *Then*

$$\begin{array}{lrcl}
(1) & \textit{for every } U \subset X \textit{ we have} & U & \subset & f^{-1}(f(U)) \\
 & \textit{furthermore, if } f \textit{ is injective, then we have} & U & = & f^{-1}(f(U)) \\
(2) & \textit{for every } V \subset Y \textit{ we have} & V & \supset & f(f^{-1}(V)) \\
 & \textit{furthermore, if } f \textit{ is surjective, then we have} & V & = & f(f^{-1}(V)) \\
(3) & \textit{for every family } \{U_i\}_{i\in I} \textit{ of subsets of } X \textit{ we have} & f\Big(\bigcup_{i\in I} U_i\Big) & = & \bigcup_{i\in I} f(U_i) \\
(4) & \textit{for every family } \{U_i\}_{i\in I} \textit{ of subsets of } X \textit{ we have} & f\Big(\bigcap_{i\in I} U_i\Big) & \subset & \bigcap_{i\in I} f(U_i) \\
(5) & \textit{for every family } \{V_i\}_{i\in I} \textit{ of subsets of } Y \textit{ we have} & f^{-1}\Big(\bigcup_{i\in I} V_i\Big) & = & \bigcup_{i\in I} f^{-1}(V_i) \\
(6) & \textit{for every family } \{V_i\}_{i\in I} \textit{ of subsets of } Y \textit{ we have} & f^{-1}\Big(\bigcap_{i\in I} V_i\Big) & = & \bigcap_{i\in I} f^{-1}(V_i) \\
(7) & \textit{for every } V \subset Y \textit{ we have} & f^{-1}(Y \setminus V) & = & X \setminus f^{-1}(V).
\end{array}$$

[1] This simple observation will be useful at times.

[2] As a totally irrelevant side remark we would like to point out that the fundamental terms "surjective", "injective" and "bijective" are actually fairly recent additions to the mathematical language. They were first introduced on page 80 of Nicholas Bourbaki's "Théorie des ensembles" first published in 1954, see [Bou2].

Lemma 1.2. (De Morgan's laws) *Let X be a set and let $\{A_i\}_{i\in I}$ be a family of subsets of X. If given a subset $Y \subset X$ we denote its complement by Y^c, then*

$$\Big(\bigcap_{i\in I} A_i\Big)^c = \bigcup_{i\in I} A_i^c \quad \textit{and} \quad \Big(\bigcup_{i\in I} A_i\Big)^c = \bigcap_{i\in I} A_i^c.$$

Or equivalently, in a more cumbersome notation, we have

$$X \setminus \Big(\bigcap_{i\in I} A_i\Big) = \bigcup_{i\in I}(X \setminus A_i) \quad \textit{and} \quad X \setminus \Big(\bigcup_{i\in I} A_i\Big) = \bigcap_{i\in I}(X \setminus A_i).$$

We continue with the following notation.

Notation.

(1) We denote by $\varnothing$ the empty set.
(2) Given a set X we denote by $\mathcal{P}(X)$ its *power set*, i.e. $\mathcal{P}(X)$ is the set of all subsets of X.

The following definition will keep us occupied for the rest of these notes.

Definition.

(1) Let X be a set. A *topology on X* is a subset $\mathcal{T}$ of $\mathcal{P}(X)$[3] with the following properties:
   (a) the empty set and the entire set X lie in $\mathcal{T}$,
   (b) the intersection of *finitely many* sets in $\mathcal{T}$ is again a set in $\mathcal{T}$,
   (c) the union of *arbitrarily many* sets in $\mathcal{T}$ is again a set in $\mathcal{T}$.

   The sets in $\mathcal{T}$ are called *open with respect to $\mathcal{T}$*. If $\mathcal{T}$ is understood from the context, then we just say *open*.
(2) A *topological space* is a pair $(X, \mathcal{T})$, where X is a set and $\mathcal{T}$ is a *topology on X*.

Remark.

(1) Usually we suppress the topology from the notation, e.g. usually we just write "let X be a topological space".
(2) If X is a topological space, then the properties of a topology imply immediately the following three statements:
   (a) the empty set and the entire set X are open,
   (b) the intersection of *finitely many* open sets is again open,
   (c) the union of *arbitrarily many* open sets is again open.

We start out with some very basic examples of topological spaces.

Examples.

(1) Let X be a set, then $\mathcal{T} = \{\varnothing, X\}$ is a topology on X. This topology is sometimes called the *trivial topology on X*.
(2) Let X be a set. Then $\mathcal{T} = \mathcal{P}(X)$ is also a topology on X. In other words, $\mathcal{T}$ is the topology such that every subset of X is open. This topology is usually referred to as the *discrete topology on X*. Sometimes we say that a topological space is discrete, if the topology is indeed the discrete topology.

[3] In more humble words, $\mathcal{T}$ is a set of subsets of X.

(3) Let $X = \mathbb{R}$ and let $\mathcal{T}$ be defined as follows:

$$U \in \mathcal{T} \;:\Longleftrightarrow\; \text{either } U = \varnothing \text{ or } U \text{ is the complement of finitely many points in } \mathbb{R}.$$

For example the sets $\varnothing, \mathbb{R}\setminus\{\pi\}, \mathbb{R}\setminus\{-1, \sqrt{2}\}$ and also $\mathbb{R}$ (since it is the complement of zero points) lie in $\mathcal{T}$. It follows easily from de Morgan's laws that $\mathcal{T}$ is a topology on $X = \mathbb{R}$.

Surely some of the most interesting examples of topological spaces arise from metric spaces. For completeness' sake we recall the definition of metric spaces.

Definition. A *metric space* is a pair (X, d) consisting of a set X and a *metric* d on X, i.e. a map

$$\begin{array}{rcl} X \times X & \to & \mathbb{R}_{\geq 0} := \{x \in \mathbb{R} \,|\, x \geq 0\}, \\ (x, y) & \mapsto & d(x, y), \end{array}$$

with the following properties:

(1) $d(x, y) = 0$ if and only if $x = y$,
(2) for all $x, y \in X$ we have

$$d(x, y) \;=\; d(y, x) \qquad\qquad \text{(symmetry)}$$

(3) for all $x, y, z \in X$ we have

$$d(x, z) \;\leq\; d(x, y) + d(y, z) \qquad \text{(triangle inequality)}.$$

Sometimes we refer to $d(x, y)$ as the *distance between x and y*.

Example. In the following we consider $\mathbb{R}^n$ as a metric space with the *Euclidean metric* given by

$$d(x, y) \;:=\; \|x - y\| \quad \text{where} \quad \|z\| \;=\; \|(z_1, \ldots, z_n)\| \;:=\; \sqrt{z_1^2 + \cdots + z_n^2}\,.$$

The following lemma shows that metric spaces give rise to topological spaces.

Lemma 1.3. *Let (X, d) be a metric space. A subset U of X is called* open *if for every $x \in U$ there exists an $\epsilon > 0$ such that $B_\epsilon(x) := \{y \in X \,|\, d(x, y) < \epsilon\}$ is contained in U. These open sets define a topology on X.*

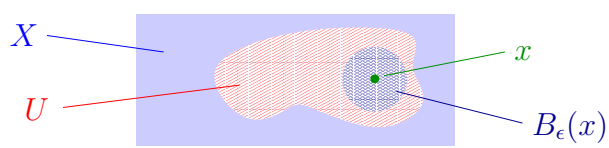

FIGURE 1. Illustration of Lemma 1.3.

Proof.

(1) It is clear that the empty set and X itself are open.

(2) Suppose $U_1, \dots, U_k$ are open subsets of X. We need to show that the intersection $U_1 \cap U_2 \cap \dots \cap U_k$ is also open. Thus let $x \in U_1 \cap U_2 \cap \dots \cap U_k$. For each $i \in \{1, \dots, k\}$ there exists an $\epsilon_i > 0$ with $B_{\epsilon_i}(x) \subset U_i$. We set $\epsilon := \min\{\epsilon_1, \dots, \epsilon_k\}$. Then

$$\begin{array}{ccccc} B_\epsilon(x) & \underset{\substack{\uparrow \\ \text{since } \epsilon \le \epsilon_i}}{\subset} & B_{\epsilon_1}(x) \cap \dots \cap B_{\epsilon_k}(x) & \underset{\substack{\uparrow \\ \text{since } B_{\epsilon_i}(x) \subset U_i}}{\subset} & U_1 \cap U_2 \cap \dots \cap U_k. \end{array}$$

(3) Let $\{U_i\}_{i \in I}$ be a family of open sets. We want to show that $\bigcup_{i \in I} U_i$ is also open. Thus let $x \in \bigcup_{i \in I} U_i$. This means that there exists an $i \in I$ with $x \in U_i$. Since U_i is open there exists an $\epsilon > 0$ with $B_\epsilon(x) \subset U_i$. Thus we have

$$B_\epsilon(x) \ \subset \ U_i \ \subset \ \bigcup_{i \in I} U_i.$$

□

Convention. Given a metric space (X, d) we always view X as a topological space with the topology defined in Lemma 1.3. In particular, unless we say explicitly otherwise, we view $\mathbb{R}^n$ with the topology arising from the Euclidean metric.

We proceed with the next definition.

Definition. Let X be a topological space. We say a subset A of X is *closed* if the complement $X \setminus A$ is open.

The following lemma is an immediate consequence of the definition of a topology and de Morgan's laws, see Lemma 1.2. The lemma mirrors the remark on page 42.

Lemma 1.4. *Let X be a topological space.*

(1) *the empty set and the entire set X are closed,*
(2) *the intersection of* arbitrarily many *closed sets is again closed,*
(3) *the union of* finitely many *closed sets is again closed.*

Remark. Let X be a set. If we specify what we mean by closed sets such that the three properties of Lemma 1.4 are satisfied, then it follows once again from de Morgan's laws that the complements of the closed sets define a topology.

The following proposition gives us important examples of closed and open subsets.

Proposition 1.5. *Let (X, d) be a metric space, let $y \in X$ and let $r \in \mathbb{R}$. Then the following statements hold:*

(1) *the set $B_r(y) = \{x \in X \mid d(x, y) < r\}$ is open in X,*
(2) *the set $\overline{B}_r(y) = \{x \in X \mid d(x, y) \le r\}$ is closed in X,*
(3) *the set $S_r(y) = \{x \in X \mid d(x, y) = r\}$ is closed in X.*

Proof. Let (X, d) be a metric space, let $y \in X$ and let $r \in \mathbb{R}$.

(1) Let $x \in B_r(y)$. We set $s := d(x,y)$. By definition of $B_r(y)$ we have $s < r$. We set $t := r - s$. Since $t > 0$ it suffices to show that $B_t(x) \subset B_r(y)$. Thus let $z \in B_t(x)$. We see that

$$d(y,z) \underset{\substack{\uparrow \\ \text{triangle inequality}}}{\leq} d(x,y) + d(x,z) \ < \ s + t \ = \ r.$$

Thus we see that $z \in B_r(y)$, which is what we needed to show. We refer to Figure 2 for an illustration.

(2) Almost the same argument as in (1) shows that $X \setminus \overline{B}_r(y)$ is open, which implies that $\overline{B}_r(y)$ is closed.

(3) We have $X \setminus S_r(y) = B_r(y) \cup (X \setminus \overline{B}_r(y))$. By (1) and (2) we see that $X \setminus S_r(y)$ is the union of two open sets, thus by the third property of a topological space we see that $X \setminus S_r(y)$ is open, thus $S_r(y)$ is indeed closed. □

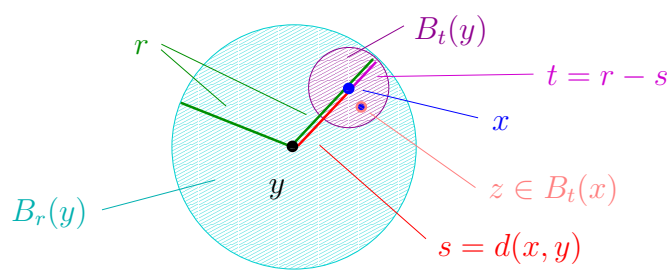

FIGURE 2.

The most frequent application of Proposition 1.5 is to the metric space $\mathbb{R}^n$. Thus we introduce the following notation.

Notation. Given $y \in \mathbb{R}^n$ and $r \in \mathbb{R}$ we write

$$\begin{array}{rcll} B_r^n(y) & := & \{x \in \mathbb{R}^n \mid \|x-y\| < r\} & \text{called } \textit{open } n\textit{-ball} \\ \overline{B}_r^n(y) & := & \{x \in \mathbb{R}^n \mid \|x-y\| \leq r\} & \text{called } \textit{closed } n\textit{-ball} \\ S_r^{n-1}(y) & := & \{x \in \mathbb{R}^n \mid \|x-y\| = r\} & \text{called } (n-1)\textit{-sphere}. \end{array}$$

We adopt the following conventions:

(1) Not surprisingly a 2-ball is often called a *disk* and a 1-sphere is usually referred to as a circle.
(2) If the parameter n is clear from the context we sometimes drop it from the notation.
(3) If $y = 0$, then we drop y from the notation and if $r = 1$, then we drop r from the notation.
(4) Sometimes we write rB^n instead of $B_r^n(0)$ and sometimes we write $r\overline{B}^n$ instead of $\overline{B}_r^n(0)$.

We sketch B^1, B^2, S^1 and S^2 in Figure 3. Of course one cannot easily sketch the 3-sphere S^3. But it is worth pointing out that in some form it has been around for a while. In [Lip, Chapter 2] and [Pet] the argument is made that the universe in Dante's Divina Commedia is precisely the 3-sphere.

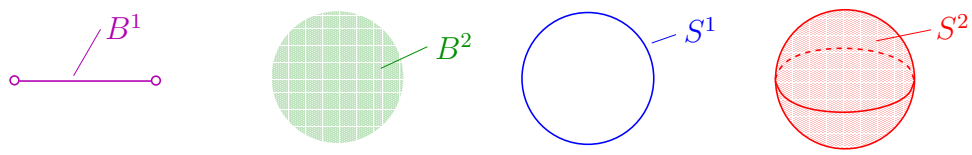

FIGURE 3.

The next definition gives us a rich source of new examples of topological spaces.

Definition. Let $(X, \mathcal{T})$ be a topological space and let $Y \subset X$ be a subset. It follows immediately from the definitions that

$$\mathcal{S} \ := \ \{Y \cap U \,|\, U \in \mathcal{T}\}$$

is a topology on Y. We refer to $\mathcal{S}$ as the *subspace topology* on Y.

Convention. Unless we say something else, we consider each subset Y of $\mathbb{R}^n$ always as a topological space with respect to the subspace topology.

We continue with the following useful lemma.

Lemma 1.6. *Let X be a topological space and let $Y \subset X$ be a subset. We equip Y with the subspace topology.*

(1) *A set $V \subset Y$ is open in Y if and only if there exists an open subset $U \subset X$ with $V = U \cap Y$.*
(2) *A set $B \subset Y$ is closed in Y if and only if there exists a closed subset $A \subset X$ with $B = A \cap Y$.*

Proof $(*)$. [4] The first statement is just a reformulation of the definition of the subspace topology. We turn to the proof of the second statement. Now let $B \subset Y$. Elementary set theory shows that for any subset U of X we have

$$(*) \qquad U \cap Y \ = \ Y \setminus B \quad \Longleftrightarrow \quad (X \setminus U) \cap Y \ = \ B.$$

We refer to Figure 4 for an illustration. Now the second statement is basically obvious. Indeed, we have

$$\begin{aligned} B \text{ is closed in } Y \ &\Longleftrightarrow \ Y \setminus B \text{ is open in } Y \\ &\Longleftrightarrow \ \text{there exists } U \subset Y \text{ open with } U \cap Y = Y \setminus B \\ &\underset{\text{by } (*)}{\Longleftrightarrow} \ \text{there exists } U \subset Y \text{ open with } (X \setminus U) \cap Y = B \\ &\Longleftrightarrow \ \text{there exists } A \subset X \text{ closed with } A \cap Y = B. \end{aligned}$$

[4] We indicate proofs and statements that can safely be skipped at a first reading of these notes by the symbol $(*)$.

□

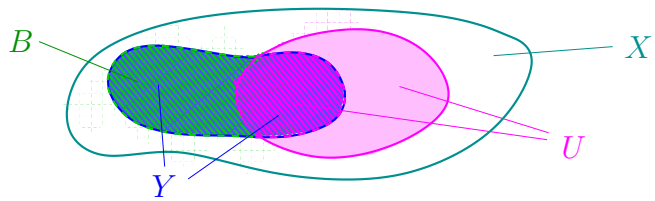

FIGURE 4. Illustration for the proof of Lemma 1.6.

Example. We consider $Y = (-1, 2]$ equipped with the subspace topology coming from $\mathbb{R}$.

(1) It follows from Lemma 1.6 that $V = (0, 2]$ is an open subset of Y, since we can write $V = (0, 4) \cap Y$ and $(0, 4)$ is an open subset of $\mathbb{R}$.
(2) It follows from Lemma 1.6 that $B = (-1, 0]$ is a closed subset of Y, since we can write $B = [-3, 0] \cap Y$ and $[-3, 0]$ is a closed subset of $\mathbb{R}$.

These two examples are illustrated in Figure 5.

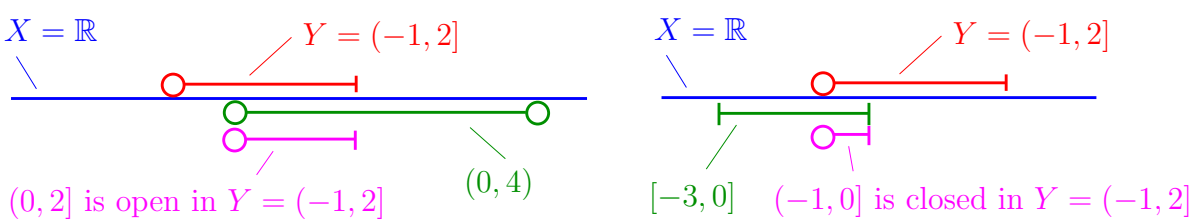

FIGURE 5.

The following lemma is crucial for many arguments.

Lemma 1.7. *Let X be a topological space and let M be a subset of X.*

(1) *Let $\{U_i\}_{i \in I}$ be a family of open subsets X with $\bigcup_{i \in I} U_i = X$. The following two statements hold:*
   (a) *M is open if and only if each intersection $M \cap U_i$ is open in U_i,*
   (b) *M is closed if and only if each intersection $M \cap U_i$ is closed in U_i.*
(2) *Let $A_1, \ldots, A_m$ be a finite collection of closed subsets of X with $A_1 \cup \cdots \cup A_m = X$. The following two statements hold:*
   (a) *M is open if and only if each intersection $M \cap A_i$ is open in A_i,*
   (b) *M is closed if and only if each intersection $M \cap A_i$ is closed in A_i.*

Remark. Note that in Lemma 1.7 we allow an arbitrary family of open subsets but we only allow a finite family of closed subsets. One can easily see that this restriction is necessary. For example, consider $X = \mathbb{R}$ and the infinite family $\{A_i\}_{i\in I}$ of closed subsets of $X = \mathbb{R}$ given by all subsets consisting of a single point. Let $M \subset \mathbb{R}$ be a subset. For each $i \in I$ the intersection $M \cap \{A_i\}$ is either the empty set or all of A_i, in particular the intersection $M \cap \{A_i\}$ is closed in A_i. But of course there is no reason why M should be a closed subset of $\mathbb{R}$.

Proof. Let X be a topological space and let M be a subset of X.

(1) Let $\{U_i\}_{i\in I}$ be a family of open subsets of X with $\bigcup_{i\in I} U_i = X$. The "only if"-directions of (a) and (b) are an immediate consequence of Lemma 1.6. It remains to prove the "if"-directions.

(a) Suppose that for every $i \in I$ the intersection $M \cap U_i$ is an open subset of U_i. By definition of the subspace topology this means that for each $i \in I$ there exists an open subset Z_i of X with $Z_i \cap U_i = M_i \cap U_i$. We have

$$M \underset{\substack{\uparrow \\ \text{since } \bigcup_{i\in I} U_i = X}}{=} \bigcup_{i\in I}(M \cap U_i) = \bigcup_{i\in I} \overbrace{(Z_i \cap U_i)}^{\text{intersection of open subsets of } X\text{, hence open in } X} \underset{\substack{\uparrow \\ \text{union of open subsets, hence open}}}{=} \text{open subset of } X.$$

(b) Now suppose that each intersection $M \cap U_i$ is closed in U_i. In other words, each set $U_i \setminus (M \cap U_i)$ is open in U_i. Since $(X \setminus M) \cap U_i = U_i \setminus (M \cap U_i)$ we obtain from (a) that $X \setminus M$ is open in X. In other words, M is closed in X.

(2) Let $A_1, \dots, A_m$ be a finite collection of closed subsets of X with $A_1 \cup \dots \cup A_m = X$. As in (1) it remains to prove the "if"-directions.

(b) We suppose that each for each $i \in \{1, \dots, m\}$ the intersection $M \cap A_i$ is a closed subset of A_i. It follows from Lemma 1.6 that for each $i \in \{1, \dots, m\}$ there exists a closed subset Z_i of X with $Z_i \cap A_i = M_i \cap A_i$. We have

$$M \underset{\substack{\uparrow \\ \text{since } A_1 \cup \dots \cup A_m = X}}{=} \bigcup_{i=1}^{m}(M \cap A_i) = \bigcup_{i=1}^{m} \overbrace{(Z_i \cap A_i)}^{\text{intersection of closed subsets of } X\text{, hence closed in } X} \underset{\substack{\uparrow \\ \text{union of finitely many closed subsets,} \\ \text{hence closed}}}{=} \text{closed subset of } X$$

(a) As in (1) we can reduce the proof of (a) to the proof of (b). □

We continue with the next basic definition.

Definition. Let X be a topological space.

(1) Let $A \subset X$ be a subset. We say $U \subset X$ is a *neighborhood of* A if there exists an open set V such that $A \subset V \subset U$. We say U is an *open neighborhood of* A, if U is furthermore open. This definition is illustrated in Figure 6.

(2) An (open) neighborhood of a point $x \in X$ is an (open) neighborhood of $\{x\}$.

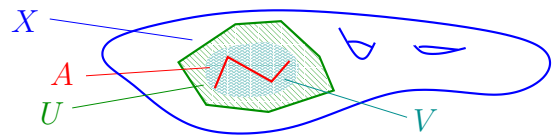

FIGURE 6.

Remark. Some books, see e.g. [Mun3, p. 96], demand that a neighborhood is open. Our definition of a neighborhood agrees with the definition in most books, e.g. [Bre, Hat, Jä1].

Example. If $X = \mathbb{R}$ and $A = [0, 2)$, then $U = (-1, 3]$ and $V = (-2, \infty)$ are neighborhoods of A in X.

The following lemma gives a useful criterion for showing that a given subset is open.

Lemma 1.8. *Let X be a topological space and let $U \subset X$ be a subset. If given any $x \in U$ there exists a neighborhood V of x that is contained in U, then U is open.*

Proof $(*)$. Let X be a topological space and let $U \subset X$ be a subset. Suppose that given any $x \in U$ there exists a neighborhood V_x of x that is contained in U. By definition of a neighborhood there exists for each $x \in U$ an open subset W_x with $x \in W_x \subset V_x$. We see that

$$U = \bigcup_{x \in U} \{x\} \subset \bigcup_{x \in U} W_x \underset{\substack{\uparrow \\ \text{since each } W_x \text{ is contained in } U}}{\subset} U.$$

It follows that $U = \bigcup_{x \in U} W_x$, i.e. U is the union of open subsets of X, thus by the third property of a topology, U itself is open. $\square$

We continue with the following definition which will show up every now and then.

Definition. Let X be a topological space. We say a subset A of X is *dense* if every non-empty open subset of X has a non-empty intersection with A.

Examples.

(1) Let $n \in \mathbb{N}$. It follows from basic facts in real analysis that $A = \mathbb{Q}^n$ is a dense subset of $X = \mathbb{R}^n$.
(2) Here is an immediate, perhaps not entirely serious application of topology to the eternal problem for how to capture a lion in the desert [Bar]: We give the desert the *leonine topology*, in which a subset is closed if it is the whole desert or if it contains no lions.[5] The set of lions is now a dense subset.[6] Now put an open cage in the

[5]Why is this a topology?
[6]Why is that?

desert. By density it contains a lion. Once we shut the cage we have caught the lion![7]

After this joke of dubious taste we return to serious mathematics.

Lemma 1.9. *Every open subset of $\mathbb{R}^n$ is the union of countably many open balls.*

Proof $(*)$. Let U be an open subset of $\mathbb{R}^n$. For $x \in U$ we define

$$\epsilon_x \ := \ \sup\{\mu \in [0,1] \,|\, B_\mu(x) \subset U\}.$$

The hypothesis that U is open implies that $\epsilon_x > 0$ and it implies that $B_{\epsilon_x}(x) \subset U$. Since $U \cap \mathbb{Q}^n$ is a countable set it suffices to prove the following claim.

Claim. The subset U is the union of all $B_{\epsilon_x}(x)$ with $x \in U \cap \mathbb{Q}^n$.

Let $y \in U$. Since $\mathbb{Q}^n$ is dense in $\mathbb{R}^n$ we can pick $x \in U \cap \mathbb{Q}^n$ with $\|x - y\| < \frac{1}{2}\epsilon_y$. Note that this implies that $y \in B_{\frac{1}{2}\epsilon_y}(x)$. Thus it remains to prove the following claim.

Claim. We have $B_{\frac{1}{2}\epsilon_y}(x) \subset B_{\epsilon_x}(x)$.

Recall that we pointed out above that $B_{\epsilon_y}(y) \subset U$. Since $\|x - y\| < \frac{1}{2}\epsilon_y$ we have by the triangle inequality that $B_{\frac{1}{2}\epsilon_y}(x) \subset B_{\epsilon_y}(y)$. Thus $B_{\frac{1}{2}\epsilon_y}(x) \subset U$. By definition of ϵ_x this implies that $B_{\frac{1}{2}\epsilon_y}(x) \subset B_{\epsilon_x}(x)$. This concludes the proof of the claim. We refer to Figure 7 for an illustration. □

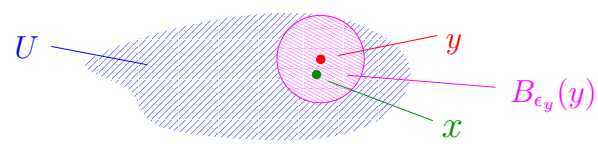

FIGURE 7. Illustration for the proof of Lemma 1.9.

We move on to the next definition.

Definition. Let X be a topological space and let A be a subset of X.

(1) The *interior* $\mathring{A}$ is defined as the union of all open sets of X that are contained in A.
(2) The *closure* $\overline{A}$ of A is defined as the intersection of all closed sets in X that contain A.
(3) The *boundary of A in X* is defined as $\partial A := \overline{A} \setminus \mathring{A}$.

We will give examples in a second, but first we record a few observations that follow almost immediately from the definitions.

Lemma 1.10. *Let X be a topological space and let A be a subset of X.*

(1) *The interior $\mathring{A}$ is an open subset of X.*

[7]This and many other mathematical approaches to hunting lions can be found in [Boa].

(2) *The closure* $\overline{A}$ *of* A *is a closed subset of* X.
(3) *We have* $\mathring{A} \subset A \subset \overline{A}$.
(4) *If* A *is open, then* $\mathring{A} = A$.
(5) *If* A *is closed, then* $\overline{A} = A$.

Proof.
(1) The union of arbitrarily many open sets is, by definition of a topology, again an open set. Thus the interior $\mathring{A}$ is an open subset of X.
(2) In Lemma 1.4 we saw that the intersection of arbitrarily many closed sets is again a closed set. It follows immediately that the closure $\overline{A}$ is a closed subset of X.

The remaining three statements follow immediately from the definitions. □

The above definition is succinct and precise, but using the definition it is perhaps difficult to find the interior and the closure of a given subset of a topological space. In many situations the following lemma takes care of that difficulty.

Lemma 1.11. *Let* X *be a topological space and let* A *be a subset of* X. *We have the following three equalities:*

$$\begin{array}{lrcl}
(1) & \mathring{A} & = & \{x \in A \mid \textit{there exists a neighborhood } U \textit{ of } x \textit{ that is contained in } A\} \\
(2) & \overline{A} & = & \{x \in X \mid \textit{every neighborhood of } x \textit{ contains at least one point in } A\} \\
(3) & \partial A & = & \{x \in X \mid \textit{every neighborhood of } x \textit{ contains at least one point in } A \\
 & & & \qquad\qquad \textit{and one point that does not lie in } A\}
\end{array}$$

Proof. The proof of the lemma is Exercise 1.3. □

Using Lemma 1.11 we can give examples of interiors, closures and boundaries.

Examples.
(1) We consider the topological space $X = \mathbb{R}$ and the subset $A = [-1, 2)$. Using Lemma 1.11 one can easily see that the interior of A is the open interval $(-1, 2)$ and that the closure of A is the closed interval $[-1, 2]$. Furthermore $\partial A = \{-1, 2\}$.
(2) Let $x \in \mathbb{R}^n$ and $r \in \mathbb{R}$. We view $B^n_r(x)$, $\overline{B}^n_r(x)$ and $S^{n-1}_r(x)$ as subsets of $\mathbb{R}^n$. Using Lemma 1.11 one can show fairly easily that
$$\overline{B^n_r(x)} \;=\; \overline{B}^n_r(x) \quad \text{and} \quad \partial\overline{B}^n_r(x) \;=\; \partial B^n_r(x) \;=\; \partial S^{n-1}_r(x) \;=\; S^{n-1}_r(x).$$
(3) In Figure 8 we show a subset of $\mathbb{R}^2$, and we also show its interior $\mathring{A}$, its closure $\overline{A}$ and its boundary ∂A.
(4) It is rather unfortunate that the notations $\mathring{A}$, $\overline{A}$ and ∂A hide the role of X. For example let us consider $A = [0, 2]$. If we view it as a subset of $X = \mathbb{R}$, then $\partial A = \partial[0, 2] = \{0, 2\}$. On the other hand, if we view $A = [0, 2]$ as a subset of $X = \mathbb{R}_{\geq 0}$, then $\partial A = \partial[0, 2] = \{2\}$. This ambiguity in the notation can sometimes be a source of confusion. Thus it would be more appropriate to specify the role of X in the above notation. But mathematicians, as all humans, tend to be lazy and thus tend to simplify the notation.

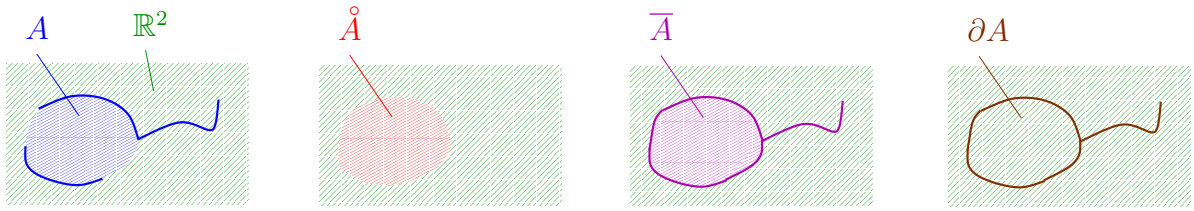

FIGURE 8.

We conclude this section with the following technical lemma.

Lemma 1.12. $(*)$ *Let X be a topological space and let $\{U_i\}_{i\in I}$ be a family of subsets. The following inclusions hold:*

$$(1) \quad \text{interior of } \bigcup_{i\in I} U_i \;\supseteq\; \bigcup_{i\in I} \mathring{U}_i \qquad \text{and} \qquad (2) \quad \text{closure of } \bigcap_{i\in I} U_i \;\subset\; \bigcap_{i\in I} \overline{U}_i.$$

Furthermore, if we are given finitely many subsets $U_1, \dots, U_n$ of X, then the following equalities hold:

$$(3) \quad \text{interior of } \bigcap_{i=1}^{n} U_i \;=\; \bigcap_{i=1}^{n} \mathring{U}_i \qquad \text{and} \qquad (4) \quad \text{closure of } \bigcup_{i=1}^{n} U_i \;=\; \bigcup_{i=1}^{n} \overline{U}_i.$$

Example. It is easy to come up with examples of two subsets U_1, U_2 in $\mathbb{R}^n$ such that inclusions in Lemma 1.12 (1) and (2) are actually proper inclusions. Some examples are illustrated in Figure 9.

FIGURE 9.

Proof. The statements follow fairly easily from the definitions. We leave it to the reader to verify the statements. □

1.2. **The Hausdorff property and convergence of sequences.** Before we introduce the Hausdorff property we introduce two more examples of topological spaces. Both are of the type "$\mathbb{R}^n$ together with an extra point".

Examples.

(1) Let $n \in \mathbb{N}$. We consider the set

$$X \;:=\; \mathbb{R}^n \cup \{\infty\},$$

i.e. X consists of $\mathbb{R}^n$ and an extra point ∞. We say $U \subset X$ is open, if both of the following two conditions are satisfied:

(a) for each point $x \in U \cap \mathbb{R}^n$ there exists an $\epsilon > 0$ such that $B_\epsilon(x) \subset U$,

(b) if $\infty \in U$, then there exists a $C > 0$ such that $\{x \in \mathbb{R}^n \mid \|x\| > C\} \subset U$.

It is straightforward to see that this defines indeed a topology on X. We refer to $\mathbb{R}^n \cup \{\infty\}$ as "$\mathbb{R}^n$ with a point at infinity". For $n = 1$ we refer to $\mathbb{R} \cup \{\infty\}$ also as the "line with a point at infinity".

(2) We consider the set

$$X \;:=\; \mathbb{R} \cup \{*\},$$

i.e. X consists of $\mathbb{R}$ and an extra point $*$. We say $U \subset X$ is open, if the following two conditions are satisfied:

(a) for each point $x \in U \cap \mathbb{R}$ there exists an $\epsilon > 0$ such that $(x - \epsilon, x + \epsilon) \subset U$,

(b) if $* \in U$, then there exists an $\epsilon > 0$ such that $(-\epsilon, 0) \cup (0, \epsilon) \subset U$.

One can easily verify that this is indeed a topology on X. We refer to this topological space as the "line with two zeros".

Even though the "line with two zeros" looks at first glance similar to the "line with a point at infinity" we will soon see that they are strikingly different topological spaces.

Now we provide the first definition of this section.

Definition. We say a topological space X is *Hausdorff*, if given any two distinct points $x \neq y$ there exist disjoint open neighborhoods U of x and V of y.

The following proposition, which very likely is well-known to most readers, says that topological spaces arising from metric spaces are Hausdorff.

Proposition 1.13. *Let (X, d) be a metric space. The corresponding topological space is Hausdorff.*

Proof. Let $x, y \in X$ be two different points. We set $\epsilon := \frac{1}{2}d(x, y)$. It follows from Proposition 1.5 that $U := B_\epsilon(x)$ and $V := B_\epsilon(y)$ are neighborhoods of x respectively y. An elementary argument using the triangle inequality shows that U and V are disjoint. $\square$

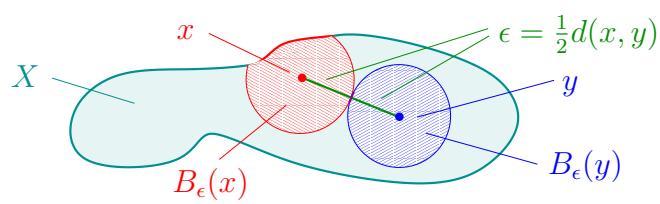

FIGURE 10.

Example. In Exercise 1.8 we will see that "$\mathbb{R}^n$ with a point at infinity" is Hausdorff and that on the other hand "the line with two zeros" is not Hausdorff.

The following lemma is basically trivial.

Lemma 1.14. *Let X be a topological space and let A be a subset of X. If X is Hausdorff, then A is also Hausdorff.*

Next we introduce the notion of a convergent sequence.

Definition. Let X be a topological space. We say that a sequence $\{a_n\}_{n\in\mathbb{N}}$ *converges* if there exists an $a \in X$ such that for any neighborhood U of a there exists an $N \in \mathbb{N}$ such that for all $n \geq N$ we have $a_n \in U$. We refer to a as a *limit* of the sequence.

Example. We consider the line with two zeros, i.e. the topological space $X = \mathbb{R} \cup \{*\}$ defined above. The sequence $a_n = \frac{1}{n}$ converges, more or less evidently with limit 0. But strikingly enough, it follows easily from the definitions that the sequence also converges to $*$. Thus we see that the limit is not unique.

The following lemma is most likely already familiar to the reader from real analysis.

Lemma 1.15. *Let X be a topological space. If X is Hausdorff, then every convergent sequence in X has a unique limit.*

Proof. Assume there exists a sequence $\{a_n\}_{n\in\mathbb{N}}$ in X that converges to two different points x and y. Since X is Hausdorff there exist two disjoint neighborhoods U and V of x and y. But by our hypothesis, for large enough n the a_n have to lie in U and V at the same time. But that is not possible and we have thus obtained a contradiction. □

1.3. **Compact topological spaces.** In this section we introduce the notion of compactness. Usually it takes a while till one appreciates the brilliance of the definition.

Definition. Let X be a topological space.

(1) An *open covering* of a subset $A \subset X$ is a family $\{U_i\}_{i\in I}$ of open subsets of X with $A \subset \bigcup_{i\in I} U_i$.
(2) We say a topological space X is *compact* if for each open covering $\{U_i\}_{i\in I}$ of X there exist finitely many indices $i_1, \dots, i_k \in I$ such that
$$X = U_{i_1} \cup \cdots \cup U_{i_k}.$$

Remark. The introduction of the notion of compact topological space by Pavel Alexandrov and Pavel Urysohn [AU] in 1929 shows that often in mathematics the really clever thing is not necessarily the proofs, but coming up with just the right definition. It is difficult to exaggerate the role of compactness in topology.

Example. Every finite topological space (regardless of the topology) is compact, since there exist only finitely many distinct open subsets. This simple example can sometimes be quite useful.

In the following we will often use the following convention.

Convention. Let P be a property of a topological space (e.g. being discrete, Hausdorff, compact). We say that a subset Y of a topological space X has the property P if Y, equipped with the subspace topology, has the property P.

Examples.

(1) The set $\mathbb{Z} \subset \mathbb{R}$ is easily seen to be a discrete subset.
(2) Any finite set of a topological space is, by the above, a compact subset.

Frequently and often subconsciously the following elementary lemma is employed.

Lemma 1.16. *Let X be a topological space, let $A \subset X$ be a subset and let $\{U_i\}_{i \in I}$ be an open covering of A. If A is compact, then there exist finitely many indices $i_1, \ldots, i_k \in I$ such that*

$$A \subset U_{i_1} \cup \cdots \cup U_{i_k}.$$

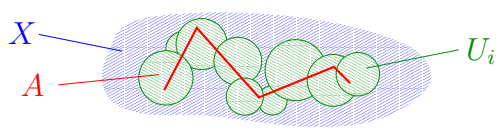

FIGURE 11. Illustration of Lemma 1.16.

Proof $(*)$. Given $i \in I$ we set $V_i := U_i \cap A$. By definition of the subspace topology each V_i is an open subset of A. Thus $\{V_i\}_{i \in I}$ is an open covering of A. Since A is compact there exist $i_1, \ldots, i_k \in I$ with $A = V_{i_1} \cup \cdots \cup V_{i_k}$. But this implies that $A \subset U_{i_1} \cup \cdots \cup U_{i_k}$. □

We continue with the following frequently employed lemma.

Lemma 1.17. *Let X be a topological space. If $K_1, \ldots, K_m$ are finitely many compact subsets of X, then the union $K_1 \cup \cdots \cup K_m$ is also compact.*

Proof. The statement follows easily from the definitions, we leave it to the reader to fill in the details. □

Before we give some more interesting examples of compact topological spaces we want to discuss a few properties of compact topological spaces and compact subsets. The following lemma is frequently used, often subconsciously, in topology.

Lemma 1.18.

(1) *Let X be a topological space. If X is compact, then any closed subset of A is also compact.*
(2) *Let X be a topological space and let $A \subset X$ be a compact subset. If X is Hausdorff, then A is a closed subset of X.*

Example. Let X be a topological space. As we pointed out on page 54, any finite subset of X is compact. Thus if X is Hausdorff, then it follows from Lemma 1.18 that any finite subset of X, in particular any point in X, is a closed subset of X.

Proof.

(1) Let X be a compact topological space and let A be a closed subset. Let $\{U_i\}_{i\in I}$ be an open covering of A. By definition of the subset topology there exists for every $i \in I$ an open subset V_i of X such that $U_i = V_i \cap A$. Since A is closed the complement $X \setminus A$ is open. The open subsets $\{V_i\}_{i\in I}$ together with $X \setminus A$ are an open covering of X. Since X is compact we can cover X by finitely many of these open sets. But then we can also cover A by finitely many of the U_i.

(2) Let X be a Hausdorff space and let $A \subset X$ be a compact subset. We want to show that $X \setminus A$ is open. By Lemma 1.8 it suffices to prove the following claim.

Claim. Let $x \in X \setminus A$. Then there exists an open neighborhood V of x that is contained in $X \setminus A$.

We apply the Hausdorff property to x and every $y \in A$. For every $y \in A$ we obtain disjoint open neighborhoods U_y of y and V_y of x. Evidently we have

$$A \;=\; \bigcup_{y\in A} \{y\} \;\subset\; \bigcup_{y\in A} (U_y \cap A) \;\subset\; A.$$

Thus we see that $\{U_y \cap A\}_{y\in A}$ is an open covering of A. Since A is compact there exist $y_1, \dots, y_k \in A$ such that

$$A \;=\; \bigcup_{i=1}^{k} (U_{y_i} \cap A).$$

Now we consider

$$V \;:=\; \bigcap_{i=1}^{k} V_{y_i}.$$

Since V is the intersection of finitely many open sets, it is open itself. Furthermore V does not intersect any of the U_{y_i}, $i = 1, \dots, k$. Hence V is disjoint from $A \subset U_{y_1} \cup \dots \cup U_{y_k}$. This concludes the proof of the claim. □

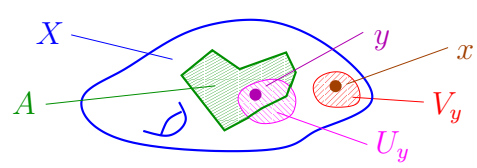

FIGURE 12. Illustration for the proof of Lemma 1.18 (2).

Before we move on to giving more interesting examples of compact topological spaces we state and prove the following elementary lemma.

Lemma 1.19.

(1) *Every discrete topological space that is compact is finite.*

(2) *Let X be a compact topological space and let A be a closed subset. If A is discrete, then A is finite.*

Proof $(*)$.

(1) Let X be a discrete topological space. Each point thus defines an open set. Evidently X is covered by all the open sets given by the points in X. Since X is compact we can cover X by finitely many of those open sets. But this means that X contains only finitely many points.
(2) Let X be a compact topological space and let A be a closed subset. It follows from Lemma 1.18 (1) that A is also compact. So if A is discrete, then it follows from (1) that A is finite. □

We continue with the following self-explanatory definition.

Definition. A subset A of $\mathbb{R}^n$ is called *bounded* if there exists a $C \geq 0$ such that $A \subset \overline{B}^n_C(0)$.

Example. Let $y \in \mathbb{R}^n$ and $r \geq 0$. It follows easily from the triangle inequality that the balls $B^n_r(y)$, $\overline{B}^n_r(y)$ and the sphere $S^{n-1}_r(y)$ are bounded.

Lemma 1.20. *Let $A \subset \mathbb{R}^n$ be a subset. If A is compact, then A is closed and it is bounded.*

Proof. Let $A \subset \mathbb{R}^n$ be a compact subset.

(1) We want to show that $\mathbb{R}^n \setminus A$ is open. Let $x \in \mathbb{R}^n \setminus A$. We need to show that there exists an $\epsilon > 0$ with $B^n_\epsilon(x) \subset \mathbb{R}^n \setminus A$. Given $j \in \mathbb{N}$ we consider the open subset $U_j = (\mathbb{R}^n \setminus \overline{B}^n_{\frac{1}{j}}(x)) \cap A$. Evidently these sets cover A. Since A is compact we know that there exist $j_1, \ldots, j_k$ with $A \subset U_{j_1} \cup \cdots \cup U_{j_k}$. We set $\epsilon = \min\{\frac{1}{j_1}, \ldots, \frac{1}{j_k}\}$. We obtain that $A \subset \mathbb{R}^n \setminus \overline{B}^n_\epsilon(x)$. Thus we have found the desired ϵ.
(2) We consider the open subsets $U_j = B^n_j(0) \cap A$ with $j \in \mathbb{N}$. Evidently these sets cover A. Since A is compact we know that there exist $j_1, \ldots, j_k$ such that $A \subset U_{j_1} \cup \cdots \cup U_{j_k}$. We set $C = \max\{j_1, \ldots, j_k\}$. We obtain that $A \subset \overline{B}^n_C(0)$. □

The ever-popular Heine-Borel Theorem says that mercifully the converse to Lemma 1.20 holds.

Theorem 1.21. (Heine-Borel) *A subset of $\mathbb{R}^n$ is compact if and only if it is bounded and closed.*

Examples.

(1) Let $y \in \mathbb{R}^n$ and $r \geq 0$. It follows from the Heine-Borel Theorem 1.21 and Proposition 1.5 that the closed ball $\overline{B}^n_r(y)$ and the sphere $S^{n-1}_r(y)$ are compact.
(2) It is an amusing exercise, see Exercise 1.8, to show, using the Heine-Borel Theorem 1.21, that "$\mathbb{R}^n$ with a point at infinity" is compact.
(3) It is an equally entertaining exercise, see Exercise 1.8, to show that the "line with two zeros" is not compact.
(4) We set $C_0 = [0, 1]$. We define sets C_i, $i \in \mathbb{N}$ iteratively by setting

$$C_i \ := \ \tfrac{1}{3}C_{i-1} \cup \left(\tfrac{2}{3} + \tfrac{1}{3}C_{i-1}\right)$$

i.e. we obtain C_i from C_{i-1} by removing the "open middle third" of each interval. See Figure 13. The *Cantor set* is defined as

$$\text{Cantor set } C \ := \bigcap_{i\in\mathbb{N}_0} C_i.$$

Each C_i is closed, hence it follows from Lemma 1.4 that C itself is a closed subset of $\mathbb{R}$. It is evidently bounded, hence the Heine-Borel Theorem 1.21 implies that the Cantor set is compact.

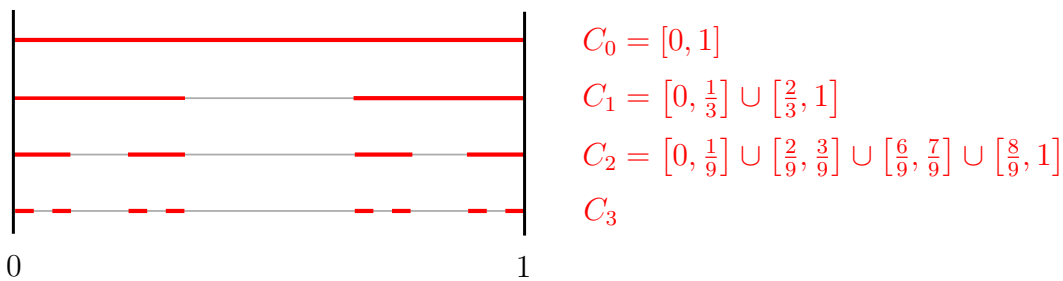

FIGURE 13.

(5) Since the concepts of being bounded and closed are initially much more intuitive than being compact it is not uncommon that people like to replace "compact" by "bounded and closed". But this equality only holds for subsets of $\mathbb{R}^n$, it does not hold for other metric spaces. For example, the set $[0,1]\cap\mathbb{Q}$ is a bounded and closed subset of the metric space $(\mathbb{Q}, d(x,y) = |x-y|)$, but as we will see in Exercise 1.17, it is not compact.

The following proposition is the key ingredient in the proof of the Heine-Borel Theorem 1.21.

Proposition 1.22. *Let $n \in \mathbb{N}$ and let $a_i < b_i$, $i = 1,\dots,n$ be real numbers. The hyperrectangle*

$$\underbrace{[a_1,b_1] \times \ldots \times [a_n,b_n]}_{:=\{(x_1,\dots,x_n)\in\mathbb{R}^n \,|\, x_i\in[a_i,b_i] \text{ for } i=1,\dots,n\}} \ \subset \ \mathbb{R}^n$$

is compact.

Proof. To simplify the notation we only treat the case $n = 1$. The general case is treated in a very similar fashion.[8] To simplify the notation we assume that $a = 0$ and $b = 1$. Thus we will now show that $I := [0,1]$ is compact. In an attempt at a proof by contradiction we suppose that I is not compact. This means that there exists an open overing $\{U_j\}_{j\in J}$ such that I cannot be covered by finitely many of the U_j.

[8]The full details are for example provided in [Rudi, Theorem 2.4.1].

Claim. There exists a sequence of closed intervals

$$I \;=\; I_0 \;\supset\; I_1 \;\supset\; I_2 \;\supset\; \dots$$

such that for any $m \in \mathbb{N}_0$ the following two conditions hold:

(1) I_m cannot be covered by finitely many of the U_j,
(2) the length of I_m equals 2^{-m}.

We prove the claim by induction. We set $I_0 := I$. Suppose we have already found $I_0, I_1, \dots, I_m$. We divide the interval I_m into two closed intervals I' and I'' of half the length. Since I_m cannot be covered by finitely many U_j it follows that at least one of the intervals I' and I'' cannot be covered by finitely many U_j either. We declare this interval to be I_{m+1}. This concludes the proof of the claim.

Claim. There exists an $x \in I$ with $x \in \bigcap\limits_{m\in\mathbb{N}} I_m$.

For every $m \in \mathbb{N}$ we pick an $a_m \in I_m$. For any $m \geq n$ we know that a_m and a_n both lie in I_n. In particular

$$|a_m - a_n| \;\leq\; \text{length of } I_n \;=\; \frac{1}{2^n}.$$

It follows that $(a_m)_{m\in\mathbb{N}}$ is a Cauchy sequence. We denote by x the limit of this Cauchy sequence. We want to show that $x \in \bigcap\limits_{m\in\mathbb{N}} I_m$. Put differently, we want to show that for every $m \in \mathbb{N}$ we have $x \in I_m$. Thus let $m \in \mathbb{N}$. For all $n \geq m$ we have $a_n \in I_n \subset I_m$. In particular, $(a_n)_{n\geq m}$ is a sequence that converges in I_m. Since I_m is closed we see[9] that $\lim_{n\to\infty} a_n \in I_m$. This concludes the proof of the claim.

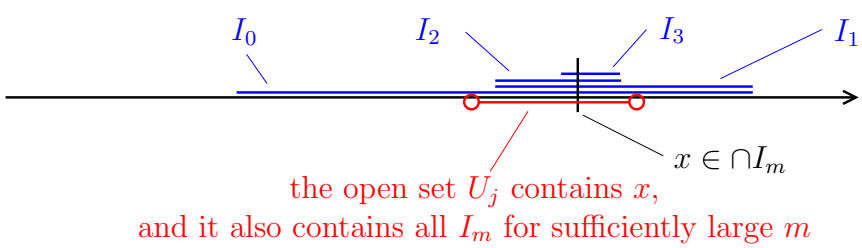

FIGURE 14. Illustration for the proof of Proposition 1.22.

Since $\{U_j\}_{j\in J}$ is an open covering of I there exists a $j \in J$ with $x \in U_j$. Since U_j is open there exists an $\epsilon > 0$ with $(x-\epsilon, x+\epsilon) \cap I \subset U_j$. We pick $m \in \mathbb{N}$ with $2^{-m} < \epsilon$. Now note that

$$\begin{array}{ccccccc} I_m & \underset{\substack{\uparrow \\ \text{since } x \in I_m \text{ and since} \\ \text{the length of } I_m \text{ equals } 2^{-m}}}{\subset} & [x-2^{-m}, x+2^{-m}] \cap I & \underset{\substack{\uparrow \\ \text{choice of } m}}{\subset} & (x-\epsilon, x+\epsilon) \cap I & \underset{\substack{\uparrow \\ \text{choice of } U_j}}{\subset} & U_j \end{array}$$

[9]Why do we see this?

i.e. I_m is contained in a unique U_j. But this contradicts property (1) of the intervals $I_m, m \in \mathbb{N}$. $\square$

Now we can finally give the proof of the Heine-Borel Theorem 1.21.

Proof of the Heine-Borel Theorem 1.21. In light of Lemma 1.20 we only need to show that if A is a bounded and closed subset of $\mathbb{R}^n$, then it is compact. Since A is bounded there exists a $C \geq 0$ such that $A \subset [-C, C]^n$. By Proposition 1.22 we know that $A \subset [-C, C]^n$ is compact. Since A is closed in $\mathbb{R}^n$ it follows from Lemma 1.6 that is also a closed subset of $[-C, C]^n$. It follows from Lemma 1.18 that A itself is compact. $\square$

1.4. **Bases of a topology.** We start out with the following definition.

Definition. Let X be a set and let $\mathcal{B} \subset \mathcal{P}(X)$ be a subset of the power set of X. We say $\mathcal{B}$ has the *basis property* if the following two conditions are satisfied:

(B1) For any $x \in X$ there exists a $B \in \mathcal{B}$ with $x \in B$.
(B2) Given any $B_1, B_2 \in \mathcal{B}$ and given any $x \in B_1 \cap B_2$ there exists a $B_3 \in \mathcal{B}$ such that $x \in B_3$ and $B_3 \subset B_1 \cap B_2$. (See Figure 15 for an illustration.)

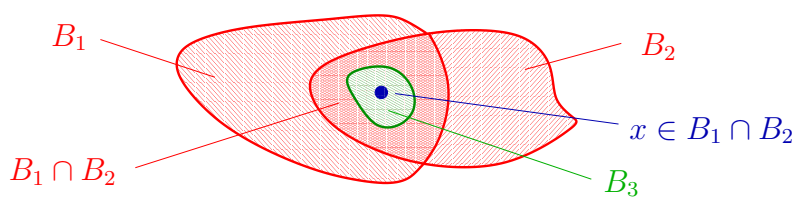

FIGURE 15.

The following lemma justifies our sudden interest in this new definition.

Lemma 1.23. *Let X be a set and let $\mathcal{B} \subset \mathcal{P}(X)$. We define*

$$\mathcal{T}(\mathcal{B}) \;:=\; \{V \subset X \,|\, \textit{for every } x \in V \textit{ there exists a } B \in \mathcal{B} \textit{ with } x \in B \subset V\}.$$

If $\mathcal{B}$ has the basis property, then $\mathcal{T}(\mathcal{B})$ is a topology on X.

Definition. Let X be a set.

(1) If $\mathcal{B} \subset \mathcal{P}(X)$ has the basis property, then we refer to $\mathcal{T}(\mathcal{B})$ as the *topology on X generated by $\mathcal{B}$*.
(2) Conversely, if $\mathcal{T}$ is a given topology on X and if $\mathcal{B} \subset \mathcal{P}(X)$ has the basis property and if $\mathcal{T} = \mathcal{T}(\mathcal{B})$, then we say that $\mathcal{B}$ is a *basis of the topology $\mathcal{T}$ of X*.

Examples.

(1) If (X, d) is a metric space, then

$$\mathcal{B} \;=\; \{\text{all balls } B_r(x) \text{ with } r > 0 \text{ and } x \in X\} \;\subset\; \mathcal{P}(X)$$

satisfies (B1) and (B2).[10] The topology generated by this family of subsets is, by definition, precisely the topology we already introduced on page 44.

(2) Let X be a set and let $\mathcal{T}$ be a topology on X. It follows easily from the definitions that $\mathcal{T}$ has the basis property. Furthermore it follows from Lemma 1.8 that the topology generated by $\mathcal{T}$ is in fact $\mathcal{T}$.

For completeness we provide the elementary proof of Lemma 1.23.

Proof $(*)$. Let X be a set and let $\mathcal{B} \subset \mathcal{P}(X)$. We write $\mathcal{T} := \mathcal{T}(\mathcal{B})$. We need to show that $\mathcal{T}$ satisfies the three properties (1), (2) and (3) in the definition of a topological space, see page 42. Given any $x \in X$ there exists by (B1) a $B \in \mathcal{B}$ with $x \in B$. By definition we see that $X \in \mathcal{T}$. Furthermore it is clear that the empty set $\varnothing$ lies in $\mathcal{T}$.
We need to show that the intersection of finitely many sets in $\mathcal{T}$ is again a set in $\mathcal{T}$.

First we consider the case of two sets in $\mathcal{T}$. Thus let $U, V \in \mathcal{T}$. We need to show that $U \cap V \in \mathcal{T}$. Let $x \in U \cap V$. Since U and V lie in $\mathcal{T}$ there exist $B, C \in \mathcal{B}$ with $x \in B \subset U$ and $x \in C \subset V$. By (B2) there exists a $D \in \mathcal{B}$ with $x \in D$ and $D \subset B \cap C$. In particular we have $x \in D \subset U \cap V$. This shows that $U \cap V \in \mathcal{T}$.

Now let $U_1, \ldots, U_k$ be sets in $\mathcal{T}$. Using the above statement and an elementary induction argument we see that $U_1 \cap \cdots \cap U_k$ lies in $\mathcal{T}$ as well.
Let $U_j, j \in J$ be a family of sets in $\mathcal{T}$. We need to show that the union $\bigcup_{j \in J} U_j$ lies in $\mathcal{T}$. Thus let $x \in \bigcup_{j \in J} U_j$. This means that there exists a $k \in J$ with $x \in U_k$. Since $U_k \in \mathcal{T}$ there exists a $B_x \in \mathcal{B}$ with $x \in B_x \subset U_k$. But then we also have

$$x \in B_x \subset U_k \subset \bigcup_{j \in J} U_j. \qquad \square$$

The following lemma can be used to show that two topologies on a given set agree.

Lemma 1.24. *Let X be a set and let $\mathcal{S}$ and $\mathcal{T}$ be topologies for X. Suppose that $\mathcal{C}$ is a basis for $\mathcal{T}$. (As discussed above we could take $\mathcal{C} = \mathcal{T}$.) If given any $x \in X$ and given any $V \in \mathcal{C}$ there exists a $U \in \mathcal{S}$ with $x \in U \subset V$, then $\mathcal{T} \subset \mathcal{S}$.*

Example. Let $n \in \mathbb{N}$. We consider the two metrics

$$\begin{array}{rcl} \mathbb{R}^n \times \mathbb{R}^n & \to & \mathbb{R}_{\geq 0} \\ (v, w) & \mapsto & \|v - w\| \end{array} \quad \text{and} \quad \begin{array}{rcl} \mathbb{R}^n \times \mathbb{R}^n & \to & \mathbb{R}_{\geq 0} \\ (v, w) & \mapsto & \max\{|v_i - w_i| \,|\, i \in \{1, \ldots, n\}\}. \end{array}$$

The former is the Euclidean metric that we introduced on page 43. We refer to the second metric as the *maximum's metric*. We leave it as an exercise to the dedicated reader to show, using Lemma 1.24, that the two topologies on $\mathbb{R}^n$ agree.

Proof. It follows immediately from Lemma 1.8 that any set in $\mathcal{C}$ is open in $\mathcal{S}$. But then, once again using Lemma 1.8 we see that any set in $\mathcal{T}$ is open in $\mathcal{S}$, i.e. $\mathcal{T} \subset \mathcal{S}$. $\square$

Sometimes the following two lemmas can be useful.

[10] Why is (B2) satisfied?

Lemma 1.25. *Let X be a set and let $\mathcal{B} \subset \mathcal{P}(X)$. If $\mathcal{B}$ has the basis property, then*

$$V \subset X \text{ is open with respect to } \mathcal{T}(\mathcal{B}) \quad \Longleftrightarrow \quad V \text{ is the union of sets in } \mathcal{B}.$$

Proof of Lemma 1.25 $(*)$. We first prove the "$\Leftarrow$"-direction. Thus let V be the union of sets in $\mathcal{B}$. Since sets in $\mathcal{B}$ are open with respect to $\mathcal{T}(\mathcal{B})$ and since $\mathcal{T}(\mathcal{B})$ is a topology we see that $V \in \mathcal{T}(\mathcal{B})$.

Now we prove the "$\Rightarrow$"-direction. Thus we suppose that $V \subset X$ is open with respect to $\mathcal{T}(\mathcal{B})$. For each $x \in V$ there exists, by definition of $\mathcal{T}(\mathcal{B})$, a set $B_x \in \mathcal{B}$ with $x \in B_x \subset V$. We obtain that

$$V \;=\; \bigcup_{x\in V} \{x\} \;\subset\; \bigcup_{x\in V} B_x \;\subset\; V, \qquad \text{thus it follows that } V \;=\; \bigcup_{x\in V} B_x. \qquad \square$$

Lemma 1.26. *Let $\mathcal{B}$ be a basis for the topology of a topological space X. Furthermore let $\{U_j\}_{j\in J}$ be an open covering of X, i.e. $\{U_j\}_{j\in J}$ is a family of open sets with $\bigcup_{j\in J} U_j = X$. Then*

$$\{B \in \mathcal{B} \,|\, \text{ there exists some } j \in J \text{ with } B \subset U_j\}$$

is also a basis for the topology of X.

Proof $(*)$. We write

$$\mathcal{C} := \{B \in \mathcal{B} \,|\, \text{ there exists some } j \in J \text{ with } B \subset U_j\}.$$

Since $\mathcal{C} \subset \mathcal{B}$ we have $\mathcal{T}(\mathcal{C}) \subset \mathcal{T}(\mathcal{B})$. It remains to show the reverse inclusion $\mathcal{T}(\mathcal{B}) \subset \mathcal{T}(\mathcal{C})$. It follows easily from Lemma 1.8 that it suffices to show that $\mathcal{B} \subset \mathcal{T}(\mathcal{C})$. In other words, it suffices to prove the following claim.

Claim. Given any $x \in X$ and any $B \in \mathcal{B}$ with $x \in B$ there exists a $C \in \mathcal{C}$ such that $x \in C \subset B$.

So let $x \in X$ and let $B \in \mathcal{B}$ with $x \in B$. By hypothesis there exists a j such that $x \in U_j$. Since U_j is open and since $\mathcal{B}$ is a basis for the topology of X there exists a $B' \in \mathcal{B}$ with $x \in B' \subset U_j$. By (B2) there exists a $B'' \in B$ with $x \in B''$ and $B'' \subset B \cap B' \subset U_j$. By definition we have $B'' \in \mathcal{C}$. This concludes the proof of the claim and thus of the lemma. (We refer to Figure 16 for an illustration of the argument.) $\square$

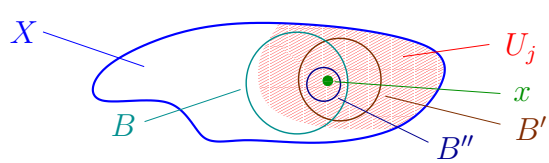

FIGURE 16. Illustration for the proof of Lemma 1.26.

Example. As we pointed out above, $\mathcal{B} = \{B_r^n(x) \,|\, r > 0 \text{ and } x \in \mathbb{R}^n\}$ is a basis for the usual topology of $\mathbb{R}^n$. We denote by $\mathcal{U}$ the family of all open sets that are contained in an open ball of radius 1. Then the open sets in $\mathcal{U}$ cover $\mathbb{R}^n$. It follows from Lemma 1.26 that

$$\{B_r^n(x) \,|\, r \in (0,1) \text{ and } x \in \mathbb{R}^n\}$$

is also a basis for $\mathbb{R}^n$.

The following lemma gives us in particular another source of topologies.

Lemma 1.27. *Let X be a set. For any $\mathcal{C} \subset \mathcal{P}(X)$ the set*

$\mathcal{B}(\mathcal{C})$:= *all subsets of X that can be written as intersections of a finite family of sets in $\mathcal{C}$*

has the basis property.

Proof $(*)$.

(1) On page 41 we pointed out that if we take the empty family of subsets of X, then the intersection is all of X. In other words, we see that $X \in \mathcal{B}(\mathcal{C})$. It follows that $\mathcal{B}(\mathcal{C})$ satisfies (B1).
(2) It is elementary to verify that $\mathcal{B}(\mathcal{C})$ satisfies (B2). □

The previous lemma leads us to the following definition.

Definition. Let X be a set and let $\mathcal{C} \subset \mathcal{P}(X)$ with $\bigcup_{C \in \mathcal{C}} C = X$.

(1) We define $\mathcal{B} = \mathcal{B}(\mathcal{C})$ as in Lemma 1.27 and we refer to $\mathcal{T}(\mathcal{B})$ as the *topology generated by $\mathcal{C}$*.
(2) Conversely, if $\mathcal{T}$ is a topology on X and if the topology generated by $\mathcal{C}$ agrees with $\mathcal{T}$, then we say that $\mathcal{C}$ is a *subbasis for $\mathcal{T}$*.

Example.

(1) Let $\mathcal{C}$ be the set of all intervals in $\mathbb{R}$ of length one. One can easily verify that $\mathcal{C}$ generates the usual topology on $\mathbb{R}$.
(2) It follows easily from the definitions that a basis of a given topology is also a subbasis of the topology.

The following lemma gives us a convenient criterion for showing that a set of open subsets is in fact a (sub-) basis for a given topology.

Lemma 1.28. *Let X be a topological space and let $\mathcal{C}$ be a family of open sets.*

(1) *Suppose $\mathcal{C}$ has the following property:*

   given any open set U and given any $x \in U$ there exists a $C \in \mathcal{C}$ with $x \in C \subset U$.

   Then $\mathcal{C}$ is a basis for the topology of X.
(2) *Suppose $\mathcal{B}$ is a basis for the topology of X. If given any $x \in X$ and given any $B \in \mathcal{B}$ there exist finitely many $C_1, \ldots, C_m \in \mathcal{C}$ with $x \in C_1 \cap \cdots \cap C_m \subset B$, then $\mathcal{C}$ is a subbasis for the topology of X.*

Example. Using Lemma 1.28 (1) and using the density of $\mathbb{Q} \subset \mathbb{R}$ one can easily show that the set of *rational* intervals forms a basis for the usual topology on $\mathbb{R}$. In particular $\mathbb{R}$ has a countable basis for its topology.

Proof $(*)$.

(1) We denote by $\mathcal{T}$ the topology of X. First we show that $\mathcal{C}$ has the basis property:
   (B1) If we apply the property of $\mathcal{C}$ to $U = X$ then we obtain immediately that given any $x \in X$ there exists a $C \in \mathcal{C}$ with $x \in C$.
   (B2) Let $x \in C_1 \cap C_2$ with $C_1, C_2 \in \mathcal{C}$. Since C_1 and C_2 are open the intersection $U = C_1 \cap C_2$ is also open. It follows from the hypothesis on $\mathcal{C}$, applied to U, that there exists a $C \in \mathcal{C}$ with $x \in C \subset C_1 \cap C_2$.

   We denote by $\mathcal{S}$ the topology on X that is generated by $\mathcal{C}$. We need to show that $\mathcal{S} = \mathcal{T}$.

   First we show the inclusion $\mathcal{S} \subset \mathcal{T}$. Since all sets in $\mathcal{C}$ are open with respect to $\mathcal{T}$ it follows from Lemma 1.25 that $\mathcal{S} \subset \mathcal{T}$.

   Finally we show the reverse inclusion $\mathcal{T} \subset \mathcal{S}$. Thus let $U \in \mathcal{T}$. We need to show that $U \in \mathcal{S}$. Thus let $x \in U$. By our hypothesis there exists a $C \in \mathcal{C}$ with $x \in C \subset U$. Therefore by definition we have $U \in \mathcal{S}$. We have thus shown that $\mathcal{T} \subset \mathcal{S}$.

(2) We leave the verification of this statement as a rather uninspiring exercise to the reader. $\square$.

We conclude this section with the following not terribly inspiring lemma.

Lemma 1.29. $(*)$ *Let X be a topological space and let $A \subset X$ be a subset. If $\mathcal{B}$ is a basis for the topology of X, then $\{B \cap A \,|\, B \in \mathcal{B}\}$ is a basis for the topology of A, equipped with the subspace topology.*

Proof $(*)$. We prove the lemma using Lemma 1.28 (1). Thus let $U \subset A$ be an open subset in A and let $x \in U$. By definition of the subspace topology there exists an open subset $V \subset X$ of X with $U = V \cap A$. Since $\mathcal{B}$ is a basis for the topology of X there exists a $B \in \mathcal{B}$ with $x \in B \subset V$. This implies that $x \in B \cap A \subset V \cap A = U$. It follows from Lemma 1.28 (1) that $\{B \cap A \,|\, B \in \mathcal{B}\}$ is indeed a basis for the topology of A. $\square$

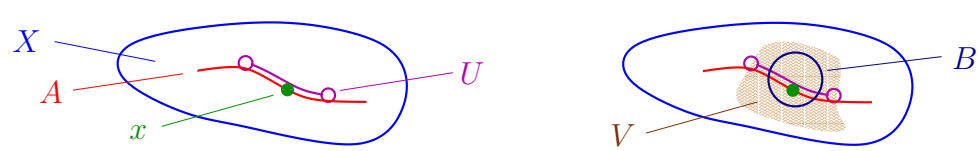

FIGURE 17. Illustration for the proof of Lemma 1.29.

Example. We consider

$$S^1 \;=\; \{(x,y) \in \mathbb{R}^2 \,|\, x^2 + y^2 = 1\} \;\subset\; \mathbb{R}^2.$$

As we saw on page 60, a basis for the topology on $\mathbb{R}^2$ is given by

$$\mathcal{B} \;=\; \{B_r(x,y) \,|\, (x,y) \in \mathbb{R}^2 \text{ and } r > 0\}.$$

The intersection of such an open ball with S^1 is an "open interval on S^1", i.e. it is a subset of the form $\{e^{i\varphi} \,|\, \varphi \in (a,b)\}$. It follows from Lemma 1.29 that these "open intervals" form a basis for the topology on S^1. We refer to Figure 18 for an illustration.

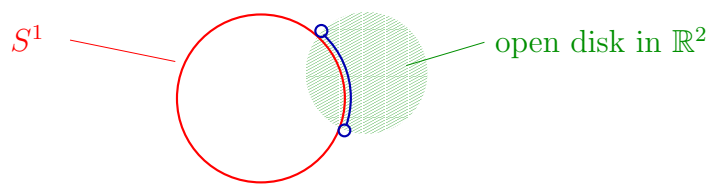

FIGURE 18.

1.5. **Continuous maps.** The following is the key definition in the context of topological spaces.

Definition. We say a map $f\colon X \to Y$ between two topological spaces X and Y is *continuous*, if for each open set U in Y the preimage $f^{-1}(U)$ is open in X.

Examples.

(1) Let X and Y be two topological spaces. If Y is equipped with the trivial topology or if X is equipped with the discrete topology, then any map $f\colon X \to Y$ is continuous.
(2) Let $n \in \mathbb{N}$. It follows easily from the definitions that for each $i \in \{1,\dots,n\}$ the projection map
$$\begin{array}{rcl} \mathbb{R}^n & \to & \mathbb{R} \\ (x_1,\dots,x_n) & \to & x_i \end{array}$$
is continuous.
(3) Let X be a topological space. On many occasions we will use the following elementary facts
   (a) If $f\colon X \to \mathbb{R}$ and $g\colon X \to \mathbb{R}$ are continuous maps, then the product and the sum of f and g, i.e. the maps $x \mapsto f(x) + g(x)$ and $x \mapsto f(x) \cdot g(x)$, are also continuous.
   (b) If $f\colon X \to \mathbb{R}$ is a map that is non-zero everywhere, then $x \mapsto \frac{1}{f(x)}$ defines a continuous map on X.
(4) We will also often use the elementary fact that if $f = (f_1,\dots,f_n)\colon X \to \mathbb{R}^n$ is a map, then f is continuous if and only if each $f_i\colon X \to \mathbb{R}$ is continuous.
(5) Let A be a real $(m \times n)$-matrix. It follows from (2), (3) and (4) that the map
$$\begin{array}{rcl} f\colon \mathbb{R}^n & \to & \mathbb{R}^m \\ v & \mapsto & Av \end{array}$$
is continuous.

(6) We consider the set $X = \{A, B, C, D\}$ where the topology is given by the set

$$\mathcal{T} := \{\varnothing, \{A\}, \{C\}, \{A, C\}, \{A, B, C\}, \{A, C, D\}, X\}.$$

We refer to this to topological spaces as the *pseudocircle*. It follows easily from the definitions that the map

$$\begin{array}{rcl} f\colon S^1 & \to & X \\ e^{it} & \mapsto & \begin{cases} A, & \text{if } t \in (-\frac{\pi}{4}, \frac{\pi}{4}), \\ B, & \text{if } t = \frac{\pi}{4}, \\ C & \text{if } t \in (\frac{\pi}{4}, \frac{3\pi}{4}), \\ D & \text{if } t = \frac{3\pi}{4}. \end{cases} \end{array}$$

is continuous. This map is illustrated in Figure 19.

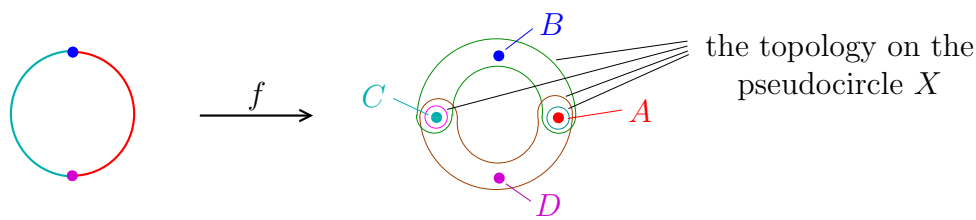

FIGURE 19.

The following lemma will be used on almost every page of these notes.

Lemma 1.30.

(1) *If $f\colon X \to Y$ and $g\colon Y \to Z$ are two continuous maps between topological spaces, then the composition $g \circ f\colon X \to Z$ is also continuous.*
(2) *Let X be a topological space and let A be a subset. If we equip A with the subspace topology, then the inclusion map $i\colon A \to X$ is continuous.*
(3) *Let $f\colon X \to Y$ be a continuous map between topological spaces and let A be a subset. If we equip A with the subspace topology, then the restriction of f to the map $f|_A\colon A \to Y$ is also continuous.*
(4) *Let $f\colon X \to Y$ be a continuous map. If $Z \subset Y$ is a subset with $f(X) \subset Z$, then the map $f\colon X \to Z$ is also continuous.*

Proof.

(1) Let $U \subset Z$ be an open subset. Then

$$(g \circ f)^{-1}(U) = f^{-1}(g^{-1}(U)) \underset{\substack{\uparrow \\ \text{since } g \text{ is continuous and } U \text{ is open}}}{=} f^{-1}(\text{the open set } g^{-1}(U)) \underset{\substack{\uparrow \\ \text{since } f \text{ is continuous}}}{=} \text{open}.$$

(2) This statement follows immediately from the definitions.

(3) This statement is an immediate consequence of (1) and (2) since the restriction of f to A is precisely the same as $f \circ i$ where $i\colon A \to X$ denotes the inclusion.
(4) For clarity we denote by $g\colon X \to Z$ the map given by $x \mapsto f(x)$. Let $U \subset Z$ be an open subset. We need to show that $g^{-1}(U)$ is an open subset of X. By definition of the subspace topology there exists an open subset $V \subset X$ with $U = Z \cap V$. Thus we see that

$$\begin{array}{ccccccccc} g^{-1}(U) & = & g^{-1}(Z \cap V) & \underset{\substack{\uparrow \\ \text{definition of } g}}{=} & f^{-1}(Z \cap V) & \underset{\substack{\uparrow \\ \text{since } f(X) \subset Z}}{=} & f^{-1}(V) & \underset{\substack{\uparrow \\ \text{since } f \text{ is continuous}}}{=} & \text{open subset of } X. \end{array}$$

□

At times it is also useful to have a characterization of continuous maps in terms of closed sets.

Lemma 1.31. *A map $f\colon X \to Y$ between two topological spaces X and Y is continuous if and only if for each closed set A in Y the preimage $f^{-1}(A)$ is closed in X.*

Proof. This lemma is a straightforward consequence of Lemma 1.1 (7) and the definitions. We leave it to the reader to fill in the details. □

By Lemma 1.30 (3) we know that the restriction of a continuous map to any subset is still continuous. The following lemma can be viewed as a converse: if "enough" restrictions of a given map are continuous, then the original map is also continuous.

Lemma 1.32. *Let $f\colon X \to Y$ be a map between topological spaces.*

(1) *If there exists a family of open subsets $\{W_i\}_{i \in I}$ of X with $\bigcup_{i \in I} W_i = X$ such that each restriction $f|_{W_i}$ is continuous, then f itself is continuous.*
(2) *If there exists a* finite *collection of closed sets $A_1, \ldots, A_m$ of X with $A_1 \cup \cdots \cup A_m = X$ such that each restriction $f|_{A_i}$ is continuous, then f itself is continuous.*

In practice often the following variation on (2) *gets used:*

(2') *If X is Hausdorff and if there exists a* finite *collection of compact sets $A_1, \ldots, A_m$ of X with $A_1 \cup \cdots \cup A_m = X$ such that each restriction $f|_{A_i}$ is continuous, then f itself is continuous.*

Remark.

(1) In practice Lemma 1.32 (2) often gets used the following way: We are given two topological spaces X and Y and closed subsets $A_1, \ldots, A_m$ of X. Furthermore we are given continuous maps $f_i\colon A_i \to Y$, $i = 1, \ldots, m$. If the f_i agree on the overlaps, then the map

$$\begin{array}{ccl} X & \to & Y \\ P & \mapsto & f_i(P) \quad \text{if } P \in A_i \end{array}$$

is well-defined and it follows from Lemma 1.32 (2) that it is continuous.

(2) Note that in Lemma 1.32 (1) we are allowed to deal with arbitrarily many open subsets whereas in Lemma 1.32 (2) we are restricted to finitely many closed subsets. It is clear that Lemma 1.32 (2) cannot be generalized to arbitrarily many closed subsets, after all, the restriction of a map $f\colon \mathbb{R} \to \mathbb{R}$ to any one-point subset $\{x\}$ is continuous, but clearly not every map $f\colon \mathbb{R} \to \mathbb{R}$ is continuous.

Proof. Let $f\colon X \to Y$ be a map between topological spaces.

(1) Let $\{W_i\}_{i\in I}$ be a family of open subsets of X with $\bigcup_{i\in I} W_i = X$ such that each $f_i := f|_{W_i}$ is continuous. Let $U \subset Y$ be an open set. We want to show that $f^{-1}(U)$ is an open subset of X. By Lemma 1.7 (1a) it suffices to show for every $i \in I$ the intersection $f^{-1}(U) \cap W_i$ is an open subset of W_i. But $f^{-1}(U) \cap W_i = f_i^{-1}(U)$ is indeed open in W_i since by hypothesis each f_i is continuous.
(2) The proof of this statement is almost identical to the proof of (1), we just need to replace Lemma 1.7 (1a) by Lemma 1.7 (2a).
(3) This statement follows immediately from (2) and Lemma 1.18 (2). □

The notion of continuity is of course already familiar from earlier analysis courses. The following proposition shows that for maps between metric spaces the earlier "$\epsilon - \delta$"–definition of continuity agrees with the above definition of continuity.

Proposition 1.33. *Let $f\colon X \to Y$ be a map between metric spaces. Then the following holds:*

$$f \text{ is continuous} \quad \Longleftrightarrow \quad \underset{x\in X}{\forall}\ \underset{\epsilon>0}{\forall}\ \underset{\delta>0}{\exists}\ \underset{x'\in B_\delta(x)}{\forall}\ d(f(x), f(x')) < \epsilon.$$

Remark. We use Proposition 1.33 to import from real analysis the various continuous functions on $\mathbb{R}$ and $\mathbb{C}$, e.g. polynomials, trigonometric functions and the exponential function. The replacement of the classic "$\epsilon - \delta$"–definition of continuity by the definition in terms of open sets can even be helpful in the context of real analysis. For example, let us consider the function

$$\begin{aligned} f\colon \mathbb{R} &\to \mathbb{R} \\ x &\mapsto \begin{cases} \frac{1}{2}x^2, & \text{if } x \geq 0, \\ -x, & \text{if } x < 0. \end{cases} \end{aligned}$$

With the "$\epsilon - \delta$"–definition it is slightly annoying to prove continuity at 0. But applying Lemma 1.32 (2) to the closed subsets $A_1 = (-\infty, 0]$ and $A_2 = [0, \infty)$ it is totally evident that this function is continuous. We refer to Figure 20 for an illustration.

The proof of Proposition 1.33 requires some preparations. In particular it builds on the following proposition that frequently makes it much easier to show that a given map is continuous.

Proposition 1.34. *Let $f\colon X \to Y$ be a map between topological spaces. Let $\mathcal{C}$ be a subbasis for the topology of Y (e.g. $\mathcal{C}$ could be a basis for the topology). Then the following holds*

$$f \text{ is continuous} \quad \Longleftrightarrow \quad \text{for each } C \in \mathcal{C} \text{ the preimage } f^{-1}(C) \text{ is open in } X.$$

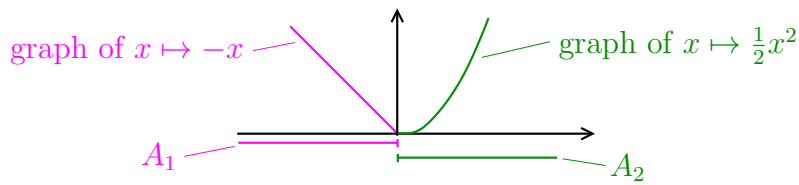

FIGURE 20.

Proof $(*)$. Let $f\colon X \to Y$ be a map between topological spaces and let $\mathcal{C}$ be a subbasis for the topology of Y. The "$\Rightarrow$"-direction of the proposition follows from the observation that elements of a subbasis are in fact open. Thus let us turn to the "$\Leftarrow$"-direction. We now assume that for each $C \in \mathcal{C}$ the preimage $f^{-1}(C)$ is open in X. We start out with a little observation. Suppose we are given $C_1, \ldots, C_k \in \mathcal{C}$, then

$$f^{-1}(C_1 \cap \cdots \cap C_k) \overset{\text{Lemma 1.1}}{\overset{\downarrow}{=}} \underbrace{f^{-1}(C_1)}_{\text{open in } X} \cap \cdots \cap \underbrace{f^{-1}(C_k)}_{\text{open in } X}$$

is also open in X. This shows, by definition, that for each $B \in \mathcal{B}(\mathcal{C})$ the preimage $f^{-1}(B)$ is open in X.

Now we turn to the actual proof that f is continuous. Thus let $U \subset Y$ be an open subset. By Lemma 1.25 there exists a family $\{B_j\}_{j \in J}$ of sets in $\mathcal{B}$ with

$$U = \bigcup_{j \in J} B_j.$$

Then we see that

$$f^{-1}(U) = f^{-1}\Big(\bigcup_{j \in J} B_j\Big) \overset{\text{Lemma 1.1}}{\overset{\downarrow}{=}} \underbrace{\bigcup_{j \in J} \underbrace{f^{-1}(B_j).}_{\text{open in } X}}_{\substack{\text{union of open} \\ \text{sets, thus open in } X}}$$

□

Now that we have Proposition 1.34 under the belt we can easily provide a proof of Proposition 1.33.

Proof of Proposition 1.33$(*)$. Let $f\colon X \to Y$ be a map between metric spaces. We need to show that

$$f \text{ is continuous} \quad \Longleftrightarrow \quad \forall_{x \in X} \ \forall_{\epsilon > 0} \ \exists_{\delta > 0} \ \forall_{y \in B_\delta(x)} \ d(f(x), f(y)) < \epsilon.$$

We prove the two directions separately:

"$\Rightarrow$" Let $x \in X$ and let $\epsilon > 0$. We consider $V := f^{-1}(B_\epsilon(f(x))) \subset X$. Since f is continuous we know that V is open. By the definition of the topology on a metric space there exists a $\delta > 0$ such that $B_\delta(x) \subset V$. This delta has the desired property.

"$\Leftarrow$" On page 60 we saw that the open balls form a basis for the topology of metric spaces. Thus by Proposition 1.34 it suffices to show that if $y \in Y$ and $\mu > 0$, then $f^{-1}(B_\mu(y))$ is an open subset of X. By the definition of the topology on X it suffices to prove the following claim.

Claim. Given any $x \in f^{-1}(B_\mu(y))$ there exists an $\epsilon > 0$ with $B_\epsilon(x) \subset f^{-1}(B_\mu(y))$.

We set $\delta = \mu - d(f(x), y)$. Note that $\delta > 0$. By the triangle inequality we have $B_\delta(f(x)) \subset B_\mu(y)$. Furthermore by our hypothesis on f there exists an $\epsilon > 0$ such that $f(B_\epsilon(x)) \subset B_\delta(f(x))$. Thus we see that $B_\epsilon(x) \subset f^{-1}(B_\mu(y))$. We refer to Figure 21 for an illustration of this argument. □

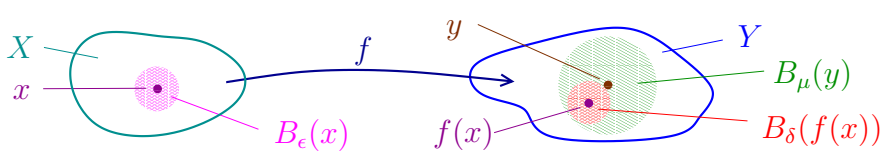

FIGURE 21. Illustration of the proof of Proposition 1.33.

We continue with the following straightforward definition.

Definition. Let $f\colon X \to Y$ be a map between topological spaces.

(1) We say f is *open* if the image of every open subset of X is open in Y.
(2) We say f is *closed* if the image of every closed subset of X is closed in Y.

Example. The projection $\mathbb{R}^2 \to \mathbb{R}$ given by $(x, y) \mapsto x$ is easily seen to be an open map but it is not a closed map.[11] On the other hand the inclusion $i\colon \mathbb{R} \to \mathbb{R}^2$, $i(x) = (x, 0)$ is evidently not an open map but it is a closed map.

Lemma 1.35. *Let X be a topological space.*

(1) *If $U \subset X$ is an open subset, then the inclusion map $i\colon U \to X$ is open.*
(2) *If $A \subset X$ is a closed subset, then the inclusion map $i\colon A \to X$ is closed.*

Proof.

(1) Suppose that V is an open subset of U. By definition of the subspace topology there exists an open subset $W \subset X$ with $V = U \cap W$. But then $i(V) = V = U \cap W$ is the intersection of two open subsets of X, thus it is an open subset of X.
(2) The proof of this statement is analogous to the proof of Statement (1), we just not to appeal to Lemma 1.6 (2) to make the necessary adjustments. □

[11] Why is not a closed map?

We have the following analogue to Proposition 1.34.

Lemma 1.36. *Let $f\colon X \to Y$ be a map between topological spaces. Let $\mathcal{B}$ be a basis for the topology of X. Then the following holds*

$$f \text{ is open} \quad \Longleftrightarrow \quad \text{for each } B \in \mathcal{B} \text{ the image } f(B) \text{ is open in } Y.$$

Proof. This statement follows easily from Lemmas 1.25 and 1.1. □

The following lemma states perhaps the most important feature of compact sets.

Lemma 1.37.

(1) *Let $f\colon X \to Y$ be a continuous map. If X is compact, then $f(X)$ is also compact.*
(2) *Let $f\colon X \to \mathbb{R}$ be a continuous map. If X is compact and non-empty, then f assumes its maximum and its minimum, i.e. there exist $x_0, x_1 \in X$ such that*

$$f(x_0) \;\le\; f(x) \;\le\; f(x_1) \quad \text{for all } x \in X.$$

(3) *Let $f\colon X \to Y$ be a continuous map. If X is compact and if Y is Hausdorff, then $f(X)$ is a closed subset of Y.*

Example. Let X be a topological space, let Y be a subset and let $K \subset Y$ be another subset. If K is a compact subset of Y, i.e. then K is also a compact subset of X. This elementary observation follows immediately from Lemma 1.37 and the fact, observed above, that inclusion maps are continuous.

Remark. The statement of Lemma 1.37 (1) is really quite astounding. More precisely, we already saw that the image of an open set under a continuous map is not necessarily open. Similarly, the image of a closed set under a continuous map is not necessarily closed. For example consider the inclusion map $i\colon X = (0,1] \to Y = \mathbb{R}$. Evidently X is a closed subset of itself, but $i(X)$ is not a closed subset of $\mathbb{R}$.

Proof.

(1) Let $\{U_i\}_{i\in I}$ be an open covering of $f(X)$. We need to show that $f(X)$ is contained in the union of finitely many U_i's. We have

$$X \;\underset{\substack{\uparrow \\ \text{Lemma 1.1}}}{\subset}\; f^{-1}(f(X)) \;\subset\; f^{-1}\Big(\bigcup_{i\in I} U_i\Big) \;\underset{\substack{\uparrow \\ \text{Lemma 1.1}}}{=}\; \bigcup_{i\in I} f^{-1}(U_i).$$

By the continuity of f we obtain that $\{f^{-1}(U_i)\}_{i\in I}$ is an open covering of X. Since X is compact there exist $i_1, \dots, i_k \in I$ such that

$$X \;\subset\; f^{-1}(U_{i_1}) \cup \cdots \cup f^{-1}(U_{i_k}).$$

We see that

$$\begin{aligned} f(X) \;&\subset\; f\left(f^{-1}(U_{i_1}) \cup \cdots \cup f^{-1}(U_{i_k})\right) \\ &\underset{\substack{\uparrow \\ \text{Lemma 1.1}}}{=}\; f\left(f^{-1}(U_{i_1})\right) \cup \cdots \cup f\left(f^{-1}(U_{i_k})\right) \;\underset{\substack{\uparrow \\ \text{Lemma 1.1}}}{\subset}\; U_{i_1} \cup \cdots \cup U_{i_k}. \end{aligned}$$

(2) It follows from (1) and the Heine-Borel Theorem 1.21 that $f(X) \subset \mathbb{R}$ is bounded and closed. Thus $y_0 := \inf(f(X))$ and $y_1 := \sup(f(x))$ exist and they lie in $f(X)$. Any choice of points $x_0 \in f^{-1}(y_0)$ and $x_1 \in f^{-1}(y_1)$ have the desired properties.
(3) This statement is an immediate consequence of Lemma 1.18 (1) and the first statement. □

On many occasions we will use the following elementary lemma.

Lemma 1.38. $(*)$ *Let $f\colon K \to X$ be a continuous map from a compact topological space K to a topological space X.*[12] *Suppose there exists a sequence $U_1, U_2, \dots$ of subsets of X with the following properties:*

(1) *each U_i is open,*
(2) *the sequence is nested, i.e. for each $i \in \mathbb{N}$ we have $U_i \subset U_{i+1}$,*
(3) *we have $X = \bigcup_{i\in\mathbb{N}} U_i$.*

Then there exists a $k \in \mathbb{N}$ with $f(K) \subset U_k$.

Proof $(*)$. For $i \in \mathbb{N}$ we write $V_i = f^{-1}(U_i)$. Since f is continuous it follows from (1) that each V_i is an open subset of K. By (3) the V_i cover all of K. Since K is compact there exist $i_1, \dots, i_n$ such that $K = V_{i_1} \cup \dots \cup V_{i_n}$. We set $k := \max\{i_1, \dots, i_n\}$. Since the U_i are nested the V_i are also nested. It follows that K is already contained in V_k, put differently, $f(K)$ is contained in U_k. □

Definition. We say a map $f\colon X \to Y$ between two topological spaces X and Y is a *homeomorphism* if the following three properties are satisfied:

(1) f is continuous,
(2) f is bijective,
(3) the inverse map $f^{-1}\colon Y \to X$ is also continuous.

If there exists a homeomorphism between X and Y we say that X and Y are *homeomorphic* and sometimes we write $X \cong Y$.

Remark. If two topological spaces are homeomorphic, then they have the same topological properties, i.e. they share all properties that are defined purely in terms of the topology. For example, if X and Y are homeomorphic, then X is Hausdorff if and only if Y is Hausdorff, X is compact if and only if Y is compact and so on.

Convention. At times we refer to a topological space that is homeomorphic to a ball or to a sphere also as a ball or a sphere.

Examples.

[12] A common application is that K is a compact subset of X and f is the inclusion map.

(1) Given $n \in \mathbb{N}$ we denote by
$$S^n_{\geq 0} \;:=\; \{(x_1, \ldots, x_{n+1}) \in S^n \mid x_{n+1} \geq 0\}$$
the upper hemisphere and we define similarly the lower hemisphere $S^n_{\leq 0}$ to be
$$S^n_{\leq 0} \;:=\; \{(x_1, \ldots, x_{n+1}) \in S^n \mid x_{n+1} \leq 0\}.$$
The maps
$$\begin{array}{rcl} \varphi\colon \overline{B}^n & \mapsto & S^n_{\geq 0} \\ x & \mapsto & \left(x, \sqrt{1 - \|x\|^2}\right) \end{array} \quad \text{and} \quad \begin{array}{rcl} p\colon S^n_{\geq 0} & \to & \overline{B}^n \\ (x_1, \ldots, x_n, x_{n+1}) & \mapsto & (x_1, \ldots, x_n) \end{array}$$
are easily seen to be continuous and inverses to one another. Thus both maps are homeomorphisms. The same way we see that the lower hemisphere is also homeomorphic to the closed ball $\overline{B}^n$.

(2) Let $A \in \mathrm{GL}(n, \mathbb{R})$ be an invertible real matrix. It follows from the discussion on page 65 that the map $\mathbb{R}^n \to \mathbb{R}^n$ given by multiplication by A is a homeomorphism. This simple observation has a useful consequence: Let V be an n-dimensional real vector space. We pick an isomorphism $\varphi\colon \mathbb{R}^n \to V$ and we equip V with the unique topology that turns φ into a homeomorphism. By the above discussion this definition of a topology does not depend on the choice of φ. Unless we say something else any finite-dimensional real vector space will be equipped with this topology. Note that with these topologies any isomorphism between real vector spaces of the same finite dimension is also a homeomorphism.

(3) We consider the map
$$\begin{array}{rcl} f\colon [0,1) & \to & S^1 \\ t & \mapsto & e^{2\pi i t}. \end{array}$$
The map f is a continuous bijection but it is not a homeomorphism. One can see this by either directly showing that f^{-1} is not continuous or by noting that $[0,1)$ is not compact whereas S^1 is compact. We illustrate this example in Figure 22. The importance of this example cannot be overestimated. It is an unfortunate fact of life that all too often one writes down a continuous map $f\colon X \to Y$ between topological spaces, checks that it is a bijection, and walks away under the warm, but mistaken, impression that one now has found a homeomorphism.

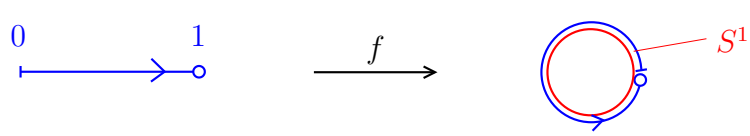

FIGURE 22.

In many situations one is given an explicit continuous bijection $f\colon X \to Y$ between two topological spaces and one would like to show that f is in fact a homeomorphism. Unfortunately usually it is very painful to write down the explicit inverse map $f^{-1}\colon Y \to X$,

let alone to verify that it is continuous. Fortunately we have two results which often help us in circumventing this difficulty.

Lemma 1.39. $(*)$ *Let $f\colon X \to Y$ be a map between topological spaces that is continuous and a bijection. If f is open or if f is closed, then f is a homeomorphism.*

Proof $(*)$. Let $f\colon X \to Y$ be a map between topological spaces that is continuous and that is a bijection. First assume that f is open. It remains to show that $g := f^{-1}\colon Y \to X$ is continuous. Thus let $U \subset X$ be an open set. We need to show that $g^{-1}(U)$ is an open subset of Y. But this is obvious, since $g^{-1}(U) = f(U)$ is an open subset since we assume that f is an open map.

Now suppose that the map f is closed. The proof is almost identical to the above argument, except that now we have to use the continuity criterion provided by Lemma 1.31. $\square$

Example. Let U be an open subset of $\mathbb{R}$ and let $f\colon U \to \mathbb{R}$ be a strictly monotonously increasing map, i.e. for any $x < y$ in U we have $f(x) < f(y)$. Note that open intervals form a basis for the topology of U. By the Intermediate Value Theorem the image of an open interval under f is again an open interval. Thus it follows from Lemma 1.36 that $f\colon U \to \mathbb{R}$ is an open map. Lemma 1.39 implies that $f\colon U \to f(U)$ is a homeomorphism.

The next proposition is certainly one of the most frequently used results in topology.

Proposition 1.40. *Let $f\colon X \to Y$ be a bijective continuous map between topological spaces. If X is compact and if Y is Hausdorff, then f is a homeomorphism.*

Remark. In the above example we saw that certainly we cannot drop the condition that X is compact from the proposition. But what about the "Hausdorff condition"? In Exercise 1.14 we will come up with an example of a bijective continuous map $f\colon X \to Y$ between two topological spaces where X is compact but such that f is nonetheless not a homeomorphism.

Proof. Let $f\colon X \to Y$ be a bijective continuous map between topological spaces. We assume that X is compact and that Y is Hausdorff. We need to show that the inverse map $g := f^{-1}\colon Y \to X$ is continuous. By Lemma 1.31 it suffices to show that for any closed subset A of X the corresponding preimage $g^{-1}(A)$ is closed in Y. In fact we have

$$\begin{array}{ccccccc} A \subset X \text{ closed} & \Rightarrow & A \text{ is compact} & \Rightarrow & f(A) \text{ is compact} & \Rightarrow & f(A) = g^{-1}(A) \text{ is closed.} \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{by Lemma 1.18 since } X \text{ is compact} & & \text{Lemma 1.37 (1)} & & \text{by Lemma 1.18 (2) since } Y \text{ is Hausdorff} & \end{array}$$

$\square$

We formulate our first application of Proposition 1.40 as a lemma.

Lemma 1.41. *We consider the map*

$$\begin{array}{rcl} \Phi\colon S^n & \to & \mathbb{R}^n \cup \{\infty\} \\ (x_1, \dots, x_{n+1}) & \mapsto & \begin{cases} \left(\dfrac{x_1}{1 - x_{n+1}}, \dots, \dfrac{x_n}{1 - x_{n+1}}\right), & \text{if } x_{n+1} < 1, \\ \infty, & \text{if } x_{n+1} = 1. \end{cases} \end{array}$$

where we equip $\mathbb{R}^n \cup \{\infty\}$ *with the topology that we introduced on page 53. We refer to* Φ *as the* stereographic projection. *This map has the following properties:*

(1) *The map* Φ *sends the "North Pole"* $N = (0, \ldots, 0, 1) \in S^n$ *to* ∞.
(2) *For any* $P \in S^n$ *that does not equal the North Pole* N *the point* $\Phi(P) \in \mathbb{R}^n$ *is the unique point such that the ray emanating from* N *and that goes through* P *intersects the plane* $\mathbb{R}^n \times \{0\}$ *in* $(\Phi(P), 0)$. *We refer to Figure 23 for an illustration.*
(3) *For any* $(v_1, \ldots, v_n, 0) \in S^n \cap (\mathbb{R}^n \times \{0\})$ *we have* $\Phi(v_1, \ldots, v_n, 0) = (v_1, \ldots, v_n)$.
(4) *The map* Φ *is continuous.*
(5) *The map* Φ *is a homeomorphism.*

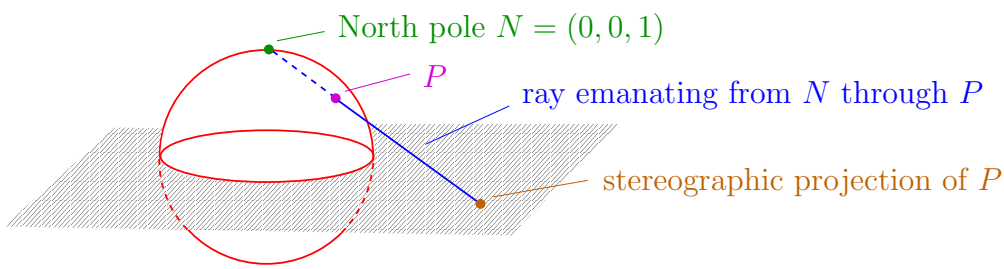

FIGURE 23. Stereographic projection from $S^2 \setminus \{(0, 0, 1)\}$ onto $\mathbb{R}^2$.

Proof.

(1) This statement follows immediately from the definition of Φ.
(2) This statement follows from an elementary calculation which we leave to the reader.
(3) This statement follows immediately from the definition of Φ.
(4) We will prove this statement in Exercise 1.21.
(5) We leave it to the reader to verify that Φ is a bijection. Note that S^n is compact by the Heine-Borel Theorem 1.21. Furthermore note that on page 53 we pointed out that $\mathbb{R}^n \cup \{\infty\}$ is Hausdorff. Hence it follows from Proposition 1.40 that Φ is a homeomorphism. □

Throughout the remainder of these lecture notes the following convention applies:

Convention. Henceforth any map between two topological spaces is assumed to be continuous, unless we say explicitly otherwise.

1.6. **Normal topological spaces** $(*)$**.** There are many other "separation axioms" that are similar to the Hausdorff condition. We refer to [Mun3, Chapter 4.2] for more details. The only property we will need at some point is the following.

Definition. A topological space X is called *normal* if any two disjoint closed subsets A and B of X are separated by neighborhoods, i.e. if there exist disjoint open neighborhoods U of A and V of B.

The following lemma nicely combines two key notions that we have introduced so far.

Lemma 1.42. $(*)$ *Let X be a topological space. If X is compact and Hausdorff, then it is also normal.*

Proof $(*)$. Let X be a topological space that is compact and Hausdorff. Furthermore let A and B be two disjoint closed subsets of X. Note that Lemma 1.18 (1) implies that A and B are also compact.

We start out with the following claim.

Claim. Given any $a \in A$ there exists an open neighborhood U_a of a and an open neighborhood V_a of B that are disjoint.

Let $a \in A$. Since X is Hausdorff we can find for any $b \in B$ disjoint open neighborhoods R_b and S_b of a and b. Since B is compact there exist $b_1, \dots, b_n \in B$ such that $B \subset S_{b_1} \cup \dots \cup S_{b_n}$. The open sets

$$U_a := R_{b_1} \cap \dots \cap R_{b_n} \quad \text{and} \quad V_a := S_{b_1} \cup \dots \cup S_{b_n}$$

have the desired properties. This concludes the proof of the claim.

Now we can prove the actual lemma. Since A is compact we can find $a_1, \dots, a_m \in A$ such that $A \subset U_{a_1} \cup \dots \cup U_{a_m}$. The open sets

$$U := U_{a_1} \cup \dots \cup U_{a_m} \quad \text{and} \quad V := V_{a_1} \cap \dots \cap V_{a_m}$$

have the desired properties. □

Remark. Mathematical psychology tells us that Hausdorff does not imply normal. Indeed, an example of a topological space that is Hausdorff but not normal is given in [Mun3, Chapter 4.2].

The following lemma is basically just a convenient reformulation of being normal.

Lemma 1.43. *Let X be a topological space and let $A \subset X$ be a closed subset and $U \subset X$ be an open subset with $A \subset U$. If X is normal, then there exists an open subset V with $A \subset V \subset \overline{V} \subset U$.*

FIGURE 24. Illustration of Lemma 1.43.

Proof. Let X be a topological space and let $A \subset X$ be a closed subset and $U \subset X$ be an open subset with $A \subset U$. We set $B := X \setminus U$. This is a closed subset with $A \cap B = \varnothing$. Since X is normal there exist disjoint neighborhoods V of A and W of B. It remains to show that $\overline{V} \subset U$. In fact we have $V \subset X \setminus W \subset U$. But since W is open we know that $X \setminus W$ is closed. By definition of $\overline{V}$ we have $\overline{V} \subset X \setminus W$. □

Lemma 1.44. *Let X be a topological space and let $U_1, \dots, U_m$ be open subsets such that $X = \bigcup_{i=1}^{m} U_i$. If X is normal, then there exist open subsets $V_i \subset U_i$ such that $\overline{V}_i \subset U_i$ and such that $X = \bigcup_{i=1}^{m} V_i$.*

Remark. A much stronger version of this lemma can be found in [Dug, Theorem 6.1] or alternatively in [Grote, Satz 43].

Proof $(*)$. To simplify the notation we only discuss the case $m = 2$. We leave it to the reader to prove the general case.

Thus let X be a topological space that is normal. Furthermore let U_1 and U_2 be two open subsets with $U_1 \cup U_2 = X$. This data is equivalent to the statement that $X \setminus U_1$ and $X \setminus U_2$ are disjoint closed subsets of X. Since X is normal there exists, by Lemma 1.43, a subset $W_1 \subset X$ with $X \setminus U_1 \subset W_1 \subset \overline{W_1} \subset U_2$. In particular we have $\overline{W_1} \cap (X \setminus U_2) = \varnothing$. Again, because of Lemma 1.43, there exists a subset $W_2 \subset X$ with $X \setminus U_2 \subset W_2 \subset \overline{W_2} \subset X \setminus \overline{W_1}$. In particular we have $\overline{W_2} \cap \overline{W_1} = \varnothing$. We claim that $V_1 = X \setminus \overline{W_1}$ and $V_2 = X \setminus \overline{W_2}$ have the desired properties.

First note that for $i = 1, 2$ we have

$$V_i \;=\; X \setminus \overline{W_i} \;\subset\; X \setminus W_i \;\subset\; U_i.$$

Finally note that

$$V_1 \cup V_2 \;=\; (X \setminus \overline{W_1}) \cup (X \setminus \overline{W_1}) \;=\; X \setminus (\overline{W_1} \cap \overline{W_2}) \;=\; X.$$

We refer to Figure 25 for an illustration. □

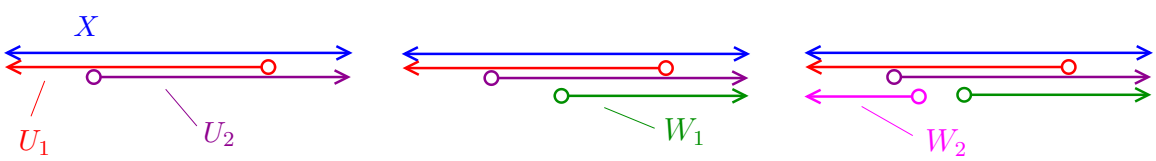

FIGURE 25.

We conclude this discussion of normal topological spaces with two significantly deeper results, namely Urysohn's Lemma and the Tietze Extension Theorem. We will not make use of these results, thus we will not provide the (non-trivial!) proofs.

We start out with what is known as Urysohn's Lemma. Despite its modest name it is actually highly non-trivial

Lemma 1.45. (Urysohn's Lemma) *Let X be a topological space X. If X is normal, then given any two disjoint closed subsets A and B there exists a continuous function $f\colon X \to \mathbb{R}$ with $f|_A \equiv 0$ and $f|_B \equiv 1$.*

Proof. Proofs are provided in many text books on general topology, see e.g. [Kel, Lemma 4.4], [Mun3, Theorem 4.3.1] or [Jä1, p. 109]. □

Theorem 1.46. (Tietze Extension Theorem) *Let X be a topological space, let $A \subset X$ be a closed subset and let $f\colon A \to \mathbb{R}$ be a continuous map. If X is normal, then there exists a continuous map $g\colon X \to \mathbb{R}$ with $g|_A = f$.*

Remark. Let X be a topological space and let A and B be two disjoint closed subsets. We consider the map on $A \cup B$ that is given by $f|_A \equiv 0$ and $f|_B \equiv 1$. If X is normal, then we can extend f by the Tietze Extension Theorem 1.46 to a continuous map on all of X. This shows that Urysohn's Lemma is an immediate consequence of the Tietze Extension Theorem 1.46.

Proof. We refer to [Kel, p. 242], [Mun3, Theorem 4.3.2] or [Jä1, p. 114] for proofs. □

1.7. **Convex subsets.** We start out with the definition of a convex subset.

Definition.

(1) We say that a subset $A \subset \mathbb{R}^n$ is *convex*, if for any two points P and Q in A the segment $\overline{PQ} := \{tP + (1-t)Q \,|\, t \in [0,1]\}$ also lies in A.
(2) Given a subset S of $\mathbb{R}^k$ the *convex hull* of S is defined as the intersection of all convex subsets of $\mathbb{R}^k$ that contain S. Since the intersection of convex sets is again convex we see that the convex hull of S is a convex subset of $\mathbb{R}^n$.

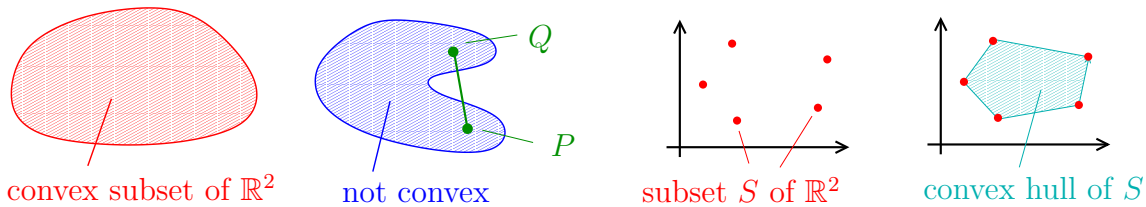

FIGURE 26.

Examples.

(1) For any point $x \in \mathbb{R}^n$ and any $\epsilon > 0$ the open ball $B^n_\epsilon(x)$ is convex. Indeed, let $P, Q \in B^n_\epsilon(x)$. Then for any $t \in [0,1]$ we have

$$\begin{aligned} \|t\cdot P + (1-t)\cdot Q - x\| &= \|t\cdot(P-x) + (1-t)\cdot(Q-x)\| \\ &\underset{\substack{\uparrow \\ \text{triangle inequality and homogeneity of } \|-\|}}{\leq} t\cdot\|P-x\| + (1-t)\cdot\|Q-x\| \underset{\substack{\uparrow \\ \text{since } P,Q \in B^n_\epsilon(x)}}{<} t\cdot\epsilon + (1-t)\cdot\epsilon = \epsilon. \end{aligned}$$

We have thus shown that $t \cdot P + (1-t) \cdot Q \in B^n_\epsilon(x)$. Basically the same way one shows that the closed ball $\overline{B}^n_\epsilon(x)$ is also convex.

(2) It is elementary to verify that any hyperrectangle $[a_1, b_1] \times \cdots \times [a_n, b_n]$ is convex.

(3) It is an invigorating exercise to show that the convex hull of points $P_1, \dots, P_n \in \mathbb{R}^k$ is given by the set

$$\Big\{ \sum_{i=1}^{n} t_i P_i \,\Big|\, t_1, \dots, t_n \in \mathbb{R}_{\geq 0} \text{ and } \sum_{i=1}^{n} t_i = 1 \Big\}.$$

The following proposition gives a useful criterion for showing that subsets of $\mathbb{R}^n$ are homeomorphic to an open or to a closed ball.

Proposition 1.47.

(1) *If A is a bounded open convex subset of $\mathbb{R}^n$, then given any $Q \in A$ there exists a canonical*[13] *homeomorphism*

$$f_Q \colon A \;\to\; B^n := \{x \in \mathbb{R}^n \mid \|x\| < 1\}$$

with $f_Q(Q) = 0$.

(2) *If A is a bounded closed*[14] *convex subset of $\mathbb{R}^n$, then given any point Q in the interior of A*[15] *there exists a canonical homeomorphism*[16]

$$f_Q \colon A \;\to\; \overline{B}^n = \{x \in \mathbb{R}^n \mid \|x\| \leq 1\}$$

with the following properies:

(a) *the homeomorphism f_Q sends Q to the origin,*

(b) *the homeomorphism f_Q restricts to a homeomorphism $\partial A \to S^{n-1}$,*

Examples.

(1) The open square $(0,1) \times (0,1)$ is clearly bounded and convex, thus it follows from Proposition 1.47 (1) that it is homeomorphic to the open disk B^2.

(2) It follows from Proposition 1.47 (2) that any triangle, i.e. any subset of $\mathbb{R}^2$ of the form $A = \{P + sv + tw \mid s, t \in [0,1] \text{ and } s + t \leq 1\}$ where $P \in \mathbb{R}^2$ and v, w are two linearly independent vectors, is homeomorphic to $\overline{B}^2$.

For readers who like gory details we present the more technical sibling of Proposition 1.47.

Proposition 1.48.

(1) *Let A is a bounded open convex subset of $\mathbb{R}^n$ and let $Q \in A$. Given $x \in A \setminus \{Q\}$ we define*[17]

$$\rho(x) \;:=\; \sup\big\{ \|rx\| \,\big|\, r \in \mathbb{R}_{>0} \textit{ and } r(x - Q) + Q \in A \big\}.$$

[13]Throughout the lecture notes we will on occasions write that "some objects exists canonically". This means that in the proof we show the existence of the object by giving an explicit construction that does not rely on any choices.

[14]Of course "bounded and closed" is in this instance, by the Heine-Borel Theorem 1.21 equivalent to "compact". In this instance we prefer to talk of "bounded closed" to stress the analogy to statement (1) of the lemma.

[15]Note that the interior might well be empty, i.e. such a point Q might not exist.

[16]This says in particular that if A is a bounded closed convex subset of $\mathbb{R}^n$ with *non-empty interior*, then A is homeomorphic to $\overline{B}^n$.

[17]The statement becomes slightly more readable if one sets $Q = 0$.

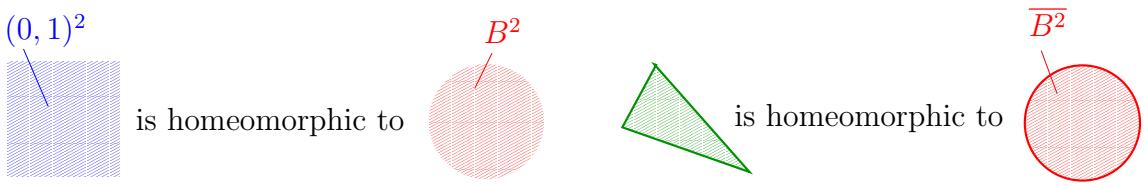

FIGURE 27.

The supremum exists for each $x \in A$ and the map

$$\begin{array}{rcl} f_Q\colon A & \to & B^n \\ x & \mapsto & \begin{cases} (x-Q)\cdot \frac{1}{\rho(x)}, & \text{if } x \neq Q, \\ 0, & \text{if } x = Q. \end{cases} \end{array}$$

is a homeomorphism with $f_Q(Q) = 0$.

(2) *Let A be a bounded closed convex subset of $\mathbb{R}^n$. If Q is a point in the interior of A, then the same expression as in (1) defines a homeomorphism $f_Q\colon A \to \overline{B}^n$ with $f_Q(Q) = 0$. Furthermore f_Q restricts to a homeomorphism $\partial A \to S^{n-1}$.*

Example. For $i = 1, \dots, n$ let $a_i < b_i$ be real numbers. We consider the "hyperrectangle" $[a_1, b_1] \times \cdots \times [a_n, b_n]$. It follows from the discussion on page 78 and from Proposition 1.22 that the hyperrectangle is convex and compact. Proposition 1.48 (2) gives us an explicit homeomorphism

$$f_Q\colon [a_1, b_1] \times \cdots \times [a_n, b_n] \ \to \ \overline{B}^n$$

that sends the boundary of the hyperrectangle to the sphere S^{n-1} and that sends the "midpoint" $Q := (\frac{a_1+b_1}{2}, \dots, \frac{a_n+b_n}{2})$ to the origin. Throughout this course we will use this homeomorphism to identify the left-hand side with the right-hand side. It follows easily from the explicit description of f_Q that the restriction of f_Q to each open cone on a side is smooth.[18] The homeomorphism from Proposition 1.48 (2) is illustrated in Figure 28.

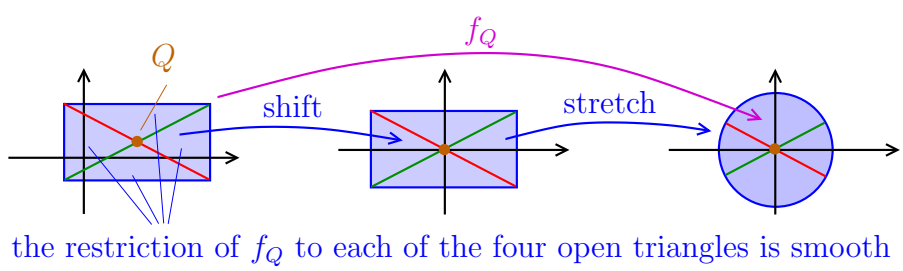

FIGURE 28.

[18]We leave it to the reader to make it precise what "open cone on a side" means. We will make use of this observation only once, and then it should be clear what we mean.

Proof $(*)$.

(2) Let A be a bounded closed convex subset of $\mathbb{R}^n$ and let Q be a point in the interior of A. After a translation we can assume that Q is the origin, in particular we can assume that the origin 0 lies in the interior of A. Given $x \in A \setminus \{0\}$ we define

$$\rho(x) \;:=\; \sup\big\{\|rx\| \,\big|\, r \in \mathbb{R}_{>0} \text{ and } rx \in A\big\}$$

and

$$f(x) \;:=\; x \cdot \frac{\rho(x)}{\|x\|}.$$

Since A is closed we have $f(x) \in A$.

Claim. The map $\rho\colon A \setminus \{0\} \to \mathbb{R}$ is positive, continuous and bounded from above and bounded from below by 1.

Since A is bounded it follows that ρ is bounded from above. It follows from the definition of ρ that ρ is bounded from below by 1. Therefore it remains to show that ρ is continuous. Now let $x \in A \setminus \{0\}$ and let $\epsilon > 0$. It suffices to show the following two statements:

(a) there exists an open neighborhood U of x in $A \setminus \{0\}$ such that $\rho(y) > \rho(x) - \epsilon$ for all $y \in U$,

(b) there exists an open neighborhood V of x in $A \setminus \{0\}$ such that $\rho(y) < \rho(x) + \epsilon$ for all $y \in V$.

We first show the existence of U. After possibly replacing ϵ by $\min\{\frac{1}{2}\rho(x), \epsilon\}$ we can suppose that $\epsilon \in (0, \rho(x))$.

Since 0 lies in the interior of A there exists an $\eta > 0$ such that $B^n_\eta(0) \subset A$. Since A is convex, the convex hull C of $B^n_\eta(0) \cup \{f(x)\}$ is still contained[19] in A. Furthermore, since $B^n_\eta(0)$ is open it is straightforward to see that $C' := C \setminus \{f(x)\}$ is an open subset of $\mathbb{R}^n$. We denote by $S^{n-1}_{\rho(x)-\epsilon}$ the sphere of radius $\rho(x) - \epsilon$ around 0. The point $x \cdot \frac{\rho(x)-\epsilon}{\|x\|}$ lies on $S^{n-1}_{\rho(x)-\epsilon}$ and it lies in C'. Since C' is open there exists an open neighborhood U' on $S^{n-1}_{\rho(x)-\epsilon}$ that is contained in C'. We set

$$U \;:=\; \{rz \,|\, z \in U' \text{ and } r \in (0,1)\}.$$

This is an open neighborhood of x and for any $y \in U$ we have $(\rho(x) - \epsilon) \cdot y \in A$, i.e. for any $y \in A$ we have $\rho(y) \geq \rho(x) - \epsilon$. Thus we have shown that the desired neighborhood U exists. The existence of V is proved in a very similar way. We refer to [Be, Chapter 11.3] for full details. This concludes the proof of the claim. Now we consider the map

$$\begin{aligned} f_Q\colon A &\to \overline{B}^n \\ x &\mapsto \begin{cases} x \cdot \frac{1}{\rho(x)}, & \text{if } x \neq 0, \\ 0, & \text{if } x = 0. \end{cases} \end{aligned}$$

[19] Why is that the case?

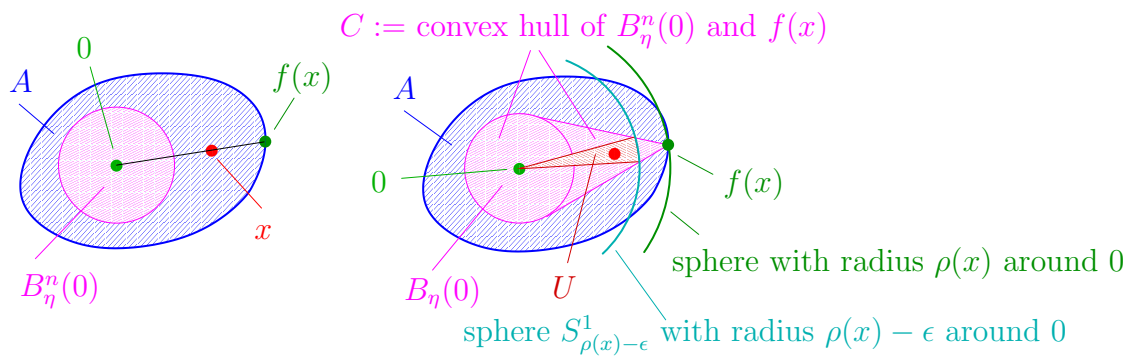

FIGURE 29. Illustration for the proof of Proposition 1.48.

It is straightforward to verify that this map is bijective[20] and it follows from the above claim[21] that f_Q is continuous. Note that our hypothesis on A and Heine-Borel Theorem 1.21 imply that A is compact. Thus we obtain from Proposition 1.40 that f_Q is in fact a homeomorphism. We leave it as a, potentially slightly annoying, exercise to verify that $f_Q(\partial A) = S^{n-1}$.

(1) We denote by $C = \overline{A}$ the closure of A. Since A is open and convex we know by Exercise 1.4 that $A = \mathring{C}$. One fairly easily verifies that C is convex. It is clear that C is bounded and it follows from Lemma 1.10 that C is closed. One verifies easily that the map f_Q defined for $C = \overline{A}$ restricts to the map f_Q defined for A. Thus it follows from (2) that the map $f_Q \colon C = \overline{A} \to \overline{B}^n$ is a homeomorphism and it restricts to a homeomorphism $f_Q \colon \mathring{C} \to B^n$. Since $\mathring{C} = A$ we get the desired homeomorphism. □

Remark. One again let A be a bounded closed convex subset A of $\mathbb{R}^n$ and let Q be a point in the interior of A. Proposition 1.48 provides us with a homeomorphism $f \colon A \to \overline{B}^n$. Since ∂A is not necessarily "smooth" (here we use smooth in a naive sense) one cannot hope to get such a map f that is smooth. But it does make sense to ask whether one can find such a map f such that the restriction to the interior $\mathring{A}$ of A is smooth, or even better, a diffeomorphism. In general the homeomorphism that we provide in Proposition 1.48 will not have this property. But we can modify the above construction to obtain a homeomorphism $f \colon A \to \overline{B}^n$ such that the restriction to $\mathring{A} \to B^n$ is a diffeomorphism. This can be achieved by replacing the linear stretching on the rays by an appropriately chosen different map,

[20]It follows easily from the convexity of A, the hypothesis that $\mathring{A} \neq \varnothing$ and the definition of f_Q that for each $v \in S^{n-1}$ the map f_Q restricts to a bijection on the "ray defined by v", i.e. it restricts to a bijection

$$A \cap \{rv \,|\, r \in \mathbb{R}_{>0}\} \;\to\; \overline{B}^n \cap \{rv \,|\, r \in \mathbb{R}_{>0}\}.$$

[21]From the continuity of ρ it follows that f_Q is continuous on $A \setminus \{0\}$. From the fact that ρ is bounded it follows easily that f_Q is continuous in 0.

e.g. we should stretch by 1 close to the origin to obtain differentiability at 0. It takes some effort to carry out this program rigorously, details can be found in [Fer, Satz 237].[22] Other approaches to finding homeomorphisms $f\colon A \to \overline{B}^n$ that restrict to a diffeomorphism $\mathring{A} \to B^n$ are sketched in [BJ, p. 86] and [GT, p. 60].

1.8. **The disjoint union of topological spaces** $(*)$**.** we start out with a short set-theoretic discussion. Sometimes, given two sets A and B one would like to consider a new set that is the "disjoint union of A and B". This leads us to the following, arguably slightly awkward definition.

Definition.

(1) Let A and B be two sets. We define the *disjoint union of A and B* as[23]

$$A \sqcup B \;:=\; (A \times \{1\}) \cup (B \times \{2\}).$$

(2) If $\{A_i\}_{i\in I}$ is a family of sets, then we define the *disjoint union* as

$$\bigsqcup_{i\in I} A_i \;:=\; \bigcup_{i\in I} (A_i \times \{i\}).$$

Convention. Let A and B be two sets. In most situations, when there is no danger of confusion, we use the obvious bijections $A = A \times \{1\}$ and $B = B \times \{1\}$ to identify A and B with the corresponding subsets of $A \sqcup B$. In particular, if A and B are already disjoint, then we make the identification $A \sqcup B = A \cup B$. The same convention applies to the disjoint union $\bigsqcup_{i\in I} A_i$. At times the author of these notes will rely on the good will of the reader to correctly interpret a given statement.

Definition. Given a family $\{X_i\}_{i\in I}$ of topological spaces we equip the disjoint union $\bigsqcup_{i\in I} X_i$ with the *disjoint union topology* that is defined by the condition that $U \subset \bigsqcup_{i\in I} X_i$ is open if and only if for each $i \in I$ the intersection $U \cap X_i$ is an open subset of X_i.

Example.

(1) One can easily verify that the topological space $S^1 \sqcup S^1$ is homeomorphic to the topological space $S^1(-2,0) \cup S^1(2,0) \subset \mathbb{R}^2$.
(2) In Exercise 1.22 we will see that the topological space $[-1,0] \sqcup (0,1]$ is homeomorphic to $[-2,-1] \cup (0,1] \subset \mathbb{R}$ and that it is not homeomorphic to $[-1,1]$.

The following lemma summarizes a few very basic properties of the disjoint union of two topological spaces. We leave the dreadfully dull proof as an exercise to the reader.

Lemma 1.49. $(*)$ *Let X, Y and Z be topological spaces.*

[22] It is worth noting that this diffeomorphism is orientation-preserving. (See later for the definition of orientation-preserving.)

[23] In other words, we replace A and B by sets that are disjoint but that admit obvious bijections to A and B.

(1) *The inclusion maps* $X \to X \sqcup Y$ *and* $Y \to X \sqcup Y$ *are homeomorphisms onto their images.*
(2) *A map* $f\colon X \sqcup Y \to Z$ *is continuous if and only if* $f|_X$ *and* $f|_Y$ *are continuous.*
(3) *Let* $f\colon X \to A$ *and* $g\colon Y \to B$ *be two continuous maps to topological spaces* A *and* B*. The map* $f \sqcup g\colon X \sqcup Y \to A \sqcup B$ *that is defined by* f *on* X *and by* g *on* Y *is continuous.*
(4) *The obvious bijection* $X \sqcup Y \to Y \sqcup X$ *is a homeomorphism.*
(5) *The obvious bijection* $(X \sqcup Y) \sqcup Z \to X \sqcup (Y \sqcup Z)$ *is a homeomorphism.*
(6) *The topological spaces* X *and* Y *are compact if and only if* $X \sqcup Y$ *is compact.*

For Statements (1)–(4) *the obvious analogues also hold if we consider the disjoint union of arbitrary families of topological spaces.*

1.9. **The product of finitely many topological spaces.** In the following two sections we introduce and discuss the topology on the product of topological spaces. In this section we deal with the product of *finitely* many topological spaces which is what we are mostly interested in. In the following section we will quickly discuss the product of arbitrarily many topological spaces.

Lemma 1.50. *Let* $X_1, \dots, X_k$ *be topological spaces. The set*

$$\mathcal{B} \;=\; \{U_1 \times \cdots \times U_k \,|\; \textit{each } U_i \textit{ is open in } X_i\}$$

has the basis property from page 60.

Proof (∗). We need to verify that $\mathcal{B}$ satisfies the conditions (B1) and (B2) formulated on page 60.

(B1) We have $X_1 \times \cdots \times X_k \in \mathcal{B}$. Thus given any $(x_1, \dots, x_k) \in X_1 \times \cdots \times X_k$ there exists a set in $\mathcal{B}$, namely $X_1 \times \cdots \times X_k$, which contains $(x_1, \dots, x_k)$. Thus $\mathcal{B}$ satisfies (B1).
(B2) Let $U_1 \times \cdots \times U_k$ and $V_1 \times \cdots \times V_k$ be two sets in $\mathcal{B}$. Then

$$(U_1 \times \cdots \times U_k) \cap (V_1 \times \cdots \times V_k) \;=\; (U_1 \cap V_1) \times \cdots \times (U_k \cap V_k)$$

is again a set in $\mathcal{B}$. Thus $\mathcal{B}$ also satisfies (B2). □

Definition. Let $X_1, \dots, X_k$ be topological spaces. The *product topology on* $X_1 \times \cdots \times X_k$ is the topology on $X_1 \times \cdots \times X_k$ that is generated by

$$\mathcal{B} \;=\; \{U_1 \times \cdots \times U_k \,|\; \text{each } U_i \text{ is open in } X_i\}.$$

Convention. Given topological spaces $X_1, \dots, X_k$ we always equip $X_1 \times \cdots \times X_k$ with the product topology, unless we explicitly say something else.

Example. Let X be a topological space and let $\{P\}$ be the topological space consisting of a single point (note that $\{X\}$ has a unique topological structure!). The obvious bijection $X \to X \times \{P\}$ is basically by definition a homeomorphism. On many occasions we will use this homeomorphism to make the identification $X = X \times \{P\}$.

The following lemma will get used implicitly on numerous occasions.

Lemma 1.51. $(*)$ *Let $X_1, \dots, X_k$ be topological spaces. If $A_i \subset X_i$, $i = 1, \dots, k$ are closed subsets, then $A_1 \times \cdots \times A_k$ is a closed subset of $X_1 \times \cdots \times X_k$.*

Proof $(*)$. We have

$$(X_1 \times \cdots \times X_k) \setminus (A_1 \times \cdots \times A_k) \underset{\substack{\uparrow \\ \text{basic set theory}}}{=} \bigcap_{i=1}^{k} \underbrace{X_1 \times \cdots \times (X_i \setminus A_i) \times \cdots \times X_k}_{\text{open in } X_1 \times \cdots \times X_k \text{ since } A_i \text{ is closed}}.$$

Thus we see that $(X_1 \times \cdots \times X_k) \setminus (A_1 \times \cdots \times A_k)$ is the intersection of finitely many open sets, i.e. the set itself is open, which implies by definition that $A_1 \times \cdots \times A_k$ is closed. $\square$

The following lemma seems obvious, but as so many statements in general topology, the actual proof requires a little bit of thought.

Lemma 1.52. $(*)$ *For any $k, l \in \mathbb{N}_0$ the map*

$$\begin{array}{rcl} \mathbb{R}^k \times \mathbb{R}^l & \to & \mathbb{R}^{k+l} \\ ((x_1, \dots, x_k), (y_1, \dots, y_l)) & \mapsto & (x_1, \dots, x_k, y_1, \dots, y_l) \end{array}$$

is a homeomorphism.

Convention. Henceforth, given $k_1, \dots, k_m \in \mathbb{N}$ we will always identify the product topological space $\mathbb{R}^{k_1} \times \cdots \times \mathbb{R}^{k_m}$ with $\mathbb{R}^{k_1 + \cdots + k_m}$. In particular, given $X_i \subset \mathbb{R}^{k_i}$, $i = 1, \dots, m$, we view $X_1 \times \cdots \times X_m$ as a subset of $\mathbb{R}^{k_1 + \cdots + k_m}$.

Proof $(*)$. It is clear that the map is a bijection. So it remains to show that the map and its inverse are continuous. The continuity of both maps can be shown using Proposition 1.34 and Lemma 1.8. We leave it to the reader to fill in the details. $\square$

Examples.

(1) Let $s_1, \dots, s_n \in \mathbb{N}_0$. We set $s = s_1 + \cdots + s_n$. By the above convention we can view $B^{s_1} \times \cdots \times B^{s_n}$ as a subset of $\mathbb{R}^s$. By definition this is an open subset of $\mathbb{R}^s$ and one verifies easily that it is convex and bounded. Thus it follows from Proposition 1.47 that there exists a canonical homeomorphism $B^{s_1} \times \cdots \times B^{s_n}$ to the ball B^s that sends $(0, \dots, 0)$ to the origin. The same statement holds for the corresponding closed balls.

(2) Let (X, d) be a metric space. In Exercise 1.26 we will see that the map

$$\begin{array}{rcl} X \times X & \to & \mathbb{R}_{\geq 0} \\ (x, y) & \mapsto & d(x, y) \end{array}$$

is continuous.

Before we can discuss more examples we introduce the following convention:

Convention.

(1) Given $m \in \mathbb{N}_0$ we make the identification

$$\begin{array}{rcl} \mathbb{C}^m & \xrightarrow{=} & \mathbb{R}^{2m} \\ (x_1 + iy_1, \dots, x_m + iy_m) & \mapsto & (x_1, y_1, x_2, y_2, \dots, x_m, y_m). \end{array}$$

(2) Given $m, n \in \mathbb{N}_0$ we make the identification

$$\begin{array}{rcl} M(m \times n, \mathbb{R}) & \xrightarrow{=} & \mathbb{R}^{m \cdot n} \\ (a_{ij})_{i=1,\dots,m, j=1,\dots,n} & \mapsto & (a_{11}, \dots, a_{1n}, \dots, a_{n1}, \dots, a_{nm}) \end{array}$$

Similarly we identify $M(m \times n, \mathbb{C})$ with $\mathbb{R}^{2mn}$.

(3) We use these maps to view (every subset of) $\mathbb{C}^m$, $M(m \times n, \mathbb{R})$ and $M(m \times n, \mathbb{C})$ as topological spaces.

Examples.

(1) It follows almost immediately from our conventions and the examples on page 65 that for any $k, l, m \in \mathbb{N}_0$ the map

$$\begin{array}{rcl} M(k \times l, \mathbb{R}) \times M(l \times m) & \to & M(k \times m) \\ (A, B) & \mapsto & A \cdot B \end{array}$$

is continuous. The same also applies to matrices over $\mathbb{C}$.

(2) It follows from (1) and Lemma 1.31 that

$$\mathrm{O}(n) = \{A \in M(n \times n; \mathbb{R}) \mid A^T A = \mathrm{id}\} = f^{-1}(\mathrm{id}_n) \quad \text{with} \quad \begin{array}{l} M(n \times n; \mathbb{R}) \xrightarrow{f} M(n \times n; \mathbb{R}) \\ \qquad A \mapsto A \cdot A^T \end{array}$$

is a closed subset of $\mathbb{R}^{n^2}$. Since each column of an orthogonal matrix has norm one we see that $\mathrm{O}(n) \subset \mathbb{R}^{n^2}$ is a bounded subset. Thus it follows from the Heine-Borel Theorem 1.21 that $\mathrm{O}(n)$ is compact. Basically the same argument shows that the set $\mathrm{U}(n)$ of unitary $n \times n$-matrices is a compact topological space.

The following lemma summarizes some key properties of the product topology. We will make use of this lemma on so many occasions that usually we do not mention it explicitly.

Lemma 1.53.

(1) (a) *The product topology is "commutative" in the sense that given two topological spaces A and B the obvious map $A \times B \to B \times A$ is a homeomorphism.*

(b) *The product topology is "associative" in the sense that given three topological spaces A, B and C the identity map is a homeomorphism between $(A \times B) \times C$, $A \times B \times C$ and $A \times (B \times C)$.*

(c) *The product topology commutes with subspace topology. More precisely, let X and Y be two topological spaces and let $A \subset X$ and $B \subset Y$ be subsets. Then the subspace topology of $A \times B \subset X \times Y$ agrees with product topology of A and B.*

(2) *Given any two topological spaces X and Y the obvious bijection between $X \times Y$ and $Y \times X$ is a homeomorphism.*

(3) *Let $X_1, \dots, X_k$ be topological spaces.*
   (a) *For each $i \in \{1, \dots, k\}$ the projection map*
$$\begin{array}{rcl} X_1 \times \cdots \times X_k & \to & X_i \\ (x_1, \dots, x_k) & \mapsto & x_i \end{array}$$
   is continuous. In fact, the product topology on $X_1 \times \cdots \times X_k$ is the smallest topology[24] *on $X_1 \times \cdots \times X_k$ that has the property that all the projection maps are continuous.*
   (b) *Let $i \in \{1, \dots, k\}$ and for $j \neq i$ let $x_j \in X_j$. The inclusion map*
$$\begin{array}{rcl} X_i & \to & X_1 \times \cdots \times X_k \\ x & \mapsto & (x_1, \dots, x, \dots, x_k) \end{array}$$
   is continuous. Furthermore the above inclusion map induces a homeomorphism
$$X_i \xrightarrow{\cong} \{x_1\} \times \cdots \times \{x_{i-1}\} \times X_i \times \{x_{i+1}\} \times \cdots \times \{x_k\}.$$
   (c) *If $f_i \colon X_i \to Y_i$, $i = 1, \dots, k$ are continuous maps between topological spaces, then the map*
$$\begin{array}{rcl} X_1 \times \cdots \times X_k & \to & Y_1 \times \cdots \times Y_k \\ (x_1, \dots, x_k) & \mapsto & (f_1(x_1), \dots, f_k(x_k)) \end{array}$$
   is continuous.
   (d) *If $f_i \colon X \to Y_i$, $i = 1, \dots, k$ are continuous maps between topological spaces, then the map*
$$\begin{array}{rcl} X & \to & Y_1 \times \cdots \times Y_k \\ x & \mapsto & (f_1(x), \dots, f_k(x)) \end{array}$$
   is continuous.

Proof. All the statements are easily verified by hand. I have never met anybody who wanted to see the full details. □

The following remark can be viewed as a sibling of the future Remark 1.67.

Remark 1.54. *We consider maps in and out of a product space $Y_1 \times Y_2$:*

(1) *In practice it is usually easy to show that a given map $X \to Y_1 \times Y_2$ to a product space is continuous. More precisely, by Lemma 1.53 (3d) we "just" need to show that the two coordinate maps $X \to Y_1$ and $X \to Y_2$ are continuous.*
(2) *There is usually no easy way to show that a map $Y_1 \times Y_2 \to X$ out of a product space is continuous.*

The following lemma is so essential that usually we will not mention it explicitly.

Lemma 1.55. *Let $X_1, \dots, X_k$ be non-empty topological spaces.*

[24] Here "smallest" means that any topology on $X_1 \times \cdots \times X_k$ that has that property contains the product topology.

(1) *The product $X_1 \times \cdots \times X_k$ is Hausdorff if and only if each X_i is Hausdorff.*
(2) *The product $X_1 \times \cdots \times X_k$ is compact if and only if each X_i is compact.*

Remark. Lemma 1.55 (2) also shows how the case $n = 1$ in Proposition 1.22 implies the general case of Proposition 1.22.

Proof $(*)$. By induction we only have to deal with the case $k = 2$. Thus let X and Y be two topological spaces.

First we deal with the "$\Rightarrow$"-direction of statement (1). Thus we assume that X and Y are Hausdorff. Let (x, y) and (x', y') be two distinct points in $X \times Y$. Without loss of generality we can assume that $x \neq x'$. By our hypothesis there exist open neighborhoods U of x and U' of x' with $U \cap U' = \varnothing$. Note that

$$(U \times Y) \cap (U' \times Y) \;=\; (U \cap U') \times Y \;=\; \varnothing \times Y \;=\; \varnothing.$$

By definition of the product topology the sets $U \times Y$ and $U' \times Y$ are open in $X \times Y$. We have thus found disjoint open neighborhoods of (x, y) and (x', y'). Therefore $X \times Y$ is Hausdorff. (This argument is sketched in Figure 30 to the left.)

Now we deal with the '$\Leftarrow$"-direction of statement (1). Therefore we suppose that $X \times Y$ is Hausdorff. We want to show that X is Hausdorff. Thus let x and x' be two different points in X. Since Y is non-empty there exists a $y \in Y$. Furthermore, since $X \times Y$ is Hausdorff there exist disjoint open neighborhoods W and W' of (x, y) and (x', y). By definition of the product topology there exist open neighborhoods U of x and U' of x' and open neighborhoods V of y and V' of y such that $(U \times V) \cap (U' \times V') = \varnothing$. In particular we see that $(U \times \{y\}) \cap (U' \times \{y\}) = \varnothing$. But this implies that $U \cap U' = \varnothing$. In particular U and U' are disjoint open neighborhoods of x and x'. Thus we have shown that X is Hausdorff. (This argument is sketched in Figure 30 to the right.) The proof that Y is also Hausdorff is evidently basically the same.

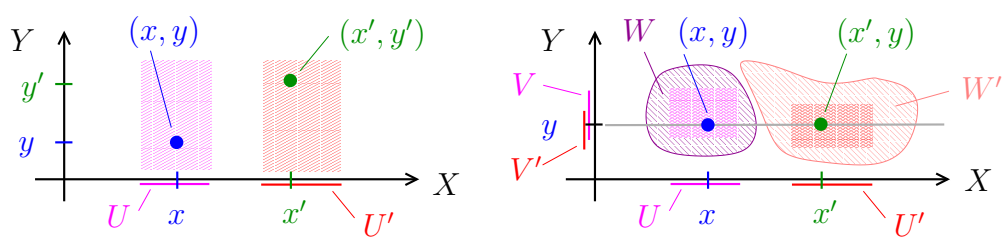

FIGURE 30. Illustration of the proof of Lemma 1.55 (1).

The '$\Rightarrow$"-direction of statement (2) is fortunately elementary, it follows immediately from Lemmas 1.53 and Lemma 1.37 (1).

Finally we deal with '$\Leftarrow$"-direction of statement (2). This is by far the hardest part of the lemma. We start out with the following claim.

Claim. Let $x_0 \in X$. If N is an open set of $X \times Y$ that contains $\{x_0\} \times Y$, then there exists a neighborhood W of $x_0 \in X$ such that $W \times Y \subset N$.

By definition of the product topology there exist sets of the form $U_i \times V_i$, $i \in I$ with the following properties:

(1) each U_i is open in X and each V_i is open in Y,
(2) each U_i contains x_0, i.e. for each i we have $\{x_0\} \times V_i \subset U_i \times V_i$,
(3) each $U_i \times V_i$ is contained in N,
(4) $\{x_0\} \times Y$ is contained in the union of the $U_i \times V_i$.

Since $\{x_0\} \times Y$ is compact we can arrange that I is a finite set, i.e. we can assume that $I = \{1, \ldots, n\}$. We set $W = U_1 \cap \cdots \cap U_n$. This is an open subset of X that contains x_0. It follows immediately from (3) and the definition of W that $W \times Y \subset N$. This concludes the proof of the claim.

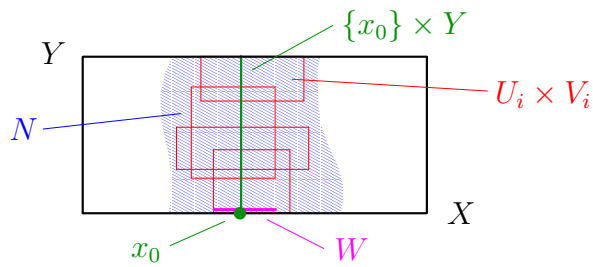

FIGURE 31. Illustration of the proof of Lemma 1.55 (2).

Now we turn to the actual proof that $X \times Y$ is compact. Thus suppose we are given an open covering $\{A_i\}_{i \in I}$ of $X \times Y$. Let $x \in X$. Since Y is compact there exists a finite set $I(x) \subset I$ such that $\{x\} \times Y \subset \bigcup_{i \in I(x)} A_i$. By the above claim there exists an open neighborhood $W(x)$ of x such that $W(x) \times Y \subset \bigcup_{i \in I(x)} A_i$.

All these open sets $\{W(x)\}_{x \in X}$ are an open covering of X. Since X is compact there exist $x_1, \ldots, x_k \in X$ such that $X = W(x_1) \cup \cdots \cup W(x_k)$. But then we see that

$$X \times Y \;=\; (W(x_1) \cup \cdots \cup W(x_k)) \times Y \;=\; \bigcup_{j=1}^{k} W(x_j) \times Y \;\subset\; \bigcup_{j=1}^{k} \bigcup_{i \in I(x_j)} A_i \;\subset\; X \times Y.$$

Thus we have successfully covered $X \times Y$ by finitely many sets in the given open covering. $\square$

Before we can state our next lemma we need to introduce the following definition.

Definition. Let X be a metric space. Given two non-empty subsets A and B we refer to

$$d(A, B) \;=\; \inf\{d(a, b) \,|\, a \in A \text{ and } b \in B\}$$

as the *distance between A and B*. If $A = \{a\}$ consists of a single point, then we write $d(a, B) := d(\{a\}, B)$.

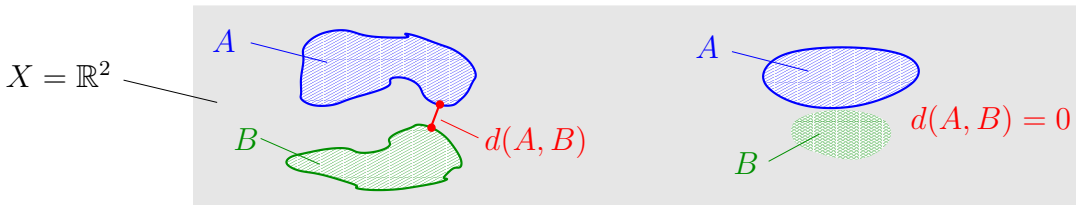

FIGURE 32.

Example. If two subsets A and B intersect, then we evidently have $d(A, B) = 0$. But in general the converse does not hold. For example if we consider $X = \mathbb{R}$, then

$$d\big(\underbrace{\text{open interval } (0,1)}_{=A}, \underbrace{\text{closed interval } [1,2]}_{=B}\big) \;=\; 0,$$

but evidently the intervals do not intersect.

The reader might justly suspect that the phenomenon of the last example is due to the fact that one of the sets is not compact. In several arguments the following corollary will play a crucial role.

Corollary 1.56. *Let X be a metric space and let K and L be two non-empty subsets. If both K and L are compact (for example if one or both of them are finite), then there exist $x \in K$ and $y \in L$ with*

$$d(x, y) \;=\; d(K, L).$$

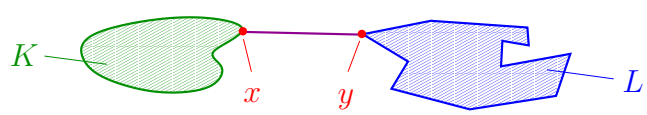

FIGURE 33.

Proof. It follows from our hypothesis and Lemma 1.55 that $K \times L$ is compact. As we pointed out above, the metric $d\colon K \times L \to \mathbb{R}_{\geq 0}$ is continuous. The corollary is now an immediate consequence of Lemma 1.37 (2). □

In Exercise 1.27 we will prove the following lemma.

Lemma 1.57. *Let X be a metric space. If $B \subset X$ is a non-empty subset, then the map*

$$\begin{array}{rcl} X & \to & \mathbb{R}_{\geq 0} \\ x & \mapsto & d(x, B) := \inf\{d(x, b) \,|\, b \in B\} \end{array}$$

is continuous.

Next we introduce some of the most popular product topological spaces.

Definition.

(1) We refer to $(S^1)^n$ as the *n-dimensional torus*. For $n = 2$ we just say *the torus*.
(2) We refer to $S^1 \times \overline{B}^2$ as the *solid torus* and we refer to $S^1 \times B^2$ as the *open solid torus*.

We deduce from Lemma 1.55 that the n-dimensional torus $(S^1)^n$ and the solid torus $S^1 \times \overline{B}^2$ are compact.

The following lemma allows us to view (solid) tori as subsets of $\mathbb{R}^3$.

Lemma 1.58. *We consider the map*[25]

$$\begin{array}{rcl} \Theta\colon \mathbb{R}^2 \times S^1 & \to & \mathbb{R}^3 \\ ((x,y), e^{i\varphi}) & \to & \underbrace{\begin{pmatrix} \cos\varphi & -\sin\varphi & 0 \\ \sin\varphi & \cos\varphi & 0 \\ 0 & 0 & 1 \end{pmatrix}}_{\textit{rotation around } z\textit{-axis}} \cdot \underbrace{\begin{pmatrix} 1+\frac{1}{2}x \\ 0 \\ -\frac{1}{2}y \end{pmatrix}}_{\substack{\textit{describes circle} \\ \textit{in } xz\textit{-plane}}} \end{array}$$

The restrictions of Θ to $S^1 \times S^1$, $\overline{B}^2 \times S^1$ and $B^2 \times S^1$ are homeomorphisms onto their images. (The restriction of Θ to $S^1 \times S^1$ is illustrated in Figure 34).

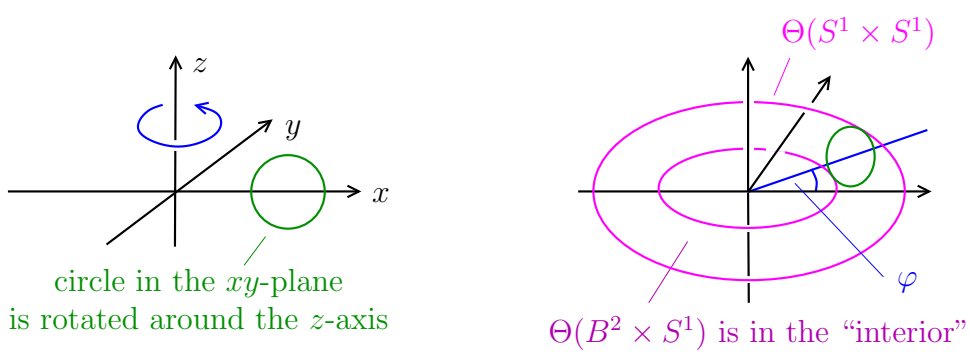

FIGURE 34.

Proof. It follows easily from the example on page 86 that the map $\Theta\colon S^1 \times \mathbb{R}^2 \to \mathbb{R}^3$ is continuous. An elementary argument shows that the restriction of Θ to $\overline{B}^2 \times S^1$ is injective. Since the solid torus $\overline{B}^2 \times S^1$ is compact we obtain from Proposition 1.40 that the restriction of Θ to $\Theta\colon \overline{B}^2 \times S^1 \to \Theta(S^1 \times \overline{B}^2)$ is a homeomorphism. But then it follows also that the restrictions of Θ to $S^1 \times S^1$ and $B^2 \times S^1$ are homeomorphisms onto their images. $\square$

[25]The map is chosen in such a way that it is orientation-preserving (we will introduce the notions of orientation and orientation later on) and such that $\Theta(\{(0,0)\} \times S^1) = S^1 \times \{0\}$.

Lemma 1.58 allows us to view (solid) tori as subsets of $\mathbb{R}^3$. The typical picture is shown in Figure 35. We refer to the images under these maps as the *standard* (*solid*) (*open*) *torus in* $\mathbb{R}^3$. Unfortunately, in a picture, it is hard to distinguish between tori, solid tori and open solid tori.

$S^1 \times S^1$ is homeomorphic to

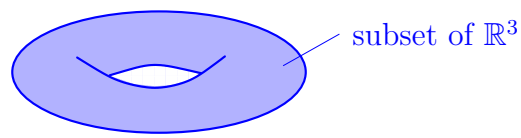

FIGURE 35.

We conclude this discussion of products of topological spaces with the following lemma.

Lemma 1.59. *Let $X_1, \dots, X_k$ be topological spaces and let $\mathcal{B}_1, \dots, \mathcal{B}_k$ be bases for these topological spaces. Then*

$$\mathcal{C} \ := \ \{B_1 \times \cdots \times B_k \mid \text{ for each } i \in \{1, \dots, k\} \text{ we have } B_i \in \mathcal{B}_i\}$$

is a basis for $X_1 \times \cdots \times X_k$.

Example. On page 64 we saw that the *rational* intervals form a basis for the usual topology on $\mathbb{R}$. Together with Lemma 1.59 it follows that the set $\mathcal{B}$ of rational hyperrectangles, i.e. that the set

$$\mathcal{B} \ = \ \{\text{all hyperrectangles } [a_1, b_1] \times \cdots \times [a_k, b_k] \text{ with } a_1, \dots, a_k, b_1, \dots, b_k \in \mathbb{Q}\} \ \subset \ \mathcal{P}(\mathbb{R}^k)$$

forms a basis for the standard topology on $\mathbb{R}^k$. In particular we see that $\mathbb{R}^k$ admits a basis for the topology that consists of only countably many sets.

Proof $(*)$. The idea is to prove the lemma using Lemma 1.28 (1). Thus let $W \subset X_1 \times \cdots \times X_k$ be an open set and let $(x_1, \dots, x_k) \in W$. By definition of the product topology there exist open sets $U_i \subset X_i$, $i = 1, \dots, k$ with $(x_1, \dots, x_k) \in U_1 \times \cdots \times U_k$ and $U_1 \times \cdots \times U_k \subset W$.

Let $i \in \{1, \dots, k\}$. Since $\mathcal{B}_i$ is a basis for X_i we see that there exists a $B_i \in \mathcal{B}_i$ with $x \in B_i \subset U_i$. It follows that

$$(x_1, \dots, x_k) \ \in \ B_1 \times \cdots \times B_k \ \subset \ U_1 \times \cdots \times U_k \ \subset \ W.$$

We deduce from Lemma 1.28 (1) that the given set $\mathcal{C}$ is indeed a basis for $X_1 \times \cdots \times X_k$. $\square$

1.10. **The product of arbitrarily many topological spaces** $(*)$**.** In this section we discuss the product of arbitrarily many topological spaces. In these notes we will only rarely deal with the case of the product of infinitely many topological spaces. Therefore we decided to deal with this case separately.

Let $\{X_i\}_{i \in I}$ a family of sets. The product of these sets is defined as the set

$$\prod_{i \in I} X_i \ := \ \Big\{ f \colon I \to \bigcup_{i \in I} X_i \,\Big|\, \text{ for every } i \in I \text{ we have } f(i) \in X_i \Big\}.$$

If the X_i are topological spaces, then we intend to equip the product with a suitable topology. Before we specify the topology we should decide what statements we want to hold. It seems reasonable to demand the following:

(A) given any $i \in I$ the projection map

$$\begin{array}{rcl} p_i \colon \prod_{i\in I} X_i & \to & X_i \\ f & \mapsto & f(i) \end{array}$$

should be continuous,

(B) given a topological space Y and continuous maps $f_i \colon Y \to X_i$ the resulting map

$$\begin{array}{rcl} F \colon Y & \to & \prod_{i\in I} X_i \\ y & \mapsto & \left(\begin{array}{ccc} I & \to & \bigcup_{i\in I} X_i \\ i & \mapsto & f_i(y) \end{array} \right). \end{array}$$

should be continuous.

The following construction provides us the with the desired topology on $\prod_{i\in I} X_i$.

Lemma 1.60. *Let $\{X_i\}_{i\in I}$ be a family of topological spaces. We set*

$$\mathcal{B} := \left\{ \prod_{i\in I} U_i \subset \prod_{i\in I} X_i \;\middle|\; \begin{array}{ll} (1) & \text{each } U_i \text{ is open in } X_i \text{ and} \\ (2) & \text{there exist only finitely many } i\text{'s with } U_i \neq X_i \end{array} \right\}.$$

Then the following statements hold:

(1) *The set $\mathcal{B}$ has the basis property that we introduced on page 60.*
(2) *The topology $\mathcal{T}(\mathcal{B})$ is the smallest topology such that the above properties (A) and (B) hold.*

Proof. Let $\{X_i\}_{i\in I}$ be a family of topological spaces.

(1) The proof that $\mathcal{B}$ has the basis property is basically identical to the proof of Lemma 1.50.
(2) (A) It follows immediately from the definitions that the projection maps p_i are continuous with respect to the given topology.
(B) Suppose we are given Y and f_i as above. We denote by F the map defined as above. We claim that F is continuous. By Proposition 1.34 it suffices to verify that the preimage of any set in $\mathcal{B}$ is open. So let $\prod_{i\in I} U_i$ be a set in $\mathcal{B}$. Then

$$F^{-1}\Big(\prod_{i\in I} U_i\Big) = \bigcap_{i\in I} f_i^{-1}(U_i) = \bigcap_{U_i \neq X_i} \underbrace{f_i^{-1}(U_i)}_{\text{open in } Y} = \begin{array}{c}\text{intersection of finitely} \\ \text{many open subsets of } Y.\end{array}$$

This concludes the proof that F is continuous.

We have thus shown that $\mathcal{T}(\mathcal{B})$ has the desired properties (A) and (B). But it is also clear that if a topology $\mathcal{S}$ on $\prod_{i\in I} X_i$ has the properties (A) and (B), then $\mathcal{B} \subset \mathcal{S}$.

But this implies that $\mathcal{T}(\mathcal{B}) \subset \mathcal{S}$. This shows that $\mathcal{T}(\mathcal{B})$ is the smallest topology with the desired properties. $\square$

The lemma leads us to the following definition.

Definition. Let $\{X_i\}_{i\in I}$ a family of topological spaces. We refer to the topology on $\prod_{i\in I} X_i$ that we defined in Lemma 1.60 as the *product topology* on $\prod_{i\in I} X_i$.

On several occasions we will use, consciously or unconsciously, the following lemma.

Lemma 1.61.

(1) *If $\{X_i\}_{i\in I}$ is a finite family of topological spaces, i.e. if I is finite, then the above product topology agrees with the product topology introduced on page 84.*
(2) *If we are given finitely many families of topological spaces $\{X_i\}_{i\in I_1}, \dots, \{X_i\}_{i\in I_k}$, then the obvious map*

$$\underbrace{\left(\prod_{i\in I_1} X_i\right) \times \cdots \times \left(\prod_{i\in I_k} X_i\right)}_{\text{product of } k \text{ topological spaces}} \to \prod_{i\in I_1 \sqcup \cdots \sqcup I_k} X_i$$

is a homeomorphism.

With basically the same proof as in Lemma 1.55 (1) one can show the following lemma.

Lemma 1.62. *Let $\{X_i\}_{i\in I}$ be a family of non-empty topological spaces. The product $\prod_{i\in I} X_i$ is Hausdorff if and only if each X_i is Hausdorff.*

The obvious generalization of Lemma 1.55 (2) also holds. But the proof is now considerably harder and thus the lemma gets upgraded to a theorem:

Theorem 1.63. (Tychonoff's Theorem)[26] *The product of arbitrarily many compact topological spaces is again a compact topological space.*

Sketch of proof. We will not really make use of Tychonoff's Theorem thus we limit ourselves to a sketch of the proof for $I = \mathbb{N}$. Thus let $\{X_i\}_{i\in\mathbb{N}}$ be a family of compact topological spaces. Furthermore let $\{U_j\}_{j\in J}$ be a family of open sets of $\prod_{i\in I} X_i$ such that we cannot cover $\prod_{i\in I} X_i$ by finitely many sets in the given open covering $\{U_j\}_{j\in J}$. We need to show that $\bigcup_{j\in J} U_j$ is a proper subset of $\prod_{i\in I} X_i$.

Claim. There exist $x_i \in X_i$, $i \in \mathbb{N}$ with the following property: Given any $k \in \mathbb{N}$ and given any open neighborhoods V_i of x_i, $i = 1, \dots, k$ the product

$$V_1 \times \cdots \times V_k \times X_{k+1} \times X_{k+2} \times \dots$$

[26] Andrey Tikhonov (1906-1993) was a Russian mathematician. The spelling for the theorem is due to the fact that Tikhonov initially published in German and his name got transcribed from the Cyrillic alphabet to the Latin alphabet as Tychonoff.

cannot be covered by finitely many sets in the given open covering.

The sequence $\{x_i\}_{i\in\mathbb{N}}$ is defined iteratively. The key to the proof is that we already know by Lemma 1.55 (2) that any finite product $X_1 \times \cdots \times X_k$ is compact. We leave it as an exercise to fill in the details. This concludes the proof of the claim.

The following claim concludes the proof of the theorem for $I = \mathbb{N}$.

Claim. The point $(x_1, x_2, \dots) \in \prod_{i\in I} X_i$ does not lie any of the U_j.

Suppose there exists a $j \in J$ with $(x_1, x_2, \dots) \in U_j$. By definition of the topology on $\prod_{i\in I} X_i$ (see Lemma 1.23) there exists a $k \in \mathbb{N}$ and open neighborhoods V_i of x_i, $i = 1, \dots, k$ such that

$$V_1 \times \cdots \times V_k \times X_{k+1} \times X_{k+2} \times \dots \ \subset \ U_j.$$

But by construction of $(x_1, x_2, \dots)$ this is impossible. This concludes the proof of the claim.

The proof of the general case of the Tychonoff Theorem can be done in a very similar way by equipping the index set I with a "total order". We refer to [Wri] for details. Alternatively proofs of Tychonoff's Theorem are provided in most textbooks on general topology, see e.g. [Mun3, Chapter 5.1] or [Jä1, Chapter X]. A particularly concise proof is also given in [Chf]. □

We continue with a very instructive example.

Example. We equip $\{0, 2\}$ with the discrete topology. We consider the map

$$\begin{aligned} \varphi\colon \prod_{i\in\mathbb{N}} \{0,2\} &\to C = \text{Cantor set from page 58} \\ (f\colon \mathbb{N} \to \{0,2\}) &\mapsto \sum_{i=1}^{\infty} \frac{f(i)}{3^i}. \end{aligned}$$

It is elementary to see that φ takes values in C. It is a refreshing exercise, left to the enthusiastic reader, to show that φ is a bijection. The left-hand side is compact by Tychonoff's Theorem 1.63 and the right-hand is evidently Hausdorff. In Exercise 1.29 we verify that φ is continuous. It thus follows from Proposition 1.40 that φ is a homeomorphism.

Initially the definition of the Cantor set is nicely explicit, but the definition looks rather arbitrary. The previous example gives a much more natural definition of the Cantor set. Amazingly there exists a characterization of the Cantor set, up to homeomorphism, in terms of basic topological properties. To state the proposition we need two easy definitions.

Definition. Let X be a topological space. A point $x_0 \in X$ is called *isolated* if $\{x_0\}$ itself is an open subset.

Examples.

(1) We consider $X = \{\frac{1}{n} \mid n \in \mathbb{N}\} \cup \{0\}$. The only point in X that is not isolated is 0.
(2) No point in the Cantor set is isolated.
(3) No point in $\prod_{i\in\mathbb{N}} \{0, 2\}$ is isolated.

(4) The topological spaces $\mathbb{Q}$ and $\mathbb{Q} \setminus \{0\}$ equipped with the subspace topology coming from $\mathbb{R}$ do not contain any isolated points.

Definition. A topological space X is called *totally disconnected* if the only connected subsets are the empty set and the subsets consisting of a single point.

Definition. It is straightforward to verify that the following topological spaces are totally disconnected:

(1) the Cantor set,
(2) the infinite product $\prod_{i \in \mathbb{N}} \{0, 2\}$,
(3) discrete topological spaces,
(4) the topological spaces $\mathbb{Q}$ and $\mathbb{Q} \setminus \{0\}$ equipped with the subspace topology coming from $\mathbb{R}$.

We conclude this section with the following amusing proposition.

Proposition 1.64. *Let X be a topological space that is compact and totally disconnected. If X contains no isolated points, then X is homeomorphic to the Cantor set.*

Proof. We will not make use of the proposition, hence we will not prove it. A proof is for example given in [Val, Theorem 7.8] or [Wil, Theorem 30.3]. □

Example. By the above examples Proposition 1.64 implies not only that the Cantor set is homeomorphic to $\prod_{i \in \mathbb{N}} \{0, 2\}$ but also to $\mathbb{Q}$ and $\mathbb{Q} \setminus \{0\}$. In particular we obtain the weird result that $\mathbb{Q}$ and $\mathbb{Q} \setminus \{0\}$ are homeomorphic.[27]

1.11. **Quotients of topological spaces.** We recall the notion of an equivalence relation and an equivalence class, even though almost certainly the reader will have encountered these notions already on numerous occasions elsewhere.

Definition.

(1) A *relation* on a set S is a subset E of $S \times S$. Often, if $(s, t) \in E$, then we write $s \sim t$.
(2) An *equivalence relation* on a set S is a subset E of $S \times S$ with the following three properties:
   (a) for any $s \in S$ we have $(s, s) \in E$ (reflexivity),
   (b) if $(s, t) \in E$, then also $(t, s) \in E$ (symmetry),
   (c) if (s, t) and (t, u) lie in E, then (s, u) also lies in E (transitivity).

   As above, if $(s, t) \in E$, then we write $s \sim t$. In this notation the above three properties translate into
   (a) for any $s \in S$ we have $s \sim s$ (reflexivity),
   (b) for any $s, t \in S$ with $s \sim t$ we also have $t \sim s$ (symmetry),
   (c) for any $s, t, u \in S$ with $s \sim t$ and $t \sim u$ we have $s \sim u$ (transitivity).

[27] Can you prove directly that $\mathbb{Q}$ and $\mathbb{Q} \setminus \{0\}$ are homeomorphic?

An *equivalence class* of $(S, \sim)$ is a *non-empty* subset C of S with the following two properties:
(a) given any two $s, t \in C$ we have $s \sim t$, and
(b) given $s \in C$ and $t \in S$ with $s \sim t$ we have $t \in C$.

We refer to [Halm, Section 7] for a confirmation of the above definitions.

We also introduce the following notation.

Notation. Given an equivalence relation $\sim$ on a set X and given $x \in X$ we denote by $[x]$ the unique equivalence class that contains x. We refer to the map

$$\begin{array}{ccc} X & \to & X/\sim \\ x & \mapsto & [x] \end{array}$$

as the *canonical projection*. Sometimes $X/\sim$ is called a *quotient* of X.

After these preliminaries we return to topological spaces.

Lemma 1.65. *Let $\sim$ be an equivalence relation on a topological space X. If we denote by $p\colon X \to X/\sim$ the canonical projection map from X onto the set of equivalence classes $X/\sim$, then the following statements hold:*

(1) *The set*
$$\mathcal{T} := \{U \subset X/\sim \mid p^{-1}(U) \text{ is open in } X\}$$
is a topology on $X/\sim$.[28]
(2) *Let $A \subset X/\sim$ be a subset. The set A is closed in $X/\sim$ if and only if the preimage $p^{-1}(A)$ is closed in X.*
(3) *The projection map $p\colon X \to X/\sim$ is continuous.*
(4) *If X is compact, then $X/\sim$ is also compact.*

Proof.

(1) This statement follows immediately from Lemma 1.1 (5) and (6).
(2) This statement follows easily from Lemma 1.1 (7).
(3) This statement is an immediate consequence of the definitions.
(4) This statement follows immediately from (2) and from Lemma 1.37. □

The following definition will not come as a surprise.

Definition. Let $\sim$ be an equivalence relation on a topological space X. We refer to the topology on $X/\sim$ from Lemma 1.65 (1) as the *quotient topology* and we refer to $X/\sim$ as a *quotient space* of X.

The following lemma is also so basic that later on we will no longer cite it explicitly.

[28] In other words, $U \subset X/\sim$ is open if and only if $p^{-1}(U) \subset X$ is open.

Lemma 1.66. *Let $\sim$ be an equivalence relation on a topological space X and let $f\colon X \to Y$ be a map with the property that $f(x) = f(y)$ whenever $x \sim y$. Then the map*

$$\begin{array}{rcl} g\colon X/\sim & \to & Y \\ [x] & \mapsto & f(x) \end{array}$$

is well-defined and it is the unique map $g\colon X/\sim \to Y$, such that $f = g \circ p$, i.e. such that the following diagram of maps commutes:

$$\begin{tikzcd} X \arrow[r, "p"] \arrow[dr, "f"'] & X/\sim \arrow[d, "g"] \\ & Y. \end{tikzcd}$$

Furthermore, if f is continuous, then g is also continuous.

Definition. Let $f\colon X \to Y$ be a map as in Lemma 1.66.

(1) We refer to the map $g\colon X/\sim \to Y$ as the *induced map*.
(2) At times we denote the induced map by $\overline{f}$. Sometimes, when there is no danger of confusion we denote the induced map just by f itself.
(3) Sometimes we also say that the map $f\colon X \to Y$ *descends* to a map $X/\sim \to Y$.

Proof $(*)$. Let $\sim$ be an equivalence relation on a set X and let $f\colon X \to Y$ be a map with the property that $f(x) = f(y)$ whenever $x \sim y$. Let a be an element of $X/\sim$. By definition there exists an $x \in X$ with $a = [x]$. We set

$$g(a) \ := \ f(x).$$

Evidently this definition does not depend on the choice of x. The map g satisfies $f = g \circ p$. Since the projection $X \to X/\sim$ is surjective we see that g is uniquely determined by this property.

Now suppose that f is continuous. We need to show that g is continuous as well. Let $U \subset Y$ be open. We need to show that $g^{-1}(U) \subset X/\sim$ is open. By definition of the quotient topology we need to show that that $p^{-1}(g^{-1}(U))$ is open in X. We observe that

$$p^{-1}(g^{-1}(U)) \ = \ (g \circ p)^{-1}(U) \ = \ f^{-1}(U)$$

is open, since f is continuous. □

The following remark can be viewed as a sibling of Remark 1.54.

Remark 1.67. *We consider maps in and out of a quotient space $X/\sim$:*

(1) *In practice it is usually easy to show that a given map $X/\sim \to Y$ out of the quotient space is continuous. More precisely, in practice it is often fairly clear that the map $X \to X/\sim \to Y$ is continuous, but then it follows from Lemma 1.66 that the original map $X/\sim \to Y$ is continuous.*
(2) *There is usually no easy way to show that a map $Y \to X/\sim$ to a quotient space is continuous.*

Notation. Let X be a topological space and let $A \subset X$ be a subset. For $P, Q \in X$ we define

$$P \sim Q \quad :\Longleftrightarrow \quad P = Q \text{ or } P, Q \text{ both lie in } A.$$

This is easily seen to be an equivalence relation on X. We write $X/A := X/\sim$ and we always equip X/A with the quotient topology.

The following lemma is elementary but useful. On numerous occasions it will allow us to slightly shift our point of view.

Lemma 1.68. $(*)$ *Let X be a topological space and let $A \subset X$ be a subset. Furthermore let Y be another topological space and let $y_0 \in Y$. The map*

$$\Phi\colon \left\{ \begin{array}{c} \textit{set of continuous maps } f\colon X \to Y \\ \textit{such that } f(A) = \{y_0\} \end{array} \right\} \to \left\{ \begin{array}{c} \textit{set of continuous maps } X/A \to Y \\ \textit{such that } f([A]) = y_0 \end{array} \right\}$$
$$(f\colon X \to Y) \mapsto (\overline{f}\colon X/A \to Y)$$

is well-defined and it is a bijection.

Proof $(*)$. It follows immediately from Lemma 1.66 that given a continuous map $f\colon X \to Y$ with $f(A) = \{y_0\}$) the corresponding map $\overline{f}\colon X/A \to Y$ is continuous. This shows that the map Φ is well-defined. It is clear that Φ is injective. Finally suppose we are given a map $g\colon X/A \to Y$ with $f([A]) = y_0$. We denote by $f\colon X \to X/A \to Y$ the map that is given by precomposing g with the obvious projection $X \to X/A$. It follows from Lemma 1.65 (3) that f is continuous. Clearly we have $\Phi(f) = g$. This shows that Φ is also a surjection. $\square$

Now we can finally give our first examples of interesting quotient spaces.

Examples.

(1) Let $a < b$ be two real numbers. It follows easily from Lemma 1.65 (4), Lemma 1.66 and Proposition 1.40 that the map

$$\begin{array}{rcl} \Omega\colon [a,b]/\{a,b\} & \to & S^1 \\ [t] & \mapsto & \exp\left(i \cdot \frac{2\pi(t-a)}{b-a}\right) \end{array}$$

is a homeomorphism.

(2) It follows easily from Lemma 1.65 (4), Lemma 1.66 and Proposition 1.40 that the map[29]

$$\begin{array}{rcl} \Omega\colon \overline{B}^n/S^{n-1} & \to & S^n \\ [r \cdot v] & \mapsto & \cos(\pi r) \cdot (1, 0, \ldots, 0) + \sin(\pi r) \cdot (0, v), \text{ with } r \in [0,1], v \in S^{n-1} \end{array}$$

is a homeomorphism that sends the point $[S^{n-1}] \in \overline{B}^n/S^{n-1}$ to $(-1, 0, \ldots, 0)$. Note that for $n = 1$ and $n = 2$ this homeomorphism is illustrated in Figure 36. Throughout this course we will use this homeomorphism, or slight variations thereof, to identify $\overline{B}^n/S^{n-1}$ with S^n.[30]

[29] Why is Ω continuous?

[30] This homeomorphism has the following nice property: The map $B^n \to \overline{B}^n/S^{n-1} \xrightarrow{\Omega} S^n$ is smooth and, if we equip B^n and S^n with the usual orientations, the map is orientation-preserving. We hope that

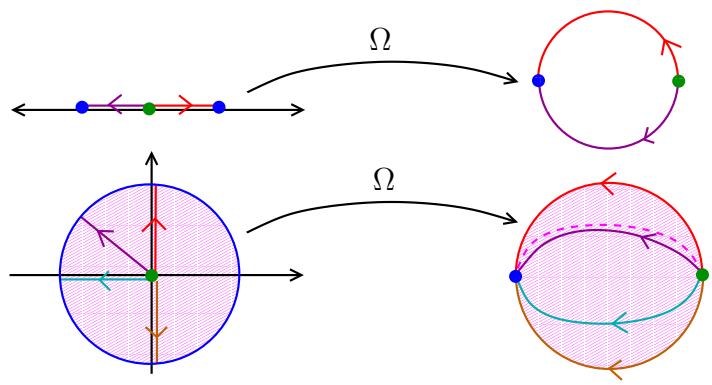

FIGURE 36.

(3) We consider the quotient of $X = \mathbb{R}$ by the compact interval $A = [-1, 1]$. This example has two interesting features:
   (a) The quotient $X/A = \mathbb{R}/[-1, 1]$ is actually homeomorphic to an old favorite, namely one can easily verify that the map

$$f\colon \mathbb{R} \to \mathbb{R}/[-1,1] \qquad\qquad g\colon \mathbb{R}/[-1,1] \to \mathbb{R}$$
$$x \mapsto \begin{cases} [x+1], \text{ if } x \geq 0 \\ [x-1], \text{ if } x < 0 \end{cases} \quad \text{and} \quad p \mapsto \begin{cases} x-1, \text{ if } p = [x] \text{ with } x \geq 1 \\ x+1, \text{ if } p = [x] \text{ with } x < -1 \end{cases}$$

   are continuous and inverses of one another.
   (b) Above we saw that projections $X \to X/\sim$ are basically by definition, continuous. One might think that projections should also be open. But in this example the projection $p\colon X = \mathbb{R} \to X/A = \mathbb{R}/[-1, 1]$ is *not* an open map, for example the image of the open set $(-1, 1) \subset \mathbb{R}$ is not open.

(4) We consider the quotient of $X = \mathbb{R}$ by the open interval $B = (-1, 1)$. We denote by $p\colon \mathbb{R} \to \mathbb{R}/(-1, 1)$ the projection map. Even though this example looks very similar to the previous one, it shows very different behavior. For example the quotient $X/B = \mathbb{R}/(-1, 1)$ is not Hausdorff. More precisely consider $[-1] \in \mathbb{R}/(-1, 1)$. Any open neighborhood U of $[-1]$ in $\mathbb{R}/(-1, 1)$ has the property that $p^{-1}(U)$ is an open subset of $\mathbb{R}$ that contains -1. In particular $U = p(p^{-1}(U))$ contains the point $[0]$. Thus $[-1]$ and $[0]$ cannot be separated by open neighborhoods.

In the last example we saw that the quotient of a topological space that is Hausdorff is not necessarily again Hausdorff. It is pretty clear that if one puts enough conditions on the equivalence relation, then one can avoid such misdemeanor. This leads us to the following definition.

Definition. Let X be a set and let $\sim$ be an equivalence relation on X.

---

the reader is not too fazed by the fact that we use some expressions that strictly speaking we will only introduce at a later stage.

(1) We refer to $\{(x,y) \in X \times X \mid x \sim y\}$ as the *graph of the equivalence relation.*
(2) Now suppose X is equipped with a topology. We say that the equivalence relation is *closed* if the graph is a closed subset of $X \times X$.

Now we can formulate the next lemma.

Lemma 1.69. $(*)$ *Let X be a topological space that is Hausdorff and compact. If $\sim$ is a closed relation, then $X/\sim$ is Hausdorff.*

Proof $(*)$. We denote by $p\colon X \to X/\sim$ the projection. We start out with the following claim.

Claim. Given any closed subset C of X the projection $p(C)$ is a closed subset of $X/\sim$.

Let C be a closed subset of X. We need to show that $p^{-1}(p(C))$ is closed in X. We denote by G the graph of the equivalence relation and we denote by $p_1, p_2\colon X \times X \to X$ the projection onto the first respectively the second factor. Then one easily sees that

$$p^{-1}(p(x)) \;=\; \{y \in X \mid \text{there exists an } x \in C \text{ with } y \sim x\} \;=\; p_2(p_1^{-1}(C) \cap G).$$

Note that $p_1^{-1}(C) = C \times X$ is a closed subset of $X \times X$.[31] Furthermore by our hypothesis G is a closed subset of $X \times X$. Thus we see that $p_1^{-1}(C) \cap G$ is closed. By Lemma 1.55 (2) and our hypothesis on X we know that $X \times X$ is compact. It follows from Lemma 1.18 (1) that $p_1^{-1}(C) \cap G$ is a compact subset of $X \times X$. But then it follows from Lemma 1.37 that $p_2(p_1^{-1}(C) \cap G)$ is a compact subset of X. But since X is Hausdorff we obtain that from Lemma 1.18 (2) that is also a closed subset of X. This concludes the proof of the claim.

Now let $[x], [y] \in X/\sim$ be two disjoint points in $X/\sim$. Since X is Hausdorff we know from Lemma 1.18 (2) that $\{x\}$ and $\{y\}$ are closed subsets of X. By the claim we see that $\{[x]\}$ and $\{[y]\}$ are closed subsets of $X/\sim$. Since the projection map $p\colon X \to X/\sim$ is continuous we see that $p^{-1}([x])$ and $p^{-1}([y])$ are two disjoint closed subsets of X. Since X is compact and Hausdorff we know that X is normal. Thus there exist open disjoint neighborhoods U and V of $p^{-1}([x])$ and $p^{-1}([y])$. We write $U' = X \setminus U$ and $V' = X \setminus V$. These are now closed subsets of X. By the claim their images are closed subsets of $X/\sim$. We now see that $(X/\sim) \setminus p(U')$ and $(X/\sim) \setminus p(V')$ are the desired open disjoint sets containing $[x]$ respectively $[y]$. $\square$

We conclude this section on quotient spaces with the following lemma.

Lemma 1.70. $(*)$ *Let X be a topological space and let $\sim$ be an equivalence relation on X. Furthermore let $\mathcal{B}$ be a basis of the topology of X. If the projection $X \to X/\sim$ is an open map, then*

$$p(\mathcal{B}) \;=\; \{p(B) \mid B \in \mathcal{B}\}$$

is a basis for the topology of $X/\sim$.

[31] This follows from the observation that $(X \times X) \setminus (C \times X) = (X \setminus C) \times X$ is the product of two open sets.

Proof $(*)$. First note that the sets in $p(\mathcal{B})$ are indeed open subsets of $X/\sim$ since we assume that the projection is open. We use the criterion provided by Lemma 1.28 (1) to show that $p(\mathcal{B})$ is a basis for the topology of $X/\sim$. Thus let $U \subset X/\sim$ be an open set and let $y \in U$. We need to show that there exists a $B \in \mathcal{B}$ with $y \in p(B) \subset U$.

We choose an $x \in X$ with $p(x) = y$. Since $\mathcal{B}$ is a basis for the topology of X and since $p^{-1}(U)$ is open in X there exists by Lemma 1.28 (1) a $B \in \mathcal{B}$ with $x \in B \subset p^{-1}(U)$. But then we also have that $y = p(x) \in p(B) \subset p(p^{-1}(U)) = U$. □

1.12. **Group actions on topological spaces.** We continue with the following definition that eventually will provide a rich source of examples of topological spaces.

Definition. Let X be a set and let G be a group with trivial element e.

(1) An *action* of G on X is a map

$$\begin{array}{rcl} G \times X & \to & X \\ (g, x) & \mapsto & g \cdot x \end{array}$$

with the following properties

$$\begin{array}{rcll} e \cdot x & = & x, & \text{for all } x \in X, \\ g \cdot (h \cdot x) & = & (gh) \cdot x, & \text{for all } x \in X \text{ and } g, h \in G. \end{array}$$

(2) The action is called *free*, if $g \cdot x = x$ for some $x \in X$ implies that $g = e$.
(3) We say G acts *transitively*, if for any x and y in X there exists a $g \in G$ with $g \cdot x = y$.
(4) If X is a topological space, then we say that the action is *continuous*, if for every $g \in G$ the map

$$\begin{array}{rcl} X & \to & X \\ x & \mapsto & g \cdot x \end{array}$$

is continuous.[32]

Remark. Sometimes what we call an "action" is referred to as a "left-action". A "right-action" is exactly the same as a left-action except that the second property gets replaced by $g \cdot (h \cdot x) = (hg) \cdot x$. Basically all the statements and definitions that we give for left-actions carry over, with minuscule modifications, to the setting of right-actions.

Examples.

(1) Given any group G the map

$$\begin{array}{rcl} G \times G & \to & G \\ (g, h) & \mapsto & ghg^{-1} \end{array}$$

defines an action of G on itself. Let G be a non-trivial group. Considering $h = e$ we see that this action is not free and it is also straightforward to see that the action is not transitive.

[32] If the action is continuous, then the map $x \mapsto g \cdot x$ is in fact a homeomorphism with inverse map given by $x \mapsto g^{-1} \cdot x$.

(2) Let $\mathbb{F}$ be a field and let V be a k-dimensional vector space over $\mathbb{F}$. We denote by B the set of all bases of V. The map

$$\begin{array}{rcl} \mathrm{GL}(k,\mathbb{F}) \times V & \to & V \\ \big((a_{ij})_{i,j=1,\ldots,k}, \{v_1,\ldots,v_k\}\big) & \mapsto & \Big(\sum\limits_{i=1}^{k} a_{i1}v_i, \ldots, \sum\limits_{i=1}^{k} a_{ik}v_i\Big) \end{array}$$

is a transitive action. It is an amusing linear algebra exercise to figure out under what circumstances this action is free.

(3) The group $G = \mathbb{Z}^n$ acts on $X = \mathbb{R}^n$ by addition. This action is evidently free and continuous but it is not transitive.

We continue with the following definition.

Definition. Let X be a set and let G be a group. It is straightforward to verify that

$$x \sim y \quad :\Longleftrightarrow \quad \text{there exists a } g \in G \text{ such that } g \cdot x = y$$

is an equivalence relation on X. We write[33]

$$X/G \ := \ X/\sim .$$

If X is a topological space, then we view X/G as a topological space equipped with the quotient topology.

Lemma 1.71. *Let X be a topological space and let G be a group that acts on X.*

(1) *The projection map $X \to X/G$ is continuous.*
(2) *If G acts continuously on X, then the projection map is also open.*

Proof. The first statement follows immediately from Lemma 1.65 (3). We turn to the proof of the second statement. Thus let $U \subset X$ be an open subset. We need to show that $p(U)$ is open in X/G. Thus we need to show that $p^{-1}(p(U))$ is an open subset of X. It follows easily from the definitions that

$$p^{-1}(p(U)) \ = \ \bigcup_{g \in G} gU.$$

Since G acts continuously the map $x \mapsto gx$ is a homeomorphism. Thus we see that $p^{-1}(p(U))$ is the union of open sets, thus it is open itself. □

The following lemma discusses one example in greater detail.

Lemma 1.72. *The map*

$$\begin{array}{rcl} \mathbb{R}^n/\mathbb{Z}^n & \to & (S^1)^n \\ [(t_1,\ldots,t_n)] & \mapsto & \big(e^{2\pi i t_1}, \ldots, e^{2\pi i t_n}\big) \end{array}$$

is a homeomorphism.

[33] It is arguably more logical to write $G\ X$ since we are dealing with a left-action and to reserve the notation X/G for right-actions. We stick to X/G since it is closer to our language "X mod G" and since we will not deal with right-actions at all.

Convention. Often we use the homeomorphism of Lemma 1.72 to make the identification $\mathbb{R}^n/\mathbb{Z}^n = (S^1)^n$.

Proof. We start out with the following observations:

(1) The map is continuous by Lemma 1.66 and it is easy to see that it is a bijection.
(2) The obvious map $[0,1]^n \to \mathbb{R}^n \to \mathbb{R}^n/\mathbb{Z}^n$ is continuous and it is easily seen to be surjective. By Proposition 1.22 we know that $[0,1]^n$ is compact. It follows from Lemma 1.37 that $\mathbb{R}^n/\mathbb{Z}^n$ is compact.
(3) From Lemma 1.55 we obtain that $(S^1)^n$ is Hausdorff.

Now it follows easily from Proposition 1.40 that the given map is indeed a homeomorphism. □

We continue with more examples of group actions and the resulting quotient topological spaces.

Examples.

(1) Let $X = S^n$ and $G = \{\pm 1\}$. The map

$$\begin{array}{rcl} \{\pm 1\} \times S^n & \to & S^n \\ (\epsilon, P) & \mapsto & \epsilon \cdot P \end{array}$$

defines an action that is free and continuous. We refer to the quotient space $S^n/\{\pm 1\}$ as the *n-dimensional real projective space* $\mathbb{R}\mathrm{P}^n$.[34] In Exercise 1.32 we will show that $\mathbb{R}\mathrm{P}^1$ is homeomorphic to S^1.

(2) Let $X = \mathbb{R}$ and $G = \{\pm 1\}$. The map

$$\begin{array}{rcl} \{\pm 1\} \times \mathbb{R} & \to & \mathbb{R} \\ (\epsilon, x) & \mapsto & \epsilon \cdot x \end{array}$$

defines an action that is continuous. But this action is not free, since $(-1) \cdot 0 = 0$, but -1 is not the trivial element in the group $G = \{\pm 1\}$. In Exercise 1.33 we will show that $\mathbb{R}/\{\pm 1\}$ is homeomorphic to the half-open interval $[0, \infty)$.

We formulate the next example as a lemma.

Lemma 1.73. *Let $n \in \mathbb{N}$.*

(1) *The group $\mathrm{O}(n+1)$ acts continuously on S^n by the usual multiplication of a matrix and a vector $S^n \subset \mathbb{R}^{n+1}$.*
(2) *The action of $\mathrm{SO}(n+1)$ on S^n is free if and only if $n = 1$.*
(3) *The action of $\mathrm{O}(n+1)$ on S^n is transitive.*
(4) *If $n \geq 2$, then the action of $\mathrm{SO}(n)$ on S^n is also transitive.*
(5) *Given any $x, y \in S^n$ there exists a homeomorphism $\varphi\colon \overline{B}^{n+1} \to \overline{B}^{n+1}$ with $\varphi(x) = y$.*

[34] For $n = 2$ we sometimes refer to $\mathbb{R}\mathrm{P}^2$ as the real projective plane.

Proof. The first two statements can be verified easily. The third and fourth statements fall in the realm of linear algebra. We leave it to the reader to undust their favorite linear algebra book and prove the statements. Finally the last statement follows from the third statement and the observation that multiplication by a matrix in $\mathrm{O}(n+1)$ defines a homeomorphism of $\overline{B}^{n+1}$. $\square$

We consider our next example in greater detail.

Examples.

(1) Let $X = \mathbb{R} \times [-1,1]$ and $G = \mathbb{Z}$. The map

$$\begin{array}{rcl} \mathbb{Z} \times (\mathbb{R} \times [-1,1]) & \to & \mathbb{R} \times [-1,1] \\ (n,(x,y)) & \mapsto & (x+n, (-1)^n \cdot y) \end{array}$$

defines an action that is free and continuous. This action is illustrated in Figure 37. We refer to the quotient $X/\mathbb{Z}$ as the *Möbius band*. The same argument as in the proof of Lemma 1.72 shows that the Möbius band is compact.

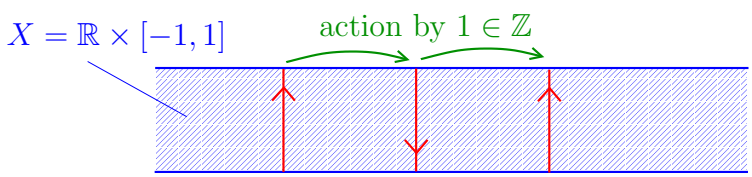

FIGURE 37.

The name "Möbius band" conjures up a certain picture. We will now see that our name is justified. Given $\varphi, \psi \in \mathbb{R}$ and $r \in [-1,1]$ we set

$$A(\varphi) := \begin{pmatrix} \cos\varphi & -\sin\varphi & 0 \\ \sin\varphi & \cos\varphi & 0 \\ 0 & 0 & 1 \end{pmatrix} \quad \text{and} \quad v(r,\psi) := \begin{pmatrix} 2 + r\sin\psi \\ 0 \\ r\cos\psi \end{pmatrix}.$$

We consider the map

$$\begin{array}{rcl} \Psi\colon (\mathbb{R} \times [-1,1])/\mathbb{Z} & \to & \mathbb{R}^3 \\ [(\varphi, r)] & \mapsto & A(2\pi \cdot \varphi) \cdot v\big(r, \pi\varphi\big). \end{array}$$

The image of Ψ is shown in Figure 38. The argument of Lemma 1.72 shows that Ψ is a homeomorphism onto its image. Thus the Möbius band, defined abstractly as above, is indeed homeomorphic to a subset of $\mathbb{R}^3$ that looks like what we had in mind.

(2) On occasion we will also be interested in the *open Möbius band* which is basically defined as above, except that we define it as the quotient of $\mathbb{R} \times (-1,1)$ instead of the quotient of $\mathbb{R} \times [-1,1]$.

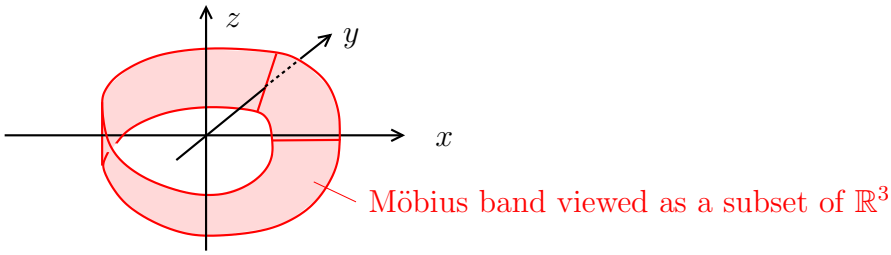

FIGURE 38.

If X is a Hausdorff space and if G acts continuously on X, then it is unfortunately not necessarily true that X/G itself is Hausdorff. For example, consider the obvious action of $G = (\mathbb{Q}, +)$ on $X = \mathbb{R}$. It is a moderately insightful exercise, see Exercise 1.34, to verify that the quotient space $\mathbb{R}/\mathbb{Q}$ is not Hausdorff.

This example leads us to the following definition.

Definition. Let X be a topological space and let G be a group that acts on X. We say that G acts *properly* if for every two points x and y in X there exist open neighborhoods U of x and V of y such that the set $\{g \in G \,|\, gU \cap V \neq \varnothing\}$ is finite.

Examples.

(1) The action of any finite group is proper by definition.
(2) One can show easily that the action of $\mathbb{Z}$ on $\mathbb{R} \times [-1, 1]$ that we had considered on page 105 to define the Möbius band, is proper.
(3) It is straightforward to show that the action of $\mathrm{O}(n+1)$ on S^n from Lemma 1.73 is not proper.

We conclude this section with the following proposition.

Proposition 1.74. *Let G be a group that acts on a topological space X. If X is Hausdorff and if the action is proper and continuous, then the quotient space X/G is also Hausdorff.*

Unless one has an insatiable appetite for technical proofs it is best to move on to the next section.

The proof of Proposition 1.74 relies on the following two lemmas.

Lemma 1.75. $(*)$ *Let G be a group that acts continuously and properly on a topological space. If X is Hausdorff, then given any two points a and b in X there exist open neighborhoods A of a and B of b with the following property: for every $g \in G$ with $ga \neq b$ we also have $gA \cap B = \varnothing$.*

Proof of Lemma 1.75 $(*)$. Let G be a group that acts continuously and properly on a topological space X that is Hausdorff. Let a and b be two points in X. Since G acts properly on X there exist open neighborhoods U of a and V of b such that $\{g \in G \,|\, gU \cap V \neq \varnothing\}$ is a finite set. We denote the elements of this finite set by $g_1, \dots, g_r$. We set

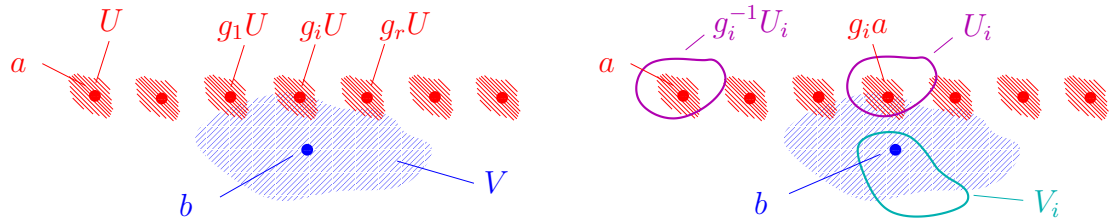

FIGURE 39. Illustration for the proof of Lemma 1.75 with $I = \{1, \dots, r\}$.

$$I \;:=\; \{i = 1, \dots, r \,|\, g_i a \neq b\}.$$

Since X is Hausdorff we can find for every $i \in I$ an open neighborhood U_i of $g_i a$ and an open neighborhood V_i of b such that $U_i \cap V_i = \varnothing$. We set

$$A \;:=\; U \cap \bigcap_{i \in I} g_i^{-1} U_i \quad \text{and} \quad B \;:=\; V \cap \bigcap_{i \in I} V_i.$$

The sets A and B are the intersection of finitely many open subsets,[35] thus they are open. In particular A is an open neighborhood of a and B is an open neighborhood of b.

Now one can easily verify that A and B have the desired properties. Indeed, let $g \in G$ with $ga \neq b$. If $g \notin \{g_1, \dots, g_r\}$, then $gU \cap V = \varnothing$, therefore $gA \cap B = \varnothing$. On the other hand, if $g \in \{g_1, \dots, g_r\}$, then there exists an $i \in I$ with $g = g_i$. It follows that $g_i(g_i^{-1}U_i) \cap V_i = U_i \cap V_i = \varnothing$, hence $g_i A \cap B = \varnothing$. □

Lemma 1.76. $(*)$ *Let G be a group that acts on a set X. We denote by $p\colon X \to X/G$ the projection. Let A and B be subsets of X. Then*

$$p(A) \cap p(B) \;=\; \varnothing \quad \Longleftrightarrow \quad \textit{for every } g \in G \textit{ we have } gA \cap B = \varnothing,$$

or equivalently,

$$p(A) \cap p(B) \;\neq\; \varnothing \quad \Longleftrightarrow \quad \textit{there exists a } g \in G \textit{ with } gA \cap B \neq \varnothing.$$

Proof of Lemma 1.76$(*)$. We prove the second statement. The first statement is easily seen to be equivalent to the second statement. We have

$$\begin{aligned} p(A) \cap p(B) \;\neq\; \varnothing \;&\Longleftrightarrow\; \text{there exist } a \in A \text{ and } b \in B \text{ with } p(a) = p(b) \in X/G \\ &\Longleftrightarrow\; \text{there exist } a \in A,\, b \in B \text{ and } g \in G \text{ with } ga = b \\ &\Longleftrightarrow\; \text{there exists a } g \in G \text{ with } gA \cap B \neq \varnothing. \end{aligned}$$ □

Now we turn to the actual proof of Proposition 1.74.

Proof of Proposition 1.74 $(*)$. Let G be a group that acts on a topological space X. We assume that X is Hausdorff and that the action is proper. We want to show that the quotient space X/G is also Hausdorff. We denote by $p\colon X \to X/G$ the projection map.

Let x and y be two distinct points in X/G. We pick a and b in X with $p(a) = x$ and $p(b) = y$. Since $p(a) = x \neq y = p(b)$ we see that for every $g \in G$ we have $ga \neq b$. By

[35] Here we use that G acts continuously, since this implies that the sets $h^{-1}U_i$ are also open.

Lemma 1.75 there exist open neighborhoods A of a and B of b such that $gA \cap B = \varnothing$ for every $g \in G$. It follows from Lemma 1.76 that $p(A)$ and $p(B)$ are disjoint.

Since A and B are open it follows from Lemma 1.71 that $p(A)$ and $p(B)$ are open subsets of X/G, in particular they are open neighborhoods of $x = p(a)$ and $y = p(b)$. We have thus found the desired disjoint open neighborhoods of x and y in X/G. □

1.13. **Continuity of zeros** $(*)$**.** Group actions can also appear in unexpected situations. For example let us consider the following question.

Question 1.77. *Let $n \in \mathbb{N}$. Do the zeros of a polynomial of degree n vary continuously with the coefficients of the polynomial?*

The first question is, what does it mean that the "zeros of a polynomial" vary "continuously"? What are the topological spaces involved so that we can talk about continuity? The following proposition kills two birds at once: it makes the question precise and it gives a complete answer.

Proposition 1.78. *Let $n \in \mathbb{N}$. We consider the action by the permutation group S_n on $\mathbb{C}^n$ that is given by permuting the coefficients. The map*[36]

$$\begin{array}{rcl} f\colon \mathbb{C}^n & \to & \mathbb{C}^n/S_n \\ (v_0,\dots,v_{n-1}) & \mapsto & \left[\begin{array}{c} \textit{set of zeros of the polynomial} \\ v_0 + v_1 z + \dots + v_{n-1}z^{n-1} + z^n, \\ \textit{counted with multiplicities} \end{array}\right] \end{array}$$

is continuous, in fact it is a homeomorphism.

Remark. For $n = 1, 2, 3, 4$ one can hope to prove Proposition 1.78 by the formulas for determining zeros of polynomials of degree n. But since no such formula exists for general polynomials of higher degree this approach is doomed for $n \geq 5$.

The proof of Proposition 1.78 makes use Rouché's Theorem from complex analysis.

Theorem 1.79. (Rouché's Theorem) *Let $U \subset \mathbb{C}$ be an open set, let $f, g\colon U \to \mathbb{C}$ be two holomorphic functions and let $z \in U$ and $r \in \mathbb{R}^+$ be such that $\overline{B}_r(z) = \{w \in \mathbb{C} \mid |w - z| \leq r\}$ is contained in U. If for all $w \in \partial\overline{B}_r(z)$ we have $|g(z)| < |f(z)|$, then f and $f + g$ have the same number of zeros (counted with multiplicities) within the open disk $B_r(z)$.*

Proof. This theorem is proved in every self-respecting book on complex analysis, see e.g. [Lan, Theorem VI.1.6]. □

Example. We consider $f(z) = z^5$ and the disk $\overline{B}_1(0)$. The polynomial $f(z)$ has one zero of multiplicity five in $\overline{B}_1(0)$. For any $a \in \mathbb{C}$ with $|a| < 1$ we have $|az| < |z^5|$ for all points $z \in \partial\overline{B}_1(0) = S^1$. Thus by Rouché's Theorem 1.79 we see that for such a the polynomial

[36]Slightly more rigorously the map f is defined as follows: given $(v_0,\dots,v_{n-1}) \in \mathbb{C}^n$ we define $f(v_0,\dots,v_{n-1}) := [(\alpha_1,\dots,\alpha_n)]$ where $\alpha_1,\dots,\alpha_n \in \mathbb{C}$ are determined uniquely (up to reordering) by the condition that $v_0 + v_1 z + \dots + v_{n-1}z^{n-1} + z^n = (z - \alpha_1)\cdot\dots\cdot(z - \alpha_n) \in \mathbb{C}[z]$.

$z^5 + az$ also has five zeros (counted with multiplicities) in $\overline{B}_1(0)$. In fact for most values of a the polynomial will have five distinct zeros, each with multiplicity one.

We will also need the following definition:

Definition. Given $w = [(w_1, \dots, w_n)]$ and $z = [(z_1, \dots, z_n)]$ in $\mathbb{C}^n/S_n$ we define

$$d(w, z) \;=\; \min_{\sigma \in S_n} \max_{1 \le j \le n} \left| w_j - z_{\sigma(j)} \right|.$$

The following lemma summarizes two key statements regarding the above definition.

Lemma 1.80.

(1) *The map*

$$\begin{array}{rcl} d\colon \mathbb{C}^n/S_n \times \mathbb{C}^n/S_n & \to & \mathbb{R}_{\ge 0} \\ (w, z) & \mapsto & d(w, z) \end{array}$$

is a metric on $\mathbb{C}^n/S_n$.

(2) *The topology defined by the metric* d *on* $\mathbb{C}^n/S_n$ *agrees with the quotient topology on* $\mathbb{C}^n/S_n$.

Proof. Both statements of the lemma are left as an exercise to the meticulous reader. □

Now we are in a position to prove Proposition 1.78.

Proof of Proposition 1.78. We consider the map[37]

$$\begin{array}{rcl} g\colon \mathbb{C}^n/S_n & \to & \mathbb{C}^n \\ [(\alpha_1, \dots, \alpha_n)] & \mapsto & \text{coefficients of the polynomial } (z - \alpha_1) \cdot \dots \cdot (z - \alpha_n). \end{array}$$

It is straightforward to check that g is continuous and that f and g are inverses of one another.

It remains to show that f is continuous. We introduce the following definitions: We denote by d the above metric on $\mathbb{C}^n/S_n$. It follows from Lemma 1.80 that we can view f as a map between the two metric spaces $(\mathbb{C}^n, \| - \|)$ and $(\mathbb{C}^n/S_n, d)$. Therefore it follows from Proposition 1.33 that it suffices to prove the following claim.

Claim.

$$\underset{v \in \mathbb{C}^n}{\forall} \; \underset{\epsilon > 0}{\forall} \; \underset{\delta > 0}{\exists} \; \underset{\substack{w \in \mathbb{C}^n \text{ with} \\ \|w\| < \delta}}{\forall} \; d(f(v), f(v + w)) < \epsilon.$$

Before we start with the proof of the claim we introduce the following definition: Given $v = (v_0, \dots, v_{n-1}) \in \mathbb{C}^n$ we denote by $p_v(z) := v_0 + v_1 z + \dots + v_{n-1} z^{n-1} + z^n$ the corresponding polynomial. Now we turn to the proof of the claim. Thus let $v = (v_0, \dots, v_{n-1}) \in \mathbb{C}^n$ and let $\epsilon > 0$. We denote by $\xi_1, \dots, \xi_k$ the *distinct* zeros of the corresponding polynomial $p_v(z)$. (Note that if $p_v(z)$ has zeros of higher multiplicity, then $k < n$.) After possibly

[37] Slightly more precisely the map g is defined as follows: given $[(\alpha_1, \dots, \alpha_n)] \in \mathbb{C}^n/S_n$ we have $f([(\alpha_1, \dots, \alpha_n)]) = (v_0, \dots, v_{n-1})$ where $v_0, \dots, v_{n-1} \in \mathbb{C}$ are uniquely determined by the condition that $v_0 + v_1 z + \dots + v_{n-1} z^{n-1} + z^n = (z - \alpha_1) \cdot \dots \cdot (z - \alpha_n) \in \mathbb{C}[z]$.

replacing ϵ by a smaller non-negative number we can assume, without loss of generality, that $\epsilon < \frac{1}{2} \cdot |\xi_i - \xi_j|$ for all $i \neq j$.

We denote by Γ the union of the circles of the radius ϵ around $\xi_1, \dots, \xi_k$. Furthermore we set

$$\eta \ := \ \inf_{z \in \Gamma} |p_v(z)| \ \in \ \mathbb{R}_{>0}.$$

It is elementary to show that there exists a $\delta > 0$ such that for all $w = (w_0, \dots, w_{n-1}) \in \mathbb{C}^n$ such that $\|w\| < \delta$ we have

$$|w_0 + w_1 + \cdots + w_{n-1} z^{n-1}| \ < \ \eta \text{ for all } z \in \Gamma.$$

We claim that this δ has the desired property. Thus let $w \in \mathbb{C}^n$ with $|w| < \delta$. It follows from the definition of δ and Rouché's Theorem 1.79 that the polynomials $p_v(z)$ and $p_{v+w}(z)$ have the same number of zeros (counted with multiplicities) in the disks $B_\epsilon(\xi_1), \dots, B_\epsilon(\xi_k)$. This means that the zeros of $p_v(z)$ and can be matched up with the zeros of $p_{v+w}(z)$ such that each zero is less then ϵ removed from its match. This statement implies immediately that $d(f(v), f(v+w)) < \epsilon$. $\square$

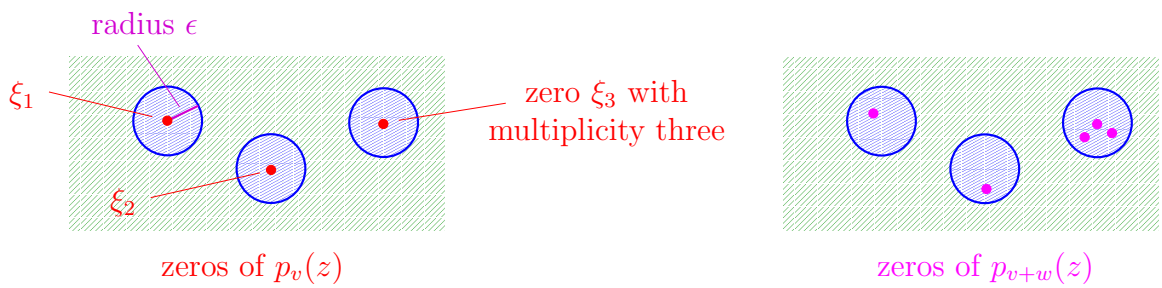

FIGURE 40. Illustration for the proof of Proposition 1.78.

Remark. With some effort one can also prove Proposition 1.78 without using Rouché's Theorem 1.79. We outline the key steps, using the notation that we introduced in the above proof of Proposition 1.78.

(1) By Lemma 1.39 it suffices to show that the map $g \colon \mathbb{C}^n/S_n \to \mathbb{C}^n$ is open.
(2) By Lemma 1.36 it suffices to show that for each $\epsilon > 0$ and each $z \in \mathbb{C}^n/S_n$ the image of the open ball $B_\epsilon(z) \subset (\mathbb{C}^n/S_n, d)$ under g is open.
(3) Thus let $\epsilon > 0$ and $z \in \mathbb{C}^n/S_n$.
(4) We pick $C \in \mathbb{R}_{\geq 0}$ such that $g(\overline{B}_\epsilon(z)) \subset B_C(0) \subset \mathbb{C}^n$.
(5) There exists a $D \in \mathbb{R}_{\geq 0}$ such that for any $v \in \mathbb{C}^n$ which satisfies $\|v\| \leq C$ we have $f(v) \in B_D(0) \subset \mathbb{C}^n/S_n$. (This statement requires some unraveling and a little bit of thought. It can be proved using Rouché's Theorem 1.79, but with a worse bound it can also be proved by hand.)
(6) By Proposition 1.40 we know that g restricted to $\overline{B}_D(0) \to g(\overline{B}_D(0))$ is a homeomorphism. Thus $g(B_\epsilon(z))$ is an open subset of $g(\overline{B}_D(0))$.

(7) By (5) and (6), and since f and g are inverses of one another, we know that $g(B_\epsilon(z))$ is also open in $B_D(0)$. But $B_D(0)$ is an open subset of $\mathbb{C}^n$, hence $g(B_\epsilon(z))$ is also open in $\mathbb{C}^n$.

1.14. **Projective spaces.** Let $n \in \mathbb{N}$. On page 104 we introduced the real projective space $\mathbb{R}\mathrm{P}^n = S^n/\{\pm 1\}$. In this section we will give an alternative definition and we will introduce the complex projective spaces. Even though these projective spaces appear initially rather arbitrary they will on several occasions play an essential role in these notes.

Let $X = \mathbb{R}^{n+1} \setminus \{0\}$ and let $G = \mathbb{R} \setminus \{0\}$, where we view G as a group via multiplication. The map

$$\begin{array}{rcl} (\mathbb{R} \setminus \{0\}) \times (\mathbb{R}^{n+1} \setminus \{0\}) & \to & \mathbb{R}^{n+1} \setminus \{0\} \\ (r, P) & \mapsto & r \cdot P \end{array}$$

defines an action that is free and continuous. It is straightforward to see that the map

$$\begin{array}{rcl} \mathbb{R}\mathrm{P}^n \;=\; S^n/\{\pm 1\} & \to & (\mathbb{R}^{n+1} \setminus \{0\})/(\mathbb{R} \setminus \{0\}) \\ [P] & \mapsto & [P] \end{array}$$

defines a homeomorphism.[38] Our new point of view on real projective spaces has the advantage that we can create a different class of examples of topological spaces by replacing $\mathbb{R}$ by $\mathbb{C}$. More precisely, this discussion leads us to the following definition:

Definition. Let $X = \mathbb{C}^{n+1} \setminus \{0\}$ and let $G = \mathbb{C} \setminus \{0\}$. The map

$$\begin{array}{rcl} (\mathbb{C} \setminus \{0\}) \times (\mathbb{C}^{n+1} \setminus \{0\}) & \to & \mathbb{C}^{n+1} \setminus \{0\} \\ (z, P) & \mapsto & z \cdot P \end{array}$$

defines an action that is free and continuous. The quotient space $(\mathbb{C}^{n+1} \setminus \{0\})/(\mathbb{C} \setminus \{0\})$ is called the *n-dimensional complex projective space* $\mathbb{C}\mathrm{P}^n$.

Notation. Let $n \in \mathbb{N}_0$.

(1) For $(x_0, \ldots, x_n) \in \mathbb{R}^{n+1} \setminus \{0\}$ we denote by $[x_0 : \ldots : x_n]$ the corresponding point in $\mathbb{R}\mathrm{P}^n$. We also use the same notation for points in complex projective spaces.
(2) Given $m \leq n$ we will often view $\mathbb{R}\mathrm{P}^m$ as a subset of $\mathbb{R}\mathrm{P}^n$ via the map

$$\begin{array}{rcl} i\colon \mathbb{R}\mathrm{P}^m & \to & \mathbb{R}\mathrm{P}^n \\ [x_0 : \cdots : x_m] & \mapsto & [x_0 : \cdots : x_m : 0 : \cdots : 0]. \end{array}$$

The same point of view applies to complex projective spaces.

The following lemma shows that real and complex projective spaces have some of our favorite properties.

Lemma 1.81. *The real projective and the complex projective spaces are compact and Hausdorff.*

[38] For example an inverse is given by the map $(\mathbb{R}^{n+1} \setminus \{0\})/(\mathbb{R} \setminus \{0\}) \to S^n/\{\pm 1\}$ that is defined by $x \mapsto [\frac{x}{\|x\|}]$.

Proof $(*)$. Let $n \in \mathbb{N}$. It follows from Lemma 1.37 and Proposition 1.74 that the real projective space $\mathbb{R}\mathrm{P}^n = S^n/\{\pm 1\}$ is compact and Hausdorff.

For the complex projective space $\mathbb{C}\mathrm{P}^n$ we need to work just a little harder. In the remainder of this proof we take the view that

$$S^{2n+1} \;=\; \{(z_1, \dots, z_{n+1}) \in \mathbb{C}^{n+1} \,|\, |z_1|^2 + \dots + |z_{n+1}|^2 = 1\}.$$

We consider the action

$$\begin{array}{rcl} S^1 \times S^{2n+1} & \to & S^{2n+1} \\ (w, (z_1, \dots, z_{n+1})) & \mapsto & (w \cdot z_1, \dots, w \cdot z_{n+1}). \end{array}$$

It is straightforward to verify that the maps

$$\begin{array}{l} f\colon S^{2n+1}/S^1 \to \mathbb{C}\mathrm{P}^n \\ [z_1, \dots, z_{n+1}] \mapsto [z_1 : \dots : z_{n+1}] \end{array} \quad \text{and} \quad \begin{array}{l} p\colon \mathbb{C}\mathrm{P}^n \to \mathbb{S}^{2n+1}/S^1 \\ [z_1 : \dots : z_{n+1}] \mapsto \left[\frac{1}{\sqrt{|z_1|^2 + \dots + |z_n|^2}}(z_1, \dots, z_{n+1})\right] \end{array}$$

are continuous and inverses of one another. Thus both maps are homeomorphisms and it suffices to show the statements for S^{2n+1}/S^1. Since S^{2n+1} is compact it follows again from Lemma 1.37 that S^{2n+1}/S^1 is compact.

It follows from Lemma 1.69 that S^{2n+1}/S^1 is Hausdorff once we have shown that the graph of the equivalence relation, which is given by

$$G \;=\; \{(v_1, v_2) \in S^{2n+1} \times S^{2n+1} \,|\, \text{there exists } w \in S^1 \text{ with } w \cdot v_1 = v_2\},$$

is a closed subset of $S^{2n+1} \times S^{2n+1}$. The graph G is the image of the map

$$\begin{array}{rcl} \Phi\colon S^{2n+1} \times S^1 & \to & S^{2n+1} \times S^{2n+1} \\ (v, w) & \mapsto & (v, w \cdot v). \end{array}$$

This map is continuous and the left-hand side is compact by Lemma 1.55 (2). Thus the image of Φ is compact by Lemma 1.37. By Lemma 1.55 (1) we know that $S^{2n+1} \times S^{2n+1}$ is Hausdorff. Thus we obtain from Lemma 1.18 that the image of Φ is a closed subset of $S^{2n+1} \times S^{2n+1}$. □

In the following lemma we give alternative descriptions of $\mathbb{R}\mathrm{P}^n$ and $\mathbb{C}\mathrm{P}^1$ that will be used on many occasions.

Lemma 1.82.

(1) *Let $n \in \mathbb{N}$. If we denote by $\sim$ the equivalence relation on $\overline{B}^n$ that is generated by $P \sim -P$ for $P \in S^{n-1} = \partial\overline{B}^n$, then the map*

$$\begin{array}{rcl} \mathbb{R}\mathrm{P}^n = S^n/\{\pm 1\} & \xrightarrow{\cong} & \overline{B}^n/\sim \\ [(x_1, \dots, x_n, x_{n+1})] & \mapsto & \begin{cases} [(x_1, \dots, x_n)], & \text{if } x_{n+1} \geq 0, \\ [-(x_1, \dots, x_n)], & \text{if } x_{n+1} < 0 \end{cases} \end{array}$$

is a homeomorphism.

(2) *The map*

$$\begin{array}{rcl} \mathbb{C}\mathrm{P}^1 & \to & \mathbb{C}\cup\{\infty\} = \mathbb{R}^2\cup\{\infty\} \\ [z_0 : z_1] & \mapsto & \begin{cases} z_0\cdot z_1^{-1}, & \textit{if } z_1 \neq 0, \\ \infty, & \textit{if } [z_0 : z_1] = [1:0] \end{cases} \end{array}$$

is a homeomorphism.

Proof. By Lemma 1.81 we know that each $\mathbb{R}\mathrm{P}^n$ and $\mathbb{C}\mathrm{P}^n$ is compact. Using Lemma 1.69 one can show that $\overline{B}^n/\sim$ is Hausdorff. Furthermore we know from Exercise 1.8 that $\mathbb{R}^2\cup\{\infty\}$ is Hausdorff. One can easily verify that both maps are continuous and bijections. Thus it follows from Proposition 1.40 that both maps are homeomorphisms. □

Convention.

(1) On many occasions we will use the homeomorphism from Lemma 1.82 to make the identification $\mathbb{R}\mathrm{P}^n = \overline{B}^n/\sim$.
(2) In Lemma 1.41 we gave an explicit homeomorphism $S^2 \to \mathbb{R}^2\cup\{\infty\}$. Combining this homeomorphism with the homeomorphism from Lemma 1.82 we obtain a homeomorphism $S^2 \to \mathbb{C}\mathrm{P}^1$ which we will often use to make the identification $S^2 = \mathbb{C}\mathrm{P}^1$.

We conclude this short section on projective spaces with two somewhat tangential remarks.

Remark.

(1) Here is a fun fact: if we consider $\mathbb{C}\mathrm{P}^2/\sim$, where $\sim$ denotes the equivalence relation defined by complex conjugation, i.e. where $[z : w] \sim [\overline{z} : \overline{w}]$, then the quotient space is homeomorphic (in fact diffeomorphic in a suitable sense) to S^4. This statement is known as the Arnold–Kuiper–Massey Theorem, see e.g. [**?**, Mas4, Sea].
(2) The definition of projective spaces makes sense for any field, even for fields of non-zero characteristic. For example, if $\mathbb{F}$ is a field of characteristic p we can still define the set $\mathbb{F}\mathrm{P}^n = (\mathbb{F}^{n+1}\setminus\{0\})/(\mathbb{F}\setminus\{0\})$. A priori this is just a set, but together with the Zariski topology, see [Har, Lecture 2] or [SKKT, Chapter 1], it actually becomes an unusual, but interesting topological space.
For any field the map

$$\begin{array}{rcl} \mathbb{F}\mathrm{P}^n = (\mathbb{F}^{n+1}\setminus\{0\})/(\mathbb{F}\setminus\{0\}) & \to & \{\text{all one-dimensional subspaces of } \mathbb{F}^{n+1}\} \\ [v] & \mapsto & \mathbb{F}\cdot v \end{array}$$

is a bijection. Thus we can view $\mathbb{F}\mathrm{P}^n$ as the set of all lines through the origin.

1.15. **Gluing two topological spaces.** In this section we consider a particularly important special case of a quotient topology which deserves its own section. Before we delve into topology we recall the following definition.

Definition. Suppose we are given a relation $\sim$ on a set X. We say $x, y \in X$ are *equivalent* if there exists a sequence $x = x_1, \ldots, x_k = y$ of elements in X such that for all $i = 1, \ldots, k-1$

the following holds: either $x_i \sim x_{i+1}$ or $x_{i+1} \sim x_i$. We write again $x \sim y$ if x and y are equivalent. It is straightforward to see that this is now indeed an equivalence relation. We say it is *generated* by the initial relation.

Example. The relations $x \sim (x+1)$ with $x \in \mathbb{R}$ on $\mathbb{R}$ generate the familiar equivalence relation $x \sim y \Leftrightarrow x - y \in \mathbb{Z}$.

Definition. Let X and Y be topological spaces, let $A \subset X$ be a subset and let $\varphi\colon A \to Y$ be a continuous map.[39] (Note that φ does not need to be injective.) We write

$$X \cup_\varphi Y \ := \ X \cup_{\varphi\colon A \to Y} Y \ := \ (X \sqcup Y)/\sim$$

where $\sim$ is the equivalence relation generated by $a \sim \varphi(a)$ for $a \in A$. We call $X \cup_\varphi Y$ the topological space obtained by *gluing X to Y via the map f*. The definition is illustrated in Figure 41.

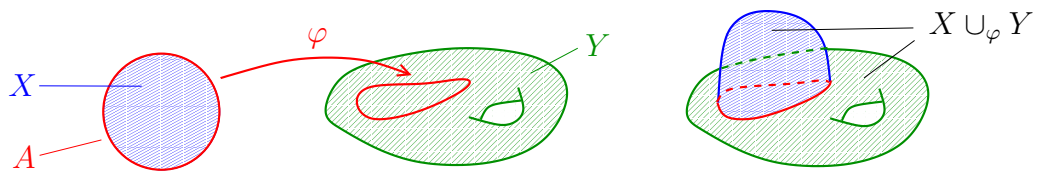

FIGURE 41.

Example. Let X be a topological space and let A be a subset. If Y is the topological space that consists of a single point, then there exists evidently precisely one map $f\colon A \to Y$ and it follows immediately from the definitions that $X \cup_\varphi Y = X/A$.

Lemma 1.83. $(*)$ *Let X and Y be two topological spaces, let $A \subset X$ be a subset and let $\varphi\colon A \to Y$ be a map. We denote by $i\colon X \to X \cup_\varphi Y$ and $j\colon Y \to X \cup_\varphi Y$ the obvious maps. The following statements hold:*

(1) *The maps $i\colon X \to X \cup_\varphi Y$ and $j\colon Y \to X \cup_\varphi Y$ are continuous.*
(2) *If A is a closed subset of X and if $\varphi(A)$ is a closed subset of Y, then $i(X)$ is a closed subset of $X \cup_\varphi Y$ and $j(Y)$ is a closed subset of $X \cup_\varphi Y$.*
(3) *Let $f\colon X \to Z$ and $g\colon Y \to Z$ be two maps to a topological space Z. If we have $g(\varphi(a)) = f(a)$ for all $a \in A$, then*

$$\begin{array}{rcl} h\colon X \cup_\varphi Y & \to & Z \\ p & \mapsto & \begin{cases} f(x) & \text{if } p = [x] \text{ for some } x \in X, \\ g(y) & \text{if } p = [y] \text{ for some } y \in Y \end{cases} \end{array}$$

is well-defined and it is the unique map $h\colon X \cup_\varphi Y \to Z$ with $h \circ i = f$ and $h \circ j = g$. Furthermore, if f and g are continuous, then h is also continuous.

[39] In principle the map φ need not be continuous, but in practice it always is, so for purely psychological reasons we put this condition in.

Proof $(*)$.

(1) This statement follows from Lemma 1.49 (1) and Lemma 1.65 (3).
(2) Suppose that A is a closed subset of X and that $\varphi(A)$ is a closed subset of Y. Let $p\colon X \sqcup Y \to X \cup_\varphi Y$ be the obvious projection map. We have $p^{-1}(i(X)) = X \sqcup \varphi(A)$. Thus it follows from Lemma 1.65 (2) that $i(A)$ is closed in $X \sqcup_\varphi A$. The proof that $j(Y)$ is closed in $X \sqcup_\varphi A$ is basically identical.
(3) The last statement is an immediate consequence of the definitions and Lemma 1.66.

□

The following lemma is quite subtle and gets used, often inadvertently, on many occasions.

Lemma 1.84. *Let X be a topological space and let A and B be two closed subsets of X with $X = A \cup B$. We denote by $\varphi\colon A \cap B \to A \cap B$ the identity map. The map*

$$\begin{array}{rcl} A \cup_{\varphi\colon A\cap B \to A\cap B} B & \to & X \\ [x] & \mapsto & x \end{array}$$

is a homeomorphism.

Remark.

(1) The statement of Lemma 1.84 also holds if A and B are both open subsets. But in all applications we will always deal with the case that A and B are both closed.
(2) In general the conclusion of the lemma does not hold without some assumptions on A and B. For example, consider $X = [-1, 1]$ together with the subsets $A = [-1, 0]$ and $B = (0, 1]$. In this case $A \cap B = \varnothing$, thus $A \cup_\varphi B$ is the disjoint union of A and B. It follows from Lemma 1.49 (5) and the Heine-Borel 1.21 Theorem that $A \sqcup B$ is not compact. On the other hand $X = [-1, 1]$ is compact by the Heine-Borel 1.21. Thus the two topological spaces $A \cup_\varphi B$ and X are not homeomorphic. We refer to Figure 42 for an illustration.

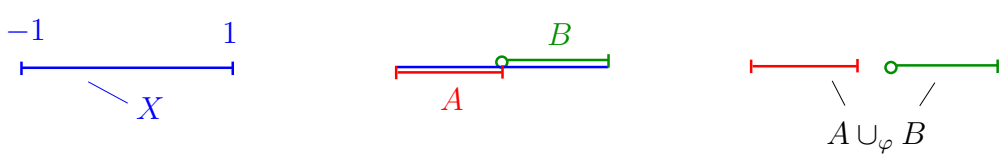

FIGURE 42.

Proof. It follows from Lemma 1.83 (3) that the given map $h\colon A \cup_{\varphi\colon A\cap B \to A\cap B} B \to X$ is continuous. Furthermore, basically by definition the map h is a bijection. By Lemma 1.39 it remains to show that the map h is closed. Thus let $W \subset A \sqcup_\varphi B$ be a closed subset. Note that $h(W) = (W \cap A) \cup (W \cap B)$. It follows from Lemma 1.65 (2), applied to the projection map

$$A \sqcup B \;\to\; A \cup_\varphi B = (A \sqcup B)/\sim,$$

that $A \cap W$ is closed in A and that $B \cap W$ is closed in B. Since A and B are by hypothesis closed in X we obtain from Lemma 1.35 (2) that $A \cap W$ and $B \cap W$ are closed in X. It follows that $h(W) = (W \cap A) \cup (W \cap B)$ is a closed subset of X. $\square$

We conclude this section with an amusing description of spheres. We introduce the following notation:

(1) We write $I = [-1, 1]$.
(2) Given $k \in \mathbb{N}_0$ we write[40]

$$\partial I^k \;=\; \{(x_1, \dots, x_k) \in I^k \mid \text{ at least one } x_i \text{ lies in } \{\pm 1\}\}.$$

(3) We recall that given $k \in \mathbb{N}_0$ there exists by Proposition 1.47 a canonical homeomorphism

$$\varphi_k \colon (\overline{B}^k, S^{k-1}) \;\xrightarrow{\cong}\; (I^k, \partial I^k)$$

with $\varphi_k(0) = 0$.

Now let $m, n \in \mathbb{N}_0$. An elementary set-theoretic argument shows that

$$((\partial I^m) \times I^n) \;\cup\; (I^m \times \partial I^n) \;=\; \partial I^{m+n}$$

and the two subsets to the left coincide in $(\partial I^m) \times (\partial I^n)$. (We refer to Figure 43 for an illustration.) It follows from Lemma 1.84 that the inclusions induce a homeomorphism

$$((\partial I^m) \times I^n) \cup_{\mathrm{id}_{\partial I^m \times \partial I^n}} (I^m \times \partial I^n) \;\xrightarrow{\cong}\; \partial I^{m+n}.$$

Together with the above homeomorphisms we obtain a canonical homeomorphism

$$(S^{m-1} \times \overline{B}^n) \cup_{\mathrm{id}_{S^{m-1} \times S^{n-1}}} (\overline{B}^m \times S^{n-1}) \;\xrightarrow{\cong}\; S^{m+n-1}.$$

For example, if we take $m = n = 2$, then we see that we can write S^3 as the union of two solid tori. We will discuss this particular case in greater detail later on.

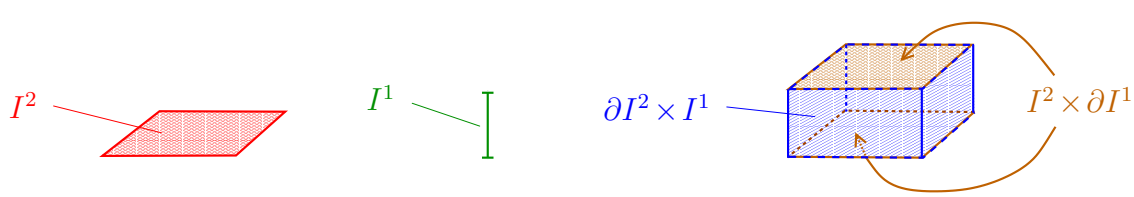

FIGURE 43.

[40]It is not difficult to see that ∂I^k is the boundary of I^k viewed as a subset of $\mathbb{R}^k$.

1.16. **Surfaces.** In this section we introduce some of my favorite topological spaces, namely surfaces.

(1) We consider $X = [0,1] \times [0,1] \subset \mathbb{R}^2$ and the equivalence relation which is generated by

$$(x,0) \ \sim \ (x,1) \qquad \text{for all } x \in [0,1].$$

The quotient topological space $X/\sim$ is obtained from the square $X = [0,1] \times [0,1]$ by identifying each point on the upper edge with the corresponding point on the lower edge. Put differently, "we glue the upper edge to the lower edge". Using Proposition 1.40 one can easily show that the map

$$\begin{array}{rcl} X/\sim & \to & S^1 \times [0,1] \\ (s,t) & \mapsto & \left(e^{2\pi i t}, s\right) \end{array}$$

is a homeomorphism. We refer to $X/\sim$ and also to $S^1 \times [0,1]$ as the *cylinder* or the *annulus*. Sometimes we refer to $S^1 \times (0,1)$, which is homeomorphic to $(0,1) \times [0,1]/\sim$, as the *open cylinder* or *open annulus*.

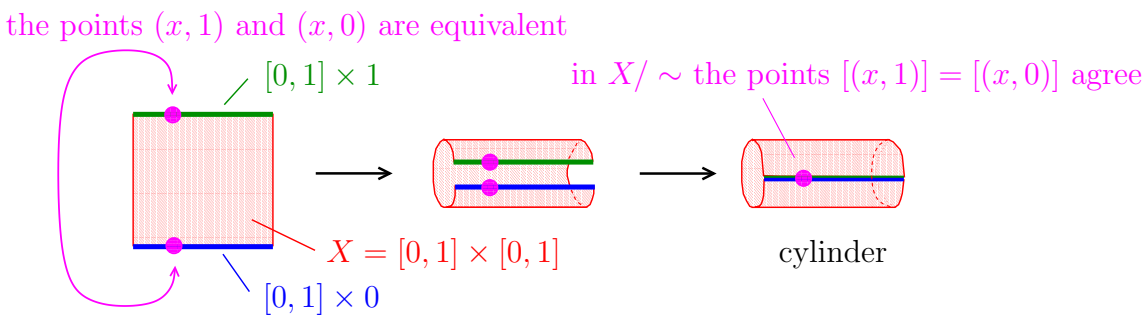

FIGURE 44. Construction of a cylinder by gluing two edges.

(2) Now we consider $X = [0,1] \times [0,1] \subset \mathbb{R}^2$, this time with the equivalence relation which is generated by

$$(0,y) \sim (1, 1-y) \qquad \text{for all } y \in [0,1].$$

The quotient space $X/\sim$ is obtained from the square X by gluing the edge on the left to the edge on the right, but this time "we glue the edges with a twist". We will now see that this topological space is homeomorphic to the Möbius band as defined on page 105. We consider the map

$$\begin{array}{rcl} ([0,1] \times [0,1])/\sim & \to & (\mathbb{R} \times [-1,1])/\mathbb{Z} \\ [(x,y)] & \mapsto & [(x, 2y-1)] \end{array}$$

The left-hand side is compact by Lemma 1.65 (4) and the right-hand side is Hausdorff by Proposition 1.74 and the discussion on page 106. The map is clearly continuous and a bijection. Thus it follows from the ever-popular Proposition 1.40 that the map is a homeomorphism. It is straightforward to see that this homeomorphism restricts

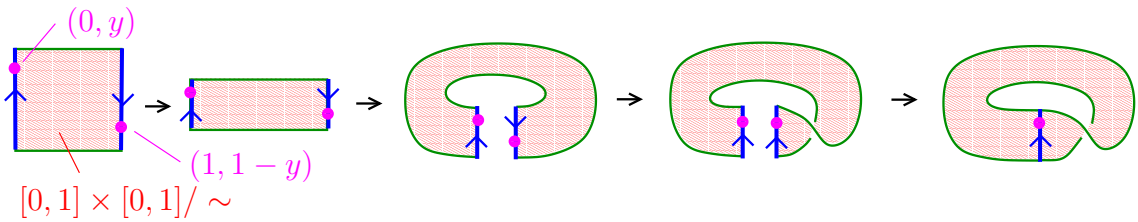

FIGURE 45. The Möbius band.

to a homeomorphism from $([0,1] \times (0,1))/(0,y) \sim (1, 1-y)$ to the open Möbius band $(\mathbb{R} \times (-1,1))/\sim$.

(3) Now we consider again $X = [0,1] \times [0,1] \subset \mathbb{R}^2$, but this time with the equivalence relation which is generated by

$$(x,0) \sim (x,1) \quad \text{for all } x \in [0,1]$$

and by

$$(0,y) \sim (1,y) \quad \text{for all } y \in [0,1].$$

Put differently, we obtain the quotient space $X/\sim$ by gluing the top edge to the bottom edge and the left-hand edge to the right-hand edge, each time without adding a twist. Figure 46 illustrates that the quotient space $X/\sim$ is indeed a torus. As in the previous

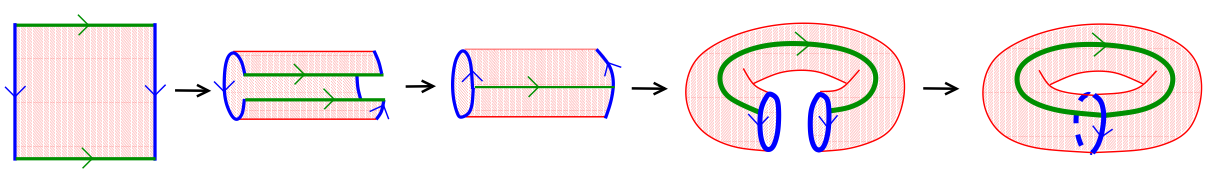

FIGURE 46. By gluing of the opposite edges of a square we obtain a torus.

example one can show that the inclusion $X \to \mathbb{R}^2$ descends to a homeomorphism $X/\sim \to \mathbb{R}^2/\mathbb{Z}^2$.

(4) Now we consider $X = [0,1] \times [0,1] \subset \mathbb{R}^2$, this time with the equivalence relation which is generated by

$$(x,0) \sim (x,1) \qquad \text{for all } x \in [0,1]$$

and by

$$(0,y) \sim (1,1-y) \quad \text{for all } y \in [0,1].$$

Thus we obtain the quotient space $X/\sim$ by gluing the upper edge to the lower edge and by gluing the edge on the left to the edge on the right with a twist. The resulting topological space is called the *Klein bottle*. In Figure 47 we show the Klein bottle to the left. Furthermore we indicate a map from the Klein bottle to $\mathbb{R}^3$. This particular map is not injective.

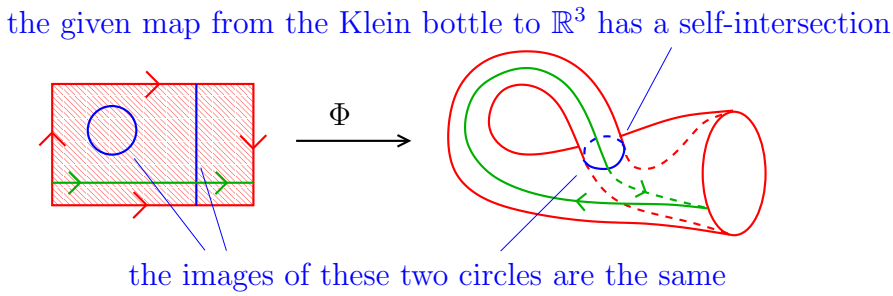

FIGURE 47. The definition of the Klein bottle.

(5) We denote by E_8 the regular octagon in $\mathbb{C}$ with the vertices $Q_k = e^{2\pi ik/16}$ where $k = 1, 3, \ldots, 15$, i.e. E_8 is the convex hull of these eight points in $\mathbb{R}^2$. Given two points $A, B \in \mathbb{R}^2 = \mathbb{C}$ we denote by $\overline{AB}$ the Euclidean segment from A to B. Furthermore, given $\varphi \in \mathbb{R}$ we denote by $r_\varphi \colon \mathbb{C} \to \mathbb{C}$ the reflection in the Euclidean line $\{te^{i\varphi} \,|\, t \in \mathbb{R}\}$. We denote by $\sim$ the equivalence relation on E_8 which is generated by

$$P \in \overline{Q_{2k-1}Q_{2k+1}} \;\sim\; r_{2\pi(2k+2)/16}(P) \;\in\; \overline{Q_{2k+3}Q_{2k+5}}$$

for $k = 0, 1, 4, 5$. These four relations are sketched in Figure 48. We refer to the topological space $E_8/\sim$ as the *surface of genus 2*. The equivalence relation is sketched in Figure 48. Furthermore, in Figure 49 we indicate how $E_8/\sim$ is related to the actual

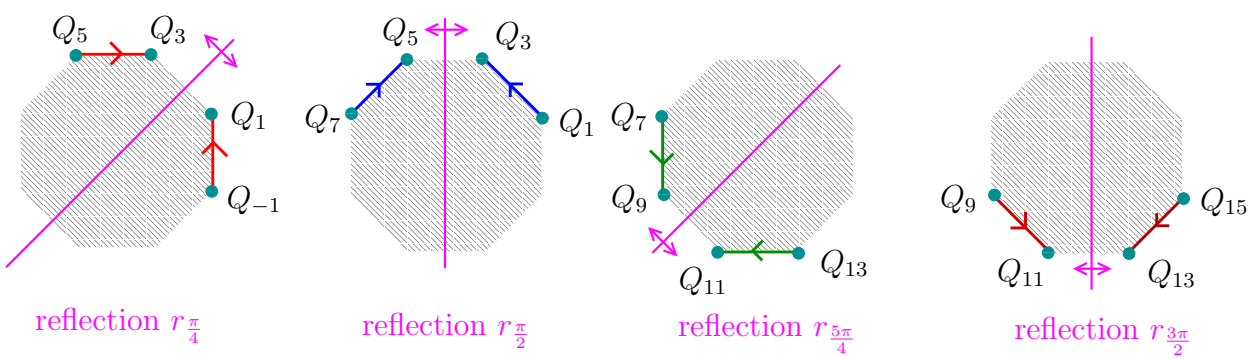

FIGURE 48.

"physical" surface of genus 2 in $\mathbb{R}^3$. The same way we can define the *surface of genus* g for any $g \geq 3$. More precisely, we take a regular $4g$-gon in $\mathbb{C}$ and for $j = 1, \ldots, g$ we identify the $(4j+1)$-st edge with the $(4j+3)$-rd edge and the $(4j+2)$-nd edge with the $(4j+4)$-th edge. Here each identification is given by a reflection. For $g = 3$ this construction is sketched in Figure 50.

Finally we refer to the sphere S^2 as the *surface of genus 0* and we refer to the torus $S^1 \times S^1$ as the *surface of genus 1*.

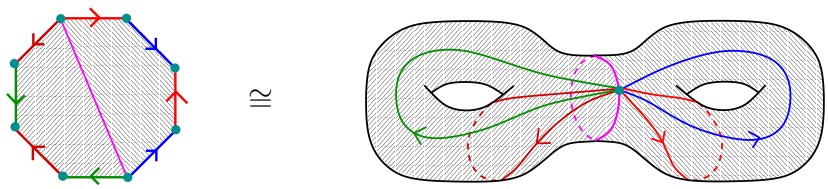

FIGURE 49.

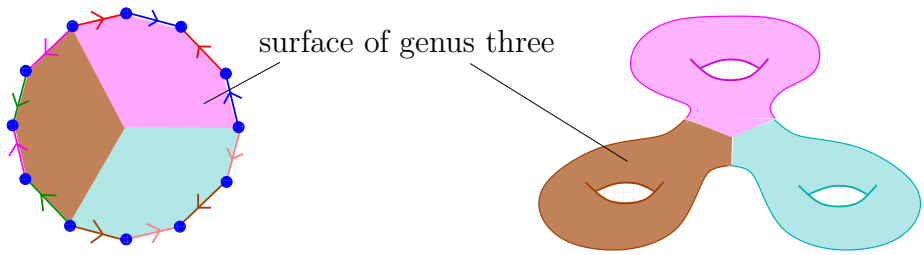

FIGURE 50. The surface of genus three.

We have now introduced many examples of topological spaces, some of them, for example the Möbius band, the torus and the surface of genus 2, can easily be pictured as subsets of "our universe", i.e. they can be viewed as subsets of $\mathbb{R}^3$. This raises the following question.

Question 1.85. *Can the real projective space* $\mathbb{R}\mathrm{P}^2$ *and the Klein bottle be viewed*[41] *as subsets of* $\mathbb{R}^3$*?*

1.17. **The two notions of connected topological spaces.** In this section we will see that there are two notions of connectedness of a topological space. As we will see, for most "reasonable" topological spaces the two notions mercifully coincide.

Definition.

(1) We say that a topological space X is *path-connected* if given any two points x and y there exists a path from x to y, i.e. there exists a map $\gamma\colon [0,1] \to X$ with $\gamma(0) = x$ and $\gamma(1) = y$.
(2) We say that a topological space X is *connected* if the following holds[42]

$$\text{if } X = U \sqcup V \text{ is the disjoint union of open sets } U, V \quad \Longrightarrow \quad X = U \text{ or } X = V.$$

Examples.

(1) It follows basically from the definitions that any convex subset of some $\mathbb{R}^n$ is path-connected. But it is much less clear whether say $\mathbb{R}^n$ is connected in the above sense.

[41]The word "view" is intentionally vague.

[42]Recall that we write $X = U \sqcup V$ if X is the disjoint union of U and V, i.e. if $X = U \cup V$ and if $U \cap V = \varnothing$.

(2) Next let $G \subset \mathbb{R}^2$ be the graph of the function $f\colon \mathbb{R} \to \mathbb{R}$ given by $x \mapsto x^2$. As in Figure 51 we consider the complement $X = \mathbb{R}^2 \setminus G$. It is pretty clear that X is not path-connected, surely there is no path from a point P below G to a point above G. But how can one show the non-existence of such a path?[43] But it is clear that X is not connected, since X is the disjoint union of the two open non-empty sets $U := \{(x,y) \,|\, y < x^2\}$ and $V := \{(x,y) \,|\, y > x^2\}$.

So we see that both notions of connectedness have their advantages and disadvantages. It is often easy to show that a given topological space is path-connected but it can be a pain to show that a given topological space is not path-connected. With connectedness it is precisely the other way round.

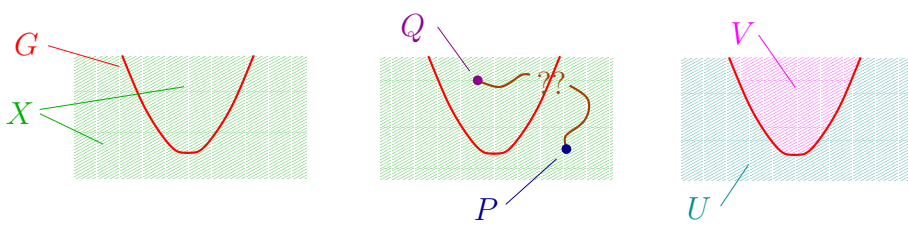

FIGURE 51.

It is basically obvious that any interval is path-connected. But as we will see, it takes some effort to show that the interval $[0,1]$ is connected.

Proposition 1.86. *The interval* $[0,1]$ *is connected.*

Proof. Let U and V be two disjoint open subsets of $[0,1]$ with $U \cup V = [0,1]$. Without loss of generality we can assume that $0 \in U$. We want to show that $U = [0,1]$. We consider

$$A \;:=\; \big\{t \in [0,1] \,\big|\, [0,t] \subset U\big\}.^{44}$$

The set A contains 0, hence it is non-empty. Evidently the set is bounded thus we can consider $T := \sup A$. We need to show that $T = 1$ and that $T \in U$.

First let us suppose that $T \notin U$. This implies that $T \in V$. Since V is open it follows that there exists an $\epsilon > 0$ such that $(T-\epsilon, T+\epsilon) \cap [0,1]$ is also contained in V. In particular we have $(T-\epsilon, T+\epsilon) \cap A = \varnothing$ which implies that $\sup A \leq T - \epsilon$. Thus we have obtained a contradiction.

Now we know that $T \in U$. We still need to show that $T = 1$. Since U is open it follows that there exists an $\epsilon > 0$ such that $(T-\epsilon, T+\epsilon) \cap [0,1] \subset U$. Thus $[0, T+\epsilon) \cap [0,1] \subset U$. In light of the definition of T that is only possible if $T = 1$. $\square$

[43]The fact that such a path does not exist can be shown, with some dexterity, using real analysis. How?

[44]Put differently,

$$A \;=\; \text{the set of all } t \in [0,1] \text{ such that the interval } [0,t] \text{ is contained in } U.$$

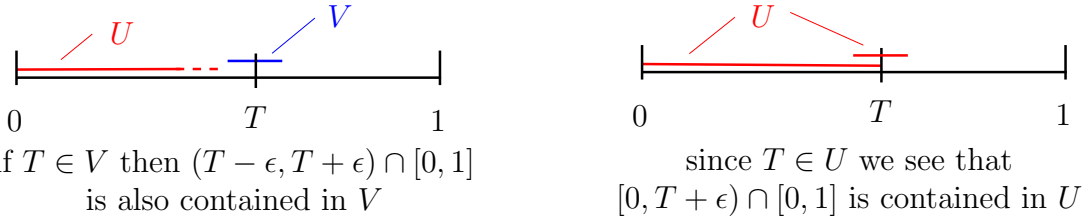

FIGURE 52. Illustration of the proof of Proposition 1.86.

Corollary 1.87. *Every path-connected topological space is also connected.*

Proof. Let X be a topological space that is path-connected. Suppose that X is not connected. This means that there exist disjoint open non-empty subsets U and V with $X = U \cup V$. Since U and V are non-empty we can find points $x \in U$ and $y \in V$. Since X is path-connected there exists a path $\gamma\colon [0,1] \to X$ with $\gamma(0) = x$ and $\gamma(1) = y$. Then $\gamma^{-1}(U) \cup \gamma^{-1}(V)$ is a decomposition of $[0,1]$ into two disjoint non-empty open subsets. But that is a contradiction to Proposition 1.86. □

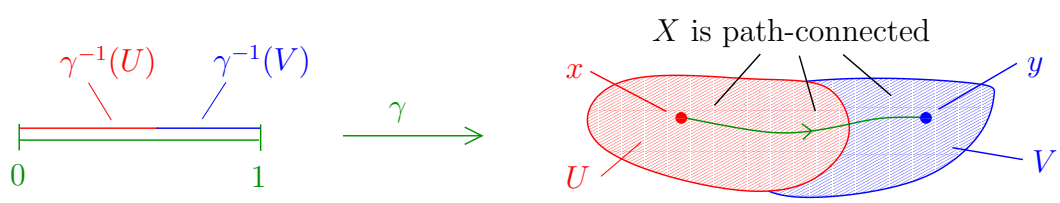

FIGURE 53. Illustration of the proof of Corollary 1.87.

.

The following lemma comes in handy on several occasions.

Lemma 1.88. *Let $f\colon X \to Y$ be a map between topological spaces.*

(1) *If X is path-connected, then $f(X)$ is also path-connected.*
(2) *If X is connected, then $f(X)$ is also connected.*

Proof. We leave the elementary proof to the reader. □

In the following lemma we show that most of the topological spaces that we had encountered so far are path-connected and connected. We will use this lemma on numerous occasions without explicitly referring to it.

Lemma 1.89.

(1) *Let $n \geq 1$. Every open ball $B^n_r(y)$, every closed ball $\overline{B}^n_r(y)$ and all of $\mathbb{R}^n$ are path-connected and connected.*
(2) *Every sphere $S^n_r(y)$ with $n \geq 1$ is path-connected and connected.*

(3) *The annulus, the Möbius band, the torus and the surface of any genus are path-connected and connected.*

Proof. By Corollary 1.87 it suffices to show that all these topological spaces are path-connected. It is clear that convex subsets of $\mathbb{R}^n$ are path-connected. It follows from the example on page 78 that all balls (open or closed) are path-connected. The lemma now follows from the Lemma 1.88 (1) and the observation that all the remaining topological spaces are the homeomorphic image of convex subsets.[45] $\square$

For better or worse, the converse to Corollary 1.87 is unfortunately not always correct.

Example. Consider the topological space

$$X \;:=\; \big\{(0,y)\,\big|\,y\in[-1,1]\big\} \cup \big\{(x,\sin(\tfrac{1}{x}))\,\big|\,x\in(0,\pi]\big\} \;\subset\; \mathbb{R}^2.$$

The topological space X is the union of the graph of $x \mapsto \sin(\frac{1}{x})$ for $x \in (0,\pi]$ and an interval on the y-axis. We sketch the topological space X in Figure 54.[46] It is a very instructive exercise, see Exercise 1.42 to show that X is connected and it is an equally instructive exercise to show that X is *not* path-connected.

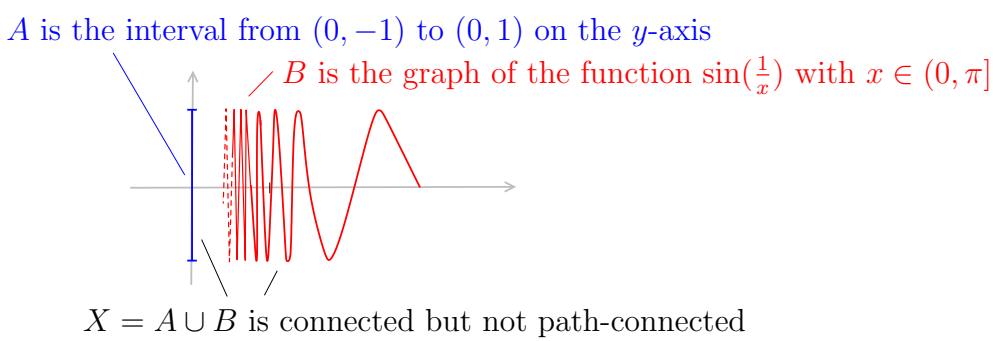

FIGURE 54.

Remark. The fact that an example of a topological space that is connected but not path-connected is so "wild" indicates that perhaps for most "reasonable" spaces the two notions of connectedness and path-connectedness agree. In fact in basically all examples of topological spaces that we encounter throughout these notes the two notions of connectedness will agree.

By a clever use of the notion of connectedness one can sometimes prove statements which at first glance have nothing to do with connectedness. For example we can now prove the following lemma.

[45] This is true by definition for all the stated topological spaces except for the spheres, but we saw on page 99 that S^n is homeomorphic to $\overline{B}^n/S^{n-1}$.

[46] This topological space is sometimes referred to as the *topologist's sine curve.*

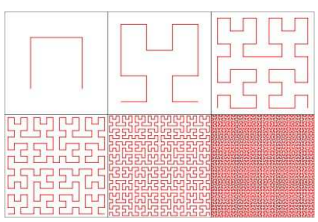
Lemma 1.90. *The topological spaces $\mathbb{R}$ and $\mathbb{R}^2$ are not homeomorphic.*

Remark. Later on we will study the question whether for $k \neq l$ the topological spaces $\mathbb{R}^k$ and $\mathbb{R}^l$ can be homeomorphic.

Proof. Let us suppose that there exists a homeomorphism $f\colon \mathbb{R} \to \mathbb{R}^2$. Let $P \in \mathbb{R}$ be a point. Then f restricts to a homeomorphism from $\mathbb{R} \setminus \{P\}$ to $\mathbb{R}^2 \setminus \{f(P)\}$. The topological space $\mathbb{R} \setminus \{P\} = (-\infty, P) \cup (P, \infty)$ is not path-connected[47], while one can easily verify that $\mathbb{R}^2 \setminus \{f(P)\}$ is path-connected. But as we remarked on page 72, homeomorphic spaces have the same topological properties. In particular two homeomorphic spaces are either both path-connected or they are both not path-connected. Thus we have obtained a contradiction. □

The proof of Lemma 1.90 also shows that the interval $[0, 1]$ is not homeomorphic to the square $[0, 1]^2$. One might think that this should surely be obvious since $[0, 1]^2$ is "clearly bigger" than $[0, 1]$. But the following proposition will disabuse the reader of this idea.

Proposition 1.91. *Let $n \in \mathbb{N}$. There exist maps[48] $f\colon [0, 1] \to [0, 1]^n$ that are surjective.*



first six stages in the construction
of the Hilbert space-filling curve

FIGURE 55. Illustration of Proposition 1.91.

Remark.

(1) A surjective map from $[0, 1]$ to $[0, 1]^n$, or from a one-dimensional manifold to some manifold of dimension ≥ 2, is often called a *space-filling curve*.
(2) It follows easily from Proposition 1.40 that for $n \geq 2$ an *injective* map $f\colon [0, 1] \to [0, 1]^n$ cannot be possibly be surjective. In other words, the maps promised by Proposition 1.91 are necessarily non-injective.

Proof.

(1) Many examples of such maps are given in [Sag], see e.g. [Sag, Theorem 2.1].
(2) This statement is an immediate consequence of [Wall, Lemma 4.11]. □

We continue with the following elementary but useful lemma.

Lemma 1.92. *Every map $f\colon X \to Y$ from a connected topological space X to a discrete topological space is constant.*

[47] Why is this topological space not path-connected? How can one show this?

[48] Just to make things clear, here we demand of course that f is continuous.

Remark. One could argue that Lemma 1.92 is the lemma in topology that is most relevant to real life. More precisely, an immediate consequence of Lemma 1.92 is that any *non-constant* map $(a, b) \to A$ from an interval to a finite set is not continuous. This is of huge significance since humanity likes to squeeze a real-parameter (e.g. time, intelligence, performance) into a finite set of values (e.g. historical stages, grades in school and exams, hired-or-fired). Any such function is non-continuous and hence very problematic.

Proof. We need to show that for any $x \in X$ we have $f(x) = f(X)$. Since Y is a discrete topological space we know that $\{f(x)\}$ and $Y \setminus \{f(x)\}$ are open subsets of Y. The preimages $U := f^{-1}(f(x))$ and $V := f^{-1}(Y \setminus \{f(x)\})$ are also open and they are evidently disjoint. Since U is non-empty and since X is connected we see that $V = \varnothing$. But this means that f is constant. $\square$

In the remainder of this section we will discuss a few lemmas which will be useful for showing that certain topological spaces are (path-) connected. For example the next lemma gives a criterion for the union of (path-) connected subsets to be (path-) connected.

Lemma 1.93. $(*)$ *Let X be a topological space and let $\{B_i\}_{i \in I}$ be a family of subsets such that the intersection $\bigcap_{i \in I} B_i$ is non-empty.*

(1) *If each B_i, $i \in I$ is path-connected, then $\bigcup_{i \in I} B_i$ is path-connected.*

(2) *If each B_i, $i \in I$ is connected, then $\bigcup_{i \in I} B_i$ is connected.*

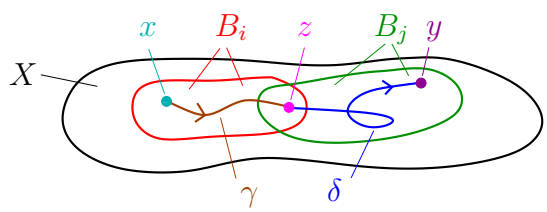


FIGURE 56. Illustration for the proof of Lemma 1.93 (1).

Proof $(*)$. Let X be a topological space and let $\{B_i\}_{i \in I}$ be a family of subsets such that the intersection $\bigcap_{i \in I} B_i$ contains a point z. We write $Z := \bigcup_{i \in I} B_i$.

(1) We suppose that each B_i, $i \in I$ is path-connected. So let $x, y \in Z$. There exists an $i \in I$ with $x \in B_i$ and there exists a $j \in I$ with $y \in B_j$. Since B_i and B_j are path-connected we can pick a path $\gamma \colon [0, 1] \to B_i$ from x to z and we can pick a path $\delta \colon [0, 1] \to B_j$ from z to y. It is clear that

$$\begin{array}{rcl} [0,1] & \to & Z \\ t & \mapsto & \begin{cases} \gamma(2t), & \text{if } t \in [0, \frac{1}{2}] \\ \delta(2t-1), & \text{if } t \in [\frac{1}{2}, 1] \end{cases} \end{array}$$

is a path[49] from x to y.

(2) We suppose that each B_i, $i \in I$ is connected. We write $Z = U \sqcup V$ where U and V are open subsets. Without loss of generality we can assume that $z \in U$. For each $i \in I$ we have a decomposition $B_i = (U \cap B_i) \sqcup (V \cap B_i)$ into disjoint open subsets (here we use the definition of the subspace topology). Since B_i is connected and since $U \cap B_i \neq \varnothing$ we see that $B_i = U \cap B_i$. Thus we have shown that

$$U \;=\; \bigcup_{i\in I}(B_i \cap U) \;=\; \bigcup_{i\in I} B_i \;=\; Z. \qquad \square$$

We conclude this section with the following lemma.

Lemma 1.94. *Let X and Y be non-empty topological spaces. Then X and Y are (path)-connected if and only if $X \times Y$ is (path)-connected.*

Proof $(*)$. If $X \times Y$ is (path)-connected, then it follows from Lemma 1.88 applied to the projection maps $X \times Y \to X$ and $X \times Y \to Y$, that X and Y are (path)-connected.[50]

Now suppose that X and Y are path-connected. We need to show that $X \times Y$ is also path-connected. Thus let (x, y) and (x', y') be two points in $X \times Y$. Since X is path-connected we can find a path $p\colon [0,1] \to X$ from x to x' and similarly we can find a path $q\colon [0,1] \to Y$ from y to y'. Then

$$\begin{array}{rcl} [0,1] & \to & X \times Y \\ t & \mapsto & \begin{cases} (p(2t), y), & \text{if } t \in [0, \frac{1}{2}], \\ (x', q(2t-1)), & \text{if } t \in (\frac{1}{2}, 1] \end{cases} \end{array}$$

is a path from (x, y) to (x', y').[51]

Finally suppose that X and Y are connected. We want to show that $X \times Y$ is also connected. We pick $a \in X$ and $b \in Y$. Let $x \in X$. Note that the subsets $\{x\} \times Y$ and $X \times \{b\}$ are connected by our hypothesis. Since these have the point (x, b) in common we deduce from Lemma 1.93 (2) that $(\{x\} \times Y) \cup (X \times \{b\})$ is also connected. Finally note that

$$X \times Y \;=\; \bigcup_{x\in X} (\{x\} \times Y) \cup (X \times \{b\}).$$

All the sets on the right are connected and they have the point (a, b) in common. Thus it follows again from Lemma 1.93 (2) that the union on the right-hand side is connected. We refer to Figure 57 for an illustration. $\square$

1.18. **The (path-) components of a topological space.**

Definition. Let x and y be two points in a topological space X. We say that the points x and y are *path-equivalent*, if there exists a map $\gamma\colon [0,1] \to X$ with $\gamma(0) = x$ and $\gamma(1) = y$.

[49] It follows from Lemma 1.32 (2) that this map is indeed continuous.

[50] Note that the projection maps are surjective since we assume that X and Y are non-empty.

[51] It follows from Lemma 1.53 (3d) and Lemma 1.32 (2) that this map is indeed continuous.

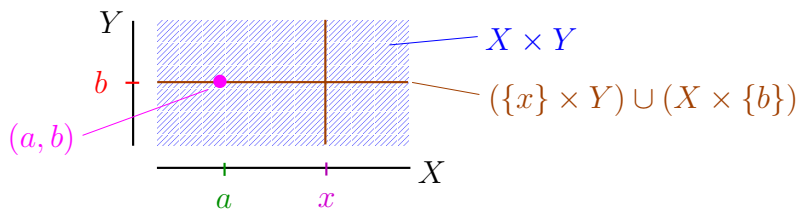

FIGURE 57. Illustration for the proof of Lemma 1.94.

Lemma 1.95. *For every topological space X the notion of path-equivalence is indeed an equivalence relation.*

Proof. All properties of an equivalence relation are trivial except possibly for transitivity. The fact that path-equivalence is transitive follows immediately from the argument in Lemma 1.93 (1). □

Definition. Let X be a topological space.

(1) We call the path-equivalence classes of points the *path-components* of X.
(2) We denote by $\pi_0(X)$ the set of path-components of X.[52] Furthermore we write $\pi_0(X) = 0$ if X is non-empty and if it consists of a single path-component.

Example. It is a straightforward consequence of the Intermediate Value Theorem that each point in $\mathbb{Q}$ is in fact already a path-component of $\mathbb{Q}$.

Later on it will at times be useful to know the path-components of certain matrix groups. The relevant results are summarized in the following lemma.

Lemma 1.96.

(1) *The general linear group*

$$\mathrm{GL}(n,\mathbb{R}) \;=\; \{A \in M(n \times n, \mathbb{R}) \,|\, \det(A) \neq 0\} \;\subset\; M(n \times n, \mathbb{R}) \;=\; \mathbb{R}^{n^2}$$

has precisely two path-components, namely

$$\mathrm{GL}_+(n,\mathbb{R}) \;:=\; \{A \in \mathrm{GL}(n,\mathbb{R}) \,|\, \det(A) > 0\} \quad \textit{and} \quad \{A \in \mathrm{GL}(n,\mathbb{R}) \,|\, \det(A) < 0\}.$$

Put differently, two invertible matrices lie in the same path-component if and only if the signs of their determinants agree. The same statement also holds for $\mathrm{O}(n)$*, more precisely* $\mathrm{O}(n)$ *has precisely two path-components, namely*

$$\mathrm{SO}(n,\mathbb{R}) \;=\; \{A \in \mathrm{O}(n,\mathbb{R}) \,|\, \det(A) > 0\} \quad \textit{and} \quad \{A \in \mathrm{O}(n,\mathbb{R}) \,|\, \det(A) < 0\}.$$

(2) *The group* $\mathrm{SL}(n,\mathbb{R}) = \{A \in M(n \times n; \mathbb{R}) \,|\, \det(A) = 1\}$ *is path-connected.*

[52] The notation "$\pi_0(X)$" might look rather odd at the moment, but it will become clearer later on why this is a perfectly sensible notation.

(3) *The unitary group* $\mathrm{U}(n)$ *and the special unitary group*

$$\mathrm{SU}(n) \;=\; \{A \in U(n) \mid \det(A) = 1\}$$

are both path-connected, thus they consist of a single path-component.

Proof. It is an instructive exercise in linear algebra to prove this lemma, see Exercise 1.45. Alternatively, the proof for both statements is given in [Bak, Chapter 9.2]. □

The following lemma follows immediately from the definitions and basic properties of equivalence relations.

Lemma 1.97. *Let X be a topological space. Then the following statements hold:*

(1) *as a set, X is the disjoint union of its path-components,*
(2) *each path-component of X is path-connected,*
(3) *each path-component C of X is a maximal path-connected subset, i.e. if $C \subsetneq D$, then D is not path-connected.*

Our goal now is to define the "components" of a topological space that should play the same role as the path-components, i.e. we want to introduce the notion of "components" such that the statements of Lemma 1.97 hold, but with "path-connected" replaced by "connected" and "path-component" replaced by "component".

We start out with the following definition.

Definition. Let x and y be two points in a topological space X. We say that the points x and y are *equivalent*, if there exists a connected subset of X that contains both x and y.

Lemma 1.98. *For every topological space X the above notion of equivalence is indeed an equivalence relation.*

Proof. All properties of an equivalence relation are trivial except for transitivity. So suppose that x and y are equivalent and that y and z are equivalent. By definition there exists a connected subset A that contains x and y and there exists a connected subset B that contains y and z. By Lemma 1.93 (2) the union $A \cup B$ is connected and it thus follows that x and z are equivalent. □

Definition. Let X be a topological space. We call the equivalence classes of points on X the *components* of X.

Examples.

(1) The topological space illustrated in Figure 54 has two path-components but only a single component.
(2) It follows easily from the definitions that a topological space is totally disconnected if every component consists of a single point.

The following is now the promised analogue of Lemma 1.99.

Lemma 1.99. *Let X be a topological space. Then the following statements hold:*

(1) *as a set X is the disjoint union of its components,*
(2) *each component of X is connected,*
(3) *each component C of X is a maximal connected subset, i.e. if $C \subsetneq D$, then D is not connected.*

Remark. Let X be a topological space and let $\{X_i\}_{i\in I}$ be its set of components. Lemma 1.99 says that as a set we have $X = \bigcup_{i\in I} X_i$. But, if we equip the right-hand side with the disjoint union topology that we introduced on page 83, then this is in general *not* an equality (or homeomorphism) of topological spaces. For example, an easy counterexample is given by $X = \mathbb{Q}$.

Proof. Let X be a topological space. The first statement is clear. Now let C be a component of X. We pick $c \in C$. For each $d \in C$ there exists by definition a connected subset Y_d of X that contains c and d. We have

$$C = \bigcup_{c\in C}\{c\} \subset \bigcup_{c\in C} Y_c \underset{\substack{\uparrow \\ \text{by definition all points in } Y_d \text{ are equivalent to } c\text{, thus we have } Y_d \subset C}}{\subset} C \quad \text{which implies that} \quad C = \bigcup_{c\in C} Y_c.$$

It follows from Lemma 1.93 (2) that C is connected. Finally the last statement of the lemma follows immediately from the definitions. □

We wrap up the discussion of the components of a topological space with the following lemma.

Lemma 1.100. *Let X be a topological space.*
(1) *Every component of X is closed.*
(2) *If X has only finitely many components, then each component is also open.*

Example. We consider $X = \mathbb{Q}$. In this case every point is already a component. We see that every component is closed, but in this case no component is an open subset. Therefore we cannot drop the condition on the number of components in the second statement of the lemma.

Proof $(*)$. Let X be a topological space.

(1) Let C be a component of X. We need to show that $X \setminus C$ is open. By Lemma 1.8 it suffices to show that any $P \in X \setminus C$ admits a neighborhood that does not intersect C. Thus let $P \in X \setminus C$. By Lemma 1.99 we know that $C \cup \{P\}$ is not connected. Therefore there exists a decomposition $C \cup \{P\} = U \sqcup V$ with U and V open subsets such that both U and V are non-empty. Without loss of generality $C \cap U \neq \varnothing$. Since C is connected and since $C = (U \cap C) \sqcup (V \cap C)$ we see that $C = U \cap C$. Since V is also non-empty we see that $V = \{P\}$. By the definition of the subspace topology that means that there exists an open subset W of X such that $W \cap (C \cup \{P\}) = V = \{P\}$. But this shows that W is an open neighborhood of P that does not intersect C. We have thus shown that the complement of C is open. We refer to Figure 58 for an illustration of the above argument.

(2) Now suppose that X has only finitely many components. Let C be a component of X. We already know from (1) that C is closed. By definition the complement of C is the union of all other components. Since there are only finitely many and since they are closed by (1) it follows that the complement of C is closed, i.e. C is open. □

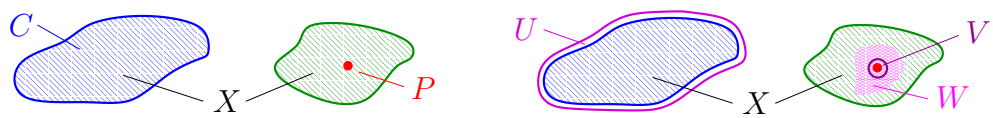

FIGURE 58. Illustration for the proof of Lemma 1.100 (1).

Remark. Let X be a topological space. We say that the points x and y are *quasi-equivalent*, if the following holds

$$\text{if } X = U \sqcup V \text{ is the disjoint union with } U, V \text{ open} \implies \text{either } x, y \in U \text{ or } x, y \in V.$$

It is straightforward to see that this indeed an equivalence relation on X. The equivalence classes of this equivalence relation are called *quasi-components*. It follows immediately from the definitions that components are contained in quasi-components. But the notions are different, for example it is shown in [SS, p. 137] that there exist topological spaces such that quasi-components are not connected. We will not make use of the concept of quasi-equivalence and quasi-components.

We conclude this section with the following lemma that can be viewed as a generalization of Lemma 1.88 and Lemmas 1.92.

Lemma 1.101. $(*)$ *Let X and Y be topological space. If X is (path-) connected and if Y consists of (path-) components $Y_i, i \in I$, then given any map $f\colon X \to Y$ there exists an $i \in I$ with $f(X) \subset Y_i$.*

Proof $(*)$. Again we leave the proof as a straightforward exercise to the reader. □

1.19. **Local properties.**

Definition. Let P be a property of topological spaces and let X be a topological space.

(1) We say X is *locally P* if given any $Q \in X$ and any neighborhood U of Q there exists a neighborhood V of Q that is contained in U that has the property P.
(2) We say X is *o-locally P* if given any $Q \in X$ and any neighborhood U of Q there exists an *open* neighborhood V of Q that is contained in U that has the property P.

Remark.

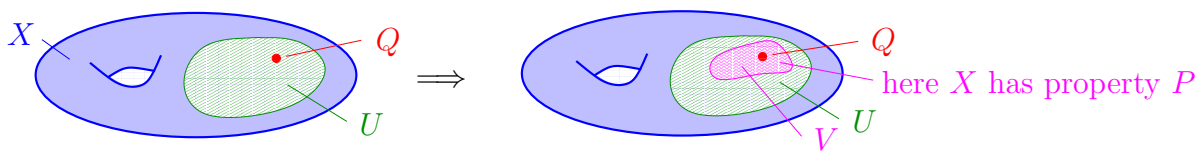

FIGURE 59.

(1) In the literature the term "locally P" is sometimes employed with subtly different definitions. The definition we use seems to be used in most books, see e.g. [Hat, Bre, Rot]. But the definition in [Mun3, p. 161] of "locally connected" is actually our definition of "o-locally connected".[53] So if one sees the notion "locally P" in the literature one needs to look up the definition to make sure what convention is used.
(2) Throughout the notes we are mostly interested in "o-local" properties. Since the term "locally P" has become fairly standard we are thus forced to carry along the prefix "o-" even though at times it makes for slightly awkward reading.

Examples.

(1) Every open subset of $\mathbb{R}^n$ is o-locally path-connected. Indeed, suppose A is an open subset of $\mathbb{R}^n$. Let $Q \in A$ and let U be a neighborhood of Q in A. Then there exists an $\epsilon > 0$ such that $B^n_\epsilon(x) \subset U$.The ϵ-ball $B^n_\epsilon(x)$ is of course path-connected.
(2) The space $X = (-2, 1) \cup [3, 6] \subset \mathbb{R}$ with the usual topology is not path-connected but it is o-locally path-connected.[54] On the other hand $X = \mathbb{Q}$ is not even o-locally path-connected.
(3) The line with two zeros, i.e. the topological space $\mathbb{R} \cup \{*\}$ with the topology from page 53, is not Hausdorff, but one can easily show that $\mathbb{R} \cup \{*\}$ is o-locally Hausdorff.

The following lemma is the key to showing that for "reasonable" topological spaces the notions of being connected and being path-connected are actually the same.

Lemma 1.102. *Let X be a topological space that is o-locally path-connected. Then*

$$X \text{ is connected} \iff X \text{ is path-connected.}$$

Proof. The "$\Leftarrow$"-direction is an immediate consequence of Corollary 1.87. In Exercise 1.46 we will show that if X is o-locally path-connected, then the converse also holds. □

In the following we discuss the notion of being locally compact.

Examples.

[53] It might not be apparent from [Mun3, p. 161] that the definition there of "locally connected" differs from ours, but the reason is that, as mentioned before on page 49, in [Mun3] a different notion of a neighborhood is being used.

[54] Why is that?

(1) Every open subset of $\mathbb{R}^n$ is locally compact. Indeed, suppose A is an open subset of $\mathbb{R}^n$. Let $Q \in A$ and let U be a neighborhood of Q in A. Then there exists an $\epsilon > 0$ such that $B^n_\epsilon(x) \subset U$. The closed ϵ-ball $\overline{B}^n_{\frac{\epsilon}{2}}(x)$ is a neighborhood[55] of x and it is compact by the Heine-Borel Theorem 1.21.
(2) Similar to (1) one can easily show that every interval is locally compact. In fact later on we will mostly need the fact that the interval $[0, 1]$ is locally compact.

In Exercise 1.48 we will see that there exists a topological space that is compact but not locally compact. The following lemma shows that this slightly unintuitive phenomenon cannot occur if we restrict ourselves to topological spaces that are Hausdorff.

Lemma 1.103. $(*)$ *Let X be a topological space. If X is compact and Hausdorff, then X is also locally compact.*

Proof. We will use Lemma 1.103 only once, in a rather inessential way. Therefore we leave the proof of this lemma as a not entirely trivial exercise to the reader. Alternatively we refer to [Wil, Theorem 18.2] for a proof. □

In the following definition we turn from properties of topological spaces to properties of maps.

Definition. Let P be a property of maps between topological spaces and let $f\colon X \to Y$ be a map between topological spaces.

(1) We say that $f\colon X \to Y$ is *locally P* at $x \in X$ if there exists an open neighborhood U of x and an open neighborhood V of $f(x)$ such that $f\colon U \to V$ has the property P.
(2) We say that f is *locally P* if it is locally P at any $x \in X$.

Remark. Considering the language regarding properties of topological spaces one could argue that the above property of maps should be called "o-locally P". But since the term "o-locally" was born out of desperation we try to reduce its usage.

Examples.

(1) One easily verifies that the map $f\colon \mathbb{R} \to \mathbb{R}$ given by $f(x) = x^2$ is a local homeomorphism at all points $x \neq 0$.
(2) The projection map $p\colon \mathbb{R} \to \mathbb{R}/\mathbb{Z}$ is a local homeomorphism. Indeed, let $Q \in \mathbb{R}$. We set $U = (Q - \frac{1}{2}, Q + \frac{1}{2})$ and $V = p(U)$. The restriction of p to $p\colon U \to V$ is continuous and a bijection. Furthermore, by Lemma 1.71 (2) this is also open. It follows from Lemma 1.39 that $p\colon U \to V$ is a homeomorphism.

We will often use the statement of the following lemma without making reference to the lemma.

Lemma 1.104. *Let $f\colon X \to Y$ be a map between two topological spaces (for once we do not assume that f is continuous). If f is locally continuous, then f itself is continuous.*

[55] It is perhaps worth stressing that in the definition of a local property we need to find *neighborhoods* with a given property.

Proof. Let $f\colon X \to Y$ be a locally continuous map between two topological spaces. It follows from Lemma 1.30 (2) that given any $x \in X$ that there exists an open neighborhood U_x of x such that the restriction of f to U_x is continuous. It is an immediate consequence of Lemma 1.32 (1) that f itself is continuous. □

1.20. **Abstract graphs and spatial graphs.** We start out with the following rather abstract definition.

Definition.

(1) An *abstract graph* G is a triple (V, E, φ) where V is a non-empty set, E is a set and φ is a map

$$\varphi\colon E \to \{\text{subsets of } V \text{ with one or two elements}\}.$$

The elements of V are called *vertices of* G and the elements of E are called the *edges of* G. Furthermore, given $e \in E$ the points in $\varphi(e)$ are called the *endpoints of* e.

(2) Let $G = (V, E, \varphi)$ and $G' = (V', E', \varphi')$ be two abstract graphs. A *map* $G \to G'$ *of abstract graphs* consists of two maps $\Phi\colon V \to V'$ and $\Psi\colon E \to E'$ such that for any $e \in E$ we have $\varphi'(\Psi(e)) = \Phi(\varphi(e))$. If Φ and Ψ are bijections, then we refer to the map as an *isomorphism of abstract graphs.*

Examples.

(A) We take $V = \{A, B, C\}$, $E = \{e, f, g, h\}$ and φ to be the map that is defined by $\varphi(e) = \{A, B\}, \varphi(f) = \{B, C\}$, $\varphi(g) = \{B, C\}$ and $\varphi(h) = \{A\}$. Then (V, E, φ) is an abstract graph.

(B) Let $a, b \in \mathbb{Z}$. We denote by $G_{a,b}$ the abstract graph with vertex set $V = \mathbb{Z}$ and edge set $\{\{x, y\} \mid x, y \in \mathbb{Z} \text{ with } x = y \pm a \text{ or } x = y \pm b\}$. The map φ is given by sending each edge $e = \{x, y\}$ to $\{x, y\}$.

(C) We take V to be the set of all subway stations in München and we take E to be the set of all segments of the subway system. The map φ then assigns to each $e \in E$ the two stations that are connected by the segment e.

Definition. We say an abstract graph (V, E, φ) is *connected* if for any two vertices $v \neq w \in V$ there exist vertices $v = v_0, v_1, \ldots, v_n = w$ and edges $e_0, \ldots, e_{n-1}$ with $\varphi(e_i) = \{v_i, v_{i+1}\}$ for $i = 0, \ldots, n-1$.

Examples. We want to determine whether or not the above examples (A), (B) and (C) of graphs are connected.

(A) This graph is connected, for example if we take $v = A$ and $w = C$, then $v_0 = A$, $v_1 = B$ and $v_2 = C$ and $e_0 = e$ and $e_1 = f$ have the desired property.

(B) Let $a, b \in \mathbb{Z}$. Basically by definition the graph $G_{a,b}$ is connected if and only if for any two integers $x, y \in \mathbb{Z}$ there exist $n, m \in \mathbb{Z}$ such that $x - y = ma + nb$. Elementary number theory says that this is the case if and only if a and b are coprime.

(C) This graph is connected since any two subway stations are connected by the subway system (one might have to change lines but that is of no concern to us).

So far this definition has little to do with topology. We will change this by introducing spatial graphs. Before we can do so we need the following definition.

Definition. An *arc* in $\mathbb{R}^n$ is a subset E of $\mathbb{R}^n$ for which there exists a map $\varphi\colon [0,1] \to \mathbb{R}^n$ with the following properties:

(1) the map φ is smooth, i.e. all derivatives are defined on the open interval $(0,1)$ and they extend to continuous maps on the closed interval $[0,1]$ that we also call derivatives,
(2) the first derivative $\varphi'(t)$ is non-zero for all $t \in [0,1]$,
(3) the restriction of φ to $(0,1)$ is injective,
(4) the set $\varphi((0,1))$ is disjoint from $\varphi(0)$ and $\varphi(1)$, and
(5) $\varphi((0,1)) = E$.

Given an arc E as above we refer to $\varphi(0)$ and $\varphi(1)$ as the *endpoints of* E.[56][57]

FIGURE 60.

Definition. A *spatial graph* G is a pair (V,E) with the following properties:

(1) V is a non-empty discrete subset of some $\mathbb{R}^n$.
(2) E is a subset of $\mathbb{R}^n$ with the following properties:
  (a) E is disjoint from V,
  (b) each component of E is an arc and the endpoints of each arc lie in V,
  (c) every bounded subset of $\mathbb{R}^n$ intersects only finitely many components of E.[58]

We refer to the points in V as the *vertices of* G and we refer to the components of E as the *edges of* G. Furthermore, given a spatial graph $G = (V,E)$ we write $|G| = V \cup E \subset \mathbb{R}^n$.

Convention. Sometimes, by a slight abuse of notation, we refer to the subset $|G|$ also a spatial graph. Furthermore, any topological space homeomorphic to such $|G|$ will also referred to as a spatial graph.

We sketch several examples of spatial graphs in Figure 61. The red dots correspond to the vertices and the blue segments correspond to the edges.[59]

[56]We leave it as an exercise to verify that the definition of "endpoints" is independent of the choice of φ. The key to proving this statement is that given E any two such maps φ and ψ differ by a reparametrization.

[57]Also note that according to our definition the endpoints of an arc do *not* lie on the arc.

[58]What is an example of (V,E) that satisfies all axioms except for 2 (c)?

[59]The starting point here are of course the pictures, in the sense that the definition is an attempt to turn the pictures of spatial graphs into a precise mathematical object.

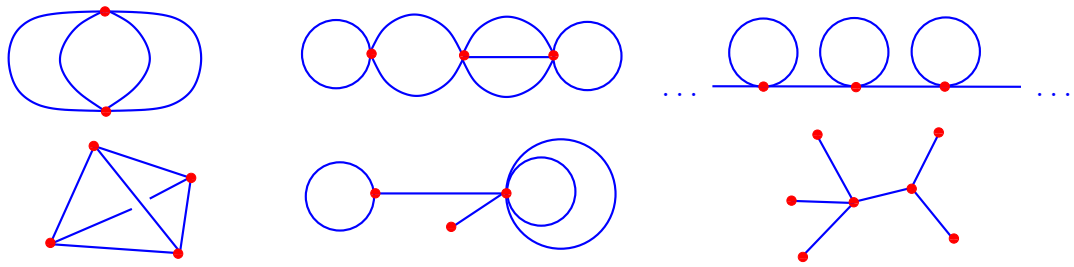

FIGURE 61.

Definition. Given a spatial graph (V, E) the *underlying abstract graph* is defined as the abstract graph (V', E', φ') given by setting

$$V := V', \quad E' := \text{the set of components of } E$$

and for $e \in E'$ we define $\varphi'(e)$ to be the set of endpoints of e. We say a spatial graph G is a *topological realization* of an abstract graph H, if the underlying abstract graph of G is isomorphic to H.

Examples. In Figure 62 we give two topological realizations of the graph from Example (A). In Figure 63 we show topological realizations of the graphs $G_{2,3}$ and $G_{0,2}$. Finally in Figure 64 we show a topological realization of the subway system of München.

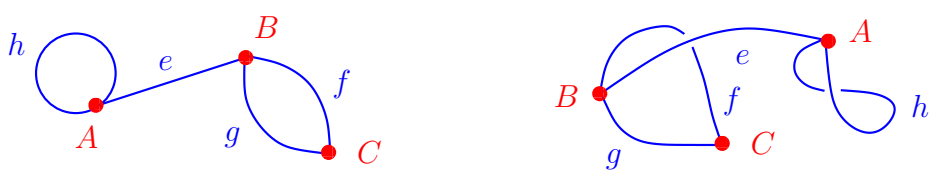

FIGURE 62.

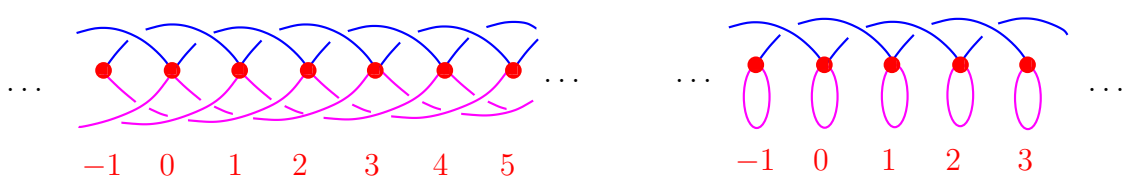

topological realization of $G_{2,3}$ topological realization of $G_{0,2}$

FIGURE 63.

Remark. It is quite easy to show that every finite graph is the underlying abstract graph of a spatial graph in $\mathbb{R}^3$. We refer to [CELR, p. 2] for an elementary proof.

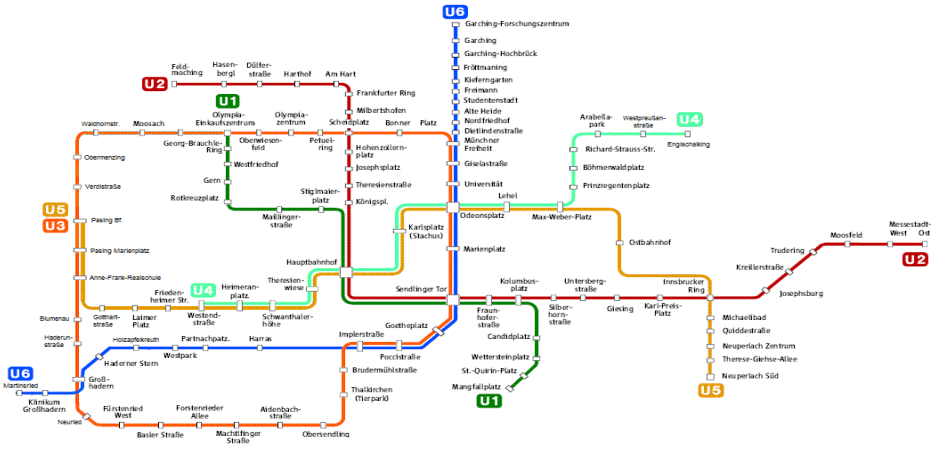

FIGURE 64. The subway system of München.

In the following we will often go back and forth between spatial graphs and abstract graphs without distinguishing these two different types of graphs in the notation. Also, very often, given a spatial graph $G = (V, E)$ we will not distinguish between G and the topological space $|G|$. Sometimes we will just talk about "graphs" and it will be clear from the context what type of graph we mean.

For the most part the two points of view are quite similar, for example given a spatial graph $G = G(V, E)$ the topological space $|G|$ is connected if and only if the underlying abstract graph is connected.[60]

Remark. The origins of graph theory go back to Euler and the problem on the seven bridges of Königsberg. The details of this story can be found on

`https://en.wikipedia.org/wiki/Seven_Bridges_of_Koenigsberg`

Euler's original article can be found here

`http://eulerarchive.maa.org//docs/originals/E053.pdf`

1.21. **Lebesgue's Lemma and uniformly continuous maps.** In this section we want to prove two statements that concern specifically maps whose domain is actually a metric space.

First we intend to formulate and prove Lebesgue's Lemma. Despite its humble name it does actually play an important role in topology. The formulation of Lebesgue's Lemma requires the following definition.

Definition. Let X be a metric space. The *diameter* of a non-empty subset A of X is defined as

$$\text{diameter}(A) \ := \ \sup\{d(a,b) \,|\, a, b \in A\} \ \in \mathbb{R}_{\geq 0} \cup \{\infty\}.$$

[60]We will not prove this statement and we will therefore not make use of it.

FIGURE 65.

Example. One can easily show that

$$\text{diameter of the hyperrectangle } [a_1, b_1] \times \cdots \times [a_n, b_n] \;=\; \sqrt{(b_1 - a_1)^2 + \cdots + (b_n - a_n)^2}.$$

Now we can state Lebesgue's Lemma.

Lemma 1.105. (Lebesgue's Lemma) *Let K be a compact metric space and let $\{U_i\}_{i \in I}$ be an open covering of K. Then there exists a $\delta > 0$ such that for every subset A with* diameter$(A) < \delta$ *there exists an $i \in I$ with $A \subset U_i$.*

Remark. Any $\delta > 0$ that has the property stated in Lebesgue's Lemma is usually called a *Lebesgue number*.

Proof. Since K is compact we can cover K with finitely many of the U_i's. Put differently, without loss of generality we can assume that $I = \{1, \ldots, n\}$ is a finite set.

If there exists an $i \in \{1, \ldots, n\}$ with $K = U_i$, then any $\delta > 0$ has the desired property. Now suppose that this is not the case, i.e. we suppose that for every i we have $U_i \subsetneq K$.[61] We first prove the following claim.

Claim. The function

$$\begin{aligned} f\colon K &\to \mathbb{R} \\ x &\mapsto f(x) := \frac{1}{n} \sum_{i=1}^{n} d(x, K \setminus U_i) \end{aligned}$$

is continuous and positive.

It follows easily from the definitions and the triangle inequality that f is continuous. Now let $x \in K$. We want to show that $f(x) > 0$. Since $K = U_1 \cup \cdots \cup U_n$ there exists an i with $x \in U_i$. Since U_i is open there exists an $r > 0$ with $B_r(x) \subset U_i$. It follows that $d(x, K \setminus U_i) \geq r$, hence $f(x) \geq \frac{r}{n}$. This concludes the proof of the claim.

Since f is continuous and since K is compact it follows from Lemma 1.37 that the function f has a global minimum δ on K. It follows from the claim that this minimum δ is greater than 0. Now we want to show that this δ has the desired property. More precisely, we want to prove the following claim.

Claim. Let A be a subset of K with diameter$(A) < \delta$. Then there exists an $i \in \{1, \ldots, n\}$ with $A \subset U_i$.

[61] Where do we use in the subsequent argument that $U_i \subsetneq K$?

Let $x \in A$. We choose an $m \in \{1, \dots, n\}$ so that $d(x, K \setminus U_m)$ is maximal. We want to show that $A \subset U_m$. Since the diameter of A is less than δ we have $A \subset B_\delta(x)$. Thus it suffices to show that $B_\delta(x) \subset U_m$. Put differently, we need to show that $d(x, K \setminus U_m) \geq \delta$. Indeed we have

$$\begin{array}{ccccccc} d(x, K \setminus U_m) & \underset{\substack{\uparrow \\ \text{since } d(x,K\setminus U_m) \geq d(x,K\setminus U_i)}}{\geq} & \frac{1}{n}\sum_{i=1}^{n} d(x, K \setminus U_i) & = & f(x) & \underset{\substack{\uparrow \\ \text{by the choice of } \delta}}{\geq} & \delta. \end{array}$$

This concludes the proof of the claim. □

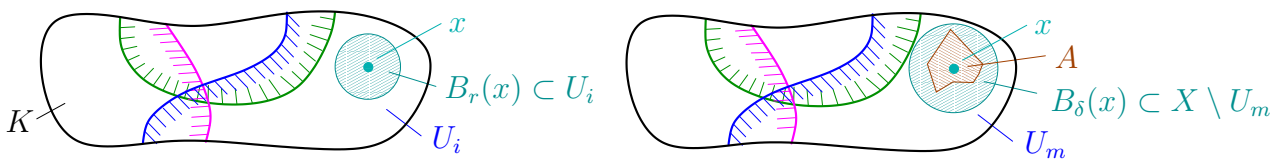

FIGURE 66. Illustration of the proof of Lebesgue's Lemma.

In many cases the following corollary is even more useful.

Corollary 1.106. *Let $f\colon [0,1]^n \to X$ be a map from the cube $[0,1]^n$ to a topological space X and let $\{V_i\}_{i\in I}$ be an open covering of X. Then there exists an $N > 0$ such that for any $a_1, \dots, a_n \in \{0, \dots, N-1\}$ there exists an $i \in I$ such that*

$$f\big(\big[\tfrac{a_1}{N}, \tfrac{a_1+1}{N}\big] \times \cdots \times \big[\tfrac{a_n}{N}, \tfrac{a_n+1}{N}\big]\big) \subset V_i.$$

More pictorially speaking the corollary says that if $f\colon [0,1]^n \to X$ is a map, and if we are given an open covering of X, then we can always find a small grid on the cube, such that each cube of the grid gets mapped into one of the open sets covering X.

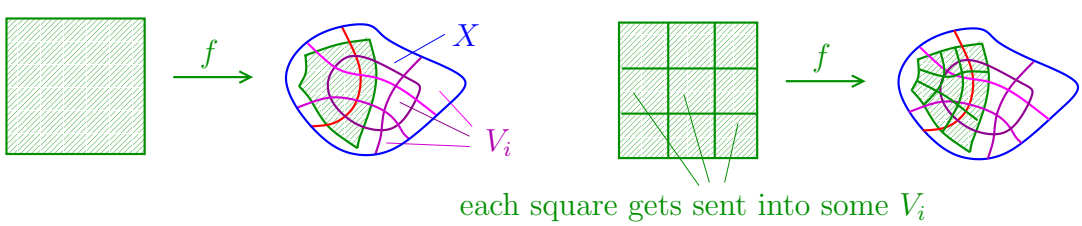

FIGURE 67. Illustration of Corollary 1.106

Proof. Let $f\colon [0,1]^n \to X$ be a map from the cube $[0,1]^n$ to a topological space and let $\{V_i\}_{i\in I}$ be an open covering of X. By Proposition 1.22 we know that $[0,1]^n$ is compact. Thus we can apply Lemma 1.105 to the open covering $U_i := f^{-1}(V_i)$, $i \in I$ of $[0,1]^n$ and we obtain a $\delta > 0$ such that for each subset A with diameter$(A) < \delta$ there exists an $i \in I$ with

$A \subset U_i = f^{-1}(V_i)$, which means that $f(A) \subset V_i$. It follows from the example on page 137 that the diameter of the cube of side length $\frac{1}{m}$ equals $\frac{1}{\sqrt{m}}$. Thus for sufficiently large N any cube of side length $\frac{1}{N}$ has diameter less than δ. $\square$

Definition. Let $f\colon X \to Y$ be map between two metric spaces X and Y. By Proposition 1.33 we know that

$$f \text{ is continuous} \quad \Longleftrightarrow \quad \underset{x\in X}{\forall} \quad \underset{\epsilon>0}{\forall} \quad \underset{\delta>0}{\exists} \quad \underset{y\in B_\delta(x)}{\forall} \quad d(f(x), f(y)) < \epsilon.$$

Now we define

$$f \text{ is } \textit{uniformly continuous} \quad :\Longleftrightarrow \quad \underset{\epsilon>0}{\forall} \quad \underset{\delta>0}{\exists} \quad \underset{x\in X}{\forall} \quad \underset{y\in B_\delta(x)}{\forall} \quad d(f(x), f(y)) < \epsilon.$$

The following proposition is the second main result of this section.

Proposition 1.107. *Let $f\colon X \to Y$ be a continuous map between two metric spaces. If X is compact, then f is uniformly continuous.*

Proof $(*)$. Let $f\colon X \to Y$ be a continuous map between two metric spaces and let $\epsilon > 0$. The "$\Leftarrow$"-direction of Proposition 1.33 tells us in particular that given any $x \in X$ there exists a $\delta(x) > 0$ such that for all $y \in B_{\delta(x)}(x)$ we have $d(f(x), f(y)) < \frac{\epsilon}{2}$. Since the open balls $B_{\delta(x)/2}(x)$ form an open covering of X and since X is compact there exist $x_1, \dots, x_k$ such that $B_{\delta(x_1)/2}(x_1) \cup \dots \cup B_{\delta(x_1)/2}(x_1) = X$. We claim that

$$\delta \;:=\; \min\left\{\frac{\delta(x_1)}{2}, \dots, \frac{\delta(x_k)}{2}\right\}$$

has the desired properties. Thus let $x, y \in X$ with $d(x, y) < \delta$. There exists a $j \in \{1, \dots, k\}$ with $x \in B_{\delta(x_j)/2}(x_j)$. From the triangle inequality and from $\delta \le \frac{\delta(x_j)}{2}$ we obtain that $y \in B_{\delta(x_j)}(x_j)$. It follows that

$$d(f(x), f(y)) \;\underset{\substack{\uparrow \\ \text{triangle inequality}}}{\le}\; d(f(x_j), f(x)) + d(f(x_j), f(y)) \;\underset{\substack{\uparrow \\ \text{since } x \in B_{\delta(x_j)}(x_j) \text{ and } y \in B_{\delta(x_j)}(x_j)}}{<}\; \frac{\epsilon}{2} + \frac{\epsilon}{2} \;=\; \epsilon.$$

We have thus shown that δ does indeed have the desired properties. $\square$

1.22. **Topological groups.** In this section we consider the notion of a topological group which will crop up every now and then in these notes.

Definition. A *topological group* is a topological space X together with a group structure, such that the two maps[62]

$$\begin{array}{rcl} X \times X & \to & X \\ (x, y) & \mapsto & x \cdot y \end{array} \qquad \text{and} \qquad \begin{array}{rcl} X & \to & X \\ x & \mapsto & x^{-1} \end{array}$$

are continuous.

[62]Here we evidently equip $X \times X$ with the product topology.

The most basic example of a topological group is given by taking any group and equipping it with the discrete topology. As we will see, somewhat surprisingly even this banal example can turn out to be interesting.

The following lemma gives us much more interesting examples of topological groups.

Lemma 1.108. *For any $n \in \mathbb{N}$ the matrix groups $\mathrm{GL}(n,\mathbb{R})$ and $\mathrm{GL}(n,\mathbb{C})$ are topological groups.*

Proof. As we pointed out on page 86, matrix multiplication is continuous. Furthermore, basic linear algebra, see e.g. [HJ, Chapter 0.8.2], says that taking the inverse is given by the map

$$\begin{array}{rcl} \mathrm{GL}(n,\mathbb{R}) & \to & \mathrm{GL}(n,\mathbb{R}) \\ A & \mapsto & \frac{1}{\det(A)} \cdot \underbrace{\begin{array}{c}\text{matrix whose } (i,j)\text{-entry is given by taking the determinant} \\ \text{of the matrix that is obtained from } A \text{ by removing} \\ \text{the } i\text{-th column and the } j\text{-th row of } A.\end{array}}_{=\text{called the adjugate of } A} \end{array}$$

But this map is clearly continuous. This shows that $\mathrm{GL}(n,\mathbb{R})$ is a topological group. Basically the same argument also shows that $\mathrm{GL}(n,\mathbb{C})$ is a topological group. □

We obtain more examples of topological groups by taking subgroups and products:

Lemma 1.109.

(1) *Let X be a topological group and let Y be a subgroup. If we equip Y with the subspace topology, then Y is also a topological group.*
(2) *Let $\{X_i\}_{i\in I}$ be a family of topological groups. If we equip $\prod_{i\in I} X_i$ with the product topology and the obvious group structure, then it is again a topological group.*

Proof.

(1) This statement follows immediately from Lemma 1.30 together with Lemma 1.53 (1b).
(2) This statement follows easily from Lemma 1.60 and Lemma 1.61 (2).

□

Example. It follows from Lemmas 1.108 and 1.109 (1) that $\mathrm{SL}(n,\mathbb{R})$, $\mathrm{O}(n)$, $\mathrm{SO}(n)$, $\mathrm{GL}(n,\mathbb{C})$, $\mathrm{U}(n)$ and $\mathrm{SU}(n)$ are topological groups.

Lemma 1.110. *Let G be a topological group.*

(1) *Given any $g \in G$ the two maps*

$$\begin{array}{rcl} l_g\colon G & \to & G \\ h & \mapsto & g\cdot h \end{array} \quad \text{and} \quad \begin{array}{rcl} r_g\colon G & \to & G \\ h & \mapsto & h\cdot g \end{array}$$

are continuous.
(2) *If G is a topological group, then any two path-components of G are homeomorphic.*

Proof $(*)$.

(1) The map l_g is the composition of the two maps

$$\begin{array}{ccc} G & \to & G \times G \\ h & \mapsto & (g,h) \end{array} \quad \text{and} \quad \begin{array}{ccc} G \times G & \to & G \\ (x,y) & \mapsto & x \cdot y. \end{array}$$

The first map is continuous by Lemma 1.53 (3b) and the second map is continuous since G is a topological group. Thus l_g itself is continuous. The same argument shows that r_g is continuous.

(2) Let X, Y be two path-components of G. We pick $x \in X$ and $y \in Y$. We consider the map $\varphi\colon G \to G$ given by $g \mapsto yx^{-1}g$. By (1) we know that φ is continuous. Furthermore it follows from Lemma 1.101 that $\varphi(X) \subset Y$.

We also consider the map $\psi\colon G \to G$ given by $g \mapsto xy^{-1}g$. The same argument as above shows that ψ is continuous and that $\psi(Y) \subset X$. Clearly φ and ψ are inverses of one another. But this implies that φ and ψ are homeomorphisms between X and Y. $\square$

Exercises for Chapter 1.

Exercise 1.1. Show that for statements (1), (2) and (4) of Lemma 1.1 there are indeed examples such that the stated inclusion is indeed a strict inclusion.

Exercise 1.2. Let $f\colon X \to Y$ be a map between two sets. Let $A \subset X$ and let $B \subset Y$ be two subsets. Prove the following equivalence of statements:

$$f(A) \subset B \qquad \Longleftrightarrow \qquad A \subset f^{-1}(B).$$

Exercise 1.3.

(a) Prove Lemma 1.11.

(b) Let U be an open subset of $\mathbb{R}^2$. Is it true that the interior of $\overline{U}$ equals U?

Exercise 1.4. Let U be an open subset of $\mathbb{R}^n$. We denote by $C = \overline{U}$ the closure of U.

(a) Suppose that U is convex. Show that $U = \mathring{C}$.

(b) Given an example of an open subset U of $\mathbb{R}^n$ where $U \neq \mathring{C}$.

Exercise 1.5. Let $f\colon X \to Y$ be a map between topological spaces and let $B \subset Y$ be a subset.

(a) Show that $f^{-1}(\overline{B}) \subset \overline{f^{-1}(B)}$.

(b) Given an example that shows that in general we do not have an equality in (a).

(c) Show that $f(f^{-1}(\overline{B})) = \overline{B}$.

Exercise 1.6. Let $\{U_i\}_{i \in I}$ be a family of subsets. If I is finite, then we know by Lemma 1.12 that the following two equalities hold:

$$\text{(a)} \quad \text{interior of } \bigcap_{i \in I} U_i \;=\; \bigcap_{i \in I} \mathring{U}_i \qquad \text{and} \qquad \text{(b)} \quad \text{closure of } \bigcup_{i \in I} U_i \;=\; \bigcup_{i \in I} \overline{U_i}.$$

Do these equalities also hold if I is infinite?

Exercise 1.7. Let (X, d) be a compact metric space. A rather surprising theorem, see [Gros] or alternatively [Ris], says that there exists a unique $r \in \mathbb{R}_{\geq 0}$ such that for any finite sequence of points $x_1, \dots, x_n \in X$ there exists an $x' \in X$ with $\frac{1}{n}\sum_{i=1}^{n} d(x_i, x') = r$. This number is called the *rendezvous value of* (X, d).

(a) Determine the rendezvous value of the interval $X = [0, 1]$ equipped with the metric $d(x, y) = |x - y|$.
(b) Determine the rendezvous value of the circle $X = S^1$ equipped with the Euclidean metric of $\mathbb{R}^2$.

Exercise 1.8.

(a) Show that "$\mathbb{R}^n$ with a point at infinity" is Hausdorff and compact.
(b) Show that "the line with two zeros" is neither Hausdorff nor compact.

Exercise 1.9.
Let $f\colon X \to Y$ be a map between topological spaces. Show that f is continuous if and only if for every $A \subset X$ we have $f(\overline{A}) \subset \overline{f(A)}$.

Exercise 1.10. Let $\mathbb{R}^n \cup \{\infty\}$ be "$\mathbb{R}^n$ with a point at infinity". Let $v \in \mathbb{R}^n$. Show that the map

$$\begin{array}{rcl} \mathbb{R}^n \cup \{\infty\} & \to & \mathbb{R}^n \cup \{\infty\} \\ Q & \mapsto & \begin{cases} Q + v, & \text{if } Q \in \mathbb{R}^n, \\ \infty, & \text{if } Q = \infty \end{cases} \end{array}$$

is continuous.

Exercise 1.11. Let f be a complex polynomial of degree ≥ 1. Show that the map

$$\begin{array}{rcl} \Theta(f)\colon \mathbb{C} \cup \{\infty\} & \to & \mathbb{C} \cup \{\infty\} \\ t & \mapsto & \begin{cases} f(t), & \text{if } t \in \mathbb{C}, \\ \infty, & \text{if } t = \infty \end{cases} \end{array}$$

is continuous.
Remark: By Lemma 1.41 we can make the identification $S^2 = \mathbb{C} \cup \{\infty\}$. Thus we see that complex polynomials of degree ≥ 1 give rise to interesting self-maps of S^2.
Remark: The analogous statement also holds for a polynomial f with real coefficients, it gives rise to a self-map $\Theta(f)$ of $\mathbb{R} \cup \{\infty\} = S^1$. We illustrate this situation in Figure 68.

Exercise 1.12. Let X be a topological space. We say a subset $U \subset X$ is *large* if U is open and dense. Show that the intersection of finitely many large subsets of X is again large.

Exercise 1.13. Let $f, g\colon X \to Y$ be two maps between two topological spaces. Let $A \subset X$ be a subset such that f and g agree on A. Show that if A is dense, if Y is Hausdorff and if f and g are continuous, then f and g agree on all of X.

Exercise 1.14.

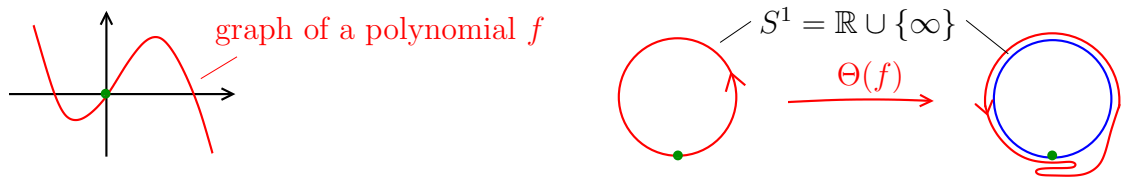

FIGURE 68. Illustration for Exercise 1.11.

(a) Give an example of a bijective continuous map $f\colon X \to Y$ between two topological spaces where X is compact but such that f is nonetheless not a homeomorphism.
(b) Show that the half-open interval $[0,1)$ and the open interval $(0,1)$ are not homeomorphic.

Exercise 1.15. Let $f\colon [0,1] \to \mathbb{R}$ be a continuous function. Let $0 \leq a < b \leq 1$. Show that f can only go finitely many times from a to b. Show that it is not possible to find numbers $x_1 < y_1 < x_2 < y_2 < x_3 < y_3 < \dots$ in $[0,1]$ such that for each $i \in \mathbb{N}$ we have $f(x_i) = a$ and we have $f(y_i) = b$.

Exercise 1.16. Are the two spatial graphs G and H shown in Figure 69 homeomorphic?

FIGURE 69.

Exercise 1.17. Show that the topological space $[0,1] \cap \mathbb{Q}$ is not compact.

Exercise 1.18.

(a) Let A be a real $m \times n$-matrix. Show that there exists a $C \in \mathbb{R}$ such that for all $v \in \mathbb{R}^n$ we have $\|Av\| \leq C \cdot \|v\|$.
(b) Let $A \in \mathrm{GL}(n, \mathbb{R})$ be an invertible matrix. Show that there exists a $\lambda > 0$ such that $\|Av\| \geq \lambda \|v\|$ for all $v \in \mathbb{R}^n$.

Hint: In both cases use that S^{n-1} is compact.

Exercise 1.19. Let A be an invertible real $m \times m$-matrix. Show that the map

$$\begin{array}{rcl} \mathbb{R}^m \cup \{\infty\} & \to & \mathbb{R}^m \cup \{\infty\} \\ x & \mapsto & \begin{cases} A \cdot x, & \text{if } x \in \mathbb{R}^m, \\ \infty, & \text{if } x = \infty \end{cases} \end{array}$$

is continuous.
Hint: use Exercise 1.18.

Exercise 1.20. Is every open map necessarily continuous? More precisely, if $f\colon X \to Y$ is a map between topological spaces with the property that for any open $U \subset X$ the image $f(U)$ is an open subset of Y, does it follow that f is continuous?

Exercise 1.21. Let $n \in \mathbb{N}$. We consider the stereographic projection

$$\begin{array}{rcl} \Phi\colon S^n & \to & \mathbb{R}^n \cup \{\infty\} \\ (x_1, \dots, x_{n+1}) & \mapsto & \begin{cases} \left(\frac{x_1}{1-x_{n+1}}, \dots, \frac{x_n}{1-x_{n+1}}\right), & \text{if } x_{n+1} < 1, \\ \infty, & \text{if } x_{n+1} = 1 \end{cases} \end{array}$$

that we introduced in Lemma 1.41. Show that Φ is continuous.

Exercise 1.22.

(a) Show that the topological space $[-1,0] \sqcup (0,1]$ is homeomorphic to the topological space $[-2,-1] \cup (0,1] \subset \mathbb{R}$.
(b) Show see that the topological space $[-1,0] \sqcup (0,1]$ is not homeomorphic to the topological space $[-1,1]$.

Exercise 1.23. Show that there are non-homeomorphic topological spaces A and B and a non-empty topological space X such that $A \times X$ is homeomorphic to $B \times X$.
Hint: you could take $A = \{0\}$ and $B = \{0,1\}$.

Exercise 1.24. Let X be a topological space. We consider the "diagonal"

$$\Delta \ := \ \{(x,x) \in X \times X \,|\, x \in X\}.$$

We equip $X \times X$ with the product topology and we equip Δ with the subspace topology. Show that the map $X \to \Delta$ given by $x \mapsto (x,x)$ is a homeomorphism.

Exercise 1.25. Let $\{X_i\}_{i \in I}$ be a family of topological spaces.

(a) Suppose that for each $i \in I$ we are given a closed subset $A_i \subset X_i$. If I is finite, then it follows from Lemma 1.51 that $\prod_{i \in I} A_i$ is a closed subset of $\prod_{i \in I} X_i$. Does this conclusion also hold if I is infinite?
(b) Let $\{X_i\}_{i \in I}$ be a family of topological spaces. Suppose that for each $i \in I$ we are given a subset $A_i \subset X_i$. Show that

$$\prod_{i \in I} \overline{A_i} \ = \ \overline{\prod_{i \in I} A_i} \ \subset \ \prod_{i \in I} X_i.$$

Exercise 1.26. Let (X,d) be a metric space. Show that the map

$$\begin{array}{rcl} X \times X & \to & \mathbb{R}_{\geq 0} \\ (x,y) & \mapsto & d(x,y) \end{array}$$

is continuous.

Exercise 1.27. Let X be a metric space and let $B \subset X$ be a non-empty subset. Show that the map

$$\begin{array}{rcl} X & \to & \mathbb{R}_{\geq 0} \\ x & \mapsto & d(x,B) := \inf\{d(x,b) \,|\, b \in B\} \end{array}$$

is continuous.

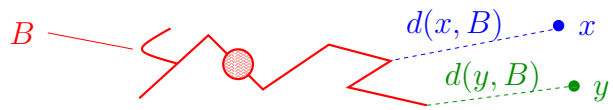

FIGURE 70. Illustration for Exercise 1.27.

Exercise 1.28. A topological space X is called *metrizable* if there exists a metric d on X such that the given topology agrees with the topology coming from d. Now suppose that X is a metrizable topological space. Show that given any closed set $A \subset X$ there exists a map $f\colon X \to \mathbb{R}$ such that $f^{-1}(\{0\}) = A$.
Hint: Use Exercise 1.27.

Exercise 1.29. Show that the map from $\prod_{i\in\mathbb{N}} \{0,2\}$ to the Cantor set, that we defined on page 95, is continuous.

Exercise 1.30. Let X be a topological space. Show that

$$X \text{ is Hausdorff} \quad \Longleftrightarrow \quad \text{the diagonal } \Delta = \{(x,x) \,|\, x \in X\} \text{ is a closed subset of } X \times X.$$

Exercise 1.31. Let $f, g\colon X \to Y$ be two maps between topological spaces. Suppose that Y is Hausdorff. Show that $\{x \in X \,|\, f(x) = g(x)\}$ is a closed subset of X.
Hint: Use Exercise 1.30.

Exercise 1.32.

(a) Show that the real projective space $\mathbb{R}\mathrm{P}^1$ is homeomorphic to S^1.
(b) Do you think that the real projective space $\mathbb{R}\mathrm{P}^2 = (\mathbb{R}^3 \setminus \{0\})/(\mathbb{R} \setminus \{0\})$ is homeomorphic to S^2? As of now we lack the tools to answer this question. Nonetheless, what do you think the answer will be?

Exercise 1.33. Show that the topological space $\mathbb{R}/\{\pm 1\} = \mathbb{R}/x \sim -x$ is homeomorphic to the half-open interval $[0, \infty)$.

Exercise 1.34. Let the group $(\mathbb{Q}, +)$ act on the topological space $\mathbb{R}$ by addition. Show that $\mathbb{R}/\mathbb{Q}$ is not Hausdorff.

Exercise 1.35. Given $v, w \in \mathbb{R}^2 \setminus \{(0,0)\}$ we define

$$\sphericalangle(v,w) := \text{unique } \varphi \in (-\pi, \pi] \text{ such that } w = r \cdot \begin{pmatrix} \cos(\varphi) & -\sin(\varphi) \\ \sin(\varphi) & \cos(\varphi) \end{pmatrix} \cdot w \text{ for some } r \in \mathbb{R}_{>0}.$$

(a) Show that the map

$$\begin{array}{rcl} \Phi\colon (\mathbb{R}^2 \setminus \{(0,0)\}) \times (\mathbb{R}^2 \setminus \{(0,0)\}) & \to & (-\pi, \pi] \\ (v,w) & \mapsto & \sphericalangle(v,w) \end{array}$$

is not continuous.

(b) Show that the map

$$\begin{array}{rcl} \Phi\colon (\mathbb{R}^2 \setminus \{(0,0)\}) \times (\mathbb{R}^2 \setminus \{(0,0)\}) & \to & \mathbb{R}/2\pi\mathbb{Z} \\ (v,w) & \mapsto & [\sphericalangle(v,w)] \end{array}$$

is continuous. (Here $\mathbb{R}/2\pi\mathbb{Z}$ denotes the quotient of the topological space $\mathbb{R}$ by the group $(2\pi\mathbb{Z},+)$.)

Exercise 1.36. We consider the following subsets of $[0,1]$:

$$A = \{0, \tfrac{1}{3}, \tfrac{2}{3}, 1\}, \quad B = \{\tfrac{1}{n} \,|\, n \in \mathbb{N}\} \quad \text{and} \quad C = \{0\} \cup B.$$

(a) Show that $[0,1]/A$ is homeomorphic to a subset of $\mathbb{R}^2$. See e.g. Figure 71 for an idea.
(b) Is $[0,1]/B$ homeomorphic to a subset of $\mathbb{R}^2$?
(c) Is $[0,1]/C$ homeomorphic to a subset of $\mathbb{R}^2$?

FIGURE 71.

Exercise 1.37. Let X be topological space and let A and B be two subsets with $A \cup B = X$. We write $C := A \cap B$. We consider the disjoint union $A \sqcup B = (A \times \{1\}) \cup (B \times \{2\})$ and we consider $Y = (A \sqcup B)/\sim$ where for each $c \in C$ we identify the point $(c,1) \in A \times \{1\}$ with the corresponding point $(c,2) \in B \times \{2\}$. We consider the map

$$p\colon Y = (A \sqcup B)/\sim \;\to\; X$$

that is given by

$$\begin{array}{rcll} [(a,1)] & \mapsto & a & \text{for } a \in A, \\ [(b,2)] & \mapsto & b & \text{for } b \in B. \end{array}$$

(a) Is the map p necessarily continuous?
(b) Is the map p necessarily open?
(c) Suppose that A and B are open subsets of X. Show that p is a homeomorphism.

Remark: The failure of p to be a homeomorphism can lead to nasty surprises.

Exercise 1.38. Let X be a topological space and let A and B be two disjoint subsets. We equip A with the subspace topology and we equip X/B with the quotient topology. We denote by $i\colon A \to X$ the inclusion map and we denote by $p\colon X \to X/B$ the projection.

(a) Show that the map $p \circ i\colon A \to X/B$ is continuous and injective.
(b) Show that the map $p \circ i\colon A \to X/B$ is not necessarily a homeomorphism onto its image.

(c) Suppose that there exists an open subset $U \subset X$ with $A \subset U$ and $U \cap B = \varnothing$. Show that the map $p \circ i \colon A \to X/B$ is a homeomorphism onto its image.

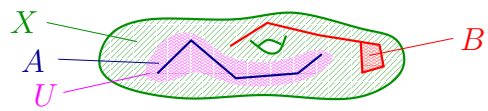

FIGURE 72. Illustration for Exercise 1.38.

Exercise 1.39. Similar to the definition of the Möbius band on page 105 we consider the action of the group $G = \mathbb{Z}$ on $X = \mathbb{R} \times \{-1, 1\}$ that is given by

$$\begin{array}{rcl} \mathbb{Z} \times (\mathbb{R} \times \{-1,1\}) & \to & \mathbb{R} \times \{-1,1\} \\ (n,(x,y)) & \mapsto & (x+n, (-1)^n \cdot y). \end{array}$$

Show that $X/G = X/\mathbb{Z}$ is homeomorphic to S^1.

Exercise 1.40. We say a group G *acts discretely* on a topological space X, if it acts continuously and if for each $x \in X$ there exists an open neighborhood U so that

$$U \cap gU \;=\; \varnothing \text{ for all } g \neq e.$$

Can the group $\mathbb{Z}$ act discretely on S^2?

Exercise 1.41. Build a Möbius band out of a strip of paper and cut it along the central curve. What topological space do you obtain that way?

Exercise 1.42. Show that the topologist's sine curve, that we defined on page 123 is connected and show that it is *not* path-connected.

Exercise 1.43. A topological space X is called *arc-connected* if given any two points $P, Q \in X$ there exists a map $f \colon [0,1] \to X$ with $f(0) = P$, $f(1) = Q$ and which has the property that f is a homeomorphism onto its image.[63]

(a) Show that the line with two zeros is not arc-connected.
(b) Let $n \geq 2$ and let X be the "$\mathbb{R}^n$ with two origins", which is defined in the hopefully obvious way. Is X arc-connected?

Remark: A rather amazing (non-trivial!) theorem says that any topological space that is path-connected *and which is Hausdorff* is in fact arc-connected. We refer to [Wil, Corollary 31.6] and [Enge, p. 381].

Exercise 1.44.

[63]Sometimes, see e.g. [Wil, Enge], such topological spaces are also called *arcwise connected*. Rather confusingly some other books, e.g. [Bre], use the term *arcwise connected* for what we call path connected. The lesson is, that in any given book one always should look up the definitions.

(a) Let $n \in \mathbb{N}_{\geq 3}$. We consider

$$X_n \;:=\; \{r \cdot e^{2\pi i t k/n} \,|\, r \in [0,1) \text{ and } k \in \{0,\dots,n-1\}\}.$$

We write $P := 0$. Show that every self-homeomorphism $f\colon X_n \to X_n$ preserves P. We refer to Figure 73 for an illustration.

(b) Does the statement in (a) also hold for $n = 1$ and/or $n = 2$?

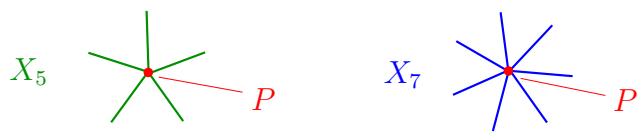

FIGURE 73.

Exercise 1.45. Let $n \in \mathbb{N}$. We consider the general linear group

$$\mathrm{GL}(n,\mathbb{R}) \;=\; \{A \in M(n \times n, \mathbb{R}) \,|\, \det(A) \neq 0\} \;\subset\; M(n \times n, \mathbb{R}) \;=\; \mathbb{R}^{n^2}.$$

Show that two matrices lie in the same path-component of $\mathrm{GL}(n,\mathbb{R})$ if and only if the signs of their determinants agree. (Put differently, the goal is to prove the first part of Lemma 1.96.)

Exercise 1.46. Let X be a topological space that is o-locally path-connected. Show that if X is connected, then it is also path-connected.

Exercise 1.47. Let X be a path-connected subset of $\mathbb{R}^2$. Is it also necessarily locally path-connected?

Exercise 1.48. We consider the set $X = (0,1)$ with the topology where the open sets are precisely the sets $\varnothing, X$ and the intervals $(0, 1 - \frac{1}{n})$. Show that X is compact and show that X is not locally compact.

Exercise 1.49. Given a topological graph $G = (V,E)$ we write $|G| = V \cup E$. Let $G = (V,E)$ and $G' = (V',E')$ be two topological graphs in $\mathbb{R}^3$. If $|G|$ is homeomorphic to $|G'|$, does it follow that the underlying abstract graphs are isomorphic?

2. General topology: some delicate bits (∗)

In this chapter we will introduce the compact-open topology and we will discuss the very delicate interplay between product and quotient topologies. In all likelihood the reader is better of with consulting the chapter only when the results of this chapter are actually used.

2.1. **The compact-open topology** (∗) **.** So far we had mostly studied topological spaces that arose more or less directly from geometry. In this section we will see that topological spaces also arise naturally from more abstract set ups.

First, recall that we saw on page 54 that a topology on a given set X makes it possible to talk of the convergence of a sequence in X. From real analysis we know that it is not only interesting to think about convergence of sequences of points but also to talk of convergence of functions. In fact, in real analysis one often encounters two different types of convergence that we now recall.

Definition. Let $U \subset \mathbb{R}^n$ be a subset, let $\{f_n \colon U \to \mathbb{R}\}_{n\in\mathbb{N}}$ be a sequence of functions and let $f \colon U \to \mathbb{R}$ be a function. We define

$$(f_n)_{n\in\mathbb{N}} \textit{ converges pointwise to } f \quad :\Longleftrightarrow \quad \underset{x\in U}{\forall} \quad \underset{\epsilon>0}{\forall} \quad \underset{N\in\mathbb{N}}{\exists} \quad \underset{n\geq N}{\forall} \quad |f_n(x) - f(x)| < \epsilon$$

and

$$(f_n)_{n\in\mathbb{N}} \textit{ converges uniformly to } f \quad :\Longleftrightarrow \quad \underset{\epsilon>0}{\forall} \quad \underset{N\in\mathbb{N}}{\exists} \quad \underset{x\in U}{\forall} \quad \underset{n\geq N}{\forall} \quad |f_n(x) - f(x)| < \epsilon.$$

Example. We consider the sequence of functions

$$\begin{aligned} f_n \colon \mathbb{R} &\to \mathbb{R} \\ x &\mapsto \begin{cases} 0, & \text{if } t < 0 \text{ or } t > \frac{2}{n}, \\ n \cdot t, & \text{if } t \in [0, \frac{1}{n}], \\ 2 - n \cdot t, & \text{if } t \in (\frac{1}{n}, \frac{2}{n}]. \end{cases} \end{aligned}$$

We refer to Figure 74 for an illustration. One easily verifies that this sequence converges pointwise to the zero function but it does not converge uniformly to the zero function.

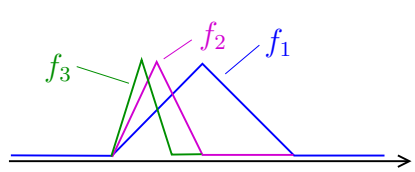

Figure 74.

At times one also wants to study convergence of sequences of continuous[64] maps between general topological spaces. This leads us to the following definition.

[64]Here and in the following we sometimes talk explicitly about "continuous" maps, even though it is usually understood in these notes that all maps are continuous.

Definition. Let X and Y be topological spaces.

(1) We denote by $X^Y = C(Y, X)$ the set of all continuous maps from Y to X.
(2) The *compact-open topology* on X^Y is the topology generated, in the sense of the definition on page 63, by all the sets of the form

$$M(K, U) \ := \ \{f \in X^Y \mid f(K) \subset U\}$$

where $K \subset Y$ is compact and where $U \subset X$ is open. This definition is illustrated in Figure 75.

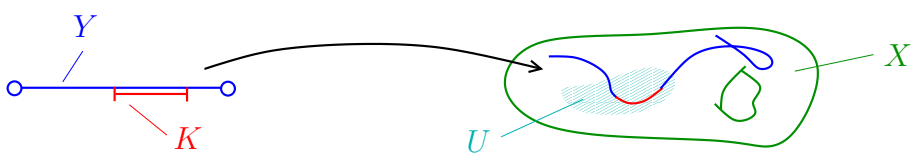

FIGURE 75.

Examples.

(1) Let $Y \subset \mathbb{R}$ be an interval. We want to consider the compact-open topology on $C(Y, \mathbb{R}) = \mathbb{R}^Y$. As usual we picture elements of $C(Y, \mathbb{R})$ by their graphs. In Figure 76 we show on the left an open set $M(K, U)$ as above and on the right we show the graph of some function $f \in C(Y, \mathbb{R})$ and an open neighborhood thereof.

Now let $f_n \in C(Y, \mathbb{R})$, $n \in \mathbb{N}$ be a sequence of functions and let $f \in C(Y, \mathbb{R})$. We leave it as an amusing, albeit somewhat lengthy, exercise to show that the following holds:

$$\begin{array}{c} (f_n)_{n\in\mathbb{N}} \text{ converges}^{65} \text{ to } f \text{ with respect} \\ \text{to the compact-open topology} \end{array} \quad \Longleftrightarrow \quad \begin{array}{c} \text{for each compact subset } K \subset Y \\ \text{the sequence } (f_n|_K)_{n\in\mathbb{N}} \\ \text{converges uniformly to } f|_K \end{array}$$

Alternatively a proof for this statement is given in [Wil, Theorem 43.7] or in [Jos, Theorem 15.1.2].

(2) We consider $Y = \{1, \dots, n\}$ which we equip with the discrete topology. In Exercise 2.4 we will see that for any topological space X we have a homeomorphism $X^Y \cong X^n$.

The final example deserves its own lemma.

Lemma 2.1. *Let $m, n \in \mathbb{N}$. We have the obvious inclusion*

$$\begin{array}{rcl} M(m \times n, \mathbb{R}) & \to & C(\mathbb{R}^n, \mathbb{R}^m) = (\mathbb{R}^m)^{\mathbb{R}^n} \\ A & \mapsto & \begin{pmatrix} \mathbb{R}^n & \to & \mathbb{R}^m \\ v & \mapsto & Av \end{pmatrix}. \end{array}$$

[65] We refer to page 54 for the definition of convergence of a sequence in a topological space.

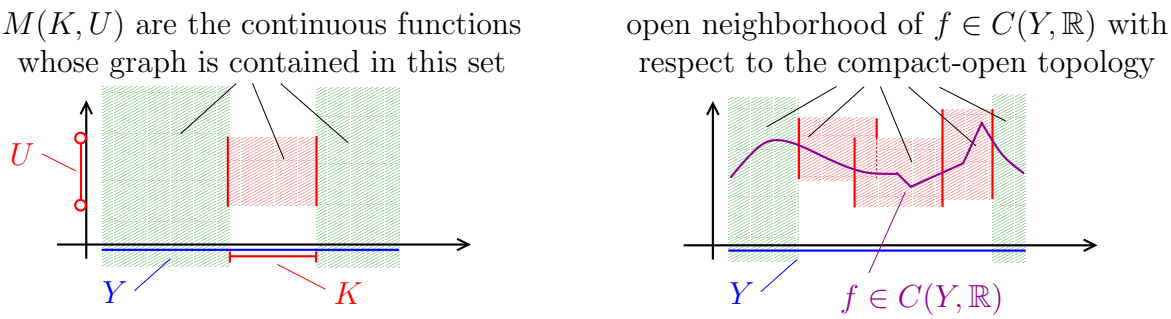

FIGURE 76.

The compact-open topology on $C(\mathbb{R}^n, \mathbb{R}^m)$ induces the usual topology on $M(n \times m, \mathbb{R})$ that we introduced on page 86.

Sketch of proof. This statement can be proved, with some effort, using Lemma 1.24. Alternatively the statement can also be deduced from [Hat, Proposition A.13] or [Mun3, Theorem 5.1]. □

To get some practice with the compact-open topology we will prove the following two lemmas in Exercises 2.1 and 2.2.

Lemma 2.2. *Let X and Y be topological spaces. If Y is Hausdorff, then X^Y is also Hausdorff.*

Lemma 2.3. *If X and Y are topological spaces, then the map*

$$\begin{array}{rcl} X & \to & X^Y \\ x & \mapsto & \text{constant map } y \mapsto x \end{array}$$

is continuous.

We continue with a few technical statements on the compact-open topology. In most applications later on we will consider the case that $Y = [0,1]$. In particular the extra hypothesis in the subsequent propositions on the topological space Y will not be an issue in our future applications.

Proposition 2.4. *Let X and Y be topological spaces. If Y is locally compact, then the following two statements hold:*

(1) *The evaluation map*[66]

$$\begin{array}{rcl} e\colon X^Y \times Y & \to & X \\ ((f\colon Y \to X), y) & \mapsto & f(y) \end{array}$$

is continuous.

[66]Here we equip $X^Y \times Y$ with the product topology from page 84.

(2) *For any $y \in Y$ the evaluation map*

$$\begin{array}{rcl} e_y \colon X^Y & \to & X \\ (f \colon Y \to X) & \mapsto & f(y) \end{array}$$

is continuous.

Proof $(*)$.

(1) Let U be an open subset of X. We need to show that $e^{-1}(U)$ is open. By Lemma 1.8 it suffices to show that given $(f, y) \in e^{-1}(U)$ there exists a neighborhood W of (f, y) with $W \subset e^{-1}(U)$. Thus let $f \in X^Y$ and $y \in Y$ with $e(f, y) = f(y) \in U$. Since f is continuous and since Y is locally compact there exists a compact neighborhood K of y which is contained in the open neighborhood $f^{-1}(U)$ of y. In other words, we have found a compact neighborhood K of y with $f(K) \subset U$. Therefore we have $f \in M(K, U)$ and the map e sends $W := M(K, U) \times K$ into U. By the definition of the product topology the set $W = M(K, U) \times K$ is in fact a neighborhood of (f, y) in $X^Y \times Y$.

(2) This statement follows from (1) and Lemma 1.53 (3b). □

We continue with the following elementary but essential lemma.

Lemma 2.5. $(*)$ *Let X and Y be topological spaces.*

(1) *If $\varphi \colon X \to \widetilde{X}$ is a continuous map, then the induced map*

$$\begin{array}{rcl} \varphi^* \colon X^Y & \to & \widetilde{X}^Y \\ (f \colon Y \to X) & \mapsto & (\varphi \circ f \colon Y \to \widetilde{X}) \end{array}$$

is continuous.

(2) *If $\psi \colon Y \to \widetilde{Y}$ is a continuous map, then the induced map*

$$\begin{array}{rcl} \psi_* \colon X^{\widetilde{Y}} & \to & X^Y \\ (f \colon \widetilde{Y} \to X) & \mapsto & (f \circ \psi \colon Y \to X) \end{array}$$

is continuous.

Proof $(*)$.

(1) We check continuity using the continuity criterion of Proposition 1.34. Thus let $K \subset Y$ be a compact subset and let $U \subset \widetilde{X}$ be an open subset. We have

$$\begin{aligned} (\varphi^*)^{-1}(M(K,U)) &= \{f \in X^Y \mid \varphi^*(f) \in M(K,U)\} = \{f \colon Y \to X \mid \overbrace{(\varphi \circ f)(K)}^{=\varphi(f(K))} \subset U\} \\ &\underset{\substack{\uparrow \\ \text{by Exercise 1.2}}}{=} \{f \colon Y \to X \mid f(K) \subset \varphi^{-1}(U)\} = M(K, \varphi^{-1}(U)). \end{aligned}$$

Since φ is continuous we see that $\varphi^{-1}(U)$ is an open subset of X. Since the sets $M(K, U)$ form by definition a basis for the topology of $\widetilde{X}^Y$ we deduce from Proposition 1.34 that φ^* is indeed continuous.

(2) Let $K \subset Y$ be a compact subset and let $U \subset X$ be an open subset. We have

$$\begin{aligned}(\psi_*)^{-1}(M(K,U)) &= \{f \in X^{\widetilde{Y}} \mid \psi_*(f) \in M(K,U)\} \\ &= \{f\colon \widetilde{Y} \to X \mid \underbrace{(f\circ\psi)(K)}_{=f(\psi(K))} \subset U\} \;=\; M(\psi(K),U).\end{aligned}$$

Since ψ is continuous we obtain from Lemma 1.37 that $\psi(K)$ is a compact subset of $\widetilde{Y}$. Thus we obtain again from Proposition 1.34 that ψ_* is indeed continuous. □

On many occasions we will also need the following rather technical proposition.

Proposition 2.6. *Let Y be a topological space that is locally compact. Furthermore let X and T be two topological spaces. Let $H\colon Y \times T \to X$ be a map. Given $t \in T$ we denote by $H_t\colon Y \to X$ the map defined by $H_t(y) := H(y,t)$. Then*

$$H\colon Y\times T \to X \text{ is continuous} \iff \begin{array}{l}(1)\ \text{each } H_t\colon Y \to X \text{ is continuous, and}\\ (2)\ \text{the map}^{67}\ T \to X^Y \text{ given by } t \mapsto H_t \text{ is continuous.}\end{array}$$

Proof (∗). [68] First we prove the "⇐"-direction. We point out that $H\colon Y \times T \to X$ is the composition of the two maps

$$\begin{array}{rcl} Y\times T &\to& X^Y \times Y \\ (y,t) &\mapsto& (H_t, y)\end{array} \quad \text{and the evaluation map} \quad \begin{array}{rcl} X^Y \times Y &\to& X \\ (f,y) &\mapsto& f(y).\end{array}$$

The first map is continuous by (2) and Lemma 1.53. Furthermore, since Y is locally compact we obtain from Proposition 2.4 that the second map is continuous. Thus H itself is continuous.

Now we turn to the "⇒"-direction. Thus we suppose that $H\colon Y \times T \to X$ is continuous.

(1) Let $t \in T$. The map H_t is the composition of the inclusion $Y \to Y \times T$, $y \mapsto (y,t)$ with the map H. The first map is continuous by Lemma 1.53 (3b) and the second map is continuous by our hypothesis. Hence H_t is also continuous. In particular we now know that H_t defines an element in X^Y.

(2) We need to show that the map $T \to X^Y$ given by $t \mapsto H_t$ is continuous. By Proposition 1.34 and Lemma 1.8 it suffices to show that for any set of the form $M(K,U) \subset X^Y$ and any $t \in T$ with $H_t \in M(K,U)$ there exists a neighborhood W of $t \in T$ such that for all $t' \in W$ we have $H_{t'} \in M(K,U)$.

Thus let K be a compact subset of Y, let U be an open subset of X and let $t \in T$ with $H_t \in M(K,U)$. We start out with the following claim.

Claim. Given any $y \in K$ there exist open neighborhoods $V_y \subset Y$ of y and $W_y \subset T$ of t such that $H(V_y \times W_y) \subset U$.

[67] Note that by (1) we know that $H_t \in X^Y$.

[68] I strongly advise against reading the proof.

By the continuity of $H\colon Y \times T \to X$ we know that $H^{-1}(U)$ is an open subset of $Y \times K$. Note that $H(y,t) = H_t(y) \in U$ since $H_t \in M(K,U)$ and $y \in K$. Thus $H^{-1}(U)$ is an open neighborhood of $(y,t) \in Y \times K$. The existence of V_y and W_y is now a consequence of the definition of the product topology of $Y \times T$. This concludes the proof of the claim.

It follows from the compactness of K and Lemma 1.16 that there exist points $y_1, \dots, y_n \in K$ with $K \subset V_{y_1} \cup \dots \cup V_{y_n}$. We set $W := W_{y_1} \cap \dots \cap W_{y_n} \subset T$. Note that this is an open neighborhood of t. Then

$$H(K \times W) \underset{\substack{\uparrow \\ \text{since } K \subset \bigcup_{i=1}^n V_{y_i}}}{\subset} H\Big(\bigcup_{i=1}^n V_{y_i} \times W\Big) \underset{\substack{\uparrow \\ \text{since } W \subset W_{y_i}}}{\subset} H\Big(\bigcup_{i=1}^n V_{y_i} \times W_{y_i}\Big) = \bigcup_{i=1}^n \underbrace{H(V_{y_i} \times W_{y_i})}_{\subset U} \subset U.$$

It follows from this observation and the definition of $H_{t'}$ and $M(K,U)$ that for any $t' \in W$ we have $H_{t'} \in M(K,U)$. □

On a later occasion we will also need the following equally technical proposition.

Proposition 2.7. *Let X, Y and Z be topological spaces. If Y and Z are both locally compact and Hausdorff, then the map*[69]

$$\begin{array}{rcl} X^{Y \times Z} & \to & (X^Y)^Z \\ (f\colon Y \times Z \to X) & \to & \left(\begin{array}{rcl} Z & \to & X^Y \\ z & \mapsto & (y \mapsto f(y,z)) \end{array} \right) \end{array}$$

is a homeomorphism.

Remark. In fact a slightly stronger version of Proposition 2.7 holds. By [Dug, Theorem 5.3] one only needs to assume that Y is locally compact, with no further restrictions on X, Y or Z. We will not need this stronger statement.

Once again no sane person will ever voluntarily read the proof. For those readers who are still around we first provide the proof of the following lemma.

Lemma 2.8. *Let X and Y be topological spaces. Furthermore let $\mathcal{V}$ be a subbasis for X. We consider*

$$\mathcal{C} = \big\{ M(K,V) \in \mathcal{P}\big(X^Y\big) \,\big|\, K \text{ a compact subset of } Y \text{ and } V \in \mathcal{V} \big\}.$$

If Y is Hausdorff, then $\mathcal{C}$ is subbasis[70] *for the topology of X^Y.*

Proof. Let K be a compact subset of Y, let U be an open subset of X and let f be a point in $M(K,U)$, i.e. $f\colon Y \to X$ is a map with $K \subset f^{-1}(U)$. By Lemma 1.28 (2) we need to show that there exist finitely many $C_1, \dots, C_m \in \mathcal{C}$ with $f \in \bigcap_{i=1}^m C_i \subset M(K,U)$.

[69]Note that the map is well-defined, in the sense that the map $Z \to X^Y$ actually defines an element in $(X^Y)^Z$. More precisely, it follows from the "$\Rightarrow$"-direction of Proposition 2.6 and the fact that Y is locally compact that the map $Z \to X^Y$ given by $z \mapsto (y \mapsto f(y,z))$ actually lies in $(X^Y)^Z$.

[70]We refer to page 63 for the definition of a subbasis of a topological space.

Since $\mathcal{V}$ is a subbasis for the topology of X we can write $U = \bigcup_{i\in I} U_i$ where each U_i is of the form $U_i = \bigcap_{V\in P_i} V$ where P_i is a finite subset of $\mathcal{V}$. Since K is compact and since f is continuous it follows from Lemma 1.16 that there exists a finite subset $J \subset I$ such that $K \subset \bigcup_{j\in J} f^{-1}(U_j)$.

Since K is compact and Hausdorff we obtain from Lemma 1.42 that K is normal. It follows from Lemma 1.44, together with Lemma 1.18 (1) and the hypothesis that Y is Hausdorff, that there exist compact subsets $K_j \subset f^{-1}(U_j)$, $j \in J$, with $K \subset \bigcup_{j\in J} K_j$.

Thus we see that

$$\begin{array}{ccccccc} f & \in & \bigcap_{j\in J} M(K_j, U_j) & = & \bigcap_{j\in J} M\Big(K_j, \bigcap_{V\in P_j} V\Big) & \overset{\text{since } M(K,A\cap B) = M(K,A)\cap M(K,B)}{=} & \bigcap_{j\in J}\bigcap_{V\in P_j} \underbrace{M(K_j,V)}_{\in\mathcal{C}} \subset M(K,U). \\ & \uparrow & & \uparrow & & & \uparrow \\ & \text{since } K_j \subset f^{-1}(U_j) & & \text{definition of } P_j & & & \text{since } K \subset \bigcup_{j\in J} K_j \text{ and since each } V \text{ lies in } U \end{array}$$

The finitely many sets $\{M(K_j, V)\}_{j\in J, V\in P_j}$ in $\mathcal{C}$ thus do the trick. □

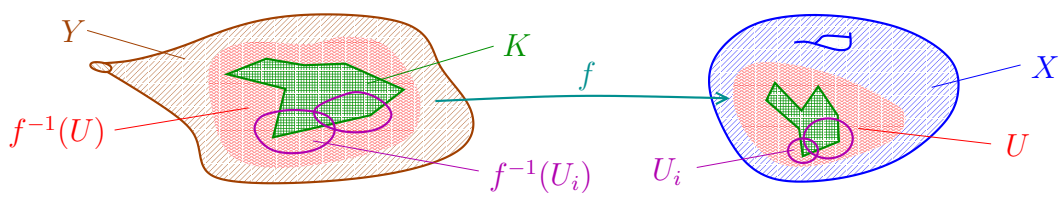

FIGURE 77. Illustration for the proof of Lemma 2.8.

Now we are finally ready to provide the proof of Proposition 2.7.

Proof of Proposition 2.7. Let X, Y and Z be topological spaces. We assume that Y and Z are both locally compact and Hausdorff. We need to show that the map

$$\begin{array}{rcl} \Phi\colon X^{Y\times Z} & \to & (X^Y)^Z \\ (f\colon Y\times Z) & \to & \left(\begin{array}{ccc} Z & \mapsto & X^Y \\ z & \mapsto & (y \mapsto f(y,z)) \end{array}\right) \end{array}$$

is a homeomorphism. We start out with the following claim.

Claim. The set

$$\mathcal{C} = \left\{ M(A\times B, U) \in \mathcal{P}\big(X^{Y\times Z}\big) \;\middle|\; \begin{array}{l} A \text{ a compact subset of } Y,\ B \text{ a compact subset of } Z \\ \text{and } U \text{ an open subset of } X \end{array} \right\}$$

is a subbasis for the topological space $X^{Y\times Z}$.

Let $K \subset Y \times Z$ be a compact subset, let U be an open subset of X and let f be a point in $M(K,U)$, i.e. $f\colon Y \times Z \to X$ is a map with $K \subset f^{-1}(U)$. By Lemma 1.28 (2) we need to show that there exist finitely many $C_1, \dots, C_m \in \mathcal{C}$ with $f \in \bigcap_{i=1}^{m} C_i \subset M(K,U)$.

Let $k \in K \subset Y \times Z$. We write $k = (y,z)$. Since $f^{-1}(U)$ is an open subset of $Y \times Z$ it follows from the definition of the product topology on $Y \times Z$ that there exist open neighborhoods $V_k \subset Y$ of y and $W_k \subset Z$ of z such that $k = (y,z) \in V_k \times W_k \subset f^{-1}(U)$. Since Y and Z are locally compact we can find a compact neighborhood $A_k \subset Y$ of y and a compact neighborhood $B_k \subset Z$ of z such that $k \in A_k \times B_k \subset V_k \times W_k \subset f^{-1}(U)$. Since K is compact it follows from Lemma 1.16 that there exist finitely many points $k_1, \dots, k_m \in K$ such that $K \subset \bigcup_{i=1}^{m} A_{k_i} \times B_{k_i}$. We now see that

$$\begin{array}{ccccccc} & & & & \text{since } M(V \cup W, U) = M(V,U) \cap M(W,U) & & \\ & & & & \downarrow & & \\ f & \in & \bigcap_{i=1}^{m} \overbrace{M(A_{k_i} \times B_{k_I}, U)}^{\in \mathcal{C}} & = & M\Big(\bigcup_{i=1}^{m} A_{k_i} \times B_{k_i}, U\Big) & \subset & M(K,U). \\ & \uparrow & & & & \uparrow & \\ & \text{since } f(A_{k_i} \times B_{k_i}) \subset U & & & & \text{since } K \subset \bigcup_{i=1}^{m} A_{k_i} \times B_{k_i} & \end{array}$$

This concludes the proof of the claim.

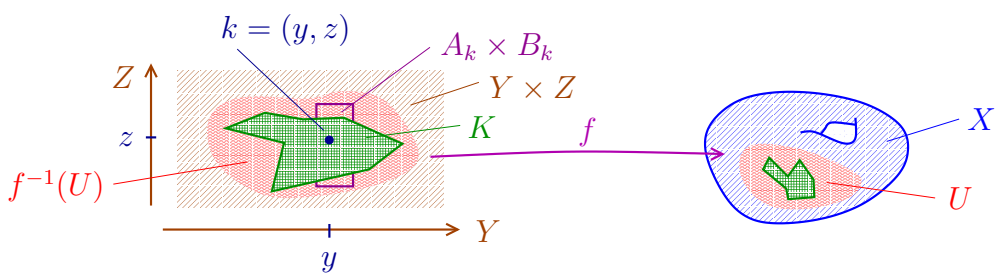

FIGURE 78. Illustration for the proof of Proposition 2.7.

The given map $\Phi\colon X^{Y \times Z} \to (X^Y)^Z$ is clearly a bijection. Furthermore under this bijection the sets $M(A \times B, U)$ are precisely the sets $M(B, M(A,U))$. By the claim the former sets form a subbasis for $X^{Y \times Z}$. Thus it suffices to show that the latter sets form a subbasis for $(X^Y)^Z$. But that is an immediate consequence of Lemma 2.8, applied twice, and our hypothesis that Y and Z are Hausdorff. $\square$

The following proposition is also somewhat technical.

Proposition 2.9. *Let X, Y and Z be topological spaces. If Y is locally compact, then the map*

$$\begin{array}{rcl} \Phi\colon X^Y \times Y^Z & \to & X^Z \\ (f,g) & \mapsto & f \circ g \end{array}$$

is continuous.

The proof of Proposition 2.9 rests on the following little lemma.

Lemma 2.10. $(*)$ *Let Y be a topological space that is locally compact. If K is a compact subset that is contained in an open subset U of Y, then there exists a compact subset L with $K \subset \mathring{L} \subset L \subset U$.*

Proof $(*)$. Let $x \in K$. Since Y is locally compact there exists a compact neighborhood $L_x \subset U$ of x. Since K is compact there exist $x_1, \ldots, x_m \in K$ with $K \subset \mathring{L}_{x_1} \cup \cdots \cup \mathring{L}_{x_m}$. We set $L := L_{x_1} \cup \cdots \cup L_{x_m}$. By Lemma 1.17 we know that L is compact. We have

$$K \;\subset\; \bigcup_{i=1}^{m} \mathring{L}_{x_i} \;\underset{\substack{\uparrow \\ \text{Lemma 1.12 (1)}}}{\subset}\; \text{interior of} \bigcup_{i=1}^{m} L_x \;=\; \mathring{L} \;\subset\; L \;\subset\; U.$$

□

Proof of Proposition 2.9 $(*)$. By Proposition 1.34 and Lemma 1.8 and the definition of the product topology on $X^Y \times Y^Z$ it suffices to prove the following claim.

Claim. Let K be a compact subset of Z and let V be an open subset of X. If $f \in X^Y$ and $g \in Y^Z$ satisfy $f \circ g \in M(K, V)$, then there exists an open subset $U \subset Y$ and a compact subset $L \subset Y$ with

$$\Phi\big(\underbrace{M(L,V)}_{\subset X^Y} \times \underbrace{M(K,U)}_{\subset Y^Z}\big) \;\subset\; M(K,V).$$

First note that $g(K) \subset Y$ is compact by Lemma 1.37 and that $f^{-1}(V) \subset Y$ is open since f is evidently continuous. Since Y is locally compact we obtain from Lemma 2.10 that there exists a compact subset L with $g(K) \subset \mathring{L} \subset L \subset f^{-1}(U)$. It is clear that $U = \mathring{L}$ and L have the desired properties. This concludes the proof of the claim. □

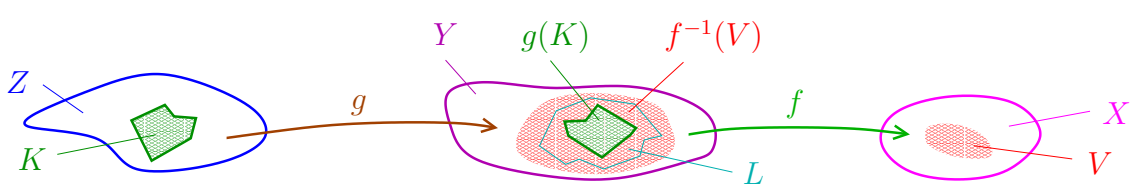

FIGURE 79. Illustration for the proof of Proposition 2.9.

The following corollary gives us a very long list of new examples of topological groups.

Corollary 2.11. *Let X be a topological space. If X is compact and Hausdorff, then the group*

$$\text{Homeo}(X) \;:=\; \textit{the set of all self-homeomorphisms of } X,$$

equipped with the subspace topology coming from X^X, is a topological group.

Remark. Let X be a topological space that is locally compact and Hausdorff. In light of Proposition 2.9 one might expect that in this case $\mathrm{Homeo}(X)$ forms a group. In [Dij] it is shown that this is in general *not* the case. On the other hand it is shown in [Are, Theorem 4] that if X is furthermore locally connected, then $\mathrm{Homeo}(X)$ is in fact a topological group.

Proof $(*)$. Let X be a topological space that is compact and Hausdorff. First note that by Lemma 1.103 we know that X is locally compact. Thus it follows from Proposition 2.9 that the multiplication map $\mathrm{Homeo}(X) \times \mathrm{Homeo}(X) \to \mathrm{Homeo}(X)$ is continuous. Therefore it suffices to show that the map

$$\begin{array}{rcl} \Phi\colon \mathrm{Homeo}(X) & \to & \mathrm{Homeo}(X) \\ f & \mapsto & f^{-1} \end{array}$$

is continuous. The proof of continuity rests on the following simple claim.

Claim. If $K \subset X$ and $U \subset X$ are subsets, then $\Phi^{-1}(M(K,U)) = M(X \setminus U, X \setminus K)$.

Let $h \in \mathrm{Homeo}(X)$. We have

$$\begin{array}{rcl} h \in \Phi^{-1}(M(K,U)) & \overset{\text{since } \Phi \text{ is a bijection and } \Phi(h)=h^{-1}}{\Longleftrightarrow} & h^{-1} \in M(K,U) \quad \Longleftrightarrow \quad h^{-1}(K) \subset U \quad \overset{\text{since } h \text{ is a bijection}}{\Longleftrightarrow} \quad K \subset h(U) \\ & \Longleftrightarrow & \underbrace{X \setminus h(U)}_{=h(X\setminus U)} \subset X \setminus K \quad \Longleftrightarrow \quad h \in M(X \setminus U, X \setminus K). \end{array}$$

This concludes the proof of the claim.

By Proposition 1.34 it suffices to prove the following claim.

Claim. If $K \subset X$ is a compact subset and if $U \subset X$ is an open subset, then $\Phi^{-1}(M(K,U))$ is an open subset of X.

By the previous claim we know that $\Phi^{-1}(M(K,U)) = M(X \setminus U, X \setminus K)$. Since U is open we know that $X \setminus U$ is closed. Since X is compact we obtain from Lemma 1.18 (1) that $X \setminus U$ is compact. Furthermore, since K is compact and since X is Hausdorff we obtain from Lemma 1.18 (2) that $X \setminus U$ is closed. Thus we see that $M(X \setminus U, X \setminus K)$ is an open subset of X^X. This concludes the proof of the claim. □

2.2. **Mixing product and quotient topologies** $(*)$**.** In this, rather technical section, we will see that mixing product and quotient topologies can be quite delicate. We start out with the following elementary lemma.

Lemma 2.12. *Let X and Y be two topological spaces. Suppose we are given an equivalence relation $\sim$ on X. We denote by $\sim_\times$ the equivalence relation on $X \times Y$ that is generated by $(x,y) \sim_\times (x',y)$ whenever $x \sim x'$. The following map is a bijection and it is continuous:*

$$\begin{array}{rcl} \varphi\colon (X \times Y)/\sim_\times & \to & (X/\sim) \times Y \\ [(x,y)] & \mapsto & ([x],y). \end{array}$$

Proof $(*)$. It follows basically immediately from the definition of $\sim_\times$ that the map φ is a bijection. We will walk cautiously through the continuity argument.

We denote by $p\colon X \times Y \to (X \times Y)/\sim_\times$ and $q\colon X \to X/\sim$ the two obvious projection maps. We have the following commutative diagram

$$\begin{tikzcd} & X \times Y \arrow[dl, "p"'] \arrow[dr, "q \times \mathrm{id}_Y"] & \\ (X \times Y)/\sim_\times \arrow[rr, "\varphi"] & & (X/\sim) \times Y. \end{tikzcd}$$

Let $W \subset (X/\sim) \times Y$ be an open subset. We need to show that $\varphi^{-1}(W)$ is an open subset of $(X \times Y)/\sim_\times$. By definition of the quotient topology we need to show that $p^{-1}(\varphi^{-1}(W))$ is an open subset of $X \times Y$.

By Lemma 1.8 and the definition of the product topology it suffices to prove the following claim.

Claim. For each $(x, y) \in p^{-1}(\varphi^{-1}(W)) \subset X \times Y$ there exists an open neighborhood U_x of $x \in X$ and an open neighborhood V_y of $y \in Y$ such that $U_x \times V_y \subset p^{-1}(\varphi^{-1}(W))$.

Since $([x], y) \in W$ and since W is an open subset of $(X/\sim) \times Y$ we obtain, by definition of the product topology, an open neighborhood $\widetilde{U}_{[x]}$ of $[x] \in X/\sim$ and an neighborhood V_y of $y \in Y$ with $\widetilde{U}_{[x]} \times V_y \subset W$. We set $U_x := q^{-1}(\widetilde{U}_{[x]})$. By definition of the quotient topology this is an open subset of X. It remains to show that $U_x \times V_y \subset p^{-1}(\varphi^{-1}(W))$. In other words, we need to show that $\varphi(p(U_x \times V_y)) \subset W$. This inclusion follows from the following short argument:

$$\varphi(p(U_x \times V_y)) = (\varphi \circ p)(U_x \times V_y) \underset{\substack{\uparrow \\ \text{by the above commutative triangle}}}{=} (q \times \mathrm{id}_Y)(U_x \times V_y) \underset{\substack{\uparrow \\ \text{since } U_x = q^{-1}(\widetilde{U}_{[x]})}}{=} q(q^{-1}(\widetilde{U}_{[x]})) \times V_y = \widetilde{U}_{[x]} \times V_y \subset W.$$

This concludes the proof of the claim and thus also of the lemma. $\square$

One would expect that the map from Lemma 2.12 surely must be a homeomorphism. But perhaps rather shockingly, the next lemma shows that in general this is not the case:

Lemma 2.13. *There exist topological spaces X and Y and an equivalence relation $\sim$ on X with the following property: If we denote by $\sim_\times$ the equivalence relation on $X \times Y$ generated by $(x, y) \sim_\times (x', y)$ whenever $x \sim x'$, then the map*

$$\begin{array}{rcl} \varphi\colon (X \times Y)/\sim_\times & \to & (X/\sim) \times Y \\ [(x, y)] & \mapsto & ([x], y) \end{array}$$

is a bijection and it is continuous, but it is not a homeomorphism.

Remark. We refer to [Fab, Theorem 1], [BrownR2, p. 111] and [Bou3, p. 128] for other examples which also show that mixing product and quotient topologies is in general a very dangerous idea.

Proof. We consider $X = \mathbb{R} \times \mathbb{N} = \{(x,n) \,|\, x \in \mathbb{R}, n \in \mathbb{N}\}$, equipped with the product topology. Let $\sim$ be the equivalence relation on X that is generated by $(0,m) \sim (0,n)$ for all $m,n \in \mathbb{N}$. We set $Y := \prod_{i\in\mathbb{N}} \mathbb{R}$, equipped with the product topology introduced on page 94. By Lemma 2.12 we know that the map

$$\begin{array}{rcl} \varphi\colon (X \times Y)/\sim_\times & \to & (X/\sim) \times Y \\ [(x,y)] & \mapsto & ([x], y) \end{array}$$

is a bijection and that it is continuous. It remains to show that φ is not a homeomorphism. We will do so by exhibiting an open subset V of $(X \times Y)/\sim_\times$ such that the image $\varphi(V)$ is not an open subset of $(X/\sim) \times Y$.

Before we can proceed we need to introduce the following notation:

(1) We denote by $q\colon X \to X/\sim$ the obvious projection.
(2) We write $f = q \times \mathrm{id}_Y\colon X \times Y \to (X/\sim) \times Y$.
(3) Given $n \in \mathbb{N}$ we set

$$U_n \;:=\; \{((t,n),(y_1,y_2,y_3,\dots)) \in X \times Y \,|\, |t \cdot y_n| < 1\}.$$

and we set $U := \bigcup_{n\in\mathbb{N}} U_n$.

The key to proving the lemma is the following claim.

Claim. The set U has the following properties:

(1) U is an open subset of $X \times Y$,
(2) $f^{-1}(f(U)) = U$,
(3) $f(U)$ is not open in $(X/\sim) \times Y$.

We set out to prove that U does indeed have the three promised properties.

(1) We want to show that U is an open subset of $X \times Y$. It suffices to show that each U_n is open. First note that the map

$$\begin{array}{rcl} \gamma\colon X \times Y = \mathbb{R} \times \mathbb{N} \times \prod_{i\in\mathbb{N}} \mathbb{R} & \to & \mathbb{R} \\ (t,n,y_1,y_2,\dots) & \mapsto & t \cdot y_n \end{array}$$

is continuous by Lemma 1.60. Furthermore note that $\{n\}$ is an open subset of $\mathbb{N}$. We now see that

$$U_n \;=\; \gamma^{-1}((-1,1)) \cap \underbrace{\mathbb{R} \times \{n\} \times \prod_{i\in\mathbb{N}} \mathbb{R}}_{\text{open by definition of the product topology}}$$

is the intersection of two open sets, thus it is open itself.

(2) We need to show $f^{-1}(f(U)) = U$. In other words, we need to show that if v is an element of U with $f(v) \in f(U)$, then $v \in U$. But this statement follows from the following claim.

Claim. Let $v = ((s,m),(y_1,y_2,\dots))$ and $w = ((t,n),(z_1,z_2,\dots))$ be two elements in $X \times Y$. If $f(v) = f(w)$ and if $w \in U$, then we also have $v \in U$.

If $v = w$, then there is nothing to show. On the other hand, if $v \neq w$, then it follows from the definition of the map f and the equivalence relation $\sim$ that $s = t = 0$. But this implies that v and w lie in every U_n, in particular they both lie in U. This concludes the proof of the claim.

(3) We prove this statement by contradiction. Thus suppose that $f(U)$ is, contrary to our hopes, an open subset of $(X/\sim) \times Y$. Note that $((0,0),(0,0,\dots)) \in U$. This implies that $f((0,0),(0,0,\dots)) = ([(0,0)],(0,0,\dots))$ is contained in $f(U)$. By definition of the product topology of $(X/\sim) \times Y$ and of the product topology of $Y = \prod_{i\in\mathbb{N}} \mathbb{R}$ there exists an open subset $V \subset X/\sim$ and open subsets $W_i \subset \mathbb{R}$ with $([(0,0)],(0,0,\dots)) \in V \times \prod_{i\in\mathbb{N}} W_i \subset f(U)$ and such that all but finitely W_i are equal to $\mathbb{R}$. We pick an $N \in \mathbb{N}$ with $W_N = \mathbb{R}$. Since $[(0,0)] \in V$ we see that $q^{-1}(V)$ is an open subset of $X = \mathbb{R} \times \mathbb{N}$ that contains the subset $q^{-1}([(0,0)]) = \{0\} \times \mathbb{N}$. In particular $q^{-1}(V)$ contains some point (s,N) with $s \neq 0$. We pick a real number $y_N > \frac{1}{|s|}$ and we consider the point

$$P \;:=\; ((s,N),(0,\dots,0,\underset{\substack{\uparrow \\ \text{the } N\text{-th entry}}}{y_N},0,\dots)) \;\in X \times Y.$$

Note that

$$P \;\underset{\substack{\uparrow \\ \text{since } (s,N)\in q^{-1}(V) \\ \text{and since } W_N=\mathbb{R}}}{\in}\; q^{-1}(V) \times \prod_{i\in\mathbb{N}} W_i \;\underset{\substack{\uparrow \\ \text{since } f = q\times \mathrm{id}_Y}}{=}\; f^{-1}\Big(V \times \prod_{i\in\mathbb{N}} W_i\Big) \;\underset{\substack{\uparrow \\ \text{see above}}}{\subset}\; f^{-1}(f(U)) \;\underset{\substack{\uparrow \\ \text{by (2)}}}{=}\; U \;=\; \bigcup_{n\in\mathbb{N}} U_n.$$

By definition of the U_n's we see that the only possibility is that $P \in U_N$. But we have $|s \cdot y_N| > 1$, i.e. P cannot possibly lie in U_N. We have thus obtained a contradiction.

This concludes the proof of the claim.

It remains to prove the following claim.

Claim. We set $V := p(U)$.

(1) V is an open subset of $(X \times Y)/\sim_\times$,
(2) $\varphi(V)$ is not an open subset of $(X/\sim) \times Y$.

We denote by $p\colon X \times Y \to (X \times Y)/\sim_\times$ the obvious projection map. We have the following commutative diagram

$$\begin{tikzcd} X \times Y \arrow[rr, "f=q\times \mathrm{id}_Y"] \arrow[dr, "p"'] & & (X/\sim) \times Y \\ & (X \times Y)/\sim_\times . \arrow[ur, "\varphi"'] & \end{tikzcd}$$

Note that

$$\begin{array}{ccccccc} p^{-1}(V) & = & p^{-1}(p(U)) & = & f^{-1}(f(U)) & = & U & = & \text{an open subset of } X \times Y. \\ & & & \uparrow & & \uparrow & & \uparrow & \\ & & \text{since } p = \varphi^{-1} \circ f \text{ and since } \varphi \text{ is a bijection} & & & & \text{by the previous claim} & & \end{array}$$

By the definition of the quotient topology on $(X \times Y)/\sim_\times$ this means that V is indeed an open subset of $(X \times Y)/\sim_\times$. Furthermore we have $\varphi(V) = \varphi(p(U)) = f(U)$. But by the previous claim we know that $f(U)$ is not an open subset of $(X/\sim) \times Y$. This concludes the proof of the claim and thus of the lemma. □

The previous lemma leads us to the following cautionary remark:

Remark.

In general products and quotients of topological spaces do not mix well.

Definition. We say that a map $f\colon X \to Y$ between topological spaces is a *quotient map* if f is surjective and if a subset $U \subset Y$ is open in Y if and only if the preimage $f^{-1}(U)$ is open in X.

Examples.

(1) We consider the map $f\colon \mathbb{R} \to \mathbb{R}$ whose graph is shown in Figure 80. This map is continuous, it is *not* an open map, but the reader is invited to verify that the map is in fact a quotient map.

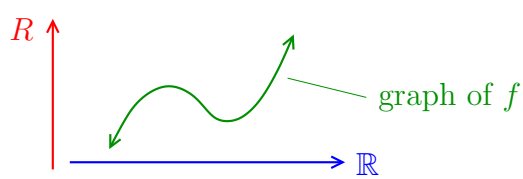

FIGURE 80.

(2) Let $X = \{0, 1\}$ be a set of two elements $0, 1$. Let $\mathcal{S}$ be the trivial topology and let $\mathcal{T}$ be the discrete topology. The identity map $(X, \mathcal{S}) \to (X, \mathcal{T})$ is a continuous bijection, but it is not a quotient map.

The following lemma summarizes a few elementary properties of quotient maps.

Lemma 2.14.

(1) *Let X be a topological space and let $\sim$ be an equivalence relation on X. The projection map $X \to X/\sim$ is a quotient map.*
(2) *If $f\colon X \to Y$ is a quotient map, then it is also continuous.*
(3) *If $f\colon X \to Y$ is a bijection between topological spaces and if it is a quotient map, then f is a homeomorphism.*

Proof.

(1) This statement follows immediately from the definition of the quotient topology on the quotient $X/\sim$.
(2) Let $f\colon X \to Y$ be a quotient map. If follows immediately from the "only if" bit of the definition of a quotient map that f is continuous.
(3) This statement follows immediately from (2) and Lemma 1.39. □

The following is the key technical theorem which in most reasonable situations will help us to navigate the choppy waters involving product and quotient maps.

Theorem 2.15. *Let $f\colon X \to Z$ be a map between topological spaces that is a quotient map. Furthermore let Y be a topological space. If Y is locally compact (e.g if $Y = [0,1]$), then the map*

$$f \times \mathrm{id}_Y \colon X \times Y \;\to\; Z \times Y$$

is also a quotient map.

Remark. This theorem is sometimes called the "Whitehead Theorem" since it was first proved by John Whitehead [Whd8, Lemma 4] in 1948.

We will provide the proof of Theorem 2.15 in the next section. In the following we first state and prove some useful consequences of Theorem 2.15. In fairness to the reader one should perhaps say that it is arguably best to move on to the next chapter. It is only advisable to read the remainder of this section once one really faces acute technical problems involving the mix of product and quotient maps.

The following little lemma is the key to many applications of Theorem 2.15.

Lemma 2.16. *Suppose we are given a commutative diagram of maps between topological spaces:*

$$\begin{tikzcd} & X \arrow[dl, "p"'] \arrow[dr, "f"] & \\ Y \arrow[rr, "\varphi"'] & & Z. \end{tikzcd}$$

The following two statements hold:

(1) *If p and f are quotient maps, then φ is also a quotient map.*
(2) *If p is a quotient map and if f is continuous, then φ is continuous.*

Proof.

(1) Suppose that p and f are quotient maps. Let $V \subset Z$ be an open subset. We have the following implications:

$$\begin{array}{ccccccc} V \text{ is open} & \Leftrightarrow & f^{-1}(V) \text{ is open} & \Leftrightarrow & p^{-1}(\varphi^{-1}(V)) \text{ is open} & \Leftrightarrow & \varphi^{-1}(V) \text{ is open.} \\ & \uparrow & & \uparrow & & \uparrow & \\ & \begin{array}{c}\text{since } f \text{ is a quotient}\\ \text{map}\end{array} & & \begin{array}{c}\text{since } f = \varphi \circ p \text{ we have}\\ f^{-1}(V) = p^{-1}(\varphi^{-1}(V))\end{array} & & \begin{array}{c}\text{since } p \text{ is a quotient map and}\\ \text{since } p(p^{-1}(\varphi^{-1}(V))) = \varphi^{-1}(V)\end{array} & \end{array}$$

Furthermore, it follows from the fact that the diagram commutes and the fact that f is surjective, that φ is surjective. We have thus verified that φ is a quotient map.

(2) Now we suppose that p is a quotient map and that f is continuous. We need to show that given an open subset $V \subset Z$ the preimage $\varphi^{-1}(V)$ is open. The argument is basically exactly the same as in (1), except that the first arrow is only a right arrow, since we only assume that f is continuous. $\square$

We have the following addendum to Lemma 2.12.

Lemma 2.17. *Let X and Y be two topological spaces. Suppose we are given an equivalence relation $\sim$ on X. We denote by $\sim_\times$ the equivalence relation on $X \times Y$ that is generated by $(x, y) \sim_\times (x', y)$ whenever $x \sim x'$.* If Y is locally compact*, then the following map is a homeomorphism:*

$$\begin{array}{rcl} \varphi\colon (X \times Y)/\sim_\times & \to & (X/\sim) \times Y \\ [(x, y)] & \mapsto & ([x], y). \end{array}$$

Proof $(*)$. As we pointed out in the proof of Lemma 2.12, it is basically clear that φ is a bijection. By Lemma 2.14 it remains to show that φ is a quotient map. We denote by $p\colon X \times Y \to (X \times Y)/\sim_\times$ and $q\colon X \to X/\sim$ the two obvious projection maps. We have the following commutative diagram

$$\begin{tikzcd} & X \times Y \arrow[dl, "p"'] \arrow[dr, "f = q \times \mathrm{id}_Y"] & \\ (X \times Y)/\sim_\times \arrow[rr, "\varphi"] & & (X/\sim) \times Y. \end{tikzcd}$$

By Lemma 2.14 (1) we know that p and q are quotient maps. Since Y is locally compact we obtain from Theorem 2.15 that $q \times_Y$ is a quotient map. It follows from Lemma 2.16 (1) that φ is also a quotient map. $\square$

Later on we will use the following special case of Lemma 2.17.

Lemma 2.18. *Let X and Y be two topological spaces, let $A \subset X$ be a subset and let $f\colon A \to Y$ be a map. Using the notation from page 114, we see that the map*

$$\begin{array}{rcl} (X \times [0,1]) \cup_{f \times \mathrm{id}_{[0,1]}} (Y \times [0,1]) & \to & (X \cup_f Y) \times [0,1] \\ [(P, t)] & \mapsto & ([P], t) \end{array}$$

is a homeomorphism.

Proof. Once one unravels the definitions it is clear that this statement follows immediately from Lemma 2.17 together with the observation that $[0, 1]$ is locally compact. $\square$

We conclude this list of Theorem 2.15 with the following proposition that gives a fairly explicit illustration of how Theorem 2.15 can be used.

Proposition 2.19. $(*)$ *Let X be a topological space, let A be a subset of X and let Y be a topological space that is locally compact. Then the map*

$$\begin{array}{rcl} \varphi\colon (X/A) \times Y & \to & (X \times Y)/(A \times Y) \\ ([x], y) & \mapsto & [(x, y)] \end{array}$$

is a quotient map, in particular it is continuous.

Example. In Figure 81 we illustrate the map studied in Proposition 2.19 in the case that $X = \mathbb{R}$, $A = [a, b]$ and $Y = [0, 1]$.

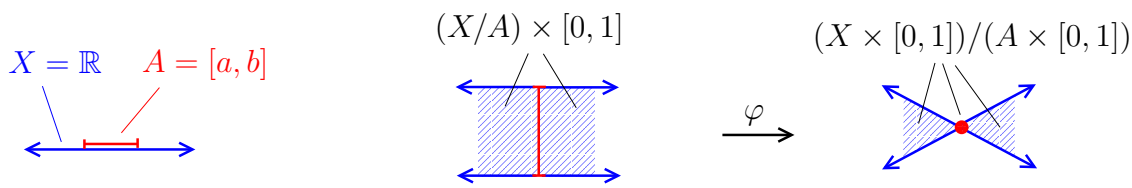

FIGURE 81.

Proof $(*)$. We denote by $p\colon X \times Y \to (X \times Y)/(A \times Y)$ and $q\colon X \to X/\sim$ the two obvious projection maps. We have the following commutative diagram

$$\begin{tikzcd} & X \times Y \arrow[dl, "q \times \mathrm{id}_Y"'] \arrow[dr, "p"] & \\ (X/A) \times Y \arrow[rr, "\varphi"] & & (X \times Y)/(A \times Y). \end{tikzcd}$$

By Lemma 2.14 the maps p and q are quotient maps. Since Y is locally compact we obtain from Theorem 2.15 that $q \times \mathrm{id}_Y$ is a quotient map. It follows from Lemma 2.16 that φ is also a quotient map. By Lemma 2.14 (2) this implies that φ is indeed continuous. $\square$

2.3. **Proof of Theorem 2.15** $(*)$**.** Now that we procrastinated for as long as possible, we will finally run out of reasons not turn to the proof of Theorem 2.15. In fact we provide two proofs.

The first proof of Theorem 2.15 cleverly reduces the proof to Proposition 2.6. This approach pushes all the set-theoretic nastiness into the proof of Proposition 2.6. The second proof of Theorem 2.15 is a bare-hands argument which can be read independently of the previous section on the compact-open topology.

First proof of Theorem 2.15, using Proposition 2.6. We write $W = Z \times Y$ and we equip W with the topology that turns

$$\begin{array}{rcl} g\colon X \times Y & \to & W \\ (x, y) & \mapsto & (f(x), y) \end{array}$$

into a quotient map. In other words, as a set we have $W = Z \times Y$, but this time equipped with the topology that is defined by the condition that $U \subset W$ is open if and only if $g^{-1}(U)$ is open. Note that with this topology on W the map g is in particular continuous. Next we consider the following diagram

$$\begin{tikzcd} X \times Y \arrow[rr, "f \times \mathrm{id}_Y"] \arrow[dr, "g(x,y)=(f(x),y)"'] & & Z \times Y \arrow[dl, "h(z,y)=(z,y)"] \\ & W & \end{tikzcd}$$

where $h\colon Z \times Y \to W$ is the identity. Since g is by definition a quotient map it remains to show that h is a homeomorphism. Evidently h is a bijection. Furthermore note that every open set in $Z \times Y$ is open in W since $f \times \mathrm{id}_Y$ is continuous. Thus it remains to show that h is continuous.

We consider the maps

$$\begin{array}{rcl} \widehat{g}\colon X & \to & W^Y \\ x & \mapsto & \left(\begin{array}{rcl} Y & \to & W \\ y & \mapsto & g(x,y) \end{array}\right) \end{array} \quad \text{and} \quad \begin{array}{rcl} \widehat{h}\colon Z & \to & W^Y \\ z & \mapsto & \left(\begin{array}{rcl} Y & \to & W \\ y & \mapsto & h(z,y) \end{array}\right) \end{array}$$

These maps fit into the following commutative diagram:

$$\begin{tikzcd} & X \arrow[dl, "f"'] \arrow[dr, "\widehat{g}"] & \\ Z \arrow[rr, "\widehat{h}"'] & & W^Y. \end{tikzcd}$$

We make the following observations:

(1) Since $g\colon X \times Y \to W$ is continuous and since Y is by hypothesis locally compact we obtain from Proposition 2.6 that $\widehat{g}\colon X \to W^Y$ is continuous.
(2) By our hypothesis the map f is a quotient map.
(3) It follows from (1) and (2), together with Lemma 2.16 (2), that the map $\widehat{h}\colon Z \to W^Y$ is continuous.
(4) It follows from Proposition 2.6 and (3) that h is indeed continuous. □

Our second proof of Theorem 2.15 is independent of earlier results. But it does mean that we will have to get our hands somewhat dirty.

Definition. Let $f\colon X \to Y$ be a map between two sets. We say $U \subset X$ is *saturated with respect to* f if $U = f^{-1}(f(U))$. If f is understood, then we just say U *is saturated*.

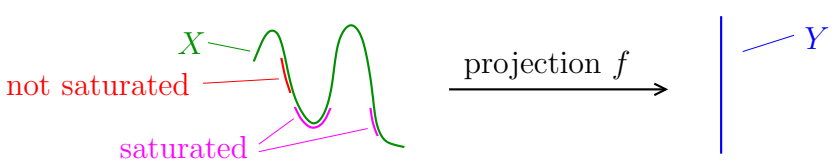

FIGURE 82.

Remark. Let $f\colon X \to Y$ be a map between two sets.

(1) Let $U \subset Y$ be a subset. By Lemma 1.1 (1) we know that $U \subset f^{-1}(f(U))$. Thus U is saturated if and only if $f^{-1}(f(U)) \subset U$.
(2) If f is an injection, then it follows from Lemma 1.1 (1) that every subset of X is saturated.

The following is, besides Lemma 1.1, the only purely set-theoretic lemma of these notes.

Lemma 2.20. *Let $f\colon X \to Z$ be a map between two sets and let Y be another set. Let $\widetilde{W}$ be a subset of $X \times Y$ that is saturated with respect to the map $f \times \mathrm{id}_Y\colon X \times Y \to Z \times Y$. Let $K \subset Y$. We consider the set*

$$U \;:=\; \{x' \in X \,|\, \{x'\} \times K \subset \widetilde{W}\}.$$

The set U is saturated with respect to f.

Proof. We write $h = f \times \mathrm{id}_Y$. By the above we need to show that $f^{-1}(f(U)) \subset U$. Thus let $x \in f^{-1}(f(U)) \subset X$. We have

$$h(\{x\}\times K) \underset{\substack{\uparrow \\ \text{definition of } h}}{=} (f\times \mathrm{id}_Y)(\{x\}\times K) = \{f(x)\}\times K \underset{\substack{\uparrow \\ \text{since } f(x)\in f(U) \text{ we know that} \\ f(x)=f(x') \text{ for some } x'\in U}}{=} \{f(x')\}\times K \underset{\substack{\uparrow \\ \text{definition of} \\ h = f\times \mathrm{id}_Y}}{=} h(\{x'\}\times K) \underset{\substack{\uparrow \\ \text{since } x'\in U}}{\subset} h(\widetilde{W}).$$

It follows that

$$\{x\}\times K \underset{\substack{\uparrow \\ \text{Lemma 1.1 (1)}}}{\subset} h^{-1}(h(\{x\}\times K) \underset{\substack{\uparrow \\ \text{by the above argument}}}{\subset} h^{-1}(h(\widetilde{W})) \underset{\substack{\uparrow \\ \text{since } \widetilde{W} \text{ is saturated}}}{=} \widetilde{W}.$$

We have thus shown that $x \in U$. □

We will also need the following lemma which is again in the realm of topological spaces.

Lemma 2.21. $(*)$ *Let X and Y be topological spaces, let $x \in X$ and let $K \subset Y$ be a compact subset. Let $\widetilde{W} \subset X \times Y$ be an open subset that contains $\{x\} \times K$. There exist open neighborhoods $U \subset X$ of x and $V \subset Y$ of K such that $\{x\} \times K \subset U \times V \subset \widetilde{W}$.*

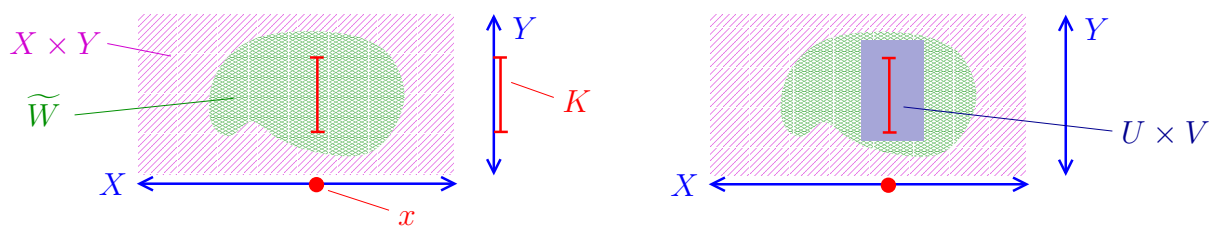

FIGURE 83.

Proof of Lemma 2.21 $(*)$. Since $\widetilde{W} \subset X \times Y$ is open and since $\{x\} \times K \subset \widetilde{W}$ we can find for any $k \in K$ open neighborhoods A_k of $x \in X$ and B_k of $k \in Y$ such that $A_k \times B_k \subset \widetilde{W}$. Since K is compact there exist $k_1, \dots, k_m \in K$ such that $K \subset V := B_{k_1} \cup \dots \cup B_{k_m}$. We define $U := U_{k_1} \cap \dots \cap U_{k_m}$. Since U is the intersection of finitely many open sets each of which contain x we see that U is an open neighborhood of x. Clearly we have the inclusions $\{x\} \times K \subset U \times V \subset \widetilde{W}$. □

For convenience we remind the reader of the following lemma.

Lemma 1.8. *Let X be a topological space and let $U \subset X$ be a subset. If given any $x \in U$ there exists a neighborhood V of x that is contained in U, then U is open.*

Now we can provide our alternative proof of Theorem 2.15.

Second proof of Theorem 2.15. Let $f\colon X \to Z$ be a map between topological spaces that is a quotient map. Furthermore let Y be a topological space that is locally compact. We need to show that the map

$$f \times \mathrm{id}_Y \colon X \times Y \;\to\; Z \times Y$$

is also a quotient map.

Since f is a quotient map we know by Lemma 2.14 (2) that f is continuous. Therefore it follows from Lemma 1.53 (3) that the map $f \times \mathrm{id}_Y$ is continuous. Thus it remains to show that if $W \subset Z \times Y$ is a subset such that the preimage $\widetilde{W} := (f \times \mathrm{id}_Y)^{-1}(W)$ is an open subset of $X \times Y$, then W itself is open.

We intend to use Lemma 1.8 to show that W is open. Thus let $(z, y) \in W$. We pick $x_0 \in f^{-1}(\{z\})$. We equip $\{x_0\} \times Y \subset X \times Y$ with the subspace topology. By Lemma 1.53 (3) the map

$$\begin{array}{rcl} i\colon Y & \to & \{x_0\} \times Y \\ y & \mapsto & (x_0, y) \end{array}$$

is a homeomorphism onto its image. In particular $Y_{x_0} := i^{-1}(\widetilde{W} \cap (\{x_0\} \times Y))$ is an open subset of Y. Note that $\{x_0\} \times Y_{x_0} \subset \widetilde{W}$. Since Y is locally compact we can find a compact neighborhood K_{x_0} of x_0 that is contained in Y_{x_0}. By definition of a neighborhood there exists an open subset Y'_{x_0} of Y with $x_0 \in Y'_{x_0} \subset K_{x_0}$. We define

$$U_{x_0} \;:=\; \{x \in X \mid \{x\} \times K_{x_0} \subset \widetilde{W}\}.$$

Claim. The set $f(U_{x_0})$ is an open subset of Z.

First we intend to use Lemma 1.8 to show that U_{x_0} is indeed an open subset of Y_{x_0}. Thus let $x \in U_{x_0}$. Since $\widetilde{W}$ is an open subset of $X \times Y$ and since K_{x_0} is compact it follows from Lemma 2.21 that there exist open subsets $A \subset X$ and $B \subset Y$ with $x \in A$ and $K_{x_0} \subset B$ such that $A \times B \subset \widetilde{W}$. Evidently this implies that $A \subset U_{x_0}$. Since $x \in A$ we have verified that the openness criterion of Lemma 1.8 is satisfied. We have thus shown that U_{x_0} is an open subset of Y_{x_0}.

Now we want to show that $V := f(U_{x_0})$ is an open subset of Z. By Lemma 2.20 we know that U_{x_0} is saturated with respect to f. In other words, we know that $U_{x_0} = f^{-1}(V)$. Now we use that by hypothesis $f\colon X \to Z$ is a quotient map. Since $f^{-1}(V) = U_{x_0}$ is open by (1) we obtain that V itself is open. But that is what we had wanted to show. This concludes the proof of the claim.

By definition of the product topology we obtain that $f(U_{x_0}) \times Y'_{x_0}$ is an open subset of $X \times Y$. Evidently we have $(x, y) \in f(U_{x_0}) \times Y'_{x_0}$. It remains to prove the following claim.

Claim. We have $f(U_{x_0}) \times Y'_{x_0} \subset W$.

The claim follows from the following equalities and inclusions:

$$f(U_{x_0}) \times Y'_{x_0} = (f \times \mathrm{id}_Y)(U_{x_0} \times Y'_{x_0}) \underset{\substack{\uparrow \\ \text{since } Y'_{x_0} \subset K_{x_0}}}{\subset} (f \times \mathrm{id}_Y)(U_{x_0} \times K_{x_0}) \underset{\substack{\uparrow \\ \text{definition of } U_{x_0}}}{\subset} (f \times \mathrm{id}_Y)(\widetilde{W}) \underset{\substack{\uparrow \\ \text{by Lemma 1.1 (2)} \\ \text{since by definition} \\ \widetilde{W} = (f \times \mathrm{id}_Y)^{-1}(W)}}{=} W.$$

This concludes the proof of the claim. □

Remark. A different proof of Theorem 2.15, based on Propositions 2.4 and 2.6, is given in [Hat, Lemma A.17].

Exercises for Chapter 2.

Exercise 2.1. Let X and Y be topological spaces. Suppose that Y is Hausdorff. Show that X^Y is also Hausdorff.

Exercise 2.2. Let X and Y be topological spaces. Show that the map

$$\begin{array}{rcl} X & \to & X^Y \\ x & \mapsto & \text{constant map } y \mapsto x \end{array}$$

is continuous.

Exercise 2.3. Let $n \in \mathbb{N}$. We consider the following map

$$\begin{array}{rcl} \Theta\colon \mathrm{SO}(n) & \to & \mathrm{Homeo}(S^{n-1}) := \text{self-homeomorphisms of } S^{n-1} \\ A & \mapsto & (P \mapsto A \cdot P). \end{array}$$

(a) Show that the map Θ is continuous.
(b) Show that the map Θ is a homeomorphism onto its image.

Hint: Use Lemma 1.30 (4) and Lemma 2.1.

Exercise 2.4. Let $Y = \{1, \ldots, n\}$ be a finite discrete topological space with n elements and let X be a topological space. Show there exists a homeomorphism $X^Y \cong X^n$.

Exercise 2.5. Let X and Y be topological spaces and let $A \subset X$ be a subset. We denote by $p\colon X \to X/A$ the obvious projection map. Show that $A \subset X$ is compact and closed, then the map

$$p \times \mathrm{id}_Y\colon X \times Y \to (X/A) \times Y$$

is a quotient map, in particular it is continuous.
Remark: Despite appearances this exercise has little to do with Proposition 2.19. Instead one should try to give a bare-hands proof using Lemma 2.21.

3. Topological manifolds and manifolds

In this chapter we introduce topological manifolds and study some basic properties. We also introduce smooth structures on topological manifolds. A topological manifold equipped with a smooth structure will just be called a manifold. In the literature the term "manifold" can be used with quite different conventions and meanings. So we try to state clearly the various definitions used throughout these notes. At the end, just for fun, we give the classification of 1-dimensional (topological) manifolds.

3.1. **Topological manifolds: definition and examples.** In this section we give the definition of a topological manifold. In these notes the study of topological manifolds will be one of our main objectives.

Unfortunately we first have to get the following technical and slightly annoying definition out of the way.

Definition. A topological space is called *second-countable* if there exists a countable basis for the topology.

Of course not every topological space is second-countable. For example consider $X = \mathbb{R}$, but for once equipped with the discrete topology. Since $\mathbb{R}$ is uncountable one sees almost immediately that $X = \mathbb{R}$ is not second-countable. We will use the next lemma to see that most topological spaces that we are interested in are actually second-countable.

Lemma 3.1.

(1) *Every subset of some $\mathbb{R}^n$ is second-countable.*
(2) *If X is a topological space that is second-countable, then every subset is also second-countable.*
(3) *If $X_1, \dots, X_k$ are topological spaces that are second-countable, then $X_1 \times \cdots \times X_k$ is second-countable.*
(4) *Let X be a topological space. If there exists a countable family of open subsets $\{U_i\}_{i\in I}$ such that $\bigcup_{i\in I} U_i = X$ and if each U_i is second-countable, then X itself is second-countable.*
(5) *Let X be a topological space and let $\sim$ be an equivalence relation on X. If X is second-countable and if the projection $X \to X/\sim$ is an open map, then $X/\sim$ is also second-countable.*

Proof $(*)$.

(1) This follows from the discussion on page 92.
(2) This statement follows from Lemma 1.29.
(3) This statement follows from Lemma 1.59.
(4) For each U_i we pick a countable basis $\mathcal{B}_i$ of the topology of U_i. It is straightforward to verify that $\bigcup_{i\in I} \mathcal{B}_i$ is a countable basis for the topology of X.
(5) This statement follows from Lemma 1.70. □

Now we can move on to the definition of a topological manifold.

Definition. Let X be a topological space.

(1) An *n-dimensional chart for X at a point $x \in X$* is a homeomorphism $\Phi\colon U \to V$ where U is an open neighborhood of x and
   (i) V is an open subset of $\mathbb{R}^n$ or
   (ii) V is an open subset of the half-space $H_n = \{(x_1, \dots, x_n) \in \mathbb{R}^n \mid x_n \geq 0\}$ and $\Phi(x)$ lies on $E_{n-1} = \{(x_1, \dots, x_n) \in \mathbb{R}^n \mid x_n = 0\}$.

   In the former case we say that Φ is a chart of type (i), in the latter case we say that Φ is a chart of type (ii). We refer to Figure 84 for an illustration.

(2) We say X is an *n-dimensional topological manifold*, if X is second-countable and Hausdorff, and if for every $x \in X$ there exists an n-dimensional chart $\Phi\colon U \to V$ at x.

(3) We say that a point x on a topological manifold is a *boundary point* if x does not admit a chart of type (i).[71] We denote by ∂X the set of all boundary points of X.

(4) We say a topological manifold X is *closed* if X is compact with $\partial X = \varnothing$.[72]

(5) An *n-dimensional atlas* for X is a family of n-dimensional charts $\{\Phi_i\colon U_i \to V_i\}_{i \in I}$ such that $\bigcup_{i \in I} U_i = X$.

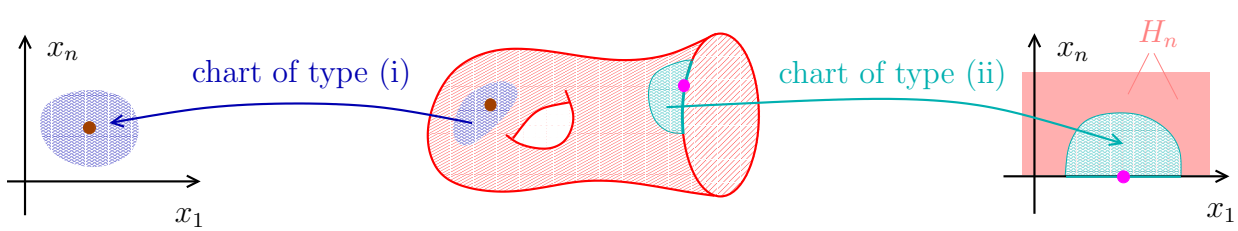

FIGURE 84.

In the following we will give several examples of topological manifolds. When it comes to verifying that a topological space is a topological manifold the main focus is usually on establishing that any point admits a chart. It is easy to forget that one also needs to verify that the topological space is second-countable and Hausdorff. In many cases this task is taken care of by the following lemma.

Lemma 3.2. *Let $n \in \mathbb{N}$. Every subset of $\mathbb{R}^n$ is second-countable and Hausdorff.*

Proof. Let A be a subset of $\mathbb{R}^n$. By Lemma 3.1 we know that A is second-countable. Furthermore, it follows from Proposition 1.13 and Lemma 1.14 that A is also Hausdorff. $\square$

[71] It might sound more natural to define a boundary point to be a point that admits a chart of type (ii). In fact we will see later that a point on a topological manifold admits *either* a chart of type (i) or a chart of type (ii). But the proof of this statement is not trivial and as of now we can not prove this statement.

[72] The latter condition just means that all points in X admit a chart of type (i).

For the record we also state the following lemma that is an immediate consequence of Lemma 3.1 (4).

Lemma 3.3. $(*)$ *If X is a topological space that admits a finite atlas, then X is second-countable.*

Now we turn to giving examples of topological manifolds.

Examples. Let $n \in \mathbb{N}$.

(1) We consider the n-dimensional sphere S^n. As usual we refer to $N := (0, \dots, 0, 1) \in S^n$ as the "North Pole" and similarly we refer to $S := (0, \dots, 0, -1) \in S^n$ as the "South Pole". It follows quite easily from slight modifications of the arguments in the proof of Lemma 1.41 that the stereographic projection $S^n \setminus \{N\} \to \mathbb{R}^n$ from the "North Pole" together with the stereographic projection $S^n \setminus \{S\} \to \mathbb{R}^n$ from the "South Pole" are two n-dimensional charts of type (i) that cover all of S^n. By Lemma 3.2 this shows that S^n is an n-dimensional topological manifold.

Note that both charts are of type (i), thus we see that the boundary of the topological manifold S^n is the empty set.[73] Finally note that S^n is compact, thus S^n is a closed n-dimensional topological manifold.

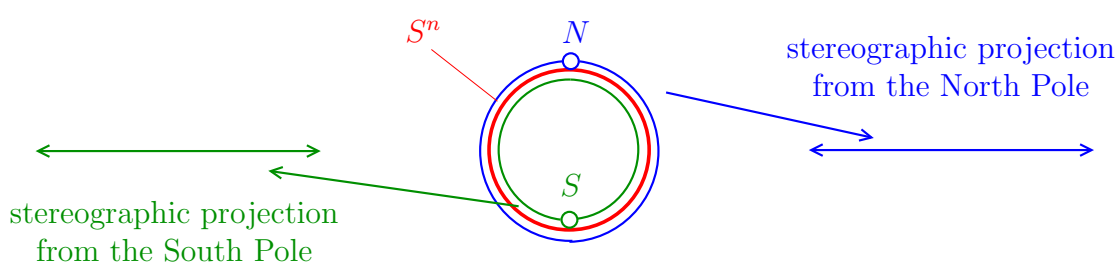

FIGURE 85.

(2) Every open subset U of $\mathbb{R}^n$ is a topological n-dimensional manifold. This follows again from Lemma 3.2 and the observation that the identity map is a chart of type (i) for all points. In particular we see that the boundary of U is empty.

(3) Let M be an open subset of the half-space $H_n = \{(x_1, \dots, x_n) \in \mathbb{R}^n \mid x_n \geq 0\}$. Again, using Lemma 3.2, it is straightforward to see that M is an n-dimensional topological manifold:

   (a) Given any point $X = (x_1, \dots, x_n) \in M$ with $x_n > 0$ the identity map on the open subset $U := \{(y_1, \dots, y_n) \in M \mid y_n > 0\}$ is a chart of type (i) around x.

[73] The vigilant reader will have noticed that we have committed a major sin: we introduced an object called "boundary" twice, with quite different meanings:

(a) On page 50 we introduced the boundary ∂A of a subset A of a topological space X.

(b) On page 171 we introduced the boundary ∂M of a topological manifold M.

Usually it is clear from the context what we mean when we write ∂.

(b) Given any point $(x_1, \ldots, x_n) \in M$ with $x_n = 0$ the identity map $M \to M$ is a chart of type (ii) around x.

In this example we run into a major, and rather painful, subtlety. Namely one would think that the boundary of M as a topological manifold should be precisely the points in M with $x_n = 0$. But at the moment we cannot draw this conclusion. After all, in principle, such points also might admit charts of type (i). Only after having introduced and studied homology groups we will see that no such charts of type (i) exist.

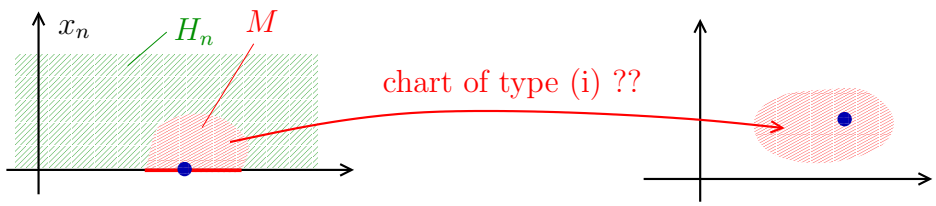

FIGURE 86.

(4) Next we want to show that the closed n-ball $\overline{B}^n$ is an n-dimensional topological manifold. We provide the following charts:

(a) We consider the chart of type (i) that is given by the identity on B^n.

(b) We set $U := \{(x_1, \ldots, x_n) \in \overline{B}^n \,|\, x_n > 0\}$ and we consider the map

$$\begin{array}{rcl} U & \to & H_n \\ (x_1, \ldots, x_n) & \mapsto & (x_1, \ldots, x_{n-1}, \sqrt{x_1^2 + \cdots + x_{n-1}^2} - x_n). \end{array}$$

This is a chart of type (ii) for all points in $\{(x_1, \ldots, x_n) \in S^{n-1} \,|\, x_n > 0\}$. We refer to Figure 87 for an illustration of this chart.

(c) We consider the obvious variations of the previous chart for $x_n < 0$ and for other coordinates.

These charts form an atlas for $\overline{B}^n$, together with Lemma 3.2 this shows that $\overline{B}^n$ is an n-dimensional topological manifold. We have found a chart of type (i) for each point in B^n and for the points on S^{n-1} we had found points of type (ii). Thus we have the strong suspicion that $\partial \overline{B}^n = S^{n-1}$ but as of right now we cannot confirm this.

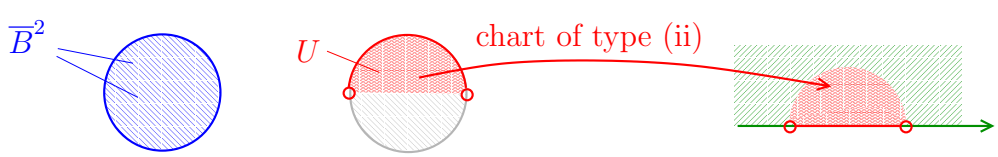

FIGURE 87.

(5) Given $a < b$ in $\mathbb{R}$ the interval $[a, b]$ is easily seen to be a 1-dimensional topological manifold. Every point in (a, b) admits a chart of type (i). Using Exercise 1.14 one can show fairly easily that the two points $a, b \in [a, b]$ do *not* admit charts of type (i). Thus the boundary of $[a, b]$ consists, as expected, of the two points a and b.

(6) In Exercise 3.1 we will verify that the line with two zeros admits a chart of type (i) for every point. It is also easy to see that the line with two zeros is second-countable. But since the line with two zeros is not Hausdorff we see that it is not a topological manifold.
(7) We consider the topological space X that is given by the set $X = \mathbb{R}$ but for once we equip $X = \mathbb{R}$ with the discrete topology. Every point of X admits a 0-dimensional chart and X is obviously Hausdorff. But X is not second-countable, thus X is not a topological manifold.
(8) We conclude this list of examples with the simplest of all examples: the empty set is a topological manifold of any dimension.

The following proposition gives a useful method for constructing more topological manifolds.

Proposition 3.4. *Let M be an m-dimensional topological manifold with possibly non-empty boundary and let N be an n-dimensional topological manifold with empty boundary. Then the following hold:*

(1) *The product $M \times N$ is an $(m+n)$-dimensional topological manifold.*
(2) *We have*[74] $\partial(M \times N) \subset \partial M \times N$.
(3) *If M and N are closed, then $M \times N$ is also closed.*

The above statements also hold with the roles of M and N reversed.

Examples.

(1) It follows from Proposition 3.4 and the above examples that for any $n \in \mathbb{N}$ the n-dimensional torus $(S^1)^n$ is a closed n-dimensional topological manifold.
(2) It follows from Proposition 3.4 and the above examples that the annulus $S^1 \times [0,1]$ is a 2-dimensional topological manifold and that $S^1 \times \overline{B}^2$ is a 3-dimensional topological manifold.

Proof $(*)$.

(1) First note that it follows from Lemma 1.55 (1) that $M \times N$ is Hausdorff and it follows from Lemma 3.1 that $M \times N$ is second-countable. One can now easily use products of charts to show that $M \times N$ is an $(m+n)$-dimensional topological manifold.
(2) The product of charts of type (i) is again a product of type (i). This immediately implies the second statement.
(3) This statement follows from (2) and Lemma 1.55 (2). □

We conclude this chapter with the following two lemmas.

Lemma 3.5. $(*)$ *Let M and N be two topological manifolds.*

(1) *If $f\colon M \to N$ is a local homeomorphism, then $f(\partial M) = (\partial N) \cap f(M)$.*

[74]Note that right now we can only prove the inclusion "$\subset$". Later on we will see that in fact we have an equality.

(2) *If $f\colon M \to N$ is in fact a homeomorphism, then f restricts to a homeomorphism $\partial M \to \partial N$.*

Proof $(*)$. The lemma follows from the elementary observation that the restriction of a chart for a point on a topological manifold has the same type as the original chart. We leave it to the reader to fill in the minuscule details. □

The following lemma is slightly more interesting than the previous lemma.

Lemma 3.6. $(*)$ *Let M be a topological manifold.*

(1) *Any union of components of ∂M is a closed subset of M. In particular ∂M itself is a closed subset of M.*
(2) *If M is compact, then ∂M is also compact.*

Proof $(*)$. Let M be a topological manifold.

(1) First note that, basically by definition, the set of points in M admitting a chart of type (i) is an open subset of M. It follows from the definition of ∂M that $M \setminus \partial M$ is an open subset. Thus the boundary ∂M is a closed subset of M. We denote by $\{Y_i\}_{i\in I}$ the components of ∂M. By Lemma 1.100 each Y_i is an open subset of ∂M. Thus for any $i \in I$ there exists, by definition of the subspace topology, an open set $Z_i \subset M$ with $Z_i \cap \partial M = Y_i$. For any $J \subset I$ we have
$$M \setminus \bigcup_{j\in J} Y_j \;=\; \underbrace{(M \setminus \partial M)}_{\text{open in } M} \;\cup\; \underbrace{\bigcup_{j\notin J} Z_j}_{\text{open in } M}.$$
We have thus shown that the union of components of ∂M corresponding to J is indeed a closed subset of M.
(2) Now suppose that M is compact. Thus ∂M is a closed subset of the compact topological space M. We obtain from Lemma 1.18 (1) that ∂M itself is compact. □

3.2. **Surfaces are topological manifolds.** The goal of this section is to prove the following proposition.

Proposition 3.7. *For any $g \in \mathbb{N}_0$ the surface of genus g is a closed 2-dimensional topological manifold.*

Proof $(*)$. We start out this proof with the discussion of the two cases $g = 0$ and $g = 1$ that we had basically dealt with already. First recall that on page 172 we saw that any S^n is a closed n-dimensional topological manifold. The surface of genus 0 is by definition the sphere S^2, thus we are done by the above. Furthermore, the surface of genus 1 is by definition the torus $S^1 \times S^1$. The desired statement thus follows from the above and Proposition 3.4.

It remains to deal with the case $g \geq 2$. To simplify the notation we prove the proposition for $g = 2$. The proof of the general case is totally analogous. We consider the octagon E_8 with the vertices $Q_k = e^{2\pi i k/16}$, $k = 1, 3, \ldots, 15$ and the equivalence relation $\sim$ that we

introduced on page 119. We illustrate the octagon together with the equivalence relation in Figure 88.

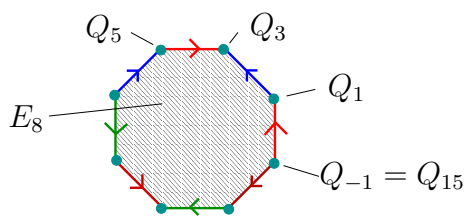

FIGURE 88.

The projection map $E_8 \to E_8/\sim$ is easily seen to be an open map. It follows from Lemma 3.1 (5) that $E_8/\sim$ is second-countable. We leave it as an exercise to verify that $E_8/\sim$ is Hausdorff. Note that E_8 is compact by the Heine-Borel Theorem 1.21. Thus we obtain from Lemma 1.37 that $E_8/\sim$ is also compact. To show that $E_8/\sim$ is a closed 2-dimensional topological manifold it remains to give an atlas for $E_8/\sim$ that consists only of charts of type (i).

First we consider the map

$$\begin{array}{rcl} \Phi\colon U := p\big(\mathring{E}_8\big) & \to & V = \mathring{E}_8 \ \subset \ \mathbb{R}^2 \\ p(X) & \mapsto & X. \end{array}$$

This is a chart of type (i) for each point in the interior of E_8.

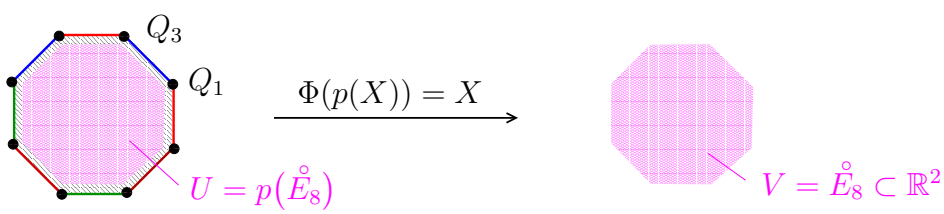

FIGURE 89.

Next we introduce charts that cover the interiors of the edges. First we consider the edge given by Q_{-1} and Q_1. We denote by U and U' the half-disks that are illustrated in Figure 90. (Note that it is understood that the line segment is included but that the circle is not included in U and U'.) Let $f\colon \mathbb{R}^2 \to \mathbb{R}^2$ be the reflection in the line that goes through Q_{-1} and Q_1. It is straightforward to verify that the map

$$\begin{array}{rcl} \Psi_1\colon p(U \ \cup \ U') & \to & \text{the open disk } U \cup f(r_{\frac{\pi}{4}}(U)) \ \subset \ \mathbb{R}^2 \\ p(X) & \mapsto & \begin{cases} X, & \text{if } X \in U \\ f(r_{\frac{\pi}{4}}(X)), & \text{if } X \in U' \end{cases} \end{array}$$

is well-defined and that it is a homeomorphism. This is a chart of type (i) for all points in the interior of the edge from Q_{-1} to Q_1. Similarly we define charts Ψ_2, Ψ_3, Ψ_4 that take care of the other pairs of edges.

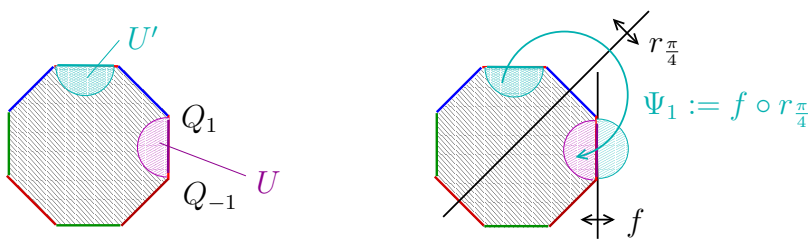

FIGURE 90.

It remains to find a chart of type (i) that takes care of the point P in $E_8/\sim$ that is represented by the vertices. (It is a fun exercise to verify that all vertices get identified.) We pick an $\eta > 0$ such that the η-disks centered at $Q_1, \dots, Q_{15}$ are disjoint. For $k = 1, 3, \dots, 15$ we set $U_k := B_\eta(Q_k) \cap E_8$. The sets $U_1, U_3, \dots, U_{15}$ are disjoint and one can easily verify that

$$p(U_1) \cup p(U_3) \cup \cdots \cup p(U_{15})$$

is an open neighborhood of $p(Q_1) = p(Q_3) = \cdots = p(Q_{15})$.

Before we write down the chart rigorously it might help to visualize the situation. To the left of Figure 91 we see the sets $U_1, \dots, U_{15}$. Next we arrange these "pieces of pie" as in the second second part of Figure 91. Thus we see the "pieces of pie" with an angle of $\frac{3\pi}{4}$ where we show the various identifications of the edges. The map from the second to the third part is given by compressing the angle of the "pieces of pie" to a third and by rotating the "pieces of pie". These eight "pieces of pie", each with an angle of $\frac{\pi}{4}$, can be combined to give a disk in $\mathbb{R}^2$.

Now we want to turn the above idea into formal mathematics. We consider the map

$$\begin{array}{rcl} \Omega\colon p(U_1) \cup \cdots \cup p(U_{15}) & \to & B^2_\eta(0) \\ p(\underbrace{Q_k + re^{i\alpha}}_{\in p(U_k)}) & \mapsto & re^{i\left(\frac{1}{3}(\alpha - \beta(k)) + \gamma(k)\right)}, \text{ for } k = 1, 3, \dots, 15, \end{array}$$

where $\beta(k)$ and $\gamma(k)$ are given by the following table:

k	1	3	5	7	9	11	13	15
$\beta(k)$	$\frac{3}{4}\pi$	π	$\frac{5}{4}\pi$	$\frac{3}{2}\pi$	$\frac{7}{4}\pi$	0	$\frac{1}{4}\pi$	$\frac{1}{2}\pi$
$\gamma(k)$	$\frac{3}{4}\pi$	π	$\frac{5}{4}\pi$	$\frac{1}{2}\pi$	$\frac{7}{4}\pi$	0	$\frac{1}{4}\pi$	$\frac{3}{2}\pi$

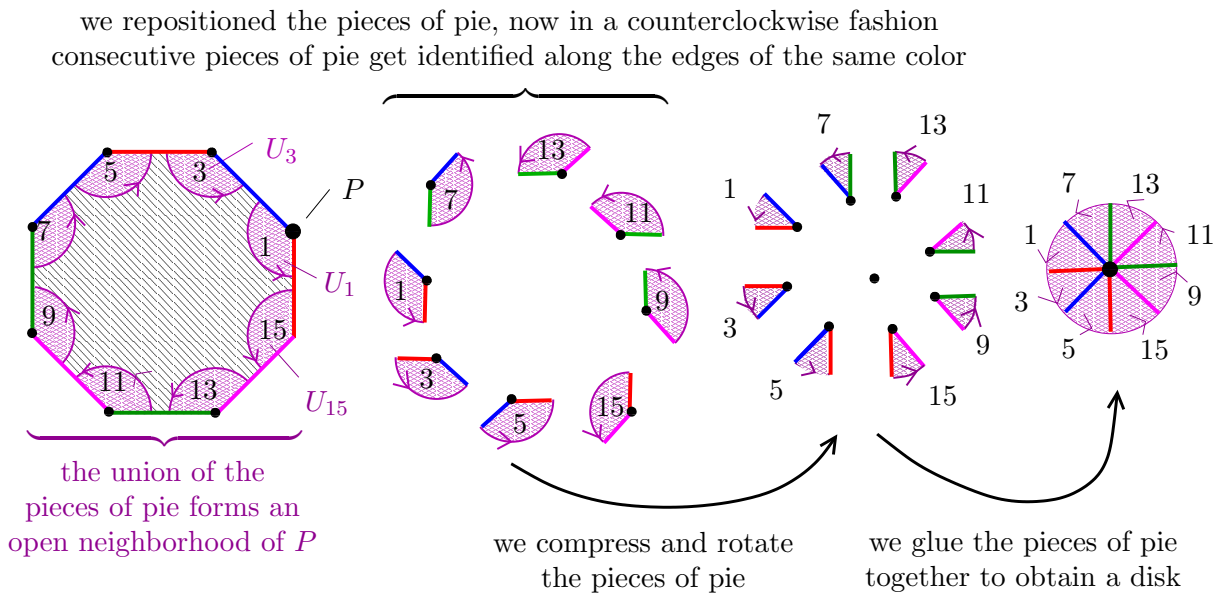

FIGURE 91.

It is fairly easily to verify that Ω is well-defined and that it is a homeomorphism. This is a chart of type (i) for P.

The eight charts $\Phi, \Psi_1, \Psi_2, \Psi_3, \Psi_4$ and Ω are now charts of type (i) that cover all of $E_8/\sim$. We have thus found the desired atlas. $\square$

3.3. **Properties of topological manifolds.** Topological manifolds are particularly important and also particularly nice topological spaces. For example the next lemma shows that when it comes to topological manifolds we do not have to worry about the two different definitions of connectedness.

Lemma 3.8.

(1) *Every topological manifold is o-locally path-connected.*
(2) *A topological manifold is connected if and only if it is path-connected.*

Throughout the lecture notes we will on many occasions make use of Lemma 3.8 (2) without referring to it explicitly.

Proof $(*)$. Let X be an n-dimensional topological manifold.

(1) Since X is o-locally homeomorphic to an open subset of $\mathbb{R}^n$ it follows easily from the fact, proved on page 131, that open subsets of $\mathbb{R}^n$ are o-locally path-connected, that X itself is o-locally path-connected. We leave it to the reader to fill in the straightforward details.
(2) The second statement is an immediate consequence of (1) and of Lemma 1.102. $\square$

On several occasions we will need the following, slightly technical lemma.

Lemma 3.9. *Let M be a topological manifold and let $\Phi\colon U \to V$ be a chart. Let $A \subset V$ be a subset that is compact. Then the corresponding subset $\Phi^{-1}(A)$ is a closed subset of M.*[75]

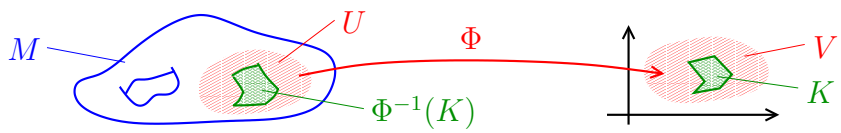

FIGURE 92. Illustration of Lemma 3.9.

Proof. Let M be a topological manifold and let $\Phi\colon U \to V$ be a chart. Let $\Psi = \Phi^{-1}\colon V \to U$ be the inverse map. Let $A \subset V$ be a subset that is compact. It follows from Lemma 1.37 that $\Psi(A)$ is a compact subset of M. But M is Hausdorff by definition of a topological manifold. Hence it follows from Lemma 1.18 (2) that $\Psi(A) = \Phi^{-1}(A)$ is closed in M. □

For completeness' sake we also mention the following much deeper theorem.

Theorem 3.10. *Every topological manifold X is* metrizable*, i.e. X admits a metric d such that the topology from the metric agrees with the given topology.*

Example. On S^1 we consider the metric that is defined by

$$d(z,w) \;=\; \min\{|s-t| \,|\, z = e^{si} \text{ and } w = e^{ti}\}.$$

Put differently, $d(z,w)$ is the length of the shortest arc from z to w. We leave it as an exercise to verify that this is a metric and that the topology defined by this metric agrees with the usual topology on S^1. Alternatively we could have taken the, much duller, Euclidean metric on $\mathbb{R}^2$, restricted to S^1.

Proof. We refer to [Mun2, Section 4.5] for a proof of the theorem. □

Next we specify what we mean by a submanifold.

Definition. Let M be an n-dimensional topological manifold.

(1) We say a subset $N \subset M$ is a *k-dimensional submanifold* if given any $P \in N$ one of the following holds:
   (α) there exists a chart $\Phi\colon U \to V$ of type (i) for M and P such that[76]
   $$\Phi(U \cap N) \;\subset\; \{(0,\ldots,0,x_1,\ldots,x_k) \,|\, x_i \in \mathbb{R}\},$$
   (β) or there exists a chart $\Phi\colon U \to V$ of type (ii) for M and P such that $\Phi(P)$ lies in E_{n-1} and
   $$\Phi(U \cap N) \;\subset\; \{(0,\ldots,0,x_1,\ldots,x_k) \in \mathbb{R}^n \,|\, x_k \geq 0\},$$

[75] It does not suffice that A is a closed subset of the topological space V. Indeed, $A = V$ is a closed subset of V, but $U = \Phi^{-1}(V)$ is in general not a closed subset of M.

[76] Why are the zeros to the left and not to the right?

(γ) or there exists a chart $\Phi\colon U \to V$ of type (i) for M and P such that $\Phi(P)$ lies in E_{n-1} and

$$\Phi(U \cap N) \ \subset \ \{(0,\dots,0,x_1,\dots,x_k) \in \mathbb{R}^n \,|\, x_k \geq 0\}.$$

We refer to such charts as *submanifold charts* of N.

(2) We say a submanifold N is *proper* if N is a closed subset of M and if for each $P \in N$ we can find submanifold charts of type (α) and (β).

We illustrate the three types of submanifold charts in Figure 93.

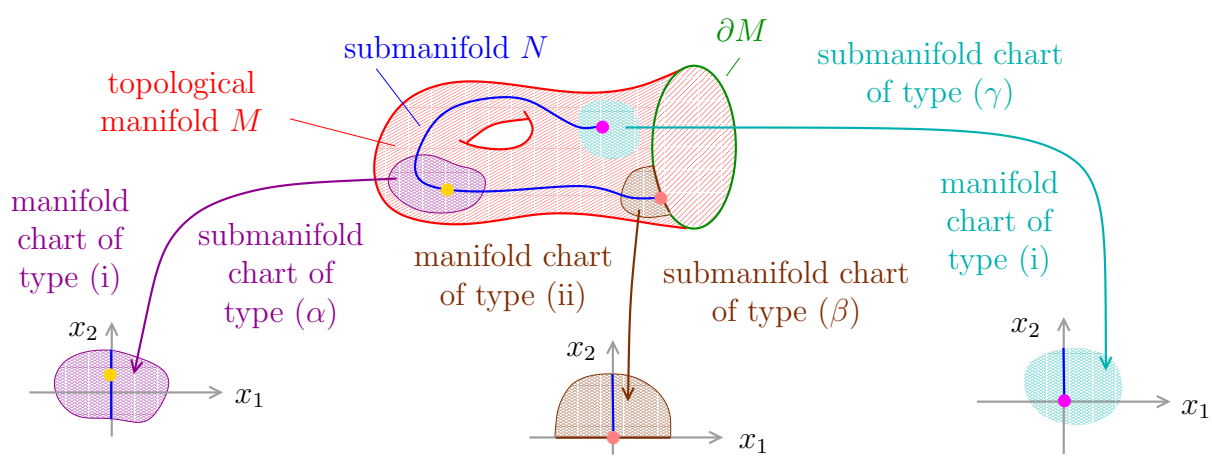

FIGURE 93.

Furthermore in Figure 94 we give typical examples of submanifolds, some of which are proper, some are not.

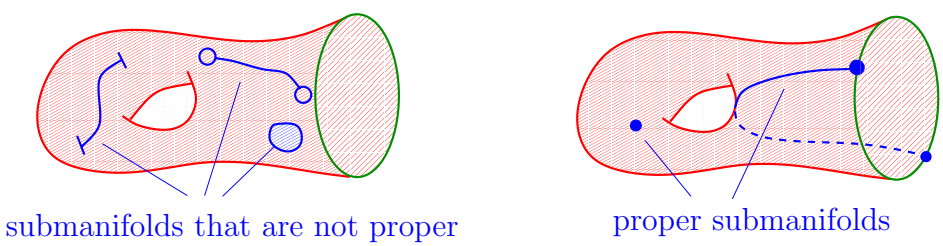

FIGURE 94.

Remark. The notion of a "submanifold" is used differently by different authors. Therefore, reading the literature it is a good idea to check what definition of a submanifold the authors use. In particular our definition of a "proper submanifold" is often used as the definition of a submanifold.

We conclude this section with the following lemma that is almost obvious.

Lemma 3.11. *Let M be a topological manifold. If $N \subset M$ is a k-dimensional submanifold, then it is also a k-dimensional topological manifold.*

Proof. It follows from Lemmas 1.14 and 3.1 that N is Hausdorff and second-countable. It is clear from the definitions that N admits a k-dimensional atlas. Thus N is indeed a k-dimensional topological manifold. □

3.4. **Manifolds.** Next we want to define smooth structures on topological manifolds. We will refer to a topological manifold that is equipped with a "smooth structure" as a manifold. One can easily fill many books with the theory of manifolds also. Since it is not our goal to write a book on manifolds we will only give a fairly quick introduction to manifolds. We refer to the many books on manifolds, e.g. [Le2, Jä3] for details.

Before we can define the notion of a smooth structure on a manifold we have to agree on what we mean by smooth maps on a subset of $\mathbb{R}^n$.

Definition.

(1) Let U be an open subset of $\mathbb{R}^n$. We say a map $f = (f_1, \dots, f_m) \colon U \to \mathbb{R}^m$ is *smooth*, if all partial derivatives, of arbitrarily large degree, of each coordinate function f_i exist.
(2) Let A be any subset of $\mathbb{R}^n$. We say a map $f \colon A \to \mathbb{R}^m$ is *smooth*, if given any $a \in A$ there exists an open neighborhood U (in $\mathbb{R}^n$) of a and a smooth map $\widetilde{f} \colon U \to \mathbb{R}^m$ which coincides with f on $A \cap U$.

Example.

(1) The function $f \colon [0, \infty) \to \mathbb{R}$ given by $f(x) = \sqrt{x}$ is not smooth, since it cannot be extended to a smooth function on any open interval (a, b) that contains 0.
(2) One can easily show that any function $f \colon \mathbb{Z} \to \mathbb{R}$ is smooth.
(3) A careful reader might have noticed that we have now given two definitions for a map $[a, b] \to \mathbb{R}^n$ to be smooth, namely besides the definition we just gave, we had also given a definition on page 134. It turns out that by Borel's Theorem, see [Strg, Theorem 4.32], these two definitions are actually the same.
(4) In the following our main interest will lie in maps defined on open subsets of the half-space $H_n = \{(x_1, \dots, x_n) \in \mathbb{R}^n \mid x_n \geq 0\}$. Thus let U be an open subset of H_n and let $f \colon U \to \mathbb{R}^m$ be a function. By a more advanced version of Borel's Theorem, see [Hör, Theorem I.1.2.6], the map f is smooth in the above sense if and only if f is continuous, if $f|_{\mathring{H}_n \cap U}$ is smooth and if all the partial derivatives of $f|_{\mathring{H}_n \cap U}$ have continuous extensions to all of U. We will not make use of this fact.

Now is a good moment to remind ourselves of the following lemma that is proved in any self-respecting analysis course, we refer to [Kön, Chapter 9] for details.

Lemma 3.12. *If $a \leq b < c \leq d$ are four real numbers, then there exists a smooth function $f \colon [a, d] \to [0, 1]$ with $f|_{[a,b]} \equiv 0$ and $f|_{[c,d]} \equiv 1$ which is strictly monotonously increasing on $[b, c]$.*

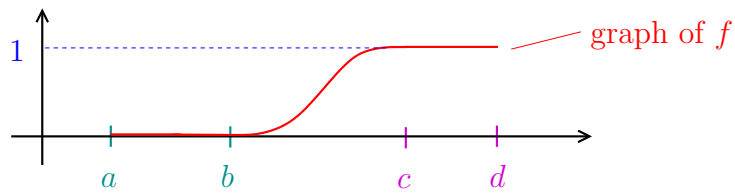

FIGURE 95.

Now we can continue with the definition of a smooth structure on a topological manifold.

Definition.

(1) An atlas $\{\Phi_i \colon U_i \to V_i\}_{i\in I}$ for an n-dimensional topological manifold X is called *smooth* if for all $i, j \in I$ the *transition map*

$$\Phi_j \circ \Phi_i^{-1} \colon \underbrace{\Phi_i(U_i \cap U_j)}_{\text{open set in } \mathbb{R}^n \text{ or } H_n} \to \underbrace{\Phi_j(U_i \cap U_j)}_{\subset \mathbb{R}^n}$$

is smooth.

(2) An *n-dimensional manifold* is a pair $(X, \mathcal{A})$ consisting of an n-dimensional topological manifold X together with a smooth atlas $\mathcal{A}$ for X. (As with many other definitions we usually suppress the choice of a smooth atlas from the notation.)

(3) We define the *boundary of a manifold* $(X, \mathcal{A})$ as the set of all points that do not admit a chart of type (i) from the given atlas $\mathcal{A}$.[77]

Remark.

(1) In the literature "topological manifolds" are sometimes referred to as "manifolds", and what we now call "manifolds" are referred to as "smooth manifolds".

(2) Rather surprisingly in 1960 Michel Kervaire [Kerv2] showed that there exists a 10-dimensional topological manifold that does not admit a smooth atlas.

The following proposition gives us interesting examples of manifolds.

Proposition 3.13. *The following topological spaces admit the structure of a manifold:*

(1) *open subsets of* $\mathbb{R}^n$,
(2) *all closed balls* $\overline{B}^n$,
(3) *all spheres* $S^n \subset \mathbb{R}^{n+1}$,
(4) *the n-dimensional torus* $(S^1)^n$,
(5) *the surfaces of genus g as defined on page 119.*

More precisely, the atlases that we provided in Section 3.1 and in the proof of Proposition 3.7 are smooth.

[77] In fact later on we will see that the boundary of a manifold in the above sense agrees with the boundary of a topological manifold. But since so far we do not have the tools to prove this statement we prefer to use this definition.

Proof (∗). It is elementary to verify that the atlases for examples (1) to (4) that we provided in Section 3.1 are smooth. It remains to consider the surfaces of genus $g \geq 2$. The atlas that we provided in the proof of Proposition 3.7 looks more dubious. In fact all transition maps are compositions of (some of) the following types of maps:

(1) reflections in lines,
(2) translations,
(3) and for some $\eta > 0$ the map

$$\begin{array}{rcl} \{re^{i\alpha} \,|\, r \in (0,\eta), \alpha \in (0, \frac{\pi}{4})\} & \to & \{re^{i\alpha} \,|\, r \in (0,\eta), \alpha \in (0, \frac{3\pi}{4})\} \\ z = re^{i\varphi} & \mapsto & re^{3i\varphi} = \frac{1}{|z|^2} \cdot z^3, \end{array}$$

(4) the inverse of (3).

It is clear that the first three types of maps are smooth. It follows from Proposition 3.20 (2) below that the fourth map is also smooth. Thus the transition maps in the atlas are smooth. □

For completeness we state the following lemma which follows easily from the definitions.

Lemma 3.14. *Let M be a manifold and let X be an open subset of M. The restrictions of the charts of the smooth atlas of M to X define a smooth atlas for X.*

We will constantly use Lemma 3.14 to view open subsets of a manifold as manifolds in their own right.

We give a few more standard definitions regarding manifolds.

Definition.

(1) A map $f\colon M \to N$ between manifolds is called *smooth* if for any chart Φ of M and any chart Ψ of N, in the respective atlases, the concatenation $\Psi \circ f \circ \Phi^{-1}$ is smooth.[78]
(2) Given two manifolds M and N we denote by $C^\infty(M, N)$ the set of all smooth maps from M to N.
(3) We say a map $f\colon M \to N$ between manifolds is a *diffeomorphism* if f is smooth, if f is a bijection and if $f^{-1}\colon N \to M$ is also smooth. If such a diffeomorphism exists, then we say that M and N are *diffeomorphic*.
(4) We say that two smooth atlases for a given topological manifold are *equivalent*, if the identity map is a diffeomorphism between the two manifolds corresponding to the smooth atlases. A *smooth structure* on a topological manifold is a choice of an equivalence class. Usually we do not distinguish between a smooth atlas and the smooth structure it represents. In particular a manifold, which by definition is a topological manifold together with a smooth atlas, is the same as a topological manifold together with a smooth structure.

[78] If M is an m-dimensional manifold and if N is an n-dimensional manifold, then the map $\Psi \circ f \circ \Phi^{-1}$ is a map from an open subset of $\mathbb{R}^m$ or from an open subset of $H_m = \{(x_1, \ldots, x_m) \,|\, x_m \geq 0\}$ to $\mathbb{R}^n$, hence the notion of smooth makes sense for such a map.

(5) Let A be a subset of a manifold M (in most applications $M = \mathbb{R}^n$), let N be a manifold and let $f\colon A \to N$ be a map. We say f is *smooth* if given any $a \in A$ there exists an open neighborhood U in M of a and a smooth map $\widetilde{f}\colon U \to N$ which coincides with f on A.[79]

Remark.

(1) There exist manifolds that are homeomorphic but not diffeomorphic. In fact John Milnor [Mi1] showed in 1956 that there exist manifolds that are homeomorphic to S^7 but that are not diffeomorphic to S^7. In other words, Milnor showed that S^7 admits at least two different smooth structures.
(2) It follows from [KSi2, p. 251] together with [KeM, Theorem 1.2] that in dimension $n \neq 4$ every topological manifold admits at most a finite number of smooth structures. (We also refer to [AMB, Chapter 7] and especially to [Sco, p. 207-224] for more details.) Amazingly, this statement is wrong in dimension 4. More precisely there is a plethora of closed topological 4-dimensional manifolds that admit an infinite number of smooth structures, see e.g. [FS2] for details.

The following harmless lemma contains three basic statements about smooth maps between manifolds.

Lemma 3.15. *Let $f\colon M \to N$ be a map between two manifolds.*

(1) *If there exists an open covering $\{U_i\}_{i\in I}$ of M such that each restriction $f|_{U_i}\colon U_i \to N$ is smooth, then f itself is smooth.*
(2) *If $f\colon M \to N$ is smooth it is also continuous.*
(3) *If $f\colon M \to N$ is a bijection (e.g. if it is a homeomorphism) and if it is a local diffeomorphism, then it is in fact a diffeomorphism.*

Proof.

(1) This statement follows from the observation that smoothness is an open condition.
(2) This statement is a straightforward consequence of Lemma 1.32 and the well-known fact that given an open set $U \subset \mathbb{R}^n$, any smooth map $U \to \mathbb{R}^m$ is also continuous. We refer to [Le2, Proposition 2.4] for more details.
(3) Let $f\colon M \to N$ be a local diffeomorphism that is a bijection. We need to show that $f^{-1}\colon N \to M$ is also smooth. But that follows immediately from (1) and our hypothesis that f is a local diffeomorphism. □

We continue with the following definition.

Definition. Given a smooth atlas $\mathcal{A}$ for a topological manifold M we define the *maximal smooth atlas* of $(M, \mathcal{A})$ to be the set of all charts of type (i) and (ii) from page 171 that are smooth maps with respect to the given smooth structure.[80]

[79] This is of course just a generalization of the definition on page 181.

[80] Let $\Phi\colon U \to V$ be a chart for M. By the convention from Lemma 3.14 we view U as a manifold. Furthermore recall that we view any open subset of $\mathbb{R}^n$ and H_n as a manifold with the obvious smooth atlas given by the identity. Thus it makes sense to ask whether or not $\Phi\colon U \to V$ is smooth.

The verification of the following lemma is left to the reader.

Lemma 3.16. *Let $(M, \mathcal{A})$ be a manifold.*

(1) *The maximal atlas of $(M, \mathcal{A})$ is a smooth atlas for M that contains $\mathcal{A}$.*
(2) *The maximal atlas of $(M, \mathcal{A})$ equals the union of all smooth atlases of M that are equivalent to the atlas $\mathcal{A}$.*

In the previous section we introduced the notion of a submanifold of a topological manifold. We add the following convention.

Convention. If M is a manifold, then we demand that in the definition of a "submanifold" on page 179 the charts come from the maximal smooth atlas.

Remark. Sometimes the above convention can be ambiguous. For example, if we consider $M = \mathbb{R}^2$ it is not clear whether we view M as a topological manifold or as a manifold. If from the context it is not clear what we mean, then we distinguish in our language between a *topological submanifold* and a *smooth submanifold*. This distinction is illustrated in Figure 96.

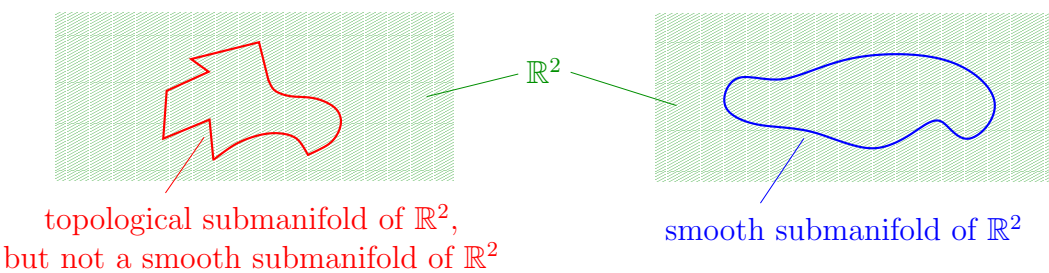

FIGURE 96.

Examples.

(1) We consider the topological manifold $M = \mathbb{R}^2$ with the smooth atlas $\mathcal{A}$ given by the identity $\Phi = \mathrm{id}_M$. Let $f\colon \mathbb{R} \to \mathbb{R}$ be a smooth function. We consider the subset $N = \{(x, f(x) \,|\, x \in \mathbb{R}\}$. We cannot use the unique chart Φ in our atlas $\mathcal{A} = \{\Phi\}$ to show that N is indeed a submanifold of the manifold $(\mathbb{R}^2, \mathcal{A})$. But the chart $\Psi\colon \mathbb{R}^2 \to \mathbb{R}^2$ given by $\Psi(x, y) = (x, y - f(x))$ lies in the maximal atlas of $(\mathbb{R}^2, \mathcal{A})$ and we can use it to verify that N is indeed a submanifold of the manifold $(\mathbb{R}^2, \mathcal{A})$.
(2) In Figure 97 we show $M = \{(x, y) \in \mathbb{R}^2 \,|\, y \geq 0\}$ together with two subsets K and $N = \{(x, x^2) \,|\, x \geq 0\}$. In Exercise 3.3 we will see that both K and N are submanifolds of the topological manifold M but that they are not submanifolds if we view M as a manifold.

Remark. As we remarked on page 180, there are various subtly different definitions of a "submanifold". This is even more pronounced when it comes to submanifolds of manifolds,

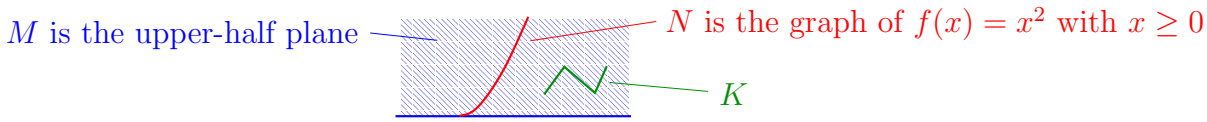

FIGURE 97.

especially if M and N are allowed to have boundary. There is no textbook that would consider K in Figure 97 as a submanifold of the manifold $M = \{(x, y) \,|\, y \geq 0\}$. As we remarked above, if we follow our convention or the convention of [Wall2, p. 31], then $N = \{(x, x^2) \,|\, x \geq 0\}$ is not a submanifold of M. On the other hand the definition used in [Le2, p. 98] or [Hirs, p. 30] views N as a submanifold of M. What we call a proper submanifold is called a neat submanifold in [Hirs, p. 30]. Sigh.

The following lemma follows almost immediately from Lemma 3.11 and the definitions. We leave it to the reader to fill in the details.

Lemma 3.17. *Let M be a manifold and let N be a submanifold of M. Then N admits a natural structure of a manifold which has the property that the inclusion map $N \to M$ is a smooth map.*

3.5. **Topological properties of manifolds.** The following proposition is usually proved in one one of the analysis courses. Since it is one of the reasons why dealing with manifolds is easier than dealing with topological manifolds we also give the proof.

Proposition 3.18.

(1) *Let $U \subset \mathbb{R}^m$ and $V \subset \mathbb{R}^n$ be open sets.*
   (a) *If $f\colon U \to V$ is a diffeomorphism, then for any $P \in U$ the differential Df_P is an invertible matrix.*
   (b) *If U and V are diffeomorphic and non-empty, then $m = n$.*

(2) *Let M be a non-empty m-dimensional manifold and let N be an n-dimensional manifold. If M and N are diffeomorphic, then $m = n$.*

Example. Suppose U is an open subset, let's say connected, of $\mathbb{R}^n$ and that $f\colon U \to \mathbb{R}^n$ is a smooth map such that Df_P is invertible for every $P \in U$. One might be tempted to think that $f\colon U \to f(U)$ is already a diffeomorphism itself. But this is not necessarily the case, a counterexample is for example given by

$$\begin{array}{rcl} f\colon \mathbb{C} \setminus \{0\} & \to & \mathbb{C} \setminus \{0\} \\ z & \mapsto & z^2. \end{array}$$

One can easily verify that Df_z is invertible for every $z \in \mathbb{C} \setminus \{0\}$. But f is evidently not injective.

Proposition 3.18 thus says, in particular, that the dimension of a non-empty manifold is well-defined. Eventually, using homology groups, we will show that the analogous statements also holds for topological manifolds.

Proof.

(1) (a) Let $f\colon U \to V$ be a diffeomorphism between open sets $U \subset \mathbb{R}^m$ and $V \subset \mathbb{R}^n$. We denote by $g\colon V \to U$ the inverse of f. Let $P \in U$. It follows from the chain rule that the matrices Df_P and $Dg_{f(P)}$ are inverses of one another, in particular Df_P is invertible.

(b) Since U is now assumed to be non-empty we can find a $P \in U$. By (1a) the $m \times n$-matrix Df_P is invertible, this means that the matrix is a square matrix, i.e. $m = n$.

(2) The second statement follows easily from the first statement by considering charts. □

The following theorem can be viewed as a partial inverse to Proposition 3.18 (1a).

Theorem 3.19. (Inverse Function Theorem) *Let $f\colon U \to V$ be a smooth map between two open subsets of $\mathbb{R}^n$ and let $P \in U$ be a point. If Df_P is invertible, then f is a local diffeomorphism at P, i.e. there exist open neighborhoods U' of P in U and V' of $f(P)$ in V such that $f|_{U'}\colon U' \to V'$ is a diffeomorphism.*

Proof. This theorem is proved in most courses on multivariable real analysis. A proof is for example given in [Le2, Corollary C.34]. □

The Inverse Function Theorem 3.19 is one of the main reasons why dealing with manifolds and smooth maps is often easier than dealing with topological manifolds and continuous maps. For example the proofs of the following two propositions rest heavily on the Inverse Function Theorem 3.19.

Proposition 3.20. (Smooth invariance of domain) *Let $U \subset \mathbb{R}^n$ be an open set and let $f\colon U \to \mathbb{R}^n$ be a smooth map such that the differential Df_P is invertible at every point P in the open set U. Then the following two statements hold:*

(1) *The map f is open, i.e. given any open subset $V \subset U$ the image $f(V)$ is an open subset of $\mathbb{R}^n$.*
(2) *If f is injective, then $f\colon U \to f(U)$ is a diffeomorphism.*

Proof. This proposition is a straightforward consequence of the Inverse Function Theorem 3.19. We leave it to the reader to fill in the few remaining details or alternatively we refer to [Le2, Corollary C.36] for a proof. □

We continue with the following, slightly subtle proposition.

Proposition 3.21. *Let X be an n-dimensional manifold, i.e. X is an n-dimensional topological manifold equipped with a smooth atlas. The following statements hold:*

(1) *Every point on X admits either a chart of type (i) from the given smooth atlas or it admits a chart of type (ii) from the given smooth atlas.*
(2) *The boundary $Y := \partial X$ has a canonical structure of an $(n-1)$-dimensional manifold with $\partial Y = \varnothing$. Furthermore the inclusion map $\partial X \to X$ is a smooth map.*

(3) (a) *Any union of components of ∂X is a closed subset of X. In particular ∂X itself is a closed subset of X.*
(b) *If X is compact, then ∂X is also compact.*

Here again we would expect that a similar statement should hold for topological manifolds. But since for topological manifolds we have fewer tools, e.g. right now we are missing an analogue of Proposition 3.20, we have to postpone a proof for topological manifolds to much later.

Proof.

(1) With a little bit of effort this statement can be deduced from Proposition 3.20. We refer to [Le2, Theorem 1.46] for the full details.
(2) The second statement is an easy consequence of the first statement.
(3) The proof of the third statement is identical to the proof of Lemma 3.6.[81] □

The following lemma is used frequently, often without noticing it.

Lemma 3.22. *Let M be an n-dimensional manifold and let X be an n-dimensional submanifold. If X is a closed subset of M (For example X could be a compact submanifold) with $X \cap \partial M = \varnothing$, then*

$$\textit{boundary of } X \textit{ as a subset of } M \;=\; \textit{boundary of } X \textit{ viewed as a manifold.}$$

In particular, the interior $\mathring{X}$ of X as a subset of M agrees with $X \setminus \partial X$ where ∂X denotes the boundary of X viewed as a manifold in its own right.

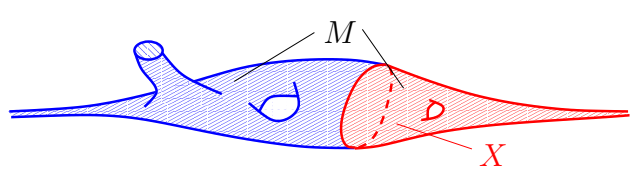

FIGURE 98. Illustration of Lemma 3.22.

[81]Note that it does not follow directly from Lemma 3.6 since our definition of the boundary of a manifold, given on page 182, is a priori different from the definition of the boundary of a topological manifold. Only later will we see that there is no difference.

Proof $(*)$. Let $P \in M$. The lemma follows from the following observations:

$$\begin{array}{ll} P \text{ lies in the boundary of } X & \overset{\text{since } X \text{ is closed}}{\overset{\downarrow}{\Longleftrightarrow}} \quad P \text{ lies on } X \text{ and every open neighborhood} \\ \text{as a subset of } M & \qquad\qquad \text{of } P \text{ contains a point in } M \setminus X \\ & \Longleftrightarrow \quad P \text{ admits a submanifold chart of type } (\gamma) \\ & \quad\uparrow \\ & \text{since } X \text{ is a submanifold of codimension zero} \\ & \Longleftrightarrow \quad P \text{ lies on the boundary of } X \text{ viewed as a manifold.} \\ & \quad\uparrow \\ & \text{Proposition 3.21 (1)} \end{array}$$

□

We continue with the following definition.

Definition. Let M be an n-dimensional manifold. We say M is *decomposed into submanifolds* $\{A_i\}_{i\in I}$ if the following conditions hold:

(1) each A_i is an n-dimensional submanifold of M,
(2) each A_i is a closed subset of M,
(3) for any $i, j \in I$ with $i \neq j$ the intersection $A_i \cap A_j$ is a union of boundary components of A_i and it is a union of boundary components of A_j,
(4) for every $i \in I$ we have

$$\text{the boundary of } A_i \text{ viewed as a manifold } = \bigcup_{j\neq i} A_i \cap A_j \ \cup \ A_i \cap \partial M.$$

This definition is illustrated in Figure 99.

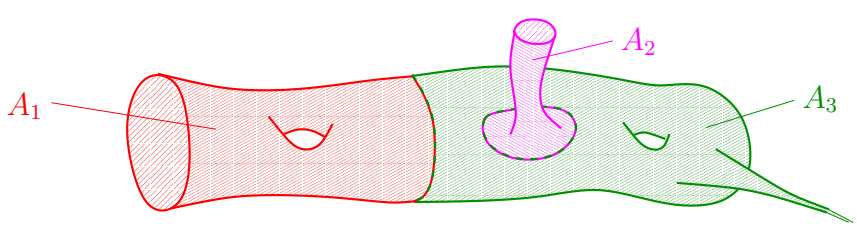

FIGURE 99.

The following lemma shows that the Klein bottle and the real projective plane admit some interesting decompositions into submanifolds.

Lemma 3.23.

(1) *We can decompose the Klein bottle into two submanifolds M and N where M and N are both diffeomorphic to the Möbius band.*
(2) *We can decompose the real projective plane into two submanifolds D and M where D is diffeomorphic to the disk $\overline{B}^2$ and M is diffeomorphic to the Möbius band.*

Proof.

(1) The proof of the first statement is sketched in Figure 100. In Figure 101 we attempt to sketch the equivalent statement that the Klein bottle is obtained from gluing two copies of the Möbius band along the common boundary.

(2) The proof of the second statement is sketched in Figure 102. Here, for $\mathbb{RP}^2$ we use the homeomorphism $\mathbb{RP}^2 \cong \overline{B}^2/\sim$ that we gave in Lemma 1.82. □

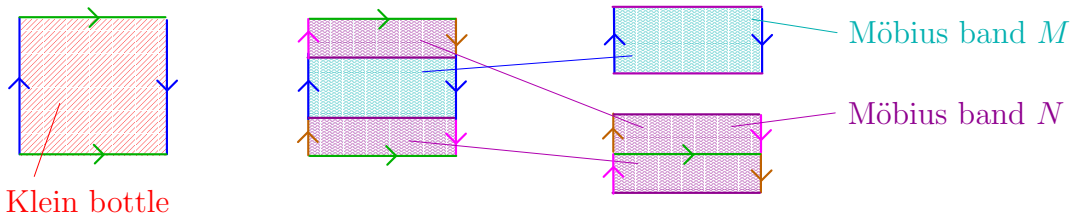

FIGURE 100.

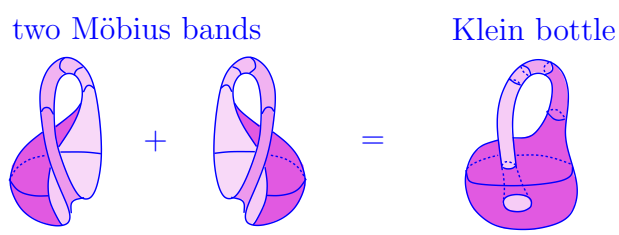

FIGURE 101.

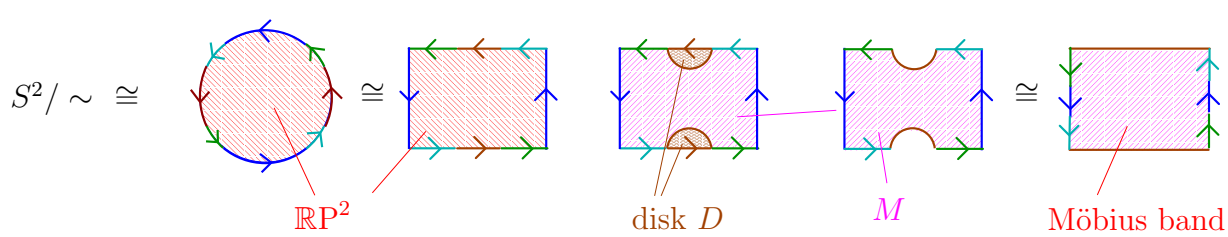

FIGURE 102.

The following proposition will be helpful on several occasions.

Proposition 3.24. *Let M be an n-dimensional manifold and let W be an n-dimensional submanifold of M with $W \cap \partial M = \varnothing$. If W is compact, then the manifold M is decomposed into the submanifolds M and $X := M \setminus \mathring{W}$. (Here the interior $\mathring{W}$ of W as a subset of M agrees with $W \setminus \partial W$ where ∂W denotes the boundary of W viewed as a manifold in its own right.)*

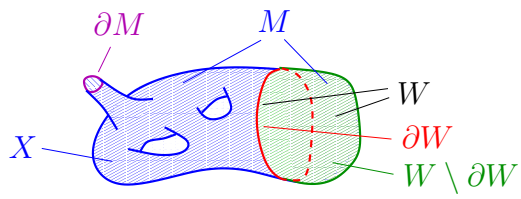

FIGURE 103. Illustration of Proposition 3.24.

Proof. First note that it is a consequence of Lemma 1.18 and the fact that manifolds are Hausdorff that W is a closed subset of M. The proposition is now a fairly immediate consequence of Lemma 3.22. We leave it to the reader to fill in the details. □

3.6. **(Topological) manifolds and group actions.** Now we return to group actions since these are one of the best ways to construct new topological spaces and (topological) manifolds.

Definition. Let M be a manifold with an action by a group G. We say that the action is *smooth* if for any $g \in G$ the map

$$\begin{array}{rcl} M & \to & M \\ x & \mapsto & g \cdot x \end{array}$$

is smooth.

Example. Basically all the actions on manifolds that we had written down so far are smooth. We will study some examples in greater detail after the next proposition.

The following proposition is the main result of this section.

Proposition 3.25. *If G is a group that acts freely, properly and continuously on an n-dimensional topological manifold M, then the following hold:*

(1) *The quotient space M/G is also an n-dimensional topological manifold and the projection map $p\colon M \to M/G$ is a local homeomorphism.*
(2) *If M is a manifold and if G acts smoothly, then there exists a unique smooth structure on M/G such that the projection map $p\colon M \to M/G$ is a local diffeomorphism.*

Furthermore, in both cases the following three statements hold:

(a) *The G-action restricts to an action on ∂M and we have $\partial(M/G) = (\partial M)/G$.*
(b) *If M is compact, then M/G is compact.*
(c) *If M is closed, then M/G is closed.*

Examples.

(1) The action

$$\begin{array}{rcl} \mathbb{Z}^n \times \mathbb{R}^n & \to & \mathbb{R}^n \\ (z, v) & \mapsto & z + v \end{array}$$

from page 103 is free, proper and smooth. It follows from Proposition 3.25 that $\mathbb{R}^n/\mathbb{Z}^n$ is an n-dimensional manifold.

(2) Using the action of $G = \mathbb{Z}$ on $M = \mathbb{R} \times [-1, 1]$ from page 105 we obtain that the Möbius band $(\mathbb{R} \times [-1, 1])/\mathbb{Z}$ is a 2-dimensional manifold. Furthermore, we have

$$\partial(\text{Möbius band}) \underset{\substack{\uparrow \\ \text{Proposition 3.25 (a)}}}{=} (\mathbb{R} \times \{-1, 1\})/\mathbb{Z} \underset{\substack{\uparrow \\ \text{see Exercise 1.39}}}{\cong} S^1.$$

(3) Finally, using the action from page 104 of $G = \{\pm 1\}$ on $M = S^n$ we obtain that the real projective space $\mathbb{R}\mathrm{P}^n = S^n/\{\pm 1\}$ is a closed n-dimensional manifold. Now let $m \leq n$. On page 111 we introduced the convention that we view $\mathbb{R}\mathrm{P}^m$ as a subset of $\mathbb{R}\mathrm{P}^n$. We leave it as an exercise to verify that $\mathbb{R}\mathrm{P}^m$ is in fact a submanifold of $\mathbb{R}\mathrm{P}^n$.

The proof of Proposition 3.25 relies on the following two somewhat technical lemmas.

Lemma 3.26. $(*)$ *Let X be a topological space and let G be a group that acts freely, properly and continuously on X. If X is Hausdorff, then for every $x \in X$ there exists an open neighborhood U such that $gU \cap U = \varnothing$ for all $g \neq e$.*

Proof of Lemma 3.26 $(*)$. Let X be a topological space that is Hausdorff. Furthermore let G be a group that acts freely, properly and continuously on X. Finally let $x \in X$. Since G acts freely we know that for every non-trivial $g \in G$ we have $gx \neq x$.

Since the action is proper and continuous we can apply Lemma 1.75 to $a = b = x$ and we obtain open neighborhoods A and B of x such that $gA \cap B = \varnothing$ for every non-trivial $g \in G$. Thus $U := A \cap B$ has the desired property □

Lemma 3.27. $(*)$ *Let X be a topological space that is Hausdorff. Furthermore let G be a group that acts continuously on X. We denote by $p\colon X \to X/G$ the projection. If $U \subset X$ is an open subset such that the map $p\colon U \to X/G$ is injective, then the map $p\colon U \to p(U)$ is a homeomorphism.*

Proof of Lemma 3.27 $(*)$. By Lemma 1.71 the projection $p\colon X \to X/G$ is continuous. Thus the restriction of p to U is also continuous. By our hypothesis the map $p\colon U \to p(U)$ is injective and evidently it is surjective. Thus the map is a bijection. By Lemma 1.71 (2) the map is furthermore open. It follows from Lemma 1.39 that the map $f\colon U \to p(U)$ is in fact a homeomorphism. □

Now we are in a position to prove Proposition 3.25. For clarity we deal with topological manifolds and manifolds separately.

Proof of Proposition 3.25 for topological manifolds. Let M be an n-dimensional topological manifold and let G be a group that acts on M. We suppose that the action is continuous, free and proper. We want to show that M/G is an n-dimensional topological manifold. Thus we need to prove the following claim.

Claim.

(1) M/G is second-countable,

(2) M/G is Hausdorff, and
(3) every point $y \in M/G$ admits an n-dimensional chart.

The first statement of the claim follows immediately from Lemma 1.71 and 3.1 (5). The second statement follows from Proposition 1.74. Thus it remains to deal with the third statement. As usual we denote by $p\colon M \to M/G$ the projection. Let $y \in M/G$. We pick an $x \in M$ with $p(x) = y$. We make the following two observations:

(a) Since M is an n-dimensional topological manifold there exists an n-dimensional chart $\Phi\colon V \to W$ with $x \in V$.
(b) By Lemma 3.26 there exists an open neighborhood U of x such that $gU \cap U \neq \varnothing$ for every $g \neq e$. Note that this implies that the restriction of $p\colon M \to M/G$ to U is injective.

After possibly replacing U and V by $U \cap V$ we can assume that $U = V$. Note that by Lemma 1.71 (2) the projection $p(U)$ is an open neighborhood of x. Now we consider the maps

$$p(U) \xrightarrow{p^{-1}} U \xrightarrow{\Phi} W.$$

The map Φ is by definition a homeomorphism. Furthermore it follows from Lemma 3.27 that the map $p\colon U \to p(U) \subset M/G$ is a homeomorphism as well. Thus the above map $\Phi \circ p^{-1}\colon p(U) \to W$ is a homeomorphism, in particular it is an n-dimensional chart for M/G that contains y. This completes the proof of the claim and thus completes the proof that M/G is an n-dimensional topological manifold.

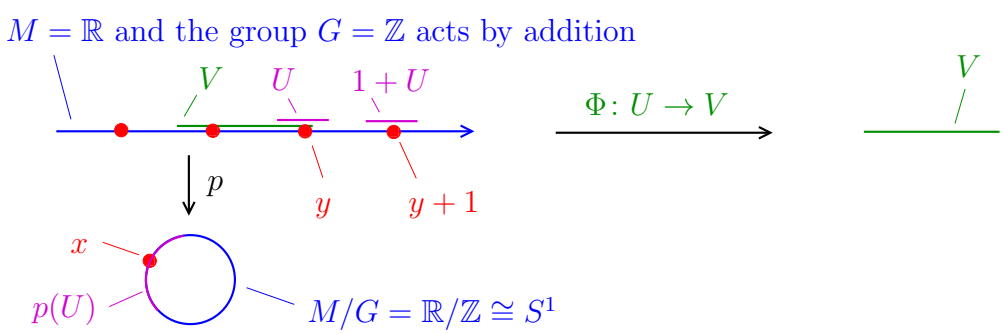

FIGURE 104. Illustration for the proof of Proposition 3.25.

It remains to prove the following claim.

Claim.

(1) The projection $p\colon M \to M/G$ is a local homeomorphism.
(2) The G-action on M restricts to an action on ∂M and we have $\partial(M/G) = (\partial M)/G$.
(3) If M is compact, then M/G is compact.
(4) If M is closed, then M/G is closed.

We turn to the proofs of these three statements.

(1) Implicitly we had already proved the first statement, indeed, given $x \in M$ we run through the above argument and we see, with the same notation, that $p(U)$ is an open subset of M/G and that $p\colon U \to p(U)$ is a homeomorphism.
(2) It follows from Lemma 3.5 (1) that the G-action on M restricts to an action on ∂M. Furthermore it follows easily from Lemma 3.5 (2) and the above statement (1) that $\partial(M/G) = (\partial M)/G$. We leave it to the reader to fill in the details.
(3) The third statement is of course just an immediate consequence of Lemma 1.37.
(4) This statement is an immediate consequence of statements (2) and (3).

This completes the proof of the second claim. □

Proof of Proposition 3.25 for manifolds $(*)$. Let $(M, \mathcal{A})$ be an n-dimensional manifold. Let G be a group that acts freely, properly and smoothly on M. We need to show that M/G admits a smooth atlas such that the projection map $p\colon M \to M/G$ is a local diffeomorphism.

(1) We run through the proof of Proposition 3.25 (1), but this time only using charts for M that lie in $\mathcal{A}$, and we obtain an atlas $\{\Phi_i\colon U_i \to V_i\}_{i\in I}$ for M/G. It is straightforward to see that any transition map $\Phi_j \circ \Phi_i^{-1}\colon \Phi_i(U_i \cap U_j) \to \Phi_j(U_i \cap U_j)$ can be written as the composition of (some) the following maps:
   (a) charts[82] and their inverses,
   (b) restrictions to open subsets,
   (c) the restriction of the action of $g \in G$ on M to some open subset.
   All these maps are smooth maps between manifolds.[83] Thus the transition maps are smooth.
(2) In the above proof of Proposition 3.25 (1) we already saw that the projection $p\colon M \to M/G$ is a local homeomorphism. It is straightforward to verify that, with our choice of a smooth atlas for M/G, the projection is in fact a local diffeomorphism.

The proof of the remaining statements (a), (b) and (c) is basically identical to the above proof for topological manifolds.

Finally, the statement that the smooth structure on M/G is uniquely determined by the smooth structure on M and the property that the projection $M \to M/G$ is a local diffeomorphism is a consequence of Lemma 3.15 (1) and the fact that the action is proper. We leave it to the reader to fill in the details. □

We conclude this section with the following amusing lemma. It gives an example of a diffeomorphism that will pop up on several occasions.

[82]Recall that we view open subsets of $\mathbb{R}^n$ as manifolds. With this convention charts are in fact diffeomorphisms between manifolds.

[83]Here the manifolds are open subsets of $\mathbb{R}^n$ or of M.

Lemma 3.28. *Let $n \in \mathbb{N}$. If $A \in \mathrm{GL}(n, \mathbb{Z})$ is a matrix, then the map*

$$\begin{array}{rcl} f(A)\colon \mathbb{R}^n/\mathbb{Z}^n & \to & \mathbb{R}^n/\mathbb{Z}^n \\ v & \mapsto & Av \end{array}$$

is a diffeomorphism.

Proof. We will provide the proof in Exercise 3.6. □

Example. We consider the map $A = \begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix} \in \mathrm{GL}(2, \mathbb{Z})$. The corresponding self-diffeomorphism $f(A)$ of $\mathbb{R}^2/\mathbb{Z}^2 = [0,1] \times [0,1]/\sim$ is illustrated in Figure 105.

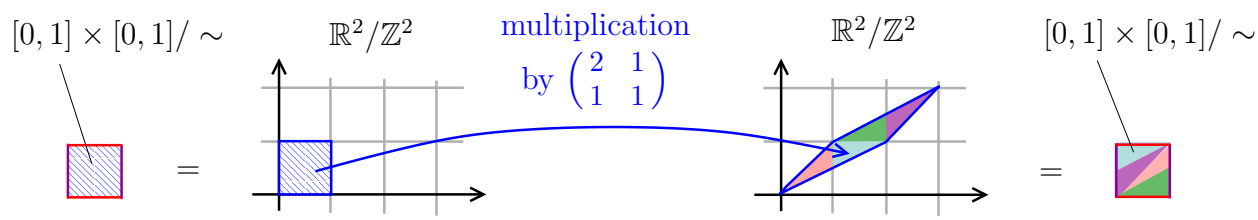

FIGURE 105.

3.7. **Tangent spaces of manifolds.** In this and the following section we introduce tangent spaces and orientations on manifolds. A more detailed account is given in most textbooks on manifolds. The following discussion is based on [Le2, Chapter 15], [Jä3, Chapter 4] and [Frie2].

Definition. Let M be a manifold and let $P \in M$.[84]

(1) A *derivation at P* is a linear map $v\colon C^\infty(M, \mathbb{R}) \to \mathbb{R}$ such that for every choice of $f, g \in C^\infty(M, \mathbb{R})$ we have

$$v(fg) \;=\; f(P) \cdot v(g) + v(f) \cdot g(P).$$

(2) The set of all derivations at P is called the *tangent space $T_P M$ at P*.

This definition of a tangent space might sound rather odd, but the following proposition should help in getting some intuition for the definition.

Proposition 3.29. *Let M be an open subset of $\mathbb{R}^n$ or of H_n. For any $P \in M$ the map*

$$\begin{array}{rcl} \mathbb{R}^n & \to & T_P M \\ v & \mapsto & \left(\begin{array}{rcl} C^\infty(M, \mathbb{R}) & \to & \mathbb{R} \\ f & \mapsto & \frac{d}{dt}\big|_{t=0} f(P + tv)) \end{array} \right) \end{array}$$

is an isomorphism of vector spaces.

[84] We should stress that we allow P to be in the boundary of M.

Proof. The proof of this proposition is an amusing exercise in real analysis. A detailed proof for the case that M is an open subset of $\mathbb{R}^n$ is given in [Le2, Proposition 3.2]. The case that M is an open subset of H_n follows fairly easily from the definition of a smooth map on H_n, see page 181. □

Convention. Given an open subset M of $\mathbb{R}^n$ or of H_n and given $P \in M$ we will use the isomorphism $\mathbb{R}^n \xrightarrow{\cong} T_P M$ from Proposition 3.29 to make the identification $T_P M = \mathbb{R}^n$.

The following proposition summarizes some basic properties of the tangent space.

Proposition 3.30.

(1) *If $f\colon M \to N$ is a smooth map, then for any $P \in M$ the map*

$$\begin{array}{rcl} Df_P = f_*\colon T_P M & \to & T_{f(P)}N \\ v & \mapsto & \left(\begin{array}{rcl} C^\infty(N,\mathbb{R}) & \to & \mathbb{R} \\ g & \mapsto & v(g\circ f) \end{array} \right) \end{array}$$

is linear. We refer to Df_P as the induced map.

(2) *The induced maps have the following two properties:*[85]
   (a) *If* $\mathrm{id}\colon M \to M$ *is the identity map, then for any $P \in M$ the induced map $D\,\mathrm{id}_P\colon T_P M \to T_P M$ is also the identity.*
   (b) *For any two smooth maps $f\colon L \to M$ and $g\colon M \to N$ between manifolds and any $P \in L$ we have*

$$D(g\circ f)_P \;=\; Dg_{f(P)} \circ Df_P\colon T_P L \;\to\; T_{(g(f(P))}N.$$

(3) *If $f\colon M \to N$ is a local diffeomorphism, then for any $P \in M$ the induced map $Df_P\colon T_P M \to T_{f(P)}N$ is an isomorphism.*

(4) *If M is an n-dimensional manifold, then for any $P \in M$ the tangent space is an n-dimensional subvector space of the vector space* $\mathrm{Hom}(C^\infty(M,\mathbb{R}),\mathbb{R})$.

Sketch of proof. The first three statements follow fairly easily from the definitions. Using charts one can reduce the proof of Statement (4) to the case that M is an open subset of $\mathbb{R}^n$ or H_n. But we had dealt with this case in Proposition 3.29. We refer to [Le2, Proposition 3.10] and [Le2, Proposition 3.6] for more details. □

There are several alternative interpretations of the tangent space of a manifold. In the following we will discuss a commonly used definition for submanifolds of $\mathbb{R}^k$.

Definition.

(1) Let M be an n-dimensional submanifold of $\mathbb{R}^k$. Given any $P \in M \setminus \partial M$ we define the *visual tangent space*

$$V_P M \;:=\; \text{all derivatives } \gamma'(0) \text{ of smooth maps } \gamma\colon (-\epsilon,\epsilon) \to M \text{ with } \gamma(0) = P.$$

This definition is illustrated in Figure 106.

[85] The reader who is already familiar with categories will notice that this statement just says that the tangent space at a point is a functor from the category of pointed manifolds to the category of real vector spaces.

(2) Let $f\colon M \to N$ be a smooth map between submanifolds of $\mathbb{R}^k$ respectively $\mathbb{R}^l$. Given any $P \in M \setminus \partial M$ with $f(P) \notin \partial N$ we define[86]

$$\begin{array}{rcl} Df_P = f_*\colon V_PM & \to & V_{f(P)}N \\ \gamma'(0) & \to & (f \circ \gamma)'(0) \end{array}$$

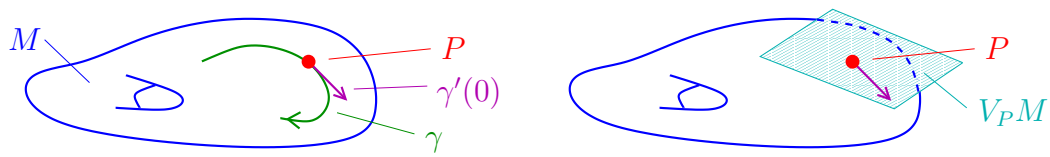

FIGURE 106.

Example.

(1) If M is an open subset of $\mathbb{R}^n$, then for any $P \in M$ we more or less evidently have $V_PM = \mathbb{R}^n$. Furthermore, if $f\colon M \to N$ is a smooth map between two open subsets of $\mathbb{R}^n$, then $Df_P\colon V_PM = \mathbb{R}^n \to V_PN = \mathbb{R}^n$ is given precisely by multiplication by the differential $Df_P \in M(n \times n, \mathbb{R})$.
(2) For $M = S^n \subset \mathbb{R}^{n+1}$ one easily shows that for any $P \in S^n$ we have the equality $V_PM = \{v \in \mathbb{R}^{n+1} \mid \langle v, P\rangle = 0\}$.

We formulate the next example as a lemma, so that later on it is easy to refer to the statement.

Lemma 3.31. $(*)$ *If $W \subset \mathbb{R}^n$ is a k-dimensional vector space, then W is a k-dimensional submanifold of $\mathbb{R}^n$ and for any $P \in W$ we have $V_PW = W$.*

Proof $(*)$. It follows from elementary linear algebra that W is a k-dimensional submanifold of $\mathbb{R}^n$. We leave it as an elementary exercise to the reader to verify that for any $P \in W$ we have $V_PW = W$. $\square$

The next proposition elucidates in particular the relationship between the tangent space T_PM and the visual tangent space V_PM of a submanifold M of $\mathbb{R}^k$.

Proposition 3.32.

(1) *The obvious analogues of the statements of Proposition 3.30 hold for the visual tangent spaces.*
(2) *Let M be an n-dimensional submanifold of $\mathbb{R}^k$ and let $P \in M \setminus \partial M$. The map*

$$\begin{array}{rcl} \Phi_M\colon V_PM & \to & T_PM \\ \gamma'(0) & \mapsto & \left(\begin{array}{rcl} C^\infty(M,\mathbb{R}) & \to & \mathbb{R} \\ f & \mapsto & \frac{d}{dt}\big|_{t=0} f(\gamma(t)) \end{array} \right) \end{array}$$

[86]Using charts and the chain rule one can show fairly easily that this map is well-defined.

is an isomorphism of vector spaces. Furthermore, if $f\colon M \to N$ is a smooth map between submanifolds of $\mathbb{R}^k$ respectively $\mathbb{R}^l$ such that $f(P) \notin \partial N$ the following diagram commutes

$$\begin{array}{ccc} V_P M & \xrightarrow{\Phi_M} & T_P M \\ {\scriptstyle f_*}\downarrow & & \downarrow{\scriptstyle f_*} \\ V_{f(P)} N & \xrightarrow{\Phi_N} & T_{f(P)} N. \end{array}$$

Proof.

(1) The proof that the obvious analogues of the statements for Proposition 3.30 hold for the visual tangent spaces is fairly elementary and is left to the reader.
(2) First note that it follows almost immediately from the definitions that the given diagram does indeed commute. It remains to show that the horizontal maps are isomorphisms. Using charts it suffices to show this for open subsets of $\mathbb{R}^n$. But in this special case that is an immediate consequence of Proposition 3.29. □

Convention. Given a submanifold M of some $\mathbb{R}^k$ and $P \in M \setminus \partial M$ we will use the isomorphism from Proposition 3.32 to make the identification $T_P M = V_P M$.

Remark.

(1) With a little bit of effort one could also define $V_P M$ for points $P \in \partial M$ and one could then extend Proposition 3.32 to this more general situation.
(2) The above reinterpretation of $T_P M$ can be generalized to any manifold. More precisely, if M is a manifold and $P \in M \setminus \partial M$ one can interpret $T_P M$ as equivalence classes of smooth paths, i.e. equivalence classes of smooth maps $\gamma\colon (-\epsilon, \epsilon) \to M$ with $\gamma(0) = P$. We refer to [Le2, p. 72] or [Jä3, Chapter 3.3] for details. The interpretation (or very often the definition) of the tangent space in terms of equivalence classes of smooth paths is very intuitive, but it has the disadvantage that it gets awkward to write down the definition of the tangent space at a point on the boundary.

The following theorem that gives a convenient criterion for a map between manifolds to be a (local) diffeomorphism.

Theorem 3.33. (Inverse Mapping Theorem) $(*)$ *Let $f\colon M \to N$ be a smooth map between two manifold.*

(1) *Let $P \in M \setminus \partial M$. If $f(P) \notin \partial N$ and if Df_P is invertible, then f is a local diffeomorphism at P, i.e. there exist open neighborhoods U of P and V of $f(P)$ such that the restriction of f to $f\colon U \to V$ is a diffeomorphism.*
(2) *If Df_P is invertible for every $P \in M$ and if f is a bijection, then f is a diffeomorphism.*

Remark. We consider the inclusion $i\colon H = \{(x, y) \in \mathbb{R}^2 \,|\, y \geq 0\} \to \mathbb{R}^2$ and the point $P = (0, 0) \in \partial H$. We see that the differential Di_P is an isomorphism, but the inclusion is

not a local diffeomorphism at P. This shows that in general we cannot drop the condition that $P \notin \partial M$.[87]

Proof.

(1) The first statement can be reduced fairly easily to the Inverse Function Theorem 3.19 that deals with maps between open subsets of some $\mathbb{R}^n$. We refer to [Le2, Theorem 4.5] for more details.
(2) The second statement follows immediately from (1) and Lemma 3.15 (3). □

3.8. **Orientations of manifolds.** In this section we introduce and study orientations of manifolds. First we need to give the following purely algebraic definition.

Definition. Let V be a finite-dimensional non-trivial real vector space. We write $k = \dim(V)$.

(1) We say that two bases[88] of V are *equivalent* if the determinant of the base change matrix is positive.
(2) An equivalence class of bases is called an *orientation* for V. An *oriented vector space* is a vector space together with an orientation.
(3) Let $\mathcal{O}$ be an orientation for V. We say $\{v_1, \dots, v_k\}$ is a *positive basis*, if $\{v_1, \dots, v_k\}$ lies in $\mathcal{O}$, otherwise we say that it is a negative basis.

Remark.

(1) It is straightforward to see that any finite-dimensional non-trivial real vector space admits precisely two orientations. Given an orientation $\mathcal{O}$ for some vector space V we denote by $-\mathcal{O}$ the other orientation.
(2) We always view $\mathbb{R}^n$ as equipped with the orientation such that the canonical basis $\{e_1, \dots, e_n\}$ is a positive basis.

Definition. Let V and W be oriented vector spaces. We say an isomorphism $\Phi\colon V \to W$ is *orientation-preserving* if the image of a positive basis of V is a positive basis of W. Otherwise we say that Φ is *orientation-reversing*.

The following lemma gets often used subconsciously:

Lemma 3.34. *Let $V_0, \dots, V_k$ be oriented vector spaces and let $f_i\colon V_i \to V_{i+1}$, $i = 0, \dots, k-1$ be isomorphisms. Then*

$$\begin{array}{c}\textit{the map } f_{k-1} \circ \cdots \circ f_0\colon V_0 \to V_k \textit{ is} \\ \textit{orientation-preserving}\end{array} \iff \begin{array}{c}\textit{the number of } f_i \textit{ which are} \\ \textit{orientation-reversing is even.}\end{array}$$

Proof. The lemma is an elementary exercise in linear algebra that is left to the reader for his or her enjoyment. □

Definition. Let M be a k-dimensional manifold with $k \geq 1$.

[87] Do we really need that $f(P) \notin \partial N$?

[88] Here and throughout the notes a basis of a finite-dimensional vector space is always understood to be an ordered basis.

(1) An *orientation for M* is a map which assigns to every tangent space T_PM, $P \in M$, an orientation such that the following condition is satisfied: [89]
   (∗) For every chart $\Phi\colon U \to V$ in the given atlas of the manifold M and any component U' of U the map

$$\begin{array}{ccccccc} \Phi_*\colon T_PM & \xleftarrow{\cong} & T_PU & \xrightarrow{\Phi_*} & T_{\Phi(P)}V & = & \mathbb{R}^k \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{isomorphisms by Proposition 3.30 (2)} & & & \text{convention on page 196} & & \end{array}$$

   is either orientation-preserving for all $P \in U'$ or it is orientation-reversing for all $P \in U'$.
(2) A manifold together with an orientation is called an *oriented manifold*.
(3) A manifold that admits an orientation is called *orientable*, otherwise we say that the manifold is *non-orientable*.

Convention.

(1) Given a picture of a 1-dimensional submanifold of $\mathbb{R}^2$ or $\mathbb{R}^3$ we indicate an orientation by drawing a positive vector (in this case a non-zero vector is already a basis for the tangent space).
(2) Given a picture of a 2-dimensional submanifold of $\mathbb{R}^3$ we often adopt one of the usual two conventions for indicating an orientation:
   (a) we draw a little circle with an arrow, this indicates that a positive basis is given by v, w where w is obtained by rotating v into the indicated direction by an angle in $(0, \pi)$,
   (b) alternatively we draw a normal vector n, in this case a basis v, w of the tangent space is positive if n, v, w is a positive basis for $\mathbb{R}^3$.

Examples.

(1) Let U be an open subset of $\mathbb{R}^n$. We equip U with the orientation where a positive basis for any tangent space $T_PU = \mathbb{R}^n$ is given by the standard basis for $\mathbb{R}^n$. Since an atlas is given by the identity map we see that this defines an orientation on U.
(2) In the following we will always view S^n as an oriented manifold with the convention that a basis $v_1, \dots, v_n \in T_PS^n = V_PS^n \subset \mathbb{R}^{n+1}$ is positive if $\det(P, v_1, \dots, v_n) > 0$.[90] For S^1 we obtain the "counterclockwise orientation". We sketch the orientations for S^1 and S^2 in Figure 107.

The next definition is basically self-explanatory.

Definition. Let $f\colon M \to N$ be a local diffeomorphism between two oriented manifolds. We say the map f is *orientation-preserving* if for any $P \in M$ the induced isomorphism $f_*\colon T_PM \to T_{f(P)}N$ is orientation-preserving.

[89] One can show fairly easily that it suffices to show that this condition holds for some family of charts that cover M. We do not need to verify it for all charts in the given atlas.

[90] How would you formulate this orientation convention purely in terms of derivations?

FIGURE 107.

The following lemma gives another approach to defining an orientation on a given manifold.

Lemma 3.35. $(*)$ *Let $(M, \mathcal{A})$ be a manifold. Suppose that all transition maps between charts in $\mathcal{A}$ are orientation-preserving. Given $P \in M$ we define*

$$\textit{orientation of } T_PM := (D\Phi_P)^{-1}(\textit{orientation of } T_{\Phi(P)}V = \mathbb{R}^n)$$

where $\Phi\colon U \to V$ is a chart around P from the given atlas. The following statements hold:

(1) *The definition of the orientation of T_PM does not depend on the choice of the chart.*
(2) *The orientations of the tangent space T_PM define an orientation for M.*

Sketch of proof $(*)$. The first statement follows easily from the hypothesis that the transition maps are orientation-preserving. The second statement is a consequence of the observation in Footnote 89. □

Example. We consider the surface Σ of genus 2. In Proposition 3.7 we gave an explicit atlas for Σ. In Proposition 3.13 we saw that the transition maps are smooth. We leave it to the reader to verify that all the transition maps are in fact orientation-preserving. Thus it follows from Lemma 3.35 that Σ is orientable. Basically the same argument shows that all surfaces of genus $g \geq 3$ are also orientable.

Lemma 3.36. *Let $f\colon X \to Y$ be a diffeomorphism between two open subsets of $\mathbb{R}^n$. Given $P \in X$ we have*[91]

$$f_* = Df_P\colon T_PX \to T_{f(P)}Y \textit{ is orientation-preserving} \iff \det(Df_P) > 0.$$

Proof. By Proposition 3.32 we have the following commutative diagram

$$\begin{tikzcd}
\mathbb{R}^n = V_PX \arrow[r, "\Phi_X"] \arrow[d, "f_*=Df_P"'] & T_PX \arrow[d, "f_*=Df_P"] \\
\mathbb{R}^n = V_{f(P)}Y \arrow[r, "\Phi_Y"] & T_{f(P)}Y.
\end{tikzcd}$$

[91]Unfortunately the symbol Df_P has several, subtly different meanings. To the left it stands for the induced map on tangent spaces. To the right it stands for the $n \times n$-matrix given by the partial derivatives of f.

where the horizontal maps are isomorphisms and where the horizontal maps are orientation-preserving by definition of the orientations of the oriented manifolds U and V. Thus it follows from Lemma 3.34 that the left-hand vertical map is orientation-preserving if and only if the right-hand vertical map is orientation-preserving. But by definition the left-hand vertical map is orientation-preserving if and only if $\det(Df_P) > 0$. □

The following lemma summarizes a few elementary properties of orientations.

Lemma 3.37. *Let M be an n-dimensional manifold*

(1) *If two orientations on M agree at a point and if M is path-connected, then the two orientations agree everywhere.*
(2) *Let $f\colon M \to N$ be a diffeomorphism. If M is path-connected, then for any $P \in M$ we have*

$$f \text{ is orientation-preserving} \iff Df_P\colon T_PM \to T_{f(P)}N \text{ is orientation-preserving.}$$

(3) *Suppose M is equipped with an orientation $\mathcal{O}$. Let $f\colon M \to M$ be a self-diffeomorphism. Then*

$$\begin{array}{c} f \text{ is orientation-preserving} \\ \text{with respect to } \mathcal{O} \end{array} \iff \begin{array}{c} f \text{ is orientation-preserving} \\ \text{with respect to } -\mathcal{O}. \end{array}$$

(4) *Let N be an open subset of M. Then N itself admits the structure of an n-dimensional manifold such that the inclusion map is a local diffeomorphism and N admits a unique orientation such that the inclusion map $N \to M$ is orientation-preserving.*
(5) *If $M \setminus \partial M$ admits an orientation, then M admits a unique orientation such that the inclusion $M \setminus \partial M \to M$ is orientation-preserving.*

Proof $(*)$.

(1) Suppose we are given two orientations on M. We denote by U the set of all points where the orientations agree and we denote by V the set of all points where the orientations disagree. It follows easily from the definitions that U and V are open. If the orientations agree at a point we see that $U \neq \varnothing$. It follows from Lemma 3.8 (2) that $U = M$.
(2) The proof of this statement is very similar to the proof of the first statement. We leave it to the reader to fill in the details.
(3) This statement follows immediately from the definitions and Lemma 3.34.
(4) This statement follows easily from Proposition 3.30.
(5) Using charts it suffices to prove this statement for manifolds that are open subsets of H_n, but in this case the statement is clear. □

The first part of the following proposition can be viewed as a refinement of Proposition 3.25.

Proposition 3.38. *Let G be a group that acts freely, properly and smoothly on an n-dimensional manifold M.*

(1) *If M is oriented and if for each $g \in G$ the map*

$$\begin{array}{rcl} M & \to & M \\ P & \mapsto & g \cdot P \end{array}$$

is orientation-preserving, then M/G admits an orientation such that the projection map $p\colon M \to M/G$ is orientation-preserving.

(2) *Conversely, if M/G admits an orientation, then there exists a unique orientation on M such that the projection map $p\colon M \to M/G$ is orientation-preserving. Furthermore this orientation has the property that the G-action on M is orientation-preserving.*

Remark. In Exercise 3.9 we will prove a partial converse to Proposition 3.9 (2).

Proof. We leave the fairly straightforward proof of the proposition as an exercise to the reader. □

Examples.

(1) Note that the differential of any translation map on $\mathbb{R}^n$ is the identity. Thus it follows from Lemma 3.37 (2) that the action of $\mathbb{Z}^n$ on $\mathbb{R}^n$ that is given by addition is orientation-preserving. It follows from Proposition 3.38 that $\mathbb{R}^n/\mathbb{Z}^n$ is orientable.

(2) In Exercise 3.4 we will see that the action of $G = \{\pm 1\}$ on S^n is orientation-preserving if and only if n is odd. It follows from Proposition 3.38 that at least for n odd the manifold $\mathbb{R}\mathrm{P}^n = S^n/\pm 1$ is orientable.

Next we intend to give examples of manifolds that are non-orientable.

Lemma 3.39. *The following manifolds are non-orientable:*

(1) *the Möbius band,*
(2) *the Klein bottle, and*
(3) *the projective plane $\mathbb{R}\mathrm{P}^2$.*

Proof. Let $X = \mathbb{R} \times (-1, 1)$ and $G = \mathbb{Z}$. Very similar to the definition on page 105 we consider the action

$$\begin{array}{rcl} \mathbb{Z} \times (\mathbb{R} \times (-1,1)) & \to & \mathbb{R} \times (-1,1) \\ (n, (x, y)) & \mapsto & (x + n, (-1)^n \cdot y). \end{array}$$

This action is again free, proper and smooth. As on page 105 we refer to the quotient as the open Möbius band.

Claim. The open Möbius band is non-orientable.

Suppose that the open Möbius band $X/\mathbb{Z}$ admits an orientation. It follows from Proposition 3.38 that $X = \mathbb{R} \times (-1, 1)$ admits an orientation such that the $\mathbb{Z}$-action is orientation-preserving. It follows from Lemma 3.37 (2) and (3) that this $\mathbb{Z}$-action preserves the

usual orientation on $X = \mathbb{R} \times (-1,1)$. Given $n \in \mathbb{Z}$ we consider the diffeomorphism of $X = \mathbb{R} \times (-1,1)$ that is given by the action by n, i.e. we consider the diffeomorphism

$$\begin{array}{rcl} \Phi_n \colon \mathbb{R} \times (-1,1) & \to & \mathbb{R} \times (-1,1) \\ (x,y) & \mapsto & (x+n, (-1)^n \cdot y). \end{array}$$

Given any $(x,y) \in X$ the differential of Φ_n is given by the matrix $\begin{pmatrix} 1 & 0 \\ 0 & (-1)^n \end{pmatrix}$. It follows from Lemma 3.36 that for n odd the diffeomorphism Φ_n is not orientation-preserving. We have thus obtained a contradiction. This concludes the proof of the claim.

We turn to the actual proof that the three given manifolds are non-orientable. By Lemma 3.37 (4) it suffices to prove the following claim.

Claim. The open Möbius band is diffeomorphic to open subsets of the Möbius band, of the Klein bottle and of the projective plane $\mathbb{R}\mathrm{P}^2$.

It is clear that the open Möbius band is an open subset of the Möbius band. The statements regarding the Klein bottle and the projective plane $\mathbb{R}\mathrm{P}^2$ follow immediately from Lemma 3.23. □

Remark. For most people starting out with mathematics the definition of a submanifold M of some $\mathbb{R}^n$ and the definition of a tangent space to M as a subvector space of $\mathbb{R}^n$ are quite natural and reasonable. But initially it is perhaps not clear why one should introduce "abstract" manifolds. Furthermore the definition on page 195 of the tangent space T_PM to such a manifold traditionally leads to a lot of head scratching.

The above proof of Lemma 3.39 is a good example why it is useful to introduce these abstract notions. In principle it is possible to show that Möbius band is non-orientable purely by working in the explicit 3-dimensional setting, see e.g. [Frie2, Lemma 9.16]. But this proof is rather messy and not very illuminating. In contrast, the fact that we can work with abstract manifolds, in this case with $(\mathbb{R} \times [-1,1])/\mathbb{Z}$, and their tangents spaces liberates us from the constraints of the 3-dimensional setting and we obtain a much clearer and much more elegant proof that the Möbius band is non-orientable.

We had just seen that odd-dimensional projective spaces are orientable and that the projective plane $\mathbb{R}\mathrm{P}^2$ is non-orientable. This raises the following question.

Question 3.40. *Is $\mathbb{R}\mathrm{P}^{2n}$ orientable for $n \geq 2$?*

In the next lemma we will see that the boundary of an oriented manifold inherits an orientation.

Lemma 3.41. *Let $n \geq 2$ and let M be an oriented n-dimensional manifold. Let $P \in \partial M$. We denote by $w \in T_PM$ a tangent vector which points into the "exterior" of M.*[92] *We say that a basis $v_1, \dots, v_{n-1}$ for $T_P(\partial M)$ is a positive basis of $T_P(\partial M)$ if $w, v_1, \dots, v_{n-1}$ is a positive basis of T_PM. The following two statements hold:*

[92] The notion of a "normal vector which points into the interior" can be made precise using charts. We leave it as an exercise to fill in the details.

(1) *The definition of a positive basis for P does not depend on the choice of w.*
(2) *These orientations of the tangent spaces of ∂M define an orientation on ∂M.*

Proof. We leave the fairly elementary verification of the lemma to the reader. Alternatively full details are given in [Le2, Proposition 15.24]. □

Convention. Let $n \geq 2$ and let M be an oriented n-dimensional manifold. Unless we say something else we always equip ∂M with the orientation given by Lemma 3.8. We refer to this orientation of ∂M as the *boundary orientation*.

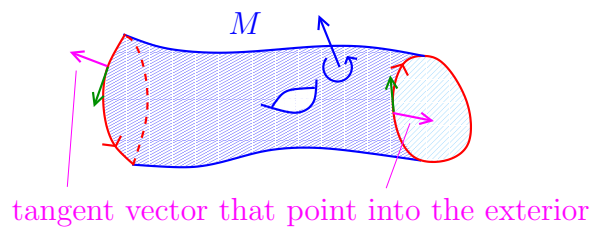

FIGURE 108.

Examples.

(1) If we equip the manifold $\overline{B}^{n+1}$ with the usual orientation coming from $\mathbb{R}^{n+1}$, then the orientation of $\partial\overline{B}^{n+1} = S^n$ agrees with the above orientation of S^n.
(2) Given an oriented manifold N we denote by $-N$ the manifold equipped with the opposite orientation. It follows easily from the definitions that $\partial(-N) = -\partial N$.

We conclude this section with the following proposition.

Proposition 3.42. $(*)$ *Let M be a manifold with possibly non-empty boundary and let N be a manifold with empty boundary. Given $Q \in N$ and $P \in M$ we consider the inclusion maps*

$$\begin{array}{rcl} i_Q\colon M & \to & M \times N \\ x & \mapsto & (x, Q) \end{array} \quad \text{and} \quad \begin{array}{rcl} j_P\colon N & \to & M \times N \\ y & \mapsto & (P, y). \end{array}$$

The following statements hold:

(1) *The product $M \times N$ admits a unique manifold structure such that products of smooth charts for M and N lie in the smooth atlas for $M \times N$.*
(2) *With the manifold structure as in* (1) *the following statements hold:*
   (a) *The projections from $M \times N$ onto M and onto N are smooth.*
   (b) *All the inclusion maps i_P and j_Q are smooth.*
(3) *If M and N are oriented, then we obtain an orientation on $M \times N$ by defining*

$$\textit{positive basis of } T_{(P,Q)}(M \times N) := \begin{array}{l} (i_Q)_*(\textit{positive basis of } T_P M), \textit{ followed by} \\ \qquad (j_P)_*(\textit{positive basis of } T_Q N). \end{array}$$

We refer to this orientation as the product orientation on $M \times N$.

(4) *We have*[93] $\partial(M \times N) = (\partial M) \times N$.
(5) *If M and N are oriented and if the dimension of M is at least two, then the equality $\partial(M \times N) = (\partial M) \times N$ from* (4) *is in fact an equality of oriented manifolds.*

All of the above statements, except for (5)*, hold also with the roles of M and N reversed.*[94]

Proof $(*)$.

(1),(2) By Proposition 3.4 we already know that $M \times N$ is a topological manifold. Furthermore it is very easy to see that the products of charts from the smooth atlases for M and for N define a smooth atlas for $M \times N$ which has the properties specified in (2).
(3) The elementary proof of this statement is left to the reader.
(4) First we want to argue that that we have the equality $\partial(M \times N) = \partial M \times N$. In Proposition 3.4 we could only show the inclusion "$\subset$". The situation is much better in the setting of manifolds since we have Proposition 3.21 (1) at our disposal. Using this proposition one can show[95] fairly easily that $\partial(M \times N) = M \times \partial N$. We also refer to [Le2, Proposition 1.45 and 2.12] for more details.
(5) It is elementary (albeit potentially slightly confusing) to deduce this statement regarding the orientations from the definitions. □

3.9. **Intersections of submanifolds**$(*)$**.** In this section we want to study the following question: given a manifold M and two submanifolds X and Y, is the intersection $X \cap Y$ again a submanifold of M? It is not difficult to show that in general the answer is negative. For example consider $M = \mathbb{R}^2$ with the two submanifolds X and Y that are shown in Figure 109. The intersection $X \cap Y$ has three components, one of which is a submanifold of dimension one, and the other two components consist of a single point. We see that $X \cap Y$ is not a manifold (after all, what would its dimension be?), in particular it is not a submanifold of M.

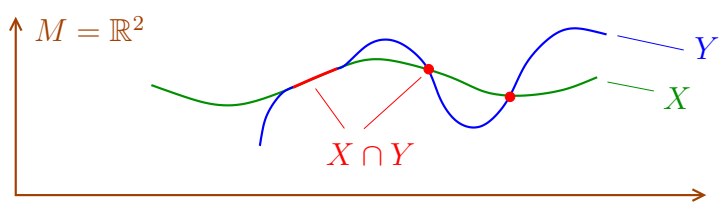

FIGURE 109.

[93]Note that here, when we are dealing with manifolds, we can determine the boundary. This is in contrast to the slightly unfortunate situation in Proposition 3.4.

[94] In Exercise 3.12 we will determine the relationship between the orientations of $\partial(M \times N)$ and $M \times \partial N$ if N is allowed to have non-empty boundary.

[95]Here we use our super subtle definition of the boundary of a manifold, see page 182.

If one spends some time pondering the question why in the previous example the intersection $X \cap Y$ is not a submanifolds, then one is inexorably led towards the following definition.

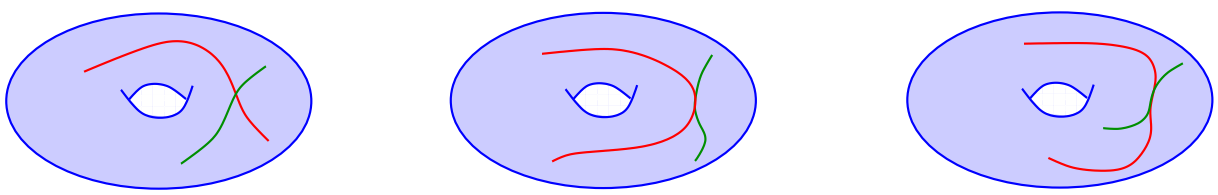
Definition. Let M be an m-dimensional manifold.[96] Let X and Y be proper submanifolds of M.

(1) Let $P \in X \cap Y$. We say P is a *transverse intersection point* if $P \notin \partial M$ and if X and Y *intersect transversally in* P, i.e. if the equality[97]

$$T_P X + T_P Y \;=\; T_P M$$

holds.

(2) We say that X and Y *intersect transversally* if each intersection point is a transverse intersection point.[98]



intersection point is transverse | intersection point is not transverse | intersection point is not transverse

FIGURE 110.

The following lemma is basically an amusing real analysis exercise.

Lemma 3.43. *Let M be an m-dimensional manifold, let $X \subset M$ a submanifold of codimension k and let Y be a submanifold of M of codimension l.*

(1) *If $P \in M$ is a transverse intersection point of X and Y, then there exists a chart $\Phi\colon U \to V$ around P with*

$$\Phi(U \cap X) = V \cap (\mathbb{R}^{m-k} \times \{0\}) \quad \textit{and} \quad \Phi(U \cap Y) = V \cap (\{0\} \times \mathbb{R}^{m-l}).$$

(2) *If the submanifolds X and Y intersect transversally, then $X \cap Y$ is a submanifold of codimension $k + l$.*

Proof.

(1) The first statement is proved in [Kos, Theorem IV.1.6] or implicitly also in [Le2, Theorem 6.30 (b)].

[96] Note that in the following we work with manifolds, we will need the smooth atlas in the definition of a transverse intersection point.

[97] Since X is a submanifold of M we can view the tangent space $T_P X$ as a subspace of $T_P M$.

[98] Note that if X and Y intersect transversally, then $X \cap Y \cap \partial M = \varnothing$.

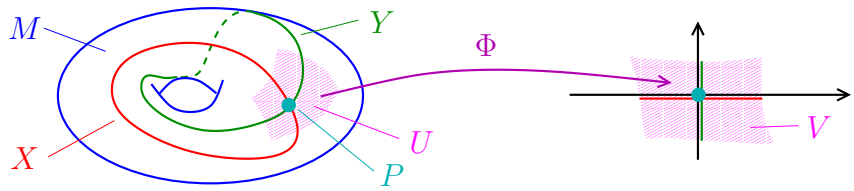


FIGURE 111. Illustration of Lemma 3.43.

(2) The second statement is an immediate consequence of the first statement. □

Example. In Figure 112 we see two infinite cylinders X and Y in the manifold $\mathbb{R}^3$. The cylinders are submanifolds of codimension one. They intersect transversally and the intersection consists of two circles, i.e. $X \cap Y$ is a one-dimensional submanifold of $\mathbb{R}^3$. Put differently, $X \cap Y$ is a submanifold of codimension two.

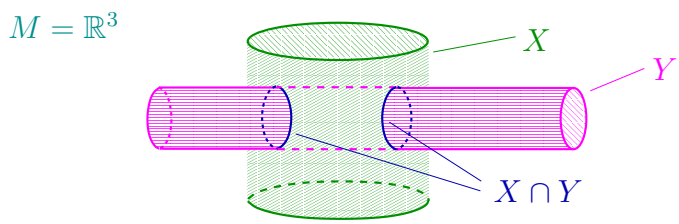

FIGURE 112.

3.10. **The Regular Value Theorem I.** In general it can be quite painful to show directly that a given object is a manifold. For example, we will shortly see that the set of orthogonal matrices $\mathrm{O}(n)$ form a manifold. But only the most enterprising reader will feel like writing down an explicit atlas.

In this section we will state the Regular Value Theorem which is a convenient way for showing that certain objects are indeed manifolds. Not surprisingly the formulation of the Regular Value Theorem is preceded by the definition of a regular value. This notion might be familiar to the reader from an earlier course on real analysis.

Definition. Let M and N be manifolds (possibly with boundary). Let $f\colon M \to N$ be a smooth map.

(1) Let $P \in M \backslash \partial M$. We say P is a *regular point* if the differential $Df_P\colon T_PM \to T_{f(P)}N$ is an epimorphism. Otherwise we say that P is a *critical point*.
(2) Let $P \in \partial M$. We say P is a *regular point* if the differential $Df_P\colon T_P(\partial M) \to T_{f(P)}N$ is an epimorphism.[99] Otherwise we say that P is a *critical point*.

[99]Note that the restriction of a map on a manifold to its boundary is also a smooth map.

(3) We say $Q \in N$ is a *regular value* if all points in the preimage $f^{-1}(Q)$ are regular. Otherwise we call Q a *critical value*.

The following elementary observation will be used several times without explicitly mentioning it.

Observation. Let $f\colon M \to N$ be a smooth map between manifolds.

(1) If $Q \in N$ is a point with $f^{-1}(Q) = \varnothing$, then Q is a regular value.
(2) If $\dim(M) < \dim(N)$, then the converse to (1) holds, thus a point $P \in N$ is a regular value if and only if $f^{-1}(P) = \varnothing$.

The following theorem is often a convenient way for showing that a given subset of a manifold, e.g. a given subset of some $\mathbb{R}^n$, is in fact a manifold.

Theorem 3.44. (Regular Value Theorem) *Let M be an m-dimensional manifold, let N be an n-dimensional manifold without boundary, let $f\colon M \to N$ be a smooth map and let $s \in N$ be a regular value of f. Then the following statements hold:*

(1) *The preimage $X := f^{-1}(s)$ is a proper $(m-n)$-dimensional submanifold of M.*
(2) *If M is orientable, then X is also orientable.*
(3) *The intersection of X with any compact set of M is compact. In particular, if M is compact, then X is also compact.*

Examples.

(1) In Figure 113 we show the torus M as a submanifold of $\mathbb{R}^3$ and we consider the "height function" $f\colon M \to \mathbb{R}$ given by $f(x,y,z) = z$. This function has precisely four critical points which are indicated in Figure 113 on the left. On the right we show a regular value s and its preimage and we show a critical value t and its preimage $f^{-1}(t)$ which in this case is *not* a submanifold.

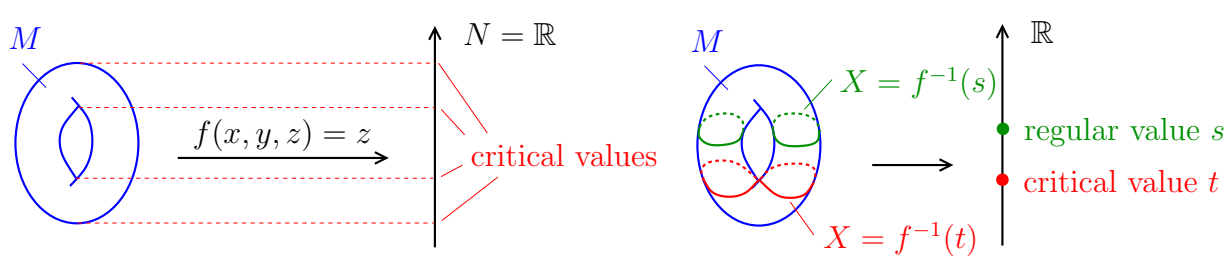

FIGURE 113. Illustration of the Regular Value Theorem 3.44.

(2) Similarly to (1) we again consider a manifold $M \subset \mathbb{R}^3$ together with the "height function". This time M has boundary and $f^{-1}(s)$ is a proper submanifold of M with non-empty boundary.

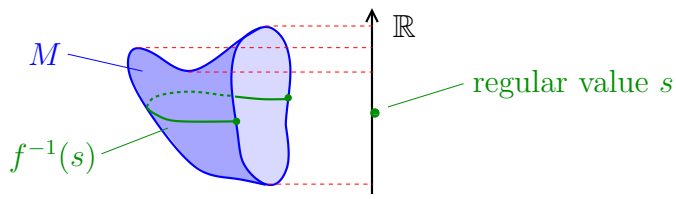

FIGURE 114. Illustration of the Regular Value Theorem 3.44.

(3) Let $g \in \mathbb{N}_0$. According to [Hirs, p. 28] there exists a polynomial function $f\colon \mathbb{R}^3 \to \mathbb{R}$ such that 0 is a regular value and such that $f^{-1}(0)$ is a surface of genus g. For example, if we take

$$f(x,y,z) \;=\; (4x^2(1-x^2)-y^2)^2 + z^2 - \tfrac{1}{4},$$

then [Hirs, p. 28] states that $f^{-1}(0)$ is a surface of genus 2.

Sketch of proof. The first statement is proved in basically every book on manifolds, see e.g. [Mi2, p. 11] or [Le2, Corollary 5.14]. The second statement is unfortunately not written down explicitly in the literature, but it can be proved without too much effort by modifying the proof of (1). The third statement follows from the observation that $f^{-1}(s)$ is a closed subset of the compact topological space M, hence it itself is compact. □

The following lemma can be viewed as a particularly interesting application of the Regular Value Theorem 3.44.

Lemma 3.45. *Let $n \in \mathbb{N}$. The set*

$$\mathrm{O}(n) \;=\; \{A \in M(n\times n,\mathbb{R}) \,|\, A^TA = \mathrm{id}\}$$

of orthogonal matrices (and thus also its component $\mathrm{SO}(n)$) is a $\frac{1}{2}n(n-1)$-dimensional submanifold of $M(n\times n,\mathbb{R}) = \mathbb{R}^{n^2}$. Furthermore the set of unitary matrices

$$\mathrm{U}(n) \;=\; \{A \in M(n\times n,\mathbb{C}) \,|\, \overline{A}^TA = \mathrm{id}\}$$

is an n^2-dimensional submanifold of $M(n\times n,\mathbb{C}) = \mathbb{C}^{n^2} = \mathbb{R}^{2n^2}$ and the set of special unitary matrices

$$\mathrm{SU}(n) \;=\; \{A \in M(n\times n,\mathbb{C}) \,|\, \overline{A}^TA = \mathrm{id} \;\; \textit{and} \;\; \det(A) = 1\}$$

is an (n^2-1)-dimensional submanifold of $M(n\times n,\mathbb{C}) = \mathbb{C}^{n^2} = (\mathbb{R}^2)^{n^2} = \mathbb{R}^{2n^2}$. All of the above examples, viewed as manifolds in their own right, are closed.

Proof. We start with a preamble: Throughout the proof we use Proposition 3.32 to identify the abstract tangent spaces T_PM with the visual tangent spaces V_PM.
Now we proceed to the actual proof of the lemma. First we prove the desired statements for $\mathrm{O}(n)$.

Claim.

(1) The set
$$\mathrm{Sym}(n,\mathbb{R}) \;=\; \{B \in M(n\times n,\mathbb{R}) \,|\, B^T = B\} \;=\; \{(b_{ij}) \in M(n\times n,\mathbb{R}) \,|\, b_{ij} = b_{ji}\}$$
is a submanifold of $M(n\times n,\mathbb{R}) = \mathbb{R}^{n^2}$ of dimension $\frac{1}{2}n(n+1)$.

(2) The map
$$\begin{array}{rcl} f\colon M(n\times n,\mathbb{R}) & \to & \mathrm{Sym}(n,\mathbb{R}) \\ A & \mapsto & A^TA \end{array}$$
is smooth and id is a regular value.

The first statement follows immediately from Lemma 3.31. We turn to the proof of the second statement. It should be clear that f is smooth and that f does indeed take values in $\mathrm{Sym}(n,\mathbb{R})$. So it remains to show that id is a regular value.

In the following we again use Lemma 3.31 which implies that the tangent spaces of the submanifolds $\mathrm{Sym}(n,\mathbb{R})$ and $M(n\times n,\mathbb{R})$ are just given by these subvector spaces. So let $A \in M(n\times n,\mathbb{R})$ with $A^TA = \mathrm{id}$ and let $C \in T_{\mathrm{id}}\,\mathrm{Sym}(n,\mathbb{R}) = \mathrm{Sym}(n,\mathbb{R})$. We need to show that there exists a B in $T_AM(n\times n,\mathbb{R}) = M(n\times n,\mathbb{R})$ with $Df_AB = C$.

We start out with the following little calculation: Given $B \in M(n,\times n,\mathbb{R})$ we have
$$\begin{aligned} \tfrac{d}{dt}\big|_{t=0} f(A+tB) &= \tfrac{d}{dt}\big|_{t=0}(A^T + tB^T)\cdot(A+tB) \\ &= \tfrac{d}{dt}\big|_{t=0}\big(A^TA + tA^TB + tB^TA + t^2B^TB\big) \;=\; A^TB + B^TA. \end{aligned}$$
Using that $A^T\cdot A = \mathrm{id}$ and $C = C^T$ it is now easy to see that $B := \frac{1}{2}A\cdot C$ satisfies $Df_AB = C$. This concludes the proof of the claim.

It follows from the claim, together with the Regular Value Theorem 3.44, that $\mathrm{O}(n)$ is a proper submanifold of $M(n\times n,\mathbb{R}) = \mathbb{R}^{n^2}$ of dimension $n^2 - \frac{1}{2}n(n+1) = \frac{1}{2}n(n-1)$. Since $\mathbb{R}^{n^2}$ has no boundary and since $\mathrm{O}(n)$ is a proper submanifold we see that the boundary of $\mathrm{O}(n)$ is also empty. Finally note that we already saw on page 86 that $\mathrm{O}(n)$ is compact. These last two observations imply that $\mathrm{O}(n)$ is in fact a closed manifold.

The proof for $\mathrm{U}(n)$ is almost verbatim the same as the proof for $\mathrm{O}(n)$. The proof for $\mathrm{SU}(n)$ requires just a little bit of extra thought. We will deal with it in Exercise 3.15. □

For later usage we introduce the notion of a submersion:

Definition. A map $f\colon M \to N$ between manifolds is called a *submersion* if f is smooth and if given any $P \in M$ the map $Df_P\colon T_PM \to T_{f(P)}N$ is an epimorphism.

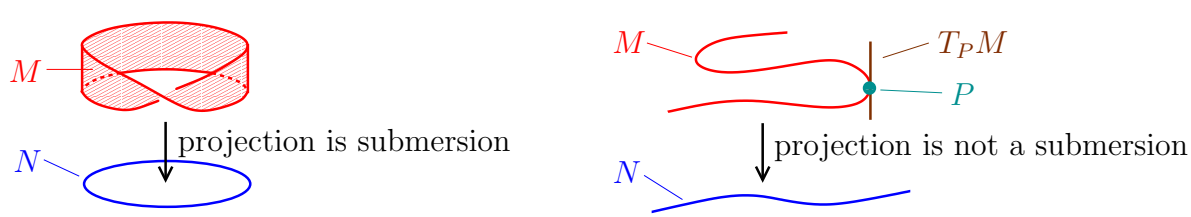

FIGURE 115.

Any projection of the form $f\colon M \times N \to N$ is evidently a submersion. The following theorem says that if C is a convex subset of $\mathbb{R}^n$, then given any compact manifold M any submersion $f\colon M \to N$ is basically precisely of that form.

Theorem 3.46. (Submersion Theorem) *Let M be a compact m-dimensional manifold, let C be an n-dimensional submanifold of $\mathbb{R}^n$ and let $f\colon M \to C$ be a surjective map. If C is a convex subset of $\mathbb{R}^n$ and if f is a submersion, then there exists a closed manifold Y and a diffeomorphism $\varphi\colon M \to C \times Y$ such that the following diagram commutes:*

$$\begin{tikzcd} M \arrow[rr, "\varphi"] \arrow[dr, "f"'] & & C \times Y \arrow[dl, "(c,y)\mapsto c"] \\ & C. & \end{tikzcd}$$

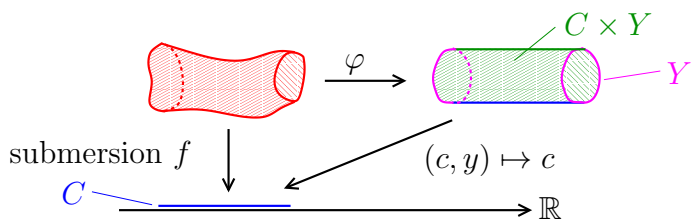

FIGURE 116. Illustration of the Submersion Theorem 3.46.

Proof. This theorem follows from the proof of [Dun, Theorem 8.5.10] or alternatively the proof of [Ebe, Theorem 4.1]. □

3.11. **Sets of measure zero and Sard's Theorem.** One can ask, whether a smooth map between manifolds always admits regular values. In this section we will formulate Sard's Theorem which gives an affirmative answer to this question.

To formulate the theorem we need the notion of a "subset of measure zero" that we will now introduce. The precise definition is not all that important, what matters in practice are the properties stated in the subsequent proposition.

Definition.

(1) A *cuboid* is any subset of $\mathbb{R}^m$ of the form $[c_1, d_1] \times \cdots \times [c_m, d_m]$. We define the volume of such a cuboid as
$$\mathrm{Vol}([c_1, d_1] \times \cdots \times [c_m, d_m]) \;=\; \prod_{i=1}^{m} (d_i - c_i).$$
(2) Let $X \subset \mathbb{R}^m$ be a subset. We say that X *has measure zero* if given any $\epsilon > 0$ there exists a countable family $\{A_i\}_{i\in I}$ of cuboids such that $X \subset \bigcup_{i\in I} A_i$ and such that $\sum_{i\in I} \mathrm{vol}(A_i) < \epsilon$. This definition is illustrated in Figure 117.
(3) Let M be an m-dimensional manifold.

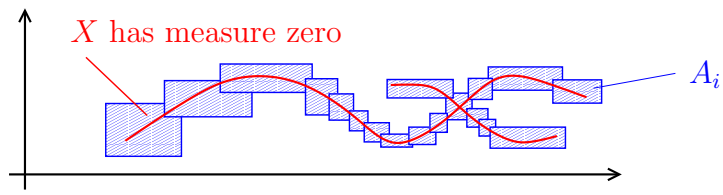

FIGURE 117.

(a) We say that a subset $X \subset M$ is a *subset of measure zero* if for any chart $\Phi\colon U \to V$ from the smooth atlas the set $\Phi(X \cap U)$ is a subset of measure zero of $\mathbb{R}^m$.
(b) We say that a subset $X \subset M$ is a *subset of full measure* if $M \setminus X$ is a subset of measure zero.

The following proposition summarizes key properties of subsets of measure zero.

Proposition 3.47. *Let M be an m-dimensional manifold.*

(1) (a) *The union of countably many subsets of measure zero is again a subset of measure zero.*
(b) *The intersection of countably many subsets of full measure is again a subset of full measure.*
(2) (a) *Given any subset X of measure zero of M the complement $M \setminus X$ is dense in M.*
(b) *Every subset of M of full measure is dense in M.*
(3) *Let X be a subset of M. If there exist charts $\{\Phi_i\colon U_i \to V_i\}_{i\in I}$ from the smooth atlas such that $\bigcup_{i\in I} U_i = M$ and such that each $\Phi_i(U_i \cap X)$ is a subset of measure zero of $\mathbb{R}^m$, then X is a subset of measure zero.*
(4) *If $f\colon M \to N$ is a smooth map between manifolds and if $\dim(M) < \dim(N)$, then $f(M)$ is a subset of measure zero in N. In other words, $N \setminus f(M)$ is a subset of full measure.*
(5) (a) *Let $f\colon M \to N$ be a smooth map between manifolds of the same dimension. If X is a subset of measure zero in M, then $f(X)$ has measure zero in N.*
(b) *If $f\colon M \to N$ is a diffeomorphism, then $X \subset M$ has full measure if and only if $f(X)$ does.*

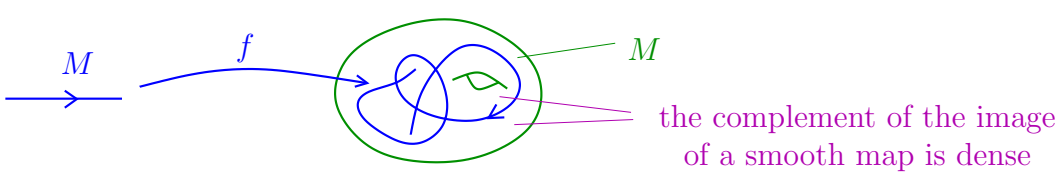

FIGURE 118. Illustration of Proposition 3.47 (2) and (4).

Sketch of proof.

(1) Let $\{X_i\}_{i\in I}$ be a countable family of subsets of measure zero of $\mathbb{R}^n$. Using the fact that $\sum_{i\in\mathbb{N}} \frac{1}{2^i} = 1$ it is straightforward to show that $\bigcup_{i\in I} X_i$ is also a subset of measure zero. Statement (1a) is an easy consequence of this observation. Statement (1b) is just a convenient reformulation of Statement (1a).

(2) Statement (2a) follows easily from the observation that a subset of $\mathbb{R}^m$ that contains an open ball $B^m_r(z)$ of radius $r > 0$ does not have measure zero. We refer to [Le2, Proposition 6.8] for more details. Once again Statement (2b) is just a reformulation of Statement (2a).

(3) This statement is proved in [Le2, Lemma 6.6].

(4) We write $m = \dim(M)$ and we write $n = \dim(N)$. We pick a countable family $\{\Phi_i \colon U_i \to V_i\}_{i\in I}$ of charts for M from the maximal smooth atlas for M such that $M = \bigcup_{i\in I} U_i$.[100] It follows easily from [Le2, Proposition 6.5] and the hypothesis that $m < n$ that every $f(\Phi_i(U_i))$ is a subset of measure zero of N. It follows from (1) that $f(M)$ is subset of measure zero of N.

(5) Statement (5a) is [Le2, Theorem 6.9]. Statement (5b) follows easily from Statement (5a). □

Now we can formulate Sard's Theorem which shows that a smooth map between manifolds always admits a plethora of regular values. The theorem is named after Arthur Sard [Sar] who first proved a similar statement in 1942.

Theorem 3.48. (Sard's Theorem) *If $f \colon M \to N$ is a smooth map between manifolds (possibly with boundary)*[101]*, then the set of critical values of f is of measure zero in N.*

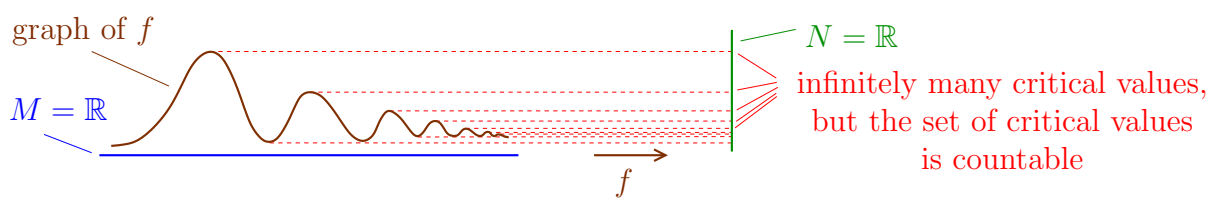

FIGURE 119. Illustration of Sard's Theorem 3.48.

Remark.

(1) As we pointed out on page 209, if $f \colon M \to N$ is a smooth map between manifolds with $\dim(M) < \dim(N)$, then a point $P \in N$ is a regular value if and only if $f^{-1}(P) = \varnothing$. It follows from this observation that Sard's Theorem 3.48 together with Proposition 3.47 (2) implies Proposition 3.47 (4).

[100] In Exercise 3.7 (2) we will show that such a countable atlas exists.

[101] We stress that M and N are allowed to have boundary, since (a) we need these cases, and (b) since many proofs in the literature assume that M and N do not have boundary.

(2) Sard's Theorem 3.48 can also be used to give one more proof of the fundamental theorem of algebra, we refer to [Bre, Corollary II.6.4] or [Mi2, p. 8] for details.

Proof. The theorem is a straightforward consequence of [Le2, Theorem 6.10]. □

3.12. **The classification of 1-dimensional (topological) manifolds** $(*)$**.** One of the goals of topology is to completely classify suitable classes of topological spaces. For example one could try to classify all connected topological manifolds of a given dimension. The following proposition gives a complete classification in the 1-dimensional case.

Proposition 3.49. *Let M be a non-empty connected 1-dimensional topological manifold. Then the homeomorphism type of M is given by the following table*[102]

	without boundary	*with boundary*
compact	*the circle* S^1	*the closed interval* $[0,1]$
non-compact	*the open interval* $(0,1)$	*the half-open interval* $[0,1)$.

Note that the adjectives "Hausdorff" and "second-countable" in the definition of a topological manifold are both necessary:

(1) The line with two zeros satisfies all axioms of a manifold except for the Hausdorff axiom.
(2) If one drops the condition that a topological manifold has to be second-countable, then there is one more example of a connected 1-dimensional topological manifold, namely the "long line", see [Gal2], [Kra, p. 66] and

`http://en.wikipedia.org/wiki/Long_line_(topology)`

Proposition 3.49 is proved in [Gal2]. In the following we only deal with the case that M is closed. Put differently, we prove the following proposition.

Proposition 3.50. *Let M be a non-empty compact connected closed 1-dimensional topological manifold. Then M is homeomorphic to S^1.*

In the proof of Proposition 3.50 we will need the following lemma.

Lemma 3.51. *Let M be a 1-dimensional topological manifold and let $\Phi\colon U \to (-2,2)$ be a chart. Let $[a,b] \subset (-2,-2)$ be a compact interval. Then $\Phi^{-1}([a,b])$ is a closed subset of M.*

Proof. Since Φ is a homeomorphism the map $\Phi^{-1}\colon (-2,2) \to U$ is also continuous. Since $[a,b]$ is compact it follows from Lemma 1.37 that $\Phi^{-1}([a,b])$ is also compact. But by Lemma 1.18 (2) any compact subspace of a Hausdorff space is closed. But M is a topological manifold, in particular M is Hausdorff. Therefore $\Phi^{-1}([a,b])$ is a closed subset of M. □

Definition. Let M be a 1-dimensional topological manifold.

[102] By Exercise 1.14 we know that the half-open interval $[0,1)$ is not homeomorphic to the open interval $(0,1)$.

(1) A *c-parametrization* for M is a homeomorphism $\Psi\colon [-1,1] \to C$ from the compact interval $[-1,1]$ to a closed subset C of M. We say the c-parametrization is *open* if $\Psi((-1,1))$ is an open subset of M.
(2) We say that two c-parametrizations Ψ and Ψ' are *almost disjoint* if
$$\Psi((-1,1)) \cap \Psi'((-1,1)) \ = \varnothing.$$
(3) A *c-atlas* is a family of c-parametrizations $\{\Psi_i\colon [-1,1] \to C_i\}_{i\in I}$ such that the union of the C_i's equals M. We call the c-atlas open if all c-parametrizations in the c-atlas are open. We say the c-atlas *almost disjoint* if any two different c-parametrizations in the c-atlas are almost-disjoint.

Using Lemma 3.51 one can prove the following lemma that is illustrated in Figure 120. We leave the proof as a voluntary exercise.

Lemma 3.52. *Let M be a 1-dimensional topological manifold and let $\Psi_1\colon [-1,1] \to C_1$ and $\Psi_2\colon [-1,1] \to C_2$ be two open c-parametrizations such that $C_1 \cap C_2$ is non-empty but such that C_2 is not contained in C_1. Then*
$$[-1,1] \setminus \Psi_1^{-1}\big(\Psi_2((-1,1)\cap C_1)\big) \ = \ [a,b]$$
for some $-1 \le a < b \le 1$.

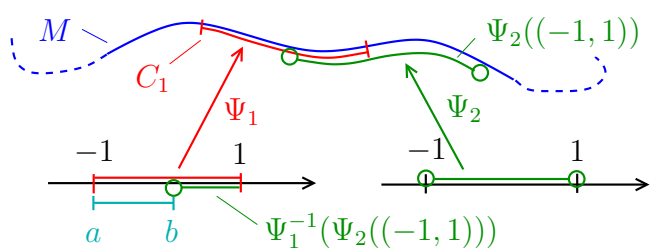

FIGURE 120. Illustration of Lemma 3.52.

Now we can provide the proof of Proposition 3.50.

Proof of Proposition 3.50. Let M be a compact connected closed 1-dimensional topological manifold. We start out with the following claim.

Claim. There exists a finite open almost-disjoint c-atlas $\Psi_i\colon [-1,1] \to C_i$ with $i = 1,\dots,k$.

Since M is assumed to be closed there exists for each $P \in M$ a chart $\Phi_P\colon U_P \to (-2,2)$ of type (i) such that $\Phi_P(P) = 0$. The open sets $\Phi_P^{-1}((-1,1))$ are an open covering of M.[103] Since M is compact there exist $P_1,\dots,P_k$ such that the open sets $\Phi_{P_i}^{-1}((-1,1))$, $i = 1,\dots,k$ are an open covering of M. It follows that the union of the sets $C_i := \Phi_{P_i}^{-1}([-1,1])$,

[103]Here we use implicitly the following fact: if U is open in M, and if V is open in U, then V is also open in M. Why is that?

$i = 1, \dots, k$ is also all of M. It follows from Lemma 3.51 that each C_i is a closed subset of M.

For $i = 1, \dots, k$ we now consider the homeomorphism Ψ_i that is given by

$$\Psi_i := \big(\Phi_{P_i}|_{C_i}\big)^{-1} \colon [-1,1] \ \xrightarrow{\cong}\ C_i.$$

By the above discussion these are open c-parametrizations. After possibly removing some c-parametrizations we can assume that no C_i is contained in any other C_j.

Now we make the following modifications to our c-atlas. If for some $i < j$ we have $\Psi_i((-1,1)) \cap \Psi_j((-1,1)) \neq \varnothing$, then it follows from Lemma 3.52 that

$$[-1,1] \setminus \Psi_i^{-1}\big(\Psi_j((-1,1)) \cap C_i\big) \ = \ [a,b]$$

for some $-1 \leq a < b \leq 1$. Now we replace Ψ_i by the map

$$[-1,1] \ \xrightarrow{\text{linear homeomorphism}}\ [a,b] \ \xrightarrow{\Psi_i}\ M.$$

Repeating this process we obtain finitely many open c-parametrizations that are furthermore almost-disjoint. These c-parametrizations form the desired c-atlas. This concludes the proof of the claim.

We say that a c-atlas is *simple* if given any $P \in M$ there exist at most two c-parametrizations that contain P.

Claim. Any almost-disjoint open c-atlas is simple.

This follows from the fact that any point P on a 1-dimensional topological manifold has the property, that given any open neighborhood U there exists an open neighborhood V of x, contained in U, such that $V \setminus \{P\}$ contains precisely two components. If a point $P \in M$ is contained in k c-parametrizations of an open almost-disjoint c-atlas, then one can easily show that P admits an open neighborhood U such that for any open neighborhood V of P contained in U the set $V \setminus \{P\}$ has at least k components. This concludes the proof of the claim.

Now let $\Psi_i \colon [-1,1] \to C_i$ and $\Psi_j \colon [-1,1] \to C_j$ be two c-parametrizations of our c-atlas such that $C_i \cap C_j$ consists of a single point. Since the c-parametrizations are almost disjoint we have $C_i \cap C_j \subset \Psi_i(\{\pm 1\})$ and $C_i \cap C_j \subset \Psi_j(\{\pm 1\})$. After possibly replacing $\Psi_i(t)$ by $\Psi_i(-t)$ and/or $\Psi_j(t)$ by $\Psi_j(-t)$ we can assume that $\Psi_i(1) = \Psi_j(-1)$. We consider the map

$$\begin{array}{rcl} \Psi \colon [-1,1] & \to & C_1 \cup C_2 \\ x & \mapsto & \begin{cases} \Psi_i(2x+1), & \text{if } x \in [-1,0], \\ \Psi_j(2x-1), & \text{if } x \in [0,1]. \end{cases} \end{array}$$

It is straightforward to verify that Ψ is a bijection and continuous. It follows from Proposition 1.40 that Ψ is in fact a homeomorphism.[104]

[104]Here we use that M is Hausdorff, hence the subset $C_i \cup C_j$ is also Hausdorff.

By iteratively applying the procedure from the previous claim to our c-atlas we obtain a finite almost-disjoint simple c-atlas[105] $\Psi_i\colon C_i \to [-1,1]$, $i = 1,\dots,k$ such that for any $i \neq j$ either $C_i \cap C_j$ is empty or it consists of two points.

Now pick a c-parametrization $\Psi_i\colon [-1,1] \to C_i$ from the c-atlas. Since M is closed and since $[-1,1]$ is not closed we see that Ψ_i is not a homeomorphism,[106] in particular $C_i \neq M$. Since M is connected[107] there exists another c-parametrization $\Psi_j\colon [-1,1] \to C_j$ such that $C_i \cap C_j \neq \varnothing$. By our choice of c-atlas the set $C_i \cap C_j$ consists of two points.

After possibly replacing $\Psi_i(t)$ by $\Psi_i(-t)$ we can assume that $\Psi_i(1) = \Psi_j(-1)$ and $\Psi_i(-1) = \Psi_j(1)$. We consider the map

$$\begin{array}{rcl} \Psi\colon [-1,1]/-1\sim 1 & \to & C_i \cup C_j \\ x & \mapsto & \begin{cases} \Psi_i(2x+1), & \text{if } x \in [-1,0], \\ \Psi_j(2x-1), & \text{if } x \in [0,1]. \end{cases} \end{array}$$

It is straightforward to verify that ψ is a bijection[108] and continuous.[109] It follows from Proposition 1.40 that Ψ is in fact a homeomorphism.

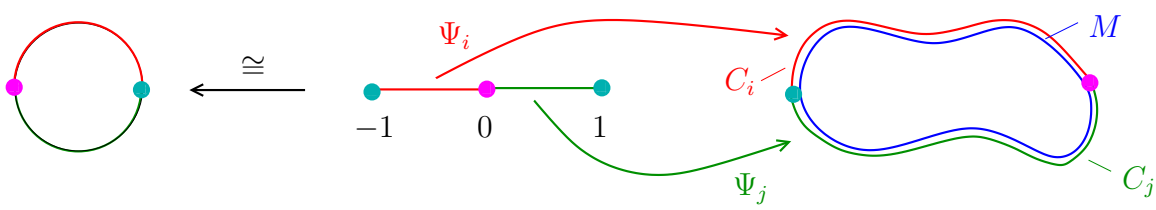

FIGURE 121.

Thus we have found a homeomorphism from $[-1,1]/-1\sim 1 = S^1$ to $C_i \cup C_j$. It remains to prove the following claim.

Claim. We have $C_i \cup C_j = M$.

The c-atlas we work with is simple and almost-disjoint. Since $\Psi_i(\pm 1) = \Psi_j(\mp 1)$ it follows that C_i and C_j did not intersect any other C_k. This shows that $C_i \cup C_j$ and $\bigcup_{k\neq i,j} C_k$ are disjoint. Since both are closed and since M is connected and since $C_i \cup C_j$ is non-empty it follows that $M = C_i \cup C_j$. □

If we consider manifolds instead of topological manifolds and diffeomorphisms instead of homeomorphisms we get the same answer. More precisely the following proposition holds.

[105]Note that we no longer claim that the resulting c-atlas is open.

[106]Careful reading shows that here we make use of the fact that a half-open interval is not homeomorphic to an open interval.

[107]Why does this follow from connectedness?

[108]Here we use that we identify -1 and 1 on the left-hand side.

[109]It is continuous at $[-1] = [1]$ since $\Psi_i(-1) = \Psi_j(1)$.

Proposition 3.53. *Let M be a non-empty connected 1-dimensional manifold. Then the diffeomorphism type of M is given by the following table*

	without boundary	*with boundary*
compact	*the circle* S^1	*the closed interval* $[0,1]$
non-compact	*the open interval* $(0,1)$	*the half-open interval* $[0,1)$.

If M has no boundary, then this proposition is proved in the appendix of [Mi2]. The case of manifolds with boundary can be reduced to the case of manifolds without boundary by first considering the interior of the manifold.

Exercises for Chapter 3.

Exercise 3.1. Show that the line with two zeros admits a chart of type (i) for every point.

Exercise 3.2. Does there exist a compact topological space that satisfies all axioms of a closed topological 1-dimensional manifold except for the Hausdorff axiom?

Exercise 3.3. In Figure 97 we show $M = \{(x,y) \,|\, y \geq 0\}$ together with two subsets K and $N = \{(x,x^2) \,|\, x \geq 0\}$. Show that both K and N are submanifolds of the topological manifold M but that they are not submanifolds if we view M as a manifold.
To make the exercise more explicit you could take K to be the union of the line segments connecting the points $(1,1)$ and $(2,2)$ and connecting the points $(2,2)$ with $(3,1)$.

Exercise 3.4. Show that the action of $G = \{\pm 1\}$ on S^n is orientation-preserving if and only if n is odd.
Hint: Use Proposition 3.32 (2) and Lemma 3.37 (2).

Exercise 3.5.

(a) Let $p\colon S^n \to \mathbb{R}^n \cup \{\infty\}$ be the stereographic projection from Lemma 1.41. It restricts to a diffeomorphism $\varphi\colon S^n \setminus \{(0,\dots,0,1)\} \to \mathbb{R}^n$. We equip both sides with the usual orientation. Show that φ is orientation-preserving if and only if n is odd.

(b) We consider the projection

$$\begin{array}{rcl} \psi\colon S^n_{>0} = \{(x_1,\dots,x_{n+1}) \in S^n \,|\, x_{n+1} > 0\} & \to & B^n \\ (x_1,\dots,x_{n+1}) & \to & (x_1,\dots,x_n). \end{array}$$

We equip both sides with the usual orientation. Show that ψ is orientation-preserving if and only if n is even.

Exercise 3.6. Provide a proof for Lemma 3.28.

Exercise 3.7.

(a) Let M be a topological manifold. Show that M admits a countable atlas.
Hint: Use that topological manifolds are second countable and use Lemma 1.26.

(b) Let M be a manifold. Show that M admits a countable atlas such that each chart lies in the maximal smooth atlas of M.

Exercise 3.8. Let M be a compact topological manifold and let $A \subset M$ be a non-empty closed subset with $A \neq M$. Show that $M \setminus A$ is not compact.
Hint: Use Theorem 3.10 and Exercise 1.28.

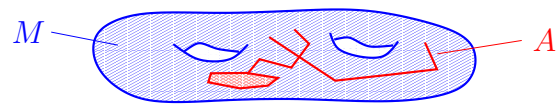

FIGURE 122. Illustration for Exercise 3.8.

Exercise 3.9. Let G be a group that acts freely, properly and smoothly on an n-dimensional oriented manifold M. Suppose that M/G is orientable.

(a) Suppose that M is path-connected. Show that every $g \in G$ acts on M in an orientation-preserving way.
Hint: Use Proposition 3.38 (2).
(b) Show that the conclusion of (a) does not hold if M is not path-connected.

Remark: This exercise can be viewed as a converse to Proposition 3.38 (1).

Exercise 3.10. Let M be a manifold. Is the boundary ∂M a submanifold of M?

Exercise 3.11. Let $M := \{(x_1, \dots, x_n) \in \mathbb{R}^n \,|\, x_1 \leq 0\}$, $N := \{(x_1, \dots, x_n) \in \mathbb{R}^n \,|\, x_1 \geq 0\}$ and $H := \{(x_1, \dots, x_n) \in \mathbb{R}^n \,|\, x_1 = 0\}$. Let $X \subset M$ be a k-dimensional topological submanifold with $\partial X = X \cap H$ and let $Y \subset N$ be a k-dimensional topological submanifold with $\partial Y = Y \cap H$. We suppose that $X \cap H = Y \cap H$. Show that $X \cup Y$ is a k-dimensional topological submanifold of $\mathbb{R}^n$.

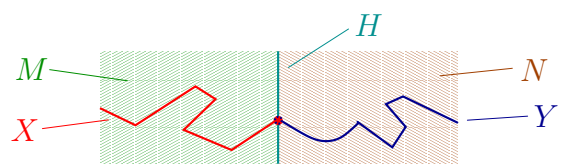

FIGURE 123. Illustration for Exercise 3.11.

Exercise 3.12. Let M be an m-dimensional manifold with possibly non-empty boundary and let N be an n-dimensional manifold with empty boundary. We equip the product manifolds $M \times N$ and $N \times M$ with the product orientations as defined in Proposition 3.4.

(a) Show that the diffeomorphism

$$\begin{array}{rcl} M \times N & \to & N \times M \\ (x, y) & \mapsto & (y, x) \end{array}$$

is orientation-preserving if and only if $m \cdot n$ is even.

(b) We equip ∂M and $N \times M$ with the boundary orientation and we equip $N \times \partial M$ with the product orientation. Show that we have the following equality of *oriented* manifolds:

$$\partial(N \times M) \;=\; \begin{cases} N \times \partial M, & \text{if } n \text{ is even,} \\ -(N \times \partial M), & \text{if } n \text{ is odd.} \end{cases}$$

Exercise 3.13. Let $f\colon M \to N$ be a smooth map between two manifolds.

(a) Show that the set of regular points of f is an open subset of M.

(b) Let $v \in N$ be a regular value such that $f^{-1}(v)$ is finite. We assume that M is compact. Show that there exists an open neighborhood U of v such that each point in U is a regular value.

(c) Show that in general the set of regular values of f is not an open subset of N.

Exercise 3.14. Let $n \in \mathbb{N}$.

(a) Show that

$$\mathrm{GL}(n, \mathbb{R}) \;=\; \{A \in M(n \times n, \mathbb{R}) \mid \det(A) \neq 0\}$$

is a manifold of dimension n^2.

(b) Show that

$$\mathrm{SL}(n, \mathbb{R}) \;=\; \{A \in M(n \times n, \mathbb{R}) \mid \det(A) = 1\}$$

is a manifold of dimension $n^2 - 1$.

Exercise 3.15. Show that

$$\mathrm{SU}(n, \mathbb{R}) \;=\; \left\{A \in M(n \times n, \mathbb{C}) \,\middle|\, \overline{A}^T A = \mathrm{id} \text{ and } \det(A) = 1\right\}$$

is a manifold of dimension $n^2 - 1$.

4. How can we show that two topological spaces are not homeomorphic?

In the previous two sections we collected many examples of topological spaces. In many cases it was relatively straightforward to see that two topological spaces are homeomorphic. For example we wrote down an explicit homeomorphism from $\mathbb{R}^n/\mathbb{Z}^n$ to $(S^1)^n$. Sometimes it is rather painful to explicitly write down a homeomorphism, for example it was not particularly easy to find a homeomorphism from the open cube $(0,1)^n$ to the open ball $B^n = \{x \in \mathbb{R}^n \mid \|x\| < 1\}$. Nonetheless, if two topological spaces are homeomorphic, then usually one can write down an explicit homeomorphism.

On the other hand, how can we tell that two topological spaces are not homeomorphic? There are a couple of trivial criteria: being compact, connected, Hausdorff are properties of topological spaces that are shared by homeomorphic topological spaces. This implies for example that the closed cube $[0,1]^n$ is not homeomorphic to the open cube $(0,1)^n$, since the former topological space is compact and the latter is not.

But these criteria are of no use when it comes to studying more subtle examples. For example they do not suffice to address the following questions:

(1) Can surfaces with different genera be homeomorphic?
(2) Given $k \in \mathbb{Z}_{\geq 0}$ we denote by U the complement of k points in $\mathbb{R}^2$. If $k \neq l$, is it possible that U_k and U_l are homeomorphic?
(3) Is the complement of the trefoil homeomorphic to the complement of the trivial knot?

In each case we suspect that the answer is no. Certainly we do not succeed in finding a homeomorphism, but how can we show that this is not due to lack of imagination, but that there is indeed no homeomorphism?

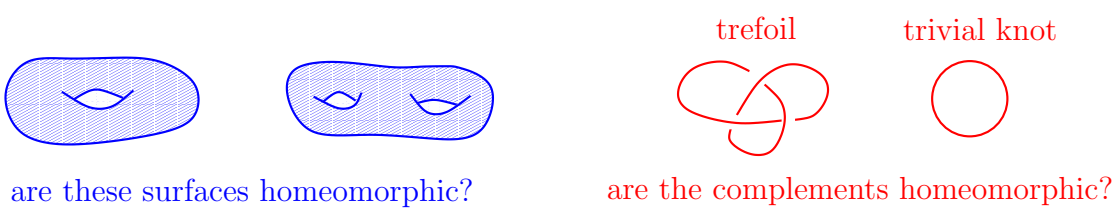

Figure 124.

The reader might have encountered some ideas for tackling these questions in one or both of the following topics:

(a) Differential forms on manifolds, in particular de Rham cohomology, as developed say in [BT, Le2].
(b) Complex analysis, see e.g. [Lan, Jä2].

For the reader who has seen differential forms and de Rham cohomology we recall that each manifold M and each $k \in \mathbb{Z}_{\geq 0}$ we can assign the de Rham cohomology group $H^k_{dR}(M)$. It

follows more or less from the definition that diffeomorphic manifolds have isomorphic de Rham cohomology groups. This approach has several disadvantages:

(1) the de Rham cohomology groups are only defined for manifolds,
(2) the de Rham cohomology groups can only be used to show that two manifolds are not *diffeomorphic*, a priori they cannot be used to show that two manifolds are not *homeomorphic*,
(3) at least just starting from the definition it is not clear how one can calculate the de Rham cohomology groups of a given manifold.

Later on we will introduce "singular cohomology" which will take care of all of these three issues.

Next we give some definitions that are familiar to the reader who has taken a course on complex analysis.

(1) Given a subset U of $\mathbb{C}$, we defined a *path* in U to be a map $\gamma\colon [a,b] \to U$. If $\gamma(a) = \gamma(b)$, then we say that γ is a *loop*.
(2) Two paths $\gamma_0, \gamma_1\colon [a,b] \to U$ with the same starting point $P := \gamma_0(a) = \gamma_1(a)$ and the same endpoint $Q := \gamma_0(b) = \gamma_1(b)$ are called *path-homotopic in* U, if there exists a map
$$\begin{array}{rcl} \Gamma\colon [a,b] \times [0,1] & \to & U \\ (t,s) & \mapsto & \Gamma(t,s), \end{array}$$
with the following properties
   (a) for every $t \in [a,b]$ we have
$$\Gamma(t,0) \;=\; \gamma_0(t) \text{ and } \Gamma(t,1) \;=\; \gamma_1(t),$$
   (b) for every $s \in [0,1]$ we have
$$\Gamma(a,s) \;=\; P \quad \text{ and } \Gamma(b,s) \;=\; Q.$$
   Put differently, a path-homotopy between two paths consists of a "continuous" family of paths $\{\Gamma(-,s)\}_{s\in[0,1]}$ from P to Q which interpolates between the paths γ_0 and γ_1. In Figure 125 we illustrate a path-homotopy between two paths.
(3) A loop $\gamma\colon [a,b] \to U$ is called *null-homotopic* if it is path-homotopic to the constant path given by $\delta(t) := \gamma(a)$ for all $t \in [a,b]$.
(4) We say U is *simply connected* if U is non-empty and if each loop is null-homotopic.

Example. Every loop in $\mathbb{R}^2 = \mathbb{C}$ is null-homotopic. Indeed, we let $\gamma\colon [0,1] \to \mathbb{C}$ be a loop with starting and endpoint P. Then
$$\begin{array}{rcl} \Gamma\colon [a,b] \times [0,1] & \to & \mathbb{R}^n \\ (t,s) & \mapsto & \gamma(t)\cdot(1-s) + P\cdot s \end{array}$$
is a path-homotopy between the loop γ and the constant path at P. The fact that every loop in $\mathbb{C}$ is null-homotopic is illustrated in Figure 126.

Now we recall the following definition from complex analysis.

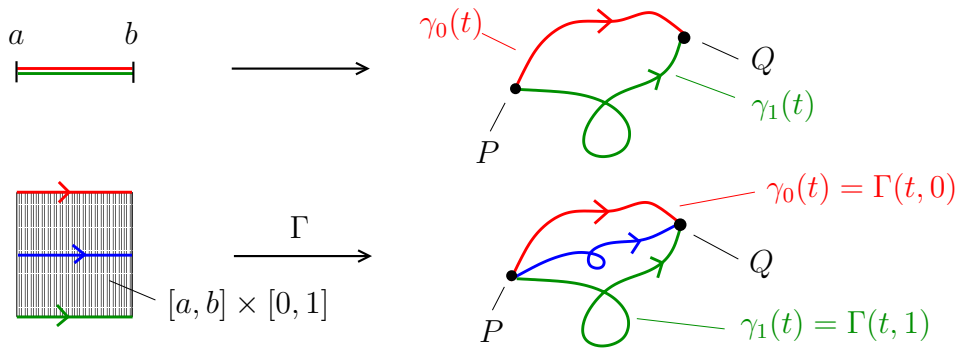

FIGURE 125. Schematic image of a path-homotopy Γ between two paths γ_0 and γ_1 from P to Q.

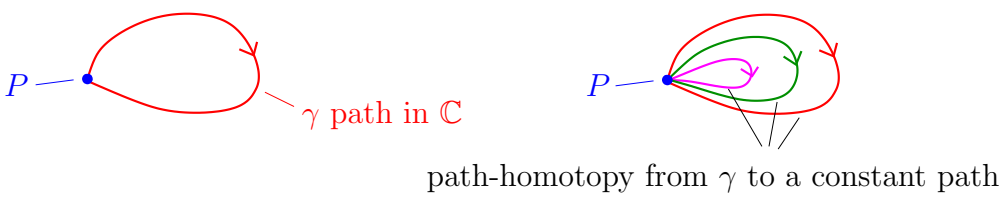

FIGURE 126.

Definition. Let $U \subset \mathbb{C}$ be an open subset, let $f\colon U \to \mathbb{C}$ be a holomorphic function and let $\gamma\colon [a,b] \to U$ be a smooth path. is defined as

$$\int_\gamma f(z)\,dz \;:=\; \int_{t=a}^{t=b} f(\gamma(t))\cdot\gamma'(t)\,dt \;\in \mathbb{C}.$$

Examples.

(1) Let $U = \mathbb{C}\setminus\{0\}$, let $f(z) = \frac{1}{z}$ and let $\gamma\colon [0,1] \to \mathbb{C}\setminus\{0\}$ be the loop given by $\gamma(t) = e^{2\pi i t}$, i.e. γ is a loop that "goes once around the origin". Then

$$\int_\gamma f(z)\,dz \;:=\; \int_{t=0}^{t=1} f(\gamma(t))\cdot\gamma'(t)\,dt \;=\; \int_{t=0}^{t=1} \tfrac{1}{e^{2\pi i t}}\cdot e^{2\pi i t}\cdot 2\pi i\,dt \;=\; 2\pi i.$$

(2) If γ is a constant path, then $\gamma'(t) \equiv 0$. This shows that the path-integral along a constant path is zero.

The following proposition is one of the main results in complex analysis, see e.g. [Lan, Theorem III.5.1].

Proposition 4.1. *Let $U \subset \mathbb{C}$ be an open subset, let $f\colon U \to \mathbb{C}$ be a holomorphic function and let $\gamma, \delta\colon [a,b] \to U$ be two smooth paths. If γ and δ are path-homotopic, then*

$$\int_\gamma f(z)\,dz \;=\; \int_\delta f(z)\,dz.$$

The following corollary is a consequence of Proposition 4.1 and of the above calculations.

Corollary 4.2. *The loop $\gamma\colon [0,1] \to \mathbb{C} \setminus \{0\}$ given by $\gamma(t) = e^{2\pi i t}$ is* not *path-homotopic to a constant path, i.e. γ is not null-homotopic.*

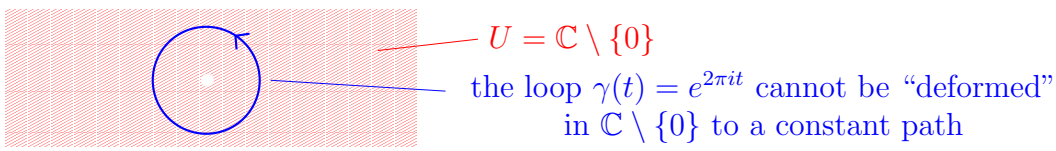

FIGURE 127.

Remark. In the following Chapter 4.2 we will use Corollary 4.2 so that we have at least one non-trivial topological statement in our toolbox. Somewhat later, after somewhat lengthy preparations, we will proof a general theorem, which in particular will provide us with a new proof of Corollary 4.2.

Example. If two subsets of $\mathbb{C}$ are homeomorphic, then evidently either both are simply connected or none is. From Corollary 4.2 it now follows immediately that $\mathbb{R}^2 = \mathbb{C}$ and $\mathbb{R}^2 \setminus \{(0,0)\} = \mathbb{C} \setminus \{0\}$ are not homeomorphic.

This second approach to showing that two topological spaces are different also has several disadvantages over the first approach:

(1) A priori these notions are defined only for subsets of $\mathbb{C}$,
(2) this approach does not allow us to show that the two subsets $U = \mathbb{C} \setminus \{0\}$ and $V = \mathbb{C} \setminus \{0,1\}$ are not homeomorphic, since neither is simply connected.

The first objection is of course easy to rectify, since the definitions make sense for any topological space. But if we work with more general situations a new problem arises: how can we show, without using complex analysis, that a topological space is not simply connected? In the following chapters we will address all these issues.

In particular, when it comes to distinguishing $U = \mathbb{C} \setminus \{0\}$ and $V = \mathbb{C} \setminus \{0,1\}$, then naively we would say that V has "more" loops that are not null-homotopic than U. In the subsequent chapter we will in particular make precise what "more" means.

5. The fundamental group

5.1. **Path-homotopy classes of paths.** In this section we extend some of the ideas and notions about paths that we introduced in the previous section to the more general setting of paths in topological spaces.

Definition. Let X be a topological space.

(1) A *path* in X is a[110] map $\gamma\colon [a,b] \to X$. We call $\gamma(a)$ the *starting point of* γ and we call $\gamma(b)$ the *endpoint of* γ. Often we say that γ is a *path from* $\gamma(a)$ *to* $\gamma(b)$.
(2) A *loop* is a path for which the starting point and the endpoint coincide.

Convention. In the following, if we do not specify the domain of a path or a loop, then it is understood to be $[0,1]$.

Definition. Given a path $\gamma\colon [0,1] \to X$ we refer to the path $\overline{\gamma}\colon [0,1] \to X$ that is given by $\overline{\gamma}(t) = \gamma(1-t)$ as the *inverse path of* γ.

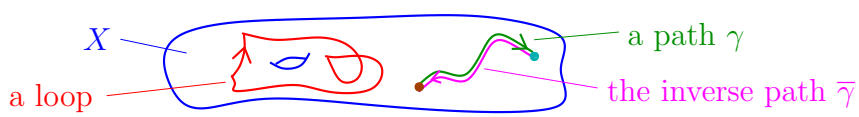

Figure 128.

Definition. Let X be a topological space.

(1) Let $\gamma_0, \gamma_1\colon [a,b] \to X$ be two paths with the same starting point P and the same endpoint Q. A *path-homotopy between the paths* γ_0 *and* γ_1 is a map
$$\begin{array}{rcl} \Gamma\colon [a,b] \times [0,1] & \to & X \\ (t,s) & \mapsto & \Gamma(t,s), \end{array}$$
with the following properties
   (a) for every $t \in [a,b]$ we have
$$\Gamma(t,0) \;=\; \gamma_0(t) \text{ and } \Gamma(t,1) \;=\; \gamma_1(t),$$
   (b) for every $s \in [0,1]$ we have
$$\Gamma(a,s) \;=\; P \quad \text{ and } \Gamma(b,s) \;=\; Q.$$
(2) If there exists a path-homotopy between two paths γ_0 and γ_1, then we say that γ_0 and γ_1 are *path-homotopic*, and we write $\gamma_0 \simeq \gamma_1$.
(3) We say a loop $\gamma\colon [a,b] \to X$ is *null-homotopic*, if it is path-homotopic to the constant path δ given by $\delta(t) = \delta(a)$ for all $t \in [a,b]$.

Examples.

[110] Recall that all maps are understood to be continuous, unless we say something else.

(A) Let $\gamma_0, \gamma_1 \colon [a,b] \to \mathbb{R}^n$ be two paths in $\mathbb{R}^n$ with same starting point and the same endpoint. Then

$$\begin{array}{rcl} \Gamma \colon [a,b] \times [0,1] & \to & \mathbb{R}^n \\ (t,s) & \mapsto & \gamma_0(t) \cdot (1-s) + \gamma_1(t) \cdot s \end{array}$$

is a path-homotopy between γ_0 and γ_1. We had already illustrated this fact in Figure 126.

(B) Let $X = \mathbb{C} \setminus \{0\} = \mathbb{R}^2 \setminus \{(0,0)\}$. As we had just seen in Corollary 4.2, the path

$$\begin{array}{rcl} \gamma \colon [0,1] & \to & X \\ t & \mapsto & e^{2\pi i t} = (\cos(2\pi t), \sin(2\pi t)) \end{array}$$

is not null-homotopic in X.

(C) Let $Y = S^1 \times (0,2)$ and consider the loop

$$\begin{array}{rcl} \widetilde{\gamma} \colon [0,1] & \to & Y = S^1 \times (0,2) \\ t & \mapsto & (e^{2\pi i t}, 1). \end{array}$$

This loop is not null-homotopic. This can be seen as follows: we consider the map

$$\begin{array}{rcl} \Phi \colon Y = S^1 \times (0,2) & \to & X = \mathbb{C} \setminus \{0\} \\ (z,t) & \mapsto & z \cdot t. \end{array}$$

If $\widetilde{\gamma}$ was null-homotopic in Y, then there would exist a path-homotopy

$$\widetilde{F} \colon [0,1] \times [0,1] \to Y$$

from $\widetilde{\gamma}$ to the constant path $\widetilde{\delta}(t) := (1,1)$, $t \in [0,1]$. But then

$$F := \Phi \circ \widetilde{F} \colon [0,1] \times [0,1] \to X$$

would be a path-homotopy in $X = \mathbb{C} \setminus \{0\}$ from the path $\gamma := \Phi \circ \widetilde{\gamma}$ to the constant path $\delta := \Phi \circ \widetilde{\delta}$. But $\gamma = \Phi \circ \widetilde{\gamma}$ is precisely the path γ from example (B) which we showed not to be null-homotopic in $X = \mathbb{C} \setminus \{0\}$.

(D) We consider the two loops in Figure 129. In both cases it is hard to see how these loops could possibly be path-homotopic to a constant path, but it is also difficult to find an argument why that should not be possible.[111]

(E) We consider the real projective space $\mathbb{R}\mathrm{P}^2$. Recall that in Lemma 1.82 we gave an identification $\mathbb{R}\mathrm{P}^2 = \overline{B}^2/\sim$ where $\sim$ is the equivalence relation on $\overline{B}^2$ generated by $P \sim -P$ for $P \in S^1 = \partial \overline{B}^2$. Then

$$\begin{array}{rcl} \gamma \colon [0,1] & \to & \overline{B}^2/\sim \\ t & \mapsto & [(\cos(\pi t), \sin(\pi t))] \end{array}$$

is a loop in $\mathbb{R}\mathrm{P}^2 = \overline{B}^2/\sim$, see Figure 130.[112] But is it null-homotopic?

[111] For example the given loop in $\mathbb{C} \setminus \{0,1\}$ is actually null-homotopic in $\mathbb{C} \setminus \{0\}$ and it is null-homotopic in $\mathbb{C} \setminus \{1\}$. In particular our trick of using Corollary 4.2 does not work in this case.

[112] Why is it a loop?

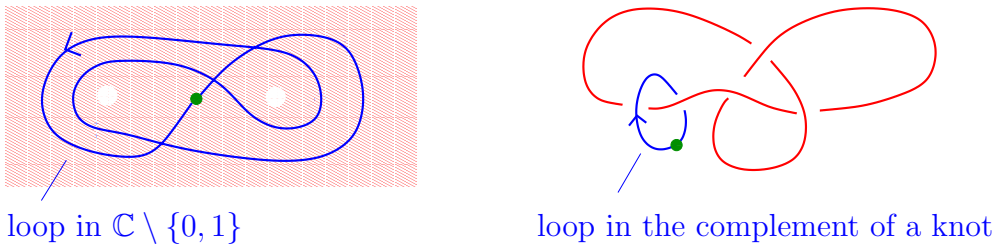

FIGURE 129.

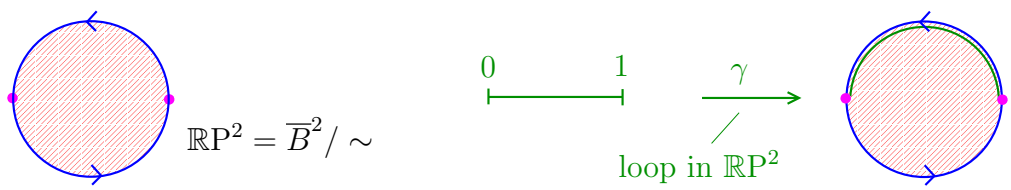

FIGURE 130.

(F) On page 66 we considered the pseudocircle, namely the set $X = \{A, B, C, D\}$ with a slightly unusual topology. Furthermore we gave an example of a continuous non-constant loop $f\colon S^1 \to X$. The question arises, is this loop null-homotopic?

Remark. Let X be a topological space and let $x_0 \in X$. It follows from Lemma 1.68 that the maps

$$\begin{array}{rcl} \{\text{loops } \gamma\colon [0,1] \to X \text{ with } \gamma(0) = \gamma(1) = x_0)\} & \Leftrightarrow & \{\text{maps } f\colon S^1 \to X \text{ with } f(1) = x_0\} \\ (\gamma\colon [0,1] \to X) & \mapsto & (z = e^{2\pi i t} \mapsto \gamma(t)) \\ (t \mapsto f(e^{2\pi i t})) & \leftarrow\!\shortmid & (f\colon S^1 \to X) \end{array}$$

are evidently bijections. Thus we can think of loops in X where the starting and endpoint is x_0 as maps from S^1 to X that send 1 to x_0. We will use this bijection to go back and forth between these two points of view.

The following lemma gives a useful criterion for a loop to be null-homotopic.

Lemma 5.1. *Let X be a topological space and let $x_0 \in X$. Let $\gamma\colon [0,1] \to X$ be a loop with $\gamma(0) = \gamma(1) = x_0$. We denote by*

$$\begin{array}{rcl} \varphi\colon S^1 & \to & X \\ z = e^{2\pi i t} & \mapsto & \gamma(t) \end{array}$$

the corresponding map from S^1 to X. Then γ is null-homotopic if and only if there exists a map $\Phi\colon \overline{B}^2 \to X$ so that $\Phi|_{S^1} = \varphi$.

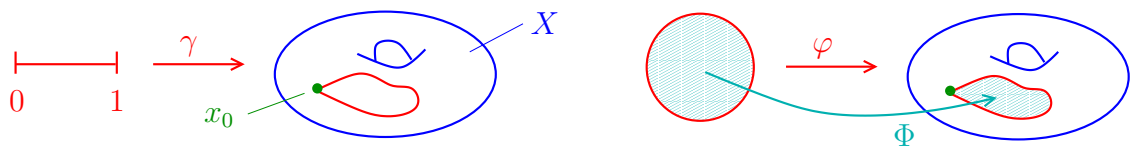

FIGURE 131. Illustration of Lemma 5.1.

Proof $(*)$. We start out with a few preparations. We write $A := ([0,1]\times\{0\})\cup(\{0,1\}\times[0,1])$ and we consider the map

$$\begin{array}{rcl} g\colon [0,1]\times[0,1] & \to & \overline{B}^2 \\ (t,s) & \mapsto & se^{2\pi it}+1-s. \end{array}$$

Note that this map has the property that all points in A get sent to $1 \in S^1$. Using this

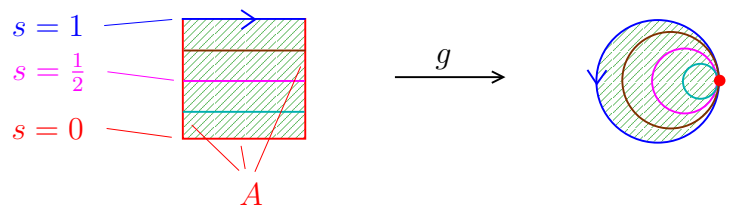

FIGURE 132.

observation, Lemma 1.66 and Proposition 1.40 we see that the map

$$\begin{array}{rcl} h\colon ([0,1]\times[0,1])/A & \to & \overline{B}^2 \\ [P] & \mapsto & g(P) \end{array}$$

is a homeomorphism.

Now we turn to the actual proof of the lemma. Thus let X be a topological space, let $x_0 \in X$ and let $\gamma\colon [0,1] \to X$ be a loop with $\gamma(0)=\gamma(1)=x_0$. We define $\varphi\colon S^1 \to X$ via $\varphi(e^{2\pi it}) = \gamma(t)$.

First we suppose that γ is null-homotopic. This means that there exists a path-homotopy $F\colon [0,1]\times[0,1] \to X$ such that $F(t,0)=x_0$ and $F(t,1)=\gamma(t)$ for all $t\in[0,1]$ and such that $F(0,s)=F(1,s)=x_0$ for all $s\in[0,1]$. In other words, F is constant on A. We consider the map[113]

$$\begin{array}{rcl} \Phi\colon \overline{B}^2 \xleftarrow[\cong]{h} ([0,1]\times[0,1])/A & \to & X \\ [P] & \mapsto & F(P). \end{array}$$

One can easily verify that we have $\Phi|_{S^1} = \varphi$.

[113]Note that we implicitly use Lemma 1.66 to argue that the map $([0,1]\times[0,1])/A \to X$ is well-defined and continuous.

Conversely, if there exists a map $\Phi\colon \overline{B}^2 \to X$ so that $\Phi|_{S^1} = \varphi$, then one can easily verify that $\Phi \circ g\colon [0,1] \times [0,1] \to X$ is a path-homotopy from the loop γ to the constant loop c_{x_0}.[114] □

Before we continue with the examples we need to gather a few more elementary facts about path-homotopies of paths.

Proposition 5.2. *Let X be a topological space and let $x, y \in X$. Then "path-homotopy" is an equivalence relation on the set of paths $\gamma\colon [a,b] \to X$ from x to y.*

The proof of Proposition 5.2 makes use of the following lemma which we will use, implicitly or explicitly, surprisingly often.

Lemma 5.3. $(*)$ *Let X be a topological space and let $a < b < c$ be real numbers. Let $f\colon X \times [a,c] \to Y$ be a map to some topological space Y. If the restrictions of f to $X \times [a,b]$ and to $X \times [b,c]$ are continuous, then f itself is continuous.*

Proof of Lemma 5.3. This statement is an immediate consequence of Lemma 1.32 (2) and the observation, see Lemma 1.51, that $X \times [a,b]$ and $X \times [b,c]$ are in fact closed subsets of $X \times [a,c]$. □

Proof of Proposition 5.2. In order to simplify the notation we only work with paths defined on the interval $[0,1]$. We have to show that "path-homotopy" satisfies the three properties of an equivalence relation. Let $\alpha, \beta, \gamma\colon [0,1] \to X$ be three paths from x to y.

(1) The "constant path-homotopy" given by $\Gamma(t,s) := \gamma(t)$ defines a path-homotopy between γ and γ.

(2) Let Γ be a path-homotopy from α to β. Then the map Γ' defined by
$$\Gamma'(t,s) \ := \ \Gamma(t, 1-s)$$
is a path-homotopy from β to α.

(3) Let Γ be a path-homotopy from α to β and let Δ be a path-homotopy from β to γ. We consider the map
$$\begin{array}{rcl} [0,1] \times [0,1] & \to & X \\ (t,s) & \mapsto & \begin{cases} \Gamma(t, 2s), & \text{if } s \in \left[0, \frac{1}{2}\right], \\ \Delta(t, 2s-1), & \text{if } s \in \left(\frac{1}{2}, 1\right] \end{cases} \end{array}$$
It follows from Lemma 5.3 that this map is continuous. It is now clear that this map is a path-homotopy from α to γ. This part of the proof is illustrated in Figure 133. □

Definition. Given a path $f\colon [0,1] \to X$ in a topological space X we denote by $[f]$ the equivalence class of f with respect to the equivalence relation which is given by path-homotopies. We call $[f]$ the *path-homotopy class of f*.

[114] Why did we not just define g to be the map that sends the horizontal lines to concentric circles where each of them is centered around the origin?

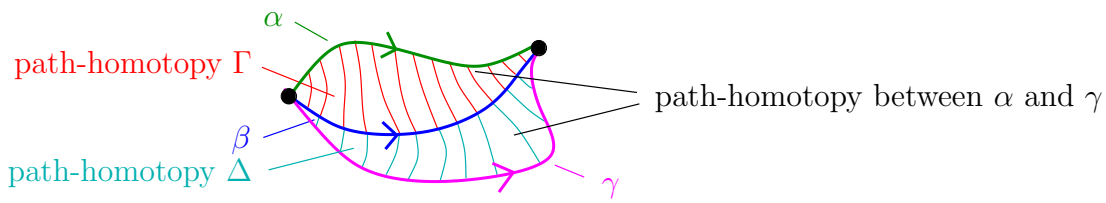

FIGURE 133.

Definition. Let $\gamma\colon [a,b] \to X$ be a path in a topological space and let $\varphi\colon [a,b] \to [a,b]$ be a map[115] with $\varphi(a) = a$ and $\varphi(b) = b$. We refer to $\gamma \circ \varphi\colon [a,b] \to X$ as a *reparametrization of* γ.

The following lemma says that reparametrizing does not change the path-homotopy class of a path.

Lemma 5.4. *Let $\gamma\colon [a,b] \to X$ be a path in a topological space. If a path $\delta\colon [a,b] \to X$ is obtained from γ by a reparametrization, then γ and δ are path-homotopic.*

Proof. Let $\gamma\colon [a,b] \to X$ be a path in a topological space and let $\varphi\colon [a,b] \to [a,b]$ be a map with $\varphi(a) = a$, $\varphi(b) = b$. Then a path-homotopy between γ and $\gamma \circ \varphi$ is given by[116]

$$\begin{array}{rcl} P\colon [a,b] \times [0,1] & \to & X \\ (t,s) & \mapsto & \gamma(t \cdot s + \varphi(t) \cdot (1-s)). \end{array}$$

□

It is pictorially clear that we can concatenate two paths if the endpoint of the first path agrees with the starting point of the second path. We use this observation to define the product of two paths.

Definition. Let X be a topological space and let $\alpha\colon [a,b] \to X$ and $\beta\colon [c,d] \to X$ be two paths with $\alpha(b) = \beta(c)$. We define the *product of* α *and* β as the path $\alpha * \beta$ which is given by[117]

$$\begin{array}{rcl} \alpha * \beta\colon [0,1] & \to & X \\ t & \mapsto & \begin{cases} \alpha(a + 2t(b-a)), & \text{if } t \in \left[0, \frac{1}{2}\right] \\ \beta(c + (2t-1)(d-c)), & \text{if } t \in \left(\frac{1}{2}, 1\right]. \end{cases} \end{array}$$

The product of two paths is thus given by "first running along α" and then "running along β". Here we reparametrized the path so that the domain of $\alpha * \beta$ is $[0,1]$. This convention might look slightly odd, but later on we will mostly work with paths that are defined on the interval $[0,1]$.

The proof of the following lemma is elementary and is left as an exercise. The statement of the lemma is illustrated in Figure 135.

[115] Note that φ is not required to be a homeomorphism.

[116] Where do we actually use the hypothesis that $\varphi(a) = a$ and $\varphi(b) = b$?

[117] It follows from Lemma 1.32 (2) and our hypothesis $\alpha(b) = \beta(c)$ that $\alpha * \beta\colon [0,1] \to X$ is a continuous map.

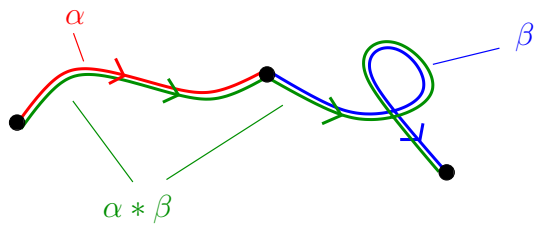

FIGURE 134. Definition of the product of two paths.

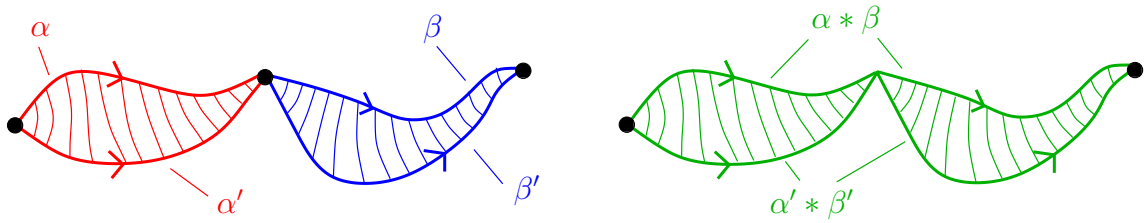
Lemma 5.5. *Let $\alpha, \alpha' \colon [a,b] \to X$ and $\beta, \beta' \colon [c,d] \to X$ be two pairs of paths in a topological space X such that $\alpha(b) = \alpha'(b) = \beta(c) = \beta'(c)$. Then*

$$\alpha \simeq \alpha' \text{ and } \beta \simeq \beta' \quad \Longrightarrow \quad \alpha * \beta \simeq \alpha' * \beta'.$$

Put differently, if $[\alpha] = [\alpha']$ and $[\beta] = [\beta']$, then $[\alpha * \beta] = [\alpha' * \beta']$.



α is path-homotopic to α'
and β is path-homotopic to β'

then $\alpha * \beta$ is path-homotopic to $\alpha' * \beta'$

FIGURE 135. Illustration of Lemma 5.5.

Definition. Let $[\alpha]$ and $[\beta]$ be two equivalence classes of paths in a topological space X with $\alpha(1) = \beta(0)$. We define the[118] *product of the equivalence classes* $[\alpha]$ *and* $[\beta]$ as

$$[\alpha] \cdot [\beta] \;=\; [\alpha * \beta].$$

The following proposition says that the product of equivalence classes of paths shares many properties of the product structure of a group.

Proposition 5.6. *Let $\alpha, \beta, \gamma \colon [0,1] \to X$ be three paths in a topological space X. Then the following hold:*

(1) *If $\alpha(1) = \beta(0)$ and $\beta(1) = \gamma(0)$, then*[119]

$$[\alpha] \cdot ([\beta] \cdot [\gamma]) \;=\; ([\alpha] \cdot [\beta]) \cdot [\gamma].$$

[118]According to Lemma 5.5 this definition does not depend on the choice of the representatives α and β of the equivalence classes.

[119]Put differently, the paths $\alpha * (\beta * \gamma)$ and $(\alpha * \beta) * \gamma$ are path-homotopic. Note that these paths are similar in the sense that both paths "run through" the points on α, β and γ, but at different speeds. In general the paths are not equal, for example we have $(\alpha * (\beta * \gamma))(\frac{1}{2}) = \alpha(1)$ and $((\alpha * \beta) * \gamma)(\frac{1}{2}) = \beta(1)$.

(2) *For $x \in X$ we denote by e_x the constant path that is given by $e_x(t) := x$, $t \in [0,1]$. Then the following equality holds*

$$[e_{\alpha(0)}] \cdot [\alpha] \;=\; [\alpha] \;=\; [\alpha] \cdot [e_{\alpha(1)}].$$

(3) *We denote by $\overline{\alpha}$ the inverse path. Then the following equalities hold*

$$[\alpha] \cdot [\overline{\alpha}] \;=\; [e_{\alpha(0)}] \quad \textit{and} \quad [\overline{\alpha}] \cdot [\alpha] \;=\; [e_{\alpha(1)}].$$

Proof $(*)$. Let $\alpha, \beta, \gamma \colon [0,1] \to X$ be three paths in a topological space X.

(1) Suppose that $\alpha(1) = \beta(0)$ and $\beta(1) = \gamma(0)$. We need to show that

$$\alpha * (\beta * \gamma) \;\simeq\; (\alpha * \beta) * \gamma.$$

We consider the map

$$\begin{array}{rcl} \Phi \colon [0,1] & \to & X \\ t & \mapsto & \begin{cases} \alpha(3t), & \text{if } t \in [0, \frac{1}{3}], \\ \beta(3t-1), & \text{if } t \in (\frac{1}{3}, \frac{2}{3}], \\ \gamma(3t-2), & \text{if } t \in (\frac{2}{3}, 1]. \end{cases} \end{array}$$

It follows from our hypothesis and Lemma 1.32 (2) that this map is indeed continuous. We consider the maps

$$\begin{array}{rcl} p \colon [0,1] & \to & [0,1] \\ t & \mapsto & \begin{cases} \frac{2}{3}t, & \text{if } t \in [0, \frac{1}{2}], \\ \frac{4}{3}t - \frac{1}{3}, & \text{if } t \in (\frac{1}{2}, 1] \end{cases} \end{array} \quad \text{and} \quad \begin{array}{rcl} q \colon [0,1] & \to & [0,1] \\ t & \mapsto & \begin{cases} \frac{4}{3}t, & \text{if } t \in [0, \frac{1}{2}], \\ \frac{2}{3}t + \frac{1}{3}, & \text{if } t \in (\frac{1}{2}, 1] \end{cases} \end{array}$$

Then

$$\begin{array}{ccccccc} \alpha * (\beta * \gamma) & = & \Phi \circ p & \simeq & \Phi & \simeq & \Phi \circ q & = & (\alpha * \beta) * \gamma \\ & \uparrow & & \uparrow & & \uparrow & & \uparrow & \\ & \text{by definition} & & \text{by Lemma 5.4} & & & & \text{by definition} & \end{array}$$

(2) We consider the map

$$\begin{array}{rcl} q \colon [0,1] & \to & [0,1] \\ t & \mapsto & \begin{cases} 0, & \text{if } t \in [0, \frac{1}{2}], \\ 2t - 1, & \text{if } t \in (\frac{1}{2}, 1]. \end{cases} \end{array}$$

Then

$$\begin{array}{ccccc} e_{\alpha(0)} * \alpha & = & \alpha \circ q & \simeq & \alpha. \\ & \uparrow & & \uparrow & \\ & \text{by definition} & & \text{by Lemma 5.4} & \end{array}$$

This shows that $[e_{\alpha(0)}] \cdot [\alpha] = [e_{\alpha(0)} * \alpha] = [\alpha]$. Almost the same argument also implies that $[\alpha] = [\alpha] \cdot [e_{\alpha(1)}]$.

(3) We write $P = \alpha(0)$. Note that $\alpha * \overline{\alpha}$ is a loop in P. We consider the map

$$\begin{array}{rcl} F \colon [0,1] \times [0,1] & \to & X \\ (t,s) & \mapsto & \begin{cases} \alpha(2t \cdot s), & \text{if } t \in \left[0, \frac{1}{2}\right], \\ \alpha(2s - 2t \cdot s), & \text{if } t \in \left(\frac{1}{2}, 1\right]. \end{cases} \end{array}$$

It follows from Lemma 5.3 that this map is indeed continuous. For $s = 0$ we obtain the constant path at P and for $s = 1$ we obtain the path $\alpha * \overline{\alpha}$. For any $s \in [0, 1]$ we furthermore have $F(0, s) = F(1, s) = P$. Thus F is a path-homotopy from the constant path to $\alpha * \overline{\alpha}$ which implies that $[e_{\alpha(0)}] = [\alpha * \overline{\alpha}] = [\alpha] \cdot [\overline{\alpha}]$. Almost the same argument shows that $[\overline{\alpha} * \alpha] = [e_{\alpha(1)}]$. □

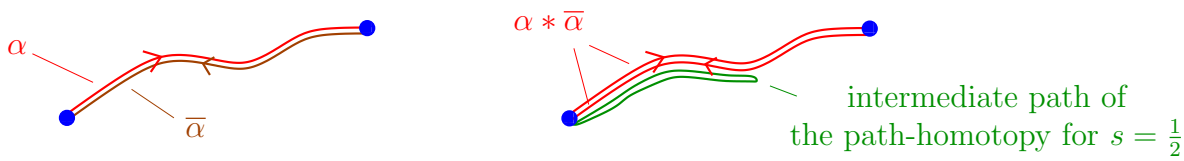


FIGURE 136. Illustration of the proof of Proposition 5.6 (3).

5.2. **The fundamental group of a pointed topological space.** In Proposition 5.6 we saw that the product of path-homotopy classes of paths shares many properties of the multiplication in a group. Nonetheless the path-homotopy classes of paths do not form a group, since the product of two paths is not defined, unless the endpoint of the first path agrees with the starting point of the second path.

We will resolve this problem by restricting our attention to loops.

Definition. Let X be a topological space and let $x_0 \in X$ be a point. A *loop in* (X, x_0) is a path $f\colon [0, 1] \to X$[120] with $f(0) = f(1) = x_0$, i.e. x_0 is the starting as well as the endpoint of f.

Proposition 5.7. *Let X be a topological space and $x_0 \in X$. The set*

$$\pi_1(X, x_0) \ := \ \{\textit{path-homotopy classes of loops in } (X, x_0)\}$$

together with the product map $[\alpha] \cdot [\beta] := [\alpha * \beta]$ forms a group where the neutral element is represented by the constant path at x_0 and where the inverse of $[\gamma]$ is given by $[\overline{\gamma}]$.

Proof. It is clear that the product of any two loops in (X, x_0) is defined. According to Lemma 5.5 the product of paths descends to a well-defined map

$$\begin{array}{rcl} \pi_1(X, x_0) \times \pi_1(X, x_0) & \to & \pi_1(X, x_0) \\ ([\alpha], [\beta]) & \mapsto & [\alpha] \cdot [\beta] := [\alpha * \beta]. \end{array}$$

According to Proposition 5.6 (1) this product map satisfies the associativity axiom. The trivial element is according to Proposition 5.6 (2) given by the path-homotopy class of the constant loop $[e_{x_0}]$. Furthermore according to Proposition 5.6 (3) the inverse of the path-homotopy class of a loop $\gamma\colon [0, 1] \to X$ in x_0 is given by the path-homotopy class of the loop defined by $\overline{\gamma}(t) := \gamma(1 - t)$, $t \in [0, 1]$. □

Definition. We call $\pi_1(X, x_0)$ the *fundamental group of X with respect to the base point x_0*.

[120]Note that part of the definition of "loop in (X, x_0)" is that the domain is the interval $[0, 1]$.

One of our main goals in the intermediate future will be to determine the fundamental group of the topological spaces that we introduced in the earlier sections.

Examples.

(1) We consider $X = \mathbb{R}^n$ and let $x_0 \in \mathbb{R}^n$ be an arbitrary point. As we pointed out on page 227, all loops in (X, x_0) are null-homotopic. More precisely, if $\gamma\colon [0,1] \to \mathbb{R}^n$ is a loop in $(\mathbb{R}^n, x_0)$, then

$$\begin{array}{rcl} F\colon [0,1] \times [0,1] & \to & \mathbb{R}^n \\ (t,s) & \mapsto & \gamma(t) \cdot (1-s) + x_0 \cdot s \end{array}$$

is a path-homotopy between the loop γ and the constant loop e_{x_0}. Thus it follows that $\pi_1(X, x_0) = 0$.[121]

(2) We say that a subset $X \subset \mathbb{R}^n$ is *star-shaped* if there exists an $x \in X$ such that for all $y \in X$ the segment $\{xt + y(1-t) \,|\, t \in [0,1]\}$ lies in X. For example open and closed balls and open and closed rectangles are star-shaped. Furthermore all convex subsets are star-shaped. Precisely the same proof as in (1) shows that the $\pi_1(X, x) = 0$.

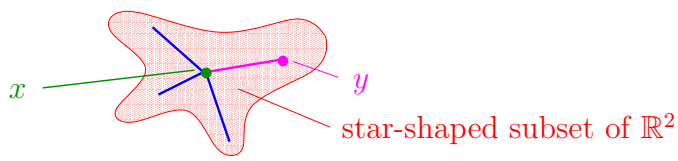

FIGURE 137.

Next we state the following theorem from complex analysis.

Theorem 5.8. *Let X be a proper subset*[122] *of $\mathbb{C}$, let $x_0 \in X$ be a point and let $w \in \mathbb{C} \setminus X$ be a point in the complement of X. The map*

$$\begin{array}{rcl} \pi_1(X, x_0) & \to & \mathbb{Z} \\ [\gamma] & \mapsto & \frac{1}{2\pi i} \int\limits_{\gamma} \frac{1}{z-w}\, dz \end{array}$$

is a well-defined homomorphism.

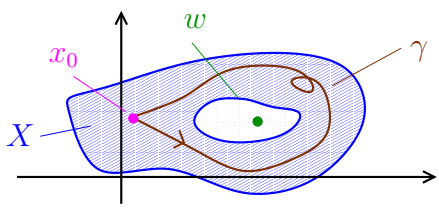
Remark. As in the case of Corollary 4.2, we do not really need Theorem 5.8 and its subsequent Corollary 5.9. If one has seen complex analysis, or if one is willing to take Theorem 5.8 on face value, it allows us to show that some fundamental groups are non-trivial, before we have developed the full machinery for calculating fundamental groups. But eventually we

[121] If $\pi_1(X, x_0)$ is the trivial group, then we usually write $\pi_1(X, x_0) = 0$. This notation is commonly used, even though it is not entirely logical: we use the multiplicative notation for the product structure on the group $\pi_1(X, x_0)$, and it would therefore make more sense to write $\pi_1(X, x_0) = 1$ if the group $\pi_1(X, x_0)$ is trivial.

[122] We say A is a proper subset of B if $A \subset B$ and if $A \neq B$.

will supplant Corollary 5.9 by a much stronger statement proved using purely topological methods.

Proof. A vigilant reader might first have noticed that the statement of Theorem 5.8 contains a slight cheat. We use the path integral over a continuous path γ, whereas so far on page 224 we gave only the definition for the integral over a smooth path. The more general definition of a path integral is given in [Lan, Chapter III.4]. The fact that the given integral takes values in $\mathbb{Z}$ is proved in [Lan, Lemma IV.4.1]. Furthermore the fact that this integral defines a well-defined map on the fundamental group is a consequence of [Lan, Theorem III.5.1]. Finally it follows almost immediately from the definitions that the given map is a homomorphism. □



the map

$$\begin{array}{rcl} \pi_1(X,x_0) & \to & \mathbb{Z} \\ [\gamma] & \mapsto & \frac{1}{2\pi i}\int\limits_\gamma \frac{1}{z-w}\,dz \end{array}$$

is a homomorphism

FIGURE 138.

The previous example together with Theorem 5.8 give us the following neat corollary.

Corollary 5.9. *There exists an epimorphism $\pi_1(S^1,1)\to\mathbb{Z}$.*

Proof. The corollary follows immediately from Theorem 5.8 and the calculation on page 224. □

This raises the following question.

Question 5.10. *Is the above epimorphism $\pi_1(S^1,1)\to\mathbb{Z}$ in fact an isomorphism?*

The definition of the fundamental group of a topological space X relies on the choice of a base point x_0. The following proposition shows that, at least for path-connected topological spaces, the choice of the base point does not affect the isomorphism type of the fundamental group.

Proposition 5.11. *Let X be a topological space, let x_0 and x_1 be two points in X and let $p\colon[0,1]\to X$ be a path from x_0 to x_1. Then the following two statements hold:*

(1) *The map*

$$\begin{array}{rcl} p_*\colon \pi_1(X,x_1) & \to & \pi_1(X,x_0) \\ [\gamma] & \mapsto & [p*\gamma*\overline{p}] \end{array}$$

is well-defined and it is a group isomorphism.

(2) *If $x_0=x_1$, then the map p_* is just conjugation by $[p]\in pi_1(X,x_0)$, i.e. for any $g\in\pi_1(X,x_0)=\pi_1(X,x_1)$ we have*

$$p_*(g) \;=\; [p]\cdot g\cdot[p]^{-1} \;\in\; \pi_1(X,x_0).$$

(3) *If $f\colon X \to Y$ is a map to another topological space, then the following diagram commutes:*

$$\begin{tikzcd} \pi_1(X,x_0) \arrow[r, "p_*"] \arrow[d, "f_*"] & \pi_1(X,x_1) \arrow[d, "f_*"] \\ \pi_1(Y,f(x_0)) \arrow[r, "(f\circ p)_*"] & \pi_1(Y,f(x_1)). \end{tikzcd}$$

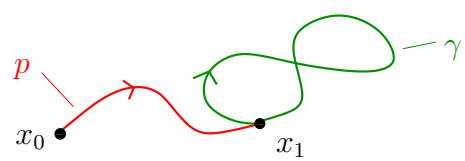


FIGURE 139. Schematic sketch of Proposition 5.11 (1).

Proof $(*)$. Let X be a topological space and let x_0 and x_1 be two points in X that are connected via a path $p\colon [0,1] \to X$ from x_0 to x_1.

(1) Let γ be a loop in (X,x_1). Then $p*\gamma*\overline{p}$ is evidently a loop in (X,x_0). From Lemma 5.5 and Proposition 5.6 it follows that the path-homotopy class of $p*\gamma*\overline{p}$ depends only on the choice of the path-homotopy class of γ, i.e. the map

$$\begin{array}{rcl} \Phi\colon \pi_1(X,x_1) & \to & \pi_1(X,x_0) \\ [\gamma] & \mapsto & [p*\gamma*\overline{p}] \end{array}$$

is well-defined. Furthermore for two loops γ,δ in (X,x_1) we have

$$\begin{array}{rclcl} \Phi([\gamma])*\Phi([\delta]) & = & [p*\gamma*\overline{p}]*[p*\delta*\overline{p}] & = & [p*\gamma*\overline{p}*p*\delta*\overline{p}] \\ & = & [p*\gamma*e_{x_1}*\delta*\overline{p}] & = & [p*(\gamma*\delta)*\overline{p}] \;=\; \Phi([\gamma*\delta]). \\ & \uparrow & & \uparrow & \\ & \text{Proposition 5.6 (3) and Lemma 5.5} & & \text{Proposition 5.6 (2) and Lemma 5.5} & \end{array}$$

Thus we have shown that Φ is a group homomorphism. Furthermore Φ is even a group isomorphism, since an inverse map is given by[123]

$$\begin{array}{rcl} \Psi\colon \pi_1(X,x_0) & \to & \pi_1(X,x_1) \\ [\delta] & \mapsto & [\overline{p}*\delta*p]. \end{array}$$

(2),(3) These two statements follow basically immediately from the definitions. □

We obtain the following corollary:

Corollary 5.12. *Let X be a path-connected topological space and let $x_0,x_1 \in X$. Then the groups $\pi_1(X,x_0)$ and $\pi_1(X,x_1)$ are isomorphic.*

[123]Why is $\Phi\circ\Psi$ the identity on $\pi_1(X,x_0)$ and why is $\Psi\circ\Phi$ the identity on $\pi_1(X,x_1)$?

Example. Let X be a star-shaped subset of $\mathbb{R}^n$. Above we saw that there exists an $x \in X$ such that $\pi_1(X, x) = 0$. It now follows from Corollary 5.12 that $\pi_1(X, y) = 0$ for any point $y \in X$. Put differently, the fundamental group of every star-shaped subset of $\mathbb{R}^n$ with respect to any base point is trivial.

If X is a path-connected topological space, then Corollary 5.12 states that the isomorphism type of the fundamental group does not depend on the choice of the base point. Sometimes we suppress the base point from the notation and we denote by $\pi_1(X)$ the isomorphism type of the fundamental group.

Definition. Let X be a non-empty path-connected topological space. If $\pi_1(X) = 0$[124], then we say that X is *simply connected.*[125]

The following lemma will be proved in Exercise 5.2.

Lemma 5.13. *Let X be a topological space and let P, Q be two points in X. If X is simply connected, then any two paths from P to Q are path-homotopic.*

We already saw on page 235 that $\mathbb{R}^n$ and more generally, all star-shaped subsets of $\mathbb{R}^n$ are simply connected. The following statement is much more interesting:

Proposition 5.14. *For any $n \geq 2$ the sphere S^n is simply connected.*

In the proof of Proposition 5.14 we will need the following lemma.

Lemma 5.15. *For any $P \in S^n$ the topological space $S^n \setminus \{P\}$ is simply connected.*

Proof. In Lemma 1.41 we showed that there exists a homeomorphism $f\colon S^n \to \mathbb{R}^n \cup \{\infty\}$. We set $Q := f^{-1}(\infty)$. Thus f restricts to homeomorphism $f\colon S^n \setminus \{Q\} \to \mathbb{R}^n$. Now let P be any other point on S^n. There exists a homeomorphism[126] $g\colon S^n \to S^n$ with $g(P) = Q$. Then $f \circ g\colon S^n \to \mathbb{R}^n \cup \{\infty\}$ restricts to a homeomorphism $S^n \setminus \{P\} \to \mathbb{R}^n$. But $\mathbb{R}^n$ is simply connected, hence $S^n \setminus \{P\}$ is also simply connected. □

Now we can turn to the proof of Proposition 5.14.

Proof of Proposition 5.14.

> Here is a very short "proof": Let $x_0 \in S^n$ and let $\gamma\colon [0,1] \to S^n$ be a loop in x_0. We have to show that γ is null-homotopic. We pick a point P that does not lie in the image of γ. By Lemma 5.15 the topological space $S^n \setminus \{P\}$ is simply connected, hence γ is null-homotopic in $S^n \setminus \{P\}$, in particular it is null-homotopic in S^n.
> This sounds convincing, except for one crucial gap: we did not justify why there

[124]Since X is a path-connected topological space it is irrelevant which base point we consider.

[125]It is straightforward to see that for subsets of $\mathbb{C}$ we obtain the same notion of "simply connectedness" as on page 223.

[126]The existence of the homeomorphism follows from Proposition 10.23. But one can also easily give an elementary proof of that fact. More precisely, using basic facts from linear algebra one can show that there exists an orthogonal matrix A with $A \cdot P = Q$. Then the map $g\colon S^n \to S^n$ that is given by multiplication by A has the desired property.

exists a point P that does not lie in the image of γ. In fact, as we saw in Proposition 1.91, such a point does not need to exist since there are surjective maps from an interval to any S^n.

We write

$$N \;:=\; (0,\dots,0,1) \quad \text{“North Pole”} \quad \text{and} \quad U \;:=\; S^n \setminus \{N\},$$

and also

$$S \;:=\; (0,\dots,0,-1) \quad \text{“South Pole”} \quad \text{and} \quad V \;:=\; S^n \setminus \{S\}.$$

We fix a base point x_0 on S^n that is neither N nor S. By Lemma 5.15 it suffices to show that any loop in (S^n, x_0) is path-homotopic to a loop in $U = S^n \setminus \{N\}$.

So let γ be a loop in (S^n, x_0).

Claim. There exists a subdivision

$$0 \,=\, t_0 \,<\, t_1 \,<\, \dots \,<\, t_{k-1} \,<\, t_k \,=\, 1,$$

such that the following hold:

(1) for each $i \in \{0,\dots,k-1\}$ we have $\gamma([t_i, t_{i+1}]) \subset U$ or $\gamma([t_i, t_{i+1}]) \subset V$, and
(2) for each $i \in \{1,\dots,k-1\}$ we have $\gamma(t_i) \neq N$ and $\gamma(t_i) \neq S$.

By Corollary 1.106 applied to $\gamma\colon [0,1] \to S^n$ and $S^n = U \cup V$ there exists a k such that for any $i \in \{0,\dots,k-1\}$ the image $\gamma([\frac{i}{k}, \frac{i+1}{k}])$ lies in U or in V. In particular the subdivision $t_i = \frac{i}{k}$, $i = 0,\dots,k$ satisfies condition (1).

Now suppose that there exists an $i \in \{1,\dots,k-1\}$ with $\gamma(t_i) = N$. Then neither $\gamma([t_{i-1}, t_i])$ nor $\gamma([t_i, t_{i+1}])$ can be contained in $U = S^n \setminus \{N\}$. So by (1) both have to be contained in V, in particular we have $\gamma([t_{i-1}, t_{i+1}]) \subset V$. But then we can remove t_i from the subdivision. Iterating this process we can assume that for each every i we have $\gamma(t_i) \neq N$. Similarly we can arrange for every i we have $\gamma(t_i) \neq S$. This concludes the proof of the claim.

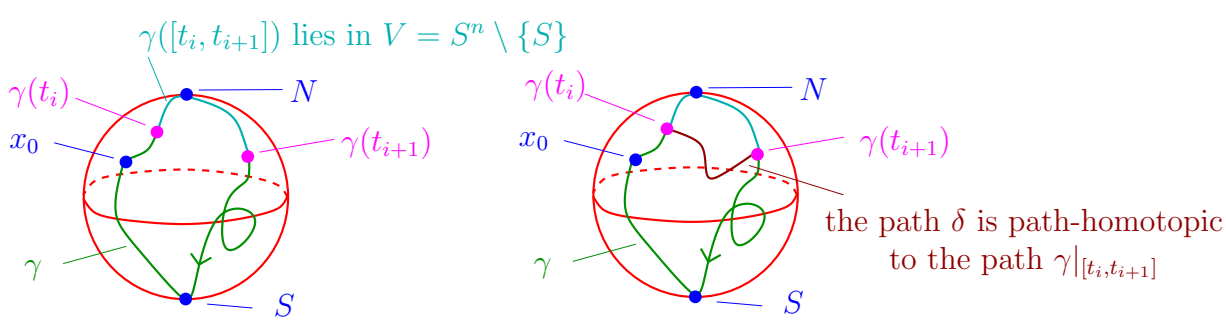

FIGURE 140. Illustration of Proposition 5.14.

As mentioned before, by Lemma 5.15 it now suffices to prove the following claim.

Claim. The loop $\gamma\colon [0,1] \to S^n$ in (S^n, x_0) is path-homotopic to a path that does not hit N.

We pick a subdivision as in the previous claim. Suppose there exists an $i \in \{0, \dots, k-1\}$ such that $\gamma([t_i, t_{i+1}])$ hits N. By the choice of our subdivision we know that $\gamma([t_i, t_{i+1}])$ lies entirely in $V = S^n \setminus \{S\}$.[127] Since $S^n \setminus \{N, S\}$ is path-connected and since $\gamma(t_i) \neq N, S$, $\gamma(t_{i+1}) \neq N, S$ we can pick a path $\delta\colon [t_i, t_{i+1}] \to U \cap V = S^n \setminus \{N, S\}$ that connects $\gamma(t_i)$ and $\gamma(t_{i+1})$. Since the paths $\gamma|_{[t_i, t_{i+1}]}$ and δ both lie in the simply connected set $V = S^n \setminus \{S\}$ they are path-homotopic by Lemma 5.13. In the loop γ we now replace $\gamma([t_i, t_{i+1}])$ by δ. We obtain a new loop that is path-homotopic to the original loop and that does not hit N on the interval $[t_i, t_{i+1}]$. Iterating this procedure gives us the desired path-homotopy to a loop that does not hit N. This concludes the proof of the claim.[128] $\square$

Exercises for Chapter 5.

Exercise 5.1. Consider the torus $T = S^1 \times S^1$ and consider the loop

$$\begin{array}{rcl} [0,1]/0 \sim 1 & \to & T = S^1 \times S^1 \\ t & \mapsto & (e^{2\pi i t}, 1). \end{array}$$

Is the loop null-homotopic? If yes, provide a path-homotopy to a constant path. If not, prove that the path is not null-homotopic.

Exercise 5.2. Prove Lemma 5.13.

Exercise 5.3.

(1) We consider the topological space

$$X \ := \ \big\{(0,y) \,\big|\, y \in [-1,1]\big\} \cup \big\{(x, \sin(\tfrac{1}{x})) \,\big|\, x \in (0,\pi]\big\} \ \subset \ \mathbb{R}^2.$$

We let $x_0 = (0,0)$. Is $\pi_1(X, x_0)$ trivial or non-trivial?

(2) Let $f\colon X \to Y$ be a surjective map of topological spaces and let $x \in X$. Is the induced map $f_*\colon \pi_1(X,x) \to \pi_1(Y, f(x))$ necessarily an epimorphism?

(3) Let $f\colon X \to Y$ be an injective map of topological spaces and let $x \in X$. Is the induced map $f_*\colon \pi_1(X,x) \to \pi_1(Y, f(x))$ necessarily a monomorphism?

---

[127] We know it lies in U or V, but since it hits N it cannot lie in U.

[128] Where did we use in the proof that $n \geq 2$?

6. Categories, functors and natural transformations

In this section we introduce the notion of a category,of a functor and of a natural transformation that many readers will already have encountered in different courses. These notions might initially appear to rather abstract, but they play an essential role in algebraic topology and they are regularly used in all branches of pure mathematics.

6.1. **Definition and examples of categories.**

Definition. A *category* $\mathcal{C}$ consists of the following data:

(1) A class[129] $\mathrm{Ob}(\mathcal{C})$ of mathematical objects which are called the *objects of the category*,
(2) for each pair (X, Y) of objects there exists a set[130] of *morphisms* $\mathrm{Mor}_{\mathcal{C}}(X, Y)$,
(3) for any three objects X, Y and Z there exists a map

$$\begin{array}{rcl} \mathrm{Mor}_{\mathcal{C}}(X,Y) \times \mathrm{Mor}_{\mathcal{C}}(Y,Z) & \to & \mathrm{Mor}_{\mathcal{C}}(X,Z) \\ (f,g) & \mapsto & g \circ f, \end{array}$$

that satisfies the following axioms:

(A) (associativity): For every $f \in \mathrm{Mor}_{\mathcal{C}}(W, X), g \in \mathrm{Mor}_{\mathcal{C}}(X, Y)$ and $h \in \mathrm{Mor}_{\mathcal{C}}(Y, Z)$ we have

$$(h \circ g) \circ f \;=\; h \circ (g \circ f) \;\in\; \mathrm{Mor}_{\mathcal{C}}(W, Z).$$

(B) (identity): For every object X there exists a morphism $\mathrm{id}_X \in \mathrm{Mor}_{\mathcal{C}}(X, X)$ with the property that

$$\begin{array}{rcl} \mathrm{id}_X \circ f & = & f \quad \text{for all } f \in \mathrm{Mor}_{\mathcal{C}}(Z,X), \quad \text{and} \\ f \circ \mathrm{id}_X & = & f \quad \text{for all } f \in \mathrm{Mor}_{\mathcal{C}}(X,Y). \end{array}$$

If the category is clear from the context, then we just write $\mathrm{Mor}(X, Y)$ instead of $\mathrm{Mor}_{\mathcal{C}}(X, Y)$.

Example.

(a) We call the category $\mathcal{C}$ with

$$\begin{array}{rcl} \mathrm{Ob}(\mathcal{C}) & := & \text{all sets}, \\ \mathrm{Mor}(X,Y) & := & \text{all maps from } X \text{ to } Y, \end{array}$$

together with the usual composition of maps the *category of all sets*.

[129] As many "working mathematicians" the author has a slightly guilty conscience for not knowing what a "set" and what a "class" is. Therefore the reader is referred to [Ci, FPr] for details. Truth be told, most mathematicians learn from logicians at some point when to say "class" instead of "set", but many mathematicians do not know exactly what they are doing at that point.

[130] One could ask why $\mathrm{Mor}_{\mathcal{C}}(X, Y)$ has to be a set, why not just a class? To the best of my knowledge the axioms on morphisms that we write down also make sense if $\mathrm{Mor}_{\mathcal{C}}(X, Y)$ is only required to be a class. Here's a long discussion which gives a satisfactory answer to people in category theory:

`http://mathoverflow.net/questions/48810/why-need-the-morphisms-to-form-a-set`

I myself do not understand the answer.

(b) We consider the category $\mathcal{C}$ with

$$\begin{aligned} \mathrm{Ob}(\mathcal{C}) &:= \text{all sets}, \\ \mathrm{Mor}(X,Y) &:= \begin{cases} \{\mathrm{id}_X\}, & \text{if } X = Y \\ \varnothing, & \text{if } X \neq Y. \end{cases} \end{aligned}$$

The composition map only needs to be defined if $X = Y = Z$[131], and in this case we define $\mathrm{id}_X \circ \mathrm{id}_X := \mathrm{id}_X$. One can easily convince oneself that this defines a category.

(c) Let $\mathbb{K}$ be a field. We refer to the category $\mathcal{C}$ with

$$\begin{aligned} \mathrm{Ob}(\mathcal{C}) &:= \text{all } \mathbb{K}\text{-vector spaces}, \\ \mathrm{Mor}(X,Y) &:= \mathrm{Hom}_{\mathbb{K}}(X,Y) = \text{all } \mathbb{K}\text{-homomorphisms from } X \text{ to } Y, \end{aligned}$$

with the usual composition of homomorphisms as the *category of* $\mathbb{K}$*-vector spaces*.

(d) We refer to the category $\mathcal{G}$ with

$$\begin{aligned} \mathrm{Ob}(\mathcal{G}) &:= \text{all groups}, \\ \mathrm{Mor}(X,Y) &:= \mathrm{Hom}(X,Y) = \text{all group homomorphisms from } X \text{ to } Y, \end{aligned}$$

with the usual composition of group homomorphisms as the *category of groups*.

(d) We refer to the category $\mathcal{A}$ with

$$\begin{aligned} \mathrm{Ob}(\mathcal{A}) &:= \text{all abelian groups}, \\ \mathrm{Mor}(X,Y) &:= \mathrm{Hom}(X,Y) = \text{all group homomorphisms from } X \text{ to } Y, \end{aligned}$$

with the usual composition of group homomorphisms as the *category of abelian groups*.

(f) We refer to the category $\mathcal{T}$ with

$$\begin{aligned} \mathrm{Ob}(\mathcal{T}) &:= \text{all topological spaces}, \\ \mathrm{Mor}(X,Y) &:= \mathcal{C}(X,Y) := \text{all continuous maps from } X \text{ to } Y, \end{aligned}$$

with the usual composition of maps as the *category of topological spaces*. A *pointed topological space* is a pair (X, x_0), where X is a topological space and x_0 is a point in X. We refer to the category $\mathcal{P}$ with

$$\begin{aligned} \mathrm{Ob}(\mathcal{P}) &:= \text{all pointed topological spaces}, \\ \mathrm{Mor}((X,x_0),(Y,y_0)) &:= \text{all continuous maps } f \text{ from } X \text{ to } Y \text{ with } f(x_0) = y_0 \end{aligned}$$

with the usual composition of maps as the *category of pointed topological spaces*.

(g) We refer to the category $\mathcal{TG}$ with

$$\begin{aligned} \mathrm{Ob}(\mathcal{TG}) &:= \text{all topological groups}, \\ \mathrm{Mor}(X,Y) &:= \text{all homomorphisms from } X \text{ to } Y \text{ that are continuous}, \end{aligned}$$

with the usual composition of maps as the *category of topological groups*.

[131] If $X \neq Y$ then $\mathrm{Mor}(X,Y) = \varnothing$, but then $\mathrm{Mor}(X,Y) \times \mathrm{Mor}(Y,Z)$ is also the empty set for any Z.

(h) We refer to the category $\mathcal{M}$ with

$$\begin{aligned} \mathrm{Ob}(\mathcal{M}) &:= \text{all manifolds,} \\ \mathrm{Mor}(X,Y) &:= \mathcal{C}(X,Y) := \text{all smooth maps from } X \text{ to } Y, \end{aligned}$$

with the usual composition of maps as the *category of manifolds*. We define the category of *pointed manifolds* the same way as we defined the category of *pointed topological spaces*.

(i) A *pair of topological spaces* is a pair (X, A), where X is a topological space and A is a subset of X. We refer to the category $\mathcal{Q}$ with

$$\begin{aligned} \mathrm{Ob}(\mathcal{Q}) &:= \text{all pairs of topological spaces,} \\ \mathrm{Mor}((X,A),(Y,B)) &:= \text{all continuous maps } f \text{ from } X \text{ to } Y \text{ with } f(A) \subset B \end{aligned}$$

with the usual composition of maps as the *category of pairs of topological spaces*. Sometimes it is helpful to exclude the case that $A = \varnothing$. We refer to a pair (X, A) of topological spaces with $A \neq \varnothing$ as a *non-trivial* pair of topological spaces. The same was a s above we obtain the *category $\mathcal{Q}'$ of non-trivial pairs of topological spaces*

There exist also more "exotic" examples of categories.

(j) Let G be an arbitrary group. We consider

$$\begin{aligned} \mathrm{Ob}(\mathcal{C}) &:= \{\text{a set with a unique element } *\}, \\ \mathrm{Mor}(*,*) &:= G. \end{aligned}$$

We define

$$\begin{aligned} \mathrm{Mor}(*,*) \times \mathrm{Mor}(*,*) &\to \mathrm{Mor}(*,*) \\ (f,g) &\mapsto g \circ f := gf \end{aligned}$$

via the group structure on $\mathrm{Mor}(*,*) = G$. The axioms of a category can be easily deduced from the group axioms of G.

The name "morphisms" suggests that morphisms are necessarily maps. But as we will later see, this is not necessarily always the case.

Convention. If the category we are working with at a given moment is understood, then we just write map instead of morphisms. For example we might write "let $f\colon X \to Y$ be a map", if X and Y are groups, then it is understood that the map is in fact a homomorphism, whereas if X and Y are topological spaces, then it is understood that f is continuous. This convention thus generalizes the convention that we introduced on page 75.

6.2. **Functors.**

Definition. Let $\mathcal{C}$ and $\mathcal{D}$ be two categories. A *covariant functor* $F\colon \mathcal{C} \to \mathcal{D}$ consists of a map

$$F\colon \mathrm{Ob}(\mathcal{C}) \to \mathrm{Ob}(\mathcal{D})$$

and for all $X, Y \in \mathcal{C}$ there exists furthermore a map

$$F\colon \mathrm{Mor}(X,Y) \to \mathrm{Mor}(F(X),F(Y)),$$

such that following axioms are satisfied

(F1) $F(\mathrm{id}_X) = \mathrm{id}_{F(X)}$ for all $X \in \mathrm{Ob}(\mathcal{C})$,
(F2) for $\phi \in \mathrm{Mor}(X,Y)$ and $\psi \in \mathrm{Mor}(Y,Z)$ the following equality holds

$$F(\psi \circ \phi) \;=\; F(\psi) \circ F(\phi) \;\in \mathrm{Mor}(F(X), F(Z)).$$

Convention. For a covariant functor F and $\phi \in \mathrm{Mor}(X,Y)$ we often write ϕ_* instead of $F(\phi)$. The second axiom then becomes $(\psi \circ \phi)_* = \psi_* \circ \phi_*$.

Now we give some examples of functors.

Examples.

(1) Let $\mathcal{V}$ be the category of real vector spaces and let W be a real vector space. Then the map

$$\begin{array}{rcl} F\colon \mathrm{Ob}(\mathcal{V}) & \to & \mathrm{Ob}(\mathcal{V}) \\ V & \mapsto & \mathrm{Hom}_{\mathbb{R}}(W,V), \end{array}$$

together with the maps

$$\begin{array}{rcl} \mathrm{Mor}(U,V) & \mapsto & \mathrm{Mor}(F(U),F(V)) \\ (\phi\colon U \to V) & \mapsto & \begin{pmatrix} \mathrm{Hom}(W,U) & \to & \mathrm{Hom}(W,V) \\ f & \mapsto & \phi \circ f \end{pmatrix} \end{array}$$

defines a covariant functor.

(2) Let $\mathcal{P}$ be the category of pointed manifolds and let $\mathcal{V}$ be the category of real vector spaces. By Proposition 3.30 (2) we know that the map

$$\begin{array}{rcl} F\colon \mathrm{Ob}(\mathcal{P}) & \to & \mathrm{Ob}(\mathcal{V}) \\ (M,P) & \mapsto & T_P M, \end{array}$$

together with the maps

$$\begin{array}{rcl} \mathrm{Mor}((M,P),(N,Q)) & \mapsto & \mathrm{Mor}(T_P M, T_Q N) \\ f & \mapsto & f_* = Df_P \end{array}$$

is a covariant functor from the category of pointed manifolds to the category of real vector spaces.

(3) Let $\mathcal{X}$ be the category of topological spaces and let $X \in \mathrm{Ob}(\mathcal{X})$. It follows easily from Lemma 1.53 (3c) that the map

$$\begin{array}{rcl} F\colon \mathrm{Ob}(\mathcal{X}) & \to & \mathrm{Ob}(\mathcal{X}) \\ Y & \mapsto & X \times Y, \end{array}$$

together with the maps

$$\begin{array}{rcl} \mathrm{Mor}(Y,Z) & \mapsto & \mathrm{Mor}(X \times Y, X \times Z) \\ f & \mapsto & \mathrm{id}_X \times f \end{array}$$

is a covariant functor from the category of topological spaces to itself.

(4) Let $\mathcal{X}$ be the category of topological spaces and let $\mathcal{C}$ be the category of all sets. It follows easily from Lemma 1.101 that the map

$$\begin{array}{rcl} F\colon \operatorname{Ob}(\mathcal{X}) & \to & \operatorname{Ob}(\mathcal{C}) \\ X & \mapsto & \pi_0(X), \end{array}$$

together with the maps

$$\begin{array}{rcl} \operatorname{Mor}(Y,Z) & \mapsto & \operatorname{Mor}(X\times Y, X\times Z) \\ C & \mapsto & f(C) \end{array}$$

is a covariant functor from the category of topological spaces to the category of sets.

We also have the following definition which looks almost the same as the previous definition.

Definition. Let $\mathcal{C}$ and $\mathcal{D}$ be two categories. A *contravariant functor* $F\colon \mathcal{C}\to\mathcal{D}$ consists of a map

$$F\colon \operatorname{Ob}(\mathcal{C}) \to \operatorname{Ob}(\mathcal{D})$$

and for all $X, Y \in \mathcal{C}$ there exists furthermore a map

$$\operatorname{Mor}(X,Y) \to \operatorname{Mor}(F(Y),F(X))$$

such that following axioms are satisfied:

(F1) $F(\mathrm{id}_X) = \mathrm{id}_{F(X)}$ for all $X \in \operatorname{Ob}(\mathcal{C})$,
(F2) for any $\phi \in \operatorname{Mor}(X,Y)$ and $\psi \in \operatorname{Mor}(Y,Z)$ we have

$$F(\psi\circ\phi) \;=\; F(\phi)\circ F(\psi) \;\in \operatorname{Mor}(F(Z),F(X)).$$

The definition of a contravariant functor looks very much the same as the definition of a covariant functor. The difference is that a contravariant functor "reverses the direction of maps" and the orders of $F(\psi)$ and $F(\phi)$ in the second axiom are swapped.

Convention. For a contravariant functor F and $\phi \in \operatorname{Mor}(X,Y)$ we often write ϕ^* instead of $F(\phi)$. The second axiom then becomes $(\psi\circ\phi)^* = \phi^*\circ\psi^*$.

Examples.

(1) Let $\mathcal{V}$ be the category of real vector spaces. Then the map

$$\begin{array}{rcl} F\colon \operatorname{Ob}(\mathcal{V}) & \to & \operatorname{Ob}(\mathcal{V}) \\ V & \mapsto & V^* := \operatorname{Hom}_{\mathbb{R}}(V,\mathbb{R}) =: \text{dual vector space of } V, \end{array}$$

together with the maps

$$\begin{array}{rcl} \operatorname{Mor}(U,V) & \mapsto & \operatorname{Mor}(V^*,U^*) \\ (\phi\colon U\to V) & \mapsto & \left(\begin{array}{rcl} \operatorname{Hom}(V,\mathbb{R}) & \to & \operatorname{Hom}(U,\mathbb{R}) \\ f & \mapsto & f\circ\phi \end{array}\right) \end{array}$$

is a contravariant functor.

(2) Let $\mathcal{T}$ be the category of topological spaces and let $\mathcal{V}$ be the category of real vector spaces. Then the map

$$\begin{array}{rcl} F\colon \operatorname{Ob}(\mathcal{T}) & \to & \operatorname{Ob}(\mathcal{V}) \\ X & \mapsto & C(X,\mathbb{R}) := \text{set of continuous functions } X \to \mathbb{R}, \end{array}$$

together with the maps

$$\begin{array}{rcl} \operatorname{Mor}(X,Y) & \mapsto & \operatorname{Mor}(C(Y,\mathbb{R}), C(X,\mathbb{R})) \\ (\phi\colon X \to Y) & \mapsto & \left(\begin{array}{rcl} C(Y,\mathbb{R}) & \to & C(X,\mathbb{R}) \\ f & \mapsto & f \circ \phi \end{array} \right) \end{array}$$

is a contravariant functor.

(3) Let $\mathcal{M}$ be the category of manifolds, let $\mathcal{V}$ be the category of real vector spaces and let $k \in \mathbb{Z}_{\geq 0}$. In [BT, Chapter 2] or [Le2, Corollary 17.3] it is shown that the map

$$\begin{array}{rcl} F\colon \operatorname{Ob}(\mathcal{M}) & \to & \operatorname{Ob}(\mathcal{V}) \\ M & \mapsto & H^k_{\mathrm{dR}}(M) := k\text{-th de Rham cohomology group of } M, \end{array}$$

together with the maps

$$\begin{array}{rcl} \operatorname{Mor}(M,N) & \mapsto & \operatorname{Mor}(H^k_{\mathrm{dR}}(N), H^k_{\mathrm{dR}}(M)) \\ (f\colon M \to N) & \mapsto & \left(\begin{array}{rcl} f^*\colon H^k_{\mathrm{dR}}(N) & \to & H^k_{\mathrm{dR}}(M) \\ \omega & \mapsto & f^*\omega \end{array} \right) \end{array}$$

is a contravariant functor.

We will not see any other examples of contravariant functors in the near future. We will come back to them when we study cohomology groups.

6.3. **The fundamental group as functor.** Now, after recalling the definition of categories and functors, we turn back to the study of fundamental groups.

Let $f\colon X \to Y$ be a map between topological spaces and let $x_0 \in X$ be a base point. If $\gamma\colon [0,1] \to X$ is a loop in the point x_0, then $f \circ \gamma\colon [0,1] \to Y$ is a loop in the point $f(x_0)$. It is straightforward to see that

$$\begin{array}{rcl} f_*\colon \pi_1(X,x_0) & \to & \pi_1(Y,f(x_0)) \\ [\gamma] & \mapsto & [f \circ \gamma] \end{array}$$

is a well-defined map, i.e. $f_*([\gamma])$ is independent of the choice of the representative of the path-homotopy class.[132] Furthermore it follows easily from the definitions[133] that f_* is a group homomorphism. We call f_* the *induced map*. It also follows easily from the definitions that

$$\begin{array}{rcll} (\mathrm{id}_X)_* & = & \mathrm{id}_{\pi_1(X,x_0)}, & \text{for all pointed pairs } (X,x_0), \\ (g \circ f)_* & = & g_* \circ f_*, & \text{for all maps } f\colon (X,x_0) \to (Y,y_0) \text{ and } g\colon (Y,y_0) \to (Z,z_0). \end{array}$$

[132]Indeed, suppose that γ and δ are two loops in (X,x_0) that are path-homotopic. Let F be a path-homotopy between γ and δ. Then $f \circ F$ is a path-homotopy between $f \circ \gamma$ and $f \circ \delta$. We had used almost the same argument on page 227.

[133]If γ and δ are loops in x_0, then it follows immediately from the definitions that $(f \circ \gamma) * (f \circ \delta) = f \circ (\gamma * \delta)$.

Summarizing we just convinced ourselves of the validity of the following proposition.

Proposition 6.1. *Let $\mathcal{P}$ be the category of pointed topological spaces and let $\mathcal{G}$ be the category of groups. Then the map*

$$\begin{array}{rcl} \mathrm{Ob}(\mathcal{P}) & \to & \mathrm{Ob}(\mathcal{G}) \\ (X, x_0) & \mapsto & \pi_1(X, x_0) \end{array}$$

together with the maps

$$\begin{array}{rcl} \mathrm{Mor}((X, x_0), (Y, y_0)) & \to & \mathrm{Mor}(\pi_1(X, x_0), \pi_1(Y, y_0)) \\ (f\colon (X, x_0) \to (Y, y_0)) & \mapsto & \left(\begin{array}{rcl} f_*\colon \pi_1(X, x_0) & \to & \pi_1(Y, y_0) \\ [\gamma] & \mapsto & [f \circ \gamma] \end{array} \right) \end{array}$$

is a covariant functor.

Next we will see that the functoriality of the fundamental groups can be helpful for studying certain questions.

Definition. Let X be a topological space and let $A \subset X$ be a subspace. We say A is a *retract of* X if there exists a retraction $r\colon X \to A$, i.e. a map[134] with $r(a) = a$ for all $a \in A$.

Examples.

(1) Let X be a topological space. Then any point $x_0 \in X$ is a retract of X, indeed, the map $r(x) = x_0$ for $x \in X$ is a retraction.
(2) The circle $S^1 \times \{1\}$ is a retract of the torus $S^1 \times S^1$, in fact a retraction is given by $r(z, w) = (z, 1)$.
(3) The circle S^1 is a retract of $\overline{B}^2 \setminus \{(0, 0)\}$, indeed, the map

$$\begin{array}{rcl} \overline{B}^2 \setminus \{(0,0)\} & \to & S^1 \\ z & \mapsto & \frac{z}{|z|} \end{array}$$

is a retraction. (Here we consider $\overline{B}^2$ as subset of $\mathbb{C}$.)
(4) The set $S^0 = \{-1, 1\}$ is not a retract of $\overline{B}^1 = [-1, 1]$. Indeed, since $[-1, 1]$ is connected and since S^0 is discrete it follows from Lemma 1.92 that any map from $[-1, 1]$ to S^0 has to be constant. Thus there does not exist a map $f\colon [-1, 1] \to S^0$ with $f(-1) = -1$ and $f(1) = 1$.

Now we can push the last example up by one dimension.

Lemma 6.2. *The circle S^1 is not a retract of $\overline{B}^2$.*

[134] As always, a map is understood to be continuous. If we did not demand continuity, then any non-empty subset of X would be a retract of X.

Proof. We denote by $i\colon S^1 \to \overline{B}^2$ the inclusion map. Suppose there exists a retraction $r\colon \overline{B}^2 \to S^1$. By definition this means that $r \circ i = \mathrm{id}_{S^1}$. We obtain the following commutative diagram of maps between topological spaces

$$\begin{tikzcd} & \overline{B}^2 \arrow[dr, "r"] & \\ S^1 \arrow[ur, "i"] \arrow[rr, "r\circ i = \mathrm{id}_{S^1}"'] & & S^1 \end{tikzcd} \quad \text{which induces} \quad \begin{tikzcd} & \pi_1(\overline{B}^2, 1) \arrow[dr, "r_*"] & \\ \pi_1(S^1, 1) \arrow[ur, "i_*"] \arrow[rr, "(r\circ i)_* = (\mathrm{id}_{S^1})_*"'] & & \pi_1(S^1, 1). \end{tikzcd}$$

It follows from the functoriality of fundamental groups that $r_* \circ i_* = (r \circ i)_*$, i.e. the diagram on the right-hand side commutes. By the functoriality we know that $(\mathrm{id}_{S^1})_*$ is the identity of $\pi_1(S^1, 1)$.

We saw on page 238 that $\pi_1(\overline{B}^2, 1)$ is the trivial group whereas we saw in Corollary 5.9 that $\pi_1(S^1, 1)$ is not the trivial group. The lower horizontal map in the second diagram is thus an isomorphism of a non-trivial group, but the upper map factors through the trivial group, i.e. the composition of i_* and r_* cannot be an isomorphism of a non-trivial group.[135] Thus we have obtained a contradiction. □

The last example and the last lemma now raise the following question.

Question 6.3. *Let $n \geq 2$. Is S^n a retract of $\overline{B}^{n+1}$?*

At the moment we cannot answer this question. We will first need to develop new invariants before we can return to this question. We will not be able to answer this question for many months.

Almost exactly the same argument as in the proof of Lemma 6.2 gives a proof of the following lemma which we will prove in Exercise 6.2.

Lemma 6.4. *Let X be a topological space and let $A \subset X$ be a retract of X. Let $a \in A$. We denote by $i\colon A \to X$ the inclusion map.*

1. *There exists an epimorphism $\varphi\colon \pi_1(X, a) \to \pi_1(A, a)$ such that $\varphi \circ i_*$ is the identity on $\pi_1(A, a)$.*
2. *The inclusion induced map $\pi_1(A, a) \to \pi_1(X, a)$ is a monomorphism.*

Example. We had just seen on page 247 that the circle $S^1 \times \{1\}$ is a retract of the torus $S^1 \times S^1$. Furthermore we saw in Corollary 5.9 that $\pi_1(S^1, 1)$ is not the trivial group. It follows from Lemma 6.4 that the fundamental group of the torus is also non-trivial. In Proposition 5.14 we saw that $\pi_1(S^2) = 0$. Thus we see that the torus $S^1 \times S^1$ and the sphere S^2 are not homeomorphic.

Lemma 6.5. $(*)$ *Let E_8 be the regular octagon from the definition of the surface of genus 2, see page 119 for details, and let $\Sigma = E_8/\sim$ be the surface of genus 2. Let P and Q be two adjacent vertices of E_8. Then the following hold:*

[135] Why not?

(1) *The map*

$$\begin{array}{rcl} \gamma\colon S^1 & \to & E_8/\sim \\ e^{2\pi i t} & \mapsto & [t\cdot P + (1-t)\cdot Q] \end{array}$$

is a homeomorphism onto its image.

(2) *There exists a map* $\Phi\colon E_8/\sim \to S^1\times S^1$ *such that the following diagram commutes*

$$\begin{tikzcd} & S^1 \arrow[dl, "\gamma"'] \arrow[dr, "z\mapsto(z,1)"] & \\ E_8/\sim \arrow[rr, "\Phi"] & & S^1\times S^1. \end{tikzcd}$$

(3) *The subset* $\gamma(S^1)$ *is a retract of* $\Sigma = E_8/\sim$.

(4) *There exists an epimorphism* $\pi_1(\Sigma, P)\to\mathbb{Z}$ *that sends* $[\gamma]$ *onto* 1.[136]

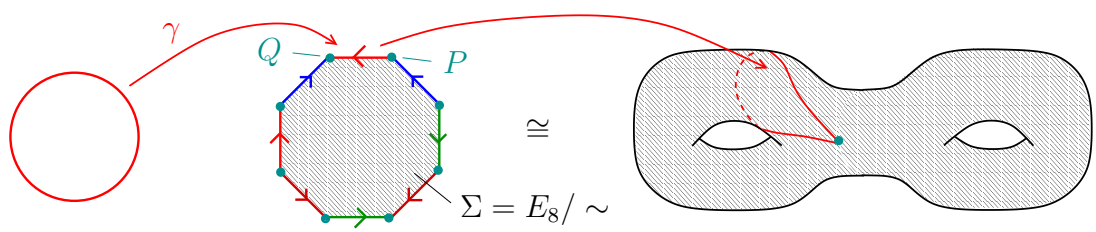

FIGURE 141. Illustration of Lemma 6.5.

Remark. The lemma shows in particular that the four loops that we drew in Figure 49 on the surface of genus 2 represent non-trivial elements in the fundamental group. Almost the same way one can show that in the surface of genus g, $g\geq 2$, defined as a quotient of a regular $4g$-gon, each edge gives rise to a non-trivial element of the fundamental group.

Proof $(*)$.

(1) It is clear that γ is continuous and injective. By Proposition 3.7 we know that $\Sigma = E_8/\sim$ is Hausdorff. It follows from Proposition 1.40 that γ is a homeomorphism onto its image.

(2) The map Φ is sketched in Figure 142 on the top. It is given by sending all points in the lower pentagon to a single point, such a map can be extended continuously to the upper pentagon in such a way that the remaining four sides of the upper

[136]Recall that by the bijection on page 228 we view maps $f\colon S^1\to\Sigma$ with $f(1)=P$ as elements in $\pi_1(\Sigma,P)$.

pentagon get sent homeomorphically to the four sides of the square.[137] [138] This map Φ has the desired property.

(3) The retraction is now given by the concatenation of the maps

$$\Sigma \xrightarrow{\Phi} S^1 \times S^1 \xrightarrow{(z,w)\mapsto z} S^1 \xrightarrow{\gamma} \Sigma.$$

(4) This statement is a consequence of (3), Lemma 6.4 and Corollary 5.9. □

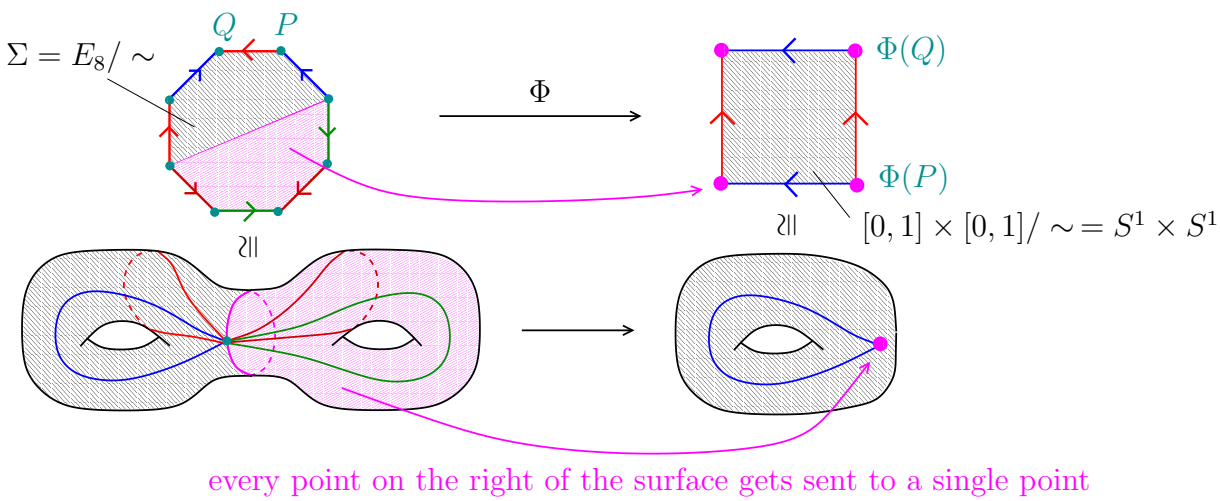

FIGURE 142.

This lemma concludes our discussion of some of the basic properties of fundamental groups. So far we could either show that the fundamental group of a given topological space is trivial, or we could show it is non-trivial by invoking Corollary 5.9. In the next section we will start with a much more systematic discussion of fundamental groups which will allow us to determine the fundamental groups of many topological spaces.

6.4. **Natural transformations.** In this last section we introduce the notion of a natural transformation between two functors. This notion will initially not play a major role, but once we introduce homology groups this notion will become an increasingly important to

[137] It is clearly slightly painful to write down this map explicitly. It is easier to write down a similar map, which maps a square X onto a triangle Y in such a way that one side of the square gets sent to a vertex of the triangle and such that the remaining three sides of the square get sent to the three sides of the triangle. For example the map

$$\begin{array}{rcl} X := [0,1]\times[0,1] & \to & Y := \{(x,y)\in\mathbb{R}^2 \,|\, x\in[0,1], y\in[0,x]\} \\ (x,y) & \mapsto & (x,xy) \end{array}$$

is of that form.

[138] In the lower part of Figure 142 we illustrate the map for the surfaces viewed as subsets of $\mathbb{R}^3$. There the map Φ is given by crushing the right-hand half of the surface of genus 2 to a single point.

state results precisely. As of right now we do not have enough functors at our hand to perhaps truly appreciate the value of the notion of a natural transformation.

After this long preamble, let us give the definition of natural transformations.

Definition. Let $\mathcal{C}$ and $\mathcal{D}$ be two categories and let $F, G\colon \mathcal{C} \to \mathcal{D}$ be two covariant functors. A *natural transformation between the functors F and G* assigns to each $X \in \mathrm{Ob}(\mathcal{C})$ a morphism $\Phi_X\colon F(X) \to G(X)$ in $\mathcal{D}$ such that for each morphism $f\colon X \to Y$ in $\mathcal{C}$ the following diagram commutes:

$$\begin{tikzcd} F(X) \arrow[r, "F_*(f)"] \arrow[d, "\Phi_X"'] & F(Y) \arrow[d, "\Phi_Y"] \\ G(X) \arrow[r, "G_*(f)"] & G(Y). \end{tikzcd}$$

If for every $X \in \mathrm{Ob}(\mathcal{C})$ the morphism $\Phi_X\colon F(X) \to G(X)$ is an isomorphism, then we refer to the natural transformation as a *natural isomorphism.* Given $X \in \mathrm{Ob}(\mathcal{C})$ we often say that $F(X)$ and $G(X)$ are *naturally* isomorphic.[139] The same way we can of course also define the notion of a natural transformation between two contravariant functors.

Remark. The notion of a natural transformation can also be summarized in the following diagram:

$$\begin{tikzcd} & F(X) \arrow[rr, "F_*(f)"] \arrow[dd, "\Phi_X"] & & F(Y) \arrow[dd, "\Phi_Y"] \\ X \arrow[ur, squiggly] \arrow[rr, "f"] \arrow[dr, squiggly] & & Y \arrow[ur, squiggly] \arrow[dr, squiggly] & \\ & G(X) \arrow[rr, "G_*(f)"] & & G(Y). \end{tikzcd}$$

Here the wiggly arrows are not maps but they are just meant to remind us which objects a functor associates to the objects X and Y.

Now we will see that we have encountered natural transformations and natural isomorphisms much more often than one might have initially thought.

Examples.

(1) Let $\mathcal{R}$ the category of commutative rings and let $\mathcal{G}$ be the category of groups. Let $n \in \mathbb{N}$. We consider the functors

$$\begin{array}{rcl} F\colon \mathcal{R} & \to & \mathcal{G} \\ R & \mapsto & \mathrm{GL}(n, R) \end{array} \quad \text{and} \quad \begin{array}{rcl} G\colon \mathcal{R} & \to & \mathcal{G} \\ R & \mapsto & R^* := \text{units in } R. \end{array}$$

[139] In the literature the words "natural isomorphism" and "canonical isomorphism" are often used indiscriminately, but whereas the expression "natural isomorphism" has a precise meaning, the expression "canonical isomorphism" is not a well-defined mathematical concept.

For each commutative ring R we consider the group homomorphism

$$\begin{array}{rcl} \Phi_R\colon \mathrm{GL}(n,R) & \to & R^* \\ A & \mapsto & \det(A). \end{array}$$

We claim that these group homomorphisms define a natural transformation from F to G. Thus let $f\colon R \to S$ be a homomorphism between commutative rings and let $A \in F(R)$, i.e. $A = (a_{ij})$ is a matrix in $\mathrm{GL}(n,R)$. We have

$$\begin{aligned} \Phi_A(F_*(f)(A)) &= \det((f(a_{ij}))_{i,j=1,\dots,n}) \overset{\text{Leibniz formula}}{\overset{\downarrow}{=}} \sum_{\sigma\in S_n} \mathrm{sign}(\sigma)\cdot\prod_{i=1}^n f(a_{i,\sigma(i)}) \\ &\underset{\substack{\uparrow \\ f \text{ is a ring homomorphism}}}{=} f\Big(\sum_{\sigma\in S_n} \mathrm{sign}(\sigma)\cdot\prod_{i=1}^n a_{i,\sigma(i)}\Big) \underset{\substack{\uparrow \\ \text{Leibniz formula}}}{=} f(\det(A)) = G_*(f)(\Phi_R(A)). \end{aligned}$$

But that means, by definition, that the Φ_R define a natural transformation from F to G.

(2) Let $\mathcal{V}$ be the category of real vector spaces and consider the functor F given by[140]

$$\text{real vector space } V \mapsto (V^*)^*$$

and

$$(f\colon V \to W) \mapsto ((f^*)^*\colon (V^*)^* \to (W^*)^*).$$

For each real vector V we denote by Φ_V the homomorphism

$$\begin{array}{rcl} V & \to & (V^*)^* \\ v & \mapsto & \left(\begin{array}{rcl} V^* & \to & \mathbb{R} \\ (\varphi\colon V \to \mathbb{R}) & \mapsto & \varphi(v) \end{array}\right). \end{array}$$

It is straightforward to verify that these maps define a natural transformation from the identity functor to the functor F.[141]

(3) On page 196, given a submanifold M of some $\mathbb{R}^n$ and a point $P \in M$, we introduced the visual tangent space V_PM which is a subvector space V_PM of $\mathbb{R}^n$. Both the usual tangent space and the visual tangent space define a functor from the category of pointed submanifolds of some $\mathbb{R}^n$ to the category of real vector spaces. Proposition 3.32 (2) says that there exists a natural isomorphism between these two functors.

The above examples are perhaps not particularly impressive. But as we will see, the notion of a natural transformation will eventually become one of the key notions in this course.

[140]As usual, given a real vector space V we denote by $V^* = \mathrm{Hom}_{\mathbb{R}}(V,\mathbb{R})$ the dual space. Therefore $(V^*)^*$ is the dual space of the dual space of V. The functor given by $V \mapsto V^*$ is contravariant, but the "double functor" $V \mapsto (V^*)^*$ is again covariant.

[141]Is this in fact a natural isomorphism, i.e. is V always isomorphic to $(V^*)^*$?

Exercises for Chapter 6.

Exercise 6.1. Show that $\pi_1(S^1 \times S^1)$ admits an epimorphism onto $\mathbb{Z}^2$.

Exercise 6.2. Prove Lemma 6.4.

Exercise 6.3. Let X be a topological space and let A be a retract.

(a) Suppose that X is Hausdorff. Show that A is a closed subset of X.
(b) Show that the conclusion of (a) does not necessarily hold if we do not assume that X is Hausdorff.

Exercise 6.4. Let $\varphi\colon X \to Y$ be a map between topological spaces. Show that if $\varphi_*\colon \pi_1(X, x_0) \to \pi_1(Y, \varphi(x_0))$ is an isomorphism (epimorphism, monomorphism) for some base point $x_0 \in X$, then for any other base point x_1 in the same path component of X the map $\varphi_*\colon \pi_1(X, x_1) \to \pi_1(Y, \varphi(x_1))$ is also an isomorphism (epimorphism, monomorphism).

7. Fundamental groups and coverings

We have now introduced the fundamental group of a (pointed) topological space and we have proved several basic facts. But the only proof that fundamental groups are non-trivial relied on a fact from complex analysis. In particular, so far we have not yet managed to compute a single fundamental group that is not the trivial group. For example, we know that $\pi_1(S^1)$ is non-trivial, but we do not know what group it is.

In this chapter we will compute many non-trivial fundamental groups using the theory of covering spaces. Before we delve into the theory of covering spaces we insert a short section on the cardinality of sets.

7.1. **The cardinality of sets** $(*)$**.** In this short section we introduce the notion of the cardinality of a set. This notion plays a role in all branches of mathematics.

Definition.

(1) We say that two given sets S and T are *equinumerous* if there exists a bijection $\varphi\colon S \to T$.[142]
(2) Given a set S we define the *cardinality* $\#S$ *of* S as the equinumerosity equivalence class of S in the class of all sets. Put differently we have
$$\#S \ := \ \text{class of all sets } T \text{ that are equinumerous with } S.$$
(3) If S is a finite set, then we write $\#S = n$ for the unique $n \in \mathbb{N}_0$ which satisfies $\#S = \#\{1, \dots, n\}$. If S infinite, then sometimes we write $\#S = \infty$.
(4) Let S be a set. If $\#S = n$ for some $n \in \mathbb{N}_0$ or $\#S = \#\mathbb{N}$, then we say that S is *countable*, otherwise we say that S is *uncountable*.

Example. We have $\#(\mathbb{R} \setminus \{0\}) = \#\mathbb{R}$. Indeed a bijection is given by
$$\begin{array}{rcl} \mathbb{R} \setminus \{0\} & \to & \mathbb{R} \\ x & \mapsto & \begin{cases} x, & \text{if } x \in \mathbb{R} \setminus \mathbb{N}_0, \\ x-1, & \text{if } x \in \mathbb{N}. \end{cases} \end{array}$$

Remark.

(1) Another way of putting the definition of cardinality is that given two sets S and T we have $\#S = \#T$ if and only if there exists a bijection from S to T.
(2) In almost any proper course on real analysis it is shown that $\mathbb{Q}$ is countable and that $\mathbb{R}$ is not countable. Thus we $\#\mathbb{Q} \neq \#\mathbb{R}$. This example also shows that the above notation $\#S = \infty$ for an infinite set S is rather dangerous, since we have $\#\mathbb{Q} = \infty$ and $\#\mathbb{R} = \infty$ even though $\#\mathbb{Q} \neq \#\mathbb{R}$.
(3) If S is countable, then any subset T is also countable.[143]

[142] It follows immediately from the definitions that being equinumerous defines an equivalence relation on the class of all sets.

[143] After excluding the case that S is finite and the case that T is finite one sees that one has to prove the following: given any infinite subset T of $\mathbb{N}$ there exists a bijection $\varphi\colon \mathbb{N} \to T$. Such a bijection is given by defining $\varphi(i)$ as the i-th smallest element of T.

Definition. Let S and T be two sets.

(1) We write $\#S \leq \#T$ if there exists a monomorphism $\varphi\colon S \to T$.
(2) We write $S < T$ if $\#S \leq \#T$ but $\#S \neq \#T$.

Examples.

(1) We have $\#\mathbb{Q} \leq \#\mathbb{R}$ but we had just pointed out that $\#\mathbb{Q} \neq \#\mathbb{R}$ since $\#\mathbb{Q} = \#\mathbb{N}$ but $\#\mathbb{R} \neq \#\mathbb{N}$. Therefore $\#\mathbb{Q} < \#\mathbb{R}$.
(2) It follows from the previous remark that a set S is countable if and only if $S \leq \#\mathbb{N}$.
(3) Given a set X we denote by $P(X)$ its power set, i.e. the set of all subsets of X. For every X we have $\#X < \#P(X)$.[144] Indeed, the map

$$\begin{array}{ccc} X & \to & P(X) \\ x & \mapsto & \{x\} \end{array}$$

is an injection, hence $\#X \leq \#P(X)$. Now let $f\colon X \to P(X)$ be a map. We have to show that it cannot be surjective. Indeed, the set

$$Y \ := \ \{x \in X \mid x \notin f(x)\}$$

is not in the range of f: if there did exist a $z \in X$ with $f(z) = Y$, then $z \in Y$ if and only if $z \notin Y$, which is a contradiction.

Theorem 7.1. (Bernstein-Schröder)[145] *Let S and T be two sets. Then*

$$\#S \leq \#T \text{ and } \#T \leq \#S \quad \Longrightarrow \quad \#S = \#T.$$

Example. Let U be an open non-empty subset of $\mathbb{R}$.[146] Then $\#U = \#\mathbb{R}$. Indeed, the inclusion $U \to \mathbb{R}$ is of course injective. Furthermore, since U is open there exists an open interval (a, b) that is a subset of U. But any open interval is homeomorphic to $\mathbb{R}$, so there exists an injective map $\mathbb{R} \xrightarrow{\cong} (a, b) \subset U$. It follows from the Bernstein-Schröder-Theorem that there exists a bijection from U to $\mathbb{R}$.

Sketch of proof $(*)$. Let $f\colon A \to B$ and $g\colon B \to A$ be two injective maps between two sets A and B. Without loss of generality we can assume that A and B are disjoint.[147] We denote by $\sim$ the equivalence relation on $A \sqcup B$ that is generated by $a \sim f(a)$ for $a \in A$ and by $g \sim g(b)$ for $b \in B$. Note that if $a \in A$ lies in the image of g, then by the injectivity of f there exists a unique element $g^{-1}(a) \in B$ and we have $a \sim g^{-1}(a)$. The same remark works with the roles of f and g reversed.

[144] This statement is known as Cantor's Theorem.

[145] The theorem was initially stated by Cantor without a proof and it was first proved by Felix Bernstein (1878-1956) and Ernst Schröder (1841-1902) in 1896. Sometimes it is also called the Cantor-Bernstein-Schröder theorem.

[146] Every open subset of $\mathbb{R}$ is the disjoint union of open intervals (a_i, b_i), $i \in I$. The number of intervals can be finite, but it can also be countably infinite and in fact it can also be uncountably infinite. For example the complement of the Cantor set consists of uncountably many open intervals.

[147] If A and B are not disjoint, then we replace A by $A' = A \times \{0\}$ and B by $B' = B \times \{1\}$, then A' and B' are disjoint, since any two elements in A' and B' now have different second coordinate.

Since $A \sqcup B$ is the disjoint union of all equivalence classes it suffices to prove the following claim.[148]

Claim. For each equivalence class I there exists a bijection $A \cap I \to B \cap I$.

So let I be an equivalence class and let $a \in A \cap I$.[149] The subset $I \subset A \sqcup B$ consists of all elements equivalent to a. The equivalence class I is then of one of the following three types:[150]

$$\begin{array}{lcccccccccl}
 & & & A & B & A & B & A & B & & \\
(1) & a' & \dots & f^{-1}(g^{-1}(a)), & g^{-1}(a), & a, & f(a), & g(f(a)), & f(g(f(a)), & \dots & \text{with } a' \in A \setminus g(B) \\
(2) & b' & \dots & f^{-1}(g^{-1}(a)), & g^{-1}(a), & a, & f(a), & g(f(a)), & f(g(f(a)), & \dots & \text{with } b' \in B \setminus f(A) \\
(3) & \dots & \dots & f^{-1}(g^{-1}(a)), & g^{-1}(a), & a, & f(a), & g(f(a)), & f(g(f(a)), & \dots &
\end{array}$$

In case (1) the map f defines a bijection $A \cap I \to B \cap I$, in case (2) the map g^{-1} defines a bijection $A \cap I \to B \cap I$ and in case (3) both f and g^{-1} define a bijection $A \cap I \to B \cap I$. This concludes the proof of the claim. $\square$

Remark. The *continuum hypothesis*, first formulated by Cantor in 1878, states that there exists no set S with $\#\mathbb{Q} < \#S < \#\mathbb{R}$. Any attempt at proving this statement relies on first of all making precise what "sets" are supposed to be or what axioms they are supposed to satisfy. As wikipedia writes "the answer to this problem is independent of ZFC set theory (that is, Zermelo-Fraenkel set theory with the axiom of choice included), so that either the continuum hypothesis or its negation can be added as an axiom to ZFC set theory, with the resulting theory being consistent if and only if ZFC is consistent." This independence was proved in 1963 by Paul Cohen for which he obtained a Fields medal in 1966. More useful information can as always be found on wikipedia:

`https://en.wikipedia.org/wiki/Continuum_hypothesis`

7.2. **Covering spaces.** Now we return to the study of topological spaces.

Definition. Let $p\colon X \to B$ be a map between topological spaces.

(1) We say an open subset $U \subset B$ is *uniformly covered*, if $p^{-1}(U)$ is the union of disjoint open subsets $\{V_i\}_{i \in I}$ with the property, that the restriction of p to each subset V_i is a homeomorphism.

[148]Indeed, recall that equivalence classes always give a disjoint decomposition of a set. In our case, if I_j, $j \in J$ denote the set of equivalence classes of $\sim$ on $A \sqcup B$, then we have

$$A \sqcup B = \bigsqcup_{j \in J} I_j \quad \text{and therefore also} \quad A = \bigsqcup_{j \in J} (A \cap I_j) \text{ and } B = \bigsqcup_{j \in J} (B \cap I_j).$$

Therefore it suffices to give a bijection $A \cap I_j \to B \cap I_j$ for every $j \in J$.

[149]There always exists an $a \in A \cap I$. Indeed, I is by definition non-empty. If it contains an element in A we are done. Otherwise it contains an element in $b \in B$, but then it also contains $g(b) \in A$, since $b \sim g(b)$.

[150]Note that we do not claim that the elements in the given sequences are distinct, for example $f\colon A \to B$ could be a bijection and $g = f^{-1}$ its inverse, then the equivalence class consists only of the two elements a and $g(a)$.

(2) We say the map $p\colon X \to B$ is a *covering*, if it is surjective and if for every $b \in B$ there exists an open neighborhood U of b which is uniformly covered.

Remark. If U is a uniformly covered subset of B, then clearly any open subset of U is also uniformly covered. For example it follows that if $p\colon X \to B$ is a covering and if B is a manifold, then any point $b \in B$ admits also a connected uniformly covered neighborhood.[151]

Examples.

(a) The map

$$\begin{array}{rcl} p\colon \mathbb{R} & \to & S^1 \\ \varphi & \mapsto & e^{i\varphi} \end{array}$$

is a covering. Indeed, let $P = e^{i\alpha}$ be a point in S^1. We pick the open neighborhood

$$U \;:=\; \left\{ e^{i\varphi} \,\middle|\, \varphi \in \left(\alpha - \tfrac{\pi}{4}, \alpha + \tfrac{\pi}{4}\right) \right\}.$$

Then

$$p^{-1}(U) \;:=\; \bigsqcup_{j\in\mathbb{Z}} \underbrace{\left(\alpha - \tfrac{\pi}{4} + 2\pi j, \alpha + \tfrac{\pi}{4} + 2\pi j\right)}_{=:V_j},$$

and for each $j \in \mathbb{Z}$ the restriction of p to $V_j \to U$ is a homeomorphism. This example is illustrated in Figure 143.

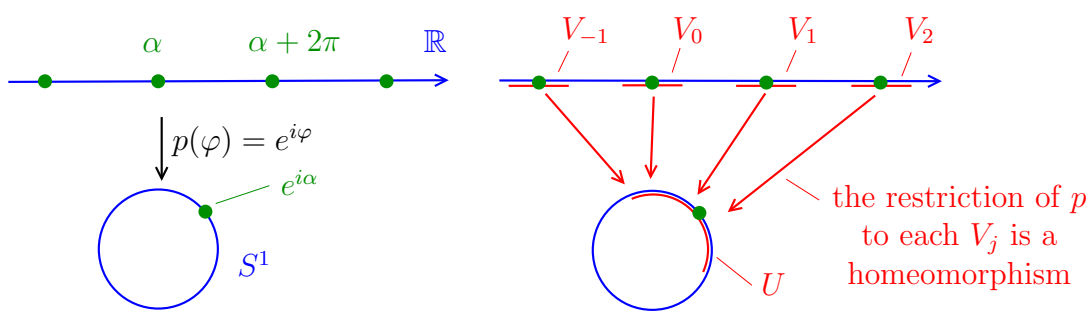

FIGURE 143.

(b) We consider the "infinite helix"

$$H \;:=\; \left\{ (re^{it}, t) \,\middle|\, r \in (1,2) \text{ and } t \in \mathbb{R} \right\}$$

together with the "annulus"

$$A \;:=\; \left\{ re^{it} \,\middle|\, r \in (1,2) \text{ and } t \in \mathbb{R} \right\}.$$

The map

$$\begin{array}{rcl} p\colon H & \to & A \\ (re^{it}, t) & \mapsto & re^{it} \end{array}$$

is a covering. This statement is illustrated in Figure 144. The proof of the statement is similar to the proof in the previous example.

[151] Why does this follow for manifolds? Why does this not hold for all topological spaces B?

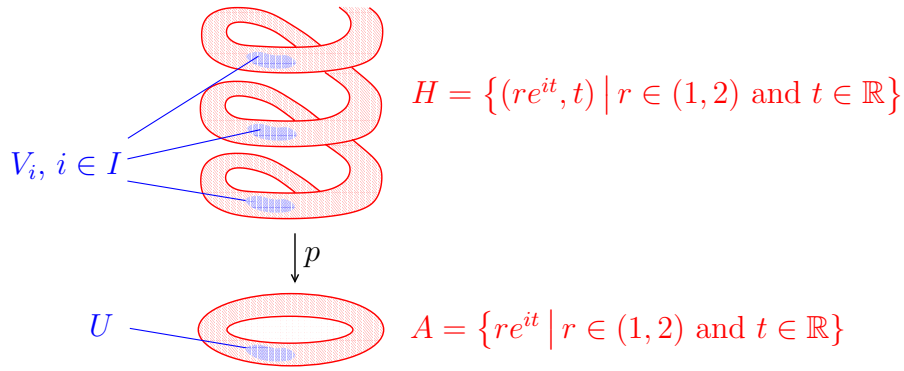

FIGURE 144.

(c) The map

$$\begin{array}{rcl} p\colon \mathbb{R}^n & \to & \mathbb{R}^n/\mathbb{Z}^n \\ x & \mapsto & [x] = x + \mathbb{Z}^n \end{array}$$

is a covering. Indeed, let $[x] = [(x_1, \dots, x_n)]$ be a point in $\mathbb{R}^n/\mathbb{Z}^n$. We consider

$$W \ := \ \left\{(y_1, \dots, y_n) \,\middle|\, |y_i - x_i| < \tfrac{1}{2}\right\} \ \subset \ \mathbb{R}^n$$

and we put $U := p(W)$. Then U is an open[152] neighborhood of $[x]$. Furthermore

$$p^{-1}(U) \ = \ \bigcup_{i \in \mathbb{Z}^n} (W + i),$$

and for each i the restriction of p to $W + i \subset \mathbb{R}^n$ is a homeomorphism.[153]

(d) For every $n \in \mathbb{N}$ the map

$$\begin{array}{rcl} p\colon S^n & \to & \mathbb{R}\mathrm{P}^n = S^n/x \sim -x \\ x & \mapsto & [x] = \{x, -x\} \end{array}$$

is a covering. Indeed, for $[x] \in \mathbb{R}\mathrm{P}^n$ we set

$$W \ = \ \{y \in S^n \mid \underbrace{x \cdot y}_{\text{scalar product}} > 0\}.$$

Then $p(W)$ is an open neighborhood of $[x]$ and it is uniformly covered by the two open sets W and $-W$.

(e) The projection map

$$\begin{array}{rcl} p\colon S^1 & \to & [-1, 1] \\ (x, y) & \mapsto & x \end{array}$$

[152]The set U is open since the projection map $p\colon \mathbb{R}^n \to \mathbb{R}^n/\mathbb{Z}^n$ is open by Lemma 1.71 (2).

[153]It is straightforward to verify that the map $p\colon V_i := W + i \to U$ is a bijection. It follows from Lemma 1.71 (1) that the projection map p is continuous and as we had just mentioned in the previous footnote, the projection map is also open. It follows that the map $p\colon V_i = W + i \to U$ is a homeomorphism.

is not a covering. Indeed, the point $b = 1 \in [-1, 1]$ has no open neighborhood that is uniformly covered. This example is illustrated in Figure 145.

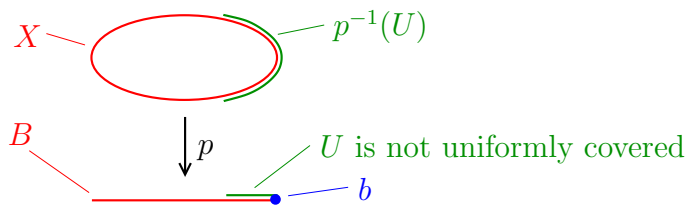

FIGURE 145.

Now we can formulate the following lemma that will be proved in Exercise 7.1.

Lemma 7.2. *Let $p\colon X \to B$ be a covering of topological spaces. If B is a path-connected topological space, then for any two points P and Q in B we have*

$$\#p^{-1}(P) \;=\; \#p^{-1}(Q).$$

Example. For a general map $p\colon X \to B$ between topological spaces the number of preimages of a point depends of course on the point chosen in B. For instance in the above example (e) we have $\#p^{-1}(0) = 2$ but $\#p^{-1}(1) = 1$.

Definition. Let $p\colon X \to B$ be a covering of a path-connected topological space.

(1) We define the *degree* $[X : B]$ *of* p as the cardinality of $\#p^{-1}(b)$ for some $b \in B$.[154]
(2) If the degree is a finite number n, then we say that p is an *n-fold covering* of B. Otherwise we say that p is an *infinite covering*. If the cardinality is countable, then sometimes we call it a *countable covering*.

Examples.

(1) We had just seen that the map $p\colon S^n \to S^n/\sim$ is a 2-fold covering of the real projective space $S^n/\sim = \mathbb{R}\mathrm{P}^n$.
(2) Let $n \in \mathbb{N}$. As usual we consider $S^1 = \{z \in \mathbb{C} \,|\, |z| = 1\}$ as a subset of $\mathbb{C}$. Then the map $p\colon S^1 \to S^1$ given by $p(z) := z^n$ is a covering. Indeed, let $z = e^{2\pi i\varphi}$ be a point in S^1. Then
$$U \;:=\; \big\{e^{2\pi i\psi} \,\big|\, \psi \in \big(\varphi - \tfrac{1}{4}, \varphi + \tfrac{1}{4}\big)\big\}$$
has the desired property. Indeed, we have
$$p^{-1}(U) \;=\; \bigsqcup_{j=1}^{n} \underbrace{\big\{e^{2\pi i\psi} \,\big|\, \psi \in \big(\tfrac{1}{n}(\varphi - \tfrac{1}{4}) + \tfrac{j}{n}, \tfrac{1}{n}(\varphi + \tfrac{1}{4}) + \tfrac{j}{n}\big)\big\}}_{=:V_j},$$
and the restriction of p to each set V_j is easily seen to be a homeomorphism. This shows that p is a covering and it is clear that p is an n-fold covering.

[154] It follows from Lemma 7.2 that this definition does not depend on the choice of b.

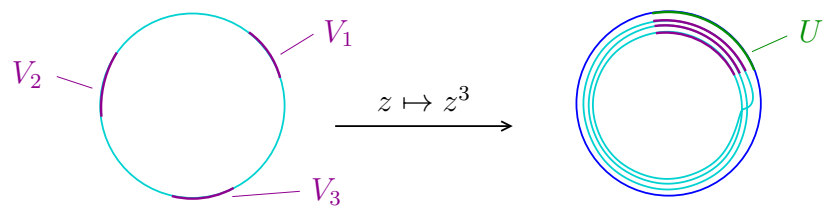

FIGURE 146.

(3) Let $n \in \mathbb{N}$. Basically the same argument as before shows that the map $p\colon \mathbb{C}\setminus\{0\} \to \mathbb{C}\setminus\{0\}$ given by $p(z) = z^n$ is an n-fold covering.
(4) We consider the map

$$\begin{array}{rcl} p\colon \overbrace{\mathbb{R}\times[-1,1]/(x,y)\sim(x+1,y)}^{\text{annulus}} & \to & \overbrace{\mathbb{R}\times[-1,1]/(x,y)\sim(x+\frac{1}{2},-y)}^{\text{Möbius band}} \\ [(x,y)] & \to & [(x,y)]. \end{array}$$

It is straightforward to show that p is a 2-fold covering. Thus we can view the annulus as a 2-fold covering of the Möbius band. This covering is illustrated in Figure 147.

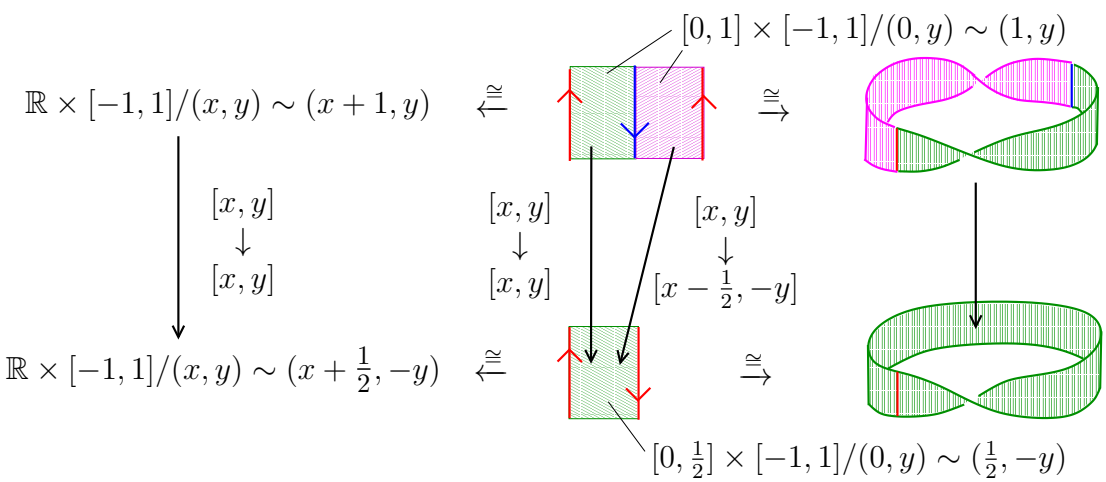

FIGURE 147.

(5) If in the previous example we replace the interval $[-1,1]$ by the circle $[-1,1]/-1\sim 1$, then on the left-hand side we obtain the torus and on the right-hand side we obtain the Klein bottle. This shows that there exists a degree 2 covering map from the torus to the Klein bottle.

(6) In Figure 148 we sketch three coverings of spatial graphs. The coverings are hereby given by sending edges of a certain color, with the indicated direction, to the edge of the same color with the indicated direction.[155]

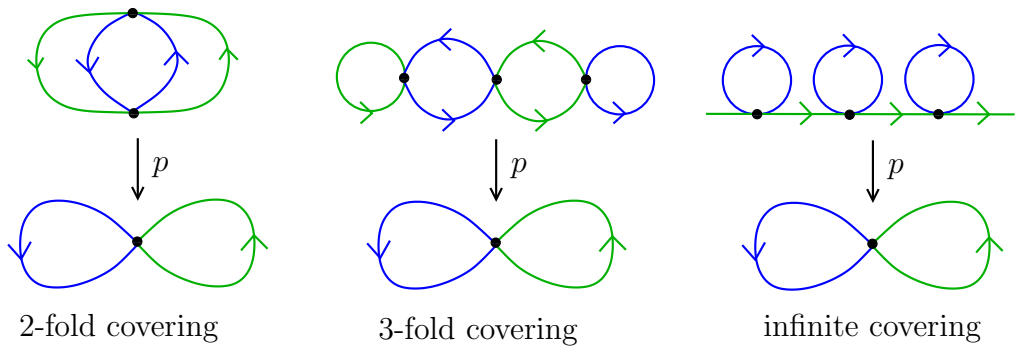

FIGURE 148.

Question 7.3. *We had just seen that there exists a covering map $S^2 \to \mathbb{R}\mathrm{P}^2$ of degree two and that there exists a covering map from the torus to the Klein bottle of degree two. This raises the question: between which surfaces do there exist covering maps? More precisely we can ask the following:*

(1) *Does there exist a covering map from the torus $S^1 \times S^1$ to the sphere S^2?*
(2) *Does there exist a covering map from the sphere S^2 to the torus $S^1 \times S^1$?*

The following lemma summarizes some basic facts about coverings.

Lemma 7.4. *Let $p\colon X \to B$ be a covering of topological spaces. Then the following hold:*

(1) *The map $p\colon X \to B$ is open.*[156]
(2) *For any $b \in B$ the preimage $p^{-1}(b)$ is a discrete subset of X.*
(3) *If B is Hausdorff, then X is also Hausdorff.*
(4) *If p is a finite covering and if B is compact, then X is also compact.*
(5) *If p is an infinite covering, then X is non-compact.*

Proof $(*)$. Let $p\colon X \to B$ be a covering of topological spaces.

(1) Let U be an open subset of X. We need to show that $p(U)$ is open. It suffices to show that for each $P \in p(U)$ there exists an open neighborhood V such that $P \in V \subset U$. Since p is a covering there exists an open neighborhood W of P such that $p^{-1}(W)$ is the union of disjoint open subsets $\{W_i\}_{i\in I}$ with the property that the restriction of p to each subset W_i is a homeomorphism.

Since $P \in p(U)$ there exists a $Q \in U$ with $p(Q) = U$. There exists an $i \in I$ with $Q \in W_i$. Since W_i is open and since U is open the set $U \cap W_i$ is also open in X. Since

[155]It is a good exercise to convince oneself, that the indicated maps are in fact coverings.
[156]Recall that this means that the image of each open set in X is open in B.

$p\colon W_i \to W$ is a homeomorphism and since $U \cap W_i$ is open in W_i the set $p(U \cap W_i)$ is also open in $p(W_i) = W$. But since W is open the set $V := p(U \cap W_i)$ is also an open subset of B. It is the desired open neighborhood of P with $P \in V \subset U$.

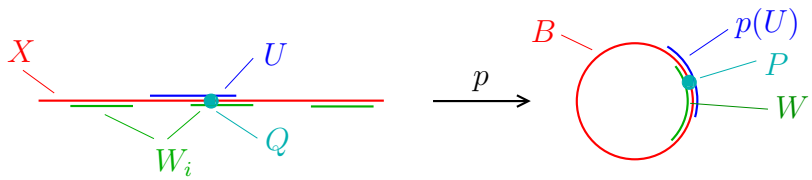

FIGURE 149. Illustration for the proof of Lemma 7.4 (1).

(2) Let $b \in B$. Since $p\colon X \to B$ is a covering there exists an open neighborhood U of b such that $p^{-1}(U)$ is the union of disjoint open subsets $\{V_i\}_{i\in I}$ with the property that the restriction of p to each subset V_i is a homeomorphism. For each $i \in I$ there exists a unique point $x_i \in V_i$ with $p(x_i) = b$ and the preimage $p^{-1}(b)$ consists of precisely the x_i, $i \in I$. Since each V_i is open in X it follows from the definition of the subspace topology that each $x_i \in p^{-1}(b)$ is an open subset of $p^{-1}(b)$. Put differently, the subspace topology on $p^{-1}(b)$ is the discrete topology. But this is equivalent to saying that $p^{-1}(b)$ is a discrete subset of X.

(3) This statement is relatively easy to prove and it in Exercise 7.4.

(4) Let $p\colon X \to B$ be an n-fold covering of a compact space B. Let $\{U_i\}_{i\in I}$ be an open covering of X. Let $b \in B$. We pick an open connected neighborhood M of b that is uniformly covered. For each $x \in p^{-1}(b)$ we denote by N_x the component of $p^{-1}(M)$ that contains x. For each point in $x \in p^{-1}(b)$ we pick an $i_x \in I$ with $x \in U_{i_x}$. We write

$$W_b \ := \bigcap_{x\in p^{-1}(b)} p(U_{i_x} \cap N_x).$$

Claim. The preimage $p^{-1}(W_b)$ is contained in the union of $n = \#p^{-1}(b)$ subsets of our open covering $\{U_i\}_{i\in I}$.

Since M is uniformly covered the map $p\colon N_x \to M$ is a homeomorphism for any $x \in p^{-1}(y)$. We denote by $p_x\colon N_x \to M$ this homeomorphism. We write $F := p^{-1}(b)$. We then have

$$p^{-1}(W_b) \ = \bigcup_{y\in F} p_y^{-1}\Big(\bigcap_{x\in F} p_x(U_{i_x} \cap N_x)\Big) \ = \bigcup_{y\in F} \overbrace{\bigcap_{x\in F} \underbrace{p_y^{-1}(p_x(U_{i_x}))}_{=U_{iy} \text{ if } y=x} \cap \underbrace{p_y^{-1}(p_x(N_x))}_{=N_y}}^{\subset U_{i_y}\cap N_y} \subset \bigcup_{y\in F} U_{i_y}.$$

This concludes the proof of the claim.

By (1) each $p(U_{i_x} \cap N_x)$ is an open subset of B and since $p^{-1}(b)$ is a finite set we see that W_b is an open subset of B. Furthermore b is contained in each $p(U_{i_x} \cap N_x)$, so W_b is in fact an open neighborhood of $b \in B$. Since B is compact we can cover B by

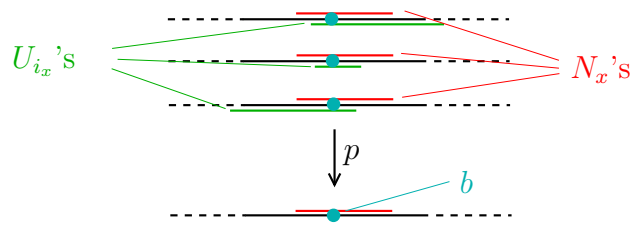

FIGURE 150. Illustration for the proof of Lemma 7.4 (4).

finitely many of these open sets, i.e. there exist $b_1, \ldots, b_k \in B$ with $B = W_{b_1} \cup \cdots \cup W_{b_k}$. The preimages $p^{-1}(W_{b_1}), \ldots, p^{-1}(W_{b_k})$ cover X. By the above claim each preimage $p^{-1}(W_{b_i})$ is contained in the union of $n = \#p^{-1}(b_i)$ subsets of our open covering $\{U_i\}_{i \in I}$. Summarizing we have shown that we can cover X by $n \cdot k$ sets out of the collection $\{U_i\}_{i \in I}$.

(5) Let $p\colon X \to B$ be an infinite covering. If B is non-compact, then it follows from Lemma 1.37 that X is also non-compact. So now suppose that B is compact. By definition we can cover B by open sets that are uniformly covered. Since B is compact we can cover B by finitely many open sets $U_1, \ldots, U_k$ that are uniformly covered. Without loss of generality we can assume that U_k is not contained in $U_1 \cup \cdots \cup U_{k-1}$.[157] Now let P be a point in $U_k \setminus (U_1 \cup \cdots \cup U_{k-1})$. Furthermore let V_i, $i \in I$ be the disjoint open subsets of X such that $p^{-1}(U_k)$ is the union of the V_i's and such that the restriction of p to each V_i is a homeomorphism. For $i \in I$ we denote by $Q_i \in V_i$ the unique point with $p(Q_i) = P$. Now we consider the open covering

$$X \;=\; p^{-1}(U_1) \cup \ldots \cup p^{-1}(U_{k-1}) \cup \bigcup_{i \in I} V_i.$$

Note that for $i \in I$ the point Q_i is contained only in V_i. This means that we cannot remove any of the open sets V_i, $i \in I$ from the open covering. Since I is infinite it follows that X does not satisfy the definition of a compact set, i.e. X is not compact. □

We conclude this section with the following lemma that we will prove in Exercise 7.3.

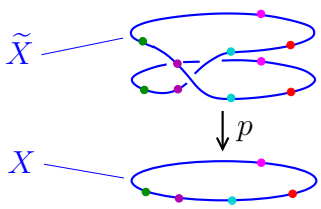
Lemma 7.5. *Let $p\colon \widetilde{X} \to X$ be a 2-fold covering. We define*

$$\begin{array}{rcl} f\colon \widetilde{X} & \to & \widetilde{X} \\ Q & \mapsto & \textit{the unique other point in } p^{-1}(p(Q)). \end{array}$$

[157] Indeed, if U_k was contained in $U_1 \cup \cdots \cup U_{k-1}$, then we could remove U_k from the collection of open sets and we continue with the collection $U_1, \ldots, U_{k-1}$.

(*The definition of f is illustrated in Figure 151*). *This map is continuous and it has the property that the following diagram commutes:*

$$\begin{tikzcd} \widetilde{X} \arrow[rr, "f"] \arrow[dr, "p"'] & & \widetilde{X} \arrow[dl, "p"] \\ & X. & \end{tikzcd}$$



$f\colon \widetilde{X} \to \widetilde{X}$ swaps the points of the same color

FIGURE 151. Illustration of Lemma 7.5.

7.3. **Group actions and covering spaces.** We recall two definitions about actions from pages 102 and 106 and we introduce one new definition.

Definition. Let G be a group which acts continuously on a topological space X.

(1) We say G acts *freely* if $g \cdot x = x$ for $g \in G$ and $x \in X$ implies that $g = e$.
(2) We say G acts *properly* if for any two points x and y in X there exist open neighborhoods U of x and V of y such that the set $\{g \in G \,|\, gU \cap V \neq \varnothing\}$ is finite.
(3) We say G *acts discretely*, if for each $x \in X$ there exists an open neighborhood U so that
$$U \cap gU \;=\; \varnothing \text{ for all } g \neq e.$$

The following lemma summarizes the relationship between these different definitions.

Lemma 7.6. *Let G be a group which acts continuously on a topological space X.*

(1) *If G is finite, then the action is proper.*
(2) *If G acts discretely, then it also acts freely.*
(3) *If X is a Hausdorff space and if the action by G is free and proper, then the action is also discrete.*

Proof. The first two statements follow immediately from the definitions. The third statement is the content of Lemma 3.26. □

Example.

(A) The group $G = \mathbb{Z}^n$ acts on $X = \mathbb{R}^n$ by addition. This action is discrete. Indeed, for each $x = (x_1, \dots, x_n) \in \mathbb{R}^n$ the open neighborhood
$$U \;=\; \big\{y = (y_1, \dots, y_n) \in \mathbb{R}^n \,\big|\, \max\{|x_1 - y_1|, \dots, |x_n - y_n|\} < \tfrac{1}{2}\big\}$$
has the desired property.

(B) Let $X = \mathbb{R} \times [-1,1]$ and $G = \mathbb{Z}$. The action

$$\begin{array}{rcl} \mathbb{Z} \times (\mathbb{R} \times [-1,1]) & \to & \mathbb{R} \times [-1,1] \\ (n,(x,y)) & \mapsto & (x+n,(-1)^n y) \end{array}$$

is discrete. Indeed, for any $(x,y) \in X$ the open neighborhood

$$U \;=\; \left\{(a,b) \,\middle|\, |a-x| < \tfrac{1}{2} \text{ and } b \in [-1,1]\right\}$$

has the desired property.

(C) Let $X = S^n$ and $G = \{\pm 1\}$. The map

$$\begin{array}{rcl} \{\pm 1\} \times S^n & \to & S^n \\ (\epsilon, P) & \mapsto & \epsilon \cdot P \end{array}$$

defines an action that is discrete. Indeed, for any $P \in S^n$ the open hemisphere

$$U \;=\; \{Q \in S^n \mid \underbrace{P \cdot Q}_{\text{scalar product}} > 0\}$$

has the desired property.[158]

(D) Every discrete action is free, but as we will see in this example, the converse does not hold. Let $X = \mathbb{R}^{n+1} \setminus \{0\}$ and $G = \mathbb{R} \setminus \{0\}$. The map

$$\begin{array}{rcl} (\mathbb{R} \setminus \{0\}) \times (\mathbb{R}^{n+1} \setminus \{0\}) & \to & \mathbb{R}^{n+1} \setminus \{0\} \\ (r, P) & \mapsto & r \cdot P \end{array}$$

defines an action. It is straightforward to see that the action is free. But the action is not discrete. Indeed, it is easy to see that for each open non-empty set U there exist uncountably many real numbers $r \neq 1$ with $U \cap rU \neq \varnothing$.

(E) We consider the following two self-homeomorphisms of $\mathbb{R}^2$:

$$\begin{array}{rcl} A\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (x,y) & \mapsto & (x+1, 1-y) \end{array} \quad \text{and} \quad \begin{array}{rcl} B\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (x,y) & \mapsto & (x, y+1). \end{array}$$

We denote by G the subgroup of all homeomorphisms of $\mathbb{R}^2$ that is generated by A and B. This means[159]

$$G \;=\; \begin{array}{c} \text{all self-homeomorphisms of } \mathbb{R}^2 \text{ that can be written} \\ \text{as a finite concatenation of the maps } A, B, A^{-1} \text{ and } B^{-1}. \end{array}$$

The group G acts by definition on $\mathbb{R}^2$. In Exercise 7.6 we will see that this action of G on $\mathbb{R}^2$ is discrete.

[158] Alternatively one can argue, that the action is obviously free and S^n is Hausdorff, hence the action is discrete by Lemma 7.6 (1) and (3).

[159] For example the map $B \circ A \circ A \circ B^{-1} \circ A$ lies in G.

We consider again the square $X = [0,1] \times [0,1]$ with the equivalence relation that is generated by $(0,y) \sim (1, 1-y)$ and $(x,0) \sim (x,1)$. It is straightforward to see that the map

$$\begin{array}{rcl} X/\sim & \to & \mathbb{R}^2/G \\ [(x,y)] & \mapsto & [(x,y)] \end{array}$$

is a homeomorphism. Put differently, $\mathbb{R}^2/G$ is homeomorphic to the Klein bottle.

(F) Let

$$X \;=\; S^3 \;=\; \{(z_1,z_2) \in \mathbb{C}^2 \,|\, |z_1|^2 + |z_2|^2 = 1\}$$

and let $G = \mathbb{Z}_p$ for some $p \in \mathbb{N}$. Furthermore let $q \in \mathbb{Z}$ with $\gcd(p,q) = 1$. Then the map

$$\begin{array}{rcl} \mathbb{Z}_p \times S^3 & \to & S^3 \\ (k + p\mathbb{Z}, (z_1,z_2)) & \mapsto & (e^{2\pi i k/p} z_1, e^{2\pi i k q/p} z_2) \end{array}$$

defines a smooth, orientation-preserving and discrete action of $\mathbb{Z}_p$ on S^3.[160] We denote by $L(p,q) = S^3/\mathbb{Z}_p$ the quotient space. It follows from Propositions 3.25 and that $L(p,q)$ is again a closed 3-dimensional manifold. Furthermore it follows from Proposition 3.38 that $L(p,q)$ is orientable, in fact it has an orientation such that the projection map $p\colon S^3 \to L(p,q)$ is orientation-preserving. We will always view $L(p,q)$ as a manifold equipped with this orientation. We refer to the manifolds $L(p,q)$ as *lens spaces*.[161] We consider two special cases:

(a) For $p = 1$ we only have the action of the trivial group on S^3 and the quotient space $L(1,q)$ is therefore just the original sphere S^3.

(b) For $p = 2$ we have q is odd, so for $k = 0$ we have $e^{2\pi i k/2} = e^{2\pi i k q/2} = 1$ and for $k = 1$ we have $e^{2\pi i k/2} = e^{2\pi i k q/2} = -1$. Put differently, the action of $\mathbb{Z}_2$ on S^3 is the same as the action of $\mathbb{Z}_2 = \{\pm 1\}$ that we had used in the definition of the real projective space $\mathbb{R}\mathrm{P}^n$. This shows that $L(2,q) = \mathbb{R}\mathrm{P}^n$.

We discuss the last type of examples in slightly more detail. For $p \in \mathbb{N}$ and $q \in \mathbb{N}$ with $\gcd(p,q) = 1$ we just introduced a new topological space, namely the lens space $L(p,q)$. It is natural to ask, for which parameters (p,q) are these topological spaces homeomorphic?

Lemma 7.7. *Let $p \in \mathbb{N}$ and furthermore let $q, r \in \mathbb{Z}$ with $\gcd(p,q) = \gcd(p,r) = 1$. If $q \equiv \pm r^{\pm 1} \bmod p$,*[162] *then $L(p,q)$ and $L(p,r)$ are diffeomorphic.*[163]

[160] It is straightforward to verify that the map does indeed define an action. It is clear that the action is smooth and a direct calculation shows that the action is orientation-preserving. One can also easily verify that the action is free. It follows from Lemma 7.6 (1) and (3) that the action is discrete.

[161] The name "lens space" comes from an alternative description of these manifolds.

[162] By our hypothesis we have $\gcd(p,r) = 1$. This implies that there exists a multiplicative inverse of r modulo p, i.e. there exists an s with $r \cdot s \bmod p$. We write $r^{-1} := s$.

[163] In particular any lens space is of the form $L(p,q)$ with $q \in \{0, \dots, p-1\}$.

Proof. Let $p \in \mathbb{N}$ and let $q, r \in \mathbb{Z}$ with $\gcd(p,q) = \gcd(p,r) = 1$. We suppose that $q \equiv \pm r^{\pm 1} \bmod p$. We define a map

$$L(p,q) \quad \to \quad L(p,r)$$

as follows:

$$\begin{array}{lrcl} \text{Case 1: } q \equiv r \bmod p. & [(z_1,z_2)] & \mapsto & [(z_1,z_2)] \\ \text{Case 2: } q \equiv -r \bmod p. & [(z_1,z_2)] & \mapsto & [(z_1,\overline{z_2})] \\ \text{Case 3: } q \equiv r^{-1} \bmod p. & [(z_1,z_2)] & \mapsto & [(z_2,z_1)] \\ \text{Case 4: } q \equiv -r^{-1} \bmod p. & [(z_1,z_2)] & \mapsto & [(z_2,\overline{z_1})] \end{array}$$

In all four cases it is straightforward to verify that the given map is well-defined and that it is in fact a diffeomorphism. □

In the proof of Lemma 7.7 it was quite straightforward to write down the homeomorphism. This raises the question whether there are homeomorphisms between more lens spaces that are harder to find, or whether all other pairs of lens spaces are non-homeomorphic. More precisely, we have the following question.

Question 7.8. *Let $p, \widetilde{p} \in \mathbb{N}$ and let $q, \widetilde{q} \in \mathbb{Z}$ with $\gcd(p,q) = \gcd(\widetilde{p},\widetilde{q}) = 1$. If $L(p,q)$ and $L(\widetilde{p},\widetilde{q})$ are homeomorphic, does it follow that $p = \widetilde{p}$ and $q \equiv \pm\widetilde{q}^{\pm 1} \bmod p$?*

This question will keep us busy for a very long time.

We had just seen on page 265 that the group $\{\pm 1\}$ acts freely and continuously on any sphere. We had also seen that any finite cyclic group $\mathbb{Z}_p$ acts freely and continuously on the 3-sphere. This raises the question, whether such an action by $\mathbb{Z}_p$ also exists on the 2-sphere. More generally we can ask the following question.

Question 7.9. *Given $n \in \mathbb{N}$, which finite cyclic groups can act freely and continuously on the n-dimensional sphere S^n?*[164]

We will come back to this question once we have introduced homology groups.

The following proposition connects the notion of discrete actions to the theory of covering spaces.

Proposition 7.10. *Let X be a topological space together with a discrete and continuous action by a group G. Then the canonical projection $p\colon X \to X/G$ is a covering.*

Example. This proposition, combined with examples (A) and (C), gives in particular new proofs that the maps $\mathbb{R}^n \to \mathbb{R}^n/\mathbb{Z}^n$ and $S^n \to S^n/\sim = \mathbb{R}\mathrm{P}^n$ are covering maps.

Proof. Let G be a group which acts discretely and continuously on a topological space X. We want to show that the projection map $p\colon X \to X/G$ is a covering. Let $[x] \in X/G$. Since the group acts discretely there exists an open neighborhood V of $x \in X$ such that

$$V \cap gV \;=\; \varnothing \text{ for all } g \neq e.$$

[164] Any cyclic group $\mathbb{Z}_k$, $k \neq 0$ admits a non-trivial action on S^n where $j \in \mathbb{Z}_k$ acts by rotation around the x-axis by the angle $2\pi\frac{j}{k}$. But this action is not free, since the points $(-1,0,\dots,0)$ and $(0,\dots,0,1)$ are fixed.

We put $U := p(V)$. It follows from Lemma 1.71 that the set U is an open neighborhood of $[x] = p(x)$. The preimage $p^{-1}(U)$ is the disjoint union of the open subsets[165] $gV, g \in G$. The restriction of the map p to any gV is a continuous, bijective[166] map $gV \to U$ and according to Lemma 1.71 this map is furthermore open. It follows that the restriction of p to any gV is in fact a homeomorphism. Thus we see that U is uniformly covered. Since this holds for any point in X/G we have shown that the projection map $p\colon X \to X/G$ is a covering. $\square$

The following proposition is a slight generalization of the previous proposition.

Proposition 7.11. *Let X be a topological space together with a discrete and continuous action by a group G. Furthermore let H be a subgroup of G. Then the canonical projection*

$$\begin{array}{rcl} p\colon X/H & \to & X/G \\ [x] & \mapsto & [x] \end{array}$$

is a covering.

For H the trivial group we recover the statement of Proposition 7.10. In fact the proof of Proposition 7.11 is almost identical to the proof of Proposition 7.10. We leave the details to the reader.

Examples.

(1) Let $X = \mathbb{R} \times [-1, 1]$ and $G = \mathbb{Z}$. Once again we consider the discrete action

$$\begin{array}{rcl} \mathbb{Z} \times (\mathbb{R} \times [-1,1]) & \to & \mathbb{R} \times [-1,1] \\ (n, (x, y)) & \mapsto & \big(x + \frac{1}{2}n, (-1)^n y\big). \end{array}$$

Let $H = 2\mathbb{Z}$. According to Proposition 7.11 the projection map $p\colon X/H \to X/G$ is a covering. Put differently, all the horizontal maps in the following commutative diagram are coverings:

$$\begin{array}{ccc} (\mathbb{R} \times [-1,1])/2\mathbb{Z} & \longrightarrow & (\mathbb{R} \times [-1,1])/\mathbb{Z} \\ \downarrow = & & \downarrow = \\ (\mathbb{R} \times [-1,1])/(x,y) \sim (x + \frac{1}{2}2k, (-1)^{2k}y) & \longrightarrow & (\mathbb{R} \times [-1,1])/(x,y) \sim (x + \frac{1}{2}k, (-1)^k y) \\ \downarrow = & & \downarrow = \\ \underbrace{(\mathbb{R} \times [-1,1])/(x,y) \sim (x+k, y)}_{=\text{the annulus}} & \longrightarrow & \underbrace{(\mathbb{R} \times [-1,1])/(x,y) \sim (x + \frac{1}{2}k, (-1)^k y)}_{=\text{Möbius band}}. \end{array}$$

Each point on X/G has precisely two preimages, so the covering is in fact a 2-fold covering. Thus we recover the result from page 260 that the annulus is a 2-fold covering of the Möbius band.

[165] Why is $p^{-1}(U) = \bigcup_{g \in G} gV$ and why are the sets gV disjoint?

[166] Why is the map bijective?

(2) We consider again the group G of self-homeomorphisms of $\mathbb{R}^2$ that is generated by

$$\begin{array}{rcl} A\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (x,y) & \mapsto & (x+1, 1-y) \end{array} \quad \text{and} \quad \begin{array}{rcl} B\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (x,y) & \mapsto & (x, y+1). \end{array}$$

We let H be the subgroup of G generated by A^2 and B. Note that A^2 is the map given by

$$\begin{array}{rcl} A^2\colon \mathbb{R}^2 & \xrightarrow{A} & \mathbb{R}^2 \xrightarrow{A} \mathbb{R}^2 \\ (x,y) & \mapsto & (x+1, 1-y) \mapsto \underbrace{((x+1)+1, (1-(1-y)).}_{=(x+2,y)} \end{array}$$

Note that A^2 and B are two homeomorphisms that commute, so any element in H is in fact of the form

$$\begin{array}{rcl} A^{2k} \circ B^l\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (x,y) & \mapsto & (x+2k, y+l) \end{array}$$

for some $k, l \in \mathbb{Z}$. By Proposition 7.11 the projection map $p\colon \mathbb{R}^2/H \to \mathbb{R}^2/G$ is a covering map. We already know that $\mathbb{R}^2/G$ is the Klein bottle. It follows immediately from the above description of H, $\mathbb{R}^2/H = \mathbb{R}^2/(2\mathbb{Z}\oplus\mathbb{Z})$, so $\mathbb{R}^2/H$ is just the 2-dimensional torus. As on page 260 we see that we can view the 2-dimensional torus as a 2-fold covering of the Klein bottle.

7.4. **Lifting of paths.**

Definition. Let $p\colon X \to B$ be a map between topological spaces and let $f\colon [a,b] \to B$ be a path. Let $x \in X$ be a point with $p(x) = f(a)$. A path $g\colon [a,b] \to X$ is called a *lift of f to the starting point x*, if $g(a) = x$ and if $p \circ g = f$, i.e. if the following diagram of maps commutes:

$$\begin{tikzcd} & X \arrow[d, "p"] \\ {[a,b]} \arrow[ur, "g"] \arrow[r, "f"'] & B. \end{tikzcd}$$

Examples.

(1) We consider the map

$$\begin{array}{rcl} p\colon \mathbb{R} & \to & S^1 \\ t & \mapsto & e^{it} \end{array}$$

and the path

$$\begin{array}{rcl} f\colon [0,b] & \to & S^1 \\ t & \mapsto & e^{2it} \end{array}$$

with starting point $f(0) = 1$. Let $x = 4\pi$. Then $p(x) = p(4\pi) = 1$ and

$$\begin{array}{rcl} g\colon [0,b] & \to & \mathbb{R} \\ t & \mapsto & 4\pi + 2t \end{array}$$

is a lift of f to the starting point 4π. Note that if $b = \pi$, then f is a loop in $(S^1, 1)$, but the lift is not a loop in $(\mathbb{R}, 4\pi)$. Put differently, the lift of a loop is not necessarily again a loop. This example is illustrated in Figure 152.

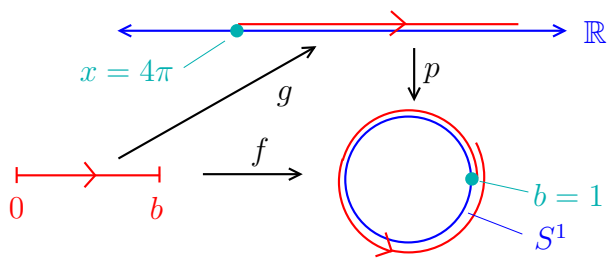


FIGURE 152.

(2) In Figure 153 we illustrate the lifting of a path in the covering $p\colon H \to A$ of an infinite helix over an annulus that we had considered on page 257.

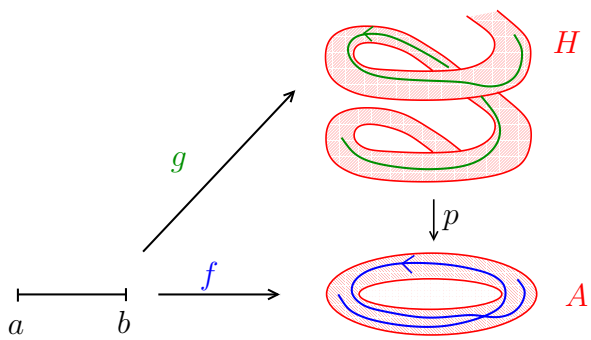

FIGURE 153.

Proposition 7.12. *Let $p\colon X \to B$ be a covering and let $f\colon [0,1] \to B$ be a path. Then given any $x \in X$ with $p(x) = f(0)$ there exists a unique lift $g\colon [0,1] \to X$ of f to the starting point x.*

Proof. Let $p\colon X \to B$ be a covering, let $f\colon [0,1] \to B$ be a path and let x be a point in X with $p(x) = f(0)$. We first show the existence of a lift and then we prove the uniqueness of the lift.

(a) We consider

$$S \;:=\; \big\{ s \in [0,1] \,\big|\, \text{there exists a lift of } f|_{[0,s]} \text{ to the starting point } x \big\}.$$

Note that S is non-empty since 0 has the desired property. We put $t := \sup(S)$. We want to show that $t = 1$ and that $t \in S$. It suffices to show that there exists an $\epsilon > 0$ such that $[t, t+\epsilon) \cap [0,1]$ still lies in S. We set $b := f(t)$. Since p is a covering there

exists an open neighborhood U of $b \in B$, which is uniformly covered. As a reminder, this means that $p^{-1}(U)$ is the union of disjoint open subsets $\{V_i\}_{i\in I}$ with the property that the restriction of p to each subset V_i is a homeomorphism. Since U is open and since f is continuous there exists an $\epsilon > 0$ such that $f((t-\epsilon, t+\epsilon) \cap [0,1]) \subset U$.

By the definition of t there exists an $s \in (t-\epsilon, t] \cap S$. We denote by g the lift of $f|_{[0,s]}$ the starting point x. There exists a unique $i \in I$ such that $g(s) \in V_i$. We denote by $p_i \colon V_i \to U$ the homeomorphism which is given by the restriction of p to V_i.

We consider the map

$$\begin{array}{rcl} h\colon [0, t+\epsilon) \cap [0,1] & \to & X \\ z & \mapsto & \begin{cases} g(z), & \text{if } z \in [0,s], \\ p_i^{-1}(f(z)), & \text{if } z \in (s, t+\epsilon) \cap [0,1]. \end{cases} \end{array}$$

Since $g(s) = p_i^{-1}(f(s))$ we see that this map is indeed continuous. It is clear that this defines a lift of f to the starting point x.

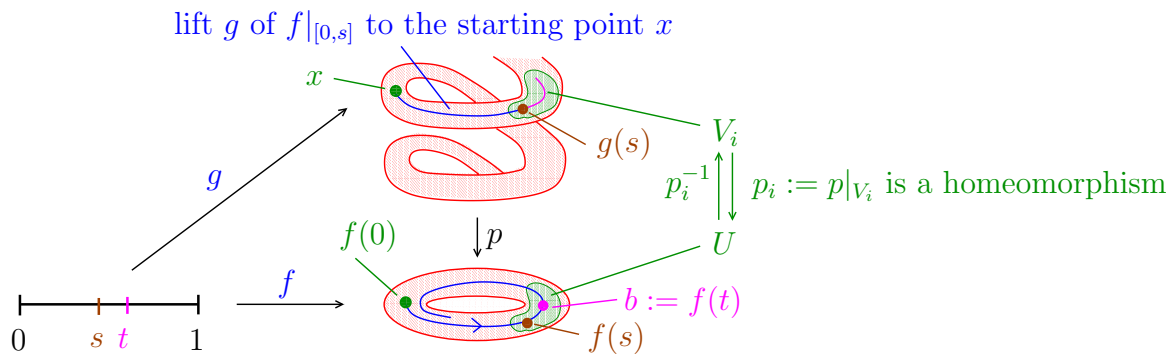

FIGURE 154.

(b) Now we show the uniqueness of the lift. The proof of that statement is similar to the proof of the existence of a lift. So suppose that $g, h\colon [0,1] \to X$ are two lifts of f to the starting point x. We want to show that $g = h$. We consider

$$S \;:=\; \{s \in [0,1] \,|\, g(t) = h(t) \text{ for all } t \in [0,s]\}\,.$$

Note that $0 \in S$, i.e. S is non-empty. We put $t := \sup(S)$. We want to show that $t = 1$ and that $t \in S$. Again it suffices to show that there exists an $\epsilon > 0$ such that $[t, t+\epsilon) \cap [0,1]$ still lies in S.

We put $b := f(t)$. Since p is a covering there exists an open neighborhood U of $b \in B$ which is uniformly covered. Since U is open and since f is continuous there exists an $\epsilon > 0$ such that $f((t-\epsilon, t+\epsilon) \cap [0,1]) \subset U$. We pick an $s \in (t-\epsilon, t] \cap [0,1]$. There exists a unique $i \in I$ such that $g(s) \in V_i$. We denote by $p_i \colon V_i \to U$ the homeomorphism which is given by the restriction of p to V_i.

Since $g(s) = h(s)$ it follows that $h(s) \in V_i$. Then it follows that $g(z) \in V_i$ and $h(z) \in V_i$ for all $z \in (t-\epsilon, t+\epsilon) \cap [0,1]$. It follows from the definitions that

$$g(z) \;=\; p_i^{-1}(f(z)) \quad \text{and} \quad h(z) \;=\; p_i^{-1}(f(z))$$

for all $z \in (t-\epsilon, t+\epsilon) \cap [0,1]$. In particular $[t, t+\epsilon) \cap [0,1]$ lies in S. □

7.5. **Lifting of path-homotopies.** In the last chapter we saw that given a covering map $p\colon X \to B$ any path $f\colon [0,1] \to B$ can be lifted to a path $g\colon [0,1] \to X$. In this chapter we want to study the question whether the lifts of path-homotopic paths are still path-homotopic.

Before we start this discussion we first generalize the notion of a lift.

Definition. Let $p\colon X \to B$ be a covering and let $f\colon Y \to B$ be a map between topological spaces. A *lift of f to X* is a map[167] $\tilde{f}\colon Y \to X$ such that $p \circ \tilde{f} = f$, i.e. such that the following diagram of maps commutes:

$$\begin{tikzcd} & X \arrow[d, "p"] \\ Y \arrow[ur, "\tilde{f}"] \arrow[r, "f"'] & B. \end{tikzcd}$$

Proposition 7.13. *Let $p\colon X \to B$ be a covering, let B be a topological space, let Y be a topological manifold*[168] *and let $f\colon Y \times [0,1] \to B$ be a map. Furthermore let $\tilde{f}\colon Y \times 0 \to X$ be a lift of $f|_{Y\times 0}$. Let*

$$\tilde{f}\colon Y \times [0,1] \;\to\; X$$

be the map that is uniquely determined[169] *by the property that for each $y \in Y$ the path $t \mapsto \tilde{f}(y,t)$ is the lift of the path $t \mapsto f(y,t)$ to the starting point $\tilde{f}(y,0)$. Then the map $\tilde{f}\colon Y \times [0,1] \to X$ is continuous.*

The statement of Proposition 7.13 is sketched in Figure 155. One way of formulating Proposition 7.13 is that a "continuous" family of paths in B lifts again to a "continuous" family of paths in X.

Proof $(*)$. Let $p\colon X \to B$ be a covering, let $f\colon Y \times [0,1] \to B$ be a continuous map and let $\tilde{f}\colon Y \times 0 \to X$ be a continuous lift of $f|_{Y\times 0}$. (Here and throughout this proof we do not suppose that all maps are continuous.) We begin with the following definitions:

(1) A *good set* $U \times I$ consists of a connected subset $U \subset Y$ and an open interval[170] $I \subset [0,1]$ such that $f(U \times I)$ lies in a uniformly covered subset of B.

[167] Once again, all maps are understood to be continuous.

[168] Later on we will apply the proposition to the case that $Y = [0,1]$ and that $Y = \overline{B}^n$ for some $n \in \mathbb{N}_0$.

[169] The existence and the uniqueness of this map is an immediate consequence of Proposition 7.12.

[170] We say $A \subset [0,1]$ is an open interval, if A is an interval and if A is open with respect to the subspace topology of $[0,1]$. Put differently, $A = (a,b)$, or $A = [0,a)$ or $A = (b,1]$ or $A = [0,1]$ for $0 \le a \le b \le 1$.

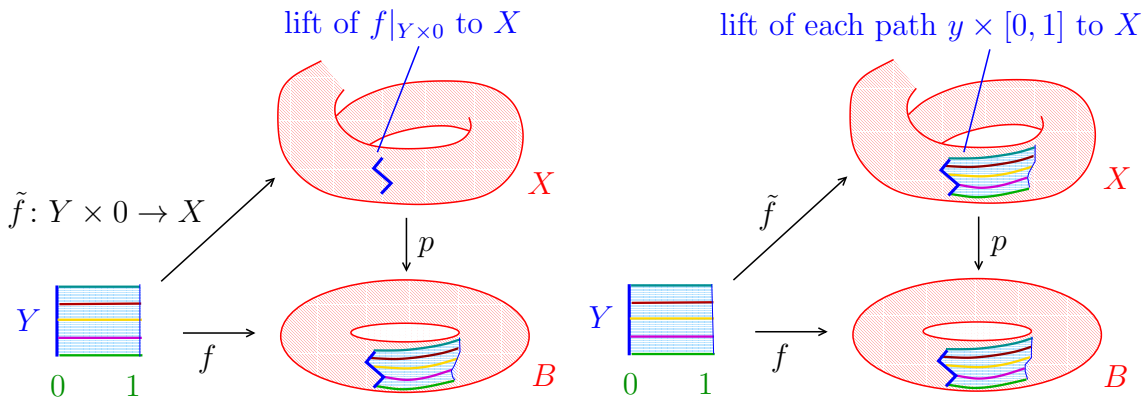

FIGURE 155. Schematic image for the lift of f.

(2) We say a good set $U\times I$ is *very good*, if there exists a $t\in I$ such that the restriction of $\tilde{f}$ to $U\times\{t\}$ is continuous.
(3) Let $y\in Y$ and $t\in[0,1]$. A (*very*) *good neighborhood of* (y,t) is a (very) good set $U\times I$ with $y\in U$ and $t\in I$.

It follows easily[171] from the continuity of f, the hypothesis that Y is a topological manifold and the fact that $p\colon X\to B$ is a covering that each point (y,t) admits a good neighborhood.[172]

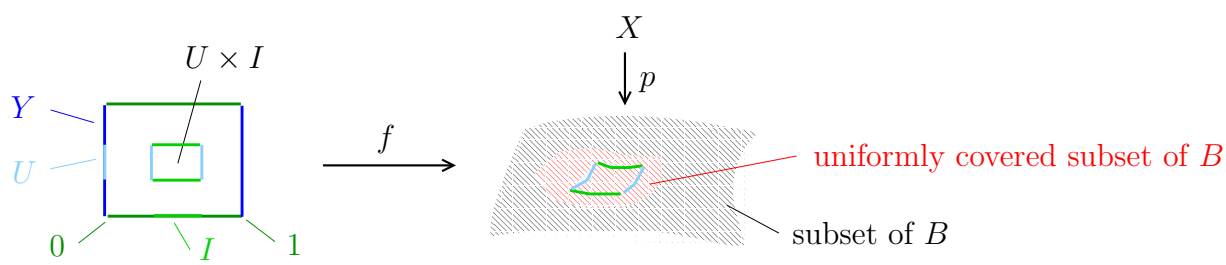

FIGURE 156. Schematic image of a good neighborhood.

Claim. Let $U\subset Y$ open and let $I\subset[0,1]$ be an open interval such that $U\times I$ is very good. Then $\tilde{f}$ is continuous on $U\times I$.

[171]Why does this follow?

[172]Here we use the fact, established in Corollary 1.87 and Lemma 3.8, that the topological manifold Y is o-locally connected.

Let $U \subset Y$ be an open connected subset and let $I \subset [0,1]$ be an interval such that $U \times I$ is very good. This means in particular that there exists a $t \in I$ such that

$$\begin{array}{rcl} U & \to & X \\ y & \mapsto & \tilde{f}(y,t) \end{array}$$

is continuous.

According to our hypothesis there exists a uniformly covered subset $W \subset B$ such that $f(U \times I) \subset W$. Since $U \times I$ is connected we can without loss of generality suppose that W is connected. Since W is uniformly covered the preimage $p^{-1}(W)$ is the union of disjoint open subsets $\{V_j\}_{j \in J}$, with the property, that the restriction of p to each subset V_j is a homeomorphism.

Now we want to show that there exists a $j \in J$ with $\tilde{f}(U \times I) \subset V_j$. We choose a $y \in U$. Then there exists a unique $j \in J$ such that $\tilde{f}(y,t) \in V_j$. Since $\tilde{f}$ is continuous $U \times \{t\}$ and since U is connected it follows from Lemma 1.101[173] that $\tilde{f}(U \times \{t\}) \subset V_j$. Now let $z \in U$. We just showed that $\tilde{f}(z,t) \in V_j$. By the construction of $\tilde{f}$ the map $\tilde{f}$ is continuous on $\{z\} \times I$. Since I is connected it follows again from Lemma 1.101 that $\tilde{f}(\{z\} \times I) \subset V_j$. We have thus shown that $\widetilde{f}(U \times I) \subset V_i$. This part of the argument is sketched in Figure 157.

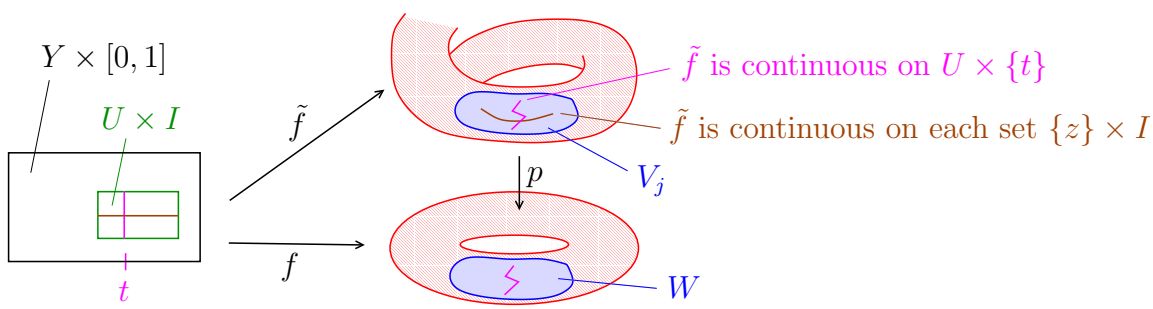

FIGURE 157.

We denote by $p_j \colon V_j \to W$ the homeomorphism which is given by the restriction of p to V_j. Since $\tilde{f}(U \times I) \subset V_j$ it follows that on $U \times I$ the map $\tilde{f}$ is given by $\tilde{f} = p_j^{-1} \circ f$. In particular the map $\tilde{f}$ is a composition of continuous maps, so it is continuous on $U \times I$. Thus we have proved the claim.

Claim. Let $y \in Y$. We consider

$$T := \{t \in [0,1] \,|\, \text{there exists a very good neighborhood of } (y,t)\}.$$

We claim that $T = [0,1]$.

Thus let $y \in Y$. Since $[0,1]$ is connected it suffices to show the following three statements:

[173] We apply Lemma 1.101 to the continuous map $U \times \{t\} \to p^{-1}(W)$ from the connected set U to the set $p^{-1}(W)$ with components V_j, $j \in J$.

(1) $T \neq \varnothing$,
(2) T is open, and
(3) T is closed.

Now we will prove these three statements:

(1) As we pointed out above, every point in $Y \times I$, in particular the point $(y, 0)$, admits a good neighborhood. By our hypothesis $\tilde{f}$ is continuous on $Y \times \{0\}$. It follows that the good neighborhood is in fact very good.
(2) It is easy to see that T is open. Indeed, suppose that we are given a very good neighborhood $U \times I$ of (y, t). Then $U \times I$ is also a very good neighborhood for any $(y, s) \in U \times I$. Therefore the open neighborhood I of t also lies in T.
(3) It remains to show that T is closed. Put differently, we need to show that T equals its closure $\overline{T}$. Thus let $t \in \overline{T}$. As we already pointed out, there exists a good neighborhood $U \times I$ of (y, t). Since $t \in \overline{T}$ there exists an $s \in T \cap I$. Since $s \in T$ it follows from the above claim that there exists a very good open neighborhood $V \times J$ of (y, s). By the previous claim the restriction of $\tilde{f}$ to $V \times J$ is continuous, in particular it is continuous on $(U \cap V) \times \{s\}$. We denote by W the component of $U \cap V$ that contains y. Then $W \times I$ is a very good neighborhood of (y, t). This step is illustrated in Figure 158.

This concludes the proof of the claim.

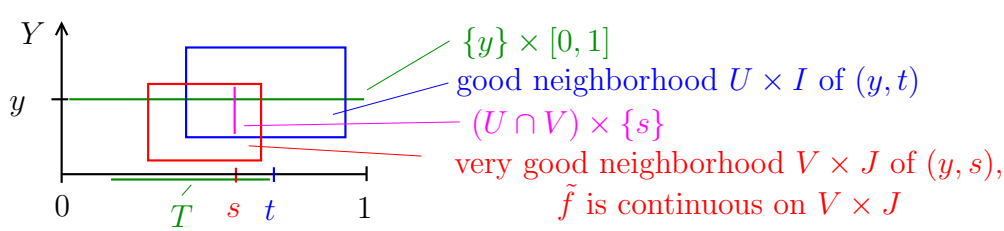

FIGURE 158.

We have just shown that given any $y \in Y$ and any $t \in [0,1]$ there exists a very good neighborhood $U_{y,t}$ of (y,t). By the first claim the map $\tilde{f}$ is continuous on each $U_{y,t}$. But the open subsets $U_{y,t}$ cover all of $Y \times [0,1]$. It follows from Lemma 1.104 that $\tilde{f}$ is continuous on $Y \times [0,1]$. $\square$

Corollary 7.14. *Let $p\colon X \to B$ be a covering and let $f, g\colon [0,1] \to B$ be two paths. Let $\tilde{f}, \tilde{g}\colon [0,1] \to X$ be two lifts with the same starting point. If f and g are path-homotopic, then the endpoints of $\tilde{f}$ and $\tilde{g}$ agree and the paths $\tilde{f}$ and $\tilde{g}$ are path-homotopic.*

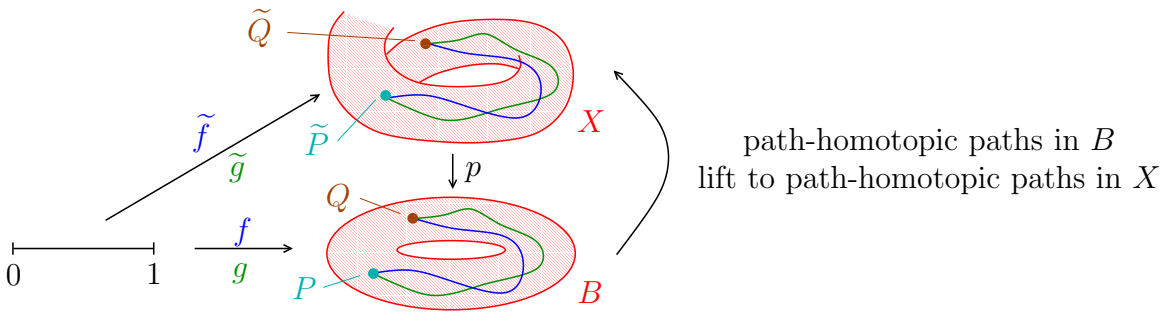

FIGURE 159. Illustration of Corollary 7.14.

Proof $(*)$. We write $P := f(0) = g(0)$ and $Q := f(1) = g(1)$. We denote by $\tilde{P} := \tilde{f}(0) = \tilde{g}(0)$ the common starting point of the lifts and we write $\tilde{Q} := \tilde{f}(1)$. Let

$$\begin{array}{rcl} H\colon [0,1]\times[0,1] & \to & B \\ (t,s) & \mapsto & H(t,s) \end{array}$$

be a path-homotopy between the paths f and g. As a reminder, H is a map such that

$$H(t,0) \;=\; f(t) \quad \text{and} \quad H(t,1) \;=\; g(t) \quad \text{for all } t\in[0,1],$$

and such that

$$H(0,s) \;=\; P \quad \text{and} \quad H(1,s) \;=\; Q \quad \text{for all } s\in[0,1].$$

On $\{0\}\times[0,1]$ we consider the lift $\widetilde{H}$ of H which is given by $\widetilde{H}(0,s) = \widetilde{P}$. Furthermore we denote by $\widetilde{H}\colon [0,1]\times[0,1]\to X$ the map which is defined as follows: for each $s\in[0,1]$ the path $t\mapsto \widetilde{H}(t,s)$ is the unique lift of the path $t\mapsto H(t,s)$ to the starting point $\tilde{P}$ lift. According to Proposition 7.13 the map $\widetilde{H}$ is in fact continuous. By definition of $\widetilde{H}$ we have

$$\widetilde{H}(t,0) \;=\; \tilde{f}(t) \quad \text{and} \quad \widetilde{H}(t,1) \;=\; \tilde{g}(t) \text{ for all } t\in[0,1],$$

For each $s\in[0,1]$ we have $p(\widetilde{H}(1,s)) = Q$. Since $\widetilde{H}$ is continuous we obtain a map

$$\begin{array}{rcl} [0,1] & \to & p^{-1}(Q) \;\subset\; X \\ s & \mapsto & \widetilde{H}(1,s). \end{array}$$

Since $[0,1]$ is connected it follows from Lemma 1.92 and Lemma 7.4 that $\widetilde{H}(1,s) = \tilde{Q}$ for all $s\in[0,1]$. In particular we obtain that

$$\tilde{f}(1) \;=\; \widetilde{H}(1,0) \;=\; \tilde{Q} \;=\; \widetilde{H}(1,1) \;=\; \tilde{g}(1).$$

Thus it follows that $\widetilde{H}$ is indeed a path-homotopy between the paths $\tilde{f}$ and $\tilde{g}$. □

Definition. Let $p\colon X\to B$ be a map between topological spaces and let $x_0\in X$ and $b_0\in B$. We say a map $p\colon X\to B$ is *a covering of pointed topological spaces*, if $p\colon X\to B$ is a covering and if $p(x_0) = b_0$.

Corollary 7.15. *For any covering $p\colon (X,x_0) \to (B,b_0)$ of pointed topological spaces the induced map $p_*\colon \pi_1(X,x_0) \to \pi_1(B,b_0)$ is a monomorphism.*

Proof. We have[174]

$$\begin{aligned} [f] \in \ker(\pi_1(X,x_0) \to \pi_1(B,b_0)) \quad &\Longrightarrow \quad [p\circ f] = e \in \pi_1(B,b_0) \quad \Longrightarrow \quad p\circ f \simeq e_{b_0} \\ &\underset{\uparrow}{\Longrightarrow} \quad f \simeq e_{x_0} \qquad\qquad\qquad \Longrightarrow \quad [f] = e \in \pi_1(X,x_0). \end{aligned}$$

by Corollary 7.14, since f is the lift of $p\circ f$ and e_{x_0} is the lift of e_{b_0} to the starting point x_0 □

Example. In Question 7.3 (1) we had asked whether there exists a covering map from the torus $S^1 \times S^1$ to the sphere S^2. By Proposition 5.14 we know that $\pi_1(S^2) = 0$ whereas we saw on page 248 that $\pi_1(S^1 \times S^1)$ is non-trivial. Using Corollary 7.15 we can now answer Question 7.3 (1) in the negative: there is no covering map from $S^1 \times S^1$ to S^2.

We conclude the section with the following lemma.

Lemma 7.16. *Let $p\colon (X,x_0) \to (B,b_0)$ be a covering of pointed topological spaces.*

(1) *Let f be a loop in (B,b_0). We denote by $\tilde{f}$ the lift of f to the starting point x_0. Then the following holds:*

$$\tilde{f} \text{ is a loop in } (X,x_0) \quad \Longleftrightarrow \quad [f] \text{ lies in } p_*(\pi_1(X,x_0)) \subset \pi_1(B,b_0).$$

(2) *Now we suppose that X is simply connected. Let f and g loops in (B,b_0) and let $\tilde{f}$ and $\tilde{g}$ be the lifts of f and g to the starting point x_0. Then the following holds:*

$$f \text{ and } g \text{ are path-homotopic loops} \quad \Longleftrightarrow \quad \text{the endpoints of } \widetilde{f} \text{ and } \widetilde{g} \text{ agree.}$$

(3) *If X is path-connected, then $[X : B] = [\pi_1(B,b_0) : p_*(\pi_1(X,x_0))]$.*

Remark. In Exercise 7.7 we use Lemma 7.16 (3) to answer Question 7.3 (2) in the negative.

Proof (∗).

(1) We prove the "⇒"-direction. So let f be a loop in (B,b_0). We denote by $\tilde{f}$ the lift of f to the starting point x_0. If $\tilde{f}$ is a loop in (X,x_0), then it defines an element in $\pi_1(X,x_0)$ and we have $[f] = [p\circ\tilde{f}] = p_*([\tilde{f}]) \in p_*(\pi_1(X,x_0))$. The proof of the "⇐"-direction is Exercise 7.7.[175]
(2) The "⇒"-direction is an immediate consequence of Corollary 7.14. The proof of the "⇐"-direction is done once again in Exercise 7.7. For that direction we need that X is simply connected.
(3) This statement is proved in Exercise 7.7. □

[174] We use the notation from page 233: for $y \in Y$ we denote by e_y the constant path $e_y(t) := x$, $t \in [0,1]$.

[175] Note that $[f]$ lies in $p_*(\pi_1(X,x_0)) \subset \pi_1(B,b_0)$ means that there exists a loop g in (X,x_0) such that $p\circ g$ is *path-homotopic* to f. A priori it does not mean that there exists a loop g with $p\circ g = f$.

7.6. **Group actions and fundamental groups.** The following proposition finally allows us to determine many fundamental groups. This proposition is the reward for the many rather theoretical results of the previous sections.

Theorem 7.17. *Let X be a simply connected topological space. Let G be a group which acts continuously and discretely on X. We choose an $x \in X$. We denote by $p\colon X \to X/G$ the canonical projection map. Then the map*

$$\begin{array}{rcl} G & \to & \pi_1(X/G, [x]) \\ g & \mapsto & [p \circ (\textit{path in } X \textit{ from } x \textit{ to } g \cdot x)] \end{array}$$

is a well-defined isomorphism of groups. In particular we have $\pi_1(X/G) \cong G$.

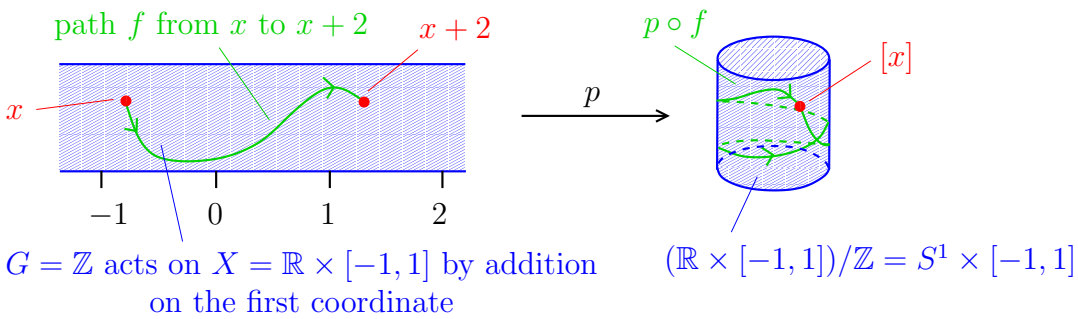

FIGURE 160. Illustration of Theorem 7.17.

Before we provide the proof of Theorem 7.17, let us impatiently use it to finally confirm our suspicion that the fundamental group of S^1 is isomorphic to $\mathbb{Z}$.

Proposition 7.18.

(1) *The maps*

$$\Phi\colon \mathbb{Z} \to \pi_1(\mathbb{R}/\mathbb{Z}, 0), \quad n \mapsto \underbrace{\left[\begin{array}{rcl} [0,1] & \to & \mathbb{R}/\mathbb{Z} \\ t & \mapsto & p(nt) = [nt] \end{array}\right]}_{\substack{\text{the map } t \mapsto nt \text{ is a} \\ \text{path from } 0 \text{ to } 0+n}} \quad \textit{and} \quad \Psi\colon \mathbb{Z} \to \pi_1(S^1, 1), \quad n \mapsto \left[\begin{array}{rcl} [0,1] & \to & S^1 \\ t & \mapsto & e^{2\pi i n t} \end{array}\right]$$

are isomorphism of groups.

(2) *Let $n \in \mathbb{N}$. We consider the map $f\colon S^1 \to S^1$ that is given by $z \mapsto z^n$. The induced map on $\pi_1(S^1, 1)$ is given by multiplication by n.*

(3) *The map*

$$\begin{array}{rcl} \Theta\colon \pi_1(S^1, 1) & \to & \mathbb{Z} \\ [\gamma] & \mapsto & \frac{1}{2\pi i} \int_\gamma \frac{1}{z}\, dz \end{array}$$

is an isomorphism.

Proof.

(1) We consider the action of $G = \mathbb{Z}$ on the simply connected topological space $X = \mathbb{R}$. We denote by $p\colon \mathbb{R} \to \mathbb{R}/\mathbb{Z}$ the canonical projection map. It follows immediately from Theorem 7.17 that the given map $\Phi\colon \mathbb{Z} \to \pi_1(\mathbb{R}/\mathbb{Z}, 0)$ is an isomorphism. We denote by $\phi\colon \mathbb{R}/\mathbb{Z} \to S^1$ the homeomorphism given by $\phi([t]) = e^{2\pi i t}$. If we compose the above isomorphism with the isomorphism $\phi_*\colon \pi_1(\mathbb{R}/\mathbb{Z}, 0) \to \pi_1(S^1, 1)$, then we see that the second map $\Psi\colon \mathbb{Z} \to \pi_1(S^1, 1)$ is also an isomorphism.

(2) This statement follows easily from the definitions. To practice the definitions we will prove this statement in Exercise 7.10.

(3) It is straightforward to see that $\Theta \circ \Psi\colon \mathbb{Z} \to \pi_1(S^1, 1) \to \mathbb{Z}$ is the identity. By (1) the first map Ψ is an isomorphism. Thus $\Theta = \Phi^{-1}$ is also an isomorphism. □

We will provide many more examples for Theorem 7.17 immediately after the proof of Theorem 7.17.

Proof of Theorem 7.17 (∗). [176] Let X be a simply connected topological space. Let G be a group which acts continuously and discretely on X. We choose an $x \in X$. We denote by $p\colon X \to X/G$ the canonical projection map. We consider the map

$$\begin{array}{rcl} \Phi\colon G & \to & \pi_1(X/G, [x]) \\ g & \mapsto & [p \circ (\text{path in } X \text{ from } x \text{ to } gx)]. \end{array}$$

We need to prove the following four statements:

(1) Φ is well-defined,
(2) Φ is a group homomorphism,
(3) Φ is surjective,
(4) Φ is injective.

Now we provide the proofs for these four claims.

(1) We first show that the map Φ is well-defined. Let $g \in G$. Since X is in particular path-connected there exists a path from x to gx. Now let f be an arbitrary path in X from x to gx. From $p(x) = [x] = [gx] = p(gx)$ it follows that $p \circ f$ is a loop in $(X/G, [x])$. In particular $p \circ f$ does indeed define an element in $\pi_1(X/G, [x])$.

Now we need to show that this element does not depend on the choice of f. So let f' be another path in X from x to gx. Since X is simply connected it follows from Lemma 5.13 that the paths f and f' are path-homotopic in X, i.e. there exists a path-homotopy $H\colon [0,1] \times [0,1] \to X$ from f to f'. But then $p \circ H\colon [0,1] \times [0,1] \to X/G$ is a path-homotopy from the loop $p \circ f$ to the loop $p \circ f'$. This shows that the map Φ is well-defined.

(2) Now we show that Φ is a group homomorphism. Let $g, h \in G$ and pick be a path k from x to gx and pick a path l from x to hx. Then gl[177] is a path from gx to ghx

[176] It is perhaps helpful to read the proof with the example of the action of $\mathbb{Z}^n$ on $\mathbb{R}^n$ in mind.

[177] Here gl denotes the path $[0,1] \to X$ that is given by $t \mapsto g \cdot l(t)$.

and $k * gl$ is a path from x to ghx. It follows that

$$\begin{aligned}\Phi(gh) \underset{\substack{\uparrow \\ \text{since } k*gl \text{ is a path from } x \text{ to } ghx}}{=} [p \circ (k * gl)] &= [(p \circ k) * (p \circ gl)] \overset{\substack{\text{since } p(gx) = p(x) \in X/G \text{ for all } x \in X \\ \downarrow}}{=} [(p \circ k) * (p \circ l)] \\ &\underset{\substack{\uparrow \\ \text{definition of } \cdot \text{ in } \pi_1(X/G,[x])}}{=} [p \circ k] \cdot [p \circ l] = \Phi(g) \cdot \Phi(h).\end{aligned}$$

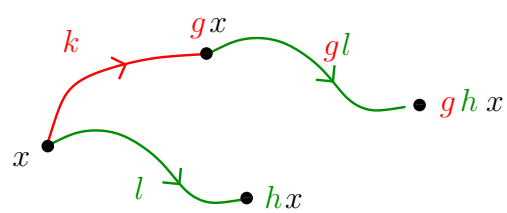

FIGURE 161. Schematic image for the proof that Φ is a group homomorphism.

Before we continue we recall that according to Proposition 7.10 the projection map $p\colon X \to X/G$ is a covering.

(3) Now we prove that Φ is surjective. We choose an arbitrary element $c \in \pi_1(X/G,[x])$ and represent it by a loop f in $(X/G,[x])$. According to Proposition 7.12 there exists a lift $\tilde{f}\colon [0,1] \to X$ of the path f to the starting point x. By definition we have $p \circ \tilde{f} = f$. In particular we obtain for the endpoint of $\tilde{f}$ that $p(\tilde{f}(1)) = [x]$, therefore it follows that $\tilde{f}(1) = gx$ for some $g \in G$. Thus we have proved that

$$\Phi(g) = \big[p \circ (\text{path from } x \text{ to } gx)\big] = [p \circ \tilde{f}] = [f] = c.$$

(4) We conclude the proof of the proposition by showing that Φ is injective. Let $g \in G$. Then the following holds:

$$\begin{aligned}\Phi(g) = e &\implies [p \circ (\text{path } f \text{ from } x \text{ to } gx)] = e \in \pi_1(X/G,[x]) \\ &\implies p \circ f \simeq e_{[x]} \text{ in } X/G \\ &\underset{\substack{\uparrow \\ \text{by Corollary 7.14, since } f \text{ is a lift of } p\circ f \text{ and } e_x \\ \text{is a lift of } e_{[x]} \text{ to the starting point } x}}{\implies} f(1) = e_x(1) \implies gx = x \underset{\substack{\uparrow \\ \text{since the action is discrete,} \\ \text{hence free}}}{\implies} g = e.\end{aligned}$$

This shows that Φ is indeed injective.

We have thus shown that Φ is a well-defined isomorphism. □

Now we can determine the fundamental groups of many of the topological spaces that we have encountered so far.

Corollary 7.19. *We have the following isomorphisms of fundamental groups*

$$
\begin{array}{lrcll}
\text{(A)} & \pi_1(\textit{n-dimensional torus}) & = & \pi_1(\mathbb{R}^n/\mathbb{Z}^n) & \cong \mathbb{Z}^n \\
 & \textit{in particular} & & & \\
 & \pi_1(S^1) & = & \pi_1(\mathbb{R}/\mathbb{Z}) & \cong \mathbb{Z}, \\
\text{(B)} & \textit{for any } n \neq 0,1 & & & \\
 & \pi_1(\textit{real projective space } \mathbb{R}\mathrm{P}^n) & = & \pi_1(S^n/\{\pm 1\}) & \cong \mathbb{Z}_2, \\
\text{(C)} & \pi_1(\textit{Möbius band }) & = & \pi_1((\mathbb{R}\times[-1,1])/\mathbb{Z}) & \cong \mathbb{Z}, \\
\text{(D)} & \pi_1(\textit{lens space } L(p,q)) & = & \pi_1(S^3/\mathbb{Z}_p) & \cong \mathbb{Z}_p.
\end{array}
$$

Proof $(*)$. By Proposition 5.14 we know that for any $n \geq 2$ the sphere S^n is simply connected. Furthermore we know by the discussion on page 235 that $\mathbb{R}^n$, $n \geq 1$, and that the strip $\mathbb{R}\times[-1,1]$ are simply connected. We saw on page 264 that all the actions are discrete. The actions are of course also continuous. The corollary is now an immediate consequence of Theorem 7.17. □

Thus we have now finally determined the fundamental groups of many spaces. In Proposition 5.14 we saw that $\pi_1(S^2) = 0$ whereas we have now seen that $\pi_1(S^1 \times S^1) \cong \mathbb{Z}^2$. The fundamental groups are not isomorphic, hence the sphere S^2 and the torus $S^1 \times S^1$ are not homeomorphic.

We also obtained a partial answer to Question 7.8: if two lens spaces $L(p,q)$ and $L(\widetilde{p},\widetilde{q})$ are homeomorphic, then $p = \widetilde{p}$. But as of right now we cannot say anything about the parameters q and $\widetilde{q}$.

Examples. Theorem 7.17 not only gives us the fact that $\pi_1(X/G)$ is isomorphic to the group G, but it also gives us an explicit isomorphism. Now we will study this isomorphism in two examples to explicitly determine non-trivial elements in the fundamental group of the torus and the real projective space.

(1) As a reminder, the torus is defined as[178]

$$T \;=\; \mathbb{R}^2/\mathbb{Z}^2 \;=\; [0,1]\times[0,1]/(x,0)\sim(x,1) \text{ and } (0,y)\sim(1,y).$$

[178]Here we are slightly generous in our usage of the equality sign. More precisely, strictly speaking $\mathbb{R}^2/\mathbb{Z}^2$ is not the same as $[0,1]\times[0,1]/\sim$. But there exists a canonical homeomorphism between these two spaces that we use to identify these spaces.

The explicit isomorphism of Theorem 7.17

$$\Phi\colon \mathbb{Z}^2 \quad \to \quad \pi_1(T,(0,0))$$

assumes in particular the following values

$$\Phi((1,0)) \quad = \quad x \quad := \quad \underbrace{\left[\begin{array}{rcl} [0,1] & \to & [0,1]\times[0,1]/\sim \\ t & \mapsto & [(t,0)] \end{array}\right]}_{t\mapsto(t,0) \text{ is a path from } (0,0) \text{ to } (1,0)}$$

and

$$\Phi((0,1)) \quad = \quad y \quad := \quad \underbrace{\left[\begin{array}{rcl} [0,1] & \to & [0,1]\times[0,1]/\sim \\ t & \mapsto & [(0,t)] \end{array}\right]}_{t\mapsto(0,t) \text{ is a path from } (0,0) \text{ to } (0,1)}.$$

In the description of the torus as a subset of $\mathbb{R}^3$, see Figure 162, these two loops correspond to the "longitude" and the "meridian".

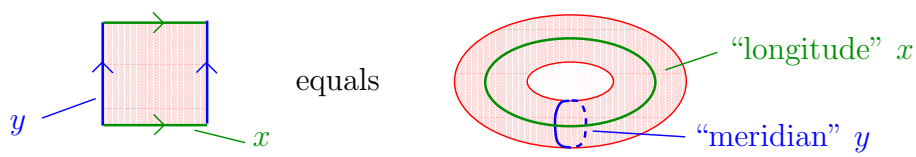

FIGURE 162.

(2) Now we consider the real projective space $\mathbb{RP}^2 = S^2/\{\pm 1\} = S^2/x \sim -x$ and as usual we denote by $p\colon S^2 \to \mathbb{RP}^2$ the projection. We put $Q := (1,0,0)$. We consider the following path in S^2:

$$\begin{array}{rcl} f\colon [0,1] & \to & S^2 \\ t & \mapsto & (\cos(\pi t), \sin(\pi t), 0). \end{array}$$

This is a path from Q to $-Q = (-1)\cdot Q$. Since -1 is the one non-trivial element of the group $G = \{\pm 1\}$ it follows from the explicit isomorphism of Theorem 7.17 that the equivalence class of $p \circ f$ is precisely the one non-trivial element of the fundamental group $\pi_1(\mathbb{RP}^2, p(Q)) \cong \{\pm 1\}$.[179] Since $\pi_1(\mathbb{RP}^2, p(Q))$ is isomorphic to $\mathbb{Z}_2$ we see that $p \circ f$ represents an element of order 2, i.e. $(p\circ f) * (p \circ f)$ represents the trivial element in the fundamental group. Put differently, $(p\circ f) * (p\circ f)$ is null-homotopic. This one can see quite explicitly. More precisely, we have

$$\begin{aligned} [p\circ f]\cdot[p\circ f] \quad &= \quad [(p\circ f)*(p\circ f)] \quad = \quad [(p\circ(-f))*(p\circ f)] \quad = \quad [p\circ(f*(-f))] \\ &= \quad \left[p \circ \underbrace{\left(\begin{array}{rcl} f\colon [0,1] & \to & S^2 \\ t & \mapsto & (\cos(2\pi t), \sin(2\pi t), 0) \end{array}\right)}_{\text{loop } g \text{ in } S^2}\right]. \end{aligned}$$

[179] In particular we have now shown that the loop in $\mathbb{RP}^2$ given on page 227 is not null-homotopic.

The loop g in (S^2, Q) is clearly null-homotopic.[180] But then the loop $p \circ g$ is also null-homotopic. This example is illustrated in Figure 163.

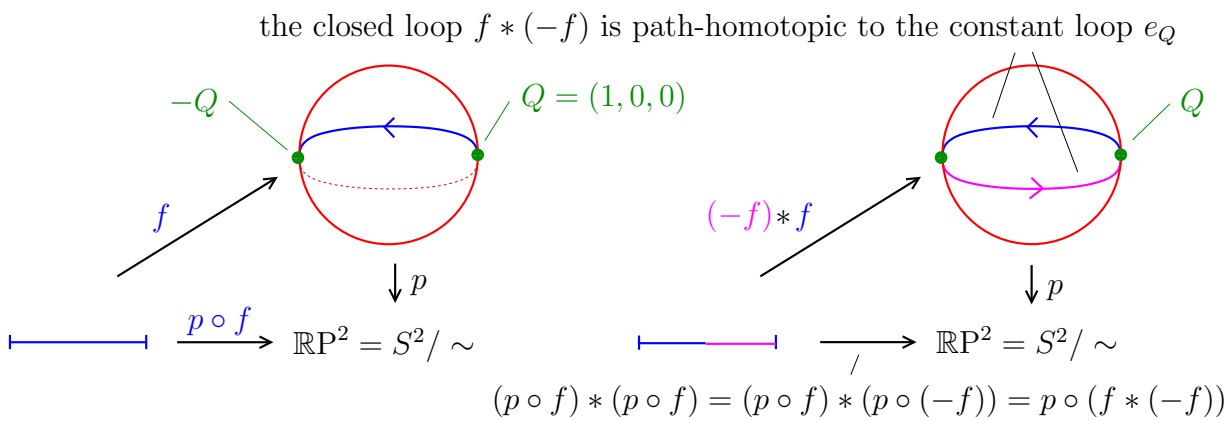

FIGURE 163.

Example. We consider the Klein bottle. Recall that on page 265 we introduced the group G that is given by all self-homeomorphisms of $\mathbb{R}^2$ that can be written as concatenations of the two self-homeomorphisms

$$\begin{array}{rcl} A\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (x,y) & \mapsto & (x+1, 1-y) \end{array} \quad \text{and} \quad \begin{array}{rcl} B\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (x,y) & \mapsto & (x, y+1) \end{array}$$

and their inverses. In Exercise 7.6 we will see G acts discretely on $\mathbb{R}^2$ and we saw on page 265 that $\mathbb{R}^2/G$ is homeomorphic to the Klein bottle. It follows from Theorem 7.17 that

$$\pi_1(\text{Klein bottle}) \;\cong\; G = \text{ group that is generated by the homeomorphisms } A \text{ and } B.$$

The maps A and B do not commute. Indeed, the map $A \circ B\colon \mathbb{R}^2 \to \mathbb{R}^2$ is given by

$$(x,y) \;\mapsto\; (x+1, (1-(y+1))) \;=\; (x+1, -y)$$

whereas the map $B \circ A\colon \mathbb{R}^2 \to \mathbb{R}^2$ is given by

$$(x,y) \;\mapsto\; (x+1, (1-y)+1) \;=\; (x+1, 2-y).$$

Thus we see that the fundamental group of the Klein bottle is a non-abelian group.

In Figure 164 we show the two elements b and c of the fundamental group of the Klein bottle $K = [0,1] \times [0,1]/\sim$ which correspond to B and $C = B^{-1} \circ A$ under the isomorphism of Theorem 7.17 and the homeomorphism from page 265. Since the two homeomorphisms $B(x,y) = (x, y+1)$ and $C(x,y) = (x+1, -y)$ do not commute, the corresponding elements $[b]$ and $[c]$ of $\pi_1(K)$ do not commute either.

[180] More precisely, it is straightforward to write down an explicit path-homotopy from g to the constant path e_Q. Alternatively one can also deduce that g is null-homotopic from our calculation $\pi_1(S^2, Q) = 0$.

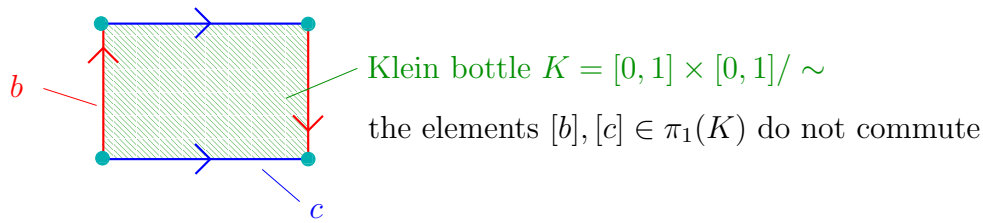

FIGURE 164.

The previous example showed that fundamental groups can be non-abelian groups. In fact, as we will see later, "most" fundamental groups are non-abelian. This will pose several major problems. For example, what is a good way to describe a non-abelian group? How can we decide whether or not two non-abelian groups are isomorphic?

We conclude this section with a more unusual topological space. Namely we remark in Exercise 7.9 we will use Theorem 7.17 to show that the fundamental group of the pseudocircle, i.e. of the topological space $X = \{A, B, C, D\}$ from page 66, is isomorphic to $\mathbb{Z}$. In particular we show that the loop given on page 66 is not null-homotopic. This answers the question we had posed on page 228.

7.7. **The fundamental group of the product of two topological spaces.** The next proposition says that the fundamental groups of the product $A \times B$ of two topological spaces A and B is the direct product of the fundamental groups of A and B. Before we state the proposition explicitly we recall the definition of the direct product of two groups.

Definition. Let G and H two groups. We can form the cartesian product

$$G \times H \ := \ \{(g,h) \,|\, g \in G \text{ and } h \in H\}.$$

This is again a group with the group structure given by

$$(g_1, h_1) \cdot (g_2, h_2) \ := \ (g_1 g_2, h_1 h_2)$$

for $g_1, g_2 \in G$ and $h_1, h_2 \in H$. We call the group $G \times H$ the *direct product of the groups G and H*.

We start out with the following lemma, which strictly speaking we will not need, but which is worth knowing.

Lemma 7.20. $(*)$ *Let $\varphi_1 \colon G_1 \to \pi$ and $\varphi_2 \colon G_2 \to \pi$ be two group homomorphisms. If for every $g_1 \in G_1$ and $g_2 \in G_2$ the images $\varphi_1(g_1) \in \pi$ and $\varphi_2(g_2) \in \pi$ commute, i.e. if we have $\varphi_1(g_1) \cdot \varphi_2(g_2) = \varphi_2(g_2) \cdot \varphi_1(g_1)$, then the map*

$$\begin{array}{rcl} \varphi_1 \times \varphi_2 \colon G_1 \times G_2 & \to & \pi \\ (g_1, g_2) & \mapsto & \varphi_1(g_1) \cdot \varphi_2(g_2) \end{array}$$

is a homomorphism.[181]

Proof (∗). We write $\Phi = \varphi_1 \times \varphi_2$. Let $g_1, g_1' \in G_1$ and let $g_2, g_2' \in G_2$. We have

$$\begin{array}{rcl} \Phi(g_1,g_2)\cdot\Phi(g_1',g_2') & = & \varphi_1(g_1)\cdot\varphi_2(g_2)\cdot\varphi_1(g_1')\cdot\varphi_2(g_2') \\ & = & \varphi_1(g_1)\cdot\varphi_1(g_1')\cdot\varphi_2(g_2)\cdot\varphi_2(g_2') \\ & \uparrow & \\ & \text{by our hypothesis} & \end{array} \begin{array}{rcl} & & \\ = & \varphi_1(g_1g_1')\cdot\varphi_2(g_2g_2') \\ = & \Phi(g_1g_1',g_2g_2'). \end{array}$$

□

Now we can formulate the promised proposition.

Proposition 7.21. *Let A and B be two topological spaces and let $a_0 \in A$ and $b_0 \in B$. We consider the inclusion maps*

$$\begin{array}{rcl} i\colon A & \to & A\times B \\ a & \mapsto & (a,b_0) \end{array} \quad \text{and} \quad \begin{array}{rcl} j\colon B & \to & A\times B \\ b & \mapsto & (a_0,b) \end{array}$$

and we consider the projection maps

$$\begin{array}{rcl} p\colon A\times B & \to & A \\ (a,b) & \mapsto & a \end{array} \quad \text{and} \quad \begin{array}{rcl} q\colon A\times B & \to & B \\ (a,b) & \mapsto & b. \end{array}$$

Then the maps

$$\begin{array}{rcl} \Phi\colon \pi_1(A,a_0)\times\pi_1(B,b_0) & \to & \pi_1(A\times B,(a_0,b_0)) \\ (x,y) & \to & i_*(x)\cdot j_*(y) \end{array}$$

and

$$\begin{array}{rcl} \Psi\colon \pi_1(A\times B,(a_0,b_0)) & \to & \pi_1(A,a_0)\times\pi_1(B,b_0) \\ z & \to & (p_*(z),q_*(z)) \end{array}$$

are both homomorphisms[182] *and they are inverses of one another, in particular both are isomorphisms.*

Example. It follows from Proposition 7.21 and the above calculations of fundamental groups that

$$\pi_1(S^1\times L(p,q)) \;\cong\; \pi_1(S^1)\times\pi_1(L(p,q)) \;\cong\; \mathbb{Z}\times\mathbb{Z}_p.$$

Of course we can also apply Proposition 7.21 several times and we see once again that

$$\pi_1(\underbrace{S^1\times\cdots\times S^1}_{n\text{ times}}) \;\cong\; \underbrace{\pi_1(S^1)\times\cdots\times\pi_1(S^1)}_{n\text{ times}} \;\cong\; \underbrace{\mathbb{Z}\times\cdots\times\mathbb{Z}}_{n\text{ times}} \;\cong\; \mathbb{Z}^n.$$

Finally it follows from Propositions 5.14 and 7.21 that for any $k,l \geq 2$ we have

$$\pi_1(S^k\times S^l) \;\cong\; \pi_1(S^k)\times\pi_1(S^l) \;\cong\; 0\times 0 \;=\; 0.$$

In particular we see that the fundamental group cannot distinguish the products of spheres of dimension ≥ 2. For example at the moment we cannot show that the two 6-dimensional manifolds $S^3\times S^3$ and $S^2\times S^2\times S^2$ are not homeomorphic.

[181] In fact the converse also holds, if $\varphi_1\times\varphi_2$ is a homomorphism, then the for every $g_1\in G_1$ and $g_2\in G_2$ the images $\varphi_1(g_1)\in\pi$ and $\varphi_2(g_2)\in\pi$ commute. Why is that?

[182] Note that a priori it is not clear that Φ is a homomorphism since it is not clear whether the hypothesis of Lemma 7.20 is satisfied.

In the proof of Proposition 7.21 we will need the following purely group-theoretic lemma.

Proof of Proposition 7.21 $(*)$. It is clear that $\Psi\colon \pi_1(A\times B,(a_0,b_0)) \to \pi_1(A,a_0)\times\pi_1(B,b_0)$ is a homomorphism. Thus it suffices to show that Φ and Ψ are inverses of one another. Once we have shown that, it follows for free that Φ is also a homomorphism.

To show that Φ and Ψ are inverses of one another we introduce another map, namely we consider[183]

$$\begin{array}{rcl} \Theta\colon \pi_1(A,a_0)\times\pi_1(B,b_0) & \to & \pi_1(A\times B,(a_0,b_0)) \\ ([f\colon (S^1,1)\to(A,a_0)],[g\colon (S^1,1)\to(B,b_0)]) & \to & \left[\begin{array}{rcl} (S^1,1) & \to & (A\times B,(a_0,b_0)) \\ z & \mapsto & (f(z),g(z)) \end{array}\right]. \end{array}$$

It is almost a tautology that Θ and Ψ are inverses of one another. Thus it remains to prove the following claim.

Claim. The two maps $\Phi,\Theta\colon \pi_1(A,a_0)\times\pi_1(B,b_0)\to\pi_1(A\times B,(a_0,b_0))$ agree.

We use the convention from page 228 to change our view of fundamental groups. Thus let $f\colon[0,1]\to A$ be a loop in (A,a_0) and $g\colon[0,1]\to B$ be a loop in (B,b_0). We need to show that

$$i_*([f])\cdot j_*([g]) \;=\; [(t\mapsto(f(t),g(t))] \;\in\; \pi_1(A\times B,(a_0,b_0).$$

In other words, we need to show that the two loops

$$\begin{array}{rcl} [0,1] & \to & A\times B \\ t & \mapsto & \begin{cases} (f(2t),b_0), & \text{if } t\in[0,\frac12] \\ (a_0,g(2t-1)), & \text{if } t\in[\frac12,1] \end{cases} \end{array} \quad \text{and} \quad \begin{array}{rcl} [0,1] & \to & A\times B \\ t & \mapsto & (f(t),g(t)) \end{array}$$

are path-homotopic. In fact an explicit path-homotopy is given by the map[184]

$$\begin{array}{rcl} F\colon [0,1]\times[0,1] & \to & A\times B \\ (t,s) & \mapsto & \begin{cases} \big(f\big(\frac{2t}{1+s}\big),g(st)\big), & \text{if } t\in[0,\frac12] \\ \big(f(st),g\big(\frac{2t-1+s}{1+s}\big)\big), & \text{if } t\in[\frac12,1]. \end{cases} \end{array}$$

□

Summarizing we have now finally managed to calculate many non-trivial fundamental groups. Nonetheless, the list of topological spaces for which we cannot yet calculate the fundamental group is still pretty long, it includes

(1) graphs,
(2) knot complements,
(3) the complement of more than one point in $\mathbb{C}$, e.g. $\mathbb{C}\setminus\{0,1\}$,
(4) surfaces of genus ≥ 2.

In the following chapters we will introduce more methods for determining the fundamental group of a given topological space. But first we give in the next section two applications of our results.

[183] One can easily verify that Θ is well-defined.

[184] Note that this is indeed a path-homotopy of loops.

7.8. **Applications: the Fundamental Theorem of Algebra and the Borsuk-Ulam Theorem.** As a first application of our methods we give a proof of the Fundamental Theorem of Algebra. Somewhat surprisingly, contrary to the standard proof [Lan, Corollary III.7.6], this proof does not make any use of complex analysis.

Theorem 7.22. (Fundamental Theorem of Algebra) *Every nonconstant polynomial with coefficients in $\mathbb{C}$ has a zero in $\mathbb{C}$.*

Proof. Let $q(z)$ be a polynomial with complex coefficients with $q(z) \neq 0$ for all $z \in \mathbb{C}$ with $|z| = r$. We consider the path

$$\begin{array}{rcl} f_r^{q(z)} \colon [0,1] & \to & S^1 \\ s & \mapsto & \dfrac{q(re^{2\pi i s})/q(r)}{\left|q(re^{2\pi i s})/q(r)\right|} \end{array}$$

Note that $f_r^{q(z)}(s=0) = f_r^{q(z)}(s=1) = 1$, i.e. $f_r^{q(z)}$ is a loop in $(S^1, 1)$. Now let

$$p(z) \quad = \quad a_n z^n + a_{n-1} z^{n-1} + \cdots + a_1 z + a_0$$

be a polynomial of degree $n \geq 1$. We assume that $p(z)$ has no zeros in $\mathbb{C}$. For $t \in [0,1]$ we also consider the polynomial

$$p_t(z) \quad := \quad a_n z^n + t(a_{n-1} z^{n-1} + \cdots + a_1 z + a_0).$$

Note that $p_1(z) = p(z)$ and $p_0(z) = a_n z^n$. Since $a_n \neq 0$ there exists an $s > 0$ such that[185]

$$|a_n z^n| \ > \ |a_{n-1} z^{n-1} + \cdots + a_1 z + a_0|$$

for any z with $|z| = s$. This inequality implies that for any $t \in [0,1]$ and any z with $|z| = s$ we have $p_t(z) \neq 0$, i.e. $p_t(z)$ has no zeros on the circle $|z| = s$.

We obtain the following sequence of path-homotopic loops:

$$\text{constant loop at } 1 \ \overset{\substack{\text{follows from the definition} \\ \downarrow}}{=} \ f_0^{p(z)} \ \underset{\substack{\uparrow \\ \text{the maps } f_r^{p(z)} \text{ with } r \in [0,s] \text{ are defined,} \\ \text{since the polynomials } p(z) \text{ has no zeros} \\ \text{and they form a path-homotopy from } f_0^{p(z)} \text{ to } f_s^{p(z)}}}{\simeq} \ f_s^{p(z)} \ = \ f_s^{p_1(z)} \ \underset{\substack{\uparrow \\ \text{the maps } f_s^{p_t(z)} \text{ with } t \in [0,1] \text{ are defined,} \\ \text{since the polynomials } p_t(z) \text{ have no zeros on } |z| = s, \\ \text{and they form a path-homotopy from } f_r^{p_1(z)} \text{ to } f_r^{p_0(z)}}}{\simeq} \ f_s^{p_0(z)} \ \overset{\substack{\text{follows from } p_0(z) = a_n z^n \\ \downarrow}}{=} \ \text{the loop} \ \begin{array}{rcl} [0,1] & \to & S^1 \\ t & \mapsto & e^{2\pi i n t}. \end{array}$$

By Proposition 7.18 we had know that the loop on the right defines a non-trivial element in the fundamental group $\pi_1(S^1, 1)$, but we had just shown that it is path-homotopic to the constant path. Thus we have obtained a contradiction. $\square$

The following theorem goes back to the Polish mathematicians Karol Borsuk (1905-1982) and Stanislaw Ulam (1909-1984).[186] It was first proved in 1932.

[185] In fact we can write it down explicitly: it follows easily from the triangle inequality that any $s \in \mathbb{R}$ such that $s \cdot |a_n| > |a_{n-1}| + \cdots + |a_0|$ will work.

[186] Ulam became much more famous through his work on the hydrogen bomb.

Theorem 7.23. (Borsuk-Ulam Theorem) *For every map $f\colon S^2 \to \mathbb{R}^2$ there exists a pair of antipodal points x and $-x$ in S^2 with $f(x) = f(-x)$.*

Example.

(1) It follows from the Borsuk-Ulam Theorem that there exist two antipodal points on earth with the same temperature and the same barometric pressure.
(2) The Borsuk-Ulam Theorem implies in particular that there is no injective map from $S^2 \to \mathbb{R}^2$.
(3) The statement of the Borsuk-Ulam Theorem also makes sense for 2 replaced by any $n \in \mathbb{N}$. For $n = 1$ one can prove the statement using elementary methods.[187] We will address the problem for $n \geq 3$ once we have introduced homology groups.

Proof. We prove the theorem by contradiction. So suppose there exists a map $f\colon S^2 \to \mathbb{R}^2$ such that $f(x) \neq f(-x)$ for all $x \in S^2$. This allows to define the map

$$\begin{array}{rcl} g\colon S^2 & \to & S^1 \\ x & \mapsto & \frac{f(x)-f(-x)}{\|f(x)-f(-x)\|}. \end{array}$$

Note that $g(-x) = -g(x)$ for all $x \in S^2$. Now let η be the loop that is defined by

$$\begin{array}{rcl} \eta\colon [0,1] & \to & S^2 \\ s & \mapsto & \eta(s) = (\cos(2\pi s), \sin(2\pi s), 0) \end{array}$$

and let $h = g \circ \eta\colon [0,1] \to S^1$ be the composition of η with g. We pick a $c \in \mathbb{R}$ such that $h(0) = e^{2\pi i c}$. We denote by $p\colon \mathbb{R} \to S^1$, $t \mapsto e^{2\pi i t}$, the usual covering map. We note that for $z, w \in \mathbb{R}$ we have

$$p(z) = p(w) \iff z - w \in \mathbb{Z} \quad \text{and} \quad p(z) = -p(w) \iff z - w \in \tfrac{1}{2} + \mathbb{Z}.$$

By Proposition 7.12 we can lift the path $h\colon [0,1] \to S^1$ to a path $\widetilde{h}\colon [0,1] \to \mathbb{R}$ with $\widetilde{h}(0) = c$. We refer to Figure 165 for an illustration of all the definitions.

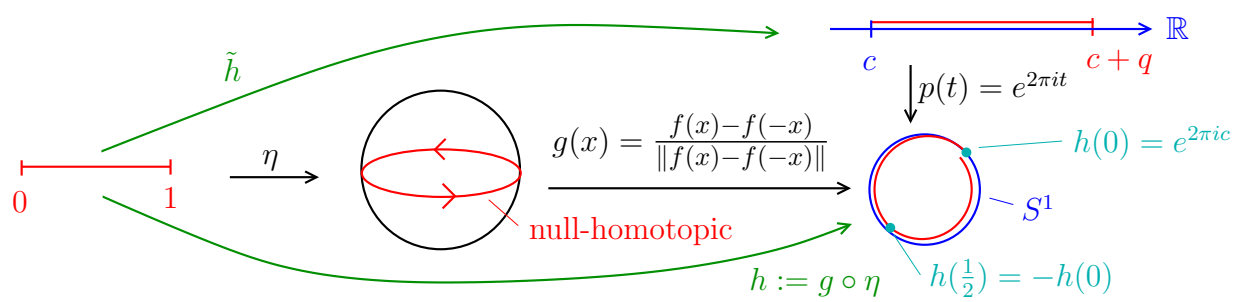

FIGURE 165. Illustration of the proof of the Borsuk-Ulam Theorem 7.23

[187] How would you prove the statement?

Given any $s \in [0, \frac{1}{2}]$ we have

$$p\big(\widetilde{h}\big(s+\tfrac{1}{2}\big)\big) \;=\; h\big(s+\tfrac{1}{2}\big) \;=\; g\big(\eta\big(s+\tfrac{1}{2}\big)\big) \underset{\substack{\uparrow \\ \text{by the definition of } \eta}}{=} g(-\eta(s)) \underset{\substack{\uparrow \\ \text{since } g(-x)=-g(x) \text{ for all } x\in S^2}}{=} -g(\eta(s)) \;=\; -h(s) \;=\; -p\big(\widetilde{h}(s)\big).$$

By the above discussion of p this implies that

$$\widetilde{h}\big(s+\tfrac{1}{2}\big) - \widetilde{h}(s) \;=:\; \frac{q(s)}{2}$$

with $q(s)$ an odd integer. The map $q\colon [0, \frac{1}{2}] \to \mathbb{Z}$ is the difference of two continuous maps, hence continuous. It follows from Lemma 1.92 that it is constant. We denote this constant value by q. Since q is odd it is in particular non-zero.

It follows from the above that

$$\widetilde{h}(1) \;=\; \widetilde{h}\big(\tfrac{1}{2}\big) + \tfrac{q}{2} \;=\; \widetilde{h}(0) + \tfrac{q}{2} + \tfrac{q}{2} \;=\; \widetilde{h}(0) + q.$$

Since q is non-zero we obtain from Lemma 7.16 that $h = g \circ \eta$ is not null-homotopic. But h was the composition $h = g \circ \eta\colon [0,1] \to S^2 \to S^1$. By Proposition 5.14 the loop η is null-homotopic in S^2 which implies by Proposition 6.1 that $h = g \circ \eta$ is null-homotopic in S^1. Thus we have obtained a contradiction. □

Exercises for Chapter 7.

Exercise 7.1. Prove Lemma 7.2.

Exercise 7.2.

(a) Let $p\colon X \to B$ be a map between topological spaces that is two-to-one, i.e. such that for any $b \in B$ the preimage $p^{-1}(b)$ consists of precisely two points. Is p necessarily a covering map?

(b) Is the map

$$\begin{array}{rcl} \mathbb{C} & \to & \mathbb{C} \setminus \{0\} \\ z & \mapsto & \exp(z) \end{array}$$

a covering map? Hint: $z = x + iy$ with $x, y \in \mathbb{R}$.

(c) Let $p\colon X \to B$ be a map between topological spaces that is a local homeomorphism and that is surjective. Is p necessarily a covering map? Give a short justification for your answer.

(d) Let $p\colon X \to B$ be a surjective map between topological spaces. Let $f\colon [0,1] \to B$ be a map. Does there always exist a lift from f to X, i.e. does there exist a map $g\colon [0,1] \to X$ such that $p \circ g = f$? Give a short justification for your answer.

Exercise 7.3. Let $p\colon \widetilde{X} \to X$ be a 2-fold covering. We define

$$\begin{array}{rcl} f\colon \widetilde{X} & \to & \widetilde{X} \\ Q & \mapsto & \text{the unique other point in } p^{-1}(p(Q)). \end{array}$$

Show that this map is continuous.

Exercise 7.4. Prove Lemma 7.4 (3).

Exercise 7.5. Consider the 5-fold covering map

$$\begin{array}{rcl} p\colon X = S^1 & \to & B = S^1 \\ z & \mapsto & z^5. \end{array}$$

Let $f\colon [0,1] \to B = S^1$ be the loop given by $t \mapsto e^{2\pi i k t}$. By Proposition 6.11 this loop lifts to a path $g\colon [0,1] \to X = S^1$. For which k is the lift g again a loop?

Exercise 7.6. We consider the following two self-homeomorphisms of $\mathbb{R}^2$:

$$\begin{array}{rcl} A\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (x,y) & \mapsto & (x+1, 1-y) \end{array} \quad \text{and} \quad \begin{array}{rcl} B\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (x,y) & \mapsto & (x, y+1). \end{array}$$

We denote by G the subgroup of all homeomorphisms of $\mathbb{R}^2$ that is generated by A and B. This means

$$G = \begin{array}{c} \text{all self-homeomorphisms of } \mathbb{R}^2 \text{ that can be written} \\ \text{as a finite concatenation of the maps } A, B, A^{-1} \text{ and } B^{-1}. \end{array}$$

(a) For $n \in \mathbb{Z}$, what is $A^{-n}BA^n$? (Perhaps start out with $n = 1$.)
(b) We write $C = A^2$. We denote by H the subgroup of all homeomorphisms of $\mathbb{R}^2$ that is generated by C and B. This means

$$H = \begin{array}{c} \text{all self-homeomorphisms of } \mathbb{R}^2 \text{ that can be written} \\ \text{as a finite concatenation of the maps } C, B, C^{-1} \text{ and } B^{-1}. \end{array}$$

Does A lie in H?
Hint: Consider which self-diffeomorphisms of $\mathbb{R}^2$ are orientation-preserving.
(c) Show that any element X of G lies in H or it is of the form $G = AY$ with $Y \in H$.
(d) Show that the group G acts discretely on $\mathbb{R}^2$.

Exercise 7.7.

(a) Prove the "$\Leftarrow$"-direction of Lemma 7.16 (1).
(b) Prove the "$\Leftarrow$"-direction of Lemma 7.16 (2).
(c) Prove Lemma 7.16 (3).
(d) Answer Question 7.3 (2) in the negative.

Exercise 7.8.

(a) Does there exist a covering map $p\colon K \to T$ from the Klein bottle to the 2-dimensional torus?
(b) Let X be a topological space and let $b \in \pi_1(X, x_0)$. Does there necessarily exist a map $f\colon (S^1, 1) \to (X, x_0)$ with $b \in f_*(\pi_1(S^1, 1))$?
(c) Let X be a topological space and let $b, c \in \pi_1(X, x_0)$. Does there necessarily exist a map $f\colon (S^1 \times S^1, (1,1)) \to (X, x_0)$ with $b, c \in f_*(\pi_1(S^1 \times S^1, (1,1)))$?

Exercise 7.9.

(a) Use Theorem 7.17 to show that the fundamental group of the pseudocircle, i.e. of the topological space $X = \{A, B, C, D\}$ from page 66, is isomorphic to $\mathbb{Z}$.
(b) Let $f\colon S^1 \to X$ be the map that we introduced on page 66. Show that the induced map $f_*\colon \pi_1(S^1, 1) \to \pi_1(X, A)$ is an isomorphism.

Exercise 7.10. Let $n \in \mathbb{N}$. We consider the map $f\colon S^1 \to S^1$ that is given by $z \mapsto z^n$. Show that the induced map on $\pi_1(S^1, 1)$ is given by multiplication by n.

Exercise 7.11. Let A and B be topological spaces and let $a_0 \in A$ and $b_0 \in B$. We consider the maps

$$\begin{array}{rcl} f\colon A & \to & A \times B \\ a & \mapsto & (a, b_0) \end{array} \quad \text{and} \quad \begin{array}{rcl} g\colon B & \to & A \times B \\ b & \mapsto & (a_0, b) \end{array}$$

and the map

$$\begin{array}{rcl} \Phi\colon \pi_1(A, a_0) \times \pi_1(B, b_0) & \to & \pi_1(A \times B, (a_0, b_0)) \\ (x, y) & \to & f_*(x) \cdot g_*(y) \end{array}$$

(a) Show that Φ is a monomorphism, i.e. that it is injective.
Hint: Consider the maps

$$\begin{array}{rcl} p\colon A \times B & \to & A \\ (a, b) & \mapsto & a \end{array} \quad \text{and} \quad \begin{array}{rcl} q\colon A \times B & \to & B \\ (a, b) & \mapsto & b. \end{array}$$

(b) Show that Φ is an epimorphism, i.e. that it is surjective.
Hint: Let $h(t) = (\alpha(t), \beta(t))$ be a loop in $(A \times B, (a_0, b_0))$. Consider the map

$$\begin{array}{rcl} \Psi\colon [0,1] \times [0,1] & \to & A \times B \\ (s, t) & \mapsto & (\alpha(s), \beta(t)). \end{array}$$

Hint: You might want to use ideas similar to the proof that the map Φ is a homomorphism.

Exercise 7.12. Let $A \in \mathrm{GL}(n, \mathbb{Z})$ be a matrix. In Lemma 3.28 we saw that the map

$$\begin{array}{rcl} f(A)\colon \mathbb{R}^n/\mathbb{Z}^n & \to & \mathbb{R}^n/\mathbb{Z}^n \\ v & \mapsto & Av \end{array}$$

is a homeomorphism. We identify $\pi_1(\mathbb{R}^n/\mathbb{Z}^n, 0)$ with $\mathbb{Z}^n$ as in Theorem 7.17. Show that the following diagram

$$\begin{tikzcd} \pi_1(\mathbb{R}^n/\mathbb{Z}^n, 0) \arrow[r, "f(A)_*"] \arrow[d, "="] & \pi_1(\mathbb{R}^n/\mathbb{Z}^n, 0) \arrow[d, "="] \\ \mathbb{Z}^n \arrow[r, "v \mapsto Av"] & \mathbb{Z}^n \end{tikzcd}$$

commutes.

8. Covering spaces and manifolds

8.1. **Coverings of manifolds.** In this section we show that covering spaces of (topological) manifolds are themselves (topological) manifolds.

Proposition 8.1. *Let $p\colon \widetilde{X} \to X$ be a countable covering*[188] *of a connected topological space X.*

(1) *If X is an n-dimensional topological manifold, then $\widetilde{X}$ is also an n-dimensional topological manifold. Furthermore, $\partial\widetilde{X} = p^{-1}(\partial X)$.*
(2) (a) *If X admits a smooth atlas, then $\widetilde{X}$ also admits a smooth atlas such that p is a local diffeomorphism,*[189] *in particular such that p is a smooth map.*
  (b) *If X is equipped with a smooth structure*[190] *then $\widetilde{X}$ admits a* unique *smooth structure such that $p\colon \widetilde{X} \to X$ is a local diffeomorphism.*
(3) *If X is an oriented manifold, then $\widetilde{X}$ also admits an orientation such that $p\colon \widetilde{X} \to X$ is orientation-preserving.*

Convention. If X is a manifold, i.e. if X is a topological manifold equipped with a smooth structure, and if we have constructed a finite covering $p\colon \widetilde{M} \to M$, then we always equip $\widetilde{M}$ with the unique smooth structure given by Proposition 8.1 (2b).

In the proof of Proposition 8.1 we will need the following technical lemma.

Lemma 8.2. *Let $p\colon \widetilde{X} \to X$ be a countable covering of a topological space X. If X is second-countable, then $\widetilde{X}$ is also second-countable.*

Proof. Let $p\colon \widetilde{X} \to X$ be a countable covering of a topological space X. Recall that we say $U \subset X$ is uniformly covered, if $p^{-1}(U)$ is the union of disjoint open subsets $\{\widetilde{U}_i\}_{i\in I}$ with the property that the restriction of p to each subset $\widetilde{U}_i$ is a homeomorphism. If U is uniformly covered, then every open subset of U is also uniformly covered.

Let $\mathcal{B}$ be a countable basis for the topology of X. We denote by $\mathcal{U} = \{U_j\}_{j\in J}$ the family of all open subsets of X that are uniformly covered. Since p is a covering we have $\bigcup_{j\in J} U_j = X$. It follows from Lemma 1.26 that

$$\mathcal{B}' := \{B \in \mathcal{B} \mid \text{ there exists a } j \in J \text{ with } B \subset U_j\}$$

is also a basis for the topology of X.

Now let $B \in \mathcal{B}'$. Since open subsets of uniformly covered subsets are uniformly covered we know that $p^{-1}(B)$ is the union of disjoint open sets B_i, $i \in I_B$ such that the restriction

[188] Recall that a covering $p\colon \widetilde{X} \to X$ of a connected topological space is called countable if the index, i.e. the cardinality of the preimage of a point in X, is countable.

[189] Recall that a map $f\colon M \to N$ between two manifolds is called a *local diffeomorphism* if given any $P \in M$ there exists an open neighborhood U of P and open neighborhood V of $f(P)$ such that $f\colon U \to V$ is a diffeomorphism.

[190] We refer to page 183 for the definition of a smooth structure on a manifold.

of p to each B_i is a homeomorphism. Since p is a countable covering the index set I_B is countable.

Claim.

$$\widetilde{\mathcal{B}} := \{B_i \mid B \in \mathcal{B}' \text{ and } i \in I_B\}$$

is a basis for the topology of $\widetilde{X}$.

It is straightforward to see that $\widetilde{\mathcal{B}}$ has the basis property. Every set in $\widetilde{\mathcal{B}}$ is of course open in $\widetilde{X}$. By Lemma 1.25 it suffices to show that given any open set W of $\widetilde{X}$ and any point $x \in W$ there exists a set B_i in $\widetilde{\mathcal{B}}$ with $x \in B \subset W$. So let $x \in W$. Since $\mathcal{B}'$ is a basis for the topology of X there exists a $B \in \mathcal{B}'$ with $p(x) \in B \subset p(W)$. But then there exists an $i \in I_B$ with $x \in B_i \subset W$. This completes the proof of the claim.

Since $\mathcal{B}'$ is countable and since each I_B is countable we see that $\widetilde{\mathcal{B}}$ consists of countably many open sets. This shows that $\widetilde{X}$ is second-countable. □

Now we can provide the proof of Proposition 8.1.

Proof of Proposition 8.1. Let $p\colon \widetilde{X} \to X$ be a countable covering of a connected n-dimensional topological manifold X.

(1) First we note that it follows from the hypothesis that X is a topological manifold that X is Hausdorff. It follows from Lemma 7.4 (3) that $\widetilde{X}$ is also Hausdorff. Similarly it follows from our hypothesis that X is a topological manifold and that p is a countable covering together with Lemma 8.2 that $\widetilde{X}$ is second-countable.

Since $p\colon \widetilde{X} \to X$ is a covering there exists a family of open subsets $\{U_i\}_{i\in I}$ of X such that each U_i is uniformly covered. Furthermore, since X is an n-dimensional manifold there exists an atlas $\{\Phi_j\colon V_j \to W_j\}_{j\in J}$ for X. After possibly replacing each V_j by the family $\{V_j \cap U_i\}_{i\in I}$ we can without loss of generality assume that each V_j is uniformly covered. Thus for each j the preimage $p^{-1}(V_j)$ is the union of disjoint open subsets $\{\widetilde{V}_{ji}\}_{i\in I_j}$ with the property, that the restriction of p to each subset $\widetilde{V}_{ji}$ is a homeomorphism. It is now clear that $\{\Phi_j \circ p\colon \widetilde{V}_{ji} \to W_j \mid j \in J \text{ and } i \in I_j\}$ is an atlas for $\widetilde{X}$.

Finally we intend to determine the boundary of $\widetilde{X}$. Let $y \in \widetilde{X}$. Using the fact that $p\colon \widetilde{X} \to X$ is a local homeomorphism one can easily show that the point $y \in \widetilde{X}$ does not admit a chart of type (i) in the sense of page 171 if and only if $p(y) \in X$ does not admit such a chart. This implies that $\partial\widetilde{X} = p^{-1}(\partial X)$.

(2) (a) The transition maps of the atlas from (1) are precisely given by restrictions to open subsets of the transition maps of the atlas $\{\Phi_j\colon V_j \to W_j\}_{j\in J}$ for X. Thus if we start out with a smooth atlas for X, then the atlas we just constructed for $\widetilde{X}$ is also smooth.

We also know that a covering map is a local homeomorphism. It follows immediately from the definitions that with this smooth atlas for $\widetilde{X}$ these homeomorphisms are in fact diffeomorphisms.

(b) This statement follows easily from (a), together with Lemma 3.15. We leave it to the reader to fill in the details.

(3) The last statement follows easily from the fact that p is a local diffeomorphism. $\square$

8.2. **The orientation covering of a non-orientable manifold.** We saw that many of our examples of non-orientable manifolds admit a 2-fold covering such that the covering space is an orientable manifold.

(1) For example the projection map $p\colon S^2 \to \mathbb{R}\mathrm{P}^2 = S^2/\{\pm 1\}$ shows that the real projective plane is covered by the sphere.

(2) On page 260 we had considered the map

$$\begin{array}{rcl} p\colon \overbrace{\mathbb{R}\times[-1,1]/(x,y)\sim(x+1,y)}^{\text{annulus}} & \to & \overbrace{\mathbb{R}\times[-1,1]/(x,y)\sim(x+\frac{1}{2},1-y)}^{\text{Möbius band}} \\ [(x,y)] & \to & [(x,y)] \end{array}$$

and we remarked this is a 2-fold covering. Thus the non-orientable Möbius band admits a 2-fold covering such that the covering space is orientable.

(3) Almost the same map as in (2) also shows that the torus is a 2-fold covering of the Klein bottle.

Now we will see that any non-orientable manifold admits a unique 2-fold covering such that the covering space is orientable.

Proposition 8.3. *Let M be a connected non-orientable manifold. The following two statements hold:*

(1) *There exists a connected 2-fold covering $p\colon \widetilde{M} \to M$ such that $\widetilde{M}$ is orientable.*

(2) *If $p\colon \widetilde{M} \to M$ and $q\colon \widehat{M} \to M$ are two connected 2-fold coverings such that $\widetilde{M}$ and $\widehat{M}$ are orientable, then there exists a diffeomorphism $\Phi\colon \widetilde{M} \to \widehat{M}$ such that the following diagram commutes:*

$$\begin{tikzcd} \widetilde{M} \arrow[rr, "\Phi"] \arrow[dr, "p"'] & & \widehat{M} \arrow[dl, "q"] \\ & M. & \end{tikzcd}$$

Definition. Let M be a connected non-orientable manifold. We refer to the covering $p\colon \widetilde{M} \to M$ from Proposition 8.3 (1) as the *orientation covering of M*. By Proposition 8.3 (2) this covering is unique in an appropriate sense, which justifies speaking of *the* orientation covering.

Proof. We start out with a general construction. Let W be an n-dimensional manifold. We consider the set

$$\widetilde{W} \;=\; \{(Q,O) \mid Q\in W \text{ and } O \text{ is an orientation of } T_QW\}$$

together with the map

$$\begin{array}{rcl} p\colon \widetilde{W} & \to & W \\ (Q,O) & \mapsto & Q. \end{array}$$

Now we have to put a topology on $\widetilde{W}$. We use the following notation:

(1) We denote by $O_{\mathbb{R}^n}$ the standard orientation of $\mathbb{R}^n$.
(2) Given an orientation O for an n-dimensional vector space we denote by $-O$ the unique other orientation.
(3) Given an isomorphism $\varphi\colon V \to W$ between vector spaces and given an orientation O on W we denote by φ^*O the corresponding orientation on V.

Given a chart $\Phi\colon U \to V$ of W and $\epsilon \in \{-,+\}$ we define[191]

$$B_\epsilon(\Phi) \ := \ \{(Q, \epsilon \cdot \Phi^* O_{\mathbb{R}^n}) \mid Q \in U\} \ \subset \ \widetilde{W}.$$

It is straightforward to show that the collection of these sets $B_\pm(\Phi)$ satisfies the basis properties (B1) and (B2) from page 60.[192] Now we endow $\widetilde{W}$ with the topology generated by the sets $B_\pm(\Phi)$. We leave it as an exercise to show that $p\colon \widetilde{W} \to W$ is continuous. Next we show that p is a 2-fold covering. So let $Q \in W$. We pick a connected chart[193] $\Phi\colon U \to V$ around Q. Then $p^{-1}(U) = B_-(\Phi) \cup B_+(\Phi)$. It follows from Lemma 3.37 (1) applied to the connected manifold U that $B_-(\Phi)$ and $B_+(\Phi)$ are disjoint. Furthermore it is straightforward to see that the two projections maps $p\colon B_\pm(\Phi) \to U$ are homeomorphisms. This shows that U is uniformly covered by two sets, i.e. p is a 2-fold covering.

In the proof of Proposition 8.1 we saw that a smooth atlas for $\widetilde{W}$ is given by all maps $B_\pm(\Phi) \xrightarrow{p} U \xrightarrow{\Phi} V$ for all connected charts $\Phi\colon U \to V$ of W. In particular $\widetilde{W}$ is again an n-dimensional manifold and with this atlas the projection map $p\colon \widetilde{W} \to W$ is a local diffeomorphism.

Now we show that $\widetilde{W}$ is orientable. So let $(Q,O) \in \widetilde{W}$. The map $p\colon \widetilde{W} \to W$ is a local diffeomorphism. Now we equip $T_{(Q,O)}\widetilde{W}$ with the orientation p^*O.[194] By Footnote 89 it suffices to consider the continuity of the orientation with respect to the above atlas. So let $\Phi\colon U \to V$ be a connected chart of W. Let $\epsilon \in \{-,+\}$ and denote by $\Phi_\epsilon\colon B_\pm(\Phi) \to V$ the corresponding chart of $\widetilde{W}$. But then by construction we know that Φ_ϵ is orientation-preserving for all points if $\epsilon = +$ and it is orientation-reversing for all points if $\epsilon = -$.

We conclude this discussion of $\widetilde{W}$ with the following claim.

Claim. Suppose W is connected. Then $\widetilde{W}$ is connected if and only if W is non-orientable.

---

[191] Strictly speaking we should write $(d_P\Phi)^*O_{\mathbb{R}^n}$ instead of just $\Phi^*O_{\mathbb{R}^n}$.

[192] OK, so why does it satisfy (B2)?

[193] Here we say a chart $\Phi\colon U \to V$ is connected if U is connected.

[194] Put differently, using p we can identify $T_{(Q,O)}\widetilde{W}$ with T_QW and we equip it with the orientation at hand, namely O.

If W is orientable, then it is straightforward to see that $\widetilde{W}$ consists of two disjoint components each of which is diffeomorphic to W. Now suppose that W is non-orientable. We need to show that $\widetilde{W}_{,}$ is connected. If it was not connected, then it would consist of at least two components $\{\widetilde{W}_{,i}\}_{i\in I}$. Since $W_{,}$ is connected the restriction of each $p\colon \widetilde{W}_{,} \to W_{,}$ to $p_i\colon \widetilde{W}_{,i} \to W_{,}$ would also be a covering. Clearly $2 = [\widetilde{W}_{,} : W_{,}] = \sum_{i\in I}[\widetilde{W}_{,i} : W_{,}]$. It follows that $\#I = 2$ and that each $p_i\colon \widetilde{W}_{,i} \to W_{,}$ is a covering of degree one, i.e. each p_i is a homeomorphism. Since p_i is a local diffeomorphism it follows that $p_i\colon \widetilde{W}_{,i} \to W_{,}$ is in fact a diffeomorphism. But that is not possible since $W_{,}$ was assumed to be non-orientable whereas $\widetilde{W}_{,i}$ is orientable. This concludes the proof of the claim.

Finally we turn to the actual proof of the proposition. Thus let M be a connected non-orientable manifold.

(1) It follows from the above discussion and the above claim that $\widetilde{M}$ is a oriented connected manifold and that $p_M\colon \widetilde{M} \to M$ is a 2-fold covering.
(2) Suppose that $q\colon N \to M$ is also a connected 2-fold covering such that N is orientable. It follows easily from the construction of $\widetilde{M}$ and $\widetilde{N}$ and the fact that q is a local diffeomorphism that there exists a 2-fold covering $\widetilde{q}\colon \widetilde{N} \to \widetilde{M}$ which makes the following diagram commute

$$\begin{tikzcd} \widetilde{N} \arrow[r, "\widetilde{q}"] \arrow[d, "p_N"'] & \widetilde{M} \arrow[d, "p_M"] \\ N \arrow[r, "q"] & M. \end{tikzcd}$$

From the above claim and the fact that N is oriented connected we obtain that $\widetilde{N}$ consists of two components $\widetilde{N}_1$ and $\widetilde{N}_2$. The restriction of p_N to $\widetilde{N}_1$ and the restriction of $\widetilde{q}$ to $\widetilde{N}_1$ are 1-fold coverings, hence diffeomorphisms. It is clear that $\widetilde{q} \circ (p_N|_{\widetilde{N}_1})^{-1}\colon N \to \widetilde{M}$ has the desired properties. □

Corollary 8.4.

(1) *If M is a connected non-orientable manifold, then there exists an epimorphism $\pi_1(M) \to \mathbb{Z}_2$.*
(2) *Any simply connected manifold is orientable.*

Proof. The second statement of the corollary is an immediate consequence of the first statement. Thus it suffices to prove the first statement.

Let M be a connected non-orientable manifold. By Proposition 8.3 there exists a connected 2-fold covering $p\colon \widetilde{M} \to M$ such that $\widetilde{M}$ is orientable. It follows from Lemma 7.16 that $p_*(\pi_1(\widetilde{M}))$ is an index 2 subgroup of $\pi_1(M)$. In Exercise 8.1 we will show that every index 2 subgroup of a group π is normal. In particular $p_*(\pi_1(\widetilde{M}))$ is a normal index 2

subgroup of $\pi_1(M)$. Thus we obtain an epimorphism $\pi_1(M) \to \Gamma := \pi_1(M)/p_*(\pi_1(\widetilde{M}))$. The group Γ has two elements, but any group with two elements is isomorphic to $\mathbb{Z}_2$. Thus we found the desired epimorphism $\pi_1(M) \to \mathbb{Z}_2$. $\square$

Remark. A similar proof of Proposition 8.3 (1) with slightly more detail is also given in [Le4, Chapter 8.7].

We conclude this section with a discussion of orientation-preserving and reversing loops.

Definition. Let M be a connected non-orientable manifold, let $x_0 \in M$ be a point and let $\gamma\colon [0,1] \to M$ be a loop in x_0. We denote by $p\colon \widetilde{M} \to M$ the orientation covering provided by Proposition 8.3. We pick $\widetilde{x}_0 \in p^{-1}(x_0)$ and we denote by $\widetilde{g}\colon [0,1] \to \widetilde{M}$ the unique lift of γ, provided by Proposition 7.12, to the starting point x_0. We say γ is *orientation-preserving* if $\widetilde{\gamma}(1) = \widetilde{\gamma}(0)$, otherwise we say that γ is *orientation-reversing*.[195]

Example. Let M be the Möbius band and let $\widetilde{M}$ be the annulus. As on page 260 we consider the 2-fold covering $p\colon \widetilde{M} \to M$ which is just an incarnation of the orientation covering. We pick a point in M and we denote by γ a loop that goes "once around M" The lift of γ is not a loop, hence γ is orientation-reversing. We refer to Figure 166 for an illustration.

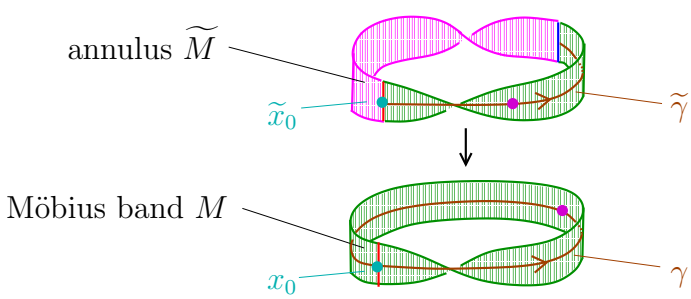

FIGURE 166.

We conclude this chapter with the following lemma which gives an alternative proof to Corollary 8.4 (1).

Lemma 8.5. *Let M be a connected non-orientable manifold and let $x_0 \in M$ be a point. The map*

$$\begin{array}{rcl} \Phi\colon \pi_1(M, x_0) & \to & \{\pm 1\} \\ [\gamma\colon [0,1] \to M] & \mapsto & \begin{cases} 1, & \text{if } \gamma \text{ is orientation-preserving,} \\ -1, & \text{if } \gamma \text{ is orientation-reversing} \end{cases} \end{array}$$

is well-defined and it is an epimorphism.

Proof. We denote by $p\colon \widetilde{M} \to M$ the orientation covering. The following three easy observations imply the lemma.

[195] It follows easily from Lemma 7.5 that this definition does not depend on the choice of $\widetilde{x}_0$.

(1) It follows immediately from Corollary 7.14 that Φ is well-defined.
(2) Using Lemma 7.5 one easily verifies that Φ is a homomorphism.
(3) We denote by $\widetilde{x}_0'$ the other point in $p^{-1}(x_0)$. By Proposition 8.3 there exists a path $\delta\colon [0,1] \to \widetilde{M}$ from $\widetilde{x}_0$ to $\widetilde{x}_0'$. It follows basically immediately from the definitions that $\Phi([p \circ \delta]) = -1$. This shows that Φ is an epimorphism. $\square$

Exercises for Chapter 8.

Exercise 8.1. Let π be a group. Show that every index 2 subgroup of π is normal.

9. Homotopy equivalent topological spaces

In this chapter we will see that "homotopy equivalent" topological spaces have isomorphic fundamental groups. In some instances this fact will allow us to reduce the calculation of fundamental groups to some of our earlier calculations.

The definition of being "homotopy equivalent" is slightly subtle and rests on the notion of two maps being homotopic.

9.1. **Homotopic maps.** In its most basic form a homotopy is a continuous deformation of maps between two topological spaces. To make this notion precise it is convenient to introduce the following notation.

Definition. Let X and Y be two topological spaces and let $a < b$ be two real numbers. Given a map $F\colon X \times [a,b] \to Y$[196] and given $t \in [a,b]$ we sometimes denote by F_t the map[197]

$$\begin{array}{rcl} F_t\colon X & \to & Y \\ x & \mapsto & F(x,t). \end{array}$$

Now we move on to the actual definition we are interested in.

Definition. Let X and Y be two topological spaces.

(1) A *homotopy from X to Y* is a map $F\colon X \times [0,1] \to Y$.
(2) Let $f_0, f_1\colon X \to Y$ be two maps. A *homotopy between the maps f_0 and f_1* is a homotopy $F\colon X \times [0,1] \to Y$ with $F_0 = f_0$ and $F_1 = f_1$. If there exists a homotopy between the maps f_0 and f_1, then we say that f_0 and f_1 are *homotopic* and sometimes we write $f_0 \simeq f_1$.

Examples.

(1) Let $X \subset \mathbb{R}^n$ be a star-shaped subset. Recall that this means that there exists an $x_0 \in X$ such that for all $x \in X$ the segment $\{x_0 \cdot (1-t) + x \cdot t \,|\, t \in [0,1]\}$ lies in X. For example all balls and also all of $\mathbb{R}^n$ are star-shaped. We consider the maps

$$\begin{array}{rcl} f_0\colon X & \to & X \\ x & \mapsto & x_0 \end{array} \quad \text{and} \quad \begin{array}{rcl} f_1 = \mathrm{id}\colon X & \to & X \\ x & \mapsto & x. \end{array}$$

Put differently, f_0 is the constant map which sends every point to the point x_0 and f_1 is the identity. Then

$$\begin{array}{rcl} F\colon X \times [0,1] & \to & X \\ (x,t) & \mapsto & \underbrace{x_0 \cdot (1-t) + x \cdot t}_{\in X \text{ since } X \text{ is star-shaped}} \end{array}$$

is a homotopy between f_0 and f_1.

[196] Recall that all maps between topological spaces are understood to be continuous.
[197] Note that the map F_t is indeed continuous.

(2) In Figure 167 we show four maps α, β, γ and δ from the circle S^1 to the annulus $X = B_2(0) \setminus B_1(0)$. The maps α and β are homotopic, whereas the maps γ and δ look as if they are not homotopic.

the maps α and β are homotopic the maps γ and δ appear not to be homotopic

FIGURE 167.

Remark. Let $\gamma_0, \gamma_1 \colon [a,b] \to Y$ be two maps from an interval to a topological space Y. We just said that the two maps are homotopic if there exists a map $\Gamma \colon [a,b] \times [0,1] \to Y$ such that

(i) $$\Gamma(t,0) = \gamma_0(t) \quad \text{and} \quad \Gamma(t,1) = \gamma_1(t) \quad \text{for all } t \in [a,b].$$

We can also view these two maps as paths. If they have the same same starting point $\gamma_0(a) = \gamma_1(a) =: P$ and the same endpoint $\gamma_0(b) = \gamma_1(b) =: Q$, then we said on page 223 that the paths are path-homotopic if there exists a map $\Gamma \colon [a,b] \times [0,1] \to Y$ that satisfies (i) and that satisfies also

(ii) $$\Gamma(a,s) = P \quad \text{and} \quad \Gamma(b,s) = Q \quad \text{for all } s \in [0,1].$$

In the literature sometimes "path-homotopic" is also called "homotopic". To distinguish the two notions of homotopies what we call "homotopic" is sometimes called "freely homotopic". Clearly two path-homotopic paths are also homotopic. But in general the converse does not hold. For example, consider the two paths

$$\begin{array}{rcl} \alpha \colon [0,1] & \to & Y = \mathbb{C} \setminus \{0\} \\ x & \mapsto & e^{2\pi i x} \end{array} \quad \text{and} \quad \begin{array}{rcl} \beta \colon [0,1] & \to & Y = \mathbb{C} \setminus \{0\} \\ x & \mapsto & 1. \end{array}$$

Here α goes counterclockwise once around the origin and β is the constant path. We saw in Corollary 4.2 that α and β are not path-homotopic. On the other hand they are homotopic. Indeed a homotopy is given by

$$\begin{array}{rcl} F \colon [0,1] \times [0,1] & \to & Y = \mathbb{C} \setminus \{0\} \\ (x,t) & \mapsto & e^{2\pi i x(1-t)}. \end{array}$$

This free is illustrated in Figure 168.

The difference between a path-homotopy and a homotopy of paths is that in the former context we want to "keep the endpoints fixed". Sometimes when we study other maps between topological spaces we also might want to keep a suitable subset fixed under a homotopy. This leads us to the following definition.

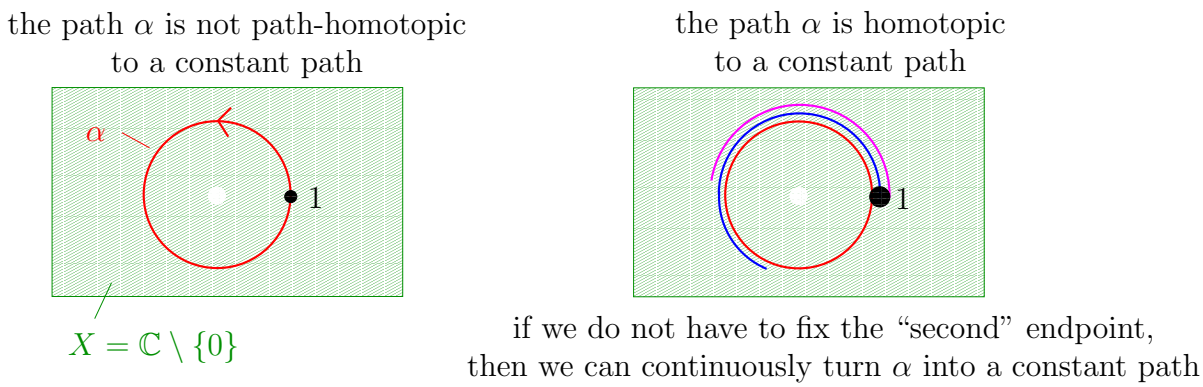

FIGURE 168.

Definition. Let X and Y be topological spaces and let $A \subset X$ be a subset.

(1) We say a map $F\colon X \times [0,1] \to Y$ is a *homotopy rel* A if for all $x \in A$ and $s, t \in [0,1]$ we have $F(x,s) = F(x,t)$.
(2) We say that two maps $f, g\colon X \to Y$ with $f|_A = g|_A$ are *homotopic rel* A if there exists a homotopy F rel A with $F_0 = f$ and $F_1 = g$.

Examples.

(1) By definition two paths $\alpha, \beta\colon [0,1] \to X$ in a topological space X are path-homotopic if and only if the two maps are homotopic rel $\{0,1\}$.
(2) We consider the two maps $f, g\colon \overline{B}^2 \to S^2$ that are shown in Figure 169. These maps agree on S^1. It is fairly easy to see that the two maps are homotopic but it seems rather unlikely that they are homotopic rel S^1. Unfortunately right now we lack the tools for showing the latter statement.

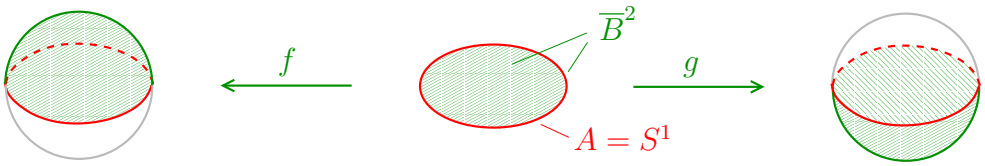

FIGURE 169.

We continue with the next variation on the notion of homotopy.

Definition. Let X and Y be two topological spaces.

(1) An *isotopy from* X *to* Y is a homotopy $F\colon X \times [0,1] \to Y$ such that for each $t \in [0,1]$ the map $F_t\colon X \to Y$ is a homeomorphism onto its image.

(2) Let $f_0, f_1 \colon X \to Y$ be two maps that are homeomorphisms onto their images. We say f_0 and f_1 are *isotopic* if there exists an isotopy $F \colon X \times [0,1] \to Y$ with $F_0 = f_0$ and $F_1 = f_1$.

Examples.

(1) In Figure 170 we show two maps $f_0, f_1 \colon [0,1] \to \mathbb{R}^2$ that are homeomorphisms onto their image. We also indicate two homotopies F and G between f_0 and f_1. The map F is an isotopy, the map G is not.

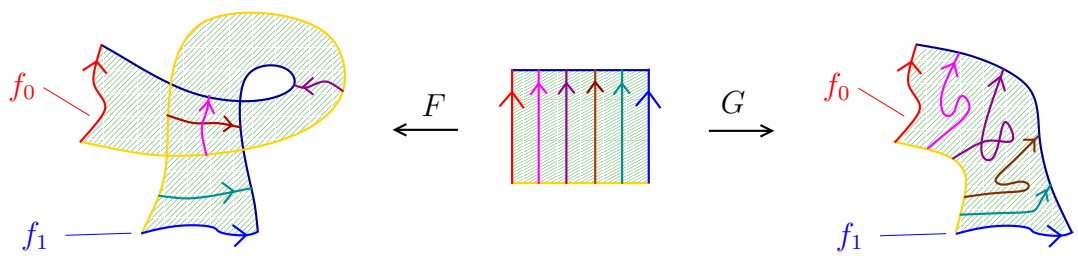

FIGURE 170.

(2) Let $n \in \mathbb{N}$. Let $f \colon \overline{B}^n \to \overline{B}^n$ be a homeomorphism. If $f|_{S^{n-1}} = \mathrm{id}_{S^{n-1}}$, then f is isotopic to $\mathrm{id}_{\overline{B}^n}$. Indeed, in Exercise 9.1 we will see that the map

$$\begin{array}{rcl} H \colon \overline{B}^n \times [0,1] & \to & \overline{B}^n \\ (x,t) & \mapsto & \begin{cases} t \cdot f(\frac{x}{t}), & \text{if } 0 \le \|x\| < t, \\ x, & \text{otherwise} \end{cases} \end{array}$$

is continuous and that each H_t is a homeomorphism. It is clear that $H_0 = \mathrm{id}$ and $H_1 = f$. Thus we see that H is the desired isotopy. The fact that f is isotopic to $\mathrm{id}_{\overline{B}^n}$ is often referred to as *Alexander's trick*.[198] The definition of the homotopy H is illustrated in Figure 171.

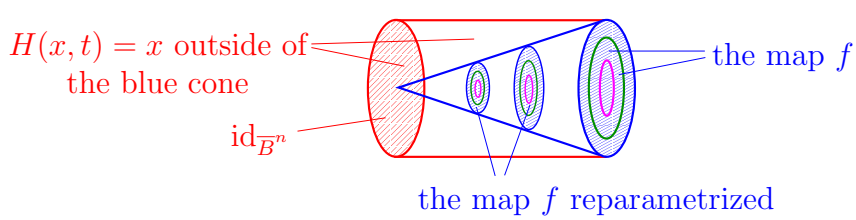

FIGURE 171.

Now we can formulate the following lemma that is a refined version of Proposition 1.47 (2).

[198]The existence of such a homotopy was first observed by a James Alexander in 1923, see [Al].

Lemma 9.1. $(*)$ *Let A be a bounded closed convex subset of $\mathbb{R}^n$ with non-empty interior. Let Q be a point in the interior of A. There exists a canonical isotopy $F\colon A \times [0,1] \to \mathbb{R}^n$ with the following three properties:*

(1) *we have $F_0 = \mathrm{id}_A$,*
(2) *the map F_1 is a homeomorphism from A to $\overline{B}^n$ and this map restricts to a homeomorphism $\partial A \to S^{n-1}$,*
(3) *for any $t \in [0,1]$ we have $F(Q,t) = (1-t) \cdot Q$.*[199]

Proof $(*)$. First consider the case that Q is the origin. In the following we use the notation that we introduced in the proof of Proposition 1.48 (2). Similar to the discussion on page 81 we consider the map

$$\begin{array}{rcl} F\colon A \times [0,1] & \to & \overline{B}^n \\ (x,t) & \mapsto & \begin{cases} x \cdot \frac{1}{(1-t)+t\cdot\rho(x)}, & \text{if } x \neq 0, \\ 0, & \text{if } x = 0. \end{cases} \end{array}$$

It is straightforward to verify that this map has all the desired properties.

We leave it as an exercise to modify the above proof to deal with the case that Q is not the origin. □

Sometimes it is useful to combine two homotopies or isotopies. This leads us to the following definition.

Lemma 9.2. $(*)$ *Let X and Y be topological spaces and let $A \subset X$ be a (possibly empty) subset of X. Let $G, H\colon X \times [0,1] \to Y$ be two homotopies rel A. If $G_1 = H_0$, then the map*

$$\begin{array}{rcl} G * H\colon X \times [0,1] & \to & Y \\ (P,t) & \mapsto & \begin{cases} G(P,2t), & \text{if } t \in [0,\frac{1}{2}], \\ H(P,2t-1), & \text{if } t \in [\frac{1}{2},1]. \end{cases} \end{array}$$

is a homotopy rel A from G_0 to H_1. Furthermore, if G and H are isotopies, then $G * H$ is also an isotopy. We refer to $G * H$ as the combination of G and H.

Proof $(*)$. We only need to verify that $G*H$ is indeed continuous, but that is a consequence of Lemma 5.3 together with our hypothesis that $G_1 = H_0$. □

In Proposition 5.2 we showed that being path-homotopic is an equivalence relation on the set of paths between two points. The first part of the following lemma is the obvious generalization to "homotopy of maps".

Lemma 9.3.

(1) *Let X be and Y topological spaces and let A be a (possibly empty) subset of X. Then "homotopy rel A of maps" forms an equivalence relation on the set of maps from X to Y.*

[199] In particular, if Q is already the origin, then F is a homotopy rel the origin.

(2) *Let $f, g\colon X \to Y$, let $\alpha\colon W \to X$ and $\beta\colon Y \to Z$ be maps between topological spaces. The following conclusion holds:*

$$f \simeq g \quad \Longrightarrow \quad f \circ \alpha \sim g \circ \alpha \quad \text{and} \quad \beta \circ f \sim \beta \circ g.$$

Proof.

(1) Not surprisingly the proof of Lemma 9.3 is basically identical to the earlier proof of Proposition 5.2. The only change is that we need to use Lemma 9.2 to show that the combination of two homotopies is indeed a homotopy, i.e. continuous.

(2) This statement is basically obvious, we just need to precompose and postcompose a homotopy H between f and g by α respectively β. □

Definition. Given two topological spaces X and Y and a map $f\colon X \to Y$ we denote by $[f]$ the equivalence class of f. Furthermore we denote by $[X, Y]$ the set of homotopy equivalence classes of maps from X to Y.

Example. We write $I = [0, 1]$. A slight generalization of the argument on page 299 shows that for any path-connected topological space X the set $[I, X]$ consists of a single element, i.e. all maps $I = [0, 1] \to X$ are freely homotopic. In Exercise 9.7 we generalize this statement to show that if A is a convex subset of $\mathbb{R}^n$ and if X is a path-connected topological space, then any two maps $f, g\colon A \to X$ are homotopic.

We continue with a rather classical type of an example.

Definition. Let $n \in \mathbb{N}$ and let $V \subset \mathbb{R}^n$ be a hyperplane, i.e. V is a subvector space of codimension one. We pick a vector v of unit length orthogonal to V. We refer to the map

$$\begin{array}{rcl} \rho_V\colon \mathbb{R}^n & \to & \mathbb{R}^n \\ w & \mapsto & w - 2 \cdot \langle v, w \rangle \cdot v \end{array}$$

as the *reflection in the hyperplane* V. We refer to Figure 172 for an illustration.

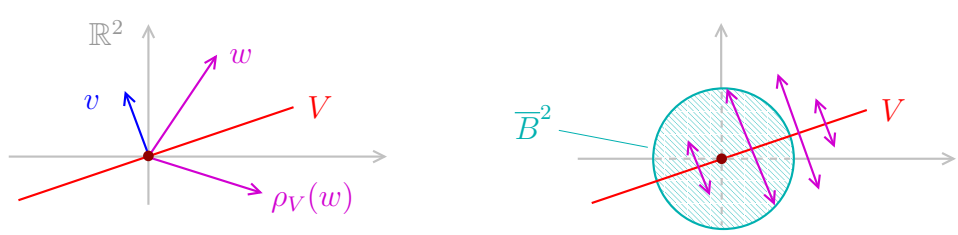

FIGURE 172.

Lemma 9.4. *Let $n \in \mathbb{N}$.*

(1) *Any reflection in a hyperplane of $\mathbb{R}^n$ has the following properties:*
   (a) *it is a diffeomorphism,*
   (b) *it is an isometry (i.e. it preserves the Euclidean distance) and preserves the origin,*

(c) *it restricts to diffeomorphisms of* $\overline{B}^n$ *and* S^{n-1}.

(2) *Any two reflections in hyperplanes are related by an isotopy* $F\colon \mathbb{R}^n \times [0,1] \to \mathbb{R}^n$ *such that each* F_t *is also a reflection. In particular the isotopies are isotopies rel the origin.*

Proof. Let $n \in \mathbb{N}$.

(1) Let ρ be a reflection in a hyperplane of $\mathbb{R}^n$. Clearly ρ is smooth and it satisfies $\rho \circ \rho = \mathrm{id}_{\mathbb{R}^n}$. This implies immediately that ρ is a diffeomorphism. A short amusing calculation shows that ρ preserves the scalar product, hence length. Since $\rho(0) = 0$ we see that ρ restricts to diffeomorphisms of $\overline{B}^n$ and S^{n-1}.

(2) Suppose we are given two hyperplanes V and W of $\mathbb{R}^n$. We pick an orthogonal matrix $A \in \mathrm{SO}(n)$ with $A \cdot V = W$.[200] By Lemma 1.96 (2) there exists a path $\gamma\colon [0,1] \to \mathrm{O}(n)$ with $\gamma(0) = \mathrm{id}$ and $\gamma(1) = A$. One can now easily verify that the map

$$\begin{array}{rcl} \mathbb{R}^n \times [0,1] & \to & \mathbb{R}^n \\ (P,t) & \mapsto & \rho_{\gamma(t)\cdot V}(P) \end{array}$$

is the desired isotopy. □

We conclude this section with the following lemma that we will prove in Exercise 9.8.

Lemma 9.5. *Let* X, Y *and* Z *be topological spaces. Let* $f, f'\colon X \to Y$ *and* $g, g'\colon Y \to Z$ *be maps.*

(1) *If* f *and* f' *are homotopic and if* g *and* g' *are homotopic, then the map* $g \circ f$ *is homotopic to* $g' \circ f'$.

(2) *If there exists a subset* A *of* X *such that* f *and* f' *are homotopic rel* A *and if there exists a subset* B *of* Y *such that* $f(A) = f'(A) \subset B$ *and such that* g *and* g' *are homotopic rel* B*, then* $g \circ f$ *is homotopic to* $g' \circ f'$ *rel* A.

Now we define the *homotopy category* $\mathcal{H}$ *of topological spaces* by

$$\begin{array}{rcl} \mathrm{Ob}(\mathcal{H}) & := & \text{all topological spaces}, \\ \mathrm{Mor}(X,Y) & := & [X,Y] \end{array}$$

with the composition[201]

$$\begin{array}{rcl} \mathrm{Mor}(X,Y) \times \mathrm{Mor}(Y,Z) & \to & \mathrm{Mor}(X,Z) \\ ([f],[g]) & \mapsto & [g \circ f]. \end{array}$$

Note that in this category the morphisms are not maps but they are equivalence classes of maps.

[200] Why does such a special orthogonal matrix A exist?

[201] The fact that this map is well-defined is a consequence of Lemma 9.5.

9.2. **Closed oriented curves and fundamental groups.** (∗) The following definition gets used frequently throughout the notes.

Definition. Let M be a manifold. A *closed* (*oriented*) *curve in* M is a closed (oriented) connected 1-dimensional submanifold either of ∂M or of M.

Convention. Often we just write "curve" instead of "closed curve".

Remark.

(1) Note that the boundary ∂M a manifold M is *not* a submanifold of M. In particular, if M is a 2-dimensional manifold and C is a closed boundary component, then C is not a submanifold of M, but it is a closed curve in M in the above sense.
(2) On occasions, when we deal with explicit examples, we will use gentle generalizations of the above notion of a closed oriented curve, which in practice should not cause any confusion.

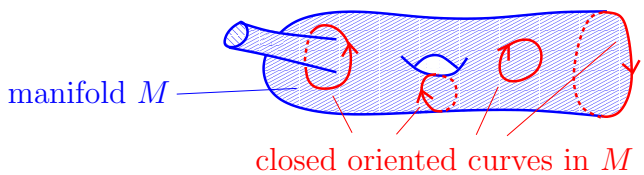

FIGURE 173.

Closed (oriented) curves in a given manifold M have the nice feature that they are easy to draw. But strictly speaking they do not represent elements in $\pi_1(M)$ since elements in $\pi_1(M)$ are represented by *maps* $S^1 \to M$ and not just the images of such maps. Thus we need to clarify the connection between curves and homotopy classes of maps.

The key to this issue is the following lemma, which is also of independent interest.

Lemma 9.6.

(1) *Let* $f\colon [0,1] \to [0,1]$ *be a self-homeomorphism.*[202]
   (a) *If* f *is monotonously increasing, then* f *is isotopic to the map* $f(x) = x$.
   (b) *If* f *is monotonously decreasing, then* f *is isotopic to the map* $f(x) = -x$.
(2) *Every self-homeomorphism of* S^1 *is isotopic to the map* $f(z) = z$ *or to the map* $g(z) = \overline{z}$.

Proof. We will provide the proof in Exercise 9.3. □

Corollary 9.7. *Let* M *be a manifold and let* $C \subset M$ *be a closed oriented curve in* M. *Furthermore let* $x_0 \in C$. *For any two orientation-preserving diffeomorphisms* $\alpha, \beta\colon S^1 \to C$ *with* $\alpha(1) = \beta(1) = x_0$ *we have* $[\alpha] = [\beta] \in \pi_1(M, x_0)$.

[202]It is an elementary real analysis exercise to show that every self-homeomorphism $f\colon [0,1] \to [0,1]$ is either monotonously increasing or monotonously decreasing.

Proof. It is fairly straightforward to prove the corollary using Lemmas 9.6 (1) and 5.4. We leave it as an exercise to the reader to fill in the details. □

Convention. Let M be a manifold and let $C \subset M$ be a closed oriented curve in M. Throughout these notes we use that Corollary 9.7 allows us to view C unambiguously as an element in $\pi_1(M, x_0)$ for any base point $x_0 \in C$.

9.3. **Homotopy equivalent topological spaces.** The following definition is one of the key definitions in topology. Unfortunately it usually takes some time to fully digest it.

Definition. Let X be and Y topological spaces.

(1) A map $f\colon X \to Y$ is a *homotopy equivalence between X and Y*, if f admits a *homotopy inverse*, i.e. a map $g\colon Y \to X$ with $g \circ f \simeq \mathrm{id}_X$ and $f \circ g \simeq \mathrm{id}_Y$.
(2) If there exists a homotopy equivalence between X and Y, then we say that X and Y are *homotopy equivalent*.
(3) We say X is *contractible*, if X is homotopy equivalent to a topological space which consists of precisely one point.

The name "homotopy equivalence" already suggests that this is an equivalence relation on the class of topological spaces. This is indeed the case.

Lemma 9.8.

(1) *If $f\colon X \to Y$ and $g\colon Y \to Z$ are homotopy equivalences, then $g \circ f\colon X \to Z$ is also a homotopy equivalence.*
(2) *The relation "homotopy equivalence" is an equivalence relation.*[203]
(3) *Let $f, g\colon X \to Y$ be two maps. If f is a homotopy equivalence and if g is homotopic to g, then g is also a homotopy equivalence.*

Proof $(*)$.

(1) Let $f\colon X \to Y$ and $g\colon Y \to Z$ are maps between topological spaces that admit homotopy inverses $f'\colon Y \to X$ and $g'\colon Z \to Y$. We have
$$(f' \circ g') \circ (g \circ f) \;=\; f' \circ (g' \circ g) \circ f \;\underset{\substack{\uparrow \\ \text{by Lemma 9.3 (2) since } g' \circ g \simeq \mathrm{id}_Y}}{\simeq}\; f' \circ \mathrm{id}_Y \circ f \;=\; f' \circ f \;\simeq\; \mathrm{id}_X\,.$$
(2) It is clear that the only property of an equivalence relation that requires any thought is transitivity. But this follows from (1).
(3) We leave the elementary verification of the last statement to the reader. □

[203]The perspicacious reader might notice that here things get logically a little dicey. More precisely, on page 96 we had recalled the notion of an equivalence relation. But we had only defined the notion of an "equivalence relation" on a set and "all topological spaces" do not form a set they "only" form a class. One can also define the notion of an "equivalence relation" on a class, see e.g. [FPr, Kapitel 2]. But we do not want to get into the discussion "what is a class?". As a cheap way out we interpret the second statement of the lemma as saying that reflexivity, symmetry and transitivity hold for "homotopy equivalence" with the obvious interpretation.

Now we will give a long list of examples of homotopy equivalent spaces.

Examples.

(1) Let X be a star-shaped subset of $\mathbb{R}^n$ and let $x_0 \in X$ be a point such that for any $x \in X$ the segment from x_0 to x lies in X. We consider the maps

$$\begin{array}{rcl} f\colon X & \to & \{x_0\} \\ x & \mapsto & x_0 \end{array} \quad \text{and} \quad \begin{array}{rcl} g\colon \{x_0\} & \to & X \\ x_0 & \mapsto & x_0. \end{array}$$

Then $f \circ g = \mathrm{id}_{\{x_0\}}$ and we had just seen on page 299 that $g \circ f \simeq \mathrm{id}_X$. Thus we showed that any star-shaped subspace of $\mathbb{R}^n$, e.g. any convex subset of $\mathbb{R}^n$ or $\mathbb{R}^n$ itself, is homotopy equivalent to a point, i.e. it is contractible.

(2) It follows from the previous example together with Lemma 9.8 that for any $n \in \mathbb{N}$ and any $k \in \mathbb{N}$ the topological spaces $\mathbb{R}^n$ and $\mathbb{R}^k$ are homotopy equivalent.

(3) We consider the Möbius band

$$X = [0,1] \times [-1,1] \ / \ (0,y) \sim (1,-y)$$

and the circle

$$Y = [0,1] \ / \ 0 \sim 1.$$

We consider the maps

$$\begin{array}{rcl} f\colon X & \to & Y \\ [(x,y)] & \mapsto & [x] \end{array} \quad \text{and} \quad \begin{array}{rcl} g\colon Y & \to & X \\ [x] & \mapsto & [(x,0)]. \end{array}$$

Then $f \circ g = \mathrm{id}_Y$ and furthermore we have $g \circ f \simeq \mathrm{id}_X$ as can be seen using the following homotopy

$$\begin{array}{rcl} F\colon X \times [0,1] & \to & X \\ ([(x,y)],t) & \mapsto & [(x, y \cdot (1-t))]. \end{array}$$

The Möbius band is thus homotopy equivalent to the circle.

We leave the proof of the following lemma as an edifying exercise to the reader, see Exercise 9.11.

Lemma 9.9. *Let $f\colon X \to Y$ be a map between topological spaces. If f is a homotopy equivalence, then f induces a bijection $\pi_0(X) \to \pi_0(Y)$. In particular, X is path-connected if and only if Y is path-connected.*

Definition. Let X be a topological space and let A be a subset.

(1) A *deformation retraction* from X to A is a map $F\colon X \times [0,1] \to X$ with the following properties:
   (a) for every $x \in X$ we have $F(x,0) = x$ and $F(x,1) \in A$,
   (b) for every $a \in A$ we have $F(a,t) = a$ for all $t \in [0,1]$.
   Put differently, a deformation retraction is a homotopy $F\colon X \times [0,1] \to X$ rel A such that $F_0 = \mathrm{id}$ and $F_1(X) \subset A$.[204]

[204]Note that $F_1\colon X \to A$ is retraction from X to A.

(2) We say A is a deformation retract of X if there exists a deformation retraction from X to A.[205]
(3) We say a retraction $r\colon X \to A$ is *realized by a deformation retraction* if there exists a deformation retraction F from X to A with $F_1 = r$.

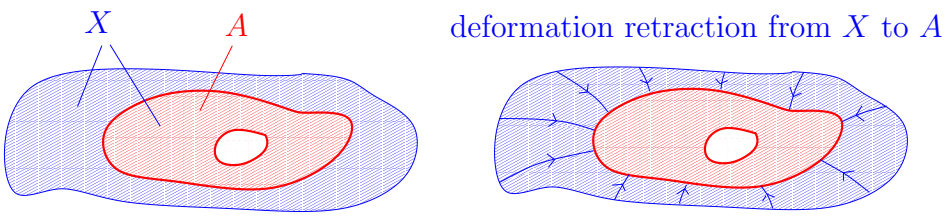

FIGURE 174. Schematic picture of a deformation retraction.

Examples.
(1) For any topological space X and any interval $I \subset \mathbb{R}$ containing 0 the subspace $X \times \{0\}$ is a deformation retract of $X \times I$. In fact the deformation retraction is given by
$$\begin{array}{rcl} (X \times I) \times [0,1] & \to & X \times I \\ ((x,s),t) & \mapsto & (x, s \cdot (1-t)). \end{array}$$
(2) In Exercise 9.12 we will see that for any $n \in \mathbb{N}$ the sphere S^{n-1} is a deformation retract of $\mathbb{R}^n \setminus \{0\}$.
(3) It follows easily from the previous examples that the central circle $[0,1] \times \{0\}$ of the Möbius band is a deformation retract of the Möbius band $[0,1] \times [-1,1]/\sim$.

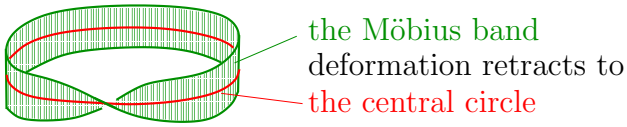

FIGURE 175.

In Exercise 9.13 we will prove the following elementary lemma.

[205]Unfortunately in the literature the term "deformation retract" is used differently by different authors. Our notion of a "deformation retract" agrees with the definition in [Hat, p. 2] and [Mun, p. 208]. What we call a "deformation retract" is called a "strong deformation retract" in [Bre, p. 45] and [Rot, p. 209]. In these books this notion is used to distinguish it from the notation of a "weak deformation retract", which means that there exists a map $F\colon X \times [0,1] \to X$ such that
(a) for every $x \in X$ we have $F(x,0) = x$ and $F(x,1) \in A$,
(b) for every $a \in A$ we have $F(a,1) = a$.
As always it is fun to find examples of pairs (X, A) of topological spaces such that A is a weak deformation retract but not a strong deformation retract of X.

Lemma 9.10. *Let A be a subset of a topological space X which admits a deformation retraction F from X to A. Then the inclusion map*

$$\begin{array}{ccc} A & \to & X \\ a & \mapsto & a \end{array} \quad \text{and the map} \quad \begin{array}{ccc} X & \to & A \\ x & \mapsto & F(x,1) \end{array}$$

are both homotopy equivalences. In particular the deformation retract A is homotopy equivalent to the total space X.

The lemma often gives a convenient way for showing that two spaces are homotopy equivalent. For example the lemma, together with the previous example implies that the sphere S^{n-1} and $\mathbb{R}^n \setminus \{0\}$ are homotopy equivalent.

The notions of a topological space being contractible and admitting a deformation retraction to a point sound quite similar. The following lemma gives the precise relationship between these two notions.

Lemma 9.11.

(1) *If a topological space X admits a deformation retraction to a point $x_0 \in X$, then X is homotopy equivalent to $\{x_0\}$, in particular X is contractible.*
(2) *If a topological space X is contractible, then given any point $x_0 \in X$ there exists a homotopy $H\colon X \times [0,1] \to X$ such that $H_0 = \mathrm{id}_X$ and $H_1(x) = x_0$ for all $x_0 \in X$.*
(3) *The "infinite zigzag comb" shown in Figure 176 is contractible, but it does not admit a deformation retraction to a point.*

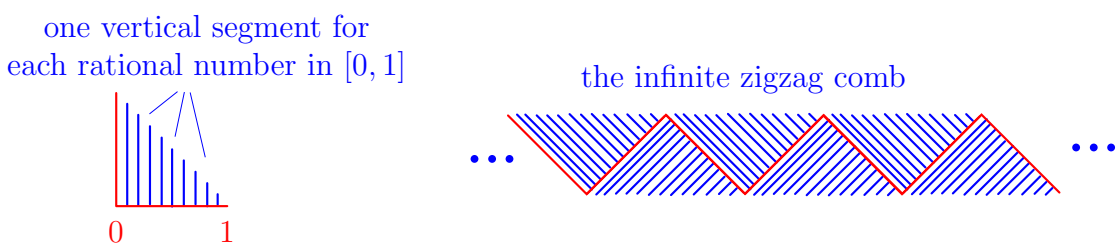

FIGURE 176.

Proof.

(1) This statement follows immediately from Lemma 9.10.
(2) Suppose X is a topological space that is contractible. This implies that there exists map $g\colon \{*\} \to X$ and a homotopy $G\colon X \times [0,1] \to X$ such that $H_0 = \mathrm{id}_X$ and such that $G_1(x) = g(*)$ for all $x \in X$. We set $x_1 = g(*)$. Note that we know from Lemma 9.9 that X is path-connected. Thus there exists a path $\gamma\colon [0,1] \to X$ from

x_1 to x_0. The desired homotopy is now given by the map[206]

$$\begin{array}{rcl} H\colon X\times[0,1] & \to & X \\ (x,t) & \mapsto & \begin{cases} G(x,2\cdot t), & \text{if } t\in[0,\frac{1}{2}], \\ \gamma(2\cdot t-1), & \text{if } t\in[\frac{1}{2},1]. \end{cases} \end{array}$$

(3) This statement will be proved in Exercise 9.6. □

9.4. **The fundamental groups of homotopy equivalent topological spaces.** Now we will see that homotopy equivalent topological spaces have isomorphic fundamental groups. On numerous occasions this fact will often greatly simplify the calculation of fundamental groups.

Proposition 9.12.

(1) *Let $f\colon X\to Y$ be a map between topological spaces which is a homotopy equivalence. Let $x_0\in X$ be a point. We put $y_0:=f(x_0)$. Then the induced map*

$$f_*\colon \pi_1(X,x_0) \;\to\; \pi_1(Y,y_0)$$

is an isomorphism.

(2) *If X is contractible topological space, then for any $x_0\in X$ we have $\pi_1(X,x_0)=0$.*

Example. It follows from Lemma 9.10, Proposition 9.12 (1), Corollary 7.19, Proposition 5.14 and the previous example that for any $n\geq 2$ and any $Q\in\mathbb{R}^n$ we have

$$\pi_1(\mathbb{R}^n\setminus\{Q\}) \;\cong\; \pi_1(\mathbb{R}^n\setminus\{0\}) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } n=2, \\ 0, & \text{if } n\geq 3. \end{cases}$$

Proof (∗). The second statement of the proposition is just a frequently used special case of the first statement. Thus let us prove the first statement. Let $f\colon X\to Y$ be a map between topological spaces which is a homotopy equivalence. Let $x_0\in X$ be a point. We put $y_0=f(x_0)$. We pick a homotopy inverse $g\colon Y\to X$ of f. We put $x_1=g(y_0)$. According to our hypothesis we have $\mathrm{id}_X\simeq g\circ f$, i.e. there exists a homotopy H between id_X and $g\circ f$.[207]

We denote by

$$\begin{array}{rcl} \alpha\colon [0,1] & \to & X \\ t & \mapsto & H(x_0,t) \end{array}$$

the path with which the homotopy H connects the points

$$H(x_0,0) \;=\; (\mathrm{id}_X)(x_0) \;=\; x_0 \quad\text{and}\quad H(x_0,1) \;=\; (g\circ f)(x_0) \;=\; x_1.$$

[206]This map is continuous by Lemma 1.32 (2).

[207]Can we already conclude from this fact that $g\circ f$ induces the identity map on fundamental groups? Unfortunately not, for example $g\circ f$ does not even induce a map on $\pi_1(X,x_0)$, since $g\circ f$ sends the base point x_0 to the point x_1, which in general is different from x_0.

Claim. The maps

$$\begin{array}{rcl} (g\circ f)_*\colon \pi_1(X,x_0) & \to & \pi_1(X,x_1) \\ [s] & \mapsto & [(g\circ f)\circ s] \end{array} \quad \text{and} \quad \begin{array}{rcl} \pi_1(X,x_0) & \to & \pi_1(X,x_1) \\ [s] & \mapsto & [\overline{\alpha}*s*\alpha] \end{array}$$

are identical.

Let $s\colon [0,1]\to X$ be a loop in (X,x_0). We want to show that the loops $(g\circ f)\circ s$ and $\overline{\alpha}*s*\alpha$ are path-homotopic. We consider the map[208]

$$\begin{array}{rcl} G\colon [0,1]\times[0,1] & \to & X \\ (r,t) & \mapsto & \begin{cases} \overline{\alpha}(4r), & \text{if } r\in\left[0,\frac{1}{4}t\right], \\ H\left(s\left(\dfrac{r-\frac{1}{4}t}{1-\frac{1}{2}t}\right),1-t\right), & \text{if } r\in(\frac{1}{4}t,1-\frac{1}{4}t), \\ \alpha(4r-3), & \text{if } r\in\left[1-\frac{1}{4}t,1\right]. \end{cases} \end{array}$$

Using Lemma 5.3 it is straightforward to verify that G is indeed a continuous map with

$$G(0,t) \;=\; G(1,t) \;=\; x_1 \quad \text{for all } t\in[0,1]$$

and which satisfies

$$G(r,0) \;=\; ((g\circ f)\circ s)(r) \quad \text{and} \quad G(r,1) \;=\; (\overline{\alpha}*s*\alpha)(r) \quad \text{for all } r\in[0,1].$$

This shows that G is in fact a path-homotopy between the loops $(g\circ f)\circ s$ and $\overline{\alpha}*s*\alpha$[209]

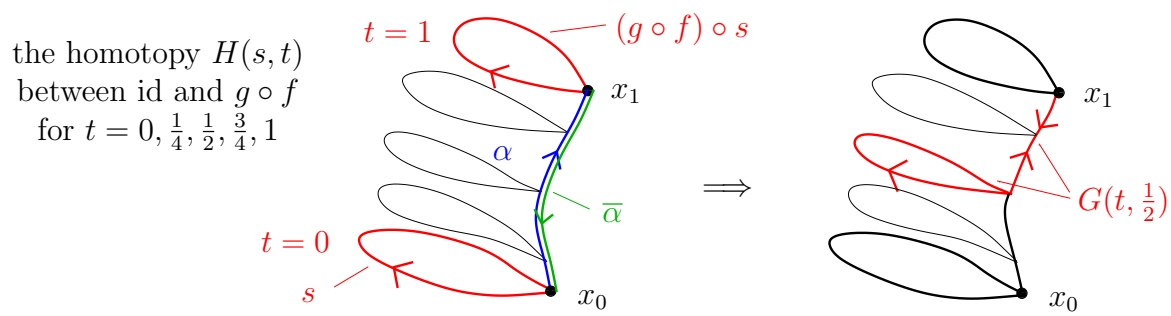

FIGURE 177. Schematic image of H and G.

in (X,x_1). Thus we have proved the claim.

[208]The map G is defined as follows: for $t\in[0,1]$ the loop $r\mapsto G(r,t)$ is given by traveling along $\overline{\alpha}$ from x_1 to $\overline{\alpha(t)}=\alpha(1-t)$, then one follows the loop given by $H(s(-),t)$, and then one returns along α back to x_1.

[209]To be precise, G is a homotopy between $(g\circ f)\circ s$ and a suitable parametrization of $\overline{\alpha}*s*\alpha$.

We consider the following diagram:

$$\begin{tikzcd}
\pi_1(X,x_0) \arrow[r, "{[s]\mapsto[\overline{\alpha}*s*\alpha]}"] \arrow[d, "f_*"] & \pi_1(X,x_1) \arrow[d, "f_*"] \\
\pi_1(Y,y_0) \arrow[r, "{[t]\mapsto[(f\circ\overline{\alpha})*t*(f\circ\alpha)]}"'] \arrow[ur, "g_*"] & \pi_1(Y,y_1).
\end{tikzcd}$$

We make the following observations:

(1) By the claim and Proposition 5.11 the map $g_* \circ f_* \colon \pi_1(X,x_0) \to \pi_1(X,x_1)$ is an isomorphism.
(2) This implies that the map $f_* \colon \pi_1(X,x_0) \to \pi_1(Y,y_0)$ is a monomorphism.
(3) If we replace the roles of f and g, then the argument of the claim and Proposition 5.11 shows that the map $f_* \circ g_* \colon \pi_1(Y,y_0) \to \pi_1(Y,y_1)$ is also an isomorphism.
(4) This implies that the map $f_* \colon \pi_1(X,x_1) \to \pi_1(Y,y_1)$ is an epimorphism.
(5) We consider the diagram

$$\begin{tikzcd}
\pi_1(X,x_0) \arrow[r, "{[s]\mapsto[\overline{\alpha}*s*\alpha]}", "\cong"'] \arrow[d, hook, "f_*"] & \pi_1(X,x_1) \arrow[d, two heads, "f_*"] \\
\pi_1(Y,y_0) \arrow[r, "\cong", "{[t]\mapsto[(f\circ\overline{\alpha})*t*(f\circ\alpha)]}"'] & \pi_1(Y,y_1).
\end{tikzcd}$$

The horizontal maps are isomorphisms by Proposition 5.11. It follows immediately from the definitions of the maps that the diagram commutes.
(6) Since the right vertical map is an epimorphism and since the horizontal maps are isomorphisms we now see that the left vertical map is also an epimorphism,
(7) The combination of (2) and (6) shows that the left vertical map is an isomorphism.

□

In Lemma 1.90 we already saw that the topological spaces $\mathbb{R}$ and $\mathbb{R}^2$ are not homeomorphic. Now we can prove a similar statement in one dimension higher.

Lemma 9.13. *The topological spaces $\mathbb{R}^2$ and $\mathbb{R}^3$ are not homeomorphic.*

Unfortunately we are still not able to settle the question whether for $k \neq l \geq 3$ the topological spaces $\mathbb{R}^k$ and $\mathbb{R}^l$ can be homeomorphic. Before we can settle this question we will have to develop a completely new set of tools.

Proof. Let us suppose that there exists a homeomorphism $f \colon \mathbb{R}^2 \to \mathbb{R}^3$. Let $P \in \mathbb{R}^2$ be a point. We put $Q := f(P)$. Then f restricts to a homeomorphism from $\mathbb{R}^2 \setminus \{P\}$ to $\mathbb{R}^3 \setminus \{Q\}$. But then we obtain that

$$\begin{array}{ccccccc}
\mathbb{Z} & \cong & \pi_1(\mathbb{R}^2 \setminus \{P\}) & \cong & \pi_1(\mathbb{R}^3 \setminus \{Q\}) & = & 0. \\
 & \uparrow & & \uparrow & & \uparrow & \\
 & \text{page 311} & & \text{since } f \text{ is a homeomorphism} & & \text{page 311} &
\end{array}$$

Thus we obtained a contradiction. □

9.5. **Homotopies on quotients and on gluings** (∗)**.** In this section we collect two slightly subtle lemmas which show that, under the right circumstances, homotopies descend to quotient spaces and that given a "gluing $X \cup_f Y$" we can also glue homotopies. This section is much less pleasant to read than the previous section and it is arguably best if the reader only takes a peak once the results are actually used.

Before we state the two technical lemmas, we point out that the proof of the lemmas eventually boils down to the rather subtle and delicate Theorem 2.15. One might view both lemmas "obvious", but they are not.

After this preamble, let us move to the first lemma which shows that homotopies descend to quotients.

Lemma 9.14. *Let X be a topological space. Furthermore let $A \subset B$ be two subsets of X. If $F\colon B \times [0,1] \to X$ is a homotopy with $F(A \times [0,1]) \subset A$, then the induced map*[210]

$$\begin{array}{rcl} \varphi\colon (B/A) \times [0,1] & \to & X/A \\ ([x],t) & \mapsto & [F(x,t)] \end{array}$$

is continuous.

Proof. We denote by $p\colon B \to B/A$ and $q\colon X \to X/A$ the obvious projection maps. We have the following commutative diagram

$$\begin{tikzcd} & B \times [0,1] \arrow[dl, "p\times \mathrm{id}_{[0,1]}"'] \arrow[dr, "q\circ F"] & \\ (B/A) \times [0,1] \arrow[rr, "\varphi", "{([x],t)\mapsto[F(x,t)]}"'] & & X/A. \end{tikzcd}$$

By Lemma 2.14 (1) the map p is a quotient map. Since $[0,1]$ is locally compact we obtain from Theorem 2.15 that $p \times \mathrm{id}_{[0,1]}$ is also a quotient map. Since $q \circ F$ is continuous we obtain from Lemma 2.16 (1) that φ is continuous. □

It is perhaps easier to appreciate the following useful corollary.

Corollary 9.15. *Let X be a topological space and let A be a subset of X. If A is a deformation retract of X, then the point A/A is a deformation retract of X/A. In particular X/A is contractible.*

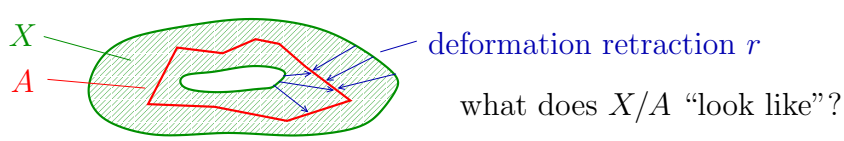

FIGURE 178. Illustration for Corollary 9.15.

[210]Since F is a homotopy rel A we see that the map is well-defined.

Proof. Let $r\colon X \times [0,1] \to X$ be a deformation retraction from X to A. Since r is deformation retraction we obtain from Lemma 9.14 that the map

$$\begin{array}{rcl} (X/A) \times [0,1] & \to & X/A \\ ([x],t) & \mapsto & [r(x,t)]. \end{array}$$

is well-defined and continuous. Now it is clear that this map is a deformation retraction from X/A to A/A. □

The second lemma shows that we can "glue homotopies".

Lemma 9.16. *Let X and Y be two topological spaces, let $A \subset X$ be a subset and let $f\colon A \to Y$ be a map. Finally let Z be another topological space. Suppose that we are given two homotopies $G\colon X \times [0,1] \to Z$ and $H\colon Y \times [0,1] \to Z$ such that for any $a \in A$ and any $t \in [0,1]$ we have $G(a,t) = H(f(a),t)$. Then the map*[211]

$$\begin{array}{rcl} F\colon (X \cup_f Y) \times [0,1] & \to & Z \\ ([P],t) & \mapsto & \begin{cases} G(P,t), & \text{if } P \in X, \\ H(P,t), & \text{if } P \in Y \end{cases} \end{array}$$

is well-defined and it is continuous.

Proof. One can easily verify that the given map F is well-defined. Recall that by Lemma 2.18 we know that the map

$$\begin{array}{rcl} \Psi\colon (X \times [0,1]) \cup_{f \times \mathrm{id}_{[0,1]}} (Y \times [0,1]) & \to & (X \cup_f Y) \times [0,1] \\ [(P,t)] & \mapsto & ([P],t) \end{array}$$

is a homeomorphism. Thus it suffices to show that the map

$$\begin{array}{rcl} F \circ \Psi\colon (X \times [0,1]) \cup_{f \times \mathrm{id}_{[0,1]}} (Y \times [0,1]) & \to & Z \\ [(P,t)] & \mapsto & \begin{cases} G(P,t), & \text{if } (P,t) \in X \times [0,1], \\ H(P,t), & \text{if } (P,t) \in Y \times [0,1] \end{cases} \end{array}$$

is continuous. But this is an immediate consequence of the hypothesis on G and H and Lemma 1.83 □

9.6. **The wedge of topological spaces.**

Definition. Let $\{X_i\}_{i \in I}$ be a family of topological spaces and suppose that for each $i \in I$ we are given a point $x_i \in X_i$.

(1) We refer to

$$\bigvee_{i \in I} X_i \ := \ \Big(\bigsqcup_{i \in I} X_i\Big)/\sim \quad \text{where } x_i \sim x_j \text{ for all } i,j \in I$$

as the *wedge of the X_i*. We refer to the point given by the identifications as the *wedge point*. If we do not say anything else it will be denoted by $*$.

[211] We refer to page 114 for the definition of $X \cup_f Y$.

(2) Let Y be a topological space and suppose that we are given a family of maps $\{f_i\colon X_i \to Z\}_{i\in I}$ such for every $i, j \in I$ we have $f_i(x_i) = f_j(x_j)$. We define the map

$$\begin{array}{rcl} \bigvee_{i\in I} f_i\colon \bigvee_{i\in I} X_i & \to & Z \\ [y] & \mapsto & f_i([y]) \text{ if } y \in X_i. \end{array}$$

It follows from Lemma 1.66 that this map is indeed continuous.

(3) If $i = \{i_1, \dots, i_k\}$ is a finite family, then often we just write $X_{i_1} \vee \cdots \vee X_{i_k}$ and similarly we just write $f_{i_1} \vee \cdots \vee f_{i_k}$.

Remark. The notation in the definition of the wedge of two topological spaces does not mention that the definition depends on the choice of the points $x_i \in X_i$. If we pick disconnected topological spaces X_i, then it is easy to see in examples that in general the homeomorphism type of the wedge $\bigvee_{i\in I} X_i$ depends on the choice of components from which we take the x_i.

But fortunately in many situations the homeomorphism type of the wedge does not depend on the choice of the x_i. For example, if the X_i are connected manifolds, then it follows from Proposition 10.23 that the homeomorphism type of the wedge does not depend on the choices of the x_i, as long as we pick these two points away from the boundary.

Examples.

(1) The wedge $A \vee B$ of two topological spaces A and B should be viewed as the result of gluing A and B along the points a and b. The wedge of two circles is shown in Figure 179.

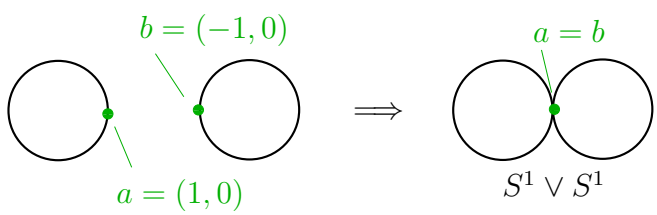

FIGURE 179. The wedge of two circles.

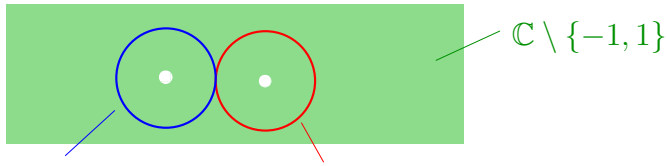
(2) If G is a connected spatial graph with one vertex and n edges, then it is straightforward to see that G is homeomorphic to the wedge of n circles.

(3) In Exercise 9.14 we will see that the wedge of two circles is homotopy equivalent to $\mathbb{C} \setminus \{\pm 1\}$. More precisely, we will show that

$$S^1 \vee S^1 \;=\; \underbrace{\{z \in \mathbb{C} \,|\, |z+1| = 1\} \cup \{z \in \mathbb{C} \,|\, |z-1| = 1\}}_{\text{two circles that meet at the origin}}$$

is a deformation retract of $\mathbb{C} \setminus \{\pm 1\}$.



$$\{z \in \mathbb{C} \,|\, |z+1| = 1\} \cup \{z \in \mathbb{C} \,|\, |z-1| = 1\} \;=\; S^1 \vee S^1$$

FIGURE 180.

Definition. Let $\{X_j\}_{j \in J}$ be a family of topological spaces and suppose that for each $j \in J$ we are given a point $x_j \in X_j$. Given $k \in I$ we refer to the maps

$$\begin{aligned} i_k \colon X_k &\to \bigvee_{j \in J} X_j \\ x &\mapsto [x] \end{aligned} \qquad \text{and} \qquad \begin{aligned} p_k \colon \bigvee_{j \in J} X_j &\to X_k \\ [x] &\mapsto \begin{cases} x, & \text{if } x \in X_k, \\ x_k, & \text{otherwise} \end{cases} \end{aligned}$$

as the *natural inclusion* respectively the *natural projection.*

Lemma 9.17. $(*)$ *Let $\{X_j\}_{j \in J}$ be a family of topological spaces and suppose that for each $j \in J$ we are given a point $x_j \in X_j$. Let $k \in K$.*

(1) *The natural inclusion i_k is a homeomorphism onto its image.*
(2) *A map $f \colon \bigvee_{j \in J} X_j \to Y$ to a topological space is continuous if and only if for each $k \in J$ the map $f \circ i_k \colon X_k \to Y$ is continuous.*
(3) *The natural projection p_k is continuous.*

Remark. In most cases Lemma 9.17 allows us to safely view each X_k as a subset of the wedge $\bigvee_{j \in J} X_j$.

Proof $(*)$.

(2) This statement follows easily from Lemma 1.49 and Lemma 1.66.
(3) This is an immediate consequence of (2).
(1) It follows easily from Lemma 1.49 and Lemma 1.65 (3) that the natural inclusion i_k is continuous. It is clear that the natural inclusion i_k is an injection. Evidently we have $p_k \circ i_k = \mathrm{id}_{X_k}$. Since the natural projection p_k is continuous we see that the natural inclusion i_k is indeed a homeomorphism onto its image. $\square$

We conclude this section with two technical lemmas which can safely be skipped at a first reading.

Lemma 9.18. $(*)$ *Let $\{(X_i, x_i)\}_{i \in I}$ be a family of pointed topological spaces and let (Z, z_0) be a pointed topological space. Let $\{f_i \colon (X_i, x_0) \to (Z, z_0)\}_{i \in I}$ and $\{g_i \colon (X_i, x_0) \to (Z, z_0)\}_{i \in I}$ be two families of maps. The following statement holds:*

for every $i \in I$ there exists a homotopy rel x_i from f_i to g_i $\iff$ *the maps $\bigvee_{i \in I} f_i$ and $\bigvee_{i \in I} g_i$ from $\bigvee_{i \in I} X_i$ to Z are homotopic rel the wedge point.*

Proof. The "$\Leftarrow$"-direction of the lemma follows immediately from Lemma 9.17 (1). If the index set I has two elements, then the "$\Rightarrow$"-direction lemma is a straightforward consequence of Lemma 9.16 which eventually reduces the problem to Lemma 2.17. For a general family the "$\Rightarrow$"-direction lemma can also be reduced easily to Lemma 2.17.

It is worth pointing out that the proof of the "$\Rightarrow$"-direction is not obvious. As we just pointed out, it all boils down to Lemma 2.17. This lemma in turn relies on the delicate, frequently overlooked, underappreciated Theorem 2.15. □

The following lemma gives in particular a nice little application of Lemma 9.18.

Lemma 9.19. $(*)$ *Let (A, a_0) and $(B, b_0$ be two pointed topological spaces. We form the wedge $A \vee B$ using the points a_0 and b_0. If $\{a_0\}$ is a deformation retract of A, then $B = \{a_0\} \vee B$ is a deformation retract of $A \vee B$.*

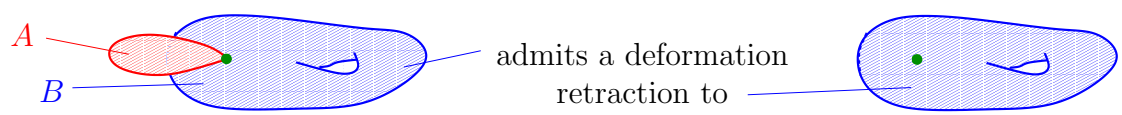


FIGURE 181. Illustration of Lemma 9.19.

Proof $(*)$. Let $F\colon A \times [0,1] \to A$ be a deformation retraction from A to $\{a_0\}$. Let G be the trivial homotopy on B. It follows again from Lemma 9.16 that we can combine the two homotopies to get the desired deformation retraction. □

9.7. **Spatial graphs.** In this section we have another look at graphs.

Definition. Let $G = (V, E)$ be a finite graph, i.e. a graph such that V and E are finite.[212]

(1) We refer to
$$\chi(G) \;=\; \#V \;-\; \#E \;=\; \text{number of vertices} \;-\; \text{number of edges}$$
as the *Euler characteristic of* G.

(2) A *tree* is a finite connected graph with Euler characteristic 1.

(3) Given a vertex v and an edge e we write
$$f(v,e) \;:=\; \begin{cases} 0, & \text{if no endpoint of } e \text{ equals } v, \\ 1, & \text{if } e \text{ has two endpoints, one of which equals } v, \\ 2, & \text{if } e \text{ has one endpoint and this one endpoint equals } v. \end{cases}$$

(4) The *valence of a vertex* v is defined as
$$\text{valence}(v) \;:=\; \sum_{\text{edge } e} f(v,e).$$

In a slightly less formal way, the valence of a vertex v is the number of edges at v, but hereby we have to count any loop at v twice, since it "goes twice into v".

[212]Note that the subsequent definition makes sense for abstract graphs and for spatial graphs.

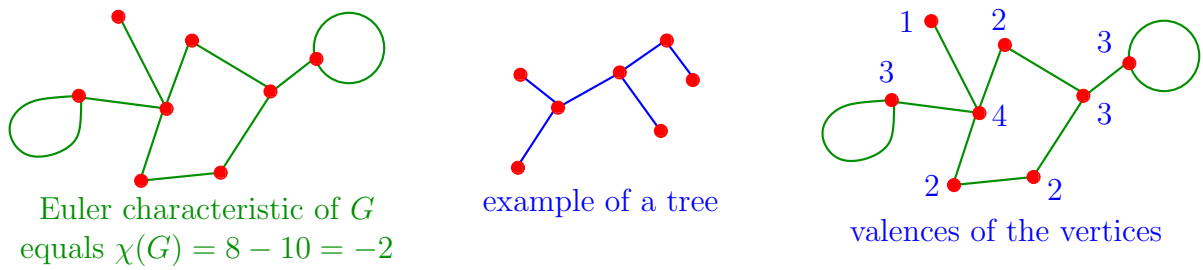

FIGURE 182.

Proposition 9.20. *Let T be a spatial graph that is a tree. Then the following hold:*

(1) *If T has at least one edge, then it admits a vertex of valence one.*
(2) *The tree T is contractible.*
(3) *The fundamental group $\pi_1(T)$ is trivial.*

Proof $(*)$. Let T be a tree. Then the following hold:

(1) We suppose that T has at least one edge. Note that a vertex with valence 0 is an isolated point. Since T has at least one edge and since it is by definition connected, we see that the tree T does not have a vertex of valence 0. Furthermore we have

$$\sum_{\text{vertex } v} \text{valence}(v) = \sum_{\text{vertex } v} \sum_{\text{edge } e} f(v,e) \underset{\substack{\uparrow \\ \text{each edge contributes 2 to the sum}}}{=} 2 \cdot \#\text{ edges} \underset{\substack{\uparrow \\ \text{since } \chi(T)=1}}{=} 2 \cdot \#\text{vertices} - 2.$$

This equality can only hold if there is at least one vertex with valence less than 2. By the above the valence has to be at least one, so there exists a vertex of valence one.

(2) We prove that any tree is contractible by induction on the number of edges. If a tree has zero edges, then it consists of precisely one point, in particular it is even homeomorphic to a point. Now suppose that we know that all trees with n edges are contractible. Let $T = (V, E)$ be a tree with $n+1$ edges. By (1) it admits a vertex v of valence one. We denote by e the unique edge with v as an endpoint. We write $T' = (V \setminus \{v\}, E \setminus e)$. We reduced the number of vertices and of edges by one, so the Euler characteristic is unchanged, i.e. $\chi(T') = \chi(T) = 1$, so T' is again a tree.

We denote by u the other endpoint of e. We consider the maps

$$\begin{aligned} f\colon T &\to T' \\ x &\mapsto \begin{cases} u, & \text{if } x \in \overline{e}, \\ x, & \text{otherwise.} \end{cases} \end{aligned} \qquad \text{and} \qquad \begin{aligned} g\colon T' &\to T \\ x &\mapsto x. \end{aligned}$$

We claim that g is a homotopy inverse to f. Evidently $f \circ g = \mathrm{id}_{T'}$. We need to show that $g \circ f \simeq \mathrm{id}_T$. We pick a homeomorphism $\varphi\colon [0,1] \to \overline{e}$ with $\varphi(0) = u$ and

$\varphi(1) = v$. Then

$$\begin{array}{rcl} H\colon T \times [0,1] & \to & T \\ (x,t) & \mapsto & \begin{cases} \varphi(\varphi^{-1}(x)\cdot t), & \text{if } x \in \overline{e}, \\ x, & \text{otherwise.} \end{cases} \end{array}$$

is a homotopy from $g \circ f$ to id_T.

We have thus shown that T is homotopy equivalent to T'. By our induction hypothesis T' is homotopy equivalent to a point. So it follows from Lemma 9.8 that T itself is also homotopy equivalent to a point, i.e. T is contractible.

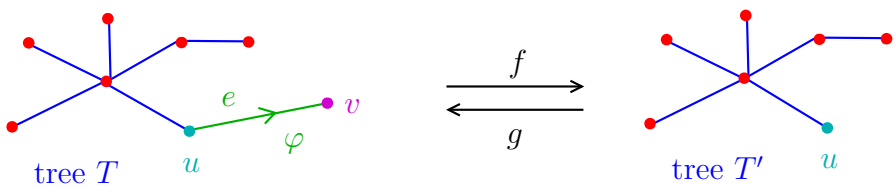

FIGURE 183. Illustration for the proof that every tree is contractible.

(3) It follows from (2) and Proposition 9.12 (2) that the fundamental group of T is trivial.

□

Now we provide a few more definitions on graphs.

Definition. Let $G = (V, E)$ be a graph.

(1) A *subgraph* of $G = (V, E)$ is a graph $G' = (V', E')$ such that $V' \subset V$ and such that E' is a union of components of E.
(2) We say an edge e is *adjacent to a subgraph* G' if e has two endpoints where one of the endpoints lies on G' and the other does not.
(3) A *spanning tree* for G is a subgraph that is a tree and which does not admit an adjacent edge.

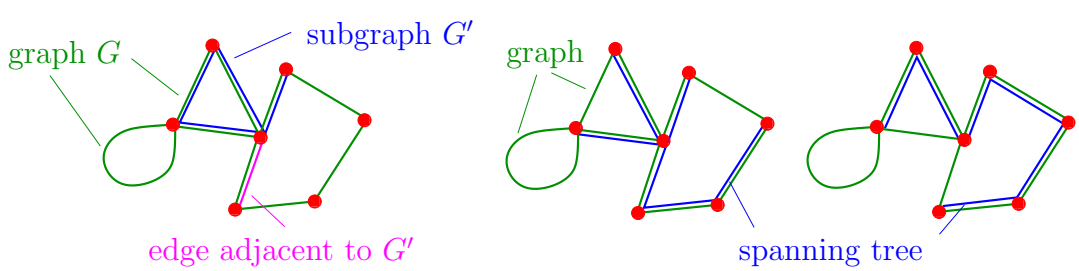

FIGURE 184.

Remark.

(1) If an edge e is adjacent to a subgraph G', then it is not part of the subgraph. Indeed, by definition of a subgraph, for any edge that is part of the subgraph also its endpoints have to lie on the subgraph.
(2) The example of Figure 184 shows that a graph usually has many different spanning trees.
(3) A spanning tree is often also called a *spanning tree*.

We conclude this discussion on graphs with the following proposition.

Proposition 9.21. *Let $G = (V, E)$ be a finite connected spatial graph.*

(1) *The graph G admits a spanning tree.*
(2) *Every spanning tree of G contains all vertices of G.*
(3) *The graph G is homotopy equivalent to the wedge of $1 - \chi(G)$ circles.*
(4) *Let T be a spanning tree and let $e_1, \dots, e_k$ be the edges that do not lie in T. The quotient map $G \to G/T$ is a homotopy equivalence and G/T is the wedge of the k circles given by identifying the endpoints of $e_1, \dots, e_k$ to a single point.*
(5) *Two finite connected spatial graphs with the same Euler characteristic are homotopy equivalent.*

We will study later the question, whether the converse to statement (4) holds: if two finite connected graphs are homotopy equivalent, does it follow that the Euler characteristics are the same?

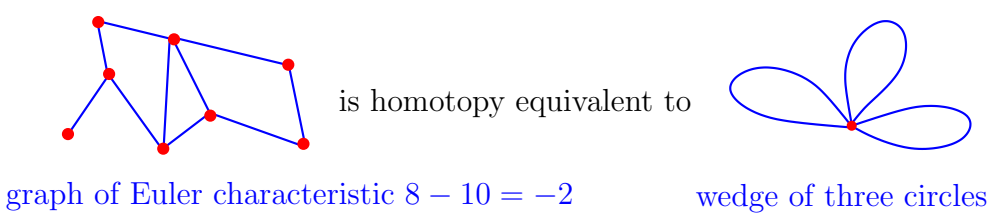

FIGURE 185. Illustration of Proposition 9.21 (3).

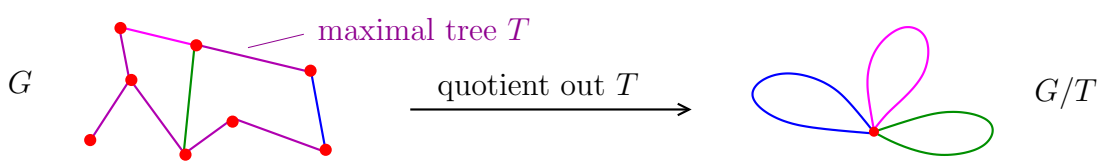

FIGURE 186. Illustration of Proposition 9.21 (4).

We only provide a sketch of the proof.

Sketch of the proof $(*)$. Let $G = (V, E)$ be a finite connected spatial graph.

(1) We pick a vertex v. We define $T_0 = \{v\}$ and view it as a subtree of G. Now we define a sequence of trees $T_0, \dots, T_k$ by iteratively attaching an adjacent edge to the previous tree. This process stops after finitely many steps since G is finite. We always add an edge and a vertex, thus we see that $\chi(T_k) = \cdots = \chi(T_0) = 1$, i.e. T_k is a tree. By definition it is in fact a spanning tree. This argument is illustrated in Figure 187 on the left.

(2) Let T be a subgraph of G that is a tree. Suppose that there exists a vertex w that does not lie in T. We will show that T is not maximal. Let v be a vertex in T. Since G is connected there exists a sequence of edges $e_0, \dots, e_n$ with the following properties:
   (a) v is a vertex of e_0,
   (b) for each $i \in \{0, \dots, n-1\}$ a vertex of e_i is also a vertex of e_{i+1}, and
   (c) w is a vertex of e_n.

   Then there exists an $i \in \{0, \dots, n-1\}$ such that a vertex of e_i lies in T and the other one does not. But then e_i is an edge adjacent to T. This shows that T was not maximal. This argument is illustrated in Figure 187 on the right.

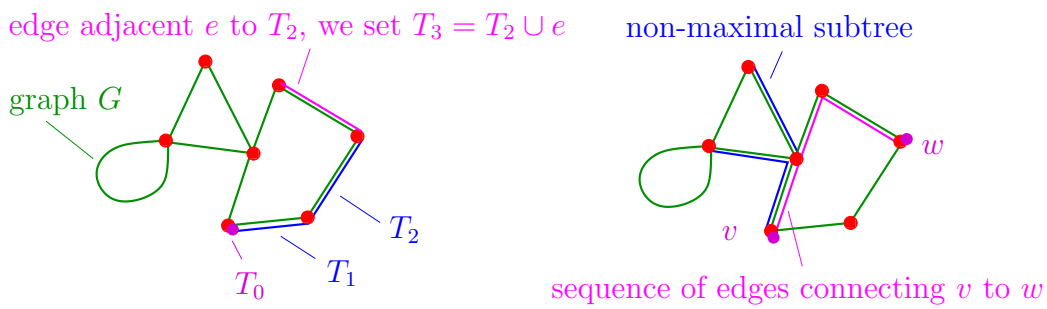

FIGURE 187. Illustration for the proofs of the first two statements of Proposition 9.21.

(3) Let G be a finite spatial graph. We write $n = 1 - \chi(G)$. We prove the statement by induction on the number of edges in a spanning tree. If a spanning tree has zero edges, then it consists of a single vertex. By (2) this means that the original graph has only one vertex and it has n edges. It follows from the discussion on page 316 that the graph is in fact homeomorphic to the wedge of n circles.

So suppose that we know the desired statement whenever the spanning tree has k edges. Now suppose that G has a spanning tree T with $k+1$ edges.

By Proposition 9.20 the tree $T = (W, F)$ has a vertex v of valence one. We denote by e the one edge in T such that v is an endpoint of e. We denote by u the other endpoint of v. By the definition of an edge there exists a homeomorphism $\varphi\colon [0,1] \to e$ such that $\varphi(0) = u$ and $\varphi(1) = v$. We denote by $f_1, \dots, f_k$ the edges in $G \setminus T$ that have v as an endpoint.

We first consider the case that for $j = 1, \dots, k$ the edge f_j has another endpoint w_j. We pick homeomorphisms $\psi_j\colon [0,1] \to f_j$, $j = 1, \dots, n$ such that $\psi_j(0) = v$ and $\psi_j(1) = w_j$. Now we denote by G' a graph that has the vertices $V \setminus \{v\}$, the edges

$E \setminus \{e, f_1, \dots, f_k\}$ and which has new edges f'_j, $j = 1, \dots, k$ with endpoints u and w_j.[213] We pick homeomorphisms $\psi'_j \colon [0,1] \to f'_j$, $j = 1, \dots, n$ such that $\psi'_j(0) = u$ and $\psi'_j(1) = w_j$. We consider the maps[214]

$$g \colon G \to G' \qquad x \mapsto \begin{cases} \psi'_j(\psi_j^{-1}(x)), & \text{if } x \in f_j, \\ u, & \text{if } x \in e, \\ x, & \text{otherwise.} \end{cases} \quad \text{and} \quad g' \colon G' \to G \qquad x \mapsto \begin{cases} \varphi(2t), & \text{if } x = \psi'_j(t), t \in [0, \frac{1}{2}], \\ \psi_j(2t-1), & \text{if } x = \psi'_j(t), t \in [\frac{1}{2}, 1], \\ x, & \text{otherwise.} \end{cases}$$

We leave it as an exercise to show that $g \circ g' \colon G' \to G'$ and $g' \circ g \colon G \to G$ are homotopic to the identity map.[215] This shows that G is homotopy equivalent to G' for which $T' = (W \setminus \{v\}, F \setminus e)$ is a spanning tree. Since T' has one edge less than T it follows from our induction hypothesis that G' is homotopy equivalent to the wedge of $1 - \chi(G') = 1 - \chi(G) = n$ circles. It follows from Lemma 9.8 that G itself is homotopy equivalent to the wedge of n circles.

The case that there are edges in $G \setminus E$ for which v is the only endpoint is dealt with in a very similar way. We leave this case as an exercise to the reader. A related statement will be proved in Exercise 9.17.

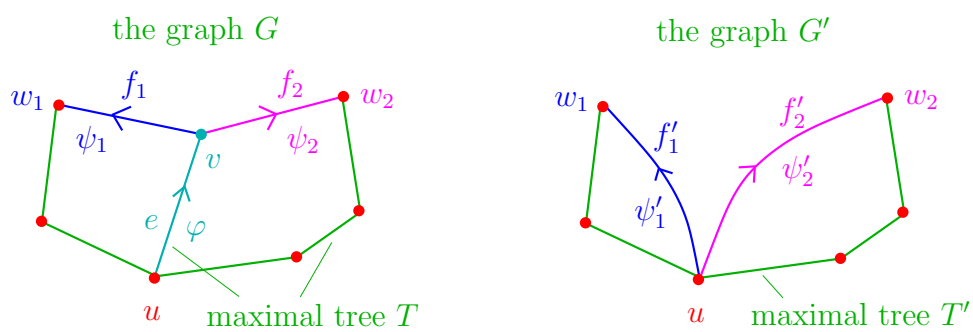

FIGURE 188. Illustration for the proof of the third statement of Proposition 9.21.

(4) This statement was proved implicitly in (3). We leave it to the reader to fill in the details.
(5) The last statement is an immediate consequence of (3) and Lemma 9.8. □

9.8. **Homotopy classes of loops** (∗)**.** In the last section of this chapter we want to study the question, when are two maps $S^1 \to X$ to a topological space homotopic? In fact the following proposition gives in some sense a complete answer to the above question.

[213] At that point one has to argue why such a graph G' exists. One way of seeing this is to take the graph $G \subset \mathbb{R}^n$ and view it as a graph in $\mathbb{R}^n = \mathbb{R}^n \times \{0\} \subset \mathbb{R}^{n+1}$. In $\mathbb{R}^{n+1}$ we can connect the points u and w_j by disjoint edges, without intersecting the previous graph.

[214] Using Lemma 1.32 (2') one can easily verify that these maps are in fact continuous.

[215] Note that if $n = 0$, then this is precisely the construction from the proof of Proposition 9.20.

Proposition 9.22. *Let X be a topological space and let $f_0, f_1 \colon S^1 \to X$ be two maps. We write $x_0 = f_0(1)$ and $x_1 = f_1(1)$.*

(1) *The following statement holds:*[216]

$$f_0 \text{ and } f_1 \text{ are homotopic} \iff \begin{array}{c}\text{there exists a path } \gamma \text{ from } x_0 \text{ to } x_1 \\ \text{such that } [\gamma * f_1 * \overline{\gamma}] = [f_0] \in \pi_1(X, x_0).\end{array}$$

(2) *If $x_0 = x_1$, then the following statement holds:*

$$f_0 \text{ and } f_1 \text{ are homotopic} \iff [f_0] \text{ and } [f_1] \text{ are conjugate in } \pi_1(X, x_0).$$

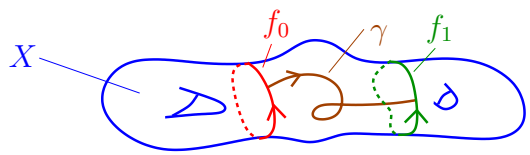

FIGURE 189. Illustration of Proposition 9.22.

Proof. Note that the second statement is an immediate consequence of the first statement and the observation that if $x_0 = x_1$ any path from x_0 to $x_1 = x_0$ is in fact a loop and thus defines an element in $\pi_1(X, x_0)$. Therefore it suffices to prove the first statement.

Now let X be a topological space. We take the view that maps $S^1 \to X$ are the same as loops, i.e. maps $[0,1] \to X$ such that 0 and 1 get sent to the same point. Thus let $f_0, f_1 \colon [0,1] \to X$ be two loops. We write $x_0 = f_0(1)$ and $x_1 = f_1(1)$.

"$\Rightarrow$" Suppose there exists a homotopy $F \colon [0,1] \times [0,1] \to X$ with $F(0,t) = F(1,t)$ for all $t \in [0,1]$ and such that $F_0 = f_0$ and $F_1 = f_1$ and. We denote by $\gamma \colon [0,1] \to X$ the path that is given by $\gamma(t) = F(0,t)$ for $t \in [0,1]$. We consider the surjective map $\Phi \colon [0,1] \times [0,1] \to [0,1] \times [0,1]$ that is shown in Figure 190. The map $\Phi \circ F$ is easily seen to be a homotopy between the loops f_0 and $\gamma * f_1 * \overline{\gamma}$. But that is exactly what we needed to show.

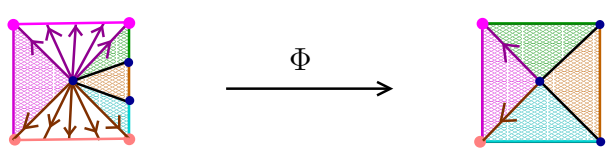

FIGURE 190. First illustration for the proof of Proposition 9.22.

[216]Sometimes two maps $S^1 \to X$ that are homotopic are called *freely homotopic* to stress the fact that no base points are fixed.

"$\Leftarrow$" Now suppose that there exists a path γ from x_0 to x_1 such that $[\gamma * f_1 * \overline{\gamma}] = [f_0] \in \pi_1(X, x_0)$. This means that there exists a homotopy $F\colon [0,1] \times [0,1] \to X$ with $F(0,t) = F(1,t) = x_0$ for all $t \in [0,1]$ and such that $F_0 = f_0$ and $F_1 = \gamma * f_1 * \overline{\gamma}$. We consider the homeomorphism $\Psi\colon [0,1] \times [0,1] \to [0,1] \times [0,1]$ that is shown in Figure 191. The map $\Psi \circ F$ is easily seen to be a homotopy between $c_{x_0} * f_0 * c_{x_0}$ and f_1, viewed as maps $S^1 \to X$. But the map $c_{x_0} * f_0 * c_{x_0}$ is easily seen to be homotopic to the map f_0. Since being homotopic is transitive we have indeed shown that f_0 and f_1 are homotopic. $\square$

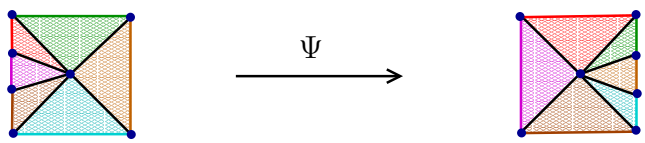

FIGURE 191. Second illustration for the proof of Proposition 9.22.

Exercises for Chapter 9.

Exercise 9.1. Let $n \in \mathbb{N}$ and let $f\colon \overline{B}^n \to \overline{B}^n$ be a homeomorphism with $f|_{S^{n-1}} = \mathrm{id}_{S^{n-1}}$. We consider the map

$$\begin{array}{rcl} H\colon \overline{B}^n \times [0,1] & \to & \overline{B}^n \\ (x,t) & \mapsto & \begin{cases} t \cdot f(\frac{x}{t}), & \text{if } 0 \leq \|x\| < t, \\ x, & \text{otherwise.} \end{cases} \end{array}$$

(a) Show that H is continuous.
(b) Show that for each $t \in [0,1]$ the map $H_t\colon \overline{B}^n \to \overline{B}^n$ is a homeomorphism.

Exercise 9.2. Let $n \in \mathbb{N}$ and let $f\colon S^n \to S^n$ be a homeomorphism. Show that there exists a homeomorphism $F\colon \overline{B}^{n+1} \to \overline{B}^{n+1}$ with $F|_{S^n} = f$.
Remark: This statement is also sometimes referred to as Alexander's trick.

Exercise 9.3.

(a) Let $f\colon [0,1] \to [0,1]$ be a self-homeomorphism.
  (i) Show that f is monotonously increasing or monotonously decreasing.
  (ii) Suppose f is monotonously increasing. Show that f is isotopic to the map $f(x) = x$.
  (iii) Suppose f is monotonously decreasing. Show that f is isotopic to the map $f(x) = -x$.
(b) Show that any self-homeomorphism of S^1 is isotopic to the map $f(z) = z$ or to the map $g(z) = \overline{z}$.
  Hint: Let $f\colon S^1 \to S^1$ be a self-homeomorphism. First consider the case that $f(1) = 1$.

Exercise 9.4. Let h be a complex polynomial of degree ≥ 1. In Exercise 1.11 we showed that the map

$$\begin{array}{rcl} \Theta(h)\colon \mathbb{C}\cup\{\infty\} & \to & \mathbb{C}\cup\{\infty\} \\ z & \mapsto & \begin{cases} h(z), & \text{if } z\in\mathbb{C}, \\ \infty, & \text{if } z=\infty \end{cases} \end{array}$$

is continuous. Now let f and g be two polynomials with complex coefficients of degree ≥ 1. Suppose that $\deg(f)=\deg(g)$. Show that the maps $\Theta(f)$ and $\Theta(g)$ are homotopic.
Remark: It is quite easy to write down a candidate for a homotopy. But why is the map you wrote down actually continuous?

Exercise 9.5. Using Lemma 1.41 we can make the identification $S^1=\mathbb{R}\cup\{\infty\}$. Now let f be a polynomial with real coefficients of degree $n\geq 1$. In Exercise 1.11 we showed that the map

$$\begin{array}{rcl} F\colon S^1=\mathbb{R}\cup\{\infty\} & \to & \mathbb{R}\cup\{\infty\}=S^1 \\ t & \mapsto & \begin{cases} f(t), & \text{if } t\in\mathbb{R}, \\ \infty, & \text{if } t=\infty \end{cases} \end{array}$$

is continuous. (See Figure 68 for an illustration.) Show that F is homotopic to one of the following three types of self-maps of S^1:

$$(1)\qquad a(z)\;=\;z \qquad\qquad (2)\qquad b(z)\;=\;\overline{z} \qquad\qquad (3)\qquad c(z)\;=\;1.$$

Exercise 9.6.

(a) We consider the topological space

$$X \;=\; \{(x,y)\,|\,x\in[0,1]\cap\mathbb{Q}, y\in[0,1-x]\}\cup([0,1]\times\{0\})$$

that is shown in Figure 192 to the left.
  (i) Show that given any point P in $[0,1]\times\{0\}$ there exists a deformation retraction from X to P.
  (ii) Show that for any point Q in X that does not lie on $[0,1]\times\{0\}$ there is no deformation retraction from X to Q.

(b) We consider the infinite zigzag comb Z that is shown in Figure 192 to the right.
  (i) Show that Z is contractible.
  (ii) Show that Z does not admit a deformation retraction to any point in Z.

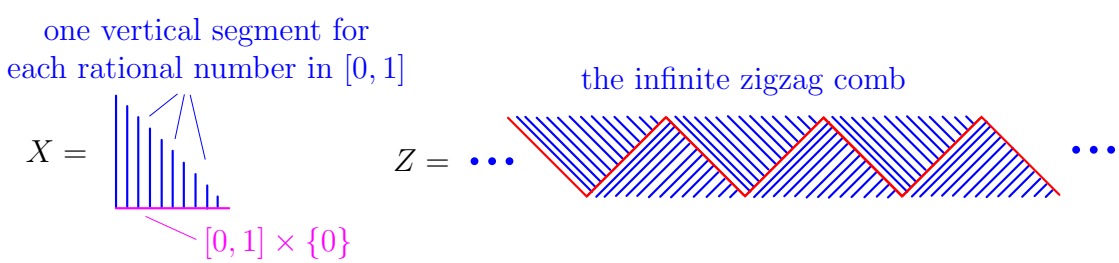

FIGURE 192.

Exercise 9.7. Let A be a convex subset of $\mathbb{R}^n$ and let X be a path-connected topological space. Show that any two maps $f, g\colon A \to X$ are homotopic.

Exercise 9.8. Prove Lemma 9.5.

Exercise 9.9. Show that the topological spaces

$$X = \{\tfrac{1}{n} \,|\, n \in \mathbb{N}\} \cup \{0\} \quad \text{and} \quad Y = \{\tfrac{1}{n} \,|\, n \in \mathbb{N}\} \cup \{-1\}$$

are not homotopy equivalent.

FIGURE 193. Illustration of Exercise 9.9.

Exercise 9.10. Let $0 < r < s$ be two real numbers. Show that the obvious inclusion map $B^n_r(0) \setminus \{0\} \to B^n_s(0) \setminus \{0\}$ is a homotopy equivalence,

Exercise 9.11. Prove Lemma 9.9.

Exercise 9.12. Show that for any $n \in \mathbb{N}$ the sphere S^{n-1} is a deformation retract of $\mathbb{R}^n \setminus \{0\}$.

Exercise 9.13. Prove Lemma 9.10.

Exercise 9.14. Show that

$$S^1 \vee S^1 = \underbrace{\{z \in \mathbb{C} \,|\, |z+1| = 1\} \cup \{z \in \mathbb{C} \,|\, |z-1| = 1\}}_{\text{two circles that meet at the origin}}$$

is a deformation retract of $\mathbb{C} \setminus \{\pm 1\}$.

Exercise 9.15. Let $X := \{(x, y) \in \mathbb{R}^2 \,|\, x^2 + y^2 \leq 1\}$. We denote by $\| - \|$ the usual Euclidean norm on X. We denote by $P = (0, 0)$ the center of X. The *Paris metric* on X is given by

$$\begin{array}{rcl} X \times X & \to & \mathbb{R}_{\geq 0} \\ (A, B) & \mapsto & \|A - P\| + \|B - P\|. \end{array}$$

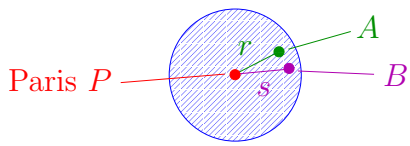
This metric takes its name from the fact that all (OK, many) train lines in France go towards Paris. So if you want to go from A to B you invariably (OK, often) have to go through Paris.

(a) Show that the map

$$\begin{array}{rcl} \varphi\colon \bigvee_{z \in S^1} [0,1]_z & \to & X \\ [r] & \mapsto & r \cdot z \quad \text{if } r \in [0,1]_z. \end{array}$$

is not homeomorphism.

(b) Does there exist a homeomorphism between $\bigvee_{z\in S^1}[0,1]_z$ and X?



in the Paris metric the distance between P and Q equals $r+s$

FIGURE 194. Illustration of Exercise 9.15.

Exercise 9.16. Let (X,x_0) and (Y,y_0) be two pointed topological spaces. We use the base points to define the wedge $X\vee Y$.

(a) Show that the map

$$\begin{array}{rcl} f\colon X\vee Y & \to & X\times Y \\ [P] & \mapsto & \begin{cases} (P,y_0), & \text{if } P\in X, \\ (x_0,P), & \text{if } P\in Y \end{cases} \end{array}$$

is a homeomorphism onto its image.
Remark: We do not assume that X and Y have any nice properties.

(b) Using (a) we can view $X\vee Y$ as a subspace of $X\times Y$. We refer to the quotient

$$X\wedge Y \;:=\; (X\times Y)/(X\vee Y)$$

as the *smash product of* (X,x_0) *and* (Y,y_0). Show that for any $m,n\in\mathbb{N}_0$ the smash product $S^m\wedge S^n$ is homeomorphic to S^{m+n}.

We refer to Figure 195 for an illustration.

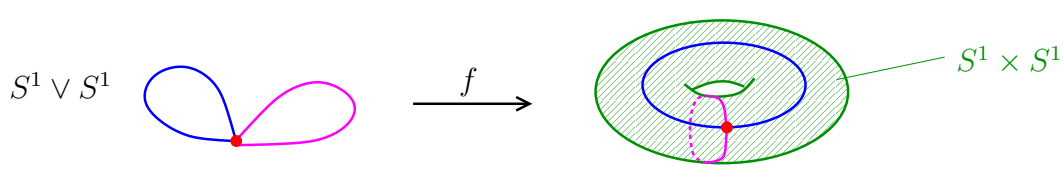


FIGURE 195. Illustration for Exercise 9.16.

Exercise 9.17. Let

$$X \;:=\; \underbrace{\{z\in\mathbb{C}\,|\,|z-2|=1\}}_{=:A} \;\cup\; [-1,1] \;\cup\; \underbrace{\{z\in\mathbb{C}\,|\,|z+2|=1\}}_{=:B}$$

and

$$Y \;:=\; \underbrace{\{z\in\mathbb{C}\,|\,|z-1|=1\}}_{=:C} \;\cup\; \underbrace{\{z\in\mathbb{C}\,|\,|z+1|=1\}}_{=:D}.$$

Show that X and Y are homotopy equivalent.

FIGURE 196. Illustration for Exercise 9.17.

Exercise 9.18. Let $\{X_i\}_{i\in I}$ be a family of topological spaces. Suppose that for each $i \in I$ we are given a point $x_i \in X_i$ with the property that $\{x_i\}$ is a closed subset of X_i. We use these points to form the wedge $\bigvee_{i\in I} X_i$. Let $K \subset \bigvee_{i\in I} X_i$ be a compact subset. Show that there exists a finite subset $J \subset I$ such that $K \subset \bigvee_{i\in J} X_i$.

Exercise 9.19. We consider the subset X of $\mathbb{R}^2$ that is shown in Figure 197. It is the union of infinitely many circles $A_i \subset \mathbb{R}^2$, $i \in \mathbb{N}$ that meet in the origin. Furthermore let $Y = \bigvee_{i\in\mathbb{N}} S^1$. There exists a fairly obvious bijection $f\colon X \to Y$ which sends each A_i to the i-th factor of Y.

(a) Is the map f continuous?
(b) Is the map f^{-1} continuous?

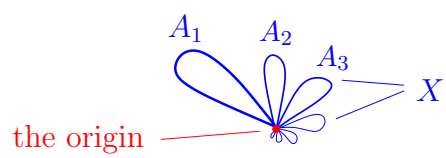

FIGURE 197. Illustration of Exercise 9.19.

Exercise 9.20. Let $f, g\colon (X, x_0) \to (Y, y_0)$ be two maps between pointed topological spaces.

(a) Show that if f and g are homotopic rel $\{x_0\}$, then $f_* = g_*\colon \pi_1(X, x_0) \to \pi_1(Y, y_0)$.
(b) Does the conclusion of (a) hold if we only demand that f and g are homotopic, but we no longer demand that they are homotopic rel the base point?

Exercise 9.21. Let $f\colon X \to Y$ be a map between two topological spaces. Let $x_0 \in X$ be a base point. We write $y_0 = f(x_0)$ and we denote by $i\colon f(X) \to Y$ the inclusion map. Suppose that $f_*\colon \pi_1(X, x_0) \to \pi_1(Y, y_0)$ is an isomorphism. Does it follow that $i_*\colon \pi_1(f(X), y_0) \to \pi_1(Y, y_0)$ is also an isomorphism?

10. Differential topology

Differential topology is the study of manifolds and their submanifolds viewed as topological spaces. In this section we will first give several basic definitions in differential topology. Afterwards we will state, without proof but with precise references, some technical results which later on will make our life much easier.

10.1. **Immersions and embeddings.** We start out with some definitions that will crop up frequently throughout these lecture notes.

Definition. Let N be a compact topological manifold and let M be any topological manifold. A map $\varphi\colon N \to M$ is called *proper* if $\varphi^{-1}(\partial M) = \partial N$.

We illustrate the definition of a proper map in Figure 198.

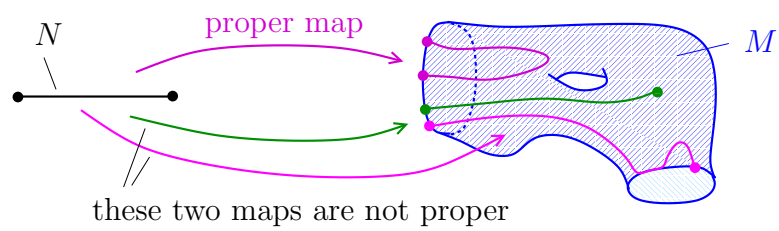

Figure 198.

The following definition is related in spirit to the notion of a submersion that we had introduced on page 211.

Definition. A map $\varphi\colon N \to M$ between two manifolds is called an *immersion* if the following conditions are satisfied:

(1) φ is smooth,
(2) for each $P \in N$ the induced map $\varphi_*\colon T_P N \to T_{\varphi(P)} M$ is a monomorphism,
(3) for each $P \in N \setminus \partial N$ we have $\varphi(P) \in M \setminus \partial M$,
(4) for each $P \in \partial N$ with $\varphi(P) \in \partial M$ the image $\varphi_*(T_P N)$ is *not* contained in $T_{\varphi(P)}(\partial M)$.[217]

An immersion that also satisfies the following extra condition

(5) $\varphi\colon N \to \varphi(N)$ is a homeomorphism,[218][219]

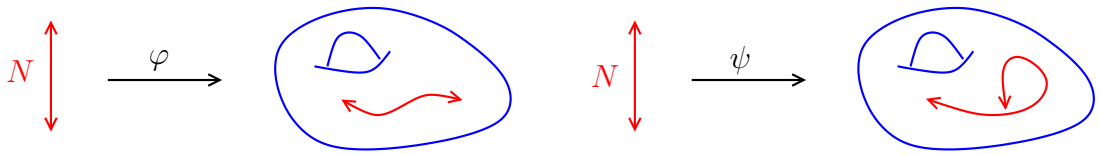
is called an *embedding*.

The following proposition relates the notion of embeddings to the notion of submanifolds.

[217]Another way of expressing this condition is that the map $T_P N \to T_{\varphi(P)} M / T_{\varphi(P)} \partial M$ is an epimorphism.

[218]Here $\varphi(N) \subset M$ is endowed with the subspace topology.

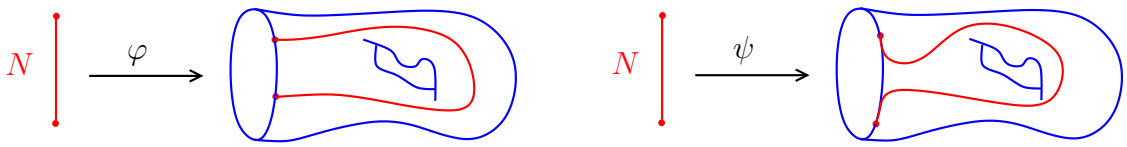
[219]If N is compact, then it follows from Proposition 1.40 that it suffices to verify that φ is injective and continuous.



φ is an embedding

ψ is not an embedding since $\varphi\colon N \to \varphi(N)$ is not a homeomorphism

FIGURE 199.



φ is an embedding

ψ is not an embedding since condition (3) is not satisfied

FIGURE 200.

Proposition 10.1. *Let N be an n-dimensional manifold and let M be a manifold.*

(1) *Let $\varphi\colon N \to M$ be an embedding, then $\varphi(N)$ is an n-dimensional submanifold of M and the map $\varphi\colon N \to \varphi(N)$ is a diffeomorphism.*
(2) *Suppose N is compact. If $\varphi\colon N \to M$ is a proper embedding, then $\varphi(N)$ is a proper n-dimensional submanifold of M and the map $\varphi\colon N \to \varphi(N)$ is a diffeomorphism.*

Proof. For (2) we need to make the following observation: If $\varphi\colon N \to M$ is a map and N is compact, then it follows from Lemma 1.37 and Lemma 1.18 that $\varphi(N)$ is a closed subset of M.

For the actual meat of the proof we have to refer to the literature. For manifolds without boundary the proposition is proved in [Le2, Proposition 5.2] and [BG, Corollary 2.6.11]. The proof for manifolds with boundary is quite similar. We leave it to the reader to fill in the details. Note that [Le2, Proposition 5.2] actually deals with manifolds with boundary. But as we pointed out on page 186, the definition of a submanifold with boundary in [Le2] differs from our definition and also the notion of an embedding differs from our definition. □

Example. It is straightforward to verify that the map $\Psi\colon \mathbb{R}^2 \times S^1 \to \mathbb{R}^3$ given in Lemma 1.58 restricts to an embedding $\Psi\colon S^1 \times S^1 \to \mathbb{R}^3$ and that it also restricts to an embedding $\Psi\colon \overline{B}^2 \times S^1 \to \mathbb{R}^3$. By Proposition 10.1 this allows us to view $S^1 \times S^1$ and $\overline{B}^2 \times S^1$ as submanifolds of $\mathbb{R}^3$.

In the following proposition we consider immersions and embeddings between manifolds of the same dimension.

Proposition 10.2. *Let M and N be manifolds of the same dimension and furthermore let $\varphi\colon N \to M \setminus \partial M$ be a map.*

(1) *If $\varphi\colon N \to M \setminus \partial M$ is an immersion, then $\varphi(N \setminus \partial N)$ is an open subset of M.*
(2) *If $\varphi\colon N \to M \setminus \partial M$ is an embedding and if N is compact, then M is decomposed into the submanifolds $\varphi(N)$ and $X := M \setminus \varphi(N \setminus \partial N)$ and the boundary of $M \setminus \varphi(N \setminus \partial N)$ as a manifold in its own right is given by $\partial M \cup \varphi(\partial N)$. (We refer to Figure 201 for an illustration.)*

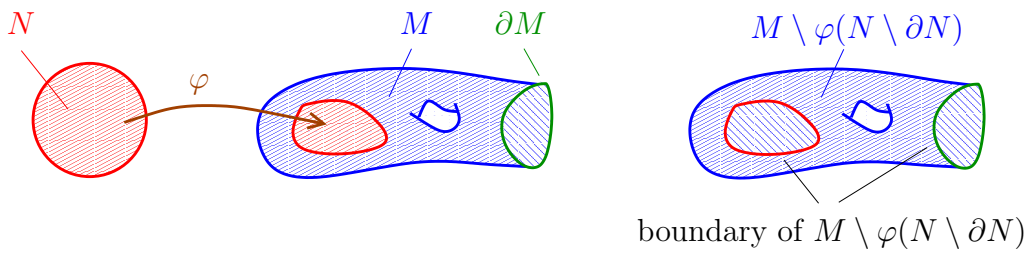


FIGURE 201. Illustration of Proposition 10.2 (2).

Sketch of proof.

(1) Let $\varphi\colon N \to M \setminus \partial M$ be an immersion. It is not difficult to deduce from Proposition 3.20 that $\varphi(N \setminus \partial N)$ is an open subset of M. We leave it to the reader to fill in the details.
(2) This statement follows immediately from Propositions 10.1 and 3.24. □

We conclude this discussion of immersions and embeddings with the following instructive example which is dressed up as a lemma.

Lemma 10.3. *Given $\lambda \in \mathbb{R}$ we consider the following map*

$$\begin{array}{rcl} \varphi_\lambda\colon \mathbb{R} & \to & \mathbb{R}^2/\mathbb{Z}^2 \\ t & \mapsto & [(t, \lambda \cdot t)]. \end{array}$$

The following statements hold:

(1) *The map φ_λ is an immersion if and only if $\lambda \neq 0$.*
(2) *The map φ_λ is injective if and only if λ is irrational.*
(3) *If λ is irrational, then $\varphi_\lambda\colon \mathbb{R} \to \mathbb{R}^2/\mathbb{Z}^2$ is* not *a homeomorphism onto its image, i.e. φ_λ is not an embedding.*
(4) *Suppose λ is rational. We write $\lambda = \frac{p}{q}$ with $p \in \mathbb{Z}$ and $q \in \mathbb{N}$ such that p and q are coprime. Then the map*

$$\begin{array}{rcl} \varphi_\lambda\colon S^1 & \to & \mathbb{R}^2/\mathbb{Z}^2 \\ e^{2\pi i t} & \mapsto & [(qt, \lambda \cdot qt)] \end{array}$$

is an embedding.

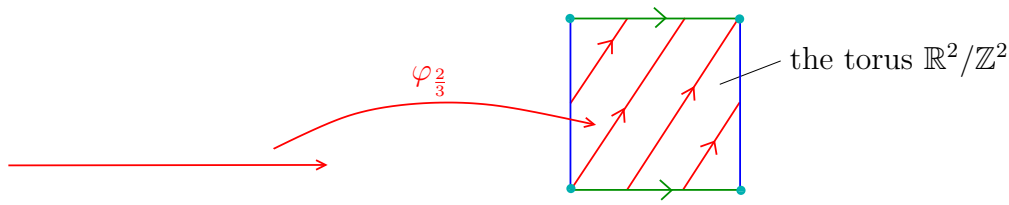

FIGURE 202.

Proof. Statements (1), (2) and (4) are amusing exercises. Statement (3) requires the simple number theoretic fact that given any $\alpha \in \mathbb{R}$ and any $N \in \mathbb{N}$ there exist $n, m \in \mathbb{Z}$ with $1 \leq n \leq N$ and with $|n\alpha - m| < \frac{1}{N}$.[220] We leave the details to the reader. □

10.2. **Smooth homotopies.** Now suppose we are given two smooth maps $f_0, f_1 \colon M \to N$ between manifolds. On page 301 we defined a homotopy between f_0 and f_1 to be a map $F \colon M \times [0,1] \to N$ with $F_0 = f_0$ and $F_1 = f_1$. As we will see shortly, on many occasions this definition is not very useful. It is much more reasonable to consider "smooth" homotopies, namely we want F itself to be a smooth map.

But this leads to a slightly annoying question: What does it mean for $F \colon M \times [0,1] \to N$ to be smooth? If M is closed, then by Proposition 3.42 (1) we can view $M \times [0,1]$ as a manifold and we know what it means for a map $F \colon M \times [0,1] \to N$ to be smooth. But what should we do if M has non-empty boundary?

This leads us to the following definition.

Definition. Let M and N be manifolds and let $a < b$ be two real numbers. We say a map $\varphi \colon M \times [a,b] \to N$ is *smooth* if the following conditions are satisfied:

(1) The map $(M \setminus \partial M) \times [a,b] \to N$ is smooth.
(2) Given any $x \in \partial M$ there exists an open neighborhood U of x in M, an $\epsilon \in (0, b-a)$ and a smooth map $\psi \colon U \times (a-\epsilon, a+\epsilon) \to N$ that agrees with φ on $U \times [a, a+\epsilon)$.
(3) Given any $x \in \partial M$ there exists an open neighborhood U of x in M, an $\epsilon \in (0, b-a)$ and a smooth map $\psi \colon U \times (b-\epsilon, b+\epsilon) \to N$ that agrees with φ on $U \times (b-\epsilon, b]$.

Note that in all three cases it makes sense to talk of a map being smooth since by Proposition 3.42 (4) we know that $(M \setminus \partial M) \times [a,b]$ is a manifold with boundary $(M \setminus \partial M) \times \{a,b\}$, that $U \times (a-\epsilon, a+\epsilon)$ is a manifold with boundary $\partial U \times (a-\epsilon, a+\epsilon)$ and finally $U \times (b-\epsilon, b+\epsilon)$ is a manifold with boundary $\partial U \times (b-\epsilon, b+\epsilon)$.

Remark.

(1) If M is a manifold without boundary, then the cases (2) and (3) do not occur and the above definition of a smooth map $\varphi \colon M \times [a,b] \to N$ is precisely the one we had always used.

[220] This statement is known as Dirichlet's Approximation Theorem, but it is actually elementary to prove, see e.g. [Le2, Lemma 4.21].

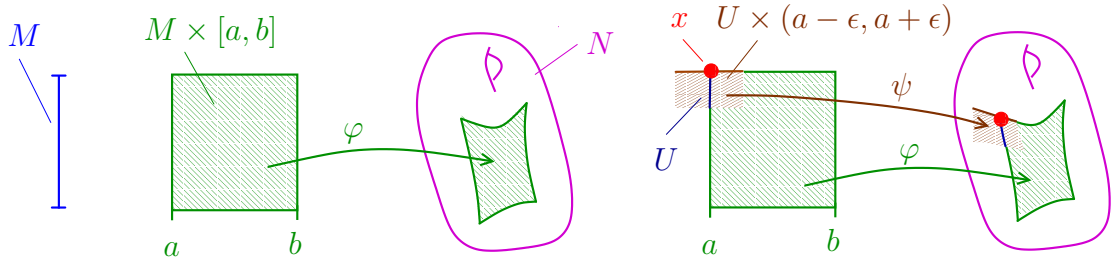

FIGURE 203.

(2) Let M be a manifold. We could view $M \times [0,1]$ as a manifold with "corners", see e.g. [Wall2, p. 30] or [Le2, Chapter 16] for a definition. The definition of a smooth map on a manifold with corners is very similar to the definition for manifolds with boundary, which in turn relies on the definition of a smooth map on an arbitrary subset of $\mathbb{R}^n$ that we gave on page 181. It follows easily from the definitions that these two definitions of a smooth map on $M \times [0,1]$ agree.

Now we can define the notion of a smooth homotopy.

Definition. Let M and N be manifolds.

(1) A *smooth homotopy* is a smooth map $F\colon M \times [0,1] \to N$.
(2) We say that two smooth maps $f_0, f_1\colon M \to N$ are *smoothly homotopic* if there exists a smooth homotopy $F\colon M \times [0,1] \to N$ with $F_0 = f_0$ and $F_1 = f_1$.

Example. Let M and N be manifold and let $F\colon M \times [0,1] \to N$ be a homotopy. If there exists an $\epsilon > 0$ and a smooth map $M \times (-\epsilon, 1+\epsilon) \to N$ that restricts to F on $M \times [0,1]$, then F is by definition smooth. For example, it follows easily from this observation that the map

$$\begin{array}{rcl} S^1 \times [0,1] & \to & \mathbb{R}^2 \\ (z,t) & \mapsto & z \cdot (1-t) \end{array}$$

is a smooth homotopy from the inclusion map $S^1 \to \mathbb{R}^2$ to a constant map.

We continue with our next definition.

Definition. Let M and N be manifolds.

(1) A (*proper*) *smooth isotopy of M in N* is a smooth[221] map

$$\begin{array}{rcl} F\colon M \times [0,1] & \to & N \\ (z,t) & \mapsto & F(z,t) \end{array}$$

such that for each $t \in [0,1]$ the map $F_t\colon M \to N$ is a (proper) embedding.

[221] We would like to stress that here we want a smooth map, not just a continuous map. Also note that we defined on page 333 what it means for the map $F\colon M \times [0,1] \to N$ to be smooth.

(2) We say that two (proper) embeddings $f_0, f_1 \colon M \to N$ are (*properly*) *smoothly isotopic* if there exists a (proper) smooth isotopy $F \colon M \times [0,1] \to N$ with $F_0 = f_0$ and $F_1 = f_1$.

If $M = N$ and if each F_t is a diffeomorphism, then we refer to a smooth isotopy as a *diffeotopy* and we say *diffeotopic* instead of *smoothly isotopic*.

The following lemma gives in particular an example of a diffeotopy.

Lemma 10.4. *Let $n \in \mathbb{N}$.*

(1) *If $\gamma \colon [0,1] \to \mathrm{O}(n)$ is a smooth path, then the map*

$$\begin{array}{rcl} F \colon \overline{B}^n \times [0,1] & \to & \overline{B}^n \\ (x,t) & \mapsto & \gamma(t) \cdot x \end{array}$$

is a diffeotopy rel the origin.

(2) *Let $A \in \mathrm{SO}(n)$. If $n \geq 2$, then there exists a diffeotopy of $\overline{B}^n$ from $\mathrm{id}_{\overline{B}^n}$ to the diffeomorphism of $\overline{B}^n$ that is given by multiplication by A.*

The same statement holds with $\overline{B}^n$ replaced by $\mathbb{R}^n$ and S^{n-1}.

Proof.

(1) The first statement is basically obvious.

(2) Suppose that $n \geq 2$ and let $A \in \mathrm{SO}(n)$. By Lemma 1.96 the manifold $\mathrm{SO}(n)$ is path-connected. Therefore, by Exercise 10.11 there exists a smooth path in $\mathrm{SO}(n)$ from id to A. The statement now follows from (1). □

Remark. The term "diffeotopic" is (alas!) used differently by different authors. Our definition agrees with the definition given in most textbooks, see e.g. [Wall2, p. 49] and [BJ, Definition 9.3]. But it differs from the definition provided in [Hirs, Chapter 8], there the map on $M \times [0,1]$ only needs to be continuous, but each F_t needs to be a diffeomorphism. At least a priori this is a weaker condition.

We leave the proof of the following lemma as a voluntary exercise to the eager reader.

Lemma 10.5. *Let M be an oriented connected manifolds and let $F \colon M \times [0,1] \to N$ be a diffeotopy. Then either all maps $F_t \colon M \to M$ are orientation-preserving or all F_t are orientation-reversing.*

For later purposes we state the following lemma.

Lemma 10.6. $(*)$ *Let N be a manifold and let M be another manifold and let $f, g, h \colon M \to N$ be proper embeddings. If f is smoothly isotopic to g and g is smoothly isotopic to h, then f is also smoothly isotopic to h. The same statement also holds for "diffeotopic" instead of "smoothly isotopic".*

Proof $(*)$. Let $\Phi \colon M \times [0,1] \to N$ be a smooth isotopy from f to g and let $\Psi \colon M \times [0,1] \to N$ be a smooth isotopy from g to h. The first idea is of course to "stack" the two smooth

isotopies together, i.e. to consider the map

$$\begin{array}{rcl} M \times [0,1] & \to & N \\ (P,t) & \mapsto & \begin{cases} \Phi(P, 2\cdot t), & \text{if } t \in [0, \frac{1}{2}], \\ \Psi(P, 2\cdot t - 1), & \text{if } t \in [\frac{1}{2}, 1]. \end{cases} \end{array}$$

By Lemma 5.3 we know that this map is continuous. The problem with this approach is that this map is not necessarily smooth at $M \times \{\frac{1}{2}\}$. Thus we have to modify the above approach slightly. It follows from Lemma 3.12 that there exist a smooth function $f\colon [0,1] \to [0,1]$ with $f(0) = 0$ such that $f(t) = 1$ for all $t \in [\frac{1}{2}, 1]$ and a smooth function $g\colon [0,1] \to [0,1]$ with $g(1) = 1$ such that $g(t) = 0$ for all $t \in [0, \frac{1}{2}]$. It is now straightforward to verify that the map

$$\begin{array}{rcl} M \times [0,1] & \to & N \\ (P,t) & \mapsto & \begin{cases} \Phi(P, f(2\cdot t)), & \text{if } t \in [0, \frac{1}{2}], \\ \Psi(P, g(2\cdot t - 1)), & \text{if } t \in [\frac{1}{2}, 1] \end{cases} \end{array}$$

is a smooth isotopy from f to h. The proof for "diffeotopic" instead of "smoothly isotopic" is verbatim the same. □

The following lemma gives an interesting example of a smooth deformation retraction.

Lemma 10.7. $(*)$ *Let $n \in \mathbb{N}_0$ and let $k \in \{1, \dots, n\}$. We write*

$$\begin{array}{rcl} \mathrm{GL}(n,k) & = & \textit{set of } k\textit{-tuples of linearly independent vectors of } \mathbb{R}^n \\ \mathrm{O}(n,k) & = & \textit{set of } k\textit{-tuples of orthonormal vectors of } \mathbb{R}^n. \end{array}$$

(Note that for $k = n$ we have $\mathrm{GL}(n,k) = \mathrm{GL}(n)$ and $\mathrm{O}(n,k) = \mathrm{O}(n)$.) We denote by $r\colon \mathrm{GL}(n,k) \to \mathrm{O}(n,k)$ the map given by the Gram-Schmidt orthonormalization process.[222] *The following statements hold:*

(1) *The above map $r\colon \mathrm{GL}(n,k) \to \mathrm{O}(n,k)$ is realized by a smooth deformation retraction*[223] *$R\colon \mathrm{GL}(n,k) \times [0,1] \to \mathrm{O}(n,k)$ which has the following extra property:*
   $(*)$ *For any k-dimensional subvector space V of $\mathbb{R}^n$ and any $t \in [0,1]$ we have*

$$R(\textit{basis of } V, t) \subset \textit{basis of } V.$$

   In particular r is smooth and it is a retraction.

(2) *The inclusion $\mathrm{O}(n,k) \to \mathrm{GL}(n,k)$ is a homotopy equivalence.*

The analogous statement hold if we replace the pair $\mathrm{O}(n,k)$ and $\mathrm{GL}(n,k)$ by one of the following four pairs:

(a) $\mathrm{SO}(n)$ *and* $\mathrm{GL}_+(n,\mathbb{R})$,
(b) $\mathrm{U}(n)$ *and* $\mathrm{GL}(n,\mathbb{C})$,
(c) $\mathrm{SO}(n)$ *and* $\mathrm{SL}(n,\mathbb{R})$.
(d) $\mathrm{SU}(n)$ *and* $\mathrm{SGL}(n,\mathbb{C})$.

[222] This map is defined in any course on linear algebra, see e.g. [Cu, Theorem 15.9].

[223] In Exercise 10.6 we will see that $\mathrm{GL}(n,k)$ is an open subset of $\mathbb{R}^{nk}$. Therefore the word "smooth" makes sense in the most naive sense.

Sketch of proof Proof $(*)$.

(1) One easily verifies that each of the $2k$ steps of the Gram-Schmidt process is realized by a smooth deformation retraction that satisfies $(*)$. The proof of Lemma 10.6 shows that we can combine these smooth deformation retractions to obtain the desired smooth deformation retraction that satisfies $(*)$.
(2) This statement follows immediately from (1) and Lemma 9.10.

We consider the four extra pairs :

(a) The given smooth deformation retraction restricts to a deformation retraction from $\mathrm{GL}_+(n,\mathbb{R})$ to $\mathrm{SO}(n)$.
(b) The proof in this case is basically identical to the proof concerning the pair $\mathrm{O}(n)$ and $\mathrm{GL}(n,\mathbb{R})$.
(c) The given smooth deformation retraction does *not* restrict to a deformation retraction from $\mathrm{SL}(n,\mathbb{R})$ to $\mathrm{SO}(n)$. The problem is that in the Gram-Schmidt process we have to successively normalize the column vectors to length one. This process does not preserve the determinant. The solution is that when we normalize the i-th column vector by a factor r, then we compensate by simultaneously rescaling the $(i+1)$-st column vector by r^{-1}. This issue does not arise when we have arrived at the last column vector, since starting out with a matrix of determinant one there is no need to rescale the last column vector.
(d) The proof in this case is basically identical to the proof of (c). □

For general culture we cite the following difficult theorem due to Jean Cerf [Cer2]. We could not find results in the literature that deal with the lower dimensional cases.

Theorem 10.8. $(*)$ *Let $n \geq 6$. Every orientation-preserving diffeomorphism of $\overline{B}^n$ is diffeotopic to the identity.*

We conclude this dense section with a short discussion of submanifolds.

Definition. Let M_0, M_1 be two (proper) submanifolds of a manifold N.

(1) A (*proper*) *smooth isotopy* is a (proper) smooth isotopy $F\colon M_0 \times [0,1] \to N$ with $F_0 = \mathrm{id}_{M_0}$ and with $F_1(M_0) = M_1$.
(2) We say that the two submanifolds are (*properly*) *smoothly isotopic* if there exists a (proper) smooth isotopy between M_0 and M_1.

If M_0 and M_1 are oriented manifolds, then we demand that the map $F_1\colon M_0 \to M_1$ is orientation-preserving.

Example. In Figure 204 we consider some oriented 1-dimensional submanifolds of a surface Σ. In some cases it is clear that submanifolds are smoothly isotopic, in other cases this looks dubious.

10.3. **The Collar Neighborhood Theorem.** After the preparations from the last two sections we now have the language to state many useful results from differential topology.

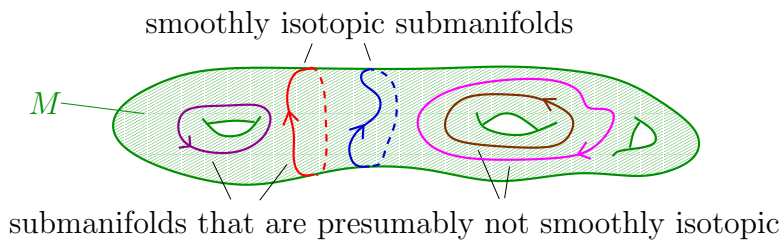

FIGURE 204.

Definition. Let M be a manifold. A *collar neighborhood* of ∂M is defined as the image of an embedding $f\colon \partial M \times [0,1] \to M$ that is the identity map on $\partial M \times \{0\} = \partial M$.

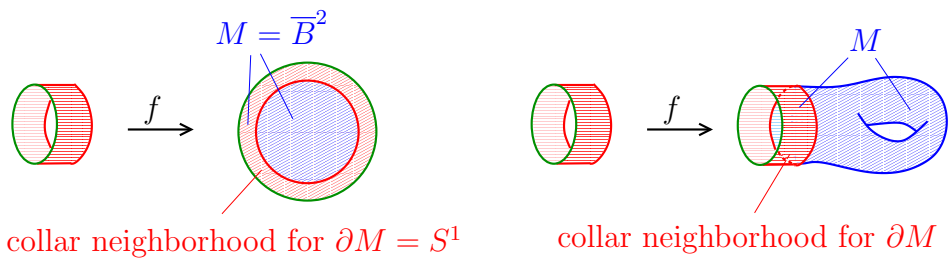

FIGURE 205.

Convention. We continue with the notation from the definition. By abuse of notation we usually denote the image of f by $\partial M \times [0,1]$ as well. In particular we make the identification $\partial M \times \{0\} = \partial M$. Sometimes we refer to $\partial M \times [0,1)$ as an *open collar neighborhood* of ∂M.

The following lemma justifies the names "collar neighborhood" and "open collar neighborhood".

Lemma 10.9. *Let M be a manifold and let $\partial M \times [0,1]$ be a collar neighborhood of ∂M. For any $t \in (0,1]$ the set $\partial M \times [0,t)$ is an open subset of M, in particular it is in fact a neighborhood of ∂M in the sense of the definition on page 48.*

Proof. The proof of this lemma is quite similar to the proof of Proposition 10.2, i.e. the proof is a reasonably straightforward consequence of Proposition 3.20. Once again we leave it to the reader to fill in the details. □

Now we can state the Collar Neighborhood Theorem.

Theorem 10.10. (Collar Neighborhood Theorem) *Every manifold admits a collar neighborhood.*

Proof. This statement is proved in basically any book on differential topology, see [Wall2, Theorem 1.5.5] or alternatively [Le2, Theorem 9.25], [BJ, Theorem 13.6], [Muk, Theorem 7.2.13]. □

The following proposition says, that under a fairly mild hypothesis, collar neighborhoods are essentially unique.

Proposition 10.11. *Let M be a manifold and let $f_0, f_1 \colon \partial M \times [0,1] \to M$ be two embeddings that are the identity map on $\partial M \times \{0\} = \partial M$. If ∂M is compact*[224]*, then there exists a diffeotopy*

$$H \colon M \times [0,1] \;\to\; M$$

rel ∂M[225] *from $H_0 = \mathrm{id}_M$ to a diffeomorphism $\Phi = H_1 \colon M \to M$ with $\Phi \circ f_0 = f_1$. In particular Φ restricts to a diffeomorphism*

$$\Phi \colon f_0(\partial M \times [0,1])) \;\to\; f_1(\partial M \times [0,1]).$$

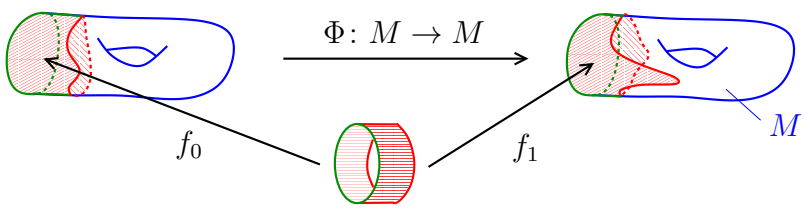

FIGURE 206.

Proof. The proposition is proved in [Wall2, Proposition 2.5.7]. A very similar statement is also proved in [BJ, Theorem 13.7]. □

We continue with the following proposition.

Proposition 10.12. *Let M be an n-dimensional manifold (we do not assume that M is connected). Let A and B be two distinct boundary components of M. Furthermore let $f \colon A \to B$ be a diffeomorphism.*[226] *Then the following statements hold:*

(1) *The topological space*

$$M/a \sim f(a) \qquad \text{for } a \in A$$

admits the structure of an n-dimensional manifold such that $M \setminus (A \cup B)$ is a submanifold. If A and B are compact, then the diffeomorphism type of this manifold is canonical.[227]

[224]It is not so clear to me whether one really needs that the boundary of M is compact, but both references prefer to assume that the boundary is compact. Fortunately for our purposes it is irrelevant whether a more general version of Proposition 10.11 holds.

[225]Recall that this means that $H(P,t) = P$ for all $P \in \partial M$ and $t \in [0,1]$.

[226]Recall that by Proposition 3.21 the boundary components A and B are canonically $(n-1)$-dimensional manifolds.

[227]The slightly annoying restriction to compact A and B is due to the fact that we need to apply Proposition 10.11. It might well be that the statement holds without any restrictions on A and B. Also note that in practice one deals almost always with the case of compact boundary components.

(2) *If M consists of two components X and Y and if $A \subset X$ and $B \subset Y$, then the images of X and Y in $M/a \sim f(a)$ are codimension zero submanifolds.*
(3) *If M is compact, then $M/a \sim f(a)$ is also compact.*
(4) *The boundary of $M/a \sim f(a)$ is given by $\partial M \setminus (A \cup B)$.*
(5) *If M is oriented, if A and B are equipped with the boundary orientations and if f is orientation-reversing, then $M/a \sim f(a)$ admits an orientation such that the inclusion $M \setminus (A \cup B) \to M/a \sim f(a)$ is orientation-preserving.*

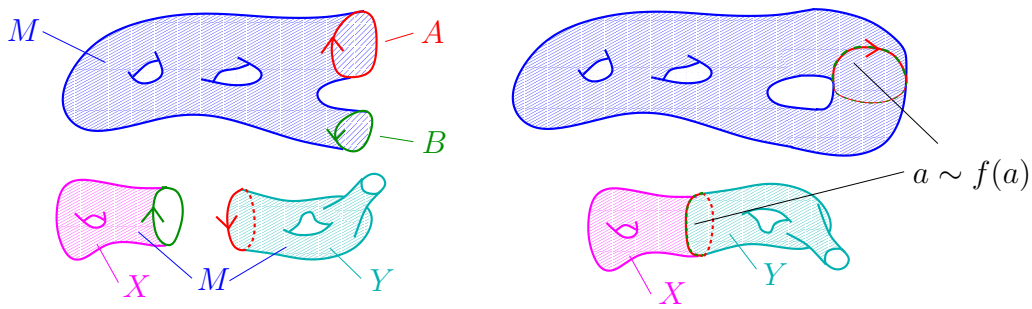

FIGURE 207. Illustration of Proposition 10.12.

Sketch of proof (∗). We first prove statement (1) of the proposition. In the following we write $W := M/a \sim f(a)$ and $M' := M \setminus (A \cup B)$. We denote by $p\colon M \to W$ the projection map. We make the following two observations:

(a) It follows from Proposition 3.21 (3a) that M' is an open subset of M and of W.
(b) It follows from the Collar Neighborhood Theorem 10.10 that there exists a collar neighborhood $\partial M \times [0,1]$ of ∂M.

First we intend to provide a smooth atlas for W. We do so as follows:

(α) We restrict all the charts in the given atlas of M to the open subset M'.
(β) We equip A with the smooth $(n-1)$-dimensional atlas $\{\Phi_i\colon U_i \to V_i\}_{i\in I}$ that is provided by Proposition 3.21. Given $i \in I$ we define

$$\begin{aligned} p(U_i \times [0,1)) \cup p(f(U_i) \times [0,1)) &\xrightarrow{\Psi_i} V_i \times (-1,1) \\ x &\mapsto \begin{cases} (\Phi_i(y), t), & \text{if } x = p(y,t) \text{ with } y \in U_i \text{ and } t \in [0,1), \\ (\Phi_i(f^{-1}(y)), -t), & \text{if } x = p(y,t) \text{ with } y \in f(U_i) \text{ and } t \in [0,1). \end{cases} \end{aligned}$$

Using (a) and (b) one easily verifies that the charts from (α) and (β) define a smooth n-dimensional atlas for W. (We refer to Figure 208 for an illustration.)

Now assume that A and B are compact. Using Proposition 10.11 one can show, with some more effort, that the smooth structure that we had just defined on W does not depend

on the choice of the collar neighborhood. Put differently, the smooth structure on W is canonical in the sense that it does not depend on any choices.

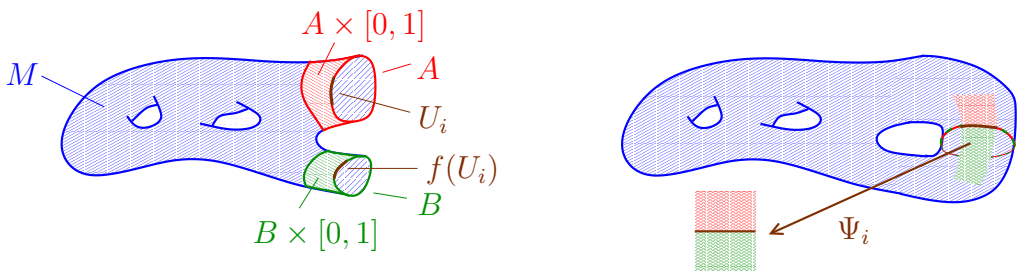

FIGURE 208.

As usual we still have to deal with the slightly annoying task of showing that W is Hausdorff and second-countable:

(i) We leave it as an exercise to show, using (a) and (b) above, that W is Hausdorff.

(ii) Let $\mathcal{B} = \{B_i\}_{i\in I}$ be a countable basis for the topology of M. Once again we leave it as an exercise to verify, using (a) and (b) above, that

$$\big\{B_i \cap M'\big\}_{i\in I} \;\cup\; \big\{p\big(((B_i \cap A) \cup (f(B_i \cap A))) \times [0, \tfrac{1}{2})\big)\big\}_{i\in I}$$

is a basis for the topology of W. Since this is a countable family of sets we see that W is second-countable.

This concludes the proof of statement (1) of the proposition.

We turn to the proofs of the remaining statements:

(2) This statement follows almost immediately from inspecting the atlas we had just constructed. We leave the details to the reader.

(3) This statement follows immediately from Lemma 1.65 (4).

(4) The atlas that we gave above for $W = M/a \sim f(a)$ has a chart of type (i) for every point in $M \setminus (\partial M \setminus (A \cup B))$ and a chart of type (ii) for every point in $\partial M \setminus (A \cup B)$. Therefore it follows from Proposition 3.21 (1) that the boundary of $W = M/a \sim f(a)$ is given by $\partial M \setminus (A \cup B)$.

(5) The final statement can be proved once again using the Collar Neighborhood Theorem 10.10. We leave the verification of this statement as a slightly annoying exercise to the dedicated reader. □

For many purposes and constructions it does not make a difference if we modify a map by a diffeotopy. For example we have the following lemma which often gets used implicitly.

Lemma 10.13. *Let M be an n-dimensional manifold (we do not assume that M is connected) with compact boundary. Let A and B be two distinct compact boundary components of M. Furthermore let f_0 and f_1 be two diffeomorphisms from A to B. If f_0 and f_1 are diffeotopic, then the results of gluing via f_0 respectively via f_1 are diffeomorphic, i.e. we have*

a diffeomorphism

$$M/x \sim f_0(x) \;\cong\; M/x \sim f_1(x).$$

Furthermore, given a neighborhood of A and given a neighborhood B one can find a diffeomorphism that is the identity outside of the chosen neighborhoods.

Sketch of proof. Since f_0 and f_1 are diffeotopic and since they are diffeomorphisms there exists a diffeotopy $F\colon A \times [0,1] \to A$ from $f_1 \circ f_0^{-1}$ to id_A. With the same approach as in the proof of Lemma 10.6 we can arrange that $F_t = \mathrm{id}_A$ for $t \in [\frac{1}{2}, 1]$.

By the Collar Neighborhood Theorem 10.10 we can pick a collar neighborhood $\partial M \times [0,1]$. (Since A is compact we can, after possibly rescaling, arrange that $A \times [0,1]$ is contained in a given neighborhood of A.) One can now easily verify that

$$\begin{array}{rcl} M/x \sim f_0(x) & \to & M/x \sim f_1(x) \\ y & \mapsto & \begin{cases} y, & \text{if } y \in M \setminus (A \times [0,1]), \\ F(a,t) & \text{if } y = (a,t) \in A \times [0,1] \end{cases} \end{array}$$

is a diffeomorphism. □

10.4. **Gluing submanifolds** $(*)$**.** In the previous section we introduced the notion of a collar neighborhood of the boundary of a given manifold M. In many situations one is also given a proper submanifold N and one would like the collar neighborhood and the submanifold to live in harmony. In this section we will deal with this situation and show that harmony can indeed be achieved. The results in this section are even more technical than in the previous section. Thus it is best to skip this section at first reading and only to look at it when we actually use it later on.

In Proposition 10.12 we saw that if we are given a manifold M (which in many examples will be disconnected) and a diffeomorphism $f\colon \partial M \to \partial M$, then any choice of a collar neighborhood of ∂M lets us view $M/x \sim f(x)$ again as a manifold. Now suppose that we are given a proper submanifold N of M with $f(\partial N) = \partial N$. We would like to view $N/x \sim f(x)$ as a submanifold of $M/x \sim f(x)$. But it is easy to find examples where this is not the case, since in all likelihood $N/x \sim f(x)$ will not be smooth at the gluing points. We refer to Figure 209 for an illustration where we consider $M = ((-\infty, 0] \times \mathbb{R}) \sqcup ([1, \infty) \times \mathbb{R})$ with the obvious gluing and the obvious collar neighborhoods.

If one thinks about this issue for a few minutes then one is almost inexorably lead to the following definition.

Definition. Let M be a manifold with a collar neighborhood $\partial M \times [0,1]$, let N be a proper submanifold of M and let $\epsilon \in [0,1]$. We say that N *is a product with respect to* $\partial M \times [0, \epsilon]$ if the map $\partial N \times [0,\epsilon] \to M \times [0,\epsilon]$ defines a diffeomorphism $\partial N \times [0,\epsilon] \to (M \times [0,\epsilon]) \cap N$.

Example. We consider $M = \mathbb{R} \times [0, \infty)$ with the obvious collar neighborhood $\mathbb{R} \times [0,1]$. Furthermore we consider the proper submanifold N that is illustrated in Figure 210. Note that N is a product with respect to $\mathbb{R} \times [0, \frac{1}{2}]$ but that it is not a product with respect to $\mathbb{R} \times [0,1]$.

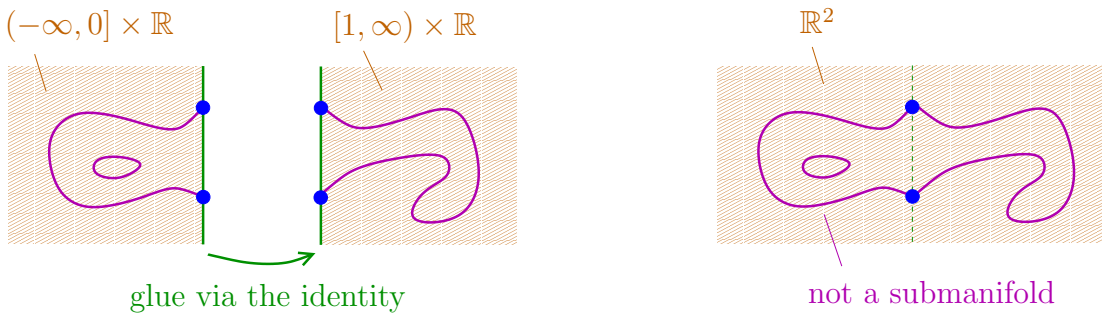

FIGURE 209.

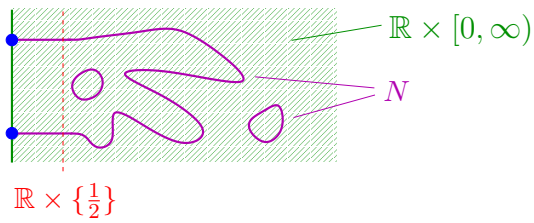

FIGURE 210.

The following proposition gives an approach to circumventing this issue. For better readability it is formatted as if it was statement (6) of Proposition 10.12.

Proposition 10.14. *Let M be an n-dimensional manifold (we do not assume that M is connected). Let A and B be two distinct boundary components of M. Furthermore let $f\colon A \to B$ be a diffeomorphism.*

(6) *Let N be a proper submanifold of M such that f restricts to a diffeomorphism $A \cap N \to B \cap N$. If there exists a collar neighborhood of M such that N is a product with respect to $\partial N \times [0, \epsilon]$ for some $\epsilon > 0$ and if we use this collar neighborhood to define the manifold structure on $M/a \sim f(a)$, then $N/a \sim f(a)$ is a submanifold of $M/a \sim f(a)$.*

Proof. The proof follows easily from the definition of the smooth structure on $M/a \sim f(a)$ as provided in the proof of Proposition 10.12 (1). We will not bore the reader with unnecessary details. □

The question arises whether we can always find such a nice collar neighborhood. For the following theorem, which is a refined version of the above Collar Neighborhood Theorem 10.15, gives an affirmative answer.

Theorem 10.15. (Collar Neighborhood Theorem) *Let M be a manifold. If N is a proper submanifold of M, then M admits a collar neighborhood $\partial M \times [0, 1]$ such that N is a product with respect to $\partial M \times [0, 1]$.*

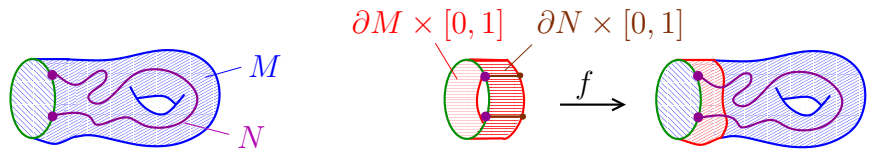

FIGURE 211. Illustration of the Collar Neighborhood Theorem 10.15.

Proof. This statement is precisely [Wall2, Proposition 1.5.6 (ii)]. □

At times one is given a collar neighborhood for the manifold M that one is quite happy with. The following proposition says that we can modify the given submanifold to still obtain the desired statement.

Proposition 10.16. $(*)$ *Let M be a manifold, let N be a compact proper submanifold of M and let $\partial M \times [0,1]$ be a collar neighborhood for M. There exists a diffeotopy F of M rel ∂M and an $\epsilon > 0$ such that $F_0 = \mathrm{id}$ and such that $F_1(N)$ is a product with respect to $\partial M \times [0,\epsilon]$.*

Sketch of proof $(*)$. If ∂M is compact, then we can take $\epsilon = 1$ and the statement follows immediately from the above Collar Neighborhood Theorem 10.15 and the uniqueness statement given by Proposition 10.11.

It ∂M is non-compact (and later on we will be interested in such cases), then we can not use the above "of the shelf argument" and we need to work a little harder. Note that it follows from the hypothesis that N is a proper submanifold that the map

$$p\colon N \cap (\partial M \times [0,1]) \xrightarrow{\text{inclusion}} \partial M \times [0,1] \xrightarrow{(x,t)\mapsto t} [0,1]$$

is a submersion in a neighborhood of ∂N. Since N is compact we see that there exists an $\eta > 0$ such that p is in fact a submersion on $p^{-1}([0,\eta])$. It follows from the Submersion Theorem 3.46 there exists an embedding $\varphi\colon \partial N \times [0,\eta] \to \partial M \times [0,\eta]$ with the following properties:

(1) $\varphi(\partial N \times [0,\eta]) = V \cap (\partial M \times [0,\eta])$,
(2) for each $t \in [0,\eta]$ we have $\varphi(\partial N \times \{t\}) \subset \partial M \times \{t\}$.

Similar to Lemma 3.12 there exists a smooth function $f\colon [0,\eta] \to [0,\eta]$ such that $f(t) = 0$ for $t \in [0, \frac{\eta}{4}]$ and such that $f(t) = t$ for $t \in [\frac{3\eta}{4}, \eta]$. One can now easily verify that

$$N' \;:=\; \{(\varphi(P, f(t)), t) \,|\, P \in \partial N \text{ and } t \in [0,\eta]\} \cup (N \setminus (N \cap (\partial M \times [0,\eta))))$$

is a submanifold that is product with respect to $\partial M \times [0, \frac{\eta}{4}]$. We refer to Figure 212 for an illustration of the argument.

It is not difficult to write down an explicit proper isotopy $E\colon N \times [0,1] \to M$ rel ∂N with $E_0 = \mathrm{id}$ and $E_1(N) = N'$. The existence of the desired isotopy F of M is now a consequence of the Isotopy Extension Theorem 10.21 (2) below. □

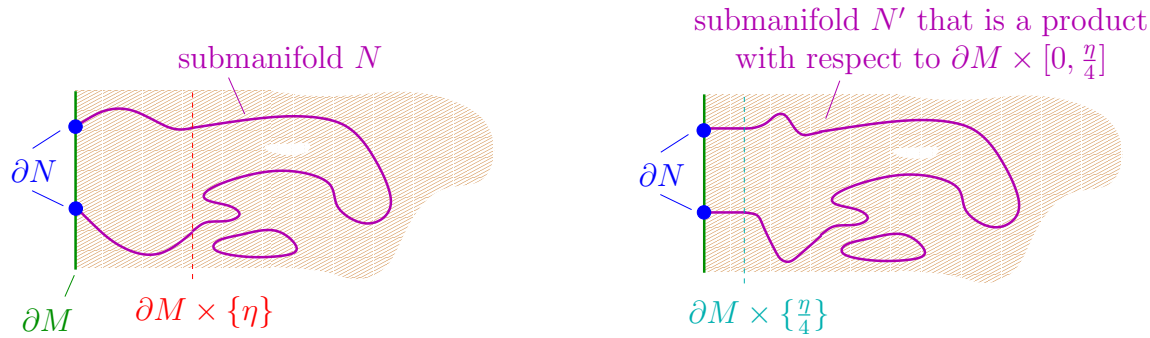

FIGURE 212.

The above results now allow us to prove the following proposition which will be used on several occasions.

Proposition 10.17. *Let M and N be two n-dimensional manifolds with boundary components $A \subset M$ and $B \subset N$ and let $f\colon A \to B$ be a diffeomorphism. Suppose we have chosen collar neighborhoods for ∂M and ∂N so that $M \cup_f N$ comes with a manifold structure. Furthermore let $X \subset M$ and $Y \subset N$ be two proper m-dimensional submanifolds such that $f(X \cap A) = Y \cap B$. Then there exists a proper submanifold $Z \subset M \cup_f N$ with the following three properties:*

(1) *$Z \cap A = X \cap A$ (and thus also $Z \cap B = Y \cap B$),*
(2) *outside of any previously chosen neighborhood of $A = B \subset M \cup_f N$ we have the equality $Z = X \cup_f Y$, and*
(3) *the submanifold Z is homeomorphic to $X \cup_f Y$.*

We refer to Figure 213 for an illustration.

Proof. The proposition can be deduced quite easily from Propositions 10.14 and 10.16. We leave it to the reader to fill in the details. □

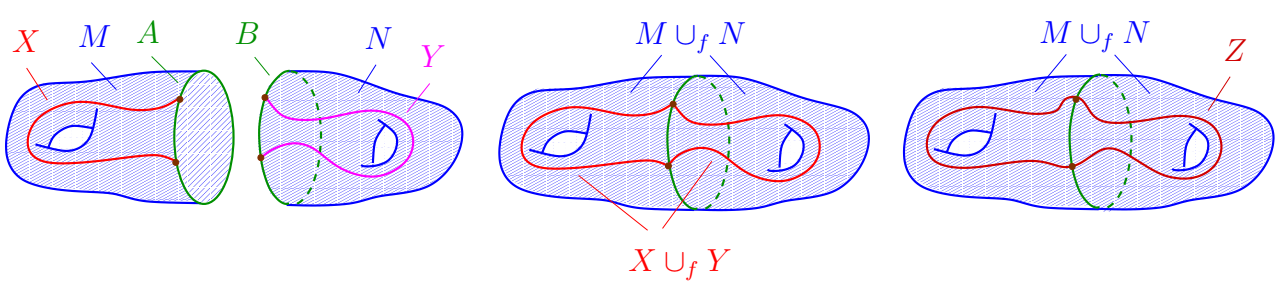

FIGURE 213. Illustration of Proposition 10.17.

10.5. **The push-in of a submanifold** $(*)$**.** In this short section we introduce the following quite natural definition.

Definition. Let W be a manifold with compact boundary and let X be a compact submanifold of ∂W. By the Collar Neighborhood Theorem 10.10 we can pick a collar neighborhood $\mu\colon \partial W \times [0,1] \to W$ and we can pick a collar neighborhood $\nu\colon \partial X \times [0,1] \to X$. Furthermore by Lemma 3.12 we can pick a smooth monotonously increasing function $\varphi\colon [0,1] \to [0,1]$ with $\varphi(0) = 0$, $\varphi(t) > 0$ for $t > 0$ and $\varphi(t) = 1$ for $t \in [\frac{1}{2}, 1]$. We consider the map

$$\begin{array}{rcl} f\colon X & \to & W \\ P & \mapsto & \begin{cases} \mu(P, \varphi(t)), & \text{if } P = \nu(Q,t) \text{ for some } Q \in \partial X \text{ and some } t \in [0,1], \\ \mu(P,1), & \text{otherwise.} \end{cases} \end{array}$$

We call $f(X)$ the *push-in of* X.[228] We refer to Figure 214 for an illustration.

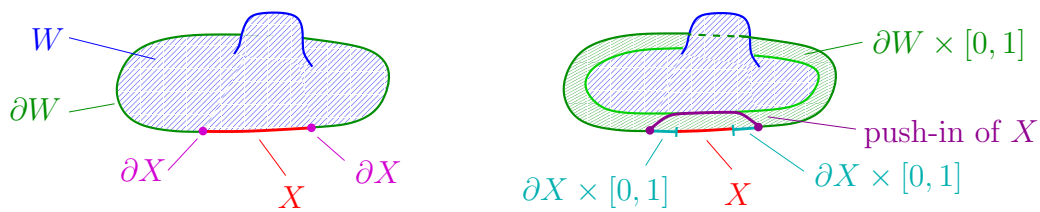

FIGURE 214.

The following lemma summarizes the key properties of push-ins.

Lemma 10.18. *Let W be a manifold with compact boundary and let X be a compact submanifold of ∂W. The push-in Y of X is a compact proper submanifold of W whose boundary equals $\partial Y = \partial X$.*

Proof. We continue with the notation from the definition of the push-in. First we claim that f is smooth. This can be seen as follows: The map f is evidently smooth on $\partial X \times [0,1)$ and $X \setminus (\partial X \times [0, \frac{3}{4}))$. Since these sets are open and since they cover all of X we see that f is indeed smooth.

Now it is straightforward to see that f is a proper embedding. It follows from Proposition 10.1 (2) that $f(X)$ is a proper submanifold. It is now straightforward to verify that $Y := f(X)$ has the desired properties. □

10.6. **The Tubular Neighborhood Theorem I.** The following definition resembles the definition of the collar of the boundary of a manifold.

Definition. Let M be an m-dimensional manifold and let N be a closed[229] n-dimensional submanifold.

[228] It follows from Proposition 10.11 that the push-in of X is unique in a suitable sense.

[229] Here by "closed" we mean that N is closed as a manifold, i.e. N is compact and $\partial N = \varnothing$.

(1) A *trivial tubular neighborhood for* N is an embedding $F\colon \overline{B}^{m-n} \times N \to M$ such that for any $P \in N$ we have $F(0, P) = P$.
(2) If M and N are oriented, then we say that a trivial tubular neighborhood for N is *orientation-preserving* if the embedding $F\colon \overline{B}^{m-n} \times N \to M$ is orientation-preserving where we equip $\overline{B}^{m-n} \times N$ with the product orientation introduced on page 205.

Example. We consider $M = S^1 \times S^1$ together with the submanifold $N = S^1 \times \{1\}$. The map

$$\begin{array}{ccccc} \overbrace{[-1,1]}^{=\overline{B}^1} & \times & \overbrace{S^1}^{=N} & \to & S^1 \times S^1 \\ & & (t, z) & \mapsto & (e^{it}, z) \end{array}$$

is a trivial tubular neighborhood for N, we refer to Figure 215 for an illustration.

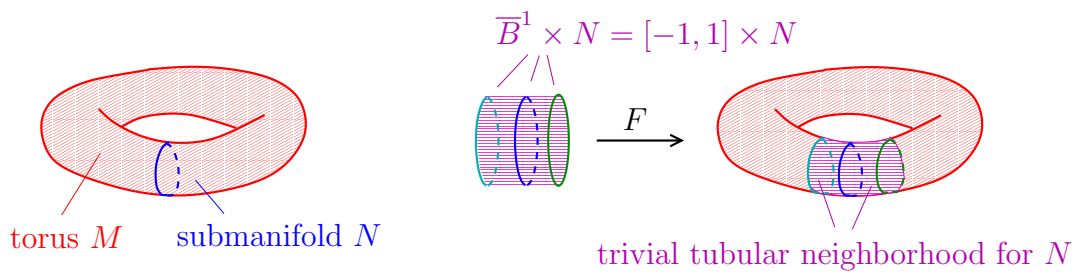

FIGURE 215.

The following Tubular Neighborhood Theorem guarantees the existence of (orientation-preserving) trivial tubular neighborhoods in some situations.

Theorem 10.19. (Tubular Neighborhood Theorem) *Let M be an m-dimensional manifold and let N be a closed n-dimensional submanifold. Suppose we are in one of the following four situations:*

(1) *N is zero-dimensional,*
(2) *N is one-dimensional and M is orientable,*
(3) *N is of codimension one and M and N are both orientable,*
(4) *we have $M = \mathbb{R}^m$ or $M = S^m$ and N is a closed orientable submanifold of codimension two,*

then N admits a trivial tubular neighborhood $F\colon \overline{B}^{m-n} \times N \to M$. Furthermore, if M and N are oriented, then we can find an orientation-preserving trivial tubular neighborhood $F\colon \overline{B}^{m-n} \times N \to M$.[230]

[230] If N is 0-dimensional, then $\overline{B}^{m-n} \times N$ is just a finite union of copies of $\overline{B}^m$ and we give it the obvious orientation.

Example. In Figure 216 we illustrate the first three of the above cases. Note that in the third example we consider the case that M is a 3-dimensional ball and N is a 2-dimensional disk. In particular in this case N actually has a boundary. This artistic freedom is due to the fact that it is rather challenging to draw a 3-dimensional manifold together with a tubular neighborhood of a closed 2-dimensional submanifold.

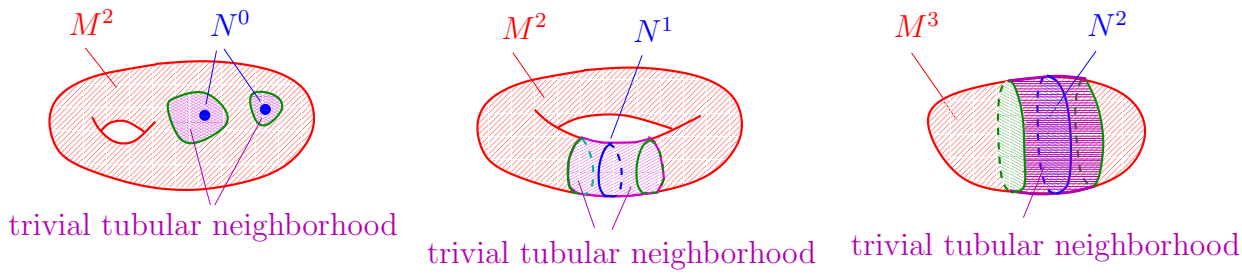

FIGURE 216.

Sketch of proof. In the following we provide a sketch of the argument if $M = \mathbb{R}^n$ and if N is a closed k-dimensional submanifold of $\mathbb{R}^n$. In the remainder of this discussion we use Proposition 3.32 to think of the tangent spaces of any submanifold of some $\mathbb{R}^m$ as a subvector space of $\mathbb{R}^m$. Given $P \in N$ we write

$$(T_P N)^\perp \;=\; \{v \in \mathbb{R}^n \,|\, \langle v, w\rangle = 0 \text{ for all } w \in T_P N\}$$

and we write $VN := \{(v, P) \,|\, P \in N \text{ and } v \in (T_P N)^\perp\}$. Without too much effort one can equip VN with an "obvious" structure of an n-dimensional submanifold of $\mathbb{R}^n \times \mathbb{R}^n$. We consider the map

$$\begin{array}{rcl} f\colon VN & \to & \mathbb{R}^n \\ (v, P) & \mapsto & P + v. \end{array}$$

One can easily verify that this map is smooth and that for each $P \in N$ the differential of f at $(0, P)$ is an isomorphism. It follows from the Inverse Mapping Theorem 3.33 that for each $P \in N$ there exists an open neighborhood U_P of P and an $\epsilon_P > 0$ such that f restricted to $\{(Q, w) \,|\, Q \in U_P, \text{ and } w \in (T_Q N)^\perp \text{ with } \|w\| < \epsilon_P\}$ is an embedding. But since N is compact this implies that there exists an $\epsilon > 0$ such that the restriction of f to

$$W \;:=\; \{(P, w) \,|\, P \in N, \text{ and } w \in (T_P N)^\perp \text{ with } \|w\| \le \epsilon\}$$

is an embedding. We refer to Figure 217 for an illustration.

We claim that W is our trivial tubular neighborhood. To show this we need to use our hypothesis on the (co-) dimensions and orientability of M and N. In fact it follows from [Hau, Proposition 9.2.3] and [MiS, Axiom 3] that in our situations there exists a diffeomorphism

$$\mathbb{R}^{n-k} \times N \;\to\; VN$$

such that for each P the map restricts to an isomorphism $\mathbb{R}^{n-k} \times \{P\} \to (T_P N)^\perp \times \{P\}$ of vector spaces. Using this diffeomorphism one can now fairly easily show that W is diffeomorphic to $\overline{B}^{n-k} \times N$.

The proof of the general case of the tubular neighborhood theorem follows along the same lines. But in general one needs to equip M with a "Riemannian structure" and instead of adding normal vectors (which no longer makes any sense) one needs to study the "exponential map" defined by geodesics. This approach constructs the analogue of W as above, see [Wall2, Theorem 2.3.3] for details. (See also [Kos, Section III.2], [Bre, Theorem II.11.14] and [Le2, Theorem 6.24] for related and similar results.) Once again appealing to [Hau, Proposition 9.2.3] and [MiS, Axiom 3] (for the last case we also need [Er, p. 100] and [Mi12, p. 44], see also [Bre, Corollary VII.14.6]) one sees that W is diffeomorphic to $\overline{B}^{n-k} \times N$.[231] □

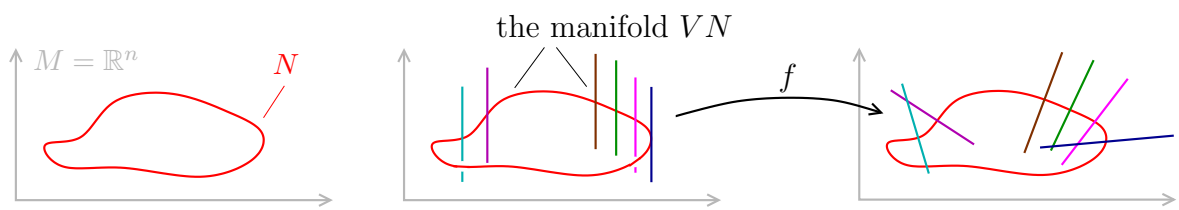

FIGURE 217. Illustration for the proof of the Tubular Neighborhood Theorem 10.19.

Remark. As many readers might already know, there exists a generalization of the Tubular Neighborhood Theorem 10.19 that deals with any compact proper submanifold N. The precise definition of a tubular neighborhood is in general somewhat lengthy and technical (and frankly often done imprecisely in the literature). Thus we postpone the formulation to a later point when we really need the more general case.

The following proposition tells us to what degree trivial tubular neighborhoods are unique.

Proposition 10.20. (Uniqueness of trivial tubular neighborhoods) *Let M be an m-dimensional manifold and let N be a closed n-dimensional submanifold. Furthermore let $F, G\colon \overline{B}^{m-n} \times N \to M$ be two trivial tubular neighborhoods for N. Then there exists a diffeotopy*

$$H\colon M \times [0,1] \;\to\; M$$

rel N[232] *from $H_0 = \mathrm{id}_M$ to a diffeomorphism $\Phi = H_1$ such that the following two statements hold:*

[231] The alert reader will correctly suspect that right now we are swiping lots of technical stuff under the rug.

[232] Recall that this means that $H(P,t) = P$ for all $P \in N$ and $t \in [0,1]$.

(1) *The diffeomorphism* $\Phi = H_1$ *restricts to diffeomorphisms*

$$\begin{aligned} \Phi\colon F(\overline{B}^{m-n} \times N) &\to G(\overline{B}^{m-n} \times N) \\ \Phi\colon M \setminus F(B^{m-n} \times N) &\to M \setminus G(B^{m-n} \times N). \end{aligned}$$

(2) *For all* $P \in N$ *the diffeomorphism* $\Phi = H_1$ *restricts to a boundary preserving diffeomorphism*

$$\Phi\colon F(\overline{B}^{m-n} \times \{P\}) \to G(\overline{B}^{m-n} \times \{P\})$$

and the self-diffeomorphism $G^{-1} \circ \Phi \circ F$ *of* $\overline{B}^{m-n} \times \{P\} = \overline{B}^{m-n}$ *is given by multiplication by a matrix* $A \in \mathrm{O}(m-n)$.

If M *and* N *are oriented and if* F *and* G *are orientation-preserving, then all the above diffeomorphisms are orientation-preserving, in particular the matrix* A *mentioned in* (2) *lies in* $\mathrm{SO}(m-n)$.

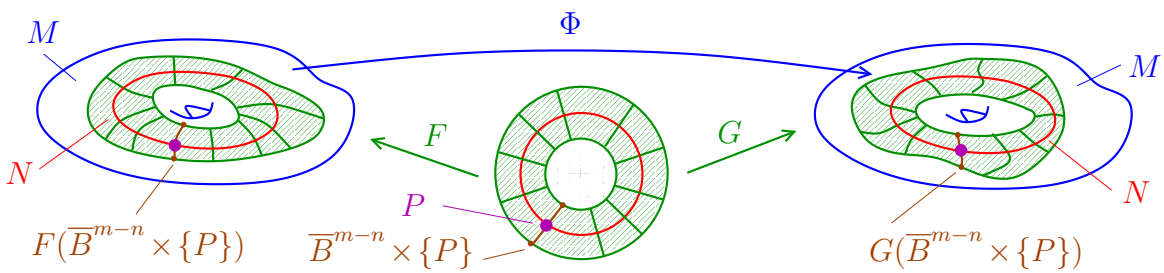

FIGURE 218. Illustration of Proposition 10.20.

Proof. A proof for the proposition is given in [Wall2, Theorem 2.5.5 and Theorem 2.5.8]. We refer to [BJ, Theorem 12.13], [Kos, Corollary III.3.2] and [Lan3, Theorem IV.6.2] for alternative approaches, which, with a little bit of mental gymnastics, can also be used to prove the proposition.

The last statement that, under the given hypotheses, the diffeomorphisms are orientation-preserving are a consequence of Lemma 10.5 and the fact that id_M is orientation-preserving. □

Convention. In the following, by a slight abuse of language, we often refer to $F(\overline{B}^{m-n} \times N)$ as a *trivial tubular neighborhood of* N. It follows immediately from Proposition 10.2 that a trivial tubular neighborhood of N is in fact a neighborhood of N in the sense of the definition on page 48.

Before we can state the next theorem we need to introduce one more innocuous definition.

Definition. Let M be a manifold. We say that a diffeotopy $F\colon M \times [0,1] \to M$ has *compact support* if there exists a compact subset $K \subset M$ such that $F(x,t) = x$ for all $x \notin K$ and all $t \in [0,1]$.

Examples.

(1) Evidently every diffeotopy of a compact manifold has compact support.
(2) The diffeotopy $F\colon \mathbb{R} \times [0,1] \to \mathbb{R}$ given by $F(x,t) = x + t$ does *not* have compact support.
(3) In Figure 219 we sketch a non-trivial diffeotopy of $\mathbb{R}$ with compact support.

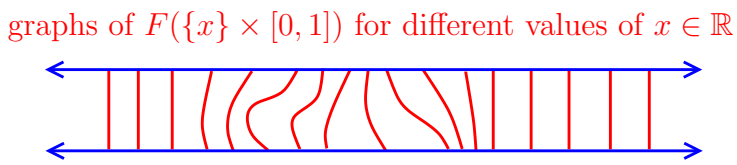

FIGURE 219.

The following theorem is one of the key technical tools for dealing with manifolds.

Theorem 10.21. (Isotopy Extension Theorem) *Let M be a manifold and let N be a compact manifold.*

(1) *Let $f\colon N \to M \backslash \partial M$ be an embedding. If $F\colon N \times [0,1] \to M \backslash \partial M$ is a smooth isotopy from f to some embedding f', then there exists a diffeotopy $G\colon M \times [0,1] \to M$ rel some neighborhood of ∂M with $G_0 = \mathrm{id}$ such that*
$$G(f(x),t) \;=\; F(x,t) \quad \text{for all } x \in N \text{ and } t \in [0,1].$$
(2) $(*)$ *Let $f\colon N \to M$ be a proper embedding. If $F\colon N \times [0,1] \to M$ is a proper smooth isotopy from f to some proper embedding f', then there exists a diffeotopy $G\colon M \times [0,1] \to M$ with $G_0 = \mathrm{id}$ such that*
$$G(f(x),t) \;=\; F(x,t) \quad \text{for all } x \in N \text{ and } t \in [0,1].$$
Furthermore, if F is an isotopy rel ∂N, then we can choose G to be a diffeotopy rel ∂M.

In both cases we can furthermore arrange that the diffeotopy G has compact support.

Examples.

(1) Let M be a manifold. The Isotopy Extension Theorem 10.21 often gets applied as follows: N is a submanifold in $M \setminus \partial M$ and we start out with the inclusion map $i\colon N \to M$. The Isotopy Extension Theorem 10.21 thus loosely says, that if we deform N in M, then we can do so by "dragging M" along.
(2) In fact often we apply (1) to the special case that $N = \{P\}$ consists of a single point $P \in M \setminus \partial M$. In this case a smooth isotopy of P is just a smooth path $F\colon [0,1] \to M \setminus \partial M$ with $F(0) = P$. The Isotopy Extension Theorem 10.21 says that there exists a diffeotopy $G\colon M \times [0,1] \to M$ rel a neighborhood of ∂M from the identity to a diffeomorphism G_1 with $G(P,t) = F(t)$ for all $t \in [0,1]$. We refer to Figure 220 for an illustration.

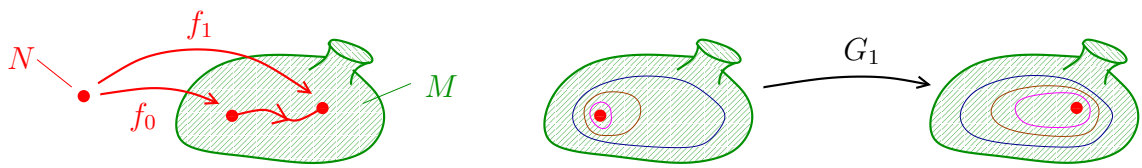

FIGURE 220. Illustration of the Isotopy Extension Theorem 10.21.

Proof of the Isotopy Extension Theorem 10.21. The theorem follows almost immediately from the statements and the proofs of Theorem 2.4.2 and Theorem 2.4.6 of [Wall2]. Note that the results of [Wall2] do not explicitly say that we can assume that $G_0 = \mathrm{id}$, but a quick look at the proof of [Wall2, Theorem 2.4.2] shows that this is the case. Similarly in (2) the fact that in the given situation we can choose G to be a diffeotopy rel ∂M is not mentioned in [Wall2], but it does follow from the proof. We also refer to [Kos, Theorem II.5.2], [Hirs2, Theorem 8.1.3] and [Pal3, Chapter 6] for related results. □

The following corollary to the Isotopy Extension Theorem 10.21 is quite useful.

Corollary 10.22. *Let M be a manifold without boundary and let N be a compact manifold. Let $f\colon N \to M$ and $g\colon N \to M$ be two embeddings. If there exists a smooth isotopy $F\colon N \times [0,1] \to M$ from f to g, then there exists a diffeomorphism*[233] *from $M \setminus f(N)$ to $M \setminus g(N)$.*

Proof. By the Isotopy Extension Theorem 10.21 there exists a diffeotopy $G\colon M \times [0,1] \to M$ with $G_0 = \mathrm{id}$ such that $G_1(f(N)) = g(N)$. But this means that $G_1\colon M \to M$ is a diffeomorphism with $G_1(f(N)) = g(N)$. It follows that G_1 restricts to a diffeomorphism $M \setminus f(N) \to M \setminus g(N)$. □

Example. The statement of Corollary 10.22 and the statement of the Isotopy Extension Theorem 10.21 are quite subtle. In Figure 221 we illustrate two embeddings $f, g\colon S^1 \to \mathbb{R}^3$ and we illustrate a map $F\colon S^1 \times [0,1] \to \mathbb{R}^3$ with $F_0 = f$, $F_1 = g$ and with the property that every single $F_t\colon S^1 \to \mathbb{R}^3$ is an embedding. But as should be pretty clear (and we will give a rigorous proof later on) the complements $\mathbb{R}^3 \setminus f(S^1)$ and $\mathbb{R}^3 \setminus g(S^1)$ are *not* diffeomorphic. This shows that in the formulations of Corollary 10.22 and the Isotopy Extension Theorem 10.21 it is essential that the map F is smooth on all of $N \times [0,1]$.

We also have the following proposition which is at times quite useful.

Proposition 10.23. *Let M be a connected n-dimensional manifold.*

(1) *Given any two points P and Q in $M \setminus \partial M$ there exists a diffeotopy rel a neighborhood of ∂M from the identity to a diffeomorphism $\Phi\colon M \to M$ with $\Phi(P) = Q$.*

[233] Since N is compact we know by Lemmas 1.37 and 1.18 that $M \setminus f(N)$ and $M \setminus g(N)$ are open subsets of M, in particular they are manifolds in their own right.

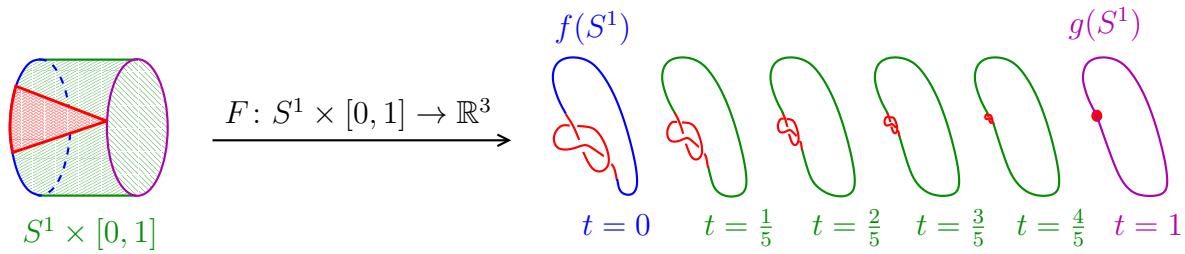

FIGURE 221.

(2) *If $n \geq 2$, then given distinct points $P_1, \ldots, P_m$ and distinct points $Q_1, \ldots, Q_m$ in $M \setminus \partial M$ there exists a diffeotopy rel a neighborhood of ∂M from the identity to a diffeomorphism $\Phi\colon M \to M$ with $\Phi(P_i) = Q_i$ for $i = 1, \ldots, m$.*

In both cases we can furthermore arrange that the diffeotopy has compact support. (Note that if M is oriented, then it follows from Lemma 10.5 that in both cases Φ is in fact orientation-preserving.)

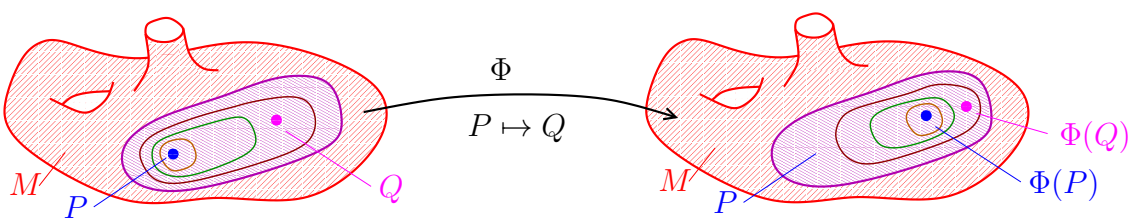

FIGURE 222. Illustration of Proposition 10.23.

In the proof of Proposition 10.23 we will make use of the following lemma which will be useful in its own right.

Lemma 10.24. *Let M be a manifold.*

(1) *Any path $\gamma\colon [0,1] \to M \setminus \partial M$ is path-homotopic in $M \setminus \partial M$ to a smooth path. (Here recall "path-homotopic" means that we keep the endpoints fixed).*
(2) *If M is connected, then any two points P, Q in $M \setminus \partial M$ can be connected by a smooth path in $M \setminus \partial M$.*

Proof of Lemma 10.24.

(1) The first statement follows from Exercise 10.11 applied to $W := M \setminus \partial M$.
(2) Now suppose that M is connected. From Lemma 3.8 and Exercise 10.5 we obtain that $M \setminus \partial M$ is path-connected. Thus the second statement follows from the first statement. □

Now we can move on to the actual proof of Proposition 10.23.

Proof of Proposition 10.23. Let M be a connected n-dimensional manifold.

(1) Let P, Q be two points in $M \setminus \partial M$. By Lemma 10.24 there exists a smooth path $F\colon [0,1] \to M \setminus \partial M$ from P to Q. The desired statement follows now from the Isotopy Extension Theorem 10.21, using the above example.

(2) $(*)$We prove this statement by induction on m. We dealt with the case $m = 1$ in (1). Now suppose that we know the statement for some $m \in \mathbb{N}_{\geq 2}$. Thus let $P_1, \dots, P_{m+1}$ and $Q_1, \dots, Q_{m+1}$ be two sets of distinct points in $M \setminus \partial M$. By induction we can without loss of generality already assume that $P_i = Q_i$ for $i = 1, \dots, m$.[234] Now pick disjoint closed n-balls around $P_1, \dots, P_m$ that are disjoint from $P := P_{m+1}$ and $Q := Q_{m+1}$. We denote by W the manifold obtained from M by removing the corresponding open balls.[235] Since $n \geq 2$ we obtain from Exercise 10.7 (2) that W is still connected. Thus we can apply (1) to P and Q in W to obtain a diffeotopy of W with all the desired properties. Since the diffeotopy is the identity near the boundary of W we can extend it via the identity to a diffeotopy of all of M. □

On one occasion later on we will need the following proposition.

Proposition 10.25. $(*)$ *Let M be a connected* non-orientable *n-dimensional manifold, let $P_1, \dots, P_m$ be points in $M \setminus \partial M$ and let $I \subset \{1, \dots, m\}$ be a subset. There exists a diffeotopy rel a neighborhood of ∂M from the identity to a diffeomorphism $\Phi\colon M \to M$ with the following properties:*

(1) *for all $i \in \{1, \dots, m\}$ we have $\Phi(P_i) = P_i$,*
(2) *the diffeotopy fixes all P_i with $i \notin I$,*
(3) *the map $D\Phi_{P_i}\colon T_{P_i}M \to T_{P_i}M$ is orientation-preserving if and only if $i \in I$.*

Furthermore can assume that the diffeotopy has compact support.

Proof. We leave it to the reader to use the paths from Lemma 8.5 to modify the proof of Proposition 10.23 to obtain a proof of the proposition. □

We conclude with the following theorem which follows easily from [Wall2, Proposition 2.4.7].

Theorem 10.26. (Extension Theorem)$(*)$ *Let $f\colon N \to M$ be an embedding of a manifold with boundary into a manifold M such that $f(N) \subset M \setminus \partial M$. Then there exists an embedding*[236]

$$f\colon \big(N \sqcup (\partial N \times [0,1])\big)/_{\partial N = \partial N \times 0} \;\to\; M$$

which restricts to the original f on N and such that the image lies in $M \setminus \partial M$.

[234]The super vigilant reader will have noticed that implicitly we are using Lemma 10.6.

[235]Here we implicitly use Lemma 3.22.

[236]Here the topological space $\big(N \sqcup (\partial N \times [0,1])\big)/_{\partial N = \partial N \times 0}$ is understood to be the topological space $(N \sqcup (\partial N \times [0,1]))/\sim$ where $P \in \partial N$ is equivalent to $P \times \{0\}$ on $\partial N \times [0,1]$.

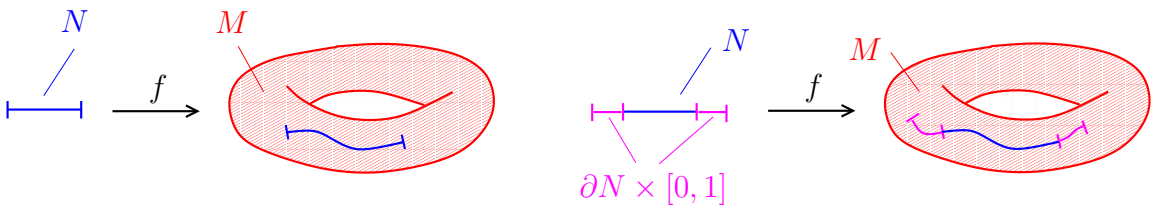

FIGURE 223. Illustration of the Extension Theorem.

10.7. **The connected sum operation.** In this section we introduce the connected sum of two manifolds. As we will see this construction combines features from the last two sections.

Definition. Let $n \in \mathbb{N}$. Let M and M' be two connected non-empty n-dimensional manifolds.

(1) Suppose that at least one of M or M' is non-orientable. We pick two embeddings $\varphi\colon \overline{B}^n \to M \setminus \partial M$ and $\varphi'\colon \overline{B}^n \to M' \setminus \partial M'$ and we define the *connected sum of M and M'* as

$$M\#M' \;:=\; \big(M \setminus \varphi(B^n)\big) \sqcup \big(M' \setminus \varphi'(B^n)\big) \,/\, \varphi(P) = \varphi'(P) \text{ for all } P \in S^{n-1}.$$

(2) If both M and M' are orientable, then we pick orientations for M and M'. Let $\varphi\colon \overline{B}^n \to M\setminus\partial M$ and $\varphi'\colon \overline{B}^n \to M'\setminus\partial M'$ be embeddings such that φ is orientation-preserving and such that φ' is orientation-reversing. As before we define the *connected sum of the oriented manifolds M and M'* as

$$M\#M' \;:=\; \big(M \setminus \varphi(B^n)\big) \sqcup \big(M' \setminus \varphi'(B^n)\big) \,/\, \varphi(P) \sim \varphi'(P) \text{ for all } P \in S^{n-1}.$$

For completeness we define the connected sum of an empty manifold with another connected manifold M to be M, i.e. $\varnothing\#M := M$.[237]

Example.

(1) In Figure 224 we sketch that the connected sum of two tori is diffeomorphic to the surface of genus two.[238]

(2) The connected sum of an n-dimensional manifold M with S^n is diffeomorphic to M. Indeed, this can be seen as follows: in the construction of the connected sum $M\#S^n$ we consider the ball $S^n_{\geq 0}$ in S^n. Since $S^n \setminus S^n_{>0} = S^n_{\leq 0}$ is again a closed ball it follows easily that $M\#S^n$ is diffeomorphic to M.

[237]The reader will surely benignly overlook the fact that in some of the proofs down the line we do not deal with this special separately.

[238]The picture should be pretty convincing, but it would be fairly painful to try to prove the statement rigorously using the official definition of the surface of genus 2 as the quotient of an octagon. This is a typical example where one is quite content to work with a convincing picture instead of providing a rigorous, but much less instructive argument.

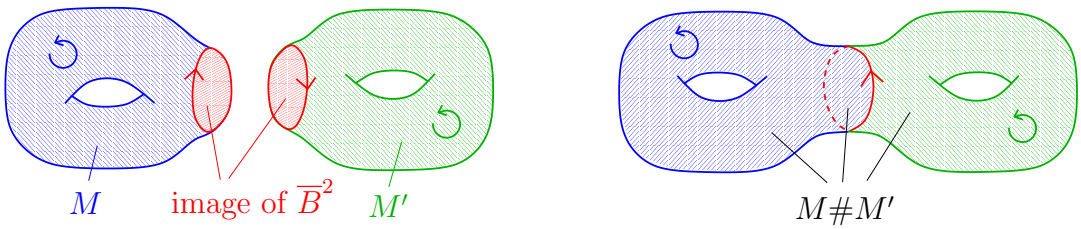

FIGURE 224.

Proposition 10.27. *Let $n \in \mathbb{N}$. Let M and M' be two connected n-dimensional manifolds. (If both M and M' are orientable, then we demand that M and M' are oriented.) Let $\varphi\colon \overline{B}^n \to M \setminus \partial M$ and $\varphi'\colon \overline{B}^n \to M' \setminus \partial M'$ be embeddings. If M and M' are orientable, then we demand that φ is orientation-preserving and that φ' is orientation-reversing. The following three statements hold:*

1. *The resulting connected sum $M\#M'$ is canonically an n-dimensional manifold.*
2. *The diffeomorphism type of $M\#M'$ does not depend on the choice of φ and φ'.*
3. *If M and M' are oriented, then the manifold $M\#M'$ admits a unique orientation that coincides with the orientations of $M \setminus \varphi(B^n)$ and $M' \setminus \varphi'(B^n)$.*

In the proof of Proposition 10.27 we will need the following theorem which was originally proved by Richard Palais [Pal] in 1960.

Theorem 10.28. *Let M be an n-dimensional manifold. (If M is orientable, then we pick an orientation for M.) Let $\varphi_1, \dots, \varphi_m\colon \overline{B}^n \to M \setminus \partial M$ and $\psi_1, \dots, \psi_m\colon \overline{B}^n \to M \setminus \partial M$ be two sets of m embeddings of $\overline{B}^n$ with disjoint images. (If M is orientable, then we demand that all φ_i and ψ_i are orientation-preserving or that all are orientation-reversing.) If $n \geq 2$ or if $m = 1$, then there exists a diffeotopy*

$$F\colon M \times [0,1] \;\to\; M$$

rel some neighborhood of ∂M from the identity $F_0 = \mathrm{id}_M$ to a diffeomorphism $F_1\colon M \to M$ such that for each $i \in \{1, \dots, m\}$ the following diagram commutes:

$$\begin{tikzcd} & \overline{B}^n \arrow[dl, "\varphi_i"'] \arrow[dr, "\psi_i"] & \\ M \arrow[rr, "F_1", "\cong"'] & & M. \end{tikzcd}$$

Furthermore we can assume that F has compact support. (Note that if M is orientable, then the diffeomorphism F_1 is in fact orientation-preserving by Lemma 10.5).

Proof of Theorem 10.28. Before we start with the actual proof we want to point out that on several occasions we implicitly use Lemma 10.5 which allows us to "compose" smooth isotopies and diffeotopies. We also introduce the notation that given $A \in \mathrm{O}(n)$ we denote by $\rho(A)$ the diffeomorphism of $\overline{B}^n$ that is given by multiplication by A.

For $i = 1, \dots, m$ we write $P_i := \varphi_i(0)$ and $Q_i := \psi_i(0)$. If $n \geq 2$ or if $m = 1$, then we can apply Proposition 10.23 so that we can arrange that $P_i = Q_i$ for $i = 1, \dots, m$.

For a short period we consider the cases that M is orientable and non-orientable separately.

(1) Suppose that M is orientable. Recall that in this case we assume that M is in fact oriented. Furthermore we assume that all the φ_i, ψ_i are either orientation-preserving or orientation-reversing. In particular for each $i \in \{1, \dots, m\}$ the map $D(\psi_i^{-1} \circ \varphi_i) \colon T_0\overline{B}^n \to T_0\overline{B}^n$ is orientation-preserving.

(2) Suppose that M is non-orientable. We denote by $I \subset \{1, \dots, m\}$ the set of i's for which $D(\psi_i^{-1} \circ \varphi_i) \colon T_0\overline{B}^n \to T_0\overline{B}^n$ is orientation-reversing. We apply Proposition 10.25 to I. Using the resulting diffeotopy we can henceforth assume that each $D(\psi_i^{-1} \circ \varphi_i) \colon T_0\overline{B}^n \to T_0\overline{B}^n$ is in fact orientation-preserving.

We continue with the common discussion.

We observe that $\varphi_1, \dots, \varphi_m$ and $\psi_1, \dots, \psi_m$ are trivial tubular neighborhoods for the closed 0-dimensional submanifold $N = \{P_1, \dots, P_m\}$. Thus it follows from Proposition 10.20 that there exist matrices $A_1, \dots, A_m \in \mathrm{O}(n)$ and a smooth isotopy rel $N = \{P_1, \dots, P_m\}$ from $\varphi_1 \cup \dots \cup \varphi_m$ to $\psi_1 \circ \rho(A_1) \sqcup \dots \sqcup \psi_m \circ \rho(A_m)$. Since each $D(\psi_i^{-1} \circ \varphi_i) \colon T_0\overline{B}^n \to T_0\overline{B}^n$ is orientation-preserving we see that each A_i lies in fact in $\mathrm{SO}(n)$.

Therefore it follows from Lemma 10.4 that there exists a smooth isotopy from the map $\psi_1 \circ \rho(A_1) \sqcup \dots \sqcup \psi_m \circ \rho(A_m)$ to the map $\psi_1 \sqcup \dots \sqcup \psi_m$. Thus we have found a smooth isotopy from $\varphi_1 \sqcup \dots \sqcup \varphi_m$ to $\psi_1 \sqcup \dots \sqcup \psi_m$. The existence of the desired diffeotopy follows from the Isotopy Extension Theorem 10.21. □

Now we can provide the proof of Proposition 10.27.

Proof of Proposition 10.27.

(1) We write $W := M \setminus \varphi(B^n)$ and $W' := M \setminus \varphi'(B^n)$. By Proposition 10.2 (2) these are both n-dimensional manifolds with boundary components $\varphi(S^{n-1})$ and $\varphi'(S^{n-1})$. Note that by definition we have

$$M \# M' \;=\; (W \sqcup W')/a \sim \varphi'(\varphi^{-1}(a)) \quad \text{where } a \in \varphi(S^{n-1}).$$

It follows from Proposition 10.12 that $M \# M'$ admits a canonical structure of an n-dimensional manifold.

(3) Now we suppose that M and M' are oriented. Recall that in this case we suppose that the map $\varphi \colon \overline{B}^n \to M \setminus \partial M$ is orientation-preserving and furthermore that the map $\varphi' \colon \overline{B}^n \to M' \setminus \partial M'$ is orientation-reversing. We continue with the notation from (1). It follows from Lemma 3.37 that W and W' inherit an orientation from M and M'. The gluing map $\varphi' \circ \varphi^{-1} \colon \varphi(S^{n-1}) \to \varphi'(S^{n-1})$ is orientation-reversing. Thus the desired statement follows from Proposition 10.12.

(2) We need to show that the definition of $M \# M'$ is independent of the choices of the embeddings φ and φ'. Given embeddings $\varphi \colon \overline{B}^n \to M \setminus \partial M$ and $\varphi' \colon \overline{B}^n \to M' \setminus \partial M'$

we now introduce the following cumbersome notation:

$$(M\#M')(\varphi,\varphi') \;:=\; \big(M\setminus\varphi\big(B^n\big)\big)\sqcup\big(M'\setminus\varphi'\big(B^n\big)\big)\,/\,\varphi(P)\sim\varphi'(P) \text{ for all } P\in S^{n-1}.$$

Below we show independence of φ and φ'.

(a) First we consider the case that both M and M' are orientable. Therefore let $\varphi,\psi\colon \overline{B}^n\to M\setminus\partial M$ be two orientation-preserving embeddings and furthermore let $\varphi',\psi'\colon \overline{B}^n\to M'\setminus\partial M'$ be two orientation-reversing embeddings. By Theorem 10.28 there exist in particular diffeomorphisms $F\colon M\to M$ with $F\circ\varphi=\psi$ and $F'\colon M'\to M'$ with $F'\circ\varphi'=\psi'$. One can now easily verify that the map

$$\begin{array}{rcl}(M\#M')(\varphi,\varphi') & \to & (M\#M')(\psi,\psi')\\ x & \mapsto & \begin{cases} F(x) & \text{if } x\in M\setminus\varphi(B^n),\\ F'(x) & \text{if } x\in M'\setminus\varphi'(B^n)\end{cases}\end{array}$$

is a diffeomorphism.

(b) Next we consider the case that M and M' are both non-orientable. Then basically the same argument as in (a) applies. The only difference is that we now apply Theorem 10.28 to the case of non-orientable manifolds, so we no longer have to make any assumptions on whether or not φ,ψ and φ',ψ' are orientation-preserving.

(c) Now consider the case that M is orientable and that M' is non-orientable. Let $\varphi,\psi\colon \overline{B}^n\to M\setminus\partial M$ be two embeddings and let $\varphi',\psi'\colon \overline{B}^n\to M'\setminus\partial M'$ be two embeddings. If φ and ψ are both orientation-preserving or if both are orientation-reversing, then the same argument as in (a) and (b) applies. Now suppose that this is not the case. We denote by $\tau\colon \overline{B}^n\to\overline{B}^n$ any orientation-reversing diffeomorphism (e.g. τ could be the reflection in one of the coordinate axes.) Then as before we see that $(M\#M')(\varphi,\varphi')$ is diffeomorphic to $(M\#M')(\psi\circ\tau,\psi'\circ\tau)$. But $(M\#M')(\psi\circ\tau,\psi'\circ\tau)$ is, basically by definition, the same as $(M\#M')(\psi,\psi')$.

(d) The case that M is non-orientable and that M' is orientable is of course dealt with the same way as in (d). □

Remark. The fact that the diffeomorphism type of the connected sum is well-defined is rather subtle

(1) If M and M' are two *orientable* manifolds, then the diffeomorphism type of the connected sum is defined only if both manifolds are in fact *oriented*, i.e. they are equipped with an orientation. In general the definition does depend on the choice of orientation. More precisely, there exist oriented manifolds M and M' such that $M\#M'$ is not diffeomorphic (in fact not even homeomorphic) to $M\#(-M')$, where $-M'$ denotes as usual the manifold M' with the opposite orientation. We will see such examples later once we have introduced the cup product on cohomology groups.

(2) Often the connected sum operation gets abbreviated as follows: *Given two manifolds we remove an open ball from each manifold and then glue M and M' together,*

along the boundary spheres that we had just created, in such a way that the orientations of the boundaries are opposite. This description is rather dangerous since the diffeomorphism type of the connected sum is only well-defined if we glue the boundary components via the diffeomorphism given by the embeddings of the closed balls.

The name "connected sum" suggests that the connected sum $M\#M'$ is connected. From the pictures this sounds reasonable, but funnily enough, it is not necessarily correct: One can easily see that the connected sum $\mathbb{R}\#\mathbb{R}$ of $\mathbb{R}$ with itself is the disjoint union of two copies of $\mathbb{R}$, thus disconnected! Fortunately, for all intents and purposes that is the only counterexample. More precisely, we have the following lemma.

Lemma 10.29. *If $n \geq 2$, then the connected sum of two connected n-dimensional manifolds is connected.*

Proof $(*)$. The key to proving the lemma is the following claim.

Claim. Let M be an n-dimensional manifold and let $\varphi\colon \overline{B}^n \to M \setminus \partial M$ be an embedding. If M is connected and if $n \geq 2$, then $M \setminus \varphi(B^n)$ is also connected.

We leave the proof of this claim to the reader, see Exercise 10.7 (b). The reader will notice that it takes an effort to provide a completely rigorous proof.

Once we have proved this claim, the lemma is an immediate consequence of the claim, Lemma 1.93 and the fact that for $n \geq 2$ the sphere S^{n-1} is connected. □

We conclude this section with the following lemma.

Lemma 10.30. *Let $n \geq 1$.*

(1) *Given two connected non-empty n-dimensional manifolds X and Y the connected sums $X\#Y$ and $Y\#X$ are diffeomorphic.*
(2) *Given three connected non-empty n-dimensional manifolds X, Y and Z the connected sums $(X\#Y)\#Z$ and $X\#(Y\#Z)$ are diffeomorphic.*

Remark. Let $n \geq 1$. It follows from Lemma 10.30 that given connected n-dimensional manifolds $M_1, \ldots, M_k$ we can unambiguously define the diffeomorphism type of the connected sum $M_1\#\ldots\#M_k$ without having to worry in what order we perform the connected sum of two manifolds.[239]

Proof. The first statement is just an immediate consequence of the definitions, whereas the second statement is a fairly straightforward consequence of Theorem 10.28. We leave it to the reader to fill in the details. □

[239]This argument is familiar from algebra: if a multiplication is associative, then we can unambiguously define the product of finitely many elements using any choice of parenthesis. This sounds reasonable and it is correct, but if one thinks about it, one realizes that this requires a proof, which is for example provided in [DF, p. 19].

10.8. **Knots and their complements.** Before we introduce knots we recall several different ways how we can describe the 3-sphere S^3. More precisely, by definition and Lemma 1.41 we have

$$S^3 = \big\{(z,w) \in \mathbb{C}^2 \big| |w|^2 + |z|^2 = 1\big\} = \big\{(w,x,y,z) \in \mathbb{R}^4 \big| w^2 + x^2 + y^2 + z^2 = 1\big\} \underset{\substack{\uparrow \\ \text{via the stereographic projection from Lemma 1.41}}}{\cong} \mathbb{R}^3 \cup \{\infty\}.$$

We will go back and forth between these models without mentioning these maps. In particular we will always view $\mathbb{R}^3$ as a subset of $S^3 = \mathbb{R}^3 \cup \{\infty\}$.

Definition. A *knot* is a 1-dimensional submanifold of $S^3 = \mathbb{R}^3 \cup \{\infty\}$ that is diffeomorphic to S^1. We say that the knot is *oriented* if it is oriented as a 1-dimensional manifold.

Remark.

(1) It follows from Proposition 10.1 that a subset of S^3 is a knot if and only if it is the image of an embedding $S^1 \to S^3$.[240]

(2) The definition of a knot is supposed to model the "physical objects" that we have in mind and that are sketched in Figure 225. It is therefore perhaps at first not clear why we consider knots in $S^3 = \mathbb{R}^3 \cup \{\infty\}$ instead of knots in $\mathbb{R}^3$. The reason is that topologists prefer, if possible, to work with compact spaces. In particular the compact space $S^3 = \mathbb{R}^3 \cup \{\infty\}$ is often strongly preferable to the non-compact space $\mathbb{R}^3$.

In Figure 225 we give three examples of knots. More precisely, we show 1-dimensional submanifolds of $\mathbb{R}^3$ that we view as 1-dimensional submanifolds of $\mathbb{R}^3 \cup \{\infty\} = S^3$.[241]

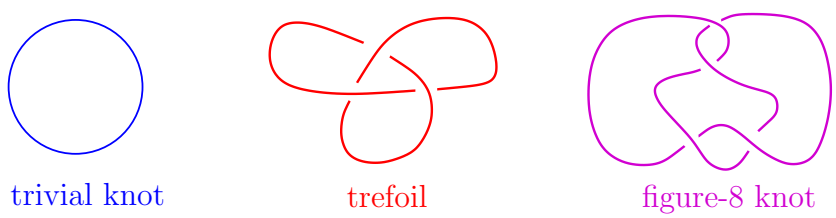

FIGURE 225. The trivial knot, the trefoil knot and the figure-8 knot.

[240]To be more precise, the "if"-direction is a consequence of Proposition 10.1. On the other hand, if $K \subset S^3$ is a knot, then by definition there exists a diffeomorphism $\varphi\colon S^1 \to K \subset S^3$ and it follows easily from the definitions that the map φ viewed as a map from $S^1 \to S^3$ is an embedding whose image is precisely K.

[241]In principle it is possible to give a precise description of these three knots. For example the trivial knot is defined as $\{(x,y,0) \,|\, x^2+y^2=1\} \subset S^3 = \mathbb{R}^3 \cup \{\infty\}$. Later on we will give a precise definition of the trefoil. It is also clear that one can give a precise description of the figure-8 knot, but this description would be painful to write down and it would not add to our understanding. We therefore stick with the picture, with the understanding, that if somebody was challenging us, we could write down a precise description in coordinates. But it is considered very impolite to challenge a topologist to give a rigorous description.

Now we want to say that two knots are "the same" if one can be "deformed" into the other. Fortunately we already have the language to make this picture precise: The notion of a smooth isotopy between submanifolds that we introduced on page 337 makes this notion precise.

For example the three knots shown in Figure 226 are smoothly isotopic. Usually we do not distinguish two knots if they are smoothly isotopic. For example, any knot that is smoothly isotopic to a trivial knot is called *trivial knot*. Sometimes we also say that a knot that is smoothly isotopic to a trivial knot is *trivial knotted*.

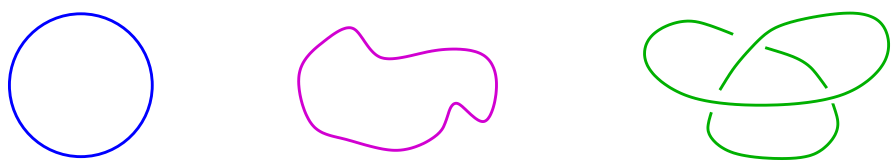

FIGURE 226. The three knots are smoothly isotopic.

Playing around with pictures for some time shows that it might be quite difficult to show that the trefoil is smoothly isotopic to the trivial knot. This arouses the suspicion, that the trefoil is in fact not smoothly isotopic to the trivial knot. This raises the following question.

Question 10.31. *How can we show that the trefoil is not smoothly isotopic to the trivial knot?*

More generally we have the following question.

Question 10.32. *Given a knot K*[242]*, how can we determine whether or not K is smoothly isotopic to the trivial knot?*

The following proposition allows us to turn these two questions into the question, whether two topological spaces are homeomorphic.

Proposition 10.33. *Let K and J be two knots. If they are smoothly isotopic, then the following two statements hold:*

(1) *There exists an orientation-preserving diffeomorphism $\Phi\colon S^3 \to S^3$ with $\Phi(K) = J$. If K and J are oriented, then Φ restricts to an orientation-preserving diffeomorphism $K \to J$.*
(2) *The knot complements $S^3 \setminus K$ and $S^3 \setminus J$ are diffeomorphic, in particular homeomorphic.*

Remark. In fact the converse to Proposition 10.33 (2) also holds. If K and J are two knots such that there exists an orientation-preserving diffeomorphism between the knot complements $S^3 \setminus K$ and $S^3 \setminus J$, then K and J are smoothly isotopic. One might think that

[242]The phrase "given a knot K" is consciously slightly vague.

this should be quite straightforward to show, but it turns out to be surprisingly difficult. A proof was given only in 1989 by Cameron Gordon and John Luecke [GL]. The proof builds on the work of William Thurston [Thu] for which he got the fields medal in 1982.

Proof. Let

$$\begin{array}{rcl} F\colon S^1 \times [0,1] & \to & S^3 \\ (z,t) & \mapsto & F(z,t) \end{array}$$

be a smooth isotopy from a knot K to a knot J. By the Isotopy Extension Theorem 10.21 we can extend the smooth isotopy F to a diffeotopy of S^3. This means in particular that there exists a diffeotopy

$$\begin{array}{rcl} G\colon S^3 \times [0,1] & \to & S^3 \\ (z,t) & \mapsto & G(z,t) \end{array}$$

from the identity to a diffeomorphism $\Phi = G_1\colon S^3 \to S^3$ with $\Phi|_K = F_1$, in particular with $\Phi(K) = J$. By Lemma 10.5 the diffeomorphism Φ is orientation-preserving. The map Φ restricts to an orientation-preserving diffeomorphism $\Phi\colon S^3 \setminus K \to S^3 \setminus J$. □

We conclude this discussion of knots with a definition.

Definition. Let K be an oriented knot in S^3. By the Tubular Neighborhood Theorem 10.19 there exists an orientation-preserving embedding

$$F\colon \overline{B}^2 \times K \;\to\; S^3$$

such that $F(0,P) = P$ for all $P \in K$. For any $P \in K$ we refer to the oriented submanifold[243] $F(S^1 \times \{P\})$ as a *meridian* of K.

It follows easily from Proposition 10.20 that any two meridians of a given knot K are smoothly isotopic in the knot complement $S^3 \setminus K$. More casually speaking, a meridian is a closed curve which circles once around a knot where the orientation is given by the right-hand-rule, i.e. if the thumb points into the direction of the knot, then the fingers point into the direction of the meridian. This rule is illustrated in Figure 228.

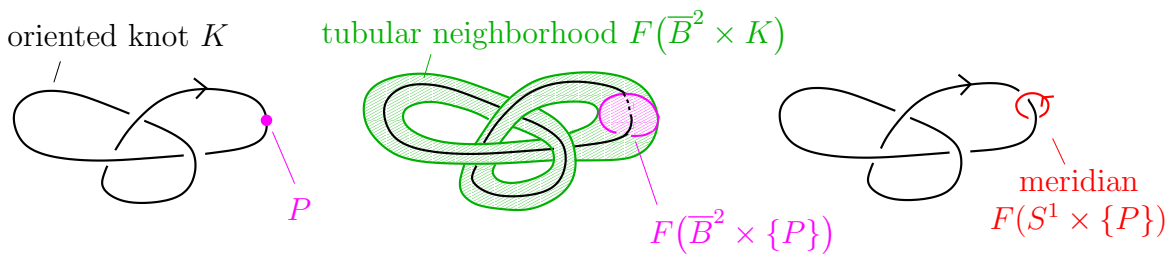

FIGURE 227.

[243]It follows easily from Proposition 10.1 that $F(S^1 \times \{P\})$ is indeed a submanifold of $S^3 \setminus K$.

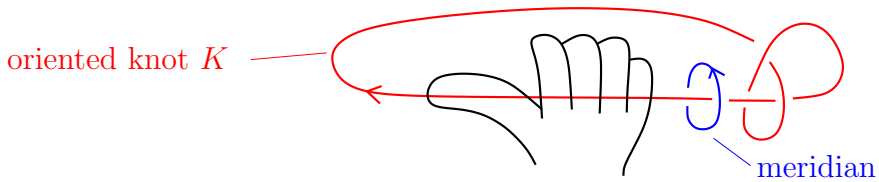

FIGURE 228.

Exercises for Chapter 10.

Exercise 10.1. Let M and N be manifolds and let $f\colon M \to N$ be an immersion. We denote by $\Delta = \{(x,x) \in M \times M \mid x \in M\}$ the "diagonal" of $M \times M$.

(a) Show that there exists an open neighborhood U of the diagonal Δ such that for any $(x,y) \in U \setminus \Delta$ we have $f(x) \neq f(y)$.
(b) We suppose that M is compact. Show that f admits only finitely many double points, i.e. that there exist only finitely many distinct pairs $(x_1,y_1),\dots,(x_n,y_n)$ in $M \times M \setminus \Delta$ such that $f(x_i) = f(y_i)$ for $i = 1,\dots,n$.

Exercise 10.2. Let $f\colon M \to N$ be an immersion between two manifolds without boundary. Show that given any $P \in M$ there exists an open neighborhood U of P such that the restriction $f|_U\colon U \to M$ is an embedding.
Hint: Use the Inverse Mapping Theorem 3.33.

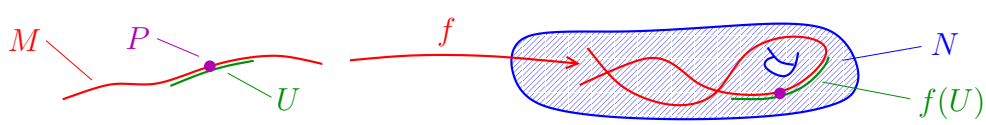

FIGURE 229. Illustration of Exercise 10.2.

Exercise 10.3. Let M and N be two manifolds with empty boundary. We suppose that $\dim(M) < \dim(N)$. Furthermore let W be a submanifold of N without boundary. Suppose that for any $P \in M$ with $f(P) \in W$ we have the equality $Df_P(T_PM) + T_{f(P)}W = T_{f(P)}N$. Show that $W \setminus f(M)$ has full measure in W.
Hint: Use Exercise 10.2, Lemma 3.43 (2) and Proposition 3.47.

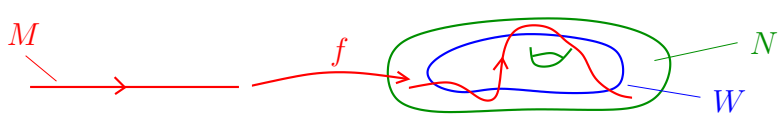

FIGURE 230.

Exercise 10.4.

(a) Show that the two oriented 1-dimensional submanifolds A and B of $S^1 \times S^1$ that are shown in Figure 231 on the left are not smoothly isotopic.
(b) We consider $\mathbb{R}^2$ with the two oriented 1-dimensional submanifolds X and Y that are shown in Figure 231 on the right. Are these X and Y smoothly isotopic?

Remark: Beware of base points.

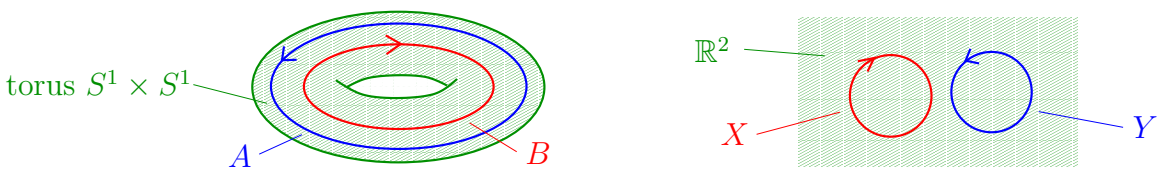

FIGURE 231.

Exercise 10.5. Let M be a manifold. Show that M is path-connected if and only if $M \setminus \partial M$ is path-connected.
Hint: use the Collar Neighborhood Theorem 10.10.

Exercise 10.6. Let $n \in \mathbb{N}_0$ and let $k \in \{1, \dots, n\}$. We write

$$\mathrm{GL}(n,k) \;=\; \underbrace{\text{set of } k\text{-tuples of linearly independent vectors of } \mathbb{R}^n}_{\mathbb{R}^n \times \cdots \times \mathbb{R}^n = \mathbb{R}^{nk}}.$$

Show that $\mathrm{GL}(n,k)$ is an open subset of $\mathbb{R}^{nk}$.

Exercise 10.7. Let M be a connected n-dimensional manifold.

(a) Let $P \in M$. Show that if $n \geq 2$, then $M \setminus \{P\}$ is also connected.
(b) Let $\varphi \colon \overline{B}^n \to M \setminus \partial M$ be an embedding. Show that if $n \geq 2$, then $M \setminus \varphi(B^n)$ is also connected.

Exercise 10.8. Does the statement of the Tubular Neighborhood Theorem 10.19 (2) also hold if the manifold M is non-orientable? More precisely, let M be an non-orientable m-dimensional manifold and let N be a 1-dimensional submanifold. Does there exist an embedding

$$F \colon \overline{B}^{m-1} \times N \;\to\; M$$

such that $F(0,P) = P$ for all $P \in N$?

Exercise 10.9. Let $K = \{(x,y,0) \in \mathbb{R}^3 \mid x^2 + y^2 = 1\}$ be the trivial knot in $\mathbb{R}^3 \cup \{\infty\} = S^3$. Let $X = S^3 \setminus K$ and let $Y = \mathbb{R}^3 \setminus K$. One of the two topological spaces X or Y is homotopy equivalent to S^1. Which one?

Exercise 10.10. We consider the disk $\overline{B}^2$ with two distinct points P and Q. By Proposition 10.23 there exists an orientation-preserving diffeomorphism f of $\overline{B}^2$ that swaps P and Q and that is the identity on S^1. Try to visualize such a map. (See also Figure 232 for a mental aid.)

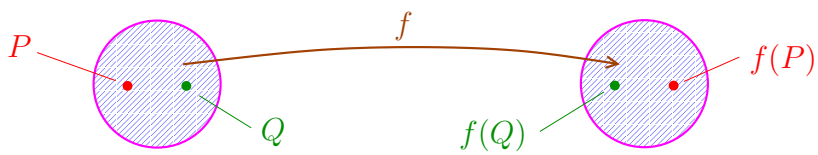

FIGURE 232.

Exercise 10.11. Let M be a manifold without boundary. We say that a path $\gamma\colon [a,b] \to M$ is *piecewise smooth* if there exists a subdivision $a = s_0 < s_1 < \cdots < s_m = b$ such that for $i = 0, \ldots, m-1$ the map $\gamma|_{[s_i, s_{i+1}]}$ is smooth.

(a) Show that any path $\alpha\colon [0,1] \to M$ is path-homotopic to a piecewise smooth path β.

(b) Show that any piecewise smooth path $\beta\colon [0,1] \to M$ is path-homotopic to a smooth path $\gamma\colon [0,1] \to M$.
Hint: Use Lemmas 3.12 and 5.4

Exercise 10.12. Show that there exists a smooth deformation retraction from $\mathrm{GL}_+(n,\mathbb{R})$ to $\mathrm{SL}(n,\mathbb{R})$.

11. Basics of group theory

Before we continue with developing the theory of fundamental groups of topological spaces we want to introduce several basic constructions in group theory and we want state several facts which we will use throughout the remainder of this course.

11.1. **Free abelian groups and finitely generated abelian groups.** The following definition will stay with us throughout these notes.

Definition.

(1) Let S be a non-empty set. We write

$$\mathbb{Z}^S := \text{ all maps from } S \text{ to } \mathbb{Z}.$$

Furthermore, for S the empty set we write $\mathbb{Z}^S := \{0\}$. We consider $\mathbb{Z}^S$ with the obvious group structure, i.e. the group structure that is given by

$$\begin{array}{rcl} \mathbb{Z}^S \times \mathbb{Z}^S & \to & \mathbb{Z}^S \\ (f,g) & \mapsto & \left(\begin{array}{rcl} S & \to & \mathbb{Z} \\ s & \mapsto & f(s)+g(s) \end{array} \right). \end{array}$$

(2) Given any set S, we are mostly interested in the subgroup

$$\mathbb{Z}^{(S)} := \text{ all maps from } S \text{ to } \mathbb{Z} \text{ which are non-zero for only finitely many } s \in S.$$

We refer to $\mathbb{Z}^{(S)}$ as the *free abelian group generated by* S or as the *free abelian group on the generating set* S.

(3) We refer to the cardinality of S as the *rank of* $\mathbb{Z}^{(S)}$.

When working with free abelian groups it is usually helpful to use the following notation.

Notation. Let S be a set.

(1) Given $s \in S$ we denote by s also the map

$$\begin{array}{rcl} S & \to & \mathbb{Z} \\ t & \mapsto & \begin{cases} 1, & \text{if } t = s, \\ 0, & \text{otherwise.} \end{cases} \end{array}$$

This map lies of course in $\mathbb{Z}^{(S)}$. Thus we can view S as a subset of $\mathbb{Z}^{(S)}$.

(2) Given $s_1, \dots, s_k \in S$ and $n_1, \dots, n_k \in \mathbb{Z}$ we obtain the corresponding element $n_1 s_1 + \dots + n_k s_k$ of $\mathbb{Z}^{(S)}$. We refer to $n_1 s_1 + \dots + n_k s_k$ as a *formal linear combination* of elements in S. Every element of $\mathbb{Z}^{(S)}$ can be written as such a formal linear combination of finitely many elements of S. Indeed, for $f \in \mathbb{Z}^{(S)}$ we can write[244]

$$f = \sum_{s \in S \text{ with } f(s) \neq 0} f(s) \cdot s.$$

[244] It is straightforward to see that both sides define the same map $S \to \mathbb{Z}$, so they are the same element of $\mathbb{Z}^{(S)}$.

The following lemma says that free abelian group generated by a set S has a "universal property". The lemma also says that possessing such a universal property classifies free abelian groups up to isomorphism.

Lemma 11.1.

(1) *Let S be a set and let $\phi\colon S \to G$ be a map to an abelian group G. Then there exists a unique homomorphism $\psi\colon \mathbb{Z}^{(S)} \to G$ that makes the following diagram commute*

$$\begin{tikzcd} S \arrow[r, hook] \arrow[dr, "\phi"'] & \mathbb{Z}^{(S)} \arrow[d, "\psi"] \\ & G. \end{tikzcd}$$

(2) *Conversely let π be a group that admits a subset S with the following universal property: given any map $\phi\colon S \to G$ to an abelian group G there exists a unique homomorphism $\psi\colon \pi \to G$ that makes the following diagram commute*

$$\begin{tikzcd} S \arrow[r] \arrow[dr, "\phi"'] & \pi \arrow[d, "\psi"] \\ & G. \end{tikzcd}$$

Then π is isomorphic to $\mathbb{Z}^{(S)}$.

Definition.

(1) We say that a group π is a *free abelian group on a generating set* S, if π has the universal property with respect to S. In other words, by Lemma 11.1, G needs to be isomorphic to $\mathbb{Z}^{(S)}$.

(2) We say that a group π is *free abelian* if it is a free abelian group on some generating set S.

Proof.

(1) We consider the map[245]

$$\begin{array}{rcl} \psi\colon \mathbb{Z}^{(S)} & \to & G \\ f = \sum_{i=1}^{n} n_i s_i & \mapsto & \psi(f) := \sum_{i=1}^{n} n_i \cdot \phi(s_i). \end{array}$$

It is straightforward to verify that ψ has the desired property and that it is the unique such homomorphism.

(2) Let π be a group that has the universal property with respect to S. We need to show that π is isomorphic to $\mathbb{Z}^{(S)}$. It is more elegant to show that it is isomorphic to any other group π' that has the universal property with respect to S.

This argument is similar to many other "universal property" proofs in algebra. We consider the inclusion maps $\varphi\colon S \to \pi$ and $\varphi'\colon S \to \pi'$. By the universal

[245]Here we assume that G is written as an additive group. If G is a multiplicative group we would need to replace $n_i \cdot \phi(s_i)$ by $\phi(s_i)^{n_i}$ and we would need to replace the sum by a product.

property of φ and φ' there exist homomorphisms $\psi\colon \pi \to \pi'$ and $\psi'\colon \pi' \to \pi$ that make the following diagrams commute:

$$\begin{tikzcd} S \arrow[r, "\varphi"] \arrow[dr, "\varphi'"'] & \pi \arrow[d, "\psi"] \\ & \pi' \end{tikzcd} \quad \text{and} \quad \begin{tikzcd} S \arrow[r, "\varphi'"] \arrow[dr, "\varphi"'] & \pi' \arrow[d, "\psi'"] \\ & \pi. \end{tikzcd}$$

In particular we get the commutative diagrams

$$\begin{tikzcd} S \arrow[r, "\varphi"] \arrow[dr, "\varphi'"] \arrow[ddr, "\varphi"'] & \pi \arrow[d, "\psi"] \\ & \pi' \arrow[d, "\psi'"] \\ & \pi \end{tikzcd} \quad \text{which simplifies to} \quad \begin{tikzcd} S \arrow[r, "\varphi"] \arrow[dr, "\varphi"'] & \pi \arrow[d, "\psi'\circ\psi"] \\ & \pi \end{tikzcd} \quad \text{and of course we also have the commutative diagram} \quad \begin{tikzcd} S \arrow[r, "\varphi"] \arrow[dr, "\varphi"'] & \pi \arrow[d, "\mathrm{id}_\pi"] \\ & \pi. \end{tikzcd}$$

It follows from the uniqueness part of the universal property applied to the two diagrams on the right that $\psi' \circ \psi = \mathrm{id}_\pi$. The same way one shows that $\psi \circ \psi' = \mathrm{id}_{\pi'}$. In particular ψ and ψ' are isomorphisms. □

Lemma 11.2.

(1) *Any subgroup G of a free abelian group F is again a free abelian group.*
(2) *If $\varphi\colon \mathbb{Z}^{(S)} \to \mathbb{Z}^{(T)}$ is a monomorphism, then*[246] $\#S \le \#T$.
(3) *If $\varphi\colon \mathbb{Z}^{(S)} \to \mathbb{Z}^{(T)}$ is an epimorphism, then $\#S \ge \#T$.*

Proof. The first two statements are proved in [Rot, Theorem 9.3]. Now let $\varphi\colon \mathbb{Z}^{(S)} \to \mathbb{Z}^{(T)}$ be an epimorphism. For each $t \in T$ there exists therefore some $\phi(t) \in S$ with $\varphi(\phi(t)) = t$. By Lemma 11.1 there exists a unique homomorphism $\psi\colon \mathbb{Z}^{(T)} \to \mathbb{Z}^{(S)}$ with $\psi(t) = \phi(t)$ for all $t \in T$. Thus we have $\varphi(\psi(t)) = \varphi(\phi(t)) = t$ for all t, so $\varphi \circ \psi = \mathrm{id}$, in particular ψ is a monomorphism. It follows from (2) that $\#T \le \#S$. □

Definition.

(1) If F is a free abelian group, then we define the *rank of F* as the cardinality of any set S with $F \cong \mathbb{Z}^{(S)}$.[247]
(2) Given an abelian group G we say that $S \subset G$ is a *generating set* if the canonical homomorphism $\mathbb{Z}^{(S)} \to G$ is an epimorphism.[248]

---

[246] Here we denote by $\#S$ and $\#T$ the cardinalities of the sets S and T, as defined on page 254.

[247] It follows from Lemma 11.2 and the Bernstein-Schröder Theorem 7.1 that the rank of a free abelian group is well-defined.

[248] Here we mean by "canonical map $\mathbb{Z}^{(S)} \to G$" the unique homomorphism $\psi\colon \mathbb{Z}^{(S)} \to G$ from Lemma 11.1 that makes the following diagram commute

$$\begin{tikzcd} S \arrow[r, hook] \arrow[dr, hook, "\phi"'] & \mathbb{Z}^{(S)} \arrow[d, "\psi"] \\ & G \end{tikzcd}$$

(3) Given an abelian group G we say that $S \subset G$ is a *basis* if the canonical homomorphism $\mathbb{Z}^{(S)} \to G$ is an isomorphism.
(4) We say that an abelian group G is *finitely generated* if it admits a finite generating set.

Example. Let S be a finite set with m elements $s_1, \ldots, s_m$. Let $\phi\colon S \to \mathbb{Z}^m$ be the map given by $\phi(s_i) = e_i$. Then the resulting homomorphism $\Psi\colon \mathbb{Z}^{(S)} \to \mathbb{Z}^m$ is an isomorphism. Put differently, $\mathbb{Z}^m$ is a free abelian group of rank m.

We leave the proof of the following useful characterizations of generating sets as an exercise to the reader.

Lemma 11.3. *Let G be an abelian group and let $S \subset G$ be a subset. Then the following two statements are equivalent:*
(1) *S is a generating set.*
(2) *Any subgroup H of S that contains S is already equal to G.*

We use this opportunity to recall the classification of finitely generated abelian groups which had been proved in the algebra course. A proof is for example also provided in [Hun, Chapter II.2].

Theorem 11.4. (Classification of finitely generated abelian groups) *Let A be a finitely generated abelian group. Then there exist non-zero natural numbers $a_1, \ldots, a_k$ with $a_i | a_{i+1}$ for $i = 1, \ldots, k-1$ and an $r \in \mathbb{N}_0$ such that*

$$A \;\cong\; \mathbb{Z}^r \oplus \bigoplus_{i=1}^{k} \mathbb{Z}_{a_i}.$$

Furthermore the numbers $a_1, \ldots, a_k$ and r are uniquely determined by A.

Definition. Given a finitely generated abelian group A we denote the direct sum of the cyclic groups on the right-hand side of Theorem 11.4 as the *canonical form of A*.

Example. The Chinese Remainder Theorem says that for any coprime m and n we have an isomorphism

$$\begin{array}{rcl} \mathbb{Z}_{mn} & \xrightarrow{\cong} & \mathbb{Z}_m \times \mathbb{Z}_n = \mathbb{Z}_m \oplus \mathbb{Z}_n \\ k + mn\mathbb{Z} & \mapsto & (k + m\mathbb{Z}, k + n\mathbb{Z}). \end{array}$$

For example consider $A = \mathbb{Z}_3 \oplus \mathbb{Z}_5$. It is not in the form of Theorem 11.4, but we have the isomorphism $\mathbb{Z}_3 \oplus \mathbb{Z}_5 \cong \mathbb{Z}_{15}$, which is of the desired form. Thus $\mathbb{Z}_{15}$ is the canonical form of $\mathbb{Z}_3 \oplus \mathbb{Z}_5$.

We will not provide a proof for Theorem 11.4, but we will sketch a proof for the following lemma. The third statement of the lemma is a somewhat weaker version of Theorem 11.4.

Lemma 11.5.

where $S \to G$ is the inclusion map.

(1) *Let V be an $m \times n$-matrix over $\mathbb{Z}$. For any two matrices $A \in \mathrm{GL}(m,\mathbb{Z})$ and $B \in \mathrm{GL}(n,\mathbb{Z})$ we have an isomorphism*

$$\mathbb{Z}^m/AVB\mathbb{Z}^n \;\cong\; \mathbb{Z}^m/V\mathbb{Z}^n.$$

(2) *Let V be an $m \times n$-matrix over $\mathbb{Z}$. Then there exist two matrices $A \in \mathrm{GL}(m,\mathbb{Z})$ and $B \in \mathrm{GL}(n,\mathbb{Z})$*[249] *such that*[250]

$$A \cdot V \cdot B \;=\; \begin{pmatrix} p_1 & 0 & 0 & 0 \\ 0 & \ddots & 0 & 0 \\ 0 & 0 & p_t & 0 \\ 0 & 0 & 0 & 0_{(m-t)\times(n-t)} \end{pmatrix} \;\in\; M(m \times n, \mathbb{Z})$$

for some $p_1, \dots, p_t \in \mathbb{N}$.

(3) *Let A be a finitely generated abelian group. Then there exists an $r \geq 0$ and $p_1, \dots, p_t \in \mathbb{N}$ such that*

$$A \;\cong\; \mathbb{Z}^r \oplus \bigoplus_{i=1}^{t} \mathbb{Z}_{p_i}.$$

As mentioned before, we will only provide sketch for the proof of the lemma.

Sketch of proof.

(1) The proof of the first statement is elementary. It is left as an exercise to the reader.

(2) First note that if an $m \times n$-matrix P is obtained from an $m \times n$-matrix Q by swapping two rows, then P is obtained by left-multiplying Q by an $m \times m$-matrix of the form[251]

$$\begin{pmatrix} \mathrm{id} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & \mathrm{id} & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \mathrm{id} \end{pmatrix}.$$

Similarly if P is obtained from an $m \times n$-matrix Q by adding the k-th row to the l-th row, then P is obtained by left-multiplying Q by an $m \times m$-matrix of the form

$$\begin{pmatrix} \mathrm{id} & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 1 & 0 \\ 0 & 0 & \mathrm{id} & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & \mathrm{id} \end{pmatrix}$$

[249] The matrices A and B are invertible over $\mathbb{Z}$, i.e. their determinants are ± 1.

[250] Here the last row and column of zeros can be arbitrarily large.

[251] Here is the reality check whether that is really correct: we have

$$\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} a & b \\ c & d \end{pmatrix} \;=\; \begin{pmatrix} c & d \\ a & b \end{pmatrix}.$$

where the extra 1 sits in the (k,l)-entry. Both these $m \times m$-matrices lie in $\mathrm{GL}(m,\mathbb{Z})$. If we do the same operations for columns, then this corresponds to right multiplication by the same type of matrices in $\mathrm{GL}(n,\mathbb{Z})$ as above.

Now let V be an $m \times n$-matrix over $\mathbb{Z}$. If V is the zero matrix, then there is nothing to show. So suppose that V is not the zero matrix. We perform the following steps:

(a) After swapping rows and columns we can arrange that the absolute value of the $(1,1)$-entry is less or equal than the absolute value of all other entries. After possibly multiplying the first column by -1 we can assume that the $(1,1)$-entry v_{11} is positive.

(b) By adding and subtracting the first column from the other columns we can arrange that all entries in the first row, except for the $(1,1)$-entry, lie between 0 and $v_{11}-1$.

(c) The same way as in (2) we can arrange that that all entries in the first column, except for the $(1,1)$-entry, lie between 0 and $v_{11}-1$.

Now we have to distinguish two cases:

(a) If there exists outside of the $(1,1)$-entry another entry in the first row or column that is non-zero, then we start again with (1). Note that the new entry $(1,1)$-entry will be less than before. So this process will come to a halt after finitely many steps.

(b) If all entries in the first row and column, except for the $(1,1)$-entry are zero, then

$$V = \begin{pmatrix} v_{11} & 0 \\ 0 & V' \end{pmatrix}$$

for some $(m-1)\times(n-1)$-matrix V' and we perform the same operations on the smaller matrix V'.

(3) Let A be a finitely generated abelian group. By the definition of a finitely generated abelian group there exists an epimorphism $\psi\colon \mathbb{Z}^m \to A$. Since $\mathbb{Z}$ is a Noetherian ring we know that $\ker(\psi)$ is again a finitely generated free abelian group of rank $n \le m$. In particular there exists an isomorphism $v\colon \mathbb{Z}^n \to \ker(\psi)$. We denote by V the $m\times n$-matrix that represents the resulting map $\mathbb{Z}^n \to \ker(\psi) \subset \mathbb{Z}^m$ with respect to the standard bases. Then $A \cong \mathbb{Z}^m/V\mathbb{Z}^n$. We pick matrices A and B as in (2). From (1) it follows that $\mathbb{Z}^m/V\mathbb{Z}^n$ is isomorphic to $\mathbb{Z}^m/AVB\mathbb{Z}^n$. But the latter is isomorphic to $\mathbb{Z}_{p_1} \oplus \cdots \oplus \mathbb{Z}_{p_t} \oplus \mathbb{Z}^{m-n}$. □

Definition. Let A be an abelian group.

(1) If A is finitely generated, then we refer to the r in the statement of Theorem 11.4 as the *rank* of the finitely generated abelian group A. We denote it by $\mathrm{rank}(A)$.[252]

[252] If A is a finitely generated free abelian group, then this definition of rank agrees with the definition given for free abelian groups on page 366.

(2) We refer to

$$\operatorname{tor}(A) \;=\; \{a \in A \mid \text{ there exists an } n \in \mathbb{N} \text{ with } na = 0\}$$

as the *torsion subgroup of* A.[253] If $\operatorname{tor}(A)$ is the trivial subgroup, then we say that A is *torsion-free*.

In the following three lemmas we collect several basic facts about finitely generated abelian groups. Most of the statements follow more or less directly from Theorem 11.4. We will not prove the lemmas and we leave it as an exercise to deduce the statements from Theorem 11.4 and the algebra course you took.

Lemma 11.6. *Let*

$$0 \;\to\; A \;\to\; B \;\to\; C \;\to\; 0$$

be a short exact sequence of abelian groups[254] *such that at least two of these groups are finitely generated. Then the following holds:*

(1) *all three groups are finitely generated abelian groups,*
(2) $\operatorname{rank}(B) = \operatorname{rank}(A) + \operatorname{rank}(C)$,
(3) *if A and C are torsion-free, then B is also torsion-free.*

Lemma 11.7. *Let $A \in M(n \times n, \mathbb{Z})$ be a matrix. Then*

$$\mathbb{Z}/A\mathbb{Z} \text{ is finite} \quad\Longleftrightarrow\quad \det(A) \neq 0.$$

Furthermore, if $\det(A) \neq 0$, *then*

$$0 \;\to\; \mathbb{Z}^n \;\xrightarrow{A\cdot}\; \mathbb{Z}^n \;\to\; \mathbb{Z}^n/A\mathbb{Z}^n \;\to\; 0$$

is a short exact sequence and $\mathbb{Z}^n/A\mathbb{Z}^n$ is a finite group with $|\det(A)|$ elements.

We also have the following lemma.

Lemma 11.8.

(1) *If A, B and C are finitely generated abelian groups, then*

$$A \oplus C \cong B \oplus C \quad\Longrightarrow\quad A \cong B.$$

(2) *If A is a subgroup of a finitely generated abelian group B, then* $\operatorname{tor}(A)$ *is a subgroup of* $\operatorname{tor}(B)$ *and* $\operatorname{rank}(A) \leq \operatorname{rank}(B)$.
(3) *If A is a subgroup of $\mathbb{Z}^r$, then A is a free abelian group with rank less or equal than r.*[255]
(4) *If A is a subgroup of $\mathbb{Z}^r$ with* $\operatorname{rank}(A) < r$, *then A is a proper subgroup, i.e. $A \neq \mathbb{Z}^r$.*
(5) *Let $\varphi\colon A \to B$ be a homomorphism between two free abelian groups of the same finite rank. If φ is an epimorphism, then φ is already an isomorphism.*

[253] Why is it a subgroup?

[254] Recall that this means that the map $A \to B$ is injective, that $B \to C$ is surjective and that the image of $A \to B$ agrees with the kernel of $B \to C$.

[255] In fact this statement is already contained in Lemma 11.2.

(6) *If A is a finitely generated abelian group and $\varphi\colon A \to B$ is an epimorphism, then B is also finitely generated and* $\operatorname{rank}(A) \geq \operatorname{rank}(B)$.

Abelian groups that are not finitely generated are not classified and they tend to be significantly harder. For example the following lemma shows that not every torsion-free abelian group is a free abelian group.

Lemma 11.9. *The abelian group $(\mathbb{Q}, +)$ is torsion-free but not free abelian.*

Proof. Clearly $(\mathbb{Q}, +)$ is torsion-free. If it was free abelian, then there would exist an epimorphism to $\mathbb{Z}$. In Exercise 11.1 to show that such an epimorphism cannot exist. □

In Exercise 11.2 (1) we will see that the conclusion of Lemma 11.8 (1) does not hold for general abelian groups. But the following statement actually does hold.

Proposition 11.10. *Let A and B be any two abelian groups. If C is a finitely generated abelian group, then*

$$A \oplus C \cong B \oplus C \quad \Longrightarrow \quad A \cong B.$$

Proof. We will consider a special case in Exercise 11.2 (b). The general case is proved in [Cohn, Walka]. □

11.2. **The free product of groups.** We first recall the definition of the direct product of two groups G and H that we already gave on page 284. The direct product of two groups G and H is defined as

$$G \times H \ := \ \{(g, h) \mid g \in G \text{ and } h \in H\}$$

together with the group structure that is given by

$$(g_1, h_1) \cdot (g_2, h_2) \ := \ (g_1 g_2, h_1 h_2)$$

for $g_1, g_2 \in G$ and $h_1, h_2 \in H$. We call the group $G \times H$ the *direct product of the groups G and H*. Via the monomorphisms

$$\begin{array}{ccc} G & \to & G \times H \\ g & \mapsto & (g, e) \end{array} \quad \text{and} \quad \begin{array}{ccc} H & \to & G \times H \\ h & \mapsto & (e, h) \end{array}$$

we can view G and H as subgroups of $G \times H$. Note that these subgroups commute, i.e. for every $g \in G$ and $h \in H$ we have the equality $(g, e)(e, h) = (g, h) = (e, h)(g, e)$.

Now we will introduce the "free product" $G * H$ of two groups G and H. The definition is perhaps initially harder than the definition of the "direct product" $G \times H$. But for many, perhaps even most applications, the free product is more useful.

So let G be and H be two groups. We consider the set $G * H$ of all finite sequences $(x_1, \ldots, x_m)$ such that the following conditions are satisfied:

(1) each x_i lies in one of the groups G or H,
(2) no x_j is the neutral element of G or of H,
(3) any two consecutive x_j's lie in two different groups.

Here we also allow the "empty sequence" ().

Let $(x_1, \dots, x_m)$ and $(y_1, \dots, y_n)$ be two elements in $G * H$. We define the product of these two elements as follows:

(1) If x_m and y_1 lie in different groups, then we define

$$(x_1, \dots, x_m) \cdot (y_1, \dots, y_n) \ := \ (x_1, \dots, x_m, y_1, \dots, y_n).$$

(2) If x_m and y_1 lie in the same group, then there exists a j such that $x_{m+1-i} = y_i^{-1}$ for $i = 1, \dots, j$, and such that $x_{m-j} \neq y_{j+1}^{-1}$. We define[256]

$$(x_1, \dots, x_m) \cdot (y_1, \dots, y_n) \ := \ (x_1, \dots, \underbrace{x_{m-j} \cdot y_{j+1}}_{\neq e}, \dots, y_n).$$

Another way of stating the product formula is as follows: given two sequences $(x_1, \dots, x_m)$ and $(y_1, \dots, y_n)$ we stack them together $(x_1, \dots, x_m, y_1, \dots, y_n)$ and then we delete any occurrence of a subsequence of the form a, a^{-1} for $a \in G$ or $a \in H$ and if a subsequence is of the form a, b with $a, b \in G$ or $a, b \in H$, then we replace it by ab.

We henceforth refer to $G * H$ together with this product structure as the *free product* of G and H. We have the following important lemma.

Lemma 11.11. *The free product of two groups G and H is again a group. The neutral element of $G * H$ is hereby given by the empty sequence* () *and the inverse of an element $(x_1, \dots, x_m) \in G * H$ is given by*

$$(x_1, \dots, x_m)^{-1} \ = \ (x_m^{-1}, \dots, x_1^{-1}) \ \in \ G * H.$$

Proof. It is clear that the empty sequence is a neutral element. It follows immediately from the definition of the product that the inverse of an element $(x_1, \dots, x_m) \in G * H$ is given by $(x_m^{-1}, \dots, x_1^{-1})$. It remains to show that the multiplication satisfies associativity.

In principle one can show associativity naively "by hand", but there are surprisingly many cases one needs to distinguish, so that the proof becomes rather painful.

We will therefore follow a different approach. We write $W = G * H$ and we denote by $(P(W), \circ)$ the group of all permutations of W, i.e. $P(W)$ is the set of all bijections from W to W and the group structure is given by composition of maps. For $g \in G$ we consider the map[257]

$$\begin{aligned} \lambda_g \colon W \ &\to \ W \\ (x_1, \dots, x_m) \ &\mapsto \ \begin{cases} (g, x_1, x_2, \dots, x_m), & \text{if } x_1 \in H, \\ (gx_1, x_2, \dots, x_m), & \text{if } x_1 \in G \text{ and } g \neq x_1^{-1}, \\ (x_2, \dots, x_m), & \text{if } g = x_1^{-1}. \end{cases} \end{aligned}$$

It is now straightforward to see that for any $g, g' \in G$ and any $(x_1, \dots, x_m) \in W$ we have $g(g' \cdot (x_1, \dots, x_m)) = (gg') \cdot (x_1, \dots, x_m)$. This means that $\lambda_g \circ \lambda_{g'} = \lambda_{gg'}$. It is now

[256]Since x_m and y_1 lie in the same group, the elements x_{m-j} and y_{j+1} also lie in the same group, so it makes sense to consider $x_{m-j} \cdot y_{j+1}$.

[257]It is straightforward to see that the sequences on the right do indeed lie in $G * H$.

straightforward to see that the map

$$\begin{array}{rcl} \lambda\colon G & \to & P(W) \\ g & \mapsto & \lambda_g \end{array}$$

is a group homomorphism. Similarly we define $\lambda\colon H \to P(W)$. Now we consider the map

$$\begin{array}{rcl} \lambda\colon W & \to & P(W) \\ (x_1,\dots,x_n) & \to & \lambda_{x_1}\circ\cdots\circ\lambda_{x_n}. \end{array}$$

This map is injective since $\lambda(x_1,\dots,x_n)$ applied to the empty word $()$ gives the word $(x_1,\dots,x_n)$. Hence $\lambda(x_1,\dots,x_n)$ is not the identity map from $W \to W$, i.e. $\lambda(x_1,\dots,x_n)$ is non-trivial in $P(W)$.

Furthermore the map $\lambda\colon W \to P(W)$ satisfies $\lambda(x\cdot y) = \lambda_x \circ \lambda_y$. Put differently, λ defines an injective map $\lambda\colon (W,\ \cdot\ ) \to (P(W),\circ)$ that preserves the product structure. But since $(P(W),\circ)$ satisfies the associativity law we now see that $(W,\ \cdot\ )$ also satisfies the associativity law. $\square$

The following lemma summarizes two main properties of the free product of two groups.

Lemma 11.12. *Let G and H groups. Then the following holds:*

(1) *The maps*

$$\begin{array}{rcl} i\colon G & \to & G*H \\ g & \mapsto & \begin{cases} (g), & \text{if } g\neq e, \\ (), & \text{if } g=e \end{cases} \end{array} \qquad \text{and} \qquad \begin{array}{rcl} j\colon H & \to & G*H \\ h & \mapsto & \begin{cases} (h), & \text{if } h\neq e, \\ (), & \text{if } h=e \end{cases} \end{array}$$

are monomorphisms.

(2) *For any two group homomorphisms $\alpha\colon G\to A$ and $\beta\colon H\to A$ there exists a unique group homomorphism $\gamma\colon G*H\to A$ such that the following diagram commutes*

$$\begin{tikzcd} G*H & G \arrow[l, "i"'] \arrow[d, "\alpha"] \\ H \arrow[u, "j"] \arrow[r, "\beta"'] & A. \end{tikzcd}$$

Example. Let G and H be two groups. We denote by $\alpha\colon G\to G\times H$ and $\beta\colon H\to G\times H$ the obvious inclusion maps. It follows from Lemma 11.12 there exists a unique homomorphism $\gamma\colon G*H\to G\times H$ which makes the following diagram commute:

$$\begin{tikzcd} G*H \arrow[dr, dashed, "\gamma"] & G \arrow[l, "i"'] \arrow[d, "\alpha"] \\ H \arrow[u, "j"] \arrow[r, "\beta"'] & G\times H. \end{tikzcd}$$

Remark. In the literature the direct product of two groups often gets introduced in a slightly different way, namely by a "universal property". More precisely, let G be and H be two groups. The *direct product of G and H* is then defined as a group K together with two

homomorphisms $i\colon G \to K$ and $j\colon G \to K$ which satisfy the following universal property: for every two group homomorphisms $\alpha\colon G \to A$ and $\beta\colon H \to A$ there exists a *unique* group homomorphism $\gamma\colon K \to A$ such that the following diagram commutes

$$\begin{tikzcd} K \arrow[dr, dashed, "\gamma"] & G \arrow[l, "i"'] \arrow[d, "\alpha"] \\ H \arrow[u, "j"] \arrow[r, "\beta"'] & A. \end{tikzcd}$$

Lemma 11.12 can now be reinterpreted as saying that the direct product of two groups always exists. An argument that is very similar to the one we gave on page 368 shows that the direct product is unique in the following sense: If $(K, i\colon G \to K, j\colon H \to K)$ and $(K', i'\colon G \to K', j'\colon H \to K')$ both satisfy the above universal property, then there exists a unique isomorphism $\Phi\colon K \to K'$ such that $i' = \Phi \circ i$ and $j' = \Phi \circ j$. [258]

Proof. It is clear that the maps i and j are injective, furthermore it follows immediately from the definition of the group structure on $G * H$ that the maps are group homomorphisms.

Now let $\alpha\colon G \to A$ and $\beta\colon H \to A$ be two group homomorphisms. For an element $(g_1, h_1, \dots, g_k, h_k) \in G * H$ with $g_i \in G, h_i \in H$, $i = 1, \dots, n$ we define

$$\gamma(g_1, h_1, \dots, g_k, h_k) \ := \ \alpha(g_1) \cdot \beta(h_1) \cdot \dots \cdot \alpha(g_k) \cdot \beta(h_k).$$

The same way we define γ for all other elements in $G * H$. Now one can show easily that γ is a group homomorphism.

It remains to show the uniqueness of γ. Any element in $G * H$ is a product of elements of the form $i(g)$, $g \in G$ and $j(h)$, $h \in H$. It follows that any homomorphism $\delta\colon G * H \to A$ is already uniquely determined by the values of δ on all elements of the form $i(g)$, $g \in G$ and $j(h)$, $h \in H$. Put differently, there is at most one homomorphism $\delta\colon G * H \to A$ with $\delta(g) = \alpha(i(g))$ for all $g \in G$ and $\delta(h) = \beta(j(h))$ for all $h \in H$. $\square$

Remark.

(1) We will use the monomorphisms from Lemma 11.12 to view G and H as subgroups of $G * H$.
(2) If there is no danger of confusion, then we often shorten $(x_1, \dots, x_m) \in G * H$ to the notation $x_1 \dots x_m$. This notation is coherent with the convention (1). Note that if $g \in G$ and $h \in H$ are non-trivial elements, then the sequences (g, h) and (h, g) both lie in $G * H$ and they are different. With the convention that we just introduced that means that $g \cdot h \neq h \cdot g$. Put differently, a non-trivial element of G never commutes with a non-trivial element of H.
(3) The construction of the free product of two groups generalizes in an obvious way to the free group of finitely many, in fact even to infinitely many groups.

[258] Why does $K = G \times H$ with the obvious maps $i\colon G \to K$ and $j\colon H \to K$ not satisfy this universal property? Or does it?

Let t be a symbol. We define

$$\langle t\rangle \;:=\; \{\dots, t^{-2}, t^{-1}, e, t, t^2, \dots\}.$$

The set $\langle t\rangle$ admits an obvious group structure that is given by $t^i \cdot t^j := t^{i+j}$. This group is called *the infinite cyclic group generated by* t. The map $\mathbb{Z} \to \langle t\rangle$, $n \mapsto t^n$ is evidently an isomorphism. Now we come to one of the main definitions in group theory.

Definition. For a set S we refer to

$$\langle S\rangle \;:=\; \text{free product of the groups } \langle s\rangle,\ s \in S$$

as the *free group on the* (*generating*) *set* S. Via the map $s \mapsto (s)$ we can and will view S as a subset of $\langle S\rangle$.

Example. If $S = \{t_1, \dots, t_k\}$, then we obtain the group

$$\langle t_1, \dots, t_k\rangle \;:=\; \langle t_1\rangle * \cdots * \langle t_k\rangle$$

which we also refer to as the *free group on the generators* $t_1, \dots, t_k$. Each element of the free group $F(t_1, \dots, t_k)$ is thus of the form

$$t_{r_1}^{s_1}\, t_{r_2}^{s_2} \,\dots\, t_{r_l}^{s_l}$$

with $r_i \neq r_{i+1}$ for $i = 1, \dots, l-1$ and $s_i \neq 0$ for $i = 1, \dots, l$.

Convention. Sometimes we denote the free group on k generators just by F_k.

Example. We consider the free group $\langle x, y\rangle$ on generators x and y. Elements in this group are of the form $xy^3x^{-2}y$ or $y^{-2}xy$. The multiplication is the "obvious one", for example

$$(xy^3x^{-1}y^2) \cdot (y^{-2}x^3yxy^{-1}) \;=\; xy^3x^2yxy^{-1}.$$

The group is not abelian since $xy \neq yx$.[259]

The following innocent looking lemma summarizes the key property of free groups.

Lemma 11.13. *Let S be a set, let G be an arbitrary group and let $g\colon S \to G$ be a map. Then there exists a unique homomorphism $\varphi\colon \langle S\rangle \to G$ with $\varphi(s) = g(s)$ for every $s \in S$.*

Proof. For $s \in S$ the map

$$\begin{array}{ccc} \langle s\rangle & \to & G \\ s^n & \mapsto & g(s)^n \end{array}$$

is evidently the unique homomorphism $\varphi_s\colon \langle s\rangle \to G$ with $\varphi_s(s) = g(s)$. It now follows from the obvious generalization of Lemma 11.12 to the case of the free product of arbitrarily many groups that there exists a unique homomorphism $\varphi\colon \langle S\rangle \to G$ with $\varphi(s) = \varphi_s(s) = g(s)$ for $s \in S$. $\square$

[259] Why is $xy \neq yx$?

Remark. Sometimes in the literature free groups are defined via a universal property. More precisely, let S be a set. A *free group on* S is sometimes defined as a group K together with a map $f\colon S \to K$ which satisfies the following universal property: for any map $g\colon S \to G$ from the set S to a group G[260] there exists a unique group homomorphism $\varphi\colon K \to G$ such that the following diagram commutes

$$\begin{tikzcd} S \arrow[r, "f"] \arrow[dr, "g"'] & K \arrow[d, "\varphi"] \\ & G. \end{tikzcd}$$

In this language our above Lemma 11.13 says that the obvious map $S \to \langle S \rangle$ is a free group on S in the above sense. As before, a slight variation of the argument on page 368 shows that the free group on S is unique in an appropriate sense.

Definition.

(1) A group G is called *free*, if it is isomorphic to the free group $\langle S \rangle$ on some set S.
(2) Given a group G we say that $S \subset G$ is a *generating set* if the canonical homomorphism $\langle S \rangle \to G$ is an epimorphism.[261] Sometimes we also say that the elements in S are *generators of* G.
(3) We say that a group G is *finitely generated* if it admits a finite generating set.

Example.

(1) As on page 265 we consider the following two self-homeomorphisms of $\mathbb{R}^2$:

$$\begin{array}{rcl} A\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (x,y) & \mapsto & (x+1, 1-y) \end{array} \quad \text{and} \quad \begin{array}{rcl} B\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (x,y) & \mapsto & (x, y+1) \end{array}$$

and we denote by G the subgroup of all homeomorphisms of $\mathbb{R}^2$ that is generated by A and B. This means that

$$G = \begin{array}{c} \text{all self-homeomorphisms of } \mathbb{R}^2 \text{ that can be written} \\ \text{as a finite concatenation of the maps } A, B, A^{-1} \text{ and } B^{-1}. \end{array}$$

We saw on page 265 that $\mathbb{R}^2/G$ equals the Klein bottle K and using Theorem 7.17 we saw on page 283 that $\pi_1(\text{Klein bottle}) \cong G$. The group G is finitely generated in the above sense. More precisely, it follows immediately from the definition of G that $S = \{A, B\} \subset G$ is a generating set for G.

---

[260] Note that in contrast to the Lemma 11.1 group G is now not necessarily abelian.

[261] Here we mean by "canonical map $\langle S \rangle \to G$" the unique homomorphism $\psi\colon \langle S \rangle \to G$ from Lemma 11.13 that makes the following diagram commute

$$\begin{tikzcd} S \arrow[r, hook] \arrow[dr, hook, "\phi"'] & \langle S \rangle \arrow[d, "\psi"] \\ & G \end{tikzcd}$$

where $S \to G$ is the inclusion map.

(2) For any set S there exists by Lemma 11.13 a unique homomorphism $\langle S\rangle \to \mathbb{Z}^{(S)}$ that sends $s \in S$ to s viewed as an element in $\mathbb{Z}^{(S)}$. Since the set $S \subset \mathbb{Z}^{(S)}$ generates $\mathbb{Z}^{(S)}$ we see that this homomorphism is an epimorphism. It follows that any finitely generated abelian group in the sense of page 369 is also a finitely generated group in the above sense.

The subgroup of a free abelian group is again a free abelian group. Does the same hold for free groups? We record this as a question for future reference.

Question 11.14. *Is every subgroup of a free group again a free group?*

The next lemma says in particular that free groups on two sets are isomorphic if and only if the cardinalities of the sets are the same.

Lemma 11.15. *Let S and T be two sets.*

(1) *If there exists an epimorphism $\langle S\rangle \to \langle T\rangle$, then $\#S \geq \#T$.*
(2) *If $\langle S\rangle$ is isomorphic to $\langle T\rangle$, then $\#S = \#T$.*
(3) *If given $n \in \mathbb{N}$ we denote by F_n the free group on n generators, then for $k \neq l$ the groups F_k and F_l are not isomorphic.*

Proof.

(1) We first recall that we had just seen in the previous example that for any set U there exists a unique epimorphism $\psi_U\colon \langle U\rangle \to \mathbb{Z}^{(U)}$ that sends $u \in U$ to u viewed as an element in $\mathbb{Z}^{(U)}$.

Now let S and T be two sets and let $\varphi\colon \langle S\rangle \to \langle T\rangle$ be an epimorphism. By Lemma 11.1 there exists a unique homomorphism $\widetilde{\varphi}\colon \mathbb{Z}^{(S)} \to \mathbb{Z}^{(T)}$ that sends $s \in S$ to $\psi_T(\varphi(s)) \in \mathbb{Z}^{(T)}$. We obtain the following diagram of homomorphisms

$$\begin{tikzcd} \langle S\rangle \arrow[r, two heads, "\varphi"] \arrow[d, two heads, "\psi_S"'] & \langle T\rangle \arrow[d, two heads, "\psi_T"] \\ \mathbb{Z}^{(S)} \arrow[r, "\widetilde{\varphi}"] & \mathbb{Z}^{(T)}. \end{tikzcd}$$

It follows immediately from the definition of $\tilde{\varphi}$ that this diagram commutes.[262] Since the top horizontal and since the vertical maps are epimorphisms we see that the bottom horizontal map is also an epimorphism. It follows from Lemma 11.2 that $\#S \geq \#T$.

(2) Let $f\colon \langle S\rangle \to \langle T\rangle$ be an isomorphism. We apply (1) to f and to f^{-1} and we obtain that $\#S \geq \#T$ and $\#T \geq \#S$. It follows from the Bernstein-Schröder Theorem 7.1 that $\#S = \#T$.

(3) This statement is an immediate consequence of (2).[263] □

[262] Here we use that a homomorphism $\gamma\colon \langle S\rangle \to G$ is uniquely determined by the values of γ on S. Put differently, if $\alpha\colon \langle S\rangle \to G$ and $\beta\colon \langle S\rangle \to G$ are two homomorphisms with $\alpha(s) = \beta(s)$ for all $s \in S$, then it follows immediately from the uniqueness statement of Lemma 11.13 that $\alpha = \beta$.

[263] Note that if we just want to prove statement (3), then in the proof of (2) we could replace the slightly esoteric Lemma 11.2 by the more conventional Lemma 11.6 that was proved in the Algebra course.

11.3. **An alternative definition of the free product of groups.** For some purposes it is sometimes useful to work with a different model for the free product of two groups.

Let A and B be two groups. We set[264]

$$S(A,B) \;:=\; \{\text{all finite sequences } (g_1,\dots,g_k) \text{ with each } g_i \text{ in } A \text{ or } B\}$$

and we denote by $\sim$ the equivalence relation on $S(A,B)$ that is generated by the relations

$$(g_1,\dots,g_l,e,g_{l+2},\dots,g_k) \;\sim\; (g_1,\dots,g_l,g_{l+2},\dots,g_k)$$

and by the relations

$$(g_1,\dots,g_l,g_{l+1},\dots,g_k) \;\sim\; (g_1,\dots,g_lg_{l+1},\dots,g_k)$$

if both g_l and g_{l+1} lie in A or both lie in B. It is now straightforward to verify that the map

$$\begin{array}{rcl} S(A,B)/\sim \;\times\; S(A,B)/\sim & \to & S(A,B)/\sim \\ ([(g_1,\dots,g_k)],[h_1,\dots,h_l]) & \mapsto & [(g_1,\dots,g_k,h_1,\dots,h_l)] \end{array}$$

is well-defined and that it defines a group structure on $S(A,B)/\sim$.[265]

Proposition 11.16. *Let A and B be two groups. Then the map*[266]

$$\begin{array}{rcl} \Phi\colon S(A,B)/\sim & \to & A*B \\ [(g_1,\dots,g_k)] & \mapsto & g_1\cdot\dots\cdot g_k \end{array}$$

is well-defined and it is an isomorphism. The inverse map is given by

$$\begin{array}{rcl} \Psi\colon A*B & \to & S(A,B)/\sim \\ (g_1,\dots,g_k) & \mapsto & [(g_1,\dots,g_k)]. \end{array}$$

In the proof of Proposition 11.16 we will need the following little lemma.

Lemma 11.17. *Let $\Phi\colon G\to H$ and $\Psi\colon H\to G$ be two group homomorphisms such that $\Phi\circ\Psi=\mathrm{id}_H$ and such that Ψ is an epimorphism. Then Φ is an isomorphism.*

The lemma can be summarized as follows, if we are given a commutative diagram of the form

$$\begin{tikzcd} & G \arrow[dr, "\Phi"] & \\ H \arrow[ur, two heads, "\Psi"] \arrow[rr, "\mathrm{id}"'] & & H, \end{tikzcd}$$

then Φ is an isomorphism.[267]

---

[264]This definition is similar to the definition of $A*B$, but now we allow that elements of the sequence are trivial and we allow that consecutive elements lie in the same group.

[265]The neutral element is again represented by the empty sequence $(\,)$ and the inverse of $[(g_1,\dots,g_k)]$ is given by $[(g_k^{-1},\dots,g_1^{-1})]$. This time associativity is not a problem. Why not?

[266]Recall that we use the canonical monomorphisms from Lemma 11.12 to view A and B as subgroups of $A*B$. If we want to be more precise, then we could say that Φ is given by $[(g_1,\dots,g_k)]\mapsto(g_1)\cdot\dots\cdot(g_k)$.

[267]Is Ψ also necessarily an isomorphism?

Proof. It follows from $\Phi \circ \Psi = \mathrm{id}_H$ that Φ is an epimorphism. It remains to show that Φ is a monomorphism. So let $g \in \ker(\Phi)$. Since Ψ is an epimorphism there exists an $h \in H$ with $\Psi(h) = g$. Since $\Phi \circ \Psi = \mathrm{id}_H$ we see that $h = \Phi(\Psi(h)) = \Phi(g) = e$. Thus $h = e$ and thus $g = \Psi(h) = \Psi(e) = e$. □

Proof. It is straightforward to verify that the map

$$\begin{array}{rcl} \Phi\colon S(A,B)/\sim & \to & A * B \\ [(g_1,\dots,g_k)] & \mapsto & g_1 \cdot \dots \cdot g_k \end{array}$$

is well-defined and that it is a homomorphism. This homomorphism is surjective since $A * B$ is a subset of $S(A,B)$. Next we consider the map[268]

$$\begin{array}{rcl} \Psi\colon A * B & \to & S(A,B)/\sim \\ (g_1,\dots,g_k) & \mapsto & [(g_1,\dots,g_k)]. \end{array}$$

It is straightforward to see that Ψ is a homomorphism. It is clear that $\Phi \circ \Psi = \mathrm{id}_{A*B}$. It is not so obvious that $\Psi \circ \Phi = \mathrm{id}_{S(A,B)/\sim}$. In fact we will proceed in a slightly different fashion: to show that Φ is an isomorphism it suffices, according to Lemma 11.17, to show that Ψ is surjective. This in turn follows from the following claim.

Claim. Any element in $S(A,B)$ is equivalent to an element in $A * B$.

We prove the claim by induction on the length of a sequence in $S(A,B)$. Clearly the claim holds for all sequences of length 0. Suppose we already know the claim for all sequences of length $\leq k-1$. Let $(g_1,\dots,g_k)$ be a sequence of length k. If $(g_1,\dots,g_k) \in A * B$, then we are done. Now suppose that this is not the case. Then one of the following occurs:

(1) either there exists an $i \in \{1,\dots,k\}$ with $g_i = e$, or
(2) there exists an $i \in \{1,\dots,k-1\}$ with $g_i, g_{i+1} \in A$, or
(3) there exists an $i \in \{1,\dots,k-1\}$ with $g_i, g_{i+1} \in B$.

In the first case the sequence is equivalent to $(g_1,\dots,g_{i-1},g_{i+1},\dots,g_k)$. In the second and third case the sequence is equivalent to $(g_1,\dots,g_{i-1}\cdot g_{i+1},\dots,g_k)$. In all three cases we have thus shown that our original sequence is equivalent to a sequence of length $k-1$. So we are done by our induction hypothesis. This concludes the proof of the claim. □

Let A and B be two groups. In the following we will use the isomorphism of Proposition 11.16 to identify the group $S(A,B)/\sim$ with the free product $A * B$. Both groups have their advantages:

(1) In the group $S(A,B)/\sim$ it is easier to write down the product of two elements, we just need to juxtapose sequences of elements in A and B.
(2) On the other hand in the group $A * B$ it is trivial to check whether two elements are the same. For example for two non-trivial elements $a \in A$ and $b \in B$ the elements (a,b) and (b,a) of $A * B$ are by definition different. But from the definition of $S(A,B)/\sim$ it is not immediately clear that $[(a,b)]$ and $[(b,a)]$ are indeed different.

[268]Put differently, $A * B \to S(A,B)/\sim$ is the homomorphism that is given by the universal property of $A * B$.

11.4. **The Grushko-Neumann Theorem.** We start out with the following natural definition.

Definition. Let G be a finitely generated group. We denote by $d(G) \in \mathbb{N}_0$ the minimal number of elements in a generating set for G.

Remark. It is an unfortunate fact of life that in the literature the number $d(G)$ is usually referred to as the rank of the group G. But for abelian groups the invariants $\operatorname{rank}(G)$ and $d(G)$ can differ quite dramatically. For example for $G = (\mathbb{Z}_2)^n$ we have $\operatorname{rank}(G) = 0$ but $d(G) = n$.

The following theorem was proved by Igor Grushko [Gru] in 1940 and independently by Bernhard Neumann [Neum] in 1940.

Theorem 11.18. (Grushko-Neumann Theorem) *Given any two finitely generated groups A and B we have*

$$d(A * B) \;=\; d(A) + d(B).$$

Proof. The proof is evidently given in the above two references, but it can also be found in any self-respecting book on combinatorial group theory, see e.g. [LS, Corollay IV.1.9] and [MKS, p. 192]. □

We already saw that some groups can be written as a direct product of two groups in different ways. For example it follows from the Chinese Remainder Theorem that the groups $\mathbb{Z}_3 \times \mathbb{Z}_{35}$ and $\mathbb{Z}_5 \times \mathbb{Z}_{21}$ are isomorphic. The following theorem says that the situation is much more rigid for free products. Before we can state the theorem we have to introduce the following definition.

Definition. A group G is *indecomposable* if it is not isomorphic to the free product of two non-trivial groups.

The following lemma will be proved in Exercise 11.4.

Lemma 11.19. *Abelian groups and finite groups are indecomposable.*

Now we can state the Grushko[269] Decomposition Theorem.

Theorem 11.20. *Let G be a finitely generated group.*

(1) *The group G is isomorphic to the free product $G = A_1 * \cdots * A_k$ of non-trivial indecomposable groups.*[270]
(2) *The isomorphism types of $A_1, \dots, A_k$ are unique up to permutation. More precisely, if $A_1, \dots, A_k$ and $B_1, \dots, B_l$ are indecomposable finitely generated groups such that*

$$A_1 * \cdots * A_k \;\cong\; B_1 * \cdots * B_l,$$

then $k = l$ and furthermore there exists a permutation $\sigma \in S_k$ such that $A_i \cong B_{\sigma(i)}$ for $i = 1, \dots, k$.

[269] Igor Grushko was a Russian mathematician. The theorem was proved in 1940.

[270] If G is trivial then $k = 0$ and the free product of zero groups is by convention the trivial group.

Proof.

(1) This statement follows easily from induction on $d(G)$ and the Grushko-Neumann Theorem 11.18. Indeed, if $d(G) = 0$ then there is nothing to prove. Next suppose that the statement is known for all groups G with $d(G) < k$. Let G be a group with $d(G) = k$. If G is indecomposable, we are done. If G is not indecomposable, then we can write G as the free product of two non-trivial groups A and B. By the Grushko-Neumann Theorem 11.18 we have $d(G) = d(A) + d(B)$. Since A and B are non-trivial we have $d(A) \geq 1$ and $d(B) \geq 1$. Thus we have $d(A) < k$ and $d(B) < k$ and by induction we can find decompositions for A and B. These two decompositions put together give the desired decomposition for $G = A * B$.

(2) The uniqueness statement follows from a refinement of Grushko's proof due to John Stallings [Sta2, p. 168f]. See also [Nel, Theorem 4.1] for a more direct reference. □

Example. It follows from Lemma 11.19 and from the Grushko Decomposition Theorem 11.20 that the free product $\mathbb{Z}_3 * \mathbb{Z}_{35}$ is not isomorphic to the free product $\mathbb{Z}_5 * \mathbb{Z}_{21}$.

Exercises for Chapter 11.

Exercise 11.1. Show that $\mathbb{Q}$ does not admit an epimorphism onto $\mathbb{Z}$.

Exercise 11.2.

(a) Show that there exists an abelian group G with $G \oplus G \cong G$.

(b) Let A be a finitely generated abelian group. Show that if B is an abelian group with $B \oplus A \cong A$, then $B \cong 0$.
Hint: Arguably it is easiest to start out with the special case that $A = \mathbb{Z}$.

Exercise 11.3. Let M be a connected manifold, let $P_1, \ldots, P_n$ and $Q_1, \ldots, Q_n$ be points on M. Does there exist an action by a free group F on M such that for any $i \in \{1, \ldots, n\}$ there exists a $g \in F$ with $g \cdot P_i = Q_i$?

Exercise 11.4. Show that abelian groups and finite groups are indecomposable.

Exercise 11.5. Let $p, q, r \in \mathbb{N}_{\geq 2}$ be coprime. By the Chinese Remainder Theorem we know that $\mathbb{Z}_{pq} \times \mathbb{Z}_r \cong \mathbb{Z}_p \times \mathbb{Z}_{qr}$. Show, without making use of the Grushko Decomposition Theorem, that $\mathbb{Z}_{pq} * \mathbb{Z}_r$ is not isomorphic to $\mathbb{Z}_p * \mathbb{Z}_{qr}$.
Perhaps it is notationally easier to write $A = \{e, a, \ldots, a^{pq-1}\}$, $B = \{e, b, \ldots, b^{r-1}\}$, $C = \{e, c, \ldots, c^{p-1}\}$ and $D = \{e, d, \ldots, d^{qr-1}\}$, where A, B, C and D have the obvious multiplicative group structure. Then the problem is to show that $A * B$ is not isomorphic to $C * D$.

Exercise 11.6. Let S and T be sets. If there exists a monomorphism $\varphi\colon \langle S \rangle \to \langle T \rangle$, does it follow that $\#S \leq \#T$?

Exercise 11.7. A group G is called *locally free* if every finitely generated subgroup is free. Is every locally free group also a free group?

12. The basic Seifert-van Kampen Theorem

We are still lacking the computation of fundamental groups of even fairly simple topological spaces. Now we will take a new approach to calculating fundamental groups. Namely in the following two chapters we will formulate and prove results which allow us to calculate the fundamental group of a given topological space from the fundamental groups of suitable subspaces.

12.1. **The formulation of the basic Seifert–van Kampen Theorem.** The idea of the Seifert-van Kampen theorem is to reduce the calculation of the fundamental group of a topological space X to the determination of fundamental groups of "simpler subsets" of X.

Let X be a topological space and let $U, V \subset X$ be two subsets with $X = U \cup V$ and with $U \cap V \neq \varnothing$. We choose a base point $x_0 \in U \cap V$ and we consider the following inclusion maps and the corresponding induced homomorphisms of the fundamental groups:

$$\begin{tikzcd} U \cap V \arrow[r] \arrow[d] & U \arrow[d, "i"] \\ V \arrow[r, "j"'] & X = U \cup V \end{tikzcd} \quad \text{and} \quad \begin{tikzcd} \pi_1(U \cap V, x_0) \arrow[r] \arrow[d] & \pi_1(U, x_0) \arrow[d, "i_*"] \\ \pi_1(V, x_0) \arrow[r, "j_*"'] & \pi_1(X, x_0) = \pi_1(U \cup V, x_0). \end{tikzcd}$$

Our goal is to determine the fundamental group of the total space $X = U \cup V$ in terms of the fundamental groups of U, V, $U \cap V$ and the induced maps $\pi_1(U \cap V, x_0) \to \pi_1(U, x_0)$ and $\pi_1(U \cap V, x_0) \to \pi_1(V, x_0)$.

We start out with the following lemma:

Lemma 12.1. *Let X be a topological space and let $U, V \subset X$ be two open subsets with $X = U \cup V$ and such that $U \cap V \neq \varnothing$. We choose a base point $x_0 \in U \cap V$. If $U \cap V$ is path-connected, then the homomorphism*

$$\pi_1(U, x_0) * \pi_1(V, x_0) \ \to \ \pi_1(X, x_0),$$

which is induced by the homomorphisms $\pi_1(U, x_0) \to \pi_1(X, x_0)$ and $\pi_1(V, x_0) \to \pi_1(X, x_0)$ and by Lemma 11.12 (2), is surjective.

Example.

(1) We consider the sphere

$$X \ = \ S^2 \ = \ \{(x, y, z) \mid x^2 + y^2 + z^2 = 1\},$$

with the covering $X = U \cup V$ given by the two open subsets

$$\begin{aligned} U &= \{(x, y, z) \mid x^2 + y^2 + z^2 = 1 \text{ and } z > -\tfrac{1}{2}\}, \\ V &= \{(x, y, z) \mid x^2 + y^2 + z^2 = 1 \text{ and } z < \tfrac{1}{2}\}. \end{aligned}$$

We pick the base point $x_0 = (1, 0, 0) \subset U \cap V$. Here the intersection $U \cap V$ is path-connected, therefore we can apply Lemma 12.1. It says that we have an epimorphism

$$\pi_1(U, x_0) * \pi_1(V, x_0) \ \to \ \pi_1(S^2, x_0).$$

The subspaces U and V are homeomorphic to an open disk,[271] thus the fundamental groups are trivial. It follows that the trivial group[272] surjects onto $\pi_1(S^2, x_0)$, thus $\pi_1(S^2, x_0)$ itself is trivial. Precisely the same argument shows that $\pi_1(S^n) = 0$ for $n \geq 3$.

We had already obtained this result in Proposition 5.14. In fact, as we will see shortly, the proof of Lemma 12.1 has clear parallels to the proof of Proposition 5.14.

(2) We consider the sphere

$$X \;=\; S^1 \;=\; \{e^{it} \mid t \in \mathbb{R}\},$$

with the covering $X = U \cup V$ given by the two open subsets

$$\begin{aligned} U &:= \{e^{it} \mid t \in (-\tfrac{\pi}{4}, \tfrac{5\pi}{4})\} \\ V &:= \{e^{it} \mid t \in (\tfrac{3\pi}{4}, \tfrac{9\pi}{4})\}. \end{aligned}$$

We pick the base point $x_0 = 1$. The subsets U and V are both homeomorphic to an open interval, hence $\pi_1(U, x_0) = \pi_1(V, x_0) = 0$, but of course we know from Corollary 7.19 that $\pi_1(X, x_0) \cong \mathbb{Z}$. Thus we see that $\pi_1(U, x_0) * \pi_1(V, x_0) \to \pi_1(X, x_0)$ is not an epimorphism. This is not a contradiction to Lemma 12.1, since in this example the intersection $U \cap V$ is not path-connected.

Now we turn to the proof of Lemma 12.1.

Proof of Lemma 12.1. Let X be a topological space and let $U, V \subset X$ be two open subsets with $X = U \cup V$ and such that $U \cap V \neq \varnothing$. We choose a base point $x_0 \in U \cap V$. It suffices to prove the following claim.[273]

Claim. Every loop $s\colon [0,1] \to X = U \cup V$ in x_0 is path-homotopic to a loop which is the product of finitely many loops in (U, x_0) or in (V, x_0).

So let $s\colon [0,1] \to X = U \cup V$ be a loop in x_0. Since U and V are open we can use Corollary 1.106 to find a subdivision

$$0 \;=\; t_0 \;<\; t_1 \;<\; t_2 \;<\; \ldots \;<\; t_k \;<\; t_{k+1} \;=\; 1$$

of the interval $[0,1]$ such that the image of each $s_i := s|_{[t_i, t_{i+1}]}$ lies in U or in V. The same argument as in the proof of Proposition 5.14 shows that we can assume that each $s(t_i)$ lies in $U \cap V$.[274] The problem is that even though the paths s_i lie in U respectively in V, they are not necessarily loops in x_0. But since $U \cap V$ is path-connected we can find for each $i \in \{1, \ldots, k\}$ a path p_i in $U \cap V$ which connects $s(t_i) \in U \cap V$ to the base point $x_0 \in U \cap V$.

[271] A homeomorphism is for example given by stereographic projection.

[272] Here we use the obvious fact that the free product of two times the trivial group is again the trivial group.

[273] Why does it suffice to prove this claim?

[274] Indeed, if $s(t_i)$ lies in $U \setminus V$, then $s([t_{i-1}, t_i])$ and $s([t_i, t_{i+1}])$ cannot lie in V, hence they both lie in U. This implies that $s_{([t_{i-1}, t_{i+1}])}$ lies in U, and therefore we can remove t_i from the subdivision.

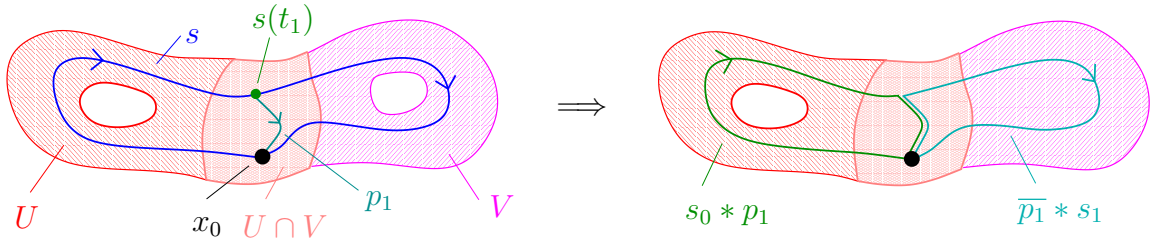

FIGURE 233. Schematic image for the proof of Lemma 12.1.

Now we have the following path-homotopies:

$$\begin{array}{ccccl}
 & & \text{by Lemma 5.4, since } s \text{ is a reparametrization of } s_0 * \cdots * s_k & & \text{since each } p_i * \overline{p_i} \text{ is null-homotopic} \\
 & & \downarrow & & \downarrow \\
s & \simeq & s_0 * \cdots * s_k & \simeq & s_0 * p_1 * \overline{p_1} * s_1 * p_2 * \overline{p_2} * s_2 * p_3 * \overline{p_3} * \ldots * \overline{p_k} * s_k \\
 & & & \simeq & (\underbrace{s_0 * p_1}_{\substack{\text{loop in } (U,x_0) \\ \text{or in } (V,x_0)}}) * (\underbrace{\overline{p_1} * s_1 * p_2}_{\substack{\text{loop in } (U,x_0) \\ \text{or in } (V,x_0)}}) * (\underbrace{\overline{p_2} * s_2 * p_3}_{\substack{\text{loop in } (U,x_0) \\ \text{or in } (V,x_0)}}) * (\overline{p_3} * \ldots * (\overline{p_k} * s_k).
\end{array}$$

Thus we have shown that s is path-homotopic to a product of loops in (U, x_0) and (V, x_0).[275] $\square$

Theorem 12.2. (Seifert-van Kampen)[276] *Let X be a topological space and let $U, V \subset X$ be two open subsets with $X = U \cup V$ and with $U \cap V \neq \varnothing$. We choose a base point $x_0 \in U \cap V$. If $U \cap V$ is simply connected, then the map*

$$\pi_1(U, x_0) * \pi_1(V, x_0) \;\to\; \pi_1(X, x_0)$$

that is induced by $\pi_1(U, x_0) \to \pi_1(X, x_0)$ and $\pi_1(V, x_0) \to \pi_1(X, x_0)$ and Lemma 11.12 (2), is an isomorphism.

Remark. One might wonder whether the hypothesis that $U \cap V$ is simply connected is really necessary. But this is indeed the case. For example we could take $X = S^1 \times [-1, 1]$ with $U = S^1 \times [-1, \frac{1}{2})$ and $V = S^1 \times (-\frac{1}{2}, 1]$. In this case we have $\pi_1(X) \cong \mathbb{Z}$ which is not isomorphic to the non-abelian group $\pi_1(U) * \pi_1(V) \cong \mathbb{Z} * \mathbb{Z}$.

We postpone the proof of the Seifert-van Kampen Theorem 12.2 to the next section and we first discuss several examples and applications of the theorem.

[275]The proof of Lemma 12.1 is arguably easier to follow than the proof of Proposition 5.14. The reason is that in the special case Proposition 5.14 we introduced more notation, e.g. North Pole and South Pole, than was perhaps strictly necessary. All we really needed was that we could cover S^2 by two open simply connected subsets U and V such that $U \cap V$ is path-connected. The precise choice of U and V is irrelevant.

[276]The theorem was proved independently by Herbert Seifert (1907-1996) and Egbert van Kampen (1908-1942).

Let A and B be two topological spaces and let $a \in A$ and $b \in B$ be two points. Recall that on page 315 we defined the wedge $A \vee B$ of A and B as

$$A \vee B \ := \ A \sqcup B \ / \ a = b.$$

We illustrate this definition in Figure 234. In the following we will often identify A and B with their respective images in $A \vee B$. Another way of thinking about the wedge of A and B is to say that the wedge $X = A \vee B$ can be decomposed into two subsets A and B such that $A \cap B$ is a point. Since $A \cap B$ is a point it is in particular simply connected. Thus it sounds like one should be able to apply the Seifert-van Kampen Theorem 12.2. This is almost correct, except that in the Seifert-van Kampen Theorem we have to deal with decompositions of a topological space X into *open* subsets. We therefore need to introduce a somewhat technical definition.

FIGURE 234. The wedge of a circle with a torus.

Definition. We say a point x in a topological space X is *good*, if the following two conditions are satisfied:

(1) $\{x\}$ is a closed subset of X and
(2) there exists an open neighborhood U of x such that x is a deformation retract of U.

Remark.

(1) As we pointed out on page 55, if X is Hausdorff, then any finite subset, in particular any subset consisting of a single point, is closed. Thus the first condition in the definition of a good point is satisfied "for free".
(2) What we call a "good point" is sometimes called a "nondegenerate point", see e.g. [Le3, p. 212]. On the other hand, the term "nondegenerate point" is defined in a subtly different way, see e.g. [Sp, p. 380] or [Bre, p. 435]. Also note that a point $x \in X$ is good if the pair $(X, \{x\})$ is good in the sense of [Hat, p. 114].

Examples.

(1) Let X be an n-dimensional topological manifold (e.g. a sphere). We claim that every point is good. Since X is by definition Hausdorff we only need to show that Condition (2) is always satisfied. Thus let $x \in X$. Using a chart around x one easily sees that x admits an open neighborhood that is homeomorphic to the open ball B^n or to the "open half-ball" $\{(x_1, \ldots, x_n) \in B^n \,|\, x_n \geq 0\}$. In both cases x is evidently a deformation retract of that open neighborhood.

(2) We consider $X = \mathbb{C} \setminus \{\frac{1}{n} \mid n \in \mathbb{N}\}$. Morally speaking the point $x = 0$ is not good, "since any open neighborhood of 0 has non-trivial fundamental group". In Exercise 12.1 we will provide a proper proof that $x = 0$ is not a good point of X.

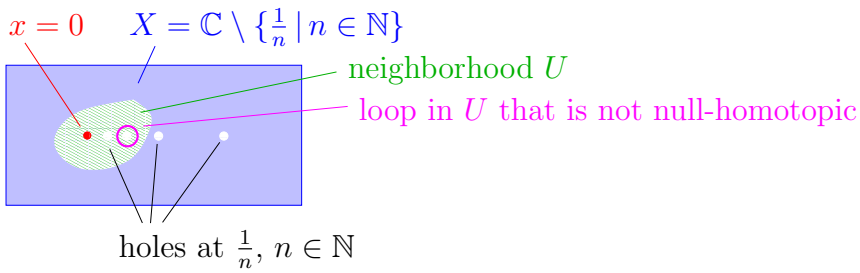

FIGURE 235. Example of a point that is not good.

Proposition 12.3. *Let A and B be two path-connected topological spaces and let $a \in A$ and $b \in B$ be good points. Then the inclusion maps induce an isomorphism*[277]

$$\pi_1(A, a) * \pi_1(B, b) \xrightarrow{\cong} \pi_1(A \vee B, a = b).$$

Remark. In the definition of a "good point" we demanded that the one-point subset given by the point is closed. Strictly speaking we do not need this fact in the proof of Proposition 12.3.

Proof. Let A and B be two path-connected topological spaces and let $a \in A$ and $b \in B$ be good points. We write $X = A \vee B$ and $x_0 = \{a, b\} \in A \vee B$. By Lemma 9.17 we can view A and B as subsets of $X = A \vee B$ in the obvious way.

We pick an open neighborhood C in A of a that deformation retracts to a. Furthermore we pick an open neighborhood D of b in B that deformation retracts to b. We consider $U := A \vee D$ and $V := B \vee C$, each viewed as subsets of $X = A \vee B$.

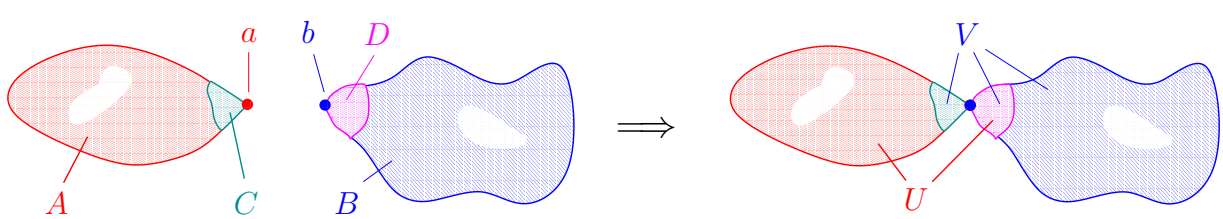

FIGURE 236. Schematic image for the proof of Proposition 12.3.

[277]More precisely, the two natural inclusions $A \to A \vee B$ and $B \to A \vee B$ induce homomorphisms $\pi_1(A, a) \to \pi_1(A \vee B, a = b)$ and $\pi_1(B, b) \to \pi_1(A \vee B, a = b)$. Combined with Lemma 11.12 (2) we obtain the homomorphism $\pi_1(A, a) * \pi_1(B, b) \to \pi_1(A \vee B, a = b)$.

Now we consider the following diagram

$$\begin{array}{ccc} \pi_1(A,a) * \pi_1(B,b) & \longrightarrow & \pi_1(X,x_0) \\ \downarrow & & \downarrow = \\ \pi_1(U,x_0) * \pi_1(V,x_0) & \longrightarrow & \pi_1(X,x_0). \end{array}$$

We make the following observations:

(1) The vertical and horizontal maps are all induced by the various inclusions of topological spaces. In particular the diagram commutes.
(2) It follows from the definition of the quotient topology on $A \vee B = (A \sqcup B)/\sim$ that U and V are open subsets of X.
(3) It follows from Lemma 9.19 that A is a deformation retract of $U = A \vee C$.
(4) As in (3) we see that B is a deformation retract of $V = B \vee D$.
(5) Furthermore, very similar to the argument in (3), we see that $A \cap B$ is a deformation retract of $U \cap V = C \vee D$. It follows from Lemma 9.10 and Proposition 9.12 (1) that $U \cap V$ is simply connected.
(6) By (2) and (5) we can apply the Seifert-van Kampen Theorem 12.2 to the decomposition $A \vee B = U \cup V$ and we obtain that the bottom horizontal map of the above diagram is an isomorphism.
(7) It follows from (3), (4) and Lemma 9.10 that the inclusions $A \to U = A \cup D$ and $B \to V = B \cup C$ are homotopy equivalences.
(8) It follows from (6) together with Proposition 9.12 (1) that the two inclusion induced maps $\pi_1(A,a) \to \pi_1(U,a)$ and $\pi_1(B,b) \to \pi_1(V,b)$ are isomorphisms, which implies that the left vertical map in the above commutative diagram is an isomorphism.
(9) We deduce that the top horizontal map is, as desired, also an isomorphism. □

Examples.

(1) We consider again the wedge $S^1 \vee S^1$ with $a = (1,0)$ and $b = (-1,0)$. These points are simple.[278] By Proposition 7.18 we know that $\pi_1(S^1, a) = \langle x \rangle$[279] and

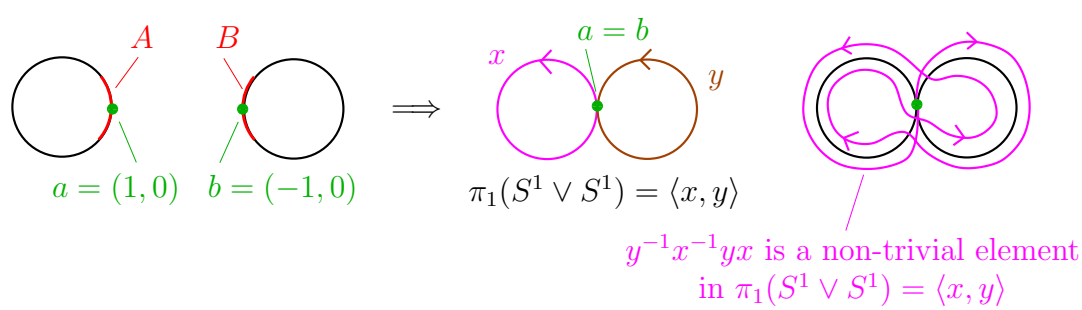

FIGURE 237. The wedge of two circles.

[278]This follows either from the general statement that any point on a topological manifold is simple, or more simply, by taking A and B to be small "intervals" around a and b.

$\pi_1(S^1, b) = \langle y \rangle$ where x and y are represented by loops that go "once around the circle", as illustrated in Figure 237. Proposition 12.3 says that the inclusion maps induce an isomorphism

$$\langle x, y \rangle \;=\; \langle x \rangle * \langle y \rangle \;=\; \pi_1(S^1, a) * \pi_1(S^1, b) \;\xrightarrow{\cong}\; \pi_1(S^1 \vee S^1, a = b).$$

(2) We consider the loop γ from page 227 in $\mathbb{C}\setminus\{\pm 1\}$ that is also illustrated in Figure 238 on the left. We had already pointed out on page 316 that there exists a deformation retraction f from $\mathbb{C} \setminus \{\pm 1\}$ to the wedge of two circles that is given by

$$S^1 \vee S^1 \;=\; \underbrace{\{z \in \mathbb{C} \mid |z+1| = 1\} \cup \{z \in \mathbb{C} \mid |z-1| = 1\}}_{\text{two circles that meet at the origin}}.$$

We then have $f_*([\gamma]) = [f \circ \gamma] = \langle y^{-1}x^{-1}yx \rangle \in \langle x, y \rangle = \pi_1(S^1 \vee S^1)$, which is non-trivial. Thus we see that $f \circ \gamma$ is not null-homotopic in $S^1 \vee S^1$ which implies that γ is not null-homotopic in $\mathbb{C} \setminus \{\pm 1\}$.[280]

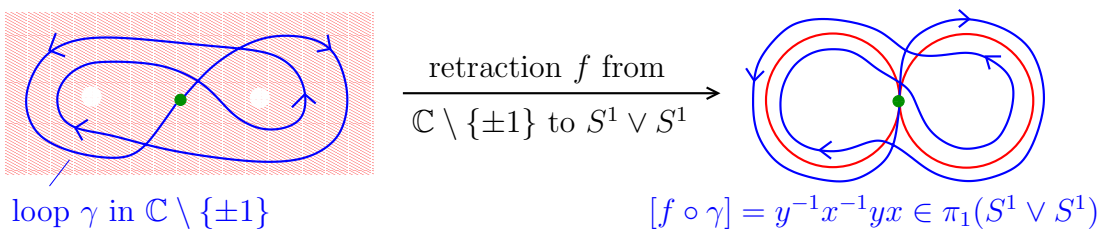

FIGURE 238.

Before we continue we condense the above example into a lemma.

Lemma 12.4. *Let $k \in \mathbb{N}_0$. The map*

$$\langle x_1, \dots, x_k \rangle \;\to\; \pi_1\Big(\bigvee_{i=1}^{k} S^1, *\Big)$$

that is given by

$$x_i \;\mapsto\; \begin{bmatrix} [0,1] & \to & S^1_i \\ t & \mapsto & e^{2\pi i t} \end{bmatrix}$$

is an isomorphism.

Convention. We refer to the images of $x_1, \dots, x_k$ under the isomorphism of Lemma 12.4 as the *standard generating set* of $\pi_1\Big(\bigvee_{i=1}^{k} S^1, *\Big)$.

[279]Recall that $\langle x \rangle$ denotes the free group generated by x, i.e. $\langle x \rangle = \{\dots, x^{-1}, e = x^0, x, x^2, \dots\}$.

[280]We could also have applied Seifert-van Kampen Theorem 12.2 to the covering $\mathbb{C} \setminus \{\pm 1\} = U \cup V$ where $U = \{z \in \mathbb{C} \setminus \{-1\} \mid \mathrm{Re}(z) < \frac{1}{2}\}$ and $V = \{z \in \mathbb{C} \setminus \{1\} \mid \mathrm{Re}(z) > -\frac{1}{2}\}$. Both sets U and V are open and they are homotopy equivalent to a circle.

Proof. Similar to the above example the lemma follows from applying Proposition 12.3 altogether $k-1$ times. □

Lemma 12.5.

(1) *Let G be a finite connected spatial graph with v vertices and e edges. Then*

$$\pi_1(G) \;\cong\; \textit{free group on } 1-\chi(G) = 1+e-v \textit{ generators.}$$

(2) *Two finite connected graphs are homotopy equivalent if and only if they have the same Euler characteristic.*

Proof.

(1) Let G be a finite connected spatial graph with v vertices and e edges. In Proposition 9.21 (3) we showed that the graph G is homotopy equivalent to the wedge of $1-\chi(G) = 1+e-v$ circles. Thus it follows from Propositions 9.12 (1) and 12.3 that $\pi_1(G)$ is isomorphic to the free group on $1-\chi(G) = 1+e-v$ generators.

(2) Let G and G' be two finite connected graphs. If $\chi(G) = \chi(G')$, then we already saw in Proposition 9.21 (5) that G and G' are homotopy equivalent. On the other hand, if $\chi(G) \neq \chi(G')$, then it follows from (1) together with Lemma 11.15 that G and G' are not homotopy equivalent. □

As a last example in this section we would like to determine the fundamental group of

$$X \;=\; \big(\mathbb{R} \sqcup (\mathbb{Z}\times S^2)\big) \,/\, n \sim (n,(0,0,-1)).$$

The space X consists of an infinite line where to each $n \in \mathbb{Z}$ we attach a 2-dimensional sphere. The space X is illustrated in Figure 239. Given $k \in \mathbb{N}$ we denote by X_k the

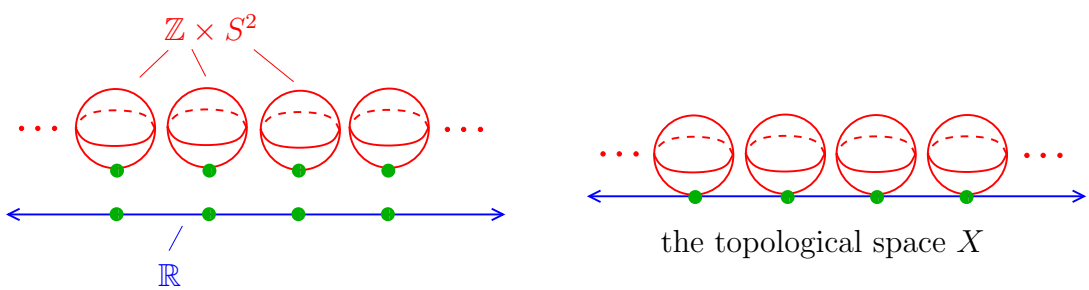

FIGURE 239.

topological space that is obtained by X by restricting oneself to the interval $(-k-\frac{1}{2}, k+\frac{1}{2})$, i.e.

$$X_k \;=\; \Big(\big(-k-\tfrac{1}{2}, k+\tfrac{1}{2}\big) \sqcup (\{-k,\dots,k-1,k\}\times S^2)\Big) \,/\, n \sim (n,(0,0,-1)).$$

Note that X_k can be viewed as the wedge of an open interval with $2k+1$ spheres. It follows immediately from Proposition 5.14, Proposition 12.3 and a straightforward induction argument that $\pi_1(X_k) = 0$ for all k. Furthermore one can easily convince oneself that the sets X_k are open. It now follows from the following lemma that $\pi_1(X)$ is also trivial.

Lemma 12.6. *Let X be a path-connected topological space and let $x_0 \in X$. Furthermore let $X_k, k \in \mathbb{N}$ be a sequence of subsets of X such that the following hold:*

(1) *each X_k is open,*
(2) *each X_k is simply connected,*
(3) *the sequence X_k is nested, i.e. for each k we have $X_k \subset X_{k+1}$,*
(4) *we have $\bigcup_{k\in\mathbb{N}} X_k = X$.*

Then $\pi_1(X, x_0) = 0$.

The proof of the lemma, which will make essential use of Lemma 1.38, is the content of Exercise 12.2.

12.2. **Proof of the Seifert-van Kampen Theorem 12.2.** After this long list of applications we finally provide the proof of the Seifert-van Kampen Theorem 12.2.

Proof. Let X be a topological space and let $U, V \subset X$ be two open subsets with $X = U \cup V$ and with $U \cap V \neq \varnothing$ such that $U \cap V$ is simply connected. We choose a base point $x_0 \in U \cap V$. We write $A := \pi_1(U, x_0)$ and $B := \pi_1(V, x_0)$. We need to show that the map

$$\Phi\colon A * B \;=\; \pi_1(U, x_0) * \pi_1(V, x_0) \;\to\; \pi_1(X, x_0)$$

that is induced by the inclusions $U \to X$ and $V \to X$ is an isomorphism. Taking into account Lemma 12.1 it suffices to show that the map is injective. To prove injectivity it is enough to show that there exists a map $\Psi\colon \pi_1(X, x_0) \to A * B$ such that $\Psi \circ \Phi = \mathrm{id}_{A*B}$. We will prove the existence of such a map Ψ in three steps:

(1) we first construct a map $\overline{\Psi}\colon \{\text{loops in } (X, x_0)\} \to A * B$,
(2) then we show that $\overline{\Psi}$ descends to a well-defined map

$$\begin{array}{rcl} \Psi\colon \pi_1(X, x_0) & \to & A * B \\ [g] & \mapsto & \overline{\Psi}(g) \end{array}$$

(3) and finally we show that $\Psi \circ \Phi = \mathrm{id}_{A*B}$.

For the remainder of the proof we will identify $A * B$ with $S(A, B)/\sim$ using the isomorphism given by Proposition 11.16.

We start out with step (1). Let $g\colon [0, 1] \to X$ be a loop in (X, x_0). We apply Corollary 1.106 to the map $g\colon [0, 1] \to X$ and the open cover $X = U \cup V$. We obtain an N such that for every $i \in \{0, \dots, N-1\}$ the image of the interval $[\frac{i}{N}, \frac{i+1}{N}]$ under the map g lies in U or in V. We introduce a few definitions.

(a) We say a subinterval of $[0, 1]$ can be *colored green* if the image of the subinterval under the map g lies in U and we say a interval can be *colored blue* if the image of the subinterval lies in V. Note that the image of a subinterval lies in $U \cap V$ if and only if the subinterval can be colored green as well as blue.
(b) A *coloring* is a map $\alpha\colon \{0, \frac{1}{N}, \dots, 1 - \frac{1}{N}\} \to \{\text{blue}, \text{green}\}$ such that each subinterval $[i, i + \frac{1}{N}]$ can be colored by $\alpha(i)$. This definition is illustrated in Figure 240.

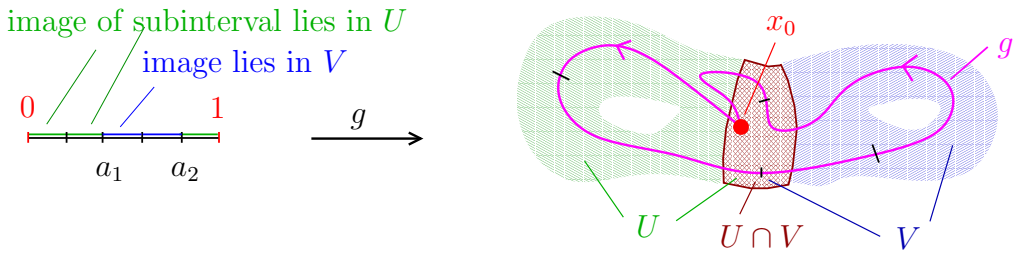

FIGURE 240.

(c) Given a coloring α we denote by $0 < a_1 < \cdots < a_{k-1} < 1$ the numbers where the coloring of the subintervals changes from one color to another. This definition is also illustrated in Figure 240. Note that for each a_i the intervals $[a_i - \frac{1}{N}, a_i]$ and $[a_i, a_i + \frac{1}{N}]$ can be colored in two different colors, which implies that $g(a_i) \in U \cap V$.

(d) A *basing* for a coloring α is a collection of paths $p_1, \ldots, p_{k-1}$ in $U \cap V$ such that each path p_i goes from x_0 to $g(a_i)$.[281]

Now given a coloring α and a basing $p_1, \ldots, p_{k-1}$ we define[282] [283]

$$\overline{\Psi}(g) \;:=\; \Big[\big[\underbrace{g|_{[0,a_1]} * \overline{p}_1}_{\substack{\text{loop in } (U,x_0) \text{ or}\\ \text{loop in } (V,x_0)}}\big], \big[\underbrace{p_1 * g|_{[a_1,a_2]} * \overline{p}_2}_{\substack{\text{loop in } (U,x_0) \text{ or}\\ \text{loop in } (V,x_0)}}\big], \ldots, \big[\underbrace{p_{k-1} * g|_{[a_{k-1},1]}}_{\substack{\text{loop in } (U,x_0) \text{ or}\\ \text{loop in } (V,x_0)}}\big]\Big] \;\in\; S(A,B)/\sim = A * B.$$

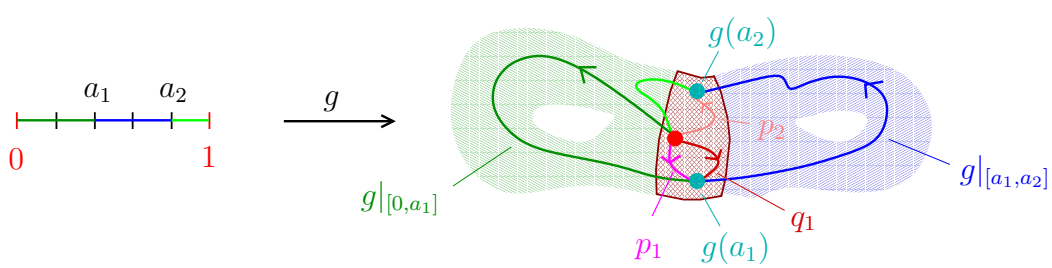

FIGURE 241.

Our next goal is to prove the following claim.

Claim. The definition of $\overline{\Psi}(g)$ does not depend on any of the choices made.

We need to prove the following three statements:

[281] Such basing exists since each $g(a_i)$ lies in $U \cap V$ and since $U \cap V$ is path-connected.

[282] Each path $p_m * g|_{[a_m,a_{m+1}]} * \overline{p}_{m+1}$ is a loop in (U, x_0) or (V, x_0), so each path represents an element in $\pi_1(U, x_0)$ or $\pi_1(V, x_0)$. Thus we obtain a sequence of elements in $\pi_1(U, x_0)$ and $\pi_1(V, x_0)$. The equivalence class of this sequence defines an element in $S(A, B)/\sim = A * B$.

[283] This definition is almost the same as in the proof of Lemma 12.1.

(a) given N and a coloring the definition does not depend on the choice of the basings,
(b) given N the definition does not depend on the choice of the coloring,
(c) the definition does not depend on the choice of N.

We first fix a coloring α and we show that the definition of $\overline{\Psi}(g)$ does not depend on the choice of the basing. First we pick a different path q_1 from x_0 to $g(a_1)$ instead of the original path p_1. (See Figure 241 for an illustration.) In this case we have

$$\begin{aligned}
&\text{definition of } \overline{\Psi}(g) \text{ using the basing } p_1, p_2, \dots, p_{k-1} \;= \\
&\qquad = \big[[g|_{[0,a_1]} * \overline{p}_1],\, [p_1 * g|_{[a_1,a_2]} * \overline{p}_2], \dots,\, [p_{k-1} * g|_{[a_{k-1},1]}]\big] \\
&\qquad \underset{\uparrow}{=} \big[[g|_{[0,a_1]} * \overline{p}_1 * q_1 * \overline{q}_1],\, [q_1 * \overline{q}_1 * p_1 * g|_{[a_1,a_2]} * \overline{p}_2], \dots,\, [p_{k-1} * g|_{[a_{k-1},1]}]\big] \\
&\qquad \text{since } q_1 * \overline{q}_1 \text{ is null-homotopic} \\
&\qquad = \big[[g|_{[0,a_1]} * \overline{q}_1],\, [q_1 * g|_{[a_1,a_2]} * \overline{p}_2], \dots,\, [p_{k-1} * g|_{[a_{k-1},1]}]\big] \\
&\qquad \uparrow \\
&\qquad \overline{p}_1 * q_1 \text{ and } \overline{q}_1 * p_1 \text{ are null-homotopic since } U \cap V \text{ is simply connected}^{284} \\
&\qquad = \text{ definition of } \overline{\Psi}(g) \text{ using the basing } q_1, p_2, \dots, p_{k-1}.
\end{aligned}$$

Precisely the same argument shows that the choices of the other paths p_i are also irrelevant. This concludes the proof of (a).

Now we show that the definition does not depend on the choice of the coloring. So suppose we have two colorings α and β. We can turn one coloring into the other by a finite sequence of color swaps of a single subinterval. Therefore it suffices to consider the case that there exists a single i where the values for $\alpha(i)$ and $\beta(i)$ differ.

We consider the case, sketched in Figure 242, with $\alpha(i) =$ blue and $\beta(i) =$ green such that the common coloring to the left is green and the common coloring to the right is blue. All other cases are dealt with in a similar way.[285]

Let $0 = a_0 < a_1 < \cdots < a_k = 1$ be the decomposition for α. We pick a basing $p_1, \dots, p_{k-1}$ for α. There exists a unique m with $a_m = i$. The corresponding decomposition for the coloring β is given by $0 = a_0 < a_1 < \cdots < a_m + \frac{1}{N} < a_{m+1} < a_k = 1$. We write $q = g_{[a_m, a_m + \frac{1}{N}]}$. Since $[a_m, a_m + \frac{1}{N}]$ can be colored green and blue we see that q lies actually

[284]This is the only time that in the proof we use the hypothesis that $U \cap V$ is simply connected. In fact if one studies the argument carefully one sees that we only used that the maps $\pi_1(U \cap V, x_0) \to \pi_1(U, x_0)$ and $\pi_1(U \cap V, x_0) \to \pi_1(V, x_0)$ are trivial.

[285]In fact the only case which requires a slightly modified argument is that the coloring to the left and right are the same, i.e. either both are blue or both are green. We leave it as an exercise to the reader to perform that argument.

in $U \cap V$. We have

$$\begin{aligned}
&\text{definition of } \overline{\Psi}(g) \text{ using the coloring } \alpha \text{ and the basing } p_1, \dots, p_{k-1} \;= \\
&\quad = \big[[g|_{[0,a_1]} * \overline{p}_1], \dots, [p_{m-1} * g|_{[a_{m-1},a_m]} * \overline{p}_m], [p_m * g|_{[a_m,a_{m+1}]} * \overline{p}_{m+1}], \dots\big] \\
&\quad \underset{\uparrow}{=} \big[[g|_{[0,a_1]} * \overline{p}_1], \dots, [p_{m-1} * g|_{[a_{m-1},a_m+\frac{1}{N}]} * \overline{q} * \overline{p}_m], [p_m * q * g|_{[a_m+\frac{1}{N},a_{m+1}]} * \overline{p}_{m+1}], \dots\big] \\
&\quad \text{since } g_{[a_{m-1},a_m]} \simeq g_{[a_{m-1},a_m+\frac{1}{N}]} * \overline{q} \text{ and } g_{[a_m,a_m+\frac{1}{N}]} \simeq q * g_{[a_m+\frac{1}{N},a_{m+1}]} \\
&\quad = \text{definition of } \overline{\Psi}(g) \text{ using the coloring } \beta \text{ and basing } p_1, \dots, p_{m-1}, p_m * q, p_{m+1}, \dots, p_{k-1}.
\end{aligned}$$

(We refer to Figure 242 for an illustration of the proof.) This concludes the proof of (b).

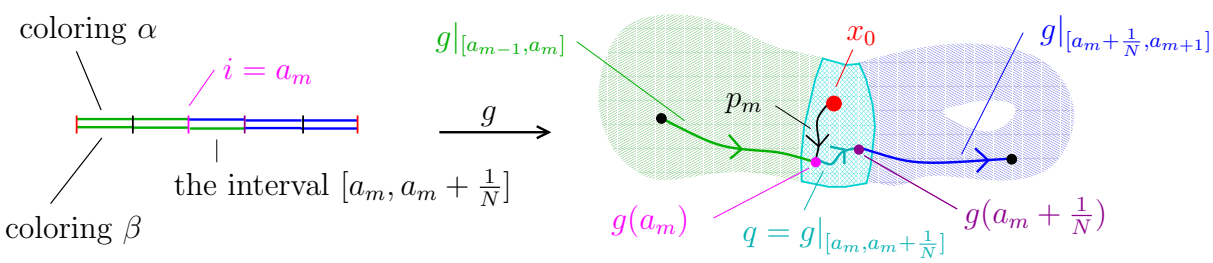

FIGURE 242.

It remains to prove (c). First suppose that instead of dividing $[0,1]$ into N intervals we divide it into $m \cdot N$ intervals for some $m \in \mathbb{N}$. A coloring for the subdivision into N subintervals then also gives rise to a coloring into $m \cdot N$ subintervals, and it follows immediately from the definitions that we end up with the same element of $A * B$. Now if had chosen a different N' instead, then we can replace N and N' by $N \cdot N'$ and by the argument we just made we obtain the same element of $A * B$. This concludes the proof of (c). Summarizing, we are now done with the proof of the claim.

We turn to step (2) of the above program. We need to prove the following claim.

Claim. If $g, g' \colon [0,1] \to X$are two path-homotopic loops in (X, x_0), then $\overline{\Psi}(g) = \overline{\Psi}(g')$.

Let $g, g' \colon [0,1] \to X$ be two path-homotopic loops in (X, x_0). We pick a path-homotopy

$$\begin{aligned} H \colon [0,1] \times [0,1] &\to X \\ (t,s) &\mapsto H^s(t). \end{aligned}$$

from the loop g to the loop g'. We apply Corollary 1.106 to the map $H \colon [0,1] \times [0,1] \to X$ and the open cover $X = U \cup V$. We obtain an N such that for each choice of $i, j \in \{0, \frac{1}{N}, \dots, 1 - \frac{1}{N}\}$ the image of the square $[i, i + \frac{1}{N}] \times [j, j + \frac{1}{N}]$ under the map H lies in U or in V. Given $j \in \{0, \frac{1}{N}, \dots, 1\}$ we now define

$$\begin{aligned} g(j) \colon [0,1] &\to X \\ t &\mapsto H^j(t) \end{aligned}$$

Note that each $g(j)$ is a loop in x_0 and that $g(0) = g$ and $g(1) = g'$. Therefore it suffices to show that for any $j \in \{0, \frac{1}{N}, \dots, 1 - \frac{1}{N}\}$ we have $\overline{\Psi}(g(j)) = \overline{\Psi}(g(j + \frac{1}{N}))$. So let $j \in \{0, \frac{1}{N}, \dots, 1 - \frac{1}{N}\}$.

As above we say that a subset of $[0,1] \times [0,1]$ can be *colored green* if the image of the subset under the map H lies in U and we say the subset can be *colored blue* if the image lies in V. We pick a map $\alpha\colon \{0, \frac{1}{N}, \dots, 1 - \frac{1}{N}\} \to \{\text{blue}, \text{green}\}$ such that for each i the value $\alpha(i)$ is a color with which the square $[i, i + \frac{1}{N}] \times [\frac{j}{N}, \frac{j+1}{N}]$ can be colored. Note that α also defines a coloring for the loops $g(j)$ and $g(j + \frac{1}{N})$.

We define $0 = a_0 < a_1 < \dots < \dots a_k = 1$ as above for the coloring α. Furthermore we pick a basing p_i, $i = 1, \dots, k-1$ for the loop $g(j)$. For $i = 0, \dots, k$ we write $q_i = H^{[j, j+\frac{1}{N}]}|_{a_i}$. Put differently, q_j connects a point on the loop $g(j)$ to the corresponding point on the loop $g(j + \frac{1}{N})$. Now we have

$$\begin{aligned}
\overline{\Psi}(g(j)) &= \overline{\Psi}(g(j)) \text{ defined using the coloring } \alpha \text{ and the basing } p_1, \dots, p_{k-1} \\
&= \big[\cdots * [p_m * \underbrace{H^j|_{[a_m, a_{m+1}]}}_{=g(j)|_{[a_m, a_{m+1}]}} * \overline{p}_{m+1}] * \dots\big] \\
&= \big[\cdots * [p_m * q_m * \overline{q}_m * H^j|_{[a_m, a_{m+1}]} * q_{m+1} * \overline{q}_{m+1} * \overline{p}_{m+1}] * \dots\big] \\
&\uparrow \\
&\text{since each } q_m * \overline{q}_m \text{ is null-homotopic} \\
&= \big[\cdots * [p_m * q_m * \underbrace{H^{j+\frac{1}{N}}|_{[a_m, a_{m+1}]}}_{=g(j+\frac{1}{N})|_{[a_m, a_{m+1}]}} * \overline{q}_{m+1} * \overline{p}_{m+1}] * \dots\big] \\
&\uparrow \\
&\text{since } H \text{ restricts to path-homotopies from } \overline{q}_m * H^j|_{[a_m, a_{m+1}]} * q_{m+1} \\
&\quad \text{to } H^{j+\frac{1}{N}}|_{[a_m, a_{m+1}]} \text{ for } m = 0, \dots, k-1 \\
&= \overline{\Psi}(g(j + \tfrac{1}{N})) \text{ defined using } \alpha \text{ and the basing } p_1 * q_1, \dots, p_{k-1} * q_{k-1}.
\end{aligned}$$

This last part of the proof is illustrated in Figure 243. This concludes the proof of the claim and thus of part (2) of our three step program.

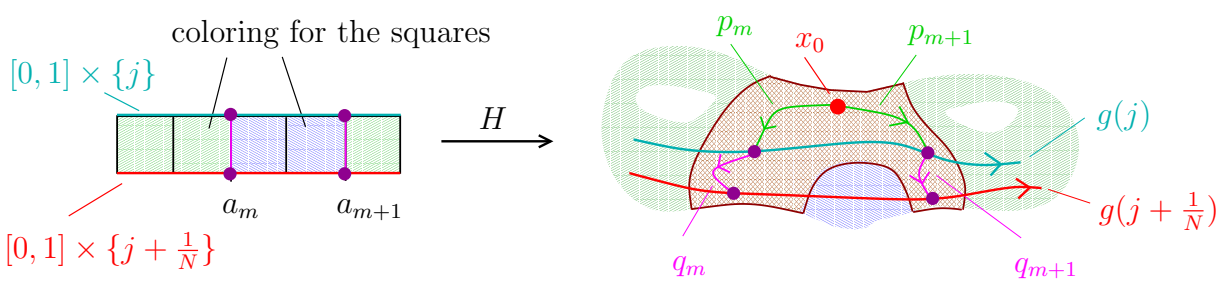

FIGURE 243.

Summarizing we now showed that the map $\overline{\Psi}$ descends to a well-defined map

$$\begin{array}{rcl} \Psi\colon \pi_1(X,x_0) & \to & A*B \\ [g] & \mapsto & \big[\,\overline{\Psi}(g)\big]. \end{array}$$

It remains to prove the following claim.

Claim. We have $\Psi\circ\Phi = \mathrm{id}_{A*B}$.

So let $[y_1]\cdot\dots\cdot[y_k]\in A*B$ where $y_1,\dots,y_k$ are loops in (U,x_0) and (V,x_0). Then

$$\begin{array}{rcl} (\Psi\circ\Phi)([y_1]\cdot\dots\cdot[y_k]) & \overset{\text{definition of } \Phi\colon A*B=\pi_1(U,x_0)*\pi_1(V,x_0)\to\pi_1(X,x_0)}{\overset{\downarrow}{=}} & \Psi([y_1*\dots*y_k]) \;=\; \big[\,\overline{\Psi}(y_1*\dots*y_k)\big] \;\underset{\substack{\text{by definition of } \overline{\Psi}\text{, where we use } N=k \text{ and where} \\ \text{we can use the constant paths as basings since} \\ y_1,\dots,y_k \text{ are already loops in } (U,x_0) \text{ and } (V,x_0)}}{\underset{\uparrow}{=}}\; [y_1*\dots*y_k] \\ & = & [y_1]\cdot\dots\cdot[y_k]. \end{array}$$

This concludes the proof of the claim and thus also the proof of the Seifert-van Kampen Theorem 12.2 □

12.3. **More examples: surfaces and the connected sum of manifolds.** Given $g\in\mathbb{N}_0$ we denote by Σ_g the surface of genus g. In this section we first want to prove the following proposition.

Proposition 12.7. *For $g\neq h$ the surface Σ_g of genus g is not homeomorphic to the surface Σ_h of genus h.*

As on several earlier occasions we want to prove this result by considering what happens if we remove a point from the topological spaces.

Lemma 12.8. *Let $g\in\mathbb{N}_0$. We denote by Σ_g the surface of genus g.*

(1) *For any point P the complement $\Sigma_g\setminus\{P\}$ is homotopy equivalent to the wedge of $2g$ circles. In particular*

$$\pi_1(\Sigma_g\setminus\{P\}) \;\cong\; \langle x_1,y_1,\dots,x_g,y_g\rangle.$$

(2) *Let $f\colon\overline{B}^2\to\Sigma_g$ be an embedding. The complement $\Sigma_g\setminus f(B^2)$ is homotopy equivalent to the wedge of $2g$ circles. Furthermore, if $Q\in f(S^1)$ is a point, then there exists an isomorphism*

$$\pi_1(\Sigma_g\setminus f(B^2),Q) \;\overset{\cong}{\to}\; \langle x_1,y_1,\dots,x_g,y_g\rangle$$

with

$$[f\colon S^1\to\Sigma_g\setminus f(B^2)] \;\mapsto\; [x_1,y_1]\cdot\dots\cdot[x_g,y_g]$$

where $[x_i,y_i]:=x_iy_ix_i^{-1}y_i^{-1}$ is the commutator of x_i and y_i. In particular the map $f\colon S^1\to\Sigma_g\setminus f(B^2)$ represents a non-trivial element in $\pi_1(\Sigma_g\setminus f(B^2),Q)$.

FIGURE 244. Illustration of Lemma 12.8.

Proof of Lemma 12.8. We prove the lemma for the surface Σ of genus 2. The proof for $g \geq 3$ is almost identical. So let $\Sigma = E_8/\sim$ as sketched in Figure 245.

(1) We denote by O the origin in $E_8 \subset \mathbb{C}$. We first show that $\Sigma \setminus \{O\}$ is homotopy equivalent to the wedge of 4 circles.

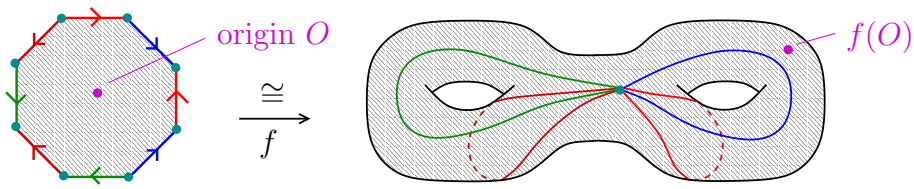

FIGURE 245.

Claim. There exists a deformation retraction from $\Sigma \setminus \{O\} = (E_8 \setminus \{O\})/\sim$ to $\partial E_8/\sim$.

First we consider the map[286][287]

$$\begin{array}{rcl} r\colon E_8 \setminus \{O\} & \to & \partial E_8 \\ re^{i\varphi} & \mapsto & \text{unique point } se^{i\varphi} \text{ on } \partial E_8. \end{array}$$

This map "projects points radially outward towards the boundary". The deformation retraction is now given by "pushing outward radially", i.e. it is given by the map

$$\begin{array}{rcl} ((E_8 \setminus \{O\})/\sim) \times [0,1] & \mapsto & (E_8 \setminus \{O\})/\sim \\ ([P], t) & \mapsto & [P \cdot (1-t) + r(P) \cdot t]. \end{array}$$

This concludes the proof of the claim.

Claim. The space $\partial E_8/\sim$ is homeomorphic to the wedge of 4 circles.

A homeomorphism is given by sending the point on $\partial E_8/\sim$ that corresponds to the vertices to the common point of the four circles, and by sending the edges that get

[286]Note that this map cannot be extended continuously to O.

[287]Here we use polar coordinates, i.e. r, s are positive real numbers.

identified to the same circle. We refer to Figure 246 for an illustration. We leave it as an exercise to write down the proof in detail.

The two claims put together show that $\Sigma \setminus \{O\}$ is homotopy equivalent to the wedge of 4 circles. We now obtain that

$$\pi_1(\Sigma_2 \setminus \{P\}) \underset{\substack{\uparrow \\ \text{Proposition 9.12 (1)}}}{\cong} \pi_1(\text{wedge of 4 circles}) \underset{\substack{\uparrow \\ \text{by Lemma 12.4}}}{\cong} \langle x_1, y_1, x_2, y_2 \rangle.$$

Now let P be some other point on Σ. By Proposition 10.23 there exists a homeomorphism $\Phi\colon \Sigma \to \Sigma$ with $\Phi(P) = O$.[288] This shows that $\Sigma \setminus \{P\}$ is homeomorphic to $\Sigma \setminus \{O\}$. We can thus appeal to the above calculation to get the desired result.

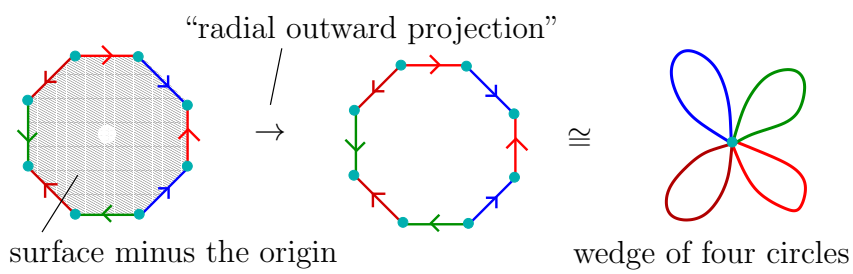

FIGURE 246.

(2) The proof of this statement is very similar to the proof of the first statement. First remove an open disk centered at O and we perform almost the same calculation as above. One easily sees that the boundary curve corresponds to the product of commutators. It follows from Theorem 10.28 that the same calculation also works for any other disk. We leave the details to the reader. □

Now we can turn to the proof of Proposition 12.7.

Proof of Proposition 12.7. Let S and T be two surfaces of genus g and h. Suppose that there exists a homeomorphism $f\colon S \to T$. Pick a point $P \in S$. We write $Q = f(P)$. The homeomorphism f restricts to a homeomorphism $f\colon S \setminus \{P\} \to T \setminus \{Q\}$. It now follows that

$$\langle x_1, \ldots, x_{2g} \rangle \underset{\substack{\uparrow \\ \text{Lemma 12.8 (1)}}}{\cong} \pi_1(S \setminus \{P\}) \xrightarrow[f_*]{\cong} \pi_1(T \setminus \{Q\}) \underset{\substack{\uparrow \\ \text{Lemma 12.8 (1)}}}{\cong} \langle y_1, \ldots, y_{2h} \rangle.$$

We obtain from Lemma 11.15 that $g = h$. □

For many applications the following theorem, which is a variation on the Seifert-van Kampen Theorem 12.9, is very useful.

[288] Note that here we use Proposition 3.13 which says that Σ is a manifold with empty boundary.

Theorem 12.9. (Seifert-van Kampen Theorem for manifolds) *Let M be an m-dimensional manifold and let $R, S \subset M$ be two m-dimensional submanifolds such that the following hold:*

1. *$M = R \cup S$,*
2. *$R \cap S$ is a component of ∂R and it is a component of ∂S,*
3. *$R \cap S$ is non-empty and simply connected,*
4. *R and S are closed subsets of M. (Note that by Lemma 1.18 (2) this condition is satisfied if R and S are compact.)*

Then for any base point $x_0 \in R \cap S$ the inclusion induced map

$$\pi_1(R, x_0) * \pi_1(S, x_0) \ \to \ \pi_1(M, x_0)$$

is an isomorphism.

Example. Let $n \geq 3$ and let $S^n_{\geq 0} := \{(x_1, \dots, x_{n+1}) \in S^n \mid x_{n+1} \geq 0\}$ be the upper hemisphere and define similarly the lower hemisphere $S^n_{\leq 0}$. Then $S^n_{\geq 0}, S^n_{\leq 0}$ are submanifolds of S^n that satisfy the hypothesis of Theorem 12.9. We saw on page 73 that both hemispheres are homeomorphic to closed balls. In particular they are compact and thus closed subsets of S^n. Therefore we obtain once again that $\pi_1(S^n) \cong \pi_1(S^n_{\geq 0}) * \pi_1(S^n_{\leq 0}) = \{e\}$.

We will of course prove Theorem 12.9 by reducing it to Theorem 12.2. As we will see, the proof is very similar to the proof of Proposition 12.3 where we determined the fundamental group of a wedge of two spaces.

The proof of Theorem 12.9 relies on the following lemma which we will use on several occasions.

Lemma 12.10. $(*)$ *Let X be a topological space and let A and B be two subsets with $X = A \cup B$. If $A \cap B$ is a deformation retract of B and if A and B are closed subsets of X, then A is a deformation retract of X.*

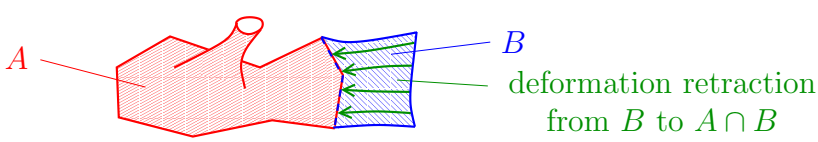

FIGURE 247. Illustration of Lemma 12.10.

Proof $(*)$. Lemma 12.10 can also be viewed as a consequence of Lemma 1.84 and the slightly scary Lemma 9.16. Since our situation is fairly straightforward we also give a direct, fairly elementary proof.

We pick a deformation retraction $F\colon B \times [0,1] \to B$ from B to $A \cap B$. We consider the map

$$\begin{array}{rcl} G\colon X \times [0,1] & \to & X \\ (x,t) & \mapsto & \begin{cases} x, & \text{if } x \in A, \\ F(x,t), & \text{if } x \in B \setminus (A \cap B). \end{cases} \end{array}$$

We claim that this map is the desired deformation retraction from X to A. Evidently all we need to do is to convince ourselves that G is continuous. It is clear that the restriction of G to $A \times [0,1]$ is continuous. Furthermore, since F is a deformation to $A \cap B$ we see that the restriction of G to $B \times [0,1]$ are continuous. By our hypothesis A and B are closed subsets of X. It follows from Lemma 1.51 that $A \times [0,1]$ and $B \times [0,1]$ are closed subsets of $X \times [0,1]$. Thus we conclude from Lemma 1.32 (2) that G is indeed continuous. $\square$

Remark. On two occasions we are going to struggle a lit bit to verify the hypothesis of Lemma 12.10 that A and B need to be closed. Thus it is good to remind ourselves of the fact that hypothesis are usually added not to vex the reader but since they are necessary. For example, let us consider the situation shown in Figure 248. Here $A \cap B$ is a deformation retract of B, but it should be pretty clear that A is not a deformation retract of $A \cup B = S^1$.

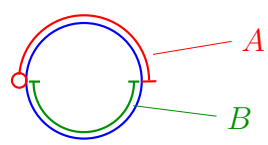

FIGURE 248.

Proof of Theorem 12.9 $(*)$. Let M be an m-dimensional manifold and let $R, S \subset M$ be two m-dimensional submanifolds such that the following hold:

(1) $M = R \cup S$,
(2) $R \cap S$ is a union of components of ∂R and it is a union of components of ∂S,
(3) $R \cap S$ is simply connected,
(4) R and S are closed subsets of M.

We pick a base point[289] $x_0 \in R \cap S$. Furthermore we pick maps $f\colon \partial R \times [0,1] \to R$ and $g\colon \partial S \times [0,1] \to S$ that are provided by the Collar Neighborhood Theorem 10.10. It follows from (2) that we can set

$$U \;:=\; R \cup \underbrace{g((R \cap S) \times [0,1))}_{\subset S \times [0,1)} \quad \text{and} \quad V \;:=\; S \cup \underbrace{f((R \cap S) \times [0,1))}_{\subset R \times [0,1)}.$$

We consider the following diagram

$$\begin{array}{ccc} \pi_1(R, x_0) * \pi_1(S, x_0) & \longrightarrow & \pi_1(M, x_0) \\ \downarrow & & \downarrow{=} \\ \pi_1(U, x_0) * \pi_1(V, x_0) & \longrightarrow & \pi_1(M, x_0). \end{array}$$

The following steps are similar to the ones we performed in the proof of Proposition 12.3.

(1) Since the vertical maps are induced by inclusions we see that the diagram commutes.

[289]Recall that being simply connected entails being non-empty, hence such a point exists.

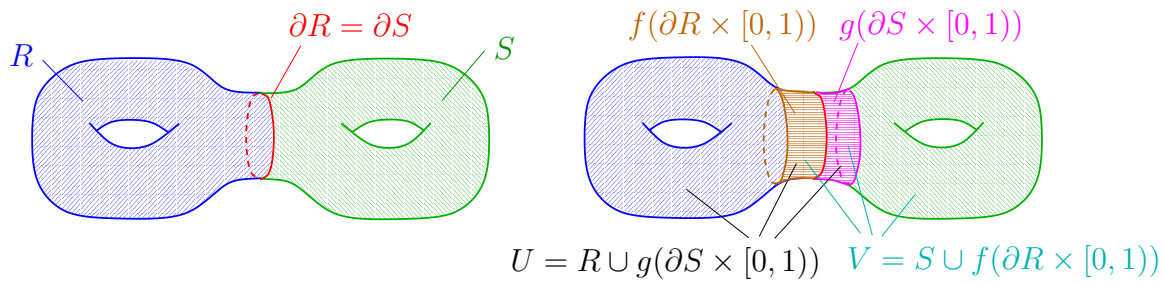

FIGURE 249. Illustration of the proof of Theorem 12.9.

(2) We claim that U is an open subset of $M = R \cup S$. Since R and S are by our hypothesis (4) closed subsets of M we obtain from Lemma 1.7 (2a) it suffices to show that $U \cap R$ is open in R and that $U \cap S$ is open in S. Evidently $U \cap R = R$ is open in R. Furthermore, $U \cap S = g((R \cap S) \times [0,1])$ is an open subset of S by (2) and Lemma 10.9.
(3) We want to use Lemma 12.10 to show that R is a deformation retract of U. We need to verify that the hypotheses of Lemma 12.10 are satisfied, i.e. we need to show that R and $g((R \cap S) \times [0,1))$ are closed subsets of U. By our hypothesis R and S are a closed subsets of M. It follows from Lemma 1.6 (2) that $R = R \cap U$ and $g((R \cap S) \times [0,1]) = S \cap U$ are closed subsets of U.
(4) The obvious analogues of (2) and (3) hold for V and S.
(5) We obtain from (2), (3), (4) and Proposition 9.12 that the vertical map on the left is an isomorphism.
(6) Similar to (3) one can show that $R \cap S$ is a deformation retract of $U \cap V$. It follows from (3), Lemma 9.10 and Proposition 9.12 (1) that $U \cap V$ is simply connected.
(7) It follows from the Seifert-van Kampen Theorem 12.2 that the bottom horizontal map of the above commutative diagram is an isomorphism.
(8) Since the vertical maps are isomorphisms we see that the top horizontal map is also an isomorphism. □

We conclude this section by considering the connected sum of two manifolds of dimension ≥ 3. More precisely, we have the following proposition:

Proposition 12.11. *Let $n \geq 3$ and let M and M' be two oriented connected non-empty n-dimensional manifolds. Then*[290]

$$\pi_1(M \# M') \;\cong\; \pi_1(M) * \pi_1(M').$$

Examples.

[290]Note that by Lemma 10.29 we know that $M \# M'$ is also connected, thus we do not need to worry about base points.

(1) Let p, q be two coprime integers and let r, s be another two coprime integers. We can then consider the lens spaces $L(p,q)$ and $L(r,s)$. It follows from Proposition 12.11 and Corollary 7.19 that
$$\pi_1(L(p,q)\#L(r,s)) \;\cong\; \mathbb{Z}_p * \mathbb{Z}_r.$$
It follows for example from this calculation of fundamental groups, from Lemma 11.19 and from the Grushko Decomposition Theorem 11.20 that the two topological spaces $L(3,1)\#L(35,1)$ and $L(5,1)\#L(21,1)$ are not homeomorphic.

(2) Let $n \geq 3$ and let M and N be two oriented connected n-dimensional manifolds. We denote by $-N$ the same manifold as N but with the opposite orientation. It follows from Proposition 12.11 that $\pi_1(M\#N) \cong \pi_1(M\#(-N))$.

Proof of Proposition 12.11. Let M and M' be two oriented connected non-empty n-dimensional manifolds and let $\varphi\colon \overline{B}^n \to M$ and $\varphi'\colon \overline{B}^n \to M'$ be two embeddings where φ is orientation-preserving and φ' is orientation-reversing. Recall that the connected sum of M and M' is defined as
$$M\#M' \;:=\; \big(\underbrace{(M \setminus \varphi(B^n))}_{=:X} \sqcup \underbrace{(M' \setminus \varphi'(B^n))}_{=:X'}\big) \,/\, \varphi(P) = \varphi'(P) \text{ for } P \in S^{n-1}.$$
We pick a base point x_0 that lies in the intersection of the images of X and X' in $M\#M'$.

Claim. The inclusion induced maps $\pi_1(X,x_0) \to \pi_1(M,x_0)$ and $\pi_1(X',x_0) \to \pi_1(M',x_0)$ are isomorphisms.

We show that the inclusion induced map $\pi_1(X,x_0) \to \pi_1(M,x_0)$ is an isomorphism. We write $Y = \varphi(\overline{B}^n)$. It follows from Proposition 10.1 that X and Y are n-dimensional submanifolds of M. Note that $X \cup Y = M$ and that $X \cap Y = \partial Y \cong S^{n-1}$. Since $n \geq 3$ we obtain from Proposition 5.14 that $X \cap Y$ is simply connected. We obtain that
$$\pi_1(X,x_0) \underset{\substack{\uparrow \\ \text{since } \pi_1(\overline{B}^n,x_0)=\{e\}}}{\xrightarrow{\cong}} \pi_1(X,x_0) * \pi_1\big(\overline{B}^n,x_0\big) \underset{\substack{\uparrow \\ \text{Theorem 12.9}}}{\xrightarrow{\cong}} \pi_1(M).$$
The same way we can show that the inclusion induced map $\pi_1(X',x_0) \to \pi_1(M',x_0)$ is an isomorphism. This concludes the proof the claim.

Now we see that[291]
$$\pi_1(M\#M,x_0) \underset{\substack{\uparrow \\ \text{by Theorem 12.9, since} \\ X\cap X' \cong S^{n-1} \text{ is simply connected}}}{\xleftarrow{\cong}} \pi_1(X,x_0) * \pi_1(X',x_0) \underset{\substack{\uparrow \\ \text{above claim}}}{\xrightarrow{\cong}} \pi_1(M,x_0) * \pi_1(M',x_0).$$
□

Remark. We cannot apply the Seifert-van Kampen Theorem 12.2 to the connected sum of two surfaces, since in this case the fundamental group of the overlap $R \cap R'$ in the proof of Proposition 12.11 is not simply connected. In particular we cannot use this approach

[291] Here the directions of the arrow indicate in which direction the obvious inclusion induced maps point.

to determine the fundamental group of the surface of genus 2, which by Figure 224 is the connected sum of two tori. Our next goal is to formulate and prove a generalization of the Seifert-van Kampen Theorem 12.2 which will allow us to determine the fundamental group of the surface of genus g for $g \geq 2$.

Exercises for Chapter 12.

Exercise 12.1. We consider $X = \mathbb{C} \setminus \{\frac{1}{n} \,|\, n \in \mathbb{N}\}$. Show that the point $x = 0$ is not good, i.e. show that there does not exist an open neighborhood U of $x = 0$ such that $x = 0$ is a deformation retract of U.

Exercise 12.2.

(a) Prove Lemma 12.6.
Hint: use Lemma 1.38.
(b) Does the conclusion of Lemma 12.6 also hold if the sets X_k are not open?

Exercise 12.3. Let M be a *topological* manifold of dimension $n \geq 3$. Let P be a point and let $x_0 \in M \setminus \{P\}$ be a base point. Show that the inclusion induced map

$$\pi_1(M \setminus \{P\}, x_0) \;\to\; \pi_1(M, x_0)$$

is an isomorphism.

Exercise 12.4.

(a) How can one hang a painting with two nails provided, such that if one removes either of the two nails, the painting falls down?
(b) What is a solution to (a) if we use three nails instead of two nails?

Hint: What does this have to do with free groups?

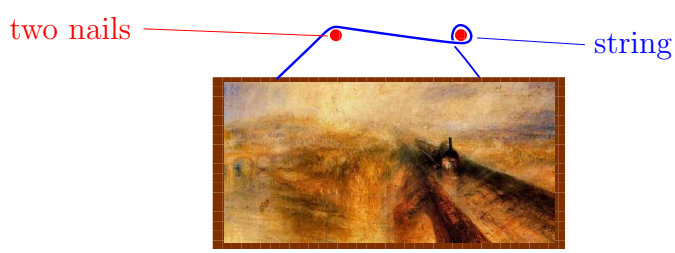

FIGURE 250. Illustration of Exercise 12.4.

Exercise 12.5. Show that condition (4) in the statement of the Seifert-van Kampen Theorem 12.9 for manifolds cannot be dropped. More precisely, give an example of an m-dimensional manifold and m-dimensional submanifolds R and S such that conditions (1), (2) and (3) are satisfied, but such that $\pi_1(R, x_0) * \pi_1(S, x_0)$ is not isomorphic to $\pi_1(M, x_0)$. Hint: The dimension m does not have to be taken particularly large.

Exercise 12.6.

(a) Let $n \geq 3$ and furthermore let $K \subset \mathbb{R}^n$ be a compact subset. We view K also as a subset of $S^n = \mathbb{R}^n \cup \{\infty\}$. Let $x_0 \in \mathbb{R}^n \setminus K$. Show that the inclusion induced map $\pi_1(\mathbb{R}^n \setminus K, x_0) \to \pi_1(S^n \setminus K, x_0)$ is an isomorphism.

(b) Does the conclusion of (a) also hold for $n = 2$?

(c) Does the conclusion of (c) also hold for non-compact subsets of $\mathbb{R}^n$?

Exercise 12.7. We consider the two topological spaces

$$X = \mathbb{R}^2 \setminus \{(\tfrac{1}{n}, 0) \,|\, n \in \mathbb{N}\} \text{ and } \quad \text{ and } Y = \mathbb{R}^2 \setminus \{(\tfrac{1}{n}, y) \,|\, n \in \mathbb{N}, y \in [-1, 1]\}.$$

We write $x_0 = (0, 0)$. We refer to Figure 251 for an illustration.

(a) Show that $\pi_1(X, x_0)$ is uncountable.
Hint: For $n \in \mathbb{N}$ we write $Z_n := \mathbb{R}^2 \setminus \{\frac{1}{n}, 0\}$ and we denote by $f_n \colon X \to Z_n$ the inclusion map. Use the induced maps $f_{n*} \colon \pi_1(X, x_0) \to \pi_1(Z_n, x_0) \cong \mathbb{Z}$ to find a homomorphism from $\pi_1(X, x_0)$ to a group such that the image is uncountable.

(b) Show that $\pi_1(Y, x_0)$ is countable.
Hint: Use Exercise 1.15 to find a monomorphism from $\pi_1(Y, x_0)$ into a countable group.

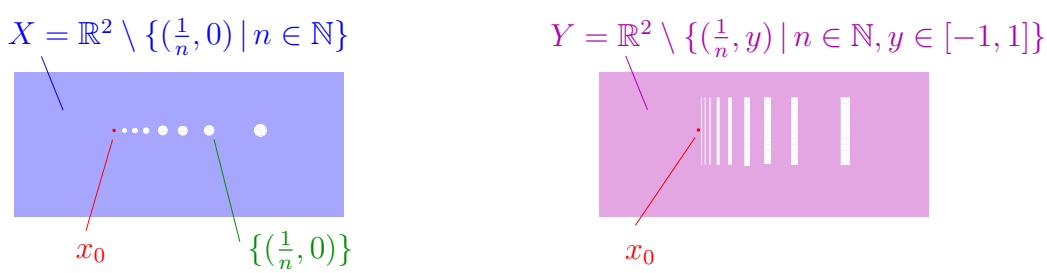

FIGURE 251.

13. Presentations of groups and amalgamated products

We have now made some progress, for example we have shown that surfaces of different genus are not homeomorphic. But this proof is perhaps slightly unsatisfactory in so far as we used the trick of removing a point, instead of dealing directly with the fundamental groups of surfaces.

In the next section we will cover the generalized Seifert-van Kampen Theorem. It will allow us to compute many more fundamental groups. In particular we will determine the fundamental groups of surfaces and knot complements.

Before we can state the generalized Seifert-van Kampen Theorem we need to introduce more concepts from group theory. We will do so in this chapter.

13.1. **Basic definitions in group theory.** Let G be a group. Recall that a subgroup H is called *normal* if for any $g \in G$ we have $g^{-1}Hg = H$. If $H \subset G$ is normal, then we often write $H \lhd G$. If H_i, $i \in I$ is a family of normal subgroups of G, then it is straightforward to see that the intersection $\bigcap_{i\in I} H_i$ is again a normal subgroup of G.

Let H be a subgroup of G. The subgroup H defines an equivalence relation on G by defining $g \sim \widetilde{g}$ if there exists an $h \in H$ with $gh = \widetilde{g}$. Put differently, $g \sim \widetilde{g}$ if $\widetilde{g}^{-1}g \in H$. The equivalence classes are precisely the sets of the form $gH = \{gh \mid h \in H\}$ for some $g \in G$. We denote the set of equivalence classes by G/H.

Remark. Let H be a normal subgroup of G.

(1) For any $h \in H$ and $a, b \in G$ we have

$$ahbH \;=\; ab \cdot \underbrace{b^{-1}hb}_{\text{in } H \text{ since } H \text{ is normal}} H \;=\; abH.$$

(2) If $aH = bH$, then for any $c, d \in G$ we have

$$cadH \;=\; cb\underbrace{(b^{-1}a)}_{\in H}dH \;\underset{\substack{\uparrow \\ \text{above remark (1)}}}{=}\; cbdH.$$

Now we will see that the group structure on G descends to a group structure on G/H. More precisely, given aH and bH we set

$$aH \cdot bH \;:=\; abH.$$

It follows immediately from the above remark (1) that this definition does not depend on the representatives a and b. It is now straightforward to see that this defines indeed a group structure on G/H. The following lemma plays the same role as Lemma 1.66 does for topological spaces.

Lemma 13.1. *Let G be a group and let H be a normal subgroup. Let $\varphi\colon G \to \Gamma$ be a group homomorphism with the property that $H \subset \ker(\varphi)$. Then there exists a unique*

homomorphism $\psi\colon G/H \to \Gamma$ *such that the following diagram commutes*

$$\begin{tikzcd} G \arrow[r] \arrow[dr, "\varphi"'] & G/H \arrow[d, "\psi"] \\ & \Gamma. \end{tikzcd}$$

Proof. For $gH \in G/H$ we put $\psi(gH) := \varphi(g)$. Since $H \subset \ker(\varphi)$ this definition is independent of the choice of the representatives g.[292] It is straightforward to verify that ψ is a homomorphism and that it is uniquely determined by the desired property. □

13.2. **Presentations of groups.**

Definition. Let G be a group and let $A \subset G$ be a subset. We define

$$\text{subgroup of } G \textit{ generated by } A \;:=\; \langle A \rangle \;:=\; \bigcap_{\substack{A \subset H \subset G \\ H \text{ subgroup}}} H,$$

i.e. $\langle A \rangle$ is the intersection of all subgroups H of G which contain A. This is again a subgroup of G, namely the smallest[293]subgroup of G which contains A. Similarly we define

$$\text{subgroup of } G \textit{ normally generated by } A \;:=\; \langle\langle A \rangle\rangle \;:=\; \bigcap_{A \subset H \lhd G} H,$$

i.e. $\langle\langle A \rangle\rangle$ is the intersection of all *normal* subgroups H of G which contain A. This is again a normal subgroup of G, namely the smallest normal subgroup of G which contains A.

The following lemma follows immediately from the definitions and from the fact that in an abelian group every subgroup is normal.

Lemma 13.2. *Let G be a group and let $A \subset G$ be a subset.*

(1) *If A is a subgroup, then $\langle A \rangle = A$.*
(2) *If A is a normal subgroup, then $\langle\langle A \rangle\rangle = A$.*
(3) *If G is abelian, then $\langle\langle A \rangle\rangle = \langle A \rangle$.*
(4) *For any $B \subset G$ with $A \subset G \subset \langle\langle A \rangle\rangle$ we have $\langle\langle B \rangle\rangle = \langle\langle A \rangle\rangle$.*
(5) *Suppose that for each $a \in A$ we are given $g_a \in A$. Then $\langle\langle \{g_a a g_a^{-1}\}_{a \in A} \rangle\rangle = \langle\langle A \rangle\rangle$.*

The following lemma gives a more explicit description of $\langle A \rangle$ and $\langle\langle A \rangle\rangle$.

Lemma 13.3. *Let G be a group and let $A \subset G$ be a subset.*

(1) *Then $\langle A \rangle$ equals the set of all elements of G which can be written as products of elements in A and their inverses, i.e.*

$$\langle A \rangle \;=\; \big\{ a_1^{\epsilon_1} \cdot \dots \cdot a_k^{\epsilon_k} \mid a_1, \dots, a_k \in A \textit{ and } \epsilon_1, \dots, \epsilon_k \in \{-1, 1\} \big\}.$$

[292]Indeed, if $gH = \tilde{g}H$, then $g = \tilde{g}h$ for some $h \in H$, therefore $\varphi(g) = \varphi(\tilde{g}h) = \varphi(\tilde{g}) \cdot \varphi(h) = \varphi(\tilde{g})$.

[293]Here "smallest" means that if B is another subgroup that contains A, then $A \subset B$. This statement is obvious, since B appears in the definition of $\langle A \rangle$ as one of the H's.

(2) *The subset* $\langle\langle A\rangle\rangle$ *equals the set of all elements of* G *which can be written as products of conjugates of elements in* A *and their inverses, i.e.*

$$\langle\langle A\rangle\rangle = \big\{g_1 a_1^{\epsilon_1} g_1^{-1} \dots g_k a_k^{\epsilon_k} g_k^{-1} \mid a_1, \dots, a_k \in A, g_1 \dots, g_k \in G \text{ and } \epsilon_1, \dots, \epsilon_k \in \{-1, 1\}\big\}.$$

Example. On page 265 we introduced a subgroup of the group H of all self-homeomorphisms of $\mathbb{R}^2$ that was generated by two given self-homeomorphisms A and B. The lemma shows that the definition of "being generated" by a subset used on page 265 agrees with the above more formal definition.

Proof. We only prove the second statement. The proof of the first statement is very similar. So let G be a group and let $A \subset G$ be a subset. The subgroup $\langle\langle A\rangle\rangle$ contains all elements of A and their inverses. The normal subgroup $\langle\langle A\rangle\rangle$ then contains also all elements of the form $ga^{\pm 1}g^{-1}, g \in G, a \in A$. Since $\langle\langle A\rangle\rangle$ is a subgroup it is also closed under multiplication, i.e. it contains products of such elements. It follows that $\langle\langle A\rangle\rangle$ contains the right-hand side of (2). Conversely it is straightforward to see that the right-hand side is indeed a normal[294] subgroup of G that contains A, hence it is contained in the left-hand side of (2). □

Lemma 13.4. *Let* G *be a group and let* $A \subset G$ *be a subset. Let* $\alpha\colon G \to \Gamma$ *be a group homomorphism such that* $\alpha(a) = e \in \Gamma$ *for all* $a \in A$. *Then there exists a unique group homomorphism* $\beta\colon G/\langle\langle A\rangle\rangle \to \Gamma$ *such that the following diagram commutes:*

$$\begin{tikzcd} G \arrow[r] \arrow[dr, "\alpha"'] & G/\langle\langle A\rangle\rangle \arrow[d, "\beta"] \\ & \Gamma. \end{tikzcd}$$

Proof. Let G be a group and let $A \subset G$ be a subset. Furthermore let $\alpha\colon G \to \Gamma$ be a group homomorphism such that $\alpha(a) = e \in \Gamma$ for all $a \in A$. This means that $A \subset \ker(\alpha)$. Since $\ker(\alpha)$ is a normal subgroup it follows from the definition of $\langle\langle A\rangle\rangle$ that $\langle\langle A\rangle\rangle \subset \ker(\alpha)$. The proposition now follows immediately from Lemma 13.1. □

The following definition will subsequently play an important role:

Definition. Let be X be a set and let R be a subset of the free group $\langle X\rangle$ generated by the set X. We define

$$\langle X \mid R\rangle \;:=\; \langle X\rangle \,/\, \langle\langle R\rangle\rangle.$$

We refer to the elements of X as *generators of* $\langle X \mid R\rangle$ and we refer to the elements of R as the *relators of* $\langle X \mid R\rangle$.

Examples.

(1) For any $k \in \mathbb{N}_0$ we have

$$\langle g \mid g^k\rangle \;=\; \langle g\rangle/\langle\langle g^k\rangle\rangle \;\underset{\substack{\uparrow \\ \text{since } \langle g\rangle \text{ is abelian it follows from Lemma 13.2 that } \langle\langle g^k\rangle\rangle = \langle g^k\rangle}}{=}\; \langle g\rangle/\langle g^k\rangle \;\cong \mathbb{Z}_k.$$

[294] Why is the right-hand side normal?

(2) The group $\langle x_1, \dots, x_k \mid \rangle$ which has no relators is just the free group on the generators $x_1, \dots, x_k$.

(3) We consider the group

$$\pi \;=\; \langle x, y \mid [x, y] \rangle$$

where $[x, y] := xyx^{-1}y^{-1}$ is the commutator of x and y. What can we say about this group? Modulo $\langle\langle [x, y] \rangle\rangle$ we have[295]

$$\underset{\substack{\uparrow \\ \text{Remark (1) on page 406}}}{yx \;=\; xyx^{-1}y^{-1} \cdot yx \;=\; xy} \qquad \text{and} \qquad \underset{\substack{\uparrow \\ \text{calculation on the left and Remark (2) on page 406}}}{xy^{-1} \;=\; y^{-1} \cdot yx \cdot y^{-1} \;=\; y^{-1} \cdot xy \cdot y^{-1} \;=\; y^{-1}x.}$$

Similarly one can show that the equalities $yx^{-1} = x^{-1}y$ and $x^{-1}y^{-1} = y^{-1}x^{-1}$ hold in $\pi = \langle x, y \mid [x, y] \rangle$. This shows that in π the elements $x^{\pm 1}$ and $y^{\pm 1}$ commute. This means that in π an arbitrary product of powers of x and y can be reordered to equal a product of the $x^m y^n$. For example in π we have the equality

$$x^3y^2x^{-1}y \;= x^3y \cdot yx^{-1} \cdot y \;\underset{\substack{\uparrow \\ \text{since } yx^{-1} = x^{-1}y}}{=}\; x^3y \cdot x^{-1}y \cdot y = x^3 \cdot yx^{-1} \cdot y^2 \;\underset{\substack{\uparrow \\ \text{since } yx^{-1} = x^{-1}y}}{=}\; x^3 \cdot x^{-1}y \cdot y^2 = x^2y^3.$$

By Lemma 11.13 there exists a unique homomorphism $\alpha\colon \langle x, y \rangle \to \mathbb{Z}^2$ which satisfies $\alpha(x) = (1, 0)$ and $\alpha(y) = (0, 1)$. Note that

$$\alpha([x, y]) \;=\; \alpha(xyx^{-1}y^{-1}) \;=\; \alpha(x) + \alpha(y) - \alpha(x) - \alpha(y) \;=\; 0.$$

Thus by Lemma 13.4 there exists a unique group homomorphism

$$\beta\colon \pi = \langle x, y \rangle / \langle\langle [x, y] \rangle\rangle = \langle x, y \mid [x, y] \rangle \;\to\; \mathbb{Z}^2$$

with $\beta(x) = (1, 0)$ and $\beta(y) = (0, 1)$. This homomorphism is evidently an epimorphism. It is also a monomorphism, indeed:

(a) we had just seen in the previous example that any element in π is equivalent to an element of the form $x^m y^m$,

(b) furthermore $\beta(x^m y^n) = (m, n)$ is zero if and only if $x^m y^n = x^0 y^0$ is the trivial element in π.

Frequently we will write relators as equations, for example we often write

$$\langle x, y \mid xyx^{-1}y^{-1} \rangle \;=\; \langle x, y \mid xyx^{-1}y^{-1} = e \rangle \;=\; \langle x, y \mid xy = yx \rangle.$$

Because of this notation one often refers to a relator also as a relation.

(4) The same way as in the above example one can show that there exists an isomorphism

$$\beta\colon \langle x_1, \dots, x_m \mid [x_i, x_j] = e \text{ for all } i, j \in \{1, \dots, m\} \rangle \;\xrightarrow{\cong}\; \mathbb{Z}^m$$

which sends each x_i to the i-th standard basis vector e_i of $\mathbb{Z}^m$.

[295] Here we follow the standard convention that in the notation we do not distinguish between an element in $\langle X \rangle$ and an element in $\langle X \mid R \rangle$, the same way as usually we do not distinguish in the notation between an element in $\mathbb{Z}$ and an element in $\mathbb{Z}_5$.

(5) We consider the following three self-homeomorphisms of $\mathbb{R}^2$:

$$\begin{array}{rcl} A\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (s,t) & \mapsto & (s+1, 1-t) \end{array} \quad \text{and} \quad \begin{array}{rcl} B\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (s,t) & \mapsto & (s, t+1) \end{array} \quad \text{and} \quad \begin{array}{rcl} \widetilde{A}\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (s,t) & \mapsto & (s+1, -t). \end{array}$$

We already know the first two maps from page 265. We denote by G the subgroup of all homeomorphisms of $\mathbb{R}^2$ that is generated by A and B. We are interested in the group G since $\mathbb{R}^2/G$ is the Klein bottle K and by Theorem 7.17 we have $\pi_1(K) \cong G$.

Note that $\widetilde{A} = B^{-1}A$. Let $X = \{x, y\}$ be the set that consists of two elements. By Lemma 11.13 there exists a unique homomorphism $\alpha\colon \langle x, y\rangle \to G$ with $\alpha(x) = \widetilde{A}$ and $\alpha(y) = B$. Now let R be the subset of $\langle X\rangle = \langle x, y\rangle$ that consists of the single element $yxyx^{-1}$. We want to consider $\alpha(yxyx^{-1}) \in G$, which is by definition a map from $\mathbb{R}^2$ to $\mathbb{R}^2$. For any point $(s,t) \in \mathbb{R}^2$ this map is given by

$$\begin{aligned} \alpha(yxyx^{-1})(s,t) \;&=\; B\widetilde{A}B\widetilde{A}^{-1}(s,t) \;=\; B\widetilde{A}B(s-1,-t) \\ &=\; B\widetilde{A}(s-1,-t+1) \;=\; B(s,t-1) = (s,t). \end{aligned}$$

This shows that $\alpha(yxyx^{-1})$ is the identity map of $\mathbb{R}^2$, i.e. it is the trivial element in G. It follows from Lemma 13.4 that α descends to a homomorphism

$$\beta\colon \langle x, y\rangle / \langle\langle yxyx^{-1}\rangle\rangle = \langle x, y \mid yxyx^{-1}\rangle \;\to\; G.$$

This homomorphism is an epimorphism, since the image of β is the group generated by $\widetilde{A} = B^{-1}A$ and B, but this group is the same as the group generated by A and B, i.e. the image of β is G. Is the homomorphism β also a monomorphism? We will come back to this question later on.

We continue with the following definitions.

Definition.

(1) A *presentation* is a set X together with a subset $R \subset \langle X\rangle$. We call the elements of X the *generators* and we call the elements of R the *relators*[296] of the presentation.
(2) Let π be a group. A *presentation for* π is a presentation (X, R) together with an isomorphism
$$\pi \;\xrightarrow{\cong}\; \langle X \mid R\rangle.$$
Very often one just says $\langle X \mid R\rangle$ is a presentation for π and the explicit isomorphism is suppressed from the notation.
(3) We say that a group π is *finitely generated*, if π admits a presentation with finitely many generators.[297]
(4) We say a group π is *finitely presented*, if π admits a presentation with finitely many generators and finitely many relators.

Now we give some examples of finitely generated and finitely presented groups.

[296]The relators are often also called relations.

[297]This definition of a finitely generated group is equivalent to the one we gave on page 378. Why is that?

Examples.

(1) Every group admits a presentation. Indeed, let π be a group. Then we set $X := \pi$, i.e. X is the set of elements of π. By Lemma 11.13 there exists a unique homomorphism $\alpha\colon \langle X\rangle \to \pi$ with $\alpha(g) = g$ for all $g \in X = \pi$. We set $R := \ker(\alpha)$. Then

$$\langle X \mid R\rangle \;=\; \langle X\rangle/\langle\langle R\rangle\rangle \;=\; \langle X\rangle/\langle\langle \ker(\alpha)\rangle\rangle \;\underset{\substack{\uparrow \\ \text{by Lemma 13.2 since } R=\ker(\alpha) \text{ is a normal subgroup}}}{=}\; \langle X\rangle/\ker(\alpha) \;\xrightarrow[\alpha]{\cong}\; G.$$

(2) We had just seen on page 409 that

$$\mathbb{Z}^n \;\cong\; \langle x_1,\dots,x_n \mid [x_i,x_j] = e \text{ with } i,j \in \{1,\dots,n\}\rangle$$

which shows that $\mathbb{Z}^n$ is a finitely presented group.

(3) In fact every finitely generated abelian group is also finitely presented. Indeed, let A be a finitely generated abelian group. Then

$$A \;\underset{\substack{\uparrow \\ \text{Theorem 11.4} \\ \text{for some } a_i \in \mathbb{N}_0}}{\cong}\; \bigoplus_{i=1}^{n} \mathbb{Z}_{a_i} \;\underset{\substack{\uparrow \\ \text{as in (2)}}}{=}\; \langle x_1,\dots,x_n \mid [x_i,x_j] = e \text{ for } i,j = 1,\dots,n, x_i^{a_i} = e \text{ for } i = 1,\dots,n\rangle.$$

(4) There exist groups which are finitely generated but not finitely presented. In fact there are countably many isomorphism types of finitely presented groups,[298] whereas there are uncountably many isomorphism types of finitely generated groups.[299] A proof for both statements is given in Chapter 14 of [Rob].

(5) We saw on page 378 that the fundamental group of the Klein bottle is finitely generated. But is it also finitely presented?

The following lemma shows that every finitely presented group admits infinitely many finite presentations.

Lemma 13.5. *Let $X = \{x_1,\dots,x_k\}$ be a finite set and furthermore let $r = \{r_1,\dots,r_l\}$ be a finite subset of $\langle X\rangle = \langle x_1,\dots,x_k\rangle$. Then for any word s in $r_1,\dots,r_l$, i.e. any element s of $\langle r_1,\dots,r_l\rangle$, we have the equality*[300]

$$\langle x_1,\dots,x_k \mid r_1,\dots,r_l\rangle \;=\; \langle x_1,\dots,x_k \mid r_1,\dots,r_l,s\rangle \tag{1}$$

and for any symbol x and any two words s,t in $x_1,\dots,x_k$ we have an isomorphism

$$\begin{array}{rcl} \langle x_1,\dots,x_k \mid r_1,\dots,r_l\rangle & \xrightarrow{\cong} & \langle x_1,\dots,x_k,x \mid r_1,\dots,r_l,s\cdot x\cdot t\rangle. \\ x_i & \mapsto & x_i \end{array} \tag{2}$$

[298] That statement is pretty obvious.

[299] This statement is much less obvious. The idea is that in a free group $\langle x_1,\dots,x_k\rangle$ there are uncountably many infinite sequences of elements $\{r_1,r_2,\dots\}$. The difficulty is to show that there exist uncountably many sequences that give raise to non-isomorphic groups.

[300] Note that these two presentations are different, since $\{r_1,\dots,r_l\}$ and $\{r_1,\dots,r_l,s\}$ are two different subsets of $\langle x_1,\dots,x_k\rangle$.

Proof.

(1) It is straightforward to see that $\langle\langle r_1, \dots, r_l \rangle\rangle$ and $\langle\langle r_1, \dots, r_l, s \rangle$ are precisely the same subsets of $\langle\langle x_1, \dots, x_k \rangle\rangle$. This shows that the two groups in (1) are identical.

(2) The fact that the map in (2) induces an isomorphism will be proved in Exercise 13.1. □

The above two methods, and their inverses, of obtaining new presentations out of a given one are called *Tietze transformations.*[301] Any two finite presentations for some given group are in fact related by a finite sequence of these two Tietze transformations. This fact is for example proved in Proposition II.2.2 of [LS].

As we will now see, finite presentations of groups are useful for finding group homomorphisms. To formulate the corresponding lemma we need the following definition.

Definition. Let $\{x_1, \dots, x_k\}$ be a set and let $r \in \langle X \rangle$. Furthermore let G be a group and let $g_1, \dots, g_k$. We say that $g_1, \dots, g_k$ *satisfy the relation* r if the homomorphism[302] $\langle x_1, \dots, x_k \rangle \to G$ that is given by $x_i \mapsto g_i$, $i = 1, \dots, k$ sends r to the trivial element.

Examples.

(1) We consider $\{x_1, x_2\}$ and the word $r = x_1 x_2 x_1^{-1} x_2^{-1}$. If a group is abelian, then any two elements g_1, g_2 satisfy the relation $x_1 x_2 x_1^{-1} x_2^{-1}$.

(2) Let G be a finite group with d elements. We consider the set $\{x\}$. It follows from Lagrange's Theorem, see e.g. [KuS, p. 8], that every element in G satisfies the relation x^d.

Lemma 13.6. *Let π be a group with a finite presentation $\pi = \langle x_1, \dots, x_k \,|\, r_1, \dots, r_l \rangle$. The map*

$$\begin{array}{rcl} \mathrm{Hom}(\pi, G) & \to & \{\textit{all } (g_1, \dots, g_k) \in G^k \textit{ that satisfy } r_1, \dots, r_l\} \\ f & \mapsto & (f(x_1), \dots, f(x_k)) \end{array}$$

is a bijection.

Remark. Note that if G is a finite group, then the right-hand side of Lemma 13.6 is a finite set. In practice it is usually straightforward, albeit tedious, to determine the right-hand side.

Proof. This lemma follows immediately from Lemma 13.4 and Lemma 11.13. □

The following lemma often works well in practice to show that two presentations correspond to isomorphic groups.

Lemma 13.7. *Let $X = \{x_1, \dots, x_k\}$ be a finite set and furthermore let $r = \{r_1, \dots, r_l\}$ be a finite subset of $\langle X \rangle = \langle x_1, \dots, x_k \rangle$. Suppose that we can write each $r_i(x_1, \dots, x_k)$ as a word $s_i(x_1, \dots, x_{k-1}, x_k \cdot w)$ where w is a word in $x_1, \dots, x_{k-1}$, then the homomorphism*

$$\langle x_1, \dots, x_k \,|\, r_1, \dots, r_l \rangle \;\to\; \langle x_1, \dots, x_{k-1}, t \,|\, s_1, \dots, s_l \rangle$$

[301] Heinrich Tietze (1880-1964) was an Austrian mathematician.

[302] The fact that there exists a unique such homomorphism is a consequence of Lemma 11.13.

that is induced by $x_i \mapsto x_i$, $i = 1, \dots, k-1$ and $x_k \mapsto tw^{-1}$ is an isomorphism.

Definition. We refer to the isomorphism of Lemma 13.7 as the *isomorphism given by the substitution $t = x_k \cdot w$.*

Example. A picky reader might decide that the formulation of Lemma 13.7 is not completely precise. But the following example should make the meaning clear:

$$\langle a, b \,|\, a^{-1}ba^{-1}bab^{-1} \rangle \;=\; \langle a, b \,|\, \underbrace{a^{-1}b \cdot a^{-1}b \cdot a \cdot (a^{-1}b)^{-1} \cdot a^{-1}}_{=a^{-1}ba^{-1}bab^{-1}} \rangle \;\underset{\substack{\uparrow \\ \text{substitution } c = a^{-1}b}}{=}\; \langle a, c \,|\, c \cdot c \cdot a \cdot c^{-1} \cdot a^{-1} \rangle.$$

Proof. It follows from Lemma 13.6 that there exists in fact a unique homomorphism

$$\langle x_1, \dots, x_k \,|\, r_1, \dots, r_l \rangle \;\to\; \langle x_1, \dots, x_{k-1}, t \,|\, s_1, \dots, s_l \rangle$$

that has the property that $x_i \mapsto x_i$, $i = 1, \dots, k-1$ and that $x_k \mapsto tw^{-1}$. Furthermore, we have a map from the right to left by the reverse substitution $t \mapsto x_k \cdot w$. It is straightforward to verify that these homomorphisms are inverses of one another, hence both are isomorphisms. □

We conclude this section with the following lemma.

Lemma 13.8. $(*)$ *Let H be a finitely presented group and let $\varphi\colon H \to G$ be a group homomorphism. If there exists a group homomorphism $\rho\colon G \to H$ such that $\rho \circ \varphi = \mathrm{id}_H$, then H is also finitely presented.*

Proof $(*)$. Let $G = \langle g_1, \dots, g_k \,|\, r_1, \dots, r_l \rangle$ be a finite presentation for the group G. We write $F = \langle g_1, \dots, g_k \rangle$ and we denote by $p\colon F \to G$ the obvious epimorphism. For each $i \in \{1, \dots, k\}$ we pick $w_i \in F$ with $p(w_i) = (\varphi \circ \rho \circ p)(g_i) \in G$. It suffices to prove the following claim.

Claim. A finite presentation for H is given by $\langle g_1, \dots, g_k \,|\, r_1, \dots, r_l, g_1^{-1}w_1, \dots, g_k^{-1}w_k \rangle$.

Let L be the group that is defined by the finite presentation of the claim. We denote by $u\colon G \to L$ and $q\colon F \to L$ the obvious projections. Note that for each $j \in \{1, \dots, l\}$ we have $\rho(p(r_i)) = \rho(e) = e$ and for each $i \in \{1, \dots, k\}$ we have

$$\rho(p(g_i^{-1}w_i)) \;=\; \rho(p(g_i^{-1})) \cdot \rho(p(w_i)) \;\underset{\substack{\uparrow \\ \text{since } p(w_i) = (\varphi \circ \rho \circ p)(g_i) \text{ and since } \rho \circ \varphi = \mathrm{id}_H}}{=}\; \rho(p(g_i^{-1})) \cdot \rho(p(g_i)) \;=\; e.$$

It follows from Lemma 13.4 that the homomorphism $p \circ \varphi\colon F \to H$ factors through a homomorphism $v\colon L \to H$.

We want to show that $u \circ \varphi$ is an isomorphism. First note that

$$v \circ (u \circ \varphi) \;=\; (v \circ u) \circ \varphi \;\underset{\substack{\uparrow \\ \text{since } \rho = v \circ u}}{=}\; \rho \circ \varphi \;=\; \mathrm{id}_H\,.$$

By Lemma 11.17 it remains to show that $u \circ \varphi$ is an isomorphism. Note that for $i = 1, \dots, k$ we have

$$(u \circ \varphi)(\underbrace{(\rho \circ p)(w_i)}_{\in H}) \;\underset{\substack{\uparrow \\ \text{since } \varphi \circ \rho = \mathrm{id}_H}}{=}\; u(p(w_i)) \;=\; q(w_i) \;\underset{\substack{\uparrow \\ \text{since } q(w_i) = g_i \in L}}{=}\; g_i \;\in\; L.$$

Since $g_1, \dots, g_k$ is a generating set for L we see that $u \circ \varphi$ is indeed an epimorphism.

For convenience we summarize all objects in the following diagram

$$\begin{tikzcd}
H \arrow[r, "\varphi"] & G = \langle g_1, \dots, g_k \,|\, r_1, \dots, r_l \rangle \arrow[l, bend right, "\rho"'] \arrow[d, "u"] & F = \langle g_1, \dots, g_k \rangle \arrow[l, "p"'] \arrow[dl, "q"] \\
& L := \langle g_1, \dots, g_k \,|\, r_1, \dots, r_l, g_1^{-1} w_1, \dots, g_k^{-1} w_k \rangle. \arrow[ul, bend left, "v"] &
\end{tikzcd}$$

□

13.3. **The abelianization of a group.** The following definition should already be familiar from the algebra course.

Definition. Let π be a group. We refer to

$$[\pi, \pi] \;:=\; \langle\!\langle \{ \underbrace{[x, y]}_{= xyx^{-1}y^{-1}} \mid x, y \in \pi \} \rangle\!\rangle$$

as the *commutator subgroup* of π.

We start out with the following elementary lemma.

Lemma 13.9. *Let π be a group. Then the following hold:*

(1) *The group $\pi/[\pi, \pi]$ is abelian.*
(2) *We have*

$$[\pi, \pi] \;:=\; \left\{ \prod_{i=1}^{n} [x_i, y_i] \,\middle|\, x_1, y_1, \dots, x_n, y_n \in \pi \right\}.$$

Remark. Note that in general not every element of the commutator subgroup is a commutator. For example, if $\pi = \langle a, b, c, d \rangle$ is the free group on four generators a, b, c, d, then we have $[a, b] \cdot [c, d] \in [\pi, \pi]$, but it is not a commutator.[303]

Proof. Let π be a group.

(1) For any two elements $x, y \in \pi$ we have

$$xy\,[\pi, \pi] \;=\; yx \cdot x^{-1}y^{-1}xy\,[\pi, \pi] \;=\; yx \cdot \underbrace{[x^{-1}, y^{-1}]}_{\in [\pi, \pi]}\,[\pi, \pi] \;=\; yx\,[\pi, \pi].$$

This shows that $\pi/[\pi, \pi]$ is indeed abelian.

[303] Why not?

(2) Note that the inverse of a commutator is again a commutator, i.e. given $x, y \in \pi$ we have

$$[x,y]^{-1} \;=\; (xyx^{-1}y^{-1})^{-1} \;=\; yxy^{-1}x^{-1} \;=\; [y,x].$$

Furthermore a conjugate of a commutator is again a commutator. Indeed, given $x, y, g \in \pi$ we have

$$\begin{aligned} g[x,y]g^{-1} = gxyx^{-1}y^{-1}g^{-1} &= gxg^{-1}gyg^{-1}gx^{-1}g^{-1}gy^{-1}g^{-1} \\ &= (gxg^{-1})(gyg^{-1})(gxg^{-1})^{-1}(gyg^{-1})^{-1} = [gxg^{-1}, gyg^{-1}]. \end{aligned}$$

It follows from this discussion and from Lemma 13.3 that each element of the commutator subgroup can be written as a product of commutators, i.e.

$$[\pi,\pi] \;:=\; \left\{ \prod_{i=1}^{n} [x_i, y_i] \,\middle|\, x_1, y_1, \ldots, x_n, y_n \in \pi \right\}.$$

□

Definition. Let π be a group. We call

$$\pi_{\mathrm{ab}} \;:=\; \pi/[\pi,\pi]$$

the *abelianization* of π.[304]

The following proposition summarizes some of the key properties of the abelianization of groups.

Proposition 13.10.

(1) *If π is abelian, then $\pi_{\mathrm{ab}} = \pi$.*

(2) *Let π be a group and let $\alpha\colon \pi \to H$ be a homomorphism to an abelian group. Then there exists a unique homomorphism $\beta\colon \pi_{\mathrm{ab}} = \pi/[\pi,\pi] \to H$ such that the following diagram commutes:*

$$\begin{tikzcd} \pi \arrow[r] \arrow[dr, "\alpha"'] & \pi_{\mathrm{ab}} = \pi/[\pi,\pi] \arrow[d, "\beta"] \\ & H. \end{tikzcd}$$

In particular for any group π and any abelian group G the map

$$\begin{array}{ccc} \mathrm{Hom}(\pi_{\mathrm{ab}}, G) & \to & \mathrm{Hom}(\pi, G) \\ (\alpha\colon \pi_{\mathrm{ab}} \to G) & \mapsto & \big(\pi \to \pi_{\mathrm{ab}} \xrightarrow{\alpha} G\big) \end{array}$$

is a bijection.

(3) *Let G and H be two groups. There exists a unique isomorphism*

$$(G * H)_{\mathrm{ab}} \;\xrightarrow{\cong}\; G_{\mathrm{ab}} \times H_{\mathrm{ab}}$$

[304]The abelianization of a group π is sometimes also written as $H_1(\pi)$. The reason for that somewhat strange looking notation will become clear later on.

which makes the following diagram commute:

$$\begin{tikzcd} G * H \arrow[r, two heads] \arrow[d, two heads] & G \times H \arrow[d, two heads] \\ (G * H)_{\mathrm{ab}} \arrow[r, "\cong"] & G_{\mathrm{ab}} \times H_{\mathrm{ab}}, \end{tikzcd}$$

where the other three maps are the obvious projection maps.

(4) *Let $F = \langle x_1, \dots, x_m \rangle$ be the free group on m generators $x_1, \dots, x_m$. Then the map*[305]

$$\begin{array}{rcl} \Phi\colon F_{\mathrm{ab}} = F/[F,F] & \to & \mathbb{Z}^m \\ [x_i] & \mapsto & e_i := \textit{the } i\textit{-th standard basis vector} \end{array}$$

is an isomorphism.

(5) *Let $\pi = \langle x_1, \dots, x_m \mid r_1, \dots, r_n \rangle$ be a finitely presented group. We denote by*

$$\Phi\colon \langle x_1, \dots, x_m \rangle \to \mathbb{Z}^m$$

the homomorphism that is given by $\Phi(x_i) = e_i$. There exists a unique isomorphism

$$\Psi\colon \pi/[\pi,\pi] \xrightarrow{\cong} \mathbb{Z}^m/\langle \Phi(r_1), \dots, \Phi(r_n) \rangle$$

such that the following diagram commutes

$$\begin{tikzcd} \langle x_1, \dots, x_m \rangle \arrow[rr, two heads, "x_i \mapsto e_i", "\Phi"'] \arrow[d, two heads] & & \mathbb{Z}^m \arrow[dd, two heads] \\ \pi = \langle x_1, \dots, x_m \rangle / \langle\langle r_1, \dots, r_n \rangle\rangle \arrow[d, two heads] & & \\ \pi_{\mathrm{ab}} = \pi/[\pi,\pi] \arrow[rr, "\Psi", "\cong"'] & & \mathbb{Z}^m/\langle \Phi(r_1), \dots, \Phi(r_n) \rangle. \end{tikzcd}$$

(6) *We denote by $\mathcal{G}$ the category of groups and we denote by $\mathcal{A}$ the category of abelian groups. Then the maps*

$$G \mapsto G_{\mathrm{ab}} = G/[G,G]$$

and

$$(\varphi\colon G \to H) \mapsto \left(\begin{array}{rcl} \varphi_*\colon G_{\mathrm{ab}} = G/[G,G] & \to & H_{\mathrm{ab}} = H/[H,H] \\ [g] & \mapsto & [\varphi(g)] \end{array} \right)$$

define a covariant functor from $\mathcal{G}$ to $\mathcal{A}$.

(7) *Let $\mathcal{G}$ be the category of groups. Given a group G we denote by*

$$\begin{array}{rcl} \Phi_G\colon G & \to & G_{\mathrm{ab}} = G/[G,G] \\ g & \mapsto & [g] \end{array}$$

[305]By Lemma 11.13 there exists a unique homomorphism $F \to \mathbb{Z}^m$ with $x_i \mapsto e_i$. By (1) this map descends to a homomorphism $F/[F,F] \to \mathbb{Z}^m$. The way we write down the map is a little bit sloppy, since we only specify the map on the generators of $F/[F,F]$.

the projection map. These maps Φ_G define a natural transformation from the identity functor $\mathcal{G} \to \mathcal{G}$ to the abelianization functor $\mathcal{G} \to \mathcal{G}$ that we had introduced in (6).[306]

(8) *Isomorphic groups have isomorphic abelianizations.*

(9) *If $\varphi\colon A \to B$ is an epimorphism, then the induced map $A_{\mathrm{ab}} \to B_{\mathrm{ab}}$ is also an epimorphism.*

Examples.

(1) By Proposition 13.10 (1) and (3) we have

$$(\mathbb{Z}_3 * \mathbb{Z}_{35})_{\mathrm{ab}} \;\cong\; \mathbb{Z}_3 \times \mathbb{Z}_{35} \quad \text{and} \quad (\mathbb{Z}_5 * \mathbb{Z}_{21})_{\mathrm{ab}} \;\cong\; \mathbb{Z}_5 \times \mathbb{Z}_{21}.$$

It follows from the Chinese Remainder Theorem that the abelianizations are isomorphic. On the other hand on page 383 we had already observed that the Grushko Decomposition Theorem 11.20 implies that the groups $\mathbb{Z}_3 * \mathbb{Z}_{35}$ and $\mathbb{Z}_5 * \mathbb{Z}_{21}$ are not isomorphic. Thus we have seen that non-isomorphic groups can have isomorphic abelianizations.

(2) We give an explicit example for statement (5). Let

$$\pi \;=\; \langle x, y \mid x^2y^{-2}x, y^{-1}x^3yx\rangle.$$

Let $\Phi\colon \langle x, y\rangle \to \mathbb{Z}^2$ be the epimorphism given by $\Phi(x) = (1, 0)$ and $\Phi(y) = (0, 1)$. Then the abelianization of π is given by[307]

$$\pi_{\mathrm{ab}} \;=\; \mathbb{Z}^2/\langle \underbrace{\Phi(x^3y^{-2})}_{=\binom{3}{-2}}, \underbrace{\Phi(y^{-1}x^3yx)}_{=\binom{4}{0}}\rangle \;=\; \mathbb{Z}^2/\begin{pmatrix} 3 & 4 \\ -2 & 0 \end{pmatrix}\mathbb{Z}^2 \;\cong\; \mathbb{Z}_8.$$

(3) Let S be a set. It is straightforward to show that the abelianization of the free group $\langle S\rangle$ generated by S is isomorphic to the free abelian group $\mathbb{Z}^{(S)}$ generated by S.

(4) Given $k \in \mathbb{N}$ we denote by S_k the permutation group on k elements and we denote by $A_k \subset S_k$ the alternating group, i.e. the group of all permutations with positive sign. In the algebra course it was shown that for $k \geq 5$ the group A_k is simple, i.e. the only normal subgroups of A_k are the trivial group and the group A_k itself.[308] The commutator subgroup $[A_k, A_k]$ is normal. Since A_k is not abelian we cannot have $[A_k, A_k] = \{e\}$. Thus we see that $[A_k, A_k] = A_k$, which implies that the abelianization of A_k is the trivial group.

Now we provide the proof of Proposition 13.10.

Proof of Proposition 13.10.

[306] Super-picky readers might argue that in (6) we introduced a functor from $\mathcal{G}$ to $\mathcal{A}$, but of course we can also view it as a functor from $\mathcal{G}$ to $\mathcal{G}$.

[307] Why is the group isomorphic to $\mathbb{Z}_8$?

[308] A proof of this statement is also given in any self-respecting algebra book, see e.g. [Rob, p. 69].

(1) The first statement is obvious.[309]
(2) Let π be a group and let $\alpha\colon \pi \to H$ be a homomorphism to an abelian group. Then $[\pi,\pi]$ lies in the kernel of α. The desired statement now follows immediately from Lemma 13.1.
(3) The maps

$$\begin{array}{rcl} \Phi\colon (G*H)_{\mathrm{ab}} & \to & G_{\mathrm{ab}} \times H_{\mathrm{ab}} \\ [(x_1,\dots,x_k)] & \mapsto & \left(\left[\prod_{x_i\in G} x_i\right], \left[\prod_{x_i\in H} x_i\right]\right) \end{array} \quad \text{and} \quad \begin{array}{rcl} \Psi\colon G_{\mathrm{ab}} \times H_{\mathrm{ab}} & \to & (G*H)_{\mathrm{ab}} \\ ([g],[h]) & \mapsto & [g\cdot h] \end{array}$$

are easily seen to be well-defined, to be homomorphisms and to be inverses of one another.
(4) This statement follows immediately from the statements (1) and (3) together with the observation that $\langle x_1,\dots,x_m\rangle = \langle x_1\rangle * \cdots * \langle x_m\rangle$, that $\langle x_i\rangle_{\mathrm{ab}} \cong \mathbb{Z}$ and that $\mathbb{Z}^m = \mathbb{Z}\times\cdots\times\mathbb{Z}$.
(5) It is straightforward to see that there exists a unique homomorphism

$$\Psi\colon \pi/[\pi,\pi] \ \to\ \mathbb{Z}^m/\langle \Phi(r_1),\dots,\Phi(r_n)\rangle$$

that makes the diagram of statement (5) commute. It remains to show that Ψ is an isomorphism. We write $F = \langle x_1,\dots,x_m\rangle$ and we write $G = \langle y_1,\dots,y_n\rangle$.We consider the following diagram

$$\begin{tikzcd} G_{\mathrm{ab}} = G/[G,G] \arrow[r, "{[y_i]\mapsto e_i}", "\cong"'] \arrow[d, "{[y_i]\mapsto[r_i]}"'] & \mathbb{Z}^n \arrow[d, "{e_i\mapsto\Phi(r_i)}"] \\ F_{\mathrm{ab}} = F/[F,F] \arrow[r, "{\Phi([x_i])=e_i}", "\cong"'] \arrow[d, two heads] & \mathbb{Z}^m \arrow[d, two heads] \\ \pi_{\mathrm{ab}} = \pi/[\pi,\pi] \arrow[r, "\Psi"] & \dfrac{\mathbb{Z}^m}{\langle \Phi(r_1),\dots,\Phi(r_n)\rangle}. \end{tikzcd}$$

Note that the diagram commutes. By (4) the top two horizontal maps are isomorphisms. The bottom vertical maps are clearly epimorphisms and it is clear that the images of the top vertical maps lie in the kernel of the bottom vertical maps. It now follows from an elementary "diagram chase" that the bottom horizontal map is also an isomorphism.[310] We leave the details to the reader.

[309] Why?

[310] More precisely, we use the following fact: suppose we are given a commutative diagram

$$\begin{tikzcd} A \arrow[r, "\cong"] \arrow[d] & A' \arrow[d] \\ B \arrow[r, "\cong"] \arrow[d, two heads] & B' \arrow[d, two heads] \\ C \arrow[r] & C', \end{tikzcd}$$

(6) This statement follows easily from the definitions and the observation that the image of a commutator under a group homomorphism is once again a commutator.
(7) This statement is basically obvious once one has internalized the definition of a natural transformation.
(8) This statement is an immediate consequence of (6).
(9) We will prove this statement in Exercise 13.3. □

13.4. **The amalgamated product of groups.** In the formulation of the generalized version of the Seifert-van Kampen theorem we will need to replace the free product of two groups by the "amalgamated product" of two groups.

In Section 11.2 we had first defined the free product via an explicit construction. We had then explained that one can also characterize the free product via a universal property. In this section we will proceed the other way round, we will first state the desired universal property and then we will explicitly construct a group which satisfies the universal property.

Proposition 13.11. *Let $\alpha\colon G \to A$ and $\beta\colon G \to B$ be two group homomorphisms. Then there exists a triple*

$$(A *_G B, \varphi\colon A \to A *_G B, \psi\colon B \to A *_G B)$$

where $A *_G B$ is a group and φ and ψ are homomorphisms with the following properties:

(a) *the following diagram commutes:*

$$\begin{tikzcd} G \arrow[r, "\alpha"] \arrow[d, "\beta"'] & A \arrow[d, "\varphi"] \\ B \arrow[r, "\psi"'] & A *_G B, \end{tikzcd}$$

(b) *if $(H', \varphi'\colon A \to H', \psi'\colon B \to H')$ is another triple which satisfies property* (a)*, then there exists a unique homomorphism $\Theta\colon A *_G B \to H'$ such that $\varphi' = \Theta \circ \varphi$ and $\psi' = \Theta \circ \psi$, i.e. such that the following diagram commutes*

$$\begin{tikzcd} G \arrow[r, "\alpha"] \arrow[d, "\beta"'] & A \arrow[d, "\varphi"] \arrow[ddr, bend left, "\varphi'"] & \\ B \arrow[r, "\psi"'] \arrow[drr, bend right, "\psi'"'] & A *_G B \arrow[dr, dashed, "\Theta"] & \\ & & H'. \end{tikzcd}$$

Proof. Let $\alpha\colon G \to A$ and $\beta\colon G \to B$ be two group homomorphisms. As usual we view A and B as subgroups of $A * B$. We put

$$A *_G B \;:=\; A * B / \langle\langle \{\alpha(g)\beta(g)^{-1}\}_{g \in G} \rangle\rangle$$

of group homomorphisms where the bottom vertical maps are epimorphisms, where the top two horizontal maps are isomorphisms and where the kernels of the bottom vertical maps are the images of the top vertical maps. Then the bottom horizontal map is also an isomorphism. This general statement can be proved by a "diagram chase". This statement can also be viewed as a special case of the "five lemma".

and we define $\varphi\colon A \to A *_G B$ as the composition of the obvious homomorphisms

$$A \;\hookrightarrow\; A * B \;\twoheadrightarrow\; A * B/\langle\langle\{\alpha(g)\beta(g)^{-1}\}_{g\in G}\rangle\rangle,$$

and precisely the same way we define the homomorphism $\psi\colon B \to A *_G B$. It follows from the construction of $A *_G B$ that $\varphi(\alpha(g)) = \psi(\beta(g))$ for all $g \in G$. Therefore the triple $(A *_G B, \varphi\colon A \to A *_G B, \psi\colon B \to A *_G B)$ satisfies property (a).

Now let $(H', \varphi'\colon A \to H', \psi'\colon B \to H')$ be another triple which satisfies property (a). We consider the following diagram

$$\begin{tikzcd}
G \arrow[rr, "\alpha"] \arrow[d, "\beta"'] & & A \arrow[dl, hook] \arrow[d, "\varphi"] \arrow[ddr, bend left, "\varphi'"] & \\
& A * B \arrow[r, two heads] \arrow[dr, hook] & A *_G B = \dfrac{A * B}{\langle\langle\alpha(g)\beta(g)^{-1}\rangle\rangle} \arrow[dr, dashed, red] & \\
B \arrow[ur, hook] \arrow[rr, "\psi"'] \arrow[rrr, bend right, "\psi'"'] & & & H'
\end{tikzcd}$$

where $\Phi\colon A * B \to H'$ is the unique homomorphism determined by ψ' and φ'. Since $\varphi' \circ \alpha = \psi' \circ \beta$ it follows that for any $g \in G$ we have

$$\Phi(\alpha(g)\cdot\beta(g)^{-1}) \;=\; \Phi(\alpha(g))\cdot\Phi(\beta(g))^{-1} \;=\; \varphi'(\alpha(g))\cdot\psi'(\beta(g))^{-1} \;=\; e.$$

Put differently, all elements of the form $\alpha(g)\beta(g)^{-1}$ in $A * B$ lie in the kernel of Φ. By Lemma 13.4 there exists a unique homomorphism $\Theta\colon A * B/\langle\langle\{\alpha(g)\beta(g)^{-1}\}_{g\in G}\rangle\rangle \to H'$ which makes the following diagram commute

$$\begin{tikzcd}
A * B \arrow[r] \arrow[dr, "\Phi"'] & A *_G B = A * B/\langle\langle\{\alpha(g)\beta(g)^{-1}\}_{g\in G}\rangle\rangle \arrow[d, "\Theta"] \\
& H'.
\end{tikzcd}$$

This proves the existence of Θ. The uniqueness follows from the observation that another choice of Θ' would give another choice for Φ, but this homomorphism is unique. $\square$

Definition. Let $\alpha\colon G \to A$ and $\beta\colon G \to B$ be two group homomorphisms. We write

$$A *_G B \;:=\; A * B/\langle\langle\{\alpha(g)\beta(g)^{-1}\}_{g\in G}\rangle\rangle$$

and we refer to $A *_G B$ as the *amalgamated product of A and B with amalgam G.*[311]

[311]The notation is a little misleading since the homomorphisms α and β do not get mentioned in the notation, even though they play of course an important role. In particular different choices of α and β can lead to non-isomorphic amalgamated products.

Remark. A variation of the argument on page 368 shows that if

$$(H, \varphi\colon A \to H, \psi\colon B \to H)$$

is a triple that has both the properties (a) and (b) of Proposition 13.11, then there exists a unique isomorphism $\Theta\colon A *_G B \xrightarrow{\cong} H$ such that $\varphi(a) = \Theta(a)$ for all $a \in A$ and $\psi(b) = \Theta(b)$ for all $b \in B$. Often we will use this uniquely defined isomorphism to identify H with the amalgamated product $A *_G B$.

Example. Let $G = \mathbb{Z}_2, A = \mathbb{Z}_4$ and $B = \mathbb{Z}_6$ and consider the homomorphisms

$$\begin{array}{rcl} \alpha\colon G & \to & A \\ [k] & \mapsto & [2k] \end{array} \quad \text{and} \quad \begin{array}{rcl} \beta\colon G & \to & B \\ [k] & \mapsto & [3k]. \end{array}$$

Furthermore we consider the homomorphisms[312]

$$\begin{array}{rcl} \varphi\colon A = \mathbb{Z}_4 & \to & \mathrm{SL}(2,\mathbb{Z}) \\ k & \mapsto & \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}^k \end{array} \quad \text{and} \quad \begin{array}{rcl} \varphi\colon B = \mathbb{Z}_6 & \to & \mathrm{SL}(2,\mathbb{Z}) \\ k & \mapsto & \begin{pmatrix} 1 & 1 \\ -1 & 0 \end{pmatrix}^k. \end{array}$$

It is straightforward to verify that[313] $\varphi \circ \alpha = \psi \circ \beta$, therefore there exists by Proposition 13.11 a homomorphism

$$A *_G B \;=\; \mathbb{Z}_4 *_{\mathbb{Z}_2} \mathbb{Z}_6 \;\to\; \mathrm{SL}(2,\mathbb{Z}).$$

More surprisingly, this homomorphism is in fact an isomorphism. We refer to [Rosb, p. 218] and [Ser, p. 35] for a proof.

The following lemma summarizes two important special cases of the amalgamated product of groups.

Lemma 13.12.

(1) *For two groups A and B and $G = \{e\}$ the trivial group, the corresponding amalgamated product is the usual free product, i.e.*

$$A *_{\{e\}} B \;= A * B.$$

(2) *If $\alpha\colon G \to A$ is a group homomorphism and if $\beta\colon G \to \{e\}$ is the trivial homomorphism, then*

$$A *_G \{e\} \;=\; A/\langle\langle \alpha(G) \rangle\rangle.$$

(3) *If $\alpha\colon G \to A$ is a group homomorphism and if $\beta\colon G \to B$ is an isomorphism, then the identity on A and $\beta^{-1}\colon B \to G$ induce an isomorphism*

$$A *_G B \;\xrightarrow{\cong}\; A.$$

[312] Are these really homomorphisms?

[313] Indeed, the one non-trivial element of $G = \mathbb{Z}_2$ gets sent under both maps to $-\mathrm{id}$.

Proof. The first two statements follow immediately from the definition

$$A *_G B \ := \ A * B / \langle\langle \{\alpha(g)\beta(g)^{-1}\}_{g\in G} \rangle\rangle.$$

For the third statement it is arguably best to work with the definition of the amalgamated product via the universal property. With this approach one quickly obtains that the given map is an isomorphism. □

The following lemma gives us a convenient description of the amalgamated product of two finitely presented groups.

Lemma 13.13. *Let*

$$A \ = \ \langle x_1, \dots, x_k \mid r_1, \dots, r_p \rangle$$

and

$$B \ = \ \langle y_1, \dots, y_l \mid s_1, \dots, s_q \rangle$$

be two finitely presented groups. Furthermore let $\alpha\colon G \to A$ *and* $\beta\colon G \to B$ *be two group homomorphisms and let* $g_1, \dots, g_m$ *be generators of* G*. Then*

$$A *_G B \ = \ \langle x_1, \dots, x_k, y_1, \dots, y_l \mid r_1, \dots, r_p, s_1, \dots, s_q \text{ and } \alpha(g_i) = \beta(g_i), i = 1, \dots, m \rangle.$$

Examples.

(1) Let $A_1 = \langle x_1, y_1 \rangle$ and $A_2 = \langle x_2, y_2 \rangle$ be two free groups and for $i = 1, 2$ let $\varphi_i\colon \langle t \rangle \to A_i$ be the homomorphism that is given by $\varphi_i(t^n) := [x_i, y_i]^n$. Then we obtain from Lemma 13.13 that

$$A_1 *_{\langle t \rangle} A_2 \ = \ \langle x_1, y_1, x_2, y_2 \mid [x_1, y_1] = [x_2, y_2] \rangle.$$

(2) Let $A = \langle a \rangle$ and let $B = \langle b \rangle$ be two infinite cyclic groups and let $G = \langle x, y \mid [x, y] \rangle$ be a group that is isomorphic to $\mathbb{Z}^2$. We consider the homomorphism $\alpha\colon G \to A$ that is given by $\alpha(x) = a$ and $\alpha(y) = e$ and we consider the homomorphism $\beta\colon G \to B$ that is given by $\beta(x) = e$ and $\beta(y) = b$. Then

$$A *_G B \ \underset{\substack{\uparrow \\ \text{Lemma 13.13}}}{=} \ \langle a, b \mid \alpha(x) = \beta(x), \alpha(y) = \beta(y) \rangle \ = \ \langle a, b \mid a = e, e = b \rangle \ \underset{\substack{\uparrow \\ \text{Tietze transformation (2), see page 412}}}{=} \ \langle | \rangle \ = \ \{e\}.$$

This shows in particular that the amalgamated product of two non-trivial groups can in fact be trivial.

Proof of Lemma 13.13. We need to show that

$$\underbrace{\frac{A*B}{\langle\langle \{\alpha(g)\beta(g)^{-1}\}_{g\in G} \rangle\rangle}}_{\text{definition of } A*_G B} = \underbrace{\frac{A*B}{\langle\langle \{\alpha(g_i)\beta(g_i)^{-1}\}_{i=1,\dots,m} \rangle\rangle}}_{\text{right-hand side of the proposition}}.$$

Put differently, we need to prove the following claim.

Claim. In the free product $A * B$ we have

$$\langle\langle \{\alpha(g)\beta(g)^{-1}\}_{g\in G} \rangle\rangle \ = \ \langle\langle \{\alpha(g_i)\beta(g_i)^{-1}\}_{i=1,\dots,m} \rangle\rangle.$$

It is clear that the right-hand side is contained in the left-hand side. To show the reverse inclusion we need to show that for each $g \in G$ we have $\alpha(g)\beta(g)^{-1} \in \langle\langle \{\alpha(g_i)\beta(g_i)^{-1}\}_{i=1,\dots,m} \rangle\rangle$. We start out with two observations:

(1) We first consider the case $g = g_i^{-1}$ for some i. Then
$$\alpha(g)\beta(g)^{-1} \;=\; \alpha(g_i^{-1})\beta(g_i^{-1})^{-1} \;=\; \alpha(g_i)^{-1}\big(\alpha(g_i)\beta(g_i^{-1})\big)^{-1}\alpha(g_i),$$
thus $\alpha(g)\beta(g)^{-1}$ is a conjugate of the inverse of $\alpha(g_i)\beta(g_i^{-1})$, in particular it lies in $\langle\langle \{\alpha(g_i)\beta(g_i)^{-1}\}_{i=1,\dots,m} \rangle\rangle$.

(2) Note that if a, b and c are elements in a group π such that ac and b lie in a normal subgroup Γ, then $abc = ac \cdot c^{-1}bc$ also lies in Γ.

Now we turn to the proof of the claim. We define the *length* of $g \in G$ as
$$\ell(g) \;=\; \min\{n \mid \text{ we can write } g = g_{i_1}^{\epsilon_1} \cdot \dots \cdot g_{i_n}^{\epsilon_n} \text{ for } \epsilon_j \in \{-1,1\} \text{ and } i_j \in \{1,\dots,m\}\}.$$
Since $g_1, \dots, g_m$ are generators of G any $g \in G$ has a length.

We prove the claim by induction on the length of $g \in G$. For $\ell(g) = 0$ there is nothing to prove. Now suppose we have shown the claim for all elements of length $n-1$. Now let $g \in G$ be an element of length n. Thus we can write $g = g_{i_1}^{\epsilon_1} \cdot \dots \cdot g_{i_n}^{\epsilon_n}$ for $\epsilon_1, \dots, \epsilon_n \in \{-1,1\}$ and $i_1, \dots, i_n \in \{1,\dots,m\}$. We then have
$$\begin{aligned}\alpha(g)\beta(g)^{-1} \;=\; \alpha(g)\beta(g^{-1}) \;&=\; \alpha\big(g_{i_1}^{\epsilon_1} \cdots g_{i_n}^{\epsilon_n}\big) \cdot \beta\big(g_{i_n}^{-\epsilon_n} \cdots g_{i_1}^{-\epsilon_1}\big) \\ &=\; \underbrace{\alpha\big(g_{i_1}^{\epsilon_1}\big) \cdots \alpha\big(g_{i_{n-1}}^{\epsilon_{n-1}}\big)}_{=:a} \cdot \underbrace{\alpha\big(g_{i_n}^{\epsilon_n}\big) \cdot \beta\big(g_{i_n}^{-\epsilon_n}\big)}_{=:b} \cdot \underbrace{\beta\big(g_{i_{n-1}}^{-\epsilon_{n-1}}\big) \cdots \beta\big(g_{i_1}^{-\epsilon_1}\big)}_{=:c}.\end{aligned}$$
Note that b lies in the normal subgroup $\langle\langle \{\alpha(g_i)\beta(g_i)^{-1}\}_{i=1,\dots,m} \rangle\rangle$ by (1) and ac lies in the normal subgroup $\langle\langle \{\alpha(g_i)\beta(g_i)^{-1}\}_{i=1,\dots,m} \rangle\rangle$ by induction. Thus $abc = \alpha(g)\beta(g)^{-1}$ lies in $\langle\langle \{\alpha(g_i)\beta(g_i)^{-1}\}_{i=1,\dots,m} \rangle\rangle$ by (2). □

In the previous example we saw that the amalgamated product of two non-trivial groups can be trivial. We conclude this introduction to amalgamated products with the following proposition that is proved in [Ser, p. 3] or alternatively [vdW]. It gives a criterion for the amalgamated product to be non-trivial.

Proposition 13.14. *Let $\alpha\colon G \to A$ and $\beta\colon G \to B$ be two group homomorphisms. If α and β are monomorphisms, then the canonical homomorphisms $A \to A *_G B$ and $B \to A *_G B$ are also monomorphisms.*

Exercises for Chapter 13.

Exercise 13.1.

(a) Show that
$$\langle x_1, \dots, x_k \mid x_k \rangle \;\cong\; \langle x_1, \dots, x_{k-1} \rangle.$$

(b) Show that in the group $\pi = \langle x, y \mid xyx^{-1}y^{-1} \rangle$ we have $yx^{-1} = x^{-1}y$.

Exercise 13.2.

(a) Let $k \geq 5$. Determine the abelianization of the permutation group S_k.
(b) Let G be an abelian group, let $\alpha\colon G \to A$ and $\beta\colon G \to B$ be epimorphisms. Show that $A *_G B$ is also abelian.

Exercise 13.3. Given a group G we denote by G_{ab} its abelianization.

(a) Let $\varphi\colon A \to B$ be an epimorphism. Show that the induced map $A_{\mathrm{ab}} \to B_{\mathrm{ab}}$ is also an epimorphism.
(b) Let $\varphi\colon A \to B$ be a monomorphism. Is the induced map $A_{\mathrm{ab}} \to B_{\mathrm{ab}}$ also a monomorphism?

Exercise 13.4. Let $\varphi\colon G \to A$ and $\psi\colon G \to B$ group monomorphisms which we use to define the amalgamated product $A *_G B$. Suppose that the map $A \to A *_G B$ is an isomorphism. Show that ψ is an isomorphism.

14. The general Seifert-van Kampen Theorem

14.1. **The formulation of the general Seifert-van Kampen Theorem.** With the group theoretic preparations from the previous chapter we can now formulate and prove the general Seifert-van Kampen Theorem.

Theorem 14.1. (Seifert–van Kampen) *Let X be a topological space and let $X = U \cup V$ be a decomposition of X in two open subsets U and V such that $U \cap V$ is non-empty and path-connected. Let $x_0 \in U \cap V$. Then there exists an isomorphism*

$$\Phi\colon \pi_1(U, x_0) *_{\pi_1(U\cap V, x_0)} \pi_1(V, x_0) \xrightarrow{\cong} \pi_1(X, x_0)$$

such that the following diagram commutes:

$$\begin{tikzcd}
\pi_1(U \cap V, x_0) \arrow[r] \arrow[d] & \pi_1(U, x_0) \arrow[d] \arrow[ddr, bend left] & \\
\pi_1(V, x_0) \arrow[r] \arrow[drr, bend right] & \pi_1(U, x_0) *_{\pi_1(U\cap V, x_0)} \pi_1(V, x_0) \arrow[dr, "\Phi", "\cong"'] & \\
& & \pi_1(X, x_0).
\end{tikzcd}$$

Here all other maps are the obvious inclusion induced homomorphisms.

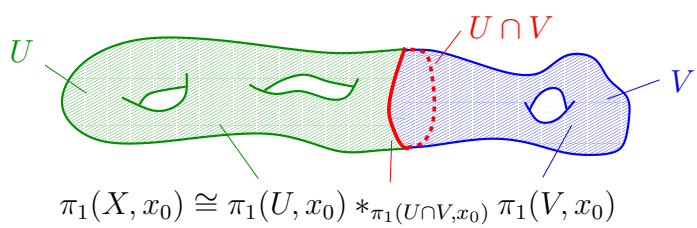

Figure 252. Illustration of Theorem 14.1.

The proof of the general Seifert-van Kampen Theorem is a modification of the proof of the more "basic" Seifert-van Kampen Theorem 12.2 where we had assumed that $U \cap V$ is in fact simply connected. We only sketch the proof of the general Seifert-van Kampen Theorem 14.1. The full details are for example given in Section 1.2 of [Hat].

Sketch of the proof. The various inclusions of topological spaces give rise to the following commutative diagram:

$$\begin{tikzcd}
\pi_1(U \cap V, x_0) \arrow[r, "i"] \arrow[d, "j"'] & \pi_1(U, x_0) \arrow[ddr] & \\
\pi_1(V, x_0) \arrow[drr] & & \\
& & \pi_1(X, x_0).
\end{tikzcd}$$

By Proposition 13.11 there exists a unique homomorphism

$$\Phi\colon \pi_1(U,x_0) *_{\pi_1(U\cap V,x_0)} \pi_1(V,x_0) \;\to\; \pi_1(X,x_0)$$

such that the following diagram commutes:

$$\begin{tikzcd}
\pi_1(U\cap V,x_0) \arrow[r, "i"] \arrow[d, "j"'] & \pi_1(U,x_0) \arrow[d, "k"] \arrow[ddr, bend left] & \\
\pi_1(V,x_0) \arrow[r, "l"] \arrow[drr, bend right] & \pi_1(U,x_0) *_{\pi_1(U\cap V,x_0)} \pi_1(V,x_0) \arrow[dr, "\Phi"] & \\
& & \pi_1(X,x_0).
\end{tikzcd}$$

It remains to show that Φ is surjective and that Φ is injective.

We first show surjectivity. We consider the following commutative diagram[314] of homomorphisms

$$\begin{tikzcd}
& \pi_1(U,x_0) *_{\pi_1(U\cap V,x_0)} \pi_1(V,x_0) \arrow[dr, "\Phi"] & \\
\pi_1(U,x_0) * \pi_1(V,x_0) \arrow[ur] \arrow[rr] & & \pi_1(X,x_0).
\end{tikzcd}$$

By Lemma 12.1 the horizontal map is surjective. It follows that the diagonal map Φ on the right is also surjective.

Now we turn to the proof of the injectivity of Φ. We write $A = \pi_1(U,x_0), B = \pi_1(V,x_0)$ and $G = \pi_1(U\cap V,x_0)$. As on page 380 we consider the set

$$S(A,B) \;:=\; \{\text{all finite sequences } (x_1,\dots,x_k) \text{ with each } x_i \text{ in } A \text{ or } B\}.$$

Furthermore we denote by $\sim_G$ the equivalence relation on $S(A,B)$ generated by the relation

$$(x_1,\dots,x_l,e,x_{l+2},\dots,x_k) \;\sim\; (x_1,\dots,x_l,x_{l+2},\dots,x_k)$$

where e is trivial in A or B, by the relation

$$(x_1,\dots,x_l,x_{l+1},\dots,x_k) \;\sim\; (x_1,\dots,x_lx_{l+1},\dots,x_k)$$

if both x_l and x_{l+1} lie in A or both lie in B, and also by the relation

$$(x_1,\dots,x_l,i(g),x_{l+2},\dots,x_k) \;\sim\; (x_1,\dots,x_l,j(g),x_{l+2},\dots,x_k)$$

for $g\in G$. Similar to Proposition 11.16 one can now show that the map

$$\begin{array}{rcl} S(A,B)/\sim_G & \to & A *_G B \\ [(x_1,\dots,x_k)] & \mapsto & x_1\cdot\dots\cdot x_k \end{array}$$

is a well-defined bijection. We will use this isomorphism to identify $S(A,B)/\sim_G$ with $A *_G B$.

The proof of the present theorem is now almost identical to the proof of Theorem 12.2, one just needs to replace the discussion involving $S(A,B)/\sim$ by the corresponding objects in $S(A,B)/\sim_G$. More precisely, in Footnote 284 we pointed out where in the proof of

[314] What are the maps, and why does the diagram commute?

Theorem 12.2 we used the hypothesis that $U \cap V$ is simply connected. At that point in the proof of Theorem 12.2 we need to replace $A * B = S(A,B)/\sim$ with $A *_G B = S(A,B)/\sim_G$. Full details for the proof can be found for example in Section 1.2 of [Hat]. $\square$

The same way that we deduced Theorem 12.9 from Theorem 12.2 we can now obtain the following theorem from Theorem 14.1.

Theorem 14.2. (Seifert-van Kampen for manifolds) *Let M be an m-dimensional manifold and let $R, S \subset M$ be two m-dimensional submanifolds such that the following hold:*

(1) *$M = R \cup S$,*
(2) *$R \cap S$ is a component of ∂R and it is a component of ∂S,*
(3) *R and S are closed subsets of M.*

We pick a base point $x_0 \in R \cap S$. Then the inclusion induced map

$$\pi_1(R, x_0) *_{\pi_1(R\cap S, x_0)} \pi_1(S, x_0) \ \to \ \pi_1(M, x_0)$$

is an isomorphism.

Example. On page 400 we saw that the earlier Seifert-van Kampen Theorem 12.9 can be applied to show that $\pi_1(S^n) = 0$ for $n \geq 3$. If we replace Theorem 12.9 by the more general Theorem 14.2, then we can also determine the fundamental group of $\pi_1(S^2)$ using the "Seifert-van Kampen method". More precisely, we denote by $S^2_{\geq 0} := \{(x,y,z) \in S^2 \mid z \geq 0\}$ the upper hemisphere and similarly we define the lower hemisphere $S^2_{\leq 0}$. Then $S^2_{\geq 0}, S^2_{\leq 0}$ are submanifolds of S^2 that satisfy the hypothesis of Theorem 14.2. By the discussion on page 73 both hemispheres are homeomorphic to $\overline{B}^2$, and we obtain once again that $\pi_1(S^2) \cong \pi_1(S^2_{\geq 0}) *_{\mathbb{Z}} \pi_1(S^2_{\leq 0}) = \{e\} *_{\mathbb{Z}} \{e\} = \{e\}$.

14.2. **The fundamental groups of surfaces.** Now we want to use the Seifert-van Kampen Theorem 14.1 to determine the fundamental groups of surfaces of genus $g \geq 2$. Before we do so we consider the torus, the Klein bottle and the real projective plane to gain some confidence in our newly acquired methods.[315]

(1) We first consider the torus $T = [0,1] \times [0,1]/\sim$. In the following we will use the following notation, see also Figure 253 for an illustration:
   (a) We denote by Q the point on T corresponding to the four vertices of the square.
   (b) We write $T = U \cup V$ where
   $$U \ = \ T \setminus \overline{B_{\frac{1}{8}}(\tfrac{1}{2}, \tfrac{1}{2})} \subset T \quad \text{ and } V \ = \ B_{\frac{1}{4}}(\tfrac{1}{2}, \tfrac{1}{2}) \subset T,$$
   i.e. U is the complement of a closed disk and V is an open disk and $U \cap V$ is an open annulus.
   (c) We let $P = (r,r) \in U \cap V$ and we denote by p the direct path from Q to P.

[315]The following examples can also be handled using Theorem 14.2 instead of Theorem 14.1. The advantage of using Theorem 14.1 at this point is that in the illustrations one can draw $U \cap V$ better if U and V are open subsets.

(d) We pick a loop γ in $(U \cap V, P)$ that "goes counterclockwise around the annulus" and that represents a generator of the infinite cyclic group $\pi_1(U \cap V, P) \cong \mathbb{Z}$.[316]

(e) We denote by x and y the two loops in (T, Q) corresponding to the horizontal and the vertical edge of the square. By a slight abuse of notation we denote the corresponding elements in $\pi_1(T, Q)$ by x and y as well.

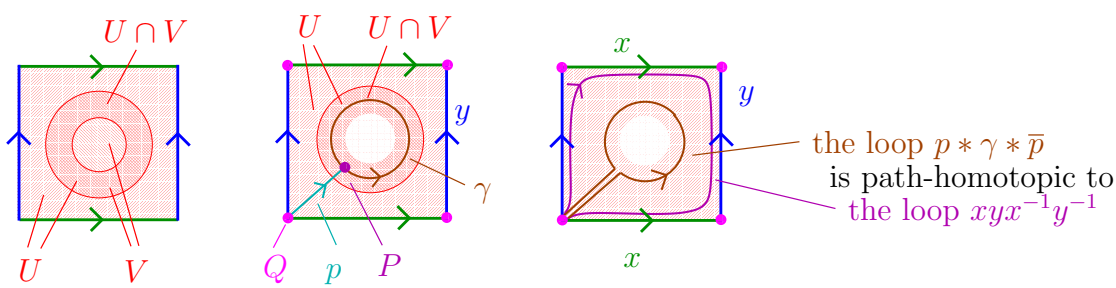

FIGURE 253.

Now we have

$$\pi_1(T,P) \underset{\substack{\uparrow \\ \text{Seifert-van Kampen Theorem 14.1}}}{\cong} \pi_1(U,P) *_{\pi_1(U\cap V,P)} \pi_1(V,P) \underset{\substack{\uparrow \\ V \text{ is a disk, hence } \pi_1(V,P)=\{e\}}}{=} \pi_1(U,P) *_{\pi_1(U\cap V,P)} \{e\}$$

$$\underset{\substack{\uparrow \\ \text{by Lemma 13.12 we have } A *_G \{e\} = A/\langle\langle \alpha(G)\rangle\rangle}}{=} \pi_1(U,P)/\langle\langle i_*(\pi_1(U\cap V,P))\rangle\rangle \underset{\substack{\uparrow \\ \text{since } \pi_1(U\cap V,P)=\langle[\gamma]\rangle}}{=} \pi_1(U,P)/\langle\langle[\gamma]\rangle\rangle$$

$$\underset{\substack{\uparrow \\ \text{by Proposition 5.11 the path } p \text{ gives} \\ \text{rise to an isomorphism } p_*}}{\overset{\cong}{\longrightarrow}} \pi_1(U,Q)/\langle\langle[p*\gamma*\overline{p}]\rangle\rangle \underset{\substack{\uparrow \\ \text{since } p*\gamma*\overline{p} \text{ is path-homotopic to } xyx^{-1}y^{-1}}}{=} \pi_1(U,Q)/\langle\langle xyx^{-1}y^{-1}\rangle\rangle = (*).$$

As in the proof of Lemma 12.8 we can show that $W := \partial([0,1]\times[0,1])/\sim$ is a deformation retract of U and that W is homeomorphic to the wedge of two circles. By Lemma 12.4 we can therefore make the identification $\pi_1(W,P) = \langle x, y\rangle$, see also Figure 254. Now we continue with the above calculation of $\pi_1(T,P)$. We have

$$(*) = \pi_1(U,Q)/\langle\langle xyx^{-1}y^{-1}\rangle\rangle \underset{\substack{\uparrow \\ \text{by Lemma 9.10 and Proposition 9.12 (1)}}}{\overset{\cong}{\longrightarrow}} \pi_1(W,P)/\langle\langle xyx^{-1}y^{-1}\rangle\rangle$$

$$\underset{\substack{\uparrow \\ \text{since } W \text{ is the wedge of the circles } x \text{ and } y}}{=} \langle x,y\rangle/\langle\langle xyx^{-1}y^{-1}\rangle\rangle = \langle x, y \mid [x,y]\rangle \underset{\substack{\uparrow \\ \text{see page 409}}}{\cong} \mathbb{Z}^2.$$

Thus we have reproved that the fundamental group of the torus is isomorphic to the free abelian group $\mathbb{Z}^2$.

[316] Since $U \cap V$ is an open annulus its fundamental group is isomorphic to $\mathbb{Z}$.

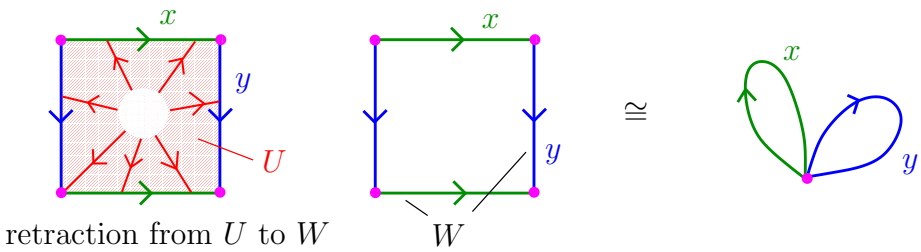

FIGURE 254.

(2) We turn to the Klein bottle K. We perform almost the same argument as for the torus, we just replace the situation illustrated in Figure 254 by the situation illustrated in Figure 255. The same argument as above shows that[317]

$$\pi_1(K) \;\cong\; \langle x, y \mid yxyx^{-1}\rangle.$$

Using this presentation and using Proposition 13.10 (5) we obtain in particular that the abelianization of $\pi_1(K)$ is given by

$$\pi_1(K)_{\mathrm{ab}} \;\cong\; \langle x, y \mid yxyx^{-1}\rangle_{\mathrm{ab}} \;\cong\; \mathbb{Z}^2/\begin{pmatrix}0\\2\end{pmatrix}\mathbb{Z} \;\cong\; \mathbb{Z}\oplus\mathbb{Z}_2.$$

On page 283 we already gave a very different calculation of $\pi_1(K)$. More precisely, we introduced the group G that is given by all self-homeomorphisms of $\mathbb{R}^2$ that can be written as concatenations of the two self-homeomorphisms

$$\begin{array}{rcl} A\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (s,t) & \mapsto & (s+1, 1-t) \end{array} \quad \text{and} \quad \begin{array}{rcl} B\colon \mathbb{R}^2 & \to & \mathbb{R}^2 \\ (s,t) & \mapsto & (s, t+1) \end{array}$$

and their inverses and we showed that $\pi_1(K) \cong G$. On page 410 we already showed that there exists a homomorphism $\Phi\colon \langle x, y \mid yxyx^{-1}\rangle \to G$ with $\Phi(x) = B^{-1}A$ and $\Phi(y) = B$. This homomorphism is in fact an isomorphism.[318]

[317] In particular this shows that $\pi_1(K)$ is finitely presented. This answers the question we had raised on page 411.

[318] This can be seen as follows. Denote by H the group of all self-homeomorphisms of $\mathbb{R}^2$. We consider the diagram

$$\begin{tikzcd} \langle x, y \mid yxyx^{-1}\rangle \arrow[r, "\cong"] \arrow[rr, bend right, "\Phi", "x\mapsto B^{-1}A, y\mapsto B"'] & \pi_1(K) & \text{subgroup of } H \text{ generated by } A, B. \arrow[l, "\cong"'] \end{tikzcd}$$

Here the isomorphisms to $\pi_1(K)$ are the ones given by the two calculations of the fundamental group. If one goes carefully through the definitions of the two horizontal maps, then one can see that the diagram commutes. Since two of the three maps are isomorphisms and since the diagram commutes it follows that Φ is also an isomorphism.

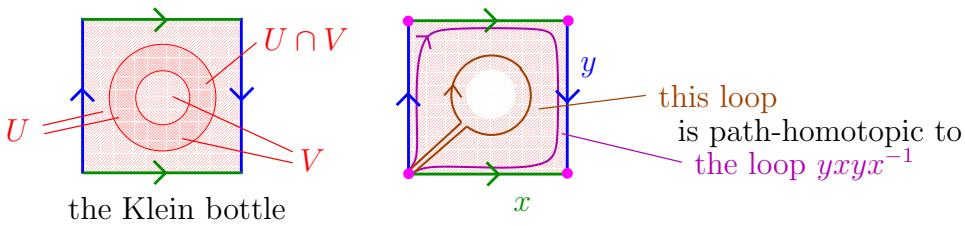

FIGURE 255.

(3) Next we consider again the real projective space $\mathbb{R}\mathrm{P}^2$. Here we use the description of $\mathbb{R}\mathrm{P}^2$ from Lemma 1.82 as

$$\mathbb{R}\mathrm{P}^2 \;=\; \overline{B}^2/\sim \qquad \text{where for } z \in S^1 \text{ we have } z \sim -z.$$

As in the previous two examples we decompose $\mathbb{R}\mathrm{P}^2$ into an open disk V and the complement of a closed disk U such that $U \cap V$ is an annulus. We consider the base point $Q = [1] = [-1] \in \mathbb{R}\mathrm{P}^2$ and we denote by α the loop

$$\begin{array}{rcl} \alpha\colon [0,1] & \to & \mathbb{R}\mathrm{P}^2 \\ t & \mapsto & [e^{i\pi t}]. \end{array}$$

By a slight abuse of notation we denote by α also the corresponding element in $\pi_1(\mathbb{R}\mathrm{P}^2, Q)$. Furthermore we denote by W the image of α in $\mathbb{R}\mathrm{P}^2$. Evidently α is a generator of $\pi_1(W, Q)$. Then, with similar arguments as in the torus case, we see that

$$\begin{array}{ccccccccc} \pi_1(\mathbb{R}\mathrm{P}^2) & \cong & \pi_1(U,Q)/\langle\langle p*\gamma*\overline{p}\rangle\rangle & \cong & \pi_1(W,Q)/\langle\langle p*\gamma*\overline{p}\rangle\rangle & \cong & \langle\alpha\rangle/\langle\alpha^2\rangle & \cong & \mathbb{Z}_2. \\ & \uparrow & & \uparrow & & \uparrow & & & \\ & \text{Seifert-van Kampen Theorem 14.1} & & \text{since } W \text{ is a deformation} & & \text{since } \pi_1(W,Q) = \langle\alpha\rangle & & & \\ & \text{and Lemma 13.12 (2)} & & \text{retract of } U & & \text{and } [p*\gamma*\overline{p}] = \alpha^2 & & & \end{array}$$

In particular we obtain the same result, as we should, as in Corollary 7.19.

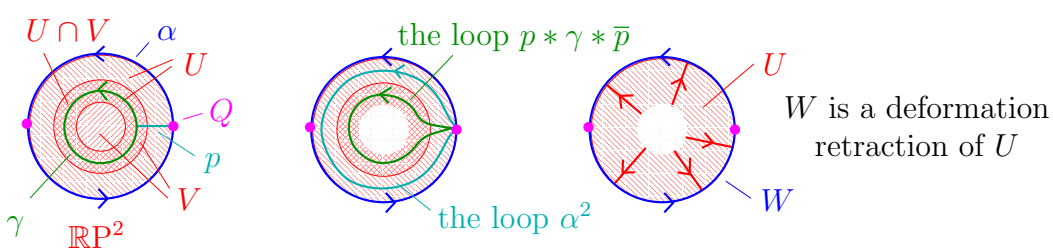

FIGURE 256.

(4) Now that we have gained some confidence that the approach of determining fundamental groups using Seifert-van Kampen Theorem 14.1 does indeed give the right fundamental groups we turn to the surfaces of higher genus that we could not handle with our previous methods.

So now we consider the surface $F = E_8/\sim$ of genus 2. As in the torus case we write $F = U \cup V$ where V is an open disk and where U is the complement of a closed disk such that $U \cap V$ is an annulus. In the following we use basically the same notation as in the torus case or alternatively we refer to Figures 257 and 258 for the notation. We write $W = \partial E_8/\sim$. By the proof of Proposition 12.7 we know that W is a deformation retraction of U and that W is homeomorphic to the wedge of four circles corresponding to x_1, y_1, x_2, y_2. See also Figure 258 for an illustration. Basically

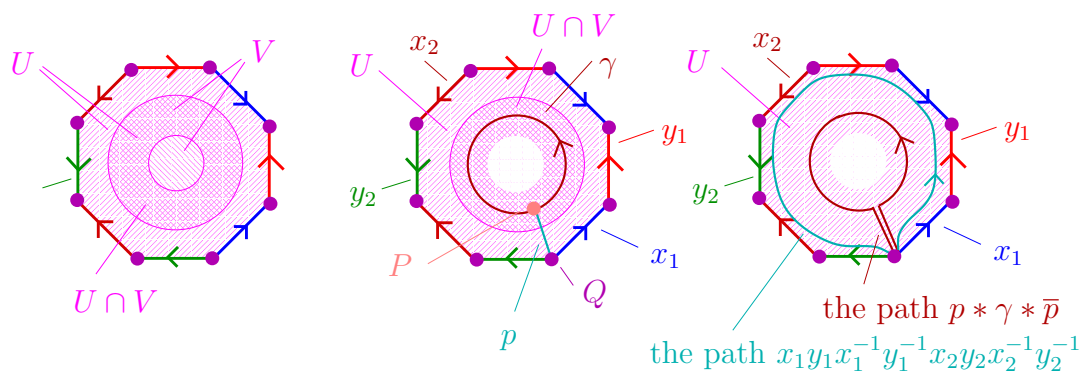

FIGURE 257.

exactly the same argument as in the torus case shows that

$$\begin{aligned}
\pi_1(E_8/\sim, P) &\cong \pi_1(U,Q)/\langle\langle \overbrace{\underbrace{x_1 y_1 x_1^{-1} y_1^{-1} x_2 y_2 x_2^{-1} y_2^{-1}}_{=[x_1,y_1][x_2,y_2]}}^{\text{path-homotopic to } p*\gamma*\overline{p}} \rangle\rangle \\
&\cong \pi_1(W,Q)/\langle\langle [x_1,y_1][x_2,y_2] \rangle\rangle \\
&\cong \langle x_1, y_1, x_2, y_2 \rangle / \langle\langle [x_1,y_1][x_2,y_2] \rangle\rangle \;=\; \langle x_1, y_1, x_2, y_2 \mid [x_1,y_1][x_2,y_2] \rangle.
\end{aligned}$$

Thus we have finally succeeded in calculating the fundamental group of the surface of genus 2.

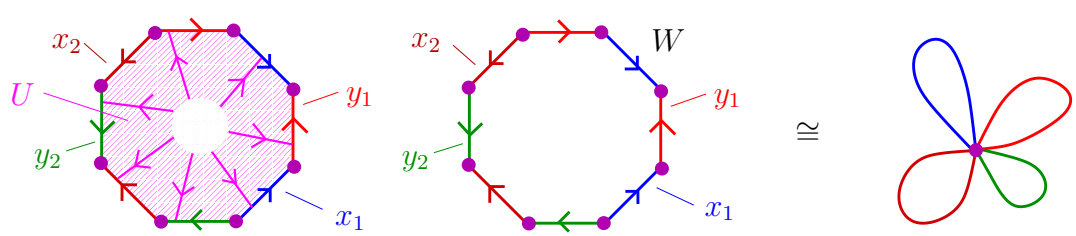

FIGURE 258.

The following gives in particular a new proof for Proposition 12.7.

Proposition 14.3.

(1) *For any* $g \in \mathbb{N}_0$ *we have*

$$\pi_1(\textit{surface of genus } g) \;\cong\; \langle x_1, y_1, \dots, x_g, y_g \mid [x_1, y_1] \cdot \dots \cdot [x_g, y_g] \rangle$$

and we have

$$\pi_1(\textit{surface of genus } g)_{\mathrm{ab}} \;\cong\; \mathbb{Z}^{2g}.$$

(2) *For* $g \neq h$ *the surfaces of genus* g *and* h *are not homeomorphic.*

Proof. Let $g \in \mathbb{N}_0$. For $g = 0$ we obtain the fundamental group from Proposition 5.14 and for $g = 1$ we obtain the presentation from the discussion on page 428. For $g \geq 2$ the presentation follows from a straightforward generalization of the calculation preceding the proposition.

The stated abelianization of the fundamental group is an immediate consequence of Proposition 13.10 (5).

Finally for $g \neq h$ we obtain from the above calculation and from the classification of finitely generated abelian groups that we gave in Theorem 11.4 that the abelianizations of the fundamental groups of the surfaces of genus g and h are not isomorphic. Hence the surfaces are not homeomorphic. □

Remark.

(1) In Figure 259 we show loops that represent the generators x_1, y_1, x_2, y_2 of the fundamental group for the surface of genus 2.

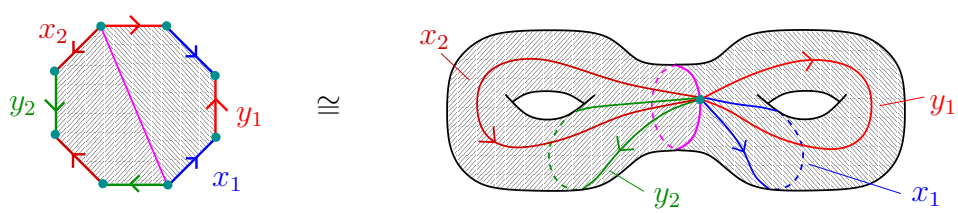

FIGURE 259.

(2) As explained in Figure 224 we can view the surface Σ of genus 2 as the connected sum of two copies of the torus T. We can also use this point of view to determine the fundamental group of the surface Σ of genus 2. More precisely, we have $\Sigma = F_1 \cup F_1$ with $F_1 = T \setminus B^2$ and $F_2 = T \setminus B^2$ where $F_1 \cap F_2 = \partial F_1 = \partial F_2 \cong S^1$ and we obtain that [319]

$$\begin{array}{lcl} & \text{Seifert-van Kampen Theorem 14.2} & \\ & \downarrow & \\ \pi_1(\Sigma) & \cong & \pi_1(F_1) *_{\pi_1(F_1 \cap F_2)} \pi_1(F_2) \\ & \cong & \langle x_1, y_1 \rangle *_{\langle t \rangle} \langle x_2, y_2 \rangle \qquad \cong \; \langle x_1, x_2, y_1, y_2 \mid [x_1, y_1] = [x_2, y_2] \rangle. \\ & \uparrow & \qquad\qquad\qquad\qquad\qquad\qquad \uparrow \\ & \text{by Lemma 12.8 (2) where} & \qquad\qquad \text{see page 422} \\ & t \mapsto [x_1, y_1] \text{ and } t \mapsto [x_2, y_2] & \end{array}$$

[319] Why is this group isomorphic to the above group $\langle x_1, y_1, x_2, y_2 \mid [x_1, y_1][x_2, y_2] \rangle$?

This approach to calculating the fundamental group of the surface of genus 2, or any higher genus, actually comes with a bonus: From Lemma 12.8 (2) we know that the curve $F_1 \cap F_2$ represents non-trivial elements in $\pi_1(F_1)$ and $\pi_1(F_2)$. But from the above description of $\pi_1(\Sigma)$ it follows from Proposition 13.14 that the curve also represents a non-trivial element in $\pi_1(\Sigma)$. An analogous statement holds for similar curves on surfaces of higher genus. We refer to Figure 260 for an illustration.

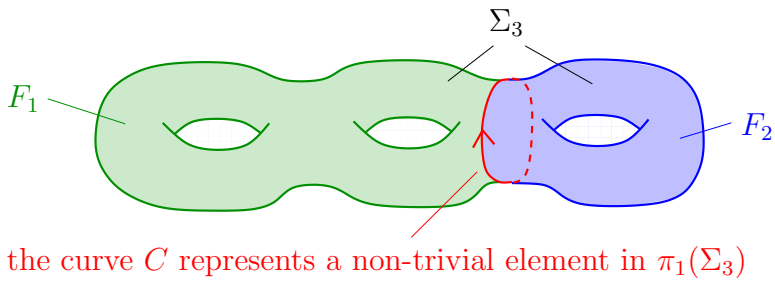

FIGURE 260.

Let $g \geq 2$ and let π be the fundamental group of the surface of genus g. We have just shown that $\pi_{\mathrm{ab}} \cong \mathbb{Z}^{2g}$. This raises the question, whether perhaps π is isomorphic to $\mathbb{Z}^{2g}$ or to the free group F_{2g} on $2g$ generators. The proof of the following lemma is Exercise 14.1.

Lemma 14.4. *The group $\pi = \langle x_1, y_1, \ldots, x_g, y_g \mid [x_1, y_1] \cdot \cdots \cdot [x_g, y_g] \rangle$ is non-abelian.*

The lemma says in particular that π is not isomorphic to $\mathbb{Z}^{2g}$. It is much harder to determine whether or not π is a free group. We record this as a question for later.

Question 14.5. *Let π be the fundamental group of the surface of genus g. Is π isomorphic to the free group F_{2g} on $2g$ generators?*

14.3. **Non-orientable surfaces.** We recall the definition of the connected sum of two manifolds in the case that one of the two manifolds is $\mathbb{R}\mathrm{P}^2$. In the following we always use Lemma 1.82 which gives us the identification

$$\mathbb{R}\mathrm{P}^2 \;=\; \overline{B}^2/\sim \qquad \text{where for } z \in S^1 \text{ we have } z \sim -z$$

and we view $\frac{1}{2}\overline{B}^2 = \{z \in \mathbb{C} \mid |z| \leq \frac{1}{2}\}$ as a subset of $\mathbb{R}\mathrm{P}^2$. Now let F be a connected 2-dimensional manifold. We pick an embedding $\varphi\colon \overline{B}^2 \to F$. According to the definition on page 355 the connected sum of F with $\mathbb{R}\mathrm{P}^2$ is defined as

$$F\#\mathbb{R}\mathrm{P}^2 \;:=\; \big(F \setminus \varphi(B^2)\big) \sqcup \big(\mathbb{R}\mathrm{P}^2 \setminus \tfrac{1}{2}B^2\big) \,/\, \big\{\varphi(z) = \tfrac{1}{2}z \,\big|\, z \in S^1\big\}.$$

The following proposition summarizes some key aspects of the connected sum in this particular example.

Proposition 14.6. *Let F be a connected 2-dimensional manifold.*

(1) *The diffeomorphism type of* $F\#\mathbb{RP}^2$ *is well-defined.*
(2) *The connected sum* $F\#\mathbb{RP}^2$ *is a connected, non-orientable 2-dimensional manifold.*

Proof. By Proposition 10.27 we only have to show that $F\#\mathbb{RP}^2$ is non-orientable. The connected sum $F\#\mathbb{RP}^2$ contains $\mathbb{RP}^2 \setminus \frac{1}{2}B^2$, i.e. it contains the real projective plane minus an open disk. We already saw in Figure 102 that $\mathbb{RP}^2$ minus an open disk is a Möbius band. For convenience we recall the argument in Figure 261. Thus we see that $F\#\mathbb{RP}^2$ contains a Möbius band, i.e. it contains a non-orientable submanifold of codimension 0. Therefore $F\#\mathbb{RP}^2$ cannot be orientable. □

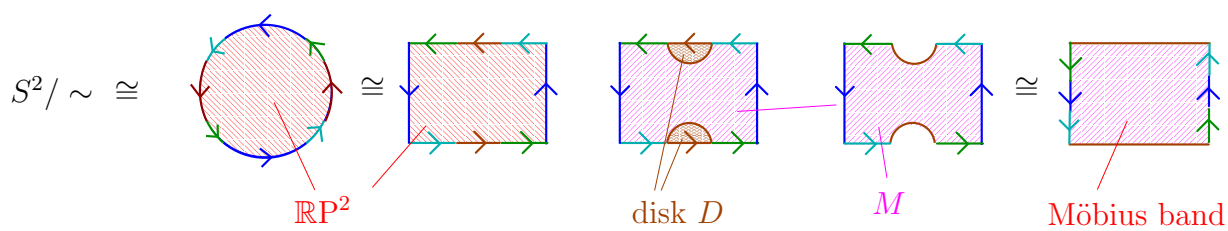

FIGURE 261.

Now we obtain many new examples of closed non-orientable 2-dimensional manifolds beyond the Klein bottle. For example the connected sum of the surface of genus g with $\mathbb{RP}^2$ or the connected sum $\mathbb{RP}^2\#\mathbb{RP}^2$ are closed non-orientable 2-dimensional manifolds.

Example. By Proposition 14.6 the connected sum $F = \Sigma_g\#\mathbb{RP}^2$ of the surface of genus g with the real projective plane is non-orientable. So according to Proposition 8.3 it admits a 2-fold covering $\widetilde{F} \to F$ that is orientable. This raises the following question: what is the genus of $\widetilde{F}$? We will return to this question at a later stage.

We want to do one more calculation of a fundamental group, namely we want to determine the fundamental group of $\mathbb{RP}^2\#\mathbb{RP}^2$. We record the result in the following lemma.

Lemma 14.7. *We have*

$$\pi_1(\mathbb{RP}^2\#\mathbb{RP}^2) \ \cong\ \langle x, y \mid x^2 = y^2\rangle.$$

Proof. In order to distinguish the two copies of $\mathbb{RP}^2$ we write $P = \mathbb{RP}^2$ and $Q = \mathbb{RP}^2$. The proof is of course a variation of the proof of Proposition 12.11. We have

$$\pi_1(\mathbb{RP}^2\#\mathbb{RP}^2) \ = \pi_1(P\#Q) \ \underset{\substack{\uparrow \\ \text{Seifert-van Kampen Theorem 14.2}}}{\cong}\ \pi_1\big(P \setminus \tfrac{1}{2}B^2\big) *_{\pi_1(\frac{1}{2}S^1)} \pi_1\big(Q \setminus \tfrac{1}{2}B^2\big).$$

We pick a generator g for $\pi_1(\frac{1}{2}S^1)$. In the calculation of the fundamental group of the real projective plane on page 430 we saw that $\pi_1(P \setminus \frac{1}{2}B^2) \cong \langle x\rangle$ and that the inclusion induced

map $\pi_1(\frac{1}{2}S^1) \to \pi_1(P \setminus \frac{1}{2}B^2)$ is given by $g \mapsto x^2$. The same holds for Q with $\pi_1(Q \setminus \frac{1}{2}B^2) = \langle y \rangle$. Summarizing we see that

$$\begin{aligned}
\pi_1(\mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2) &\cong \pi_1\big(P \setminus \tfrac{1}{2}B^2\big) *_{\pi_1(\frac{1}{2}S^1)} \pi_1\big(Q \setminus \tfrac{1}{2}B^2\big) \\
&\cong \text{amalgamated product of } \begin{pmatrix} \langle g \rangle & \to & \langle x \rangle \\ g & \mapsto & x^2 \end{pmatrix} \text{ and } \begin{matrix} \langle g \rangle & \to & \langle y \rangle \\ g & \mapsto & y^2 \end{matrix} \Big) \\
&\underset{\substack{\uparrow \\ \text{Lemma 13.13}}}{\cong} \langle x, y \mid x^2 = y^2 \rangle \;=\; \langle x, y \mid x^2 y^{-2} \rangle.
\end{aligned}$$

□

Now the question is whether $\mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2$ is a "new" 2-dimensional manifold or whether we have already seen it before. A first step towards understanding the fundamental group $\pi_1(\mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2) = \langle x, y \mid x^2 = y^2 \rangle$ is to determine its abelianization. Using Proposition 13.10 (5) we see that

$$\pi_1(\mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2)_{\mathrm{ab}} \;\cong\; \langle x, y \mid x^2 y^{-2} \rangle_{\mathrm{ab}} \;\cong\; \mathbb{Z}^2 / \begin{pmatrix} 2 \\ -2 \end{pmatrix} \mathbb{Z} \;\cong\; \mathbb{Z} \oplus \mathbb{Z}_2.$$

Interestingly we obtain the same abelianization as we got on page 429 for the abelianization of the fundamental group of the Klein bottle. This raises the question whether $\mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2$ is homeomorphic to the Klein bottle K.

At first glance it is not clear what the answer should be. We had just seen that

$$\pi_1(\mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2) \;\cong\; \langle x, y \mid x^2 = y^2 \rangle$$

whereas we saw on page 429 that

$$\pi_1(K) \;\cong\; \langle x, y \mid yxyx^{-1} \rangle.$$

So at the very least there is no obvious isomorphism between these two groups. We therefore decide to have a closer look at the two topological spaces involved.

(1) We had just seen in Figure 261 that removing an open disk from $\mathbb{R}\mathrm{P}^2$ we obtain the Möbius band. This shows that $\mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2$ is given by gluing two Möbius bands along their common boundary.
(2) In Figure 262 we see a closed curve in the Klein bottle that decomposes the Klein bottle into two Möbius bands.

Put differently, we see that both $\mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2$ and the Klein bottle are the result of gluing two Möbius bands along their boundary. It is now straightforward to see that the Klein bottle is homeomorphic to $\mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2$.[320]

Given $k \in \mathbb{N}$ we now denote by $k \cdot \mathbb{R}\mathrm{P}^2$ the connected sum of k copies of the real projective plane.[321] By Proposition 14.6 the topological space $k \cdot \mathbb{R}\mathrm{P}^2$ is a non-orientable 2-dimensional manifold.

We conclude this section with the following lemma.

[320]Now we know that the groups $\pi_1(\mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2) \cong \langle x, y \mid x^2 = y^2 \rangle$ and $\pi_1(K) \cong \langle x, y \mid yxyx^{-1} \rangle$ are isomorphic. But what is an explicit isomorphism between these two groups?

[321]To be more precise, we define $0 \cdot \mathbb{R}\mathrm{P}^2$" $= S^2$ and iteratively $k \cdot \mathbb{R}\mathrm{P}^2 := (k-1) \cdot \mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2$ for $k \in \mathbb{N}$.

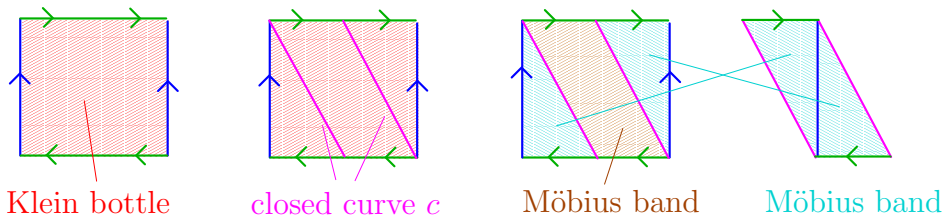

FIGURE 262.

Lemma 14.8. *Let $k \in \mathbb{N}$. Then*

$$\pi_1(k \cdot \mathbb{R}\mathrm{P}^2) \;\cong\; \langle x_1, \dots, x_k \mid x_1^2 \cdot \dots \cdot x_k^2 \rangle \quad \textit{and} \quad \pi_1(k \cdot \mathbb{R}\mathrm{P}^2)_{\mathrm{ab}} \;\cong\; \mathbb{Z}^{k-1} \oplus \mathbb{Z}_2.$$

Proof. A straightforward induction argument and a generalization of the argument of Lemma 14.7 gives the desired presentation for $\pi_1(k \cdot \mathbb{R}\mathrm{P}^2)$.[322] The abelianization can be determined easily from the presentation using Proposition 13.10 (5). We leave the details to the reader. □

14.4. **The classification of closed 2-dimensional (topological) manifolds.** The following proposition now gives the complete classification of connected closed topological 2-dimensional manifolds up to homeomorphism.

Theorem 14.9. *Every non-empty closed connected 2-dimensional topological manifold is homeomorphic to either*

(1) *a surface of genus g for some unique $g \in \mathbb{N}_0$ or*
(2) *to $k \cdot \mathbb{R}\mathrm{P}^2$ for some unique $k \in \mathbb{N}$.*

Proof. By Radó's Theorem [Rad] every closed connected 2-dimensional topological manifold can be "triangulated". A proof that every non-empty closed connected "triangulated" 2-dimensional topological manifold is homeomorphic to a surface of genus g or to $k \cdot \mathbb{R}\mathrm{P}^2$ for some k is for example given in [ST, ST2] or alternatively in [FW, Gl] or [Mas2, Theorem 5.1] or in [GX, Theorem 6.2].

It remains to prove the uniqueness statement. This means that we have to show that the topological spaces listed in (1) and (2) are pairwise non-homeomorphic. It follows from Proposition 14.3 and Lemma 14.8 together with the classification of finitely generated groups, see Theorem 11.4, that the abelianizations of the fundamental groups of the topological manifolds listed in (1) and (2) are pairwise non-isomorphic. But then it follows from Proposition 13.10 (8) that also the fundamental groups are pairwise non-isomorphic, which in turn implies that the given topological manifolds are pairwise not homeomorphic. □

The following theorem gives the classification of closed connected 2-dimensional manifolds up to diffeomorphism.

Theorem 14.10. *Let Σ be a non-empty closed connected 2-dimensional manifold.*

[322] Why is for $k = 2$ this group isomorphic to the group given in Lemma 14.7?

(1) *If Σ is orientable, then it is diffeomorphic to a surface of genus g for some unique $g \in \mathbb{N}_0$. Furthermore, if Σ is oriented, then we can chose the diffeomorphism to be orientation-preserving.*
(2) *If Σ is non-orientable, then it is diffeomorphic to $k \cdot \mathbb{R}\mathrm{P}^2$ for some unique $k \in \mathbb{N}$.*

Proof. The fact that any non-empty closed connected 2-dimensional manifold is diffeomorphic to one of the given manifolds is [Hirs, Theorems 9.3.5 and 9.3.10]. The uniqueness statement for g and k is an immediate consequence of the uniqueness statement of Theorem 14.9. □

Examples.

(1) It is perhaps tempting do dismiss Theorem 14.10 (1) as "obvious". After all, what other closed connected 2-dimensional manifold could there possibly be? It is thus instructive to consider Figure 263. It shows a hexagon and a decagon where *opposite sides* are identified. The same proof that showed that the $4g$-gon, with appropriate sides identified, is a closed orientable 2-dimensional manifold also shows that the topological spaces shown in Figure 263 are closed orientable 2-dimensional manifolds. To which of the standard surfaces are they diffeomorphic to? We will come back to this question at a later stage.

hexagon with opposite sides identified dodecagon with opposite sides identified

FIGURE 263.

(2) Let $g \in \mathbb{N}$ and denote by Σ_g the surface of genus g. The connected sum $\Sigma_g \# \mathbb{R}\mathrm{P}^2$ contains a Möbius band as a submanifold of codimension 0,[323] hence $\Sigma_g \# \mathbb{R}\mathrm{P}^2$ is non-orientable. It follows from Theorem 14.10 that $\Sigma_g \# \mathbb{R}\mathrm{P}^2$ is diffeomorphic to $k \cdot \mathbb{R}\mathrm{P}^2$ for some unique $k \in \mathbb{N}$. In Exercise 14.2 we will determine k as a function of g.

14.5. **The classification of 2-dimensional (topological) manifolds with boundary.** Now we turn to the classification of compact 2-dimensional (topological) manifolds with boundary. We first prove the following proposition.

[323]This follows from the observation that $\Sigma_g \# \mathbb{R}\mathrm{P}^2$ contains $\mathbb{R}\mathrm{P}^2$ minus a disk, which by Figure 102 is a Möbius band.

Proposition 14.11. *If F is a 2-dimensional topological manifold, then the corresponding boundary $Y := \partial F$ is a 1-dimensional topological manifold which has no boundary, i.e. such that $\partial Y = \varnothing$.*

Remark. It might come as a surprise that we do not yet know the statement of the proposition. In fact in Proposition 3.21 we saw that the boundary of any n-dimensional manifold is an $(n-1)$-dimensional manifold. But we did not show the corresponding statement for topological manifolds. In fact at the moment we can prove the statement only for topological manifolds of dimension *two*. We will deal with the case of higher-dimensional topological manifolds after we will have introduced and studied homology groups.

The key ingredient in the proof of Proposition 14.11 is the following lemma.

Lemma 14.12. *Let $H = \{(x,y) \in \mathbb{R}^2 \mid y \geq 0\}$ be the closed upper half-space in $\mathbb{R}^2$. If V is an open subset of H with $V \cap \partial H \neq \varnothing$, then V is not homeomorphic to an open subset of $\mathbb{R}^2$.*

For example it follows from the lemma that the half-open square $(0,1) \times [0,1)$ is not homeomorphic to any open subset of $\mathbb{R}^2$.

Proof. Let V be an open subset of the closed upper half-space H which contains a point $Q \in \partial H = \{(x,0) \mid x \in \mathbb{R}\}$. Furthermore let U be an open subset of $\mathbb{R}^2$. Suppose there exists a homeomorphism $\Phi\colon U \to V$. We write $\Psi := \Phi^{-1}$ and we write $P = \Psi(Q)$.

Since U is open in $\mathbb{R}^2$ we can pick a $\sigma > 0$ with $B_\sigma(P) \subset U$. Since V is open in H and since Ψ is continuous there exists an $\epsilon > 0$ with $B_\epsilon(Q) \cap H \subset V$ and with $\Psi(B_\epsilon(Q)) \subset B_\sigma(P)$. Furthermore, by the continuity of Φ there exists an $\eta > 0$ with $\Phi(B_\eta(P)) \subset B_\epsilon(Q))$. We refer to Figure 264 for an illustration. We consider the following commutative diagram of maps

$$\begin{tikzcd}
 & (B_\epsilon(Q) \setminus \{Q\}) \cap H \arrow[dr, "\Psi = \Phi^{-1}"] & \\
B_\eta(P) \setminus \{P\} \arrow[ur, "\Phi"] \arrow[rr, "i"'] & & B_\sigma(P) \setminus \{P\},
\end{tikzcd}$$

where $i\colon B_\eta(P) \setminus \{P\} \to B_\sigma(P) \setminus \{P\}$ denotes the inclusion map. Now we pick a base point $x \in B_\eta(P) \setminus \{P\}$. By the functoriality of fundamental groups, the above commutative diagram of maps gives rise to the following commutative diagram

$$\begin{tikzcd}
 & \pi_1((B_\epsilon(Q) \setminus \{Q\}) \cap H, \Phi(x)) \arrow[dr, "\Psi_* = \Phi_*^{-1}"] & \\
\pi_1(B_\eta(P) \setminus \{P\}, x) \arrow[ur, "\Phi_*"] \arrow[rr, "i_*"'] & & \pi_1(B_\sigma(P) \setminus \{P\}, x).
\end{tikzcd}$$

We make the following observations:

(1) the topological spaces on the left and on the right are homotopy equivalent to S^1, in particular the fundamental groups are non-trivial,

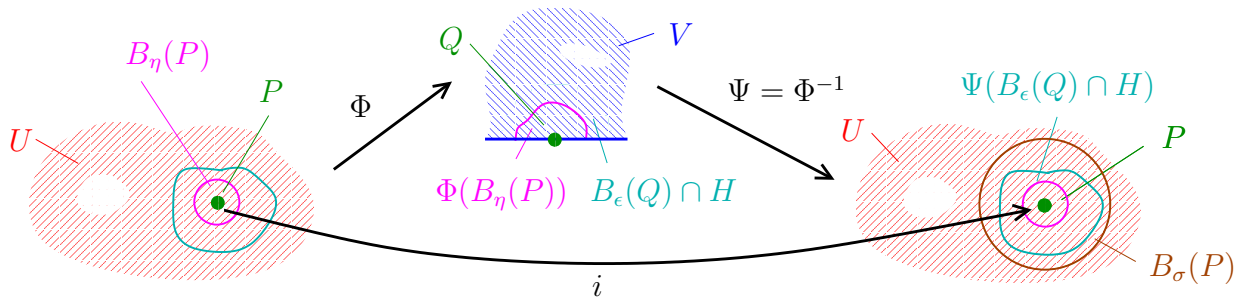

FIGURE 264.

(2) by Exercise 9.10 the inclusion map $B_\eta(P) \setminus \{P\} \to B_\sigma(P) \setminus \{P\}$ is a homotopy equivalence, therefore it follows from Proposition 9.12 (1) that the inclusion induced map $i_*\colon \pi_1(B_\eta(P) \setminus \{P\}, x) \to \pi_1(B_\sigma(P) \setminus \{P\}, x)$ is an isomorphism,
(3) the topological space $(B_\epsilon(Q) \setminus \{Q\}) \cap H$ is star-shaped[324], which implies by the discussion on page 238 that $\pi_1((B_\epsilon(Q) \setminus \{Q\}) \cap H, \Phi(x)) = 0$.

Summarizing we just showed that an isomorphism of non-trivial groups factors through the trivial group. This is not possible and hence we have obtained the desired contradiction. □

Now we can turn to the proof of Proposition 14.11.

Proof of Proposition 14.11. Let F be a 2-dimensional topological manifold with $\partial F \neq \varnothing$. We first recall some definitions.

(a) A 2-*dimensional chart for* F *at a point* $x \in X$ is a homeomorphism $\Phi\colon U \to V$ where U is an open neighborhood of x and V is one of the following:
  (i) V is an open subset of $\mathbb{R}^2$ or
  (ii) V is an open subset of the half-space $H := \{(x, y) \in \mathbb{R}^2 \mid y \geq 0\}$ and $\Phi(x)$ lies on $\partial H = \{(x, y) \in \mathbb{R}^2 \mid y = 0\}$.
  In the former case we say that Φ is a chart of type (i) in the latter case we say that Φ is a chart of type (ii).
(b) We say that a point x on a topological manifold is a *boundary point* if x does not admit a chart of type (i). We denote by ∂X the set of all boundary points of X.

We start our actual proof with the following claim.

Claim. Let x be a point on F. Then x admits either a chart of type (i) or it admits a chart of type (ii).

If a point did admit a chart $\Phi\colon U \to V$ of type (i) and a chart $\Psi\colon X \to Y$ of type (ii), then $\Phi \circ \Psi^{-1}\colon \Psi(U \cap X) \to \Phi(U \cap X)$ would give rise to a homeomorphism from an open set of H containing a point on $\partial H = \{(x, 0) \mid x \in \mathbb{R}\}$ to an open set in $\mathbb{R}^2$. But by Lemma 14.12 such a homeomorphism cannot exist. This concludes the proof of the claim.

[324]Why is that?

The following claim recalls the statement that we actually want to prove.

Claim. The boundary ∂F is a 1-dimensional topological manifold which has no boundary, i.e. such that $\partial Y = \varnothing$.

Let $P \in F$ be a point on the boundary. Let $\Phi\colon U \to V$ be a chart of type (ii) for P. It follows from the claim and the definitions that $\partial F \cap U = \Phi^{-1}(\partial H \cap V)$. Thus we see that Φ restricts to a chart $\Phi\colon \partial F \cap U \to \partial H \cap V$ of type (i), here we view $\partial H \cap V$ as an open subset of $\partial H = \mathbb{R}$. This shows that ∂F admits a 1-dimensional atlas where all charts are charts of type (i). Since F is second-countable and Hausdorff we obtain from Lemma 3.1 (2) and Lemma 1.14 that ∂F is also second-countable and Hausdorff. This completes the proof that ∂F is indeed a 1-dimensional topological manifold with no boundary points. □

After this rather technical discussion we go back to more hands-on topology.

Definition. Given a non-empty closed connected 2-dimensional manifold Σ and $n \in \mathbb{N}_0$ we define Σ *minus n open disks* as the result of removing the interiors of n disjoint closed disks.[325]

The following lemma captures some of the main features of the above definition.

Lemma 14.13. *Let Σ be a non-empty closed connected 2-dimensional manifold Σ and let $n \in \mathbb{N}_0$.*

1. *The topological space Σ minus n open disks is a compact connected submanifold of Σ with n boundary components.*
2. *The diffeomorphism type of Σ minus n open disks does not depend on the choice of the disks.*
3. *We denote the boundary components of Σ minus open disks by $C_1, \dots, C_n$. Given any permutation $\sigma \in S_n$ there exists a diffeomorphism f of Σ minus n open disks with $f(C_i) = C_j$, $i = 1, \dots, n$. Furthermore, if Σ is oriented, then f can be chosen to be orientation-preserving.*

Sketch of proof.

1. This statement follows from Proposition 10.2 (2).
2. This statement follows easily from Theorem 10.28.
3. Conveniently enough this statement also follows almost immediately from Theorem 10.28. □

This leads us to the following notation:

Notation. Given $g, n \in \mathbb{N}_0$ we write

$$\Sigma_{g,n} \;:=\; \text{the surface of genus } g \text{ minus } n \text{ open disks.}$$

Sometimes we refer to g as the genus of $\Sigma_{g,n}$. Furthermore for $k \in \mathbb{N}$ and $n \in \mathbb{N}_0$ we write

$$R_{k,n} \;:=\; \text{the manifold } k \cdot \mathbb{R}\mathrm{P}^2 \text{ minus } n \text{ open disks.}$$

[325] Why did we not make the definition as "the result of removing n disjoint open disks"? Wouldn't that be much easier?

Examples.

(1) The surface $\Sigma_{0,2}$ is the result of removing two open disjoint disks from the 2-sphere. The resulting topological space is homeomorphic to a cylinder. We refer to Figure 265 for an illustration of this statement.

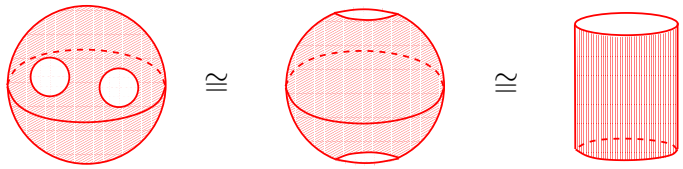

FIGURE 265.

(2) We saw in Figure 261 that the result of removing an open disk from $\mathbb{R}\mathrm{P}^2$ is the Möbius band, i.e. $R_{1,1}$ is the Möbius band.

Theorem 14.14. *Every non-empty compact connected 2-dimensional topological manifold is homeomorphic to either*

(1) *the surface $\Sigma_{g,n}$ for unique $g, n \in \mathbb{N}_0$ or*
(2) *to the surface $R_{k,n}$ for unique $k \in \mathbb{N}$ and $n \in \mathbb{N}_0$.*

Sketch of the proof. Let F be a non-empty compact connected 2-dimensional topological manifold. By Lemma 3.6 and Proposition 14.11 the boundary ∂F is a compact 1-dimensional topological manifold with no boundary. Since ∂F is compact it has finitely many components that we denote by $C_1, \dots, C_n$. (Note that we allow that case that $n = 0$.) Each component C_i is compact and has no boundary. Thus it follows from Propositions 3.49 that for each $i = 1, \dots, n$ there exists a homeomorphism $f_i \colon S^1 \to C_i$.

We denote by $\widehat{F}$ the result of gluing a disk to each boundary component. More precisely, we consider

$$\widehat{F} \ := \ \Big(F \sqcup \bigsqcup_{i=1}^{n} \overline{B}^2 \times \{i\}\Big) \,/\, \sim \ \text{ where } f_i(P) \sim (P, i) \text{ for } P \in S^1 \text{ and } i \in \{1, \dots, n\}.$$

The resulting topological space $\widehat{F}$ is a non-empty closed connected, 2-dimensional topological manifold[326]. Furthermore the homeomorphism type of $\widehat{F}$ does not depend on the choices of the homeomorphisms $f_1, \dots, f_n$.[327]

Now we apply Theorem 14.9. There are two possible conclusions:

[326]This statement requires more justification, we skip the details, hence we refer to it only as a "sketch of proof".

[327]This statement also needs a justification. This is the second reason why it is called "sketch of a proof".

(1) Either there exists exists a homeomorphism $\Phi\colon \Sigma_g \to \widehat{F}$ from the surface of genus g to $\widehat{F}$ for a unique $g \in \mathbb{N}_0$. Then Φ restricts to a homeomorphism

$$\Phi\colon \Sigma_{g,n} \;=\; \Sigma_g \setminus \bigcup_{i=1}^{n} \Phi^{-1}\big(B^2 \times \{i\}\big) \;\to\; F.$$

(2) Or there exists a homeomorphism $\Phi\colon k \cdot \mathbb{RP}^2 \to \widehat{F}$ for a unique $k \in \mathbb{N}$. Then Φ restricts to a homeomorphism

$$\Phi\colon R_{k,n} \;=\; k \cdot \mathbb{RP}^2 \setminus \bigcup_{i=1}^{n} \Phi^{-1}\big(B^2 \times \{i\}\big) \;\to\; F.$$

In both cases n is uniquely determined as the number of boundary components of F. Thus we have shown that F is homeomorphic to either $\Sigma_{g,n}$ or $R_{k,n}$ for some $g \in \mathbb{N}_0$ or $k \in \mathbb{N}$ and $n \in \mathbb{N}_0$ which are furthermore unique. □

The following theorem gives us the analogous classification statement for manifolds with boundary up to *diffeomorphism*.

Theorem 14.15. *Let Σ be a non-empty compact connected 2-dimensional manifold.*

(1) *If Σ is orientable, then Σ is diffeomorphic to the surface $\Sigma_{g,n}$ for some unique $g, n \in \mathbb{N}_0$. If Σ is oriented, then the diffeomorphism can be chosen to be orientation-preserving.*
(2) *If Σ is non-orientable, then Σ is diffeomorphic to the surface $R_{k,n}$ for some unique $k \in \mathbb{N}$ and $n \in \mathbb{N}_0$.*

Proof. The theorem is proved in a very similar fashion as Theorem 14.14. One needs to replace Proposition 3.49 by Proposition 3.53. Furthermore we have to use Theorem 14.10 instead of Theorem 14.9. Full details are given in [Hirs, Theorem 9.3.7]. □

The following corollary is an immediate, arguably rather striking, consequence of Theorem 14.15 and Lemma 14.13.

Corollary 14.16. *Let Σ be a compact connected 2-dimensional manifold. We denote the boundary components of Σ by $C_1, \dots, C_n$. Given any permutation $\sigma \in S_n$ there exists a diffeomorphism f of Σ minus n open disks with $f(C_i) = C_j$, $i = 1, \dots, n$. Furthermore, if Σ is oriented, then we can choose f to be orientation-preserving.*

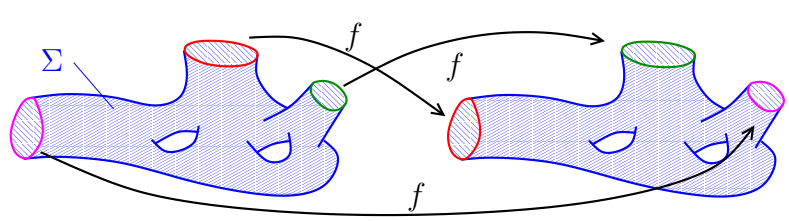

FIGURE 266. Illustration of Corollary 14.16.

It is natural to ask whether we can also classify non-compact 2-dimensional manifolds. For example a first guess would be that perhaps all non-compact orientable 2-dimensional manifolds without boundary are "the surface of infinite genus". But as we see in Figure 267 there exist several 2-dimensional manifolds for which the name "infinite genus" seems appropriate. In Exercise 14.3 we will show that the "surfaces of infinite genus" X and Y shown in Figure 267 not homeomorphic. This already shows that the classification of non-compact 2-dimensional manifolds can get a little tricky. In fact the classification for orientable 2-dimensional manifolds without boundary was first given by Ian Richards [Ric] in 1963, building on earlier work of Béla Kerékjártó [Kere] from 1923. In [PM] this result was extended to the case of 2-dimensional manifolds with non-empty boundary. As a side

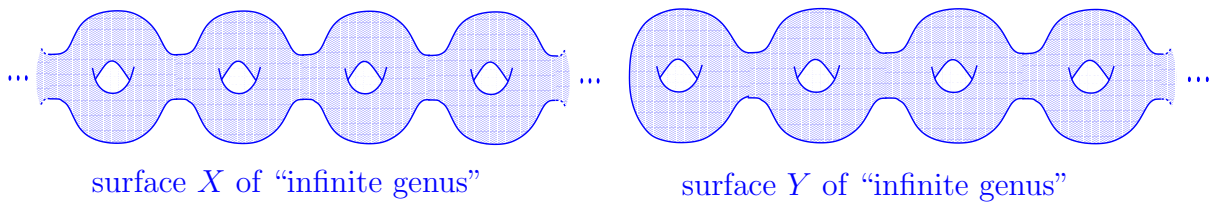

FIGURE 267.

we point out that the surface Y of infinite genus shown in Figure 267 is sometimes called the Loch Ness monster. The reason is shown in Figure 268: the visible part of an infinite Loch Ness monster, together with the surface of the infinite Loch Ness form a 2-dimensional manifold that is diffeomorphic to Y. More information on the mathematical Loch Ness monster and an explicit rigorous construction are given in [ARM].

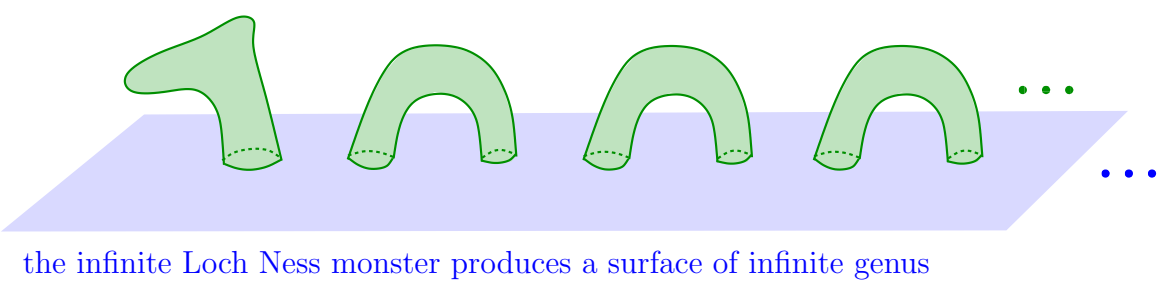

FIGURE 268.

We conclude this chapter with a short discussion of the properties of fundamental groups of 2-dimensional manifolds. We recall that the fundamental group of the real projective space $\mathbb{R}\mathrm{P}^2$ is isomorphic to $\mathbb{Z}_2$, therefore it is torsion and in particular it is not torsion-free. It is less clear whether or not the fundamental groups of the other 2-dimensional manifolds are torsion-free. More precisely, we have the following question.

Question 14.17.

(1) *Let $g \in \mathbb{N}$. Is the fundamental group*

$$\pi_1(\textit{surface of genus } g) \;\cong\; \langle x_1, y_1, \dots, x_g, y_g \mid [x_1, y_1] \cdot \dots \cdot [x_g, y_g] \rangle$$

torsion-free?

(2) *Let $k \geq 2$. Is the fundamental group*

$$\pi_1(k \cdot \mathbb{R}\mathrm{P}^2) \;\cong\; \langle x_1, \dots, x_k \mid x_1^2 \cdot \dots \cdot x_k^2 \rangle$$

torsion-free?

We will come back to this question at a much later stage.

14.6. **Retractions onto boundary components of 2-dimensional manifolds.** Let X be a topological space and let $A \subset X$ be a subset. Recall that we say that A is a *retract of* X if there exists a retraction $r\colon X \to A$, i.e. a map with $r(a) = a$ for all $a \in A$. We also recall the statement of Lemma 6.2.

Lemma 6.2. *The circle S^1 is not a retract of $\overline{B}^2$.*

We quickly recall the proof of Lemma 6.2.

Proof. We denote by $i\colon S^1 \to \overline{B}^2$ the inclusion map. Suppose there exists a retraction $r\colon \overline{B}^2 \to S^1$, i.e. a map with $r \circ i = \mathrm{id}_{S^1}$. We obtain the commutative diagram

$$\begin{tikzcd} & \overline{B}^2 \arrow[dr, "r"] & \\ S^1 \arrow[ur, "i"] \arrow[rr, "r\circ i = \mathrm{id}_{S^1}"'] & & S^1 \end{tikzcd}$$

which induces the commutative diagram

$$\begin{tikzcd} & \underbrace{\pi_1(\overline{B}^2, 1)}_{=0} \arrow[dr, "r_*"] & \\ \underbrace{\pi_1(S^1, 1)}_{\cong\mathbb{Z}} \arrow[ur, "i_*"] \arrow[rr, "(r\circ i)_* = (\mathrm{id}_{S^1})_*"'] & & \underbrace{\pi_1(S^1, 1)}_{\cong\mathbb{Z}}. \end{tikzcd}$$

But a commutative diagram as given on the right-hand side cannot exist since an isomorphism of a non-trivial group cannot factor through the trivial group. □

Given $g \in \mathbb{N}_0$ and $n \in \mathbb{N}$ we define, as on page 440

$$\Sigma_{g,n} \;:=\; \text{the surface of genus } g \text{ minus } n \text{ open disks.}$$

For example $\Sigma_{0,1}$ is the result of removing an open disk from S^2, i.e. $\Sigma_{0,1}$ is a disk. In light of Lemma 6.2 the following question arises:

Question 14.18. *Let $g \in \mathbb{N}_0$ and let $n \in \mathbb{N}$. Let C be a boundary component of $\Sigma_{g,n}$. Is C a retract of $\Sigma_{g,n}$?*

Lemma 6.2 says that the answer to Question 14.18 is no if $g = 0$ and $n = 1$. The proof of Lemma 6.2 suggests that if we want to answer Question 14.18, then given a boundary component C of $\Sigma_{g,n}$ we should try to understand the inclusion induced map $\pi_1(C) \to \pi_1(\Sigma_{g,n})$.

Lemma 14.19. *Let $g \in \mathbb{N}_0$ and let $n \in \mathbb{N}$. We denote the boundary components of $\Sigma_{g,n}$ by $C_1, \ldots, C_n$. Then the following statements hold:*

(1) *Let $* \in \Sigma_{g,n} \setminus \partial\Sigma_{g,n}$ be a base point. We pick an orientation for $\Sigma_{g,n}$. There exists a presentation*

$$\pi_1(\Sigma_{g,n}, *) \;=\; \langle x_1, y_1, \ldots, x_g, y_g, z_1, \ldots, z_n \mid [x_1, y_1] \cdot \cdots \cdot [x_g, y_g] \cdot z_1 \cdot \cdots \cdot z_n \rangle$$

with the following property: for any $i \in \{1, \ldots, n\}$ the element z_i is represented by a curve of the form $\alpha * \gamma * \overline{\alpha}$ where α is a path from $*$ to a point on C_i and γ is a path that goes once around C_i in an orientation-preserving way.[328] *We refer to Figure 269 for an illustration.*

(2) *If $g \geq 1$, then for any $i \in \{1, \ldots, n\}$ the inclusion induced map $\pi_1(C_i) \to \pi_1(\Sigma_{g,n})$ is a monomorphism.*

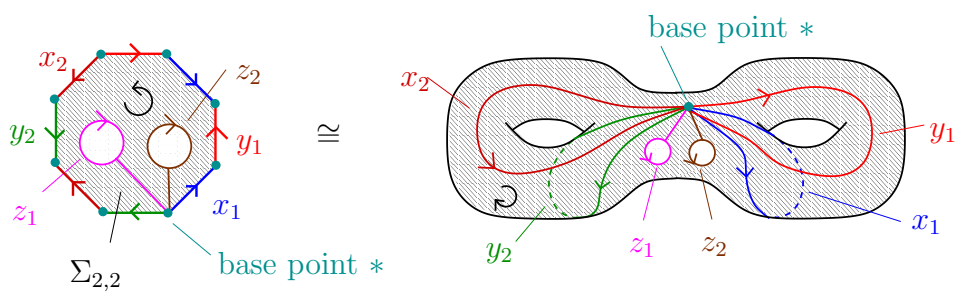

FIGURE 269. Illustration of the curves in Lemma 14.19.

Sketch of the proof. Let $g \in \mathbb{N}_0$ and let $n \in \mathbb{N}$.

(1) First note that by Proposition 10.23 we can without loss of generality assume that the base point corresponds to any of the vertices of the $4g$-gon as shown in Figure 270. The following argument is very similar to the argument on the pages 428 and 431 and it relies heavily on the notation from Figure 270. We have

$$\begin{aligned}
\pi_1(\Sigma_{g,n}) &\overset{\text{Seifert-van Kampen Theorem 14.1}}{=} \pi_1(U) *_{\pi_1(U \cap V)} \underbrace{\pi_1(V)}_{=\{e\}} \overset{\text{Lemma 13.12}}{\cong} \pi_1(U) / \langle\langle \pi_1(U \cap V) \rangle\rangle \\
&\underset{\substack{\text{followings from the deformation retraction shown in Figure 270} \\ \text{together with Lemma 9.10 and Proposition 9.12 (1)}}}{=} \langle x_1, y_1, \ldots, x_g, y_g, z_1, \ldots, z_n \rangle / \langle\langle [x_1, y_1] \cdot \cdots \cdot [x_g, y_g] \cdot z_1 \cdot \cdots \cdot z_n \rangle\rangle.
\end{aligned}$$

[328] Since we picked an orientation for $\Sigma_{g,n}$ each boundary component also inherits an orientation.

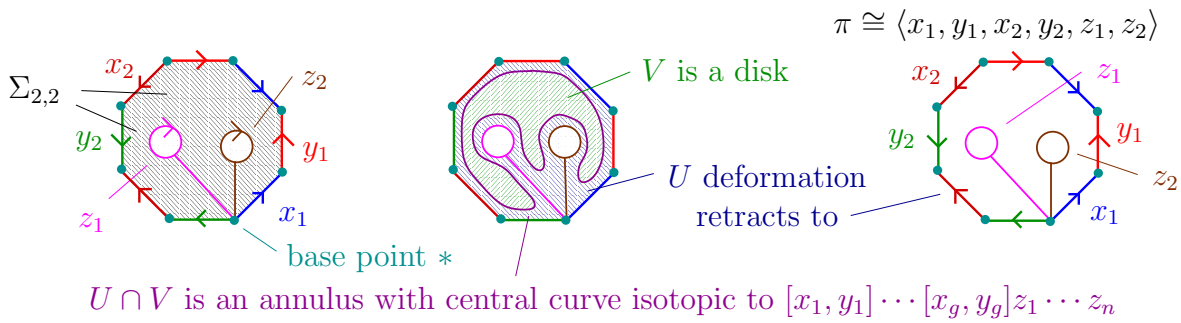

FIGURE 270. Illustration for the proof of Lemma 14.19.

(2) Now suppose that $g \geq 1$. Let $i \in \{1, \dots, n\}$. The image of $\pi_1(C_i)$ in $\pi := \pi_1(\Sigma_{g,n})$ is the subgroup generated by z_i. It suffices to show that z_i is an element of infinite order in π. It follows immediately from Lemmas 11.13 and 13.4 that there exists a homomorphism

$$\langle x_1, y_1, \dots, x_g, y_g, z_1, \dots, z_n \mid [x_1, y_1] \cdots [x_g, y_g] \cdot z_1 \cdots z_n \rangle \to \langle x_1, y_1, \dots, x_g, y_g \rangle$$

with

$$\begin{array}{rcll} x_j & \mapsto & x_j & \text{for } j = 1, \dots, g \\ y_j & \mapsto & y_j & \text{for } j = 1, \dots, g \end{array} \quad \text{and} \quad \begin{array}{rcll} z_i & \mapsto & ([x_1, y_1] \cdots [x_g, y_g])^{-1} & \\ z_j & \mapsto & e & \text{for } j \neq i. \end{array}$$

The image of z_i has infinite order in the free group $\langle x_1, y_1, \dots, x_g, y_g \rangle$,[329] hence z_i is already an element of infinite order in π. □

We continue with the notation from Lemma 14.19. We consider the case $n \geq 1$, i.e. we consider the case that we have non-empty boundary. In this case it follows from Lemma 13.5 (2) that for any $i \in \{1, \dots, n\}$ the obvious map

$$\langle x_1, y_1, \dots, x_g, y_g, z_1, \dots, \widehat{z_i}, \dots, z_n \rangle \to \langle x_1, y_1, \dots, x_g, y_g, z_1, \dots, z_n \mid [x_1, y_1] \dots [x_g, y_g] \cdot z_1 \dots z_n \rangle$$

is an isomorphism. In particular $\pi_1(\Sigma_{g,n})$ is a free group on $2g + n - 1$ generators. The following lemma gives an alternative, more topological approach to seeing that $\pi_1(\Sigma_{g,n})$ is a free group on $2g + n - 1$ generators.

Lemma 14.20. *Let $g \in \mathbb{N}_0$ and let $n \in \mathbb{N}$. We denote the boundary components of $\Sigma_{g,n}$ by $C_1, \dots, C_n$. Given any $i \in \{1, \dots, n\}$ there exists a homotopy equivalence*[330]

$$\Sigma_{g,n} \to C_1 \vee \dots \vee \widehat{C_i} \vee \dots \vee C_n \vee \underbrace{S^1 \vee \dots \vee S^1}_{2g \text{ copies}}$$

which is the identity on $C_1, \dots, \widehat{C_i}, \dots, C_n$. In particular, by Proposition 9.12 (1) and the discussion on page 390 we see that $\pi_1(\Sigma_{g,n})$ is a free group on $2g + n - 1$ generators.

[329] Why does it have infinite order?

[330] Here $\widehat{C_i}$ means that we leave out C_i.

Sketch of proof. In Figure 271 we show that, starting from any boundary component of $\Sigma_{g,n}$, we can push "inward" to obtain a deformation retraction to a subset that is a spatial graph G with a unique spanning tree. By Proposition 9.21 (4), is homotopy equivalent to a wedge of $2g+n-1$ circles where the circles correspond to $x_1, y_1, \ldots, x_g, y_g$ and the remaining boundary components.[331][332] □

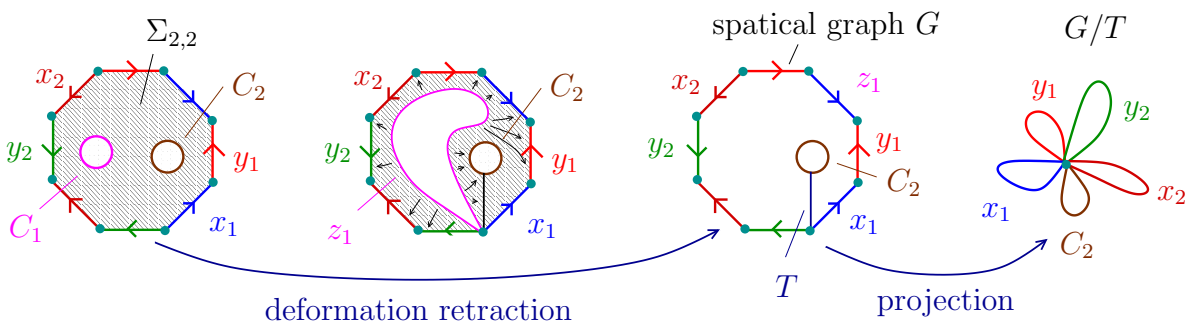

FIGURE 271.

The following lemma gives an answer to Question 14.18.

Lemma 14.21. *Let $g \in \mathbb{N}_0$.*

(1) *The unique boundary component of $\Sigma_{g,1}$ is not a retract of $\Sigma_{g,1}$.*
(2) *For $k \geq 2$ every boundary component of $\Sigma_{g,k}$ is a retract of $\Sigma_{g,k}$.*

Proof. Let $g \in \mathbb{N}_0$.

(1) The case $g = 0$ was dealt with in Lemma 6.2. Now we assume that $g \geq 1$. We denote by C the unique boundary component of $\Sigma := \Sigma_{g,1}$. We had just seen in Lemma 14.19 that $\pi_1(C) \to \pi_1(\Sigma)$ is a monomorphism if $g \geq 1$. So we cannot apply the same argument as in Lemma 6.2 where we studied the induced map on the level of fundamental groups. The idea now is to study instead the induced map on the *abelianizations* of the fundamental groups.

We denote by $i\colon C \to \Sigma$ the inclusion map and we suppose that there exists a retraction $r\colon \Sigma \to C$, i.e. a map with $r \circ i = \mathrm{id}_C$. We write $\pi_1(C) = \langle t \rangle$ and we use the isomorphism from Lemma 14.19 (1) to make the identification

$$\pi_1(\Sigma) \;=\; \langle x_1, y_1, \ldots, x_g, y_g, z \mid [x_1, y_1] \cdot \cdots \cdot [x_g, y_g] \cdot z \rangle$$

[331] We leave it to others with more time and energy to write down a rigorous argument.
[332] This argument is evidently closely related to the proof of Lemma 12.8.

where z corresponds to t under the inclusion $C = \partial\Sigma \to \Sigma$. We obtain the commutative diagram

$$\begin{tikzcd} & \Sigma \arrow[dr, "r"] & \\ C \arrow[ur, "i"] \arrow[rr, "r\circ i = \mathrm{id}_C"'] & & C \end{tikzcd}$$

which induces by Proposition 13.10 (6) the commutative diagram

$$\begin{tikzcd} & \pi_1(\Sigma)_{\mathrm{ab}} \arrow[dr, "r_*"] & \\ \underbrace{\pi_1(C)_{\mathrm{ab}}}_{=\langle t\rangle} \arrow[ur, "i_*", "t\mapsto z"'] \arrow[rr, "(r\circ i)_* = \mathrm{id}"'] & & \underbrace{\pi_1(C)_{\mathrm{ab}}}_{=\langle t\rangle}. \end{tikzcd}$$

In $\pi_1(\Sigma)$ we have

$$z \;=\; ([x_1, y_1] \cdot \dots \cdot [x_g, y_g])^{-1} \;\in\; \pi_1(\Sigma).$$

This shows that z lies in the commutator subgroup of $\pi_1(\Sigma)$, i.e. z represents the trivial element in $\pi_1(\Sigma)_{\mathrm{ab}}$. Thus we have shown that the left diagonal map is the zero map. But the bottom horizontal map is an isomorphism of a non-trivial group and the diagram commutes. We have thus obtained a contradiction.

(2) This statement follows immediately from Lemma 14.20 since we can project the wedge of circles onto any circle. Alternatively, a retraction from $\Sigma_{2,n}$ to a boundary component is sketched in Figure 272. The general case is treated the same way.[333] □

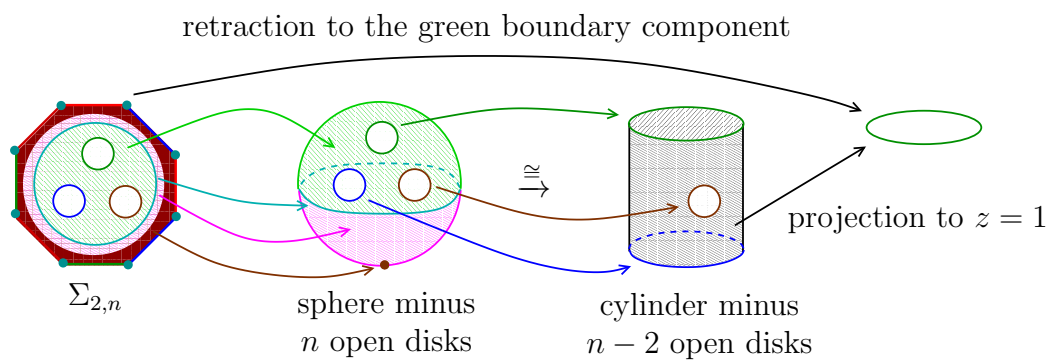

FIGURE 272.

Exercises for Chapter 14.

Exercise 14.1. Provide a proof for Lemma 14.4. Put differently, let $g \in \mathbb{N}_{\geq 2}$. Show that the group

$$\pi \;:=\; \pi_1(\text{surface of genus } g) \;\cong\; \langle x_1, y_1, \dots, x_g, y_g \,|\, [x_1, y_1] \cdot \dots \cdot [x_g, y_g] \rangle$$

is not abelian.
Hint: You could try to show that the group admits an epimorphism onto a non-abelian group.

[333] The proof is somewhat similar to the proof of Lemma 6.5.

Exercise 14.2. Let $g \in \mathbb{N}$. By Theorem 14.10 we know that $\Sigma_g \# \mathbb{R}\mathrm{P}^2$ is diffeomorphic to $k \cdot \mathbb{R}\mathrm{P}^2$ for some unique $k \in \mathbb{N}$. Determine k as a function of g.

Exercise 14.3. Prove that the two surfaces shown in Figure 267 are not homeomorphic.
Remark: Evidently a solution to a problem can only be as rigorous as its formulation. In this case one could perhaps consider the complements of suitable compact subsets.

Exercise 14.4.

(a) Let M be a oriented connected m-dimensional manifold and let N be a 1-dimensional submanifold *that is diffeomorphic to* S^1. Let $x_0 \in M \setminus N$. Suppose that $m \geq 4$. Show that the inclusion induced map $\pi_1(M \setminus N, x_0) \to \pi_1(M, x_0)$ is an isomorphism.
Hint: Use the Tubular Neighborhood Theorem 10.19.

(b) Show that the conclusion (a) does not hold for $m = 3$, i.e. give an example of a connected 3-dimensional manifold M and a connected 1-dimensional submanifold N such that the inclusion induced map $\pi_1(M \setminus N, x_0) \to \pi_1(M, x_0)$ is not an isomorphism.
Remark: the manifold M in the example does not have to be closed.

Exercise 14.5. Let F be the sphere minus k open disks. (Alternatively, let F be the disk $\overline{B}^2$ minus $k-1$ open disks.) We denote by $C_1, \ldots, C_k$ the boundary components of F. We pick a base point $x_0 \in F$. Furthermore for each $i \in \{1, \ldots, k\}$ we pick a path γ_i from a point on C_i to x_0. Finally let $\Gamma \subsetneq \pi_1(F, x_0)$ be a proper normal subgroup. Show that there exists an $i \in \{1, \ldots, k\}$ such that C_i, viewed as an element in $\pi_1(F, x_0)$ via the path γ_i, does not lie in Γ.
Hint: You might want to start out with your preferred base point x_0 and your preferred paths $\gamma_1, \ldots, \gamma_k$, e.g. as shown in Figure 273.

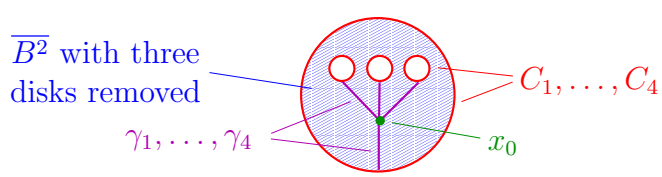

FIGURE 273.

15. Cones, suspensions, cylinders

In this section we first introduce two systematic ways to construct new topological spaces out of a given topological space and we present three systematic ways to construct new topological spaces out of a map $f\colon X \to Y$ between given topological spaces. Initially it might not be entirely apparent why we should be interested, but all five examples will play an important role at various points. The main excuse for presenting these constructions at this very moment is that they allow us to play a little bit with our newly acquired abilities for computing fundamental groups.

15.1. **The cone and suspension of a topological space.**

In this section we define the cone and suspension of a topological space. The cone of a topological space is a particularly easy construction.

Definition. Given a topological space X the *cone on* X is defined to be the topological space

$$\mathrm{Cone}(X) := (X\times[0,1])/(X\times\{0\}) = (X\times[0,1])/\sim \text{ where } (x,0)\sim(x',0) \text{ for all } x,x'\in X.$$

We refer to the point $X\times\{0\}$ as the *tip of the cone* $\mathrm{Cone}(X)$ or alternatively as the *cone point*.

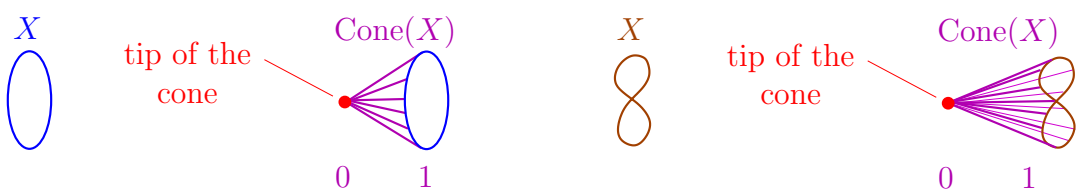

Figure 274.

Examples.

(1) Let $n\in\mathbb{N}_0$. It follows from Lemma 1.66 that the map

$$\begin{array}{rcl}\mathrm{Cone}(S^n) & \to & \overline{B}^{n+1}\\ [(v,t)] & \mapsto & v\cdot t\end{array}$$

is continuous. One can easily verify that the map is a bijection. It follows immediately from Lemmas 1.37 and 1.55 that $\mathrm{Cone}(S^n)$ is compact. Since $\overline{B}^{n+1}$ is Hausdorff we obtain from Proposition 1.40 that the given map is a homeomorphism.

(2) Let X be a subset of $\mathbb{R}^n$. We define its *physical cone* as

$$\widetilde{\mathrm{Cone}}(X) := \text{ union of all line segments from } \underbrace{(x,0)}_{\in\mathbb{R}^{n+1}} \text{ to } \underbrace{(0,1)}_{\in\mathbb{R}^{n+1}} \subset \mathbb{R}^{n+1}.$$

(a) In Exercise 15.1 we will see that if X is a compact subset of $\mathbb{R}^n$, then the map

$$\begin{array}{rcl} f_X\colon \operatorname{Cone}(X) & \to & \widetilde{\operatorname{Cone}}(X) \\ [(x,t)] & \mapsto & t\cdot(x,0)+(1-t)\cdot(0,1) \end{array}$$

is a homeomorphism.

(b) After looking at Figure 274 and considering Examples (1) and (2a) one might walk away with the feeling that one has a pretty good understanding of the cone construction. But this optimism is potentially ill-founded. For example in Exercise 15.1 we see will see that for $X=(0,1)\subset\mathbb{R}$ the above map $f_X\colon \operatorname{Cone}(X)\to\widetilde{\operatorname{Cone}}(X)$ from (2a) is *not* a homeomorphism.

This definition does not seem to be particularly interesting, but we have one lemma whose proof is perhaps slightly more subtle than one might initially think.

Lemma 15.1. *Let X be a topological space. The tip of the cone* $\operatorname{Cone}(X)$ *is a deformation retract of* $\operatorname{Cone}(X)$.

Proof. We consider the "obvious" map

$$\begin{array}{rcl} \varphi\colon \overbrace{(X\times[0,1])/(X\times\{0\})\times[0,1]}^{=\operatorname{Cone}(X)\times[0,1]} & \to & \overbrace{(X\times[0,1])/(X\times\{0\})}^{=\operatorname{Cone}(X)} \\ ([(x,s)],t) & \mapsto & [(x,s\cdot(1-t))] \end{array}$$

One might think that this map "obviously" does the trick. The wary reader will not have failed to notice that here we are mixing the product and the quotient topologies, which, as we have learned the painful way in Section 2.2, can be quite dangerous and can lead to non-continuous maps.

So let us show that the map φ is indeed continuous.[334] Since there is an abundance of intervals we now write $S=[0,1]$ and $T=[0,1]$. We consider the following two maps

$$\begin{array}{rcl} H\colon (X\times S)\times T & \to & X\times S \\ ((x,s),t) & \mapsto & (x,s\cdot(1-t)) \end{array} \quad\text{and}\quad \begin{array}{rcl} p\colon X\times S & \to & \operatorname{Cone}(X) \\ (x,s) & \mapsto & [(x,s)]. \end{array}$$

Note that H and p are continuous.[335] We have the following commutative diagram

$$\begin{tikzcd} & (X\times S)\times T \arrow[dl, "p\times\mathrm{id}_T"'] \arrow[dr, "p\circ H"] & \\ \operatorname{Cone}(X)\times T \arrow[rr, "\varphi"] & & \operatorname{Cone}(X). \end{tikzcd}$$

By Lemma 2.14 the map p is a quotient map. Since T is locally compact we obtain from Theorem 2.15 that $p\times\mathrm{id}_T$ is a quotient map. By the discussion above we know that $p\circ H$ is continuous. Thus it follows from Lemma 2.16 (2) that φ is continuous. $\square$

[334]The fact that one actually needs to prove that the map φ is continuous seems to get swept under the carpet in every single book on (algebraic) topology that I have consulted.

[335]The map p is continuous by definition of the topology on $\operatorname{Cone}(X)$. But what is a super-formal argument for showing that H is continuous?

We move on to the next definition.

Definition. Let X be a topological space. We define the *suspension of* X to be the topological space

$$\Sigma(X) \ := \ (X \times [-1,1])/\sim$$

where we identify all points in $X \times \{-1\}$ to a single point and we identify all points in $X \times \{1\}$ to a single point.

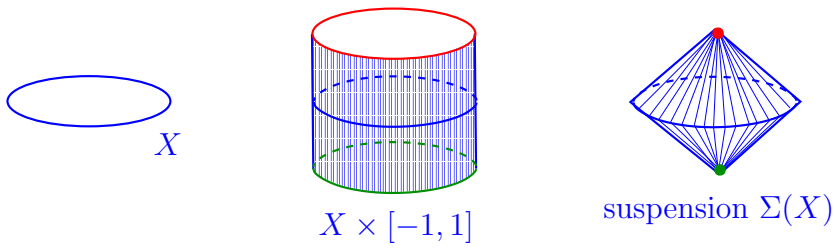

FIGURE 275.

Before we give an example we state a basic lemma regarding suspensions.

Lemma 15.2. *Let X be a topological space.*

(1) *If X is compact, then* $\mathrm{Cone}(X)$ *and the suspension* $\Sigma(X)$ *are also compact.*
(2) *If X is Hausdorff, then* $\mathrm{Cone}(X)$ *and the suspension* $\Sigma(X)$ *are also Hausdorff.*
(3) $(*)$ *The injections*

$$\begin{array}{rcl} X & \to & \mathrm{Cone}(X) \\ x & \mapsto & [(x,1)] \end{array} \quad \textit{and} \quad \begin{array}{rcl} \mathrm{Cone}(X) & \to & \Sigma(X) \\ [(x,t)] & \mapsto & [(x,1-t)] \end{array}$$

are homeomorphisms onto their images. We will use these maps to view X as a subset of $\mathrm{Cone}(X)$ *and to view* $\mathrm{Cone}(X)$ *as a subset of* $\Sigma(X)$*. In particular we can and will view X as a subset of* $\Sigma(X)$*.*

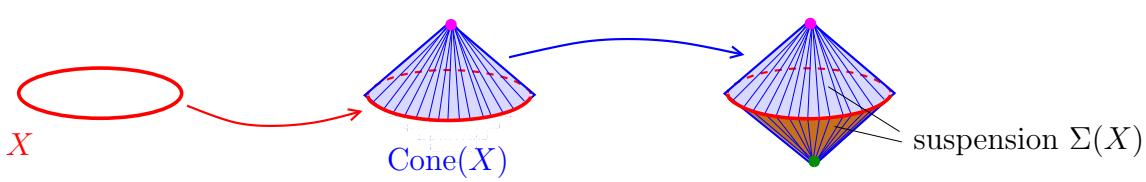

FIGURE 276. Illustration of Lemma 15.2 (3).

Proof.

(1) This statement follows from Lemmas 1.37 and 1.55.
(2) In Exercise 15.2 we sill show that $\Sigma(X)$ is Hausdorff, if X is Hausdorff. The proof for $\mathrm{Cone}(X)$ is basically identical.

(3) We will prove this statement in Exercise 15.3. □

Example. It is pretty clear from Figure 275 that the suspension of S^n is homeomorphic to S^{n+1}. In fact throughout the course we will use the following homeomorphism[336] to identify $\Sigma(S^n)$ with S^{n+1}:

$$\begin{array}{rcl} \Sigma(S^n) & \xrightarrow{\cong} & S^{n+1} \subset \mathbb{R}^{n+1} \times \mathbb{R} \\ [(P,t)] & \mapsto & \big(\underbrace{P\cos\left(\frac{\pi}{2}t\right)}_{\in\mathbb{R}^{n+1}}, \underbrace{\sin\left(\frac{\pi}{2}t\right)}_{\in\mathbb{R}}\big). \end{array}$$

Note that this homeomorphism sends the "North Pole" of $\Sigma(S^n)$ to the "North Pole" of S^{n+1}.

For future reference we record the following lemma.

Lemma 15.3. *If X is a path-connected topological space, then its suspension $\Sigma(X)$ is simply-connected.*

Proof $(*)$. Let $p\colon X \times [-1,1] \to \Sigma(X)$ be the obvious projection map. We consider the subsets $U = p(X \times [-1, \frac{1}{2})$ and $V = p(X \times (-\frac{1}{2}, 1])$. It follows from the definition of the quotient topology on $\Sigma(X)$ that U and V are open subsets of $\Sigma(X)$. We pick a base point x on $X = X \times \{0\} \subset \Sigma(X)$. We calculate that

$$\pi_1(\Sigma(X),x) \underset{\substack{\uparrow \\ \text{Seifert–van Kampen} \\ \text{Theorem 14.1}}}{\cong} \pi_1(U,x) *_{\pi_1(U\cap V,x)} \pi_1(V,x) \underset{\substack{\uparrow \\ \text{as in Lemma 15.1 we see that } U \text{ and } V \text{ are contractible} \\ \text{hence their fundamental groups are trivial by Proposition 9.12 (2)}}}{=} \begin{array}{c}\text{amalgamated product} \\ \text{of trivial groups}\end{array} = \text{trivial group.}$$

We have thus shown that $\Sigma(X)$ is indeed simply connected. □

We conclude this discussion of suspensions with the fairly obvious notion of the suspension of a map.

Definition. Given a map $f\colon X \to Y$ between topological spaces we denote by

$$\begin{array}{rcl} \Sigma(f)\colon \Sigma(X) & \to & \Sigma(Y) \\ [(x,t)] & \mapsto & [(f(x),t)] \end{array}$$

the *suspension of f*.

We conclude this section with the following lemma.

Lemma 15.4. $(*)$

(1) *If $f\colon X \to Y$ is a map between topological spaces, then $\Sigma(f)\colon \Sigma(X) \to \Sigma(Y)$ is also continuous.*
(2) *If $f\colon X \to Y$ and $g\colon Y \to Z$ are maps between topological spaces, then the maps $\Sigma(g \circ f)$ and $\Sigma(g) \circ \Sigma(f)$ from $\Sigma(X)$ to $\Sigma(Z)$ agree.*

[336] Using Proposition 1.40 and Lemma 15.2 (1) one easily verifies that this map is indeed a homeomorphism.

(3) *The maps*

$$\begin{array}{rcl} X & \mapsto & \Sigma(X) \\ (f\colon X \to Y) & \mapsto & (\Sigma(f)\colon \Sigma(X) \to \Sigma(Y)) \end{array}$$

define a covariant functor from the category of topological spaces to the category of topological spaces. We refer to this functor as the suspension functor*.*

(4) *Let $f, g\colon X \to Y$ be two maps between topological spaces. If f and g are homotopic rel a (possibly empty) subset A, then $\Sigma(f)$ and $\Sigma(g)$ are homotopic rel $\Sigma(A)$.*

(5) *If $f\colon X \to Y$ is a homotopy equivalence of topological spaces, then the suspension $\Sigma(f)\colon \Sigma(X) \to \Sigma(Y)$ is also a homotopy equivalence.*

Proof $(*)$.

(1) We consider the following commutative diagram

$$\begin{tikzcd} X \times [-1,1] \arrow[r, "f\times \mathrm{id}_{[-1,1]}"] \arrow[d] \arrow[dr, dashed] & Y \times [-1,1] \arrow[d] \\ \Sigma(X) \arrow[r, "\Sigma(f)"'] & \Sigma(Y). \end{tikzcd}$$

By Lemma 1.53 (3c) we know that the top horizontal map is continuous. By Lemma 1.65 (3) the right vertical map is continuous. It follows that the diagonal map is continuous. Finally we obtain from Lemma 1.66 that the bottom horizontal map is continuous.

(2) This statement follows immediately from (1) and (2) and the definitions.

(3) Clearly it suffices to prove the following claim.

Claim. If $F\colon X \times [0,1] \to Y$ is a map, then the map

$$\begin{array}{rcl} G\colon \overbrace{((X \times [-1,1])/\sim)}^{=\Sigma(X)} \times [0,1] & \to & \overbrace{(Y \times [-1,1])/\sim}^{=\Sigma(Y)} \\ ([(x,t)], s) & \mapsto & [(F(x,s),t)] \end{array}$$

is continuous.

Verifying this claim is more subtle than one might have thought.[337] We denote by $\sim_\times$ the equivalence relation on $(X \times [-1,1]) \times [0,1]$ that is generated by $((x,t),s) \sim_\times$

[337] At the very least it is more subtle than the author of these modest notes had been thinking for 20 years.

$((x',t'),s)$ whenever $(x,t) \sim (x',t')$. We consider the following diagram:

$$\begin{tikzcd}
((X\times[-1,1])/\sim)\times[0,1] \arrow[ddrr, "G"'] & & ((X\times[-1,1])\times[0,1])/\sim_\times \arrow[ll, "{([(x,t)],s)\leftarrow[((x,t),s)]}"'] \arrow[d, "{[(x,t,s)]\mapsto(F(x,s),t)}"] \\
& & Y\times[-1,1] \arrow[d, "{(y,t)\mapsto[(y,t)]}"] \\
& & (Y\times[-1,1])/\sim .
\end{tikzcd}$$

The top map is a homeomorphism by Lemma 2.17 and the fact that $[0,1]$ is locally compact. The top vertical map is continuous by Lemma 1.66 and the bottom vertical map is continuous by Lemma 1.65 (3). It is clear that the diagram commutes. It now follows that G is continuous. This concludes the proof of the claim.

(4) The last statement is an immediate consequence of the proof of (3). □

15.2. **Mapping cylinder, mapping cone and mapping torus.** In this section we associate to a map $f\colon X \to Y$ between two topological manifold three different topological spaces. The main interest in these topological spaces is that these topological spaces encode some of the information contained in the actual map. On numerous occasions this will allow us to translate questions about maps between topological spaces into questions about topological spaces.

We start out with the definition of a mapping cylinder.

Definition. Let $f\colon X \to Y$ be map between topological spaces. We define the corresponding *mapping cylinder* to be the topological space

$$\mathrm{Cyl}(f) := \mathrm{Cyl}(f\colon X\to Y) := (X\times[0,1]\sqcup Y)/\sim \quad \text{where } (x,1)\sim f(x) \text{ for all } x\in X.$$

We illustrate the definition in Figure 277.

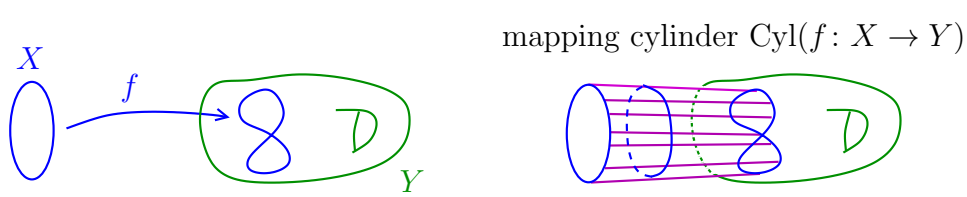

FIGURE 277.

Example. If X is a topological space and if $f\colon X \to \{y\}$ is the constant map to the topological space consisting of a single element y, then the mapping cylinder $\mathrm{Cyl}(f)$ is, basically by definition, homeomorphic to $\mathrm{Cone}(X)$.

Definition. Let $f\colon X \to Y$ be map between topological spaces. We refer to the maps

$$\begin{array}{rcl} X & \to & \mathrm{Cyl}(f\colon X \to Y) \\ x & \mapsto & [(x,0)] \end{array} \quad \text{and} \quad \begin{array}{rcl} Y & \to & \mathrm{Cyl}(f\colon X \to Y) \\ y & \mapsto & [y] \end{array}$$

as the *natural inclusions*. Sometimes we use these inclusions to identify X and Y with the corresponding subsets of the mapping cylinder.

The following lemma says that the natural inclusions are homeomorphisms onto their images. This means that we can legitimately identify X and Y with their images in the mapping cylinder $\mathrm{Cyl}(f\colon X \to Y)$. On many occasions we will implicitly use the lemma without actually referring to it.

Lemma 15.5. $(*)$ *If $f\colon X \to Y$ is a map between topological spaces, then the natural inclusions $X \to \mathrm{Cyl}(f\colon X \to Y)$ and $Y \to \mathrm{Cyl}(f\colon X \to Y)$ are homeomorphisms onto their images, in particular they are continuous.*

Proof. We will provide the proof in Exercise 15.4. □

We continue with a (non-) example. We will not really make use of this lemma, but Lemma 15.6 should warn the reader that the topology on a mapping cylinder is not necessarily what one might think it is.

Lemma 15.6. $(*)$ *Let X be a topological space and let $A \subset X$ be a subset. We denote by $i\colon A \to X$ the inclusion map and we consider the map*

$$\begin{array}{rcl} \Theta\colon\ \mathrm{Cyl}(i) = ((A \times [0,1]) \sqcup X)/(a,1) \sim i(a) & \to & \overbrace{(A \times [0,1]) \cup (X \times \{0\})}^{\substack{\text{equipped with the subspace topology} \\ \text{coming from the product } X \times [0,1]}} \\ [P] & \mapsto & \begin{cases} P, & \text{if } P \in A \times [0,1], \\ (P,1), & \text{if } P \in X. \end{cases} \end{array}$$

The following two statements hold:

(1) *The map Θ is continuous and it is a bijection.*
(2) *If A is a closed subset of X, then Θ is a homeomorphism.*
(3) *There exist situations, e.g. $X = [0,\infty)$ and $A = [0,1)$, in which Θ is* not *a homeomorphism.*

Proof.

(1) It follows easily from Lemma 1.66 that the given map Θ is continuous. Furthermore it is basically clear that Θ is a bijection.
(2) Suppose that A is a closed subset of X. Note that $A \times \{1\}$ is a closed subset of $A \times [0,1]$. It follows basically from Lemma 1.84 that Θ is a homeomorphism.
(3) We consider the case $X = [0,\infty)$ and $A = [0,1)$. We denote by

$$p\colon (A \times [0,1)) \sqcup X \ \to\ \mathrm{Cyl}(i) = ((A \times [0,1)) \sqcup X)/\sim$$

the projection map. We consider the open set $U := \{(x,t) \in [0,1) \times [0,1] \,|\, x > t\}$ of $A \times [0,1)$. Furthermore we consider the open subset $V := [0,2)$ of $X = \mathbb{R}$. Note

that $p^{-1}(p(U \sqcup V)) = U \sqcup V$. Thus it follows immediately from the definition of the quotient topology on $\mathrm{Cyl}(i(= ((A \times [0,1)) \sqcup X)/\sim$ that $p(U \sqcup V)$ is an open subset of $\mathrm{Cyl}(i)$. On the other hand we have

$$\Theta(p(U \sqcup V)) \;=\; U \cup \{(x,1) \,|\, x \in V\},$$

but considering the point $(1,1)$ one can easily verify that this is *not* an open subset of $(A \times [0,1]) \cup (X \times \{0\})$. □

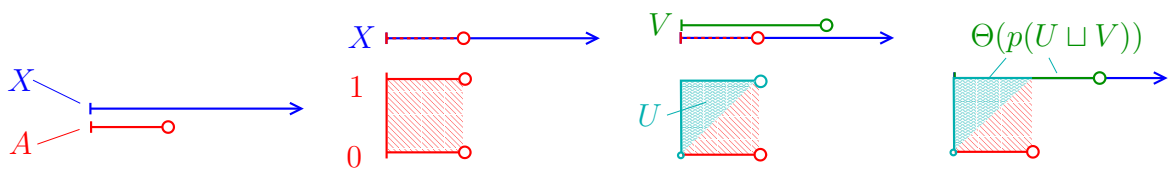

FIGURE 278. Illustration of the proof of Lemma 15.6 (3).

The following lemma summarizes some basic properties of the mapping cylinder.

Lemma 15.7. *Let $f\colon X \to Y$ be a map between topological spaces.*

(1) *The subspace Y is a deformation retract of $\mathrm{Cyl}(f\colon X \to Y)$, in fact an explicit deformation retraction is given by the following map*

$$\begin{aligned} H\colon \mathrm{Cyl}(f\colon X \to Y) \times [0,1] \;&\to\; \mathrm{Cyl}(f\colon X \to Y) \\ (P,t) \;&\mapsto\; \begin{cases} P, & \text{if } P \in Y, \\ [(Q, s\cdot(1-t)+t)], & \text{if } P = [(Q,s)] \text{ where,} \\ & \quad Q \in X \text{ and } s \in [0,1]. \end{cases} \end{aligned}$$

(2) *We denote by $r = H_1$ the retraction $\mathrm{Cyl}(f\colon X \to Y) \to Y$ given by (1). If we denote by $i\colon X \to \mathrm{Cyl}(f)$ and $j\colon Y \to \mathrm{Cyl}(f)$ the natural inclusions, then the following statements hold:*
   (a) $r \circ j = f\colon X \to Y$,
   (b) *the map $j\colon Y \to \mathrm{Cyl}(f\colon X \to Y)$ is a homotopy equivalence,*
   (c) *the map $i\colon X \to \mathrm{Cyl}(f\colon X \to Y)$ is a homotopy equivalence if and only if the map $f\colon X \to Y$ is a homotopy equivalence.*
   (d) *Let $y_0 \in Y$ be a point. The inclusion induced map $\pi_1(Y, y_0) \to \pi_1(\mathrm{Cyl}(f), y_0)$ is an isomorphism.*

Remark. On page 455 we saw that the mapping cylinder of a constant map $f\colon X \to \{y\}$ is homeomorphic to the cone on X. Thus we see that Lemma 15.7 (1) can be viewed as a generalization of Lemma 15.1.

Proof.

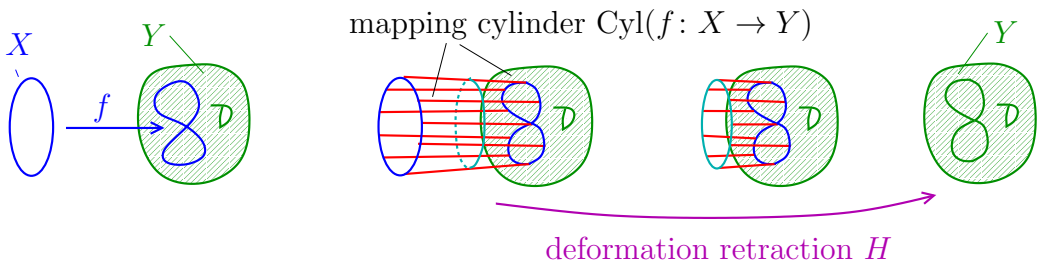

FIGURE 279. Illustration of Lemma 15.7 (1).

(1) We need to show that the map H is continuous. First note that the two maps

$$\begin{array}{rcl} (X\times[0,1])\times[0,1] & \to & \mathrm{Cyl}(f) \\ (Q,t) & \mapsto & [(Q, s\cdot(1-t)+t)] \end{array} \quad \text{and} \quad \begin{array}{rcl} Y\times[0,1] & \to & \mathrm{Cyl}(f) \\ (P,t) & \mapsto & P \end{array}$$

are continuous[338]. But this implies, by the somewhat delicate Lemma 9.16, that

$$H\colon ((X\times[0,1])\cup_{(x,1)\mapsto f(x)} Y)\times[0,1] \ \to\ \mathrm{Cyl}(f)$$

itself is continuous. Once continuity is out of the way it is basically clear that H is a deformation retraction. Therefore it follows from Lemma 9.10 that the inclusion $Y\to\mathrm{Cyl}(f\colon X\to Y)$ is a homotopy equivalence.

(2) It is clear that $r\circ j = f$. It follows from Lemma 9.10 that j and r are homotopy equivalences. Therefore (c) is a consequence of Lemma 9.8 (1). Finally (d) follows immediately from (2b) together with Proposition 9.12 (1). □

In the above discussion we associated to a map $f\colon X\to Y$ between topological spaces a new topological space, namely the mapping cylinder $\mathrm{Cyl}(f\colon X\to Y)$. But we see in Lemma 15.7 (1) that the mapping cylinder, as a topological space, is a little, it is basically the same as Y. Therefore we move on to the definition of the mapping cone which is a much more interesting construction.

Definition. Given a map $f\colon A\to X$ between topological spaces the corresponding *mapping cone* is defined as

$$\mathrm{Cone}(f\colon A\to X) \ :=\ (\mathrm{Cone}(A)\sqcup X)/\sim \ \text{ where } [(a,1)]\sim f(a) \text{ for all } a\in A.$$

We refer to the point $[A\times\{0\}]$ as the *cone point* of the mapping cone. We illustrate the definition in Figure 280.

Remark. Let $f\colon A\to X$ be a map between topological spaces. It follows immediately from the definitions that

$$\mathrm{Cone}(f\colon A\to X) \ =\ \mathrm{Cyl}(f\colon A\to X)/(A\times\{0\}).$$

The following lemma summarizes some properties of mapping cones.

[338]For once this is basically obvious

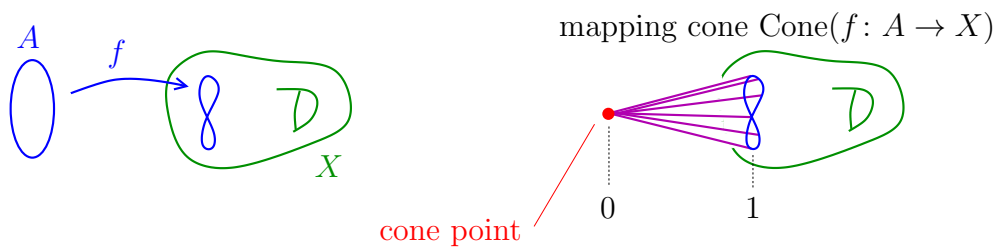

FIGURE 280.

Lemma 15.8. (∗) *Let $f\colon A \to X$ be a map between topological spaces.*

(1) *The natural inclusion*

$$\begin{array}{rcl} X & \to & \mathrm{Cone}(f\colon A \to X) \\ x & \mapsto & [x] \end{array}$$

is a homeomorphism onto its image. Often we will use this natural inclusion to identify X with its image in $\mathrm{Cone}(f\colon A \to X)$.

(2) *The map*

$$\begin{array}{rcl} \mathrm{Cone}(f\colon A \to X)/X & \to & \Sigma(A) \\ [(a,t)] & \mapsto & [(a, 1-2t)] \end{array}$$

is a natural homeomorphism.

(3) *The cone point defines a closed subset of* $\mathrm{Cone}(f\colon A \to X)$.

(4) *The subset X is a deformation retract of the complement of the cone point.*

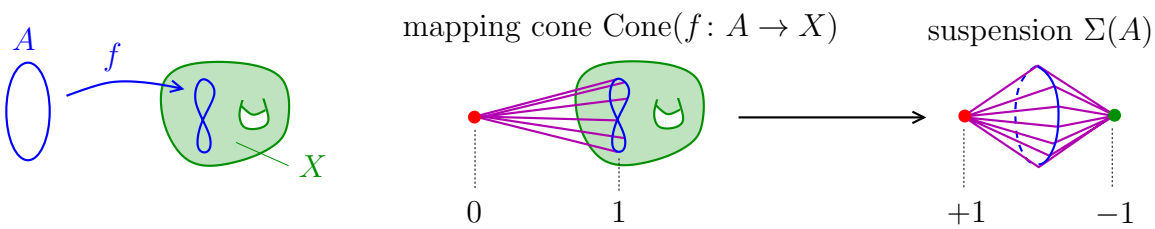

FIGURE 281. Illustration of Lemma 15.8 (2).

Sketch of proof.

(1) This statement can be proved easily by hand or it can be deduced from Lemma 15.5 together with Exercise 1.38 (3).

(2) It is clear that the given map is a bijection. One can easily verify, without any extra wizardry, that the given map is indeed a homeomorphism.

(3) This statement follows quite easily from the definition of the topologies involved.

(4) The proof of this statement is basically identical to the proof of Lemma 15.7 (1). □

So what have we done so far? We have associated to a map $f\colon X \to Y$ between topological spaces the topological space $\mathrm{Cone}(f\colon X \to Y)$. This construction will allow us to turn questions about maps between topological spaces into questions about topological spaces. As always in algebraic topology, not only do we want a map

$$\text{set of maps between topological spaces} \;\to\; \text{set of topological spaces},$$

but we really want a functor. It is clear what the category should be on the right. It is a little less clear what the category should be on the left. Here it is.

Definition. We refer to the category $\mathcal{M}$ with

$$\begin{aligned} \mathrm{Ob}(\mathcal{M}) &:= \text{all maps between topological spaces,} \\ \mathrm{Mor}(f\colon X \to Y, \widetilde{f}\colon \widetilde{X} \to \widetilde{Y}) &:= \begin{array}{c} \text{all pairs of maps} \\ (\varphi\colon X \to \widetilde{X}, \psi\colon Y \to \widetilde{Y}) \\ \text{such that the diagram} \end{array} \begin{array}{ccc} X & \xrightarrow{f} & Y \\ {\scriptstyle\varphi}\downarrow & & \downarrow{\scriptstyle\psi} \\ \widetilde{X} & \xrightarrow{\widetilde{f}} & \widetilde{Y} \end{array} \text{ commutes} \end{aligned}$$

with the (hopefully) obvious composition of morphisms as the *category of maps between topological spaces.*

The following lemma says that we can view "taking the mapping cone" and "taking the mapping cylinder" as covariant functors.

Lemma 15.9. $(*)$

(1) *The maps*

$$(f\colon X \to Y) \mapsto \mathrm{Cyl}(f\colon X \to Y)$$

and

$$(\varphi\colon X \to \widetilde{X}, \psi\colon Y \to \widetilde{Y}) \mapsto \left(\begin{array}{l} \mathrm{Cyl}(f\colon X \to Y) \to \mathrm{Cyl}(\widetilde{f}\colon \widetilde{X} \to \widetilde{Y}) \\ \qquad\qquad [P] \mapsto \begin{cases} [(\varphi(x), t)], & \text{if } P = (x,t) \text{ with,} \\ & \quad x \in X,\ t \in [0,1] \\ [\psi(y)], & \text{if } P = y \text{ with } y \in Y \end{cases} \end{array} \right).$$

define a covariant functor from the category $\mathcal{M}$ of maps between topological spaces to the category $\mathcal{T}$ of topological spaces.

(2) *If, in the setting of* (1)*, the maps φ and ψ are homeomorphisms onto their images, then the corresponding map* $\mathrm{Cyl}(f\colon X \to Y) \to \mathrm{Cyl}(\widetilde{f}\colon \widetilde{X} \to \widetilde{Y})$ *is also a homeomorphism onto its image.*

(3) *The analogues of* (1) *and* (2)*, with obvious modifications, hold if we replace mapping cylinders by mapping cones.*

(4) *Given a morphism*[339]

$$\begin{array}{ccc} X & \xrightarrow{f} & Y \\ {\scriptstyle\varphi}\downarrow & & \downarrow{\scriptstyle\psi} \\ \widetilde{X} & \xrightarrow{\widetilde{f}} & \widetilde{Y} \end{array}$$

the map from (3) *for mapping cones fits into the following commutative diagram:*

$$\begin{array}{ccccc} Y & \hookrightarrow & \mathrm{Cone}(f\colon X \to Y) & \longrightarrow & \Sigma(X) \\ {\scriptstyle\psi}\downarrow & & \downarrow & & \downarrow{\scriptstyle\Sigma(\varphi)} \\ \widetilde{Y} & \hookrightarrow & \mathrm{Cone}(\widetilde{f}\colon \widetilde{X} \to \widetilde{Y}) & \longrightarrow & \Sigma(\widetilde{X}) \end{array}$$

where the horizontal maps to the left are the inclusions maps introduced in Lemma 15.8 (1) and where the horizontal maps are given by the projection and the homeomorphism from Lemma 15.8 (2).

Proof (∗). One needs to convince oneself that the map between the mapping cylinders and the mapping cones is in fact continuous. For the mapping cylinders that is an immediate consequence of Lemma 1.83 (3). For the mapping cones first note that the same argument as in the proof of Lemma 15.4 (1) shows that the map

$$\begin{array}{rcl} \mathrm{Cone}(X) & \to & \mathrm{Cone}(\widetilde{X}) \\ [(x,t)] & \mapsto & [(\varphi(x),t)] \end{array}$$

is continuous. The continuity of the map between the mapping cones now follows again from Lemma 1.83 (3).

The second statement will be proved in Exercise 15.6. Finally statement (4) of the lemma follows basically from the definitions. □

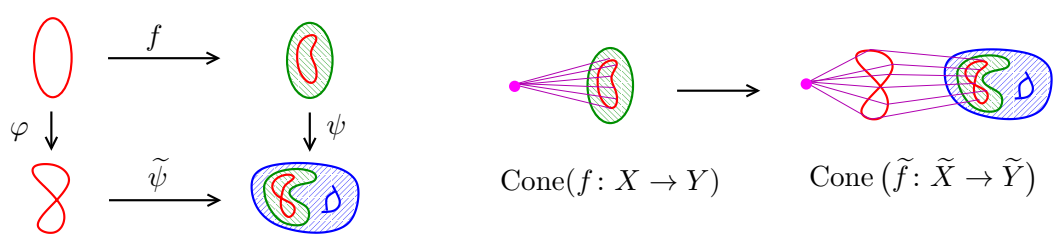

FIGURE 282. Illustration of Lemma 15.9.

The following lemma shows in particular that homotopic maps give rise to homotopy equivalent mapping cones. In particular at times this lemma allows us to translate the question whether two maps are homotopic to the question whether two topological spaces are homotopy equivalent.

[339]In fancy speak this commutative diagram says that the inclusion maps into the mapping cone and the projection from the mapping cone to the suspension are natural transformations between suitable functors.

Proposition 15.10. *Let $f_0, f_1 \colon A \to X$ be maps between topological spaces. If f_0, f_1 are homotopic, then there exists a homotopy equivalence* $\mathrm{Cone}(f_0) \to \mathrm{Cone}(f_1)$ *rel the union of X and the cone point.*

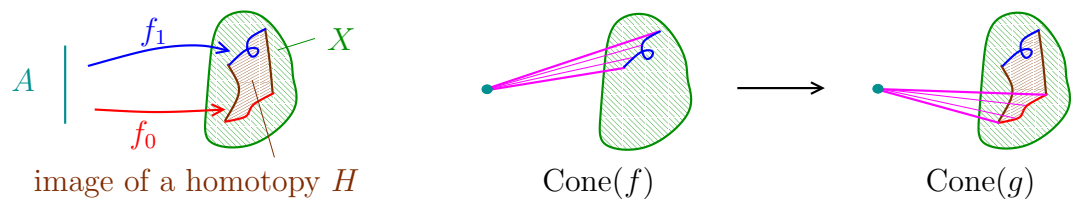

FIGURE 283. Illustration of Proposition 15.10.

It is not that difficult to write down explicit maps between the cones and to write down explicit homotopies. But we prefer to go take a more conceptual approach. Namely, instead of proving Proposition 15.10 directly we will prove the following more technical lemma.

Lemma 15.11. $(*)$ *Let $f_0, f_1 \colon A \to X$ be maps between topological spaces. Furthermore let $H \colon A \times [0,1] \to X$ be a homotopy between f_0 and f_1. Let $j \in \{0,1\}$. We denote by $i_j \colon A \to A \times \{j\}$ the obvious inclusion map.*

(1) *The inclusion map i_j induces by Lemma 15.9(3) a map* $\mathrm{Cone}(f_j) \to \mathrm{Cone}(H)$. *This map is a homeomorphism onto its image.*
(2) *If we use the map from* (1) *to view* $\mathrm{Cone}(f_j)$ *as a subset of* $\mathrm{Cone}(H)$, *then it is a deformation retract of* $\mathrm{Cone}(H)$.

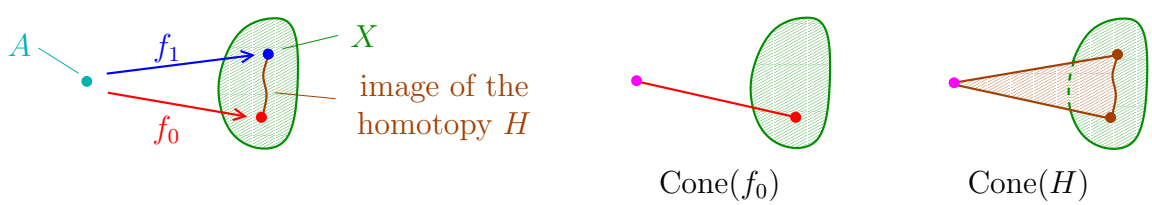

FIGURE 284. Illustration of Lemma 15.11.

Proof of Proposition 15.10 assuming Lemma 15.11 $(*)$. Let H be a homotopy between f_0 and f_1. By Lemma 15.11 we can view $\mathrm{Cone}(f_0)$ and $\mathrm{Cone}(f_1)$ as deformation retracts of $\mathrm{Cone}(H)$. It follows from Lemma 9.10 and Lemma 9.8 that $\mathrm{Cone}(f_0)$ and $\mathrm{Cone}(f_1)$ are homotopy equivalent. A quick inspection of the maps involved shows that the two cones are homotopy equivalent rel the union of X and the cone point. $\square$

Proof of Lemma 15.11 (∗). Let $f_0, f_1 \colon A \to X$ be maps between topological spaces. Furthermore let $H \colon A \times [0,1] \to X$ be a homotopy between f_0 and f_1. For notational convenience we only deal with the case $j = 0$. We denote by $i \colon A \to A \times \{0\}$ the obvious inclusion map. We get a commutative diagram

$$\begin{array}{ccc} A & \xrightarrow{f_0} & X \\ {\scriptstyle i}\downarrow & & \downarrow{\scriptstyle =} \\ A \times [0,1] & \xrightarrow{H} & X. \end{array}$$

Thus we get from Lemma 15.9 (3) a map $\mathrm{Cone}(f_0) \to \mathrm{Cone}(H)$. It follows almost immediately from Lemma 15.9 (3) that this map is a homeomorphism onto its image.

Since this proof suffers from an abundance of intervals playing different roles we rescale two of the intervals:

(1) We use the interval $[0,1]$ for the homotopy H.
(2) We use the interval $[0,2]$ for the definition of the mapping cone.
(3) We use the interval $[0,3]$ for the definition of the desired deformation retraction.

With this convention out of the way we pick a deformation retraction

$$\varphi \colon ([0,1] \times [0,2]) \times [0,3] \ \to \ [0,1] \times [0,2]$$

rel $([0,2] \times \{0\}) \cup (\{2\} \times [0,1])$ such that $\varphi(r,s,t) = (r, \frac{1}{3}st)$ whenever $r \in [0, \frac{1}{2}]$. It is elementary to see that such a deformation retraction exists. We refer to Figure 285 for an illustration.

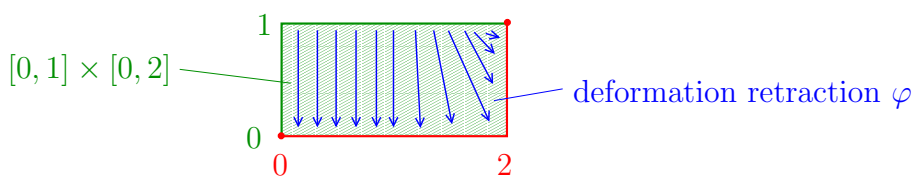

FIGURE 285.

Now we consider the map

$$\begin{array}{rcl} G \colon (\overbrace{((A \times [0,1] \times [0,2]) \sqcup X)/\sim}^{=\mathrm{Cone}(H\colon A\times[0,1]\to X)}) \times [0,3] & \to & \mathrm{Cone}(H) \\ ([P], z) & \mapsto & \begin{cases} [(a, r(x,y,z))], & \text{if } P = (a,x,y), \\ P, & \text{if } P \in X. \end{cases} \end{array}$$

Using Lemma 1.65 (3) and Lemma 9.16 one can easily show that this map G is continuous. It is straightforward to verify that this map has the desired properties. □

For completeness sake we also state the following corollary.

Corollary 15.12. $(*)$ *Let $f\colon A \to X$ be a map between topological space and let $g\colon X \to Y$ be a homotopy equivalence. The map*

$$\begin{array}{rcl} \mathrm{Cyl}(f\colon A \to X) & \to & \mathrm{Cyl}(g \circ f\colon A \to Y) \\ [P] & \mapsto & \begin{cases} [(a,t)], & \text{if } P = (a,t) \in A \times [0,1], \\ [g(P)], & \text{if } P \in X \end{cases} \end{array}$$

is a homotopy equivalence rel $A \times \{0\}$. The same way one sees that the mapping cones of f and g are homotopy equivalent.

Example. Let $f\colon S^1 \to \mathbb{R}^2$ be the inclusion and let $g\colon \mathbb{R}^2 \to \{*\}$ be the retraction to the origin. In Figure 286 we show the corresponding mapping cones, which we now know are homotopy equivalent by Corollary 15.12.

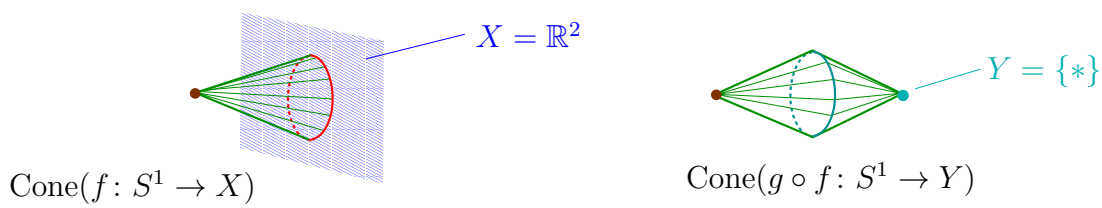

FIGURE 286.

Proof. The corollary is a straightforward consequence of Proposition 15.10. We leave it to the reader to fill in the details. □

The following lemma calculates the fundamental groups of mapping cones.

Lemma 15.13. $(*)$ *Let $f\colon A \to X$ be a map between topological spaces and let $a_0 \in A$. We write $x_0 := f(a_0)$. If A is path-connected, then the inclusion induces an isomorphism*

$$\pi_1(X, x_0)/f_*(\pi_1(A, a_0)) \;\to\; \pi_1(\mathrm{Cone}(f\colon A \to X), [x_0]).$$

Example. Let $n \in \mathbb{N}$ and let $A = X = S^1$. We consider the map $f\colon A = S^1 \to X = S^1$ that is given by $f(z) = z^n$. It follows from Lemma 15.13 and Proposition 7.18, perhaps counter-intuitively, that $\pi_1(\mathrm{Cone}(f\colon A \to X)) \cong \mathbb{Z}_n$. We refer to Figure 287 for an attempt at an illustration of this example.

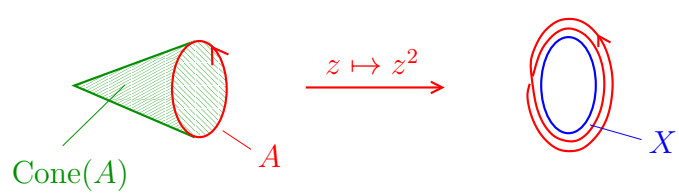

FIGURE 287.

Proof. We will provide the proof in Exercise 15.7. □

We conclude our discussion of mapping cones with the following proposition.

Proposition 15.14. (∗) *Let X be a topological space and let A be a subset of X. We denote by $i\colon A \to X$ the inclusion map. We use Lemma 15.8 (1) to view X as a subset of* $\mathrm{Cone}(i\colon A \to X)$.

(1) *If A is contractible, then given any $a_0 \in A$ there exists a deformation retraction G from* $\mathrm{Cone}(i\colon A \to X)$ *to X such that $G_1(\text{cone point } [A \times \{0\}]) = a_0$.*
(2) *If $a_0 \in A$ is a deformation retract of A, then there exists a deformation retraction G from* $\mathrm{Cone}(i\colon A \to X)$ *to X such that for any $t \in [0,1]$ we have $G_1([(a_0,t)]) = a_0$.*

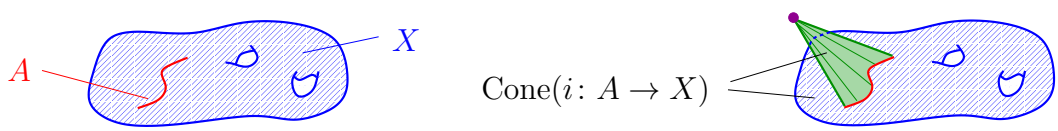

FIGURE 288. Illustration of Proposition 15.14.

Proof. We first prove Statement (1). Thus let $a_0 \in A$. Since A is contractible it follows from Lemma 9.11 (2) that there exists a map $r\colon A \times [0,1] \to A$ such that $r_0 = \mathrm{id}$ and such that $r_1(a) = a_0$ for all $a \in A$. We pick continuous functions $x, y\colon [0,1] \times [0,1] \to [0,1]$ with the following properties:

(a) For any $t \in [0,1]$ we have $x(0,t) = 1$ or $y(0,t) = 0$.
(b) We have $x(s,0) = 0$ and $y(s,0) = s$ for all $s \in [0,1]$.
(c) We have $y(s,1)$ for all $s \in [0,1]$.
(d) We have $x(1,t) = 0$ and $y(1,t) = 1$ for all $t \in [0,1]$.

We sketch graphs of such functions x and y in Figure 289. Now we consider the map

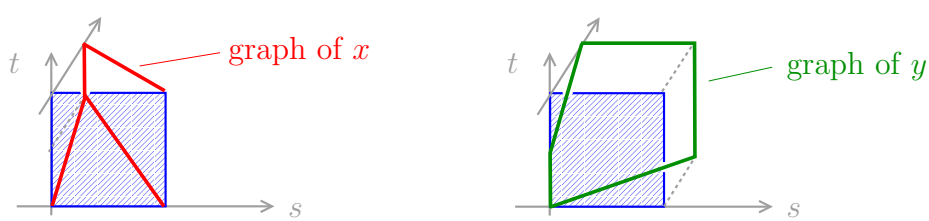

FIGURE 289.

$$\begin{array}{rcl} F\colon \overbrace{((A \times [0,1])/(A \times \{0\}))}^{=\mathrm{Cone}(A)} \times [0,1] & \to & \overbrace{(A \times [0,1])/(A \times \{0\})}^{=\mathrm{Cone}(A)} \\ ([(a,s)],t) & \mapsto & [(r(a,x(s,t)), y(s,t))]. \end{array}$$

We make the following observations:

(0) Since x and y are continuous and since $[0,1]$ is locally compact we obtain from Lemmas 1.66 and Lemma 2.17 that F is continuous.
(1) It follows from (a) that F is actually well-defined.
(2) It follows from (b) that $F_0 = \mathrm{id}$.
(3) It follows from (c) that F_1 takes values in $A \times \{1\}$.
(4) It follows from (d) that F is a homotopy rel $A \times \{1\}$.

In summary this shows that F is a deformation retraction from $\mathrm{Cone}(A)$ to $A \times \{1\}$. Now we consider the map

$$\begin{array}{rcl} G\colon \overbrace{(\mathrm{Cone}(A) \cup_{(a,1)=a} X)}^{=\mathrm{Cone}(i\colon A\to X)} \times [0,1] & \to & \mathrm{Cone}(i\colon A \to X) \\ ([P],t) & \mapsto & \begin{cases} [F(P,t)] & \text{if } P \in \mathrm{Cone}(A), \\ [P], & \text{if } P \in X. \end{cases} \end{array}$$

It follows from Lemma 9.16 that this map is continuous. Clearly G is a deformation retract from $\mathrm{Cone}(i\colon A \to X)$ to X. By construction it sends the cone point to a_0.

It remains to prove Statement (2). If we start out with a deformation retraction r form A to a_0, then the above homotopy F has the desired property. □

15.3. **The mapping cone of a suspension** $(*)$**.** In this section we show that under favorable circumstances the operation of taking a mapping cone (or mapping cylinder) commutes with the operation of taking the suspension of a map. This technical proposition will play a useful role later on. The proposition is also a good way to test whether we really understand the various topologies involved in the definition of mapping cones, mapping cylinders and suspensions.

Proposition 15.15. *If $f\colon X \to Y$ is a map between topological spaces, then the map*[340]

$$\begin{array}{rcl} \Phi\colon \Sigma(\mathrm{Cone}(f\colon X \to Y)) & \to & \mathrm{Cone}(\Sigma(f)\colon \Sigma(X) \to \Sigma(Y)) \\ P & \mapsto & \begin{cases} [([(x,t)],s)], & \textit{if } P = [([(x,s)],t)] \textit{ with } x \in X,\ t \in [-1,1] \\ & \qquad \textit{and with } s \in [0,1], \\ [([y],t)], & \textit{if } P = [([y],t)] \textit{ with } y \in Y \textit{ and } t \in [-1,1]. \end{cases} \end{array}$$

is a homeomorphism.

In the proof of Proposition 15.15 we will need the following lemma which is quite similar to Proposition 2.19.

Lemma 15.16. *Let X be a topological space. If Y is a locally compact topological space (e.g. $Y = [0,1]$), then the map*

$$\begin{array}{rcl} \varphi\colon \Sigma(X) \times Y & \to & \Sigma(X \times Y) \\ ([(x,t)],y) & \mapsto & [((x,y),t)] \end{array}$$

is continuous.

[340] It takes a major effort to disentangle the notation. We write $[\,-\,]$ to indicate the equivalence class corresponding to a suspension and we write $[\,-\,]$ to indicate the equivalence class corresponding to the equivalence relation used to define mapping cones.

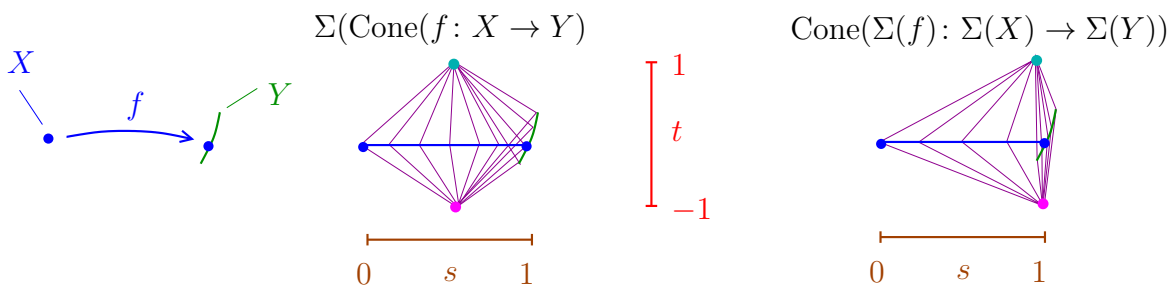

FIGURE 290. Illustration of Proposition 15.15.

In Figure 291 we illustrate Lemma 15.16. This cute picture is not meant to hide the grim reality that for arbitrary topological spaces X it actually requires a non-trivial input to prove Lemma 15.16.

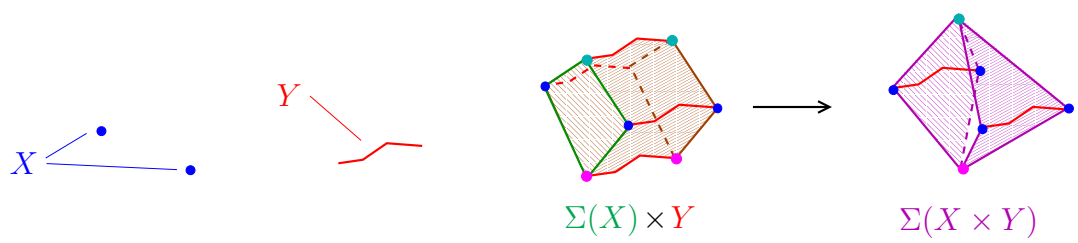

FIGURE 291. Illustration of Lemma 15.16.

Proof. We denote by $p\colon (X \times Y) \times [-1,1] \to \Sigma(X \times Y)$ and $q\colon X \times [-1,1] \to \Sigma(X)$ the two obvious projection maps. We have the following commutative diagram

$$\begin{tikzcd}
(X \times [-1,1]) \times Y \arrow[r, "(x,t,y)\mapsto(x,y,t)", "\cong"'] \arrow[d, "q\times \mathrm{id}_Y"'] & (X \times Y) \times [-1,1] \arrow[d, "p"] \\
\Sigma(X) \times Y \arrow[r, "\varphi"] & \Sigma(X \times Y).
\end{tikzcd}$$

By Lemma 1.53 the top horizontal map is a homeomorphism. By Lemma 2.14 the maps p and q are quotient maps. Since Y is locally compact we obtain from Theorem 2.15 that $q \times \mathrm{id}_Y$ is a quotient map. It follows from Lemma 2.16 that φ is also a quotient map. By Lemma 2.14 (2) this implies that φ is indeed continuous. $\square$

Proof of Proposition 15.15. Let $f\colon X \to Y$ be a map between topological spaces. One can easily verify that the given map Φ is a bijection. It remains to show that Φ and Φ^{-1} are continuous. We will do so in the following two claims. The domain and the target of Φ are both a scary mix of product and quotient topologies. Thus we need to tread super carefully.

Claim. The map Φ is continuous.

We introduce the following notation:

(a) We consider the map $\varphi\colon X \times \{1\} \to Y$ that is given by $\varphi(x,1) = f(x)$.
(b) We denote by $p\colon \operatorname{Cone}(f\colon X \to Y) \times [-1,1] \to \Sigma(\operatorname{Cone}(f\colon X \to Y))$ the projection map.

We consider the following diagram:

$$\begin{tikzcd}
(X \times [0,1]) \times [-1,1] \arrow[d, "i"] & Y \times [-1,1] \arrow[d, "j"] & \\
((X \times [0,1]) \times [-1,1]) \cup_{\varphi \times \mathrm{id}_{[-1,1]}} \arrow[d, "{[(P,t)] \mapsto ([P],t)}"] & (Y \times [-1,1]) \arrow[ddr, bend left, "=:\Psi"] & \\
((X \times [0,1]) \cup_{\varphi} Y) \times [-1,1] \arrow[d, "="] & & \\
\operatorname{Cone}(f\colon X \to Y) \times [-1,1] \arrow[d, "q", "{(P,t) \mapsto [(P,t)]}"'] & & \\
\Sigma(\operatorname{Cone}(f\colon X \to Y)) \arrow[rr, "\Phi"] & & \operatorname{Cone}(\Sigma(f)\colon \Sigma(X) \to \Sigma(Y)).
\end{tikzcd}$$

We make the following observations:

(1) By Lemma 2.18 we know that the vertical map between the second and the third row is a homeomorphism.
(2) It follows from (1) together with Lemma 1.66, applied to the projection map q, that Φ is continuous if Ψ is continuous.
(3) It follows from Lemma 1.83 (3) that Ψ is continuous if $\Psi \circ i$ and $\Psi \circ j$ are continuous.
(4) We have the following commutative diagram:

$$\begin{tikzcd}
Y \times [-1,1] \arrow[rr, "\Psi \circ i"] \arrow[dr, "{(P,t) \mapsto [(P,t)]}"'] & & \operatorname{Cone}(\Sigma(f)\colon \Sigma(X) \to \Sigma(Y)). \\
& \Sigma(Y) \arrow[ur, "{Q \mapsto [Q]}"'] &
\end{tikzcd}$$

The diagonal maps are continuous by Lemma 1.65 (3) and Lemma 1.83 (3). Thus we see that $\Psi \circ i$ is continuous. The same argument shows that $\Psi \circ j$ is continuous.

The combination of (2), (3) and (4) shows that Φ is indeed continuous. This concludes the proof of the claim.

Claim. The map

$$\Phi^{-1}\colon \overbrace{\mathrm{Cone}(\Sigma(f)\colon \Sigma(X)\to\Sigma(Y))}^{=((\Sigma(X)\times[0,1])\sqcup\Sigma(Y))/\sim} \to \Sigma(\mathrm{Cone}(f\colon X\to Y))$$
$$P \mapsto \begin{cases} [([(x,s)],t)], & \text{if } P=[([(x,t)],s)] \text{ with } s\in[0,1] \text{ and} \\ & \text{with } [(x,t)]\in\Sigma(X), \text{ i.e. } x\in X,\ t\in[-1,1], \\ [([y],t)], & \text{if } P=[([y],t)] \text{ with } t\in Y,\ t\in[-1,1]. \end{cases}$$

is continuous.

By Lemma 1.83 it suffices to show that the maps

$$\begin{array}{rcl} \Sigma(X)\times[0,1] & \to & \Sigma(\mathrm{Cone}(f\colon X\to Y)) \\ ([(x,t)],s) & \mapsto & [([(x,s)],t)] \end{array} \quad \text{and} \quad \begin{array}{rcl} \Sigma(Y) & \to & \Sigma(\mathrm{Cone}(f\colon X\to Y)) \\ [(y,t)] & \mapsto & [([y],t)] \end{array}$$

are continuous. The second map is continuous by Lemma 15.4 (1). Furthermore it follows from the combination of Lemma 15.16 with Lemma 15.4 (1) that the first map is continuous. This concludes the proof of the claim. □

15.4. **The mapping torus.** In this last section we discuss the mapping torus. This construction gives rise to many interesting topological spaces. We will also see that determining the fundamental group of a mapping torus is somewhat challenging, but not impossible.

Definition. Let X be a topological space and let $f\colon X\to X$ be a homeomorphism.[341] We refer to

$$M(X,f) \;:=\; (X\times[0,1])\,/\,(x,0)\sim(f(x),1)$$

as the *mapping torus of* (X,f). We refer to the map

$$\begin{array}{rcl} M(X,f)=(X\times[0,1])/(x,0)\sim(f(x),1) & \to & S^1 \\ [(x,t)] & \mapsto & e^{2\pi i t} \end{array}$$

as *the canonical projection onto* S^1. Sometimes X is called the *fiber* of the mapping torus and f is called the *monodromy* of the mapping torus.

The following lemma takes care of our two favorite properties of topological spaces, namely compactness and being Hausdorff.

Lemma 15.17. *Let X be a topological space and let $f\colon X\to X$ be a homeomorphism.*

(1) *If X is Hausdorff, then the mapping torus $M(X,f)$ is Hausdorff.*
(2) *If X is compact, then the mapping torus $M(X,f)$ is compact.*

Proof.

(1) This statement will be proved in Exercise 15.8.
(2) This statement follows immediately from Lemma 1.55 (2) and Lemma 1.37. □

[341] In principle one could also work with maps $f\colon X\to X$ that are not homeomorphisms. But for simplicity we only discuss the case that f is in fact a homeomorphism.

Next we will see that several well-established topological spaces are actually mapping tori.

Examples.

(1) We consider the topological space $[0,1]$ and let $f\colon [0,1] \to [0,1]$ be the self-homeomorphism of $[0,1]$ that is given by $f(w) = 1-w$. It follows immediately from the definitions that the corresponding mapping torus $M([0,1], f)$ is precisely the Möbius band as defined on page 117. We refer to Figure 292 for an illustration.

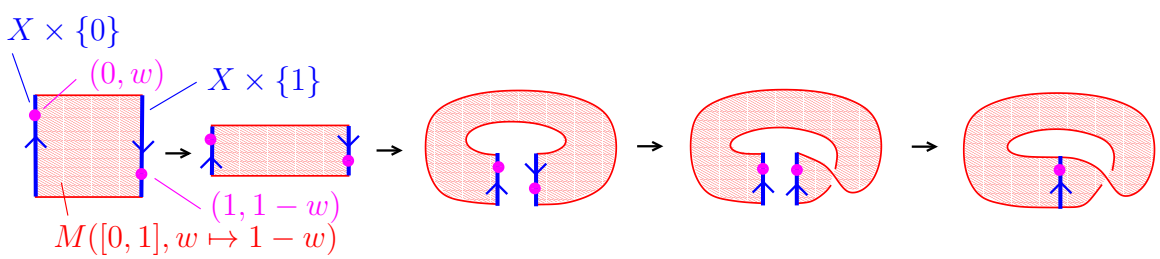

FIGURE 292. The Möbius band as a mapping torus.

(2) Let $X = S^1$ and let $f\colon X \to X$ be the homeomorphism that is given by $f(z) = \overline{z}$. It follows easily from Proposition 1.40 and Lemma 15.17 (1) that the map

$$\begin{array}{rcl} \overbrace{([0,1]\times[0,1])\,/\,(x,0)\sim(x,1),(0,y)\sim(1,1-y)}^{\text{Klein bottle}} & \to & M(S^1,f) \\ [(x,y)] & \mapsto & [(e^{2\pi i y},x)] \end{array}$$

is a homeomorphism from the Klein bottle to the mapping torus $M(S^1, f)$.[342] This homeomorphism is also illustrated in Figure 293.

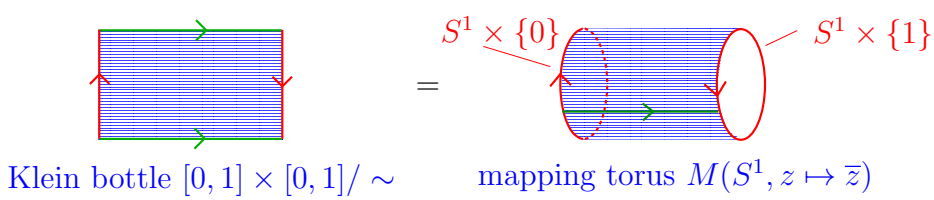

FIGURE 293.

We slow down a little to consider the case $\varphi = \mathrm{id}$ in more detail. On page 117 we already saw that $M(S^1, \mathrm{id})$ is homeomorphic to the torus $S^1 \times S^1$. Thus the following lemma does not come as a surprise.

[342] What does the mapping torus $M(S^1, z \mapsto -z)$ look like?

Lemma 15.18. *Given any topological space X the map*

$$\begin{array}{rcl} \Phi\colon M(X,\mathrm{id}) & \to & X\times S^1 \\ [(x,t)] & \mapsto & (x,e^{2\pi it}) \end{array}$$

is a homeomorphism.

Remark. This lemma is often viewed as "obvious". But even though it is indeed pretty clear that Φ is a bijection and continuous, it is much less clear why the map is actually a homeomorphism since this is another instance where we mix product and quotient topologies. Fortunately in our present situation it is not difficult to prove "by hand" that the map is a homeomorphism.

Proof $(*)$. It is easy to verify that Φ is a bijection. Using Remark 1.67 (1) one can easily show that Φ is continuous. It still remains to show that Φ is actually a homeomorphism.

Let us first consider the special, and perhaps most common case, that X is compact and Hausdorff. By Lemma 15.17 we know that $M(X,\mathrm{id})$ is compact. Furthermore it follows from Lemma 1.55 (1) that $X\times S^1$ is Hausdorff. Thus we obtain from Proposition 1.40 that Φ is a homeomorphism.

Now let us consider the general case which requires more effort. Those readers who have solved Exercise 2.5 (using that $\{0,1\}$ is a compact and closed subset of $[0,1]$) can apply Lemma 2.16 to deduce that Φ^{-1} is continuous. On the other hand the readers who have not solved Exercise 2.5 need to stick around a little longer.

By Lemma 1.39 it remains to show that Φ is an open map. So let U be an open subset of $M(X,\mathrm{id}) = (X\times[0,1])/\sim$. Let $P := [(x,t)]\in U$ be a point. We can assume that $t\in[0,1)$. We need to show that $Q := \Phi([(x,t)])$ admits an open neighborhood Y that is contained in $V := \Phi(U)$. In the following we denote by $p\colon X\times[0,1]\to M(X,\mathrm{id})$ the projection map.

If $t\in(0,1)$, then by the definition of the topology on $M(X,\mathrm{id})$ there exists an open subset $W\subset X$ and an open interval $(a,b)\subset(0,1)$ with $P\in W\times(a,b)\subset U$. We set $Y := \Phi(W\times(a,b)) = W\times\{e^{2\pi it}\,|\,t\in(a,b)\}$. Note that $p^{-1}(Y)=Y$ is an open subset of $X\times[0,1]$. Thus Y has the desired property

Now suppose that $t=0$. In $X\times[0,1]$ we pick an open neighborhood $W_1\times[0,\epsilon_1)$ of the point $(x,0)$ that is contained in $p^{-1}(U)$. Similarly we pick an open neighborhood $W_2\times(1-\epsilon_2,1]$ of the point $(x,1)$ that is also contained in $p^{-1}(U)$. It is now straightforward to see that $Y := (W_1\cap W_2)\times\{e^{2\pi is}\,|\,s\in(-\epsilon_2,\epsilon_1)\}$ has the desired property. $\square$

Now we continue the discussion of mapping tori with a few more examples.

Examples.

(1) In [Rol, Chapter 10.I.10] and [BZH, Section 5.C] it is shown that the complement of the trefoil knot and the complement of the figure-8 knot are homeomorphic to a mapping torus, where the fiber is given by removing a point from the torus.
(2) If one wants to construct new interesting topological spaces out of a given topological space we need to find "non-trivial" self-homeomorphisms. For example let Σ be an

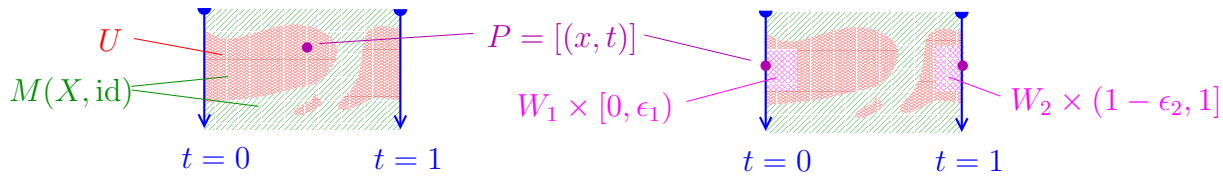

FIGURE 294.

oriented surface and let $C \subset \Sigma$ be a closed oriented curve on Σ, i.e. C is an oriented submanifold diffeomorphic to S^1. By the Tubular Neighborhood Theorem 10.19 there exists an orientation-preserving embedding $\Phi\colon [-1,1] \times S^1 \to \Sigma$ such that $\Phi\colon \{0\} \times S^1 \to C$ is an orientation-preserving diffeomorphism. We refer to the homeomorphism[343]

$$\begin{array}{ccc} \Sigma & \to & \Sigma \\ P & \mapsto & \begin{cases} P, & \text{if } P \notin \Phi([-1,1] \times S^1), \\ \Phi\big(t, ze^{2\pi \frac{t+1}{2} i}\big) & \text{if } P = \Phi(t,z) \text{ for some } z \in S^1, t \in [-1,1] \end{cases} \end{array}$$

as the *Dehn*[344] *twist along the curve* C. The definition of a Dehn twist is illustrated in Figure 295.

At times it is convenient to replace the function $\frac{t+1}{2}$ in the exponent by a smooth transition function as in Lemma 3.12, this gives rise to a diffeomorphism (why?) that we refer to as *smooth Dehn twist*.

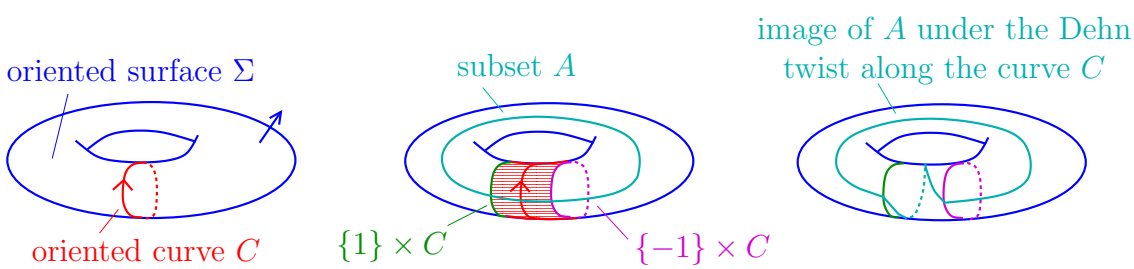

FIGURE 295.

For completeness we also state the following lemma.

Lemma 15.19. *Let X be an n-dimensional manifold and let $f\colon X \to X$ be a diffeomorphism. Then the following statements hold:*

[343]Using Lemma 1.32 (2') and Proposition 10.2 it is straightforward to see that the map is indeed continuous. Clearly the map is also a bijection. What is the inverse map?

[344]Max Dehn (1878-1952) was a German–Jewish mathematician. In 1939 he fled to Norway. After the German occupation of Norway he fled to America via Siberia and Japan. He died in 1952 in Black Mountain, North Carolina.

(1) *the mapping torus $M(X,f)$ is an $(n+1)$-dimensional manifold such that the obvious inclusion map $X \times (0,1) \to M(X,f)$ is a smooth map,*
(2) *the boundary $\partial M(X,f)$ is given by the mapping torus $M(\partial X, f|_{\partial X})$, in particular, if X is closed, then $M(X,f)$ is also closed,*
(3) *if X is orientable and if f is orientation-preserving, then $M(X,f)$ is also an orientable manifold.*

Proof $(*)$. First consider the case that X has no boundary. By Proposition 3.42 (4) we know that $X \times [0,1]$ is an $(n+1)$-dimensional manifold with boundary given by $M \times \{0,1\}$. Note that we obtain the mapping torus $M(X,f)$ from the manifold $M \times [0,1]$ by identifying the boundary component $M \times \{0\}$ with $M \times \{1\}$. Thus the statements are an immediate consequence of Proposition 10.12.

We will not make use of Lemma 15.19 when X has non-empty boundary. Thus we leave it to the curious reader to modify the above argument to the general case. □

The lemma says in particular that self-diffeomorphisms of surfaces give rise to 3-dimensional manifolds. This construction is an important source of examples of 3-dimensional manifolds.

Definition. Let X and Y be topological spaces. Two homeomorphisms $f, g\colon X \to Y$ are called *isotopic*, if there exists an *isotopy* from f to g, i.e. a map

$$\begin{array}{rcl} H\colon X \times [0,1] & \to & Y \\ (x,t) & \mapsto & H(x,t) \end{array}$$

such that the following hold:

(1) We have $H(x,0) = f(x)$ and $H(x,1) = g(x)$ for all $x \in X$,
(2) for each $t \in [0,1]$ the map $X \to Y$ given by $x \mapsto H(x,t)$ is a homeomorphism.

Examples.

(1) We consider $X = [0,2]$ and the two self-homeomorphisms given by $f(x) = x$ and by $g(x) = \frac{1}{2} \cdot x^2$. Then[345]

$$\begin{array}{rcl} H\colon X \times [0,1] & \to & X \\ (x,t) & \mapsto & f(x) \cdot (1-t) + g(x) \cdot t \end{array}$$

is an isotopy from f to g.
(2) Lickorish [Lic] showed that any self-homeomorphism of a compact orientable 2-dimensional manifold is isotopic to the concatenation of finitely many Dehn twists.

The following lemma will be proved in Exercise 15.9.

Lemma 15.20. *Let X be a topological space. If $f, g\colon X \to X$ are two homeomorphisms that are isotopic, then the mapping tori $M(X,f)$ and $M(X,g)$ are homeomorphic.*

[345] Let $t \in [0,1]$. Why is the map $[0,2] \to [0,2]$ given by $x \mapsto H(x,t)$ a homeomorphism?

Example. We consider $X = S^1$ and the self-homeomorphism that is given by $g(z) = -z$. The map $H(z,t) = e^{\pi i t} z$ defines an isotopy from $f = \mathrm{id}$ to g. It follows from Lemma 15.20 that the mapping torus $M(S^1, g(z) = -z)$ is homeomorphic to the torus $M(S^1, \mathrm{id}) = S^1 \times S^1$.

Now we can determine which surfaces are mapping tori.

Proposition 15.21. *The annulus, the Möbius band, the torus and the Klein bottle are, up to homeomorphism, the only connected, compact 2-dimensional topological manifolds that can be written as a mapping torus $M(X, f)$ of a connected 1-dimensional topological manifold X.*

Proof. By the examples (1), (2) on page 470 and by Lemma 15.18 we know that there exist the following types of homeomorphisms:

$$\begin{array}{rcl} \text{annulus } S^1 \times [0,1] & \cong & M([0,1], \mathrm{id}) \\ \text{Möbius band} & \cong & M([0,1], x \mapsto 1-x) \end{array} \quad \text{and} \quad \begin{array}{rcl} \text{torus } S^1 \times S^1 & \cong & M(S^1, \mathrm{id}) \\ \text{Klein bottle} & \cong & M(S^1, z \mapsto \overline{z}). \end{array}$$

In particular all these four manifolds are homeomorphic to mapping tori. It remains to show that these are the only connected, compact 2-dimensional topological manifolds that can be written as a mapping torus.

It follows from Proposition 3.49 that any compact connected topological 1-dimensional manifold is homeomorphic to $[0,1]$ or to S^1. We know from Lemma 9.6 that any self-homeomorphism is isotopic to one of the self-homeomorphisms that we had written down above. But then it follows from Lemma 15.20 that any mapping torus is homeomorphic to one from the above list. □

For proving statements about mapping tori the following lemma gives a useful alternative point of view. We leave the elementary proof as an exercise to the reader.

Lemma 15.22. *Let X be a topological space and let $f\colon X \to X$ be a homeomorphism. Then the following hold:*

(1) *The map*[346]

$$\begin{array}{rcl} \mathbb{Z} \times (X \times \mathbb{R}) & \to & X \times \mathbb{R} \\ (n, (x,t)) & \mapsto & (f^n(x), t+n) \end{array}$$

defines a continuous, proper and discrete action[347] *of the group $\mathbb{Z}$ on $X \times \mathbb{R}$.*

(2) *The map*

$$\begin{array}{rcl} M(X,f) = X \times [0,1])/\sim & \to & (X \times \mathbb{R})/\mathbb{Z} \\ [(x,t)] & \mapsto & [(x,t)] \end{array}$$

is a homeomorphism.

---

[346]Here for $n \geq 1$ we write $f^n(x) = (\overbrace{f \circ \cdots \circ f}^{n\text{-times}})(x)$, for $n = 0$ we write $f^0(x) = x$ and for $n \leq -1$ we write $f^n(x) = (\underbrace{f^{-1} \circ \cdots \circ f^{-1}}_{|n|\text{-times}})(x)$.

[347]Why is it an action?

In the following, given a topological space X and a homeomorphism $f\colon X \to X$ we denote the corresponding quotient space by $(X \times \mathbb{R})/\mathbb{Z}_f$ and we will identify the mapping torus $M(X, f)$ with $(X \times \mathbb{R})/\mathbb{Z}_f$ using the homeomorphism of Lemma 15.22.

Remark. It follows from Lemma 15.22 together with Proposition 3.25 that if X is a topological n-dimensional manifold and f is a homeomorphism, then the corresponding mapping torus $M(X, f) = (X \times \mathbb{R})/\mathbb{Z}_f$ is a topological $(n+1)$-dimensional manifold. Furthermore, if X is in fact an n-dimensional manifold and $f\colon X \to X$ is a diffeomorphism, then almost the same argument shows that the mapping torus $M(X, f) = (X \times \mathbb{R})/\mathbb{Z}_f$ is an $(n+1)$-dimensional manifold.

Lemma 15.23. *Let X be a topological space and let $f\colon X \to X$ be a homeomorphism. Then the map*

$$\begin{array}{rcl} X \times \mathbb{R} & \to & (X \times \mathbb{R})/\mathbb{Z}_f = M(X, f) \\ (x, t) & \mapsto & [(x, t)] \end{array}$$

is a covering of infinite degree. Furthermore for $k \in \mathbb{N}$ the map

$$\begin{array}{rcl} M(X, f^k) = (X \times \mathbb{R})/\mathbb{Z}_{f^k} & \to & (X \times \mathbb{R})/\mathbb{Z}_f = M(X, f) \\ [(x, t)] & \mapsto & [(x, k \cdot t)] \end{array}$$

is a k-fold covering.

Proof. Let X be a topological space and let $f\colon X \to X$ be a homeomorphism. The first statement is an immediate consequence of Lemma 15.22 and Proposition 7.11.

Now let $k \in \mathbb{N}$. We consider the following commutative diagram of maps:

$$\begin{tikzcd} (X \times \mathbb{R})/\mathbb{Z}_{f^k} \arrow[rr, "{[(x,t)]\mapsto[(x,k\cdot t)]}"] \arrow[dr, "{[(x,t)]\mapsto[(x,k\cdot t)]}"'] & & (X \times \mathbb{R})/\mathbb{Z}_f. \\ & (X \times \mathbb{R})/(k \cdot \mathbb{Z})_f \arrow[ur, "{[(x,t)]\mapsto[(x,t)]}"'] & \end{tikzcd}$$

The left diagonal map is easily seen to be well-defined and to be a homeomorphism. By Proposition 7.11 the right diagonal map is a k-fold covering. It follows that the top horizontal map is also a k-fold covering. □

Example.

(1) We apply Lemma 15.23 to $X = [0, 1]$ and the homeomorphism that is given by $f(x) := 1 - x$. Note that $f^2(x) = f(f(x)) = f(1-x) = 1-(1-x) = x$ for all x, i.e. $f^2 = \mathrm{id}$. Thus we recover the statement from page 260 that the annulus $M([0, 1], \mathrm{id})$ is a 2-fold covering of the Möbius band $M([0, 1], f(x) = 1 - x)$.

(2) We apply Lemma 15.23 to $X = S^1$ and the self-homeomorphism of $X = S^1$ that is given by $f(z) := \overline{z}$. As in the previous example we see that $f^2 = \mathrm{id}$. Thus we get, after the discussion on page 269, a new proof that the torus $M(S^1, \mathrm{id})$ is a 2-fold covering of the Klein bottle $M(S^1, f(z) = \overline{z})$.

Our next goal is to determine the fundamental groups of mapping tori. Before we can do so we need to introduce a new concept from group theory.

Definition. Let N be a group, let $k \in \mathbb{N}_0$ and let $\varphi\colon N \to N$ be an isomorphism such that $\varphi^k = \mathrm{id}$.[348] We define the *semidirect product of N and $\mathbb{Z}_k$ with respect to φ* as the group $N \rtimes_\varphi \mathbb{Z}_k$ where the underlying set is given by the direct product $N \times \mathbb{Z}_k$,[349] but where the group multiplication[350] is given by

$$(h, m) \cdot (h', m') \;:=\; (h \cdot \varphi^m(h'), m + m').$$

If φ is understood from the context, then we drop it from the notation, i.e. we write $N \rtimes \mathbb{Z}_k$ instead of $N \rtimes_\varphi \mathbb{Z}_k$.

Examples.

(1) Let N be a group and $\varphi = \mathrm{id}_N$, then $N \rtimes_{\mathrm{id}} \mathbb{Z} = N \times \mathbb{Z}$ is the direct product of N and $\mathbb{Z}$.
(2) Let $G = \mathbb{Z}_2$ and let $N = \mathbb{Z}_n$ for some $n \in \mathbb{N}_0$. We denote by $\varphi\colon \mathbb{Z}_n \to \mathbb{Z}_n$ the isomorphism that is given by multiplication by -1. Clearly this isomorphism satisfies $\varphi^2 = \mathrm{id}$, thus we can form the semidirect product $\mathbb{Z}_n \rtimes_\varphi \mathbb{Z}_2$, which is called the *$n$-th dihedral group D_n*. It has $2n$ elements. As an example, the third dihedral group D_3 is isomorphic to the permutation group S_3 via the isomorphism [351]

$$\begin{array}{rcl} \Psi\colon \mathbb{Z}_3 \rtimes \mathbb{Z}_2 & \to & S_3 \\ (h, m) & \mapsto & (1\ 2\ 3)^h \cdot (1\ 2)^m. \end{array}$$

Remark. In Exercise 15.10 we will see that $N = \{(h, 0) \mid h \in N\} \subset N \rtimes \mathbb{Z}_k$ is a normal subgroup of $N \rtimes \mathbb{Z}_k$. Put differently, we have $N \lhd N \rtimes \mathbb{Z}_k$. This is the reason for the symbol "$\rtimes$" in the notation of the semidirect product.

We have the following elementary lemma.

---

[348] Note that this condition is automatically satisfied if $k = 0$, i.e. for any isomorphism φ of any group we always have $\varphi^0 = \mathrm{id}$.

[349] In particular, if N is finite and $k \in \mathbb{N}$, then the cardinality of $N \rtimes \mathbb{Z}_k$ is given by $|N| \cdot k$.

[350] It is an elementary argument to show that $N \rtimes_\varphi \mathbb{Z}$ with the given multiplication is indeed a group.

[351] First note that a straightforward calculation shows that $(1\,2)^{-1} \cdot (1\,2\,3) \cdot (1\,2) = (1\,3\,2) = (1\,2\,3)^{-1}$. This implies that also for any $m \in \mathbb{Z}_2$ and $s \in \mathbb{Z}$ we have $(1\,2)^{-m} \cdot (1\,2\,3)^s \cdot (1\,2)^m = (1\,2\,3)^{s(-1)^m}$. Now for any $(h, m), (h', m') \in \mathbb{Z}_n \rtimes_\varphi \mathbb{Z}_2$ we have

$$\begin{aligned} \Psi(h,m)\Psi(h',m') &= (1\,2\,3)^h \cdot (1\,2)^m \cdot (1\,2\,3)^{h'} \cdot (1\,2)^{m'} = (1\,2\,3)^h \cdot (1\,2)^m \cdot (1\,2)^{-m} \cdot (1\,2\,3)^{(-1)^m h'} \cdot (1\,2)^m \cdot (1\,2)^{m'} \\ &= (1\,2\,3)^{h+(-1)^m h'} \cdot (1\,2)^{m+m'} = \Psi(h + (-1)^m h', m + m') = \Psi((h,m) \cdot (h',m')). \end{aligned}$$

We have thus shown that Ψ is a homomorphism.

Lemma 15.24. *Let G be a group and let $\gamma\colon G \to \mathbb{Z}$ be an epimorphism. We pick an element $t \in G$ with $\gamma(t) = 1$ and we write $N := \ker(\gamma)$. We denote by φ the isomorphism*

$$\begin{array}{rcl} \varphi\colon N & \to & N \\ h & \mapsto & tht^{-1}. \end{array}$$

Then the map[352]

$$\begin{array}{rcl} \Psi\colon G & \to & N \rtimes_\varphi \mathbb{Z} \\ g & \mapsto & \big(gt^{-\gamma(g)}, \gamma(g)\big) \end{array}$$

is an isomorphism of groups.

Proof. It is straightforward to verify that Ψ is injective and bijective. It remains to show that Ψ is a homomorphism: given $g, h \in G$ we have indeed

$$\begin{aligned} \Psi(g \cdot h) \;=\; (ght^{-\gamma(gh)}, \gamma(gh)) \;&=\; (gt^{-\gamma(g)} \cdot \underbrace{t^{\gamma(g)} \cdot ht^{-\gamma(h)} \cdot t^{-\gamma(g)}}_{=\varphi^{\gamma(g)}(ht^{-\gamma(h)})}, \gamma(g) + \gamma(h)) \\ &=\; (gt^{-\gamma(g)}, \gamma(g)) \cdot (ht^{-\gamma(h)}, \gamma(h)) \;=\; \Psi(g) \cdot \Psi(h). \end{aligned}$$

□

The following proposition shows that the fundamental group of a mapping torus $M(X, f)$ is isomorphic to semidirect product of $\pi_1(X)$ with $\mathbb{Z}$.

Proposition 15.25. *Let X be a path-connected topological space and let $f\colon X \to X$ be a homeomorphism. Then there exists an isomorphism $\psi\colon \pi_1(M(X, f)) \cong \pi_1(X) \rtimes \mathbb{Z}$ such that the following diagram commutes*

$$\begin{tikzcd} \pi_1(X) \arrow[r] \arrow[d] & \pi_1(M(X,f)) \arrow[r] \arrow[d, "\cong"', "\psi"] & \pi_1(S^1) \arrow[d, "\cong"] \\ \pi_1(X) \arrow[r] & \pi_1(X) \rtimes \mathbb{Z} \arrow[r] & \mathbb{Z}. \end{tikzcd}$$

Here the top-left horizontal map is induced by the inclusion $X = X \times \{0\} \to M(X, f)$ and the top-right horizontal map is induced by the canonical projection map $M(X, f) \to S^1$. The bottom-left horizontal map is given by the natural inclusion into the first term of the semidirect product and the bottom-right horizontal map is given by the projection onto the second term of the semidirect product.[353]

In the proof of Proposition 15.25 we will need the following lemma which is a straightforward generalization of Theorem 7.17 and the proof thereof. We leave the details of the proof to the reader.

Lemma 15.26. *Let X be a path-connected*[354] *topological space. Let G be a group which acts continuously and discretely on X. We choose an $x \in X$. We denote by $p\colon X \to X/G$*

[352]Note that $\gamma(gt^{-\gamma(g)}) = \gamma(g) + \gamma(t)(-\gamma(g)) = 0$, i.e. $gt^{-\gamma(g)}$ does indeed lie in $N = \ker(\gamma)$.

[353]Note that both maps on the bottom are group homomorphisms.

[354]In Theorem 7.17 we had assumed that X is simply connected.

the corresponding covering map.[355] *Then the map*

$$\begin{array}{rcl} \pi_1(X/G,[x]) & \to & G \\ & & \textit{unique } g \in G \textit{ such that for the unique lift}^{356} \\ [\gamma\colon [0,1] \to X/G] & \mapsto & \widetilde{\gamma}\colon [0,1] \to X \textit{ of the path } \gamma \textit{ with } \widetilde{\gamma}(0) = x \\ & & \textit{we have } \widetilde{\gamma}(1) = g \cdot x. \end{array}$$

is an epimorphism with kernel isomorphic to $\pi_1(X,x)$.

Now we can give the proof of Proposition 15.25.

Proof of Proposition 15.25. We have

$$\begin{array}{ccccccc} \pi_1(M(X,f)) & = & \pi_1((X\times\mathbb{R})/\mathbb{Z}_f) & \cong & \pi_1(X\times\mathbb{R})\rtimes\mathbb{Z} & \cong & \pi_1(X)\rtimes\mathbb{Z}. \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{Lemma 15.22} & & \text{Lemmas 15.26 and 15.24} & & \text{Proposition 9.12} & \end{array}$$

Thus we have obtained an isomorphism $\psi\colon \pi_1(M(X,f)) \xrightarrow{\cong} \pi_1(X)\rtimes\mathbb{Z}$. We leave the verification that the given diagram commutes to the reader. □

Remark. A careful reading of the proof of the proposition shows that we can identify the automorphism in the semidirect product. More precisely, let X be a path-connected topological space and let $f\colon X \to X$ be a homeomorphism. Let x be a base point and let γ be path from $f(x)$ to x. We denote by φ the automorphism of $\pi_1(X,x)$ that is given by

$$\begin{tikzcd} \pi_1(X,x) \arrow[r, "f_*"] \arrow[rr, bend right, "=:\varphi"'] & \pi_1(X,f(x)) \arrow[r, "\cong", "\text{Prop. 5.11}"'] & \pi_1(X,x). \end{tikzcd}$$

Then $\pi_1(M(X,f)) \cong \pi_1(X,x)\rtimes_\varphi \mathbb{Z}$.

We conclude this section with a discussion of several examples.

Examples.

(1) Let $K = M(S^1, f(z) := \overline{z})$ be the Klein bottle. Then the automorphism $f_* =: \varphi$ of $\pi_1(S^1) = \mathbb{Z}$ is multiplication by -1. It follows from the previous remark[357] that

$$\pi_1(\text{Klein bottle}) \;\cong\; \mathbb{Z}\rtimes_\varphi\mathbb{Z}.$$

(2) Let $A \in \mathrm{GL}(n,\mathbb{Z})$ be a matrix. In Exercise 7.12 we showed that the map $f(A)\colon \mathbb{R}^n/\mathbb{Z}^n \to \mathbb{R}^n/\mathbb{Z}^n$ given by $[v] \mapsto [Av]$ is a homeomorphism. Furthermore we know that, under the usual identification $\pi_1(\mathbb{R}^n/\mathbb{Z}^n, 0) = \mathbb{Z}^n$ as in Theorem 7.17, the induced map $f(A)_*$ on $\pi_1(\mathbb{R}^n/\mathbb{Z}^n, 0) = \mathbb{Z}^n$ is given by multiplication by A. It follows from the above remark

[355] Recall that by Proposition 7.10 the map $p\colon X \to X/G$ is a covering.

[356] Recall that by Proposition 7.12 there exists a unique lift $\widetilde{\gamma}$ of γ to the starting point $\widetilde{\gamma}(0) = x$.

[357] On page 429 we saw that $\pi_1(K) \cong \langle x,y \,|\, yxyx^{-1}\rangle$. What is an explicit isomorphism between the groups $\langle x,y \,|\, yxyx^{-1}\rangle$ and $\mathbb{Z}\rtimes_\varphi\mathbb{Z}$?

that $\pi_1(M(\mathbb{R}^n/\mathbb{Z}^n, f(A))) \cong \mathbb{Z}^n \rtimes_A \mathbb{Z}$. Note that this implies that $\pi_1(M(\mathbb{R}^n/\mathbb{Z}^n, f(A)))$ is solvable.[358]

(3) Let X be a connected topological space. We calculate that

$$\pi_1(X \times S^1) \underset{\substack{\uparrow \\ \text{Lemma 15.18}}}{=} \pi_1(M(X, \mathrm{id}_X)) \underset{\substack{\uparrow \\ \text{by the above remark}}}{\cong} \pi_1(X) \rtimes_{\mathrm{id}} \mathbb{Z} = \pi_1(X) \times \mathbb{Z} = \pi_1(X) \times \pi_1(S^1).$$

So in this special case we obtain the same result as in Proposition 7.21.

Exercises for Chapter 15.

Exercise 15.1. Given a subset X of $\mathbb{R}^n$ we define its *physical cone* as

$$\widetilde{\mathrm{Cone}}(X) := \text{union of all line segments from } \underbrace{(x,1)}_{\in\mathbb{R}^{n+1}} \text{ to } \underbrace{(0,0)}_{\in\mathbb{R}^{n+1}} \subset \mathbb{R}^{n+1}$$

and we consider the map

$$\begin{aligned} f_X\colon \mathrm{Cone}(X) &\to \widetilde{\mathrm{Cone}}(X) \\ [(x,t)] &\mapsto t\cdot(x,1) + (1-t)\cdot(0,1). \end{aligned}$$

(a) Let X be a compact subset of $\mathbb{R}^n$. Show that the map f_X is a homeomorphism.

(b) Let $X = (0,1) \subset \mathbb{R}$. Show that the map f_X is not a homeomorphism.
Remark: It is actually true that f_X is continuous and a bijection. To show that f_X is not a homeomorphism we need to show that there exists an open subset U of $\mathrm{Cone}(X)$ such that the image under f_X is not open. You could try your hand at

$$U := \mathrm{Cone}(X) \setminus \{[(\tfrac{1}{n}, \tfrac{1}{n})] \mid n \in \mathbb{N}_{\geq 2}\}.$$

We refer to Figure 296 for an illustration.

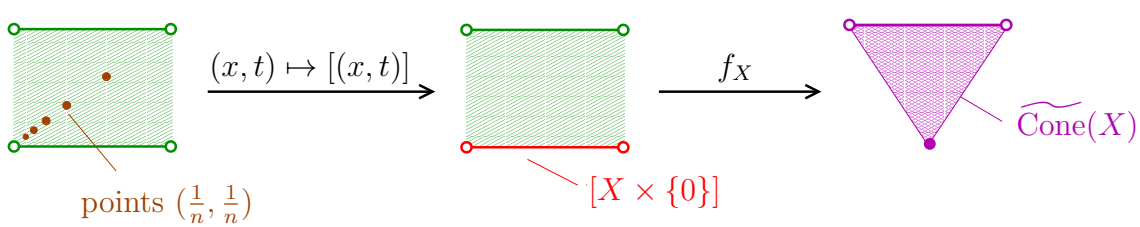

FIGURE 296.

Exercise 15.2. Let X be a topological space that is Hausdorff. Show that the suspension $\Sigma(X)$ is also Hausdorff.

[358] Recall that a group G is solvable if there exist subgroups $G_0 = \{1\} \subset G_1 \subset G_2 \subset \cdots \subset G_k = G$ such that for $i = 0, \ldots, k-1$ the group G_i is normal in G_{i+1} and such that G_{i+1}/G_i is abelian. In our case the filtration is given by $\{0\} \subset \mathbb{Z}^n \subset \mathbb{Z}^n \rtimes_A \mathbb{Z}$.

Exercise 15.3. Let X be a topological space. Show that the injections

$$\begin{array}{rcl} X & \to & \mathrm{Cone}(X) \\ x & \mapsto & [(x,1)] \end{array} \quad \text{and} \quad \begin{array}{rcl} \mathrm{Cone}(X) & \to & \Sigma(X) \\ [(x,t)] & \mapsto & [(x,1-t)] \end{array}$$

are homeomorphisms onto their images.

Exercise 15.4. Let $f\colon X \to Y$ be a map between topological spaces. Show that the natural inclusions

$$\begin{array}{rcl} X & \to & \mathrm{Cyl}(f\colon X \to Y) \\ x & \mapsto & (x,0) \end{array} \quad \text{and} \quad \begin{array}{rcl} Y & \to & \mathrm{Cyl}(f\colon X \to Y) \\ y & \mapsto & [y] \end{array}$$

are homeomorphisms onto their images.

Exercise 15.5. Let X be a topological space and let A be a subset of X.

(a) We denote by $i\colon A \to X$ the inclusion. Show that the map

$$\begin{array}{rcl} A \times [0,1] & \to & \mathrm{Cyl}(i) = ((A \times [0,1]) \sqcup X)/\sim \\ (a,t) & \mapsto & [(a,t)] \end{array}$$

is a homeomorphism onto its image.

(b) Let $f\colon A \to X$ be a homeomorphism onto its image. Is the map $A \times [0,1] \to \mathrm{Cyl}(f)$ necessarily a homeomorphism onto its image?

Exercise 15.6. Give a proof of Lemma 15.9 (3).

Exercise 15.7. Let $f\colon A \to X$ be a map between topological spaces and let $a_0 \in A$. We write $x_0 := f(a_0)$. We suppose that A is path-connected. Show that the natural inclusion map $X \to \mathrm{Cone}(f\colon A \to X))$ induces an isomorphism

$$\pi_1(X,x_0)/f_*(\pi_1(A,a_0)) \;\to\; \pi_1(\mathrm{Cone}(f\colon A \to X)).$$

Exercise 15.8. Let X be a topological space and let $f\colon X \to X$ be a homeomorphism. We assume that X is Hausdorff. Show that the mapping torus $M(X,f)$ is also Hausdorff.

Exercise 15.9. Prove Lemma 15.20. More precisely, let X be a topological space. Show that if $f,g\colon X \to X$ are two homeomorphisms that are isotopic, then the mapping tori $M(X,f)$ and $M(X,g)$ are homeomorphic.

Exercise 15.10. Let N be a group, let $k \in \mathbb{N}_0$ and let $\varphi\colon N \to N$ be an isomorphism such that $\varphi^k = \mathrm{id}$. We define the *semidirect product of N and $\mathbb{Z}_k$ with respect to φ* as the group $N \rtimes_\varphi \mathbb{Z}_k$ where the underlying set is given by the direct product $N \times \mathbb{Z}_k$, and where the multiplication is given by

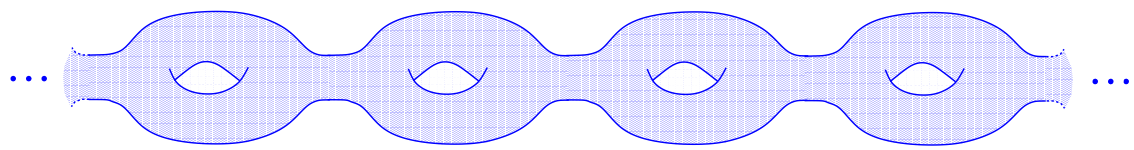
$$(h,m)\cdot(h',m') \;:=\; (h\cdot\varphi^m(h'), m+m').$$

(a) Show that $N \rtimes_\varphi \mathbb{Z}_k$ is indeed a group.
(b) Show that $N = \{(h,0) \in N \rtimes_\varphi \mathbb{Z}_k \,|\, h \in N\}$ is a normal subgroup of $N \rtimes \mathbb{Z}_k$.
(c) Is $\mathbb{Z}_k = \{(0,n) \in N \rtimes_\varphi \mathbb{Z}_k \,|\, n \in \mathbb{Z}_k\} \subset N \rtimes_\varphi \mathbb{Z}_k$ necessarily a normal subgroup?

Exercise 15.11. Let X be a topological space and let $f\colon X \to X$ be a homeomorphism. Show that the mapping torus $M(X, f\circ f)$ is a 2-fold covering of the mapping torus $M(X,f)$.

16. Limits

The goal of this section is to determine the fundamental group of "unbounded spaces", e.g. we would like to determine the fundamental group of the surface of "infinite genus" illustrated in Figure 297.[359] One idea might be to view the surface of "infinite genus" as the limit of a sequence given by compact surfaces. But then we need to make precise what we mean by a "limit of topological spaces" and "limit of the corresponding fundamental groups". We will do so in the following sections.



surface of "infinite genus"

Figure 297.

16.1. **Preordered and directed sets.**

Definition. Let X be a set and let $\leq$ be a relation on X.

(1) The relation is called *reflexive* if for any $x \in X$ we have $x \leq x$.
(2) The relation is called *transitive* if for any $x, y, z \in X$ we have
$$x \leq y \text{ and } y \leq z \quad \Longrightarrow \quad x \leq z.$$
(3) A reflexive and transitive relation is called a *preorder*.
(4) A set together with a preorder is called a *preordered set*.
(5) A *directed set* is a preordered set such that for any $x, y \in X$ there exists a $z \in X$ with $x \leq z$ and $y \leq z$.

Examples.

(1) Let X be a subset of $\mathbb{R}$ and denote by $\leq$ the usual "less or equal" relation on the real numbers. Then $(X, \leq)$ is a directed set. In particular $(\mathbb{N}, \leq)$ is a directed set.
(2) Given any set X the relation "$\leq$" where $x \leq y$ only if $x = y$ is a preorder, which we call the *trivial preorder* on X.
(3) Let M be a set. We denote by $\mathcal{P}(M)$ the power set of M, i.e. the set of all subsets of M. Then "being a subset", i.e. the relation given by "$\subseteq$", defines a preorder on $\mathcal{P}(M)$. Thus $(\mathcal{P}(M), \subseteq)$ is a preordered set, in fact it is straightforward to see that it is even a directed set.
(4) The set $X = \{0, x, y\}$ with the trivial relations $0 \leq 0, x \leq x, y \leq y$ and the non-trivial relations $0 \leq x$ and $0 \leq y$ is a preordered set. We refer to $(\{0, x, y\}, \leq)$ as the *push-pull set*. Note that this is not a directed set, since there is no $z \in X$ with $x \leq z$ and $y \leq z$.

[359] Actually we also need to make precise what we mean by the surface of "infinite genus".

(5) We consider the set $\mathbb{N}$. The divisibility relation $k|l$ for $k, l \in \mathbb{N}$ is a preorder on $\mathbb{N}$ and with this preorder $\mathbb{N}$ is in fact a directed set.[360]

16.2. **The direct limit of a direct system.**

Definition. Let $(I, \leq)$ be a preordered set[361] and let $\mathcal{C}$ be a category. A *direct system in the category $\mathcal{C}$ over I* is a family of objects $\{X_i\}_{i\in I}$ in $\mathcal{C}$, together with a family of morphisms $\{f_{ij}\colon X_i \to X_j\}$ for all $i, j \in I$ with $i \leq j$ such that the following two conditions are satisfied:

$$\begin{array}{lrcll} (1) & f_{ii} & = & \mathrm{id}_{X_i} & \text{for all } i \in I, \\ (2) & f_{ik} & = & f_{jk} \circ f_{ij} & \text{for all } i, j, k \in I \text{ with } i \leq j \leq k. \end{array}$$

Examples.

(A) We consider the directed set $I = (\mathbb{N}, \leq)$ and the category of groups. For $i \in \mathbb{N}$ we consider the group $\mathbb{Z}^i$ and for $i \leq j$ we denote by

$$\begin{array}{rcl} f_{ij}\colon \mathbb{Z}^i & \to & \mathbb{Z}^j \\ (x_1, \dots, x_i) & \mapsto & (x_1, \dots, x_i, 0, \dots, 0) \end{array}$$

the inclusion map. Then $(\{\mathbb{Z}^i\}_{i\in\mathbb{N}}, \{f_{ij}\}_{i\leq j})$ forms clearly a direct system.

(B) Again we consider $I = (\mathbb{N}, \leq)$ and the category of groups. Given $i \in \mathbb{N}$ we define

$$F_i \ := \ \langle x_1, \dots, x_i \rangle \ = \ \text{the free group on } i \text{ generators}$$

and given $i \leq j$ we set

$$\begin{array}{rcl} f_{ij}\colon F_i & \to & F_j \\ x_k & \mapsto & x_k, \ \text{for } k = 1, \dots, i. \end{array}$$

This is clearly a direct system of groups.

(C) Given $r \in \mathbb{N} \cup \{\infty\}$ we set

$$X_r \ := \ \left(0, r + \tfrac{1}{2}\right) \ \cup \ \bigcup_{j=1}^{r} \underbrace{\left\{ z \in \mathbb{C} \,\middle|\, \left|z - (j + \tfrac{1}{4}i)\right| = \tfrac{1}{4} \right\}}_{\text{circle of radius } \frac{1}{4} \text{ around } j + \frac{1}{4}i \in \mathbb{C}} \ \subset \ \mathbb{C}.$$

For example, for $r \in \mathbb{N}$ the set X_r is the subset of $\mathbb{C} = \mathbb{R}^2$ that is given by the interval $(0, r + \frac{1}{2})$ with r circles attached. We refer to Figure 298 for an illustration.

Now we consider the directed set $(\mathbb{N}, \leq)$ and for $r \leq s$ we denote by $f_{rs}\colon X_r \to X_s$ the obvious inclusion map. This is clearly a direct system of topological spaces.

(D) We can generalize example (C) as follows. Let $(I, \leq)$ be a preordered set and let $\{X_i\}_{i\in I}$ be a family of topological spaces such that for any $i \leq j$ we have $X_i \subset X_j$. Given $i \leq j$ we denote by $\iota_{ij}\colon X_i \to X_j$ the inclusion map. Then $(\{X_i\}_{i\in I}, \{\iota_{ij}\}_{i\leq j})$ is a preordered system in the category of topological spaces.

[360] Indeed, given $k, l \in \mathbb{N}$ we have $k|kl$ and $l|kl$.

[361] In the literature one often demands that I is a directed set, see e.g. [Hat, p. 243], but this is not necessary.

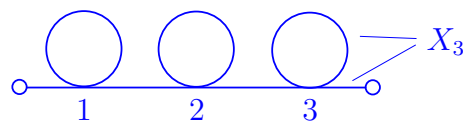


FIGURE 298.

(E) Let $(\{0, x, y\}, \leq)$ be the push-pull set and let $\mathcal{C}$ be a category. A direct system in the category $\mathcal{C}$ over the preordered set $(\{0, x, y\}, \leq)$ consists of three objects A_0, A_x, A_y, the identity morphisms $\mathrm{id}_{A_0}, \mathrm{id}_{A_x}, \mathrm{id}_{A_y}$ and morphisms $f_x \colon A_0 \to A_x$ and $f_y \colon A_0 \to A_y$. We refer to such a system as a *pushout system* and often we arrange the morphisms in a diagram as follows

$$\begin{tikzcd} A_0 \arrow[r, "f_x"] \arrow[d, "f_y"'] & A_x \\ A_y. & \end{tikzcd}$$

Definition. Let $(I, \leq)$ be a preordered set and let $\mathcal{C}$ be a category. Suppose we are given a direct system $(\{X_i\}_{i \in I}, \{f_{ij}\}_{i \leq j})$ in the category $\mathcal{C}$. A *direct limit*[362] of the direct system is an object Y in $\mathcal{C}$ together with morphisms $g_i \colon X_i \to Y, i \in I$ in the category $\mathcal{C}$ such that the following two conditions are satisfied:

(1) For all $i \leq j$ we have $g_j \circ f_{ij} = g_i \colon X_i \to Y$, i.e. for all $i \leq j$ the following diagram commutes

$$\begin{tikzcd} X_j \arrow[dr, "g_j"] & \\ & Y. \\ X_i \arrow[uu, "f_{ij}"] \arrow[ur, "g_i"'] & \end{tikzcd}$$

(2) If we are given another object Y' and morphisms $g'_i \colon X_i \to Y', i \in I$ that satisfy (1), then there exists a unique morphism $F \colon Y \to Y'$ such that for all $i \leq j$ the following diagram commutes[363]

$$\begin{tikzcd} X_j \arrow[dr, "g_j"] \arrow[drr, bend left, "g'_j"] & & \\ & Y \arrow[r, dashed, "F", "\exists!"'] & Y'. \\ X_i \arrow[uu, "f_{ij}"] \arrow[ur, "g_i"'] \arrow[urr, bend right, "g'_i"'] & & \end{tikzcd}$$

[362]Somewhat confusingly a "direct limit" is often also called a "projective limit" or "colimit of a direct system".

[363]The notation $\exists!$ means that there exists a uniquely defined morphism that makes the diagram commute.

The "usual argument" for objects that satisfy a universal property[364] shows, that if the direct limit exists, then it is unique in an appropriate sense. We denote the direct limit by $\varinjlim X_i$ or sometimes by $\varinjlim_I X_i$.[365]

Example. Now we discuss the direct limits of the direct systems we had discussed above.

(A) We consider the above direct system in the category of groups that is given by the free abelian groups $\mathbb{Z}^i$, $i \in \mathbb{N}$, with the obvious inclusion homomorphisms $\mathbb{Z}^i \to \mathbb{Z}^j$ for $i \leq j$. We claim that[366]

$$\varinjlim \mathbb{Z}^i \;=\; \mathbb{Z}^{(\mathbb{N})} \;=\; \{(x_1, x_2, \dots) \mid x_i \in \mathbb{Z} \text{ but only finitely many } x_i\text{'s are non-zero}\},$$

where the maps $\mathbb{Z}^j \to \varinjlim \mathbb{Z}^i = \mathbb{Z}^{(\mathbb{N})}$, $j \in \mathbb{N}$ are the obvious inclusion maps. Indeed, given a group Y' and homomorphisms $g'_j \colon \mathbb{Z}^j \to Y'$ that satisfy condition (1) we define

$$\begin{array}{rcl} F \colon \varinjlim \mathbb{Z}^i \;=\; \mathbb{Z}^{(\mathbb{N})} & \to & Y' \\ (x_1, \dots, x_j, 0, \dots) & \mapsto & g'_j(x_1, \dots, x_j). \end{array}$$

It is straightforward to see that this definition is well-defined, i.e. independent of the choice of x_j.[367] It is clear that the diagram (2) commutes. Furthermore, since $(x_1, \dots, x_j, 0, \dots) = g_j(x_1, \dots, x_j)$ it is clear that F is the unique homomorphism that makes the diagram (2) commute.

Thus we have now shown that the direct limit is the free abelian group on an infinite countable generating set.

(B) We consider the above direct system in the category of groups that is given by the free groups $F_i := \langle x_1, \dots, x_i \rangle$, $i \in \mathbb{N}$, with the obvious inclusion homomorphisms $F_i \to F_j$ for $i \leq j$. Similar to the proof of (A) one can show that

$$\varinjlim F_i \;=\; \langle x_1, x_2, x_3, \dots \rangle \;=\; \text{free group on the generators } x_1, x_2, x_3, \dots$$

where the maps $F_j \to \varinjlim F_i = \langle x_1, x_2, \dots \rangle$, $j \in \mathbb{N}$ are the obvious maps. Put differently, the direct limit is the free group on an infinite countable generating set.

(C) We continue with the direct system $(X_r, r \in \mathbb{N})$ in the category of topological spaces from above. Perhaps not surprisingly the direct limit is the interval $(0, \infty)$ with infinitely many circles attached, i.e.

$$\varinjlim X_r \;=\; X_\infty \;=\; \big(0, \infty\big) \;\cup\; \bigcup_{j=1}^{\infty} \big\{ z \in \mathbb{C} \,\big|\, \big|z - (j + \tfrac{1}{4}i)\big| = \tfrac{1}{4} \big\} \;\subset\; \mathbb{C},$$

where the maps $X_s \to \varinjlim X_r = X_\infty$, $s \in \mathbb{N}$ are the obvious inclusion maps. We leave the verification of this statement as an exercise.

[364] See for instance the discussion on page 368 for an example of such an argument.

[365] Here we ignore the maps f_{ij} and g_i in the notation. Usually these maps are clear from the context.

[366] Why is the direct limit not given by $\mathbb{Z}^{\mathbb{N}}$, i.e. the group of all infinite sequences?

[367] Here we did not demand that $x_j \neq 0$.

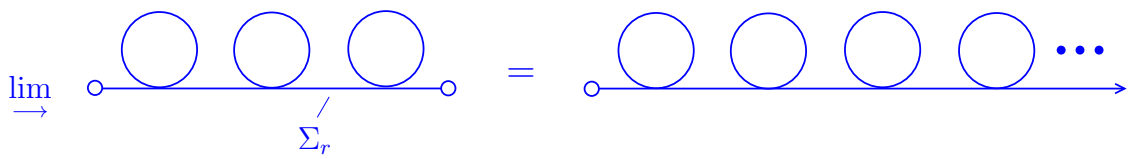

FIGURE 299.

(D) Let $(I, \leq)$ be a preordered set and let $\{X_i\}_{i\in I}$ be a family of topological spaces such that for any $i \leq j$ we have $X_i \subset X_j$. In the category of topological spaces we have

$$\varinjlim X_i \;=\; X \;:=\; \bigcup_{i\in I} X_i,$$

where the topology on $X = \bigcup_{i\in I} X_i$ is given by the rule that $U \subset X$ is open if and only if $U \cap X_i$ is open for all $i \in I$. Furthermore the maps $g_j \colon X_j \to X = \bigcup_{i\in I} X_i, j \in \mathbb{N}$ are the obvious inclusion maps.[368] The verification of this statement is Exercise 16.1.

Definition. If the direct limit of a pushout system

$$\begin{tikzcd} A_0 \arrow[r, "f_x"] \arrow[d, "f_y"'] & A_x \\ A_y & \end{tikzcd}$$

exists, then we refer to it as the *pushout* of the *pushout system*. The defining property of the pushout Z can be summarized in the following commutative diagram[369]

$$\begin{tikzcd} A_0 \arrow[r, "f_x"] \arrow[d, "f_y"'] & A_x \arrow[d, "g_x"] \arrow[ddr, bend left, "g'_x"] & \\ A_y \arrow[r, "g_y"] \arrow[drr, bend right, "g'_y"'] & \text{pushout } Z \arrow[dr, dashed, "\exists!"] & \\ & & Z'. \end{tikzcd}$$

Examples.

(1) We first consider the pushout in the category of groups. By Proposition 13.11 the pushout of a pushout system in the category of groups

$$\begin{tikzcd} G \arrow[r, "\alpha"] \arrow[d, "\beta"'] & A \\ B & \end{tikzcd} \qquad \text{is given by} \qquad \begin{tikzcd} G \arrow[r, "\alpha"] \arrow[d, "\beta"'] & A \arrow[d] \\ B \arrow[r] & A *_G B = \dfrac{A * B}{\langle\langle \{\alpha(g)\cdot\beta(g)^{-1}\}_{g\in G} \rangle\rangle}. \end{tikzcd}$$

[368]Why are the maps g_j continuous, i.e. why are they morphisms in the category of topological spaces.

[369]Here we suppress the morphism $g_0 \colon A_0 \to Z$ from the diagram since it is given by $g_x \circ f_x = g_y \circ f_y$.

(2) Now we consider the pushout in the category of topological spaces. In Exercise 16.3 we will see that the pushout of the pushout system of topological spaces

$$\begin{tikzcd} X \arrow[r, "f"] \arrow[d, "g"'] & Y \\ Z & \end{tikzcd} \quad \text{is given by} \quad \begin{tikzcd} X \arrow[r, "f"] \arrow[d, "g"'] & Y \arrow[d] \\ Z \arrow[r] & Y \sqcup_X Z := (Y \sqcup Z)/f(x) \sim g(x). \end{tikzcd}$$

Here we equip $Y \sqcup_X Z$ with the quotient topology induced from the obvious topology on $Y \sqcup Z$.

(3) The direct limit of a direct system does not always exist. For example, denote by $\mathcal{C}$ the category with two objects, namely the trivial group and the group $\mathbb{Z}_2$, and where the morphisms are the usual group homomorphisms. Then the pushout system

$$\begin{tikzcd} 0 \arrow[r] \arrow[d] & \mathbb{Z}_2 \\ \mathbb{Z}_2 & \end{tikzcd} \quad \begin{array}{c} \text{does not have a direct limit} \\ \text{since there is no commutative} \\ \text{diagram of the form} \end{array} \quad \begin{tikzcd} 0 \arrow[r] \arrow[d] & \mathbb{Z}_2 \arrow[d, "\beta"] \\ \mathbb{Z}_2 \arrow[r, "\alpha"] & C \end{tikzcd}$$

with $C = 0$ or $C = \mathbb{Z}_2$ such that in the following two diagrams there exists the desired diagonal maps from C to $Y' = \mathbb{Z}_2$:[370]

$$\begin{tikzcd} 0 \arrow[r] \arrow[d] & \mathbb{Z}_2 \arrow[d, "\beta"] \arrow[ddr, bend left, "x \mapsto x"] & \\ \mathbb{Z}_2 \arrow[r, "\alpha"] \arrow[drr, bend right, "x \mapsto 0"'] & C \arrow[dr] & \\ & & Y' = \mathbb{Z}_2 \end{tikzcd} \quad \text{and} \quad \begin{tikzcd} 0 \arrow[r] \arrow[d] & \mathbb{Z}_2 \arrow[d, "\beta"] \arrow[ddr, bend left, "x \mapsto 0"] & \\ \mathbb{Z}_2 \arrow[r, "\alpha"] \arrow[drr, bend right, "x \mapsto x"'] & C \arrow[dr] & \\ & & Y' = \mathbb{Z}_2. \end{tikzcd}$$

Proposition 16.1. *The direct limit of any direct system exists in the following categories:*

(0) *the category of sets,*
(1) *the category of topological spaces,*
(2) *the category of groups,*
(3) *the category of abelian groups,*
(4) *the category of rings,*[371]
(5) *the category of R-modules, where R is a commutative ring.*

Sketch of proof. Let $(I, \leq)$ be a preordered set and let $\mathcal{C}$ be one of the six given categories. Furthermore let $(\{X_i\}_{i \in I}, \{f_{ij} \colon X_i \to X_j\}_{i \leq j})$ be a direct system in $\mathcal{C}$.

(0),(1) If we work in the category of sets, then we define the direct limit as the set

$$\varinjlim X_i \ := \ \Big(\bigsqcup_{i \in I} X_i \Big) / \sim \quad \text{where } x \sim f_{ij}(x) \text{ for all } i \leq j,\ x \in X_i.$$

[370] Why is there no such diagram with $C = 0$ or $C = \mathbb{Z}_2$ and homomorphisms α and β?

[371] Throughout the lecture notes a *ring* is understood to be associative and it is understood to have a multiplicatively neutral element, unless we say explicitly otherwise. We do not demand that a ring is commutative.

If we work in the category of topological spaces, then $\bigsqcup_{i\in I} X_i$ is equipped with the topology where a subset U is open if and only if $U \cap X_i$ is open for all i.[372]

(2) If we work in the category of groups, then we cannot use the definition of (0) and (1), since the union of groups is not a group. Therefore we define the direct limit via the "smallest group that contains all X_i", i.e. we define it as the group

$$\varinjlim X_i \;:=\; \Big(\mathop{\ast}_{i\in I} X_i\Big) / \langle\!\langle \{ f_{ij}(x)\cdot x^{-1} \mid i \le j \text{ and } x \in X_i \} \rangle\!\rangle.$$

(3),(4),(5) If we work in the category of abelian groups, or in the category of rings or in the category of R-modules, then we define[373]

$$\varinjlim X_i \;:=\; \Big(\bigoplus_{i\in I} X_i\Big) / \{ f_{ij}(x) - x \mid \; i \le j \text{ and } x \in X_i \}.$$

Furthermore in all six cases we denote by $g_j \colon X_j \to \varinjlim X_i$, $j \in I$ the obvious maps. It is now straightforward to verify that in all five categories we provided a direct limit. We leave the details to the reader. □

Remark.

(1) Suppose we are given a direct system $(\{X_i\}_{i\in I}, \{f_{ij} \colon X_i \to X_j\}_{i\le j})$ in any of the four algebraic categories mentioned in the previous proposition. Now we assume that $(I, \le)$ is not only a preordered set, but that it is in fact a directed set. Then, as for direct limits of sets and topological spaces, we can also define

$$\varinjlim X_i \;:=\; \Big(\bigsqcup_{i\in I} X_i\Big) / \sim \quad \text{where } x \sim f_{ij}(x) \text{ for all } i \le j,\, x \in X_i$$

and we denote by $g_j \colon X_j \to \varinjlim X_i$, $j \in I$, the obvious maps. If we work in the category of groups, then $\varinjlim X_i$ is naturally a group as follows: if we are given $a \in X_i$ and $b \in X_j$, by definition of a directed set there exists $k \in I$ with $i \le k$ and $j \le k$, and we define

$$[a]\cdot[b] \;:=\; \big[\underbrace{f_{ik}(a)}_{\in X_k} \cdot \underbrace{f_{jk}(b)}_{\in X_k}\big] \;\in\; \varinjlim X_i.$$

It follows easily from the definition of a direct system that this definition of the product structure is independent of the choice of k and that this defines indeed a group structure on $\varinjlim X_i$. Similarly we deal with the case that we work in the other three algebraic categories.

[372]Note that for the above example of the pushout we do *not* get the same topological space (why not?) but we get a topological space that is homeomorphic (why?) to the above pushout. Since we only care about the direct limit up to homeomorphism this makes no difference.

[373]Here we really mod out by the subgroup generated by the differences $f_{ij}(x) - x$.

(2) An important special case is given by $I = \mathbb{N}_0$ and where the maps $f_{ij}\colon X_i \to X_j$ are inclusion maps. In this case one can in fact take

$$\varinjlim X_i \;:=\; \bigcup_{i\in\mathbb{N}_0} X_i.$$

In the above algebraic categories the algebraic structure are defined as in the previous remark. In the topological category the topology on $X := \bigcup_{i\in\mathbb{N}_0} X_i$ is given, as in the proof of Proposition 16.1, by the condition that $U \subset X$ is open if and only if each $U \cap X_i$ is an open subset of X_i.

We conclude this section with the following lemma that gives a particularly simple but commonly used calculation of a direct limit.

Lemma 16.2. *Let $f_n\colon X_n \to X_{n+1}$ be a sequence of morphisms in any category. Suppose there exists an $N \in \mathbb{N}$ such that all f_n for $n \geq N$ are isomorphisms. Then $\varinjlim X_n$ exists and it is naturally isomorphic to X_N, more precisely, a direct limit is given by $\varinjlim X_n := X_N$ and the maps*

$$\begin{array}{rcll} f_{N-1}\circ\circ f_{n+1}\circ f_n\colon X_n & \to & X_N & \text{if } n \leq N, \\ (f_n\circ\cdots\circ f_{N+1}\circ f_N)^{-1}\colon X_n & \to & X_n & \text{if } n > N \end{array}$$

define a direct limit.

Proof. We will provide the proof in Exercise 16.2. □

16.3. **Fundamental groups and direct limits.** In this section we want to address the following question:

Question 16.3. *Let $(\{X_i\}_{i\in I}, \{f_{ij}\}_{i\leq j})$ be a direct system of topological spaces. Now we can form the direct limit $\varinjlim X_i$ of the topological spaces. The maps f_{ij} also induce homomorphisms on fundamental groups. The question is, when does "taking limits commute with taking fundamental groups", i.e. under what circumstances do we have*[374]

$$\pi_1\big(\varinjlim X_i\big) \;=\; \varinjlim \pi_1(X_i)\ ?$$

Example. We have already seen two instances where the equality of the question holds.

(1) Suppose X is a topological space that is the union of two open subsets U and V such that U, V and $U \cap V$ are path-connected. We fix a base point in $U \cap V$. Then

$$\pi_1\left(\varinjlim \begin{array}{c} U\cap V \to U \\ \downarrow \\ V \end{array}\right) \underset{\substack{\uparrow \\ \text{see page 486}}}{=} \pi_1(X) \underset{\substack{\uparrow \\ \text{Seifert-van Kampen} \\ \text{Theorem 14.1}}}{=} \pi_1(U) *_{\pi_1(U\cap V)} \pi_1(V) \underset{\substack{\uparrow \\ \text{see page 485}}}{=} \varinjlim \begin{array}{c} \pi_1(U\cap V) \to \pi_1(U) \\ \downarrow \\ \pi_1(V) \end{array}$$

[374]As it is this question is not well-phrased, since fundamental groups depend on base points and we ignored them in the above discussion.

(2) Let X be a path-connected topological space and let X_k, $k \in \mathbb{N}$ be a sequence of subsets of X such that the following hold:
   (a) each X_k is open,
   (b) each X_k is simply connected,
   (c) the sequence X_k is nested, i.e. for each k we have $X_k \subset X_{k+1}$,
   (d) we have $\bigcup_{k\in\mathbb{N}} X_k = X$.

   Then for any $w \in X_1$ we have[375]

$$\pi_1\big(\varinjlim X_i, w\big) \underset{\substack{\uparrow \\ \text{see page 488}}}{=} \pi_1\Big(\bigcup_{i\in\mathbb{N}} X_i, x_0\Big) \underset{\substack{\uparrow \\ \text{Lemma 12.6}}}{=} \{e\} = \varinjlim \{e\} = \varinjlim \pi_1(X_i, w).$$

The following proposition generalizes the second example.

Proposition 16.4. *Let $X_i, i \in \mathbb{N}$ be a sequence of topological spaces such that the following holds:*

(1) *the sequence is nested, i.e. for each $i \in \mathbb{N}$ we have $X_i \subset X_{i+1}$,*

and such that one of the following two conditions holds:

(2) *every compact subset of $\varinjlim X_i$ is already contained in one of the X_i, or*

(3) *each X_i is open in X_{i+1}.*

Then for any $w \in X_1$ we have

$$\pi_1\big(\varinjlim X_i, w\big) = \varinjlim \pi_1(X_i, w).$$

Remark. We will see that the proof of Proposition 16.4 is a generalization of the ideas behind the proof of Lemma 12.6.

The following lemma shows that the hypothesis (3) in Proposition 16.4 implies in fact hypothesis (2).

Lemma 16.5. *Let $X_i, i \in \mathbb{N}$ be a sequence of topological spaces such that each X_i is open in X_{i+1}. Then every compact subset of $\varinjlim X_i$ is already contained in one of the X_i.*

Proof of Lemma 16.5. Let $X_i, i \in \mathbb{N}$ be a nested sequence of topological spaces such that each X_i is open in X_{i+1}.

Claim. For every $i \in \mathbb{N}$ the subset X_i is open in X.

By the definition of the topology on X we have to show that for each $j \in \mathbb{N}$ the intersection $X_i \cap X_j$ is open in X_j. Since the sequence is nested it follows that for $j \leq i$ we have $X_i \cap X_j = X_j$, in particular $X_i \cap X_j$ is open in X_j. Now we need to show that X_i is open

[375]Recall that by the discussion on page 482 the topological spaces $\{X_i\}_{i\in\mathbb{N}}$ together with the inclusion maps form a direct system in the category of topological spaces. The direct limit is given by the union of all X_i's, where the union is given a suitable topology. Furthermore note that the inclusion induced maps $\pi_1(X_i, w) \to \pi_1(X_j, w)$ turn the groups $\{\pi_1(X_i, w)\}_{i\in\mathbb{N}}$ into a direct system in the category of groups.

in any X_{i+k} with $k \in \mathbb{N}_0$. We do so by induction on k. For $k = 0$ the statement is clear. Suppose we already know that X_i is open in X_{i+k}. Then X_i is an open subset in X_{i+k} and X_{i+k} is in turn an open subset of X_{i+k+1} by our hypothesis. It follows that X_i is open in X_{i+k+1}.[376] This concludes the proof of the claim.

Now let $K \subset \varinjlim X_i$ be a compact subset. From the claim we know that each X_i is open in $X = \varinjlim X_i$ we obtain immediately from Lemma 1.38 and the hypothesis that the X_i's are nested that there exists a $k \in \mathbb{N}$ such that $K \subset X_i$. $\square$

Proof of Proposition 16.4. By Lemma 16.5 we only have to prove the proposition under the hypothesis (2). Thus let $X_i, i \in \mathbb{N}$ be a nested sequence of topological spaces such that every compact subset of $\varinjlim X_i$ is already contained in one of the X_i. Let $w \in X_1$. We write $X = \bigcup_{i \in I} X_i = \varinjlim X_i$.

Given $k \leq l$ we denote by φ_{kl} the inclusion induced map $\pi_1(X_k, w) \to \pi_1(X_l, w)$. We denote by $\Phi \colon \varinjlim \pi_1(X_i, w) \to \pi_1(X, w)$ the unique homomorphism that makes the following diagram commute for any $k \leq l$:

$$\begin{tikzcd}
\pi_1(X_l, w) \arrow[dr, "\psi_l"] \arrow[drr, bend left] & & \\
& \varinjlim \pi_1(X_i, w) \arrow[r, dashed, "\Phi", "\exists!"'] & \pi_1(X, w). \\
\pi_1(X_k, w) \arrow[uu, "\varphi_{kl}"] \arrow[ur, "\psi_k"] \arrow[urr, bend right] & &
\end{tikzcd}$$

We need to show that Φ is an isomorphism. First we show that the map Φ is surjective. Let $g \in \pi_1(X, w)$. We represent g by a loop $\gamma \colon [0,1] \to X$. By Lemma 1.37 and our hypothesis (2) there exists a $k \in \mathbb{N}$ such that the image of γ lies in X_k. We consider the following commutative diagram

$$\begin{tikzcd}
& \varinjlim \pi_1(X_i, w) \arrow[r, "\Phi"] & \pi_1(X, w). \\
\pi_1(X_k, w) \arrow[ur] \arrow[urr, bend right, "{[\gamma] \mapsto g}"'] & &
\end{tikzcd}$$

By our choice of k we see that g lies in the image of the curved map, hence it also lies in the image of Φ. This concludes the proof that Φ is surjective.

Now we show that the map Φ is injective. So let $g \in \varinjlim \pi_1(X_i, w)$. Since $(\mathbb{N}, \leq)$ is a directed set we can use the description of the direct limit from page 487, i.e. we can write

$$\varinjlim \pi_1(X_i, w) \;=\; \Big(\bigsqcup_{i \in \mathbb{N}} \pi_1(X_i, w) \Big) / \sim \quad \text{where } g \sim \varphi_{kl}(g) \text{ for all } k \leq l,\ g \in \pi_1(X_k, w).$$

[376] Here we use the following general fact: if U is an open subset in V and V is an open subset of W, then U is an open subset of W. Why is that true?

In particular we see that there exists a k such that g lies in the image of the map $\psi_k\colon \pi_1(X_k,w) \to \varinjlim \pi_1(X_k,w)$. We pick a loop $\gamma\colon [0,1] \to X_k$ such that $\psi_k([\gamma]) = g$. Now suppose that $\Phi(g)$ is trivial. By definition this means that there exists a path-homotopy $H\colon [0,1]\times[0,1] \to X$ from the path γ to the constant path. As above we can apply Lemma 1.37 and our hypothesis (2) to deduce that there exists an $l \geq k$ such that the image of H lies in X_l. This implies that $\varphi_{kl}([\gamma])$ is trivial in $\pi_1(X_l,w)$. We obtain the following diagram

$$\begin{tikzcd}
\pi_1(X_l,w) \arrow[dr] & & \\
& \varinjlim \pi_1(X_i,w) \arrow[r, "g\mapsto e"] & \pi_1(X,w). \\
\pi_1(X_k,w) \arrow[uu, "{[\gamma]\mapsto e}"] \arrow[ur, "{[\gamma]\mapsto g}"'] & &
\end{tikzcd}$$

It follows immediately that g itself is trivial. This concludes the proof that Φ is injective. $\square$

Examples.

(1) As on page 482 we denote by X_∞ the interval $(0,\infty)$ with infinitely many circles attached. We pick the base point $w = \frac{1}{4}$. We then have [377]

$$\pi_1\big(X_\infty,w\big) \underset{\substack{\uparrow\\ \text{see page 484}}}{=} \pi_1\big(\varinjlim X_r,w\big) \underset{\substack{\uparrow\\ \text{Proposition 16.4}}}{=} \varinjlim \pi_1\big(X_r,w\big) \underset{\substack{\uparrow\\ \text{Lemma 12.5}}}{=} \varinjlim \langle x_1,\dots,x_r\rangle \underset{\substack{\uparrow\\ \text{see page 484}}}{=} \langle x_1,x_2,\dots\rangle.$$

Furthermore the proof of Lemma 12.5 and the above argument show that the generators $x_1,x_2,\dots$ of $\pi_1(X_\infty)$ can be chosen such that x_n, $n\in\mathbb{N}$, corresponds to a loop which goes "once around the n-th circle".

(2) Now we consider

$$\widetilde{X} \;:=\; \mathbb{R} \;\cup\; \bigcup_{j\in\mathbb{Z}} \underbrace{\big\{z\in\mathbb{C}\,\big|\,\big|z-(j+\tfrac{1}{4}i)\big| = \tfrac{1}{4}\big\}}_{\text{circle of radius } \frac{1}{4} \text{ around } j+\frac{1}{4}i\,\in\,\mathbb{C}} \;\subset\; \mathbb{C}.$$

Put differently, $\widetilde{X}$ is the real axis with infinitely many circles attached. The same argument as in (1) shows that $\pi_1(\widetilde{X})$ is the free group on infinitely many generators x_n, $n\in\mathbb{Z}$. In Figure 300 we illustrate a covering map $p\colon \widetilde{X} \to X = S^1\vee S^1$.

[377] The third equality follows from Lemma 12.5, to be more precise, it follows from the fact that for any $r\leq s$ the inclusion map $\iota_{rs}\colon X_r \to X_s$ and the isomorphisms of Lemma 12.5 give rise to a commutative diagram

$$\begin{tikzcd}
\pi_1(X_r,w) \arrow[r, "\cong"] \arrow[d, "(\iota_{rs})_*"'] & \langle x_1,\dots,x_r\rangle \arrow[d, "x_i\mapsto x_i"] \\
\pi_1(X_s,w) \arrow[r, "\cong"] & \langle x_1,\dots,x_s\rangle.
\end{tikzcd}$$

The fact that this diagram commutes follows easily from the proof of Lemma 12.5. We leave the details to the reader.

By Corollary 7.15 the map $\pi_1(\widetilde{X}) \to \pi_1(X)$ is a monomorphism. We had just seen that $\pi_1(\widetilde{X})$ is a free group on infinitely generators and by the discussion on page 390 we know that $\pi_1(X)$ is a free group on two generators. In fact, with appropriate orientations and conventions this shows that the homomorphism

$$\begin{array}{rcl} \pi_1(\widetilde{X}) = \langle \dots, x_{-2}, x_{-1}, x_0, x_1, x_2, \dots \rangle & \to & \langle s, t \rangle = \pi_1(X) \\ x_n & \mapsto & s^n t s^{-n} \end{array}$$

is a monomorphism. In particular we see that the free group $\langle s, t \rangle$ contains a subgroup that is "much larger" than the original free group itself.

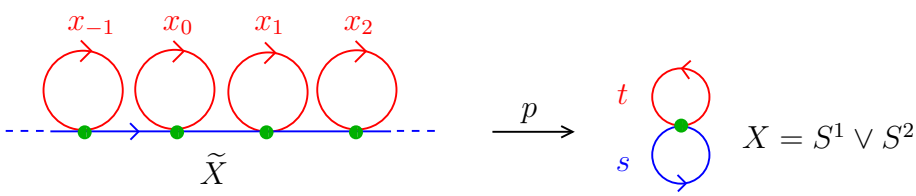

FIGURE 300.

(3) An argument similar to (1) shows that $\pi_1(\mathbb{C} \setminus \mathbb{Z})$ is a free group generated by $x_n, n \in \mathbb{Z}$ where x_n is a loop which goes "once around the n-th hole". We leave the details as an exercise to the reader. We refer to Figure 301 for an illustration.

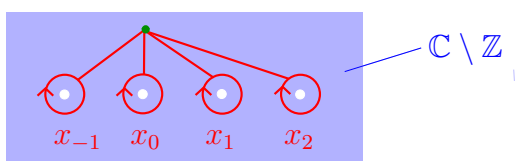

FIGURE 301.

Finally we return to the initial goal of this section, namely to determine the fundamental group of the surface of "infinite genus" that we illustrate in Figure 302. Before we can calculate its fundamental group we have to give a precise description of the surface of infinite genus. We write

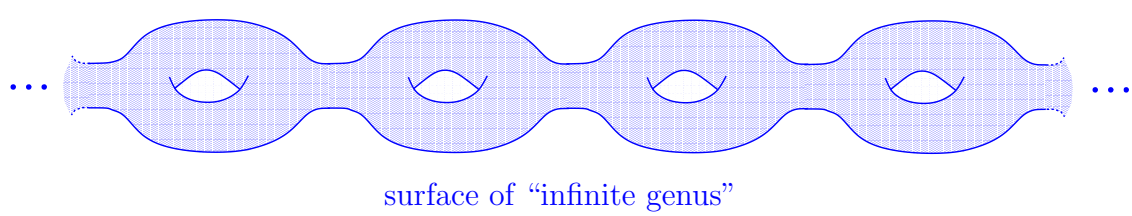

FIGURE 302.

$$F \;:=\; \text{the torus minus two open disks.}$$

We define $X_0 = S^1 \times [-1,1]$ and for $i \geq 0$ we define iteratively

$$X_{i+1} \;:=\; X_i \text{ with a copy of } F \text{ attached to each of the two boundary components of } X_i.$$

Note that each X_i is a surface of genus $2i$ with two open disks removed. We define

$$\text{surface of infinite genus} \;:=\; \varinjlim X_i \;=\; \bigcup_{i\in\mathbb{N}_0} X_i.$$

It should be clear that this definition gives a rigorous description of the surface that we had sketched in Figure 302.

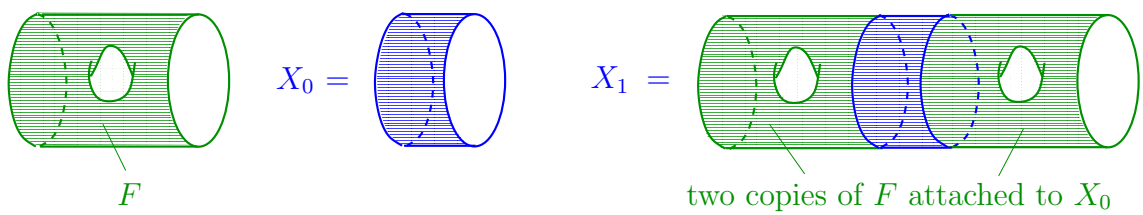

FIGURE 303.

Lemma 16.6. *The fundamental group of the surface of infinite genus is the free group on infinitely many generators.*

Remark. More generally, the fundamental group of any non-compact 2-dimensional manifold is a free group, this is for example proved in [Sti, p. 142].

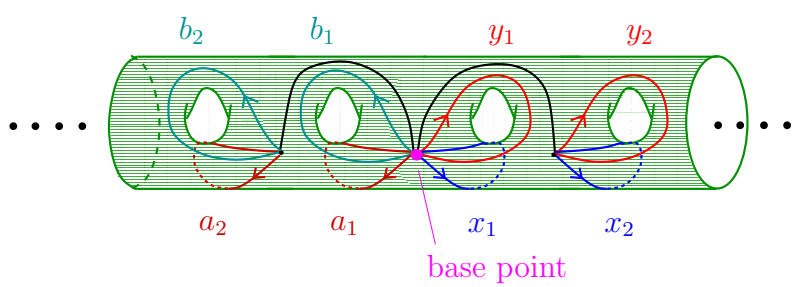

FIGURE 304. A set of generators for the fundamental group of a surface of infinite genus.

Proof. By Lemma 14.19 we have[378]

$$\pi_1(F) \;=\; \langle a,b,c,c' \mid c = [a,b]\cdot c'\rangle \;=\; \langle x,y,z,z' \mid z = [x,y]\cdot z'\rangle$$

[378]This is indeed a consequence of Lemma 14.19, the only change is that we reversed the orientation of one of the boundary curves.

where the generators z, z' and c, c' correspond to the two boundary components. We refer to Figure 305 for an illustration. An induction argument, using the Seifert-van Kampen

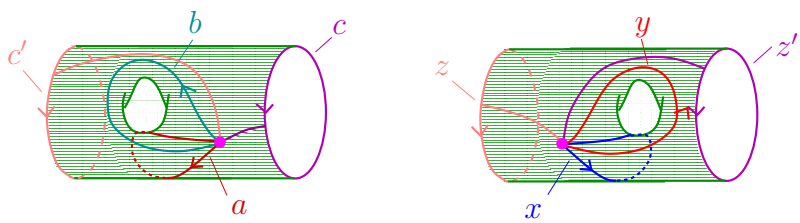

FIGURE 305.

Theorem 14.2 for manifolds together with Lemma 13.13 and the above presentations of $\pi_1(F)$ shows that for any $l \geq k$ we have a commutative diagram

$$\begin{array}{ccc}
\pi_1(X_k) & \xrightarrow{\cong} & \left\langle \begin{matrix} x_1, y_1, ..., x_k, y_k \\ a_1, b_1, ..., a_k, b_k \end{matrix} z_k, c_k \;\middle|\; \prod_{j=1}^{k} [a_j, b_j] c_k = \prod_{j=1}^{k} [x_j, y_j] z_k \right\rangle \\
\Big\downarrow & & \Big\downarrow {\scriptstyle c_k \mapsto \prod_{j=k+1}^{l} [a_j, b_j] c_l \;\; z_k \mapsto \prod_{j=k+1}^{l} [x_j, y_j] z_l} \\
\pi_1(X_l) & \xrightarrow{\cong} & \left\langle \begin{matrix} x_1, y_1, ..., x_l, y_l \\ a_1, b_1, ..., a_l, b_l \end{matrix} z_l, c_l \;\middle|\; \prod_{j=1}^{l} [a_j, b_j] c_l = \prod_{j=1}^{l} [x_j, y_j] z_l \right\rangle
\end{array}$$

where the left vertical map is induced by the inclusion $X_k \to X_l$. We leave the details to the energetic reader. For any $l \geq k$ we also have the following commutative diagram of

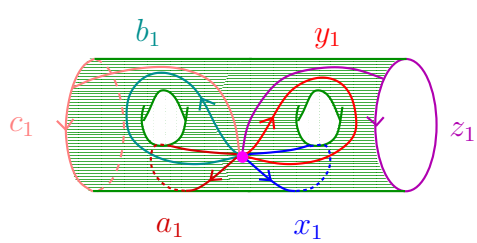

FIGURE 306.

homomorphisms:

$$\begin{tikzcd}
\left\langle \begin{matrix} x_1, y_1, ..., x_k, y_k \\ a_1, b_1, ..., a_k, b_k \end{matrix} p \right\rangle \arrow[r, "\cong", "p \mapsto \prod_{j=1}^{k} [a_j, b_j] c_k"'] \arrow[d, hook] & \left\langle \begin{matrix} x_1, y_1, ..., x_k, y_k \\ a_1, b_1, ..., a_k, b_k \end{matrix} z_k, c_k \;\middle|\; \prod_{j=1}^{k} [a_j, b_j] c_k = \prod_{j=1}^{k} [x_j, y_j] z_k \right\rangle \arrow[d, "c_k \mapsto \prod_{j=k+1}^{l} [a_j, b_j] c_l \quad z_k \mapsto \prod_{j=k+1}^{l} [x_j, y_j] z_l"] \\
\left\langle \begin{matrix} x_1, y_1, ..., x_l, y_l \\ a_1, b_1, ..., a_l, b_l \end{matrix} p \right\rangle \arrow[r, "\cong", "p \mapsto \prod_{j=1}^{l} [a_j, b_j] c_l"'] & \left\langle \begin{matrix} x_1, y_1, ..., x_l, y_l \\ a_1, b_1, ..., a_l, b_l \end{matrix} z_l, c_l \;\middle|\; \prod_{j=1}^{l} [a_j, b_j] c_l = \prod_{j=1}^{l} [x_j, y_j] z_l \right\rangle
\end{tikzcd}$$

The horizontal homomorphisms are in fact isomorphisms, this is for example a consequence of the Tietze transformations from page 412.[379]

We denote by Σ_∞ the surface of infinite genus. Furthermore given any $i \in \mathbb{N}_0$ we write $U_i = X_i \setminus \partial X_i$. Note that each U_i is in fact an open subset of Σ_∞. We have

$$\pi_1(\Sigma_\infty) \underset{\substack{\uparrow \\ \text{since } \Sigma_\infty = \bigcup_{i \in \mathbb{N}_0} U_i}}{=} \pi_1\big(\varinjlim U_i\big) \overset{\substack{\text{Proposition 16.4} \\ \downarrow}}{=} \varinjlim \pi_1(U_i) \underset{\substack{\uparrow \\ \text{since } \pi_1(U_i) \xrightarrow{\cong} \pi_1(X_i)}}{=} \varinjlim \pi_1(X_i) \overset{\substack{\text{by the above two} \\ \text{commutative diagrams} \\ \downarrow}}{=} \varinjlim \left\langle \begin{matrix} x_1, y_1, ..., x_i, y_i \\ a_1, b_1, ..., a_i, b_i \end{matrix} p \right\rangle \underset{\substack{\uparrow \\ \text{see example on} \\ \text{page 484}}}{=} \left\langle \begin{matrix} x_1, y_1, ... \\ a_1, b_1, ... \end{matrix} p \right\rangle.$$

This concludes the proof of the lemma. □

16.4. **The inverse limit of an inverse system.** For completeness' sake we also introduce the inverse limit of an inverse system, even though it will not play a role in the intermediate future.

Definition. Let $(I, \leq)$ be a preordered set and let $\mathcal{C}$ be a category. An *inverse system in the category $\mathcal{C}$ over I* is a family of objects $\{X_i\}_{i \in I}$ in $\mathcal{C}$, together with a family of morphisms $\{f_{ji} \colon X_j \to X_i\}$ for all $i, j \in I$ with $i \leq j$[380] such that the following two conditions are satisfied:

(1)	f_{ii}	$=$	id_{X_i}	for all $i \in I$,
(2)	f_{ki}	$=$	$f_{ji} \circ f_{kj}$	for all $i, j, k \in I$ with $i \leq j \leq k$.

Examples.

---

[379]Indeed, we write $X = \{x_1, y_1, \ldots, x_m, y_m, a_1, b_1, \ldots, a_m, b_m\}$, $u = \prod_{j=1}^{m} [a_j, b_j]$, $v = \prod_{j=1}^{m} [x_j, y_j]$, $c = c_m$ and $z = z_m$, then

$$\langle X, z, c \mid uc = vz \rangle = \langle X, z, c \mid z = v^{-1}uc \rangle \xleftarrow{\cong} \langle X, c \rangle \xrightarrow{\cong} \langle X, c, p \mid p = uc \rangle = \langle X, c, p \mid X, c = u^{-1}p \rangle \xleftarrow{\cong} \langle X, p \rangle$$

where all three isomorphisms are the isomorphisms of the Tietze transformation (2). It is straightforward to see that the concatenation equals for $m = k, l$ precisely the horizontal maps in the diagram.

[380]So here for $i \leq j$ we have a morphism $X_j \to X_i$ instead of $X_i \to X_j$ in a direct system.

(A) For each $i \in \mathbb{N}$ we define $X_i := \mathbb{Z}^i$ and for $i \leq j$ we denote by

$$\begin{array}{rcl} f_{ji}\colon \mathbb{Z}^j & \to & \mathbb{Z}^i \\ (x_1, \dots, x_j) & \mapsto & (x_1, \dots, x_i) \end{array}$$

the projection onto the first i coordinates. Then $(\{\mathbb{Z}^i\}_{i\in\mathbb{N}}, \{f_{ji}\}_{i\leq j})$ forms an inverse system in the category of groups.

(B) Let p be a prime. For each $i \in \mathbb{N}$ we define $X_i := \mathbb{Z}_{p^i}$ and for $i \leq j$ we denote by

$$\begin{array}{rcl} f_{ji}\colon \mathbb{Z}_{p^j} & \to & \mathbb{Z}_{p^i} \\ n + p^j\mathbb{Z} & \mapsto & n + p^i\mathbb{Z} \end{array}$$

the obvious projection map. Then $(\{\mathbb{Z}_{p^i}\}_{i\in\mathbb{N}}, \{f_{ji}\}_{i\leq j})$ forms an inverse system in the category of rings.

(C) We let $I = \mathbb{N}$, but this time we use the preorder given by divisibility, i.e. we write $k \leq l$ if and only if $k|l$. For each $k \in \mathbb{N}$ we define $X_k := \mathbb{Z}_k$ and for $k|l$ we denote by

$$\begin{array}{rcl} f_{lk}\colon \mathbb{Z}_l & \to & \mathbb{Z}_k \\ n + l\mathbb{Z} & \mapsto & n + k\mathbb{Z} \end{array}$$

the obvious projection map. Then $(\{\mathbb{Z}_k\}_{k\in\mathbb{N}}, \{f_{lk}\}_{k|l})$ forms an inverse system in the category of rings.

The following definition is the "mirror" image of the definition of the direct limit of a direct system.

Definition. Let $(I, \leq)$ be a preordered set and let $\mathcal{C}$ be a category. Furthermore suppose we are given an inverse system $(\{X_i\}_{i\in I}, \{f_{ji}\}_{i\leq j})$ in the category $\mathcal{C}$. An *inverse limit*[381] of the inverse system is an object Y in $\mathcal{C}$ together with morphisms $g_i\colon Y \to X_i$, $i \in I$, in the category $\mathcal{C}$ such that the following two conditions are satisfied:

(1) For all $i \leq j$ we have $f_{ji} \circ g_j = g_i\colon Y \to X_i$, i.e. for all $i \leq j$ the following diagram commutes

$$\begin{tikzcd} & X_j \arrow[d, "f_{ji}"] \\ Y \arrow[ur, "g_j"] \arrow[r, "g_i"'] & X_i. \end{tikzcd}$$

(2) If we are given another object Y' and morphisms $g_i'\colon Y' \to X_i$, $i \in I$, that satisfy (1), then there exists a unique morphism $F\colon Y' \to Y$ such that for all $i \leq j$ the

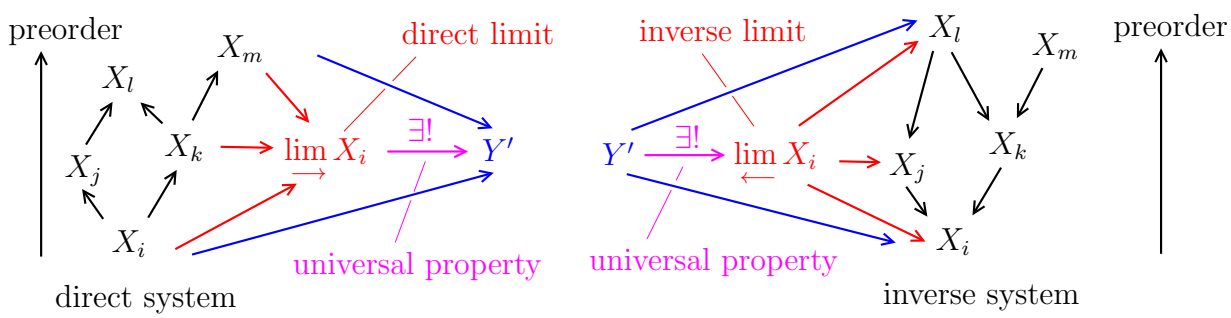
[381]Somewhat confusingly an "inverse limit" is often also called an "inductive limit" or "limit of an inverse system".

following diagram commutes

$$\begin{tikzcd}
 & & X_j \arrow[dd, "f_{ji}"] \\
Y' \arrow[urr, bend left, "g'_j"] \arrow[r, dashed, "F", "\exists!"'] \arrow[drr, bend right, "g'_i"'] & Y \arrow[ur, "g_j"] \arrow[dr, "g_i"] & \\
 & & X_i.
\end{tikzcd}$$

The "usual argument" for objects that satisfy a universal property shows, that if the inverse limit exists, then it is unique in an appropriate sense. We denote the inverse limit by $\varprojlim X_i$ or sometimes by $\varprojlim_I X_i$.

In the following diagram we compare schematically the definition of the direct limit of a direct system to the inverse limit of an inverse system:[382]



Examples. In order to get an idea of how to construct inverse limits we first consider the special case that the preorder on I is trivial, in the sense that we have $i \leq j$ if and only if $i = j$.

(D) Let I be a set with the trivial preorder. Suppose that for any $i \in I$ we are given a set X_i. Together with the identity maps of the X_i this defines an inverse system over I

[382]The difference between a direct limit and an inverse limit is not the direction of the arrows between the X_i. In fact given a preorder "$\leq$" one could define a preorder "$\widetilde{\leq}$" via $a \widetilde{\leq} b$ if and only if $b \leq a$, hence a direct system over $(I, \leq)$ is an inverse system over $(I, \widetilde{\leq})$. The real difference is whether the X_i map to the limit, or whether the limit maps to the X_i.

in the category of sets. We claim that the inverse limit is given by[383]

$$\varprojlim X_i \;=\; \prod_{i\in I} X_i$$

together with the maps g_i that are given by the projection onto the i-component. Now we verify this statement. Since we only have $i \le j$ if $i = j$ there is nothing to verify in part (1) of the definition of the inverse limit. Now suppose we are given a set Y' and maps $g_i' \colon Y' \to X_i$. Then we define

$$\begin{array}{rcl} F\colon Y' & \to & \varprojlim X_i \\ y & \mapsto & \left(\begin{array}{ccc} I & \to & \prod_{i\in I} X_i \\ i & \mapsto & g_i'(y) \end{array}\right). \end{array}$$

It is straightforward to verify that F is uniquely determined and that it has the desired property. We have thus determined the inverse limit $\varprojlim X_i$.

(E) Let I be a set with the trivial preorder and suppose that for any $i \in I$ we are given a topological space X_i. Together with the identity maps of the X_i this defines an inverse system over I in the category of topological spaces. As in (D) we define

$$\varprojlim X_i \;=\; \prod_{i\in I} X_i$$

and each map g_i is again given by the projection onto the i-component.

To conclude that we have found an inverse limit in the category of topological spaces we still have to equip $\prod_{i\in I} X_i$ with a topology which has the following two properties:

(i) the maps $g_i \colon \prod_{i\in I} X_i \to X_i$ are continuous,

(ii) given a topological space Y' and continuous maps $g_i' \colon Y' \to X_i$ the map F, defined as in (D), is continuous.[384]

We set

$$\mathcal{B} \;:=\; \left\{ \prod_{i\in I} U_i \;\subset\; \prod_{i\in I} X_i \;\middle|\; \begin{array}{ll} (1) & \text{each } U_i \text{ is open in } X_i \text{ and} \\ (2) & \text{there exist only finitely many } i\text{'s with } U_i \neq X_i \end{array} \right\}.$$

[383]Recall that the product $\prod_{i\in I} X_i$ is defined as the set of all maps $f \colon I \to \bigsqcup_{i\in I} X_i$ with the property that $f(i) \in X_i$ for all $i \in I$. Such a map f is often written as $(f(i))_{i\in I}$ and often we refer to $f(i)$ as the *i-component* of f. Furthermore we refer to the map

$$\begin{array}{rcl} \prod_{i\in I} X_i & \to & X_i \\ f & \mapsto & f(i) \end{array}$$

as the *projection onto the i-component*. Note that if the X_i's are groups, rings or modules, then the product inherits this algebraic structure by component-wise multiplication and addition.

[384]On the product $\prod_{i\in I} X_i$ we could also consider the topology $\mathcal{T}$ that is generated by all sets of the form $\prod_{i\in I} U_i$ with U_i open in X_i. This might be a more "natural" topology on $\prod_{i\in I} X_i$. But with this topology $\mathcal{T}$ the map F does not necessarily have to be continuous. The problem is that $\mathcal{T}$ has "too many" open sets.

It is straightforward to verify that $\mathcal{B}$ has the basis property that we introduced on page 60. We equip $\prod_{i\in I} X_i$ with the topology generated by this basis and we refer to this topology as the *product topology.*[385] Now we need to verify that we found the correct topology on the direct limit.

(i) It follows immediately from the definitions that the maps g_i are continuous with respect to the product topology.

(ii) Suppose we are given Y and g_i' as above. We denote by F the map defined as above. We claim that F is continuous. By Proposition 1.34 it suffices to verify that the preimage of any set in $\mathcal{B}$ is open. So let $\prod_{i\in I} U_i$ be a set in $\mathcal{B}$. Then

$$F^{-1}\Big(\prod_{i\in I} U_i\Big) = \bigcap_{i\in I}(g_i')^{-1}(U_i) = \bigcap_{U_i\neq X_i}\underbrace{(g_i')^{-1}(U_i)}_{\text{open in } Y'} = \begin{array}{c}\text{intersection of finitely}\\ \text{many open subsets of } Y'.\end{array}$$

This concludes the proof that F is continuous.

Now we can prove fairly easily that inverse limits exist in many categories that are of interest to us.

Proposition 16.7. *The inverse limit of any inverse system exists in the following categories:*

(0) *the category of sets,*
(1) *the category of topological spaces,*
(2) *the category of groups,*
(3) *the category of topological groups,*
(4) *the category of abelian groups,*
(5) *the category of rings,*
(6) *the category of R-modules, where R is a commutative ring.*

Furthermore, the direct limits of (0),...,(6) *are "coherent". For example if $\{X_i\}_{i\in I}$ is a direct system of topological groups, then the direct limit is the direct system of the corresponding topological spaces together together with an appropriate group structure.*

We will see that the proof of Proposition 16.7 is a relatively straightforward generalization of the examples (D) and (E) above.

Proof. Let $(I,\leq)$ be a preordered set and let $\mathcal{C}$ be one of the seven given categories. Furthermore let $(\{X_i\}_{i\in I}, \{f_{ji}\colon X_j \to X_i\}_{i\leq j})$ be an inverse system in the category $\mathcal{C}$. We define

$$\varprojlim X_i \;:=\; \big\{(x_i)_{i\in I} \in \prod_{i\in I} X_i \,\big|\, f_{ji}(x_j) = x_i \text{ for all } i\leq j\big\}.$$

Furthermore we denote by $g_i\colon \varprojlim X_i \to X_i$ the obvious projection maps. It follows immediately from the definitions that for any $i\leq j$ we have $f_{ji}\circ g_j = g_i$. Furthermore, given an

[385]If the index set I is finite, i.e. if we consider the product of finitely many topological spaces, then this definition of the product topology agrees with the definition given on page 84.

object Y' and morphisms $g_i'\colon Y' \to X_i$, $i \in I$ which satisfy the condition $f_{ji} \circ g_j' = g_i'$ for all $i \in I$ we define

$$\begin{array}{rcl} F\colon Y' & \to & \varprojlim X_i \\ y & \mapsto & \left(\begin{array}{ccc} I & \to & \prod\limits_{i\in I} X_i \\ i & \mapsto & g_i'(y) \end{array} \right). \end{array}$$

It is straightforward to verify that $F(Y')$ lies in $\varprojlim X_i$ and that F is the unique map with the desired property. This shows that the inverse limit exists in the category of sets.[386]

For the remaining six categories we will use the same definition of the direct limit as a set and the same maps, but we now have to verify that we have objects and morphisms in the given category.

(1) Suppose that we work in the category of topological spaces. We equip $\prod\limits_{i\in I} X_i$ with the product topology that we defined in Example (E) above. We equip $\varprojlim X_i$ with the subspace topology. The same argument as in Example (E) shows that the maps g_i and F are continuous.

(2) In the category of groups we view $\prod\limits_{i\in I} X_i$ as a group via component-wise multiplication. Since the f_{ij} are group homomorphisms we see that $\varprojlim X_i$ is a subgroup of $\prod\limits_{i\in I} X_i$. It is straightforward to verify that the above maps are all morphisms in the category of groups.

(3) We equip the set $\varprojlim X_i$ with the topological structure and the group structure as in the above statements (1) and (2). It follows from Lemma 1.109 that this turns $\varprojlim X_i$ into a topological group, which turns out to be the inverse limit of the inverse system of topological groups.

(4),(5),(6) These categories are dealt with the same way as (2).

For all seven categories we have now provided an inverse limit. Since we always equipped the same set with different structures we see that the direct limits are coherent. □

Remark. We consider the important special case that the preordered set $(I, \leq) = (\mathbb{N}, \leq)$. Furthermore let

$$(\{X_n\}_{n\in\mathbb{N}}, \{f_{nm}\colon X_n \to X_m\}_{m\leq n})$$

[386]Now we will see that we can use the "same" inverse limit for all the categories, this is very different from the construction of the direct limit for the same categories. There, in the proof of Proposition 16.1, we had to use several different construction.

be an inverse system over $(\mathbb{N}, \leq)$ in any of the above seven categories. Given $n \in \mathbb{N}_{\geq 2}$ we write $g_n := f_{n,n-1} \colon X_n \to X_{n-1}$. We have

$$\begin{aligned} \varprojlim X_i &= \big\{(x_1, x_2, x_3, \dots) \mid x_n \in X_n \text{ for all } n \in \mathbb{N} \text{ and } f_{nm}(x_n) = x_m \text{ for all } m \leq n\big\} \\ &= \big\{(x_1, x_2, x_3, \dots) \mid x_n \in X_n \text{ for all } n \in \mathbb{N} \text{ and } g_n(x_n) = x_{n-1} \text{ for all } n \in \mathbb{N}_{\geq 2}\big\} \\ &\uparrow \end{aligned}$$

follows from $f_{nm} = f_{n,n-1} \circ \cdots \circ f_{m+1,m} = g_n \circ \cdots \circ g_{m+1}$

$$= \text{all infinite sequences of the form } \begin{array}{ccc} \vdots & & \vdots \\ \downarrow & & \downarrow \\ x_3 & \in & X_3 \\ \downarrow & & \downarrow g_3 \\ x_2 & \in & X_2 \\ \downarrow & & \downarrow g_2 \\ x_1 & \in & X_1 \end{array}$$

This discussion shows that we can view of elements in the inverse limit as "upward going sequences".

Now we return to our initial examples of inverse systems and their inverse limits.

Examples.

(A) It follows quite easily from the previous remark that

$$\varprojlim_{n \in \mathbb{N}} \mathbb{Z}^n = \{(x_1, x_2, x_3, \dots) \mid x_n \in \mathbb{Z}\} \cong \mathbb{Z}^{\mathbb{N}}.$$

Note that this is an uncountable group. Recall that on page 484 we had determined that

$$\varinjlim \mathbb{Z}^i = \mathbb{Z}^{(\mathbb{N})} = \{(x_1, x_2, \dots) \mid x_i \in \mathbb{Z} \text{ but only finitely many } x_i \text{ are non-zero}\}$$

which is a countable group.[387] Thus we see that in this particular case the inverse limit is "much larger" than the direct limit.[388]

(B) Let p be a prime. The inverse limit $\widehat{\mathbb{Z}}_p := \varprojlim \mathbb{Z}_{p^i}$ of the rings $\mathbb{Z}_{p^i} = \mathbb{Z}/p^i\mathbb{Z}$ is called the *ring of the p-adic numbers*.[389] The p-adic numbers play a very prominent role in many branches of pure mathematics.

[387] Why is $\mathbb{Z}^{(\mathbb{N})}$ countable?

[388] Note though that we are comparing limits of different system, first of a direct system and then of an inverse system.

[389] In number theory one often uses a different convention, namely one writes explicitly $\mathbb{Z}/p\mathbb{Z}$ for the quotient ring and one denotes the p-adic numbers by $\mathbb{Z}_p$. If the expression "$\mathbb{Z}_p$" appears in a paper or a book it is a good idea to check the convention used by the author.

(C) The inverse limit $\widehat{\mathbb{Z}} := \varprojlim \mathbb{Z}_n$ of the rings $\mathbb{Z}_n$, $n \in \mathbb{N}$, with the preorder on $\mathbb{N}$ defined by the divisibility relation $k|l$, is called the *ring of the profinite integers*. Using the Chinese Remainder Theorem one can show that

$$\widehat{\mathbb{Z}} \cong \prod_{\text{prime } p} \widehat{\mathbb{Z}}_p.$$

Now we continue with three examples that we had not considered yet.

(D) We let $(I, \leq) = (\mathbb{N}, \leq)$. Given $i \in \mathbb{N}$ we set $X_i := \mathbb{N}$ and for $i \leq j$ we define

$$\begin{aligned} f_{ji} \colon X_j = \mathbb{N} &\to X_i = \mathbb{N} \\ n &\mapsto n + (j - i). \end{aligned}$$

Then $(\{X_i = \mathbb{N}\}_{i \in \mathbb{N}}, \{f_{ji}\}_{i \leq j})$ forms an inverse system in the category of sets. In Exercise 16.6 we will see that in this case the inverse limit is the empty set.

(E) Let X be a topological space. We denote by K the set of all compact subsets of X. We consider K with the preorder given by inclusion, i.e. we have $A \leq B$ if $A \subseteq B$. Given $A \in K$ we define $X_A := X \setminus A$. Furthermore given $A \leq B$ we denote by[390] $f_{AB} \colon \pi_0(X_B) \to \pi_0(X_A)$ the map induced by the inclusion $X_B \to X_A$. It is straightforward to verify that the sets $\{\pi_0(X_A)\}_{A \in K}$, together with the inclusion induced maps f_{AB} for $A \leq B$ define an inverse system in the category of sets. The elements of $\operatorname{ends}(X) := \varprojlim \pi_0(X_A)$ are called the *ends of* X. In Exercise 16.8 we will determine the number of ends of $X = \mathbb{R}^n$.

(F) Given a topological space Y we denote by $C(Y, \mathbb{R})$ the abelian group of all continuous functions on Y. Note that for each subset $W \subset Y$ we have a homomorphism $C(Y, \mathbb{R}) \to C(W, \mathbb{R})$ given by $f \mapsto f|_W$, i.e. given by restricting a function on Y to a function on W.

Let X be a topological space and let $\{U_i\}_{i \in \mathbb{N}}$ be sequence of open subsets such for each $i \in \mathbb{N}$ we have $U_i \subset U_{i+1}$ and such that $\bigcup_{i \in \mathbb{N}} U_i = X$. Then the groups $\{C(U_i, \mathbb{R})\}_{i \in \mathbb{N}}$ together with the restriction maps form an inverse system. We leave it as an exercise to verify that the restriction maps from X to the U_i gives rise to an isomorphism

$$C(X, \mathbb{R}) \to \varprojlim C(U_i, \mathbb{R}).$$

Definition. Let $(\{0, x, y\}, \leq)$ be the push-pull set as defined on page 481, i.e. the preordered set with the non-trivial relations $0 \leq x$ and $0 \leq y$, and let $\mathcal{C}$ be a category. An inverse system in the category $\mathcal{C}$ over $(\{0, x, y\}, \leq)$ consists of three objects A_0, A_x, A_y, the identity morphisms $\mathrm{id}_{A_0}, \mathrm{id}_{A_x}, \mathrm{id}_{A_y}$ and morphisms $f_x \colon A_x \to A_0$ and $f_y \colon A_y \to A_0$. We refer to such a system as a *pullback system* and often we arrange the morphisms in a diagram as follows

[390] Recall that on page 127, given a topological space Y we defined $\pi_0(Y)$ as the set of path-components of Y. A map $f \colon Y \to Z$ between two topological spaces induces a map $f_* \colon \pi_0(Y) \to \pi_0(Z)$ in an obvious way.

$$\begin{tikzcd} & A_y \arrow[d, "f_y"] \\ A_x \arrow[r, "f_x"'] & A_0. \end{tikzcd}$$

If the inverse limit of such a pullback system exists, then we refer to it as the *pullback* of the *pullback system*. The defining property of the pullback Z can be summarized in the following diagram

$$\begin{tikzcd} Z' \arrow[dr, dashed, "\exists!"] \arrow[drr, bend left, "g'_y"] \arrow[ddr, bend right, "g'_x"'] & & \\ & \text{pullback } Z \arrow[r, "g_x"'] \arrow[d, "g_y"] & A_y \arrow[d, "f_y"] \\ & A_x \arrow[r, "f_x"'] & A_0. \end{tikzcd}$$

The following lemma deals with the pullback in the category of topological spaces.

Lemma 16.8. *Let $p\colon X \to B$ be a map of topological spaces, let C be a topological space and let $f\colon C \to B$ be a map.*

(1) *In the category of topological spaces the pullback of the pullback system*

$$\begin{tikzcd} & X \arrow[d, "p"] \\ C \arrow[r, "f"'] & B \end{tikzcd} \quad \textit{is given by} \quad \begin{tikzcd} \{(c,x) \in C \times X \mid f(c) = p(x)\} \arrow[r, "(c,x)\mapsto x"] \arrow[d, "(c,x)\mapsto c"'] & X \arrow[d, "p"] \\ C \arrow[r, "f"'] & B. \end{tikzcd}$$

Often the pullback is denoted by f^*X.

(2) *If $p\colon X \to B$ is a covering, then the pullback $f^*X \to C$ is also a covering of the same degree.*

Proof.

(1) This statement follows quite easily from the definitions or alternatively from the proof of Proposition 16.7.

(2) This statement will be proved in Exercise 16.9. □

We conclude this section on inverse limits with the following lemma.

Lemma 16.9. *Let $(I, \leq)$ be a preordered set and let $(\{X_i\}_{i\in I}, \{f_{ji}\colon X_j \to X_i\}_{i\leq j})$ be an inverse system of topological spaces. If all the X_i's are compact and Hausdorff, then the inverse limit $\varprojlim X_i$ is also compact.*[391]

[391]Note that this is very different from the situation of the direct limit. The direct limit of topological spaces is not necessarily compact, for example the direct limit of the direct system $[0, n]$, $n \in \mathbb{N}$ is given by the non-compact space $\bigcup_{n\in\mathbb{N}} [0, n] = [0, \infty)$.

Example. Let p be a prime. The abelian group $\widehat{\mathbb{Z}}_p$ is the inverse limit of finite, hence compact groups. It follows from Proposition 16.10 that $\widehat{\mathbb{Z}}_p$ is also a compact topological group. On the other hand $\widehat{\mathbb{Z}}_p$ is infinite,[392] which shows that the topology on $\widehat{\mathbb{Z}}_p$ is *not* the discrete topology.

Proof. Let $(I, \leq)$ be a preordered set and let $(\{X_i\}_{i\in I}, \{f_{ji}\colon X_j \to X_i\}_{i\leq j})$ be an inverse system of compact topological spaces that are Hausdorff. Given $i \in I$ we denote by $p_i\colon \prod_{j\in J} X_j \to X_i$ the projection map and we denote by $D_i = \{(x,x) \mid x \in X_i\} \subset X_i \times X_i$ the diagonal. By Exercise 1.30 the hypothesis that X_i is Hausdorff implies that the diagonal D_i is a closed subset of $X_i \times X_i$. By the proof of Proposition 16.7 we have

$$\begin{aligned}\varprojlim X_i &:= \big\{(x_i)_{i\in I} \in \prod_{i\in I} X_i \,\big|\, f_{lk}(x_l) = x_k \text{ for all } k \leq l\big\}\\ &= \bigcap_{k\leq l}\big\{x \in \prod_{i\in I} X_i \,\big|\, \underbrace{((f_{lk}\circ p_l)\times p_k)}_{\substack{(f_{lk}\circ p_l)\times p_k \text{ is a map}\\ \prod_{i\in I} X_i \to X_k \times X_k}}(x) \in D_k\big\} \;=\; \bigcap_{k\leq l} \underbrace{((f_{lk}\circ p_l)\times p_k)^{-1}(D_k)}_{\text{closed since } D_k \text{ closed}}.\end{aligned}$$

Thus we see that $\varprojlim X_i$ is the intersection of closed subsets of $\prod_{i\in I} X_i$, hence $\varprojlim X_i$ itself is a closed subset. But $\prod_{i\in I} X_i$ is compact by Tychonoff's Theorem 1.63, hence the closed subset $\varprojlim X_i$ is also compact. □

16.5. **The profinite completion of a group** $(*)$**.** Note that we can view any group as a topological group by equipping it with the discrete topology. With this topology a group is compact if and only if it is finite. Furthermore any homomorphism of groups equipped with the discrete topology is also a morphism in the category of topological groups.

Proposition 16.10. *Let $(I, \leq)$ be a preordered set and let $(\{G_i\}_{i\in I}, \{f_{ji}\colon G_j \to G_i\}_{i\leq j})$ be an inverse system of finite groups. Then the inverse limit $\varprojlim G_i$ exists in the category of topological groups and it is a compact topological group.*

Proof. It follows from Proposition 16.7 that the inverse limit $\varprojlim G_i$ exists in the category of topological groups. Since all the G_i's are finite, in particular compact, it follows from Lemma 16.9 that the inverse limit $\varprojlim G_i$ is also compact. □

Now let π be a group. We consider the set of all finite index normal subgroups $\{\pi_i\}_{i\in I}$. We equip the index set I with the preorder defined by the convention that $i \leq j$ if and only if $\pi_j \subset \pi_i$.[393] Given $i \leq j$ we denote by $\varphi_{ji}\colon \pi/\pi_j \to \pi/\pi_i$ the obvious projection map. Then $(\{\pi/\pi_i\}_{i\in I}, \{\varphi_{ji}\colon \pi/\pi_j \to \pi/\pi_i\}_{i\leq j})$ forms an inverse system. We refer to

$$\widehat{\pi} := \varprojlim \pi/\pi_i$$

[392] In fact $\widehat{\mathbb{Z}}_p$ is uncountable (why?).

[393] Note that we wrote $\pi_j \subset \pi_i$ instead of $\pi_i \subset \pi_j$.

as the *profinite completion of* π. By Proposition 16.10 the profinite completion $\widehat{\pi}$ is a compact topological group. It follows immediately from the definition of an inverse limit that there exists a unique homomorphism $\pi \to \widehat{\pi}$ such that for any i the following diagram commutes:

$$\begin{tikzcd} \pi \arrow[r] \arrow[drr, bend right] & \widehat{\pi} \arrow[dr] & \\ & & \pi/\pi_i. \end{tikzcd}$$

Examples.

(1) The profinite completion $\widehat{\mathbb{Z}}$ of the group $\mathbb{Z}$ equals precisely the profinite integers that we had encountered on page 502.
(2) The profinite completion of a finite group G is the group itself, i.e. $\widehat{G} = G$.[394]
(3) Let $G = \mathbb{Q}$. This group has no proper subgroups of finite index.[395] It follows immediately from the definitions that $\widehat{\mathbb{Q}} = \{0\}$.

Now let $\varphi\colon A \to B$ be a group homomorphism. We denote by $\{B_i\}_{i\in I}$ the finite index normal subgroups of B. For $B_j \subset B_i$ we denote again by $p_{ji}\colon B/B_j \to B/B_i$ the projection map. For every $i \in I$ the preimage $\varphi^{-1}(B_i)$ is a finite index normal subgroup of A.[396] Now we define $\psi_i\colon \widehat{A} \to A/\varphi^{-1}(B_i) \xrightarrow{\varphi} B/B_i$. Note that ψ_i is continuous since the first map is continuous by definition and the second map is a map between two topological spaces that are equipped with the discrete topology. It follows immediately from the definitions that for $B_j \subset B_i$ we have $p_{ji} \circ \psi_j = \psi_i$. It now follows from the definition of the inverse limit in the category of topological groups that there exists a unique continuous homomorphism $\widehat{\varphi}\colon \widehat{A} \to \widehat{B}$ such that for any i the following diagram commutes

$$\begin{tikzcd} \widehat{A} \arrow[r, "\widehat{\varphi}"] \arrow[drr, bend right, "\psi_i"'] & \widehat{B} \arrow[dr] & \\ & & B/B_i. \end{tikzcd}$$

It follows easily from the definitions and Proposition 16.10 that the maps

$$A \mapsto \widehat{A}$$

together with the maps

$$\begin{array}{rcl} \mathrm{Mor}(A, B) & \to & \mathrm{Mor}(\widehat{A}, \widehat{B}) \\ (\varphi\colon A \to B) & \mapsto & (\widehat{\varphi}\colon \widehat{A} \to \widehat{B}) \end{array}$$

define a functor from the category of groups to the category of compact topological groups.

---

[394] Why is that?
[395] Why not?
[396] Why is it a finite index subgroup?

Exercises for Chapter 16.

Exercise 16.1. Let $(I, \leq)$ be a preordered set and let $\{X_i\}_{i\in I}$ be a family of topological spaces such that for any $i \leq j$ we have $X_i \subset X_j$. We define

$$\varinjlim X_i \;=\; X \;:=\; \bigcup_{i\in I} X_i,$$

where the topology on $X = \bigcup_{i\in I} X_i$ is given by the rule that $U \subset X$ is open if and only if $U \cap X_i$ is open for all $i \in I$. Furthermore we denote by $g_j \colon X_j \to X = \bigcup_{i\in I} X_i, j \in \mathbb{N}$ the obvious inclusion maps. Show that $\varinjlim X_i$ together with the maps g_j is the direct limit of the direct system in the category of topological spaces.

Exercise 16.2.

(a) For $i \in \mathbb{N}$ we define $F_i = \langle x_i, x_{i+1}\rangle$. For $i \in \mathbb{N}$ we denote by $g_i \colon F_i \to F_{i+1}$ the homomorphism that is given by $g_i(x_i) = e, g_i(x_{i+1}) = x_{i+1}$. Furthermore for $i < j$ we define $f_i \colon F_i \to F_j$ to be the homomorphism $g_{j-1} \circ \cdots \circ g_{i+1} \circ g_i$. What is the direct limit $\varinjlim F_i$ in the category of groups?

(b) Given $k \in \mathbb{N}$ we define $X_k = \mathbb{N}$ to be the topological space where the open sets are $\{1, \dots, k\}, \{k+1\}, \{k+2\}, \dots$. For $k \leq l$ we denote by $f_{kl} \colon X_k \to X_l$ the identity map. (Note that with the choice of our topologies on X_k and X_l this map is in fact continuous). What is the direct limit $\varinjlim X_k$ in the category of topological spaces?

Remark: as a set the direct limit is again $\mathbb{N}$, but what is the topology?

Exercise 16.3. Show that the pushout of the pushout system of topological spaces

$$\begin{tikzcd} X \arrow[r, "f"] \arrow[d, "g"'] & Y \\ Z & \end{tikzcd} \quad \text{is given by} \quad \begin{tikzcd} X \arrow[rr, "f"] \arrow[d, "g"'] & & Y \arrow[d] \\ Z \arrow[rr] & & Y \sqcup_X Z := (Y \sqcup Z)/f(x) \sim g(x). \end{tikzcd}$$

Here we equip $Y \sqcup_X Z$ with the quotient topology induced from the obvious topology on $Y \sqcup Z$.

Exercise 16.4. Suppose we are given two pushouts

$$\begin{tikzcd} X \arrow[r] \arrow[d] & Y \arrow[d, dashed] \\ Z \arrow[r, dashed] & P \end{tikzcd} \quad \text{and} \quad \begin{tikzcd} \widetilde{X} \arrow[r] \arrow[d] & \widetilde{Y} \arrow[d, dashed] \\ \widetilde{Z} \arrow[r, dashed] & \widetilde{P}. \end{tikzcd}$$

Furthermore suppose we are given a commutative diagram

$$\begin{tikzcd} X \arrow[rr] \arrow[dd] \arrow[dr] & & Y \arrow[dr] \arrow[dd, dashed] & \\ & \widetilde{X} \arrow[rr] \arrow[dd, dashed] & & \widetilde{Y} \arrow[dd, dashed] \\ Z \arrow[rr, dashed] \arrow[dr] & & P \arrow[dr, dashed, "\exists!"] & \\ & \widetilde{X} \arrow[rr, dashed] & & \widetilde{P}. \end{tikzcd}$$

An example for such a situation is sketched in Figure 307

(a) Show that there exists a unique map $P \to \widetilde{P}$ which makes the cube commute.

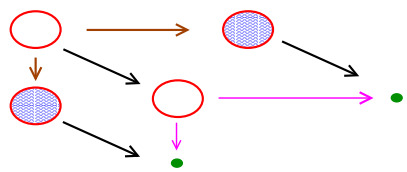


FIGURE 307.

(b) Suppose that the maps $X \to \widetilde{X}$, $Y \to \widetilde{Y}$ and $Z \to \widetilde{Z}$ are homotopy equivalences. Does it follows that the map $P \to \widetilde{P}$ is a homotopy equivalence?

Exercise 16.5. Proof Lemma 16.2. It is best to prove it using the definition of direct limits instead of using any of the above explicit descriptions of direct limits.

Exercise 16.6. We let $(I, \leq) = (\mathbb{N}, \leq)$. Given $i \in \mathbb{N}$ we set $X_i := \mathbb{N}$ and for $i \leq j$ we define

$$\begin{array}{rcl} f_{ji} \colon X_j = \mathbb{N} & \to & X_i = \mathbb{N} \\ n & \mapsto & n + (j - i). \end{array}$$

Then $(\{X_i = \mathbb{N}\}_{i \in \mathbb{N}}, \{f_{ji}\}_{i \leq j})$ forms an inverse system in the category of sets. Show that the inverse limit is the empty set.

Exercise 16.7. Let

$$\begin{array}{ccc} A & \xrightarrow{g} & B \\ {\scriptstyle f}\downarrow & & \\ C & & \end{array}$$

be a pushout system in the category of groups, R-modules or topological spaces such that $f \colon A \to B$ is an isomorphism (respectively homeomorphism). We consider the direct limit, i.e. the pushout

$$\begin{array}{ccc} A & \xrightarrow{g} & B \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle r} \\ C & \xrightarrow{s} & X. \end{array}$$

Show that $r \colon B \to X$ is also an isomorphism (respectively homeomorphism).

Exercise 16.8. Let X be a topological space. We denote by K the set of all compact subsets of X. We consider K with the preorder given by inclusion, i.e. we have $A \leq B$ if $A \subseteq B$. Given $A \in K$ we define[397] $X_A := \pi_0(X \setminus A)$. Furthermore given $A \leq B$ we denote by $f_{AB} \colon \pi_0(X_B) \to \pi_0(X_A)$ the map induced by the inclusion $X_B \to X_A$. It follows immediately from the discussion on page 245 that the sets $\{\pi_0(X_A)\}_{A \in K}$, together with the inclusion induced maps f_{AB} for $A \leq B$ define an inverse system in the category of sets.

[397]Recall that by the definition on page 127, given a topological space Y we had denoted $\pi_0(Y)$ by the set of path-components of X.

The elements of $\varprojlim \pi_0(X_A)$ are called the *ends of* X.
Let $n \in \mathbb{N}$. Determine the number of ends of $X = \mathbb{R}^n$.

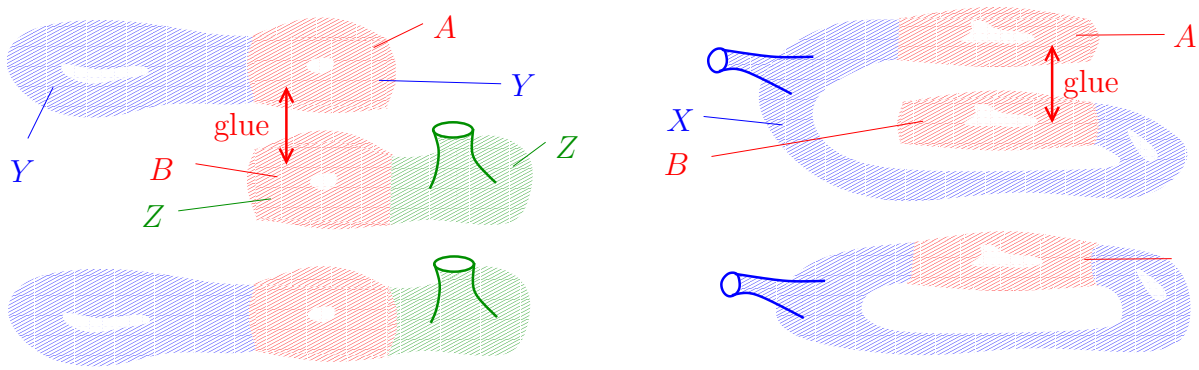
Exercise 16.9. Prove Lemma 16.8 (2), i.e. show that the pullback $f^*X \to C$ of a covering $p\colon X \to B$ under a map $f\colon C \to B$ is again a covering of the same degree.

17. The HNN-Seifert-van Kampen Theorem

One of our main goals at the moment is to calculate fundamental groups of interesting topological spaces. As we have discovered, one of the most powerful tools is the Seifert-van Kampen Theorem 14.1.

In light of Exercise 1.37 (c) we can say, modulo technical details, that the Seifert-van Kampen Theorem 14.1 allows us to calculate the fundamental group of a topological space $X = Y \cup_f Z$ that is obtained from gluing two path-connected topological spaces Y and Z along path-connected open subsets $A \subset X$ and $B \subset Y$. This situation is illustrated in Figure 308 to the left.

Sometimes one is given the situation that is shown in Figure 308 to the right. Namely we are given a path-connected topological space X and we glue two disjoint path-connected open subsets A and B together. In this chapter we will prove the HNN-Seifert-van Kampen Theorem which will allow us to calculate the fundamental group in the latter situation.



$\pi_1(Y \cup_f Z) = \pi_1(Y) *_{\pi_1(A)} \pi_1(Z)$ $\qquad$ $\pi_1 =???$

Figure 308.

We start out with the following notation.

Notation. Let X be a topological space, let A and B be two subsets of X and let $f\colon A \to B$ be a homeomorphism. We write

$$X(f) \;:=\; X(f\colon A \to B) \;:=\; X/\sim \qquad \text{where } f(a) \sim a \text{ for } a \in A.$$

Examples.

(1) Let X be the torus with two open disks removed. We denote by A and B the two boundary components and we endow them with the orientation coming from a fixed orientation of the torus. Let $f\colon A \to B$ be an orientation-reversing diffeomorphism. Then, with some effort, one sees that $X(f\colon A \to B)$ is diffeomorphic[398] to the surface of genus 2. This statement is illustrated in Figure 309.[399]

[398] Note that by Lemma 10.13 we know that $X(f\colon A \to B)$ is indeed a manifold.

[399] What topological space do we obtain if f is chosen to be orientation-preserving?

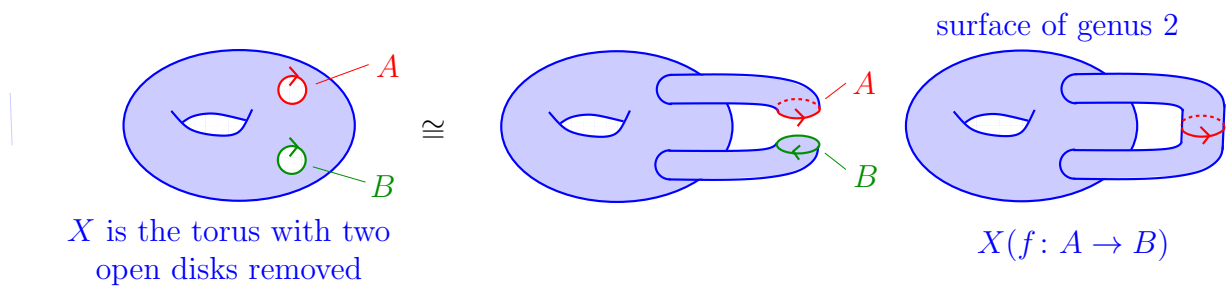


FIGURE 309.

(2) Let Y be a topological space and let $f\colon Y \to Y$ be a homeomorphism. We consider $X = Y \times [0,1]$ and by a slight abuse of notation we denote by $f\colon Y \times \{0\} \to Y \times \{1\}$ also the map defined by $f(y,0) = (f(y),1)$. It follows immediately from the definitions that
$$X(f) \;=\; (Y \times [0,1])(f) \;=\; M(X,f),$$
where $M(X,f)$ denotes the mapping torus that we introduced on page 469.

Our goal now is to determine $\pi_1(X(f))$ in terms of the fundamental groups of X, A and the induced map $f_*\colon \pi_1(A) \to \pi_1(B)$. Perhaps not surprisingly, we again need a new construction from group theory.

Definition. Let π and Γ be two groups and let $\alpha, \beta\colon \Gamma \to \pi$ be two homomorphisms. We refer to
$$\langle \pi, t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle \;:=\; (\pi * \langle t \rangle) \,/\, \langle\langle \{\alpha(g)t\beta(g)^{-1}t^{-1}\}_{g\in\Gamma} \rangle\rangle$$
as the *HNN-extension of* (π, α, β).[400]

Remark.

(1) If $\pi = \langle x_1, \dots, x_k \mid r_1, \dots, r_l \rangle$ is a finitely presented group and if $g_1, \dots, g_m$ is a generating set for Γ, then it follows easily from the definitions that the HNN-extension of (π, α, β) is given by
$$\langle x_1, \dots, x_k, t \mid r_1, \dots, r_l, \alpha(g_i) = t\beta(g_i)t^{-1} \text{ for } i = 1, \dots, m \rangle.$$

(2) If $\alpha, \beta\colon \Gamma \to \pi$ are monomorphisms, then it follows from [Ser, p. 45] that the obvious map $\pi \to \langle \pi, t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle$ is also a monomorphism.

Examples.

(1) Let $\pi = \Gamma$, let $\alpha = \mathrm{id}$ and let $\beta\colon \pi \to \pi$ be an isomorphism. Then it is straightforward to see that the map
$$\begin{array}{rcl} \Phi\colon \pi \rtimes_\beta \mathbb{Z} & \to & \langle \pi, t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle \\ (g,n) & \mapsto & g \cdot t^{-n} \end{array}$$

[400]The concept of such a group was introduced by Graham Higman, Bernhard Neumann and Hannah Neumann [HNN] in 1950, whence the name.

is an isomorphism.[401] Put differently, we have now shown that a semidirect product is a special case of an HNN-extension.

(2) Let π be a group and let Γ be the trivial group. It follows immediately from the definitions that the corresponding HNN-extension is the free product $\pi * \langle t \rangle$.

(3) Let π and Γ be two groups and let $\alpha, \beta \colon \Gamma \to \pi$ be two homomorphisms. Then there exists an epimorphism

$$\langle \pi, t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle \ \to \ \mathbb{Z}$$

that is uniquely determined by $g \mapsto 0$ if $g \in \pi$ and $t^n \mapsto n$.

The following proposition, which is proved in [Ser, p. 45], is an analogue of Proposition 13.14.

Proposition 17.1. $(*)$ *Let π and Γ be two groups and let $\alpha, \beta \colon \Gamma \to \pi$ be two homomorphisms. If α and β are monomorphisms, then the obvious inclusion map*

$$\begin{array}{rcl} \pi & \to & \langle \pi, t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle \ := \ (\pi * \langle t \rangle) \,/\, \langle\langle \{\alpha(g)t\beta(g)^{-1}t^{-1}\}_{g \in \Gamma} \rangle\rangle \\ h & \mapsto & h \end{array}$$

is also a monomorphism.

We now return to topological spaces. The following theorem can be considered a sibling of the Seifert-van Kampen Theorem 14.1.

Theorem 17.2. (HNN-Seifert-van Kampen Theorem) *Let X be a path-connected topological space, let A and B be two open path-connected subsets of X and let $f \colon A \to B$ be a homeomorphism. We pick a base point $x \in A$ and we pick a path γ in X from x to $f(x)$. We write $\Gamma = \pi_1(A, x)$. Furthermore we denote by*

$$\alpha \colon \Gamma = \pi_1(A, x) \ \to \ \pi_1(X, x)$$

the inclusion induced map and we denote by

$$\beta \colon \Gamma = \pi_1(A, x) \ \xrightarrow{f_*} \ \pi_1(B, f(x)) \ \to \ \pi_1(X, f(x)) \ \xrightarrow{\gamma_*} \ \pi_1(X, x)$$

the concatenation of the maps induced by f, the inclusion and the base point change isomorphism from Proposition 5.11, using the path γ. Then there exists an isomorphism

$$\Phi \colon \pi_1(X(f), x) \ \xrightarrow{\cong} \ \langle \pi_1(X, x), t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle.$$

which has the following two properties:

---

[401] As a reality check, here is the calculation that the given map is indeed a homomorphism: let (g, m) and (h, n) be two elements in $\pi \rtimes_\beta \mathbb{Z}$, then

$$\begin{array}{rcl} \Phi(g,m)\Phi(h,n) \ = \ gt^{-m} \cdot ht^{-n} \ \underset{\substack{\uparrow \\ \text{since } h = \alpha(h) = t\beta(h)t^{-1} = t \cdot t\beta(\beta(h))t^{-1} \cdot t^{-1} = \dots}}{=} \ gt^{-m} \cdot t^m\beta^m(h)t^{-m} \cdot t^{-n} \ = \ g\beta^m(h)t^{-m-n} & = & \Phi(g\beta^m(h), m+n) \\ & = & \Phi((g,m)(h,n)). \end{array}$$

This shows that Φ is indeed a homomorphism.

(1) *The diagram*

$$\begin{tikzcd} & \pi_1(X,x) \arrow[dl] \arrow[dr] & \\ \pi_1(X(f),x) \arrow[rr, "\Phi"] & & \langle \pi_1(X,x), t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1}\rangle \end{tikzcd}$$

with the obvious diagonal maps commutes.

(2) *The closed loop in $X(f)$ defined by γ corresponds under the isomorphism Φ to t.*

Example. As on page 509 we consider the surface X that is given by removing two open disks from a torus. We refer to the two boundary components as A and B. We equip A and B with the orientations given in Figure 310. We pick a diffeomorphism $f\colon A \to B$ that preserves the orientation. Then $X(f)$ is the surface of genus two.

We pick a base point $x \in A$. We pick a loop a in (A,x) we pick loops c,d in (X,x), a path γ in X from x to $f(x)$ and a loop b in $(B,f(x))$ as indicated indicated in Figure 310. Finally we write $\tilde{b} = \gamma * b * \overline{\gamma}$. By Lemma 14.19 and as in the proof of Lemma 16.6 we have an isomorphism

$$\pi_1(X) \;=\; \langle c,d,a,\tilde{b} \mid a = [c,d]\cdot\tilde{b}\rangle.$$

We write $\Gamma = \pi_1(A,x)$. Note that $\Gamma = \langle a\rangle$ and $\alpha(a) = a$ and $\beta(a) = \tilde{b}$. It follows from Theorem 17.2 and the remark on page 510 that

$$\begin{array}{ccccc} \pi_1(X(f),x) & \underset{\substack{\uparrow \\ \text{Theorem 17.2}}}{\cong} & \langle \pi_1(X), t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1}\rangle & \underset{\substack{\uparrow \\ \text{remark on page 510}}}{=} & \langle c,d,a,\tilde{b},t \mid a = [c,d]\cdot\tilde{b}, a = t\tilde{b}t^{-1}\rangle \\ & \underset{\substack{\uparrow \\ \text{Tietze transformations}}}{=} & \langle c,d,\tilde{b},t \mid [c,d]\cdot\tilde{b} = t\tilde{b}t^{-1}\rangle & = & \langle c,d,\tilde{b},t \mid \underbrace{[c,d]\cdot\tilde{b}t\tilde{b}^{-1}t^{-1}}_{=[c,d][\tilde{b},t]}\rangle \end{array}$$

Thus we have now obtained the same presentation that we had already obtained in Proposition 14.3.

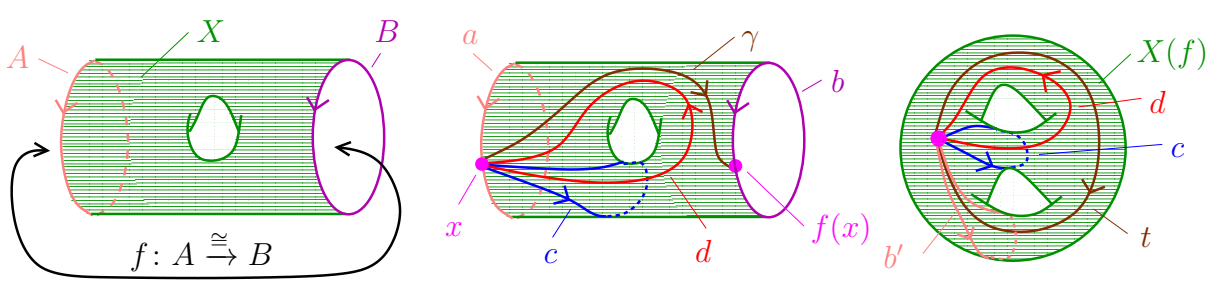

FIGURE 310.

Sketch of the proof of Theorem 17.2(∗). [402] Let X be a path-connected topological space, let A and B be two open path-connected subsets of X and let $f\colon A \to B$ be a homeomorphism. We pick a base point $x \in A$ and we pick a path γ in X from x to $f(x)$. For $i \in \mathbb{Z}$ we now define $X_i := X \times \{i\}$, $A_i := A \times \{i\}$, $B_i := B \times \{i\}$ and $x_i := \{x\} \times \{i\}$. Furthermore we define

$$\widetilde{X} \;:=\; \Big(\bigcup_{i\in\mathbb{Z}} X_i\Big) \,/\, (a,i) \sim (f(a), i-1) \qquad \text{for } a \in A \text{ and } i \in \mathbb{Z}.$$

There is an obvious action of $\mathbb{Z}$ on $\widetilde{X}$ given by $n \cdot [(x,i)] := [(x, i+n)]$ for $(x,i) \in X_i$. It is straightforward to see that this action is discrete and continuous. It follows easily from the definitions that the map

$$\begin{array}{rcl} \Phi\colon X(f) & \to & \widetilde{X}/\mathbb{Z} \\ [x] & \mapsto & [(x,0)] \end{array}$$

is a homeomorphism. We refer to Figure 311 for an illustration.

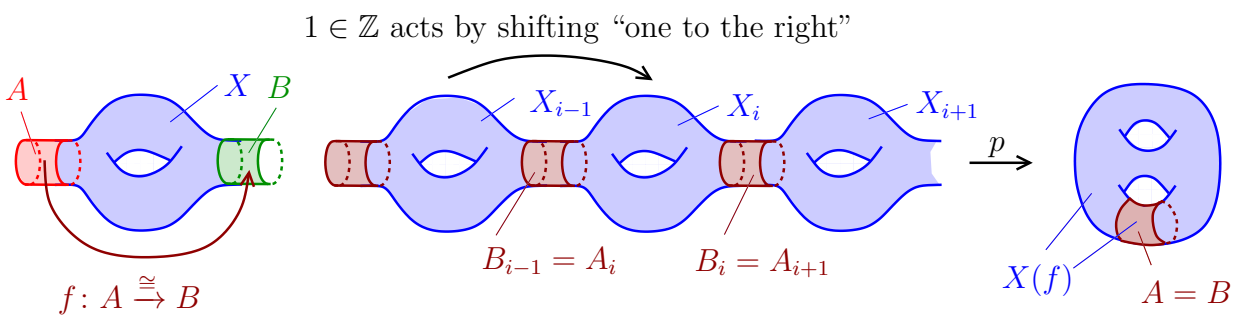

FIGURE 311.

Given $i \in \mathbb{Z}$ we write $\pi_i := \pi_1(X_i, x_i)$ and $\Gamma_i = \pi_1(A_i, x_i)$.

Claim. There exists an isomorphism[403]

$$\pi_1(\widetilde{X}) \;\cong\; \ldots \pi_{-2} \underset{\Gamma_{-1}}{*} \pi_{-1} \underset{\Gamma_0}{*} \pi_0 \underset{\Gamma_1}{*} \pi_1 \underset{\Gamma_2}{*} \pi_2 \ldots$$

Given any $n \in \mathbb{N}$ we write

$$\widetilde{X}_n \;:=\; \Big(\bigcup_{i=-n}^{n} X_i\Big) \,/\, (a,i) \sim (f(a), i-1) \qquad \text{for } a \in A, i \in \{-n+1, \ldots, n\}.$$

It follows from the Seifert-van Kampen Theorem 14.1 applied iteratively $2n$ times that

$$\pi_1\big(\widetilde{X}_n\big) \;\cong\; \pi_{-n} \underset{\Gamma_{-n+1}}{*} \pi_{-n+1} \ldots \pi_{n-1} \underset{\Gamma_n}{*} \pi_n.$$

[402] As we saw on pages 510 and 511, we can view Theorem 17.2 as a generalization of Proposition 15.25. In fact the subsequent proof is partly modelled on the proof of Proposition 15.25.

[403] This claim is somewhat imprecise, we do not explain what exactly we mean by "…" and we are not careful with the base points. This is one reason why this argument is referred to as a "sketch" of a proof.

Now we see that

$$\pi_1\big(\widetilde{X}\big) \;=\; \pi_1\big(\lim_{\longrightarrow}\widetilde{X}_n\big) \;\underset{\substack{\uparrow\\ \text{Proposition 16.4}}}{=}\; \lim_{\longrightarrow}\pi_1\big(\widetilde{X}_n\big) \;\underset{\substack{\uparrow\\ \text{above calculation}}}{=}\; \dots\pi_{-2}\underset{\Gamma_{-1}}{*}\pi_{-1}\underset{\Gamma_0}{*}\pi_0\underset{\Gamma_1}{*}\pi_1\underset{\Gamma_2}{*}\pi_2\dots$$

This concludes the proof of the claim.

Now we denote by φ the automorphism of the infinite amalgamated product of the claim that "shifts every term by one to the right". Then we obtain an isomorphism[404]

$$\pi_1(X) \;\overset{\substack{\text{above homeomorphism}\\ \downarrow}}{\cong}\; \pi_1\big(\widetilde{X}/\mathbb{Z}\big) \;\overset{\substack{\text{Lemma 15.24 and the above claim}\\ \downarrow}}{\cong}\; \big(\dots\pi_{-1}\underset{\Gamma_0}{*}\pi_0\underset{\Gamma_1}{*}\pi_1\dots\big)\rtimes_\varphi\mathbb{Z} \;\overset{\cong}{\to}\; \langle\pi_1(X,x),t\mid\alpha(\Gamma)=t\beta(\Gamma)t^{-1}\rangle$$
$$(g_i,n) \;\mapsto\; gt^{-i}\cdot t^n,\ \text{where } g_i\in\pi_i$$

□

Remark. One of the key inputs in the proof of Theorem 17.2 was the Seifert-van Kampen Theorem 14.1. If we use instead the Seifert-van Kampen Theorem for manifolds, see Theorem 14.2, then we obtain a "manifold version" of Theorem 17.2. We leave it as an exercise to formulate that version and to make the necessary changes to the proof.

In many situations the following corollary to the HNN-Seifert-van Kampen Theorem 17.2 is quite useful.

Corollary 17.3. *Let X be a topological space which can be written as a union $X = Y\cup Z$ such that the following conditions are satisfied:*

(1) *Y and Z are open subsets,*
(2) *Y is path-connected,*
(3) *Z is simply connected,*
(4) *$Y\cap Z$ consists of two simply-connected path components A and B, each of which is open in X.*

Let y be a point in Y and let γ be the concatenation of a path in Y from y to a point $a\in A$, a path in Z from a to a point $b\in B$ and a path in Y from b to y. Then the map

$$\pi_1(Y,y)*\langle t\rangle \;\to\; \pi_1(X,y)$$

that is given by the inclusion induced map $\pi_1(Y,y)\to\pi_1(X,y)$ and given by $t\mapsto[\gamma]$ is an isomorphism.

Example. We consider the topological space X that is obtained from "gluing an interval"" to the torus. Using the notation from Figure 313 one can show quite easily, using Corollary 17.3 that $\pi_1(X,x_0)\cong\langle x,y,t\,|\,[x,y]\rangle\cong\mathbb{Z}^2*\langle t\rangle$. We will work out the details of this example in Exercise 17.1.

[404]Here we also skip many details.

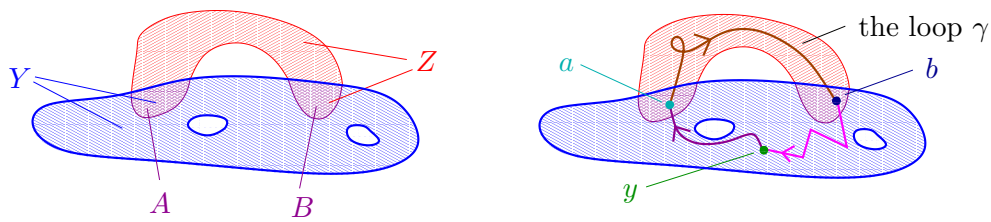

FIGURE 312.

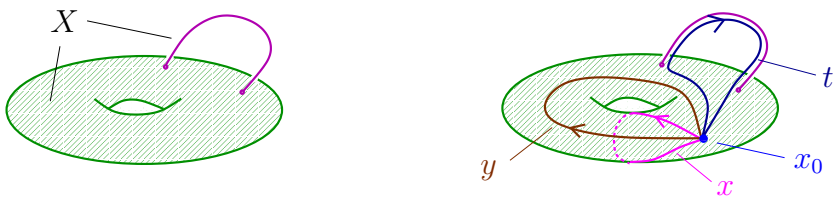

FIGURE 313.

Proof. Let Z' be a disjoint copy of Z (e.g. we could set $Z' = Z \times \{0\}$). We consider $X' = (Y \sqcup Z')/a \sim a'$ where we identify each point $a \in A$ with the corresponding point in Z'. It follows from our hypothesis that A, Y, Z are open in X that Y and Z' are open subsets of X'. Thus we can apply Seifert-van Kampen Theorem 12.2. Since $Z = Z'$ and A are simply connected we obtain that the inclusion induced map $\pi_1(Y, y) \to \pi_1(X', y)$ is an isomorphism.

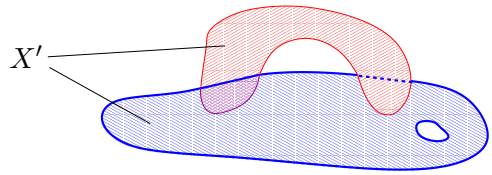

FIGURE 314. Illustration for the proof of Corollary 17.3.

We denote by B' the copy of B in Z' and thus also the copy in X'. Thus we see that we see that B and its doppelgänger B' are contained in X'. If $f\colon B' \to B$ is the obvious homeomorphism, then the desired statement follows immediately from our hypothesis that $B = B'$ is simply connected and the HNN-Seifert-van Kampen Theorem 17.2. $\square$

We conclude this chapter with the following lemma.

Lemma 17.4. $(*)$ *Let $n \in \mathbb{N}$ and let M be the 2-sphere with n open disks removed. We enumerate the boundary components by $C_1, \ldots, C_n$. For $i = 1, \ldots, n$ we pick a path $\beta_i\colon [0,1] \to C_i$ that goes one around C_i. We pick a base point $* \in M \setminus \partial M$. We pick paths $\alpha_1, \ldots, \alpha_n\colon [0,1] \to M$ with the following properties:*

(1) *each* α_i *is an embedding,*
(2) *each* α_i *is a path from* $*$ *to the point* $\beta_i(0)$*,*
(3) *for each* i *we have* $\alpha_i([0,1)) \subset M \setminus \partial M$*,*
(4) *the images of the paths only intersect at* $*$*.*

For any $j \in \{1, \dots, n\}$ *the homomorphism*

$$\begin{array}{rcl} \langle y_1, \dots, y_{j-1}, y_{j+1}, \dots, y_n \rangle & \to & \pi_1(M, *) \\ y_i & \mapsto & [\alpha_i * \beta_i * \overline{\alpha_i}] \end{array}$$

is an isomorphism.

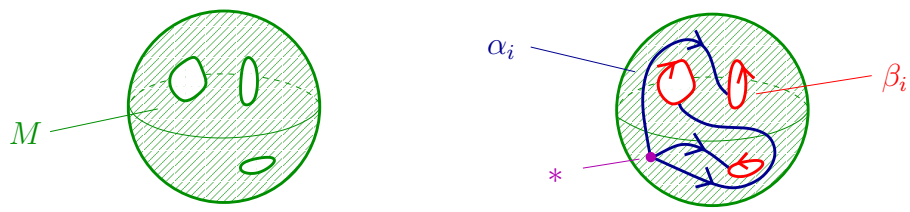

FIGURE 315. Illustration of Lemma 17.4.

Remark.

(1) This proposition should ring a bell, it sounds quite like Lemma 14.19. The difference is that in Lemma 14.19 we only said that certain paths β_i such that the given map is an isomorphism. The above lemma gives a more precise statement what type of paths work.
(2) One might think that perhaps one can use any old paths α_i to obtain a basis for the free group $\pi_1(M, *)$. But as we will see in Exercise 17.3, this is not the case.

We conclude this chapter with a sketch of a proof of Lemma 17.4. Perhaps the most friendly words that can be uttered regarding the proof are that the proof shows that it can be quite hard to write down rigorous arguments once one leaves the friendly word of submanifolds and instead tries to deal with more general subsets.

Sketch of a proof. Without loss of generality we can assume that $j = n$. We consider $N := M \setminus \alpha_n([0,1])$. This is an open subset of the manifold M, thus N itself is a manifold. Furthermore by Exercise 64.2 we know that the inclusion $M \setminus \alpha_n([0,1]) \to M$ is a homotopy equivalence.[405] For $i = 1, \dots, n-1$ we write $X_i := \alpha_i((0,1]) \subset N$. It follows from (1) and

[405]The alert reader will not have failed to notice that we are referring to an exercise that is dealt with later in the notes. Fortunately we do not need to be afraid of circular logic. The exercise builds on an extension of the Tubular Neighborhood Theorem 10.19 to submanifolds with boundary. This formulation, see Theorem 64.7, is just a little awkward and was thus postponed to later on. But if one uses a naive extension of the Tubular Neighborhood Theorem 10.19 to the case of submanifolds with boundary, then one can easily prove Exercise 64.2 with our present knowledge.

Proposition 10.1 (1) that $X = X_1 \cup \cdots \cup X_{n-1}$ is a submanifold of N. By the Tubular Neighborhood Theorem 10.19 we can pick a tubular neighborhood $[-1,1] \times X$. We write $W := N \setminus (-1,1) \times X$, we pick a base point $\star \in W$ and we pick path p in M from $*$ to $\star$.

Using Corollary 17.3 one can prove[406] the following:

(1) there exists loops $\eta_1, \ldots, \eta_{n-1}$ in $(N, \star)$ such that the obvious map

$$\pi_1(W, \star) * \langle [\eta_1], \ldots, [\eta_{n-1}] \rangle \ \to \ \pi_1(N, \star)$$

is an isomorphism,

(2) for each $i \in \{1, \ldots, n-1\}$ the loop $p * \eta_i * \overline{p}$ is path-homotopic to $\alpha_i * \beta_i * \overline{\alpha_i}$.

Putting everything together we see that we have an isomorphism

$$\pi_1(W) * \langle [\alpha_1 * \beta_1 * \overline{\alpha_1}], \ldots, [\alpha_{n-1} * \beta_{n-1} * \overline{\alpha_{n-1}}] \rangle \ \xrightarrow{\cong} \ \pi_1(M).$$

By Lemma 14.19 we know that the right-hand side is a free group of rank $n-1$. It follows from the Grushko-Neumann Theorem 11.18 that $\pi_1(W)$ is trivial. We have thus obtained the desired isomorphism.[407] □

Exercises for Chapter 17.

Exercise 17.1. Give full details for the calculation of the fundamental group of the topological space shown in Figure 313.

Exercise 17.2. Let X be a path-connected topological space. Furthermore let $f \colon X \to X$ be a homeomorphism. In Proposition 15.25 we saw that there exists an isomorphism $\psi \colon \pi_1(M(X,f)) \cong \pi_1(X) \rtimes \mathbb{Z}$. Give an alternative proof of this statement using the HNN-Seifert-van Kampen Theorem 17.2.

Exercise 17.3. We consider the permutation group S_4 where given $\alpha, \beta \in S_4$ we write $\alpha \cdot \beta = \alpha \circ \beta$. We consider the cycles[408]

$$\sigma = (1\,2\,3\,4) = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 2 & 3 & 4 & 1 \end{pmatrix}, \ \mu = (1\,2) = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 2 & 1 & 3 & 4 \end{pmatrix} \ \text{ and } \nu = (1\,3) = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 3 & 2 & 1 & 4 \end{pmatrix}.$$

(a) Show that σ and μ form a generating set for S_4.

---

[406] Here is the point where the demanding reader might feel that not enough details are provided.

[407] The esthetically-inclined reader might object to the use of the Grushko-Neumann Theorem 11.18. But any other approach also opens up a can of worms. For example one might be tempted to show that W is contractible.

[408] Recall that for pairwise disjoint $a_1, \ldots, a_k \in \{1, \ldots, n\}$ we denote by $(a_1\ a_2\ \ldots\ a_k) \in S_n$ the permutation that is given by

$$\begin{array}{rcl} \{1,\ldots,n\} & \to & \{1,\ldots,n\} \\ m & \mapsto & \begin{cases} a_{i+1}, & \text{if } m = a_i \text{ for some } i \in \{1,\ldots,k-1\}, \\ a_1 & \text{if } m = a_k, \\ m, & \text{otherwise.} \end{cases} \end{array}$$

Put differently, the numbers $(a_1, \ldots, a_k)$ get cyclically permuted and all other numbers stay the same.

(b) Show that σ and ν do not form a generating set for S_4.
(c) Show that $(\mu \cdot \sigma) \cdot \mu \cdot (\mu \cdot \sigma)^{-1} = \nu$.
(d) Show that the endomorphism $\langle x, y\rangle \to \langle x, y\rangle$ that is given by $x \mapsto (yx)^{-1}x(yx)$ and $y \mapsto y$ is not an isomorphism.
(e) We consider M which is defined as the disk $\overline{B}^2$ minus two open disks[409] We consider the base point $*$ and the curves β_1 and β_2 as shown in Figure 316. Show that for $i = 1, 2$ there exist paths α_i from $*$ to the starting point of β_i such that $[\alpha_1 * \beta_1 * \overline{\alpha_1}]$ and $[\alpha_2 * \beta_2 * \overline{\alpha_2}]$ do *not* form a generating set for $\pi_1(M, *)$.

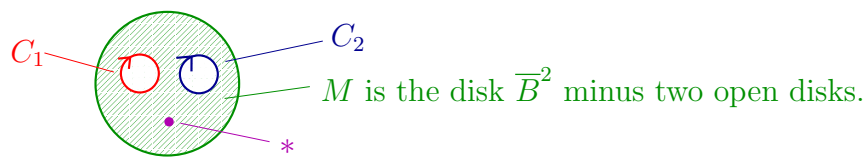

FIGURE 316.

[409]It follows easily from stereographic projection that M is diffeomorphic to S^2 minus three open disks.

18. An excursion into knot theory

In this chapter we will study the fundamental groups of the complements of knots. In particular we will use these calculations to show that the trivial knot, the trefoil and the figure-8 knot are pairwise different, i.e. pairwise they are not smoothly isotopic.

18.1. **One more avatar of the 3-sphere.** We first recall that we have different descriptions of the 3-dimensional sphere S^3, i.e. we have

$$S^3 = \big\{(w,x,y,z)\,\big|\,w^2+x^2+y^2+z^2=1\big\} = \big\{(z,w)\in\mathbb{C}^2\,\big|\,|w|^2+|z|^2=1\big\} \underset{\substack{\uparrow \\ \text{via the stereographic projection as defined in Lemma 1.41} \\ \text{note that in Exercise 3.5 we saw that this map} \\ \text{is (lucky us!) orientation-preserving}}}{=} \mathbb{R}^3\cup\{\infty\}.$$

Furthermore, on page 116 we had given a canonical homeomorphism

$$(\overline{B}^2\times S^1)\sqcup_{S^1\times S^1}(S^1\times\overline{B}^2)\ \xrightarrow{\cong}\ S^3.$$

Even though the homeomorphism is canonical, it is not particularly explicit. Furthermore it has the disadvantage that, if one looks up the definition, one sees that the restriction to the two solid tori on the left is not smooth. The following lemma rectifies these two problems.

Lemma 18.1. *We consider the following two maps*[410]

$$\begin{aligned}\Phi\colon \overline{B}^2\times S^1 &\to A := \big\{(z,w)\in\mathbb{C}^2\,\big|\,|w|^2+|z|^2=1 \text{ and } |z|^2\geq\tfrac12\big\}\\ (a,b) &\mapsto \left(\frac{b}{\sqrt{|a|^2+|b|^2}},\frac{a}{\sqrt{|a|^2+|b|^2}}\right)\end{aligned}$$

and

$$\begin{aligned}\Psi\colon S^1\times\overline{B}^2 &\to B := \big\{(z,w)\in\mathbb{C}^2\,\big|\,|w|^2+|z|^2=1 \text{ and } |w|^2\geq\tfrac12\big\}\\ (a,b) &\mapsto \left(\frac{b}{\sqrt{|a|^2+|b|^2}},\frac{a}{\sqrt{|a|^2+|b|^2}}\right).\end{aligned}$$

These maps have the following properties:

(1) *The maps $\Phi\colon\overline{B}^2\times S^1\to A$ and $\Phi\colon S^1\times\overline{B}^2\to B$ are orientation-preserving diffeomorphisms.*[411]

(2) *The map*

$$\begin{aligned}\Theta\colon (\overline{B}^2\times S^1)\sqcup_{S^1\times S^1}(S^1\times\overline{B}^2) &\to S^3\\ [P] &\mapsto \begin{cases}\Phi(P), & \text{if } P\in\overline{B}^2\times S^1,\\ \Psi(P), & \text{if } P\in S^1\times\overline{B}^2\end{cases}\end{aligned}$$

is well-defined and it is a homeomorphism.

[410]The flipping of the order of the coordinates is not a typo but it is in fact done on purpose.

[411]Note that A and B are submanifolds of codimension zero of the oriented manifold S^3, thus they inherit an orientation from S^3.

(3) *The submanifolds A and B of S^3 have the following properties:*
   (a) *A and B are diffeomorphic to the solid torus $S^1 \times \overline{B}^2$,*
   (b) *$S^3 = A \cup B$,*
   (c) *$A \cap B = \partial A = \partial B$ is a torus, i.e. diffeomorphic to $S^1 \times S^1$.*

Convention. We use the homeomorphism Θ from Lemma 18.1 (2) to add the topological space $(\overline{B}^2 \times S^1) \sqcup_{S^1 \times S^1} (S^1 \times \overline{B}^2)$ to our list of avatars of S^3.

Remark. We continue with the notation from Lemma 18.1 but we now view A and B as subsets of $S^3 = \mathbb{R}^3 \cup \{\infty\}$. In this setting we have

$$\text{“central curve of } A\text{”} \;=\; \Phi(\{0\} \times S^1) \;=\; S^1 \times \{0\} \;=\; \text{the trivial knot}$$

and we have

$$\text{“central curve of } B\text{”} \;=\; \Psi(S^1 \times \{0\}) \;=\; \text{the } z\text{-axis} \cup \{\infty\}.$$

We visualize the solid torus A and the central curve of the solid torus B in Figure 317. The solid torus B is more difficult to illustrate. It consists of a closed disk attached to each point on the central curve. For example the closed disk attached to the origin is just the “obvious” closed disk in the xy-plane that touches the torus $\Phi(S^1 \times S^1)$.[412]

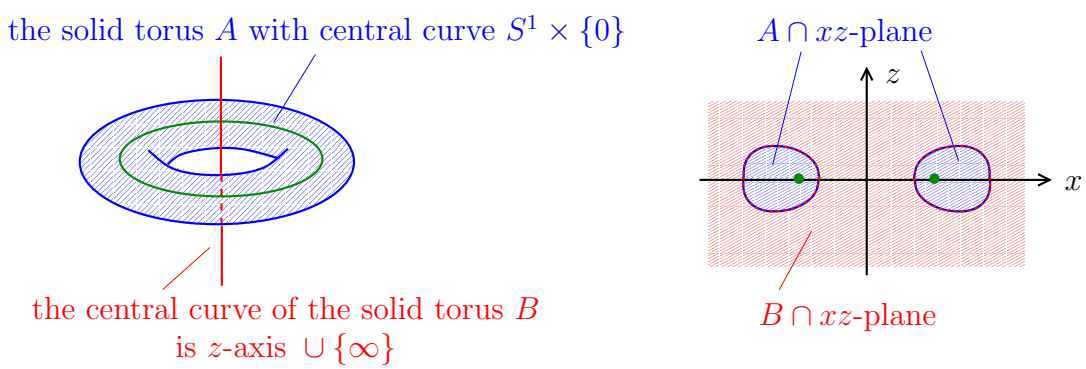

FIGURE 317.

Sketch of proof $(*)$.

(1) First we show that the map $\Phi\colon \overline{B}^2 \times S^1 \to A$ is an orientation-preserving diffeomorphism. We leave it to the reader to verify that the image of Φ does indeed lie in A. Next we consider the map

$$\begin{aligned} \widetilde{\Phi}\colon A = \left\{(z,w) \in \mathbb{C}^2 \,\middle|\, |w|^2 + |z|^2 = 1 \text{ and } |z|^2 \geq \tfrac{1}{2}\right\} &\to \overline{B}^2 \times S^1 \\ (z,w) &\mapsto \left(\tfrac{w}{|z|}, \tfrac{z}{|z|}\right). \end{aligned}$$

One can easily verify that $\widetilde{\Phi}$ and Φ are inverses of one another and that Φ and $\widetilde{\Phi}$ are smooth. This observation implies that $\Phi\colon \overline{B}^2 \times S^1 \to A$ is a diffeomorphism. It

[412] What is the disk attached to the point ∞?

remains to show that Φ is orientation-preserving. By Lemma 3.37 it suffices to show that at the point $(0,1) \in \overline{B}^2 \times S^1$ the differential $D\Phi_{(0,1)}$ is orientation-preserving. This can be done by hand easily. Almost the same argument shows that the map $\Psi\colon S^1 \times \overline{B}^2 \to B$ is an orientation-preserving diffeomorphism.

(2) It is clear that Φ and Ψ agree on $S^1 \times S^1$. Therefore it follows from Lemma 1.66 that the given map $\Theta\colon (\overline{B}^2 \times S^1) \sqcup_{S^1 \times S^1} (S^1 \times \overline{B}^2) \to S^3$ is well-defined and continuous. Using (1) one easily verifies that the map is a bijection. It follows from Proposition 1.40 that the map Θ is a homeomorphism.

(3) The last statement is an immediate consequence of (1) and (2). □

Lemma 1.58 and Lemma 18.1 give us two embeddings of the 2-dimensional torus $S^1 \times S^1$ into $\mathbb{R}^3$. The following lemma says that these two embeddings are essentially the same.

Lemma 18.2. $(*)$ *We denote by $\Omega\colon S^3 \setminus \{(0,1)\} \to \mathbb{R}^3$ the stereographic projection as defined in Lemma 1.41. We consider the two embeddings*[413]

$$\begin{array}{rcl} \overline{B}^2 \times S^1 & \xrightarrow{\Theta} & \mathbb{R}^3 \\ ((x,y), e^{i\varphi}) & \mapsto & \begin{pmatrix} \cos\varphi & -\sin\varphi & 0 \\ \sin\varphi & \cos\varphi & 0 \\ 0 & 0 & 1 \end{pmatrix} \cdot \begin{pmatrix} 1+\frac{x}{2} \\ 0 \\ -\frac{y}{2} \end{pmatrix} \end{array} \quad \textit{and} \quad \begin{array}{rcl} \overline{B}^2 \times S^1 & \xrightarrow{\Phi} & S^3 \setminus \{(0,1)\} \xrightarrow{\Omega} \mathbb{R}^3 \\ (z,w) & \mapsto & \left(\frac{w}{\sqrt{|z|^2+|w|^2}}, \frac{z}{\sqrt{|z|^2+|w|^2}} \right) \end{array}$$

provided by Lemma 1.58 and provided by Lemma 18.1. There exists a smooth diffeotopy G of S^3 rel $\{(0,0)\} \times S^1$ with $G_0 = \mathrm{id}$ and $G_1 \circ \Theta = \Omega \circ \Phi$.

Convention. In all the future examples we will not distinguish between the two embeddings of the solid torus $\overline{B}^2 \times S^1 \to \mathbb{R}^3$ that are given in Lemma 18.2.

Sketch of proof $(*)$. By the Isotopy Extension Theorem 10.21 it suffices to show that there exists a smooth isotopy rel $\{(0,0)\} \times S^1$ from Θ to $\Omega \circ \Phi$.

We write $H = \{(x,0,z) \in \mathbb{R}^3 \,|\, x > 0\}$. Let us first consider the restrictions of Θ and $\Omega \circ \Phi$ to the disk $\overline{B}^2 \times \{1\}$. In both cases the image lies in H. These maps are illustrated in Figure 318. We leave it to the dear reader to show that there exists a smooth isotopy $F\colon \overline{B}^2 \times \{1\} \times [0,1] \to H$ rel $\{(0,0,1)\}$ from Θ to $\Omega \circ \Phi$.

The desired isotopy is given by "rotating F" around the z-axis. Slightly more precisely it is given by the map

$$\begin{array}{rcl} \overline{B}^2 \times S^1 \times [0,1] & \to & \mathbb{R}^3 \\ ((x,y), e^{i\varphi}, t) & \mapsto & \text{rotation of } F((x,y),t) \in \mathbb{R}^3 \text{ by } \varphi \text{ around the } z\text{-axis.} \end{array}$$ □

18.2. **The fundamental group of the complement of the trefoil.** Now we want to finally turn to the study of knots. In particular we would like to study the knots that are illustrated in Figure 319. In Question 10.31 we had raised the question, how can one show that the trefoil is not trivial?

[413] As a reality check note that it follows from Lemma 1.41 that Θ and $\Omega \circ \Phi$ agree on $\{(0,0)\} \times S^1$.

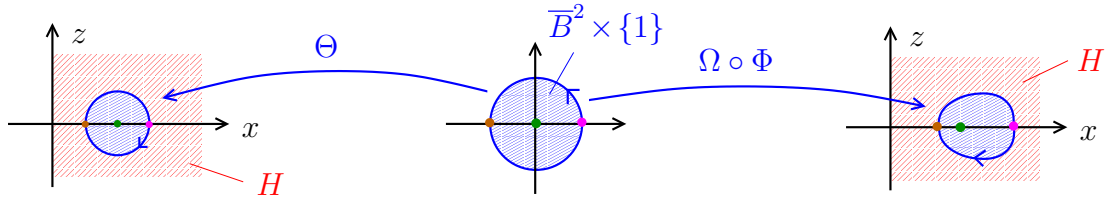

FIGURE 318. Illustration for the proof of Lemma 18.2.

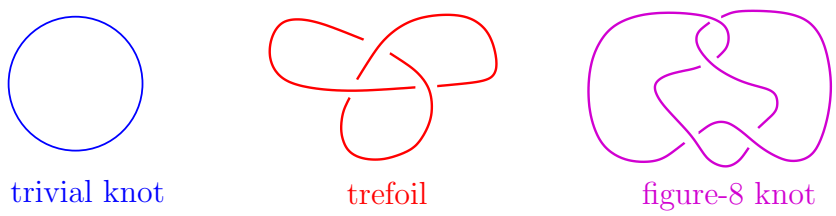

FIGURE 319. The trivial knot, the trefoil knot and the figure-8 knot.

Now we have some tools to attack this question. We saw in Proposition 10.33 that if K and J are smoothly isotopic knots, then the knot complements $S^3 \setminus K$ and $S^3 \setminus J$ are diffeomorphic. In particular if $\pi_1(S^3 \setminus K)$ and $\pi_1(S^3 \setminus J)$ are not isomorphic, then K and J are not smoothly isotopic. Thus we arrive at the following variation of Question 10.31.

Question 18.3. *Can the fundamental group be used to distinguish the trefoil from the trivial knot?*

Before we continue we want to give a precise description of the trivial knot and the trefoil know. We define the *trivial knot* as the knot[414]

$$U := \{(e^{it}, 0) \mid t \in \mathbb{R}\} \subset \left\{(z, w) \in \mathbb{C}^2 \,\middle|\, |w|^2 + |z|^2 = 1\right\}$$

or equivalently

$$U := \{(\cos t, \sin t, 0) \mid t \in \mathbb{R}\} \subset \mathbb{R}^3 \cup \{\infty\}.$$

Now we want to give a rigorous definition of the trefoil knot. We consider the curve $C = \{(2t, 3t) \mid t \in \mathbb{R}\}$ on the torus $T = [0, 2\pi] \times [0, 2\pi]/\sim$. We define the trefoil K as the image of C under the map

$$\begin{aligned} \Phi\colon T = [0, 2\pi] \times [0, 2\pi]/\sim &\to S^3 \\ (s, t) &\mapsto \left(\tfrac{1}{\sqrt{2}} e^{is}, \tfrac{1}{\sqrt{2}} e^{it}\right). \end{aligned}$$

This definition of the trefoil is illustrated in Figure 320.

Now we turn to the calculation of the fundamental groups of the complements of the trivial knot and the trefoil knot.

[414]The name U comes from the fact that the trivial knot is often also called the *unknot*.

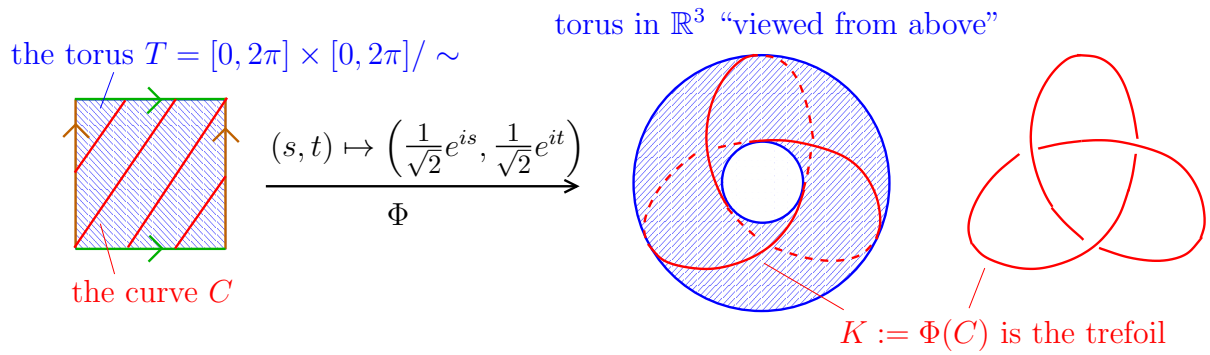

FIGURE 320.

Proposition 18.4. *If U is the trivial knot, then $S^3 \setminus U$ is diffeomorphic to $S^1 \times \mathbb{C}$, in particular $\pi_1(S^3 \setminus U) \cong \mathbb{Z}$.*

Proof. Note that

$$\begin{aligned} S^3 \setminus U &= \{(z,w) \in \mathbb{C}^2 \mid |z|^2 + |w|^2 = 1\} \setminus \{(z,0) \mid |z| = 1\} \\ &= \{(z,w) \in \mathbb{C}^2 \mid |z|^2 + |w|^2 = 1 \text{ and } |w| > 0\}. \end{aligned}$$

Now basically the same argument as in the proof of Lemma 18.1 shows that the map

$$\begin{aligned} \Phi\colon S^1 \times \mathbb{C} &\to S^3 \setminus U = \left\{(z,w) \in \mathbb{C}^2 \,\middle|\, |w|^2 + |z|^2 = 1 \text{ and } |w|^2 > 0\right\} \\ (a,b) &\mapsto \left(\frac{b}{\sqrt{|a|^2+|b|^2}}, \frac{a}{\sqrt{|a|^2+|b|^2}}\right) \end{aligned}$$

is a diffeomorphism. Since $S^1 \times \mathbb{C}$ is homotopy equivalent to S^1 we obtain from the above and from Proposition 9.12 (1) that $\pi_1(S^3 \setminus U) = \pi_1(S^1 \times \mathbb{C}) = \pi_1(S^1) \cong \mathbb{Z}$. □

Remark. Let U be the trivial knot. A careful reading of the proof of Proposition 18.4 shows that a generator of $\pi_1(S^3 \setminus U)$ is given by a meridian that we defined on page 362. We refer to Figure 321 for an illustration of the trivial knot and a meridian.

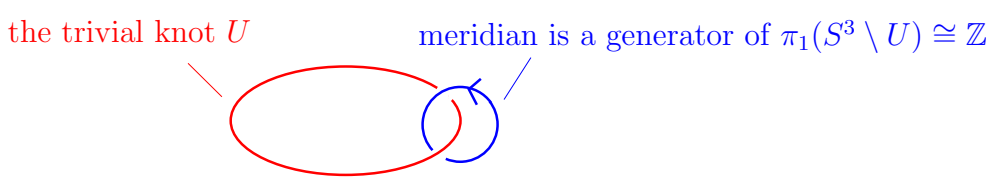

FIGURE 321.

Proposition 18.5. *If K is the trefoil, then*

$$\pi_1(S^3 \setminus K) \cong \langle x, y \mid x^2 = y^3 \rangle.$$

Proof. By Lemma 18.1 there exists a diffeomorphism

$$\Phi\colon S^3 \xrightarrow{\cong} \underbrace{\left(S^1 \times \overline{B}^2\right)}_{=:A} \cup_{S^1\times S^1 = S^1\times S^1} \underbrace{\left(\overline{B}^2 \times S^1\right)}_{=:B}$$

which is, up to scaling by a factor of $\sqrt{2}$, the identity on $T := S^1 \times S^1$. We identify the trefoil with its image under Φ, i.e. we have

$$K \;=\; \{(e^{2si}, e^{3si}) \mid s \in \mathbb{R}\} \;\subset\; T.$$

We write $A_K = A \backslash K, B_K = B \backslash K$ and $T_K = T \backslash K$. Note that A_K and B_K are submanifolds of $X_K := S^3 \setminus K$ and with[415] $A_K \cap B_K = \partial A_k = \partial B_K = T_K$ and with $A_K \cup B_K = X_K$. Note that $x := S^1 \times \{0\}$ is a deformation retract of A_K and that $y := \{0\} \times S^1$ is a deformation retract of B_K. Finally note that T_K retracts onto a parallel copy of K. More precisely, for $\epsilon > 0$ sufficiently small, the subset T_K retracts onto the loop

$$z \;=\; \{(e^{2si+\epsilon}, e^{3si}) \mid s \in \mathbb{R}\} \;\subset\; T_K.$$

By an abuse of notation we denote by x, y and z also the loops corresponding to the circles x, y and z with the obvious orientation. Then the inclusion induced maps

$$\begin{array}{ccccc} \pi_1(A_K) & \leftarrow & \pi_1(T_K) & \rightarrow & \pi_1(B_K) \\ i_*(g) & \leftarrow\!\shortmid & g & \mapsto & j_*(g) \end{array} \quad \text{become} \quad \begin{array}{ccccc} \langle x\rangle & \leftarrow & \langle z\rangle & \rightarrow & \langle y\rangle \\ x^2 & \leftarrow\!\shortmid & z & \mapsto & y^3. \end{array}$$

Thus we see that

$$\begin{array}{ccccccc} \pi_1(X_K) & = & \pi_1(A_K) *_{\pi_1(T_K)} \pi_1(B_K) & \cong & \langle x\rangle *_{x^2=y^3} \langle y\rangle & = & \langle x, y \mid x^2 = y^3\rangle. \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{Seifert-van Kampen Theorem 14.2} & & \text{above discussion} & & \text{Lemma 13.13} & \end{array}$$

□

Now the question is whether or not $\pi_1(S^3 \setminus K) = \langle x, y \mid x^2 = y^3\rangle$ is isomorphic to $\pi_1(S^3 \setminus U) = \mathbb{Z}$. As usual we first consider the abelianization of $\pi_1(S^3 \setminus K)$, but it is straightforward to see, using Proposition 13.10 that the abelianization is isomorphic to $\mathbb{Z}$.[416][417] Despite this slight setback the following lemma does fortunately show that the group $\pi_1(S^3 \setminus K) = \langle x, y \mid x^2 = y^3\rangle$ is not isomorphic to $\pi_1(S^3 \setminus U) = \mathbb{Z}$.

Lemma 18.6.

(1) *The group $\langle x, y \mid x^2 = y^3\rangle$ admits an epimorphism onto the permutation group S_3, in particular the group $\langle x, y \mid x^2 = y^3\rangle$ is not isomorphic to $\mathbb{Z}$.*
(2) *The trefoil is not smoothly equivalent to the trivial knot.*

Proof.

[415] Here we mean by ∂A_K and ∂B_K the boundary of A_K and B_K viewed as submanifolds of S^3.

[416] In fact that is not a coincidence, using homology groups we will soon see that for any knot J the abelianization of $\pi_1(S^3 \setminus J)$ is isomorphic to $\mathbb{Z}$.

[417] If one goes very carefully through the definitions and calculations then one can see that a meridian once again becomes a generator of the abelianization.

(1) It follows from Lemma 13.4 and a straightforward calculation that there exists a unique homomorphism

$$\Phi\colon \langle x, y \mid x^2 = y^3\rangle \quad \to \quad S_3 = \text{permutation group on three elements}$$

with

$$\Phi(x) \quad = \quad \sigma \ := \ (1\,2) \ = \ \begin{pmatrix} 1 & 2 & 3 \\ 2 & 1 & 3 \end{pmatrix}$$

and

$$\Phi(y) \quad = \quad \tau \ := \ (1\,2\,3) \ = \ \begin{pmatrix} 1 & 2 & 3 \\ 2 & 3 & 1 \end{pmatrix}.$$

The permutations σ and τ do not commute, hence the image of Φ is a non-abelian subgroup of S_3.[418] On the other hand the abelian group $\mathbb{Z}$ cannot admit an epimorphism onto an non-abelian group[419].

(2) It follows from (1) and above discussion that the trefoil is non-trivial. □

18.3. **Knot diagrams.** In the previous section we gave a completely rigorous calculation of the isomorphism type of the fundamental group of the complement of a trefoil and we used this to show that the trefoil is not smoothly isotopic to the trivial knot. In the next section we will give a practical algorithm for determining the isomorphism type of the fundamental group of the complement of a given knot. The key to formulating the algorithm is the notion of a knot diagram that we will study in this section.

Before we start with knot theory we introduce one bit of notation.

Notation. Given a smooth map $f\colon S^1 \to \mathbb{R}^n$ and $z = e^{is} \in S^1$ we write

$$f'(z) \ := \ \text{derivative at the point } s \text{ of the function } \mathbb{R} \to \mathbb{R}^n \text{ given by } t \mapsto f(e^{it}).$$

Definition. A map $\gamma\colon S^1 \to \mathbb{R}^2$ is called *diagrammatic* if the following conditions are satisfied:

(a) the map is an immersion,
(b) if $z \neq w \in S^1$ satisfy $\gamma(z) = \gamma(w)$, then $\gamma'(z)$ and $\gamma'(w)$ are linearly independent,
(c) given any $P \in \gamma(S^1)$ the preimage $\gamma^{-1}(P)$ consists of either one or two points.

Furthermore any $z \in S^1$ for which there exists a $w \neq z \in S^1$ with $\gamma(z) = \gamma(w)$ is called a *double point of* γ. The definitions are illustrated in Figure 322.

The following lemma will be proved in Exercise 18.2.

Lemma 18.7. *Every diagrammatic map has only finitely many double points.*

Definition.

[418] In fact it is easy to see that the only non-abelian subgroup of S_3 is S_3 itself, i.e. Φ is an epimorphism onto S_3.

[419] Why not?

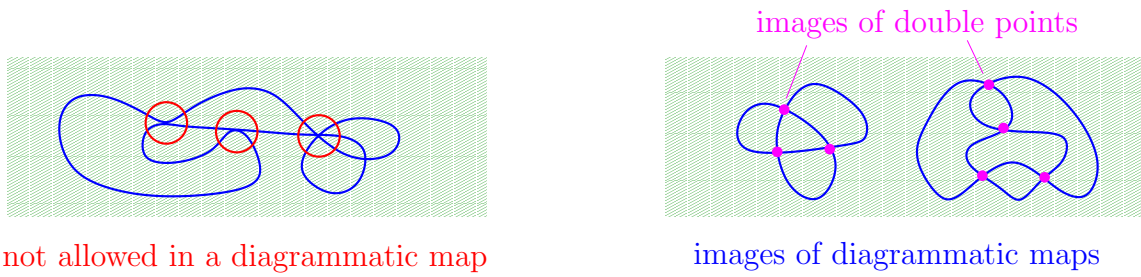

FIGURE 322.

(1) A *knot diagram* is a diagrammatic map $\gamma\colon S^1 \to \mathbb{R}^2$ together with a map
$$c\colon \{\text{double points of } \gamma\} \ \to\ \{\pm 1\}$$
which has the property that for $z \neq w \in S^1$ with $\gamma(z) = \gamma(w)$ we have $c(z) \neq c(w)$.
(2) Let (γ, c) be a knot diagram. Let z be a double point. If $c(z) = +1$, then we say that the double point is an *overcrossing*, otherwise we call it an *undercrossing*.

The next lemma shows that knot diagrams give rise to knots.

Lemma 18.8. *Let $(\gamma\colon S^1 \to \mathbb{R}^2, c)$ be a knot diagram. We can pick disjoint compact segments $I_1, \dots, I_k$ of S^1 and a smooth function $\eta\colon S^1 \to [-1, 0]$ with the following properties:*
(a) *Each segment contains a unique undercrossing and each undercrossing is contained in some segment.*
(b) *No segment contains an overcrossing.*
(c) *The value of η outside the segments is equal to 0.*
(d) *On each segment the function has a unique local minimum, namely at the corresponding undercrossing where the value of η is equal to -1.*

The following two statements hold:
(1) *The image of S^1 under the map $S^1 \to \mathbb{R}^3$ given by $z \mapsto (\gamma(z), \eta(z))$ is a knot.*
(2) *Any two choices of segments and η as above give rise to smoothly isotopic knots.*

If we equip S^1 with the standard orientation, then in the above statements we can also replace "knot" by "oriented knot".

Lemma 18.8 shows that a knot diagram gives rise to an essentially unique (oriented) knot. We refer to this knot as the *knot associated to the knot diagram*. At times we will rather blur the difference between a knot diagram and the associated knot.

Example. In Figure 323 we show to the left a knot diagram. To the right we show the associated knot. It is pretty clear that the resulting knot is smoothly isotopic to the trefoil.

Proof. It follows quite easily from Lemma 3.12 that such segments $I_1, \dots, I_k$ and that such a function η exist. Given such a function it is clear that the map $z \mapsto (\gamma(z), \eta(z))$ is injective. Since γ is an immersion it follows that the map $z \mapsto (\gamma(z), \eta(z))$ is in fact an

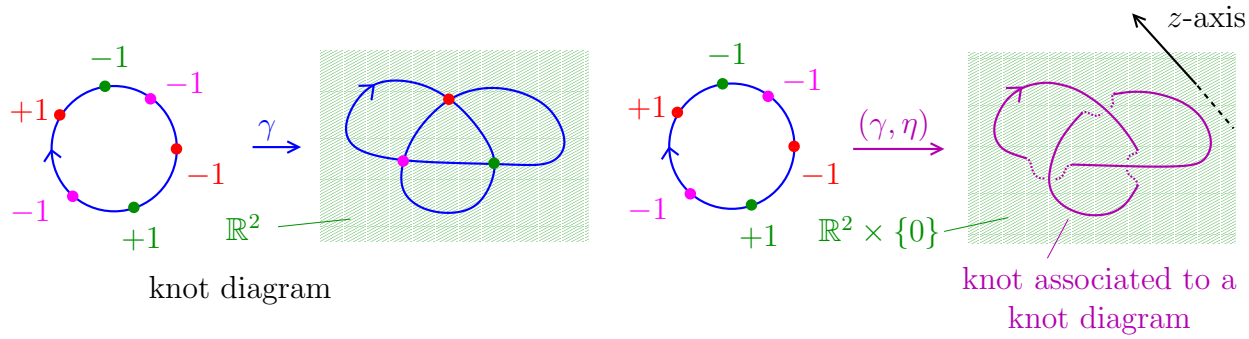

FIGURE 323.

embedding. Thus it follows from Proposition 10.1 (1) that the image is a one-dimensional submanifold of $\mathbb{R}^3 \cup \{\infty\} = S^3$ that is diffeomorphic to S^1. In other words, the image is a knot.

Finally suppose we are given functions η and η' with the properties stated as above. We consider the map

$$\begin{array}{rcl} H\colon S^1 \times [0,1] & \to & \mathbb{R}^3 \cup \{\infty\} = S^3 \\ (z,t) & \mapsto & (\gamma(z), \eta(z) \cdot (1-t) + \eta'(z) \cdot t). \end{array}$$

This map is smooth. By construction we know that for any two distinct points $z, w \in S^1$ with $\gamma(z) = \gamma(w)$ we have $\eta(z) < \eta(w)$ if and only if $c(z) = -1$ if and only if $\eta'(z) < \eta'(w)$. Using this observation one can easily verify that each H_t is an embedding. In other words, the map H_t is a smooth isotopy between the two (oriented) knots corresponding to η and η'. $\square$

In practice, i.e. in future examples, we do what every other sane topologist does, namely we draw a suggestive picture and we interpret it as a knot diagram and a corresponding knot in the obvious way. For example in Figure 324 we show the first knots in the standard table of knots. We refer to the standard textbooks on knot theory [Rol, BZH] for a continuation of the table. But it should already be pretty clear from this table that knots form a straightforward way to produce an almost endless list of interesting topological problems.

In Lemma 18.8 we saw that any knot diagram gives rise to a knot. The following proposition gives us the converse:

Proposition 18.9. *Given any knot $K \subset S^3$ there exists a knot diagram such that K is smoothly isotopic to the knot associated to the knot diagram.*

The proof of Proposition 18.9 mostly rests on the next lemma. The formulation of this lemma requires the following notation.

Notation. Given $v \in S^2$ we denote by

$$\begin{array}{rcl} \pi_v\colon \mathbb{R}^3 & \to & v^\perp := \{w \in \mathbb{R}^3 \mid \langle v, w\rangle = 0\} \\ w & \mapsto & w - \langle v, w\rangle v \end{array}$$

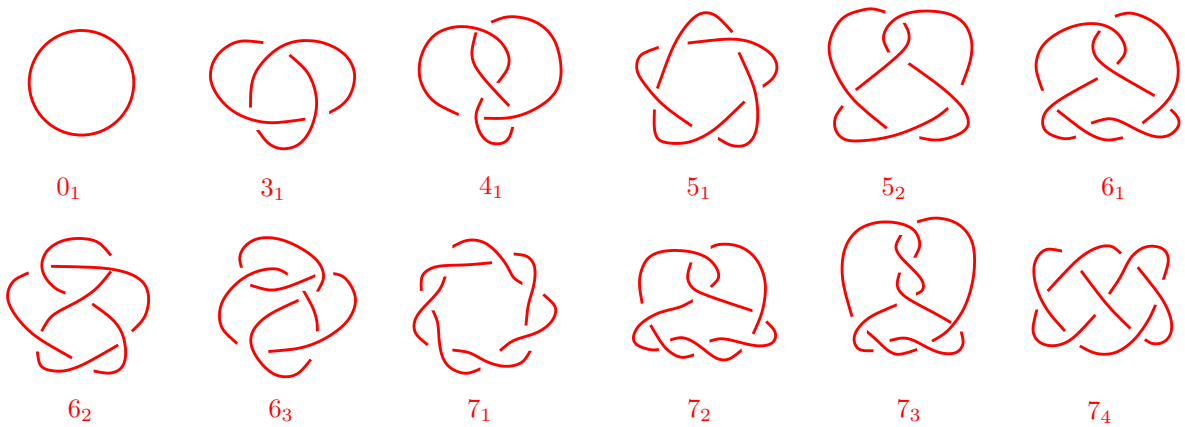

FIGURE 324.

the projection onto the orthogonal complement of v.

Now we can formulate the lemma.

Lemma 18.10. *Let $K \subset \mathbb{R}^3$ be a knot. We pick a diffeomorphism $f\colon S^1 \to K$. We consider the following three properties of a vector $v \in S^2$:*

(a) *the map $\pi_v \circ f\colon S^1 \to v^\perp = \{w \in \mathbb{R}^3 \mid \langle v, w\rangle = 0\}$ is an immersion,*
(b) *whenever $z \neq w \in S^1$ satisfy $(\pi_v \circ f)(z) = (\pi_v \circ f)(w)$, then $(\pi_v \circ f)'(z)$ and $(\pi_v \circ f)'(w)$ are linearly independent,*
(c) *for every $P \in (\pi_v \circ f)(S^1)$ the preimage $(\pi_v \circ f)^{-1}(P)$ consists of either one or two points.*

The set

$$\{v \in S^2 \mid v \text{ satisfies (a), (b) and (c)}\}$$

has full measure in S^2.[420]

Remark. In Proposition 3.47 (2) we showed that a subset of full measure is dense. The chronically bored reader can try to show that the set $\{v \in S^2 \mid v$ satisfies (a), (b) and (c)$\}$ considered in Lemma 18.10 is open.

Proof. Let $K \subset \mathbb{R}^3$ be a knot. We pick a diffeomorphism $f\colon S^1 \to K$. We say that a subset of a manifold W is *large* if it is open and if it has full measure in W. It follows from Proposition 3.47 (5b) that the intersection of two large subsets is again large. Furthermore, it follows from Proposition 3.47 (1) that any self-diffeomorphism of S^2 sends large sets to large sets.

It is convenient to consider an extra property of vectors in S^2 which is somewhat weaker than the above property (c):

[420]We refer to page 213 for the definition of a subset of full measure.

(c′) given any $P \in (\pi_v \circ f)(S^1)$ the preimage $(\pi_v \circ f)^{-1}(P)$ consists of finitely many points.

We write

$$V(a) \ := \ \{v \in S^2 \mid \ v \text{ satisfies (a)}\}.$$

Similarly we define $V(b), V(c), V(a,b), V(a,b,c')$ and so on. Note that with this language we need to show that $V(a,b,c)$ has full measure.

Let $v \in S^2$. We start out with three elementary observations regarding the projection maps π_v.

(1) Given $u \in \mathbb{R}^3 \setminus \{0\}$ we have

$$\pi_v(u) = 0 \quad \Longleftrightarrow \quad u \in \mathbb{R} \cdot v \quad \Longleftrightarrow \quad \tfrac{u}{\|u\|} \in \{v, -v\}.$$

(2) The projection map π_v is linear, hence for any $P \in \mathbb{R}^3$ we have $(D\pi_v)_P = \pi_v$.

(3) It follows from (2) and the chain rule that given any $z \in S^1$ we have the equality $(\pi_v \circ f)'(z) = \pi_v(f'(z))$.

Next we consider the three maps[421] [422]

$$\begin{aligned} \varphi\colon S^1 &\to S^2 \\ z &\mapsto \tfrac{f'(z)}{\|f'(z)\|} \end{aligned} \qquad \begin{aligned} \psi\colon \overbrace{\{(z,w) \in S^1 \times S^1 \mid z \neq w\}}^{=:M} &\to S^2 \\ (z,w) &\mapsto \tfrac{f(z)-f(w)}{\|f(z)-f(w)\|} \end{aligned} \quad \text{and} \quad \begin{aligned} \rho\colon S^2 &\to S^2 \\ v &\mapsto -v. \end{aligned}$$

We make the following observations:

(4) If X is a subset of full measure (respectively large subset) of S^2, then it follows from the above discussion that $X \cap \rho(X)$ is also a subset of full measure (respectively large).

(5) Since f is smooth we see that the map φ is also smooth.

(6) Given $v \in S^2$ it follows easily from (1) and (3) that $\pi_v \circ f$ is an immersion if and only if neither v nor $-v$ lies in $\varphi(S^1)$. In other words, we have the equality $V(a) = (S^2 \setminus \varphi(S^1)) \cap \rho(S^2 \setminus \varphi(S^1))$.

(7) Note that $M = \{(z,w) \in S^1 \times S^1 \mid z \neq w\}$ is an open subset of the manifold $S^1 \times S^1$, thus it is a manifold in an obvious way. With this manifold structure the map $\psi\colon M \to S^2$ is easily seen to be smooth.

---

[421] Since f is an immersion we see that the map φ is well-defined, i.e. we do not divide by zero. Similarly, since f is in particular injective we see that the map ψ is well-defined, i.e. once again we do not divide by zero.

[422] The astute reader will notice that throughout the argument it might be more reasonable to work with maps φ and ψ that take values in $\mathbb{R}\mathrm{P}^2 = S^2/x \sim -x$ instead of taking values in S^2. We stick with the maps to S^2 since S^2 has the advantage that its tangent spaces can be described easily as subvector spaces of $\mathbb{R}^3$, which makes it easy to write down differentials. Also, the approach of working with maps to $\mathbb{R}\mathrm{P}^2$ instead also creates an extra layer of notation which is as annoying as our notation which requires the extra map ρ.

(8) For each $(x, y) \in S^1$ we make the identification[423] $T_{(x,y)}S^1 = \mathbb{R}$ via the basis vector $(-y, x)$. Given $(z, w) \in M$ we use the above identification to make the identification $T_{(z,w)}M = T_{(z,w)}(S^1 \times S^1) = \mathbb{R}^2$. Furthermore given $v \in S^2$ we already saw on page 197 that we have the equality $T_vS^2 = v^\perp = \{w \in \mathbb{R}^3 \mid \langle v, w\rangle = 0\} \subset \mathbb{R}^3$.

(9) Using the identifications from (8) an elementary calculation[424] shows that for a point $(z, w) \in M$ we can write the differential $D\psi_{(z,w)}$, viewed as a homomorphism $T_{(z,w)}M = \mathbb{R}^2 \to T_{\psi(z,w)}S^2 \subset \mathbb{R}^3$, in the following way as a (3×2)–matrix:

$$D\psi_{(z,w)} \;=\; \tfrac{1}{\|f(z)-f(w)\|} \cdot \underbrace{\big(\pi_{\psi(z,w)}(f'(z)) \quad -\pi_{\psi(z,w)}(f'(w))\big)}_{(3\times 2)\text{-matrix}}.$$

(10) It follows from (9) that $(z, w) \in M$ is a regular point of ψ if and only if the vectors $\pi_{\psi(z,w)}(f'(z))$ and $\pi_{\psi(z,w)}(f'(w))$ are linearly independent.

(11) Let $v \in S^2$. It follows immediately from (1) and the linearity of π_v that we have $\pi_v(f(z)) = \pi_v(f(w))$ if and only if $\psi(z, w) = v$ or $\psi(z, w) = -v$.

(12) We denote by $\sigma\colon S^1 \times S^1$ the diffeomorphism given by $(z, w) \mapsto (w, z)$. It follows immediately from the definitions that $\psi \circ \sigma = \rho \circ \psi$.

(13) It follows easily from (3), (10), (11) and (12) that

$$V(b) \;=\; \{\text{regular values of } \psi\}.$$

After these initial remarks we turn to our first claim.

Claim.

(α) The sets $V(a)$ and $V(a, b)$ are large.

(β) We have $V(a) = V(a, c')$ and $V(a, b) = V(a, b, c')$.

We prove the two statements of the claim in several steps.

(i) Since S^1 is compact we obtain from Lemma 1.37 and Lemma 1.18 that $S^2 \setminus \varphi(S^1)$ is an open subset of S^2. Furthermore, since φ is smooth and since $\dim(S^1) < \dim(S^2)$ we obtain from Proposition 3.47 (5) that $S^2 \setminus \varphi(S^1)$ is a subset of full measure. In summary, we have shown that $S^2 \setminus \varphi(S^1)$ is large. It follows from (5) and (6) that $V(a) = (S^2 \setminus (\varphi(S^1)) \cap \rho(S^2 \setminus (\varphi(S^1)))$ is large.

(ii) It follows from Sard's Theorem 3.48 that the set of regular values of ψ is a subset of full measure. It follows from (i) and (13), together with Proposition 3.47 (1) that $V(a, b) = V(a) \cap V(b)$ has full measure.

(iii) Let $v \in V(a)$. It follows from (11), the fact that S^1 is compact and Exercise 10.1 that $\psi^{-1}(v)$ is finite. In particular we see that $V(a, c') = V(a)$ and thus also $V(a, b, c') = V(a, b)$.

[423] As on many other occasions we use Proposition 3.32 to view the tangent space of a submanifold of some $\mathbb{R}^n$ as a subvector space of $\mathbb{R}^n$.

[424] This calculation can be performed easily using the chain rule and by writing ψ as the composition of the map $(z, w) \mapsto f(z) - f(w)$ followed by the map $P \mapsto \frac{P}{\|P\|}$.

(iv) It remains to show that $V(a,b)$ is open. Let $v \in V(a,b) = V(a) \cap V(b)$. From (13) and (iii), together with Exercise 3.13 (2), we obtain an open neighborhood U of $v \in S^2$ that is still contained in $V(b)$. Since $V(a)$ is open we see that $U \cap V(a)$ is an open neighborhood of $v \in S^2$ that is still contained in $V(a,b)$. It follows from Lemma 1.8 that $V(a,b)$ is indeed open.

This concludes the proof of the claim.

Before we continue it is perhaps helpful to summarize what we have shown so far: In the claim we have seen that $V(a,b,c') = V(a,b)$ is large, in particular that it has full measure. But our actual goal is to show that $V(a,b,c)$ has full measure.

To do so we consider the map

$$\begin{array}{rcl} \Xi\colon \overbrace{\{(x,y,z) \in S^1 \times S^1 \times S^1 \,|\, x \neq y \text{ and } x \neq z\}}^{=:N} & \to & S^2 \times S^2 \\ (x,y,z) & \mapsto & (\psi(x,y), \psi(x,z)). \end{array}$$

We make the following simple observations:

(14) We view N as a manifold in an obvious way. Evidently the map Ξ is smooth.

(15) It follows easily from (1) that we have $v \in V(c)$ if and only if none of the four vectors $(\pm v, \pm v)$ lies in $\Xi(N)$.

(16) If one of the four vectors $(\pm v, \pm v)$ lies in $\Xi(N)$, then so does (v,v). This can be seen as follows: If $\Xi(x,y,z) \in \{(\pm v, \pm v)\}$, then $f(x), f(y), f(z)$ lie on the line $\mathbb{R} \cdot v$. After possibly permuting x, y, z we can assume that $f(x) = f(y) + r \cdot v$ and that $f(x) = f(z) + s \cdot v$ with $r, s > 0$. But with this permutation we have $\Xi(x,y,z) = (v,v)$.

Claim. We consider the "partial diagonal"

$$\Delta \;:=\; \{(v,v) \in S^2 \times S^2 \,|\, v \in V(a,b)\}.$$

The complement of $\Xi(N) \cap \Delta$ has full measure in Δ.

In the previous claim we saw that $V(a,b)$ is an open subset of S^2. Using this fact it is straightforward to see that Δ is a 2-dimensional submanifold of $S^2 \times S^2$. Thus, by Exercise 10.3 (b) it suffices to prove that if $(x,y,z) \in N$ satisfies $\Xi(x,y,z) = (v,v)$ for some $v \in V(a,b)$, then Ξ intersects Δ transversally, i.e. we have the equality

$$(D\Xi_{(x,y,z)})(T_{(x,y,z)}N) + T_{(v,v)}\Delta \;=\; T_{(v,v)}(S^2 \times S^2) \;\subset\; \mathbb{R}^3 \times \mathbb{R}^3 = \mathbb{R}^6.$$

We write $p = \pi_v(f'(x))$, $q = \pi_v(f'(y))$ and $r = \pi_v(f'(z))$ and we write $\mu = \frac{1}{\|f(x)-f(y)\|}$ and $\nu = \frac{1}{\|f(x)-f(z)\|}$. By (10) and (13), and by the fact that $v \in V(b)$, we know that p, q and r are pairwise linearly independent. In particular q and r form a basis for T_vS^2. Note that this implies that $\begin{pmatrix} q \\ q \end{pmatrix}$ and $\begin{pmatrix} r \\ r \end{pmatrix}$ form a basis for $T_{(v,v)}(S^2 \times S^2)$. Thus, using (9) we see that

$$(D\Xi_{(x,y,z)})(T_{(x,y,z)}N) + T_{(v,v)}\Delta \;=\; \text{span of the columns of } \begin{pmatrix} \mu \cdot p & -\mu \cdot q & 0 & q & r \\ \nu \cdot p & 0 & -\nu \cdot r & q & r \end{pmatrix}.$$

Using that p, q and r are pairwise linearly independent it is not hard to see that the five columns of the matrix on the right span a 4-dimensional subspace of $\mathbb{R}^6$. Since this subspace is contained in the 4-dimensional subspace $T_{(v,v)}(S^2 \times S^2)$ we see that it equals $T_{(v,v)}(S^2 \times S^2)$. This concludes the proof of the claim.

We consider the "diagonal map" $d\colon V(a,b) \to \Delta \subset S^2 \times S^2$ that is given by $d(v) = (v,v)$. One can easily show that $d\colon V(a,b) \to \Delta$ is a diffeomorphism. It follows from (16) that $V(a,b,c) = d^{-1}(\Delta \setminus \Xi(N))$. By the claim $\Delta \setminus \Xi(N)$ is a subset of full measure of Δ. Since d is a diffeomorphism we obtain from Proposition 3.47 (5b) that $V(a,b,c) = d^{-1}(\Delta \setminus \Xi(N))$ has full measure in $V(a,b)$. We saw above that $V(a,b)$ has full measure in S^2. It follows easily from Proposition 3.47 (5a) that $\Delta \setminus \Xi(N)$ has full measure in S^2. □

Now we can provide the proof of Proposition 18.9.

Proof of Proposition 18.9. Let $K \subset S^3 = \mathbb{R}^3 \cup \{\infty\}$ be a knot. It follows from Lemma 1.73 (4) and Lemma 10.4 (2) that, possibly after applying a smooth isotopy, we can assume that $K \subset \mathbb{R}^3$.

We pick $v \in S^2$ as in Lemma 18.10. It follows from Lemma 1.73 (4) and Lemma 10.4 (2) that, possibly after applying a smooth isotopy, we can assume that $v = e_3$. We define $\gamma := \pi_{e_3} \circ f\colon S^1 \to \mathbb{R}^2 \times \{0\} = \mathbb{R}^2$. It follows immediately from the fact that $v = e_3$ has the three properties (a), (b) and (c) stated in Lemma 18.10 that γ is diagrammatic. Next we consider the function

$$\begin{array}{rcl} \epsilon\colon S^1 & \to & \mathbb{R} \\ w & \mapsto & z\text{-coordinate of } f(w). \end{array}$$

Furthermore, given $z_1 \neq z_2 \in S^1$ with $\gamma(z_1) = \gamma(z_2)$ we define

$$c(z_i) \ := \ \begin{cases} +1, & \text{if } \epsilon(z_i) > \epsilon(z_{3-i}), \\ -1, & \text{if } \epsilon(z_i) < \epsilon(z_{3-i}). \end{cases}$$

It is clear that (γ, c) is a knot diagram. We pick a function $\eta\colon S^1 \to [-1,0]$ as in Lemma 18.8. We consider the map

$$\begin{array}{rcl} H\colon S^1 \times [0,1] & \to & \mathbb{R}^3 \\ (z,t) & \mapsto & (\gamma(z), (1-t)\cdot\epsilon(t) + t\cdot\eta(t)). \end{array}$$

Clearly this map is smooth. Given any $z, w \in S^1$ with $\gamma(z) = \gamma(w)$ we have $\eta(z) < \eta(w)$ if and only if $c(z) = -1$ if and only if $\eta(z) < \eta(w)$. From this observation we deduce that each H_t is actually an embedding. Thus we see that H is a smooth isotopy from K to the knot associated to the knot diagram (γ, η). □

We have now seen that every knot, up to smooth isotopy, arises from a knot diagram. The question arises, when do two knot diagrams give rise to smoothly isotopic knots. The following theorem gives a complete answer. We formulate the theorem in a slightly informal way since we will not make use of it.

Theorem 18.11. *Two knot diagrams give rise to smoothly isotopic knots if and only if the two diagrams are related by a finite sequence of smooth isotopies of $\mathbb{R}^2$ and Reidemeister moves. The three Reidemeister moves are illustrated in Figure 325.*

Proof. The theorem, not surprisingly, goes back to work of Kurt Reidemeister [Rei2, Chapter 3] in 1932. The formulation and proof in [Rei2] is in terms of "polygonal knots". The statement of the theorem is well known in our setting, where knots are defined as submanifolds of S^3 and it appears in any textbook on knot theory. A satisfactory proof can be found in [OSS, Theorem B.1.1]. □

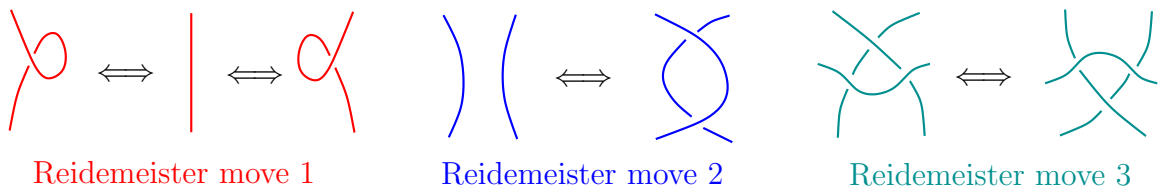

FIGURE 325.

Remark. Throughout these lecture notes we will see on several occasions that the tools of algebraic topology, e.g. fundamental groups, linking pairings and Reidemeister torsion can be used fruitfully to study knots. Proposition 18.9 and Theorem 18.11 open up an alternative route to studying knots. More precisely, these two results show that there exists a bijection

$$\begin{array}{c}\text{knot diagrams up to smooth isotopy}\\ \text{and Reidemeister moves}\end{array} \xrightarrow{\cong} \text{knots up to smooth isotopy}$$

This bijection lies at the heart of the definition of several knot invariants, like the Jones polynomial [Jon] that was introduced in 1984 and the HOMFLY-PT polynomial [FYHLMO, PT] that was discovered in 1985. These polynomial invariants are quite different from any of the invariants that are obtained through algebraic-topological methods. We refer to [Lic3, Chapters 3 and 15] and [BZH, Chapter 17] for more information on these invariants.

18.4. **The Wirtinger presentation.** In the previous section we saw that we can associate a knot diagram to any given knot. In this section we will see that we give an explicit algorithm that, given a knot diagram, produces a presentation for the fundamental group of the complement $S^3 \setminus K$ of a knot K.

In this section we will take several liberties and we will not attempt to give full details in the proofs. The issue is that any attempt to make the proofs completely rigorous renders them totally unreadable.

Before we can state the promised algorithm we need to introduce a few more definitions.

Definition. Let K be an oriented knot that is associated to a knot diagram $(f\colon S^1 \to \mathbb{R}^2, c)$.

(1) We refer to the images of the double points as the *crossings of* K.

(2) Let $x \in f(S^1)$ be a crossing. Let $z, w \in S^1$ with $f(z) = f(w) = x$ and such that z is an undercrossing and w is an overcrossing. We say x is a *positive crossing* if the ordered basis $\{f'(w), f'(z)\}$ is a positive basis for $\mathbb{R}^2$. Otherwise we say that x is a *negative crossing*.

(3) We refer to the components of $K \cap (\mathbb{R}^2 \times \{0\})$ as the *strands of* K.

These definitions are illustrated in Figures 326 and 327.

Remark. In a picture of a diagram the strands are understood to correspond precisely to the segments drawn.

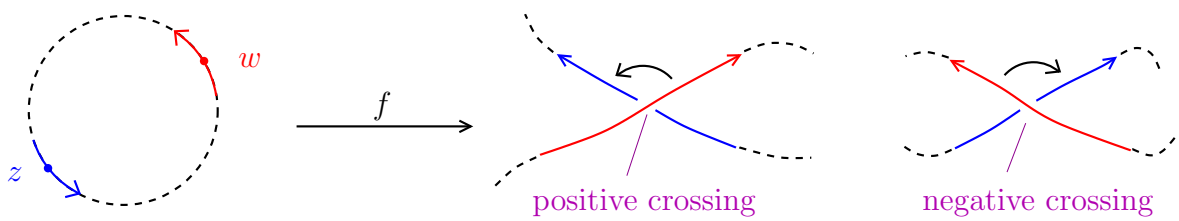

FIGURE 326.

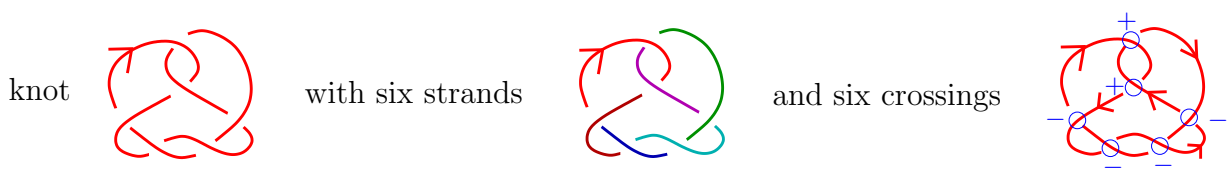

FIGURE 327.

The following lemma will be proved in Exercise 18.5.

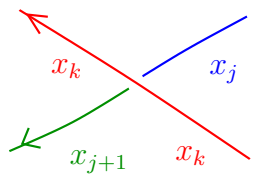
Lemma 18.12. *If a knot diagram has at least one crossing, then the number of crossings equals the number of strands.*

The following proposition shows how to determine the fundamental group of a knot that is associated to a knot diagram. We will sacrifice some rigor in the formulation in an attempt to make it more readable. We leave it to the reader to make the proposition totally rigorous.

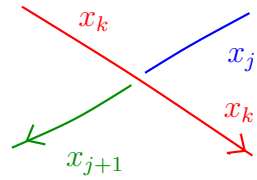
Proposition 18.13. *Let K be a knot that is associated to a given knot diagram that has at least one crossing. We enumerate the strands cyclically by $x_1, \dots, x_n$ where we make the identifications $x_0 = x_n$ and $x_{n+1} = x_1$. For the crossing between the strands x_j and x_{j+1} we define a relation r_j as shown in Figure 328. Then we have an isomorphism*

$$\pi_1(S^3 \setminus K) \;\cong\; \langle x_1, \dots, x_n \,|\, r_1, \dots, r_n \rangle.$$

Furthermore we can drop any one of the relations and we still obtain an isomorphism.



the positive crossing gives rise to the relation $r_j = x_k \cdot x_{j+1} \cdot x_k^{-1} \cdot x_j^{-1}$



the negative crossing gives rise to the relation $r_j = x_k^{-1} \cdot x_{j+1} \cdot x_k \cdot x_j^{-1}$

FIGURE 328.

Remark. Given a knot K, any presentation with n generators and $n-1$ relators as obtained from Proposition 18.13 is called a *Wirtinger presentation of* $\pi_1(S^3 \setminus K)$.

In the following we first explain why Proposition 18.13 is plausible. Afterwards we will provide the technical proof of Proposition 18.13.

"Plausibility argument for Proposition 18.13". Suppose we are given a knot diagram that has n crossings. We denote by K the corresponding knot. We work with the base point $* = (0,0,2) \in \mathbb{R}^3$ which lies "above" the knot K. We enumerate the strands cyclically. For the j-th strand we denote by x_j the oriented triangle that starts at $*$ and "circles once around the j-th strand" according to the "right-hand rule". We illustrate the definition in Figure 329.

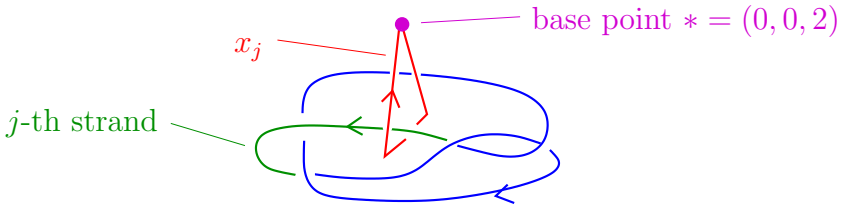


FIGURE 329.

Next we consider the situation at a positive crossing. By "sliding" various x_j along the strands and by some further path-homotopies we can assume that we are in the situation in Figure 330 on the left. If one follows the loop $x_k * x_{j+1} * \overline{x_k} * \overline{x_j}$ on its journey one realizes that on three occasions one goes back and forth to the base point. Thus the loop is actually path-homotopic to the loop shown in Figure 330 on the right. But that loop is clearly null-homotopic. Almost the same logic applies to negative crossings.

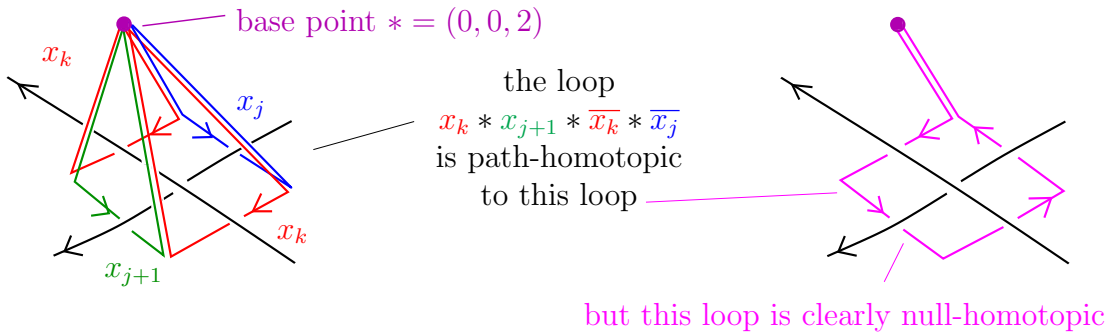

FIGURE 330.

This discussion, together with Lemmas 11.13 and 13.4, shows that there exists a unique group homomorphism

$$\langle x_1, \dots, x_n \,|\, \text{relations corresponding to crossings}\rangle \;\to\; \pi_1(S^3 \setminus K, *)$$

with

$$x_i \;\mapsto\; [x_i].$$

It remains to show that this group homomorphism is in fact an isomorphism. We will do so next in the proper proof of Proposition 18.13. □

Sketch of a proof for Proposition 18.13. Suppose once again that we are given a knot diagram $(\gamma\colon S^1 \to \mathbb{R}^2, c)$ that has $n \geq 1$ crossings. We denote by $P_1, \dots, P_n$ the double points of γ. We pick a smooth function $\eta\colon S^1 \to [-1, 0]$ as in the statement of Lemma 18.8. We denote by K the image of the map $S^1 \to \mathbb{R}^3$ given by $z \mapsto (\gamma(z), \eta(z))$. It follows from property (d) of Lemma 18.8 that

$$K \cap (\mathbb{R}^2 \times \mathbb{R}_{\leq -1}) \;=\; K \cap (\mathbb{R}^2 \times \{-1\}) \;=\; \{(P_1, -1), \dots, (P_n, -1)\}.$$

In contrast to the above plausibility argument we now actually work with the base point $\infty \in S^3 = \mathbb{R}^3 \cup \{\infty\}$. We set

$$A \;:=\; (\{(x,y,z) \in \mathbb{R}^3 \,|\, z \geq -1\} \cup \{\infty\}) \setminus K,$$

and

$$B \;:=\; (\{(x,y,z) \in \mathbb{R}^3 \,|\, z \leq -1\} \cup \{\infty\}) \setminus K.$$

We start out with the following claim.

Claim 1. The inclusion maps induce an isomorphism

$$\pi_1(A, \infty) *_{\pi_1(A \cap B, \infty)} \pi_1(B, \infty) \;\cong\; \pi_1(S^3 \setminus K).$$

Evidently the statement of the claim smells like it should be a consequence of the Seifert–van Kampen 14.1. The problem is that A and B are not open subsets of $S^3 \setminus K$. We rectify

this problem by replacing A and B by suitable open subsets. We define

$$U := A \cup (\mathbb{R}^2 \setminus \{P_1, \dots, P_n\}) \times (-2, -1)$$

and

$$\begin{aligned} V := B &\cup (\mathbb{R}^2 \setminus \gamma(S^1)) \times [-1, 0) \\ &\cup \{(z,t) \mid \text{ there exists } w \in S^1 \text{ with } z = \gamma(w) \text{ and } t \in [-1, \eta(z))\}. \end{aligned}$$

One can easily verify that U and V are open subsets of $S^3 \setminus K$. Furthermore the "obvious retractions" of the blue sets to the corresponding subsets of $\mathbb{R}^2 \times \{-1\}$ show that A is a deformation retract of U, that B is a deformation retract of V and that $A \cap B$ is a deformation retract of $U \cap V$. Now we see that the inclusion maps induce isomorphisms

$$\begin{array}{ccccc} \pi_1(S^3 \setminus K) & \overset{\cong}{\leftarrow} & \pi_1(U, \infty) *_{\pi_1(U \cap V, \infty)} \pi_1(V, \infty) & \overset{\cong}{\rightarrow} & \pi_1(A, \infty) *_{\pi_1(A \cap B, \infty)} \pi_1(B, \infty). \\ & \uparrow & & \uparrow & \\ & \text{by the Seifert–van Kampen Theorem 14.1} & & \begin{array}{c}\text{by the above, Lemma 9.10} \\ \text{and Proposition 9.12 (1)}\end{array} & \end{array}$$

This concludes the proof of the claim.

Our next goal is to understand the groups $\pi_1(A, \infty)$, $\pi_1(B, \infty)$ and $\pi_1(A \cap B, \infty)$. We handle these three groups consecutively. To better understand $\pi_1(A, \infty)$ we introduce the following objects.

(1) As in the plausibility argument we set $* = (0, 0, 2)$. We fix once and for all a path connecting $*$ to ∞.
(2) We write $D := \{(\gamma(z), w) \mid z \in S^1 \text{ and } w \in [-1, \eta(z))\}$.
(3) We cyclically enumerate the strands of the knot.
(4) For $j \in \{1, \dots, n\}$ we denote by D_j the unique component of D that contains the j-th strand in its closure.
(5) For $j = 1, \dots, n$ we denote by x_j a loop in $*$ that is the boundary of a triangle that intersects D_j precisely once in a positive[425] direction. We use the path from (1) to view each x_j as a loop in ∞.

Some of the above objects are illustrated on the left of Figure 331.

Claim 2. The obvious map $\langle x_1, \dots, x_n \rangle \to \pi_1(A, \infty)$ is an isomorphism.

Note that each D_j is contractible and hence simply connected. Furthermore one can easily show that $A \setminus D$ is contractible. We can now use Corollary 17.3 iteratively n times to prove the claim. We leave it to the assiduous reader to fill in the details.[426] This concludes the proof of the claim.

Fortunately the next group $\pi_1(B, \infty)$ on our list is easy to handle.

Claim 3. The group $\pi_1(B, \infty)$ is trivial.

[425]Here by "positive direction" we mean that the orientation vectors of the triangle followed by the orientation vector of the knot should form a positive basis for $\mathbb{R}^3$.

[426]The details involve replacing the set D_j by a suitable open subset to be able to apply Corollary 17.3.

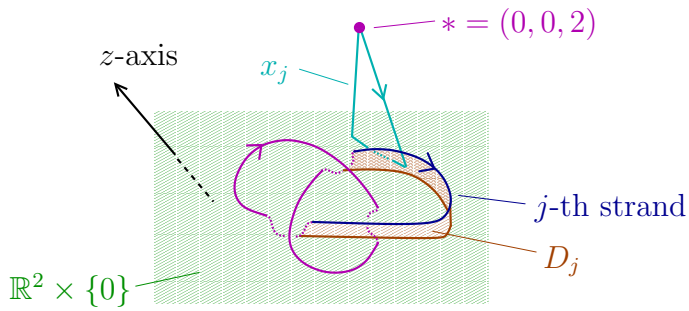

FIGURE 331.

Using the stereographic projection from Lemma 1.41 and using the map defined on page 73 it is not hard to see that there exists a homeomorphism

$$f\colon (\{(x,y,z) \in \mathbb{R}^3 \,|\, z \leq -1\} \cup \{\infty\} \;\to\; \overline{B}^3$$

which sends the points in $\mathbb{R}^2 \times \{-1\}$ to S^2. Since $K \cap (\mathbb{R}^2 \times \mathbb{R}_{\leq -1}) = \{(P_1,-1),\dots,(P_n,-1)\}$ we see that B is homeomorphic to $\overline{B}^3$ with n points on its boundary removed. But this does not change the fact that the origin is a deformation retract. We have thus shown that $f(B)$, and hence also B, is contractible. But this implies by Proposition 9.12 (2) that $\pi_1(B,\infty)$ is indeed trivial. This concludes the proof of the claim.

Finally we turn to the group $\pi_1(A \cap B, \infty)$. We pick orientation-preserving embeddings $\varphi_i\colon \overline{B}^2 \to \mathbb{R}^2 \times \{-1\}$, $i = 1,\dots,n$ with disjoint images and such that for each i we have $\varphi_i(0) = (P_i,-1)$. It follows almost immediately[427] from Lemma 17.4 that we have an equality

$$\langle z_1,\dots,z_n \mid z_1 \cdot \dots \cdot z_n \rangle \;=\; \pi_1(A \cap B, \infty)$$

where for any $i \in \{1,\dots,n\}$ the element z_i is represented by a curve of the form $\alpha_i * \gamma_i * \overline{\alpha}_i$ where α_i is a suitable path from ∞ to a point on $\varphi_i(S^1)$ and γ_i is a path that goes once around $\varphi_i(S^1)$ in an orientation-preserving way.

Now we can finally prove the desired statement. Indeed, we have

$$\begin{array}{ccccc}
\pi_1(S^3 \setminus K) & \cong & \pi_1(A,\infty) *_{\pi_1(A\cap B,\infty)} \pi_1(B,\infty) & \cong & \pi_1(A,\infty)/\langle\langle \pi_1(A \cap B,\infty)\rangle\rangle \\
 & \uparrow & & \uparrow & \\
 & \text{by Claim 1} & & \text{by Claim 3 and Lemma 13.12 (2)} & \\
 & \cong & \langle x_1,\dots,x_n\rangle/\langle\langle z_1,\dots,z_n\rangle\rangle & \cong & \langle x_1,\dots,x_n\rangle/\langle\langle r_1,\dots,r_n\rangle\rangle. \\
 & \uparrow & & \uparrow & \\
 & \begin{array}{c}\text{by Claim 2, Lemma 13.2 (4) and the} \\ \text{above fact that } \{z_1,\dots,z_n\} \text{ is a} \\ \text{generating set for } \pi_1(A\cap B,\infty)\end{array} & & \begin{array}{c}\text{the “plausibility argument shows that each} \\ z_i \text{ is conjugate to } r_i\text{, thus it follows from} \\ \text{Lemma 13.2 (5) that } \langle\langle z_1,\dots,z_n\rangle\rangle = \langle\langle r_1,\dots,r_n\rangle\rangle\end{array} &
\end{array}$$

[427]The slightly cautious “almost” refers to the fact that we also make use of the fairly obvious fact that $((\mathbb{R}^2 \times \{-1\}) \cup \{\infty\}) \setminus \bigcup_{i=1}^{n} \varphi_i(B^2)$ is a deformation retract of $A \cap B = ((\mathbb{R}^2 \times \{-1\}) \cup \{\infty\}) \setminus \{P_1,\dots,P_n\}$.

It remains to show that we can drop any one of the relations. Thus let $j \in \{1, \dots, n\}$. It follows easily from $z_1 \cdot \dots \cdot z_n = e$ that $z_j \in \langle z_1, \dots, z_{j-1}, z_{j+1}, \dots, z_n \rangle$. But by Lemma 13.2 (4) this implies that $\langle\langle z_1, \dots, z_n \rangle\rangle = \langle\langle z_1, \dots, z_{j-1}, z_{j+1}, \dots, z_n \rangle\rangle$. Therefore we see that in the above equality we can drop the relation r_j. $\square$

As mentioned above, we continue with two examples, namely the trefoil and the figure-8 knot. First we consider the knot diagram for the trefoil K that is shown in Figure 332 to the left. We number the strands as shown. To the right we show how the three crossings give rise to three relations. As pointed out in Proposition 18.13, we can drop any one of the relations.

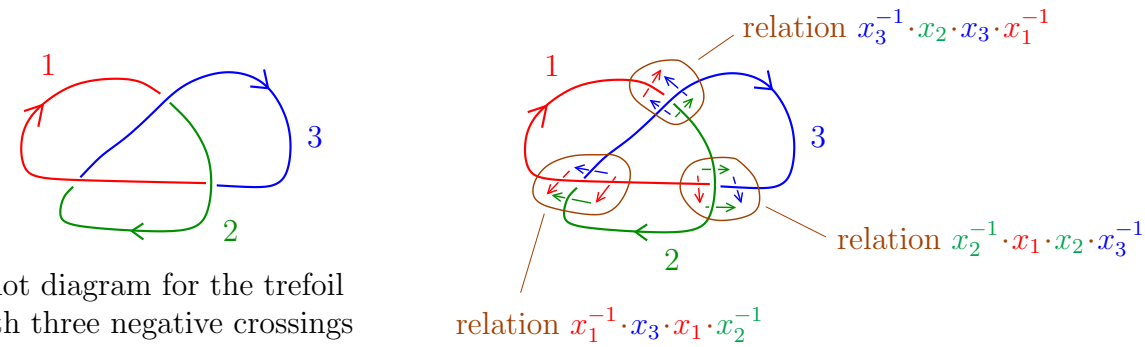

FIGURE 332.

This discussion shows that we have proved the following lemma.

Lemma 18.14. *Let K be the trefoil. There exists an isomorphism*

$$\pi_1(S^3 \setminus K) \;\cong\; \langle x_1, x_2, x_3 \,|\, x_3^{-1} x_2 x_3 x_1^{-1}, x_2^{-1} x_1 x_2 x_3^{-1} \rangle.$$

Remark. Let K be the trefoil. In Proposition 18.5 we had also shown that there exists an isomorphism $\pi_1(S^3 \setminus K) \cong \langle x, y \mid x^2 = y^3 \rangle$. In particular we have now shown that the two groups $\langle x_1, x_2, x_3 \,|\, x_3^{-1} x_2 x_3 x_1^{-1}, x_2^{-1} x_1 x_2 x_3^{-1} \rangle$ and $\langle x, y \mid x^2 = y^3 \rangle$ are isomorphism. In Exercise 18.6 we will give a purely algebraic proof of this statement.

The following corollary to Proposition 18.13 gives us the disappointing news that our old trick of using abelianizations of fundamental groups cannot be used to distinguish knots.

Corollary 18.15. *Given any knot K the abelianization of the group $\pi_1(S^3 \setminus K)$ is isomorphic to $\mathbb{Z}$.*

Proof. We will prove the corollary in Exercise 18.3. Later on, once we have introduced homology groups we will give a different, arguably more conceptual proof of the lemma. $\square$

After this sobering corollary we move on to the next example.

Lemma 18.16. *Let J be the figure-8 knot. There exists an isomorphism*

$$\pi_1(S^3 \setminus J) \;\cong\; \langle x_1, x_2, x_3, x_4 \,|\, x_3 x_2 x_3^{-1} x_1^{-1}, x_4^{-1} x_3 x_4 x_2^{-1}, x_1 x_4 x_1^{-1} x_3^{-1} \rangle.$$

Proof. We leave it to the reader to use the knot diagram shown in Figure 333 to prove the lemma. □

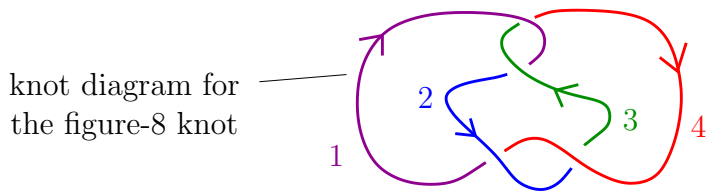

FIGURE 333.

On its own Lemma 18.16 is not particularly enlightening. It is initially not clear whether this group is isomorphic to $\mathbb{Z}$ or to the fundamental group of the complement of the trefoil. By Corollary 18.15 we know that there is no hope that the abelianization will tell us something interesting.

So we need a different approach. Recall that in Lemma 18.6 we used the (non-) existence of an epimorphism onto the symmetric group S_3 to distinguish the trefoil from the trivial knot. The idea now is to repeat this trick with a different finite group. Recall that on page 476 we introduced the dihedral groups D_n which have $2n$ elements. It is encouraging that $D_3 \cong S_3$ thus we try our luck with D_5.[428]

Using Lemma 13.6 and enough time on our hands we obtain the following table:

	trivial knot	trefoil	figure-8 knot
epimorphism onto S_3	✗	✓	✗
epimorphism onto the dihedral group D_5	✗	✗	✓

This table shows that we have proved the following corollary.

Corollary 18.17. *The trivial knot, the trefoil and the figure-8 knot are pairwise not smoothly isotopic.*

This approach of trying to distinguish knots by the (non-) existence of epimorphisms onto finite groups is rather ad hoc, but not without its merits. For example the following proposition is proved in [BF, BR].

Proposition 18.18. *Let K be either the trivial knot, the trefoil or the figure-8 knot. Furthermore let J be another knot. If for all finite groups G the group $\pi_1(S^3 \setminus K)$ admits an epimorphism onto G if and only if $\pi_1(S^3 \setminus J)$ does, then J is smoothly isotopic to K or to the mirror image of K, i.e. the reflection of K in the xy-plane.*

We conclude this section with the following question which is still open.

[428]The reader might ask, why we do not try our luck with D_4. But for reasons we cannot get into right now, given a knot K and an even number $2n$ there cannot be an epimorphism $\pi_1(S^3 \setminus K) \to D_{2n}$.

Question 18.19. *Let K and J be two knots in $\mathbb{R}^3 \subset \mathbb{R}^3 \cup \{\infty\} = S^3$. Suppose that the finite groups onto which $\pi_1(S^3 \setminus K)$ and $\pi_1(S^3 \setminus J)$ admit epimorphisms are the same. Does this imply that K and J are smoothly isotopic, up to possibly taking a reflection in the xy-plane?*

18.5. **The Reidemeister-Schreier process.** Even though Corollary 18.15 was quite disappointing, using a clever jiu-jitsu move we will see in this section that we can actually turn Corollary 18.15 to our advantage. The key to doing so is contained in the following definition and the subsequent lemma.

Definition. Let π be a group and let $n \in \mathbb{N}$. We say that a subgroup $\Gamma \subset \pi$ is *cocyclic of order n* if Γ is a normal subgroup such that π/Γ is isomorphic to $\mathbb{Z}_n$.

Lemma 18.20. *If π is a group whose abelianization is isomorphic to $\mathbb{Z}$, then given any $n \in \mathbb{N}$ there exists a unique subgroup that is cocyclic of order n. It is given by the kernel of any epimorphism $\pi \to \mathbb{Z}_n$.*

Proof $(*)$. Let π be a group whose abelianization is isomorphic to $\mathbb{Z}$ and let $n \in \mathbb{N}$. We denote by $\psi\colon \pi \to \pi_{\mathrm{ab}}$ the obvious projection and we pick an isomorphism $\varphi\colon \pi_{\mathrm{ab}} \xrightarrow{\cong} \mathbb{Z}$. It is clear that $(\varphi \circ \psi)^{-1}(n\mathbb{Z})$ is a subgroup of π that is cocyclic of order n. On the other hand, suppose that Γ is a subgroup of π that is cocyclic of order n. We pick an isomorphism $\theta\colon \pi/\Gamma \cong \mathbb{Z}_n$. It follows from Proposition 13.10 that there exists a unique epimorphism $\alpha\colon \mathbb{Z} \to \mathbb{Z}_n$ such that the following diagram commutes:

$$\begin{tikzcd}
\pi \arrow[r, "\psi", "\cong"'] \arrow[d, two heads, "g \mapsto g\Gamma"'] & \pi_{\mathrm{ab}} \arrow[r, "\varphi", "\cong"'] & \mathbb{Z} \arrow[d, two heads, "\alpha"] \\
\pi/\Gamma \arrow[rr, "\theta", "\cong"'] & & \mathbb{Z}_n.
\end{tikzcd}$$

It follows immediately that $\Gamma = (\varphi \circ \psi)^{-1}(n\mathbb{Z})$. $\square$

Corollary 18.15 and Lemma 18.20 allow us to make the following definition.

Definition. Given a knot K and $n \in \mathbb{N}$ we denote by $\pi(K, n)$ the unique subgroup of $\pi_1(S^3 \setminus K)$ that is cocyclic of order n.

Example. If K is the trivial knot, then we saw in Proposition 18.4 that we can make an identification $\pi_1(S^3 \setminus K) = \mathbb{Z}$. It follows easily that for any $n \in \mathbb{N}$ we have $\pi(K, n) = n \cdot \mathbb{Z}$, in particular $\pi(K, n)$ is isomorphic to $\mathbb{Z}$.

We have now a new tool for trying to distinguish knots:

Lemma 18.21. *Let K and J be two knots. If K and J are smoothly isotopic, then given any $n \in \mathbb{N}$ the groups $\pi(K, n)$ and $\pi(J, n)$ are isomorphic. In particular the abelianizations of these groups are isomorphic.*

The question arises, given a knot K and $n \in \mathbb{N}$, how can we determine $\pi(K,n)$ from a given presentation for $\pi_1(S^3 \setminus K)$? Fortunately the following proposition gives us an explicit algorithm. To facilitate the uptake we formulate the following proposition in a slightly informal way.

Proposition 18.22. *Let $\pi = \langle x_1, \dots, x_m, t \,|\, r_1, \dots, r_l \rangle$ be a group and let $\phi\colon \pi \to \mathbb{Z}_n$ be an epimorphism such that $\phi(x_1) = \dots = \phi(x_m) = 0$ and $\phi(t) = 1$. Then a presentation for the subgroup $\ker\{\phi\colon \pi \to \mathbb{Z}_n\}$ is given by*

$$\langle y_{1,0}, \dots, y_{1,n-1}, \dots, y_{m,0}, \dots, y_{m,n-1}, u \,|\, s_1^0, \dots, s_1^{n-1}, \dots, s_l^0, \dots, s_l^{n-1} \rangle$$

where each s_i^j is obtained as follows:

(1) *For $i = 1, \dots, m$ and $j = 0, \dots, n-1$ we write $t^j r_i t^{-j}$ as an expression in*

$$x_1, tx_1t^{-1}, \dots, t^{n-1}x_1t^{-n+1}, \dots, x_m, tx_mt^{-1}, \dots, t^{n-1}x_mt^{-n+1} \text{ and } t^n.$$

(2) *Then we replace each term $t^j x_i t^{-j}$ by $y_{i,j}$ and we replace t^n by u. We obtain a word in the new generators and denote it by s_i^j.*

The inclusion map $\ker\{\phi\colon \pi \to \mathbb{Z}_n\} \to \pi$ is then given by sending each $y_{i,j}$ to $t^j x_i t^{-j}$ and by sending u to t^n.

Proof. As we had mentioned above, the proposition follows fairly easily from the more general Reidemeister-Schreier process that is explained in [LS, Chapter II.4], [MKS, Chapter 2.3] or [Bog, Chapter 2.9]. □

Instead of studying the proof of Proposition 18.22 our time is better spent trying to understand two explicit examples.

Example. Let $K \subset S^3$ be the trefoil. We write $\pi = \pi_1(S^3 \setminus K)$. In Proposition 18.5 we showed that we can make the identification $\pi = \langle x, t \mid \underbrace{x^3 \cdot t^{-2}}_{=r} \rangle$. By Lemma 13.6 there exists a unique epimorphism $\phi\colon \pi \to \mathbb{Z}_2$ with $\phi(x) = 0$ and $\phi(t) = 1$. Evidently $\pi(K,2) = \ker\{\phi\colon \pi \to \mathbb{Z}_2\}$. Now we will use Proposition 18.22 to find a presentation $\langle y_0, y_1, u \,|\, s_0, s_1 \rangle$ for $\ker\{\phi\colon \pi \to \mathbb{Z}_2\}$. We write

$$t^0 r t^{-0} = \underbrace{x^3}_{=y_0^3} \cdot \underbrace{t^{-2}}_{=u^{-1}} \text{ and more interestingly } t^1 r t^{-1} = tx^3t^{-3} = (txt^{-1})^3 \cdot t^{-2} = (\underbrace{txt^{-1}}_{y_1^3})^3 \cdot \underbrace{t^{-2}}_{=u^{-1}}.$$

Thus we see that

$$\pi(K,2) = \ker\{\phi\colon \pi \to \mathbb{Z}_2\} \underset{\substack{\uparrow \\ \text{Proposition 18.22}}}{=} \langle y_0, y_1, u \,|\, y_0^3 u^{-1}, y_1^3 u^{-1} \rangle \underset{\substack{\uparrow \\ \text{by the Tietze transformations of Lemma 13.5}}}{=} \langle y_0, y_1 \,|\, y_0^3 = y_1^3 \rangle.$$

Using Proposition 13.10 we can now easily compute that the abelianization of the above group $\pi(K,2) = \ker\{\phi\colon \pi \to \mathbb{Z}_2\}$ is isomorphic to $\mathbb{Z} \oplus \mathbb{Z}_3$.

This calculation, together with Lemma 18.21 and the above discussion of the trivial knot, gives a new proof of Lemma 18.6.

The previous example was fairly straightforward since we had started out with a presentation where one generator got sent to one, and the other ones got sent to zero. Unfortunately this is not the case for Wirtinger presentations, so we will need to work somewhat harder. In the following example we consider the figure-8 knot K and we carry out the first steps needed to calculate the isomorphism type of $\pi(K,2)$.

Example. Let J be the figure-8 knot. In Lemma 18.16 we saw that we can make the identification

$$\pi_1(S^3 \setminus J) \;=\; \langle y_1, y_2, y_3, y_4 \,|\, y_1^{-1}y_4y_1y_3^{-1}, y_3^{-1}y_2y_3y_1^{-1}, y_2^{-1}y_1y_2y_4^{-1}\rangle.$$

We denote by $\phi\colon \pi_1(S^3 \setminus J) \to \mathbb{Z}_2$ the epimorphism that is given by sending each y_i to 1. We set $t := y_1$. The goal is to replace the generators y_1, y_2, y_3 by generators x_1, x_2, x_3 which satisfy $\phi(x_i) = 0$. In fact we have

$$\begin{aligned}
\pi_1(S^3 \setminus J) &= \langle t, y_2, y_3, y_4 \,|\, t^{-1}y_4ty_3^{-1}, y_3^{-1}y_2y_3t^{-1}, y_2^{-1}ty_2y_4^{-1}\rangle \\
&= \langle t, y_2, y_3, y_4 \,|\, \underbrace{t^{-1}y_4t^{-1}tty_3^{-1}}_{=t^{-1}y_4ty_3^{-1}}, \underbrace{t^{-1}ty_3^{-1}y_2t^{-1}ty_3t^{-1}}_{=y_3^{-1}y_2y_3t^{-1}}, \underbrace{t^{-1}ty_2^{-1}ty_2t^{-1}ty_4^{-1}}_{=y_2^{-1}ty_2y_4^{-1}}\rangle \\
&= \langle t, x_2, x_3, x_4 \,|\, t^{-1}x_4tx_3^{-1}, t^{-1}x_3^{-1}x_2tx_3, t^{-1}x_2^{-1}tx_2x_4^{-1}\rangle. \\
&\uparrow \\
&\text{substitution } x_i = y_it^{-1},\ x_i^{-1} = ty_i^{-1}, \text{ see Lemma 13.7}
\end{aligned}$$

At this point we have a presentation to which we can apply Proposition 18.22. A heroic calculation shows that $\pi(J,2)_{\mathrm{ab}} \cong \mathbb{Z} \oplus \mathbb{Z}_5$. Thus we obtain a new proof that the figure-8 knot and the trefoil are not smoothly isotopic.

The above procedure for distinguishing knots works fairly well in practice. For example, with enough time at one's hand, or alternatively a convenient computer implementation, one can use the above methods to show that all the knots shown in Figure 324 are in fact pairwise different.

Nonetheless, the above approach is not overly satisfying. It would be much better to have invariants of knots that are much quicker to calculate. We will come back to this challenge at a much later point.

The above discussion, in particular Proposition 18.22 raises the following purely algebraic question.

Question 18.23. *Let π be a group with a given finite presentation and let $\phi\colon \pi \to G$ be an epimorphism onto a finite group.*

(1) *Is the kernel* $\ker\{\phi\colon \pi \to G\}$ *a finitely presented group?*
(2) *If the answer to* (1) *is yes, how can we determine a finite presentation for the kernel in terms of the given data?*

It turns out that the answer to the first question is yes.

Proposition 18.24. *If π is a finitely presented group and $\phi\colon \pi \to G$ is an epimorphism onto a finite group, then* $\ker\{\phi\colon \pi \to G\}$ *is also finitely presented.*

The proof of the proposition is given in most books on combinatorial group theory, see e.g. [LS, Chapter II.4], [MKS, Chapter 2.3] or [Bog, Chapter 2.9]. In fact the proof is algorithmic, in particular it also gives an affirmative answer to the second question. The algorithm is called the *Reidemeister-Schreier process*. The general Reidemeister-Schreier process is somewhat messy to formulate. Thus we refer to the above literature for details.

Remark. In the proof of Lemma 18.6 we showed that the group $\langle x, t \,|\, x^3 \cdot t^{-2} \rangle$ admits an epimorphism α onto the permutation group S_3. In [Bog, Example 2.9.3] the general Reidemeister-Schreier process is used to determine a presentation for the kernel of $\alpha \colon \langle x, t \,|\, x^3 \cdot t^{-2} \rangle \to S_3$.

Exercises for Chapter 18.

Exercise 18.1. We consider the two knot diagrams shown in Figure 334. Use Reidemeister moves to show that the associated knots are smoothly isotopic.

FIGURE 334.

Exercise 18.2. Show that every diagrammatic map has only finitely many double points.

Exercise 18.3. Let K be a knot. Use Proposition 18.13 to show that the abelianization of the group $\pi_1(S^3 \setminus K)$ is isomorphic to $\mathbb{Z}$.

Exercise 18.4. We defined the sign of a crossing of a diagram of an oriented knot. How does the sign change if we reverse the orientation of the knot?

Exercise 18.5. Show that if a knot diagram has at least one crossing, then the number of crossings equals the number of strands.

Exercise 18.6. Give a purely algebraic proof that the two groups $\langle x, y \mid x^2 = y^3 \rangle$ and $\langle a, b, c \,|\, c^{-1}bca^{-1}, b^{-1}abc^{-1} \rangle$ are isomorphic.
Remark: You could use the Tietze transformations introduced in Lemma 13.5 and you could use Lemma 13.7.

Exercise 18.7. Let $K \subset S^3$ be the trefoil. We consider the "cone"

$$C \;:=\; \{r \cdot P \,|\, P \in K \text{ and } r \in [0,1]\} \;\subset\; \overline{B}^4.$$

(a) Show that C is homeomorphic to the disk $\overline{B}^2$.
(b) Suppose that F is a proper 2-dimensional topological submanifold of $\overline{B}^4$. Show that given any point $P \in F \cap B^4$ there exists a closed neighborhood N of $P \in B^4$ and a homeomorphism $\Phi \colon N \to \overline{B}^4$ such that $\Phi(N \cap F)$ is the trivial knot in S^3.

(c) Show that C is not a *topological submanifold* of $\overline{B}^4$.
Hint: Evidently the idea is to apply (b) to the point $P = 0 \in C$. The difficulty is that N does not have to be a standard closed ball of the form $\overline{B}^4_r(0)$. But what is true is that given any such N there exist $r, s \in (0,1)$ with $\overline{B}^4_r(0) \subset N \subset \overline{B}^4_s(0)$. How can this information be put to good use?

FIGURE 335. Illustration for Exercise 18.7.

Exercise 18.8. Let K be the trefoil. Compute the abelianization of the group $\pi(K, 3)$.

19. Decision problems

In the last chapters we had developed several techniques for determining the fundamental groups of topological spaces. In particular we managed to find finite presentations for the fundamental groups of large classes of topological spaces, e.g. graphs, surfaces, knot complements and mapping tori. In fact we now have enough tools to determine, with enough effort and perseverance, a presentation for the fundamental groups of most "nice" spaces. Furthermore we will see later on that the fundamental group of every compact manifold admits a *finite* presentation.

The question that now arises is, what information can we extract from a finite presentation of a group? Here are a couple of natural questions.

Question 19.1.

(1) *Does there exist an algorithm that can decide whether or not a given finite presentation* $\pi = \langle g_1, \dots, g_k \mid r_1, \dots, r_l \rangle$ *represents the trivial group?*
(2) *Does there exist an algorithm that can decide whether or not two given finite presentations* $\pi = \langle g_1, \dots, g_k \mid r_1, \dots, r_l \rangle$ *and* $\Gamma = \langle h_1, \dots, h_m \mid s_1, \dots, s_n \rangle$ *represent isomorphic groups?*[429]
(3) *Does there exist an algorithm that can determine, given*
   (a) *a finite presentation* $\pi = \langle g_1, \dots, g_k \mid r_1, \dots, r_l \rangle$ *and*
   (b) *a word* w *in* $g_1, \dots, g_k$*, i.e. an element* $w \in \langle g_1, \dots, g_k \rangle$*,*
   whether or not w *represents the trivial element in the group* π*?*[430]

Remark. The above question is formulated in a slightly informal way. After all, what is an "algorithm" supposed to be? The questions are made more precise in [CZ, Chapter 7].

On page 412 we introduced the Tietze transformations on presentations. We pointed out that two finite presentations for a given group are in fact related by a finite sequence of Tietze transformations. In particular, if $\pi = \langle g_1, \dots, g_k \mid r_1, \dots, r_l \rangle$ is a presentation for the trivial group, then we can turn the presentation after finitely many Tietze transformations into the trivial presentation $\langle | \rangle$. The problem is that we do not know how many Tietze transformations are required to turn a presentation of a trivial group into a trivial presentation. In particular at times it can be very hard to find the correct Tietze transformations.

Example. We consider the presentation

$$\pi \;=\; \langle a, b, c \mid a^3, b^3, c^4, ac = ca^{-1}, aba^{-1} = bcb^{-1} \rangle.$$

This is a presentation of the trivial group as can be seen as follows:[431]

(1) from $aba^{-1} \sim bcb^{-1}$ we get $(aba^{-1})^3 \sim (bcb^{-1})^3$,
(2) since $a^{-1}a \sim 1$ and $b^{-1}b \sim 1$ it follows that $(aba^{-1})^3 \sim ab^3a^{-1}$ and $(bcb^{-1})^3 \sim bc^3b^{-1}$,

[429] The question whether such an algorithm exists is often called the *isomorphism problem.*
[430] The question whether such an algorithm exists is often called the *word problem.*
[431] For elements g, h of $\langle a, b, c \rangle$ we write $g \sim h$ if they represent the same element in π.

(3) we have $b^3 \sim 1$, hence $ab^3a^{-1} \sim 1$, therefore we get from (1) and (2) that $bc^3b^{-1} \sim 1$ hence $c^3 \sim 1$,
(4) we have $c^3 \sim 1$ but we also have the relation $c^4 \sim 1$, so $c \sim 1$,
(5) since $aba^{-1} \sim bcb^{-1}$ it follows that $aba^{-1} \sim 1$ and so $b \sim 1$,
(6) from $ac \sim ca^{-1}$ and $c \sim 1$ it follows that $a \sim a^{-1}$, hence $a^2 \sim 1$,
(7) together with $a^3 \sim 1$ we obtain $a \sim 1$.
(8) we now showed that a, b, c are all equivalent to 1, thus we see that the group defined by the presentation is the trivial group.

This example shows that if a presentation corresponds to the trivial group, then it can be surprisingly complicated to verify this statement.

Now suppose we are given a finite presentation and we have to decide whether or not it is a presentation of the trivial group. We can modify the presentation using Tietze transformations. If at some point we end up with the trivial presentation we know that the given presentation corresponds to the trivial group. But what happens if after many attempts at modifying the presentation using Tietze transformations we still do not have the trivial presentation. Does that mean that the presentation corresponds to a non-trivial group? Or does it just mean that we did not try long enough?

So the real question is, does there exist an algorithm, that given a presentation which defines a non-trivial group, actually verifies that the group is non-trivial?

Unfortunately the answer is quite sobering.

Theorem 19.2. *The answer to all three questions of Question 19.1 is no.*

Remark. Here "no" means that one can show that no such algorithm exists. This is a much stronger statement than saying that we do not know of an example of such an algorithm.

Proof.
(1) Adyan [Ady] and Rabin [Rab] showed in 1955 that the answer to the first question is no.
(2) An algorithm that performs (2) would also give an algorithm for determining whether or not a given presentation is isomorphic to the trivial group with the empty presentation $\langle | \rangle$. But since the answer to (1) is no, it follows that the answer to (2) is also no.
(3) If there did exist an algorithm that dealt with the third problem, then we could apply it in particular to the generators. Since a presentation presents the trivial group if and only if all generators are trivial, it follows that an algorithm for (3) would also give an algorithm for (1). Since the latter cannot exist, the former cannot exist either. □

Remark. The statement of Theorem 19.2 that the answer to all three questions of Question 19.1 is no, is of course somewhat disappointing. But this raises the question whether there are interesting classes of groups for which the answer is actually yes. For example

Mikhail Gromov [Grom][432] introduced the notion of a "word hyperbolic group" for which the answer to all three questions turns out to be yes. Examples of word hyperbolic groups are given by

(1) finite groups,
(2) free groups, fundamental groups of surfaces of genus ≥ 2,
(3) fundamental groups of hyperbolic manifolds of any dimension,
(4) fundamental groups of "Riemannian manifolds with negative sectional curvature".

In fact in a precise sense a "random" finitely presented group is word hyperbolic, see e.g. [Ol] for more details.

The topic of word hyperbolic groups is a very important topic of mathematics in its own right. See e.g. [Lö] for an introduction to word hyperbolic groups.

Of course our main goal is not to classify groups, but our goal is to understand "nice" topological spaces. For example, given $n \in \mathbb{N}$ we would like to classify closed, orientable connected n-dimensional manifolds up to diffeomorphism. For $n = 1$ we did so in Proposition 3.53 and for $n = 2$ we saw the classification in Theorem 14.9. In particular we saw that in these dimensions only "few groups" appear as fundamental groups.

The situation is very different in higher dimensions. First of all we have the following proposition, which is actually fairly easy to prove, see e.g. [CZ, Theorem 5.1.1] for details.[433]

Proposition 19.3. *Given any finitely presented group π and any $n \geq 4$ there exists a closed orientable connected n-dimensional manifold with fundamental group π.*

Markov [Mar] used Proposition 19.3 and Theorem 19.2 to prove the following theorem.[434]

Theorem 19.4. *Let $n \geq 4$. Then there is no algorithm that can decide whether or not two closed orientable n-manifolds are homeomorphic.*

This leaves us with the case of 3-dimensional manifolds. It turns out that in this dimension there does in fact exist such an algorithm.

Theorem 19.5. *There exists an algorithm that can decide whether or not two closed orientable connected 3-manifolds are diffeomorphic.*

In this case the algorithm is considerably more complicated than in the 1-dimensional and the 2-dimensional case. The proof that such an algorithm exists is due to the work of many mathematicians, first and foremost William Thurston [Thu] and Grigori Perelman. The proof of the theorem was completed about 2003. It is impossible to mention here all the work that goes into proving Theorem 19.5. We refer to the survey paper [AFW, Theorem 4.27] for details and precise references.

[432]Mikhail Gromov (1943-) is a French-Russian mathematician famous for his many contributions to geometry and group theory. He was the first person to view groups as "geometric objects", giving rise to the subject of "geometric group theory".

[433]We will provide a proof in "Introduction to Knot Theory II".

[434]Is Theorem 19.4 an immediate consequence of Proposition 19.3 and Theorem 19.2?

20. The universal covering of reasonable topological spaces

After spending a lot of time on determining the fundamental groups of topological spaces we now want to return to the study of covering maps. One key goal of this section is to address the following question.

Question 20.1. *Does every path-connected topological space B admit a path-connected covering $p\colon X \to B$ such that X is simply connected?*

We know of course that the answer is yes for the torus, the Klein bottle and the Möbius band. But does such a covering exist for the surface of genus 2? Or does it exist for the complement $S^3 \setminus K$ of a knot $K \subset S^3$? How about the wedge $S^1 \vee S^1$ of two circles?

20.1. **Local properties of topological spaces.** Before we can address Question 20.1 we need to recall the definition of a local property of topological spaces that we already gave in Section 1.19.

Definition. Let P be a property of topological spaces. We say a topological space X is *o-locally P* if given any $Q \in X$ and any neighborhood U of Q there exists an open neighborhood V of Q that is contained in U that has the property P.

Examples.

(1) Every simply connected topological space is by definition path-connected, thus every o-locally simply connected topological space is also o-locally path-connected.
(2) On page 131 we saw that every open subset of $\mathbb{R}^n$ is o-locally simply connected.
(3) According to Lemma 3.8 every topological manifold is o-locally path-connected. In fact almost the same proof shows that every topological manifold is o-locally simply connected.
(4) It is straightforward to see that each spatial graph is o-locally simply connected. Similarly it is easy to verify that the wedge of two manifolds is o-locally simply connected.
(5) We consider
$$X \;:=\; \mathbb{R}^2 \;\setminus\; \bigcup_{n=1}^{\infty} \tfrac{1}{n} \times [-1,1],$$
with the usual subspace topology coming from $\mathbb{R}^2$. Then X is path-connected but not o-locally path-connected. Indeed, we consider the point $(0,0) \in X$ and the neighborhood $U = (-\frac{1}{2}, \frac{1}{2}) \times (-\frac{1}{2}, \frac{1}{2}) \cap X$. It is straightforward to show that there does not exist a path-connected neighborhood V of $(0,0)$ which is contained in U. We refer to Figure 336 for an illustration.
(6) We consider
$$X \;:=\; \mathbb{R}^2 \;\setminus\; \bigcup_{n=1}^{\infty} \big(\tfrac{1}{n}, 0\big),$$
with the subspace topology coming from $\mathbb{R}^2$. Then X is path-connected, o-locally path-connected but it is not o-locally simply connected. Indeed the origin admits

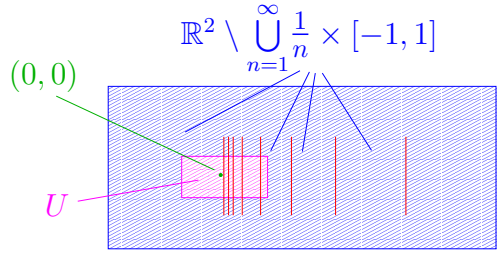

FIGURE 336.

no neighborhood of the desired form, since any neighborhood of the origin contains "infinitely many holes". We made this statement precise in Exercise 12.1.

20.2. **Lifting maps to coverings.** Let $p\colon (X,x_0) \to (B,b_0)$ be a covering of pointed topological spaces. Furthermore let $f\colon (Z,z_0) \to (B,b_0)$ be a map. Recall that on page 272 we said that f *lifts*, if there exists a *lift* $\widetilde{f}\colon (Z,z_0) \to (X,x_0)$, i.e. a map $\widetilde{f}\colon Z \to X$ with $\widetilde{f}(z_0) = x_0$ and which makes the following diagram commute

$$\begin{tikzcd} & (X,x_0) \arrow[d, "p"] \\ (Z,z_0) \arrow[ur, "\widetilde{f}"] \arrow[r, "f"'] & (B,b_0). \end{tikzcd}$$

For example, if $f\colon ([0,1],0) \to (B,b_0)$ is a map from the interval $[0,1]$ to B, i.e. if f is a path with starting point b_0, then we saw in Proposition 7.12 that there exists a unique lift of f to a map $\widetilde{f}\colon ([0,1],0) \to (X,x_0)$.

Example. Consider the following maps:

$$\begin{tikzcd} & (S^1,1) \arrow[d, "p"', "z\mapsto z^3"] \\ (S^1,1) \arrow[ur, dashed, "???\ \text{lift}\ \widetilde{f}\ ???"] \arrow[r, "z\mapsto z^2", "f"'] & (S^1,1). \end{tikzcd}$$

Here the map p is a 3-fold covering. Does the map f lift to a map $\widetilde{f}$?

To answer the question we need to study lifts of maps a little more carefully. Let $p\colon (X,x_0) \to (B,b_0)$ be a covering of pointed topological spaces and let $f\colon (Z,z_0) \to (B,b_0)$ be a map. Suppose that there exists a lift $\widetilde{f}\colon (Z,z_0) \to (X,x_0)$. We then obtain the commutative diagram

$$\begin{tikzcd} & (X,x_0) \arrow[d, "p"] \\ (Z,z_0) \arrow[ur, "\widetilde{f}"] \arrow[r, "f"'] & (B,b_0) \end{tikzcd}$$

from the functoriality of the fundamental group it follows that $f_* = \big(p \circ \widetilde{f}\big)_* = p_* \circ \widetilde{f}_*$, i.e. we get the commutative diagram

$$\begin{tikzcd} & \pi_1(X,x_0) \arrow[d, "p_*"] \\ \pi_1(Z,z_0) \arrow[ur, "\widetilde{f}_*"] \arrow[r, "f_*"'] & \pi_1(B,b_0). \end{tikzcd}$$

Thus it follows that if f lifts, then

$$\operatorname{im}(f_*) \;=\; \operatorname{im}\left(\left(p \circ \widetilde{f}\right)_*\right) \;=\; \operatorname{im}\left(p_* \circ \widetilde{f}_*\right) \;\subset\; \operatorname{im}(p_*).$$

So summarizing, if there exists a lift of f, then

$$\operatorname{im}(f_*\colon \pi_1(Z, z_0) \to \pi_1(B, b_0)) \;\subset\; \operatorname{im}(p_*\colon \pi_1(X, x_0) \to \pi_1(B, b_0)).$$

Example. In the above example we have $\pi_1(S^1, 1) = \mathbb{Z}$ and $\operatorname{im}(f_*) = 2\mathbb{Z}$ whereas we have $\operatorname{im}(p_*) = 3\mathbb{Z}$. So we see that f does not lift.

The following proposition says, that the above conclusion has a converse, for "reasonably" topological spaces. More precisely, we have the following proposition which, under a modest technical hypothesis, gives a complete criterion for when a map lifts.

Proposition 20.2. *Let $p\colon (X, x_0) \to (B, b_0)$ be a covering of pointed topological spaces. Furthermore let Z be a path-connected topological space and let $f\colon (Z, z_0) \to (B, b_0)$ be a map.*

(1) *If Z is o-locally path-connected, then we have the following equivalence of statements:*

$$\begin{tikzcd} & (X, x_0) \arrow[d, "p"] \\ (Z, z_0) \arrow[r, "f"'] \arrow[ur, dashed, "\text{there exists a lift } \widetilde{f}"] & (B, b_0) \end{tikzcd} \qquad \Longleftrightarrow \qquad \operatorname{im}(f_*) \subset \operatorname{im}(p_*).$$

(2) *There exist at most one such lift, in other words, any two such lifts agree.*[435]

Example. Let $p\colon (X, x_0) \to (B, b_0)$ be a covering of pointed topological spaces.

(1) The condition on the fundamental groups in Proposition 20.2 is automatically satisfied if Z is simply connected.
(2) Now let $f\colon (S^n, s_0) \to (B, b_0)$ be a map. The topological manifold S^n is path-connected and o-locally path-connected. By Proposition 5.14 the sphere S^n is simply connected if $n \geq 2$. Thus it follows from (1) that there exists a uniquely determined lift $\widetilde{f}\colon (S^n, s_0) \to (X, x_0)$ of the map $f\colon (S^n, s_0) \to (B, b_0)$.

In the proof of Proposition 20.2 we will need the following lemma.

Lemma 20.3. *Let $p\colon (X, x_0) \to (B, b_0)$ be a covering of pointed spaces, let γ be a path in B with starting point b_0 and let δ be another path in B with $\delta(0) = \gamma(1)$. We denote by $\widetilde{\gamma}$ the lift of γ with starting point x_0. Then*

$$\begin{array}{c}\textit{endpoint of the lift of } \gamma * \delta \\ \textit{to the starting point } x_0\end{array} \quad = \quad \begin{array}{c}\textit{endpoint of the lift of } \delta \\ \textit{to the starting point } \widetilde{\gamma}(1).\end{array}$$

[435]Note that for (2) we do not need the annoying hypothesis that Z is o-locally path-connected.

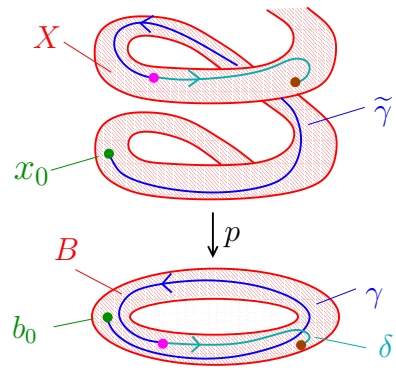

FIGURE 337. Illustration of Lemma 20.3

Proof. Let $p\colon (X, x_0) \to (B, b_0)$ be a covering of pointed spaces, let γ be a path in B with starting point b_0 and let δ be another path in B with $\delta(0) = \gamma(1)$. We denote by $\widetilde{\gamma}$ the lift of γ with starting point x_0 and we denote by $\widetilde{\delta}$ the lift of δ to the starting point $\widetilde{\gamma}(1)$. Finally we denote by $\widetilde{\gamma * \delta}$ the lift of $\gamma * \delta$ to the starting point x_0. For $t \in [0,1]$ we write $\beta(t) = (\gamma * \delta)(\frac{1}{2}(t+1))$ and $\widetilde{\beta}(t) = (\widetilde{\gamma * \delta})(\frac{1}{2}(t+1))$. Note that by definition we have $\beta(t) = \delta(t)$ for $t \in [0,1]$ and that $\widetilde{\beta}$ and $\widetilde{\delta}$ are both lifts of $\beta = \delta$ to the starting point $\beta(0) = \gamma(1) = \delta(0)$. Thus it follows that

$$\text{endpoint of } \widetilde{\gamma * \delta} \;=\; (\widetilde{\gamma * \delta})(1) \;=\; \widetilde{\beta}(1) \;\underset{\substack{\uparrow \\ \text{by Proposition 7.12}}}{=}\; \widetilde{\delta}(1) \;=\; \text{endpoint of } \widetilde{\delta}.$$

□

Now we can give the proof of Proposition 20.2. To make the proof slightly more readable we prove the two statements (1) and (2) separately.

Proof of Proposition 20.2 (1). Let $p\colon (X, x_0) \to (B, b_0)$ be a covering of pointed topological spaces. Furthermore let Z be a path-connected and o-locally path-connected topological space and let $f\colon (Z, z_0) \to (B, b_0)$ be a map.

By the discussion on page 551 we only have to prove the "$\Longleftarrow$"-direction of the proposition. So suppose that we have

$$\operatorname{im}(f_*\colon \pi_1(Z, z_0) \to \pi_1(B, b_0)) \;\subset\; \operatorname{im}(p_*\colon \pi_1(X, x_0) \to \pi_1(B, b_0)).$$

We have to construct a lift $\widetilde{f}\colon (Z, z_0) \to (X, x_0)$. We will do so as follows. Let $z \in Z$ be a point. Since Z is path-connected we can find a path $\alpha\colon [0,1] \to Z$ with $\alpha(0) = z_0$ and $\alpha(1) = z$. According to Proposition 7.12 we can lift the path $f \circ \alpha\colon [0,1] \to B$ to a path $\widetilde{(f \circ \alpha)}\colon [0,1] \to X$ with starting point x_0. We define

$$\widetilde{f}(z) \;:=\; \widetilde{(f \circ \alpha)}(1).$$

This definition is illustrated in Figure 338.

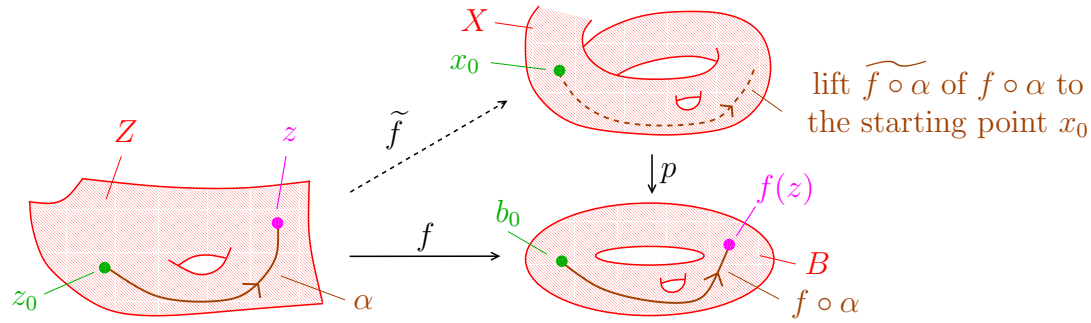

FIGURE 338.

We have to verify the following statements:

(1) the map $\widetilde{f}\colon Z \to X$ is well-defined,
(2) the map $\widetilde{f}$ is continuous,
(3) the map $\widetilde{f}$ is a lift.
(4) and the map $\widetilde{f}$ is the unique lift.

We will do so in the following:

(1) We have to show that for $z \in Z$ the point $\widetilde{f}(z) \in X$ is well-defined, i.e. independent of the choice of the path α. Thus let $\beta\colon [0,1] \to Z$ be another path with $\beta(0) = z_0$ and $\beta(1) = z$. (This situation is illustrated in Figure 339.) It follows that

$$\begin{aligned}
\widetilde{(f \circ \alpha)}(t=1) &= (\text{lift of } f \circ \alpha \text{ to the starting point } x_0)(t=1) \\
&= (\text{lift of } (f \circ \alpha) * \overline{(f \circ \beta)} * (f \circ \beta) \text{ to the starting point } x_0)(t=1) \\
&\uparrow \\
&\text{by Corollary 7.14 since } f \circ \alpha \text{ and } (f \circ \alpha) * \overline{(f \circ \beta)} * (f \circ \beta) \text{ are path-homotopic} \\
&= (\text{lift of } (f \circ (\underbrace{\alpha * \overline{\beta}}_{=:\gamma,\ \text{a loop in } (Z, z_0)})) * (f \circ \beta) \text{ to the starting point } x_0)(t=1) \\
&= (\text{lift of } f \circ \beta \text{ to the starting point } (\widetilde{f \circ \gamma})(1))(t=1) \\
&\uparrow \\
&\text{Lemma 20.3, where } \widetilde{f \circ \gamma} \text{ denotes the lift of } f \circ \gamma \text{ to the starting point } x_0 \\
&= (\text{lift of } f \circ \beta \text{ to starting point } x_0)(t=1) \;=\; \widetilde{(f \circ \beta)}(t=1). \\
&\uparrow \\
&\text{by our hypothesis we have } [f \circ \gamma] = f_*([\gamma]) \in \operatorname{im}(f_*) \subset p_*(\pi_1(X, x_0)), \\
&\text{hence } \widetilde{f \circ \gamma} \text{ is a loop in } x_0 \text{ by Lemma 7.16}^{436}
\end{aligned}$$

Thus we have shown that the map $\widetilde{f}$ is well-defined.

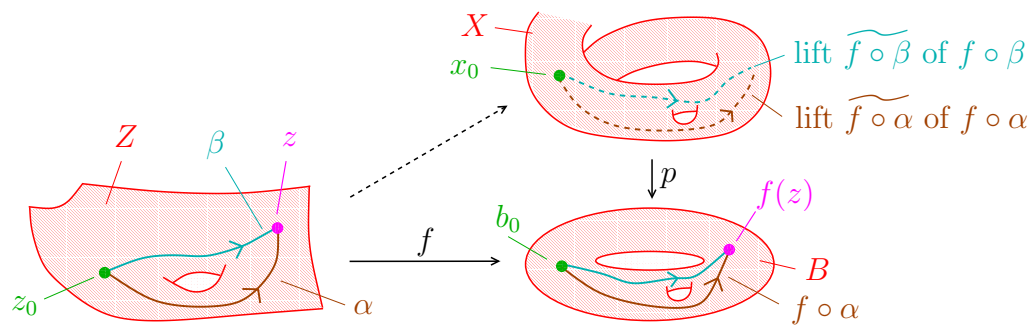

FIGURE 339.

(2) Now we want to show that $\widetilde{f}$ is continuous. So let $z \in Z$. We pick a path α from z_0 to z. Since p is a covering there exists an open neighborhood V of $\widetilde{f}(z)$ such that the restriction of p to V is a homeomorphism onto its image. We denote by $q\colon p(V) \to V$ the inverse map. Since Z is o-locally path-connected there exists an open neighborhood U of z that is contained in $f^{-1}(p(V))$ and that is path-connected. Since f and q are continuous it suffices to prove the following claim.

Claim. On the open neighborhood U of z the map $\widetilde{f}$ agrees with $q \circ f$.

So let $w \in U$. Since U is path-connected there exists a path δ from z to w that lies in U. Then

$$\begin{aligned}
\widetilde{f}(w) &= \text{endpoint of the lift of } f\circ(\alpha * \delta) = (f\circ\alpha) * (f\circ\delta) \text{ to the starting point } x_0 \\
&= \text{endpoint of the lift of } f\circ\delta \text{ to the starting point } \widetilde{f}(z) \\
&\uparrow \\
&\text{by Lemma 20.3 and the definition of } \widetilde{f}(z) \text{ as the endpoint of } \widetilde{f\circ\alpha} \\
&= \text{endpoint of } q\circ(f\circ\delta) \;=\; (q\circ f)(\delta(1)) \;=\; (q\circ f)(w). \\
&\uparrow \\
&\text{since } q = p^{-1} \text{ we know that } q\circ(f\circ\delta) \text{ is the lift of } f\circ\delta \text{ to the starting point } f(z)
\end{aligned}$$

(3) We need to show that $\widetilde{f}$ is a lift, i.e. we need to show that $p \circ \widetilde{f} = f$. So let $z \in Z$. Then

$$p\big(\widetilde{f}(z)\big) \;\underset{\uparrow}{=}\; p\big(\big(\widetilde{f\circ\alpha}\big)(1)\big) \;=\; (f\circ\alpha)(1) \;=\; f(\alpha(1)) \;=\; z.$$

pick path α from z_0 to z and denote by $\widetilde{f\circ\alpha}$ the lift of $f\circ\alpha$

[436]Lemma 7.16 (1) says the following: if δ is a loop in (B, b_0) and if $\widetilde{\delta}$ denotes the lift of δ to the starting point x_0, then the following holds:

$$\widetilde{\delta} \text{ is a loop in } (X, x_0) \quad\Longleftrightarrow\quad [\delta] \text{ lies in } p_*(\pi_1(X, x_0)) \subset \pi_1(B, b_0).$$

We apply the lemma to $\delta = f\circ\gamma$.

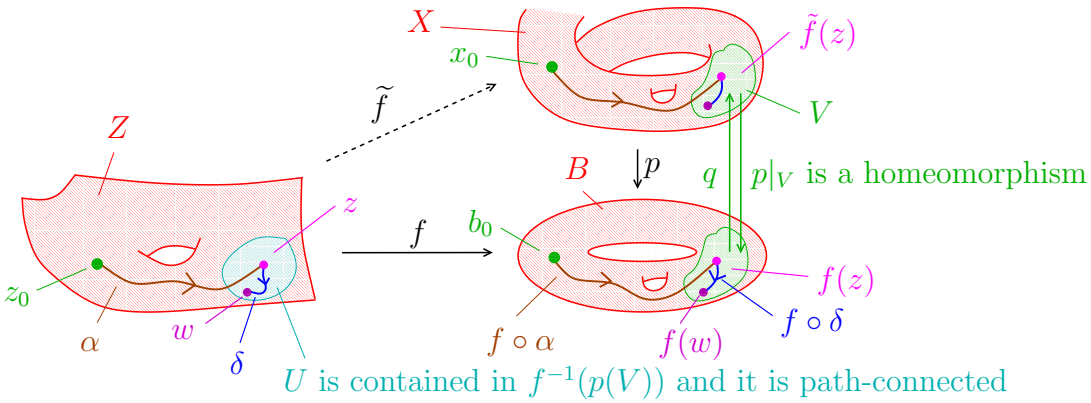

FIGURE 340.

□

Proof of Proposition 20.2 (2). Let $p\colon (X, x_0) \to (B, b_0)$ be a covering of pointed topological spaces. Furthermore let Z be a path-connected topological space. Finally suppose we are given a map $f\colon (Z, z_0) \to (B, b_0)$.

We will now see, using the uniqueness of the lift of paths established in Proposition 7.12, that any two lifts $\widetilde{f}, \widetilde{f'}\colon (Z, z_0) \to (X, x_0)$ agree. Thus let $z \in Z$. Since Z is path-connected there exists a path $\alpha\colon [0,1] \to Z$ from z_0 to z. Then $f \circ \alpha\colon [0,1] \to B$ is a path and $\widetilde{f} \circ \alpha$ and $\widetilde{f'} \circ \alpha$ are both lifts of $f \circ \alpha$ to the starting point x_0. By Proposition 7.12 we have $\widetilde{f} \circ \alpha = \widetilde{f'} \circ \alpha$. In particular the endpoints agree. But this implies the desired statement that $\widetilde{f}(z) = (\widetilde{f} \circ \alpha)(1) = (\widetilde{f'} \circ \alpha)(1) = \widetilde{f'}(z)$. □

In Exercise 20.2 we will prove the following corollary.

Corollary 20.4. *Let $\pi\colon X \to B$ be a covering of topological spaces. Then any open simply connected and o-locally path-connected subset $U \subset B$ is uniformly covered.*

Proposition 20.2 can also be useful in dealing with situations where it is initially not apparent why covering spaces should be useful. For example we can now prove the following proposition.

Proposition 20.5. *Let $f\colon S^1 \to S^1$ be a diffeomorphism. If f is orientation-preserving, then f is diffeotopic to the identity, otherwise f is diffeotopic to the reflection $r\colon S^1 \to S^1$ given by $(x, y) \mapsto (x, -y)$.*[437]

Proof. As usual we identify S^1 with $\mathbb{R}/\mathbb{Z}$. Thus let $f\colon \mathbb{R}/\mathbb{Z} \to \mathbb{R}/\mathbb{Z}$ be a diffeomorphism. First we consider the case that f is orientation-preserving. We denote by $p\colon \mathbb{R} \to \mathbb{R}/\mathbb{Z}$

[437]Note that in Lemma 9.6 we proved an analogous statement for self-homeomorphisms of S^1. The case of self-homeomorphisms is technically easier since it is often easier to write down a continuous map than to write down a smooth map.

the usual covering map. By Proposition 20.2 there exists a map $\widetilde{f}\colon \mathbb{R} \to \mathbb{R}$ such that the following diagram commutes:

$$\begin{tikzcd} \mathbb{R} \arrow[r, "\widetilde{f}"] \arrow[d, "p"'] & \mathbb{R} \arrow[d, "p"] \\ \mathbb{R}/\mathbb{Z} \arrow[r, "f"] & \mathbb{R}/\mathbb{Z}. \end{tikzcd}$$

We make the following observations regarding $\widetilde{f}$:

(1) Since p is a local diffeomorphism and since f is a smooth map we see that $\widetilde{f}$ is also smooth.
(2) Since f is orientation-preserving and since p is a local diffeomorphism we see that $\widetilde{f}$ is also orientation-preserving. This implies[438] that $\widetilde{f}$ is a strictly monotonously increasing function.
(3) Since f is a diffeomorphism and since the above diagram commutes we see that for any $x \in \mathbb{R}$ the restriction of $\widetilde{f}$ to the interval $[x, x+1)$ defines a bijection with $[f(x), f(x+1))$.
(4) For any $x \in \mathbb{R}$ we have by the commutativity of the diagram that $f(x+1) - f(x) \in \mathbb{Z}$.
(5) It follows easily from (2), (3) and (4) that for any $x \in \mathbb{R}$ we have $f(x+1) = f(x)+1$.

Now we consider the map

$$\begin{aligned} \widetilde{F}\colon \mathbb{R} \times [0,1] &\to \mathbb{R} \\ (x,t) &\mapsto \widetilde{f}(x) \cdot (1-t) + x \cdot t. \end{aligned}$$

This map is evidently smooth. Since $x \mapsto x$ is a strictly monotonously increasing diffeomorphism of $\mathbb{R}$ one can see easily that for any $t \in [0,1]$ the map $\widetilde{F}_t\colon \mathbb{R} \to \mathbb{R}$ has the above Properties (1) to (5). This implies in particular that the map $\widetilde{F}$ descends to a map

$$\begin{aligned} F\colon (\mathbb{R}/\mathbb{Z}) \times [0,1] &\to \mathbb{R}/\mathbb{Z} \\ (x,t) &\mapsto \widetilde{f}(x) \cdot (1-t) + x \cdot t \end{aligned}$$

where each $F_t\colon \mathbb{R}/\mathbb{Z} \to \mathbb{R}/\mathbb{Z}$ is a homeomorphism. Since each $\widetilde{F}_t$ is a local diffeomorphism and since p is a local diffeomorphism we obtain from Lemma 3.15 (3) that each F_t is in fact a diffeomorphism. We have thus shown that F is indeed a diffeotopy from f to the identity.

Finally we consider the case that f is orientation-reversing. In this case $r \circ g$ is orientation-preserving. We apply the above result to $r \circ g$ and we easily obtain the desired diffeotopy from f to r. □

The following corollary is an immediate consequence of Proposition 20.5.

Corollary 20.6. *If C and D are two oriented manifolds that are diffeomorphic to S^1, then any two orientation-preserving diffeomorphisms $C \to D$ are diffeotopic.*

[438] Why?

We conclude this section with the following corollary.

Corollary 20.7. *Let M be a 2-dimensional manifold (possibly disconnected) and let A and B be two distinct boundary components of M. Suppose A and B are equipped with orientations. Given any two orientation-preserving diffeomorphisms $f, g\colon A \to B$ the resulting manifolds*

$$M/f(a) \sim a \quad \text{and} \quad M/g(a) \sim \quad (\text{in both cases with } a \in A)$$

are diffeomorphic.

Loosely speaking, the corollary says that if we glue two oriented boundary components of a surface together in an orientation-preserving way, then the diffeomorphism type of the resulting manifold does not depend on the specific choice of the orientation-preserving diffeomorphism.

Proof. It follows from Proposition 3.21 and Proposition 3.53 that A and B are both diffeomorphic to S^1. The corollary is now an immediate consequence of Lemma 10.13 and Corollary 20.6. □

20.3. **Existence of covering spaces.** Let $p\colon (X, x_0) \to (B, b_0)$ be a covering of pointed topological spaces. In Corollary 7.15 we saw that

$$p_*\colon \pi_1(X, x_0) \ \to \ \pi_1(B, b_0)$$

is an injective map. Thus we can view $\pi_1(X, x_0)$ as a subgroup of $\pi_1(B, b_0)$.

Generalizing Question 20.1 one can now ask, whether to each subgroup Γ of $\pi_1(B, b_0)$ there exists a corresponding covering with $p_*(\pi_1(X, x_0)) = \Gamma$. We will see that this is indeed the case, at least under the rather technical assumption that the topological space B is o-locally simply connected.

In the following the main property we will be interested in is being o-locally simply connected. To save us working with this tongue-twister we introduce the following definition.

Definition. A topological space that is o-locally simply connected, is called *reasonable.*[439]

The following proposition gives in particular an affirmative answer to Question 20.1 under rather modest hypotheses.

Proposition 20.8. *Let Y be a path-connected reasonable topological space, let $y_0 \in Y$ and let $\Gamma \subset \pi = \pi_1(Y, y_0)$ be a subgroup.*

(1) *There exists a path-connected covering*[440] *$p\colon (X, x_0) \to (Y, y_0)$ of pointed topological spaces such that $p_*(\pi_1(X, x_0)) = \Gamma$.*
(2) *For the covering p from (1) we have*

$$[X : Y] \ = [\pi_1(Y, y_0) : \Gamma].$$

[439]The name is chosen since mos topological spaces that are "reasonable" in a colloquial sense will also be reasonable in the technical sense.

[440]Here we say that a covering $p\colon X \to Y$ is path-connected if X is path-connected.

Example.

(1) We consider $(Y, y_0) = (S^1, 1)$. We pick an identification[441] $\pi_1(S^1, 1) = \mathbb{Z}$. Given $n \in \mathbb{N}$ we consider $\Gamma = n\mathbb{Z} \subset \mathbb{Z} = \pi_1(S^1, 1)$. Then the covering

$$\begin{array}{rcl} p\colon S^1 & \to & S^1 \\ z & \mapsto & z^n \end{array}$$

has the property that $p_*(\pi_1(S^1, 1)) = n\mathbb{Z}$. Another example is given by the covering

$$\begin{array}{rcl} q\colon \mathbb{R}/n\mathbb{Z} & \to & S^1 \\ t + n\mathbb{Z} & \mapsto & e^{2\pi i t}. \end{array}$$

Here we also have $\operatorname{im}(q_*) = n\mathbb{Z}$.

(2) Let Z be a simply connected topological space and let $z_0 \in Z$. Furthermore let π be a group that acts on Z continuously and discretely. We consider $Y = Z/\pi$, we denote by $q\colon Z \to Y = Z/\pi$ the projection map and we write $y_0 = q(z_0)$. Using the isomorphism of Theorem 7.17 we can identify π with $\pi_1(Y, y_0)$.

Now let $\Gamma \subset \pi = \pi_1(Y, y_0)$ be a subgroup. Then the group Γ also acts on Z and we can consider the projection map

$$p\colon X := Z/\Gamma \ \to \ Y := Z/\pi$$

We denote by x_0 the image of z_0 under the projection map $Z \to X = Z/\Gamma$. One can show easily that $p\colon X = Z/\Gamma \to Y = Z/\pi$ is a covering map with $p_*(\pi_1(X, x_0)) = \Gamma$. We summarize the situation in the following diagram

$$\begin{tikzcd} Z \arrow[dr] \arrow[dd, "q"'] & & \\ & X = Z/\Gamma \arrow[dl, "p"] & \\ Y = Z/\pi & & \end{tikzcd} \qquad \begin{tikzcd} \pi_1(Z, z_0) = \{e\} \arrow[d] \\ \pi_1(X, x_0) = \Gamma \arrow[d, hook, "p_*"'] \\ \pi_1(Y, y_0) = \pi. \end{tikzcd}$$

Proof of Proposition 20.8. Let Y be a path-connected and reasonable[442] topological space, let $y_0 \in Y$ and let $\Gamma \subset \pi = \pi_1(Y, y_0)$ be a subgroup. We only need to show the existence of such a covering, the statement about the degree of the covering is an immediate consequence of Lemma 7.16 (3).

To get an idea for the construction, let us first consider the case that Γ is the trivial group. In this case we want to construct a covering $p\colon X \to Y$ such that X is simply connected. Let us assume for a second, that we have such an X. Pick x_0 with $p(x_0) = y_0$. Then, somewhat similar to the statement of Theorem 7.17, we

[441] This means that we pick an isomorphism $\pi_1(S^1, 1) \xrightarrow{\cong} \mathbb{Z}$ and then ignore it in the notation.

[442] Several times we will make use of the fact that a reasonable topological is in particular o-locally path-connected.

have a map

$$\begin{array}{rcl} \Phi\colon X & \to & \{\text{path-homotopy classes of paths starting in } y_0\} \\ x & \mapsto & p \circ (\text{any path from } x_0 \text{ to } x). \end{array}$$

In fact the proof of Theorem 7.17 comes close to showing that the map Φ is a bijection. Hence Φ is in fact a homeomorphism, provided we equip the right-hand side with an appropriate topology.

Now that we are not given X, the idea is, that given (Y, y_0) we can define the right-hand side of the above bijection, and with a suitable topology we will have found our X.

We first consider[443]

$$W := \{\text{all paths in } Y \text{ with starting point } y_0\}.$$

For $u, v \in W$ we write

$$u \sim v \quad :\Longleftrightarrow \quad u \text{ and } v \text{ have the same endpoint and } [u * \overline{v}] \in \Gamma.$$

Using the fact that $\Gamma \subset \pi_1(Y, y_0)$ is a subgroup one can show easily that $\sim$ is indeed an equivalence relation on W. The definitions of W and $\sim$ are illustrated in Figure 341. We write $X := W/\sim$ and $x_0 := [e_{y_0}]$, i.e. x_0 is the equivalence class of the constant path.

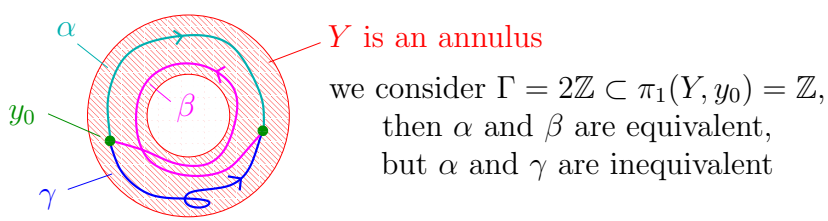

FIGURE 341.

Now we consider the map

$$\begin{array}{rcl} p\colon X = W/\sim & \to & Y \\ [v] & \mapsto & v(1). \end{array}$$

Note that this map is well-defined, i.e. it is independent of the choice of the representative v.

What remains to be done is to verify that our construction gives the desired object. We still need to do the following steps:

(1) we have to put a suitable topology on X,
(2) we have to show that with the topology from (1) the above map $p\colon X \to Y$ is continuous and open,
(3) we need to prove that the map $p\colon X \to Y$ is a covering,

[443] At a first reading of the proof of the proposition it is perhaps best to just think of the case that $Y = S^1 \times [-1, 1]$ and that $\Gamma \subset \pi_1(S^1)$ is the trivial group.

(4) we have to show that $X = W/\sim$ with the topology from (1) is path-connected,
(5) finally we need to show that we have the desired equality $p_*(\pi_1(X, x_0)) = \Gamma$.

Now we perform these steps.

(1) Let $x = [f] \in X = W/\sim$ and let V be an open path-connected neighborhood of $p(x) = f(1) \in Y$. We consider

$$U(x, V) \;:=\; \{[f * u] \mid u \text{ is a path in } V \text{ with starting point } f(1)\} \subset X = W/\sim .$$

We denote by $\mathcal{B}$ the family of all such subsets of X. We have to verify that these sets satisfy the "basis property" that we introduced on page 60.

(B1) For each $x \in X$ there exists an open path-connected neighborhood V.[444] Clearly we have $x \in U(x, V)$. This shows that $\mathcal{B}$ satisfies (B1).

(B2) Now let $x = [f]$ be a point in the intersection of $U(a, A)$ and $U(b, B)$. Since Y is in particular o-locally path-connected there exists an open path-connected neighborhood V of $f(1)$ with $V \subset A \cap B$. It is straightforward to see that $U(x, V) \subset U(a, A) \cap U(b, B)$. We refer to Figure 342 for an illustration.

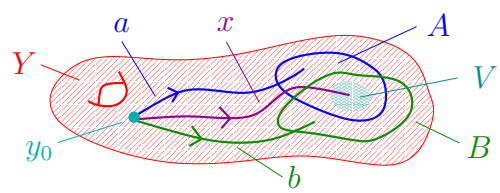

FIGURE 342.

We henceforth consider X as topological space with the topology generated by $\mathcal{B}$.[445]

(2) Now we want to show that the map $p\colon X = W/\sim \to Y$ is continuous and open. We start with the following observation: for every $x \in X$ and every open path-connected neighborhood V of $p(x)$ we have $p(U(x, V)) = V$.[446]

Now we turn to the actual proof of continuity. So let $A \subset Y$ be an open subset and let $x = [f] \in p^{-1}(A)$. It suffices to show that there exists an open subset B of Y such that $U(x, B) \subset p^{-1}(A)$. Since Y is o-locally path-connected, there exists an open neighborhood B of x that is contained in A and that is path-connected. By the above observation we have $p(U(x, B)) = B \subset A$, i.e. $U(x, B) \subset p^{-1}(A)$.

Finally we show that p is also open. By Lemma 1.36 it suffices to verify that images of the basis of the topology of X are open. But this statement we had just verified in the above observation.

[444] Here we use that Y is reasonable, in particular it is o-locally path-connected.

[445] If we equip $W \subset Y^{[0,1]}$ with the compact-open topology from page 150, then one can see fairly easily that the above topology on X is just the resulting quotient topology. We could have immediately equipped X with this topology, but we will need later on that the sets $U(x, V)$ form a basis for this topology.

[446] By definition we have $p(U(x, V)) \subset V$. But since V is path-connected we also have $V \subset p(U(x, V))$.

(3) Now we want to prove that $p\colon X = W/\sim \to Y$ is a covering map. So let $y \in Y$ be a point. We need to show that there exists a connected open neighborhood V of y such that the restriction of p to each component of $p^{-1}(V)$ is a homeomorphism.

Since Y is reasonable, i.e. since it is o-locally simply connected, there exists an open simply connected neighborhood V of y. We claim that V already has the desired property.

Claim.

$$p^{-1}(V) \;=\; \bigsqcup_{\widetilde{y}\in p^{-1}(y)} U(\widetilde{y}, V).$$

It is clear that the right-hand side is contained in the left-hand side. Next we want to show that the left-hand side is contained in the right-hand side. So let $[g] \in p^{-1}(V)$. Here g is a path in Y from y_0 to a point $v \in V$. Since V is in particular path-connected there exists a path h in V from v to y. We then have

$$[g] \;=\; [g * h * \overline{h}] \;\in\; U(\underbrace{[g * h]}_{\in p^{-1}(y)}, V).$$

We refer to Figure 343 for an illustration.

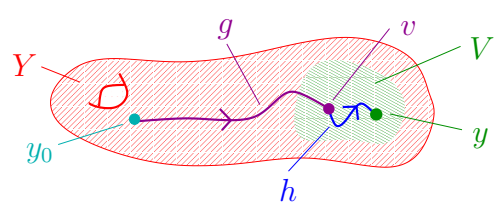

FIGURE 343.

It remains to show that the sets on the right-hand side of the claim are disjoint. So let $[v'], [v''] \in p^{-1}(y)$ and let $[g] \in U([v'], V) \cap U([v''], V)$. Then there exist paths u' and u'' in V with $[v' * u'] = [v'' * u'']$. It follows that

$$[v'] \;=\; [v' * u' * \overline{u}'] \;=\; [v'' * u'' * \overline{u}'] \;\underset{\substack{\uparrow \\ u''*\overline{u}' \text{ is null-homotopic since } V \text{ is simply connected}}}{=}\; [v''].$$

Thus $U([v'], V) \cap U([v''], V)$ intersect only if $[v'] = [v'']$. We refer to Figure 344 for an illustration. This concludes the proof of the claim.

Since the sets $U(\widetilde{y}, V)$ are open and disjoint it now suffices to prove the following claim.

Claim. For each $\widetilde{y} \in p^{-1}(y)$ the restriction of the projection map $p\colon X = W/\sim \to Y$ to the map $p\colon U(\widetilde{y}, V) \to V$ is a homeomorphism.

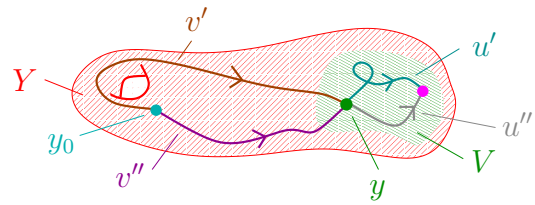

FIGURE 344.

So let $\widetilde{y} \in p^{-1}(y)$. As we had just pointed out in (2), the map $p\colon U(\widetilde{y}, V) \to V$ is surjective. From the fact that V is simply connected it also follows immediately that p is injective. Furthermore we had just verified in (2) that p is continuous and open. Therefore $p\colon U(\widetilde{y}, V) \to V$ is a homeomorphism.

(4) Now we want to show that $X = W/\sim$ is path-connected. We start out with the following claim.

Claim. Let $\alpha\colon [0,1] \to Y$ be a path. Then

$$\begin{array}{rcl} \widetilde{\alpha}\colon [0,1] & \to & X = W/\sim \\ t & \mapsto & \left[\begin{array}{rcl} [0,1] & \to & Y \\ s & \mapsto & \alpha(ts) \end{array}\right]. \end{array}$$

is a continuous map.

By Proposition 1.34 it suffices to show that for each $U(x, V)$ in the basis $\mathcal{B}$ of the topology on X the preimage $\widetilde{\alpha}^{-1}(U(x, V))$ is open in $[0,1]$. So suppose we are given $U(x, V)$. We denote by $\{I_j\}_{j \in J}$ the path-components of $\alpha^{-1}(V)$. Since α is continuous each I_j is an open subset of $[0,1]$. Note that for each $j \in J$ we either have[447] $\widetilde{\alpha}(I_j) \subset U(x, V)$ or $\widetilde{\alpha}(I_j) \cap U(x, V) = \varnothing$. It follows that

$$\widetilde{\alpha}^{-1}(U(x, V)) \;=\; \text{union of all the } I_j \text{ with the property that } \widetilde{\alpha}(I_j) \subset U(x, V).$$

Thus we see that $\widetilde{\alpha}^{-1}(U(x, V))$ is a union of open subsets of $[0,1]$, hence the preimage itself is open. This concludes the proof of the claim.

To show that X is path-connected it suffices to show that for every point $x \in X$ there exists a path in X from $x_0 = [e_{y_0}]$ to x. So let $x = [\alpha] \in X$. Then such a path is given by $\widetilde{\alpha}\colon [0,1] \to X$, where $\widetilde{\alpha}$ is defined as in the claim. By the claim $\widetilde{\alpha}$ is indeed continuous.

(5) It remains to show that $p_*(\pi_1(X, x_0)) = \Gamma$. Let $g \in \pi_1(Y, y_0)$. We choose a representatives $\alpha\colon [0,1] \to Y$ of g. We consider the following path[448] in $X = W/\sim$

$$\begin{array}{rcl} \widetilde{\alpha}\colon [0,1] & \to & X = W/\sim \\ t & \mapsto & \left[\begin{array}{rcl} [0,1] & \to & Y \\ s & \mapsto & \alpha(ts) \end{array}\right]. \end{array}$$

[447] This might require a few minutes of thought.

[448] Note that this map is continuous by the claim in (4).

Note that $\widetilde{\alpha}$ is evidently the lift of α to the starting point x_0. Then we have

$$g \in p_*(\pi_1(X,x_0)) \underset{\substack{\uparrow \\ \text{Lemma 7.16 (1)}}}{\Leftrightarrow} \widetilde{\alpha} \text{ is a loop} \Leftrightarrow \text{in } X = W/\sim \text{ we have } \widetilde{\alpha}(1) = x_0 = [e_{y_0}] \underset{\substack{\uparrow \\ \text{definition of } \sim \text{ on } W}}{\Leftrightarrow} \alpha \in \Gamma. \qquad \square$$

Now the question arises, to what degree is the covering corresponding to the subgroup Γ unique. To answer that question we need an appropriate notion of two coverings being equivalent.

Definition. Let $p\colon X \to B$ and $q\colon Y \to B$ be two coverings of a topological space B. We say p and q are *equivalent*, if there exists a homeomorphism $\Phi\colon X \to Y$ such that the following diagram commutes:

$$\begin{tikzcd} X \arrow[rr, "\Phi", "\cong"'] \arrow[dr, "p"'] & & Y \arrow[dl, "q"] \\ & B. & \end{tikzcd}$$

Similarly we define the equivalence of coverings of pointed topological spaces.

Example. Given $n \in \mathbb{N}$ the two coverings

$$\begin{array}{rcl} p\colon S^1 & \to & S^1 \\ z & \mapsto & z^n \end{array} \quad \text{and} \quad \begin{array}{rcl} q\colon \mathbb{R}/n\mathbb{Z} & \to & S^1 \\ t + n\mathbb{Z} & \mapsto & e^{it} \end{array}$$

are equivalent. In fact the desired map $\Phi\colon S^1 \to \mathbb{R}/n\mathbb{Z}$ is given by $e^{2\pi i t} \mapsto [nt]$.

Now we can formulate the following proposition:

Proposition 20.9. *Let B be a topological space, let $b_0 \in B$ and let $\Gamma \subset \pi_1(B,b_0)$ be a subgroup.*

(1) *Let $p\colon (X,x_0) \to (B,b_0)$ be a path-connected and o-locally path-connected covering such that $p_*(\pi_1(X,x_0)) = \Gamma$. This covering has the following universal property: for any other path-connected covering $q\colon (Y,y_0) \to (B,b_0)$ with $\Gamma \subset q_*(\pi_1(Y,y_0))$ there exists a unique covering $r\colon (X,x_0) \to (Y,y_0)$ such that the following diagram commutes:*

$$\begin{tikzcd} (X,x_0) \arrow[d, "p"'] \arrow[dr, dashed, "\exists!\, r"] & \\ (B,b_0). & (Y,y_0) \arrow[l, "q"] \end{tikzcd}$$

(2) *If B is path-connected reasonable, then there exists, up to equivalence, a unique path-connected covering $p\colon (X,x_0) \to (B,b_0)$ of pointed topological spaces such that $p_*(\pi_1(X,x_0)) = \Gamma$.*

Proof. Let B be a topological space and let $b_0 \in B$.

(1) Let $p\colon (X,x_0) \to (B,b_0)$ and $q\colon (Y,y_0) \to (B,b_0)$ be two path-connected coverings such that $p_*(\pi_1(X,x_0)) \subset q_*(\pi_1(Y,y_0))$. We assume furthermore that X is o-locally path-connected. It follows from Proposition 20.2 that there exists a unique map $r\colon (X,x_0) \to (Y,y_0)$ which makes the following diagram commute

$$\begin{tikzcd} & (Y,y_0) \arrow[d, "q"] \\ (X,x_0) \arrow[ur, "r"] \arrow[r, "p"'] & (B,b_0). \end{tikzcd}$$

It remains to show that r is a covering. This will be done in Exercise 20.3.

(2) The existence of such a covering is just the statement of Proposition 20.8. The uniqueness statement is an immediate consequence of (1)[449] and the usual proof of uniqueness for an object satisfying a universal property. We leave the details to the reader. □

Definition. Let B be a topological space, let $b_0 \in B$ and let $\Gamma \subset \pi_1(B,b_0)$ be a subgroup. We refer to any path-connected covering $p\colon (X,x_0) \to (B,b_0)$ of pointed topological spaces with $p_*(\pi_1(X,x_0)) = \Gamma$ as *the covering of B corresponding to* Γ. Put differently, in our language we usually suppress the fact that the covering provided by Proposition 20.9 (2) is well-defined only up to equivalence.

Proposition 20.9 can be viewed as a "machine" that constructs covering spaces of a given topological space X. In the next section we discuss the case that X is a surface in somewhat greater detail to get a better feeling for what is happening.

20.4. **Covering spaces of surfaces.** Suppose we start out with a surface F of genus g and a finite index subgroup Γ of $\pi_1(F)$, then by Proposition 20.8 we obtain a corresponding finite covering $p\colon \widetilde{F} \to F$. By Proposition 8.1 and Lemma 7.4 (4) the topological space $\widetilde{F}$ is again a closed orientable connected 2-dimensional manifold. From Theorem 14.10 we know that $\widetilde{F}$ is again a surface of some genus h. How can we determine h from g and Γ?

For future reference we record the question.

Question 20.10. *Given a surface F of genus g and a finite index subgroup Γ of $\pi_1(F)$, what is the genus of the corresponding finite cover?*

It will take a while till we can give a satisfactory answer. In fact we will obtain a complete answer only once we have introduced the Euler characteristic.

But we want to discuss one example in detail. We consider the surface F of genus two that we view as the connected sum of two tori $S = S^1 \times S^1$ and $T = S^1 \times S^1$. We denote by u, v the standard generators for $\pi_1(S)$ given by the two copies of S^1 in each torus. Similarly we denote by x, y the standard generators for $\pi_1(T)$. We pick an embedded closed disk

[449] If one does the argument carefully, then one sees, that here we use the following fact: if B is reasonable, then also every covering space of B is reasonable, in particular every covering space of B is o-locally path-connected.

in S and an embedded closed disk in T which both lie in the complement of the standard generators. We denote the corresponding open disks by D and E and we write $S^* = S \setminus D$ and $T^* \setminus E$. We build the connected sum $S\#T$ by gluing S^* to T^* along the boundary.[450] Furthermore, by a slight abuse of notation, we denote by u, v and x, y also the generators of $\pi_1(S^*) = \langle u, v\rangle$ and $\pi_1(T^*) = \langle x, y\rangle$.

By the discussion on page 432 the abelianization of $\pi_1(S\#T) = \pi_1(S^* \cup_{\partial S^* = \partial T^*} T^*)$ is the free abelian group on u, v, x, y. Now we consider the epimorphism

$$\varphi\colon \pi_1(S\#T) \;\to\; \pi_1(S\#T)/[\pi_1(S\#T), \pi_1(S\#T)] \;\to\; \mathbb{Z}_3$$

given by $u \mapsto 1, v \mapsto 0, x \mapsto 0$ and $y \mapsto 0$. Our goal in the following discussion is to visualize the covering $p\colon \widetilde{F} \to F = S\#T$ corresponding to $\ker(\varphi)$. Since φ is an epimorphism onto a group of order 3 we see that $\ker(\varphi)$ is a subgroup of index 3. By Lemma 7.16 this implies that p is a 3-fold covering.

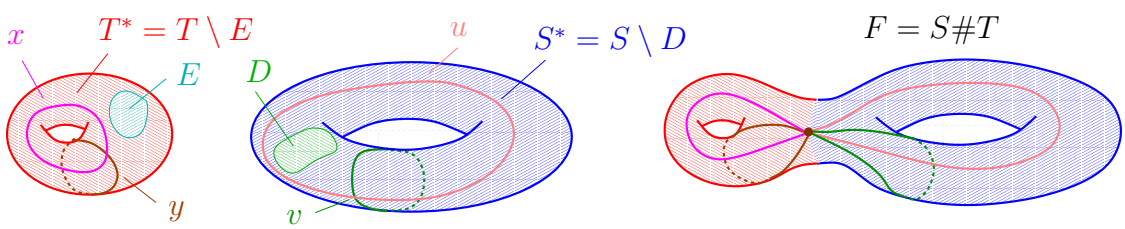

FIGURE 345.

We first consider the torus $S = S^1 \times S^1$ and furthermore we consider the epimorphism $\psi\colon \pi_1(S) = \langle u, v \mid [u, v]\rangle \to \mathbb{Z}_3$ given by $\psi(u) = 1$ and $\psi(v) = 0$. The covering corresponding to $\ker(\psi) \subset \pi_1(S)$ is equivalent to the covering[451]

$$\begin{array}{rcl} \widetilde{S} = S^1 \times S^1 & \to & S = S^1 \times S^1 \\ (a, b) & \mapsto & (a^3, b). \end{array}$$

Now we consider the epimorphism $\psi^*\colon \pi_1(S^*) \to \mathbb{Z}_3$ given by $\psi^*(u) = 1$ and $\psi^*(v) = 0$. By the argument of Footnote 451 the covering corresponding to $\ker(\psi^*)$ is then given by $p\colon \widetilde{S}^* := \widetilde{S} \setminus p^{-1}(D) \to S^* = S \setminus D$. Recall that we perform the connected sum operation $S\#T$ by gluing $T^* := T \setminus E$ to $S^* = S \setminus D$ to obtain $F = S\#T$. The same way we can

[450]It follows from Corollary 20.7 that we can be a bit casual in our language, i.e. we can talk about "gluing surfaces" without specifying explicit diffeomorphisms of boundary components, as long as we take into account orientations.

[451]Indeed, since $\widetilde{S} \to S$ is a connected 3-fold covering we know from Lemma 7.16 that $p_*(\pi_1(\widetilde{S}))$ is a subgroup of $\pi_1(S)$ of index three. Furthermore it is contained in the subgroup $\ker\left(\pi_1(S) \xrightarrow{\psi} \mathbb{Z}_3\right)$ which also has index three, thus $p_*(\pi_1(\widetilde{S})) = \ker(\psi\colon \pi_1(S) \to \mathbb{Z}_3)$. But by Proposition 20.9 all path-connected coverings that correspond to the same subgroup are equivalent.

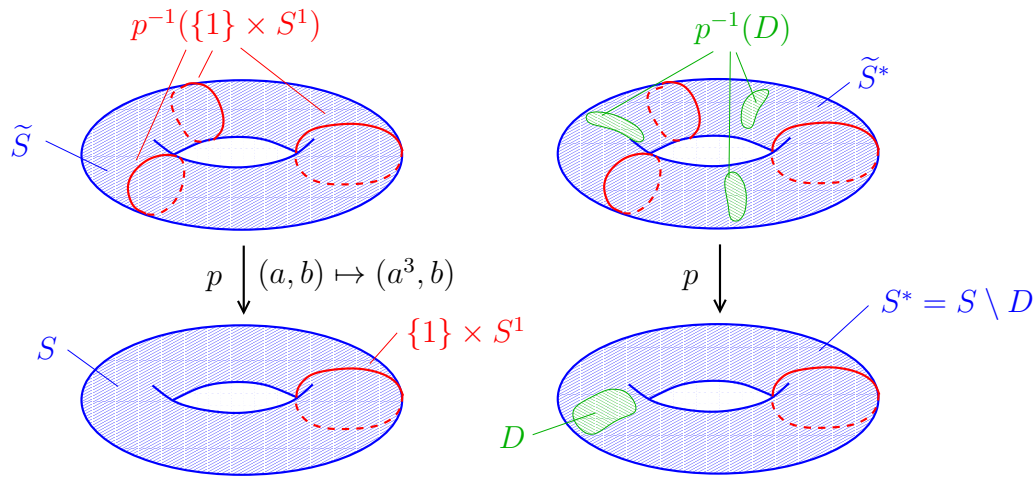

FIGURE 346.

also glue three copies of T^*, i.e. $T^* \times \{1,2,3\}$, to the three boundary components of $\widetilde{S}^*$ to obtain a closed manifold $\widetilde{F}$. It follows from Lemma 1.32 (2') that the map

$$\begin{array}{rcl} q\colon \widetilde{F} & \to & F \\ P & \mapsto & \begin{cases} p(P), & \text{if } P \in \widetilde{S}^*, \\ Q, & \text{if } P = Q \times \{n\} \text{ with } Q \in T^* \text{ and } n \in \{1,2,3\} \end{cases} \end{array}$$

is continuous. Similar to Footnote 451 one can now see that $q\colon \widetilde{F} \to F$ is indeed the covering of F corresponding to $\ker(\varphi)$. This construction is illustrated in Figure 347 which also shows that $\widetilde{F}$ is a surface of genus 4.

20.5. **The universal covering of a reasonable topological space.** In Proposition 20.9 we saw that subgroups of fundamental groups give rise to covering spaces. An obvious choice of a subgroup is the trivial group and we immediately obtain the following corollary to Proposition 20.9.

Corollary 20.11. *Let X be a path-connected and reasonable topological space and let $x_0 \in X$. Then the following holds:*

(1) *There exists, up to equivalence, a unique path-connected covering*

$$p\colon (\widetilde{X}, \widetilde{x}_0) \to (X, x_0)$$

such that $\widetilde{X}$ is simply connected.

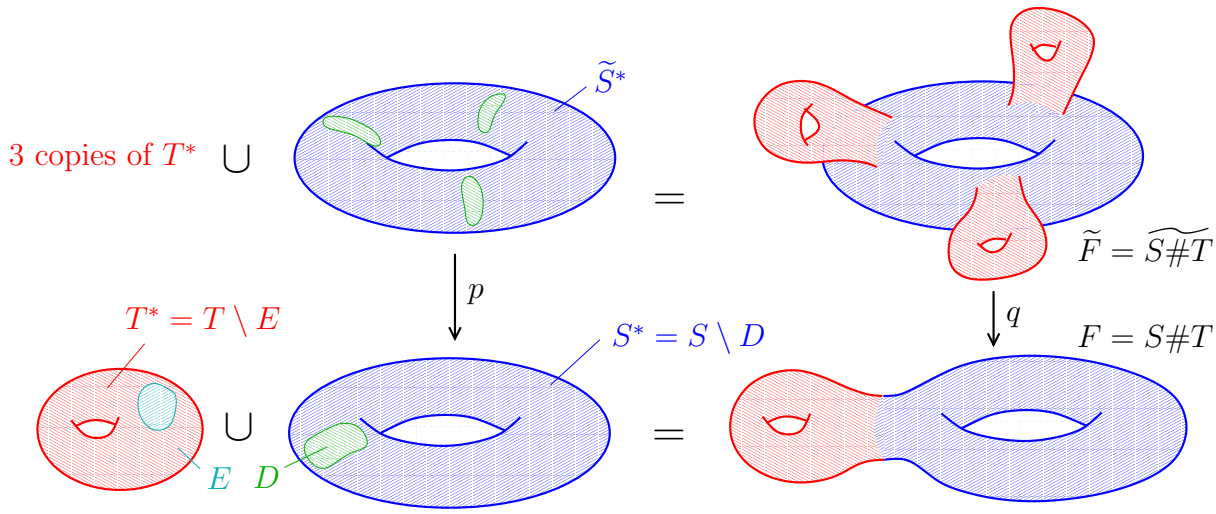

FIGURE 347.

(2) *Let $q\colon (Y, y_0) \to (X, x_0)$ be another path-connected covering. Then there exists a unique covering $r\colon (\widetilde{X}, \widetilde{x}_0) \to (Y, y_0)$ such that the following diagram commutes:*

$$\begin{tikzcd} (\widetilde{X}, \widetilde{x}_0) \arrow[dr, "r"] \arrow[dd, "p"'] & \\ & (Y, y_0) \arrow[dl, "q"] \\ (X, x_0). & \end{tikzcd}$$

Proof. Let X be a path-connected and reasonable topological space and let $x_0 \in X$.

(1) We apply Proposition 20.9 to the trivial subgroup of $\pi_1(X, x_0)$ and we obtain, up to equivalence, a unique path-connected covering $p\colon (\widetilde{X}, \widetilde{x}_0) \to (X, x_0)$ such that $p_*(\pi_1(\widetilde{X}, \widetilde{x}_0))$ is the trivial group. But then it follows from Corollary 7.15 that $\widetilde{X}$ is simply connected.

(2) The second statement is also an immediate consequence of Proposition 20.9. $\square$

Definition. Let X be a path-connected and reasonable topological space. We refer to the covering $p\colon \widetilde{X} \to X$ such that $\widetilde{X}$ is simply connected as the *universal covering* of X. As in the previous definition we suppress the fact that the universal covering is well-defined only up to equivalence.[452]

Remark. Recall that most "reasonable" topological spaces are reasonable in the technical sense. For example we saw on page 549 that every topological manifold is reasonable. Thus, given a path-connected topological manifold we can talk of is universal covering.

[452]In the literature the universal covering of a topological space is usually indicated by the same symbol but decorated with a tilde, e.g. the universal covering of X is usually denoted by $\widetilde{X}$.

Examples.

(1) The map
$$\begin{array}{rcl} p\colon \mathbb{R} & \to & \mathbb{R}/\mathbb{Z} = S^1 \\ t & \mapsto & e^{2\pi i t} \end{array}$$
is the universal covering of S^1.

(2) More generally, the map
$$\begin{array}{rcl} p\colon \mathbb{R}^n & \to & (S^1)^n \\ (t_1, \dots, t_n) & \mapsto & \left(e^{2\pi i t_1}, \dots, e^{2\pi i t_n}\right) \end{array}$$
is the universal covering of the n-dimensional torus $(S^1)^n$.

(3) The projection map $p\colon S^3 \to S^3/\mathbb{Z}_p = L(p,q)$ is the universal covering of the lens space $L(p,q)$.

Remark. The universal covering is often also just called the *universal cover*. Also very often one suppresses the actual map p from the notation. For example, often one says that "$\mathbb{R}^n$ is the universal covering of $(S^1)^n$". The name "universal cover(ing)" stems from the fact, proved in Corollary 20.11, that the universal cover(ing) of a topological space X "covers" every other covering of X.

We have now shown that for every reasonable topological space X there exists a universal covering $p\colon \widetilde{X} \to X$. So far we have given an abstract construction, but if possible we would like to visualize it. We have just given an explicit description of the universal covering of the n-dimensional torus $(S^1)^n$ and the lens spaces. Now we will describe the universal covers of $X = S^1 \vee S^2$ and $X = S^1 \vee S^1$.

First we consider $X = S^1 \vee S^2$ where we identify $i \in S^1$ with $(0,0,-1) \in S^2$. As on page 391 we consider the topological space
$$\widetilde{X} \;=\; \left(\mathbb{R} \cup (\mathbb{Z} \times S^2)\right) / \, n \sim (n, (0,0,-1)), \quad n \in \mathbb{Z}.$$
It is straightforward to see that the map
$$\begin{array}{rl} p\colon \left(\mathbb{R} \cup (\mathbb{Z} \times S^2)\right) / \, n \sim (n,(0,0,-1)) & \to S^1 \vee S^2 \\ P & \mapsto \begin{cases} e^{i(2\pi P + \frac{\pi}{2})}, & \text{if } P \in \mathbb{R} \\ Q, & \text{if } P = (n,Q) \text{ with } n \in \mathbb{Z}, Q \in S^2 \end{cases} \end{array}$$
is well-defined and in fact a covering. We saw on page 391 that $\widetilde{X}$ is simply connected. Thus $p\colon \widetilde{X} \to X$ is the universal covering of X.

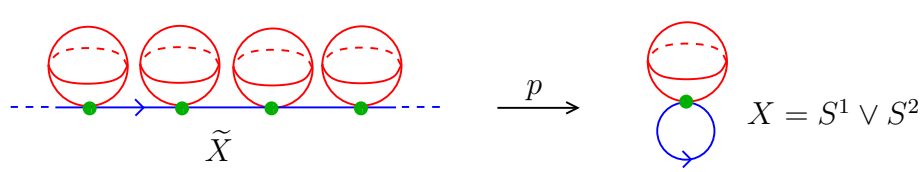

FIGURE 348.

Now we turn to $X = S^1 \vee S^1$. In the following we give a semi-rigorous description of the universal covering of $S^1 \vee S^1$ as a subset of $\mathbb{R}^2$. Iteratively we build a sequence of topological spaces Y_k, $k \in \mathbb{N}_0$ as follows:

(1) The space Y_0 is the cross centered at the origin where each segment has length 1.
(2) Given Y_k we attach to each endpoint of Y_k three segments of length $\frac{1}{4^k}$[453] such that each endpoint of Y_k now has a neighborhood that is a cross. We denote the resulting space by Y_{k+1}.

Finally we put $Y = \bigcup_{k \in \mathbb{N}_0} Y_k$. This construction is illustrated in Figure 349. We summarize

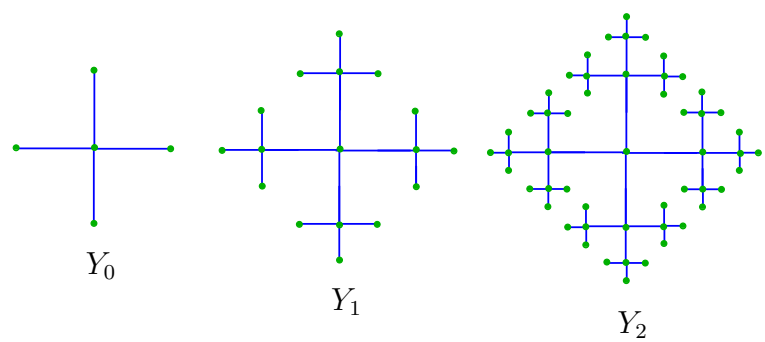

FIGURE 349.

some of the key properties of the construction in the following claim.

Claim.

(1) Each Y_k is a tree.[454]
(2) Y is simply connected.

Sketch of proof. First note that $\chi(Y_0) = 5 - 4 = 1$. For $k \geq 1$ we obtain Y_k from Y_{k-1} by adding three vertices and three edges, hence $\chi(Y_k) = \chi(Y_{k-1}) = \cdots = \chi(Y_0) = 1$. This shows that each Y_k is a tree. It follows from Proposition 9.20 that each Y_k is simply connected.

Given $k \in \mathbb{N}$ we denote by U_k the result of removing the 4^{k+1} endpoints of Y_k. Note that each U_k is open in Y_k, hence each U_k is open in Y. Furthermore each U_k deformation retracts to Y_{k-1}. Hence it follows from the fact that each Y_k is simply connected that also each U_k is simply connected.

It follows as in Lemma 12.6 that $Y = \bigcup_{k \in \mathbb{N}} Y_k = \bigcup_{k \in \mathbb{N}} U_k$ itself is simply connected. $\square$

Now we construct a covering $p\colon Y \to S^1 \vee S^1$. To distinguish the two copies of S^1 we name them A and B, which are wedged together along $a \in A$ and $b \in B$. We give both

[453] In Figure 349 and 350 the lengths of the segments is $\frac{1}{2^k}$ since these are easier to draw.

[454] Recall that a tree is a graph with finitely many vertices V and edges E, such that the Euler characteristic $\chi(G) = \#V - \#E = 1$.

A and B the usual counterclockwise orientation. Furthermore we orient each edge of the infinite graph Y as indicated in Figure 350. We consider the map $p\colon Y \to A \vee B$ that is

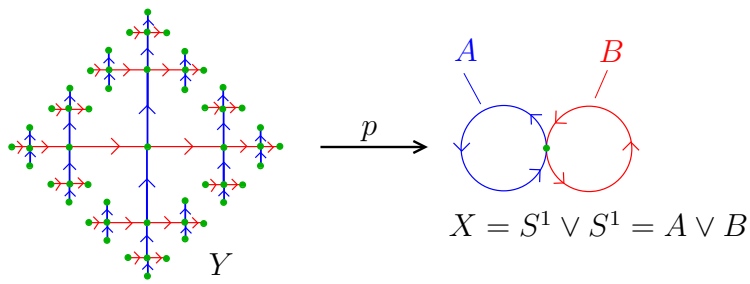

FIGURE 350.

given as follows:

(1) each vertex of the infinite graph Y gets sent to the point $a = b \in A \vee B$,
(2) each horizontal edge of Y gets sent in an orientation-preserving way to $A \setminus \{a\}$,
(3) each vertical edge of Y gets sent in an orientation-preserving way to $B \setminus \{b\}$.

This map is illustrated in Figure 350. It is relatively straightforward to convince oneself that $p\colon Y \to X$ is in fact a covering.[455] Since Y is simply connected, this is the universal covering of $X = A \vee B = S^1 \vee S^1$.

We have now determined explicitly the universal covers of several topological spaces. The surfaces of genus $g \geq 2$ are arguably one of the most interesting types of topological manifolds. Therefore it is natural to ask the following question.

Question 20.12. *What does the universal covering of the surface of genus $g \geq 2$ look like?*

We conclude this section with a more general statement. Recall that in Theorem 7.17 we saw that if X is a simply connected topological space and if G is a group that acts continuously and discretely on X, then the fundamental group of the quotient space X/G is isomorphic to G. Now we will show that, under modest extra hypotheses, the converse holds. More precisely, we have the following proposition.

Proposition 20.13. $(*)$*Let Y be a path-connected, reasonable topological space and let $y_0 \in Y$. We write $\pi = \pi_1(Y, y_0)$. Then there exists a simply connected topological space X, namely the universal covering of Y, and a continuous and discrete action of π on X such that Y is homeomorphic to X/π.*

[455] We have to check that each point in $X = A \vee B$ admits an open neighborhood that is uniformly covered. It is clear that such a point exists for all points that are not the wedge point. For the wedge point itself the desired open neighborhood is given by small open intervals on A and B. Then each component of the preimage consists of a little cross with center P, with one horizontal edge going into P, one horizontal edge going out of P, one vertical edge going into P and one vertical edge going out of P.

Proof $(*)$. Let Y be a path-connected, reasonable topological space and let $y_0 \in Y$ be a base point. In Proposition 20.8 we already showed that Y admits a simply connected covering. We recall the explicit construction given in the proof of Proposition 20.8. Thus we consider

$$W \;:=\; \{\text{all paths in } Y \text{ with starting point } y_0\}.$$

For $u, v \in W$ we write

$$u \sim v \quad :\Leftrightarrow \quad u \text{ and } v \text{ have the same endpoint and } [u * \overline{v}] = e \in \pi_1(Y, y_0)$$

and we put $X = W/\sim$. As on page 560, given $x = [f] \in X = W/\sim$ and an open path-connected neighborhood V of $f(1)$ we define

$$U(x, V) \;:=\; \{[f * u] \mid u \text{ is a path in } V \text{ with starting point } f(1)\} \;\subset\; Y = W/\sim .$$

Furthermore, as in the proof of Proposition 20.8 we endow X with the topology generated by these sets $U(x, V)$.

Claim. The map

$$\begin{array}{rcl} \pi_1(Y, y_0) \times X & \to & X \\ ([g], [u]) & \mapsto & [g * u] \end{array}$$

is a well-defined action.

We first show that the map is independent of the choice of u. So suppose that $u, v \in W$ are equivalent. Then $g * u$ and $g * v$ still have the same endpoint. Now we need to consider the second condition in the definition of $\sim$. We have

$$[(g * u) * (\overline{g * v})] \;=\; [g * u * \overline{v} * \overline{g}] \;=\; [g] * \underbrace{[u * \overline{v}]}_{=e \in \pi_1(Y, y_0)} * [g]^{-1} \;=\; e \;\in \pi_1(Y, y_0).$$

It is straightforward to see that the map does not depend on the choice of representative g. Finally we want to show that it is indeed an action. So let $[g], [h] \in \pi_1(Y, y_0)$. Then

$$[g] \cdot ([h] \cdot [u]) \;=\; [g] \cdot [h * u] \;=\; [g * (h * u)] \;=\; [(g * h) * u] \;=\; [g * h] \cdot [u] \;=\; ([g] \cdot [h]) \cdot [u].$$

This concludes the proof of the claim.

Now we need to show the following:

(1) the group $\pi_1(Y, y_0)$ acts continuously and discretely on $X = W/\sim$,
(2) there exists a homeomorphism $f\colon X/\pi_1(Y, y_0) \to Y$.

We do this in the following two steps:

(1) It follows immediately from the definition of the topology on $X = W/\sim$ and from Proposition 1.34 that the action is continuous.

Now we need to show that the action is discrete. So let $x = [w] \in W/\sim$. Since W is reasonable we can pick a simply connected neighborhood V around the endpoint P of w. It suffices to show that for $[g] \in \pi_1(Y, y_0)$ we have

$$[g] \cdot U(x, V) \cap U(x, V) \neq \varnothing \quad \Longrightarrow \quad [g] = e \in \pi_1(Y, y_0).$$

So suppose that $[g] \cdot U(x,V) \cap U(x,V) \neq \varnothing$. This means that there exist paths a and b in U, starting from P such that $g * w * a$ and $w * b$ have the same endpoint and they are path-homotopic. But then

$$[g] \;=\; [g] \cdot \underbrace{[w] \cdot \overbrace{[a * \bar{b}]}^{=e\in\pi_1(Y,y_0)=\{e\}} * [w]^{-1}}_{=e\in\pi_1(Y,y_0)} \;=\; [(g * w * a) * \overline{(w * b)}] \;=\; e \in \pi_1(Y, y_0).$$

We refer to Figure 351 for an illustration.

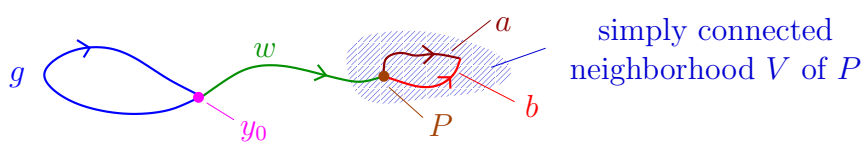

FIGURE 351.

(2) We consider the map

$$\begin{aligned} f\colon X/\pi_1(Y,y_0) &\to Y \\ [w] &\mapsto w(1). \end{aligned}$$

It is straightforward to see that this map is a bijection. It follows immediately from Lemma 1.66 that the map is continuous and it follows from Lemma 1.36 that the map is open. Thus it is a homeomorphism. □

20.6. **Preimages of subsets under coverings** $(*)$**.** Let (B, b_0) be a pointed topological space that is path-connected reasonable. In Proposition 20.8 (2) we saw that subgroups of $\pi_1(B, b_0)$ give rise to coverings of B. Arguably the most common source of subgroups is given by considering kernels of group homomorphisms $\pi_1(B, b_0) \to G$.

Example. Let B be the 2-dimensional sphere S^2 minus three open disks. We pick a base point b_0 for B and we pick loops u, v, w as shown in Figure 352. From Lemma 14.19 we know that $\pi_1(B, b_0) = \langle u, v, w \,|\, uvw \rangle$. By Lemma 13.4 there exists a unique homomorphism $\varphi\colon \pi_1(B, b_0) \to \mathbb{Z}_6$ with $\varphi(u) = 2$, $\varphi(v) = 3$ and $\varphi(w) = -5$. Let $p\colon X \to B$ be the covering corresponding to $\ker(\varphi)$. It is pretty clear, and we will see it in the subsequent Proposition8.1, that X is again a compact orientable 2-dimensional manifold with boundary given by $\partial X = p^{-1}(\partial B)$. Thus we know from Theorem 14.14 that there exist unique $g \in \mathbb{N}_0$ and $n \in \mathbb{N}$ such that X is homeomorphic to $\Sigma_{g,n}$, i.e. such that X is homeomorphic to the surface of genus g minus n open disks.

Therefore the following question arises:

Question 20.14. *In the previous example, what are g and n?*

The final proposition of this chapter will allow us to answer one half of Question 20.14, namely we can determine n. We will determine g at a later stage.

FIGURE 352.

Proposition 20.15. *Let (B, b_0) be a pointed topological space that is path-connected reasonable. Furthermore let $\varphi\colon \pi_1(B, b_0) \to G$ be a group epimorphism and let $p\colon (X, x_0) \to (B, b_0)$ be the covering with $p_*(\pi_1(X, x_0)) = \ker(\varphi)$. Finally let A be a path-connected subset of B and let $a_0 \in A$. We denote by $i\colon A \to B$ the inclusion map and we pick a path γ from b_0 to a_0. We consider the homomorphism*

$$\psi := \varphi \circ \gamma_* \circ i_*\colon \pi_1(A, a_0) \xrightarrow{i_*} \pi_1(B, a_0) \xrightarrow{\gamma_*} \pi_1(B, b_0) \xrightarrow{\varphi} G.$$

With these preparations the following two statements hold:

(1) *Each path-component of $p^{-1}(A)$ is the covering of A corresponding to the subgroup $\ker\{\psi\colon \pi_1(A, a_0) \to G\}$.*
(2) *If G is a finite group, then*

$$b_0(p^{-1}(A)) \;=\; [G : \mathrm{im}\{\psi\colon \pi_1(A, a_0) \to G\}].$$

Example. As promised we can now determine the number n of boundary components of the covering X in the previous example. More precisely, denote by U, V, W the three boundary components of B. We make the following three observations:

(1) The image of $\pi_1(U)$ in $\mathbb{Z}_6$ is the subgroup generated by $\varphi(u) = 2$, thus the subgroup has index two, which by Proposition 20.15 implies that $p^{-1}(U)$ consists of two components.
(2) The image of $\pi_1(U)$ in $\mathbb{Z}_6$ is the subgroup generated by $\varphi(v) = 3$, thus $p^{-1}(V)$ consists of three components.
(3) The image of $\pi_1(U)$ in $\mathbb{Z}_6$ is the subgroup generated by $\varphi(v) = -5$. Since -5 is coprime to 6 we see that this subgroup is all of $\mathbb{Z}_6$, thus $p^{-1}(W)$ consists of precisely one component.

Altogether we see that X has $2 + 3 + 1 = 6$ boundary components.

Remark. The reader who is in need of a brain teaser might want to come up with an appropriate generalization of Proposition 20.15 to the case where we consider coverings of B coming from a non-normal subgroup.

Proof. To simplify the notation a little bit we assume that $a_0 = b_0$, in particular we ignore the role of γ. Throughout the proof we refer to Figure 353 for an illustration.

(1) Let W be a path-component of $p^{-1}(A)$. We pick a point $w_0 \in W$ with $p(w_0) = a_0$. We start out with the following slightly subtle claim.

Claim.
$$p_*(\pi_1(X, w_0)) \;=\; \ker\{\varphi\colon \pi_1(B, a_0) \to G\}.$$

We pick a path γ in X from x_0 to w_0. Since $p \circ \gamma$ is a loop in a_0 we can write $h := [p \circ \gamma] \in \pi_1(B, a_0)$. We consider the following diagram

$$\begin{tikzcd}
\pi_1(X, w_0) \arrow[r, "\gamma_*", "\cong"'] \arrow[d, "p_*"] & \pi_1(X, x_0) \arrow[d, "p_*"] \\
\pi_1(B, a_0) \arrow[r, "g \mapsto hgh^{-1}", "\cong"'] \arrow[d, "\varphi"] & \pi_1(B, a_0) \arrow[d, "\varphi"] \\
G \arrow[r, "g \mapsto \varphi(h) g \varphi(h)^{-1}", "\cong"'] & G.
\end{tikzcd}$$

The top square commutes by Proposition 5.11 (2) and (3). Evidently the bottom square also commutes. By definition of (X, x_0) we have
$$p_*(\pi_1(X, x_0)) \;=\; \ker\{\varphi\colon \pi_1(B, a_0) \to G\}.$$
The claim now follows from the fact that the diagram commutes and that the horizontal maps are isomorphisms.

In the following we denote by $j\colon W \to X$ the inclusion map. We consider the following diagram

$$\begin{tikzcd}
\pi_1(W, w_0) \arrow[r, "j_*"] \arrow[d, "p_*"] & \pi_1(X, w_0) \arrow[d, "p_*"] \\
\pi_1(A, a_0) \arrow[r, "i_*"] \arrow[dr, "\psi"'] & \pi_1(B, a_0) \arrow[d, "\varphi"] \\
& G.
\end{tikzcd}$$

Recall that we need to show the equality $p_*(\pi_1(W, w_0)) = \ker(\psi)$. We show the two inclusions separately.

"$\subset$" This inclusion follows immediately from the definitions, from the commutativity of the above diagram and from the claim.

"$\supset$" Thus let $g \in \ker(\psi)$. We represent it by a loop γ in (A, a_0). By the above claim and Lemma 7.16 the loop $i \circ \gamma$ in (B, a_0) lifts to a loop $\widetilde{\gamma}$ in (X, w_0). By definition the image of $\widetilde{\gamma}$ lies in $p^{-1}(A)$ and it contains w_0. In particular the image of $\widetilde{\gamma}$ lies in the path-component of $p^{-1}(A)$ that contains w_0, in other words, $\widetilde{\gamma}$ is actually a loop in (W, w_0). Since $g = p_*([\widetilde{\gamma}])$ we obtain that $g \in p_*(\pi_1(W, w_0))$.

(2) We write $n = |G|$ and $k = |\operatorname{im}\{\psi\colon \pi_1(A, a_0) \to G\}|$. It follows from Lemma 7.16 and (1) that each path-component of $p^{-1}(A)$ is a k-fold covering of A. By Lemma 7.16 the map $p\colon X \to B$ is an n-fold covering. Evidently $p\colon p^{-1}(A) \to A$ is also an

n-fold covering. It follows almost immediately that $p^{-1}(A)$ has necessarily n/k path-components. But $n/k = |G|/|\operatorname{im}(\psi)|$ is by definition the degree of $\operatorname{im}(\psi)$ in G. $\square$

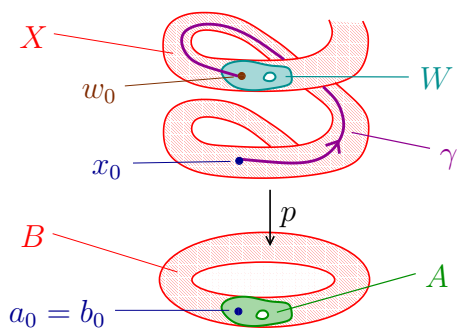

FIGURE 353. Illustration for the proof of Proposition 20.15.

Exercises for Chapter 20.

Exercise 20.1. Show that there is no algorithm that can decide whether or not a given finite presentation $\pi = \langle g_1, \ldots, g_k \mid r_1, \ldots, r_l \rangle$ represents a group that is isomorphic to $\mathbb{Z}$.

Exercise 20.2. Prove Corollary 20.4.

Exercise 20.3. Let $p\colon (X, x_0) \to (B, b_0)$ and $q\colon (Y, y_0) \to (B, b_0)$ be two path-connected coverings of topological spaces such that $p_*(\pi_1(X, x_0)) \subset q_*(\pi_1(Y, y_0))$. It follows from Proposition 20.2 that there exists a unique map $r\colon (X, x_0) \to (Y, y_0)$ which makes the following diagram commute

$$\begin{tikzcd} & (Y, y_0) \arrow[d, "q"] \\ (X, x_0) \arrow[ur, "r"] \arrow[r, "p"'] & (B, b_0). \end{tikzcd}$$

Show that r is a covering.

Exercise 20.4. We consider Figure 354.

(a) Let X be the wedge of two circles and let $p\colon Y \to X$ be the universal covering that is illustrated in the figure. Denote the usual generators of $\pi_1(X)$ by a and b. By an abuse of notation we denote by a and b also representing loops. What does the lift of the loop $a * b * \overline{a} * \overline{b}$ to Y to the starting point y_0 look like?

(b) We continue with the notation from (1). Now consider the loop

$$\gamma := a * a * b * a * a * \overline{b} * \overline{a} * b * b * \overline{a} * \overline{a} * \overline{b} * \overline{a} * \overline{b}.$$

We denote by $\widetilde{\gamma}$ the lift of γ to the starting point y_0. Is y_0 the endpoint of $\widetilde{\gamma}$?

(c) Does there exist a homeomorphism $f\colon Y \to Y$ with $f(y_0) = z_0$?

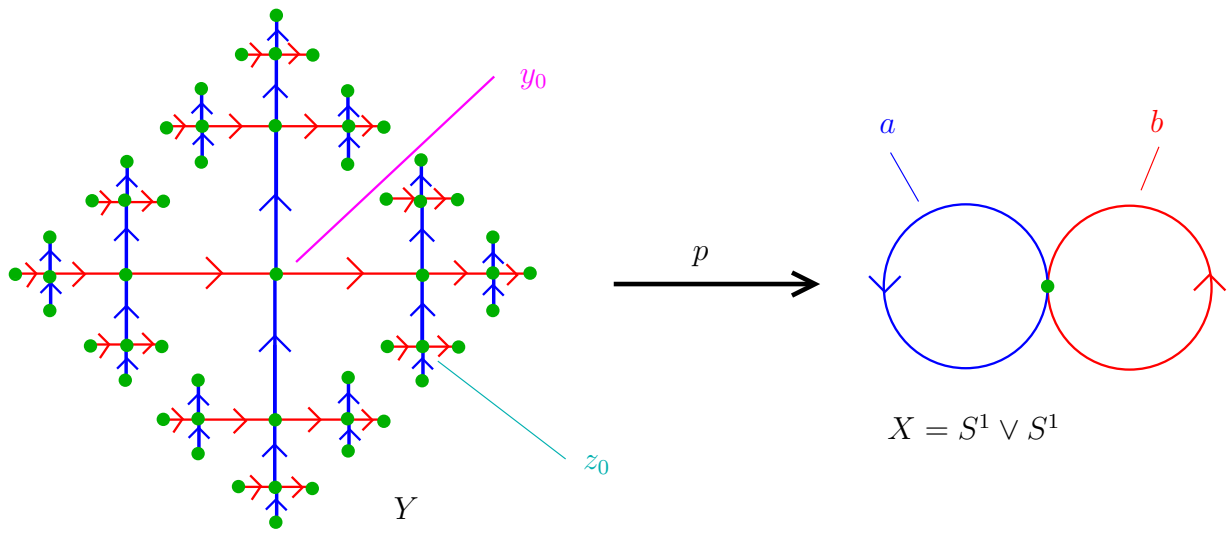

FIGURE 354.

Exercise 20.5.

(a) Let M be the Möbius band. We pick an identification $\pi_1(M) = \mathbb{Z}$. Given $k \in \mathbb{N}$ we denote by Γ_k the kernel of the epimorphism $\pi_1(M) = \mathbb{Z} \to \mathbb{Z}_k$. Let $M_k \to M$ be the covering corresponding to Γ_k. What well-known topological space is M_k? You do not have to justify your answer.

(b) Draw the universal covering of $\mathbb{R}\mathrm{P}^2 \vee S^1$ as a subset of $\mathbb{R}^3$.

(c) Let $X = A \vee B$ be the wedge of two circles. Let $\Gamma \subset \pi_1(X) = \langle a, b\rangle$ be the commutator subgroup. What does the covering $p\colon \widetilde{X} \to X$ corresponding to Γ look like? You can draw it as a subset of $\mathbb{R}^2$.
Hint: You have seen $\widetilde{X}$ many times in your life.

Exercise 20.6. Let X be a topological space and let $f\colon X \to X$ be a homeomorphism. We denote by $M := M(X, f) := (X \times [0,1])/(x,0) \sim (f(x),1)$ the corresponding mapping torus (see page 469.) Let $p\colon \widetilde{M} \to M$ be a finite covering. Show that $\widetilde{M}$ is homeomorphic to a mapping torus.

Exercise 20.7. We say two manifolds M and N are *commensurable* if M and N admit finite covers $\widetilde{M}$ and $\widetilde{N}$ that are diffeomorphic.

(a) Show that the torus and the surface of genus two are not commensurable.

(b) Let $g, h \in \mathbb{N}_{n\geq 2}$. Let M be the surface of genus g and let N be the surface of genus h. Show that M and N are commensurable.

(c) Determine which compact connected 2-dimensional manifolds are commensurable.

Exercise 20.8. Let $f\colon S^1 \to S^1$ be a homeomorphism with $f(1) = 1$. Let $p\colon \mathbb{R} \to S^1$ be the covering that is given by $t \mapsto e^{it}$.

(a) Show that there exists a unique map $\widetilde{f}\colon \mathbb{R} \to \mathbb{R}$ with $f(0) = 0$ such that the following diagram commutes:

$$\begin{tikzcd} \mathbb{R} \arrow[r, "\widetilde{f}"] \arrow[d, "p"'] & \mathbb{R} \arrow[d, "p"] \\ S^1 \arrow[r, "f"] & S^1. \end{tikzcd}$$

(b) Show that the map $\widetilde{f}$ from (a) is a homeomorphism.

21. Complex manifolds

Eventually our goal will be to give an explicit description of the universal covering of the surfaces of genus $g \geq 2$. This will require a surprisingly long journey through complex manifolds, Riemannian manifolds and hyperbolic geometry. In this chapter we start out with a very short introduction to complex manifolds.

First we recall the definition of a holomorphic function.

Definition. Let $U \subset \mathbb{C}$ be an open subset. A function $f\colon U \to \mathbb{C}$ is *holomorphic* if for any $z_0 \in U$ the limit

$$\frac{d}{dz} f(z_0) \;:=\; f'(z_0) \;:=\; \lim_{z \to z_0} \frac{f(z) - f(z_0)}{z - z_0} \;\in \mathbb{C}$$

exists.

Example. In any textbook on complex analysis it is shown that polynomials, the exponential function, and more generally functions defined by power series are holomorphic. Moreover products, fractions, sums and compositions of holomorphic functions are again holomorphic.

The definition of a complex function being holomorphic is almost verbatim the same as the definition of a real function being smooth. But rather surprisingly being holomorphic is significantly more restrictive, as is shown in the following two standard results in complex analysis, see e.g. [Jä2] or [Lan].

Theorem 21.1. (Liouville's Theorem) *Every bounded holomorphic map $f\colon \mathbb{C} \to \mathbb{C}$ is constant.*

Theorem 21.2. (Maximum Principle) *Let U be an open connected subset of $\mathbb{C}$ and let $f\colon U \to \mathbb{C}$ be a holomorphic function. If the function $|f|\colon U \to \mathbb{R}_{\geq 0}$ has a local maximum, then f is constant.*

The following proposition also belongs to the usual repertoire of a course on complex analysis, see e.g. [Lan, Chapter IX.1].

Proposition 21.3. (Schwarz Reflection Principle) *Let U be an open subset of the upper half-plane $\{z \in \mathbb{C} \mid \operatorname{Im}(z) \geq 0\}$ and let $f\colon U \to \mathbb{C}$ be a continuous function with the following properties:*

1. *f is holomorphic on $\mathring{U} = \{z \in U \mid \operatorname{Im}(z) > 0\}$,*
2. *f only assumes real values on $U \cap \mathbb{R}$.*

We set $U' := \{\overline{z} \mid z \in U\}$, i.e. U' is the reflection of U in the x-axis. Then the function

$$\begin{aligned} \widetilde{f}\colon U \cup U' &\to \mathbb{C} \\ z &\mapsto \begin{cases} f(z), & \text{if } z \in U, \\ \overline{f(\overline{z})}, & \text{if } z \in U', \end{cases} \end{aligned}$$

is holomorphic.

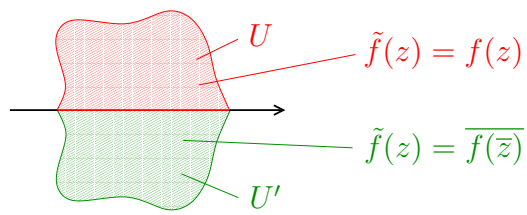

FIGURE 355. Illustration of the Schwarz reflection principle.

Given a topological manifold we now introduce the notion of a holomorphic atlas and a complex manifold. The definition is almost the same as for a smooth atlas and a manifold, except that we have to replace "smooth" by "holomorphic".

Definition.

(1) Let $U \subset \mathbb{C}^m$ be open. We say that a map $f = (f_1, \dots, f_n) \colon U \to \mathbb{C}^n$ is *holomorphic* if for any $i \in \{1, \dots, m\}$, $j \in \{1, \dots, n\}$ and any $(w_1, \dots, w_{i-1}, w_{i+1}, \dots, w_m) \in \mathbb{C}^{m-1}$ the map

$$\begin{array}{rcl} \overbrace{\{z \in \mathbb{C} \mid (w_1, \dots, w_{i-1}, z, w_{i+1}, \dots, w_m) \in U\}}^{\text{open subset of } \mathbb{C}} & \to & \mathbb{C} \\ z & \mapsto & f_j(w_1, \dots, w_{i-1}, z, w_{i+1}, \dots, w_m) \end{array}$$

is holomorphic

(2) Let M be a $2n$-dimensional topological manifold M without boundary. An atlas $\{\Phi_i \colon U_i \to V_i\}_{i \in I}$ for M is called *holomorphic* if for all $i, j \in I$ the transition map

$$\Phi_j \circ \Phi_i^{-1} \colon \underbrace{\Phi_i(U_i \cap U_j)}_{\text{open in } \mathbb{R}^{2n} = \mathbb{C}^n} \to \underbrace{\Phi_j(U_i \cap U_j)}_{\subset \mathbb{R}^{2n} = \mathbb{C}^n}$$

is holomorphic.

(3) An *n-dimensional complex manifold* is a pair $(M, \mathcal{A})$ consisting of a $2n$-dimensional topological manifold M without boundary, together with a holomorphic atlas for M.

(4) We define the *maximal holomorphic atlas* of a complex manifold the same way as we defined the maximal smooth atlas of a manifold, see page 184.

Remark. Since holomorphic maps are in particular smooth we see that every n-dimensional complex manifold is in particular a $2n$-dimensional manifold.

Examples.

(1) Let U be an open subset of $\mathbb{C}^n$. The identity map is an atlas for U and it is evidently a holomorphic atlas. Thus U is an n-dimensional complex manifold.

(2) We consider the action

$$\begin{array}{rcl} (\mathbb{Z} \oplus \mathbb{Z}i) \times \mathbb{C} & \to & \mathbb{C} \\ ((a + bi), z) & \mapsto & z + a + bi. \end{array}$$

The same argument as in the proof of Proposition 3.25 shows that $\mathbb{C}/(\mathbb{Z} \oplus \mathbb{Z}i)$ is a 1-dimensional complex manifold. The topological space $\mathbb{C}/(\mathbb{Z} \oplus \mathbb{Z}i)$ is evidently diffeomorphic to the torus $\mathbb{R}^2/\mathbb{Z}^2 = S^1 \times S^1$. Thus we can view the torus as a complex manifold.

The following proposition shows in particular that the Klein bottle and the real projective plane $\mathbb{R}\mathrm{P}^2$ are *not* complex manifolds.

Proposition 21.4. *An n-dimensional complex manifold, viewed as a $2n$-dimensional real manifold, comes with a canonical orientation. More precisely, we can equip any complex manifold with an orientation which has the following two properties:*

(1) *any open subset of $\mathbb{C}^n = \mathbb{R}^{2n}$ inherits the usual orientation,*
(2) *the orientations are preserved under local biholomorphisms.*

Before we can prove Proposition 21.4 we need the following definition and the subsequent lemma.

Definition. Let V be an n-dimensional complex vector space. We say that a set of vectors $\{v_1, \dots, v_n\}$ in V is *totally real* if the vectors $v_1, iv_1, \dots, v_n, iv_n$ form a basis of V, viewed as a $2n$-dimensional real vector space.

Lemma 21.5. *Let V be an n-dimensional complex vector space.*

(1) *V admits a set of totally real vectors.*
(2) *If $\{v_1, \dots, v_n\}$ and $\{w_1, \dots, w_n\}$ are two sets of totally real vectors for a complex vector space V, then the bases $\{v_1, iv_1, \dots, v_n, iv_n\}$ and $\{w_1, iw_1, \dots, w_n, iw_n\}$ are equivalent in the sense of page 199.*

Given a finite dimensional complex vector space we refer to the orientation introduced in Lemma 21.5 as the *canonical* orientation.

Proof. The first statement follows from the observation that V is isomorphic, as a complex vector space, to $\mathbb{C}^n$, and for $\mathbb{C}^n$ a totally real basis is given by vectors $e_i = (0, \dots, 1, \dots, 0)$, $i = 1, \dots, n$.

We turn to the proof of the second statement. First we consider the case $n = 1$. In this case we are given two non-zero vectors v and w. Then $v = (a + ib)w$ for some $a + bi \neq 0$. The base change matrix from the real basis $\{v, iv\}$ to the real basis $\{w, iw\}$ is given by the real 2×2-matrix

$$\begin{pmatrix} a & -b \\ b & a \end{pmatrix}.$$

Evidently the determinant of this matrix is positive. This concludes the proof of the claim for $n = 1$. The general statement is basically just an exercise in linear algebra. This

exercise though turns out to be slightly harder than one might expect.[456] A proof is for example given in [CCL, Theorem 7.2.1]. □

Now we sketch a proof of Proposition 21.4.

Sketch of a proof of Proposition 21.4. Let M be an n-dimensional complex manifold. It is relatively straightforward to see that each tangent space T_PM is canonically an n-dimensional complex vector space. Now we equip it with the above canonical orientation. These orientations of the tangent spaces define a canonical orientation on the $2n$-dimensional real manifold M. One can easily verify that the orientations have the desired properties (1) and (2). □

The next lemma gives us an example of a complex manifold that will play a major role later on.

Lemma 21.6. *Let $n \in \mathbb{N}$. On page 111 we introduced the complex projective space*

$$\mathbb{C}\mathrm{P}^n \;=\; (\mathbb{C}^{n+1} \setminus \{0\})/(\mathbb{C} \setminus \{0\}).$$

For $i = 0, \dots, n$ we consider the map

$$\begin{array}{rcl} \Phi_i \colon \{[z_0 : \cdots : z_n] \,|\, z_i \neq 0\} & \to & \mathbb{C}^n \\ [z_0 : \cdots : z_n] & \mapsto & \big(\frac{z_0}{z_i}, \dots, \frac{z_{i-1}}{z_i}, \frac{z_{i+1}}{z_i}, \dots, \frac{z_n}{z_i}\big). \end{array}$$

These maps form a holomorphic atlas for $\mathbb{C}\mathrm{P}^n$ that turn the complex projective space $\mathbb{C}\mathrm{P}^n$ into an n-dimensional compact complex manifold, in particular we can view $\mathbb{C}\mathrm{P}^n$ as a closed $2n$-dimensional oriented real manifold.

Proof. In Lemma 1.81 we saw that each $\mathbb{C}\mathrm{P}^n$ is compact and Hausdorff. As we will show below, $\mathbb{C}\mathrm{P}^n$ admits a finite atlas, thus it follows from Lemma 3.3 that $\mathbb{C}\mathrm{P}^n$ is second-countable. For the remaining statements it is easy to overlook that first one needs to prove the following claim.

Claim. If $i \in \{0, \dots, n\}$, then

$$V_i \;:=\; \{[z_0 : \cdots : z_n] \in \mathbb{C}\mathrm{P}^n \,|\, z_i \neq 0\}$$

is an open subset of $\mathbb{C}\mathrm{P}^n$.

The claim is equivalent to showing that the complement $\mathbb{C}\mathrm{P}^n \setminus V_i$ is a closed subset of $\mathbb{C}\mathrm{P}^n$. We note that

$$\mathbb{C}\mathrm{P}^n \setminus V_i \;=\; \text{the image of the map } \begin{array}{rcl} f \colon \mathbb{C}\mathrm{P}^{n-1} & \to & \mathbb{C}\mathrm{P}^n \\ [w_0 : \cdots : w_{n-1}] & \mapsto & [w_0 : \cdots : w_{i-1} : 0 : w_i : \cdots : w_{n-1}]. \end{array}$$

[456] Basically the problem is as follows: Let A and B be two real $n \times n$-matrices such that $\det(A + iB) \in \mathbb{C}$ is non-zero. Why does it follow that the determinant of the real matrix

$$\begin{pmatrix} A & -B \\ B & A \end{pmatrix}$$

is positive?

The map f is easily seen to be continuous. Since $\mathbb{C}\mathrm{P}^{n-1}$ is compact we obtain from Lemma 1.37 that $f(\mathbb{C}\mathrm{P}^{n-1})$ is compact. But since $\mathbb{C}\mathrm{P}^n$ is Hausdorff we obtain from Lemma 1.18 (2) that $f(\mathbb{C}\mathrm{P}^{n-1}) = \mathbb{C}\mathrm{P}^n \setminus V_i$ is in fact a closed subset of $\mathbb{C}\mathrm{P}^n$. This concludes the proof of the claim.

Using this claim it is now straightforward to verify that the given maps $\Phi_0, \dots, \Phi_n$ form a holomorphic atlas for $\mathbb{C}\mathrm{P}^n$. This shows that $\mathbb{C}\mathrm{P}^n$ is a complex n-dimensional manifold. Note that the charts are of type (i). This shows that $\mathbb{C}\mathrm{P}^n$ has no boundary points, in particular since it is compact, it is closed Finally the last statement is an immediate consequence of Proposition 21.4. □

Remark. The notion of a submanifold also extends in the obvious way to the setting of complex manifolds. Let $m \leq n$. On page 111 we introduced the convention that we view $\mathbb{C}\mathrm{P}^m$ as a subset of $\mathbb{C}\mathrm{P}^n$. Using the above atlas one can easily that $\mathbb{C}\mathrm{P}^m$ is in fact a complex submanifold of $\mathbb{C}\mathrm{P}^n$.

As we had already pointed out on page 113, the one-dimensional projective space $\mathbb{C}\mathrm{P}^1$ is homeomorphic to S^2. This shows that S^2 can be viewed as a 1-dimensional complex manifold. We had just seen that the 2-sphere and the torus are complex manifolds and we saw that non-orientable manifolds cannot be complex manifolds. The following question now arises:

Question 21.7. *Let $g \geq 2$. Does the surface of genus g have the structure of a complex manifold?*

We will discuss this question later on.

Remark. It is often very hard to determine whether or not a given orientable even-dimensional manifold can also be a complex manifold. For example, Armand Borel and Jean-Pierre Serre [BS][457] showed in 1953 that for $n \neq 2, 6$ the n-dimensional sphere S^n cannot be a complex manifold. On the other hand it is still an open question whether S^6 is a complex manifold.

Definition. We say that a map $f\colon M \to N$ between two complex manifolds is *holomorphic* if f is continuous and if for every chart $\Phi\colon U \to V$ in the holomorphic atlas of M and every chart $\Psi\colon W \to Y$ in the holomorphic atlas of N the map

$$\Phi(f^{-1}(W) \cap U) \xrightarrow{\Psi \circ f \circ \Phi^{-1}} Y$$

is holomorphic.

The following proposition will be proved in Exercise 21.1.

Proposition 21.8. *Let M be a compact 1-dimensional complex manifold. Then any holomorphic function $f\colon M \to \mathbb{C}$ is constant.*

[457] Armand Borel (1923–2003) was a Swiss mathematician, Jean-Pierre Serre (*1926) is a French mathematician who was awarded a Fields medal in 1954.

Remark. If $M = \mathbb{C}/(\mathbb{Z} \oplus \mathbb{Z}i)$, then we can also give another, arguably easier proof. More precisely, let $f\colon \mathbb{C}/(\mathbb{Z} \oplus \mathbb{Z}i) \to \mathbb{C}$ be a holomorphic function. Since $\mathbb{C}/(\mathbb{Z} \oplus \mathbb{Z}i)$ is compact the function f is bounded. We denote by $p\colon \mathbb{C} \to \mathbb{C}/(\mathbb{Z} \oplus \mathbb{Z}i)$ the projection map. Then the composition $f \circ p\colon \mathbb{C} \to \mathbb{C}$ is a bounded holomorphic function, thus constant by the Liouville Theorem 21.1. Since p is surjective it follows that f is also constant.

In the next definition we generalize the notion of (local) diffeomorphism in the obvious way to the complex setting.

Definition.

(1) We say that a map $f\colon M \to N$ between two complex manifolds is a *biholomorphism* if f is a bijection and if both f and f^{-1} are holomorphic.
(2) We say that a map $f\colon M \to N$ between two complex manifolds is a *local biholomorphism* if given any $P \in M$ there exists an open neighborhood U of P and an open neighborhood V of $f(P)$ such that $f\colon U \to V$ is a biholomorphism.

Examples.

(1) In some cases one can explicitly write down a biholomorphism. For example, for the upper half-plane $\mathbb{H} = \{x + iy \mid y > 0\}$ and the open disk $\mathbb{D} = \{z \in \mathbb{C} \mid |z| < 1\}$ it is straightforward to verify that the maps
$$\begin{array}{rcl} \Phi\colon \mathbb{H} & \to & \mathbb{D} \\ z & \mapsto & \frac{z-i}{z+i} \end{array} \quad \text{and} \quad \begin{array}{rcl} \Psi\colon \mathbb{D} & \to & \mathbb{H} \\ w & \mapsto & \frac{i+iw}{1-w} \end{array}$$
are biholomorphisms that are inverse to one-another.
(2) The proof of Proposition 3.25 shows that $\mathbb{C}/(\mathbb{Z}+i\mathbb{Z})$ has the structure of a complex 1-dimensional manifold in such a way that the projection map $\mathbb{C} \to \mathbb{C}/(\mathbb{Z} + i\mathbb{Z})$ is a local biholomorphism.
(3) Let $a, b \in \mathbb{C}$ be two complex numbers that are linearly independent over $\mathbb{R}$. We write $T(a, b) = \mathbb{C}/(\mathbb{Z}a + \mathbb{Z}b)$. The same argument as in (2) shows that this is a 1-dimensional complex manifold such that the projection map $p\colon \mathbb{C} \to T(a, b)$ is a local biholomorphism. Now suppose that $v, w \in \mathbb{C}$ are also two complex numbers that are linearly independent over $\mathbb{R}$. We can form the torus $T(v, w) = C/(\mathbb{Z}v + \mathbb{Z}w)$. The tori $T(a, b)$ and $T(v, w)$ are diffeomorphic. But the argument of [Bal, p. 15] shows that the 1-dimensional complex manifolds $T(a, b)$ and $T(v, w)$ are biholomorphic only if $ab^{-1} = vw^{-1} \in \mathbb{C}$ or if $ab^{-1} = wv^{-1} \in \mathbb{C}$.

Lemma 21.9.

(1) *Let $p\colon \widetilde{X} \to X$ be a countable covering of a complex manifold X. Then $\widetilde{X}$ is also a complex manifold in such a way that p is a local biholomorphism.*
(2) *Let $p\colon \widetilde{X} \to X$ be a covering of complex manifolds such that p is a local biholomorphism. If Z is a complex manifold and if $f\colon Z \to X$ is a holomorphic map, then any lift $\widetilde{f}\colon Z \to \widetilde{X}$ is also holomorphic.*

Proof. The first statement is proved almost the same way as Proposition 8.1 (2). The second statement is an immediate consequence of the fact that p is a local biholomorphism and that being holomorphic is a local condition. We leave the details to the reader. $\square$

In general it is hard to write down an explicit biholomorphism between two complex manifolds. One of the main sources of biholomorphisms is the Riemann Mapping Theorem.

Theorem 21.10. (Riemann Mapping Theorem) *Let $U \subset \mathbb{C}$ be a simply connected open subset U of $\mathbb{C}$. If $U \neq \mathbb{C}$, then U is biholomorphic to $\mathbb{D}$.*

This theorem is proved in [Jä2] or alternatively in [Lan, Chapter X].

In many applications it is also useful to know that the biholomorphism from the Riemann Mapping Theorem extends to the boundary of U and $\mathbb{D}$. To state the corresponding theorem we need one more definition.

Definition.

(1) We write $\overline{\mathbb{C}} = \mathbb{C} \cup \{\infty\}$ which we equip with the topology that we defined on page 53.
(2) Given $U \subset \overline{\mathbb{C}}$ we denote by $\overline{U}$ the closure of U in $\overline{\mathbb{C}}$.
(3) A *Jordan curve* is the image of an injective map $S^1 \to \overline{\mathbb{C}}$.

The following theorem was proved in 1913 by Constantin Carathéodory.[458] A proof is for example provided in [GM, Chapter I.3].

Theorem 21.11. (Carathéodory Theorem) *Let $U \subsetneq \mathbb{C}$ be a simply connected open subset U of $\mathbb{C}$ and let $\phi\colon U \to \mathbb{D}$ be a biholomorphism. If $\partial\overline{U}$ is a Jordan curve, then ϕ extends to a homeomorphism $\overline{U} \to \mathbb{C}$.*

Example. We consider the open subset U of $\mathbb{C}$ that is shown in Figure 356. It is a simply connected open proper subset of $\mathbb{C}$ and the boundary is clearly a Jordan curve. Thus it follows from the Riemann Mapping Theorem and from Carathéodory's Theorem that there exists a homeomorphism $\phi\colon \overline{U} \to \overline{\mathbb{D}}$ which restricts to a biholomorphism $\phi\colon U \to \mathbb{D}$.

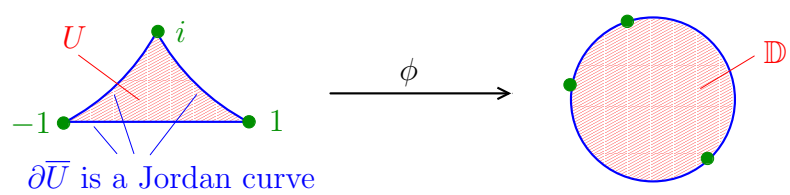

FIGURE 356.

[458]Constantin Carathéodory (1873-1950) was a Greek mathematician who was in particular a professor at the LMU in Munich.

Exercise for Chapter 21.

Exercise 21.1. Let M be a compact connected 1-dimensional complex manifold. Show that any holomorphic function $f\colon M \to \mathbb{C}$ is constant.
Hint: Use the Maximum Principle, i.e. use Theorem 21.2.

22. Hyperbolic geometry

22.1. **Hyperbolic space.** We start out with the following definition.

Definition. Let V be a real vector space. A *symmetric form on* V is a map[459]

$$g\colon V \times V \to \mathbb{R}$$

that is bilinear, i.e. for all $u, v, w \in V$ and $\mu, \lambda \in \mathbb{R}$ we have

$$\begin{aligned} g(\lambda u + \mu v, w) &= \lambda g(u, w) + \mu g(v, w) \\ g(u, \lambda v + \mu w) &= \lambda g(u, v) + \mu g(u, w) \end{aligned}$$

and that is symmetric, i.e. for all $v, w \in V$ we have

$$g(v, w) = g(w, v).$$

We say g is *positive-definite* if for all $v \in V \setminus \{0\}$ we have

$$g(v, v) > 0.$$

Now we can recall that following key definition from the theory of manifolds, see e.g. [Le2, Chapter 17].

Definition. A *Riemannian structure* on a manifold M is a smooth[460] map g which assigns to each point P a positive-definite symmetric form g_P on the tangent space $T_P M$.

In this chapter and the following chapter we are mostly interested in Riemannian structures on surfaces, and more specifically, in hyperbolic structures. Now we recall the definition of hyperbolic space.

Definition.

(1) The *hyperbolic half-plane* is the manifold

$$\mathbb{H} = \{(x, y) \in \mathbb{R}^2 \mid y > 0\} = \{z = x + iy \in \mathbb{C} \mid y > 0\}$$

together with the Riemannian structure that assigns to the tangent space $T_z\mathbb{H} = \mathbb{R}^2$ at a point $z = x + iy \in \mathbb{H}$ the positive-definite symmetric form

$$\begin{aligned} g\colon \mathbb{R}^2 \times \mathbb{R}^2 &\to \mathbb{R} \\ (v, w) &\mapsto \frac{1}{y^2}\langle v, w\rangle \end{aligned}$$

where $\langle v, w\rangle$ denotes the usual scalar product on $\mathbb{R}^2$.

(2) A *Möbius transformation* of $\mathbb{H}$ is a map of the form[461]

$$\begin{aligned} \mathbb{H} &\to \mathbb{H} \\ z &\mapsto \frac{az + b}{cz + d} \end{aligned}$$

[459] Sometimes such a structure is called a *bilinear symmetric form*, but we abbreviate this to *symmetric form*.

[460] The notion of "smooth" in this context is made precise in [Le2, Chapter 17]. Once one has digested the definition of a "smooth map" it is straightforward to see that all examples below satisfy this condition.

[461] An elementary calculation shows that the image of a Möbius transformation $\mathbb{H} \to \mathbb{C}$ does indeed lie again in $\mathbb{H}$.

where $a, b, c, d \in \mathbb{R}$ with $ad - bc = 1$.

Example. In Figure 357 we see a decomposition of $\mathbb{H}$ into angels and devils. With respect to the hyperbolic metric all the angels have the same size and all the devils have the same size, even though they differ in the usual Euclidean sense.

FIGURE 357.

Examples. We give three special types of Möbius transformations of $\mathbb{H}$:

(1) given $r > 0$ the scalar multiplication $z \mapsto rz = \frac{\sqrt{r}\cdot z+0}{0\cdot z+\frac{1}{\sqrt{r}}}$ is a Möbius transformation,
(2) given $d \in \mathbb{R}$ the horizontal translation $z \mapsto z + d = \frac{1\cdot z+d}{0\cdot z+1}$ is a Möbiustransformation,
(3) the map $z \mapsto -\frac{1}{z} = \frac{0\cdot z+1}{(-1)\cdot z+0}$ is a Möbius transformation.

The third Möbius transformation is the composition of taking the inverse $z \mapsto \frac{1}{z}$ and the reflection $z \mapsto -z$ in the origin. We illustrate this map in Figure 358. For simplicity we refer to the map $z \mapsto -\frac{1}{z}$ as an inversion.

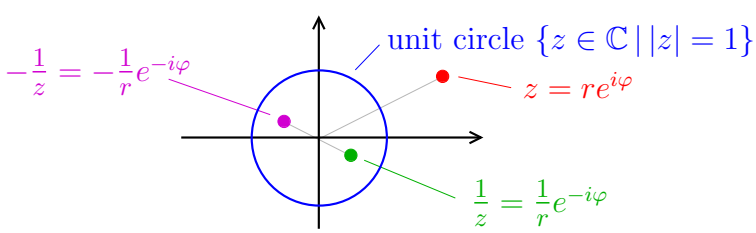

FIGURE 358.

Proposition 22.1. *Every Möbius transformation of $\mathbb{H}$ is the composition of scalar multiplications, horizontal translations and inversions.*

Proof. Let $a, b, c, d \in \mathbb{R}$ with $ad - bc = 1$ and denote by

$$\Phi(z) \;=\; \frac{az+b}{cz+d}$$

the corresponding Möbius transformation. If $c = 0$, then

$$\Phi(z) \;=\; \frac{a}{d}z + \frac{b}{d}$$

is the composition of the scalar multiplication[462] $z \mapsto \frac{a}{d}z$ with the horizontal translation $z \mapsto \frac{b}{d} + z$. If $c \neq 0$, then

$$\Phi(z) \;=\; \frac{az+b}{cz+d} \;=\; \frac{acz+bc}{c^2z+dc} \;\underset{\substack{\uparrow \\ \text{since } ad-bc=1}}{=}\; \frac{acz+ad-1}{c^2z+cd} \;=\; \frac{-1+a(cz+d)}{c^2z+cd} \;=\; \frac{-1}{c^2z+dc} + \frac{a}{c}.$$

Thus we see that Φ is the composition of the following maps

$$z \mapsto c^2z, \quad z \mapsto z + dc, \quad z \mapsto \frac{-1}{z} \quad \text{and } z \mapsto z + \frac{a}{c}.$$

□

Definition.

(1) The *hyperbolic disk*[463]is the manifold

$$\mathbb{D} \;=\; \{z \in \mathbb{C} \mid |z|^2 < 1\}$$

together with the Riemannian structure which assigns to the tangent space $T_z\mathbb{D} = \mathbb{R}^2$ at a point $z \in \mathbb{D}$ the positive-definite symmetric form

$$\begin{array}{rcl} g_z\colon \mathbb{R}^2 \times \mathbb{R}^2 & \to & \mathbb{R} \\ (v, w) & \mapsto & \frac{2}{(1-|z|^2)^2}\langle v, w\rangle \end{array}$$

where, as above, $\langle v, w\rangle$ denotes the usual scalar product on $\mathbb{R}^2$.

(2) A *Möbius transformation* of $\mathbb{D}$ is a map of the form[464]

$$\begin{array}{rcl} \mathbb{D} & \to & \mathbb{D} \\ z & \mapsto & e^{i\theta} \cdot \frac{z-a}{1-\overline{a}z} \end{array}$$

for some $\theta \in \mathbb{R}$ and $a \in \mathbb{D}$.

Examples.

(1) In Figure 359 we see three different decompositions of $\mathbb{D}$ into subsets. In each of the three cases these subsets have the same hyperbolic size, even though they differ in the usual Euclidean sense.

---

[462]Note that $c = 0$ implies that $1 = ad - bc = ad$, in particular $ad > 0$, hence $\frac{a}{d} > 0$.

[463]The hyperbolic disk is often also called the *Poincaré model for hyperbolic space*.

[464]An elementary calculation shows that the image of a Möbius transformation $\mathbb{D} \to \mathbb{C}$ does indeed lie again in $\mathbb{D}$.

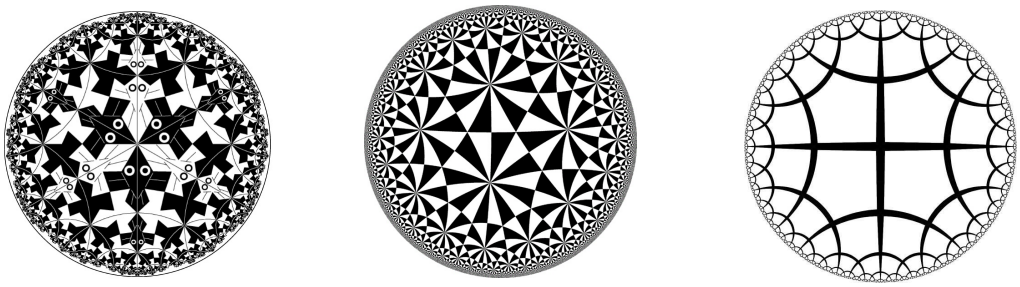

FIGURE 359.

(2) If we set $a = 0$ in the definition of a Möbius transformation of $\mathbb{D}$, then we obtain precisely the rotation by the angle θ. Put differently, the Möbius transformations preserving 0 are precisely given by rotations around the origin.

Before we can state the next proposition we give a few more definitions regarding maps between (Riemannian) manifolds.

Definition.

(1) Given a smooth map $f\colon M \to N$ between manifolds and given $P \in M$ we denote by $df_P = f_*\colon T_PM \to T_{f(P)}N$ the differential, i.e. the induced homomorphism from the tangent space T_PM to the tangent space $T_{f(P)}N$.
(2) Let $f\colon M \to N$ be a local diffeomorphism. Given a Riemannian structure h on N we denote by f^*h the Riemannian structure on M that at each point $P \in M$ is given by $(f^*h)(v, w) = h(f_*v, f_*w)$.[465]
(3) We say that a map $f\colon (M, g) \to (N, h)$ between Riemannian manifolds is a (*local*) *isometry* if f is a (local) diffeomorphism and if $g = f^*h$.
(4) We say that Riemannian manifolds (M, g) and (N, h) are *isometric* if there exists an isometry from (M, g) to (N, h).

The following proposition will allow us to go back and forth between the hyperbolic half-plane and the hyperbolic disk.

Proposition 22.2. *The maps*

$$\begin{array}{rcl} \Phi\colon \mathbb{H} & \to & \mathbb{D} \\ z & \mapsto & \frac{z-i}{z+i} \end{array} \quad \textit{and} \quad \begin{array}{rcl} \Psi\colon \mathbb{D} & \to & \mathbb{H} \\ w & \mapsto & \frac{i+iw}{1-w} \end{array}$$

have the following properties:

(1) *Φ and Ψ are inverses to one another, in particular they are biholomorphisms,*
(2) *they extend to homeomorphisms between $\overline{\mathbb{H}} = \{z \in \mathbb{C} \mid \mathrm{Im}(z) \geq 0\} \cup \{\infty\}$*[466] *and $\overline{\mathbb{D}} = \{z \in \mathbb{C} \mid |z| \leq 1\}$,*

[465] It follows from [Le2, Proposition 13.9] that f^*h is indeed a Riemannian structure on M. Note that in the proof, to show that f^*h is indeed non-degenerate, one needs that f is a local diffeomorphism.

[466] Here $\overline{\mathbb{H}}$ has the same topology as defined on page 53.

(3) *they are orientation-preserving,*[467]
(4) *they are isometries,*
(5) *they give a bijection between the Möbius transformations of* $\mathbb{D}$ *and* $\mathbb{H}$.[468]

Proof. All five statements follow from a straightforward calculation. The statements can also be deduced, more or less directly, from any book that deals with Möbius transformations, see e.g. [Schwe, Chapter 6] and [And, Chapter 2]. □

Remark. Proposition 22.2 says that $\mathbb{D}$ and $\mathbb{H}$ are two equivalent ways to describe hyperbolic space. In fact there are several other ways to describe hyperbolic space, for example we could also use the Beltrami-Klein model

`https://en.wikipedia.org/wiki/Beltrami-Klein_model`

or the hyperboloid model

`https://en.wikipedia.org/wiki/Hyperboloid_model`.

Some of the connections between these models are explained in the following video of Henry Segerman and Saul Schleimer:

`https://www.youtube.com/watch?v=eGEQ_UuQtYs`.

The following proposition summarizes some of the key properties of Möbius transformations.

Proposition 22.3. [469]

(1) *Compositions of Möbius transformations are again Möbius transformations and the inverse of a Möbius transformation is again a Möbius transformation.*
(2) *Möbius transformations are biholomorphisms, they are isometries and they are orientation-preserving.*
(3) *Möbius transformations act transitively, i.e. given any two points* P *and* Q *there exists a Möbius transformation which sends* P *to* Q.
(4) *Given* $P, Q \in \mathbb{D}$ *and non-zero vectors* $v \in T_P\mathbb{D}$ *and* $w \in T_Q\mathbb{D}$ *with* $\|v\|_g = \|w\|_g$ *there exists a Möbius transformation* ϕ *with* $\phi(P) = Q$ *and* $d\phi_P(v) = w$.
(5) *Let* ϕ *and* ψ *be two Möbius transformations. Suppose there exists a* $P \in \mathbb{D}$ *such that* $\phi(P) = \psi(P)$ *and such that* $d\phi_P = d\psi_P$. *Then* $\phi = \psi$.

Proof. By Proposition 22.2 it suffices to prove the statements for $\mathbb{D}$ or for $\mathbb{H}$, whichever is more convenient.

(1),(2) The first two statements follow from a straightforward calculation, see e.g. [Schwe, p. 43].

[467]The hyperbolic half-plane $\mathbb{H}$ and the hyperbolic disk $\mathbb{D}$ are both subsets of $\mathbb{C} = \mathbb{R}^2$ and inherit from $\mathbb{C} = \mathbb{R}^2$ the canonical orientation.

[468]More precisely, if α is a Möbius transformation of $\mathbb{H}$, then $\Phi \circ \alpha \circ \Psi$ is a Möbius transformation of $\mathbb{D}$ and conversely, if α is a Möbius transformation of $\mathbb{D}$, then $\Psi \circ \alpha \circ \Phi$ is a Möbius transformation of $\mathbb{H}$.

[469]The statement of the proposition applies to Möbius transformations of $\mathbb{D}$ and to Möbius transformations of $\mathbb{H}$.

(3) We prove this statement for $\mathbb{D}$. By (1) it suffices to show that given any $P \in \mathbb{D}$ there exists a Möbius transformation ψ with $\psi(P) = 0$. But such a Möbius transformation is given by
$$\psi(z) \;=\; \tfrac{z-P}{1-\overline{P}z}.$$
(4) Using (3) we see that we only have to deal with the case that $P = Q = 0$. But then the desired Möbius transformation is given by a rotation.
(5) By (3) there exists a Möbius transformation θ such that $\theta(0) = P$ and there exists a Möbius transformation ω such that $\omega(\phi(P)) = \omega(\psi(P)) = 0$. We consider the Möbius transformations $\phi' = \omega \circ \phi \circ \theta$ and $\psi' = \omega \circ \psi \circ \theta$. It follows from our hypothesis that both ϕ' and ψ' fix 0. As we pointed out above, the only Möbius transformations of $\mathbb{D}$ that fix 0 are rotations.

By our hypothesis we have $d\phi'_0 = d\psi'_0$, which means that the rotations ϕ' and ψ' agree. But this implies that ϕ and ψ also agree. □

Note that Möbius transformations extend in an obvious way uniquely to homeomorphisms of $\overline{\mathbb{D}} = \{z \in \mathbb{C} \mid |z| \leq 1\}$ and $\overline{\mathbb{H}} = \{z \in \mathbb{C} \mid \mathrm{Im}(z) \geq 0\} \cup \{\infty\}$. We will denote the extension of a Möbius transformation with the same symbol.

Lemma 22.4. *Let $\{P, Q, R\}$ and let $\{S, T, U\}$ be two sets of three distinct points on the boundary $\partial\overline{\mathbb{H}} = \mathbb{R} \cup \{\infty\}$. Then there exists a Möbius transformation ψ of $\mathbb{H}$ with $\psi(P) = S$ and $\psi(\{Q, R\}) = \{T, U\}$.*

Proof. Let P, Q, R be three distinct points on $\partial\overline{\mathbb{H}} = \mathbb{R} \cup \{\infty\}$. It suffices to show that there exists a Möbius transformation ψ with $\psi(P) = \infty$ and with $\psi(\{Q, R\}) = \{0, 1\}$. We proceed as follows:

(1) We first claim that there exists a Möbius transformation α with $\alpha(P) = \infty$. Indeed, if $P = \infty$ then we just take $\alpha = \mathrm{id}$. Otherwise we can combine a horizontal translation with the inversion to obtain a Möbius transformation α with $\alpha(P) = \infty$. Given such α we write $Q' = \alpha(Q)$ and $R' = \alpha(R)$. Note that the points Q', R' lie on $\mathbb{R} = \overline{\mathbb{H}} \setminus \{\infty\}$. Without loss of generality we can assume that $Q' < R'$.
(2) Next we pick a horizontal translation such that $\beta(Q') = 0$. Note that we still have $(\beta \circ \alpha)(P) = \beta(\infty) = \infty$. Also note that it follows from $Q' < R'$ that $\beta(R') > 0$.
(3) Finally we pick a scalar multiplication γ such that $(\gamma \circ \beta)(R') = 1$. Note that γ fixes 0 and ∞. Thus we see that $\psi = \gamma \circ \beta \circ \alpha$ has the desired property. □

Definition. A *hyperbolic line* is a subset of $\mathbb{D}$ of one of the following two types:

(1) it is the intersection of $\mathbb{D}$ with a Euclidean line through the origin,
(2) it is the intersection of $\mathbb{D}$ with a Euclidean circle that intersects the circle $S^1 = \partial\overline{\mathbb{D}}$ orthogonally.

In each of the two cases we refer to the intersection of the Euclidean object with $S^1 = \partial\overline{\mathbb{D}}$ as the *endpoints* of the hyperbolic line. We refer to Figure 360 for an illustration.

Lemma 22.5.

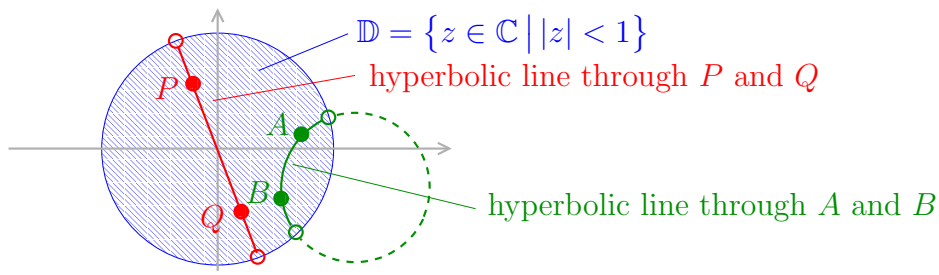

FIGURE 360.

(1) *For any two distinct points P and Q in $\mathbb{D}$ there exists a unique hyperbolic line that contains P and Q.*
(2) *For any two distinct points P and Q in $\partial\overline{\mathbb{D}}$ there exists a unique hyperbolic line with P and Q as endpoints.*
(3) *Let P and Q be two distinct points in $\partial\overline{\mathbb{D}}$. Every Möbius transformation ϕ sends the hyperbolic line with endpoints P and Q to the hyperbolic line with endpoints $\phi(P)$ and $\phi(Q)$.*
(4) *Möbius transformations act transitively on hyperbolic lines, i.e. given any two hyperbolic lines g and h there exists a Möbius transformation ϕ with $\phi(g) = h$.*

Proof. In principle one can prove the lemma directly in $\mathbb{D}$. But it is easier to prove it using $\mathbb{H}$. In $\mathbb{H}$ the hyperbolic lines are defined to be vertical lines $\{x + iy \mid y > 0\}$ and Euclidean half-circles such that the origin lies on $\mathbb{R}$. It is straightforward to see that the diffeomorphisms of Proposition 22.2 define a bijection between the hyperbolic lines in $\mathbb{D}$ and in $\mathbb{H}$.

The corresponding statements for hyperbolic lines in $\mathbb{H}$ are straightforward to prove. They can also be obtained from any textbook on hyperbolic geometry, see e.g. [And] and [Bon, Chapter 2]. □

22.2. **Angles in Riemannian manifolds.** We continue our quick introduction to Riemannian manifolds and hyperbolic space with a short discussion of angles.

Definition.

(1) Let g be a positive-definite symmetric form on a real vector space V. Given $v, w \in V \setminus \{0\}$ we define[470]

$$\text{angle between } v \text{ and } w \ := \ \text{unique } \alpha \in [0, \pi] \text{ with } g(v, w) = \cos(\alpha) \cdot \|v\| \cdot \|w\|.$$

(2) Given a Riemannian manifold (M, g) and non-zero vectors $v, w \in T_P M$ we use the form g_P to define the angle between v and w.

Examples.

[470]We have $|g(v, w)| \leq \big|\|v\| \dot{\|} w\|\big|$ by the Cauchy-Schwarz inequality.

(1) Let U be an open subset of $\mathbb{R}^n$ and let $f\colon U \to \mathbb{R}_{>0}$ be a smooth function. For any $P \in U$ we can define a positive-definite symmetric form g_P on $T_PU = \mathbb{R}^n$ via
$$g_P(v,w) \;=\; f(P)\cdot\langle v,w\rangle,$$
where $\langle\,,\,\rangle$ denotes the usual scalar product. A straightforward calculation shows that in this Riemannian structure the angle at any point is the usual Euclidean angle in $\mathbb{R}^n$. This argument implies in particular to the Riemannian manifolds $\mathbb{D}$ and $\mathbb{H}$, in both cases the hyperbolic angle, defined by the hyperbolic Riemannian structure, is the same as the Euclidean angle.

(2) A hyperbolic triangle is defined to be a compact subset of $\mathbb{H}$ whose boundary is given by segments of three hyperbolic lines. One of the many elegant theorems in hyperbolic geometry, see [And, Theorem 5.16], says that given such a hyperbolic triangle its angle sum equals π minus its "area". Even without the definition of "area" it is pretty clear that this result implies that the angle sum of a hyperbolic triangle is always less than π. This statement is illustrated in Figure 361.

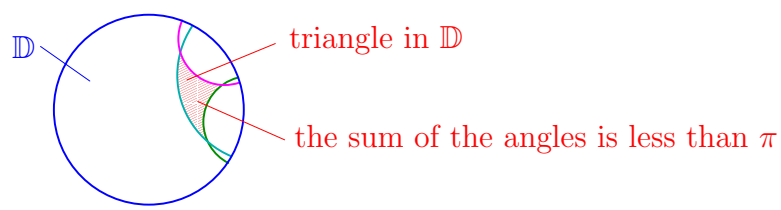

FIGURE 361.

The following lemma follows easily from the definitions and from Proposition 22.3 (2).

Lemma 22.6. *Local isometries, in particular Möbius transformations, preserve angles.*

Definition.

(1) Let $P \in \mathbb{D}$ and let g be a hyperbolic line through P. Let Q be one of the two endpoints of g. We refer to the set of points between P and Q as a *ray emanating from P*.

(2) Let $P \in \mathbb{D}$ and let r, s be two rays emanating from P. We refer to the angle between the tangent vectors of r and s at P as the *angle between the rays r and s*.

Examples.

(1) Given $\varphi \in [0, 2\pi)$ the set $S_\varphi := \{re^{i\varphi} \mid r \in [0,1)\}$ is a ray emanating from 0.

(2) It follows from the above discussion of angles in $\mathbb{D}$, that given $\varphi, \theta \in [0, 2\pi)$ the angle between the two rays S_φ and S_θ in $\mathbb{D}$ is the usual Euclidean angle.

Lemma 22.7. *Let r, s be two rays emanating from $P \in \mathbb{D}$ and let r', s' be two rays emanating from $P' \in \mathbb{D}$. Then the following holds:*
$$\begin{array}{c}\textit{there is a Möbius transformation } \phi \\ \textit{with } \phi(r\cup s) = r'\cup s'\end{array} \quad\Longleftrightarrow\quad \textit{angle between } r,s \;=\; \textit{angle between } r',s'.$$

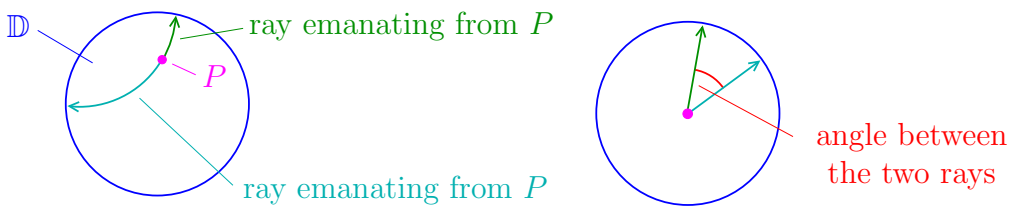

FIGURE 362.

Furthermore, if such a Möbius transformation exists, then it is unique.

Proof. By Lemma 22.6 Möbius transformations preserve angles and by Proposition 22.3 Möbius transformations act transitively on $\mathbb{D}$. Therefore we can without loss of generality assume that $P = P' = 0$. The lemma follows from the observation, made on page 589, that Möbius transformations preserving 0 are precisely given by rotations around the origin. $\square$

22.3. **The distance metric of a Riemannian manifold.**

Definition. Let (M, g) be a connected Riemannian manifold.

(1) Given $v \in T_P M$ we write $\|v\|_g = \sqrt{g_P(v, v)}$. If g is understood from the context, then we just write $\|v\|$.
(2) Let $\gamma\colon [a, b] \to M$ be a piecewise smooth path. By definition we can pick a subdivision $a = s_0 < s_1 < \cdots < s_m = b$ such that for $i = 0, \dots, m-1$ the map $\gamma|_{[s_i, s_{i+1}]}$ is smooth. We define the *length of* γ as[471]
$$\ell_{(M,g)}(\gamma) \ := \ \sum_{i=0}^{m-1} \int_{t=s_i}^{t=s_{i+1}} \|\gamma'(t)\|_g \, dt.$$
If (M, g) is understood from the context, then we write $\ell(\gamma)$ instead of $\ell_{(M,g)}(\gamma)$.
(3) Let P and Q be two points on M.
$$d_{(M,g)}(P, Q) \ := \ \inf\{\ell(\gamma) \mid \underbrace{\gamma \text{ is a smooth path in } M \text{ from } P \text{ to } Q}_{\text{exists by Lemma 10.24}}\}.$$
If (M, g) is understood from the context, then we just write $d(P, Q)$.

We start our discussion of the distance function d on Riemannian manifolds with the following somewhat technical proposition.

Proposition 22.8. *Let (M, g) be a connected Riemannian manifold. Then the following hold:*

(1) *the pair $(M, d_{(M,g)})$ is a metric space,*
(2) *the topology defined by the metric $d_{(M,g)}$ agrees with the topology of M,*

[471]Recall that given a smooth path $\delta\colon [a, b] \to M$ and given any $t \in [a, b]$ the path defines, basically by definition of the tangent space $T_{\delta(t)}M$, an element in $T_{\delta(t)}M$. We denote this vector by $\delta'(t)$.

(3) *given any $P \in M$ and given any open neighborhood U of P there exists an $r > 0$ such that*

$$B_r^{(M,g)}(P) \;:=\; \{Q \in M \mid d_{(M,g)}(P,Q) < r\} \;\subset\; U.$$

Proof. Let (M,g) be a connected n-dimensional Riemannian manifold. We first show that $(M, d_{(M,g)})$ is a metric space.

It is clear that $d = d_{(M,g)}$ is symmetric. It follows easily from the definitions and the fact that the concatenation of two piecewise smooth paths is again piecewise smooth that d satisfies the triangle inequality.

Now let $P \neq Q$ be two distinct points in M. We need to show that $d(P,Q) > 0$. Since M is Hausdorff and since it is o-locally diffeomorphic to open subsets of $\mathbb{R}^n$ we can find a chart $\Phi\colon U \to B_{2r}(0)$ for P with $\Phi(P) = 0$ and such that $Q \notin U$. We write $\Psi = \Phi^{-1}$. Before we continue we introduce the following definitions:

(1) We write $U_r = \Phi^{-1}(\{x \in \mathbb{R}^n \mid \|x\| = r\})$ and given a subset $I \subset [0, 2r)$ we write $U_I = \Phi^{-1}(\{x \in \mathbb{R}^n \mid \|x\| \in I\})$.

(2) For a positive-definite bilinear form h on $\mathbb{R}^n$ we set

$$\|h\| \;:=\; \min\Big\{\sqrt{h(v,v)}\;\Big|\; v \in S^{n-1}\Big\}.$$

Note that h is positive-definite, that $h\colon \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$ is continuous and that S^{n-1} is compact. It follows from Lemma 1.37 that the minimum exists and that $\|h\| > 0$. It is straightforward to see that for any $v \in \mathbb{R}^n$ we have

$$h(v,v) \;\geq\; \|h\| \cdot \|v\|_{\text{eucl}}.$$

(3) We set

$$C \;:=\; \min\Big\{\|(\Psi^* g)_P\|\;\Big|\; P \in \overline{B_r(0)}\Big\}.$$

Since $P \mapsto \|(\Psi^* g)_P\|$ is continuous and since $\overline{B_r(0)}$ is compact it follows from Lemma 1.37 that $C > 0$.

Claim. Let $\gamma\colon [0,1] \to M$ be a piecewise smooth path from P to Q. There exists a $t \in [0,1]$ with $\gamma(t) \in U_r$.

Suppose there is no $t \in (0,1)$ with $\gamma(t) \in U_r$. We consider the sets $A = U_{[0,r)}$ and $B = M \setminus U_{[0,r]}$. The set A is clearly open. Furthermore it follows from Lemma 3.9 that $U_{[0,r]}$ is closed, hence B is open. Since $\gamma([0,1]) \cap U_r = \varnothing$ we have $[0,1] = \gamma^{-1}(A) \sqcup \gamma^{-1}(B)$. But both sets $\gamma^{-1}(A)$ and $\gamma^{-1}(B)$ are open by the continuity of γ and both are non-empty since $0 \in \gamma^{-1}(A)$ and $1 \in \gamma^{-1}(B)$. But this contradicts the fact, established with some effort in Proposition 1.86, that $[0,1]$ is connected. This concludes the proof of the claim.

Now it suffices to prove the following claim.

Claim. Let $\gamma\colon [0,1] \to M$ be a piecewise smooth path from P to Q. Then $\ell_g(\gamma) \geq C \cdot r$.

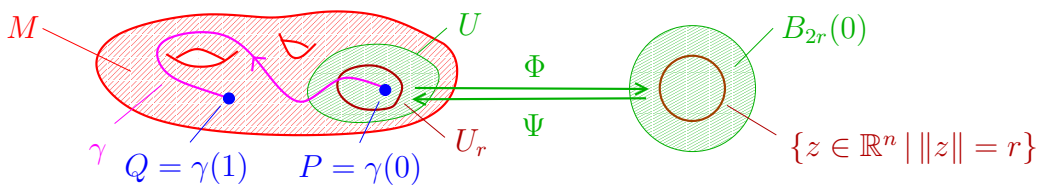

FIGURE 363. Illustration of the proof of Proposition 22.8

Let $T := \inf\{t \in (0,1) \mid \gamma(t) \in U_r\}$. By the above claim this definition makes sense since we take the infimum of a non-empty set. By Lemma 3.9 the set U_r is a closed subset of M. Since γ is continuous we also have $\gamma(T) \in U_r$. Now we have

$$\begin{aligned}
\ell_g(\gamma) \;\geq\; \ell_g(\gamma|_{[0,T]}) \;&=\; \ell_{\Psi^* g}(\Phi \circ \gamma|_{[0,T]}) &&=\; \int_{t=0}^{t=T} \|(\Phi\circ\gamma)'(t)\|_{\Psi^* g}\, dt \\
&\underset{\substack{\uparrow \\ \text{for any } v \in T_P\overline{B_r(0)} = \mathbb{R}^n \text{ we have} \\ \|v\|_{(\Psi^* g)_P} \;\geq\; \|(\Psi^* g)_P\| \cdot \|v\|_{\text{eucl}}}}{\geq} \int_{t=0}^{t=T} C \cdot \|(\Phi\circ\gamma)'(t)\|_{\text{eucl}}\, dt &&\underset{\substack{\uparrow \\ \text{[Rudi, Theorem 6.13]}}}{\geq}\; C \cdot \Big\| \int_{t=0}^{t=T} (\Phi\circ\gamma)'(t)\, dt \Big\|_{\text{eucl}} \\
&=\; C \cdot \|\underbrace{(\Phi\circ\gamma)(T)}_{\|-\|_{\text{eucl}}=r} - \underbrace{(\Phi\circ\gamma(0))}_{=0}\|_{\text{eucl}} \;=\; C \cdot r.
\end{aligned}$$

This concludes the proof of the claim and therefore the proof of statement (1) of the proposition.

Next we turn to the proof of statement (2). This means that we need to show that the topology defined by d is the same as the original topology of M. The proof is again somewhat technical and uses ideas similar to the proof of (1). We refer to [Le1, Lemma 6.2] for the proof.

Finally statement (3) is just an immediate consequence of the definitions and of statement (2). □

Lemma 22.9. *Let (M,g) and (N,h) be two connected Riemannian manifolds. Furthermore let $f\colon (M,g) \to (N,h)$ be a local isometry. Then the following hold:*

(1) *For any piecewise smooth path $\gamma\colon [a,b] \to M$ we have*
$$\ell_{(N,h)}(f\circ\gamma) \;=\; \ell_{(M,g)}(\gamma).$$

(2) *For any $P, Q \in M$ we have*
$$d_{(N,h)}(f(P), f(Q)) \;\leq\; d_{(M,g)}(P,Q).$$

Proof. Let $f\colon (M,g) \to (N,h)$ be a local isometry. We start out with the following claim.

Claim.

(1) For a smooth path $\gamma\colon [c,d] \to M$ and $t \in (c,d)$ we have $\|(f\circ\gamma)'(t)\|_{(N,h)} = \|\gamma'(t)\|_{(M,g)}$.

(2) For any piecewise smooth path $\gamma\colon [a,b] \to M$ we have $\ell_{(N,h)}(f \circ \gamma) = \ell_{(M,g)}(\gamma)$.

Now we provide the proof of the two statements.

(1) The first statement is an immediate consequence of the definitions and the hypothesis that f is a local isometry.
(2) By the additivity of the lengths of piecewise smooth paths it suffices to consider the case that $\gamma\colon [a,b] \to M$ is a smooth path. But in that case the equality follows immediately from the definitions and from (1).

This concludes the proof of the claim.

Now let P and Q be two points on M. For any piecewise smooth path p in M from P to Q we have

$$\begin{array}{ccccc} d_{(N,h)}(f(P), f(Q)) & \underset{\substack{\uparrow \\ \text{by definition of } d_{(N,h)}}}{\leq} & \ell_{(N,h)}(f \circ p) & \underset{\substack{\uparrow \\ \text{by the claim}}}{=} & \ell_{(M,g)}(p). \end{array}$$

It follows that the left-hand side is also less or equal than the infimum over all paths on the right-hand side. Thus $d_{(N,h)}(f(P), f(Q)) \leq d_{(M,g)}(P, Q)$. □

22.4. **The hyperbolic distance function.** We start out with the following definition.

Definition. Let (M, g) be a Riemannian manifold. A path $\gamma\colon [0,a] \to M$ is called a *geodesic* if the following conditions are satisfied:

(1) γ is smooth,
(2) $\|\gamma'(t)\|_g = 1$ for every $t \in [0,a]$ and
(3) $\ell(\gamma) = d_{(M,g)}(\gamma(0), \gamma(a))$.

The following proposition summarizes the key facts about the distance metric on $\mathbb{D}$.

Proposition 22.10.

(1) *Let $r \in (0,1)$ and $\varphi \in \mathbb{R}$. In the Riemannian manifold $\mathbb{D}$ the path*

$$\begin{array}{rcl} \gamma\colon [0,r] & \to & \mathbb{D} \\ t & \mapsto & te^{i\varphi} \end{array}$$

is, up to reparametrization, the unique shortest path from 0 to $re^{i\varphi}$.

(2) *We have*

$$d_{(\mathbb{D},g)}\big(0, re^{i\varphi}\big) \;=\; \ell(\gamma) \;=\; \int_{t=0}^{t=r} \frac{\sqrt{2}}{1-|\gamma(t)|^2} \|\gamma'(t)\|_{\text{eucl}}\, dt \;=\; \int_{t=0}^{t=r} \frac{\sqrt{2}}{1-t^2}\, dt.$$

(3) *Given $\varphi \in \mathbb{R}$ we have*

$$\lim_{r \to 1} d_{(\mathbb{D},g)}\big(0, re^{i\varphi}\big) \;=\; \infty.$$

(4) *Given any P and Q in $\mathbb{D}$ there is a unique geodesic from P to Q.*

Proof. The first statement can be deduced easily from [Bon, Lemma 2.4 and Proposition 2.22]. The second statement follows immediately from the first statement, and the third statement is a straightforward consequence of the second statement. For the fourth statement, note that it suffices to prove it for $P = 0$. In that case it is a straightforward consequence of (1). $\square$

Lemma 22.11. *Let (P, Q) and (S, T) be two pairs of distinct points on $\mathbb{D}$ such that $d(P, Q) = d(S, T)$. Then there exists a unique Möbius transformation ϕ with $\phi(P) = S$ and $\phi(Q) = T$.*

Example. Let $r \in (0, 1)$, $\varphi \in [0, 2\pi]$, $\psi \in [0, 2\pi]$ and $\gamma \in (0, \pi)$. We consider the pairs of points $P = re^{i\varphi}, Q = re^{i(\varphi+\gamma)}$ and $S = re^{i\psi}, T = re^{i(\psi-\gamma)}$. We then have

$$d(S, T) \;=\; d(T, S) \;=\; d(re^{i(\psi-\gamma)}, re^{i\psi}) \;\underset{\substack{\uparrow \\ \text{since rotation by } \varphi+\gamma-\psi \text{ is an isometry}}}{=}\; d(re^{i\varphi}, re^{i(\varphi+\gamma)}).$$

By Lemma 22.11 there exists a Möbius transformation ϕ with $\phi(P) = S$ and $\phi(Q) = T$. This Möbius transformation is illustrated in Figure 364. Recall that from Proposition 22.3 and Lemma 22.5 we know that Möbius transformations preserve hyperbolic lines and that they are orientation-preserving. In particular ϕ sends the hyperbolic line through P and Q to the hyperbolic line through S and T. Since ϕ is orientation-preserving it "swaps" the two sides of the hyperbolic line. We refer to Figure 364 for an illustration.

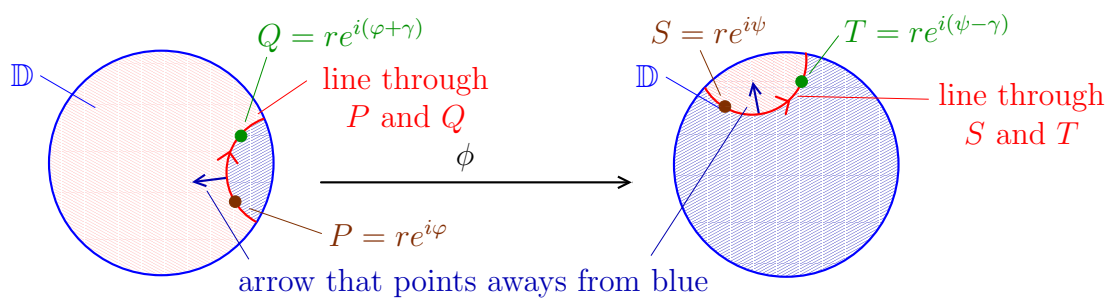

FIGURE 364.

Proof of Lemma 22.11. It follows from Proposition 22.3 (3) that, without loss of generality, we can assume that $P = 0$ and $S = 0$. We write $Q = re^{i\varphi}$ and $T = se^{i\psi}$. It is a direct consequence of Proposition 22.10 (1) and our hypothesis that

$$d(0, re^{i\varphi}) \;=\; d(P, Q) \;=\; d(S, T) \;=\; d(0, se^{i\psi})$$

that we have $r = s$. But this means that we can apply the rotation by the angle $\varphi - \psi$, which is a Möbius transformation, to turn (P, Q) into (S, T). This proves the existence of ϕ. The uniqueness follows from the observation, that we had made already on page 589, that the only Möbius transformations that fix 0 are precisely rotations. $\square$

Lemma 22.12. *Let $P \in \mathbb{D}$ and $r > 0$. Let $S, T \in B_r(P)$. Then the image of the unique geodesic in $\mathbb{D}$ from S to T lies in $B_r(P)$.*

Proof. As usual, this time by Propositions 22.3, 22.5 and 22.10, it suffices to prove the lemma for $P = 0$. In that case it follows from an elementary argument. We leave the details of the proof as an exercise. We also refer to Figure 365 for an illustration. □

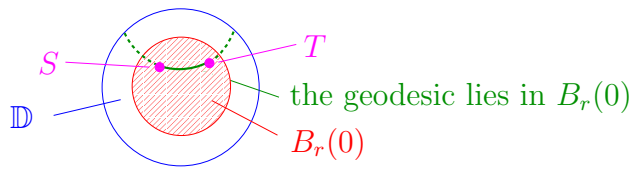

FIGURE 365.

22.5. **Complete metric spaces.** We conclude this chapter with a short discussion of complete metric spaces.

Definition.

(1) We say that a metric space (X, d) is *complete* if every Cauchy sequence in (X, d) converges.
(2) We say that a connected Riemannian manifold (M, g) is *complete* if the corresponding metric space $(M, d_{(M,g)})$ is complete.

Examples.

(1) The metric space given by $\mathbb{R}^n$ and the Euclidean metric is complete.
(2) The metric space given by the open ball B^n and the Euclidean metric is not complete. Indeed the sequence $a_n = 1 - \frac{1}{n}$ is a Cauchy sequence, but it does not converge in the open ball B^n. Similarly we see that for example the metric space $\mathbb{C} \setminus \{0, 1\}$ with the usual Euclidean metric is not complete.

The following proposition gives a useful criterion for a metric space to be complete.

Proposition 22.13. *Every compact metric space is complete.*

Proof. Let (X, d) be a compact metric space and let $(a_n)_{n\in\mathbb{N}}$ be a Cauchy sequence in (X, d). We want to show that the sequence converges, i.e. we want to show that

$$\underset{x\in X}{\exists} \ \underset{\epsilon>0}{\forall} \ \underset{N\in\mathbb{N}}{\exists} \ \underset{n\geq N}{\forall} \ d(a_n, x) < \epsilon.$$

Let us assume that no such x exists. Thus we negate the above statement and we obtain that

$$\underset{x\in X}{\forall} \ \underset{\epsilon>0}{\exists} \ \underset{N\in\mathbb{N}}{\forall} \ \underset{n\geq N}{\exists} \ d(a_n, x) \geq \epsilon.$$

Given $x \in X$ we pick $\epsilon_x > 0$ as above and we write

$$U_x \ := \ B_{\epsilon_x}(x) \quad \text{and} \quad V_x \ := \ B_{\epsilon_x/2}(x).$$

Note each U_x has the property that it does not contain all but finitely many of the a_n.

The family of open sets $\{V_x\}_{x\in X}$ covers X. Since X is compact there exist $x_1,\dots,x_k$ such that $X = V_{x_1}\cup\dots\cup V_{x_k}$. Now let $\epsilon := \frac{1}{2}\min\{\epsilon_{x_1},\dots,\epsilon_{x_k}\}$. For this $\epsilon>0$ we pick $N\in\mathbb{N}$ as in the definition of a Cauchy sequence. This means in particular that for all $m\geq N$ we have $d(a_N,a_m)<\epsilon$.

Since $X = V_{x_1}\cup\dots\cup V_{x_k}$ there exists an $i\in\{1,\dots,k\}$ with $a_N\in V_{x_i}$. It suffices to prove the following claim to obtain the desired contradiction.

Claim. For any $m\geq N$ we have $a_m\in U_{x_i}$.

Let $m\geq N$. We see that

$$\begin{array}{ccccccccc} d(x_i,a_m) & \underset{\uparrow}{\leq} & d(x_i,a_N)+d(a_N,a_m) & \underset{\uparrow}{<} & \frac{1}{2}\epsilon_{x_i}+\epsilon & \underset{\uparrow}{\leq} & \frac{1}{2}\epsilon_{x_i}+\frac{1}{2}\epsilon_{x_i} & = & \epsilon_{x_i}. \\ & \text{triangle inequality} & & \text{since } a_N\in V_{x_i} \text{ and } d(a_N,a_m)<\epsilon & & \text{since } \epsilon\leq\frac{1}{2}\epsilon_{x_i} & & & \end{array}$$

This implies that $a_m\in B_{\epsilon_{x_i}}(x_i) = U_{x_i}$. This concludes the proof of the claim. □

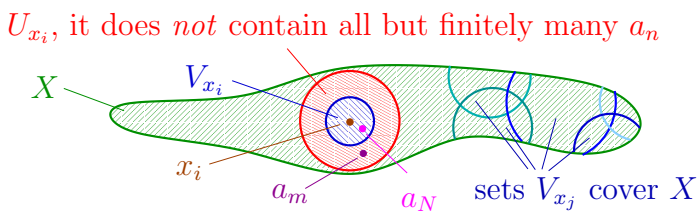

FIGURE 366. Illustration of the proof of Proposition 22.13.

The Riemannian manifolds $\mathbb{D}$ and $\mathbb{H}$ are of course not compact, but nonetheless, as we will now see, we can use Proposition 22.13 to show that $\mathbb{D}$ and $\mathbb{H}$ are complete.

Lemma 22.14. *The Riemannian manifolds $\mathbb{D}$ and $\mathbb{H}$ are complete.*

Proof. By Proposition 22.2 the two Riemannian manifolds $\mathbb{D}$ and $\mathbb{H}$ are isometric. Therefore it suffices to show that $\mathbb{D}$ is complete. We denote by $d = d_{(\mathbb{D},g)}$ the metric on $\mathbb{D}$ corresponding to the Riemannian structure. Let $\{a_n\}_{n\in\mathbb{N}}$ be a Cauchy sequence with respect to d. An elementary argument using the triangle inequality and the definition of a Cauchy sequence shows that there exists a $C\in\mathbb{R}$ such that $d(0,a_n)\leq C$ for all $n\in\mathbb{N}$.

It follows from Proposition 22.10 that there exists an $r\in(0,1)$ such that all a_n are contained in the closed Euclidean ball $\overline{B}_r^{eucl}(0)$. By the Heine-Borel Theorem 1.21 this ball is a compact subset of $\mathbb{R}^2$, viewed with the usual topology. It follows from Proposition 22.8 that $\overline{B}_r^{eucl}(0)$ is also compact in the topology defined by d. Now we see that $\{a_n\}_{n\in\mathbb{N}}$ is a Cauchy sequence in the compact metric space $(\overline{B}_r^{eucl}(0),d)$. It follows from Proposition 22.13 that the sequence converges. □

Exercises for Chapter 22.

Exercise 22.1. Does the manifold $B^2 \setminus \{0\}$ admit a complete Riemannian metric?

23. The universal covering of surfaces

Throughout this chapter we mean by a *surface* a connected 2-dimensional manifold. For example the surface of genus g, $g \geq 0$, but also $\mathbb{C}$, $\mathbb{C} \setminus \{0,1\}$ and the result of removing finitely many points from Σ_g are surfaces.

Definition. Let M be a surface. We say that a Riemannian structure g on M is *hyperbolic* if the following two conditions are satisfied:

(1) (M,g) is o-locally isometric to $\mathbb{D}$, i.e. if given any $P \in M$ there exists an isometry $\Phi\colon U \to V$ from an open neighborhood U of P to an open subset V of $\mathbb{D}$,
(2) (M,g) is complete.

If g is hyperbolic, then we refer to (M,g) as a hyperbolic surface.

Remark. By Proposition 22.13 the condition (2) of the definition is automatically satisfied if M is a closed surface.

In this chapter we will pursue the following three goals:

(1) we want to show that for any $g \geq 2$ the surface of genus g is a complex manifold,
(2) we intend to prove that for any $g \geq 2$ the surface of genus g is hyperbolic,
(3) given $g \geq 2$ we want to determine the universal covering of the surface of genus g.

23.1. **Hyperbolic surfaces.** In this section we will show that the surfaces of genus ≥ 2 are complex manifolds and that they are hyperbolic. In the subsequent subsection we will then consider more general types of surfaces.

Definition. Let M be a 2-dimensional topological manifold without boundary. A *Möbius structure* for M is a family of homeomorphisms $\{\Phi_i\colon U_i \to V_i\}_{i\in I}$ from open subsets of M to open subsets of $\mathbb{D}$ such that $\bigcup_{i\in I} U_i = M$ and such that for any $i,j \in I$ the transition map

$$\underbrace{\Phi_i(U_i \cap U_j)}_{\subset \mathbb{D}} \xrightarrow{\left(\Phi_i|_{U_i\cap U_j}\right)^{-1}} U_i \cap U_j \xrightarrow{\Phi_j|_{U_i\cap U_j}} \underbrace{\Phi_j(U_i \cap U_j)}_{\subset \mathbb{D}}$$

is given by a Möbius transformation. Sometimes we refer to a manifold together with a Möbius structure as a *Möbius manifold*.

Example.

(1) We will always view $\mathbb{D}$ as equipped with the Möbius structure that is given by the chart $\mathrm{id}\colon \mathbb{D} \to \mathbb{D}$.
(2) Any open subset of a Möbius manifold is also a Möbius manifold.

The following lemma says that Möbius structures are useful for solving two problems at once: we can use them to show that a manifold is a complex manifold and we can use them to show that a manifold has a hyperbolic structure.

Lemma 23.1. *Let M be a surface and let $\{\Phi_i\colon U_i \to V_i\}_{i\in I}$ be a Möbius structure for M. Then the following hold:*

(1) *The charts form a holomorphic atlas for M, in particular M is a complex 1-dimensional manifold.*
(2) (a) *The manifold M admits a unique Riemannian structure g such that all the charts in the atlas $\{\Phi_i\colon U_i \to V_i\}_{i\in I}$ are isometries.*
(b) *If the Riemannian structure from* (a) *is complete, then (M, g) is hyperbolic.*

In the following we will always view a Möbius manifold as a complex 1-dimensional manifold and a Riemannian manifold with the structures coming from Lemma 23.1.

Proof. Let M be a surface and let $\{\Phi_i\colon U_i \to V_i\}_{i\in I}$ be a Möbius structure for M.

(1) The first statement is an immediate consequence of the definitions and of the fact, proved in Proposition 22.3 (2), that Möbius transformations are biholomorphisms.
(2) (a) We denote by g the Riemannian structure on $\mathbb{D}$. We define a Riemannian structure on M as follows. Let $P \in M$. We pick a chart $\Phi_i\colon U_i \to V_i$ from our Möbius structure and we define $h_P := \Phi_i^*(g_{\Phi_i(P)})$. Now suppose that we had picked a different chart Φ_j from the Möbius structure. The transition map from Φ_i to Φ_j is by definition a Möbius transformation, which is an isometry by Proposition 22.3 (2). It follows easily that Φ_j gives rise to the same definition of h_P. It is now straightforward to verify that this defines a Riemannian structure on M and that it has the desired properties.
(b) This statement is an immediate consequence of (a) and of the definition of a hyperbolic surface. □

The following proposition gives in particular an affirmative answer to Question 21.7.

Proposition 23.2. *Let $g \geq 2$. Then the following hold:*
(1) *The surface of genus g admits a Möbius structure.*
(2) *The surface of genus g is a complex 1-dimensional manifold.*
(3) *The surface of genus g is hyperbolic.*

Proof. We prove the proposition for the case that $g = 2$. The general case is proved by almost the same argument.

We first show that the surface of genus 2 admits a Möbius structure. By [Bon, Lemma 5.3] (see also [Frie2, Lemma 21.5]) there exists an $r > 0$ such that the interior angle at any vertex of the hyperbolic octagon H_8 in $\mathbb{D}$, defined by $Q_k = re^{2\pi ik/16}$, $k = 1, 3, \ldots, 15$, equals $\frac{\pi}{4}$.[472] This hyperbolic octagon is illustrated in Figure 367.

Let $k \in \{0, 1, 4, 5\}$. By Lemma 22.11 and the example on page 598 there exists a unique Möbius transformation Φ_k with $\Phi_k(Q_{2k-1}) = Q_{2k+5}$ and $\Phi_k(Q_{2k+1}) = Q_{2k+3}$. The Möbius transformations Φ_0 and Φ_1 are illustrated in Figure 368.

[472]Here is a sketch for the proof: For $r \to 0$ the interior angle converges to the interior angle of a Euclidean regular octagon, namely $\frac{3\pi}{4}$, whereas for $r \to \infty$ the interior angle converges to 0. The interior angle changes continuously with r (that is sort of clear, except that it is somewhat painful to provide a rigorous proof), so by the Intermediate Value Theorem there exists an r such that the interior angle equals $\frac{\pi}{4}$.

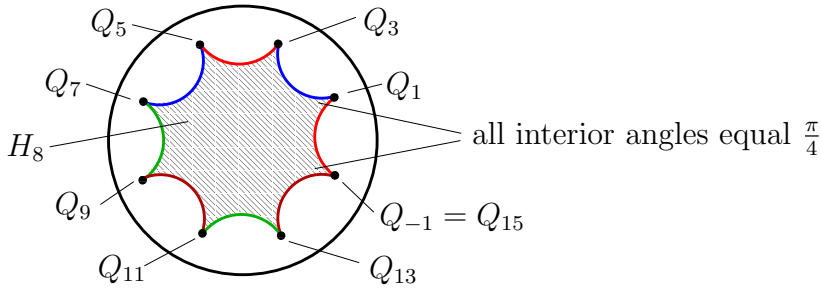

FIGURE 367.

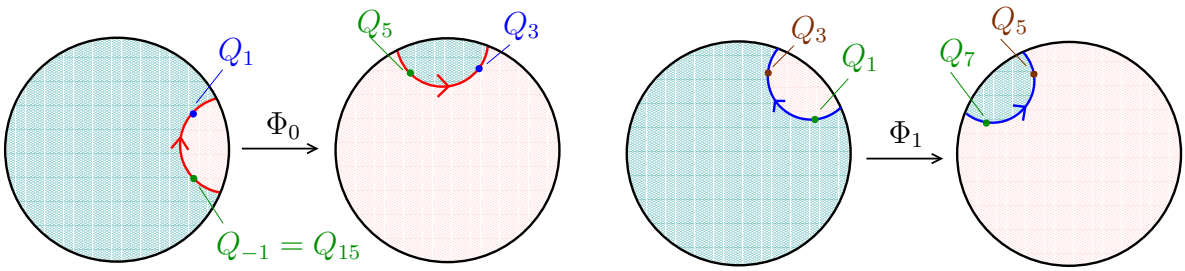

FIGURE 368.

Given $k \in \{0, 1, 4, 5\}$ we declare any point P on the edge connecting Q_{2k-1} and Q_{2k+1} to be equivalent to $\Phi_k(P)$. We denote by $\sim$ the equivalence relation that is generated by these equivalences. It is straightforward to see that $H_8/\sim$ is homeomorphic to the surface of genus 2 that we defined on page 119 as $E_8/\sim$. In the following we denote by $p\colon H_8 \to H_8/\sim$ the obvious projection map.

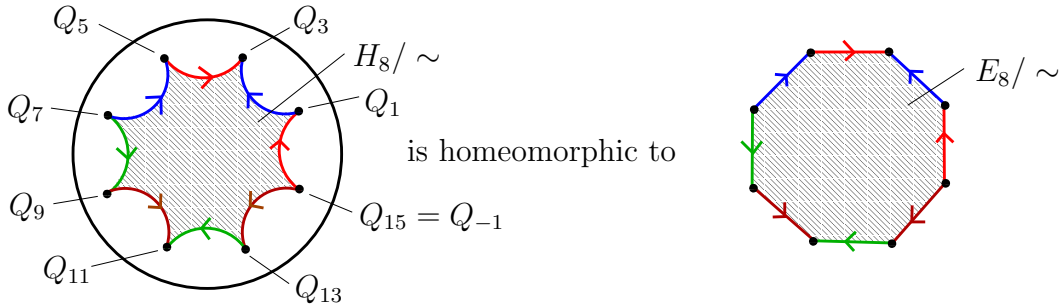

FIGURE 369.

Now we will give an explicit Möbius structure for $H_8/\sim$. More precisely, given any $P \in H_8/\sim$ we will give a chart ψ_P such that the transitions maps are given by Möbius transformations. So let $P \in H_8/\sim$.

(1) If $P = p(z)$ for some $z \in \mathring{H}_8$, then the map

$$\begin{array}{rcl} \psi_P \colon p(\mathring{H}_8) & \to & \mathring{H}_8 \\ p(w) & \mapsto & w \end{array}$$

is a chart around $P = p(z)$.

(2) Now suppose that $P = p(z)$ where z lies in the interior of one of the eight edges of ∂H_8. In the following we deal with the case that z lies on the edge from Q_{-1} to Q_1. We pick an $r > 0$ such that $B_{2r}(z)$ does not contain any of the vertices $Q_1, Q_3, \ldots, Q_{15}$ and does not hit any of the other edges. Then we consider the map

$$\begin{array}{rcl} \psi_P \colon p(B_r(z) \cap H_8) \cup p(\Phi_0(B_r(z)) \cap H_8) & \to & B_r(z) \\ p(w) & \mapsto & \begin{cases} w, & \text{if } w \in B_r(z) \cap H_8 \\ \Phi_0^{-1}(w), & \text{if } w \in \Phi_0(B_r(z)) \cap H_8. \end{cases} \end{array}$$

This map is a chart around $P = p(z)$. We refer to Figure 370 for an illustration of the definition of the map ψ_P.

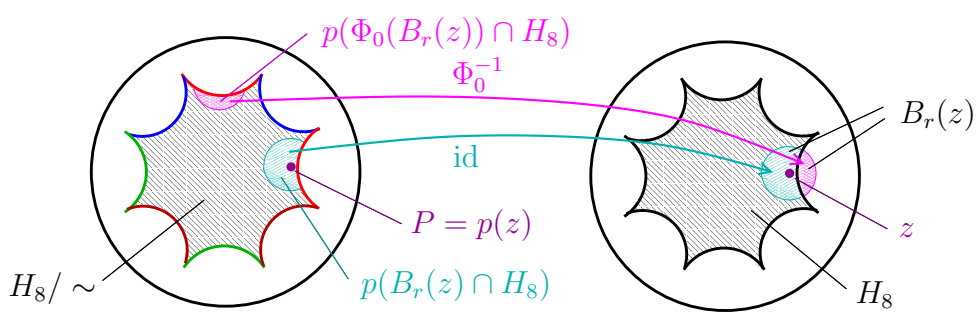

FIGURE 370.

(3) Finally suppose that $P = p(Q_1) = \cdots = p(Q_{15})$. We choose $r \in (0, \frac{1}{2}d(Q_{-1}, Q_1))$. Given $k \in \{1, 3, \ldots, 15\}$ we define $\gamma(k)$ via the following table:

k	1	3	5	7	9	11	13	15
$\gamma(k)$	$\frac{3}{4}\pi$	π	$\frac{5}{4}\pi$	$\frac{1}{2}\pi$	$\frac{7}{4}\pi$	0	$\frac{1}{4}\pi$	$\frac{3}{2}\pi$.

Recall that we had chosen the octagon H_8 such that the angle at any vertex equals $\frac{\pi}{4}$. For $k = 1, 3, \ldots, 15$ we can therefore apply Lemma 22.7 to find a unique Möbius transformation θ_k with the following two properties:

(a) $\theta_k(Q_k) = 0$,

(b) θ_k applied to the two rays emanating from Q_k equals the two rays $\{se^{i\gamma(k)} \mid s \geq 0\}$ and $\{se^{i(\gamma(k)+\frac{\pi}{4})} \mid s \geq 0\}$ emanating from 0.

We consider the map

$$\begin{array}{rcl} \psi_P \colon p(B_r(Q_1) \cap H_8) \cup \cdots \cup p(B_r(Q_{15}) \cap H_8) & \to & B_r(0) \\ p(z) & \mapsto & \theta_k(z), \quad \text{if } z \in B_r(Q_k) \cap H_8. \end{array}$$

We leave it as an exercise to verify that ψ_P is well-defined and that it is indeed a homeomorphism. This map is a chart around $P = p(z)$. We refer to Figure 371 for an illustration of the definition of the map ψ_P.

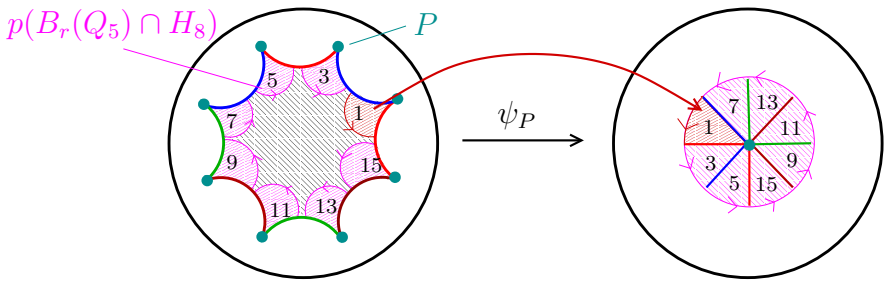

FIGURE 371.

It is straightforward to verify that all the transition maps between the above maps are given by Möbius transformations. We have thus shown that the maps $\{\psi_P\}_{P \in H_8}$ form a Möbius structure for $H_8/\sim$. This concludes the proof of (1).

Now we turn to the proof of (2). The existence of a Möbius structure together with Lemma 23.1 (2) shows immediately that the surface of genus 2 is a complex 1-dimensional manifold.

Finally we provide the proof of (3). In light of (1) and Lemma 23.1 (2) it suffices to show that the Riemannian manifold $(H_8/\sim, g)$ is complete. By Proposition 22.8 the topology on M defined by the metric $d_{(M,g)}$ agrees with the given topology of M. Since M is compact it now follows from Proposition 22.13 that (M, g) is complete. □

23.2. **More hyperbolic structures on the surfaces of genus $g \geq 2$ $(*)$.** Now we want to study the question, how many hyperbolic metrics does a surface of genus g admit. To make this question more precise, we introduce the following definition.

Definition. Let M be a surface of genus $g \geq 2$ and let h, h' be two hyperbolic metrics on M. We say h and h' are *equivalent* if there exists an isometry from (M, h) to (M, h').

This raises the question, whether a surface of genus $g \geq 2$ admits non-equivalent hyperbolic metrics. We return to the construction of a hyperbolic metric in Proposition 23.2. In our construction we started out with a regular $4g$-gon with interior angle $\frac{2\pi}{4g}$ and we identified pairs of sides. Two facts were crucial to obtain a hyperbolic metric:

(1) the sides were identified via an isometry,
(2) the sum of the interior angles equals 2π.

Or put differently, any choice of a $4g$-gon with side lengths $k_1, \ldots, k_{4g}$ and interior angles $\alpha_1, \ldots, \alpha_{4g}$ that satisfy the equations

$$k_1 = k_3,\ k_2 = k_4,\ \ldots,\ k_{4g-3} = k_{4g-1},\ k_{4g-2} = k_{4g} \quad \text{and} \quad \alpha_1 + \cdots + \alpha_{4g} = 2\pi$$

gives rise to a hyperbolic metric on a topological space that is homeomorphic to the surface of genus g. It is of course not clear whether different parameters give rise to non-equivalent hyperbolic structures. One way to distinguish them, in principle at least, is to look at the shortest length of a closed curve that is not null-homotopic. We will not elaborate on this procedure.

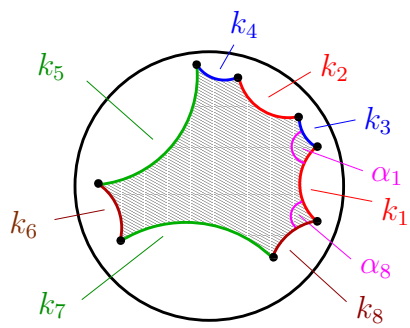

FIGURE 372.

How many such $4g$-gons are there? On the one hand we have parameters $k_1, k_3, \ldots, k_{4g-1}$ and $\alpha_1, \ldots, \alpha_{4g}$. On the other hand we have the condition that $\alpha_1 + \cdots + \alpha_{4g} = 2\pi$. Furthermore we want a $4g$-gon, so the last angle and the length of the last edge are determined by the others. Thus we obtain two other conditions. Summarizing we have $2g + 4g = 6g$ parameters that need to satisfy 3 conditions. Of course it is not clear which of these Riemannian structures are isometric. This naive discussion suggests that the space of hyperbolic metrics is $(6g-3)$-dimensional. Surprisingly this is not too far off the correct answer, in fact in [BP, Chapter B.4] the following proposition is proved.

Proposition 23.3. *The space of hyperbolic metrics on a surface of genus $g \geq 2$ can be viewed as a manifold of dimension $6g - 6$.*

We will not make use of this proposition. The space of hyperbolic metric is called the *Teichmüller space*, more information can be found at

`https://en.wikipedia.org/wiki/Teichmueller_space`.

The theory is named after Oswald Teichmüller (1913-1943) who was a brilliant mathematician and an ardent Nazi, see

`https://en.wikipedia.org/wiki/Oswald_Teichmueller`

`http://www-history.mcs.st-andrews.ac.uk/Biographies/Teichmuller.html`

and

`https://de.wikipedia.org/wiki/Oswald_Teichmueller`.

23.3. **More examples of hyperbolic surfaces.** In this section we will generalize the discussion from the previous section to surfaces that are non-compact.

In the following let $Q_1 = 1, Q_2 = i, Q_3 = -1$ and $Q_0 = Q_4 = -i$. We denote by H_4 the closed, non-compact subset of $\mathbb{D}$ that is bounded by the four hyperbolic lines with endpoints Q_k, Q_{k+1} where $k = 0, 1, 2, 3$. We refer to Figure 374 for an illustration.

We consider the Möbius transformations[473]

$$\Phi_1(z) := (-i) \cdot \frac{z - \frac{-1+i}{2}}{1 - \frac{-1-i}{2} z} \quad \text{and} \quad \Phi_2(z) := (-i) \cdot \frac{z + \frac{-1-i}{2}}{1 + \frac{-1+i}{2} z}.$$

We record a few key properties of Φ_1 and Φ_2 in a lemma.

Lemma 23.4.

(1) *We have $\Phi_1(Q_2) = Q_4$ and $\Phi_1(Q_3) = Q_3$ and we have $\Phi_2(Q_2) = Q_4$ and $\Phi_1(Q_1) = Q_1$.*
(2) *The restriction of Φ_1 to the hyperbolic line with endpoints Q_3 and Q_2 is given by reflection in the x-axis.*[474]
(3) *The restriction of Φ_2 to the hyperbolic line with endpoints Q_1 and Q_2 is given by reflection in the x-axis.*

Proof. The first statement follows immediately from plugging in the points. A straightforward, albeit slightly painful calculation shows that for any $\alpha \in \mathbb{R}$ we have

$$\Phi_1\big(-1 + i + e^{-i\alpha}\big) = -1 - i + e^{i\alpha}.$$

This proves the second statement. The third statement is proved by a similarly tedious calculation. □

Remark. We consider the Möbius transformation Φ_1 in more detail. It sends the hyperbolic line with endpoints Q_3 and Q_2 to the hyperbolic line with endpoints Q_3 and Q_4. In particular it sends the two halves determined by the hyperbolic lines to one-another. Which half gets sent to which half is determined by the fact that Φ_1 is orientation-preserving. We refer to Figure 373 for an illustration of the Möbius transformations Φ_1 and Φ_2.

Given $k \in \{1, 2\}$ we declare any point P on the line with the endpoints Q_k and Q_{k+1} to be equivalent to $\Phi_{3-k}(P)$. We denote by $\sim$ the equivalence relation that is generated by these equivalences.

Proposition 23.5.

(1) *The topological space $H_4/\sim$ admits a Möbius structure. In particular it is a 1-dimensional complex manifold.*

[473]Recall that a Möbius transformation of $\mathbb{D}$ is a map of the form $\psi(z) = e^{i\theta} \cdot \frac{z-a}{1-\bar{a}z}$ for some $\theta \in \mathbb{R}$ and $a \in \mathbb{D}$.

[474]The Möbius transformation Φ_1 sends the hyperbolic line with endpoints Q_3 and Q_2 to the hyperbolic line with endpoints Q_3 and Q_4. There are many such Möbius transformations, but the Möbius transformation we picked has the extra property, that on the hyperbolic line it is the "obvious map".

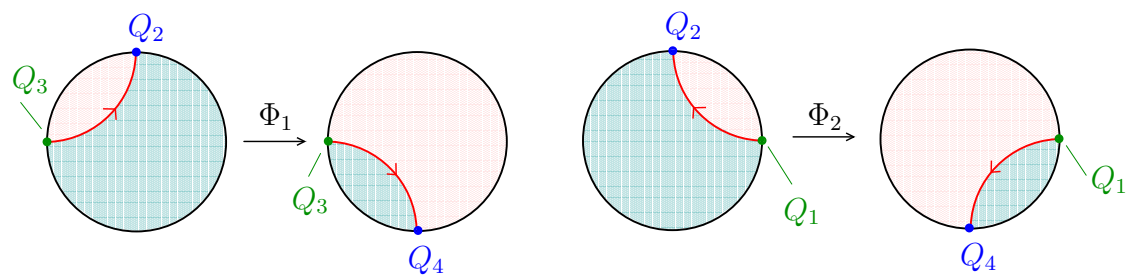

FIGURE 373.

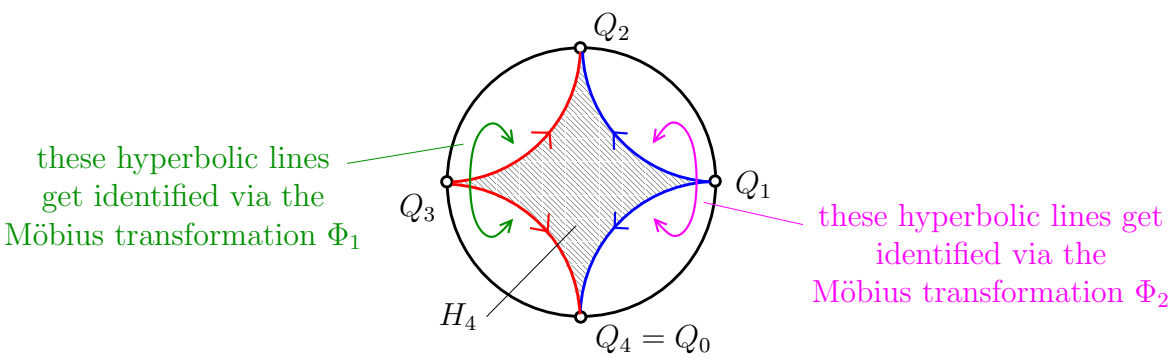

FIGURE 374.

(2) *The Riemannian structure on $H_4/\sim$ coming from* (1) *and Lemma 23.1 is complete.*
(3) *The topological space $H_4/\sim$ admits a hyperbolic metric.*

Proof. We start out with the proof of (1). We have to show that $H_4/\sim$ admits a Möbius structure. The following argument is almost identical to the proof of Proposition 23.2 (1).

We denote by $p\colon H_4 \to H_4/\sim$ the projection map. In the following let $P \in H_4/\sim$.

(1) If $P = p(z)$ for some $z \in \mathring{H}_4$, then

$$\begin{array}{rcl} \psi_P\colon p\big(\mathring{H}_4\big) & \to & \mathring{H}_4 \\ p(w) & \mapsto & w \end{array}$$

is a chart around $P = p(z)$.

(2) Now suppose that $P = p(z)$ where z lies on ∂H_4. In the following we deal with the case that z lies on the edge from Q_1 to Q_2. All other cases are dealt with almost the same way. We pick an $r > 0$ such that $B_{2r}(z)$ intersects no other component of ∂H_4. We consider the map

$$\begin{array}{rcl} \psi_P\colon p(B_r(z) \cap H_4) \cup p(\Phi_2(B_r(z)) \cap H_4) & \to & B_r(z) \\ p(w) & \mapsto & \begin{cases} w, & \text{if } w \in B_r(z) \cap H_4 \\ \Phi_2^{-1}(w), & \text{if } w \in \Phi_1^{-1}(B_r(z)) \cap H_4. \end{cases} \end{array}$$

This map is a chart around $P = p(z)$.

The charts that we just constructed form an atlas for $H_4/\sim$. It follows immediately from the definitions that all transition maps are given by Möbius transformations. It follows that the maps ψ_P form a Möbius structure for $H_4/\sim$. As in the proof of Proposition 23.2 it follows that $H_4/\sim$ is a 1-dimensional complex manifold and that these charts satisfy the conditions of Lemma 23.1. This concludes the proof of (1).

We continue with the proof of (2). We have to show that the Riemannian structure on $H_4/\sim$ coming from (1) and Lemma 23.1 is complete. The subsequent argument is a variation of the proof of Proposition 22.13.

We denote by d the metric corresponding to the Riemannian structure on $H_4/\sim$. Let $\{a_n\}_{n\in\mathbb{N}}$ be a Cauchy sequence in $H_4/\sim$ with respect to d. As in the proof of Proposition 22.13 we see that there exists a $C \in \mathbb{R}$ such that $d(0, a_n) \leq C$ for all $n \in \mathbb{N}$.

Claim. There exists an $r \in [0,1)$ such that for any $z \in H_4$ with $d(0, p(z)) \leq C$ we have $|z| \leq r$.

Given $s \in [0,1)$ we define

$$g(s) \;:=\; \int\limits_{t=0}^{t=s} \frac{\sqrt{2}}{1-t^2}\, dt.$$

Clearly we have $\lim\limits_{s\to 1} g(s) = \infty$. In particular there exists an $r \in [0,1)$ such that $g(s) > C+1$ for all $s \geq \frac{1}{2}r$.

We claim that r has the desired property. So let $z = x + iy \in H_4$ with $|z| > r$. Since H_4 is a subset of the square spanned by ± 1 and $\pm i$ we see that we have $|z| \leq |x| + |y|$. Put differently, we have $|x| \geq \frac{1}{2}r$ or $|y| \geq \frac{1}{2}r$. Without loss of generality we can assume that $|x| \geq \frac{1}{2}r$.

We need to show that $d(0, p(z)) \geq C + 1$. It suffices to show that for any piecewise smooth path $\gamma\colon [0,a] \to H_4/\sim$ with $\gamma(0) = 0$ and $\gamma(a) = p(z)$ we have $\ell(\gamma) \geq C + 1$.

We denote by

$$\begin{array}{rcl} q\colon H_4/\sim & \to & (-1,1) \\ [x+iy] & \mapsto & x \end{array}$$

the projection onto the real part. It follows from Lemma 23.4 that this map is indeed well-defined. A straightforward calculation shows that for all $t \in [0,a]$ we have

$$\big\|\gamma'(t)\big\|_{H_4/\sim} \;\geq\; \big\|(q\circ\gamma)'(t)\big\|_{\mathbb{D}}.$$

It follows that

$$\ell(\gamma) \;=\; \int\limits_0^a \big\|\gamma'(t)\big\|_{H_4/\sim}\, dt \;\underset{\substack{\uparrow \\ \text{above inequality}}}{\geq}\; \int\limits_0^a \big\|(q\circ\gamma)'(t)\big\|_{\mathbb{D}}\, dt \;\underset{\substack{\uparrow \\ \text{definition of } d_{(\mathbb{D},g)}}}{\geq}\; d_{(\mathbb{D},g)}(0, \overbrace{q(\gamma(a))}^{=x}) \;\underset{\substack{\uparrow \\ \text{Proposition 22.10}}}{=}\; g(|x|) \;\overset{\substack{\text{since } |x| \geq \frac{1}{2}r \\ \downarrow}}{\geq}\; C+1.$$

This concludes the proof of the claim.

By the above claim the sequence $\{a_n\}_{n\in\mathbb{N}}$ lies in the compact set $p(\{z \in H_4 \mid |z| \leq r\})$. But by Proposition 22.13 the metric space $p(\{z \in H_4 \mid |z| \leq r\})$ is complete, so the sequence $\{a_n\}_{n\in\mathbb{N}}$ converges in $p(\{z \in H_4 \mid |z| \leq r\})$, in particular it converges in $p(H_4) = H_4/\sim$. Thus we have proved that $H_4/\sim$ is complete. This concludes the proof of (2).

Finally statement (3) is an immediate consequence of the definition of a hyperbolic metric and of statement (2). □

We had just seen in Proposition 23.5 that $H_4/\sim$ admits a Möbius structure, in particular it is a 1-dimensional complex manifold. It is relatively straightforward to show that $H_4/\sim$ is homeomorphic to the sphere minus three points, or equivalently, to $\mathbb{C}$ minus two points. Now we show the much stronger statement that $H_4/\sim$ is actually biholomorphic to $\mathbb{C} \setminus \{0, 1\}$.

Proposition 23.6. *There exists a biholomorphism* $H_4/\sim \to \mathbb{C} \setminus \{0, 1\}$.

Remark. We equip $H_4/\sim$ with the Riemannian metric g coming from the Möbius structure and we equip $\mathbb{C} \setminus \{0, 1\}$ with the usual Euclidean Riemannian metric that we denote by h.

By Proposition 23.5 the metric space $(H_4/\sim, g)$ is complete whereas $(\mathbb{C} \setminus \{0, 1\}, h)$ is evidently not complete. Thus we see that the biholomorphism $H_4/\sim \to \mathbb{C} \setminus \{0, 1\}$ from Proposition 23.6 is *not* an isometry.

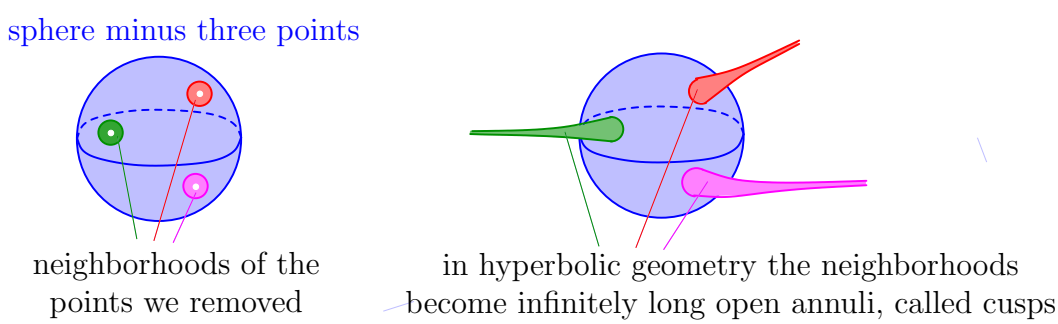

FIGURE 375.

Proof of Proposition 23.6. We denote by Δ the open subset of $\mathbb{D}$ bounded by the three hyperbolic lines with endpoints $-1, 1$ and i. (We refer to Figure 376 for an illustration of Δ.) It follows from applying the Riemann Mapping Theorem 21.10 together with Carathéodory's Theorem 21.11 that there exists a biholomorphism $\Psi\colon \Delta \to \mathbb{D}$ that extends to a homeomorphism $\Psi\colon \overline{\Delta} \to \overline{\mathbb{D}}$. We combine Ψ with the biholomorphism from $\mathbb{D}$ to $\mathbb{H}$ coming from Proposition 22.2. This way we obtain a biholomorphism $\Phi\colon \Delta \to \mathbb{H}$ that extends to a homeomorphism $\Phi\colon \overline{\Delta} \to \overline{\mathbb{H}}$.

Using Lemma 22.4 we can, if necessary, compose Φ with a Möbius transformation of $\mathbb{H}$, to arrange that $\Phi(i) = \infty$ and that $\Phi(\{-1, 1\}) = \{0, 1\}$.

Note that Φ restricts to a homeomorphism $\Phi\colon \partial\overline{\Delta} \to \partial\overline{\mathbb{H}} = \mathbb{R} \cup \{\infty\}$. By the above we have $\Phi(\partial\overline{\Delta}) = \mathbb{R} \setminus \{0,1\}$. Now we consider the map

$$\begin{array}{rcl} \Psi\colon H_4 & \to & \mathbb{C} \setminus \{0,1\} \\ z & \mapsto & \begin{cases} \Phi(z), & \text{if } z \in \overline{\Delta}, \\ \overline{\Phi(\overline{z})}, & \text{if } \overline{z} \in \overline{\Delta}, \end{cases} \end{array}$$

Note that by the above we have $f((-1,1)) = (0,1)$. Thus it follows from the Schwarz Reflection Principle, see Proposition 21.3, that the restriction of Ψ to the interior of H_4 is holomorphic. It follows from Lemma 23.4 that if P and Q are two equivalent points on ∂H_4, then $\Psi(P) = \Psi(Q)$. Therefore the map Ψ factors through a map $H_4/\sim \to \mathbb{C} \setminus \{0,1\}$. Using once again the Schwarz Reflection Principle one can show that this map is in fact a biholomorphism. We leave the verification of this step as an exercise to the reader. □

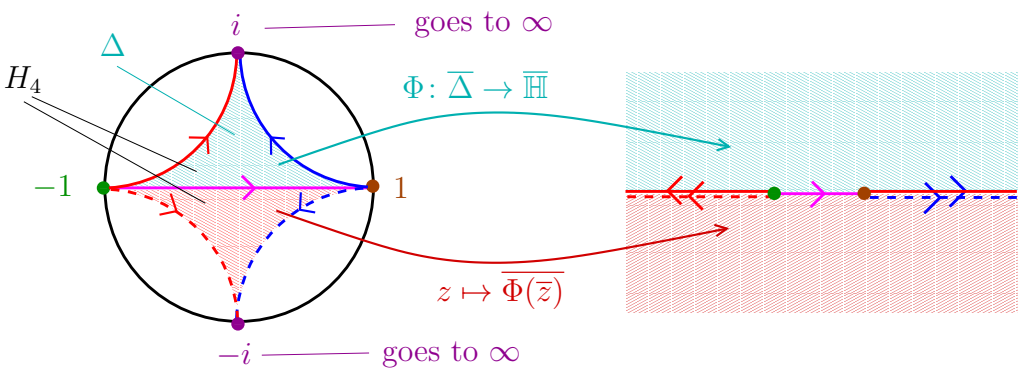

FIGURE 376. Illustration of the proof of Proposition 23.6

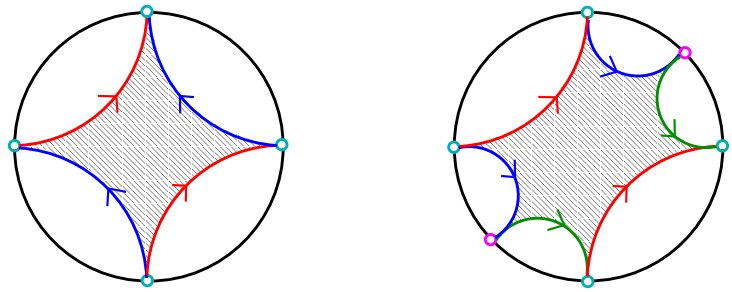
Definition. Given $g \in \mathbb{N}_0$ and $n \in \mathbb{N}_0$ we now denote by $F_{g,n}$ the surface that is obtained from the surface of genus g by removing n points. We refer to $F_{g,n}$ as the *n-punctured surface of genus g*.

For example the three-punctured sphere $F_{0,3}$ is the sphere with three points removed. As we pointed out above, $F_{0,3}$ is diffeomorphic to $\mathbb{C} \setminus \{0,1\}$. In particular, as we have just seen, the three-punctured sphere admits a hyperbolic structure. The following theorem says that "most" surfaces admit a hyperbolic structure.

Theorem 23.7. *Let $g \in \mathbb{N}_0$ and let $n \in \mathbb{N}_0$. If $2g+n-2 > 0$, then $F_{g,n}$ admits a hyperbolic structure.*

Sketch of a proof. Let $g \in \mathbb{N}_0$ and let $n \in \mathbb{N}_0$. If $2g+n-2 > 0$ then variations on the argument of Propositions 23.2 and 23.5 show that $F_{g,n}$ admits a hyperbolic metric. In Figure 377 we sketch the constructions needed to show that the once-punctured and the twice-punctured torus have a Möbius structure. The proof that the corresponding Riemannian manifolds are complete is similar to the proof of Proposition 23.5. □



once punctured torus twice punctured torus

FIGURE 377.

23.4. **The universal covering of surfaces.**

Definition. Let $f\colon M \to N$ be a map between two Möbius manifolds.

(1) We say that f is a *Möbius map* if for any chart $\Phi\colon U \to V$ in the Möbius structure of M and any chart $\Psi\colon X \to Y$ in the Möbius structure of N the restriction of the map

$$\underbrace{\Phi(U \cap f^{-1}(X))}_{\subset \mathbb{D}} \xrightarrow{\Psi \circ f \circ \Phi^{-1}} \underbrace{\Psi(X \cap f(U))}_{\subset \mathbb{D}}$$

to any component of $\Phi(U \cap f^{-1}(X))$ is given by a Möbius transformation.

(2) We say that f is a *Möbius isomorphism*, if f is a *Möbius map*, if f is a bijection, and if f^{-1} is also a *Möbius map*.

The following lemma is an immediate consequence of the definitions and the fact, proved in Proposition 22.3, that Möbius transformations are biholomorphisms and isometries.

Lemma 23.8. *Let M and N be two Möbius manifolds and let $f\colon M \to N$ be a Möbius map. Then the following two statements hold:*

(1) *the map f is a local biholomorphism,*
(2) *the map f is a local isometry.*

The following theorem is the main result of this chapter.

Theorem 23.9. (Hadamard's Theorem) *Let $g \geq 2$, and let $M = H_{4g}/\sim$ be the surface of genus g with the Möbius structure constructed in Proposition 23.2. Then there exists a covering map $p\colon \mathbb{D} \to M$ with the following properties:*

(1) *p is a Möbius map,*
(2) *p is a local isometry,*
(3) *p is a local biholomorphism.*

The hyperbolic disk $\mathbb{D}$ is of course simply connected. The theorem thus says that for any $g \geq 2$ the hyperbolic disk $\mathbb{D}$ is the universal covering of the surface of genus g. Thus we have now answered Question 20.12.

The proof of Theorem 23.9 will require the following two sections.

23.5. **Proof of Theorem 23.9 I.** In this section we will lay the technical foundations for the proof of Theorem 23.9.

In the following lemma we first summarize a few properties of Möbius maps.

Lemma 23.10.

(1) *If $U \subset \mathbb{D}$ is a connected subset and if $f\colon U \to \mathbb{D}$ is a Möbius map, then f is given by a Möbius transformation.*
(2) *Let $f\colon M \to N$ be a map between two Möbius manifolds. If f is o-locally a Möbius map, then f is a Möbius map.*
(3) *The composition of two Möbius maps is again a Möbius map.*
(4) *A bijective Möbius map is a Möbius isomorphism.*

Proof.

(1) Let $U \subset \mathbb{D}$ be a connected subset and let $f\colon U \to \mathbb{D}$ be a Möbius map. It follows from Proposition 22.3 (4) that given $P \in U$ there exists a unique Möbius transformation ϕ_P such that $f = \phi_P$ in an open neighborhood of P. We consider the map
$$\begin{array}{rcl} \phi\colon U & \to & \text{set of all Möbius transformations} \\ P & \mapsto & \phi_P. \end{array}$$
We equip the right-hand side of the map ϕ with the discrete topology. It follows from the definitions that this map is continuous. But then it follows from Lemma 1.92 that this map is constant. But that is exactly what we had tried to show.
(2) This statement follows immediately from (1) and the definitions.
(3) This statement is an immediate consequence of definitions and the fact, proved in Proposition 22.3, that the compositions of two Möbius transformations is again a Möbius transformation.
(4) Let $f\colon M \to N$ be a bijective Möbius map. In Proposition 22.3 we saw that the inverse of a Möbius transformation is again a Möbius transformation. It follows that f^{-1} is o-locally a Möbius map. But then it follows from (2), that f^{-1} is in fact a Möbius map. □

Lemma 23.11. *Let U be an open connected subset of $\mathbb{D}$ and let M be a Möbius manifold. Furthermore let $\Phi, \Psi\colon U \to M$ be two Möbius maps.*[475] *Suppose one of the following two conditions is satisfied:*

(1) *There exists an open non-empty subset of U on which Φ and Ψ agree, or*
(2) *there exists a point $Q \in U$ with $\Phi(Q) = \Psi(Q)$ and a non-zero vector $v \in T_Q\mathbb{D}$ such that $d\Phi_Q(v) = d\Psi_Q(v)$,*

then the Möbius maps Φ and Ψ agree on all of U.

[475]Here we view $U \subset \mathbb{D}$ as equipped with the obvious Möbius structure.

Proof. Let U be an open connected subset of $\mathbb{D}$, let M be a Möbius manifold and let $\Phi, \Psi \colon U \to M$ be two Möbius maps. We consider one more statement:

(3) There exists a point $Q \in U$ such that $\Phi(Q) = \Psi(Q)$ and such that $d\Phi_Q = d\Psi_Q$.

Clearly we have (1) $\Rightarrow$ (3). We also have (2) $\Rightarrow$ (3). Indeed, the differentials $d\Phi_Q$ and $d\Psi_Q$ are homomorphisms between two 1-dimensional complex vector spaces. So if they are agree on one non-zero vector, then they agree on all of the vector space $T_Q\mathbb{D}$.

So it suffices to show that if (3) is satisfied, then the maps Φ and Ψ agree on all of U. So suppose that there exists a point $Q \in U$ such that $\Phi(Q) = \Psi(Q)$ and such that $d\Phi_Q = d\Psi_Q$. We consider

$$Y \ := \ \{P \in U \mid \Phi(P) = \Psi(P) \text{ and } d\Phi_P = d\Psi_P\}.$$

By our hypothesis we know that Y contains Q, in particular Y is non-empty. Since Φ and Ψ are smooth it follows that Y is closed. It remains to show that Y is open.

So let $P \in Y$. We pick a map $\Theta \colon W \to \mathbb{D}$ from the Möbius structure of M such that W is an open neighborhood of $\Phi(P) = \Psi(P)$. We denote by V the component of $\Phi^{-1}(W) \cap \Psi^{-1}(W)$ that contains P. Since Φ and Ψ are Möbius maps it follows from Lemma 23.10 (3) that the maps $\Theta \circ \Phi \colon V \to \mathbb{D}$ and $\Theta \circ \Psi \colon V \to \mathbb{D}$ are also Möbius maps. Since V is connected it follows from Lemma 23.10 (1) that both maps are given by Möbius transformations. These two Möbius transformations agree at P and they have the same differential at P. It follows from Proposition 22.3 (5) that Φ and Ψ agree on an open neighborhood of P. This shows that Y is also open. $\square$

Definition. Let M be a Möbius manifold and let $Q \in M$ and $r > 0$. We say $B_r^M(Q)$ is *small* if there exists a Möbius isomorphism $\Omega \colon B_r^{\mathbb{D}}(0) \to B_r^M(Q)$ with $\Omega(0) = Q$.

Proposition 23.12. *Let M be a Möbius manifold and let $Q \in M$. Then there exists an $r > 0$ such that $B_r^M(Q)$ is small.*

In the proof of Proposition 23.12 we will make use of the following lemma.

Lemma 23.13. *Let (X, g) and (Y, h) be Riemannian manifolds. Let $Q \in X$ and $r > 0$. Let $f \colon B_{3r}^X(Q) \to (Y, h)$ be a local isometry and let $S, T \in B_r^X(Q)$. Then we have*

$$d_Y(f(S), f(T)) \ \leq \ d_X(S, T).$$

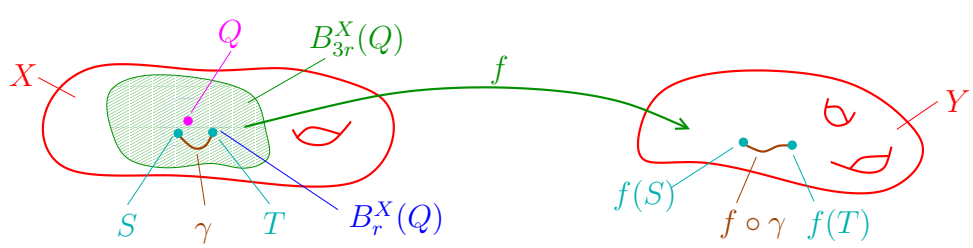


FIGURE 378. Illustration for Lemma 23.13.

Proof. Let $S, T \in B_r^X(Q)$. Furthermore let $\epsilon > 0$. By the triangle inequality we have $d_X(S,T) < 2r$. In particular there exists a piecewise smooth path γ in X from S to T such that $\ell_X(\gamma) < 2r$ and with $\ell_X(\gamma) < d_X(S,T) + \epsilon$. Given any t we have

$$d_X(Q, \gamma(t)) \;\le\; d_X(Q,S) + d_X(S, \gamma(t)) \;<\; r + \ell_X(\gamma) \;<\; 3r.$$

Thus we have shown that the image of γ lies in $B_{3r}^X(Q)$. In particular the image of γ lies in the domain of f. Thus we see that

$$d_Y(f(S), f(T)) \;\underset{\substack{\uparrow \\ \text{since } f\circ\gamma \text{ is a path from} \\ f(S) \text{ to } f(T)}}{\le}\; \ell_Y(f\circ\gamma) \;\underset{\substack{\uparrow \\ \text{by Lemma 22.9, since} \\ f \text{ is a local isometry}}}{=}\; \ell_X(\gamma) \;<\; d_X(S,T) + \epsilon.$$

Since this inequality holds for all $\epsilon > 0$ we see that $d_Y(f(S), f(T)) \le d_X(S,T)$. □

Now we can provide the proof of Proposition 23.12.

Proof of Proposition 23.12. Let M be a Möbius manifold and let $Q \in M$. We pick a map $\Phi\colon U \to V$ from the Möbius structure of M such that U is an open neighborhood of Q. By Proposition 22.3 (3), after possibly composing Φ with a Möbius transformation, we can furthermore assume that $\Phi(Q) = 0$. We write $\Omega := \Phi^{-1}$. By Proposition 22.8 (3) and by the openness of V there exists an $r > 0$ such that $B_{3r}^M(Q) \subset U$ and such that $B_{3r}^{\mathbb{D}}(0) \subset V$.[476]

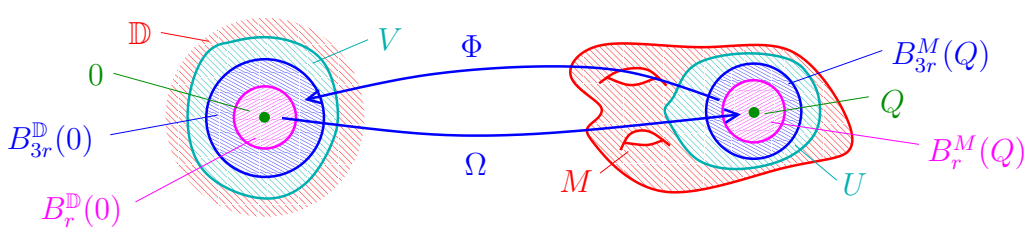

FIGURE 379. Illustration for the proof of Proposition 23.12.

It follows immediately from Lemmas 23.8 and 23.13 and from our choice of r that the following holds:

(1) For any $S, T \in B_r^M(Q)$ we have $d_{\mathbb{D}}(\Phi(S), \Phi(T)) \le d_M(S,T)$.
(2) For any $S, T \in B_r^{\mathbb{D}}(Q)$ we have $d_M(\Omega(S), \Omega(T)) \le d_{\mathbb{D}}(S,T)$.

It follows immediately from these two inequalities, from $\Phi(Q) = 0$ and from the fact that $\Phi = \Omega^{-1}$ that Ω restricts to an isometry $\Omega\colon (B_r^{\mathbb{D}}(0), d_{\mathbb{D}}) \to (B_r^M(Q), d_M)$ of metric spaces which is furthermore a bijection. Furthermore, since Φ is a Möbius isomorphism it follows that the inverse map $\Omega = \Phi^{-1}\colon (B_r^{\mathbb{D}}(0), d_{\mathbb{D}}) \to (B_r^M(Q), d_M)$ is also a Möbius isomorphism. □

[476]Note the discrete factor 3 in the radius of the ball.

Lemma 23.14. *Let M be a Möbius manifold. Let $Q \in M$ and let $r > 0$ such that $B_r^M(Q)$ is small. Let $\Phi\colon \mathbb{D} \to M$ be a Möbius map such that $B_r^M(Q) \subset \Phi(\mathbb{D})$. Then the following hold:*

1. *For any $X \in \Phi^{-1}(Q)$ the map Φ restricts to a Möbius isomorphism $B_r^{\mathbb{D}}(X) \to B_r^M(Q)$.*
2. *Let $s \leq \frac{r}{2}$ and let $Y \in \mathbb{D}$ such that $\Phi(Y) \in B_s^M(Q)$. Then there exists an $X \in \Phi^{-1}(Q)$ with $Y \in B_s^{\mathbb{D}}(X)$.*

Proof. Let M be a Möbius manifold. Let $Q \in M$ and let $r > 0$ such that $B_r^M(Q)$ is small. We pick a Möbius isomorphism $\Omega\colon B_r^{\mathbb{D}}(0) \to B_r^M(Q)$ as in the definition of "small". Let $\Phi\colon \mathbb{D} \to M$ be a Möbius map such that $B_r^M(Q) \subset \Phi(\mathbb{D})$.

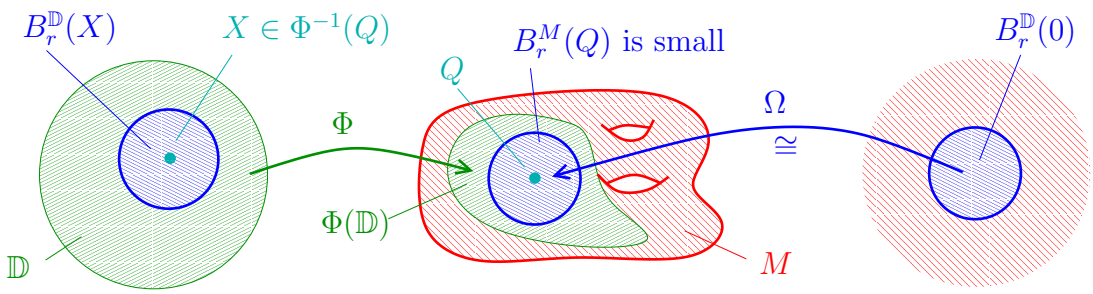

FIGURE 380. Illustration for the proof of Lemma 23.14 (1).

(1) Let $X \in \Phi^{-1}(Q)$. It follows immediately from the fact that Möbius maps are local isometries and from Lemma 23.13 that $\Phi(B_r^{\mathbb{D}}(X)) \subset B_r^M(Q)$. Therefore we can consider the Möbius map $\Omega^{-1} \circ \Phi\colon B_r^{\mathbb{D}}(X) \to B_r^{\mathbb{D}}(0)$. By Lemma 23.10 this Möbius map is the restriction of a Möbius transformation. In particular it is a Möbius isomorphism. But since Ω is also a Möbius isomorphism it follows that $\Phi\colon B_r^{\mathbb{D}}(X) \to B_r^M(Q)$ is also a Möbius isomorphism.

(2) Let $s \leq \frac{r}{2}$ and let $Y \in \mathbb{D}$ such that $\Phi(Y) \in B_s^M(Q)$, i.e. such that $d_M(Q, \Phi(Y)) < s$. By the triangle inequality we have
$$B_s^M(\Phi(Y)) \;\subset\; B_{2s}^M(Q) \;\subset\; B_r^M(Q).$$
The same argument as in (1) shows that the map Φ restricts to a Möbius isomorphism $B_s^{\mathbb{D}}(Y) \to B_s^M(\Phi(Y))$. We have $d_M(Q, \Phi(Y)) < s$, i.e. we have $Q \in B_s^M(\Phi(Y))$. Hence there exists an $X \in B_s^{\mathbb{D}}(Y)$ with $\Phi(X) = Q$. We refer to Figure 381 for an illustration. □

23.6. **Proof of Theorem 23.9 II.** In this section we will now finally provide the proof of Theorem 23.9. We will only cover the case $g = 2$, the proof of the general case is almost identical.

Throughout this section let $M = H_8/\sim$ be the surface of genus 2 with the Möbius structure constructed in Proposition 23.2. In the following we will show that there exists

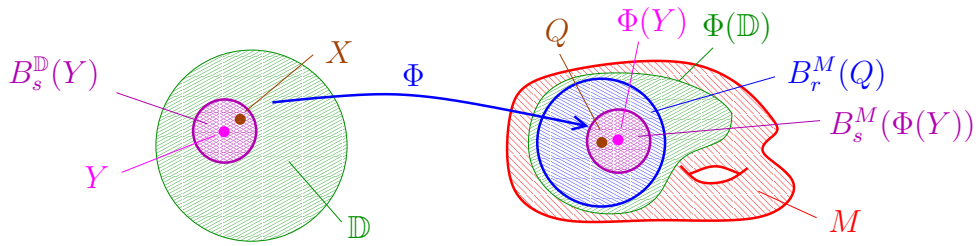

FIGURE 381. Illustration for the proof of Lemma 23.14 (2).

a Möbius map $p\colon \mathbb{D} \to M$ that is in fact a covering map. It then follows from Lemma 23.8 that p is also a local isometry and a local biholomorphism.

For the remainder of the proof we adopt the following notation and conventions.

(1) We view $\mathring{H}_8$ as a subset of $\mathbb{D}$ and also of $H_8/\sim$.
(2) Given $Z \in \mathbb{D}$ we denote by

$$\begin{array}{rcl} \gamma_Z\colon [0,1] & \to & \mathbb{D} \\ t & \mapsto & t \cdot Z \end{array}$$

the radial path from the origin $0 \in \mathbb{D}$ to Z.
(3) We say that $U \subset \mathbb{D}$ is *convex* if it is convex in the usual Euclidean sense, i.e. if given any $P, Q \in U$ the points $t \cdot P + (1-t) \cdot Q$, $t \in [0,1]$ also lie in U. On several occasions throughout the proof we will make use of the following elementary observations:
   (a) convex sets are path-connected,
   (b) the intersection of two convex sets is also convex,
   in particular, combining (a) and (b) we get
   (c) the intersection of two convex sets is path-connected.

Our first goal is to construct a suitable map $p\colon \mathbb{D} \to M = H_8/\sim$. So let $Z \in \mathbb{D}$. We write $\gamma = \gamma_Z$. We say $t \in [0,1]$ is *good* if there exists a convex open neighborhood U of $\gamma([0,t])$ and a map $\Psi\colon U \to M$ which has the following properties:

(i) Ψ is a Möbius map,
(ii) it restricts to the identity on $\mathring{H}_8 \cap U \subset M$.

We start out with the following lemma.

Lemma 23.15. *The point $t = 1$ is good.*

Proof. We set

$$T := \{t \in [0,1] \mid t \text{ is good}\}.$$

We start out with the following observations:

(1) We have that $0 \in T$ since the identity on the open neighborhood $\mathring{H}_8$ of 0 has the required properties.[477]

[477]Here we use that for each point $Z \in \mathring{H}_8$ the identity map $\mathrm{id}\colon \mathring{H}_8 \to \mathring{H}_8$ is part of the Möbius structure of M.

(2) Being good is clearly an open condition, hence $T \subset [0,1]$ is open.

We want to show that $T = [0,1]$. By the above, and since $[0,1]$ is connected, it suffices to show that $s := \sup(T)$ is good.

Since $0 \in S$ and since T is open we see that $s > 0$. Therefore there exists an increasing sequence $\{t_n\}_{n\in\mathbb{N}}$ of good numbers $t_n \in [0,t)$ that converges to s. Since each t_n is good we can pick for each n a convex open neighborhood U_n of $\gamma([0,t_n])$ and a map $\Psi_n \colon U_n \to M$ that has the desired properties (i) and (ii).

Let $m, n \in \mathbb{N}$. The Möbius maps Ψ_m and Ψ_n agree on the non-empty open connected subset $\overset{\circ}{H}_8 \cap U_n \cap U_m$. It follows from Lemma 23.11 that the maps Ψ_m and Ψ_n agree on $U_n \cap U_m$.

By the continuity of γ the sequence $\{\gamma(t_n)\}_{n\in\mathbb{N}}$ converges to $\gamma(t)$, in particular it is a Cauchy sequence with respect to $d_{\mathbb{D}}$. It follows from Lemma 22.9 that $\{\Psi_n(\gamma(t_n))\}_{n\in\mathbb{N}}$ is a Cauchy sequence with respect to d_M.[478] It follows from Proposition 23.2 that the metric space $(M = H_8/\sim, d_M)$ is complete. Therefore the Cauchy sequence $\{\Psi_n(\gamma(t_n))\}_{n\in\mathbb{N}}$ converges to a point $S \in M$.

It follows from Proposition 23.12 that there exists an $r > 0$ and a Möbius isomorphism $\Omega \colon B_r^{\mathbb{D}}(0) \to B_r^M(S)$ such that $\Omega(0) = S$. We pick an n such that $\Psi_n(\gamma(t_n)) \in B_r^M(S)$ and such that $d_{\mathbb{D}}(\gamma(t), \gamma(s)) < r$. We write $t = t_n, \Psi = \Psi_n, U = U_n$ and we write $X = \gamma(t)$. Let $v \in T_X\mathbb{D}$ be a non-zero vector. We let $w := d(\Omega^{-1} \circ \Psi)_X(v)$. The Möbius maps Ω and Ψ are in particular local isometries, therefore we have $\|w\| = \|v\|$. It follows from Proposition 22.3 (4) that there exists a Möbius transformation Θ with $\Theta(X) = \Omega^{-1}(\Psi(X))$ and such that $d\Theta_X(v) = w$.

The situation is illustrated in Figure 382. The Möbius maps $\Omega \circ \Theta \colon B_r^{\mathbb{D}}(X) \to M$ and $\Psi \colon U \to M$ agree at $X = \gamma(t)$ and we have $d(\Omega \circ \Theta)_X(v) = d\Psi_X(v)$. It follows from Lemma 23.11 that $\Omega \circ \Theta$ and Ψ agree on the path-connected set $B_r^{\mathbb{D}}(X) \cap U$.

Now we consider the map

$$\begin{array}{rcl} \Phi \colon U \cup B_r^{\mathbb{D}}(\gamma(t)) & \to & M \\ Q & \mapsto & \left\{ \begin{array}{rl} \Psi(Q), & \text{if } Q \in U, \\ \Omega^{-1}(\Theta(Q)), & \text{if } Q \in B_r^{\mathbb{D}}(\gamma(t)). \end{array} \right. \end{array}$$

By the above discussion this map is well-defined and it is o-locally a Möbius map. It follows from Lemma 23.10 (3) that this map is a Möbius map. It follows from $d_{\mathbb{D}}(\gamma(t), \gamma(s)) < r$ and the fact that γ is a geodesic in $\mathbb{D}$ that $\gamma([t,s]) \subset B_r^{\mathbb{D}}(\gamma(t))$, in particular $U \cup B_r^{\mathbb{D}}(\gamma(t))$ is an open subset of $\mathbb{D}$ that contains $\gamma([0,t]) \cup \gamma([t,s]) = \gamma([0,s])$. It is now straightforward

[478] Indeed, suppose we have $\epsilon > 0$. Since $\{\gamma(t_n)\}_{n\in\mathbb{N}}$ is a Cauchy sequence there exists an N such that $d_{\mathbb{D}}(\gamma(t_m), \gamma(t_n)) < \epsilon$ for all $m, n \geq N$. Now let $m, n \geq N$. Without loss of generality we have $m > n$. Then

$$\begin{array}{ccccc} d_M(\Psi_m(\gamma(t_m)), \Psi_n(\gamma(t_n))) & \underset{\uparrow}{=} & d_M(\Psi_m(\gamma(t_m)), \Psi_m(\gamma(t_n))) & \underset{\uparrow}{\leq} & d_{\mathbb{D}}(\gamma(t_m), \gamma(t_n)) \ < \ \epsilon. \\ & \text{since } \Psi_m \text{ and } \Psi_n \text{ agree on } \gamma|_{[0,t_n]} & & \text{Lemma 22.9} & \end{array}$$

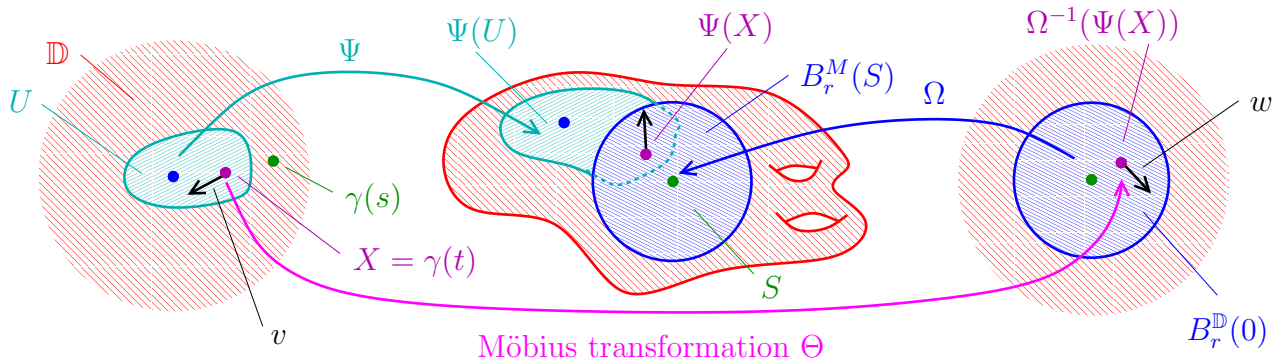

FIGURE 382.

to see that we can find a *convex* open subset W of $U \cup B_r^{\mathbb{D}}(\gamma(t))$ that contains $\gamma([0,s])$. The Möbius map $\Phi\colon W \to M$ now certifies that s is also good. $\square$

Thus we have now shown that there exists a convex open neighborhood U of $\gamma([0,1])$ and a local isometry $\Psi\colon U \to H_8/\sim$ which agrees with the identity map on $U \cap \mathring{H}_8$. We define $p(Z) := \Psi(Z)$. By Lemma 23.11 this definition does not depend on the choice of U and Ψ.

Lemma 23.16. *The map $p\colon \mathbb{D} \to M$ is a Möbius map.*

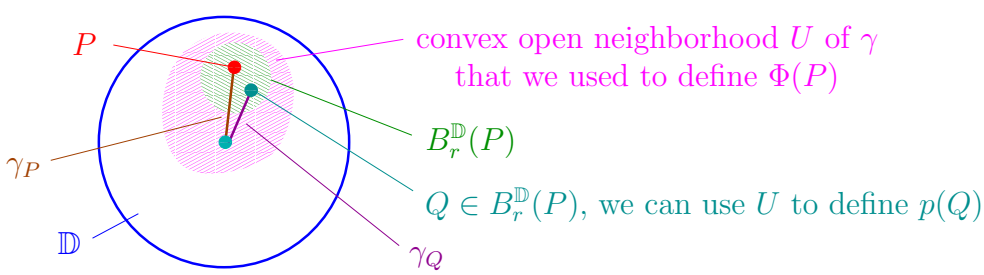

FIGURE 383. Illustration of the proof of Lemma 23.16.

Proof. By Lemma 23.10 (2) it suffices to show that p is o-locally a Möbius map. This means that it suffices to show that every point $P \in \mathbb{D}$ admits an open neighborhood W such that the restriction of p to W is a Möbius map. Thus let $P \in \mathbb{D}$. By the above claim there exists a convex open neighborhood U of $\gamma_P([0,1])$ and a Möbius map $\Psi\colon U \to H_8/\sim$ which restricts to the identity on $U \cap \mathring{H}_8$. Since U is open we can find an $r > 0$ such that for all $Q \in B_r^{\mathbb{D}}(P)$ the image of the radial path γ_Q from 0 to Q also lies in U. (We refer to Figure 383 for an illustration.) This implies that we can use the Möbius map $\Psi\colon U \to M$ to define p for any $Q \in B_r^{\mathbb{D}}(P)$. Put differently, $p = \Psi$ on $B_r^{\mathbb{D}}(P)$. We have thus shown that the restriction of p to the open neighborhood $W = B_r^{\mathbb{D}}(P)$ of P is a Möbius map. $\square$

The following lemma now concludes the proof of Theorem 23.9

Lemma 23.17. *The map $p\colon \mathbb{D} \to M = H_8/\sim$ is a covering map.*

Proof. First we show that the map $p\colon \mathbb{D} \to M = H_8/\sim$ is surjective. Recall that by construction p is the identity on $\mathring{H}_8$. Since p is continuous[479] it follows that the restriction of p to $H_8 \to M = H_8/\sim$ is surjective.[480]

It remains to show that every $Q \in M$ admits a uniformly covered neighborhood. Let $Q \in M$. By Proposition 23.12 there exists an $r > 0$ such that $B^M_{2r}(Q)$ is small.[481] We claim that $B^M_r(Q)$ is uniformly covered. More precisely, we make the following claims:

(1) $p^{-1}(B^M_r(Q)) = \bigcup_{X \in p^{-1}(Q)} B^{\mathbb{D}}_r(X)$,
(2) for $X \neq X' \in p^{-1}(Q)$ we have $B^{\mathbb{D}}_r(X) \cap B^{\mathbb{D}}_r(X') = \varnothing$,
(3) given any $X \in p^{-1}(Q)$ the restriction of p to $B^{\mathbb{D}}_r(X) \to B^M_r(Q)$ is a homeomorphism.

We apply Lemma 23.14 to the map $p\colon \mathbb{D} \to M$. It gives us the following three facts:

(a) If $Y \in \mathbb{D}$ satisfies $p(Y) \in B^M_r(Q)$, then there exists an $X \in p^{-1}(Q)$ with $Y \in B^{\mathbb{D}}_r(X)$.
(b) For any $X \in p^{-1}(Q)$ the restriction of p to $B^{\mathbb{D}}_r(X) \to B^M_r(Q)$ is a Möbius isomorphism, in particular it is a homeomorphism.
(c) For any $X \in p^{-1}(Q)$ the restriction of p to $B^{\mathbb{D}}_{2r}(X)$ is injective.

Now the desired properties (1) and (3) follow immediately from (a) and (b). It remains to prove (2). Suppose that we have $X \neq X' \in p^{-1}(Q)$ with $B^{\mathbb{D}}_r(X) \cap B^{\mathbb{D}}_r(X') \neq \varnothing$. We need to show $X = X'$. We pick $Y \in B^{\mathbb{D}}_r(X) \cap B^{\mathbb{D}}_r(X')$. The triangle inequality implies that $X' \in B^{\mathbb{D}}_{2r}(X)$. But p restricted to $B^{\mathbb{D}}_{2r}(X)$ is injective by (c). Hence $X = X'$. □

23.7. **Picard's Theorem.** We also have the following variation of Theorem 23.9.

Proposition 23.18. *Let $H_4/\sim$ be the three-punctured sphere with the Möbius structure constructed in Proposition 23.5. Then there exists a covering map $p\colon \mathbb{D} \to H_4/\sim$ with the following properties:*

(1) *p is a Möbius map,*
(2) *p is a local isometry,*
(3) *p is a local biholomorphism.*

Proof. The proof of Proposition 23.18 is almost the same as the proof of Theorem 23.9. In the proof of Theorem 23.9 we used that $H_8/\sim$ is complete. In the present case it follows from Proposition 23.5 (3) that $H_4/\sim$ is complete. The construction of the Möbius map $\Phi\colon \mathbb{D} \to H_4/\sim$ is verbatim the same as the construction of the Möbius map $\Phi\colon \mathbb{D} \to H_8/\sim$.

[479]The map p is a Möbius map, in particular it is a local biholomorphism which implies that it is a local homeomorphism. Thus it follows from Lemma 1.104 that p itself is continuous.

[480]This is the only part of the proof where we actually use that we work with $H_8/\sim$, the remainder of the proof works for any manifold M with a Möbius structure such that the corresponding Riemannian manifold is complete.

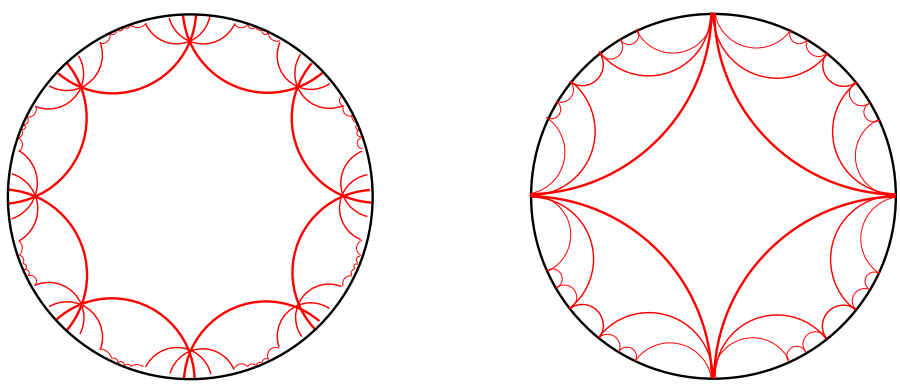
[481]Note the factor 2.

The same argument as before shows that $\Phi\colon \mathbb{D} \to H_4/\sim$ is surjective and that it is a covering map. $\square$

Remark. We consider again the covering $p\colon \mathbb{D} \to H_8/\sim$ that we had just constructed. It follows from Corollary 20.4 that the interior of H_8 is uniformly covered. In particular we see that

$$\mathbb{D} \setminus \underbrace{p^{-1}(\partial H_8)}_{\text{“1-dimensional”}} = \bigsqcup \text{ copies of } \mathring{H}_8.$$

Put differently, up to the “one-dimensional” subset $p^{-1}(\partial H_8)$ we can cover $\mathbb{D}$ by infinitely many disjoint copies of the open hyperbolic octagon. Such a decomposition is often called a *tessellation*. This tessellation is shown in Figure 384 on the left. The same argument also applies to the covering $\mathbb{D} \to H_4/\sim$ that we also had just constructed. The corresponding tessellation of $\mathbb{D}$ is shown in Figure 384 on the right.



preimages of $\mathring{H}_8$ under the universal cover $p\colon \mathbb{D} \to H_8/\sim$

preimages of $\mathring{H}_4$ under the universal cover $p\colon \mathbb{D} \to H_4/\sim$

FIGURE 384.

At the end of this chapter we return to complex analysis. There are different types of holomorphic functions defined on $\mathbb{C}$.

(1) There are the (rather dull) constant functions.
(2) There are holomorphic functions $f\colon \mathbb{C} \to \mathbb{C}$ that are surjective. For example it is an easy consequence of the fundamental theorem of algebra that all maps defined by non-constant polynomials are surjective.
(3) There are also non-constant maps that are not surjective, for example the exponential function $z \mapsto \exp(z)$ is never zero[482], in fact its image is $\mathbb{C} \setminus \{0\}$.

On the other hand it is fairly easy prove, using Liouville's Theorem 21.1, that the image of a non-constant holomorphic function on $\mathbb{C}$ is dense.

[482]Why not?

Now we can prove Picard's Theorem[483] which is a significantly stronger statement than the above statement that the image is dense.

Theorem 23.19. (Picard's Theorem) *Let $f\colon \mathbb{C} \to \mathbb{C}$ be a non-constant holomorphic function. Then there exists at most one $z \in \mathbb{C}$ which does not lie in the image of f.*

Proof. Let $f\colon \mathbb{C} \to \mathbb{C}$ be a holomorphic function such that there exist two different complex numbers a, b that do not lie in the image of f. We need to show that f is constant. We consider the biholomorphism

$$\begin{array}{rcl} \alpha\colon \mathbb{C} \setminus \{a,b\} & \to & \mathbb{C} \setminus \{0,1\} \\ z & \mapsto & \dfrac{z-a}{b-a}. \end{array}$$

Furthermore we denote by $\beta\colon \mathbb{C} \setminus \{0,1\} \to H_4/\sim$ the biholomorphism from Proposition 23.6. Now we consider the following diagram of maps

$$\begin{tikzcd} & & & \mathbb{D} \arrow[d, "\Phi"] \\ \mathbb{C} \arrow[r, "f"] & \mathbb{C} \setminus \{a,b\} \arrow[r, "\alpha", "\cong"'] & \mathbb{C} \setminus \{0,1\} \arrow[r, "\beta", "\cong"'] & H_4/\sim \end{tikzcd}$$

where $\Phi\colon \mathbb{D} \to H_4/\sim$ is the covering map from Proposition 23.18. Recall that Φ is a Möbius map which implies by Lemma 23.8 that Φ is a local biholomorphism.

Since $\mathbb{C}$ is simply connected we can appeal to Proposition 20.2 to obtain a lift of the map $\beta \circ \alpha \circ f\colon \mathbb{C} \to H_4/\sim$ to the universal covering. More precisely, there exists a map $\widetilde{\beta \circ \alpha \circ f}\colon \mathbb{C} \to \mathbb{D}$ such that the following diagram commutes

$$\begin{tikzcd} & & & \mathbb{D} \arrow[d, "\Phi"] \\ \mathbb{C} \arrow[r, "f"'] \arrow[urrr, "\widetilde{\beta\circ\alpha\circ f}"] & \mathbb{C} \setminus \{a,b\} \arrow[r, "\alpha", "\cong"'] & \mathbb{C} \setminus \{0,1\} \arrow[r, "\beta", "\cong"'] & H_4/\sim . \end{tikzcd}$$

As we pointed out in Lemma 21.9, it follows from the fact that $\beta \circ \alpha \circ f$ is holomorphic and the fact that Φ is a local biholomorphism, that the map $\widetilde{\beta \circ \alpha \circ f}\colon \mathbb{C} \to \mathbb{D}$ is also holomorphic. But $\mathbb{D}$ is of course bounded. Therefore it follows from Liouville's Theorem 21.1 that $\widetilde{\beta \circ \alpha \circ f}$ is constant. But then $\beta \circ \alpha \circ f$ is also constant. Since α and β are biholomorphisms this implies that f itself is already constant. $\square$

Remark. In the literature Theorem 23.19 is sometimes referred to as Picard's Little Theorem, to distinguish it from Picard's Great Theorem which says that if z_0 is an essential singularity of a holomorphic function, then in any neighborhood of z_0 the function f assumes all, but possibly one, value *infinitely* many times. We refer to [Con, Section 12] for details.

[483]Emile Picard (1856-1941) was a French mathematician. Many readers will have encountered him already in real analysis, as one of the two namesakes of the Picard-Lindelöf Theorem.

24. The deck transformation group (∗)

Definition. Let $p\colon X \to B$ be a covering.

(1) A *deck transformation* is a homeomorphism $d\colon X \to X$ such that $p(d(x)) = p(x)$ for all x, i.e. such that the following diagram commutes:

$$\begin{tikzcd} X \arrow[rr, "d", "\cong"'] \arrow[dr, "p"'] & & X \arrow[dl, "p"] \\ & B. & \end{tikzcd}$$

The group of deck transformations[484] is called the *deck transformation group* of the covering $p\colon X \to B$ and we denote it by $D(p\colon X \to B)$.

(2) We say that the covering is *regular* if for any $b \in B$ the deck transformation group D acts transitively on $p^{-1}(b)$, i.e. if given any two points x, x' with $p(x) = p(x') = b$ there exists a deck transformation d with $d(x) = x'$. Otherwise we say that the covering is *irregular*.

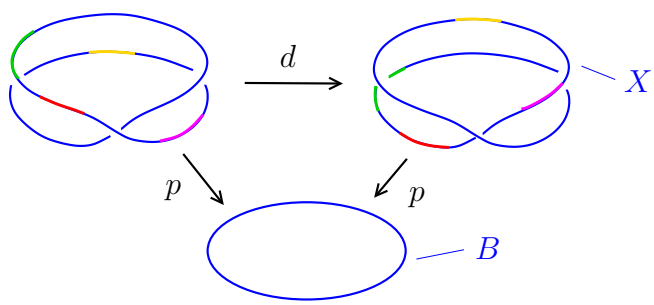


Figure 385. Schematic image of a deck transformation.

Example.

(1) We consider the covering

$$\begin{array}{rcl} p\colon S^1 & \to & S^1 \\ z & \mapsto & z^2. \end{array}$$

Then the map $d\colon S^1 \to S^1$ given by $d(z) := -z$ is a deck transformation. It is now clear that the covering is regular.

(2) Let $p\colon \widetilde{X} \to X$ be a 2-fold covering. We define

$$\begin{array}{rcl} f\colon \widetilde{X} & \to & \widetilde{X} \\ Q & \mapsto & \text{the unique other point in } p^{-1}(p(Q)). \end{array}$$

In Lemma 7.5 we saw that f is a deck transformation. It follows immediately that any 2-fold covering is regular.

[484] Why do deck transformations form a group?

(3) As an important special case of (2) consider a non-orientable path-connected manifold M. As in the proof of Proposition 8.3 we consider the 2-fold covering

$$\begin{array}{rcl} \widetilde{M} := \{(Q,O) \mid Q \in M \text{ and } O \text{ an orientation of } T_QM\} & \to & M \\ (Q,O) & \mapsto & Q. \end{array}$$

It is easy to show that the map $d\colon \widetilde{M} \to \widetilde{M}$ given by $d((Q,O)) := (Q,-O)$ is a deck transformation of p.

(4) We consider again the first two coverings of graphs from Figure 148 which are also shown again in Figure 386. The covering maps are the ones suggested by the colors and the directions. We first make the following observations. A deck transformation d does the following:
   (a) it sends a vertex again to a vertex,
   (b) it sends a blue edge to a blue edge, preserving the orientation,
   (c) it sends a red edge to a red edge, preserving the orientation,
   (d) if e is an edge with endpoints P and Q, then $d(e)$ is an edge with endpoints $d(P)$ and $d(Q)$, in particular if e is a loop, then $d(e)$ is also a loop.

   Now we consider the two examples.
   (a) The example on the left admits one non-trivial deck transformation, namely the map that is given by "rotation by π" around the center of the graph. The covering is now easily seen to be regular.
   (b) The loop a_3 in the graph on the right is the only red loop, so any deck transformation has to send it to itself. It follows that there can be no deck transformation that sends the vertex to the right to any of the other vertices.[485] Thus the covering on the right is irregular.

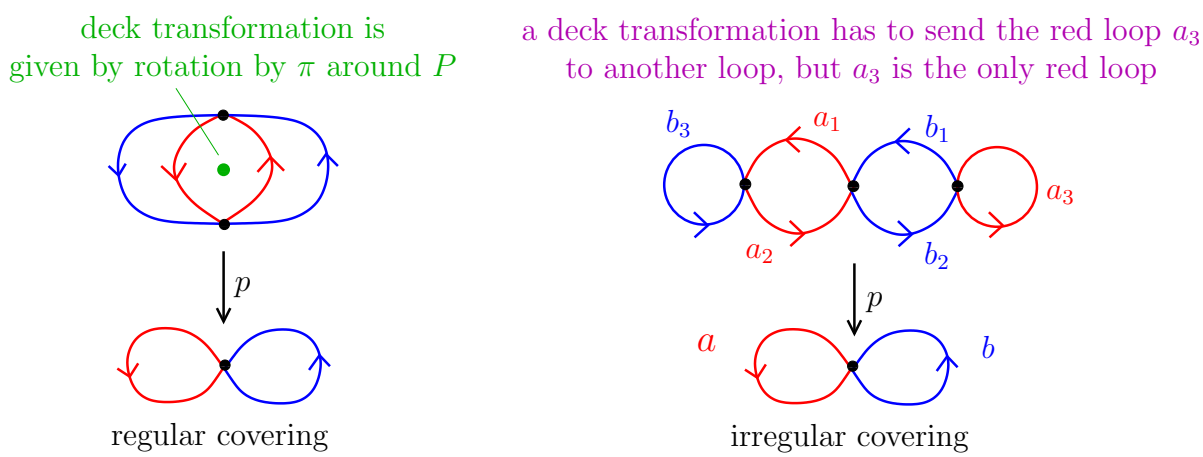

FIGURE 386.

[485] Does this covering admit any deck transformation?

(5) Finally we consider the 4-fold coverings illustrated in Figure 387. They are both regular coverings. For the graph on the left the deck transformation group is isomorphic to $\mathbb{Z}_4$, a generator is given by "rotation by $\frac{\pi}{2}$". The deck transformation group on the right is isomorphic to $\mathbb{Z}_2 \oplus \mathbb{Z}_2$, here one $\mathbb{Z}_2$ summand is given by "rotation by π" and the other one corresponds to "swapping the inner and the outer circle".

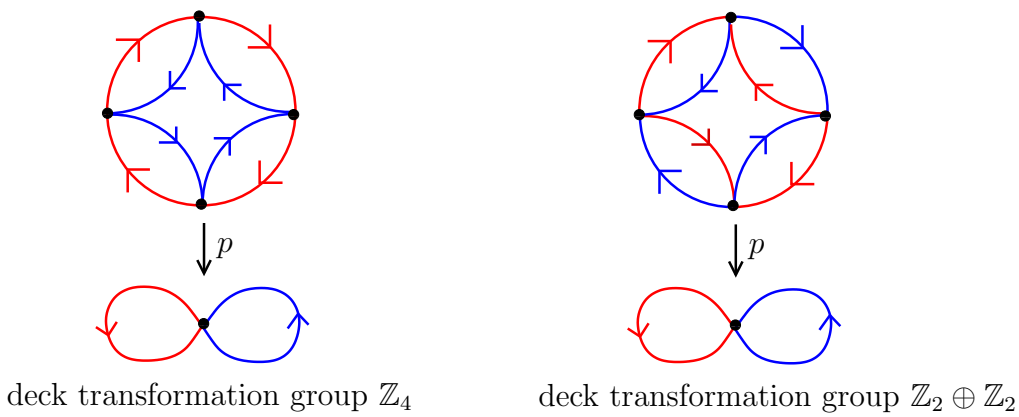

FIGURE 387.

Lemma 24.1. *Let $p\colon (X, x_0) \to (B, b_0)$ be a covering of pointed path-connected topological spaces and let d_1 and d_2 be two deck transformations of p. Then the following holds*

$$d_1 \;=\; d_2 \quad \Longleftrightarrow \quad d_1(x_0) \;=\; d_2(x_0).$$

Proof. Evidently we only need to show the "$\Leftarrow$"-direction. Thus let d be a deck transformation of p. One way of stating that d is a deck transformation is to state that the following diagram commutes:

$$\begin{tikzcd} & (X, d(x_0)) \arrow[d, "p"] \\ (X, x_0) \arrow[ur, "d"] \arrow[r, "p"'] & (B, b_0). \end{tikzcd}$$

Put differently, the map d can be viewed as a lift of the map $(X, x_0) \to (B, b_0)$ to the covering $(X, d(x_0)) \to (B, b_0)$. By the uniqueness of lifts[486], that we showed in Proposition 20.2 (2), we now see that two deck transformations d_1 and d_2 of p with $d_1(x_0) = d_2(x_0)$ agree. □

Example. We let $B = (S^1 \times \{a\} \sqcup S^1 \times \{b\})/(1, a) \sim (1, b)$, i.e. B is the wedge of two circles and we consider

$$X \;=\; (S^1 \sqcup (S^1 \times \mathbb{Z}_5))/(e^{2\pi i n/5} \sim (1, n)) \text{ for } n \in \mathbb{Z}_5,$$

[486]Here we use that X is path-connected.

i.e. X is a circle with five circles attached at the points $e^{2\pi ik/5}$, $k = 0, \dots, 4$. Then the map

$$p\colon (S^1 \sqcup (S^1 \times \mathbb{Z}_5))/\sim \to\ G = (S^1 \times \{a\} \sqcup S^1 \times \{b\})/(1,a) \sim (1,b)$$

that is given by $p(z) = (z^5, a)$ for $z \in S^1$ and $p((z,n)) = (z,b)$ for $(z,n) \in S^1 \times \mathbb{Z}_5$, is a covering map of degree five. This covering illustrated in Figure 388.

We consider the map

$$\begin{array}{rcl} \mathbb{Z}_5 & \to & D(p\colon X \to B) \\ m & \mapsto & \left(\begin{array}{rcll} X & \to & X & \\ z & \mapsto & e^{2\pi im/5}z, & \text{for } z \in S^1, \\ (z,n) & \mapsto & (z, m+n) & \text{for } (z,n) \in S^1 \times \mathbb{Z}_5 \end{array}\right) \end{array}$$

In Figure 388 this corresponds to "rotation of X by the angle $\frac{2\pi m}{5}$". It is straightforward to show that this map is well-defined, i.e. the maps on the right are deck transformations, and using Lemma 24.1 one can easily see that this map is an isomorphism. Also one can now convince oneself easily that the covering $p\colon X \to B$ is regular.

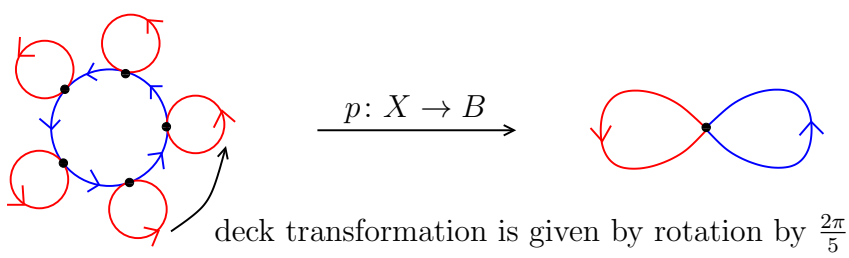

FIGURE 388.

Lemma 24.2. *Let X be a path-connected topological space on which a group G acts continuously and discretely. We consider the corresponding covering $p\colon X \to X/G$. Then $p\colon X \to X/G$ is regular and the map*

$$\begin{array}{rcl} \Phi\colon G & \mapsto & D(p\colon X \to X/G) \\ g & \mapsto & \begin{pmatrix} X & \mapsto & X \\ x & \mapsto & gx \end{pmatrix} \end{array}$$

is an isomorphism of groups.

Proof. It is straightforward to see that the maps $x \mapsto gx$ are indeed deck transformations. It follows almost immediately that the covering $p\colon X \to X/G$ is regular. Also it follows easily from the axioms of a group action that Φ is a homomorphism of groups. Furthermore it is clear that Φ is a monomorphism.

It remains to show that Φ is an epimorphism. So let $d \in D(p\colon X \to X/G)$ be a deck transformation. We pick $x \in X$. Since $p(d(x)) = p(x)$ we have $d(x) = gx$ for some $g \in G$. Since X is path-connected it follows from Lemma 24.1 that $d(y) = gy$ for all $y \in X$. This shows that Φ is an epimorphism. $\square$

Lemma 24.3. *Any 2-fold covering of path-connected topological spaces is regular and the deck transformation group contains precisely two elements.*

Proof. Let $p\colon X \to B$ be a 2-fold covering of path-connected topological spaces. By Lemma 7.5 we know that

$$\begin{array}{rcl} d\colon X & \to & X \\ x & \mapsto & \text{the unique other element of } p^{-1}(p(x)) \end{array}$$

is a deck transformation. Evidently it is regular. It follows easily from Lemma 24.1 and our hypothesis that X, B are path-connected that any deck transformation of p is either the identity or it equals the above deck transformation d. □

We recall the following important, albeit somewhat technical, definition.

Definition. Let G be a group and let $H \subset G$ be a subgroup. The *normalizer* $N(H)$ of the subgroup $H \subset G$ is defined as

$$N(H) \ := \ \{g \in G \mid g^{-1}Hg = H\}.$$

The following lemma summarizes a few elementary properties of the normalizer of a subgroup.

Lemma 24.4. *Let G be a group and let $H \subset G$ be a subgroup.*

(1) *The subgroup H of G is normal if and only if $N(H) = G$.*
(2) *The normalizer $N(H)$ of $H \subset G$ is a subgroup of G.*
(3) *The normalizer $N(H)$ of $H \subset G$ is the largest subgroup of G which contains H as a normal subgroup, in the sense that if A is a subgroup of G which contains H as a normal subgroup, then $A \subset N(H)$.*

Proof. Both statements are easily verified. Alternatively see [Isa, p. 26] for the elementary proof. □

We return to topology and we consider one more example in detail.

Example. Let Y be a path-connected and reasonable topological space and let $y_0 \in Y$. Furthermore let $\Gamma \subset \pi = \pi_1(Y, y_0)$ be a subgroup. By Proposition 20.8 there exists a path-connected covering $p\colon (X, x_0) \to (Y, y_0)$ of pointed topological spaces such that $p_*(\pi_1(X, x_0)) = \Gamma$. We recall the construction of X. We first considered

$$W \ := \ \{\text{all paths in } Y \text{ with starting point } y_0\}$$

and for $u, v \in W$ we wrote

$$u \sim v \quad :\Leftrightarrow \quad u \text{ and } v \text{ have the same endpoint and } [u * \overline{v}] \in \Gamma.$$

We defined $X = W/\sim$ and the projection map $p\colon W/\sim \to Y$ that is given by $[w] \mapsto w(1)$. We then showed that, with an appropriate topology on $W/\sim$, the map $p\colon W/\sim \to Y$ is a path-connected covering with $p_*(\pi_1(W/\sim, x_0)) = \Gamma$.

As in the proof of Proposition 20.13 we now would like to construct deck transformations by precomposing elements in W by a loop in y_0. More precisely, let g be a loop in (Y, y_0). We consider the map

$$\begin{array}{rcl} W & \to & W \\ w & \mapsto & g * w \end{array}$$

We need to check that the map respects our equivalence relation $\sim$ on W. So suppose that $u, v \in W$ are equivalent. Then $g * u$ and $g * v$ still have the same endpoint. Now we need to consider the second condition. We have

$$[(g * u) * (\overline{g * v})] \;=\; [g * u * \overline{v} * \overline{g}] \;=\; [g] * \underbrace{[u * \overline{v}]}_{\in \Gamma} * [g]^{-1}.$$

In general it is not the case that the right-hand side lies again in Γ. But it is true if $[g]$ lies in the normalizer of Γ. As in the proof of Proposition 20.13 it is now straightforward to see that the map

$$\begin{array}{rcl} \Psi\colon N(\Gamma)/\Gamma & \to & D(p\colon X \to Y) \\ [g] & \mapsto & \begin{pmatrix} W/\sim & \to & W/\sim \\ [u] & \mapsto & [g * u] \end{pmatrix} \end{array}$$

is a well-defined homomorphism. We will see in Proposition 24.5 that this in fact an isomorphism of groups.

Now we want to consider the general case of a covering. So let $p\colon (X, x_0) \to (B, b_0)$ be a covering of pointed path-connected topological spaces. We write $\pi := \pi_1(B, b_0)$ and $\Gamma := p_*(\pi_1(X, x_0))$.[487] Now the question arises whether there is a connection between the groups π, Γ and $D(p\colon X \to B)$.

Similar to the proof of Theorem 7.17 we can consider the following map[488]

$$\begin{array}{rcl} \Phi\colon D(p\colon X \to B) & \mapsto & \pi/\Gamma \\ d & \mapsto & \big[p \circ (\text{path in } X \text{ from } x_0 \text{ to } d(x_0))\big]. \end{array}$$

It is straightforward to see that this map is well-defined, i.e. it does not depend on the choice of the path.

The question now arises, whether this map Φ is a group isomorphism. But in general this is not the case, after all, if Γ is not normal in π, then π/Γ is not even a group. But we have the following proposition:

Proposition 24.5. *Let $p\colon (X, x_0) \to (B, b_0)$ be a covering of pointed topological spaces. We suppose that X and B are path-connected and o-locally path-connected. We write*

[487] Recall that by Corollary 7.15 the induced map $p_*\colon \Gamma \to \pi$ is injective, thus $\Gamma \cong \pi_1(X, x_0)$.

[488] We denote hereby with $[p \circ f]$ not only the equivalence class of the loop $p \circ f$ in π, but also its equivalence class π/Γ, since the notation $[p \circ f]\Gamma$ is too cumbersome.

$\pi := \pi_1(B, b_0)$ and $\Gamma := p_*(\pi_1(X, x_0))$. The above map

$$\begin{array}{rcl} \Phi\colon D(p\colon X \to B) & \mapsto & \pi/\Gamma \\ d & \mapsto & \big[p \circ (\textit{path in } X \textit{ from } x_0 \textit{ to } d(x_0))\big]. \end{array}$$

restricts to an isomorphism of groups

$$\Phi\colon D(p\colon X \to B) \xrightarrow{\cong} N(\Gamma)/\Gamma.$$

Proof. Let $p\colon (X, x_0) \to (B, b_0)$ be a covering of pointed path-connected topological spaces. We write $\pi := \pi_1(B, b_0)$, $\Gamma := p_*(\pi_1(X, x_0))$ and $D := D(p\colon X \to B)$.

(A) First we have to show that $\Phi(D)$ lies indeed in $N(\Gamma)/\Gamma$. Thus let $d \in D$. We need to show that $\Phi(d)$ lies in $N(\Gamma)/\Gamma$. Thus let f be a loop in (X, x_0) and and let g be a path in X from x_0 to $d(x_0)$. We have to verify that $[\overline{p \circ f}] \cdot [p \circ g] \cdot [p \circ f] \in \Gamma$. Indeed the following holds

$$[\overline{p \circ f}] \cdot [p \circ g] \cdot [p \circ f] \;=\; \big[\overline{p \circ f} * p \circ g * p \circ f\big] \;=\; \big[p \circ \big(\underbrace{\overline{f} * g * f}_{\text{loop in } (X, x_0)}\big)\big] \;\in\; p_*(\pi_1(X, x_0)) = \Gamma.$$

(B) Now we have to show that Φ is a group homomorphism. So let d and e be two deck transformations. We pick a path g from x_0 to $d(x_0)$ and we pick a path h from x_0 to $e(x_0)$. Then

$$\Phi(d) \cdot \Phi(e) \;\underset{\substack{\uparrow \\ \text{definition of } \Phi(e) \text{ and } \Phi(d)}}{=}\; [p \circ g] \cdot [p \circ h] \;\underset{\substack{\uparrow \\ \text{since } p \circ d = p}}{=}\; [p \circ g] \cdot [p \circ (d \circ h)] \;\overset{\substack{\text{endpoint of } g \text{ equals starting point of } d \circ h \\ \downarrow}}{=}\; [g * (d \circ h)] \;\underset{\substack{\uparrow \\ \text{since } g * (d \circ h) \text{ is a path} \\ \text{from } x_0 \text{ to } d(e(x_0)), \text{ see Figure 389}}}{=}\; \Phi(e \circ d).$$

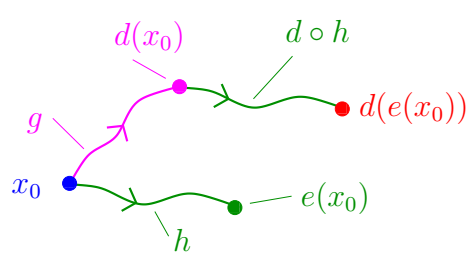

FIGURE 389.

(C) Now we will construct a map $\Psi\colon N(\Gamma)/\Gamma \to D$ in the inverse direction. Thus let $[f] \in N(\Gamma) \subset \pi = \pi_1(B, b_0)$ where f is a loop in (B, b_0). Let x_1 be the endpoint of the lift $\widetilde{f}$ of f to the starting point x_0.[489] We have $p(x_1) = p\big(\widetilde{f}(1)\big) = f(1) = x_0$. Thus we

[489] According to Corollary 7.14 the definition of x_1 does not depend on the choice of the representative of $[f] \in N(\Gamma)$.

obtain the following diagram of maps of pointed topological spaces:

$$\begin{array}{ccc} & & (X, x_1) \\ & & \big\downarrow p \\ (X, x_0) & \xrightarrow{p} & (B, b_0). \end{array}$$

Then

$$\begin{array}{rcl} p_*(\pi_1(X, x_1)) & = & \left\{ \left[p \circ \left(\overline{\widetilde{f}} * g * \widetilde{f} \right) \right] \,\middle|\, [g] \in \pi_1(X, x_0) \right\} \\ & \uparrow & \\ \text{by Proposition 5.11 since } \widetilde{f} \text{ is a path from } x_0 \text{ to } x_1 & & \end{array} \begin{array}{rl} = & [f]\, p_*(\pi_1(X, x_0))\, [f]^{-1} \\ = & p_*(\pi_1(X, x_0)). \\ \uparrow & \\ \text{since } [f] \in N(\Gamma) & \end{array}$$

It follows from Proposition 20.2 that there exists a lift $\widetilde{p}\colon (X, x_0) \to (X, x_1)$ of p, i.e. there exists a map $\widetilde{p}$ such that the following diagram commutes:

$$\begin{array}{ccc} & \overset{\widetilde{p}}{\nearrow} & (X, x_1) \\ & & \big\downarrow p \\ (X, x_0) & \xrightarrow{p} & (B, b_0). \end{array}$$

The map is $\widetilde{p}$ is now by definition a deck transformation.

We have thus constructed a map $N(\Gamma) \to D$. We still need to show that this map descends to a map $N(\Gamma)/\Gamma \to D$. So let $[f] \in N(\Gamma)$ and let $[g] \in \Gamma$. We denote by $\widetilde{f}$ the lift of f to the starting point x_0. Similarly we define $\widetilde{g * f}$. By the above we only need to show that the endpoints of $\widetilde{f}$ and $\widetilde{g * f}$ agree. In fact we have

$$\begin{array}{rcl} \widetilde{g * f}(1) & = & \text{endpoint of the lift of } f \\ & & \text{to the starting point } \widetilde{g}(1) \\ & \uparrow & \\ & \text{Lemma 20.3} & \end{array} \begin{array}{rcl} & = & \text{endpoint of the lift of } f \\ & & \text{to the starting point } x_0 \\ & \uparrow & \\ & \text{by Lemma 7.16 (2) (1) since } [g] \in p_*(\pi_1(X, x_0)) & \end{array} \begin{array}{rl} = & \widetilde{f}(1) \\ & \\ & \\ & \end{array}$$

(D) Now we want to show that Φ is a bijection. It suffices to show that $\Psi \circ \Phi = \mathrm{id}$ and $\Phi \circ \Psi = \mathrm{id}$.

First let $d \in D$. Then

$$\begin{array}{rcl} \Psi(\Phi(d)) & = & \Psi(\text{loop } f \text{ in } (B, b_0) \text{ that lifts to a path from } x_0 \text{ to } d(x_0)) \\ & = & \text{deck transformation that sends } x_0 \text{ to } d(x_0) \;=\; d \\ & & \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \uparrow \\ & & \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \text{Lemma 24.1} \end{array}$$

This shows that $\Psi \circ \Phi$ is the identity.

Now let $g \in N(\Gamma)/\Gamma$. We pick a representative loop s in b_0 and we denote by $\widetilde{s}$ the lift of s to the starting point x_0. We denote by x_1 the endpoint of $\widetilde{s}$. Then

$$\Phi(\Psi(g)) \;=\; \big[p \circ \big(\text{path in } X \text{ from } x_0 \text{ to } \overbrace{\Psi(g)(x_0)}^{=x_1}\big)\big] \;\underset{\substack{\uparrow \\ \widetilde{s} \text{ is a path from } x_0 \text{ to } x_1}}{=}\; \big[p \circ \widetilde{s}\big] \;=\; [s] \;=\; g.$$

This shows that $\Phi \circ \Psi$ is the identity. □

In most applications we will use the following special case of Proposition 24.5.

Proposition 24.6. *Let X be a path-connected and reasonable topological space and let $x_0 \in X$. Let $\gamma\colon \pi_1(X, x_0) \to G$ be an epimorphism onto a group G. We denote by $p\colon (\widetilde{X}, \widetilde{x}_0) \to (X, x_0)$ the covering corresponding to $\ker(\gamma)$ that is given by Proposition 20.8 and that is unique up to covering equivalence by Proposition 20.9. Then the map*

$$\begin{array}{rcl} \Phi\colon D(p\colon \widetilde{X} \to X) & \to & \pi_1(X, x_0)/p_*(\pi_1(\widetilde{X}, \widetilde{x}_0)) \xrightarrow{\gamma} G. \\ d & \mapsto & \big[p \circ (\textit{path from } x_0 \textit{ to } d(x_0))\big] \end{array}$$

is an isomorphism.

Proof. First note that $p_*(\pi_1(\widetilde{X}, \widetilde{x}_0)) = \ker(\gamma)$ is a normal subgroup of $\pi_1(X, x_0)$. Therefore the normalizer of $\Gamma := p_*(\pi_1(\widetilde{X}, \widetilde{x}_0))$ equals $\pi_1(X, x_0)$. It now follows immediately from Proposition 24.5 that the homomorphism on the left is an isomorphism. The homomorphism on the right is an isomorphism since $p_*(\pi_1(\widetilde{X}, \widetilde{x}_0)) = \ker(\gamma)$. □

The following lemma now gives a complete characterization of regular coverings.

Corollary 24.7. *Let $p\colon (X, x_0) \to (B, b_0)$ be a covering of pointed path-connected topological spaces. Then the following statements are equivalent:*

(1) *The covering is regular.*
(2) *The deck transformation group $D(p\colon X \to B)$ acts transitively on $p^{-1}(b_0) \subset X$.*
(3) *The subgroup $p_*(\pi_1(X, x_0))$ is a normal subgroup of $\pi_1(B, b_0)$.*
(4) *There exists a group G which acts discretely on X and there exists a homeomorphism $f\colon X/G \to B$ such that the following diagram commutes:*

$$\begin{tikzcd} & X \arrow[dl, "q"'] \arrow[dr, "p"] & \\ X/G \arrow[rr, "f"'] & & B \end{tikzcd}$$

where $q\colon X \to X/G$ is the canonical projection map.

If p is a finite covering then the above statements are furthermore equivalent to

(5) $\#D(p\colon X \to B) \;=\; [X : B]$.

Remark. Let $p\colon (X,x_0) \to (B,b_0)$ be a 2-fold covering of path-connected pointed topological spaces. In Lemma 24.3 we saw that p is regular, which by Corollary 24.7 means that the index two subgroup $p_*(\pi_1(X,x_0))$ of $\pi_1(B,b_0)$ is normal. In fact we already showed in Exercise 8.1 that any index 2 subgroup Γ of a group π is normal.[490]

Proof. Let $p\colon (X,x_0) \to (B,b_0)$ be a covering of pointed path-connected topological spaces. We write $\pi := \pi_1(B,b_0)$, $\Gamma := p_*(\pi_1(X,x_0))$ and $D = D(p\colon X \to B)$. The following four steps prove the equivalence of (1), (2) (3) and (4).

(1) $\Leftrightarrow$ (2) Recall that a covering is regular if for any $b \in B$ the group D acts transitively on $p^{-1}(b)$. Thus (1) $\Rightarrow$ (2) is trivial. Now suppose that d acts transitively on $p^{-1}(b_0)$. Let b be some other point in B. Since B is path-connected there exists a path s from b to b_0.

Now let x, x' be two points in $p^{-1}(b)$. We denote by $\widetilde{s}$ the lift of s to the starting point x and similarly we define $\widetilde{s}'$. We denote by x_0 and x_0' the endpoints of $\widetilde{s}$ and $\widetilde{s}'$. Since D acts transitively on $p^{-1}(b_0)$ there exists a deck transformation d with $d(x_0) = x_0'$. By the uniqueness of lifts to a starting point we then also have $d \circ \widetilde{s} = \widetilde{s}'$. But then we also have that d turns the starting point of $\widetilde{s}$ into the starting point of $\widetilde{s}'$, i.e. we have $d(x) = x'$.

(2) $\Leftrightarrow$ (3) We consider again the map

$$\begin{array}{rcl} \Phi\colon D(p\colon X \to B) & \mapsto & \pi/\Gamma \\ d & \mapsto & \big[p \circ (\text{path in } X \text{ from } x_0 \text{ to } d(x_0))\big]. \end{array}$$

We first prove the following claim.

Claim. We have the following equivalence of statements:

$$D \text{ acts transitively on } p^{-1}(b_0) \subset X \quad \Leftrightarrow \quad \Phi\colon D \to \pi/\Gamma \text{ is surjective.}$$

First suppose that D acts transitively on $p^{-1}(b_0) \subset X$. Let $g \in \pi/\Gamma$ and pick a loop f that represents g. We denote by $\widetilde{f}$ the lift of f to the starting point x_0 and we denote by $\widetilde{x}_0$ the endpoint of $\widetilde{f}$. Since D acts transitively there exists a deck transformation d with $d(x_0) = \widetilde{x}_0$. Now

$$\Phi(d) = [p \circ (\text{path in } X \text{ from } x_0 \text{ to } d(x_0))] \underset{\substack{\uparrow \\ \text{since } \widetilde{f} \text{ is a path from } x_0 \text{ to } d(x_0)}}{=} [p \circ (d \circ \widetilde{f})] \underset{\substack{\uparrow \\ \text{since } p \circ d = p}}{=} [p \circ \widetilde{f}] = [f] = g.$$

Now suppose that $\Phi\colon D \to \pi/\Gamma$ is surjective. Let $\widetilde{x}_0 \in p^{-1}(b_0)$. We pick a path $\widetilde{f}$ from x_0 to $\widetilde{x}_0$ and we denote by f the loop $p \circ \widetilde{f}$. Since Φ is surjective there exists a deck transformation d with $\Phi(d) = [f]$. But then $d(x_0) = \widetilde{x}_0$. This concludes the proof of the claim.

[490] We already made use of this fact in the proof of Corollary 8.4.

Now we have the following equivalences

$$\begin{array}{rcl} D \text{ acts transitively on } p^{-1}(b_0) \subset X & \Longleftrightarrow & \Phi\colon D \to \pi/\Gamma \text{ is surjective} \\ & \underset{\substack{\uparrow \\ \text{Proposition 24.5}}}{\Longleftrightarrow} & \pi = N(\Gamma) \underset{\substack{\uparrow \\ \text{by the definitions}}}{\Longleftrightarrow} \Gamma \text{ is normal in } \pi. \end{array}$$

(1) ⇒ (4) We will show that the deck transformation group D has the desired properties.

We first show that the deck transformation group acts discretely on X. So let $x \in X$. We write $b = p(x)$. Since $p\colon X \to B$ is a covering there exists a connected open neighborhood U of b that is uniformly covered. This means that the restriction of p to each component of $p^{-1}(U)$ is a homeomorphism. Now let V be the component of $p^{-1}(U)$ that contains x. Then $gV \cap V = \varnothing$ for each non-trivial g. This shows that the action of D is discrete.

The map $p\colon X \to B$ has the property that $p(gx) = p(x)$ for all $g \in D$. Therefore the map p factors through a map $f\colon X/D \to B$. The map f is clearly surjective. Furthermore it is injective since we suppose that D acts transitively on each $p^{-1}(b)$. Finally the map f is not only continuous but, as follows easily from Lemma 7.4 (1), it is also open. Thus f is a homeomorphism.

(4) ⇒ (1) Now suppose that such a homeomorphism $f\colon X/G \to B$ exists. First note that for each $g \in G$ the map $x \mapsto gx$ not only defines a deck transformation of the covering $q\colon X \to X/G$ but also of the covering $p\colon X \to B$. Now let $b \in B$ and let $x, x' \in X$ with $p(x) = p(x')$. Since f is a homeomorphism we also have $q(x) = q(x')$. Hence there exists a $g \in G$ with $gx = x'$.

Now we suppose that p is a finite covering. We show the following equivalence:

(5) ⇔ (3) We have the following equivalences:[491]

$$\begin{array}{rcl} \#D = [X : B] & \underset{\substack{\text{Lemma 7.16 (3)} \\ \downarrow}}{\Longleftrightarrow} & \#D = [\pi : \Gamma] \underset{\substack{\text{Proposition 24.5} \\ \downarrow}}{\Longleftrightarrow} [N(\Gamma) : \Gamma] = [\pi : \Gamma] \\ & \Longleftrightarrow & N(\Gamma) = \pi \quad \Longleftrightarrow \Gamma \subset \pi \text{ is a normal subgroup.} \end{array}$$

□

We conclude this chapter with the following proposition which often, rather conveniently, allows us to replace an irregular covering by a regular covering.

Proposition 24.8. *Let $p\colon (X, x_0) \to (B, b_0)$ be a covering of pointed topological spaces that are path-connected reasonable. If p is a finite-degree covering, then there exists a covering $q\colon (Y, y_0) \to (X, x_0)$ such that $p \circ q\colon (Y, y_0) \to (B, b_0)$ is a finite-degree* regular *covering.*

[491] Where do we actually use in the argument that the covering is finite?

For convenience this statement is summarized in the following diagram:

$$\begin{tikzcd}
(Y, y_0) \arrow[d, "\text{(2) there exists a covering } q"'] \arrow[dd, bend left, "\text{(3) such that } p \circ q \text{ is a finite-degree regular covering}"] \\
(X, x_0) \arrow[d, "\text{(1) given a finite-degree covering } p"'] \\
(B, b_0).
\end{tikzcd}$$

The proof of Proposition 24.8 rests on the following group-theoretic concept.

Definition. Let G be a group and let H be a subgroup. We refer to

$$H^c \ := \ \bigcap_{g \in G} gHg^{-1}$$

as the *normal core of* G.

The following lemma summarizes a few properties of the normal core.

Lemma 24.9. *Let G be a group and let H be a subgroup.*

(1) *The normal core of H is a normal subgroup of G that is contained in H.*
(2) *If X is a subgroup of G that is contained in H and that is normal in G, then $X \subset H^c$.*
(3) *If H is of finite-index in G, then H^c is also of finite-index in G.*

Proof of Lemma 24.9.

(1) The proof of the first statement is a routine exercise.
(2) Let X be a subgroup of G that is contained in H and that is normal in G. Then

$$\begin{array}{ccccccc} X & = & \bigcap_{g \in G} gXg^{-1} & \subset & \bigcap_{g \in G} gHg^{-1} & = & H^c. \\ & & \uparrow & & \uparrow & & \\ & & \text{since } X \text{ normal in } G & & \text{since } X \subset H & & \end{array}$$

(3) The proof of the last statement is arguably more interesting. Thus let H be a finite-index subgroup of G. We consider the set G/H of right coset of G with respect to H. We denote by $\mathrm{Perm}(G/H)$ the group of permutations of G/H, i.e. it is the group of all bijections of the set G/H. Note that G/H and thus also $\mathrm{Perm}(G/H)$ are finite. We consider the map

$$\begin{array}{rcl} \varphi \colon G & \mapsto & \mathrm{Perm}(G/H) \\ g & \mapsto & \left(\begin{array}{ccc} G/H & \to & G/H \\ xH & \mapsto & gxH \end{array} \right). \end{array}$$

This map is easily seen to be a homomorphism. Since $\mathrm{Perm}(G/H)$ is finite we see that $\ker(\varphi)$ is a finite-index normal subgroup of G. We claim that $\ker(\varphi) \subset H$. Thus let $g \in \ker(\varphi)$. This implies in particular that $\varphi(g)(H) = H$, but that means that $gH = H$, i.e. that $g \in H$. We have thus shown that indeed $\ker(\varphi) \subset H$. From (2)

and the above observation that $\ker(\varphi)$ is normal in G we obtain that $\ker(\varphi) \subset H^c$. But since $\ker(\varphi)$ has finite-index in G we see that H^c also has finite-index in G. $\square$

Now we can provide the proof of Proposition 24.8.

Proof of Proposition 24.8. Let $p\colon (X, x_0) \to (B, b_0)$ be a finite-degree covering of pointed topological spaces that are path-connected and reasonable. In the following we write $G := \pi_1(X, x_0)$ and $H := p_*(\pi_1(B, b_0))$. By Lemma 7.16 we know that H is a finite-index subgroup of G. It follows from Lemma 24.9 that the normal core H^c of H in G is a finite-index normal subgroup of G that is contained in H. Since B is reasonable we obtain from Proposition 20.8 a finite-degree path-connected covering $r\colon (Y, y_0) \to (B, b_0)$ of pointed topological spaces such that $r_*(\pi_1(Y, y_0)) = H^c$.

The existence of the desired covering map $q\colon (Y, y_0) \to (X, x_0)$ with $r = p \circ q$ is an immediate consequence of Proposition 20.9 and the fact that H^c is contained in H. $\square$

25. Related constructions in algebraic geometry and Galois theory (∗)

In this short chapter we indicate some connections between the topics that we have covered so far to algebraic geometry and Galois theory. Since the author of these notes does not know much about either field the following discussion should be taken with a grain of salt. In particular for an expert the subsequent discussion will certainly look too simplistic.

25.1. **The fundamental group of an algebraic variety** (∗).

Definition. Let $\mathbb{K}$ be a field.[492]

(1) Given a set of multivariable polynomials S, i.e. given a subset $S \subset \mathbb{K}[t_1, \dots, t_n]$ we denote by

$$V(S) \;=\; \{(x_1, \dots, x_n) \in \mathbb{K}^n \mid f(x_1, \dots, x_n) = 0 \text{ for all } f \in S\}$$

the *vanishing set of* S, i.e. the set of all points in $\mathbb{K}^n$ where all the polynomials in S, viewed as maps $\mathbb{K}^n \to \mathbb{K}$, vanish.

(2) We say $U \subset \mathbb{K}^n$ is *Zariski open*,[493] if there exists a subset S of $\mathbb{K}[t_1, \dots, t_n]$ such that $U = \mathbb{K}^n \setminus V(S)$.

Remark. Let S be a subset of $\mathbb{K}[t_1, \dots, t_n]$. Since the ring $\mathbb{K}[t_1, \dots, t_n]$ is Noetherian there exists a finite set $\{f_1, \dots, f_k\} \subset \mathbb{K}[t_1, \dots, t_n]$ such that $V(S) = V(f_1, \dots, f_k)$.

Lemma 25.1. *Let $\mathbb{K}$ be a field. The Zariski open subsets form a topology on $\mathbb{K}^n$.*

Remark.

(1) The topology defined by the Zariski open subsets is of course called the *Zariski topology on* $\mathbb{K}^n$.

(2) If $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$, then every Zariski open subset is also open with respect to the usual topology on $\mathbb{R}^n$ or $\mathbb{C}^n = \mathbb{R}^{2n}$. But for $n \geq 1$ the converse does not hold, in fact "most" subsets that are open with respect to the usual topology are not open with respect to the Zariski topology.

Proof. Let $\mathbb{K}$ be a field.

(1) The vanishing set of the empty set, i.e. $V(\varnothing)$ is all of $\mathbb{K}^n$, hence the empty set $\varnothing = \mathbb{K}^n \setminus V(\varnothing)$ is open.

(2) The vanishing set of the constant polynomial $f = 1$ is the empty set, therefore $\mathbb{K}^n = \mathbb{K}^n \setminus V(1)$ is open.

(3) We need to show that the intersection of finitely many Zariski open sets is again Zariski open. By induction it suffices to consider the case of two Zariski open sets.

[492] For example we could take $\mathbb{K} = \mathbb{Q}, \mathbb{R}, \mathbb{C}$ but $\mathbb{K}$ could also be a field of non-zero characteristic, e.g. for a prime p we could take $\mathbb{K} = \mathbb{F}_p$ or $\mathbb{K}$ could be the algebraic closure $\overline{\mathbb{F}}_p$ of $\mathbb{F}_p$.

[493] Oscar Zariski (1899-1986) was a Russian-American mathematician working in algebraic geometry.

So suppose we are given Zariski open sets $X = \mathbb{K}^n \setminus V(S)$ and $Y = \mathbb{K}^n \setminus V(T)$. Then

$$\mathbb{K}^n \setminus (X \cap Y) \;=\; (\mathbb{K}^n \setminus X) \cup (\mathbb{K}^n \setminus Y) \;=\; V(S) \cup V(T) \;=\; V\big(\{s \cdot t\}_{s \in S, t \in T}\big).$$

(4) We need to show that the union of Zariski open sets is again Zariski open. So suppose we are given a family of Zariski open sets $X_i = \mathbb{K}^n \setminus V(S_i)$, $i \in I$. Then

$$\mathbb{K}^n \setminus \bigcup_{i \in I} X_i \;=\; \bigcap_{i \in I} (\mathbb{K}^n \setminus X_i) \;=\; \bigcap_{i \in I} V(S_i) \;=\; V\Big(\bigcup_{i \in I} S_i\Big).$$

Thus we have verified that the Zariski open sets have all the properties of a topology. □

Definition. Let $\mathbb{K}$ be a field.

(1) A *variety over* $\mathbb{K}$ is defined as the vanishing set of a set of multivariable polynomials.
(2) The *Zariski topology on a variety* $V \subset \mathbb{K}^n$ is defined as the subspace topology on V induced from the Zariski topology on $\mathbb{K}^n$.

Example. Let $\mathbb{K}$ be a field and let and $f(s,t) = s^2 + t^2 - 1$. We define

$$S^1_{\mathbb{K}} \;:=\; V(f) \;=\; \{(x,y) \in \mathbb{K}^2 \mid f(x,y) = x^2 + y^2 - 1 = 0\} \;=\; \{(x,y) \in \mathbb{K}^2 \mid x^2 + y^2 = 1\}.$$

For $\mathbb{K} = \mathbb{R}$ we obtain the usual circle S^1.

Any variety V is again a topological space, so in principle one could study the usual fundamental group. But in many cases, e.g. if the characteristic of $\mathbb{K}$ is non-zero, one will see that all continuous maps $S^1 \to V$ are constant, hence the usual fundamental group is trivial.

The correct analogue of a finite covering $p\colon X \to B$ between topological spaces for varieties is a finite étale morphism. The precise definition of a finite étale morphism is irrelevant for our purpose.[494] A heuristic fact is that varieties tend to have many finite étale morphisms, but there is no well-behaved analogue of an infinite covering in the context of varieties. In particular usually there is no concept of a "universal" étale morphism. The question is now, whether one can recover the notion of a fundamental group from the knowledge of finite covers.

Given a variety V we can consider all finite regular étale morphisms $p_i\colon W_i \to V$, $i \in I$. The corresponding deck transformations groups $D(p_i\colon W_i \to V)$, $i \in I$ are finite groups that form an inverse system. Now we can define the étale fundamental group of V as

$$\pi_1^{\text{ét}}(V) \;:=\; \varprojlim_i D(p_i\colon W_i \to V).$$

By Proposition 16.10 the étale fundamental group $\pi_1^{\text{ét}}(V)$ is naturally a compact topological group. In algebraic geometry the étale fundamental group of a variety plays a role similar to the role of the fundamental group of a topological space in topology.

If V is a complex variety without singularities, then the étale fundamental group is isomorphic to the profinite completion[495] of the usual topological fundamental group $\pi_1(V)$,

[494] Furthermore it is unknown to the author of these lecture notes.

[495] Recall that on page 505 we introduced the profinite-completion $\widehat{\pi}$ of a group π.

i.e. we have

$$\pi_1^{\text{ét}}(V) \;\cong\; \widehat{\pi_1(V)}.$$

We refer to [Groth] for a proof of this statement.

More information on this topic can be found at

`https://en.wikipedia.org/wiki/etale_fundamental_group`

25.2. **Galois theory** $(*)$**.** The theory of coverings of topological spaces has some similarities to the Galois theory of field extensions.

Throughout this section let K be a field of characteristic zero[496] and let L/K be a field extension of K, i.e. L is a field which contains K as a subfield. The dimension of L as a K vector space is denoted by $[L : K]$. We consider the group

$$\mathrm{Gal}(L/K) = \text{ all field automorphisms of } L \text{ which are the identity on } K.$$

Put differently, a field automorphism $f\colon L \to L$ lies in $\mathrm{Gal}(L/K)$ if and only if the following diagram commutes:

$$\begin{tikzcd} & K \arrow[dl] \arrow[dr] & \\ L \arrow[rr, "f"] & & L. \end{tikzcd}$$

We consider two examples:

(1) $\mathbb{Q}(\sqrt{2})/\mathbb{Q}$ is a field extension with $[\mathbb{Q}(\sqrt{2})\colon \mathbb{Q}] = 2$ and $\mathrm{Gal}(\mathbb{Q}(\sqrt{2})/\mathbb{Q})$ consists of the identity and the homomorphism $a + b\sqrt{2} \mapsto a - b\sqrt{2}$.
(2) $\mathbb{Q}(\sqrt[3]{2})/\mathbb{Q}$ is a field extension with $[\mathbb{Q}(\sqrt[3]{2})\colon \mathbb{Q}] = 3$ and the group $\mathrm{Gal}(\mathbb{Q}(\sqrt[3]{2})/\mathbb{Q})$ consists only of the identity.

Given a field K we denote by $\overline{K}$ the algebraic closure of K. A field extension L/K is called *Galois*, if for each $f \in \mathrm{Gal}(\overline{K}/K)$ we have $f(L) = L$.[497] In the usual course on Galois theory one shows that L/K is Galois if and only if each polynomial in $K[x]$ which admits a zero in L splits over L, i.e. all other zeros of f lies also in L. For a Galois extension L/K we refer to $\mathrm{Gal}(L/K)$ as the *Galois group* of the field extension.

We return to the above two examples:

(1) $\mathbb{Q}(\sqrt{2})/\mathbb{Q}$ is a Galois field extension.
(2) $\mathbb{Q}(\sqrt[3]{2})/\mathbb{Q}$ is not a Galois field extension, since $\sqrt[3]{2}$ is a zero of x^3-2, but the complex zero $\sqrt[3]{2}e^{2\pi i/3}$ of f does not lie in $\mathbb{Q}(\sqrt[3]{2})$.[498]

If L/K is a finite extension, then the main theorem of Galois theory says that the following two statements are equivalent:

(1) The field extension L/K is Galois.

[496] This restriction to characteristic zero is not necessary, but it simplifies the discussion.

[497] Strictly speaking this is the definition of a normal extension, but since K is a field of characteristic zero, a normal extension is already Galois.

[498] We put $z = \sqrt[3]{2}$ and $w = e^{2\pi i/3}$. It is a good exercise to show that $\mathbb{Q}(z, w)/\mathbb{Q}$ is a normal field extension with $[\mathbb{Q}(z, w)\colon \mathbb{Q}] = 6$. The group $\mathrm{Gal}(\mathbb{Q}(z, w)/\mathbb{Q})$ is isomorphic to the permutation group S_3.

(2) $\#\operatorname{Gal}(L/K) = [L : K]$.

The statement is formally very similar to the statement of Corollary 24.7 which says that for some finite covering $p\colon X \to B$ of topological spaces the following statements are equivalent:

(1) The covering $p\colon X \to B$ is regular.
(2) $\#D(p\colon X \to B) = [X : B]$.

The analogy between Galois theory and covering theory goes considerably further. Many statements about the Galois group of a Galois extension have a corresponding statement for the deck transformation group of a normal covering. For example, given a finite extension L/K the (normal) subgroups of Galois group $\operatorname{Gal}(L/K)$ correspond to (normal) intermediate fields and (normal) subgroups of the deck transformation group correspond to (regular) intermediate coverings.

Now let L/K be a Galois extension of infinite degree. All finite intermediate Galois extensions of K, i.e. all finite Galois extensions F/K with $F \subset L$, form a preordered set via the inclusion. The corresponding Galois groups form an inverse set. Indeed, given two finite Galois extensions F/K and G/K with $F \subseteq G$ the restriction of an automorphism of G to an automorphism of F defines a group homomorphisms $\operatorname{Gal}(G/K) \to \operatorname{Gal}(F/K)$. Therefore we can form the inverse limit of these Galois groups. By [FJ, Section 1.3] there exists a canonical isomorphism of groups

$$\operatorname{Gal}(L/K) \;=\; \varprojlim_{\substack{F/K \text{ finite} \\ \text{Galois extension}}} \operatorname{Gal}(F/K).$$

On the right-hand side we consider the inverse limit of an inverse system of finite groups. It follows from Proposition 16.10 that the right-hand side, and thus also the Galois group $\operatorname{Gal}(L/K)$, is naturally a compact topological group. This topology on $\operatorname{Gal}(L/K)$ is called the *Krull topology*.

Example. Let p be a prime. We denote by $\mathbb{F}_p$ the finite field with p elements and we denote by $\overline{\mathbb{F}}_p$ its algebraic closure. It is shown in [FJ, Section 1.5] that there exists a canonical isomorphism

$$\operatorname{Gal}\left(\overline{\mathbb{F}}_p/\mathbb{F}_p\right) \;\cong\; \widehat{\mathbb{Z}}$$

where $\widehat{\mathbb{Z}}$ denotes the profinite completion of $\mathbb{Z}$, or equivalently the profinite integers that we introduced on page 502.

26. CW-complexes I: Definitions, basic properties and constructions

In this chapter we will introduce CW-complexes. Initially the definition of a CW-complex might look rather confusing and artificial. But in this and the subsequent chapter we see that the notion of a CW-complex strikes the right balance:

(1) CW-complexes are topological space that have many desirable properties,
(2) the notion is flexible enough so that most of the topological spaces that we are interested in are actually CW-complexes.

26.1. **A word on homotopies.** Before we introduce CW-complexes we have to spend a minute talking about the concept of homotopies. Recall that on page 299 we defined what it means for two maps $f, g\colon X \to Y$ between topological spaces to be homotopic. Before we do anything else we want to discuss two relative versions of "homotopy". The first version we already saw on page 301. For the reader's convenience we recall the definition.

Definition. Let $f, g\colon X \to Y$ be two maps between topological spaces and let $A \subset X$ be a subset such that $f|_A = g|_A$.

(1) A *homotopy between f and g rel A* is a homotopy $H\colon X \times [0,1] \to Y$ between f and g such that $H(a,t) = f(a) = g(a)$ for all $t \in [0,1]$ and all $a \in A$.
(2) We say *f and g are homotopic rel A*, if such a homotopy rel A exists.

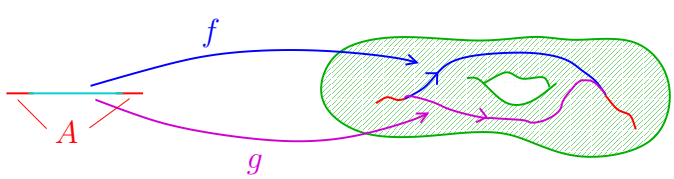

Figure 390. The maps f and g are homotopic, but they are not homotopic rel A.

We continue with another notion of a "relative homotopy".

Definition. Let X and Y be topological spaces and let $A \subset X$ and $B \subset Y$ be subsets.

(1) A map $f\colon (X,A) \to (Y,B)$ is defined as a map[499] $f\colon X \to Y$ such that $f(A) \subset B$.

Now let $f, g\colon (X,A) \to (Y,B)$ be two maps.

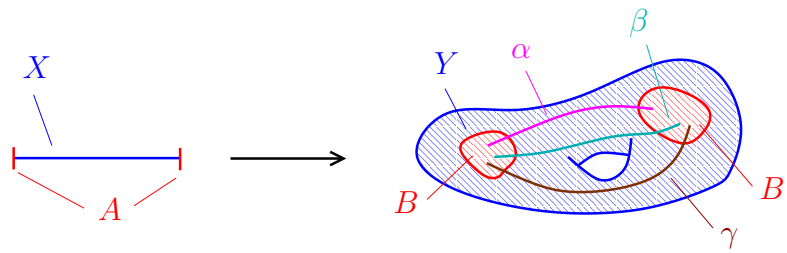
(2) A *homotopy between f and g* is a map[500]

$$H\colon X \times [0,1] \to Y,$$

such that the following two conditions are satisfied:
(a) $H(x,0) = f(x)$ and $H(x,1) = g(x)$ for all $x \in X$, and
(b) $H(a,t) \in B$ for all $a \in A$ and all $t \in [0,1]$.

[499] As usual all maps between topological spaces are understood to be continuous.
[500] For $A = B = \varnothing$ we get the usual notion of a homotopy between maps $f, g\colon X \to Y$.

(3) If there exists a homotopy between f and g, then we say that f and g are *homotopic* and we write $f \simeq g$.



$\alpha, \beta\colon (X, A) \to (Y, B)$ are homotopic but $\alpha, \gamma\colon (X, A) \to (Y, B)$ are not homotopic

FIGURE 391.

For completeness we also mention the following definition which is the obvious relative analogue of the concepts that we introduced on page 307.

Definition. Let (X, A) and (Y, B) be two pairs of topological spaces.

(1) A map $f\colon (X, A) \to (Y, B)$ is a *homotopy equivalence between* (X, A) *and* (Y, B), if there exists a map $g\colon (Y, B) \to (X, A)$ such that the following hold:
   (a) $g \circ f$ and id_X are homotopic as maps of (X, A) to itself,
   (b) $f \circ g$ and id_Y are homotopic as maps of (Y, B) to itself.

(2) If there exists a homotopy equivalence between (X, A) and (Y, B), then we say that (X, A) and (Y, B) are *homotopy equivalent*.

Example. The two pairs of topological spaces (X, A) and (Y, B) shown in Figure 392 are homotopy equivalent.

FIGURE 392.

The above notions can be generalized even further. For example, one could define triples of topological spaces and there is an obvious definition of what it means for maps $f, g\colon (X, A, B) \to (Y, C, D)$ between triples of topological spaces to be homotopic. Similarly, given pairs of topological spaces (X, A) and (Y, B) and a subset Z of A there is an obvious definition for what it means for two maps $f, g\colon (X, A) \to (Y, B)$ to be homotopic rel Z. We will not spell out all the definitions. From the context it should always be clear what we mean.

26.2. **Definition of finite-dimensional CW-complexes and examples.** We start out with the definition of a finite-dimensional CW-complex and its topological realization.

Definition.

(a) A *CW-complex X of dimension* ≤ -1 is defined to be the empty set. Its *topological realization* $|X|$ is also defined to be the empty set.

(b) We define inductively higher dimensional CW-complexes. Let $n \in \mathbb{N}_0$. A *CW-complex X^n of dimension* $\leq n$ consists of the following:
   (a) a CW-complex X^{n-1} of dimension $\leq n-1$, with topological realization denoted by $|X^{n-1}|$,
   (b) together with a set of maps $\{\varphi_i \colon S^{n-1} \to |X^{n-1}|\}_{i \in I_n}$.

   The *topological realization* $|X^n|$ *of* X^n is defined as the topological space

$$|X^n| \ := \ \Big(|X^{n-1}| \ \sqcup \ \bigsqcup_{i \in I_n} \overline{B}^n\Big) / \sim$$

   where for each $i \in I_n$ we use the map φ_i to identify the points on the corresponding copy of $S^{n-1} = \partial \overline{B}^n$ with the corresponding points in $|X^{n-1}|$.

(c) A *CW-structure* for a topological space Y is a CW-complex X together with a homeomorphism $f \colon |X| \to Y$.

Remark.

(1) Note that $\overline{B}^0$ consists of a point and that $S^{-1} = \varnothing$. It follows from the above definition that a CW-complex of dimension ≤ 0 is exactly the same as set of points with the discrete topology.

(2) CW-complexes were introduced by John H. C. Whitehead[501]. The name comes from "C" for "closure-finite", and the "W" for "weak topology"[502]. Some people also say it goes back to the initials C. W. of Whitehead.

(3) In the notation we usually do not distinguish between the CW-complex and its topological realization, i.e. we usually denote the topological realization of a CW-complex X again by X.

Before we discuss a long list of examples of CW-complexes we want to introduce a few more definitions.

Definition. Let X be a CW-complex as above. We continue with the notation used in the previous definition

(1) The images of the $\overline{B}_i^k$, $i \in I_k$, in X are called the *k-dimensional cells*, or often short *k-cells*, of X.

(2) The images of the B_i^k, $i \in I_k$, in X are called the *open k-cells* of X.

(3) The maps $\varphi_i \colon S_i^{k-1} \to X$ are called the *attaching maps* of the k-cells and the maps $\overline{B}_i^k \to X$ are referred to as the *characteristic maps* of the k-cells.

[501] John Henry Constantine Whitehead (1904-1960) was a British mathematician.

[502] We will explain later on what "closure-finite" and "weak topology" mean.

(4) The union of the cells of dimension $\leq k$ is called the *k-skeleton* of X and we denote it by X^k.
(5) If X is non-empty, then we define the dimension $\dim(X) \in \mathbb{N}_0 \cup \{\infty\}$ as the maximal dimension of a cell.

Example. We consider the topological space which is sketched in Figure 393, namely

$$Y \;:=\; [-1,1] \times [-1,1] \cup \{(x,y) \in \mathbb{R}^2 \,|\, x^2 + (y-1)^2 = 1 \text{ and } y \geq 1\}.$$

The topological space X thus consists of a square together together with a semicircle.

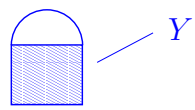


FIGURE 393.

Our goal is to find a CW-structure for X. First we consider the 0-dimensional CW-complex which consists of the 4 vertices of the square. Next we add a 1-cell. To do so we consider the map φ which sends $\partial\overline{B}^1 = \{\pm 1\}$ to the two points $\pm 1 \times -1$. The topological space $X^0 \cup_\varphi \overline{B}^1$ consists of the four points $\{\pm 1, \pm 1\}$ together with an edge which connects the lower two points. This topological space is sketched in the center of Figure 394. The

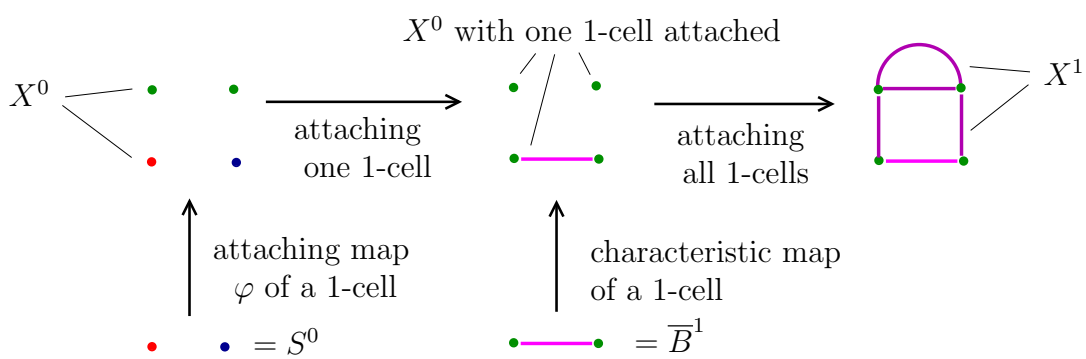

FIGURE 394. The CW-complex X^1.

same way we attach four more 1-cells and we obtain the 1-dimensional CW-complex which is sketched on the right of Figure 394. Finally we attach a 2-cell to X^1 with the attaching map shown in Figure 395 and we obtain a CW-complex X^2 whose topological realization is homeomorphic to Y.

Now we will see that most of the topological spaces that we have encountered so far can be described as CW-complexes.

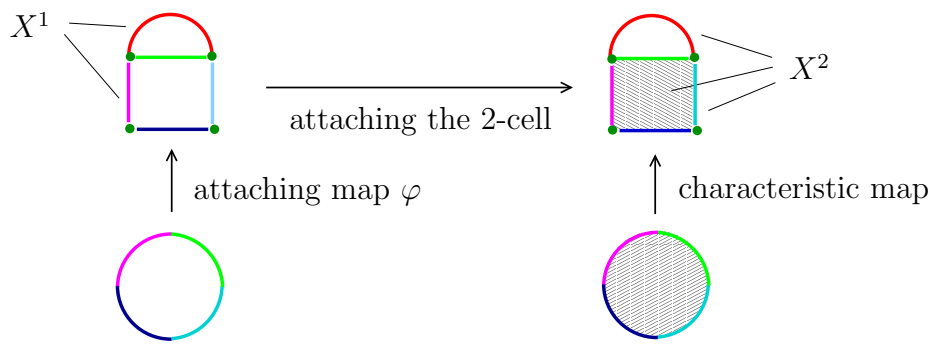

FIGURE 395. Attaching the 2-cell to the 1-skeleton X^1.

(1) Any spatial graph, as defined on page 134, is a one-dimensional CW-complex where the vertices correspond precisely to the 0-cells and the edges correspond precisely to the open 1-cells. In the following we refer to every one-dimensional CW-complex also as a topological graph. Here we refer to the 0-cells as the vertices and to the open 1-cells as the edges.[503]

(2) As a special case of (1) we see that S^1 can be viewed as a CW-complex with one 0-cell and one 1-cell. Furthermore we can view the wedge $S^1 \vee S^1$ as a CW-complex with one 0-cell and two 1-cells. Finally $\mathbb{R}$ can be viewed as a CW-complex where the 0-cells are given by the integers $\mathbb{Z}$ and the 1-cells are given by the intervals $[k, k+1]$ with $k \in \mathbb{Z}$. We refer to Figure 396 for an illustration.

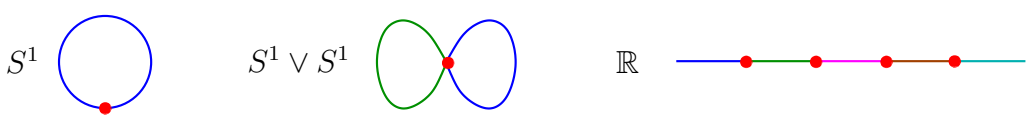

FIGURE 396.

(3) Now we consider the torus $T = [0,1] \times [0,1]/\sim$. We denote by $p\colon [0,1] \times [0,1] \to T$ the obvious projection map. We can view T as a CW-complex with one 0-cell corresponding to the point $p(0,0) = p(0,1) = p(1,0) = p(1,1)$, two 1-cells corresponding to $p(0 \times [0,1]) = p(1 \times [0,1])$ and to $p([0,1] \times 0) = p([0,1] \times 1)$ and one 2-cell corresponding to $p([0,1] \times [0,1])$. Note that since we have only one 0-cell there is a unique choice of attaching map for the 1-cells. Finally the attaching map for the 2-cell is illustrated

[503]In fact, if X is a CW-complex with finitely many 0-cells and 1-cells, then it is relatively straightforward to show that there exists a graph G in the sense of page 134 such that G is homeomorphic to X.

in Figure 397.[504] In Figure 397 we sketch the CW-structure of the torus and also the corresponding CW-structure of the torus viewed as a subset of $\mathbb{R}^3$. We refer to it as the *standard CW-structure* of the torus.

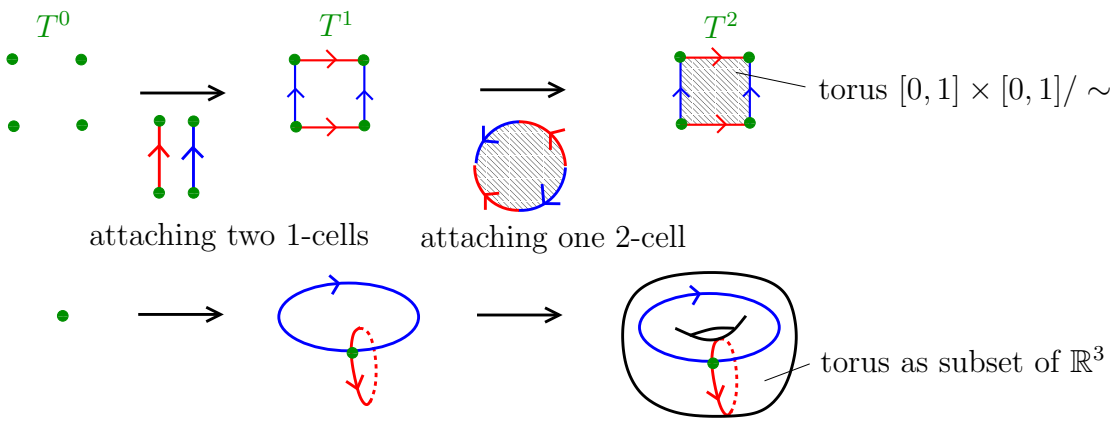

FIGURE 397. The torus as CW-complex.

(4) Next we consider the Klein bottle $K = [0,1]\times[0,1]/\sim$. As usual we denote by $p\colon [0,1]\times[0,1] \to K$ the projection map. Similar to the torus we can view K as CW-complex with one 0-cell corresponding to $p(0,0) = p(0,1) = p(1,0) = p(1,1)$, two 1-cells corresponding to $p(0\times[0,1]) = p(1\times[0,1])$ and to $p([0,1]\times 0) = p([0,1]\times 1)$ and one 2-cell corresponding to $p([0,1]\times[0,1])$ with the attaching map sketched in Figure 398.[505]
The 1-skeleta of the torus and the Klein bottle are both wedges of two circles. Furthermore both CW-complexes have precisely one 2-cell. The difference between the torus and the Klein bottle is that the attaching maps for the 2-cells are different.
(5) In Figure 399 we show that we can endow the torus with different CW-structures.
(6) In Figure 400 we sketch how we can view the projective plane $\mathbb{R}\mathrm{P}^2$, the Möbius band and the surface of genus 2 as CW-complexes.[506]

[504]Strictly speaking the attaching map is given by

$$\begin{array}{ccl} S^1 & \mapsto & T^1 \\ e^{it} & \mapsto & \begin{cases} p(\frac{2}{\pi}t, 0), & \text{if } t\in[0,\frac{\pi}{2}] \\ p(1, \frac{2}{\pi}(t-\frac{\pi}{2})), & \text{if } t\in[\frac{\pi}{2},\pi] \\ p(1-\frac{2}{\pi}(t-\pi), 1), & \text{if } t\in[\pi,\frac{3\pi}{2}] \\ p(0, 1-\frac{2}{\pi}(t-\frac{3}{2}\pi)), & \text{if } t\in[\frac{3\pi}{2},2\pi]. \end{cases} \end{array}$$

But writing out the attaching map with explicit formulas is clearly not very instructive.

[505]Evidently, as in Footnote 504, one could spell out the attaching map with precise formulas, but there is no point in doing it.

[506]What does the 1-skeleton of the given CW-structure for the surface of genus two look like, if we view the surface Σ as a "physical object" in $\mathbb{R}^3$?

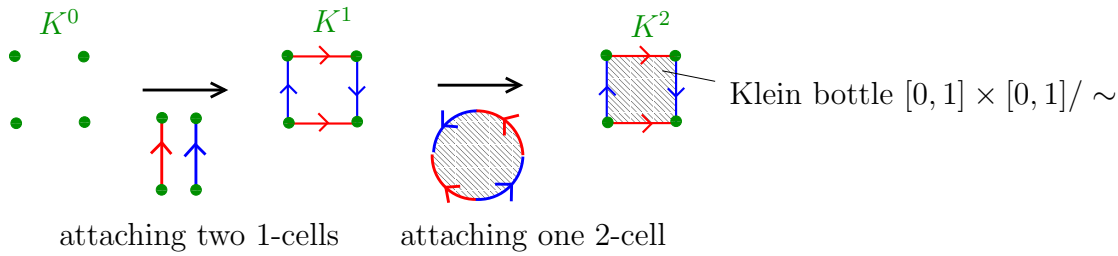

FIGURE 398. The Klein bottle as CW-complex.

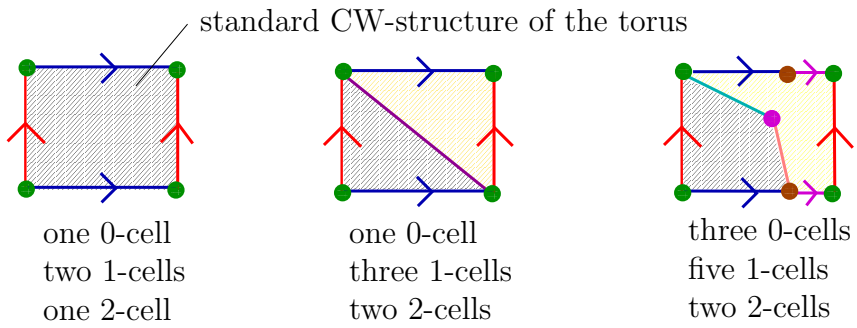

FIGURE 399. The torus with three different CW-structures.

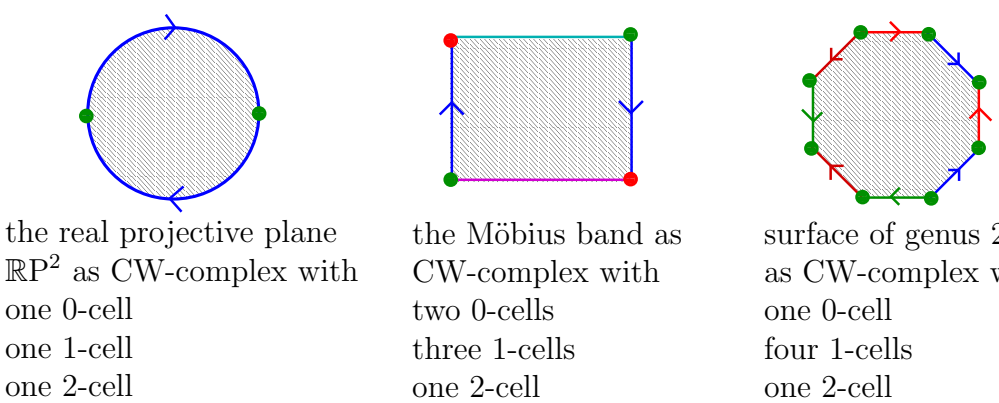

FIGURE 400.

(7) We conclude this discussion of surfaces with the 2-sphere. We can describe the 2-sphere as a CW-complex X as follows: We take a single 0-cell given by a point P and one 2-cell where the attaching map $\varphi\colon S^1 \to X^0 = \{P\}$ sends the whole boundary S^1 to

the point P. The topological realization of X is thus given by

$$X^0 \cup_\varphi \overline{B}^2 \;=\; \{P\} \cup_{P=\partial\overline{B}^2} \overline{B}^2 \;=\; \overline{B}^2/S^1 \;\underset{\substack{\uparrow \\ \text{see page 99}}}{\cong}\; S^2.$$

The example of the 2-sphere can be generalized to spheres of arbitrary dimensions: given any $n \geq 1$ we can view S^n as a CW-complex with one 0-cell and one n-cell.

We continue with the following basically self-explanatory definition.

Definition. A *subcomplex* of a CW-complex X is a subset of X that is the union of arbitrarily many cells of X.

Example. In Figure 401 we consider the topological space X that is given by removing an open disk from a torus. We see that X has the structure of a CW-structure such that the boundary ∂X is a CW-subcomplex.

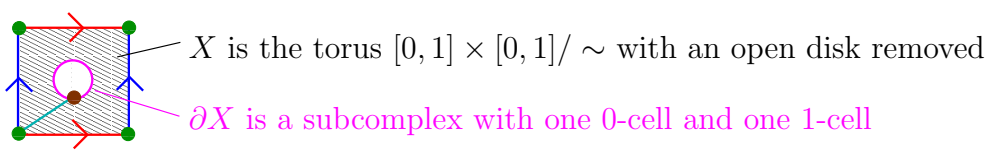

FIGURE 401.

The following lemma shows that some straightforward constructions provide examples of CW-complexes.

Lemma 26.1. *If A is a subcomplex of a CW-complex X, then the CW-structure on X restricts to a CW-structure on A.*

Proof. We set $|A^{-1}| = \varnothing$. For $n = 0, 1, 2, 3, \dots$ we iteratively consider the attaching maps $\{\varphi_i \colon S^{n-1} \to |A^{n-1}|\}_{i\in I}$ from the CW-structure of X whose image lies in $|A^{n-1}|$ and we set $|A^n| \;:=\; \Big(|A^{n-1}| \sqcup \bigsqcup_{i\in I} \overline{B}^n\Big)/\sim$. One can easily verify that this defines a CW-structure on A. $\square$

We continue the discussion of CW-complexes with two more explicit examples, namely the real projective spaces and the complex projective spaces which we had already defined on page 111. In the following let $\mathbb{A} = \mathbb{R}$ or $\mathbb{A} = \mathbb{C}$. We denote by $\sim$ the equivalence relation on $\mathbb{A}^{n+1} \setminus \{0\}$ given by multiplication by an element in $\mathbb{A} \setminus \{0\}$ and we define

$$\mathbb{A}\mathrm{P}^n \;:=\; (\mathbb{A}^{n+1} \setminus \{0\})/\sim .$$

On page 192 and Lemma 21.6 we saw that $\mathbb{A}\mathrm{P}^n$ is a manifold. Given a point $(v_0, \dots, v_n) \in \mathbb{A}^{n+1} \setminus \{0\}$ we denote by $[v_0 : \dots : v_n]$ its equivalence class. For $k \leq n$ the map

$$\begin{array}{rcl} \mathbb{A}\mathrm{P}^k & \to & \mathbb{A}\mathrm{P}^n \\ [v_0 : \dots : v_k] & \mapsto & [v_0 : \dots : v_k : 0 : \dots : 0] \end{array}$$

is easily seen to be an embedding and we use it to view $\mathbb{A}\mathrm{P}^k$ as a submanifold of $\mathbb{A}\mathrm{P}^n$.

We can give an explicit description of $\mathbb{R}\mathrm{P}^n$ and $\mathbb{C}\mathrm{P}^n$ as CW-complexes.

Lemma 26.2. *Let $n \in \mathbb{N}_0$.*

(1) *We can view $\mathbb{R}\mathrm{P}^n$ as a CW-complex with the following properties:*
   (a) *the CW-structure has exactly one cell in the dimensions $0, 1, \ldots, n$ and no other cells,*
   (b) *for each $k \leq n$ the k-skeleton of $\mathbb{R}\mathrm{P}^n$ is given by $\mathbb{R}\mathrm{P}^k$.*

(2) *We can view $\mathbb{C}\mathrm{P}^n$ as a CW-complex with the following properties:*
   (a) *the CW-structure has exactly one cell in the dimensions $0, 2, \ldots, 2n$ and no other cells,*
   (b) *for each $k \leq n$ the $2k$-skeleton of $\mathbb{C}\mathrm{P}^n$ is given by $\mathbb{C}\mathrm{P}^k$.*

Proof. We give the proof for $\mathbb{R}\mathrm{P}^n$. The proof for $\mathbb{C}\mathrm{P}^n$ is basically identical. We prove the lemma by induction on n. For $n = 0$ the topological space $\mathbb{R}\mathrm{P}^0$ consists of a single point which means that it is a CW-complex with a single 0-cell. Now suppose that we have equipped $\mathbb{R}\mathrm{P}^{n-1}$ with a CW-structure with the properties stated in (a) and (b). We view $\mathbb{R}\mathrm{P}^{n-1}$ as the subspace of $\mathbb{R}\mathrm{P}^n$ that is given by setting the last coordinate to zero. We consider the attaching map

$$\begin{array}{rcl} \varphi\colon S^{n-1} & \to & \mathbb{R}\mathrm{P}^{n-1} \\ (x_1, \ldots, x_n) & \mapsto & [x_1 : \ldots : x_n : 0]. \end{array}$$

It remains to show that there exists a homeomorphism $\mathbb{R}\mathrm{P}^{n-1} \cup_\varphi \overline{B}^n \to \mathbb{R}\mathrm{P}^n$ that restricts to the identity on $\mathbb{R}\mathrm{P}^{n-1}$. We consider the map[507]

$$\begin{array}{rcl} \mathbb{R}\mathrm{P}^{n-1} \cup_\varphi \overline{B}^n & \to & \mathbb{R}\mathrm{P}^n \\ \underbrace{[(rx_1, \ldots, rx_n)]}_{\substack{\text{with } r \in [0,1] \text{ and} \\ (x_1, \ldots, x_n) \in S^{n-1}}} & \mapsto & [x_1 : \ldots : x_n : 1 - r]. \end{array}$$

It is clear that the restriction to $\mathbb{R}\mathrm{P}^{n-1}$ is the identity. Using Lemmas 1.81 and 1.66 and Proposition 1.40 one can easily verify that the map is a homeomorphism. □

We conclude this section with the following result which is proved in [Hirs, Section 6.4], see also [Mi4, Theorem 3.5] or [Ni, pages 21 and 41] or [Mun2, Theorem 10.6]. The second statement follows from the argument of the proof of [Mc, Theorem 5.1].

Theorem 26.3. *Every compact connected n-dimensional manifold M admits a finite CW-structure with the following properties:*

(1) *the maximal dimension of a cell is n,*
(2) *there is precisely one cell of dimension n,*
(3) *the boundary ∂M is a subcomplex.*

[507] Here we use that φ is a surjection, i.e. any point in $\mathbb{R}\mathrm{P}^{n-1} \cup_\varphi \overline{B}^n$ is represented by a point in $\overline{B}^n$.

Furthermore, if $M = A \cup B$ is a decomposition into two n-dimensional submanifolds such that $A \cap B$ is a union of boundary components of A and a union of boundary components of B, then we can find a CW-structure on M which has all the above properties and such that A and B are subcomplexes.

Remark. The theorem is stated for manifolds and not for topological manifolds. The situation for topological manifolds is more complicated and we will deal with it later on in 45.1.

In the above discussion we have seen that arguably most of the topological spaces we are interested in can be viewed as CW-complexes. But note that not every topological space can be described as a CW-complex. For example consider the topological space X which consists of precisely two points P and Q and which is endowed with the trivial topology. (Recall that this means that the only open sets are the empty set and all of X.) Then we cannot view X as CW-complex since any CW-complex with finitely many points consists only of 0-cells together with the *discrete* topology. For the same reason $\{0\} \cup \{\frac{1}{n} \,|\, n \in \mathbb{N}\}$ is not a CW-complex.

Remark. Let X be a topological space and let $f, g \colon S^{n-1} \to X$ be two maps. If these two maps are homotopic, then the topological spaces $X \cup_f \overline{B}^n$ and $X \cup_g \overline{B}^n$ are homotopy equivalent. We leave the proof of this statement as a slightly challenging exercise.

26.3. **Two topologies on $\mathbb{R}^\infty$.** In the next section we want to introduce infinite-dimensional CW-complexes. Before we do so we want to get more acquainted with $\mathbb{R}^\infty$ and topologies on the set $\mathbb{R}^\infty$. First of all we write

$$\mathbb{R}^\infty \;:=\; \mathbb{R}^{(\mathbb{N})} \;:=\; \{(x_1, x_2, \dots) \,|\, \text{only finitely many } x_i \text{ are non-zero}\}.$$

As in the finite-dimensional case we can equip $\mathbb{R}^\infty$ with the Euclidean metric[508]

$$d((x_1, x_2, \dots), (y_1, y_2, \dots)) \;:=\; \sqrt{\textstyle\sum_{i=1}^{\infty} |x_i - y_i|^2}.$$

By Lemma 1.3 the metric d defines a topology on $\mathbb{R}^\infty$, more precisely

$$\mathcal{S} \;:=\; \{U \subset \mathbb{R}^\infty \,|\, \text{ for every } P \in U \text{ there exists an } \epsilon > 0 \text{ such that } B_\epsilon(P) \subset U\}$$

is a topology on $\mathbb{R}^\infty$.

This topology might feel like it is the "right topology" on $\mathbb{R}^\infty$. But the next two examples might sow some doubts.

Examples.

(1) We claim that the function

$$\begin{aligned} \alpha \colon \mathbb{R}^\infty &\to \mathbb{R} \\ (x_1, x_2, \dots) &\mapsto \sum_{i=1}^{\infty} 2^i \cdot x_i \end{aligned}$$

[508]Note that the series on the right is in fact a finite sum, since all but finitely many terms are zero. It is again straightforward to verify that d is a metric.

is not continuous with respect to $\mathcal{S}$. To show this claim we consider the open subset $(-1,1) \subset \mathbb{R}$, then $\alpha^{-1}((-1,1))$ contains the origin 0. We claim that there is no $\epsilon > 0$ with $B_\epsilon(0) \subset \alpha^{-1}((-1,1))$. Indeed, suppose such $\epsilon > 0$ exists. We pick $i \in \mathbb{N}$ with $\frac{1}{2^i} < \epsilon$ and we consider the point

$$Q \;=\; (0,\dots,0,\tfrac{1}{2^i},0,\dots).$$

Then $Q \in B_\epsilon(0)$ but $\alpha(Q) = 1$, i.e. $Q \notin \alpha^{-1}((-1,1))$.

(2) Let B be the infinite diagonal matrix where the diagonal entries are given by 2^i for $i = 1,2,\dots$, i.e. let

$$B \;:=\; \begin{pmatrix} 2 & 0 & 0 & \dots \\ 0 & 4 & 0 & \dots \\ 0 & 0 & 8 & \dots \\ \vdots & \vdots & \vdots & \ddots \end{pmatrix}.$$

We claim that the map

$$\begin{array}{rcl} \beta\colon \mathbb{R}^\infty & \to & \mathbb{R}^\infty \\ x & \mapsto & B\cdot x \end{array}$$

is not continuous with respect to $\mathcal{S}$. Indeed, an argument similar to (1) shows that the preimage of the open set $U = B_1(0)$ is not open.

The maps α and β feel quite natural, so we might want to look around for a different topology on $\mathbb{R}^\infty$ for which these two maps are in fact continuous. Of course that would be achieved by equipping $\mathbb{R}^\infty$ with the discrete topology, but clearly that's not what we want. Another reasonable condition on the desired topology is that for any $n \in \mathbb{N}_0$ the inclusion map

$$\begin{array}{rcl} \iota_n\colon \mathbb{R}^n & \hookrightarrow & \mathbb{R}^\infty \\ (x_1,\dots,x_n) & \mapsto & (x_1,\dots,x_n,0,\dots) \end{array}$$

should also be continuous. This immediately eliminates the discrete topology as a contender for the "right topology".

In fact this last condition leads us almost immediately to an alternative topology on $\mathbb{R}^\infty$. We saw in the proof of Proposition 16.1 that in the category of topological spaces we have

$$\varinjlim \mathbb{R}^n \;=\; \mathbb{R}^\infty,$$

where $\mathbb{R}^\infty$ is equipped with the "weak topology", i.e. with the topology

$$\mathcal{T} \;:=\; \{U \subset \mathbb{R}^\infty \,|\, \text{for every } n \in \mathbb{N} \text{ the set } U \cap \mathbb{R}^n \text{ is open in } \mathbb{R}^n\}.$$

Put differently, a map $f\colon \mathbb{R}^\infty \to X$ to a topological space X is continuous with respect to $\mathcal{T}$ if and only if for each $n \in \mathbb{N}$ the map $\mathbb{R}^n \hookrightarrow \mathbb{R}^\infty \xrightarrow{f} X$ is continuous.

Examples.

(1) By definition of $\mathcal{T}$ the inclusion map $\mathbb{R}^n \to \mathbb{R}^\infty$ is continuous with respect to $\mathcal{T}$.

(2) The above map $\alpha\colon \mathbb{R}^\infty \to \mathbb{R}$ is continuous with respect to the topology $\mathcal{T}$. Indeed, for any $n \in \mathbb{N}$ the restriction $\mathbb{R}^n \to \mathbb{R}^\infty \to \mathbb{R}$ is a linear map, hence continuous.
(3) In Exercise 26.2 we will see that $\mathcal{S} \subset \mathcal{T}$. This implies in particular that the identity map defines a continuous map $(\mathbb{R}^\infty, \mathcal{T}) \to (\mathbb{R}^\infty, \mathcal{S})$.
(4) Let a_i, b_i, $i \in \mathbb{N}$ be real numbers. The infinite hyperrectangle

$$(a_1, b_1) \times (a_2, b_2) \times (a_3, b_3) \times \dots$$

is easily seen to be an open subset of $(\mathbb{R}^\infty, \mathcal{T})$.[509]

The following lemma shows in particular that the above map $\beta\colon \mathbb{R}^\infty \to \mathbb{R}^\infty$ is continuous with respect to the topology $\mathcal{T}$.

Lemma 26.4. *Let $C = (c_{ij})_{i,j\in\mathbb{N}}$ be an infinite diagonal matrix. Then the map*[510]

$$\begin{array}{rcl} \gamma\colon \mathbb{R}^\infty & \to & \mathbb{R}^\infty \\ x & \mapsto & C \cdot x \end{array}$$

is continuous with respect to the topology $\mathcal{T}$.

Proof. Let $U \in \mathcal{T}$. We need to show that $\gamma^{-1}(U)$ lies in $\mathcal{T}$. So given any $n \in \mathbb{N}$ we need to show that $\gamma^{-1}(U) \cap \mathbb{R}^n$ is an open subset of $\mathbb{R}^n$. So let $n \in \mathbb{N}$. Given $m \in \mathbb{N}$ we denote by $C_{m,n}$ the submatrix of C given by the top left $m \times n$-submatrix of C and we denote by $\gamma_{m,n}\colon \mathbb{R}^n \to \mathbb{R}^m$ the map given by $x \mapsto C_{m,n} \cdot x$. We have[511]

$$\begin{aligned} \gamma^{-1}(U) \cap \mathbb{R}^n &= \big\{x \in \mathbb{R}^n \,\big|\, C \cdot x \in U\big\} &&= \big\{x \in \mathbb{R}^n \,\big|\, C \cdot x \in \bigcup_{m\in\mathbb{N}} (U \cap \mathbb{R}^m)\big\} \\ &= \bigcup_{m\in\mathbb{N}} \big\{x \in \mathbb{R}^n \,\big|\, C \cdot x \in U \cap \mathbb{R}^m\big\} &&= \bigcup_{m\in\mathbb{N}} \big\{x \in \mathbb{R}^n \,\big|\, C_{m,n} \cdot x \in U \cap \mathbb{R}^m\big\}. \\ &= \bigcup_{m\in\mathbb{N}} \underbrace{\gamma_{m,n}^{-1}(\overbrace{U \cap \mathbb{R}^m}^{\text{open in } \mathbb{R}^m})}_{\substack{\text{open in } \mathbb{R}^n \text{ since} \\ \gamma_{m,n} \text{ is continuous}}}. \end{aligned}$$

This shows that $\gamma^{-1}(U) \cap \mathbb{R}^n$ is a union of open subsets of $\mathbb{R}^n$, hence itself is open. □

This discussion shows hopefully that the following convention is reasonable.

Convention. Unless we say something else we will view $\mathbb{R}^\infty$ as a topological space with the topology $\mathcal{T}$. Put differently, we think of $\mathbb{R}^\infty$ as $\mathbb{R}^\infty = \varinjlim \mathbb{R}^n$. Similarly we define $\mathbb{C}^\infty = \varinjlim \mathbb{C}^n$ as topological spaces.

---

[509] This example is less obvious. The topology $\mathcal{T}$ has more open sets than $\mathcal{S}$ which made it easier in (2) to argue that the map α is continuous. But here in (3) it also makes it harder, since we have to check the continuity for more open sets on the right-hand side.

[510] Does this also work for any infinite-square matrix?

[511] For each $k \in \mathbb{N}$ we view $\mathbb{R}^k$ as a subset of $\mathbb{R}^\infty$ via the inclusion ι_k.

Remark. As a warm-up exercise the reader can verify that the map

$$\begin{array}{rcl} \mathbb{C}^\infty & \to & \mathbb{R}^\infty \\ (x_1+iy_1, x_2+iy_2, \dots) & \to & (x_1, y_1, x_2, y_2, \dots) \end{array}$$

is a homeomorphism. At times we will use this homeomorphism to make the identification $\mathbb{C}^\infty = \mathbb{R}^\infty$.

In the future, the more we work with $\mathbb{R}^\infty$ and $\mathbb{C}^\infty$, the more we will see that the "direct limit topology" is in fact the "right" topology to work with.

To get acquainted with this new topological space we want to prove the following lemma.

Lemma 26.5. *Given any compact subset K of $\mathbb{R}^\infty$ there exists an $n \in \mathbb{N}$ with $K \subset \mathbb{R}^n$.*

Proof. So let $K \subset \mathbb{R}^\infty$ be a compact set. Suppose that there is no $n \in \mathbb{N}$ such that $K \subset \mathbb{R}^n$. Then there exists an infinite increasing sequence $n_1, n_2, n_3, \dots$ of natural numbers and points $x_1, x_2, x_3, \dots$ in K such that $x_i \in \mathbb{R}^{n_i} \setminus \mathbb{R}^{n_i-1}$. We denote by X the set whose elements are precisely the x_i.

Claim 1. The set X is a discrete subset of $\mathbb{R}^\infty$.

To simplify the notation we assume that $n_i = i$ for all $i \in \mathbb{N}$. For each i we denote by z_i the i-coefficient of x_i. Put differently, z_i is the highest non-zero coefficient of x_i. Furthermore for each $i \in \mathbb{N}$ we pick $\epsilon_i \in (0, \frac{\|z_i|}{2})$. Finally, given $x \in \mathbb{R}$ and $\epsilon > 0$ we write $I_\epsilon(x) = (x-\epsilon, x+\epsilon)$. We define

$$\begin{array}{rcccccccccc} U_1 & = & I_{\epsilon_1}(z_1) & \times & I_{\epsilon_2}(0) & \times & I_{\epsilon_3}(0) & \times & I_{\epsilon_4}(0) & \times & \dots \\ U_2 & = & \mathbb{R} & \times & I_{\epsilon_2}(z_2) & \times & I_{\epsilon_3}(0) & \times & I_{\epsilon_4}(z_4) & \times & \dots \\ U_3 & = & \mathbb{R} & \times & \mathbb{R} & \times & I_{\epsilon_3}(z_3) & \times & I_{\epsilon_4}(0) & \times & \dots \\ \vdots & & & & & & & & & & \end{array}$$

As we remarked on page 652, each U_i is an open subset of $\mathbb{R}^\infty$. Evidently U_i contains x_i and thus each U_i is an open neighborhood of x_i. Furthermore the sets U_i, $i \in \mathbb{N}$ are easily seen to be disjoint. But this shows, by definition of the subspace topology, that X is discrete. This concludes the proof of the claim.

Claim 2. The set X is a closed subset of K.

We need to show that $X \setminus K$ is open. By definition of the subspace topology it suffices to show that $\mathbb{R}^\infty \setminus X$ is open. In the following we continue with the notation from the previous claim. Thus let $y \in \mathbb{R}^\infty$. We pick $n \in \mathbb{N}$ such that $y \in \mathbb{R}^n$. In $\mathbb{R}^n$ we can and will pick an open neighborhood U of $(y_1, \dots, y_n)$ that does not contain $x_1, \dots, x_n \in \mathbb{R}^n$. One can now verify easily that

$$V := U \times I_{\epsilon_{n+1}}(0) \times I_{\epsilon_{n+2}}(0) \times \dots$$

is an open neighborhood of $y \in \mathbb{R}^\infty$ that does not intersect X. This concludes the proof of the claim.

It follows from Claim 1, Claim 2 and Lemma 1.19 (2) that X is indeed finite. But that is a contradiction to our assumption that there is no $n \in \mathbb{N}$ such that K is contained in $\mathbb{R}^n$. $\square$

26.4. **Infinite-dimensional CW-complexes.**

Definition.

(a) A *CW-complex* X is defined as a sequence

$$X^{-1} \;:=\; \varnothing \subset X^0 \subset X^1 \subset X^2 \subset \dots$$

of CW-complexes (in the sense of the definition of page 643) such that for each $m \leq n$ the CW-complex X^m is the m-skeleton of X^n. The cells of the X^n are called the cells of X.

(b) We define the *topological realization* $|X|$ of such a CW-complex X as[512]

$$|X| \;:=\; \varinjlim |X^n|.$$

In other words, a subset $U \subset X$ is open if and only if for every $n \in \mathbb{N}_0$ the intersection $U \cap X^n$ is an open subset of X^n. As before, in the notation we usually do not distinguish between the notation for a CW-complex and its topological realization.

(c) We define the dimension $\dim(X) \in \mathbb{N}_0 \cup \{\infty\}$ of a non-empty CW-complex X as the maximal dimension of a cell.[513]

(d) We say a CW-complex is *finite* if it has only finitely many cells and we say it is *countable* if it has only countably many cells.

(e) A *CW-structure* for a topological space Y is a CW-complex X together with a homeomorphism $f\colon X \to Y$.

Example. We consider the infinite sphere

$$S^\infty \;=\; \{x \in \mathbb{R}^\infty \,|\, d(x, \text{origin}) = 1\} \;=\; \Big\{(x_1, x_2, \dots) \in \mathbb{R}^\infty \,\Big|\, \sum_{i=1}^\infty x_i^2 = 1\Big\}$$

which equip with the subspace topology coming from $\mathbb{R}^\infty$. It follows easily from the fact that $\mathbb{R}^\infty = \varinjlim \mathbb{R}^n$ that we have the equality $S^\infty = \varinjlim S^n$. We consider iteratively the spheres S^n as CW-complexes, where S^0 consists of two 0-cells and where S^n is built starting from S^{n-1} by attaching two n-cells ("the upper hemisphere and the lower hemisphere") to S^{n-1}. We then obtain an ascending sequence

$$S^0 \;\subset\; S^1 \;\subset\; S^2 \;\subset\; \dots$$

[512]This topology on a union of topological spaces is called the *weak topology*. This explains the "W" of the name CW-complex.

[513]Here we define $\dim(X) := \infty$ if X admits cells of arbitrarily large dimensions.

of CW-complexes which satisfies precisely the required properties of a CW-complex as defined above. This shows that the sphere S^∞ is an infinite-dimensional CW-complex. We refer to Figure 402 for an illustration.[514]

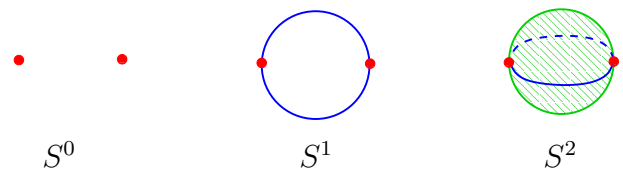

FIGURE 402.

FIGURE 403. An ascending sequence of CW-complexes $S^0 \subset S^1 \subset S^2 \dots$.

The following definition and notation is the obvious infinite-dimensional analogue of the finite-dimensional definitions introduced on page 111.

Definition. Let $\mathbb{A} = \mathbb{R}$ or $\mathbb{A} = \mathbb{C}$.

(1) We define the *infinite-dimensional projective space* $\mathbb{A}\mathrm{P}^\infty$ as the set
$$\mathbb{A}\mathrm{P}^\infty \;=\; (\mathbb{A}^\infty \setminus \{0\})/(\mathbb{A} \setminus \{0\})$$
together with the quotient topology.

(2) Given a point $(x_1, x_2, \dots) \in \mathbb{A}^\infty \setminus \{0\}$ we denote its equivalence class in $\mathbb{A}\mathrm{P}^\infty$ by $[x_1 : x_2 : \dots]$.

(3) Given $n \in \mathbb{N}$ we view $\mathbb{A}\mathrm{P}^n$ as a subset of $\mathbb{A}\mathrm{P}^\infty$ via the inclusion map
$$\begin{array}{ccc} \mathbb{A}\mathrm{P}^n & \to & \mathbb{A}\mathrm{P}^\infty \\ [x_0 : \dots : x_n] & \mapsto & [x_0 : \dots : x_n : 0 : \dots]. \end{array}$$

The following lemma shows in particular that we can view the real infinite projective space $\mathbb{R}\mathrm{P}^\infty$ as an infinite-dimensional CW-complex.

Lemma 26.6.

(1) *The inclusion maps $\mathbb{R}\mathrm{P}^n \to \mathbb{R}\mathrm{P}^\infty$ define a homeomorphism $\varinjlim \mathbb{R}\mathrm{P}^n \xrightarrow{\cong} \mathbb{R}\mathrm{P}^\infty$.*

(2) *The topological space $\mathbb{R}\mathrm{P}^\infty$ admits a CW-structure such that for every $n \in \mathbb{N}$ the n-skeleton is given by $\mathbb{R}\mathrm{P}^n \to \mathbb{R}\mathrm{P}^\infty$ where $\mathbb{R}\mathrm{P}^n$ is equipped with the CW-structure coming from Lemma 26.2.*

(3) *The infinite real projective space $\mathbb{R}\mathrm{P}^\infty$ admits a CW-structure which has precisely one n-cell for every $n \in \mathbb{N}_0$.*

(4) (a) *The action $\{\pm 1\} \times S^\infty \to S^\infty$ given by $(\epsilon, v) \mapsto \epsilon \cdot v$ is continuous and discrete.*
(b) *The obvious projection $S^\infty \to S^\infty/x \sim -x$ is a 2-fold covering.*

[514] If we equip S^∞ with the topology $\mathcal{S}$ coming from the Euclidean metric on $\mathbb{R}^\infty$, then this argument does not work and it is not clear (and presumably wrong), that $(S^\infty, \mathcal{S})$ is a CW-complex.

(c) *The map*

$$\begin{array}{rcl} S^\infty/x \sim -x & \to & \mathbb{R}\mathrm{P}^\infty \\ [(x_1, x_2, \dots)] & \mapsto & [x_1 : x_2 : \dots] \end{array}$$

is a homeomorphism.

Proof (∗).

(1) Given $n \in \mathbb{N}$ we denote by $p_n \colon \mathbb{R}^{n+1} \setminus \{0\} \to \mathbb{R}\mathrm{P}^n$ the obvious projection map and we denote by $p \colon \mathbb{R}^\infty \setminus \{0\} \to \mathbb{R}\mathrm{P}^\infty$ the obvious projection map. Let $\mathcal{S}$ be the topology of $\mathbb{R}\mathrm{P}^\infty$. By definition $U \subset \mathbb{R}\mathrm{P}^\infty$ is open if and only if for every $n \in \mathbb{N}$ the set $p^{-1}(U) \cap (\mathbb{R}^{n+1} \setminus \{0\})$ is open. Next note that it follows from the discussion on page 488 that $\varinjlim \mathbb{R}\mathrm{P}^n = \mathbb{R}\mathrm{P}^\infty$ with the topology $\mathcal{T}$ that is defined by the condition that $U \subset \mathbb{R}\mathrm{P}^\infty$ is an open subset if and only if $U \cap \mathbb{R}\mathrm{P}^n$ is open for every $n \in \mathbb{N}$, i.e. U is open if and only if $p_n^{-1}(U \cap \mathbb{R}\mathrm{P}^n)$ is open for every $n \in \mathbb{N}$. Finally we make the observation that for every $U \in \mathbb{R}\mathrm{P}^\infty$ and every $n \in \mathbb{N}$ we have the equality

$$p_n^{-1}(U \cap \mathbb{R}\mathrm{P}^n) \;=\; p^{-1}(U) \cap (\mathbb{R}^{n+1} \setminus \{0\}).$$

It follows from this observation that $\mathcal{S} = \mathcal{T}$.

(2) This statement follows immediately from (1) and the definition of a CW-complex on page 654.

(3) This statement is an immediate consequence of (2) and the definition of the CW-structure on eahc $\mathbb{R}\mathrm{P}^n$.

(4) (a) The statement is not difficult to prove, but on needs to argue carefully with the given topology on S^∞. We will fill in the details in Exercise 26.3.
(b) This statement follows from (a) and Proposition 7.10.
(c) It is straightforward to verify that the given map is a bijection. We leave it as an exercise to the reader to verify that the map is continuous and that its inverse is continuous. □

The following lemma is the complex sibling of Lemma 26.6.

Lemma 26.7.

(1) *The inclusion maps* $\mathbb{C}\mathrm{P}^n \to \mathbb{C}\mathrm{P}^\infty$ *define a homeomorphism* $\varinjlim \mathbb{C}\mathrm{P}^n \xrightarrow{\cong} \mathbb{C}\mathrm{P}^\infty$.

(2) *The topological space* $\mathbb{C}\mathrm{P}^\infty$ *admits a CW-structure such that for every* $n \in \mathbb{N}$ *the* $2n$*-skeleton is given by* $\mathbb{C}\mathrm{P}^n \to \mathbb{C}\mathrm{P}^\infty$ *where* $\mathbb{C}\mathrm{P}^n$ *is equipped with the CW-structure coming from Lemma 26.2.*

(3) *The infinite complex projective space* $\mathbb{C}\mathrm{P}^\infty$ *admits a CW-structure which has precisely one* n*-cell for every even* $n \in \mathbb{N}_0$.

Proof. The proof of this lemma is basically verbatim the same as the proof of the corresponding parts of Lemma 26.6. □

The following lemma gives a convenient approach to showing that a map starting at a CW-complex is continuous.

Lemma 26.8. *Let X be a CW-complex. We denote by $\{\Phi_i \colon \overline{B}^{n_i} \to X\}_{i\in I}$ the characteristic maps of all the cells of X. The following two statements hold:*

(1) *A subset $U \subset X$ is open if and only if for each $i \in I$ the preimage of U under the characteristic map Φ_i is open, i.e. if each $\Phi_i^{-1}(U) \subset \overline{B}^{n_i}$ is an open subset of $\overline{B}^{n_i}$.*
(2) *A map $f \colon X \to Y$ to a topological space Y is continuous if and only if each map $f \circ \Phi_i \colon \overline{B}^{n_i} \to Y$ is continuous.*

Proof. Once one has unraveled the definition of the topology on a CW-complex one sees that the first statement of the lemma is obvious. The second statement is an immediate consequence of the first statement. □

For completeness we reiterate the definition of a subcomplex that we had initially given on page 648 for finite-dimensional CW-complex but which also makes sense in the more general setting of arbitrary CW-complexes.

Definition. A *subcomplex* of a CW-complex X is a subset of X that is the union of arbitrarily many cells of X.

Lemma 26.9. *Let X be a CW-complex and let $\{X_i\}_{i\in I}$ be a family of subcomplexes such that $\bigcup_{i\in I} X_i = X$. The following three statements hold:*

(1) *A subset $U \subset X$ is open if and only if each $X_i \cap U$ is an open subset of X_i.*
(2) *A subset $A \subset X$ is closed if and only if each $X_i \cap A$ is a closed subset of X_i.*
(3) *A map $f \colon X \to Y$ to a topological space Y is continuous if and only if each map $f|_{X_i} \colon X_i \to Y$ is continuous.*

Proof.

(1) This statement is an easy consequence of Lemma 26.8 (1).
(2) This statement follows from (1) and the elementary observation that for $A \subset X$ we have $(X \setminus A) \cap X_i = X_i \setminus (X_i \cap A)$.
(3) This statement is an easy consequence of Lemma 26.8 (2). □

The following lemma shows in particular that some straightforward constructions provide examples of subcomplexes.

Lemma 26.10. *Let X be a CW-complex.*

(1) *If A is a subcomplex of A, then the CW-structure on X restricts to a CW-structure on A.*
(2) *Every subcomplex of X is a closed subset of X.*
(3) *For any $n \in \mathbb{N}_0$ the n-skeleton X^n is a subcomplex of X.*
(4) *The union and also the intersection of arbitrarily many subcomplexes is again a subcomplex.*
(5) *Every path-component of a complex is again a subcomplex.*

Proof.

(1) The proof is basically identical to the proof of Lemma 26.1.
(2) This statement follows quite easily from the definition of the topology on A.
(3) This statement is clear.
(4) This statement is also clear.
(5) This statement is basically obvious since each closed ball is path-connected. □

Proof. The proof is basically identical to the proof of Lemma 26.10, we just need Lemma 26.9 (2) to take care of statement (2), i.e. of the statement that every subcomplex is a closed subset. □

26.5. **Properties of CW-complexes.** In the previous section we saw that, as promised, most examples of topological spaces that we are interested in are indeed CW-complexes. The following, somewhat technical, proposition shows that CW-complexes have, again as promised, many nice topological properties.

Proposition 26.11.

(1) *Every point on a CW-complex is closed.*
(2) *CW-complexes are Hausdorff.*
(3) *Every cell of a CW-complex X is compact and it is a closed subset of X.*
(4) *Let X be a CW-complex. Given any $x \in X$ and given any open neighborhood U of x there exists an open neighborhood V of x that is contained in U and that admits a deformation retraction to $\{x\}$.*
(5) *Every point on a CW-complex is good in the sense of the definition on page 387.*
(6) *CW-complexes are are o-locally*[515] *contractible, o-locally path-connected and o-locally simply-connected.*[516]
(7) *A CW-complex is connected if and only if it is path-connected.*
(8) *There exists a map Φ which assigns to each subcomplex A a subset $\Phi(A) \subset X$ such that the following statements hold:*
   (a) *for each subcomplex A the set $\Phi(A)$ is an open neighborhood of A such that A is a deformation retract of $\Phi(A)$,*
   (b) *for any two subcomplexes A_1 and A_2 we have*
$$\Phi(A_1 \cap A_2) = \Phi(A_1) \cap \Phi(A_2) \quad \text{and} \quad \Phi(A_1 \cup A_2) = \Phi(A_1) \cup \Phi(A_2),$$
   (c) *for any two subcomplexes A and B with $A \subset B$ we have $\Phi(A) \subset \Phi(B)$.*

Remark.

(1) In a slightly simplified form Proposition 26.11 (8) says that we can assign to each subcomplex A in a "systematic way" an open neighborhood $\Phi(A)$ that deformation retracts to A.

[515] We refer to page 130 for the definition of "o-local".
[516] Recall that on page 557 we called a topological space *reasonable* if it is o-locally simply connected.

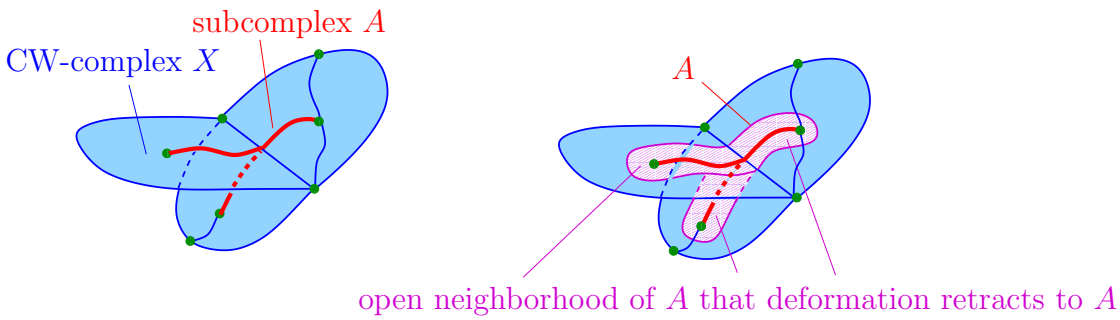

FIGURE 404. Illustration of Proposition 26.11 (8).

(2) In Proposition 26.11 (8) it is essential that A is a subcomplex. For example, if we consider $X = \mathbb{R}$ and $A = \{0\} \cup \{\frac{1}{n} \,|\, n \in \mathbb{N}\}$, then A does not admit an open neighborhood U such that A is a deformation retract of U.[517]
(3) It follows from Proposition 26.11 (3) that every finite CW-complex is compact.
(4) Proposition 26.11 (6) sounds somewhat technical, but it ensures that later on we can apply Proposition 20.8 to obtain coverings of CW-complexes.
(5) Many other useful properties of CW-complexes are proved in [LW, Section II.3].

Proof $(*)$. [518][519] We start out with the following notation. Given a subset A of $\overline{B}^n$ and $\epsilon > 0$ we denote by

$$N_\epsilon(A) \;:=\; \big\{x \in \overline{B}^n \,\big|\, \text{ there exists an } y \in A \text{ with } \|x - y\| < \epsilon\big\}$$

the ϵ-neighborhood around A. Furthermore given two subsets X and Y of $\overline{B}^n$ we write

$$d(X, Y) \;:=\; \inf\{\|x - y\| \,|\, x \in X \text{ and } y \in Y\}.$$

Now let X be a CW-complex. We denote by Γ the set of cells of X and given $n \in \mathbb{N}_0$ we denote by Γ_n the set of n-cells. Given a cell γ we denote by Φ_γ the characteristic map.

Let $A \subset X$ be a subset and let ϵ be a function that assigns to each $\gamma \in \Gamma$ a positive number ϵ_γ. Given $n \in \mathbb{N}_0$ we define a subset $N^n_\epsilon(A)$ inductively as follows:

(1) For $n = 0$ we define $N^0_\epsilon(A) := A \cap X^0$.

[517] Why not?

[518] Proofs marked with $(*)$ were only sketched or not done at all in the lectures. The proofs marked with $(*)$ tend to be technical and not overly enlightening. It might make sense to browse through the proof to get an idea of what methods are used. Only if you have lots of time would I recommend to read the proofs in detail.

[519] Since I did not do the proofs in the lectures the probability that there are mistakes is also higher.

(2) Suppose that $N_\epsilon(A)^n$ has already been defined. We define

$$N_\epsilon^{n+1}(A) \;:=\; N_\epsilon^n(A) \cup \bigcup_{\gamma\in\Gamma_{n+1}} \Phi_\gamma\Big(N_{\epsilon_\gamma}(\overbrace{\Phi_\gamma^{-1}(A)}^{\subset \overline{B}^{n+1}}) \cup \underbrace{(1-\epsilon_\gamma, 1] \times \overbrace{\Phi_\gamma^{-1}(N_\epsilon^n(A))}^{\subset S^n}}_{\text{radial coordinates on } \overline{B}^{n+1}}\Big).$$

It is straightforward to verify that each $N_\epsilon^n(A)$ is an open neighborhood of $A \cap X^n$ in X^n. The definition of $N_\epsilon^{n+1}(A)$ is illustrated in Figure 405. Finally we set $N_\epsilon(A) := \bigcup_{n\in\mathbb{N}} N_\epsilon^n(A)$.

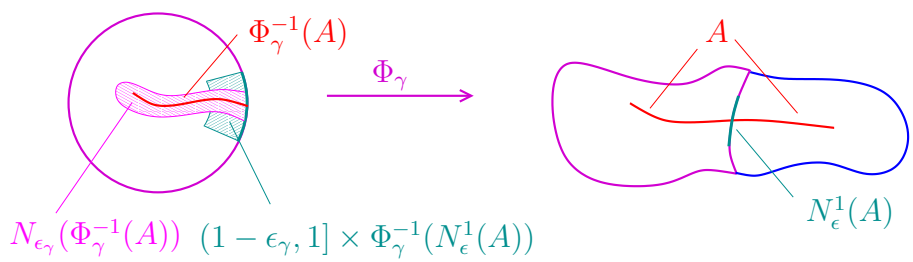

FIGURE 405.

It follows easily from the definition of the topology of a CW-complex that $N_\epsilon(A)$ is an open neighborhood of A in X. The definition of $N_\epsilon(A)$ is illustrated in Figure 406.

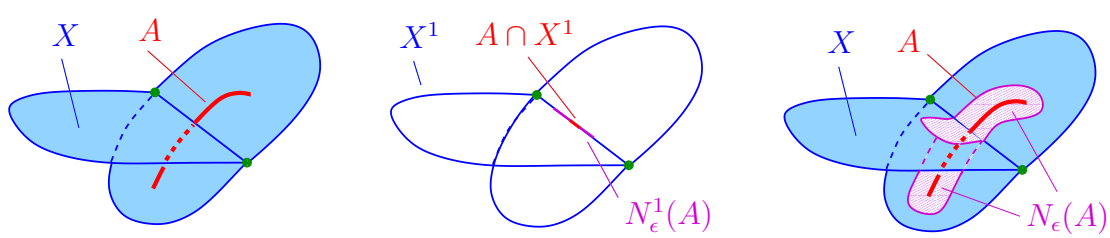

FIGURE 406.

Now we turn to the proofs of the seven statements:

(1) It follows easily from the definition of the topology on a CW-complex that every point is closed. We will fill in the details in Exercise 26.1.

(2) We will prove the following statement: given any two disjoint closed subsets A and B of X there exist open disjoint neighborhoods of A and B. By (1) this implies that X is Hausdorff.
So let A and B be two disjoint closed subsets of X. We will find ϵ as above such that $N_\epsilon(A)$ and $N_\epsilon(B)$ are disjoint. We will define the values of ϵ inductively on the dimension of the cells. For 0-cells we take $\epsilon = 1$. Now suppose that we have already found disjoint open sets $N_\epsilon^n(A)$ and $N_\epsilon^n(B)$. Let γ be an $(n+1)$-cell with characteristic map $\Phi_\gamma\colon \overline{B}^{n+1} \to X$.

Claim. We have

$$\begin{aligned} \mu_1 := d(\Phi_\gamma^{-1}(N_\epsilon^n(A)), \Phi_\gamma^{-1}(B)) &> 0, \\ \mu_2 := d(\Phi_\gamma^{-1}(N_\epsilon^n(B)), \Phi_\gamma^{-1}(A)) &> 0, \\ \mu_3 := d(\Phi_\gamma^{-1}(B), \Phi_\gamma^{-1}(A)) &> 0. \end{aligned}$$

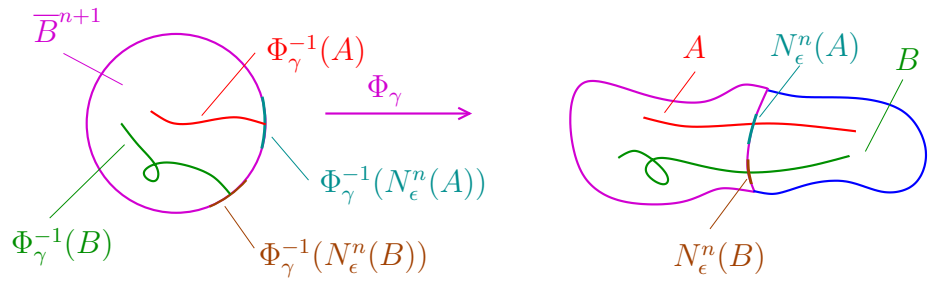

FIGURE 407.

We first consider μ_1. Suppose that $\mu_1 = 0$. If this was the case then there would exist a sequence of points in $\Phi_\gamma^{-1}(B)$ that converges to a point of $\Phi_\gamma^{-1}(B)$ in $\partial\overline{B}^{n+1}$ of distance zero from $\Phi_\gamma^{-1}(N_\epsilon^n(A))$. But this is impossible since $\Phi_\gamma^{-1}(N_\epsilon^n(B))$ is a neighborhood of $\Phi_\gamma^{-1}(B)) \cap \partial\overline{B}^{n+1}$ in $\partial\overline{B}^{n+1}$ which is disjoint from $\Phi_\gamma^{-1}(N_\epsilon^n(A))$. The second inequality $\mu_2 > 0$ is proved exactly the same way. Finally we have $\mu_3 > 0$ since $\Phi_\gamma^{-1}(A)$ and $\Phi_\gamma^{-1}(B)$ are disjoint closed, hence compact, subsets of $\overline{B}^{n+1}$.[520] This concludes the proof of the claim.

We set $\epsilon_\gamma := \frac{1}{2}\min\{\mu_1, \mu_2, \mu_3\}$. We do this for all $(n+1)$-cells γ. It then follows immediately from the definitions that $N_\epsilon^{n+1}(A)$ and $N_\epsilon^{n+1}(B)$ are disjoint.

(3) Every k-cell is the image of the compact set $\overline{B}^k$, hence it is compact by Lemma 1.37. It follows from Lemma 1.18 (2) and the fact, proved in (2), that X is Hausdorff that every k-cell is also a closed subset of X.

(4) Let $x \in X$ and let U be an open neighborhood of x. We leave it as an exercise to show that there exists an ϵ such that $N_\epsilon(x)$ is contained in U.

It remains to show that $N_\epsilon(x)$ admits a deformation retraction to $\{x\}$. We denote by m the unique natural number with $x \in X^m \setminus X^{m-1}$. It follows easily from the definitions that $N_\epsilon^m(x)$ is an open ball around x, in particular $N_\epsilon^m(x)$ deformation retracts onto $\{x\}$. Therefore it suffices to find a deformation retraction from $N_\epsilon(x)$ to $N_\epsilon^m(x)$.

First note that for $n > m$ we can construct a deformation retraction r_n from $N_\epsilon^n(x)$ to $N_\epsilon^{n-1}(x)$ by sliding outward along radial segments in the n-cells. We refer to Figure 408 for an illustration. A deformation retraction of $N_\epsilon(x)$ onto $N_\epsilon^m(x)$ is then obtained by performing the deformation retraction r_n from $N_\epsilon^n(x)$ to $N_\epsilon^{n-1}(x)$ during

[520] Here we use the following general fact: if K and L are two compact disjoints subsets of $\mathbb{R}^n$, then $d(K, L) > 0$. How would you prove this?

the "time-interval" $[\frac{1}{2^n}, \frac{1}{2^{n-1}}]$ where the points of $N_\epsilon(x) \setminus N_\epsilon^{n-1}(x)$ stay fixed during that time interval.

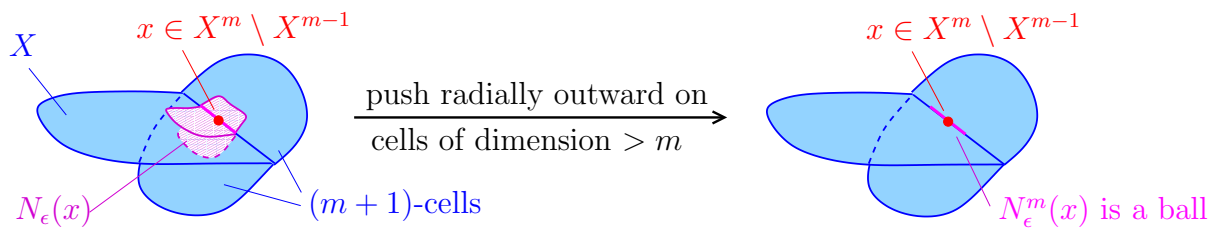

FIGURE 408.

(5) This statement follows immediately from (2) and (4).
(6) This statement follows immediately from (4) since every topological space that admits a deformation retraction to a point is contractible, and since every contractible topological space is path-connected and simply connected.
(7) By Lemma 1.102 a o-locally path-connected topological space is connected if and only if it is path-connected.
(8) We pick an $\epsilon \in (0,1)$. Given a subcomplex A of X we set $\Phi(A) := N_\epsilon(A)$. In each cell of $X \setminus A$ the set $N_\epsilon(A)$ is a product neighborhood of the boundary of this cell. So a deformation retraction of $N_\epsilon(A)$ onto A can be constructed as in (4). We leave the details to the reader. It is clear that Φ has all the other desired properties. □

Remark. Recall that on page 75 we introduced the definition that a topological space X is called *normal* if any two disjoint closed subsets A and B of X are separated by neighborhoods, i.e. if there exist disjoint neighborhoods U of A and V of B. In the proof of Proposition 26.11 (2) we actually showed that CW-complexes are normal.

One of the curses of the working topologist is the unfortunate fact that a bijection continuous map between topological spaces does not need to be a homeomorphism. The following lemma gives a nice criterion for a map between CW-complexes to be a homeomorphism.

Lemma 26.12. *Let $f\colon X \to Y$ be a map between CW-complexes. Suppose the following three conditions are satisfied:*

(1) *f is a bijection,*
(2) *f is continuous,*
(3) *the images of the cells of X are precisely the cells of Y.*

Then $f\colon X \to Y$ is a homeomorphism.

Proof (∗). We denote by $g = f^{-1}\colon Y \to X$ the inverse of f. It remains to show that g is continuous. Let $\{\Phi_i\colon \overline{B}^{m_i} \to X\}_{i\in I}$ be the characteristic maps of the CW-complex X and let $\{\Phi_j\colon \overline{B}^{n_j} \to Y\}_{j\in J}$ be the characteristic maps of the CW-complex Y. By Lemma 26.8 it suffices to show that for each $j \in J$ the map $g \circ \Psi_j\colon \overline{B}^{n_j} \to X$ is continuous. We consider the cell $\Psi_j(\overline{B}^{n_j})$. By hypothesis (3) there exists an $i \in I$ such that $f(\Phi_i(\overline{B}^{m_i})) = \Psi_j(\overline{B}^{n_j})$.

Since $\Phi_i(\overline{B}^{m_i})$ is compact and since we know by Proposition 26.11 that $\Psi_j(\overline{B}^{n_j}) \subset Y$ is Hausdorff it follows from Proposition 1.40 that $f\colon \Phi_i(\overline{B}^{m_i}) \to \Psi_j(\overline{B}^{n_j})$ is a homeomorphism. But this implies that $f^{-1} = g$ is continuous on $\Psi_j(\overline{B}^{n_j})$. But this implies that $g \circ \Psi_j$ is continuous. $\square$

Using Proposition 26.11 we can now prove the following very useful version of the Seifert–van Kampen Theorem 14.1. In view of Theorem 26.3 it can be viewed as a generalization of the Seifert-van Kampen Theorem 14.2 for manifolds.

Theorem 26.13. (Seifert–van Kampen for CW-complexes) *Let X be a CW-complex and let $X = A \cup B$ be a decomposition of X in two subcomplexes such that $A \cap B$ is path-connected. Let $x_0 \in A \cap B$. Then*

$$\pi_1(X, x_0) \;\cong\; \pi_1(A, x_0) *_{\pi_1(A\cap B, x_0)} \pi_1(B, x_0).$$

Examples.

(1) Let X be the wedge of two circles. We can view X as a CW-complex with one 0-cell x_0 and two 1-cells a and b. Then $A = \{x_0, a\}$ and $B = \{x_0, b\}$ are subcomplexes, each of which is homeomorphic to S^1. We refer to Figure 409 for an illustration. It follows, as on page 390, that

$$\pi_1(X, x_0) \;\underset{\substack{\uparrow \\ \text{Theorem 26.13}}}{\cong}\; \pi_1(A, x_0) *_{\pi_1(A\cap B, x_0)} \pi_1(B, x_0) \;\underset{\substack{\uparrow \\ \text{since } A \text{ and } B \text{ are homeomorphic to circles}}}{\cong}\; \langle a\rangle * \langle b\rangle \;=\; \langle a, b\rangle.$$

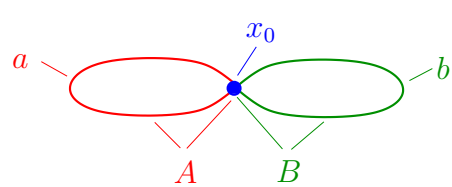

FIGURE 409.

(2) We consider

$$K \;:=\; \underbrace{S^1 \times S^1}_{=:A} \cup \underbrace{\overline{B}^2 \times \{1\}}_{=:B},$$

i.e. K is given by a torus where the "central hole" is filled in with a disk. We refer to Figure 410 for an illustration.[521] In the above definition of K we already wrote K as the union of two subsets. It is quite straightforward to see that K can be given

[521] Here the name K stands for "kiacherl".

a CW-structure such that A and B are subcomplexes.[522] We pick the base point $x_0 = (1,1)$. We obtain that

$$\pi_1(K,x_0) \underset{\substack{\uparrow \\ \text{Theorem 26.13}}}{\cong} \pi_1(A,x_0) *_{\pi_1(A\cap B,x_0)} \pi_1(B,x_0) \underset{\substack{\uparrow \\ \text{since } A\cap B = S^1\times\{1\}}}{\cong} \underbrace{\langle x,y|[x,y]\rangle *_{\langle s\rangle} \{e\}}_{\text{with } x \leftarrow\!\shortmid s} \underset{\substack{\uparrow \\ \text{Lemma 13.12}}}{\cong} \langle y\rangle.$$

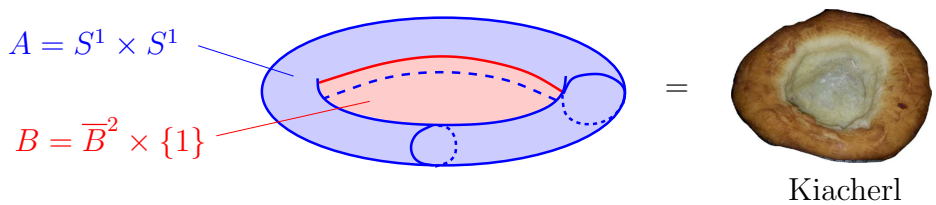

FIGURE 410.

Proof of Theorem 26.13 (∗). [523] Let X be a CW-complex and let $X = A \cup B$ be a decomposition of X in two subcomplexes such that $A \cap B$ is path-connected. Note that $A \cap B$ is also a subcomplex. Let $x_0 \in A \cap B$.

We use the notation of Proposition 26.11 (8). We write $U = \Phi(A)$ and $V = \Phi(B)$. Note that by Proposition 26.11 (8b) we have $U \cap V = \Phi(A \cap B)$. Since $A \cap B$ is path-connected and since $A \cap B$ is a deformation retract of $\Phi(A \cap B)$ we see that $U \cap V = \Phi(A \cap B)$ is also path-connected. Therefore we can apply the Seifert–van Kampen Theorem 14.1 to the decomposition $X = U \cup V$. We obtain the following commutative diagram

$$\begin{array}{ccc} \pi_1(U,x_0) *_{\pi_1(U\cap V,x_0)} \pi_1(V,x_0) & \xrightarrow{\cong} & \pi_1(X,x_0) \\ \uparrow & & =\uparrow \\ \pi_1(A,x_0) *_{\pi_1(A\cap B,x_0)} \pi_1(B,x_0) & \longrightarrow & \pi_1(X,x_0), \end{array}$$

where the two vertical maps are induced by the inclusions. By Proposition 26.11 (8a) and Proposition 9.12 (1) the three inclusion induced maps $\pi_1(A,x_0) \to \pi_1(U,x_0)$, $\pi_1(B,x_0) \to \pi_1(V,x_0)$ and $\pi_1(A \cap B,x_0) \to \pi_1(U \cap V,x_0)$ are isomorphisms. The top horizontal map is an isomorphism by the Seifert–van Kampen Theorem 14.1. It follows that the bottom horizontal map is also an isomorphism. □

The following proposition is one of the key technical results about infinite CW-complexes.

Proposition 26.14. *Every compact* (*connected*) *subset of a CW-complex X is contained in a finite* (*connected*) *subcomplex.*

Remark. The statement of the proposition and also its proof have more than a passing resemblance with Lemma 26.5.

[522] How would you define the CW-structures?

[523] The proof is very similar to the proof of the Seifert-van Kampen Theorem for manifolds 14.2.

Before we start out with the proof of Proposition 26.14 we formulate the following pretty corollary.

Corollary 26.15. *A CW-complex is compact if and only if it is finite.*

Proof. As we remarked before, it is a consequence of Proposition 26.11 (3) that every finite CW-complex is compact. Now suppose that X is a compact CW-complex. It follows from Proposition 26.14 that X is contained in a finite subcomplex Y of X. But from $X \subset Y \subset X$ it follows that $X = Y$, ie. X si a finite CW-complex. □

The proof of Proposition 26.14 will be a fairly straightforward consequence of the following rather technical lemma.

Lemma 26.16. *Let X be a CW-complex. Then the following statements hold:*

(1) *Let $A \subset X$ be a subset. If every open cell of X contains at most one point of A, then A is closed and discrete.*
(2) *If $C \subset X$ is a compact subset, then C is contained in a finite union of open cells.*
(3) *Every cell of X is contained in a finite subcomplex of X.*[524]

Proof of Lemma 26.16 $(*)$. We start out with the following claim.

Claim. Let Y be a CW-complex. Then the statements (1), (2) and (3) are equivalent.

Let Y be a CW-complex. First we show (1) $\Rightarrow$ (2). Let $C \subset Y$ be a compact subset. For each cell that intersects C we pick a single point. We denote the resulting set of points by A. By (1) the set A is closed and discrete. Since A is a closed subset of compact set we obtain from Lemma 1.18 (1) that A is compact. Since A is compact and discrete we obtain from Lemma 1.19 (1) that A is in fact finite. But that means that C intersects only finitely many cells, i.e. C is contained in a finite union of open cells as claimed.

Now we will prove (2) $\Rightarrow$ (3). So let $C_\sigma \subset Y$ be an n-cell. We denote by U_σ the corresponding open cell. By Proposition 26.11 (3) and by definition of a cell we know that $C_\sigma \setminus U_\sigma$ is a compact subset of the $(n-1)$-skeleton Y^{n-1}. It follows from (2) that the subset $C_\sigma \setminus U_\sigma$ is contained in a finite union of open cells of dimension $\leq n-1$. By the same argument each of these lower-dimensional closed cells is again contained in a finite union of open cells of smaller dimension, except again for the cell itself. A straightforward induction argument now shows that we end up with finitely many cells which form a subcomplex of Y.

Next we will show (3) $\Rightarrow$ (1). Let $A \subset Y$ be a subset such that no two points lie in the same open cell. We consider the intersection of A with a closed cell. By (3) this intersection is contained in a finite subcomplex Y'. Since A has at most one point in common with any open cell this intersection $A \cap Y'$ must be finite and hence closed in $A \cap Y'$ by Proposition 26.11 (1). By Proposition 26.11 (3) the finite subcomplex Y' is a closed subset of X. Hence $A \cap Y'$ is a closed subset of X. For any point $x \in A$ the set

[524] This implies in particular that the *closure* of each open cell is contained in the union of *finitely* many open cells. This property is sometimes referred to as X being "closure finite" which explains the "C" in the name CW-complex.

$A \setminus \{x\}$ also satisfies the hypothesis for A, and so it must also be a closed subset of X. Hence $\{x\}$ is open in A, so A is discrete. This concludes the proof of the claim.

Now let X be a CW-complex. First note that statement (1) holds for X^0 by definition of the topology on X^0. Now suppose we know (1) for the n-skeleton X^n for some $n \in \mathbb{N}_0$. By claim we know that (2) and (3) also for X^n. But the proof of (2) $\Rightarrow$ (3) for a given n-cell only used (2) for subsets of X^{n-1}. Thus we actually have (3) for X^{n+1}. Thus we also have (1) for X^{n+1}. Summarizing we have all three statements for X^n for all n. But any cell lies in some X^n, and so we know (3) for X itself, and by the claim this implies that (1) and (2) also hold for X. □

Now we can provide the proof of Proposition 26.14.

Proof of Proposition 26.14. Let X be a CW-complex and let $C \subset X$ be a compact subset. By Lemma 26.16 (2) the subset C is contained in a union of finitely many open cells. By Lemma 26.16 (3) each of these open cells is contained in a finite subcomplex. The union of these finitely many finite subcomplexes is a finite subcomplex Z which contains C.
If C is connected, then we take the component of Z that contains C. By Lemma 26.10 (4) this is again a subcomplex. □

In many situations the following proposition makes it possible to reduce the study of arbitrary CW-complexes to the study of finite CW-complexes.

Proposition 26.17. *Let X be a CW-complex with countably many cells. Then the following hold:*

(a) *There exists a sequence $A_1 \subset A_2 \subset \dots$ of* finite *subcomplexes A_i of X such that $X = \bigcup_{i \in \mathbb{N}_0} A_i$.*
(b) *If X is connected, then we can arrange in* (a) *that every A_i is connected.*

Proof. Let X be a CW-complex with countably many cells. We number them with $e_1, e_2, \dots$. By Lemma 26.16 (3) and Proposition 26.14 there exists for each i a finite connected subcomplex B_i that contains e_i. We define $A_1 := B_1$ and iteratively we define $A_i := A_{i-1} \cup B_i$. By Lemma 26.10 (4) we know that each A_i is a finite subcomplex. Thus this sequence satisfies (a).

Now suppose that X is connected. We define the sequence by $A_1 := B_1$ and iteratively we define A_i as follows:

(1) We pick a path $p\colon [0,1] \to X$ from a point in A_{i-1} to a point in B_i.
(2) Then we denote by A_i any finite connected subcomplex that contains the compact connected set $A_{i-1} \cup B_i \cup p([0,1])$. Such a finite connected subcomplex exists by Lemma 26.16 (3) and Proposition 26.14.

This sequence clearly has the desired properties (a) and (b). □

Corollary 26.18. *Let X be a CW-complex and let $X_1 \subset X_2 \subset X_3 \subset \dots$ be a sequence of subcomplexes such that $X = \bigcup_{i \in \mathbb{N}} X_i$. Given any compact subset K of X there exists an $i \in \mathbb{N}$ with $K \subset X_i$.*

Proof. Let K be a compact subset of X. It follows from Proposition 26.17 that K is contained in a finite subcomplex Y of X. From $X = \bigcup_{i\in\mathbb{N}} X_i$ and from the fact that each X_i is a subcomplex of X we obtain that every cell is contained in some X_i. But this implies that the finite subcomplex Y is also contained in some X_i. $\square$

We conclude this section with the following proposition that is an immediate consequence of Proposition 16.4 and Corollary 26.18.

Proposition 26.19. *Let X be a CW-complex and let $X_1 \subset X_2 \subset X_3 \subset \dots$ be a sequence of subcomplexes such that $X = \bigcup_{i\in\mathbb{N}} X_i$. Then for any $w \in X_1$ we have*

$$\pi_1(X, w) \;=\; \varinjlim \pi_1(X_i, w).$$

Examples.

(1) We have[525]

$$\pi_1(\mathbb{R}\mathrm{P}^\infty) \underset{\substack{\uparrow \\ \text{see page 655}}}{=} \pi_1\Big(\bigcup_{n\in\mathbb{N}} \mathbb{R}\mathrm{P}^n\Big) \underset{\substack{\uparrow \\ \text{Proposition 26.19}}}{=} \varinjlim \begin{array}{c} \uparrow \\ \pi_1(\mathbb{R}\mathrm{P}^3) \\ \uparrow \\ \pi_1(\mathbb{R}\mathrm{P}^2) \\ \uparrow \\ \pi_1(\mathbb{R}\mathrm{P}^1) \end{array} = \varinjlim \begin{array}{c} \uparrow\cong \\ \mathbb{Z}_2 \\ \uparrow\cong \\ \mathbb{Z}_2 \\ \uparrow \\ \mathbb{Z} \end{array} \cong \mathbb{Z}_2.$$

(2) In Exercise 26.4 we will use Proposition 26.19 to show that there exists a CW-complex X with $\pi_1(X) \cong (\mathbb{Q}, +)$.

26.6. **Constructions of more CW-complexes.** In this and the next section we will see how one can build new CW-complexes out of given CW-complexes. We start out with the following lemma.

Lemma 26.20.

(1) *Let $\{X_i\}_{i\in I}$ be a family of CW-complexes. The disjoint union $\bigsqcup_{i\in I} X_i$ admits a natural CW-structure such that each X_i is a subcomplex.*
(2) *Let X be a CW-complex and let A be a subcomplex. The quotient X/A admits a natural CW-structure such that the projection map $X \to X/A$ is cellular and where the cells of X/A are in one-to-one correspondence to the cells of X that do not entirely lie in A together with one 0-cell given by the point $[A]$.*
(3) *Let $\{X_i\}_{i\in I}$ be a family of CW-complexes and suppose that for each $i \in I$ we are given a point $a_i \in X_i^0$. If we use these points to form the wedge $\bigvee_{i\in I} X_i$, then the wedge admits a natural CW-complex structure such that each X_i is a subcomplex.*

[525] By Corollary 7.19 we know that $\pi_1(\mathbb{R}\mathrm{P}^n) \cong \mathbb{Z}_2$ for $n \geq 2$. But why is $\pi_1(\mathbb{R}\mathrm{P}^1) \cong \mathbb{Z}$?

(4) *Let X and Y be CW-complexes, let A be a subcomplex of X and let $f\colon A \to Y$ be a cellular map. Then*

$$(X \sqcup Y)/\sim \qquad \text{where } a \sim f(a) \text{ for } a \in A$$

admits a natural CW-structure such that X and Y are subcomplexes.

Convention. When we form the wedge of a family of a CW-complexes, then we always use a point that lies in the 0-skeleton, so that we can view the wedge in a natural way as a CW-complex.

Proof.

(1) The first statement is basically obvious.

(2), (4) In both cases it should be pretty clear what the CW-structure should be. The problem that arises is that one needs to show that the topology of the new CW-complex agrees in fact with the intended topology. If X (and Y) are finite CW-complexes then this follows easily from Proposition 1.40. The general case gets more technical. We refer to [LW, p. 60 and Theorem 5.11] or alternatively to [FPi, p. 63] for complete proofs.

(3) This follows easily from (1) and (2). □

Later on we will make good use of the following lemma.

Lemma 26.21. *Let X be a CW-complex and let $n \in \mathbb{N}$. Let $\{\varphi_i\colon \overline{B}^{n+1} \to X^n\}_{i\in I}$ be the characteristic maps of the $(n+1)$-cells of X. For each $i \in I$ let $\overline{B}_i^{n+1}$ be a copy of $\overline{B}^{n+1}$ and let S_i^n be a copy of S^n. We write $S_i^n = \partial\overline{B}_i^{n+1}$.*

(1) *The map*

$$\begin{aligned} f\colon \bigvee_{i\in I} \overbrace{(\overline{B}_i^{n+1}/S_i^n)}^{\text{homeomorphic to } S^{n+1}\text{, see page 99}} &\to X^{n+1}/X^n \\ [x] &\mapsto [\varphi_i(x)] \quad \text{if } x \in \overline{B}_i^{n+1} \end{aligned}$$

is a homeomorphism.

(2) *If X has only one 0-cell $\{x_0\}$ and no cells in dimensions $1, \dots, n$, then the homeomorphism f, together with the homeomorphism $\overline{B}^{n+1}/S^n \to S^{n+1}$ from page 99 induces a homeomorphism*

$$\bigvee_{i\in I} S_i^{n+1} \to X^{n+1}.$$

Example. In Figure 411 we see the torus together with a CW-structure X that has two 2-dimensional cells. It follows from Lemma 26.21 (1) that $X/X^1 = X^2/X^1$ is homeomorphic to the wedge of two spheres.

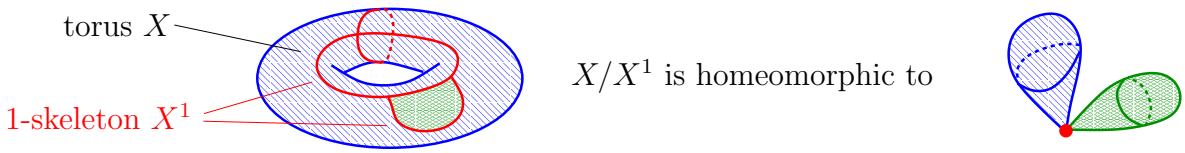

FIGURE 411.

Proof. Clearly (2) is just a neat special case of (1). Thus it remains to prove (1). First note that it is basically clear that the given map f is a bijection. Furthermore it follows immediately from Lemma 9.17 that f is continuous. We use Lemma 26.20 to view both sides of Lemma 26.21 as CW-complexes. The map f gives a bijection between the cells of the two sides. Thus it follows from Lemma 26.12 that f is a homeomorphism. □

Lemma 26.22. *Let $f_i\colon X_i \to X_{i+1}$, $i \in \mathbb{N}$ be a sequence of cellular inclusion maps between CW-complexes. Then the direct limit*[526] $\varinjlim X_i = \bigcup_{i\in I} X_i$ *admits a CW-structure such that each X_i is a subcomplex of* $\varinjlim X_i = \bigcup_{i\in I} X_i$.

Example. Lemma 26.22 allows us to view the line with infinitely many spheres attached as a CW-complex. We refer to Figure 412 for an illustration.

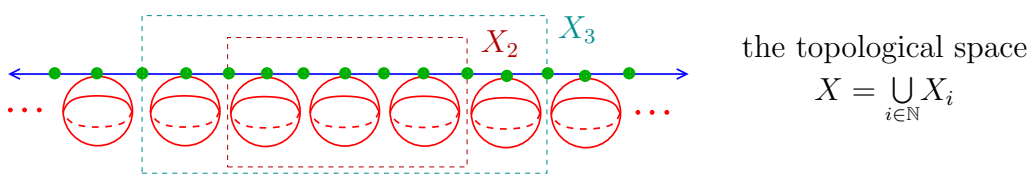

FIGURE 412.

Proof. We leave it to the reader to write down the, notationally messy but mathematically elementary, proof. □

Let X and Y be two CW-complexes. We can form the product topological space $X \times Y$. We would like to equip $X \times Y$ with a CW-structure. Using the homeomorphism from Proposition 1.48 (2) we identify in the following the n-dimensional closed ball $\overline{B}^n$ with the n-dimensional cube $I^n = [0,1]^n$. For $p + q = n$ we evidently have $I^n = I^p \times I^q$. The idea is now to define a CW-structure on $X \times Y$ such that the product of a p-cell in X with a q-cell in Y corresponds to a $(p+q)$-cell in $X \times Y$.

[526] We write explicitly "direct limit" to remind the reader that, according to the discussion on page 485, the topology on $\varinjlim X_i = \bigcup_{i\in I} X_i$ is given by the condition that a subset U is open if and only if each intersection $U \cap X_i$ is an open subset of X_i.

In the following we want to execute this idea rigorously. We first make the observation that

$$\partial(I^n) \;=\; \partial I^p \times I^q \cup I^p \times \partial I^q.$$

We define a CW-structure on $X \times Y$ inductively as follows:

(1) We put $(X \times Y)^0 = X^0 \times Y^0$.
(2) Now we suppose that the $(n-1)$-skeleton $(X \times Y)^{(n-1)}$ has already been defined. We consider a p-cell e in X which is given by a characteristic map $\varphi\colon I^p \to X^p$ and an $(n-p)$-cell f in Y which is given by a characteristic map $\psi\colon I^{n-p} \to Y^{n-p}$. Then we denote by $e \times f$ the n-cell in $X \times Y$ which is given by the attaching map[527]

$$\begin{array}{rcl} \partial(I^n) = \partial I^p \times I^{n-p} \cup I^p \times \partial I^{n-p} & \to & (X \times Y)^{n-1} \\ (x, y) & \mapsto & (\varphi(x), \psi(y)). \end{array}$$

All these n-cells together define the n-skeleton of $X \times Y$.

We refer to this CW-structure on $X \times Y$ as the *product CW-structure*.

Examples.

(1) If we equip $S^1 = [0,1]/0 \sim 1$ with the usual CW-structure with one 0-cell and one 1-cell, then the product CW-structure on the torus $S^1 \times S^1 = [0,1] \times [0,1]/\sim$ is precisely the CW-structure that we had already encountered on page 646. We refer to Figure 413 for an illustration.

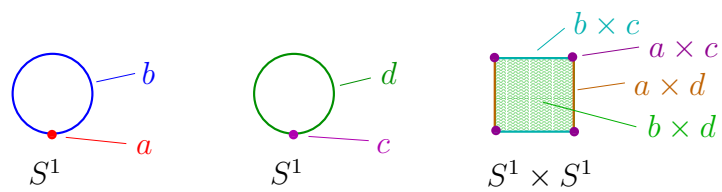

FIGURE 413.

(2) Given $a = s_0 < s_1 < \cdots < s_k = b$ and $c = t_0 < t_1 < \cdots < t_l = d$ we can view the intervals $[a, b]$ and $[c, d]$ as CW-complexes where the 1-cells are given precisely by the intervals $[s_i, s_{i+1}]$, $i = 0, \ldots, k-1$ and $[t_j, t_{j+1}]$, $j = 0, \ldots, l-1$. The product CW-complex is the topological space $[a, b] \times [c, d]$ where the 2-cells are given by the rectangles $[s_i, s_{i+1}] \times [t_j, t_{j+1}]$ with $i \in \{0, \ldots, k-1\}$ and $j \in \{0, \ldots, l-1\}$. The analogous statement holds also for higher-dimensional hyperrectangles. For example, given $k \in \mathbb{N}$ and $n \in \mathbb{N}$ we can equip the cube $[0,1]^n$ with a CW-structure where the n-cells are precisely given by the cubes $[\frac{s_1}{k}, \frac{s_1+1}{k}] \times \cdots \times [\frac{s_n}{k}, \frac{s_n+1}{k}]$ with $s_1, \ldots, s_n \in \{0, \ldots, k-1\}$.

[527] Why does the image of this attaching map lie in $(X \times Y)^{n-1}$?

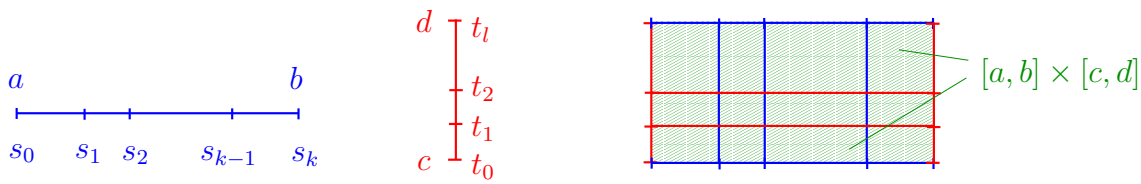

FIGURE 414.

Now comes a major subtlety. We just equipped the set $X \times Y$ with a CW-structure and thus with a topology, but does this topology equal the original topology?

We have the following proposition which deals with all the situations we will care about.

Proposition 26.23. *Let X and Y be CW-complexes. If at least one of the two CW-complexes has only countably many cells, then the product CW-structure is indeed a CW-structure for the topological space $X \times Y$.*

Example. One of the most relevant examples for us is the case $Y = [0,1]$ where Y is equipped with the usual CW-structure with two 0-cells and one 1-cell. It follows from Proposition 26.23 that given any CW-complex X the product CW-structure defines a CW-structure on $X \times [0,1]$. By definition of the product CW-structure $X \times \{0\}$ and $X \times \{1\}$ are subcomplexes.[528]

Proof. If X and Y are both finite CW-complexes, then the conclusion is again a consequence of Proposition 1.40. The general case is dealt with in [LW, Theorem II.5.2]. (If one of X or Y is a finite CW-complex, then the statement is also proved in [Hat, Theorem A.6]. If both CW-complexes have countably many cells, then the statement is also proved in [FPi, Proposition 2.2.3] or [Mi14, Lemma 2.1].) □

Remark. The formulation of Proposition 26.23 already suggests that the conclusion does not hold without some assumptions on X and Y. In fact, as discussed in [LW, Chapter II.5], the hypotheses of Proposition 26.23 can be loosened even further. But, as shown in [Dow] or [Hat, p. 524], there are indeed examples of CW-complexes X and Y such that the above product CW-structure on $X \times Y$ is not a CW-structure for the topological space $X \times Y$. Finally, [Broo, Theorem 1] gives a necessary and sufficient condition for the product of two CW-complexes to be a CW-complex.

We conclude this section with the following corollary that shows that several constructions that we are familiar with can also be performed in the category of CW-complexes.

Corollary 26.24. *Let X be a CW-complex.*[529]

[528] In fact this special case can be proved along the same lines as Lemma 27.1.

[529] Strictly speaking, or Bourbakily speaking if that's an adverb, we should really specify in each case what the "natural CW-structure" is. But this should hopefully be clear in each case, and we do not encumber the reader with unnecessary extra notation.

(1) *The cone*

$$\mathrm{Cone}(X) \;=\; (X \times [0,1])/\sim \qquad \textit{where } (x,0) \sim (y,0) \textit{ for every } x,y \in X$$

admits a natural CW-structure such that $X = X \times \{1\}$ *is a subcomplex.*

(2) *The suspension*

$$\Sigma(X) \;=\; (X \times [-1,1])/\sim \qquad \textit{where for every } x,y \in X \textit{ we have } (x,-1) \sim (y,-1) \textit{ and } (x,1) \sim (y,1)$$

admits a natural CW-structure such that $X = X \times \{0\}$ *is a subcomplex.*

(3) *If* A *is a CW-complex and if* $f\colon A \to X$ *is a cellular map, then the mapping cone*

$$\mathrm{Cone}(f\colon A \to X) \;=\; (X \sqcup \mathrm{Cone}(A))/\sim \;\; \textit{where } (a,1) \sim f(a) \textit{ for all } a \in A.$$

and the mapping cylinder

$$\mathrm{Cyl}(f\colon A \to X) \;=\; (A \times [0,1] \sqcup X)/\sim \;\; \textit{where } (a,1) \sim f(a) \textit{ for all } a \in A.$$

admit natural CW-structures. In both cases X *is naturally a subcomplex and in the latter case* $A = A \times \{0\}$ *is also a subcomplex.*

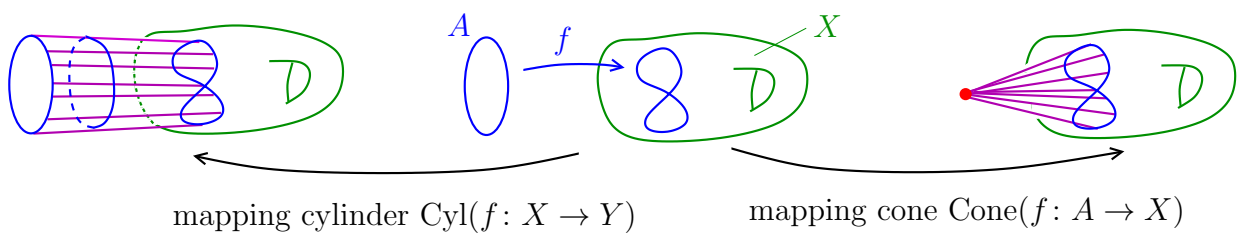

FIGURE 415.

Proof. All four statements can be proved easily using Proposition 26.23 and Lemma 26.20. We leave it to the reader to fill in the details. □

26.7. **Coverings of CW-complexes.**

Proposition 26.25. *Let* $p\colon \widetilde{X} \to X$ *be a covering of a connected CW-complex* X*. We can equip* $\widetilde{X}$ *with the structure of a CW-complex such that the following statements hold:*

(1) *The map* $p\colon \widetilde{X} \to X$ *is a cellular map.*

(2) *For any* $k \in \mathbb{N}_0$ *we have*[530]

$$\#k\text{-cells of } \widetilde{X} \;=\; \big[\widetilde{X} : X\big] \cdot \#k\text{-cells of } X.$$

(3) *The dimension of* $\widetilde{X}$ *is the same as the dimension of* X*.*

[530]Note that this is an equality of cardinalities. For example, if $[\widetilde{X} : X]$ is infinite countable and if X has finitely many k-cells, then $\widetilde{X}$ has infinitely many, but countably many, k-cells.

(4) *If X is a finite CW-complex and if p is a finite covering, then*

$$\chi(\widetilde{X}) \;=\; [\widetilde{X} : X] \cdot \chi(X).$$

Proof. Let $p\colon \widetilde{X} \to X$ be a covering of a connected CW-complex X. We write $n := [\widetilde{X} : X]$. Let $\psi\colon \overline{B}^k \to X$ be a characteristic map of a k-cell of X. We write $x = \psi(0)$. We consider the following diagram

$$\begin{tikzcd} & \widetilde{X} \arrow[d, "p"] \\ \overline{B}^k \arrow[ur, dashed, "\widetilde{\psi}"] \arrow[r, "\psi"'] & X. \end{tikzcd}$$

Since $\overline{B}^k$ is simply connected and o-locally path-connected we can apply Proposition 20.2 which says in this context that for each $\widetilde{x} \in p^{-1}(x)$ there exists a unique lift $\overline{B}^k \to \widetilde{X}$ with $\widetilde{\psi}(0) = \widetilde{x}$. By the definition on page 259, the degree $n = [\widetilde{X} : X]$ of the covering equals the cardinality of $p^{-1}(x)$. Thus we see that ψ gives rise to n maps $\overline{B}^k \to \widetilde{X}$. It is straightforward to verify that all these lifts of the characteristic maps for the cells of X define a CW-structure for $\widetilde{X}$. We leave the verification of the details as an exercise to the reader. Alternatively we refer to [Bre, Theorem IV.8.10] for details.

It follows immediately from the above construction and the definitions that the CW-structure we had just defined on $\widetilde{X}$ has the desired properties (1) to (4). □

Examples.

(1) We equip S^1 with the CW-structure consisting of one 0-cell and one 1-cell. We denote by $p\colon \mathbb{R} \to S^1$, $t \mapsto e^{2\pi i t}$ the universal covering of S^1. If we apply the construction of the CW-structure on $\mathbb{R}$ given in the proof of Proposition 26.25, then we end up equipping $\mathbb{R}$ with the CW-structure where the 0-cells correspond to $\mathbb{Z}$ and the 1-cells are precisely the intervals $[k, k+1]$, with $k \in \mathbb{Z}$. We illustrate the CW-structure of $\mathbb{R}$ in Figure 416.

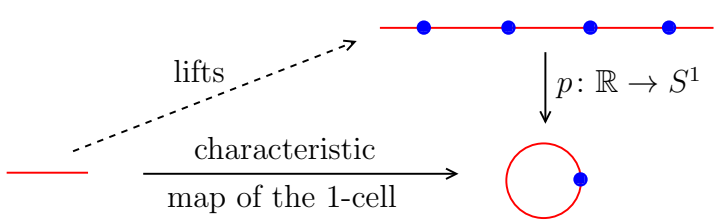

FIGURE 416.

(2) Almost the same approach as in (1), applied to the universal covering $\mathbb{R}^2 \to S^1 \times S^1$, endows $\mathbb{R}^2$ with a CW-structure that is illustrated in Figure 417.

(3) In the proof of Hadamard's Theorem 23.9 we constructed an explicit covering map $\mathbb{D} \to H_8/\sim \;\cong E_8/\sim$. If we equip $E_8/\sim$ with the "usual" CW-structure then we

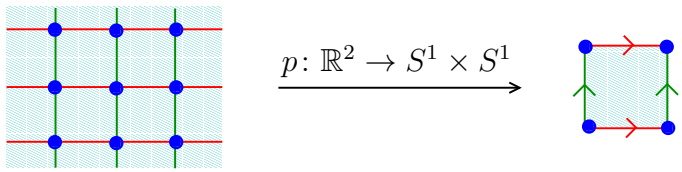

FIGURE 417.

obtain from Proposition 26.25 the CW-structure on $\mathbb{D}$ that is shown in Figure 418.

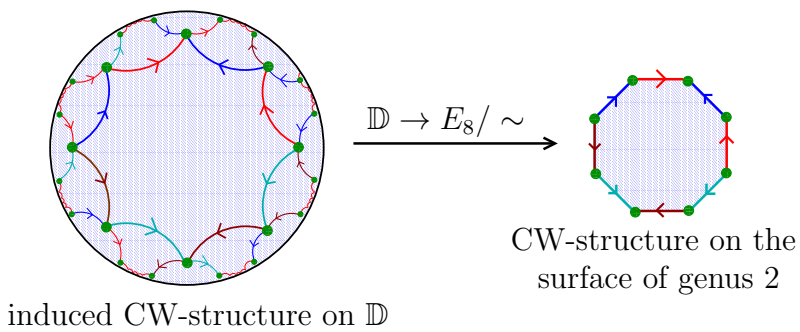

FIGURE 418.

We conclude this discussion of CW-complexes with an application to group theory. Given a free group F, i.e. given a group F that is isomorphic to the free group $\langle S\rangle$ generated by some set S we refer to the cardinality of S as the *rank* of F.[531]

Now we can formulate the following corollary to Proposition 26.25. The statement is purely group theoretic, but it is surprisingly hard to prove the statement without appealing to topological methods.[532]

Corollary 26.26. *Let F be a finitely generated free group.*

(1) *Every subgroup of F is again a free group.*[533]
(2) *If G is a finite-index subgroup of F, then*[534]

$$\operatorname{rank}(G) - 1 \;=\; [F : G] \cdot (\operatorname{rank}(F) - 1).$$

Examples.

[531]It follows from the discussions on the pages 417 and 368 that the rank of F is well-defined.

[532]Try to prove it using only group theoretic methods!

[533]This statement was first proved in 1927 by Otto Schreier [Schre].

[534]Does the equality hold if G is infinite-index and if we interpret $[F : G] \cdot (\operatorname{rank}(F) - 1)$, as usual, as $\infty \cdot (\operatorname{rank}(F) - 1) = \infty$ for $F \ncong \mathbb{Z}$?

(1) If $F = \mathbb{Z}$ then the formula from Corollary 26.26 does indeed show that every finite-index subgroup of $\mathbb{Z}$ is again a free group of rank one, i.e. every finite-index subgroup isomorphic to $\mathbb{Z}$.
(2) Let $\alpha\colon F := \langle a, b\rangle \to \mathbb{Z}_3$ be the epimorphism defined given by $\alpha(a) = 1$ and $\alpha(b) = 0$. It follows from Corollary 26.26 that the kernel $G := \ker(\alpha)$ is a free group of rank $[F : G] \cdot (\mathrm{rank}(F) - 1) + 1 = 3 \cdot 1 + 1 = 4$. In Exercise 26.7 we will determine four elements of $G = \ker(\alpha)$ that are generators for this free group.

Proof. Let F be a free group of rank m and let G be a subgroup of F. Let X be a 1-dimensional CW-complex with one 0-cell P and m 1-cells. By Proposition 27.9 we have $\pi_1(X, P) \cong F$.

By Proposition 26.11 (6) and Proposition 20.8 there exists a covering $p\colon (Y, Q) \to (X, P)$ of degree $[F : G]$ such that $p_*(\pi_1(Y, Q)) = G$. By Corollary 7.15 the map p_* is injective. Thus we see that $\pi_1(Y, Q)$ itself is isomorphic to G.

By Proposition 26.25 we can equip Y with the structure of a 1-dimensional CW-structure. We deduce from Proposition 27.9 that $G \cong \pi_1(Y, Q)$ is a free group.

Finally, suppose that G is in fact a finite-index subgroup of F. It follows from Proposition 26.25 that $\chi(Y) = [F : G] \cdot \chi(X)$. It is now a consequence of Proposition 27.9 that $\mathrm{rank}(G) - 1 = [F : G] \cdot (\mathrm{rank}(F) - 1)$. □

Remark.

(1) It is not hard to modify the proof of Corollary 26.26 to show that the subgroup of any free group (not necessarily finitely generated) is again a free group.
(2) There are purely group theoretic proofs of Corollary 26.26, see e.g. [Schre], [HallM, Theorem 7.2.1] or [Bau, Chapter III.3], but the topological proof that we had just provided is arguably the clearest proof.
(3) In principle one could have tried to prove Corollary 26.26 using spatial graphs in the sense of page 134 instead of using CW-complexes. But then one would have had to show that coverings of spatial graphs are again spatial graphs. This would have been exceedingly painful[535], whereas, as we have just seen in Proposition 26.25, it is almost a triviality to show that coverings of 1-dimensional CW-complexes are again 1-dimensional CW-complexes. This shows that sometimes it pays to use more abstract language to prove statements even about "basic objects".
(4) Corollary 26.26 is a special case of the *Kurosh Subgroup Theorem*. This theorem says that if G is the product of groups $A_i, i \in I$ and if H is a subgroup of G, then H is a free product of a free group and groups $B_i, i \in I$ where each B_i is a (potentially trivial) group that is conjugate to a subgroup of A_i. We refer to [LS, Theorem IV.1.10] for details and a proof.

Example. Let G be a graph with one vertex v and two edges which we denote by s and t. By a slight abuse of notation we denote the corresponding elements in $\pi_1(G, v)$ by s and t

[535] You can try to do this by hand.

as well. By Lemma 12.5 we can identify $\pi_1(G,v)$ with the free group $\langle s,t\rangle$ on the generators s and t. Now let $\phi\colon \pi_1(G,v) = \langle s,t\rangle \to \mathbb{Z}$ be the homomorphism that is given by $\phi(s) = 0$ and $\phi(t) = 1$. By Proposition 20.8 there exists a covering $q\colon (\widehat{G},\widehat{v}) \to (G,v)$ with $q_*(\pi_1(\widehat{G},\widehat{v})) = \ker(\phi)$, furthermore by Proposition 20.9 this covering is unique up to equivalence, in the sense of the definition on page 563.

We consider the infinite covering illustrated in Figure 148, which is very similar to the finite covering studied on pages 627.[536] For $i \in \mathbb{Z}$ we denote by x_i the loop in $(\widetilde{G},\widetilde{v})$ as illustrated in Figure 420. We denote by x_i also the corresponding element in $\pi_1(\widetilde{G},\widetilde{v})$. It follows from Proposition 26.27 that $\pi_1(\widetilde{G},\widetilde{v})$ equals the free group $\langle \dots x_{-2}, x_{-1}, x_0, x_1, x_2 \dots\rangle$. It is straightforward to see that

$$p_*(x_i) \;=\; t^i s t^{-i}.$$

By Corollary 7.15 the homomorphism p_* is a monomorphism. Thus we see that $t^i s t^{-i}$, $i \in \mathbb{Z}$, generate an infinitely generated free subgroup of the finitely generated generated free group $\langle s,t\rangle$. Furthermore we see that $p_*(\pi_1(\widetilde{G},\widetilde{v})) \subset \ker(\phi\colon \pi_1(G,v) \to \mathbb{Z})$. It is easy to see that the deck transformation group is isomorphic to $\mathbb{Z}$.

Now we claim that the coverings $p\colon \widetilde{G} \to G$ and $q\colon \widehat{G} \to G$ are equivalent. By Proposition 20.9 it suffices to show that $p_*(\pi_1(\widetilde{G},\widetilde{v})) = q_*(\pi_1(\widehat{G},\widehat{v}))$. We consider the following sequence of maps

$$\begin{array}{ccccccc}
\mathbb{Z} & \cong & D(p\colon \widetilde{G} \to G) & \cong & \pi_1(G,v)/p_*(\pi_1(\widetilde{G},\widetilde{v})) & \twoheadrightarrow & \pi_1(G,v)/\ker(\phi\colon \pi_1(G,v) \to \mathbb{Z}) \xrightarrow[\cong]{\phi} \mathbb{Z} \\
 & \uparrow & & \uparrow & & \uparrow & \\
 & \text{see above} & & \text{isomorphism of Proposition 24.6} & & \text{since } p_*(\pi_1(\widetilde{G},\widetilde{v})) \subset \ker(\phi\colon \pi_1(G,v) \to \mathbb{Z}) &
\end{array}$$

Thus, reading from left to right, we get an epimorphism from $\mathbb{Z}$ onto itself. But any such epimorphism has to be an isomorphism. It follows that the third map is also an isomorphism, i.e. $p_*(\pi_1(\widetilde{G},\widetilde{v})) = \pi_1(G,v)/\ker(\phi\colon \pi_1(G,v) \to \mathbb{Z})$, but the latter group is precisely $q_*(\pi_1(\widehat{G},\widehat{v}))$. So we get the desired equality of subgroups.

26.8. **Spanning trees of graphs** $(*)$**.** In Proposition 27.9 we saw that the fundamental group of every connected 1-dimensional CW-complex is a free group. In this short section we will specify more precisely what are generators of this free group. To do so we need the following definition.

Definition.

(1) A *tree* is a contractible graph.

[536]This covering can also be described rigorously. More precisely, we view G as the union of two copies A and B of S^1 glued along the common point 1. We define

$$\widetilde{G} \;=\; (\mathbb{R} \sqcup (S^1 \times \mathbb{Z}))/(n \sim (1,n)) \text{ for } n \in \mathbb{Z}.$$

Then the projection map

$$p\colon (\mathbb{R} \sqcup (S^1 \times \mathbb{Z}))/\sim \;\to\; G = (S^1 \times \{A\} \sqcup S^1 \times \{B\})/(1,A) \sim (1,B)$$

is given by $p(x) = (e^{2\pi i x}, A)$ for $x \in \mathbb{R}$ and $p((z,n)) = (z,B)$ for $(z,n) \in S^1 \times \mathbb{Z}$.

deck transformation is given by translation by $n \in \mathbb{Z}$

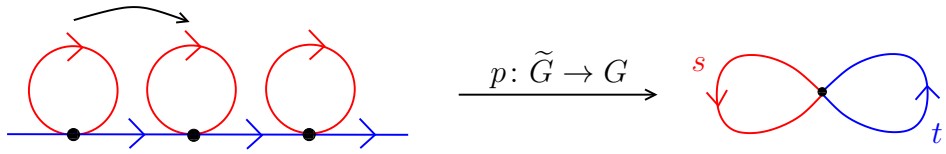

FIGURE 419.

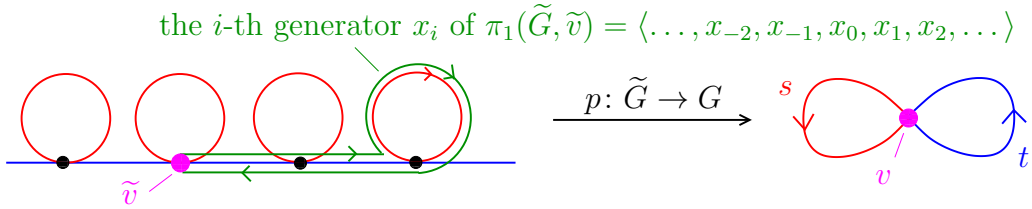

FIGURE 420.

(2) Let G be a graph. A *spanning tree* is a subcomplex T that is a tree and that contains all vertices of G.

Remark.

(1) It follows from Proposition 9.20 that the above definition of a tree is consistent with the definition that we had given on page 318.
(2) We leave it to the reader to show that for a finite group the above definition of a spanning tree is equivalent to the one we had given on page 320.

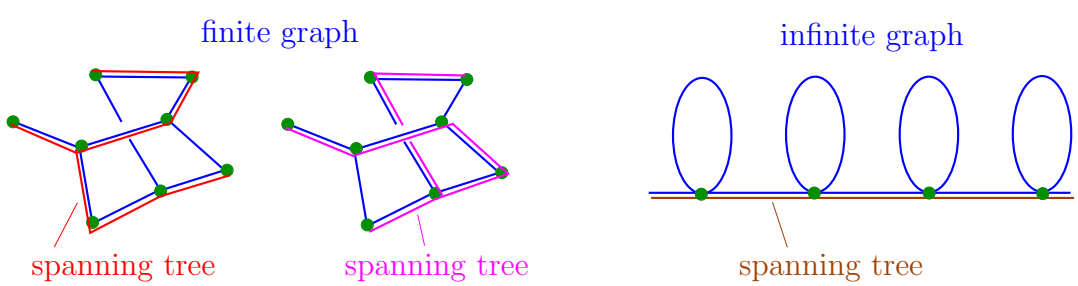

FIGURE 421.

In Figure 421 we give examples of spanning trees in graphs. We see in particular that in general there is no unique spanning tree. Now we can formulate the following generalization of Lemma 12.5.

Proposition 26.27. *Let G be a connected graph. Then the following holds:*

(1) *The graph G admits a spanning tree T. In fact, given any vertex P on G there exists a tree that admits a deformation retraction to P.*

(2) *The group $\pi_1(G)$ is isomorphic to a free group where the cardinality of the generating set equals the cardinality of the set of edges in $G \setminus T$.*

(3) *An explicit description of the isomorphism in (2) is given as follows. Pick a base point v in the spanning tree and for each cell e in $G \setminus T$ pick a path a_e from p to one of the endpoints and pick a path b_e from the other endpoint back to p*[537] *and let t_e be the loop given by first going along a_e, then going through e and then going back to the base point via b_e. Then the map*

$$\begin{array}{rcl} \left\langle \{x_e\}_{e \text{ edge in } G \setminus T} \right\rangle & \to & \pi_1(G, v) \\ x_e & \mapsto & [t_e] \end{array}$$

is an isomorphism.

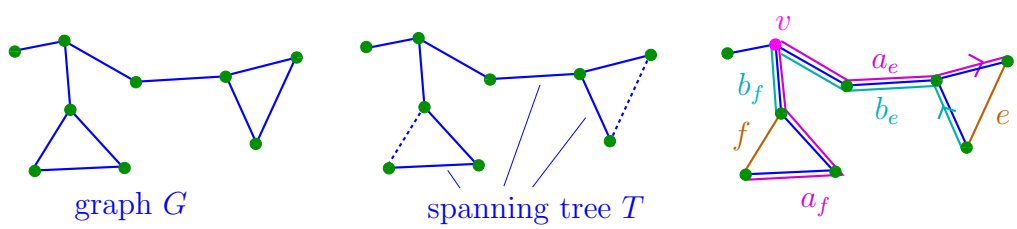

FIGURE 422.

Sketch of proof. We only provide an outline of the proof. The full details can be found in [Hat, p. 84] or [FPi, Lemma 2.6.3]. Let G be a connected graph.

(1) We pick a vertex P on G. We define $V_0 = \{P\}$ and iteratively we define for $i \geq 1$ the set V_i to be the set of all vertices that are not contained in V_{i-1} but that are connected to a vertex in V_{i-1} by an edge. Now we define $T_0 = \{P\}$. Once T_{i-1} is defined we pick for each vertex in V_i a single edge that connects the vertex to a vertex in V_{i-1}. Then it shown in [Hat, Proposition 1.A.1] that $\bigcup_{i \geq 0} T_i$ is a spanning tree.[538]

(2) If G is a finite graph, then the argument of the proof of Proposition 9.21 shows that the projection map $G \to G/T$ is a homotopy equivalence. The same statement also holds if G is an infinite graph, in this case the statement is proved in [Hat, Proposition 1.A.2]. The topological space G/T is again a graph with one vertex, given by the point $[T] \in G/T$ and an edge for each edge in $G \setminus T$. In particular G/T is homeomorphic to the wedge of circles, one for each edge in $G \setminus T$. It then follows from the straightforward generalization of Proposition 12.3 to the case of the wedge

[537] The two paths exist since a tree is in particular connected.

[538] Since G is connected, every vertex lies in some V_i, hence each vertex lies in some T_i. It is also straightforward to see that each T_i is the deformation retract of T_{i+1}. Now one just needs to work a little harder to show that $T_0 = \{P\}$ is a deformation retract of T, i.e. T is contractible.

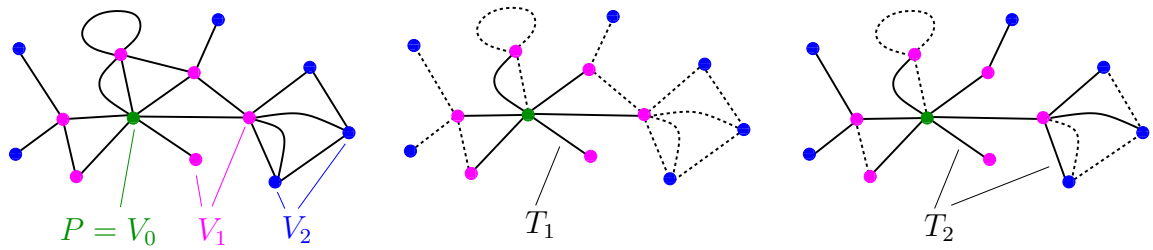

FIGURE 423.

of arbitrarily many topological spaces that the fundamental group of such a wedge of circles is the free group, where the generators correspond precisely to the circles, i.e. the edges in $G \setminus T$. □

Exercises for Chapter 26.

Exercise 26.1.

(a) Is every compact subset of $\mathbb{R}^2$ a CW-complex?
(b) Is the open ball $B_1(0)$ a CW-complex?
(c) Let X be a CW-complex and let $x \in X$. Show that $\{x\}$ is a closed subset of X.

Exercise 26.2.

(a) We equip $\mathbb{R}^\infty$ with the metric that is given by

$$d((x_1, x_2, \dots), (y_1, y_2, \dots)) \ := \ \sqrt{\sum_{i=1}^{\infty} |x_i - y_i|^2}.$$

We consider the following two topologies on $\mathbb{R}^\infty$:

$$\mathcal{S} \ := \ \{U \subset \mathbb{R}^\infty \mid \text{ for every } P \in U \text{ there exists } \epsilon > 0 \text{ such that } B_\epsilon(P) \subset U\}$$

and

$$\mathcal{T} \ := \ \{U \subset \mathbb{R}^\infty \mid \text{for every } n \in \mathbb{N} \text{ the set } U \cap \mathbb{R}^n \text{ is open in } \mathbb{R}^n\}.$$

Show that $\mathcal{S} \subset \mathcal{T}$.

(b) We view $\mathbb{R}^\infty$ as equipped with the topology $\mathcal{S}$. Does the Heine-Borel Theorem hold in $\mathbb{R}^\infty$? More precisely, is every bounded closed subset of $\mathbb{R}^\infty$ compact?
(c) We view $\mathbb{R}^\infty$ as equipped with the topology $\mathcal{T}$. Show that the projection map $p\colon \mathbb{R}^\infty \to \mathbb{R}^n$ is continuous and open.

Exercise 26.3. Show that the action

$$\begin{array}{rcl} \{\pm 1\} \times S^\infty & \to & S^\infty \\ (\epsilon, v) & \mapsto & \epsilon \cdot v \end{array}$$

of the group $\{\pm 1\}$ on the topological space S^∞ is continuous and discrete.

Exercise 26.4. Let $A = S^1 \times [0, 1]$ be an annulus.

(a) (i) We consider

$$X := \Big(\bigcup_{k\in\mathbb{N}_0} A\times\{k\}\Big)/(z,0,k)\sim(z^2,1,k-1) \quad \text{for } z\in S^1, k\in\mathbb{N}.$$

What is $\pi_1(X)$?

(ii) We consider

$$Y := \Big(\bigcup_{k\in\mathbb{N}_0} A\times\{-k\}\Big)/(z,0,-k)\sim(z^2,1,-k-1) \quad \text{for } z\in S^1, k\in\mathbb{N}.$$

What is $\pi_1(Y)$?

In both cases the group you obtain is an abelian group that is a subgroup of $(\mathbb{R},+)$.

(b) Give an example of topological space Z such that $\pi_1(Z)\cong(\mathbb{Q},+)$.

Exercise 26.5. We equip $\mathbb{R}\mathrm{P}^2$ with the CW-structure with one cell in dimensions $0,1,2$. Let $p\colon S^2\to\mathbb{R}\mathrm{P}^2 = S^2/\pm 1$ be the usual 2-fold covering. The CW-structure on $\mathbb{R}\mathrm{P}^2$ induces a CW-structure on S^2. What does this CW-structure on S^2 look like?

Exercise 26.6. We consider the following subset of $\mathbb{R}^2$:

$$X := \bigcup_{n\in\mathbb{N}} \text{circle of radius } \tfrac{1}{n} \text{ around } (\tfrac{1}{n},0) = \bigcup_{n\in\mathbb{N}} \{(x,y)\in\mathbb{R}^2 \mid (x-\tfrac{1}{n})^2+y^2=\tfrac{1}{n^2}\}.$$

This subset, equipped with the subspace topologically is colloquially referred to as the *Hawaiian earrings*, see Figure 424 for an illustration.

(a) Let $A=\{0\}\cup\{\frac{1}{n}\mid n\in\mathbb{N}\}$. Show that X is homeomorphic to $[0,1]/A$.
Remark: We encountered the topological space $[0,1]/A$ in Exercise 1.36.
(b) Show that X is compact.
(c) Is X homeomorphic to the wedge of countably infinitely many circles?
(d) Show that $\pi_1(X)$ is infinitely generated.
(e) Even better than (d): Show that $\pi_1(X)$ is uncountable generated.
(f) Can X be equipped with a CW-structure?

The combination of (b) and (d) implies, perhaps somewhat surprisingly, that there exist compact topological spaces whose fundamental groups are infinitely generated.
Remark: The precise determination of $\pi_1(X)$ is actually rather delicate, we refer to [MoM] and [Smi] for details. In particular, despite appearances, it is shown in [Smi] that $\pi_1(X)$ is not a free group.

Exercise 26.7. Let $\alpha\colon\langle a,b\rangle\to\mathbb{Z}_3$ be the epimorphism defined given by $\alpha(a)=1$ and $\alpha(b)=0$. Furthermore let X be the wedge of two circles A and B. As usual we equip X with the CW-structure with one 0-cell P and two 1-cells a and b. Furthermore we make the identification $\pi_1(X)=\langle a,b\rangle$.

(a) "Construct" the covering $p\colon\widetilde{X}\to X$ corresponding to $\ker(\alpha)$, i.e. construct the covering p such that $p_*(\pi_1(\widetilde{X}))=\ker(\alpha)$. More precisely, give the CW-structure on $\widetilde{X}$ and indicate, e.g. using colors, the cellular map p.

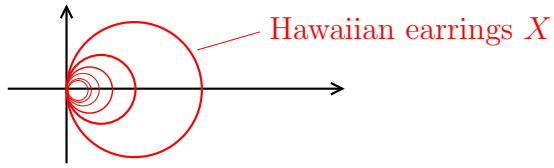

FIGURE 424.

(b) We know from Corollary 26.26 that $\ker(\alpha)$ is a free group on four generators. Determine four elements of $\ker(\alpha)$ that generate $\ker(\alpha)$ as a free group. You do not have to justify your answer.

27. CW-complexes II: Advanced properties

In this chapter we will prove several key technical theorems on CW-complexes, in particular we will prove the Homotopy Extension Theorem 27.4 and the Cellular Approximation Theorem 27.15. The reader who is in a hurry could just have a look at the Cellular Approximation Theorem 27.15 and then move on.

27.1. **Constructing homotopies on infinite-dimensional CW-complexes** $(*)$**.** On several occasions throughout these notes we will want to construct a homotopy on an infinite-dimensional CW-complex by working our way up through the skeleta. In the end one needs to combine infinitely many homotopies which obviously leads to continuity issues. This rather technical section deals with these issues. It is best to initially skip this section and to go back to it if later on one really wants to know how an argument works.

We start out with the following subtle lemma.

Lemma 27.1. *Let X be a CW-complex.*

(1) *The following two topologies on $X \times [0,1]$ agree:*
   (a) *The product topology on the product $X \times [0,1]$.*
   (b) *The topology on $X \times [0,1]$ viewed as the direct limit $\varinjlim (X^k \times [0,1])$. In other words, as discussed on page 488, this is the topology where a given subset W of $X \times [0,1] = \varinjlim (X^k \times [0,1])$ is open if and only each intersection $W \cap (X^k \times [0,1])$ is an open subset of $X^k \times [0,1]$.*

(2) *A map $\Phi\colon X \times [0,1] \to Y$ to a topological space Y is continuous if and only if all the restrictions to $X^k \times [0,1]$, $k \in \mathbb{N}_0$, are continuous.*

Proof. Let X be a CW-complex. First note that second statement is an immediate consequence of the of the first statement. Also, it follows immediately from the fact that $X = \varinjlim X_k$ that any set that is open with respect to (a) is also open with respect to (b). Thus it suffices to show that any set that is open with respect to (b) is also open with respect to (a).

Let $W \subset X \times [0,1]$ be a set that is open in $\varinjlim (X^k \times [0,1])$. We need to show that W is also open with respect to the product topology on $X \times [0,1]$. Let $(x_0, t_0) \in W$ be a point. By Lemma 1.59 it suffices to show that there exists a neighborhood V of $x_0 \in X$ and a neighborhood K of $t_0 \in [0,1]$ such that $V \times K$ is contained in W. We start out with the following claim.

Claim. There exists a compact neighborhood K of $t_0 \in [0,1]$ such that $\{x_0\} \times K \subset W$.

To prove the claim we pick $k \in \mathbb{N}_0$ with $x_0 \in X^k$. Since W is open in $\varinjlim (X^k \times [0,1])$ we know that the intersection $(X^k \times [0,1]) \cap W$ is an open neighborhood of $(x_0, t_0) \in X^k \times [0,1]$. By definition of the product topology on $X^k \times [0,1]$ there exists in particular an open neighborhood J of $t_0 \in [0,1]$ such that $\{x_0\} \times J \subset W \cap (X^k \times [0,1])$. In the topological

space $[0,1]$ any open neighborhood J of x_0 also contains a compact neighborhood K. This K has the desired properties. This concludes the proof of the claim.

Next we consider $V := \{x \in X \,|\, \{x\} \times K \subset W\}$. Note that $x_0 \in V$. Thus by the discussion in the beginning of the proof it remains to prove the following claim.

Claim. The subset V is open in X.

We use Lemma 26.8 to show that V is open in X. Thus let $\Phi_e \colon \overline{B}^n \to X$ be the characteristic map of an n-cell of X. We need to show that the preimage $\Phi_e^{-1}(V)$ is open in $\overline{B}^n$. We write $U := (\Phi_e \times \mathrm{id}_{[0,1]})^{-1}(W \cap (X^n \times [0,1]))$. Note that U is an open subset of $\overline{B}^n \times [0,1]$ since $W \cap (X^n \times [0,1])$ is open by our hypothesis on W and since the map $\Phi_e \times \mathrm{id}_{[0,1]} \colon \overline{B}^n \times [0,1] \to X^n \times [0,1]$ is continuous. Basically by definition we have the equality

$$\Phi_e^{-1}(V) \;=\; \{y \in \overline{B}^n \,|\, \{y\} \times K \subset U\}.$$

Now that we are dealing with $\overline{B}^n \times [0,1]$ it is an elementary topology exercise to show that the set on the right-hand side is indeed open. This concludes the proof of the second claim and thus of the lemma. □

In Lemma 9.2 we saw that one can combine finitely many homotopies. Later on we will want to combine infinitely many homotopies of CW-complexes. This slightly delicate procedure can be performed using the following lemma.

Lemma 27.2. *Let X be a CW-complex, let A be a subset of X and let Y be a topological space. Finally let $W_0 \subset W_1 \subset W_2 \subset \dots$ be a sequence of subcomplexes of X such that for each $k \in \mathbb{N}_0$ there exists an $l \in \mathbb{N}_0$ such that the k-skeleton X^k is contained in W_l. (In many applications we have $W_k = X^k$.) Let $f_0, f_1, \dots$ be maps from X to Y. Suppose that for each $k \in \mathbb{N}_0$ we are given a homotopy $H(k) \colon X \times [0,1] \to Y$ rel $A \cup W_k$ from f_k to f_{k+1}. (Since it is easy to overlook this bit of the hypothesis we stress that $H(k)$ is in particular a homotopy rel W_k). We define*[539]

$$\begin{array}{rcl} g \colon X & \to & Y \\ x & \mapsto & f_k(x) \quad \textit{where } k \in \mathbb{N}_0 \textit{ such that } x \in W_k. \end{array}$$

For $k = 0, 1, 2, \dots$ we write $s_k = \sum_{j=1}^{k} \frac{1}{2^j}$. Then the map

$$\begin{array}{rcl} H \colon X \times [0,1] & \to & Y \\ (x,t) & \mapsto & \begin{cases} H(k)(x, 2^{k+1} \cdot (t - s_k)), & \textit{if } t \in [s_k, s_{k+1}), \\ g(x), & \textit{if } t = 1 \end{cases} \end{array}$$

that is illustrated in Figure 425 is a homotopy from f_0 to g. We refer to the homotopy H as the combination of $\{H(k)\}_{k \in \mathbb{N}_0}$.

[539] It follows easily from the setup that the map g is well-defined, i.e. given $x \in X$ the point $g(x)$ does not depend on the choice of k.

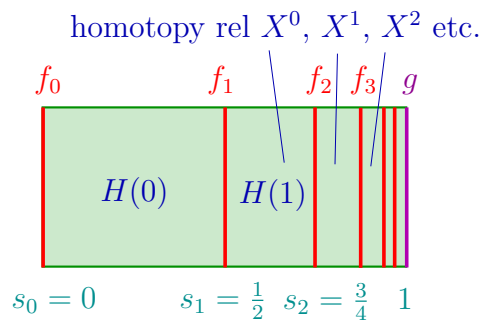

FIGURE 425. Illustration of Lemma 27.2.

Proof. We only need to show that H is continuous. Note that for each $l \in \mathbb{N}_0$ it follows from our choice of maps f_l and Lemma 5.3 that the restriction of H to $W_l \times [0,1]$ is continuous. Since each X^k is contained in some W_l we see that the restriction of H to each $X^k \times [0,1]$ is continuous. But now it follows from Lemma 27.1 (2) that $H\colon X \times [0,1] \to Y$ is also continuous. □

We conclude this technical section with an application that we will need once on a much later occasion. But the application doubles also a nice illustration for how to apply the previous lemma.

Definition. Let Z be a CW-complex. We equip $[0,\infty)$ with the CW-structure where the 0-skeleton is given by $\mathbb{N}_0$. We equip $Z \times [0,\infty)$ with the product CW-structure. We refer to the subcomplex

$$T(Z) \;:=\; \bigcup_{i \in \mathbb{N}_0} Z^i \times [i, i+1] \quad \subset \; Z \times [0,\infty)$$

as the *telescope of* Z..

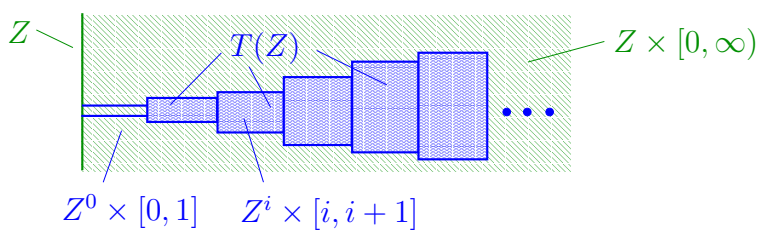

FIGURE 426.

The following lemma shows that the telescope $T(Z)$ is homotopy equivalent to Z.

Lemma 27.3. *Let Z be a CW-complex. Suppose we are in the following situation:*

($*$) *For each $k \in \mathbb{N}_0$ we are given a deformation retraction r_k from $Z \times [0,1]$ to the subset $(Z^k \times [0,1]) \cup (Z \times \{1\})$. (Later on in Lemma 27.8 we will see that such that a deformation retraction always exists.)*

The following statements hold:

(1) *$T(Z)$ is a deformation retract of $Z \times [0,\infty)$.*
(2) *The telescope $T(Z)$ is homotopy equivalent to Z.*

Proof. First note that $Z = Z \times \{0\}$ is clearly a deformation retract of $Z \times [0,\infty)$. Thus it follows from Lemmas 9.10 and 9.8 that (2) is a consequence of (1). Therefore it remains to prove (1).

As in the definition of the telescope $T(Z)$ we view $[0,\infty)$, $X := Y := Z \times [0,\infty)$ and $T(Z)$ as CW-complexes. For each $k \in \mathbb{N}_0$ we are given a deformation retraction

$$r_k \colon (Z \times [0,1]) \times [0,1] \;\to\; Z \times [0,1]$$

from $Z \times [0,1]$ to $(Z^k \times [0,1]) \cup (Z \times \{1\})$. We denote by

$$\begin{array}{rcl} \rho_k \colon Z \times [k,k+1] & \to & (Z^{k-1} \times [k,k+1]) \cup (Z^k \times \{k+1\}) \\ (z,t) & \mapsto & (r_k(z,t-k) + (0,k), 1) \end{array}$$

the corresponding retraction, with the intervals shifted by k. We make the following preparations:

(1) Given $k \in \mathbb{N}_0$ we define $W_k := Z^k \times [0,\infty)$. Note that it follows from the definition of the product CW-structure on $Z \times [0,\infty)$ that the k-skeleton of $X = Z \times [0,\infty)$ is contained in W_{k+1}.
(2) For each $k \in \mathbb{N}_0$ we consider the map

$$\begin{array}{rcl} f_k \colon X = Z \times [0,\infty) & \to & Y = Z \times [0,\infty) \\ (z,t) & \mapsto & \begin{cases} (z,t), & \text{if } x \in Z^k \text{ and } t \geq k+1, \\ (\rho_k \circ \cdots \circ \rho_1 \circ \rho_0)(x), & \text{if } z \in Z^k \text{ and } t < k+1. \end{cases} \end{array}$$

(3) We consider the map

$$\begin{array}{rcl} H(k) \colon X \times [0,1] & \to & Y = Z \times [0,\infty) \\ ((z,t),s) & \to & \begin{cases} (z,t), & \text{if } t \geq k+1, \\ r_{k+1}(\rho_k(z,t),s), & \text{if } t < k+1. \end{cases} \end{array}$$

This defines a homotopy from f_k to f_{k+1} rel W_k. Note that $H(0)_1 = \mathrm{id}_X$.

As in the statement of Lemma 27.2 we consider the map

$$\begin{array}{rcl} g \colon X & \to & Y \\ x & \mapsto & f_k(x) \quad \text{where } k \in \mathbb{N}_0 \text{ such that } x \in W_k. \end{array}$$

One can easily verify that this is a retraction of $X = Z \times [0,\infty)$ to the telescope $T(Z)$. It follows from Lemma 27.2 that there exists a homotopy from $H(0)_1 = \mathrm{id}$ to g, i.e. $T(Z)$ is in fact a deformation retract of $X = Z \times [0,\infty)$. $\square$

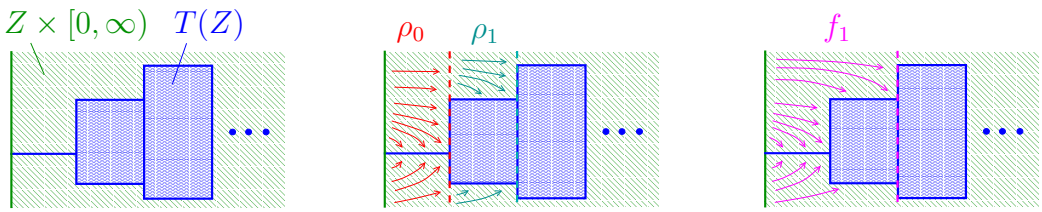

FIGURE 427.

27.2. **The Homotopy Extension Theorem.** On several occasions we will need the following somewhat technical theorem.

Theorem 27.4. (Homotopy Extension Theorem) *Let X be a CW-complex, let Y be a topological space and let $f_0\colon X \to Y$ be map. Furthermore, suppose that $A \subset X$ is a subcomplex and suppose we are given a homotopy $G\colon A \times [0,1] \to Y$ from $g_0 := f_0|_A$ to some map $g_1\colon A \to Y$. Then there exists a homotopy $F\colon X \times [0,1] \to Y$ starting from f_0 such that the restriction $F|_{A\times[0,1]}$ equals G.*

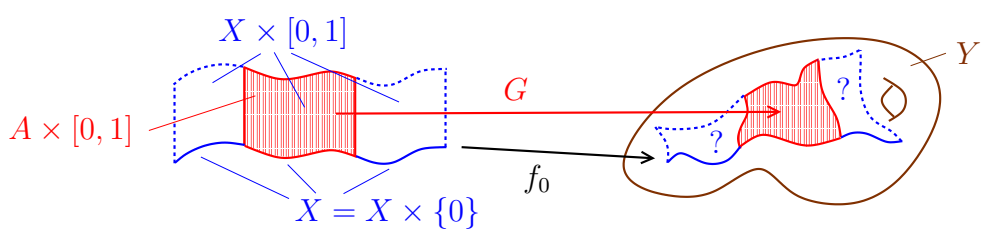

FIGURE 428. Illustration of the Homotopy Extension Theorem 27.4.

Remark. The statement of the Homotopy Extension Theorem does not hold for arbitrary subsets of X. For example, let $X = \mathbb{R}$ and $A = (0,1)$. We write $Y = \mathbb{R} \times \{0\} \cup (0,1) \times [0,1]$ and let $f\colon X \to Y$ be the obvious inclusion map and let $G\colon (0,1) \times [0,1] \to Y$ be the obvious inclusion map. (See Figure 429 for an illustration.) It is an amusing exercise to show that G cannot be extended to a homotopy on all of $\mathbb{R}$.[540] It is an equally amusing exercise to show that the homotopy can be extended if throughout we replace the open interval $A = (0,1)$ by the closed interval $A = [0,1]$.

Before we delve into the long and strenuous proof of the Homotopy Extension Theorem 27.4 let us prove the following neat corollary.

Corollary 27.5. *Let X be connected CW-complex, let P be a point in the 0-skeleton of X and let Q be some other point on Y. There exists a map $h\colon X \to X$ with $h(P) = Q$ that is homotopic to the identity, in particular h is a homotopy equivalence.*

[540]Here is a hint: if there was an extension of G to a homotopy $F\colon X \times [0,1] \to Y$, what would/should $F(1,1)$ be?

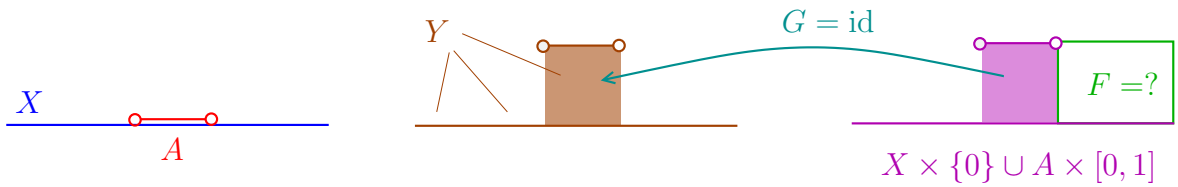

FIGURE 429.

Example. We consider the CW-complex X and the two points P and Q shown in Figure 430. It should be pretty clear that there is no homeomorphism f of X with $f(P) = Q$. But Corollary 27.5 gives us a decent replacement, namely a map $h\colon X \to X$ with $h(P) = Q$ which is homotopic to the identity.

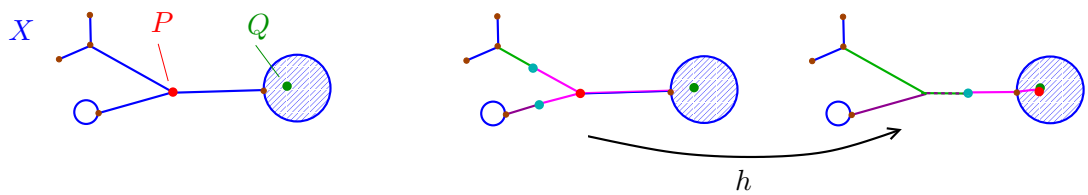

FIGURE 430.

Proof. Let X be connected CW-complex, let P be a point in the 0-skeleton of X and let Q be some other point on Y. We write $A := \{P0\}$. Since P is a point in the 0-skeleton of X we see that A is a subcomplex of A. Since X is connected we obtain from Proposition 26.11 that there exists a map $\gamma\colon [0,1] \to X$ with $\gamma(0) = P$ and $\gamma(1) = Q$. We apply the Homotopy Extension Theorem 27.4 to $f_0 = \mathrm{id}\colon X \to X$, $g_0(P) := P$, $g_1(P) = Q$ and $G(P,t) = \gamma(t)$. The resulting homotopy $F\colon X \times [0,1] \to X$ and $h := F_1$ give us the desired homotopy and the desired map. Since id is a homotopy equivalence and since $h = F_1$ is homotopic to $\mathrm{id} = F_0$ we obtain from Lemma 9.8 that h is also a homotopy equivalence. □

Before we can provide the proof of Theorem 27.4 we will need to formulate and prove several lemmas.

Lemma 27.6. *For any $n \in \mathbb{N}_0$ there exists a deformation retraction from the solid cylinder $\overline{B}^n \times [0,1]$ to the "cup" $\overline{B}^n \times \{0\} \cup S^{n-1} \times [0,1]$.*

Proof. It is straightforward to verify that the map

$$\begin{array}{rcl} r\colon \overline{B}^n \times [0,1] & \to & (\overline{B}^n \times \{0\}) \cup (S^{n-1} \times [0,1]) \\ P & \mapsto & \text{the unique point on } \overline{B}^n \times \{0\} \cup S^{n-1} \times [0,1] \text{ that} \\ & & \text{gets hit by the ray from } (0,2) \in \mathbb{R}^n \times \mathbb{R} \text{ through } P. \end{array}$$

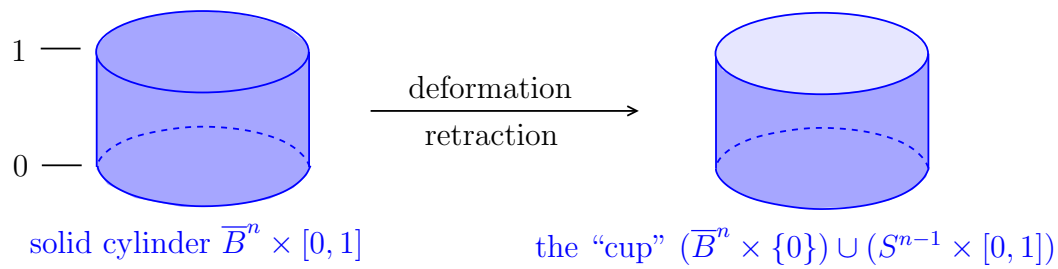

FIGURE 431.

is a retraction. We refer to Figure 432 for an illustration. Since $\overline{B}^n \times [0,1]$ is convex we can define the corresponding deformation retraction as follows:

$$\begin{array}{rcl} (\overline{B}^n \times [0,1]) \times [0,1] & \to & \overline{B}^n \times [0,1] \\ (P,t) & \mapsto & P \cdot (1-t) + r(P) \cdot t. \end{array}$$

□

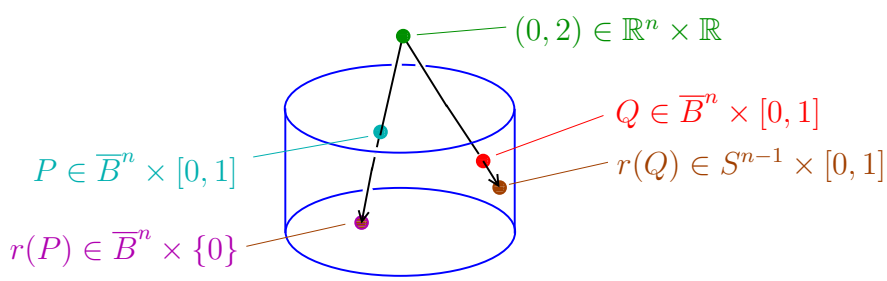

FIGURE 432.

Lemma 27.7. *If X is a CW-complex and if A is a subcomplex of X, then there exists a retraction from $X \times [0,1]$ to the subcomplex $(X \times \{0\}) \cup (A \times [0,1])$.*

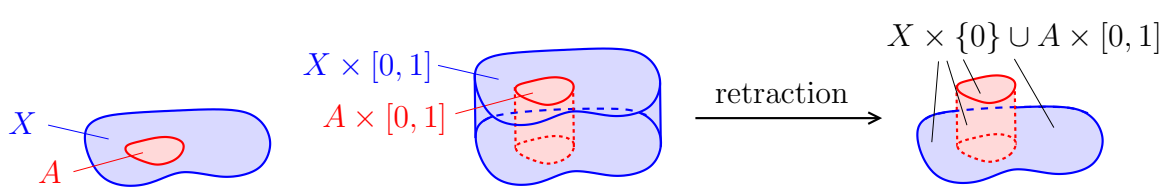

FIGURE 433. Illustration of Lemma 27.7.

Proof. Let X be a CW-complex and let A be a subcomplex. We start out with the following claim.

Claim. For every $n \in \mathbb{N}_0$ there exists a retraction

$$r_n \colon X \times \{0\} \ \cup \ (X^n \cup A) \times [0,1] \ \to \ X \times \{0\} \ \cup \ (X^{n-1} \cup A) \times [0,1].$$

Let $n \in \mathbb{N}_0$. We denote by $\varphi_i \colon \overline{B}^n \to X$, $i \in I$, the characteristic maps of all the n-cells of X that do not lie in A. By Lemma 27.6 there exists a retraction r from $\overline{B}^n \times [0,1]$ to $\overline{B}^n \times \{0\} \cup S^{n-1} \times [0,1]$. The idea is to apply this retraction to all k-cells of X to obtain the desired retraction. More precisely we consider the map

$$\begin{aligned} r_n \colon X \times \{0\} \cup (X^n \cup A) \times [0,1] \ &\to \ X \times \{0\} \cup (X^{n-1} \cup A) \times [0,1] \\ (P,t) \ &\mapsto \ \begin{cases} \varphi_i(r(Q,t)), & \text{if } P = \varphi_i(Q) \text{ with } Q \in \overline{B}^n \text{ and } i \in I, \\ (P,t), & \text{otherwise.} \end{cases} \end{aligned}$$

This map is easily seen to be a retraction.[541] This concludes the proof of the claim.

Now we turn to the actual proof of the lemma. For clarity we first consider the case that X is a finite-dimensional CW-complex. So let $n \in \mathbb{N}_0$ be the dimension of the CW-complex X. We denote by $r_0, \dots, r_n$ the retractions from the claim. Then the map

$$s_n := r_0 \circ r_1 \circ \cdots \circ r_n \colon \underbrace{X \times \{0\} \cup (X^n \cup A) \times [0,1]}_{= X \times [0,1]} \ \to \ \underbrace{X \times \{0\} \cup (X^{-1} \cup A) \times [0,1]}_{= X \times \{0\} \cup A \times [0,1]}$$

is the desired retraction. We refer to Figure 434 for an illustration of the argument.

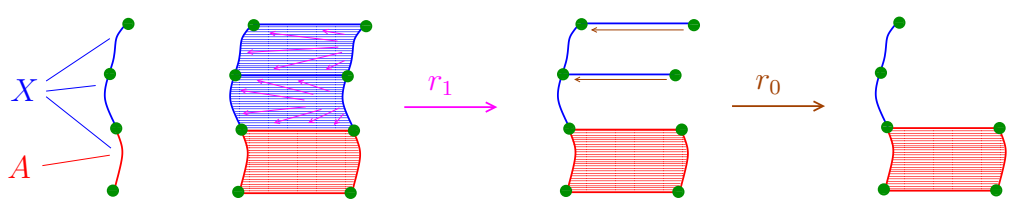

FIGURE 434.

Now we turn to the general case, i.e. X can now be infinite-dimensional. As before we denote by $r_0, r_1, \dots$ the retractions provided by the claim and given $k \in \mathbb{N}_0$ we again consider the retraction

$$s_k := r_0 \circ \cdots \circ r_k \colon X \times \{0\} \cup (X^k \cup A) \times [0,1] \ \to \ X \times \{0\} \cup (A \times [0,1]).$$

We consider the following map

$$\begin{aligned} H \colon X \times [0,1] \ &\to \ X \times \{0\} \cup A \times [0,1] \\ (x,t) \ &\mapsto \ s_k(x,t) \quad \text{if } x \in X^k. \end{aligned}$$

We make the following observations:

(1) It follows immediately from the fact that the r_k are appropriate retractions that the map H is well-defined, i.e. given $(x,t) \in X \times [0,1]$ the value of $s_k(x,t)$ is independent of the choice of k.

[541] It follows from Lemma 26.8 that the map is in fact continuous.

(2) Let $k \in \mathbb{N}_0$. By (1) the restriction of H to $X^k \times [0,1]$ agrees with the restriction of the map s_k to $X^k \times [0,1]$. The map s_k is the composition of finitely many continuous maps, thus continuous. It follows from Lemma 27.1 (2) that the map s on $X \times [0,1]$ is continuous with respect to the usual product topology.
(3) It follows immediately from the definition of H that it is the identity on the subset $(X \times \{0\}) \cup (A \times [0,1])$ of $X \times [0,1]$.

We have thus shown that H is indeed the desired retraction. □

In one situation later on we will need the following stronger version of Lemma 27.7. For most readers it is best to skip this lemma.

Lemma 27.8. $(*)$ *If X is a CW-complex and if A is a subcomplex of X, then there exists a* deformation *retraction from $X \times [0,1]$ to the subcomplex $(X \times \{0\}) \cup (A \times [0,1])$.*

Proof $(*)$. Let X be a CW-complex and let A be a subcomplex. Using the fact that the retraction in Lemma 27.6 comes actually from a deformation retraction one can show, using basically the same argument as in Lemma 27.8, that for every $n \in \mathbb{N}_0$ there exists a *deformation* retraction

$$R(n)\colon (X \times \{0\} \ \cup \ (X^n \cup A) \times [0,1]) \times [0,1] \ \to \ X \times \{0\} \ \cup \ (X^{n-1} \cup A) \times [0,1].$$

We denote by $r_n := R(n)_1$ the corresponding retraction. For each $k \in \mathbb{N}$ we consider the map

$$\begin{array}{rcl} f_k\colon X \times [0,1] & \to & (X^{k-1} \cup A) \times [0,1] \\ (x,t) & \mapsto & \begin{cases} (r_k \circ \cdots \circ r_l)(x,t), & \text{if } x \in X^l \text{ and } l \geq k, \\ (x,t), & \text{if } x \in X^{k-1}. \end{cases} \end{array}$$

It follows from Lemma 27.1 (2) that this map f_k is continuous. Now we consider the following map

$$\begin{array}{rcl} F\colon (X \times [0,1]) \times [0,1] & \to & X \times [0,1] \\ ((x,t),s) & \mapsto & \begin{cases} (x,t), & \text{if } x \in X^k \text{ and } t \in [0, \frac{1}{2^{k+1}}], \\ r_k\big((x,t), 2^{k+1} \cdot (s - \frac{1}{2^{k+1}})\big), & \text{if } x \in X^k \text{ and } t \in [\frac{1}{2^{k+1}}, \frac{1}{2^k}], \\ f_k(x,t), & \text{if } x \in X^k \text{ and } t \in [\frac{1}{2^k}, 1]. \end{cases} \end{array}$$

We refer to Figure 435 for an illustration. It follows from Lemma 5.3 that the restriction of F to each $(X^k \times [0,1]) \times [0,1]] = (X \times [0,1])^{k+1} \times [0,1]$ is continuous. Thus it follows from Lemma 27.1 (2) that $F\colon X \times [0,1] \to X \times [0,1]$ is continuous. This map is the desired deformation retraction. □

Now we can easily provide a proof of Theorem 27.4.

Proof of Theorem 27.4. Let X be a CW-complex, let Y be a topological space and let $f_0\colon X \to Y$ be map. Furthermore, suppose that $A \subset X$ is a subcomplex and suppose we are given a homotopy $G\colon A \times [0,1] \to Y$ from $g_0 := f_0|_A$ to some map $g_1\colon A \to Y$. By Lemma 27.7 there exists a retraction

$$H\colon X \times [0,1] \ \to \ (X \times \{0\}) \cup (A \times [0,1]).$$

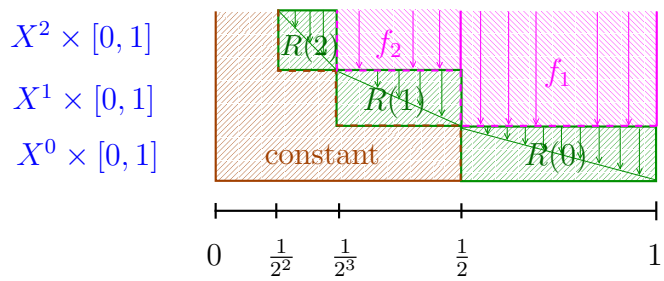

FIGURE 435. Illustration for the proof of Lemma 27.8.

The theorem follows from the following claim.

Claim. The map

$$\begin{array}{rcccl} F\colon X \times [0,1] \xrightarrow{H} (X \times \{0\}) \cup (A \times [0,1]) & \to & Y & & \\ (x,0) & \mapsto & f_0(x), & \text{for } x \in X, \\ (a,t) & \mapsto & G(a,t), & \text{for } (a,t) \in A \times [0,1]. \end{array}$$

has all the desired properties.

First we have to verify that the map is continuous. In fact, for continuity we do have to worry a little bit about the right-hand map. But note that Lemma 26.10 (2) says that the subcomplex A is a closed subset of X. Thus we see that the map on the right-hand side is continuous when restricted to the *closed* subsets $X \times \{0\}$ and $A \times [0,1]$. Thus it is continuous by Lemma 1.32 (2). Note it is clear that F has the desired properties, i.e. that it is a homotopy $F\colon X \times [0,1] \to Y$ starting from f_0 such that the restriction $F|_{A\times[0,1]}$ equals G. This concludes the proof of the claim. □

27.3. **Fundamental groups of CW-complexes.**

Definition. Given a finite CW-complex X we define its Euler characteristic $\chi(X)$ as follows:

$$\chi(X) \;:=\; \sum_n (-1)^n \cdot \text{number of } n\text{-cells}.$$

Examples.

(1) If G is a finite graph, then, according to the discussion on page 645, we can view G as a CW-complex. In this case the Euler characteristic agrees with the definition of the Euler characteristic of a graph that we gave on page 318.
(2) For the CW-structures provided by Lemma 26.2 we have $\chi(\mathbb{R}\mathrm{P}^n) = \frac{1}{2}(1 + (-1)^n)$ and $\chi(\mathbb{C}\mathrm{P}^n) = n + 1$.
(3) A short glance at the three examples in Figure 399 shows that these three different CW-structures for the torus have the same Euler characteristic. Later on we will find out whether or not that is a coincidence.

Proposition 27.9. *Let X be a connected 1-dimensional CW-complex and let $x_0 \in X$. Then the following hold:*

(1) *The fundamental group $\pi_1(X, x_0)$ is a free group.*
(2) *If X is a finite CW-complex, then $\pi_1(X, x_0)$ is a free group with $1-\chi(X)$ generators.*

Proof. In Lemma 12.5 we showed that if G is a finite connected graph, then $\pi_1(G)$ is a free group with $1 - \chi(G)$ generators. Verbatim the same proof applies to finite 1-dimensional CW-complexes, which proves (2).

Now we turn to the proof of (1). We will only provide the proof for the case that X has countably many cells. The general case is proved in [Hat, Proposition 1.A.1]. Thus let X be a connected countable 1-dimensional CW-complex and let $x_0 \in X$. If X is finite, then we are already done by the above argument. So suppose that X is infinite. Since X is connected this implies that X has infinitely many 1-cells. We start out with the following claim.

By Proposition 26.17 there exists a sequence of finite connected subcomplexes A_i, $i \in \mathbb{N}_0$ with the following properties:

(a) each A_i is a subcomplex of A_{i+1},
(b) $X = \bigcup_{i \in \mathbb{N}_0} A_i$.

By Proposition 5.11 we can assume without loss of generality that x_0 is a point in A_1.

The proof of the following claim is a slight generalization of the proof of Lemma 12.5. We leave the details as an exercise to the reader.

Claim. Let C be a connected finite 1-dimensional CW-complex and let B be a connected subcomplex. Let $x \in B$. Suppose we are given a finite set b and an isomorphism $\phi\colon \pi_1(B, x) \cong \langle b \rangle$. Then there exists a finite set c, disjoint from b, and an isomorphism $\psi\colon \pi_1(C, x) \cong \langle b \sqcup c \rangle$ such that the following diagram commutes:

$$\begin{array}{ccc} \pi_1(B, x) & \xrightarrow{\cong} & \langle b \rangle \\ \downarrow & & \downarrow \\ \pi_1(C, x) & \xrightarrow{\cong} & \langle b \sqcup c \rangle, \end{array}$$

where the left vertical map is the inclusion induced map and the right vertical map is the obvious map.

Iteratively we apply the claim to the above sequence $A_0, A_1, A_2, \dots$ of connected 1-dimensional CW-complexes and we obtain disjoint finite sets $a_0, a_1, a_2, \dots$ and identifications $\pi_1(A_i, x_0) = \langle a_0 \sqcup \cdots \sqcup a_i \rangle$. We obtain that

$$\pi_1(X, x_0) \underset{\substack{\uparrow \\ \text{Proposition 26.19}}}{\cong} \varinjlim \pi_1(A_i, x_0) = \varinjlim \langle a_0 \sqcup \cdots \sqcup a_i \rangle \underset{\substack{\uparrow \\ \text{as on page 484}}}{=} \Big\langle \bigsqcup_{i \in \mathbb{N}} a_i \Big\rangle.$$

We have thus shown that $\pi_1(X, x_0)$ is a free group. $\square$

The following definition is evidently inspired by the definition of a CW-complex.

Definition. Let X be a topological space and let $\varphi\colon S^{n-1} \to X$ be a map. We refer to $X \cup_\varphi \overline{B}^n$ as the *topological space X with an n-cell attached via the attaching map φ*. We refer to the image of $\overline{B}^n$ in $X \cup_\varphi \overline{B}^n$ as an n-cell.

The following proposition now tells us how attaching a cell affects the fundamental group of a given topological space.

Proposition 27.10. *Let X be a topological space, let $n \geq 2$, let $\varphi\colon S^{n-1} \to X$ be a map and let x_0 be a point in $\varphi(S^{n-1})$. Then the following hold:*

(a) *If $n > 2$, then the inclusion induced map $\pi_1(X, x_0) \to \pi_1(X \cup_\varphi \overline{B}^n, x_0)$ is an isomorphism.*

(b) *If $n = 2$, then $\varphi\colon S^1 \to X$ defines an element in $\pi_1(X, x_0)$ that we denote by $[\varphi]$, and the inclusion induced map $\pi_1(X, x_0) \to \pi_1(X \cup_\varphi \overline{B}^n, x_0)$ descends to an isomorphism*

$$\pi_1(X, x_0)/\langle\langle[\varphi]\rangle\rangle \xrightarrow{\cong} \pi_1\big(X \cup_\varphi \overline{B}^n, x_0\big).$$

Examples.

(1) Let $X = S^1$ and let $n \in \mathbb{N}$. We attach to S^1 a 2-cell via the attaching map $\varphi\colon S^1 \to S^1$ that is given by $\varphi(z) = z^n$. Then[542]

$$\pi_1\big(S^1 \cup_\varphi \overline{B}^2, 1\big) \underset{\substack{\uparrow \\ \text{by Proposition 27.10}}}{=} \pi_1(S^1, 1)/\langle[\varphi]\rangle \underset{\substack{\uparrow \\ \text{see Proposition 7.18}}}{=} \langle x\rangle/\langle x^n\rangle \cong \mathbb{Z}_n.$$

(2) We attach a 2-cell to $X = \mathbb{R}^2$ via the attaching map $\mathrm{id} = \varphi\colon S^1 \to S^1$ that is given by the identity. The resulting topological space is illustrated in Figure 436. This topological space is again simply connected by Proposition 27.10.

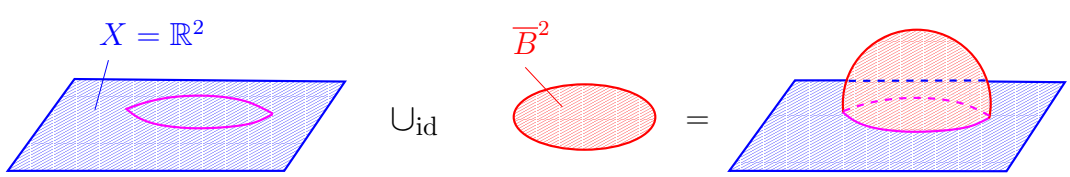

FIGURE 436.

(3) Using Propositions 27.9 and 27.10 we can now easily compute fundamental groups of finite CW-complexes. For example, as in Figure 437 we view the surface Σ of genus 2 as a CW-complex with one 0-cell P, four 1-cells x_1, y_1, x_2, y_2 and one 2-cell. We denote

[542] We leave it as an exercise to convince yourself that for $n = 2$ the topological space $S^1 \cup_\varphi \overline{B}^2$ is actually homeomorphic to $\mathbb{R}\mathrm{P}^2$.

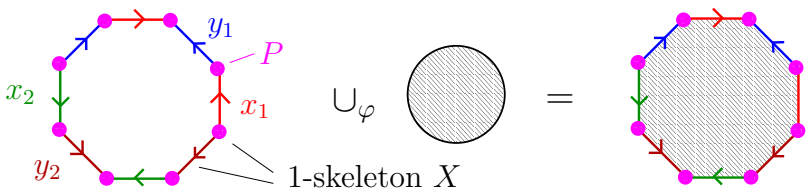

FIGURE 437.

by X the 1-skeleton of Σ and we denote by $\varphi\colon S^1 \to X$ the attaching map of the 2-cell. We have

$$\pi_1(\Sigma, P) \;=\; \pi_1\big(X \cup_\varphi \overline{B}^2, P\big) \;\underset{\substack{\uparrow \\ \text{by Proposition 27.10}}}{=}\; \pi_1(X,P)/\langle\!\langle[\varphi]\rangle\!\rangle \;\underset{\substack{\uparrow \\ \text{by Proposition 27.9 and since } [\varphi]=[x_1,y_1][x_2,y_2]}}{=}\; \langle x_1, y_1, x_2, y_2\rangle/\langle\!\langle[x_1,y_1][x_2,y_2]\rangle\!\rangle.$$

Of course we had obtained the same result much earlier. The advantage of CW-complexes is that Proposition 27.10 absorbs many of the technical arguments we had to deal with in the proof of Proposition 14.3, i.e. in our initial calculation of $\pi_1(\Sigma, P)$.

Proof $(*)$. Let X be a topological space, let $n \geq 2$, let $\varphi\colon S^{n-1} \to X$ be a map and let x_0 be a point in $\varphi(S^{n-1})$. The key idea of the proof is to apply the Seifert–van Kampen Theorem 14.1 to the following two open[543] subsets of of $X \cup_\varphi \overline{B}^n$

$$U \;=\; X \cup_\varphi \big\{z \in \overline{B}^n \,\big|\, \|z\| > \tfrac{1}{4}\big\} \quad \text{and} \quad V \;=\; \big\{z \in \overline{B}^n \,\big|\, \|z\| < \tfrac{3}{4}\big\}.$$

The remainder of the proof consists in showing that the resulting isomorphism implies the desired, a priori slightly different, isomorphism.

We pick a point $x_1 \in U \cap V$ and we pick a path in U from x_0 to x_1. We refer to Figure 438 for an illustration. Note that V is a ball, hence $\pi_1(V, x_1)$ is the trivial group. We consider

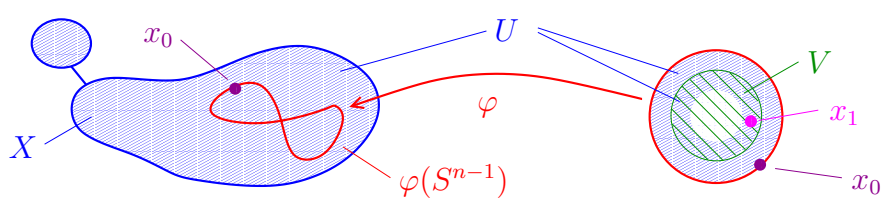

FIGURE 438.

[543]Why are they open subsets?

the following diagram of maps

$$\begin{tikzcd}
\pi_1(X,x_0) \arrow[r] \arrow[d, "\cong"'] & \pi_1(X\cup_\varphi \overline{B}^n, x_0) \arrow[d, "="'] \\
\pi_1(U,x_0) \arrow[r] \arrow[d, "\cong"'] & \pi_1(X\cup_\varphi \overline{B}^n, x_0) \arrow[d, "\cong"] \\
\pi_1(U,x_1) \arrow[r] \arrow[d] & \pi_1(X\cup_\varphi \overline{B}^n, x_1) \arrow[d, "="] \\
\pi_1(U,x_1)/\langle\langle \pi_1(U\cap V,x_1)\rangle\rangle \arrow[r] \arrow[d, "\cong"', "\text{Lemma 13.12}"] & \pi_1(X\cup_\varphi \overline{B}^n, x_1) \arrow[d, "="] \\
\pi_1(U,x_1) *_{\pi_1(U\cap V,x_1)} \underbrace{\pi_1(V,x_1)}_{=\{e\}} \arrow[r, "\cong", "\text{Seifert–van Kampen}"'] & \pi_1(X\cup_\varphi \overline{B}^n, x_1).
\end{tikzcd}$$

We want to prove the following three statements:

(i) the diagram commutes,
(ii) all vertical maps except possibly the third vertical map on the left are isomorphisms,
(iii) the bottom horizontal map is an isomorphism.

The two vertical maps on the second level are the isomorphisms induced by the choice of base point coming from the chosen path from x_0 to x_1. All the other vertical and horizontal maps are induced by inclusions or they are the obvious algebraic map. It follows easily that the diagram commutes.

Most of the maps are obviously isomorphisms. The top left vertical map is an isomorphism by Lemma 9.10 and Proposition 9.12 (1) since X is a deformation retract of U.[544] The bottom vertical map on the left is an isomorphism by Lemma 13.12.

Finally the bottom horizontal map is an isomorphism by the Seifert–van Kampen Theorem 14.1.

Now we consider the case $n \geq 3$. In this case $\pi_1(U\cap V, x_1)$ is trivial since $U\cap V$ is homotopy equivalent to S^{n-1} which has trivial fundamental group by Proposition 5.14. It is now clear that the one missing vertical map on the left is also an isomorphism. Since all vertical maps are now isomorphisms and since the bottom horizontal map is an isomorphism it follows that the top horizontal map is an isomorphism.

Finally we consider the case $n = 2$. In this case $U\cap V$ is homotopy equivalent to S^1 which implies that $\pi_1(U\cap V, x_1) \cong \mathbb{Z}$. Under the isomorphism $\Phi\colon \pi_1(X,x_0) \to \pi_1(U,x_1)$ this infinite cyclic subgroup corresponds to $\langle[\varphi]\rangle$. It is straightforward to see that we get a

[544] Why is it a deformation retract?

commutative diagram

$$\begin{tikzcd}
\pi_1(X,x_0) \arrow[rr] \arrow[dr] \arrow[dd] & & \pi_1\big(X\cup_\varphi \overline{B}^n, x_0\big) \arrow[dd] \\
& \pi_1(X,x_0)/\langle\langle[\varphi]\rangle\rangle \arrow[ur] \arrow[dl, "\cong"'] & \\
\pi_1(U,x_1)/\langle\langle\pi_1(U\cap V,x_1)\rangle\rangle \arrow[rr, "\cong"'] & & \pi_1\big(X\cup_\varphi \overline{B}^n, x_1\big).
\end{tikzcd}$$

This concludes the proof of the proposition. □

The following corollary says that every finitely presented group is the fundamental group of a finite CW-complex.

Corollary 27.11. *Given any finitely presented group π there exists a finite connected 2-dimensional CW-complex Y with $\pi_1(Y)\cong\pi$.*

Proof. Let $\pi=\langle g_1,\dots,g_k\,|\,r_1,\dots,r_m\rangle$ be a finitely presented group. We denote by X the wedge of k circles which we view as a CW-complex with one 0-cell x_0 and k 1-cells. Following the discussion on page 390 we can make the identification $\pi_1(X,x_0)=\langle g_1,\dots,g_k\rangle$. Now given $i=1,\dots,m$ we pick a loop $\varphi_i\colon S^1\to X$ in the base point x_0 such that $[\varphi_i]$ represents $r_i\in\pi_1(X,x_0)=\langle g_1,\dots,g_k\rangle$. We write $Y_0=X$ and for $i=1,\dots,m$ we iteratively define Y_i to be the 2-dimensional CW-complex that is given by attaching a 2-cell to Y_{i-1} with the attaching map φ_i. It follows immediately from Proposition 27.10, applied m times, that

$$\begin{aligned}\pi_1(Y_m,x_0) &\cong \langle g_1,\dots,g_k\rangle/\langle\langle[\varphi_1]\rangle\rangle\dots/\langle\langle[\varphi_k]\rangle\rangle\\ &= \langle g_1,\dots,g_k\rangle/\langle\langle r_1,\dots,r_m\rangle\rangle \;=\; \langle g_1,\dots,g_k\,|\,r_1,\dots,r_m\rangle.\end{aligned}$$ □

The following proposition says in particular that the fundamental group of a CW-complex is the same as the fundamental group of its 2-skeleton.

Proposition 27.12. *Let X be a connected CW-complex with countably many cells and let x_0 be a point in the 0-skeleton of X.*

1. *The inclusion induced map*[545] $\pi_1(X^1,x_0)\to\pi_1(X,x_0)$ *is an epimorphism.*
2. *For any $k\geq 2$ the inclusion induced map $\pi_1(X^k,x_0)\to\pi_1(X,x_0)$ is an isomorphism.*
3. *If X has only finitely many cells in dimensions 0 and 1, then $\pi_1(X,x_0)$ is finitely generated.*
4. *If X has only finitely many cells in dimensions 0, 1 and 2, then $\pi_1(X,x_0)$ is finitely presented.*

Example. Let $X=\mathbb{R}\mathrm{P}^\infty$ be the infinite real projective space with the CW-structure from page 655. For this CW-complex the 1-skeleton is $X^1=\mathbb{R}\mathrm{P}^1\cong S^1$ and the 2-skeleton is $X^2=\mathbb{R}\mathrm{P}^2$. It follows from Proposition 27.12 (1) that $\mathbb{Z}\cong\pi_1(S^1)\to\pi_1(\mathbb{R}\mathrm{P}^\infty)$ is an epimorphism and it follows from Proposition 27.12 (2) that $\mathbb{Z}_2\cong\pi_1(\mathbb{R}\mathrm{P}^2)\to\pi_1(\mathbb{R}\mathrm{P}^\infty)$ is

[545]Recall that for $k\in\mathbb{N}$ we denote by X^k the k-skeleton of X, i.e. the union of all cells of dimension $\leq k$.

an isomorphism. This calculation of $\pi_1(\mathbb{R}\mathrm{P}^\infty)$ is certainly easier than the argument from page 667.

Proof. We first suppose that X is a finite CW-complex. Then the first two statements follow immediately from iteratively applying Proposition 27.10 finitely many times. If X is an infinite CW-complex, but with countably many cells, then one can reduce the first two statements to the finite case using Propositions 26.17 and 26.19. We leave the details to the reader.

Now we turn to the proof of (3). By (1) it suffices to show that the fundamental group of a finite connected 1-dimensional CW-complex is finitely generated, but we showed this in Proposition 27.9.

Finally we turn to the proof of (4). By (2) it suffices to show that a finite connected 2-dimensional CW-complex X has a finitely presented fundamental group. Let $x_0 \in X$. We denote by $\varphi_1, \dots, \varphi_k$ the attaching maps of the 2-cells. For $i = 1, \dots, k$ we pick a path p_i from x_0 to a point on $\varphi_i(S^1)$ and we write $\psi_i = p_i * \varphi_i * \overline{p}_i$. We then have

$$\begin{array}{ccccl} \pi_1(X) & \cong & \pi_1(X^1)/\langle\langle[\psi_1]\rangle\rangle \dots /\langle\langle[\psi_k]\rangle\rangle & = & \pi_1(X^1)/\langle\langle[\psi_1], \dots, [\psi_k]\rangle\rangle. \\ & \uparrow & & = & \{\text{finitely generated free group}\}/\langle\langle[\psi_1], \dots, [\psi_k]\rangle\rangle. \\ & \text{Propositions 5.11 and 27.10} & & \uparrow & \\ & & & \text{Statement (3)} & \end{array}$$

We have thus shown that $\pi_1(X)$ is a finitely presented group. □

The following proposition is an immediate consequence of Proposition 27.12 and Theorem 26.3.

Proposition 27.13. *The fundamental group of any connected, compact manifold M is finitely presented.*

The following corollary is an immediate but useful consequence of Proposition 27.12 (1).

Corollary 27.14. *Let X be a connected CW-complex with countably many cells. If X has no 1-cells, then X is simply connected, i.e. $\pi_1(X) = 0$.*

Examples.

(1) On page 648 we pointed out that for $n \geq 2$ the sphere S^n admits a CW-structure with one 0-cell and one n-cell. From Corollary 27.14 we now recover the result from Proposition 5.14 that S^n is simply connected.
(2) It follows from Lemma 26.2 and Corollary 27.14 that for any n we have $\pi_1(\mathbb{C}\mathrm{P}^n) = 0$. Similarly it follows, using Lemma 26.7, that $\pi_1(\mathbb{C}\mathrm{P}^\infty) = 0$.

27.4. **The Cellular Approximation Theorem.** When we study maps between CW-complexes it is reasonable to consider maps that respect the CW-structures. This leads us to the following definition.

Definition. A map $g\colon X \to Y$ between CW-complexes is called *cellular* if for each $n \in \mathbb{N}_0$ we have $g(X^n) \subset Y^n$.

Example. In general maps between CW-complexes are not cellular. For example consider the CW-complex $X = [0,1]$ with two 0-cells and one 1-cell and we consider the CW-complex $Y = [0,1] \times [0,1]$ with four 0-cells, two 1-cells and one 2-cell. Then the diagonal map

$$\begin{array}{rcl} g\colon X = [0,1] & \to & Y = [0,1] \times [0,1] \\ t & \mapsto & (t,t) \end{array},$$

which is illustrated in Figure 439 on the left, is not a cellular map.

Remark. It is clear that the composition of two cellular maps is again cellular. Thus we can form the *category of CW-complexes* where the objects are CW-complexes and where the morphisms are cellular maps.

The following theorem is the main result of this section.

Theorem 27.15. (Cellular Approximation Theorem) *Let $g\colon X \to Y$ be a map between CW-complexes and let A be a subcomplex of X such that the restriction of g to A is a cellular map.*[546] *The map g is homotopic rel A to a cellular map $\widetilde{g}\colon X \to Y$.*

Remark. Let $g\colon X \to Y$ be a *homeomorphism* between CW-complexes. By the Cellular Approximation Theorem 27.15 we know that g is homotopic to a cellular map h. But in general we cannot arrange that h is again a *homeomorphism*. For example consider the torus $T = ([0,1] \times [0,1])/\sim = \mathbb{R}^2/\mathbb{R}^2$ with the standard CW-structure from page 646 which has precisely one 0-cell $*$ that corresponds to the origin. As in Theorem 7.17 we make the identification $\pi_1(\mathbb{R}^n/\mathbb{Z}^2, *)$ with $\mathbb{Z}^2$. Let $P = \begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix} \in \mathrm{GL}(2,\mathbb{Z})$. We consider the map

$$\begin{array}{rcl} f\colon \mathbb{R}^2/\mathbb{Z}^2 & \to & \mathbb{R}^2/\mathbb{Z}^2 \\ v & \mapsto & P \cdot v. \end{array}$$

In Lemma 3.28 we saw that this map is a homeomorphism. Furthermore, in Exercise 7.12 we saw that the induced map on $\pi_1(\mathbb{R}^2/\mathbb{Z}^2, *) = \mathbb{Z}^2$ is given by multiplication by P. On the other hand the map on $\pi_1(\mathbb{R}^2/\mathbb{Z}^2, *) = \mathbb{Z}^2$ induced by any *cellular homeomorphism* $\widetilde{g}$ on $\mathbb{R}^2/\mathbb{Z}^2$ is represented by a matrix of the form[547] $\begin{pmatrix} \pm 1 & 0 \\ 0 & \pm 1 \end{pmatrix}$ or $\begin{pmatrix} 0 & \pm 1 \\ \pm 1 & 0 \end{pmatrix}$. It follows from Exercise 9.20 (a) that g cannot be homotopic, rel $*$, to any such $\widetilde{g}$.

[546] For example $f\colon X \to Y$ could be any map between CW-complexes, then the hypothesis is satisfied for A the empty set.

[547] Why is that?

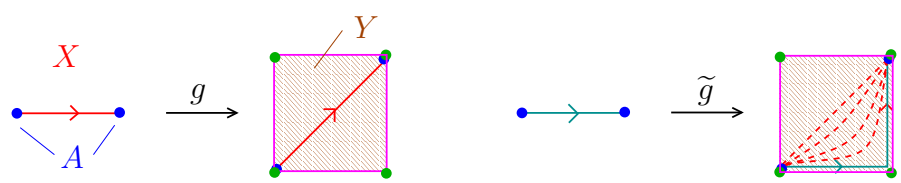
Example. We consider again the above example of a non-cellular map. More precisely, we consider again the above diagonal map

$$\begin{array}{rcl} g\colon X = [0,1] & \to & Y = [0,1]\times[0,1] \\ t & \mapsto & (t,t). \end{array}$$

We want to deform g into a cellular map, while keeping the endpoints fixed. Put differently, we want to find a homotopy rel $A = \{(0,0),(1,1)\}$ from g to a cellular map $\widetilde{g}$. Such a map $\widetilde{g}$ is given by

$$\begin{array}{rcl} \widetilde{g}\colon X = [0,1] & \to & Y = [0,1]\times[0,1] \\ t & \mapsto & \begin{cases} (2t,0), & \text{if } t\in[0,\frac{1}{2}] \\ (1,2t-1), & \text{if } t\in[\frac{1}{2},1] \end{cases} \end{array}$$

One way of stating this example is that we turn g into a cellular map $\widetilde{g}$ by "pushing g off



g is not a cellular map $\widetilde{g}$ is a cellular map

FIGURE 439.

the high-dimensional cell". The proof of Cellular Approximation Theorem 27.15 is built on the same concept. But somewhat similar to the proof of Proposition 5.14, we have to worry about space-filling curves that exist by Proposition 1.91.

Before we attack the proof of the Cellular Approximation Theorem 27.15 we want to formulate a relative version thereof. To formulate this relative version we need the following semi-obvious definition.

Definition. A *pair of CW-complexes* is a pair (X,A) where X is a CW-complex and A is a subcomplex of X.

Now we can formulate the promised theorem.

Theorem 27.16. (Cellular Approximation Theorem for Pairs) *Suppose we are given a map $g\colon (X,A)\to(Y,B)$ between pairs of CW-complexes. Let Z be a subcomplex of A such that the restriction of g to Z is a cellular map. Then g is homotopic rel Z to a cellular map $\widetilde{g}\colon (X,A)\to(Y,B)$.*[548]

Proof assuming the Cellular Approximation Theorem 27.15. The desired homotopy is constructed as follows:

[548]Here we refer to page 642 for the discussion on the notion of homotopies of pairs of topological spaces rel a subset.

(1) By the Cellular Approximation Theorem 27.15 applied to $g|_A\colon A \to B$ there exists a homotopy F rel Z from $g|_A\colon A \to B$ to a cellular map.
(2) By the Homotopy Extension Theorem 27.4 we can extend the homotopy F from (1) to a homotopy $G\colon X \times [0,1] \to Y$. Note that G is still a homotopy rel Z. We write $h = g_1\colon X \to Y$. Note that $h|_A$ is cellular and that $h(A) \subset B$.
(3) We apply the Cellular Approximation Theorem 27.15 to h and we obtain a homotopy H rel A from h to a cellular map.
(4) The combination of the homotopies G and H has all the desired properties. □

Now we turn to the proof of Cellular Approximation Theorem 27.15. The following proposition is the key step towards the desired proof.

Proposition 27.17. *Let V be a CW-complex and W be a topological space. Furthermore let $\psi\colon S^{n-1} \to V^{n-1}$ be a map to the $(n-1)$-skeleton of V and let $\varphi\colon S^{k-1} \to W$ be another map. Finally let*

$$h\colon V \cup_\psi \overline{B}^n \;\to\; W \cup_\varphi \overline{B}^k$$

be a map with $h(\psi(S^{n-1})) \subset W$. If $n < k$, then h is homotopic rel V to a map h' such that $h'(B^n)$ does not intersect B^k.

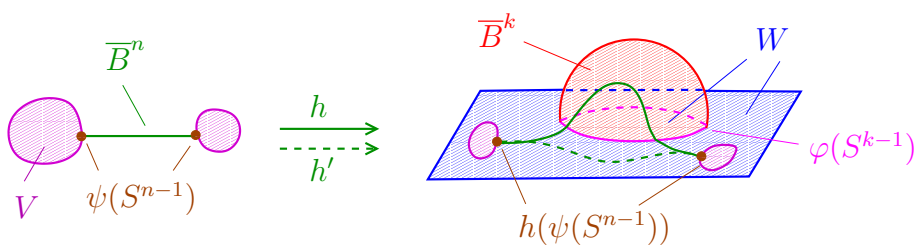


FIGURE 440. Illustration of Proposition 27.17.

The statement of Proposition 27.17 is fairly obvious, if there exists a point $P \in B^k$ that does not get hit by $h(B^n)$. Indeed, if such a point P exists, then we can use the deformation retraction $\overline{B}^n \setminus \{p\} \to S^{n-1}$ to push h on B^n off the ball B^k. Put in general such a point P does not exist, since even for $n < k$ there exist continuous surjective maps $B^n \to B^k$. To get around this problem requires a fairly hard, not particularly inspiring, argument which we will give later on in Section 27.5.

In the following we will use Proposition 27.17 to prove the Cellular Approximation Theorem 27.15.

Corollary 27.18. *Let Z be a finite n-dimensional CW-complex.*

(1) *Let $g\colon Z \to Y$ be a map to a k-dimensional CW-complex Y with $g(Z^{n-1}) \subset Y^{n-1}$. Let B be a subcomplex of Z with $g(B) \subset Y^n$. If $n < k$, then g is homotopic rel $Z^{n-1} \cup B$ to a map g' with $g'(Z) \subset Y^{k-1}$.*

(2) *Let $g\colon Z \to Y$ be a map to a CW-complex Y such that $g(Z^{n-1}) \subset Y^{n-1}$. Let B be a subcomplex of Z with $g(B) \subset Y^n$. The map g is homotopic rel $Z^{n-1} \cup B$ to a map g' with $g'(Z) \subset Y^n$.*

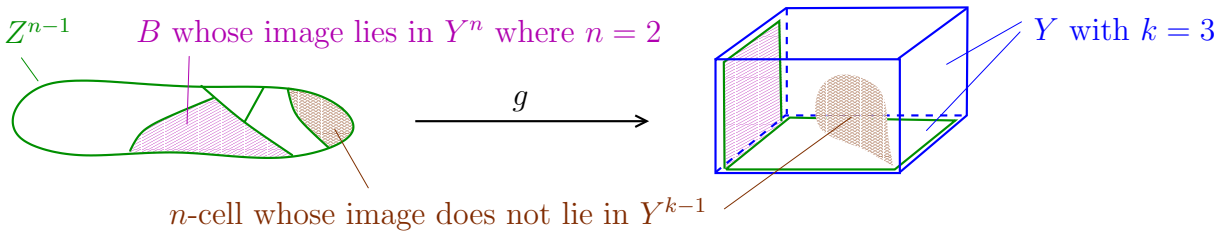

FIGURE 441. Illustration for Corollary 27.18 (1).

Proof. Let Z be a finite n-dimensional CW-complex. By Proposition 26.11 (3) the CW-complex Z is compact. It follows from Proposition 26.14 that the image of the compact set Z in a CW-complex is contained in a finite subcomplex. Therefore we can assume in both (1) and (2) that Y is in fact a finite CW-complex.

(1) Let $g\colon Z \to Y$ be a map to a finite k-dimensional CW-complex Y such that $g(Z^{n-1}) \subset Y^{n-1}$. Let B be a subcomplex of Z with $g(B) \subset Y^n$. We suppose that $n < k$. We denote by $\widehat{Z}$ the union of Z^{n-1} with all the n-cells of Z whose image is contained in Y^{k-1}. In other words we can write $Z = \widehat{Z} \cup e_1 \cup \cdots \cup e_r$ where $e_1, \ldots, e_r$ are the n-cells such that the image is not contained in Y^{k-1}. We denote by $f_1, \ldots, f_s$ the k-cells of Y. Note that by hypothesis on B the interiors of the cells $e_1, \ldots, e_r$ are disjoint from B.

In the following we apply Proposition 27.17 precisely $r \cdot s$ times to get the desired homotopy. More precisely, we do the following:

(a) We apply Proposition 27.17 to the map

$$h\colon (\widehat{Z} \cup e_1 \cup \cdots \cup e_{r-1}) \cup e_r \quad \to \quad (Y \cup f_1 \cup \cdots \cup f_{s-1}) \cup f_s$$

to obtain a homotopy rel $\widehat{Z} \supset Z^{n-1} \cup B$ to a map h_{rs} such that the image of the interior of e_r under the map h_{rs} does not intersect the interior of f_s. Next we apply Proposition 27.17 to the map

$$h_{rs}\colon (\widehat{Z} \cup e_1 \cup \cdots \cup e_{r-2} \cup e_r) \cup e_{r-1} \quad \to \quad (Y \cup f_1 \cup \cdots \cup f_{s-1}) \cup f_s.$$

Iterating this process we obtain a homotopy rel $\widehat{Z}$ to a map such that the image of the interiors of the cells $e_1, \ldots, e_r$ does not intersect the interior of f_s.

(b) Again iterating the process above we obtain a homotopy rel $\widehat{Z}$ to a map such that image of the interiors of the cells $e_1, \ldots, e_r$ does not intersect the interior of any of the f_i. But that means that the image of Z lies in Y^{k-1}.

(2) Let $g\colon Z \to Y$ be a map to a CW-complex Y such that $g(Z^{n-1}) \subset Y^{n-1}$ and let B be a subcomplex of Z with $g(B) \subset Y^n$. As we pointed out in the beginning of the proof, we can assume that Y is finite-dimensional, we denote the dimension by k. But then statement (2) is just an immediate consequence of applying (1) iteratively $k-n$ times. □

Now we turn to the proof of the Cellular Approximation Theorem 27.15.

Proof. Let X be a CW-complex and let A be a (possibly empty) subcomplex of X. Furthermore let Y be a CW-complex. We prove the Cellular Approximation Theorem 27.15 only in the special case that X has finitely many cells. The general case is dealt with in [Hat, Theorem 4.8].

Let $g\colon X \to Y$ be map.

(1) We say an n-cell e of X is *g-bad* if $g(e)$ is not contained in Y^n.
(2) If g is non-cellular, then we define

$$n(g) \ := \ \text{minimal dimension of a cell that is } g\text{-bad.}$$

If g is cellular, then we define $n(g) := \infty$.

Claim. Let $g\colon X \to Y$ be a non-cellular map such that the restriction of g to A is a cellular map. Then there exists a homotopy from g to a map g' rel A such that $n(g') > n(g)$.

We write $n = n(g)$. We apply Corollary 27.18 (2) to $g\colon Z := X^n \to Y$ and $B = A^n$.[549] We obtain a homotopy G rel $X^{n-1} \cup A^n$ from $g\colon Z = X^n \to Y$ to a map $g'\colon Z = X^n \to Y$ with $g'(X^n) \subset Y^n$. We can extend this homotopy to a homotopy G on $(X^n \cup A) \times [0,1]$ via the trivial homotopy on $A \times [0,1]$. Now we apply the Homotopy Extension Theorem 27.4 to obtain a homotopy rel $X^n \cup A$ from $g\colon X \to Y$ to a map $g'\colon X \to Y$ such that $g'(X^n) \subset Y^n$. Note that by the choice of our homotopy we have $g'|_{X^{n-1}} = g|_{X^{n-1}}$. By definition of $n(g)$ the map $g'|_{X^{n-1}} = g|_{X^{n-1}}$ is cellular. Thus we see that $n(g') \geq n+1 = n(g)+1$. This concludes the proof of the claim.

Finally let $g\colon X \to Y$ be a non-cellular map such that the restriction of g to A is a cellular map. We apply the claim iteratively as many times as possible to obtain a sequence of maps $g = g_1, g_2, g_3, \ldots : X \to Y$, each of which is homotopic to g rel A, such that $n(g) = n(g_1) < n(g_2) < \ldots$. Note that n can take on only finitely many values, namely $\{0, \ldots, \dim(X), \infty\}$. This means that the sequence is finite which implies that the last map is cellular. □

27.5. **Proof of Proposition 27.17** $(*)$. [550] Before we can even think of proving Proposition 27.17 we need to introduce a few more definitions and we need to prove a rather technical lemma.

Definition.

[549] Note that by definition of n we have $g(X^{n-1}) \subset Y^{n-1}$.

[550] Here the $(*)$ indicates once again that we do not provide the proof in the lecture. You are reading this section at your own risk.

(1) A *closed half-space in* $\mathbb{R}^n$ is a set of the form $\{v \in \mathbb{R}^n \mid \langle v, w\rangle \geq 0\}$, for some fixed non-zero vector $w \in \mathbb{R}^n$.
(2) A *convex polyhedron in* $\mathbb{R}^n$ is a bounded subset of $\mathbb{R}^n$ that is the intersection of finitely many closed half-spaces.
(3) A *polyhedron in* $\mathbb{R}^n$ is the union of a finite number of convex polyhedra.[551]
(4) Given a polyhedron P a map $f\colon P \to \mathbb{R}^k$ is called *piecewise linear*if there exists a subdivision of P into finitely many convex polyhedra $Q_1, \ldots, Q_m$ such that the restriction of f to each Q_i is affine linear.[552]

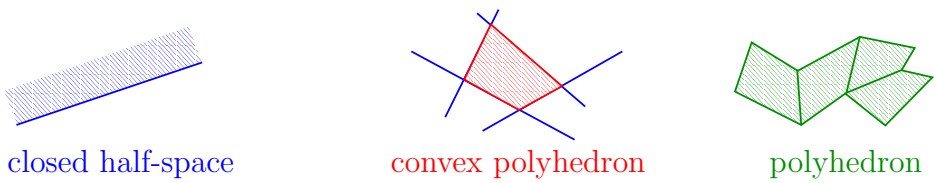

FIGURE 442.

The following, very technical lemma, will get us around the problem of space filling curves, i.e. it will get us around the problem that we saw in Proposition 1.91 that there exist surjective continuous maps $\overline{B}^n \to \overline{B}^k$ even if $n < k$.

Lemma 27.19. *Let W be a topological space and let $\varphi\colon S^{k-1} \to W$ be map. Furthermore let $g\colon [0,1]^n \to Z := W \cup_\varphi \overline{B}^k$ be a map. Then there exists a (possibly empty) polyhedron $K \subset [0,1]^n$ and a map $\widetilde{g}\colon [0,1]^n \to Z$ with the following properties:*
(1) *The map $\widetilde{g}$ is homotopic to g rel $g^{-1}(W)$.*
(2) *We have $\widetilde{g}(K) \subset B^k$.*
(3) *The restriction $\widetilde{g}|_K\colon K \to B^k$ is piecewise linear.*
(4) *There exists a non-empty open subset $U \subset B^k$ such that $\widetilde{g}^{-1}(U) \subset K$.*

Example. Suppose that in the setting of Lemma 27.19 there exists an open subset $U \subset B^k$ such that $g([0,1]^n) \cap U = \varnothing$. Then the empty polyhedron $K = \varnothing$ and the map $\widetilde{g} = g$ already have the desired property.

Proof. Let W be a topological space and let $\varphi\colon S^{k-1} \to W$ be map. Furthermore let $g\colon [0,1]^n \to Z := W \cup_\varphi \overline{B}^k$ be a map. We write $D_1 := \overline{B}_{\frac{1}{4}}(0) \subset B^k$ and $D_2 := \overline{B}_{\frac{1}{2}}(0) \subset B^k$. The set $g^{-1}(D_2) \subset [0,1]^n$ is closed and therefore compact by the Heine-Borel Theorem 1.21. We obtain from Proposition 1.107 that g is uniformly continuous on $g^{-1}(D_2)$.[553] This implies that we can find an $\epsilon > 0$ with the following two properties:

[551]Note that the union of zero convex polyhedra is the empty set.
[552]A map $f\colon V \to \mathbb{R}^k$ from a subset V of $\mathbb{R}^n$ is called *affine linear* if there exists a $P \in \mathbb{R}^k$ and a $k \times n$-matrix A such that $f(v) = P + Av$ for all $v \in V$.
[553]Why can't we conclude that g is uniformly continuous on all of $[0,1]^n$?

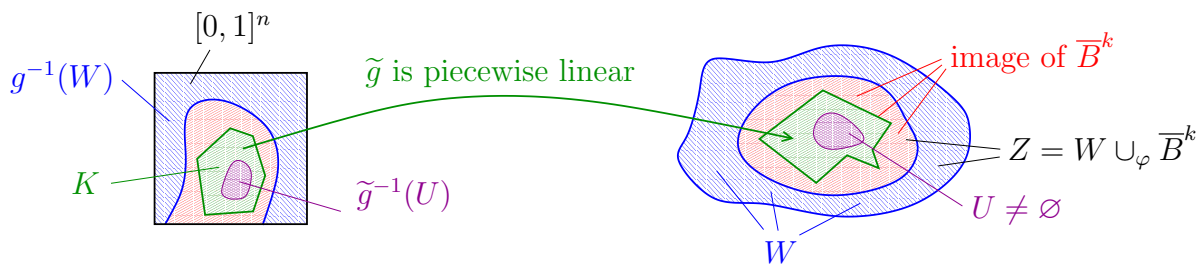

FIGURE 443. Illustration of Lemma 27.19.

(i) For any $x, y \in g^{-1}(D_2)$ with $\|x - y\| < \epsilon$ we have $\|g(x) - g(y)\| < \frac{1}{8}$.
(ii) We have[554]

$$\epsilon \ < \ \text{distance between } g^{-1}(D_1) \text{ and } [0,1]^n \setminus g^{-1}\big(\mathring{D}_2\big).$$

We divide $[0,1]^n$ into cubes such that the diameter of each cube is less than ϵ. We denote by K_1 the union of all the cubes that meet $g^{-1}(D_1)$ and we denote by K_2 the union of all the cubes meeting K_1. By the second property of ϵ we have $K_2 \subset g^{-1}(D_2)$. We refer to Figure 444 for an illustration.

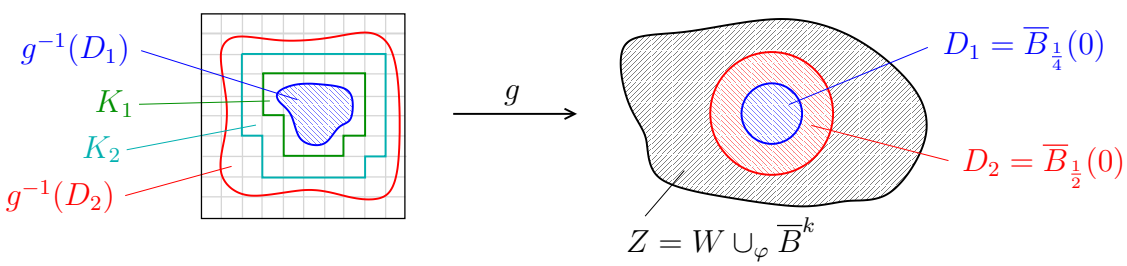

FIGURE 444.

We need one more definition: Suppose we are given points $P_1, \dots, P_{n+1} \in \mathbb{R}^n$ such that the vectors $P_2 - P_1, \dots, P_{n+1} - P_1$ are linearly independent. We refer to

$$\text{convex hull of } P_1, \dots, P_{n+1} \ = \ \left\{ \sum_{i=1}^{n+1} t_i P_i \,\middle|\, \sum_{i=1}^{n+1} t_i = 1 \right\}$$

[554]Here recall that, according to the definition on page 89, for two non-empty subsets A and B of $\mathbb{R}^n$ we refer to

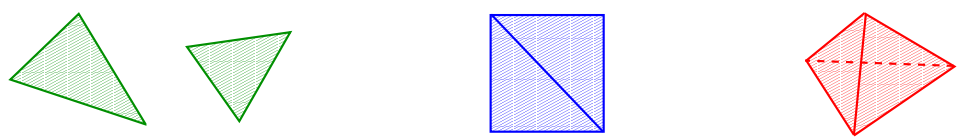
$$d(A,B) \ := \ \inf\{\|P - Q\| \mid P \in A \text{ and } Q \in B\}$$

as the distance between A and B. If A and B are compact and disjoint, then it follows from Corollary 1.56 that $d(A,B) > 0$.

as a *simplex* in $\mathbb{R}^n$.[555] We will make use of the following trivial observation: if we are given $w_1, \ldots, w_{n+1} \in \mathbb{R}^k$, then there exists a unique affine linear map Φ with $\Phi(P_i) = w_i$, namely the map that is given by

$$\Phi\Big(\sum_{i=1}^{n+1} t_i P_i\Big) \ := \ \sum_{i=1}^{n+1} t_i w_i.$$

We leave it as an exercise to show that each cube can be subdivided[556] into simplices. We also refer to Figure 445 for an illustration.



simplices in $\mathbb{R}^2$ | a square can be decomposed into two simplices | simplex in $\mathbb{R}^3$

FIGURE 445.

Now we subdivide all the cubes in K_2 into simplices. By the above discussion there exists a map $h\colon K_2 \to \mathbb{R}^k$ that equals g on all the vertices of the simplices in the subdivision of the cubes.[557] Furthermore we choose a map $\psi\colon K_2 \to [0,1]$ with $\psi|_{\partial K_2} \equiv 0$ and $\varphi|_{K_1} \equiv 1$.[558] Now we consider the homotopy[559]

$$\begin{array}{rcl} F\colon [0,1]^n \times [0,1] & \to & Z = W \cup_\varphi \overline{B}^k \\ (P,t) & \mapsto & \begin{cases} (1 - t\cdot\psi(P))\cdot g(P) + t\cdot\psi(P)\cdot h(P), & \text{if } P \in K_2 \\ g(P), & \text{otherwise.} \end{cases} \end{array}$$

This is a homotopy from g to a map $\widetilde{g}\colon [0,1] \to Z = W \cup_\varphi \overline{B}^k$ that restricts to the piecewise linear map h on K_1.

Claim. The point $0 \in D_1$ does not lie in $\widetilde{g}\big(\overline{[0,1]^n \setminus K_1}\big)$.

[555]Given a subset S of $\mathbb{R}^k$ we defined on page 78 the *convex hull* of S as the intersection of all convex subsets of $\mathbb{R}^k$ that contain S. As we pointed out, if S is a finite subset of $\mathbb{R}^k$, then the *convex hull* of S is given by

$$\Big\{ \sum_{s\in S} a_s \cdot s \,\Big|\, a_s \in [0,1] \text{ and } \sum_{s\in S} a_s = 1 \Big\}.$$

[556]Here, by "subdivide" we mean that given any cube K there exist simplices $S_1, \ldots, S_k$ such that the interiors of the S_i are disjoint and such that $K = S_1 \cup \cdots \cup S_k$.

[557]Note that it follows from the uniqueness statement above that the map g is in fact continuous.

[558]Such a map can be constructed as follows: we assign the value 1 to all vertices in K_1 and we assign the value 0 to all other vertices in K_2. By the above "trivial observation" this defines a map on K_2 with the desired property.

[559]Since $\varphi|_{\partial K_2} \equiv 0$ we see that F is indeed continuous.

Now we provide the proof of the claim.

(1) On $[0,1]^n \setminus K_2$ we have $\widetilde{g} = g$. By Property (ii) of ϵ we have $g^{-1}(D_1) \subset K_2$. It follows that the image of $[0,1]^n \setminus K_2$ lies outside of D_1.

(2) Now let σ be a simplex of K_2 that does not lie in K_1. Note that $K_2 \subset g^{-1}(D_2)$. It follows from Property (i) of ϵ that $g(\sigma)$ is contained in some ball B_σ of radius $\frac{1}{8}$. Since $g(\sigma) \subset B_\sigma$ and since B_σ is convex we also have $h(\sigma) \subset B_\sigma$. Again by the convexity of B_σ we have $\widetilde{g}(\sigma) \subset B_\sigma$. We know that B_σ is not contained in D_1 since σ contains points outside K_1, hence outside $g^{-1}(D_1)$. The radius of B_σ is half that of D_1, so it follows that 0 is not in B_σ, and hence 0 does not lie in $\widetilde{g}(\sigma)$.

This concludes the proof of the claim.

Since $\widetilde{g}\big(\overline{[0,1]^n \setminus K_1}\big)$ is compact it follows from the claim that there exists in fact an open neighborhood U of 0 that does not intersect the image of $[0,1]^n \setminus K_1$. Put differently, we have $\widetilde{g}^{-1}(U) \subset K_1$. It is now straightforward to verify that $K = K_1$, $\widetilde{g}$ and U have the desired properties. □

Lemma 27.20. *Let W be a topological space and let $\varphi\colon S^{k-1} \to W$ be the attaching map of a k-cell. Furthermore let $h\colon \overline{B}^n \to Z := W \cup_\varphi \overline{B}^k$ be a map with $h(S^{n-1}) \subset W$. If $n < k$, then h is homotopic rel S^{n-1} to a map h' that misses B^k.*

Proof. Let W be a topological space and let $\varphi\colon S^{k-1} \to W$ be the attaching map of a k-cell. Furthermore let $h\colon \overline{B}^n \to Z := W \cup_\varphi \overline{B}^k$ be a map with $h(S^{n-1}) \subset W$. We suppose that $n < k$. We have to show that h is homotopic rel S^{n-1} to a map h' that misses B^k.

By Proposition 1.47 there exists a homeomorphism $\Phi\colon [0,1]^n \to \overline{B}^n$. So after precomposing h with Φ we might as well assume that the domain of h is $[0,1]^n$, i.e. that h is a map $h\colon [0,1]^n \to Z := W \cup_\varphi \overline{B}^k$ with $h(\partial[0,1]^n) \subset W$.

We pick a polyhedron K, a map $\widetilde{h}\colon [0,1]^n \to Z$ and a non-empty open subset $U \subset B^n$ with $\widetilde{h}^{-1}(U) \subset K$ as in the statement of Lemma 27.19. Since $n < k$ and since $\widetilde{h}|_K\colon K \to B^k$ is piecewise linear we deduce that $\widetilde{h}(K)$ cannot contain the open subset U of B^n.[560] We pick a point $P \in U \setminus \widetilde{h}(K)$. By statement (4) of Lemma 27.19 we know that P does not lie in the image of $\widetilde{h}\colon [0,1]^n \to Z$.

As we pointed out on page 309, there exists a deformation retraction from $\overline{B}^k \setminus \{P\}$ to S^{k-1}. We can extend this deformation retraction via the identity map to a deformation retraction from $Z = W \cup_\varphi (\overline{B}^k \setminus \{P\})$ to W. If we compose $\widetilde{h}$ with this deformation retraction we obtain a homotopy, rel S^{n-1}, from $\widetilde{h}$ to a map h' that misses B^k. □

Now we can finally provide the proof of Proposition 27.17.

Proof of Proposition 27.17. Let V be a CW-complex and W be a topological space. Furthermore let $\psi\colon S^{n-1} \to V^{n-1}$ be a map to the $(n-1)$-skeleton of V and let $\varphi\colon S^{k-1} \to W$

[560] Indeed, since $\widetilde{h}|_K\colon K \to B^k$ is piecewise linear and since $n < k$ we know that the image $\widetilde{h}(K)$ is set of Lebesgue-measure zero in B^n whereas a non-empty open subset has positive Lebesgue-measure.

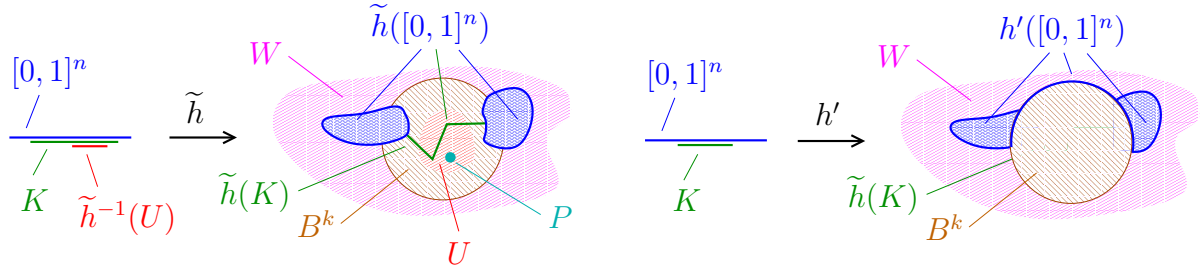


FIGURE 446. Illustration for the proof of Proposition 27.17.

be another map. Finally let

$$h\colon V \cup_\psi \overline{B}^n \;\to\; W \cup_\varphi \overline{B}^k$$

be a map with $h(\psi(S^{n-1})) \subset W$. We suppose that $n < k$.

We denote by θ the obvious map $\overline{B}^n \to V \cup_\psi \overline{B}^n$, furthermore we write $h = g \circ \theta$. By our hypothesis we have $h(S^{n-1}) \subset W$. By Lemma 27.20 there exists a homotopy G rel S^{n-1} from h to a map $h'\colon \overline{B}^n \to W$ that misses B^k. The desired homotopy is now given by[561][562]

$$\begin{array}{rcl} F\colon (V \cup_\psi \overline{B}^n) \times [0,1] & \to & W \cup_\varphi \overline{B}^k \\ (P,t) & \mapsto & \begin{cases} G(Q,t), & \text{if } P = \theta(Q), \text{ for some } Q \in \overline{B}^k, \\ g(P), & \text{otherwise.} \end{cases} \end{array}$$

□

Exercises for Chapter 27.

Exercise 27.1. Let X be a CW-complex and let $A \subset X$ be a subcomplex. Suppose that A admits a deformation retraction to a point. Show that X/A is homotopy equivalent to X.
Hint: Use the Homotopy Extension Theorem 27.4.

Exercise 27.2. We consider the map

$$\begin{array}{rcl} \varphi\colon S^1 & \to & S^1 \\ e^{it} & \mapsto & \begin{cases} e^{3it}, & \text{if } t \in [0, \frac{2\pi}{3}], \\ e^{-3it}, & \text{if } t \in [\frac{2\pi}{3}, \frac{4\pi}{3}], \\ e^{3it}, & \text{if } t \in [\frac{4\pi}{3}, 2\pi]. \end{cases} \end{array}$$

[561] We view $V \cup_\psi \overline{B}^n$ as a CW-complex where V is a subcomplex and the image of $\overline{B}^n$ is an n-cell. Furthermore we equip $V \cup_\psi \overline{B}^n$ with the product CW-structure. It follows from Lemma 27.1 and Lemma 26.9, applied to the subcomplexes given by $V \times [0,1]$ and $\theta(\overline{B}^n) \times [0,1]$, that the map F is continuous.

[562] One might be tempted to use a different approach to show that F is continuous: Namely one might want to write $(V \cup_\psi \overline{B}^n) \times [0,1] = (V \times [0,1]) \cup_{\psi \times \mathrm{id}_{[0,1]}} (\overline{B}^n \times [0,1])$ and then argue using Lemma 1.83 (3) that the given map is continuous. But this approach is problematic since it is not clear that the two topologies on $(V \cup_\psi \overline{B}^n) \times [0,1] = (V \times [0,1]) \cup_{\psi \times \mathrm{id}_{[0,1]}} (\overline{B}^n \times [0,1])$ agree.

Put differently, φ wraps S^1 first around S^1 clockwise, then counter clockwise and then once again clockwise. We write $Y = S^1$ and we consider

$$X \ := \ Y \cup_\varphi \overline{B^2},$$

where we identify $z \in \partial\overline{B}^2 = S^1$ with $\varphi(z) \in S^1 = Y$.

(a) Show that X is homotopy equivalent to $\overline{B}^2$.

(b) Is X homeomorphic to $\overline{B}^2$?

28. Higher homotopy groups

After this somewhat technical chapter on CW-complexes we now return to our original goal, namely trying to distinguish topological spaces. Using the fundamental group we had established several non-trivial results, for example we proved that

(1) S^1 and S^k with $k \geq 2$ are not homeomorphic,
(2) $\mathbb{R}^2$ and $\mathbb{R}^n$ with $n \geq 3$ are not homeomorphic,
(3) surfaces of different genus are not homeomorphic,
(4) we showed that S^1 is not a deformation retract of $\overline{B}^2$,
(5) the trefoil knot is not isotopic to the trivial knot.

On the other hand there are still many even rather elementary questions we cannot answer. For example at the moment we cannot show that for $k \neq l$ with $k, l \geq 2$ the spheres S^k and S^l are not homeomorphic and we cannot show that for $k \neq l$ with $k, l \geq 3$ the topological spaces $\mathbb{R}^k$ and $\mathbb{R}^l$ are not homeomorphic. Also, the somewhat mysterious lens spaces $L(p, q)$ still evaded our attempts at distinguishing them for a given p.

The problem with fundamental groups is that we only probe a topological space X with loops. The natural idea is now to go from using maps $S^1 \to X$ to studying maps $S^n \to X$ for $n \geq 2$. As we will see, this idea leads us naturally to the definition of the "higher homotopy groups" of a topological space.

28.1. **Definition of the higher homotopy groups.**

Notation. Throughout this chapter we write $I = [0, 1]$ for the unit interval. Given $n \in \mathbb{N}$ we denote by $I^n \subset \mathbb{R}^n$ the cube in $\mathbb{R}^n$ and we denote, as usual, by ∂I^n its boundary as a subset of $\mathbb{R}^n$.

Now let X be a topological space and let $x_0 \in X$. With the definitions from page 641 we can write

$$\pi_1(X, x_0) \;=\; \text{homotopy classes of maps } (I, \partial I) \to (X, x_0).$$

This definition can be easily generalized to higher dimensions:

Definition. Given a pointed topological space (X, x_0) and $n \in \mathbb{N}_0$ we define

$$\pi_n(X, x_0) \;=\; \text{homotopy classes of maps } (I^n, \partial I^n) \to (X, x_0).$$

For $n \geq 1$ we refer to $\pi_n(X, x_0)$ as the *n-th homotopy group.*

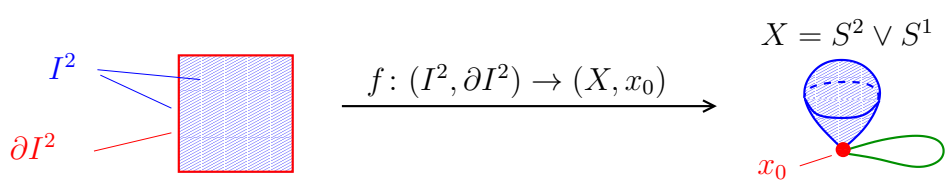

Figure 447. Illustration of an element in $\pi_2(S^2 \vee S^1, x_0)$.

Remark. This definition makes in particular sense for $n = 0$, we can thus consider $\pi_0(X, x_0)$. In Section 1.17 we had already defined $\pi_0(X)$ as the set of path-components of X. In fact it is straightforward to see that the map

$$\begin{array}{rcl} \pi_0(X, x_0) & \to & \pi_0(X) \\ [\gamma\colon I^0 = \{0\} \to X] & \to & \text{path-component of } X \text{ that contains } \gamma(0) \end{array}$$

is a bijection.

Note that $\pi_n(X, x_0)$ is a priori only a set. So to justify the name "homotopy group" we need to define a group structure on $\pi_n(X, x_0)$ which for $n = 1$ agrees with our previous definition of the group structure. Here is what we do:

Definition. Let $((X, x_0)$ be a pointed topological space. Let $n \geq 1$ and let $f, g\colon (I^n, \partial I^n) \to (X, x_0)$ be two maps. We define

$$\begin{array}{rcl} f * g\colon (I^n, \partial I^n) & \to & (X, x_0) \\ (x_1, \dots, x_n) & \mapsto & \begin{cases} f(2x_1, \dots, 2x_n), & \text{if } (x_1, \dots, x_n) \in [0, \frac{1}{2}]^n, \\ g(2x_1 - 1, \dots, 2x_n - 1), & \text{if } (x_1, \dots, x_n) \in [\frac{1}{2}, 1]^n, \\ x_0, & \text{otherwise.} \end{cases} \end{array}$$

This map is illustrated in Figure 448.[563] Applying Lemma 5.3 several times one sees that

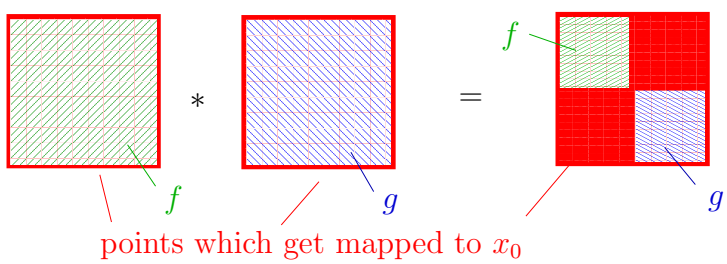

FIGURE 448.

this map is indeed continuous.

It is straightforward to see that the homotopy class of $f * g$ only depends on the homotopy classes of f and g. This leads us to the following definition:

Definition. Let $((X, x_0)$ be a pointed topological space and let $n \geq 1$. We define

$$\begin{array}{rcl} \pi_n(X, x_0) \times \pi_n(X, x_0) & \to & \pi_n(X, x_0) \\ ([f], [g]) & \mapsto & [f] \cdot [g] := [f * g]. \end{array}$$

Note that for $n = 1$ this is precisely the same definition of the product structure that we had we already introduced in Chapter 5.2.

[563]For mysterious reasons in all figures of this chapter the origin $(0, 0)$ is in the top left corner and the point $(1, 1)$ is the vertex at the bottom right.

Now we can formulate the following proposition:

Proposition 28.1. *Let (X, x_0) be a pointed topological space and let $n \geq 1$. The following two statements hold:*

(1) *The map*

$$\begin{array}{rcl} \pi_n(X, x_0) \times \pi_n(X, x_0) & \to & \pi_n(X, x_0) \\ ([f], [g]) & \mapsto & [f] \cdot [g] := [f * g] \end{array}$$

defines a group structure on $\pi_n(X, x_0)$.

(2) *Given a map $f\colon (I^n, \partial I^n) \to (X, x_0)$ the inverse of $[f] \in \pi_n(X, x_0)$ is represented by the map $f \circ \Phi\colon (I^n, \partial I^n) \to (X, x_0)$ where $\Phi\colon I^n \to I^n$ is the homeomorphism given by $\Phi(x_1, x_2, \ldots, x_n) = (1 - x_1, x_2, \ldots, x_n)$.*

As we will see, the proof of Proposition 28.1 is very similar to the proof of Proposition 5.7 and the proof of Proposition 5.6. To deal with the technical differences between the case $n = 1$ and the general case we need a few more definitions and one lemma.

Definition.

(1) A *cuboid* is any subset of $\mathbb{R}^n$ of the form $[c_1, d_1] \times \cdots \times [c_n, d_n]$.
(2) We say a cuboid $[c_1, d_1] \times \cdots \times [c_n, d_n]$ is *non-degenerate* if for all $i = 1, \ldots, n$ we have $d_i > c_i$.

Let X be a topological space, let $x_0 \in X$ and let $f\colon I^n \to X$ be a map.

(3) We say a cuboid $A \subset I^n$ is *boundary-trivial* if f sends all points on the boundary ∂A of A to x_0.
(4) Let $A = [a_1, b_1] \times \cdots \times [a_n, b_n] \subset I^n$ be a boundary-trivial cuboid and furthermore let $C = [c_1, d_1] \times \cdots \times [c_n, d_n]$ be a non-degenerate cuboid that is contained in A. We define

$$\begin{array}{rcl} f(A, C)\colon I^n & \to & X \\ x = (x_1, \ldots, x_n) & \mapsto & \begin{cases} f(x), & \text{if } x \notin A, \\ x_0, & \text{if } x \in A \setminus C, \\ f\Big(a_1 + (x_1 - c_1)\frac{b_1 - a_1}{d_1 - c_1}, \ldots, a_n + (x_n - c_n)\frac{b_n - a_n}{d_n - c_n}\Big) & \text{if } x \in C. \end{cases} \end{array}$$

By applying Lemma 5.3 several times one can easily verify that this map is continuous.

The definition of $f(A, C)$ is sketched in Figure 449.

Lemma 28.2. *Let (X, x_0) be a pointed topological space and let $f\colon (I^n, \partial I^n) \to (X, x_0)$ be a map. Furthermore let $A \subset I^n$ be a boundary-trivial cuboid and let C be a non-degenerate cuboid that is contained in A. Then the maps f and $f(A, C)$ from $(I^n, \partial I^n)$ to (X, x_0) are homotopic.*

Proof $(*)$. Let $f\colon (I^n, \partial I^n) \to (X, x_0)$ be a map, let $A = [a_1, b_1] \times \cdots \times [a_n, b_n] \subset I^n$ be a boundary-trivial cuboid and let $C = [c_1, d_1] \times \cdots \times [c_n, d_n]$ be a non-degenerate cuboid that is contained in A. For $t \in [0, 1]$ we write

$$C_t = \big[a_1(1 - t) + c_1 t, b_1(1 - t) + d_1 t\big] \times \cdots \times \big[a_n(1 - t) + c_n t, b_n(1 - t) + d_n t\big].$$

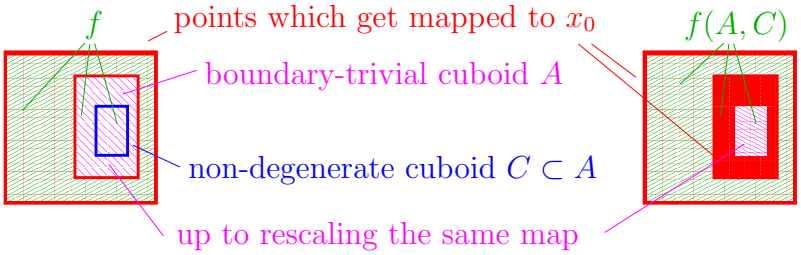

FIGURE 449.

Note that $C_0 = A$ and $C_1 = C$. It is now straightforward to see that the map

$$\begin{array}{rcl} I^n \times [0,1] & \to & X \\ (x,t) & \mapsto & F(A, C_t)(x) \end{array}$$

is a homotopy between f and $f(A,C)$. □

Now we can provide the proof of Proposition 28.1

Proof of Proposition 28.1. The neutral element of the product structure is given by the equivalence class of the constant map

$$\begin{array}{rcl} c_{x_0} \colon I^n & \to & X \\ x & \mapsto & x_0. \end{array}$$

Indeed, it follows immediately from Lemma 28.2, applied to $A = [0,1]^n$ and $C = [0, \frac{1}{2}]^n$, that given any map $f \colon (I^n, \partial I^n) \to (X, x_0)$ we have $f * c_{x_0} \simeq f$. Basically the same argument shows also that $c_{x_0} * f \simeq f$.

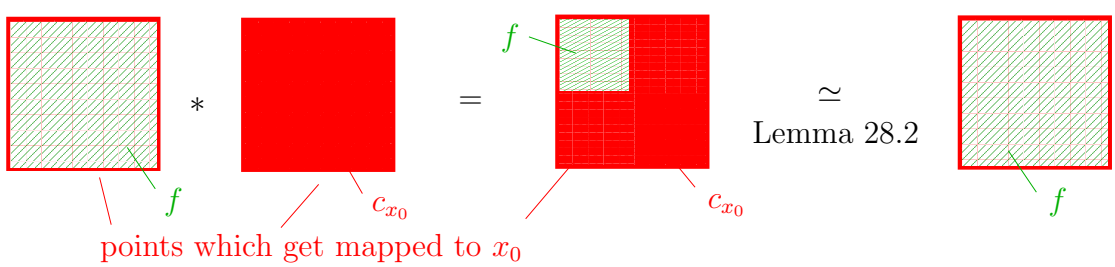

FIGURE 450.

Now consider three maps $f, g, h \colon (I^n, \partial I^n) \to (X, x_0)$. By applying Lemma 28.2 several times one can easily show that $(f * g) * h \simeq f * (g * h)$, see e.g. Figure 451. This proves that the multiplication on $\pi_n(X, x_0)$ is associative.

Now we turn to the most interesting question, namely finding the inverse of a given element in $\pi_n(X, x_0)$. Thus suppose we are given a map $f \colon (I^n, \partial I^n) \to (X, x_0)$. We

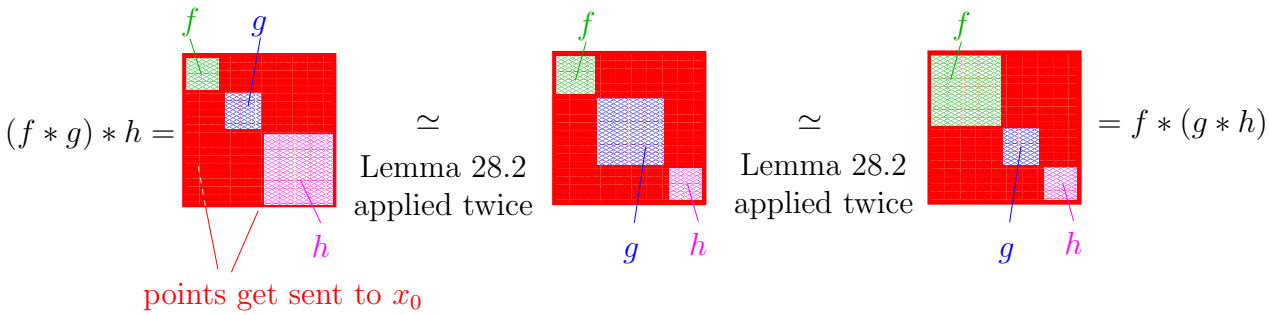

FIGURE 451.

consider the map

$$\begin{array}{rcl} \overline{f}\colon I^n & \to & X \\ (x_1,\dots,x_n) & \mapsto & f(1-x_1,x_2,\dots,x_n). \end{array}$$

We claim that $[f]\cdot[\overline{f}] = [f * \overline{f}] = [c_{x_0}]$. Thus we need to show that $f * \overline{f}$ is homotopic to c_{x_0}. It follows from Lemma 28.2 that $f * \overline{f}$ is homotopic to the map

$$\begin{array}{rcl} h\colon (I^n, \partial I^n) & \to & (X, x_0) \\ (x_1,\dots,x_n) & \mapsto & \begin{cases} f(2x_1,x_2,\dots,x_n), & \text{if } x_1 \in [0,\frac{1}{2}], \\ \underbrace{\overline{f}(2x_1-1,x_2,\dots,x_n)}_{=f(2-2x_1,x_2,\dots,x_n)}, & \text{if } x_1 \in [\frac{1}{2},1]. \end{cases} \end{array}$$

Thus it suffices to show that h is homotopic to c_{x_0}. It is in fact straightforward to see that the map[564][565]

$$\begin{array}{rcl} H\colon I^n \times [0,1] & \to & X \\ (x_1,\dots,x_n,t) & \mapsto & \begin{cases} f(2(x_1-\frac{t}{2}),x_2,\dots,x_n), & \text{if } x_1 \in [\frac{t}{2},\frac{1}{2}], \\ f(2-2(x_1+\frac{t}{2}),x_2,\dots,x_n), & \text{if } x_1 \in (\frac{1}{2},1-\frac{t}{2}], \\ x_0, & \text{otherwise} \end{cases} \end{array}$$

is a homotopy from h to c_{x_0}. We refer to Figure 452 for an illustration of the argument. Basically the same argument also shows that $[\overline{f}]\cdot[f] = [\overline{f} * f] = [c_{x_0}]$. We have thus verified both statements of the proposition. □

Example. There is one non-empty topological space for which we can immediately compute the higher homotopy groups, namely the topological space consisting of a single point P. In this case the only map $I^n \to \{P\}$ is the constant map, hence we see that $\pi_n(\{P\}) = 0$ for any $n \geq 1$.

[564]This map is continuous by Lemma 5.3.

[565]Even for $n = 1$ this homotopy is different from the homotopy used in Proposition 5.6 (3). Why is that?

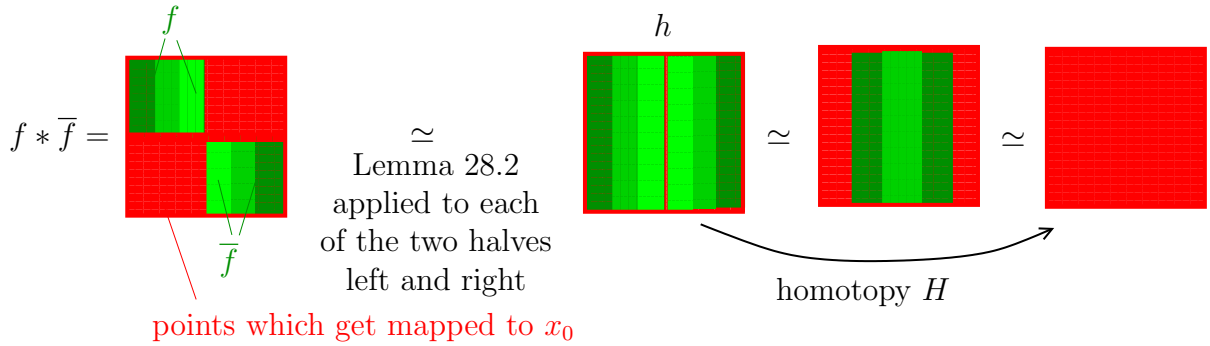

FIGURE 452.

The higher homotopy groups $\pi_n(X, x_0)$ seem even more complicated than the fundamental group. Surprisingly at least their algebraic structure is much simpler.

Proposition 28.3. *For any pointed topological space (X, x_0) and any $n \geq 2$ the homotopy group $\pi_n(X, x_0)$ is abelian.*

Proof. Suppose we are given two maps $f, g\colon (I^n, \partial I^n) \to (X, x_0)$. We have to show that $f * g$ is homotopic to $g * f$. The homotopy is described in Figure 453 for $n = 2$. It is straightforward to write down an explicit homotopy between $f * g$ and $g * f$ by composing four instances of the homotopy provided by Lemma 28.2. We leave the details to the reader. □

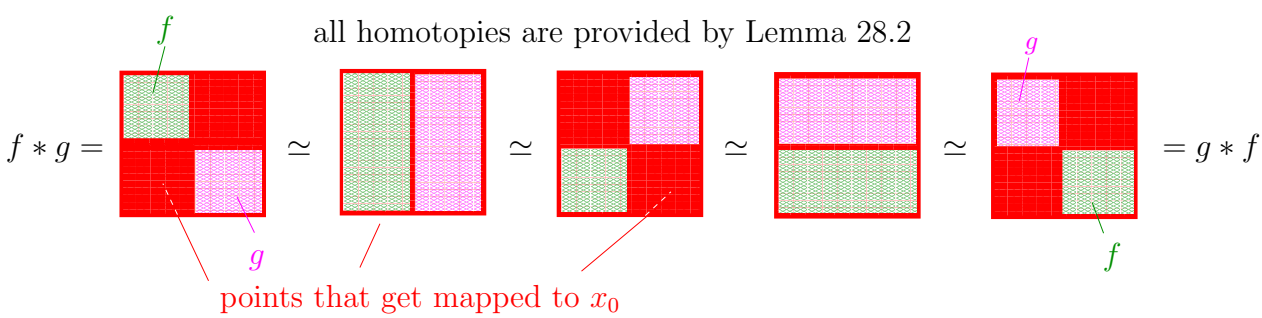

FIGURE 453. Illustration of the proof of Proposition 28.3.

28.2. **Alternative descriptions of homotopy groups.** In this short section we present several alternative points of views regarding elements in homotopy groups. In the following let $n \in \mathbb{N}$.

(1) We denote by $\Phi\colon (I^n, \partial I^n) \to (\overline{B}^n, S^{n-1})$ the homeomorphism from page 80.
(2) We write $* = (-1, 0, \dots, 0) \in S^n$. We denote by $\Psi\colon (\overline{B}^n / S^{n-1}, [S^{n-1}]) \to (S^n, *)$ the homeomorphism from page 99.

Now let X be a topological space and let $x_0 \in X$. The above homeomorphisms Φ and Ψ, together with Lemma 1.68, define bijections

$$\begin{array}{ll} & \text{(homotopy classes) of maps } (I^n, \partial^n) \to (X, x_0) \\ \iff & \text{(homotopy classes) of maps } (\overline{B}^n, S^{n-1}) \to (X, x_0) \\ \iff & \text{(homotopy classes) of maps } (\overline{B}^n/S^{n-1}, [S^{n-1}]) \to (X, x_0) \\ \iff & \text{(homotopy classes) of maps } (S^n, *) \to (X, x_0). \end{array}$$

The four equivalences combined say that we can view elements in $\pi_n(X, x_0)$ as homotopy classes of maps $(S^n, *) \to (X, x_0)$. This point of view is perhaps closest to our visual approach to thinking about topological spaces. But as we have seen above, for technical purposes it is often much easier to work with the maps $(I^n, \partial I^n) \to (X, x_0)$.

Remark. It is visually most natural to work with the last point of view, namely to think of elements in $\pi_n(X, x_0)$ as homotopy classes of maps $(S^n, *) \to (X, x_0)$. Unfortunately with this definition it is a little less clear how the group structure on $\pi_n(X, x_0)$ is defined. To visualize the group structure we need to work a little:

(1) First note that the homeomorphism $\Phi\colon (I^n, \partial I^n) \to (\overline{B}^n, S^{n-1})$ descends to a homeomorphism $\overline{\Phi}\colon I/\partial I^n \to \overline{B}^n/S^{n-1}$.
(2) We consider the homeomorphism $\Theta := \overline{\Phi}^{-1} \circ \Psi^{-1}\colon S^n \to I^n/\partial I^n$.
(3) We write $K := \{(x_1, \ldots, x_n) \in I^n \mid x_1 = \frac{1}{2}\}$.

In Figure 454 we show K and its journey through the maps Φ and Ψ.

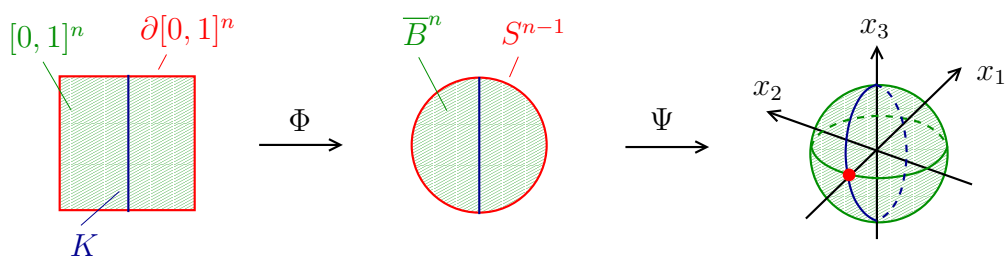

FIGURE 454.

(4) We denote by $S_1^n \vee S_2^n$ the wedge of two copies of S^n along the point $* \in S^n$.
(5) We refer to the map[566]

$$\begin{array}{rcl} S^n \xrightarrow{\Theta} I^n/\partial I^n & \to & I^n/(\partial I^n \cup K) \to S_1^n \vee S_2^n \\ [x_1, \ldots, x_n] & \mapsto & \begin{cases} \Theta^{-1}([2x_1, x_2, \ldots, x_n]) \in S_1^n, & \text{if } x_1 \in [0, \frac{1}{2}), \\ \Theta^{-1}([2x_1 - 1, x_2, \ldots, x_n]), & \text{if } x_1 \in [\frac{1}{2}, 1] \end{cases} \end{array}$$

as the *pinching map*.

[566]It follows easily from Lemma 1.32 (2') that this map is continuous.

(1) It follows basically immediately from the definitions that the group structure on $\pi_n(X, x_0)$ is given as follows:

$$\begin{array}{rcl} \pi_n(X,x_0) \times \pi_n(X,x_0) & \to & \pi_n(X,x_0) \\ ([f_1\colon S^n \to X],[f_2\colon S^n \to X]) & \mapsto & \big[S^n \ \to \ S^n_1 \vee S^n_2 \ \xrightarrow{f_1 \vee f_2} \ X\big]. \end{array}$$

In Figure 455 we sketch the pinching map and we sketch the corresponding definition of the group structure on $\pi_n(X, x_0)$.[567]

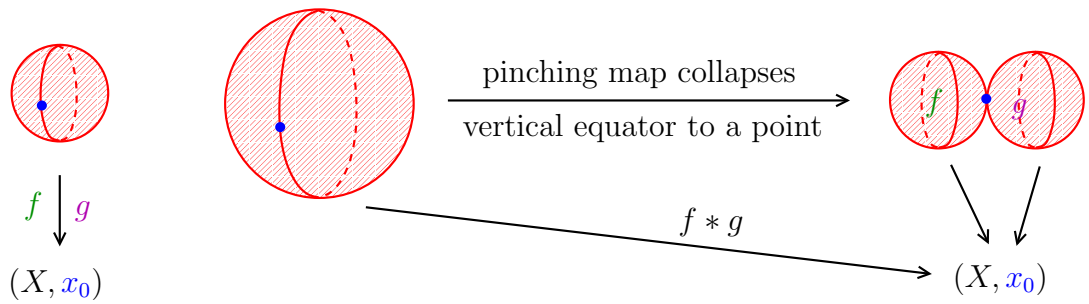

FIGURE 455.

We conclude this section with the following lemma that can be viewed as a generalization of Lemma 5.1.

Lemma 28.4. *Let X be a topological space, let $x_0 \in X$ and let $n \geq 1$. Furthermore let $f\colon (S^n, *) \to (X, x_0)$ be a map. Then the following statements are equivalent:*

(1) *the map $f\colon S^n \to X$ is homotopic to a constant map,*
(2) *there exists a map $F\colon \overline{B}^{n+1} \to X$ so that $F|_{S^n} = f$,*
(3) *f represents the trivial element in $\pi_n(X, x_0)$.*

Proof $(*)$. The equivalence of (2) and (3) is proved in a similar way as Lemma 5.1. We leave it to the reader to make the fairly straightforward modifications.

We turn to the proof that (3) implies (2). This is basically obvious. Indeed, the fact that f represents the trivial element in $\pi_n(X, x_0)$ means that there exists a homotopy of maps of pairs $(S^n, *) \to (X, x_0)$ from f to the constant map. But this means in particular that f is homotopic to the constant map c_{x_0}.

Finally suppose that (1) holds. This means that we assume that there exists a homotopy $H\colon S^n \times [0,1] \to X$ with $H_0 = f$ and $H_1 = c_{x_0}$. This time we do not assume that $H(*, t) = *$ for all $\in [0,1]$. We consider the map

$$\begin{array}{rcl} F\colon \overline{B}^{n+1} & \to & X \\ P & \mapsto & \begin{cases} H(Q, 2-2t), & \text{if } P = Q \cdot t \text{ with } Q \in S^n \text{ and } t \in [1, \frac{1}{2}], \\ x_0, & \text{otherwise.} \end{cases} \end{array}$$

[567]The meticulous reader will notice that it is perhaps not completely clear how the maps f and g are defined on the two smaller spheres.

It follows from Lemma 1.32 (2) that this map is indeed continuous. By construction we have $F|_{S^n} = f$. Thus we see that (2) is satisfied. This concludes the proof that all three statements are equivalent. $\square$

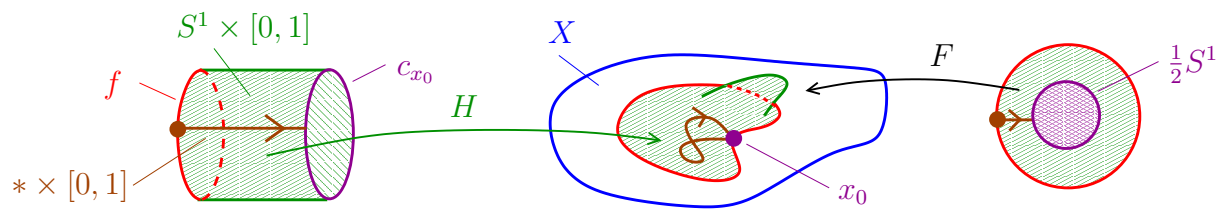

FIGURE 456. Illustration for the proof of Lemma 28.4.

28.3. **Properties and basic calculations of higher homotopy groups.** Now we want to understand some of the basic properties of higher homotopy groups. Perhaps not surprisingly, many of the basic statements about the fundamental group can be easily generalized to the setup of higher homotopy groups.

For example the following proposition can be viewed as a generalization of Proposition 5.11.

Proposition 28.5. *Let X be a topological space. Furthermore let x_0 and x_1 be two points in X which lie in the same component of X. Then the groups $\pi_n(X, x_0)$ and $\pi_n(X, x_1)$ are isomorphic.*

Remark. If X is a path-connected topological space and if we are only interested in the isomorphism type of the n-th homotopy group of X, then sometimes we use this proposition as an excuse to just write $\pi_n(X)$, i.e. we suppress the base point from the notation.

Proof. Let X be a topological space and let x_0 and x_1 be two points which lie in the same component of X. By definition this means that x_0 and x_1 are connected through a path $\gamma\colon [0,1] \to X$. Let $f\colon (I^n, \partial I^n) \to (X, x_1)$ be a map. We consider the map[568][569]

$$\begin{aligned} f^\gamma\colon (I^n, \partial I^n) &\to (X, x_0) \\ (t_1, \dots, t_n) &\to \begin{cases} f\big(2t_1 - \frac{1}{2}, \dots, 2t_n - \frac{1}{2}\big), & \text{if } (t_1, \dots, t_n) \in \big[\frac{1}{4}, \frac{3}{4}\big]^n, \\ \gamma(t), & \text{if } (t_1, \dots, t_n) \in \partial\big(\big[\frac{t}{4}, \frac{4-t}{4}\big]^n\big) \text{ for } t \in [0,1]. \end{cases} \end{aligned}$$

The definition of f^γ is illustrated in Figure 457. It remains to prove the following claim:

Claim.

(1) the map $\Phi\colon \pi_n(X, x_1) \to \pi_n(X, x_0)$ given by $[f] \mapsto [f^\gamma]$ is well-defined,
(2) the map Φ is a bijection, and

[568] If we view elements in $\pi_1(X, x_i)$ as represented by maps $(S^1, *) \to (X, x_i)$, what does the corresponding map $\pi_1(X, x_1) \to \pi_1(X, x_0)$ look like?

[569] One can easily verify that the map is continuous.

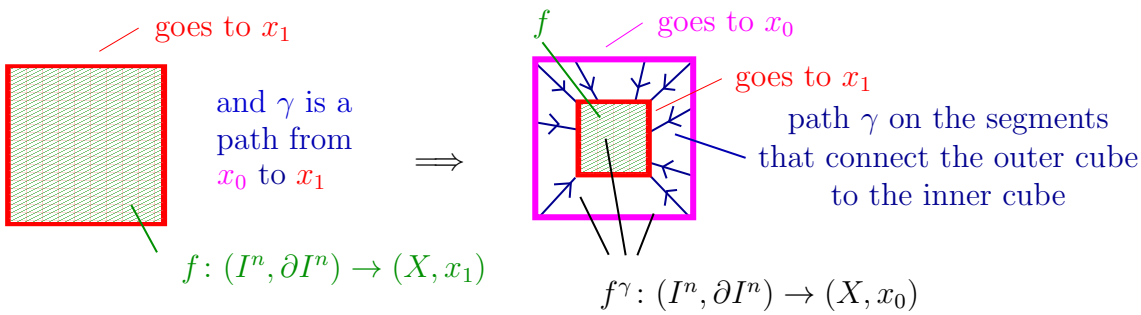

FIGURE 457. Illustration of the proof of Proposition 28.5.

(3) the map Φ is a group homomorphism.

We quickly discuss the three statements of the claim:

(1) This statement can be verified easily by hand.
(2) As usual we denote by $\overline{\gamma}$ the path given by $\overline{\gamma}(t) = \gamma(1-t)$. It is straightforward to verify that the map $\Psi\colon \pi_n(X, x_0) \to \pi_n(X, x_1)$ given by $[g] \mapsto [f^{\overline{\gamma}}]$ is an inverse to Φ.
(3) Now let $f, g\colon (I^n, \partial I^n) \to (X, x_0)$ be maps. We need to show that $f^\gamma * g^\gamma$ is homotopic to $(f * g)^\gamma$. (These two maps are illustrated in Figure 458.) It should be clear that verifying this statement is elementary, in the sense that one can write down an explicit homotopy. On the other hand it should also be clear that writing down an explicit homotopy is supremely painful and highly non-instructive. Thus we will skip this step and leave it to the eager reader to fill in the details. □

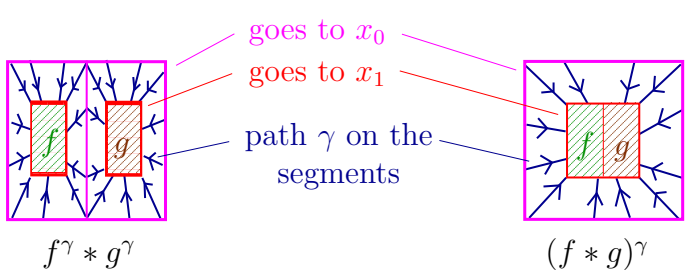

FIGURE 458. Second illustration of the proof of Proposition 28.5.

Definition. Let $f\colon X \to Y$ be a map between two topological spaces, let $n \in \mathbb{N}$ and let $x_0 \in X$. We write $y_0 = f(x_0)$. The map

$$\begin{array}{rcl} f_*\colon \pi_n(X, x_0) & \to & \pi_n(Y, y_0) \\ [\sigma\colon (I^n, \partial I^n) \to (X, x_0)] & \mapsto & [f \circ \sigma\colon (I^n, \partial I^n) \xrightarrow{\sigma} (X, x_0) \xrightarrow{f} (Y, y_0)] \end{array}$$

is well-defined map and it is a group homomorphism for every $n \geq 1$.[570] As usual we say that f_* is the map induced by f.

The following proposition is straightforward generalization of Proposition 6.1.

Proposition 28.6. *Let $n \geq 1$, let $\mathcal{T}$ be the category of pointed topological spaces and let $\mathcal{G}$ be the category of groups. Then*

$$\begin{array}{rcl} \mathrm{Ob}(\mathcal{T}) & \to & \mathrm{Ob}(\mathcal{G}) \\ (X, x_0) & \mapsto & \pi_n(X, x_0) \end{array}$$

together with the maps

$$\begin{array}{rcl} \mathrm{Mor}(\mathcal{T}) & \to & \mathrm{Mor}(\mathcal{G}) \\ (f\colon (X, x_0) \to (Y, y_0)) & \mapsto & (f_*\colon \pi_n(X, x_0) \to \pi_n(Y, y_0)) \end{array}$$

is a covariant functor.

Proof. It follows immediately from the definitions that

$$\mathrm{id}_* = \mathrm{id} \qquad \text{for all pointed pairs } (X, x_0),$$

and that

$$(g \circ f)_* = g_* \circ f_* \quad \text{for all maps } f\colon (X, x_0) \to (Y, y_0) \text{ and } g\colon (Y, y_0) \to (Z, z_0).$$

But this is exactly what we need to show. □

We continue with the following fairly elementary but useful proposition.

Proposition 28.7. *Let $n \geq 1$.*

(1) *Let $f\colon X \to Y$ be a map between topological spaces and let $x_0 \in X$ be a point. If f is a homotopy equivalence, then*

$$f_*\colon \pi_n(X, x_0) \to \pi_n(Y, f(x_0))$$

is an isomorphism.

(2) *If X is a contractible topological space, then the following two statements hold:*
   (a) *for any base point $x_0 \in X$ we have $\pi_n(X, x_0) = 0$,*
   (b) *any map $f\colon S^n \to X$ can be extended to a map $\overline{B}^{n+1} \to X$.*

(3) *Let (X, x_0) be a pointed topological space. If we denote by Y the component of X that contains x_0 and if we denote by $i\colon Y \to X$ the inclusion map, then the map*

$$i_*\colon \pi_n(Y, x_0) \to \pi_n(X, x_0)$$

is an isomorphism.

Proof.

(1) This statement is proved the same way as Proposition 9.12.
(2) Let X be a contractible topological space.

[570] Both statements follow basically immediately from the definitions.

(a) By definition of "contractible" the topological space X is homotopy equivalent to a topological space consisting of a single point $\{*\}$. Evidently $\pi_n(\{*\},*)=0$, which by (1) implies that $\pi_n(X,x_0)=0$ for some base point x_0. In Lemma 9.9 we saw that a contractible topological space is path-connected. Thus it follows from Proposition 28.5 that $\pi_n(X,x_0)=0$ for any base point x_0.

(b) This statement is proved basically the same way as Lemma 5.1. For completeness' sake we carry out the argument. So let $f\colon S^n\to X$ be a map. We pick a base point $*$ for S^n and we set $x_0:=f(*)$. By (a) we know that $\pi_n(X,x_0)=0$. We take the point of view from page 715. Thus we can view $[f]$ as an element in $\pi_n(X,x_0)=0$. By definition $[f]=0$ means that there exists a homotopy $F\colon S^n\times[0,1]\to X$ such that $F(p,0)=f(p)$ for all $p\in S^n$, that $F(p,1)=x_0$ for all $p\in S^n$ and that $F(*,t)=x_0$ for all $t\in[0,1]$. Then the desired extension is given by the map

$$\begin{array}{rcl}\overline{B}^{n+1} & \to & X\\ r\cdot v & \mapsto & F(v,(1-r))\end{array}$$

where we write a point in $\overline{B}^{n+1}$ as $r\cdot v$ with $r\in[0,1]$ and $v\in S^n$.

(c) This statement is an easy consequence of Lemma 1.101 and the fact that I^n is path-connected. □

Example. The topological space $\mathbb{R}^n$ is homotopy equivalent to a point P. Thus it follows from Proposition 28.7 and the discussion on page 713 that $\pi_k(\mathbb{R}^n)\cong\pi_k(P)\cong 0$. Exactly the same way, using the discussion on page 308, one can show that all the higher homotopy groups of convex subsets of $\mathbb{R}^n$ vanish, e.g. we have $\pi_k\big(\overline{B}^n\big)=\pi_k(B^n)=0$.

The following proposition is the high-dimensional analogue of Proposition 7.21.

Proposition 28.8. *Let A and B be two topological spaces and let $a_0\in A$ and $b_0\in B$. We consider the inclusion maps*

$$\begin{array}{rcl} i\colon A & \to & A\times B\\ a & \mapsto & (a,b_0)\end{array}\quad \textit{and}\quad \begin{array}{rcl} j\colon B & \to & A\times B\\ b & \mapsto & (a_0,b)\end{array}$$

and we consider the projection maps

$$\begin{array}{rcl} p\colon A\times B & \to & A\\ (a,b) & \mapsto & a\end{array}\quad \textit{and}\quad \begin{array}{rcl} q\colon A\times B & \to & B\\ (a,b) & \mapsto & b.\end{array}$$

Then the maps

$$\begin{array}{rcl} \Phi\colon \pi_n(A,a_0)\times\pi_n(B,b_0) & \to & \pi_n(A\times B,(a_0,b_0))\\ (x,y) & \to & i_*(x)\cdot j_*(y)\end{array}$$

and

$$\begin{array}{rcl} \Psi\colon \pi_n(A\times B,(a_0,b_0)) & \to & \pi_n(A,a_0)\times\pi_n(B,b_0)\\ z & \to & (p_*(z),q_*(z))\end{array}$$

are both homomorphisms[571] *and they are inverses of one another, in particular both are isomorphisms.*

Proof. The proof of this proposition is almost verbatim the same as the proof of Proposition 7.21. □

In Proposition 5.14 we saw that $\pi_1(S^n) = 0$ for $n \geq 2$. Now we can prove the analogous statement for higher homotopy groups. More precisely, we have the following proposition.

Proposition 28.9. *Let $n \in \mathbb{N}$. For any $k \in \{1, \ldots, n-1\}$ we have*

$$\pi_k(S^n) \;=\; 0.$$

The proof of Proposition 28.9 relies on the following more general and actually very convenient proposition.

Proposition 28.10. *Let X be a CW-complex with a single 0-cell x_0 and let $n \in \mathbb{N}$. If X has no cells in dimensions $1, \ldots, n$, then $\pi_n(X, x_0) = 0$ for $k = 1, \ldots, n$.*

Note that the above proposition is a generalization of Corollary 27.14.

Proof of Proposition 28.10. Let X be a CW-complex with a single 0-cell x_0 and let $n \in \mathbb{N}$. We suppose that X has no cells in dimensions $1, \ldots, n$. Let $k \in \{1, \ldots, n\}$. We want to show that $\pi_k(X, x_0) = 0$. We take the point of view from page 715, i.e. we view elements of $\pi_k(X, x_0)$ as homotopy classes of maps $(S^k, *) \to (X, x_0)$. As on page 648 we consider the k-sphere S^k as a CW-complex with one 0-cell $*$ and one k-cell. Let $g\colon (S^k, *) \to (X, x_0)$ be a map. By the Cellular Approximation Theorem 27.15, applied to $g\colon S^k \to X$ and the subcomplex $\{*\} \subset S^k$, there exists a homotopy F rel $\{*\}$ from the map g to a cellular map $\widetilde{g}$. Since F is a homotopy rel $\{*\}$ we see that F also defines a homotopy of maps $(S^k, *) \to (X, x_0)$ of pairs of topological spaces. Thus we see that $[g] = [\widetilde{g}] \in \pi_k(X, x_0)$.

Since $\widetilde{g}$ is cellular we know that $\widetilde{g}(S^k)$ lies in the k-skeleton of X. But by our hypothesis on X the k-skeleton of X consists only of the point x_0. Put differently, $\widetilde{g}$ is the constant map that sends all points in S^k to x_0. We have thus shown that $\pi_k(X, x_0) = 0$. □

Proof of Proposition 28.9. Again, as on page 648 we consider the n-sphere S^n as a CW-complex with one 0-cell and one n-cell. With this CW-structure it follows immediately from Proposition 28.10 that $\pi_k(S^n) = 0$ for $k = 1, \ldots, n-1$. □

The following proposition is also a straightforward generalization from the setting of fundamental groups to the setting of higher homotopy groups. The proof is almost verbatim the same as the proof of Proposition 26.19 and of Proposition 16.4.

Proposition 28.11. *Let X be a topological space and let $X_1 \subset X_2 \subset X_3 \subset \ldots$ be a sequence of subsets such that $X = \bigcup_{i \in \mathbb{N}} X_i$ and such that of one the following three conditions holds:*

[571] In fact in this case it follows immediately from Proposition 28.3 and Lemma 7.20 that Φ is a homomorphism.

(1) *every compact subset of X is already contained in one of the X_i, or*
(2) *each X_i is open in X, or*
(3) *X is a CW-complex and each X_i is a subcomplex.*

Then for any $w \in X_1$ and any $n \in \mathbb{N}$ the inclusion induced maps $\pi_n(X_i, w) \to \pi_n(X, w)$ induce an isomorphism

$$\pi_n(X, w) \;=\; \lim_{\longrightarrow} \pi_n(X_i, w).$$

From this proposition we obtain immediately the following, perhaps not overly surprising, corollary.

Corollary 28.12. *For every $n \in \mathbb{N}$ we have $\pi_n(S^\infty) = 0$.*

Proof. We equip S^∞ and all spheres S^k, $k \in \mathbb{N}$ with the CW-complex structure that we defined on page 655. We have

$$\pi_n(S^\infty) \;=\; \pi_n\Big(\bigcup_{k\in\mathbb{N}} S^k\Big) \;\overset{\substack{\text{by Proposition 28.11 and by definition}\\ \text{of the topology of } S^\infty}}{\overset{\downarrow}{=}}\; \lim_{\longrightarrow} \pi_n(S^k) \;\overset{\substack{\text{by Proposition 28.9 we have}\\ \pi_n(S^k)=0 \text{ for } k>n}}{\overset{\downarrow}{=}}\; 0.$$

□

28.4. **Covering spaces and higher homotopy groups.** One of the main tools in studying fundamental groups was to study the relationship between the fundamental group of a topological space and coverings of the given topological space. Perhaps somewhat surprisingly, for $n \geq 2$ we have a completely different relationship between the n-th homotopy group and coverings.

Proposition 28.13. *Let $p\colon (X, x_0) \to (B, b_0)$ be a covering of pointed topological spaces. Let $n \geq 2$. Then the following two statements hold:*

(1) *The map $p_*\colon \pi_n(X, x_0) \to \pi_n(B, b_0)$ is an isomorphism.*
(2) *The map*[572]

$$\begin{array}{rcl} \pi_n(B, b_0) & \to & \pi_n(X, x_0) \\ [f\colon (S^n, *) \to (B, b_0)] & \to & [\textit{unique lift of } f \textit{ to a map } (S^n, *) \to (X, x_0)] \end{array}$$

is well-defined and it is the inverse to p_*.

The following is an immediate, and very useful, corollary to Proposition 28.13.

Corollary 28.14. *Let X be a path-connected and reasonable topological space. Given any $n \geq 2$ we have*[573]

$$\pi_n(X) \;\cong\; \pi_n(\textit{universal covering of } X).$$

[572]Here we take the point of view from page 715 where we saw that we view the elements of $\pi_n(B, b_0)$ as homotopy classes of maps $(S^n, *) \to (B, b_0)$.

[573]In Corollary 20.11 we showed that every connected, path-connected and reasonable topological space X admits a universal covering $p\colon \widetilde{X} \to X$, i.e. a covering such that $\widetilde{X}$ is simply connected.

Now we present some examples for Corollary 28.14. We will consider a few more examples after the proof of Proposition 28.13.

Examples.

(1) Let $k \in \mathbb{N}$ and $n \geq 2$. We have

$$\pi_n((S^1)^k) \;=\; \pi_n(\mathbb{R}^k/\mathbb{Z}^k) \;\underset{\substack{\uparrow \\ \text{Proposition 28.13 page 720}}}{\cong}\; \pi_n(\mathbb{R}^k) \;\underset{\uparrow}{=}\; 0.$$

In particular we see that all of the higher homotopy groups of S^1 and the torus $S^1 \times S^1$ vanish.

(2) We consider $X = S^1 \vee S^2$. On page 568 we had determined its universal covering $\widetilde{X}$. For convenience we picture it again in Figure 459. It follows from Proposition 28.13 that $\pi_2(S^1 \vee S^2)$ is isomorphic to $\pi_2(\widetilde{X})$. At the moment we cannot determine $\pi_2(\widetilde{X})$, but since $\widetilde{X}$ has "infinitely many spheres" one might expect $\pi_2(\widetilde{X})$ to be pretty big.

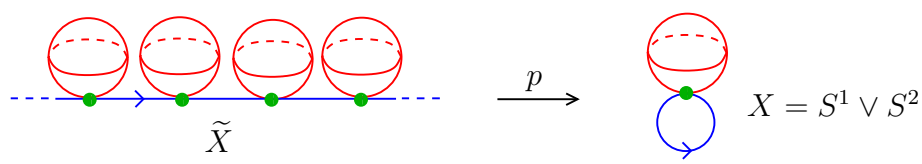

FIGURE 459.

(3) One of our goals is still to complete the classification of lens spaces, in particular we would like to answer Question 7.8. So let $L(p,q)$ and $L(p,r)$ be two lens spaces. Then for any $n \geq 2$ we have

$$\pi_n(L(p,q)) \;\underset{\substack{\uparrow \\ \text{Proposition 28.13}}}{=}\; \pi_n(S^3) \;\underset{\uparrow}{=}\; \pi_n(L(p,r)).$$

We do not know the higher homotopy groups of S^3, but this argument shows that higher homotopy groups are useless for distinguishing lens spaces.

Proof of Proposition 28.13. Let $p\colon (X,x_0) \to (B,b_0)$ be a covering of pointed topological spaces and furthermore let $n \geq 2$. Our goal is to construct an inverse to the map $p_*\colon \pi_n(X,x_0) \to \pi_n(B,b_0)$.

We saw on page 715 that we can think of elements in $\pi_n(B,b_0)$ as homotopy classes of maps $(S^n,*) \to (B,b_0)$. Thus let $f\colon (S^n,*) \to (B,b_0)$ be given. We are in the following

setting[574]

$$\begin{tikzcd} & (X,x_0) \arrow[d, "p"] \\ (S^n,*) \arrow[r, "f"'] & (B,b_0). \end{tikzcd} \quad \xrightarrow[\text{since } \pi_1(S^n)=0]{\text{by Proposition 20.2}} \quad \begin{tikzcd} & (X,x_0) \arrow[d, "p"] \\ (S^n,*) \arrow[r, "f"'] \arrow[ur, dashed, "\text{exists unique } \widetilde{f}"] & (B,b_0). \end{tikzcd}$$

Furthermore it follows again from Proposition 20.2, applied to $Z = S^n \times [0,1]$, that the lifts of two homotopic maps $(S^n,*) \to (B,b_0)$ are two homotopic maps $(S^n,*) \to (X,x_0)$.[575] Summarizing we just constructed a map

$$\begin{array}{rcl} \lambda\colon \pi_n(B,b_0) & \to & \pi_n(X,x_0) \\ [f] & \mapsto & [\widetilde{f}]. \end{array}$$

Now we have to show that λ is an inverse to p_*. First of all, given any $[f] \in \pi_n(B,b_0)$ we have

$$(p_* \circ \lambda)([f]) \;=\; p_*\big([\widetilde{f}]\big) \;=\; \big[p \circ \widetilde{f}\big] \;=\; [f].$$

Now let $[g] \in \pi_n(X,x_0)$. We then have

$$(\lambda \circ p_*)([g]) \;=\; \lambda([p \circ g]) \;\underset{\substack{\uparrow \\ \text{since } g \text{ is the unique lift of } p\circ g \text{ to } x_0.}}{=}\; [g].$$

□

Now we give a few more applications of Proposition 28.13.

Examples.

(1) Let Σ be a surface of genus ≥ 2. In Theorem 23.9 we have seen that there exists a covering $p\colon \mathbb{D} \to \Sigma$ where $\mathbb{D} = B_1(0) \subset \mathbb{C}$. Since $\mathbb{D}$ is convex it follows from Proposition 28.13 and the discussion on page 720 that $\pi_n(\Sigma) \cong \pi_n(\mathbb{D}) = 0$ for all $n \geq 2$.

Together with the example on page 723 we have now shown that the higher homotopy groups of every surface of genus ≥ 1 vanish.

(2) Let Σ be a surface of genus ≥ 1 and let $f\colon \Sigma \to \Sigma$ be a self-homeomorphism. We denote by $M(\Sigma, f)$ the mapping torus that we introduced on page 469. For $n \geq 2$

[574] In Proposition 20.2 we need that the sphere S^n is of path-connected and o-locally path-connected, but there are no hypotheses on B or X.

[575] Here there is a little hidden subtlety: if $F\colon S^n \times [0,1] \to B$ is a homotopy between two maps $f, g\colon (S^n,*) \to (B,b_0)$, then we can lift f, g to maps $\widetilde{f}, \widetilde{g}\colon (S^n,*) \to (X,x_0)$. Furthermore we can apply Proposition 20.2 to lift F to a map $\widetilde{F}\colon S^n \times [0,1] \to X$ such that $\widetilde{F}(*,0) = x_0$. We still need to show that $\widetilde{F}(*,t) = x_0$ for all $t \in [0,1]$. We know that for every $t \in [0,1]$ we have $\widetilde{F}(*,t) \in p^{-1}(b_0)$. By Lemma 7.4 the preimage $p^{-1}(b_0)$ is discrete. Since $[0,1]$ is connected it follows that the map $p\colon [0,1] \to p^{-1}(b_0)$ is constant by Lemma 1.92. But since it takes the value x_0 for $t = 0$ it takes the value x_0 for all $t \in [0,1]$.

we have

$$\pi_n(M(\Sigma,f)) \underset{\substack{\uparrow \\ \text{by Lemma 15.23} \\ \text{and Proposition 28.13}}}{\cong} \pi_n(\Sigma\times\mathbb{R}) \underset{\substack{\uparrow \\ \text{Proposition 28.7}}}{\cong} \pi_n(\Sigma) \underset{\substack{\uparrow \\ \text{previous example}}}{=} 0.$$

Lemma 28.15. *Let X be a 1-dimensional CW-complex and let $x_0 \in X$ be base point. Then $\pi_n(X,x_0)=0$ for every $n\geq 2$.*

Sketch of proof. Let X be a 1-dimensional CW-complex, let $x_0\in X$ and let $n\geq 2$. We first assume that X is finite and connected. We write $k=1-\chi(X)$. We have

$$\pi_n(X) \underset{\substack{\uparrow \\ \text{Proposition 9.21 and} \\ \text{Proposition 28.7}}}{\cong} \pi_n\Big(\bigvee_{i=1}^{k} S^1\Big) \underset{\substack{\uparrow \\ \text{Proposition 28.13}}}{\cong} \pi_n\Big(\text{universal covering of } \bigvee_{i=1}^{k} S^1\Big) \underset{\substack{\uparrow \\ \text{Proposition 28.11 and Figure 460}}}{\cong} \varinjlim \pi_n(\text{trees } T_i) \underset{\substack{\uparrow \\ \text{Proposition 9.20} \\ \text{and Proposition 28.7}}}{=} \varinjlim 0 = 0.$$

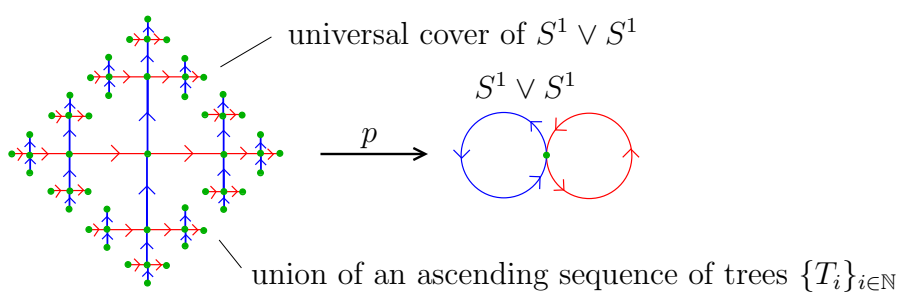

FIGURE 460.

Now suppose that X is an arbitrary 1-dimensional CW-complex. Let $[f]\in\pi_n(X,x_0)$. It follows from Proposition 26.14 that the image of f lies in a finite connected subcomplex Y of X. But by the above discussion $[f]=0\in\pi_n(Y,x_0)$, hence, by functoriality of π_n, we also have $[f]=0\in\pi_n(X,x_0)$. □

28.5. **Are there any higher homotopy groups that are non-trivial?** We have now computed lots of higher homotopy groups, but so far the results have been rather dull, all the groups we have computed so far are trivial.

So are there are any higher homotopy groups that are non-trivial? A natural candidate for a non-trivial group is surely $\pi_n(S^n)$. The following question naturally arises:

Question 28.16. *Let $n\geq 2$. Does the identity map* $\mathrm{id}\colon S^n\to S^n$ *define a non-trivial element in the homotopy group $\pi_n(S^n,*)$?*

We can also ask, what are the higher homotopy groups of spheres, i.e. what can we say about $\pi_k(S^n)$ for $k>n$? On page 723 we saw that all these groups are trivial for $n=1$. But what happens for $n>1$? Can the higher homotopy groups of spheres be non-trivial?

To construct our first example of a potentially interesting map from a higher-dimensional to a lower-dimensional sphere we recall that on page 113 we gave an identification $\mathbb{C}\mathrm{P}^1 = S^2$. We consider the following map which is usually referred to as the *Hopf*[576] *map*:

$$\begin{array}{rcl} H\colon S^3 = \{(z_1, z_2) \in \mathbb{C}^2 \,|\, |z_1|^2 + |z_2|^2 = 1\} & \to & S^2 = \mathbb{C}\mathrm{P}^1 \\ (z_1, z_2) & \mapsto & [z_1 : z_2]. \end{array}$$

The homotopy class of H defines an element in $\pi_3(S^2)$.

Question 28.17. *Does the Hopf map $H\colon S^3 \to S^2$ represent a non-trivial element in the homotopy group $\pi_3(S^2)$?*

Remark. The definition of the Hopf map is very elegant, but unfortunately we pay for the elegance by loosing any intuition for what the map looks like. So how are supposed to think about the Hopf map? A straightforward calculation shows that for each $P \in S^2$ the preimage $H^{-1}(P)$ is a circle. Furthermore, if we use the explicit homeomorphism from Lemma 1.41 to make the identification of S^3 with $\mathbb{R}^3 \cup \{\infty\}$ then we can make the following observations:

(1) the circle $S^1 \times \{0\}$ corresponds to the points $(z, 0) \in S^3$, in particular the circle gets sent to the point $[1 : 0] \in \mathbb{C}\mathrm{P}^1$,
(2) the circle that is given by the z-axis together with ∞ corresponds to the points $(0, z) \in S^3$, in particular the circle gets sent to the point $[0 : 1] \in \mathbb{C}\mathrm{P}^1$.

Next recall that Lemma 18.1 we gave an explicit identification[577]

$$\left(\overline{B}^2 \times S^1\right) \sqcup_{S^1 \times S^1} \left(S^1 \times \overline{B}^2\right) \xrightarrow{\cong} S^3.$$

It follows from the definition of this identification that on the torus $S^1 \times S^1$ the "diagonal circle" $\{(z, z) \,|\, z \in S^1\}$ is the preimage of the point $[1 : 1] \in \mathbb{C}\mathrm{P}^1$. In Figure 461 we show the preimages of H for some points in $\mathbb{C}\mathrm{P}^2 = S^2$.

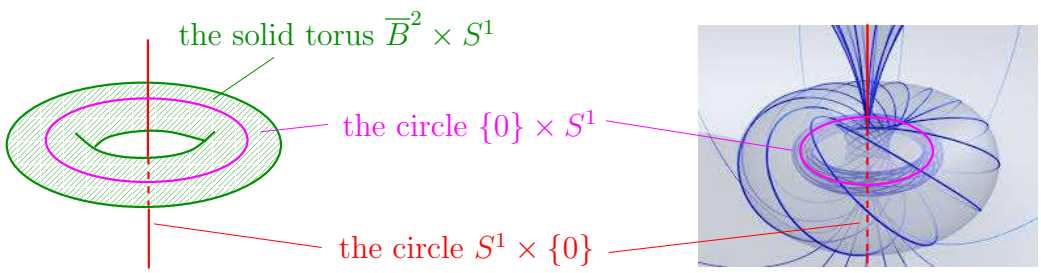

FIGURE 461.

We introduce one more construction of maps that represent potentially non-trivial elements in homotopy groups of spheres.

[576]Heinz Hopf (1894-1971) was a German mathematician.

[577]Note that in Lemma 18.2 we saw that the corresponding embedding $\overline{B}^2 \times S^1 \to S^3$ is essential given by the standard embedding.

Definition.

(1) Let X be a topological space. Recall that on page 452 we defined the *suspension of* X to be the topological space

$$\Sigma(X) \ := \ (X \times [-1,1])/\sim$$

where we identify all points in $X \times \{-1\}$ to a single point and we identify all points in $X \times \{1\}$ to a single point. We refer to the point $[X \times \{1\}]$ as the *North Pole* of $\Sigma(X)$.

(2) Given a map $f\colon X \to Y$ between topological space we denote by

$$\begin{array}{rcl} \Sigma(f)\colon \Sigma(X) & \to & \Sigma(Y) \\ [(x,t)] & \mapsto & [(f(x),t)] \end{array}$$

the *suspension of* f.

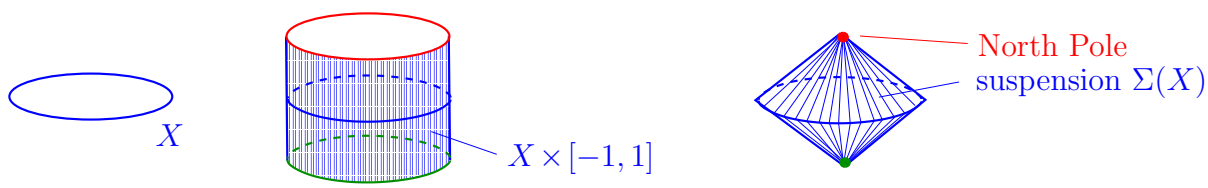

FIGURE 462.

Remark. Let $n \in \mathbb{N}_0$. Recall that on page 453 we wrote down an explicit homeomorphism $\Sigma(S^n) \to S^{n+1}$ that sends the North Pole of $\Sigma(S^n)$ to the North Pole $(0,\dots,0,1)$ of S^{n+1}. We will use this homeomorphism to identify $\Sigma(S^n)$ with S^{n+1}.

Now we have the following elementary lemma.

Lemma 28.18. *Let $k \in \mathbb{N}_0$.*

(1) *Let (X,x_0) be a pointed topological space. We denote by $*$ the North Pole of $\Sigma(X)$. The map*

$$\begin{array}{rcl} \pi_k(X,x_0) & \to & \pi_{k+1}(\Sigma(X),*) \\ [f\colon S^k \to X] & \mapsto & \big[\Sigma(f)\colon \Sigma(S^k) = S^{k+1} \to \Sigma(X)\big] \end{array}$$

is a well-defined group homomorphism. We refer to it as the suspension homomorphism.

(2) *Let $n \in \mathbb{N}_0$. We denote by $*$ the North Pole of S^n and S^{n+1}. The map*

$$\begin{array}{rcl} \pi_k(S^n,*) & \to & \pi_{k+1}(S^{n+1},*) \\ [f\colon S^k \to S^n] & \mapsto & \big[\Sigma(f)\colon \Sigma(S^k) = S^{k+1} \to \Sigma(S^n) = S^{n+1}\big] \end{array}$$

is a well-defined group homomorphism. We refer to it also as the suspension homomorphism.

Proof.

(1) It follows from Lemma 15.4 (4) that this map is well-defined.[578] We leave it as an exercise to show that the map is in fact a group homomorphism.[579]
(2) This statement follows immediately from (1). □

We conclude this chapter with the following question:

Question 28.19. *Let $H\colon S^3 \to S^2$ be the Hopf map. Is the image of $[H] \in \pi_3(S^2)$ under the iterated suspension homomorphisms $\pi_3(S^2, x_0) \to \pi_{3+k}(S^{2+k}, x_1)$ non-trivial?*

Unfortunately at the moment we do not have the tools to answer any of the above questions. In general it is very hard to compute higher homotopy groups as there are few computational techniques that can be used to show that higher homotopy groups are non-zero. One of the key problems is that there is no analogue to the Seifert-van Kampen Theorem 14.1. We will get to know a few techniques to compute higher homotopy groups of spheres, but we will cover these only in much later chapter, since the calculations will require the use of singular homology groups. But even then we will only be able to determine some homotopy groups of spheres, in fact the full computation of homotopy groups of spheres is still an open problem.

This sorry state of affairs means that as of right now we cannot use higher homotopy groups to distinguish any of the topological spaces that we could not distinguish already using the fundamental group. In particular we still cannot show that for $k \neq l$ the topological spaces $\mathbb{R}^k$ and $\mathbb{R}^l$ are not homeomorphic. We will only be able to do so after developing a new tool, namely the singular homology groups, in the coming sections.

28.6. **The Poincaré Conjecture.** Before we bid a temporary farewell to the fundamental group and to higher homotopy groups we want to quickly discuss the Poincaré Conjecture.

Definition.

(1) Let $k \in \mathbb{N}_0$. We say that a topological space X is *k-connected*, if $\pi_i(X) = 0$ for $i = 0, \dots, k$.[580][581]
(2) An n-dimensional topological manifold X that is closed and that is $\lfloor \frac{n}{2} \rfloor$-connected is called an *n-dimensional homotopy sphere*. If X is in fact a manifold, then we refer to it as a *smooth n-dimensional homotopy sphere*.

Remark.

[578] In an earlier version of these it was written that "it is straightforward to see that the map is well-defined". If one traces through the ancestry of Lemma 15.4 (4) one realizes that this lemma is, despite appearances, by no means obvious.

[579] This exercise might in fact be rather painful if one does not pick the correct point of view. It seems like most authors agree, since I could not find a single reference where it is shown that the suspension map is indeed a homomorphism.

[580] For example, X is 0-connected if and only if X is path-connected and *non-empty*. Furthermore, X is 1-connected if and only if it is simply connected.

[581] Since a k-connected topological space is in particularly 0-connected and thus path-connected we see that we can ignore base points.

(1) Since $\lfloor \frac{3}{2} \rfloor = 1$ we see that a 3-dimensional homotopy sphere is the same as a connected closed 3-dimensional topological manifold with $\pi_1(M) = 0$.
(2) We have seen in Proposition 28.9 that each S^n is in fact a homotopy sphere. A smooth n-dimensional homotopy sphere is thus a closed n-dimensional manifold that cannot be distinguished from the standard sphere S^n using the first $\lfloor \frac{n}{2} \rfloor$ homotopy groups.
(3) The definition using $\lfloor \frac{n}{2} \rfloor$-connected sounds slightly arbitrary, but we will see in a later chapter that an n-dimensional manifold that is $\lfloor \frac{n}{2} \rfloor$-connected is in fact $(n-1)$-connected. Furthermore we will see that a homotopy sphere cannot be distinguished from an ordinary sphere by any of the higher homotopy groups either.

One can now ask whether every (smooth) homotopy sphere is S^n. Here one needs to be a little careful what one means by "is". There are two reasonable interpretations. One could either interpret "is" as "is diffeomorphic to" or as "is homeomorphic to". So we really have two, a priori different, questions that we can ask:

Question 28.20. *Let $n \in \mathbb{N}$.*
(1) *Is every smooth n-dimensional homotopy sphere diffeomorphic to S^n?*
(2) *Is every n-dimensional homotopy sphere homeomorphic to S^n?*

For $n = 1$ we saw in Proposition 3.53 and Proposition 3.49 that the answer to both questions is "yes". Similarly we saw in Theorems 14.9 and 14.9 that the answer to questions is also "yes" for $n = 2$. For $n = 1$ and $n = 2$ it was basically known by the end of the 19th century that the answers are "yes".[582]

The above question was first raised in dimension $n = 3$ by Henri Poincaré in 1905. This special case became known as the Poincaré Conjecture in dimension three.

The first important result dealing with Question 28.20 was proved by John Milnor [Mi1] in 1956. In 1962 he obtained the Fields medal for proving the following theorem which shows that the above two questions raised in Question 28.20 are indeed two different questions.[583]

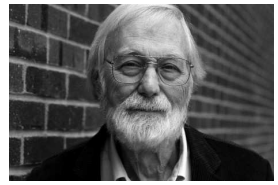
Theorem 28.21. (Milnor) *There exists a 7-dimensional manifold that is a homeomorphic to S^7 but that is not diffeomorphic to S^7.*

Remark. An n-dimensional manifold that is homeomorphic to S^n but not diffeomorphic to S^n is often called an *exotic n-sphere*. Milnor thus showed that in dimension 7 there exists an exotic 7-sphere. Michel Kervaire and John Milnor [KeM] showed that for $n \geq 5$ there exist at most finitely many, pairwise non-diffeomorphic, exotic n-spheres. Furthermore, in dimensions 5 and 6 there do not exist any exotic spheres. Somewhat earlier it had been shown in 1952 by Edwin Moise [Moi] that in dimension 3 there does not exist an exotic sphere. On the other hand, it follows from the work of Kervaire–Milnor [KeM] and

[582] Even though at that point the concept of a (topological) manifold was not fully developed yet.

[583] The Fields medal is the most prestigious award in mathematics. It is awarded every four years to usually 2-4 mathematicians. One of the conditions is that you can only be awarded a Fields medal if you are under 40.

Henri Poincaré (1854-1912)



John Milnor (∗1931)

FIGURE 463.

FIGURE 464. The Fields medal

much more recent work of Hill–Hopkins–Ravenel [HHR] and Wang–Xu [WX] that the only odd dimensions n for which S^n has a unique smooth structure are 1, 3, 5 and 61. It is conjectured, see e.g. [WX, Conjecture 1.17] that for dimensions greater than 4, the only spheres with a unique smooth structure are S^5, S^6, S^{12}, [56] and S^{61}. We refer to [BHHM] for some recent work regarding even-dimensional spheres.

In 1961 Stephen Smale [Sma] proved the following theorem, for which he obtained the Fields medal in 1966.

Theorem 28.22. (Smale) *In dimensions $n \geq 5$ every homotopy sphere is homeomorphic to S^n.*

The next major result was obtained by Michael Freedman [Fre] in 1981. He was also awarded a Fields medal for his work.

Theorem 28.23. (Freedman) *Every 4-dimensional homotopy sphere is homeomorphic to S^4.*

The proof by Freedman is so hard and specialized that only very few mathematicians have ever understood the proof.[584]

Now we turn to the dimension $n = 3$. Now is a good moment to state the following theorem which implies, in particular, that in the 3-dimensional setting the two questions asked Question 28.20 are equivalent.

[584] I was told at some point that the total number of mathematicians who understood the proof is six, it is not clear whether at this moment anybody understands the proof.

Theorem 28.24. *Let $n = 2$ or $n = 3$. Every topological n-dimensional manifold*[585] *admits a unique smooth structure, in particular two n-dimensional manifolds are diffeomorphic if and only if they are homeomorphic.*

Proof. The 2-dimensional case was proved by Tibor Radó [Rad], see also [AS], [Moi2, p. 60] and [Hat4] for more modern proofs.

We turn to the 3-dimensional case. By work of Edwin Moise [Moi] [Moi2, p. 252 and 253] any topological 3-manifold (not necessarily compact) admits a unique "piecewise-linear structure". (See also [Bin, Shal] for alternative proofs). By work of Munkres [Mun4, p. 333][Mun2, Theorems 6.2 and 6.3], and independently Whitehead [Whd4, Corollary 1.18], this implies that a topological 3-manifold admits a unique smooth structure. (See also [Kui], [Thu2, Chapter 3.10] and for a more detailed discussion.) □

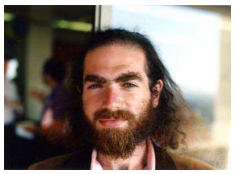
After Freedman's work it took another 20 years before finally the original Poincaré Conjecture was dealt with. More precisely, in 2002 Grigori Perelman [Per1, Per2, Per3, MTi] proved the following result.

Theorem 28.25. (Perelman) *Every 3-dimensional homotopy sphere is diffeomorphic to S^3.*

Perelman would have gotten the Fields medal in 2006 if he had not turned it down. Furthermore, the Poincaré Conjecture was one of the seven Millennium Problems[586] for which the Clay foundation awards a prize of one million dollars. This prize was also turned down by Perelman.

Stephen Smale (∗1930)

Michael Freedman (∗1951)



Grigory Perelman (∗1966)

Figure 465.

What remains to be done is the following problem which is often referred to as the *smooth Poincaré Conjecture in dimension 4*.

Question 28.26. *Does there exist a 4-dimensional manifold that is homeomorphic to S^4 but that is not diffeomorphic to S^4?*

[585] Note that here we do not add any extra hypothesis, so the topological manifold could be non-compact.
[586] https://en.wikipedia.org/wiki/Millennium_Prize_Problems

This question is considered to be one of the hardest problems in topology. Unfortunately there has been very little progress so far.

It might be surprising to see that the last open problem in this context is in dimension 4. But it turns out that the study of 4-dimensional manifolds is much harder than the study of manifolds in lower or higher dimensions.

The following theorem shows very clearly the special role played by 4-dimensional topology.

Theorem 28.27.

(1) *For $n \neq 4$ every n-dimensional manifold homeomorphic to $\mathbb{R}^n$ is also diffeomorphic to $\mathbb{R}^n$.*
(2) *In dimension 4 there exist uncountably many manifolds that are homeomorphic to $\mathbb{R}^4$ but that are pairwise non-diffeomorphic.*

The first statement was proved by John Stallings [Sta] in 1961. The second statement was proved by Cliff Taubes [Tau] in 1987. The latter result builds on the ground breaking work of Simon Donaldson [Don] which he proved as a second year PhD student and for which he obtained a Fields medal in 1986.

Exercises for Chapter 28.

Exercise 28.1. Let X be a topological space, let $x_0 \in X$ and let $f\colon (I^n, \partial I^n) \to (X, x_0)$ be a map with $n \geq 1$. We consider the map

$$\begin{array}{rcl} \overline{f}\colon I^n & \to & X \\ (x_1, \dots, x_n) & \mapsto & f(1-x_1, 1-x_2, \dots, 1-x_n). \end{array}$$

Is $[\overline{f}] \in \pi_n(X, x_0)$ the inverse of $[f] \in \pi_n(X, x_0)$?

Exercise 28.2. Let $k \leq l$ be natural numbers, let $f\colon S^k \to S^l$ be a map and let $x_0 \in S^k$. Show that for any $i \in \mathbb{N}$ the map $f_*\colon \pi_i(S^k, x_0) \to \pi_i(S^l, f(x_0))$ is the trivial map.
Hint: Use Proposition 28.9.

Exercise 28.3. In this exercise you can assume that we already know that $\pi_3(S^2) \cong \mathbb{Z}$. Show that there exists an epimorphism $\pi_3(S^1 \vee S^2) \to \mathbb{Z}^3 \oplus \mathbb{Z}_4$.

Exercise 28.4. Let $n \in \mathbb{N}$ and let K be a non-empty compact subset of $\mathbb{R}^n$. Let $r \in \mathbb{R}$ such that $r > \sup\{\|P\| \mid P \in K\}$. Show that for any $k \in \mathbb{N}$ the inclusion induced map $\pi_k(S_r^{n-1}(0)) \to \pi_k(\mathbb{R}^n \setminus K)$ is a monomorphism.

Exercise 28.5. We consider the pseudocircle, i.e. we consider the slightly weird topological space $X = \{A, B, C, D\}$ from page 66. Show that $\pi_n(X, A) = 0$ for any $n \geq 2$.
Hint: Find a convenient covering space of X.

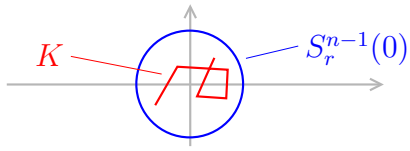


FIGURE 466. Illustration of Exercise 28.4.

Exercise 28.6. Let (X, x_0) be a topological space. We denote by $\Sigma(X)$ the suspension of X and we denote by $*$ the North Pole of $\Sigma(X)$. Is the suspension homomorphism

$$\pi_1(X_0, x_0) \ \to \ \pi_2(\Sigma(X), *),$$

that we introduced in Lemma 28.18, necessarily a monomorphism?

Exercise 28.7. Let M be a connected n-dimensional topological manifold with non-trivial fundamental group. Show that the suspension $\Sigma(M)$ is not an $(n+1)$-dimensional topological manifold.
Hint: Consider one of the two suspension points. Show that there is no neighborhood of such a point that is homeomorphic to an open subset of $\mathbb{R}^{n+1}$.
Remark: It is surprisingly tricky to write down a rigorous argument. Also note that the exercise is similar in spirit to Exercise 18.7.

29. The homology groups of a topological space

One of our main goals is to show that for $m \neq n$ the spheres S^m and S^n are not homeomorphic. We have seen that for most cases fundamental groups are of no use. Furthermore, it might be that in principle higher homotopy groups can distinguish such spheres, but since we cannot compute higher homotopy groups, those are of no use either. So we need a new approach to finding invariants that can distinguish spheres.

In this chapter we want to introduce a new functor from the category of topological spaces to an algebraic category, more precisely, we will introduce a functor from the category of topological spaces to the category of abelian groups.

29.1. **Singular chains.**

Definition.

(1) Given k points $P_1, \dots, P_k$ in $\mathbb{R}^n$ such that $P_2 - P_1, \dots, P_k - P_1$ are linearly independent we refer to the convex hull of $P_1, \dots, P_k$ as a *k-simplex*.

(2) Given $n \in \mathbb{N}_0$ we refer to the convex hull of the standard basis vectors $e_1, \dots, e_{n+1}$ of $\mathbb{R}^{n+1}$, i.e. to

$$\Delta^n \ := \ \{(x_0, \dots, x_n) \in \mathbb{R}^{n+1} \,|\, x_0 + \dots + x_n = 1 \text{ and } x_i \geq 0 \text{ for all } i = 0, \dots, n\}$$

as the *standard n-simplex*.

(3) Given the standard n-simplex Δ^n we define its boundary as[587]

$$\partial \Delta^n \ = \ \bigcup_{i=0}^{n} \{(t_0, \dots, t_n) \in \Delta^n \,|\, t_i = 0\}.$$

Example. The standard 0-simplex Δ^0 is just the point $\{1\} \in \mathbb{R}$, the standard 1-simplex Δ^1 equals the segment in $\mathbb{R}^2$ from $(1,0)$ to $(0,1)$ and the standard 2-simplex Δ^2 is the triangle in $\mathbb{R}^3$ spanned by the vertices $(1,0,0), (0,1,0)$ and $(0,0,1)$. We refer to Figure 467 for an illustration of the standard simplices in dimension 0, 1 and 2 and for an illustration of the boundary of the standard 2-simplex.

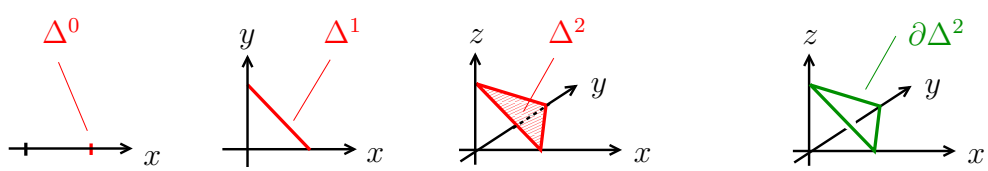

Figure 467.

For the record we state the following elementary lemma.

[587]The definition of the "boundary" of the standard n-simplex Δ^n is the "obvious one". Nonetheless note that if we had taken the original definition of the boundary of a subset A in some subspace X as introduced on page 50 and applied it to $\Delta^n \subset \mathbb{R}^{n+1}$, then the boundary of Δ^n in $\mathbb{R}^{n+1}$ would be all of Δ^n.

Lemma 29.1. *The map*

$$\begin{array}{rcl} \Delta^n & \overset{\cong}{\to} & \left\{(x_1,\dots,x_n)\in[0,1]^n \,\middle|\, \sum_{i=1}^n x_i \in [0,1]\right\} \xrightarrow[\text{to } Q=(\frac{1}{n+1},\dots,\frac{1}{n+1})]{\text{Proposition 1.48 (2) applied}} \overline{B}^n \\ (t_0,\dots,t_n) & \mapsto & (t_0,\dots,t_{n-1}). \end{array}$$

is a homeomorphism that restricts to a homeomorphism from $\partial\Delta^n$ to the sphere S^{n-1}.

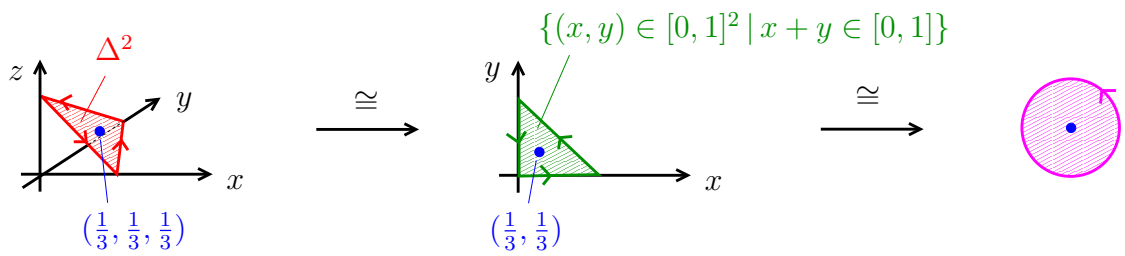

FIGURE 468. Illustration of the canonical homeomorphism from Lemma 29.1.

Definition. An *r-dimensional face* of the standard n-simplex is defined as a subset of the form

$$\{(t_0,\dots,t_n)\in\Delta^n \,|\, t_{d_1}=t_{d_2}=\dots=t_{d_{n-r}}=0\},$$

where $d_1<d_2<\dots<d_{n-r}\in\{0,\dots,n\}$ are fixed. We illustrate the definition in Figure 469 on the left.

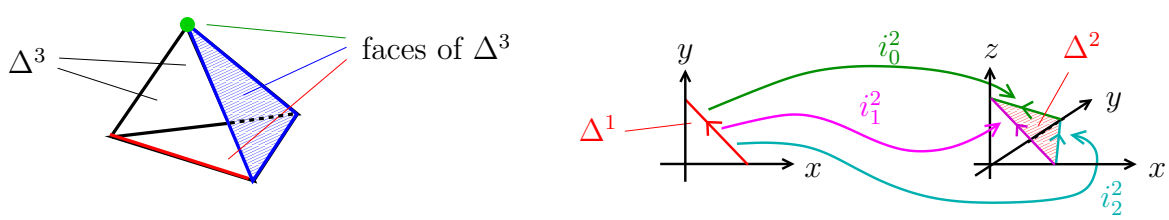

FIGURE 469.

Remark.

(1) The boundary $\partial\Delta^n$ of the standard n-simplex is the union of all $(n-1)$-dimensional faces of Δ^n.

(2) Every r-dimensional face of Δ^r is homeomorphic to the standard r-simplex. For later we fix homeomorphism in the case of $(n-1)$-dimensional faces. More precisely, for $j\in\{0,\dots,n\}$ we consider the map

$$\begin{array}{rcl} i_j^n\colon \Delta^{n-1} & \to & \Delta^n \\ (t_0,\dots,t_{n-1}) & \mapsto & (t_0,\dots,t_{j-1},0,t_j,\dots,t_{n-1}). \end{array}$$

This map is sometimes called the *j-th face map*. It is straightforward to see that these face maps are homeomorphisms. The face maps $i_0^2, i_1^2, i_2^2 \colon \Delta^1 \to \Delta^2$ are illustrated in Figure 469 on the right.

The first idea for the definition of homology groups is now the following. In the definition of the fundamental group $\pi_1(X, x_0)$ we had considered all maps $f \colon [0,1] \to X$ with the extra condition $f(0) = f(1) = x_0$. Using this extra condition we could concatenate loops to eventually end up with a group structure. Now given $n \in \mathbb{N}_0$ we want to consider all maps from Δ^n to X with no extra condition on the boundary. This time there is no reasonable way how two such maps can be composed to give a new map. Since we nonetheless want the notion of a group we turn the set of all maps $\Delta^n \to X$ into a group by "brute force", i.e. by considering the free abelian group generated by these maps.

This leads us to the following definition.

Definition. Let X be a topological space and let $n \in \mathbb{N}_0$.

(1) A *singular n-simplex* is a map $\sigma \colon \Delta^n \to X$.
(2) We define

$$C_n(X) \ := \ \text{free abelian group generated by the set of singular } n\text{-simplices in } X.$$

For $n \in \mathbb{Z}_{<0}$ we set $C_n(X) = 0$.
(3) We refer to an element in $C_n(X)$ as a *singular n-chain in X*.

Examples.

(1) For $n = 0$ a singular n-simplex is a map from Δ^0 to X. Such a map is uniquely determined by the corresponding point in X. Therefore frequently we will identify singular 0-simplices with points in X.
(2) For points $z_0, \dots, z_k \in \mathbb{R}^n$ we consider the map

$$\begin{aligned} [z_0, \dots, z_k] \colon \Delta^k &\to \mathbb{R}^n \\ (t_0, \dots, t_k) &\mapsto \sum_{j=0}^{k} t_j \cdot z_j. \end{aligned}$$

The map $[z_0, \dots, z_k]$ thus sends the standard k-simplex Δ^k to the simplex spanned by $z_0, \dots, z_k$ in $\mathbb{R}^n$. Put differently, $[z_0, \dots, z_k]$ is a singular k-simplex in $\mathbb{R}^n$.

Remark. Let X be a topological space. By the discussion on page 366 we can view every element in $C_n(X)$, i.e. every singular n-chain, as a linear combination $a_1\sigma_1 + \dots + a_k\sigma_k$ where $a_1, \dots, a_k \in \mathbb{Z}$ and where $\sigma_1, \dots, \sigma_k$ are singular n-simplices.

Now let $f \colon X \to Y$ be a map between topological spaces. For each n we consider

$$\begin{aligned} f_* \colon C_n(X) &\to C_n(Y) \\ \sum_{i=1}^{k} a_i \cdot \sigma_i &\mapsto \sum_{i=1}^{k} a_i \cdot (f \circ \sigma_i). \end{aligned}$$

It is easy to verify that $X \mapsto C_n(X)$ and $f \mapsto f_*$ defines a functor from the category of topological spaces to the category of abelian groups.

Have we made any progress towards our goal of distinguishing topological spaces? Not really. For example, if X is a manifold of dimension ≥ 1, then given any $n \in \mathbb{N}_0$ there exist uncountable many maps $\Delta^n \to X$, i.e. the group $C_n(X)$ is a free abelian group with uncountably many generators. Such groups are totally useless for distinguishing non-homeomorphic topological spaces.

29.2. **Definition of the homology groups of a topological space.** Before we give the definition of homology groups it is perhaps helpful to recall the definition of de Rham cohomology.

Let M be a manifold. We write

$$\Omega^n(M) \ := \ \{\text{smooth } n\text{-forms on } M\}.$$

The isomorphism type of this vector space is an invariant of the diffeomorphism type of the manifold M, but it is rather useless, since for $1 \leq n \leq \dim(M)$ this is a vector space of uncountable dimension. To cut $\Omega^n(M)$ into something much smaller we defined linear maps $d_n \colon \Omega^n(M) \to \Omega^{n+1}(M)$ with $d_{n+1} \circ d_n = 0$. Finally we defined the n–th de Rham cohomology group of M as

$$H^n_{\mathrm{dR}}(M) \ := \ \ker\{d_n \colon \Omega^n(M) \to \Omega^{n+1}(M)\}/\operatorname{im}\{d_{n-1} \colon \Omega^{n-1}(M) \to \Omega^n(M)\}.$$

We are now in a similar situation: to a topological space X we associated the free abelian group $C_n(X)$ which is "too big". The idea now is to introduce a "differential" as for the case of differential forms. But in this case there is no good way to associate to a map $\Delta^n \to X$ a new map $\Delta^{n+1} \to X$. But by restricting the map $\Delta^n \to X$ to each of the $(n-1)$-dimensional faces of Δ^n which are, as we have seen, homeomorphic to the standard $(n-1)$-simplex, we can associate to a singular n-simplex $\sigma \colon \Delta^n \to X$ a sum of singular $(n-1)$-simplices, i.e. a singular $(n-1)$-chain. To do this we will use the maps $i^n_k \colon \Delta^{n-1} \to \Delta^n$, $k = 0, \ldots, n$ from page 735 to identify the standard $(n-1)$-simplex with the $(n-1)$-dimensional faces of Δ^n. Now we can define

$$\widetilde{\partial}_n \sigma \ := \ \sum_{j=0}^{n} \sigma \circ i^n_j.$$

By Lemma 11.1 this defines a map $\widetilde{\partial}_n \colon C_n(X) \to C_{n-1}(X)$. But it is quite straightforward to see that for this definition the composition of the maps $\widetilde{\partial}_n \colon C_n(X) \to C_{n-1}(X)$ and $\widetilde{\partial}_{n-1} \colon C_{n-1}(X) \to C_{n-2}(X)$ is not zero[588]. But we can rectify this problem by cleverly introducing signs. This leads us to the following definition.

[588]Indeed, let S be a set and let $\mathbb{Z}^{(S)}$ be the free abelian group generated by S. We define $\epsilon \colon \mathbb{Z}^{(S)} \to \mathbb{Z}$ to be the linear map that assigns to each $s \in S$ the value 1. It follows easily from the definitions that for any $\sigma \colon \Delta^n \to X$ we have $\epsilon(\widetilde{\partial}_n \sigma) = n+1$ and $\epsilon((\widetilde{\partial}_{n-1} \circ \widetilde{\partial}_n)(\sigma)) = n \cdot (n+1)$.

Definition. Let X be a topological space and let $\sigma\colon \Delta^n \to X$ be a singular n-simplex. The *boundary* $\partial_n\sigma \in C_{n-1}(X)$ of σ is defined as

$$\partial_n\sigma \;:=\; \sum_{j=0}^{n}(-1)^j \cdot \sigma \circ i_j^n.$$

By Lemma 11.1 the map $\sigma \mapsto \partial_n\sigma$ extends uniquely to a linear map

$$\begin{array}{rcl} \partial_n\colon C_n(X) & \to & C_{n-1}(X) \\ \sum_{i=1}^{k} a_i\sigma_i & \mapsto & \sum_{i=1}^{k} a_i \cdot \partial\sigma_i, \end{array}$$

which we refer to as the *n-th boundary map*. If it is clear with what dimension we are working with, then we just write ∂ instead of ∂_n.

Examples.

(1) For any singular 1-simplex $\sigma\colon \Delta^1 \to X$ we have[589]

$$\partial\sigma \;=\; (-1)^0 \cdot \sigma \circ i_0^1 + (-1)^1 \cdot \sigma \circ i_1^1 \;=\; \sigma(0,1) - \sigma(1,0).$$

Put differently, a singular 1-simplex can be viewed as a map σ from the "interval" Δ^1 to X. The boundary of σ is thus the "endpoint" $\sigma(0,1)$ "minus" the "starting point" $\sigma(1,0)$. Here we view points in X again as singular 0-simplices. We sketch the definition of a singular 1-simplex in Figure 470.

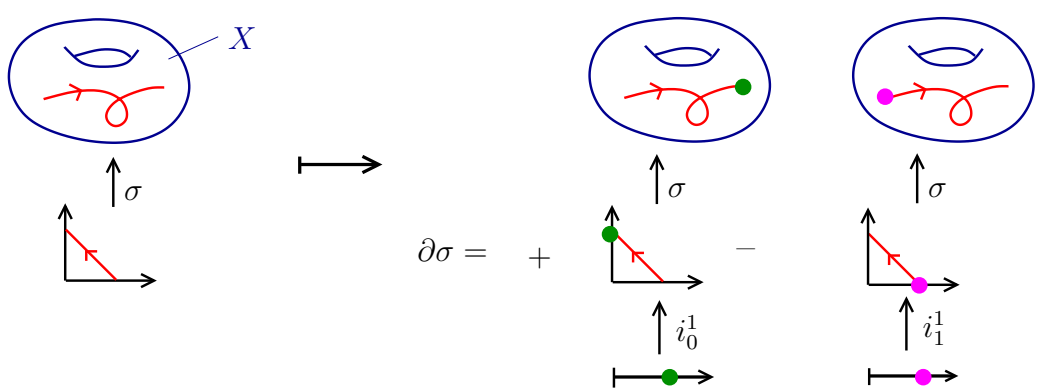

FIGURE 470. Boundary of a singular 1-simplex.

(2) In Figure 471 we sketch the boundary of a singular 2-simplex.

As promised, these boundary maps have the following fundamental property:

Proposition 29.2. *Let X be a topological space. For any $n \in \mathbb{N}_0$ the composition*

$$\partial_{n-1} \circ \partial_n\colon C_n(X) \;\to\; C_{n-2}(X)$$

[589]Here we again use the convention that given a point $x \in X$ we denote by x also the corresponding singular 0-simplex.

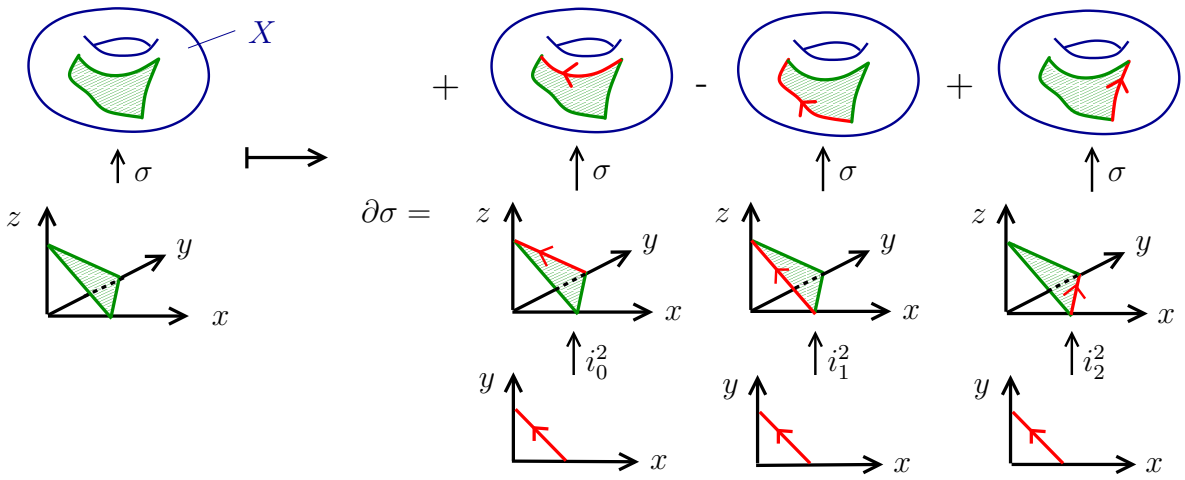

FIGURE 471. Boundary of a singular 2-simplex.

is the zero map.

Proof. It suffices to show that $\partial_{n-1}(\partial_n(\sigma)) = 0$ for every singular n-simplex $\sigma\colon \Delta^n \to X$. Thus let $\sigma\colon \Delta^n \to X$ be a singular n-simplex. Then it follows immediately from the definitions that

$$\begin{aligned}\partial_{n-1}(\partial_n(\sigma)) &= \partial_{n-1}\Big(\sum_{j=0}^{n}(-1)^j\cdot\sigma\circ i_j^n\Big) = \sum_{k=0}^{n-1}(-1)^k\sum_{j=0}^{n}(-1)^j\cdot(\sigma\circ i_j^n)\circ i_k^{n-1}\\ &= \sum_{0=k<j\le n}(-1)^{k+j}\cdot\sigma\circ(i_j^n\circ i_k^{n-1}) + \sum_{0=j\le k\le n-1}(-1)^{k+j}\cdot\sigma\circ(i_j^n\circ i_k^{n-1}) =: (*).\end{aligned}$$

Now we want to show that each expression $\sigma\circ(i_j^n\circ i_k^{n-1})$ appears precisely twice, but with opposite signs. From the definitions it follows easily that for $j\le k$ we have[590]

$$i_j^n\circ i_k^{n-1} = i_{k+1}^n\circ i_j^{n-1}.$$

Now we continue with the above calculation:

$$\begin{aligned}(*) &\underset{\substack{\uparrow\\ \text{above calculation of } i_j^n\circ i_k^{n-1}}}{=} \sum_{0=k<j\le n}(-1)^{k+j}\cdot\sigma\circ(i_j^n\circ i_k^{n-1}) + \sum_{0=j\le k\le n-1}(-1)^{k+j}\cdot\sigma\circ(i_{k+1}^n\circ i_j^{n-1})\\ &\underset{\substack{\uparrow\\ \text{substitution } l=k+1}}{=} \sum_{0=k<j\le n}(-1)^{k+j}\cdot\sigma\circ(i_j^n\circ i_k^{n-1}) + \sum_{0=j<l\le n}(-1)^{l+j-1}\cdot\sigma\circ(i_l^n\circ i_j^{n-1}) \underset{\substack{\uparrow\\ \text{all summands left and right cancel}}}{=} 0.\end{aligned}$$

□

The following is arguably the most important definition of algebraic topology.

[590]Indeed, if $j\le k$, then the zero-entries of $(i_j^n\circ i_k^{n-1})(t_0,\dots,t_{n-1})$ are the entries j and $k+1$.

Definition. Let X be a topological space and $n \in \mathbb{N}_0$. We define the *n-th singular homology group of X* as the quotient group[591]

$$H_n(X) \ := \ \ker\{\partial_n \colon C_n(X) \to C_{n-1}(X)\} \,/\, \operatorname{im}\{\partial_{n+1} \colon C_{n+1}(X) \to C_n(X)\}.$$

For $n \in \mathbb{Z}_{<0}$ we extend this definition to $H_n(X) := 0$. Throughout the lecture notes we will mostly shorten the name "singular homology" to "homology".[592]

One of the key goals of this course is to develop tools for computing homology groups of topological spaces. In particular we want to compute the homology groups for all spheres. In the subsequent discussions it is helpful to introduce a few more definitions.

Definition. Let X be a topological space.

(1) We say $c \in C_n(X)$ is an *n-cycle*, if $\partial c = 0$.
(2) If c is an n-cycle, then we refer to $[c] \in H_n(X)$ as the *homology class of c*.
(3) We say two singular n-chains c and d are *homologous* if there exists a singular $(n+1)$-chain e with $\partial e = c - d$. In particular, if c and d are cycles, then they are homologous if they represent the same homology class.
(4) An n-cycle c is called *null-homologous*, if $[c] = 0 \in H_n(X)$.
(5) Given a singular 1-simplex $\sigma \colon \Delta^1 \to X$ we denote by $\overline{\sigma}$ the singular 1-simplex that is given by $\overline{\sigma}(t, 1-t) = \sigma(1-t, t)$. Put differently, $\overline{\sigma}$ is given by reversing the orientation of σ.

The following lemma will be proved in Exercises 29.1 and 29.3.

Lemma 29.3. *Let X be a topological space and let $\sigma \colon \Delta^1 \to X$ be a singular 1-simplex.*

(1) *If σ is a constant map, then σ is null-homologous.*
(2) *The singular 1-chains $-\sigma$ and $\overline{\sigma}$ are homologous.*
(3) *Let $s \in (0,1)$ and consider the singular 1-simplices*

$$\begin{array}{rcl} \alpha \colon \Delta^1 & \to & X \\ (t, 1-t) & \mapsto & \sigma(st, 1-st) \end{array} \quad \textit{and} \quad \begin{array}{rcl} \beta \colon \Delta^1 & \to & X \\ (t, 1-t) & \mapsto & \sigma(s + t(1-s), 1 - (s + t(1-s))). \end{array}$$

Then the singular 1-chains σ and $\alpha + \beta$ are homologous.

The second part of the lemma says that for a singular 1-simplex the geometric operation of reversing the orientation is (up to the boundary of a simplicial 2-chain) the same as algebraically inverting the sign. Furthermore, the third part of the lemma says that for a singular 1-simplex (again up to the boundary of a simplicial 2-chain) it does not make a difference whether or not we split the singular 1-simplex into two singular 1-simplices.

[591] It follows from Proposition 29.2 that we have the following inclusion:

$$\operatorname{im}\{\partial_{n+1} \colon C_{n+1}(X) \to C_n(X)\} \ \subset \ \ker\{\partial_n \colon C_n(X) \to C_{n-1}(X)\}.$$

Furthermore the groups $C_*(X)$ are abelian, in particular any subgroup is also abelian and normal. Therefore it does indeed make sense to consider the quotient group.

[592] Later on we will also introduce "cellular homology". At that point it will be useful to remember that our present homology groups have a more precise name, namely singular homology groups.

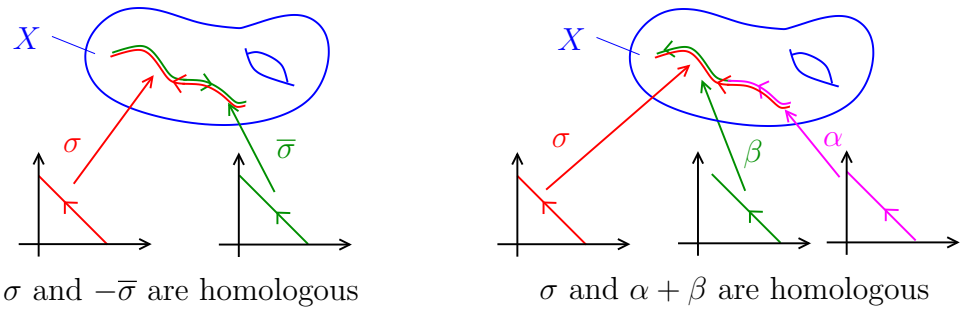

FIGURE 472. Illustration of Lemma 29.3.

Examples.

(1) We consider Figure 473. We see three singular chains on the torus, and it is straightforward to show that all three singular chains are cycles. Now the question arises,

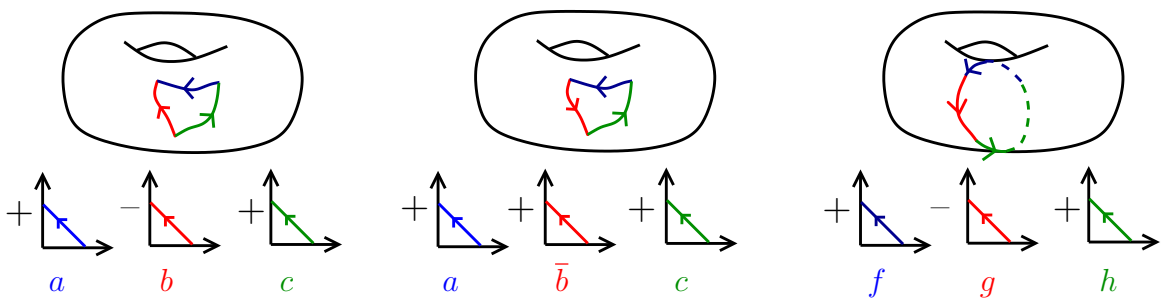

FIGURE 473. Three examples of 1-cycles on the torus.

which of these cycles are in fact null-homologous. In Figure 1 we see that the first cycle $a-b+c$ in Figure 473 is the boundary of a singular 2-simplex D. One can easily

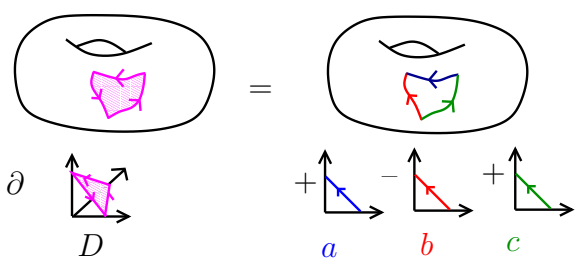

FIGURE 474. The first cycle in Figure 473 is the boundary of a 2-dimensional singular chain.

see that the second cycle, $a+\overline{b}+c$ in Figure 473 is *not* the boundary of a singular 2-simplex. On the other hand by Lemma 29.3 we know that $b+\overline{b}$ is a null-homologous

cycle, i.e. there exists an $E \in C_2(X)$ such that $b + \bar{b} = \partial E \in C_1(X)$. Thus it follows that

$$a + \bar{b} + c \;=\; a + \partial E - b + c \;=\; a - b + c + \partial E = \partial D + \partial E \;=\; \partial(D + E),$$

i.e. $a + \bar{b} + c$ is null-homologous.

It is not clear whether the third cycle in Figure 473 is the boundary of a 2-dimensional singular chain. We will see later that this not the case. But it will take us quite some time to develop the techniques which will allow us to prove this statement.

(2) In Figure 475 we show the torus $T = [0,1] \times [0,1]/\sim$ and two singular simplices $\alpha\colon \Delta^2 \to T$ and $\beta\colon \Delta^2 \to T$ that are given by affine linear maps.[593] It is straightforward to verify that $\alpha - \beta$ is a cycle, hence it represents an element in $H_2(T)$. We will later see whether or not this element is zero in $H_2(T)$.

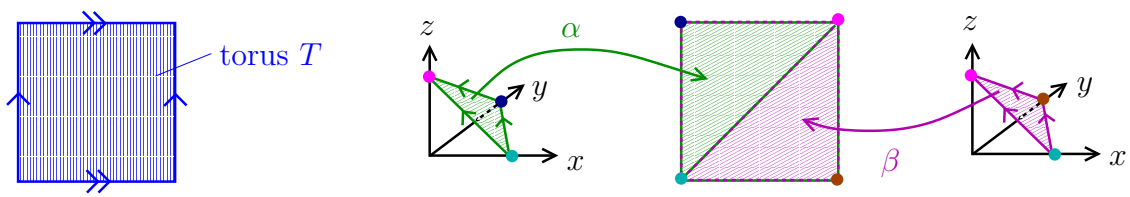

FIGURE 475.

(3) In Exercise 29.4 we will try to generalize the approach taken for the torus to other 2-dimensional manifolds, namely the sphere, the Klein bottle and the projective space $\mathbb{R}P^2$.

29.3. **First calculations of homology groups.** Given a topological space the corresponding homology groups are defined as the quotient of two abelian groups which in general will be infinitely generated. Somewhat surprisingly we will see in the coming chapters that the homology groups are nonetheless very frequently finitely generated abelian groups.

We start out our computations of homology groups with the 0-th homology of a path-connected topological space. The key to the calculation is the following definition.

Definition. Given a topological space X we refer to the map

$$\begin{aligned} \epsilon_X\colon C_0(X) &\to \mathbb{Z} \\ \sum_{i=1}^{k} a_i\sigma_i &\mapsto \sum_{i=1}^{k} a_i \end{aligned}$$

as the *augmentation map*.

[593]More precisely, α is the unique affine linear map with $\alpha(1,0,0) = [(0,0)]$, $\alpha(0,1,0) = [(1,0)]$ and $\alpha(0,0,1) = [(1,1)]$ whereas β is the unique affine linear map with $\beta(1,0,0) = [(0,0)]$, $\beta(0,1,0) = [(0,1)]$ and $\beta(0,0,1) = [(1,1)]$.

The following lemma shows that the augmentation map is a neat addition to the singular chain complex of a topological space.

Lemma 29.4. *Let X be a topological space X.*

(1) *The map $\epsilon_X \circ \partial_1 \colon C_1(X) \to \mathbb{Z}$ is the zero map.*
(2) *The map*

$$\begin{array}{rcl} \epsilon_X \colon H_0(X) & \to & \mathbb{Z} \\ [\sigma] & \mapsto & [\epsilon_X(\sigma)] \end{array}$$

is well-defined. In the following we refer to this map also as the augmentation map.

Proof. Let X be a topological space.

(1) Let $c = \sum\limits_{i=1}^{n} b_i \sigma_i \in C_1(X)$. We calculate that

$$\epsilon(\partial_1(c)) \;=\; \epsilon\Big(\sum_{i=1}^{n} b_i \cdot \partial_1(\sigma_i)\Big) \;\underset{\substack{\uparrow \\ \text{for every singular 1-simplex } \sigma \text{ we} \\ \text{have } \partial\sigma = \sigma(0,1) - \sigma(1,0), \text{ see page 738}}}{=}\; \epsilon\Big(\sum_{i=1}^{n} b_i \cdot \sigma_i(0,1) - b_i \cdot \sigma_i(1,0)\Big) \;\underset{\substack{\uparrow \\ \text{by definition of } \epsilon}}{=}\; \sum_{i=1}^{n} b_i - \sum_{i=1}^{n} b_i \;=\; 0.$$

(2) Note that

$$\begin{array}{rcl} H_0(X) & = & \ker\{\partial_0 \colon C_0(X) \to C_{-1}(X)\} \,/\, \operatorname{im}\{\partial_1 \colon C_1(X) \to C_0(X)\} \\ & = & C_0(X) \,/\, \operatorname{im}\{\partial_1 \colon C_1(X) \to C_0(X)\}. \\ & \underset{\substack{\uparrow \\ \text{since } C_{-1}(X) = 0}}{} & \end{array}$$

Thus we see that Statement (2) is an immediate consequence of Statement (1). □

Now we can formulate the following proposition.

Proposition 29.5. *Let X be a path-connected non-empty topological space and let P be a point in X. Then the augmentation map*

$$\epsilon = \epsilon_X \colon H_0(X) \;\to\; \mathbb{Z}$$

is an isomorphism where the inverse is given by the map

$$\begin{array}{rcl} \iota \colon \mathbb{Z} & \to & H_0(X) \\ n & \mapsto & n \cdot [P]. \end{array}$$

In particular we have $H_0(X) \cong \mathbb{Z}$.

Proof. Let X be a non-empty path-connected topological space. Let P be a point in X. It is clear that $\epsilon \circ \iota = \mathrm{id}_{\mathbb{Z}}$, in particular the homomorphism ϵ is surjective. It remains to show that ϵ is injective.

Thus let $c \in C_0(X)$ with $\epsilon(c) = 0$. By definition of $C_0(X)$ we can find points $Q_1, \ldots, Q_k$ in X and $a_1, \ldots, a_k \in \mathbb{Z}$ such that $c = \sum\limits_{i=1}^{k} a_i \cdot Q_i$. We choose a point P in X. Since X is

path-connected we can find, for $i = 1, \dots, k$, a path from P to Q_i. Put differently, for each $i = 1, \dots, k$ we can find a singular 1-simplex σ_i with $\partial\sigma_i = Q_i - P$. Then we have

$$\partial\left(\sum_{i=1}^{k} a_i\sigma_i\right) \;=\; \sum_{i=1}^{k} a_i\partial\sigma_i \;=\; \sum_{i=1}^{k} a_i(Q_i - P) \;=\; \sum_{i=1}^{k} a_iQ_i - \underbrace{\left(\sum_{i=1}^{k} a_i\right)}_{=\epsilon(c)=0} \cdot P \;=\; \sum_{i=1}^{k} a_iQ_i.$$

This implies that $[c] = 0 \in H_0(X)$. Thus we have shown that ϵ is injective. □

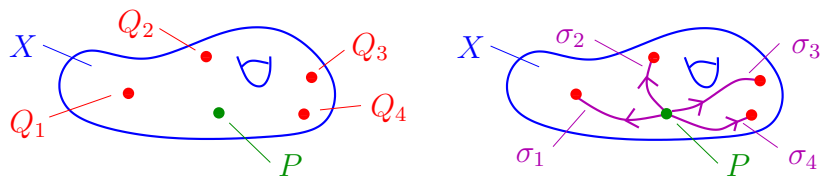

FIGURE 476. Illustration of the proof of Proposition 29.5.

The proof of the following lemma is Exercise 29.2.

Lemma 29.6. *Let X be a topological space which consists of a single point. Then the following holds*

$$H_n(X) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } n = 0, \\ 0, & \text{if } n \neq 0. \end{cases}$$

The calculation of $H_0(X)$ in Proposition 29.5 and the calculation of the homology of a point in Lemma 29.6 are the only calculations of homology groups of path-connected topological spaces that one can do "by hand". For all other topological spaces we will need to work significantly harder.

29.4. **Algebraic chain complexes.** Before we continue with the discussion of homology groups it is convenient to introduce several algebraic definitions. The following definitions are just the obvious algebraic abstractions of the definitions that we had already introduced.

Definition.

(1) An (*algebraic*) *chain complex* (C_*, ∂_*) is a sequence

$$\dots \to C_n \xrightarrow{\partial_n} C_{n-1} \xrightarrow{\partial_{n-1}} \dots C_1 \xrightarrow{\partial_1} C_0 \to 0$$

of maps between abelian groups[594] such that for every $i \in \mathbb{N}$ we have $\partial_{i-1} \circ \partial_i = 0$. As before we introduce the convention that $C_n = 0$ for $n \in \mathbb{Z}_{<0}$.

(2) We define the *n-th homology group of the chain complex* precisely the same way as we defined the homology of a topological space, namely we set

$$H_n(C) \;:=\; \ker\{\partial_n \colon C_n \to C_{n-1}\} \,/\, \operatorname{im}\{\partial_{n+1} \colon C_{n+1} \to C_n\}.$$

[594]It is perhaps worth pointing out that we do not assume that the chain groups C_* are free abelian groups.

(3) As before we refer to elements in the kernel of $\partial_n \colon C_n \to C_{n-1}$ as *cycles*. Furthermore we say that a cycle $z \in C_n$ is *null-homologous* if $[z] = 0 \in H_n(C)$.

On some occasions we will need the following generalization:

(4) A *generalized* (*algebraic*) *chain complex* (C_*, ∂_*) is a sequence

$$\ldots \to C_3 \xrightarrow{\partial_3} C_2 \xrightarrow{\partial_2} C_1 \xrightarrow{\partial_1} C_0 \xrightarrow{\partial_0} C_{-1} \xrightarrow{\partial_{-1}} C_{-2} \to \ldots$$

of maps between abelian groups such that for every $i \in \mathbb{Z}$ we have $\partial_{i-1} \circ \partial_i = 0$. Basically all present and future definitions and results for chain complexes also make sense for generalized chain complexes.

Now we introduce a new notion, namely the notion of a chain map between chain complexes.

Definition. A *chain map* $f \colon C_* \to D_*$ between two chain complexes[595] consists of a family $\{f_n \colon C_n \to D_n\}_{n \in \mathbb{N}_0}$ of maps such that for each n the following equality holds:[596]

$$f_{n-1} \circ \partial_n \;=\; \partial_n \circ f_n.$$

Put differently the maps f_n have the property that the following diagram commutes:

$$\begin{tikzcd}
\ldots \arrow[r, "\partial"] & C_{n+1} \arrow[r, "\partial_{n+1}"] \arrow[d, "f_{n+1}"] & C_n \arrow[r, "\partial_n"] \arrow[d, "f_n"] & C_{n-1} \arrow[r, "\partial_{n-1}"] \arrow[d, "f_{n-1}"] & \ldots \\
\ldots \arrow[r, "\partial"] & D_{n+1} \arrow[r, "\partial_{n+1}"] & D_n \arrow[r, "\partial_n"] & D_{n-1} \arrow[r, "\partial_{n-1}"] & \ldots
\end{tikzcd}$$

Remark. On many occasions we will use the elementary observation that the composition of two chain maps $f \colon C_* \to D_*$ and $g \colon D_* \to E_*$ defines a chain map $g \circ f \colon C_* \to E_*$.

Now we can prove the following lemma:

Lemma 29.7. *Let $f \colon C_* \to D_*$ be a chain map between chain complexes C_* and D_*. Then the map*

$$\begin{array}{rcl} f_* \colon H_n(C_*) & \to & H_n(D_*) \\ [c] & \mapsto & [f_n(c)] \end{array}$$

is well-defined.

In the following we refer to the map $f_* \colon H_n(C) \to H_n(D)$ as the *induced map on homology*.

---

[595] As usual we suppress bits from the notation which are understood from the context. In this instance we suppress the notation for the boundary maps in the chain complexes. Put differently, instead of saying "let (C_*, ∂_*) be a chain complex" we say simply "let C_* be a chain complex".

[596] More precisely, for any $c \in C$ we have $f_{n-1}(\partial_n(c)) = \partial_n(f_n(c))$ where on the left-hand side we consider the boundary map $C_n \to C_{n-1}$, and on the right-hand side we consider the boundary map $D_n \to D_{n-1}$ which we also denote by ∂_n. Usually it is obvious from the context which boundary map we consider.

Proof. Let $c \in C_n$ be a cycle. First we have to show that $f_n(c)$ is again a cycle. Indeed we have

$$\partial_n(f_n(c)) \underset{\substack{\uparrow \\ \text{definition of a chain map}}}{=} f_{n-1}(\partial_n c) \underset{\substack{\uparrow \\ \text{since } c \text{ is a cycle}}}{=} f_n(0) = 0.$$

Now let $c, d \in C_n$ be two cycles which represent the same element in $H_n(C)$. We have to show that $[f_n(c)] = [f_n(d)]$. Indeed we have

$$[f_n(c)] - [f_n(d)] = [f_n(c-d)] \underset{\substack{\uparrow \\ \text{since } c,d \text{ are homologous there} \\ \text{exists an } e \in C_{n+1} \text{ with } \partial_{n+1} e = c-d}}{=} [f_n(\partial_{n+1}(e))] \underset{\substack{\uparrow \\ \text{definition of a chain map}}}{=} [\partial_{n+1}(f_{n+1}(e))] = 0 \in H_n(D).$$

□

We can state the above results more formally. More precisely, we consider the category $\mathcal{C}$ of chain complexes which is given by the objects

$$\mathrm{Ob}(\mathcal{C}) := \text{all chain complexes},$$

and for $C_*, D_* \in \mathrm{Ob}(\mathcal{C})$ the morphisms are given by

$$\mathrm{Mor}(C_*, D_*) := \text{all chain maps from } C_* \text{ to } D_*.$$

The following lemma follows easily from Lemma 29.7 and from the definitions:

Lemma 29.8. *For each $n \in \mathbb{N}_0$ the maps*

$$C_* \mapsto H_n(C_*)$$

and

$$(f\colon C_* \to D_*) \mapsto (f_*\colon H_n(C_*) \to H_n(D_*))$$

define a functor from the category of chain complexes to the category of abelian groups.

29.5. **The functoriality of homology groups.** Let $f\colon X \to Y$ be a map between topological spaces. We already saw on page 736 that for each $n \in \mathbb{N}_0$ the map f induces a map

$$\begin{aligned} f_*\colon C_n(X) &\to C_n(Y) \\ \sum_{i=1}^k a_i \cdot \sigma_i &\mapsto \sum_{i=1}^k a_i \cdot f \circ \sigma_i. \end{aligned}$$

Now we can formulate the following lemma:

Lemma 29.9.

(1) *Let $f\colon X \to Y$ be a map between topological spaces and let $n \in \mathbb{N}_0$. For any $c \in C_n(X)$ we have*

$$f_*(\partial_n c) = \partial_n(f_*(c)) \in C_n(Y).$$

In particular $f_*\colon C_*(X) \to C_*(Y)$ is a chain map.

(2) *The maps*

$$\begin{array}{rcl} \textit{topological space } X & \mapsto & C_*(X) \end{array}$$

and

$$\begin{array}{rcl} (f\colon X \to Y) & \mapsto & (f_*\colon C_*(X) \to C_*(Y)) \end{array}$$

define a functor from the category of topological spaces to the category of chain complexes.

Proof.

(1) Let $f\colon X \to Y$ be a map between topological spaces and let $\sigma\colon \Delta^n \to X$ be a singular n-simplex. We have

$$f_*(\partial\sigma) = f_*\left(\sum_{j=0}^{n}(-1)^j\cdot\sigma\circ i_j^n\right) = \sum_{j=0}^{n}(-1)^j\cdot f\circ(\sigma\circ i_j^n) = \sum_{j=0}^{n}(-1)^j\cdot\underbrace{(f\circ\sigma)}_{=f_*\sigma}\circ i_j^n = \partial(f_*\sigma).$$

Since the singular n-simplices generate $C_n(X)$ we obtain the desired equality for all singular n-chains. By definition this means that $f_*\colon C_*(X) \to C_*(Y)$ is a chain map.

(2) The second statement is an almost immediate consequence of the first statement. □

In particular, using Lemma 29.7 we immediately obtain the following lemma.

Lemma 29.10. *Let $f\colon X \to Y$ be a map between topological spaces. Then the map*

$$\begin{array}{rcl} f_*\colon H_n(X) & \to & H_n(Y) \\ \left[\sum_{i=1}^{k} a_i\cdot\sigma_i\right] & \mapsto & \left[\sum_{i=1}^{k} a_i\cdot(f\circ\sigma_i)\right] \end{array}$$

is well-defined.

Example. Let $f\colon X \to Y$ be a map between two topological spaces. It follows immediately from the definitions that the following diagram commutes

$$\begin{tikzcd} H_0(X) \arrow[rr, "f_*"] \arrow[dr, "\epsilon_X"'] & & H_0(Y). \arrow[dl, "\epsilon_Y"] \\ & \mathbb{Z} & \end{tikzcd}$$

where the maps ϵ_X and ϵ_Y denote the augmentation maps. In particular, if X and Y are path-connected topological spaces, then it follows easily from Proposition 29.5 that the map $f_*\colon H_0(X) \to H_0(Y)$ is an isomorphism. Furthermore, if $X = Y$, i.e. if f is a self-map on a path-connected topological space X, then f_* is in fact the identity on $H_0(X)$.

The combination of Lemmas 29.9 and 29.8 now gives us the following lemma.

Lemma 29.11. *For each $n \in \mathbb{N}_0$ the map*

$$X \mapsto H_n(X)$$

together with the map

$$(f\colon X \to Y) \mapsto \begin{pmatrix} f_*\colon H_n(X) & \to & H_n(Y) \\ \left[\sum_{i=1}^k a_i \cdot \sigma_i\right] & \mapsto & \left[\sum_{i=1}^k a_i \cdot (f \circ \sigma_i)\right] \end{pmatrix}$$

defines a functor from the category of topological spaces to the category of abelian groups.

29.6. **Direct products and direct sums** $(*)$**.** In this short section we recall the definition of the direct product and the direct sum of a family of abelian groups.

Let $G_i, i \in I$ be a family of abelian groups. We define the *direct product* as

$$\prod_{i\in I} G_i := \Big\{\text{all maps } g\colon I \to \bigcup_{i\in I} G_i \text{ such that for all } i \in I \text{ we have } g(i) \in G_i\Big\}.$$

Given such a map we usually write $g_i := g(i)$ for $i \in I$ and we denote such a map by $\{g_i\}_{i\in I}$. The direct product is again a group with respect to the group structure

$$\begin{array}{rcl} \prod_{i\in I} G_i \times \prod_{i\in I} G_i & \to & \prod_{i\in I} G_i \\ \big((a_i)_{i\in I}, (b_i)_{i\in I}\big) & \mapsto & (a_i + b_i)_{i\in I}. \end{array}$$

Furthermore we consider the *direct sum*

$$\bigoplus_{i\in I} G_i := \Big\{(g_i)_{i\in I} \in \prod_{i\in I} G_i \,\Big|\, \text{there exists only finitely many } i \in I \text{ with } g_i \neq e\Big\}.$$

The same way one can also define the direct product respectively the direct sum of rings, algebras, vector spaces, modules and so on.

Example. Let $I = \mathbb{N}$ and for each $i \in I = \mathbb{N}$ we pick $G_i = \mathbb{R}$. Then

$$\prod_{i\in\mathbb{N}} \mathbb{R} = \text{all real-valued sequences } i \mapsto a_i$$

and

$$\bigoplus_{i\in\mathbb{N}} \mathbb{R} = \text{all real-valued sequences with only finitely many non-zero terms.}$$

In general the direct product is "significantly larger" than the direct sum. For example the direct product $\prod_{i\in\mathbb{N}} \mathbb{Z}$ is uncountable while the direct sum $\bigoplus_{i\in\mathbb{N}} \mathbb{Z}$ is countable.[597]

For some element $g_j \in G_j$, following the discussion on page 366, we sometimes denote by g_j also the element in $\bigoplus_{i\in I} G_i$ that is given by $i \mapsto e$ if $i \neq j$ and $j \mapsto g_j$. In particular we

[597] Why is that the case?

can view each G_j as a subgroup of $\bigoplus_{i\in I} G_i$. Furthermore for $i_1,\dots,i_l \in I$ and $g_{i_j} \in G_{i_j}$ we can consider the corresponding element

$$g_{i_1} + \cdots + g_{i_l} \in \bigoplus_{i\in I} G_i.$$

It follows immediately from the definitions that any element of $\bigoplus_{i\in I} G_i$ is of that form.

Finally let $G_i, i \in I$ be a family of abelian groups, let H be an abelian group and let $\varphi_i\colon G_i \to H, i \in I$ be a family of homomorphisms. We refer to

$$\begin{array}{rcl} \bigoplus_{i\in I}\varphi_i \quad : \bigoplus_{i\in I} G_i & \to & H \\ g_{i_1} + \cdots + g_{i_l} & \mapsto & \varphi_{i_1}(g_{i_1}) + \cdots + \varphi_{i_l}(g_{i_l}) \end{array}$$

as the direct sum of the homomorphisms φ_i, $i \in I$.

29.7. **The homology groups of a direct sum.** Now we return to the study of chain complexes. Let C_* and D_* be two chain complexes. The same way as we introduced the direct sum of abelian groups we can also define the direct sum of chain complexes. The following lemma says that homology commutes with direct sums and direct products. The proof is a standard exercise in homological algebra, which oddly enough nobody ever feels like doing, see [Weib, p. 5].

Lemma 29.12. *If $\{C_a\}_{a\in A}$ is a family of chain complexes, then the obvious inclusion maps $C_a \to \bigoplus_{a\in A} C_a$ and $C_a \to \prod_{a\in A} C_a$ induce isomorphisms*

$$\bigoplus_{a\in A} H_n(C_a) \xrightarrow{\cong} H_n\Big(\bigoplus_{a\in A} C_a\Big) \quad \text{and} \quad \prod_{a\in A} H_n(C_a) \xrightarrow{\cong} H_n\Big(\prod_{a\in A} C_a\Big).$$

Now we can formulate and prove the following lemma.

Lemma 29.13. *Let X be a topological space with path-components $\{X_a\}_{a\in A}$. Given $a \in A$ we denote by $i_a\colon X_a \to X$ the inclusion map. Then the map*

$$\bigoplus_{a\in A} i_a\colon \quad \bigoplus_{a\in A} C_*(X_a) \to C_*(X)$$

is an isomorphism of chain complexes. In particular for each $n \in \mathbb{N}_0$ the map

$$\bigoplus_{a\in A} i_{a*}\colon \quad \bigoplus_{a\in A} H_n(X_a) \to H_n(X)$$

is an isomorphism.

The lemma says in particular that the homology groups of a topological space X are the direct sum of the homology groups of the path-components of X. Put differently, this shows that in most cases it suffices to consider the homology groups of path-connected topological spaces.

Example. One of our goals is to calculate the homology groups of the spheres. Now we can calculate the homology groups of the 0-dimensional sphere $S^0 = \{\pm 1\}$. More precisely, by Lemmas 29.6 and 29.13 we have

$$H_n(S^0) \cong \begin{cases} \mathbb{Z}^2, & \text{if } n = 0, \\ 0, & \text{if } n \neq 0. \end{cases}$$

We will later reduce the computation of the homology groups of all other spheres to this calculation.

Proof. Since the standard simplex Δ^n is path-connected, the image of a map $\sigma\colon \Delta^n \to X$ lies in a path-component X_a. This shows that

$$\bigsqcup_{a\in A} \text{singular } n\text{-simplices in } X_a \quad = \quad \text{singular } n\text{-simplices in } X.$$

It follows that the map

$$\begin{aligned} \bigoplus_{a\in A} i_a \colon \bigoplus_{a\in A} C_n(X_a) &\to C_n(X) \\ \Big(\sum_{i=1}^k c_i(\sigma\colon \Delta^n \to X_{a_i})\Big) &\mapsto \Big(\sum_{i=1}^k c_i(\sigma\colon \Delta^n \to X_{a_i})\Big) \end{aligned}$$

is an isomorphism of free abelian groups. From the definitions it follows immediately that this a chain map. The second statement of the lemma now follows from Lemma 29.12. □

The following corollary is an immediate consequence of Proposition 29.5 and Lemma 29.12.

Corollary 29.14. *Let X be a topological space. As on page 127 we denote by $\pi_0(X)$ the set of path-components of X. Then*

$$H_0(X) \cong \mathbb{Z}^{(\pi_0(X))}.$$

In particular, if X consists of n path-components with $n \in \mathbb{N}$, then

$$H_0(X) \cong \mathbb{Z}^n.$$

Exercises for Chapter 29.

Exercise 29.1.

(a) Let X be a topological space and let $x \in X$. For each $n \in \mathbb{N}_0$ denote by σ_n the singular n-simplex $\sigma_n\colon \Delta^n \to X$ which is defined by $\sigma_n(P) = x$ for all $P \in \Delta^n$. Determine $\partial\sigma_n \in C_{n-1}(X)$.

(b) Let X be a topological space and let $\sigma\colon \Delta^1 \to X$ be a singular 1-simplex. Show that if σ is a constant map, then σ is null-homologous.

Exercise 29.2. Prove Lemma 29.6.

Exercise 29.3.

(a) Let X be a topological space and let $\sigma\colon \Delta^1 \to X$ be a singular 1-simplex. We consider the singular 1-simplices

$$\begin{array}{rcl} \sigma_1\colon \Delta^1 & \to & X \\ (t, 1-t) & \mapsto & \sigma(\frac{1}{2}t, 1-\frac{1}{2}t) \end{array} \quad \text{and} \quad \begin{array}{rcl} \sigma_2\colon \Delta^1 & \to & X \\ (t, 1-t) & \mapsto & (\frac{1}{2}+\frac{1}{2}t, \frac{1}{2}-\frac{1}{2}t). \end{array}$$

Show that σ and $\sigma_1 + \sigma_2$ are homologous.

(b) Let X be a topological space and let $\sigma\colon \Delta^1 \to X$ be a singular 1-simplex. We consider the singular 1-simplex

$$\begin{array}{rcl} \overline{\sigma}\colon \Delta^1 & \to & X \\ (t, 1-t) & \mapsto & \sigma(1-t, t). \end{array}$$

Show that $\sigma + \overline{\sigma}$ is a cycle and that this cycle is null-homologous.

We refer to Figure 472 for an illustration of the definitions.

Exercise 29.4.

(a) Try to find "interesting" elements in the following homology groups:
  (i) $H_2(S^2)$,
  (ii) H_2(surface Σ of genus 2),
  (iii) H_2(Klein bottle K) and
  (iv) $H_2(\mathbb{R}\mathrm{P}^2)$.
  More precisely, try to find singular 2-cycles such that the images of the singular 2-simplices cover the whole surface and such that the images of the singular 2-simplices overlap only in "1-dimensional" subsets.

(b) Make a guess for which surfaces you expect H_2 to be zero and for which it is non-zero.

Exercise 29.5. Provide an example of a chain complex (C_*, ∂_*) such that all C_* are finitely generated free abelian groups and such that $H_i(C_*) = 0$ for all even $i \in \mathbb{N}_0$ and such that $H_i(C_*) = \mathbb{Z}_2$ for all odd $i \in \mathbb{N}_0$.

Exercise 29.6.

(a) Determine the isomorphism types of the homology groups of the chain complex

$$0 \to C_1 = \mathbb{Z}^2 \xrightarrow{\begin{pmatrix} 3 & 7 \\ 4 & 2 \end{pmatrix}} C_0 = \mathbb{Z}^2 \to 0.$$

(b) Determine the isomorphism types of the homology groups of the chain complex

$$0 \to C_2 = \mathbb{Z}^2 \xrightarrow{\begin{pmatrix} 2 & 5 \\ 4 & 10 \end{pmatrix}} C_1 = \mathbb{Z}^2 \xrightarrow{\begin{pmatrix} -2 & 1 \end{pmatrix}} C_0 = \mathbb{Z} \to 0.$$

(Why is this a chain complex?)

30. Homology and homotopies

It was not overly difficult to introduce the homology groups of a topological space. We also proved several straightforward properties of homology groups. But so far we are unable to calculate any interesting homology group. In this section we will show in particular that homotopy equivalent topological spaces have isomorphic homology groups. That does not yet lead to the calculation of non-trivial homology groups, but this result will play an important role in the calculation of the homology groups of spheres later on.

30.1. **Chain homotopies.** In this section we introduce a criterion that ensures that two chain maps $f, g\colon C_* \to D_*$ induce the same maps on the corresponding homology groups.

Definition. Let $f, g\colon C_* \to D_*$ be chain maps between chain complexes C_* and D_*. A *chain homotopy* $P = \{P_n\}_{n\in\mathbb{N}_0}$ *between* f *and* g consists of family $\{P_n\colon C_n \to D_{n+1}\}_{n\in\mathbb{N}_0}$ such that for each $n \in \mathbb{N}_0$ we have

$$\partial_{n+1} \circ P_n + P_{n-1} \circ \partial_n \;=\; f_n - g_n.$$

If there exists a chain homotopy between chain maps f and g, then we say that f and g are *chain homotopic* and we write $f \simeq g$.

For the definition of a chain homotopy and the subsequent discussion of chain homotopies it is sometimes helpful to keep in mind the following diagram that combines all objects involved in the definition:

$$\begin{tikzcd}
{} \arrow[r, "\partial_{n+2}"] & C_{n+1} \arrow[r, "\partial_{n+1}"] \arrow[d, "f_*,g_*"] & C_n \arrow[r, "\partial_n"] \arrow[d, "f_*,g_*"] \arrow[dl, "P_n"'] & C_{n-1} \arrow[r, "\partial_{n-1}"] \arrow[d, "f_*,g_*"] \arrow[dl, "P_{n-1}"'] & {} \\
{} \arrow[r, "\partial_{n+2}"] & D_{n+1} \arrow[r, "\partial_{n+1}"] & D_n \arrow[r, "\partial_n"] & D_{n-1} \arrow[r, "\partial_{n-1}"] & {}
\end{tikzcd}$$

The following basic lemma will be proved in Exercise 30.1

Lemma 30.1. *Let C_* and D_* be two chain complexes.*

(1) *Chain homotopy defines an equivalence relation on the set of all chain maps from C_* to D_*. In particular, if $f, g, h\colon C_* \to D_*$ are chain maps with $f \simeq g$ and $g \simeq h$, then $f \simeq h$.*
(2) *Let $f, g\colon C_* \to D_*$ be chain maps, and let $e\colon B_* \to C_*$ and $h\colon D_* \to E_*$ be two other chain maps. Then*

$$f \simeq g \quad\Longrightarrow\quad f \circ e \simeq g \circ e \quad \text{and} \quad h \circ f \simeq h \circ g.$$

Now we can formulate the following lemma.

Lemma 30.2. *Let $f, g\colon C_* \to D_*$ be two chain maps between chain complexes. Then*

$$f \simeq g \quad\Longrightarrow\quad f_* = g_*\colon H_n(C) \to H_n(D) \text{ for all } n \in \mathbb{N}_0.$$

Proof. Let $P = \{P_n\}_{n\in\mathbb{N}_0}$ be a chain homotopy between f and g. Then for any cycle $z \in C_n$ we get the equalities

$$f(z) - g(z) \;=\; (f-g)(z) \;=\; (\partial_{n+1}P_n + P_{n-1}\partial_n)(z) \;=\; (\partial_{n+1}P_n)(z) + P_{n-1}\underbrace{\partial_n z}_{=0} \;=\; \partial P_n z,$$

i.e. $f(z)$ and $g(z)$ are homologous. □

Definition. Let C_* and D_* be two chain complexes.

(1) A chain map $f\colon C_* \to D_*$ is called a *chain homotopy equivalence between C_* and D_**, if it admits a chain homotopy inverse, i.e. a chain map $g\colon D_* \to C_*$ with $g\circ f \simeq \mathrm{id}_{C_*}$ and $f\circ g \simeq \mathrm{id}_{D_*}$.
(2) If there exists a chain homotopy equivalence between C_* and D_*, then we say that the chain complexes C_* and D_* are *chain homotopy equivalent* and we write $C_* \simeq D_*$.

Remark. It is again straightforward to show that "homotopy equivalence" of chain complexes is indeed an equivalence relation.

For later we record the following straightforward corollary to Lemma 30.2.

Corollary 30.3. *If $f\colon C_* \to D_*$ is a chain homotopy equivalence between chain complexes, then the induced maps $f_*\colon H_n(C) \to H_n(D)$ are isomorphisms.*

We also record the following useful little lemma.

Lemma 30.4. $(*)$ *Let (C_*, ∂_*) be a chain complex. If there exist maps $P_n\colon C_n \to C_{n+1}$ such that for every $n \in \mathbb{N}_0$ we have*

$$\partial_{n+1}\circ P_n + P_{n-1}\circ\partial_n \;=\; \mathrm{id}_{C_n},$$

then all homology groups of (C_*, ∂_*) vanish.

Proof $(*)$. Let D_* be the zero chain complex and for each $n \in \mathbb{N}_0$ let $f_n\colon C_n \to D_n = 0$ be the trivial map. Since the homology groups of D_* it suffices, by Corollary 30.3, to show that f_* is a chain homotopy equivalence. For each $n \in \mathbb{N}_0$ let $g_n\colon D_n \to C_n$ be the trivial map. Evidently $f_n \circ g_n = \mathrm{id}_{D_*}$. Thus it remains to show that $g_*\circ f_* \simeq \mathrm{id}_{C_*}$. In other words we need to show that $0 \simeq \mathrm{id}_{C_*}$. But that is exactly what the maps P_n do. □

30.2. **Homology and homotopic maps.** The name *chain homotopy* introduced in the previous section suggests that this concept is related to the notion of a homotopy between two topological spaces. As we will see shortly, this is indeed the case. For the reader's convenience we recall that if $f, g\colon X \to Y$ are two maps between topological spaces, then a *homotopy between the maps f and g* is a map

$$F\colon X \times [0,1] \to Y,$$

such that

$$F(x,0) \;=\; f(x) \text{ and } F(x,1) \;=\; g(x) \text{ for all } x \in X.$$

If there exists a homotopy between f and g, then we say that f and g are *homotopic* and we write $f \simeq g$.

Proposition 30.5. *Let X and Y be two topological spaces and let $f, g\colon X \to Y$ be two maps. If f and g are homotopic, then the following hold:*

(1) *the induced maps f_* and g_* from $C_*(X)$ to $C_*(Y)$ are chain homotopic,*
(2) *for each $n \in \mathbb{N}_0$ we have $f_* = g_*\colon H_n(X) \to H_n(Y)$.*

Remark. The proposition can be stated more succinctly as follows:

$$f \simeq g\colon X \to Y \quad \Longrightarrow \quad f_* \simeq g_*\colon C_*(X) \to C_*(Y) \quad \Longrightarrow \quad f_* = g_*\colon H_n(X) \to H_n(Y).$$

We start out with a discussion of the key idea behind the proof of Proposition 30.5. Afterwards we will fill in the details details. So let $f, g\colon X \to Y$ be two maps between topological spaces and let $F\colon X \times [0,1] \to Y$ be a homotopy between the maps f and g. Our goal is to find a chain homotopy between f_* and g_*. Thus let $\sigma\colon \Delta^n \to X$ be a singular n-simplex. We need to find $P(\sigma) \in C_{n+1}(Y)$ and $P(\partial\sigma) \in C_n(Y)$ such that

$$\partial P(\sigma) \;=\; -P(\partial\sigma) \,+\, f_*(\sigma) \,-\, g_*(\sigma).$$

Note that $F \circ (\sigma \times \mathrm{id}_{[0,1]})$ defines a map $\Delta^n \times [0,1] \to Y$. Now we can rewrite the above desired equality as follows:

$$\partial P(\sigma) \;=\; -P(\partial\sigma) + \begin{matrix}\text{map } F \circ (\sigma \times \mathrm{id}_{[0,1]}) \\ \text{restricted to } \underbrace{\Delta^n \times \{0\}}_{=\Delta^n}\end{matrix} - \begin{matrix}\text{map } F \circ (\sigma \times \mathrm{id}_{[0,1]}) \\ \text{restricted to } \underbrace{\Delta^n \times \{1\}}_{=\Delta^n}\end{matrix}.$$

To get an idea we consider Figure 477. We make the following trivial observation: we have

$$\partial(\Delta^n \times [0,1]) \;=\; \partial\Delta^n \times [0,1] \;\cup\; \Delta^n \times \{0\} \;\cup\; \Delta^n \times \{1\}.$$

Comparing the desired equality of maps and the equality of sets suggests that each map $P_k\colon C_k(X) \to C_{k+1}(Y)$ should take the role of replacing a singular k-simplex $\mu\colon \Delta^k \to X$ by the map $F \circ (\mu \times \mathrm{id}_{[0,1]})\colon \Delta^k \times [0,1] \to Y$. This is a good idea, but the problem is that $\Delta^k \times [0,1]$ is not a $(k+1)$-simplex. The idea now is to write $\Delta^k \times [0,1]$ as the union of $(k+1)$-simplices. In Figure 478 we see for example that we can view $\Delta^1 \times [0,1]$ as the union of the triangles with the vertices v_0, w_0, w_1 respectively v_0, v_1, w_1.

To generalize this observation we have to introduce some more notation.

Notation. Let $n \in \mathbb{N}_0$.

(1) For $i = 0, \dots, n$ we write

$$v_i \;:=\; (0, \dots, 1, 0, \dots, 0) \times \{0\} \;\in\; \mathbb{R}^{n+1} \times \{0\},$$

and

$$w_i \;:=\; (0, \dots, 1, 0, \dots, 0) \times \{1\} \;\in\; \mathbb{R}^{n+1} \times \{1\}.$$

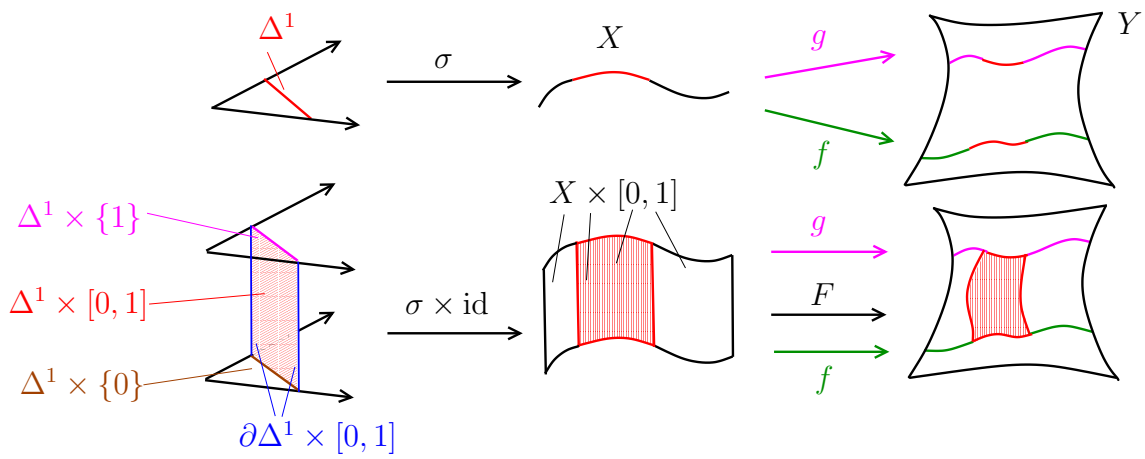

FIGURE 477.

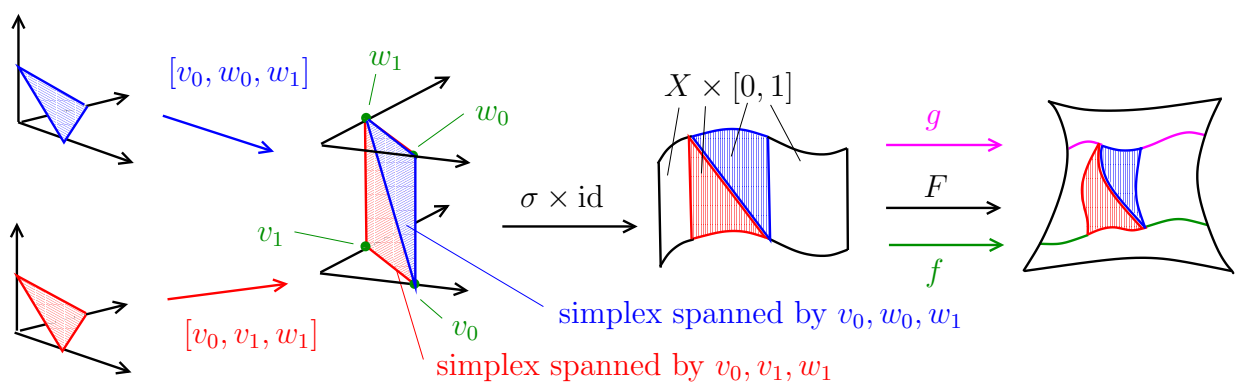

FIGURE 478.

The points $v_0, \ldots, v_n$ thus span the simplex $\Delta^n \times 0$ and the points $v_0, \ldots, v_n$ span the simplex $\Delta^n \times 1$. Furthermore for each i the points $v_0, \ldots, v_i, w_i, \ldots, w_n$ span an $(n+1)$-simplex that is a subset of $\Delta^n \times [0,1]$.[598]

(2) For $a_1, \ldots, a_{k+1} \in \Delta^n \times [0,1]$ we consider, as on page 736, the map

$$\begin{aligned} [a_0, \ldots, a_k] \colon \Delta^k &\to \Delta^n \times [0,1] \\ (\lambda_0, \ldots, \lambda_k) &\mapsto \sum_{j=0}^{k} \lambda_j a_j. \end{aligned}$$

The map $[a_0, \ldots, a_k]$ thus sends the standard k-simplex Δ^k to the simplex spanned by $a_0, \ldots, a_k$ in $\Delta^n \times [0,1]$.

[598]It is a straightforward exercise to show that the union of these $(n+1)$-dimensional simplices is precisely $\Delta^n \times [0,1]$. We will not make use of this fact.

(3) We define

$$\Omega_n \;:=\; \sum_{j=0}^{n} (-1)^j \cdot \underbrace{[v_0,\dots,v_j,w_j,\dots,w_n]}_{\Delta^{n+1}\to\Delta^n\times[0,1]} \;\in\; C_{n+1}(\Delta^n\times[0,1]).$$

In the following lemma we compute the boundary of $\Omega_n \in C_{n+1}(\Delta^n \times [0,1])$. The statement might not be particularly visually appealing, but it will turn out to be very useful.

Lemma 30.6. *Let $n \in \mathbb{N}_0$. Given $t \in \{0,1\}$ we write*

$$\begin{array}{rcl} \eta_t\colon \Delta^n & \to & \Delta^n\times[0,1] \\ x & \mapsto & (x,t). \end{array}$$

With this notation we have

$$\partial_{n+1}(\Omega_n) + \sum_{j=0}^{n}(-1)^j\cdot(i_j^n\times \mathrm{id}_{[0,1]})_*\big(\underbrace{\Omega_{n-1}}_{\in C_n(\Delta^{n-1}\times[0,1])}\big) \;=\; \eta_1-\eta_0 \;\in\; C_n(\Delta^n\times[0,1]).$$

Proof. The proof of the lemma is basically an elementary, albeit slightly confusing calculation. First note that

$$\begin{aligned} \partial\Omega_n &= \partial\Big(\sum_{j=0}^{n}(-1)^j\cdot[v_0,\dots,v_j,w_j,\dots,w_n]\Big) \\ &= \sum_{k=0}^{n+1}(-1)^k\cdot\sum_{j=0}^{n}(-1)^j\cdot[v_0,\dots,v_j,w_j,\dots,w_n]\circ i_k^{n+1}. \end{aligned}$$

It is straightforward to see that for any $k \in \{0,\dots,n+1\}$ we have[599]

$$[v_0,\dots,v_j,w_j,\dots,w_n]\circ i_k^{n+1} \;=\; \begin{cases} [v_0,\dots,\widehat{v_k},\dots,v_j,w_j,\dots,w_n], & \text{if } k\le j, \\ [v_0,\dots,v_j,w_j,\dots,\widehat{w_{k-1}},\dots,w_n], & \text{if } k>j. \end{cases}$$

Thus it follows that[600]

$$\begin{aligned} \partial\Omega_n \;=\; & \sum_{0\le k\le j\le n} (-1)^k\cdot(-1)^j\cdot[v_0,\dots,\widehat{v_k},\dots,v_j,w_j,\dots,w_n] \\ & + \sum_{n+1\ge k>j\ge 0}(-1)^k\cdot(-1)^j\cdot[v_0,\dots,v_j,w_j,\dots,\widehat{w_{k-1}},\dots,w_n]. \end{aligned}$$

[599]The first case, $k \le j$ is slightly easier: one has to figure out, where the h-th vertex e_h of the standard n-simplex gets sent to. If $h < k$, then i_k^{n+1} sends the h-th vertex again to the h-th vertex, and $[v_0,\dots,v_j,w_j,\dots,w_n]$ sends this vertex to v_h. If $h \ge k$, then i_k^{n+1} sends the h-th vertex again to the $(h+1)$-th vertex, and $[v_0,\dots,v_j,w_j,\dots,w_n]$ sends this vertex to v_{h+1}. If $k \le j$ this corresponds just to the map $[v_0,\dots,\widehat{v_k},\dots,v_j,w_j,\dots,w_n]$.
The second case, $k > j$ is proved precisely the same way.

[600]Here we use the usual notation that $\widehat{v_k}$ means that we do not plug in $\widehat{v_k}$, the same applies to $\widehat{w_{k-1}}$.

Now we split the first sum into the cases $k = j$ and $k < j$ and we split the second sum into the cases $k = j + 1$ and $k > j + 1$. This leads us to the following equality:

$$\begin{aligned}\partial\Omega_n \quad = \quad & \sum_{k=0}^{n}(-1)^{2k}\cdot[v_0,\dots,v_{k-1},w_k,\dots,w_n] \\ & +\sum_{k=1}^{n+1}(-1)^{2k+1}\cdot[v_0,\dots,v_{k-1},w_k,\dots,w_n] \\ & + \sum_{0\le k<j\le n}(-1)^k\cdot(-1)^j\cdot[v_0,\dots,\widehat{v_k},\dots,v_j,w_j,\dots,w_n] \\ & + \sum_{n+1\ge k>j+1\ge 1}(-1)^k\cdot(-1)^j\cdot[v_0,\dots,v_j,w_j,\dots,\widehat{w_{k-1}},\dots,w_n].\end{aligned}$$

Next we consider the first two sums. The summands cancel each other, except for the summands for $k = 0$ and $k = n + 1$. Thus we obtain that

$$(*)\qquad \begin{aligned}\partial\Omega_n \quad = \quad & [w_0,\dots,w_n]-[v_0,\dots,v_n] \\ & + \sum_{0\le k<j\le n}(-1)^k\cdot(-1)^j\cdot[v_0,\dots,\widehat{v_k},\dots,v_j,w_j,\dots,w_n] \\ & + \sum_{n+1\ge k>j+1\ge 1}(-1)^k\cdot(-1)^j\cdot[v_0,\dots,v_j,w_j,\dots,\widehat{w_k},\dots,w_n].\end{aligned}$$

The first summand is just η_1 and the second is $-\eta_0$. It remains to show that the remaining summand corresponds to the remaining term in the formula. Thus we continue our proof with the discussion of the one term in the statement of the lemma that we have not studied yet. We have[601]

$$\sum_{j=0}^{n}(-1)^j\cdot(i_j^n\times\mathrm{id}_{[0,1]})_*(\Omega_{n-1}) \underset{\substack{\uparrow \\ \text{definition of } (i_j^n\times\mathrm{id}_{[0,1]})_* \text{ and substitution } r=j}}{=} \sum_{r=0}^{n}\sum_{s=0}^{n-1}(-1)^r\cdot(-1)^s\cdot(i_r^n\times\mathrm{id}_{[0,1]})\circ[v_0,\dots,v_s,w_s,\dots,w_{n-1}].$$

It follows from an elementary (but arguably confusing) argument, using only the definitions, that we have the following equalities of maps $\Delta^n \to \Delta^n \times [0, 1]$:

$$(i_r^n\times\mathrm{id}_{[0,1]})\circ[v_0,\dots,v_s,w_s,\dots,w_{n-1}] \quad = \quad \begin{cases}[v_0,\dots,\widehat{v_r},\dots,v_{s+1},w_{s+1},\dots,w_n], & \text{if } r\le s,\\ [v_0,\dots,v_s,w_s,\dots,\widehat{w_{r+1}},\dots,w_n], & \text{if } r>s.\end{cases}$$

Thus we see that

$$\begin{aligned}\sum_{j=0}^{n}(-1)^j\cdot(i_j^n\times\mathrm{id}_{[0,1]})_*(\Omega_{n-1}) \quad = \quad & \sum_{0\le r\le s\le n-1}(-1)^s\cdot(-1)^r\cdot[v_0,\dots,\widehat{v_r},\dots,v_{s+1},w_{s+1},\dots,w_n] \\ & + \sum_{n\ge r>s\ge 0}(-1)^s\cdot(-1)^r\cdot[v_0,\dots,v_s,w_s,\dots,\widehat{w_{r+1}},\dots,w_n].\end{aligned}$$

[601] Here $v_0,\dots,v_{n-1},w_0,\dots,w_{n-1}$ are now, unfortunately somewhat confusingly, the corresponding vertices of $\Delta^{n-1}\times[0,1]$.

In the first term we perform the substitutions $r = k$ and $s = j - 1$ and in the second term we perform the substitutions $r = k - 1$, $s = j$. We obtain the following equality:

$$\begin{aligned}\sum_{j=0}^{n}(-1)^j\cdot(i_j^n \times \mathrm{id}_{[0,1]})_*(\Omega_{n-1}) \;&=\; \sum_{0\le k\le j-1\le n-1}(-1)^{j-1}\cdot(-1)^k\cdot[v_0,\dots,\widehat{v_k},\dots,v_j,w_j,\dots,w_n]\\ &\quad+\sum_{n\ge k-1>j\ge 0}(-1)^j\cdot(-1)^{k-1}\cdot[v_0,\dots,v_j,w_j,\dots,\widehat{w_k},\dots,w_n].\end{aligned}$$

We see immediately that these terms are just the negatives of the corresponding terms in the above equation $(*)$. □

The following lemma implies in particular the first statement of Proposition 30.5. The second statement of Proposition 30.5 regarding the induced maps on homology follows immediately from the first statement together with Lemma 30.2. In other words, the following lemma completes the proof of Proposition 30.5.

Lemma 30.7. *Let X be a topological space and let $F\colon X\times[0,1]\to X$ be a homotopy from a map f to a map g. Given any $n\in\mathbb{N}_0$ we define*

$$P_n\colon C_n(X) \;\to\; C_{n+1}(Y)$$

to be the map that is induced by

$$(\sigma\colon\Delta^n\to X) \;\mapsto\; (F\circ(\sigma\times\mathrm{id}_{[0,1]}))_*(\Omega_n).$$

Then for any $n\in\mathbb{N}_0$ we have

$$\partial P_n + P_{n-1}\partial \;=\; g_* - f_*$$

as maps from $C_n(X)$ to $C_n(Y)$.

Proof. Let X be a topological space and let $F\colon X\times[0,1]\to X$ be a homotopy from a map f to a map g. Furthermore let $\sigma\colon\Delta^n\to X$ be a singular k-simplex. Then

$$\begin{aligned}(\partial P_n + P_{n-1}\partial)(\sigma) \;&=\; \partial(P_n(\sigma)) + P_{n-1}\Big(\sum_{j=0}^{n}(-1)^j\cdot\sigma\circ i_j^n\Big) \;=\; \partial(P_n(\sigma)) + \sum_{j=0}^{n}(-1)^j\cdot P_{n-1}(\sigma\circ i_j^n)\\ &=\; \partial((F\circ(\sigma\times\mathrm{id}_{[0,1]}))_*(\Omega_n)) + \sum_{j=0}^{n}(-1)^j\cdot(F\circ(\sigma\circ_j^n\times\mathrm{id}_{[0,1]}))_*(\Omega_{n-1})\\ &=\; (F\circ(\sigma\times\mathrm{id}_{[0,1]}))_*\Big(\partial(\Omega_n)) + \sum_{j=0}^{n}(-1)^j\cdot(i_j^n\times\mathrm{id}_{[0,1]})_*(\Omega_{n-1})\Big)\\ &\quad\uparrow\\ &\quad\text{by Lemma 29.9 (1) and since } (\sigma\times\mathrm{id})\circ(i_j^n\times\mathrm{id}) = (\sigma\circ i_j^n)\times\mathrm{id}\\ &=\; (F\circ(\sigma\times\mathrm{id}_{[0,1]}))_*(\eta_1-\eta_0) \;=\; f\circ\sigma - g\circ\sigma \;=\; g_*(\sigma) - f_*(\sigma).\\ &\quad\uparrow \qquad\qquad\qquad\qquad \uparrow\\ &\quad\text{Lemma 30.6} \qquad\qquad\qquad \text{since } F \text{ is a homotopy from } f \text{ to } g\end{aligned}$$

□

We recall the following definition from page 307.

Definition. Let X and Y be topological spaces.

(1) A map $f\colon X \to Y$ is a *homotopy equivalence between X and Y*, if there exists a homotopy inverse to f, i.e. a continuous map $g\colon Y \to X$ with $g \circ f \simeq \mathrm{id}_X$ and $f \circ g \simeq \mathrm{id}_Y$.
(2) If there exists a homotopy equivalence between X and Y, then we say that the topological spaces X and Y are *homotopy equivalent* and we write $X \simeq Y$.
(3) We say X is *contractible*, if X is homotopy equivalent to $Y = \{*\}$, i.e. if X is homotopy equivalent to a topological space which consists of precisely one point.

Now we obtain the following corollary to Proposition 30.5. This corollary mirrors the fact, proved in Propositions 9.12 (1) and 28.7, that homotopy equivalences induce isomorphisms of fundamental groups and higher homotopy groups.

Corollary 30.8. *Let X and be Y topological spaces and let $n \in \mathbb{N}_0$.*

(1) *If $f\colon X \to Y$ is a homotopy equivalence (e.g. a homeomorphism), then the induced map $f_*\colon H_n(X) \to H_n(Y)$ is an isomorphism.*
(2) *If X and Y are homotopy equivalent, then $H_n(X) \cong H_n(Y)$.*
(3) *If X is contractible, then $H_0(X) \cong \mathbb{Z}$ and $H_n(X) = 0$ for $n \geq 1$.*
(4) *If X is a deformation retract of Y, then the inclusion induced map $H_n(X) \to H_n(Y)$ is an isomorphism.*

Proof.

(1) Let $f\colon X \to Y$ be a homotopy equivalence and let $g\colon Y \to X$ be a homotopy inverse of f, i.e. g is a map such that $f \circ g \simeq \mathrm{id}_Y$ and $g \circ f \simeq \mathrm{id}_X$. It follows from Proposition 30.5 and the functoriality of homology that $f_* \circ g_* = (f \circ g)_* = \mathrm{id}_{H_n(Y)}$ and similarly $g_* \circ f_* = \mathrm{id}_{H_n(X)}$. But that means precisely that $f_*\colon H_n(X) \to H_n(Y)$ is an isomorphism.
(2) This statement follows immediately from (1).
(3) This statement follows immediately from (2) and Lemma 29.6.
(4) This statement follows immediately from (1) and Lemma 9.10. □

Examples.

(1) On page 308 we saw that every convex subset of $\mathbb{R}^n$, e.g. the open disk B^n, the closed disk $\overline{B}^n$, any simplex or $\mathbb{R}^n$, is contractible. Thus it follows from Corollary 30.8, that

$$H_i(\text{convex subset of } \mathbb{R}^n) \;\cong\; H_i(B^n) \;\cong\; H_i(\overline{B}^n) \;\cong\; H_i(\mathbb{R}^n) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } i = 0, \\ 0, & \text{if } i > 0. \end{cases}$$

(2) In Exercise 30.2 we will use Corollary 30.8 to show that if A is a compact convex subset of $\mathbb{R}^n$ and if $x \in A$, then the inclusion $\mathbb{R}^n \backslash A \to \mathbb{R}^n \backslash \{x\}$ induces isomorphisms $H_i(\mathbb{R}^n \setminus A) \to H_i(\mathbb{R}^n \setminus \{x\})$ for all i.

Remark. Given a map $f\colon X \to Y$ between topological spaces we denote by $[f]$ the homotopy equivalence class of f, and we denote by $[X, Y]$ the set of equivalence classes of maps from X

to Y. As we pointed out on page 305,

$$\begin{array}{rcl} \mathrm{Ob}(\mathcal{H}) & := & \text{all topological spaces,} \\ \mathrm{Mor}(X,Y) & := & [X,Y] \end{array}$$

together with the composition

$$\begin{array}{rcl} \mathrm{Mor}(X,Y)\times\mathrm{Mor}(Y,Z) & \to & \mathrm{Mor}(X,Z) \\ ([f],[g]) & \mapsto & [g\circ f] \end{array}$$

defines a category $\mathcal{H}$, called the *homotopy category*. Proposition 30.5 thus says that for each n the maps

$$X \mapsto H_n(X)$$

and

$$[f] \mapsto f_*\colon H_n(X)\to H_n(Y)$$

define a functor from the category $\mathcal{H}$ to the category $\mathcal{A}$ of abelian groups. In particular we now have the following commutative diagram of categories and functors:

$$\begin{tikzcd} \text{category } \mathcal{T} \text{ of topological spaces} \arrow[rr, "X\mapsto X"] \arrow[dr, "X\mapsto H_n(X)"'] & & \text{homotopy category } \mathcal{H} \arrow[dl, "X\mapsto H_n(X)"] \\ & \text{category of abelian groups.} & \end{tikzcd}$$

Exercises for Chapter 30.

Exercise 30.1. Prove Lemma 30.1.

Exercise 30.2. Let A be a compact convex subset of $\mathbb{R}^n$ and let $x\in A$. Show that the inclusion $\mathbb{R}^n\setminus A\to\mathbb{R}^n\setminus\{x\}$ induces isomorphisms $H_i(\mathbb{R}^n\setminus A)\to H_i(\mathbb{R}^n\setminus\{x\})$ for all i.

31. Long exact sequences and the homology of quotient spaces

In this section, given a topological space X and a "good" subset A we will relate the homology groups of X, A and the quotient space X/A via a long exact sequence. We will use this long exact sequence to fulfill our dream of calculating the homology groups of all spheres. Unfortunately it will take a very long time to prove the existence of this long exact sequence.

31.1. **Reduced homology groups.** In this section we introduce the reduced homology groups of a topological space. These are a minute but at times surprisingly useful variation on the usual homology groups.

Definition. Let X be a a topological space. By Lemma 29.4 (1) we know that the following is a generalized[602] chain complex

$$\begin{array}{ccccccccc} & & & & & & \text{degree } 0 & & \text{degree } -1 \\ & & & & & & \downarrow & & \downarrow \\ \dots & \xrightarrow{\partial_3} & C_2(X) & \xrightarrow{\partial_2} & C_1(X) & \xrightarrow{\partial_1} & C_0(X) & \xrightarrow{\epsilon} & \mathbb{Z} \to 0. \\ & & & & & & \sum_{i=1}^{k} n_i\sigma_i & \mapsto & \sum_{i=1}^{k} n_i \end{array}$$

We introduce the following three definitions.

(1) We refer to this chain complex as the *augmented chain complex* $\widetilde{C}_*(X)$ *of* X.
(2) We define the *k-th reduced homology group* $\widetilde{H}_k(X)$ *of* X to be the k-th homology group of the augmented chain complex.
(3) If $f\colon X \to Y$ is a map between topological spaces we denote by $f_*\colon \widetilde{C}_*(X) \to \widetilde{C}_*(Y)$ the map that is the usual map on $\widetilde{C}_k(X) = C_k(X)$ for $k \geq 0$ and that is the identity on the final $\mathbb{Z}$-term.

The following elementary lemma summarizes a few properties of reduced homology groups.

Lemma 31.1.

(1) *If $f\colon X \to Y$ is a map between two topological spaces, then the induced maps $f_*\colon \widetilde{C}_*(X) \to \widetilde{C}_*(Y)$ are chain maps. In particular we see that we get well-defined induced maps $f_*\colon \widetilde{H}_n(X) \to \widetilde{H}_n(Y)$.*
(2) *For any $n \in \mathbb{N}_0$ the maps*

$$\begin{array}{rcl} X & \mapsto & \widetilde{H}_n(X) \\ (f\colon X \to Y) & \mapsto & (f_*\colon \widetilde{H}_n(X) \to \widetilde{H}_n(Y)) \end{array}$$

define a functor from the category of topological spaces to the category of abelian groups.

[602] Recall that a generalized chain complex is like a chain complex, but we also allow non-zero groups in negative degrees.

(3) *For each $n \in \mathbb{N}_0$ the maps*

$$\begin{array}{rcl} \widetilde{H}_n(X) & \to & H_n(X) \\ [\sigma] & \to & [\sigma] \end{array}$$

are well-defined. Furthermore they define a natural transformation from the functor $X \mapsto \widetilde{H}_n(X)$ to the functor $X \mapsto H_n(X)$.

(4) *For every non-empty topological space X the following statements hold:*
   (a) *Given any point $P \in X$ the map*

$$\begin{array}{rcl} \widetilde{H}_0(X) \oplus \mathbb{Z} & \to & H_0(X) \\ \sigma \oplus n & \mapsto & \sigma + [n \cdot P] \end{array}$$

   is an isomorphism.
   (b) *Given any $n \geq 1$ the natural map $\widetilde{H}_n(X) \to H_n(X)$ is an isomorphism.*

(5) *If X is a topological space with $n \in \mathbb{N}$ path-components, then $\widetilde{H}_0(X) \cong \mathbb{Z}^{n-1}$.*

(6) *The statements of Corollary 30.8* (1), (2) *and* (4) *also hold the same way for reduced homology groups and the corresponding induced maps. For example, if X is a deformation retract of some topological space Y, then the inclusion induced maps $\widetilde{H}_k(X) \to \widetilde{H}_k(Y)$ are isomorphisms for all $k \in \mathbb{N}_0$.*

(7) *If X is a contractible topological space, then $\widetilde{H}_k(X) = 0$ for all $k \in \mathbb{N}_0$.*

The lemma shows in particular that reduced homology groups are almost the same as the usual homology groups. So it might sound slightly silly to introduce them. But we will see that on several occasions reduced homology groups make it easier to formulate some statements.

Remark.

(1) If X is a non-empty topological space, then it follows from Lemma 31.1 (4) that we have isomorphisms

$$H_n(X) \;\cong\; \begin{cases} \widetilde{H}_0(X) \oplus \mathbb{Z}, & \text{if } n = 0, \\ \widetilde{H}_n(X), & \text{if } n \neq 0. \end{cases}$$

Furthermore, by Lemma 31.1 (3), the isomorphism for $n \geq 1$ is natural. The isomorphism for $n = 0$ depends on the choice of a point.

(2) By Lemma 31.1 (7) we know for any $k \in \mathbb{N}_0$ and any $n \in \mathbb{N}_0$ we have

$$\widetilde{H}_n(\Delta^k) \;=\; \widetilde{H}_n(B^k) \;=\; \widetilde{H}_n(\overline{B}^k) \;=\; \widetilde{H}_n(\mathbb{R}^k) \;=\; 0.$$

(3) We will often use Lemma 31.1 without explicitly mentioning it. For example we will refer to earlier results about homology groups and state the corresponding results for reduced homology groups.

Proof.

(1) Let $f\colon X \to Y$ be a map between two topological spaces. It is a straightforward consequence of the definition of the augmentation maps that the following diagram commutes:

$$\begin{tikzcd} C_0(X) \arrow[rr, "f_*"] \arrow[dr, "\epsilon"'] & & C_0(Y) \arrow[dl, "\epsilon"] \\ & \mathbb{Z}. & \end{tikzcd}$$

It follows almost immediately from the fact that this diagram commutes that the induced maps $f_*\colon \widetilde{C}_*(X) \to \widetilde{C}_*(Y)$ are chain maps. Furthermore we obtain from Lemma 29.7 that we get induced maps on reduced homology.

(2) This statement is basically obvious.

(3) This statement follows easily from the definitions.

(4) Let X be a non-empty topological space. By the definition of $\widetilde{H}_n(X)$ we only have to deal with the case $n = 0$. We pick a point $P \in X$. We denote by $i\colon \mathbb{Z} \to H_0(X)$ the map that is given by $i(n) = [n \cdot P]$. Evidently we have $\epsilon \circ i = \mathrm{id}_{\mathbb{Z}}$. It follows easily from this observation and from $\widetilde{H}_0(X) = \ker(\epsilon)$ that the map[603]

$$\begin{array}{rcl} \widetilde{H}_0(X) \oplus \mathbb{Z} & \to & H_0(X) \\ c \oplus n & \mapsto & c + i(n) \end{array}$$

is an isomorphism.

(5) This statement follows immediately from (1), Corollary 29.14 and Lemma 11.8 (4).

(6) This statement is proved exactly the same way as Corollary 30.8.

(7) This final statement follows immediately from (5) and (6). □

31.2. **Long exact sequences.** We need two more definitions before we can formulate one of the key theorems of homology theory.

Definition. Let X be a topological space and let $A \subset X$ be a subset. We say A is *good* if A is closed and if there exists an open neighborhood U of A in X such that A is a deformation retract of U.

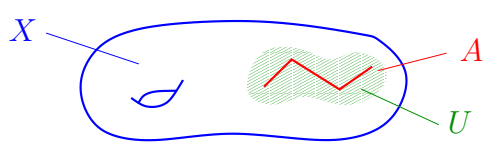

FIGURE 479. Illustration of a good subset.

Remark. Our definition of a good subset is the same as on [Hat, p. 114], except that we do not demand that a good subset is non-empty.

Examples.

[603] Why is this map an epimorphism?

(1) Let $x \in X$ be a point. Basically by definition the subset $\{x\} \subset X$ is good in the above sense if and only the point is good in the sense of the definition on page 387.
(2) The sphere S^{n-1} is a good subset of the closed ball $\overline{B}^n$. It is clear that S^{n-1} is a closed subset. Furthermore, if we consider the open neighborhood $U = \overline{B}^n \setminus \{0\}$, then a deformation retraction is given by the map
$$\begin{array}{rcl} (\overline{B}^n \setminus \{0\}) \times [0,1] & \to & \overline{B}^n \setminus \{0\} \\ (x,t) & \mapsto & \left(1 - t\frac{1-\|x\|}{\|x\|}\right) \cdot x. \end{array}$$
(3) We can generalize the first example: It follows easily from Proposition 3.21 (3) and the Collar Neighborhood Theorem 10.10 that every boundary component of a manifold is good.
(4) Finally it follows from Lemma 26.10 (2) and Proposition 26.11 (8a) that every subcomplex A of a CW-complex X is good.

The following definition might be familiar from earlier algebra courses.

Definition. A sequence of group homomorphisms
$$\dots A_{n+1} \xrightarrow{f_{n+1}} A_n \xrightarrow{f_n} A_{n-1} \xrightarrow{f_{n-1}} A_{n-2} \to \dots$$
is called *exact*, if for each n we have
$$\ker(f_n) \;=\; \operatorname{im}(f_{n+1}).$$

Remark.
(1) An exact sequence satisfies in particular that $f_n \circ f_{n+1} = 0$ for all $n \in \mathbb{N}_0$.
(2) We have the following equivalences of statements:
$$\begin{array}{rcl} \text{the sequence } 0 \to A \xrightarrow{f} B \quad \text{is exact} & \Longleftrightarrow & f \text{ is injective} \\ \text{the sequence } \quad A \xrightarrow{f} B \to 0 \text{ is exact} & \Longleftrightarrow & f \text{ is surjective} \\ \text{the sequence } 0 \to A \xrightarrow{f} B \to 0 \text{ is exact} & \Longleftrightarrow & f \text{ is an isomorphism} \end{array}$$
(3) Sometimes we also use the following observations:
$$\begin{array}{rcl} \text{the sequence } 0 \to A \to B \xrightarrow{f} C \text{ is exact} & \Longrightarrow & A \cong \ker(f) \\ \text{the sequence } A \xrightarrow{f} B \to C \to 0 \text{ is exact} & \Longrightarrow & C \cong \operatorname{coker}(f) \end{array}$$

Now we can formulate the following theorem.

Theorem 31.2. *Let X be a topological space and let $A \subset X$ be a non-empty good subset. We denote by $i\colon A \to X$ the inclusion map and we denote by $p\colon X \to X/A$ the projection map. Then for each n there exists a homomorphism $\partial\colon \widetilde{H}_n(X/A) \to \widetilde{H}_{n-1}(A)$ such that the sequence*
$$\begin{array}{rcccccc} & & & \dots & \xrightarrow{p_*} & \widetilde{H}_{n+1}(X/A) & \xrightarrow{\partial} \\ \to & \widetilde{H}_n(A) & \xrightarrow{i_*} & \widetilde{H}_n(X) & \xrightarrow{p_*} & \widetilde{H}_n(X/A) & \xrightarrow{\partial} \\ \to & \widetilde{H}_{n-1}(A) & \xrightarrow{i_*} & \dots & & & \end{array}$$

is exact.

It will take a while to prove Theorem 31.2. Therefore we will first consider several applications which will convince us that proving Theorem 31.2 is worth the effort.

31.3. **The homology groups of spheres.** Using Theorem 31.2 we can now determine the homology groups of spheres and we get a nice and satisfactory result.

Proposition 31.3. *For each n we have*

$$\widetilde{H}_k(S^n) \cong \begin{cases} \mathbb{Z}, & \text{if } k = n, \text{ and} \\ 0, & \text{if } k \neq n. \end{cases}$$

Put differently, the combination of Lemma 31.1 and Proposition 31.3 says that for any $n > 0$ we have

$$H_k(S^n) \cong \begin{cases} \mathbb{Z}, & \text{if } k = 0 \text{ or } k = n, \text{ and} \\ 0, & \text{if } k \neq 0, n. \end{cases}$$

Furthermore we have

$$H_k(S^0) \cong \begin{cases} \mathbb{Z}^2, & \text{if } k = 0, \text{ and} \\ 0, & \text{if } k \neq 0. \end{cases}$$

By Proposition 3.18 (2) we know that the for $k \neq l$ the spheres S^k and S^l are not diffeomorphic. The following corollary is a serious upgrade of this fact.

Corollary 31.4. *For $k \neq l$ the spheres S^k and S^l are not homeomorphic.*

So we have finally managed to distinguish spheres of different dimensions. Our initial attempt had been to use higher homotopy groups to prove that result. The definition of higher homotopy groups is arguably much more natural than the definition of homology groups, but the latter groups are significantly easier to compute.

Proof of Proposition 31.3 assuming Theorem 31.2. We prove the proposition by induction on n. If $n = 0$, then $S^n = S^0$ consists of precisely two points, and the proposition follows from Lemmas 29.6, 29.13 and 31.1.

Now we suppose that the statement of the proposition holds for $n - 1$. We want to determine the reduced homology of S^n. On page 99 we remarked that S^n is homeomorphic to $\overline{B}^n/S^{n-1}$. We had just seen on page 764 that S^{n-1} is a good subset of $\overline{B}^n$. Therefore we can apply Theorem 31.2 to $X = \overline{B}^n$ and the closed subset $A = S^{n-1}$ and we obtain the following exact sequence

$$\begin{array}{rcrcrcl} \dots & \longrightarrow & \widetilde{H}_{k+1}(\overline{B}^n) & \xrightarrow{p_*} & \widetilde{H}_{k+1}(\overline{B}^n/S^{n-1}) & \xrightarrow{\partial} & \\ \rightarrow \quad \widetilde{H}_k(S^{n-1}) & \xrightarrow{i_*} & \widetilde{H}_k(\overline{B}^n) & \xrightarrow{p_*} & \widetilde{H}_k(\overline{B}^n/S^{n-1}) & \xrightarrow{\partial} & \\ \rightarrow \quad \widetilde{H}_{k-1}(S^{n-1}) & \xrightarrow{i_*} & \dots & & & & \end{array}$$

From the induction hypothesis, from the homeomorphism $S^n \cong \overline{B}^n/S^{n-1}$ and from the fact that $\widetilde{H}_i(\overline{B}^n) = 0$ for all i (obtained on page 762) we now see that the above long exact

sequence is of the following form:

$$\begin{array}{rcccccc} & \dots & \longrightarrow & 0 & \xrightarrow{p_*} & \widetilde{H}_{k+1}(S^n) & \xrightarrow{\partial} \\ \to & \widetilde{H}_k(S^{n-1}) & \xrightarrow{i_*} & 0 & \xrightarrow{p_*} & \widetilde{H}_k(S^n) & \xrightarrow{\partial} \\ \to & \widetilde{H}_{k-1}(S^{n-1}) & \xrightarrow{i_*} & \dots & & & \end{array}$$

In particular we obtain for each k an exact sequence

$$0 \;\to\; \widetilde{H}_{k+1}(S^n) \;\xrightarrow{\partial}\; \widetilde{H}_k(S^{n-1}) \;\to\; 0.$$

But this means that the maps ∂ are isomorphisms, and using our induction hypothesis we obtain the desired result that

$$\widetilde{H}_k(S^n) \;=\; \widetilde{H}_{k-1}(S^{n-1}) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k-1 = n-1, \text{ i.e. if } k = n \text{ and} \\ 0, & \text{if } k \neq n. \end{cases}$$

□

In Lemma 1.90 we had used elementary arguments to show that $\mathbb{R}$ is not homeomorphic to $\mathbb{R}^2$. Furthermore, in Lemma 9.13 we had used the fundamental group to prove that $\mathbb{R}^2$ is not homeomorphic to $\mathbb{R}^n$ for $n \geq 3$. Now we can finally show that for any $k \neq l$ the topological spaces $\mathbb{R}^k$ and $\mathbb{R}^l$ are not homeomorphic.

Proposition 31.5. *For any $k \neq l$ the topological spaces $\mathbb{R}^k$ and $\mathbb{R}^l$ are not homeomorphic.*

Proof. Clearly we only have to deal with the case $k, l \geq 1$. Let $k, l \in \mathbb{N}$ and suppose there exists a homeomorphism $f\colon \mathbb{R}^k \to \mathbb{R}^l$. Then we obtain that

$$\begin{array}{ccccccccc} & & \text{Corollary 30.8} & & & & \text{Corollary 30.8} & & \\ & & \downarrow & & & & \downarrow & & \\ \mathbb{Z} & \cong & \widetilde{H}_{k-1}(S^{k-1}) & \cong & \widetilde{H}_{k-1}(\mathbb{R}^k \setminus \{0\}) & \cong & \widetilde{H}_{k-1}(\mathbb{R}^l \setminus \{f(0)\}) & \cong & \widetilde{H}_{k-1}(S^{l-1}). \\ & \uparrow & & & & \uparrow & & & \\ & \text{Proposition 31.3} & & & & \text{since } f \text{ is a homeomorphism} & & & \end{array}$$

So we have $\widetilde{H}_{k-1}(S^{l-1}) \cong \mathbb{Z}$. But by Proposition 31.3 that is only possible if $k = l$. □

In Lemma 6.2 we had used the fundamental group to show that S^1 is not a retract of $\overline{B}^2$. Precisely the same argument, together with Proposition 31.3, now gives us the following proposition.

Proposition 31.6. *For any $n \in \mathbb{N}$ the sphere $S^{n-1} = \partial\overline{B}^n$ is not a retract of the closed ball $\overline{B}^n$.*

Remark. I found the following amusing description of Proposition 31.6 online:
"Suppose a shark jumps into a shoal of fish (a kind of big ball). The small fishes start escaping in all directions towards the border of the shoal, where the fishes stand still. Yet they escape with a certain disposition to follow a continuous flow, as they usually do, since everybody tends to follow its neighborhoods. But since there is no continuous retraction to the boundary, somebody doesn't know where to go, and stay there for a moment, much to the shark's satisfaction. There is also a 2D version, with a wolf entering into a herd of sheep."

Proof. Let us suppose there exists a retraction $r\colon \overline{B}^n \to S^{n-1}$. We denote by $i\colon S^{n-1} \to \overline{B}^n$ the inclusion map. We consider the following diagram

$$\begin{tikzcd} & \widetilde{H}_{n-1}(\overline{B}^n) \arrow[dr, "r_*"] & \\ \widetilde{H}_{n-1}(S^{n-1}) \arrow[ur, "i_*"] \arrow[rr, "(r\circ i)_*"] & & \widetilde{H}_{n-1}(S^{n-1}). \end{tikzcd}$$

This diagram commutes since it follows from the functoriality of the homology groups that $r_* \circ i_* = (r \circ i)_*$. Since r is a retraction it follows that $r \circ i = \mathrm{id}_{S^{n-1}}$, i.e. $(r \circ i)_* = (\mathrm{id}_{S^{n-1}})_*$ is the identity map on $\widetilde{H}_{n-1}(S^{n-1})$ which, by Proposition 31.3, is isomorphic to $\mathbb{Z}$. The lower map is thus an isomorphism, but the upper map factorizes through the trivial group, i.e. the composition of i_* and r_* cannot be an isomorphism of $\mathbb{Z}$. Thus we have obtained a contradiction. $\square$

Theorem 31.7. (Brouwer[604] Fixed Point Theorem) *Every map $f\colon \overline{B}^n \to \overline{B}^n$ admits a fixed point, i.e. for every map $f\colon \overline{B}^n \to \overline{B}^n$ there exists a point $x \in \overline{B}^n$ such that $f(x) = x$.*[605]

Proof. Suppose there exists a map $f\colon \overline{B}^n \to \overline{B}^n$ without a fixed point. Since f admits no fixed points there exists for each x precisely one ray which starts at $f(x)$ and which goes through x. We consider the following map which is illustrated in Figure 480:

$$\begin{array}{rcl} \Phi\colon \overline{B}^n & \to & \overline{B}^n \\ x & \mapsto & \begin{array}{l}\text{the intersection point of } S^{n-1} \text{ with the} \\ \text{uniquely determined ray from } f(x) \text{ to } x.\end{array} \end{array}$$

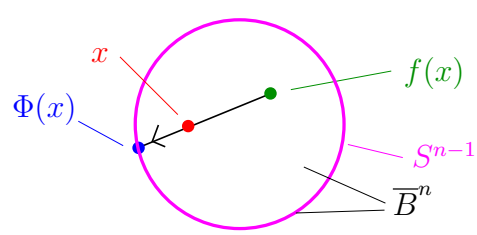

FIGURE 480.

It is elementary to show that Φ is continuous.[606] It is evident that $\Phi(x) = x$ for all $x \in S^{n-1}$ and that $\Phi(x) \in S^{n-1}$ for all $x \in S^{n-1}$. The map Φ is thus a retraction from

[604]Luitzen Brouwer (1881-1966) was a Dutch mathematician.

[605]How can one prove the statement for $n = 1$ using elementary methods from real analysis?

[606]Here is the precise argument: given $x \in \overline{B}^n$ the ray r_x emanating from x and through $f(x)$ is given by $r + x(t) = x + t(f(x) - x)$ for $t \in \mathbb{R}_{\geq 0}$. For any x there exists a unique $t_x \geq 0$ with $\|r_x(t_x)\| = 1$, and $\Phi(x) = r_x(t_x)$. It suffices to show that $x \mapsto t_x$ is continuous. One can determine t_x through the

$\overline{B}^n$ to S^{n-1}. But according to Proposition 31.6 this not possible. Thus we have obtained a contradiction. □

The Brouwer Fixed Point Theorem pops up many times in mathematics. For example we can use it to prove the following theorem in linear algebra.

Theorem 31.8. (Perron-Frobenius Theorem) *Let $A = (a_{ij})$ be an $n \times n$-real matrix. If all entries are positive, then A has a positive eigenvalue λ with an eigenvector v such that all entries of v are non-negative.*

Remark. There are more precise statements one can prove about matrices with positive entries we refer to [Meyr, Section 8.2] and also to

`https://en.wikipedia.org/wiki/Perron-Frobenius_theorem`

for details. Supposedly the Perron-Frobenius Theorem and some of the more refined results mentioned in [Meyr, Section 8.2] play a major role in Google's algorithm, see e.g.

`http://www.math.pku.edu.cn/teachers/yaoy/Fall2011/lecture07.pdf`

for more information.

Proof. We consider the convex set

$$T \ := \ \big\{(t_1, \dots, t_n) \in [0,1]^n \,\big|\, \sum_{i=1}^n t_i = 1\big\}.$$

This set is just the standard $(n-1)$-simplex endowed with a different name. We saw in Lemma 29.1 that it is homeomorphic to $\overline{B}^{n-1}$. It follows immediately from this observation and from the Brouwer Fixed Point Theorem 31.7 that any self-map $f\colon T \to T$ has a fixed point.

Let $A = (a_{ij})$ be an $n \times n$-real matrix such that all entries are positive. We consider the map

$$\begin{array}{rcl} f\colon T & \to & T \\ v = (v_1, \dots, v_n) & \mapsto & \frac{Av}{|Av|}. \end{array}$$

Note that this map is defined since our hypothesis that all a_{ij} are positive and the fact that all entries of v are non-negative and that at least one entry of v is positive imply that $Av \neq 0$. As we had just discussed above, the map $f\colon T \to T$ has a fixed point $v \in T$. But this means that $Av = |Av| \cdot v$. Put differently, we have just shown that v is an eigenvector to the positive eigenvalue $|Av|$. □

We conclude this discussion of the Brouwer Fixed Point Theorem with two applications outside of mathematics:

---

quadratic equation

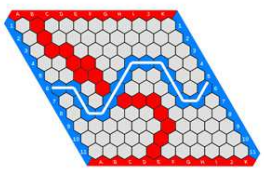
$$1 = \|r_x(t_x)\|^2 = \langle r_x(t_x), r_x(t_x)\rangle = 2\langle x, f(x) - x\rangle + \|f(x) - x\| = \langle x + t_x(f(x) - x), x + t_x(f(x) - x)\rangle$$

and the quadratic formula for polynomials of degree two which is continuous in the coefficients.

(1) The board game "Hex" was invented in 1942 by Piet Hein[607] and it was re-invented in 1948 by John Nash[608] The game is illustrated in Figure 481 and an online version can be found at

`http://www.lutanho.net/play/hex.html`

David Gale [Gal] showed in 1979 that the statement that the board game "Hex" cannot end in a draw, is equivalent to the Brouwer Fixed-Point Theorem. We also refer to [Gh, p. 102] for a discussion of Hex and the Brouwer Fixed-Point Theorem.



11×11 Hex gameboard showing a winning configuration for Blue

FIGURE 481.

(2) The Brouwer Fixed Point Theorem can also be used to show the existence of a "Nash equilibrium" in game theory. We refer to the following website for more information:

`https://en.wikipedia.org/wiki/Nash_equilibrium`.

31.4. **Basic homological algebra.** Now that we have made use of Theorem 31.2 we also need to provide a proof of Theorem 31.2. In this chapter we will first develop several algebraic methods which later on will be used in the proof of the existence of the exact sequence of Theorem 31.2.

Definition. A *short exact sequence* is an exact sequence of the form

$$0 \to A \to B \to C \to 0,$$

which consists of at most three non-trivial groups. A *short exact sequence of chain complexes*

$$0 \to A_* \xrightarrow{i} B_* \xrightarrow{p} C_* \to 0$$

consists of chain complexes A_*, B_*, C_* and chain maps $i\colon A_* \to B_*$ and $p\colon B_* \to C_*$ such that for each n the maps

$$0 \to A_n \xrightarrow{i} B_n \xrightarrow{p} C_n \to 0$$

form a short exact sequence.

[607]Piet Hein (1905-1996) was a Danish mathematician.

[608]John Nash (1928-2015) was an American mathematician who was awarded the Nobel prize in economics in 1994. The movie "a beautiful mind" was based on his struggles with schizophrenia.

Remark. Throughout the subsequent discussion in the following pages it is helpful to keep in mind the following commutative diagram of short exact sequences:

$$\begin{tikzcd}
0 \arrow[r] & A_{n+1} \arrow[r, "i"] \arrow[d, "\partial_{n+1}"] & B_{n+1} \arrow[r, "p"] \arrow[d, "\partial_{n+1}"] & C_{n+1} \arrow[r] \arrow[d, "\partial_{n+1}"] & 0 \\
0 \arrow[r] & A_n \arrow[r, "i"] \arrow[d, "\partial_n"] & B_n \arrow[r, "p"] \arrow[d, "\partial_n"] & C_n \arrow[r] \arrow[d, "\partial_n"] & 0 \\
0 \arrow[r] & A_{n-1} \arrow[r, "i"] \arrow[d, "\partial_{n-1}"] & B_{n-1} \arrow[r, "p"] \arrow[d, "\partial_{n-1}"] & C_{n-1} \arrow[r] \arrow[d, "\partial_{n-1}"] & 0 \\
0 \arrow[r] & A_{n-2} \arrow[r, "i"] & B_{n-2} \arrow[r, "p"] & C_{n-2} \arrow[r] & 0.
\end{tikzcd}$$

Now suppose that we are given such a short exact sequence of chain complexes. We will define a map

$$\partial_n \colon H_n(C) \ \to \ H_{n-1}(A)$$

as follows:

(1) Let $z \in H_n(C)$.
(2) We pick $c \in C_n$ with $z = [c]$.
(3) By the surjectivity of p we have $c = p(b)$ for some $b \in B_n$.
(4) We have

$$\begin{array}{ccccccc} p(\partial b) & = & \partial p(b) & = & \partial c & = & 0. \\ & & \uparrow & & & \uparrow & \\ & & \text{since the diagram commutes} & & & \text{since } c \text{ is a cycle} & \end{array}$$

(5) Since the second horizontal row in the above diagram is exact it follows immediately from (4) that $\partial b = i(a)$ for some uniquely determined $a \in A_{n-1}$.
(6) We put $\partial_n(z) := [a]$.

We refer to this map $\partial_n \colon H_n(C) \to H_{n-1}(A)$ as the *connecting homomorphism.*

The following lemma summarizes two of the key properties of the connecting homomorphisms.

Lemma 31.9.

(1) *Let $0 \to A_* \to B_* \to C_* \to 0$ be a short exact sequence of chain complexes. The connecting homomorphism $\partial_n \colon H_n(C) \to H_{n-1}(A)$ is well-defined and it is indeed a homomorphism.*
(2) *If*

$$\begin{tikzcd}
0 \arrow[r] & A_* \arrow[r, "i"] \arrow[d, "a"] & B_* \arrow[r, "p"] \arrow[d, "b"] & C_* \arrow[r] \arrow[d, "c"] & 0 \\
0 \arrow[r] & A'_* \arrow[r, "i"] & B'_* \arrow[r, "p"] & C'_* \arrow[r] & 0
\end{tikzcd}$$

is a commutative diagram of chain maps where the horizontal sequences are exact, then the following diagram commutes for every $n \in \mathbb{N}$:

$$\begin{array}{ccc} H_n(C) & \xrightarrow{\partial_n} & H_{n-1}(A) \\ \downarrow{\scriptstyle c_*} & & \downarrow{\scriptstyle a_*} \\ H_n(C') & \xrightarrow{\partial_n} & H_{n-1}(A') \end{array}$$

The proof of this lemma and the following proposition are done by a "diagram chase". This means that one needs to keep the commutative diagram on page 770 in mind and one has to use on several occasions that the vertical maps are chain maps and that the horizontal sequences are exact. In both cases the proofs are quite elementary.

Proof.

The proof below is elementary but not very readable. It is much easier to prove the proposition on your own than to try to read the proof.

(1) We start out with the following claim.

Claim. The map

$$\partial_n \colon H_n(C) \ \to \ H_{n-1}(A)$$

is well-defined.

Let $z \in H_n(C)$. We denote by c, b and a the elements as in the definition of ∂_n. We need to show that the element a is indeed a cycle and that the definition of $\partial_n([c])$ does not depend on the choices of c and b.

The proofs of these two statements is not particularly difficult and it is done via "diagram chasing". First we note that

$$i(\partial a) \ \underset{\substack{\uparrow \\ \text{since the diagram commutes}}}{=} \ \partial i(a) \ = \ \partial(\partial b) \ = \ 0.$$

Since i is injective we obtain that $\partial a = 0$, i.e. a is indeed a cycle. Now we show that the homology class $[a]$ depends only on the homology class $[c]$.

(a) If we chose a different element in B_n, then it follows from the fact that the horizontal sequences are exact that this element would be of the form $b + i(a')$ for some $a' \in A_n$. But then we obtain the following equality:

$$\partial(b + i(a')) \ = \ \partial b + \partial(i(a')) \ \overset{\substack{\text{since the diagram commutes} \\ \downarrow}}{=} \ \underbrace{\partial b}_{=i(a)} + i(\partial a') \ = \ i(a + \partial a').$$

Since $[a] = [a + \partial a'] \in H_{n-1}(A)$ this does not change the homology class.

(b) If we picked an other representative for $[c]$, then this representative would be of the form $c + \partial c'$ for some $c' \in C_{n+1}$. Since the map $p\colon B_n \to C_n$ is an epimorphism there exists a $b' \in B_{n+1}$ with $p(b') = c'$. It follows that

$$p(b + \partial b') \;=\; p(b) + p(\partial b') \;\underset{\substack{\uparrow \\ \text{since the diagram commutes}}}{=}\; c + \partial p(b') \;=\; c + \partial c'.$$

Since $\partial(b + \partial b') = \partial b$ we have ended up with the same element in B_{n-1} as before.

This concludes the proof of the claim.

Claim. The map

$$\partial_n\colon H_n(C) \;\to\; H_{n-1}(A)$$

is a homomorphism.

Thus let $[c_1]$ and $[c_2]$ be given. For $j = 1, 2$ we choose b_j as in this definition of ∂_n, and we denote by a_j the uniquely determined element with $i(a_j) = \partial b_j$. Then we also have $p(b_1 + b_2) = c_1 + c_2$ and $i(a_1 + a_2) = i(a_1) + i(a_2) = \partial b_1 + \partial b_2 = \partial(b_1 + b_2)$. It follows that

$$\partial_n([c_1 + c_2]) \;=\; [a_1 + a_2] \;=\; [a_1] + [a_2] \;=\; \partial_n([c_1]) + \partial_n([c_2]).$$

Thus we have proved the claim.

(2) The second statement follows easily from the definitions. We leave the verification of the details as an exercise to the reader. □

Now we can formulate the following proposition which explains the name "connecting homomorphism".

Proposition 31.10. *Let*

$$0 \;\to\; A_* \;\xrightarrow{i}\; B_* \;\xrightarrow{p}\; C_* \;\to\; 0$$

be a short exact sequence of chain complexes. Then the sequence

$$\ldots \to H_n(A) \xrightarrow{i_*} H_n(B) \xrightarrow{p_*} H_n(C) \xrightarrow{\partial} H_{n-1}(A) \xrightarrow{i_*} H_{n-1}(B) \xrightarrow{p_*} \ldots$$

is exact.

Remark.

(1) In the following we refer to the exact sequence of Proposition 31.10 as the as *long exact sequence in homology* corresponding to the short exact sequence of chain complexes.

(2) Let

$$\begin{array}{ccccccccc}
0 & \longrightarrow & A_* & \xrightarrow{\;i\;} & B_* & \xrightarrow{\;p\;} & C_* & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle a} & & \downarrow{\scriptstyle b} & & \downarrow{\scriptstyle c} & & \\
0 & \longrightarrow & A'_* & \xrightarrow{\;i\;} & B'_* & \xrightarrow{\;p\;} & C'_* & \longrightarrow & 0
\end{array}$$

be a commutative diagram of chain maps where the horizontal sequences are exact. It follows from Lemma 31.9 that the following diagram commutes:

$$\begin{array}{ccccccccc}
\dots \longrightarrow & H_n(A) & \xrightarrow{i_*} & H_n(B) & \xrightarrow{p_*} & H_n(C) & \xrightarrow{\partial} & H_{n-1}(A) & \longrightarrow \dots \\
& \downarrow a_* & & \downarrow b_* & & \downarrow c_* & & \downarrow a_* & \\
\dots \longrightarrow & H_n(A') & \xrightarrow{i_*} & H_n(B') & \xrightarrow{p_*} & H_n(C') & \xrightarrow{\partial} & H_{n-1}(A') & \longrightarrow \dots
\end{array}$$

Put differently, we have defined a functor form the category of short exact sequences of chain complexes[609] to the category[610] of long exact sequences of abelian groups.

Proof of Proposition 31.10.

The proof below is elementary but not very readable. It is much easier to prove the proposition on your own than to try to read the proof.

Let

$$0 \;\to\; A_* \;\xrightarrow{i}\; B_* \;\xrightarrow{p}\; C_* \;\to\; 0$$

be a short exact sequence of chain complexes. Then the sequence

$$\dots \to H_n(A) \xrightarrow{i_*} H_n(B) \xrightarrow{p_*} H_n(C) \xrightarrow{\partial} H_{n-1}(A) \xrightarrow{i_*} H_{n-1}(B) \xrightarrow{p_*} \dots$$

is exact. We examine the exactness at the three groups $H_{n-1}(A), H_n(B)$ and $H_n(C)$. Put differently, at each of the three groups we want to show the following two statements:

(1) the image of the map to the left is contained in the image of the map to the right, or equivalently, the composition of the map to the left and the map to the right is zero,
(2) the kernel of the map to the right is contained in the image of the map to the left.

Now we perform these steps:

(A) First let $[c] \in H_n(C)$. We want to show that $i(\partial[c]) = 0$. We choose b with $p(b) = c$ and denote by $a \in A_{n-1}$ the element with $i(a) = \partial b$. Then we have

$$i(\partial[c]) \;\underset{\substack{\uparrow \\ \text{definition of } \partial\colon H_n(C) \to H_{n-1}(A)}}{=}\; i([a]) \;=\; [\partial b] \;=\; 0 \in H_{n-1}(B).$$

Now let $[a] \in \ker(i_*)$. Then $i(a) = \partial b$ for some $b \in B_n$. It follows immediately from the definitions that $\partial[p(b)] = [a]$.

[609]Here the objects are short exact sequences of chain complexes and morphisms between two short exact sequences $0 \to A_* \to B_* \to C_* \to 0$ and $0 \to A'_* \to B'_* \to C'_* \to 0$ are given by a triple of chain maps $a\colon A_* \to A'_*$, $b\colon B_* \to B'_*$ and $c\colon C_* \to C'_*$ such that the following diagram commutes:

$$\begin{array}{ccccccccc}
0 \longrightarrow & A_* & \longrightarrow & B_* & \longrightarrow & C_* & \longrightarrow & 0 \\
& \downarrow a & & \downarrow b & & \downarrow c & & \\
0 \longrightarrow & A'_* & \longrightarrow & B'_* & \longrightarrow & C'_* & \longrightarrow & 0.
\end{array}$$

[610]Here the objects are chain complexes of abelian groups and morphisms are chain maps.

(B) From $p \circ i = 0$ it follows that $p_* \circ i_* = 0$, i.e. $\mathrm{im}(i_*) \subset \ker(p_*)$.
Conversely let $b \in \ker(p_*)$. Then $p(b) = \partial c'$ for some $c' \in C_{n+1}$. Since p is surjective, there exists a $b' \in B_{n+1}$ with $p(b') = c'$. From the commutativity it follows that $p(\partial b') = \partial p(b') = \partial c' = p(b)$. Thus it follows that $p(b - \partial b') = 0$, i.e. $b - \partial b' = i(a)$ for some $a \in A_n$. But then it follows that $[b] = [b - \partial b'] = [i(a)] \in \mathrm{im}(i_*)$.

(C) Let $[b] \in H_n(B)$. We have to show that $\partial(p_*([b])) = 0$. In the definition of $\partial p_*([b])$ we choose some $b \in B$. Since $\partial b = 0$ it follows immediately that $\partial p_*([b]) = 0$.
Finally let $[c] \in \ker(\partial\colon H_n(C) \to H_{n-1}(A))$. We choose $b \in B_n$ with $p(b) = c$. Then there exists a uniquely determined $a \in A_{n-1}$ with $i(a) = \partial b$. Since we have $[a] = \partial[c] = 0 \in H_{n-1}(A)$ there exists an $a' \in A_n$ with $\partial a' = a$. Then it follows that

$$\partial(b - i(a')) \;=\; \partial b - \partial i(a') \;=\; \partial b - i(\partial a') \;=\; \partial b - i(a) \;=\; 0,$$

i.e. $b - i(a')$ is a cycle. On the other hand we have $p(b - i(a')) = p(b) - (p \circ i)(a') = p(b)$. Thus we see that $p_*([b - i(a')]) = [c]$. We have thus shown that $\ker(\partial) \subset \mathrm{im}(p_*)$.

Thus we have proved the claim and therefore we have also completed the proof of the proposition. □

The proof of the following lemma is also done via "diagram chasing". We will provide the proof in Exercise 31.4.

Lemma 31.11. (Five Lemma) *Let*

$$\begin{tikzcd}
A \arrow[r, "i"] \arrow[d, two heads, "a"] & B \arrow[r, "j"] \arrow[d, "b", "\cong"'] & C \arrow[r, "k"] \arrow[d, "c"] & D \arrow[r, "l"] \arrow[d, "d", "\cong"'] & E \arrow[d, hook, "e"] \\
A' \arrow[r, "i'"] & B' \arrow[r, "j'"] & C' \arrow[r, "k'"] & D' \arrow[r, "l'"] & E'
\end{tikzcd}$$

be a diagram of groups (*here for once we do not suppose that the groups are abelian*) *such that the horizontal sequences are exact and such that every squares commute* (*if all the groups are abelian, then it suffices it the squares commute up to a sign*)*. If a is surjective, if b and d are isomorphisms, and if e is injective, then c is an isomorphism.*[611]

31.5. **Relative homology groups.** In this section we will introduce the relative homology groups which will play an important role in the proof of Theorem 31.2 and also in the remainder of this course.

Definition. Let (X, A) be a pair of topological spaces.[612] We view each chain group $C_n(A)$ as a subgroup of $C_n(X)$. Thus we can define

$$C_n(X, A) \;:=\; C_n(X)/C_n(A)$$

[611] In many applications it suffices to remember the following slightly weaker statement: if the two vertical maps on the left and right are isomorphisms, then the middle map is also an isomorphism.

[612] Recall that according to the definition on page 243 this means that X is a topological space and $A \subset X$ is a subset.

and we consider the boundary map[613]

$$\begin{array}{rcl} \partial_n \colon C_n(X,A) & \to & C_{n-1}(X,A) \\ [c] & \mapsto & [\partial_n c]. \end{array}$$

We refer to

$$\ldots C_{n+1}(X,A) \xrightarrow{\partial_{n+1}} C_n(X,A) \xrightarrow{\partial_n} C_{n-1}(X,A) \xrightarrow{\partial_{n-1}} \ldots$$

as the chain complex of the pair (X,A).[614] Given any $n \in \mathbb{N}_0$ we define the *n-th relative homology group of* (X,A) as follows:

$$H_n(X,A) \ := \ H_n(C_*(X,A)).$$

Remark. Let (X,A) be a pair of topological spaces and let $n \in \mathbb{N}_0$. We write

$$S \ := \ \{\sigma \colon \Delta^n \to X \mid \operatorname{im}(\sigma) \cap (X \setminus A) \neq \varnothing\},$$

i.e. S denotes the set of all singular n-simplices of X that are not completely contained in A. Then it is straightforward to show that the map

$$\begin{array}{rcl} \mathbb{Z}^{(S)} & \to & C_n(X,A) \\ \sum\limits_{i=1}^{n} n_i\sigma_i & \mapsto & \left[\sum\limits_{i=1}^{n} n_i\sigma_i\right] \end{array}$$

is an isomorphism. In particular we see that $C_n(X,A)$ is a free-abelian group.

Examples.

(1) If $A = \varnothing$, then for all $n \in \mathbb{N}_0$ we have $C_n(\varnothing) = 0$ and $C_n(X,\varnothing) = C_n(X)$, i.e. we have $H_n(X,\varnothing) = H_n(X)$. In the following we will freely go back and forth between the notations $H_n(X,\varnothing)$ and $H_n(X)$.

(2) If X is a path-connected topological space and if A is non-empty, then $H_0(X,A) = 0$. Indeed, let $P \in X$ be a point. We pick a point $Q \in A$. Since X is path-connected we can pick a map $\sigma \colon \Delta^1 \to X$ such that $\sigma(0,1) = P$ and $\sigma(1,0) = Q$. As discussed on page 738, in $C_*(X,A)$ we have $\partial\sigma = P - Q$, but since $Q = 0 \in C_0(X,A)$ we have $\partial\sigma = P$, which shows that $P = 0 \in H_0(X,A)$. But this clearly implies that $H_0(X,A) = 0$. We refer to Figure 482 for an illustration.

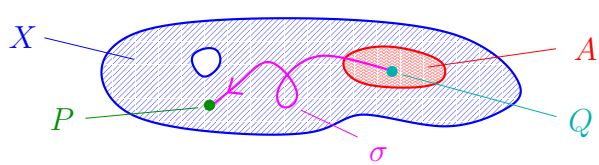


FIGURE 482.

[613]The map ∂_n is well-defined, since for any $c \in C_n(A) \subset C_n(X)$ the boundary ∂c lies obviously in $C_{n-1}(A) \subset C_{n-1}(X)$.

[614]Since $\partial_{n-1} \circ \partial_n \colon C_n(X) \to C_{n-2}(X)$ is the zero map it follows that $\partial_{n-1} \circ \partial_n \colon C_n(X,A) \to C_{n-2}(X,A)$ is also the zero map.

(3) We let $X = \mathbb{R}^2$ and $A = B_1(-2) \cup B_1(2)$. Let $\sigma\colon \Delta^1 \to X$ be a singular 1-simplex with $\sigma(0,1) \in B_1(2)$ and $\sigma(1,0) \in B_1(-2)$. (We refer to Figure 483 for an illustration.) Then we have

$$\partial\sigma \;=\; \underbrace{\sigma(0,1)}_{\in B_1(2)} - \underbrace{\sigma(1,0)}_{\in B_1(-2)}.$$

This shows that $\partial\sigma$ lies in $C_0(A)$. Put differently, the singular 1-simplex σ, viewed as an element in $C_1(X,A)$, is a cycle and therefore it represents an element in $H_1(X,A)$. Later on we will see whether or not $[\sigma] \in H_1(X,A)$ is non-trivial.

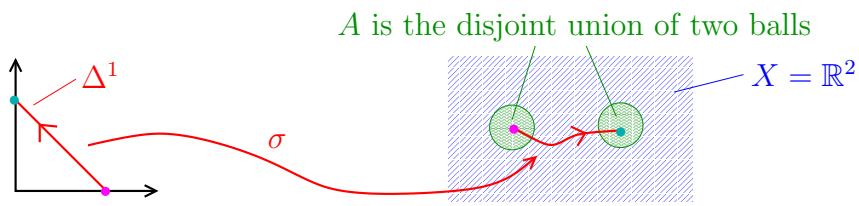

FIGURE 483.

Now let $f\colon (X,A) \to (Y,B)$ be a map of pairs of topological spaces, i.e. a map $f\colon X \to Y$ with $f(A) \subset B$. Then f induces maps

$$\begin{array}{rcl} f_*\colon H_n(X,A) & \to & H_n(Y,B) \\ \left[\sum\limits_{j=1}^n a_j\sigma_j\right] & \to & \left[\sum\limits_{j=1}^n a_j(f\circ\sigma_j)\right]. \end{array}$$

It is straightforward to show that these maps are well-defined.[615]

Remark. If (Y,B) is a pair of topological spaces and if $X \subset Y$ and $A \subset B$, then we have the obvious inclusion map $(X,A) \to (Y,B)$ and we therefore obtain the induced maps $H_n(X,A) \to H_n(Y,B)$ in relative homology. If it is clear from the context that we are dealing with such an inclusion induced map, then on many occasions we will not explicitly point out that we are working with the inclusion induced maps.

Now we consider the homology of a topological space relative to a point.

[615]We refer to the category that is given by

$$\begin{array}{rcl} \mathrm{Ob}(\mathcal{P}) & := & \text{all pairs of topological spaces,} \\ \mathrm{Mor}((X,A),(Y,B)) & := & \text{all maps } (X,A) \to (Y,B) \end{array}$$

with the usual composition of maps as the *category of topological pairs*. Then for each $n \in \mathbb{N}_0$ the maps

$$(X,A) \;\to\; H_n(X,A)$$

and

$$(f\colon (X,A) \to (Y,B)) \;\mapsto\; (f_*\colon H_n(X,A) \to H_n(Y,B))$$

define a functor from the category of topological pairs to the category of groups.

Lemma 31.12. *Given a topological space X, a point $x_0 \in X$ and $n \in \mathbb{N}_0$ we consider the map*

$$\begin{tikzcd} \widetilde{H}_n(X) \arrow[r] \arrow[rrr, bend right, "=:\Phi_{X,x_0}"'] & H_n(X) \arrow[r, "="] & H_n(X,\varnothing) \arrow[r] & H_n(X,\{x_0\}). \end{tikzcd}$$

Then the following holds:

(1) *The map*

$$\Phi_{X,x_0}\colon \widetilde{H}_n(X) \;\to\; H_n(X,\{x_0\})$$

is an isomorphism.

(2) *For any map $f\colon X \to Y$ of topological spaces and any $a \in X$ we have the following commutative diagram*

$$\begin{tikzcd} \widetilde{H}_n(X) \arrow[r, "f_*"] \arrow[d, "\Phi_{X,x_0}"'] & \widetilde{H}_n(Y) \arrow[d, "\Phi_{Y,f(x_0)}"] \\ H_n(X,\{x_0\}) \arrow[r, "f_*"] & H_n(Y,\{f(x_0)\}). \end{tikzcd}$$

In other words, if we denote by $\mathcal{P}$ the category of pointed topological spaces and we denote by $\mathcal{A}$ the category of abelian groups, then the isomorphisms from Lemma 31.12 (1) *give a natural transformation from the functor*

$$\begin{array}{rcl} \mathcal{P} & \to & \mathcal{A} \\ (X,x_0) & \mapsto & H_n(X,x_0) \end{array} \quad \textit{to the functor} \quad \begin{array}{rcl} \mathcal{P} & \to & \mathcal{A} \\ (X,x_0) & \mapsto & \widetilde{H}_n(X). \end{array}$$

In particular, the relative homology groups $H_n(X,x_0)$ and the reduced homology group $\widetilde{H}_n(X)$ are naturally isomorphic.

Proof. We will provide the proof of the first statement in Exercise 31.7. The second statement follows basically immediately from the definitions. □

Before we can state the next proposition we need to introduce the notion of a triple of topological spaces which is defined in almost the same fashion as a pair of topological spaces.

Definition.

(1) A *triple of topological spaces* is a triple (X,B,A) where X is a topological space and $A \subset B \subset X$ are subsets.
(2) A map $f\colon (X,B,A) \to (X',B',A')$ between triples of topological spaces is a continuous map $f\colon X \to X'$ such that $f(B) \subset B'$ and $f(A) \subset A'$.

Proposition 31.13. *Let X be a topological space and let $A \subset B \subset X$ be two subsets. We denote by $i\colon (B,A) \to (X,A)$ and by $p\colon (X,A) \to (X,B)$ the obvious maps. Then the following statements hold:*

(1) *For each $n \in \mathbb{N}_0$ the map*[616][617]

$$\begin{array}{rcl} \partial_n \colon H_n(X,B) & \to & H_{n-1}(B,A) \\ \Big[\sum\limits_{j=1}^{k} a_j \cdot (\sigma_j \colon \Delta^n \to X)\Big] & \mapsto & \Big[\sum\limits_{j=1}^{k} a_j \cdot \partial\sigma_j\Big] \end{array}$$

is well-defined.

(2) *Let $\mathcal{T}$ be the category of triples of topological spaces.*[618] *The maps ∂_n from* (1) *define a natural transformation from the functor $(X,B,A) \to H_n(X,B)$ to the functor $(X,B,A) \to H_{n-1}(B,A)$. In down-to-earth language this means that for a map $f\colon (X,A,B) \to (\widetilde{X},\widetilde{A},\widetilde{B})$ of triples of topological spaces the following diagram commutes:*

$$\begin{tikzcd} H_n(X,B) \arrow[r, "\partial_n"] \arrow[d, "f_*"'] & H_{n-1}(B,A) \arrow[d, "f_*"] \\ H_n(\widetilde{X},\widetilde{B}) \arrow[r, "\partial_n"] & H_{n-1}(\widetilde{B},\widetilde{A}). \end{tikzcd}$$

(3) *The maps*

$$\ldots \to H_n(B,A) \xrightarrow{i_*} H_n(X,A) \xrightarrow{p_*} H_n(X,B) \xrightarrow{\partial_n} H_{n-1}(B,A) \to \ldots$$

form an exact sequence.

(4) *The map in* (3) *which assigns to a triple (X,B,A) of topological spaces a long exact sequence of homology groups is functorial. More precisely, given a map $f\colon (X,B,A) \to (X',B',A')$ between triples of topological spaces the following diagram commutes*

$$\begin{tikzcd} \ldots \arrow[r] & H_n(B,A) \arrow[r] \arrow[d, "f_*"] & H_n(X,A) \arrow[r] \arrow[d, "f_*"] & H_n(X,B) \arrow[r, "\partial"] \arrow[d, "f_*"] & H_{n-1}(B,A) \arrow[r] \arrow[d, "f_*"] & \ldots \\ \ldots \arrow[r] & H_n(B',A') \arrow[r] & H_n(X',A') \arrow[r] & H_n(X',B') \arrow[r, "\partial"] & H_{n-1}(B',A') \arrow[r] & \ldots. \end{tikzcd}$$

The long exact sequence of Proposition 31.13 (2) is sometimes called the *long exact sequence of the triple* (X,B,A) and we refer to ∂_n as the *connecting homomorphism* of the triple (X,B,A).

Proof. It follows immediately from the definitions and the third isomorphism theorem[619] that

$$0 \to C_*(B,A) \xrightarrow{i_*} C_*(X,A) \xrightarrow{p_*} C_*(X,B) \to 0$$

[616]The fact that here the symbol "∂_n" denotes the boundary map of singular chains and the desired map $H_n(X,B) \to H_{n-1}(B,A)$ is an unfortunate problem in our choice of notation.

[617]Here we use that every homology class in $H_n(X,B)$ admits by definition a representative in the quotient $C_n(X,B) = C_n(X)/C_n(B)$, so it can be represented by a singular n-chain in X.

[618]It should be clear from the definitions preceding the definition what the objects and morphisms of this category are.

[619]The third isomorphism theorem implies that $(C_*(X)/C_*(A))/(C_*(B)/C_*(A)) \cong C_*(X)/C_*(B)$.

is a short exact sequence of chain complexes.

Claim. The maps ∂_n introduced in Statement (1) of the propositions are precisely the connecting homomorphisms, as defined on page 770, of the above short exact sequence of chain complexes. In particular the maps ∂_n are well-defined.

The claim follows basically immediately from the definitions. But for completeness' sake we give some details. We consider the following commutative diagram

$$\begin{array}{ccccccccc} 0 & \longrightarrow & C_n(B,A) & \longrightarrow & C_n(X,A) & \longrightarrow & C_n(X,B) & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle\partial} & & \downarrow{\scriptstyle\partial} & & \downarrow{\scriptstyle\partial} & & \\ 0 & \longrightarrow & C_{n-1}(B,A) & \longrightarrow & C_{n-1}(X,A) & \longrightarrow & C_{n-1}(X,B) & \longrightarrow & 0. \end{array}$$

Let $z \in H_n(X,A)$. Now we will determine the image of z under the connecting homomorphism $H_n(X,B) \to H_{n-1}(B,A)$ which during the proof of the claim we denote by ∂^c.

We pick a representative $\sum_{j=1}^{k} a_j \cdot (\sigma_j \colon \Delta^n \to X)$ in $C_n(X)$. Note that $\sum_{j=1}^{k} a_j \cdot (\sigma_j \colon \Delta^n \to X)$ also defines an element in $C_n(X,A)$. We then take the boundary of the above singular n-chain under the boundary map $\partial_n \colon C_n(X,A) \to C_{n-1}(X,A)$ and we end up with the singular n-chain $\sum_{j=1}^{k} a_j \cdot \partial\sigma_j \in C_{n-1}(X,A)$. As we have seen in the proof of Lemma 31.9 this singular n-chain lies in fact in $C_{n-1}(B,A) \subset C_{n-1}(X,A)$. The homology class thereof is by definition precisely $\partial^c(z) \in H_{n-1}(B,A)$. Summarizing we have shown that

$$\partial^c(z) \;=\; \Big[\sum_{j=1}^{k} a_j \cdot \partial\sigma_j\Big].$$

This shows that the map defined in (1) agrees with ∂^c. This concludes the proof of the claim.

Statement (2) of the lemma is an easy consequence of Lemma 31.9. The fact that the stated sequence of homology groups is exact is now an immediate consequence of Proposition 31.10. Finally the functoriality of the long exact sequence is an immediate consequence of (2). □

For convenience we record two important special cases of Proposition 31.13 in the following corollary.

Corollary 31.14. *Let X be a topological space and let $B \subset X$ be a subset. Then there exists a long exact sequence*

$$\ldots \;\to\; H_n(B) \;\xrightarrow{i_*}\; H_n(X) \;\xrightarrow{p_*}\; H_n(X,B) \;\xrightarrow{\partial}\; H_{n-1}(B) \;\to\; \ldots$$

Furthermore, if B is non-empty then there exists also a long exact sequence

$$\ldots \;\to\; \widetilde{H}_n(B) \;\xrightarrow{i_*}\; \widetilde{H}_n(X) \;\xrightarrow{p_*}\; H_n(X,B) \;\xrightarrow{\partial}\; \widetilde{H}_{n-1}(B) \;\to\; \ldots$$

Both long exact sequences define a functor from the category of pairs of topological spaces that we defined on page 243, to the category of chain complexes.

The long exact sequence of Corollary 31.14 is sometimes called the *long exact sequence* (*in reduced homology*) *of the pair* (X, B).

Proof. The first statement follows from Proposition 31.13 applied to $A = \varnothing$ and the second statement follows from Proposition 31.13 applied to $A = \{a\}$ a point in B. $\square$

Remark. Let (X, B, A) be a triple of topological spaces. Then $(X, B, \varnothing) \to (X, B, A)$ is a map between triples of topological spaces and by the naturality of the long exact sequence we obtain the following commutative diagram

$$\begin{array}{ccccccccc}
\dots \longrightarrow & H_n(B) & \longrightarrow & H_n(X) & \longrightarrow & H_n(X,B) & \xrightarrow{\partial} & H_{n-1}(B) & \longrightarrow \dots \\
& \downarrow & & \downarrow & & \downarrow{=} & & \downarrow & \\
\dots \longrightarrow & H_n(B,A) & \longrightarrow & H_n(X,A) & \longrightarrow & H_n(X,B) & \xrightarrow{\partial} & H_{n-1}(B,A) & \longrightarrow \dots .
\end{array}$$

Example. We let $X = \mathbb{R}^2$ and $A = B_1(-2) \cup B_1(2)$. We want to determine the relative homology groups of (X, A). We denote by $i\colon A \to X$ the inclusion map. By Corollary 31.14 we have a long exact sequence

$$H_2(X) \to H_2(X,A) \to H_1(A) \xrightarrow{i_*} H_1(X) \to H_1(X,A) \to H_0(A) \to H_0(X) \to H_0(X,A) \to 0.$$

By Corollary 30.8 (3) together with Lemma 29.13 we have $H_i(X) = H_i(\mathbb{R}^2) = 0$ and also $H_i(A) = H_i(B_1(-2)) \oplus H_i(B_1(2)) = 0$ for $i \geq 1$. Thus we see from the above long exact sequence that $H_i(X, A) = 0$ for $i \geq 2$. We denote by $\epsilon\colon H_0(\mathbb{R}^2) \to \mathbb{Z}$ the augmentation map that is an isomorphism by Proposition 29.5. Similarly we denote by $\mu_1\colon H_0(B_1(-2)) \to \mathbb{Z}$ and $\mu_2\colon H_0(B_1(2)) \to \mathbb{Z}$ the isomorphisms that are given by the augmentation maps. We obtain the following commutative diagram

$$\begin{array}{ccccccccc}
0 \longrightarrow & H_1(X,A) & \xrightarrow{\partial} & H_0(A) & \xrightarrow{i_*} & H_0(X) & \longrightarrow & H_0(X,A) & \longrightarrow 0 \\
& {\scriptstyle =}\downarrow & & {\scriptstyle \mu_1\oplus\mu_2}\downarrow{\scriptstyle \cong} & & {\scriptstyle \cong}\downarrow{\scriptstyle \epsilon} & & \downarrow{\scriptstyle =} & \\
0 \longrightarrow & H_1(X,A) & \longrightarrow & \mathbb{Z}^2 & \longrightarrow & \mathbb{Z} & \longrightarrow & H_0(X,A) & \longrightarrow 0.
\end{array}$$

We want to determine the matrix representing the homomorphism $\mathbb{Z}^2 \to \mathbb{Z}$ at the bottom. We do so in the following claim.

Claim. The homomorphism $\epsilon \circ i_* \circ (\mu_1 \oplus \mu_2)^{-1}\colon \mathbb{Z}^2 \to \mathbb{Z}$ is given by the matrix $(1\ 1)$.

We pick a point $P \in B_1(-2)$ and we pick a point $Q \in B_1(2)$. It follows from Proposition 29.5 and Lemma 29.13 that the map

$$\begin{array}{rcl}
\Psi\colon \mathbb{Z}^2 & \to & H_0(A) = H_0(B_1(-2)) \oplus H_0(B_1(2)) \\
(m,n) & \mapsto & [m \cdot P + n \cdot Q]
\end{array}$$

is the inverse to $\mu_1 \oplus \mu_2$. Now it is easy to verify that $\epsilon \circ i_* \circ (\mu_1 \oplus \mu_2)^{-1} = \epsilon \circ i_* \circ \Psi$ applied to $(1, 0)$ and $(0, 1)$ gives in both cases the value 1. So the map is described by the matrix $(1\ 1)$. This concludes the proof of the claim.

Since the top sequence in the above commutative diagram is exact and since the vertical maps are isomorphisms we see that the bottom sequence is also exact. It is now straightforward to see that

$$H_1(X,A) \;\cong\; \ker\left\{\mathbb{Z}^2 \xrightarrow{(1\;1)} \mathbb{Z}\right\} \;\cong\; \mathbb{Z} \quad \text{and} \quad H_0(X,A) \;\cong\; \operatorname{coker}\left\{\mathbb{Z}^2 \xrightarrow{(1\;1)} \mathbb{Z}\right\} \;\cong\; 0.$$

Now we return to the situation of the example on page 776. Let $\sigma\colon \Delta^1 \to X$ be a singular 1-simplex with $\sigma(0,1) \in B_1(2)$ and $\sigma(1,0) \in B_1(-2)$. We have

$$((\mu_1 \oplus \mu_2) \circ \partial)[\sigma]) \;\underset{\substack{\uparrow \\ \text{description of } \partial \text{ in Proposition 31.13}}}{=}\; ((\mu_1 \oplus \mu_2)([\partial\sigma]) \;=\; (\mu_1 \oplus \mu_2)([\underbrace{\sigma(0,1)}_{\in B_1(2))}] - [\underbrace{\sigma(1,0)}_{\in B_1(-2))}]) \;=\; (1,-1).$$

Since $(1,-1)$ is a generator of the kernel of $\mathbb{Z}^2 \xrightarrow{(1\;1)} \mathbb{Z}$ we see that $[\sigma]$ is in fact a generator of $H_1(X,A) \cong \mathbb{Z}$. In particular it is non-zero.

Recall that, as defined on page 641, we say that two maps $f,g\colon (X,A) \to (Y,B)$ between pairs of topological spaces are homotopic, if there exists a map $F\colon X \times [0,1] \to Y$ such that $F(x,0) = f(x)$ and $F(x,1) = g(x)$ for all $x \in X$, and $F(a,t) \in B$ for all $a \in A$ and all $t \in [0,1]$. The following proposition extends Proposition 30.5 to the relative case.

Proposition 31.15. *Let $f,g\colon (X,A) \to (Y,B)$ be two maps between pairs of topological spaces. If f and g are homotopic, then the maps $f_*, g_*\colon C_*(X,A) \to C_*(Y,B)$ are chain homotopic, in particular for every $n \in \mathbb{N}_0$ we have*

$$f_* \;=\; g_*\colon H_n(X,A) \;\to\; H_n(Y,B).$$

Proof. Let $f,g\colon (X,A) \to (Y,B)$ be two homotopic maps between pairs of topological spaces. To prove the proposition we have to look again at the proof of Proposition 30.5. There in the proof we had explicitly constructed a chain $P_n\colon C_n(X) \to C_{n+1}(Y)$, $n \in \mathbb{N}_0$ between the maps f_* and g_* from $C_*(X)$ to $C_*(Y)$. It follows immediately from the definition of the chain homotopy that it has the property that $C_n(A)$ gets sent to $C_{n+1}(B)$. In particular the chain homotopy descends to maps $Q_n\colon C_n(X,A) \to C_{n+1}(Y,B)$ which then form a chain homotopy between the maps f_* and g_* from $C_*(X,A)$ to $C_*(Y,B)$. It now follows immediately from Lemma 30.2 that $f_* = g_*\colon H_n(X,A) \to H_n(Y,B)$. $\square$

We conclude this section with the following corollary.

Corollary 31.16. *Let X be a topological space.*

(1) *Let $A \subset B$ be subsets of X. If A is a deformation retract of B, then for any $n \in \mathbb{N}_0$ the inclusion induced map*

$$H_n(X,A) \;\to\; H_n(X,B)$$

is an isomorphism.

(2) *If A is a deformation retract of X, then $H_n(X,A) = 0$ for all $n \in \mathbb{N}_0$.*

(3) *Let $A \subset Y$ be subsets of X. If Y is a deformation retract of X, then for any $n \in \mathbb{N}_0$ the inclusion induced map*

$$H_n(Y, A) \ \to \ H_n(X, A)$$

is an isomorphism.

Proof. Let X be a topological space.

(1) Let $A \subset B$ be a deformation retract of B. We consider the following commutative diagram

$$\begin{array}{ccccccccc} H_n(A) & \longrightarrow & H_n(X) & \longrightarrow & H_n(X,A) & \longrightarrow & H_{n-1}(A) & \longrightarrow & H_{n-1}(X) \\ \downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\ H_n(B) & \longrightarrow & H_n(X) & \longrightarrow & H_n(X,B) & \longrightarrow & H_{n-1}(B) & \longrightarrow & H_{n-1}(X), \end{array}$$

where the vertical maps are induced by the inclusions of topological spaces and the horizontal maps are given by the long exact sequences of the pairs (X, A) and (X, B) from[620] Corollary 31.14. The second and the fifth vertical map are both evidently isomorphisms. Since A is a deformation retract of B we obtain from Corollary 30.8 that the first and the fourth map are isomorphisms. We conclude with the Five Lemma 31.11 that the middle vertical map is also an isomorphism.

(2) The second statement follows from the first statement applied to $B = X$ and the trivial observation that $H_n(X, X) = 0$ for all $n \in \mathbb{N}_0$.

(3) The third statement is proved almost the same way as the first statement. □

The statement of Corollary 31.14 looks already very similar to the statement of Theorem 31.2 that we actually want to prove. Now we "only" have to find the connection between the groups $H_n(X, A)$ and $H_n(X/A)$. The notations already look very similar, and they do so for good reasons, since in both cases "one ignores what lies in A". Nonetheless, proving the precise relationship will still require some substantial piece of work.

31.6. **The Excision Theorem.** The key step in finding the connection between the groups $H_n(X, A)$ and $H_n(X/A)$ is given by the following Excision Theorem 31.17.

Theorem 31.17. (Excision Theorem) *Let X be a topological space and let $Z \subset A \subset X$ be subsets such that the closure of Z is contained in the interior of A. Then the inclusion $(X \setminus Z, A \setminus Z) \to (X, A)$ induces for each $n \in \mathbb{N}_0$ an isomorphism*

$$H_n(X \setminus Z, A \setminus Z) \ \stackrel{\cong}{\to} \ H_n(X, A).$$

The proposition thus says in particular that if we are given a pair of topological spaces (X, A) and if we excise [621] a subset Z from the interior of A, then this does not affect the relative homology groups.

[620] Note that here we use not only the existence of the two long exact sequences in homology but we also use the functoriality of the long exact sequence.

[621] The verb "to excise" means to cut out, or in German "ausschneiden".

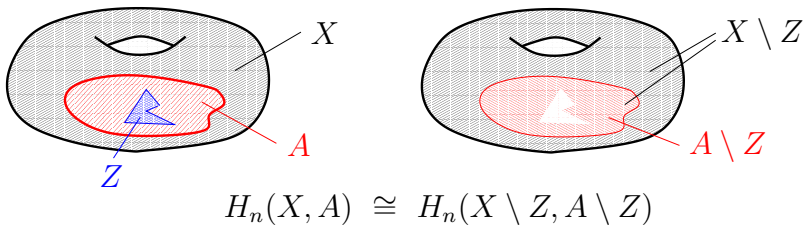

FIGURE 484. Illustration of the Excision Theorem 31.17.

Before we turn to the proof of the Excision Theorem 31.17 we first want to show that we can now relate the relative homology groups of a pair (X, A) to the homology groups of the quotient space X/A, assuming $A \subset X$ is non-empty and good. To do so we need the following definition.

Definition. Let X be a topological space and let $A \subset X$ be a non-empty[622] subset. We denote by $p\colon (X, A) \to (X/A, A/A)$ the obvious projection map. For each $n \in \mathbb{N}_0$ we refer to

$$\begin{tikzcd} H_n(X,A) \arrow[r, "p_*"] \arrow[rr, bend right] & H_n(X/A, A/A) & \widetilde{H}_n(X/A) \arrow[l, "\text{Lemma 31.12}"', "\cong"] \end{tikzcd}$$

as the *natural homomorphism* $H_n(X, A) \to \widetilde{H}_n(X/A)$.

Lemma 31.18. $(*)$ *We denote by $\mathcal{Q}'$ the category of non-trivial pairs*[623] *of topological spaces that we introduced on page 243. Furthermore denote by $\mathcal{A}$ the category of abelian groups. The above natural homomorphisms define a natural transformation from the functor*

$$\begin{array}{ccc} \mathcal{Q}' & \to & \mathcal{A} \\ (X,A) & \mapsto & H_n(X,A) \end{array} \quad \textit{to the functor} \quad \begin{array}{ccc} \mathcal{Q}' & \to & \mathcal{A} \\ (X,A) & \mapsto & \widetilde{H}_n(X/A). \end{array}$$

Proof. This lemma follows basically immediately from the definitions. □

The following proposition is much more interesting than the previous lemma.

Proposition 31.19. *Let X be a topological space and let $A \subset X$ be a subset and let $n \in \mathbb{N}_0$. If A is non-empty and good, then the natural homomorphism $H_n(X, A) \to \widetilde{H}_n(X/A)$ is an isomorphism.*

Example. Let X be a topological space, let $A \subset X$ be a non-empty subset and let $n \in \mathbb{N}_0$. For better or worse the natural homomorphism $H_n(X, A) \to \widetilde{H}_n(X/A)$ is in general not an isomorphism. In fact the situation is worse, in general the two groups $H_n(X, A)$ and $\widetilde{H}_n(X/A)$ are in general not even abstractly isomorphic.

[622] Readers who have too much time on their hands can start a discussion on whether the definition also makes sense if A is the empty set.

[623] A pair (X, A) of topological spaces is called non-trivial if $A \neq \varnothing$.

For example consider $X = [0,1]$ and $A = \{0\} \cup \{\frac{1}{n} \,|\, n \in \mathbb{N}\}$. In Exercise 26.6 we showed that the quotient space X/A is homeomorphic to the Hawaiian earrings. (See Figure 485 for an illustration.) In Exercise 31.11 we will prove the following two statements:

(1) The group $H_1(X, A)$ is countable.
(2) The group $H_1(X/A)$ is uncountable.

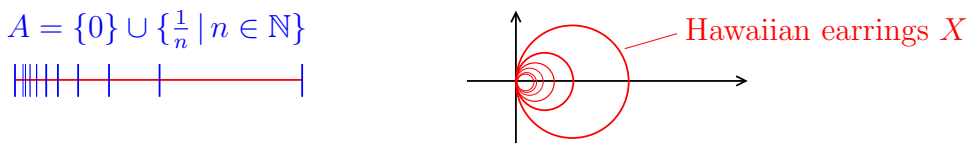

FIGURE 485.

Proof of Proposition 31.19 assuming the Excision Theorem 31.17. Let X be a topological space and let $A \subset X$ be a non-empty good subset. We make the following simple preparations:

(1) Since A is good we can pick an open neighborhood U of A in X such that A is a deformation retract of U.
(2) We denote by $p\colon X \to X/A$ the projection map.
(3) We denote by $q\colon X \setminus A \to X/A \setminus A/A$ the restriction of p to $X \setminus A$. For completeness' sake we point out that it follows from Lemma 1.30 that q is continuous.

Now we consider the following diagram

$$\begin{array}{ccccc} H_n(X,A) & \longrightarrow & H_n(X,U) & \longleftarrow & H_n(X \setminus A, U \setminus A) \\ \downarrow p_* & & \downarrow p_* & & \downarrow q_* \\ H_n(X/A, A/A) & \longrightarrow & H_n(X/A, U/A) & \longleftarrow & H_n(X/A \setminus A/A, U/A \setminus A/A), \end{array}$$

here all the horizontal maps are induced by inclusions of pairs of topological spaces. It follows easily from the definitions that the diagram commutes.

We start out with the following claim.

Claim. The map

$$q\colon (X \setminus A, U \setminus A) \;\to\; (X/A \setminus A/A, U/A \setminus A/A)$$

is a homeomorphism of pairs of topological spaces.

It is clear that $q\colon X \setminus A \to X/A \setminus A/A$ is a bijection with $q(U \setminus A) = U/A \setminus A/A$. By Lemma 1.39 it remains to show that $q\colon X \setminus A \to X/A \setminus A/A$ is continuous and open. As we pointed out above, q is continuous. Thus it remains to show that q is open. Now let $V \subset X \setminus A$ be a subset that is open with respect to the subspace topology. We need to show that $q(V) \subset X/A \setminus A/A$ is open. We break the argument into four steps:

(1) It follows from Lemma 1.35 (1) and the fact that A is by hypothesis closed[624], that V is also an open subset of X.
(2) Since $A \cap V = \varnothing$ we see that $p^{-1}(p(V)) = V$, which by (1) is an open subset of X.
(3) It follows from (2) and the definition of the quotient topology that $p(V)$ is an open subset of X/A.
(4) We have $q(V) = p(V) \cap (X/A \setminus A/A)$. It follows from (3) and the definition of the subspace topology that $q(V)$ is an open subset of $X/A \setminus A/A$.

This concludes the proof of the claim.

It follows from the claim that the vertical map on the right is an isomorphism. Our actual goal is to show that the vertical map on the left is an isomorphism. This follows from the commutativity of the above diagram and from the following claim:

Claim. All horizontal maps are isomorphisms.

We distinguish three different situations:

(1) It follows from the Excision Theorem 31.17 that both the top horizontal and the bottom horizontal map on the right-hand side are isomorphisms.
(2) Since A is deformation retract of U we obtain from Corollary 31.16 that the top left horizontal map is an isomorphism.
(3) Recall that A is a deformation retract of U. It follows from Corollary 9.15 that A/A is a deformation retract of U/A.[625] As in (2) we now see that the bottom-left horizontal map is an isomorphism.

Thus we have proved the claim. □

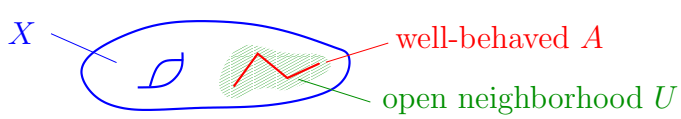

FIGURE 486. Illustration for the proof of Proposition 31.19.

Proof of Theorem 31.2 assuming the Excision Theorem 31.17. Let X be a topological space and let $A \subset X$ be a non-empty good subset. We denote by $i\colon A \to X$ the inclusion and we denote by $q\colon X \to X/A$ the projection map. We consider the following diagram:

$$\begin{tikzcd}
\dots \arrow[r] & \widetilde{H}_n(A) \arrow[r, "i_*"] & \widetilde{H}_n(X) \arrow[r, "p_*"] \arrow[dr, "q_*"'] & H_n(X,A) \arrow[r, "\partial"] \arrow[d] & \widetilde{H}_{n-1}(A) \arrow[r] & \widetilde{H}_{n-1}(X) \arrow[r, "i_*"] & \dots \\
& & & \widetilde{H}_n(X/A). & & &
\end{tikzcd}$$

[624]The property of being "closed" is the easily overlooked second condition for being good.

[625]The diligent reader who checks the statements we refer to will not fail to notice, that Corollary 9.15 rests eventually on the not-so-trivial Theorem 2.15. It is all too often overlooked (see see e.g. earlier version of these notes) that Corollary 9.15 is required and that it is non-trivial.

We make the following comments and observations:

(1) The horizontal sequence is the long exact coming from Corollary 31.14.
(2) The vertical map is the above natural homomorphism. It follows easily from the definition of the vertical map that the triangle commutes.
(3) Since A is good we obtain from Proposition 31.19 that the vertical map is an isomorphism.

We now define $\widetilde{H}_n(X) \to \widetilde{H}_n(X/A)$ in the obvious way. By the above discussion we obtain the desired long exact sequence. □

31.7. **The proof of the Excision Theorem 31.17: the idea.** We are still not done with the proof of Theorem 31.2 since we still have to prove the Excision Theorem 31.17. In this section we want to come up with the idea for the proof of the Excision Theorem 31.17. The full details of the proof will then be given in the following section.

Thus let X be a topological space and let $Z \subset A \subset X$ be two subsets such that the closure of Z is contained in the interior of A. Our goal is to show that the inclusion $(X \setminus Z, A \setminus Z) \to (X, A)$ induces for every $n \in \mathbb{N}_0$ an isomorphism

$$H_n(X \setminus Z, A \setminus Z) \ \to \ H_n(X, A).$$

Let us attempt to prove that the map $H_n(X \setminus Z, A \setminus Z) \to H_n(X, A)$ is surjective. We take an element in $H_n(X, A)$ and we choose a representative $a_1\sigma_1 + \cdots + a_r\sigma_r$ where $\sigma_i \colon \Delta^n \to X$, $i = 1, \dots, r$ are singular n-simplices in X.

We make the following two basic observations:

(1) If the singular n-simplices $\sigma_1, \dots, \sigma_r$ lie in $X \setminus Z$,[626] then $[a_1\sigma_1 + \cdots + a_r\sigma_r]$ evidently lies in the image of the inclusion induced map $H_n(X \setminus Z, A \setminus Z) \to H_n(X, A)$.
(2) If a singular n-simplex lies entirely in A, then it represents the zero element in the quotient group $C_n(X, A) = C_n(X)/C_n(A)$.

The combination of these two observations proves the following lemma.

Lemma 31.20. *Let X be a topological space and let $Z \subset A$ be two subsets of X. Let $c = a_1\sigma_1 + \cdots + a_r\sigma_r$ be a cycle in X such that each σ_i lies entirely in A or it lies entirely in $X \setminus Z$. Then $[c]$ lies in the image of $H_n(X \setminus Z, A \setminus Z) \to H_n(X, A)$.*

Unfortunately not every cycle in $C_n(X)$ satisfies the hypothesis of the lemma. But we will see in the next section that we can subdivide each singular simplex into smaller singular simplices that lie entirely in A or lie entirely in $X \setminus Z$.

31.8. **The proof of the Excision Theorem 31.17: the full details.** In this chapter we will now turn the vague idea of the last section into a rigorous proof of the Excision Theorem 31.17. This will take a surprisingly long time.

[626] Given a topological space X and a subset A we say that *a singular simplex $\sigma \colon \Delta^n \to X$ lies in A* if the image of σ lies in A.

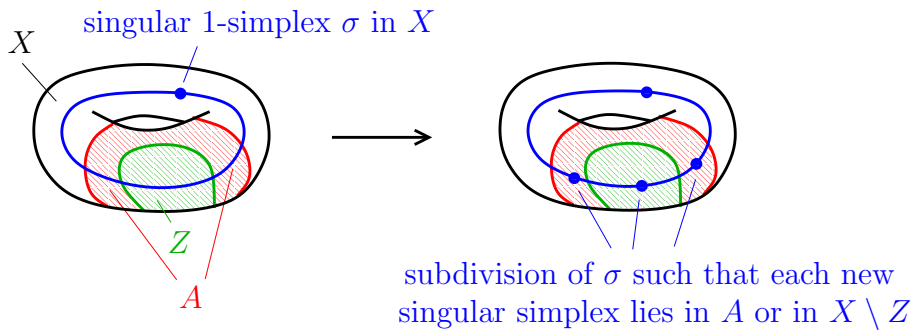

FIGURE 487. Illustration of the key idea of the proof of the Excision Theorem 31.17.

Thus let again X be a topological space. A *covering of* X is a family $\mathcal{U} = \{U_i\}_{i\in I}$ of subsets of X such that

$$X \;=\; \bigcup_{i\in I} \mathring{U}_i.$$

Given a covering $\mathcal{U} = \{U_i\}_{i\in I}$ we consider the following subgroup of $C_n(X)$:

$$C_n^{\mathcal{U}}(X) \;:=\; \Big\{ \sum_{j=1}^{k} a_j\sigma_j \,\Big|\, \text{for each } j \text{ there exists a } U_i \in \mathcal{U} \text{ such that the image of } \sigma_j \text{ lies in } U_i \Big\}.$$

It follows quite easily from the definitions that the restriction of usual the boundary map $\partial_n\colon C_n(X) \xrightarrow{\partial} C_{n-1}(X)$ to $C_n^{\mathcal{U}}(X)$ restricts to a map $\partial_n\colon C_n^{\mathcal{U}}(X) \xrightarrow{\partial} C_{n-1}^{\mathcal{U}}(X)$. Since this map is the restriction of the usual boundary map it follows in particular that the composition $\partial_n \circ \partial_{n+1}\colon C_{n+1}^{\mathcal{U}}(X) \xrightarrow{\partial} C_{n-1}^{\mathcal{U}}(X)$ is the zero map. We write

$$\begin{aligned} H_n^{\mathcal{U}}(X) \;&:=\; H_n\big(C_*^{\mathcal{U}}(X), \partial_*\big) \\ &=\; \ker\big\{\partial_n\colon C_n^{\mathcal{U}}(X) \to C_{n-1}^{\mathcal{U}}(X)\big\} \,/\, \operatorname{im}\big\{\partial_{n+1}\colon C_{n+1}^{\mathcal{U}}(X) \to C_n^{\mathcal{U}}(X)\big\}. \end{aligned}$$

The homology groups $H_n^{\mathcal{U}}(X)$ are thus defined by singular chains which are "small" in the sense that the image of each singular simplex lies in some U_i.

The following proposition says that we can determine the homology of a topological space through such "small" singular chains. As we will see later, this proposition is at the heart of many methods for computing homology groups.

Proposition 31.21. *Let X be a topological space and let $\mathcal{U} = \{U_i\}_{i\in I}$ be a covering of X. Then the inclusion map*

$$C_*^{\mathcal{U}}(X) \;\to\; C_*(X)$$

induces for every $n \in \mathbb{N}_0$ an isomorphism

$$H_n^{\mathcal{U}}(X) \;\xrightarrow{\cong}\; H_n(X).$$

Remark. In fact a stronger statement holds: the inclusion map $C_*^{\mathcal{U}}(X) \to C_*(X)$ is in fact a chain homotopy equivalence. In a later chapter we will show that this stronger statement follows in fact from Proposition 31.21 and a purely algebraic argument. Alternatively one

can fight one's way through the proof of Proposition 31.21 and upgrade the prove to this stronger statement. This approach is for example pursued in [Hat, Proposition 2.21]. The disadvantage is that it makes the proof even more complicated than it already is.

The idea of the proof of Proposition 31.21 is the one we already described in the previous section. We want to replace systematically each singular n-simplex $\sigma\colon \Delta^n \to X$ by a singular n-chain of the form $\sum_{j=1}^{r} a_j \cdot \sigma_j$ such that the image of each singular simplex σ_j lies in some $U_i \in \mathcal{U}$. As we have seen before in Lemma 29.3 in the 1-dimensional case, an appropriate subdividing procedure does not change the homology class. The systematic approach we are going to use is given by "barycentric subdivision". The key idea is sketched in Figure 488 for the case $n = 2$.

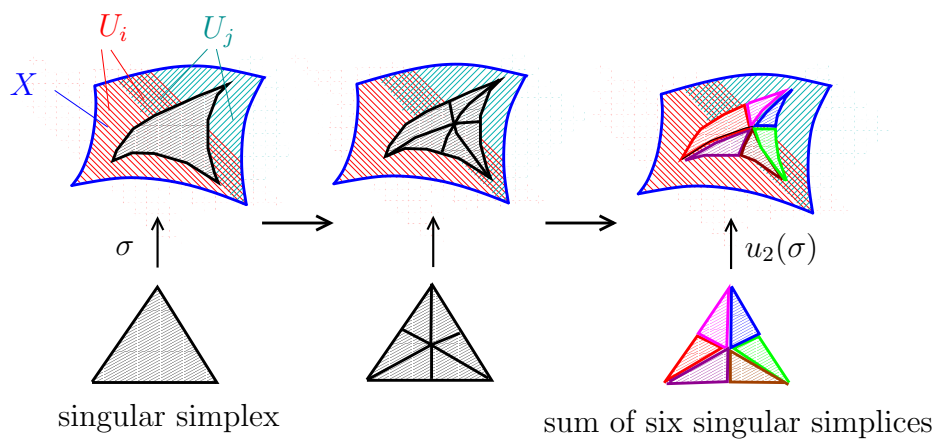

FIGURE 488. Barycentric decomposition of a singular 2-simplex.

Before we can execute this idea we have to introduce a few more definitions.

(1) Given $n \in \mathbb{N}_0$ we denote by $B_n := (\frac{1}{n+1}, \dots, \frac{1}{n+1}) \in \Delta^n$ the *barycenter*[627] of the standard n-simplex Δ^n.

(2) Given a singular l-simplex $\mu\colon \Delta^l \to \Delta^n$ we consider the singular $(l+1)$-simplex $c_{l+1}(\mu)$ which is defined as follows:[628]

$$\begin{aligned} c_{l+1}(\mu)\colon \Delta^{l+1} &\to \Delta^n \\ (t_0, \dots, t_{l+1}) &\mapsto \begin{cases} \mu\Big(\overbrace{\frac{1}{t_0+\dots+t_l} \cdot (t_0, \dots, t_l)}^{\in \Delta^l}\Big) \cdot (1 - t_{l+1}) + B_n \cdot t_{l+1}, & \text{if } t_{l+1} < 1, \\ B_n, & \text{if } t_{l+1} = 1. \end{cases} \end{aligned}$$

[627]The word "barycenter" comes from the Greek word "barys" which means heavy. In physics the barycenter of an object is the center of mass, in our case the barycenter of the standard n-simplex is the center of mass if we view Δ^k as a physical object of uniform density.

[628]It is straightforward to verify that the image of $c_{l+1}(\mu)$ lies in Δ^n and that $c_{l+1}(\mu)$ is indeed continuous.

Pictorially speaking the singular $(l+1)$-simplex $c_{l+1}(\mu)$ thus corresponds to the "cone" which is given by the singular l-simplex μ and the barycenter B_n. By Lemma 11.1 this map $\mu \to c_{l+1}(\mu)$ defines a linear map $C_l(\Delta^n) \to C_{l+1}(\Delta^n)$ that we also denote by c_{l+1} and which we call the $(l+1)$-*st cone map*.

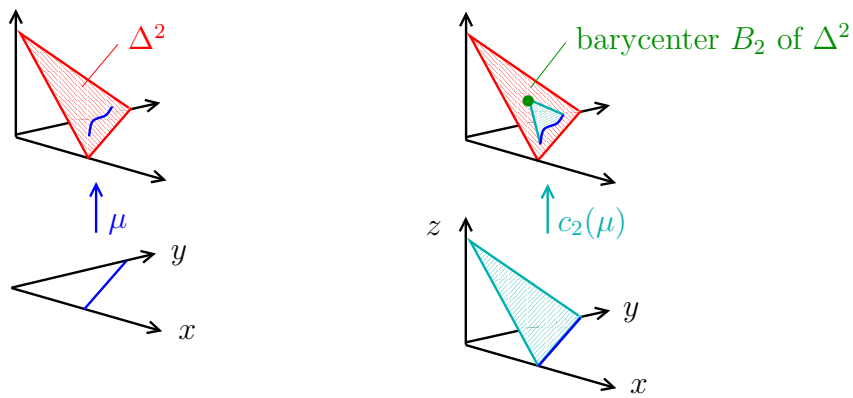

FIGURE 489. Illustration of the cone map.

(3) For $n = 0, 1, 2, 3, \ldots$ we now inductively do the following:
  (a) we define an element $\chi_n \in C_n(\Delta^n)$,
  (b) and furthermore for each topological space X we define a homomorphism $u_n \colon C_n(X) \to C_n(X)$.

We do this inductive procedure as follows:
  (i) We set $\chi_0 = \mathrm{id} \colon \Delta^0 \to \Delta^0$ and for each topological space X we define u_0 to be the identity on $C_0(X)$.
  (ii) Now suppose $\chi_{n-1} \in C_{n-1}(\Delta^{n-1})$ and that furthermore all the homomorphisms $u_{n-1} \colon C_{n-1}(X) \to C_{n-1}(X)$ are already defined. Then we define

$$\chi_n \;:=\; (-1)^n \cdot c_n(u_{n-1}(\underbrace{\partial\,\mathrm{id}_{\Delta^n}}_{\in C_{n-1}(\Delta^n)})) \;\in\; C_n(\Delta^n).$$

Furthermore, for each topological space X we define

$$\begin{array}{rcl} u_n \colon C_n(X) & \to & C_n(X) \\ \sum_{l=1}^{r} a_l \cdot (\sigma_l \colon \Delta^n \to X) & \mapsto & \underbrace{\sum_{l=1}^{r} a_l \cdot (\sigma_l)_*(\underbrace{\chi_n}_{\in C_n(\Delta^n)})}_{\in C_n(X)}. \end{array}$$

Note that with this notation we have $u_n(\mathrm{id}_{\Delta^n}) = \chi_n$. The map u_n is illustrated for $n = 1$ in Figure 490. For $n = 2$ we already gave a more schematic sketch in Figure 488 without considering signs and orientations.

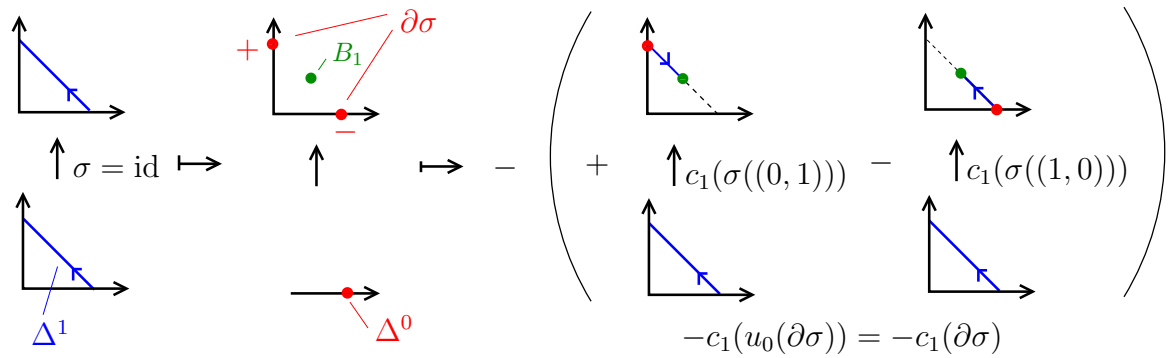

FIGURE 490. Illustration of the definition of first subdivision map.

The definition of χ_1 is illustrated in Figure 490.

Before we can continue we need to prove several technical lemmas about the subdivision maps.

Lemma 31.22. *For any map $f\colon X \to Y$ between topological spaces and any $n \in \mathbb{N}_0$ we have*

$$f_* \circ u_n \;=\; u_n \circ f_*\colon C_n(X) \;\to\; C_n(Y).$$

As we will see, Lemma 31.22 follows immediately from the definitions.

Proof. Let $\sigma\colon \Delta^n \to X$ be a singular n-simplex. Then

$$\begin{array}{ccccc} f_*(u_n(\sigma)) & = & f_*(\sigma_*(\chi_n)) & = & (f\circ\sigma)_*(\chi_n) & = & u_n(f_*(\sigma)). \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{by definition of } u_n(\sigma) & & \begin{array}{c}\text{since } (f\circ\sigma)_* = f_*\circ\sigma_* \\ \text{as maps } C_n(\Delta^n)\to C_n(Y)\end{array} & & \begin{array}{c}\text{by definition of } u_n(f_*(\sigma))\end{array} & \end{array}$$

Since the desired equality holds for all generators of $C_n(X)$ it also holds for all of $C_n(X)$. $\square$

Remark. For category-language aficionados Lemma 31.22 can be reformulated as follows. Given $n \in \mathbb{N}_0$ we consider the functor C_n from the category of topological spaces to the category of abelian groups which is given by

$$\text{topological space } X \;\mapsto\; C_n(X)$$

and

$$(f\colon X \to Y) \;\mapsto\; (f_*\colon C_n(X) \to C_n(Y)).$$

Given a topological space X we denote by $\Phi_X\colon C_n(X) \to C_n(X)$ the map that is given by the n-th subdivision map that we defined on page 789. It follows from Lemma 31.22 that these maps define a natural transformation from the functor C_n to itself.

Lemma 31.23. *Let X be a topological space. The maps $u_n\colon C_n(X) \to C_n(X)$, $n \in \mathbb{N}_0$, form a chain map from the chain complex $(C_*(X), \partial)$ to itself.*

The statement of Lemma 31.23 is equivalent to the statement that for any singular n-simplex σ in X we have

$$u_{n-1}(\partial\sigma) \;=\; \partial(u_n(\sigma)).$$

Put differently, Lemma 31.23 says that it does not make a difference whether we first take the boundary and then subdivide, or whether we first subdivide and then take the boundary. This statement is sketched in Figure 491. The picture is quite convincing.

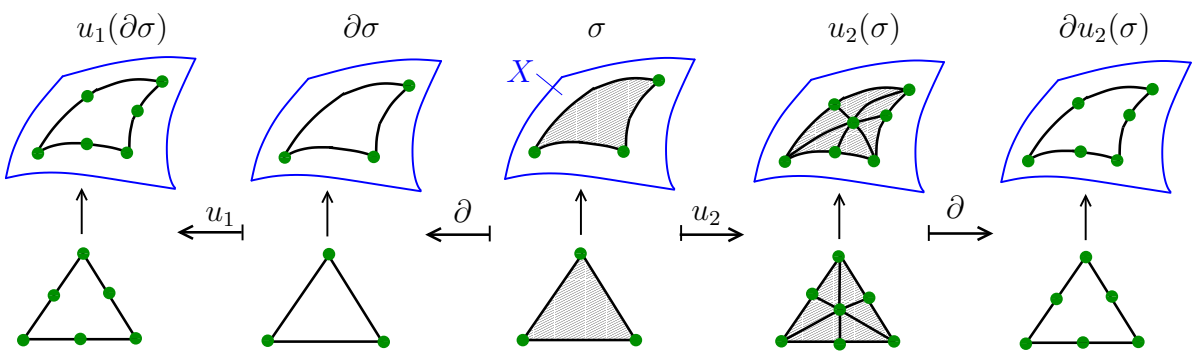

FIGURE 491. Illustration of Lemma 31.23.

Proof of Lemma 31.23 $(*)$. [629] We adopt the following notation and we make the following remarks:

(1) We denote the barycenter of Δ^n by b.
(2) As on page 736, given points $x_0, \ldots, x_k \in \Delta^n$ we denote by $[x_0, \ldots, x_k]$ the singular k-chain $\Delta^k \to \Delta^n$ that is given by[630]

$$\begin{array}{rcl} \Delta^k & \to & \Delta^n \\ (t_0, \ldots, t_k) & \mapsto & \sum\limits_{i=0}^{k} t_i x_i, \end{array}$$

we refer to such a singular k-simplex as a *linear* singular simplex.
(3) We denote by $C_k^{\mathrm{lin}}(\Delta^n)$ the subgroup of $C_k(\Delta^n)$ generated by all the linear singular k-simplices. Note that the boundary map $\partial\colon C_k(\Delta^n) \to C_{k-1}(\Delta^n)$ restricts to a boundary map $\partial\colon C_k^{\mathrm{lin}}(\Delta^n) \to C_{k-1}^{\mathrm{lin}}(\Delta^n)$.
(4) For $x_0, \ldots, x_k \in \Delta^n$ we write

$$[x_0, \ldots, \widehat{x_i}, \ldots, x_k] \;:=\; [x_0, \ldots, x_{i-1}, x_{i+1}, \ldots, x_k].$$

The proof of the lemma will be broken into three claims.

[629] We will not do this proof in the lectures. The proof is somewhat lengthy but straightforward. The cleverness hereby does not lie in the proof, but in the cleverly chosen definitions, which turn the verification into a simple calculation.

[630] It is straightforward to show that this map does indeed take values in Δ^n.

Claim. For any $\mu \in C_k^{\mathrm{lin}}(\Delta^n)$ we have

$$\partial(c_{k+1}(\mu)) \;=\; c_k(\partial\mu) + (-1)^{k+1}\cdot\mu \;\in\; C_k(\Delta^n).$$

We illustrate the claim in Figure 492. To prove the claim we first note that for any choice

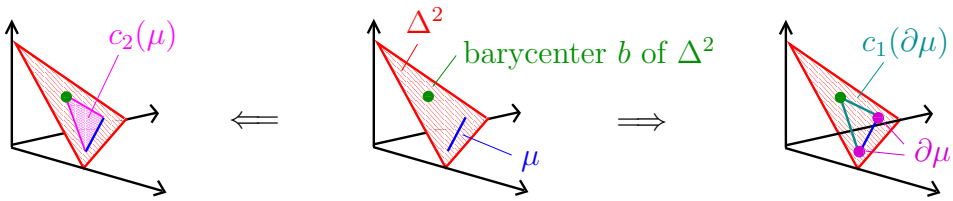

FIGURE 492.

of points $x_0,\dots,x_{l-1}\in\Delta^n$ we have by definition of c_l that

$$c_l([x_0,\dots,x_{l-1}]) \;=\; [x_0,\dots,x_{l-1},b].$$

It now follows that for any $w_0,\dots,w_k\in\Delta^n$ we have the following equality in $C_k(\Delta^n)$:

$$\begin{aligned}
\partial(c_{k+1}([w_0,\dots,w_k])) &\overset{\substack{\text{by the above equality}\\ \downarrow}}{=} \partial([w_0,\dots,w_k,b])\\
&\underset{\substack{\uparrow\\ \text{definition of }\partial\text{ and by the above equality}}}{=} \sum_{j=0}^{k}(-1)^j\cdot[w_0,\dots,\widehat{w_j},\dots,w_k,b] + (-1)^k\cdot[w_0,\dots,w_k]\\
&\overset{\downarrow}{=} c_k(\partial([w_0,\dots,w_k])) + (-1)^k\cdot[w_0,\dots,w_k].
\end{aligned}$$

The claim immediately follows from this equality.

Claim. For any $n\in\mathbb{N}_0$ and any $\nu\in C_n^{\mathrm{lin}}(\Delta^n)$ we have

$$\partial u_n(\nu) \;=\; u_{n-1}(\partial\nu).$$

We will prove this claim by induction on n. The case $n=0$ is trivial. So now suppose we have already shown the case $n-1$. It suffices to show the claim for all linear singular

n-simplices. So let $\nu\colon \Delta^n \to \Delta^n$ be a linear singular n-simplex. We then have

$$\begin{aligned}
\partial u_n(\nu) &\overset{\substack{\text{definition of } u_n \text{ and } \chi_n\text{, see page 789}\\ \downarrow}}{=} \partial(\nu_*(\chi_n)) \overset{\downarrow}{=} (-1)^n \cdot \partial(\nu_*(c_n(u_{n-1}(\partial\,\mathrm{id}_{\Delta^n})))) \overset{\substack{\text{since } \partial\circ\nu_* = \nu_*\circ\partial\\ \downarrow}}{=} (-1)^n \cdot \nu_*\big(\partial(c_n(\underbrace{u_{n-1}(\partial\,\mathrm{id}_{\Delta^n})}_{=:\mu}))\big)\\
&\underset{\substack{\uparrow\\ \text{we can apply the previous claim since } \mu := u_{n-1}(\partial\,\mathrm{id}_{\Delta^n}) \in C^{\mathrm{lin}}_{n-1}(\Delta^n)}}{=} (-1)^n \cdot \nu_*\big(c_{n-1}(\partial(u_{n-1}(\partial\,\mathrm{id}_{\Delta^n})) + (-1)^n \cdot u_{n-1}(\partial\,\mathrm{id}_{\Delta^n})\big)\\
&\underset{\substack{\uparrow\\ \text{by induction hypothesis we have } \partial u_{n-1}(\rho) = u_{n-2}(\partial\rho) \text{ for } \rho \in C^{\mathrm{lin}}_{n-1}(\Delta^n)\text{, applied here to } \rho = \partial\,\mathrm{id}_{\Delta^n}}}{=} (-1)^n \cdot \nu_*\big(c_{n-1}(u_{n-2}(\underbrace{\partial\partial\,\mathrm{id}_{\Delta^n}}_{=0}))\big) \;+\; \nu_*(u_{n-1}(\partial\,\mathrm{id}_{\Delta^n}))\\
&\underset{\substack{\uparrow\\ \text{Lemma 31.22 applied to } f=\nu}}{=} u_{n-1}(\nu_*(\partial\,\mathrm{id}_{\Delta^n})) \underset{\substack{\uparrow\\ \text{by definition}}}{=} u_{n-1}(\partial\nu).
\end{aligned}$$

This concludes the proof of the claim.

The following claim is just a reformulation of the statement of the lemma.

Claim. For any singular n-simplex σ in X we have $u_{n-1}(\partial\sigma) = \partial(u_n(\sigma))$.

So let $\sigma\colon \Delta^n \to X$ be a singular n-simplex in X. Then we have

$$\begin{aligned}
\partial(u_n(\sigma)) &= \partial(u_n(\sigma_*(\mathrm{id}_{\Delta^n}))) \overset{\substack{\text{Lemma 31.22 applied to } f=\sigma\\ \downarrow}}{=} \partial(\sigma_*(u_n(\mathrm{id}_{\Delta^n}))) \overset{\substack{\text{since } \sigma_* \text{ is a chain map}\\ \downarrow}}{=} \sigma_*(\partial(u_n(\mathrm{id}_{\Delta^n})))\\
&\underset{\substack{\uparrow\\ \text{by the previous claim}}}{=} \sigma_*(u_{n-1}(\partial\,\mathrm{id}_{\Delta^n})) \underset{\substack{\uparrow\\ \text{Lemma 31.22 applied to } f=\sigma}}{=} u_{n-1}(\sigma_*(\partial\,\mathrm{id}_{\Delta^n})) \underset{\substack{\uparrow\\ \text{since } \sigma_* \text{ is a chain map}}}{=} u_{n-1}(\partial\sigma_*(\mathrm{id}_{\Delta^n})) = u_{n-1}(\partial\sigma).
\end{aligned}$$

This concludes the proof of the claim. □

Lemma 31.24. *Let X be a topological space. The chain maps*

$$u_n\colon C_n(X) \;\to\; C_n(X)$$

are chain homotopic to the identity.

Proof. Showing that the chain maps $(u_n)_{n\in\mathbb{N}}$ are chain homotopic to the identity requires us to find maps $P_n\colon C_n(X) \to C_{n+1}(X), n \in \mathbb{N}_0$ such that for each $n \in \mathbb{N}_0$ the following equality holds:

$$\partial_{n+1} \circ P_n \;=\; -P_{n-1} \circ \partial_n + u_n - \mathrm{id}\,.$$

First we consider the case that X is a convex subset of some $\mathbb{R}^m$. Recall that we defined $C_{-1}(X) = 0$, accordingly we define $P_{-1}\colon C_{-1}(X) \to C_0(X)$ to be the zero map. Let us suppose that we have have already found maps $P_{-1}, \dots, P_{n-1}$ with the desired properties.

We want to define the next map $P_n\colon C_n(X) \to C_{n+1}(X)$. This map has to have the property that for each singular n-simplex σ we have

$$\partial_{n+1}(P_n(\sigma)) \;=\; -(P_{n-1}\circ\partial_n)(\sigma) \,+\, (u_n - \mathrm{id})(\sigma).$$

Put differently, to define $P_n(\sigma)$ we have to find a singular $(n+1)$-chain $E_\sigma \in C_{n+1}(X)$ with

$$\partial E_\sigma \;=\; -(P_{n-1}\circ\partial)(\sigma) + (u_n - \mathrm{id})(\sigma),$$

so that we can then define $P_n(\sigma) := E_\sigma$. Thus let $\sigma\colon \Delta^n \to X$ be a singular n-simplex.

(1) For $n = 0$ we have

$$\big(\underbrace{P_{-1}}_{=0}\circ\partial_0 + \underbrace{u_0}_{=\mathrm{id}} - \mathrm{id}\big)(\sigma) \;=\; 0 \in C_0(X),$$

and we put $E_\sigma := 0 \in C_1(X)$.

(2) Now suppose that $n > 0$. Since X is convex we know from the discussion on page 759 that $H_n(X) = 0$. Therefore to show that an element $c \in C_n(X)$ is the boundary of some element in $C_{n+1}(X)$ it suffices to show that $\partial c = 0$. In our specific situation we calculate

$$\begin{aligned}
\partial\big(\,(-P_{n-1}\partial_n + u_n - \mathrm{id})\,(\sigma)\big) \;&\overset{\substack{\text{by Lemma 31.23 the subdivision maps form a chain map, i.e. } \partial\circ u_n = u_{n-1}\circ\partial \\ \downarrow}}{=}\; -\partial P_{n-1}\partial\sigma + u_{n-1}\partial\sigma - \partial\sigma \\
&=\; \underbrace{(-\partial P_{n-1} + u_{n-1} - \mathrm{id})}_{=P_{n-2}\partial}(\partial\sigma) \;=\; P_{n-2}(\underbrace{\partial\partial\sigma}_{=0}) \;=\; 0.
\end{aligned}$$

As we had just remarked, this implies that there exists an $E_\sigma \in C_{n+1}(X)$ with $\partial(E_\sigma) = (P_{n-1}\partial_n - u_{n-1} - \mathrm{id})(\sigma)$.

Now we denote by $P_n\colon C_n(X) \to C_{n+1}(X)$ the map which assigns to each singular n-simplex σ the element $E_\sigma \in C_{n+1}(X)$. Then it follows from the definition of E_σ that

$$\partial_{n+1}\circ P_n + P_{n-1}\circ\partial_n \;=\; u_n - \mathrm{id}$$

as maps $C_n(X) \to C_n(X)$. This concludes the proof of Lemma 31.24 if X is a convex subset of some $\mathbb{R}^m$.

Now we deal with the general case. So let X be a topological space. We consider

$$\begin{aligned}
P_n\colon C_n(X) \;&\to\; C_{n+1}(X) \\
\sum_{l=1}^{r} a_l\cdot(\sigma_l\colon \Delta^n \to X) \;&\mapsto\; \sum_{l=1}^{r} a_l\cdot(\sigma_l)_*(\underbrace{P_n(\mathrm{id}_{\Delta^n})}_{\substack{\uparrow \\ \text{defined since } \Delta^n \text{ is convex}}}).
\end{aligned}$$

It is straightforward to see that this is a chain homotopy from the subdivision map to the identity map. □

Definition. Given a topological space X and $m \in \mathbb{N}_0$ we denote by u_n^m the m-fold composition of $u_n\colon C_n(X) \to C_n(X)$.

Lemma 31.25. *For each topological space X and every $m \in \mathbb{N}$ the maps $\{u_n^m\}_{n\geq 0}$ form a chain map $C_*(X) \to C_*(X)$ that is chain homotopic to the identity.*

Proof. In Lemma 31.23 we already saw that the maps $\{u_n\}_{n\geq 0}$ form a chain map $C_*(X) \to C_*(X)$. As we remarked on page 745, the composition of chain maps is again a chain map. Thus for any $m \in \mathbb{N}_0$ the maps $\{u_n^m\}_{n\geq 0}$ are also chain maps.

By Lemma 31.24 we have $u_* \simeq \mathrm{id}$. By Lemma 30.1 (2) this implies $u_*^2 \simeq u_*$, and by Lemma 30.1 (1) this implies $u_*^2 \simeq \mathrm{id}$. An induction argument now shows that $u_*^m \simeq \mathrm{id}$ for all m. □

Definition. Given a singular chain c we can write it uniquely as $c = a_1\sigma_1 + \cdots + a_s\sigma_s$ with $a_1, \ldots, a_s \in \mathbb{Z} \setminus \{0\}$ and where the σ_i are pairwise different. We then say $\sigma_1, \ldots, \sigma_s$ are the *pieces* of c.

If $\sigma\colon \Delta^n \to X$ is a singular n-simplex, then the pieces of $u_n(\sigma)$ are evidently "smaller" than the pieces of σ, and by iteratively applying u_n one can hope to make the resulting pieces "arbitrary small". In the following two lemmas we will make it precise what we mean by "arbitrary small". Before we formulate the first lemma we need to recall and introduce several definitions.

Definition.

(1) Given a bounded subset A of $\mathbb{R}^{n+1}$ the *diameter* is defined as
$$d(A) \;:=\; \sup\big\{\|a-b\| \,\big|\, a, b \in A\big\} \in \mathbb{R}_{\geq 0}.$$
(2) Given a singular simple $\sigma\colon \Delta^n \to X$ we denote by $|\sigma|$ the image of σ.

Now we can formulate the following lemma.

Lemma 31.26. *For any $x_0, \ldots, x_k \in \mathbb{R}^n$ and any piece τ of $u_k([x_0, \ldots, x_k])$ we have*[631]
$$d(|\tau|) \;\leq\; \tfrac{n}{n+1} \cdot d(|[x_0, \ldots, x_k]|).$$

FIGURE 493. Illustration of Lemma 31.26.

In the proof of Lemma 31.26 we will need the following elementary[632] geometric lemma.

[631] Recall the definition on page 736 of the map $[x_0, \ldots, x_k]\colon \Delta^k \to \mathbb{R}^n$.

[632] Here "elementary" means that the statement and the proof are basically high school level mathematics which does not mean that the proofs are entirely obvious.

Lemma 31.27. *Let $y_0, \dots, y_k \in \mathbb{R}^n$.*

(1) *We have the equality*

$$d(|[y_0, \dots, y_k]|) \;=\; \max\big\{\|y_i - y_j\| \;\big|\; i, j = 1, \dots, k\big\}.$$

(2) *We denote by $b = \frac{1}{k}\sum_{i=0}^{k} y_i$ the barycenter of $y_0, \dots, y_k$. Then for any $i = 0, \dots, k$ we have*

$$\|y_i - b\| \;\le\; d(|[y_0, \dots, y_k]|).$$

Proof of Lemma 31.27 $(*)$.

(1) The inequality "$\ge$" follows immediately from the definitions and the observation that each y_i lies in

$$|[y_0, \dots, y_k]| \;=\; \Big\{\sum_{i=0}^{k} t_i \cdot y_i \;\Big|\; t_i \in [0,1] \text{ and } \sum_{i=0}^{k} t_i = 1\Big\}.$$

We turn to the proof of the reverse inequality "$\le$". So we pick $a, b \in |[y_0, \dots, y_k]|$. By definition we can write $a = \sum_{i=0}^{k} s_i y_i$ and $b = \sum_{i=0}^{k} t_i y_i$ with $s_i, t_i \in [0,1]$ and $\sum_{i=0}^{k} s_i = \sum_{i=0}^{k} t_i = 1$. We then have

$$\begin{aligned}
\|a - b\| \;&\overset{\text{since } \sum_{i=0}^{k} t_i = 1}{\overset{\downarrow}{=}}\; \Big\|a - \sum_{i=0}^{k} t_i y_i\Big\| \;=\; \Big\|\sum_{i=0}^{k} t_i (a - t_i y_i)\Big\| \;\le\; \sum_{i=0}^{k} \|t_i (a - t_i y_i)\| \\
&\le\; \sum_{i=0}^{k} t_i \cdot \max_{i=0,\dots,k}\{\|a - y_i\|\} \;\underset{\text{since } \sum_{i=0}^{k} t_i = 1}{\overset{\uparrow}{=}}\; \max_{i=0,\dots,k}\{\|a - y_i\|\} \;\underset{\text{same argument applied to } a = \sum_{j=0}^{k} s_j y_j}{\overset{\uparrow}{\le}}\; \max_{i,j=0,\dots,k}\{\|y_j - y_i\|\}
\end{aligned}$$

(2) We denote by b_i the barycenter of $y_0, \dots, \widehat{y_i}, \dots, y_k$, i.e.

$$b_i \;=\; \tfrac{1}{k}\sum_{j \ne i} y_j.$$

We then have

$$b \;=\; \tfrac{1}{k+1} y_i + \tfrac{k}{k+1} b_i.$$

It follows that

$$\begin{aligned}
\|b - y_i\| \;=\; \Big\|\tfrac{1}{k+1} y_i + \tfrac{k}{k+1} b_i - y_i\Big\| \;&=\; \Big\|\tfrac{k}{k+1} b_i - \tfrac{k}{k+1} y_i\Big\| \\
&=\; \tfrac{k}{k+1}\|b_i - y_i\| \;\le\; \tfrac{k}{k+1} d(|[y_0, \dots, y_k]).
\end{aligned}$$

Thus we have obtained the desired inequality. □

Now we are ready to provide the proof of Lemma 31.26.

Proof of Lemma 31.26 (∗). We need to show that for any $x_0, \dots, x_k \in \mathbb{R}^n$ and any piece τ of $u_k([x_0, \dots, x_k])$ we have

$$d(|\tau|) \;\leq\; \tfrac{n}{n+1} \cdot d(|[x_0, \dots, x_k]|).$$

We prove the claim by induction on k. For $k = 0$ all the diameters are zero, so the inequality holds trivially. Now suppose that the claim holds for $k-1$. Let $x_0, \dots, x_k \in \Delta^n$ and denote by $b = \frac{1}{k}\sum_{i=0}^{k} x_i$ the barycenter of $x_0, \dots, x_k$. We denote by $\sigma_1, \dots, \sigma_r$ the pieces of $\partial[x_0, \dots, x_k]$.[633]

Now let τ be a piece of $u_k([x_0, \dots, x_k])$. By the definition of the subdivision map given on page 789 we see that $|\tau| = |[w_0, \dots, w_{k-1}, b]|$ where $[w_0, \dots, w_{k-1}]$ is a piece of $u_{k-1}(\sigma_s)$ for some $s \in \{1, \dots, r\}$. By Lemma 31.27 (1) it now suffices to prove the following claim.

Claim.

(1) For any $i, j = 0, \dots, k-1$ we have $\|w_i - w_j\| \leq \frac{k}{k+1} d(|[x_0, \dots, x_k]|)$.
(2) For any $i = 0, \dots, k-1$ we have $\|w_i - b\| \leq \frac{k}{k+1} d(|[x_0, \dots, x_k]|)$.

Now we provide a proof of these two inequalities. First let $i, j \in \{0, \dots, k-1\}$. Then

$$\|w_i - w_j\| \;\leq\; d([w_0, \dots, w_{k-1}]) \;\underset{\substack{\uparrow \\ \text{induction hypothesis} \\ \text{applied to } \sigma_s}}{\leq}\; \tfrac{k-1}{k} d(\sigma_s) \;\underset{\substack{\uparrow \\ \text{since } |\sigma_s| \subset |[x_0, \dots, x_k]| \text{ and } \frac{k-1}{k} \leq \frac{k}{k+1}}}{\leq}\; \tfrac{k}{k+1} d([x_0, \dots, x_k]).$$

Now let $i \in \{0, \dots, k-1\}$. We then have

$$\|w_i - b\| \;\underset{\substack{\uparrow \\ \text{Lemma 31.27 (2)}}}{\leq}\; \tfrac{k}{k+1} d(|[w_0, \dots, w_{k-1}]|) \;\underset{\substack{\uparrow \\ \text{since } |[w_0, \dots, w_{k-1}]| \subset |[x_0, \dots, x_k]|}}{\leq}\; \tfrac{k}{k+1} d(|[x_0, \dots, x_k]|)$$

This concludes the proof of the claim. □

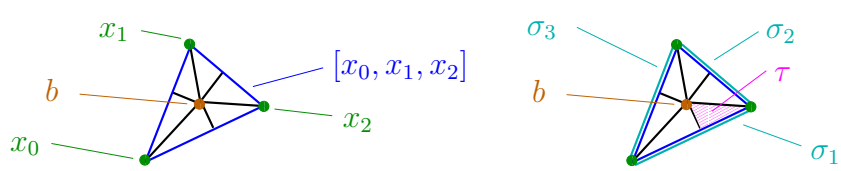

FIGURE 494. Illustration of the proof of Lemma 31.26.

Lemma 31.28. *Let X be a topological space and let $\mathcal{U} = \{U_i\}_{i \in I}$ be a covering of X. For every singular n-simplex $\sigma \colon \Delta^n \to X$ there exists an m such that $u_n^m(\sigma)$ lies in $C_n^{\mathcal{U}}(X)$.*

[633] Why does it not say that the number of pieces is $k+1$?

Proof. Let X be a topological space, let $\mathcal{U} = \{U_i\}_{i\in I}$ be a covering of X and let $\sigma\colon \Delta^n \to X$ be a singular n-simplex. By Lebesgue's Lemma 1.105 there exists a $\delta > 0$ such that for any subset A of Δ^n with diameter $d(A) < \delta$ there exists an $i \in I$ such that $A \subset \sigma^{-1}(\mathring{U}_i)$.

We pick an $m \in \mathbb{N}$ such that $\left(\frac{n}{n+1}\right)^m < \delta$. We have

$$\begin{aligned} u_n^m(\sigma) \;=\; u_n^m(\sigma_*(\mathrm{id}_{\Delta^n})) \;&\overset{\text{Lemma 31.22}}{=}\; \sigma_*(u_n^m(\mathrm{id}_{\Delta^n})) \;\overset{\text{by Lemma 31.26 and } \left(\frac{n}{n+1}\right)^m < \delta}{=}\; \sigma_*\begin{pmatrix}\text{simplicial chain such that the image}\\ \text{has diameter less than } \delta\end{pmatrix} \\ &\underset{\text{by definition of } \delta}{=}\; \sigma_*\begin{pmatrix}\text{simplicial chain such that the image}\\ \text{of each piece lies in some } \sigma^{-1}(\mathring{U}_i)\end{pmatrix}. \end{aligned}$$

But this means precisely that $u_n^m(\sigma) \in C_n^{\mathcal{U}}(X)$. □

Now we can prove Proposition 31.21.

Proof of Proposition 31.21. Let X be a topological space and let $\mathcal{U} = \{U_i\}_{i\in I}$ be a covering of X. We want to show that the inclusion map $\iota\colon C_*^{\mathcal{U}}(X) \to C_*(X)$ induces for each n an isomorphism

$$\iota_*\colon H_n^{\mathcal{U}}(X) \;\xrightarrow{\cong}\; H_n(X).$$

We first show that the map $\iota_*\colon H_n^{\mathcal{U}}(X) \xrightarrow{\cong} H_n(X)$ is surjective. Let $z \in H_n(X)$ be given. We choose a cycle $c = \sum_{j=1}^{r} a_j\sigma_j \in C_n(X)$ which represents $z \in H_n(X)$. It follows from Lemma 31.28, applied to the singular n-simplices $\sigma_1, \dots, \sigma_r$, that there exists an $m \in \mathbb{N}$ such that $u_n^m(c) \in C_n^{\mathcal{U}}(X)$. By Lemma 31.25 the maps $\{u_n^m\}_{n\in\mathbb{N}_0}$ form a chain map that is chain homotopic to the identity. By definition this means that there exists a chain homotopy $P_k\colon C_k(X) \to C_{k+1}(X)$, $k \in \mathbb{N}_0$. Thus we obtain that

$$z \;=\; [c] \;\underset{\text{since } \partial_{n+1}P_n + P_{n-1}\partial_n \;=\; u_n^m - \mathrm{id}}{=}\; \big[u_n^m(c) - P_{n-1}\overbrace{\partial_n(c)}^{=0} - \partial_{n+1}P_n(c)\big] \;=\; \big[u_n^m(c) - \partial_{n+1}P_n(c)\big] \;\underset{\text{equality in } H_n(X)}{=}\; \overbrace{[u_n^m(c)]}^{\in \iota_*(H_n^{\mathcal{U}}(X))}.$$

Thus we have shown that $\iota_*\colon H_n^{\mathcal{U}}(X) \xrightarrow{\cong} H_n(X)$ is surjective.

The argument that the map $\iota_*\colon H_n^{\mathcal{U}}(X) \xrightarrow{\cong} H_n(X)$ is injective is very similar. Indeed, let $[c] \in H_n^{\mathcal{U}}(X)$ be an element such that $[c] = 0 \in H_n(X)$. This means that there exists an $e \in C_{n+1}(X)$ with $\partial e = c$. From Lemma 31.28 it follows, as above, that there exists an $m \in \mathbb{N}$ with $u_{n+1}^m(e) \in C_{n+1}^{\mathcal{U}}(X)$. We again choose a chain homotopy $\{P_k\}_{k\in\mathbb{N}_0}$ between the chain maps $\{u_k^m\}_{k\in\mathbb{N}_0}$ and id. Then we have

$$c \;=\; \partial e \;\underset{\text{since } \partial P_{n+1} + P_n\partial = u_{n+1}^m - \mathrm{id}}{=}\; \partial\big(u_{n+1}^m(e) - \partial P_{n+1}(e) - P_n\partial e\big) \;=\; \partial\underbrace{u_{n+1}^m(e)}_{\in C_{n+1}^{\mathcal{U}}(X)} \;-\; \partial\underbrace{P_n(c)}_{\in C_{n+1}^{\mathcal{U}}(X)}.$$

Thus have we have shown that c is indeed the boundary of an $(n+1)$-dimensional singular chain, in $C^{\mathcal{U}}_{n+1}(X)$ i.e. $[c] = 0 \in H^{\mathcal{U}}_n(X)$. Put differently, we have now proved that $\iota_*\colon H^{\mathcal{U}}_n(X) \xrightarrow{\cong} H_n(X)$ is injective. $\square$

Using Proposition 31.21 we can now prove the Excision Theorem 31.17.

Proof of the Excision Theorem 31.17. Let X be a topological space and let $Z \subset A \subset X$ be subsets such that the closure of Z is contained in the interior of A. We have to show that the inclusion $(X \setminus Z, A \setminus Z) \to (X, A)$ induces for each $n \in \mathbb{N}_0$ an isomorphism

$$H_n(X \setminus Z, A \setminus Z) \ \xrightarrow{\cong}\ H_n(X, A).$$

We put $B := X \setminus Z$. Note that $A \cap B = A \setminus Z$. It follows from our hypothesis on Z and A that X is the union of the interiors of A and B, put differently, the two sets $\{A, B\}$ is a covering of X.

For each n we consider the following commutative diagram of abelian groups:[634]

$$\begin{tikzcd}
0 \arrow[r] & C_n(A) \arrow[r] \arrow[d, "="] & C_n^{\{A,B\}}(X) \arrow[r] \arrow[d, hook] & C_n^{\{A,B\}}(X)/C_n(A) \arrow[r] \arrow[d] & 0 \\
0 \arrow[r] & C_n(A) \arrow[r] & C_n(X) \arrow[r] & C_n(X, A) \arrow[r] & 0.
\end{tikzcd}$$

Note that by definition the horizontal sequences are in fact short exact sequences of chain complexes. We first make the observation that it follows immediately from the definition of $C_n^{\{A,B\}}(X)$ that the inclusion

$$C_n(B) \ \to\ C_n^{\{A,B\}}(X)$$

induces a chain map

$$C_n(B, A \cap B) \ \to\ C_n^{\{A,B\}}(X)/C_n(A)$$

that is in fact an isomorphism. Thus in the above diagram we can replace the chain complex $C_n^{\{A,B\}}(X)/C_n(A)$ by $C_n(B, A \cap B) = C_n(X \setminus Z, A \setminus Z)$.

Now we consider the long exact sequence of homology groups arising from the above short exact sequences of chain complexes. From the remark on page 772 we obtain the following commutative diagram

$$\begin{tikzcd}
\dots \arrow[r] & H_n(A) \arrow[r] \arrow[d, "="] & H_n^{\{A,B\}}(X) \arrow[r] \arrow[d] & \overbrace{H_n(B, A \cap B)}^{=H_n(X\setminus Z, A\setminus Z)} \arrow[r, "\partial"] \arrow[d] & H_{n-1}(A) \arrow[r] \arrow[d, "="] & H_{n-1}^{\{A,B\}}(X) \arrow[r] \arrow[d] & \dots \\
\dots \arrow[r] & H_n(A) \arrow[r] & H_n(X) \arrow[r] & H_n(X, A) \arrow[r, "\partial"] & H_{n-1}(A) \arrow[r] & H_{n-1}(X) \arrow[r] & \dots
\end{tikzcd}$$

[634]Here we use the definition from page 787 which in this context says that

$$C_n^{\{A,B\}}(X) \ :=\ \{\sigma + \tau \,|\, \sigma \in C_n(A) \text{ and } \tau \in C_n(B)\}.$$

From Proposition 31.21 it follows that the second and fifth vertical map are isomorphisms. Since the first and fourth map are evidently isomorphisms it now follows from the Five Lemma 31.11 that the middle map is also an isomorphism. □

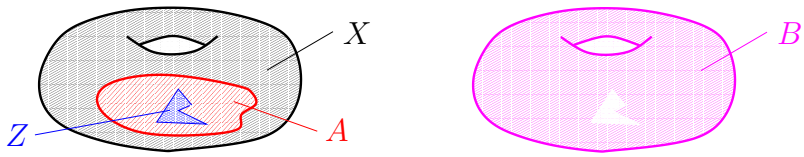

FIGURE 495. Illustration for the proof of the Excision Theorem 31.17.

Exercises for Chapter 31.

Exercise 31.1. Let

$$\mathbb{Z} \xrightarrow{f} B \xrightarrow{g} \mathbb{Z} \oplus \mathbb{Z}_6 \to 0$$

be an exact sequence, i.e. we know that $g \circ f = 0$, we know that $\operatorname{im}(f) = \ker(g)$ and we know that g is an epimorphism. What are the possible isomorphism types of the group B?

Exercise 31.2. Let X be a topological space with $\widetilde{H}_0(X) \cong \mathbb{Z}$.

(a) Show that given any $\epsilon \in \{-1, 0, 1\}$ there exists a map $f\colon X \to X$ such that the induced map f_* on $\widetilde{H}_0(X)$ is given by multiplication by ϵ.

(b) Show that given any map $f\colon X \to X$ the induced map f_* on $\widetilde{H}_0(X)$ is given by multiplication by some $\epsilon \in \{-1, 0, 1\}$.

Exercise 31.3. Determine the homology groups of $S^2 \vee S^1$.

Exercise 31.4.

(a) Let

$$\begin{array}{ccccccccc} A & \xrightarrow{i} & B & \xrightarrow{j} & C & \xrightarrow{k} & D & \xrightarrow{l} & E \\ \downarrow a & & \downarrow b & & \downarrow c & & \downarrow d & & \downarrow e \\ A' & \xrightarrow{i'} & B' & \xrightarrow{j'} & C' & \xrightarrow{k'} & D' & \xrightarrow{l'} & E' \end{array}$$

be a commutative diagram such that the horizontal sequences are exact. Show that if a is surjective, if b and d are isomorphisms, and if e is injective, then c is an isomorphism.

(b) Does the statement in (a) also hold, if a injective and if e is surjective ?

Exercise 31.5. Let

$$\begin{array}{ccccccccc} 0 & \longrightarrow & A_* & \xrightarrow{\varphi} & B_* & \xrightarrow{\psi} & C_* & \longrightarrow & 0 \\ & & \downarrow a & & \downarrow b & & \downarrow c & & \\ 0 & \longrightarrow & A'_* & \xrightarrow{\varphi'} & B'_* & \xrightarrow{\psi'} & C'_* & \longrightarrow & 0 \end{array}$$

be a commutative diagram of homomorphisms between abelian groups. Show that there exists an exact sequence

$$\begin{tikzcd}
0 \arrow[r] & \ker(a) \arrow[r, "\varphi"] & \ker(b) \arrow[r, "\psi"] & \ker(c) \arrow[dll, rounded corners] \\
& \operatorname{coker}(a) \arrow[r, "\varphi'"] & \operatorname{coker}(b) \arrow[r, "\psi'"] & \operatorname{coker}(c) \arrow[r] & 0.
\end{tikzcd}$$

This statement is sometimes referred to as the "Snake Lemma".
Hint: Try to prove the statement with as little effort as possible.

Exercise 31.6. For readers who really really enjoy diagram chases we have the following problem on offer. Suppose we are given the following commutative diagram of

$$\begin{tikzcd}
& 0 \arrow[d] & 0 \arrow[d] & 0 \arrow[d] & \\
0 \arrow[r] & A_* \arrow[r] \arrow[d] & B_* \arrow[r, "h_B"] \arrow[d, "v_B"] & C_* \arrow[r] \arrow[d] & 0 \\
0 \arrow[r] & D_* \arrow[r, "h_D"] \arrow[d, "v_D"] & E_* \arrow[r] \arrow[d] & F_* \arrow[r] \arrow[d] & 0 \\
0 \arrow[r] & G_* \arrow[r] \arrow[d] & H_* \arrow[r] \arrow[d] & J_* \arrow[r] \arrow[d] & 0 \\
& 0 & 0 & 0 &
\end{tikzcd}$$

where the vertical and horizontal sequences are exact. We suppose that the chain complex H_* is acyclic, i.e. we suppose that homology groups of H_* vanish. Show that for any $k \in \mathbb{N}_0$ the following diagram commutes up to a minus sign:

$$\begin{tikzcd}
H_k(D_*) \arrow[r, "v_{D*}"] \arrow[d] & H_k(G_*) & H_{k+1}(K_*) \arrow[l, "\partial", "\cong"'] \arrow[d, "\partial"', "\cong"] \\
H_k(E) \arrow[r, "v_{B*}^{-1}", "\cong"'] & H_k(B) \arrow[r, "h_{B*}"] & H_k(C).
\end{tikzcd}$$

Exercise 31.7. Let X be a topological space, let $x_0 \in X$ be a point and let $n \in \mathbb{N}_0$. Show that the map

$$\begin{tikzcd}
\widetilde{H}_n(X) \arrow[r] \arrow[rrr, bend right, "=:\Phi_{X,x_0}"'] & H_n(X) \arrow[r, "="] & H_n(X, \varnothing) \arrow[r] & H_n(X, \{x_0\})
\end{tikzcd}$$

is an isomorphism.

Exercise 31.8. We say that a map $f\colon \mathbb{R}^n \to \mathbb{R}^n$ has *bounded displacement* if there exists a $C \in \mathbb{R}$ such that for any $x \in \mathbb{R}^n$ we have $\|x - f(x)\| \leq C$. Show that any map $f\colon \mathbb{R}^n \to \mathbb{R}^n$ of bounded displacement is onto.
Hint: use the Brouwer Fixed Point Theorem.

Exercise 31.9. Let (X, A) be a pair of topological spaces. Suppose there exists a deformation retraction $r\colon X \times [0,1] \to X$ from X to some subset $Y = r_1(X)$. We write $B = r_1(A)$. Show that the inclusion induced maps $H_k(Y, B) \to H_k(X, A)$ are isomorphisms.

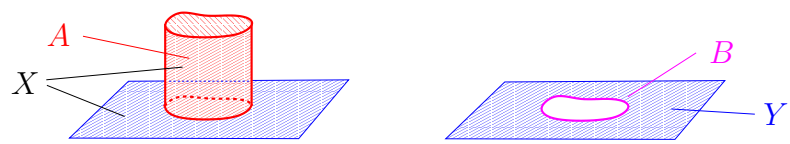

FIGURE 496. Illustration of Exercise 31.9.

Exercise 31.10. Let $X_0 \subset X_1 \subset X_2 \subset \cdots \subset X_m$ be a nested sequence of topological spaces.

(a) Suppose that for each $k = 0, \dots, m-1$ we have $H_n(X_{k+1}, X_k) = 0$ for all $n \in \mathbb{N}_0$. Show that $H_n(X_m, X_0) = 0$ for all $n \in \mathbb{N}_0$.
(b) Let $n \in \mathbb{N}_0$. Suppose that for each $k = 0, \dots, m-1$ we have $H_n(X_{k+1}, X_k) = 0$. Does it also follow that $H_n(X_m, X_0) = 0$?

Exercise 31.11. We consider $X = [0,1]$ and $A = \{0\} \cup \{\frac{1}{n} \mid n \in \mathbb{N}\}$. Prove the following two statements:

(a) The group $H_1(X, A)$ is countable.
(b) The group $H_1(X/A)$ is uncountable. For psychological reasons it might be convenient to recall that in Exercise 26.6 we showed that the quotient space X/A is homeomorphic to the Hawaiian earrings.

Exercise 31.12. Let X be a non-empty bounded subset of $\mathbb{R}^n$. We pick an $r \in \mathbb{R}_{>0}$ such that X is contained in the bounded n-ball $\overline{B}^n_r$ of radius r. We consider the map

$$\begin{array}{rcl} f\colon S^{n-1} & \to & \mathbb{R}^n \setminus X \\ x & \mapsto & 2r \cdot x. \end{array}$$

Show that the induced map $f_*\colon H_{n-1}(S^{n-1}) \to H_{n-1}(\mathbb{R}^n \setminus X)$ is a monomorphism.

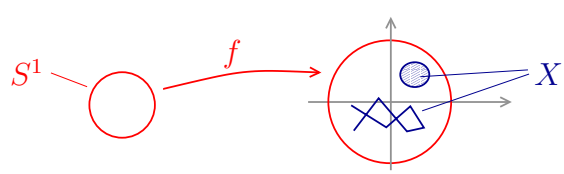

FIGURE 497. Illustration of Exercise 31.12.

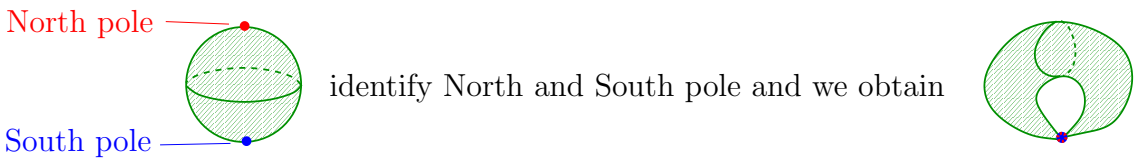
Exercise 31.13. Show that for $k \geq 1$ the wedge $S^k \vee S^k$ is not a manifold.

Exercise 31.14. Compute the homology groups of the quotient of S^2 obtained by identifying the North and South Pole to a point. We refer to Figure 498 for an illustration.



North pole
South pole
identify North and South pole and we obtain

Figure 498.

32. Applications of the long exact sequence in homology

32.1. **Applications to topological manifolds** (∗)**.** In this section we will apply some of the results that we have obtained in the previous chapter to the study of topological manifolds. For the most part these results will generate a sense of déjà vu. In fact we had proved many of these results for manifolds using different methods. The generalization of these results to topological manifolds is non-trivial, but most readers will have a hard time building up enthusiasm for these results. Thus it might be best to have a quick glimpse at the results and then move on to the next section.

First of all we can now generalize Proposition 14.11 from the case of 2-dimensional topological manifolds to the higher-dimensional case.

Proposition 32.1. *Let X be an n-dimensional topological manifold. The following statements hold:*

(1) *Every point on X admits either a chart of type (i) or it admits a chart of type (ii).*
(2) *The boundary $Y := \partial X$ is an $(n-1)$-dimensional topological manifold with $\partial Y = \varnothing$.*
(3) *If X is a closed topological manifold, then ∂X is also a closed $(n-1)$-dimensional topological manifold.*
(4) *If Z is a proper submanifold of X, then $\partial Z = X \cap Y$.*
(5) *Any open subset Y of X is an n-dimensional topological manifold with $\partial Y = Y \cap \partial X$.*
(6) *Let M be an m-topological manifold with empty boundary and let N be an n-dimensional topological manifold with possibly non-empty boundary. Then $M \times N$ is an $(m+n)$-dimensional topological manifold with $\partial(M \times N) = M \times \partial N$.*

This proposition can be viewed as the analogue of Proposition 3.21 for topological manifolds.

Example. It follows from Proposition 32.1 and the examples of charts for $\overline{B}^n$ given on page 173 that the boundary of the n-dimensional topological manifold is indeed S^{n-1}. We had suspected this for a long time, but only do we have the tools for providing a proof.

Remark.

(1) Given a topological manifold X we had on page 171 defined its boundary as the set of all points that do not admit a chart of type (i). If X is equipped with a smooth structure, i.e. if we view X as a manifold, then on page 182 we defined the boundary of the manifold X as the set of all points that do not admit a chart of type (i) *from the given smooth atlas*. A priori we thus had two different definitions of the boundary. Fortunately Proposition 32.1 (1) tells us that these two definitions coincide.
(2) Let M and N be two n-dimensional topological manifolds with empty boundary. If $M \times [0,1]$ is homeomorphic to $N \times [0,1]$, then it follows from Proposition 32.1 (6) that M and N are homeomorphic. Even though this sounds quite reasonable, very similar sounding statements can easily be wrong. For example there exists a 3-dimensional topological manifold W (called the *Whitehead manifold*) which is

non-compact and has no boundary, which is not homeomorphic to $\mathbb{R}^3$ but such that $W \times \mathbb{R}$ is homeomorphic to $\mathbb{R}^3 \times \mathbb{R} = \mathbb{R}^4$. We refer to [Kir4, p. 87] and [AR] for details.

Proof. For $n = 2$ we proved (1) and (2) in Proposition 14.11. In the general case the proof of (1) and (2) is formally exactly the same as the proof of Proposition 14.11 where we proved the statement for $n = 2$. We just need to replace the fundamental group by the $(n-1)$-st reduced homology groups and we need to replace the properties of the fundamental group we used in the proof of Proposition 14.11 by the corresponding properties of the reduced homology groups. In particular we need to replace the fact that $\pi_1(S^1) \neq 0$ by the corresponding statement, given in Proposition 31.3, that $\widetilde{H}_{n-1}(S^{n-1}) = \mathbb{Z}$ and we need to replace the fact that the fundamental group of a star-shaped subset of $\mathbb{R}^2$ has trivial fundamental group by the fact, obtained in Corollary 30.8, that the $(n-1)$-st reduced homology group of a star-shaped subset of $\mathbb{R}^n$ vanishes. We leave the details to the reader.

We turn to the proofs of the remaining statements:

(3) We assume that X is closed, i.e. it is compact and it has no boundary. By (2) we know that ∂X also has no boundary. Furthermore, by Lemma 3.6 (2) we know that ∂X is compact. Thus ∂X is also a closed topological manifold.
(4) Statement (4) is proved in a fashion similar to (1). We leave the details as an exercise to the reader.
(5) This statement follows easily from (1).
(6) In Proposition 3.4 we already showed that $M \times N$ is an $(m+n)$-dimensional topological manifold. As in the proof of Proposition 3.42 this statement follows easily from (1). □

Let X be a topological manifold and let Y be a submanifold. It follows almost immediately from the definitions that Y is topological manifold in its own right. In particular it makes sense to consider its boundary ∂Y and in particular it makes sense to introduce the following definition.

Definition. Let X be a topological manifold and let Y be a submanifold. We write

$$\partial_0 Y \;:=\; \underset{\substack{\uparrow \\ \text{here } \partial Y \text{ denotes the boundary of } Y \text{ viewed as a topological manifold}}}{\partial Y} \cap \overline{X \setminus Y} \quad \text{and } \partial_1 Y \;:=\; Y \cap \partial X.$$

The definition is illustrated in Figure 499.

The next proposition gives us some results on the boundary of submanifolds. It can be viewed as an analogue of Proposition 3.24.

Proposition 32.2. *Let X be an m-dimensional topological manifold and let Y be an n-dimensional submanifold.*

(1) *$\partial_0 Y$ and $\partial_1 Y$ are disjoint and each of them is a union of components of ∂Y.*
(2) *If Y is a proper submanifold, then $\partial Y = \partial_1 Y = Y \cap \partial X$.*

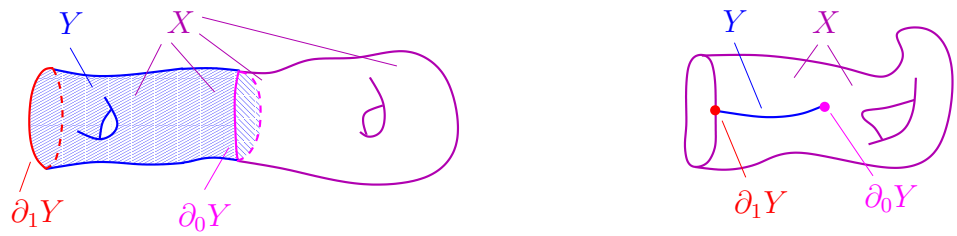


FIGURE 499.

(3) *If Y is of codimension zero, then the interior $\mathring{Y}$ of Y as a subset of X agrees with $Y \setminus \partial_0 Y$. In particular $Y \setminus \partial_0 Y$ is an open subset of X.*
(4) *If Y is of codimension zero and if Y is compact, then the set $Z := X \setminus \mathring{Y}$ is also an n-dimensional submanifold of X and we have $Y \cap Z = \partial_0 Y = \partial_0 Z$.*

Proof. All four statements can be deduced from Proposition 32.1 and the methods of the proof thereof. We leave the details of the proof as an exercise to the reader. □

Lemma 32.3. *Let M be a k-dimensional topological manifold. Then for any $P \in M$ and any $l \in \mathbb{N}_0$ we have*

$$H_l(M, M \setminus \{P\}) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } P \in M \setminus \partial M \text{ and } l = k, \\ 0, & \text{otherwise.} \end{cases}$$

Proof. Let P be a point on a k-dimensional topological manifold M. First consider the case that $P \in M \setminus \partial M$. It follows from the definition of ∂M, given on page 171, that we can pick a chart $\Phi\colon U \to B^k$ for P with $\Phi(P) = 0$. We then have

$$\begin{array}{ccccccc}
 & & \text{isomorphism since } \Phi \text{ is a homeomorphism} & & & & \\
 & & \downarrow & & & & \\
H_l(M, M \setminus \{P\}) & \leftarrow & H_l(U, U \setminus \{P\}) & \xrightarrow{\Phi_*} & H_l(B^k, B^k \setminus \{0\}) & \xrightarrow{\partial} & \widetilde{H}_{l-1}(B^k \setminus \{0\}) \leftarrow \widetilde{H}_{l-1}(S^{k-1}). \\
 & \uparrow & & & \uparrow & & \uparrow \\
 & \begin{array}{c}\text{isomorphism by the} \\ \text{Excision Theorem 31.17 applied} \\ \text{to } X = M, A = M \setminus \{P\}, Z = M \setminus U\end{array} & & & \begin{array}{c}\text{isomorphism by the long exact} \\ \text{sequence in reduced homology} \\ \text{of the pair } (B^k, B^k \setminus \{0\}) \text{ and the} \\ \text{fact that } \widetilde{H}_*(B^k) = 0 \text{ by page 762}\end{array} & & \begin{array}{c}\text{isomorphism since} \\ S^{k-1} \text{ is homotopy} \\ \text{equivalent to } B^k \setminus \{0\}\end{array}
\end{array}$$

For $P \in M \setminus \partial M$ the statement now follows from the calculation of the reduced homology groups of spheres given in Proposition 31.3.

The case that $P \in \partial M$ is dealt with in a very similar way. The proof of this case is dealt with in Exercise 32.3. □

Examples. Our goal now is to give explicit generators for the relative homology groups $H_k(M, M \setminus \{x\}) \cong \mathbb{Z}$. We first do so for open subsets of $\mathbb{R}^k$ and then we "transport" those generators to topological manifolds using charts.

(1) Let $U \subset \mathbb{R}^k$ be an open subset that contains 0. Let $\sigma\colon \Delta^k \to U$ be an injective affine linear map. We suppose that 0 lies in the image of the interior $\overset{\circ}{\Delta}{}^k := \Delta^k \setminus \partial\Delta^k$ of Δ^k. We claim that σ represents a generator of $H_k(U, U \setminus \{0\})$. To prove this claim we consider the commutative diagram

$$\begin{tikzcd}
H_k(\Delta, \partial\Delta^k) \arrow[rr, "\sigma_*"] \arrow[d, "\sigma_*"] & & H_k(U, U \setminus \{0\}) \arrow[d, "\cong"] \\
