H_k(\sigma(\Delta^k), \sigma(\partial\Delta^k)) \arrow[r] & H_k(\mathbb{R}^k, \sigma(\partial\Delta^k)) \arrow[r] & H_k(\mathbb{R}^k, \mathbb{R}^k \setminus \{0\})
\end{tikzcd}$$

where the maps that are not induced by σ are induced by the obvious inclusions. The left vertical map is an isomorphism since $\sigma\colon \Delta^k \to \sigma(\Delta^k)$ is a homeomorphism. The horizontal maps are isomorphisms by Corollary 31.16 since $\sigma(\Delta^k)$ is a deformation retract of $\mathbb{R}^k$ and since $\sigma(\partial\Delta^k)$ is deformation retract of $\mathbb{R}^k \setminus \{0\}$. By Lemma 32.9 we know that id_{Δ^n} represents a generator of $H_n(\Delta^n, \partial\Delta^n)$. It follows from the above that $\sigma \circ \mathrm{id}_{\Delta^n} = \sigma$ represents a generator of $H_k(\mathbb{R}^k, \mathbb{R}^k \setminus \{0\})$. But the right vertical map is an isomorphism by the Excision Theorem 31.17, hence σ also represents a generator of $H_k(U, U \setminus \{0\})$.

(2) Let M be a k-dimensional topological manifold and let $P \in M \setminus \partial M$. In the following we want to give an example of an explicit singular k-simplex that represents a generator for $H_k(M, M \setminus \{P\}) \cong \mathbb{Z}$. We pick a chart $\Phi\colon U \to B^k$ around P with $\Phi(P) = 0$ and we pick an affine linear map $\sigma\colon \Delta^k \to B^k$ as in (1). It follows from (1) and the proof of Lemma 32.3 together that $\Phi^{-1} \circ \sigma\colon \Delta^k \to M$ represents a generator of $H_k(M, M \setminus \{P\})$. We refer to Figure 500 for an illustration.

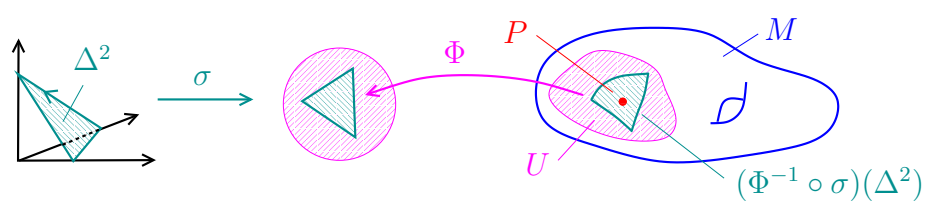

FIGURE 500.

We will prove the following corollary in Exercise 32.2.[635]

Corollary 32.4. *If M is a non-empty topological manifold, then $M \neq \partial M$, i.e. there exists a point in $M \setminus \partial M$.*

The following proposition is the generalization of Proposition 3.18 from manifolds to topological manifolds.

[635]One might think that the statement of the corollary is obvious, but it does not follow from the definition of a topological manifold. One really does need to use Lemma 32.3.

Proposition 32.5. *Let M be an m-dimensional non-empty topological manifold and let N be an n-dimensional topological manifold. If M is homeomorphic to an open subset of N (e.g. if M is homeomorphic to N), then $m = n$.*

It follows in particular from Proposition 32.5 that the dimension of a non-empty topological manifold is well-defined.

Proof. By Proposition 32.1 (5) it suffices to consider the case that we are given a homeomorphism $f\colon M \to N$ between a non-empty m-dimensional topological manifold M and a topological manifold N. By Corollary 32.4 we can find a point $P \in M \setminus \partial M$. Then

$$\begin{array}{ccccc} \mathbb{Z} & \cong & H_m(M, M \setminus \{P\}) & \xrightarrow{\cong} & H_m(N, N \setminus \{f(P)\}). \\ & \uparrow & & \uparrow & \\ & \text{Lemma 32.3} & & \text{since } f \text{ is a homeomorphism} & \end{array}$$

It now follows from Lemma 32.3 that N is also m-dimensional. □

We conclude this section with the following variation of the Excision Theorem 31.17.

Theorem 32.6. *Let X be a topological space and let $Z \subset A \subset X$ be two subsets. We suppose that there exists a subset $U \subset Z$ such that the closure of U is contained in the interior of A and such that following statements hold:*

(1) *$X \setminus Z$ is a deformation retract of $X \setminus U$*
(2) *$A \setminus Z$ is a deformation retract of $A \setminus U$.*

Then the inclusion $(X \setminus Z, A \setminus Z) \to (X, A)$ induces for each $n \in \mathbb{N}_0$ an isomorphism

$$H_n(X \setminus Z, A \setminus Z) \xrightarrow{\cong} H_n(X, A).$$

The hypotheses of Theorem 32.6 might sound complicated, but as we will see, in practice these conditions are often satisfied.

Example. Let $n \in \mathbb{N}$. We denote by $\overline{B}^{\pm}_n$ the upper and lower hemisphere of S^n and we view S^{n-1} as a subset of S^n in the obvious way. It follows from Theorem 32.6 and the choices of X, A, Z and U illustrated in Figure 501 that the inclusion induced map

$$H_n(\overline{B}^n_+, S^{n-1}) \to H_n(S^n, \overline{B}^n_-)$$

is an isomorphism.

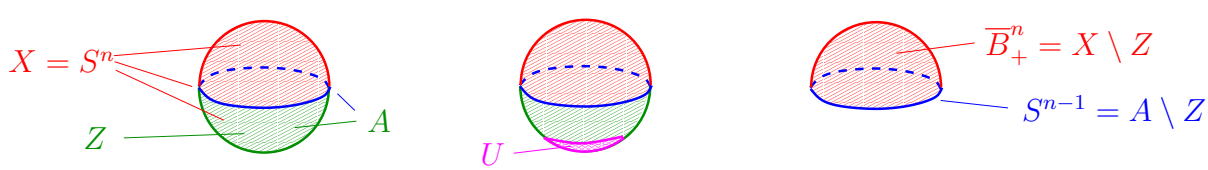

FIGURE 501. excision-lower-hemisphere

We can easily generalize the above example. More precisely, Theorem 32.6 also allows us to prove the following variation of the Excision Theorem 31.17. It says, under mild technical hypothesis, that in the relative homology of an m-dimensional manifold we can excise the interior of an m-dimensional submanifold.

Theorem 32.7. (Excision Theorem for Manifolds) *Let X be an m-dimensional manifold and let A be a subset of X. Furthermore let B be a compact m-dimensional submanifold of X that is contained in A. We write*[636] $\mathring{B} := B \setminus \partial_0 B$. *If $\mathring{B} \subset A$, then for every $n \in \mathbb{N}_0$ the inclusion induced map*

$$H_n\big(X \setminus \mathring{B}, A \setminus \mathring{B}\big) \xrightarrow{\cong} H_n(X, A)$$

is an isomorphism.

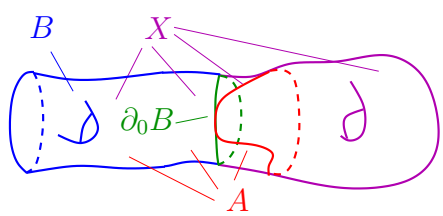

FIGURE 502. Illustration of Theorem 32.7.

Proof of Theorem 32.7 using Theorem 32.6. By Proposition 32.2 we know that $\partial_0 B$ is a union of boundary components of B. Thus we can apply the Collar Neighborhood Theorem 10.10 to $\partial_0 B$. We obtain an embedding $\varphi\colon \partial_0 B \times [-1,0] \to B$ that is the identity map on $\partial_0 B \times \{0\} = \partial_0 B$. To simplify the notation we identify $\partial_0 B \times [-1,0]$ with its image in B. We set $Z = \mathring{B} = B \setminus \partial_0 B \times \{0\}$ and we set $U = B \setminus (\partial_0 B \times (-1,0])$.

Claim. There exists a deformation retract from $X \setminus U$ to $X \setminus Z$.

First note that we can write $X \setminus U = (X \setminus Z) \cup (\partial_0 B \times [-1,0])$. Furthermore note that $(X \setminus Z) \cap (\partial_0 B \times [-1,0]) = \partial_0 B \times \{0\}$. The idea is to use Lemma 12.10 to conclude that the obvious deformation retraction from $\partial_0 B \times [-1,0]$ to $\partial_0 B \times \{0\}$ gives rise to the desired deformation retraction.

Unfortunately we have to go to the laborious task of verifying the hypothesis of Lemma 12.10, i.e. we need to argue that $X \setminus Z$ and $\partial_0 B \times [-1,0]$ are closed subsets of $X \setminus U$. To do so we note that the hypothesis that B is compact implies by Proposition 3.21 that $\partial_0 B$ is compact and thus that $(\partial_0 B \times [-1,0]$ is compact. It follows from Lemma 1.18 that $\partial_0 B \times [-1,0]$ is a closed subset of $X \setminus U$. Furthermore, since $Z = \mathring{B}$ we see that $X \setminus Z$ is a closed subset of X. It follows from Lemma 1.6 that $X \setminus Z$ is also a closed subset of $X \setminus U$. Thus we have now verified that the hypothesis of Lemma 1.6 hold. This concludes the proof of the claim.

[636]The amnesic reader is reminded of the fact that we defined $\partial_0 B$ on page 805.

Claim. There exists a deformation retract from $A \setminus U$ to $A \setminus Z$.

Since $\mathring{B} \subset A$ we have $A \setminus U = (A \setminus Z) \cup (\partial_0 B \times [-1,0])$. Furthermore note that $(A \setminus Z) \cap (\partial_0 B \times [-1,0]) = \partial_0 B \times \{0\}$. Thus basically the same argument as in the proof of the previous claim shows that such a deformation retraction exists. This concludes the proof of the claim.

The statement of Theorem 32.7 now follows immediately from Theorem 32.6. □

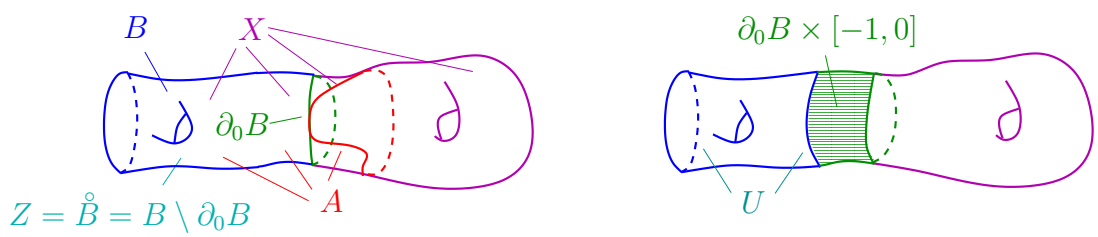

FIGURE 503. Illustration of the proof of Theorem 32.7.

Proof of Theorem 32.6. We consider the following commutative diagram of inclusion induced maps

$$\begin{tikzcd} H_n(X \setminus Z, A \setminus Z) \arrow[r] \arrow[d] & H_n(X, A) \\ H_n(X \setminus U, A \setminus U). \arrow[ur, "\cong"'] & \end{tikzcd}$$

The diagonal map is an isomorphism by the Excision Theorem 31.17. Thus it suffices to show that the vertical map is an isomorphism.

We consider the following commutative diagram:

$$\begin{tikzcd} H_n(A \setminus Z) \arrow[r] \arrow[d, "="] & H_n(X \setminus Z) \arrow[r] \arrow[d] & H_n(X \setminus Z, A \setminus Z) \arrow[r] \arrow[d] & H_{n-1}(A \setminus Z) \arrow[r] \arrow[d, "="] & H_{n-1}(X \setminus Z) \arrow[d] \\ H_n(A \setminus Z) \arrow[r] \arrow[d] & H_n(X \setminus U) \arrow[r] \arrow[d, "="] & H_n(X \setminus U, A \setminus Z) \arrow[r] \arrow[d] & H_{n-1}(A \setminus Z) \arrow[r] \arrow[d] & H_{n-1}(X \setminus U) \arrow[d, "="] \\ H_n(A \setminus U) \arrow[r] & H_n(X \setminus U) \arrow[r] & H_n(X \setminus U, A \setminus U) \arrow[r] & H_{n-1}(A \setminus U) \arrow[r] & H_{n-1}(X \setminus U). \end{tikzcd}$$

Here the horizontal maps are pieces of the long exact sequences of the various pairs of topological spaces provided by Corollary 31.14. Furthermore the vertical maps are induced by the various inclusion maps. On the upper level the first and the fourth vertical maps are the identity. Furthermore it follows from the hypothesis that $X \setminus Z$ is a deformation retract of $X \setminus U$ and from Corollary 31.16 that the second and the fifth vertical map are also isomorphisms. It follows from the Five Lemma 31.11 that the upper middle vertical map is also an isomorphism.

Using the hypothesis that $A \setminus Z$ is a deformation retract of $A \setminus U$ one can show exactly the same way that the lower middle vertical map is also an isomorphism. Combining the two middle vertical maps we obtain the desired isomorphism. □

32.2. **Explicit generators of homology groups.** By Proposition 31.3 we know that for any $n \in \mathbb{N}_0$ we have

$$\widetilde{H}_k(S^n) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k = n, \text{ and} \\ 0, & \text{if } k \neq n. \end{cases}$$

Thus we have determined the homology groups of all finite-dimensional spheres. In this section, given $n \in \mathbb{N}_0$, we want to determine an explicit singular n-chain which is a generator of $\widetilde{H}_n(S^n)$.

We start out with the following elementary lemma that we will use explicitly and implicitly on many occasions.

Lemma 32.8. *Let $n \in \mathbb{N}_0$. We have*

$$\widetilde{H}_k(\overline{B}^n, S^{n-1}) \;\cong\; \begin{cases} \mathbb{Z}, & \textit{if } k = n, \\ 0, & \textit{otherwise.} \end{cases}$$

Proof. We consider the long exact sequence in reduced homology of the pair $(\overline{B}^n, S^{n-1})$:

$$\ldots \;\to\; \underbrace{\widetilde{H}_k(\overline{B}^n)}_{= 0,\ \text{see page } 762} \;\to\; H_k(\overline{B}^n, S^{n-1}) \;\xrightarrow{\partial}\; \widetilde{H}_{k-1}(S^{n-1}) \;\to\; \underbrace{\widetilde{H}_{k-1}(\overline{B}^n)}_{= 0,\ \text{see page } 762} \;\to\; \ldots$$

The statement of the lemma is now an immediate consequence of Proposition 31.3. □

We continue with the following lemma.

Lemma 32.9. *For any $n \in \mathbb{N}_0$ the following two statements hold:*

(1) $H_n(\Delta^n, \partial\Delta^n) \cong \mathbb{Z}$.
(2) *The identity map* $\mathrm{id}\colon \Delta^n \to \Delta^n$ *represents a generator of* $H_n(\Delta^n, \partial\Delta^n) \cong \mathbb{Z}$.

Proof. The first statement is an immediate consequence of Lemmas 32.8 and 29.1. Now we turn to the proof of the second statement. We prove the second statement by induction on n. It follows easily from Proposition 29.5 that the statement holds for $n = 0$. Now we suppose that the desired statement holds for $n - 1$ with $n \in \mathbb{N}$.

Our next goal is to find a connection between the two homology groups $H_n(\Delta^n, \partial\Delta^n)$ and $H_{n-1}(\Delta^{n-1}, \partial\Delta^{n-1})$. We introduce the following notation:

(1) We consider

$$\Lambda \;:=\; \bigcup_{i=0}^{n-1} \{(t_0, \ldots, t_n) \in \Delta^n \mid t_i = 0\},$$

i.e. Λ is the union of all $(n-1)$-dimensional faces of Δ^n except for the face given by $t_n = 0$. It is elementary[637] to show that Λ is a deformation retract of Δ^n. We refer to Figure 504 for an illustration.

(2) We write

$$\mathring{\Lambda} := \bigcup_{i=0}^{n-1} \{(t_0, \dots, t_n) \in \Lambda \,|\, t_i = 0 \text{ and } t_n > 0\},$$

the set $\mathring{\Lambda}$ is thus the "interior"[638] of Λ.

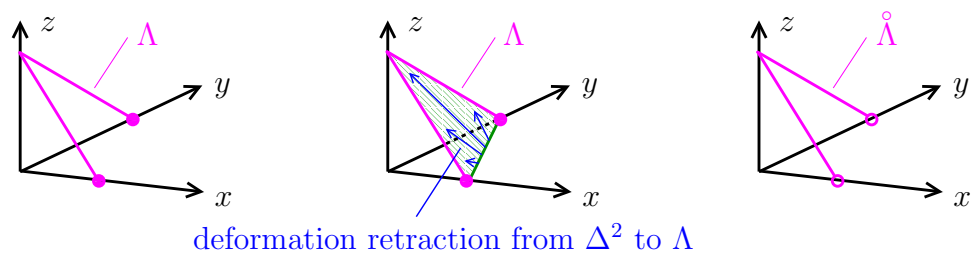

FIGURE 504.

In the following we view $\mathbb{R}^n$ as the subset of $\mathbb{R}^{n+1}$ given by setting the last coordinate equal to zero. This point of view allows us to view Δ^{n-1} as a subset of Δ^n. Note that with this convention we have $\partial\Delta^{n-1} \subset \Lambda$.

Claim. We consider the maps

$$H_n(\Delta^n, \partial\Delta^n) \xrightarrow{\partial} H_{n-1}(\partial\Delta^n, \Lambda) \xleftarrow{i_*} H_{n-1}(\Delta^{n-1}, \partial\Delta^{n-1}).$$

Here the map on the left is the connecting homomorphism in the long exact sequence of the triple $(\Delta^n, \partial\Delta^n, \Lambda)$ and the right-hand map is induced by the inclusion. Then the following holds:

(1) Both maps are isomorphisms.
(2) $\partial([\mathrm{id}_{\Delta^n}]) = (-1)^n \cdot i_*([\mathrm{id}_{\Delta^{n-1}}])$.

It is clear that a proof of the claim together with the induction hypothesis implies that $[\mathrm{id}_{\Delta^n}]$ is a generator of $H_n(\Delta^n, \partial\Delta^n)$. In particular a proof of the claim implies Lemma 32.9.

Now we turn to the proof of the claim. Of the two maps in the claim we first consider the map ∂ on the left. It follows from the exact sequence of the triple $(\Delta^n, \partial\Delta^n, \Lambda)$ that

[637]When we say that it is "elementary to show something" this usually means that one can show the statement using basic methods without the need to use advanced results. In this case one can write down a deformation retraction "by hand", but it is not entirely easy to do so. We leave it as an exercise to write down such a deformation retraction.

[638]Why is "interior" put in quotes?

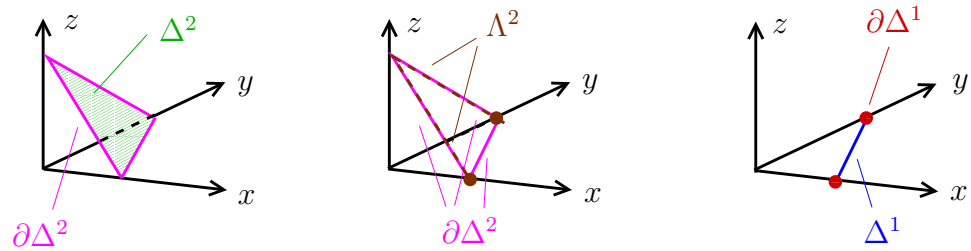

FIGURE 505. Illustration of the pairs $(\Delta^n, \partial\Delta^n)$, $(\partial\Delta^n, \Lambda)$ and $(\Delta^{n-1}, \partial\Delta^{n-1})$.

the following sequence is exact:

$$\underbrace{H_n(\Delta^n, \Lambda)}_{\substack{= 0 \text{ by Corollary 31.16 since} \\ \Lambda \text{ is a def. retract of } \Delta^n}} \xrightarrow{p} H_n(\Delta^n, \partial\Delta^n) \xrightarrow{\partial} H_{n-1}(\partial\Delta^n, \Lambda) \xrightarrow{i_*} \underbrace{H_{n-1}(\Delta^n, \Lambda)}_{\substack{= 0 \text{ by Corollary 31.16 since} \\ \Lambda \text{ is a def. retract of } \Delta^n}}.$$

This shows that $H_n(\Delta^n, \partial\Delta^n) \xrightarrow{\partial} H_{n-1}(\partial\Delta^n, \Lambda)$ is an isomorphism. Furthermore we have

$$\partial([\mathrm{id}_{\Delta^n}]) \underset{\substack{\uparrow \\ \text{Proposition 31.13}}}{=} [\partial\, \mathrm{id}_{\Delta^n}] = \Big[\underbrace{\sum_{j=0}^{n-1} (-1)^j\, \mathrm{id} \circ i_j^n}_{\text{lies in } C_{n-1}(\Lambda)} + (-1)^n \cdot \underbrace{\mathrm{id} \circ i_n^n}_{=\mathrm{id}_{\Delta^{n-1}}}\Big] \underset{\substack{\uparrow \\ \text{since we work in } H_{n-1}(\partial\Delta^n, \Lambda)}}{=} (-1)^n \cdot [\mathrm{id}_{\Delta^{n-1}}].$$

Now we turn our attention to the right-hand map in the statement of the claim. It follows from Theorem 32.6, applied to $X = \partial\Delta^n$, $A = \Lambda$, $Z = \mathring{\Lambda}$ and $U = (0, \ldots, 0, 1)$[639] that the inclusion induced map

$$H_{n-1}(\Delta^{n-1}, \partial\Delta^{n-1}) = H_{n-1}(\underbrace{\partial\Delta^n \setminus \mathring{\Lambda}}_{=\Delta^{n-1}}, \underbrace{\Lambda \setminus \mathring{\Lambda}}_{=\partial\Delta^{n-1}}) \xrightarrow{i_*} H_{n-1}(\partial\Delta^n, \Lambda)$$

is an isomorphism. Furthermore we evidently have $i_*([\mathrm{id}_{\Delta^{n-1}}]) = [\mathrm{id}_{\Delta^{n-1}}]$.

Thus we have proved that both maps in the claim are isomorphisms and that

$$\partial([\mathrm{id}_{\Delta^n}]) = (-1)^{\cdot}[\mathrm{id}_{\Delta^{n-1}}] = (-1)^n \cdot i_*([\mathrm{id}_{\Delta^{n-1}}]).$$

This concludes the proof of the claim and thus also of the lemma. □

Now we want to find explicit generators of $H_n(S^n) \cong \mathbb{Z}$ for $n \geq 1$. We consider the map $\alpha\colon \Delta^n \to S^n$ that is given by the concatenation of the following two maps

$$\begin{array}{rcl} \Delta^n \xrightarrow{\text{Lemma 29.1}} \overline{B}^n & \to & S^n \subset \mathbb{R}^{n+1} = \mathbb{R}^n \times \mathbb{R} \\ x & \mapsto & \big(x, \sqrt{1 - \|x\|^2}\big). \end{array}$$

This map restricts to a homeomorphism $\Delta^n \to S^n_{\geq 0} = \{(x_1, \ldots, x_{n+1}) \in S^n \,|\, x_{n+1} \geq 0\}$ and it sends $\partial\Delta^n$ to $S^{n-1} = \{(x_1, \ldots, x_{n+1}) \in S^n \,|\, x_{n+1} = 0\}$. The definition of α is also sketched in Figure 506.

[639] One can easily show that U has the property required in Theorem 32.6.

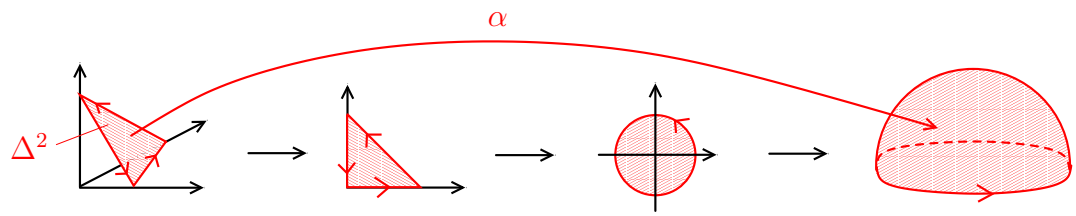

FIGURE 506.

Now we denote by $\beta\colon \Delta^n \to S^n$ the map which is the composition of α with reflection in the hyperplane defined by $x_{n+1} = 0$. The maps $\alpha\colon \Delta^n \to S^n$ and $\beta\colon \Delta^n \to S^n$ both define singular n-chains in S^n. Note that α and β agree on $\partial\Delta^n$. Both maps are sketched in Figure 507.

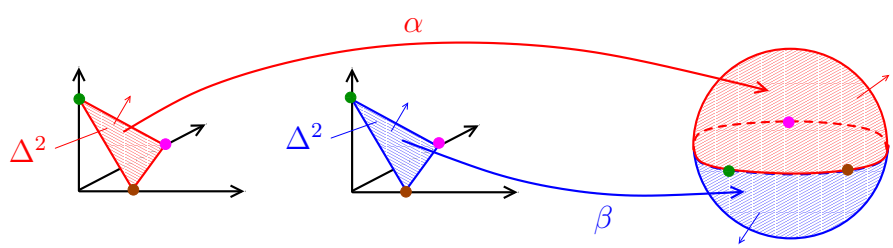

FIGURE 507.

Lemma 32.10. *Let $n \geq 1$. The above singular n-chain $\alpha - \beta$ is a cycle and it represents a generator of $\widetilde{H}_n(S^n) = H_n(S^n)$.*

Definition.

(1) We refer to the generator from Lemma 32.10 as the *standard generator of $H_n(S^n)$*.[640] With great foresight we denote it by $[S^n]$.
(2) Slightly more generally, if I is an interval and x is a point in I, then the inclusion $S^n \times \{x\} \to S^n \times I$ is a homotopy equivalence which implies by Corollary 30.8 that $H_n(S^n \times \{x\}) \to H_n(S^n \times I)$ is an isomorphism. We refer to the image of the standard generator of $H_n(S^n \times \{x\}) = H_n(S^n)$ as the *standard generator* of $H_n(S^n \times I)$.[641]

Proof. We start out with the following claim.

Claim. The singular n-chain $\alpha - \beta$ is a cycle.

[640]It follows easily from Lemma 29.3 and the definitions that the two definitions of standard generator of $H_1(S^1)$ agree.

[641]It follows from Corollary 30.8 that the definition of the standard generator of $H_n(S^n \times I)$ does not depend on the choice of x.

We denote by ρ the reflection in the hyperplane defined by $x_{n+1} = 0$. We have

$$\begin{array}{ccccccc} & & & & \text{since } \alpha(\partial\Delta^n) \subset \mathbb{R}^n \times 0 \text{ we have } \partial\alpha \in C_{n-1}(\mathbb{R}^n \times 0) & & \\ & & & & \downarrow & & \\ \partial(\alpha - \beta) & = & \partial(\alpha - \rho_*(\alpha)) & = & (\mathrm{id} - \rho_*)(\partial\alpha) & = & 0. \\ & & & \uparrow & & \uparrow & \\ & & & \text{since } \rho_* \text{ is a chain map} & & \text{since } \rho = \mathrm{id} \text{ on } \mathbb{R}^n \times 0 \subset \mathbb{R}^{n+1} & \end{array}$$

This concludes the proof of the claim.

We denote by

$$S^n_{\geq 0} \quad := \quad \{(x_1, \ldots, x_{n+1}) \in S^n \,|\, x_{n+1} \geq 0\}$$

and

$$S^n_{\leq 0} \quad := \quad \{(x_1, \ldots, x_{n+1}) \in S^n \,|\, x_{n+1} \leq 0\}$$

the two "hemispheres". By the discussioin on page 73 both hemispheres are homeomorphic to the closed ball $\overline{B}^n$, in particular they are contractible which implies by the discussion on page 762 that their reduced homology groups vanish. We also consider the "equator"

$$S^n_{=0} \quad := \quad \{(x_1, \ldots, x_{n+1}) \in S^n \,|\, x_{n+1} = 0\}.$$

Next we consider the following sequence of maps

$$\begin{array}{ccccccc} \text{isomorphism by the long exact} & & \text{isomorphism by the} & & & & \\ \text{sequence in reduced homology} & & \text{Excision Theorem} & & \text{isomorphism since} & & \\ \text{of the pair } (S^n, S^n_{\leq 0}) & & \text{for Manifolds 32.7} & & \alpha \text{ is a homeomorphism} & & \\ \downarrow & & \downarrow & & \downarrow & & \\ \widetilde{H}_n(S^n) & \to & H_n(S^n, S^n_{\leq 0}) & \xleftarrow{i_*} & H_n(S^n_{\geq 0}, S^n_{=0}) & \xleftarrow{\alpha_*} & H_n(\Delta^n, \partial\Delta^n) \\ [\alpha - \beta] & \mapsto & [\alpha - \beta] = [\alpha] & \leftarrow\!\shortmid & [\alpha] & \leftarrow\!\shortmid & [\mathrm{id}_{\Delta^n}]. \\ & & \uparrow & & & & \\ & & \text{since } \beta = 0 \text{ in } C_n(S^n, S^n_{\leq 0}) & & & & \end{array}$$

So we have seen that all maps are isomorphisms. Furthermore, by Lemma 32.9 we know that $[\mathrm{id}_{\Delta^n}]$ is a generator of $H_n(\Delta^n, \partial\Delta^n)$. But $[\mathrm{id}_{\Delta^n}]$ and $[\alpha - \beta]$ get sent to the same element in $H_n(S^n, S^n_{\leq 0})$, therefore $[\alpha - \beta]$ must also be generator of $\widetilde{H}_n(S^n)$. $\square$

In the following lemma we give an alternative description of the standard generator of $H_1(S^1)$.

Lemma 32.11. *The singular 1-simplex*

$$\begin{array}{rcl} \sigma\colon \Delta^1 & \to & S^1 \\ (1-t, t) & \mapsto & e^{2\pi i t} \end{array}$$

is a cycle that represents the standard generator $[S^1]$ *of* $H_1(S^1) \cong \mathbb{Z}$.

FIGURE 508. Two representatives of the standard generator of $H_1(S^1)$.

Proof. We denote by $\alpha, \beta\colon \Delta^1 \to S^1$ the singular 1-simplices in the definition of the standard generator of $H_1(S^1)$. We have

$$\begin{array}{ccccccc} [\alpha - \beta] & = & [\alpha + \overline{\beta}] & = & [\sigma] & \in & H_1(S^1). \\ & \uparrow & & \uparrow & & & \\ & \text{by Lemma 29.3 (2) and (3)} & & & & & \end{array}$$

We refer to Figure 508 for an illustration. □

Remark. By Lemma 32.11 we know that there exists a singular 1-simplex σ that represents a generator of $H_1(S^1)$. In Exercise 32.1 we will discuss the question, for which $n \in \mathbb{N}$ does there exist a singular n-simplex $\sigma\colon \Delta^n \to S^n$ that represents a generator of $H_n(S^n)$.

We conclude this section with a short discussion of several related homology groups and their "standard generators".

Definition. Let $n \in \mathbb{N}$. The *standard generator of* $H_n(\overline{B}^n, S^{n-1})$ is defined to be the unique element that gets sent to the standard generator of $\widetilde{H}_{n-1}(S^{n-1})$ under the connecting homomorphism $H_n(\overline{B}^n, S^{n-1}) \to \widetilde{H}_{n-1}(S^{n-1})$ of the long exact sequence in reduced homology of the pair $(\overline{B}^n, S^{n-1})$. We denote the standard generator by $[\overline{B}^n]$.

We continue with the following lemma that relates several of the generators of homology groups that we have encountered so far.

Lemma 32.12. *Let $n \in \mathbb{N}$. We denote by $f\colon (\Delta^n, \partial\Delta^n) \to (\overline{B}^n, S^{n-1})$ the homeomorphism from Lemma 29.1 and we denote by $g\colon \overline{B}^n/S^{n-1} \to S^n$ the homeomorphism from page 99. We consider the following diagram of isomorphisms*

$$\begin{array}{ccccccccc} H_n(\Delta^n, \partial\Delta^n) & \xrightarrow{f_*} & H_n(\overline{B}^n, S^{n-1}) & \longrightarrow & H_n(\overline{B}^n/S^{n-1}, [S^{n-1}]) & \xrightarrow{g_*} & H_n(S^n, *) & \longleftarrow & H_n(S^n). \\ \downarrow{\scriptstyle\partial} & & \downarrow{\scriptstyle\partial} & & & & & & \\ \widetilde{H}_{n-1}(\partial\Delta^{n-1}) & \xrightarrow{f_*} & \widetilde{H}_{n-1}(S^{n-1}) & & & & & & \end{array}$$

Then the following statements hold:

(1) *The standard generator $[S^n]$ of $H_n(\overline{B}^n, S^{n-1})$ has the same image in $H_n(S^n, *)$ as the standard generator $[\overline{B}^n]$ of $H_n(S^n)$.*

(2) *We have*

$$f_*([\mathrm{id}_{\Delta^n}]) \;=\; (-1)^n \cdot \textit{standard generator } [\overline{B}^n] \textit{ of } H_n(\overline{B}^n, S^{n-1}).$$

(3) *The image of the standard generator* $[\overline{B}^n]$ *in* $H_{n-1}(S^{n-1})$ *equals the standard generator* $[S^{n-1}]$ *of* $H_{n-1}(S^{n-1})$.

(4) *We have*

$$f_*(\partial[\mathrm{id}_{\Delta^n}]) \;=\; (-1)^n \cdot \textit{standard generator } [S^{n-1}] \textit{ of } H_{n-1}(S^{n-1}).$$

Proof. The proof of the first two statements is an annoying exercise which mischievously we leave to the reader. The third statement is just a repetition of the definition of the standard generator $[\overline{B}^n]$. Finally the last statement is an immediate consequence of (2) and (3) together with the fact, shown in Proposition 31.13, that the square in the above diagram commutes. □

We conclude this section with the following lemma.

Lemma 32.13. *Let* $n \in \mathbb{N}$. *We consider the following sequence of maps*

$$H_n(S^n) \;\to\; H_n(S^n, \overline{B}^n_+) \;\underset{\substack{\uparrow \\ \textit{isomorphism by the discussion on page 808}}}{\overset{\cong}{\longleftarrow}}\; H_n(\overline{B}^n_+, S^{n-1}) \;\xrightarrow{\partial}\; \widetilde{H}_{n-1}(S^{n-1}).$$

The image of the standard generator $[S^n] \in H_n(S^n)$ *under this map is* $(-1)^n \cdot [S^{n-1}]$.

Proof. Let $\alpha, \beta \in C_n(S^n)$ be the n-chains in the definition of the standard generator $[S^n]$. It follows easily from the definitions of the above maps that $[S^n] = [\alpha - \beta]$ gets sent to $[\partial\alpha] \in H_{n-1}(S^{n-1})$. But by Lemma 32.12 (4) this equals $(-1)^n \cdot [S^{n-1}]$. □

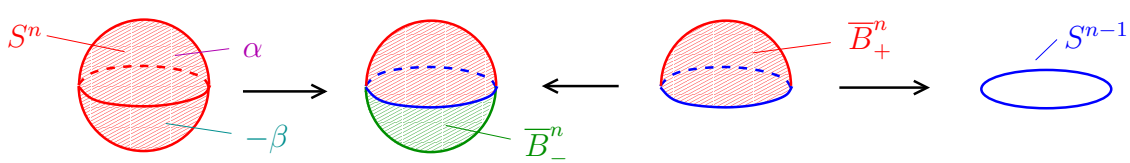

FIGURE 509. Illustration for the proof of Lemma 32.13.

32.3. **Suspensions and homology groups.** In the next section we will study self-maps of spheres. In that section it will be useful to consider the effect of taking suspensions on homology. Since this is going to be interesting for larger classes of topological spaces we dedicate this short section to the study of homology groups of suspensions of topological spaces.

The following definition follows the definition on page 452 and the convention given by Lemma 15.2 (3).

Definition. Let X be a topological space.

(1) We define the *suspension of* X to be the topological space
$$\Sigma(X) \;:=\; (X \times [-1,1])/\sim$$
where we identify all points in $X \times \{-1\}$ to a single point and we identify all points in $X \times \{1\}$ to a single point.

(2) We denote by $p\colon X \times [-1,1] \to \Sigma(X)$ be the obvious projection. We write
$$C_-X \;:=\; p(X \times [-1,1)) \quad \text{and} \quad C_+X \;:=\; p(X \times (-1,1]).$$

As shown in Lemma 15.2 (3) we can view $X = X \times \{0\}$ as a subspace of $C_\pm(X)$ and of $\Sigma(X)$.

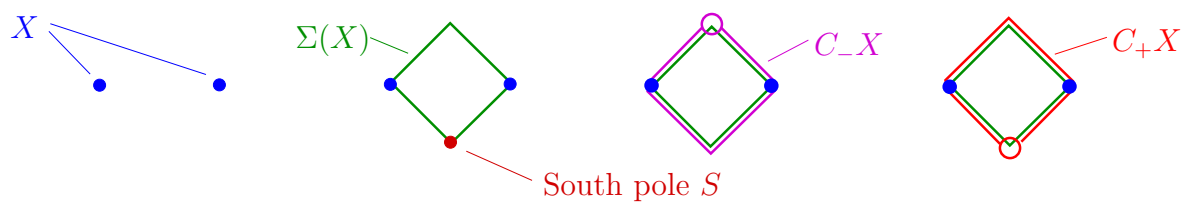

FIGURE 510.

The following proposition is the main result of this section.

Proposition 32.14. *Let X be a non-empty topological space and let $n \in \mathbb{Z}$.*[642]

(1) *The following maps are isomorphisms:*[643]
$$\widetilde{H}_n(X) \;\xleftarrow{\partial}\; H_{n+1}(C_+X, X) \;\to\; H_{n+1}(\Sigma(X), C_-X) \;\leftarrow\; \widetilde{H}_{n+1}(\Sigma(X)).$$
The first horizontal map is the connecting homomorphism of the pair (C_+X, X) from Corollary 31.14. The second horizontal map is induced by the inclusion $(C_+X, C_-X \cap C_+X) \to (\Sigma(X), C_-X)$. Finally the third horizontal map is the natural map given by Lemma 31.1 (3).

(2) *The resulting isomorphism*
$$\Sigma_X\colon \widetilde{H}_n(X) \;\xrightarrow{\cong}\; \widetilde{H}_{n+1}(\Sigma(X))$$
is natural. In other words, given any map $f\colon X \to Y$ between topological spaces the following diagram commutes:
$$\begin{array}{ccc} \widetilde{H}_n(X) & \xrightarrow{\Sigma_X} & \widetilde{H}_{n+1}(\Sigma(X)) \\ {\scriptstyle f_*}\big\downarrow & & \big\downarrow{\scriptstyle \Sigma(f)_*} \\ \widetilde{H}_n(Y) & \xrightarrow{\Sigma_Y} & \widetilde{H}_{n+1}(\Sigma(Y)). \end{array}$$

Proof. Let $n \in \mathbb{N}$.

[642]Note that the proposition has non-trivial content for $n = -1$.

[643]We use Lemma 15.2 (3) to make the identification $X = C_-X \cap C_+$.

(a) By the same argument as in the proof of Lemma 15.1 we see that both C_-X and C_+X admit a deformation retraction to a point. It follows from Lemma 9.10 that both are contractible, therefore by Lemma 31.1 (7) the reduced homologies of C_-X and C_+X vanish. It follows in particular that the connecting homomorphism $\partial\colon H_{n+1}(C_+(X), X) \to \widetilde{H}_n(X)$ is an isomorphism.
(b) It is straightforward to show that the obvious map $X \times (-1,1) \to C_-X \cap C_+X$ is a homeomorphism. It follows easily that X is a deformation retract of $C_-X \cap C_+X$. Thus we obtain from Corollary 31.16 that the first horizontal map is an isomorphism.
(c) We denote by $S := [X \times \{-1\}] \in \Sigma(X)$ the "South Pole" of the suspension. Note that $\Sigma(X) \setminus S = C_+X$ and $C_-X \setminus S = C_-X \cap C_+X$. Using this observation we now see that the second horizontal map is an isomorphism by the Excision Theorem 31.17.[644]
(d) Similar to (a) we obtain from Corollary 31.16 that the third horizontal map is an isomorphism.
(d) First note that the connecting homomorphism is natural by Proposition 31.13 (2) and the fact that $\Sigma(f)|_X = f$. It is clear that all the horizontal maps in the definition of the isomorphism Σ_X are natural. Thus Σ_X itself is natural. □

Example. Let $n \in \mathbb{N}$. Let $\Sigma(S^n) \to S^{n+1}$ be the homeomorphism from page 453. It follows quite easily from the definition of the suspension isomorphism $\Sigma_{S^n}\colon H_n(S^n) \to H_{n+1}(S^{n+1})$ and Lemma 32.13 that

$$\Sigma_{S^n}([S^n]) \;=\; (-1)^{n+1} \cdot [S^{n+1}] \;\in\; H_{n+1}(S^{n+1}).$$

32.4. **The degree of a self-map of a sphere.** Now that we know the homology groups of spheres, we want to study the maps on homology induced by maps $f\colon S^n \to S^n$. This is interesting in its own right, but it will also play a major role later on when we will try to determine the homology groups of CW-complexes.

Definition. Let $n > 0$ and let $f\colon S^n \to S^n$ be map. Since $H_n(S^n)$ is isomorphic to $\mathbb{Z}$ we know that the induced map $f_*\colon H_n(S^n) \to H_n(S^n)$ is given by multiplication by a uniquely determined integer $\deg(f) \in \mathbb{Z}$ which we call the *degree of* f.

Remark. Let $n > 0$ and let $f\colon S^n \to S^n$ be a map. If $a \in H_n(S^n)$ is non-trivial, then the degree $\deg(f)$ is uniquely determined by the equality $f_*(a) = \deg(f) \cdot a$.

Example. We consider the map $f\colon S^1 \to S^1$ that is illustrated in Figure 511 on the left.[645] We denote by $\tau\colon \Delta^1 \to S^1$ the singular 1-simplex that is given by $\tau(1-t, t) = e^{2\pi i t}$. By Lemma 32.11 we know that $[\tau] \in H_1(S^1)$ is a generator.

[644] One can easily verify that the hypotheses for the Excision Theorem 31.17 are satisfied.

[645] More precisely, given an "interval" on S^1 going from $e^{i\alpha}$ to $e^{i\beta}$ we mean the singular 1-simplex that is given by $(1-t, t) \mapsto e^{i(\alpha\cdot(1-t)+\beta\cdot t)}$.

We pick singular 1-simplices $\sigma_1, \dots, \sigma_5$ as in the middle of Figure 511 and we denote by $\gamma\colon \Delta^1 \to S^1$ the constant singular 1-simplex that sends all points to 1. Then

$$\begin{aligned} f_*([\tau]) \overset{\text{by Lemma 29.3 (3)}}{\overset{\downarrow}{=}} f_*([\sigma_1 + \dots + \sigma_5]) &= [\overbrace{\sigma_1 \circ f}^{=\gamma} + \overbrace{\sigma_2 \circ f}^{=\tau} + \overbrace{\sigma_3 \circ f}^{=\gamma} + \overbrace{\sigma_4 \circ f}^{=\overline{\tau}} + \overbrace{\sigma_5 \circ f}^{=\tau}] \\ &= [2 \cdot \tau + \overline{\tau} + 2 \cdot \gamma] \underset{\substack{\uparrow \\ \text{Lemma 29.3 (2)}}}{=} [\tau] = \underbrace{(+1)}_{=:\deg(f)} \cdot [\tau]. \end{aligned}$$

Summarizing we have shown that $\deg(f) = +1$. With almost the same approach we can

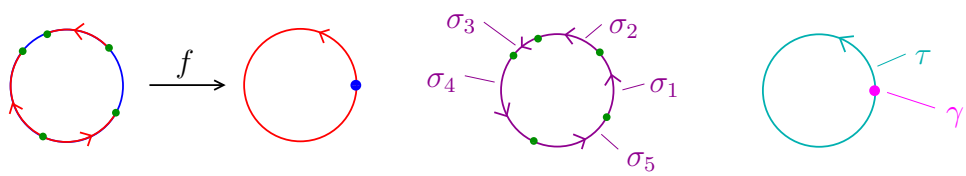

FIGURE 511.

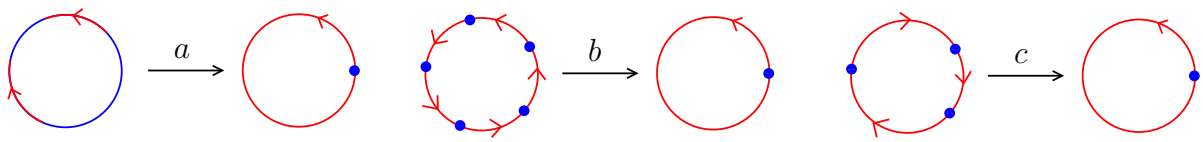
calculate the degrees of the maps that are illustrated in Figure 512.



$\deg(a) = 0$ $\deg(b) = +5$ $\deg(c) = -3$

FIGURE 512.

The same arguments that we used in discussion of the examples gives us the following lemma. We leave the details as an exercise to the reader.

Lemma 32.15. *For any $k \in \mathbb{Z}$ the degree of the map*

$$\begin{array}{ccc} S^1 & \to & S^1 \\ z & \mapsto & z^k \end{array}$$

equals k.

Proof. We denote by $\tau\colon \Delta^1 \to S^1$ the singular 1-simplex that is given by $\tau(1-t, t) = e^{2\pi i t}$. By Lemma 32.11 we know that $[\tau] \in H_1(S^1)$ is a generator.

Now we first consider the case $k \geq 1$. For $j = 0, \dots, k-1$ we denote by $\sigma_j \colon \Delta^1 \to S^1$ the singular 1-simplex that is given by $(1-t, t) \mapsto e^{2\pi i(\frac{t+j}{k})}$. Then

$$f_*([\tau]) \underset{\substack{\uparrow \\ \text{by Lemma 29.3 (3)}}}{=} f_*([\sigma_0 + \cdots + \sigma_{k-1}]) = \big[\overbrace{f \circ \sigma_0}^{=\tau} + \cdots + \overbrace{f \circ \sigma_{k-1}}^{=\tau}\big] = k \cdot [\tau].$$

The case $k < 0$ is proved is proved in a similar fashion using Lemma 29.3 (2). Finally the case $k = 0$ follows from the fact that the constant map $S^1 \to S^1$, $z \mapsto 1$ factors through a point which by Lemma 29.6 has trivial first homology. $\square$

In the following lemma we summarize several properties of the degree of the self-map of a sphere.

Lemma 32.16. *Let $f, g \colon S^n \to S^n$ be two maps. Then the following hold:*

(1) $\deg(\mathrm{id}_{S^n}) = 1$,
(2) *if f is not surjective, then* $\deg(f) = 0$,
(3) *if f is homotopic to g, then* $\deg(f) = \deg(g)$,
(4) $\deg(f \circ g) = \deg(f) \cdot \deg(g)$,
(5) *if f is a self-homeomorphism of S^n, then* $\deg(f^{-1}) = \deg(f)$,
(6) *if f is the reflection in a hyperplane, then* $\deg(f) = -1$,
(7) *if f is the reflection in the origin i.e. if $f(x) = -x$ for all $x \in S^n$, then we have* $\deg(f) = (-1)^{n+1}$,

Proof.

(1) Since $(\mathrm{id}_{S^n})_* = \mathrm{id}_{H_n(S^n)}$ we know that $\deg(\mathrm{id}_{S^n}) = 1$.
(2) Suppose that the map $f \colon S^n \to S^n$ misses the point $P \in S^n$. We consider the commutative diagram

$$\begin{tikzcd} & S^n \setminus \{P\} \arrow[dr, hook, "i"] & \\ S^n \arrow[ur, "f"] \arrow[rr, "f"'] & & S^n \end{tikzcd}$$

which gives rise to the commutative diagram

$$\begin{tikzcd} & H_n(S^n \setminus \{P\}) \arrow[dr, "i_*"] & \\ H_n(S^n) \arrow[ur, "f_*"] \arrow[rr, "f_*"'] & & H_n(S^n). \end{tikzcd}$$

Since $S^n \setminus \{P\}$ is homeomorphic to B^n we know that it is contractible which implies by Corollary 30.8 that $H_n(S^n \setminus \{P\}) = 0$. But this means that $f_* \colon H_n(S^n) \to H_n(S^n)$ factors through the zero group, i.e. f_* is the zero map.
(3) If f is homotopic to g, then it follows from Proposition 30.5 that $\deg(f) = \deg(g)$.
(4) We consider the following diagram

$$\begin{tikzcd} H_n(S^n) \arrow[r, "f_*", "\cdot \deg(f)"'] \arrow[rr, bend right, "(f \circ g)_*"'] & H_n(S^n) \arrow[r, "g_*", "\cdot \deg(g)"'] & H_n(S^n). \end{tikzcd}$$

This diagram commutes since $(f \circ g)_* = f_* \circ g_*$. It follows that the curved map is given by multiplication by $\deg(f) \cdot \deg(g)$, i.e. $\deg(f \circ g) = \deg(f) \cdot \deg(g)$.

(5) This statement follows immediately from (1) and (4).

(6) We consider again the singular chain

$$\begin{array}{rcl} \alpha\colon \Delta^n & \overset{\cong}{\to} & \Big\{(x_1,\dots,x_n) \in [0,1]^n \,\Big|\, \sum\limits_{i=1}^n x_i \in [0,1]\Big\} \overset{\cong}{\to} \overline{B}^n \to S^n. \\ (t_0,\dots,t_n) & \mapsto & (t_0,\dots,t_{n-1}) \qquad\qquad\qquad\qquad x \mapsto \big(x, \sqrt{1-\|x\|^2}\big). \end{array}$$

that we had already considered on page 813. Let ρ be the reflection in the hyperplane V defined by $x_{n+1} = 0$. We write $\beta = \rho \circ \alpha$. In Lemma 32.10 we saw that the singular n-chain $\alpha - \beta$ is a generator of $H_n(S^n)$.

We then have

$$\rho_*([\alpha - \beta]) \;=\; [\rho \circ \alpha] - [\rho \circ \beta] \;=\; [\beta] - [\underbrace{\rho \circ \rho}_{=\mathrm{id}} \circ \alpha] \;=\; [\beta] - [\alpha] \;=\; -[\alpha - \beta].$$

The map ρ_* is therefore given by multiplication with -1. This shows that reflection in V has degree -1.

Now let f be the reflection in some other hyperplane W of $\mathbb{R}^{n+1}$. It follows from Lemma 9.4 that ρ and f are homotopic maps of S^{n-1} to itself. By Proposition 30.5 this implies that τ and ρ induce the same map on $H_n(S^n)$, thus we see that $\deg(\tau) = \deg(\rho) = -1$.

(7) The reflection in the origin is the composition of the reflections in the $(n+1)$ hyperplanes $H_i := \{(t_1,\dots,t_{n+1}) \in \mathbb{R}^{n+1} \,|\, t_i = 0\}$, $i = 1,\dots,n+1$. The desired statement thus follows from (4) and (6). □

Lemma 32.17. *Let $A \in \mathrm{O}(n+1)$ be an orthogonal matrix. Then*

$$\deg\begin{pmatrix} S^n & \to & S^n \\ P & \mapsto & A \cdot P \end{pmatrix} \;=\; \det(A).$$

Proof. Let $A \in \mathrm{O}(n+1)$ be an orthogonal matrix. We give two slightly different proofs that $\deg(A) = \det(A)$.

(1) It is a standard fact proved in Linear Algebra, see e.g. [Cu, Theorem 33.1], that the map $P \mapsto A \cdot P$ is the composition of reflections in finitely many hyperplanes $H_1,\dots,H_k$.[646] We see that

$$\begin{array}{lllll} \deg(A) & = \deg(H_1) \cdot \dots \cdot \deg(H_k) & = (-1)^k & = \det(H_1) \cdot \dots \cdot \det(H_k) & = \det(A). \\ & \uparrow & \uparrow & \uparrow & \\ & \text{Lemma 32.16 (4)} & \text{Lemma 32.16 (6)} & \text{determinant of reflection} = -1 & \end{array}$$

(2) For the second proof we first assume that $\det(A) = 1$, i.e. that $A \in \mathrm{SO}(n+1)$. By Lemma 1.96 we know that $\mathrm{SO}(n+1)$ is path-connected, so there exists a map

[646]For example, a matrix in $\mathrm{O}(2)$ corresponds to rotation by an angle α. But rotation by α is the same as the composition of the reflection in the line defined by the angle $\varphi = \frac{\alpha}{2}$ and the reflection in the line defined by the angle $\varphi = \alpha$.

$h\colon [0,1] \to \mathrm{SO}(n+1)$ with $h(0) = \mathrm{id}$ and $h(1) = A$. But then $F(x,t) = h(t) \cdot x$ defines a homotopy from id to multiplication by A. It follows from Lemma 32.16 (1) and (3) that $\deg(A) = 1$.
Now suppose that $\det(A) \neq 1$. Then $\det(A) = -1$ and if we compose A with the map h that is given by reflection in a hyperplane, then multiplicativity of determinants shows that $\det(h \circ A) = \det(h) \cdot \det(A) = (-1)^2 = 1$. From the above we see that $\deg(h \circ A) = 1$. From Lemma 32.16 (4) and (6) we easily obtain that $\deg(A) = -1$. □

We have now seen that the circle admits self-maps of arbitrary degrees and that every sphere admits self-maps of degree $-1, 0, 1$. It is natural to ask whether there are also maps on higher-dimensional spheres that have other degrees. The combination of Lemma 32.15 and the following lemma shows that in fact every $k \in \mathbb{Z}$ is realized as the degree of every high-dimensional sphere.

Lemma 32.18. *Let $n \in \mathbb{N}$ and let $f\colon S^n \to S^n$ be a map. Following the discussion on page 820, we denote by $\Sigma(f)\colon \Sigma(S^n) \to \Sigma(S^n)$ the suspension of f and we make the identification $\Sigma(S^n) = S^{n+1}$. Then*

$$\deg(\Sigma(f)\colon S^{n+1} \to S^{n+1}) \;=\; \deg(f\colon S^n \to S^n).$$

Example. Let $k \in \mathbb{Z}$. We view S^2 as a subset of $\mathbb{R}^3 = \mathbb{C} \times \mathbb{R}$. We consider the map

$$\begin{array}{rcl} g\colon S^2 & \to & S^2 \\ (re^{i\varphi}, w) & \mapsto & (re^{i\varphi k}, w). \end{array}$$

Under the identification $S^2 = \Sigma(S^1)$ from page 820 the map g equals $\Sigma(z \mapsto z^k)$. Thus it follows from Lemmas 32.15 and 32.18 that $\deg(g) = \deg(\Sigma(z \mapsto z^k)) = k$.

Proof. We consider the following diagram

$$\begin{array}{ccc} \widetilde{H}_n(S^n) & \xrightarrow{\Sigma_{S^{n+1}}} & \widetilde{H}_{n+1}(S^{n+1}) \\ {\scriptstyle \cdot \deg(f)} \big\downarrow {\scriptstyle f_*} & & {\scriptstyle \cdot \deg(\Sigma(f))} \big\downarrow {\scriptstyle \Sigma(f)_*} \\ \widetilde{H}_n(S^n) & \xrightarrow{\Sigma_{S^{n+1}}} & \widetilde{H}_{n+1}(S^{n+1}). \end{array}$$

By Proposition 32.14 the diagram commutes and the horizontal maps are isomorphisms. Thus we see that $\deg(\Sigma(f)) = \deg(f)$. □

Theorem 32.19. *Let $f\colon S^n \to S^n$ be a map. If $\deg(f) \neq (-1)^{n+1}$, then f has a fixed-point.*

Example. Theorem 32.19 says in particular that every map $f\colon S^2 \to S^2$ of degree one has a fixed-point. Together with Lemma 32.16 this implies that every map $f\colon S^2 \to S^2$ that is homotopic to the identity has a fixed-point. This means that we cannot "deform" the identity to a map that is fixed point free. This is in contrast to the case $n = 1$ where we can "deform" the identity into the map that is given by rotation by a small angle, which is of course a fixed-point free map.

Proof. Let $f\colon S^n \to S^n$ be a map which admits no fixed point. This means that for all $x \in S^n$ we have $f(x) \neq x$. We need to show that $\deg(f) = (-1)^{n+1}$. We will do this by showing that f is homotopic to $-\operatorname{id}$.

Our hypothesis implies that $(1-t)f(x) \neq tx$ for all $t \in [0,1]$ and all $x \in S^n$.[647] Therefore we can consider the map

$$\begin{array}{rcl} F\colon S^n \times [0,1] & \to & S^n \\ (x,t) & \mapsto & \dfrac{(1-t)f(x) - tx}{\|(1-t)f(x) - tx\|}. \end{array}$$

This map is a homotopy between the maps $x \mapsto f(x)$ and $x \mapsto -x$. Thus it follows that

$$\begin{array}{ccccc} \deg(f) & = & \deg(-\operatorname{id}) & = & (-1)^{n+1}. \\ & \uparrow & & \uparrow & \\ & \text{Lemma 32.16 (3)} & & \text{Lemma 32.16 (7)} & \end{array}$$

□

In the following we recall the definition of the "naive" tangent space of a submanifold of $\mathbb{R}^n$.

Definition. Let $M \subset \mathbb{R}^n$ be a submanifold and let $P \in M \setminus \partial M$.

(1) A vector $v \in \mathbb{R}^n$ is called a *tangent vector to M in the point P* if there exists a smooth path

$$\begin{array}{rcl} \gamma\colon (-\epsilon,\epsilon) & \to & M \\ t & \mapsto & \gamma(t) \end{array}$$

such that $\gamma(0) = P$ and $\gamma'(0) = v$.

(2) The set of all tangent vectors at the point P is called the *tangent space* T_PM.[648]

(3) A *vector field* on M is a continuous map $v\colon M \to \mathbb{R}^n$ such that for any $P \in M$ we have $v(P) \in T_PM$.

Examples.

(1) Some fairly elementary considerations show that the tangent space of the sphere S^n at a point P is given as follows:

$$T_PS^n = \{v \in \mathbb{R}^{n+1} \mid P \cdot v = 0\}.$$

(2) For an odd-dimensional sphere S^{2k-1} a vector field is given by[649]

$$\begin{array}{rcl} v\colon S^{2k-1} & \to & \mathbb{R}^{2k} \\ (x_1, x_2, \dots, x_{2k-1}, x_{2k}) & \mapsto & (-x_2, x_1, \dots, -x_{2k}, x_{2k-1}). \end{array}$$

[647]This case be seen as follows: if $t \neq \frac{1}{2}$ we have $\|(1-t)f(x)\| = 1-t \neq t = \|tx\|$. On the other hand, for $t = \frac{1}{2}$ we have $(1-t)f(x) = \frac{1}{2}f(x) \neq \frac{1}{2}x = tx$.

[648]For the sake of exposition we use Proposition 3.32 to blur the distinction between the "official" tangent space T_PM that we introduced on page 195 and the visual tangent space V_PM that we introduced on page 196.

[649]Indeed, for any $P \in S^{2k-1}$ we have $P \cdot v(P) = 0$, i.e. $v(P)$ does indeed lie in the tangent space T_PS^{2k-1}.

This vector field has the property that it is nowhere vanishing. In the case of the 1-sphere S^1 this is just the vector field of constant length 1 that points in the "counterclockwise direction".

(3) For even-dimensional sphere S^{2k} a vector field is similarly given by

$$\begin{array}{rcl} v\colon S^{2k} & \to & \mathbb{R}^{2k+1} \\ (x_1, x_2, \ldots, x_{2k-1}, x_{2k}, x_{2k+1}) & \mapsto & (-x_2, x_1, \ldots, -x_{2k}, 0). \end{array}$$

This vector field vanishes at the "north pole" $(0, \ldots, 0, 1)$ and it also vanishes at the "south pole" $(0, \ldots, 0, -1)$. Both types of vector fields are sketched in Figure 513.

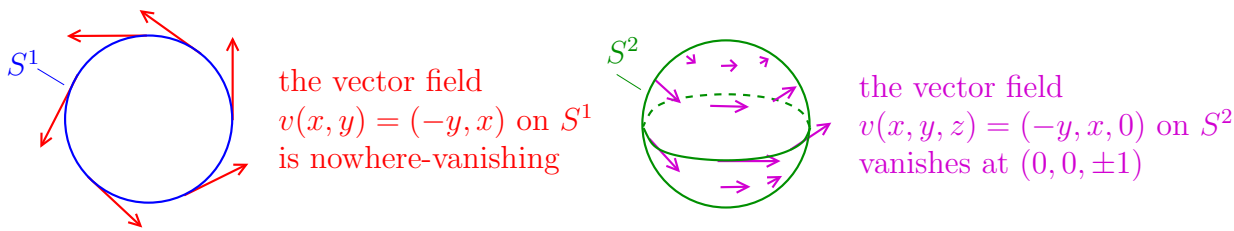


FIGURE 513.

One can now ask whether it is possible to find a nowhere vanishing vector field on even-dimensional spheres. The following proposition says that this is not possible.

Theorem 32.20. *Every vector field on an even-dimensional sphere S^{2k} vanishes on at least one point.*[650]

Remark.

(1) For $n = 2$ we get the following "real life application": on the surface of earth there always exists at least one point where the wind does not blow at all. This fact is illustrated at the following website

`https://earth.nullschool.net/`

(2) In the literature Theorem 32.20 is known as the "hairy ball theorem" since the theorem says that "you can't comb a hairy ball flat without creating a cowlick".

(3) In German we refer to Theorem 32.20 as the "Satz vom (gekämmten) Igel", for the same reason as we refer to it as the "hairy ball theorem" in English.

Proof. Let v be a vector field on the sphere S^n which is nowhere-vanishing. We have to show that n is odd. We consider the vector field w on S^n that is given by rescaling v to length one, i.e. which is given by

$$\begin{array}{rcl} S^n & \to & \mathbb{R}^{n+1} \\ x & \mapsto & w(x) := \frac{1}{\|v(x)\|} v(x). \end{array}$$

[650] On S^{2k} we had so far found vector fields which vanish at *two* points. Can we find a vector field on S^{2k} which vanishes on only *one* point? We will discuss this question in Exercise 32.4.

Furthermore we consider the map

$$\begin{array}{rcl} F\colon S^n \times [0,1] & \mapsto & S^n \\ (x,t) & \mapsto & \cos(\pi t)x + \sin(\pi t)w(x). \end{array}$$

We refer to Figure 514 for an illustration. The map does indeed take values in S^n, since

$$(\cos(\pi t)x + \sin(\pi t)w(x)) \cdot (\cos(\pi t)x + \sin(\pi t)w(x)) \underset{\substack{\uparrow \\ \text{since } w(x)\cdot x = 0}}{=} \cos(\pi t)^2\|x\|^2 + \sin(\pi t)^2\|w(x)\|^2 \underset{\substack{\uparrow \\ \text{since } \|x\| = \|w(x)\| = 1}}{=} 1.$$

The map $F_0 = F(-,0)$ is the identity and the map $F_1 = F(-,1)$ equals F is $-\operatorname{id}$. Put differently, the map F is a homotopy between the two maps id and $-\operatorname{id}$. It follows that

$$1 \underset{\substack{\uparrow \\ \text{Lemma 32.16 (1)}}}{=} \deg(\operatorname{id}) \underset{\substack{\uparrow \\ \text{Lemma 32.16 (3)}}}{=} \deg(-\operatorname{id}) \underset{\substack{\uparrow \\ \text{Lemma 32.16 (7)}}}{=} (-1)^{n+1}.$$

But this means that n is odd. □

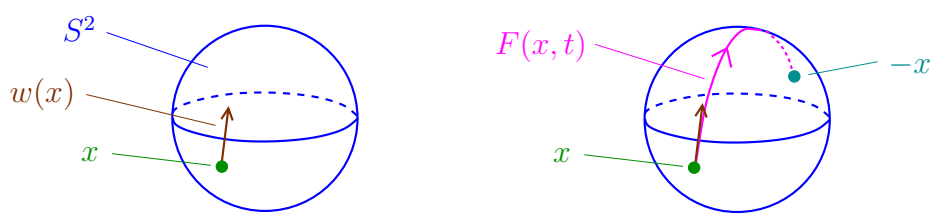

FIGURE 514.

32.5. **The local degree.** As the reader will have noticed, it is not entirely trivial to compute the isomorphism types of the homology groups of a given topological space. But there is one problem which is often even harder, namely given a map $f\colon X \to Y$ between topological spaces, how can we determine the induced map on homology? For example, let us consider the following question.

Question 32.21. *Let f be a complex polynomial of degree ≥ 1. By Exercise 1.11 we know that the map*

$$\begin{array}{rcl} \Theta(f)\colon S^2 = \mathbb{C}\cup\{\infty\} & \to & \mathbb{C}\cup\{\infty\} = S^2 \\ z & \mapsto & \begin{cases} f(z), & \text{if } z \in \mathbb{C}, \\ \infty, & \text{if } z = \infty \end{cases} \end{array}$$

is continuous. What is the induced map on homology, i.e. what is the degree of $\Theta(f)$?

In this section we will develop a method for determining the degree of a self-map of a sphere which can be applied in many "reasonable" cases. In particular we will be able to answer Question 32.21. The answer will give us a new proof of the Fundamental Theorem of Algebra.

We start out with the following convention.

Convention. Let $n \geq 1$. We use the standard generator of $H_n(S^n) \cong \mathbb{Z}$, as defined on page 814, to make the identification $H_n(S^n) = \mathbb{Z}$. Now let $x \in S^n$ be a point and let U be a neighborhood of x in S^n. We have isomorphisms

$$\begin{array}{ccccccc} \mathbb{Z} & = & H_n(S^n) & \overset{\cong}{\rightarrow} & H_n(S^n, S^n \setminus \{x\}) & \overset{\cong}{\leftarrow} & H_n(U, U \setminus \{x\}). \\ & & & \uparrow & & \uparrow & \\ & & & \text{isomorphism by the long exact} & & \text{isomorphism by the} & \\ & & & \text{of the pair } (S^n, S^n \setminus \{x\}) & & \text{Excision Theorem 31.17} & \end{array}$$

Throughout this section will use these isomorphisms to identify the above homology groups with $\mathbb{Z}$.

Definition.

(1) Let $\Phi\colon \mathbb{Z} \to \mathbb{Z}$ be a homomorphism. It is given by multiplication by a unique integer which we refer to as the *degree* $\deg(\phi)$.
(2) We say a map $f\colon X \to Y$ between two topological spaces is *nice at a point* $x \in X$ if there exists a neighborhood U of x such that for all $x' \neq x$ in U we have $f(x') \neq f(x)$. We refer to such a neighborhood as a *nice neighborhood of* x.
(3) Let $n \geq 1$, let $f\colon S^n \to S^n$ be a map and let $x \in S^n$ be a nice point. Let U be a nice neighborhood of x and let V be a neighborhood of $f(x)$ such that $f(U) \subset V$. The *local degree of* f *at the point* x is defined as[651]

$$\deg f|_x \ := \ \deg\big(f_*\colon \underbrace{H_n(U, U \setminus \{x\})}_{=\mathbb{Z}} \ \to \ \underbrace{H_n(V, V \setminus \{f(x)\})}_{=\mathbb{Z}}\big).$$

Example. We consider the functions

$$\begin{array}{rcl} f\colon \mathbb{R} & \to & \mathbb{R} \\ t & \mapsto & t^2 \end{array} \quad \text{and} \quad \begin{array}{rcl} g\colon \mathbb{R} & \to & \mathbb{R} \\ t & \mapsto & \begin{cases} 0, & \text{if } t = 0, \\ t\sin(\frac{1}{t}), & \text{if } t \neq 0. \end{cases} \end{array}$$

For the function f every point on $\mathbb{R}$ is nice, in fact for $x < 0$ we can take $U = (-\infty, 0)$, for $x > 0$ we can take $U = (0, \infty)$ and for $x = 0$ we can take $U = \mathbb{R}$. On the other hand it is straightforward to see that for the function g the point $x = 0$ is not nice.

Lemma 32.22. *The local degree* $\deg f|_x$ *of a map* $f\colon S^n \to S^n$ *at a nice point* $x \in S^n$ *is well-defined.*

Proof. Let $n \geq 1$, let $f\colon S^n \to S^n$ be a map and let $x \in S^n$ be a nice point. Let U, U' be nice neighborhoods of x and let V, V' be neighborhoods of $f(x)$ such that $f(U) \subset V$ and such that $f(U') \subset V'$. After replacing U' by $U \cap U'$ and replacing V' by $V \cap V'$ we can without loss of generality assume that $U' \subset U$ and $V' \subset V$. We consider the following

[651]Note that f induces a map of pairs $(U, U \setminus \{x\}) \to (V, V \setminus \{f(x)\})$ since U is nice.

commutative diagram

$$\begin{array}{ccc} H_n(U', U' \setminus \{x\}) & \xrightarrow{f_*} & H_n(V', V' \setminus \{f(x)\}) \\ \downarrow\cong & & \downarrow\cong \\ H_n(U, U \setminus \{x\}) & \xrightarrow{f_*} & H_n(V, V \setminus \{f(x)\}). \end{array}$$

The vertical maps are isomorphisms by the Excision Theorem 31.17. It follows immediately that the degree of the top map agrees with the degree of the bottom map. □

Lemma 32.23. *Let $n \geq 1$, let $f\colon S^n \to S^n$ be a map and let $x \in S^n$. If f is a homeomorphism, then for every nice point $x \in S^n$ we have*

$$\deg f|_x \;=\; \deg f.$$

Proof. From the hypothesis that f is a homeomorphism we obtain that $U = S^n$ is a nice neighborhood for x. We take $V = S^n$ and we consider the following diagram

$$\begin{array}{ccc} H_n(S^n) & \xrightarrow{f_*} & H_n(S^n) \\ \downarrow\cong & & \downarrow\cong \\ H_n(S^n, S^n \setminus \{x\}) & \xrightarrow{f_*} & H_n(S^n, S^n \setminus \{f(x)\}) \end{array}$$

The statement now follows immediately from the definitions. □

The following lemma can often be used to determine the local degree of a map.

Lemma 32.24. *Let $f\colon S^n \to S^n$ be a map with $n \geq 1$ and let $x \in S^n$.*

(1) *If f is a local homeomorphism around x, then x is nice and*

$$\deg f|_x \;=\; \pm 1.$$

(2) *If f is a local diffeomorphism around x, then x is nice and*

$$\deg f|_x \;=\; \begin{cases} 1, & \text{if } f \text{ is o-locally orientation-preserving at } x, \\ -1, & \text{if } f \text{ is o-locally orientation-reversing at } x. \end{cases}$$

Example. We consider the map $f\colon S^1 \to S^1$ given by $(x, y) \mapsto (x, |y|)$. It follows from Lemma 32.24 (2) that for every point on the open upper semicircle the local degree is $+1$ and that for every point on the open lower semicircle the local degree is -1. In Exercise 35.3 we will prove that the local degree at the points ± 1 is in both cases zero.

In the proof of Lemma 32.24 we will make use of the following lemma which we will also use on several other occasions later on.

Lemma 32.25. *Let $f\colon U \to V$ be a diffeomorphism between two open subsets of $\mathbb{R}^n$. Let $P \in U$. We denote by*

$$\begin{array}{rcl} \lambda\colon \mathbb{R}^n & \to & \mathbb{R}^n \\ x & \mapsto & (D_P f)(x) + f(P) \end{array}$$

the linearization of P.

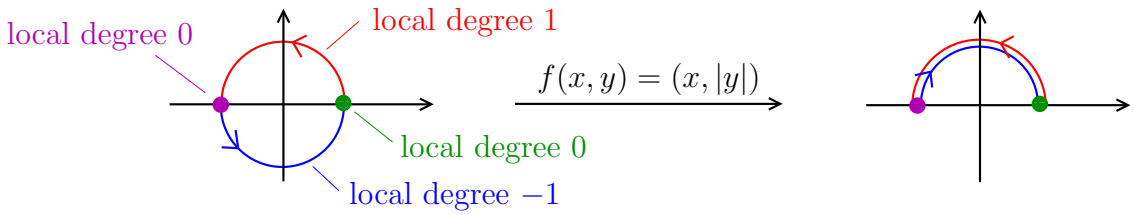

FIGURE 515.

(1) *There exists an open neighborhood $U' = B_r(P)$ of P that is contained in U such that for any $t \in [0,1]$ the map*

$$\begin{array}{rcl} g_t \colon U' & \to & \mathbb{R}^n \\ x & \mapsto & (1-t)\cdot f(x) \,+\, t\cdot \lambda(x) \end{array}$$

is a diffeomorphism onto its image and such that the image $g_t(U') = g_t(B_r(P))$ is convex.

(2) *The restrictions of f and φ to maps $(U', U' \setminus \{P\}) \to (\mathbb{R}^n, \mathbb{R}^n \setminus \{f(P)\})$ are homotopic, in particular we have for any $k \in \mathbb{N}_0$ that*

$$f_* \,=\, \varphi_* \colon H_k(U', U' \setminus \{P\}) \;\to\; H_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{f(P)\}).$$

Proof.

(1) The existence of $U' = B_r(P)$ is an amusing exercise that requires a good understanding of what the differential actually means. We will fill in the details in Exercise 35.5.
(2) Since each g_t is a diffeomorphism onto its image with $g_t(P) = f(P)$ we see that each g_t maps $U' \setminus \{P\}$ to $\mathbb{R}^n \setminus \{f(P)\}$. Thus we see that the maps f and φ define homotopic maps $(U', U' \setminus \{P\}) \to (\mathbb{R}^n, \mathbb{R}^n \setminus \{f(P)\})$ of pairs of topological spaces. The final statement regarding the induced maps on relative homology groups is an immediate consequence of Proposition 31.15. □

Now we can provide the proof of Lemma 32.24.

Proof of Lemma 32.24. Let $f \colon S^n \to S^n$ be a map with $n \geq 1$ and let $x \in S^n$.

(1) Suppose that f is a local homeomorphism around the point x. Recall that this means that there exists an open neighborhood U of x and an open neighborhood V of $f(x)$ such that $f \colon U \to V$ is a homeomorphism. It is clear that U is nice. Since the map f restricts to a homeomorphism $(U, U \setminus \{x\}) \to (V, V \setminus \{f(x)\})$ of pairs we see that the induced map $H_n(U, U \setminus \{x\}) \to H_n(V, V \setminus \{f(x)\})$ is an isomorphism, which implies immediately that $\deg f|_x = \pm 1$.
(2) We only sketch the proof of (2). We leave it as an exercise to fill in the details. First of all we introduce the following conventions and definitions:

(a) Let U of $\mathbb{R}^n$ be an open subset that contains 0. We use the obvious isomorphisms

$$\begin{array}{ccccccc} H_{n-1}(S^{n-1}) & \xrightarrow{\cong} & H_{n-1}(\mathbb{R}^n \setminus 0) & \xrightarrow{\cong} & H_n(\mathbb{R}^n, \mathbb{R}^n \setminus 0) & \xleftarrow{\cong} & H_n(U, U \setminus 0) \\ & & & \uparrow & & \uparrow & \\ & & & \text{long exact sequence of the pair } (\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}) & & \text{Excision Theorem 31.17} & \end{array}$$

and the standard generator of $H_{n-1}(S^{n-1})$ to identify $H_{n-1}(U, U \setminus 0)$ with $\mathbb{Z}$.

(b) Given an open subset U of $\mathbb{R}^n$ and a map $f\colon U \to \mathbb{R}^n$ with $f(0) = 0$ we define

$$\deg(f) \;=\; \deg\big(f_*\colon \underbrace{H_n(U, U \setminus 0)}_{=\mathbb{Z}} \to \underbrace{H_n(\mathbb{R}^n, \mathbb{R}^n \setminus 0)}_{=\mathbb{Z}}\big).$$

(c) Given a matrix $A \in \mathrm{GL}(n, \mathbb{R})$ we write $\deg(A)$ for the degree of the map $\mathbb{R}^n \setminus 0 \to \mathbb{R}^n \setminus 0$ that is given by multiplication by A.

Using orientation-preserving charts one sees easily that it suffices to prove the following claim.

Claim. Let $f\colon U \to V$ be a diffeomorphism between two open subsets of $\mathbb{R}^n$ such that $f(0) = 0$. Then

$$\deg(f) \;=\; \begin{cases} 1, & \text{if } f \text{ is orientation-preserving,} \\ -1, & \text{if } f \text{ is orientation-reversing.} \end{cases}$$

We start out with the following four observations:

(a) Since f is a diffeomorphism we know that the differential $D_0 f$ is an invertible matrix.[652] Furthermore, basically by definition, we know that f is orientation-preserving if $\det(D_0 f) > 0$ and we know that f is orientation-reversing if $\det(D_0 f) < 0$.

(b) It follows immediately from Lemma 32.25 applied to $f\colon U \to V$ that f and D_0 have the same degree.

(c) If A and B are two matrices in $\mathrm{GL}(n, \mathbb{R})$ that lie in the same path-component of $\mathrm{GL}(n, \mathbb{R})$, then the corresponding maps $(\mathbb{R}^n, \mathbb{R}^n \setminus 0) \to (\mathbb{R}^n, \mathbb{R}^n \setminus 0)$ are homotopic.[653] In particular they have the same degree by Proposition 31.15.

(d) We denote by R the matrix corresponding to the reflection in the hyperplane defined by $x_n = 0$. By Lemma 1.96 (1) a matrix $A \in \mathrm{GL}(n, \mathbb{R})$ lies in the same path-component of $\mathrm{GL}(n, \mathbb{R})$ as the identity matrix id if $\det(A) > 0$ and it lies in the same path-component of $\mathrm{GL}(n, \mathbb{R})$ as R if $\det(A) < 0$.

[652] Indeed, by the chain rule for differentials the inverse of the $D_0 f$ is given by the differential of f^{-1} at the point $f(0) = 0$.

[653] Why is that?

Summarizing we have

$$\deg(f) \underset{\substack{\uparrow \\ \text{by (b)}}}{=} \deg(D_0 f) \underset{\substack{\uparrow \\ \text{by (a), (c) and (d)}}}{=} \begin{cases} \deg(\mathrm{id}), & \text{if } f \text{ or.-pres.} \\ \deg(R), & \text{if } f \text{ or.-rev.} \end{cases} \underset{\substack{\uparrow \\ \text{similar argument as in Lemma 32.16 (6)}}}{=} \begin{cases} 1, & \text{if } f \text{ or.-pres.} \\ -1, & \text{if } f \text{ or.-rev.} \end{cases}$$

This concludes the proof of the claim. □

Using the following proposition we can now determine the degree of a map from local degrees.

Proposition 32.26. *Let $f\colon S^n \to S^n$ be a map where $n > 0$ and let $y \in S^n$ such that $f^{-1}(y)$ consists of finitely many points $x_1, \dots, x_m$.*[654] *Then*[655]

$$\deg f = \sum_{i=1}^{m} \deg f|_{x_i}.$$

Proof (∗). We choose disjoint open neighborhoods $U_1, \dots, U_m$ for $x_1, \dots, x_m$ and we choose an open neighborhood V of y such that $f(U_i) \subset V$ for $i = 1, \dots, m$. We consider the following diagram:

$$\begin{tikzcd}
H_n(S^n) \arrow[rr, "f_*"] \arrow[d] \arrow[dr, "j"] & & H_n(S^n) \arrow[d, "\cong"] \\
\bigoplus_{i=1}^{m} H_n(S^n, S^n \setminus x_i) & H_n(S^n, S^n \setminus f^{-1}(y)) \arrow[l, "\oplus p_i"'] \arrow[r, "f_*"] & H_n(S^n, S^n \setminus y) \\
\bigoplus_{i=1}^{m} H_n(U_i, U_i \setminus x_i) \arrow[u, "\cong"] \arrow[ur, "\oplus k_i"'] \arrow[rr, "f_*"] & & H_n(V, V \setminus y). \arrow[u, "\cong"', "q"]
\end{tikzcd}$$

Here the maps k_i and p_i are induced by inclusions. One sees easily that this diagram is commutative.

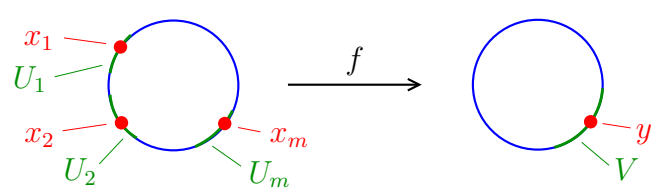

FIGURE 516. Illustration for the proof of Proposition 32.26.

[654] Does there always exist such a y?

[655] The hypothesis implies immediately that all the points $x_1, \dots, x_m$ are nice, hence the local degrees are defined.

It follows from the Excision Theorem 31.17 that the map[656]

$$\bigoplus_{i=1}^{m} k_i \,:\, \bigoplus_{i=1}^{m} H_n(U_i, U_i \setminus x_i) \;\xrightarrow{\cong}\; H_n(S^n, S^n \setminus f^{-1}(y))$$

is an isomorphism. From the commutativity of the lower triangle it follows immediately that the map

$$\bigoplus_{i=1}^{m} p_i \,:\, H_n(S^n, S^n \setminus f^{-1}(y)) \;\to\; \bigoplus_{i=1}^{m} H_n(S^n, S^n \setminus x_i)$$

is also an isomorphism. Recall that we make the identifications

$$\mathbb{Z} \;=\; H_n(S^n, S^n \setminus x_i) \;=\; H_n(U_i, U_i \setminus x_i) \;=\; H_n(V, V \setminus y).$$

The commutativity of the triangles and the choice of the identifications with $\mathbb{Z}$ implies that $(p_i \circ j)(1) = (p_i \circ k_i)(1)$ for $i = 1, \dots, m$. Thus we see that

$$\sum_{i=1}^{m} (p_i \circ j)(1) \;=\; \sum_{i=1}^{m} (k_i \circ j)(1).$$

In particular it follows that

$$((p_1 \circ j)(1), \dots, (p_m \circ j)(1)) \;=\; ((p_1 \circ k_1)(1), \dots, (p_m \circ k_m)(1)).$$

Since $\bigoplus_{i=1}^{m} p_i$ is an isomorphism, we now obtain that

$$j(1) \;=\; \sum_{i=1}^{m} k_i(1).$$

Now we see that[657]

$$\begin{aligned}
\deg f \;&\overset{\substack{\text{by the definition of } \deg f \text{ and} \\ \text{by the chosen identifications with } \mathbb{Z}}}{=}\; (q^{-1} \circ f_*)(j(1_{H_n(S^n)})) \;=\; (q^{-1} \circ f_*)\Big(\sum_{i=1}^{m} k_i(1)\Big) \\
&= \sum_{i=1}^{m} (q^{-1} \circ f_* \circ k_i)(1_{H_n(U_i, U_i \setminus x_i)}) \;\underset{\substack{\text{by the commutativity of the} \\ \text{lower rectangle}}}{=}\; \sum_{i=1}^{m} f_*(1_{H_n(U_i, U_i \setminus x_i)}) \;\underset{\substack{\text{by the definition of } \deg f|_{x_i} \\ \text{and the identifications with } \mathbb{Z}}}{=}\; \sum_{i=1}^{m} \deg f|_{x_i}.
\end{aligned}$$

□

Examples.

[656]More precisely, it follows from the following commutative diagram

$$\begin{tikzcd}
\bigoplus_{i=1}^{m} H_n(U_i, U_i \setminus x_i) \arrow[rr, "\cong"] \arrow[dr] & & H_n\Big(\bigcup_i U_i, \bigcup_i U_i \setminus x_i\Big) \arrow[dl, "\cong", "\text{Excision Theorem 31.17}"'] \\
& H_n(S^n, S^n \setminus f^{-1}(y)). &
\end{tikzcd}$$

that the left diagonal map is an isomorphism.

[657]Here we write $1_{H_n(S^n)}$ to indicate $1 \in H_n(S^n)$ and we use the same notation for the other spaces.

(1) The map $f\colon S^1 \to S^1$ given by $f(x,y) = (x,|y|)$ that is illustrated in Figure 515 has degree zero by Lemma 32.16. Taking preimages of points in S^1 one sees that in each case the sum of the local degrees of the preimages is zero.
(2) In Figure 517 we sketch a map $f\colon S^1 \to S^1$ and we choose several points $y \in S^1$. We

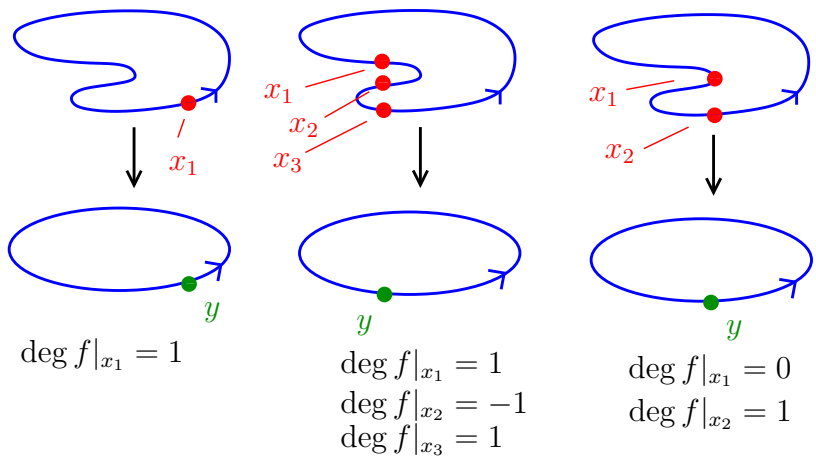

FIGURE 517.

use Lemma 32.24 to determine the various degrees at the given points.[658] We see that the number of preimages and the degrees at the points in the preimages vary, but in all three cases the sum of the degrees at the points in the preimage is the same.
(3) We consider the map

$$\begin{array}{rcl} f\colon S^1 & \to & S^1 \\ z & \mapsto & z^m \end{array}$$

We had already determined in Lemma 32.15 that $\deg(f) = m$. Now we will show that the degree can also easily be determined using Proposition 32.26.

First let $m \neq 0$. Then we choose $y = 1$. The preimages of y are given by $x_j = e^{2\pi i j/m}$ where $j = 1, \dots, m$. It follows from Lemma 32.24 (2) that for each i we have

$$\deg f|_{x_i} = \begin{cases} 1, & \text{if } m > 0, \\ -1, & \text{if } m < 0. \end{cases}$$

Thus it follows from Proposition 32.26 that $\deg f = |m| \cdot \operatorname{sign}(m) = m$. If $m = 0$, then $\deg f = 0$. The easiest way to see this is to take $y = -1$, since in this case the preimage is the empty set.

As promised, we can now provide an answer to Question 32.21:

[658] Why is in the third example the degree $\deg f|_{x_1}$ equal to zero?

Proposition 32.27. *Let f be a complex polynomial of degree ≥ 1. The degree of the map*

$$\begin{array}{rcl} \Theta(f)\colon S^2 = \mathbb{C}\cup\{\infty\} & \to & \mathbb{C}\cup\{\infty\} = S^2 \\ z & \mapsto & \begin{cases} f(z), & \text{if } z\in\mathbb{C}, \\ \infty, & \text{if } z=\infty \end{cases} \end{array}$$

equals the degree of the polynomial f.

Sketch of proof. Let f be a complex polynomial of degree $n \geq 1$. We also consider the polynomial $g(z) = z^n$. We calculate that

$$\deg(\Theta(f)) \overset{\substack{\text{by Lemma 32.16 (3), since by Exercise 9.4 we know that } \Theta(f) \text{ and } \Theta(g) \text{ are homotopic} \\ \downarrow}}{=} \deg(\Theta(g(z)=z^n)) \underset{\substack{\uparrow \\ \text{follows from Proposition 32.26 and Lemma 32.24, see Exercise 32.5}}}{=} n.$$

□

More excitingly, we can provide a new proof for the Fundamental Theorem of Algebra.

Theorem 7.22. (Fundamental Theorem of Algebra) *Every nonconstant polynomial with coefficients in $\mathbb{C}$ has a zero in $\mathbb{C}$.*

Proof. Let f be a nonconstant polynomial with complex coefficients. In other words, f is a complex polynomial of degree $n \geq 1$. By Proposition 32.27 we know that the degree of the self-map $\Theta(f)$ of $S^2 = \mathbb{C}\cup\{\infty\}$ equals $n \geq 1$. By Lemma 32.16 (2) this implies that $\Theta(f)\colon \mathbb{C}\cup\{\infty\} \to \mathbb{C}\cup\{\infty\}$ is surjective, in particular 0 lies in the image of $\Theta(f)$. Since $\Theta(f)(\infty) = \infty$ we see that 0 lies in the image of $\mathbb{C}$. In other words, there exists a $z \in \mathbb{C}$ with $\underbrace{\Theta(f)(z)}_{=f(z)} = 0$. □

Exercises for Chapter 32.

Exercise 32.1. For which $n \in \mathbb{N}$ does there exist a singular simplex $\sigma\colon \Delta^n \to S^n$ that represents a generator of $H_n(S^n)$?

Exercise 32.2. Let M be a non-empty topological manifold. Show that $M \neq \partial M$, i.e. show that there exists a point in $M \setminus \partial M$.

Exercise 32.3. Let M be an m-dimensional topological manifold and let $P \in \partial M$. Show that $H_k(M, M\setminus\{P\}) = 0$ for all k.

Exercise 32.4. On S^{2k} we had found a vector field which vanishes at *precisely two* points. Does there exist a vector field on S^2 which vanishes on only *one* point?

Exercise 32.5. Let $n \geq 1$. We consider the complex polynomial $g(z) = z^n$. Show that the degree of the map $\Theta(g)\colon S^2 \to S^2$ equals n.
Hint: Use Proposition 32.26 and Lemma 32.24.

Exercise 32.6. Let $f = f(z)$ be a polynomial with complex coefficients of degree ≥ 1. Let $\Theta(f)$ be the corresponding self-map of $S^2 = \mathbb{C} \cup \{\infty\}$. Show that the local degree of $\Theta(f)$ at a root of $f(z)$ equals the multiplicity of the root.

33. The Mayer–Vietoris sequence and its applications

In this chapter we will state and prove the Mayer–Vietoris sequence for homology groups. It makes it possible to compute the homology groups of a topological space from the homology groups of appropriate subspaces. The role of the Mayer–Vietoris sequence in homology theory is similar to the role of the Seifert-van Kampen Theorem 14.1 for fundamental groups. The Mayer–Vietoris sequence will give us the tool to compute the homology groups of many topological spaces that we are interested in. In particular we will determine the homology groups of $\mathbb{R}\mathrm{P}^2$, the torus and the Klein bottle.

33.1. **Split exact sequences.** We already saw in Theorem 31.2 that homology groups of different topological spaces are sometimes related by a long exact sequence of homology groups. The Mayer–Vietoris sequence that we will introduce later on in this chapter is another instance of such a long exact sequence. Very often one ends up in the situation that one knows the homology groups of two out of three topological spaces and we would like to determine the homology groups of the third topological space from the long exact sequence.

Algebraically the question is as follows: suppose we are given an exact sequence

$$\ldots \to A_n \to B_n \to C_n \to A_{n-1} \to \ldots$$

of abelian groups where we know the groups A_* and C_*, can we determine the groups B_* from this long exact sequence? The same question of course also arises when the roles of A, B and C are switched.

In this section we will study the simplest case, namely the case of a short exact sequence

$$0 \to A \to B \to C \to 0.$$

If we know A and C, can we read "read off" B from this short exact sequence? In general the answer is no. For example the short exact sequence

$$0 \to \mathbb{Z}_2 \longrightarrow B \longrightarrow \mathbb{Z}_2 \to 0$$

could be of the form

$$0 \to \mathbb{Z}_2 \xrightarrow{x\mapsto(x,0)} \mathbb{Z}_2 \oplus \mathbb{Z}_2 \xrightarrow{(x,y)\mapsto y} \mathbb{Z}_2 \to 0$$

but it could also be of the form[659]

$$0 \to \mathbb{Z}_2 \xrightarrow{x\mapsto 2x} \mathbb{Z}_4 \xrightarrow{x\mapsto x} \mathbb{Z}_2 \to 0.$$

In this short section we will give a criterion for when the naive guess $B \cong A \oplus C$ is actually the correct answer.

Definition. We say that a short exact sequence

$$0 \to A \xrightarrow{i} B \xrightarrow{p} C \to 0$$

of (not necessarily abelian) groups *splits*, if there exists a *splitting* $s\colon C \to B$, i.e. a homomorphism $s\colon C \to B$ such that $p \circ s = \mathrm{id}_C$.

[659] Are there any other possibilities for the isomorphism type of B?

For example the short exact sequence

$$0 \to \mathbb{Z} \xrightarrow{k \mapsto (k,0)} \mathbb{Z} \oplus \mathbb{Z}_n \xrightarrow{(k,l) \mapsto l} \mathbb{Z}_n \to 0$$

splits, in fact a splitting is given by the map $b \mapsto (0, b)$. On the other hand the short exact sequence

$$0 \to \mathbb{Z} \xrightarrow{k \mapsto nk} \mathbb{Z} \to \mathbb{Z}_n \to 0.$$

does not split.[660]

Lemma 33.1. *Let*

$$0 \to A \xrightarrow{i} B \xrightarrow{p} C \to 0$$

be a short exact sequence of abelian groups. If C is a free abelian group, then the short exact sequence splits.

Proof. Let $\{c_i\}_{i \in I}$ be a basis of the free abelian group C. For each $c_i \in C$ we choose a $b_i \in B$ with $p(b_i) = c_i$. By Lemma 11.1 there exists a unique homomorphism $s\colon C \to B$ with $s(c_i) = b_i$ for all i. We have $(p \circ s)(c_i) = c_i$ for each c_i. But then it follows from the uniqueness part of Lemma 11.1 that $p \circ s = \mathrm{id}_C$. The homomorphism s is thus indeed a splitting. □

The following lemma gives two useful criteria for a short exact sequence to split.

Lemma 33.2. *Let*

$$0 \to A \xrightarrow{i} B \xrightarrow{p} C \to 0$$

be a short exact sequence of abelian groups. Then the following statements are equivalent:

(1) *there exists a homomorphism $t\colon B \to A$ such that $t \circ i = \mathrm{id}_A$,*
(2) *there exists an isomorphism $\Phi\colon B \to A \oplus C$ such that the following diagram commutes:*

$$\begin{tikzcd}
 & & B \arrow[dd, "\Phi", "\cong"'] \arrow[dr, "p"] & & \\
0 \arrow[r] & A \arrow[ur, "i"] \arrow[dr] & & C \arrow[r] & 0 \\
 & & A \oplus C \arrow[ur] & &
\end{tikzcd}$$

where the lower left diagonal map is the obvious inclusion and the lower right diagonal map is the obvious projection map,
(3) *the short exact sequence splits.*

Proof.
(3)⇒(1) Let $s\colon C \to B$ be a splitting, i.e. let s be a homomorphism such that $p \circ s = \mathrm{id}_C$. We need to find an appropriate homomorphism $t\colon B \to A$. Since the sequence

[660] Why does it not split?

is exact, our task is basically the same as finding an appropriate homomorphism $B \to \ker(p)$. Let $b \in B$. We have

$$p(b - s(p(b))) \;=\; p(b) - (\underbrace{p \circ s}_{=\mathrm{id}})(p(b)) \;=\; p(b) - p(b) \;= 0.$$

By the exactness of the short exact sequence there exists a unique $a \in A$ with $i(a) = b - s(p(b))$. We define $t(b) := a$. It follows easily from the fact that p and s are homomorphisms that the map $t\colon B \to A$ is a homomorphism. It remains to show that $t \circ i = \mathrm{id}_A$. Let $a \in A$. We have to show that $t(i(a)) - a = 0$. Since i is injective it suffices to show that $i(t(i(a))) - i(a) = 0$. We have

$$i(t(i(a))) - i(a) \;\underset{\substack{\uparrow \\ \text{since } t(y) \text{ is the unique element} \\ \text{with } i(t(y)) = y - s(p(y))}}{=}\; (i(a) - s(p(i(a)))) - i(a) \;\underset{\substack{\uparrow \\ \text{since } p \circ i = 0}}{=}\; i(a) - i(a) \;=\; 0.$$

(1)⇒(2) Let $t\colon B \to A$ be a homomorphism such that $t \circ i = \mathrm{id}_A$. We define

$$\begin{aligned} \Phi\colon B &\to A \oplus C \\ b &\mapsto t(b) \oplus p(b). \end{aligned}$$

It follows easily from the exactness of the initial sequence that this map is in fact an isomorphism.[661] It is straightforward to verify that Φ has all the other desired properties.

(2)⇒(3) Now suppose we are given an isomorphism $\Phi\colon B \to A \oplus C$ such that the given diagram commutes. It follows immediately from the definitions and given properties that the map

$$C \xrightarrow{c \mapsto (0,c)} A \oplus C \xrightarrow{\Phi^{-1}} B$$

is a splitting. □

Remark. We quickly want to discuss the more general case of short exact sequences of groups that are not necessarily abelian. The three statements of Lemma 33.2 (with minor modifications) still make sense. But it is no longer true that (3) implies (1).[662] But it is true that (1) and (2) are equivalent, in fact one can use almost verbatim the same proof. For the reader's convenience we spell out the statement, namely given a short exact sequence

$$\{e\} \;\to\; A \;\xrightarrow{i}\; B \;\xrightarrow{p}\; C \;\to\; \{e\}$$

of groups the following two statements are equivalent:

(1) there exists a homomorphism $t\colon B \to A$ such that $t \circ i = \mathrm{id}_A$,

[661] In fact the argument is basically the same as in the proof of Lemma 31.1 (4a).

[662] In the above proof of (3) ⇒ (1) we did use that B is abelian. In fact one can also give easy counterexamples, e.g. consider $0 \to \mathbb{Z}_3 \to S_3 \to \mathbb{Z}_2 \to 0$ where $S_3 \to \mathbb{Z}_2$ is the unique epimorphism from the permutation group S_3 onto $\mathbb{Z}_2$.

(2) there exists an isomorphism $\Phi\colon B \to A \times C$ such that the following diagram commutes:

$$\begin{tikzcd}
 & & B \arrow[dr, "p"] \arrow[dd, "\Phi", "\cong"'] & & \\
0 \arrow[r] & A \arrow[ur, "i"] \arrow[dr] & & C \arrow[r] & 0. \\
 & & A \times C \arrow[ur] & &
\end{tikzcd}$$

In many applications we only need the following corollary that is an immediate consequence of Lemmas 33.1 and 33.2.

Corollary 33.3. *Let*

$$0 \;\to\; A \;\xrightarrow{i}\; B \;\xrightarrow{p}\; C \;\to\; 0$$

be a short exact sequence of abelian groups. Then the following hold:

(1) *If C is a free abelian group, then $B \cong A \oplus C$.*
(2) *Suppose A and C are free abelian groups. If X is a basis for A and if $Y \subset B$ is a subset such that $p(Y)$ is a basis for C, then $X \cup Y$ is a basis for the free abelian group B.*

Proof. The first statement is an immediate consequence of Lemmas 33.1 and 33.2. The second statement follows easily from Lemma 33.2 (1) $\Rightarrow$ (3). We leave the details as an exercise to the reader. □

The above discussion deals with the case of a short exact sequence. The following lemma allows us to break a long exact sequence into shorter exact sequences.

Lemma 33.4. *Let*

$$\ldots \;\to\; A_{n+2} \;\xrightarrow{f_{n+2}}\; A_{n+1} \;\xrightarrow{f_{n+1}}\; A_n \;\xrightarrow{f_n}\; A_{n-1} \;\xrightarrow{f_{n-1}}\; A_{n-2} \;\to\; \ldots$$

be an exact sequence of abelian groups. Then for any n the sequences

$$0 \;\to\; \operatorname{coker}\left\{A_{n+2} \xrightarrow{f_{n+2}} A_{n+1}\right\} \;\xrightarrow{f_{n+1}}\; A_n \;\xrightarrow{f_n}\; A_{n-1} \;\xrightarrow{f_{n-1}}\; A_{n-2} \;\to\; \ldots$$

and

$$\ldots \;\to\; A_{n+2} \;\xrightarrow{f_{n+2}}\; A_{n+1} \;\xrightarrow{f_{n+1}}\; A_n \;\xrightarrow{f_n}\; \ker\left\{A_{n-1} \xrightarrow{f_{n-1}} A_{n-2}\right\} \;\to\; 0$$

are also exact. In particular

$$0 \;\to\; \operatorname{coker}\left\{A_{n+2} \xrightarrow{f_{n+2}} A_{n+1}\right\} \;\xrightarrow{f_{n+1}}\; A_n \;\xrightarrow{f_n}\; \ker\left\{A_{n-1} \xrightarrow{f_{n-1}} A_{n-2}\right\} \;\to\; 0$$

is a short exact sequence.

Proof. The statements follow immediately from the definitions. □

Example. A typical application is that if we are given an exact sequence

$$\dots\ A_{n+2} \xrightarrow{f_{n+2}} A_{n+1} \xrightarrow{f_{n+1}} A_n \xrightarrow{f_n=0} A_{n-1} \xrightarrow{f_{n-1}} A_{n-2} \xrightarrow{f_{n-2}} A_{n-3}\dots$$

of abelian groups such that the map f_n is the zero map, then the exact sequence can be split "into the two halves" along that zero map, i.e.

$$0 \quad \to \quad A_{n-1} \xrightarrow{f_{n-1}} A_{n-2} \xrightarrow{f_{n-2}} A_{n-3}\dots$$

and

$$\dots\ A_{n+2} \xrightarrow{f_{n+2}} A_{n+1} \xrightarrow{f_{n+1}} A_n \quad \to 0$$

are also exact sequences. In the remainder of this course we will frequently use this fact without explicitly citing Lemma 33.4.

33.2. **The Mayer–Vietoris sequence.** In the following theorem and throughout the subsequent discussion we will use the following notation: given a topological space D and a subset $C \subset D$, we denote the corresponding inclusion map $C \to D$ by i_C. To avoid pandemonium with subscripts we often drop denote the inclusion induced maps on homology by i_C instead of the more accurate $(i_C)_*$.

Theorem 33.5. (Mayer–Vietoris) [663] *Let X be a topological space and let $A, B \subset X$ be subsets such that $X = \mathring{A} \cup \mathring{B}$. Then the following two statements hold:*

(1) *For each $n \in \mathbb{N}$ there exists a unique homomorphism*

$$\partial_n \colon H_n(X) \ \to\ H_{n-1}(A \cap B)$$

which has the following property: for every $a \in C_n(A)$ and $b \in C_n(B)$ such that $a + b \in C_n(X)$ is a cycle we have[664]

$$\partial_n([a+b]) \ = \ [\,\partial a\,] \ = \ -\,[\,\partial b\,] \ \in\ H_{n-1}(A \cap B).$$

We refer to $\partial_n H_n(X) \to H_{n-1}(A \cap B)$ as the connecting homomorphisms *corresponding to (X, A, B).*

(2) *The following sequence is exact:*

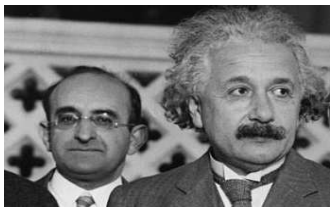
$$\cdots \to H_n(A \cap B) \xrightarrow{i_{A\cap B} \oplus -i_{A\cap B}} H_n(A) \oplus H_n(B) \xrightarrow{i_A + i_B} H_n(X) \xrightarrow{\partial_n} H_{n-1}(A \cap B) \to \dots$$

Totally analogous statements also hold if we replace the homology groups of $A \cap B, A, B$ and X by the corresponding reduced homology groups.

The long exact sequence in Theorem 33.5 is usually called the Mayer–Vietoris sequence of the decomposition $X = A \cup B$.

[663] Walther Mayer (1887-1948) and Leopold Vietoris (1891-2002) were two Austrian mathematicians. Vietoris was the longest living Austrian man ever.

[664] Here in the expression ∂a we mean by ∂ the boundary map $\partial \colon C_n(A) \to C_{n-1}(A)$. In our case we will see that $\partial a \in C_{n-1}(A \cap B) \subset C_{n-1}(A)$. A similar statement holds for ∂b.



Walther Mayer (1887-1948) with some other person

Leopold Vietoris (1891-2002) at 110

FIGURE 518.

Example. In Figure 519 we consider the annulus X together with two closed subsets A and B with $X = \mathring{A} \cup \mathring{B}$. Furthermore we show chains $a \in C_1(A)$ and $b \in C_1(B)$ such that $a + b$ form a cycle in $C_1(X)$. The connecting homomorphism of the Mayer–Vietoris sequence sends $[a + b] \in H_1(X)$ to $[\partial a] = -[\partial b] \in H_0(A \cap B)$.

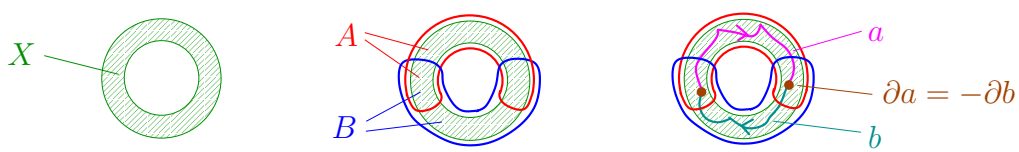


FIGURE 519.

Proof. Let X be a topological space and let $A, B \subset X$ be subsets such that $X = \mathring{A} \cup \mathring{B}$. As a reminder, following the notation from page 787 we write

$$C_n^{\{A,B\}}(X) \ := \ \{a + b \,|\, a \in C_n(A) \text{ and } b \in C_n(B)\}.$$

The inclusion maps induce the following sequence of chain maps:

$$0 \to C_*(A \cap B) \xrightarrow{i_{A\cap B} \oplus -i_{A\cap B}} C_*(A) \oplus C_*(B) \xrightarrow{i_A + i_B} C_*^{\{A,B\}}(X) \to 0.$$

Claim. The above sequence of chain maps is exact.

We prove the claim in the following four steps:

(1) It is clear that each of the maps $C_*(A \cap B) \to C_*(A)$ and $C_*(A \cap B) \to C_*(B)$ is already injective, in particular the map $i_{A\cap B} \oplus -i_{A\cap B}$ is injective.
(2) It is an immediate consequence of the definition of $C_*^{\{A,B\}}(X)$ that the map $i_A + i_B$ is surjective.
(3) It follows immediately from the definitions that the composition of both maps is the zero map,[665] i.e. $\mathrm{im}(i_{A\cap B} \oplus -i_{A\cap B}) \subset \ker(i_A + i_B)$.

[665]Note that here we use the minus-sign that appears in the first map.

(4) It remains to show that $\ker(i_A + i_B) \subset \operatorname{im}(i_{A\cap B} \oplus -i_{A\cap B})$. Thus let $x \in C_n(A)$ and $y \in C_n(B)$ such that $(i_A + i_B)(x + y) = 0$. By definition this means that x and y, viewed as elements in $C_n(X)$, satisfy $x = -y$. This means that x lies in $C_n(A)$ and also in $C_n(B)$. Put differently, $x \in C_n(A) \cap C_n(B) = C_n(A \cap B)$. But then we have $(i_{A\cap B} \oplus -i_{A\cap B})(x) = x + y$.

Thus we have proved the claim.

For each $n \in \mathbb{N}$ we denote by

$$p_n \colon H_n^{\{A,B\}}(X) \;\to\; H_{n-1}(A \cap B)$$

the connecting homomorphism of the above short exact sequence of chain complexes, as defined on page 770. We deduce from Proposition 31.10 that

$$\cdots \to H_n(A\cap B) \xrightarrow{i_{A\cap B}\oplus -i_{A\cap B}} H_n(A) \oplus H_n(B) \xrightarrow{i_A+i_B} H_n^{\{A,B\}}(X) \xrightarrow{p_n} H_{n-1}(A\cap B) \to \dots$$

is an exact sequence. It follows from Proposition 31.21, together with our hypothesis that $X = \mathring{A} \cup \mathring{B}$, that for every $n \in \mathbb{N}_0$ the inclusion map

$$C_*^{\{A,B\}}(X) \;\to\; C_*(X)$$

induces an isomorphism

$$\Phi_n \colon H_n^{\{A,B\}}(X) \;\xrightarrow{\cong}\; H_n(X).$$

For each $n \in \mathbb{N}_0$ we now write $\partial_n := p_n \circ \Phi_n^{-1}$.

It remains to show that these maps have the two desired properties stated in the theorem:

(2) It is clear from the above discussion that the sequence given in (2) is indeed exact.

(1) We leave it as an exercise to verify that it follows from the definition of the connecting homomorphism p_n on page 770 that for every $a \in C_n(A)$ and $b \in C_n(B)$ such that $a + b \in C_n(X)$ is a cycle we have

$$\partial_n([a+b]) \;=\; p_n([a+b]) \;=\; [\partial a] \;=\; -\,[\partial b] \;\in\; H_{n-1}(A\cap B).$$

Furthermore, the isomorphism $\Phi_n \colon H_n^{\{A,B\}}(X) \xrightarrow{\cong} H_n(X)$ shows that every element in $H_n(X)$ is of the form $[a + b]$ for some $a \in C_n(A)$ and $b \in C_n(B)$, which implies that ∂_n is uniquely determined by the above rule.

We leave it as an exercise to verify that the analogous statements also hold if we replace the homology groups of $A\cap B, A, B$ and X by the corresponding reduced homology groups. □

In some applications it is useful to know that the connecting homomorphisms from the Mayer–Vietoris Theorem 33.5 behaves well under induced maps, i.e. that it is a natural map. This is formulated more precisely in the following lemma.

Lemma 33.6. $(*)$ *Let X and Y be two topological spaces and let $A, B \subset X$ and $C, D \subset Y$ be subsets with $X = \mathring{A} \cup \mathring{B}$ and $Y = \mathring{C} \cup \mathring{D}$. If $f \colon X \to Y$ is a map with $f(A) \subset C$ and*

$f(B) \subset D$, then for every $n \in \mathbb{N}$ the following diagram commutes

$$\begin{tikzcd} H_n(X) \arrow[r, "\partial"] \arrow[d, "f_*"'] & H_{n-1}(A \cap B) \arrow[d, "f_*"] \\ H_n(Y) \arrow[r, "\partial"] & H_{n-1}(C \cap D) \end{tikzcd}$$

where the horizontal maps are the connecting homomorphisms introduced in the Mayer–Vietoris Theorem 33.5 (1).

Proof. The statement follows immediately from the definition of the connected homomorphisms. □

We conclude this section with the following variation on the Mayer–Vietoris Theorem 33.5. This theorem might sound rather unnatural, but it will play an important role in a later chapter.

Theorem 33.7. (The inverted Mayer–Vietoris Theorem) $(*)$ *Let X be a topological space and let U and V be open subsets. Then for all $n \in \mathbb{N}_0$ there exists a natural homomorphism $\partial_n \colon H_n(X, U \cup V) \to H_{n-1}(X, U \cap V)$ such that*

$$\ldots \to H_n(X, U \cap V) \xrightarrow{i \oplus -i} H_n(X, U) \oplus H_n(X, V) \xrightarrow{i+i} H_n(X, U \cup V) \xrightarrow{\partial} H_{n-1}(X, U \cap V) \to \ldots$$

is an exact sequence.

Proof $(*)$. As in the proof of Theorem 33.5 we have a short exact sequence

$$0 \;\to\; C_n(X, U \cap V) \;\to\; C_n(X, U) \oplus C_n(X, V) \;\to\; C_n(X)/C_n^{\{U,V\}}(U \cup V) \;\to\; 0.$$

Thus we get a corresponding long exact sequence of homology groups. It suffices to show that the homology groups of the chain complex on the right are precisely the homology groups of the pair $(X, U \cup V)$. To do so we consider the following commutative pair of short exact sequences

$$\begin{tikzcd} 0 \arrow[r] & C_*^{\{U,V\}}(U \cup V) \arrow[r] \arrow[d] & C_*(X) \arrow[r] \arrow[d] & C_*(X)/C_*^{\{U,V\}}(U \cup V) \arrow[r] \arrow[d] & 0 \\ 0 \arrow[r] & C_*(U \cup V) \arrow[r] & C_*(X) \arrow[r] & C_*(X, U \cup V) \arrow[r] & 0. \end{tikzcd}$$

We obtain the corresponding long exact sequence of homology groups:

$$\begin{tikzcd} \ldots \arrow[r] & H_n^{\{U,V\}}(U \cup V) \arrow[r] \arrow[d] & H_n(X) \arrow[r] \arrow[d] & H_n\big(C_*(X)/C_*^{\{U,V\}}(U \cup V)\big) \arrow[r] \arrow[d] & H_{n-1}^{\{U,V\}}(U \cup V) \arrow[r] \arrow[d] & \ldots \\ \ldots \arrow[r] & H_n(U \cup V) \arrow[r] & H_n(X) \arrow[r] & H_n(X, U \cup V) \arrow[r] & H_{n-1}(U \cup V) \arrow[r] & \ldots \end{tikzcd}$$

It follows from Proposition 31.21 that the first and fourth vertical map are an isomorphism. The second map and the fifth map (which for space reasons is not shown) are the identity. Hence it follows from the Five Lemma 31.11 that the third vertical map is also an isomorphism. □

33.3. **Applications of the Mayer–Vietoris sequence.** As a warm-up we first consider the homology groups of the suspension $\Sigma(X)$ of a topological space X. More precisely, we have the following lemma which basically gives a new proof for Proposition 32.14.

Lemma 33.8. *Let $k \in \mathbb{Z}$. Given any topological space X we have a natural isomorphism*

$$\Sigma_X \colon \widetilde{H}_k(X) \xrightarrow{\cong} \widetilde{H}_{k+1}(\Sigma(X)).$$

Remark. Let X be a topological space. In Exercise 33.4 we will see that the two natural isomorphisms $\widetilde{H}_k(\Sigma(X)) \xrightarrow{\cong} \widetilde{H}_{k-1}(X)$ that we constructed in Proposition 32.14 and that we constructed in the proof of Lemma 33.8 are actually the same on the nose.

Proof. Let $k \in \mathbb{Z}$.

(1) Let X be a topological space. We denote by $p \colon X \times [-1,1] \to \Sigma(X)$ the obvious projection. As on page 818 we consider the subspaces $C_+X = p(X \times (-1,1]))$ and $C_-X = p(X \times [-1,1))$. Note that C_+X and C_-X are both open subsets of $\Sigma(X)$ and that $\Sigma(X) = C_+X \cup C_-X$. By the same argument as in the proof of Lemma 15.1 we see that both C_+X and C_-X admit a deformation retraction to a point. It follows from Lemma 9.10 that both are contractible, therefore by Lemma 31.1 (7) the reduced homologies of C_+X and C_-X vanish. It follows immediately from the long exact sequence in reduced homology from the Mayer–Vietoris Theorem 33.5 that the connecting homomorphism

$$\partial \colon \widetilde{H}_{k+1}(\Sigma(X)) \to \widetilde{H}_k(C_+X \cap C_-X)$$

is in fact an isomorphism. But $X = X \times \{0\}$ is evidently a deformation retract of $C_+X \cap C_-X = X \times (-1,1)$. Thus we obtain from Lemma 31.1 (6) that the inclusion induced map $i_* \colon \widetilde{H}_k(X \times \{0\}) \to \widetilde{H}_k(C_+X \cap C_-X)$ is an isomorphism. We define Σ_X to be the map

$$\widetilde{H}_k(X) = \widetilde{H}_k(X \times \{0\}) \xrightarrow{i_*} \widetilde{H}_k(C_+X \cap C_-X) \xrightarrow{\partial^{-1}} \widetilde{H}_{k+1}(\Sigma(X)).$$

(2) It follows easily from the definition of Σ_X and Lemma 33.6 that the isomorphism Σ_X is natural. □

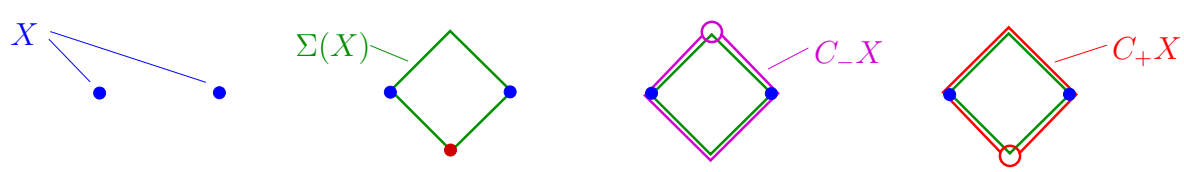

FIGURE 520. Illustration for the proof of Lemma 33.8.

As our next example we want to determine the homology groups of the 2-dimensional projective space $\mathbb{R}\mathrm{P}^2$.

Lemma 33.9. *We have*

$$H_n(\mathbb{R}\mathrm{P}^2) \;\cong\; \begin{cases} 0, & \text{if } n \geq 2, \\ \mathbb{Z}_2, & \text{if } n = 1, \\ \mathbb{Z}, & \text{if } n = 0. \end{cases}$$

Proof. In the proof of Lemma 33.9 we use the description from page 113 of $\mathbb{R}\mathrm{P}^2$ as

$$\mathbb{R}\mathrm{P}^2 \;=\; \overline{B}^2/\sim \quad \text{where } x \sim y \text{ if } x, y \in \partial\overline{B}^2 \text{ and } x = -y.$$

In the following we denote by p the projection map $\overline{B}^2 \to \overline{B}^2/\sim$. We consider the open subsets

$$A \;:=\; p\big(\big\{z \in \overline{B}^2 \,\big|\, |z| > \tfrac{1}{4}\big\}\big) \quad \text{and} \quad B \;:=\; p\big(\big\{z \in \overline{B}^2 \,\big|\, |z| < \tfrac{3}{4}\big\}\big).$$

Evidently we have $\mathring{A} \cup \mathring{B} = A \cup B = \mathbb{R}\mathrm{P}^2$. From Mayer–Vietoris Theorem 33.5 we obtain the following long exact sequence of homology groups:

$$\cdots \to \widetilde{H}_2(A) \oplus \widetilde{H}_2(B) \;\to\; \widetilde{H}_2(\mathbb{R}\mathrm{P}^2) \;\xrightarrow{\partial}\; \widetilde{H}_1(A \cap B) \;\to\; \widetilde{H}_1(A) \oplus \widetilde{H}_1(B) \;\to\; \widetilde{H}_1(\mathbb{R}\mathrm{P}^2) \;\to \ldots$$

Now we have to collect all the available information on the reduced homology groups of

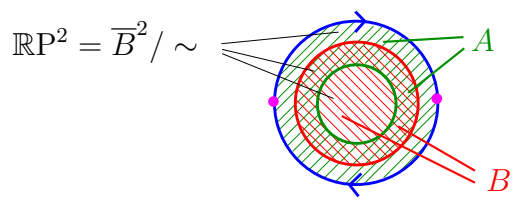

FIGURE 521. Illustration for the proof of Lemma 33.9.

A, B and $A \cap B$. We make the following observations:

(1) We remarked on page 762 that the reduced homology of a disk vanishes, i.e. we have $\widetilde{H}_n(B) = 0$ for all $n \in \mathbb{N}_0$.

(2) The map $j\colon S^1 \to A \cap B = p(\{z \in \overline{B}^2 \,|\, |z| \in (\frac{1}{4}, \frac{3}{4})\}$ given by $z \mapsto \frac{1}{2}z$ is a homotopy equivalence, since $p(\frac{1}{2}S^1)$ is a deformation retract of $A \cap B$. It follows from Corollary 30.8 (2) and Proposition 31.3 that $\widetilde{H}_n(A \cap B) = 0$ for $n \neq 1$ and that $j_*\colon \widetilde{H}_1(S^1) \to \widetilde{H}_1(A \cap B)$ is an isomorphism.

(3) We consider the retraction

$$\begin{array}{rcl} r\colon A & \to & \{z \in \partial\overline{B}^2\}/z \sim -z \\ p(se^{i\varphi}) & \mapsto & e^{i\varphi} \end{array}$$

which is easily seen to be a homotopy equivalence and we also consider the homeomorphism

$$\begin{array}{rcl} f\colon \{z \in \partial\overline{B}^2\}/z \sim -z & \to & S^1 \\ z & \mapsto & z^2. \end{array}$$

As in (2) it follows that $\widetilde{H}_n(A) = 0$ for $n \neq 1$ and that $(f \circ r)_* \colon \widetilde{H}_1(A) \to \widetilde{H}_1(S^1)$ is an isomorphism.

The above Mayer–Vietoris sequence is thus in our case of the following form:

$$\begin{array}{ccccccccccc}
\ldots \to 0 \to \widetilde{H}_3(\mathbb{R}\mathrm{P}^2) \to 0 \to 0 \to \widetilde{H}_2(\mathbb{R}\mathrm{P}^2) & \xrightarrow{\partial} & \widetilde{H}_1(A \cap B) & \xrightarrow{\quad i_* \quad} & \widetilde{H}_1(A) & \xrightarrow{i_*} & \widetilde{H}_1(\mathbb{R}\mathrm{P}^2) \to 0 \\
 & & {\scriptstyle j_*}\uparrow{\scriptstyle \cong} & & {\scriptstyle \cong}\downarrow{\scriptstyle (f\circ r)_*} & & \\
 & & H_1(S^1) & \xrightarrow[\cdot \deg(f\circ r\circ i\circ j)]{(f\circ r\circ i\circ j)_*} & H_1(S^1). & &
\end{array}$$

We obtain immediately that $\widetilde{H}_n(\mathbb{R}\mathrm{P}^2) = 0$ for $n \geq 3$. Furthermore it follows immediately from the definitions that the map $f \circ r \circ i \circ j \colon S^1 \to S^1$ is given by $z \mapsto z^2$ which implies by Lemma 32.15 that $\deg(f \circ r \circ i \circ j) = 2$. Thus we obtain the following exact sequence

$$0 \;\to\; \widetilde{H}_2(\mathbb{R}\mathrm{P}^2) \;\to\; \mathbb{Z} \;\xrightarrow{\cdot 2}\; \mathbb{Z} \;\to\; \widetilde{H}_1(\mathbb{R}\mathrm{P}^2) \;\to\; 0.$$

It follows from the discussion on page 764 that

$$\widetilde{H}_2(\mathbb{R}\mathrm{P}^2) \;\cong\; \ker\left\{\mathbb{Z} \xrightarrow{\cdot 2} \mathbb{Z}\right\} \;=\; 0 \quad \text{and} \quad \widetilde{H}_1(\mathbb{R}\mathrm{P}^2) \;\cong\; \operatorname{coker}\left\{\mathbb{Z} \xrightarrow{\cdot 2} \mathbb{Z}\right\} \;=\; \mathbb{Z}_2. \qquad \square$$

33.4. **The Mayer–Vietoris Theorem for manifolds and CW-complexes.** When we studied fundamental groups we first proved the Seifert-van Kampen Theorem 14.1 for the decomposition of a topological space X into two *open* subsets. Later on we showed in Theorem 14.2 and Theorem 26.13 that an analogous statement holds if we decompose a manifold into suitable submanifolds and if decompose a CW-complex into subcomplexes.

In a similar fashion we now state and prove the "manifold version" and the "CW-complex version" of the Mayer–Vietoris Theorem 33.5.

Theorem 33.10. (Mayer–Vietoris Theorem for manifolds) *Let X be an m-dimensional manifold and let $A, B \subset X$ be two m-dimensional submanifolds such that the following statements hold:*

(1) $X = A \cup B$,
(2) $A \cap B$ is a union of components of ∂A and it is a union of components of ∂B,
(3) A and B are closed subsets of X.

The following two statements hold:

(1) *For each $n \in \mathbb{N}$ there exists a unique homomorphism $\partial_n \colon H_n(X) \to H_{n-1}(A \cap B)$ which has the following property: If $a \in C_n(A)$ and $b \in C_n(B)$ are such that $a + b \in C_n(X)$ is a cycle, then*

$$\partial_n([a+b]) \;=\; [\partial a] \;=\; -\,[\partial b] \;\in\; H_{n-1}(A \cap B).$$

(2) *The following sequence is exact:*

$$\cdots \to H_n(A \cap B) \xrightarrow{i_{A\cap B} \oplus -i_{A \cap B}} H_n(A) \oplus H_n(B) \xrightarrow{i_A + i_B} H_n(X) \xrightarrow{\partial_n} H_{n-1}(A \cap B) \to \ldots$$

A totally analogous statement also holds if we replace the homology groups of $A \cap B, A, B$ and X by the corresponding reduced homology groups.

Proof $(*)$. Let X be an m-dimensional manifold and let $A, B \subset X$ be two m-dimensional submanifolds such that $X = A \cup B$ and such that $A \cap B$ is a union of components of ∂A and it is a union of components of ∂B.

We pick maps $f\colon \partial A \times [0,1) \to A$ and $g\colon \partial B \times [0,1) \to B$ that are provided by the Collar Neighborhood Theorem 10.10. We set

$$U \;:=\; A \cup \underbrace{g((A \cap B) \times [0,1))}_{\subset B \times [0,1)} \quad \text{and} \quad V \;:=\; B \cup \underbrace{f((A \cap B) \times [0,1))}_{\subset A \times [0,1)}.$$

As in the proof of Theorem 14.2 we note that the following statements hold:

(1) A is a deformation retract of U,
(2) B is a deformation retract of V, and
(3) $A \cap B$ is a deformation retract of $U \cap V$.

Now we consider the following diagram

$$\begin{tikzcd}
\dots \arrow[r, dotted] & H_n(A \cap B) \arrow[r, "i \oplus -i"] \arrow[d] & H_n(A) \oplus H_n(B) \arrow[r, "i+i"] \arrow[d] & H_n(X) \arrow[r, dotted, "\partial_n"] \arrow[d, "="] & H_{n-1}(A \cap B) \arrow[r] \arrow[d] & \dots \\
\dots \arrow[r] & H_n(U \cap V) \arrow[r, "i \oplus -i"] & H_n(U) \oplus H_n(V) \arrow[r, "i+i"] & H_n(X) \arrow[r, "\partial_n"] & H_{n-1}(U \cap V) \arrow[r] & \dots
\end{tikzcd}$$

where the bottom sequence is given by the Mayer–Vietoris Theorem 33.5. We make the following observations:

(1) The two squares to the left commute since all the relevant maps are given by inclusions.
(2) The vertical maps are isomorphisms by Corollary 30.8.
(3) By (2) we can now define the dotted map $H_n(X) \xrightarrow{\partial_n} H_{n-1}(A \cap B)$ such that the third square also commutes.

The theorem is now an immediate consequence of the Mayer–Vietoris Theorem 33.5. $\square$

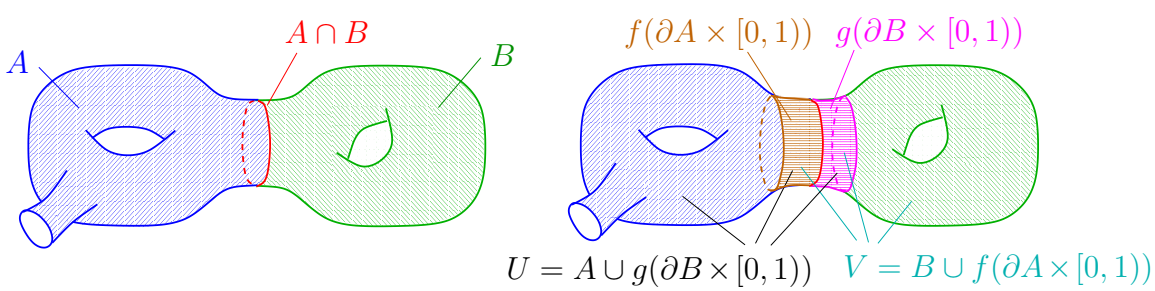

FIGURE 522. Illustration of the proof of Theorem 33.10.

Now we turn to CW-complexes.

Theorem 33.11. (Mayer–Vietoris Theorem for CW-complexes) *Let X be a CW-complex. If A and B are two subcomplexes of X such that $X = A \cup B$, then exactly the same conclusion as in the Mayer–Vietoris Theorem 33.10 for manifolds holds.*

Proof $(*)$. Let X be a CW-complex and let A and B be two subcomplexes of X with $X = A \cup B$. By Proposition 26.11 (8) there exist open neighborhoods U of A and V of B such that the following statements hold:

(1) A is a deformation retract of U,
(2) B is a deformation retract of V, and
(3) $A \cap B$ is a deformation retract of $U \cap V$.

The proof is now verbatim the same as the proof of the Mayer–Vietoris Theorem 33.10 for manifolds. □

Later on we will generalize the above Mayer–Vietoris theorems to "excisive triads". But for the time being we will be able to handle most situations with the Mayer–Vietoris theorems that we had stated.

33.5. **The homology groups of the torus and the Klein bottle.** In this section we will determine the homology groups of the torus and the Klein bottle.

Lemma 33.12. *Let $T = S^1 \times S^1$ be the torus, then*

$$H_n(T) \cong \begin{cases} \mathbb{Z}, & \text{if } n = 0, 2, \\ \mathbb{Z}^2, & \text{if } n = 1, \\ 0, & \text{otherwise.} \end{cases}$$

Proof. Throughout the proof we identify the torus T with $S^1 \times \mathbb{R}/4\mathbb{Z}$ in the obvious way. As usual we denote by $p\colon S^1 \times \mathbb{R} \to T = S^1 \times \mathbb{R}/4\mathbb{Z}$ the projection map. In the following we write $A := p(S^1 \times ([0,1] \cup [3,4]))$ and $B := p(S^1 \times [1,3])$. Evidently we have $T = A \cup B$. Furthermore we write $C_1 := p(S^1 \times \{1\})$ and $C_2 := p(S^1 \times \{3\})$. Evidently we have $A \cap B = C_1 \cup C_2$.

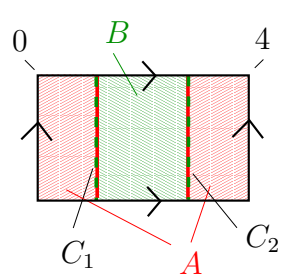

FIGURE 523.

Clearly the hypotheses for the Mayer–Vietoris Theorem 33.10 for manifolds are satisfied for $T = A \cup B$ and we obtain the following long exact sequence in homology[666]

$$\begin{array}{ccccccc}
 & & & \dots & \to & H_2(T) & \xrightarrow{\partial} \\
\to & \begin{matrix} H_1(C_1) \\ H_1(C_2) \end{matrix} & \xrightarrow{\begin{pmatrix} i_{C_1} & i_{C_2} \\ -i_{C_1} & -i_{C_2} \end{pmatrix}} & \begin{matrix} H_1(A) \\ H_1(B) \end{matrix} & \xrightarrow{i_A+i_B} & H_1(T) & \xrightarrow{\partial} \\
\to & \begin{matrix} H_0(C_1) \\ H_0(C_2) \end{matrix} & \xrightarrow{\begin{pmatrix} i_{C_1} & i_{C_2} \\ -i_{C_1} & -i_{C_2} \end{pmatrix}} & \begin{matrix} H_0(A) \\ H_0(B) \end{matrix} & \xrightarrow{i_A+i_B} & H_0(T) & \longrightarrow \quad 0.
\end{array}$$

By Lemma 32.11, for each interval I and each point $x \in I$ the map $(1-t, t) \to (e^{2\pi i t}, x)$ is a singular chain that represents a generator of $H_1(S^1 \times I) \cong \mathbb{Z}$. Now we use this generator to identify the groups $H_1(A)$, $H_1(B)$, $H_1(C_1)$ and $H_1(C_2)$ with $\mathbb{Z}$. The topological spaces A, B, C_1 and C_2 are path-connected, so we can identify their 0-th homology groups with $\mathbb{Z}$ using the isomorphism from Proposition 29.5. Thus we obtain the following Mayer–Vietoris sequence

$$\begin{array}{ccccccc}
 & & & 0 & \to & H_2(T) & \xrightarrow{\partial} \\
\to & \begin{matrix} \mathbb{Z} \\ \mathbb{Z} \end{matrix} & \xrightarrow{\begin{pmatrix} i_{C_1} & i_{C_2} \\ -i_{C_1} & -i_{C_2} \end{pmatrix}} & \begin{matrix} \mathbb{Z} \\ \mathbb{Z} \end{matrix} & \xrightarrow{i_A+i_B} & H_1(T) & \xrightarrow{\partial} \\
\to & \begin{matrix} \mathbb{Z} \\ \mathbb{Z} \end{matrix} & \xrightarrow{\begin{pmatrix} i_{C_1} & i_{C_2} \\ -i_{C_1} & -i_{C_2} \end{pmatrix}} & \begin{matrix} \mathbb{Z} \\ \mathbb{Z} \end{matrix} & \xrightarrow{i_A+i_B} & H_0(T) & \longrightarrow \quad 0.
\end{array}$$

To determine the homology groups $H_2(T)$ and $H_1(T)$ we now need to understand the maps in the above long exact sequence. It follows immediately from the choice of the identifications of the 0-th and first homology groups that all the inclusion maps induce the identity. Put differently, we obtain the following long exact sequence:

$$\begin{array}{ccccccc}
 & & & 0 & \to & H_2(T) & \xrightarrow{\partial} \\
\to & \begin{matrix} \mathbb{Z} \\ \mathbb{Z} \end{matrix} & \xrightarrow{\begin{pmatrix} 1 & 1 \\ -1 & -1 \end{pmatrix}} & \begin{matrix} \mathbb{Z} \\ \mathbb{Z} \end{matrix} & \xrightarrow{(1\ 1)} & H_1(T) & \xrightarrow{\partial} \\
\to & \begin{matrix} \mathbb{Z} \\ \mathbb{Z} \end{matrix} & \xrightarrow{\begin{pmatrix} 1 & 1 \\ -1 & -1 \end{pmatrix}} & \begin{matrix} \mathbb{Z} \\ \mathbb{Z} \end{matrix} & \xrightarrow{(1\ 1)} & \mathbb{Z} & \longrightarrow \quad H_0(T).
\end{array}$$

[666]Here we write

$$\begin{matrix} H_i(C_1) \\ H_i(C_2) \end{matrix} \text{ instead of } H_i(C_1) \oplus H_i(C_2) \quad \text{and} \quad \begin{matrix} H_i(A) \\ H_i(B) \end{matrix} \text{ instead of } H_i(A) \oplus H_i(B).$$

The reason is that we think of direct sums as columns vectors so that we can use the usual matrix notation for describing the maps between the direct sums.

It follows from the discussion on page 764 that

$$H_2(T) \;\cong\; \ker\left(\begin{matrix}\mathbb{Z}\\ \mathbb{Z}\end{matrix} \xrightarrow{\begin{pmatrix}1 & 1\\ -1 & -1\end{pmatrix}} \begin{matrix}\mathbb{Z}\\ \mathbb{Z}\end{matrix} \right) \;=\; \mathbb{Z}\cdot\begin{pmatrix}1\\ -1\end{pmatrix} \;\cong\; \mathbb{Z}.$$

Using Lemma 33.4 we obtain the following short exact sequence:

$$0 \;\to\; \underbrace{\operatorname{coker}\left(\begin{matrix}\mathbb{Z}\\ \mathbb{Z}\end{matrix} \xrightarrow{\begin{pmatrix}1 & 1\\ -1 & -1\end{pmatrix}} \begin{matrix}\mathbb{Z}\\ \mathbb{Z}\end{matrix} \right)}_{\cong \begin{matrix}\mathbb{Z}\\ 0\end{matrix}} \;\to\; H_1(T) \;\to\; \underbrace{\ker\left(\begin{matrix}\mathbb{Z}\\ \mathbb{Z}\end{matrix} \xrightarrow{\begin{pmatrix}1 & 1\\ -1 & -1\end{pmatrix}} \begin{matrix}\mathbb{Z}\\ \mathbb{Z}\end{matrix} \right)}_{\cong \mathbb{Z}\cdot\left(\begin{smallmatrix}1\\ -1\end{smallmatrix}\right)} \;\to\; 0.$$

Thus we obtain a short exact sequence

$$0 \;\to\; \begin{matrix}\mathbb{Z}\\ 0\end{matrix} \;\to\; H_1(T) \;\to\; \mathbb{Z}\cdot\begin{pmatrix}1\\ -1\end{pmatrix} \;\to\; 0.$$

It follows from Corollary 33.3 that $H_1(T) \cong \mathbb{Z}^2$. Finally it follows from the above long exact sequence and the discussion on page 764 that[667]

$$H_0(T) \;\cong\; \operatorname{coker}\left(\begin{matrix}\mathbb{Z}\\ \mathbb{Z}\end{matrix} \xrightarrow{\begin{pmatrix}1 & 1\\ -1 & -1\end{pmatrix}} \begin{matrix}\mathbb{Z}\\ \mathbb{Z}\end{matrix} \right) \;\cong\; \mathbb{Z}.$$

This concludes the proof of the lemma. □

Now we also want to determine explicit generators for $H_1(T) \cong \mathbb{Z}^2$ and $H_2(T) \cong \mathbb{Z}$. We will do so in the following lemma.

Lemma 33.13. *Let $T = S^1 \times S^1$ be the torus, then the following hold:*[668]

(1) *The singular 1-simplices c and d shown in Figure 524 on the left are generators for $H_1(T) \cong \mathbb{Z}^2$.*
(2) *The singular 2-chain $\alpha - \beta$ that is given by the singular 2-simplices α and β shown in Figure 524 on the right is a generator for $H_2(T) \cong \mathbb{Z}$.*[669]

Proof. We continue with the notation that we introduced in the proof of Lemma 33.12. Recall that this means that we identify the torus T with the product $S^1 \times \mathbb{R}/4\mathbb{Z}$, we denote by $p\colon S^1 \times \mathbb{R} \to T = S^1 \times \mathbb{R}/4\mathbb{Z}$ the projection map, we write $A := p(S^1 \times ([0,1] \cup [3,4]))$, $B := p(S^1 \times [1,3])$ and we write $C_1 := p(S^1 \times \{1\})$ and $C_2 := p(S^1 \times \{3\})$.

(1) Let c be the standard generator of $H_1(B)$ and let a and b be the singular simplices in A and B that are indicated in Figure 525. We consider the following short exact

[667] Of course we already knew by Proposition 29.5 that $H_0(T) \cong \mathbb{Z}$.

[668] Here the singular simplices in Figure 524 are understood to be given by the obvious affine maps $\Delta^n \to [0,1] \times [0,1]/\sim$.

[669] This singular 2-chain is precisely the one that we had already considered in Figure 475. In particular this answers our question from page 742, the cycle $\alpha - \beta$ does indeed represent a non-trivial element in $H_2(T)$.

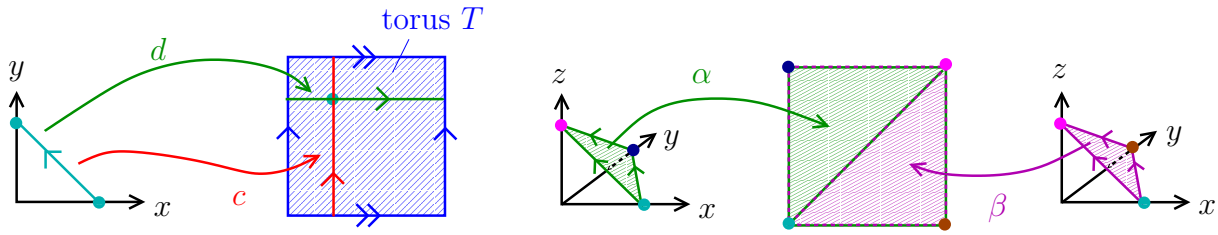

FIGURE 524.

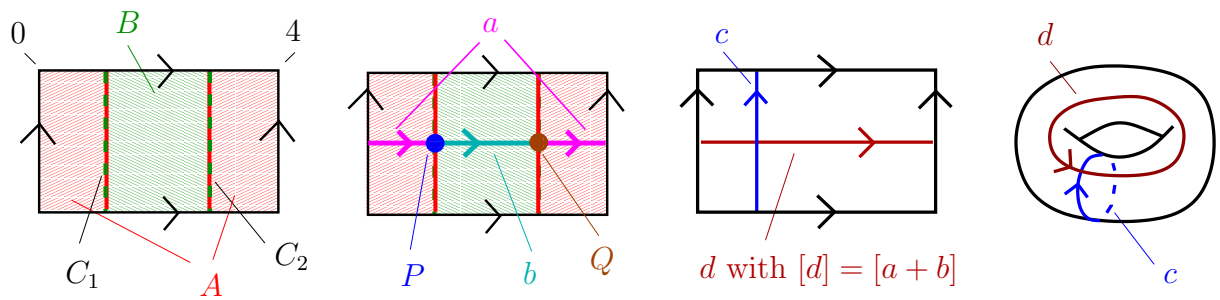

FIGURE 525.

sequence that we had obtained in the proof of Lemma 33.12:

$$0 \to \operatorname{coker}\begin{pmatrix} H_1(C_1)=\mathbb{Z} \\ H_1(C_2)=\mathbb{Z} \end{pmatrix} \xrightarrow{\begin{pmatrix} 1 & 1 \\ -1 & -1 \end{pmatrix}} \begin{matrix} H_1(A)=\mathbb{Z} \\ H_1(B)=\mathbb{Z} \end{matrix}\Bigg) \to H_1(T) \xrightarrow{\partial_1} \ker\begin{pmatrix} H_0(C_1)=\mathbb{Z} \\ H_0(C_2)=\mathbb{Z} \end{pmatrix} \xrightarrow{\begin{pmatrix} 1 & 1 \\ -1 & -1 \end{pmatrix}} \begin{matrix} H_0(A)=\mathbb{Z} \\ H_0(B)=\mathbb{Z} \end{matrix}\Bigg) \to 0.$$

It is clear that $c = \begin{pmatrix} 1 \\ 0 \end{pmatrix} \in \begin{matrix} H_1(C_1)=\mathbb{Z} \\ H_1(C_2)=\mathbb{Z} \end{matrix}$ represents a generator of the group on the left-hand side. Furthermore note that $a+b$ is a cycle in T with $a \in C_1(A)$ and $b \in C_1(B)$, thus we have

$$\partial_1([a+b]) \underset{\substack{\uparrow \\ \text{see the definition of } \partial_1 \text{ in Theorem 33.10 (1)}}}{=} [\partial a] = [P-Q] = \begin{pmatrix} 1 \\ -1 \end{pmatrix} \in \begin{matrix} H_1(C_1)=\mathbb{Z} \\ H_1(C_2)=\mathbb{Z} \end{matrix}$$

Thus we see that $\partial_1([a+b])$ is a generator of the group on the right-hand side of the above short exact sequence. It follows from Corollary 33.3 (2) that $[c]$ and $[a+b]$ generate the free abelian group $H_1(T) \cong \mathbb{Z}^2$. The desired statement now follows from the observation that Lemma 29.3 (3) implies that $[a+b] = [d]$.

(2) Let α and β be the two singular 2-simplices that are shown in Figure 524 on the right. As we will see, the proof that $\alpha - \beta$ represents a generator of $H_2(T)$ is quite similar to the proof of Lemma 32.10.

First note that it is straightforward to verify that the singular 2-chain $\alpha - \beta$ is indeed a cycle. We denote by A and B the images of $\alpha\colon \Delta^2 \to T$ and $\beta\colon \Delta^2 \to T$. (We refer

to Figure 526 for an illustration.) We consider the following maps

$$\begin{tikzcd}
H_2(T) \arrow[d] \arrow[dr, "{[\alpha-\beta]\mapsto[\alpha-\beta]}"] & & & H_2(\Delta^2,\partial\Delta^2) \arrow[dlll, "{[\mathrm{id}_{\Delta^2}]\mapsto[\alpha]}"'] \arrow[d, "\cong"'] \\
H_2(T/B) \arrow[r] & \underbrace{H_2(T/B,B/B)}_{\text{here } [\alpha-\beta]=[\alpha]} & H_2(A/\partial A,\partial A/\partial A) \arrow[l, "\cong"] & H_2(\Delta^2/\partial\Delta^2,\partial\Delta^2/\partial\Delta^2). \arrow[l, "\alpha_*"', "\cong"]
\end{tikzcd}$$

We make the following observations:

(a) By Lemma 32.9 we know that $[\mathrm{id}_{\Delta^2}] \in H_2(\Delta^2,\partial\Delta^2) \cong \mathbb{Z}$ is a generator.
(b) The two horizontal maps on the right are induced by homeomorphisms of pairs, hence they are isomorphisms.
(c) The vertical homomorphism on the right is an isomorphism by Proposition 31.19 and Lemma 31.12.
(d) The statements (a), (b) and (c) imply that $[\alpha]$ represents a generator of the group $H_2(T/B,B/B) \cong \mathbb{Z}$.
(e) The singular 2-simplex $\beta\colon \Delta^2 \to B$ is zero in $C_2(T/B,B/B)$. Therefore we have $[\alpha-\beta]=[\alpha] \in H_2(T/B,B/B)$.
(f) The statements (d) and (e) imply that the image of $[\alpha-\beta] \in H_2(T) \cong \mathbb{Z}$ under the map $H_2(T) \to H_2(T/B,B/B)$ is a generator of $H_2(T/B,B/B) \cong \mathbb{Z}$. But this implies that $[\alpha-\beta]$ is a generator of $H_2(T) \cong \mathbb{Z}$. □

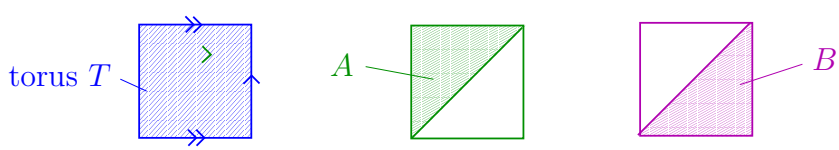

FIGURE 526. Illustration for the proof of Lemma 33.13 (2).

In Exercise 33.1 we will determine the homology groups of the Klein bottle. More precisely, using the Mayer–Vietoris Theorem 33.10 for manifolds we will prove the following lemma.

Lemma 33.14. *We denote by K the Klein bottle. Then*

$$H_n(K) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } n=0,\\ \mathbb{Z}\oplus\mathbb{Z}_2, & \text{if } n=1,\\ 0, & \text{otherwise.}\end{cases}$$

Furthermore we can determine explicitly two generators of $H_1(K)$. More precisely, we consider Figure 527. There the singular 1-simplex d generates the $\mathbb{Z}_2$-summand and the

singular 1-simplex c generates a $\mathbb{Z}$-summand of $H_1(K)$.[670] We leave the verification of this statement as an exercise to the reader.

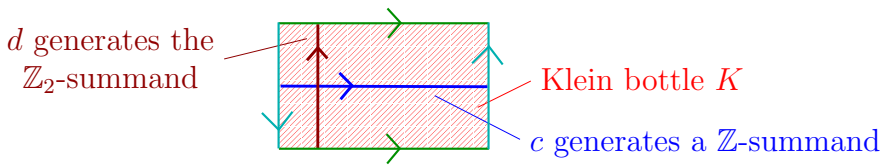

FIGURE 527.

Remark. With some effort one could now use the Mayer–Vietoris Theorem 33.10 to compute the homology groups of the surfaces of genus ≥ 2. We will not do so, since we will soon get to know an alternative approach to calculating homology groups, with which we can easily compute these homology groups.[671]

33.6. **The homology groups of a knot complement.** Finally we want to determine the first homology group of the complement of a knot. We recall the relevant definitions from pages 360 and 362.

(1) A *knot* is a 1-dimensional submanifold of S^3 that is diffeomorphic to S^1.
(2) Let K be an oriented knot in S^3. By the Tubular Neighborhood Theorem 10.19 there exists an orientation-preserving embedding $F\colon \overline{B}^2 \times S^1 \to S^3$ with $\Phi(\{0\} \times S^1) = K$. For any $* \in S^1$ we refer to the oriented submanifold $F(S^1 \times \{*\})$ as a *meridian* of the knot K.

We refer to Figure 528 for an illustration of an oriented knot and a meridian. We also introduce one new definition:

(3) Let M be a manifold and let C be a closed oriented curve in M, see page 306 for the definition. Sometimes, by a slight abuse of notation, we denote by C also the element in $H_1(M)$ that is given by the image of the standard generator $[S^1]$ of $H_1(S^1)$ under the map $H_1(S^1) \xrightarrow{\Phi_*} H_1(C) \to H_1(M)$.[672]

Lemma 33.15. *Let $K \subset S^3$ be a knot. Then*[673]

$$H_0(S^3 \setminus K) \;\cong\; \mathbb{Z} \quad \textit{and} \quad H_1(S^3 \setminus K) \;\cong\; \mathbb{Z}.$$

Furthermore every meridian is a generator of $H_1(S^3 \setminus K)$.

[670] It is straightforward to see that c generates an element of infinite order since the "vertical projection" $K \to [0,1]/\sim$ sends c to a generator of $H_1([0,1]/\sim) = H_1(S^1)$.

[671] Of course it is a great exercise to determine the homology groups of the surfaces of genus ≥ 2 with our present knowledge.

[672] It follows from Proposition 20.5 and Proposition 30.5 that, up to a sign, the homology class does not depend on the choice of the orientation-preserving diffeomorphism Φ.

[673] By Proposition 29.5 the first statement just says that $S^3 \setminus K$ is path-connected. This seems obvious from the pictures, but it is nonetheless non-trivial to prove.

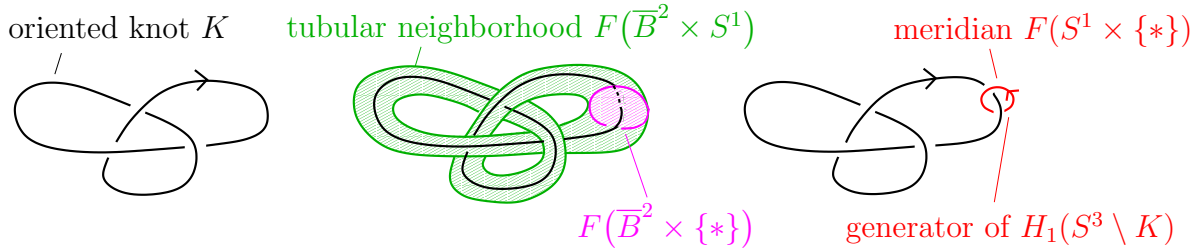

FIGURE 528.

Later on we will compute the other homology groups of $S^3 \setminus K$.

Remark. The result of Lemma 33.15 is easy to state but also slightly disappointing since it shows that the first homology groups cannot be used to distinguish different knots. In contrast to this fact we saw in Proposition 18.5 and Lemma 18.6 that the fundamental group can be used to distinguish the trivial knot from the trefoil.

Proof. Let $K \subset S^3$ be a knot. By the Tubular Neighborhood Theorem 10.19 there exists an embedding $\Phi\colon \overline{B}^2 \times S^1 \to S^3$ with $\Phi(\{0\} \times S^1) = K$. In the following we write $\overline{B}^2 \times S^1$ instead of $\Phi(\overline{B}^2 \times S^1)$. It is clear that the interiors of $S^3 \setminus K$ and $\overline{B}^2 \times K$ cover S^3. Therefore we can apply the Mayer–Vietoris Theorem 33.5 to $S^3 = (S^3 \setminus K) \cup (\overline{B}^2 \times K)$ and we obtain the following exact sequence

$$\begin{array}{ccccccc}
\overbrace{H_2(S^3)}^{=0} & \longrightarrow & H_1\big((\overline{B}^2 \setminus 0) \times K\big) & \longrightarrow & H_1(S^3 \setminus K) \oplus H_1(\overline{B}^2 \times K) & \longrightarrow & \overbrace{H_1(S^3)}^{=0} \longrightarrow \\
 & \longrightarrow & \widetilde{H}_0((\overline{B}^2 \setminus 0) \times K) & \longrightarrow & \widetilde{H}_0(S^3 \setminus K) \oplus \widetilde{H}_0\big(\overline{B}^2 \times K\big) & \longrightarrow & \underbrace{\widetilde{H}_0(S^3)}_{=0} \longrightarrow 0.
\end{array}$$

Now we have to study the homology groups of the various spaces in more detail.

(1) We denote by $\mu = \Phi(S^1 \times \{*\})$ the meridian and we define $\lambda = \Phi(\{*\} \times S^1)$. It follows from Lemma 33.13 that μ and λ is a basis for $H_1(\Phi(S^1 \times S^1))$. The inclusion $S^1 \times S^1 \to (\overline{B}^2 \setminus 0) \times K$ is a homotopy equivalence. It follows from the above, Proposition 29.5 and Corollary 30.8 that $H_1\big((\overline{B}^2 \setminus 0) \times K\big) \cong \mathbb{Z} \cdot \mu \oplus \mathbb{Z} \cdot \lambda$ and that $\widetilde{H}_0((\overline{B}^2 \setminus 0) \times K) = 0$.

(2) We write $\gamma = \{0\} \times K$. The inclusion $\{0\} \times K \to \overline{B}^2 \times K$ is a homotopy equivalence. Similar to (1) we see that $H_1(\overline{B}^2 \times K) \cong \mathbb{Z} \cdot \gamma$ and that $\widetilde{H}_0(\overline{B}^2 \times K) = 0$.

(3) Under the inclusion induced map $H_1\widetilde{((\overline{B}^2 \setminus 0) \times K)} = \mathbb{Z} \cdot \mu \oplus \mathbb{Z} \cdot \lambda \to H_1(\overline{B}^2 \times K) = \mathbb{Z} \cdot \gamma$ we have $\mu \mapsto 0$[674] and we have $\lambda \mapsto \gamma$.[675].

[674]This can be seen as follows: the map $H_1(* \times S^1) \to H_1(\overline{B}^2 \times K)$ factors through $H_1(* \times \overline{B}^2) = 0$.
[675]Why is that?

Thus we obtain an exact sequence of the following form

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathbb{Z}\cdot\mu\oplus\mathbb{Z}\cdot\lambda & \xrightarrow[\cong]{\substack{\mu\mapsto(\mu,0)\\ \lambda\mapsto(\lambda,\gamma)}} & H_1(S^3\setminus K)\oplus\mathbb{Z}\cdot\gamma & \longrightarrow & 0 & \longrightarrow & \\ & \longrightarrow & 0 & \longrightarrow & \widetilde{H}_0(S^3\setminus K)\oplus 0 & \longrightarrow & 0 & \longrightarrow & 0. \end{array}$$

Now it follows immediately from Corollary 33.3 and Lemma 11.8 (1) that $H_1(S^3\setminus K)\cong\mathbb{Z}$ and that $\widetilde{H}_0(S^3\setminus K)\cong 0$.[676] Furthermore it follows easily that $\mu\in H_1(S^3\setminus K)=H_1(S^3\setminus K)$ is a generator.[677] $\square$

Remark. In the proof of Lemma 33.15 we used the Mayer–Vietoris Theorem 33.5 in a different way than in the previous examples. More precisely, instead of decomposing $S^3\setminus K$ into smaller pieces, we used that for a decomposition $X=U\cup V$ the Mayer–Vietoris sequence not only relates the homology groups of U,V and $U\cap V$ to the homology groups of X, but also that it relates the homology groups of U to the homology groups of $V,U\cap V$ and X.

The following lemma will be proved in Exercise 33.5.

Lemma 33.16. *Let $X\subset\mathbb{R}^n$ be a non-empty compact subset. We denote by $S^n=\mathbb{R}^n\cup\{\infty\}$ the topological space $\mathbb{R}^n$ with a "point at infinity". Then for any $k\in\mathbb{N}_0$ we have*

$$H_k(\mathbb{R}^n\setminus X)\ \cong\ \begin{cases} H_k((\mathbb{R}^n\cup\{\infty\})\setminus X)\oplus\mathbb{Z}, & \text{if } k=n-1,\\ H_k((\mathbb{R}^n\cup\{\infty\})\setminus X), & \text{otherwise.}\end{cases}$$

33.7. **The homology groups of a mapping cone** $(*)$**.** In this section we will discuss the homology groups of a mapping cone. Before we start the discussion we recall the relevant definitions.

(1) On page 450, given a topological space A we defined the *cone on A* as

$$\mathrm{Cone}(A)\ :=\ (A\times[0,1])/\sim \qquad \text{where } (a,0)\sim(a',0) \text{ for all } a,a'\in A.$$

(2) Given a map $f\colon A\to X$ between topological spaces we defined on page 458 the corresponding *mapping cone* as

$$\mathrm{Cone}(f\colon A\to X)\ :=\ (X\sqcup\mathrm{Cone}(A))/\sim \ \text{ where } (a,1)\sim f(a) \text{ for all } a\in A.$$

First we intend to understand the homology groups of the mapping cone of an inclusion $i\colon A\to X$ where A is a non-empty subset of some topological space X. We refer to $P=[A\times 0]$ as the cone point of $\mathrm{Cone}(A)$ and of $\mathrm{Cone}(i\colon A\to X)$. We have the following

[676] Can we use the same approach to determine $H_2(S^3\setminus K)$?

[677] Why does this follow?

isomorphisms

$$\begin{array}{ccccc}
 & \text{by Corollary 31.14 since we know by Lemma 15.1 that the Cone}(A)\text{ is contractible} & & & \\
 & \downarrow & & & \\
\underbrace{\widetilde{H}_n((X \sqcup \mathrm{Cone}(A))/\sim)}_{=\widetilde{H}_n(\mathrm{Cone}(i\colon A\to X))} & \overset{\cong}{\to} & H_n((X \sqcup \mathrm{Cone}(A))/\sim, \mathrm{Cone}(A)) & & \\
 & \overset{\cong}{\leftarrow} & H_n((X \sqcup \mathrm{Cone}(A))/\sim \backslash P, \mathrm{Cone}(A)\backslash P) & \overset{\cong}{\leftarrow} & H_n(X,A). \\
 & \uparrow & & \uparrow & \\
 & \text{Excision Theorem 31.17} & \text{from a slight variation on Lemma 15.7 (1) we obtain a deformation retraction, thus the inclusion induces an isomorphism by Exercise 31.9} & &
\end{array}$$

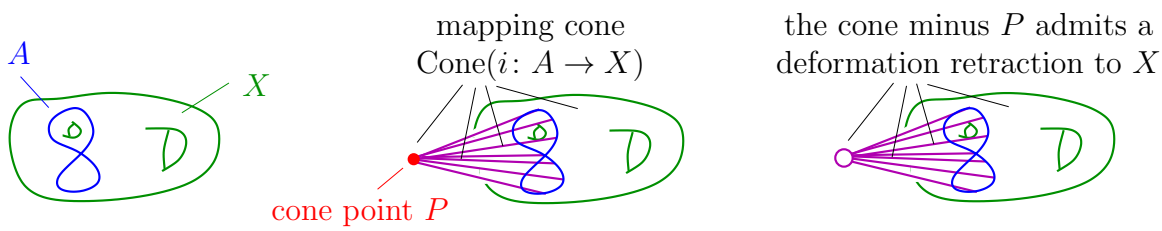

FIGURE 529.

The following lemma summarizes the discussion.

Lemma 33.17. *We denote by $\mathcal{P}$ the category of pairs of topological spaces and we denote by $\mathcal{A}$ the category of abelian groups. The above isomorphisms define a natural isomorphism from the functor*[678]

$$\begin{array}{rcl} \mathcal{P} & \to & \mathcal{A} \\ (X,A) & \mapsto & \widetilde{H}_n(\mathrm{Cone}(i\colon A\to X)) \end{array} \quad \textit{to the functor} \quad \begin{array}{rcl} \mathcal{P} & \to & \mathcal{A} \\ (X,A) & \mapsto & H_n(X,A). \end{array}$$

Remark.

(1) It is worth comparing Lemma 31.12 to Lemma 33.17.
(2) In Proposition 31.19 we showed that, under favorable circumstances, we can replace the relative homology group $H_n(X,A)$ by the homology group $\widetilde{H}_n(X/A)$. Lemma 33.17 says that we can replace any relative homology group by the homology group of the mapping cone of the inclusion.
(3) Loosely speaking, Lemma 33.17 says that for all intents and purposes we can always replace relative the homology groups of a pair (X,A) of topological spaces by the relative homology of the mapping cone of the inclusion $A \to X$.

Proof. We had just seen that the map is an isomorphism. It is straightforward to verify that the maps define a natural transformation. □

[678] As in Lemma 15.9 (3) we see that the left-hand side does indeed define a functor.

Given an inclusion map $i\colon A \to X$ of (non-empty) topological spaces we just saw in Lemma 33.17 that the reduced homology of the mapping cone is naturally isomorphic to the relative homology groups of (X, A). One of the key features of relative homology groups is that they fit into a long exact sequence of homology groups.

The following lemma proves the neat fact that the homology groups of any mapping cone fit into a long exact sequence.

Lemma 33.18.

(1) *Let $f\colon A \to X$ be a map between topological spaces.*
   (a) *We denote by $j(f)\colon X \to \mathrm{Cone}(f) = (\mathrm{Cone}(A) \cup X)/\sim$ the obvious inclusion map.*
   (b) *We denote by U the image of $A \times [0, \frac{3}{4})$ in $\mathrm{Cone}(f)$ and we denote by V the complement of the image of $A \times [0, \frac{1}{4}]$. (See also Figure 530.) We consider the following diagram*

$$\begin{tikzcd}
\dots \arrow[r] & H_k(U) \oplus H_k(V) \arrow[r] & H_k(\mathrm{Cone}(f)) \arrow[r, "\partial"] \arrow[dr, "=:\partial^{k-1}(f)"'] & H_{k-1}(U \cap V) \arrow[r] \arrow[d, "="] & \dots \\
 & & & H_{k-1}(A). &
\end{tikzcd}$$

Here the top sequence is the long exact sequence arising from the Mayer–Vietoris Theorem 33.5[679]*. Furthermore the vertical map comes from the obvious identifications $H_{k-1}(U \cap V) = H_{k-1}(A \times \frac{1}{2}) = H_{k-1}(A)$. From the above diagram we obtain a map*

$$\partial_k(f)\colon H_k(\mathrm{Cone}(f)) \ \to \ H_{k-1}(A).$$

With these definitions the following sequence is exact

$$\dots \longrightarrow H_k(A) \xrightarrow{f_*} H_k(X) \xrightarrow{j(f)_*} \widetilde{H}_k(\mathrm{Cone}(f)) \xrightarrow{\partial_k(f)} H_{k-1}(A) \longrightarrow \dots$$

(2) *The connecting homomorphism in* (1) *is natural. In particular given any commutative diagram*

$$\begin{tikzcd}
A \arrow[r, "f"] \arrow[d, "\varphi"'] & X \arrow[d, "\psi"] \\
\widetilde{A} \arrow[r, "\widetilde{f}"] & \widetilde{X}
\end{tikzcd}$$

of maps between topological spaces the following diagram commutes:

$$\begin{tikzcd}
\dots \arrow[r] & H_k(A) \arrow[r, "f_*"] \arrow[d, "\varphi_*"] & H_k(X) \arrow[r, "j(f)_*"] \arrow[d, "\psi_*"] & \widetilde{H}_k(\mathrm{Cone}(f)) \arrow[r, "\partial_k(f)"] \arrow[d] & H_{k-1}(A) \arrow[r] \arrow[d, "\varphi_*"] & \dots \\
\dots \arrow[r] & H_k(\widetilde{A}) \arrow[r, "\widetilde{f}_*"] & H_k(\widetilde{X}) \arrow[r, "j(\widetilde{f})_*"] & \widetilde{H}_k(\mathrm{Cone}(\widetilde{f})) \arrow[r, "\partial_k(\widetilde{f})"] & H_{k-1}(\widetilde{A}) \arrow[r] & \dots.
\end{tikzcd}$$

[679]Note that U and V are open subsets of $\mathrm{Cone}(f)$.

Here the vertical maps between the homology groups of the mapping cones are induced by the maps from Lemma 15.9 (3).

(3) *Let X be a topological space and let $A \subset X$ be a non-empty subset. We denote by $i\colon A \to X$ the inclusion map. The following diagram*

$$\begin{tikzcd}
\dots \arrow[r] & \widetilde{H}_k(A) \arrow[r, "i"] \arrow[d, "="] & \widetilde{H}_k(X) \arrow[r] \arrow[d, "="] & H_k(X,A) \arrow[r, "\partial"] \arrow[d, "\cong"] & \widetilde{H}_{k-1}(A) \arrow[r] \arrow[d, "="] & \widetilde{H}_{k-1}(X) \arrow[r] \arrow[d, "="] & \dots \\
\dots \arrow[r] & \widetilde{H}_k(A) \arrow[r, "i"] & \widetilde{H}_k(X) \arrow[r] & \widetilde{H}_k(\mathrm{Cone}(i)) \arrow[r, "\partial"] & \widetilde{H}_{k-1}(A) \arrow[r] & \widetilde{H}_{k-1}(X) \arrow[r] & \dots
\end{tikzcd}$$

commutes. Here the middle vertical map is the natural isomorphism from Lemma 33.17, the top sequence is the long exact sequence arising from Corollary 31.14 the bottom sequence is the exact sequence from (1).

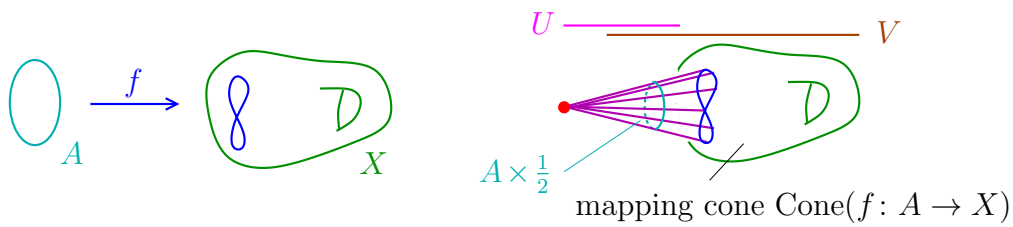

FIGURE 530. Illustration of Lemma 33.18.

Proof.

(1) The statement follows from the Mayer–Vietoris Theorem 33.5 applied to the open covering $\mathrm{Cone}(f) = U \cup V$ and the following two observations:
   (a) As in Lemma 15.1 we see that the topological space U is homotopy equivalent to a point, in particular it only contributes to the exact sequence in dimension 0, which then gets swallowed up by replacing $H_0(\mathrm{Cone}(f);\mathbb{Z})$ by the reduced version.
   (b) The subset $X \subset V$ is a deformation retract.

   We leave it as a highly instructive exercise to fill in the remaining details.

(2) This statement follows from Lemma 33.6.

(3) We will prove this statement in Exercise 33.9. □

The last lemma of this section gives a neat reinterpretation of the connecting homomorphism in the long exact sequence of Lemma 33.18.

Lemma 33.19. $(*)$ *Let $f\colon A \to X$ be a map between topological spaces. For any $k \in \mathbb{N}_0$ the following diagram commutes:*

$$\begin{array}{ccc} \widetilde{H}_k(\mathrm{Cone}(f\colon A \to X)) & \xrightarrow{\quad\partial\quad} & \widetilde{H}_{k-1}(A) \\ \downarrow & & \cong\downarrow \Sigma_A \\ \widetilde{H}_k(\mathrm{Cone}(f\colon A \to X)/X) & \xrightarrow[\cong]{\varphi} & \widetilde{H}_k(\Sigma(A)). \end{array}$$

Here we used the following notation:

1. *The top horizontal map is the connecting homomorphism of the long exact sequence given in Lemma 33.18.*
2. *The left vertical map is induced by the obvious projection.*
3. *The map $\varphi\colon \mathrm{Cone}(f\colon A \to X)/X \to \Sigma(A)$ is the natural homeomorphism from Lemma 15.8 (2).*
4. *The map $\Sigma_A\colon \widetilde{H}_{k-1}(A) \to \widetilde{H}_k(A)$ is the natural isomorphism from Lemma 33.8.*

Proof $(*)$. The statement follows immediately from the explicit definition of the maps ∂ and Φ_A via Mayer-Vietoris sequences, from the explicit definition of the map φ, and from the naturality of the connecting homomorphism of the Mayer-Vietoris sequence, see Lemma 33.6. We leave it to the reader to fill in the details. □

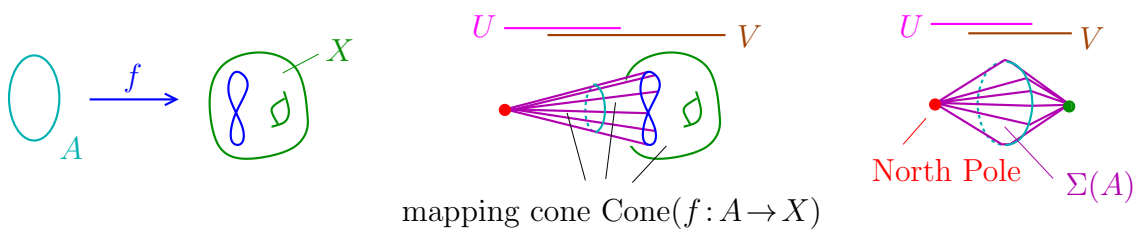

FIGURE 531. Illustration for the proof of Lemma 33.19.

33.8. **The homology groups of a mapping torus** $(*)$**.** On page 469 we defined the mapping torus of a self-homeomorphism and in Proposition 15.25 we had determined the fundamental group of the mapping torus. In this section we will determine the homology groups of a mapping torus.

For convenience we recall from page 469 the definition of the mapping torus of a self-homeomorphism. Let X be a topological space and let $f\colon X \to X$ be a homeomorphism. We refer to

$$M(X,f) \;:=\; X \times [0,1]/(x,0) \sim (f(x),1)$$

as the *mapping torus of* (X,f).

Proposition 33.20. *Let X be a topological space and let $f\colon X \to X$ be a homeomorphism. Then for any $n \in \mathbb{N}_0$ we have a short exact sequence*[680]

$$0 \to \operatorname{coker}\big(H_n(X) \xrightarrow{f_*-\mathrm{id}} H_n(X)\big) \xrightarrow{i} H_n(M(X,f)) \to \ker\big(H_{n-1}(X) \xrightarrow{f_*-\mathrm{id}} H_{n-1}(X)\big) \to 0,$$

where the map i is induced by the inclusion $X = X \times \{0\} \to M(X,f)$.

Example. First let $X = S^1$ and let $f\colon S^1 \to S^1$ be the self-homeomorphism that is given by $f(z) = \overline{z} = z^{-1}$. We saw on page 470 that the mapping torus $M(S^1, f)$ is homeomorphic to the Klein bottle. We make the standard identifications $H_0(S^1) = \mathbb{Z}$ and $H_1(S^1) = \mathbb{Z}$. It follows from the discussion on page 747 the induced map $f_*\colon H_0(S^1) \to H_0(S^1)$ is the identity map. Furthermore we showed in Lemma 32.15 that the induced homomorphism $f_*\colon \mathbb{Z} = H_1(S^1) \to H_1(S^1) = \mathbb{Z}$ is given by multiplication by -1. The short exact sequences of Proposition 33.20 are therefore of the form

$$\begin{array}{lccccccccc}
n=2\colon & & & & 0 & \to & H_2(M(S^1,f)) & \to & \ker\{\mathbb{Z} \xrightarrow{\cdot 2} \mathbb{Z}\} & \to & 0 \\
n=1\colon & 0 & \to & \operatorname{coker}\{\mathbb{Z} \xrightarrow{\cdot 2} \mathbb{Z}\} & \to & & H_1(M(S^1,f)) & \to & \ker\{\mathbb{Z} \xrightarrow{\cdot 0} \mathbb{Z}\} & \to & 0
\end{array}$$

and

$$n=0\colon \quad 0 \to \operatorname{coker}\{\mathbb{Z} \xrightarrow{\cdot 0} \mathbb{Z}\} \to H_0(M(S^1,f)) \to 0.$$

Using Corollary 33.3 we now deduce that

$$H_2(M(S^1,f)) = 0, \quad H_1(M(S^1,f)) \cong \mathbb{Z}_2 \oplus \mathbb{Z} \quad \text{and} \quad H_0(M(S^1,f)) = 0.$$

This confirms, as it should, the calculation that we had made in Lemma 33.14.

Proof. The proof of the proposition is quite similar to the calculation of the homology groups of the torus.[681] Let X be a topological space and let $f\colon X \to X$ be a homeomorphism. We compute the homology of the following space that is clearly homeomorphic to the mapping torus:

$$M := X \times [0,10]/(x,0) \sim (f(x),10).$$

We denote by $p\colon X \times [0,10] \to M$ the obvious projection map. Furthermore we write $A := p(X \times ([0,4) \cup (6,10])) \subset M$ and $B := p(X \times (2,8)) \subset M$. Evidently the interiors of A and B cover all of M. Finally we write $C_1 := p(X \times (2,4))$ and $C_2 := p(X \times (6,8))$. Thus we have $A \cap B = C_1 \cup C_2$. Finally, given $t \in [0,10]$ we denote by

$$\begin{array}{rcl} i_t\colon X & \to & p(X \times \{t\}) \\ x & \mapsto & p(x,t) \end{array}$$

the obvious inclusion map. We write $i_{3,A}$ for the composition of i_3 with the inclusion map $p(X \times \{3\}) \to A$. We denote analogous compositions by the obvious variations in the notation.

The following claim is a straightforward consequence of Proposition 30.5. We leave the details as an exercise to the reader.

[680] Recall that $H_{-1}(X)$ is defined to be the trivial group.

[681] In fact if one reads the subsequent proof with $X = S^1$ and $f = \mathrm{id}$ in mind, then one obtains almost the same argument as for the torus.

Claim. For any $n \in \mathbb{N}_0$ the following two diagrams commute

$$\begin{tikzcd} H_n(X) \arrow[rr, "\mathrm{id}"] \arrow[dr, "i_{3,B}"'] & & H_n(X) \arrow[dl, "i_{7,B}"] \\ & H_n(B) & \end{tikzcd} \quad \text{and} \quad \begin{tikzcd} H_n(X) \arrow[rr, "f_*^{-1}"] \arrow[dr, "i_{3,A}"'] & & H_n(X) \arrow[dl, "i_{7,A}"] \\ & H_n(B) & \end{tikzcd} .$$

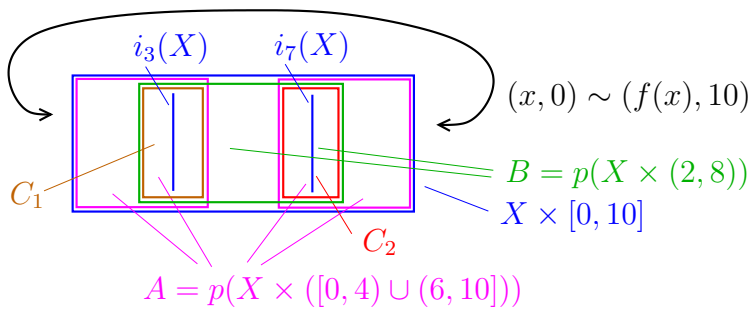

FIGURE 532.

We consider the following diagram:[682]

$$\begin{tikzcd}[column sep=small] \arrow[r] & \begin{matrix} H_n(C_1) \\ H_n(C_2) \end{matrix} \arrow[r, "\begin{pmatrix} i_{C_1} & i_{C_2} \\ -i_{C_1} & -i_{C_2} \end{pmatrix}"] & \begin{matrix} H_n(A) \\ H_n(B) \end{matrix} \arrow[r, "(i_A\ i_B)"] & H_n(M) \arrow[r, "\partial"] & \begin{matrix} H_{n-1}(C_1) \\ H_{n-1}(C_2) \end{matrix} \arrow[r, "\begin{pmatrix} i_{C_1} & i_{C_2} \\ -i_{C_1} & -i_{C_2} \end{pmatrix}"] & \begin{matrix} H_{n-1}(A) \\ H_{n-1}(B) \end{matrix} \arrow[r] & {} \\ \arrow[r] & \begin{matrix} H_n(X) \\ H_n(X) \end{matrix} \arrow[u, "\begin{pmatrix} i_3 & 0 \\ 0 & i_7 \end{pmatrix}"] \arrow[r, "\begin{pmatrix} \mathrm{id} & f_* \\ -\mathrm{id} & -\mathrm{id} \end{pmatrix}"] & \begin{matrix} H_n(X) \\ H_n(X) \end{matrix} \arrow[u, "\begin{pmatrix} i_3 & 0 \\ 0 & i_7 \end{pmatrix}"] \arrow[r, "(i_A\ i_B)"] & H_n(M) \arrow[u, "="] \arrow[r, "\partial"] & \begin{matrix} H_{n-1}(X) \\ H_{n-1}(X) \end{matrix} \arrow[u, "\begin{pmatrix} i_3 & 0 \\ 0 & i_7 \end{pmatrix}"] \arrow[r, "\begin{pmatrix} \mathrm{id} & f_* \\ -\mathrm{id} & -\mathrm{id} \end{pmatrix}"] & \begin{matrix} H_{n-1}(X) \\ H_{n-1}(X) \end{matrix} \arrow[u, "\begin{pmatrix} i_3 & 0 \\ 0 & i_7 \end{pmatrix}"] \arrow[r] & {} \\ \arrow[r] & H_n(X) \arrow[u, "\begin{pmatrix} \mathrm{id} \\ -\mathrm{id} \end{pmatrix}"] \arrow[r, "\mathrm{id} - f_*"] & H_n(X) \arrow[u, "\begin{pmatrix} \mathrm{id} \\ 0 \end{pmatrix}"] \arrow[r, "i"] & H_n(M) \arrow[u, "="] \arrow[r, "\partial"] & H_{n-1}(X) \arrow[u, "\begin{pmatrix} \mathrm{id} \\ -\mathrm{id} \end{pmatrix}"] \arrow[r, "\mathrm{id} - f_*"] & H_{n-1}(X) \arrow[u, "\begin{pmatrix} \mathrm{id} \\ 0 \end{pmatrix}"] \arrow[r] & 0. \end{tikzcd}$$

The above diagram arose as follows:

(1) On top we wrote down the Mayer–Vietoris sequence from Theorem 33.5 for the decomposition $M = A \cup B$, which is of course exact.

(2) We observed that the topological spaces A, B, C_1, C_2 are homotopy equivalent to X, more precisely, the maps $i_3 \colon X \to A, i_3 \colon X \to C_1$, $i_7 \colon X \to C_2$ and $i_7 \colon X \to B$ are homotopy equivalences. It follows from Corollary 30.8 that the induced maps on homology are isomorphisms. In particular the vertical maps between the first and the second horizontal sequence are isomorphisms.

[682]Here we use the same notation as on page 849.

(3) We wanted the top part of the diagram to commute. Since the top horizontal maps and the vertical maps were given we had to find the appropriate maps for the second horizontal sequence. For the first square to commute we needed to find maps $a, b, c, d\colon H_n(X) \to H_n(X)$ such that

$$\underbrace{\begin{pmatrix} i_{C_1,A} & i_{C_2,A} \\ -i_{C_1,B} & -i_{C_2,B} \end{pmatrix}\begin{pmatrix} i_{3,C_1} & 0 \\ 0 & i_{7,C_2} \end{pmatrix}}_{=\begin{pmatrix} i_{3,A} & i_{7,A} \\ -i_{3,B} & -i_{7,B} \end{pmatrix}} = \underbrace{\begin{pmatrix} i_{3,A} & 0 \\ 0 & i_{7,B} \end{pmatrix}\begin{pmatrix} a & b \\ c & d \end{pmatrix}}_{=\begin{pmatrix} i_{3,A}\circ a & i_{3,A}\circ b \\ i_{7,B}\circ c & i_{7,B}\circ d \end{pmatrix}}.$$

It follows from the above claim that a solution is given by $a = \mathrm{id}, b = f_*, c = -\mathrm{id}$ and $d = -\mathrm{id}$.

(4) It is straightforward to see that the bottom squares in the above diagram commute. We leave it as an exercise to verify that the bottom sequence is also exact.

As we had just pointed out, the bottom horizontal sequence is exact. The proposition is thus an immediate consequence of Lemma 33.4. □

Now we can also easily prove the following lemma.

Lemma 33.21. *Let X be a topological space. Then for any $n \in \mathbb{N}_0$ we have an isomorphism*

$$H_n(X \times S^1) \;\cong\; H_n(X) \oplus H_{n-1}(X).$$

Example. Applying Lemma 33.21 iteratively one can show that for $k = 0, \dots, n$ we have

$$H_k(n\text{-dimensional torus } (S^1)^n) \;=\; \text{free abelian group of rank } \binom{n}{k}$$

and that all other homology groups vanish.

Proof. Let $n \in \mathbb{N}_0$. We identify $X \times S^1$ with $M(X, f := \mathrm{id})$. By Proposition 33.20 we have a short exact sequence

$$0 \to \operatorname{coker}\big(H_n(X) \xrightarrow{f_*-\mathrm{id}} H_n(X)\big) \xrightarrow{i} H_n(M(X,f)) \to \ker\big(H_{n-1}(X) \xrightarrow{f_*-\mathrm{id}} H_{n-1}(X)\big) \to 0,$$

where the map i is induced by the inclusion $X = X \times \{0\} \to M(X, f)$. In our case $f_* - \mathrm{id}_* = 0$, so we obtain the short exact sequence

$$0 \;\to\; H_n(X) \;\xrightarrow{i}\; H_n(X \times S^1) \;\to\; H_{n-1}(X) \;\to\; 0$$

where the map i is induced by the inclusion $X = X \times \{1\} \to X \times S^1$. The inclusion map $X \to X \times S^1$ admits the splitting $p\colon X \times S^1 \to X$ that is given by projection onto the first factor. In particular $p_* \circ i_* = (p \circ i)_* = \mathrm{id}$. It follows from Lemma 33.2 that the above short exact sequence splits and we obtain the desired result. □

Remark. A careful reading of the proof of Lemma 33.21 shows that we can write down explicitly two homomorphisms $p\colon H_n(X \times S^1) \to H_n(X)$ and $q\colon H_n(X \times S^1) \to H_{n-1}(X)$ such that $p \oplus q\colon H_n(X \times S^1) \to H_{n-1}(X) \oplus H_{n-1}(X)$ is an isomorphism. In fact two such homomorphisms are given as follows:

(1) First we consider the homomorphism $p\colon H_n(X \times S^1) \to H_n(X)$ that is induced by the projection $X \times S^1 \to X$.
(2) Secondly we consider the homomorphism that is given by

$$\begin{array}{ccccc} H_n(X \times S^1) & \to & H_n(X \times S^1, X \times S^1_{\leq 0}) & \underset{\substack{\uparrow \\ \text{Excision Theorem 31.17}}}{\overset{\cong}{\leftarrow}} & H_n(X \times S^1_{\geq 0}, X \times \{\pm 1\}) \\ & \underset{\substack{\uparrow \\ \text{connecting homomorphism}}}{\to} & H_{n-1}(X \times \{\pm 1\}) & \underset{\substack{\uparrow \\ \text{projection induced homomorphism}}}{\to} & H_{n-1}(X \times \{1\}) \;=\; H_{n-1}(X). \end{array}$$

We conclude this long chapter with the following lemma.

Lemma 33.22. *Let X be a path-connected topological space and let $f\colon X \to X$ be a homeomorphism. Then there exists a short exact sequence*

$$0 \;\to\; \operatorname{coker}\big(H_1(X) \xrightarrow{f_* - \mathrm{id}} H_1(X)\big) \;\xrightarrow{i}\; H_1(M(X,f)) \;\to\; \mathbb{Z} \;\to\; 0$$

and we have an isomorphism

$$H_1(M(X,f)) \;\cong\; \mathbb{Z} \oplus \operatorname{coker}\big(H_n(X) \xrightarrow{f_* - \mathrm{id}} H_n(X)\big).$$

Proof. It follows from the discussion on page 747 that in this case $f_* - \mathrm{id}\colon H_0(X) \to H_0(X)$ is the zero map. Thus we obtain from Proposition 33.20 the short exact sequence

$$0 \;\to\; \operatorname{coker}\big(H_1(X) \xrightarrow{f_* - \mathrm{id}} H_1(X)\big) \;\xrightarrow{i}\; H_1(M(X,f)) \;\to\; \mathbb{Z} \;\to\; 0.$$

Since $\mathbb{Z}$ is free abelian it follows from Corollary 33.3 that

$$H_1(M(X,f)) \;\cong\; \mathbb{Z} \oplus \operatorname{coker}\big(H_n(X) \xrightarrow{f_* - \mathrm{id}} H_n(X)\big).$$

□

Exercises for Chapter 33.

Exercise 33.1.

(a) We denote by

$$K \;=\; [0,1] \times [0,1]/\sim \;\text{ with } (x,0) \sim (x,1) \text{ and } (0,y) \sim (1, 1-y)$$

the Klein bottle. Show that

$$H_n(K) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } n = 0, \\ \mathbb{Z} \oplus \mathbb{Z}_2, & \text{if } n = 1, \\ 0, & \text{otherwise.} \end{cases}$$

(b) Give an example of a map $f\colon S^1 \to K$ such that the inclusion induced map $f_*\colon H_1(S^1) \to H_1(K)$ is a monomorphism. Prove that the map f that you provide does indeed have this property.

Exercise 33.2. Compute the isomorphism types of the homology groups of the real line with two zeros.

Exercise 33.3. Determine the isomorphism types of the homology groups of the topologist's sine curve that we introduced on page 123.

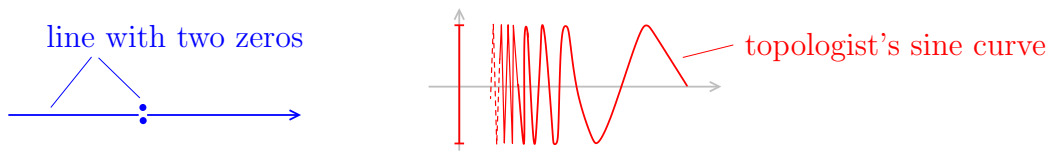

FIGURE 533. Illustration for Exercises 33.2 and 33.3.

Exercise 33.4. Let X be a topological space and let $k \in \mathbb{Z}$. Show that the two natural isomorphisms $\widetilde{H}_k(X) \xrightarrow{\cong} \widetilde{H}_{k-1}(\Sigma(X))$ that we constructed in Proposition 32.14 and that we constructed in the proof of Lemma 33.8 are actually the same.

Exercise 33.5. Let $X \subset \mathbb{R}^n$ be a non-empty compact subset. We denote by $S^n = \mathbb{R}^n \cup \{\infty\}$ the space $\mathbb{R}^n$ with a "point at infinity".

(a) Show that for $k \neq n-1$ we have
$$H_k(\mathbb{R}^n \setminus X) \;\cong\; H_k(\underbrace{(\mathbb{R}^n \cup \{\infty\})}_{=S^n} \setminus X).$$

(b) Show that there exists a short exact sequence
$$0 \;\to\; \mathbb{Z} \;\to\; H_{n-1}(\mathbb{R}^n \setminus X) \;\to\; H_{n-1}((\mathbb{R}^n \cup \{\infty\}) \setminus X) \;\to\; 0.$$

(c) Show that the short exact sequence in (b) splits.

Exercise 33.6. Let X be a topological space and let $n \in \mathbb{N}$. What is the isomorphism type of $H_n(X \times S^1)$ in terms of the homology groups of X?

Exercise 33.7. Let $k \in \mathbb{N}$. We consider the topological space
$$X_k \;:=\; ([-k,k] \cup S^2 \times \{-k,\dots,k\})/\sim$$
where given $i \in \{-k,\dots,k\}$ we identify $i \in [-k,k]$ with $((0,0,-1),i) \in S^2 \times \{-k,\dots,k\}$. For $i = -k,\dots,k$ we denote by
$$\begin{array}{rcl} f_i\colon S^2 & \to & X_k \\ P & \mapsto & (P,i) \end{array}$$
the various "obvious" inclusion maps. (We refer to Figure 534 for an illustration.)

(a) Show that $H_0(X_k) \cong \mathbb{Z}$.
(b) Show that $H_i(X_k) = 0$ for $i \neq 0,2$.
(c) Let $[S^2] \in H_2(S^2)$ be the standard generator. Show that the map
$$\begin{array}{rcl} \mathbb{Z}^{2k+1} & \to & H_2(X_k) \\ (a_{-k},\dots,a_k) & \to & \sum\limits_{i=-k}^{k} a_i \cdot f_{i*}([S^2]) \end{array}$$
is an isomorphism.

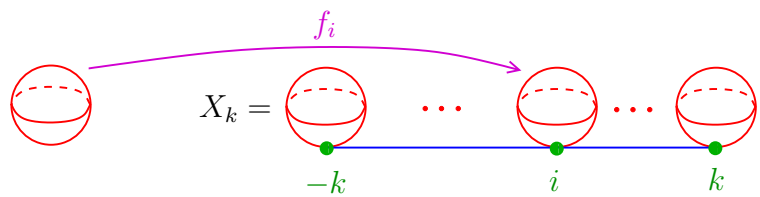

FIGURE 534.

Exercise 33.8. Let X be a topological space. We consider the corresponding suspension $\Sigma(X) = (X \times [-1,1])/\sim$ which is given by identifying all points in $X \times \{-1\}$ and by identifying all points in $X \times \{1\}$.

(a) Given a singular k-simplex $\sigma\colon \Delta^k \to X$ we define the two maps

$$\begin{array}{rcl} c_\pm(\sigma)\colon \Delta^{k+1} & \to & \Sigma(X) \\ (t_0, t_1, \ldots, t_{k+1}) & \mapsto & \begin{cases} \left(\left[\left(\sigma\left(\frac{1}{1-t_0}(t_1, \ldots, t_{k+1})\right), \pm t_0\right)\right], & \text{if } t_0 < 1, \\ [X \times \{\pm 1\}], & \text{if } t_0 = 1. \end{cases} \end{array}$$

Show that the maps $c_-(\sigma)$ and $c_+(\sigma)$ are continuous. (We refer to Figure 535 for an illustration of the definition of $c_\pm$.)
Hint: Consider $\Delta^k \times [0,1]$ and $(\Delta^k \times [0,1])/(\Delta^k \times \{1\})$.

(b) We extend $c_\pm$ in an obvious way to maps $c_\pm\colon C_k(X) \to C_k(\Sigma(X))$ and we define $s = (-1)^{k+1} \cdot (c_+ - c_-)$. Show that for any $\sigma\colon \Delta^k \to X$ we have

$$\partial s(\sigma) \;=\; \begin{cases} s(\partial\sigma), & \text{if } k > 0, \\ [X \times \{1\}] - [X \times \{-1\}], & \text{if } k = 0. \end{cases}$$

(c) Let $k \in \mathbb{N}_0$. Show that the map

$$\begin{array}{rcl} \widetilde{H}_k(X) & \to & H_{k+1}(\Sigma(X)) \\ \sigma & \mapsto & s(\sigma) \end{array}$$

is well-defined and that it is an isomorphism.

Remark: We refer to c_+, c_- as *cone operators* and we refer to s as the *suspension operator*..

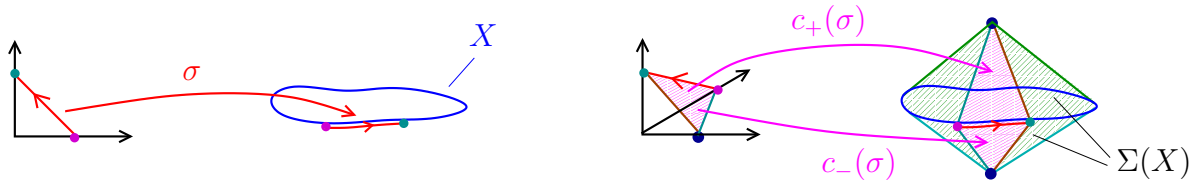

FIGURE 535.

Exercise 33.9. Let X be a topological space and let $A \subset X$ be a non-empty subset. We denote by $i\colon A \to X$ the inclusion map. We consider the following diagram

$$\begin{tikzcd}
\dots \arrow[r] & \widetilde{H}_n(A) \arrow[r, "i"] \arrow[d, "="] & \widetilde{H}_n(X) \arrow[r] \arrow[d, "="] & H_n(X,A) \arrow[r, "\partial"] \arrow[d, "\cong"] & \widetilde{H}_{n-1}(A) \arrow[r] \arrow[d, "="] & \widetilde{H}_{n-1}(X) \arrow[r] \arrow[d, "="] & \dots \\
\dots \arrow[r] & \widetilde{H}_n(A) \arrow[r, "i"] & \widetilde{H}_n(X) \arrow[r] & \widetilde{H}_n(\mathrm{Cone}(i)) \arrow[r, "\partial"] & \widetilde{H}_{n-1}(A) \arrow[r] & \widetilde{H}_{n-1}(X) \arrow[r] & \dots
\end{tikzcd}$$

where the middle vertical map is the natural isomorphism from Lemma 33.17, where the top sequence is the long exact sequence arising from Corollary 31.14. and where the bottom sequence is the exact sequence from Lemma 33.18. Show that the diagram commutes.

Exercise 33.10. Let $X = \mathbb{Z}_n$ be the topological space whose underlying set is $\mathbb{Z}_n$ and whose topology is given by the discrete topology. Let $f\colon X = \mathbb{Z}_n \to X = \mathbb{Z}_n$ be the homeomorphism given by $f(x) = x + 1 \in \mathbb{Z}_n$. Compute the homology groups of the mapping torus $M(X, f)$.

34. Homology groups and direct limits

In this chapter we will discuss the relationship between homology groups and direct limits. This will allow us to determine the homology groups of suitable nested sequences of topological spaces. In a similar vein we will determine the homology groups of the wedge of arbitrarily many topological spaces. We concludes this chapter with the introduction of the Moore spaces. We will in particular see that all abelian group can appear as homology groups of topological spaces.

For the reader who is in a hurry only few of the results of this chapter are really important. In particular, very soon we will make use of Proposition 34.9. For this proposition we give two proofs, one building on the theme of this chapter. The other proof can be read independently of the rest of the chapter.

34.1. **Direct limits and induced maps.** Given a directed set $(I, \leq)$ and a direct system $(\{K_i\}_{i\in I}, \{\chi_{ij}\}_{i\leq j})$ of abelian groups we write, as on page 487

$$\varinjlim K_i \ := \ \Big(\bigsqcup_{i\in I} K_i\Big)/\sim \quad \text{where } k_i \sim \chi_{ij}(k_i) \text{ for all } i \leq j,\ k_i \in K_i$$

We adopt the following notation, given $k_i \in K_i$ we denote by $[k_i] \in \varinjlim K_i$ the element represented by k_i. We make the following observation that follows immediately from the above definition of the direct limit.

Observation 34.1. *Any element in* $\varinjlim K_i$ *is of the form* $[k_i]$ *for some* $k_i \in K_i$.

Definition. Let $(I, \leq)$ be a directed set and let $(\{K_i\}_{i\in I}, \{\chi_{ij}\}_{i\leq j})$ and $(\{L_i\}_{i\in I}, \{\lambda_{ij}\}_{i\leq j})$ be direct systems of abelian groups.

(1) We define a *homomorphism between the above two direct systems* to be a family $\{f_i\colon K_i \to L_i\}_{i\in I}$ of homomorphisms that has the property that for any $i \leq j$ the following diagram commutes:

$$\begin{tikzcd} K_i \arrow[r, "f_i"] \arrow[d, "\chi_{ij}"'] & L_i \arrow[d, "\lambda_{ij}"] \\ K_j \arrow[r, "f_j"] & L_j. \end{tikzcd}$$

(2) Given such a homomorphism we refer to

$$\begin{array}{ccc} \varinjlim K_i & \to & \varinjlim L_i \\ [k_i] & \mapsto & [f_i(k_i)] \end{array}$$

as the induced map. Sometimes we denote it by $\varinjlim f_i$.[683][684] It is straightforward to verify that the induced maps are functorial.

Proposition 34.2. *Let $(I, \leq)$ be a directed set. Also let $(\{K_i\}_{i\in I}, \{k_{ij}\}_{i\leq j})$, $(\{L_i\}_{i\in I}, \{l_{ij}\}_{i\leq j})$ and $(\{M_i\}_{i\in I}, \{m_{ij}\}_{i\leq j})$ be direct systems of abelian groups. Furthermore suppose that we are given homomorphisms $f_i\colon K_i \to L_i$ and $g_i\colon L_i \to M_i$ of the direct systems. If for all $i \in I$ the sequence*

$$K_i \xrightarrow{f_i} L_i \xrightarrow{g_i} M_i$$

is exact, then the induced sequence

$$\varinjlim K_i \xrightarrow{\varinjlim f_i} \varinjlim L_i \xrightarrow{\varinjlim g_i} \varinjlim M_i$$

is also exact.

Proof. We write $f = \varinjlim f_i$ and $g = \varinjlim g_i$. We have to prove that $g \circ f = 0$ and that $\ker(g) \subset \operatorname{im}(f)$. Both statements statements follow our hypothesis together with Observation 34.1 and the fact that in the definition of the induced map between direct limits we can take any representative. We leave the few remaining details to the reader. □

The following corollary says that direct limits commute with kernels and cokernels.

Corollary 34.3. *Let $(I, \leq)$ be a directed set and let $(\{K_i\}_{i\in I}, \{k_{ij}\}_{i\leq j})$ and $(\{L_i\}_{i\in I}, \{l_{ij}\}_{i\leq j})$ be direct systems of abelian groups. Furthermore suppose that we are given a homomorphism $f_i\colon K_i \to L_i$ of the direct systems. Then there exist canonical isomorphisms*

$$\varinjlim \ker(f_i\colon K_i \to L_i) \xrightarrow{\cong} \ker\big(\varinjlim K_i \to \varinjlim L_i\big)$$

and

$$\varinjlim \operatorname{coker}(f_i\colon K_i \to L_i) \xrightarrow{\cong} \operatorname{coker}\big(\varinjlim K_i \to \varinjlim L_i\big).$$

Proof. For each $i \in I$ the sequence

$$0 \to \ker(f_i) \to K_i \xrightarrow{f_i} L_i \to \operatorname{coker}(f_i) \to 0.$$

is exact. Evidently these homomorphisms form a homomorphism between the various direct systems. It follows from Proposition 34.2 (applied four times!) that the sequence

$$0 \to \varinjlim \ker(f_i) \to \varinjlim K_i \to \varinjlim L_i \to \varinjlim \operatorname{coker}(f_i) \to 0$$

is also exact. But this observation already implies the desired statements. □

[683] It follows immediately from the definitions that this map is well-defined, i.e. the map does not depend on the choice $[k_i]$ of a representative for an element in the direct limit.

[684] More formally one could say that the maps $K_i \to L_i \to \varinjlim L_i$ induce, by the universal property of a direct limit, a map $\varinjlim K_i \to \varinjlim L_i$. It is straightforward to see that this map is exactly the one we wrote down.

34.2. **The homology groups of a nested sequence of topological spaces.** In Propositions 16.4 and 28.11 we saw that in favorable situations the homotopy groups of a union of a nested sequence of topological spaces is the direct limit of the corresponding fundamental groups. Now we will see that a similar statement holds for homology groups.

Proposition 34.4. *Let X be a topological space and let $X_1 \subset X_2 \subset X_3 \subset \dots$ be a sequence of subsets such that $X = \bigcup_{i\in\mathbb{N}} X_i$ and such that one the following three conditions holds:*

(1) *every compact subset of X is already contained in one of the X_i, or*
(2) *each X_i is open in X, or*
(3) *X is a CW-complex and each X_i is a subcomplex.*

Then for any $n \in \mathbb{N}_0$ the inclusion induced maps $H_n(X_i) \to H_n(X)$ induce an isomorphism

$$\varinjlim H_n(X_i) \xrightarrow{\cong} H_n(X).$$

We remark that by Corollary 26.18 hypothesis (3) implies hypothesis (1) and that by Lemma 16.5 hypothesis (2) implies hypothesis (1). Thus it suffices to prove Proposition 34.4 under the hypothesis (1). But in that case the proposition is an immediate consequence of the next two lemmas.

Lemma 34.5. *Let X be a topological space and let $X_1 \subset X_2 \subset X_3 \subset \dots$ be a sequence of subsets such that every compact subset of X is already contained in one of the X_i. Then the chain complexes $C_*(X_i), i \in \mathbb{N}$ together with the inclusion induced chain maps $C_*(X_i) \to C_*(X_j)$ for $i \leq j$ form a direct system of chain complexes.*[685] *Furthermore the inclusion induced maps $C_*(X_i) \to C_*(X)$ induce an isomorphism*[686]

$$\varinjlim C_*(X_i) \xrightarrow{\cong} C_*(X)$$

of chain complexes.

Proof. Given a topological space Y and $n \in \mathbb{N}_0$ we denote by $S_n(Y)$ the set of singular n-simplices in Y. It follows immediately from our hypothesis on the X_i, the fact that Δ^n is compact and Lemma 1.37 that

$$S_n(X) = \bigcup_{i\in\mathbb{N}} S_n(X_i).$$

As in the example on page 484 we now see that

$$\varinjlim C_n(X_i) = \varinjlim \mathbb{Z}^{(S_n(X_i))} = \mathbb{Z}^{(S_n(X))} = C_n(X).$$

We leave it as an exercise to verify that the inclusion maps also induce an isomorphism of chain complexes. □

The second lemma required for the proof of Proposition 34.4 is purely algebraic.

[685] We refer to page 482 for the definition of a direct system.

[686] The argument of Proposition 16.1 or respectively of page 487 shows that the direct limit of a direct system of chain complexes always exists.

Lemma 34.6. *Let $(I, \leq)$ be a directed set and furthermore let $(\{C_i\}_{i\in I}, \{f_{ij}\}_{i\leq j})$ be a direct system of chain complexes. Then for each $n \in \mathbb{N}_0$ we obtain an induced direct system $(\{H_n(C_i)\}_{i\in I}, \{f_{ij*}\}_{i\leq j})$ of abelian groups. Furthermore, given any $n \in \mathbb{N}_0$ the maps $H_n(C_i) \to H_n\big(\varinjlim C_i\big)$ induce an isomorphism*

$$\varinjlim H_n(C_i) \xrightarrow{\cong} H_n\big(\varinjlim C_i\big).$$

Proof. We have

$$\begin{aligned} \varinjlim H_n(C_i) &= \varinjlim \operatorname{coker}\{C_{i+1} \to \ker\{C_i \to C_{i-1}\}\} \\ &\underset{\substack{\uparrow \\ \text{Corollary 34.3 applied twice}}}{=} \operatorname{coker}\big\{\varinjlim C_{i+1} \to \ker\big\{\varinjlim C_i \to \varinjlim C_{i-1}\big\}\big\} \;=\; H_n\big(\varinjlim C_i\big). \end{aligned}$$

The fact that this isomorphism is induced by the maps $H_n(C_i) \to H_n(\varinjlim C_i)$ follows easily from the various definitions. □

We conclude this short section with a few examples:

Example. For any $n \in \mathbb{N}_0$ we have

$$H_n(S^\infty) \underset{\substack{\uparrow \\ \text{by Proposition 34.4,} \\ \text{where we view } S^\infty \text{ as a} \\ \text{CW-complex as on page 655}}}{=} \varinjlim_{k\in\mathbb{N}} H_n(S^k) \underset{\substack{\uparrow \\ \text{Proposition 31.3}}}{=} \varinjlim_{k\in\mathbb{N}} \begin{cases} \mathbb{Z}, & \text{if } n = k, 0, \\ 0, & \text{else} \end{cases} \underset{\substack{\uparrow \\ \text{Lemma 16.2}}}{=} \begin{cases} \mathbb{Z}, & \text{if } n = 0, \\ 0, & \text{else.} \end{cases}$$

The next lemma is basically also just an example. But since we will need it later on we formulate it as a lemma.

Lemma 34.7. *We consider the real line with infinitely many 2-dimensional spheres attached, i.e. we consider*

$$X \;:=\; (\mathbb{R} \cup (S^2 \times \mathbb{Z}))/\sim \qquad \textit{where } n \sim ((0,0,-1), n) \textit{ for } n \in \mathbb{Z}.$$

Then[687]

$$H_n(X) \;\cong\; \begin{cases} \mathbb{Z}, & \textit{if } n = 0, \\ \mathbb{Z}^\infty, & \textit{if } n = 2, \\ 0, & \textit{else.} \end{cases}$$

[687]Recall that

$$\mathbb{Z}^\infty \;:=\; \mathbb{Z}^{(\mathbb{N})} \;=\; \{(x_1, x_2, \dots) \,|\, x_i \in \mathbb{Z} \text{ but only finitely many } x_i\text{'s are non-zero}\}.$$

In fact we can specify an isomorphism on $H_2(X)$. Given $i \in \mathbb{Z}$ we denote by $f_i \colon S^2 \to X$ the "obvious" i-th inclusion map. Then an isomorphism is given by

$$\begin{array}{rcl} \mathbb{Z}^\infty \cong \bigoplus_{i\in\mathbb{Z}} \mathbb{Z} & \to & H_2(X) \\ \bigoplus_{i\in\mathbb{Z}} a_i & \mapsto & \sum_{i\in\mathbb{Z}} a_i \cdot f_i([S^2]). \end{array}$$

Proof. We view X as a CW-complex in the obvious way. Furthermore, given $k \in \mathbb{N}$ we consider the subcomplex

$$X_k \ := \ ([-k,k] \cup S^2 \times \{-k,\dots,k\})/\sim .$$

Note that X_k is the interval $[-k,k]$ with $2k+1$ spheres attached. (We refer to Figure 536 for an illustration.) We have

$$H_n(X) \underset{\substack{\uparrow \\ \text{Proposition 34.4}}}{=} \varinjlim H_n(X_k) \underset{\substack{\uparrow \\ \text{see Exercise 33.7}}}{=} \varinjlim \begin{cases} \mathbb{Z}, & \text{if } n=0, \\ \mathbb{Z}^{2k+1}, & \text{if } n=2, \\ 0, & \text{else} \end{cases} \underset{\substack{\uparrow \\ \text{see page 484 and Lemma 16.2}}}{=} \begin{cases} \mathbb{Z}, & \text{if } n=0, \\ \mathbb{Z}^\infty, & \text{if } n=2, \\ 0, & \text{else.} \end{cases}$$

The statement about the precise isomorphism of $H_2(X)$ also follows from the explicit description of the isomorphism Exercise 33.7 and the discussion on page 484. □

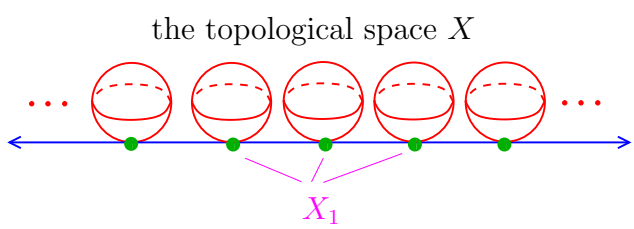

FIGURE 536.

34.3. **The homology groups of the wedge of topological spaces.** The following proposition says that under a mild hypothesis "homology groups are additive" under the operation of taking the wedge of two topological spaces. The proposition is very similar in vein to Proposition 12.3.

Proposition 34.8. *Let A and B be two topological spaces and let $a \in A$ and $b \in B$ be good points. We denote by $A \vee B$ the wedge defined using a and b. Then the natural inclusion maps $i \colon A \to A \vee B$ and $j \colon B \to A \vee B$ that we introduced on page 317 induce for every*

$n \in \mathbb{N}_0$ an isomorphism

$$i_* \oplus j_* \colon \widetilde{H}_n(A) \oplus \widetilde{H}_n(B) \quad \to \quad \widetilde{H}_n(A \vee B).$$

Furthermore, if we denote by $p \colon A \vee B \to A$ and $q \colon A \vee B \to A$ the natural projection maps, then an inverse to the above isomorphism is given by

$$p_* + q_* \colon \widetilde{H}_n(A \vee B) \quad \to \quad \widetilde{H}_n(A) \oplus \widetilde{H}_n(B).$$

Proof $(*)$. We write $X = A \vee B$ and $x_0 = \{a, b\} \in A \vee B$. We pick an open neighborhood C in A of a such that $\{a\}$ is a deformation retract of C. Furthermore we pick an open neighborhood D of b in B such that b is a deformation retract of D. We consider $U := A \vee D$

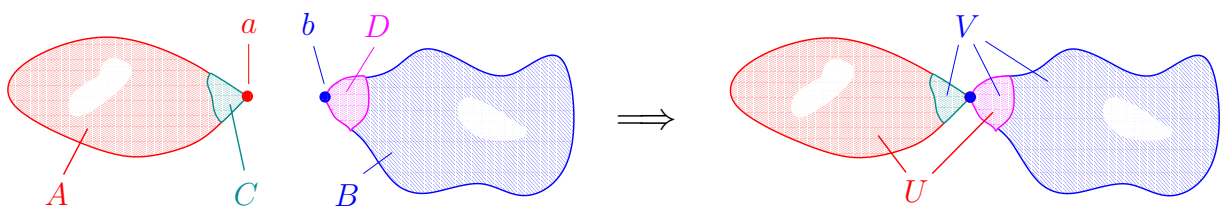

FIGURE 537. Schematic image for the proof of Proposition 34.8.

and $V := B \vee C$. We consider the following diagram of maps

$$\begin{array}{ccccccccc} & & & & \widetilde{H}_n(A) \oplus \widetilde{H}_n(B) & & & & \\ & & & & \cong\downarrow \qquad \downarrow\cong & & & & \\ \dots & \longrightarrow & \widetilde{H}_n(U \cap V) & \longrightarrow & \widetilde{H}_n(U) \oplus \widetilde{H}_n(V) & \longrightarrow & \widetilde{H}_n(X) & \longrightarrow & \widetilde{H}_{n-1}(U \cap V) \longrightarrow \dots \end{array}$$

We make the following observations:

(1) The bottom sequence is exact by the Mayer–Vietoris Theorem 33.5.
(2) As in the proof of Proposition 12.3 we see that the intersection $U \cap V$ deformation retracts to x_0, in particular we obtain from Corollary 30.8 that we have the equality $\widetilde{H}_n(U \cap V) = \widetilde{H}_{n-1}(U \cap V) = 0$.
(3) By the proof of Proposition 12.3 we know that A is a deformation retract of U and that B is a deformation retract of V. Therefore the vertical maps are isomorphisms by Corollary 30.8.

The combination of these three observations shows that

$$i_* \oplus j_* \colon \widetilde{H}_n(A) \oplus \widetilde{H}_n(B) \quad \to \quad \widetilde{H}_n(A \vee B)$$

is an isomorphism. It is clear that $(p_* + q_*) \circ (i_* + j_*)$ is the identity on $\widetilde{H}_n(A) \oplus \widetilde{H}_n(B)$, so we also get the second isomorphism. $\square$

Proposition 34.8 has nothing to do with the content of the present chapter, we could easily have proved it in the previous chapter. But odd as it may sound, soon we will be quite

interested in the homology groups of the wedge $\bigvee_{i\in I} X_i$ of an arbitrary family of topological spaces. If I is a finite set, i.e. if we take the wedge of finitely many topological spaces, then we can use Proposition 34.8 and an elementary induction argument to determine the homology groups.

It is a priori less clear how one can deal with the case that I is an infinite set. Fortunately the next proposition allows us to handle the general situation. Proposition 34.8 to the wedge of an arbitrary family of topological spaces.

Proposition 34.9. *Let $\{A_k\}_{k\in K}$ be a family of topological spaces. For each $k \in K$ suppose that we are given a good point $a_k \in A_k$.*[688] *Given $j \in K$ we denote by*

$$i_j\colon A_j \to \bigvee_{k\in K} A_k \quad \textit{respectively} \quad p_j\colon \bigvee_{k\in K} A_k \to A_j$$

the natural inclusion map respectively the natural projection map that we introduced on page 317. Then for every $n \in \mathbb{N}_0$ the map

$$\bigoplus_{k\in K} p_{k*}\colon \widetilde{H}_n\Big(\bigvee_{k\in K} A_k\Big) \to \bigoplus_{k\in K} \widetilde{H}_n(A_k)$$

is an isomorphism where the inverse is given by

$$\bigoplus_{k\in K} i_{k*}\colon \bigoplus_{k\in K} \widetilde{H}_n(A_k) \to \widetilde{H}_n\Big(\bigvee_{k\in K} A_k\Big)$$

We like Proposition 34.9 so much that we provide two different proofs. The first proof is quick and slick, but depending on your taste the first proof might have feel slightly unsatisfactory. The second proof is somewhat longer, but it fits in better with the discussion of this chapter.

First proof of Proposition 34.9. We have the following isomorphisms:

$$\widetilde{H}_n\Big(\bigvee_{k\in K} A_k\Big) \underset{\substack{\uparrow \\ \text{definition of the} \\ \text{wedge operation}}}{=} \widetilde{H}_n\Big(\bigsqcup_{k\in K} A_k \Big/ \bigsqcup_{k\in K}\{a_k\}\Big) \underset{\substack{\uparrow \\ \text{since each } a_k\in A_k \text{ is simple we see} \\ \text{that } \bigsqcup_{k\in K}\{a_k\} \text{ is a good subset of } \bigsqcup_{k\in K} A_k, \\ \text{thus we can apply Proposition 31.19}}}{\overset{\cong}{\longleftarrow}} H_n\Big(\bigsqcup_{k\in K} A_k, \bigsqcup_{k\in K}\{a_k\}\Big) \underset{\substack{\uparrow \\ \text{by the obvious generalization} \\ \text{of Lemma 29.13}}}{\overset{\cong}{\longleftarrow}} \bigsqcup_{k\in K} H_k(A_k, \{a_k\})$$

$$\underset{\substack{\uparrow \\ \text{Lemma 31.12}}}{\overset{\cong}{\longleftarrow}} \bigsqcup_{k\in K} \widetilde{H}_k(A_k).$$

We leave it as an exercise to verify that the isomorphism is indeed given by $\bigoplus_{k\in K} p_{k*}$ and that the inverse is the map $\bigoplus_{k\in K} i_{k*}$. □

[688] Recall that by the discussion on page 387 any point on a topological manifold is good and that by Proposition 26.11 (5) any point on a CW-complex is good.

Second proof of Proposition 34.9. Let $\{A_k\}_{k\in K}$ be a family of topological spaces. We will show that the map

$$\bigoplus_{k\in K} i_k \colon \bigoplus_{k\in K} \widetilde{H}_n(A_k) \;\to\; \widetilde{H}_n\Big(\bigvee_{k\in K} A_k\Big)$$

is an isomorphism. Once we will have established this fact it is straightforward to show that the inverse is given by $\bigoplus_{k\in K} p_{k*}$.

The idea of the proof is to show that the map is a monomorphism and an epimorphism, in a way which is reminiscent to the approach taken in the proofs of Proposition 34.4 and 34.4. Given a subset $J \subset K$ we write $B_J := \bigvee_{j\in J} A_j$ and we write $B := B_K$. Given any two finite subsets $J \subset \widetilde{J} \subset K$ we have the following commutative diagram

$$\begin{tikzcd}
\bigoplus_{j\in J} \widetilde{H}_n(A_j) \arrow[rr, "\cong"] \arrow[dr, hook] \arrow[ddr, hook] & & \widetilde{H}_n(B_J) \arrow[dr] \arrow[ddr] & \\
& \bigoplus_{j\in \widetilde{J}} \widetilde{H}_n(A_j) \arrow[rr, "\cong"] \arrow[dl, hook] \arrow[ddr] & & \widetilde{H}_n(B_{\widetilde{J}}) \arrow[ddl] \\
\bigoplus_{k\in K} \widetilde{H}_n(A_k) \arrow[rr] & & \widetilde{H}_n(B). &
\end{tikzcd}$$

We make the following observations and comments:

(1) The maps are either the obvious algebraic inclusion maps or they are the obvious maps induced by inclusions of topological spaces.
(2) Since J and $\widetilde{J}$ are finite we obtain, as pointed out above, from Proposition 34.8 that the top two horizontal maps are isomorphisms.
(3) By Exercise 9.18 we know that given any compact subset $L \subset B$ there exists a finite subset $J \subset K$ with $L \subset B_J$.

Now we show that the above map $\bigoplus_{k\in K} i_{k*}$ is an epimorphism. So suppose we are given a homology class $[\sigma] \in \widetilde{H}_n(B)$. As in the proof of Lemma 34.5 we see that it follows from (3) there exists a finite subset $J \subset K$ such that $\sigma \in C_n(B_J)$. But considering the above blue diagram, and using the fact that the top horizontal map is an isomorphism we see that $[\sigma]$ actually lies in the image of $\bigoplus_{k\in K} i_k$.

In Exercise 34.1 we will use the above diagram in its full glory to show that the map $\bigoplus_{k\in K} i_{k*}$ is also a monomorphism. $\square$

34.4. **Moore spaces** $(*)$**.** Now that we have played with homology groups the following question arises: which sequences of abelian groups can appear as the sequence of homology groups $H_*(X)$ of a topological space? It turns out that anything goes, there are basically no restrictions, except that we know by Corollary 29.14 that $H_0(X)$ is necessarily a free abelian group.

In other words, we have the following proposition.

Proposition 34.10. *If $\{A_n\}_{n\in\mathbb{N}_0}$ is a sequence of abelian groups. If A_0 is a free abelian group, then there exists a CW-complex X such that for any $n \in \mathbb{N}_0$ we have $H_n(X) \cong A_n$.*

This proposition is hardly the most exciting result of these notes. But the following definition, which we will need in the proof of Proposition 34.10, will in fact turn out to be convenient.

Definition. Let $n \in \mathbb{N}$ and let π be an abelian group. We say that a topological space X is a *Moore space of type $M(\pi, n)$* if the following conditions are satisfied:

(1) $H_n(X) \cong \pi$,
(2) for any $i \neq n$ we have $\widetilde{H}_i(X) = 0$.
(3) If $n \geq 2$, then we also demand that X is simply connected.

Example. Let $n \in \mathbb{N}$. It follows from Proposition 5.14 and Proposition 31.3 that S^n is a Moore space of type $(\mathbb{Z}, n)$.

Proposition 34.11. *Given any $n \in \mathbb{N}$ and given any abelian group π there exists an $(n+1)$-dimensional CW-complex that has no cells in dimensions $1, \ldots, n-1$ and that is a Moore space of type $M(\pi, n)$.*

Proof of Proposition 34.10 assuming Proposition 34.11. Let $\{A_n\}_{n\in\mathbb{N}_0}$ be a sequence of abelian groups. By Proposition 34.11 we can find for each $n \in \mathbb{N}$ a CW-complex X_n that is a Moore space of type $M(\pi, n)$. We consider the wedge $Y := \bigvee_{n\in\mathbb{N}} X_n$. By Lemma 26.20 (3) we can equip Y with a CW-structure. It follows from Proposition 34.9 that for every $n \in \mathbb{N}$ we have $H_n(X) \cong H_n(X_n) \cong A_n$. □

In the proof of Proposition 34.11 we will also need the following little calculation which will be of independent use.

Lemma 34.12. *Let (X, x_0) be a pointed topological space, let $n \in \mathbb{N}$, let $\omega \in H_n(X, x_0)$ and let $f, g\colon (I^n, \partial I^n) \to (X, x_0)$ be two maps. Then*

$$[f_*(\omega)] + [g_*(\omega)] \underset{\substack{\uparrow \\ \text{product of } f \text{ and } g \text{ as defined on page 710}}}{=} [(f * g)_*(\omega)] \in H_n(X, x_0) = H_n(X).$$

Proof $(*)$. We write $J = I^n$, $J_1 = [0, \frac{1}{2}] \times I^{n-1}$ and $J_2 = [\frac{1}{2}, 1] \times I^{n-1}$. Furthermore we write $K = \partial J \cup (\{\frac{1}{2}\} \times I^{n-1})$. We refer to Figure 538 for an illustration. For $k = 1, 2$ we denote by $i_k\colon (J_k, \partial J_k) \to (J, K)$ the inclusion map and we denote by $\varphi_k\colon (J_k, \partial J_k) \to (J, \partial J)$ the obvious homeomorphism given by stretching the last coordinate.

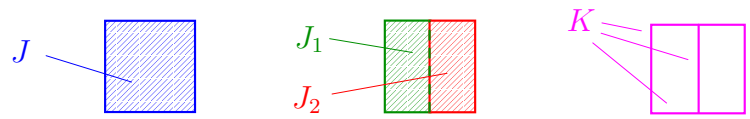

FIGURE 538. Illustration for the proof of Lemma 34.12.

The map $f * g\colon (J, \partial J) \to (X, x_0)$ factors through a map $(J, K) \to (X, x_0)$ that we also denote by $f * g$. Thus we have have the following commutative diagram

$$\begin{tikzcd}
 & (J_1, \partial J_1) \arrow[d, "i_1"] \arrow[dr, "f\circ\varphi_1^{-1}"] & \\
(J, \partial J) \arrow[ur, "\varphi_1"] \arrow[r, "i"] \arrow[dr, "\varphi_2"'] & (J, K) \arrow[r, "f*g"] & (X, x_0) \\
 & (J_2, \partial J_2). \arrow[u, "i_2"'] \arrow[ur, "g\circ\varphi_2^{-1}"'] &
\end{tikzcd}$$

For $k = 1, 2$ we write $\omega_k = (\varphi_k)_*(\omega)$. Thus it suffices to show that $i_{1*}(\omega_1) + i_{2*}(\omega_2) = i_*(\omega)$. To prove this equality we consider the following commutative diagram[689]

$$\begin{tikzcd}
 & H_n(J_1, \partial J_1) \arrow[r, "k_1"] \arrow[d, "i_1"] & H_n(J, \partial J_1 \cup J_2) \\
H_n(J, \partial J) \arrow[ur, "\varphi_1"] \arrow[r, "i"] \arrow[dr, "\varphi_2"'] & H_n(J, K) \arrow[ur, "j_1"'] \arrow[dr, "j_2"] & \\
 & H_n(J_2, \partial J_2) \arrow[u, "i_2"'] \arrow[r, "k_2"'] & H_n(J, J_1 \cup \partial J_2),
\end{tikzcd}$$

where all maps, except for φ_1 and φ_2, are induced by the obvious inclusion maps. We have

$$(j_1)(i(\omega)) \;=\; (k_1 \circ \varphi_1)(\omega) \;=\; j_1(i_1(\omega_1)) \;\underset{\substack{\uparrow \\ \text{since } j_1 \circ i_2 = 0}}{=}\; j_1(i_1(\omega_1)) + j_1(i_2(\omega_2))$$

and similarly we show that $(j_2)(i(\omega)) = j_2(i_1(\omega_1)) + j_2(i_2(\omega_2))$.

It remains to show that $\ker(j_1) \cap \ker(j_2) = 0$. We consider the following diagram

$$\begin{tikzcd}
 & & H_n(J, \partial J_1 \cup J_2) \\
 & H_n(J, K) \arrow[ur, "j_1"'] \arrow[dr, "j_2"] & \\
H_n(J, \partial J_1 \cup J_2) \arrow[ur] & H_n(J_2, \partial J_2) \arrow[l, "\cong"] \arrow[u, "i_2"'] \arrow[r, "k_2", "\cong"'] & H_n(J, J_1 \cup \partial J_2).
\end{tikzcd}$$

[689]To simplify the notation we denote the induced map by the same symbol as the map between pairs of topological spaces, i.e. we drop the subscript $*$ from the notation.

The bottom two horizontal maps are isomorphisms by the Excision Theorem 32.6. The diagonal sequence is exact by Proposition 31.13. It now follows from some mild diagram chasing that $\ker(j_1) \cap \ker(j_2) = 0$. □

Lemma 34.13.

(1) *Let $f\colon S^n \to S^n_1 \vee S^n_2$ be the pinching map that we introduced on page 715. Let $i \in \{1,2\}$. If we denote by $S^n_1 \vee S^n_2 \to S^n_i = S^n$ the obvious projection, then the induced map $(p_i \circ f)_*\colon H_n(S^n) \to H_n(S^n)$ is the identity.*

(2) *Given any $k \in \mathbb{Z}$ there exists a map $g_k\colon S^n \to S^n$ with $g_k(*) = *$ such that $g_{k*}\colon H_n(S^n) \to H_n(S^n)$ is given by multiplication by k.*

Proof.

(1) The first statement follows easily from Lemma 34.12.

(2) The second statement follows almost immediately from Lemma 32.15 together with Proposition 32.14. □

Now we turn to the proof of Proposition 34.11.

Proof of Proposition 34.11. Let $n \in \mathbb{N}$ and and let π be an abelian group. Since π is abelian it follows immediately from Lemma 42.16 (1)[690] that there exist sets A and B, a homomorphism $\varphi\colon \mathbb{Z}^{(A)} \to \mathbb{Z}^{(B)}$ and a homomorphism $\rho\colon G \to \pi$ such that the following sequence is exact:

$$0 \to \mathbb{Z}^{(A)} \xrightarrow{\varphi} \mathbb{Z}^{(B)} \xrightarrow{\rho} \pi \to 0.$$

We let $X := \bigvee_{a\in A} S^n_a$ and we let $Y := \bigvee_{b\in B} S^n_b$. By Lemma 26.20 (3) we can equip X with the obvious CW-structure which has precisely one 0-cell and which has precisely one n-cell for each $a \in A$. Similarly we equip Y with the obvious CW-structure. Using Proposition 34.9 and using the standard generator of $H_n(S^n)$ we can make the obvious identifications $H_n(X) = \mathbb{Z}^{(S)}$ and $H_n(Y) = \mathbb{Z}^{(T)}$.

Claim. There exists a map $h\colon X \to Y$ such that the following diagram commutes:

$$\begin{array}{ccc} H_n(X) & \xrightarrow{h_*} & H_n(Y) \\ {\scriptstyle =}\downarrow & & \downarrow{\scriptstyle =} \\ \mathbb{Z}^{(A)} & \xrightarrow{\varphi} & \mathbb{Z}^{(B)}. \end{array}$$

This map φ can be constructed explicitly using the following ingredients:

(1) the pinching map $f\colon S^n \to S^n_1 \vee S^n_2$,

(2) the maps $g_k\colon S^n \to S^n$ from Lemma 34.13,

(3) the natural inclusions and projections from page 317,

(4) and the wedge of maps as introduced on page 316.

[690] In this case the fact that we refer to a later lemma need not worry us. As the reader can see, the proof of Lemma 42.16 (1) relies only on information that we already know.

The notation becomes somewhat cumbersome, thus we leave it as an exercise to the reader to fill in the details. A baby example is the content of Exercise 34.2. This concludes the proof of the claim.

Now let $Z := \mathrm{Cone}(h\colon X \to Y)$ be the mapping cone of the map $h\colon X \to Y$. It follows from the above claim and Lemma 33.18 that we have the following commutative diagram of long exact sequences

$$\begin{array}{ccccccccccccc}
\dots \longrightarrow & \overbrace{H_{n+1}(Y)}^{=0} & \longrightarrow & H_{n+1}(Z) & \longrightarrow & H_n(X) & \xrightarrow{h_*} & H_n(Y) & \longrightarrow & H_n(Z) & \longrightarrow & \overbrace{H_{n-1}(X)}^{=0} & \longrightarrow \dots \\
 & \downarrow & & \downarrow{=} & & \downarrow{=} & & \downarrow{=} & & & & \downarrow & \\
\dots \longrightarrow & 0 & \longrightarrow & H_{n+1}(Z) & \longrightarrow & \mathbb{Z}^{(A)} & \xrightarrow{\varphi} & \mathbb{Z}^{(B)} & \longrightarrow & H_n(Z) & \longrightarrow & 0 & \longrightarrow \dots .
\end{array}$$

It follows that $H_n(Z) \cong \mathrm{coker}(\varphi) \cong \pi$. Furthermore, since φ is injective we see that $H_{n+1}(Z) = 0$. Furthermore we see that all other reduced homology groups of Z are also zero.

Next we equip Z with the natural CW-structure coming from Corollary 26.24. There is one small fly in the ointment. The CW-structure has two 0-cells (namely one corresponding to the tip of the cone and the 0-cell of Y), one 1-cells and otherwise indeed only cells in dimensions n and $n+1$. Let A be the subcomplex that consists of the 1-cell that connects the two 0-cells. By Lemma 26.20 we can view X/A as a CW-complex which now has only one 0-cell and otherwise only cells in dimension n and $n+1$. By the discussion on page 764 we know that A is a good subset of X. It follows from Theorem 31.2 that the reduced homology groups of X/A coincide with the reduced homology groups of X. Thus we see that X/A is the CW-complex of our dreams. □

Exercises for Chapter 34.

Exercise 34.1. In the second proof of Proposition 34.9, given on page 874, show that the map

$$\bigoplus_{k\in K} i_{k*}\colon \bigoplus_{k\in K} \widetilde{H}_n(A_k) \;\to\; \widetilde{H}_n\Big(\bigvee_{k\in K} A_k\Big)$$

is a monomorphism.
Hint: Consider the commutative diagram shown on page 874.

Exercise 34.2. Let $n \in \mathbb{N}$ and let $X = S^n \vee S^n$ and let $Y = S^n \vee S^n \vee S^n$. As in the proof of Proposition 34.11 we can make the identification $H_n(X) = \mathbb{Z}^2$ and $H_n(Y) = \mathbb{Z}^3$. Show that there exists a map $\varphi\colon X \to Y$ such that the map $\varphi_*\colon H_n(X) \to H_n(Y)$ is represented by the matrix

$$\begin{pmatrix} 2 & 1 \\ -5 & 1 \\ 0 & 7 \end{pmatrix}.$$

Exercise 34.3. Let X and Y be topological spaces and let $x_0 \in X$ and $y_0 \in Y$ be good points. We write $\widetilde{x}_0 = [(x_0, 0)] \in \Sigma(X)$ and $\widetilde{y}_0 = [(y_0, 0)] \in \Sigma(Y)$.

(a) Show that $\widetilde{x}_0 \in \Sigma(X)$ and $\widetilde{y}_0 \in \Sigma(Y)$ are good points. We use these points to define the wedge $\Sigma(X) \vee \Sigma(Y)$.

(b) Let $i\colon X \to X \vee Y$ and $j\colon Y \to X \vee Y$ be the obvious maps. Show that the map

$$(\Sigma(i) \vee \Sigma(j))_*\colon H_k(\Sigma(X) \vee \Sigma(Y)) \;\to\; H_k(\Sigma(X \vee Y))$$

is an isomorphism for each k.

Remark: You could make use of the *natural* isomorphism of Lemma 33.8.

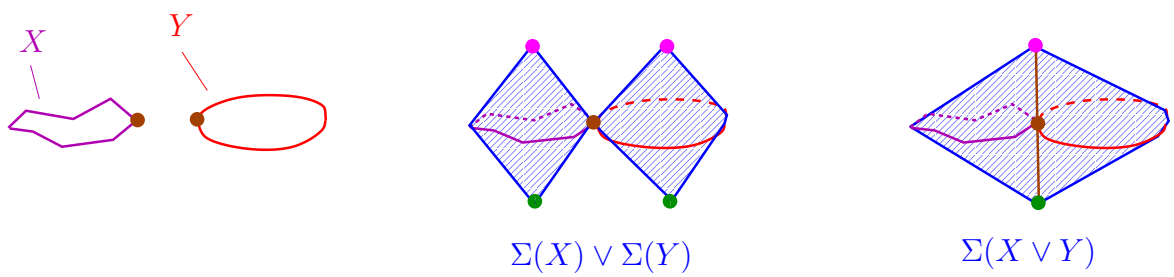

FIGURE 539. Illustration of Exercise 34.3.

35. Cellular homology

We saw in Propositions 27.9 and 27.10 that it is quite easy to compute the fundamental group of a finite CW-complex. In this section we will develop a relatively straightforward method for computing the homology groups of a finite CW-complex. We will use this method for finally determining the homology groups of the surfaces of genus ≥ 2 and all the projective spaces $\mathbb{R}\mathrm{P}^n$ and $\mathbb{C}\mathrm{P}^n$.

35.1. **The definition of cellular homology.** Now we turn, as promised, to the study of homology groups of CW-complexes. We need to recall two definitions:

(1) First recall that in Lemma 29.1 we gave a homeomorphism $f\colon (\Delta^n, \partial\Delta^n) \to (\overline{B}^n, \partial\overline{B}^n)$. This homeomorphism together with Lemma 32.9 gives us the following isomorphism:

$$\begin{array}{ccccc} \mathbb{Z} & \xrightarrow{\cong} & H_n(\Delta^n, \partial\Delta^n) & \xrightarrow[\cong]{f_*} & H_n(\overline{B}^n, \partial\overline{B}^n) \\ 1 & \mapsto & [\mathrm{id}_{\Delta^n}] & & \end{array}$$

In the following we will usually identify $H_n(\overline{B}^n, \partial\overline{B}^n)$ with $\mathbb{Z}$ using the above isomorphism.

(2) Let X be a topological space and let $A \subset X$ be a non-empty subset. Following the discussion on page 783 we refer to

$$\begin{tikzcd} H_n(X,A) \arrow[r] \arrow[rr, bend right] & H_n(X/A, A/A) & \widetilde{H}_n(X/A) \arrow[l, "\text{Lemma 31.12}"', "\cong"] \end{tikzcd}$$

as the natural homomorphism $H_n(X,A) \to \widetilde{H}_n(X/A)$. We will often write down this map without explicitly referring to it as being the natural homomorphism.

Now we can formulate one of the key lemmas regarding homology groups of CW-complexes.

Lemma 35.1. *For every CW-complex X the following statements hold:*

(1) *Denote by I_n the set of n-cells and given $i \in I_n$ denote by $\Phi_i\colon \overline{B}^n_i \to X^n$ the corresponding characteristic map. Then for every $k \in \mathbb{N}_0$ all the maps*[691]

$$\bigoplus_{i\in I_n} H_k(\overline{B}^n_i, \partial\overline{B}^n_i) \;\to\; \bigoplus_{i\in I_n} \widetilde{H}_k\big(\overline{B}^n_i/\partial\overline{B}^n_i\big) \;\xrightarrow{\oplus\Phi_i}\; \widetilde{H}_k(X^n/X^{n-1}) \;\leftarrow\; H_k(X^n, X^{n-1})$$

are isomorphisms. In particular the following holds:

(a) *For $k \neq n$ we have $H_k(X^n, X^{n-1}) = 0$.*

(b) *The group $H_n(X^n, X^{n-1})$ is a free abelian group where the rank equals the cardinality of the set of n-cells in the CW-structure.*

(2) *For $k > n$ we have $H_k(X^n) = 0$.*

(3) *For $k < n$ the inclusion $i\colon X^n \to X$ induces an isomorphism $i_*\colon H_k(X^n) \xrightarrow{\cong} H_k(X)$.*

(4) *The inclusion $i\colon X^n \to X$ induces an epimorphism $i_*\colon H_n(X^n) \twoheadrightarrow H_n(X)$.*

Remark. The statements (3) and (4) of Lemma 35.1 can be viewed as "homology analogues" of Proposition 27.12.

[691] Here the maps to the left and right are examples of the aforementioned natural homomorphism

Proof. Let X be a CW-complex.

(1) We have

$$\begin{array}{ccccccc}
 & \text{isomorphism by Proposition 31.19} & & \text{isomorphism by Proposition 34.9} & & & \\
 & \downarrow & & \downarrow & & & \\
\bigoplus_{i\in I_n} H_k(\overline{B}_i^n, \partial\overline{B}_i^n) & \to & \bigoplus_{i\in I_n} \widetilde{H}_k(\overline{B}_i^n/\partial\overline{B}_i^n) & \to & \widetilde{H}_k\Big(\bigvee_{i\in I_n} \overline{B}_i^n/\partial\overline{B}_i^n\Big) & & \\
 & & & \to & \widetilde{H}_k(X^n/X^{n-1}) & \leftarrow & H_k(X^n, X^{n-1}). \\
 & & & \uparrow & & \uparrow & \\
 & & & \text{by Lemma 26.21 (1) we know that the characteristic maps induce a homeomorphism } \bigvee_{i\in I_n} \overline{B}_i^n/\partial\overline{B}_i^n \to X^n/X^{n-1} & & \text{isomorphism by Proposition 31.19 and Proposition 26.11 (8)} &
\end{array}$$

The remaining statements are now an immediate consequence of Lemma 32.8.

(2) We fix $k \in \mathbb{N}$. We want to show that $H_k(X^n) = 0$ for $n = 0, \dots, k-1$. First of all we have $H_k(X^0) = 0$ by Proposition 29.5 and Lemma 29.13.[692] Now assume that we already know that $H_k(X^n) = 0$ for some $n < k-1$. We want to show that $H_k(X^{n+1}) = 0$. We consider the long exact sequence of the pair (X^{n+1}, X^n):

$$\dots \to H_{k+1}(X^{n+1}, X^n) \to \underbrace{H_k(X^n)}_{=0} \to H_k(X^{n+1}) \to \underbrace{H_k(X^{n+1}, X^n)}_{\substack{= 0 \text{ by (1) since } n<k\text{-1} \\ \text{i.e. since } k \neq n+1}} \to \dots$$

Thus we obtain that indeed $H_k(X^{n+1}) = 0$.

(3) We fix $k \in \mathbb{N}_0$. Let $m > k$. This time we consider the following excerpt from the long exact sequence of the pair (X^{m+1}, X^m):

$$\dots \to \underbrace{H_{k+1}(X^{m+1}, X^m)}_{= 0 \text{ by (1) since } k<m} \to H_k(X^m) \to H_k(X^{m+1}) \to \underbrace{H_k(X^{m+1}, X^m)}_{= 0 \text{ by (1) since } k<m} \to \dots$$

This implies in particular that for each $k < n \leq l$ we have inclusion induced isomorphisms $H_k(X^n) \xrightarrow{\cong} H_k(X^{n+1}) \xrightarrow{\cong} \dots \xrightarrow{\cong} H_k(X^l)$. In particular, if X is finite-dimensional, then claim (3) follows immediately from this observation. The infinite-dimensional case follows from the finite-dimensional case together with Proposition 34.4.

(4) In (3) we showed that $H_n(X^{n+1}) \to H_n(X)$ is an isomorphism. Hence it suffices to show that $H_n(X^n) \to H_n(X^{n+1})$ is an epimorphism. To show this we consider the following excerpt from long exact sequence of the pair (X^{n+1}, X^n):

$$\dots \to H_{n+1}(X^{n+1}, X^n) \to H_n(X^n) \to H_n(X^{n+1}) \to \underbrace{H_n(X^{n+1}, X^n)}_{= 0 \text{ by (1)}} \to \dots$$

We see that the inclusion induced map $H_n(X^n) \to H_n(X^{n+1})$ is indeed an epimorphism. □

[692] Here we use that X^0 has the discrete topology.

Definition. Given a CW-complex X, we denote by $d = d_n$ the map

$$\begin{tikzcd} H_n(X^n, X^{n-1}) \arrow[r, "\partial_n"] \arrow[rr, bend right, "=:d=d_n"'] & H_{n-1}(X^{n-1}) \arrow[r, "j_{n-1}"] & H_{n-1}(X^{n-1}, X^{n-2}) \end{tikzcd}$$

where ∂_n is the connecting map in the long exact sequence of the pair (X^n, X^{n-1}) and where j_{n-1} is the map induced by the projection $C_{n-1}(X^{n-1}) \to C_{n-1}(X^{n-1}, X^{n-2})$. We refer to d_n as the *cellular boundary map*.[693]

The name "cellular boundary map" already suggests that the maps d_n have the following important property:

Lemma 35.2. *For all $n \in \mathbb{N}_0$ we have $d_n \circ d_{n+1} = 0$.*

Proof. We consider the following commutative diagram of maps

$$\begin{tikzcd} & H_n(X^n) \arrow[dr, "j_n"] & & & \\ H_{n+1}(X^{n+1}, X^n) \arrow[ur, "\partial_{n+1}"] \arrow[rr, "d_{n+1}"] & & H_n(X^n, X^{n-1}) \arrow[rr, "d_n"] \arrow[dr, "\partial_n"] & & H_{n-1}(X^{n-1}, X^{n-2}) \\ & & & H_{n-1}(X^{n-1}) \arrow[ur, "j_{n-1}"'] & \end{tikzcd}$$

The map $\partial_n \circ j_n \colon H_n(X^n) \to H_{n-1}(X^{n-1})$ is the composition of two successive maps in the long exact sequence of the pair (X^n, X^{n-1}), i.e. the map $\partial_n \circ j_n$ is the zero map. Since the diagram commutes we obtain that $d_n \circ d_{n+1} = 0$. □

Definition. Let X be a CW-complex.

(1) We write $C_n^{\mathrm{CW}}(X) := H_n(X^n, X^{n-1})$ and we refer to $(C_*^{\mathrm{CW}}(X), d_n)$ as the *cellular chain complex* of the CW-complex X.[694]
(2) We denote the homology groups of the cellular chain complex by $H_n^{\mathrm{CW}}(X)$ and we refer to these groups as the *cellular homology groups of the CW-complex X*.

Example. We consider the n-sphere S^n for $n \geq 2$. On page 648 we showed that we can view S^n as a CW-complex with one 0-cell and one n-cell. The cellular chain complex $C_*^{\mathrm{CW}}(X)$ is thus of the form

$$0 \to \underbrace{\mathbb{Z}}_{=C_n^{\mathrm{CW}}(X)} \to 0 \to \ldots \to 0 \to \underbrace{\mathbb{Z}}_{=C_0^{\mathrm{CW}}(X)} \to 0.$$

Since $n \geq 2$ both the $\mathbb{Z}$'s are separated by at least one zero group. The cellular boundary maps are therefore necessarily the zero maps and we obtain that

$$H_i^{\mathrm{CW}}(X) \cong \begin{cases} \mathbb{Z}, & \text{if } i = 0, n, \\ 0, & \text{otherwise.} \end{cases}$$

[693]It follows easily from the definitions that d_n is precisely the connecting homomorphism of the long exact sequence of the triple (X^n, X^{n-1}, X^{n-2}).

[694]It follows from Lemma 35.2 that $(H_n(X^n, X^{n-1}), d_n)$ is indeed a chain complex.

These are of course isomorphic to the "usual" homology groups of S^n. In the next section we will see that this is not a coincidence.

The "usual" homology groups define functors from the category of topological spaces to the category of abelian groups. We will now see that in a more restricted setting cellular homology groups also define a functor.

Definition.

(1) A map $f\colon X \to Y$ between CW-complexes is called *cellular* if for each $n \in \mathbb{N}_0$ we have $f(X^n) \subset Y^n$.
(2) We denote by $\mathcal{CW}$ the category of CW-complexes where the objects are CW-complexes and where the morphisms are cellular maps.

We conclude this section with the following lemma.

Lemma 35.3.

(1) *Every cellular map $f\colon X \to Y$ induces a chain map*
$$f_*\colon C_*^{\mathrm{CW}}(X) \;\to\; C_*^{\mathrm{CW}}(Y)$$
and hence also maps
$$f_*\colon H_*^{\mathrm{CW}}(X) \;\to\; H_*^{\mathrm{CW}}(Y)$$
on cellular homology.
(2) *For each $n \in \mathbb{N}_0$ the maps*
$$\begin{array}{rcl} X & \mapsto & H_n^{\mathrm{CW}}(X) \\ (f\colon X \to Y) & \mapsto & (f_*\colon H_n^{\mathrm{CW}}(X) \to H_n^{\mathrm{CW}}(Y)) \end{array}$$
define a covariant functor from the category $\mathcal{CW}$ of CW-complexes to the category $\mathcal{A}$ of abelian groups.

Proof.

(1) Let $f\colon X \to Y$ be a cellular map. Since f is cellular we get for every $n \in \mathbb{N}_0$ an induced map $H_n(X^n, X^{n-1}) \to H_n(Y^n, Y^{n-1})$, i.e. we get an induced map $f_*\colon C_n^{\mathrm{CW}}(X) \to C_n^{\mathrm{CW}}(Y)$. It follows almost immediately from the naturality of the connecting homomorphism, see Proposition 31.13 (2), that the above maps $f_*\colon C_n^{\mathrm{CW}}(X) \to C_n^{\mathrm{CW}}(Y)$, $n \in \mathbb{N}_0$ actually form a chain map.
(2) This statement follows easily from the fact that the usual chain complexes and homology groups are covariantly functorial. □

35.2. **The relationship between cellular and singular homology.** Now we can formulate and prove the following proposition.

Proposition 35.4. *Let $n \in \mathbb{N}_0$.*

(1) *For each CW-complex X there exists a uniquely determined isomorphism*
$$\Phi_X\colon H_n(X) \;\xrightarrow{\cong}\; H_n^{\mathrm{CW}}(X)$$

with the property that the following diagram commutes:[695]

$$\begin{tikzcd} & H_n(X) \arrow[dr, "\Phi_X"] & \\ H_n(X^n) \arrow[ur] \arrow[dr, "j_n"'] & & H_n^{\mathrm{CW}}(X). \\ & \ker(d_n) \arrow[ur, two heads] & \end{tikzcd}$$

(2) *We denote by $\mathcal{CW}$ the category of CW-complexes where the objects are CW-complexes and where the morphisms are cellular maps. The homomorphisms from* (1) *define a natural isomorphism between the functors $X \mapsto H_n(X)$ and the functor $X \mapsto H_n^{\mathrm{CW}}(X)$. In other words, for every cellular map $f\colon X \to Y$ and any $n \in \mathbb{N}_0$ the following diagram commutes*

$$\begin{tikzcd} H_n(X) \arrow[r, "f_*"] \arrow[d, "\Phi_X"', "\cong"] & H_n(Y) \arrow[d, "\Phi_Y", "\cong"'] \\ H_n^{\mathrm{CW}}(X) \arrow[r, "f_*"] & H_n^{\mathrm{CW}}(Y) \end{tikzcd} .$$

Example. Even though the cellular boundary maps in the cellular chain complex are still somewhat mysterious we can already use the proposition to do some calculations. As an example, we return to the *n-dimensional complex projective space* $\mathbb{C}\mathrm{P}^n$ which he defined on page 111 as

$$\mathbb{C}\mathrm{P}^n \;:=\; (\mathbb{C}^{n+1} \setminus \{0\})/(\mathbb{C} \setminus \{0\}).$$

In Lemma 26.2 we showed that we can view $\mathbb{C}\mathrm{P}^n$ as a CW-complex which admits exactly one cell in dimensions $0, 2, \dots, 2n$ and which admits no other cells. In particular the cellular chain complex is of the form

$$0 \to \underbrace{C_{2n}^{\mathrm{CW}}(\mathbb{C}\mathrm{P}^n)}_{\cong\mathbb{Z}} \to \underbrace{C_{2n-1}^{\mathrm{CW}}(\mathbb{C}\mathrm{P}^n)}_{=0} \to \cdots \to \underbrace{C_{2}^{\mathrm{CW}}(\mathbb{C}\mathrm{P}^n)}_{\cong\mathbb{Z}} \to \underbrace{C_{1}^{\mathrm{CW}}(\mathbb{C}\mathrm{P}^n)}_{=0} \to \underbrace{C_{0}^{\mathrm{CW}}(\mathbb{C}\mathrm{P}^n)}_{\cong\mathbb{Z}} \to 0.$$

Since every other group is trivial it follows that all boundary maps are also zero. In particular the homology groups equal the cellular chain groups. Thus we have shown that

$$H_k(\mathbb{C}\mathrm{P}^n) \;\underset{\substack{\uparrow \\ \text{Proposition 35.4}}}{\cong}\; H_k^{\mathrm{CW}}(\mathbb{C}\mathrm{P}^n) \;\cong\; C_k^{\mathrm{CW}}(\mathbb{C}\mathrm{P}^n) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k = 0, 2, 4, \dots, 2n, \\ 0, & \text{otherwise.} \end{cases}$$

[695]Here we again denote by $j_n\colon H_n(X^n) \to H_n(X^n, X^{n-1})$ the obvious map. In the long exact sequence of the pair (X^n, X^{n-1}) we see that the image of $H_n(X^n)$ in $H_n(X^n, X^{n-1})$ lies in the kernel of the connecting homomorphism ∂_n. This implies that the map $j_n\colon H_n(X^n) \to H_n(X^n, X^{n-1})$ takes values in $\ker(d_n)$.

It follows immediately from inspecting the cellular chain complex that for any $k \leq l$ and any $i \in \{0, \ldots, 2k\}$ the inclusion induced map

$$H_i^{\mathrm{CW}}(\mathbb{C}\mathrm{P}^k; \mathbb{Z}) \xrightarrow{\cong} H_i^{\mathrm{CW}}(\mathbb{C}\mathrm{P}^l; \mathbb{Z})$$

is an isomorphism. By the naturality of the isomorphism of Proposition 35.4 the same conclusion also holds for the inclusion induced map

$$H_i(\mathbb{C}\mathrm{P}^k; \mathbb{Z}) \xrightarrow{\cong} H_i(\mathbb{C}\mathrm{P}^l; \mathbb{Z})$$

on singular homology. It follows from Lemma 26.7 (2) that we can view the infinite-dimensional complex projective space $\mathbb{C}\mathrm{P}^\infty$ as a CW-complex that has precisely one cell in each even dimension and no cells in odd dimensions. From the arguments above it now follows that

$$H_k(\mathbb{C}\mathrm{P}^\infty) \;\cong\; H_k^{\mathrm{CW}}(\mathbb{C}\mathrm{P}^\infty) \;\cong\; C_k^{\mathrm{CW}}(\mathbb{C}\mathrm{P}^\infty) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k \text{ is even,} \\ 0, & \text{if } k \text{ is odd.} \end{cases}$$

Furthermore, as above we see that the inclusion induced map

$$H_i(\mathbb{C}\mathrm{P}^k; \mathbb{Z}) \xrightarrow{\cong} H_i(\mathbb{C}\mathrm{P}^\infty; \mathbb{Z})$$

is an isomorphism for $i \leq k+1$.

Proof of Proposition 35.4. We add a couple of maps to the commutative diagram that we had already encountered in the proof of Lemma 35.2:

$$\begin{tikzcd}
 & & & 0 \\
0 \arrow[dr] & & H_n(X^{n+1}) \arrow[ur] & \\
 & H_n(X^n) \arrow[ur, two heads] \arrow[dr, hook, "j_n"] & & \\
H_{n+1}(X^{n+1}, X^n) \arrow[ur, "\partial_{n+1}"] \arrow[rr, "d_{n+1}"] & & H_n(X^n, X^{n-1}) \arrow[rr, "d_n"] \arrow[dr, "\partial_n"'] & & H_{n-1}(X^{n-1}, X^{n-2}). \\
 & & & H_{n-1}(X^{n-1}) \arrow[ur, hook, "j_{n-1}"'] & \\
 & & 0 \arrow[ur] & &
\end{tikzcd}$$

Claim. All the diagonal sequences in the above commutative diagram are exact.

From Lemma 35.1 (1) and (2) we know that

$$H_n(X^{n+1}, X^n) \;=\; 0, \quad H_n(X^{n-1}) \;=\; 0 \quad \text{and} \quad H_{n-1}(X^{n-2}) \;=\; 0.$$

It thus follows that the diagonal sequences in the above commutative diagram are just the long exact sequences of the corresponding pairs of topological spaces. In particular all the diagonal sequences are exact. This concludes the proof of the claim.

Now we consider the inclusion induced maps

$$\begin{array}{ccccc} H_n(X^n)/\operatorname{im}(\partial_{n+1}) & \xrightarrow{\cong} & H_n(X^{n+1}) & \xrightarrow{\cong} & H_n(X). \\ & \uparrow & & \uparrow & \\ & \text{isomorphism since the left} & & \text{isomorphism by} & \\ & \text{diagonal sequence is exact} & & \text{Lemma 35.1 (3)} & \end{array}$$

We us this map to make the identification $H_n(X) = H_n(X^n)/\operatorname{im}(\partial_{n+1})$. Next we prove the following claim.

Claim. The map $j_n\colon H_n(X^n) \to H_n(X^n, X^{n-1})$ induces an isomorphism

$$\Phi\colon H_n(X) = H_n(X^n)/\operatorname{im}(\partial_{n+1}) \ \to\ \ker(d_n)/\operatorname{im}(d_{n+1}) = H_n^{\mathrm{CW}}(X).$$

We will prove this claim once again by a "diagram chase".[696]

(1) Since $\partial_n \circ j_n = 0$ it follows that $j_n(H_n(X^n)) \subset \ker(d_n)$.
(2) The map j_{n-1} is injective, i.e. $\ker(d_n) = \ker(\partial_n) = \operatorname{im}(j_n)$, i.e. the map j_n induces an epimorphism

$$H_n(X^n) \ \to\ \ker(d_n).$$

Since the left triangle commutes it also induces an epimorphism

$$H_n(X^n)/\operatorname{im}(\partial_{n+1}) \ \to\ \ker(d_n)/\operatorname{im}(d_{n+1}).$$

(3) If an element $j_n(c) \in H_n(X^n, X^{n-1})$ lies in the image of $d_{n+1} = j_n \circ \partial_{n+1}$, then $j_n(c) = j_n(\partial_{n+1}(d))$ for some $d \in H_{n+1}(X^{n+1}, X^n)$. Since j_n is injective it follows that $c = \partial_{n+1}(d)$. Thus we have now shown that the map

$$H_n(X^n)/\operatorname{im}(\partial_{n+1}) \ \to\ \ker(d_n)/\operatorname{im}(d_{n+1})$$

is injective.

This concludes the proof of the claim.

By construction the isomorphism Φ has the property that the following diagram commutes:

$$\begin{tikzcd} & H_n(X) \arrow[dr, "\Phi"] & \\ H_n(X^n) \arrow[ur, two heads] \arrow[dr, "j_n"'] & & H_n^{\mathrm{CW}}(X). \\ & \ker(d_n) \arrow[ur, two heads] & \end{tikzcd}$$

Note that the top-left diagonal map is an epimorphism by Lemma 35.1 (4). This implies immediately that Φ is uniquely determined.

Finally we leave it as a straightforward exercise to the reader that the maps Φ define a natural isomorphism. $\square$

[696]It is arguably best not to read the remainder of the proof but to go on the chase on one's own.

On page 884 we already saw that Proposition 35.4 can be useful, even if we cannot determine the boundary maps d_n. Another, more theoretical application is, that the cellular chain complex is "much smaller" than the singular chain complex. For example, if X is a CW-complex with finitely many cells, then the chain group $C_*^{\mathrm{CW}}(X)$ in the cellular chain complex are *finitely generated* free abelian groups. This is in contract to the singular chain groups $C_*(X)$ which are in almost all cases free abelian groups of uncountable rank.[697]

Using this observation we can now easily prove the following proposition. It can be viewed as an analogue to Proposition 27.12.

Proposition 35.5. *Let X be a CW-complex. The following statements hold:*

(1) *If X contains precisely $d \in \mathbb{N}_0$ cells of dimension n, then $H_n(X)$ is generated by at most d elements.*
(2) *If X consists only of finitely many cells, then all homology groups of X are finitely generated groups.*
(3) *If X is finite-dimensional, then*

$$H_k(X) \;=\; 0 \;\; \textit{for all } k > \dim(X).$$

(4) *If X is an n-dimensional CW-complex, then $H_n(X)$ is a free abelian group.*

Example. It follows from Proposition 35.5 that for any graph G we have $H_i(G) = 0$ for every $i \geq 2$ and that $H_1(G)$ is a free abelian group.

Proof. Let X be a CW-complex X.

(1) If X contains precisely d cells of dimension n, then it follows from Lemma 35.1 that $C_n^{\mathrm{CW}}(X) \cong \mathbb{Z}^d$. By Lemma 11.8 any subgroup U of $\mathbb{Z}^d$ is a free abelian group with rank $\operatorname{rank}(U) \leq d$. Thus it follows that

$$H_n(X) \;\cong\; \underbrace{\ker\left\{d_n\colon C_n^{\mathrm{CW}}(X) \to C_{n-1}^{\mathrm{CW}}(X)\right\}}_{\text{free abelian group of rank} \leq d} \Big/ \operatorname{im}\left\{d_{n+1}\colon C_{n+1}^{\mathrm{CW}}(X) \to C_n^{\mathrm{CW}}(X)\right\}$$

is generated by at most d elements.
(2) This statement follows immediately from (1).
(3) This statement is in fact already a consequence of Lemma 35.1 (2).
(4) Now suppose that X is an n-dimensional CW-complex X. We have

$$\begin{array}{ccccc} H_n(X) & \cong & H_n^{\mathrm{CW}}(X) & = & \ker\left\{d_n\colon C_n^{\mathrm{CW}}(X) \to C_{n-1}^{\mathrm{CW}}(X)\right\}, \\ & \uparrow & & \uparrow & \\ & \text{Proposition 35.4} & & \text{we have } C_{n+1}^{\mathrm{CW}}(X) = 0 \text{ since } X \text{ is } n\text{-dimensional} & \end{array}$$

i.e. $H_n(X)$ is a subgroup of the free abelian group $C_n^{\mathrm{CW}}(X)$. It follows from Lemma 11.2 that the group $H_n(X)$ itself is a free abelian group. □

[697] For which topological spaces and which n is the singular chain complex $C_n(X)$ finitely generated? Can you give a complete answer?

In Theorem 26.3 we saw that every compact n-dimensional manifold admits a CW-structure with finitely many cells and such that the maximal dimension of a cell is n. If we combine this result with Proposition 35.5 we obtain immediately the following useful result.

Proposition 35.6. *Let M be a compact n-dimensional manifold. Then the following holds:*

(1) *All homology groups are finitely generated abelian groups.*
(2) *For any $k > n$ we have $H_k(M) = 0$.*

Remark.

(1) Note that the statement of Proposition 35.6 is in contrast to the situation for higher homotopy groups. As formulated in Question 28.17 we have the strong suspicion that $\pi_3(S^2) \neq 0$.
(2) Thus we have now shown that for a CW-complex X the singular homology groups $H_n(X)$ are isomorphic to the cellular homology groups $H_n^{\mathrm{CW}}(X)$. One might now ask, whether one can generalize this statement, namely whether the singular chain complex $(C_*(X), \partial_*)$ and the cellular chain complex (C_*^{CW}, d_*) are in fact chain homotopic. This is indeed the case. But the proof requires more homological algebra than we have at the moment at our disposal. Therefore we postpone the proof to a later chapter.

35.3. **The cellular boundary maps.** If we want to use Proposition 35.4 to calculate homology groups of CW-complexes we need to develop tools for computing the cellular boundary maps d_n in the cellular chain complex. Let X be a CW-complex. Throughout this section we will use the following notation:

(1) For $n \in \mathbb{N}_0$ we denote by I_n the set of n-cells of X.
(2) Given an n-cell α we denote by $\varphi_\alpha \colon S_\alpha^{n-1} \to X^{n-1}$ the corresponding attaching map and we denote by $\Phi_\alpha \colon \overline{B}_\alpha^n \to X^n$ the corresponding characteristic map.
(3) Given $n \in \mathbb{N}_0$ we denote by
$$\Psi_n \colon \bigvee_{\alpha \in I_n} \overline{B}_\alpha^n / \partial \overline{B}_\alpha^n \;\to\; X^n / X^{n-1}$$
the map that is given by
$$x \;\mapsto\; \Phi_\alpha(x), \qquad \text{if } x \in \overline{B}_\alpha^n.$$
It is straightforward to verify that Ψ_n is a homeomorphism.
(4) Given $\beta \in I_n$ we denote by
$$i_\beta \colon \overline{B}_\beta^n / \partial \overline{B}_\beta^n \to \bigvee_{\alpha \in I_n} \overline{B}_\alpha^n / \partial \overline{B}_\alpha^n \quad \text{and} \quad p_\beta \colon \bigvee_{\alpha \in I_n} \overline{B}_\alpha^n / \partial \overline{B}_\alpha^n \to \overline{B}_\beta^n / \partial \overline{B}_\beta^n,$$
the obvious inclusion map respectively the obvious projection map. By Proposition 34.9 the maps
$$\bigoplus_{\beta \in I} H_n\big(\overline{B}_\beta^n / \partial \overline{B}_\beta^n\big) \underset{\oplus i_\beta}{\overset{\oplus p_\beta}{\rightleftarrows}} H_n\Big(\bigvee_{\beta \in I_n} \overline{B}_\beta^n / \partial \overline{B}_\beta^n\Big).$$
are inverses of one-another.

(5) Given $\alpha \in I_n$ we denote, by a slight abuse of notation, the standard generator of $H_n(\overline{B}^n_\alpha, \partial\overline{B}^n_\alpha) \cong \mathbb{Z}$, as defined on page 816, by α. Put differently, we make the identification $H_n(\overline{B}^n_\alpha, \partial\overline{B}^n_\alpha) = \mathbb{Z}\cdot\alpha$.

It follows from the discussion above and from Lemma 35.1 and its proof that all the maps in the following sequence are isomorphisms:

$$\begin{tikzcd}
\bigoplus_{\alpha\in I_n} \overbrace{H_n\big(\overline{B}^n_\alpha, \partial\overline{B}^n_\alpha\big)}^{=\mathbb{Z}\cdot\alpha} \arrow[r, "\cong"] \arrow[rrr, bend right, "=:\Omega_n"'] & \bigoplus_{\alpha\in I_n} \widetilde{H}_n(\overline{B}^n_\alpha/\partial\overline{B}^n_\alpha) \arrow[r, "\cong"] & \widetilde{H}_n\big(\bigvee_\alpha \overline{B}^n_\alpha/\partial\overline{B}^n_\alpha\big) \arrow[r, "\cong", "\Psi_n"'] & \widetilde{H}_n(X^n/X^{n-1}) & H_n(X^n, X^{n-1}). \arrow[l, "\cong"']
\end{tikzcd}$$

By another abuse of notation we often denote $\Omega_n(\alpha)$ also by α. Put differently, we identify $C_n^{\mathrm{CW}}(X) = H_n(X^n, X^{n-1})$ with the free abelian group generated by the set I_n of all n-cells.

Our goal now is to determine the matrix of the cellular boundary map

$$d_n\colon \quad \overbrace{\underbrace{H_n(X^n, X^{n-1})}_{\substack{\text{free abelian group}\\ \text{generated by } I_n}}}^{=C_n^{\mathrm{CW}}(X)} \quad \to \quad \overbrace{\underbrace{H_{n-1}(X^{n-1}, X^{n-2})}_{\substack{\text{free abelian group}\\ \text{generated by } I_{n-1}}}}^{=C_{n-1}^{\mathrm{CW}}(X)}.$$

corresponding to the bases given by the cells. As a warm-up with start out with the case $n = 1$.

Lemma 35.7. *Let X be a CW-complex. We adopt all the notations introduced above.*

(1) *For a 1-cell α with attaching map $\varphi_\alpha\colon \overline{B}^1 \to X^0$ we have*

$$d_1(\alpha) \;=\; \varphi_\alpha(1) - \varphi_\alpha(-1).$$

(2) *If X has precisely one 0-cell, then the cellular boundary map d_1 is the zero map.*

Proof. The second statement of the lemma is evidently a consequence of the first statement. Therefore it suffices to prove the first statement. So let α be a 1-cell with characteristic map $\Phi_\alpha\colon \overline{B}^1 \to X^0$. We have to determine the map

$$\begin{tikzcd}
\mathbb{Z}\cdot\alpha \arrow[r] & \bigoplus_{j\in I_1} H_1(\overline{B}^1_j, \partial\overline{B}^1_j) \arrow[r, "\Omega_1"] & H_1(X^1, X^0) \arrow[d, "d_1"] & & \\
& & H_0(X^0, \underbrace{X^{-1}}_{=\varnothing}) \arrow[r, "\Omega_0^{-1}"] & \bigoplus_{i\in I_0} H_0(\overline{B}^0_i, \underbrace{\partial\overline{B}^0_i}_{=\varnothing}). &
\end{tikzcd}$$

Since $X^{-1} = \varnothing$ we see that in the present case we have $d_1 = \partial_1$, i.e. the cellular boundary map d_1 is the connecting homomorphism $H_1(X^1, X^0) \to H_0(X^0)$ of the long exact sequence of the pair (X^1, X^0). It follows immediately from the definitions of the connecting homomorphism, as defined in Proposition 31.13 (1), that $d_1(\alpha) = \varphi_\alpha(1) - \varphi_\alpha(-1)$. $\square$

Example. We consider the graph G that is given in Figure 540 with two vertices β_1, β_2 and four edges $\alpha_1, \dots, \alpha_4$. We view it as a CW-complex in the obvious way. According to

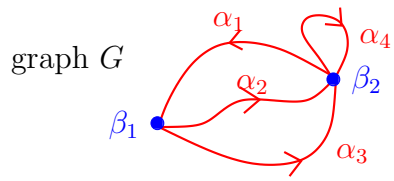

FIGURE 540.

Lemma 35.7 the cellular chain complex of X is of the following form

$$0 \;\to\; C_1^{\mathrm{CW}}(G) = \mathbb{Z}^4 \xrightarrow{\begin{array}{c|cccc} & \alpha_1 & \alpha_2 & \alpha_3 & \alpha_4 \\ \hline \beta_1 & 1 & -1 & -1 & 0 \\ \beta_2 & -1 & 1 & 1 & 0 \end{array}} C_0^{\mathrm{CW}}(G) = \mathbb{Z}^2 \;\to\; 0.$$

Thus we obtain from Proposition 35.4 that

$$H_1(G) \cong \ker\left(\mathbb{Z}^4 \xrightarrow{\begin{pmatrix} 1 & -1 & -1 & 0 \\ 1 & 1 & 1 & 0 \end{pmatrix}} \mathbb{Z}^4\right) \cong \mathbb{Z}^3 \quad \text{and} \quad H_0(G) \cong \operatorname{coker}\left(\mathbb{Z}^4 \xrightarrow{\begin{pmatrix} 1 & -1 & -1 & 0 \\ 1 & 1 & 1 & 0 \end{pmatrix}} \mathbb{Z}^4\right) \cong \mathbb{Z}.$$

After this example we return to the discussion of the cellular boundary maps. Now let $n > 1$. We want to determine the cellular boundary map

$$d_n \colon H_n(X^n, X^{n-1}) \;\to\; H_{n-1}(X^{n-1}, X^{n-2}).$$

Given an n-cell α and an $(n-1)$-cell β we consider the map

$$S_\alpha^{n-1} = \partial \overline{B}_\alpha^n \xrightarrow{\varphi_\alpha} X^{n-1} \xrightarrow{q} X^{n-1}/X^{n-2} \xrightarrow[\cong]{\Psi_{n-1}^{-1}} \bigvee_{j \in I_{n-1}} \overline{B}_j^{n-1}/\partial \overline{B}_j^{n-1} \xrightarrow{p_\beta} \overline{B}_\beta^{n-1}/\partial \overline{B}_\beta^{n-1} \xrightarrow[\cong]{\Theta} S_\beta^{n-1}$$

where $q \colon X^{n-1} \to X^{n-1}/X^{n-2}$ is the quotient map and where $\Theta \colon \overline{B}^n/\partial \overline{B}^n \xrightarrow{\cong} S^{n-1}$ denotes the homeomorphism from page 99. Since S_α^{n-1} and S_β^{n-1} are copies of S^{n-1} we can consider the degree of the map as defined on page 819.

Now we will see that this degree is just the $\beta \times \alpha$–entry of the matrix that represents the cellular boundary map d_n with respect to the bases given by all n-cells and all $(n-1)$-cells. More precisely we have the following proposition:

Proposition 35.8. *Let X be a CW-complex. We use all the notation that we introduced above. Then for each n-cell α we have*

$$d_n(\alpha) \;=\; \sum_{\beta \in I_{n-1}} d_{\alpha,\beta} \cdot \beta$$

where

$$d_{\alpha\beta} \;:=\; \textit{degree of the map } S_\alpha^{n-1} \xrightarrow{\Theta \circ p_\beta \circ \Psi_{n-1}^{-1} \circ q \circ \varphi_\alpha} S_\beta^{n-1}.$$

Proof. We consider the following commutative[698][699] diagram

$$\begin{tikzcd}
\bigoplus_{i\in I_n} H_n(\overline{B}_i^n,\partial\overline{B}_i^n) \arrow[r, "\cong"'] \arrow[rrr, bend left, "\Omega_n"] & \bigoplus_{i\in I_n} \widetilde{H}_n(\overline{B}_i^n/\partial\overline{B}_i^n) \arrow[dr, "\cong"'] & & \widetilde{H}_n(X^n/X^{n-1}) \arrow[r, "\cong"'] & H_n(X^n,X^{n-1}) \arrow[d, "\partial_n"'] \arrow[ddd, bend left, "d_n"] \\
H_n(\overline{B}_\alpha^n,\partial\overline{B}_\alpha^n) \arrow[u] \arrow[d, "\cong"', "\partial"] & & \widetilde{H}_n\Big(\bigvee_{i\in I_n} \overline{B}_i^n/\partial\overline{B}_i^n\Big) \arrow[ur, "\Psi_n"', "\cong"] & & \\
\widetilde{H}_{n-1}(S_\alpha^{n-1}) \arrow[rrr] \arrow[d, "\cdot d_{\alpha\beta}"] & & & \widetilde{H}_{n-1}(X^{n-1}) \arrow[dl, "q"] \arrow[d, "j_{n-1}"'] \\
\widetilde{H}_{n-1}(S_\beta^{n-1}) & & \widetilde{H}_{n-1}\Big(\bigvee_{j\in I_{n-1}} \overline{B}_j^{n-1}/\partial\overline{B}_j^{n-1}\Big) \arrow[dl, "p_\beta"] & \widetilde{H}_{n-1}(X^{n-1}/X^{n-2}) \arrow[l, "\Psi_{n-1}^{-1}"', "\cong"] & H_{n-1}(X^{n-1},X^{n-2}). \arrow[l, "\cong"'] \arrow[lll, bend left, "\Omega_{n-1}^{-1}"] \\
H_{n-1}(\overline{B}_\beta^{n-1},\partial\overline{B}_\beta^{n-1}) \arrow[u, "\cong"', "\partial"] \arrow[r, "\cong"'] & \widetilde{H}_{n-1}(\overline{B}_\beta^{n-1}/\partial\overline{B}_\beta^{n-1}) \arrow[ul, "\Theta_*"'] & & &
\end{tikzcd}$$

The proposition now follows directly from the definitions and the commutativity of the above diagram. We leave it as an exercise to the reader to unravel all the definitions and to digest the diagram. □

Example.

(1) We consider the surface Σ of genus 2. As usual we view Σ as a CW-complex with one 0-cell P, four 1-cells a, b, c, d and one 2-cell F. We denote by $\varphi\colon S^1 \to \Sigma^1$ the attaching map of the 2-cell F. (We refer to Figure 541 for an illustration.) It follows from the discussion on page 819 that the degree of the map $p_a \circ \Psi_1^{-1} \circ q \circ \varphi\colon S_F^1 \to S_a^1$ is zero. The same conclusion holds for all other 1-cells. It follows from Proposition 35.8 that the cellular boundary map d_2 in the cellular chain complex of Σ is zero. Since Σ has only one 0-cell we know from Lemma 35.7 that the cellular boundary map d_1 is also zero. Thus we see that

$$\begin{array}{ccccccc} H_n(\Sigma) & \cong & H_n^{\mathrm{CW}}(\Sigma) & = & C_n^{\mathrm{CW}}(\Sigma) & \cong & \begin{cases} 0, & \text{if } n \geq 3, \\ \mathbb{Z}, & \text{if } n = 2, \\ \mathbb{Z}^4, & \text{if } n = 1, \\ \mathbb{Z}, & \text{if } n = 0. \end{cases} \\ & \uparrow & & \uparrow & & & \\ & \text{Proposition 35.4} & & \begin{array}{c}\text{since all the cellular} \\ \text{boundary maps are zero}\end{array} & & & \end{array}$$

In Figure 542 on the left-hand side we show closed curves a, b, c, d. It follows fairly easily from the above calculation and the explicit isomorphism of Proposition 35.4

[698] Why is the diagram commutative?

[699] The strange shape of the diagram is due to space constraints.

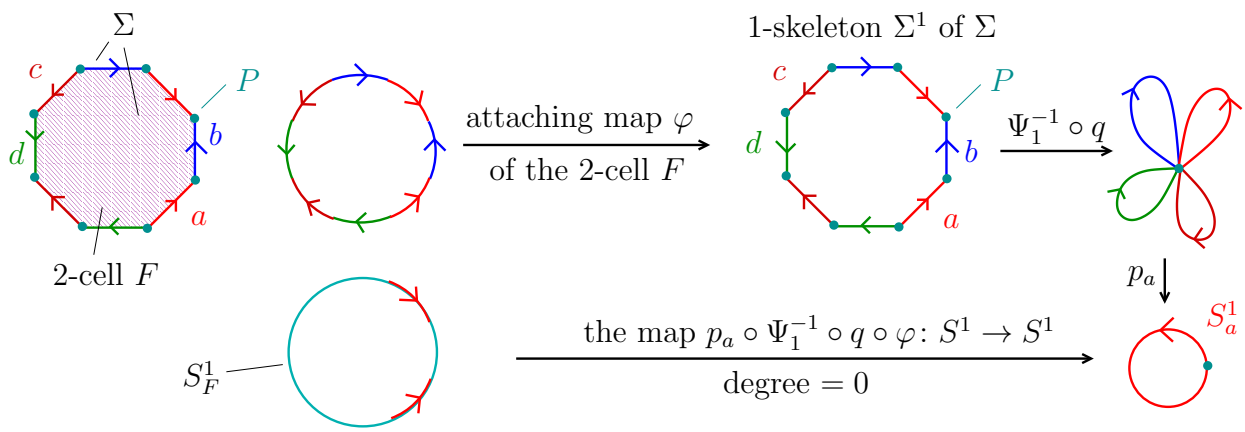

FIGURE 541.

that these curves represent a basis for $H_1(\Sigma) \cong \mathbb{Z}^4$. These curves in turn are isotopic to the curves a', b', c', d' on the right-hand side, which therefore, by Proposition 30.5, also represent a basis for $H_1(\Sigma) \cong \mathbb{Z}^4$.

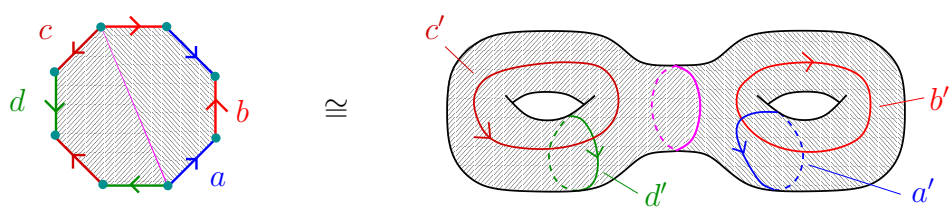

FIGURE 542. A basis for $H_1(\Sigma)$.

(2) As a reality check we also consider once again the Klein bottle K. We view K as a CW-complex with one 0-cell P, two 1-cells a, b and one 2-cell F. (We refer to Figure 543 for an illustration.) It follows from Proposition 35.8, the discussion on page 819 and Lemma 35.7 that the cellular chain complex is of the form

$$0 \to \mathbb{Z} \xrightarrow{\begin{pmatrix} -2 \\ 0 \end{pmatrix}} \mathbb{Z}^2 \xrightarrow{\begin{pmatrix} 0 & 0 \end{pmatrix}} \mathbb{Z} \to 0.$$

Therefore we see that $H_2(K) = 0$, $H_1(K) \cong \mathbb{Z}_2 \oplus \mathbb{Z}$ and $H_0(K) \cong \mathbb{Z}$. This is of course the same result that we had already obtained in Lemma 33.14.

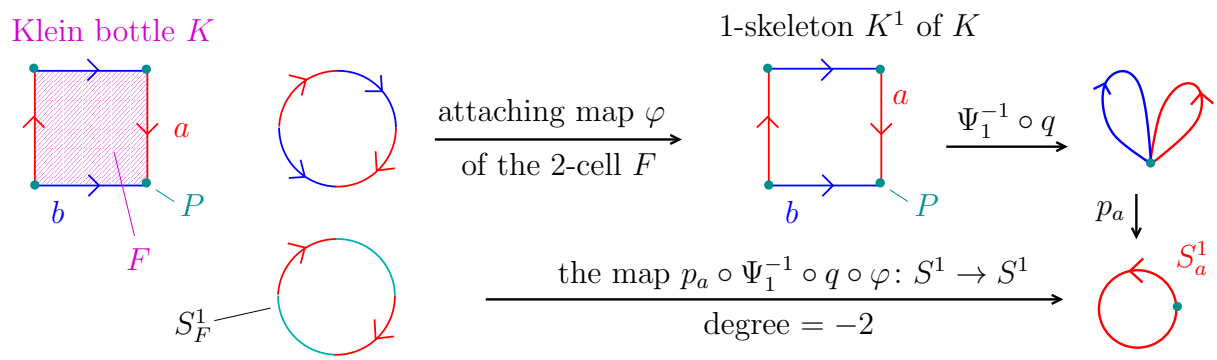

FIGURE 543.

35.4. **The homology groups of 2-dimensional manifolds.** Recall that given $g, m \in \mathbb{N}_0$ we write[700]

$$\Sigma_{g,m} \quad := \quad \text{the surface of genus } g \text{ minus } m \text{ open disks}$$

and for $k \in \mathbb{N}$ and $m \in \mathbb{N}_0$ we write

$$R_{k,m} \quad := \quad \text{the manifold } k \cdot \mathbb{R}\mathrm{P}^2 \text{ minus } m \text{ open disks.}$$

In Theorem 14.14 we saw that every connected, compact 2-dimensional topological manifold is homeomorphic to either $\Sigma_{g,m}$ for unique $g, m \in \mathbb{N}_0$ or to $R_{k,m}$ for unique $k \in \mathbb{N}$ and $m \in \mathbb{N}_0$.

Our goal in this section will be to determine the homology groups of $\Sigma_{g,n}$ and $R_{k,n}$. Before we consider the general case we will consider the special case $\Sigma_{2,1}$ in great detail.

Example. We consider $\Sigma_{2,1}$ and we equip it with the CW-structure that is illustrated in Figure 544. This CW-structure has two 0-cells P, Q, six 1-cells a, b, c, d, w, z and it has one 2-cell F. Given $i = 1, 2$ we denote by A_i the matrix that represents the cellular boundary

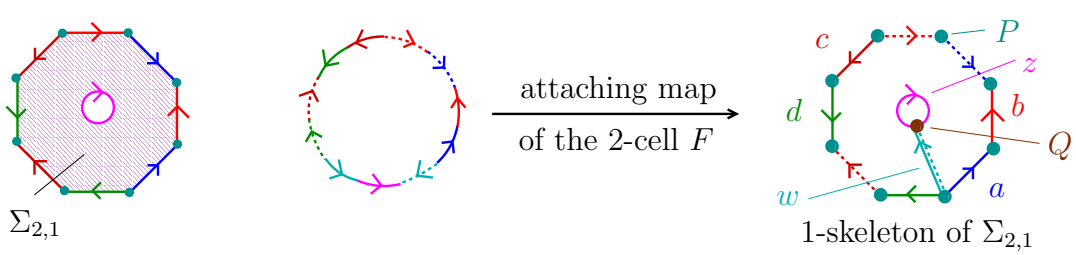

FIGURE 544.

[700]Also recall the definition on page 440 what we mean by a "surface minus m open disks".

map $d_i\colon C_i^{\mathrm{CW}}(\Sigma_{2,1}) \to C_{i-1}^{\mathrm{CW}}(\Sigma_{2,1})$ with respect to the given bases.

The argument on page 891 shows that $A_2 = \begin{array}{c} \\ a \\ b \\ c \\ d \\ w \\ z \end{array} \begin{array}{c} F \\ \begin{pmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 1 \end{pmatrix} \end{array}$ It follows from Lemma 35.7 that we have $A_1 = \begin{array}{c} \\ P \\ Q \end{array} \begin{array}{c} \begin{array}{cccccc} a & b & c & d & w & z \end{array} \\ \begin{pmatrix} 0 & 0 & 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \end{pmatrix} \end{array}$.

Some elementary linear algebra shows that

$$H_n(\Sigma_{2,1}) \underset{\substack{\uparrow \\ \text{Proposition 35.4}}}{\cong} H_n^{\mathrm{CW}}(\Sigma_{2,1}) = H_n\Big(0 \to \mathbb{Z} \xrightarrow{A_2} \mathbb{Z}^6 \xrightarrow{A_1} \mathbb{Z}^2 \to 0\Big) \cong \begin{cases} 0, & \text{if } n \geq 3, \\ 0, & \text{if } n = 2, \\ \mathbb{Z}^4, & \text{if } n = 1, \\ \mathbb{Z}, & \text{if } n = 0. \end{cases}$$

From this discussion we get in fact a more precise statement. Namely, by the choice of the CW-structure on $\Sigma_{2,1}$ we have that the map inclusion map $\partial\Sigma_{2,1} \to \Sigma_{2,1}$ is in fact a cellular map. Therefore it follows from Proposition 35.4 (2) that the following diagram commutes

$$\begin{tikzcd} H_1(\partial\Sigma_{2,1}) \arrow[r, "f_*"] \arrow[d, "\cong"'] & H_1(\Sigma_{2,1}) \arrow[d, "\cong"] \\ \mathbb{Z} = H_1^{\mathrm{CW}}(\partial\Sigma_{2,1}) \arrow[r, "f_*", "{[z]\mapsto[z]}"'] & H_1^{\mathrm{CW}}(\Sigma_{2,1}) = \mathbb{Z}^4 \end{tikzcd}$$

where the vertical maps denote the isomorphisms from Proposition 35.4. The 1-cell z is null-homologous in $C_*^{\mathrm{CW}}(\Sigma_{2,1})$ since we have just seen that it is the boundary of the 2-cell F. Thus we see that the bottom horizontal map is the zero map, but that implies that the top horizontal map is also the zero map.

After the calculations that we just did it we can now easily prove the following lemma.

Lemma 35.9.

(1) *Let $g \in \mathbb{N}_0$. Then the inclusion induced map*

$$H_1(\partial\Sigma_{g,1}) \to H_1(\Sigma_{g,1})$$

is the zero map.

(2) *Let M be a manifold and let C be an oriented curve in M. If there exists a $g \in \mathbb{N}_0$ and a map $\psi\colon \Sigma_{g,1} \to M$ such that $\psi(\partial\Sigma_{g,1}) = C$, then $C = 0 \in H_1(M)$.*[701]

[701] Following the convention of page 853 the curve C defines a homology class in $H_1(M)$ that we also denote by C.

Example. Loosely speaking Lemma 35.9 (2) says that if a curve C is the boundary of an compact orientable surface in M, then C is null-homologous. For example in Figure 545 we see a curve C on a surface M. Since C is the boundary of a compact orientable subsurface contained in M we see that $C = 0 \in H_1(M)$.

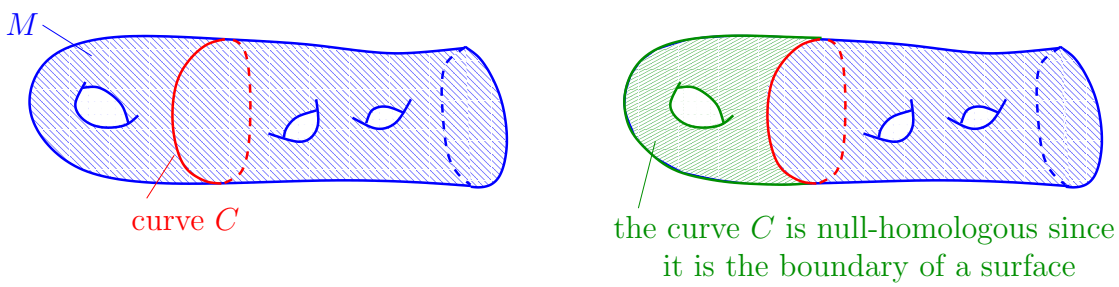

FIGURE 545.

Proof.

(1) For $g = 1$ we proved the statement in the previous example. The general case is proved entirely the same way.
(2) Now let M be a manifold and let C be an oriented curve in M. Suppose there exists a $g \in \mathbb{N}_0$ and a map $\psi\colon \Sigma_{g,1} \to M$ such that $\psi(\partial\Sigma_{g,1}) = C$. We get the commutative diagram

$$\begin{tikzcd}
 & & H_1(C) \arrow[dr] & \\
H_1(S^1) \arrow[urr] \arrow[dr] & & & H_1(M). \\
 & H_1(\partial\Sigma_{g,1}) \arrow[r] & H_1(\Sigma_{g,1}) \arrow[ur, "\psi_*"'] &
\end{tikzcd}$$

By the first statement the bottom horizontal map is the zero map. But that shows that the homology class represented by C is also zero. $\square$

In the following proposition we give the calculation for the homology groups of all connected, compact 2-dimensional topological manifolds.

Proposition 35.10. *For any $g \in \mathbb{N}_0$ we have*

$$H_n(\Sigma_g) \cong \begin{cases} 0, & \text{if } n \geq 3, \\ \mathbb{Z}, & \text{if } n = 2, \\ \mathbb{Z}^{2g}, & \text{if } n = 1, \\ \mathbb{Z}, & \text{if } n = 0. \end{cases} \qquad \begin{array}{c}\textit{Furthermore} \\ \textit{for } m \geq 1 \\ \textit{we have}\end{array} \qquad H_n(\Sigma_{g,m}) \cong \begin{cases} 0, & \text{if } n \geq 3, \\ 0, & \text{if } n = 2, \\ \mathbb{Z}^{2g+m-1}, & \text{if } n = 1, \\ \mathbb{Z}, & \text{if } n = 0. \end{cases}$$

For any $k \in \mathbb{N}$ we have

$$H_n(k \cdot \mathbb{R}\mathrm{P}^2) \cong \begin{cases} 0, & \text{if } n \geq 3, \\ 0, & \text{if } n = 2, \\ \mathbb{Z}_2 \oplus \mathbb{Z}^{k-1}, & \text{if } n = 1, \\ \mathbb{Z}, & \text{if } n = 0. \end{cases} \qquad \begin{array}{c}\textit{Furthermore} \\ \textit{for } m \geq 1 \\ \textit{we have}\end{array} \qquad H_n(R_{k,m}) \cong \begin{cases} 0, & \text{if } n \geq 3, \\ 0, & \text{if } n = 2, \\ \mathbb{Z}^{k+m-1}, & \text{if } n = 1, \\ \mathbb{Z}, & \text{if } n = 0. \end{cases}$$

Proof. The calculation of the homology groups $\Sigma_{g,m}$ is a slight generalization of the arguments that we provided above and on page 891. We leave the details to the reader.

We will deal with the homology of $R_{k,m}$ in Exercise 35.1. The calculation is evidently just a variation of the arguments we provided for Σ_2 and $\Sigma_{2,2}$. □

Remark. A careful reading of the Proof of Proposition 35.10 gives us some extra information. First of all we endow $\Sigma_{g,m}$ with an orientation. The boundary components of $\Sigma_{g,m}$ then inherit an orientation. By the discussion on page 853 the boundary components, viewed as oriented curves, then define elements $c_1, \dots, c_m \in H_1(\Sigma_{g,m})$. Then there exists an exact sequence

$$0 \to \mathbb{Z} \xrightarrow{1 \mapsto \sum c_i} \bigoplus_{i=1}^{m} \mathbb{Z} \cdot c_i \to H_1(\Sigma_{g,m}) \underset{\substack{\uparrow \\ \text{inclusion induced map}}}{\to} H_1(\Sigma_g) \to 0.$$

As we saw in Figure 542, a basis for $H_1(\Sigma_g)$ is given by a pair of curves for each "hole". The above exact sequence shows that a basis for the homology group $H_1(\Sigma_{g,m}) \cong \mathbb{Z}^{2g+m-1}$ is obtained by a pair of curves for each "hole" together with boundary curves for all except one boundary component. This statement is illustrated in Figure 546.

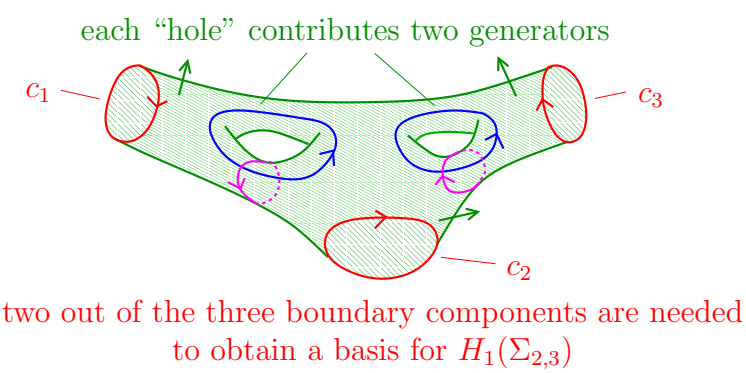

FIGURE 546.

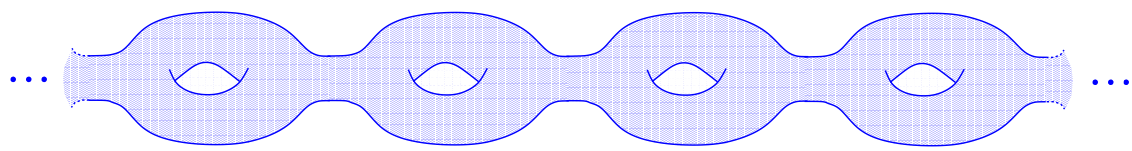
We conclude this section with the surface Σ_∞ of infinite genus that we had already encountered on page 492. Using a variation of the proof of Lemma 16.6 one can show, using the above calculations and Proposition 34.4, that

$$H_n(\Sigma_\infty) \;\cong\; \begin{cases} 0, & \text{if } n \geq 2, \\ \mathbb{Z}^\infty, & \text{if } n = 1, \\ \mathbb{Z}, & \text{if } n = 0. \end{cases}$$

We leave the details as an exercise to the reader.



surface of "infinite genus"

FIGURE 547.

35.5. **The homology groups of real projective spaces.** In this section we will compute the homology groups of real projective spaces $\mathbb{R}\mathrm{P}^n$. This calculation is significantly trickier than the previous ones, since the calculation of the cellular boundary maps is not as straightforward as in our previous examples. This time we will need the theory of local degrees that we developed in Section 32.5.

Proposition 35.11. *For any $n \in \mathbb{N}_0$ we have*[702]

$$H_k(\mathbb{R}\mathrm{P}^n) \;\cong\; \begin{cases} \mathbb{Z}, & \textit{if } k = 0, \\ \mathbb{Z}_2, & \textit{if } k \textit{ is odd and } k < n, \\ 0, & \textit{if } k \textit{ is even and } 0 < k \neq 0, \\ 0, & \textit{if } k > n, \\ \mathbb{Z}, & \textit{if } k = n \textit{ and } n \textit{ is odd.} \end{cases}$$

Proof $(*)$. As a reminder we defined

$$\mathbb{R}\mathrm{P}^n \;=\; S^n/\sim \qquad \text{where } x \sim -x \text{ for all } x \in S^n.$$

In Lemma 26.2 we already saw that we can view $\mathbb{R}\mathrm{P}^n$ as a CW-complex with the following two properties:

(1) the CW-structure has exactly one cell in the dimensions $0, 1, \ldots, n$ and no other cells,
(2) for each $k \leq n$ the k-skeleton of $\mathbb{R}\mathrm{P}^n$ is given by $\mathbb{R}\mathrm{P}^k$.

[702]For $n = 2$ we thus obtain, as we should, the same result as in Section 33.3.

Now we recall the definition of this CW-structure. For each $k \in \mathbb{N}_0$ we define

$$\begin{array}{rcl} \varphi_k \colon S^{k-1} = \partial \overline{B}^k & \to & \mathbb{R}\mathrm{P}^{k-1} \\ (x_1, \dots, x_k) & \mapsto & [(x_1, \dots, x_k)]. \end{array}$$

Then we obtain a homeomorphism

$$\begin{array}{rcl} \mathbb{R}\mathrm{P}^{k-1} \cup_{\varphi_k} \overline{B}^k & \xrightarrow{\cong} & \mathbb{R}\mathrm{P}^k \\ x & \mapsto & \begin{cases} (x, 0), & \text{if } x \in \mathbb{R}\mathrm{P}^{k-1} \\ \big[\big(x, \sqrt{1 - \|x\|^2}\big)\big], & \text{if } x \in \overline{B}^k. \end{cases} \end{array}$$

Thus we see inductively that we can view $\mathbb{R}\mathrm{P}^n$ as a CW-complex with a single cell in the dimensions $0, \dots, n$ where the attaching maps are given precisely by the maps $\varphi_1, \dots, \varphi_n$. As usual we denote the characteristic map of the k-cell, which in this case is the obvious map $\overline{B}^k \to \mathbb{R}\mathrm{P}^k$, by Φ_k.

Claim. For each $k = 1, \dots, n$ the cellular boundary map

$$d_k \colon \mathbb{Z} = C_k^{\mathrm{CW}}(X) \ \to \ C_{k-1}^{\mathrm{CW}}(X) = \mathbb{Z}$$

is given by multiplication by $1 + (-1)^k$.

Let $k \in \{1, \dots, n\}$. We denote by $\Theta \colon \overline{B}^{k-1} / \partial \overline{B}^{k-1} \to S^{k-1}$ the homeomorphism from page 99 and we denote by $q \colon \mathbb{R}\mathrm{P}^{k-1} \to \mathbb{R}\mathrm{P}^{k-1} / \mathbb{R}\mathrm{P}^{k-2}$ the projection map. By Proposition 35.8 it suffices to show that the degree of the map

$$\begin{tikzcd} S^{k-1} \arrow[r, "\varphi_k"] \arrow[rrr, bend right, "=:\Omega"'] & \mathbb{R}\mathrm{P}^{k-1} \arrow[r, "q"] & \mathbb{R}\mathrm{P}^{k-1} / \mathbb{R}\mathrm{P}^{k-2} \arrow[r, "\Phi_{k-1}^{-1}"] & \overline{B}^{k-1} / \partial \overline{B}^{k-1} \arrow[r, "\Theta"] & S^{k-1} \end{tikzcd}$$

equals $1 + (-1)^k$. (We refer to Figure 548 for an illustration of the map.) We pick the point $y = (0, \dots, 0, 1) \in S^{k-1}$. The preimages of y under the map Ω are $x_1 = (0, \dots, 0, 1)$ and $x_2 = (0, \dots, 0, -1)$. We leave it as an exercise to verify that[703] $\deg \Omega|_{x_1} = 1$ and that $\deg \Omega|_{x_2} = (-1)^n$. The desired statement now follows from Proposition 32.26. This concludes the proof of the claim.

It follows from the claim that the cellular chain complex of X is of the form

$$0 \ \to \ \mathbb{Z} \ \xrightarrow{1+(-1)^n} \ \mathbb{Z} \ \dots \ \mathbb{Z} \ \xrightarrow{\cdot 2} \ \mathbb{Z} \ \xrightarrow{0} \ \mathbb{Z} \ \to \ 0.$$

It is now straightforward to determine the cellular homology groups which, by Proposition 35.4, are isomorphic to the singular homology groups of $\mathbb{R}\mathrm{P}^n$. $\square$

[703] It is not entirely easy to struggle through all the orientation conventions and all the maps, but it can indeed be done.

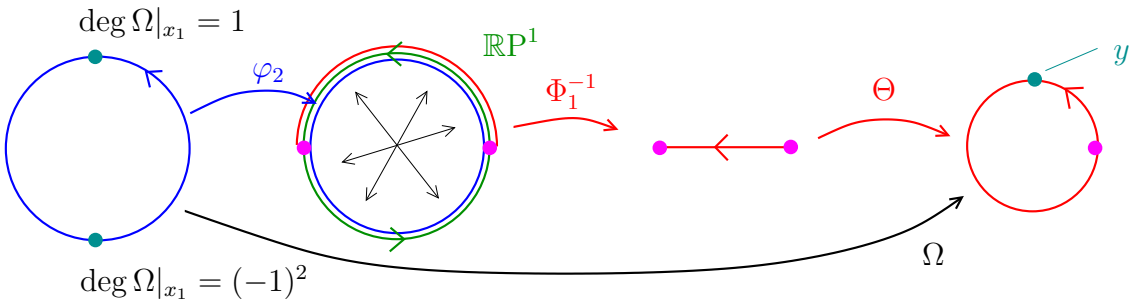


FIGURE 548. Illustration from the proof of Proposition 35.11.

Remark. Using the approach of the proof of Proposition 35.11, applied to the infinite CW-complex $\mathbb{R}\mathrm{P}^\infty$, or alternatively using $\mathbb{R}\mathrm{P}^\infty = \bigcup_n \mathbb{R}\mathrm{P}^n$ and Proposition 34.4, we see that

$$H_k(\mathbb{R}\mathrm{P}^\infty) \cong \begin{cases} \mathbb{Z}, & \text{if } k = 0, \\ \mathbb{Z}_2, & \text{if } k \text{ is odd}, \\ 0, & \text{if } k \text{ is even and } k > 0. \end{cases}$$

Remark. We have now seen that the homology groups of CW-complexes can be computed fairly easily using cellular chain complexes. One might ask, why did we introduce singular chain complexes, if it is so much easier to do calculations with cellular chain complexes. There are two related answers:

(1) we also want to study topological spaces that are not CW-complexes,
(2) it is much harder to prove some statements using cellular chain complexes, for example it is very difficult, if not impossible, to show that homeomorphic CW-complexes have isomorphic homology groups, just using the definition of cellular chain complexes.

A general slogan in topology is that for calculations it is usually best to work with "small objects", whereas for proving general properties, it is often best to work with "big objects".

Exercises for Chapter 35.

Exercise 35.1.

(a) Determine the homology groups of $\mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2$.
(b) Determine the homology groups of $\mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2$ minus an open disk.

Note: In both parts you can make use of the CW-structure for $\mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2$ illustrated in Figure 549.
Remark: The homology groups are stated as Proposition 35.10. But it is a very good exercise to try to determine the homology groups without looking at the proposition.

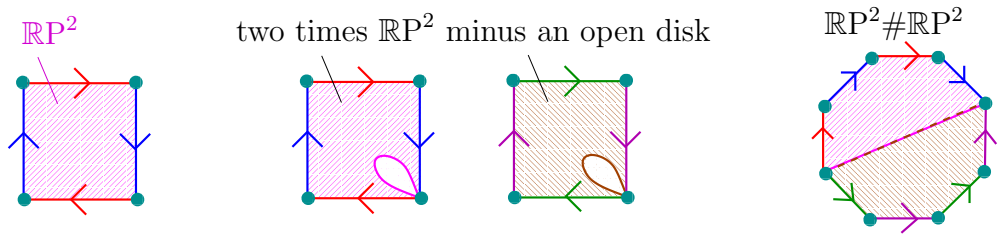

FIGURE 549.

Exercise 35.2. Compute the homology groups of the quotient of S^2 obtained by identifying north and south poles to a point.

Exercise 35.3.

(a) We consider the map $f\colon S^1 \to S^1$ given by $(x, y) \mapsto (x, |y|)$. Give a careful proof that the local degree at the point -1 is zero.

(b) Let $f\colon S^1 \to S^1$ be a map and let $z \in S^1$ be a nice point. Suppose that $\deg f|_z = 1$. Does it follow that f is a local homeomorphism at z? It suffices to give a short justification for your answer.

Exercise 35.4. Show that given any finitely generated abelian group A there exists a topological space X with $H_0(X) = \mathbb{Z}$ and $H_1(X) \cong A$ and with $H_i(X) = 0$ for $i \geq 2$.

Exercise 35.5. Let U be an open subset of $\mathbb{R}^n$ with $0 \in U$. Let $f\colon U \to \mathbb{R}^n$ be a differentiable map with $f(0) = 0$ such that $A := Df_0$ is invertible. We consider the linearization

$$\begin{array}{rcl} \lambda\colon \mathbb{R}^n & \to & \mathbb{R}^n \\ x & \mapsto & A \cdot x \end{array} \quad \text{and the homotopy} \quad \begin{array}{rcl} F\colon \mathbb{R}^n \times [0,1] & \to & \mathbb{R}^n \\ (x,t) & \mapsto & (1-t)\cdot f(x) + t \cdot \lambda(x). \end{array}$$

Show that there exists an open neighborhood $V = B_r(0)$ of 0, contained in U, with the following properties:

(1) for each $t \in [0, 1]$ the map $F_t\colon V \to \mathbb{R}^n$ is a diffeomorphism onto its image,
(2) for each $t \in [0, 1]$ the image $F_t(V) = F_t(B_r(0))$ is a convex subset of $\mathbb{R}^n$.

Remarks:

(1) Recall that the hypothesis on f implies that
$$\lim_{v \to 0} \frac{f(v) - Av}{\|v\|} = 0.$$
(2) Since A is invertible we know from Exercise 1.18 that there exists a $\lambda > 0$ such that $\|Av\| \geq \lambda v$ for all v.
(3) Hint: it is not as hard as it sounds.

Exercise 35.6.

(a) Let X be the quotient space of S^2 under the identification $x \sim -x$ for all $x \in S^1$. Determine the homology groups of $X = S^2/\sim$.

(b) Let $m, n \in \mathbb{N}$ with $m < n$. As usual we view $\mathbb{R}\mathrm{P}^m$ as a subset of $\mathbb{R}\mathrm{P}^n$. Compute the homology groups of the quotient space $\mathbb{R}\mathrm{P}^n/\mathbb{R}\mathrm{P}^m$.

Exercise 35.7. Let C be a closed curve in a manifold M. Suppose that C is the boundary of an embedded compact orientable surface in M. Show that the inclusion induced map $H_1(C) \to H_1(M)$ is the zero map.
More concisely, if a closed curve bounds an compact orientable surface, then the closed curve represents the trivial element in homology.

Exercise 35.8. Let A be a finitely generated abelian group. Does there exist a topological space X with $H_0(X) = \mathbb{Z}$, $H_3(X) \cong A$ and $H_i(X) = 0$ for $i \neq 0, 3$?

Exercise 35.9. Let X be a topological space and let $n \in \mathbb{N}_0$. Suppose X is compact. Does it follow that $H_n(X)$ is a finitely generated group?

36. The Jordan Curve Theorem

We start out with the following proposition.

Proposition 36.1.

(1) *For every injective map* $h\colon \overline{B}^k \to S^n$ *we have*

$$\widetilde{H}_i\big(S^n \setminus h(\overline{B}^k)\big) \;=\; 0 \quad \textit{for all } i \in \mathbb{N}_0.$$

(2) *For every injective map* $h\colon S^k \to S^n$ *we have*

$$\widetilde{H}_i\big(S^n \setminus h(S^k)\big) \;\cong\; \begin{cases} \mathbb{Z}, & \textit{if } i = n-k-1, \\ 0, & \textit{otherwise.} \end{cases}$$

Example.

(1) Let $K \subset S^3$ be a knot, i.e. let K be a 1-dimensional submanifold of $S^3 = \mathbb{R}^3 \cup \{\infty\}$ that is diffeomorphic to S^1. This means in particular that there exists an embedding $h\colon S^1 \to S^3$ with $h(S^1) = K$. In Lemma 33.15 we had already determined that $H_1(S^3 \setminus K) \cong \mathbb{Z}$. Now we can compute the higher homology groups as well. More precisely, the combination of Proposition 36.1 (2) and Lemma 31.1 says that

$$H_i(S^3 \setminus K) \;=\; H_i(S^3 \setminus h(S^1)) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } i = 0, 1, \\ 0, & \text{otherwise.} \end{cases}$$

(2) In Proposition 36.1 we do not assume that h is in any way smooth. For example there are injective maps $h\colon S^1 \to S^2$ of infinite length, see e.g.

`https://en.wikipedia.org/wiki/Koch_snowflake`,

to which the proposition nonetheless applies. Reduced homology is only defined for non-empty topological spaces. It is implicit in the statement of Proposition 36.1 that $S^n \setminus h(\overline{B}^k)$ is not the empty set. Even this statement is not entirely obvious since, as we have pointed out on several occasions, there are non-injective maps $h\colon \overline{B}^1 \to S^n$ that are in fact surjective.

(3) In Figure 550 we see the image of an injective map $\varphi\colon [0,1] \to S^3 = \mathbb{R}^3 \cup \{\infty\}$ and we see a closed curve $C \subset S^3 \setminus \varphi([0,1])$. It follows from Proposition 36.1 (1) that $H_1(S^3 \setminus \varphi([0,1])) = 0$, in particular C is null-homologous in $H_1(S^3 \setminus \varphi([0,1])) = 0$.[704] But on [Sti, p. 152] it is shown that the curve C represents in fact a non-trivial element in $\pi_1(S^3 \setminus \varphi([0,1]))$.

To make the exposition more readable we prove the two parts of Proposition 36.1 separately.

[704] In Lemma 35.9 we saw that the boundary curve of an orientable surface with one boundary component is null-homologous. In Exercise 36.1 we will see that the closed curve C is in fact the boundary of an orientable surface that is embedded in $S^3 \setminus \varphi([0,1])$.

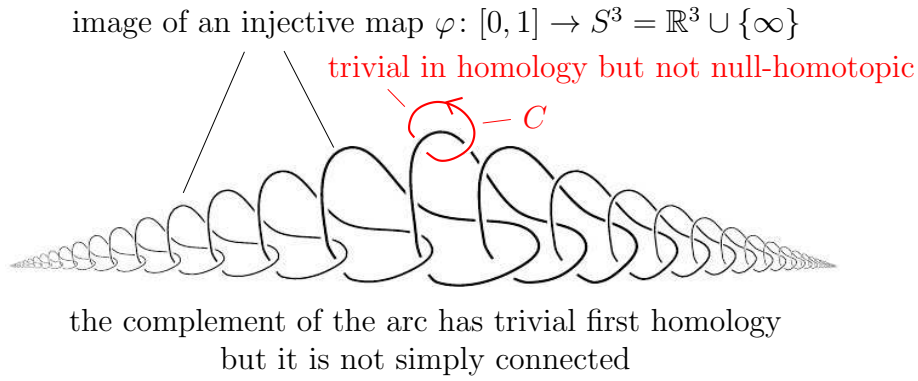

FIGURE 550.

Proof of Proposition 36.1 (1). We write $I = [-1,1]$. By Proposition 1.47 (2) there exists a homeomorphism $I^k \xrightarrow{\cong} \overline{B}^k$. Therefore in the statement of Proposition 36.1 (1) we can replace $\overline{B}^k$ by I^k. So we now want to show that for any injective map $h\colon I^k \to S^n$ we have

$$\widetilde{H}_i(S^n \setminus h(I^k)) \;=\; 0 \qquad \text{for all } i \in \mathbb{N}_0.$$

We will prove this statement by induction on k. We start out with $k = 0$. So let $h\colon I^0 = \{0\} \to S^n$ be an injective map. It follows from the stereographic projection defined in Lemma 1.41 that $S^n \setminus h(\{0\})$ is homeomorphic to $\mathbb{R}^n$. Hence we obtain from Corollary 30.8 (3) that $\widetilde{H}_*(S^n \setminus h(\{0\})) = 0$.

Now we do the induction step. We assume we know the desired statement for all injective maps $I^{k-1} \to S^n$. Now let $h\colon I^k \to S^n$ be an injective map. We suppose that the desired conclusion does not hold, i.e. we suppose that $\widetilde{H}_j(S^n \setminus h(I^k)) \neq 0$ for some j. We pick a non-trivial element $g_0 \in \widetilde{H}_j(S^n \setminus h(I^k))$.

We write $Q = I^{k-1}$, $J_0 = I$ and we write

$$A_1 \;=\; S^n \setminus h(Q \times [0, \tfrac{1}{2}]) \quad \text{and} \qquad A_2 \;=\; S^n \setminus h(Q \times [\tfrac{1}{2}, 1]).$$

Since h is injective we have

$$A_1 \cap A_2 \;=\; S^n \setminus h(I^k) \qquad \text{and} \quad A_1 \cup A_2 \;=\; S^n \setminus h(Q \times \{\tfrac{1}{2}\}).$$

From Lemma 1.37 (3) we know that A_1 and A_2 are open subsets of $A_1 \cup A_2$. Therefore we can apply the Mayer-Vietoris Theorem 33.5 and we obtain the long exact sequence

$$\ldots \to \underbrace{\widetilde{H}_{j+1}(A_1 \cup A_2)}_{=0 \text{ by induction}} \to \widetilde{H}_j(A_1 \cap A_2) \;\to\; \widetilde{H}_j(A_1) \oplus \widetilde{H}_j(A_2) \;\to\; \underbrace{\widetilde{H}_i(A_1 \cup A_2)}_{=0 \text{ by induction}} \to \ldots$$

So we see that the middle map is an isomorphism. Thus there exists an $i \in \{1,2\}$ such that the image of g_0 is non-trivial in $\widetilde{H}_j(A_i)$. If $i = 1$, then we set $J_1 := [0, \frac{1}{2}]$, otherwise

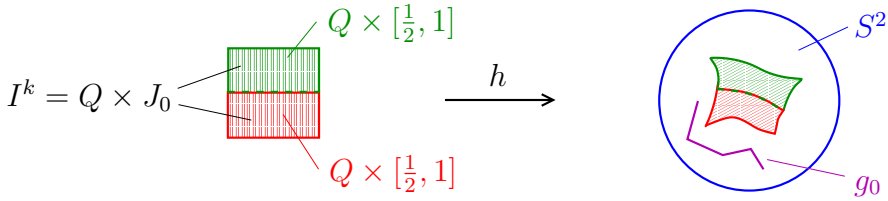

FIGURE 551. Illustration for the proof of Proposition 36.1 (1).

we set $J_1 := [\frac{1}{2}, 1]$. We denote by

$$\varphi_1 \colon \widetilde{H}_j(S^n \setminus h(Q \times J_0)) \;\to\; \widetilde{H}_j(S^n \setminus h(Q \times J_1))$$

the inclusion induced map. By the above exact sequence φ_1 is an epimorphism. We denote by ρ_1 the inverse of the induced isomorphism

$$\widetilde{H}_j(S^n \setminus h(Q \times J_0))/\ker(\varphi_1) \;\to\; \widetilde{H}_j(S^n \setminus h(Q \times J_1)).$$

Now we iterate this process by running the same argument with J_0 replaced by J_1 and so on. For each $m \in \mathbb{N}$ we can find an interval J_m of length $\frac{1}{2^m}$ that is contained in J_{m-1} such that for the inclusion induced homomorphism

$$\varphi_m \colon \widetilde{H}_j(S^n \setminus h(Q \times J_{m-1})) \;\to\; \widetilde{H}_j(S^n \setminus h(Q \times J_m))$$

we have that $g_m := \varphi_m(g_{m-1})$ is non-zero. We define ρ_m the same way from φ_m as we had obtained ρ_1 from φ_1.

By the definition of the direct limit we have the following commutative diagram:[705]

$$\begin{tikzcd}
\vdots & & \\
\widetilde{H}_j(S^n \setminus h(Q \times J_2)) \arrow[u, two heads, "\varphi_3"] \arrow[rr] \arrow[drr, "\rho_2 \circ \rho_1"] & & \varinjlim \widetilde{H}_j(S^n \setminus h(Q \times J_m)) \arrow[d, dashed] \\
\widetilde{H}_j(S^n \setminus h(Q \times J_1)) \arrow[u, two heads, "\varphi_2"] \arrow[urr] \arrow[drr, "\rho_1"] & & \\
\widetilde{H}_j(S^n \setminus h(Q \times J_0)) \arrow[u, two heads, "\varphi_1"] \arrow[urr] \arrow[rr, "\text{image of } g_0 \text{ is non-zero}"'] & & \dfrac{\widetilde{H}_j(S^n \setminus h(Q \times I))}{\bigcup_{m \in \mathbb{N}} \ker(\varphi_m \circ \cdots \circ \varphi_1)}
\end{tikzcd}$$

[705]Note that we have

$$\ker(\varphi_1) \subset \ker(\varphi_2 \circ \varphi_1) \subset \ker(\varphi_3 \circ \varphi_2 \circ \varphi_1) \subset \ldots$$

It follows that the union of these subgroups is again a subgroup.

Since each J_m has half the length of J_{m-1} we conclude that the intersection $\bigcap_{m\in\mathbb{N}} J_m$ contains a unique point $t \in [0,1]$.[706] We have

$$\lim_{\longrightarrow} \widetilde{H}_j(S^n \setminus h(Q \times J_m)) \underset{\substack{\uparrow \\ \text{by Proposition 34.4 since the} \\ \text{subsets } S^n \setminus h(Q\times J_m) \text{ are open}}}{\cong} \widetilde{H}_j\Big(\bigcap_{m\in\mathbb{N}} S^n \setminus h(Q \times J_m)\Big) \underset{\substack{\uparrow \\ \text{since } h \text{ is injective}}}{=} \widetilde{H}_j(S^n \setminus h(Q \times \{t\})) \underset{\substack{\uparrow \\ \text{by induction} \\ \text{since } Q\times\{t\} \cong I^{k-1}}}{=} 0.$$

But we have now obtained a contradiction, since the bottom horizontal map of the above commutative diagram has a non-trivial image but it factors through the trivial group. □

Proof of Proposition 36.1 (2). We have to show that for every injective map $h\colon S^k \to S^n$ we have

$$\widetilde{H}_i\big(S^n \setminus h(S^k)\big) \cong \begin{cases} \mathbb{Z}, & \text{if } i = n-k-1, \\ 0, & \text{otherwise.} \end{cases}$$

We prove this statement by induction on k. For $k = 0$ we have

$$\widetilde{H}_i(S^n \setminus h(S^0)) \underset{\substack{\uparrow \\ \text{since } S^n\setminus h(S^0) \text{ is homotopy} \\ \text{equivalent to } S^{n-1}}}{=} \widetilde{H}_i(S^{n-1}) \underset{\substack{\uparrow \\ \text{by Proposition 31.3}}}{\cong} \begin{cases} \mathbb{Z}, & \text{if } i = n-1, \\ 0, & \text{otherwise.} \end{cases}$$

[707]

Now suppose we know the statement for some $k \in \mathbb{N}$. Suppose we are given an injective map $h\colon S^{k+1} \to S^n$. We denote by $S^{k+1}_{\le 0}$ the lower hemisphere of S^{k+1} and we denote by $S^{k+1}_{\ge 0}$ the upper hemisphere of S^{k+1}. Note that $S^{k+1}_{\le 0} \cap S^{k+1}_{\ge 0} = S^k$. We apply the Mayer-Vietoris Theorem 33.5 to the decomposition of $S^n \setminus h(S^{k+1})$ into the open sets $S^n \setminus h(S^{k+1}_{\le 0})$ and $S^n \setminus h(S^{k+1}_{\ge 0})$. We obtain a long exact sequence[708]

$$\cdots \to \widetilde{H}_i(S^n \setminus h(S^k)) \to \underbrace{\widetilde{H}_i((S^n \setminus h(S^{k+1}_{\le 0}))}_{\substack{= 0 \text{ by part (1) and} \\ \text{since } S^{k+1}_{\le 0} \cong \overline{B}^{k+1}}} \oplus \underbrace{\widetilde{H}_i(S^n \setminus h(S^{k+1}_{\ge 0}))}_{\substack{= 0 \text{ by part (1) and} \\ \text{since } S^{k+1}_{\ge 0} \cong \overline{B}^{k+1}}} \to \widetilde{H}_i(S^n \setminus h(S^{k+1})) \to \dots.$$

Thus we see that

$$\widetilde{H}_i(S^n \setminus h(S^{k+1})) \cong \widetilde{H}_{i-1}(S^n \setminus h(S^k)) \underset{\substack{\uparrow \\ \text{by induction}}}{\cong} \begin{cases} \mathbb{Z}, & \text{if } i-1 = n-k-1, \\ 0, & \text{otherwise.} \end{cases}$$

□

The following immediate corollary to Proposition 36.1 says that every closed curve in $\mathbb{R}^2$, i.e. the image of an injective map $S^1 \to \mathbb{R}^2$, separates S^2 into two path-components. This

[706] Why does this follow? What results from real analysis do we need to draw that conclusion?

[707] Can you give a rigorous proof for the statement that the complement of two points in S^n is homotopy equivalent to S^{n-1}?

[708] Here we use, as in the proof of Proposition 36.1 (1), implicitly the injectivity of h.

might be intuitively obvious, but it is actually non-trivial.[709] The theorem was first proved in 1887 by Camille Jordan.[710]

Corollary 36.2. (Jordan Curve Theorem) *If C is a subset of $\mathbb{R}^2$ that is homeomorphic to S^1, then $\mathbb{R}^2 \setminus C$ consists of two path-connected components.*

Proof. Let C be a subset of $\mathbb{R}^2$ that is homeomorphic to S^1. We pick an injective map $h\colon S^1 \to S^2 = \mathbb{R}^2 \cup \{\infty\}$ with $h(S^1) = C$. Now we see that

$$\begin{array}{ccccccc} \widetilde{H}_0(\mathbb{R}^2 \setminus C) & = & \widetilde{H}_0(\mathbb{R}^2 \setminus h(S^1)) & \cong & \widetilde{H}_0(S^2 \setminus h(S^1)) & \cong & \mathbb{Z} \\ & & & \uparrow & & \uparrow & \\ & & & \text{see Exercise 33.5} & & \text{Proposition 36.1 (2)} & \end{array}$$

It follows from Lemma 31.1 (5) that $\mathbb{R}^2 \setminus C$ has precisely two path-components. □

Proposition 36.1, together with Lemma 31.1, says in particular, that if $h\colon S^{n-1} \to S^n$ is an injective map, then

$$H_i(S^n \setminus h(S^{n-1})) \cong \begin{cases} \mathbb{Z}^2, & \text{if } i = 0, \\ 0, & \text{otherwise.} \end{cases}$$

Put differently, homologically the topological space $S^n \setminus h(S^{n-1})$ looks like the disjoint union of two open n-dimensional balls. One might now suspect that $S^n \setminus h(S^{n-1})$ is in fact homeomorphic to the union of two open n-dimensional balls.

This is in fact true in dimension $n = 2$. More precisely Arthur Schönflies[711] proved in 1908 the following theorem. We refer to [Tn, Section 3] for a proof of the theorem.[712]

Theorem 36.3. (Schönflies Theorem) *Let $h\colon S^1 \to S^2$ be an injective map. Then h extends to a homeomorphism of S^2, i.e. there exists a homeomorphism $H\colon S^2 \to S^2$ such that $H|_{S^1} = h$. In particular both components of $S^2 \setminus h(S^1)$ are homeomorphic to open disks.*

Remark. If $h\colon S^1 \to S^2$ is an embedding, then the conclusion of the Schönflies Theorem 36.3 also follows from the much easier Proposition 40.16.

It is natural to ask whether the conclusion of the Schönflies Theorem also holds in higher dimensions. But this hope breaks down already one dimension higher. More precisely, James Alexander [713] showed in 1924 that there exists an injective map $S^2 \to \mathbb{R}^3$ such that neither of the two components of the complement of $h(S^2)$ is simply connected. The

[709] Try to give an elementary proof for the statement.

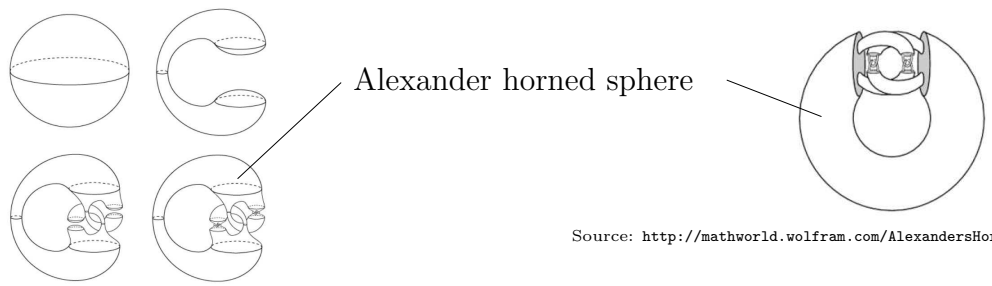
[710] Camille Jordan (1838-1922) was a French mathematician. It is the same Jordan whom you encountered in linear algebra.

[711] Arthur Schönflies (1853–1928) was a German mathematician.

[712] More precisely, in [Tn, Section 3] a proof for the following statement is given:
Let $g\colon S^1 \to \mathbb{R}^2$ be an injective map. Then g extends to a homeomorphism of $\mathbb{R}^2$.
We leave it as an exercise to deduce Theorem 36.3 from that statement.

[713] James Alexander (1888-1971) was an American mathematician. He also introduced the Alexander polynomial of a knot.

image $h(S^2)$ is called the *Alexander horned sphere*. It is illustrated in Figure 552. A more detailed description of the Alexander horned sphere and the proof that the complement is not simply connected is given in [Al] and also [Hat, p. 170].



Source: https://conan777.wordpress.com/2010/04/18/

Source: http://mathworld.wolfram.com/AlexandersHornedSphere.html

FIGURE 552.

We have now seen that injective maps $S^2 \to S^3$ can be pretty "wild". The map that defines the Alexander horned sphere is continuous, but it is certainly not smooth. So what happens if we restrict ourselves to smooth maps? In fact in the smooth setting we have the following theorem.

Theorem 36.4. (Generalized smooth Schönflies Theorem) *Let $h\colon S^{n-1} \to S^n$ be an embedding. If $n \neq 4$, then there exists a diffeomorphism $H\colon S^n \to S^n$ with $H|_{S^{n-1}} = h$.*

For $n = 2$ the statement follows fairly easily from the classification of smooth 2-dimensional manifolds that we gave in Theorem 14.14, see e.g. [Hirs, p. 207]. For $n = 3$ this statement was proved by James Alexander [Al2], see also [Hat3, Chapter 1] for an exposition of the proof. For $n \geq 5$ this statement was independently proved by Barry Mazur [Maz] in 1959 and by Morton Brown [BrownM] in 1960.

The case $n = 4$ is missing in the Generalized Schönflies Theorem. In fact it is still unknown whether the statement holds for $n = 4$.

Question 36.5. *Is it true that given any embedding $h\colon S^3 \to S^4$ there exists a diffeomorphism $H\colon S^4 \to S^4$ with $H|_{S^3} = h$?*

This question is very much open and there is not even a consensus whether one expects the answer to be yes or no. If you can answer this question you would almost certainly obtain a Fields medal.[714]

We conclude this section with two more consequences of Proposition 36.1. The following theorem was first proved by Luitzen Brouwer [Brou] in 1911. It can be viewed as a significant strengthening of Proposition 3.20 (1).

[714]But hurry up, you can only get a Fields medal if you are under 40.

Theorem 36.6. (Invariance of Domain Theorem) *Let U be an open subset of $\mathbb{R}^n$ and let $h\colon U \to \mathbb{R}^n$ be an injective map. Then $h(U)$ is also an open subset of $\mathbb{R}^n$.*[715]

Remark. The Open Mapping Theorem from complex analysis, see [Lan, Theorem II.6.2], says that if $G \subset \mathbb{C}$ is an open subset and if $f\colon G \to \mathbb{C}$ is a non-constant *holomorphic* function, then $f(G)$ is also open. In fact, one can deduce the "Open Mapping Theorem" from the Invariance of Domain Theorem 36.6 since by [Jä2, Satz 10] every non-constant holomorphic function on an open subset of $\mathbb{C}$ is o-locally the power of an injective function.

In the proof of Theorem 36.6 we need the following elementary lemma.

Lemma 36.7. *Let $U \subset \mathbb{R}^n$ be a subset. If U is open in $\mathbb{R}^n$, then every path-component of U is also an open subset of $\mathbb{R}^n$.*

Proof. Let C be a path-component of the subset subset $U \subset \mathbb{R}^n$. Let $P \in C$. Since U is open there exists an $r > 0$ such that $B_r(P) \subset U$. But all points in $B_r(P)$ are path-equivalent to P, hence $B_r(P) \subset C$. □

Now we can provide the proof of Theorem 36.6.

Proof of Theorem 36.6. By the homeomorphism from Lemma 1.41 we can view $\mathbb{R}^n$ as an open subset of $\mathbb{R}^n \cup \{\infty\} = S^n$. So we can view h as a map from U to S^n and we need to show that $h(U)$ is an open subset of S^n.

Let $x \in U$. We pick a closed n-ball B in U that contains x in the interior. It suffices to show that $h(B \setminus \partial B) \subset h(U)$ is open in S^n. Note that $S^n \setminus h(\partial B)$ is open by Lemma 1.37 (3). By Lemma 36.7 it therefore suffices to show that $h(B \setminus \partial B)$ is a path-component of $S^n \setminus h(\partial B)$. We will do so in the following claim.

Claim. The topological space $S^n \setminus h(\partial B)$ has precisely two path-components namely the subsets $h(B \setminus \partial B)$ and $S^n \setminus h(B)$.

By Proposition 36.1 (2) and Lemma 31.1 we know that

$$S^n \setminus h(\partial B) \;=\; h(B \setminus \partial B) \sqcup (S^n \setminus h(B))$$

has two path-components. It suffices to show that the two sets on the right-hand side are path-connected. The first set $h(B \setminus \partial B)$ is path-connected since it is the image of the path-connected topological space $B \setminus \partial B$, while the second set $S^n \setminus h(B)$ is path-connected by Proposition 36.1 (1) and Lemma 31.1. This concludes the proof of the claim. □

Corollary 36.8. *Let M be a non-empty closed n-dimensional topological manifold and let N be a connected n-dimensional topological manifold without boundary. Let $h\colon M \to N$ be a map.*

(1) *If $h\colon M \to N$ is o-locally injective, then h is also surjective.*
(2) *If h is injective, then h is already a homeomorphism.*

[715] How can one prove the theorem for $n = 1$ using only the methods from real analysis?

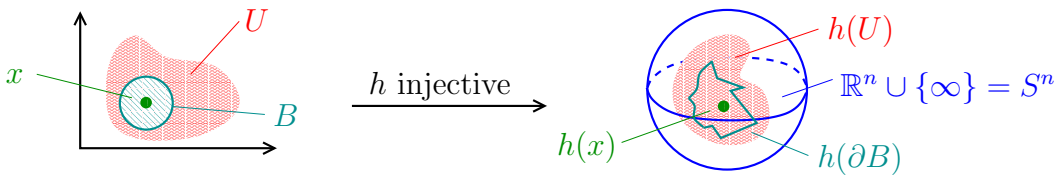


FIGURE 553. Illustration for the proof of Theorem 36.6.

Example. Corollary 36.8 implies in particular that there exists no injective map from the closed manifold S^n into the manifold $\mathbb{R}^n$.[716]

Proof. The second statement of the corollary is an immediate consequence of the first statement and Proposition 1.40. So it suffices to prove the first statement.

Let $h\colon M \to N$ be a strongly locally injective map from a non-empty closed n-dimensional topological manifold M to a connected n-dimensional topological manifold N without boundary.

The image $h(M)$ is closed in N since M is compact and since N is Hausdorff. Since N is connected and since M is non-empty it suffices to show that $h(M)$ is also open in N.

So let $Q \in h(M)$. We pick $P \in M$ with $h(P) = Q$. We pick a chart $\Phi\colon U \to V$ around P and we pick a chart $\Psi\colon W \to X$ around Q. After possibly replacing U by $U \cap h^{-1}(W)$ we can assume that $h(U) \subset W$. Since h is o-locally injective we can, after possibly shrinking U even more, assume that $h|_U$ is injective.

From Theorem 36.6 we know that $(\Psi \circ h \circ \Phi^{-1})(V)$ is an open subset of $\mathbb{R}^n$. Since Ψ is a homeomorphism we see that $h(\Phi^{-1}(V)) = h(U)$ is an open neighborhood of Q that is contained in $h(M)$. $\square$

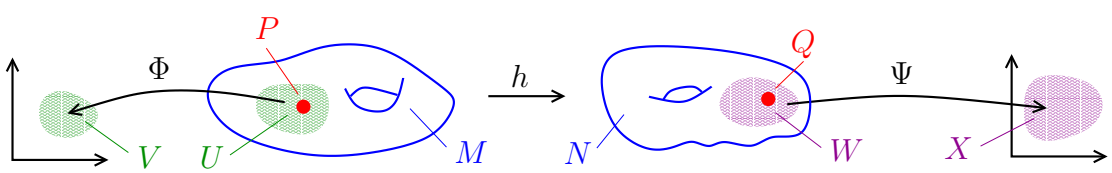

FIGURE 554. Illustration for the proof of Corollary 36.8.

Exercises for Chapter 36.

Exercise 36.1. In Figure 555 we see the image of an injective map $\varphi\colon I \to S^3 = \mathbb{R}^3 \cup \{\infty\}$ and we see a curve $C \subset S^3 \setminus \varphi(I)$. We know from Proposition 36.1 (1) that x is null-homologous. Show that x is the boundary of an orientable surface Σ that is embedded in $S^3 \setminus \varphi(I)$. (In this context this can be seen as the converse to Exercise 35.7.)

[716] How can you show this for $n = 1$, just using methods from real analysis?

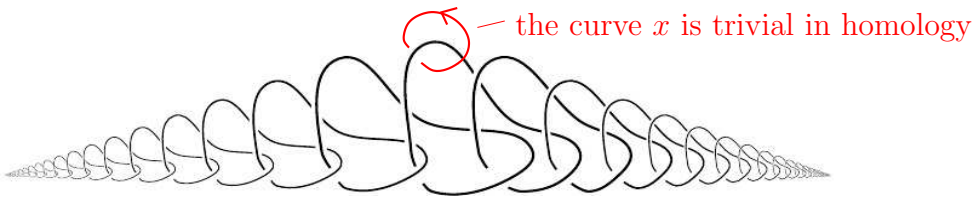

FIGURE 555.

37. Topological robotics

In this chapter we will first study the matrix groups SO(3) and SU(2), viewed as topological spaces. In particular we will determine $\pi_1(\mathrm{SO}(3))$ and we will use this result to give an application to topological robotics.

37.1. **The matrix groups** SO(3) **and** SU(2)**.** We recall that Lemma 3.45 implies in particular that we can view SO(3) and SU(2) as closed 3-dimensional manifolds. In this section we will see that the manifolds SO(3) and SU(2) are diffeomorphic to manifolds we are already very familiar with.

We start out our discussion of SO(3) and SU(2) with some definitions. We consider the set of matrices[717]

$$T \;:=\; \big\{B \in \mathrm{SL}(2,\mathbb{C}) \,\big|\, \mathrm{tr}(B) = 0 \text{ and } B = \overline{B}^T\big\}.$$

Note that T is a 3-dimensional real vector space. We equip it with the basis given by the so-called "Pauli matrices"[718]

$$E_1 \;=\; \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad E_2 \;=\; \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \quad \text{and} \quad E_3 \;=\; \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix},$$

and we equip T with the inner product given by

$$\begin{array}{rcl} T \times T & \mapsto & \mathbb{R} \\ (A,B) & \mapsto & g(A,B) := \frac{1}{2}\,\mathrm{tr}\left(A\overline{B}^T\right). \end{array}$$

We consider the isomorphism

$$\begin{array}{rcl} \Phi\colon \mathbb{R}^3 & \to & T \\ e_i & \mapsto & E_i. \end{array}$$

It follows from a straightforward calculation that Φ defines an isometry from $(\mathbb{R}^3, \langle\,,\,\rangle)$ to (T,g).[719] It follows immediately from this observation that Φ induces an isomorphism $\mathrm{SO}(3) \to \mathrm{SIsom}(T,g)$, where $\mathrm{SIsom}(T,g)$ denotes the group of isometries of (T,g) of determinant $+1$. We use this isomorphism to identify these two groups.

Lemma 37.1. *The map*

$$\begin{array}{rcl} q\colon \mathrm{SU}(2) & \to & \mathrm{SIsom}(T,g) = \mathrm{SO}(3) \\ A & \mapsto & (B \mapsto ABA^{-1}) \end{array}$$

is a smooth map between manifolds and it is a well-defined group homomorphism. Furthermore for $A, A' \in \mathrm{SU}(2)$ we have

$$q(A) \;=\; q(A') \quad \Longleftrightarrow \quad A \;=\; \pm A'.$$

[717]Recall that the trace $\mathrm{tr}(A)$ of a matrix is defined as the sum of all the diagonal entries.

[718]Wolfgang Pauli (1900–1958) was Swiss-American theoretical physicist and one of the pioneers of quantum physics. These matrices were also independently introduced by Paul Dirac. Wikipedia write: "In 1928, building on 2×2-spin matrices which he [Paul Dirac] discovered independently of Wolfgang Pauli's work on non-relativistic spin systems, [...] he proposed the Dirac equation as a relativistic equation of motion for the wave function of the electron. This work led Dirac to predict the existence of the positron, the electron's antiparticle [...]."

[719]In the calculation we only have to show that $g(E_i, E_j) = \frac{1}{2}\,\mathrm{tr}(E_i\overline{E}_j^T) = \delta_{ij} = \langle e_i, e_j\rangle$ for all choices of $i, j \in \{1,2,3\}$. But this can be verified easily.

Example. Given $t \in \mathbb{R}$ we consider the matrix

$$A = \begin{pmatrix} e^{-it} & 0 \\ 0 & e^{it} \end{pmatrix} \in \mathrm{SU}(2).$$

We want to determine $q(A) \in \mathrm{SO}(3)$. This means that we have to express the linear map $T \to T$ that is given by $B \mapsto ABA^{-1}$ with respect to the ordered basis $\{E_1, E_2, E_3\}$. A straightforward calculation shows that

$$\begin{aligned} AE_1A^{-1} &= E_1, \\ AE_2A^{-1} &= \begin{pmatrix} 0 & e^{-2it} \\ e^{2it} & 0 \end{pmatrix} \underset{\substack{\uparrow \\ \text{since } e^{is} = \cos(s) + i\sin(s) \\ \downarrow}}{=} \cos(2t) \cdot E_2 + \sin(2t) \cdot E_3, \\ AE_3A^{-1} &= \begin{pmatrix} 0 & -ie^{-2it} \\ ie^{2it} & 0 \end{pmatrix} = -\sin(2t) \cdot E_2 + \cos(2t) \cdot E_3. \end{aligned}$$

But this implies that the homomorphism $T \to T$ given by conjugation with A, with respect to the ordered basis $\{E_1, E_2, E_3\}$ is given by the matrix

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos(2t) & -\sin(2t) \\ 0 & \sin(2t) & \cos(2t) \end{pmatrix}, \text{ put differently, we have } q\begin{pmatrix} e^{-it} & 0 \\ 0 & e^{it} \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos(2t) & -\sin(2t) \\ 0 & \sin(2t) & \cos(2t) \end{pmatrix}.$$

Proof of Lemma 37.1 $(*)$. First we have to show that for $A \in \mathrm{SU}(2)$ and $B \in T$ we also have $ABA^{-1} \in T$. This is indeed the case since

$$\mathrm{tr}(ABA^{-1}) = \mathrm{tr}(B) = 0 \quad \text{and} \quad \left(\overline{ABA^{-1}}\right)^T = (\overline{A}^{-1})^T \overline{B}^T \overline{A}^T \underset{\substack{\uparrow \\ \text{since } B = \overline{B}^T \text{ and } A^{-1} = \overline{A}^T}}{=} A\overline{B}^T A^{-1}.$$

It follows easily from the definition that q is a group homomorphism. We also have to show that for $A \in \mathrm{SU}(2)$ we get indeed an isometry of (T, g). So let $B, C \in T$. Then we have indeed

$$\begin{aligned} g(q(A)(B), q(A)(C)) &= \tfrac{1}{2}\,\mathrm{tr}\left(ABA^{-1} \cdot \overline{ACA^{-1}}^T\right) = \tfrac{1}{2}\,\mathrm{tr}\left(AB\overbrace{A^{-1} \cdot (\overline{A}^{-1})^T}^{=\mathrm{id}}\overline{C}^T\overline{A}^T\right) \\ &= \tfrac{1}{2}\,\mathrm{tr}\left(AB\overline{C}^T\overline{A}^T\right) = \tfrac{1}{2}\,\mathrm{tr}\left(B\overline{C}^T\underbrace{\overline{A}^T A}_{=\mathrm{id}}\right) = \tfrac{1}{2}\,\mathrm{tr}\left(B \cdot \overline{C}^T\right). \end{aligned}$$

This shows that q defines group homomorphism $\mathrm{SU}(2) \to \mathrm{O}(3)$. By Lemma 1.96 we know that $\mathrm{SU}(2)$ is path-connected. The image $q(\mathrm{SU}(2))$ is a path-connected subset of $\mathrm{O}(3)$ that contains $q(\mathrm{id}) = \mathrm{id}$. It follows again Lemma 1.96 that $q(\mathrm{SU}(2))$ is contained in $\mathrm{SO}(3)$.

Finally let $A, A' \in \mathrm{SU}(2)$. If $A = -A'$ then we clearly have $q(A) = q(A')$. Now suppose that conversely we have $q(A) = q(A')$. We then have in particular $q(A)(E_i) = q(A')(E_i)$ for $i = 1, 2, 3$, i.e. we have $AE_iA^{-1} = A'E_i(A')^{-1}$ for $i = 1, 2, 3$. These equalities give us equations relating the four entries of the matrix A to the four entries of the matrix A'. An elementary calculation then shows that the only solutions are $A = \pm A'$. We leave the details to the reader.

This discussion shows that q is a well-defined map and that it is a group homomorphism. After one has unraveled the definitions it will also have become apparent that the map g is indeed a smooth map between manifolds. $\square$

The following theorem is the main result of this section.

Theorem 37.2. *We denote by* $q\colon \mathrm{SU}(2) \to \mathrm{SIsom}(T, g) = \mathrm{SO}(3)$ *the map from Lemma 37.1. Then the following two statements hold:*

(1) *the map q is a 2-fold covering map,*
(2) *there exist diffeomorphisms $f\colon S^3 \to \mathrm{SU}(2)$ and $g\colon \mathbb{R}\mathrm{P}^3 \to \mathrm{SO}(3)$ such that the following diagram commutes:*

$$\begin{tikzcd} S^3 \arrow[r, "f", "\cong"'] \arrow[d, "p"'] & \mathrm{SU}(2) \arrow[d, "q"] \\ \mathbb{R}\mathrm{P}^3 \arrow[r, "g", "\cong"'] & \mathrm{SO}(3), \end{tikzcd}$$

where we denote by $p\colon S^3 \to \mathbb{R}\mathrm{P}^3 = S^3/\pm 1$ the usual projection map.

In the proof of Theorem 37.2 we will need the following technical lemma.

Lemma 37.3. *Let $q\colon M \to N$ be a map between two n-dimensional topological manifolds. Suppose the following conditions are satisfied:*

(1) *the map q is surjective,*
(2) *the map q is o-locally injective, i.e. for each $P \in M$ there exists a neighborhood U such that $q|_U$ is injective,*
(3) *for each point $Q \in N$ the preimage $q^{-1}(Q)$ is a finite set.*

Then q is a covering map.

Proof $(*)$. Since q is surjective we only have to show that each $Q \in N$ admits an open neighborhood that is uniformly covered. So let $Q \in N$. We denote its preimages by $P_1, \ldots, P_r$. Let $i \in \{1, \ldots, m\}$. It follows easily from (2) and the hypothesis that M is a topological manifold that we can pick a closed ball B_i which is a neighborhood around P_i and such that $q\colon B_i \to N$ is injective. Since the topological manifold N is in particular Hausdorff it follows from Proposition 1.40 that $q\colon B_i \to q(B_i)$ is a homeomorphism. It follows from the proof of Corollary 36.8 that $q(\overset{\circ}{B}_i)$ is an open neighborhood of Q. It is now straightforward to see that $U := \bigcap_{i=1}^{m} q(\overset{\circ}{B}_i)$ is a uniformly covered open neighborhood of Q. $\square$

Now we can provide the proof of Theorem 37.2.

Proof of Theorem 37.2. Somewhat confusingly the proof of Theorem 37.2 is given in three steps (a), (b) and (c).

(a) One can easily show that the map

$$\begin{array}{rcl} f\colon S^3 & \to & \mathrm{SU}(2) \\ (z,w) & \mapsto & \begin{pmatrix} z & -\overline{w} \\ w & \overline{z} \end{pmatrix} \end{array} \quad \text{and} \quad \begin{array}{rcl} \widetilde{f}\colon \mathrm{SU}(2) & \to & S^3 \\ \begin{pmatrix} z & -\overline{w} \\ w & \overline{z} \end{pmatrix} & \mapsto & (z,w) \end{array}$$

are inverses to one another and that both maps are smooth. This implies that both maps, in particular f, is a diffeomorphism.

(b) Now we want to show that $q\colon \mathrm{SU}(2) \to \mathrm{SO}(3)$ is a 2-fold covering map. By Lemma 37.1 we know that q is o-locally injective. But then it follows from Corollary 36.8 and the fact that SU(2) and SO(3) are closed 3-dimensional manifolds and the fact that SO(3) is connected (which follows from the Lemma 1.96 (1) together with Lemma 1.102) that q is in fact also a surjection. Since the preimage of each $A \in \mathrm{SO}(3)$ consists of precisely two points in SU(2) we can apply Lemma 37.3 to deduce that q is indeed a 2-fold covering map.

(c) For any $(z,w) \in S^3$ we have $q(f(-z,-w)) = q(-f(z,w)) = q(f(z,w))$. Thus we see that the map

$$\begin{array}{rcl} g\colon \mathbb{R}\mathrm{P}^3 & \to & \mathrm{SO}(3) \\ [(z,w)] & \mapsto & q(f(z,w)) \end{array}$$

is well-defined. It follows immediately from the fact, obtained in (b), that q is surjective, that g is also surjective. Similarly it is straightforward to show, using (b), that the map g is injective. Since q, f and p are local diffeomorphisms and since locally g is given by a composition of q, f, p and their local inverses we see that g is a local diffeomorphism. But by Lemma 3.15 (3) map between manifolds that is a local diffeomorphism and a bijection is in fact a diffeomorphism.

Finally we note that it follows easily from the definitions that $g \circ p = q \circ f$, i.e. the diagram given in the theorem commutes. □

Remark. An elegant direct proof that $\mathbb{R}\mathrm{P}^3 = \overline{B}^3/\sim$ is homeomorphic to SO(3) is given at wikipedia:

`https://en.wikipedia.org/wiki/Rotation_group_SO(3)`

under "topology".

From Theorem 37.2 and Corollary 7.19 we obtain immediately the following, perhaps initially somewhat surprising, corollary.

Corollary 37.4. *We have*

$$\pi_1(\mathrm{SU}(2)) \;=\; 0 \quad \textit{and} \quad \pi_1(\mathrm{SO}(3)) \;\cong\; \mathbb{Z}_2.$$

In particular SU(2) *is the universal covering of* SO(3).[720]

[720]The fact SU(2) is the universal covering of SO(3) plays an important role in theoretical physics and it is essential in understanding the notion of "spin" of an electron. At least that is a slogan that I remember from the days when I studied physics.

Remark. We can actually give an explicit description of the non-trivial element in the fundamental group $\pi_1(\mathrm{SO}(3)) \cong \mathbb{Z}_2$. More precisely, we consider the loop

$$\begin{array}{rcl} \gamma\colon [0,1] & \to & \mathrm{SO}(3) \\ t & \mapsto & \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos(2\pi t) & \sin(2\pi t) \\ 0 & -\sin(2\pi t) & \cos(2\pi t) \end{pmatrix} \end{array}$$

at the base point $\mathrm{id} \in \mathrm{SO}(3)$. The calculation on page 912 shows that a lift of the path $\gamma\colon [0,1] \to \mathrm{SO}(3)$ to a path $[0,1] \to \mathrm{SU}(2)$ to the starting point $\mathrm{id} \in \mathrm{SU}(2)$ is given by

$$\begin{array}{rcl} \widetilde{\gamma}\colon [0,1] & \to & \mathrm{SO}(3) \\ t & \mapsto & \begin{pmatrix} e^{-i\pi t} & 0 \\ 0 & e^{i\pi t} \end{pmatrix}. \end{array}$$

Note that $\widetilde{\gamma}(1) = -\mathrm{id}$, i.e. $\widetilde{\gamma}$ is *not* a loop. Since $q\colon \mathrm{SU}(2) \to \mathrm{SO}(3)$ is a covering and since $\mathrm{SU}(2)$ is simply connected it follows from Lemma 7.16 that $[\gamma]$ is non-trivial in $\pi_1(\mathrm{SO}(3), \mathrm{id})$.

Corollary 37.4 also raises the following question.

Question 37.5. *Let $n \geq 4$. What is $\pi_1(\mathrm{SO}(n))$?*[721][722]

We will return to this question later on in a later chapter.

37.2. **The belt trick.** In this section we will see that one can visualize the non-trivial element in $\pi_1(\mathrm{SO}(3)) \cong \mathbb{Z}_2$ using a belt. We proceed as follows.

(1) First of all note that a matrix in $\mathrm{SO}(3)$ is precisely given by an ordered orthonormal basis, i.e. by a choice of an ordered set of three orthogonal vectors v_1, v_2, v_3 of length 1 in $\mathbb{R}^3$.
(2) We equip $\mathrm{SO}(3)$ with the base point given by the identity matrix, i.e. by the standard basis $\{e_1, e_2, e_3\}$.
(3) Now suppose we are given a belt with a buckle, a red edge and a green edge, with a blue top side and a pink lower side.
(4) Any point on a twisted belt defines a triple of orthogonal vectors:
    (a) the first vector lies in the plane defined by the belt and points away from the buckle,
    (b) the second vector also lies in the plane defined by the belt and points towards the red edge,
    (c) the third is orthogonal to the belt and it is attached to the top side of the belt.
(5) In the remainder of the discussion we fix the buckle in the xy-plane such that it points in the x-direction, so that to a point at the buckle we assign the identity matrix.

[721] Recall that Lemma 1.96 (1) says that $\mathrm{SO}(n)$ is path-connected.
[722] What is $\pi_1(\mathrm{SO}(2))$?

(6) We say that the end of the belt is in standard position if it lies in a plane parallel to the plane of the buckle and if it points into the x-direction. Put differently, the end of the belt is in standard position precisely if the matrix assigned to it is the identity matrix.

(7) When we walk on the middle curve of the belt from the buckle towards the other end of the belt, then we obtain a path $[0,1] \to \mathrm{SO}(3)$. In particular, if the end of the belt is in standard position, then the path defined by the belt is in fact a loop in $\mathrm{SO}(3)$ at the base point id.

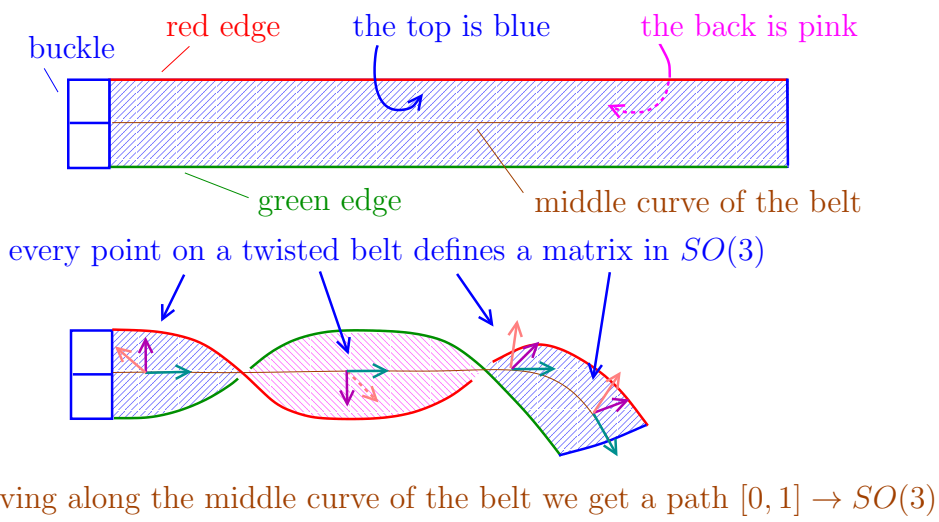

FIGURE 556.

(8) When we hold the belt tightly without twisting it, then we assign the identity matrix to every point on the belt, i.e. the belt defines the constant loop $t \mapsto \mathrm{id} \in \mathrm{SO}(3)$.

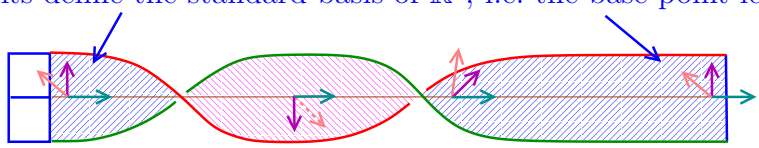
(9) Now we give the belt, that is still fixed at the buckle, a full twist. As in (7) this defines a loop $\gamma\colon [0,1] \to \mathrm{SO}(3)$, in fact it is straightforward to see that this loop is precisely the loop that we had considered on page 915. In particular we have visualized the non-trivial element $[\gamma] \in \pi_1(\mathrm{SO}(3), \mathrm{id}) \in \mathbb{Z}_2$.

(10) The loop $\gamma * \gamma\colon [0,1] \to \mathrm{SO}(3)$ is given by performing another full twist along the belt. It follows from Corollary 37.4 that $[\gamma * \gamma] = [\gamma]^2$ is trivial in $\pi_1(\mathrm{SO}(3), \mathrm{id}) \cong \mathbb{Z}_2$, i.e. $\gamma * \gamma$ is null-homotopic.

(10) One can see that the loop $\gamma * \gamma$ is null-homotopic as follows: one can untwist the belt while keeping the end in standard position, put differently, we can find a path-homotopy from the loop $\gamma * \gamma$ to the trivial loop. This homotopy is illustrated in Figure 559.

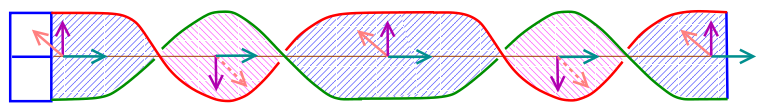
The fact that $\pi_1(\mathrm{SO}(3)) \cong \mathbb{Z}_2$ lies at the heart of some other tricks, in particular the "plate trick" and "Dirac's string trick". More information and some videos can be found

both points define the standard basis of $\mathbb{R}^3$, i.e. the base point $\mathrm{id} \in SO(3)$



the path $\gamma\colon [0,1] \to SO(3)$ defined by the matrices along the middle curve is a loop and thus defines an element $[\gamma] \in \pi_1(SO(3), \mathrm{id})$

FIGURE 557.



the double full twist defines the loop $\gamma * \gamma$ which represents $[\gamma]^2 \in \pi_1(SO(3), \mathrm{id})$

37.3. **Topological robotics.** In this section we want to discuss a "real-life" application of Corollary 37.4. Let us assume that we are given a solid ball and we are allowed to perform the following operations:

(1) first we can rotate the ball around the z-axis by an angle $\gamma \in S^1$,
(2) then we can rotate the ball around the y-axis by an angle $\beta \in S^1$, finally

(3) we can rotate the ball around the x-axis by an angle $\alpha \in S^1$.

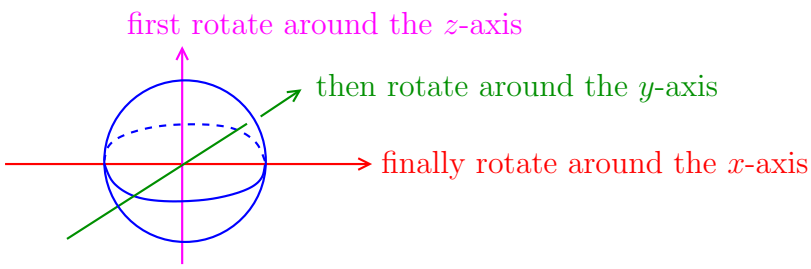

FIGURE 560.

Using these three operations, in that order, we can rotate the ball into any position. More precisely, we have the following lemma:

Lemma 37.6. *The map*

$$\begin{array}{rcl} \Phi\colon S^1 \times S^1 \times S^1 & \to & \mathrm{SO}(3) \\ (\alpha,\beta,\gamma) & \mapsto & \begin{array}{c}\textit{rotation by } \alpha \\ \textit{around the } x\textit{-axis}\end{array} \circ \begin{array}{c}\textit{rotation by } \beta \\ \textit{around the } y\textit{-axis}\end{array} \circ \begin{array}{c}\textit{rotation by } \gamma \\ \textit{around the } z\textit{-axis}\end{array} \end{array}$$

is a surjection.[723]

Remark. One can use Lemma 37.6 and a variation of the argument on page 912 to give an alternative proof for the statement that $q\colon \mathrm{SU}(2) \to \mathrm{SO}(3)$ is surjective.

Sketch of proof. Let $A \in \mathrm{SO}(3)$ be matrix with columns v_1, v_2, v_3. After a rotation around the z-axis we can assume that v_1 lies in the xz-plane. After a rotation around the y-axis we can then arrange that v_1 lies in fact on the x-axis, i.e. we can arrange that $v_1 = e_1$. Since $v_1 = e_1, v_2, v_3$ is an orthonormal basis we see that v_2, v_3 lie in the yz-plane. After a rotation around the x-axis we can finally arrange that $v_2 = e_2$ and $v_3 = e_3$. $\square$

This lemma gives rise to the following practical problem: given a matrix $P \in \mathrm{SO}(3)$, can we continuously find parameters $\alpha(P), \beta(P), \gamma(P) \in S^1$ such that these parameters give back the matrix P? More precisely, we have the following question.

Question 37.7. *Does there exist a continuous map* $\Psi\colon \mathrm{SO}(3) \to S^1 \times S^1 \times S^1$ *such that* $\Phi \circ \Psi = \mathrm{id}_{\mathrm{SO}(3)}$*?*

It turns out that the answer is negative. More precisely, we have the following proposition.

Proposition 37.8. *There is no continuous map* $\Psi\colon \mathrm{SO}(3) \to S^1 \times S^1 \times S^1$ *such that* $\Phi \circ \Psi = \mathrm{id}_{\mathrm{SO}(3)}$.

[723]The map is also continuous. Why is that?

This proposition falls into the area of "topological robotics", more information on this example and on topological robotics can be found in [Gh, p. 76]. Other aspects of topological robotics are discussed in the monograph [Far].

Proof. Let us suppose there exists a continuous map $\Psi\colon \mathrm{SO}(3) \to S^1 \times S^1 \times S^1$ such that $\Phi \circ \Psi = \mathrm{id}_{\mathrm{SO}(3)}$. Then we get the following commutative diagram

$$\begin{tikzcd}
 & \overbrace{\pi_1(S^1 \times S^1 \times S^1)}^{\cong \mathbb{Z}^3} \arrow[dr, "\Phi_*"] & \\
\underbrace{\pi_1(\mathrm{SO}(3))}_{\cong \mathbb{Z}_2} \arrow[ur, "\Psi_*"] \arrow[rr, "\mathrm{id}_*"] & & \underbrace{\pi_1(\mathrm{SO}(3))}_{\cong \mathbb{Z}_2}.
\end{tikzcd}$$

By Corollary 37.4 we have that $\pi_1(\mathrm{SO}(3)) \cong \mathbb{Z}_2$ and from Corollary 7.19 we know that $\pi_1(S^1 \times S^1 \times S^1) \cong \mathbb{Z}^3$. Since $\mathbb{Z}_2$ is a finite group and since $\mathbb{Z}^3$ is torsion-free we see that the homomorphism $\Psi_*\colon \pi_1(\mathrm{SO}(3)) \to \pi_1(S^1 \times S^1 \times S^1)$ is the trivial map. But that is not possible since the horizontal map is an isomorphism of a non-trivial group. $\square$

37.4. **Linkages.** We conclude this chapter with a somewhat unrelated but fun topic that also appears in topological robotics.

(1) We recall that an abstract graph G is a triple (V, E, λ) where V is a non-empty set, E is a set and λ is a map

$$\lambda\colon E \ \to \ \{\text{subsets of } V \text{ with one or two elements}\}.$$

The elements of V are called *vertices of* G and the elements of E are called the *edges of* G. Furthermore, given $e \in E$ the points in $\lambda(e)$ are called the *endpoints of* e.

(2) Given $n \in \mathbb{N}$ we define the *linear graph of length* n to be the graph $G(n)$ which is given by the vertex set $V = \{0, \dots, n\}$ and the edge set $\{e_0, \dots, e_{n-1}\}$ with $\lambda(e_i) = \{i, i+1\}$ for $i = 0, \dots, n-1$. This graph is illustrated in Figure 561.

the linear graph $G(4)$

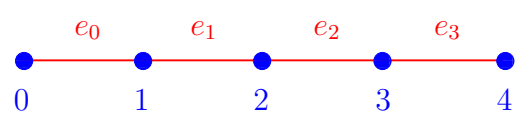

FIGURE 561.

Definition.

(1) A *planar linkage* is a triple $(G = (V, E), \lambda, \psi)$ consisting of a finite abstract graph $G = (V, E)$, a function $\lambda\colon E \to \mathbb{R}_{>0}$ and a map $\psi\colon W \to \mathbb{C} = \mathbb{R}^2$ where W is a subset of V. Put differently, λ assigns a length to each edge and ψ represents a subset of the vertices by points in $\mathbb{C}$.

(2) A *configuration* of a planar linkage $(G = (V, E), \lambda, \psi)$ is a map $f\colon V \to \mathbb{R}^2 = \mathbb{C}$ such that $f|_W = \psi$ and such that for every edge e the distance between the endpoints of e is $\lambda(e)$.[724]

(3) The set $C(G = (V, E), \lambda, \psi)$ of all configurations is called the *configuration space* of the linkage. We have an injective map

$$\begin{array}{rcl} C(G = (V, E), \lambda, \psi) & \to & \mathbb{C}^{|V|} := \text{maps}(V \to \mathbb{C}) \\ f & \mapsto & (v \mapsto f(v)) \end{array}$$

thus we can view the configuration space $C(G = (V, E), \lambda, \psi)$ as a topological space.

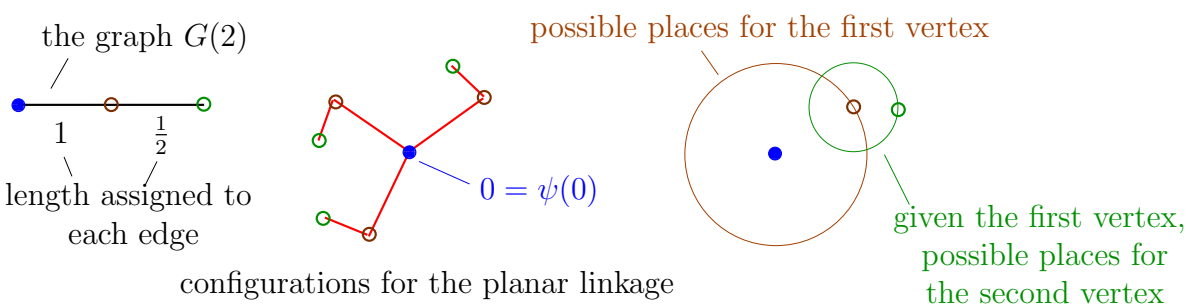

FIGURE 562.

In some cases the topological shape of the configuration space of a planar linkage is easy to describe. More precisely, we have the following lemma which is a straightforward consequence of the definitions and Proposition 1.40. We leave the proof as an exercise.

Lemma 37.9. *Let $G(m)$ be the linear graph with m edges. We consider a planar linkage of the form $(G(m), \lambda, \psi(0) = 0)$. For $i = 1, \dots, m$ we write $r_i = \lambda(e_i)$. Then the map*

$$\begin{array}{rcl} (S^1)^m = S^1 \times \cdots \times S^1 & \to & C(G(m), \lambda, \psi) \\ (z_1, \dots, z_m) & \mapsto & \left(\begin{array}{rcl} \{0, \dots, m\} & \to & \mathbb{C} \\ k & \mapsto & \sum_{i=1}^{k} r_i z_i \end{array} \right) \end{array}$$

is a homeomorphism.

For general linkages the topology of the configuration spaces are much harder to describe than for free planar linkages.

(1) Given $r_1, \dots, r_m > 0$ we denote by $C(r_1, \dots, r_m, P, Q)$ the configuration space corresponding to the planar linkage defined by $G(m)$, $\lambda(e_i) = r_i$ and by the conditions that $\psi(0) = P$ and $\psi(m) = Q$.

[724] In particular if e has only one endpoint, then we need $\lambda(e) = 0$.

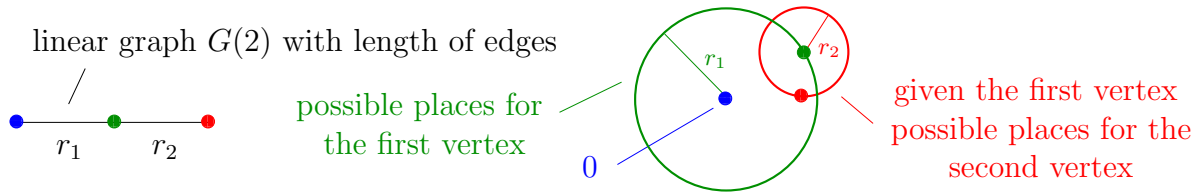

FIGURE 563. Sketch for the proof of Lemma 37.9.

(a) Using elementary arguments one can easily show that

$$C(r_1, r_2, P, Q) \;=\; \begin{cases} \varnothing, & \text{if } r_1 + r_2 < d(P,Q), \\ \text{one point}, & \text{if } r_1 + r_2 = d(P,Q), \\ \text{two points}, & \text{if } r_1 + r_2 > d(P,Q). \end{cases}$$

(b) Kevin Walker [Walkb, p. 35], see also [Gh, p. 12], showed in 1985 in his bachelor thesis that the surfaces of genus $0, 1, \ldots, 4$ are homeomorphic to configuration spaces of the type $(r_1, r_2, r_3, r_4, P, Q)$ for suitable values of $r_1, \ldots, r_4$ and points P and Q.

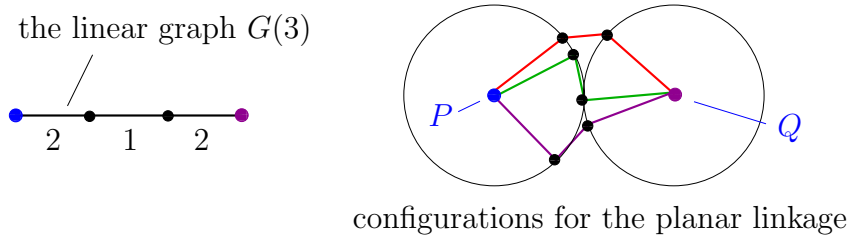

FIGURE 564.

(2) Michael Kapovich and John Millson [KaM] showed that given any compact manifold M there exists a planar linkage such that each component of the configuration space is homeomorphic to M. In particular this shows that any compact manifold can be represented by a 2-dimensional physical object.

38. The first homology group and the fundamental group

In this section we want to relate the first homology group to the fundamental group of a path-connected topological space X. Both are defined by mapping 1-dimensional manifolds into X, hence it is reasonable to expect that there is a relationship. But in general these two groups associated to a topological space cannot be the same, since the first homology group is by definition abelian, whereas we saw on many occasions that fundamental groups can be non-abelian.

38.1. **The Hurewicz homomorphism.** Let X be a topological space. Throughout this section we denote by Φ the following bijection:

$$\begin{array}{rcl} \Phi\colon \{\text{paths } [0,1]\to X\} & \to & \{\text{singular 1-simplices in } X\} \\ (\gamma\colon [0,1]\to X) & \mapsto & \begin{pmatrix} \Delta^1 & \to & X \\ (1-t,t) & \mapsto & \gamma(t) \end{pmatrix}. \end{array}$$

On many occasions we will use the trivial observation that for any path $\gamma\colon [0,1]\to X$ we have $\Phi(\overline{\gamma}) = \overline{\Phi(\gamma)}$.

We start out with the following lemma.

Lemma 38.1. *Let X be a topological space. If f and g are two paths in X such that the endpoint of f agrees with the starting point of g, then the singular 1-chains $\Phi(f)+\Phi(g)$ and $\Phi(f*g)$ are homologous.*

Proof. The lemma follows quite easily from Lemma 29.3. We refer to Figure 565 for a sketch of the proof. We leave it as an exercise to fill in the details. □

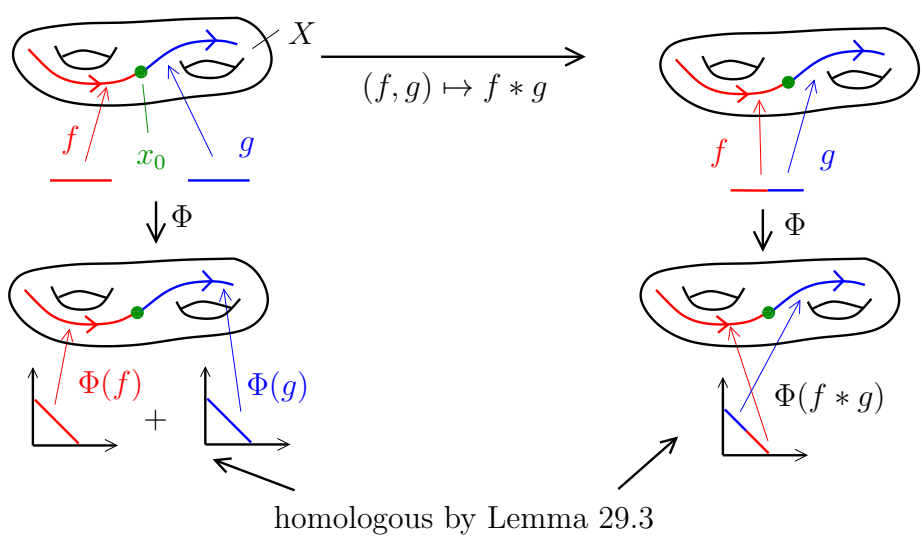

Figure 565. Illustration of the proof of Lemma 38.1.

Now we can easily prove the following proposition.

Proposition 38.2. *Let (X, x_0) be a pointed topological space.*

(1) *If γ is a loop in (X, x_0), then $\Phi(\gamma) \in C_1(X)$ is a cycle.*
(2) *The map Φ induces a well-defined map*

$$\begin{array}{rcl} \Phi_{(X,x_0)} \colon \pi_1(X, x_0) & \to & H_1(X) \\ [\gamma] & \mapsto & [\Phi(\gamma)]. \end{array}$$

(3) *The map $\Phi_{(X,x_0)} \colon \pi_1(X, x_0) \to H_1(X)$ is a group homomorphism.*
(4) *Let $\mathcal{P}$ be the category of pointed topological spaces and let $\mathcal{G}$ be the category of groups. The Hurewicz homomorphisms*

$$\Phi_{(X,x_0)} \colon \pi_1(X, x_0) \ \to \ H_1(X)$$

define a natural transformation from the functor

$$\begin{array}{rcl} \mathcal{P} & \to & \mathcal{G} \\ (X, x_0) & \mapsto & \pi_1(X, x_0) \end{array} \quad \text{to the functor} \quad \begin{array}{rcl} \mathcal{P} & \to & \mathcal{G} \\ (X, x_0) & \mapsto & H_1(X). \end{array}$$

In plain English this means the following, given a map $f \colon X \to Y$ between topological spaces and given $x_0 \in X$ the following diagram commutes:

$$\begin{tikzcd} \pi_1(X, x_0) \arrow[r, "f_*"] \arrow[d, "\Phi_{(X,x_0)}"'] & \pi_1(Y, f(x_0)) \arrow[d, "\Phi_{(Y,f(x_0))}"] \\ H_1(X) \arrow[r, "f_*"] & H_1(Y). \end{tikzcd}$$

Proof.

(1) The first statements follows immediately from the definitions and the description of $\partial_1 \colon C_1(X) \to C_0(X)$ given on page 738.
(2) We denote by $\sim$ the equivalence relation on $[0, 1]$ that is generated by $0 \sim 1$. We denote by $\alpha \colon \Delta^1 \to [0, 1]/\sim$ the map that is given by $\alpha(1 - t, t) = [t]$. Note that α defines an element in $H_1([0, 1]/\sim)$. Now suppose that $f, g \colon [0, 1] \to X$ are two path-homotopic loops in x_0. We denote by $\widetilde{f}, \widetilde{g} \colon [0, 1]/\sim \to X$ the induced maps. Then

$$\begin{array}{ccccccccc} [\Phi(f)] & = & \big[\widetilde{f} \circ \alpha\big] & = & \widetilde{f}_*([\alpha]) & = & \widetilde{g}_*([\alpha]) & = & \big[\widetilde{g} \circ \alpha\big] & = & [\Phi(g)]. \\ & \uparrow & & & & \uparrow & & & & & \\ & \text{since } \Phi(f) \text{ and } \widetilde{f} \circ \alpha \text{ are the same map} & & & & \text{by Proposition 30.5, since } \widetilde{f} \text{ and } \widetilde{g} \text{ are homotopic maps } [0,1]/\sim \to X & & & & & \end{array}$$

(3) The third statement is an immediate consequence of Lemma 38.1.
(4) The last statement follows easily from the definitions. □

[724]Recall that we denote by $\mathcal{P}$ the category of pointed topological spaces and that we denote by $\mathcal{G}$ the category of groups.

Definition. Given a pointed topological space (X, x_0) we refer to the homomorphism

$$\begin{array}{rcl} \Phi_{(X,x_0)}\colon \pi_1(X,x_0) & \to & H_1(X) \\ [\gamma] & \mapsto & [\Phi(\gamma)] \end{array}$$

as the *Hurewicz homomorphism.*[725]

It is clear that the Hurewicz homomorphism is in general neither injective nor surjective:

(1) The Hurewicz homomorphism is in general not injective since $\pi_1(X, x_0)$ is in many cases a non-abelian group whereas $H_1(X)$ is an abelian group, and it is not possible that a non-abelian group is a subgroup of an abelian group.
(2) The Hurewicz homomorphism is in general not surjective, since $\pi_1(X, x_0)$ depends only on the path-component of x_0, while $H_1(X)$ "sees" all path-components of X. But as we will see in the next lemma, this turns out to be the only obstacle to Φ being surjective.

Proposition 38.3. *Let X be a topological space and let $x_0 \in X$. If X is path-connected, then the Hurewicz homomorphism*

$$\Phi_{(X,x_0)}\colon \pi_1(X,x_0) \ \to \ H_1(X)$$

is surjective.

In the proof of of Proposition 38.3 we will need the following lemma.

Lemma 38.4. *Let X be a set and let $x_1, \dots, x_k$ and $y_1, \dots, y_l$ be elements in X. If*

$$\sum_{i=1}^{k} x_i \ - \ \sum_{i=1}^{l} y_i \ = \ 0 \ \in \ \mathbb{Z}^{(X)},$$

then $k = l$ and there exists a permutation $s \in S_k$ such that $y_i = x_{s(i)}$ for $i = 1, \dots, k$.

Proof $(*)$. Let X be a set and let $x_1, \dots, x_k$ and $y_1, \dots, y_l$ be elements in X such that

$$\underbrace{\sum_{i=1}^{k} x_i}_{=:a} \ = \ \underbrace{\sum_{i=1}^{l} y_i}_{=:b} \ \in \ \mathbb{Z}^{(X)}.$$

It follows from Lemma 11.1 that there exists a unique homomorphism $\psi\colon \mathbb{Z}^{(X)} \to \mathbb{Z}$ with the property that $\psi(x) = 1$ for all $x \in X$. By definition we have $\psi(a) = k$ and $\psi(b) = l$. So from $a = b$ we deduce that $k = l$.

It follows again from Lemma 11.1 that there exists a unique homomorphism $\psi\colon \mathbb{Z}^{(X)} \to \mathbb{Z}$ with the property that $\psi(x_k) = 1$ and $\psi(x) = 0$ for all $x \in X \setminus \{x_k\}$. By definition we have $\psi(a) > 0$. From $\psi(b) = \psi(a) > 0$ it follows that there exists an $n \in \{1, \dots, k\}$ such that $y_n = x_k$. We define $s(k) = n$. We obtain an equality

$$\sum_{i=1}^{k-1} x_i \ = \ \sum_{i \in \{1,\dots,k\} \setminus \{s(k)\}} y_i \ \in \ \mathbb{Z}^{(X)}$$

[725]Witold Hurewicz (1904-1956) was a Polish mathematician.

and we iterate this procedure to define $s(k-1), \dots, s(1)$. By construction the map $s\colon \{1,\dots,k\} \to \{1,\dots,k\}$ is a bijection $\square$

Now we can provide the proof of Proposition 38.3.

Proof of Proposition 38.3. We denote by Ψ the inverse of the above bijection

$$\Phi\colon \{\text{paths } [0,1] \to X\} \;\to\; \{\text{singular 1-simplices in } X\}$$

We pick a homology class $z \in H_1(X)$. Let $c = \sum_{i=1}^{k} a_i\sigma_i$ be a cycle in $C_1(X)$ that represents z. It follows from Lemma 29.3 that, after possibly replacing a singular chain σ_i by $\overline{\sigma}_i$, we can assume that all the coefficients a_i are positive. Furthermore, since we do not require that the σ_i's are different, we can in fact suppose that $a_1 = \dots = a_k = 1$. Since c is a cycle we have

$$0 \;=\; \partial_1(c) \;=\; \partial_1\Big(\sum_{i=1}^{k}\sigma_i\Big) \;\underset{\substack{\uparrow \\ \text{see discussion on page 738}}}{=}\; \sum_{i=1}^{k}\sigma_i(0,1) - \sigma_i(1,0)$$

It follows from Lemma 38.4 that there exists a permutation $s \in S_k$ such that for each i the "endpoint" $\sigma_i(0,1)$ of σ_i is just the "starting point" $\sigma_{s(i)}(1,0)$ of $\sigma_{s(i)}$.

Since X is path-connected we can choose for each $i \in \{1,\dots,k\}$ a path p_i from the base point x_0 to the starting point $\sigma_i(1,0)$ of σ_i.

We obtain the following equality in $H_1(X)$:

$$\begin{aligned}
c \;=\; \sum_{i=1}^{k}\sigma_i \;&\overset{\substack{\text{by Lemma 29.3 the singular chain} \\ \Phi(p_i)+\Phi(\overline{p_i}) = \Phi(p_i)+\overline{\Phi(p_i)} \\ \text{is a null-homologous cycle} \\ \downarrow}}{=}\; \sum_{i=1}^{k}\sigma_i + \sum_{i=1}^{k}\Phi(p_i) + \sum_{i=1}^{k}\Phi(\overline{p}_i) \;\overset{\substack{\text{since } \Phi\circ\Psi = \mathrm{id} \text{ and since permutation of the} \\ \text{summands does not change the sum} \\ \downarrow}}{=}\; \sum_{i=1}^{k}\big(\Phi(p_i) + \Phi(\Psi(\sigma_i)) + \Phi(\overline{p}_{s(i)})\big) \\
&\underset{\substack{\uparrow \\ \text{by Lemma 38.1}}}{=}\; \sum_{i=1}^{k}\Phi\big(\underbrace{p_i * \Psi(\sigma_i) * \overline{p}_{s(i)}}_{\substack{\text{loop in } (X,x_0) \\ \text{by choice of } s}}\big) \;\underset{\substack{\uparrow \\ \text{by Lemma 38.1}}}{=}\; \Phi\Bigg(\underbrace{\prod_{i=1}^{k} p_i * \Psi(\sigma_i) * \overline{p}_{s(i)}}_{\text{loop in } (X,x_0)}\Bigg).
\end{aligned}$$

Thus we have shown that $z = [c] \in \Phi(\pi_1(X,x_0))$. This concludes the proof that the Hurewicz homomorphism $\Phi_{(X,x_0)}\colon \pi_1(X,x_0) \to H_1(X)$ is surjective. $\square$

In the following we want to study to what degree the Hurewicz homomorphism fails to be injective. Before we can do so we need to recall some definitions and results from Section 13.3.

Definition. Let π be a group.

(1) For $x, y \in \pi$ we denote by $[x,y] := xyx^{-1}y^{-1}$ the *commutator of x and y*.
(2) We refer to

$$[\pi,\pi] \;:=\; \langle\!\langle \{[x,y] \mid x,y \in \pi\} \rangle\!\rangle \;=\; \Big\{ \prod_{i=1}^{n}[x_i,y_i] \;\Big|\; x_1,y_1,\dots,x_n,y_n \in \pi \Big\}$$

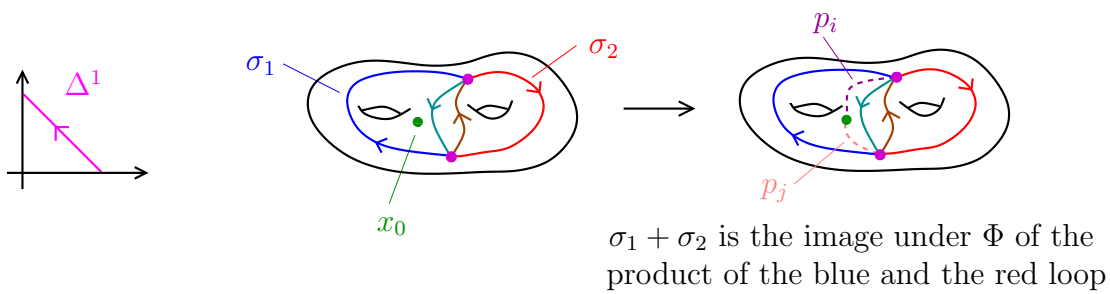

FIGURE 566. Sketch for the proof of Proposition 38.3.

as the *commutator subgroup* of π.

(3) We refer to $\pi_{\mathrm{ab}} := \pi/[\pi,\pi]$ as the *abelianization* of π.

In Section 13.3 we saw that the abelianization is "the largest abelian quotient" of π. More precisely, if $\alpha\colon \pi \to H$ is a homomorphism from π to an abelian group H, then Proposition 13.10 says that there exists a unique homomorphism $\beta\colon \pi_{\mathrm{ab}} = \pi/[\pi,\pi] \to H$ such that the following diagram commutes:

$$\begin{tikzcd} \pi \arrow[r] \arrow[dr, "\alpha"'] & \pi_{\mathrm{ab}} = \pi/[\pi,\pi] \arrow[d, "\exists!\,\beta"] \\ & H. \end{tikzcd}$$

In particular, given a pointed topological space (X, x_0) the corresponding Hurewicz homomorphism $\Phi_{(X,x_0)}\colon \pi_1(X,x_0) \to H_1(X)$ induces a homomorphism $\pi_1(X,x_0)_{\mathrm{ab}} \to H_1(X)$ that we also denote by $\Phi_{(X,x_0)}$ and that we also refer to as the Hurewicz homomorphism. Now we can formulate the following proposition.

Theorem 38.5. (Hurewicz Theorem) *Let (X, x_0) be a pointed topological space. If X is path-connected, then the Hurewicz homomorphism*

$$\Phi_{(X,x_0)}\colon \pi_1(X,x_0)_{\mathrm{ab}} \;\to\; H_1(X)$$

is a natural[726] *isomorphism.*

Examples.

(1) If we compare our calculations of fundamental groups with our calculations of homology groups, then we see that we had encountered this isomorphism many times.
   (a) In Corollary 7.19 we showed that $\pi_1((S^1)^n) \cong \mathbb{Z}^n$, whereas on page 862 we saw that $H_1((S^1)^n) \cong \mathbb{Z}^n$.

[726] Whenever we write "natural" one needs to work out what the categories and functors are. In this case we consider the category of path-connected topological spaces, the category of groups and the functors $(X,x_0) \to \pi_1(X,x_0)_{\mathrm{ab}}$ and $(X,x_0) \mapsto H_1(X)$.

(b) For $n \geq 2$ we saw in Corollary 7.19 that $\pi_1(\mathbb{R}\mathrm{P}^n) \cong \mathbb{Z}_2$ and in Lemma 33.9 we had calculated that $H_1(\mathbb{R}\mathrm{P}^n) \cong \mathbb{Z}_2$.

(c) In Proposition 14.3 we showed that

$$\pi_1(\text{Klein bottle}) \;\cong\; \langle x, y \,|\, yxyx^{-1}\rangle.$$

The abelianization of that group is isomorphic to $\mathbb{Z} \oplus \mathbb{Z}_2$ which is isomorphic to the first homology of the Klein bottle that we had determined in Lemma 33.14.

(d) In Proposition 14.3 we showed that for any $g \in \mathbb{N}$ we have

$$\pi_1(\text{surface of genus } g) \;\cong\; \langle x_1, y_1, \ldots, x_g, y_g \,|\, [x_1, y_1] \cdot \cdots \cdot [x_g, y_g]\rangle.$$

The abelianization of this group is isomorphic to $\mathbb{Z}^{2g}$ which is precisely the first homology group that we had determined in Proposition 35.10.

(e) Let X be a path-connected topological space and let $f\colon X \to X$ be a homeomorphism. On page 863 we saw that there exists a short exact sequence

$$0 \;\to\; \operatorname{coker}\big(H_1(X) \xrightarrow{f_* - \mathrm{id}} H_1(X)\big) \;\xrightarrow{i}\; H_1(M(X,f)) \;\to\; \mathbb{Z} \;\to\; 0.$$

On the other hand it follows from Proposition 15.25 and the remark on page 478 that there exists an isomorphism $\psi\colon \pi_1(M(X,f)) \cong \pi_1(X) \rtimes \mathbb{Z}$ where the action of $1 \in \mathbb{Z}$ on $\pi_1(X)$ is induced by f. Therefore we can put $\pi_1(M(X,f))$ into a short exact sequence

$$0 \;\to\; \pi_1(X) \;\to\; \pi_1(M(X,f)) \;\to\; \mathbb{Z} \;\to\; 0$$

Now we apply the abelianization functor to these groups and homomorphisms. We obtain the exact sequence[727]

$$\pi_1(X)_{\mathrm{ab}} \;\to\; \pi_1(M(X,f))_{\mathrm{ab}} \;\to\; \mathbb{Z} \;\to\; 0$$

which, using the Hurewicz Theorem 38.5, we can rewrite as

$$H_1(X) \;\to\; H_1(M(X,f)) \;\to\; \mathbb{Z} \;\to\; 0.$$

This is, fortunately, consistent with the above short exact sequence.

(2) Note that we now have a new, and depending on one's taste, more satisfying proof of Corollary 18.15: The Hurewicz Theorem 38.5 together with Lemma 33.15 implies that given any knot $K \subset S^3$ the abelianization of $\pi_1(S^3 \setminus K)$ is isomorphic to $\mathbb{Z}$.

Proof of the Hurewicz Theorem 38.5 $(*)$. Let (X, x_0) be a pointed path-connected topological space. We write $\pi := \pi_1(X, x_0)$. By Proposition 38.2 we know that the Hurewicz homomorphism $\Phi_{(X,x_0)}\colon \pi_{\mathrm{ab}} \to H_1(X)$ is natural. Furthermore it follows from Proposition 38.3 that the Hurewicz homomorphism $\Phi_{(X,x_0)}\colon \pi_{\mathrm{ab}} \to H_1(X)$ is surjective. It remains to show that $\Phi_{(X,x_0)}$ is injective.

[727] In Exercise 13.3 we saw that if $\varphi\colon A \to B$ is an epimorphism, then the induced map $A_{\mathrm{ab}} \to B_{\mathrm{ab}}$ is also an epimorphism. We had also seen that there exist monomorphisms $\varphi\colon A \to B$ such that the induced map $A_{\mathrm{ab}} \to B_{\mathrm{ab}}$ is not a monomorphism.

In the following we will make the identification $[0,1] = \Delta^1$ that is given by the homeomorphism $t \mapsto (1-t, t)$. In particular we will identify paths $[0,1] \to X$ with singular 1-simplices $\Delta^1 \to X$.

So let $f\colon [0,1] = \Delta^1 \to X$ be a loop in (X, x_0) such that $[f] = 0 \in H_1(X)$. By definition this means that there exists a 2-chain $\sum_{j=1}^{s} n_j \sigma_j$ in X whose boundary is the singular 1-simplex f. Furthermore, since we do not demand that the σ_j are distinct, we can assume that all n_j are either -1 or 1. Given $j \in \{1, \dots, s\}$ and $k \in \{0,1,2\}$ we write[728]

$$\mu_{(j,k)} \;:=\; \sigma_j \circ i_k^2 \colon [0,1] = \Delta^1 \to X \quad \text{ and } n_{(j,k)} \;:=\; (-1)^k \cdot n_j.$$

We write $A = \{1, \dots, s\} \times \{0,1,2\}$. We have the following equality in $C_1(X)$:

$$f \;=\; \partial_1\Big(\sum_{j=1}^{s} n_j \sigma_j\Big) \;\underset{\substack{\uparrow \\ \text{definition of } \partial_1}}{=}\; \sum_{j=1}^{s}\sum_{k=0}^{2} n_{(j,k)} \cdot \mu_{j,k} \;=\; \sum_{a \in A} n_a \cdot \mu_a.$$

By comparing the left and the right-hand side of this equality we see that there exists a $b \in A$ with $n_b \cdot \mu_b = 1 \cdot f$. We write $A_\pm = \{a \in A \setminus \{b\} \,|\, n_a = \pm 1\}$. Now we obtain from the above equality that

$$\sum_{a \in A_+} \mu_a \;+\; \sum_{a \in A_-} (-1) \cdot \mu_a \;=\; 0.$$

We make the following choices and introduce the following definitions:

(1) For each point P in X that is a starting or an endpoint of some μ_a we pick a path β_P from x_0 to P. For $P = x_0$ we just pick the constant path.
(2) Given $\mu_{(i,j)}\colon [0,1] = \Delta^1 \to X$ we write

$$\widehat{\mu}_{(i,j)} \;:=\; \beta_{\text{starting point of } \mu_{(i,j)}} * \mu_{(i,j)} * \overline{\beta}_{\text{endpoint of } \mu_{(i,j)}}.$$

Note that $\widehat{\mu}_{(i,j)}$ is a loop in (X, x_0), in particular it defines an element in the group $\pi = \pi_1(X, x_0)$ which, by a slight abuse of notation, we denote again by $\widehat{\mu}_{(i,j)}$.

We make the following elementary observation: for any $(i,j) \in \{1, \dots, s\} \times \{0,1,2\}$ we have the following equality in $\pi = \pi_1(X, x_0)$:

$$(*) \qquad \widehat{\mu}_{(i,j)}^{-1} \;:=\; \beta_{\text{starting point of } \overline{\mu}_{(i,j)}} * \overline{\mu}_{(i,j)} * \overline{\beta}_{\text{endpoint of } \overline{\mu}_{(i,j)}}.$$

[728]Recall that for $j \in \{0, \dots, n\}$ we denote by i_j^n the map

$$\begin{array}{rcl} i_j^n\colon \Delta^{n-1} & \to & \Delta^n \\ (t_0, \dots, t_{n-1}) & \mapsto & (t_0, \dots, t_{j-1}, 0, t_j, \dots, t_{n-1}). \end{array}$$

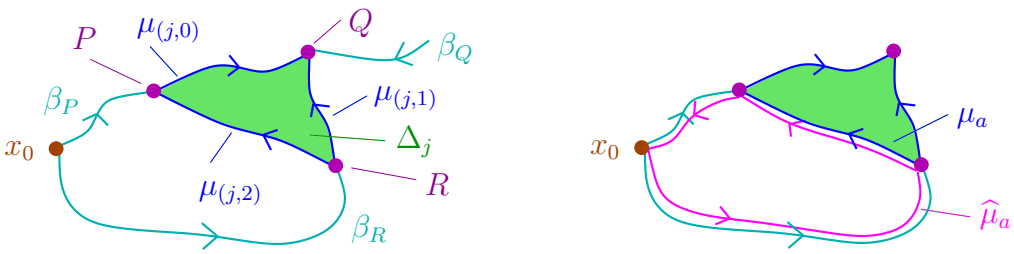

FIGURE 567. Illustration for the proof of the Hurewicz Theorem 38.5.

In π_{ab} we have the following equalities:[729]

$$e \underset{\uparrow}{=} \prod_{j=1}^{s} \beta_{\text{starting point of } \mu_{(j,0)}} * \big(\overbrace{\mu_{(j,0)} * \overline{\mu}_{(j,1)} * \mu_{(j,2)}}^{\text{loop in the starting point of } \mu_{(j,0)}}\big)^{n_j} * \overline{\beta}_{\text{starting point of } \mu_{(j,0)}}$$

since $\mu_{(j,0)} * \overline{\mu}_{(j,1)} * \mu_{(j,2)}$ is null-homotopic

$$\underset{\uparrow}{=} \prod_{j=1}^{s} \widehat{\mu}_{(j,0)}^{n_{(j,0)}} \cdot \widehat{\mu}_{(j,1)}^{n_{(j,1)}} \cdot \widehat{\mu}_{(j,2)}^{n_{(j,2)}} \qquad = \prod_{a \in \{1,\dots,k\} \times \{0,1,2\}} \widehat{\mu}_a^{n_a}$$

follows from inserting null-homotopic paths $\overline{\beta}_P * \beta_P$ together with the above equality $(*)$

$$\underset{\uparrow}{=} f \cdot \prod_{a \in A_-} \widehat{\mu}_a^{n_a} \cdot \widehat{\mu}_{\psi(a)}^{n_{\psi(a)}} \qquad \underset{\uparrow}{=} f \cdot \prod_{a \in A_-} \widehat{\mu}_a^{n_a} \cdot \widehat{\mu}_a^{-n_a} = f.$$

since $\{1,\dots,k\} \times \{0,1,2\} = (1,0) \sqcup A_- \sqcup \psi(A_-)$ since $\mu_{(1,0)} = f$ and since $\beta_{x_0} = c_{x_0}$ for $a \in A_-$ we have $\mu_{\psi(a)} = \mu_a$ and $n_a = -n_a$.

This completes the proof of the proposition.[730] □

For most topological spaces for which we had computed the fundamental group we had also determined the homology groups. But there is one rather interesting exception, namely the lens spaces. From Corollary 7.19 and the Hurewicz Theorem 38.5 we obtain immediately the following corollary.

Corollary 38.6. *For any coprime $p, q \in \mathbb{N}$ we have*

$$H_1(\textit{lens space } L(p,q)) \cong \mathbb{Z}_p.$$

Remark. The Hurewicz Theorem 38.5 is perhaps a mixed blessing. On the one hand it allows us to use the techniques that we had developed in earlier chapters to determine first homology groups. On the other hand it tells us that all the information that is contained in the first homology group is already contained in the fundamental group. So we do not get any new information. In particular, as we saw in Corollary 38.6, the first homology

[729] In the notation we do not distinguish between loops and elements they represent in π_{ab}.

[730] Where did we actually use that we work with π_{ab} instead of π?

group cannot help us in our long-standing goal of distinguishing lens spaces with the same fundamental group.

Calculating (isomorphism types) of homology groups can get quite involved. But what is often even harder is to determine the maps on homology groups induced by maps between topological spaces. Using Proposition 38.2 (4) we can transfer calculations of induced maps on fundamental groups to obtain the corresponding induced maps on homology groups.

For example we have the following lemma, which later on will be used on many occasions.

Lemma 38.7. *Let $n \in \mathbb{N}$. We denote by $T = \mathbb{R}^n/\mathbb{Z}^n = (S^1)^n$ the n-dimensional torus.*

(1) *We denote by $\sigma \in H_1(S^1)$ the standard generator introduced on page 814. Given $i \in \{1, \dots, n\}$ we denote by*

$$\begin{array}{rcl} p_i \colon S^1 & \to & (S^1)^n \\ z & \mapsto & (1, \dots, 1, z, 1, \dots, 1) \end{array}$$

the obvious i-th inclusion map and we write $z_i = p_{i*}(\sigma)$. Then $e_1, \dots, e_n$ is a basis of $H_1(T)$.

(2) *Let $A \in \mathrm{SL}(n, \mathbb{Z})$ be a matrix. We denote by $T = \mathbb{R}^n/\mathbb{Z}^n$ the n-dimensional torus. By Exercise 7.12, the map*

$$\begin{array}{rcl} f(A) \colon T = \mathbb{R}^n/\mathbb{Z}^n & \to & T = \mathbb{R}^n/\mathbb{Z}^n \\ [v] & \mapsto & [Av] \end{array}$$

is a homeomorphism. With respect to the above basis $e_1, \dots, e_n$ of $H_1(T)$ the induced map $f(A)_* \colon H_1(T) \to H_1(T)$ is given by multiplication by the matrix A.

Proof.

(1) This statement follows easily from the definitions, Theorem 7.17 and the Hurewicz Theorem 38.5.

(2) We use the isomorphism from Theorem 7.17 to make the identification $\pi_1(T, 0) = \mathbb{Z}^n$. By Proposition 38.2 (4), Theorem 7.17 and Exercise 7.12 we obtain the following commutative diagram

$$\begin{tikzcd} H_1(T) \arrow[d, "f(A)"'] & \pi_1(T,0) \arrow[l, "\Phi_{(T,0)}"'] \arrow[r, "\cong"] \arrow[d, "f(A)_*"] & \mathbb{Z}^n \arrow[d, "v \mapsto A \cdot v"] \\ H_1(T) & \pi_1(T,0) \arrow[l, "\Phi_{(T,0)}"'] \arrow[r, "\cong"] & \mathbb{Z}^n. \end{tikzcd}$$

The desired statement follows from the observation that the horizontal identifications of $H_1(T)$ with $\mathbb{Z}^n$ are precisely the ones corresponding to the basis $e_1, \dots, e_n$. □

As another illustration of Proposition 38.2 (4) we also prove the following corollary.

Corollary 38.8. $(*)$ *Let $p\colon Y \to X$ be a finite-index covering of path-connected topological spaces. Then the cokernel of the map*

$$p_*\colon H_1(Y) \;\to\; H_1(X)$$

is finite.

Remark. Let $p\colon Y \to X$ be a finite-index covering of path-connected topological spaces. Let $y_0 \in Y$. By Corollary 7.15 the induced map $p_*\colon \pi_1(Y, y_0) \to \pi_1(X, p(y_0))$ is a monomorphism. On the other hand it is in general not true that that the induced homomorphism $p_*\colon H_1(Y) \to H_1(X)$ is a monomorphism. For example on page 260 we saw that there exists a 2-fold covering map $p\colon T \to K$ from the torus T to the Klein bottle K. By Lemmas 33.12 and 33.14 we know that $H_1(T) \cong \mathbb{Z}^2$ and that $H_1(K) \cong \mathbb{Z} \oplus \mathbb{Z}_2$. By Lemma 11.8 (2) there is no monomorphism from the group $\mathbb{Z}^2$ to $\mathbb{Z} \oplus \mathbb{Z}_2$.

Proof $(*)$. We pick a base point y_0 of Y and we write $x_0 = p(y_0)$. We consider the following diagram of maps:

$$\begin{tikzcd}
\pi_1(Y, y_0) \arrow[rr, "p_*"] \arrow[dd, "\Phi_Y"'] \arrow[dr] & & \pi_1(X, x_0) \arrow[dd, "\Phi_X"] \arrow[dr] & \\
& \pi_1(Y, y_0)_{\mathrm{ab}} \arrow[rr, "p_*"] \arrow[dl, "\cong"'] & & \pi_1(X, x_0)_{\mathrm{ab}} \arrow[dl, "\cong"'] \\
H_1(Y) \arrow[rr, "p_*"] & & H_1(X). &
\end{tikzcd}$$

Here it follows from the Hurewicz Theorem 38.5 that the lower diagonal maps are isomorphisms. The "big rectangle in the back" commutes by Proposition 38.2 (4). The upper parallelogram commutes by Proposition 13.10 (7). Since the lower diagonal maps are isomorphisms it follows that the lower parallelogram also commutes.

By Lemma 7.16 and by our hypothesis that p is a finite covering we know that $p_*(\pi_1(Y, y_0))$ is a finite index subgroup of $\pi_1(X, x_0)$, i.e. $p_*\colon \pi_1(Y, y_0) \to \pi_1(X, x_0)$ has a finite cokernel. It follows[731] that $p_*\colon \pi_1(Y, y_0)_{\mathrm{ab}} \to \pi_1(X, x_0)_{\mathrm{ab}}$ also has a finite cokernel. From the commutativity of the lower parallelogram it follows that the map $p_*\colon H_1(Y) \to H_1(X)$ has a finite cokernel as well. $\square$

38.2. **The Hurewicz homomorphism in higher dimensions.** The Hurewicz Theorem 38.5 also raises the question whether there is a connection between higher homotopy groups and higher homology groups.

[731]This can be seen as follows: First we write $G = \pi_1(X, x_0)$ and $H = p_*(\pi_1(Y, y_0))$. Let $g_1, \ldots, g_k$ be coset representatives for G/H. One can easily verify that the images of $g_1, \ldots, g_k$ in G_{ab} have the property that $G_{\mathrm{ab}} = g_1 H_{\mathrm{ab}} \cup \cdots \cup g_k H_{\mathrm{ab}}$.

Definition. Let X be a topological space, let $x_0 \in X$ and let $n \geq 1$. We denote by $\omega \in H_n(S^n) \cong \mathbb{Z}$ the standard generator as defined on page 814. We refer to the map

$$\begin{array}{rcl} \Phi_{(X,x_0)} \colon \pi_n(X,x_0) & \to & H_n(X) \\ [f \colon S^n \to X] & \mapsto & f_*(\omega) \end{array}$$

as the *Hurewicz homomorphism.*[732]

Remark. Using the bijection given on page 228 and using Lemma 32.11 one can easily show that for $n = 1$ this definition of the Hurewicz homomorphism agrees with the definition given on page 924.

In the next lemma we show in particular that the Hurewicz homomorphism is in fact a homomorphism.

Lemma 38.9.

(1) *Let X be a topological space, let $x_0 \in X$ and let $n \geq 1$. The Hurewicz homomorphism*

$$\Phi_{(X,x_0)} \colon \pi_n(X,x_0) \ \to \ H_n(X)$$

is a homomorphism.

(2) *Let $\mathcal{P}$ be the category of pointed topological spaces and let $\mathcal{G}$ be the category of groups. The Hurewicz homomorphisms define a natural transformation from the functor*

$$\begin{array}{rcl} \mathcal{P} & \to & \mathcal{G} \\ (X,x_0) & \mapsto & \pi_n(X,x_0) \end{array} \quad \textit{to the functor} \quad \begin{array}{rcl} \mathcal{P} & \to & \mathcal{G} \\ (X,x_0) & \mapsto & H_n(X). \end{array}$$

Proof $(*)$. As usual we write $I = [0,1]$. By Proposition 1.47 (2) and Lemma 29.1 there exists a homeomorphism $\varphi \colon (\Delta^n, \partial\Delta^n) \to (I^n, \partial I^n)$. It follows from Lemma 32.9 that $\varphi \colon \Delta^n \to I^n$ represents a generator of $H_n(I^n, \partial I^n)$. Now we write $\omega := [\varphi] \in H_n(I^n, \partial I^n)$. Using the bijection from page 715 we see that it suffices show that for any two maps $f, g \colon (I^n, \partial I^n) \to (X, x_0)$ we have

$$[f_*(\omega)] + [g_*(\omega)] \ = \ [(f * g)_*(\omega)] \ \in \ H_n(X,x_0) = H_n(X).$$

But we showed precisely this equality in Lemma 34.12. □

The following lemma gives in particular an affirmative answer to Question 28.16.

Lemma 38.10. *For every $n \in \mathbb{N}$ the Hurewicz homomorphism*

$$\Phi \colon \pi_n(S^n, *) \ \to \ H_n(S^n) \ \cong \ \mathbb{Z}$$

sends $[\mathrm{id}_{S^n} \colon S^n \to S^n] \in \pi_n(S^n)$ to the standard generator of $H_n(S^n)$, in particular the Hurewicz homomorphism is an epimorphism.

[732]It follows from Proposition 30.5 that the Hurewicz homomorphism is indeed well-defined.

Proof. We denote by $\omega \in H_n(S^n)$ the standard generator. By definition of the Hurewicz homomorphism we have

$$\Phi(\underbrace{[\mathrm{id}_{S^n}\colon S^n \to S^n]}_{\in \pi_n(S^n,*)}) \;=\; (\mathrm{id}_{S^n})_*([\omega]) \;=\; [\omega].$$

Thus we see that the standard generator of $H_n(S^n) \cong \mathbb{Z}$ lies in the image of the Hurewicz homomorphism. But this implies that the Hurewicz homomorphism $\Phi\colon \pi_n(S^n,*) \to H_n(S^n)$ is an epimorphism. □

It is natural to ask whether, given a path-connected topological space X and $n \geq 2$, the Hurewicz homomorphism

$$\Phi_{(X,x_0)}\colon \pi_n(X,x_0) \;\to\; H_n(X)$$

is necessarily an isomorphism. But browsing through our examples shows that the Hurewicz homomorphism is in general neither a monomorphism nor an isomorphism:

(1) In Lemma 33.12 we showed that $H_2(T) \cong \mathbb{Z}$ is non-zero, whereas on page 723 we showed that $\pi_2(T) = 0$. This shows that the Hurewicz homomorphism $\pi_2(T) \to H_2(T)$ is not an epimorphism.
(2) Here are two examples that show that in general the Hurewicz homomorphism is not a monomorphism:
   (a) We consider $X = \mathbb{R}\mathrm{P}^2$. By Proposition 28.13 and Lemma 38.10 we know that $\pi_2(\mathbb{R}\mathrm{P}^2) \cong \pi_2(S^2)$ is non-trivial. On the other hand we saw in Lemma 33.9 that $H_2(\mathbb{R}\mathrm{P}^2) = 0$.
   (b) We consider $X = S^1 \vee S^2$. It follows immediately from Propositions 31.3 and 34.8 that $H_2(S^1 \vee S^2) \cong \mathbb{Z}$. On the other hand we know by Proposition 28.13 and the discussion on page 568 that $\pi_2(S^1 \vee S^2)$ is isomorphic to $\pi_2(\widetilde{X})$ where $\widetilde{X}$ is the real line "with infinitely many 2-spheres attached", see e.g. Figure 459 for an illustration. Using the projections onto the various spheres and using Lemma 38.10 one can now show that $\pi_2(\widetilde{X})$ admits an epimorphism onto $\mathbb{Z}^\infty$.[733] It follows from Lemma 11.8 (2) that there is no monomorphism from $\pi_2(X) = \pi_2(\widetilde{X})$ into $H_2(X) \cong \mathbb{Z}$. In particular the Hurewicz homomorphism $\pi_2(X) \to H_2(X)$, whatever it is precisely, cannot be a monomorphism.

Now we recall that for $\mathbb{A} = \mathbb{R}$ or $\mathbb{A} = \mathbb{C}$ and $k \leq l$ we can view $\mathbb{A}\mathrm{P}^k$ as a submanifold of $\mathbb{A}\mathrm{P}^l$. Now we can formulate the following application of Lemma 38.10.

Lemma 38.11. *For $k < l$ the submanifold $\mathbb{R}\mathrm{P}^k$ is not a retract of $\mathbb{R}\mathrm{P}^l$.*

Proof. We have

$$\underset{\substack{\uparrow \\ \text{Proposition 28.13}}}{\pi_k(\mathbb{R}\mathrm{P}^k) \;\cong\; \pi_k(S^k)} \underset{\substack{\uparrow \\ \text{Lemma 38.10}}}{\;\neq\; 0} \qquad \text{and} \qquad \underset{\substack{\uparrow \\ \text{Proposition 28.13}}}{\pi_k(\mathbb{R}\mathrm{P}^l) \;\cong\; \pi_k(S^l)} \underset{\substack{\uparrow \\ \text{Proposition 28.9}}}{\;=\; 0.}$$

[733] The proof of this statement is a slight variation of the proof of Exercise 28.3.

With this calculation, and the fact that π_n is functorial, the argument of Lemma 6.2 can be easily modified to show that $\mathbb{R}\mathrm{P}^k$ is not a retract of $\mathbb{R}\mathrm{P}^l$. $\square$

We conclude this chapter with the following question.

Question 38.12. *Let $k < l$. Is the complex projective space $\mathbb{C}\mathrm{P}^k$ a retract of $\mathbb{C}\mathrm{P}^l$?*

Exercises for Chapter 38.

Exercise 38.1. Let $T = S^1 \times S^1$ be the torus. Let $\varphi, \psi \colon S^1 \to T$ be two embeddings such that $\varphi_*([S^1]) = \psi_*([S^1]) \in H_1(T)$. Show that φ and ψ are homotopic maps.

39. Simplicial complexes and homology groups of manifolds

In this section we introduce the notion of a simplicial complex. Simplicial complexes can be viewed as special classes of CW-complexes with particularly nice properties. We will see that every manifold admits the structure of a simplicial complex and we will use this fact to obtain several results on homology groups of manifolds.

Remark. The eternal problem in topology is to strike the right balance between rigor and geometric intuition. In this chapter we will at times be slightly less rigorous than in the other chapters.

Later on, in a later chapter we will reprove most of the results from this section more generally for topological manifolds. These proofs will then be very rigorous but much less intuitive.

39.1. **Simplicial complexes.** In the following we recall several definitions from page 734.

Definition.

(1) Given $n \in \mathbb{N}_0$ we refer to

$$\Delta^n := \{(x_1, \dots, x_{n+1}) \in \mathbb{R}^{n+1} \,|\, x_1 + \cdots + x_{n+1} = 1 \text{ and } x_i \geq 0 \text{ for all } i = 1, \dots, n+1\}$$

as the *standard n-simplex*.

(2) A *face* of codimension r of the standard n-simplex is defined as a subset of the form

$$\{(x_1, \dots, x_{n+1}) \in \Delta^n \,|\, x_{d_1} = x_{d_2} = \cdots = x_{d_r} = 0\},$$

where $d_1 < d_2 < \cdots < d_r \in \{1, \dots, n+1\}$ are fixed. We refer to Figure 469 for an illustration.

(3) The boundary $\partial\Delta^n$ of the standard n-simplex is defined as the union of all faces of Δ^n of codimension 1.

We also introduce two new definitions:

(4) We refer to

$$\mathring{\Delta}^n \;:=\; \Delta^n \setminus \partial\Delta^n$$

as the *interior of* Δ^n. This is an n-dimensional submanifold of $\mathbb{R}^{n+1}$ and we equip it with the orientation which is given by the rule that a basis $\{v_1, \dots, v_n\}$ for $T_P\mathring{\Delta}^n$ is positive, if the basis $\{(1, \dots, 1), v_1, \dots, v_n\}$ is a positive basis for $\mathbb{R}^{n+1}$.[734]

(5) Given $i \in \{1, \dots, n+1\}$ let

$$F_i \;=\; \{(x_1, \dots, x_{n+1}) \in \Delta^n \,|\, x_i = 0\}$$

be the face of Δ^n that is given by setting $x_i = 0$. We equip the interior of F_i with the orientation which is given by the rule that a basis $\{v_1, \dots, v_{n-1}\}$ for $T_P\mathring{F}_i$ is positive, if the basis $\{(1, \dots, 1), v_1, \dots, v_{n-1}, e_i\}$ is a positive basis for $\mathbb{R}^{n+1}$.

[734]Here, as always, we equip $\mathbb{R}^k$ with the orientation that is defined by the standard basis $e_1, \dots, e_k$.

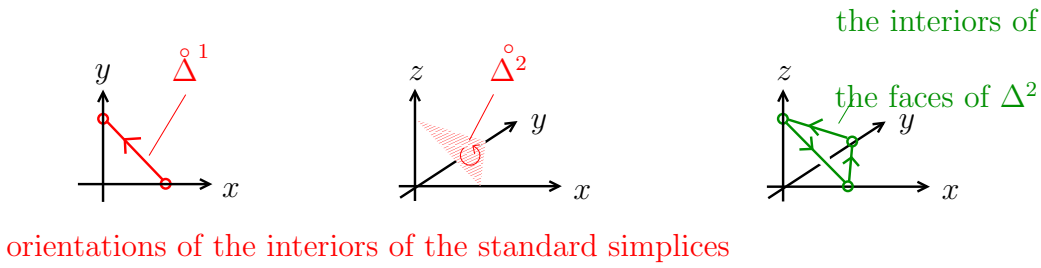

FIGURE 568.

Remark. The homeomorphism $\Delta^n \to S^n_{\geq 0} = \{(x_1, \dots, x_{n+1}) \in S^n \mid x_{n+1} \geq 0\}$ that is given in page 813 and that is illustrated in Figure 506 restricts to an orientation-preserving diffeomorphism $\mathring{\Delta}^n \to S^n_{>0}$.

Next we introduce the notion of a simplicial precomplex.

Definition.

(1) A *simplicial precomplex* is a topological space X that is Hausdorff together with a family of injective maps $\varphi_i \colon \Delta^{n_i} \to X$, $i \in I$.[735]
(2) We refer to the image of a map $\varphi_i \colon \Delta^{n_i} \to X$ as an *n_i-dimensional simplex of X*.[736] The image of a face of Δ^{n_i} is called a *face of the simplex*, the image of $\partial\Delta^{n_i}$ is called the *boundary of the simplex*, and the image of the interior $\mathring{\Delta}^{n_i}$ is called the *interior of the simplex*.
(3) The *dimension* $\dim(X) \in \mathbb{N}_0 \cup \{\infty\}$ of a non-empty simplicial precomplex X is defined as the maximum dimension of a simplex.
(4) A *subcomplex* of a simplicial precomplex X is defined as a union of simplices of X.

Now we can introduce the notion of a simplicial complex, which is what we are really interested in.

Definition. A *simplicial complex* is a simplicial precomplex $(X, \{\varphi_i \colon \Delta^{n_i} \to X\}_{i \in I})$ such that the following conditions are satisfied:

(1) For each $x \in X$ there exists a unique simplex such that x lies in the interior of the simplex.
(2) Every face of every simplex of X is again a simplex of X.
(3) If the images of φ_i and φ_j intersect, then there exist faces F_i of Δ^{n_i} and F_j of Δ^{n_j} such that the following two conditions are satisfied:
   (a) we have $\varphi_i(\Delta^{n_i}) \cap \varphi_j(\Delta^{n_j}) = \varphi_i(F_i) = \varphi_j(F_j)$,

[735]Note that it follows from Proposition 1.40 that each map $\varphi_i \colon \Delta^{n_i} \to X$ is a homeomorphism onto its image.

[736]It follows from Footnote 735 together with Proposition 32.5 that the definition of the dimension of a simplex is well-defined. More precisely, it follows that for two injective maps $\varphi \colon \Delta^k \to X$ and $\psi \colon \Delta^l \to X$ with $k \neq l$ the images have to be different.

(b) the map $\varphi_j^{-1} \circ \varphi_i \colon F_i \to F_j$ is an affine homeomorphism.[737]

(4) A subset $U \subset X$ is open if and only if for every $i \in I$ the preimage $\varphi_i^{-1}(U)$ is open in Δ^{n_i}.[738]

Remark. The above definition of a simplicial complex is highly non-standard. We use it since it allows us to quickly state and prove the desired results on homology groups of manifolds. We refer to [Mun] for the standard definition of a simplicial complex.

Put slightly more naively, a simplicial complex is a topological space which is "built out of simplices glued along faces". We refer to Figure 569 for an illustration of examples and non-examples of simplicial complexes.

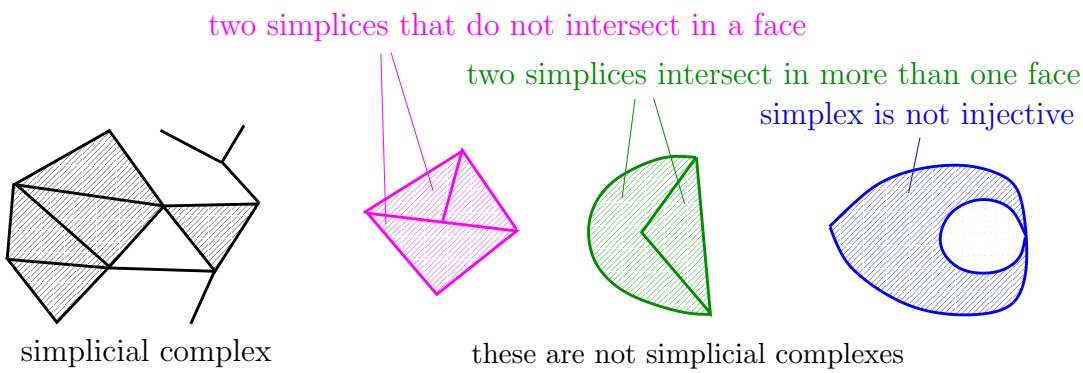

FIGURE 569.

We leave the straightforward proof of the following lemma as an exercise to the reader.

Lemma 39.1. *Let X be a simplicial complex.*

(1) *The boundary of every n-simplex is contained in a subcomplex of dimension $\leq n-1$.*

(2) *If A is a subcomplex and if c is a simplex of X such that the interior of c intersects A, then c already lies in A.*

Let $n \in \mathbb{N}_0$. Recall that in Lemma 29.1 we had written down a specific homeomorphism $(\overline{B}^n, S^{n-1}) \to (\Delta^n, \partial\Delta^n)$. If we now precompose the maps $\Delta^n \to X$ of a simplicial complex with these homeomorphisms we easily obtain the following lemma from Lemma 39.1 (2). We leave it as an exercise to the reader to fill in all the details.

Lemma 39.2. *Any simplicial complex can also be viewed as CW-complex where given any $n \in \mathbb{N}$ the n-simplices of the simplicial complex correspond precisely to the n-cells of the CW-complex.*

[737]Note that F_i respectively F_j are subsets of $\mathbb{R}^{n_i}$ respectively $\mathbb{R}^{n_j}$. An *affine homeomorphism* between F_i and F_j is an affine, linear bijective map from F_i to F_j, i.e. it is a map of form $v \mapsto A \cdot v + P$ for some invertible matrix A and vector P that restricts to a bijection from F_i to F_j.

[738]From the continuity of the maps $\varphi_i, i \in I$ it follows that if $U \subset X$ is open, then for all $i \in I$ the preimage $\varphi_i^{-1}(U)$ is open in Δ^{n_i}. The statement of (4) is thus that the converse also holds.

Remark. It is straightforward to see that every 1-dimensional CW-complex is also a 1-dimensional simplicial complex. On the other hand not every CW-complex is necessarily a simplicial complex. For example, if $n \geq 2$ and if we consider the CW-complex with one 0-cell and one n-cell, then this CW-complex is not a simplicial complex.

39.2. **The top-dimensional homology group of a manifold.**

Definition. Let X be a Hausdorff space. A *simplicial structure* for X consists of a family of injective maps $\varphi_i \colon \Delta^{n_i} \to X$, $i \in I$ such that $(X, \{\varphi_i\}_{i\in I})$ is a simplicial complex.[739]

The following proposition is one of the keys for getting a grip on the invariants of manifolds.

Proposition 39.3. *Let M be an n-dimensional manifold. Then M admits an n-dimensional simplicial structure $\{\varphi_i \colon \Delta^{n_i} \to M\}_{i\in I}$ with the following properties:*

(1) *for each $i \in I$ the restriction of φ_i to $\varphi_i \colon \mathring{\Delta}^{n_i} \to M$ is an embedding,*[740]
(2) $(*)$ *for each $i \in I$ the map*[741]

$$\begin{aligned} \Big\{(t_1, \dots, t_{n_i}) \in [0,1]^{n_i} \;\Big|\; \sum_{j=1}^{n_i} t_j \in [0,1]\Big\} &\to M \\ (t_1, \dots, t_{n_i}) &\to \varphi_i\Big(t_1, \dots, t_{n_i}, 1 - \sum_{j=1}^{n_i} t_j\Big) \end{aligned}$$

is smooth,
(3) *the boundary ∂M is a subcomplex.*

Furthermore, if N is a closed submanifold of M, then one can arrange that the following extra statement holds:

(4) *The submanifold N is a subcomplex.*

Remark. As we had just pointed out in Lemma 39.2, every simplicial complex is also a CW-complex. Thus we can view Proposition 39.3 as a strengthening of Theorem 26.3.

Proof. The fact that one can find a simplicial structure that satisfied (1), (2) and (3) is precisely is [Mun2, Theorem 10.6]. Given a submanifold it follows from solving [Mun2, Problem 10.14] that we can also arrange (4) to hold. □

Examples.

(1) In Figure 570 we show the torus $T = [0,1] \times [0,1]/\sim$ with three different sets of maps $\Delta^2 \to T$. Only the maps on the right define a simplicial structure for the torus.
(2) In Figure 571 we show simplicial structures for the annulus, the 2-dimensional sphere and for the torus minus an open disk.

[739] In the literature a simplicial structure is also often called a *triangulation*.

[740] Note that given $n \geq 2$ the standard-simplex $\Delta^n \subset \mathbb{R}^{n+1}$ is not a submanifold of $\mathbb{R}^{n+1}$ (why not?), but the interior $\mathring{\Delta}^n$ is an n-dimensional submanifold of $\mathbb{R}^{n+1}$.

[741] The left-hand side is a subset of $\mathbb{R}^{n_i}$ and the right-hand side is a manifold. Thus by the definition on page 184 it makes sense to say whether nor not this map is smooth.

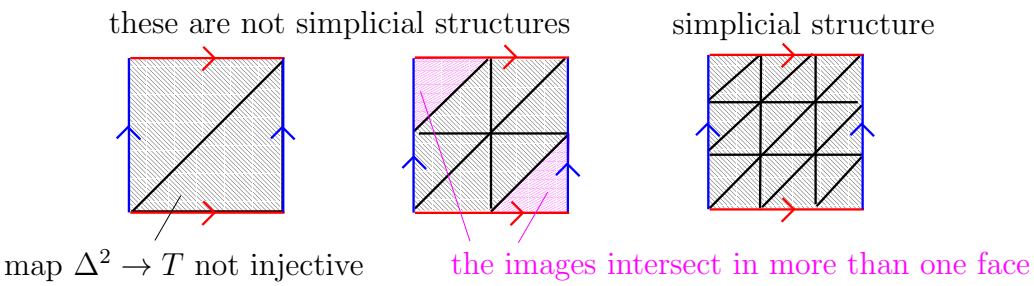

FIGURE 570. The torus as a simplicial complex.

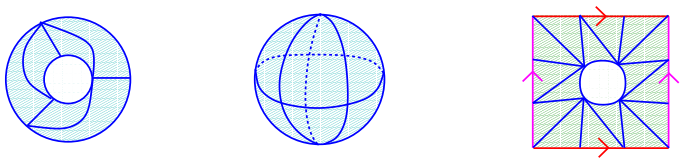

FIGURE 571.

(3) A simplicial structure for a surface can be viewed as an approximation by triangles. Such simplicial structures play an important role in computer visualizations. In this context one usually talks of triangulations. We refer to Figure 572 for more illustrations.

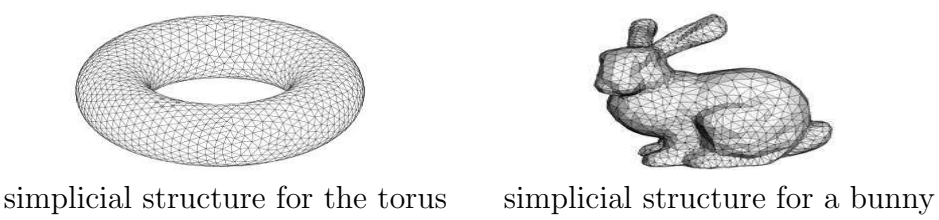

FIGURE 572.

Definition. Let X be a simplicial complex and let c be a k-simplex of X. We say c has *order* r, if there exist precisely r simplices of dimension $k+1$ which contain c as a face.

Lemma 39.4. *Let M be an n-dimensional manifold that is equipped with a simplicial structure.*

(1) *If $k \leq n-1$, then every k-dimensional simplex of M has order at least one.*
(2) *The simplicial structure has finitely many simplices if and only if it has finitely many n-simplices.*

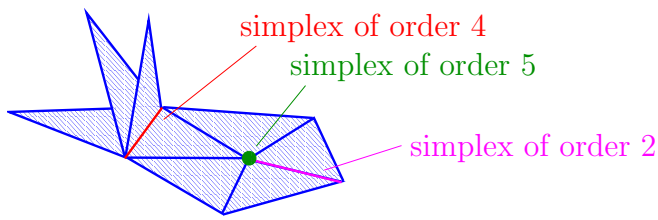

FIGURE 573.

(3) *Let c be an $(n-1)$-dimensional simplex of M. Then one of the following holds:*
   (a) *Either c lies in the boundary of M, in this case the order of c equals one,*
   (b) *or the interior of c lies in the interior of M, in this case the order is equal to two.*

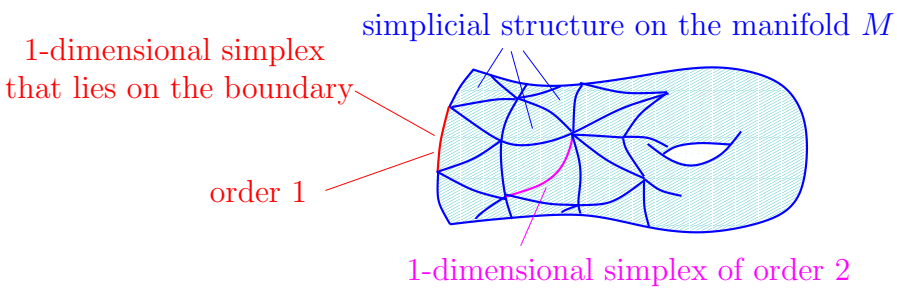

FIGURE 574. Illustration of Lemma 39.4.

Sketch of a proof for Lemma 39.4 $(*)$. Let M be an n-dimensional manifold that is equipped with a simplicial structure.

(1) Let $k \leq n-1$. Suppose there exists a k-dimensional simplex c of M of order 0. Let P be a point in the interior of c. Since c has order 0 the interior $U = \mathring{c}$ of the simplex c is an open neighborhood of P in M.[742] But then we have

$$H_k(M, M \setminus \{P\}) \underset{\substack{\uparrow \\ \text{Excision Theorem 31.17}}}{\cong} H_k(U, U \setminus \{P\}) \underset{\substack{\uparrow \\ \text{by Lemma 32.3 since } U \text{ is a} \\ k\text{-dimensional manifold} \\ \text{without boundary}}}{\cong} \mathbb{Z}.$$

But since $k \leq n-1$ this contradicts Lemma 32.3 applied to the n-dimensional manifold M.

(2) We only have to show that if M has finitely many n-simplices, then for $k = n, \dots, 0$ the number of k-simplices is finite. This clearly holds for $k = n$. Suppose we know the statement for some $k \in \{1, \dots, n\}$. Each k-simplex has only finitely many faces, so

[742] This statement requires a little bit of thought.

there exist only finitely many $(k-1)$-simplices that are the face of a k-simplex. But by (1) every $(k-1)$-simplex is the face of a k-simplex.

(3) Let c be an $(n-1)$-dimensional simplex of M. We start out with the following claim.

Claim. Let P be a point in the interior of c.
(i) If P lies on the boundary of M, then c has order one.
(ii) If P lies in the interior of M, then c has order two.

Suppose that c has order k. By (1) we know that $k \geq 1$. We write

$$X_k := \big\{(z,w) \,\big|\, z = re^{2\pi ij/k}, r \in [0,1), j \in \{0,\dots,k-1\} \text{ and } w \in \mathbb{R}^{n-1} \text{ with } \|w\| < 1\big\}.$$

We sketch X_k for $k = 1,2,3$ in Figure 575. Since P lies in the interior of c it follows[743]

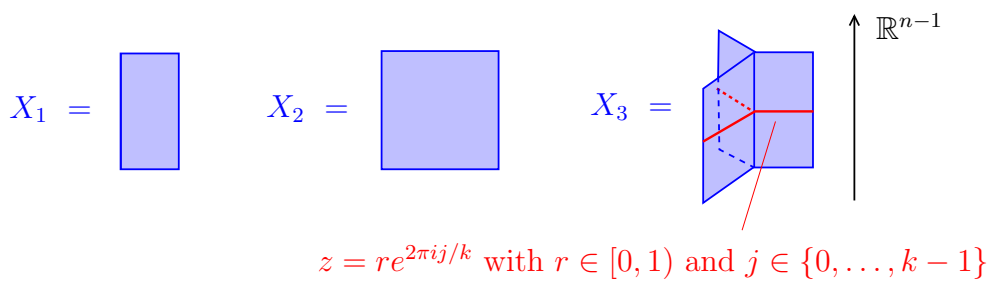

FIGURE 575.

that there exists an open neighborhood U of P and a homeomorphism $\Phi\colon U \to X_k$ with $\Phi(P) = 0$. Now we see that

$$\begin{array}{ccccccc} H_n(M, M\setminus\{P\}) & \cong & H_n(U, U\setminus\{P\}) & \xrightarrow{\Phi} & H_n(X_k, X_k\setminus\{0\}) & \cong & \mathbb{Z}^{k-1}. \\ & \uparrow & & & & \uparrow & \\ & \text{Excision Theorem 31.17} & & & & \text{left as an exercise} & \end{array}$$

The desired statement now follows from Lemma 32.3. This concludes the proof of the claim.

Finally we turn to the actual proof of statement (3) of the lemma.

(a) First suppose that the interior of c contains a point on the boundary of M. Then it follows from the claim that the order of c equals one. Since ∂M is a subcomplex of M it follows from Lemma 39.1 (3) that all of c is contained in the boundary of M.

(b) Now suppose that the interior of c does not contain a point that lies on the boundary of M, i.e. we suppose that the interior c lies in the interior of M. It follows from the claim that the order of c equals two. □

[743]This step requires some thought.

In Proposition 35.6 we already saw that for a given n-dimensional compact manifold M all homology groups are finitely generated abelian groups and that for $k > n$ we have $H_k(M) = 0$. Now we can prove the following proposition which gives us more information on homology groups of manifolds.[744]

Proposition 39.5. *Let M be a connected non-empty n-dimensional manifold. Then the following holds*[745]

$$H_n(M) \cong \begin{cases} \mathbb{Z}, & \textit{if } M \textit{ is orientable and closed,} \\ 0, & \textit{otherwise.} \end{cases}$$

Examples.

(1) In Question 3.40 we had asked whether $\mathbb{R}\mathrm{P}^{2n}$ is orientable. Now we can answer this question in the negative. More precisely, it follows from Proposition 39.5 and the calculation of the homology of real projective spaces in Proposition 35.11 that $\mathbb{R}\mathrm{P}^{2n}$ is non-orientable.
(2) On page 266 we pointed out that every lens space $L(p, q)$ is an orientable closed compact 3-dimensional manifold. It follows from Proposition 39.5 that $H_3(L(p, q)) \cong \mathbb{Z}$. Unfortunately the calculation does not help us in our goal of answering Question 7.8.

Sketch of a proof of Proposition 39.5. [746] Let M be a connected non-empty n-dimensional manifold. We pick an n-dimensional simplicial structure $\{\varphi_k \colon \Delta^{n_k} \to M\}_{k\in K}$ for M as in Proposition 39.3. Now we introduce some notation and conventions.

(1) We denote by $I \subset K$ the subset corresponding to the $(n-1)$-simplices. Given $i \in I$ we write $X_i = \varphi_i(\Delta^{n-1})$.
(2) Similarly we denote by $J \subset K$ the subset corresponding to the n-simplices of M. Given $j \in J$ we write $Y_j = \varphi_j(\Delta^n)$.
(3) By Lemma 39.2 we can view M as a CW-complex, where the cells correspond to the simplices.
(4) It follows from Proposition 26.14, statement (3) and Lemma 39.4 (2) that M is compact if and only if J is finite.
(5) Using the orientations for the interiors of the standard simplices that we introduced on page 935 and using the embeddings $\varphi_k, k \in K$ we view the interiors of $X_i, i \in I$ as oriented $(n-1)$-dimensional submanifolds of M and we view the interiors of Y_j, $j \in J$, as oriented n-dimensional submanifolds of M.[747]
(6) We use the convention introduced on page 889 to view the $X_i, i \in I$ as a basis for $C^{\mathrm{CW}}_{n-1}(M)$ and to view the $Y_j, j \in J$ as a basis for $C^{\mathrm{CW}}_n(M)$.

[744] Note that Proposition 39.5 is consistent with the calculation of H_2 of 2-dimensional manifolds that we gave in Proposition 35.10.

[745] Recall that a manifold is called closed if it is compact and if it has no boundary.

[746] A careful reading of the proof shows that the argument has several little gaps. We leave it as an exercise to find all gaps and to fill them. Alternatively you can wait for a later chapter.

[747] Here we use that the restrictions of the maps φ_i to $\overset{\circ}{\Delta}{}^{n_i}$ are embeddings.

(7) Given $i \in I$ and $j \in J$ we denote by a_{ij} the coefficient of X_i in $d_n(Y_j)$ where $d_n \colon C_n^{\mathrm{CW}}(M) \to C_{n-1}^{\mathrm{CW}}(M)$ denotes the cellular boundary map.

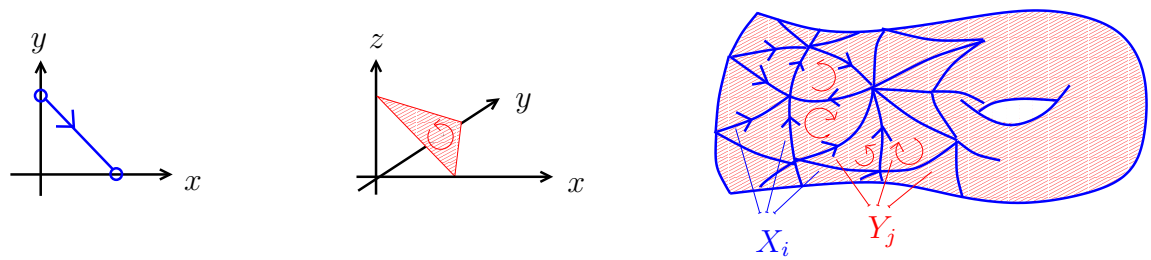

FIGURE 576. Illustration for the proof of Proposition 39.5.

We start out with the following observation:

$$(*) \quad H_n(M) \underset{\substack{\uparrow \\ \text{Proposition 35.4}}}{\cong} H_n^{\mathrm{CW}}(M) \underset{\substack{\uparrow \\ M \text{ has no simplices of dimension } n+1\text{, hence } C_{n+1}^{\mathrm{CW}}(M)=0}}{=} \ker\left\{C_n^{\mathrm{CW}}(M) \xrightarrow{d_n} C_{n-1}^{\mathrm{CW}}(M)\right\} = \{\text{cycles in } C_n^{\mathrm{CW}}(M)\}.$$

We continue with the following claim which is the key ingredient to the proof of Proposition 39.5.

Claim 1. Let $i \in I$. Then the following hold:

(1) If the $(n-1)$-simplex X_i lies on the boundary of M, then there exists precisely one $j \in J$ with $a_{ij} \neq 0$ and we have $a_{ij} = \pm 1$.
(2) If the $(n-1)$-simplex X_i does not lie the boundary of M, then there exist precisely two $j_1, j_2 \in J$ with $a_{i,j_1} \neq 0$ and $a_{i,j_2} \neq 0$. Furthermore we have $a_{i,j_1} = \pm 1$ and $a_{i,j_2} = \pm 1$. Finally, we have $a_{i,j_1} = -a_{i,j_2}$ if and only if the orientations of Y_{j_1} and Y_{j_2} agree along X_i.

Most of the statements of the claim follow immediately from Lemma 39.4, from the calculation of the cellular boundary map in Proposition 35.8 and from the definitions. It only remains to prove the statement regarding the orientations.

So suppose that an $(n-1)$-simplex X_i lies on the face of an n-simplex Y_j. Recall that we denote by $\varphi_i \colon \Delta^{n-1} \to M$ and $\varphi_j \colon \Delta^n \to M$ the corresponding maps from the simplicial structure. We denote by $F \subset \Delta^n$ the corresponding face of Δ^n. Using Proposition 35.8 and Lemma 32.24 one can provide an elementary, albeit lengthy, argument to show that, with the sign conventions from page 935, the following equalities:

$$a_{ij} = \begin{cases} +1, & \text{if } \varphi_i^{-1} \circ \varphi_j \colon F \to \Delta^{n-1} \text{ is orientation-preserving,} \\ -1, & \text{if } \varphi_i^{-1} \circ \varphi_j \colon F \to \Delta^{n-1} \text{ is orientation-reversing.} \end{cases}$$

Now suppose we have two simplices Y_{j_1} and Y_{j_2} that meet along X_i. Then it is straightforward to see that the orientations of Y_{j_1} and Y_{j_2} agree along X_i if and only if they induce

the opposite orientations on X_i. We refer to Figure 577 for an illustration. This concludes the proof of Claim 1.

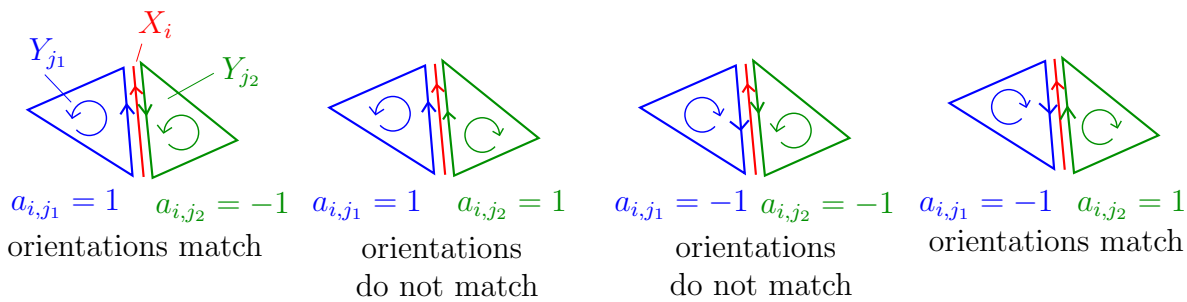

FIGURE 577.

Now we will prove the following claim that clearly implies the proposition:

Claim 2.

(1) If M is orientable and closed, then $H_n(M) \cong \mathbb{Z}$.
(2) If $H_n(M) \neq 0$, then M is orientable and closed.

First we suppose that M is orientable and closed. As we had observed above, the hypothesis that M is compact implies that I is finite. We choose an orientation for M. Given $i \in I$ we define

$$\epsilon_i \ := \ \begin{cases} +1, & \text{if the orientations of } M \text{ and } Y_i \text{ match,} \\ -1, & \text{otherwise.} \end{cases}$$

It follows immediately from Claim 1 that

$$c \ := \ \sum_{i \in I} \epsilon_i \cdot Y_i \ \in \ C_n^{\mathrm{CW}}(M)$$

is an n-cycle in $C_n^{\mathrm{CW}}(M)$. Now suppose that we are given another cycle $d = \sum_{i \in I} d_i \cdot Y_i$. We pick $i_0 \in I$ and we define $m \in \mathbb{Z}$ via $d_{i_0} = m \cdot \epsilon_{i_0}$. We set $I' := \{i \in I \,|\, d_i = m \cdot \epsilon_i\}$. It follows from Claim 1 and the hypothesis that M is connected that $I' = I$. Thus we see that $d = m \cdot c$. Together with the above observation $(*)$ we now see that $H_n(M)$ is isomorphic to $\mathbb{Z}$. This concludes the proof if M is orientable and closed.

Now suppose that $H_n(M) \neq 0$. We need to show that M is orientable and closed. By the observation $(*)$ there exists a non-zero cycle $d = \sum_{i \in I} d_i \cdot Y_i$. We pick $i_0 \in I$ with $d_{i_0} \neq 0$. We set $I' = \{i \in I \,|\, |d_i| = |d_{i_0}|\}$. We write $M' = \bigcup_{i \in I'} Y_i$. This is a submanifold[748] of M which, by the Claim 1 is closed. Since M is connected we obtain from Corollary 36.8 that $M' = M$. But this implies that M is closed.

[748]This statement is frankly not so clear.

Given $k = 0, \dots, n$ we denote by M^k the union of all k-simplices, i.e. M^k is the k-skeleton of M, viewed as a CW-complex. Now we can orient M as follows:

(i) Given a point $P \in \overset{\circ}{Y}_i$ we now endow it with the orientation of Y_i if $a_i > 0$, otherwise we endow it with the opposite orientation. This defines an orientation on $M^n \setminus M^{n-1}$.

(ii) It follows again from Claim 1 that the orientations from (1) extend to orientations on the interiors of $(n-1)$-simplices. This defines an orientation on $M^n \setminus M^{n-2}$.

(iii) Finally let P be a point on M^{n-2}. We pick a chart $\Phi\colon U \to V$ around P such that V is an open ball in $\mathbb{R}^n$. Since $M^{n-2} \cap U$ is of codimension 2 we see that $U \setminus (U \cap M^{n-2})$ is connected.[749]. It follows that Φ is either orientation-preserving for all $Q \in U \setminus (U \cap M^{n-2})$ or Φ is orientation-reversing for all $Q \in U \setminus (U \cap M^{n-2})$. Now we can use Φ to define an orientation for all points in U that agrees with the given orientation on $U \setminus (U \cap M^{n-2})$.

This concludes the proof of Claim 2. □

In a very similar fashion to Proposition 39.5 we can also prove the following proposition. We leave the details to the reader.

Proposition 39.6. *Let M be a connected non-empty n-dimensional manifold. Then the following holds:*

$$H_n(M, \partial M) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } M \text{ is orientable and compact,} \\ 0, & \text{otherwise.} \end{cases}$$

39.3. **The fundamental class of a compact orientable manifold.** In the previous section we had just seen that for a connected, orientable, compact non-empty n-dimensional manifold M we have $H_n(M, \partial M) \cong \mathbb{Z}$. In the following we will see that a choice of an orientation determines a generator $[M]$ of $H_n(M, \partial M)$.

We recall that in Lemma 29.1 we gave a homeomorphism $\Theta\colon \Delta^n \to \overline{B}^n$ that restricts to a homeomorphism $\partial\Delta^n \to \partial\overline{B}^n$. Furthermore we recall that in Lemma 32.9 we showed that id_{Δ^n} represents a generator of $H_n(\Delta^n, \partial\Delta^n)$. Now we write[750]

$$\left[\,\overline{B}^n\right] \;:=\; (-1)^n \cdot \Theta_*([\mathrm{id}_{\Delta^n}]) \;=\; (-1)^n \cdot [\Theta] \;\in\; H_n(\overline{B}^n, \partial\overline{B}^n).$$

Now we can formulate the following proposition.

Proposition 39.7. *Let M be a compact oriented connected non-empty n-dimensional manifold. Then there exists a unique generator $[M]$ of $H_n(M, \partial M) \cong \mathbb{Z}$ with the following property: For any orientation-preserving embedding*[751] *$\Phi\colon \overline{B}^n \to M$ with $\Phi\big(\overline{B}^n\big) \subset M \setminus \partial M$ we have*

$$\Phi_*\big(\big[\overline{B}^n\big]\big) \;=\; \textit{the image of } [M] \textit{ under the map } H_n(M, \partial M) \to H_n(M, M \setminus \Phi(B^n)).$$

[749]This statement requires an argument that we are skipping

[750]The sign $(-1)^n$ is only necessary to make sure that the various sign conventions are consistent.

[751]We view $\overline{B}^n$ as a manifold with boundary and we equip it with the usual orientation where the standard basis $e_1, \dots, e_n$ is a positive basis for each tangent space.

Proof $(*)$. Let M be a compact oriented connected non-empty n-dimensional manifold. To simplify the notation we prove the proposition only in the closed case.

We pick a simplicial structure for the manifold M. We can and will assume that all the maps $\varphi_i\colon \Delta^n \to M$, restricted to $\mathring{\Delta}^n$, are orientation-preserving. We denote by $Y_i = \varphi_i(\Delta^n)$, $i = 1, \dots, k$ the corresponding n-simplices. In the proof of Proposition 39.5 we saw that

$$c \;:=\; \sum_{i\in I} Y_i \;\in\; C_n^{\mathrm{CW}}(M)$$

is a cycle. In the following we denote by $[M]$ the image of $[c]$ under the inverse of the isomorphism $H_n(M) \to H_n^{\mathrm{CW}}(M)$ from Proposition 35.4. We claim that $[M]$ has the desired properties. More precisely, we will prove the following claim.

Claim.

(a) There exists an orientation-preserving embedding $\Psi\colon \overline{B}^n \to M$ such that

$$\Psi\big([\overline{B}^n]\big) \;=\; \text{the image of } [M] \text{ under the map } H_n(M) \to H_n(M, M\setminus \Psi(B^n)).$$

(b) For any orientation-preserving embedding $\Phi\colon \overline{B}^n \to M$ we have

$$\Phi\big([\overline{B}^n]\big) \;=\; \text{the image of } [M] \text{ under the map } H_n(M) \to H_n(M, M\setminus \Phi(B^n)).$$

We start out with the proof of (a). We pick an orientation-preserving embedding map $\Psi\colon \overline{B}^n \to M$ such that $\Psi(\overline{B}^n)$ lies in the interior of an n-simplex Y_i of M and such that ∂Y_i is a deformation retract of $Y_i \setminus \Psi(B^n)$. (We refer to Figure 578 for an illustration.) We consider the following commutative diagram of homomorphisms:

$$\begin{tikzcd}
H_n(\Psi(\overline{B}^n), \Psi(\partial\overline{B}^n)) \arrow[r, "\cong", "\text{exc.}"'] & H_n(Y_i, Y_i\setminus\Psi(B^n)) \arrow[r, "\cong", "\text{exc.}"'] & H_n(M, M\setminus\Psi(B^n)) & H_n(M) \arrow[l] \\
H_n(\overline{B}^n, \partial\overline{B}^n) \arrow[u, "\Psi_*", "\cong"'] & H_n(Y_i, \partial Y_i) \arrow[u, "(*)", "\cong"'] \arrow[r, "\cong", "\text{exc.}"'] & H_n(M, M\setminus\mathring{Y}_i) \arrow[u, "\cong"'] & H_n(M) \arrow[l] \arrow[u, "\text{id}", "\cong"'] \\
H_n(\Delta^n, \partial\Delta^n) \arrow[u, "\Theta_*", "\cong"'] \arrow[r, "\varphi_{i*}"] & H_n^{\mathrm{CW}}(Y_i, \partial Y_i) \arrow[u, "\cong"'] \arrow[r, "\cong"] & H_n^{\mathrm{CW}}(M, M\setminus\mathring{Y}_i) \arrow[u, "\cong"'] & H_n^{\mathrm{CW}}(M). \arrow[l] \arrow[u, "\cong"', "{[M]}", "{[c]}"'] \arrow[lll, bend left, "{[\varphi_i]\mapsto[c]}"]
\end{tikzcd}$$

Here are the justification for some of the arrows and the claim that the diagram commutes:

(1) The horizontal maps in the first and second row and the vertical maps from the second to the first row are the obvious inclusion maps, which implies that the two top squares commute.
(2) The maps marked by "exc." are isomorphisms by the Excision Theorem 31.17.
(3) The bottom vertical maps are the isomorphisms from Proposition 35.4.
(4) The lower two squares commute by Proposition 35.4.[752]

[752]To be precise, one really needs a natural isomorphism between relative singular and cellular homology. That can be proved the same way as we proved Proposition 35.4.

(5) It follows from the long exact sequence in homology of the triple $(Y_i, Y_i \setminus \Psi(B^n), \partial Y_i)$, from the fact that we chose Ψ such that ∂Y_i is a deformation retract of $Y_i \setminus \Psi(B^n)$, and from Corollary 30.8 (4) that the homomorphism $(*)$ is an isomorphism.
(6) We denote by $[\varphi_i] \in H_n^{\mathrm{CW}}(Y_i, \partial Y_i)$ the generator which is defined by the homeomorphism $\varphi_i \colon (\Delta^n, \partial\Delta^n) \to (Y, \partial Y)$.
(7) It follows immediately from the definition of c that the image of $[c]$ under the map $H_n^{\mathrm{CW}}(M) \to H_n^{\mathrm{CW}}(Y_i, \partial Y_i)$ is precisely $[\varphi_i]$. Using this observation one obtains easily that the rectangle to the left commutes.

The homeomorphism $\Theta \colon \Delta^n \to \overline{B}^n$ restricts to a diffeomorphism $\mathring{\Delta}^n \to B^n$. It follows easily from the definitions that this diffeomorphism is orientation-preserving if and only if $(-1)^n$ is even. Since φ_i and Ψ are orientation-preserving we see, using a slight variation of Lemma 32.24, that the images of $[\overline{B}^n] = (-1)^n \cdot [\Theta]$ and $[\varphi_i]$ in $H_n(Y_i, Y_i \setminus \Psi(B^n))$ agree. From the commutative diagram it follows that $[\overline{B}^n]$ and $[M]$ get sent to the same element of $H_n(M, M \setminus \Psi(B^n))$. This concludes the proof of part (a) of the claim.

Now we turn to the proof of part (b). Thus let $\Phi \colon \overline{B}^n \to M$ be another orientation-preserving embedding. By Theorem 10.28 there exists a diffeomorphism f of M with the following two properties:

(1) the map f is homotopic to the identity,
(2) $f \circ \Psi = \Phi$.

It follows from (1) and from Proposition 30.5 that the map $f_* \colon H_n(M) \to H_n(M)$ is the identity. We consider the following commutative diagram

$$\begin{tikzcd}
 & H_n(M, M \setminus \Psi(\overline{B}^n)) \arrow[dd, "f_*"'] & H_n(M) \arrow[l] \arrow[dd, "f_*=\mathrm{id}"'] \\
H_n(\overline{B}^n, \partial\overline{B}^n) \arrow[ur, "\Psi_*"] \arrow[dr, "\Phi_*"'] & \Psi_*([\overline{B}^n]) \downarrow \Phi_*([\overline{B}^n]) & [M] \downarrow [M] \\
 & H_n(M, M \setminus \Phi(\overline{B}^n)) & H_n(M). \arrow[l]
\end{tikzcd}$$

It now follows immediately from this diagram that $[M]$ also has the desired property for Φ. This concludes the proof of part (b) of the claim. $\square$

Definition.

(1) Let M be a compact, oriented, connected, non-empty n-dimensional manifold. We refer to the uniquely determined element $[M] \in H_n(M, \partial M)$ from Proposition 39.7 as the *fundamental class of M*.
(2) If M is a compact oriented non-empty n-dimensional manifold with components $N_1, \ldots, N_k$, then we define

$$[M] \;:=\; \sum_{i=1}^{k} [N_i] \;\in\; H_n(M, \partial M) \;=\; \bigoplus_{i=1}^{k} H_n(N_i, \partial N_i).$$

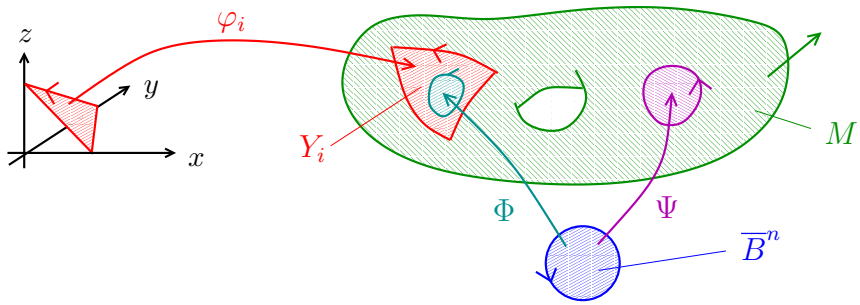

FIGURE 578. Illustration for the proof of Proposition 39.7.

Examples.

(1) If we apply Proposition 39.7 to $\mathrm{id}\colon \overline{B}^n \to \overline{B}^n$ we see that the homology class $\left[\overline{B}^n\right]$ that we introduced on page 945 is indeed the fundamental class of the oriented manifold $\overline{B}^n$.
(2) We endow S^n with the usual orientation, i.e given $P \in S^n$ and a basis $v_1, \dots, v_n$ of $T_P M$ we say it is a positive basis if $P, v_1, \dots, v_n$ is a positive basis for $\mathbb{R}^{n+1}$. It follows easily from the definitions that the corresponding fundamental class $[S^n] \in H_n(S^n)$ is precisely the standard generator that we introduced on page 814.
(3) If we make the usual identification $T = [0,1] \times [0,1]/\sim$ and if we give $[0,1] \times [0,1]$ the usual orientation, then the generator of $H_2(T)$ given in Lemma 33.13 equals *minus* the fundamental class of T.

Given an oriented manifold M we denote, as usual, by $-M$ the same manifold but with opposite orientation. Now we can formulate the following lemma.

Lemma 39.8. *For any compact, oriented, non-empty n-dimensional manifold M we have*

$$[-M] \;=\; -[M] \;\in\; H_n(M).$$

Proof $(*)$. Let M be a compact, oriented, non-empty n-dimensional manifold. We claim that $-[M]$ is the fundamental class of $-M$. We pick an embedding $\Phi\colon \overline{B}^n \to M \setminus \partial M$ that is orientation-preserving with respect to the standard orientation of $\overline{B}^n$ and the orientation $-M$. We denote by $r\colon H_n(M, \partial M) \to H_n(M, M \setminus \Phi(B^n))$ the obvious map. Furthermore we denote by $\rho\colon \overline{B}^n \to \overline{B}^n$ the map that is given reflection in the x-axis. Then

$$\Phi_*([\overline{B}^n]) \;\underset{\substack{\uparrow \\ \text{since } \rho^2 = \mathrm{id}}}{=}\; (\Phi \circ \rho)_*(\rho_*([\overline{B}^n])) \;\underset{\substack{\uparrow \\ \text{as in Lemma 32.16}}}{=}\; -(\Phi \circ \rho)_*([\overline{B}^n]) \;\underset{\substack{\uparrow \\ \text{since } \rho \circ \Phi\colon \overline{B}^n \to M \text{ is} \\ \text{orientation-preserving}}}{=}\; -r([M]) \;=\; r(-[M]).$$

□

On 205 we saw that the boundary of an oriented manifold inherits an orientation. For compact manifolds the following proposition gives the relationship between the fundamental class of the manifold and of its boundary.

Proposition 39.9. *If M is a compact, oriented n-dimensional manifold with non-empty boundary, then the connecting homomorphism*

$$\partial\colon H_n(M,\partial M) \;\to\; H_{n-1}(\partial M)$$

of the long exact sequence in homology of the pair $(M,\partial M)$ has the property that

$$[M] \;\mapsto\; [\partial M].$$

Proof $(*)$. Let M be a compact, oriented n-dimensional manifold with boundary components $N_1,\dots,N_k$. By Proposition 39.3 the manifold M admits a simplicial structure such that ∂M is a subcomplex. We can and will assume that all the maps for the n-simplices in the simplicial structure are orientation-preserving. Now we use this simplicial structure to define the cellular n-cycle $c \in C_n^{\mathrm{CW}}(M)$ as in the proof of Proposition 39.7. We also use the restriction of the simplicial structure to the various boundary components to define cellular cycles $d_i \in C_{n-1}^{\mathrm{CW}}(N_i)$, $i=1,\dots,k$. Now we consider the following diagram

$$\begin{tikzcd}
H_n^{\mathrm{CW}}(M) \arrow[r, "{[c]\mapsto[d_1]+\cdots+[d_k]}"] \arrow[d, "{[c]\mapsto[M]}"', "\cong"] & \bigoplus_{i=1}^{k} H_{n-1}^{\mathrm{CW}}(N_i) \arrow[d, "\cong"', "{[d_i]\mapsto[N_i]}"] \\
H_n(M) \arrow[r] & \bigoplus_{i=1}^{k} H_{n-1}(N_i)
\end{tikzcd}$$

where the vertical isomorphisms are given by Proposition 35.4. The proposition is an immediate consequence of the following observations:

(1) As in the proof of Propositions 39.5 we see that in the cellular chain complex of M we have $d_n(c) = d_1 + \cdots + d_k$.[753] This observation explains why on the top we have the assignment $[c] \mapsto [d_1] + \cdots + [d_k]$.[754]
(2) By definition of the fundamental classes the vertical maps send $[c]$ to $[M]$ and $[d_i]$ to $[N_i]$.
(3) The diagram commutes by Proposition 35.4. □

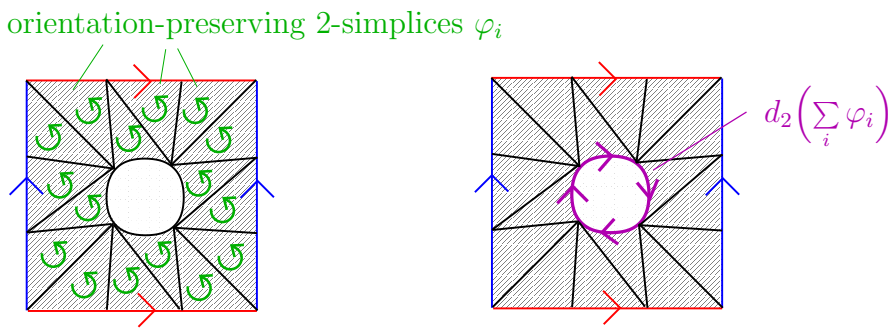
Example. In Figure 579 we consider the surface F that is given removing an open disk from a torus. We illustrate a simplicial structure with oriented 2-simplices. The sum of the oriented 2-simplices is a generator of $H_2^{\mathrm{CW}}(F,\partial F) = H_2(F,\partial F)$, and the boundary of the sum is a generator of $H_1^{\mathrm{CW}}(\partial F) = H_1(\partial F)$.

For the record we state the following elementary corollary to Proposition 39.9.

Corollary 39.10. *Let M be a compact, oriented n-dimensional manifold with non-empty boundary. We denote by $i\colon H_{n-1}(\partial M) \to H_{n-1}(M)$ the inclusion map.*

[753] A careful proof would require checking that all the various sign conventions work out to give the desired result.

[754] We skip the evidently painful discussion of the signs that arise.



torus, minus one open disk, viewed as a simplicial complex

FIGURE 579.

(1) *We have*[755]

$$\ker\left\{i_*\colon H_{n-1}(\partial M) \;\to\; H_{n-1}(M)\right\} \;=\; \mathbb{Z}\cdot[\partial M] \;\in\; H_{n-1}(\partial M).$$

(2) *If M has one boundary component, then $i_*\colon H_{n-1}(\partial M) \to H_{n-1}(M)$ is the zero map.*

(3) *The boundary ∂M is not a retract of M.*

Remark.

(1) In Proposition 31.6 we showed that the sphere $S^{n-1} = \partial\overline{B}^{n-1}$ is not a retract of the closed ball $\overline{B}^n$. Corollary 39.10 (3) can thus be viewed as a generalization of Proposition 31.6 from $\overline{B}^n$ to the case of compact oriented connected manifolds with non-trivial boundary.

(2) The question now arises, whether the condition that M is oriented is necessary in the statement of Corollary 39.10. We will discuss the case of the Klein bottle minus one open disk in Exercise 39.2.

Proof. Let M be a compact, oriented n-dimensional manifold with non-empty boundary.

(1) Using Proposition 39.9 and the long exact sequence in homology of the pair $(M, \partial M)$ we obtain that the following sequence is exact:

$$H_n(M,\partial M) \xrightarrow{[M]\mapsto[\partial M]} H_{n-1}(\partial M) \xrightarrow{i_*} H_{n-1}(M).$$

Statement (1) is now an immediate consequence.

[755]Put differently, if M has boundary components $N_1,\dots,N_k$, then

$$\ker\left\{H_{n-1}(\partial M) \;\to\; H_{n-1}(M)\right\} \;=\; \sum_{i=1}^{k}[N_i] \;\in\; H_{n-1}(\partial M) \;=\; \bigoplus_{j=1}^{k} H_{n-1}(N_j).$$

(2) This statement is an immediate consequence of (1) and the fact that $[\partial M]$ is a generator of $H_{n-1}(\partial M) \cong \mathbb{Z}$.
(3) Using (1) one can prove the last statement almost the same way as Proposition 31.6. We just need to replace π_n by H_n. We leave the details to the reader. □

The following proposition gives us some extra information about homology groups of manifolds with boundary.

Proposition 39.11. *Let M be a connected n-dimensional manifold. If M is non-compact or if M has non-empty boundary, then the following statements hold:*
(1) *M is homotopy equivalent to an $(n-1)$-dimensional CW-complex,*
(2) *$H_{n-1}(M)$ is a free abelian group.*

Examples.
(1) The Möbius band and the annulus are both homotopy equivalent to S^1.
(2) Given $g \in \mathbb{N}_0$ and $k \in \mathbb{N}_0$ we denote as usual by $\Sigma_{g,k}$ the surface of genus g with k open disks removed. In Figure 580 we sketch a deformation retraction from $\Sigma_{2,2}$ to the graph of Euler characteristic -4.
More generally, almost the same argument shows that $\Sigma_{g,k}$ with $k \geq 1$ admits a deformation retraction to a graph with k vertices and $2g+2(k-1)$ edges, i.e. a graph of Euler characteristic $k-(2g+2(k-1)) = -2g-k+2$. Using Proposition 9.21 we also see that $\Sigma_{g,k}$ is homotopy equivalent to the wedge of $2g+k-1$ circles.

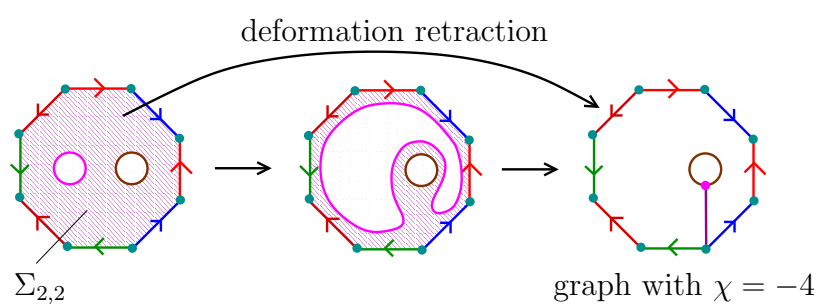


FIGURE 580.

(3) The non-compact manifold that is given by removing a point from the torus is easily seen to be homotopy equivalent to the wedge of two circles.
(4) In Figure 581 we show the surface M of infinite genus, which is non-compact, and a 1-dimensional CW-complex that is deformation retract of M. It is admittedly not overly obvious why the 1-dimensional CW-complex is indeed a deformation retract of M.

Proof. Let M be a connected n-dimensional manifold. We first consider the case that M is non-compact. In this situation it follows from [NR, Theorem 2.2], or alternatively [Whd5, Lemma 2.1], that M is homotopy equivalent to an $(n-1)$-dimensional CW-complex. It

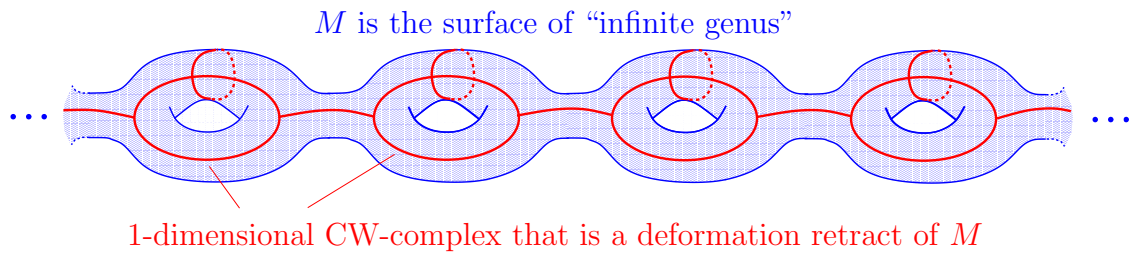

FIGURE 581.

is then a consequence of Corollary 30.8 (4) and Proposition 35.5 that $H_{n-1}(M)$ is a free abelian group.

Now suppose that M is compact, but that it has a non-empty boundary. By the Collar Neighborhood Theorem 10.10 there exists a collar neighborhood $\partial M \times [0,1)$. We write $N = M \setminus \partial M \times [0, \frac{1}{2})$. It is straightforward to see that N is a deformation retract of both M and $M \setminus \partial M$. In particular M is homotopy equivalent to the non-compact manifold $M \setminus \partial M$, which, by the above, is in turn homotopy equivalent to an $(n-1)$-dimensional CW-complex. □

Remark. Let M be a compact connected n-dimensional manifold with non-empty boundary. In this remark we give an intuitive argument why M is homotopy equivalent to a finite $(n-1)$-dimensional CW-complex.

First of all, by Proposition 39.3 we know that M admits a simplicial structure such that ∂M is a subcomplex. From Lemma 39.4 it follows that M contains an $(n-1)$-simplex c of order one. Let d be the n-dimensional simplex of W with $c \subset \partial d$. We denote by c' the union of all faces of d except for c. As on page 812 one can easily show that c' is a deformation retract of d. We denote by V_1 the union of all simplices of M except for d. Since c' is a deformation retract of d we see that V_1 is a deformation retract of M. We refer to Figure 582 for an illustration.

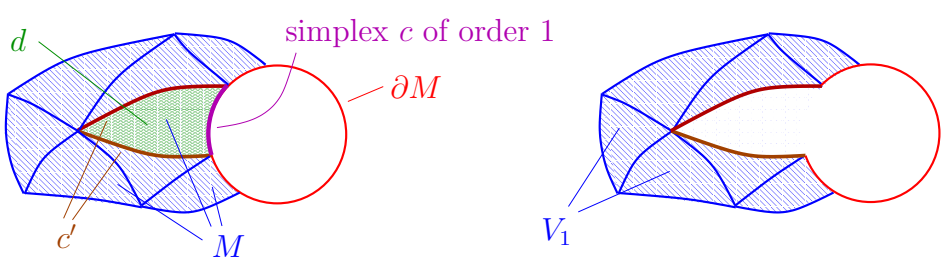

FIGURE 582.

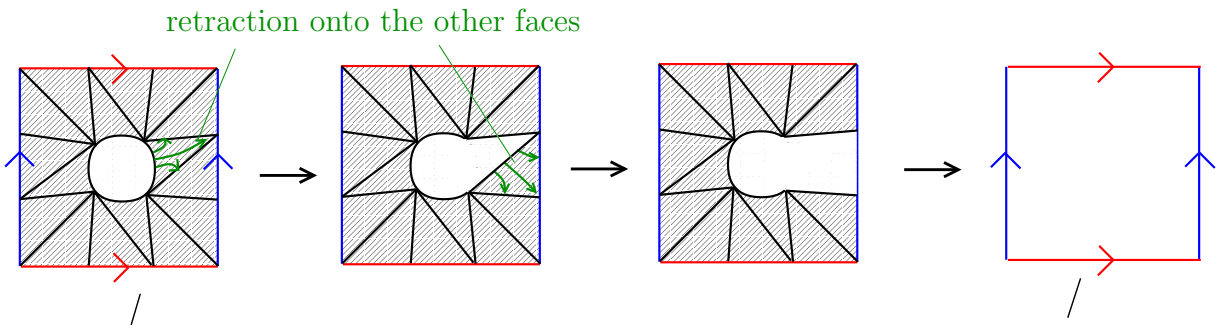
Now we iterate this procedure[756] and we obtain a sequence $M =: V_0 \supset V_1 \supset \cdots \supset V_k$ of subcomplexes such that V_k has no n-simplices and where each V_{i+1} is a deformation retract of V_i. This implies in particular that the $(n-1)$-dimensional CW-complex V_k is also a deformation retract of M. This procedure is illustrated in Figure 583 for M the torus minus one open disk.



simplicial structure for the surface of genus one with one boundary component

1-dimensional simplicial complex

FIGURE 583.

We conclude this section with the following corollary.

Corollary 39.12. *Let M be a connected 2-dimensional manifold. If M is non-compact, then $\pi_1(M)$ is a free group.*

Remark. The statement of Corollary 39.12 generalizes Lemma 16.6.

Proof. Let M be a connected 2-dimensional manifold that is non-compact. By Proposition 39.11 we know that M is homotopy equivalent to a one-dimensional CW-complex. It follows from Proposition 9.12 (1) and Proposition 27.9 (1) that $\pi_1(M)$ is a free group. □

We conclude this section with a short discussion of fundamental groups of 2-dimensional manifolds.

Proposition 39.13.

(1) *If M is a connected 2-dimensional manifold that is non-compact, then $\pi_1(M)$ is a free group.*
(2) *If M is a connected 2-dimensional manifold, then every subgroup of $\pi_1(M)$ of infinite index is free.*
(3) *If M is a surface of genus ≥ 2 and if $\Gamma \subset \pi_1(M)$ is a* normal *non-trivial subgroup of infinite-index, then $\pi_1(M)$ is a free group of infinite index.*

[756]Here is the snag: how can one prove that we can iterate this procedure, i.e. why can we always find an $(n-1)$-simplex of degree one?

Example. The 2-dimensional manifolds shown in Figure 584 are non-compact and thus their fundamental groups are free. For the example on the left we saw this already in Lemma 16.6.

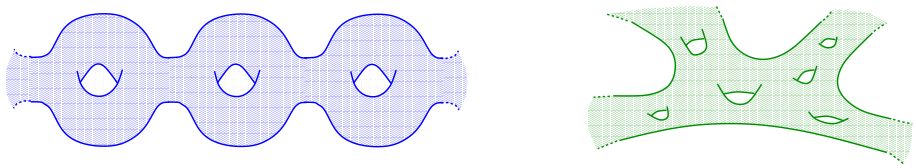


FIGURE 584.

Proof.

(1) Let M be a connected 2-dimensional manifold that is non-compact. By Proposition 39.11 we know that M is homotopy equivalent to a one-dimensional CW-complex. It follows from Proposition 9.12 (1) and Proposition 27.9 (1) that $\pi_1(M)$ is a free group.

(2) Let M be a connected 2-dimensional manifold and let $\Gamma \subset \pi_1(M)$ be a subgroup of infinite index. By Proposition 20.8 there exists a connected covering $p\colon \widetilde{M} \to M$ of infinite degree with $\pi_1(\widetilde{M}) \cong \Gamma$. By Lemma 7.4 (5) we know that $\widetilde{M}$ is non-compact so it follows from Proposition 8.1 (2) and from statement (1) above that $\Gamma \cong \pi_1(\widetilde{M})$ is a free group.

(3) By (2) it remains to show that Γ is infinitely generated. A proof for this statement is given in [Cat, Lemma 3.4], alternatively one can prove the second statement using [Lü4, Theorem 0.7]. A significantly stronger statement is proved in [BH, Theorem 1]. □

We will prove the following corollary in Exercise 39.1.

Corollary 39.14. *For any $g \in \mathbb{N}$ the fundamental group of the surface of genus g is torsion-free.*

39.4. **The homology groups of the connected sum of two manifolds.** Let M and N be oriented two closed oriented connected n-dimensional manifolds. Now we recall the definition of the connected sum $M\#N$ that we gave on page 355. First we pick an orientation-preserving embedding $\varphi\colon \overline{B}^n \to M \setminus \partial M$ and we pick an orientation-reversing embedding $\psi\colon \overline{B}^n \to N \setminus \partial N$. Then we set

$$M\#N \;:=\; \big(M \setminus \varphi(B^n)\big) \sqcup \big(N \setminus \psi(B^n)\big) \,/\, \big\{\varphi(P) = \psi(P) \,\big|\, P \in S^{n-1}\big\}.$$

In Proposition 12.11 we showed that $\pi_1(M\#N)$ is the free product of $\pi_1(M)$ and $\pi_1(N)$. Now we have a very similar result for the homology groups of $M\#N$.

Proposition 39.15. *Let M and N be two closed oriented connected n-dimensional non-empty manifolds. Then for any $k \in \mathbb{N}_0$ we have*

$$H_k(M\#N) \;\cong\; \begin{cases} H_k(M) \oplus H_k(N), & \text{if } k \neq 0, n, \\ \mathbb{Z}, & \text{if } k = 0, n. \end{cases}$$

Moreover, for $k \neq 0, n$ the inclusion maps induce isomorphisms

$$H_k(M) \oplus H_k(N) \;\xleftarrow{\cong}\; H_k(M \setminus B^n) \oplus H_k(N \setminus B^n) \;\xrightarrow{\cong}\; H_k(M\#N)$$

where $B^n \subset M$ and $B^n \subset N$ denote the open balls used in the definition of the connected sum of M and N.

Remark. In Exercise 39.6 we will consider the homology groups of $M\#N$ if we drop the condition that the manifolds are closed.

The key to the proof of Proposition 39.15 is the following lemma.

Lemma 39.16. *Let X and Y be two compact orientable connected n-dimensional manifolds such that $\partial X \cong S^{n-1}$ and $\partial Y \cong S^{n-1}$. We pick a diffeomorphism $\varphi\colon \partial X \to \partial Y$.*

(1) *There exists an isomorphism*

$$H_n(X \cup_\varphi Y) \;\cong \mathbb{Z}$$

and for any $k < n$ the inclusion maps induce isomorphisms

$$\widetilde{H}_k(X) \oplus \widetilde{H}_k(Y) \;\xrightarrow{\cong}\; \widetilde{H}_k(X \cup_\varphi Y).$$

(2) *In particular for $Y = \overline{B}^n$ we obtain that for any $k < n$ the inclusion induces an isomorphism*

$$\widetilde{H}_k(X) \;\xrightarrow{\cong}\; \widetilde{H}_k(X \cup_\varphi \overline{B}^n).$$

Proof. The second statement is an immediate consequence of the first statement and the fact that $\widetilde{H}_k(\overline{B}^n) = 0$. So it suffices to prove the first statement. To simplify the notation we write $S^{n-1} = \partial X = \partial Y$. We also write $Z = X \cup_\varphi Y$. It follows the Mayer-Vietoris Theorem 33.10 that there exists a long exact sequence

$$\to \widetilde{H}_k(S^{n-1}) \xrightarrow{i \oplus -i} \widetilde{H}_k(X) \oplus \widetilde{H}_k(Y) \xrightarrow{i+i} \widetilde{H}_k(Z) \xrightarrow{\partial_k} \widetilde{H}_{k-1}(S^{n-1}) \to \dots$$

where i always stands for the corresponding inclusion induced map. By Proposition 31.3 we have $\widetilde{H}_n(S^n) \cong \mathbb{Z}$ and $\widetilde{H}_k(S^n) = 0$ for $k \neq n$. We see immediately that for any $k < n$ the inclusion maps induce an isomorphism $\widetilde{H}_k(X) \oplus \widetilde{H}_k(Y) \to \widetilde{H}_k(Z)$.

Now we turn to the n-th homology of Z. First note that by Proposition 39.6 we have $\widetilde{H}_n(X) = \widetilde{H}_n(Y) = 0$. Therefore the above long exact sequence gives rise to an exact sequence

$$0 \to \widetilde{H}_n(Z) \xrightarrow{\partial_{n-1}} \widetilde{H}_{n-1}(S^{n-1}) \xrightarrow{i \oplus -i} \widetilde{H}_{n-1}(X) \oplus \widetilde{H}_{n-1}(Y) \to \widetilde{H}_{n-1}(Z) \to 0.$$

Since S^{n-1} is the unique boundary component of X we deduce from Corollary 39.10 that the inclusion induced map $\widetilde{H}_{n-1}(S^{n-1}) \to \widetilde{H}_{n-1}(X)$ is the zero map. The same way we

see that the inclusion induced map $\widetilde{H}_{n-1}(S^{n-1}) \to \widetilde{H}_{n-1}(Y)$ is also the zero map. It now follows from the above long exact sequence that $\widetilde{H}_n(Z) \cong \widetilde{H}_{n-1}(S^{n-1}) \cong \mathbb{Z}$. $\square$

Now we can easily provide the proof of Proposition 39.15.

Proof of Proposition 39.15. Let M and N be oriented two closed oriented connected non-empty n-dimensional manifolds. As required in the definition of the connected sum of M and N we pick an orientation-preserving embedding $\varphi\colon \overline{B}^n \to M \setminus \partial M$ and we pick an orientation-reversing embedding $\psi\colon \overline{B}^n \to N \setminus \partial N$. Recall that

$$M\#N \;:=\; \big(M \setminus \varphi(B^n)\big) \sqcup \big(N \setminus \psi(B^n)\big) \,/\, \big\{\varphi(P) = \psi(P) \,\big|\, P \in S^{n-1}\big\}.$$

We write $X = M \setminus \varphi(B^n)$ and $Y = N \setminus \psi(B^n)$. It follows immediately from Lemma 39.16 (1) that $H_n(M\#N) = H_n(X \cup_{S^{n-1}} Y) \cong \mathbb{Z}$.

Now let $k < n$. In this case we have

$$\begin{array}{ccccc} H_k(M) \oplus H_k(N) & \xleftarrow{\cong} & H_k(\underbrace{M \setminus \varphi(B^n)}_{=X}) \oplus H_k(\underbrace{N \setminus \psi(B^n)}_{=Y}) & \xrightarrow{\cong} & H_k(M\#N) \\ & \uparrow & & \uparrow & \\ & \text{Lemma 39.16 (1) applied to} & & \text{Lemma 39.16 (1) applied to } M\#N = X \cup Y & \\ & M = X \cup \overline{B}^n \text{ and } N = Y \cup \overline{B}^n & & & \end{array}$$

$\square$

Examples.

(1) On page 884 we showed that

$$H_k(\mathbb{C}\mathrm{P}^2) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k = 0, 2, 4, \\ 0, & \text{otherwise.} \end{cases}$$

It follows from Proposition 39.15 that

$$H_k(\mathbb{C}\mathrm{P}^2\#\mathbb{C}\mathrm{P}^2) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k = 0, 4, \\ \mathbb{Z} \oplus \mathbb{Z}, & \text{if } k = 2, \\ 0, & \text{otherwise.} \end{cases}$$

Since the homology groups do not depend on the orientation we have the same homology groups for $\overline{\mathbb{C}\mathrm{P}}^2$ and the calculation shows that the homology groups of $\mathbb{C}\mathrm{P}^2\#\mathbb{C}\mathrm{P}^2$ and $\mathbb{C}\mathrm{P}^2\#\overline{\mathbb{C}\mathrm{P}}^2$ agree.

(2) Let $T = S^1 \times S^1$ be the torus. In Figure 224 we saw that the connected sum $T\#T$ is the surface Σ_2 of genus 2. More generally, the same argument shows that the connected sum of g copies of the torus T is the surface Σ_g of genus g. Together with the calculation of the homology groups of the torus in Lemma 33.12 we now see that

$$H_k(\Sigma_g) \;\cong\; H_k(\underbrace{T\#\ldots\#T}_{g \text{ copies}}) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k = 0, 2, \\ \mathbb{Z}^{2g}, & \text{if } k = 1, \\ 0, & \text{if } k > 2. \end{cases}$$

This agrees of course with the result obtained in Proposition 35.10.

Proposition 39.17. *If M is a closed, orientable, connected n-dimensional manifold, then the homology group $H_{n-1}(M)$ is a free abelian group.*

Remark. Note the example of $M = \mathbb{R}\mathrm{P}^2$ shows that the statement of Proposition 39.17 does not hold if we drop the condition that M has to be orientable.

Proof. Let M be a closed, orientable, connected n-dimensional manifold. We pick an embedding $\Phi\colon \overline{B}^n \to M$. Since M is closed, orientable and connected we can apply Lemma 39.16 which says that $H_{n-1}(M) \cong H_{n-1}(M \setminus \Phi(B^n))$. But $M \setminus \Phi(B^n)$ is a manifold with boundary, hence it follows from Proposition 39.11 that $H_{n-1}(M \setminus \Phi(B^n))$ is a free abelian group. □

Remark. In this section we have obtained many results on the homology groups of manifolds. It is natural to ask whether the statements also hold for topological manifolds. In the above arguments we made use of the fact that manifolds have a simplicial structure. This is in general not the case for topological manifolds. In a later chapter we will reprove the above statements for topological manifolds using a different approach. This new approach will be more general, but also more abstract and less intuitive.

39.5. **Representing homology classes by manifolds** $(*)$.

Definition. Let M be a manifold.

(1) If N is a closed, oriented, non-empty n-dimensional submanifold of M, then, by a slight abuse of notation, we denote by $[N]$ the image of the fundamental class $[N]$ in $H_n(M)$ under the inclusion induced map $H_n(N) \to H_n(M)$.
(2) We say that a homology class $z \in H_n(M)$ *is represented by a submanifold* if there exists an n-dimensional closed, oriented, non-empty submanifold N such that $[N] = z \in H_n(M)$.

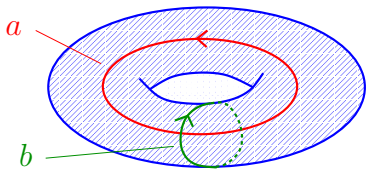
Examples.

(1) We first consider the 2-dimensional torus $T = S^1 \times S^1$. Under the usual isomorphism $H_1(S^1 \times S^1) \cong \mathbb{Z}^2$ the basis element $(1, 0)$ is represented by the oriented submanifold $S^1 \times \{1\}$ and the basis element $(0, 1)$ is represented by the oriented submanifold $\{1\} \times S^1$. This situation is illustrated in Figure 586 on the left.

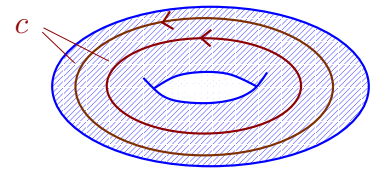
    Next we consider the homology class $(2, 0)$. As shown in Figure 586 on the right, we can represent it by a disconnected submanifold. But can we also represent it by a connected submanifold?
(2) We consider the surface Σ_2 of genus 2. As in Figure 224 we view Σ_2 as the connected sum $T\#T$ of two tori. If we use the calculation on page 956 to determine an isomorphism $H_1(\Sigma_2) \cong \mathbb{Z}^4$, then the basis elements are represented by the submanifolds a_1, b_1, a_2, b_2 that are illustrated in Figure 586.[757] [758]

[757] Another point of view is that the submanifolds a_1, b_1, a_2, b_2 are given by deforming the curves x_1, y_1, x_2, y_2 that are shown in Figure 259.

[758] What do these submanifolds look like in the formal picture of the surface of genus 2 as the quotient $E_8/\sim$ of the Euclidean octagon?

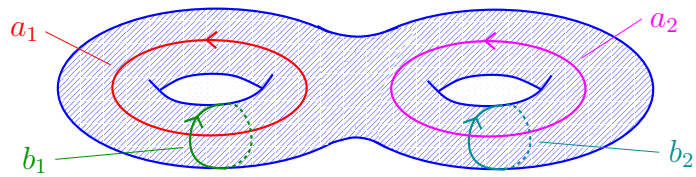


basis for homology of H_1(torus)



homology class represented
by a disconnected submanifold

FIGURE 585.



basis for homology of H_1(surface of genus 2)

FIGURE 586.

(3) We consider again the complex projective space $\mathbb{C}\mathrm{P}^n$. We saw on page 649 that for $k \leq n$ the map

$$\begin{array}{rcl} \mathbb{C}\mathrm{P}^k & \to & \mathbb{C}\mathrm{P}^n \\ [v_0 : \ldots : v_k] & \mapsto & [v_0 : \ldots : v_k : 0 : \ldots : 0] \end{array}$$

is an embedding. We use this map to view $\mathbb{C}\mathrm{P}^k$ as a submanifold of $\mathbb{C}\mathrm{P}^n$. It follows from the discussion on page 884 and the natural isomorphism of Proposition 35.4 that

$$H_k(\mathbb{C}\mathrm{P}^n) \cong \begin{cases} \mathbb{Z} \cdot [\mathbb{C}\mathrm{P}^i], & \text{if } k = 2i \text{ for some } i \in \{0, \ldots, n\}, \\ 0, & \text{otherwise.} \end{cases}$$

Put differently, the generators of the non-trivial homology groups of the complex projective space $\mathbb{C}\mathrm{P}^n$ are represented by the complex projective spaces $\mathbb{C}\mathrm{P}^k$ with $k = 0, \ldots, n$.

If X is a topological space that is not a manifold, then it does not make sense to ask whether a homology class is represented by a submanifold. But given a homology class $c \in H_n(X)$ it still makes sense to ask whether there exists a map from a closed oriented manifold M such that the image of the fundamental class $[M]$ equals c. This leads to the following definition.

Definition. Let X be a topological space and let $z \in H_n(X)$ be a homology class. We say *z can be realized by a manifold* if there exists an n-dimensional closed oriented connected, non-empty manifold M and a map $f\colon M \to X$ such that $f_*([M]) = z$.

Example. If X is a path-connected topological space, then it follows from Proposition 38.3 that any class in $H_1(X)$ is realized by a manifold. Furthermore a relatively straightforward argument, see [Cal, p. 3] shows that also every class in $H_2(X)$ is realized by a manifold.

The following theorem was first proved by René Thom [Tho, Tho2] in 1954[759] (See also [Rudy, Theorem IV.7.37]). The proof of the theorem uses methods that go well beyond our present abilities. We will not make use of the theorem.

Theorem 39.18.

(1) *If X is a topological space, then every homology class of dimension ≤ 6 can be realized by a manifold.*
(2) *Given any $n \geq 7$ there exists a topological space X and a homology class in $H_n(X)$ that is not realized by a manifold.*
(3) *Given any $n \in \mathbb{N}_0$ there exists a $k \in \mathbb{N}$ such that for any topological space X and any homology class $z \in H_n(X)$ the class $k \cdot z$ can be realized by a manifold.*

39.6. **The degree of a map between oriented manifolds.**

Definition. Let $f\colon M \to N$ be a map between two closed oriented connected, non-empty n-dimensional manifolds. We denote by $\deg(f) \in \mathbb{Z}$ the unique integer with

$$f_*([M]) \;=\; \deg(f) \cdot [N].$$

We refer to $\deg(f)$ as the *degree of f*.

Example. For a map $f\colon S^n \to S^n$ the above degree is exactly the same as the degree that we defined on page 819.

In the following lemma we summarize two key properties of the degree.

Lemma 39.19.

(1) *Let $f\colon L \to M$ and $g\colon M \to N$ be two maps between two closed oriented connected, non-empty n-dimensional manifolds. Then*

$$\deg(g \circ f) \;=\; \deg(g) \cdot \deg(f).$$

(2) *Let $f\colon M \to N$ be a map between two closed oriented connected, non-empty n-dimensional manifolds. Let $y \in N$ such that $f^{-1}(y)$ consists of finitely many points $x_1, \ldots, x_m$ and such that f is a local diffeomorphism around each x_i. Then*

$$\deg f \;=\; \sum_{i=1}^{m} \begin{array}{rl} 1, & \text{if } f \text{ is strongly locally orientation-preserving at } x_i \\ -1, & \text{if } f \text{ is o-locally orientation-reversing at } x_i. \end{array}$$

Proof.

(1) Exactly as in the proof of Lemma 32.16 (4) we have

$$(g \circ f)_*([L]) \;=\; g_*(f_*([L])) \;=\; g_*(\deg(f) \cdot [L]) \;=\; \deg(g) \cdot \deg(f) \cdot [L].$$

This shows that $\deg(g \circ f) = \deg(g) \cdot \deg(f)$.

[759] René Thom (1923-2002) was a French mathematician who received the Fields Medal in 1958.

(2) The second statement is proved in a very similar fashion to Proposition 32.26 and Lemma 32.24. We leave it as an exercise to make the not overly difficult modifications of the proofs. □

The following proposition gives us many examples of degrees of maps between manifolds.

Proposition 39.20. *Let $p\colon \widetilde{N} \to N$ be a finite covering of closed oriented connected, non-empty manifolds. If p is orientation-preserving, then*

$$\deg(p) \;=\; [\widetilde{N} : N].$$

Proof. This proposition follows immediately from Lemma 39.19 (2). □

Proposition 39.21. *Let M be a closed, oriented, non-empty n-dimensional manifold. Then for any $k \in \mathbb{Z}$ there exists a map $f\colon M \to S^n$ of degree k.*

Proof. Let M be a closed, oriented, non-empty n-dimensional manifold and let $k \in \mathbb{Z}$. By Lemmas 32.15 and 32.18 there exists a map $g\colon S^n \to S^n$ of degree k. It follows from this fact and Lemma 39.19 that it suffices to show that there exists a map $f\colon M \to S^n$ of degree ± 1. We will show the existence in the remainder of the proof.

First we pick an orientation-preserving embedding $\Phi\colon \overline{B}^n \to M$. This map descends to a homeomorphism $\overline{B}^n/S^{n-1} \to M/(M \setminus \Phi(B^n))$ that we denote by $\overline{\Phi}$. We denote by $\Omega\colon \overline{B}^n/S^{n-1} \to S^n$ the homeomorphism from page 99. We denote by f the map given by

$$f\colon M \;\to\; M/(M \setminus \Phi(B^n)) \;\xrightarrow{\overline{\Phi}^{-1}}\; \overline{B}/S^{n-1} \;\xrightarrow{\Omega}\; S^n.$$

We claim that f is a map of degree ± 1. This follows quite easily from Lemma 39.19 (2), but since we did not prove that lemma we will give a direct proof.

It suffices to show that f induces an isomorphism $\widetilde{H}_n(M) \to \widetilde{H}_n(S^n)$. Since $\overline{\Phi}$ and Ω are homeomorphisms it suffices to show that the first map induces an isomorphism on homology. We consider the following diagram of homomorphisms

$$\begin{tikzcd}
\underbrace{\widetilde{H}_n(M \setminus \Phi(B^n))}_{=0} \arrow[r] & \widetilde{H}_n(M) \arrow[r] \arrow[dr] & H_n(M, M \setminus \Phi(B^n)) \arrow[r] \arrow[d, "\cong"'] & \widetilde{H}_{n-1}(M \setminus \Phi(B^n)) \arrow[r] & \widetilde{H}_{n-1}(M) \\
& & \widetilde{H}_n(M/(M \setminus \Phi(B^n))). & &
\end{tikzcd}$$

We make the following remarks:

(1) The horizontal sequence is the long exact sequence in reduced homology of the pair $(M, M \setminus \Phi(B^n))$,
(2) the group on the left is zero by Proposition 39.5,
(3) the map on the right is an isomorphism by Lemma 39.16.
(4) the vertical map is the natural isomorphism of Proposition 31.19.

It follows that the diagonal map is an isomorphism. □

The following theorem says that the degree of a map is a complete invariant up to homotopy. We will not make use of this theorem.

Theorem 39.22. (Hopf Theorem) *Let M be a closed oriented connected, non-empty n-dimensional manifold and let $f, g\colon M \to S^n$ be two maps. Then*

$$\deg(f) = \deg(g) \quad \Longleftrightarrow \quad \textit{the maps } f \textit{ and } g \textit{ are homotopic.}$$

Proof. The "$\Leftarrow$"-direction is an immediate consequence of Proposition 30.5. The "$\Rightarrow$"-direction is much harder, it was initially proved by Heinz Hopf whom we had already encountered on page 726. We refer to [OR, p. 191] or [Mi2, p. 51] for a proof. We will prove a generalization later on in Theorem **??** □

For the record we also state the following open question, see [Kir2, Problem 5.26], which was initially posed by Heinz Hopf.

Question 39.23. (Hopf) *Given a closed, orientable manifold M, is every map $f\colon M \to M$ of degree ± 1 a homotopy equivalence?*

In the following discussion, given $g \in \mathbb{N}_0$ we denote as usual by Σ_g the surface of genus g.

Lemma 39.24. *For any $g \geq k$ there exists a degree-one map from Σ_g to Σ_k*

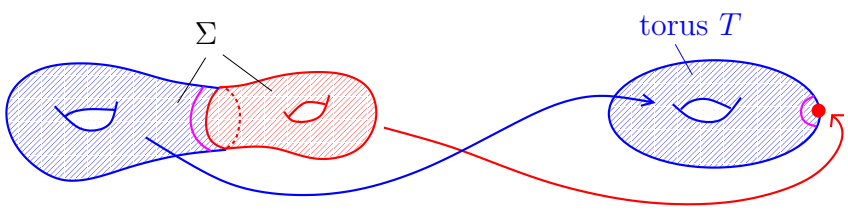


FIGURE 587. A degree-one map from the surface of genus 2 to the torus.

Proof. The case $k = 0$ follows immediately from Proposition 39.21. In the following we will cover the case $g = 2$ and $k = 1$. All other cases will be a variation of the subsequent argument and we leave them as an exercise to the reader. We denote by Σ the surface of genus 2 and we denote by T the torus.

We consider the maps $\Phi\colon \overline{B}^2 \to \Sigma$, $\Psi\colon \overline{B}^2 \to T$ and $\mu\colon \Sigma \to T$ that are illustrated in Figure 588. These maps can be chosen such that $\Psi = \mu \circ \Phi$. We had already encountered the map μ on page 250. We claim that μ is a degree-one map. This follows fairly easily from Lemma 39.19 (2), but since we did not prove that lemma we will give a direct proof.

We will follow the construction of the proof of Proposition 39.21 to obtain a degree-one map $f\colon \Sigma \to S^2$ from Φ and to obtain a degree-one map $g\colon T \to S^2$ from Ψ. It follows from $\Psi = \mu \circ \Phi$ and the explicit constructions that $f = g \circ \mu$. We obtain the following commutative diagram

$$\begin{tikzcd} H_2(\Sigma) \arrow[rr, "\mu_*"] \arrow[dr, "f_*", "{[\Sigma]\to[S^2]}"'] & & H_2(T) \arrow[dl, "g_*"', "{[T]\mapsto[S^2]}"] \\ & H_2(S^2). & \end{tikzcd}$$

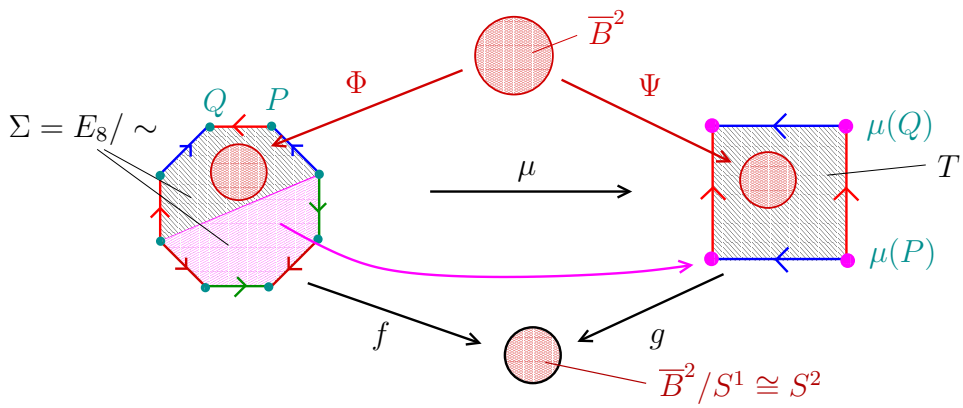

FIGURE 588.

Since f and g are by degree-one maps we see that the diagonal maps are isomorphisms with $f_*([\Sigma]) = [S^2]$ and $g_*([T]) = [S^2]$. We have thus shown that $\mu\colon \Sigma \to T$ is a degree-one map. $\square$

The following question arises naturally.

Question 39.25. *Suppose that $g < k$. Does there exist a degree-one map from Σ_g to Σ_k?*

The following proposition is the key to answering Question 39.25.

Proposition 39.26. *Let $f\colon M \to N$ be a map between closed oriented connected, non-empty n-dimensional manifolds. If $\deg(f) = \pm 1$, then $f_*\colon \pi_1(M) \to \pi_1(N)$ is an epimorphism.*

The statement of Proposition 39.26 is somewhat surprising, in so far as it takes as input fairly simple information, namely the induced map on n-th homology, which is an abelian group, and gives as output information about fundamental groups, which are usually much harder to deal with. Also it is a priori not clear why the homology in the maximal dimension should have any impact on fundamental groups.

Proof. Let $f\colon M \to N$ be a map between closed oriented connected n-dimensional manifolds. We fix a base point $P \in M$ and we write $Q = f(P)$. Furthermore we write $\pi = \pi_1(N, Q)$ and $\Gamma = f_*(\pi_1(M, P))$.

By Proposition 20.8[760] there exists a path-connected covering $p\colon (\widetilde{N}, \widetilde{Q}) \to (N, Q)$ such that $p_*(\pi_1(\widetilde{N}, \widetilde{Q})) = \Gamma$ and such that $[\widetilde{N} : N] = [\pi : \Gamma]$. By Proposition 8.1 the covering space $\widetilde{N}$ is an oriented manifold without boundary. By Proposition 20.2 the map $f\colon (M, P) \to (N, Q)$ lifts to a map $\widetilde{f}\colon (M, P) \to (\widetilde{N}, \widetilde{Q})$. We can summarize the situation

[760]Here we use that according to the discussion on pages 549 any manifold is reasonable.

in the following simple commutative diagram

$$\begin{tikzcd} & \widetilde{N} \arrow[d, "p", "\text{covering of degree } [\pi\colon\Gamma]"'] \\ M \arrow[ur, "\widetilde{f}"] \arrow[r, "f"'] & N. \end{tikzcd}$$

First suppose that Γ is a subgroup of π of infinite index. It follows immediately from $[\widetilde{N} : N] = [\pi : \Gamma]$ and Lemma 7.4 (5) that $\widetilde{N}$ is not compact. By Proposition 39.5 we therefore have $H_n(\widetilde{N}) = 0$. But this shows that $f_* = p_* \circ \widetilde{f}_* \colon H_n(M) \to H_n(N)$ factors through the trivial group. Hence $\deg(f) = 0$. But this is a contradiction to our hypothesis that $\deg(f) = \pm 1$.

So now we know that Γ is in fact a finite-index subgroup. It follows from $[\widetilde{N} : N] = [\pi : \Gamma]$ and Lemma 7.4 (4) that $\widetilde{N}$ is compact. Therefore, by the above we now know that $\widetilde{N}$ is a closed oriented connected n-dimensional manifold. We deduce that

$$\pm 1 \;=\; \deg(f) \;\underset{\substack{\uparrow \\ \text{Lemma 39.19}}}{=}\; \deg(\widetilde{f}) \cdot \deg(p) \;\underset{\substack{\uparrow \\ \text{Proposition 39.20}}}{=}\; \deg(\widetilde{f}) \cdot [\widetilde{N} : N] \;=\; \deg(\widetilde{f}) \cdot [\Gamma\colon \pi].$$

This shows that $[\Gamma\colon \pi] = 1$, i.e. $\Gamma = \pi$. □

Now we can give a negative answer to Question 39.25.

Corollary 39.27. *If there exists a degree-one map from Σ_g to Σ_k, then $g \geq k$.*

Proof. Suppose that there exists a degree-one map from Σ_g to Σ_k. By Proposition 39.26 we obtain an epimorphism $\pi_1(\Sigma_g) \to \pi_1(\Sigma_k)$. In particular we obtain an epimorphism from the abelianization $\pi_1(\Sigma_g)$ onto the abelianization of $\pi_1(\Sigma_k)$. By Proposition 14.3 the former is isomorphic to $\mathbb{Z}^{2g}$ and the latter is isomorphic to $\mathbb{Z}^{2k}$. It follows from Lemma 11.6 that $g \geq k$. □

We conclude this chapter with several questions. Recall that it follows from Lemma 39.24 that there exists a degree-one map $S^2 \times S^2 \to S^4$. It is natural to ask whether the converse holds.

Question 39.28. *Does there exist a degree-one map from the 4-dimensional sphere S^4 to $S^2 \times S^2$?*

Later on we will also address the following question.

Question 39.29. *Does there exist a degree-one map from $S^1 \times S^2$ to $\mathbb{R}\mathrm{P}^3$?*

Finally it is also interesting to study degrees of self-maps of manifolds. It follows from Lemmas 32.15 and 32.18 that given any $k \in \mathbb{Z}$ and given any $n \in \mathbb{N}$ there exists a map $f\colon S^n \to S^n$ of degree k. Furthermore it follows easily from Proposition 39.20 that the torus $T = S^1 \times S^1$ admits a self-map of any degree.

We conclude with the following questions.

Question 39.30.

(1) *Let $g \geq 2$. Does there exist a self-map $f\colon \Sigma_g \to \Sigma_g$ of degree -1?*
(2) *Let $g \geq 2$ and let $k \geq 2$. Does there exist a self-map $f\colon \Sigma_g \to \Sigma_g$ of degree k?*
(3) *Does there exist a self-map $f\colon \mathbb{C}\mathrm{P}^2 \to \mathbb{C}\mathrm{P}^2$ of degree -1?*

We will address the first question in Exercise 39.5 and we will address the last two questions in a later chapter.

Exercises for Chapter 39.

Exercise 39.1. Let $g \in \mathbb{N}_{\geq 2}$. Use Proposition 39.13 to show that the fundamental group of the surface of genus g is torsion-free.

Exercise 39.2. Let K be the Klein bottle minus one open disk. Is ∂K a retract of K?

Exercise 39.3. Let $K \subset S^3$ be a knot and let $\Phi\colon S^1 \times \overline{B}^2 \to S^3$ be an embedding such that $\Phi(S^1 \times 0) = K$, i.e. $\Phi(S^1 \times \overline{B}^2)$ is a tubular neighborhood of K. We refer to $X = S^3 \setminus \Phi(S^1 \times B^2)$ as the exterior of the knot K. This is a compact 3-manifold with boundary that is given by the torus $\Phi(S^1 \times S^1)$. We denote by $\mu = \Phi(* \times S^1)$ the meridian of K. In Lemma 33.15 we saw that μ, viewed as an element in $H_1(X)$, is a generator of $H_1(X)$.

(a) Show that the kernel of $H_1(\Phi(S^1 \times S^1)) \to H_1(X)$ is isomorphic to $\mathbb{Z}$. We refer to either of the two generators of the kernel as the longitude λ of K.
(b) Sketch longitudes for the three knots that are shown in Figure 589.
(c) Now suppose that we are given two knots K and J. We define X_K, X_J, μ_K, μ_J and λ_K and λ_J as above. We pick a homeomorphism $\varphi\colon \partial X_K \to \partial X_J$ with $\varphi_*(\mu_K) = \lambda_J$ and $\varphi_*(\lambda_K) = \mu_K$. We denote by $Y = X_K \cup_\varphi X_J$ the result of gluing X_K to X_J along the boundary. Compute the homology groups of Y.

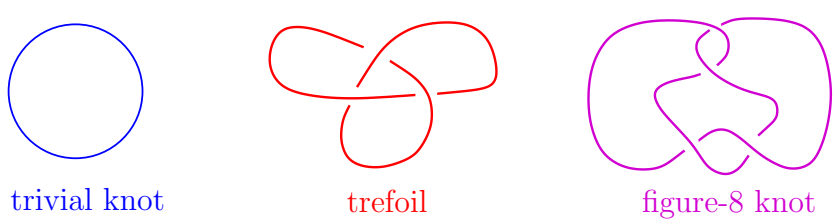

FIGURE 589.

Exercise 39.4.

(a) Let $L \subset S^3$ be a m-component link, i.e. L is a union of m disjoint 1-dimensional submanifolds $L_1, \dots, L_m$ of S^3, each of which is diffeomorphic to S^1. We pick disjoint tubular neighborhoods $L_i \times \overline{B}^2$, $i = 1, \dots, m$. We write $X_L := S^3 \setminus \bigcup_{i=1}^m L_i \times B^2$.

Determine the homology groups of X_L.
Hint: Use the Mayer-Vietoris sequence for manifolds.

(b) In Figure 590 we see two 2-component links, namely the unlink and the Hopf link. Are these two links isotopic?

2-component trivial link Hopf link

FIGURE 590.

Exercise 39.5. Given $g \in \mathbb{N}$ we denote by Σ_g the surface of genus g.

(a) Let $g = 2$. Does there exist a self-map $f\colon \Sigma_g \to \Sigma_g$ of degree -1?
(b) Let $g \geq 1$ and let $k \geq 2$. Does there exist a self-map $f\colon \Sigma_g \to \Sigma_g$ of degree k?

Exercise 39.6. Let M and N be two oriented, connected n-dimensional manifolds. We suppose that M is closed and that N has *non-empty* boundary. Express the homology groups of $M\#N$ in terms of the homology groups of M and N.

40. The Euler characteristic

40.1. **The Euler characteristic and homology groups.** Let X be a finite CW-complex, i.e. let X be a CW-complex with finitely many cells. Recall that on page 691 we defined the Euler characteristic $\chi(X)$ as follows:

$$\chi(X) \;=\; \sum_n (-1)^n \cdot \text{number of } n\text{-cells}.$$

A short glance on the examples in Figure 399 shows that the three different CW-structures for the torus provided in that figure have the same Euler characteristic.

The following proposition explains why this is not a coincidence.

Proposition 40.1. *Let X be a finite CW-complex, then*[761]

$$\chi(X) \;=\; \sum_n (-1)^n \cdot \operatorname{rank}(H_n(X)).$$

Examples.

(1) It follows either from the CW-structure of the n-dimensional sphere S^n with one 0-cell and one n-cell given on page 648 or from the calculation of the homology groups in Proposition 31.3 that

$$\chi(S^n) \;=\; 1 + (-1)^n \;=\; \begin{cases} 0, & \text{if } n \text{ is odd,} \\ 2, & \text{if } n \text{ is even.} \end{cases}$$

(2) Let $n \in \mathbb{N}_0$. We want to determine the Euler characteristic of $\overline{B}^n$. It is actually somewhat tricky to write down a CW-structure for $\overline{B}^n$. But it follows immediately from Proposition 40.1 and Corollary 30.8 (3) that $\chi(\overline{B}^n) = 1$.

(3) Given any $k, n \in \mathbb{N}_0$ we deduce from Corollary 30.8, Proposition 31.3 and Proposition 40.1 that $\chi(S^k \times \overline{B}^n) = \chi(S^k) = 1 + (-1)^k$.

(4) It follows either from the CW-structure provided on page 646 or alternatively from Proposition 35.10 that for a surface Σ_g of genus g we have

$$\chi(\Sigma_g) \;=\; 2 - 2g.$$

(5) It follows immediately from the CW-structures provided in Lemma 26.2 that for any $n \in \mathbb{N}_0$ we have

$$\chi(\mathbb{R}\mathrm{P}^n) \;=\; \begin{cases} 0, & \text{if } n \text{ is odd,} \\ 1, & \text{if } n \text{ is even} \end{cases} \qquad \text{and} \qquad \chi(\mathbb{C}\mathrm{P}^n) \;=\; n+1.$$

Before we turn to the proof of Proposition 40.1 we draw the following corollary.

[761] As a reminder, if G is a finitely generated abelian group, then it follows from the classification of finitely generated abelian groups, see Theorem 11.4, that G is isomorphic to $\mathbb{Z}^r \oplus T$, where T is finite. We then call r the *rank* of G. Put differently, let $T \subset G$ be the torsion subgroup, then G/T is isomorphic to $\mathbb{Z}^r$ for an r, and this r is just the rank of G.

Corollary 40.2. *Let X and Y be finite CW-complexes. Then*

$$X \text{ and } Y \text{ are homotopy equivalent} \quad \Longrightarrow \quad \chi(X) = \chi(Y).$$

Proof. The corollary is an immediate consequence of Proposition 40.1 together with Corollary 30.8 (2). □

Example. On page 437 we introduced two examples of closed orientable 2-dimensional manifolds for which we found it difficult to determine the genus. We show the same surfaces also in Figure 591. Let us first consider the surface on the left: it is given identifying opposite sides of the hexagon E_6. The obvious CW-structures on the hexagon H_6 descends to a CW-structure on $E_6/\sim$. We make the following observations:

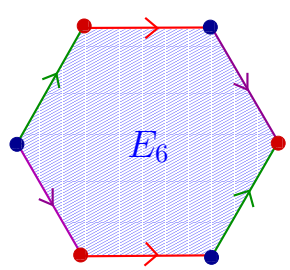
(1) the single 2-cell on E_6 defines a 2-cell for $E_6/\sim$,
(2) we identify every 1-cell of E_6 with the opposite 1-cell, thus $E_6/\sim$ has three 1-cells,
(3) we identify all 0-cells that differ by an even number of vertices, thus $E_6/\sim$ has precisely two 0-cells.

Summarizing we see that $E_6/\sim$ has Euler characteristic $2-3+1=0$. We had just seen on page 966 that the surface of genus g has Euler characteristic $2-2g$. Thus we obtain from Theorem 14.10 that $E_6/\sim$ is diffeomorphic to the surface of genus zero, i.e. the torus.

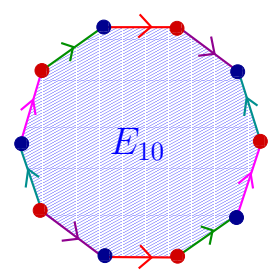
The same argument shows that $E_{10}/\sim$ has Euler characteristic $2-5+1=-2$ and that it is diffeomorphic to the surface of genus one. Evidently the same argument shows that if we take a regular $(4g+2)$-gon and if we identify opposite sides, then we obtain the surface of genus g.

It is a great mental exercise to visualize that the surface on the left is a torus and that the surface on the right is a surface of genus one.

hexagon with opposite sides identified



dodecagon with opposite sides identified



in each case there are two equivalence classes of vertices: red and blue

FIGURE 591.

The key step in the proof of Proposition 40.1 is the following purely algebraic lemma.

Lemma 40.3. *Let*

$$0 \to C_k \xrightarrow{\partial_k} C_{k-1} \xrightarrow{\partial_{k-1}} \dots C_1 \xrightarrow{\partial_1} C_0 \to 0$$

be a chain complex of finitely generated abelian groups. Then the following equality holds:

$$\sum_{n=0}^{k}(-1)^n \operatorname{rank} C_n \;=\; \sum_{n=0}^{k}(-1)^n \operatorname{rank} H_n(C_*).$$

The same statement holds if the C_i are vector spaces over a field and if we replace ranks by dimensions.

Proof. For the above chain complex (C_n, ∂_n) we write for each $n \in \mathbb{N}_0$[762]

$$Z_n := \ker(\partial_n), \quad B_n := \operatorname{im}(\partial_{n+1}) \quad \text{and} \quad H_n = Z_n/B_n.$$

These groups form the following two types of short exact sequences

(a) $$0 \hookrightarrow Z_n \to C_n \xrightarrow{\partial_n} B_{n-1} \to 0,$$

and

(b) $$0 \hookrightarrow B_n \to Z_n \to H_n \to 0.$$

Now we see that

$$\begin{aligned}
\sum_{n=0}^{k}(-1)^n \operatorname{rank} C_n &\overset{\substack{\text{by (a) and Lemma 11.6 (2) we know that } \operatorname{rank} C_n = \operatorname{rank} Z_n + \operatorname{rank} B_{n-1}\\ \downarrow}}{=} \sum_{n=0}^{k}(-1)^n(\operatorname{rank} Z_n + \operatorname{rank} B_{n-1})\\
&\underset{\substack{\uparrow\\ \text{by (b) and Lemma 11.6 (2) we know that } \operatorname{rank} Z_n = \operatorname{rank} B_n + \operatorname{rank} H_n}}{=} \sum_{n=0}^{k}(-1)^n(\operatorname{rank} B_n + \operatorname{rank} H_n + \operatorname{rank} B_{n-1})\\
&= \sum_{n=0}^{k}(-1)^n \operatorname{rank} H_n + \sum_{n=0}^{k}(-1)^n \operatorname{rank} B_n + \sum_{n=0}^{k}(-1)^n \operatorname{rank} B_{n-1}\\
&\underset{\substack{\uparrow\\ \text{we do the substitution } m=n-1 \text{ and we use that } B_k=0 \text{ and } B_{-1}=0}}{=} \sum_{n=0}^{k}(-1)^n \operatorname{rank} H_n + \sum_{n=0}^{k-1}(-1)^n \operatorname{rank} B_n - \sum_{m=0}^{k-1}(-1)^m \operatorname{rank} B_m\\
&= \sum_{n=0}^{k}(-1)^n \operatorname{rank} H_n.
\end{aligned}$$

Basically the same proof also applies if the C_i are vector spaces over a field and if we replace ranks by dimensions. □

Now we can easily provide the proof of Proposition 40.1.

[762]It is a common notation to call these groups Z_n and B_n, the names go back to the German words "Zykel" and "Bild".

Proof of Proposition 40.1. Let X be a finite k-dimensional CW-complex. We have

$$\begin{array}{rcl} \chi(X) & = & \sum\limits_{n=0}^{k}(-1)^n \cdot \text{number of } n\text{-cells} \overset{\substack{\text{Lemma 35.1}\\ \downarrow}}{=} \sum\limits_{n=0}^{k}(-1)^n \cdot \operatorname{rank}(C_n^{\mathrm{CW}}(X)) \\ & \underset{\substack{\uparrow\\ \text{Lemma 40.3}}}{=} & \sum\limits_{n=0}^{k}(-1)^n \cdot \operatorname{rank}(H_n^{\mathrm{CW}}(X)) \underset{\substack{\uparrow\\ \text{Proposition 35.4}}}{=} \sum\limits_{n=0}^{k}(-1)^n \cdot \operatorname{rank}(H_n(X)). \end{array}$$

□

Using Lemma 40.3 we can also easily proof the following lemma which be will useful on several occasions.

Lemma 40.4. *Let*

$$0 \to A_k \to A_{k-1} \to \ldots \to A_1 \to A_0 \to 0$$

be an exact sequence of finitely generated abelian groups. Then

$$\sum_{n=0}^{k}(-1)^n \cdot \operatorname{rank} A_n = 0.$$

Proof. We can view this exact sequence of finitely generated abelian groups as a chain complex whose homology groups vanish. The lemma is therefore an immediate consequence of Lemma 40.3. □

Definition.

(1) Given a topological space X and $n \in \mathbb{N}_0$ such that $H_n(X)$ is a finitely generated abelian group we refer to

$$b_n(X) := \operatorname{rank}(H_n(X))$$

as the *n-th Betti number of X*.[763]

(2) Let X be a topological space. If all homology groups are finitely generated and if $\sum\limits_n b_n(X)$ is finite, then we define the *Euler characteristic of X* to be

$$\chi(X) := \sum_n (-1)^n \cdot b_n(X).$$

It follows from Proposition 40.1 that this new definition of the Euler characteristic of a finite CW-complex agrees with the earlier definition.

Example. Using Proposition 33.20 and using Lemma 40.4 several times we will prove the following statement in Exercise 40.3. Let X be a topological space that is homotopy equivalent to a finite CW-complex. Then for any self-homeomorphism f of X we have

$$\chi(M(X,f)) = 0.$$

[763]These numbers are named after the Italian mathematician Enrico Betti (1823-1892)

`http://de.wikipedia.org/wiki/Enrico_Betti`

who had studied an early version of homology groups.

40.2. **Properties of the Euler characteristic.** The Euler characteristic is an invariant which "sees less" than the homology groups. On the other hand we will now see that it behaves better than the homology groups under several natural operations.

The following lemma makes it possible to determine the Euler characteristic of a CW-complex from suitable decompositions.

Lemma 40.5. *Let $X = Y \cup Z$ be a decomposition of a finite CW-complex X into two subcomplexes Y and Z. Then the following equality holds*

$$\chi(X) \;=\; \chi(Y) + \chi(Z) - \chi(Y \cap Z).$$

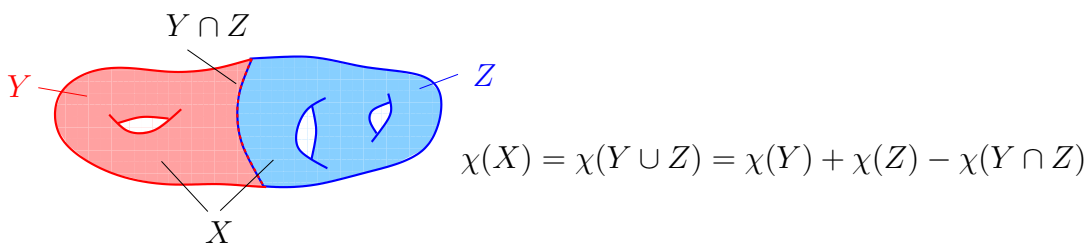


FIGURE 592.

Proof. We give two proofs for the lemma:

(1) Given $n \in \mathbb{N}_0$ and given a subset W we denote by $n(W)$ the number of open n-cells that are contained in W. In our case we have

$$n(X) \;\underset{\uparrow}{=}\; n(Y) + n(Z) - n(Y \cap Z).$$

since every open n-cell of X lies in Y or Z, the n-cells that lie in $Y \cap Z$ get counted twice in $n(Y) + n(Z)$, so we have to subtract $n(Y \cap Z)$

By performing the alternating sum over all n we obtain immediately that

$$\chi(X) \;=\; \chi(Y) + \chi(Z) - \chi(Y \cap Z).$$

We have thus proved the desired equality.

(2) The lemma also follows from applying Lemma 40.4 and Proposition 40.1 to the long exact sequence of homology groups that we obtain by applying the Mayer-Vietoris Theorem for CW-complexes 33.11 to the decomposition $X = Y \cup Z$. □

Example. As usual, given $g \in \mathbb{N}_0$ and $n \in \mathbb{N}_0$ we denote by $\Sigma_{g,n}$ the surface Σ_g of genus g minus n open disks. Now we want to determine the Euler characteristic $\chi(\Sigma_{g,n})$. We could do so by using Propositions 40.1 and 35.10. But here we use an alternative approach. By Theorem 26.3 there exists a CW-structure on Σ_g such that $\Sigma_{g,n}$ and the closed disks that we remove are subcomplexes. It now follows that

$$2 - 2g \;\underset{\substack{\uparrow \\ \text{see page 966}}}{=}\; \chi(\Sigma_g) \;=\; \chi\Big(\Sigma_{g,n} \cup \bigcup_{i=1}^{n} \overline{B}^2\Big) \;\underset{\substack{\uparrow \\ \text{Lemma 40.5}}}{=}\; \chi(\Sigma_{g,n}) + \sum_{i=1}^{n} \chi(\overline{B}^2) - \sum_{i=1}^{n} \chi(\partial \overline{B}^2) \;\underset{\substack{\uparrow \\ \text{see page 966}}}{=}\; \chi(\Sigma_{g,n}) + n.$$

Thus we see that $\chi(\Sigma_{g,n}) = 2 - 2g - n$.

We record the above example in a lemma.

Lemma 40.6.

(1) *Let $g \in \mathbb{N}_0$ and $n \in \mathbb{N}_0$. If we denote by $\Sigma_{g,n}$ the surface Σ_g of genus g minus n open disks, then $\chi(\Sigma_{g,n}) = 2 - 2g - n$.*

(2) *Let Σ and Σ' be two compact orientable connected 2-dimensional manifolds. If Σ and Σ' have the same number of boundary components and if $\chi(\Sigma) = \chi(\Sigma')$, then Σ and Σ' are diffeomorphic.*

Proof.

(1) We proved this statement in the example preceding the lemma.

(2) This statement follows immediately from (1) and the classification of compact orientable connected 2-dimensional manifolds, see Theorem 14.15. □

We return to the ever-popular study of knots in S^3.

Definition. Let $K \subset S^3$ be a knot. By the Tubular Neighborhood Theorem 10.19 there exists an embedding $\Phi\colon \overline{B}^2 \times S^1 \to S^3$ with $\Phi(\{0\} \times S^1) = K$. We refer to

$$X_K \;:=\; S^3 \setminus \Phi(B^2 \times S^1)$$

as the *exterior of K*.

Lemma 40.7. *For any knot $K \subset S^3$ the following statements hold:*

(1) *The exterior X_K of the knot K is a compact orientable connected 3-dimensional manifold and the boundary ∂X_K is diffeomorphic to the torus.*

(2) *The diffeomorphism type of X_K as an oriented manifold does not depend on the choice of Φ.*

(3) *The exterior X_K is a deformation retract of the knot complement $S^3 \setminus K$.*

(4) *We have $\chi(X_K) = 0$.*

(5) *For every $n \in \mathbb{N}_0$ we have*[764]

$$H_n(S^3 \setminus K) \underset{\substack{\uparrow \\ \text{induced by the inclusion} \\ X_K \to S^3 \setminus K}}{\overset{\cong}{\leftarrow}} H_n(X_K) \;=\; \begin{cases} 0, & \text{if } n \geq 2, \\ \mathbb{Z} \cdot [\mu_K], & \text{if } n = 1, \\ \mathbb{Z}, & \text{if } n = 0. \end{cases}$$

where μ_K denotes a meridian of K.

Proof $(*)$. Let $K \subset S^3$ be a knot. We pick an embedding $\Phi\colon \overline{B}^2 \times S^1 \to S^3$ such that $\Phi(\{0\} \times S^1) = K$.

(1) This statement is basically a consequence of Proposition 10.1 and 3.24.

(2) This statement is an immediate consequence of Proposition 10.20.

[764] We gave an alternative calculation of these homology groups in Exercise 39.4.

(3) A deformation retraction from $S^3 \setminus K$ to X_K is given by the map

$$\begin{array}{rcl} (S^3 \setminus K) \times [0,1] & \to & X_K = S^3 \setminus \Phi(\overline{B}^2 \times S^1) \\ (x,t) & \mapsto & \begin{cases} x, & \text{if } x \in Y = S^3 \setminus \Phi(\overline{B}^2 \times S^1), \\ \Phi(((1-t)r+t)e^{i\alpha}, z), & \text{if } x = \Phi(re^{i\alpha}, z) \in \Phi(\overline{B}^2 \times S^1). \end{cases} \end{array}$$

It follows easily from Lemma 1.32 (2) and Proposition 10.2 that this map is indeed continuous.

(4) By Theorem 26.3 there exists a CW-structure for S^3 such that X_K and $\Phi(\overline{B}^2 \times S^1)$ are subcomplexes. We have

$$\underset{\substack{\uparrow \\ \text{see page 966}}}{0 =} \chi(S^3) = \chi\big(X_K \cup \Phi(\overline{B}^2 \times S^1)\big) \underset{\substack{\uparrow \\ \text{Lemma 40.5}}}{=} \chi(X_K) + \chi\big(\overline{B}^2 \times S^1\big) - \chi\big(\partial\overline{B}^2 \times S^1\big) \underset{\substack{\uparrow \\ \text{see page 966}}}{=} \chi(X_K).$$

(5) By Corollary 30.8, Lemma 9.10 and by (3) we know that the inclusion $X_K \to S^3 \setminus K$ induces an isomorphism on all homology groups. Furthermore, together with Lemma 33.15 we already know that $H_0(X_K) = \mathbb{Z}$ and that $H_1(X_K) = \mathbb{Z} \cdot [\mu_K]$. Since X_K is a compact, oriented n-dimensional manifold with non-empty boundary it follows from Proposition 39.11 that $H_2(X_K)$ is a free abelian group and that $H_i(X_K) = 0$ for $i \geq 3$. Thus it now suffices to show that $\operatorname{rank}(H_2(X_K)) = 0$. But this follows immediately from $\chi(X_K) = 0$ and from the calculation of all the other homology groups of X_K. □

Lemma 40.8. *If M and N are two compact oriented connected n-dimensional manifolds, then*

$$\chi(M\#N) \;=\; \chi(M) + \chi(N) + \begin{cases} -2, & \textit{if } n \textit{ is even}, \\ 0, & \textit{if } n \textit{ is odd}. \end{cases}$$

Proof (∗). In this case we again have two slightly different proofs. First of all, the lemma follows quite easily from Proposition 40.1 together with the calculation of the homology groups of connected sum that we gave in Proposition 39.15. Alternatively we can argue directly using Lemma 40.5.

More precisely, we have

$$\chi(M \setminus B^n) \;\underset{\substack{\uparrow \\ \text{Lemma 40.5}}}{=}\; \chi(M) - \chi(\overline{B}^n) + \chi(S^{n-1}) \;\underset{\substack{\uparrow \\ \text{since } \chi(\overline{B}^n) = 1 \text{ and } \chi(S^{n-1}) = 1 + (-1)^{n-1}}}{=}\; \chi(M) + (-1)^{n-1}.$$

The same way we also see that $\chi(N \setminus B^n) = \chi(N) + (-1)^{n-1}$. It then follows, using the same type of arguments, that

$$\begin{array}{rcl} \chi(M\#N) & = & \chi(M \setminus B^n) + \chi(N \setminus B^n) - \chi(S^{n-1}) \\ & = & \chi(M) + (-1)^{n-1} + \chi(N) + (-1)^{n-1} - (1 + (-1)^{n-1}) \\ & = & \chi(M) + \chi(N) - 1 + (-1)^{n-1}. \end{array}$$

□

Examples.

(1) In Figure 224 we saw that the connected sum of two tori is the surface of genus two. By Lemma 40.8 we obtain that[765]

$$\chi(\text{surface of genus two}) \;=\; \underbrace{\chi(\text{torus})}_{=0} + \underbrace{\chi(\text{torus})}_{=0} - 2 \;=\; -2.$$

We had obtained the same result on page 966 using a different method.

(2) From the CW-structure for $\mathbb{R}\mathrm{P}^2$ that we gave in Figure 400 we read off that $\chi(\mathbb{R}\mathrm{P}^2) = 1$. It follows from Lemma 40.8 that for any $k \in \mathbb{N}$ we have

$$\chi(k \cdot \mathbb{R}\mathrm{P}^2) \;=\; 1 - k.$$

Using the same argument as in Lemma 40.6 one can also show that

$$\chi(k \cdot \mathbb{R}\mathrm{P}^2 \text{ minus } n \text{ open disks}) \;=\; 1 - k - n.$$

Let X and Y be two finite CW-complexes. On page 670 we introduced the product CW-structure which by Proposition 26.23 is indeed a CW-structure for the topological space $X \times Y$. The following lemma relates the Euler characteristics of X, Y and $X \times Y$ in an appealing way.

Lemma 40.9. *Let X and Y be two finite CW-complexes, then*

$$\chi(X \times Y) \;=\; \chi(X) \cdot \chi(Y).$$

Example. For any finite CW-complex X we have $\chi(S^1 \times X) = \chi(S^1) \cdot \chi(X) = 0$.

Proof. Let X and Y be two finite CW-complexes. Given $k \in \mathbb{N}_0$ we denote by c_k the number of k-cells of X and we denote by d_k the number of k-cells of Y.

We equip $X \times Y$ with the product CW-structure from page 670. By construction we have

$$\#n\text{-cells of } X \times Y \;=\; \sum_{k+l=n} \#k\text{-cells of } X \cdot \#l\text{-cells of } Y \;=\; \sum_{k+l=n} c_k \cdot d_l.$$

It follows that

$$\chi(X) \cdot \chi(Y) \;=\; \Big(\sum_k (-1)^k \cdot c_k\Big) \cdot \Big(\sum_l (-1)^l \cdot d_l\Big) \;=\; \sum_n (-1)^n \sum_{k+l=n} c_k \cdot d_l \;=\; \chi(X \times Y). \;\square$$

Now let $p\colon \widetilde{X} \to X$ be a k-fold covering of path-connected topological spaces. We saw in Corollary 7.15 that the induced map $p_*\colon \pi_1(\widetilde{X}) \to \pi_1(X)$ is a monomorphism and we saw in Lemma 7.16 (3) that $p_*(\pi_1(\widetilde{X}))$ is a subgroup of index k of $\pi_1(X)$. There is no analogous statement for homology groups. For example the projection map $p\colon S^2 \to S^2/\sim = \mathbb{R}\mathrm{P}^2$ is a 2-fold covering, but $H_2(S^2) = \mathbb{Z}$ and $H_2(\mathbb{R}\mathrm{P}^2) = 0$, which shows that the induced map on homology is in general not a monomorphism.

It is therefore perhaps surprising that we already saw in Proposition 26.25 that the Euler characteristic behaves well under finite coverings. For convenience we recall, a slightly

[765] How many arguments can you find in the lecture notes that show that the Euler characteristic of the torus is zero?

simplified version, of the statement of Proposition 26.25.

Proposition 26.25. *Let $p\colon \widetilde{Y} \to Y$ be a finite covering of a finite connected CW-complex Y. Then $\widetilde{Y}$ is also a finite CW-complex with*

$$\chi(\widetilde{Y}) \;=\; [\widetilde{Y} : Y] \cdot \chi(Y).$$

Example. We consider again the 2-fold covering $p\colon S^2 \to \mathbb{R}\mathrm{P}^2$. In this case we have by the calculation on page 846 or alternatively in Proposition 35.11 that

$$\begin{array}{rcl} H_0(S^2) & \cong & \mathbb{Z}, \\ H_1(S^2) & \cong & 0, \\ H_2(S^2) & \cong & \mathbb{Z}, \\ H_i(S^2) & \cong & 0, \text{ for } i \geq 3, \end{array} \quad \text{and} \quad \begin{array}{rcl} H_0(\mathbb{R}\mathrm{P}^2) & \cong & \mathbb{Z}, \\ H_1(\mathbb{R}\mathrm{P}^2) & \cong & \mathbb{Z}_2, \\ H_2(\mathbb{R}\mathrm{P}^2) & \cong & 0, \\ H_i(\mathbb{R}\mathrm{P}^2) & \cong & 0, \text{ for } i \geq 3. \end{array}$$

Thus we see that the homology groups are quite different. Nonetheless we observe that $\chi(S^2) = 2$ is indeed twice $\chi(\mathbb{R}\mathrm{P}^2) = 1$, as we had determined on page 966.

Now we can finally give an answer to Question 20.10, i.e. we can determine how the genus of a surface changes if we take finite covers. More precisely we have the following lemma.

Lemma 40.10. *Let Σ be the surface of genus g and let $p\colon \widetilde{\Sigma} \to \Sigma$ be a k-fold connected covering. Then*[766]

$$\textit{genus}(\widetilde{\Sigma}) \;=\; k \cdot (g-1) + 1.$$

Example. In Figure 347 we illustrate a 3-fold covering of the surface of genus 4 over the surface of genus 2.

Proof. We denote by $\widetilde{g}$ the genus of $\widetilde{\Sigma}$. The lemma follows immediately from the following two facts:

(1) By the remark on page 966 we have $\chi(\Sigma) = 2 - 2g$ and $\chi(\widetilde{\Sigma}) = 2 - 2\widetilde{g}$.
(2) By Proposition 26.25 we have $\chi(\widetilde{\Sigma}) = k \cdot \chi(\Sigma)$. □

Remark. In a similar vein one can now also answer Question 20.14. Recall that in that question we had considered a 6-fold covering $X \to B$ where B is the 2-dimensional sphere minus three open disks. On page 573 we saw that X has six boundary components. We leave it as an exercise to adapt the above arguments to determine the genus of X. (Hint: it is non-zero!)

In Question 14.5 we had asked whether the fundamental group of the surface of genus g is isomorphic to the free group F_{2g} on $2g$ generators. Now we can answer this question in the negative.

[766]Recall that by Theorem 14.10 there exists precisely one $\widetilde{g}$ such that the closed, oriented 2-dimensional manifold $\widetilde{\Sigma}$ is diffeomorphic to precisely the surface of genus $\widetilde{g}$.

Proposition 40.11. *If $g \geq 1$, then the group*

$$\pi_1(\textit{surface of genus } g) \;\cong\; \langle x_1, y_1, \ldots, x_g, y_g \,|\, [x_1, y_1] \cdot \cdots \cdot [x_g, y_g] \rangle$$

is not isomorphic to the free group F_{2g} on $2g$ generators.

Proof. Let Σ be a surface of genus $g \geq 1$. We write $\pi = \pi_1(\Sigma)$. Suppose that there exists an isomorphism $\varphi\colon \pi \to F$ where F is the free group on $2g$ generators. Let $\alpha\colon \pi \to \mathbb{Z}_k$ be an epimorphism for some $k \geq 2$.[767] We denote by $p\colon \widetilde{\Sigma} \to \Sigma$ the covering which satisfies $p_*(\pi_1(\widetilde{\Sigma})) = \ker(\alpha)$ which is given by Proposition 20.8. By Lemma 7.16 (3) this is a k-fold covering. We get the following commutative diagram:

$$\begin{tikzcd}
\pi \arrow[d, "\varphi", "\cong"'] & \ker(\alpha) \arrow[l] \arrow[r, "\cong", "\text{Lemma 40.10}"'] \arrow[d, "\varphi", "\cong"'] & \pi_1(\Sigma_{k\cdot(g-1)+1}) \arrow[r, "\text{abelianization}"] \arrow[d, "\cong"] \arrow[dr] & \mathbb{Z}^{2k(g-1)+2} \arrow[d, "\cong"] \\
F & \ker(\alpha \circ \varphi^{-1}) \arrow[l] \arrow[r, "\cong", "\text{Corollary 26.26}"'] & F_{k(2g-1)+1} \arrow[r, "\text{abelianization}"] & \mathbb{Z}^{k(2g-1)+1} \\
 & & & H_1(\Sigma_{k\cdot(g-1)+1}) \arrow[u, "\cong"']
\end{tikzcd}.$$

It follows from $k \geq 2$ that $2k(g-1)+2 \neq k(2g-1)+1$, hence the two groups on the right cannot by isomorphic. We have thus obtained a contradiction. $\square$

Remark. One can more generally ask, if X is a finite set, and if r is a non-trivial element in the free group $\langle X \rangle$ generated by X, can the group $\langle X \mid r \rangle$ be isomorphic to $\langle X \rangle$? It turns out that the answer is no, one approach to proving this purely group theoretic statement is as follows:

(1) A group π is called *Hopfian*[768] if every epimorphism $\varphi\colon \pi \to \pi$ is in fact a monomorphism.[769]
(2) Every finitely generated free group is Hopfian. This follows from the fact that free groups are residually finite and that finitely generated residually finite groups are Hopfian. We refer to [Cohe2, p. 11] and [Bog, Chapter 2.29] for details. See also [MKS, p. 109] for an alternative proof that free groups are Hopfian.
(3) Now suppose there does exist an isomorphism $\varphi\colon \langle X \,|\, r \rangle \to \langle X \rangle$. We denote by $\psi\colon \langle X \rangle \to \langle X \,|\, r \rangle$ the obvious epimorphism. Then $\varphi \circ \psi\colon \langle X \rangle \to \langle X \rangle$ is an epimorphism. By (2) it is an isomorphism, which implies in particular that ψ is a monomorphism. But r lies in the kernel of ψ, this is only possible if $r = e \in \langle X \rangle$.

At the end of this section we return to the study of lens spaces. Now we are finally in a position where we can calculate all the homology groups.

[767] Why does such an epimorphism exist?
[768] This notion is once again named after Heinz Hopf.
[769] For example Lemma 11.8 (5) says that every finitely generated free abelian group is Hopfian.

Lemma 40.12. *Let p, q be coprime natural numbers. For the corresponding lens space $L(p,q)$ we have*

$$H_n(L(p,q)) \cong \begin{cases} \mathbb{Z}, & \text{if } n = 0,3 \\ 0, & \text{if } n = 2 \text{ or } n > 3 \\ \mathbb{Z}_p, & \text{if } n = 1. \end{cases}$$

The calculation of this lemma is rather disappointing, it shows that homology groups cannot distinguish between two lens spaces of the form $L(p,q)$ and $L(p,r)$. In particular we have made no progress at all on Question 7.8.

Proof. It follows from Proposition 7.10 and the definition of a lens space that $L(p,q)$ is finitely covered by S^3. It follows from $\chi(S^3) = 0$ together with Proposition 26.25 that $\chi(L(p,q)) = 0$. We already know from Proposition 29.5 that $H_0(L(p,q)) \cong \mathbb{Z}$, from Corollary 38.6 that $H_1(L(p,q)) \cong \mathbb{Z}_p$ and from page 942 that $H_3(L(p,q)) \cong \mathbb{Z}$. Also we know from Proposition 35.6 that $H_n(L(p,q)) = 0$ for $n \geq 4$. So at the moment we are still missing $H_2(L(p,q))$. It now follows from Proposition 40.1 that

$$\operatorname{rank} H_2(L(p,q)) = \underbrace{\chi(L(p,q))}_{=0} - \underbrace{\operatorname{rank} H_0(L(p,q))}_{=1} + \underbrace{\operatorname{rank} H_1(L(p,q))}_{=0} + \underbrace{\operatorname{rank} H_3(L(p,q))}_{=1} = 0.$$

Furthermore we know from Proposition 39.17 that $H_2(L(p,q))$ is a free abelian group. Therefore we see that $H_2(L(p,q)) = 0$. □

40.3. **Groups acting on spheres.** We recall that by definition a group G acts *freely* on a topological space X if for any $g \neq e$ and any $x \in X$ we have $g \cdot x \neq x$. For example for each $k \in \mathbb{N}$ the action

$$\begin{array}{rcl} \mathbb{Z}_k \times S^1 & \to & S^1 \\ (l, z) & \mapsto & e^{2\pi i l/k} \cdot z \end{array}$$

is free. We can easily generalize this example. More precisely, let S^{2n-1} be an odd-dimensional sphere. We view S^{2n-1} as subset of $\mathbb{R}^{2n} = \mathbb{C}^n$. Then it is straightforward to show that

$$\begin{array}{rcl} \mathbb{Z}_k \times S^{2n-1} & \to & S^{2n-1} \\ (l, (z_1, \dots, z_n)) & \mapsto & (e^{2\pi i l/k} z_1, \dots, e^{2\pi i l/k} z_n) \end{array}$$

is a free and continuous action of $\mathbb{Z}_k$ on S^{2n-1}.

It is less clear what finite groups can act freely and continuously on even-dimensional spheres. The group $\mathbb{Z}_2 \cong \{\pm 1\}$ acts of course freely and continuously on any sphere. The following proposition says that $\mathbb{Z}_2$ is in fact the only finite non-trivial group that can act freely and continuously on an even-dimensional sphere. This proposition and the above example give a complete answer to Question 7.9.

Proposition 40.13. *If a finite group G acts freely and continuously on S^{2n}, then G is either trivial or $G \cong \mathbb{Z}_2$.*

Proof. Let G be a finite group that acts freely and continuously on S^{2n}. By Lemma 7.6 the action is also discrete. By Proposition 7.10 the projection map $S^{2n} \to S^{2n}/G$ is a covering of degree $|G|$. We obtain the equalities

$$\begin{array}{ccccc} 2 & = & \chi(S^{2n}) & = & |G| \cdot \chi(S^{2n}/G). \\ & \uparrow & & \uparrow & \\ & \text{see page 765} & & \text{Proposition 26.25} & \end{array}$$

If follows that $|G|$ divides two, i.e. $|G| = 1$ or $|G| = 2$. In first case the group G is the trivial group and in the second case we have $G \cong \mathbb{Z}_2$.[770] □

Example. Let Σ be the surface of genus four. By the remark on page 966 we know that $\chi(\Sigma) = -6$. The proof of Proposition 40.13 shows that the order of any finite group acting freely and continuously on Σ has to have an order that divides 6.

In Figure 593 we sketch a discrete and continuous action of the group $\mathbb{Z}_3$ on Σ. We leave it as an exercise to give a rigorous description of this action and to determine whether the groups $\mathbb{Z}_2$ and $\mathbb{Z}_6$ can act continuously and freely on Σ.

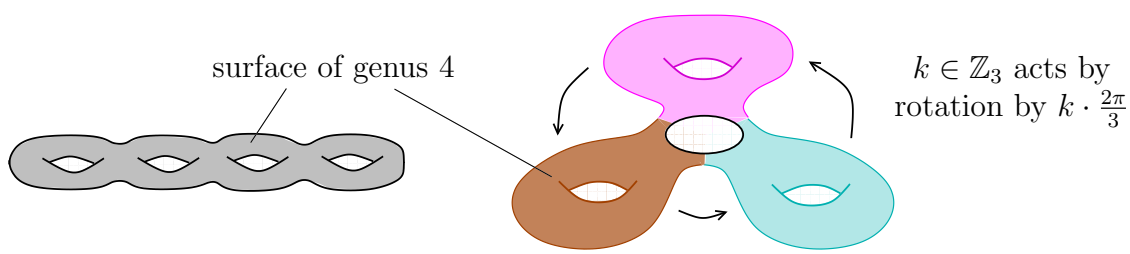

FIGURE 593.

40.4. **Curves on surfaces.** We start out with the following definition.

Definition. Let Σ be an oriented 2-dimensional manifold and let C and D be two closed oriented curves in Σ. We say C and D are *equivalent* if there exists an orientation-preserving self-diffeomorphism f of Σ which restricts to an orientation-preserving diffeomorphism $f\colon C \to D$.

In this section we want to give an easy and useful criterion for showing that two curves on a given 2-dimensional manifold are equivalent. The key to formulating the criterion is the following definition.

Definition. Let M be a compact orientable connected n-dimensional manifold and furthermore let $N \subset M$ be a proper submanifold of codimension one.

(1) We say N is *separating* if $M \setminus N$ is disconnected, otherwise we see that N is *non-separating*. (This definition is illustrated in Figure 594.)

[770] Why is every group with two elements isomorphic to $\mathbb{Z}_2$?

(2) If N is closed and separating, then we pick a tubular neighborhood $[-1,1]\times N$ as provided by the Tubular Neighborhood Theorem 10.19. We refer to $M\setminus((-1,1)\times N)$ as M *cut along* N. By Proposition 3.24 we know that M cut along N is again an n-dimensional manifold.[771] (This definition is illustrated in Figure 595.)

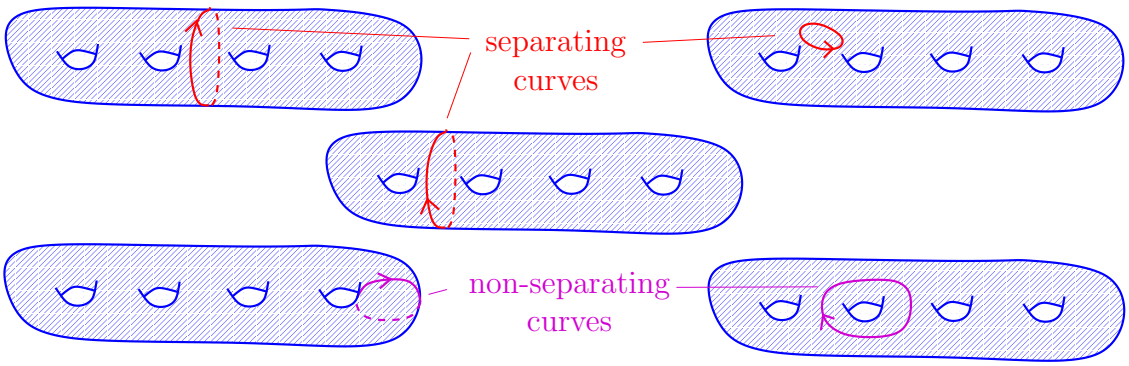

FIGURE 594.

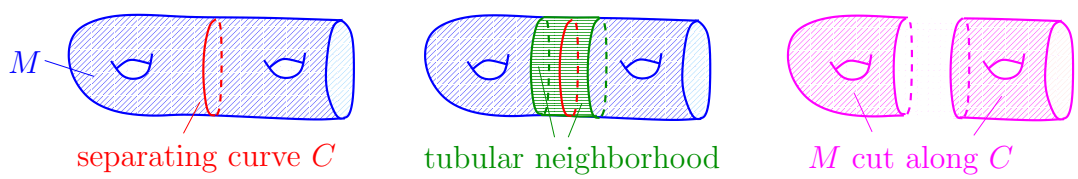

FIGURE 595.

It is clear that if two curves are equivalent, then either both are separating or both are non-separating. Furthermore if they are both separating, then the results of cutting the 2-dimensional manifold along the curves are diffeomorphic. The following proposition gives us the converse to this observation.

Proposition 40.14. *Let Σ a compact oriented connected 2-dimensional manifold and let C and D be two closed oriented curves in $\Sigma\setminus\partial\Sigma$.*

(1) *If C and D are non-separating, then C and D are equivalent.*
(2) *Suppose C and D are separating. If Σ cut along C is diffeomorphic to Σ cut along D, then C and D are equivalent.*

Example. It follows easily from Proposition 40.14 and Exercise 40.5 that any separating curve on the surface of genus four is equivalent to one of the separating curves shown in Figure 594. Furthermore, it follows from Proposition 40.14 that the two non-separating curves shown in Figure 594 are actually equivalent

[771] It follows from Proposition 10.20 that the definition of the diffeomorphism type of "M cut along N" does not depend on the choice of the tubular neighborhood.

Proof. We only prove statement (1). We leave it to the reader to make the minor adjustments that are needed to handle statement (2). Thus let Σ a compact oriented connected 2-dimensional manifold and let C and D be two closed oriented non-separating curves on Σ. We pick two tubular neighborhoods $[-1,1] \times C$ and $[-1,1] \times D$. We write $M := \Sigma \setminus (-1,1) \times C$ and we write $N := \Sigma \setminus (-1,1) \times D$. It follows from Proposition 3.24 that M and N are compact oriented connected 2-dimensional manifolds. Note that M and N have the same number of boundary components. Furthermore note that it follows easily from Lemma 40.5 that $\chi(M) = \chi(\Sigma) = \chi(N)$. Therefore we conclude from Lemma 40.6 that there exists an orientation-preserving diffeomorphism $\Phi\colon M \to N$. It follows from Corollary 14.16 that in fact we can find such an orientation-preserving diffeomorphism that has the extra property that $\Phi(\{\epsilon\} \times C) = \{\epsilon\} \times D$ for $\epsilon \in \{-1,1\}$. In fact, if one takes the orientation conventions into account one sees that Φ restricts to orientation-preserving diffeomorphisms $\Phi\colon \{\epsilon\} \times C \to \{\epsilon\} \times D$ for $\epsilon \in \{-1,1\}$.

Using Proposition 20.5 it is now straightforward to see that Φ extends to an orientation-preserving diffeomorphism $\Psi\colon \Sigma \to \Sigma$ that in turn restricts to an orientation-preserving diffeomorphism $C \to D$. □

We conclude this section with two corollaries to Proposition 40.14.

Corollary 40.15. *Let Σ be a compact 2-dimensional manifold and let C be a closed oriented curve on Σ. If C is non-separating, then C is not null-homotopic.*

Proof. Let Σ be a compact 2-dimensional manifold and let C be a closed oriented non-separating curve on Σ. By Theorem 14.14 we can assume that Σ is the surface of genus g, for some $g \in \mathbb{N}_0$, with some open disks removed. Since adding the disks does not change connectivity we can in fact assume that Σ is the surface of genus g. It follows from Exercise 40.6 that $g \geq 1$. It follows from the calculation of the fundamental group of the surface Σ of genus g, see e.g. Proposition 14.3, that Σ admits closed oriented non-separating curves that are not null-homotopic. By Proposition 40.14 this means that C is also not null-homotopic. □

Remark. What is the "right" proof for a statement is often a matter of taste. In this instance one could make the case that the results of Section 17 give the more natural proof of Corollary 40.15.

The following proposition might sound self-evident, but as we will see, the proof requires some serious input from our earlier work.

Proposition 40.16. *Let Σ be a compact orientable 2-dimensional manifold. Furthermore let $f\colon S^1 \to \Sigma$ be an embedding. If f is null-homotopic, then there exists an embedding $F\colon \overline{B}^2 \to \Sigma$ with $F|_{S^1} = f$.*

Sketch of proof. Let Σ be a compact orientable 2-dimensional manifold. Furthermore let $f\colon S^1 \to \Sigma$ be an embedding that is null-homotopic. We write $C = f(S^1)$. By Corollary 40.15 we know that C is separating. Let A and B be the two components of Σ cut

along C. The argument from page 433 shows that if neither A nor B is a disk, then C would represent a non-trivial element in $\pi_1(\Sigma)$. Thus by our hypothesis one of A or B is a disk. But this observation, together with Proposition 20.5, easily implies that there exists such an embedding F. □

40.5. **Graphs** (∗)**.** Recall that on page 645 we defined a topological graph to be a 1-dimensional CW-complex. Furthermore recall that we refer to the 0-cells as the vertices of the graph and we refer to the 1-cells as the edges of the graph. The Euler characteristic of a finite graph G is thus given by

$$\chi(G) \;=\; \#\text{vertices} - \#\text{edges}.$$

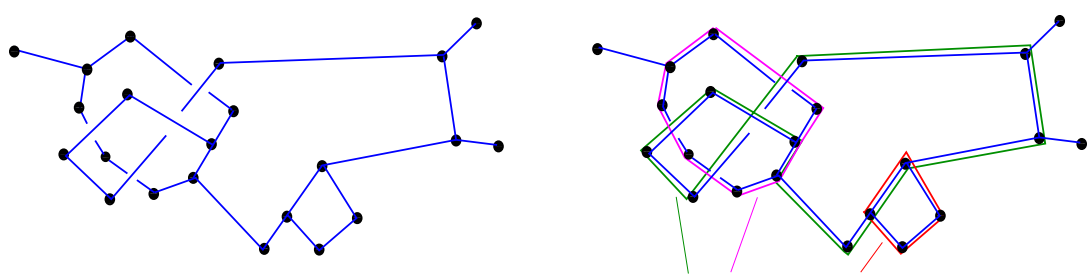
In particular this matches the original definition that we gave on page 318.

Using the results of this chapter we can now easily prove the following lemma:

Lemma 40.17. *Let G be a connected graph with v vertices and e edges. Then*

$$H_0(G) \cong \mathbb{Z}, \quad H_1(G) \cong \mathbb{Z}^{e-v+1} \quad \text{and} \quad H_i(G) = 0 \text{ for } i \geq 2.$$

Example. In Figure 596 we see a connected graph G with 22 vertices and 24 edges. It follows from Lemma 40.17 that its first homology group is isomorphic to $\mathbb{Z}^3$. In Figure 596 we sketched three cycles which represent a generating set for $H_1(G) \cong \mathbb{Z}^3$. But there are infinitely many other choices of generating sets.[772]



graph G with 22 vertices and 24 edges generating set for $H_1(G) \cong \mathbb{Z}^3$

FIGURE 596.

Proof. Let G be a connected graph with v vertices and e edges. Now that we have developed so many techniques for computing homology groups it is perhaps not surprising that we can provide three different proofs for the lemma.

(1) First of all, from Proposition 29.5 together with Proposition 26.11 (7) it follows immediately that $H_0(G) \cong \mathbb{Z}$. Furthermore, from Proposition 35.5 it follows that $H_i(G) = 0$ for $i \geq 2$ and that $H_1(G)$ is torsion-free.

[772] What are other examples of generating sets for $H_1(G)$?

From Proposition 40.1 we obtain that

$$\chi(X) \;=\; \sum_i (-1)^i \operatorname{rank}(H_i(X)).$$

Putting everything together we see that

$$1-\operatorname{rank}(H_1(G)) \;=\; \chi(X) \;=\; \#0\text{-cells} - \#1\text{-cells} \;=\; v-e.$$

Since $H_1(G)$ is torsion-free we obtain that $H_1(G) \cong \mathbb{Z}^{e-k+1}$.

(2) We can also modify the argument of (1) as follows: instead of calculating $H_1(G)$ using the Euler characteristic, we could also have determined that $H_1(G) \cong \mathbb{Z}^{e-k+1}$ by combining the calculation of the fundamental group in Lemma 12.5 with the isomorphism of the Hurewicz Theorem 38.5.

(3) An alternative proof for Lemma 40.17 is given as follows: we have

$$\begin{array}{ccccccc} \widetilde{H}_j(G) & \cong & \widetilde{H}_j(\text{wedge of } 1-\chi(G) \text{ circles}) & \cong & \bigoplus_{i=1}^{1-\chi(G)} \widetilde{H}_j(S^1) & \cong & \begin{cases} \mathbb{Z}^{1-\chi(G)}, & \text{if } j=1, \\ 0, & \text{otherwise.} \end{cases} \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{Proposition 9.21 (3) and Corollary 30.8} & & \text{Proposition34.8} & & \text{Proposition 31.3} & \end{array}$$

It is a matter of taste which of the three proof is the nicest. □

40.6. **The Lefschetz Fixed Point Theorem** (∗)**.** The following theorem was proved by Solomon Lefschetz in the 1920s.[773]

Theorem 40.18. (Lefschetz Fixed Point Theorem) *Let X be a finite CW-complex (e.g. a compact manifold) and let $f\colon X \to X$ be a map. If*[774]

$$\tau(f) \;:=\; \sum_{n\in\mathbb{N}_0} (-1)^n \cdot \operatorname{tr}(f_*\colon H_n(X) \to H_n(X)) \;\neq\; 0,$$

then f has a fixed point, i.e. there exists an $x \in X$ with $f(x) = x$.

A proof for the Lefschetz Fixed Point Theorem 40.18 is given in [Hat, Theorem 2.C.3] or in [BrownR]. In fact the book by Brown [BrownR] is completely dedicated to the proof of the Lefschetz Fixed Point Theorem 40.18 and its numerous applications and generalizations.

Corollary 40.19. *Let X be a finite connected CW-complex such that $H_n(X)$ is torsion for all $n \geq 1$. Then any map $f\colon X \to X$ has a fixed point.*

---

[773] Solomon Lefschetz (1884-1972) was an American mathematician.

[774] Let H be a finitely generated abelian group and let $\varphi\colon H \to H$ be a homomorphism. We write $\overline{H} := H/\text{torsion}$. The homomorphism φ defines a homomorphism $\overline{\varphi}\colon \overline{H} \to \overline{H}$. By the classification of finitely generated abelian groups, see Theorem 11.4, there exists an isomorphism $\psi\colon \overline{H} \xrightarrow{\cong} \mathbb{Z}^k$. We define $\operatorname{tr}(\varphi)$ to be the trace of the homomorphism $\mathbb{Z}^k \xrightarrow{\psi^{-1}} \overline{H} \xrightarrow{\overline{\varphi}} \overline{H} \xrightarrow{\psi} \mathbb{Z}^k$. As in linear algebra one can easily show that this definition does not depend on the choice of ψ.

Proof. Let X be a finite connected CW-complex such that $H_n(X)$ is torsion for all $i \geq n$. We calculate that

$$\tau(f) \;:=\; \mathrm{tr}(\underbrace{f_*\colon H_0(X) \to H_0(X)}_{\substack{f_* = \mathrm{id} \text{ by the discussion} \\ \text{on page 747}}}) \;+\; \sum_{n\in\mathbb{N}} (-1)^n \cdot \underbrace{\mathrm{tr}(f_*\colon H_n(X) \to H_n(X))}_{= 0, \text{ since } H_n(X) \text{ torsion}} \;=\; 1.$$

It follows from the Lefschetz Fixed Point Theorem 40.18 that f has a fixed point. □

Examples.

(1) If we apply Corollary 40.19 to $X = \overline{B}^n$, then we recover the Brouwer Fixed Point Theorem 31.7.
(2) In Proposition 35.11 we saw that the hypothesis of Corollary 40.19 are satisfied for even-dimensional real projective spaces $\mathbb{R}\mathrm{P}^{2n}$. Thus we see that every self-map $f\colon \mathbb{R}\mathrm{P}^{2n} \to \mathbb{R}\mathrm{P}^{2n}$ has a fixed point.[775]
(3) We consider the CW-complex S^n. Let $f\colon S^n \to S^n$ be a map. By the discussion on page 747 and the definition of the degree of f we have

$$\tau(f) \;=\; \tau(\mathrm{id}) = 1 + (-1)^n \cdot \deg(f).$$

The Lefschetz Fixed Point Theorem 40.18 thus says that if $\deg(f) \neq (-1)^{n+1}$, then f has a fixed point. Thus we see that Theorem 32.19 is a special case of the Lefschetz Fixed Point Theorem 40.18.

Exercises for Chapter 40.

Exercise 40.1. Show that every CW-structure for the torus with one 0-cell has precisely one 2-cell.

Exercise 40.2. Let $g \in \mathbb{N}_0$. By Proposition 14.6 the connected sum $F = \Sigma_g \# \mathbb{R}\mathrm{P}^2$ of the surface of genus g with the real projective plane is non-orientable. So according to Proposition 8.3 it admits a 2-fold covering $\widetilde{F} \to F$ that is orientable. Determine the genus of $\widetilde{F}$?
Note: we had raised this as a question on page 434.

Exercise 40.3. Let X be a topological space and let $f\colon X \to X$ be a homeomorphism. In Proposition 33.20 we showed that for any $n \in \mathbb{N}_0$ there exists a short exact sequence

$$0 \to \mathrm{coker}\big(H_n(X) \xrightarrow{f_*-\mathrm{id}} H_n(X)\big) \to H_n(M(X,f)) \to \ker\big(H_{n-1}(X) \xrightarrow{f_*-\mathrm{id}} H_{n-1}(X)\big) \to 0.$$

(a) Let $T = \mathbb{R}^2/\mathbb{Z}^2$ be the torus. Given $A \in \mathrm{SL}(2,\mathbb{Z})$ we consider the homeomorphism

$$\begin{aligned} f(A)\colon \mathbb{R}^2/\mathbb{Z}^2 &\to \mathbb{R}^2/\mathbb{Z}^2 \\ [v] &\mapsto [Av]. \end{aligned}$$

[775] What happens for odd-dimensional real projective spaces? For example, does there exists a self-map $\mathbb{R}\mathrm{P}^3 \to \mathbb{R}\mathrm{P}^3$ without fixed-points?

Determine the homology groups of $M(T, f(-\mathrm{id}))$.
Remark: You can use the fact that under the usual identification $H_1(T) = \mathbb{Z}^2$ the induced map $f(A)_*$ is given by multiplication by A.[776]

(b) Does there exist a matrix $A \in \mathrm{SL}(2, \mathbb{Z})$ such that $H_1(M(T, f(A))) \cong \mathbb{Z}$?

(c) Let X be a topological space that is homotopy equivalent to a finite CW-complex. Show that for any self-homeomorphism f of X we have

$$\chi(M(X, f)) \;=\; 0.$$

Exercise 40.4. For a topological space X and $n \in \mathbb{N}_0$ we denote by $b_n(X) \in \mathbb{N}_0 \cup \{\infty\}$ the rank of $H_n(X)$. Does there exist a topological space X such that $b_1(X) < \infty$ but such that for a *finite* cover $\widetilde{X}$ of X we have $b_1(\widetilde{X}) = \infty$?

Exercise 40.5. Given $g, n, \in \mathbb{N}_0$ we denote by $\Sigma_{g,n}$ the surface of genus g minus n open disks. Let $g, k, m, n \in \mathbb{N}_0$. Suppose there exists an embedding $\Sigma_{g,m} \to \Sigma_{k,n}$. Show that $g \leq k$.
Hint: use Proposition 3.24.

Exercise 40.6. Show that $\overline{B}^2$ and S^2 do not admit closed non-separating curves.
Hint: Given a closed curve C on $X = \overline{B}^2$ or $X = S^2$ consider the Euler characteristic of X cut along C.

Exercise 40.7. Let Σ be a 2-dimensional manifold. A *curve system* is a collection of disjoint curves (i.e. closed connected 1-dimensional manifolds) $C_1, \ldots, C_k$ on Σ with the following two properties:

(1) None of the C_i is the boundary of a disk on F.
(2) There is no annulus on F such that the boundary is the union of two curves.

In Figure 597 on the right we see a curve system on the surface of genus two consisting of three curves.

(a) Is there a curve system consisting of four curves on the surface of genus two?
(b) Given $g \in \mathbb{N}_0$, what is the maximal number of curves in a curve system on the surface of genus g?

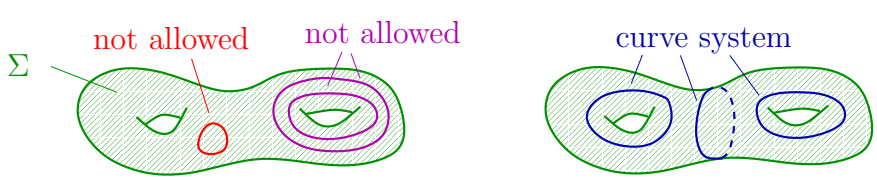


FIGURE 597.

[776] Why does this hold?

Exercise 40.8. Let $\varphi\colon A \to B$ be a homomorphism between free groups of the same finite rank. Suppose that $\varphi_*\colon H_1(A) \to H_1(B)$ is an isomorphism. Show that φ is a monomorphism.
Hint: Use that finitely generated free groups are Hopfian. I.e. given any finitely generated free group F any epimorphism $\varphi\colon \pi \to \pi$ is in fact a monomorphism.

41. Applications of the Euler characteristic (∗)

In this chapter we show that the fairly simple concept of the Euler characteristic can be used to give answers to several questions about 3-dimensional objects.

41.1. **Building a leather football.** In this section we will discuss the shapes of footballs and the platonic solids. The results of this section will not be used later on and we will present some of the material in a slightly informal, somewhat less rigorous style.

First we recall that an n-gon on the 2-dimensional sphere S^2 is called *regular* if the isometry group of the sphere acts transitively on the set of vertices and the set of faces of the n-gon. In particular all interior angles are the same. For example the classical leather football, see Figure 598, is made out of regular pentagons and hexagons.

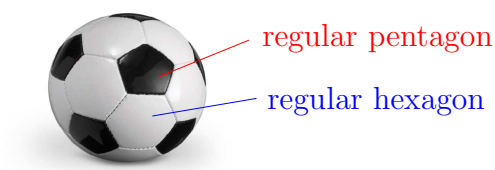

Figure 598.

Now we want to determine how many pentagons and hexagons are required to make a football. So suppose a football is made out of p spherical regular pentagons and h spherical regular hexagons where the vertices of the pentagons are precisely the vertices of hexagons. This endows S^2 with a CW-structure. We first note that each 1-cell bounds two 2-cells. Furthermore, elementary spherical geometry, see e.g. [Bon, p. 53] or [Fen, p. 260], says that the interior angle of a spherical pentagon and a spherical hexagon are larger than the corresponding Euclidean angles. Therefore we see that that interior angles are larger than[777] $\pi - \frac{2\pi}{5} = \frac{3}{5}\pi$. So at any vertex there are not more than three hexagons and pentagons that meet, which of course implies that there are precisely three hexagons and pentagons that meet. Therefore we see that

$$\begin{aligned} \#\text{2-cells} &= p + h \\ \#\text{1-cells} &= \tfrac{1}{2}(5p + 6h) \\ \#\text{0-cells} &= \tfrac{1}{3}(5p + 6h). \end{aligned}$$

By Proposition 40.1 and the above calculation of the Euler characteristic of S^2 we now have

$$2 \;=\; \chi(S^2) \;=\; \sum_{n=0}^{2}(-1)^n \cdot \#n\text{-cells} \;=\; \tfrac{1}{3}(5p+6h) - \tfrac{1}{2}(5p+6h) + (p+h) \;=\; \tfrac{1}{6}p.$$

Thus we see that a football has to have precisely 12 pentagons. On the other hand, the number of hexagons is not fixed. For example, the standard football has 20 hexagons, as

[777] Where does that formula come from?

pictured in Figure 599 on the left. But in principle one could also build a football with zero hexagons, see Figure 600 one the right, and one obtains a spherical dodecahedron. One could also build with many hexagons, but they would be much less round since they would have bigger flat parts.

The 1-skeleton of this CW-structure were in fact already "invented by nature", more precisely, there exists a molecule, called the Buckminsterfullerene C_{60}, built out of 60 carbon atoms, which has exactly the same shape as a football. More information can be found at

`https://en.wikipedia.org/wiki/Buckminsterfullerene`

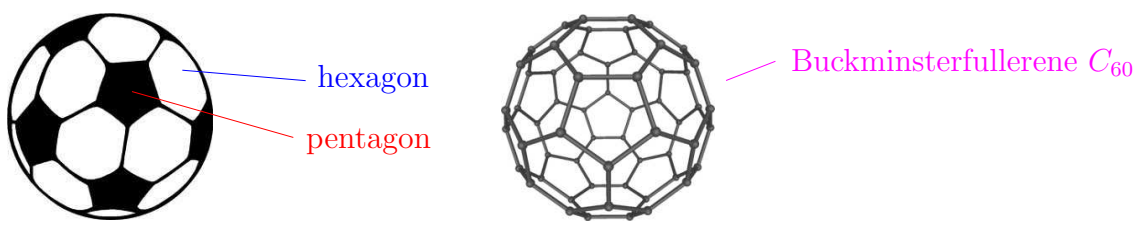

FIGURE 599.

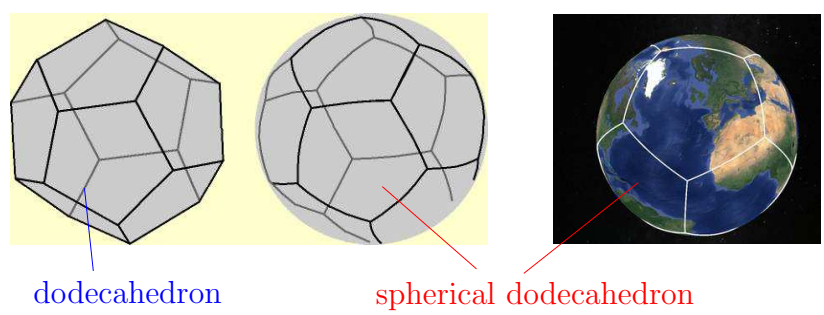

FIGURE 600.

41.2. **Platonic solids.** Recall that on page 78 we defined the *convex hull* of a subset $S \subset \mathbb{R}^n$ as the intersection of all convex subsets of $\mathbb{R}^k$ that contain S. Since the intersection of convex sets is again convex we see that the convex hull of S is a convex subset of $\mathbb{R}^k$.

Definition.

(1) A *convex polyhedron* is the convex hull of finitely many points in $\mathbb{R}^k$.[778] [779][780]
(2) The *dimension of a convex polyhedron* is defined as the minimal dimension of an affine subspace of $\mathbb{R}^k$ that contains the convex polyhedron.

We leave the proof of the following lemma as an exercise to the reader.

Lemma 41.1. *If P is a convex polyhedron in $\mathbb{R}^k$, then there exists a unique finite set V such that P is the convex hull of V, but such that for any proper subset W of V, P is not the convex hull of W.*

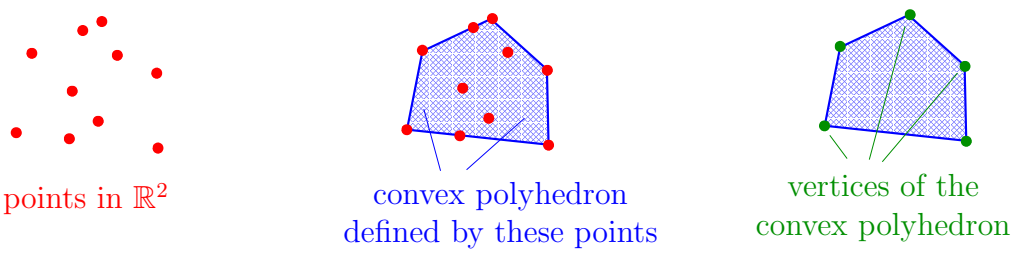

FIGURE 601. Illustration of Lemma 41.1.

Definition. Let P be a convex polyhedron in $\mathbb{R}^k$.

(1) We refer to the finite set of Lemma 41.1 as the *vertices of the convex polyhedron* P.
(2) If P is a k-dimensional convex polyhedron, then an *edge* of the convex polyhedron is the convex hull of two vertices that has the property that it lies on ∂P.
(3) If P is a k-dimensional convex polyhedron, then an *m-dimensional face* of the convex polyhedron is the convex hull of m vertices that has the property that it lies on ∂P. (In particular, by definition a 1-dimensional face is exactly the same as an edge.)
(4) An edge is a 1-dimensional face and sometimes we refer to a 2-dimensional face just as a face, without specifying the dimension.
(5) The *valence* of a vertex is defined as the number of edges that contain the vertex.
(6) Two convex polyhedra P and Q in $\mathbb{R}^k$ are called *equivalent* if there exists an $r > 0$, a point $v \in \mathbb{R}^k$, and an orthogonal matrix $A \in \mathrm{O}(k)$ with $P = A \cdot (r \cdot Q) + v$.

Example. The notion of a vertex, an edge, a face and the valence of a vertex are illustrated in Figure 602.

[778] It is an amusing little exercise to show that this notion of a convex polyhedron agrees with the notion that we had originally defined on page 703.

[779] In the literature a convex polyhedron is often also called a polytope.

[780] Recall that we saw on page 79 that the convex hull of points $P_1, \dots, P_n \in \mathbb{R}^k$ is given by the set

$$\Big\{ \sum_{i=1}^n t_i P_i \,\Big|\, t_1, \dots, t_i \in \mathbb{R}_{\geq 0} \text{ and } \sum_{i=1}^n t_n = 1 \Big\}.$$

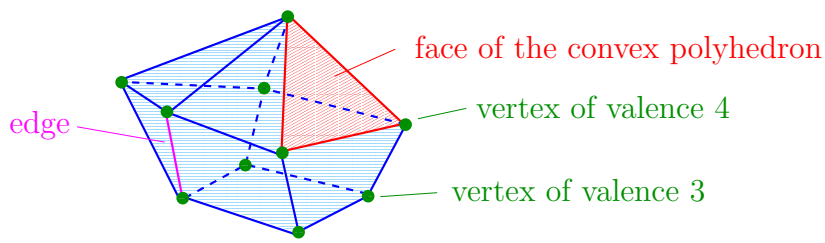

FIGURE 602.

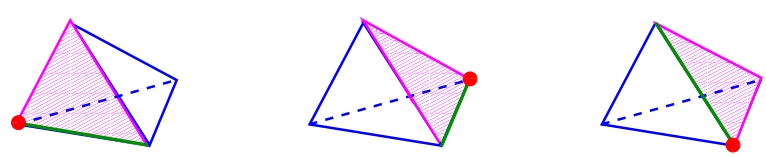
We move on to the next definition.

Definition. Let P be a convex m-dimensional polyhedron in $\mathbb{R}^k$.

(1) A *rotational symmetry* of P in $\mathbb{R}^k$ is a matrix $A \in \mathrm{O}(k)$ such that $A \cdot P = P$. The *rotational symmetry group* $S(P) \subset \mathrm{O}(k)$ is defined as the group of all rotational symmetries of P.
(2) A *flag* of P is a sequence $F_0 \subset F_1 \dots F_{m-1}$ of faces of P such that each F_i is i-dimensional.
(3) A convex polyhedron P is called *regular* if the rotational symmetry group $S(P)$ acts transitively on the set of flags of P.



three flags in the regular tetrahedron T

FIGURE 603.

Example.

(1) Let T be the 3-dimensional polyhedron in $\mathbb{R}^3$ that has four 2-dimensional faces, each of which is an equilateral triangle. We show T together with three flags in Figure 603. Some elementary geometry shows that T is, up to equivalence, uniquely defined and it is regular. We refer to T as the *regular tetrahedron*.
(2) The standard n-simplex Δ^n is an n-dimensional convex polyhedron in $\mathbb{R}^{n+1}$ with vertex set $\{(1,0,\dots,0),(0,1,0,\dots,0),\dots,(0,\dots,0,1)\}$. Each vertex has valence n. In this case the above definition of a face agrees with the definition that we gave on page 935. It is straightforward to see that Δ^n is regular.
(3) Let $n \in \mathbb{N}_{\geq 3}$ and $r > 0$. The convex hull of the points $r, re^{2\pi i/n}, \dots, re^{2\pi i(n-1)/n}$ in $\mathbb{C} = \mathbb{R}^2$ is a regular convex polyhedron with vertices $r, re^{2\pi i/n}, \dots, re^{2\pi i(n-1)/n}$, where each vertex has valence 2. We leave it as an exercise to show that, up to

equivalence, these are all regular 2-dimensional convex polyhedra in $\mathbb{R}^2$. We refer to Figure 604 for an illustration.

(4) The convex polyhedron spanned by $\{(\pm 1, 0, 0), (0, \pm 1, 0), (0, 0, \pm 1)\}$ is a regular 3-dimensional convex polyhedron where each vertex has valence 4. This convex polyhedron is usually called the *regular octahedron*. We refer to Figure 604 for an illustration.

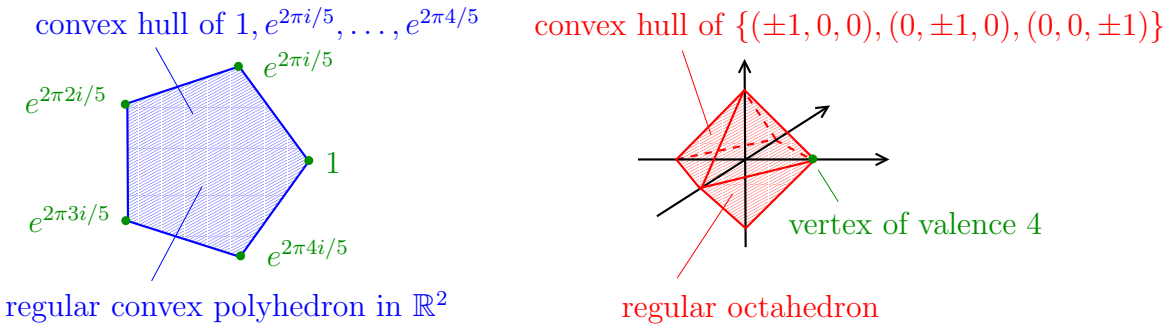


FIGURE 604.

(5) We consider the cube $[-1, 1]^3 \subset \mathbb{R}^3$. In [Arm, p. 38] it is shown that $S([-1, 1]^3)$ is isomorphic to S_4. More precisely, we denote by D the set of the diagonals in the cube, i.e. the segments in $\mathbb{R}^3$ spanned by opposite vertices of the cube. Note that D has precisely four elements. We refer to Figure 605 for an illustration. Then the map

$$\begin{array}{rcl} S([-1,1]^3) & \to & S_4 \cong \text{permutation group of } D \\ A & \mapsto & \left(\begin{array}{ccc} D & \to & D \\ d & \mapsto & A \cdot d \end{array} \right) \end{array}$$

is shown in [Arm, p. 38] to be an isomorphism.[781] It is clear that the cube is a regular convex polyhedron. Since it has six sides it is in our context also referred to as *regular hexahedron*.

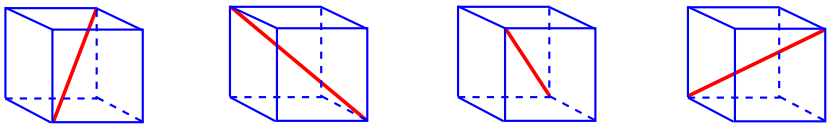

FIGURE 605. The four diagonals in a cube.

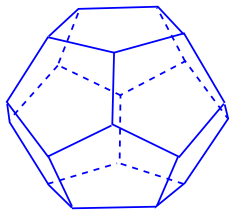
(6) Finally we consider the regular dodecahedron D shown in Figure 606.[782] We can inscribe five cubes $C_1, \ldots, C_5$ into the regular dodecahedron. Then the map

$$\begin{array}{rcl} S(D) & \to & A_5 \cong \text{positive permutations of } \{C_1, \ldots, C_5\} \\ A & \mapsto & (C_i \mapsto A \cdot C_i) \end{array}$$

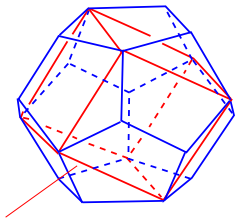
[781] It is a good exercise to verify this statement.

[782] The fact that a regular dodecahedron really exists is shown rigorously in [Cox, Section 6.7].

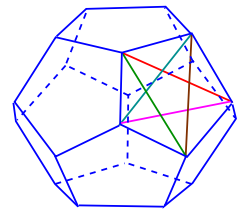
is shown in [Arm, p. 40] to be an isomorphism.



regular dodecahedron



cube inscribed into the regular dodecahedron



the five diagonals of a face correspond precisely to one inscribed cube

FIGURE 606.

The following definition is one of the oldest in the history of mathematics.

Definition. A *Platonic solid* is a regular 3-dimensional convex polyhedron in $\mathbb{R}^3$.

Theorem 41.2. *Up to rotation and stretching the only regular convex 3-dimensional polyhedra in $\mathbb{R}^3$ are the platonic solids illustrated in Figure 607.*[783] *They have the following types of faces and valences and they have the following rotational symmetry groups:*

	tetrahedron	*hexahedron*	*octahedron*	*dodecahedron*	*icosahedron*
number of faces	4	6	8	12	20

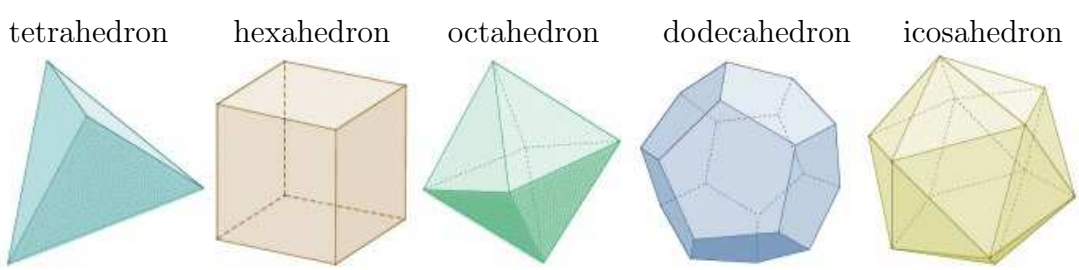

FIGURE 607. The five platonic solids.

[783] A precise definition of the platonic solids in Figure 607 is given in [Cox, Section 1.2].

Sketch of proof. We will not provide a full proof for the theorem. We refer to [Cox, Section 6.7] for a full proof of the first three rows and we refer to [Arm, p. 40] or alternatively to [Aa, Chapter 5.5] for a proof of the statement regarding the rotational symmetry groups.[784] But we will show that any platonic solid fits into the table of the theorem.

So let P be a regular convex 3-dimensional polyhedron in $\mathbb{R}^3$. We make the following observations:

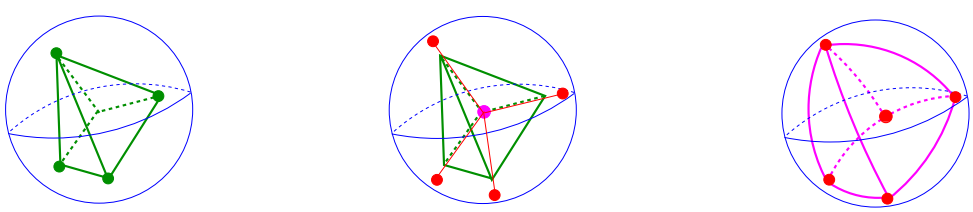
(1) It follows easily from the definition of a regular polyhedron that there exists an m such that each face of P is a regular m-gon.
(2) The number of faces that meet a vertex is the same for every vertex and it is at least three.

The following claim tells us the possible values for m and the number of faces that meet at a vertex.

Claim.

possible values for m	3	4	5
faces that meet at a vertex	$3, 4, 5$	4	3

First note that after a translation we can assume that the sum of all vertices is in the origin. Next we shrink the convex polyhedron so that it fits into the sphere S^2. Then we consider the projection of the vertices and edges of the convex polyhedron onto the sphere, see Figure 608. Recall that the spherical interior angle of a regular m-gon is greater than the Euclidean angle of a regular m-gon. So it follows that in our case the interior angle is greater than the angle of a regular m-gon in $\mathbb{R}^3$, i.e. it is greater than $\pi - \frac{2\pi}{m}$. Since at any vertex at least three faces meet we obtain the restriction that $3(\pi - \frac{2\pi}{m}) < 2\pi$. It is now straightforward to see that we obtain the stated table. This concludes the proof of the claim.



embed polyhedron in the 3-ball | projection of vertices onto the sphere | projection of edges onto the sphere

FIGURE 608.

We now treat the cases $m = 3, 4, 5$ separately. First we first consider the case $m = 3$, i.e. all the faces of the convex polyhedron are equilateral triangles. Using Proposition 1.47 (2)

[784]We had sketched the proofs for the regular hexahedron and the regular dodecahedron above.

one can easily show that P admits a CW-structure such that

$$\begin{array}{rcl} \#\text{ of 0-cells} &=& \#\text{ of vertices,} \\ \#\text{ of 1-cells} &=& \#\text{ of edges,} \\ \#\text{ of 2-cells} &=& \#\text{ of faces,} \\ \#\text{ of 3-cells} &=& 1. \end{array}$$

Let us first consider the case that three triangles meet at a vertex. Then we have

$$\#2\text{-cells} = k, \quad \#1\text{-cells} = \tfrac{1}{2}\cdot 3k \quad \text{and} \quad \#0\text{-cells} = \tfrac{1}{3}\cdot 3k.$$

Since the Euler characteristic of S^2 equals two we get

$$2 = \chi(S^2) = \sum_{n=0}^{2}(-1)^n\cdot \#n\text{-cells} = k - \tfrac{3}{2}k + k = \tfrac{1}{2}k.$$

It follows that $k = 4$. Almost the same calculation shows that if four triangles meet at a vertex, then $k - \frac{3}{2}k + \frac{3}{4}k = 2$, i.e. $k = 8$. Finally by the above claim it remains to consider the case that five triangles meet at a vertex. In this case we see that $k - \frac{3}{2}k + \frac{3}{5}k = 2$, i.e. $k = 20$.

Next we consider the case $m = 4$, i.e. each face is a square. The same argument as above shows that the valence of a vertex can only be three and the same calculation shows that there have to be precisely six faces. Finally if $m = 5$, i.e. if each face is a regular pentagon, then as above we see that the valence of a vertex can only be three and that there have to be precisely twelve faces. □

On page 989 we had just seen that there exist infinitely many equivalence classes of regular convex polyhedra in $\mathbb{R}^2$. On the other hand we have just seen in Theorem 41.2 that in $\mathbb{R}^3$ there are only finitely many, namely precisely five equivalence classes of regular convex polyhedra in $\mathbb{R}^3$. This begs the question, what is the number in higher dimensions? It turns out that in $\mathbb{R}^4$ there are six equivalence classes of regular convex polyhedra, whereas in all higher dimensions there are only three equivalence classes of convex polyhedra. A nice exposition of these facts is given on the following website:

`http://math.ucr.edu/home/baez/platonic.html`

41.3. **Homology spheres.**

Definition. We say that an n-dimensional topological manifold X is a *homology n-sphere* if for any $k \in \mathbb{N}_0$ we have $H_k(X) \cong H_k(S^n)$.

It follows from the classification of 1-dimensional topological manifolds that we had stated in Proposition 3.49 and Theorem 14.9 and the calculation of homology groups in Proposition 35.10 that for $n = 1, 2$ every homology n-sphere is homeomorphic to the standard sphere S^n. In 1900 Henri Poincaré[785] claimed that the same also holds for $n = 3$, i.e he claimed that every homology 3-sphere is in fact homeomorphic to S^3. Shortly

[785]Henri Poincaré (1854-1912) was a French mathematician. He can be viewed as the "father of algebraic topology", he first introduced the fundamental group and the homology groups of topological spaces. We

afterwards, in 1904, Henri Poincaré himself found a counterexample to this claim. More precisely, he proved the following proposition.

Proposition 41.3. *There exists a* 3*-dimensional manifold M that is a homology* 3*-sphere, but such that $\pi_1(M)$ is a non-trivial group.*

After proving Proposition 41.3 Henri Poincaré formulated the following conjecture.

Conjecture 41.4. (Poincaré Conjecture) *If M is a topological homology 3- sphere that is simply connected, then M is homeomorphic to S^3.*

As we had discussed in Section 28.6, this conjecture was solved almost a 100 years later by Grigori Perelman [Per1, Per2, Per3, MTi].

Nowadays there are many ways to prove Proposition 41.3. In the following we will give Poincaré's example of such a manifold.[786]

In Theorem 41.2 we saw that we can view A_5 as a subgroup of SO(3). In Lemma 37.1 we gave an explicit group homomorphism $q\colon S^3 = \mathrm{SU}(2) \to \mathrm{SO}(3)$. It is a consequence of Theorem 37.2 (1) that q is an epimorphism and that the kernel of q is given by $\pm\,\mathrm{id}$. We write $\Gamma := q^{-1}(A_5)$. Since A_5 has $\frac{1}{2}5! = 60$ elements and since q has a kernel with two elements we see that Γ is a group with 120 elements.

Proposition 41.5. *The topological space $M := S^3/\Gamma$ is a homology 3-sphere with non-trivial fundamental group.*

The manifold M is called the *Poincaré homology sphere*. It was initially discovered by Henri Poincaré in 1904 by a different construction. The Poincaré homology sphere is ubiquitous in topology and can be described in many different ways. We refer to [KSc] for altogether eight different ways to construct the Poincaré homology sphere.

In the proof of Proposition 41.5 we will make use of the following lemma.

Lemma 41.6. *Let M be an orientable closed 3-dimensional manifold that is finitely covered by S^3. If $H_1(M) = 0$, then M is a homology 3-sphere.*

As we will see, the proof of Lemma 41.6 is almost entirely the same as the proof of Lemma 40.12.

Proof. Let M be an orientable closed 3-dimensional manifold that admits a k-fold covering $p\colon S^3 \to M$. Suppose that $H_1(M) = 0$. By Proposition 39.5 it remains to show that

had encountered Henri Poincaré before, the disk model $\mathbb{D}$ for hyperbolic space goes back to Poincaré and it is often called the "Poincaré model of hyperbolic space".

[786]In Exercise 39.3 we saw that if we glue two knot complements to one another in an appropriate way, then we obtain a homology 3-sphere. To obtain a proof of Proposition 41.3 one still needs to show that with that construction one gets a manifold that is not diffeomorphic to S^3. For example one can show that if one glues two non-trivial knots to one another, then the fundamental group is always non-trivial. This statement is in turn a consequence of the "Loop Theorem" [Pap] in 3-manifold topology, together with basic facts in group theory [Ser, Theorem 1, p.3].

$H_2(M) = 0$. By Proposition 39.17 we know that $H_2(M)$ is a free abelian group. So it suffices to show that $b_2(M) = 0$. We have

$$\begin{array}{ccccccc} b_2(M) & = & \chi(M) & = & \frac{1}{k} \cdot \chi(S^3) & = & 0. \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{since } b_0(M) = b_3(M) = 1 & & \text{Proposition 26.25} & & \text{page 966} & \\ & \text{and } b_1(M) = 0 & & & & & \end{array}$$

□

Now we can provide the proof of Proposition 41.5.

Proof of Proposition 41.5. It follows from Proposition 3.25 that $M := S^3/\Gamma$ is a 3-dimensional manifold and it follows from Proposition 5.14 and Theorem 7.17 that $\pi_1(M) \cong \Gamma$.

Now we will show the slightly weaker statement that M or a 2-fold cover of M is a homology sphere. The fact that M is indeed a homology sphere is proved in [Bre, p. 354] or alternatively in [Toen, p. 133]. By Lemma 41.6 it suffices to prove the following claim.

Claim. We either have $H_1(M) = 0$ or there exists a 2-fold cover M' of M with $H_1(M') = 0$.

By the Hurewicz Theorem 38.5 it suffices to show that the abelianization of Γ is trivial. Since Γ is a finitely generated group this is equivalent to showing that Γ does not admit an epimorphism onto a non-trivial abelian group. By construction the group Γ fits into a short exact sequence

$$0 \to \mathbb{Z}_2 \xrightarrow{\rho} \Gamma \to A_5 \to 0.$$

By Proposition 13.10 we get an induced exact sequence

$$\mathbb{Z}_2 \xrightarrow{\rho} \Gamma_{\text{ab}} \to (A_5)_{\text{ab}} \to 0.$$

From the algebra course we know that the abelianization of A_5 is trivial. This means there are now two possibilities:

(1) Either $\Gamma_{\text{ab}} = 0$, in which case we are done.
(2) Or the map $\mathbb{Z}_2 \xrightarrow{\rho} \Gamma_{\text{ab}}$ is an isomorphism.[787] In this case the map $\Gamma \to \Gamma_{\text{ab}} \xrightarrow{\rho^{-1}} \mathbb{Z}_2$ is a splitting of $\rho\colon \mathbb{Z}_2 \to \Gamma$. The argument of Lemma 33.2 shows that this implies that $\Gamma \cong \mathbb{Z}_2 \times A_5$. In particular A_5 is a subgroup of $\pi_1(M) = \Gamma$ of index two. By Proposition 20.8 there exists a 2-fold covering M' of M with fundamental group A_5. But then $H_1(M') = (A_5)_{\text{ab}} = 0$.

This concludes the proof of the claim. □

41.4. **Planar graphs.** We recall several definitions that we had made along the way:

(1) On page 133 we defined an *abstract graph* G as a triple (V, E, φ) where V is a non-empty set, E is a set and φ is a map

$$\varphi\colon E \to \{\text{subsets of } V \text{ with one or two elements}\}.$$

[787] In fact this case does not occur, see e.g. [KSc] for details. But I don't know a quick argument which proves that $\Gamma_{\text{ab}} = 0$.

The elements of V are called *vertices of* G and the elements of E are called the *edges of* G.

(2) On page 645 we defined a topological graph to be a one-dimensional CW-complex.
   (a) We refer to the 0-cells as the *vertices* and the 1-cells as the *edges* of the topological graph.
   (b) Given a topological the *underlying abstract graph* is defined as the abstract graph $(V, E, \varphi\colon V \to E)$ given by setting V to the be set vertices and E the set of edges and given $e \in E$ we define $\varphi(e)$ to be the vertices that lie on e.

Examples.

(1) For $n \in \mathbb{N}$ we define the *complete graph* K_n as the abstract graph with vertex set $V = \{v_1, \ldots, v_n\}$ and edge set $E = \{\{v_i, v_j\} \mid i, j \in \{1, \ldots, n\} \text{ with } i \neq j\}$. Furthermore we define $\varphi\colon E \to V$ via $\varphi(e) = e$. Put differently, the complete graph K_n has n vertices and each vertex is connected to any other vertex by precisely one edge. In Figure 610 we show topological realizations of the complete graphs K_1, K_2, K_3, K_4 and K_5.

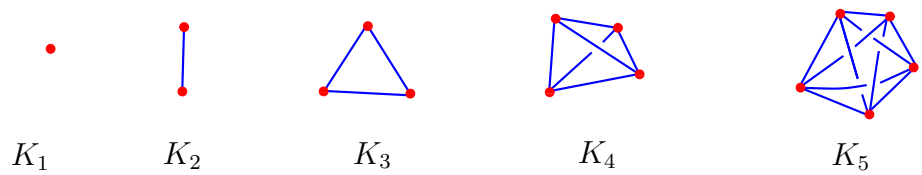


FIGURE 609.

(2) For $m, n \in \mathbb{N}$ we define the *complete bipartite graph* $K_{m,n}$ as the abstract graph which is defined by the vertex set $V = \{x_1, \ldots, x_m\} \cup \{y_1, \ldots, y_n\}$, the edge set $E = \{\{x_i, y_j\} \mid i \in \{1, \ldots, m\} \text{ and } j \in \{1, \ldots, n\}\}$ and the map $\varphi\colon E \to V$ via $\varphi(e) = e$. Put differently, the complete bipartite graph $K_{m,n}$ consists of m "red-colored" vertices, n "green-colored" vertices and each "red-colored" vertex is connected to any "green-colored" vertex by precisely one edge. In Figure 610 we show topological realizations of the complete bipartite graphs $K_{2,3}$, $K_{1,5}$ and $K_{3,3}$.

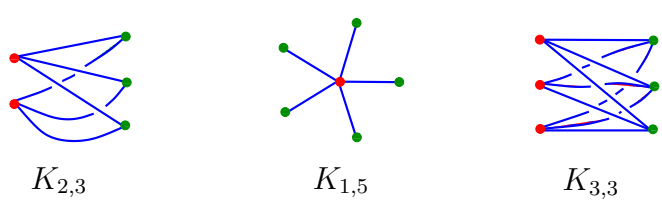

FIGURE 610.

On page 135 we had already mentioned that every finite graph can be realized as a spatial graph in $\mathbb{R}^3$. It is natural to ask whether we can reduce this dimension from 3 to 2. This leads us to the following dimension.

Definition.

(1) We say a finite topological graph G is *planar* if there exists a spatial graph in $\mathbb{R}^2$ that is homeomorphic to G.
(2) We say a finite abstract graph is *planar* if it admits a planar topological realization.

Examples.

(1) The above graphs K_1, K_2, K_3 and $K_{1,5}$ are planar. The above topological realizations of K_4 and $K_{2,3}$ are not planar. But as we see in Figure 611 both graphs admit planar realizations.

topological realizations of K_4 topological realizations of $K_{2,3}$

FIGURE 611.

(2) One can easily verify that given an $m \in \mathbb{N}$ the bipartite graph $K_{2,m}$ is planar.

Now the following question arises.

Question 41.7. *Are the graphs K_5 and $K_{3,3}$ also planar?*

If this question sounds to abstract and bipartite graphs sound too otherworldly let me reformulate the question regarding $K_{3,3}$.

Question 41.8. *Suppose we are in charge of finding efficient bus routes in a given city. Furthermore suppose the city has three main employers A, B and C. After work the employees, naturally, either want to go to the train station α, or the swimming pool β or the shopping mall γ. Is it possible to find bus routes which connect each of the three employers with each of the three destinations such that the bus routes do not intersect?*[788]

To answer that question we need a few more definitions.

Definition. Let G be a graph.

(1) Given $n \in \mathbb{N}$ we denote by X_n the "circular graph with n vertices and n edges", more precisely, X_n is the graph with

$$V(X_n) = \{1, \dots, n\} \quad \text{and} \quad E(X_n) = \{\{1,2\}, \{2,3\}, \dots, \{n-1,n\}, \{n,1\}\}.$$

[788]It follows easily from Proposition 10.23 that the answer to this question does not depend on the precise location of A, B, C and α, β, γ, as long as they are distinct.

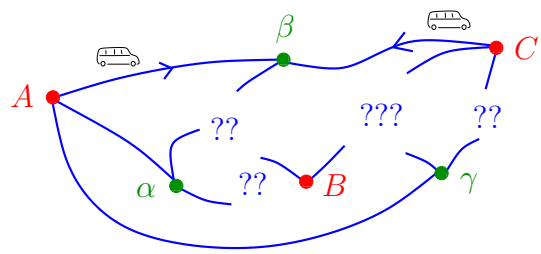

FIGURE 612.

(2) A *cycle of length* n in G is an injective map $\varphi\colon X_n \to G$ of graphs.[789]
(3) The *girth* of G is the shortest length of a cycle in G. If G has no cycles, then we define its girth as ∞.

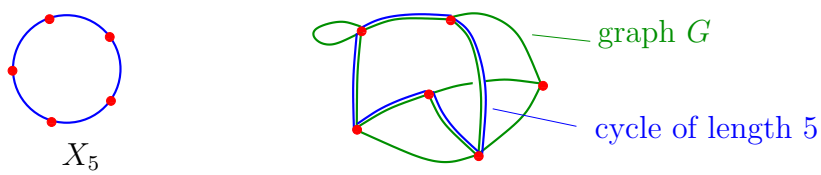

FIGURE 613.

Examples.

(1) A topological realization of X_n is given by S^1 equipped with the CW-structure that has n zero-cells and n one-cells.
(2) The girth of the graph shown in Figure 613 to the right is one, since it has an edge where the two endpoints agree.
(3) For any $n \geq 3$ the girth of the complete graphs K_n equals three.
(4) For any $n, m \geq 2$ the girth of the complete bipartite graphs $K_{n,m}$ equals four.

Proposition 41.9. *Let G be a graph with v vertices and e edges. We denote by g the girth of G. If G is planar and if $g < \infty$, then*

$$e \;\leq\; \tfrac{g}{g-2} \cdot (v-2).$$

Sketch of proof. Let G be a with v vertices and e edges which admits a planar realization and for which the girth g is finite. By abuse of notation we denote the planar realization by G as well. Without loss of generality we can assume that G lies in $\overline{B}^2$.

Now we view G as a subset of the sphere $S^2 = \overline{B}^2/S^1$. We refer to the closures of the components of $S^2 \setminus G$ as *faces* and we denote by f the number of faces. We refer to Figure 614 for an illustration. We make the following observation:

[789]We refer to page 133 for the definition of a map between abstract graphs.

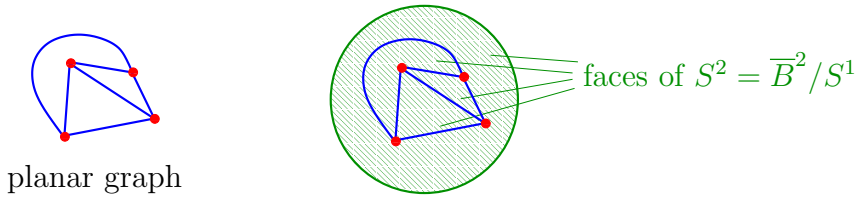

FIGURE 614.

(1) The vertices, edges and faces define a CW-structure for $S^2 = \overline{B}^2/S^1$.[790]
(2) We make the following two observations:
   (a) The boundary of each face is a cycle. By the definition of the girth each face is bounded by at least g edges.
   (b) Each edge lies in the boundary of at most two faces.

   Now we deduce that

$$\begin{aligned} g \cdot f &\leq \sum_{\text{faces } f} \text{number of edges in the boundary of } f \\ &= \text{number of pairs } (f,e) \text{ where } f \text{ is a face and } e \text{ an edge in the boundary of } f \\ &= \sum_{\text{edges } e} \text{number of faces that contain } e \text{ in the boundary } \leq 2e. \end{aligned}$$

   Here the first inequality follows from (a) and the last inequality follows from (b). Summarizing we see that $g \cdot f \leq 2e$.

Now we see that

$$\begin{array}{ccccccccc} 2 & = & \chi(S^2) & = & v - e + f & \leq & v - e + \frac{2}{g}e & = & v - \frac{g-2}{g}e. \\ & \uparrow & & & & \uparrow & & & \\ & \text{see page 966} & & & & \text{since } g \cdot f \leq 2e & & & \end{array}$$

Solving for e we get the desired inequality $e \leq \frac{g}{g-2} \cdot (v-2)$. □

The following proposition gives in particular a negative answer to Question 41.7.

Proposition 41.10. *If a graph G contains the complete graph K_5 or the complete bipartite graph $K_{3,3}$ as a subgraph, then G itself cannot be planar.*

Proof.

(1) Let $m \in \mathbb{N}_{\geq 3}$. It is straightforward to see that the complete graph K_m has m vertices and $\frac{1}{2}m(m-1)$ edges. Furthermore the girth is three. It is straightforward to verify that the inequality of Proposition 41.9 is only satisfied for $m = 3$ and $m = 4$.

[790] Here is the reason why it is the sketch of a proof: we do not prove that each face is in fact homeomorphic to a closed disk. This statement is "clear from the picture" and it can be proved using the Schönflies Theorem 36.3. But we will not attempt to give a rigorous proof.

(2) Let $m, n \in \mathbb{N}_{\geq 2}$. Again it easy to verify that the complete bipartite graph $K_{m,n}$ has $m + n$ vertices and $m \cdot n$ edges. Furthermore,as we pointed out above, the girth is four. It is straightforward to verify that the inequality of Proposition 41.9 is only satisfied if $m = 2$ or $n = 2$.
(3) The Proposition now follows from (1) and (2) and the observation that if a graph is planar, then any subgraph is also planar. □

Remark. Let G be a graph that contains the complete graph K_7. By Proposition 41.10 the graph G cannot be planar. John Conway and Cameron Gordon [CG] showed in 1984 a stronger statement: any spatial embedding of G in $\mathbb{R}^3$ contains a non-trivial knot. More precisely, for any topological realization of G as a topological graph in $\mathbb{R}^3$ there exists a C in $G \subset S^3$ that is knotted in the sense that $\pi_1(\mathbb{R}^3 \setminus C)$ is not isomorphic to $\mathbb{Z}$.

Now we will consider the question, to what degree the converse of Proposition 41.10 holds. We start out with the following definition.

Definition. We say a graph is *simple* if its girth is at least three.

Put differently, a graph G is simple if the following two conditions are satisfied:

(1) the graph G has no loops, i.e. if there is no edge where the two endpoints agree,
(2) the graph G does not have multiple edges, i.e. there are no two edges with the same endpoints.

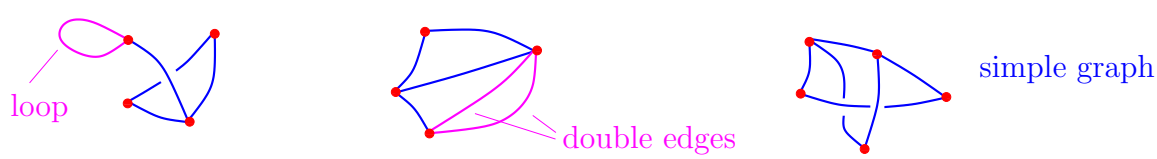

FIGURE 615.

In the remainder of this section we restrict ourselves to simple graphs. We start out with the following observations.

(1) If a simple graph G admits a vertex v of valence[791] one, then v is the endpoint of a single edge e. If we delete v and e we obtain a new graph G' such that the topological realization of G' is homotopy equivalent to the topological realization of G. It is straightforward to see that G is planar if and only if G' is planar.
(2) If a simple graph admits a vertex v of valence two, then v is the endpoint of two edges e_1 and e_2. We can combine e_1 and e_2 into one edge and eliminate v. This way we obtain a new graph with a homeomorphic topological realization.

This shows that for the most part we can restrict ourselves to simple graphs where every vertex has valence at least three.

[791]Recall that the *valence* of a vertex is defined as the number of edges that contain the vertex.

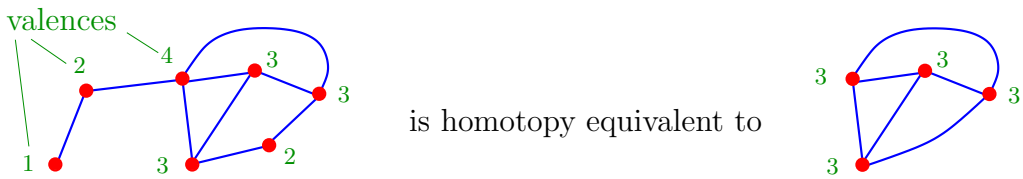

FIGURE 616.

If we restrict ourselves to simple graphs such that every vertex has valence at least three, then the graphs K_5 and $K_{3,3}$ turn out to be the only obstruction to being planar. More precisely the following theorem was proved by Kuratowski[792] in 1930. We refer to [BoM, Chapter 10.5] for a proof.

Theorem 41.11. (Kuratowski's Reduction Theorem) *Let G be a finite simple graph such that every vertex has valence at least three. Then the following holds:*

$$G \text{ is planar} \quad \Longleftrightarrow \quad G \text{ contains neither } K_5 \text{ nor } K_{3,3}.$$

[792]Kazimierz Kuratowski (1896-1980) was a Polish mathematician.

42. Homology with coefficients

In this chapter we will introduce the homology groups of a topological space X with coefficients in a ring R. These homology groups will have many applications, for example they will be essential in relating the homology groups of a manifold M to the de Rham cohomology groups of M. They will also be essential in proving theoretic statements, for example we will need to work with $\mathbb{F}_2$-coefficients to prove the higher-dimensional analogue of the Borsuk-Ulam Theorem 7.23. Before we can introduce the homology groups with coefficients we will need to introduce or recall some basic algebraic concepts.

42.1. **The tensor product of abelian groups.** The key to defining homology groups with coefficients is the notion of the tensor product of two abelian groups.

Definition. Let A and B be abelian groups. We define the *tensor product* $A \otimes B$ as follows:

$$A \otimes B \ := \left\{ \begin{array}{l} \text{free abelian group which is generated by all} \\ \text{symbols of the form } a \otimes b \text{ with } a \in A,\, b \in B \end{array} \right\} / \, N(A,B)$$

where $N(A,B)$ is the subgroup generated by the elements of the form

$$(a+a') \otimes b - (a \otimes b + a' \otimes b) \qquad \text{and} \qquad a \otimes (b+b') - (a \otimes b + a \otimes b')$$

with $a, a' \in A$ and $b, b' \in B$. For $a \in A$ and $b \in B$ we denote, by a slight abuse of notation, the image of $a \otimes b$ in $A \otimes B$ again by $a \otimes b$.

We summarize some elementary properties of the tensor product of two abelian groups in the following lemma.

Lemma 42.1. *Let A and B be two abelian groups.*

(1) *For any $a, a' \in A$ and $b, b' \in B$ we have*

$$\begin{array}{rcl} (a+a') \otimes b & = & a \otimes b + a' \otimes b \ \in \ A \otimes B \\ a \otimes (b+b') & = & a \otimes b + a \otimes b' \ \in \ A \otimes B. \end{array}$$

(2) *For any $a \in A, b \in B$ and $m \in \mathbb{Z}$ we have*

$$(m \cdot a) \otimes b \ = \ a \otimes (m \cdot b) \ = \ m \cdot (a \otimes b).$$

(3) *Any element in $A \otimes B$ is of the form $\sum_{i=1}^{n} a_i \otimes b_i$.*

(4) *Let $n \in \mathbb{N}$. For any $c \in A \otimes \mathbb{Z}_n$ we have $n \cdot c = 0 \in A \otimes \mathbb{Z}_n$.*

Proof. Let A and B be two abelian groups.

(1) This statement is an immediate consequence of the definition of the tensor product.

(2) Let $a \in A$ and $b \in B$. We first consider the case that $m > 0$. We have

$$(m \cdot a) \otimes b \ = \ \left(\sum_{i=1}^{m} a\right) \otimes b \ \underset{\substack{\uparrow \\ \text{by (1)}}}{=} \ \sum_{i=1}^{m} a \otimes b \ = \ m \cdot (a \otimes b) \ \underset{\substack{\uparrow \\ \text{same argument backwards}}}{=} \ \ldots \ = \ a \otimes (m \cdot b).$$

It follows easily from (1) that $0\otimes b = a\otimes 0 = 0$ and that $(-a)\otimes b = a\otimes(-b) = -a\otimes b$. Using these observations we get statement (2) for $m = 0$ and we can easily reduce the case $m < 0$ of (2) to the case $m > 0$ of (2).

(3) It follows immediately from the definition of the tensor product, together with the notational convention of "formal linear combinations" that we introduced on page 366 that any element in $A \otimes B$ is of the form $\sum_{i=1}^{n} r_i \cdot (a_i \otimes b_i)$. But by (2) we know that $r_i \cdot (a_i \otimes b_i) = (r_i \cdot a_i) \otimes b_i$ thus we get the desired result.

(4) Let $n \in \mathbb{N}$ and let $c \in A\otimes\mathbb{Z}_n$. By (3) we can write $c = \sum_{i=1}^{m} a_i \otimes r_i$ with $a_1, \dots, a_m \in A$ and $r_1, \dots, r_m \in \mathbb{Z}_n$. Then

$$n \cdot c \;=\; n \cdot \Big(\sum_{i=1}^{m} a_i \otimes r_i\Big) \;\underset{\substack{\uparrow \\ \text{by statement (2)}}}{=}\; \sum_{i=1}^{m} a_i \otimes \underbrace{n \cdot r_i}_{=0} \;=\; 0.$$

□

Definition. Let A, B and C be abelian groups. We say that a map $f\colon A\times B \to C$ is *bilinear*, if for all $a, a' \in A$, $b, b' \in B$ the following equalities hold:

$$f(a + a', b) \;=\; f(a, b) + f(a', b) \quad \text{and} \quad f(a, b + b') \;=\; f(a, b) + f(a, b').$$

We leave the elementary proof of the following lemma as an exercise to the reader.

Lemma 42.2. *Let A and B be abelian groups.*

(1) *The map*

$$\begin{array}{rcl} f\colon A \times B & \to & A \otimes B \\ (a, b) & \mapsto & a \otimes b \end{array}$$

is bilinear.

(2) *Given any abelian group G and any bilinear map $g\colon A \times B \to G$ there exists a unique homomorphism $\varphi\colon A \otimes B \to G$ such that the following diagram commutes:*

$$\begin{tikzcd} A \times B \arrow[r, "f"] \arrow[dr, "g"'] & A \otimes B \arrow[d, "\varphi \text{ unique}"] \\ & G. \end{tikzcd}$$

(3) *Given any abelian group G the map*

$$\begin{array}{rcl} \mathrm{Hom}(A \otimes B, G) & \to & \textit{set of bilinear maps } A \times B \to G \\ (\varphi\colon A \otimes B \to G) & \mapsto & (A \times B \xrightarrow{f} A \otimes B \xrightarrow{\varphi} C) \end{array}$$

is a bijection.

Remark. One can show quite easily that if a homomorphism $g\colon A \times B \to H$ is bilinear and if this homomorphism satisfies the universal property of Lemma 42.2 (2), then there exists an isomorphism $H \xrightarrow{\cong} A \otimes B$. We will not make use of this observation.

On many occasions we will also make use of the following lemma.

Lemma 42.3. *Let A, B, C and $A_i, i \in I$ be abelian groups.*

(1) *The maps*

$$\begin{array}{rcl} A \otimes B & \to & B \otimes A \\ \sum_{i=1}^{n} a_i \otimes b_i & \mapsto & \sum_{i=1}^{n} b_i \otimes a_i \end{array} \quad \text{and} \quad \begin{array}{rcl} \left(\bigoplus_{i\in I} A_i\right) \otimes B & \to & \bigoplus_{i\in I} A_i \otimes B \\ \left(\sum_{i=1}^{n} a_i\right) \otimes b & \mapsto & \sum_{i=1}^{n} a_i \otimes b \end{array}$$

are well-defined and they are isomorphisms.

(2) *The map*

$$\begin{array}{rcl} (A \otimes B) \otimes C & \to & A \otimes (B \otimes C) \\ \sum_{j=1}^{n} (a_j \otimes b_j) \otimes c_j & \mapsto & \sum_{j=1}^{n} a_j \otimes (b_j \otimes c_j) \end{array}$$

is well-defined and it is an isomorphism.

(3) *Let $k \in \mathbb{N}$. The maps*[793]

$$\begin{array}{rcl} \mathbb{Z}_k \otimes A & \to & A/kA \\ \sum_{i=1}^{m} n_i \otimes a_i & \mapsto & \sum_{i=1}^{m} n_i a_i \end{array} \quad \text{and} \quad \begin{array}{rcl} \mathbb{Z} \otimes A & \to & A \\ \sum_{i=1}^{m} n_i \otimes a_i & \mapsto & \sum_{i=1}^{m} n_i a_i. \end{array}$$

are well-defined and they are isomorphisms.

(4) *Suppose $(I, \leq)$ is an ordered set and $(\{A_i\}_{i\in I}, \{\varphi_{ij}\}_{i\leq j})$ is a direct system of abelian groups. Then*

$$\lim_{\longrightarrow} (A_i \otimes B) \;=\; \left(\lim_{\longrightarrow} A_i\right) \otimes B.$$

Proof. We refer to [Lan2, Corollary XVI.2.2] for a proof for the distributivity in (1). The other statements in (1) to (3) follow fairly easily from the definitions and Lemma 42.1. We refer to [Mun, Chapter 50] for details. A proof of the last statement is given in Bourbaki[794] [Bou, Chapter II.6.3] or alternatively in [Matb, Theorem A1]. □

Remark.

(1) The isomorphisms of Lemma 42.3 are natural, in the sense that they define natural transformations between appropriate functors. For example if we denote by $\mathcal{A}$ the category of abelian groups, then the isomorphisms of Lemma 42.3 (3) define a natural transformation between the two functors

$$\begin{array}{rcl} \mathcal{A} & \to & \mathcal{A} \\ A & \mapsto & A \end{array} \quad \text{and} \quad \begin{array}{rcl} \mathcal{A} & \to & \mathcal{A} \\ A & \mapsto & \mathbb{Z} \otimes A. \end{array}$$

[793]Note that for an abelian group A and $k \in \mathbb{Z}$ the set $kA := \{k \cdot a \,|\, a \in A\}$ is a subgroup of A and we can thus form the quotient A/kA.

[794]More information on the books written by "Nicolas Bourbaki" can be found here

`https://en.wikipedia.org/wiki/Nicolas_Bourbaki`

As an example, for every $k \in \mathbb{N}$ and any abelian group A we get a commutative diagram

$$\begin{tikzcd} \mathbb{Z} \otimes A \arrow[r, "\cong", "n\otimes a \mapsto n\cdot a"'] \arrow[d, "\cdot k \otimes \mathrm{id}"'] & A \arrow[d, "\cdot k"] \\ \mathbb{Z} \otimes A \arrow[r, "\cong", "n\otimes a \mapsto n\cdot a"'] & A. \end{tikzcd}$$

We use these natural isomorphisms from Lemma 42.3 to identify the various groups.

(2) Note that Lemma 42.3 (2) allows us to write the tensor product $A \otimes B \otimes C$ unambiguously without having to worry about parentheses.

(3) In Lemma 42.3 we saw that the tensor product commutes with forming direct sums. The analogous statement is not true if we replace direct sums by direct products. More precisely, in Exercise 42.6 we will see that

$$\Big(\prod_{n\in\mathbb{N}} \mathbb{Z}_n\Big) \otimes \mathbb{Q} \neq 0 \quad \text{but} \quad \prod_{n\in\mathbb{N}} \underbrace{(\mathbb{Z}_n \otimes \mathbb{Q})}_{=0,\text{ by Lemma 42.3 (3)}} = 0.$$

Examples.

(1) Let $m, n \in \mathbb{N}$. We write $r = \gcd(m,n)$ and $s = m/r$. Then

$$\mathbb{Z}_m \otimes \mathbb{Z}_n \underset{\substack{\uparrow \\ \text{Lemma 42.3 (3)}}}{\cong} \mathbb{Z}_n/m\mathbb{Z}_n = \mathbb{Z}_n/rs\mathbb{Z}_n = \mathbb{Z}_n/r\cdot(s\mathbb{Z}_n) \underset{\substack{\uparrow \\ \text{since } s \text{ is coprime to } n}}{=} \mathbb{Z}_n/r\mathbb{Z}_n \xleftarrow[\cong]{\cdot n/r} Z_r = \mathbb{Z}_{\gcd(m,n)}.$$

(2) Let A be a finitely generated abelian group of rank r. By the classification of finitely generated abelian groups, see Theorem 11.4, we have $A \cong \mathbb{Z}^r \oplus \bigoplus_{i=1}^n \mathbb{Z}_{a_i}$ where $a_1, \dots, a_n$ are non-zero natural numbers. For $S = \mathbb{Q}, S = \mathbb{R}$ or $S = \mathbb{C}$ we have

$$A \otimes S \cong \Big(\mathbb{Z}^r \oplus \bigoplus_{i=1}^n \mathbb{Z}_{a_i}\Big) \otimes S \underset{\substack{\uparrow \\ \text{Lemma 42.3 (1)}}}{=} (\mathbb{Z}\otimes S)^r \oplus \Big(\bigoplus_{i=1}^n \mathbb{Z}_{a_i} \otimes S\Big) \underset{\substack{\uparrow \\ \text{Lemma 42.3 (3)}}}{\cong} S^r \oplus \bigoplus_{i=1}^n S/a_iS \underset{\substack{\uparrow \\ \text{since } a_i \neq 0 \text{ in } S = \mathbb{Q},\mathbb{R},\mathbb{C}}}{=} S^r.$$

(3) Let A be an abelian group, then

$$\ker\begin{pmatrix} A & \to & A\otimes\mathbb{Q} \\ a & \mapsto & a\otimes 1 \end{pmatrix} = \text{all torsion elements of } A.$$

If A is finitely generated, then this follows easily from the classification of finitely generated abelian groups together with Lemma 42.3. If A is infinitely generated, then we can view it as the direct limit of finitely generated abelian groups and using Lemma 42.3 the statement can be reduced to the finitely generated case. We leave the details as an exercise to the reader.

(4) Recall that given a set W we denote by $\mathbb{Z}^{(W)}$ the free abelian group generated by W. Let A and B be two sets. We then have

$$\mathbb{Z}^{(A)} \otimes \mathbb{Z}^{(B)} = \Big(\bigoplus_{a\in A} \mathbb{Z}\cdot a\Big) \otimes \Big(\bigoplus_{b\in B} \mathbb{Z}\cdot b\Big) \overset{\text{Lemma 42.3 (1)}}{\overset{\downarrow}{=}} \bigoplus_{a\in A, b\in B} \mathbb{Z}\cdot a \otimes \mathbb{Z}\cdot b \overset{\text{Lemma 42.3 (3)}}{\overset{\downarrow}{=}} \bigoplus_{a\in A, b\in B} \mathbb{Z}\cdot (a,b) = \mathbb{Z}^{(A\times B)}.$$

(5) Let A and B be two finitely generated abelian groups. Using examples (1) and (2), the classification of finitely generated abelian groups and Lemma 42.3 (1) and (4) one can now easily show that

$$\operatorname{rank}(A\otimes B) \;=\; \operatorname{rank}(A)\cdot \operatorname{rank}(B).$$

Definition. Let $f\colon A \to A'$ and $g\colon B \to B'$ be homomorphisms between abelian groups. We define $f\otimes g$ to be the homomorphism that is given by[795]

$$\begin{array}{rcl} f\otimes g\colon A\otimes B & \to & A'\otimes B' \\ \sum\limits_{i=1}^{n} a_i\otimes b_i & \mapsto & \sum\limits_{i=1}^{n} f(a_i)\otimes g(b_i) \end{array}$$

For future reference we record the following lemma:

Lemma 42.4. *Let $f\colon A\to A'$ and $f'\colon A'\to A''$ be homomorphisms and let $g\colon B\to B'$ and $g'\colon B'\to B''$ be homomorphisms between abelian groups. Then we have*

$$(f'\otimes g')\circ(f\otimes g) \;=\; (f'\circ f)\otimes(g'\otimes g).$$

Proof. The statement follows immediately from the definitions. □

The following elementary lemma will play a major role.

Lemma 42.5. *Let R be a commutative ring.*

(1) *Given any abelian group A the map*

$$\begin{array}{rcl} (A\otimes R)\times R & \mapsto & A\otimes R \\ \Big(\sum\limits_{i=1}^{n} a_i\otimes b_i, r\Big) & \mapsto & \sum\limits_{i=1}^{n} a_i\otimes b_i r \end{array}$$

defines an R-module structure on $A\otimes R$.

(2) *If $f\colon A\to B$ is a homomorphism of abelian groups, then the map*

$$\begin{array}{rcl} f\otimes \mathrm{id}\colon A\otimes R & \to & B\otimes R \\ \sum\limits_{i} a_i\otimes r_i & \mapsto & \sum\limits_{i} f(a_i)\otimes r_i \end{array}$$

is a homomorphism of R-modules.

(3) *The map*

$$\begin{array}{rcl} A & \mapsto & A\otimes R \\ (f\colon A\to B) & \mapsto & (f\otimes \mathrm{id}\colon A\otimes R\to B\otimes R) \end{array}$$

defines a functor from the category of abelian groups to the category of R-modules.

[795] It is straightforward to verify that the map $f\otimes g$ is indeed well-defined and that it is a homomorphism.

Proof. Once again the statements follow immediately from the definitions. □

Lemma 42.5 shows that tensoring with a commutative ring "turns" an abelian group into a module. In particular if we tensor with a field, we obtain a vector space. This is very convenient since sometimes it allows us to reduce problems about abelian groups into problems about vector spaces that we can handle with techniques from linear algebra.

For example we can now give a meaningful definition of the rank of any abelian group.

Definition. The rank of an abelian group A is defined as

$$\operatorname{rank}(A) \ := \ \dim_{\mathbb{Q}}(A \otimes \mathbb{Q}).$$

Remark. Previously, on page 371 we introduced the rank of finitely generated abelian groups. It follows from the discussion on page 1004 that for finitely generated abelian groups the two definitions of rank agree. Put differently, the above definition is an extension of the earlier notion of rank to all abelian groups.

We conclude this section with the following lemma.

Lemma 42.6. *Let*

$$0 \ \to \ A \ \xrightarrow{i} \ B \ \xrightarrow{p} \ C \ \to \ 0$$

be a short exact sequence and let G be an abelian group. If the short exact sequence splits, then

$$0 \ \to \ A \otimes G \ \xrightarrow{i \otimes \mathrm{id}} \ B \otimes G \ \xrightarrow{p \otimes \mathrm{id}} \ C \otimes G \ \to \ 0$$

is also a short exact sequence and it also splits.

Remark. In most applications we will consider a short exact sequence

$$0 \ \to \ A \ \xrightarrow{i} \ B \ \xrightarrow{p} \ C \ \to \ 0$$

where C is a free abelian group. It then follows from Lemma 33.1 that the short exact sequence splits, which then implies by Lemma 42.6 that for any abelian group G the sequence

$$0 \ \to \ A \otimes G \ \xrightarrow{i \otimes \mathrm{id}} \ B \otimes G \ \xrightarrow{p \otimes \mathrm{id}} \ C \otimes G \ \to \ 0$$

is also a short exact sequence which furthermore splits.

Proof. According to Lemma 33.2 we can without loss of generality suppose that the short exact sequence is of the form

$$0 \ \to \ A \ \xrightarrow{a \mapsto (a,0)} \ A \oplus C \ \xrightarrow{(a,c) \mapsto c} \ C \ \to \ 0.$$

If we tensor this short exact sequence with G, then using $(A \oplus C) \otimes G = A \otimes G \oplus C \otimes G$ we obtain the sequence

$$0 \to A \otimes G \xrightarrow{\sum_i a_i \otimes g_i \mapsto \left(\sum_i a_i \otimes g_i, 0\right)} A \otimes G \oplus C \otimes G \xrightarrow{\left(\sum_i a_i \otimes g_i, \sum_j c_j \otimes g_j\right) \mapsto \sum_j c_j \otimes g_j} C \otimes G \to 0,$$

which is evidently exact. It is also clear that the short exact sequence splits. □

42.2. **The homology groups of a topological space with coefficients.** Let

$$\ldots \xrightarrow{\partial_{n+1}} C_n \xrightarrow{\partial_n} C_{n-1} \xrightarrow{\partial_{n-1}} \ldots \xrightarrow{\partial_2} C_1 \xrightarrow{\partial_1} C_0 \to 0$$

be an algebraic chain complex and let G be an abelian group. We tensor the chain complex with G, i.e. we consider the following sequence of homomorphisms:[796]

$$\ldots \to C_n \otimes G \xrightarrow{\partial_n \otimes \mathrm{id}} C_{n-1} \otimes G \xrightarrow{\partial_{n-1} \otimes \mathrm{id}} \ldots \xrightarrow{\partial_2 \otimes \mathrm{id}} C_1 \otimes G \xrightarrow{\partial_1 \otimes \mathrm{id}} C_0 \otimes G \to 0.$$

For all i we have

$$(\partial_{i-1} \otimes \mathrm{id}) \circ (\partial_i \otimes \mathrm{id}) \underset{\substack{\uparrow \\ \text{Lemma 42.4}}}{=} (\partial_{i-1} \circ \partial_i) \otimes \mathrm{id} = 0 \otimes \mathrm{id} = 0,$$

i.e. the above sequence of maps is again a chain complex. We denote the corresponding homology groups by $H_n(C;G) := H_n(C_* \otimes G, \partial_* \otimes \mathrm{id})$. If we tensor the chain complex C_* with a commutative ring R, then it follows from the discussion in the previous section that we obtain a chain complex of R-modules, i.e. all chain groups are R-modules and all chain maps are R-homomorphisms. In particular also all homology groups are R-modules.

Remark. Most of the results which we have proved for chain complexes of abelian groups hold, with the obvious modifications, also for chain complexes of R-modules. In particular one can easily convince oneself that Lemma 29.7, Lemma 30.2, Corollary 30.3 and Propositions 31.10 and Lemma 31.9 also hold in in this more general context. In the remainder of the course we will use these generalizations without further comment.

Now we are ready to define the homology groups of a topological space with coefficients in an abelian group G.

Definition. Let X be a topological space. For an abelian group G we define

$$C_*(X;G) := C_*(X) \otimes G.$$

As discussed above, we obtain a chain complex and we denote by

$$H_k(X;G) := H_k(C_*(X;G), \partial \otimes \mathrm{id})$$

the corresponding homology groups. We call $H_k(X;G)$ the *k-th homology group of X with G-coefficients*. We define the notions of "cycle", "homologous" and "null-homologous" in exactly the same way as on page 740.

Example. We consider an electric circuit as a finite graph X where at the vertices we have resistors or capacitors. Kirchhoff's current rule, see e.g.

`https://en.wikipedia.org/wiki/Kirchhoff's_circuit_laws`

states that

[796]Note that if G has also the structure of a commutative ring, then this becomes a chain complex of G-modules.

at any node (vertex) in an electrical circuit, the sum of currents flowing into that node is equal to the sum of currents flowing out of that node,

or equivalently

the algebraic sum of currents in a network meeting at a point is zero.

Put differently, a current defines a 1-cycle in $C_1(X;\mathbb{R})$.[797]

electric circuit 
FIGURE 617.

We start out with the following three observations. Let X be a topological space.

(1) If the coefficients are given by a commutative ring R, e.g. if $R = \mathbb{Z}_n$ or $R = \mathbb{Q}, \mathbb{R}, \mathbb{C}$, then, as we pointed out above, each $C_n(X;R) = C_n(X) \otimes R$ is an R-module, each boundary map is an R-module homomorphism, and each homology group $H_n(X;R)$ is also an R-module.

(2) From Lemma 42.3 (3) it follows immediately that we have natural isomorphisms $C_*(X;\mathbb{Z}) \cong C_*(X)$ and $H_*(X;\mathbb{Z}) \cong H_*(X)$. In the following we will identify these groups and we will go back and forth between these two notations, depending on which one is more convenient.

(3) Let G be an abelian group. Given any singular k-simplex σ, given any $a \in \mathbb{Z}$ and any $g \in G$ we have by definition of the tensor product that $a\sigma \otimes g = \sigma \otimes ng$. From this observation it follows that any element in $C_k(X;G)$ can be written as

$$\sum_{i=1}^{n} \sigma_i \otimes g_i \quad \text{where } \sigma_1, \dots, \sigma_n \text{ are singular } k\text{-simplices and } g_1, \dots, g_n \in G.$$

Most results for homology groups of topological spaces carry over, with the obvious modifications, to the theory of homology groups with G-coefficients. For example, given an abelian group G we have the following statements:

(1) A map $f\colon X \to Y$ between two topological spaces X and Y induces a chain map

$$f_* \otimes \mathrm{id}\colon C_*(X;G) \to C_*(Y;G)$$

which in turn, for each $k \in \mathbb{N}_0$, induces a homomorphism

$$(f_* \otimes \mathrm{id})_*\colon H_k(X;G) \to H_k(Y;G).$$

To simplify the notation we usually denote this induced map on homology groups also by f_*.

(2) The k-th homology group with G-coefficients defines a functor from the category of topological spaces to the category of abelian groups.

[797]This observation and the figure are due to Ghrist's excellent book on applied topology [Gh].

(3) If R is a commutative ring, then a map $f\colon X \to Y$ between topological spaces induces a chain map of R-homomorphisms $C_*(X;R) \to C_*(Y;R)$ and R-homomorphisms $f_*\colon H_k(X;R) \to H_k(Y;R)$. Furthermore the k-th homology group with R-coefficients defines a functor from the category of topological spaces to the category of R-modules.

(4) The augmentation map $\epsilon\colon H_0(X;G) \to G$ is defined almost the same way as in Lemma 29.4. More precisely, it is given by the map

$$\begin{aligned} \epsilon_X\colon H_0(X;G) &\to G \\ \Big[\sum_{i=1}^k \sigma_i \otimes g_i\Big] &\mapsto \sum_{i=1}^k g_i. \end{aligned}$$

If X is path-connected, then the argument of Proposition 29.5 implies immediately that the augmentation map $\epsilon\colon H_0(X;G) \to G$ is an isomorphism. At times we will use this natural isomorphism to make the identification $H_0(X;G) = G$.

(5) Precisely as on page 761 we can use the augmentation map $\epsilon\colon H_0(X;G) \to G$ to define reduced homology groups $\widetilde{H}_k(X;G)$ with G-coefficients.

(6) We saw in Proposition 30.5 that if $f, g\colon X \to Y$ are two homotopic maps between topological spaces, then the induced maps $f_*, g_*\colon C_*(X) \to C_*(Y)$ are chain homotopic. By tensoring the chain homotopies we see that the corresponding induced maps $C_*(X) \otimes G \to C_*(Y) \otimes G$ are also chain homotopic, and we see that for any $n \in \mathbb{N}_0$ we have

$$f_* = g_*\colon H_n(X;G) \to H_n(Y;G).$$

In particular, if X and Y are homotopy equivalent topological spaces, then for any $n \in \mathbb{N}_0$ we have an isomorphism

$$H_n(X;G) \xrightarrow{\cong} H_n(Y;G).$$

(7) Given a pair (X, A) of topological spaces we can tensor the relative chain complex $C_*(X, A)$ with G. We obtain the *relative chain complex* $C_*(X, A; G) := C_*(X, A) \otimes G$. The corresponding homology groups are the *relative homology groups* $H_k(X, A; G)$.

(8) Let (X, B, A) be a triple of topological spaces. As pointed out on page 775, the relative chain groups $C_n(X, B; G)$ are free abelian groups. Thus it follows from the discussion on page 1006 that we obtain a short exact sequence of chain complexes $0 \to C_*(B, A; G) \to C_*(X, A; G) \to C_*(X, B; G) \to 0$. By applying the obvious generalization of Proposition 31.10 to this short exact sequence we obtain the following long exact sequence of homology groups with G-coefficients:

$$\ldots \to H_n(B, A; G) \xrightarrow{i_*} H_n(X, A; R) \xrightarrow{p_*} H_n(X, B; G) \xrightarrow{\partial} H_{n-1}(B, A; G) \to \ldots$$

(9) We have an obvious version of the Mayer-Vietoris Theorem 33.5 for homology groups with G-coefficients. The proof is basically identical to the proof of Theorem 33.5, we only have to note that when we consider the exact sequence

$$0 \to C_*(A \cap B) \xrightarrow{i_{A\cap B} \oplus -i_{A\cap B}} C_*(A) \oplus C_*(B) \xrightarrow{i_A + i_B} C_*^{\{A,B\}}(X) \to 0,$$

then it is a consequence of the discussion on page 1006 that the corresponding sequence with G-coefficients is also exact.

(10) We also have an obvious version of the Excision Theorem 31.17, the proof for G-coefficients is almost verbatim the same as before.

(11) For a CW-complex X we can also consider the corresponding cellular chain complex $C_*^{\mathrm{CW}}(X;G) := C_*^{\mathrm{CW}}(X) \otimes G$ and the corresponding cellular homology groups $H_*^{\mathrm{CW}}(X;G)$. Then, as in Proposition 35.4, one can show that there exists a natural isomorphism $H_*(X;G) \xrightarrow{\cong} H_*^{\mathrm{CW}}(X;G)$.

(12) If X is a finite CW-complex and if $\mathbb{F}$ is a field, then the argument of Proposition 40.1 shows that

$$\chi(X) \;=\; \sum_i (-1)^i \cdot \dim_{\mathbb{F}}(H_i(X;\mathbb{F})).$$

Examples.

(1) Let $n \in \mathbb{N}$. As on page 648 we equip S^n with the CW-structure with one 0-cell and one n-cell. For any abelian group G it follows from (10), and similar to the discussion on page 882, that

$$H_k(S^n;G) \;=\; H_k^{\mathrm{CW}}(S^n;G) \;\cong\; \begin{cases} G, & \text{if } k = 0, n, \\ 0, & \text{otherwise.} \end{cases}$$

The same result holds for reduced homology with G-coefficients except that in this case we have $\widetilde{H}_0(S^n;G) = 0$.

(2) It follows from (10) and the same argument as in the proof of Proposition 35.6 that for any compact n-dimensional manifold M and any abelian group G we have $H_k(M;G) = 0$ for $k > n$.

(3) We want to determine homology groups of the real projective plane $\mathbb{R}\mathrm{P}^2$ with $\mathbb{F}_2$-coefficients. As usual we equip $\mathbb{R}\mathrm{P}^2$ with the CW-structure with one 0-cell, one 1-cell and one 2-cell that we introduced on page 898. In the proof of Proposition 35.11 we saw that the cellular chain complex is given by

$$0 \;\to\; \mathbb{Z} \;\xrightarrow{\cdot 2}\; \mathbb{Z} \;\xrightarrow{0}\; \mathbb{Z} \;\to\; 0,$$

i.e. $H_2(\mathbb{R}\mathrm{P}^2) = 0$, $H_1(\mathbb{R}\mathrm{P}^2) = \mathbb{Z}_2$ and $H_0(\mathbb{R}\mathrm{P}^2) = \mathbb{Z}$. On the other hand, if we tensor the above cellular chain complex with $\mathbb{F}_2$, then using Lemma 42.3 (3) we obtain the chain complex

$$0 \;\to\; \mathbb{F}_2 \;\xrightarrow{\cdot 2 = 0}\; \mathbb{F}_2 \;\xrightarrow{0}\; \mathbb{F}_2 \;\to\; 0.$$

Using the isomorphism between cellular and singular homology with $\mathbb{F}_2$-coefficients we obtain that $H_2(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) = \mathbb{F}_2$, $H_1(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) = \mathbb{F}_2$ and $H_0(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) = \mathbb{F}_2$.

Note that even though the homology groups of $\mathbb{R}\mathrm{P}^2$ with $\mathbb{Z}$-coefficients and $\mathbb{F}_2$-coefficients are quite different, in both cases the alternating sums of the dimensions and ranks give, as promised in Proposition 40.1 and in (10) above, the Euler characteristic.

Indeed, we have

$$\operatorname{rank}(H_0(X)) - \operatorname{rank}(H_1(X)) + \operatorname{rank}(H_2(X)) \;=\; 1-0+0 \;=\; 1,$$

and

$$\dim_{\mathbb{F}_2}(H_0(X;\mathbb{F}_2)) - \dim_{\mathbb{F}_2}(H_1(X;\mathbb{F}_2)) + \dim_{\mathbb{F}_2}(H_2(X;\mathbb{F}_2)) \;=\; 1-1+1 \;=\; 1.$$

(4) Basically the same argument as in (3) shows that for any $n \in \mathbb{N}$ we have

$$H_k(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2) \;\cong\; \begin{cases} \mathbb{F}_2, & \text{if } k = 0,\dots,n, \\ 0, & \text{otherwise.} \end{cases}$$

Remark. Why should we study the homology groups of a topological space with G-coefficients? There are several answers one can give:

(1) At times it is easier to work over a field instead of working over the ring $\mathbb{Z}$. For example, if we only want to determine the Euler characteristic of a CW-complex we can now use a field, even a very simple one like $\mathbb{F}_2$, instead of working with the integers.
(2) If we work over the field $\mathbb{F}_2$ then many calculations become particularly simple, since we do not need to worry about signs. Even in the previous example we already saw that working with $\mathbb{F}_2$-coefficients can simplify calculations.
(3) Recall that given a manifold M we denote its de Rham cohomology groups $H^k_{\mathrm{dR}}(M)$, which are in fact real vector space. For each k we can now also study the homology groups $H_k(M;\mathbb{R})$ which are also real vector spaces. The notations $H^k_{\mathrm{dR}}(M)$ and $H_k(M;\mathbb{R})$ look similar and the names "de Rham cohomology" and "homology" also sound similar. We will study the relationship between these two objects later on in a later chapter.

Throughout this chapter we will use the following notation:

Notation. We denote by $\mathcal{A}$ the category of abelian groups.

We conclude this section with the following elementary lemma which follows immediately from the definitions.

Lemma 42.7.

(1) *Let X be a topological space and let $\varphi\colon A \to B$ be a homomorphism of abelian groups. Then the maps*

$$\begin{aligned} \varphi_*\colon C_*(X;A) &\to C_*(X;B) \\ \Big[\sum_{i=1}^k \sigma_i \otimes a_i\Big] &\mapsto \Big[\sum_{i=1}^k \sigma_i \otimes \varphi(a_i)\Big] \end{aligned}$$

form a chain map, in particular for each $n \in \mathbb{N}_0$ we obtain an induced map

$$\varphi_*\colon H_n(X;A) \;\to\; H_n(X;B).$$

(2) *Given a topological space X and $n \in \mathbb{N}_0$ the maps $A \mapsto H_n(X;A)$ from (1) define a covariant functor from the category of abelian groups $\mathcal{A}$ to itself.*

(3) *The maps from* (1) *define a natural transformation from "homology with A-coefficients" to "homology with B-coefficients", i.e. given a map $f\colon X \to Y$ of topological spaces we get a commutative diagram*

$$\begin{array}{ccc} H_n(X;A) & \xrightarrow{f_*} & H_n(Y;A) \\ \downarrow{\scriptstyle \varphi_*} & & \downarrow{\scriptstyle \varphi_*} \\ H_n(X;B) & \xrightarrow{f_*} & H_n(Y;B). \end{array}$$

42.3. **Exact functors.** The following question naturally arises from the discussion in the previous section:

Question 42.8. *Given a topological space X and an abelian group G, what is the relationship between the usual homology groups of X and the homology groups with G-coefficients?*

The example on page 1010 shows that the naive guess that perhaps $H_k(X;G) \cong H_k(X) \otimes G$ is in general not correct. More precisely, we saw that

$$\mathbb{F}_2 = H_2(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) \ \neq \ H_2(\mathbb{R}\mathrm{P}^2) \otimes \mathbb{F}_2 = 0.$$

In the following section we will see that, despite this sobering example, one can always deduce the homology groups $H_*(X;G)$ of a topological space X from the usual homology groups $H_*(X)$. But the connection between these homology groups will turn out to be less naive than one might have thought initially.

Before we can hope to answer Question 42.8 we have to introduce many more definitions and algebraic tools. We start out with the following definition from category theory.

Definition. Let $F\colon \mathcal{A} \to \mathcal{A}$ be a covariant functor from the category $\mathcal{A}$ of abelian groups to itself.

(1) We say F is *left-exact*, if for every exact sequence

$$0 \longrightarrow A \xrightarrow{i} B \xrightarrow{j} C$$

of abelian groups the sequence

$$0 \longrightarrow F(A) \xrightarrow{F(i)} F(B) \xrightarrow{F(j)} F(C)$$

is also exact.

(2) We say F is *right-exact*, if for every exact sequence

$$A \xrightarrow{i} B \xrightarrow{j} C \longrightarrow 0$$

of abelian groups the sequence

$$F(A) \xrightarrow{F(i)} F(B) \xrightarrow{F(j)} F(C) \longrightarrow 0$$

is also exact.

(3) We say F is *exact* if it is left-exact and right-exact, put differently, the functor F is exact, if for every exact sequence

$$0 \longrightarrow A \xrightarrow{i} B \xrightarrow{j} C \longrightarrow 0$$

of abelian groups the sequence

$$0 \longrightarrow F(A) \xrightarrow{F(i)} F(B) \xrightarrow{F(j)} F(C) \longrightarrow 0$$

is also exact.

Remark. Let $\varphi\colon A \to B$ be a homomorphism between two abelian groups and let $F\colon \mathcal{A} \to \mathcal{A}$ be a covariant functor from the category $\mathcal{A}$ of abelian groups to itself.

(1) If F is a left-exact functor, then "taking F" commutes with "taking kernels", more precisely, if $\varphi\colon A \to B$ is a homomorphism, then by applying F to the exact sequence $0 \to \ker(\varphi) \to A \to B$ we see that $F(\ker(\varphi)) = \ker(\varphi_*\colon F(A) \to F(B))$.
(2) Similarly, if F is right-exact, then "taking F" commutes with "taking cokernels", i.e. if $\varphi\colon A \to B$ is a homomorphism, then by applying F to the exact sequence $A \to B \to \operatorname{coker}(\varphi) \to 0$ we see that $F(\operatorname{coker}(\varphi)) = \operatorname{coker}(\varphi_*\colon F(A) \to F(B))$.

Lemma 42.9. *Let G be an abelian group. If G is free abelian, then tensoring with G is exact.*

Proof. Let

$$0 \to A \xrightarrow{\varphi} B \xrightarrow{\psi} C \to 0$$

be a short exact sequence and let $G \cong \mathbb{Z}^{(S)}$ be a free abelian group. It follows from Lemma 42.3 (1) and (3) that tensoring the above short exact sequence with $G \cong \mathbb{Z}^{(S)}$ results in an exact sequence that is isomorphic to the direct sum of S copies of the original sequence, hence it is again exact. □

Example. In contrast to the previous lemma we will now see that tensoring with an abelian group G is in general not a *left-exact* functor. For example for any $k \in \mathbb{N}_{\geq 2}$ the sequence

$$0 \longrightarrow \mathbb{Z} \xrightarrow{\cdot k} \mathbb{Z} \longrightarrow \mathbb{Z}_k$$

is exact, but after tensoring with $\mathbb{Z}_k$ we obtain, using Lemma 42.3 (3), the sequence

$$0 \longrightarrow \mathbb{Z}_k \xrightarrow[=0]{\cdot k} \mathbb{Z}_k \longrightarrow \mathbb{Z}_k$$

that is not exact.

In contrast to the previous example we will now see that tensoring with an abelian group G is a *right-exact* functor.

Lemma 42.10. *We denote by $\mathcal{A}$ the category of abelian groups. For every abelian group G the functor*

$$\begin{array}{ccc} \mathcal{A} & \to & \mathcal{A} \\ A & \mapsto & A \otimes G \end{array}$$

is right-exact.

Proof. Let

$$A \quad \xrightarrow{i} \quad B \quad \xrightarrow{j} \quad C \quad \to \quad 0$$

be an exact sequence of abelian groups and let G be an abelian group. We have to show that the sequence

$$A \otimes G \quad \xrightarrow{i\otimes \mathrm{id}} \quad B \otimes G \quad \xrightarrow{j\otimes \mathrm{id}} \quad C \otimes G \quad \to \quad 0$$

is also exact.

(a) Since $j\colon B \to C$ is an epimorphism it follows immediately from Lemma 42.1 (3) that the homomorphism

$$\begin{aligned} j \otimes \mathrm{id}\colon B \otimes G &\to C \otimes G \\ \sum_{i=1}^{n} b_i \otimes g_i &\mapsto \sum_{i=1}^{n} j(b_i) \otimes g_i \end{aligned}$$

is also an epimorphism.

(b) By Lemma 42.4 we have $(j \otimes \mathrm{id}) \circ (i \otimes \mathrm{id}) = (j \circ i) \otimes \mathrm{id} = 0$, i.e. we have

$$\mathrm{im}\{i \otimes \mathrm{id}\colon A \otimes G \to B \otimes G\} \ \subset \ \ker\{j \otimes \mathrm{id}\colon B \otimes G \to C \otimes G\}.$$

(c) By (b) it remains to show that

$$\ker\{j \otimes \mathrm{id}\colon B \otimes G \to C \otimes G\} \ \subset \ \mathrm{im}\{i \otimes \mathrm{id}\colon A \otimes G \to B \otimes G\}.$$

Put differently it remains to show that the homomorphism

$$\Psi\colon B \otimes G/\,\mathrm{im}\{i \otimes \mathrm{id}\colon A \otimes G \to B \otimes G\} \quad \to \quad C \otimes G$$

that is induced by $j \otimes \mathrm{id}$, i.e. that is given by[798]

$$[b \otimes g] \quad \mapsto \quad j(b) \otimes g,$$

is a monomorphism. We will do so by providing a left-inverse for Ψ, i.e. we will provide a map Φ with $\Phi \circ \Psi = \mathrm{id}$.

Claim. The map

$$\begin{aligned} \varphi\colon C \times G &\to B \otimes G/\,\mathrm{im}\{i \otimes \mathrm{id}\colon A \otimes G \to B \otimes G\} \\ (c, g) &\mapsto b \otimes g \quad \text{ where } b \in B \text{ is an element with } j(b) = c. \end{aligned}$$

is well-defined.

Let $(c, g) \in C \times G$. Since j is by hypothesis surjective we know that there exists a $b \in B$ with $j(b) = c$. We have to show that $\varphi(c, g)$ is independent of the choice of b. So let $b, b' \in B$ with $j(b) = j(b') = c$, i.e. with $j(b - b') = 0$. From the exactness of the original short exact sequence at B it follows that $b - b' = i(a)$ for an $a \in A$. Then we obtain that

$$b \otimes g - b' \otimes g \ = \ (b - b') \otimes g \ = \ i(a) \otimes g \in \mathrm{im}\{i \otimes \mathrm{id}\colon A \otimes G \to B \otimes G\}.$$

Thus we have proved that φ is well-defined. This concludes the proof of the claim.

[798] Note that it is a consequence of (b) that Ψ is well-defined.

The map φ is easily seen to bilinear. It follows from Lemma 42.2 (2) that φ induces a well-defined map

$$\begin{array}{rcl} \Phi\colon C\otimes G & \to & B\otimes G/\operatorname{im}\{i\otimes \mathrm{id}\colon A\otimes G\to B\otimes G\} \\ \sum\limits_{i=1}^{k} c_i\otimes g_i & \mapsto & \sum\limits_{i=1}^{k}\varphi(c_i,g_i). \end{array}$$

By construction we have $(\Phi\circ\Psi)([b\otimes g]) = [b\otimes g]$ for all $b\in B$ and $g\in G$. But the elements $b\otimes g$ generate $B\otimes G$, hence $\Phi\circ\Psi = \mathrm{id}$, i.e. the map Φ is indeed a right-inverse to the map Ψ. □

42.4. **The G-torsion of an abelian group.** Our final goal is to relate the homology groups $H_*(C)$ of a chain complex to the homology groups $H_*(C;G)$ of the same chain complex with G-coefficients. To state the theorem relating these groups we need to introduce the G-torsion of an abelian group.

We start our discussion with the definition of a free abelian group that we already gave on page 366, we also recall some basic facts regarding free abelian groups, and we introduce one new definition.

(1) Let S be a non-empty set. We refer to

$$\mathbb{Z}^{(S)} := \text{all maps from } S \text{ to } \mathbb{Z} \text{ which are non-zero for only finitely many } s\in S$$

as the free abelian group generated by S.

(2) A group G is called *free abelian* if there exists a set S and also an isomorphism $G\xrightarrow{\cong}\mathbb{Z}^{(S)}$.

(3) It follows easily from the definitions that a group G is free abelian if and only if there exists a subset $\mathcal{B}=\{b_i\}_{i\in I}\subset G$ with the following property: For any abelian group A and each choice of elements $a_i\in A, i\in I$ there exists a unique homomorphism $\varphi\colon G\to A$ such that $\varphi(b_i)=a_i$ for all $i\in I$. As on page 369 we call such a subset $\mathcal{B}$ a *basis* of G.

(4) A *free resolution* of an abelian group H is an exact sequence

$$\ldots \xrightarrow{f_3} F_2 \xrightarrow{f_2} F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H \to 0$$

where the F_i are free abelian groups. If there exists an $n\in\mathbb{N}_0$ with $F_n\neq 0$ but $F_m=0$ for $m>n$, then we refer to n as the *length* of the resolution. If no such n exists, then we say that the length of the resolution is infinite.

Examples.

(1) Let $m\in\mathbb{N}$, then a free resolution for $H=\mathbb{Z}_m$ is given by

$$0\to\mathbb{Z}\xrightarrow{\cdot m}\mathbb{Z}\to\mathbb{Z}_m\to 0.$$

(2) Let G be a *finitely generated* abelian group. By the classification of finitely generated abelian groups, see Theorem 11.4, there exists an $r\in\mathbb{N}_0$, non-zero natural numbers

$a_1, \dots, a_k$ and an isomorphism

$$\Phi\colon G \xrightarrow{\cong} \mathbb{Z}^r \oplus \bigoplus_{i=1}^{k} \mathbb{Z}_{a_i}.$$

Thus we obtain a free resolution[799]

$$0 \to \mathbb{Z}^k \xrightarrow{0 \oplus \begin{pmatrix} a_1 & 0 & 0 \\ 0 & \ddots & 0 \\ 0 & 0 & a_k \end{pmatrix}} \mathbb{Z}^r \oplus \mathbb{Z}^k \to \underbrace{\mathbb{Z}^r \oplus \bigoplus_{i=1}^{k} \mathbb{Z}_{a_i}}_{\cong G} \to 0.$$

In most cases, when we want to work with explicit examples, this type of free resolution will turn out to be the most useful free resolution.

(3) We recall the following basic fact: if M is an abelian group, then by Lemma 11.1 there exists a unique homomorphism $\alpha(M)\colon \mathbb{Z}^{(M)} \to M$ such that for each $m \in M$ we have $\alpha(M)(m) = m$. Evidently this map is an epimorphism. Now let H be an abelian group. We consider

$$\mathbb{Z}^{(H)} \xrightarrow{\alpha(H)} H \to 0.$$

The group $\mathbb{Z}^{(H)}$ is free abelian and $\alpha(H)$ is an epimorphism. In particular the sequence is exact. We set $H_1 := \ker\left(\mathbb{Z}^{(H)} \xrightarrow{\alpha(H)} H\right)$. Then

$$H_1 \hookrightarrow \mathbb{Z}^{(H)} \xrightarrow{\alpha(H)} H \to 0$$

is exact. Now we consider

$$\mathbb{Z}^{(H_1)} \xrightarrow{\alpha(H_1)} \mathbb{Z}^{(H)} \xrightarrow{\alpha(H)} H \to 0.$$

This sequence is exact and both the groups $\mathbb{Z}^{(H_1)}$ and $\mathbb{Z}^{(H)}$ are free abelian. Now we set $H_2 := \ker\left(\mathbb{Z}^{(H_1)} \xrightarrow{\alpha(H)} H\right)$ and we iterate this procedure. This way we obtain a free resolution of H.[800] Note that this free resolution is unambiguously defined, we did not make any choices along the way. Therefore we refer to this free resolution of H as the *canonical free resolution of H*.

The last example provides the proof for the following lemma.

Lemma 42.11. *Every abelian group (not necessarily finitely generated) admits a canonical free resolution.*

The following definition is one of the key definitions in homological algebra.

[799] Note that the homomorphism to the left is a monomorphism since $a_1, \dots, a_k$ are non-zero.

[800] Note that this procedure does not stop, i.e. it produces an infinite free resolution.

Definition. Let G and H be abelian groups. We denote by

$$\ldots \to F_2 \xrightarrow{f_2} F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H \to 0$$

the canonical free resolution from page 1016. We define the *n-th G-torsion group of H* as

$$\mathrm{Tor}_n(H,G) := H_n(F_* \otimes G).$$

The following proposition is the key to calculating torsion-groups.

Proposition 42.12. *Let G and H be abelian groups and let*

$$\ldots \to F_2 \xrightarrow{f_2} F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H \to 0$$

be a free resolution of H. Then there exists a canonical isomorphism

$$\mathrm{Tor}_n(H,G) \xrightarrow{\cong} H_n(F_* \otimes G).$$

Example. In many situations we are only interested in determining the isomorphism type of $\mathrm{Tor}_n(H,G)$ where H is a given finitely generated abelian group. In such situations it is usually much more convenient to work with the free resolution given on page 1016. For example, let $m,n \in \mathbb{N}$. We want to determine the isomorphism type of $\mathrm{Tor}_i(\mathbb{Z}_m,\mathbb{Z}_n)$ for $i \in \mathbb{N}_0$. We will do so by doing the following three step process:

(1) We pick the free resolution $0 \to \mathbb{Z} \xrightarrow{\cdot m} \mathbb{Z} \to \mathbb{Z}_m \to 0$,
(2) we tensor this free resolution of $\mathbb{Z}_m$ with $\mathbb{Z}_n$ and from Lemma 42.3 (3) we obtain the sequence $0 \to \mathbb{Z}_n \xrightarrow{\cdot m} \mathbb{Z}_n \to \mathbb{Z}_m \otimes \mathbb{Z}_n \to 0$,
(3) we drop the term to the right and we compute the homology groups.

Now using an argument as in the calculation of the tensor product $\mathbb{Z}_m \otimes \mathbb{Z}_n$ on page 1004 we see that

$$\mathrm{Tor}_1(\mathbb{Z}_m,\mathbb{Z}_n) = H_1\big(0 \to \mathbb{Z}_n \xrightarrow{\cdot m} \mathbb{Z}_n \to 0\big) = \ker\{\mathbb{Z}_n \xrightarrow{\cdot m} \mathbb{Z}_n\} \cong \mathbb{Z}_{\gcd(m,n)}$$

and

$$\mathrm{Tor}_0(\mathbb{Z}_m,\mathbb{Z}_n) = H_0\big(0 \to \mathbb{Z}_n \xrightarrow{\cdot m} \mathbb{Z}_n \to 0\big) = \mathrm{coker}\{\mathbb{Z}_n \xrightarrow{\cdot m} \mathbb{Z}_n\} \cong \mathbb{Z}_{\gcd(m,n)}.$$

We will fill in the details in Exercise 42.5.

The proof of Proposition 42.12 will require some effort. We start out with the following definition.

Definition. Let $\alpha\colon H \to H'$ be a homomorphism between abelian groups. Furthermore let F_* be a free resolution of H and let F'_* be a free resolution of H'. An *extension of α to the free resolutions F_* and F'_** is a sequence of homomorphisms $\alpha_i\colon F_i \to F'_i$, $i \in \mathbb{N}_0$ such that the following diagram commutes:

$$\begin{tikzcd}
\ldots \arrow[r] & F_2 \arrow[r, "f_2"] \arrow[d, "\alpha_2"] & F_1 \arrow[r, "f_1"] \arrow[d, "\alpha_1"] & F_0 \arrow[r, "f_0"] \arrow[d, "\alpha_0"] & H \arrow[r] \arrow[d, "\alpha"] & 0 \\
\ldots \arrow[r] & F'_2 \arrow[r, "f'_2"] & F'_1 \arrow[r, "f'_1"] & F'_0 \arrow[r, "f'_0"] & H' \arrow[r] & 0.
\end{tikzcd}$$

Note that the horizontal exact sequences on top and bottom are in particular chain complexes and the maps α_* define a chain map from one complex to the other.

The following lemma shows in particular that extensions of homomorphisms between abelian groups always exist.

Lemma 42.13. *Let $\alpha\colon H \to H'$ be a homomorphism between abelian groups. Furthermore let F_* be a free resolution of H and let F'_* be a free resolution of H'. Then the following statements hold:*

(1) *There exists an extension of α to the free resolutions F_* and F'_*.*
(2) *Any two extensions α_* and α'_*, viewed as chain maps, are chain homotopic.*
(3) *Let $\alpha_n\colon F_n \to F'_n$, $n \in \mathbb{N}_0$ be an extension of $\alpha\colon H \to H$ and let G be an abelian group. The map*

$$\begin{array}{rcl} \alpha_n \otimes \mathrm{id}\colon H_n(F_* \otimes G) & \to & H_n(F'_* \otimes G) \\ \left[\sum\limits_{i=1}^{k} c_i \otimes g_i\right] & \mapsto & \left[\sum\limits_{i=1}^{k} \alpha_n(c_i) \otimes g_i\right] \end{array}$$

is well-defined and it is independent of the choice of the extension.

Proof $(*)$. Let F_* be a free resolution of H and let F'_* be a free resolution of H'. Statements (1) and (2) are both a straightforward consequence of some mild diagram chasing and the flexibility which Lemma 11.1 provides for defining homomorphisms starting from a free abelian group. In the following we fill in all the details.

(1) We have to show that there exists a sequence $\{\alpha_i\}_{i\in\mathbb{N}_0}$ of homomorphisms such that the following diagram commutes:

$$\begin{tikzcd} \dots \arrow[r] & F_2 \arrow[r, "f_2"] \arrow[d, "\alpha_2"] & F_1 \arrow[r, "f_1"] \arrow[d, "\alpha_1"] & F_0 \arrow[r, "f_0"] \arrow[d, "\alpha_0"] & H \arrow[r] \arrow[d, "\alpha"] & 0 \\ \dots \arrow[r] & F'_2 \arrow[r, "f'_2"] & F'_1 \arrow[r, "f'_1"] & F'_0 \arrow[r, "f'_0"] & H' \arrow[r] & 0. \end{tikzcd}$$

First we define the homomorphism α_0. We choose a basis $\mathcal{B}_0$ of the free abelian group F_0. For each $x_i \in \mathcal{B}_0$ we choose an $x'_i \in F'_0$ with $f'_0(x'_i) = \alpha(f_0(x_i))$. This is possible, since f'_0 is surjective. By Lemma 11.1 there exists a unique homomorphism $\alpha_0\colon F_0 \to F'_0$ with $\alpha_0(x_i) = x'_i$ for all $i \in I$. It is now evident that the right square commutes.

Now we turn to the definition of the map α_1. We choose a basis $\mathcal{B}_1$ of the free abelian group F_1. Let $x_i \in \mathcal{B}_1$. It follows from the commutativity of the square on the right that

$$f'_0((\alpha_0 \circ f_1)(x_i)) \;=\; \alpha(\underbrace{(f_0 \circ f_1)}_{=0}(x_i)) \;=\; 0.$$

Since the lower sequence is exact there exists an $x'_i \in F'_1$ with $f'_1(x'_i) = (\alpha_0 \circ f_1)(x_i)$. Again by Lemma 11.1 there exists a unique homomorphism $\alpha_1\colon F_1 \to F'_1$ such that $\alpha_1(x_i) = x'_i$ for all $i \in I$. It is now evident that the "second square from the right"

also commutes. It is now clear how inductively we can construct the homomorphisms $\alpha_2, \alpha_3, \ldots$.

(2) Now let $\alpha_i, \alpha'_i \colon F_i \to F'_i, i \in \mathbb{N}_0$ be two extensions of α to the free resolutions F_* and F'_*. We have to find a chain homotopy from the chain map α_i to the chain map α'_i. The maps $\beta_i = \alpha_i - \alpha'_i$ are an extension of the zero map $\beta = 0 \colon H \to H'$. Therefore it suffices to find a chain homotopy λ from $\beta_i = \alpha_i - \alpha'_i$ to the zero chain map. The construction of the chain homotopy is very similar to the construction of the maps α_i in the first part of the proof.

Recall that we have to find a sequence of homomorphisms λ_i, $i \in \mathbb{N}_0$ such that for any $i \in \mathbb{N}_0$ we have

$$f'_{i+1} \circ \lambda_i + \lambda_{i-1} \circ f_i \;=\; \beta_i.$$

In the following discussion it is convenient to keep an eye on the following diagram that contains all the homomorphisms that we are given and that we need to construct:

$$\begin{tikzcd}
\ldots \arrow[r] & F_2 \arrow[r, "f_2"] \arrow[d, "\beta_2"] \arrow[dl, "\lambda_2"] & F_1 \arrow[r, "f_1"] \arrow[d, "\beta_1"] \arrow[dl, "\lambda_1"] & F_0 \arrow[r, "f_0"] \arrow[d, "\beta_0"] \arrow[dl, "\lambda_0"] & H \arrow[r] \arrow[d, "\beta=0"] \arrow[dl, "\lambda_{-1}"] & 0 \\
\ldots \arrow[r] & F'_2 \arrow[r, "f'_2"'] & F'_1 \arrow[r, "f'_1"'] & F'_0 \arrow[r, "f'_0"'] & H' \arrow[r] & 0.
\end{tikzcd}$$

We put $\lambda_{-1} = 0$. Next we need to find a map $\lambda_0 \colon F_0 \to F'_1$ such that $\beta_0 = f'_1 \circ \lambda_0$. For each $x \in \mathcal{B}_0$ we choose an $x' \in F'_1$ with $f'_1(x') = \beta_0(x)$. The existence of such x' follows from the observation that $f'_0(\beta_0(x)) = \beta(f_0(x)) = 0$ and from the exactness of the lower sequence.

Now we suppose that we have already found maps $\lambda_0, \ldots, \lambda_{i-1}$ which have the desired property that

$$(*) \qquad f'_j \circ \lambda_{j-1} + \lambda_{j-2} \circ f_{j-1} \;=\; \beta_{j-1} \quad \text{for } j = 0, \ldots, i.$$

We choose again a basis $\mathcal{B}_i$ of the free abelian group F_i. We have to assign to x an element $x' \in F'_{i+1}$ which satisfies the equation

$$f'_{i+1}(x') \;=\; \beta_i(x) - \lambda_{i-1}(f_i(x)).$$

From the exactness of the lower sequence it follows that $\operatorname{im}(f'_{i+1}) = \ker(f'_i)$. Thus it suffices to show that $f'_i \circ (\beta_i - \lambda_{i-1} \circ f_i) = 0$. It turns out that indeed we have

$$\begin{aligned}
f'_i \circ (\beta_i - \lambda_{i-1} \circ f_i) \;&=\; f'_i \circ \beta_i - f'_i \circ \lambda_{i-1} \circ f_i \;\underset{\substack{\uparrow \\ \text{since the } \beta_i\text{'s are a chain map, i.e. } f'_i \circ \beta_i = \beta_{i-1} \circ f_i}}{=}\; \beta_{i-1} \circ f_i - f'_i \circ \lambda_{i-1} \circ f_i \\
&=\; (\beta_{i-1} - f'_i \circ \lambda_{i-1}) \circ f_i \;\underset{\substack{\uparrow \\ \text{by } (*)}}{=}\; \lambda_{i-2} \circ f_{i-1} \circ f_i \;\underset{\substack{\uparrow \\ \text{since } f_{i-1} \circ f_i = 0}}{=}\; 0.
\end{aligned}$$

(3) It is straightforward to verify that the map is well-defined. It follows from (2) and Lemma 30.2 that any two extensions induce the same map on the homology groups. □

Using Lemma 42.13 we can now prove the following lemma.

Lemma 42.14. *Let*

$$\ldots \to F_2 \xrightarrow{f_2} F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H \to 0$$

and

$$\ldots \to F'_2 \xrightarrow{f'_2} F'_1 \xrightarrow{f'_1} F'_0 \xrightarrow{f'_0} H \to 0$$

be two free resolutions of an abelian group H. We pick an extension $\alpha_i, i \in \mathbb{N}$ of the identity map $\mathrm{id}\colon H \to H$ *to the free resolutions F_* and F'_*.*

(1) *The maps α_* form a chain homotopy equivalence between the two chain complexes F_* and F'_*.*
(2) *Let G be an abelian group. The*

$$H_n(F_* \otimes G) \xrightarrow{\cong} H_n(F'_* \otimes G)$$

from Lemma 42.13 (3) *is an isomorphism.*

Remark. The statement of Lemma 42.14 (1) is sometimes called the *fundamental theorem of homological algebra*, see e.g. [Lü, Satz 6.3].

Proof. We pick an extension $\alpha_i, i \in \mathbb{N}$ of the identity map $\mathrm{id}\colon H \to H$.

(1) We apply Lemma 42.13 to the free resolutions F'_* and F_* (i.e. we swap the roles of the free resolutions) and we obtain maps $\{\beta_i\}_{i\in\mathbb{N}_0}$ that give us the lower half of the following commutative diagram.

$$\begin{tikzcd}
\ldots \arrow[r] & F_2 \arrow[r, "f_2"] \arrow[d, "\alpha_2"] & F_1 \arrow[r, "f_1"] \arrow[d, "\alpha_1"] & F_0 \arrow[r, "f_0"] \arrow[d, "\alpha_0"] & H \arrow[r] \arrow[d, "\mathrm{id}"] & 0 \\
\ldots \arrow[r] & F'_2 \arrow[r, "f'_2"] \arrow[d, "\beta_2"] & F'_1 \arrow[r, "f'_1"] \arrow[d, "\beta_1"] & F'_0 \arrow[r, "f'_0"] \arrow[d, "\beta_0"] & H \arrow[r] \arrow[d, "\mathrm{id}"] & 0 \\
\ldots \arrow[r] & F_2 \arrow[r, "f_2"] & F_1 \arrow[r, "f_1"] & F_0 \arrow[r, "f_0"] & H \arrow[r] & 0.
\end{tikzcd}$$

The maps $\beta_i \circ \alpha_i$ now provide us with the following commutative diagram:

$$\begin{tikzcd}
\ldots \arrow[r] & F_2 \arrow[r, "f_2"] \arrow[d, "\beta_2\circ\alpha_2"] & F_1 \arrow[r, "f_1"] \arrow[d, "\beta_1\circ\alpha_1"] & F_0 \arrow[r, "f_0"] \arrow[d, "\beta_0\circ\alpha_0"] & H \arrow[r] \arrow[d, "\mathrm{id}"] & 0 \\
\ldots \arrow[r] & F_2 \arrow[r, "f_2"] & F_1 \arrow[r, "f_1"] & F_0 \arrow[r, "f_0"] & H \arrow[r] & 0.
\end{tikzcd}$$

This shows that the maps $\beta_i \circ \alpha_i$ define an extension of $\mathrm{id}\colon H \to H$ to the free resolutions F_i and F_i. But the identity maps also define an extension. By Lemma 42.13 the extensions $\{\beta_i \circ \alpha_i\}_{i\in\mathbb{N}_0}$ and $\{\mathrm{id}\}_{i\in\mathbb{N}_0}$ are chain homotopic. The same way one shows that the extensions $\{\alpha_i \circ \beta_i\}_{i\in\mathbb{N}_0}$ and $\{\mathrm{id}\}_{i\in\mathbb{N}_0}$ are chain homotopic.

(2) We had just shown that $\alpha_*\colon F_* \to F'_*$ is a chain homotopy equivalence. One easily verifies that $\alpha_* \otimes \mathrm{id}\colon F_* \otimes G \to F'_* \otimes G$ is also a chain homotopy equivalence. The statement now follows from Corollary 30.3. □

We are now also in a position to prove Proposition 42.12.

Proof. Let G and H be abelian groups and let (F_*, f_*) be a free resolution of H. We denote by (F'_*, f'_*) the canonical free resolution of H. Then by Lemma 42.14 we have a canonical isomorphism

$$\mathrm{Tor}_n(H, G) \;=\; H_n(F'_* \otimes G) \;\xrightarrow{\cong}\; H_n(F_* \otimes G).$$ □

Remark. Using Lemma 42.13 we can now show that the torsion groups $\mathrm{Tor}_n(G, H)$ are "covariantly functorial in both entries". More precisely the following two statements hold:

(1) We fix a group G. Let $\beta\colon H \to H'$ be a homomorphism between two abelian groups. It follows from Lemma 42.13 (3) applied to the canonical free resolutions of H and H' that β induces for each n a canonical homomorphism

$$\beta_*\colon\ \mathrm{Tor}_n(H, G) \;\to\; \mathrm{Tor}_n(H', G).$$

One can now easily show that the maps given by

$$\begin{array}{rcl} H & \mapsto & \mathrm{Tor}_n(H, G) \\ (\beta\colon H \to H') & \mapsto & (\beta_*\colon\ \mathrm{Tor}_n(H, G) \to \mathrm{Tor}_n(H', G)) \end{array}$$

define a covariant functor from the category of abelian groups to the category of abelian groups.

(2) We fix a group H. Let $\alpha\colon G \to G'$ be a homomorphism between two abelian groups. Let F_* be the canonical free resolution of H. Then $\mathrm{id} \otimes \alpha$ defines a chain map from $F_* \otimes G$ to $F_* \otimes G'$ and we get an induced map

$$\alpha_*\colon\ \mathrm{Tor}_n(H, G) \;\to\; \mathrm{Tor}_n(H, G').$$

One can now easily show that the maps given by

$$\begin{array}{rcl} G & \mapsto & \mathrm{Tor}_n(H, G) \\ (\alpha\colon G \to G') & \mapsto & (\alpha_*\colon\ \mathrm{Tor}_n(H, G) \to \mathrm{Tor}_n(H, G')) \end{array}$$

define a covariant functor from the category of abelian groups to the category of abelian groups.

The following lemma shows that the 0-th torsion groups are objects that we are already familiar with.

Lemma 42.15. *Let G and H be abelian groups, then there exists a natural isomorphism* [801]

$$\mathrm{Tor}_0(H, G) \;\xrightarrow{\cong}\; H \otimes G.$$

[801] Note that "natural isomorphism" means in this context that given an abelian group G we have natural isomorphisms from the functor $H \mapsto \mathrm{Tor}_0(H, G)$ to the functor $H \mapsto H \otimes G$ and also from the functor $G \mapsto \mathrm{Tor}_0(H, G)$ to the functor $G \mapsto H \otimes G$.

In the remainder of this course we will use the isomorphism from Lemma 42.15 to identify the groups $\mathrm{Tor}_0(H,G)$ and $H \otimes G$.

Proof. Let G and H be abelian groups. Let

$$\cdots \to F_2 \xrightarrow{f_2} F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H \to 0$$

be the canonical free resolution of H. We know from Lemma 42.10 that the sequence

$$(*) \qquad F_1 \otimes G \xrightarrow{f_1 \otimes \mathrm{id}} F_0 \otimes G \xrightarrow{f_0 \otimes \mathrm{id}} H \otimes G \to 0$$

is exact. Now we obtain the following isomorphism

$$\begin{aligned} \mathrm{Tor}_0(H,G) &\overset{\text{by definition}}{=} H_0\big(\cdots \to F_1 \otimes G \xrightarrow{f_1 \otimes \mathrm{id}} F_0 \otimes G \to 0\big) \\ &= \mathrm{coker}\,\big(F_1 \otimes G \xrightarrow{f_1 \otimes \mathrm{id}} F_0 \otimes G\big) \underset{\text{isomorphism since } (*) \text{ is exact}}{\xrightarrow{f_0 \otimes \mathrm{id}}} H \otimes G. \end{aligned}$$

It is straightforward to verify that these isomorphisms define in fact a natural isomorphism from the functor $H \mapsto \mathrm{Tor}_0(H,G)$ to the functor $H \mapsto H \otimes G$ and also from the functor $G \mapsto \mathrm{Tor}_0(H,G)$ to the functor $G \mapsto H \otimes G$. □

The following lemma shows that we do not need to worry about higher torsion groups for abelian groups.

Lemma 42.16.

(1) *Every abelian group H admits a free resolution of length* 1.
(2) *For any two abelian groups H and G we have* $\mathrm{Tor}_n(H,G) = 0$ *for* $n \geq 2$.

Proof.

(1) Let H be an abelian group. If H is finitely generated, then we already saw on page 1016 that H admits a free resolution of length 1. Now suppose that H is any abelian group. We have the exact sequence

$$0 \to \ker\big(\alpha(H)\colon \mathbb{Z}^{(H)} \to H\big) \to \mathbb{Z}^{(H)} \xrightarrow{\alpha(H)} H \to 0$$

where $\alpha(H)$ is defined as in the proof of Lemma 42.11. It follows from Lemma 11.2 that the group $\ker\big(\alpha(H)\colon \mathbb{Z}^{(H)} \to H\big)$, as the subgroup of the free abelian group $\mathbb{Z}^{(H)}$, is itself free abelian. So in this general case we also found a free resolution of length 1.

(2) Let G and H be abelian groups. By (1) there exists a free resolution of length 1, i.e. of the form

$$0 \to F_1 \to F_0 \to H \to 0.$$

It follows immediately from Proposition 42.12 that $\mathrm{Tor}_n(H,G) \cong H_n(F_* \otimes G) = 0$ for $n \geq 2$. □

Definition. Given two abelian groups H and G we now write $\mathrm{Tor}(H,G) := \mathrm{Tor}_1(H,G)$ and we refer to this group as as the *G-torsion of H*.

Remark. For many purposes the long discussion of G-torsion groups can be summarized in the following statement: it follows from Proposition 42.12 that for a free resolution $0 \to F_1 \xrightarrow{i} F_0 \xrightarrow{j} H \to 0$ of an abelian group H we have

$$\mathrm{Tor}(H,G) \;\cong\; \ker\big\{F_1 \otimes G \xrightarrow{i\otimes \mathrm{id}} F_0 \otimes G\big\}.$$

Now we summarize several properties of the torsion groups $\mathrm{Tor}(H,G)$ in the following lemma.

Lemma 42.17. *Let G, H, $\{H_i\}_{i\in I}$ and $\{G_j\}_{j\in J}$ be abelian groups. Then the following holds:*

(1) *there exists a natural isomorphism* $\mathrm{Tor}\big(\bigoplus_i H_i, G\big) \;\cong\; \bigoplus_i \mathrm{Tor}(H_i,G)$,
(2) *there exists a natural isomorphism* $\mathrm{Tor}\big(H, \bigoplus_j G_j\big) \;\cong\; \bigoplus_j \mathrm{Tor}(H,G_j)$,
(3) *if H is a torsion-free abelian group, then* $\mathrm{Tor}(H,G) = 0$,
(4) *if G is a torsion-free abelian group, then* $\mathrm{Tor}(H,G) = 0$,
(5) *if T denotes the torsion subgroup*[802] *of H, then* $\mathrm{Tor}(H,G) = \mathrm{Tor}(T,G)$,
(6) *for all $n \in \mathbb{N}$ we have a natural isomorphism* $\mathrm{Tor}(\mathbb{Z}_n, G) \;\cong\; \ker\big\{G \xrightarrow{\cdot n} G\big\}$,
(7) *for all $n, m \in \mathbb{N}$ we have* $\mathrm{Tor}(\mathbb{Z}_n, \mathbb{Z}_m) \;\cong\; \mathbb{Z}_{\gcd(n,m)}$.

Remark.

(1) Using this lemma one can usually determine the G-torsion of an abelian group H without any problems. For example the groups $(\mathbb{Q},+)$, $(\mathbb{R},+)$ and $(\mathbb{C},+)$ are torsion-free abelian groups[803] Thus it follows immediately from Lemma 42.17 (4) that for every abelian group H we have
$$\mathrm{Tor}(H,\mathbb{Q}) \;=\; \mathrm{Tor}(H,\mathbb{R}) \;=\; \mathrm{Tor}(H,\mathbb{C}) \;=\; 0.$$
(2) It is a straightforward consequence of the classification of finitely generated abelian groups, see Theorem 11.4, together with Lemma 42.17 that for any two finitely generated abelian groups G and H the corresponding torsion group $\mathrm{Tor}(H,G)$ is finite.[804]

Proof.

(1) For each $i \in I$ we choose a free resolution F^i_* of H_i. Then $\bigoplus_i F^i_*$ is a free resolution of $\bigoplus_i H_i$. The statement follows easily from the natural isomorphisms
$$\Big(\bigoplus_i F^i_j\Big) \otimes G \;\cong\; \bigoplus_i (F^i_j \otimes G)$$

[802]The torsion subgroup of an abelian group is defined as the subgroup of all elements of finite order.
[803]Note though that in Lemma 11.9 we saw that the abelian group $(\mathbb{Q},+)$ is not free abelian.
[804]This fact explains the name "torsion group".

of Lemma 42.3 together with Lemma 29.12 and Proposition 42.12.

(2) We pick a free resolution F_* for H. As in (1) the statement follows easily from the natural isomorphisms

$$F_i \otimes \bigoplus_j G_j \;\cong\; \bigoplus_j F_i \otimes G_j$$

of Lemma 42.3 together with Lemma 29.12 and Proposition 42.12.

(3) If H is a free abelian group, then $0 \to F_0 := H \xrightarrow{\text{id}} H \to 0$ is already a free resolution, and it follows immediately from Proposition 42.12 that $\operatorname{Tor}(H,G) = 0$. Later on we will only use the special case that H is a free abelian group. Therefore we do not provide the proof of the general case of a torsion-free abelian group which is not free. We refer to [Hat, p. 265] for the proof.

(4) By Lemma 42.16 (1) we can pick a free resolution $0 \to F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H$ of length 1 for H. First we consider the case that G is a free abelian group. In this case we have $G \cong \bigoplus_I \mathbb{Z}$ for an index set I. It follows that

$$\operatorname{Tor}(H,G) = \operatorname{Tor}\big(H, \bigoplus_I \mathbb{Z}\big) \underset{\substack{\uparrow \\ \text{by (1)}}}{=} \bigoplus_I \operatorname{Tor}(H,\mathbb{Z}) \underset{\substack{\uparrow \\ \text{Proposition 42.12}}}{\cong} \bigoplus_I H_1(0 \to \underbrace{F_1 \otimes \mathbb{Z}}_{=F_1} \to \underbrace{F_0 \otimes \mathbb{Z}}_{=F_0} \to 0) \;= 0.$$

Now we no longer suppose that G is free abelian, we just suppose that G is an abelian group that is torsion-free. We denote by $\{G_i\}_{i\in I}$ the set of finitely generated subgroups of G. It follows from Theorem 11.4 that each G_i is a free abelian group. We write $i \le j$ if and only if $G_i \subset G_j$. Together with the inclusion maps the groups $\{G_i\}_{i\in I}$ form a direct system. We leave it as an exercise to verify that

$$G \;=\; \varinjlim G_i.$$

We have

$$\begin{aligned}
\operatorname{Tor}(H,G) \;=\; \operatorname{Tor}(H, \varinjlim G_i) \;&=\; H_1\big(0 \to F_1 \otimes \varinjlim G_i \to F_0 \otimes \varinjlim G_i\big) \\
&\underset{\substack{\uparrow \\ \text{by Lemma 42.3 (4)}}}{=} H_1\big(\varinjlim (0 \to F_1 \otimes G_i \to F_0 \otimes G_i \to 0)\big) \\
&\underset{\substack{\uparrow \\ \text{Lemma 34.6}}}{=} \varinjlim \underbrace{H_1(0 \to F_1 \otimes G_i \to F_0 \otimes G_i \to 0)}_{\substack{= 0\text{, by the above, since } G_i \text{ is a} \\ \text{free abelian group}}} \;=\; 0.
\end{aligned}$$

(5) If H is a finitely generated abelian group, then it follows from Theorem 11.4 that we can write H as a direct sum $F \oplus T$, where is T the torsion subgroup and where F is a free abelian group. It follows from (1) and (2) that

$$\operatorname{Tor}(H,G) \;\cong\; \operatorname{Tor}(F \oplus T, G) \underset{\substack{\uparrow \\ \text{by (1)}}}{\cong} \operatorname{Tor}(F,G) \oplus \operatorname{Tor}(T,G) \underset{\substack{\uparrow \\ \text{by (3)}}}{=} \operatorname{Tor}(T,G).$$

For the proof in the case that H is not finitely generated we once again refer to [Hat, p. 265] for a proof.

(6) We consider the free resolution

$$0 \to \mathbb{Z} \xrightarrow{\cdot n} \mathbb{Z} \to \mathbb{Z}_n \to 0$$

for $H = \mathbb{Z}_n$. After tensoring with the abelian group G, and using Lemma 42.3 we obtain the sequence

$$0 \to G \xrightarrow{\cdot n} G \to \mathbb{Z}_n \to 0.$$

It follows from Proposition 42.12 that $\mathrm{Tor}(\mathbb{Z}_n, G) = \ker\left\{G \xrightarrow{\cdot n} G\right\}$.[805]

(7) We showed this isomorphism on page 1017. Alternatively one can deduce the statement using (6). □

42.5. **The Universal Coefficient Theorem.** Before we can state the Algebraic Universal Coefficient Theorem we need to introduce the following definition.

Definition. Let (C_*, ∂_*) be a chain complex and let G be an abelian group. Throughout this chapter, given $n \in \mathbb{N}_0$, we denote by μ the natural[806] homomorphism[807]

$$\begin{array}{rcl} \mu\colon H_n(C_*) \otimes G & \to & H_n(C_* \otimes G) \\ \sum\limits_{i=1}^{m} [c_i] \otimes g_i & \mapsto & \left[\sum\limits_{i=1}^{m} c_i \otimes g_i\right]. \end{array}$$

Now we can formulate and prove the following theorem which is the key result of the whole chapter.

Theorem 42.18. (The Algebraic Universal Coefficient Theorem) *Let (C_n, ∂_n) be a chain complex of free abelian groups and let G be an abelian group. Then for each $n \in \mathbb{N}_0$*

[805]The same argument, together with Lemma 42.15 can be used to give a proof of Lemma 42.3 (3), which back then was perhaps shoved under the carpet a little too quickly.

[806]Here "natural" means that for a chain map $f_*\colon C_* \to D_*$ and a homomorphism $\varphi\colon G \to G'$ between abelian groups the following diagram commutes:

$$\begin{array}{ccc} H_n(C_*) \otimes G & \xrightarrow{\mu} & H_n(C_* \otimes G) \\ \downarrow & & \downarrow \\ H_n(D_*) \otimes G' & \xrightarrow{\mu} & H_n(D_* \otimes G') \end{array}$$

where the vertical maps are induced by f and φ in the, hopefully, obvious way.

[807]It is straightforward to show that the map is well-defined. We will discuss in Exercise 42.1 whether the "obvious converse" is also well-defined.

there exists a natural[808] *short exact sequence of the form*

$$0 \;\to\; H_n(C) \otimes G \;\xrightarrow{\mu}\; H_n(C;G) \;\xrightarrow{p}\; \mathrm{Tor}(H_{n-1}(C), G) \;\to\; 0.$$

Proof. Let (C_n, ∂_n) be a chain complex of free abelian groups. For each $n \in \mathbb{N}_0$ we write as always $Z_n := \ker(\partial_n)$ and $B_n := \mathrm{im}(\partial_{n+1})$. Note that it follows from Lemma 11.2 that B_n and Z_n are free abelian groups.

We consider the following diagram

$$\begin{tikzcd}
 & \vdots \arrow[d] & \vdots \arrow[d] & \vdots \arrow[d] & \\
0 \arrow[r] & Z_n \arrow[r] \arrow[d, "0"] & C_n \arrow[r, "\partial_n"] \arrow[d, "\partial_n"] & B_{n-1} \arrow[r] \arrow[d, "0"] & 0 \\
0 \arrow[r] & Z_{n-1} \arrow[r] \arrow[d] & C_{n-1} \arrow[r, "\partial_{n-1}"] \arrow[d] & B_{n-2} \arrow[r] \arrow[d] & 0 \\
 & \vdots & \vdots & \vdots &
\end{tikzcd}$$

One sees easily that this diagram is commutative and that the horizontal sequences are exact. We can and will view the left and the right vertical columns as chain complexes. In other words, the above diagram is a short exact sequence of chain complexes. Recall that the groups B_n are free abelian groups, thus it follows from Lemmas 33.1 that each of the horizontal sequences splits.

[808]Here "natural" means that if we are given a chain map $f\colon C \to D$ and a homomorphism $\varphi\colon G \to G'$ between abelian groups, then the diagram

$$\begin{tikzcd}
0 \arrow[r] & H_n(C) \otimes G \arrow[r, "\mu"] \arrow[d] & H_n(C;G) \arrow[r, "p"] \arrow[d] & \mathrm{Tor}(H_{n-1}(C), G) \arrow[r] \arrow[d] & 0 \\
0 \arrow[r] & H_n(D) \otimes G' \arrow[r, "\mu"] & H_n(D;G') \arrow[r, "p"] & \mathrm{Tor}(H_{n-1}(D), G') \arrow[r] & 0
\end{tikzcd}$$

commutes. Here the vertical maps are all induced by the chain map $f\colon C \to D$ and the homomorphism $\varphi\colon G \to G'$. (Wait, in which way do f and φ induce the three vertical maps?) We had already pointed out above that the left-hand square commutes.

Now let G be an abelian group. We tensor the above short exact sequence of chain complexes with G and we obtain the following diagram:

$$\begin{tikzcd}
 & \vdots \arrow[d] & \vdots \arrow[d] & \vdots \arrow[d] & \\
0 \arrow[r] & Z_n \otimes G \arrow[r] \arrow[d, "0"] & C_n \otimes G \arrow[r, "\partial_n \otimes \mathrm{id}"] \arrow[d, "\partial_n \otimes \mathrm{id}"] & B_{n-1} \otimes G \arrow[r] \arrow[d, "0"] & 0 \\
0 \arrow[r] & Z_{n-1} \otimes G \arrow[r] \arrow[d] & C_{n-1} \otimes G \arrow[r, "\partial_{n-1} \otimes \mathrm{id}"] \arrow[d] & B_{n-2} \otimes G \arrow[r] \arrow[d] & 0 \\
 & \vdots & \vdots & \vdots &
\end{tikzcd}$$

This is again a sequence of chain complexes.

Since the original short exact sequences split it follows from Lemmas 42.6 that the horizontal sequences obtained from tensoring with G are still exact. Therefore we can apply Proposition 31.10 to obtain a long exact sequence of homology groups. Since the vertical boundary maps on the left and on the right are the zero maps, we obtain the following long exact sequence

$$\ldots \to B_n \otimes G \xrightarrow{d_n} Z_n \otimes G \to H_n(C;G) \xrightarrow{\partial_n} B_{n-1} \otimes G \xrightarrow{d_{n-1}} Z_{n-1} \otimes G \to \ldots$$

where the maps d_n are the connecting homomorphisms of the long exact sequence. It follows easily from the definition that the connecting homomorphism $d_n \colon B_n \otimes G \to Z_n \otimes G$ is the map that is given by $i_n \otimes \mathrm{id} \colon B_n \otimes G \to Z_n \otimes G$ where $i_n \colon B_n \to Z_n$ denotes the obvious inclusion map.[809]

Using Lemma 33.4 the above discussion implies that we obtain the following short exact sequence

$$0 \to \operatorname{coker}\left(B_n \otimes G \xrightarrow{i_n \otimes \mathrm{id}} Z_n \otimes G\right) \to H_n(C;G) \to \ker\left(B_{n-1} \otimes G \xrightarrow{i_{n-1} \otimes \mathrm{id}} Z_{n-1} \otimes G\right) \to 0.$$

We still have to show that the expressions left and right coincide with the desired expressions. We have

$$\begin{array}{ccccc}
\operatorname{coker}\left(B_n \otimes G \xrightarrow{i_n \otimes \mathrm{id}} Z_n \otimes G\right) & \cong & \operatorname{Tor}_0(H_n(C), G) & \cong & H_n(C) \otimes G \\
 & \uparrow & & \uparrow & \\
 & \text{by Proposition 42.12 since } B_n \xrightarrow{i_n} Z_n \to H_n(C) & & \text{Lemma 42.15} & \\
 & \text{is a free resolution of } H_n(C) & & &
\end{array}$$

Similarly we have

$$\ker\left(B_{n-1} \otimes G \xrightarrow{i_{n-1} \otimes \mathrm{id}} Z_{n-1} \otimes G\right) \cong \operatorname{Tor}(H_{n-1}(C), G).$$

We have thus shown the existence of the desired short exact sequences. The statement that the short exact sequence is natural follows easily from the definitions and Lemma 42.13 (2). We leave the verification of the details as an exercise to the reader. □

[809] Why is this the case?

The following theorem is for us the main application of the Universal Coefficient Theorem 42.18.

Theorem 42.19. (Universal Coefficient Theorem) *Let (X, A) be a pair of topological spaces and let G be an abelian group. Then for each $n \in \mathbb{N}_0$ there exists a natural*[810] *short exact sequence*

$$0 \;\to\; H_n(X,A) \otimes G \;\xrightarrow{\mu}\; H_n(X,A;G) \;\to\; \mathrm{Tor}(H_{n-1}(X,A), G) \;\to\; 0.$$

Proof. Let (X, A) be a pair of topological spaces and let G be an abelian group. As we pointed out on page 775, the chain groups $C_n(X, A)$, $n \in \mathbb{N}_0$, are free abelian groups. Thus we can apply the Universal Coefficient Theorem 42.18 and we immediately obtain the desired short exact sequence. □

Examples.

(1) We consider again the real projective space $\mathbb{R}\mathrm{P}^n$. In Proposition 35.11 we saw that

$$H_k(\mathbb{R}\mathrm{P}^n) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k = 0, \\ \mathbb{Z}_2, & \text{if } k \text{ is odd and } k < n, \\ 0, & \text{if } k \text{ is even and } 0 < k \le n, \\ 0, & \text{if } k > n, \\ \mathbb{Z}, & \text{if } k = n \text{ and } n \text{ is odd.} \end{cases}$$

It follows from the Universal Coefficient Theorem 42.19, the discussion on page 1004 and Lemma 42.17 (7) that for any even number $2k \in \{0, \dots, n\}$ we have a short exact sequence

$$0 \;\to\; \underbrace{H_{2k}(\mathbb{R}\mathrm{P}^n) \otimes \mathbb{F}_2}_{\cong 0 \otimes \mathbb{F}_2 = 0} \;\xrightarrow{\mu}\; H_{2k}(\mathbb{R}\mathrm{P}^n; \mathbb{F}_2) \;\to\; \underbrace{\mathrm{Tor}(H_{2k-1}(\mathbb{R}\mathrm{P}^n), \mathbb{F}_2)}_{\cong \mathrm{Tor}(\mathbb{F}_2, \mathbb{F}_2) \cong \mathbb{F}_2} \;\to\; 0$$

whereas for $2k + 1 \in \{0, \dots, n\}$ an odd number we have a short exact sequence

$$0 \;\to\; \underbrace{H_{2k+1}(\mathbb{R}\mathrm{P}^n) \otimes \mathbb{F}_2}_{\cong \mathbb{F}_2 \otimes \mathbb{F}_2 \cong \mathbb{F}_2 \text{ or} \cong \mathbb{Z} \otimes \mathbb{F}_2 \cong \mathbb{F}_2} \;\xrightarrow{\mu}\; H_{2k+1}(\mathbb{R}\mathrm{P}^n; \mathbb{F}_2) \;\to\; \underbrace{\mathrm{Tor}(H_{2k}(\mathbb{R}\mathrm{P}^n), \mathbb{F}_2)}_{\cong \mathrm{Tor}(0, \mathbb{F}_2) = 0 \text{ or } \cong \mathrm{Tor}(\mathbb{Z}, \mathbb{F}_2) = 0} \;\to\; 0.$$

Also it follows easily that $H_k(\mathbb{R}\mathrm{P}^n) = 0$ for $k > n$. Summarizing we obtain the following result

$$H_k(\mathbb{R}\mathrm{P}^n; \mathbb{F}_2) \;\cong\; \begin{cases} \mathbb{F}_2, & \text{if } k = 0, \dots, n, \\ 0, & \text{otherwise.} \end{cases}$$

[810] Here "natural" means that for every map $f\colon (X, A) \to (Y, B)$ between pairs of topological spaces and any homomorphism $\varphi\colon G \to G'$ between abelian groups we obtain the following *commutative* diagram of short exact sequences:

$$\begin{array}{ccccccccc} 0 & \longrightarrow & H_n(X,A) \otimes G & \xrightarrow{\mu} & H_n(X,A;G) & \longrightarrow & \mathrm{Tor}(H_{n-1}(X,A), G) & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & H_n(Y,B) \otimes G' & \xrightarrow{\mu} & H_n(Y,B;G') & \longrightarrow & \mathrm{Tor}(H_{n-1}(Y,B), G') & \longrightarrow & 0, \end{array}$$

where the vertical maps are the obvious (?) ones induced by f and φ.

Fortunately this calculation agrees with the calculation on page 1011.

(2) As on pages 99 and 113 we make the identifications $S^2 = \overline{B}^2/S^1$ and $\mathbb{R}\mathrm{P}^2 = \overline{B}^2/z \sim -z$ where $z \in S^1$. We denote by f the obvious projection map[811]

$$f\colon \mathbb{R}\mathrm{P}^2 = \overline{B}^2/z \sim -z \;\to\; S^2 = \overline{B}^2/S^1.$$

As in Figure 400 we equip $\mathbb{R}\mathrm{P}^2$ with the CW-structure with one 0-cell, one 1-cell and one 2-cell and as on page 648 we equip S^2 with the CW-structure with one 0-cell and one 2-cell. With these CW-structures the above map f is given by collapsing the 1-cell to the unique 0-cell of S^2, in particular f is a cellular map. By Proposition 35.4 and the discussion on page 1010 we obtain the following commutative diagram

$$\begin{tikzcd}
H_2(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) \arrow[r, "f_*"] \arrow[d, "\Phi_{\mathbb{R}\mathrm{P}^2}", "\cong"'] & H_2(S^2;\mathbb{F}_2) \arrow[d, "\cong"', "\Phi_{S^2}"] \\
H_2^{\mathrm{CW}}(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) \arrow[r, "f_*"] & H_2^{\mathrm{CW}}(S^2;\mathbb{F}_2).
\end{tikzcd}$$

As we saw on page 1010, the 2-cell is a generator of $H_2^{\mathrm{CW}}(S^2;\mathbb{F}_2)$ and it gets sent to the 2-cell in S^2 which is, as we saw on page 882, a generator of $H_2^{\mathrm{CW}}(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2)$. Thus we see that the bottom map is an isomorphism, it follows that the top map is also an isomorphism. Summarizing the short exact sequences of the Universal Coefficient Theorem 42.19 give us the following commutative diagram:

$$\begin{tikzcd}
0 \arrow[r] & \overbrace{H_2(\mathbb{R}\mathrm{P}^2)\otimes\mathbb{F}_2}^{=0} \arrow[r, "\mu"] \arrow[d, "f_*", "=0"'] & \overbrace{H_2(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2)}^{\cong\mathbb{F}_2} \arrow[r] \arrow[d, "f_*", "\cong"'] & \overbrace{\mathrm{Tor}(H_1(\mathbb{R}\mathrm{P}^2),\mathbb{F}_2)}^{\cong\mathbb{F}_2} \arrow[r] \arrow[d, "f_*", "=0"'] & 0 \\
0 \arrow[r] & \underbrace{H_2(S^2)\otimes\mathbb{F}_2}_{\cong\mathbb{F}_2} \arrow[r, "\mu"] & \underbrace{H_2(S^2;\mathbb{F}_2)}_{\cong\mathbb{F}_2} \arrow[r] & \underbrace{\mathrm{Tor}(H_1(S^2),\mathbb{F}_2)}_{=0} \arrow[r] & 0.
\end{tikzcd}$$

In the following corollary we give two instances where the tor-terms in the Universal Coefficient Theorem 42.19 are zero, i.e. two instances where we can "pull out" the coefficients.

Corollary 42.20.

(1) *Let (X,A) be a pair of topological spaces and let G be a subgroup of $(\mathbb{C},+)$. Then for each $n \in \mathbb{N}_0$ the map*

$$\mu\colon H_n(X,A;\mathbb{Z})\otimes G \;\to\; H_n(X,A;G)$$

is an isomorphism.

(2) *Let M be a closed, orientable, connected, non-empty n-dimensional manifold, then for any abelian group G the map*

$$\mu\colon H_n(M;\mathbb{Z})\otimes G \;\to\; H_n(M;G)$$

[811]Note that this is not a covering map and that this map has nothing to do with the more familiar projection map $S^2 \to \mathbb{R}\mathrm{P}^2$.

is an isomorphism.

Example. It follows immediately from Proposition 35.11 together with Corollary 42.20 and Lemma 42.3 (3) that

$$H_k(\mathbb{R}\mathrm{P}^{2n+1};\mathbb{R}) \;\cong\; \begin{cases} \mathbb{R}, & \text{if } k=0,2n+1,\\ 0, & \text{otherwise.}\end{cases} \qquad \text{and} \qquad H_k(\mathbb{R}\mathrm{P}^{2n};\mathbb{R}) \;\cong\; \begin{cases} \mathbb{R}, & \text{if } k=0,\\ 0, & \text{otherwise.}\end{cases}$$

Proof. The first statement is an immediate consequence of the Universal Coefficient Theorem 42.19 and the fact, obtained in Lemma 42.17 (4), that the torsion-groups are zero for any subgroup of $(\mathbb{C},+)$. The second statement follows similarly, we just need to replace Lemma 42.17 (4) by Lemma 42.17 (3) together with Proposition 39.17. □

Remark.

(1) Let (X,A) be a pair of topological spaces and let R be a subring of $\mathbb{C}$. Since the map $\mu\colon H_n(X,A;\mathbb{Z})\otimes R \to H_n(X,A;R)$ is functorial we can and we will in the following identify the groups $H_n(X,A;\mathbb{Z})\otimes R$ and $H_n(X,A;R)$ using the isomorphism from Corollary 42.20.
(2) Let R be a subring of $\mathbb{C}$. Lemma 42.17 (4) and the Universal Coefficient Theorem 42.18 show that taking the tensor product with R is an exact functor in the sense of the definition on page 1013.
(3) If M is a closed, *oriented*, connected n-dimensional manifold, then the fundamental class allows us to make the identification $H_n(M;\mathbb{Z}) = \mathbb{Z}$ and the corollary now allows us to make the identification $H_n(M;G) = G$ for any abelian group G.

We conclude this section with the following lemma which we will need later on in the generalization of the Borsuk-Ulam Theorem 7.23 to higher dimensions.

Lemma 42.21. *Let $f\colon S^n \to S^n$ be a map and let $k\in\mathbb{N}$. Then the induced map*

$$f_*\colon H_n(S^n;\mathbb{Z}_k) \;\to\; H_n(S^n;\mathbb{Z}_k)$$

is given by multiplication by $\deg(f)$.

Proof $(*)$. Let $f\colon S^n \to S^n$ be a map and let $k\in\mathbb{N}$. Since the short exact sequence of the Universal Coefficient Theorem 42.19 is natural we obtain the following commutative diagram

$$\begin{array}{ccccccccc}
0 & \longrightarrow & H_n(S^n)\otimes\mathbb{Z}_k & \xrightarrow{\mu} & H_n(S^n;\mathbb{Z}_k) & \longrightarrow & \mathrm{Tor}(H_{n-1}(S^n),\mathbb{Z}_k) & \longrightarrow & 0\\
 & & \downarrow{\scriptstyle f_*\otimes\mathrm{id}} & & \downarrow{\scriptstyle f_*} & & \downarrow{\scriptstyle f_*} & & \\
0 & \longrightarrow & H_n(S^n)\otimes\mathbb{Z}_k & \xrightarrow{\mu} & H_n(S^n;\mathbb{Z}_k) & \longrightarrow & \mathrm{Tor}(H_{n-1}(S^n),\mathbb{Z}_k) & \longrightarrow & 0.
\end{array}$$

Note that $H_{n-1}(S^n)$ is torsion-free, hence $\mathrm{Tor}(H_{n-1}(S^n),\mathbb{Z}_k) = 0$ by Lemma 42.17. It follows from the exactness of the horizontal sequences that the horizontal maps μ on the left are isomorphisms. By definition the map $f_*\colon H_n(S^n)\to H_n(S^n)$ is given by multiplication by $\deg(f)$, hence $f_*\otimes\mathrm{id}$ is also given by multiplication by $\deg(f)$. It now follows that the middle vertical map is also given by multiplication by $\deg(f)$. □

42.6. **Splittings of the Universal Coefficient Theorem.** Our goal had been to determine the homology groups $H_n(C;G)$ only in terms of the original groups $H_k(C)$ and the abelian group G. The Algebraic Universal Coefficient Theorem 42.18 gave us a short exact sequence

$$0 \;\to\; H_n(C)\otimes G \;\xrightarrow{\mu}\; H_n(C;G) \;\xrightarrow{p}\; \mathrm{Tor}(H_{n-1}(C),G) \;\to\; 0.$$

But in general, as we already saw on page 836, given a short exact sequence, it is not possible to determine the middle group of a short exact sequence from the groups to the left and the right. But we saw in Lemma 33.2 that if a short exact sequence of abelian groups

$$0 \;\to\; A \;\xrightarrow{i}\; B \;\xrightarrow{p}\; C \;\to\; 0$$

splits, then the middle group B is the direct sum of the "outer" groups A and C. The question arises, whether the short exact sequence in the Universal Coefficient Theorem 42.18 splits. This is fortunately the case:

Proposition 42.22. *Let (C_n,∂_n) be a free chain complex*[812] *and let G be an abelian group. Then for any $n\in\mathbb{N}_0$ the short exact sequence*

$$0 \;\to\; H_n(C)\otimes G \;\xrightarrow{\mu}\; H_n(C;G) \;\to\; \mathrm{Tor}(H_{n-1}(C),G) \;\to\; 0$$

of the Algebraic Universal Coefficient Theorem 42.18 splits. In particular there exists an isomorphism

$$H_n(C;G) \;\cong\; H_n(C)\otimes G \oplus \mathrm{Tor}(H_{n-1}(C),G).$$

Proof. Let (C_n,∂_n) be a chain complex of free abelian groups and furthermore let G be an abelian group. According to Lemma 33.2 it suffices to construct a homomorphism $\eta\colon H_n(C;G)\to H_n(C)\otimes G$ such that $\eta\circ\mu$ is the identity on $H_n(C)\otimes G$.

For each $n\in\mathbb{N}_0$ we write as always $Z_n := \ker(\partial_n)$ and $B_n := \mathrm{im}(\partial_{n+1})$. We consider the short exact sequence

$$0 \;\to\; Z_n \;\hookrightarrow\; C_n \;\xrightarrow{\partial_n}\; B_{n-1} \;\to\; 0.$$

The group $B_{n-1}\subset C_{n-1}$ is a subgroup of a free abelian group, thus it is itself a free abelian group by Lemma 11.2. Therefore we can deduce from Lemma 33.1 that the above short exact sequence splits. In particular, according to Lemma 33.2, for each $n\in\mathbb{N}_0$ there exists a homomorphism $p_n\colon C_n\to Z_n$ such that p_n is the identity on $Z_n\subset C_n$.

[812] A chain complex (C_*,∂_*) is called *free*, if all the groups C_n are free abelian groups.

Claim. The following diagram commutes:

$$\begin{tikzcd}
\dots \arrow[r] & C_{n+1} \arrow[r, "\partial_{n+1}"] \arrow[d, shift left, "p_{n+1}"] \arrow[dr, "\partial_{n+1}"] & C_n \arrow[r, "\partial_n"] \arrow[d, shift left, "p_n"] \arrow[dr, "\partial_n"] & C_{n-1} \arrow[r, "\partial_{n-1}"] \arrow[d, shift left, "p_{n-1}"] & \dots \\
& Z_{n+1} \arrow[u, hook, shift left] \arrow[d, two heads, "q_{n+1}"] & Z_n \arrow[u, hook, shift left] \arrow[d, two heads, "q_n"] & Z_{n-1} \arrow[u, hook, shift left] \arrow[d, two heads, "q_{n-1}"] & \\
\dots \arrow[r] & \underbrace{H_{n+1}(C)}_{=Z_{n+1}/B_{n+1}} \arrow[r, "0"] & \underbrace{H_n(C)}_{=Z_n/B_n} \arrow[r, "0"] & \underbrace{H_{n-1}(C)}_{=Z_{n-1}/B_{n-1}} \arrow[r, "0"] & \dots
\end{tikzcd}$$

where the maps q_n are just the obvious projection maps.

We start at C_{n+1}. If we go down and then right, then we end up with the zero map to $H_n(C)$. On the other hand, if we first go right, then we end up in $B_n \subset Z_n$, but then the projection q_n to $H_n(C) = Z_n/B_n$ is also the zero map. This concludes the proof of the claim.

The top and the bottom horizontal sequences of the claim are chain complexes. Since the diagram commutes we see that the vertical maps from top to bottom are chain maps.

Now we tensor the top and the bottom horizontal sequences with G and we obtain the following diagram of chain complexes.

$$\begin{tikzcd}
\dots \arrow[r] & C_{n+1} \otimes G \arrow[r, "\partial_{n+1}\otimes\mathrm{id}"] \arrow[d, "(q_{n+1}\circ p_{n+1})\otimes\mathrm{id}"] & C_n \otimes G \arrow[r, "\partial_n\otimes\mathrm{id}"] \arrow[d, "(q_n\circ p_n)\otimes\mathrm{id}"] & C_{n-1} \otimes G \arrow[r, "\partial_{n-1}\otimes\mathrm{id}"] \arrow[d, "(q_{n-1}\circ p_{n-1})\otimes\mathrm{id}"] & \dots \\
\dots \arrow[r] & H_{n+1}(C) \otimes G \arrow[r, "0"] & H_n(C) \otimes G \arrow[r, "0"] & H_{n-1}(C) \otimes G \arrow[r, "0"] & \dots
\end{tikzcd}$$

The induced maps on the homology of these two chain complexes give us a homomorphism

$$\eta\colon H_n(C;G) \;=\; H_n(C_* \otimes G) \;\to\; H_n(\text{lower sequence}) = H_n(C) \otimes G.$$

It remains to prove the following claim.

Claim. The composition $\eta \circ \mu$ is the identity on $H_n(C) \otimes G$.

Let $[\sigma] \otimes g \in H_n(C) \otimes G$ where $\sigma \in Z_n$. Then

$$(\eta \circ \mu)([\sigma] \otimes g) \;=\; \eta([\sigma \otimes g]) \;\underset{\substack{\uparrow \\ \text{definition of } \eta}}{=}\; (q_n(p_n(\sigma))) \otimes g \;\underset{\substack{\uparrow \\ \text{since } p_n = \mathrm{id} \text{ on } Z_n}}{=}\; q_n(\sigma) \otimes g \;=\; [\sigma] \otimes g.$$

This concludes the proof of the claim. □

The following immediate corollary to Proposition 42.22 shows in particular that the homology groups with G-coefficients of a topological space X are completely determined by the usual homology groups of X and the abelian group G.

Theorem 42.23. *Let (X, A) be a pair of topological spaces and let G be an abelian group. Then for each $n \in \mathbb{N}_0$ the short exact sequence*

$$0 \;\to\; H_n(X, A) \otimes G \;\xrightarrow{\mu}\; H_n(X, A; G) \;\to\; \mathrm{Tor}(H_{n-1}(X, A), G) \;\to\; 0$$

from the Universal Coefficient Theorem 42.19 splits. In particular there exists an isomorphism

$$H_n(X, A; G) \;\cong\; H_n(X, A) \otimes G \oplus \mathrm{Tor}(H_{n-1}(X, A), G).$$

The question now arises, whether given an abelian group G there exists in fact a *natural* isomorphism

$$H_n(X; G) \;\cong\; H_n(X) \otimes G \oplus \mathrm{Tor}(H_{n-1}(X), G).$$

The following proposition says that such a natural isomorphism does not exist for $G = \mathbb{F}_2$. More precisely, we have the following proposition.

Proposition 42.24. *It is not possible assign to each topology space X an isomorphism*

$$\Phi_X \colon H_n(X; \mathbb{F}_2) \;\to\; H_n(X) \otimes \mathbb{F}_2 \oplus \mathrm{Tor}(H_{n-1}(X), \mathbb{F}_2)$$

such that for any map $f \colon X \to Y$ between topological spaces the following diagram commutes:

$$\begin{tikzcd}
H_n(X; \mathbb{F}_2) \arrow[r, "\Phi_X", "\cong"'] \arrow[d, "f_*"] & H_n(X) \otimes \mathbb{F}_2 \oplus \mathrm{Tor}(H_{n-1}(X), \mathbb{F}_2) \arrow[d, "f_*"] \arrow[d, phantom, shift right=6ex, "f_*"] \\
H_n(Y; \mathbb{F}_2) \arrow[r, "\Phi_Y", "\cong"'] & H_n(Y) \otimes \mathbb{F}_2 \oplus \mathrm{Tor}(H_{n-1}(Y), \mathbb{F}_2).
\end{tikzcd}$$

Proof. So suppose instead that such a map Φ_X exists for every topological space X. We consider the map

$$f \colon \mathbb{R}\mathrm{P}^2 = \overline{B}^2/z \sim -z \;\to\; S^2 = \overline{B}^2/S^1$$

from page 1029. We obtain the following diagram:

$$\begin{tikzcd}
\overbrace{H_2(\mathbb{R}\mathrm{P}^2; \mathbb{F}_2)}^{\cong \mathbb{F}_2} \arrow[r, "\Phi_{\mathbb{R}\mathrm{P}^2}", "\cong"'] \arrow[d, "f_*"'] & \overbrace{H_2(\mathbb{R}\mathrm{P}^2) \otimes \mathbb{F}_2}^{=0} \oplus \overbrace{\mathrm{Tor}(H_1(\mathbb{R}\mathrm{P}^2), \mathbb{F}_2)}^{\cong \mathbb{F}_2} \arrow[d, "f_*", "=0"'] \arrow[d, phantom, shift right=6ex, "f_*", "=0"'] \\
\underbrace{H_2(S^2; \mathbb{F}_2)}_{\cong \mathbb{F}_2} \arrow[r, "\Phi_{\mathbb{R}\mathrm{P}^2}", "\cong"'] & \underbrace{H_2(S^2) \otimes \mathbb{F}_2}_{\cong \mathbb{F}_2} \oplus \underbrace{\mathrm{Tor}(H_1(S^2), \mathbb{F}_2)}_{=0}.
\end{tikzcd}$$

The horizontal maps are by hypothesis isomorphisms. We saw on page 1029 that the vertical map on the left is an isomorphism. On the other hand the two vertical maps on the right are zero since either the domain or the target is zero. Thus this diagram cannot possibly commute. We have thus found a contradiction to our assumption. $\square$

42.7. **Isomorphisms on homology groups induce chain homotopies** $(*)$**.** We have now all the tools to prove the following purely algebraic proposition.

Proposition 42.25. *Let C_* and C'_* be two free chain complexes. Suppose that for each $n \in \mathbb{N}_0$ we are given an isomorphism $\varphi_n \colon H_n(C_*) \to H_n(C'_*)$, then there exists a chain map $C_* \to C'_*$, which induces the maps φ_n, and which is a chain homotopy equivalence.*

Remark. Let C_* be a chain complex and let G be a group. The combination of the Universal Coefficient Theorem 42.18 with Theorem 42.23 shows that the homology groups of the tensor product $C_* \otimes G$ do not contain more formation than was already contained in the homology groups of C_*. Proposition 42.25 gives another explanation for this fact since it shows that the chain complex C_*, is up to chain homotopy, determined by its homology groups. But the homology groups of $C_* \otimes G$ depend only on the chain homotopy type of C_*.

The statement of Proposition 42.25 is going to be an immediate consequence of the next two lemmas. Before we can state the first lemma we need to introduce one more definition.

Definition. We say that a chain complex is *basic* if it is of the form $0 \to E_n \xrightarrow{e_n} E_{n-1} \to 0$ where E_n and E_{n-1} are free abelian groups and where e_n is injective.

The first lemma implies Proposition 42.25 in the special case that both chain complexes are basic.

Lemma 42.26. *Suppose that we have two basic chain complexes $0 \to E_n \overset{e_n}{\hookrightarrow} E_{n-1} \to 0$ and $0 \to F_n \overset{f_n}{\hookrightarrow} F_{n-1} \to 0$. Then for every isomorphism*

$$\varphi \colon H_{n-1}(E_*) = \operatorname{coker}(e_n) \ \to \ \operatorname{coker}(f_n) = H_{n-1}(F_*)$$

there exists a chain map $E_* \to F_*$ that induces that isomorphism and that is a homotopy equivalence.

Proof. By Lemma 42.13, applied twice, there exist maps $\alpha_i \colon E_i \to F_i$, $i = n-1, n$ and there exist maps $\beta_i \colon F_i \to E_i$, $i = n-1, n$ such that the diagram

$$\begin{tikzcd}
0 \arrow[r] & E_n \arrow[r, "e_n"] \arrow[d, "\alpha_n"] & E_{n-1} \arrow[r, "p"] \arrow[d, "\alpha_{n-1}"] & \operatorname{coker}(e_n) \arrow[r] \arrow[d, "\varphi"] & 0 \\
0 \arrow[r] & F_n \arrow[r, "f_n"] \arrow[d, "\beta_n"] & F_{n-1} \arrow[r, "q"] \arrow[d, "\beta_{n-1}"] & \operatorname{coker}(f_n) \arrow[r] \arrow[d, "\varphi^{-1}"] & 0 \\
0 \arrow[r] & E_n \arrow[r, "e_n"] & E_{n-1} \arrow[r, "p"] & \operatorname{coker}(e_n) \arrow[r] & 0
\end{tikzcd}$$

commutes. From the second part of Lemma 42.13 it follows that $\beta_* \circ \alpha_* \simeq \mathrm{id}_{E_*}$ and that $\alpha_* \circ \beta_* \simeq \mathrm{id}_{F_*}$. Put differently, α_* is a chain homotopy equivalence. $\square$

The next lemma says that we can decompose every free chain complex into a direct sum of basic chain complexes. Proposition 42.25 is an immediate consequence of Lemma 42.26, Lemma 29.12 and the following lemma.

Lemma 42.27. *Let (C_*, ∂_*) be a free chain complex. Then there exist basic chain complexes (F_*^n, ∂_*), $n \in \mathbb{N}_0$ such that*

$$C_* \;\cong\; \bigoplus_{n\in\mathbb{N}_0} F_*^n.$$

Proof. Let (C_*, ∂_*) be a chain complex. For $n \in \mathbb{N}_0$ we write $Z_n = \ker(\partial_n \colon C_n \to C_{n-1})$ and $B_n = \operatorname{im}(\partial_{n+1} \colon C_{n+1} \to C_n)$. Note that we have a short exact sequence

$$0 \;\to\; Z_n \;\to\; C_n \;\xrightarrow{\partial_n}\; B_{n-1} \;\to\; 0.$$

Since C_{n-1} is free abelian it follows from Lemma 11.2 that the subgroup B_{n-1} is also free abelian. It follows immediately from Lemmas 33.1 and 33.2 that there exists an isomorphism $\Phi_n \colon C_n \to Z_n \oplus B_{n-1}$ such that the following diagram commutes:

$$\begin{tikzcd}
 & & C_n \arrow[dr, "\partial_n"] \arrow[dd, "\cong", "\Phi_n"'] & & \\
0 \arrow[r] & Z_n \arrow[ur, "i"] \arrow[dr] & & B_{n-1} \arrow[r] & 0 \\
 & & Z_n \oplus B_{n-1} \arrow[ur] & &
\end{tikzcd}$$

where the lower left diagonal map is the obvious inclusion and the lower right diagonal map is the obvious projection map. Given $n \in \mathbb{N}_0$ we now denote by F_*^n the chain complex that is given by

$$0 \;\to\; B_{n-1} \;\hookrightarrow\; Z_{n-1} \;\to\; 0.$$

As before it follows from Lemma 11.2 that this is a basic chain complex. It is straightforward to verify that

$$\bigoplus_{n\in\mathbb{N}_0} \Phi_n \colon C_* \;\to\; \bigoplus_{n\in\mathbb{N}_0} F_*^n$$

is an isomorphism of chain complexes. □

At the end of this section we return to the relationship between cellular and singular chain complexes of a CW-complex. More precisely, let X be a CW-complex. In Proposition 35.4 we showed that for any $n \in \mathbb{N}_0$ there exists a natural isomorphism $H_n(X) \to H_n^{\mathrm{CW}}(X)$. Picking up the discussion from page 888 we can now generalize this statement. More precisely from Proposition 35.4 and 42.25 we immediately obtain the following corollary.

Corollary 42.28. *Let X be a CW-complex. Then the singular chain complex $C_*(X)$ is chain homotopic to the cellular chain complex $C_*^{\mathrm{CW}}(X)$.*

42.8. **Homological algebra over an arbitrary commutative ring** $(*)$**.** A lot of the algebra that we had studied in the previous sections can be generalized from the case of abelian groups, i.e. the case of $\mathbb{Z}$-modules, to modules over a commutative ring. We will not make use of the generalizations that we discuss in this short section.

Throughout this section let R be a commutative ring. Let V and W be two R-modules. We say that an R-homomorphism $f\colon V \times W \to X$ to an R-module X is *R-bilinear*, if for all $v, v' \in V$, $w, w' \in W$ and $r \in R$ the following holds:

$$\begin{array}{rcl} f(v+v',w) & = & f(v,w)+f(v',w), \\ f(rv,w) & = & rf(v,w) \end{array} \quad \text{and} \quad \begin{array}{rcl} f(v,w+w') & = & f(v,w)+f(v,w') \\ f(v,rw) & = & rf(v,w). \end{array}$$

We say an R-bilinear map $f\colon V \times W \to X$ has the *universal R-bilinear property*, if for every R-bilinear map $g\colon V \times W \to Y$ there exists a *unique* R-homomorphism $\varphi\colon X \to Y$ such that the following diagram commutes:

$$\begin{tikzcd} V \times W \arrow[r, "f"] \arrow[dr, "g"'] & X \arrow[d, "\varphi \text{ unique}"] \\ & Y. \end{tikzcd}$$

Using a variation of the definition of the tensor product of abelian groups that we gave on page 1001 one can now fairly easily prove that there exists an R-bilinear map $f\colon V \times W \to X$ which has the universal R-bilinear property.

A variation of the usual "universal property" argument shows that if $f\colon V \times W \to X$ and $f'\colon V \times W \to X'$ are maps that both have the universal R-bilinear property, then there exists a unique isomorphism $\varphi\colon X \to X'$ of R-modules such that $\varphi(f(v,w)) = f'(v,w)$ for all $v \in V$ and $w \in W$.

We denote by $V \otimes_R W$ the R-module that satisfies satisfies the above property. (By the universal property we see that $V \otimes_R W$ is uniquely determined up to isomorphism.) Note that $V \otimes_R W$ comes with an R-bilinear map $V \times W \to V \otimes_R W$. Given $v \in V$ and $w \in W$ we denote the image of (v,w) by $v \otimes w$. If $R = \mathbb{Z}$, then it follows from the remark after Lemma 42.2 that $V \otimes_{\mathbb{Z}} W$ is isomorphic to $V \otimes W$.

As before we see that given an R-module W the map $V \mapsto V \otimes_R W$ defines a functor from the category of R-modules to the category of R-modules. The proof of Lemma 42.10 shows that this functor is right-exact.

We define a *free R-module* precisely the same way as we defined a free abelian group. A *free resolution* of an R-module M is an exact sequence

$$\cdots \to \ F_2 \ \xrightarrow{f_2} \ F_1 \ \xrightarrow{f_1} \ F_0 \ \xrightarrow{f_0} \ M \ \to \ 0$$

where each F_i is a free R-module. We can construct the canonical free resolution of an R-module M the same was as we did on page 1016.

Given two R-modules M and N we can define the torsion R-modules $\operatorname{Tor}_n^R(M,N)$ as before. More precisely, we take the canonical free resolution

$$\cdots \to \ F_2 \ \xrightarrow{f_2} \ F_1 \ \xrightarrow{f_1} \ F_0 \ \xrightarrow{f_0} \ M \ \to \ 0$$

and we define

$$\operatorname{Tor}_n^R(M,N) \ := \ H_n(F_* \otimes_R N).$$

Here the following statements hold:

(1) As in Proposition 42.12 one can show that the isomorphism type of $\mathrm{Tor}_n^R(M,N)$ can be determined using any free resolution for M.
(2) The argument of page 1021 shows that for each $n \in \mathbb{N}_0$ the R-torsion module $\mathrm{Tor}_n^R(M,N)$ is covariantly functorial in both entries.
(3) The proof of Lemma 42.15 can also be generalized to show that given any two R-modules M and N we have a natural isomorphism $\mathrm{Tor}_0^R(M,N) \cong M \otimes_R N$.
(4) The obvious analogues of Lemma 42.17 (1) and (2) also hold in the more general context. Furthermore the obvious analogues of Lemma 42.17 (3) and (4) hold if we replace "torsion-free abelian group" by "free R-module".[813] In general there are no analogues of Lemma 42.17 (5), (6) and (7).
(5) For general commutative rings it is no longer true though that $\mathrm{Tor}_i^R(M,N) = 0$ for $i \geq 2$. For example for $R = \mathbb{Q}[t_1, \ldots, t_k]$ the R-torsion modules can be non-zero for $i = 1, \ldots, k$ and they are only zero for $i > k$. We refer to [Mac, Chapter VII.4] for details.

Now let (C_*, ∂_*) be a chain complex of R-modules. Furthermore let M be another R-module. We consider the chain complex $C_* \otimes_R M$ of R-modules. It is natural to ask whether one can again determine the homology groups of $C_* \otimes_R M$ from the torsion groups $\mathrm{Tor}_k^R(H_l(C), M)$ with $k \in \mathbb{N}_0$. If R is a principal ideal domain (usually abbreviated by PID), then almost the same statement as in the Universal Coefficient Theorem 42.18 holds. On the other hand, if R is not a principal ideal, then as we pointed out above, the higher torsion groups are in general non-zero and the problem becomes much more subtle. The torsion-terms and the homology with M-coefficients are then related by a "spectral sequence", see e.g. [Rot2, Theorem 10.90] for details.

42.9. **The Eilenberg-Steenrod axioms for homology** $(*)$**.** In this section we give a very short introduction to the concept of (co-) homology theories which was introduced in the seminal book of Eilenberg–Steenrod [ES].

Before we can do so we introduce the following definition.

Definition. Let R be a commutative ring and let S be a set.

(1) An *S-graded R-module* is defined as an R-module M together with a direct sum decomposition $M = \bigoplus_{s \in S} M_s$ into R-modules M_s, $s \in S$. If $x \in M$ lies in some M_s, then we call x *homogeneous* and we refer to $\deg(x) := s$ as the *degree of* x.
(2) A *morphism $f\colon M \to N$ between S-graded R-modules M and N* is an R-module homomorphism such that for each $s \in S$ we have $f(M_s) \subset N_s$. Equivalently, it is a family of R-module homomorphisms $\{f_s\colon M_s \to N_s\}_{s \in S}$.
(3) The *category of S-graded R-modules* is the category where the objects are S-graded R-modules and the morphisms are the ones described in (2).

[813] Note that in general "R-torsion free module" is not going to be strong enough.

Examples. Given a pair of topological spaces (X, Y) and an abelian group G we write

$$H_*(X, Y; G) \ := \ \bigoplus_{n \in \mathbb{N}_0} H_n(X, Y; G)$$

and we view $H_*(X, Y; G)$ as an $\mathbb{N}_0$-graded $\mathbb{Z}$-module.

The following definition goes back to [ES] and [Mi10].

Definition. A *homology theory* is a covariant functor

$$\mathcal{H}\colon \text{category of pairs of topological spaces} \ \to \ \text{category of } \mathbb{N}_0\text{-graded abelian groups}$$

that satisfies the following axioms:[814]

(1) (Homotopy invariant) If $f, g\colon (X, A) \to (Y, B)$ are homotopic maps between pairs of topological spaces, then $f_* = g_*$.
(2) (Connecting homomorphism) Given any pair (X, A) of topological spaces and any $n \in \mathbb{N}$ there exists a natural connecting homomorphism $\partial\colon \mathcal{H}_n(X, A) \to \mathcal{H}_{n-1}(A)$[815] such that the sequence
$$\ldots \ \to \ \mathcal{H}_{n+1}(X, A) \ \xrightarrow{\partial} \ \mathcal{H}_n(A) \ \to \ \mathcal{H}_n(X) \ \to \ \mathcal{H}_n(X, A) \ \xrightarrow{\partial} \ \mathcal{H}_{n-1}(A) \ \to \ \ldots$$
is exact.
(3) (Excision) If U and A are subsets of a topological space X with $\overline{U} \subset \mathring{A}$, then for each $n \in \mathbb{N}_0$ the map $\mathcal{H}_n(X \setminus U, A \setminus U) \to \mathcal{H}_n(X, A)$ is an isomorphism.
(4) (Additivity) Let $\{(X_j, A_j)\}_{j \in J}$ be a family of pairs of topological spaces. We write $X = \bigsqcup_{j \in J} X_j$ and $A = \bigsqcup_{j \in J} A_j$. If given $j \in J$ we denote by $i_j\colon X_j \to X$ the obvious inclusion map, then for any $k \in \mathbb{N}_0$ the induced map
$$\bigoplus_{j \in J} i_{j*}\colon \bigoplus_{j \in J} \mathcal{H}_k(X_j, A_j) \ \to \ \mathcal{H}_k(X, A)$$
is an isomorphism.
(5) (Dimension axiom) We denote by $\star$ the topological space that consists of a single point. For $n \neq 0$ we have $H_n(\star) = 0$.

Example. It follows from Proposition 31.15, Corollary 31.14, the Excision Theorem 31.17, the obvious generalization of Lemma 29.13 and Lemma 29.6 that singular homology is indeed a homology theory.

The following theorem gives a uniqueness statement for homology theories.

Theorem 42.29. *Let $\mathcal{H}$ and $\mathcal{H}'$ be two homology theories and let $\varphi\colon \mathcal{H}_0(\star) \to \mathcal{H}'_0(\star)$ be an isomorphism. Then there exists a natural isomorphism between $\mathcal{H}$ and $\mathcal{H}'$ viewed as functors*

$$\textit{category of CW-complexes} \ \to \ \textit{category of } \mathcal{N}_0\textit{-graded groups.}$$

[814]The axioms are usually called Eilenberg-Steenrod axioms.

[815]Here we use the obvious notation that for a topological space Y we write $\mathcal{H}_n(Y) := \mathcal{H}_n(Y, \varnothing)$.

Sketch of a proof. Let G be an abelian group. We start our proof with the following observation: Given a pair (X, A) of CW-complexes we saw in Corollary 26.24 (3) that we can equip the mapping cone $\mathrm{Cone}(i\colon A \to X)$ of the inclusion map with a natural CW-structure. Given $n \in \mathbb{N}_0$ we define the n-th cellular homology $H_n^{\mathrm{CW}}(X, A; G)$ as the reduced cellular homology with G-coefficients of the mapping cone.

Proposition 35.4, together with Lemma 33.17, Proposition 35.4 and the discussion on page 1010 shows that for pairs of CW-complexes there exists a natural isomorphism between singular homology with G-coefficients and cellular homology with G-coefficients. Closer inspection of the proof shows that we can prove this statement only using the above Eilenberg-Steenrod axioms and the fact that $H_0(\star; G) \cong G$.

Now let $\alpha\colon \mathcal{H}_0(\star) \to G$ be an isomorphism. By the above one can show that there exists a natural isomorphism from $\mathcal{H}$ to $H_n^{\mathrm{CW}}(-; G)$. The same applies to $\mathcal{H}'$ and we obtain the theorem as long as φ is an isomorphism. This approach to the proof is developed in more detail in [tD2, Chapter 12.2]. □

Remark.

(1) Closely related results are also proved in [ES, p. 100] and [Hu, p. 52], see also [GH, p. 138].
(2) The axioms of a cohomology theory are defined basically the same way with the obvious modifications and the analogue of Theorem 42.29 also holds in this context, see [DK, Theorem 1.31].
(3) If one drops the dimension axiom, then there are other (co-) homology theories, for example "topological K-theory". We refer to [Karo] for details.

Exercises for Chapter 42.

Exercise 42.1. Let (C_*, ∂_*) be a chain complex and let G be an abelian group. We consider the following map:

$$\begin{array}{ccc} H_n(C_* \otimes G) & \to & H_n(C_*) \otimes G \\ \left[\sum\limits_{i=1}^{n} c_i \otimes g_i\right] & \mapsto & \sum\limits_{i=1}^{n} [c_i] \otimes g_i \end{array}$$

Is this map well-defined?

Exercise 42.2. What are the homology groups of $\mathbb{R}\mathrm{P}^5$ with $\mathbb{F}_3$-coefficients?

Exercise 42.3. Let $A \to B \to C$ be a short exact sequence of abelian groups and let G be an abelian group. Show that there exists an exact sequence of the form

$$0 \to \mathrm{Tor}(A, G) \to \mathrm{Tor}(B, G) \to \mathrm{Tor}(C, G) \to A \otimes G \to B \otimes G \to C \otimes G \to 0.$$

Exercise 42.4. Determine $\mathrm{Tor}(\mathbb{Z}_n, \mathbb{Q}/\mathbb{Z})$.

Exercise 42.5. Let $m, n \in \mathbb{N}$. Show that

$$\mathrm{Tor}(\mathbb{Z}_m, \mathbb{Z}_n) \cong \mathbb{Z}_{\gcd(m,n)}.$$

Exercise 42.6. Show that

$$\Big(\prod_{n\in\mathbb{N}} \mathbb{Z}_n\Big) \otimes \mathbb{Q} \neq 0.$$

43. The Künneth Theorem

In this chapter we want to study the following question:

Question 43.1. *Let X and Y be two topological spaces. What is the connection between the homology groups of X and Y on the one hand and the homology groups of the product topological space $X \times Y$ on the other hand?*

43.1. **The tensor product of chain complexes.** First we want to find some connection between the chain complexes of X, Y and $X \times Y$. To do so we need the notion of the tensor product of chain complexes. Therefore we start out with a short excursion into homological algebra, i.e. into the study of chain complexes.

Lemma 43.2. *Let $\mathcal{C} = (C_*, \partial_*)$ and $\mathcal{C}' = (C'_*, \partial'_*)$ be two chain complexes. Given $n \in \mathbb{N}_0$ we define*

$$(\mathcal{C} \otimes \mathcal{C}')_n \ := \bigoplus_{p+q=n} C_p \otimes C'_q.$$

The consider the maps

$$d\colon (\mathcal{C} \otimes \mathcal{C}')_n \ \to \ (\mathcal{C} \otimes \mathcal{C}')_{n-1}$$

which are uniquely determined by

$$c_p \otimes c'_q \ \mapsto \ \partial c_p \otimes c'_q + (-1)^p \cdot c_p \otimes \partial' c'_q$$

for $c_p \in C_p$ and $c'_q \in C'_q$. The maps turn $\mathcal{C} \otimes \mathcal{C}'$ into a chain complex, called the tensor product $\mathcal{C} \otimes \mathcal{C}'$ of the chain complexes $\mathcal{C}$ and $\mathcal{C}'$.

We illustrate the definition of the tensor product of chain complexes in Figure 618.

$$\begin{tikzcd}
C_0 \otimes C'_2 \arrow[d, "\mathrm{id} \otimes \partial'_2"] & C_1 \otimes C'_2 \arrow[l, "\partial_1 \otimes \mathrm{id}"'] \arrow[d, "-\mathrm{id} \otimes \partial'_2"] & C_2 \otimes C'_2 \arrow[l, "\partial_2 \otimes \mathrm{id}"'] \arrow[d, "\mathrm{id} \otimes \partial'_2"] \\
C_0 \otimes C'_1 \arrow[d, "\mathrm{id} \otimes \partial'_1"] & C_1 \otimes C'_1 \arrow[l, "\partial_1 \otimes \mathrm{id}"'] \arrow[d, "-\mathrm{id} \otimes \partial'_1"] & C_2 \otimes C'_1 \arrow[l, "\partial_2 \otimes \mathrm{id}"'] \arrow[d, "\mathrm{id} \otimes \partial'_1"] \\
C_0 \otimes C'_0 & C_1 \otimes C'_0 \arrow[l, "\partial_1 \otimes \mathrm{id}"'] & C_2 \otimes C'_0 \arrow[l, "\partial_2 \otimes \mathrm{id}"']
\end{tikzcd}$$

Figure 618. The tensor product of chain complexes.

Proof. We still have to show that the maps d are indeed boundary maps of a chain complex, i.e. we have to verify that $d \circ d = 0$. This is the case since for any $c_p \in C_p$ and $c'_q \in C'_q$ we

have

$$\begin{aligned} d(d(c_p \otimes c'_q)) &= d(\overbrace{\partial c_p}^{\in C_{p-1}} \otimes c'_q) + d((-1)^p \cdot c_p \otimes \overbrace{\partial' c'_q}^{\in C'_{q-1}}) \\ &= \underbrace{\partial\partial c_p}_{=0} \otimes c'_q + (-1)^{p-1} \cdot \partial c_p \otimes \partial' c'_q + (-1)^p \cdot \partial c_p \otimes \partial' c'_q + (-1)^p \cdot c_p \otimes \underbrace{\partial'\partial' c'_q}_{=0} \\ &= (-1)^{p-1} \cdot \partial c_p \otimes \partial' c'_q - (-1)^{p-1} \cdot \partial c_p \otimes \partial' c'_q \;=\; 0. \end{aligned}$$

Thus we have shown that $(\mathcal{C} \otimes \mathcal{C}', d)$ is indeed a chain complex.[816] □

Example. Let

$$\mathcal{C} \;=\; \cdots \to C_n \xrightarrow{\partial_n} C_{n-1} \xrightarrow{\partial_{n-1}} C_{n-2} \to \dots \qquad \text{and} \qquad \mathcal{C}' \;=\; 0 \;\to\; \underset{\substack{\uparrow \\ \text{in degree } k}}{G} \;\to\; 0$$

be two chain complexes where the second consists of a single abelian group. In this case we have

$$(\mathcal{C}_* \otimes \mathcal{C}'_*)_n \;=\; \mathcal{C}_{n-k} \otimes G,$$

i.e. the tensor product is just given by tensoring the chain groups of $\mathcal{C}$ by G and shifting the degrees by $-k$.

We conclude this section with the following lemma.

Lemma 43.3. *Let $\mathcal{C}$ and $\mathcal{D}$ be two chain complexes.*

(1) *Given two chain maps $f\colon \mathcal{C} \to \mathcal{D}$ and $f'\colon \mathcal{C}' \to \mathcal{D}'$ the induced map*

$$\begin{aligned} f \otimes f'\colon \mathcal{C} \otimes \mathcal{C}' &\to \mathcal{D} \otimes \mathcal{D}' \\ \sum_{i=1}^n c_i \otimes c'_i &\mapsto \sum_{i=1}^n f(c_i) \otimes f'(c'_i) \end{aligned}$$

is also a chain map.

(2) *If $f, g\colon \mathcal{C} \to \mathcal{D}$ and $f', g'\colon \mathcal{C}' \to \mathcal{D}'$ are chain homotopic maps, then the induced maps*

$$f \otimes f', g \otimes g'\colon \mathcal{C} \otimes \mathcal{C}' \;\to\; \mathcal{D} \otimes \mathcal{D}'$$

are also chain homotopic.

(3) *If $f\colon \mathcal{C} \to \mathcal{D}$ and $f'\colon \mathcal{C}' \to \mathcal{D}'$ are homotopy equivalences, then the induced map*

$$f \otimes f'\colon \mathcal{C} \otimes \mathcal{C}' \;\to\; \mathcal{D} \otimes \mathcal{D}'$$

is also a homotopy equivalence.

[816] Note that in the calculation we made use of the extra-term $(-1)^p$ in the definition of the boundary map. If we defined the boundary map "naively" as $d(c_p \otimes c'_q) = \partial c_p \otimes c'_q + c_p \otimes \partial' c'_q$, then the result would not have been a chain complex.

Proof. The proof of the lemma is elementary. For completeness' sake and for a good conscience we provide the proof of the first statement. So let $\mathcal{C}$ and $\mathcal{D}$ be two chain complexes and let $f\colon \mathcal{C} \to \mathcal{D}$ and $f'\colon \mathcal{C}' \to \mathcal{D}'$ be chain maps. Let $c \in C_k$ and $c' \in C'_l$, then

$$\begin{aligned}\partial(f(c)\otimes f'(c')) &\underset{\substack{\uparrow \\ \text{since } \deg(f(c))=\deg(c)=k}}{=} \partial f(c)\otimes f'(c') + (-1)^k\cdot f(c)\otimes \partial f'(c') \underset{\substack{\uparrow \\ \text{since } f \text{ and } f' \text{ are chain maps}}}{=} f(\partial c)\otimes f'(c') + (-1)^k\cdot f(c)\otimes f'(\partial c') \\ &= (f\otimes f')\big(\partial c\otimes c' + (-1)^k\cdot c\otimes \partial c'\big) \qquad = (f\otimes f')(\partial(c\otimes c')).\end{aligned}$$

□

43.2. **The Eilenberg-Zilber Theorem.** The following theorem, which was first proved in 1953, relates the singular chain complex $C_*(X\times Y)$ of the product of two topological spaces X and Y to the tensor product $C_*(X)\otimes C_*(Y)$ of the two individual chain complexes.

Theorem 43.4. (Eilenberg-Zilber) *Let X and Y be topological spaces. Then there exist natural*[817] *chain maps*

$$\Upsilon\colon C_*(X)\otimes C_*(Y) \;\to\; C_*(X\times Y)$$

and

$$\Theta\colon C_*(X\times Y) \;\to\; C_*(X)\otimes C_*(Y),$$

which are naturally chain homotopy-inverses of one another. In particular for each $n\in\mathbb{N}_0$ we have a natural isomorphism

$$H_n(X\times Y) \xrightarrow[\cong]{\Theta_*} H_n(C_*(X)\otimes C_*(Y)).$$

Remark. The proof of the Eilenberg-Zilber Theorem is technically rather intricate. We postpone the proof to algebraic topology III. For the time being we refer to [Mun, Theorem 59.2] or alternatively to [Mas2, Chapter XI.6] or to [Bre, Chapter VI.1.4] for a proof. What we will do instead is that we will prove an analogous statement for CW-complexes which will be sufficient for the calculations of homology groups that we want to do in this chapter.

Proposition 43.5. *Let X and Y be two CW-complexes with finitely many cells in each dimension. Then there exists a natural*[818] *isomorphism*

$$C_*^{\mathrm{CW}}(X\times Y) \xrightarrow{\cong} C_*^{\mathrm{CW}}(X)\otimes C_*^{\mathrm{CW}}(Y)$$

of chain complexes.

[817]Here "natural" means that for maps $f\colon X\to X'$ and $g\colon Y\to Y'$ we obtain commutative diagrams

$$\begin{tikzcd} C_*(X)\otimes C_*(Y) \arrow[r, "\Upsilon"] \arrow[d, "f_*\otimes f'_*"] & C_*(X\times Y) \arrow[d, "(f\times g)_*"] \\ C_*(X')\otimes C_*(Y') \arrow[r, "\Upsilon"] & C_*(X'\times Y') \end{tikzcd} \quad\text{and}\quad \begin{tikzcd} C_*(X\times Y) \arrow[r, "\Theta"] \arrow[d, "(f\times g)_*"] & C_*(X)\otimes C_*(Y) \arrow[d, "f_*\otimes f'_*"] \\ C_*(X'\times Y') \arrow[r, "\Theta"] & C_*(X')\otimes C_*(Y'). \end{tikzcd}$$

[818]Here the notion "natural" means "natural" in the category of CW-complexes, i.e. the isomorphisms Φ_{XY} are only natural with respect to cellular maps $X\to X'$ and $Y\to Y'$, i.e. the commutative diagram from Footnote 817 only exists for such cellular maps.

Remark. Recall that, following the convention of page 752, given two chain complexes C_* and D_* we write $C_* \simeq D_*$ if they are homotopy equivalent. Suppose that X and Y are CW-complexes which have only finitely many cells in each dimension. Then we have

$$\begin{array}{ccccccc} C_*(X\times Y) & \simeq & C_*^{\mathrm{CW}}(X\times Y) & \xrightarrow{\cong} & C_*^{\mathrm{CW}}(X)\otimes C_*^{\mathrm{CW}}(Y) & \simeq & C_*(X)\otimes C_*(Y). \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{Corollary 42.28 and Lemma 43.3} & & \text{Proposition 43.5} & & \text{Corollary 42.28 and Lemma 43.3} & \end{array}$$

For such X and Y this argument proves the existence of the chain homotopies in the statement of the Eilenberg-Zilber Theorem 43.4. But note that the chain homotopy equivalences of Lemma 43.3 are not natural, hence the above chain equivalences are not natural.

Proof. Let X and Y be two CW-complexes with finitely many cells in each dimension. On page 669 we introduced a CW-structure on $X\times Y$ where the n-cells of $X\times Y$ are precisely of the form $e\times f$ where e is a p-cell of X and f is an $(n-p)$-cell of Y. We quickly recall the definition of the product CW-structure on $X\times Y$:

(1) Using the homeomorphism from Proposition 1.48 (2) we identify the n-dimensional closed ball $\overline{B}^n$ with the n-dimensional cube $I^n=[0,1]^n$.
(2) We put $(X\times Y)^0 = X^0\times Y^0$.
(3) Now we suppose that the $(n-1)$-skeleton $(X\times Y)^{(n-1)}$ has already been defined. We consider a p-cell e in X which is given by a characteristic map $\varphi\colon I^p\to X^p$ and an $(n-p)$-cell f in Y which is given by a characteristic map $\psi\colon I^{n-p}\to Y^{n-p}$. Then we denote by $e\times f$ the n-cell in $X\times Y$ which is given by the attaching map

$$\begin{array}{rcl} \partial(I^n)=\partial I^p\times I^{n-p}\cup I^p\times\partial I^{n-p} & \to & (X\times Y)^{n-1} \\ (x,y) & \mapsto & (\varphi(x),\psi(y)). \end{array}$$

All these n-cells together define the n-skeleton of $X\times Y$.

Since X and Y have only finitely many cells in each dimension the above construction does indeed define a CW-structure on $X\times Y$.

Given $n\in\mathbb{N}_0$ we consider the map

$$C_n^{\mathrm{CW}}(X\times Y) \;\to\; C_p^{\mathrm{CW}}(X)\otimes C_{n-p}^{\mathrm{CW}}(Y)$$

which is induced by the property that for any p-cell e of X and any $(n-p)$-cell f of Y we have[819]

$$[e\times f] \;\mapsto\; [e]\otimes[f].$$

As on page 1005 one can show that this map is an isomorphism. It remains to prove that the above maps form a chain map. This statement in turn is equivalent to the following claim.

[819]We follow the convention of page 889 where saw that cells naturally give rise to a basis of the cellular chain complex.

Claim. For any p-cell e of X and any q-cell f of Y we have

$$\underbrace{\partial(e\times f)}_{\in C^{\mathrm{CW}}_{p+q-1}(X\times Y)} \;=\; \underbrace{\partial e\otimes f}_{\in C^{\mathrm{CW}}_{p-1}(X)\otimes C^{\mathrm{CW}}_{q}(Y)} \;+\; (-1)^p\cdot \underbrace{e\otimes\partial f}_{\in C^{\mathrm{CW}}_{p}(X)\otimes C^{\mathrm{CW}}_{q-1}(Y)}.$$

It is possible to prove this formula using the description of the cellular boundary map in Proposition 35.8 and by doing a very careful sign-analysis. We illustrate this argument in Figure 619.

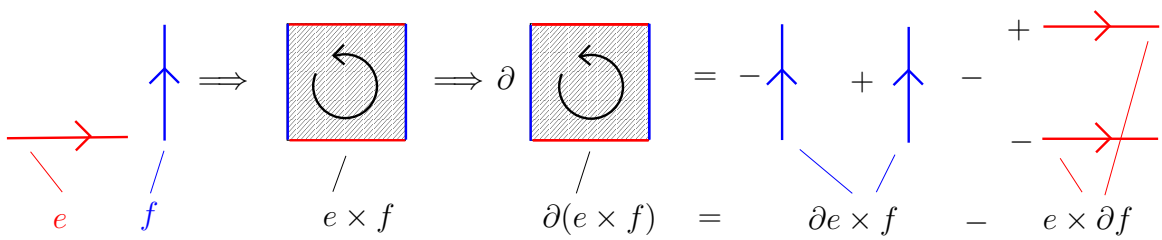

FIGURE 619. The boundary of the product of two 1-cells.

Following [Bre, Theorem 12.2] we will give an alternative proof instead. Given an k-cell σ and an $(k-1)$-cell μ we denote by $[\mu:\sigma]$ the coefficient of μ in $\partial\sigma$. It follows quite easily from Proposition 35.8 that for $p,q\in\mathbb{N}_0$ there exists a unique sign $\epsilon_{p,q}\in\{-1,1\}$ such that for any CW-complexes K and L, any p-cell e of K, any q-cell f of L and any $(q-1)$-cell g of L we have

$$[e\times g : e\times f] \;=\; \epsilon_{p,q}\cdot[g:f].$$

It follows immediately from the definitions that $\epsilon_{0,q}=1$ for all q.

Now let e be a p-cell of a CW-complex K and let f be a q-cell of a CW-complex L. We denote by τ the set of $(p-1)$-cells of K and we denote by ϕ the set of $(q-1)$-cells of L. We compute that

$$\begin{aligned}\partial(e\times f) \;&=\; \sum_\tau[\tau\times f : e\times f]\cdot(\tau\times f) \;+\; \sum_\phi[e\times\phi : e\times f]\cdot(e\times\phi)\\ &=\; \sum_\tau[\tau:e]\cdot(\tau\times f) \;+\; \sum_\phi\epsilon_{p,q}\cdot[\phi:f]\cdot(e\times\phi) \;=\; (\partial e)\times f \;+\; \epsilon_{p,q}\cdot e\times(\partial f).\end{aligned}$$

It remains to show that $\epsilon_{p,q}=(-1)^p$. We will prove this indirectly. More precisely, since we know that $\partial^2=0$ in the cellular chain complex we obtain that

$$\begin{aligned}0 \;=\; \partial\partial(e\times f) \;&=\; \overbrace{(\partial\partial e)\times f}^{=0} + \epsilon_{p-1,q}\cdot(\partial e)\times(\partial f) + \epsilon_{p,q}\cdot(\partial e)\times(\partial f) + \epsilon_{p,q-1}\epsilon_{p,q}\cdot e\times\overbrace{(\partial\partial f)}^{=0}\\ &=\; \epsilon_{p-1,q}\cdot(\partial e)\times(\partial f) + \epsilon_{p,q}\cdot(\partial e)\times(\partial f) \;=\; (\epsilon_{p-1,q}+\epsilon_{p,q})\cdot(\partial e)\times(\partial f).\end{aligned}$$

But this equality can hold for all CW-complexes K and L only if $\epsilon_{p,q}=-\epsilon_{p-1,q}$. Since $\epsilon_{0,q}=1$ we obtain iteratively that $\epsilon_{p,q}=(-1)^p$. $\square$

43.3. **The Künneth Theorem for chain complexes.** Our goal is to determine the homology groups of the product $X \times Y$ of two topological spaces in terms of the homology groups of X and Y. In light of the Eilenberg-Zilber Theorem 43.4, or alternatively, considering Proposition 43.5, we have to find a connection between the homology groups of two chain complexes $\mathcal{C}$, $\mathcal{C}'$ and the corresponding tensor product $\mathcal{C} \otimes \mathcal{C}'$.

We start out with the following elementary lemma.

Lemma 43.6. *Let $\mathcal{C}$ and $\mathcal{C}'$ be two chain complexes. The map*

$$\begin{array}{rcl} \Theta\colon H_p(\mathcal{C}) \otimes H_q(\mathcal{C}') & \to & H_{p+q}(\mathcal{C} \otimes \mathcal{C}') \\ \sum_{i=1}^{r} [c_i] \otimes [c_i'] & \mapsto & \sum_{i=1}^{r} [c_i \otimes c_i'] \end{array}$$

is well-defined and it is natural with respect to the chain complexes $\mathcal{C}$ and $\mathcal{C}'$.

Proof. Let $\mathcal{C} = (C_n, \partial_n)$ and $\mathcal{C}' = (C_n', \partial_n')$ be two chain complexes. First note that if $c_i \in C_p$ and $c_i' \in C_q$ are cycles, then

$$d(c_i \otimes c_i') \;=\; \underbrace{\partial c_i}_{=0} \otimes c_i' + (-1)^p c_i \otimes \underbrace{\partial c_i'}_{=0} \;=\; 0$$

i.e. $c_i \otimes c_i' \in \mathcal{C} \otimes \mathcal{C}'$ is indeed a cycle. Second, if $c_i + \partial e_i$ is an other representative of $[c_i]$ then

$$[(c_i + \partial e_i) \otimes c_i'] \;\underset{\substack{\uparrow \\ \text{since } \partial' c' = 0}}{=}\; [c_i \otimes c_i' + d(e_i \otimes c_i')] \;=\; [c_i \otimes c_i'].$$

The same way one can show that the value of Θ does not depend on the choice of representative of the class in $H_q(\mathcal{C}')$. It is straightforward to verify that Θ is in fact a natural map. □

Example. In some instances the homomorphism Θ from Lemma 43.6 is an isomorphism. For example let $\mathcal{C} = (C_n, \partial_n)$ be a chain complex of free abelian groups such that all boundary maps $C_n \to C_{n-1}$ in $\mathcal{C}$ are the zero map. In this case we have for any chain complex $\mathcal{C}'$ that

$$\bigoplus_{n \in \mathbb{N}_0} H_p(\mathcal{C}) \otimes H_{n-p}(\mathcal{C}_*') \;\underset{\substack{\uparrow \\ \text{since all boundary maps} \\ \text{in } \mathcal{C} \text{ are zero}}}{=}\; \bigoplus_{n \in \mathbb{N}_0} C_p \otimes H_n(\mathcal{C}_{*-p}') \;\underset{\substack{\uparrow \\ \text{by Theorem 42.18} \\ \text{and Lemma 42.17 (3)} \\ \text{since all } C_p \text{ are free abelian}}}{=}\; \bigoplus_{n \in \mathbb{N}_0} H_n(C_p \otimes \mathcal{C}_{*-p}') \;\underset{\substack{\uparrow \\ \text{by the example on page 1042} \\ \text{since } \mathcal{C} \text{ is a direct sum} \\ \text{of trivial chain complexes}}}{=}\; H_n(\mathcal{C}_* \otimes \mathcal{C}_*').$$

Now we can formulate the following proposition which is the key algebraic result of this chapter.

Theorem 43.7. (Künneth Theorem for Chain Complexes)[820] *Let $\mathcal{C}$ and $\mathcal{C}'$ be two chain complexes. If $\mathcal{C}$ is free, i.e. if all chain groups of the chain complex $\mathcal{C}$ are free abelian*

[820] Hermann Künneth (1892-1975) was a German mathematician.

groups, then there exists a natural short exact sequence

$$0 \;\to\; \bigoplus_{p+q=n} H_p(\mathcal{C}) \otimes H_q(\mathcal{C}') \;\xrightarrow{\Theta}\; H_n(\mathcal{C} \otimes \mathcal{C}') \;\to\; \bigoplus_{p+q=n-1} \mathrm{Tor}(H_p(\mathcal{C}), H_q(\mathcal{C}')) \;\to\; 0.$$

If $\mathcal{C}'$ is also a free chain complex, then this short exact sequence splits.

Remark.

(1) The adjective "natural" means in this context that if $f\colon \mathcal{C} \to \mathcal{D}$ and $f'\colon \mathcal{C}' \to \mathcal{D}'$ are chain maps, then we obtain a commutative diagram of short exact sequences:

$$\begin{tikzcd}
0 \arrow[r] & \bigoplus_{p+q=n} H_p(\mathcal{C}) \otimes H_q(\mathcal{C}') \arrow[r, "\Theta"] \arrow[d, "f_* \otimes f'_*"] & H_n(\mathcal{C} \otimes \mathcal{C}') \arrow[r] \arrow[d, "(f \otimes f')_*"] & \bigoplus_{p+q=n} \mathrm{Tor}(H_p(\mathcal{C}), H_q(\mathcal{C}')) \arrow[r] \arrow[d, "\mathrm{Tor}(f_*, f'_*)"] & 0 \\
0 \arrow[r] & \bigoplus_{p+q=n} H_p(\mathcal{D}) \otimes H_q(\mathcal{D}') \arrow[r, "\Theta"] & H_n(\mathcal{D} \otimes \mathcal{D}') \arrow[r] & \bigoplus_{p+q=n} \mathrm{Tor}(H_p(\mathcal{D}), H_q(\mathcal{D}')) \arrow[r] & 0.
\end{tikzcd}$$

Here the middle map is given by Lemma 43.3 (1) and the map on the right is given by the functoriality of the torsion-groups that we had discussed on page 1021.

(2) If $\mathcal{C}'$ is a chain complex which consists of a single abelian group G, i.e. if it is of the form $0 \to G \to 0$ with G in degree 0, then $H_0(\mathcal{C}') = G$ and all other homology groups are zero. The Künneth Theorem together with the example on page 1042 thus gives us the short exact sequence

$$0 \;\to\; H_n(\mathcal{C}) \otimes G \;\to H_n(\underbrace{\mathcal{C} \otimes G}_{=\mathcal{C}\otimes\mathcal{C}'}) \;\to\; \mathrm{Tor}(H_{n-1}(\mathcal{C}), G) \;\to\; 0,$$

i.e. we recover the Universal Coefficient Theorem 42.18 as a special case of the Künneth Theorem. In fact, as we will see, the proof of the Künneth Theorem is quite similar to the proof of the Universal Coefficient Theorem 42.18.

(3) The fact that the short exact sequence of the Künneth Theorem splits implies that the middle group is isomorphic to the direct sum of the two groups to the left and right. But, as we saw in the discussion of the Universal Coefficient Theorem 42.18, see Proposition 42.24, this isomorphism is not natural.

Proof. Let $\mathcal{C} = (C_n, \partial_n)$ and $\mathcal{C}' = (C'_n, \partial'_n)$ be two chain complexes such that all C_n are free abelian groups. As we will see, the proof of the theorem is quite similar to the proof of the Universal Coefficient Theorem 42.18.

For $p \in \mathbb{N}_0$ we consider again

$$Z_p \;:=\; \ker\{\partial_p\colon C_p \to C_{p-1}\} \quad \text{and} \quad B_p \;:=\; \mathrm{im}\{\partial_{p+1}\colon C_{p+1} \to C_p\}.$$

We denote by $i\colon Z_p \to C_p$ the inclusion map. Furthermore we denote by $\mathcal{Z}$ the chain complex which is given by the groups Z_p where all the boundary maps are the zero map. The same way we obtain from the groups B_p a chain complex $\mathcal{B}$.

Claim. The sequence

$$0 \;\to\; \mathcal{Z}\otimes\mathcal{C}' \;\xrightarrow{i\otimes\mathrm{id}}\; \mathcal{C}\otimes\mathcal{C}' \;\xrightarrow{\partial\otimes\mathrm{id}}\; \mathcal{B}\otimes\mathcal{C}' \;\to\; 0$$

is a sequence of chain maps and it is exact at each degree.

It follows easily from the definitions of the boundary maps in the various chain complexes, see also the diagram on page 1027, that the homomorphisms $i\otimes\mathrm{id}\colon \mathcal{Z}\otimes\mathcal{C}'\to\mathcal{C}\otimes\mathcal{C}'$ and $\partial\otimes\mathrm{id}\colon \mathcal{C}\otimes\mathcal{C}'\to\mathcal{B}\otimes\mathcal{C}$ are chain maps. It remains to show that the sequence is exact at each degree. The argument is exactly the same as on page 1027. For the reader's convenience we recall the argument. First note that by definition the sequences

$$0 \;\to\; Z_p \;\xrightarrow{i}\; C_p \;\xrightarrow{\partial}\; B_{p-1} \;\to\; 0$$

are exact. Also recall that by hypothesis each C_n is a free abelian group. It follows from Lemma 11.2 that each B_n is also free abelian. By Lemma 33.1 this means that the above short exact sequence splits. But then it follows from Lemma 42.6 that the sequence stays exact even after tensoring it with any C'_q. The claim is an immediate consequence of these observations.

From Proposition 31.10 and the claim we thus obtain the following long exact sequence[821]

$$\cdots\to H_n(\mathcal{B}\otimes\mathcal{C}') \xrightarrow{d_n} H_n(\mathcal{Z}\otimes\mathcal{C}') \to H_n(\mathcal{C}\otimes\mathcal{C}') \to H_{n-1}(\mathcal{B}\otimes\mathcal{C}') \xrightarrow{d_{n-1}} H_{n-1}(\mathcal{Z}\otimes\mathcal{C}')\to\dots$$

The connecting homomorphism $d_n\colon H_n(\mathcal{B}\otimes\mathcal{C}')\to H_n(\mathcal{Z}\otimes\mathcal{C}')$ from Proposition 31.10 is hereby, as in the proof of the Universal Coefficient Theorem 42.18, induced by the map $i\otimes\mathrm{id}$ where i denotes the inclusion $\mathcal{B}\to\mathcal{Z}$.

Since the boundary maps in the chain complexes $\mathcal{B}$ and $\mathcal{Z}$ are the zero maps it follows from the example on page 1046 that we obtain the following long exact sequence:

$$\dots\xrightarrow{i\otimes\mathrm{id}}\bigoplus_{p+q=n} Z_p\otimes H_q(\mathcal{C}')\to H_n(\mathcal{C}\otimes\mathcal{C}')\to\bigoplus_{p+q=n-1} B_p\otimes H_q(\mathcal{C}')\xrightarrow{i\otimes\mathrm{id}}\bigoplus_{p+q=n-1} Z_p\otimes H_q(\mathcal{C}')\to\dots$$

From Lemma 33.4 we obtain a short exact sequence

$$0 \;\to\; \bigoplus_{p+q=n}\overbrace{\operatorname{coker}\left\{B_p\otimes H_q(\mathcal{C}')\xrightarrow{i\otimes\mathrm{id}} Z_p\otimes H_q(\mathcal{C}')\right\}}^{\substack{=H_p(\mathcal{C})\otimes H_q(\mathcal{C}\text{'}),\text{ since}\\ 0\to B_p\to Z_p\to H_p(\mathcal{C})\to 0\text{ is a free resolution}}} \;\to\; H_n(\mathcal{C}\otimes\mathcal{C}') \;\to$$
$$\to\; \bigoplus_{p+q=n-1}\underbrace{\ker\left\{B_p\otimes H_q(\mathcal{C}')\xrightarrow{i\otimes\mathrm{id}} Z_p\otimes H_q(\mathcal{C}')\right\}}_{\substack{=\operatorname{Tor}(H_p(\mathcal{C}),H_q(\mathcal{C}\text{'})),\text{ since}\\ 0\to B_p\to Z_p\to H_p(\mathcal{C})\to 0\text{ is a free resolution}}} \to 0.$$

This proves the existence of the short exact sequence. Using Lemma 42.13 one can show that this short exact sequence is natural. We leave the verification of the details as an exercise to the reader.

[821]The index goes down by one in the map $H_n(\mathcal{C}\otimes\mathcal{C}')\to H_{n-1}(\mathcal{B}\otimes\mathcal{C}')$, since the map is induced by the short exact sequence $0\to Z_p\to C_p\to B_{p-1}\to 0$.

Finally we suppose that $\mathcal{C}'_*$ is also a free chain complex. We leave it as an exercise to adapt the argument of the proof of Proposition 42.22 to show that the above short exact sequence splits. Alternatively we refer to [Mun, Chapter 58] for details. $\square$

43.4. **The Künneth Theorem for topological spaces.** Now we return to our initial Question 43.1 of the chapter, namely, what is the relationship between the homology groups of the topological spaces X, Y and $X \times Y$?

The Eilenberg-Zilber Theorem 43.4 together with the Künneth Theorem for chain complexes from Theorem 43.7 now gives us the following proposition:

Theorem 43.8. (The Künneth Theorem for topological spaces) *Let X and Y be topological spaces. Then there exists a short exact sequence*

$$0 \to \bigoplus_{p+q=n} H_p(X) \otimes H_q(Y) \xrightarrow{\Theta} H_n(X \times Y) \to \bigoplus_{p+q=n-1} \mathrm{Tor}(H_p(X), H_q(Y)) \to 0,$$

and this short exact sequence is natural with respect to the topological spaces X and Y. Furthermore the above short exact sequence splits.[822]

Examples.

(1) Let X be a topological space. We want to determine the homology groups of $S^1 \times X$. The homology groups of S^1 are of course $\mathbb{Z}$ in the dimensions 0 and 1. For any abelian group A we have by Lemma 42.3 that $\mathbb{Z} \otimes A = A$ and by Lemma 42.17 we have $\mathrm{Tor}(\mathbb{Z}, A) = 0$. It follows from the Künneth Theorem 43.8 for topological spaces that there exists an isomorphism

$$H_n(S^1 \times X) \xrightarrow{\cong} H_{n-1}(X) \oplus H_n(X).$$

This is of course precisely the same result as in Lemma 33.21.

The map $H_n(X) \to H_n(S^1 \times X)$ is fairly easily seen to be the map induced by the projection $S^1 \times X \to X$. It is less clear what the map $H_n(S^1 \times X) \to H_{n-1}(X)$ should be. Some more effort shows that this map is precisely the map that we had described in detail on page 863.

(2) Let X and Y be two path-connected topological spaces. Then we have isomorphisms

$$\begin{array}{ccccccc} H_1(X \times Y) & \cong & H_1(X) \otimes H_0(Y) \oplus H_0(X) \otimes H_1(Y) & = & H_1(X) \oplus H_1(Y). \\ & \uparrow & & \uparrow & \\ & \text{Künneth Theorem 43.8 for topological spaces} & & \text{Proposition 29.5 and Lemma 42.3} & \end{array}$$

This is consistent with the product formula for fundamental groups proved in Proposition 7.21 and with the isomorphism of the Hurewicz Theorem 38.5.

[822] But as in the case of the Universal Coefficient Theorem 42.18, see Proposition 42.24, the splitting is not natural.

Now we discuss the product $S^2 \times S^4$ in slightly more detail. It follows easily from the Künneth Theorem 43.8 for topological spaces, Proposition 31.3, Proposition 29.5, Lemma 42.3 and Lemma 42.17 that

$$H_k(S^2 \times S^4) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k = 0, 2, 4, 6, \\ 0, & \text{otherwise.} \end{cases}$$

But by the calculation on page 884 these are precisely the homology groups of the complex projective space $\mathbb{C}\mathrm{P}^3$. Furthermore it follows from Propositions 5.14 and 7.21 that $S^2 \times S^4$ is simply connected and it follows from the discussion on page 697 that $\mathbb{C}\mathrm{P}^3$ is also simply connected. So all the invariants we are aware of, and that we know how to compute[823], agree for $S^2 \times S^4$ and $\mathbb{C}\mathrm{P}^3$. This raises the following question which we will answer in a later chapter.

Question 43.9. *Are the topological spaces $S^2 \times S^4$ and $\mathbb{C}\mathrm{P}^3$ homeomorphic?*

In a very similar fashion to the above calculation of the homology groups of $S^2 \times S^4$ one can show that

$$H_k(S^2 \times S^2) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k = 0, 4, \\ \mathbb{Z} \oplus \mathbb{Z}, & \text{if } k = 2, \\ 0, & \text{otherwise.} \end{cases}$$

But by the calculation on page 956 these are precisely the homology groups of the connected sums $\mathbb{C}\mathrm{P}^2 \# \mathbb{C}\mathrm{P}^2$ and $\mathbb{C}\mathrm{P}^2 \# \overline{\mathbb{C}\mathrm{P}}^2$. As above, all three topological spaces are furthermore simply connected. So this raises the following question.

Question 43.10. *Are the topological spaces $S^2 \times S^2$, $\mathbb{C}\mathrm{P}^2 \# \mathbb{C}\mathrm{P}^2$ and $\mathbb{C}\mathrm{P}^2 \# \overline{\mathbb{C}\mathrm{P}}^2$ homeomorphic?*

The Künneth Theorem 43.8 for topological spaces can also be used to prove more theoretical results. For example we have the following proposition.

Proposition 43.11. *Let M and N be two closed manifolds. Then the following holds:*

$$M \times N \text{ is orientable} \quad \Longleftrightarrow \quad M \text{ and } N \text{ are orientable.}$$

Example. It follows from the proposition and the fact that the Klein bottle K is not orientable, see Lemma 3.39, that the product $K \times K$ is also not orientable.

Proof. Let M be an m-dimensional closed manifold and let N be an n-dimensional closed manifold. By restricting to the various components of M and N we can without loss of generality assume that M and N are connected.

By the Künneth Theorem 43.8 for topological spaces we have a short exact sequence

$$0 \to \bigoplus_{p+q=m+n} H_p(M) \otimes H_q(N) \xrightarrow{\Theta} H_{m+n}(M \times N) \to \bigoplus_{p+q=m+n-1} \mathrm{Tor}(H_p(M), H_q(N)) \to 0.$$

We consider the two terms to the left and right of the short exact sequence:

[823]As of right now we do not know the higher homotopy groups of these two manifolds, but these will not turn out to be very useful.

(1) By Proposition 35.6 we know that all homology groups of a manifold beyond its dimension vanish. It follows that there is only one potentially non-zero summand left, namely $H_m(M) \otimes H_n(N)$.
(2) Again using Proposition 35.6 we see that the only potentially non-zero summands on the right are terms involving $H_m(M)$ and $H_n(N)$, but these are torsion-free by Proposition 39.5. Therefore the torsion-groups are zero by Lemma 42.17.

We have thus shown that the above short exact sequences reduces to an isomorphism

$$H_m(M) \otimes H_n(N) \xrightarrow{\cong} H_{m+n}(M \times N).$$

The proposition now follows immediately from Proposition 39.5. □

We conclude this chapter with the following proposition.

Proposition 43.12. $(*)$ *Let M and N be manifolds and let $\varphi \in H_k(M)$ and $\psi \in H_l(N)$. If φ is realized by a closed, oriented k-dimensional submanifold A and if ψ is realized by a closed, oriented l-dimensional submanifold B, then $\Theta(\varphi \times \psi) \in H_{k+l}(M \times N)$ is realized by the closed $(k+l)$-dimensional submanifold $A \times B$, equipped with an appropriate orientation.*

Example. If we use the isomorphism from Künneth Theorem 43.8 for topological spaces and the standard generators of $H_2(S^2)$ to make the identification

$$H_2(S^2 \times S^2) \;=\; H_2(S^2) \otimes H_0(S^2) \;\oplus\; H_0(S^2) \otimes H_2(S^2) \;=\; \mathbb{Z} \oplus \mathbb{Z},$$

then the element $(1,0)$ is represented by the submanifold $S^2 \times \{*\}$ and the element $(0,1)$ is represented by the submanifold $\{*\} \times S^2$.

Proof. Let M and N be manifolds. Suppose $\varphi \in H_k(M)$ is realized by a closed, oriented k-dimensional submanifold A and that $\psi \in H_l(N)$ is realized by a closed, oriented l-dimensional submanifold B. By Proposition 43.11 we know that $A \times B$ is a closed, orientable $(k+l)$-dimensional submanifold of $M \times N$.

Claim. With an appropriate orientation the submanifold $A \times B$ represents $\Theta(\varphi, \psi)$.

We denote by $i\colon A \to M$ and by $j\colon B \to N$ the inclusion maps. By the naturality of the Künneth Theorem 43.8 for topological spaces we have the following commutative diagram

$$\begin{tikzcd}
0 \arrow[r] & \bigoplus_{p+q=k+l} H_p(A) \otimes H_q(B) \arrow[r, "\Theta"] \arrow[d, "i_* \otimes j_*"] & H_{k+l}(A \times B) \arrow[r] \arrow[d, "(i \times j)_*"] & \bigoplus_{p+q=k+l-1} \mathrm{Tor}(H_p(A), H_q(B)) \arrow[r] \arrow[d, "\mathrm{Tor}(i_*, j_*)"] & 0 \\
0 \arrow[r] & \bigoplus_{p+q=k+l} H_p(M) \otimes H_q(N) \arrow[r, "\Theta"] & H_{k+l}(M \times N) \arrow[r] & \bigoplus_{p+q=k+l-1} \mathrm{Tor}(H_p(M), H_q(N)) \arrow[r] & 0.
\end{tikzcd}$$

By considering only the terms corresponding to $H_k(A) = \mathbb{Z} \cdot [A]$ and $H_l(B) = \mathbb{Z} \cdot [B]$ we obtain the following commutative diagram:

$$\begin{tikzcd}
\mathbb{Z} \cdot [A] \otimes \mathbb{Z} \cdot [B] \arrow[r, "\Theta"] \arrow[d, "{[A] \otimes [B] \mapsto \varphi \otimes \psi}"] & H_{k+l}(A \times B) = \mathbb{Z} \cdot [A \times B] \arrow[d, "(i \times j)_*"] \\
H_k(M) \otimes H_l(N) \arrow[r, "\Theta"] & H_{k+l}(M \times N).
\end{tikzcd}$$

The claim now follows from the fact, pointed out in the proof of Proposition 43.11, that the top horizontal map is an isomorphism. $\square$

Exercises for Chapter 43.

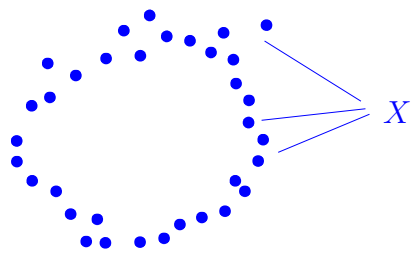
Exercise 43.1. Let $n \in \mathbb{N}$. Show that for any $k \in \mathbb{N}_0$ there exists an isomorphism

$$H_k((S^1)^n) \;\cong\; \mathbb{Z}^{\binom{n}{k}} \quad \text{where } \binom{n}{k} := \begin{cases} \frac{n!}{k! \cdot (n-k)!}, & \text{if } k \in \{0, \dots, n\}, \\ 0, & \text{otherwise.} \end{cases}$$

44. Applications of homology groups

44.1. **Persistent homology** (∗)**.** In this section we outline the idea behind "persistent homology". Persistent homology was introduced by Gunnar Carlsson [Carl] about ten years ago. More information and a much more careful treatment of persistent homology can for example be found in [EH]. Some extra information can also be found in [Gh].

We consider Figure 620. What do we see? If we forget about topology for a second, then we would say that we see a set X of dots that form a loop.



dots that appear to the eye to form a loop

Figure 620.

If we view X as a topological space, then it is just a finite discrete subset of $\mathbb{R}^2$. In particular its homology groups are non-zero only in dimension 0. So how can we use the mathematical machine that we have developed over the last two semesters to "see the loop"?

Given $r \in [0, \infty)$ we denote by $X(r)$ the subset of $\mathbb{R}^2$ that is given by replacing each point $x \in X$ by the closed ball $\overline{B}_r(x)$ of radius r around x. The homeomorphism type of $X(r)$ changes with the radius r. For example in Figure 621 we see that at $r = 1$ all but one ball are joined up and we see that $H_1(X(1)) \cong \mathbb{Z}^3$. We show three cycles c_1, c_2, c_3 in $X(1)$ which form a basis for $H_1(X(1))$. Two of the generators, namely c_1, c_2 are formed "by accident", namely they arise from balls which are close by. This gets captured by the fact that they become null-homologous in $H_1(X(2))$ whereas c_3 represents a non-trivial element for "much longer", i.e. for much larger values of r. Put differently, c_3 is a persistent element in homology, hence it captures global information.

Summarizing, given a subset X of $\mathbb{R}^2$ we can study the topological spaces $X(r)$ for any $r \in [0, \infty)$ and furthermore for any $r < s$ we can study the inclusion induced map $H_n(X(r)) \to H_n(X(s))$. If there is a non-zero element in $H_n(X(r))$ which stays non-zero for a "long time", then we say it is persistent and we hope that it captures something interesting.

The same approach can be applied to any finite subset of some $\mathbb{R}^n$. Pretty much any data one has in practice, e.g. blue pixels of a picture, measurements in an experiment, statistical data and so on, can be viewed as a finite subset of some $\mathbb{R}^n$, so in principle one can study its persistent homology. The real question is, whether one captures something

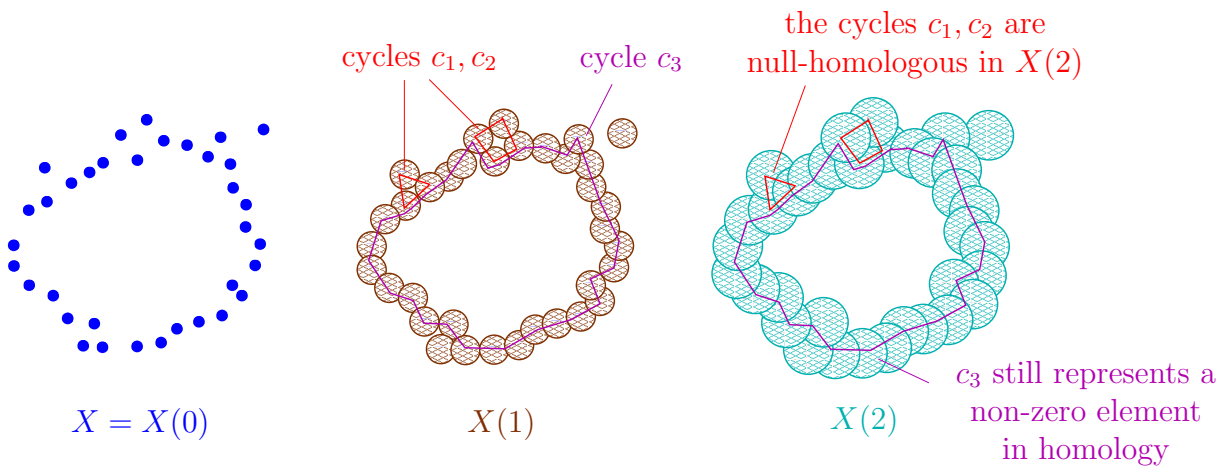


FIGURE 621.

significant or not. For example persistent homology was applied in [SHP][824] to study the "The topological shape of Brexit". It is perhaps debatable whether one can really obtain anything meaningful about the politics of Brexit using persistent homology.

44.2. **Division algebras.** We start out with the following purely algebraic definition.

Definition. An *algebra* over a field $\mathbb{F}$ is an $\mathbb{F}$-vector space A together with an $\mathbb{F}$-bilinear map

$$\begin{array}{ccc} A \times A & \to & A \\ (v, w) & \mapsto & v \cdot w. \end{array}$$

(1) We say that the algebra is *commutative* if for all $a, b \in A$ we have $a \cdot b = b \cdot a$.
(2) We say that the algebra is *associative* if for all $a, b, c \in A$ we have $a \cdot (b \cdot c) = (a \cdot b) \cdot c$.
(3) We say that the algebra *has an identity* if there exists an element $1 \in A$ with $1 \neq 0$ such that $1 \cdot a = a \cdot 1 = a$ for all $a \in A$.
(4) A *division algebra* is an algebra such that for all $a \neq 0$ and $b \in A$ there exists an $x \in A$ with $a \cdot x = b$ and a $y \in A$ with $y \cdot a = b$.

Examples.

(1) The complex numbers $\mathbb{C} = \mathbb{R} \oplus \mathbb{R} \cdot i$ with the usual multiplication are an algebra over $\mathbb{R}$ that is commutative and associative, it has an identity, and it is a division algebra.
(2) The set of $(n \times n)$-matrices $M(n \times n, \mathbb{F})$ over a field $\mathbb{F}$, where the multiplication is given by the usual matrix multiplication, is an associative algebra over $\mathbb{F}$ with an identity. If $n \geq 2$ this algebra is clearly neither commutative nor is it a division algebra.

[824]Here is an easy way to tell that that paper was not written by mathematicians: In a mathematics paper the authors are invariably listed according to the alphabetic order of their last names. In most other sciences this is not the case.

(3) The real vector space $\mathbb{R}^3$ together with the cross product

$$\begin{array}{ccc} \mathbb{R}^3 \times \mathbb{R}^3 & \to & \mathbb{R}^3 \\ \begin{pmatrix} v_1 \\ v_2 \\ v_3 \end{pmatrix}, \begin{pmatrix} w_1 \\ w_2 \\ w_3 \end{pmatrix} & \mapsto & \begin{pmatrix} v_2w_3 - w_2v_3 \\ -(v_1w_3 - w_1v_3) \\ v_1w_2 - w_1v_2 \end{pmatrix} \end{array}$$

is an algebra over $\mathbb{R}$. We recall that the geometric interpretation of the cross product is given as follows: for $v, w \in \mathbb{R}^3$ the cross product $v \times w$ is the unique vector in $\mathbb{R}^3$ that satisfies the following three properties:

(a) the vector is orthogonal to v and w,
(b) the length equals the area of the parallelogram spanned by v and w,
(c) we have $\det(v\ w\ v \times w) \geq 0$.[825]

We make the following observations:

(a) Clearly we have $v \times w = -w \times v$, hence the algebra is non-commutative.
(b) We have

$$(e_1 \times e_1) \times e_2 \ = \ 0 \times e_2 \ = \ 0 \ \neq \ -e_2 \ = \ e_1 \times e_3 \ = \ e_1 \times (e_1 \times e_2),$$

which shows that this algebra is non-associative.
(c) It follows easily from the definition or the geometric interpretation that for $v \neq 0$ there is no vector w with $v \times w = v$, hence the algebra does not have an identity element.
(d) Finally it is straightforward to see that $(\mathbb{R}^3, \times)$ is not a division algebra. More precisely, one can easily show, using the geometric interpretation of the cross product, that given $a, b \in \mathbb{R}^3$ there exists a vector $x \in \mathbb{R}^3$ with $a \times x = b$ if and only if b is orthogonal to a.

We consider the next example in greater detail.

Definition. The *quaternions* $\mathbb{H}$ are defined as the 4-dimensional real vector space $\mathbb{R}^4$ spanned by $1, i, j, k$ and the multiplication which is determined by

(1) $i^2 = j^2 = k^2 = -1$,
(2) $1 \cdot i = i \cdot 1 = i, \quad 1 \cdot j = j \cdot 1 = j, \ \ 1 \cdot k = k \cdot 1 = k$, and
(3) $i \cdot j = k$, $j \cdot k = i$, $k \cdot i = j$ and $j \cdot i = -k$, $k \cdot j = -i$, $i \cdot k = -j$.[826]

For a quaternion

$$z \ := \ a \cdot 1 + b \cdot i + c \cdot j + d \cdot k \in \mathbb{H}$$

we define the *conjugate*

$$\overline{z} \ := \ a \cdot 1 - b \cdot i - c \cdot j - d \cdot k$$

and the *norm*

$$|z| \ := \ \sqrt{a^2 + b^2 + c^2 + d^2}$$

[825] If v and w are non-zero this just means that v, w and $v \times w$ form a positive basis for $\mathbb{R}^3$.

[826] Put differently, we have $i \cdot j = k$ and $j \cdot i = -k$, and both of the equalities hold for *cyclic* permutations of $\{i, j, k\}$.

the same way as we did for complex numbers.

The following lemma summarizes a few key properties of the quaternions. In particular we see that the conjugate and the norm of the quaternions behave in a quite similar fashion as the conjugate and norm of complex numbers.

Lemma 44.1.

(1) *The quaternions are a non-commutative algebra with identity.*
(2) *The quaternions are associative.*
(3) *For all $z, w \in \mathbb{H}$ we have*

$$\overline{\overline{z}} \;=\; z, \quad \overline{z+w} \;=\; \overline{z}+\overline{w} \quad \text{and} \quad \overline{z\cdot w} \;=\; \overline{w}\cdot\overline{z}.$$

(4) *If we make the obvious identification $\mathbb{H} = \mathbb{R}^4$, then the norm $|-|$ on $\mathbb{H}$ agrees with the Euclidean norm $\|-\|$ on $\mathbb{R}^4$.*
(5) *For all $z, w \in \mathbb{H}$ we have $|z \cdot w| = |z| \cdot |w|$.*
(6) *For every $z \in \mathbb{H}$ we have $z \cdot \overline{z} = |z|^2 \in \mathbb{R} = \mathbb{R} \cdot 1$.*
(7) *For every $z \neq 0$ a multiplicative inverse is given by $z^{-1} := \frac{\overline{z}}{|z|^2}$.*
(8) *The quaternions are a division algebra.*

FIGURE 622. Brougham Bridge in Dublin

Proof. The first statement is clear. We turn to the proof of associativity. Since the quaternions are an algebraic we only have to check associativity for products of three of the generators $\{1, i, j, k\}$ and that can be done easily by hand.

Statements (3), (4), (5), (6) and (7) follow from elementary calculations. Finally note that it follows from (1) and (7) that the quaternions are in fact a division algebra. □

In Theorem 37.2 we saw that SU(2) is diffeomorphic to S^3. We can now give a refined version of this statement.

Proposition 44.2.

(1) *The set $S^3 = \{z \in \mathbb{H} = \mathbb{R}^4 \,|\, |z| = 1\}$ forms a group under multiplication of quaternions.*

(2) *The map*[827]

$$\begin{aligned} q\colon S^3 &\to \mathrm{SU}(2) \\ (z,w) = z + w\cdot j &\mapsto \begin{pmatrix} z & -\overline{w} \\ w & \overline{z} \end{pmatrix} \end{aligned}$$

from Lemma 37.1 is a diffeomorphism and it defines an isomorphism of groups.

Proof.

(1) This statement follows immediately from Lemma 44.1 (5).
(2) We already saw that in Theorem 37.2 that this map is a diffeomorphism. An elementary, albeit slightly tedious calculation, shows that the map

$$\begin{aligned} q\colon \mathbb{H} &\to M(2\times 2,\mathbb{C}) \\ (z,w) = z + w\cdot j &\mapsto \begin{pmatrix} z & -\overline{w} \\ w & \overline{z} \end{pmatrix} \end{aligned}$$

is a ring homomorphism, in particular it preserves the ring structure. This implies that the given map $q\colon S^3 \to \mathrm{SU}(2)$ is a group homomorphism. □

Before we move on to the octonions it is helpful to give an alternative description of the quaternions. Namely we define the Hamiltonians as elements in $\mathbb{C}\oplus\mathbb{C}$ with the multiplication given by

$$(z_1,z_2)\cdot(w_1,w_2) \;:=\; (z_1w_1 - \overline{w}_2z_2, z_2\overline{w}_1 + w_2z_1)$$

the conjugate given by

$$\overline{(w,z)} \;:=\; (\overline{w},-z)$$

and the norm given by

$$|(w,z)| \;:=\; \sqrt{(w,z)\cdot\overline{(w,z)}}.$$

One easily verifies that this norm is multiplicative, i.e. given $a,b\in\mathbb{H}=\mathbb{C}\oplus\mathbb{C}$ one has $|a\cdot b| = |a|\cdot|b|$. An elementary calculation shows that the map $(w,z)\mapsto w+zj$ defines an isomorphism between the two descriptions of $\mathbb{H}$, furthermore this isomorphism preserves the conjugate and the norm.

Considering the above description of the quaternions one might hope to be lucky and just try to recycle the definitions:

Definition. The *Cayley octonions* $\mathbb{O}$ (or usually just *octonions*) are defined as $\mathbb{O}=\mathbb{H}\oplus\mathbb{H}$ with the multiplication multiplication given by[828]

$$(z_1,z_2)\cdot(w_1,w_2) \;:=\; (z_1w_1 - \overline{w}_2z_2, z_2\overline{w}_1 + w_2z_1)$$

the *conjugate* given by

$$\overline{(w,z)} \;:=\; (\overline{w},-z)$$

[827]Note that it follows from $i\cdot j = k$ that any quaternion $a\cdot 1 + b\cdot i + c\cdot j + d\cdot k$ can be uniquely written as $(a\cdot 1 + b\cdot i) + (c\cdot 1 + d\cdot i)\cdot j$ where $a\cdot 1 + b\cdot i$ and $c\cdot 1 + d\cdot i$ are complex numbers.

[828]In fact these formulas also work for defining $\mathbb{C}$ as $\mathbb{R}\oplus\mathbb{R}$ where we equip $\mathbb{R}$ with the trivial involution.

and the *norm* given by

$$|(w,z)| \ := \ \sqrt{(w,z)\cdot\overline{(w,z)}}.$$

The same argument as in the proof of Lemma 44.1 also gives us the following "lemma".

Lemma 44.3. *The statements of Lemma 44.1 also hold for octonions, except that the octonions are not associative.*

In particular we see that $\mathbb{O}$ is again a division algebra. Evidently this algebra is not commutative, but even worse, it is not even associative.[829]

Remark. The octonions were discovered[830] by Arthur Cayley in 1845, shortly after Hamilton found the quaternions.

Even though the octonions are not associative they have a faint shadow of associativity which will actually turn out to be useful:

Lemma 44.4. *Given any two elements $x, y \in \mathbb{O}$ the subalgebra generated by x and y is associative.*[831]

Proof. This lemma is proved on [Bae, p. 149].. □

The discussion shows, that starting from $\mathbb{R}$ one can construct the complex numbers, which give rise to the quaternions and finally we obtain the octonions. When we move from the complex numbers to the quaternions we loose commutativity and when we go from the quaternions to the octonions we also loose associativity. As is explained in [Bae, Section 2.2] there is one underlying principle behind these constructions, and in fact one can continue to obtain a 16-dimensional algebra $\mathcal{S}$ with an identity, this algebra is evidently neither commutative nor associative, it has multiplicative inverses, i.e. for each $a \in \mathcal{S}\setminus\{0\}$ there exists a $b \in \mathcal{S}$ with $a\cdot b = b\cdot a = 1$, but it is not a division algebra.[832]

After the discovery of quaternions and the octonions the question arose whether one can also find division algebras on $\mathbb{R}^n$ for some $n \neq 1, 2, 4, 8$. We will discuss this question in the remainder of this section.

The following theorem is the best theorem that we can prove in this direction with our present knowledge.

Theorem 44.5. *Any finite-dimensional division algebra over $\mathbb{R}$ which is commutative and which has an identity is isomorphic either to $\mathbb{R}$ or to $\mathbb{C}$.*

Remark.

[829] To quote from [Frie3, p. 5], "here, associativity is obviously a concern".

[830] Or were they invented by Arthur Cayley? This question whether mathematics is "discovered" or "invented" is a source for endless philosophical discussion.

[831] An algebra which has such a property is sometimes called *alternative*.

[832] How can it be that an algebra has multiplicative inverses, but it is not a division algebra?

(1) Note that in Theorem 44.5 we do not assume that the division algebra is associative. It is a nice exercise in algebra and real analysis to show, using the Fundamental Theorem of Algebra, the weaker statement that if V is a finite-dimensional commutative and *associative* division algebra over $\mathbb{R}$, then V is isomorphic either to $\mathbb{R}$ or to $\mathbb{C}$.
(2) The statement of Theorem 44.5 does not hold if we drop the "finite dimension" condition. For example the field $\mathbb{R}(t)$ of rational functions over $\mathbb{R}$ is a division algebra, but it is an infinite-dimensional real vector space.

In the proof of Theorem 44.5 we will need the following basic lemma which might already be familiar from earlier algebra courses.

Lemma 44.6. *Let A be a* finite-dimensional *algebra over a field $\mathbb{F}$. The following two statements are equivalent:*

(1) *A is a division algebra,*
(2) *A has no zero-divisors, i.e. for any $a, b \in A$ with $a \cdot b = 0$ we have $a = 0$ or $b = 0$.*

Remark. Let A be a division algebra over a field $\mathbb{F}$. If A is associative, then it is clear that A has no zero-divisors. Indeed, if $a \cdot b = 0$ with $a \neq 0$, then we pick x with $x \cdot a = 1$ and we see that $0 = x \cdot 0 = x \cdot (a \cdot b) = (x \cdot a) \cdot b = 1 \cdot b = b$. The point about Lemma 44.6 is that it applies to non-associative algebras, as long as they are finite-dimensional.

Proof. Let A be a finite-dimensional algebra over a field $\mathbb{F}$. Let $a \in A$ be non-zero. Then the following holds:

$$\begin{aligned}
\text{for any } y \in A \text{ there exists } x \in A \text{ with } ax = y \quad &\Leftrightarrow \text{ the map } A \to A,\ x \mapsto ax \text{ is surjective} \\
&\Leftrightarrow \text{ the map } A \to A,\ x \mapsto ax \text{ is injective} \\
&\underset{\substack{\text{since } x \mapsto ax \text{ is a homomorphism of finite-dimensional } \mathbb{F}\text{-vector spaces}}}{\uparrow} \\
&\Leftrightarrow \text{ for any } b \neq 0 \text{ we have } ab \neq 0.
\end{aligned}$$

The same statement holds for left-multiplication. The equivalence of (1) and (2) now follows easily from this observation and the definitions. □

Now we turn to the proof of Theorem 44.5.

Proof of Theorem 44.5. Let $(A, *)$ be a finite-dimensional division algebra over $\mathbb{R}$ which is commutative and which has an identity. Since A is a finite-dimensional vector space we can, after applying an isomorphism, assume that $A = \mathbb{R}^n$ for some $n \in \mathbb{N}$.

We first consider the case $n = 1$. We define $a := 1 * 1$. Since "$*$" is bilinear we have for all $x, y \in \mathbb{R}$ that $x * y = (x \cdot 1) * (y \cdot 1) = x \cdot (1 * 1) \cdot y = xay$. Since the algebra is a division algebra we obtain from Lemma 44.6 that $a \neq 0$. Then the map $\varphi(x) = ax$ defines an isomorphism from the algebra $(\mathbb{R}, *)$ to the algebra $(\mathbb{R}, \cdot)$.[833]

[833]Indeed, for $x, y \in \mathbb{R}$ we have $\varphi(x * y) = \varphi(x \cdot a \cdot y) = a \cdot x \cdot a \cdot y = (a \cdot x) \cdot (a \cdot y) = \varphi(x) \cdot \varphi(y)$.

Now suppose that $n \geq 2$. We first want to show that $n = 2$. To do this we consider the map

$$\begin{array}{rcl} f\colon S^{n-1} & \to & S^{n-1} \\ x & \mapsto & f(x) := \dfrac{x * x}{\|x * x\|}. \end{array}$$

This is indeed well-defined, since for $x \neq 0$ it follows from our hypothesis on $(\mathbb{R}^n, *)$ and from Lemma 44.6 that $x * x \neq 0$. The map f is continuous since the multiplication map $\mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}^n$ is bilinear, hence continuous.[834]

Since "$*$" is bilinear we have $f(-x) = f(x)$ for all $x \in \mathbb{R}^n$. It follows from Lemma 1.66 that the map f descends to a continuous map

$$\begin{array}{rcl} \overline{f}\colon \mathbb{R}\mathrm{P}^{n-1} & \to & S^{n-1} \\ [x] & \mapsto & \overline{f}([x]) := f(x). \end{array}$$

Claim. The map $\overline{f}\colon \mathbb{R}\mathrm{P}^{n-1} \to S^{n-1}$ is injective.

So let $[x], [y] \in \mathbb{R}\mathrm{P}^{n-1} = S^{n-1}/\sim$. We have

$$\begin{aligned} \underbrace{\overline{f}([x])}_{=f(x)} = \underbrace{\overline{f}([y])}_{=f(y)} \implies f(x) = f(y) \implies & x * x = \alpha^2 \cdot (y * y) \text{ for } \alpha := \sqrt{\|x * x\| \cdot \|y * y\|^{-1}} \\ \implies & 0 = x * x - \alpha^2 \cdot (y * y) \underset{\substack{\uparrow \\ \text{since "}*\text{" is commutative and bilinear}}}{=} (x + \alpha y) * (x - \alpha y) \\ \underset{\substack{\uparrow \\ \text{Lemma 44.6}}}{\implies} & x = \pm \alpha y \underset{\substack{\uparrow \\ \text{since } x, y \in S^{n-1}}}{\implies} x = \pm y \implies [x] = [y]. \end{aligned}$$

This concludes the proof of the claim.

Since S^{n-1} is closed and connected (here we use that $n \geq 2$) and since $\mathbb{R}\mathrm{P}^{n-1}$ is a closed manifold it follows from Corollary 36.8 that $\overline{f}\colon \mathbb{R}\mathrm{P}^{n-1} \to S^{n-1}$ is in fact a homeomorphism. In particular the fundamental groups of $\mathbb{R}\mathrm{P}^{n-1}$ and S^{n-1} are isomorphic. But it follows from Proposition 5.14 and Corollary 7.19 that this is only possible if $n = 2$.

It remains to show that the algebra $(A, *) = (\mathbb{R}^2, *)$ is isomorphic to the algebra $(\mathbb{C}, \cdot)$. We start out with the following claim.

Claim. There exists a $k \in A \setminus \mathbb{R} \cdot 1$ with $k * k = c \cdot 1$ for some $c \in \mathbb{R}_{<0}$.

We first pick a random element $j \in A \setminus \mathbb{R} \cdot 1$. Then 1 and j are a basis for $A = \mathbb{R}^2$ and therefore we can write $j * j = a \cdot 1 + b \cdot j$ for some $a, b \in \mathbb{R}$. Then multiplying out and using this equality we see that

$$\underbrace{\left(j - \tfrac{b}{2} \cdot 1\right)}_{=:k} * \underbrace{\left(j - \tfrac{b}{2} \cdot 1\right)}_{=:k} = \underbrace{\left(a + \tfrac{1}{4} b^2\right)}_{=:c} \cdot 1.$$

[834]Indeed, the fact that the map is bilinear implies that there exists a real $n \times n$-matrix P such for any $v, w \in \mathbb{R}^n$ we have $v \cdot w = v^T P w$, hence the map is continuous.

We set $k := j - \frac{b}{2} \cdot 1$ and $c := a + \frac{1}{4}b^2$. We still need to show that $c < 0$. Suppose that $c \geq 0$. Then $k * k = c \cdot 1$ implies that $(k + \sqrt{c} \cdot 1) * (k - \sqrt{c} \cdot 1) = k * k - c \cdot 1 = 0$. From Lemma 44.6 we conclude that $k = \pm\sqrt{c} \cdot 1$. But this is not possible since $k = j - \frac{b}{2} \cdot 1$ is linearly independent from 1. This concludes the proof of the claim.

One can now easily verify that

$$\begin{array}{rcl} A & \to & \mathbb{C} \\ x \cdot 1 + y \cdot k & \mapsto & x + y \cdot \frac{i}{\sqrt{-c}} \quad \text{with } x, y \in \mathbb{R} \end{array}$$

is an isomorphism from the algebra $(A, *)$ to the algebra $(\mathbb{C}, \cdot)$. □

It is natural to ask what other division algebras exist. The following theorem classifies associative division algebras.

Theorem 44.7. *Any finite-dimensional division algebra over $\mathbb{R}$ which is associative and which has an identity is isomorphic to $\mathbb{R}, \mathbb{C}$ or to $\mathbb{H}$.*

Proof. The statement was first proved by Frobenius in 1878. A short self-contained proof is for example given in [Pal2]. □

Later on, once we have introduced cohomology groups, we will address the following question.

Question 44.8. *For which n, besides $n = 1, 2, 4, 8$ does $\mathbb{R}^n$ admit the structure of a division algebra?*

We conclude this section with a short discussion of quaternionic projective spaces and an interesting open question.

On page 648, given $n \in \mathbb{N}_0$, we introduced the real projective space $\mathbb{R}\mathrm{P}^n$ and the complex projective spaces $\mathbb{C}\mathrm{P}^n$. In the following we will introduce the quaternionic projective spaces $\mathbb{H}\mathrm{P}^n$. Since the quaternions $\mathbb{H}$ are non-commutative we do the constructions carefully.

Lemma 44.9. *Given $v, w \in \mathbb{H}^{n+1} \setminus \{(0, \ldots, 0)\}$ we write $v \sim w$ if there exists a non-zero $h \in \mathbb{H}$ with $h \cdot v = w$. This defines an equivalence relation on $\mathbb{H}^{n+1} \setminus \{(0, \ldots, 0)\}$.*

Proof.

(1) It is clear that $\sim$ is reflexive.
(2) Since $\mathbb{H}$ is a skew field we see that $\sim$ is symmetric.
(3) Finally suppose that $u \sim v$ and $v \sim w$. Thus there exist $g, h \in \mathbb{H} \setminus \{0\}$ with $gu = v$ and $hv = w$. Then

$$(hg)u \underset{\substack{\uparrow \\ \text{since the quaternions are associative!}}}{=} h(gu) = hv = w.$$

□

Now we can define the quaternionic projective spaces.

Definition. Let $n \in \mathbb{N}_0$.

(1) For $(h_0, \dots, h_n) \in \mathbb{H}^{n+1} \setminus \{0\}$ we denote by $[h_0 : \dots : h_n]$ the corresponding equivalence class.
(2) Given $n \in \mathbb{N}$ we define the *quaternionic projective space*

$$\mathbb{H}\mathrm{P}^n \ := \ (\mathbb{H}^{n+1} \setminus \{(0, \dots, 0)\})/\sim .$$

The following lemma summarizes some key properties of quaternionic projective spaces. $\mathbb{H}\mathrm{P}^n$. We will make use of some them later on.

Lemma 44.10. *Let $n \in \mathbb{N}_0$.*
(1) *$\mathbb{H}\mathrm{P}^n$ is a $4n$-dimensional closed orientable manifold.*
(2) *The map*

$$\begin{array}{rcl} \mathbb{H}\mathrm{P}^1 & \to & \mathbb{H} \cup \{\infty\} = \mathbb{R}^4 \cup \{\infty\} \overset{\text{by Lemma 1.41}}{\overset{\downarrow}{=}} S^4 \\ [z_0 : z_1] & \mapsto & \begin{cases} z_0 \cdot z_1^{-1}, & \text{if } z_1 \neq 0, \\ \infty, & \text{if } [z_0 : z_1] = [1 : 0] \end{cases} \end{array}$$

is a homeomorphism.
(3) *$\mathbb{H}\mathrm{P}^n$ admits a CW-structure that has exactly one cell in the dimensions $0, 4, 8, \dots, 4n$.*
(4) *We have $\chi(\mathbb{H}\mathrm{P}^n) = n + 1$.*
(5) *$\mathbb{H}\mathrm{P}^n$ is 3-connected, i.e. we have $\pi_i(\mathbb{H}\mathrm{P}^3) = 0$ for $i = 1, 2, 3$.*

Proof.
(1) This statement is proved in a very similar way as Lemma 21.6.
(2) The proof of this statement is basically the same as the proof of Lemma 1.82 (2).
(3) The proof of this statement is an easy modification of the proof of Lemma 26.2.
(4) This statement follows immediately from (3).
(5) This follows from (3) and Proposition 28.10. □

Since the octonions are not associative the definition on page 648 cannot be applied to the octonions. But there is some hope in low dimensions. More precisely, as we will now see, one can use the octonions to construct manifolds that have all the properties that one would naively expect $\mathbb{O}\mathrm{P}^1$ and $\mathbb{O}\mathrm{P}^2$ to have.

Definition.
(1) We equip[835]

$$T_2 \ := \ \{(x, y) \in \mathbb{O}^2 \,|\, |x|^2 + |y|^2 = 1\}$$

with the equivalence relation

$$(x_1, y_1) \sim (x_2, y_2) \quad \Longleftrightarrow \quad x_1\overline{x_1} \ = \ x_2\overline{x_2}, \quad x_1\overline{y_1} \ = \ x_2\overline{y_2}, \quad x_1\overline{y_1} \ = \ x_2\overline{y_2}.$$

We set

$$\mathbb{O}\mathrm{P}^1 \ := \ T_2/\sim$$

and we refer to $\mathbb{O}\mathrm{P}^1$ as the *octonion projective line*.

[835] What happens if we use these definitions of $\mathbb{O}\mathrm{P}^1$ and $\mathbb{O}\mathrm{P}^2$, but if we replace the octonions by our more familiar friends $\mathbb{R}$, $\mathbb{C}$ and $\mathbb{H}$?

(2) We equip

$$T_3 \ := \ \left\{ (x,y,z) \in \mathbb{O}^3 \,\middle|\, \begin{array}{c} |x|^2+|y|^2+|z|^2 = 1 \text{ and } x,y,z \\ \text{generate an associative algebra} \end{array} \right\}$$

with the equivalence relation

$$(x_1,y_1,z_1) \sim (x_2,y_2,z_2) \quad \Longleftrightarrow \quad \begin{array}{ccc} x_1\overline{x_1} = x_2\overline{x_2}, & x_1\overline{y_1} = x_2\overline{y_2}, & x_1\overline{z_1} = x_2\overline{z_2}, \\ y_1\overline{y_1} = y_2\overline{y_2}, & y_1\overline{z_1} = y_2\overline{z_2}, & z_1\overline{z_1} = z_2\overline{z_2}. \end{array}$$

We set

$$\mathbb{O}\mathrm{P}^2 \ := \ T_3/\sim$$

and we refer to $\mathbb{O}\mathrm{P}^2$ as the *octonion projective plane*. In the literature the octonion projective plane is often also called the *Cayley projective plane*.

(3) We denote the equivalence class of a point $(x,y) \in T_2$ by $[x:y]$ and we denote the equivalence class of a point $(x,y,z) \in T_3$ by $[x:y:z]$.

The following proposition hopefully convinces the reader that the octonion line $\mathbb{O}\mathrm{P}^1$ and the octonion plane $\mathbb{O}\mathrm{P}^2$ deserve their names.

Proposition 44.11.

(1) *The map*

$$\begin{array}{rcl} \mathbb{O}\mathrm{P}^1 & \to & \mathbb{O}\cup\{\infty\} = \mathbb{R}^8\cup\{\infty\} \overset{\text{by Lemma 1.41}}{=} S^8 \\ [x:y] & \mapsto & \begin{cases} x\cdot y^{-1}, & \text{if } y \neq 0, \\ \infty, & \text{if } [x:y] = [1:0] \end{cases} \end{array}$$

is a homeomorphism.

(2) *The octonion projective plane $\mathbb{O}\mathrm{P}^2$ is a closed orientable 16-dimensional manifold.*

(3) *The map*[836]

$$\begin{array}{rcl} \mathbb{O}\mathrm{P}^1 & \to & \mathbb{O}\mathrm{P}^2 \\ [x_1:y_1] & \mapsto & [x_1:y_1:0] \end{array}$$

is a homeomorphism onto its image. We use it to view $\mathbb{O}\mathrm{P}^1$ as a subspace of $\mathbb{O}\mathrm{P}^1$.

(4) *The octonion projective plane $\mathbb{O}\mathrm{P}^2$ admits a CW-structure with precisely one cell in dimensions 0, 8 and 16, and which has no other cells. Furthermore this CW-structure can be chosen such that the 8-skeleton is precisely $\mathbb{O}\mathrm{P}^1$.*

(5) *We have $\chi(\mathbb{O}\mathrm{P}^2) = 3$.*

(6) *$\mathbb{O}\mathrm{P}^2$ is 7-connected, i.e. we have $\pi_i(\mathbb{O}\mathrm{P}^2) = 0$ for $i = 1,2,\ldots,7$.*

Proof. The proof of the first statement is basically identical to the proof of Lemma 1.82 (2). Statements are (3), (4) and (5) are shown in [Lackm].[837] Statement (5) is an immediate consequence of (4) and Statement (6) follows from (4) and Proposition 28.10. □

[836] It follows from Lemma 44.4 that this map is well-defined, i.e. given any point $(x_1,y_1) \in T_2$ we have indeed $(x_1,y_1,0) \in T_3$.

[837] Many of the statements can also be found in [Bae].

It is natural to ask whether there exists a manifold that deserves the name $\mathbb{O}\mathrm{P}^n$ for $n \geq 3$. This slightly vague question can be formulated in different ways. Here is one possible interpretation of this question.

Question 44.12. *Let $n \geq 3$. Does there exist a closed orientable $8n$-dimensional manifold that admits a CW-structure with precisely one cell in dimensions $0, 8, 16, \dots, 8n$?*

We will return to this question at a later stage.

Proposition 44.11 says in particular that the octonion plane $\mathbb{O}\mathrm{P}^2$ is a closed orientable 16-dimensional manifold that is 7-connected and that has odd Euler characteristic. The following question is, to the best of my knowledge, open:

Question 44.13. *Does there exist an 8-connected, closed, orientable manifold with odd Euler characteristic?*

In [Hoe, Theorem 1.2] it is shown that the dimension of an 8-connected, closed, orientable manifold with odd Euler characteristic, if it exists, has to be divisible by 16.

44.3. **The transfer map.** Before we can give the next application of homology theory, namely the Borsuk-Ulam Theorem in higher dimensions, we need to introduce and study the transfer map in homology corresponding to a finite covering.

Let $p\colon \widetilde{X} \to X$ be a k-fold covering of a topological space X. Let $\sigma\colon \Delta^n \to X$ be a singular simplex. Since Δ^n is simply connected[838] it follows from Proposition 20.2 that there exist precisely k different lifts of σ to $\widetilde{X}$, i.e. there exist precisely k different singular simplices $\widetilde{\sigma}_1, \dots, \widetilde{\sigma}_k\colon \Delta^n \to \widetilde{X}$ with $p \circ \widetilde{\sigma}_i = \sigma$ for $i = 1, \dots, k$. We write

$$p^*(\sigma) \ := \ \sum_{i=1}^{k} \widetilde{\sigma}_i.$$

Given any commutative ring R we refer to the map

$$\begin{array}{rcl} p^*\colon C_*(X;R) & \to & C_*(\widetilde{X};R) \\ \sum_{i=1}^{n} \sigma_i \otimes r_i & \mapsto & \sum_{i=1}^{n} p^*(\sigma_i) \otimes r_i \end{array}$$

as the *transfer map* of the covering. It is straightforward to verify that the transfer map is in fact a chain map. In particular it induces a map

$$p^*\colon H_*(X;R) \ \to \ H_*(\widetilde{X};R).$$

Example. Let $p\colon \widetilde{M} \to M$ be a finite covering of a compact, oriented, non-empty n-dimensional manifold. We equip M with a simplicial structure. Similar to the proof of Proposition 26.25 we can lift this simplicial structure of M to a simplicial structure on $\widetilde{M}$. It follows now easily from the proof of Proposition 39.7 that the transfer map applied to the fundamental class of M equals the fundamental class of the compact oriented manifold $\widetilde{M}$, i.e. that $p^*([M]) = [\widetilde{M}]$.

[838] To be precise, we also use that Δ^n is o-locally path-connected.

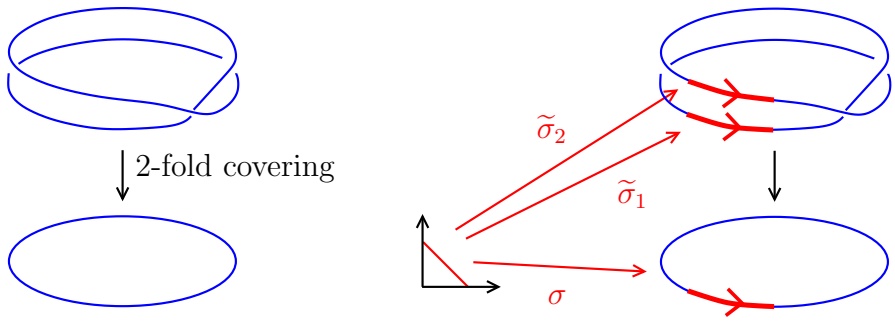

FIGURE 623.

Proposition 44.14. *Let $p\colon \widetilde{X} \to X$ be a covering of degree $k \in \mathbb{N}$ of a topological space X and let $n \in \mathbb{N}_0$. Then the following hold:*

(1) *For any commutative ring R the transfer map $p^*\colon C_n(X;R) \to C_n(\widetilde{X};R)$ is a monomorphism.*
(2) *For any commutative ring R the map $p_* \circ p^*\colon H_n(X;R) \to H_n(X;R)$ is given by multiplication by k.*
(3) *The projection map $p_*\colon H_n(\widetilde{X};\mathbb{Q}) \to H_n(X;\mathbb{Q})$ is an epimorphism.*

Remark.

(1) If $p\colon \widetilde{X} \to X$ is a finite covering of path-connected topological spaces, then we saw in Corollary 38.8 that the map $p_*\colon H_1(\widetilde{X}) \to H_1(X)$ has finite cokernel. This implies in particular[839] that $p_*\colon H_1(\widetilde{X};\mathbb{Q}) \to H_1(X;\mathbb{Q})$ is an epimorphism. Therefore we can view Proposition 44.14 (3) as a generalization of Corollary 38.8.
(2) The conclusion of Proposition 44.14 (3) does not hold if we drop the condition that the covering is finite. For example, we have an infinite covering $p\colon \mathbb{R} \to S^1$ but $0 = H_1(\mathbb{R};\mathbb{Q}) \xrightarrow{p_*} H_1(S^1;\mathbb{Q}) = \mathbb{Q}$ is not an epimorphism.

Proof. Let $p\colon \widetilde{X} \to X$ be a k-fold covering of a topological space X.

(1) Let $c \in C_n(X;R)$ be non-trivial. We write $c = \sum_{i=1}^{n} \sigma_i \otimes r_i$ where $\sigma_1, \dots, \sigma_n$ are pairwise different singular simplices in X and where $r_1, \dots, r_n$ are all non-zero. Since each σ_i lifts to k different singular simplices and since for $i \neq j$ the lifts of σ_i and σ_j differ we see immediately from the definition that $p^*(\sigma)$ is also non-zero.
(2) Let R be a commutative ring. We denote by $p^*\colon C_n(X;R) \to C_n(\widetilde{X};R)$ the transfer map. Let $\sigma\colon \Delta^m \to X$ be a singular simplex. We denote the corresponding lifts by $\widetilde{\sigma}_1, \dots, \widetilde{\sigma}_k$. Then
$$(p_* \circ p^*)(\sigma) \;=\; p_*(\widetilde{\sigma}_1 + \cdots + \widetilde{\sigma}_k) \;=\; \underbrace{p \circ \widetilde{\sigma}_1 + \cdots + p \circ \widetilde{\sigma}_k}_{k \text{ summands}} \;=\; \underbrace{\sigma + \cdots + \sigma}_{k \text{ summands}} \;=\; k \cdot \sigma.$$

[839] Why does this follow?

We thus see that $p_* \circ p^* \colon C_m(X) \to C_m(X)$ is multiplication by k for any m. It follows easily that the map

$$H_n(X;R) \xrightarrow{p^*} H_n(\widetilde{X};R) \xrightarrow{p_*} H_n(X;R)$$

is also given by multiplication by k.

(3) Since multiplication by $k \neq 0$ is an isomorphism of any rational vector space we obtain from (1) that $p_* \circ p^* \colon H_n(X;\mathbb{Q}) \to H_n(X;\mathbb{Q})$ is an isomorphism. In particular the second map, namely p_*, is an epimorphism. □

Proposition 44.15. *Let $p \colon \widetilde{X} \to X$ be a 2-fold covering. Then there exists a long exact sequence of the form*

$$\ldots \to H_n(X;\mathbb{F}_2) \xrightarrow{p^*} H_n(\widetilde{X};\mathbb{F}_2) \xrightarrow{p_*} H_n(X;\mathbb{F}_2) \xrightarrow{\partial} H_{n-1}(X;\mathbb{F}_2) \to \ldots.$$

Example. Now we will see that we can use Proposition 44.15 to calculate the homology groups $H_k(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2)$ just using the following basic facts:

(1) By the discussion on page 1010 we know that

$$H_k(S^n;\mathbb{F}_2) \cong \begin{cases} \mathbb{F}_2, & \text{if } k=0 \text{ or } k=n, \\ 0, & \text{otherwise} \end{cases}$$

(2) By the obvious generalization of Proposition 29.5 we know that $H_0(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2) = \mathbb{F}_2$.

(3) Since $\mathbb{R}\mathrm{P}^n$ is an n-dimensional manifold we know from the discussion on page 1010 that $H_k(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2) = 0$ for $k > n$.

In the following discussion we write $\mathbb{F} = \mathbb{F}_2$ for space reasons. Applying Proposition 44.15 to the 2-fold covering $p \colon S^n \to \mathbb{R}\mathrm{P}^n$ we obtain the following long exact sequence:

$$\to \underbrace{H_{n+1}(\mathbb{R}\mathrm{P}^n;\mathbb{F})}_{=0} \xrightarrow{\partial} H_n(\mathbb{R}\mathrm{P}^n;\mathbb{F}) \xrightarrow{p^*} \underbrace{H_n(S^n;\mathbb{F})}_{=\mathbb{F}} \xrightarrow{p_*} H_n(\mathbb{R}\mathrm{P}^n;\mathbb{F}) \xrightarrow{\partial} H_{n-1}(\mathbb{R}\mathrm{P}^n;\mathbb{F}) \xrightarrow{p^*} \underbrace{H_{n-1}(S^n;\mathbb{F})}_{=0} \to$$

which continues all the way to

$$\ldots \to H_1(\mathbb{R}\mathrm{P}^n;\mathbb{F}) \xrightarrow{p^*} \underbrace{H_1(S^n;\mathbb{F})}_{=0} \xrightarrow{p_*} H_1(\mathbb{R}\mathrm{P}^n;\mathbb{F}) \xrightarrow{\partial} H_0(\mathbb{R}\mathrm{P}^n;\mathbb{F}) \xrightarrow{p^*} \underbrace{H_0(S^n;\mathbb{F})}_{=\mathbb{F}} \xrightarrow{p_*} \underbrace{H_0(\mathbb{R}\mathrm{P}^n;\mathbb{F})}_{=\mathbb{F}} \to 0.$$

Now we can make the following observations:

(1) If we work our way upward through the long exact sequence we see that the connecting homomorphisms give us isomorphisms

$$H_{n-1}(\mathbb{R}\mathrm{P}^2;\mathbb{F}) \xrightarrow[\cong]{\partial} H_{n-2}(\mathbb{R}\mathrm{P}^2;\mathbb{F}) \xrightarrow[\cong]{\partial} \ldots \xrightarrow[\cong]{\partial} H_1(\mathbb{R}\mathrm{P}^2;\mathbb{F}) \xrightarrow[\cong]{\partial} H_0(\mathbb{R}\mathrm{P}^2;\mathbb{F}) \cong \mathbb{F}.$$

(2) Now that we know that $H_{n-1}(\mathbb{R}\mathrm{P}^n;\mathbb{F}) \cong \mathbb{F}$ we obtain from the upper end of the long exact sequence that[840]

$$H_n(\mathbb{R}\mathrm{P}^n;\mathbb{F}) \xrightarrow{p^*} H_n(S^n;\mathbb{F}) \quad \text{and} \quad H_n(\mathbb{R}\mathrm{P}^n;\mathbb{F}) \xrightarrow{\partial} H_{n-1}(\mathbb{R}\mathrm{P}^n;\mathbb{F})$$

[840] Why does this follow, why are there no other possibilities?

are also isomorphisms.

Summarizing we have shown that

$$H_k(\mathbb{R}\mathrm{P}^n;\mathbb{F}) \;\cong\; \begin{cases} \mathbb{F}, & \text{if } k=0,\dots,n,\\ 0, & \text{otherwise.}\end{cases}$$

This agrees of course with the result that we had obtained on page 1011.

Proof of Proposition 44.15. Let $p\colon \widetilde{X} \to X$ be a 2-fold covering. By Proposition 31.10 it suffices to show that the following sequence of chain maps

$$0 \;\to\; C_*(X;\mathbb{F}) \;\xrightarrow{p^*}\; C_*(\widetilde{X};\mathbb{F}) \;\xrightarrow{p_*}\; C_*(X;\mathbb{F}) \;\to\; 0$$

is in fact exact. As in Lemma 7.5 we consider the continuous map

$$\begin{aligned} f\colon \widetilde{X} &\to \widetilde{X}\\ x &\mapsto \text{the unique other element of } p^{-1}(p(x)).\end{aligned}$$

Using Proposition 20.2 we pick for each singular cell σ of X a lift $\widetilde{\sigma}$ to $\widetilde{X}$. We make the following observations which follow easily from the definitions and Proposition 20.2:

(a) given any singular n-simplex σ we have $p_*(\widetilde{\sigma}) = \sigma$,
(b) given any singular n-simplex σ we have $p^*(\sigma) = \widetilde{\sigma} + f_*(\widetilde{\sigma})$,
(c) given any singular simplex μ of $\widetilde{X}$ we have $p_*(f_*(\mu)) = p_*(\mu)$,
(d) any singular singular n-simplex μ of $\widetilde{X}$ is of the form $\mu = \widetilde{\sigma}$ or $\mu = f_*(\widetilde{\sigma})$ for some singular n-simplex σ of X.

Now we turn to the proof of the exactness of the above sequence.

(1) We first show that the map $p_*\colon C_n(\widetilde{X};\mathbb{F}) \to C_n(X;\mathbb{F}) = C_n(X)\otimes\mathbb{F}$ is surjective. So let $c = \sigma_1\otimes b_1 + \cdots + \sigma_k \otimes b_k \in C_n(X;\mathbb{F})$. It follows from (a) that

$$p_*\big(\widetilde{\sigma}_1\otimes b_1 + \cdots + \widetilde{\sigma}_k\otimes b_k\big) \;=\; \sigma_1\otimes b_1 + \cdots + \sigma_k\otimes b_k \;=\; c.$$

(2) By Proposition 44.14 we know that the transfer map p^* is a monomorphism.
(3) Next we show that $\mathrm{im}(p^*) \subset \ker(p_*)$. For any singular n-simplex σ of $\widetilde{X}$ we have by (c) above that[841] $(p_*\circ p^*)(\sigma) = p_*(\widetilde{\sigma} + f_*(\widetilde{\sigma})) = 2\sigma$, but it follows from Lemma 42.1 (4) that any multiple of two is zero in $C_*(X;\mathbb{F}) = C_*(X)\otimes\mathbb{F}$.

[841]That is of course basically the same argument as in the proof of Proposition 44.14.

(4) Finally we have to show that $\ker(p_*) \subset \operatorname{im}(p^*)$. So let $c \in \ker(p_*)$. By (d) we can write

$$c = (\widetilde{\sigma}_1 \otimes a_1 + f_*(\widetilde{\sigma}_1) \otimes b_1) + \cdots + (\widetilde{\sigma}_k \otimes a_k + f_*(\widetilde{\sigma}_k) \otimes b_k)$$

where $\sigma_1, \dots, \sigma_k$ are pairwise different and where $a_1, \dots, a_k, b_1, \dots, b_k \in \mathbb{F}$. By (c) we have

$$p(c) = \sigma_1 \otimes (a_1 + b_1) + \cdots + \sigma_k(a_k + b_k).$$

But this implies that $a_i = -b_i$ for $i = 1, \dots, k$. But since we work over $\mathbb{F}$ we actually have $a_i = b_i$ for $i = 1, \dots, k$. It follows from (b) that

$$c = p^*(\sigma_1 \otimes a_1 + \cdots + \sigma_k \otimes a_k),$$

as desired. □

44.4. **The Borsuk-Ulam Theorem and the Ham-Sandwich Theorem.** Our goal in this section is to prove the following generalization of Theorem 7.23 from the 2-dimensional case to the higher-dimensional situation.

Theorem 44.16. (Borsuk-Ulam) *For every map $f\colon S^n \to \mathbb{R}^n$ there exists a pair of antipodal points x and $-x$ on S^n with $f(x) = f(-x)$.*

Example. If our universe happens to be diffeomorphic to S^3, then there are two antipodal points where the temperature, distance to the Kneitinger and strength of the magnetic field agree.

The key ingredient in the proof of Theorem 44.16 is the following proposition.

Proposition 44.17. *Let $f\colon S^n \to S^n$ be a map. If $f(-x) = -f(x)$ for all $x \in S^n$, then $\deg(f)$ is odd.*

Proof. Let $f\colon S^n \to S^n$ be a map such that $f(-x) = -f(x)$ for all $x \in S^n$. By Lemma 42.21 it suffices to show that $f_*\colon H_n(S^n;\mathbb{Z}_2) \to H_n(S^n;\mathbb{Z}_2)$ is an isomorphism.

We start out with the observation that the map $f\colon S^n \to S^n$ evidently descends to a well-defined map

$$\begin{aligned} \overline{f}\colon \mathbb{R}\mathrm{P}^n &\to \mathbb{R}\mathrm{P}^n \\ [x] &\mapsto [f(x)]. \end{aligned}$$

Claim. The diagram

$$\begin{array}{ccccccccccc}
\to H_k(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) & \xrightarrow{p^*} & H_k(S^n;\mathbb{Z}_2) & \xrightarrow{p_*} & H_k(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) & \xrightarrow{\partial} & H_{k-1}(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) & \xrightarrow{p^*} & H_{k-1}(S^n;\mathbb{Z}_2) & \to \\
\downarrow{\scriptstyle \overline{f}_*} & & \downarrow{\scriptstyle f_*} & & \downarrow{\scriptstyle \overline{f}_*} & & \downarrow{\scriptstyle \overline{f}_*} & & \downarrow{\scriptstyle f_*} & \\
\to H_k(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) & \xrightarrow{p^*} & H_k(S^n;\mathbb{Z}_2) & \xrightarrow{p_*} & H_k(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) & \xrightarrow{\partial} & H_{k-1}(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) & \xrightarrow{p^*} & H_{k-1}(S^n;\mathbb{Z}_2) & \to
\end{array}$$

where the horizontal sequences are the exact sequences given by Proposition 44.15, commutes.

By the remark on page 772 it suffices to show that the following diagram commutes for any $k \in \mathbb{N}_0$:

$$\begin{tikzcd}
0 \arrow[r] & C_k(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) \arrow[r, "p^*"] \arrow[d, "\overline{f}_*"] & C_k(S^n;\mathbb{Z}_2) \arrow[r, "p_*"] \arrow[d, "f_*"] & C_k(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) \arrow[r] \arrow[d, "\overline{f}_*"] & 0 \\
0 \arrow[r] & C_k(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) \arrow[r, "p^*"] & C_k(S^n;\mathbb{Z}_2) \arrow[r, "p_*"] & C_k(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) \arrow[r] & 0.
\end{tikzcd}$$

Here the right-hand square commutes since by definition we have $p \circ f = \overline{f} \circ p$. Now we argue that the left-hand square commutes. So let $\sigma\colon \Delta^k \to \mathbb{R}\mathrm{P}^n$ be a singular k-simplex. We pick a point $P \in \Delta^k$. Furthermore we pick $Q \in S^n$ with $[Q] = \sigma(1, 0, \ldots, 0) \in \mathbb{R}\mathrm{P}^n$. We denote by $\widetilde{\sigma}_1$ and $\widetilde{\sigma}_2$ the two lifts of σ to S^n. Now we consider the singular simplex $\overline{f} \circ \sigma$. It remains to show that $p^*(\overline{f} \circ \sigma) = f \circ \widetilde{\sigma}_1 + f \circ \widetilde{\sigma}_2$. But this is indeed the case for the following reason:

(1) by construction we have $p \circ f = \overline{f} \circ p$ which implies that $f \circ \widetilde{\sigma}_1$ and $f \circ \widetilde{\sigma}_2$ are both lifts of $\overline{f} \circ \sigma$,
(2) it follows from $f(Q) = -f(Q)$ that $f \circ \widetilde{\sigma}_1$ and $f \circ \widetilde{\sigma}_2$ are two different lifts.

This concludes the proof of the claim.

Now we consider the following diagram:

$$\begin{tikzcd}
H_n(S^n;\mathbb{Z}_2) \arrow[d, "f_*"] & H_n(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) \arrow[l, "p^*"'] \arrow[r, "\partial"] \arrow[d, "\overline{f}_*"] & H_{n-1}(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) \arrow[r, "\partial"] \arrow[d, "\overline{f}_*"] & \ldots \arrow[r, "\partial"] & H_1(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) \arrow[r, "\partial"] \arrow[d, "\overline{f}_*"] & H_0(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) \arrow[d, "\overline{f}_*"] \\
H_n(S^n;\mathbb{Z}_2) & H_n(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) \arrow[l, "p^*"'] \arrow[r, "\partial"] & H_{n-1}(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) \arrow[r, "\partial"] & \ldots \arrow[r, "\partial"] & H_1(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2) \arrow[r, "\partial"] & H_0(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2).
\end{tikzcd}$$

We make the following observations:

(1) the diagram commutes by the previous claim,
(2) all the horizontal maps are isomorphisms by the discussion on page 1066,
(3) by the discussion on page 747 the right vertical map is an isomorphism.

It follows that the left vertical map is an isomorphism. But that is exactly what we had wanted to prove. □

Now we turn to the proof of the Borsuk-Ulam Theorem 44.16.

Proof of Theorem 44.16. Let $g\colon S^n \to \mathbb{R}^n$ be a map. Suppose there exists no pair of antipodal points x and $-x$ in S^n with $g(x) = g(-x)$. Put differently, suppose that for any $x \in S^n$ we have $g(x) \neq g(-x)$. We consider the composition of the following two maps

$$\begin{array}{rcccl}
\Phi\colon S^{n-1} \times [0,1] & \to & S^n & \to & S^{n-1}. \\
(y,t) & \mapsto & (y \cdot \sqrt{1-t^2}, t) & & \\
 & & x & \mapsto & \underbrace{\frac{g(x)-g(-x)}{\|g(x)-g(-x)\|}}_{\text{defined since } g(x) \neq g(-x)}
\end{array}$$

The map $\Phi\colon S^{n-1}\times[0,1]\to S^{n-1}$ defines a homotopy from the map $f_0(x):=\Phi(x,0)$ to the map $f_1(x):=\Phi(x,1)$.

(1) By definition we have $f_0(-x)=\Phi(-x,0)=-\Phi(x,0)=-f_0(x)$. It follows from Proposition 44.17 that f_0 has odd degree.
(2) The map f_1 is a constant map, hence it has has degree zero.

But homotopic maps have the same degree by Lemma 32.16 (3). We have thus obtained a contradiction. □

The Borsuk-Ulam Theorem has an almost endless string of consequences, many of which lie in combinatorics and graph theory, we refer to [Mato] for an extensive discussion of the Borsuk-Ulam theorem and its corollaries. In the following we will state and prove two particularly interesting consequences of the Borsuk-Ulam Theorem 44.16. The first theorem was first proved by the Soviet mathematicians Lazar Lusternik and Lev Schnirelmann in 1930.

Theorem 44.18. (Lusternik-Schnirelmann) *Let $A_1,\dots,A_{n+1}$ be closed subsets of S^n with $A_1\cup\dots\cup A_{n+1}=S^n$. Then there exists an $i\in\{1,\dots,n+1\}$ such that A_i contains antipodal points, i.e. there exists a point x on S^n such that both x and $-x$ lie in A_i.*

Examples.

(1) For $n=1$ we obtain that if we have a decomposition $S^1=A\cup B$ with A and B two closed subsets (which do not need to be connected), then the subset A or the subset B contains antipodal points. How can one prove this statement "naively"?
(2) We consider the surface of our earth, we take A_1 to be the closure of the land mass, we take A_2 to be the closure of the Pacific ocean and we take A_3 to be the closure of all seas except for the Pacific. Then at least one of A_1,A_2 or A_3 contains a pair of antipodal points. Which of A_1,A_2 and A_3 is it?
(3) The proposition is optimal in the following sense: it is easy to find three closed subsets A_1,A_2,A_3 that cover all of S^1, but such that none of the A_i contains antipodal points.

Proof. Let $A_1,\dots,A_{n+1}$ be closed subsets of S^n with $A_1\cup\dots\cup A_{n+1}=S^n$. Without loss of generality we can assume that all A_i are non-empty. (Indeed, at least one of the A_i is evidently non-empty, if one of them is empty we just replace it with the non-empty A_i.) Given a non-empty subset A of S^n and $x\in S^n$ we write

$$d(x,A)\ :=\ \inf\{d(x,a)\mid a\in A\},$$

where $d(x,a)$ denotes the distance function on the Riemannian manifold S^n that we introduced on page 594.[842] We make the following two observations:

(1) If A is closed, then $d(x,A)=0$ if and only if $x\in A$.
(2) It follows easily from Proposition 22.8 that $d(x,A)$ is continuous in x.

[842]Put differently, $d(x,a)$ is the infimum of all lengths of piecewise smooth paths on S^n from x to a.

Now we consider the function

$$\begin{aligned} f\colon S^n &\to \mathbb{R}^n \\ x &\mapsto (d(x, A_1), \ldots, d(x, A_n)). \end{aligned}$$

By the Borsuk-Ulam Theorem 44.16 there exists an $x \in S^n$ with $f(x) = f(-x)$. We first suppose that there exists an $i \in \{1, \ldots, n\}$ with $d(x, A_i) = 0$. From $f(x) = f(-x)$ it follows that $d(-x, A_i) = 0$ as well. Since A_i is closed it follows that both x and $-x$ lie in A_i.

Now suppose that $d(-x, A_i) = d(x, A_i) \neq 0$ for $i = 1, \ldots, n$. Since $A_1 \cup \cdots \cup A_{n+1} = S^n$ it follows that both x and $-x$ lie in A_{n+1}. □

Before we can state the next consequence of the Borsuk-Ulam Theorem 44.16 we need to introduce one more definition.

Definition. Let $A \subset \mathbb{R}^n$ be a measurable subset[843] of finite volume. We say a hyperplane $H \subset \mathbb{R}^n$ *bisects* A if for the two half-spaces V, V' determined by H we have the equality $\mathrm{vol}(A \cap V) = \mathrm{vol}(A \cap V')$.

We conclude this chapter with the following pretty theorem.

Theorem 44.19. (Ham-Sandwich Theorem) *Let $A_1, \ldots, A_n$ be measurable finite-volume subsets of $\mathbb{R}^n$. Then there exists an $(n-1)$-dimensional hyperplane in $\mathbb{R}^n$ that bisects $A_1, \ldots, A_n$.*

Remark.

(1) The Ham-Sandwich Theorem gets its name from the following "application". Suppose we are given a sandwich with an upper piece of bread A_1, some ham A_2 and a lower piece of bread A_3. Then using a knife one can cut the sandwich, along a hyperplane, into two pieces such that each piece of bread and the ham are bisected. This situation is, more or less convincingly, illustrated in Figure 624.

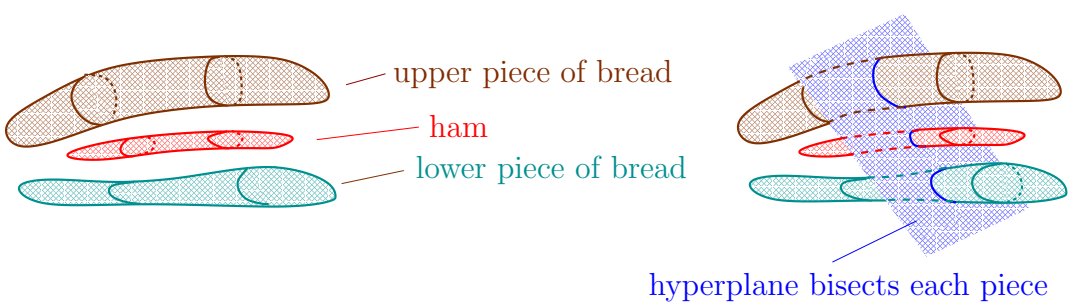

FIGURE 624. Illustration of the "Ham-Sandwich Theorem".

(2) The 2-dimensional version of the Ham-Sandwich Theorem is sometimes referred to as the "Pancake Theorem", since one can bisect the two pancakes along a line into two equal sized halves.

[843]Here "measurable" means Lebesgue-measurable in the sense of say [Frie4, Caro] or [Rudi2, Chapter 2].

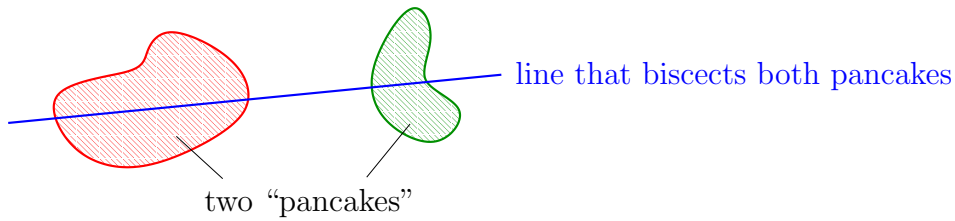

FIGURE 625. Illustration of the "Pancake Theorem".

In the proof of the Ham-Sandwich Theorem we will need the following result from measure theory.

Proposition 44.20. *Suppose that for each $t \in \mathbb{R}$ we have a measurable subset X_t of $\mathbb{R}^n$ such that for each $s \leq t \in \mathbb{R}$ we have $X_s \subset X_t$. Then $\bigcup_{t\in\mathbb{R}} X_t$ is also measurable and*

$$\lim_{t\to\infty} \operatorname{vol}(X_t) \;=\; \operatorname{vol}\Big(\bigcup_{t\in\mathbb{R}} X_t\Big).$$

Proof of Proposition 44.20. The proposition can be deduced easily from basic facts of the Lebesgue measure, see [Caro, Chapter 16] or [Frie3, Proposition 6.2 (6)]. □

Now we can provide the proof of the Ham-Sandwich Theorem.

Proof of the Ham-Sandwich Theorem. Let $A_1, \dots, A_n$ be measurable finite-volume subsets of $\mathbb{R}^n$. Without loss of generality we can assume that the volume of A_n is positive. Given a point $P \in S^{n-1}$ and $t \in \mathbb{R}$ we write

$$H_{P,t} \;:=\; \{t \cdot P + w \mid P \cdot w = 0\}$$

and

$$\begin{aligned} V^+_{P,t} &:= \{t \cdot P + w \mid P \cdot w \geq 0\} \\ V^-_{P,t} &:= \{t \cdot P + w \mid P \cdot w \leq 0\}. \end{aligned}$$

(We refer to Figure 626 on the left for an illustration.) Put differently, $H_{P,t}$ is the hyperplane through $t \cdot P$ orthogonal to P, and $V^\pm_{P,t}$ are the two half-spaces determined by $H_{P,t}$. We make the following two observations:

(i) by definition we have $V^\pm_{-P,-t} = V^\mp_{P,t}$,
(ii) for a subset $A \subset \mathbb{R}^n$ of finite volume we have the equality

$$\operatorname{vol}(A \cap V^\pm_{P,t}) \;\underset{\substack{\uparrow \\ \text{since } H_{P,t} = V^+_{P,t} \cap V^-_{P,t} \text{ is a set of measure zero}}}{=}\; \operatorname{vol}(A \cap (\mathbb{R}^n \setminus V^\mp_{P,t})) \;=\; \operatorname{vol}(A) - \operatorname{vol}(V^\mp_{P,t}).$$

We continue with the following claim.

Claim. There exists a function

$$t\colon S^{n-1} \;\to\; \mathbb{R}$$

with the following two properties:

(1) for any $P \in S^{n-1}$ we have $\mathrm{vol}(A_n \cap V^+_{P,t(P)}) = \frac{1}{2}\,\mathrm{vol}(A_n)$, i.e. the hyperplane $H_{P,t(P)}$ bisects A_n,
(2) for any $P \in S^{n-1}$ we have $t(-P) = -t(P)$,
(3) the function t is continuous.

To prove the claim we first fix $P \in S^{n-1}$. We consider the function

$$\begin{array}{rcl} \mathbb{R} & \to & \mathbb{R}_{\geq 0} \\ t & \mapsto & \mathrm{vol}(A_n \cap V^+_{P,t}). \end{array}$$

This function is continuous[844] and we have

$$\lim_{t\to\infty} \mathrm{vol}(A_n \cap V^+_{P,t}) \underset{\substack{\uparrow \\ \text{Proposition 44.20}}}{=} \mathrm{vol}\Big(\bigcup_{t\in\mathbb{R}} (A_n \cap V^+_{P,t})\Big) = \mathrm{vol}(A_n).$$

and

$$\lim_{t\to-\infty} \mathrm{vol}(A_n \cap V^+_{P,t}) \underset{\substack{\uparrow \\ \text{by (ii)}}}{=} \mathrm{vol}(A_n) - \underbrace{\lim_{t\to-\infty} \mathrm{vol}(A_n \cap V^-_{P,t})}_{=\,\mathrm{vol}(A_n)\text{ by Proposition 44.20}} = 0.$$

We deduce from the Intermediate Value Theorem that

$$T := \big\{ t \in \mathbb{R} \,\big|\, \mathrm{vol}(A_n \cap V^+_{P,t}) = \tfrac{1}{2}\,\mathrm{vol}(A_n) \big\}$$

is a non-empty set.[845] It is straightforward to see that it is a connected subset of $\mathbb{R}$, i.e. it is an interval. Since $\mathrm{vol}(A_n) > 0$ we know that T is a finite interval. We define

$$t(P) := \tfrac{1}{2}(\inf(T) + \sup(T)).$$

Note that it follows immediately from the definitions that $t(-P) = -t(P)$. Furthermore with some elementary measure theory one can show that the function $S^{n-1} \to \mathbb{R}$ given by $P \mapsto t(P)$ is continuous. We leave the verification of the details as an exercise to the reader. This concludes the proof of the claim.

Now we consider the map

$$\begin{array}{rcl} f\colon S^{n-1} & \to & \mathbb{R}^{n-1} \\ P & \mapsto & \big(\mathrm{vol}\big(A_1 \cap V^+_{P,t(P)}\big), \ldots, \mathrm{vol}\big(A_{n-1} \cap V^+_{P,t(P)}\big)\big). \end{array}$$

From the continuity of $t\colon S^{n-1} \to \mathbb{R}$ it follows that f itself is continuous. By the Borsuk-Ulam Theorem 44.16, there exists a point $P \in S^{n-1}$ with $f(P) = f(-P)$. We claim that the hyperplane $H_{P,t(P)}$ has the desired property.

[844] This requires at least a little bit of thought since we do not assume that A is bounded, we only assume it has finite volume. We leave it as an exercise to prove this statement using basics facts of Lebesgue measures.

[845] One might think that T consists of just a point, but for example if A_n is disconnected, then it can happen that T is in fact a interval that is not just a point.

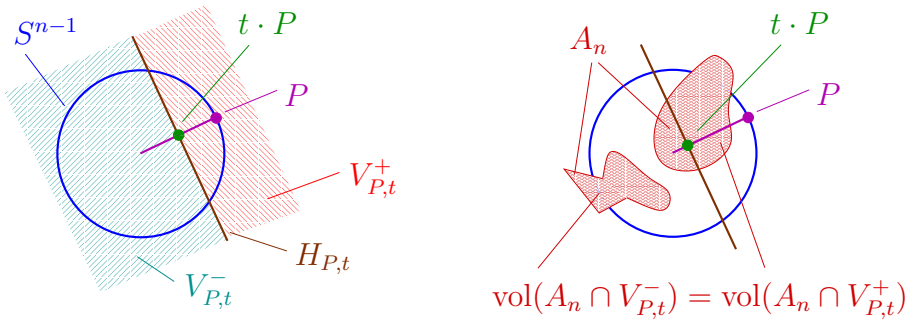

FIGURE 626. Illustration for the proof of the Ham-Sandwich Theorem 44.19

By definition of $t(P)$ the hyperplane $H_{P,t(P)}$ bisects A_n. Furthermore, for $i = 1, \dots, n-1$ we have

$$\mathrm{vol}\left(A_i \cap V^+_{P,t(P)}\right) \underset{\substack{\uparrow \\ \text{since } f(P)=f(-P)}}{=} \mathrm{vol}\left(A_i \cap V^+_{-P,t(-P)}\right) \underset{\substack{\uparrow \\ \text{since } t(-P)=-t(P)}}{=} \mathrm{vol}\left(A_i \cap V^+_{-P,-t(P)}\right) \underset{\substack{\uparrow \\ \text{since } V^+_{P,s}=V^-_{-P,-s}}}{=} \mathrm{vol}\left(A_i \cap V^-_{P,t(P)}\right).$$

This shows that the hyperplane $H_{P,t(P)}$ also bisects $A_1, \dots, A_{n-1}$. □

Remark. The proof for the existence of the hyperplane that bisects the given sets $A_1, \dots, A_n$ is non-constructive, in the sense that even with some flexibility in mathematical rigor one cannot turn it into an algorithm that given $A_1, \dots, A_n$ finds the hyperplane that bisects all of the subsets.

Exercises for Chapter 44.

Exercise 44.1. Let $q_1, q_2 \in S^3 = \{h \in \mathbb{H} \mid |h| = 1\}$. We consider the map

$$\begin{array}{rcl} \mathbb{R}^4 = \mathbb{H} & \to & \mathbb{R}^4 = \mathbb{H} \\ z & \mapsto & q_1 z q_2^{-1}. \end{array}$$

Show that the map is linear and that it is represented by a matrix in SO(4).

45. Topological manifolds

In this chapter we will discuss topological manifolds in more detail. In particular we will generalize some results that we had initially obtained for manifolds to topological manifolds. We will also introduce the notion of orientability for topological manifolds which extends the notion of orientability that we introduced in Section 3.8 for manifolds.

45.1. **Topological manifolds and CW-structures.** In Chapters 35 and 39 we had discussed the homology groups of manifolds at length. The key tool hereby was that compact manifolds are finite CW-complexes and that every manifold can be viewed as a simplicial complex. The situation is more complicated for topological manifolds. The following theorem can be viewed as a weak version of Theorem 26.3 for topological manifolds.

Theorem 45.1.

(1) *Every topological manifold is homotopy equivalent to a CW-complex.*
(2) *Every compact topological manifold is homotopy equivalent to a finite CW-complex.*

Proof. Olof Hanner [Han, Theorem 3.3] showed in 1950 that every topological manifold is an "absolute neighborhood retract". By [Mi9, Theorem 1] this implies that M is homotopy equivalent to a CW-complex.[846]

James West [Wes] showed in 1977 that every compact "absolute neighborhood retract" is homotopy equivalent to a compact CW-complex. But by Corollary 26.15, a compact CW-complex is the same as a finite CW-complex. An alternative proof for the theorem of James West is given by Rob Kirby and Larry Siebenmann [KSi, KSi2]. □

Of course it would be much nicer if every compact topological manifold was in fact a simplicial complex or at least a CW-complex. In the following we summarize what is known about the existence of simplicial structures and of CW-structures on topological manifolds. We will not make use of these more general statements, in the lecture notes we will only use Theorem 45.1.

(1) Tibor Radó [Rad] (see also [MTh, Theorem 3.1.1]) showed in 1926 that every compact 2-dimensional topological manifold has a simplicial structure, in particular it has a CW-structure. In 1952 Edwin Moise [Moi] proved the analogous result for 3-dimensional topological manifolds.
(2) In the 1970s Rob Kirby and Larry Siebenmann [KSi2, Essay III.2] showed that every *closed* topological manifold of dimension ≥ 6 has a CW-structure. In 1982 Frank Quinn [Qu] extended this result to the case of 5-dimensional manifolds.
(3) Andrew Casson, see [AM, page xvi] showed in the 1980s that there exist closed topological 4-dimensional manifolds that do not have a simplicial structure.
(4) Ciprian Manolescu [Man] showed in 2013 that for every $n \geq 5$ there exists a closed n-dimensional topological manifold that does not admit a simplicial structure.

[846] In fact in [Mi9, Proposition 1] it is shown that every compact topological manifold is "dominated" by a finite CW-complex which is good enough for many conclusions.

(5) It seems to be unknown whether every closed 4-dimensional topological manifold has a CW-structure and it seems to be unknown whether every compact n-dimensional topological manifold with non-empty boundary of dimension $n \geq 4$ has a CW-structure.
(6) Using [Wall, Corollary 5.1] and the computations of homology groups of topological manifolds one can prove the following refinement of Theorem 45.1:
   (a) Every closed n-dimensional topological manifold is homotopy equivalent to a finite n-dimensional CW-complex.
   (b) Every compact, connected n-dimensional topological manifold with non-empty boundary is homotopy equivalent to a finite $(n-1)$-dimensional CW-complex.

   The proof of these statements (a) and (b) actually relies on the Poincaré Duality Theorem that we will prove later on.

We can summarize most of the above statements in the following table:

	$n=1,2,3$	$n=4$	$n \geq 5$
each closed top. n-mfd. is homotopy equiv. to a finite CW-cplx.	✓	✓	✓
each closed top. n-mfd. admits a CW-structure	✓	?	✓
each compact top. n-mfd. is homotopy equ. to a finite CW-cplx.	✓	✓	✓
each compact top. n-manifold admits a CW-structure	✓	?	?

In this and the following chapter we will see that many of the results that we had stated and proved for manifolds also hold for topological manifolds. In particular we will extend the results from Chapter 39 on homology groups of manifolds to the case of topological manifolds. The proofs of this chapter are also more rigorous than the proofs in Chapter 39, but they are arguably at times less intuitive than the arguments using simplicial structures.

We start out with the following proposition which is the generalization of Propositions 27.13 and 35.6 (1) to the case of topological manifolds.

Proposition 45.2. *Let M be a compact topological manifold and let $\mathbb{F}$ be a field. Then the following hold:*

(1) *The group $\pi_1(M)$ is finitely presented.*
(2) *All homology groups $H_k(M)$ are finitely generated abelian groups and the homology groups $H_k(M;\mathbb{F})$ are finite-dimensional. Furthermore there exists an l such that all homology groups in dimension $\geq l$ vanish.*[847]
(3) *Let X be a subset of M that is homeomorphic to a compact manifold. (For example, X could be a compact submanifold, or by Lemma 3.6 (2), we could take*[848] *$X = \partial M$.) Then all relative homology groups $H_k(M, X)$ are finitely generated abelian groups and the homology groups $H_k(M, X;\mathbb{F})$ are finite-dimensional.*

[847]These statements can also be proved without the full power of Theorem 45.1, see e.g. [Bre, E.5.Corollary] or [Hat, p. 527].

[848]Note that the boundary of a topological manifold is in general *not* a submanifold.

Proof. The first two statements of the proposition are an immediate consequence of Theorem 45.1 together with Proposition 27.12, Corollary 30.8, Proposition 35.5 and the discussion on page 1010.

For the final statement we consider the long exact sequence of the pair (M, X), given by Corollary 31.14. By (2) the homology groups of X and M are finitely generated respectively finite-dimensional. It follows from Lemma 11.6 that the relative homology groups are also finitely generated respectively finite-dimensional. □

45.2. **The Topological Collar Neighborhood Theorem.** The following theorem is the analogue of the Collar Neighborhood Theorem 10.10 for topological manifolds.

Theorem 45.3. (Topological Collar Neighborhood Theorem) *Let M be a topological manifold. Then there exists a map $\Phi\colon \partial M \times [0,1] \to M$ with the following three properties:*

(1) *the map Φ is a homeomorphism onto its image,*
(2) *the image of $\partial M \times [0,1)$ is an open subset of M,*
(3) *for all $P \in \partial M$ we have $\Phi(P, 0) = P$.*

Proof. If M is compact, then the proof is fairly elementary, see e.g. [Vic, Theorem Appendix II.7] or [Hat, p. 253]. If M is non-compact, then the proof is harder, see e.g. [BrownM2, Theorem 3], where we actually need that topological manifolds are "metrizable", see Theorem 3.10. We also refer to [Arm2] for a proof of the theorem and some more refined statements. □

The following uniqueness statements for collar neighborhoods is almost verbatim the same as the statement of Proposition 10.11.

Proposition 45.4. $(*)$ *Let M be a topological manifold and let $f_0, f_1\colon \partial M \times [0,1] \to M$ be two embeddings that are the identity map on $\partial M \times \{0\} = \partial M$. If ∂M is compact, then there exists an isotopy*

$$H\colon M \times [0,1] \;\to\; M$$

rel ∂M from $H_0 = \mathrm{id}_M$ to a homeomorphism $\Phi = H_1\colon M \to M$ with $\Phi_1 \circ f_0 = f_1$. In particular Φ restricts to a homeomorphism

$$\Phi\colon f_0(\partial M \times [0,1])) \;\to\; f_1(\partial M \times [0,1]).$$

Proof $(*)$. The proof is sketched in [KSi, Essay I, Theorem A.2]. □

Convention. Let M be a compact topological manifold. We pick a map $\Phi\colon \partial M \times [0,1] \to M$ as in the conclusion of the Topological Collar Neighborhood Theorem 45.3. Usually we identify $\partial M \times [0,1]$ with the image in M under the map Φ and we just refer to $\partial M \times [0,1]$ as a "collar neighborhood of ∂M". Sometimes we also find it convenient to use other intervals in our notation, e.g. we might write "let $\partial M \times [-3,0]$ be a collar neighborhood". It is then understood that $\partial M \times \{0\} = \partial M$.

For later we record the following corollary to the Topological Collar Neighborhood Theorem 45.3.

Corollary 45.5. *Let M be an n-dimensional topological manifold. If ∂M is non-empty, then M is homotopy equivalent to a non-compact n-dimensional topological manifold without boundary.*

Proof. By the Topological Collar Neighborhood Theorem 45.3 we can pick a collar neighborhood $\partial M \times [0,2]$. We write $W := M \setminus (\partial M \times [0,1))$ and we set $M' := M \setminus \partial M$. We consider the map

$$\begin{array}{rcl} F\colon M \times [0,1] & \to & M \\ (Q,t) & \mapsto & \begin{cases} (R, s(1-t)+t), & \text{if } Q = (R,s) \in \partial M \times [0,1], \\ Q, & \text{otherwise.} \end{cases} \end{array}$$

Using Lemma 1.32 (2) and Proposition 10.2 one can show that this map is continuous. This map defines a deformation retraction from M to W and also from $M \setminus \partial M$ to W. It follows from Lemmas 9.10 and 9.8 that M and M' are homotopy equivalent. In Exercise 45.5 we will see that M' is non-compact. Finally note that it follows from Proposition 32.1 that M' does not have any boundary. □

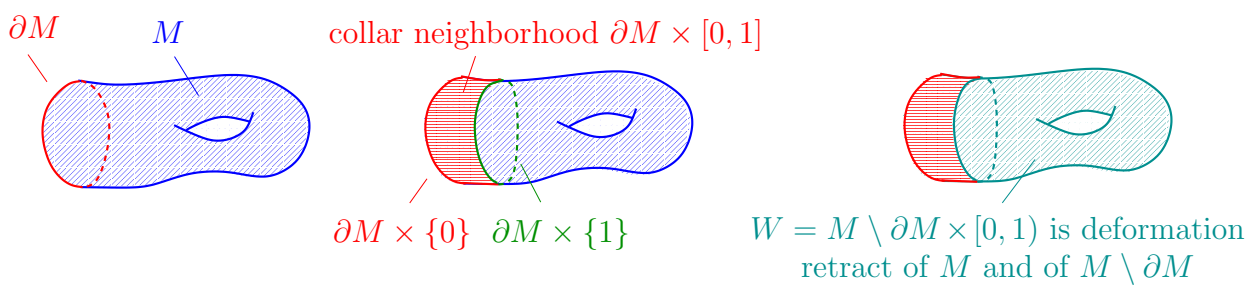

FIGURE 627. Illustration for the proof of Corollary 45.5.

We conclude this discussion of the Topological Collar Neighborhood Theorem 45.3 with the following proposition that looks uncannily similar to Proposition 10.12.

Proposition 45.6. *Let M be an n-dimensional topological manifold (we do not assume that M is connected). Let A and B be two distinct boundary components of M. Furthermore let $f\colon A \to B$ be a homeomorphism. Then the following two statements hold:*

(1) *The topological space*

$$M/a \sim f(a) \quad \text{for } a \in A$$

is an n-dimensional topological manifold.

(2) *If M consists of two components X and Y and if $A \subset X$ and $B \subset Y$, then the images of X and Y in $M/a \sim f(a)$ are codimension zero submanifolds.*

(3) *If M is compact, then $M/a \sim f(a)$ is also compact.*

(4) *The boundary of $M/a \sim f(a)$ is given by $\partial M \setminus (A \cup B)$.*

Proof. The proof of Proposition 45.6 is almost the same as the proof of Proposition 10.12. We just need to make the following replacements:

(1) We need to replace Proposition 3.21 (3a) by Lemma 3.6.
(2) We need to replace the Collar Neighborhood Theorem 10.10 by the Topological Collar Neighborhood Theorem 45.3.
(3) We need to replace Proposition 3.21 (1) by Proposition 32.1 (1). □

45.3. **The Euler characteristic of compact topological manifolds.** The following definition is a slight generalization of the definition from page 969.

Definition.

(1) Given a pair (X, A) of topological spaces and $n \in \mathbb{N}_0$ we refer to[849]
$$b_n(X, A) \ := \ \mathrm{rank}(H_n(X, A))$$
as the *n-th Betti number of* (X, A). For $A = \varnothing$ we write of course $b_n(X) := b_n(X, \varnothing)$.
(2) Let (X, A) be a pair of topological spaces. If all $b_n(X, A)$ are finite and if the sum $\sum\limits_{n\in\mathbb{N}_0} b_n(X, A)$ is finite, then we define the Euler characteristic of (X, A) to be
$$\chi(X, A) \ := \ \sum_{n\in\mathbb{N}_0} (-1)^n \cdot b_n(X, A).$$
For $A = \varnothing$ we write $\chi(X) := \chi(X, \varnothing)$.

Remark.

(1) It follows from Proposition 40.1 that for a finite CW-complex the above definition agrees with the original definition of the Euler characteristic of a finite CW-complex.
(2) Let X be a compact manifold and let A be a compact submanifold. It follows from Proposition 45.2 that the Euler characteristic $\chi(X, A)$ is defined.

It turns out that the formulas we proved before for the Euler characteristic of CW-complexes also hold for topological manifolds. More precisely, we have the following proposition, of which the first three statements are the analogue of Lemmas 40.9 and 40.5 and of Proposition 26.25 in our new context.

Proposition 45.7.

(1) *Let X and Y be homotopy equivalent topological spaces. If the Euler characteristic is defined for one of the two topological spaces, then it is defined for the other topological space and we have*
$$\chi(X) \ = \ \chi(Y).$$
(2) *Let X be and Y be two compact topological manifolds, then*
$$\chi(X \times Y) \ = \ \chi(X) \cdot \chi(Y).$$

[849] We refer to page 1006 for the definition of the rank of an arbitrary abelian group.

(3) *Let $X = Y \cup Z$ be a decomposition of a compact topological manifold into two compact submanifolds Y and Z such that $Y \cap Z$ is also a compact submanifold of X. Then the following equality holds*

$$\chi(X) \;=\; \chi(Y) + \chi(Z) - \chi(Y \cap Z).$$

(4) *If X is a compact topological manifold and A is a compact submanifold, then*

$$\chi(X, A) \;=\; \chi(X) \;-\; \chi(A).$$

Furthermore, for any field $\mathbb{F}$ we have

$$\chi(X, A) \;=\; \sum_i (-1)^i \cdot \dim_{\mathbb{F}}(H_i(X, A; \mathbb{F})).$$

(5) *Let X be a compact topological manifold and let $p\colon \widetilde{X} \to X$ be a finite covering. Then*

$$\chi(\widetilde{X}) \;=\; \left[\widetilde{X} : X\right] \cdot \chi(X).$$

Sketch of proof.

(1) This statement follows immediately from Corollary 30.8.

(2) This equality can be proved using the Künneth Theorem 43.7 for Chain Complexes. We will fill in the details in Exercise 45.1.

(3) We will not make use of this statement. Therefore we hide, with a good conscience, the proof in Exercise 45.2.

(4) Let X be a compact topological manifold and let A be a compact submanifold.

(a) It follows immediately from considering the long exact sequence in homology of the pair (X, A) together with Lemma 40.4 that $\chi(X, A) = \chi(X) - \chi(A)$.

(b) Let $\mathbb{F}$ be a field. Let Y be a compact topological manifold. From Theorem 45.1 we know that Y is homotopy equivalent to a finite CW-complex Z. We observe that

$$\chi(Y) \;\underset{\substack{\uparrow \\ \text{Corollary 30.8}}}{=}\; \chi(Z) \;\underset{\substack{\uparrow \\ \text{see page 1010}}}{=}\; \sum_i (-1)^i \cdot \dim_{\mathbb{F}}(H_i(Z; \mathbb{F})) \;\underset{\substack{\uparrow \\ \text{by the generalization of Corollary 30.8} \\ \text{to } \mathbb{F}\text{-coefficients, see page 1009}}}{=}\; \sum_i (-1)^i \cdot \dim_{\mathbb{F}}(H_i(Y; \mathbb{F})).$$

Using this observation we can now prove that

$$\chi(X, A) \;\underset{\substack{\uparrow \\ \text{by (a)}}}{=}\; \chi(X) - \chi(A) \;\underset{\substack{\uparrow \\ \text{by the above observation}}}{=}\; \sum_i (-1)^i \cdot \dim_{\mathbb{F}}(H_i(X; \mathbb{F})) - \sum_i (-1)^i \cdot \dim_{\mathbb{F}}(H_i(A; \mathbb{F}))$$

$$\underset{\substack{\uparrow \\ \text{by the long exact sequence of the pair } (X, A) \text{ with } \mathbb{F}\text{-coefficients and Lemma 40.3}}}{=}\; \sum_i (-1)^i \cdot \dim_{\mathbb{F}}(H_i(X, A; \mathbb{F})).$$

(5) Let X be a compact topological manifold and let $p\colon \widetilde{X} \to X$ be a finite covering. Without loss of generality we can assume that X and $\widetilde{X}$ are connected. By Theorem 45.1 there exists a homotopy equivalence $f\colon X \to Y$, where Y is a finite

CW-complex. By Proposition 20.8 there exists a connected covering $q\colon \widetilde{Y} \to Y$ such that $q_*(\pi_1(\widetilde{Y})) = f_*(p_*(\pi_1(\widetilde{X})))$. Using Proposition 20.2 one can now easily show that $f\colon X \to Y$ lifts to map $\widetilde{f}\colon \widetilde{X} \to \widetilde{Y}$ and that this map is again a homotopy equivalence[850]. Now we obtain that

$$\begin{array}{ccccccc}
 & & & \text{we have } \big[\pi_1(\widetilde{Y}) : \pi_1(Y)\big] = \big[\pi_1(\widetilde{X}) : \pi_1(X)\big] \text{ since } f_* \text{ is an isomorphism} & & & \\
 & & & \downarrow & & & \\
\chi\big(\widetilde{X}\big) & = & \chi\big(\widetilde{Y}\big) & = \big[\pi_1(Y) : q_*(\pi_1(\widetilde{Y}))\big]\cdot\chi(Y) & = & \big[\pi_1(X) : p_*(\pi_1(\widetilde{X}))\big]\cdot\chi(X) & \\
 & \uparrow & & \uparrow & & \uparrow & \\
 & \text{by (1) since } \widetilde{X} \text{ and } \widetilde{Y} & & \text{Proposition 26.25} & & \text{by (1) we have } \chi(Y) = \chi(X) \text{ since } X & \\
 & \text{are homotopy equivalent} & & \text{and Lemma 7.16} & & \text{and } Y \text{ are homotopy equivalent} & \\
 & & & & & = \big[\widetilde{X} : X\big]\cdot\chi(X). & \\
 & & & & & \uparrow & \\
 & & & & & \text{Lemma 7.16} &
\end{array}$$

□

45.4. **Variations of the excision theorem.** One of the key tools throughout this course will be the Excision Theorem 31.17 and its many different incarnations. Recall that given an abelian group G the Excision Theorem 31.17 says that given a topological space X and subsets $Z \subset A \subset X$ the inclusion induces an isomorphism

$$H_n(X \setminus Z, A \setminus Z; G) \xrightarrow{\cong} H_n(X, A; G)$$

under the technical, and often quite annoying, condition, that $\overline{Z} \subset \mathring{A}$. In this short section we state two theorems that deal with this technical condition in favorable situations. The first of the two theorems is basically just a reformulation.

Theorem 45.8. (Excision Theorem)

(1) *Let X be a topological space, let $U \subset X$ be an open subset and let $K \subset X$ be a subset such that $\overline{K} \subset U$. Then for any abelian group G and any $n \in \mathbb{N}_0$ the inclusion induced map*

$$H_n(U, U \setminus K; G) \to H_n(X, X \setminus K; G)$$

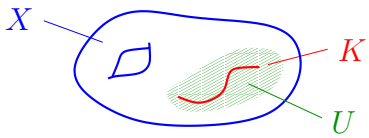
is an isomorphism.

(2) *The hypotheses of* (1) *are satisfied if X is Hausdorff* (*e.g. if X is a topological manifold*) *and if K is a compact subset that is contained in an open set U.*

Proof.

(1) Let X be a topological space, let $U \subset X$ be an open subset and let $K \subset X$ be a subset such that $\overline{K} \subset U$. We set $Z := X \setminus U$ and $A := X \setminus K$. By our hypothesis

[850]Here the point is that not only the homotopy equivalences but also the homotopies lift to the covering spaces. We leave the details to the reader.



here we have $H_n(U, U \setminus K; G) \xrightarrow{\cong} H_n(X, X \setminus K; G)$

FIGURE 628. Illustration of the Excision Theorem 45.8.

on K we have $Z \subset A$. We then have

$$\begin{array}{ccccc} H_n(U, U \setminus K; G) & \xrightarrow{=} & H_n(X \setminus Z, A \setminus Z; G) & \xrightarrow{\cong} & H_n(X, X \setminus K; G) \\ & & \uparrow & & \uparrow \end{array}$$

since $X \setminus Z = U$ and $A \setminus Z = U \setminus K$ — we have $\overline{Z} = Z = X \setminus U \subset X \setminus \overline{K} \subset$ interior of $X \setminus K = \mathring{A}$ thus we can apply the Excision Theorem 31.17

(2) If X is a topological manifold and if K is a compact subset that is contained in an open set U, then it follows from Lemma 1.18 (2)[851] that K is also a closed subset, hence we have $\overline{K} \subset U$. □

The next lemma is at first glance a little dull, but later on it will be used on several occasions. In the proof we will also require the Excision Theorem 45.8.

Lemma 45.9. *Let U be an open subset of $\mathbb{R}^n$, let A be a convex bounded subset of U with $\overline{A} \subset U$ and let $x \in A$. Then for any abelian group G and any $i \in \mathbb{N}_0$ the following inclusion induced maps are isomorphisms:*

$$\begin{array}{rrcl} (1) & H_i(\mathbb{R}^n \setminus A; G) & \to & H_i(\mathbb{R}^n \setminus \{x\}; G) \\ (2) & H_i(\mathbb{R}^n, \mathbb{R}^n \setminus A; G) & \to & H_i(\mathbb{R}^n, \mathbb{R}^n \setminus \{x\}; G) \\ (3) & H_i(U, U \setminus A; G) & \to & H_i(U, U \setminus \{x\}; G). \end{array}$$

If $\mathring{A}$ is non-empty and if $x \in \mathring{A}$ is a point, then also the following inclusion induced maps are isomorphisms

$$\begin{array}{rrcl} (4) & H_i(\partial\overline{A}; G) & \to & H_i(\mathbb{R}^n \setminus \{x\}; G) \\ (5) & H_i(\mathbb{R}^n, \partial\overline{A}; G) & \to & H_i(\mathbb{R}^n, \mathbb{R}^n \setminus \{x\}; G) \end{array}$$

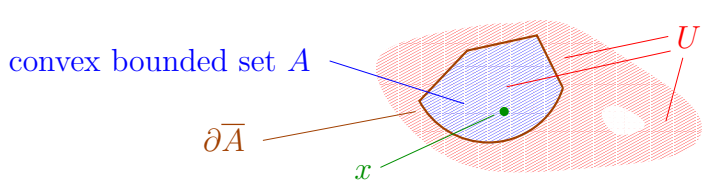


FIGURE 629. Illustration of Lemma 45.9.

[851] Note that we use that topological manifolds are by definition Hausdorff.

Proof. Let U be an open subset of $\mathbb{R}^n$, let A be a convex bounded subset of U with $\overline{A} \subset U$ and let $x \in A$. To simplify the notation we drop the coefficients G from the notation and without loss of generality we assume that $x = 0$. Now let $i \in \mathbb{N}_0$.

(1) We have to show that the inclusion induced map $H_i(\mathbb{R}^n \setminus A) \to H_i(\mathbb{R}^n \setminus \{0\})$ is an isomorphism. We had already stated this fact in Exercise 30.2. Now that we actually need the statement we give the full details.

Since A is bounded we can pick an $r > 0$ such that $A \subset B^n_{r/2}(0)$. Note that if $y \notin A$, then it follows from the convexity of A and the fact that $0 \in A$, that for any $s \geq 1$ the point sy cannot lie in A either. It is now straightforward to verify that the map

$$\begin{array}{rcl} F\colon (\mathbb{R}^n \setminus A) \times [0,1] & \to & \mathbb{R}^n \setminus A \\ x & \mapsto & \begin{cases} (x,t), & \text{if } x \in \mathbb{R}^n \setminus B^n_r(0), \\ x \cdot \underbrace{\left((1-t) + t \cdot \frac{r}{\|x\|}\right)}_{\geq 1 \text{ since } r > \|x\|}, & \text{if } x \in B^n_r(0) \setminus A. \end{cases} \end{array}$$

is a deformation retraction from $\mathbb{R}^n \setminus A$ to $\mathbb{R}^n \setminus B^n_r(0)$.[852] Clearly $\mathbb{R}^n \setminus B^n_r(0)$ is also a deformation retract of $\mathbb{R}^n \setminus \{0\}$. Now we consider the following commutative diagram

$$\begin{tikzcd} H_i(\mathbb{R}^n \setminus A) \arrow[rr] & & H_i(\mathbb{R}^n \setminus \{0\}) \\ & H_i(\mathbb{R}^n \setminus B^n_r(0)). \arrow[ul] \arrow[ur] & \end{tikzcd}$$

It follows from Corollary 30.8 and the above discussion that the two diagonal maps are isomorphisms. It follows that the horizontal map is also an isomorphism.

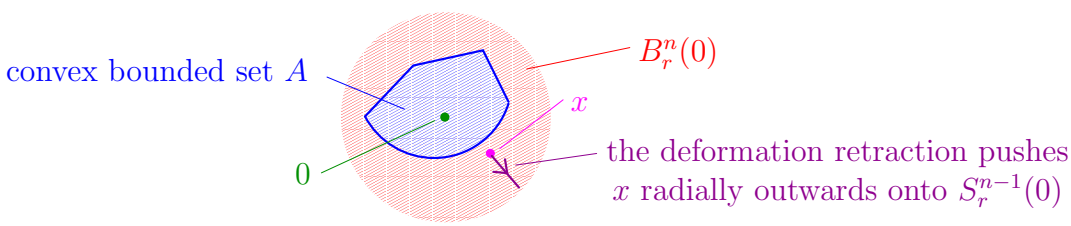

FIGURE 630.

(2) Now we consider the following commutative diagram of long exact sequences

$$\begin{tikzcd} \dots \arrow[r] & H_i(\mathbb{R}^n \setminus A) \arrow[r] \arrow[d, "\cong"] & H_i(\mathbb{R}^n) \arrow[r] \arrow[d, "\cong"] & H_i(\mathbb{R}^n, \mathbb{R}^n \setminus A) \arrow[r] \arrow[d, "\cong"] & H_{i-1}(\mathbb{R}^n \setminus A) \arrow[r] \arrow[d, "\cong"] & H_{i-1}(\mathbb{R}^n) \arrow[r] \arrow[d, "="] & \dots \\ \dots \arrow[r] & H_i(\mathbb{R}^n \setminus \{x\}) \arrow[r] & H_i(\mathbb{R}^n) \arrow[r] & H_i(\mathbb{R}^n, \mathbb{R}^n \setminus \{x\}) \arrow[r] & H_{i-1}(\mathbb{R}^n \setminus \{x\}) \arrow[r] & H_{i-1}(\mathbb{R}^n) \arrow[r] & \dots \end{tikzcd}$$

[852] As always, checking that a map is a deformation retraction also requires showing that the map is continuous. In this case the map is continuous by Lemma 1.104 and the fact we pick r such that $A \subset B^n_{r/2}(0)$.

By (1) the first and the fourth vertical maps are isomorphisms. The second and the fifth vertical map are the identity. It follows from the Five Lemma 31.11 that the middle vertical map is also an isomorphism.

(3) We consider the following commutative diagram

$$\begin{array}{ccc} H_i(U, U \setminus A) & \longrightarrow & H_i(U, U \setminus \{x\}) \\ \downarrow & & \downarrow \\ H_i(\mathbb{R}^n, \mathbb{R}^n \setminus A) & \longrightarrow & H_i(\mathbb{R}^n, \mathbb{R}^n \setminus \{x\}) \end{array}$$

of inclusion induced homomorphisms. Since $\overline{A} \subset U$ we deduce from Theorem 45.8 that the two vertical maps are isomorphisms. By (2) we know that the bottom horizontal map is an isomorphism. Hence the top horizontal map is also an isomorphism.

Now we suppose that $\mathring{A}$ is non-empty and we suppose that x is a point in $\mathring{A}$. Without loss of generality we can assume that $x = 0$ and that $A = \overline{A}$.

(4) By Lemma 9.1 we know that there exists an isotopy

$$F\colon A \times [0,1] \ \to \ \mathbb{R}^n$$

from the inclusion map $i\colon A \to \mathbb{R}^n$ to a homeomorphism $\varphi\colon A \to \overline{B}^n$ that has the following two properties:

(a) $F_1 = \varphi$ restricts to a homeomorphism $\partial A \to S^{n-1}$, and

(b) F has the property that $F(0,t) = 0$ for all $t \in [0,1]$.

Now we have the following diagram

$$\begin{array}{ccccc} & & H_k(\partial A) & & \\ & \swarrow^{\cong}_{\varphi_*} & \downarrow \varphi_* & \searrow^{(i|_{\partial A})_*} & \\ H_k(S^{n-1}) & \xrightarrow[\cong]{} & H_k(\mathbb{R}^n \setminus \{0\}) & \xrightarrow[=]{} & H_k(\mathbb{R}^n \setminus \{0\}). \end{array}$$

Here all the unmarked maps are induced by inclusions. The right-hand triangle commutes by Corollary 30.8 since, by the above property (b), the isotopy F restricts to an isotopy $\partial A \times [0,1] \to \mathbb{R}^n \setminus \{0\}$. The left horizontal map is an isomorphism since S^{n-1} is a deformation retract of $\mathbb{R}^n \setminus \{0\}$. It is now clear that the right-hand diagonal map is also an isomorphism.

(5) With the same argument as in (2) we can reduce the proof of this statement to (4). □

We conclude this section with another variation on the Excision Theorem. It can be summarized as saying that in relative homology one can excise the interior of a codimension 0 submanifold.

Theorem 45.10. (Excision Theorem for topological Manifolds) *Let X be an m-dimensional topological manifold and let A be a subset of X. Furthermore let B be an m-dimensional submanifold of X. We write $\overset{\circ}{B} := B \setminus \partial_0 B$.*[853] *If $\overset{\circ}{B} \subset A$, then for every $n \in \mathbb{N}_0$ and any abelian group G the inclusion induced map*

$$H_n\big(X \setminus \overset{\circ}{B}, A \setminus \overset{\circ}{B}; G\big) \xrightarrow{\cong} H_n(X, A; G)$$

is an isomorphism.

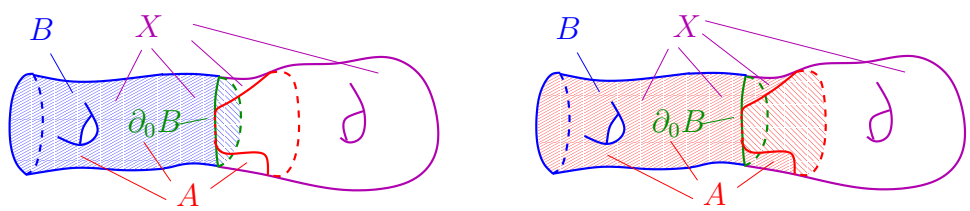

FIGURE 631. Illustration of the Excision Theorem 45.10.

The proof of Theorem 45.10 is verbatim the same as the proof of Theorem 32.7, except that in the proof we need to replace the Collar Neighborhood Theorem 10.10 by the Topological Collar Neighborhood Theorem 45.3 and we need to replace Proposition 3.21 (3) by Lemma 3.6.

45.5. **The double of a (topological) manifold.** In this short section we introduce the double of a topological manifold.

Definition. Given a topological manifold M we refer to

$$DM \;:=\; (M \times \{1\}) \cup_{\partial M \times \{1\} = \partial M \times \{2\}} (M \times \{2\})$$

as the *double of* M. We view M as a subset of DM via the inclusion $P \mapsto [(P, 1)]$.

Example. The double of M is given by taking two copies of M and identifying the boundary points "left and right" in the obvious way.

(1) The double of the n-ball $\overline{B}^n$ is homeomorphic to the n-dimensional sphere S^n. We refer to Figure 632 for an illustration.
(2) The double of the torus minus two open disks is the surface of genus 3. We refer to Figure 633 for an illustration.
(3) In Exercise 45.6 we will determine the double of the Möbius band and the Klein bottle minus an open disk.

The following lemma says in particular that the double of a compact (topological) manifold is a closed (topological) manifold.

[853] We refer to page 805 for the definition of $\partial_0 B$.

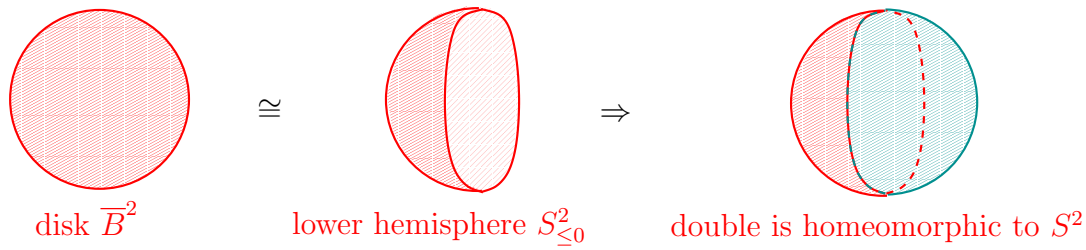

FIGURE 632.

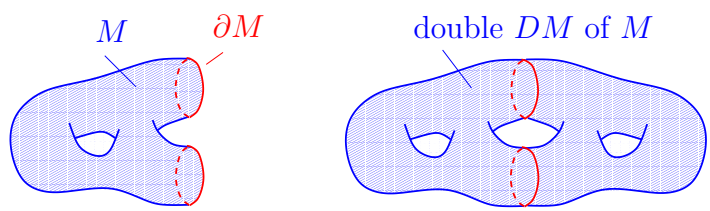

FIGURE 633.

Lemma 45.11. *Let M be a (topological) n-dimensional manifold, then the following statements hold:*

(1) *The double DM is also a (topological) n-dimensional manifold such that $M \subset DM$ is a submanifold.*
(2) *The boundary of the double DM is empty.*
(3) *If M is compact, then the double DM is also compact.*

Proof. For a topological manifold the statements follow immediately from Proposition 45.6 and for a manifold the statements follow immediately from Proposition 10.12. □

Lemma 45.11 says in particular that we can turn any (topological) manifold into a (topological) manifold without boundary by doubling. In particular, if the original (topological) manifold is compact, then the double is a closed (topological) manifold. The doubling trick is often useful when one tries to extend results for closed (topological) manifolds to results for compact (topological) manifolds.

The following definition allows us to relate a topological manifold to its double.

Definition. Let M be a topological manifold. We refer to the map

$$\begin{array}{rcl} r\colon DM = (M \times \{1\} \cup M \times \{2\})/\sim & \to & M \\ [(P,i)] & \mapsto & P \end{array}$$

as the *folding map*. We refer to Figure 634 for an illustration. (Note that it follows easily from Lemma 1.83 (3) that the folding map is continuous.)

The following lemma relates some of the algebraic invariants of a manifold M to the invariants of its double DM.

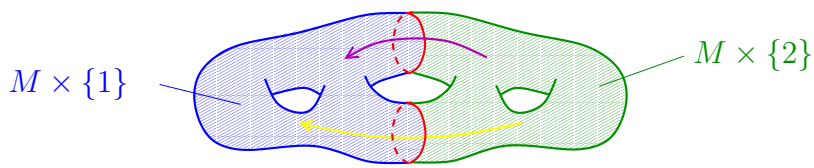

FIGURE 634. Illustration of the folding map $DM \to M$.

Lemma 45.12. *Let M be a topological manifold.*

(1) *The folding map $DM \to M$ is retraction, in particular the submanifold M is a retract of the double DM.*
(2) *Let G be an abelian group. Then for every $i \in \mathbb{N}_0$ the inclusion induced map $H_i(M;G) \to H_i(DM;G)$ is a monomorphism.*
(3) *If ∂M is non-empty and if x_0 is a point in ∂M, then the inclusion induced map $\pi_1(M,x_0) \to \pi_1(DM,x_0)$ is a monomorphism.*

Proof. We denote by $i\colon M = M \times \{1\} \to DM$ the obvious inclusion map. Clearly we have $r \circ i = \mathrm{id}_M$, i.e. r is a retraction and M is a retract of the double DM. The other two statements follow as usual from the functoriality of homology groups and fundamental groups. More precisely, in both cases we have $r_* \circ i_* = \mathrm{id}_*$, i.e. i_* needs to be a monomorphism. $\square$

We conclude this introduction to the double of a topological manifold with the following harmless but at times useful lemma. The lemma follows almost immediately from the definition, hence we leave it to the conscientious reader to fill in the details.

Lemma 45.13. *Let M be a topological manifold. For $i = 1,2$ we view $M \times \{i\}$ as a subset of DM and we denote by $j_i\colon M \to M \times \{i\}$ be the obvious map.*

(1) *For any $k \in \mathbb{N}_0$ and any commutative ring R the map*
$$\begin{array}{rcl} D\colon C_k(M,\partial M;R) & \to & C_k(DM;R) \\ [\underbrace{\sigma}_{\in C_k(M;R)}] & \mapsto & j_{1*}(\sigma) - j_{2*}(\sigma) \end{array}$$
is well-defined.
(2) *The maps from (1) define a chain map, in particular for any $k \in \mathbb{N}_0$ these maps induce a map*
$$D\colon H_k(M,\partial M;R) \to H_k(DM;R)$$
which is called the doubling homomorphism.
(3) *We make the identification $M = j_1(M \times \{1\})$ and we write $M' = j_2(M \times \{2\})$. The doubling homomorphism has the property that the following diagram commutes*
$$\begin{tikzcd} H_k(M,\partial M;R) \arrow[rr, "D"] \arrow[dr] & & H_k(DM;R) \arrow[dl] \\ & H_k(DM,M';R), & \end{tikzcd}$$

where the diagonal maps are the obvious maps.

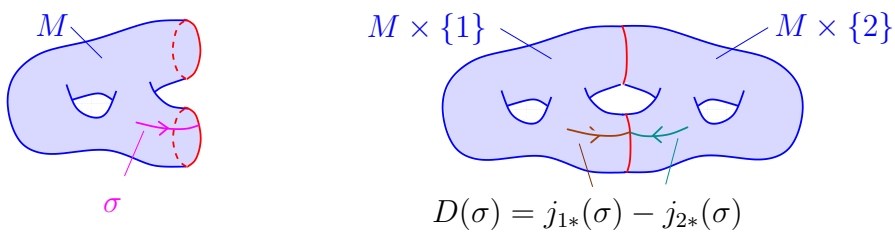

FIGURE 635.

45.6. **The local homology of topological manifolds.** Given a topological space X and a point $x_0 \in X$ the homology groups $H_n(X, X \setminus \{x_0\}; R)$ are often called the *local homology* of X at the point x_0. In this section we will study the local homology of topological manifolds, in particular we want to gain a good understanding of generators of these groups.

Some of the following definitions and conventions we had already introduced earlier.

Definition and notation. Let $n \in \mathbb{N}$.

(1) We equip $\mathbb{R}^n$ with the orientation given by the standard basis $e_1, \dots, e_n$. With this orientation we can view any open subset of $\mathbb{R}^n$ as an oriented manifold.
(2) We write
$$\partial\Delta^n \;=\; \bigcup_{i=0}^{n} \{(t_0, \dots, t_n) \in \Delta^n \,|\, t_i = 0\}.$$
and we refer to $\mathring{\Delta}^n := \Delta^n \setminus \partial\Delta^n$ as the *interior* of Δ^n.
(3) As on page 935 we say that a basis $\{v_1, \dots, v_n\}$ for $T_P\mathring{\Delta}^n$ is *positive*, if the ordered set of vectors $\{(1, \dots, 1), v_1, \dots, v_n\}$ is a positive basis for $\mathbb{R}^{n+1}$. This equips $\mathring{\Delta}^n$ with the structure of an oriented manifold.
(4) Given a subset V of $\mathbb{R}^n$ we say that a map $f\colon V \to \mathbb{R}^k$ is *affine linear* if there exists a $P \in \mathbb{R}^k$ and a $k \times n$-matrix A such that $f(v) = P + Av$ for all $v \in V$.

FIGURE 636.

Example. The projection map

$$\begin{array}{rcl} p\colon \Delta^n & \to & \mathbb{R}^n \\ (x_1,\dots,x_{n+1}) & \mapsto & (x_1,\dots,x_n) \end{array}$$

is an injective affine linear map. One can easily verify that the restriction of this map to the interior $\mathring{\Delta}^n$ is orientation-preserving if and only if n is even. We refer to Figure 637 for an illustration.

projection is orientation-reversing projection is orientation-preserving

FIGURE 637.

We continue with the following lengthy lemma.

Lemma 45.14. *Let R be a commutative ring.*

(1) *For any $k \in \mathbb{N}_0$ we have*

$$H_k(\Delta^n, \partial\Delta^n; R) \;=\; \begin{cases} 0, & \text{if } k \neq n, \\ R \cdot [\mathrm{id}_{\Delta^n} \otimes 1], & \text{if } k = n. \end{cases}$$

(2) *Let $\Phi\colon \Delta^n \to \mathbb{R}^n$ be an injective affine linear map such that 0 lies in the image of $\mathring{\Delta}^n$ and such that the restriction of Φ to $\mathring{\Delta}^n$ is orientation-preserving. Then for any $k \in \mathbb{N}_0$ the induced map*

$$\Phi_*\colon H_k(\Delta^n, \partial\Delta^n; R) \;\to\; H_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}; R)$$

is an isomorphism and this map does not depend on the choice of Φ.

(3) *Let $P \in \mathbb{R}^n$. We pick $r > 0$ such that $B_r^n(0)$ contains P. Then for any $k \in \mathbb{N}_0$ the inclusion induced maps*

$$H_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}; R) \;\leftarrow\; H_k\big(\mathbb{R}^n, \mathbb{R}^n \setminus B_r^n(0); R\big) \;\leftarrow\; H_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{P\}; R)$$

are isomorphisms and the resulting isomorphism

$$H_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}; R) \;\xrightarrow{\cong}\; H_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{P\}; R)$$

does not depend on the choice of r.

(4) *Let $P \in \mathbb{R}^n$ be a point. If $\rho\colon \mathbb{R}^n \to \mathbb{R}^n$ is the reflection in an affine hyperplane through P, then the induced map*

$$\rho_*\colon H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{P\}; R) \to H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{P\}; R)$$

is given by multiplication by minus -1. The same conclusion also holds if we replace $\mathbb{R}^n$ by any open ball centered at P.

(5) *Let $U \subset \mathbb{R}^n$ be an open set and let $\overline{B}^n_r(Q) \subset U$ be a closed ball. Then for any $P \in B^n_r(Q)$ the inclusion induced maps*

$$\begin{array}{ccc} H_k(U, U \setminus B^n_r(Q); R) & \longrightarrow & H_k(\mathbb{R}^n, \mathbb{R}^n \setminus B^n_r(Q); R) \\ \downarrow & & \downarrow \\ H_k(U, U \setminus \{P\}; R) & \longrightarrow & H_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{P\}; R) \end{array}$$

are isomorphisms and they form a commutative diagram.

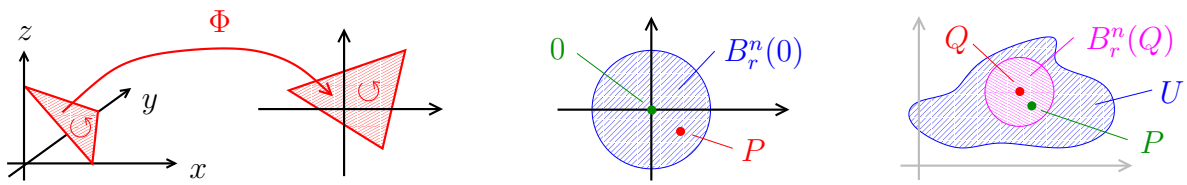

FIGURE 638. Illustration for Lemma 45.14 (2), (3) and (5)

Proof (∗).

(1) For $k \neq n$ the statement is proved the same way as Lemma 32.8. In Lemma 32.9 (2) we saw that the identity map $\mathrm{id}\colon \Delta^n \to \Delta^n$ represents a generator of $H_n(\Delta^n, \partial\Delta^n; \mathbb{Z}) \cong \mathbb{Z}$. Basically the same proof shows that for any commutative ring R the element $\mathrm{id}_{\Delta^n} \otimes 1 \in C_n(\Delta^n, \partial\Delta^n; R)$ represents a generator of the homology group $H_n(\Delta^n, \partial\Delta^n; R) \cong R$.

(2) Let $\Phi\colon \Delta^n \to \mathbb{R}^n$ be an injective affine linear map such that 0 lies in the image of $\mathring{\Delta}^n$ and such that the restriction of Φ to $\mathring{\Delta}^n$ is orientation-preserving. Note that it follows from Proposition 1.40 that Φ is a homeomorphism onto its image.

Then we have the following commutative diagram

$$\begin{array}{ccc} H_k(\Delta^n, \partial\Delta^n; R) & \xrightarrow{\Phi_*} & H_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}; R). \\ {\scriptstyle \Phi_*}\downarrow & & \uparrow \\ H_k(\Phi(\Delta^n), \Phi(\partial\Delta^n); R) & \longrightarrow & H_k(\mathbb{R}^n, \Phi(\partial\Delta^n); R) \end{array}$$

where the bottom and the right vertical map are induced by inclusions. Here the left vertical map is an isomorphism since Φ is a homeomorphism onto its image.

Since Φ is an injective affine linear map we see that $\Phi(\Delta^n)$ is a convex subset of $\mathbb{R}^n$ with non-empty interior. By our hypothesis the point 0 lies in the interior of $\Phi(\Delta^n)$. It follows from Lemma 45.9 (5) that the right vertical map is an isomorphism. Clearly $\Phi(\Delta^n) \to \mathbb{R}^n$ is a homotopy equivalence, hence it follows from Corollary 31.16 that the bottom horizontal map is an isomorphism. Since the diagram commutes we have thus now shown, as desired, that the top horizontal map is also an isomorphism.

If $\Psi\colon \Delta^n \to \mathbb{R}^n$ is another such injective affine linear orientation-preserving map, then it follows from elementary linear algebra that there exists some $P \in \mathbb{R}^n$ and a matrix A with *positive* determinant such that

$$\Phi \;=\; (v \mapsto P + A \cdot v) \circ \Psi\colon \Delta^n \to \mathbb{R}^n.$$

We write $\Omega = A \circ \Psi$. it suffices to show that Ψ and Ω and also Ω and Φ induce the same maps $H_k(\Delta^n, \partial\Delta^n; R) \to H_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}; R)$.

(a) By Lemma 1.96 (1) we know that $\{A \in \mathrm{GL}(n, \mathbb{R}) \mid \det(A) > 0\}$ is path-connected, in particular there exists a path $\gamma\colon [0,1] \to \mathrm{GL}(n, \mathbb{R})$ with $\gamma(0) = \mathrm{id}$ and $\gamma(1) = A$. We consider the map

$$\begin{array}{rcl} F\colon \Delta^n \times [0,1] & \to & \mathbb{R}^n \\ (Q,t) & \mapsto & \gamma(t) \cdot \Psi(Q). \end{array}$$

Since by hypothesis we have $0 \notin \Phi(\partial\Delta^n)$ and since $\gamma(t)(0) = 0$ we see that $\gamma(t)(\partial\Delta^n) \subset \mathbb{R}^n \setminus \{0\}$ for all t. In particular we deduce that F defines a homotopy between Ψ and Ω as maps $(\Delta^n, \partial\Delta^n) \to (\mathbb{R}^n, \mathbb{R}^n \setminus \{0\})$. But by Proposition 31.15 this means that $\Psi_* = \Omega_*$ as maps on relative homology.

(b) Now we compare Ω and $\Phi = (w \mapsto P + w) \circ \Omega$. We consider the map

$$\begin{array}{rcl} G\colon \Delta^n \times [0,1] & \to & \mathbb{R}^n \\ (Q,t) & \mapsto & (P \cdot t + \Omega(Q)). \end{array}$$

Note that $0 \in \Omega(\mathring{\Delta}^n) = A(\Psi(\mathring{\Delta}^n))$ and that $0 \in \Phi(\mathring{\Delta}^n)$ which implies by $\Phi = P + \Omega$ that $-P \in \Omega(\mathring{\Delta}^n)$. Since $\Omega(\mathring{\Delta}^n)$ is convex we see that G defines a homotopy between Ω and Φ as maps $(\Delta^n, \partial\Delta^n) \to (\mathbb{R}^n, \mathbb{R}^n \setminus \{0\})$. But again by Proposition 31.15 this means that $\Omega_* = \Phi_*$ as maps on relative homology.

(3) The fact that both inclusion induced maps are isomorphisms is an immediate consequence of Lemma 45.9 (2). Now suppose we are given another such $s > 0$. Without loss of generality we can assume that $r \geq s$. We obtain the following commutative diagram:

$$\begin{tikzcd} & H_k(\mathbb{R}^n, \mathbb{R}^n \setminus B^n_r(0); R) \arrow[dl, "\cong"'] \arrow[dr, "\cong"] \arrow[dd] & \\ H_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}; R) & & H_k(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}; R). \\ & H_k(\mathbb{R}^n, \mathbb{R}^n \setminus B^n_s(0); R) \arrow[ul, "\cong"] \arrow[ur, "\cong"'] & \end{tikzcd}$$

All maps are induced by inclusions, so the diagram commutes. By Lemma 45.9 the diagonal maps are isomorphisms. It is now obvious that the composition of the top maps and the composition of the bottom maps agree.

(4) Let $\rho\colon \mathbb{R}^n \to \mathbb{R}^n$ be the reflection in an affine hyperplane V through a point P. We denote by $f\colon \mathbb{R}^n \to \mathbb{R}^n$ the map that is given by addition by P and furthermore we write $W = f^{-1}(V)$. Note that W goes through the origin. Finally we denote by

$\sigma\colon \mathbb{R}^n \to \mathbb{R}^n$ the reflection in the hyperplane W. We consider the following diagram

$$\begin{array}{ccccccc}
H_{n-1}(S^{n-1}) \otimes R & \xrightarrow[\cong]{\mu} & H_{n-1}(S^{n-1}; R) & \xrightarrow{f_*} & H_{n-1}(\mathbb{R}^n \setminus \{P\}; R) & \xleftarrow[\cong]{\partial} & H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{P\}; R) \\
\downarrow{\scriptstyle \sigma_* \otimes \mathrm{id}} & & \downarrow{\scriptstyle \sigma_*} & & \downarrow{\scriptstyle \rho_*} & & \downarrow{\scriptstyle \rho_*} \\
H_{n-1}(S^{n-1}) \otimes R & \xrightarrow[\cong]{\mu} & H_{n-1}(S^{n-1}; R) & \xrightarrow{f_*} & H_{n-1}(\mathbb{R}^n \setminus \{P\}; R) & \xleftarrow[\cong]{\partial} & H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{P\}; R).
\end{array}$$

where μ is the natural map from page 1025 and where the right-hand horizontal maps are the connecting homomorphisms from Corollary 31.14.

It follows from Lemma 32.16 that the vertical map on the left is given by multiplication by -1. It is straightforward to verify that the diagram commutes and that all horizontal maps are isomorphisms. Furthermore the horizontal maps on the top and bottom are identical. It thus follows that the vertical map on the right is also given by multiplication by -1.

(5) It is clear that the diagram commutes since all maps are induced by inclusions. The horizontal maps are isomorphisms by the Excision Theorem 45.8 and the vertical maps are isomorphisms by Lemma 45.9. □

Convention. We use the isomorphisms from Lemma 45.14 to identify the various relative homology modules. In particular, for any open set U of $\mathbb{R}^n$, any open ball $B_r(P)$ with $\overline{B}_r(P) \subset U$, any point $Q \in U$ and any commutative ring R we make the identifications

$$R = H_n(\Delta^n, \partial\Delta^n; R) = H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{0\}; R) = H_n(U, U \setminus B_r(P); R) = H_n(U, U \setminus \{Q\}; R).$$

Furthermore, we refer to the image of the generator $[\mathrm{id}_{\Delta^n} \otimes 1] \in H_n(\Delta^n, \partial\Delta^n; R)$ as the *standard generator* of the various relative homology modules.

Example. We refer to Figure 639 for an illustration of representatives of the standard generators.[854] Here, for simplicity, given a singular 2-simplex $\Delta^2 \to \mathbb{R}^2$ we only sketch the image of $\partial\Delta^2$ with the given orientation. Finally note that it follows from Lemma 45.14 (4) that the singular simplex illustrated in the middle of Figure 639 represents *minus* the standard generator.

Lemma 45.15. *Let R be a commutative ring, let U be an open subset of $\mathbb{R}^n$, let $P \in U$ and let $\sigma\colon \Delta^n \to U$ be a singular n-simplex with the following properties:*

(1) *the point P lies in the image of $\mathring{\Delta}^n$,*
(2) *the restriction of σ to a map $\mathring{\Delta}^n \to U$ is a diffeomorphism onto its image.*

Then $\sigma \otimes 1 \in C_n(U) \otimes R$ represents a generator of $H_n(U, U \setminus \{P\}; R)$.[855] *Furthermore, if*

(3) *the restriction of σ to a map $\mathring{\Delta}^n \to U$ is orientation-preserving,*

[854] At this occasion it is good to remember that if $\sigma\colon \Delta^k \to X$ is a map with $\sigma(\partial\Delta^n) \subset A$, then σ is a cycle in $C_k(X, A)$, i.e. it represents a class in $H_k(X, A)$.

[855] Note that we do not make any assumptions on the behavior of σ restricted to $\partial\Delta^n$. If one looks very carefully, then one realizes that one has to convince oneself that $\sigma(\partial\Delta^n)$ is a subset of $U \setminus \{P\}$, i.e. one has to show that it follows from (1) and (2), that $P \notin \sigma(\partial\Delta^n)$. How can one prove this statement?

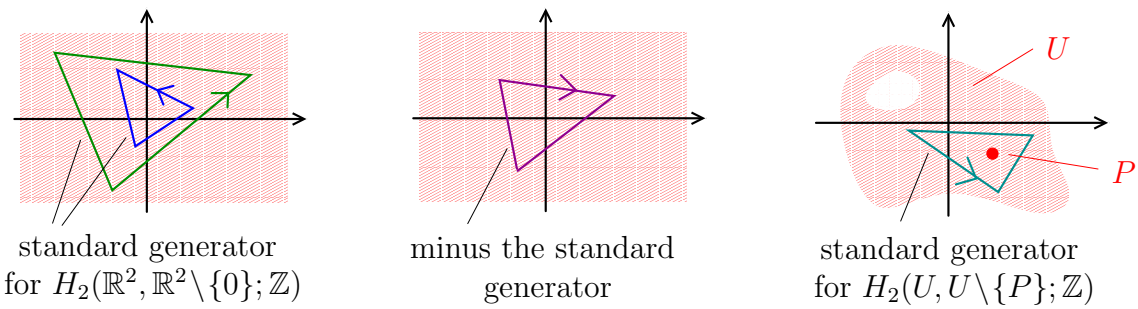

FIGURE 639.

then $\sigma \otimes 1$ represents the standard generator of $H_n(U, U \setminus \{P\}; R)$.

We refer to Figure 640 for an illustration of Lemma 45.15.

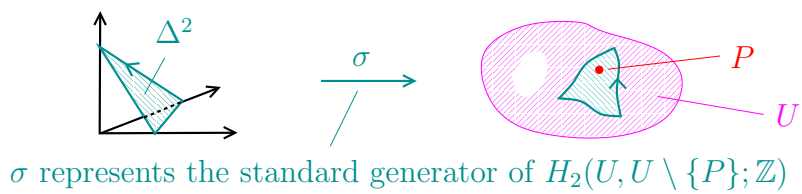

FIGURE 640.

Proof. We denote by $Q \in \mathring{\Delta}^n$ the point with $\sigma(Q) = P$. To simplify the notation we work throughout the proof with the coefficients $R = \mathbb{Z}$. Using the fact that the inclusion induced map

$$H_n(U, U \setminus \{P\}) \xrightarrow{\cong} H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{P\})$$

is an isomorphism by the Excision Theorem 45.8 we can without loss of generality assume that $U = \mathbb{R}^n$. As always we denote by $D_Q\sigma \colon T_Q\mathring{\Delta}^n \to T_P U = \mathbb{R}^n$ the differential of σ at the point Q. We denote by

$$\begin{array}{rcl} f \colon \Delta^n & \to & \mathbb{R}^n \\ x & \mapsto & (D_Q\sigma)\underbrace{(x - Q)}_{\in T_Q\Delta^n} + P \end{array}$$

the linear approximation of σ at the point Q. We make the following two observations:

(1) Since $\sigma \colon \mathring{\Delta}^n \to U$ is a diffeomorphism onto its image we obtain that $D_Q\sigma$ is an isomorphism of vector spaces, in particular f is an injective affine linear map.
(2) Basically the same argument as in the proof of Lemma 32.25 shows that there exists an open neighborhood V of Q in $\mathring{\Delta}^n$ such that the restrictions of σ and f to maps

$$\sigma, f \colon (V, V \setminus \{Q\}) \to (\mathbb{R}^n, \mathbb{R}^n \setminus \{P\})$$

are homotopic.

Now consider the following diagram

$$\begin{array}{ccccccccc}
H_n(\Delta^n,\partial\Delta^n) & \longrightarrow & H_n(\Delta^n,\Delta^n\backslash\{Q\}) & \leftarrow & H_n(V,V\backslash\{Q\}) & \xrightarrow{=} & H_n(V,V\backslash\{Q\}) & \rightarrow & H_n(\Delta^n,\Delta^n\backslash\{Q\}) \\
\downarrow{\sigma_*} & & \downarrow{\sigma_*} & & \downarrow{\sigma_*} & & \downarrow{f_*} & & \downarrow{f_*} \\
H_n(\mathbb{R}^n,\mathbb{R}^n\backslash\{P\}) & \xrightarrow{=} & H_n(\mathbb{R}^n,\mathbb{R}^n\backslash\{P\}) & \xrightarrow{=} & H_n(\mathbb{R}^n,\mathbb{R}^n\backslash\{P\}) & \xrightarrow{=} & H_n(\mathbb{R}^n,\mathbb{R}^n\backslash\{P\}) & \xrightarrow{=} & H_n(\mathbb{R}^n,\mathbb{R}^n\backslash\{P\}).
\end{array}$$

It is clear that the first two squares and the last square commute. Furthermore the third square commutes by the above observation (2) together with Proposition 31.15. As in the proof of Lemma 45.14 (2) we see that the last vertical map is an isomorphism. It now follows easily that $\sigma \in C_n(\mathbb{R}^n)$ represents a generator of $H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \{P\})$.

Finally suppose that the restriction of σ to a map $\mathring{\Delta}^n \to U$ is orientation-preserving. In this case, by definition of orientation-preserving, the map f is also orientation-preserving, therefore by the above commutative diagram the singular n-simplex σ does indeed represent the standard generator of $H_n(U, U \setminus \{P\})$. □

We continue with the following lemma which is almost identical to Lemma 32.3.

Lemma 45.16. *Let M be an n-dimensional topological manifold and let R be a commutative ring. Then for every $x \in M \setminus \partial M$ and any $k \in \mathbb{N}_0$ we have*

$$H_k(M, M \setminus \{x\}; R) \;\cong\; \begin{cases} R, & \text{if } k = n, \\ 0, & \text{otherwise.} \end{cases}$$

Furthermore, if $\Phi\colon U \to V$ is a chart around x and if $\sigma\colon \Delta^n \to V$ represents a generator of $H_n(V, V \setminus \{\Phi(x)\}; R)$, then $\Phi^{-1} \circ \sigma$ represents a generator of $H_n(M, M \setminus \{x\}; R)$.

We refer to Figure 641 for an illustration of Lemma 45.16.

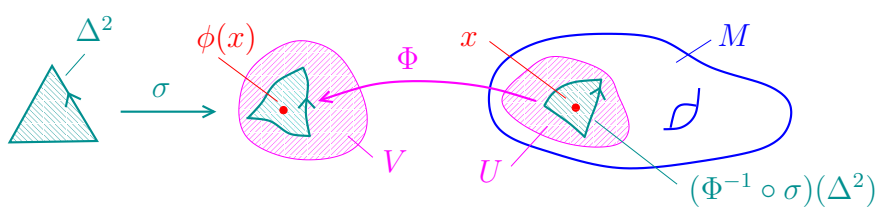

FIGURE 641.

Remark. Let $n \in \mathbb{N}_0$. A topological space X that has the property that for each $x \in X$ we have

$$H_k(X, X \setminus \{x\}; \mathbb{Z}) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k = n, \\ 0, & \text{otherwise} \end{cases}$$

is often called a *homology manifold*. By Lemma 45.16 such topological spaces can be viewed as generalizations of closed topological manifolds.

Let Y be an n-dimensional homology sphere.[856] By Proposition 32.14 we know that the suspension $\Sigma(Y)$ of Y is a homology manifold. On the other hand we saw in Exercise 28.7 that the suspension $\Sigma(Y)$ is *not* a topological manifold.[857] The famous Double Suspension Theorem of Jim Cannon [Can] and Richard Edwards [Edw] says that the double suspension $\Sigma(\Sigma(Y))$ of any n-dimensional homology sphere is homeomorphic to S^{n+2}. We will not make use of this deep theorem.

The proof of Lemma 45.16 is basically identical to the proof of Lemma 32.3. We recall the argument just in case some readers might have forgotten.

Proof. Let M be an n-dimensional topological manifold, let R be a commutative ring and let $x \in M \setminus \partial M$. Since $x \notin \partial M$ we can pick a chart $\Phi\colon U \to V$ such that V is an open subset of $\mathbb{R}^n$. We write $y = \Phi(x)$. For any $k \in \mathbb{N}_0$ we then have

$$\begin{array}{ccccc} H_k(M, M\setminus\{x\}; R) & \overset{\cong}{\longleftarrow} & H_k(U, U\setminus\{x\}; R) & \xrightarrow[\cong]{\Phi_*} & H_k(V, V\setminus\{y\}; R) & \xrightarrow{\cong} & \begin{cases} R, & \text{if } k = n, \\ 0, & \text{otherwise.} \end{cases} \\ & \uparrow & \uparrow & & \uparrow & & \\ & \text{Excision Theorem 45.8} & \text{since } \Phi \text{ is a homeomorphism} & & \text{see Lemma 45.14 (5)} & & \end{array}$$

The last statement regarding generators now follows immediately from the above isomorphisms. □

45.7. **R-Sections on topological manifolds.** In Section 3.8 we defined the notion of an oriented manifold via orientations of the tangent spaces. The notion of a tangent space requires the smooth structure on a manifold, put differently, topological manifolds do not come with tangent spaces. In the next section we will see that we can still define the notion of an orientation of a topological manifold. Furthermore we will see that for manifolds this new notion of an orientation will be equivalent to the previous notion of an orientation.

The key to defining the new notion of orientation is the following, initially rather obscure definition.

Definition. Let M be an n-dimensional topological manifold and let R be a commutative ring.

(1) An *R-section for M at $x \in M \setminus \partial M$* is an element $\mu_x \in H_n(M, M\setminus\{x\}; R) \cong R$.
(2) An *R-section for M* is a choice for each $x \in M \setminus \partial M$ of an R-section μ_x such that the following "continuity condition" is satisfied: for each $x \in M$ there exists an open neighborhood U of x in $M \setminus \partial M$ and an element $\mu_U \in H_n(M, M\setminus U; R)$ such that for each $y \in U$ the image of μ_U under the map

$$H_n(M, M\setminus U; R) \;\to\; H_n(M, M\setminus\{y\}; R)$$

[856]Recall that by the definition on page 992 an n-dimensional homology sphere is an n-dimensional topological manifold X such that for any $k \in \mathbb{N}_0$ we have $H_k(X;\mathbb{Z}) \cong H_k(S^n;\mathbb{Z})$. On page 993 we saw that there exists a 3-dimensional homology sphere with non-trivial fundamental group, namely the Poincaré homology sphere.

[857]To be super-precise we showed that it is not an $(n+1)$-dimensional topological manifold, but it follows easily from Proposition 32.5 that if $\Sigma(Y)$ was a topological manifold it would need to be $(n+1)$-dimensional.

equals μ_y.

(3) We denote by $\Gamma_R(M)$ the set of all R-sections of M.

Remark. Let M be an n-dimensional topological manifold and let R be a commutative ring. An example of an R-section for M is given by assigning to each $x \in M \setminus \partial M$ the zero element in $H_n(M, M \setminus \{x\}; R) \cong R$. It is clear that R-sections can be added and that one can multiply them by an element in R. This shows that the set $\Gamma_R(M)$ is an R-module in an obvious way.

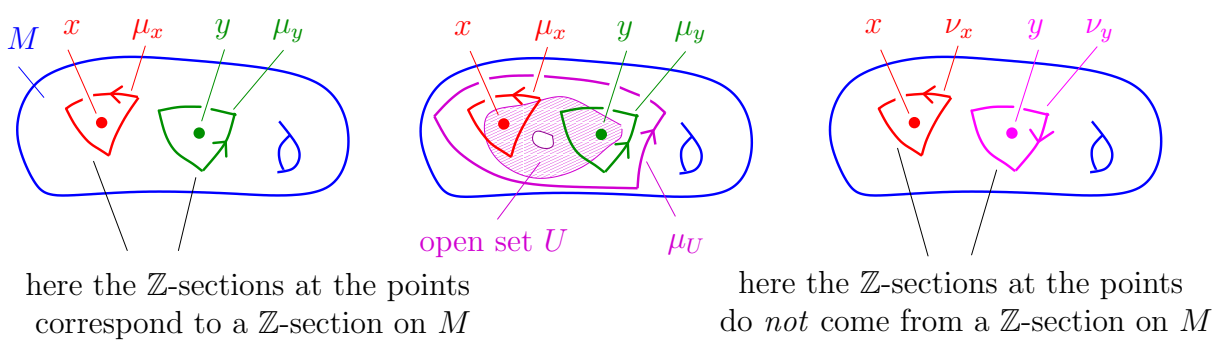
Example. In Figure 642 we attempt to illustrate the definition of a $\mathbb{Z}$-section on a surface M. Here, for simplicity, given a singular 2-simplex $\Delta^2 \to M$ we only sketch the image of $\partial\Delta^2$ with the given orientation.

(1) On the left of Figure 642 we show two points x and y with singular 2-simplices representing $\mu_x \in H_2(M, M \setminus \{x\}; \mathbb{Z})$ and $\mu_y \in H_2(M, M \setminus \{y\}; \mathbb{Z})$. Furthermore we sketch an open set U that contains x and y and an element $\mu_U \in H_2(M, M \setminus U; \mathbb{Z})$ that gets sent to μ_x and μ_y via the obvious maps[858]

$$H_n(M, M\setminus U; \mathbb{Z}) \to H_n(M, M\setminus\{x\}; \mathbb{Z}) \text{ and } H_n(M, M\setminus U; \mathbb{Z}) \to H_n(M, M\setminus\{y\}; \mathbb{Z}).$$

In fact one can show that these $\mathbb{Z}$-sections at x and y form part of a $\mathbb{Z}$-section of M.

(2) To the right of Figure 642 we show two $\mathbb{Z}$-sections ν_x and ν_y that cannot be part of a $\mathbb{Z}$-section of M.



here the $\mathbb{Z}$-sections at the points correspond to a $\mathbb{Z}$-section on M

here the $\mathbb{Z}$-sections at the points do *not* come from a $\mathbb{Z}$-section on M

FIGURE 642.

The following proposition will be used on many occasions.

Proposition 45.17. *Let M be a connected topological manifold.*

(1) *Let R be a commutative ring and let $\{\alpha_x\}_{x\in M\setminus\partial M}$ and $\{\beta_x\}_{x\in M\setminus\partial M}$ be two R-sections for M. If there exists an $x \in M \setminus \partial M$ with $\alpha_x = \beta_x$, then the two R-sections agree.*

[858]Note that in this example the group $H_2(M, M \setminus U; \mathbb{Z})$ is not isomorphic to $\mathbb{Z}$, i.e. the two maps are not isomorphisms.

(2) *Let* $\{\alpha_x\}_{x\in M\setminus\partial M}$ *be a* $\mathbb{Z}$*-section for* M*. Suppose there exists a* $y \in M \setminus \partial M$*, an* $m \in \mathbb{Z}$ *and a* $\beta_y \in H_n(M, M \setminus \{y\}; \mathbb{Z})$ *such that* $\alpha_y = m \cdot \beta_y$*, then there exists a* $\mathbb{Z}$*-section* $\{\beta_x\}_{x\in M\setminus\partial M}$ *such that* $\alpha_x = m \cdot \beta_x$ *for every* $x \in M \setminus \partial M$*.*

(3) *Let* $\{\alpha_x\}_{x\in M\setminus\partial M}$ *be a* $\mathbb{Z}$*-section for* M*. If there exists a* $y \in M\setminus\partial M$ *such that* α_y *is a generator of* $H_n(M, M\setminus\{y\}; \mathbb{Z}) \cong \mathbb{Z}$*, then* α_x *is a generator of* $H_n(M, M\setminus\{x\}; \mathbb{Z}) \cong \mathbb{Z}$ *for every* $x \in M \setminus \partial M$*.*

Before we provide the proof of Proposition 45.17 we need to prove one little lemma which in turn requires the following definition.

Definition. Let M be an n-dimensional topological manifold. We say that $Y \subset M$ is a *small ball* in M if there exists a chart $\Phi\colon U \to V$ such that $B_2^n(0) \subset V$ and such that $\Phi(Y) = B^n$. We illustrate the definition of a small ball in Figure 643.

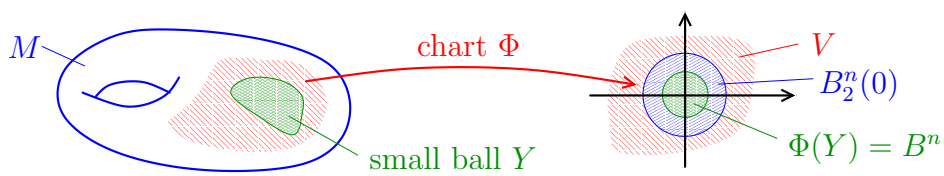


FIGURE 643.

Lemma 45.18. *Let* M *be an* n*-dimensional topological manifold.*

(1) *Given any point* $x \in M \setminus \partial M$ *and any neighborhood* U *of* x *there exists a small ball contained in* U*.*

(2) *Let* R *be a commutative ring. For any point* x *in a small ball* Y *and any* $k \in \mathbb{N}_0$ *the map*

$$H_k(M, M \setminus Y; R) \;\to\; H_k(M, M \setminus \{x\}; R)$$

is an isomorphism.

Proof. Let M be an n-dimensional topological manifold.

(1) The proof of the first statement is elementary.

(2) Now let x be a point that is contained in a small ball Y. To simplify the notation we drop the commutative ring R from the notation. We consider the long exact sequence of the triple $(M, M \setminus \{x\}, M \setminus Y)$ given by Corollary 31.14:

$$\to H_k(M\setminus\{x\}, M\setminus Y) \to H_k(M, M\setminus Y) \to H_k(M, M\setminus\{x\}) \to H_{k-1}(M\setminus\{x\}, M\setminus Y) \to$$

We see immediately that it suffices to show that all the relative homology groups $H_k(M \setminus \{x\}, M \setminus Y)$ vanish. Since Y is a small ball we can pick a chart $\Phi\colon U \to V$ such that $B_2^n(0) \subset V$ and such that $\Phi(Y) = B^n$. We pick $s \in (1, 2)$ and we write

$Z = \Phi^{-1}(B^n_s(0))$. Then

$$\underset{\substack{\uparrow \\ \text{Excision Theorem 45.8}}}{H_k(M\setminus\{x\}, M\setminus Y) \xleftarrow{\cong} H_k(Z\setminus\{x\}, Z\setminus Y)} \xrightarrow[\cong]{\Phi_*} \underset{\substack{\uparrow \\ \text{by Corollary 31.16, since } B^n_s(0)\setminus B^n \text{ is a} \\ \text{deformation retract of } B^n_s(0)\setminus\{\Phi(x)\}}}{H_k(B^n_s(0)\setminus\{\Phi(x)\}, B^n_s(0)\setminus B^n) = 0.}$$

We refer to Figure 644 for an illustration of the proof. □

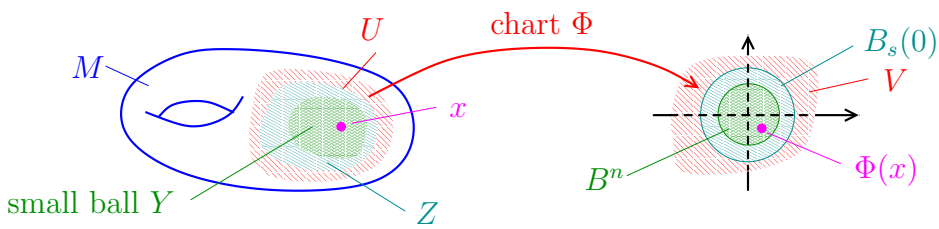

FIGURE 644. Illustration for the proof of Lemma 45.18.

Now we can provide the proof of Proposition 45.17.

Proof of Proposition 45.17. Let M be a connected n-dimensional topological manifold and let R be a commutative ring.

(1) Let $\{\alpha_x\}_{x\in M\setminus\partial M}$ and $\{\beta_x\}_{x\in M\setminus\partial M}$ be two R-sections for M such that there exists an $x \in M \setminus \partial M$ with $\alpha_x = \beta_x$. We set

$$V \;:=\; \{y \in M \setminus \partial M \,|\, \alpha_y = \beta_y\} \quad \text{and} \quad W \;:=\; \{y \in M \setminus \partial M \,|\, \alpha_y \neq \beta_y\}.$$

Since M is connected we also know that $M \setminus \partial M$ is connected.[859]. Since V is non-empty it suffices to show that V and W are both open. It suffices to prove the following claim.

Claim. Let $x \in M\setminus\partial M$. There exists an open neighborhood U of x such that either α_z and β_z agree for every $z \in U$ or disagree for every $z \in U$.

Let $x \in M \setminus \partial M$. It follows easily from the definition of an R-section and Lemma 45.18 (1) that there exists a small ball U in $M \setminus \partial M$ that contains x and elements $\alpha_U, \beta_U \in H_n(M, M \setminus U; R)$ such that for each $z \in U$ the image of α_U respectively β_U under the map

$$H_n(M, M \setminus U; R) \;\to\; H_n(M, M \setminus \{z\}; R)$$

equals α_z respectively β_z. By Lemma 45.18 this map is an isomorphism. So either α_z and β_z agree on all of U or they disagree on all of U. This concludes the proof of the claim.

[859]We will prove this statement in Exercise 45.4.

(2) Let $n \in \mathbb{N}$. We start out with the following definition: Given an element g of a group G with $G \cong \mathbb{Z}$ we say that g is divisible by n if there exists an $h \in G$ with $n \cdot h = g$. In this case we write $g/n := h$. Note that h is well-defined since $G \cong \mathbb{Z}$.

Let $\{\alpha_x\}_{x \in M \setminus \partial M}$ be a $\mathbb{Z}$-section for M. Given $n \in \mathbb{N}$ we consider the two sets

$$V \;:=\; \{y \in M \setminus \partial M \,|\, \alpha_y \text{ is divisible by } n\}$$

and

$$W \;:=\; \{y \in M \setminus \partial M \,|\, \alpha_y \text{ is not divisible by } n\}.$$

As in (1) one shows that V and W are open.

If V is non-empty, then $V = M \setminus \partial M$ and it is straightforward to verify that $\beta_y := \alpha_y/n$, $y \in M \setminus \partial M$, is in fact a $\mathbb{Z}$-section. We leave the details as an exercise to the reader.

(3) Let $\{\alpha_x\}_{x \in M \setminus \partial M}$ be a $\mathbb{Z}$-section for M. Let $y \in M \setminus \partial M$ be a point such that α_y is a generator of $H_n(M, M \setminus \{y\}; \mathbb{Z}) \cong \mathbb{Z}$. Now let $z \in M \setminus \partial M$. If α_z is not a generator, then there exists a $\beta_z \in H_n(M, M \setminus \{z\}; \mathbb{Z}) \cong \mathbb{Z}$ and some $n \geq 2$ such that $\alpha_z = n \cdot \beta_z$. By (2) we can extend β_z to a $\mathbb{Z}$-section $\{\beta_x\}_{x \in M \setminus \partial M}$ such that $\alpha_x = n \cdot \beta_x$ for every $x \in M \setminus \partial M$. But this implies that α_y is not a generator. So we have obtained a contradiction. □

45.8. **Orientations of topological manifolds.** After the technical preparations from the last section we can now finally introduce the notion of an orientation of a topological manifold.

Definition. Let M be an n-dimensional topological manifold and let R be a commutative ring.

(1) An R-section for M at a point $x \in M \setminus \partial M$ that is in fact a generator of the R-module $H_n(M, M \setminus \{x\}; R) \cong R$ is called an *R-orientation for M at $x \in M$*.
(2) An *R-section for M* that is an R-orientation at each point $x \in M \setminus \partial M$ is called an *R-orientation of M*.
(3) The topological manifold M is called *R-orientable* if it admits an R-orientation.
(4) Let M and N be two n-dimensional topological manifolds that are equipped with R-orientations $\{\alpha_x\}_{x \in M \setminus \partial M}$ and $\{\beta_x\}_{x \in N \setminus \partial N}$. Let $f \colon M \to N$ be a map that is a local homeomorphism. We say the map f is *orientation-preserving* if the following holds: for any open set $U \subset M$, such that $f \colon U \to f(U)$ is a homeomorphism and such that $f(U)$ is open, and any $x \in U \setminus \partial M$ the image of α_x under the map[860] [861] [862]

$$\begin{array}{ccccc} & \text{these maps are isomorphisms by the Excision Theorem 45.8} & & & \\ & \downarrow & & & \downarrow \\ H_n(M, M \setminus \{x\}) & \xleftarrow{\cong} & H_n(U, U \setminus \{x\}) & \xrightarrow[\cong]{f_*} & H_n(f(U), f(U) \setminus \{f(x)\}) \xrightarrow{\cong} H_n(N, N \setminus \{f(x)\}). \end{array}$$

[860] Since $f \colon U \to f(U)$ is a homeomorphism we have $f(U \setminus \{x\}) = f(U) \setminus \{f(x)\}$.

[861] It follows from the fact that $f \colon U \to f(U)$ is a homeomorphism, the fact that $x \in U \setminus \partial U$ and Propositionprop:boundary-of-n-dimensional-manifold that $f(x) \notin \partial N$.

[862] We suppress the R-coefficients from the notation for space reasons.

equals $\beta_{f(x)}$. Otherwise we call f *orientation-reversing.*

We leave the proof of the following lemma as an amusing exercise to the reader.

Lemma 45.19. *Let M and N be two n-dimensional topological manifolds and furthermore let $f, g\colon M \to N$ be two homeomorphisms. If f and g are isotopic, then f is orientation-preserving if and only if g is orientation-preserving.*

Before we start with the discussions of orientations in detail we get the following technical lemma out of the way.

Lemma 45.20. *Let M be a connected n-dimensional topological manifold.*

(1) *Let R be a commutative ring. If M is R-orientable, then for any $x \in M \setminus \partial M$ the map*
$$\begin{array}{rcl} \Phi\colon \Gamma_R(M) & \to & \overbrace{H_n(M, M \setminus \{x\}; R)}^{\cong R} \\ \{\alpha_y\}_{y \in M \setminus \partial M} & \mapsto & \alpha_x \end{array}$$
is an isomorphism of R-modules.

(2) *If M is non-orientable, then $\Gamma_{\mathbb{Z}}(M) = 0$.*

Proof. Let M be a connected n-dimensional topological manifold.

(1) Let R be a commutative ring such that M is R-orientable. We pick an R-orientation $\{\mu_y\}_{y \in M \setminus \partial M}$ for M. Now let $x \in M \setminus \partial M$. By definition μ_x is a generator of the R-module $H_n(M, M \setminus \{x\}; R) \cong R$, i.e. every element in $H_n(M, M \setminus \{x\}; R)$ is of the form $r \cdot \mu_x$ for some unique $r \in R$. We consider the map
$$\begin{array}{rcl} \Psi\colon H_n(M, M \setminus \{x\}; R) & \to & \Gamma_R(M) \\ r \cdot \mu_x & \mapsto & \{r \cdot \mu_y\}_{y \in M \setminus \partial M}. \end{array}$$
Evidently we have $\Phi \circ \Psi = \mathrm{id}$. It follows from our hypothesis that M is connected and from Proposition 45.17 (1) that $\Psi \circ \Phi$ is also the identity.

(2) Now we suppose that M admits a non-zero $\mathbb{Z}$-section $\{\alpha_x\}_{x \in M \setminus \partial M}$. We need to show that M is orientable. We pick $y \in M \setminus \partial M$ such that $\alpha_y \neq 0$. We pick a generator $\beta_y \in H_n(M, M \setminus \{y\}; \mathbb{Z}) \cong \mathbb{Z}$. Then $\alpha_y = n \cdot \beta_y$ for some $n \in \mathbb{Z}$. It follows again from our hypothesis that M is connected and from Proposition 45.17 (2) that there exists a $\mathbb{Z}$-section $\{\beta_x\}_{x \in M \setminus \partial M}$ such that $\alpha_x = n \cdot \beta_x$ for all $x \in M \setminus \partial M$.

It follows immediately from Proposition 45.17 (3) that $\{\beta_x\}_{x \in M \setminus \partial M}$ is an orientation for M. □

In the following lemma we collect some basic facts about $\mathbb{Z}$-orientations.

Lemma 45.21. *Let M be a topological manifold of dimension ≥ 1.*

(1) *For any point $x \in M \setminus \partial M$ there exist precisely two $\mathbb{Z}$-orientations for M at x.*

(2) *If M is connected and orientable, then M admits precisely two $\mathbb{Z}$-orientations.*

Proof. The first statement is an immediate consequence of the fact, proved in Lemma 45.16, that for any $x \in M \setminus \partial M$ we have $H_n(M, M \setminus \{x\}; \mathbb{Z}) \cong \mathbb{Z}$. The second statement follows easily from Proposition 45.17 and the definitions. □

Examples.

(1) Let V be a connected open subset of $\mathbb{R}^n$. For any $x \in V$ we define

$$\mu_x \ := \ \text{the standard generator of } H_n(V, V \setminus \{x\}; \mathbb{Z}) \text{ as defined on page 1092.}$$

We claim that the μ_x define a $\mathbb{Z}$-orientation for V. Indeed, let $x \in V$. We pick an $r > 0$ such that $\overline{B}_r(x) \subset V$. We set $U := B_r(x)$. We denote by μ_U the standard generator of $H_n(V, V \setminus U; \mathbb{Z})$ as defined on page 1092. It follows from Lemma 45.14 (5) that μ_U has the desired property. We refer to this $\mathbb{Z}$-orientation as the *standard $\mathbb{Z}$-orientation* of V.

By Lemma 45.21 (2) the topological manifold V admits precisely two different $\mathbb{Z}$-orientations. We have already given one orientation above. By Lemma 45.14 the other one is given by a reflection of the standard generators in hyperplanes. In Figure 645 we sketch the two different orientations of V.

standard generators for $H_2(V, V \setminus \{x\}; \mathbb{Z})$ — the negative of the standard generators

FIGURE 645.

(2) In Figure 646 we sketch the two different orientations of the torus.

FIGURE 646.

(3) Let R be a commutative ring. Recall that for $n \geq 1$ we denote by $[S^n] \in H_n(S^n; \mathbb{Z})$ the standard generator that we introduced on page 814. It follows from the Universal Coefficient Theorem 42.19 together with Lemma 42.17 (3) that the natural map

$$H_n(S^n) \otimes R \ \to \ H_n(S^n; R)$$

is an isomorphism. By a slight abuse of notation we denote by $[S^n]$ also the image of $[S^n] \otimes 1 \in H_n(S^n; R)$ under the above map. Note that $[S^n] \in H_n(S^n; R) \cong R$ is a generator. We refer to it as the *standard generator of* $H_n(S^n; R)$. For any $x \in S^n$ it

follows easily from the long exact sequence of homology groups with R-coefficients of the pair $(S^n, S^n \setminus \{x\})$ that the natural map

$$H_n(S^n; R) \;\to\; H_n(S^n, S^n \setminus \{x\}; R)$$

is an isomorphism. We denote by $\mu_x \in H_n(S^n, S^n \setminus \{x\}; R)$ the image of $[S^n]$. By the above μ_x is an R-orientation at x. In fact all these R-orientations $\{\mu_x\}_{x \in S^n}$ define an R-orientation of S^n. Indeed, in the definition on page 1099 we just need to set $U = S^n$ and $\mu_U = [S^n] \in H_n(S^n, \underbrace{S^n \setminus S^n}_{=\varnothing}; \mathbb{Z})$. We refer to this orientation of S^n as the *standard R-orientation of S^n*.

The following proposition shows in particular that for manifolds the notion of orientability from Section 3.8 agrees with the above notion of orientability.

Proposition 45.22.

(1) *Give any manifold M there exists a bijection*

$$\left\{ \begin{array}{c} \textit{orientations on } M \textit{ in} \\ \textit{the sense of Section 3.8} \end{array} \right\} \xrightarrow{\cong} \{\, \mathbb{Z}\textit{-orientations on } M \,\}$$

such that the following two statements hold:

(a) *For any open subsets of some $\mathbb{R}^n$ the above bijections sends the standard orientation from page 199 to the above standard $\mathbb{Z}$-orientation.*

(b) *If $f\colon M \to N$ is a local diffeomorphism between oriented connected manifolds, then the following two statements are equivalent:*

(i) *f preserves the orientations on M and N in the sense of Section 3.8,*

(ii) *f preserves the $\mathbb{Z}$-orientations on M and N.*

(2) *Given an n-dimensional manifold M we have*

$$M \textit{ is orientable in the sense of Section 3.8} \iff M \textit{ is } \mathbb{Z}\textit{-orientable.}$$

In the proof of Proposition 45.22 we will use the following lemma which is basically just a slight reformulation of Lemma 32.25.

Lemma 45.23. *Let $\Psi\colon V \to V'$ be a diffeomorphism between two open subsets of $\mathbb{R}^n$. Then for any $x \in V$ we have*

$$\begin{array}{c} \Psi \textit{ preserves the standard} \\ \mathbb{Z}\textit{-orientation of } V \textit{ at the point } x \end{array} \iff \begin{array}{c} \Psi \textit{ preserves the orientation of } V \textit{ in the} \\ \textit{sense of Section 3.8 at the point } x. \end{array}$$

Now we can provide the proof of Proposition 45.22.

Sketch of the proof of Proposition 45.22. First note that statement (2) is just a reader-friendly condensation of statement (1). Thus we need to prove statement (1). We define the promised bijections. Thus let M be an n-dimensional manifold. We first suppose that M is oriented in the sense of Section 3.8. Let $x \in M \setminus \partial M$. We pick a chart $\Phi\colon U \to V$ around x that is orientation-preserving in the sense of Section 3.8. We define

$$\mu_x \;:=\; \Phi_*^{-1}\big(\text{standard generator of } H_n(V, V \setminus \{\Phi(x)\}; \mathbb{Z}) \text{ as defined on page 1092}\big).$$

It follows from Lemma 45.23 that this definition does not depend on the choice of the orientation-preserving chart Φ. We claim that the classes $\{\mu_x\}_{x\in M\setminus\partial M}$ form a $\mathbb{Z}$-orientation for M. We only have to show that these classes satisfy the "continuity condition". We claim that for any $x \in M\setminus\partial$ a sufficiently small ball U containing x has the desired property. The proof of this fact is very similar to the arguments used in the proof of Proposition 45.17. We leave the details as an exercise to the reader.

Now we define the inverse map. So suppose we are given a $\mathbb{Z}$-orientation $\{\mu_x\}_{x\in M\setminus\partial M}$ for M. By Lemma 3.37 we only need to find an orientation for $M \setminus \partial M$. Thus let $x \in M \setminus \partial M$. We pick a chart $\Phi\colon U \to V$ around x such that V is connected. It follows from Lemma 45.14 that, after possibly reflecting V in a hyperplane, we can assume that Φ preserves the $\mathbb{Z}$-orientation at x, i.e. it sends the given $\mathbb{Z}$-orientation μ_x to the standard orientation of the open subset V of $\mathbb{R}^n$ that we introduced on page 1101. We define

$$\text{orientation of } T_xM := \Phi^*(\text{standard orientation of } T_{\Phi(x)}V = \mathbb{R}^n).$$

It follows from Lemma 45.23 that this definition does not depend on the choice of Φ. As before, using small balls, one can show that this defines an orientation of M in the sense of Section 3.8. We leave the verification of the details once again as an exercise to the reader.

It is basically clear, that by construction, the bijections have the desired properties (a) and (b). This concludes the proof of statement (1). □

Convention. Proposition 45.22 says in particular that for manifolds the notion of orientability that we introduced in Section 3.8 agrees with the notion of $\mathbb{Z}$-orientability that we had just introduced. For $R = \mathbb{Z}$ we will therefore often drop the "R" from the definitions on page 1099, i.e. often we just say *orientation at a point*, *orientation* and *orientable*.

Remark. It follows basically from the definition that this definitions that under the equivalence of Proposition 45.22 the orientations of S^n introduced on page 200 and page 1102 agree.

The following proposition shows that the notion of R-orientability is more flexible than the previous notion of orientability.

Proposition 45.24. *Every topological manifold is $\mathbb{F}_2$-orientable.*

Example. Proposition 45.24 says in particular that the real projective plane, the Klein bottle and the Möbius band are $\mathbb{F}_2$-orientable.

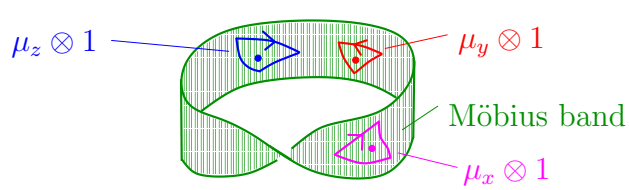

FIGURE 647.

Proof. Let M be an n-dimensional topological manifold. Let $x \in M \setminus \partial M$. By Lemma 45.16 we know that $H_n(M, M \setminus \{x\}; \mathbb{F}_2) \cong \mathbb{F}_2$. We define μ_x to be the unique non-trivial element in $H_n(M, M \setminus \{x\}; \mathbb{F}_2) \cong \mathbb{F}_2$. Using Lemma 45.18 it is straightforward to show that the continuity condition is satisfied, in particular we have defined an $\mathbb{F}_2$-orientation on M. $\square$

Lemma 45.25. *Let M be a topological manifold. If M is orientable, then it is R-orientable for any commutative ring R.*

Proof. Let M be an n-dimensional orientable topological manifold and let R be a commutative ring. Let $x \in M \setminus \partial M$. It follows from the Universal Coefficient Theorem 42.19, together with the fact that $H_{n-1}(M, M \setminus \{x\}; \mathbb{Z}) = 0$ obtained in Lemma 45.16, that the natural map

$$\begin{array}{rcl} \mu\colon H_n(M, M \setminus \{x\}; \mathbb{Z}) \otimes R & \to & H_n(M, M \setminus \{x\}; R) \\ \sum_{i=1}^{k} [\sigma_i] \otimes r_i & \mapsto & \left[\sum_{i=1}^{k} \sigma_i \otimes r_i\right] \end{array}$$

is an isomorphism.

Now we pick an orientation $\{\alpha_x\}_{x \in M \setminus \partial M}$ for M. For each $x \in M \setminus \partial M$ we denote by $\widetilde{\alpha}_x \in H_n(M, M \setminus \{x\}; R)$ the image of $\alpha_x \otimes 1$ under the above isomorphism. It is straightforward to verify that these generators $\{\widetilde{\alpha}_x\}_{x \in M \setminus \partial M}$ define an R-orientation for the topological manifold M. $\square$

We continue with the following proposition which is a variation of Proposition 8.3.

Proposition 45.26. *Let M be a connected non-orientable topological manifold without boundary. The following two statements hold:*

1. *There exists a connected 2-fold covering $p\colon \widetilde{M} \to M$ such that $\widetilde{M}$ is orientable.*
2. *If $p\colon \widetilde{M} \to M$ and $q\colon \widehat{M} \to M$ are two connected 2-fold coverings such that $\widetilde{M}$ and $\widehat{M}$ are orientable, then there exists a homeomorphism $\Phi\colon \widetilde{M} \to \widehat{M}$ such that the following diagram commutes:*

$$\begin{tikzcd} \widetilde{M} \arrow[rr, "\Phi"] \arrow[dr, "p"'] & & \widehat{M} \arrow[dl, "q"] \\ & M. & \end{tikzcd}$$

Remark. The statement of Proposition 45.26 also holds for connected non-orientable topological manifolds *with boundary*. How would you prove this more general statement? We will only need Proposition 45.26 for closed topological manifolds, so we will not attempt to prove the case of topological manifolds with boundary.

Definition. Let M be a connected non-orientable topological manifold without boundary. We refer to the connected 2-fold covering $p\colon \widetilde{M} \to M$ from Proposition 45.26, which is unique up to equivalence, as the *orientation covering* of M.

Sketch of proof. The proof is almost identical to the proof of Proposition 8.3. First let W be a topological manifold with empty boundary. We consider the set

$$\widetilde{W} := \{\mu_x \mid x \in W \text{ and } \mu_x \text{ is a } \mathbb{Z}\text{-orientation for } W \text{ at the point } x\}$$

and the projection map $p\colon \widetilde{W} \to W$ given by $\mu_x \mapsto x$. By hypothesis W has no boundary. It thus follows from Lemma 45.21 (1) that for every $x \in W$ the preimage $p^{-1}(x)$ has precisely two elements.

We equip $\widetilde{W}$ with a topology as in the proof of Proposition 8.3. It is then straightforward to see that $p\colon \widetilde{W} \to W$ is a 2-fold covering. Similar to the proof of Proposition 8.3 one can show that $\widetilde{W}$ is orientable.

Furthermore, if W is connected, then almost the same argument as in the proof of Proposition 8.3 shows that $\widetilde{W}$ is connected if and only if W is non-orientable. The conclusion of the proof of the proposition is, not surprisingly, almost verbatim the same as the denouement in the proof of Proposition 8.3. We leave it to the reader to flesh out all the details. □

Finally we conclude this section with the following corollary which is closely related to Corollary 8.4.

Corollary 45.27. *Let M be a connected topological manifold without boundary. If M is non-orientable, then there exists an epimorphism $\pi_1(M) \to \mathbb{Z}_2$.*

Proof. The proof of the corollary is basically identical to the proof of Corollary 8.4, we just need to replace Proposition 8.3 by Proposition 45.26. □

45.9. **Induced orientations.** (∗) In this final section we will show that various constructions of new topological manifolds out of a given oriented topological manifold are naturally equipped with orientations. For the most part the statements sound reasonable and familiar from the setting of manifolds. Nonetheless, the constructions of the induced representations for topological manifolds are at times quite different from the constructions of induced orientations for manifolds. Truth be told, the reader will not miss out on much by just moving on to the next chapter.

Lemma 45.28. *Let R be a commutative ring and let M be a topological manifold that is equipped with an R-orientation.*

(1) *Let N be a topological manifold and let $f\colon N \to M$ be a map. If f is a local homeomorphism, then there exists a unique R-orientation on N such that f is orientation-preserving.*
(2) *If N is a submanifold of codimension zero (for example N could be an open subset of M), then N admits an R-orientation such that the inclusion map $N \to M$ is orientation-preserving.*
(3) *If $p\colon \widetilde{M} \to M$ is a covering, then there exists a unique orientation on $\widetilde{M}$ that turns p into an orientation-preserving map.*

Proof. To simplify the notation we suppress the ring R from the notation. Thus let M be an n-dimensional topological manifold that is equipped with an orientation $\{\alpha_x\}_{x\in M\setminus\partial M}$.

(1) Let N be a topological manifold and let $f\colon N\to M$ be a local homeomorphism. Let $x\in N\setminus\partial N$. We pick an open neighborhood U of x such that $f\colon U\to f(U)$ is a homeomorphism and such that the image $f(U)$ is an open subset of M. We define $\beta_x\in H_n(N,N\setminus\{x\};R)$ to be the image of α_x under the map[863]

$$\begin{array}{ccccccc} & & \text{these maps are isomorphisms by the Excision Theorem 45.8} & & & & \\ & & \downarrow & & & & \downarrow \\ H_n(M,M\setminus\{f(x)\}) & \xleftarrow{\cong} & H_n(f(U),f(U)\setminus\{f(x)\}) & \xrightarrow[\cong]{f_*^{-1}} & H_n(U,U\setminus\{x\}) & \xrightarrow{\cong} & H_n(N,N\setminus\{x\}). \end{array}$$

We leave it to the reader to verify that these classes β_x define an orientation on N. By definition the map f is orientation-preserving with respect to the orientations on M and N. It is elementary to verify that the orientation on N is uniquely determined.

(2) This statement follows from (1) since the inclusion map of a codimension zero submanifold is, basically by definition, a local homeomorphism.

(3) This statement also follows from (1) since a covering map is a local homeomorphism. □

The following lemma says in particular that the double of an R-orientable manifold is again R-orientable.

Lemma 45.29. *Let M be a connected topological manifold with non-empty boundary and let R be a commutative ring. Then*

$$M \text{ is } R\text{-orientable} \iff \text{the double } DM \text{ is } R\text{-orientable.}$$

Furthermore, if M is equipped with an R-orientation, then DM admits a unique R-orientation such that the inclusion map $M\to DM$ is orientation-preserving.

Sketch of proof $(*)$. Let M be a connected topological manifold. In the following we write $DM=(M\sqcup M')/\sim$ where M' is another copy of M. We apply the Topological Collar Neighborhood Theorem 45.3 to obtain a collar neighborhood $\partial M\times[-2,0]$ of ∂M in M. To simplify the notation we henceforth drop the coefficient ring R from the notation.

If DM is orientable, then it follows immediately from Lemma 45.28 that the submanifold M is also orientable.

Now suppose that M is equipped with an orientation $\{\mu_x\}_{x\in M\setminus\partial M}$. We define orientations for the points of DM in $M\setminus\partial M$, $M'\setminus\partial M'$ and in $\partial M=\partial M'$ separately.

(1) Given $x\in M\setminus\partial M$ we denote by α_x the image of μ_x under the inclusion induced isomorphism $H_n(M,M\setminus\{x\})\to H_n(DM,DM\setminus\{x\})$ given by the Excision Theorem 45.10.

(2) We denote by $r\colon DM\to DM$ the obvious homeomorphism given by interchanging the two copies of M in DM. Given $x\in M'\setminus\partial M'$ we define $\alpha_x:=-r_*^{-1}(\alpha_{r(x)})$.

[863]Since $f\colon U\to f(U)$ is a homeomorphism we have $f(U\setminus\{x\})=f(U)\setminus\{f(x)\}$. Furthermore it follows from the fact that $x\in U\setminus\partial U$ and Proposition 32.1 that $f(x)\notin\partial N$.

(3) Finally let $x \in \partial M$. We define $\alpha_x \in H_n(DM, DM \setminus \{x\})$ to be the image of the class $\alpha_{x\times\{-1\}} \in H_n(DM, DM \setminus x \times \{-1\})$, which we defined in (1), under the isomorphism

$$H_n(DM, DM \setminus x\times\{-1\}) \underset{\uparrow}{\overset{\cong}{\Longleftarrow}} H_n(DM, DM \setminus x\times[-1,0]) \underset{\uparrow}{\overset{\cong}{\Longrightarrow}} H_n(DM, DM \setminus \overbrace{x\times\{0\}}^{=x}).$$

these maps are isomorphisms by an excision argument together with Lemma 45.9

We leave it as a slightly annoying exercise to the indefatigable reader to show that $\{\alpha_x\}_{x\in DM}$ does indeed define an orientation on DM. By construction of the orientation on DM the inclusion $M \to DM$ is orientation-preserving. The uniqueness of the orientation on DM is a consequence of Proposition 45.17 (1) and of our hypothesis that M is connected. $\square$

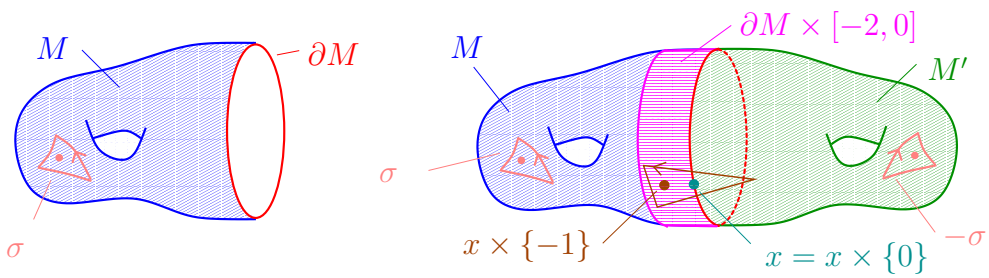

FIGURE 648.

Finally let M be an n-dimensional topological manifold equipped with an orientation $\{\mu_x\}_{x\in M\setminus\partial M}$. Now we will see that the given orientation induces an orientation on ∂M.

Proposition 45.30. *Given any topological manifold M of dimension ≥ 2 exists a natural map*

$$\{\textit{orientations of } M\} \;\to\; \{\textit{orientations of } \partial M\}.$$

Here natural means that if $f\colon M \to N$ is a homeomorphism, then the following diagram commutes:

$$\begin{array}{ccc} \{\textit{orientations of } M\} & \longrightarrow & \{\textit{orientations of } \partial M\} \\ \downarrow f_* & & \downarrow f_* \\ \{\textit{orientations of } N\} & \longrightarrow & \{\textit{orientations of } \partial N\}. \end{array}$$

Convention. If M is an oriented topological manifold of dimension ≥ 2, then we always equip ∂M with the orientation provided by the construction in the proof of Proposition 45.30.

Proof $(*)$. We suppose we are given an orientation $\{\mu_y\}_{y\in M\setminus\partial M}$ for M. In the following we will define a natural orientation for ∂M.

We set $n := \dim(M)$ and we write $A = [0,1] \times [-1,1]^n$, we write $A_0 := \{0\} \times [-1,1]^{n-1}$ and we write $A' = [0,1) \times (-1,1)^n$. Now let $x \in \partial M$. Since M is a topological manifold

and since $x \in \partial M$ we can pick a chart $\Phi\colon U \to [0,2) \times (-2,2)^{n-1}$. We write $\Psi := \Phi^{-1}$. Furthermore we write $V = \Psi(A)$, $V_0 = \Psi(A_0)$ and we write $V' = \Psi(A')$. Finally we pick a point $y \in V'$. (We refer to Figure 649 for an illustration.)

We consider the following sequence of maps

$$\begin{array}{ccccc} H_n(M, M\setminus\{y\}) & \xleftarrow{(1)} & H_n\big(M, M\setminus V'\big) & \xrightarrow[(2)]{\partial} & H_{n-1}(M\setminus V', (M\setminus V')\setminus\{x\}) \\ & & & & \uparrow{\scriptstyle (3)} \\ & & & & H_{n-1}(V_0, V_0\setminus\{x\}) \xrightarrow[(4)]{} H_{n-1}(\partial M, \partial M\setminus\{x\}). \end{array}$$

Here all the maps are induced by the obvious inclusions of pairs of topological spaces, except for the second map which is the connecting homomorphism of the long exact sequence of the triple $(M, M \setminus V', (M\setminus V')\setminus\{x\})$ that is provided by Proposition 31.13.

Claim. All the maps in the above diagram are isomorphisms.

In the following we treat the four maps separately.

(1) It is elementary to see that $A \setminus \Psi^{-1}(y)$ is a deformation retract of ∂A. It follows that $M \setminus V'$ is a deformation retract of $M \setminus \{y\}$.[864] We obtain from Corollary 31.16 that (1) an isomorphism.

(2) We consider the long exact sequence of the triple $(M, M \setminus V', (M\setminus V')\setminus\{x\})$ that is provided by Proposition 31.13:

$$H_n(M, (M\setminus V')\setminus\{x\}) \to H_n(M, M\setminus V') \xrightarrow{\partial} H_{n-1}(M\setminus V', M\setminus V) \to H_{n-1}(M, (M\setminus V')\setminus\{x\}).$$

Similarly to (1) one sees that $(M \setminus V') \setminus \{x\}$ is a deformation retract of M. Therefore it follows from Corollary 31.16 that the groups to the left and right are zero. In other words, the connecting homomorphism is an isomorphism.

(3) It follows quite easily from the Excision Theorem 31.17 that (3) is an isomorphism.

(4) Replace (3) by (4) in the previous sentence.

This concludes the proof of the claim.

Given $x \in \partial M$ we now define $\nu_x \in H_{n-1}(\partial M, \partial M \setminus \{x\})$ to be the image of the generator $\mu_y \in H_n(M, M\setminus\{y\})$ under the above sequence of isomorphisms. We continue with our next claim.

Claim.

(1) The definition of ν_x is independent of the choice of y.

[864]Looking at Figure 649 this statement sounds reasonable. But the statement nonetheless requires a proof. So let r be a deformation retraction from $A \setminus \Psi^{-1}(y)$ to ∂A. We consider the map

$$\begin{array}{rcl} s\colon (M\setminus\{y\}) \times [0,1] & \to & M\setminus\{y\} \\ (P,t) & \mapsto & \begin{cases} P, & \text{if } P \notin V\setminus\{y\}, \\ \Psi(r(\Psi^{-1}(P), t)), & \text{if } P \in V\setminus\{y\}. \end{cases} \end{array}$$

Note that $V \setminus \{y\}$ and $M \setminus \Psi(A')$ are closed subsets of $M \setminus \{y\}$. (Hmm, why is that?). It follows from Lemma 1.32 (2) that the map s is continuous.

(2) The definition of ν_x is independent of the choice of Φ.

We turn to the proof of the two statements.

(1) We need to show that for any $z \in \Psi(V')$ we have

$$\begin{array}{c}\text{preimage of } \mu_y \text{ under the map} \\ H_n(M, M\backslash V') \xrightarrow{\cong} H_n(M, M\backslash\{y\})\end{array} = \begin{array}{c}\text{preimage of } \mu_z \text{ under the map} \\ H_n(M, M\backslash V') \xrightarrow{\cong} H_n(M, M\backslash\{z\}).\end{array}$$

But this statement can be shown in a similar fashion as Proposition 45.17 (1). We leave it to the reader to fill in the details.

(2) Suppose we are given a different chart than Φ. We define W, W_0, W' in the obvious way. By possibly taking a third chart whose image lies in the intersection of V and W we can assume, without loss of generality, that $W \subset V$. (We refer to Figure 650 for an illustration.) Furthermore by (1) we can work with a point $y \in W$ for both charts. We consider the following diagram

$$\begin{tikzcd}
H_n(M, M\backslash\{y\}) & & H_n\big(M, M\backslash V'\big) \arrow[ll, "\cong", "(1)"'] \arrow[dl, dashed] \arrow[d, "(2)"', "\partial"] \\
H_n\big(M, M\backslash W'\big) \arrow[u, "\cong"', "(1)"] \arrow[d, "(2)"', "\partial"] & & H_{n-1}(M\backslash V', (M\backslash V')\backslash\{x\}) \arrow[dl, dashed] \\
H_{n-1}(M\backslash W', (M\backslash W')\backslash\{x\}) & & H_{n-1}(V_0, V_0\backslash\{x\}) \arrow[u, "(3)", "\cong"'] \arrow[d, "(4)"'] \\
H_{n-1}(W_0, W_0\backslash\{x\}) \arrow[u, "(3)"', "\cong"] \arrow[urr, dashed] \arrow[rr, "(4)"'] & & H_{n-1}(\partial M, \partial M\backslash\{x\}).
\end{tikzcd}$$

Here the two "outer paths" from the top left to the lower right correspond to the two "competing" definitions of ν_x. The dashed arrows are given by inclusions. We make the following observations:

(a) The triangle on top commutes since all maps are induced by inclusions.
(b) The upper parallelogram commutes since the connecting homomorphism is natural, see Proposition 31.13 (3) for details.
(c) The lower parallelogram commutes since all the maps are induced by inclusions. (Note that the reversal of the direction of the arrow is not a typo.)
(d) The triangle on the bottom commutes since all maps are induced by inclusions.

We saw above that all maps (1), (2), (3) and (4) are isomorphisms. By going from the top to the bottom we see that all the dashed arrows are isomorphisms.

Since all pieces of the diagram commute and since all maps are isomorphisms we see that the total diagram commutes. This shows that the two "'competing" definitions of ν_x agree.

This concludes the proof of the claim.

Using the previous claim it is now straightforward to show that the $\{\nu_x\}_{x\in\partial M}$ form an orientation for ∂M and that this orientation is natural. $\square$

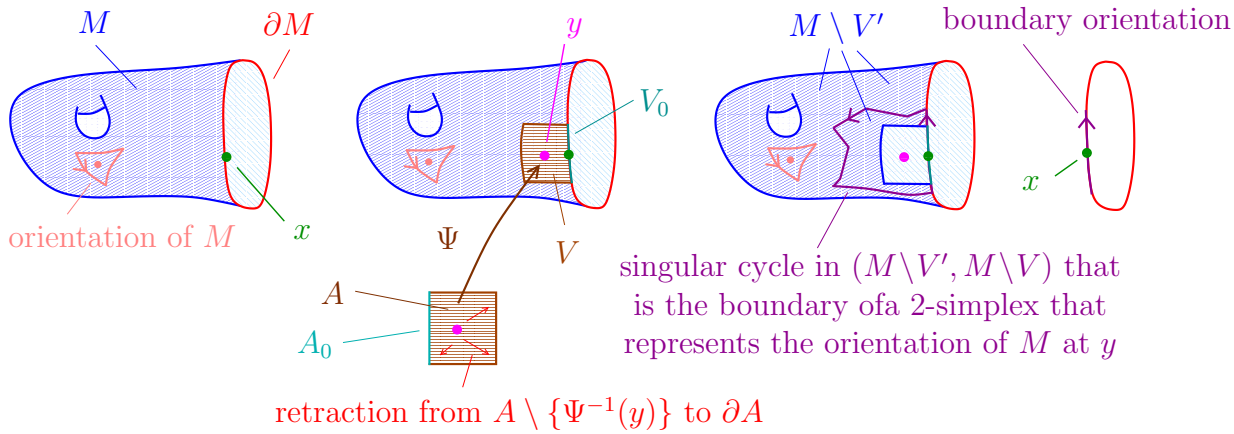

FIGURE 649.

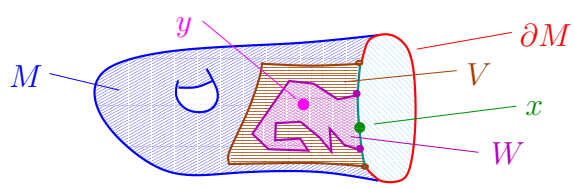

FIGURE 650.

Remark. Let M be an n-dimensional manifold that is equipped with an orientation in the sense of Section 3.8. On page 205 we had equipped the $(n-1)$-dimensional manifold ∂M with an orientation in the sense of Section 3.8. If one takes the strenuous journey through all conventions and definitions one sees that the boundary orientations from page 205 and the proof of Proposition 45.30 are compatible. More precisely, for any oriented n-dimensional M we have the following commutative "diagram"

$$\begin{tikzcd}
\text{oriented manifold } M \arrow[r, mapsto, "\text{take boundary}"] \arrow[d, mapsto, "\text{Proposition 45.22}"] & \text{oriented manifold } \partial M \arrow[d, mapsto, "\text{Proposition 45.22}"] \\
\mathbb{Z}\text{-oriented manifold } M \arrow[r, mapsto, "\text{take boundary}"] & \mathbb{Z}\text{-oriented manifold } \partial M.
\end{tikzcd}$$

Exercises for Chapter 45.

Exercise 45.1. Let X be and Y be two compact topological manifolds. Show that

$$\chi(X \times Y) \;=\; \chi(X) \cdot \chi(Y).$$

Exercise 45.2. Let $X = Y \cup Z$ be a decomposition of a compact topological manifold into two compact submanifolds Y and Z such that $\partial Y = \partial Z$ is a submanifold of X. Show that

$$\chi(X) \;=\; \chi(Y) + \chi(Z) - \chi(Y \cap Z).$$

Exercise 45.3. Let X be a compact topological space. Is $H_1(X)$ necessarily finitely generated?

Exercise 45.4. Let M be a connected topological manifold. Show that $M \setminus \partial M$ is still connected.

Exercise 45.5. Let M be a topological manifold with non-empty boundary. Show that the topological space $M \setminus \partial M$ is non-compact.

Exercise 45.6. What is the double of the Möbius band and what is the double of the Klein bottle minus an open disk?

Exercise 45.7. We recall the following definitions:

(1) The suspension of a topological space X is defined to be the topological space
$$\Sigma(X) \ := \ (X \times [-1,1])/\sim$$
where we identify all points in $X \times \{-1\}$ and we identify all points in $X \times \{1\}$.

(2) A topological space X that has the property that for each $x \in X$ we have
$$H_k(X, X \setminus \{x\}; \mathbb{Z}) \ \cong \ \begin{cases} \mathbb{Z}, & \text{if } k = n, \\ 0, & \text{otherwise} \end{cases}$$
is called an *n-dimensional homology manifold*.

(3) We say that an n-dimensional topological manifold X is a *homology n-sphere* if for any $k \in \mathbb{N}_0$ we have $H_k(X;\mathbb{Z}) \cong H_k(S^n;\mathbb{Z})$.

Let Y be an n-dimensional homology sphere.

(a) Show that $Y \times \mathbb{R}$ is an $(n+1)$-dimensional homology manifold.
(b) Show that the suspension $\Sigma(Y)$ of Y is an $(n+1)$-dimensional homology manifold.
(c) Show that if if $\pi_1(Y)$ is non-trivial, then the suspension $\Sigma(Y)$ is *not* a topological manifold.

Exercise 45.8. We view $\mathbb{R}$ as a topological manifold and we equip it with the standard $\mathbb{Z}$-orientation that we had introduced on page 1101. Let $f\colon \mathbb{R} \to \mathbb{R}$ be a map that is a local homeomorphism and that is orientation-preserving. Show that f is strictly monotonously increasing.

46. The fundamental class

46.1. The fundamental class of an oriented topological manifold.

Notation. Throughout this chapter we adopt the following notation. Let M be a topological manifold, let R be a commutative ring and let $x \in M \setminus \partial M$. Given any $k \in \mathbb{N}_0$ we denote by ρ_x the obvious map

$$\rho_x \colon H_k(M, \partial M; R) \quad \to \quad H_k(M, M \setminus \{x\}; R).$$

Given $\alpha \in H_k(M, \partial M; R)$ we often write $\alpha_x := \rho_x(\alpha)$, i.e. the above map is also written as

$$\alpha \quad \mapsto \quad \alpha_x.$$

With this notation we can now formulate the following elementary lemma.

Lemma 46.1. *Let M be an n-dimensional topological manifold and let R be a commutative ring. Then the map*

$$\begin{array}{rcl} H_n(M, \partial M; R) & \to & \Gamma_R(M) \\ \alpha & \mapsto & \{\alpha_x\}_{x \in M \setminus \partial M} \end{array}$$

is a well-defined homomorphism of R-modules.

Proof. We only need to show that $\{\alpha_x\}_{x \in M \setminus \partial M}$ is an R-section, but this follows immediately from setting $U = M \setminus \partial M$ and $\alpha_U = \alpha$ in the definition given on page 1095. (Note that here we used that we showed in Lemma 3.6 (1) that $U = M \setminus \partial M$ is an open subset of M.) □

The following three theorems contain most of the main results of this chapter.

Theorem 46.2. *Let M be a compact, connected, non-empty n-dimensional topological manifold. Then the following statements are equivalent:*

(1) *the topological manifold M is orientable,*
(2) $H_n(M, \partial M; \mathbb{Z}) \neq 0$,
(3) $H_n(M, \partial M; \mathbb{Z}) \cong \mathbb{Z}$,
(4) *for every $x \in M \setminus \partial M$ the map*

$$\begin{array}{rcl} \rho_x \colon H_n(M, \partial M; \mathbb{Z}) & \to & H_n(M, M \setminus \{x\}; \mathbb{Z}) \\ \alpha & \mapsto & \alpha_x \end{array}$$

is an isomorphism.

Theorem 46.3. *Let M be a compact, connected, non-empty n-dimensional topological manifold M. Then the following two statements hold:*

(1) $H_n(M, \partial M; \mathbb{F}_2) \cong \mathbb{F}_2$, *and*
(2) *for every $x \in M \setminus \partial M$ the map*

$$\begin{array}{rcl} \rho_x \colon H_n(M, \partial M; \mathbb{F}_2) & \to & H_n(M, M \setminus \{x\}; \mathbb{F}_2) \\ \alpha & \mapsto & \alpha_x \end{array}$$

is an isomorphism.

Theorem 46.4. *Let M be a connected n-dimensional topological manifold and let R be a commutative ring. Then the following two statements hold:*

(1) *If M is not closed, then $H_i(M;R) = 0$ for $i \geq n$.*
(2) *If M is closed, then we have $H_i(M;R) = 0$ for $i > n$.*

Remark.

(1) Let M be a connected n-dimensional manifold. In Proposition 35.6 (2) we already saw, using Theorem 26.3, that $H_i(M) = 0$ for $i > n$. Furthermore, in Proposition 39.5 we showed that

$$H_n(M) \cong \begin{cases} \mathbb{Z}, & \text{if } M \text{ is orientable and closed,} \\ 0, & \text{otherwise.} \end{cases}$$

Theorems 46.2 and 46.4 thus generalize these earlier results to topological manifolds. The new proofs are also more self-contained since they do not make use of the existence of CW-structures and simplicial structures on manifolds.

(2) One might be tempted to consider Theorem 46.4 (2) as "intuitively clear". After all, how could an n-dimensional object possibly have homology groups in higher dimensions? To shatter this belief, fix some $n \geq 2$. We consider the following subset of $\mathbb{R}^n$:[865]

$$\begin{aligned} X &:= \bigcup_{n\in\mathbb{N}} n\text{-dimensional sphere of radius } \tfrac{1}{n} \text{ around } (\tfrac{1}{n}, 0, \ldots, 0) \\ &= \bigcup_{n\in\mathbb{N}} \{x \in \mathbb{R}^n \mid \|x - (\tfrac{1}{n}, 0, \ldots, 0)\| = \tfrac{1}{n^2}\}. \end{aligned}$$

In [BaM] it is shown, rather shockingly, that for every q with $q \equiv 1 \bmod (r-1)$ the group $H_q(X;\mathbb{Q})$ is not only non-zero, it is even uncountable.

We will not immediately prove these three theorems, but we will first draw many conclusions, before we head towards the somewhat intricate proofs of the above three theorems.

Definition. Let M be a compact n-dimensional topological manifold and let R be a commutative ring. An *R-fundamental class of M* is an element $\beta \in H_n(M, \partial M; R)$ with the property that for any $x \in M \setminus \partial M$ the element $\beta_x \in H_n(M, M \setminus \{x\}; R)$ is a generator. For $R = \mathbb{Z}$ we just say *fundamental class*.

Remark. Let M be a compact n-dimensional topological manifold and let R be a commutative ring.

(1) Let $[M]$ be a $\mathbb{Z}$-fundamental class for M. The image of $[M]\otimes 1$ under the natural map $\mu\colon H_n(M;\mathbb{Z}) \otimes R \to H_n(M;R)$ is an R-fundamental class. Indeed, let $x \in M \setminus \partial M$.

[865] As the reader will surely have noticed, this example can be viewed as a high-dimensional analogue of the Hawaiian Earings that we introduced in Exercise 26.6.

From Lemma 42.7 (3) we obtain a commutative diagram

$$\begin{array}{ccc} H_n(M;\mathbb{Z})\otimes R & \xrightarrow{\quad\mu\quad} & H_n(M;R) \\ \downarrow & & \downarrow \\ H_n(M,M\setminus\{x\};\mathbb{Z})\otimes R & \xrightarrow{\mu} & H_n(M,M\setminus\{x\};R) \end{array}$$

By Lemma 45.16 and the Universal Coefficient Theorem 42.19 the bottom horizontal map is an isomorphism. Since the image of the $\mathbb{Z}$-fundamental class $[M]$ under the obvious map $H_n(M;\mathbb{Z}) \to H_n(M, M\setminus\{x\};\mathbb{Z})$ is a generator it follows from the commutative diagram that the image of $\mu([M]\otimes 1)$ under the obvious map $H_n(M;R) \to H_n(M, M\setminus\{x\};R)$ is indeed a generator.

(2) If M has connected components $M_1,\dots,M_k$ and if for $i = 1,\dots,k$ we are given R-fundamental classes $[M_i]_R \in H_n(M_i,\partial M_i;R)$, then

$$\sum_{i=1}^{k}[M_i]_R \in H_n(M,\partial M;R) = \bigoplus_{i=1}^{k} H_n(M_i,\partial M_i;R)$$

is easily seen to be a R-fundamental class of M. The fundamental classes for the M_i are unique if and only if the fundamental class for M is unique.

The following corollary to Theorem 46.2 says in particular that an orientation determines and is in turn uniquely determined by a fundamental class.

Corollary 46.5. *Let M be a compact n-dimensional topological manifold.*

(1) *If $[M]$ is a fundamental class, then $\{[M]_x\}_{x\in M\setminus\partial M}$ defines an orientation for M.*
(2) *If $\{\alpha_x\}_{x\in M\setminus\partial M}$ is an orientation for M, then there exists a unique fundamental class $[M]\in H_n(M,\partial M;\mathbb{Z})$ with $[M]_x = \alpha_x$ for all $x\in M\setminus\partial M$.*

Furthermore, if M is connected, non-empty and orientable, then the following two statements hold:

(3) *Every fundamental class $[M]\in H_n(M,\partial M;\mathbb{Z})$ is a generator of $H_n(M,\partial M;\mathbb{Z})\cong\mathbb{Z}$.*
(4) *Every generator of $H_n(M,\partial M;\mathbb{Z})\cong\mathbb{Z}$[866] is a fundamental class.*

Proof. Let M be a compact n-dimensional topological manifold. By considering the components of M separately we see that without loss of generality we can assume that M is connected. It is also clear that we only have to study the case that M is non-empty.

(1) Let $[M]$ be a fundamental class for the topological manifold M. It follows from Lemma 46.1 that the homology classes $\{\rho_x([M])\}_{x\in M\setminus\partial M}$ form a section on M. By definition of a fundamental class each $\rho_x([M])$ is a generator. Therefore the section $\{\rho_x([M])\}_{x\in M\setminus\partial M}$ is indeed an orientation.

[866]Here we use that in Theorem 46.2 we saw that for a compact orientable, non-empty n-dimensional topological manifold we have $H_n(M,\partial M;\mathbb{Z})\cong\mathbb{Z}$.

(2) Suppose we are given an orientation $\{\alpha_x\}_{x\in M\setminus\partial M}$ for M. By Theorem 46.2 (1) $\Rightarrow$ (4) we know that for every $x \in M \setminus \partial M$ the map

$$\rho_x\colon H_n(M, \partial M; \mathbb{Z}) \;\to\; H_n(M, M \setminus \{x\}; \mathbb{Z})$$

is an isomorphism. Now pick a $y \in M$. We write $[M] := \rho_y^{-1}(\alpha_y)$. Since ρ_y is an isomorphism the class $[M]$ is uniquely determined. So it remains to show that $[M]_x = \alpha_x$ for all $x \in M \setminus \partial M$. By Lemma 46.1 the classes $\{[M]_x\}_{x\in M\setminus\partial M}$ form a $\mathbb{Z}$-section. It follows from Proposition 45.17 that $[M]_x = \alpha_x$ for all $x \in M \setminus \partial M$.

(3) This statement follows immediately from the definition of a fundamental class and Theorem 46.2 (1) $\Rightarrow$ (4).

(4) The last statement is an immediate consequence of Lemma 46.1 and Theorem 46.2 (1) $\Rightarrow$ (4). □

We also have the following corollary to Theorem 46.3 which deals with $\mathbb{F}_2$-coefficients.

Corollary 46.6. *Let M be a compact, non-empty n-dimensional topological manifold. Then the following statements hold:*

(1) *If M is connected, then*[867]

$$[M]_{\mathbb{F}_2} \;:=\; \textit{the unique non-zero element of } H_n(M, \partial M; \mathbb{F}_2) \cong \mathbb{F}_2$$

is the unique $\mathbb{F}_2$-fundamental class of M.

(2) *If M has connected components $M_1, \dots, M_k$, then*

$$[M]_{\mathbb{F}_2} \;:=\; \sum_{i=1}^{k} [M_i]_{\mathbb{F}_2} \;\in\; H_n(M, \partial M; \mathbb{F}_2) = \bigoplus_{i=1}^{k} H_n(M_i, \partial M_i; \mathbb{F}_2)$$

is the unique $\mathbb{F}_2$-fundamental class of M.

Proof. It follows immediately from Theorem 46.3 (2) that the class $[M]_{\mathbb{F}_2}$ that we had just defined in (1) is indeed an $\mathbb{F}_2$-fundamental class for M and that it is unique. As we pointed out on page 1114, the second statement is an immediate consequence of the first statement. □

Remark. We have just shown in Corollary 46.6 that for every closed, connected n-dimensional topological manifold M there exists a uniquely determined $\mathbb{F}_2$-fundamental class $[M]_{\mathbb{F}_2}$. Given a topological space X and a homology class $z \in H_n(X; \mathbb{F}_2)$ it was shown by René Thom [Tho, Tho2][868] in about 1954 (see also [Rudy, Theorem IV.7.33]) that there exists an n-dimensional closed, connected manifold M and a map $f\colon M \to X$ such that $f_*([M]_{\mathbb{F}_2}) = z$. This can be viewed as the $\mathbb{F}_2$-analogue of Theorem 39.18. We will not make use of this fact.

Let M be a compact n-dimensional manifold that is oriented in the sense of Section 3.8. In Proposition 39.7 we defined the fundamental class $[M]$ in $H_n(M, \partial M; \mathbb{Z})$. On the other hand, in Proposition 45.22 we saw that the orientation of M also determines a $\mathbb{Z}$-orientation

[867] Here in the formulation we already use Theorem 46.3 (1) to guarantee that $H_n(M, \partial M; \mathbb{F}_2) \cong \mathbb{F}_2$.

[868] We had already encountered the Fields medalist René Thom on page 959.

and thus we obtain a fundamental class $[M] \in H_n(M, \partial M; \mathbb{Z})$ by Corollary 46.5. Not surprisingly we will now see that these two definitions agree.

Lemma 46.7. *The two definitions of the fundamental class of a compact oriented manifold agree.*

Proof $(*)$. Let M be a compact n-dimensional manifold that is oriented in the sense of Section 3.8. To simplify the notation we assume that M is closed and connected. We denote by $\alpha \in H_n(M; \mathbb{Z})$ the fundamental class of Proposition 39.7 and we denote by $\beta \in H_n(M; \mathbb{Z})$ the fundamental class of Corollary 46.5.

Let $x \in M$. By Theorem 46.2 (1) $\Rightarrow$ (4) it suffices to show that $\alpha_x = \beta_x \in H_n(M, M \setminus \{x\}; \mathbb{Z})$. We make the following choices:

(1) We pick an orientation-preserving chart $\Phi\colon U \to V$ around x with $\Phi(x) = 0$ and such that $\overline{B}^n \subset V$.
(2) We denote by $\Theta\colon \Delta^n \to \overline{B}^n$ the homeomorphism from Lemma 29.1. Note that with the orientation of $\mathring{\Delta}^n$ given on page 935 and the usual orientation of B^n this map Θ restricts to an orientation-preserving diffeomorphism $\mathring{\Delta}^n \to B^n$.

Now we consider the following diagram of maps

$$\begin{tikzcd}
H_n(M;\mathbb{Z}) \arrow[r] \arrow[dd] & H_n(M, M\setminus\Phi^{-1}(B^n);\mathbb{Z}) \arrow[ddl] & H_n(\overline{B}^n, \partial\overline{B}^n;\mathbb{Z}) \arrow[l, "\Phi_*^{-1}"'] \\
 & & H_n(\Delta^n, \partial\Delta^n;\mathbb{Z}) \arrow[u, "\Theta_*"'] \arrow[d, "\Theta_*"] \\
H_n(M, M\setminus\{x\};\mathbb{Z}) & H_n(U, U\setminus\{x\};\mathbb{Z}) \arrow[l, "\cong"] & H_n(V, V\setminus\{0\};\mathbb{Z}) \arrow[l, "\Phi_*^{-1}"']
\end{tikzcd}$$

where all maps without a name are induced by the obvious inclusions of pairs of topological spaces. It is straightforward to verify that the diagram commutes.

By definition of α the class $\alpha_x \in H_n(M, M \setminus \{x\}; \mathbb{Z})$ is given by starting with the class $[\mathrm{id}^n_\Delta] \in H_n(\Delta^n, \partial\Delta^n; \mathbb{Z})$ and traveling "counterclockwise" through the diagram. On the other hand, it follows from Lemma 45.15 that $\Theta_*([\mathrm{id}_{\Delta^n}])$ represents a standard generator of $H_n(V, V \setminus \{0\}; \mathbb{Z})$. From this it follows that the class $\beta_x \in H_n(M, M \setminus \{x\}; \mathbb{Z})$ is given by starting with $[\mathrm{id}^n_\Delta] \in H_n(\Delta^n, \partial\Delta^n; \mathbb{Z})$ and traveling "clockwise" through the diagram. Since the diagram commutes we have now shown that $\alpha_x = \beta_x$. $\square$

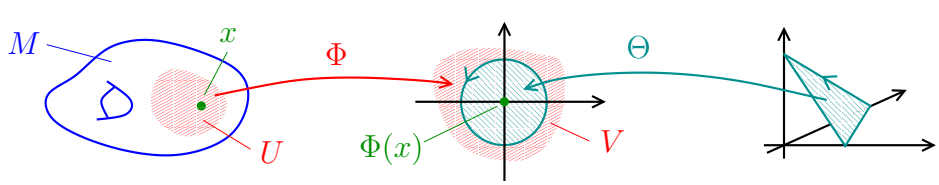

FIGURE 651. Illustration for the proof of Lemma 46.7.

The following proposition gives a useful criterion for showing that a given singular chain represents the fundamental class of a manifold.

Proposition 46.8. *Let M be a compact, connected n-dimensional manifold.*

(1) *Suppose that M is an oriented manifold. Let $\sum_{i=1}^{m} r_i \cdot \sigma_i \in C_n(M, \partial M; \mathbb{Z})$ be a cycle. Suppose there exists a $j \in \{1, \dots, m\}$ such that the following four conditions are satisfied:*
   (a) *the map $\sigma_j \colon \mathring{\Delta}^n \to M$ is a diffeomorphism onto its image,*[869]
   (b) *for $i \neq j$ we have $\sigma_i(\Delta^n) \cap \sigma_j(\mathring{\Delta}^n) = \varnothing$,*
   (c) *$r_j = 1$,*
   (d) *$\sigma_j \colon \mathring{\Delta}^n \to M$ is orientation-preserving.*
   Then the cycle represents the fundamental class of the oriented manifold, i.e. we have

$$\left[\sum_{i=1}^{m} r_i \cdot \sigma_i\right] \;=\; [M] \;\in\; H_n(M, \partial M; \mathbb{Z}) \;\cong\; \mathbb{Z}.$$

(2) *Let $\sum_{i=1}^{m} \sigma_i \otimes r_i \in C_n(M, \partial M; \mathbb{F}_2)$ be a cycle for which there exists again a $j \in \{1, \dots, m\}$ that satisfies the above conditions* (a), (b) *and* (c), *then the cycle represents the $\mathbb{F}_2$-fundamental class of M, i.e. we have*

$$\left[\sum_{i=1}^{m} \sigma_i \otimes r_i\right] \;=\; [M]_{\mathbb{F}_2} \;\in\; H_n(M, \partial M; \mathbb{F}_2) \;\cong\; \mathbb{F}_2.$$

Notation. We will give many examples of fundamental classes of 2-dimensional manifolds. Since we want to be very careful what singular simplex we mean by a given picture we adopt the following convention:

A triangle T with a dot in a corner and a directional arrow in the center means the unique affine linear map $\Delta^2 \to T$ which sends $(1, 0, 0)$ to the vertex decorated with the dot and which respects the orientation of the vertices. We illustrate this notation in Figure 652. We also take some artistic liberties and allow triangles where the boundary is not given by segments and where the boundary consists of curves. In this case we expect that the boundary curves are parametrized with constant speed. Since the precise definition of the

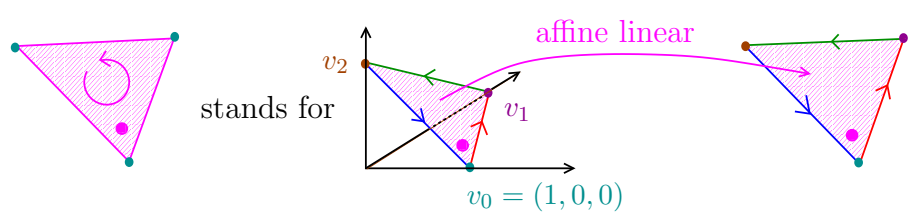

FIGURE 652.

[869]Note that we do *not* place any conditions on the restriction of σ_j to $\partial\Delta^n$.

boundary of a singular 2-simplex is often a source of confusion we recall the definition in Figure 653.

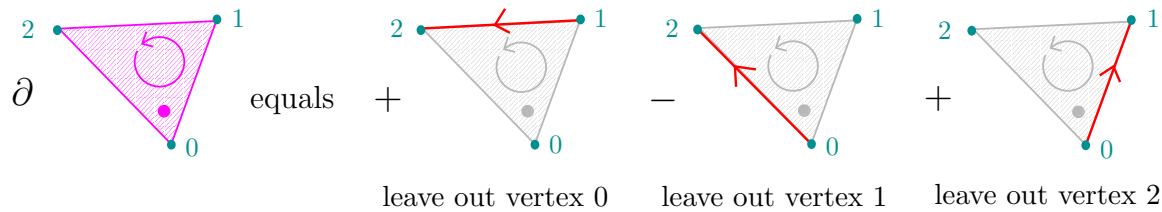

FIGURE 653.

Example. In Figure 654 we show the torus $T = [0,1] \times [0,1]/\sim$. We equip T with the orientation coming from the standard orientation on $(0,1) \times (0,1) \subset T$, which we can also view as an open subset of $\mathbb{R}^2$. In Figure 654 we also show two singular 2-simplices σ_1 and σ_2. It is straightforward to verify that $-\sigma_1 + \sigma_2$ is a cycle. (In the verification it is very helpful to keep Figure 653 in mind.) The summand σ_2 satisfies the conditions imposed in Proposition 46.8, thus we see that $-\sigma_1 + \sigma_2$ represents a fundamental class of T, in particular it represents a generator of $H_2(T)$. This is of course the same cycle that we had already initially encountered on page 742. We already saw in Lemma 33.13 in a somewhat ad hoc argument that it represents a generator of $H_2(T)$.

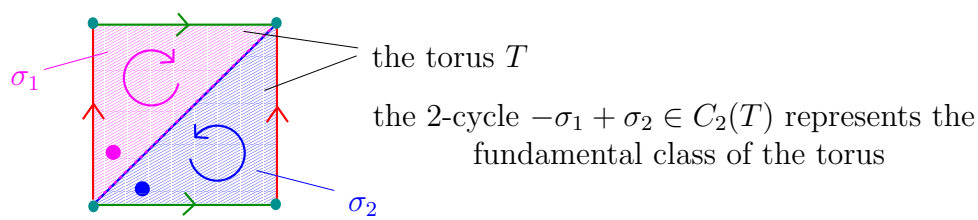

FIGURE 654.

Example. It follows easily from Proposition 46.8 and our orientation conventions that the standard generator of $H_n(S^n)$ as defined on page 814 represents the fundamental class of the manifold S^n with the usual orientation. In particular it follows from Lemma 32.11 that the singular 1-simplex $\mu\colon \Delta^1 \to S^1$ given by $\mu(1-t,t) = e^{2\pi i t}$ represents the fundamental class of the oriented manifold S^1.

Proof of Proposition 46.8 $(*)$. Let M be a compact n-dimensional manifold. To simplify the notation we only consider the case that M is closed. In the following we prove the proposition for $R = \mathbb{Z}$. The proof for $R = \mathbb{F}_2$ is almost identical, one just needs to replace Theorem 46.2 by Theorem 46.3

Thus let $\sum_{i=1}^{m} r_i \cdot \sigma_i \in C_n(M;\mathbb{Z})$ be a cycle and $j \in \{1,\dots,m\}$ such that the following four conditions are satisfied:

(a) the map $\sigma_j\colon \mathring{\Delta}^n \to M$ is a diffeomorphism onto its image,
(b) for $i \neq j$ we have $\sigma_i(\Delta^n) \cap \sigma_j\big(\mathring{\Delta}^n\big) = \varnothing$,
(c) $r_j = 1$,
(d) $\sigma_j\colon \mathring{\Delta}^n \to M$ is orientation-preserving.

We first consider the special case that there exists a chart $\Phi\colon U \to V$ with $\sigma_j(\Delta^n) \subset U$. After possibly composing Φ with a reflection in $\mathbb{R}^n$ we can assume that Φ is in fact orientation-preserving. We pick $x \in \sigma_j(\mathring{\Delta}^n)$ and we write $y = \Phi(x)$. (We refer to Figure 655 for an illustration.) We consider the maps

$$\begin{array}{ccccccc}
 & \text{isomorphism by Theorem 46.2} & & & \text{isomorphism by the Excision Theorem 45.8} & & \text{isomorphism since } \Phi \text{ is a homeomorphism} \\
 & \downarrow & & & \downarrow & & \downarrow \\
H_n(M;\mathbb{Z}) & \to & H_n(M, M\setminus\{x\};\mathbb{Z}) & & \leftarrow H_n(U, U\setminus\{x\};\mathbb{Z}) & \xrightarrow{\Phi_*} & H_n(V, V\setminus\{y\};\mathbb{Z}) \\
\Big[\sum\limits_{i=1}^m r_i\cdot\sigma_i\Big] & \mapsto & \Big[\sum\limits_{i=1}^m r_i\cdot\sigma_i\Big] = [\underbrace{r_j\cdot\sigma_j}_{=\sigma_j}] & & \leftarrow\!\shortmid\ [\sigma_j] & & \mapsto\ [\Phi\circ\sigma_j].
\end{array}$$

since (b) implies that for $i \neq j$ we have $\sigma_i(\Delta^n) \subset M \setminus \{x\}$
and since by (c) we have $r_j = 1$

It follows immediately from our hypothesis (a) together with Lemmas 45.16 and 45.15 that $[\Phi \circ \sigma_j]$ is a generator of $H_n(V, V \setminus \{y\};\mathbb{Z})$. Furthermore, since $\sigma_j\colon \mathring{\Delta}^n \to M$ is orientation-preserving and since Φ is orientation-preserving, the desired equality follows easily from Lemma 45.23.

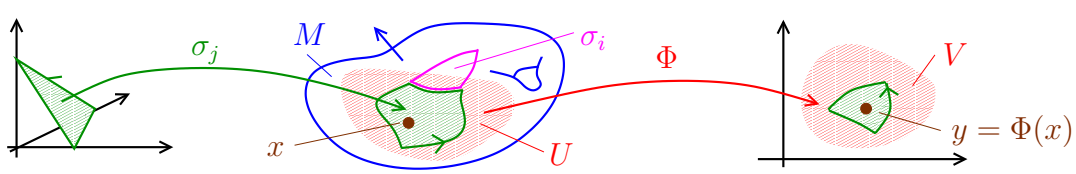

FIGURE 655. Illustration for the first part of the proof of Proposition 46.8.

Now we no longer assume that such a chart exists. We sketch the argument how to deal with this case. First we recall that on page 789 we introduced the subdivision map $u_k\colon C_k(M) \to C_k(M)$ with $k \in \mathbb{N}_0$. In Lemma 31.23 and 31.24 we saw that these maps form a chain map that is homotopy equivalent to the identity, in particular for any cycle $c \in C_n(M;\mathbb{Z})$ we have $[u_n(c)] = [c] \in H_n(M;\mathbb{Z})$.

Now we apply Lemma 31.28 to the open covering of M that is given by the domains of all charts in the atlas of the smooth structure on M. Then we obtain an $m \in \mathbb{N}$ and a singular chain $u_n^m(\sigma) = (u_n \circ \cdots \circ u_n)(\sigma)$ such that the image of each singular simplex appearing in $u_n^m(\sigma)$ lies in a chart and such that $u_n^m(\sigma)$ is homologous to σ. It follows easily from the definition of the subdivision map that $u_n^m(\sigma)$ still satisfies properties (a) to (d) for

an appropriate choice of summand. It follows from the previous observations that $u_n^m(\sigma)$ represents the fundamental class, but then so does σ. $\square$

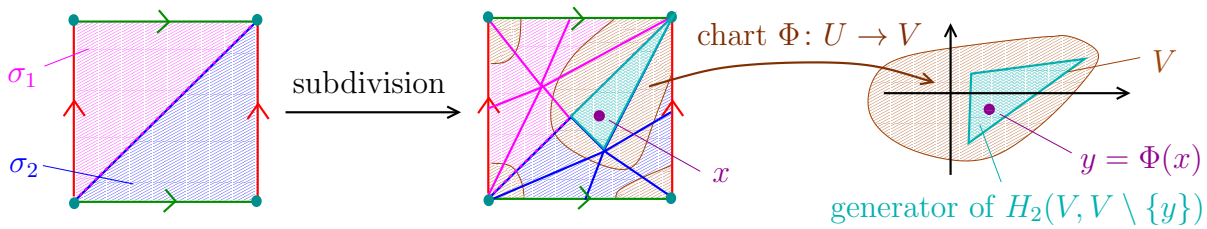

FIGURE 656. Illustration for the second part of the proof of Proposition 46.8.

Examples. In Figure 657 we show the surface of genus 2 with eight singular 2-simplices $\sigma_1, \sigma_2, \sigma_3, \sigma_4$ and $\tau_1, \tau_2, \tau_3, \tau_4$. The interior of the octagon is an open subset of $\mathbb{R}^2$ and we equip the surface of genus 2 with the orientation coming from the standard orientation of $\mathbb{R}^2$. It is a fun exercise to verify that the singular 2-chain

$$\sigma_1 - \sigma_2 + \sigma_3 - \sigma_4 \; + \; \tau_1 - \tau_2 + \tau_3 - \tau_4$$

is indeed a cycle. It follows easily from Proposition 46.8 that the singular 2-chain represents a fundamental class of the surface of genus 2.

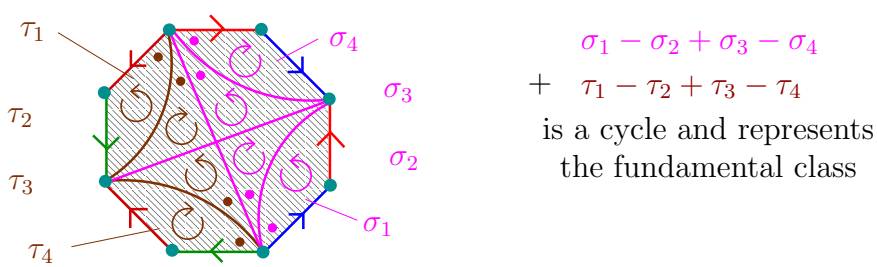

FIGURE 657.

Now we consider $\mathbb{F}_2$-fundamental classes of non-orientable 2-dimensional manifolds. Before we consider these examples we introduce one new piece of notation.

Notation. A bigon T with a cross in a corner and a directional arrow in the center means a map $\sigma\colon \Delta^2 \to T$ with the following three properties:

(1) the map σ collapses the face from v_0 to v_2 to the vertex decorated with the cross,
(2) on the two remaining faces the map σ is of constant speed,
(3) the restriction of σ to the interior is a diffeomorphism onto its image and it is orientation-preserving with the orientation specified.

We illustrate this notation in Figure 658.

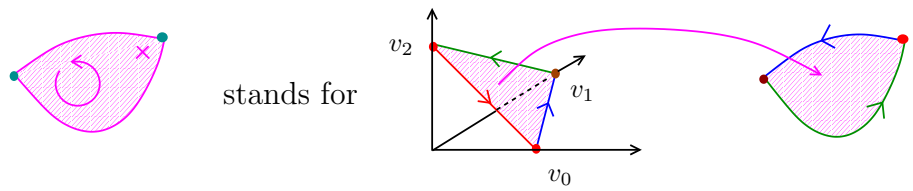

FIGURE 658.

Examples.

(1) Now we will give a representative for the $\mathbb{F}_2$-fundamental class for the real projective plane $\mathbb{R}\mathrm{P}^2$. More precisely, we consider the four singular simplices $\sigma_1, \sigma_2, \tau_1$ and τ_2 of $\mathbb{R}\mathrm{P}^2$ shown in Figure 659. It is straightforward to see that the singular 2-chain $(\sigma_1 + \sigma_2 + \tau_1 + \tau_2) \otimes 1 \in C_2(\mathbb{R}\mathrm{P}^2; \mathbb{F}_2)$ is a cycle. Using Proposition 46.8 we see that it represents the $\mathbb{F}_2$-fundamental class of the real projective plane.

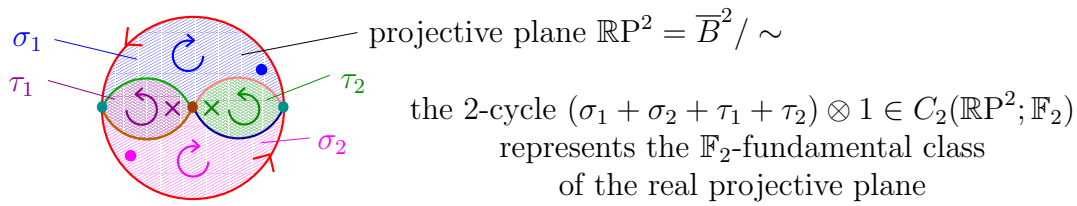

FIGURE 659.

(2) In Exercise 46.1 we will write down a representative for the $\mathbb{F}_2$-fundamental class of the Klein bottle.

46.2. **Lifts of sections on manifolds.** In this section we will prove the fundamental theorem of topological manifolds which lies at the heart of the proofs of Theorems 46.2, 46.3 and 46.4. Before we can state the lemma we introduce the following helpful notation.

Notation. Let M be a topological manifold without boundary, let R be a commutative ring and let $A \subset M$ be a subset.

(1) We write $H_n(M|A; R) := H_n(M, M \setminus A; R)$. Given a point $x \in M$ we use the obvious abbreviation $H_n(M|x; R) := H_n(M|\{x\}; R)$.
(2) Given a homology class $\alpha \in H_n(M|A; R)$ and a point $x \in A$ we denote by α_x the image of α under the obvious map $H_n(M|A; R) \to H_n(M|x; R)$.
(3) Let $\{\alpha_x\}_{x \in M}$ be an R-section on M and let $A \subset M$ be a subset. We call a class $\beta \in H_n(M|A; R)$ a *lift to* A if for all $x \in A$ we have $\beta_x = \alpha_x$.

The following lemma follows immediately from the definitions. But since we will refer to it on several occasions it is good to write it down.

Lemma 46.9. *Let M be a topological manifold without boundary, let R be a commutative ring and let $A \subset B \subset M$ be subsets:*

(1) *Since* $M \setminus B \subset M \setminus A$ *we have an inclusion induced map* $H_n(M|B;R) \to H_n(M|A;R)$.
(2) *Let* $\{\alpha_x\}_{x\in M}$ *be an* R*-section on* M*. If* $\mu_B \in H_n(M|B;R)$ *is a lift to* B*, then the image of* μ_B *under the above map* $H_n(M|B;R) \to H_n(M|A;R)$ *is a lift of the* R*-section to the subset* A*.*

The following theorem is the main technical result of this chapter.

Theorem 46.10. *Let* M *be an* n*-dimensional topological manifold with empty boundary and let* $A \subset M$ *be a compact subset. Let* R *be a commutative ring. Then the following hold:*

(i) *If* $\{\alpha_x\}_{x\in M}$ *is an* R*-section for* M*, then there exists a unique lift* $\alpha_A^M = \alpha_A$ *to* A*, i.e. there exists a unique class* $\alpha_A^M = \alpha_A \in H_n(M|A;R)$ *such that for each* $x \in A$ *we have* $\alpha_{A,x} = \alpha_x$*.*
(ii) *For* $i > n$ *we have* $H_i(M|A;R) = 0$*.*

Remark. To avoid any nervousness later on we remark that the statements (i) and (ii) hold trivially for $A = \varnothing$ since $H_n(M|\varnothing;R) = H_n(M,M;R) = 0$.

For later on we record the following lemma.

Lemma 46.11. *Let* M *be an oriented* n*-dimensional topological manifold with empty boundary and let* R *be a commutative ring. We suppose that* M *is equipped with an* R*-orientation. We use the notation from Theorem 46.10.*

(1) *Let* $K \subset L \subset M$ *be compact subsets. We denote by* $f_{KL}\colon (M, M\setminus L) \to (M, M\setminus K)$ *the inclusion map of pairs. The map* $f_{KL*}\colon H_n(M, M\setminus L) \to H_n(M, M\setminus K)$ *sends* α_L^M *to* α_K^M*.*
(2) *Let* U *be an open subset of* M *and let* $A \subset U$ *be a compact subset. We use Lemma 45.28 to view* U *as an oriented topological manifold. If* $i\colon U \to M$ *denotes the inclusion map, then* $i_*(\alpha_A^U) = \alpha_A^M$*.*

Proof. The lemma follows easily from the functoriality of homology groups and the uniqueness statement of Theorem 46.10. □

The very rough idea behind the proof of the fundamental theorem of topological manifolds can be summarized as follows:

(1) Using Mayer–Vietoris sequences we want to show that if the compact subsets A, B and $A \cap B$ have the desired properties, then so does $A \cup B$.
(2) Using charts we want to reduce the proof of the theorem to the case that $M = \mathbb{R}^n$.
(3) Finally for $M = \mathbb{R}^n$ we want to reduce the proof of the theorem to compact convex subsets A of $\mathbb{R}^n$.

The following lemmas give us the tools to put this idea into practice.

Lemma 46.12. *Let* M *be an* n*-dimensional topological manifold, let* R *be a commutative ring and let* A *and* B *be two compact subsets of* M*. If the statements* (i) *and* (ii) *from Theorem 46.10 hold for* A*,* B *and* $A \cap B$*, then they also hold for* $A \cup B$*.*

Proof. Let M be an n-dimensional topological manifold, let R be a commutative ring and let A and B be two compact subsets of M such that A, B and $A \cap B$ satisfy statements (i) and (ii). To simplify the notation we drop R from the notation. We consider the inverted Mayer–Vietoris Sequence from Theorem 33.7

$$\cdots \to \overbrace{H_{n+1}(M|A \cap B)}^{=0,\text{ by hypothesis on } A\cap B} \to H_n(M|A \cup B) \xrightarrow{\Phi} H_n(M|A) \oplus H_n(M|B) \xrightarrow{\Psi} H_n(M|A \cap B) \to \dots$$
$$\alpha \mapsto (\alpha, -\alpha) \qquad (\alpha, \beta) \mapsto \alpha + \beta$$

Now we can prove that $A \cup B$ also satisfies statements (i) and (ii).

(ii) For $i > n$ the group $H_i(M|A \cup B)$ is stuck, by our hypothesis on A, B and $A \cap B$, between groups that are zero, thus we see that $H_i(M|A \cup B) = 0$ for $i > n$.

(i) Now suppose we are given a section $\{\alpha_x\}_{x \in M}$. We denote by α_A, α_B and $\alpha_{A\cap B}$ the unique lifts to A, B and $A \cap B$ given by our hypothesis. By Lemma 46.9 the images of α_A and α_B in $H_n(M|A \cap B)$ are lifts to $A \cap B$. By the uniqueness of the lift $\alpha_{A\cap B}$ these images thus equal $\alpha_{A\cap B}$. By the exactness of the above sequence we see that $(\alpha_A, -\alpha_B) = \Phi(\alpha_{A\cup B})$ for some $\alpha_{A\cup B} \in H_n(M|A \cup B)$. We claim that $\alpha_{A\cup B}$ is indeed a lift to $A \cup B$. So let $x \in A \cup B$. First we consider the case that $x \in A$. We have the following commutative diagram

$$\begin{tikzcd} H_n(M|A \cup B) \arrow[r, "{[\alpha_{A\cup B} \mapsto \alpha_A]}"] \arrow[dr] & H_n(M|A) \arrow[d] \\ & H_n(M|x). \end{tikzcd}$$

We see that the image of $\alpha_{A\cup B}$ in $H_n(M|x)$ is the image of α_A in $H_n(M|x)$, hence it equals α_x. The same argument applies to the case that $x \in B$.

It remains to prove the uniqueness of the lift $\alpha_{A\cup B}$. If $\beta \in H_n(M|A \cup B)$ is another lift, then it follows immediately from Lemma 46.9 and the uniqueness of α_A and α_B that $\Phi(\beta) = (\alpha_A, -\alpha_B)$. By the exactness of the sequence we see that we already have the equality $\alpha_{A\cup B} = \beta$ in $H_n(M|A \cup B)$. □

Later on we will need the following variation of Lemma 46.12.

Lemma 46.13. *Let M be an n-dimensional topological manifold, let R be a commutative ring. Let $\mathcal{A}$ be a family of compact subsets of M with the following two properties:*

(1) *Statements* (i) *and* (ii) *from Theorem 46.10 hold for each $A \in \mathcal{A}$.*
(2) *The family $\mathcal{A}$ is closed under intersections, i.e. whenever $A, B \in \mathcal{A}$, then $A \cap B \in \mathcal{A}$.*

Then the statements hold for all finite unions of elements in $\mathcal{A}$.

Proof. Given $k \in \mathbb{N}$ we write

$$\mathcal{U}_k := \{\text{all subsets of } M \text{ that are the union of at most } k \text{ subsets in } \mathcal{A}\}.$$

We claim that for every $k \in \mathbb{N}$ statements (i) and (ii) hold for all elements in $\mathcal{U}_k$. We prove this claim by induction on k.

(1) If $k = 1$, then the claim holds by hypothesis (1).
(2) Suppose that the claim holds for some k. Let $A_1, \dots, A_k, A_{k+1} \in \mathcal{A}$. We write $B = A_2 \cup \dots \cup A_{k+1}$. Note that

$$A_1 \cap B \;=\; A_1 \cap (A_2 \cup \dots \cup A_{k+1}) \;=\; \bigcup_{i=2}^{k+1} \underbrace{(A_1 \cap A_i)}_{\in \mathcal{A} \text{ by (2)}} \;\in \mathcal{U}_k.$$

Thus by induction hypothesis we see that the statements hold for A_1, B and also for $A_1 \cap B$. So the statements also hold for $A_1 \cup B = A_1 \cup \dots \cup A_{k+1}$ by Lemma 46.12. □

Our next goal is to prove Theorem 46.10 for $M = \mathbb{R}^n$. We will proceed in several steps.

Lemma 46.14. *Let R be a commutative ring and let $\{\mu_x\}_{x \in \mathbb{R}^n}$ be an R-section on $\mathbb{R}^n$, let $A \subset \mathbb{R}^n$ be a convex bounded subset and let $\beta \in H_n(\mathbb{R}^n | A; R)$. If $\mu_y = \beta_y$ for some $y \in A$, then $\mu_x = \beta_x$ for all $x \in A$, i.e. β is a lift to A.*

Proof. The proof is very similar to the proof of Proposition 45.17. The following are the two key observations:

(1) a convex set is path-connected and thus connected,
(2) since A is convex, for any $x \in A$ and any $\epsilon > 0$ the intersection $A \cap B_\epsilon(x)$ is the intersection of two convex bounded sets, hence convex and bounded.

In the proof of Proposition 45.17 we now need to replace Lemma 45.18 by Lemma 45.9. We leave it as an exercise for the reader to modify the proof of Proposition 45.17 to get a proof of Lemma 46.14. □

Lemma 46.15. *Statements* (i) *and* (ii) *from Theorem 46.10 hold for $M = \mathbb{R}^n$, any commutative ring R and any convex compact subset A of $\mathbb{R}^n$.*

Proof. Let A be a convex compact subset of $\mathbb{R}^n$ and let R be a commutative ring. As pointed out above, if $A = \varnothing$, then there is nothing to prove. Thus we can assume that $A \neq \varnothing$.

Now we can prove that A satisfies the statements (i) and (ii).

(i) Let $\{\alpha_x\}_{x \in \mathbb{R}^n}$ be a section for $\mathbb{R}^n$. Since $A \neq \varnothing$ we can pick a $y \in A$. We denote by $\alpha_A \in H_n(\mathbb{R}^n | A)$ the preimage of α_y under the isomorphism

$$H_n(\mathbb{R}^n | A; R) \;\to\; H_n(\mathbb{R}^n | \{y\}; R)$$

given by Lemma 45.9. It follows from Lemma 46.14 that $\alpha_{A,x} = \alpha_x$ for all $x \in A$, i.e. we have shown that α_A is a lift to A. The uniqueness of the lift α_A follows again from the above isomorphism.

(ii) It follows Lemma 45.9 and 32.3 that $H_i(\mathbb{R}^n | A; R) = H_i(\mathbb{R}^n | \{y\}; R) = 0$ for every $i > n$. □

Lemma 46.16. *Every subset of $\mathbb{R}^n$ that is the union of finitely many convex compact sets satisfies the statements* (i) *and* (ii) *from Theorem 46.10.*

Proof. We consider

$$\mathcal{A} := \{\text{all convex compact subsets of } \mathbb{R}^n\}.$$

This family of subsets of $\mathbb{R}^n$ is closed under intersections.[870] By Lemma 46.15 the two statements hold for each $A \in \mathcal{A}$. The lemma is now an immediate consequence of Lemma 46.13. □

The following lemma is arguably the hardest step towards proving the fundamental theorem of topological manifolds.

Lemma 46.17. *Statements* (i) *and* (ii) *from Theorem 46.10 hold for $M = \mathbb{R}^n$, any commutative ring R and any compact subset A of $\mathbb{R}^n$.*

Proof. To simplify the notation we again drop the R from the notation. Let $\{\alpha_x\}_{x\in\mathbb{R}^n}$ be a section for $\mathbb{R}^n$ and let $A \subset \mathbb{R}^n$ be an arbitrary compact set.

We first prove statement (i). We pick a closed ball B that contains A. We denote by $\alpha_B \in H_n(\mathbb{R}^n|B)$ the lift constructed in Lemma 46.15. By Lemma 46.9 the image α_A of the class α_B under the map $H_n(\mathbb{R}^n|B) \to H_n(\mathbb{R}^n|A)$ is a lift to A. To complete the proof of statement (i) we still need to prove the uniqueness of α_A.

This uniqueness statement is equivalent to showing that if $\beta \in H_n(\mathbb{R}^n|A)$ is a class such that $\beta_x = 0$ for all $x \in A$, then β is already zero. So let $\beta \in H_n(\mathbb{R}^n|A)$. We pick a singular n-chain $z \in C_n(\mathbb{R}^n)$ that represents β. We denote by $C \subset \mathbb{R}^n \setminus A$ the union of the images of the singular simplices appearing in $\partial z \subset C_{n-1}(\mathbb{R}^n \setminus A)$. Note that C is the union of finitely many compact sets, hence C itself is compact.

Claim. There exist finitely many closed balls $B_1, \dots, B_m$ with the following three properties:

(1) each B_i is contained in $\mathbb{R}^n \setminus C$,
(2) each B_i contains a point $x_i \in A$,
(3) we have $A \subset B_1 \cup \cdots \cup B_m$.

Since C is compact and since $A \cap C = \varnothing$ we can find for each $x \in A$ an $r_x > 0$ with $B_{2r_x}(x) \subset \mathbb{R}^n \setminus C$. Since A is compact there exist finitely many points $x_1, \dots, x_m$ in A such that A is contained in $B_{r_{x_1}}(x_1) \cup \cdots \cup B_{r_{x_m}}(x_m)$. It is now clear that $B_i := \overline{B}_{r_{x_i}}(x_i)$, $i = 1, \dots, m$ have the desired property. We refer to Figure 660 for an illustration. This concludes the proof of the claim.

We write $K := B_1 \cup \cdots \cup B_m$. By (1) the singular n-chain $z \in C_n(\mathbb{R}^n)$ also represents an element $\gamma \in H_n(\mathbb{R}^n|K)$. Note that for each $x \in A$ we have a commutative diagram

$$\begin{tikzcd} H_n(\mathbb{R}^n|K) \arrow[rr, "\gamma=[z]\mapsto\beta=[z]"] \arrow[dr, "\gamma\mapsto\gamma_x"'] & & H_n(\mathbb{R}^n|A) \arrow[dl, "\beta\mapsto\beta_x"] \\ & H_n(\mathbb{R}^n|x). & \end{tikzcd}$$

[870]Here we use one of the most convenient properties of convex sets: the intersection of two convex sets is again convex.

It follows in particular from the commutative diagram that it suffices to show that we have $\gamma = 0 \in H_n(\mathbb{R}^n|K)$. We do so as follows:

(1) By our hypothesis on β and by the above commutative diagram we know that for each $i \in \{1, \dots, m\}$ we have $\gamma_{x_i} = \beta_{x_i} = 0$.
(2) Let $i \in \{1, \dots, m\}$. Since $\gamma_{x_i} = 0$ and since B_i is convex and bounded it follows from Lemma 46.14 (applied to the zero section and to the image of $\gamma \in H_n(\mathbb{R}^n|B_i)$) that $\gamma_x = 0$ for all $x \in B_i$.
(3) By (2) we know that $\gamma_x = 0$ for all $x \in K = B_1 \cup \dots \cup B_m$.
(4) But now it follows from Lemma 46.16 that $\gamma = 0$.

This concludes the proof of statement (i).

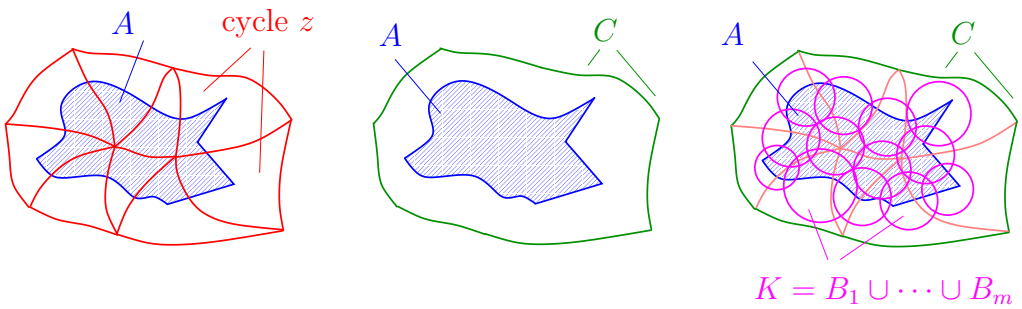

FIGURE 660. Illustration for the proof of Theorem 46.10.

Finally we need to show statement (ii) for A, i.e. we need to show that $H_i(\mathbb{R}^n|A) = 0$ for $i > n$. So let $\beta \in H_i(\mathbb{R}^n|A)$. As above we pick a singular n-chain $z \in C_n(\mathbb{R}^n)$ that represents β. We define C, K and γ as above. By Lemma 46.16 we have $\gamma = 0 \in H_i(\mathbb{R}^n|K)$. But as before this implies that also $\beta = 0 \in H_i(\mathbb{R}^n|A)$. □

Lemma 46.18. *Let M be an n-dimensional topological manifold with empty boundary and let $A \subset M$ be a compact subset. If there exists a chart $\Phi\colon U \to \mathbb{R}^n$ such that A is contained in U, then statements* (i) *and* (ii) *hold for A.*

Proof. The lemma is a fairly straightforward consequence of Lemma 46.17 and the fact that we have isomorphisms

$$\begin{array}{ccccc} H_n(M, M \setminus A; R) & \xleftarrow{\cong} & H_n(U, U \setminus A; R) & \xrightarrow{\Phi} & H_n(\mathbb{R}^n, \mathbb{R}^n \setminus \Phi(A); R) \\ & \uparrow & & \uparrow & \\ & \text{Excision Theorem 45.8} & & \text{isomorphism since } \Phi \text{ is a homeomorphism} & \end{array}$$

We leave it to the reader to fill in the details. □

Now we can finally complete the proof of Theorem 46.10.

Proof of Theorem 46.10. Let M be an n-dimensional topological manifold with empty boundary. We consider

$\mathcal{A}$:= all compact subsets A of M for which there exists a chart $\Phi\colon U \to \mathbb{R}^n$ with $A \subset U$.

By Lemma 46.18 statements (i) and (ii) hold for all subsets in $\mathcal{A}$. It is clear that $\mathcal{A}$ is closed under intersections. Thus it follows from Lemma 46.13 that the statements (i) and (ii) hold for all finite unions of sets in $\mathcal{A}$. Therefore it suffices to prove the following claim.

Claim. Every compact subset A of M is the union of finitely many sets in $\mathcal{A}$.

Let A be a compact subset of M. It is clear that given any point $x \in A$ there exists a chart $\Phi_x\colon U_x \to V_x$ around x such that the image is some open ball in $\mathbb{R}^n$. But since each open ball in $\mathbb{R}^n$ is homeomorphic to $\mathbb{R}^n$ we can find around each $x \in A$ a chart around x such that the image V_x equals $\mathbb{R}^n$. Now we write $A_x := A \cap \Phi_x^{-1}(\overline{B}_1^n(0))$ and $U'_x := \Phi_x^{-1}(B_1^n(0))$. Since A is compact we can find finitely many $x_1, \dots, x_m$ in A such that A is contained in $U'_{x_1} \cup \cdots \cup U'_{x_m}$. By construction the corresponding charts $\Phi_i := \Phi_{x_i}\colon U_{x_i} \to \mathbb{R}^n$ and the sets $A_i := A_{x_i}$ have the desired properties. This concludes the proof of the claim.

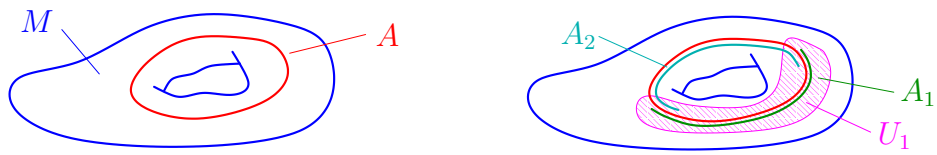

FIGURE 661. Illustration for the proof of Lemma 46.18.

It follows from Lemma 46.18 that statements (i) and (ii) hold for all the A_i and for all arbitrary intersections of the A_i. But then Lemma 46.12 implies that they also hold for $A = A_1 \cup \cdots \cup A_m$. □

46.3. **Proof of Theorem 46.4.** Now we are in a position that we can provide the long-delayed proofs of Theorems 46.2, 46.3 and 46.4. We start out with the proof of Theorem 46.4 since we will use that theorem in the proof of Theorem 46.2.

The key extra ingredient in the proof of Theorem 46.4 is the following proposition.

Proposition 46.19. *Let M be a connected n-dimensional topological manifold and let R be a commutative ring. If M is non-compact and if $\partial M = \varnothing$, then $H_k(M; R) = 0$ for every $k \geq n$.*

Proof. Let M be a connected non-compact n-dimensional topological manifold such that $\partial M = \varnothing$, let R be a commutative ring and let $k \geq n$. Let $\alpha \in H_k(M; R)$. We need to show that $\alpha = 0$. We represent α by a cycle $z = \sum_{i=1}^{m} \sigma_i \otimes r_i \in C_k(M; R) = C_k(M) \otimes R$. The union of the images of $\sigma_1, \dots, \sigma_m$ is a compact subset K of M. Since K is compact it follows from Exercise 46.3 that there exists an open subset $U \subset M$ that contains K and such that the

closure $\overline{U}$ is compact. We consider the open subset $V = M \setminus \overline{U}$ and we consider the long exact sequence of the triple $(M, U \cup V, V)$, see Corollary 31.14. It fits into the following commutative diagram

$$\begin{array}{ccccccc} \dots \longrightarrow H_{k+1}(M, U\cup V; R) & \xrightarrow{\partial} & H_k(U\cup V, V; R) & \longrightarrow & H_k(M, V; R) & \longrightarrow & \dots \\ & & \cong\uparrow & & \uparrow & & \\ & & H_k(U; R) & \xrightarrow{[z]\mapsto[z]=\alpha} & H_k(M; R). & & \end{array}$$

Here the left vertical map is an isomorphism since $U \cup V$ is the disjoint union of the open sets U and V.[871]

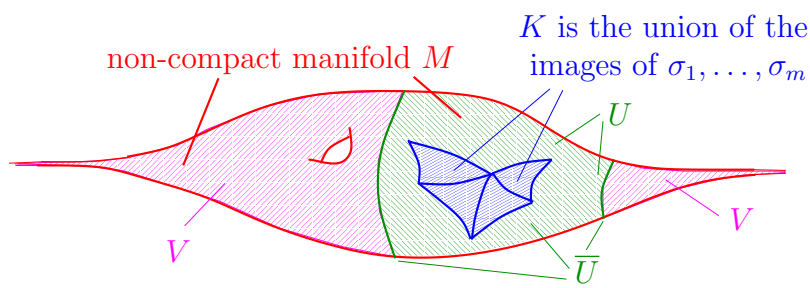

FIGURE 662. Illustration for the proof of Proposition 46.19.

Now we consider the modules to the top-left and top-right of the diagram. We have

$$\begin{array}{rcl} H_{k+1}(M, U\cup V; R) & = & H_{k+1}(M|\overbrace{M\setminus(U\cup V)}^{=\overline{U}\setminus U}; R) \;=\; 0 \quad \text{if } k > n-1 \\ & & \uparrow \\ & & \text{by Theorem 46.10 (ii) since } M \text{ has no boundary and since } \overline{U} \text{ and } \overline{U}\setminus U \text{ are compact} \\ & & \downarrow \\ H_k(M, V; R) & = & H_k(M|\underbrace{M\setminus V}_{=\overline{U}}; R) \;=\; 0 \quad \text{if } k > n. \end{array}$$

After these preparations we come to the actual proof that $\alpha = [z] = 0 \in H_k(M; R)$. We first consider the case $k > n$. We deduce from the above exact sequence and the above calculations that $H_k(U; R) = 0$. But z represents an element in $H_k(U; R)$. It follows that $[z] = 0$ in $H_k(M; R)$.

[871] One could at this point refer to the Excision Theorem 31.17 but this isomorphism follows already from the observation that $C_*(U \cup V) = C_*(U) \oplus C_*(V)$ as chain complexes, since U and V are both open subsets of $U \cup V$.

Now we consider the case $k = n$. It follows from the above discussion that we have a commutative diagram

$$\begin{array}{ccc} H_n(U \cup V, V; R) & \hookrightarrow & H_n(M, V; R) \\ \cong\uparrow & & \uparrow \\ H_n(U; R) & \xrightarrow{[z]\mapsto[z]=\alpha} & H_n(M; R). \end{array}$$

Thus it suffices to show that the image of α in $H_n(M, V; R)$ is zero. We showed in Lemma 46.1 that $\{\alpha_x\}_{x\in M}$ is an R-section of M.[872] Since M is non-compact we can find a point x outside of the compact set K. The class $\alpha_x \in H_n(M, M \setminus \{x\}; R)$ is again represented by z which lies in $K \subset M \setminus \{x\}$. It is thus clear that $\alpha_x = 0 \in H_n(M, M \setminus \{x\}; R)$. But since M is connected it follows from Proposition 45.17 (1) that $\{\alpha_x\}_{x\in M}$ is the zero section. Both the image of α in $H_n(M, V; R)$ and the zero-class are lifts of the zero section to $H_n(M, V; R)$. By Theorem 46.10 (i) both lifts agree, i.e. the image of α in $H_n(M, V; R)$ is zero. □

Now we can easily provide the proof of Theorem 46.4.

Proof of Theorem 46.4. Let M be a connected n-dimensional topological manifold and let R be a commutative ring. Recall that we need to prove the following two statements.

(1) If M is not closed, then $H_i(M; R) = 0$ for $i \geq n$.
(2) If M is closed, then we have $H_i(M; R) = 0$ for $i > n$.

First suppose that M is not closed. The hypothesis that M is not closed means that M is not compact or that it has a non-empty boundary. If M is not compact without boundary, then we had just proved in Proposition 46.19 that $H_i(M; R) = 0$ for $i \geq n$. If M has non-empty boundary, then we saw in Corollary 45.5 that M is homotopy equivalent to a non-compact n-dimensional topological manifold N without boundary. It follows from Corollary 30.8 and Proposition 46.19 that for any $i \geq n$ we have $H_i(M; R) \cong H_i(N; R) = 0$.

Now suppose that M is closed. Let $i > n$. We have

$$H_i(M; R) \;=\; H_i(M, \overbrace{M \setminus M}^{=\varnothing}; R) \;=\; H_i(M|M; R) \;\underset{\substack{\uparrow \\ \text{by Theorem 46.10 (ii) since } M \text{ is compact and since } M \text{ has no boundary}}}{=}\; 0.$$

□

46.4. **Proof of Theorems 46.2 and 46.3.** The key to proving Theorems 46.2 and 46.3 is the following proposition which later on we will apply to $R = \mathbb{Z}$ and $R = \mathbb{F}_2$.

Proposition 46.20. *Let M be a connected, compact n-dimensional topological manifold and let R be a commutative ring. Then the following hold:*

[872] Here we used a second time that M has no boundary.

(1) *If M is R-orientable, then for any $x \in M \setminus \partial M$ the map*

$$\begin{array}{ccccc} H_n(M, \partial M; R) & \to & H_n(M, M \setminus \{x\}; R) & \cong & R \\ & & & \uparrow & \\ & & & \textit{isomorphism by Lemma 45.16} & \end{array}$$

is an isomorphism.

(2) *If M is not orientable, then $H_n(M, \partial M; \mathbb{Z}) = 0$.*

Proof. Let M be a connected, compact n-dimensional topological manifold and let R be a commutative ring.

We first consider the case that M is actually closed. Recall that we denote by $\Gamma_R(M)$ the set of all R-sections of M. By Lemma 46.1 we have a well-defined R-module homomorphism

$$\begin{array}{rcl} H_n(M; R) & \mapsto & \Gamma_R(M) \\ \alpha & \mapsto & \{\alpha_x\}_{x \in M}. \end{array}$$

Since M is closed we can apply Theorem 46.10 (i) to the special case of the compact subset $A = M$ and we obtain that the above map is an isomorphism. The desired statements (1) and (2) now both follow from Lemma 45.20.

Now we consider the case that M is not closed, i.e. we suppose that $\partial M \neq \varnothing$. As usual we denote by DM the double of M. The idea now is to prove the desired statements for M by reducing them to the equivalent statements for the closed topological manifold DM that we had just proved.

As before we think of the double as $DM = (M \sqcup M')/\sim$ where M' is another copy of M. We consider the maps

$$\begin{tikzcd} \underbrace{H_n(M'; R)}_{= 0 \text{ by Thm. 46.4}} \arrow[r] & H_n(DM; R) \arrow[r] \arrow[dr, "\Phi"'] & H_n(DM, M'; R) \arrow[r] & H_{n-1}(M'; R) \arrow[r, "\text{injective}", "\text{by 45.12}"'] & H_{n-1}(DM; R) \\ & & H_n(M, \partial M; R), \arrow[u, "\cong"'] & & \end{tikzcd}$$

where on the top we have written down the long exact sequence of the pair (DM, M'). Note that the vertical map is an isomorphism by the Excision Theorem 45.10. The map Φ is defined to be the unique homomorphism that makes the triangle commute.

It follows immediately from the information provided in the above diagram that the map $\Phi\colon H_n(DM; R) \to H_n(M, \partial M; R)$ is an isomorphism. Now we turn to the proof of the two statements of the proposition.

(1) Now suppose that M is R-orientable. Let $x \in M \setminus \partial M$. We consider the following diagram

$$\begin{tikzcd}
H_n(DM;R) \arrow[rr, "{[DM]\mapsto\sigma_x}", "\text{isomorphism since } DM \text{ closed}"'] \arrow[dr, "\cong"'] & & H_n(DM, DM\setminus\{x\};R) \\
& H_n(DM, M';R) \arrow[ur] & \\
H_n(M,\partial M;R) \arrow[uur, "\cong", "\text{Excision Thm. 45.10}"'] \arrow[rr] & & H_n(M, M\setminus\{x\};R). \arrow[uu, "\mu_x\mapsto\sigma_x"', "\text{Excision Thm. 45.10}"]
\end{tikzcd}$$

Here all maps are the obvious inclusion induced maps. This implies that the diagram commutes. Since DM is closed and since it is R-orientable by Lemma 45.29 we know from the first part of the proof that the top horizontal map is an isomorphism. Furthermore by the above discussion we know that the top-left diagonal map is an isomorphism. Finally two of the maps are isomorphisms by the Excision Theorem 45.10. It now follows immediately that the bottom horizontal map is also an isomorphism. But that is exactly what we were supposed to show.

(2) If M is not orientable, then it follows from Lemma 45.29 that the double DM is not orientable either. We obtain that

$$\begin{array}{ccccc}
H_n(M,\partial M;\mathbb{Z}) & \cong & H_n(DM;\mathbb{Z}) & = & 0. \\
& \uparrow & & \uparrow & \\
& \text{see above} & \multicolumn{2}{l}{\text{since } DM \text{ is closed and non-orientable and}} & \\
& & \multicolumn{2}{l}{\text{since we have proved (1) in the closed case}} &
\end{array}$$

□

Remark. Note that the second statement of Proposition 46.20 only deals with integer coefficients. A more general statement is given by [Hat, Theorem 3.26]. This theorem says that if M is a closed connected n-dimensional topological manifold that is *not* R-orientable, then for any $x \in M$ the map $\rho_x \colon H_n(M;R) \to H_n(M, M\setminus\{x\};R) \cong R$ is injective with image $\{r \in R \mid 2r = 0\}$. For example for $R = \mathbb{Z}$ we have $\{r \in \mathbb{Z} \mid 2r = 0\} = \{0\}$, i.e. the map ρ_x is the zero map and by injectivity we have $H_n(M;\mathbb{Z}) = 0$. In the case of closed topological manifolds we can thus view [Hat, Theorem 3.26] as a generalization of Proposition 46.20 (2). We will not make use of [Hat, Theorem 3.26].

Now we can finally provide the proofs of Theorems 46.2 and 46.3.

Proof of Theorem 46.2. Let M be a compact, connected, non-empty n-dimensional topological manifold. We have to show that the following statements are equivalent:

(1) the topological manifold M is orientable,
(2) $H_n(M,\partial M;\mathbb{Z}) \neq 0$,
(3) $H_n(M,\partial M;\mathbb{Z}) \cong \mathbb{Z}$,
(4) for every $x \in M \setminus \partial M$ the map

$$\rho_x \colon H_n(M,\partial M;\mathbb{Z}) \;\to\; H_n(M, M\setminus\{x\};\mathbb{Z})$$

is an isomorphism.

We have (1) $\Rightarrow$ (4) by Proposition 46.20 (1) applied with $R = \mathbb{Z}$. Since M is non-empty we obtain from Corollary 32.4 that there exists a point $x \in M \setminus \partial M$. Therefore we have (4) $\Rightarrow$ (3) by Lemma 45.16. Evidently we have (3) $\Rightarrow$ (2). Furthermore we have (2) $\Rightarrow$ (1) by Proposition 46.20 (2). $\square$

Proof of Theorem 46.3. Let M be a compact, connected, non-empty n-dimensional topological manifold. We have to show the following two statements:

(1) $H_n(M, \partial M; \mathbb{F}_2) \cong \mathbb{F}_2$, and
(2) for every $x \in M \setminus \partial M$ the map

$$\rho_x \colon H_n(M, \partial M; \mathbb{F}_2) \quad \to \quad H_n(M, M \setminus \{x\}; \mathbb{F}_2)$$

is an isomorphism.

By Proposition 45.24 we know that M admits an $\mathbb{F}_2$-orientation. Statement (2) follows immediately from this fact and Proposition 46.20 (1) applied to $R = \mathbb{F}_2$. As in the proof of Theorem 46.2, the first statement is an immediate consequence of the second statement, together with the fact that there exists a point in $M \setminus \partial M$ and Lemma 45.16. $\square$

46.5. **Further properties of topological manifolds.** Let M be a compact n-dimensional topological manifold. With Theorem 46.2 we now completely understand the n-dimensional homology of M. In this section we will obtain some results on the $(n-1)$-dimensional homology of M.

The first part of the following proposition generalizes the result of Proposition 39.17 from manifolds to topological manifolds. The second part is new even for manifolds.

Proposition 46.21. *Let M be a connected, compact n-dimensional topological manifold.*

(1) *If M is orientable or if M is not closed, then $H_{n-1}(M; \mathbb{Z}) \cong \mathbb{Z}^k$ for some $k \in \mathbb{N}_0$.*
(2) *If M is non-orientable and closed, then $H_{n-1}(M; \mathbb{Z}) \cong \mathbb{Z}_2 \oplus \mathbb{Z}^k$ for some $k \in \mathbb{N}_0$.*

Remark.

(1) As a reality check it is good to recall the calculation of the homology groups of closed topological 2-dimensional manifolds that we gave in Proposition 35.10. There we showed for any $g \in \mathbb{N}_0$ and any $k \in \mathbb{N}_0$ we have

$$H_n(\Sigma_g) \;\cong\; \begin{cases} 0, & \text{if } n \geq 3, \\ \mathbb{Z}, & \text{if } n = 2, \\ \mathbb{Z}^{2g}, & \text{if } n = 1, \\ \mathbb{Z}, & \text{if } n = 0 \end{cases} \qquad \text{and} \qquad H_n(k \cdot \mathbb{R}\mathrm{P}^2) \;\cong\; \begin{cases} 0, & \text{if } n \geq 3, \\ 0, & \text{if } n = 2, \\ \mathbb{Z}_2 \oplus \mathbb{Z}^{k-1}, & \text{if } n = 1, \\ \mathbb{Z}, & \text{if } n = 0, \end{cases}$$

where, as always, we denote by Σ_g the surface of genus g. Fortunately these calculations are coherent with Proposition 46.21.

(2) It follows immediately from the Universal Coefficient Theorem 42.19, Theorem 46.2, Proposition 46.21 (1) and Lemma 42.17 that for any closed orientable n-dimensional topological manifold and any abelian group G we have $H_n(M; G) \cong G$.

In the proof of Proposition 46.21 we will use the following lemma which is an immediate consequence of the classification of finitely generated abelian groups, see Theorem 11.4, and of Lemma 42.17.

Lemma 46.22. *Let A be a finitely generated abelian group. Then the following holds:*

$$A \text{ is a free abelian group} \quad \Longleftrightarrow \quad \operatorname{Tor}(A, \mathbb{Z}_p) = 0 \text{ for all primes } p.$$

Now we can provide the proof of Proposition 46.21. We consider the two cases that the topological manifold is closed and that it has non-empty boundary separately.

Proof of Proposition 46.21 for closed topological manifolds. Let M be a closed, connected n-dimensional topological manifold. By Proposition 45.2 we know that $H_{n-1}(M;\mathbb{Z})$ is a finitely generated abelian group.

We first consider the case that M is orientable. We want to show that $H_{n-1}(M;\mathbb{Z})$ is a free abelian group. By Lemma 46.22 it suffices to show that $\operatorname{Tor}(H_{n-1}(M;\mathbb{Z}), \mathbb{F}_p) = 0$ for all primes p.

So let p be a prime. We have

$$\begin{array}{ccccc}
\mathbb{F}_p & \cong H_n(M;\mathbb{F}_p) & \cong H_n(M;\mathbb{Z}) \otimes \mathbb{F}_p \oplus \operatorname{Tor}(H_{n-1}(M;\mathbb{Z}), \mathbb{F}_p) & \cong \mathbb{F}_p \oplus \operatorname{Tor}(H_{n-1}(M;\mathbb{Z}), \mathbb{F}_p). \\
 & \uparrow & \uparrow & \uparrow \\
 & \begin{array}{c}\text{by Proposition 46.20 (1),} \\ \text{since by Lemma 45.25} \\ M \text{ is also } \mathbb{F}_p\text{-orientable}\end{array} & \text{Universal Coefficient Theorem 42.23} & \begin{array}{c}\text{by Theorem 46.2 (3) we} \\ \text{have } H_n(M;\mathbb{Z}) \cong \mathbb{Z}\end{array}
\end{array}$$

It follows from Lemma 11.8 that $\operatorname{Tor}(H_{n-1}(M;\mathbb{Z}), \mathbb{F}_p) = 0$.

Now we turn to the case that M is non-orientable. By Proposition 45.26 there exists a connected 2-fold covering $q\colon \widetilde{M} \to M$ such that $\widetilde{M}$ is orientable. We consider the maps

$$\begin{tikzcd}
H_{n-1}(M;\mathbb{Z}) \arrow[r, "q^*"] \arrow[rr, bend right, "\cdot 2"'] & H_{n-1}(\widetilde{M};\mathbb{Z}) \arrow[r, "q_*"] & H_{n-1}(M;\mathbb{Z}).
\end{tikzcd}$$

Here q^* denotes the transfer map that we introduced on page 1064 and q_* denotes of course the map induced by the projection q. By Proposition 44.14 the composition of q^* and q_* is given by multiplication by 2. Put differently, the above diagram commutes.

Since $\widetilde{M}$ is orientable we obtain from the case that we had just proved that $H_{n-1}(\widetilde{M};\mathbb{Z})$ is torsion-free. Now we see that

$$\begin{array}{ccccc}
\text{torsion subgroup of } H_{n-1}(M;\mathbb{Z}) & \subset \ker(q^*) & \subset \ker(q_* \circ q^*) & \subset \{a \in H_{n-1}(M;\mathbb{Z}) \mid 2a = 0\}. \\
 & \uparrow & & \uparrow \\
 & \text{since } H_{n-1}(\widetilde{M};\mathbb{Z}) \text{ is torsion-free} & & \text{by the above commutative diagram}
\end{array}$$

From these inclusions and the classification of finitely generated abelian groups we obtain easily that $H_{n-1}(M;\mathbb{Z}) \cong (\mathbb{Z}_2)^r \oplus \mathbb{Z}^k$ for some $r \in \mathbb{N}_0$ and some $k \in \mathbb{N}_0$.

It remains to show that $r = 1$. In light of Lemma 42.17 it suffices to show that we have $\operatorname{Tor}(H_{n-1}(M;\mathbb{Z}), \mathbb{F}_2) \cong \mathbb{F}_2$. The argument is very similar to the argument in the orientable

case. More precisely, we have

$$\begin{array}{ccccccc} \mathbb{F}_2 & \cong & H_n(M;\mathbb{F}_2) & \cong & H_n(M;\mathbb{Z})\otimes\mathbb{F}_2 \oplus \operatorname{Tor}(H_{n-1}(M;\mathbb{Z}),\mathbb{F}_2) & \cong & 0 \oplus \operatorname{Tor}(H_{n-1}(M;\mathbb{Z}),\mathbb{F}_2). \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{by Proposition 45.24} & & \text{Universal Coefficient Theorem 42.23} & & \text{by Theorem 46.2 (3)} & \\ & \text{and Theorem 46.3} & & & & \text{we have } H_n(M;\mathbb{Z})=0 & \end{array}$$

□

Proof of Proposition 46.21 for topological manifolds with non-empty boundary (∗). Let M be a connected, compact n-dimensional topological manifold with non-empty boundary. We need to show that $H_{n-1}(M;\mathbb{Z})$ is a free abelian group. There are two approaches to the proof of this statement.

(1) We can imitate the proof of the closed case, or
(2) we reduce the proof of the proposition to the case of closed manifolds that we had just dealt with.

We will pursue the second approach. First recall that by Lemma 45.29 the double DM is orientable if and only if M is orientable.

We first consider the case that M is orientable. By Proposition 46.21 we know that $H_{n-1}(DM;\mathbb{Z})$ is a finitely generated free abelian group. It follows from Lemma 45.12 that the group $H_{n-1}(M;\mathbb{Z})$ is isomorphic to a subgroup of $H_{n-1}(DM;\mathbb{Z})$, hence by Lemma 11.8 (3) it is also a finitely generated free abelian group.

Now we consider the case that M is non-orientable. We denote by M' a copy of M and as usual we denote by $DM = M \cup_{\partial M=\partial M'} M'$ the double. We consider the Mayer–Vietoris sequence[873]

$$\cdots \to H_n(DM;\mathbb{Z}) \to H_{n-1}(\partial M;\mathbb{Z}) \to H_{n-1}(M;\mathbb{Z}) \oplus H_{n-1}(M';\mathbb{Z}) \to H_{n-1}(DM;\mathbb{Z}) \to \dots$$

We make the following observations:

(1) By Proposition 32.1 (3) we know that ∂M is a closed $(n-1)$-dimensional topological manifold. Thus we obtain from Theorem 46.2 that $H_{n-1}(\partial M;\mathbb{Z})$ is isomorphic to a free abelian group $\mathbb{Z}^r$ for some $r \in \mathbb{N}_0$. (We do not have any control over the orientability of ∂M and the number of components of ∂M but this does not matter.)
(2) Since DM is non-orientable we know from Theorem 46.2 that $H_n(DM;\mathbb{Z}) = 0$ and we know from Proposition 46.21 that $H_{n-1}(DM;\mathbb{Z}) \cong \mathbb{Z}^s \oplus \mathbb{Z}_2$ for some $s \in \mathbb{N}_0$.
(3) Since $M = M'$ we have $H_{n-1}(M;\mathbb{Z}) = H_{n-1}(M';\mathbb{Z})$. By the classification of finitely generated abelian groups we can pick an isomorphism $H_{n-1}(M;\mathbb{Z}) \cong F \oplus T$ where F is a free abelian group and T is a torsion group.

We can thus rewrite the above sequence as follows:

$$0 \;\to\; \mathbb{Z}^r \;\xrightarrow{\varphi}\; F \oplus F \oplus T \oplus T \;\to\; \mathbb{Z}^s \oplus \mathbb{Z}_2 \;\to\; \dots$$

The map $\varphi\colon \mathbb{Z}^r \to F \oplus F \oplus T \oplus T$ is a monomorphism, but since $\mathbb{Z}^r$ is torsion-free and since T is finite we see that $\operatorname{im}(\varphi) \cap (T \oplus T)$ is trivial. But this implies that $T \oplus T$ is isomorphic

[873]The existence of such a Mayer–Vietoris sequence is proved in a very similar fashion to the Mayer–Vietoris Theorem 33.10 for manifolds, we just need to replace the Collar Neighborhood Theorem 10.10 by the Topological Collar Neighborhood Theorem 45.3.

to a subgroup of $\mathbb{Z}^s \oplus \mathbb{Z}_2$. But this is only possible if $T = 0$. This concludes the proof that $H_{n-1}(M;\mathbb{Z})$ is a free abelian group. $\square$

46.6. **The fundamental class and induced orientations.** In Section 45.9 we saw that an orientation on a topological manifold M induces orientations on codimension-zero submanifolds of M, on the boundary ∂M and on covering spaces of M. If M is compact, then M admits a fundamental class and we will see in this section how it is related to the fundamental classes of the various corresponding oriented topological manifolds.

First of all, in Lemma 45.28 we saw that a codimension zero submanifold W of an oriented topological manifold M inherits an orientation. For compact topological manifolds the following lemma shows the relationship between the corresponding fundamental classes.

Lemma 46.23. *Let M be a compact n-dimensional topological manifold and let $W \subset M$ be a compact n-dimensional submanifold. We write $\mathring{W} = W \setminus \partial W$. Then the following two statements hold:*

(1) *The inclusion induced map $j_*\colon H_n(W, \partial W;\mathbb{Z}) \to H_n(M, M \setminus \mathring{W};\mathbb{Z})$ is an isomorphism.*
(2) *If M is oriented and if $[M]$ is the corresponding fundamental class, then the image of $[M]$ under the map*

$$H_n(M, \partial M;\mathbb{Z}) \;\to\; H_n(M, M \setminus \mathring{W};\mathbb{Z}) \;\xrightarrow{j_*^{-1}}\; H_n(W, \partial W;\mathbb{Z})$$

is the fundamental class for the oriented topological manifold W.

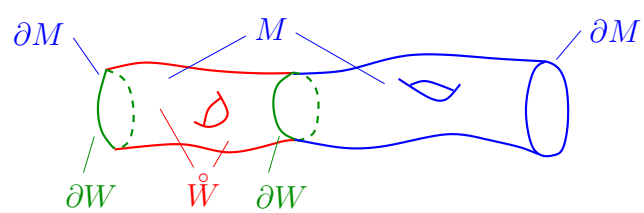

FIGURE 663. Illustration for the proof of Lemma 46.23.

Proof $(*)$.

(1) The first statement is an immediate consequence of the Excision Theorem 45.10 for topological manifolds.
(2) We denote by $\Phi\colon H_n(M, \partial M;\mathbb{Z}) \to H_n(W, \partial W;\mathbb{Z})$ the map given in statement (2). We have to show that $\Phi([M])$ is the fundamental class for W. But this follows immediately from Corollary 46.5 and from considering for each $x \in W \setminus \partial W$ the

following commutative diagram

$$\begin{tikzcd}
H_n(M,\partial M;\mathbb{Z}) \arrow[r] \arrow[d] \arrow[rr, bend left, "\Phi"] & H_n(M, M\setminus \mathring{W};\mathbb{Z}) \arrow[dl] & H_n(W,\partial W;\mathbb{Z}) \arrow[l, "\cong", "j_*"'] \arrow[d] \\
H_n(M, M\setminus\{x\};\mathbb{Z}) & & H_n(W, W\setminus\{x\};\mathbb{Z}). \arrow[ll, "\cong"']
\end{tikzcd}$$

We leave the few remaining details to the reader. □

In Lemma 45.28 (3) we showed that a covering space $\widetilde{M}$ of an oriented topological manifold M inherits an orientation from M. The following proposition can now be viewed as a generalization of Proposition 39.20.

Proposition 46.24. *Let M be a compact oriented n-dimensional topological manifold and let $p\colon \widetilde{M} \to M$ be a finite covering. We denote by $[M]$ the fundamental class of M. Then*[874] *$p^*([M])$ equals the fundamental class $\big[\widetilde{M}\big]$ of the oriented topological manifold $\widetilde{M}$ and we have $p_*\big(\big[\widetilde{M}\big]\big) = \big[\widetilde{M} : M\big] \cdot [M]$.*

Proof $(*)$. Let M be a compact n-dimensional topological manifold. To simplify the notation we assume that M is closed. Furthermore let $p\colon \widetilde{M} \to M$ be a finite covering and let $\{\mu_x\}_{x\in M}$ be an orientation for M. We denote by $\{\nu_x\}_{x\in\widetilde{M}}$ the orientation on $\widetilde{M}$ that we defined in Lemma 45.28 (3).

We want to show that $p^*([M])$ equals the fundamental class $\big[\widetilde{M}\big]$. By Corollary 46.5 it suffices to show that for all $y \in \widetilde{M}$ we have $p^*([M])_y = \nu_y \in H_n(\widetilde{M}, \widetilde{M}\setminus\{y\};\mathbb{Z})$. So let $y \in \widetilde{M}$. We pick an open neighborhood V around y such that $U := p(V)$ is uniformly covered. We write $x = p(y)$ and we denote by $q\colon U \to V$ the inverse of the homeomorphism $p\colon V \to U$.

We pick a representative $z = a_1 \cdot \sigma_1 + \cdots + a_m \cdot \sigma_m \in C_n(M)$ for $[M]$. By applying Proposition 31.21 to the *open* covering of M given by $\{U, M\setminus\{x\}\}$ we can arrange that the image of each σ_i lies in U or in $M\setminus\{x\}$. We denote by z' the sum of all summands in z such that the image of σ_i lies in U.

A moment's thought shows that in $H_n(M, M\setminus\{x\};\mathbb{Z})$ we have $[z] = [z']$ and that in $H_n(\widetilde{M}, \widetilde{M}\setminus\{y\})$ we have $[p^*(z)] = [q_*(z')]$. From these observations we deduce that the following diagram commutes:

$$\begin{tikzcd}
H_n(M;\mathbb{Z}) \arrow[rrr, "p^*"] \arrow[d, "{[M]=[z]\mapsto[z]=[z']=[\mu_x]}"] & & & H_n(\widetilde{M};\mathbb{Z}) \arrow[d, "{[p^*z]\mapsto[p^*z]=[q_*(z')]}"'] \\
H_n(M, M\setminus\{x\};\mathbb{Z}) \arrow[rrr, bend right, "\mu_x\mapsto\nu_y"'] & H_n(U, U\setminus\{x\};\mathbb{Z}) \arrow[l, "\cong"'] \arrow[r, "\cong", "q_*"'] & H_n(V, V\setminus\{y\};\mathbb{Z}) \arrow[r, "\cong"] & H_n(\widetilde{M}, \widetilde{M}\setminus\{y\};\mathbb{Z}).
\end{tikzcd}$$

[874]Here $p^*\colon H_k(M;\mathbb{Z}) \to H_k(\widetilde{M};\mathbb{Z})$ denotes the transfer map that we introduced on page 1064.

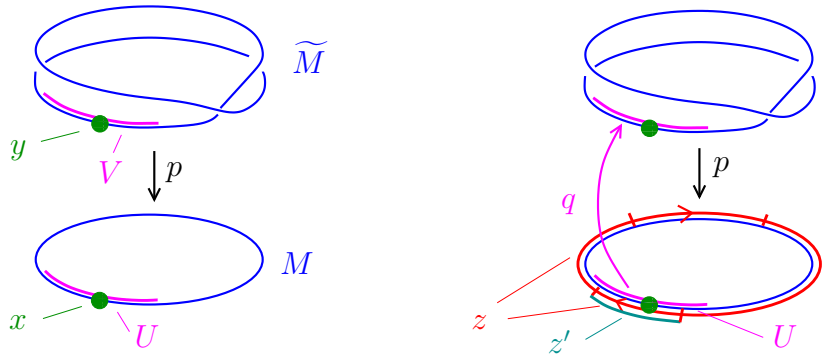

FIGURE 664.

Note that the bottom horizontal maps to the left and right are isomorphisms by the Excision Theorem 45.8 and the middle horizontal map is an isomorphism since q is a homeomorphism. It follows from this diagram that we indeed have $p^*([M])_y = \nu_y$.

Finally we have

$$p_*\big([\widetilde{M}]\big) \underset{\substack{\uparrow \\ \text{by the above}}}{=} p_*(p^*([M])) \underset{\substack{\uparrow \\ \text{Proposition 44.14}}}{=} [\widetilde{M} : M] \cdot [M].$$

□

In Lemma 45.29 we saw that the double of an oriented topological manifold with non-empty boundary comes with a natural orientation. The following lemma following relates the various fundamental classes in this construction.

Lemma 46.25. *Let M be a compact oriented n-dimensional topological manifold with non-empty boundary. If we equip DM with the orientation coming from Lemma 45.29, then*

$$[DM] \;=\; D([M]) \;\in\; H_n(DM;\mathbb{Z}),$$

where $D\colon H_n(M,\partial M;\mathbb{Z}) \to H_n(DM;\mathbb{Z})$ denotes the doubling homomorphism that we introduced in Lemma 45.13.

Proof. Let $\{\mu_x\}_{x\in M\setminus\partial M}$ be an orientation for M. We denote by $\{\alpha_x\}_{x\in DM}$ the corresponding orientation for DM that we had constructed in Lemma 45.29. To simplify the notation we write $DM = (M \sqcup M')/\sim$ where M' is a copy of M and we view M as a submanifold of the double. By Corollary 32.4 there exists an $x \in M \setminus \partial M$. We consider the following

diagram

$$\begin{tikzcd}
H_k(M,\partial M;\mathbb{Z}) \arrow[rr, "D"] \arrow[dr] \arrow[dd] & & H_k(DM;\mathbb{Z}) \arrow[dl] \arrow[ddl, "\cong"] \\
& H_k(DM,M';\mathbb{Z}) \arrow[d] & \\
H_n(M,M\setminus\{x\};\mathbb{Z}) \arrow[r, "\cong", "\mu_x\mapsto\alpha_x"'] & H_n(DM,DM\setminus\{x\};\mathbb{Z}). &
\end{tikzcd}$$

Here all maps are the obvious maps for pairs of topological spaces. The lemma follows from the following observations:

(1) The top triangle commutes by Lemma 45.13 (3). The parallelogram on the left and the triangle on the right commute by the functoriality of homology.
(2) The homomorphism to the bottom left is an isomorphism by the Excision Theorem 45.10 for topological Manifolds.
(3) The right diagonal map is an isomorphism by Theorem 46.2.
(4) By definition $[M]$ gets sent to $\mu_x \in H_n(M, M \setminus \{x\};\mathbb{Z})$ and by definition μ_x gets sent to α_x. It follows from the commutativity of the diagram that $D([M])$ gets sent to α_x. But since the right diagonal map is an isomorphism it follows, from the definition of $[DM]$, that $[DM] = D([M])$. □

In Proposition 45.30 we saw that the boundary of an oriented topological manifold inherits an orientation. The following proposition can now be seen as a generalization of Proposition 39.6 from manifolds to topological manifolds.

Proposition 46.26. *Let M be a compact n-dimensional topological manifold.*

(1) *We denote by $\partial\colon H_n(M,\partial M;\mathbb{Z}) \to H_{n-1}(\partial M;\mathbb{Z})$ the connecting homomorphism of the long exact sequence of the pair $(M,\partial M)$. If M is oriented, then*[875]
$$\partial[M] \;=\; [\partial M] \;\in\; H_{n-1}(\partial M;\mathbb{Z}).$$
(2) *Similarly, for the connecting homomorphism $\partial\colon H_n(M,\partial M;\mathbb{F}_2) \to H_{n-1}(\partial M;\mathbb{F}_2)$ we have*
$$\partial[M]_{\mathbb{F}_2} \;=\; [\partial M]_{\mathbb{F}_2} \;\in\; H_{n-1}(\partial M;\mathbb{F}_2).$$

Proof. The proof of the first part of the proposition follows from the definition of the orientation of the boundary ∂M and a judicious use of the Excision Theorem 31.17. We leave it as an exercise to the sedulous reader to fill in the details. Alternatively a proof can be found in [Bre, Lemma 9.1].

The second part is proved in a similar fashion. Not surprisingly for this part we also decline to provide the details of the argument. □

[875]Note that ∂M is a closed $(n-1)$-dimensional topological manifold by Proposition 32.1 (3).

Remark. Given a compact oriented n-dimensional topological manifold the conclusion of Proposition 46.26 can also be summarized in the following commutative "diagram"

$$\begin{tikzcd}
\mathbb{Z}\text{-oriented manifold } M \arrow[r, mapsto, "\text{take boundary}"] \arrow[d, mapsto, "\text{take fundamental class}"] & \mathbb{Z}\text{-oriented manifold } \partial M \arrow[d, mapsto, "\text{take fundamental class}"] \\
{[M]} \arrow[r, mapsto, "\text{apply connecting homomorphism}", "H_n(M,\partial M;\mathbb{Z})\to H_{n-1}(\partial M;\mathbb{Z})"'] & \partial[M] = [\partial M].
\end{tikzcd}$$

Example. We will illustrate Proposition 46.26 with the Möbius band M. By Proposition 45.24 and Theorem 46.3 it has an $\mathbb{F}_2$-fundamental class $[M] \in H_2(M, \partial M; \mathbb{F}_2)$. In Figure 665 we consider the Möbius band with two singular 1-simplices α_1, α_2 and two singular 2-simplices σ_1, σ_2. In this case we have

$$\partial\big(\underbrace{\sigma_1 + \sigma_2}_{=:\mu}\big) \;=\; \underbrace{\alpha_1 + \alpha_2}_{\in C_1(\partial M)}.$$

In particular, $\mu \otimes 1$ is a cycle in $C_2(M, \partial M; \mathbb{F}_2)$. It easily follows from Proposition 46.8 that $\mu \otimes 1$ represents the $\mathbb{F}_2$-fundamental class in $H_2(M, \partial M; \mathbb{F}_2)$. Furthermore, if we denote by $\partial\colon H_2(M, \partial M; \mathbb{F}_2) \to H_1(\partial M; \mathbb{F}_2)$ the connecting homomorphism of the long exact sequence in $\mathbb{F}_2$-homology of the pair $(M, \partial M)$, then

$$\partial[M] \;=\; \partial[\mu \otimes 1] \;\underset{\substack{\uparrow \\ \text{Proposition 31.13}}}{=}\; [\partial\mu \otimes 1] \;\underset{\substack{\uparrow \\ \text{by the above}}}{=}\; \big[(\alpha_1 + \alpha_2) \otimes 1\big],$$

but the last class is clearly[876] an $\mathbb{F}_2$-fundamental class for the circle ∂M.

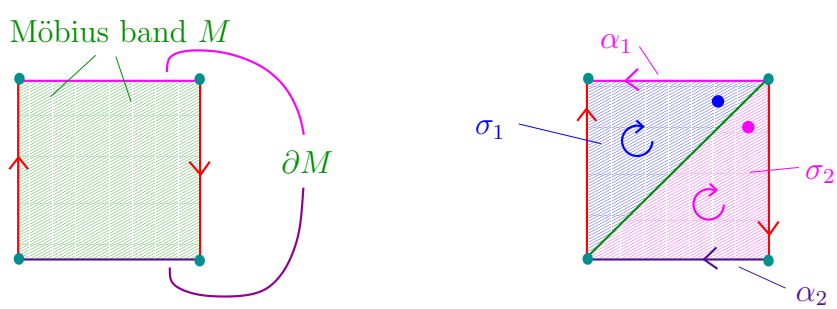

FIGURE 665.

The following corollary is the generalization of Corollary 39.10 to the case of topological manifolds.

[876]Why is this clear?

Corollary 46.27. *Let M be a compact n-dimensional topological manifold. Then the following two statements hold:*

(1) *We have*

$$\ker\left\{H_{n-1}(\partial M;\mathbb{F}_2) \to H_{n-1}(M;\mathbb{F}_2)\right\} = \mathbb{F}_2\cdot[\partial M]_{\mathbb{F}_2} \in H_{n-1}(\partial M;\mathbb{F}_2).$$

Furthermore, if M is oriented, then

$$\ker\left\{H_{n-1}(\partial M;\mathbb{Z}) \to H_{n-1}(M;\mathbb{Z})\right\} = \mathbb{Z}\cdot[\partial M] \in H_{n-1}(\partial M;\mathbb{Z}).$$

(2) *Let M be a compact n-dimensional topological manifold with non-trivial boundary. Then the boundary ∂M is not a retract of M.*

Proof. The proof is verbatim the same as the proof of Corollary 39.10, the only difference in the proof is that we need to replace Proposition 39.9 by Proposition 46.26.

As a reminder, the first statement is proved using the long exact sequence in homology of the pair $(M,\partial M)$ together with Proposition 46.26. The second statement follows from the first statement and the usual functoriality argument, this time we employ the functoriality of homology with $\mathbb{F}_2$-coefficients and the fact that $[\partial M]_{\mathbb{F}_2}$ is non-zero. □

Example. It follows from Corollary 46.27 that the boundary of the Möbius band M is not a retract of the Möbius band. A more down-to-earth proof is given as follows: we pick a base point $x_0\in\partial M$ and we denote by α and β the loops shown in Figure 666. Note that α represents a generator of $\pi_1(\partial M,x_0)\cong\mathbb{Z}$ and that β represents a generator of $\pi_1(M,x_0)\cong\mathbb{Z}$. We denote by $i\colon\partial M\to M$ the inclusion map. Note that $i_*([\alpha])=2\cdot[\beta]$. If there was a retraction $r\colon M\to\partial M$, then we would obtain a commutative diagram

$$\begin{tikzcd} & \pi_1(M,x_0) \arrow[dr, "r_*"] & \\ \pi_1(\partial M,x_0) \arrow[ur, "i_*"] \arrow[rr, "(r\circ i)_*"'] & & \pi_1(\partial M,x_0) \end{tikzcd}$$

which by the above gives rise to the commutative diagram

$$\begin{tikzcd} & \mathbb{Z} \arrow[dr, "??"] & \\ \mathbb{Z} \arrow[ur, "\cdot 2"] \arrow[rr, "\mathrm{id}"'] & & \mathbb{Z}, \end{tikzcd}$$

but such a commutative diagram cannot exist. Looking more carefully one sees that the two proofs that ∂M is not a retract of the Möbius band M are in some sense the same proof. More precisely, we have the following commutative diagram

$$\begin{tikzcd} \mathbb{Z}=\pi_1(\partial M,x_0) \arrow[r, "i_*"] \arrow[d] & \pi_1(M,x_0)=\mathbb{Z} \arrow[d] \\ \mathbb{Z}=H_1(\partial M;\mathbb{Z}) \arrow[r, "i_*"] \arrow[d] & H_1(M;\mathbb{Z})=\mathbb{Z} \arrow[d] \\ \mathbb{F}_2=H_1(\partial M;\mathbb{F}_2) \arrow[r, "i_*"] & H_1(M;\mathbb{F}_2)=\mathbb{F}_2. \end{tikzcd}$$

Here the top vertical maps are given by the Hurewicz homomorphism from page 924 and the bottom vertical maps are given by the map $[\alpha]\mapsto[\alpha\otimes 1]$ from page 1025. Since both maps are natural, see Proposition 38.2 (4) and page 1025, we see that the diagram commutes. The above observation that the top horizontal map is given by multiplication by 2 translates into the fact that the bottom horizontal map is the zero map.

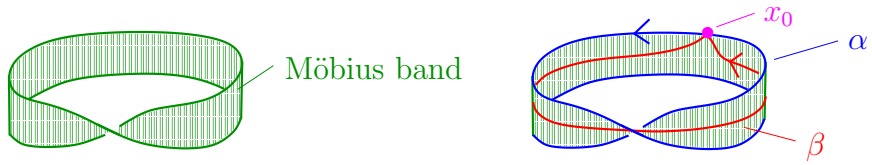

FIGURE 666.

46.7. **Lifts of homology orientations for topological manifolds with boundary** $(*)$**.** In this very technical section we generalize Theorem 46.10 (i) to the case of topological manifolds with boundary. Unless the reader is blessed with a surplus of energy it is best to skip this section.

Definition. Let M be a topological manifold. We say a compact subset $A \subset M$ is a *product close to the boundary* if there exists a collar neighborhood $\partial M \times [0,1]$ for the boundary ∂M and a compact subset $K \subset \partial M$ such that $A \cap (\partial M \times [0,1]) = K \times [0,1]$.

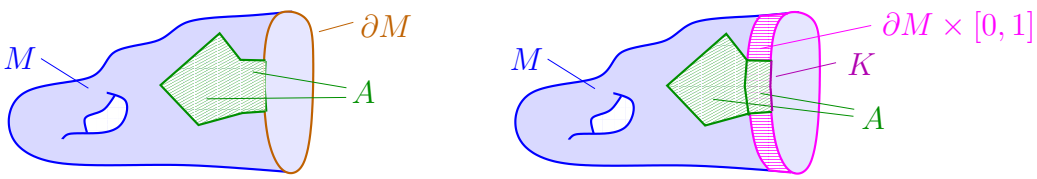

FIGURE 667.

Remark. If M is a topological manifold with *empty boundary*, then every compact subset is in fact a product close to the boundary.

We leave the proof of the following elementary lemma as an exercise to the reader.

Lemma 46.28. *Let M be a topological manifold and let $\partial M \times [0,1]$ be a collar neighborhood (which always exists by the topological Collar Neighborhood Theorem 45.3). Given any compact subset K of M there exists a compact subset A that contains K and that is a product close to the boundary.*

Throughout this section we will need the following notation.

Notation. Given a subset A of a topological manifold M we write $A_\partial := A \cap (M \setminus \partial M)$. In other words, we have $A_\partial = A \setminus \partial M$. Note that $(M \setminus A) \cup \partial M = M \setminus A_\partial$.

Now we can formulate the main result of this section.

Theorem 46.29. *Let M be an n-dimensional topological manifold and let $A \subset M$ be a compact subset that is a product close to the boundary. Let R be a commutative ring. If $\{\alpha_x\}_{x \in M \setminus \partial M}$ is an R-section for M, then there exists a unique lift $\alpha_A^M = \alpha_A$ to A_∂, i.e. there exists a unique class $\alpha_A^M = \alpha_A \in H_n(M, M \setminus A_\partial; R)$ such that for each $x \in A_\partial$ we have $\alpha_{A,x} = \alpha_x$.*

Proof. Let M be an n-dimensional topological manifold and let R be a commutative ring. Furthermore let $A \subset M$ be a compact subset that is a product close to the boundary. We introduce the following notation and conventions:

(1) As usual we denote by DM the double of M. As before we think of the double as $DM = (M \sqcup M')/\sim$ where M' is another copy of M. We recall that by Lemma 45.11 we know that DM is an n-dimensional topological manifold with empty boundary such that $M \subset DM$ is a submanifold.
(2) By definition there exists a collar neighborhood $\partial M \times [0,1]$ for the boundary ∂M and a compact subset $K \subset \partial M$ such that $A \cap (\partial M \times [0,1]) = K \times [0,1]$.
(3) We denote by $DA = A \cup A' \subset DM$ the double of A. As DA is the union of two compact sets we see that DA itself is compact.
(4) Given $t \in (0,1]$ we write $A_t := A \setminus (K \times [0,t)) = A \cap (M \setminus (\partial M \times [0,t)))$. It follows easily from Lemma 1.18 that A_t is again compact.
(5) It follows from the Excision Theorem 45.10 for topological manifolds that for any $P \in M \setminus \partial M$ the inclusion induced map

$$H_n(M, M \setminus \{P\}; R) \;\to\; H_n(DM, DM \setminus \{P\}; R)$$

is an isomorphism. We will use this isomorphism to identify these two homology groups.

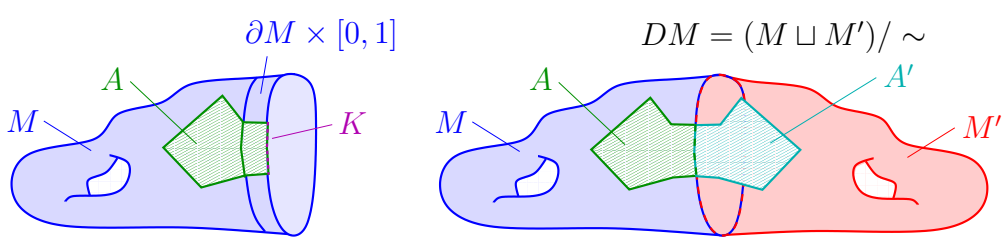

FIGURE 668. Illustration for the proof of Theorem 46.29.

The idea now is the same as in the proof of Proposition 46.20. Namely we want to prove the desired statement for M by reducing it to a corresponding statement for the topological manifold DM that has no boundary.

Claim. The inclusion induced map

$$\beta\colon H_n(M, M \setminus A_\partial; R) \;\to\; H_n(DM, (M \setminus A) \cup M'; R)$$

is an isomorphism.

Recall that A is a product close to the boundary. Using this fact and using a gentle generalization of the Excision Theorem 45.10 for topological manifolds one can easily show that the inclusion induced map is an isomorphism. We leave it to the reader to fill in the details. This concludes the proof of the claim.

We denote by Φ the composition of the following two maps

$$H_n(DM, DM \setminus DA; R) \;\to\; H_n(DM, (M \setminus A) \cup M'; R) \xrightarrow{\beta^{-1}} H_n(M, M \setminus A_\partial; R).$$

After all these preparations we now turn to the actual proof of the theorem. Thus let $\{\alpha_x\}_{x \in M \setminus \partial M}$ be an R-section for M. As in the proof of Lemma 45.29 we see that there exists an R-section $\{\alpha_x\}_{x \in DM}$ for DM that restricts to the given R-section on M. By Theorem 46.10 (i) there exists a lift $\mu_{DA} \in H_n(DM, DM \setminus DA; R)$ of the R-section on DM. We claim that $\Phi(\mu_{DA})$ is a lift for M. So let $P \in A_\partial$. We have the following commutative diagram

$$\begin{tikzcd}
H_n(DM, DM \setminus DA; R) \arrow[r] \arrow[d] \arrow[rr, bend left, "\Phi"] & H_n(DM, (M \setminus A) \cup M'; R) \arrow[d] & H_n(M, M \setminus A_\partial; R) \arrow[l, "\beta", "\cong"'] \arrow[d] \\
H_n(DM, DM \setminus \{P\}; R) \arrow[r, "="] & H_n(DM, DM \setminus \{P\}; R) & H_n(M, M \setminus \{P\}; R). \arrow[l, "\cong"']
\end{tikzcd}$$

Since all maps are induced by inclusions of pairs of topological spaces we see that the diagram commutes. By definition of μ_{DA} the left-hand vertical map sends μ_{DA} to α_P. But this implies that the right-hand vertical map sends $\Phi(\mu_{DA})$ to $\alpha_P \in H_n(M, M \setminus \{P\}; R)$.

Now we turn to the proof of the uniqueness of a lift. The following claim is the key to proving uniqueness.

Claim. Let $t \in (0, 1)$. Note that $A_t \subset A_\partial$. The two inclusion induced maps

$$\begin{aligned}
\gamma\colon H_n(M, M \setminus A_\partial; R) &\;\to\; H_n(M, M \setminus A_t; R) \\
\delta\colon H_n(M, M \setminus A_t; R) &\;\to\; H_n(DM, DM \setminus A_t; R)
\end{aligned}$$

are isomorphisms.

It follows immediately from the Excision Theorem 45.10 for topological manifolds that the map δ is an isomorphism. Regarding the map γ, note that it follows from the long exact sequence of the triple $(M, M \setminus A_t, M \setminus A_\partial)$, see Proposition 31.13, that it suffices to show that $H_i(M \setminus A_t, M \setminus A_\partial; R) = 0$ for all i. We pick $s \in (t, 1)$. We see that indeed we have

$$\begin{array}{c}
\text{by the Excision Theorem 31.17 where we excise everything in the complement of } (\partial M \times [0, s)) \cap A \\
\downarrow \\
H_i(M \setminus A_t, M \setminus A_\partial; R) \xleftarrow{\cong} H_i((\partial M \times [0, s)) \setminus (K \times [t, s)), (\partial M \times [0, s)) \setminus (K \times (0, s)); R) = 0. \\
\uparrow \\
\text{follows from Corollary 31.16 since } (\partial M \times [0, s)) \setminus (K \times (0, s)) \text{ is a} \\
\text{deformation retract of } (\partial M \times [0, s)) \setminus (K \times [t, s))
\end{array}$$

This completes the proof of the claim.

Now let $\mu, \nu \in H_n(M, M \setminus A_\partial; R)$ be two lifts of the R-section $\{\alpha_x\}_{x \in M \setminus \partial M}$. With the same arguments as before one can convince oneself easily of the fact that $\delta^{-1}(\gamma(\mu))$

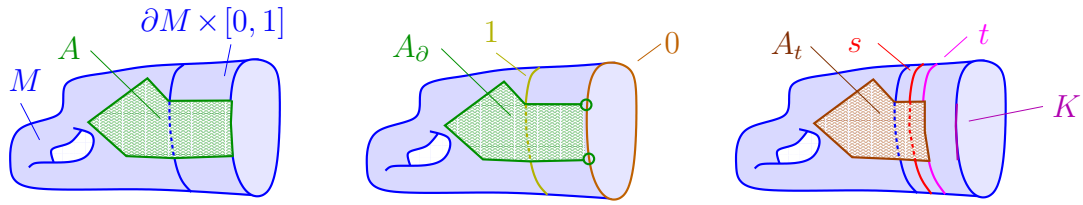

FIGURE 669. Second illustration for the proof of Theorem 46.29.

and $\delta^{-1}(\gamma(\nu))$ are lifts of the R-section $\{\alpha_x\}_{x\in DM}$. By Theorem 46.10 these two lifts are identical. But then it follows from the claim that also $\mu = \nu$. □

We conclude this long and tiring chapter with the following lemma that is a generalization of Lemma 46.11.

Lemma 46.30. *Let M be an oriented n-dimensional topological manifold and let R be a commutative ring. We suppose that M is equipped with an R-orientation. We use the notation from Theorem 46.29.*

(1) *Let $K \subset L \subset M$ be compact subsets that are products close to the boundary. We denote by $f_{KL}\colon (M, M\setminus L) \to (M, M\setminus K)$ the inclusion map of pairs. The map $f_{KL*}\colon H_n(M, M\setminus L) \to H_n(M, M\setminus K)$ sends α_L^M to α_K^M.*
(2) *Let U be an open subset of M and let $A \subset U$ be a compact subset that is a product close to the boundary. We use Lemma 45.28 to view U as an oriented topological manifold. If $i\colon U \to M$ denotes the inclusion map, then $i_*(\alpha_A^U) = \alpha_A^M$.*

Proof. The lemma follows easily from the functoriality of homology groups and the uniqueness statement of Theorem 46.29. □

Exercises for Chapter 46.

Exercise 46.1. Give an example of a representative for the $\mathbb{F}_2$-fundamental class for the Klein bottle.

Exercise 46.2. Can you find a representative for the $\mathbb{F}_2$-fundamental class of $\mathbb{R}\mathrm{P}^2$ with two or three summands?

Exercise 46.3. Let M be a connected n-dimensional topological manifold without boundary and let K be a compact subset. Show that there exists an open subset $U \subset M$ that contains K and such that the closure $\overline{U}$ is compact.

Exercise 46.4. Let M be a closed orientable connected non-empty topological manifold of dimension $n \geq 3$. We now know that $H_n(M;\mathbb{Z}) \cong \mathbb{Z}$ and that $H_{n-1}(M;\mathbb{Z})$ is torsion-free. Furthermore we know that $H_0(M;\mathbb{Z}) \cong \mathbb{Z}$. Can we also say something about the other homology groups? More precisely, are there any restrictions on $H_{n-2}(M;\mathbb{Z})$ or can any finitely generated abelian group be isomorphic to $H_{n-2}(M;\mathbb{Z})$ for some such manifold?

Exercise 46.5.

(a) Let M be a compact, connected n-dimensional topological manifold with non-empty boundary. Show that $H_{n-1}(M;\mathbb{Z}) \cong \mathbb{Z}^k$ for some $k \in \mathbb{N}_0$.
Hint: You can use that we already obtained some results for closed manifolds, in particular we have a good understanding of $H_{n-1}(DM;\mathbb{Z})$. You could start with the case that M is orientable and afterwards you could consider the case that M is non-orientable.

(b) Let M be a connected n-dimensional topological manifold. Suppose that M is non-compact. Does it follow that $H_{n-1}(M;\mathbb{Z})$ is a free abelian group? It suffices to give a short justification for your answer.

Exercise 46.6. Let $X = S^1 \cup \{*\}$ be the topological space that is given by the circle "with two 1's", where the topology is defined in the same way as we defined the topology on the "line with two 0's" on page 53. It is straightforward to see that X is o-locally homeomorphic to open subsets of $\mathbb{R}$, in fact one can easily find a finite atlas for X. Furthermore we know by Lemma 3.1 (4) that X is second-countable. But X is not a topological manifold since it is not Hausdorff. The argument of Exercise 33.2 shows that $H_1(X;\mathbb{F}_2) \cong \mathbb{F}_2^2$. This shows that in the proof of Theorem 46.3 at some point we must have used that topological manifolds are Hausdorff. Where did we make use of this fact?

47. Chirality

In this section we will take a short break from overly abstract concepts and we study chirality of objects in $\mathbb{R}^3$, knots and manifolds. We will run into several questions which will motivate us to develop new tools in the study of topological spaces.

47.1. **Chiral objects.** In physics or chemistry an object X in $\mathbb{R}^3$ is called *amphichiral* (or often short *achiral*) if it agrees with its mirror image, otherwise it is called *chiral*. To make this definition more precise we have to explain what we mean by "mirror image" and what we mean by "agree".

First of all, given a hyperplane $H \subset \mathbb{R}^3$ through the origin we denote by $\rho_H \colon \mathbb{R}^3 \to \mathbb{R}^3$ the reflection in the hyperplane H.[877] Sometimes in this chapter we will extend ρ_H to a map from $S^3 = \mathbb{R}^3 \cup \{\infty\}$ to itself by setting $\rho_H(\infty) = \infty$.

The following lemma says that any two reflections in a hyperplane through the origin differ by multiplication by a matrix in SO(3).

Lemma 47.1. *If H and G are two hyperplanes in $\mathbb{R}^3$ through the origin, then there exists a matrix $A \in \mathrm{SO}(3)$ such that for all $v \in \mathbb{R}^3$ we have*

$$\rho_G(v) \;=\; A \cdot \rho_H(v).$$

Sketch of proof. With respect to the standard basis of $\mathbb{R}^3$ the maps ρ_G and ρ_H are represented by orthogonal matrices P and Q with determinant -1. The matrix $A = PQ^{-1}$ then lies in SO(3) and for any $v \in \mathbb{R}^3$ we have $\rho_G(v) = Pv = A \cdot Qv = A \cdot \rho_H(v)$. □

The above discussion leads us to the following definitions.

Definition. Let X be a subset of $\mathbb{R}^3$.

(1) We say another subset Y of $\mathbb{R}^3$ *agrees with* X if there exists a matrix $A \in \mathrm{SO}(3)$ and a point $P \in \mathbb{R}^3$ such that $X = A \cdot Y + P = \{A \cdot y + P \,|\, y \in Y\}$.
(2) For every hyperplane $H \subset \mathbb{R}^3$ we refer to $\rho_H(X)$ as the *mirror image* of X.[878]
(3) We say X is *amphichiral* if its mirror image agrees with X, otherwise we say X is *chiral*.

Examples.

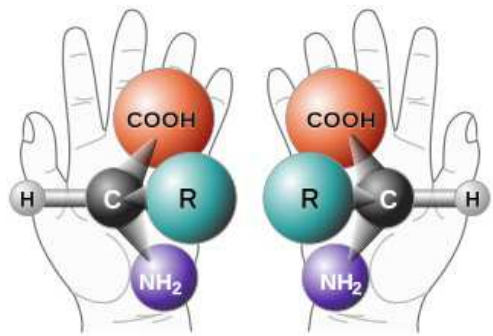
(1) Human hands are chiral, indeed, the left-hand does not agree with the right-hand. In fact the term chirality is derived from the Greek word for hand, $\chi\epsilon\iota\rho$.[879]
(2) Many molecules are chiral, see e.g. Figure 670 for an example of a chiral molecule.[880]

[877] How is the reflection in a hyperplane defined?

[878] To be precise, the definition of the mirror image depends on the choice of the hyperplane. By Lemma 47.1 reflections in two different hyperplanes differ by multiplication by a matrix in SO(3), i.e. the mirror images with respect to different hyperplanes agree in the above sense.

[879] The same word is also the etymological root for the German word "Chirurg".

[880] In fact, how can you show that the molecule is chiral?



source: `https://en.wikipedia.org/wiki/Chirality`

FIGURE 670.

47.2. **Chiral knots.** Now we turn our focus to knots. We recall some of the relevant definitions from Section 10.8.

Definition.

(1) A *knot* is a 1-dimensional submanifold of $S^3 = \mathbb{R}^3 \cup \{\infty\}$ that is diffeomorphic to S^1.
(2) Given a knot $K \subset \mathbb{R}^3$ the reflection of K in any hyperplane is called *mirror* of K and denoted by K^*.[881]

Example. In Figure 47.2 we show the trefoil and its mirror and we also show the figure-8 knot and its mirror.

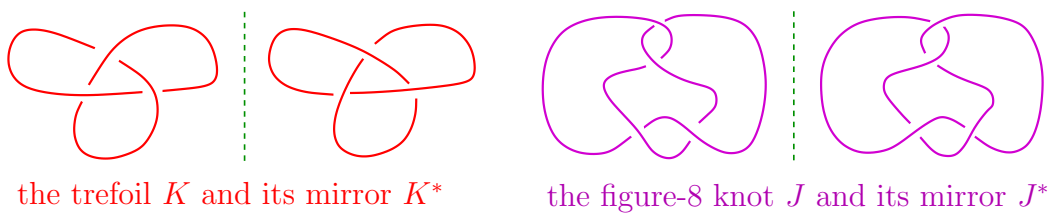


FIGURE 671.

Usually we are only interested in knots "up to deformation", i.e. we say that two knots are equivalent if one knot can be deformed into the other. This leads us to the following definition.

Definition. We say that *two knots K and J are equivalent* if there exists a smooth isotopy from K to J, i.e. a smooth map

$$\begin{array}{rcl} F\colon S^1 \times [0,1] & \to & S^3 \\ (z,t) & \mapsto & F(z,t) \end{array}$$

[881] Usually in pictures we consider the reflection in the xz-plane.

such that the following hold:

(1) we have $F(S^1 \times \{0\}) = K$ and $F(S^1 \times \{1\}) = J$, and
(2) for each $t \in [0,1]$ the map $S^1 \to S^3$ given by $z \mapsto F(z,t)$ is an embedding.

Examples.

(1) The knots shown in Figure 672 are equivalent.

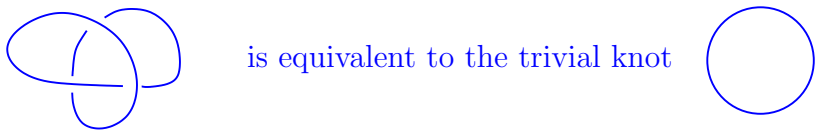

FIGURE 672.

(2) Let K and J be knots in $\mathbb{R}^3$. We claim that if K and J agree, then they are also equivalent. We pick $A \in \mathrm{SO}(3)$ and $P \in \mathbb{R}^3$ with $J = A \cdot K + P$. By Lemma 1.96 (1) we know that $\mathrm{SO}(3)$ is path-connected, in particular there exists a path $\gamma\colon [0,1] \to \mathrm{SO}(3)$ with $\gamma(0) = \mathrm{id}$ and $\gamma(1) = A$. We pick an embedding $f\colon S^1 \to S^3$ with $f(S^1) = K$. The desired isotopy from K to $J = A \cdot K + P$ is then given by $F(z,t) := \gamma(t) \cdot f(z) + t \cdot P$.

We are now naturally led to the following definition.

Definition. We say that a knot K in $\mathbb{R}^3$ is *amphichiral* if it is equivalent to its mirror image, otherwise we call the knot K *chiral*.

Examples.

(1) The trivial knot equals of course its mirror, in particular the trivial knot is amphichiral.
(2) In Figure 673 we show that the figure-8 knot J is equivalent to its mirror image J^*, i.e. the figure-8 knot is also amphichiral.

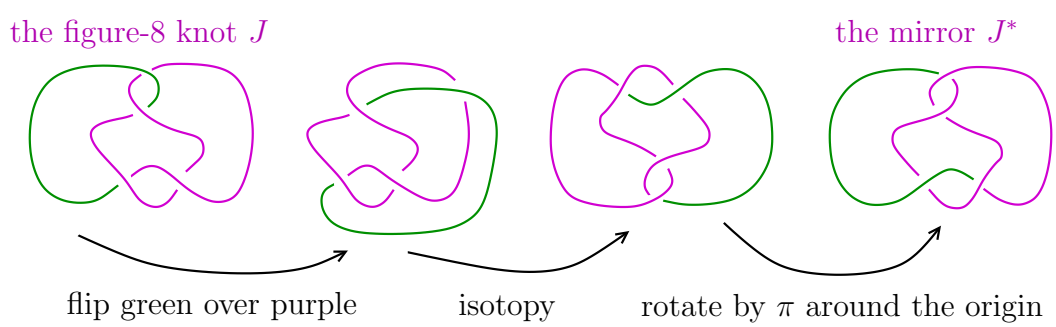

FIGURE 673.

It is now natural to ask whether the trefoil is amphichiral. But endless hours of playing around with the trefoil do not lead to any success. So the suspicion arises that the following question should be answered in the negative.

Question 47.2. *Is the trefoil chiral?*

The question that naturally arises is, what does this discussion have to do with homology groups? How can we address this question using the tools of algebraic topology? In the following section we will turn Question 47.2 into a question about homology groups.

47.3. **Chiral topological manifolds.**

Definition. Let M be a compact oriented topological manifold. We say that M is *amphichiral* if M admits an orientation-reversing self-homeomorphism, otherwise we say that M is *chiral*.

In the next proposition we will give several criteria for a self-homeomorphism to be orientation-preserving.

Proposition 47.3. *Let M be a compact oriented connected n-dimensional topological manifold and let $f\colon M \to M$ be a homeomorphism. Then the following three statements are equivalent:*

(1) *the map f is orientation-preserving in the sense of the definition on page 1099,*
(2) *there exists a point $x \in M \setminus \partial M$ and an open neighborhood U of x, e.g. $U = M$, such that*[882]

$$f_*(\underbrace{\textit{orientation at } x}_{\in H_n(U,U\setminus\{x\};\mathbb{Z})}) \;=\; \underbrace{\textit{orientation at } f(x)}_{\in H_n(f(U),f(U)\setminus\{f(x)\};\mathbb{Z})},$$

(3) *we have $f_*([M]) = [M]$.*

Suppose M is in fact a manifold and that f is a diffeomorphism. We equip M with the orientation in the sense of Section 3.8 coming from Proposition 45.22. Then the above are equivalent to the statement

(4) *the map f is orientation-preserving in the sense of Section 3.8.*

Analogously the above statements also hold if in (1) *and* (4) *we replace "orientation-preserving" by "orientation-reversing" and if in* (2) *and* (3) *we add a minus sign.*

For the most part the proof of Proposition 47.3 boils down to the following lemma which is also useful in its own right.

Lemma 47.4. *Let $f\colon M \to N$ be a map between compact oriented connected n-dimensional topological manifolds such that $f(\partial M) \subset \partial N$. Let $x \in M \setminus \partial M$ and let U be an open*

[882]Recall that by the construction of Lemma 45.28 the orientation on M induces an orientation on any open subset.

neighborhood of x with the property that f restricts to a homeomorphism $f\colon U \to f(U)$ and such that $f^{-1}(f(x)) = \{x\}$. Then

$$\begin{aligned}\deg(f\colon M \to N) &= \deg(f_*\colon H_n(M, M \setminus \{x\}; \mathbb{Z}) \to H_n(N, N \setminus \{f(x)\}; \mathbb{Z}) \\ &= \deg(f_*\colon H_n(U, U \setminus \{x\}; \mathbb{Z}) \to H_n(f(U), f(U) \setminus \{f(x)\}; \mathbb{Z}).\end{aligned}$$

Proof. Let M and N be compact connected n-dimensional topological manifolds that are equipped with orientations $\{\mu_x\}_{x \in M \setminus \partial M}$ and $\{\nu_x\}_{x \in N \setminus \partial N}$. Furthermore let f, $x \in M \setminus \partial M$ and U as above. We consider the following commutative diagram

$$\begin{tikzcd}
H_n(M, \partial M; \mathbb{Z}) \arrow[r, "f_*"] \arrow[d] & H_n(N, \partial N; \mathbb{Z}) \arrow[d] \\
H_n(M, M \setminus \{x\}; \mathbb{Z}) \arrow[r, "f_*"] & H_n(N, N \setminus \{f(x)\}; \mathbb{Z}) \\
H_n(U, U \setminus \{x\}; \mathbb{Z}) \arrow[r, "f_*"] \arrow[u] & H_n(f(U), f(U) \setminus \{f(x)\}; \mathbb{Z}). \arrow[u]
\end{tikzcd}$$

We make the following observations:

(1) the top vertical maps are isomorphisms by Theorem 46.2,
(2) the bottom vertical maps are isomorphisms by the Excision Theorem 45.8,
(3) it follows from Corollary 46.5 that the vertical maps send the fundamental classes $[M]$ and $[N]$ to the orientations μ_x respectively $\nu_{f(x)}$.

The desired equalities follow easily from these observations.[883] □

Now we can also provide a proof for Proposition 47.3.

Sketch of the proof $(*)$. The equivalence of (1), (2) and (3) follows easily from Lemma 47.4. Now suppose M that is in fact a manifold and that f is a diffeomorphism. The equivalence of (2) and (4) is a straightforward consequence of Lemma 45.23 and the Excision Theorem 45.8. Once again we leave it to the reader to fill in the details. □

Examples. Let $n \in \mathbb{N}_0$.

(1) It follows from Lemma 32.16 (6) that the map

$$\begin{aligned}\rho\colon S^n &\to S^n \\ (x_0, \dots, x_{n-1}, x_n) &\mapsto (x_0, \dots, x_{n-1}, -x_n),\end{aligned}$$

i.e. the map that is given by reflection in the $x_n = 0$ hyperplane, is orientation-reversing. This shows that the sphere S^n is amphichiral.

(2) Let M be a closed, oriented topological manifold. It follows from (1) and the naturality of the Künneth Theorem 43.8 for topological spaces that the map

$$\begin{aligned}S^n \times M &\to S^n \times M \\ (x, P) &\mapsto (\rho(x), P),\end{aligned}$$

[883] Where on earth did we use the hypothesis that $f^{-1}(f(x)) = \{x\}$?

is orientation-reversing. This shows that the product of the sphere S^n with any closed, oriented topological manifold is amphichiral.

Now we want to relate the notion of amphichiral knots to the notion of amphichiral manifolds. Before we can do so we recall the following definition.

Definition. Let $K \subset \mathbb{R}^3$ be a knot. We pick a trivial tubular neighborhood $\overline{B}^2 \times K$ as provided by the Tubular Neighborhood Theorem 10.19. We refer to $X_K := S^3 \setminus (B^2 \times K)$ as the *exterior of* K.[884]

FIGURE 674.

The following proposition together with Proposition 47.3 now relates Question 47.2 to homology groups.

Proposition 47.5. *Let $K \subset \mathbb{R}^3$ be a knot. If K is amphichiral, then the knot exterior X_K is also amphichiral.*

Remark. We had just seen in Proposition 47.5 that the exterior of an amphichiral knot is amphichiral. The converse of that statement is also true, i.e. if the exterior of a knot is amphichiral, then the knot is also amphichiral. But this direction is much harder to prove. To the best of my knowledge it follows from a very difficult theorem by Cameron Gordon and John Luecke [GL, p. 371] from 1989.

Proof. Let $K \subset \mathbb{R}^3$ be an amphichiral knot. We pick a trivial tubular neighborhood $\nu K = \overline{B}^2 \times K$ as provided by the Tubular Neighborhood Theorem 10.19 and we use it to define the knot exterior X_K. By Proposition 47.3 it suffices to show that there exists a homeomorphism $f\colon X_K \to X_K$ with $f_*([X_K]) = -[X_K]$.

We denote by ρ the reflection in a hyperplane of $\mathbb{R}^3$. As usual we extend ρ to a self-homeomorphism of $S^3 = \mathbb{R}^3 \cup \{\infty\}$ by setting $\rho(\infty) = \infty$. We write $K^* = \rho(K)$ and $\nu K^* = \rho(\nu K)$. By hypothesis there exists a smooth isotopy from K^* to K. By the Isotopy Extension Theorem 10.21 this smooth isotopy extends to a smooth diffeotopy of S^3. This means that we have a smooth map

$$F\colon S^3 \times [0,1] \;\to\; S^3$$

[884]As we pointed out in Lemma 40.7, the exterior X_K is a compact orientable manifold and the diffeomorphism type of X_K as an oriented manifold is well-defined, i.e. it is independent of the choice of the tubular neighborhood.

such that $F_0 = \mathrm{id}$, such that each F_t is a diffeomorphism and such that $F_1(K^*) = K$. We write $\Phi := F_1 \colon S^3 \to S^3$. Then $\Phi(\nu K^*)$ is also a closed tubular neighborhood for K and by Proposition 10.20 there exists an orientation-preserving diffeomorphism $\Psi \colon S^3 \to S^3$ with $\Psi(\Phi(\nu K^*)) = \nu K$. We write $f := \Psi \circ \Phi \circ \rho$.

Now we consider the following commutative diagram

$$\begin{tikzcd}
H_3(S^3) \arrow[r, "\rho_*"] \arrow[d, "\cong"] & H_3(S^3) \arrow[r, "\Phi_*"] \arrow[d, "\cong"] & H_3(S^3) \arrow[r, "\Psi_*"] \arrow[d, "\cong"] & H_3(S^3) \arrow[d, "\cong"] \\
H_3(S^3, \nu K) \arrow[r, "\rho_*"] & H_3(S^3, \nu K^*) \arrow[r, "\Phi_*"] & H_3(S^3, \Phi(\nu K^*)) \arrow[r, "\Psi_*"] & H_3(S^3, \nu K) \\
H_3(X_K, \partial X_K) \arrow[u, "\cong"] \arrow[r, "\rho_*"] \arrow[rrr, bend right, "f_* = (\Psi \circ \Phi \circ \rho)_*"'] & H_3(X_{K^*}, \partial X_{K^*}) \arrow[u, "\cong"] \arrow[r, "\Phi_*"] & H_3(\Phi(X_{K^*}), \Phi(\partial X_{K^*})) \arrow[u, "\cong"] \arrow[r, "\Psi_*"] & H_3(X_K, \partial X_K). \arrow[u, "\cong"]
\end{tikzcd}$$

Here the upper left vertical map is an isomorphism by the long exact sequence of the pair $(S^3, \nu K)$ and the fact that $H_i(\nu K) = 0$ for $i = 2, 3$ since $\nu K = K \times B^2$ is homotopy equivalent to S^1. Exactly the same argument shows that in fact all upper vertical maps are isomorphisms. The lower vertical maps are induced by the inclusion of pairs of topological spaces. All of them are isomorphisms by the Excision Theorem for Manifolds 45.10.

By Proposition 47.3 we are done once we have shown that the composition of three bottom horizontal maps is given by multiplication by -1. By the commutative diagram it suffices to prove the analogous statement for the composition of the top three horizontal maps. It follows from Lemma 32.16 (6) that the top-left horizontal map is given by multiplication by -1. It is a consequence of Proposition 30.5 that the top-middle horizontal map is the identity, since Φ is homotopic to the identity. Finally using Proposition 47.3 we see that the top-right horizontal map is the identity since Ψ is orientation-preserving. $\square$

Now we continue with our discussion of examples of amphichiral manifolds.

Examples.

(1) We had just seen on page 1150 that topological manifolds of the type $S^n \times M$ are amphichiral. It follows that the torus $S^1 \times S^1$ is amphichiral.
(2) The surface of genus 2 is amphichiral. Pictorially an orientation-reversing self-homeomorphism is given by "reflection in the yz-plane", see Figure 675 on the left. In the "octagon-picture" an orientation-reversing self-homeomorphism is given by the reflection f in the line illustrated in Figure 675 on the left. It follows easily from Proposition 47.3 applied to the point $x = 0$ and U an open disk around x together with Lemma 45.14 that the map f is indeed orientation-reversing.
(3) All other compact oriented 2-dimensional manifolds are also amphichiral. We show some of the orientation-reversing maps in Figure 676. In Exercise 47.2 we will discuss how these maps can be described rigorously.

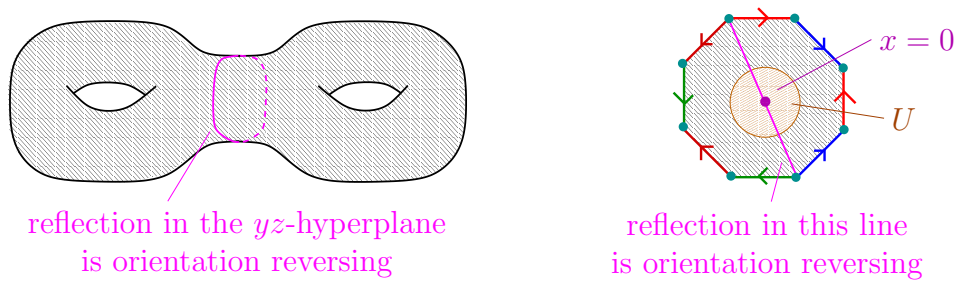

FIGURE 675.

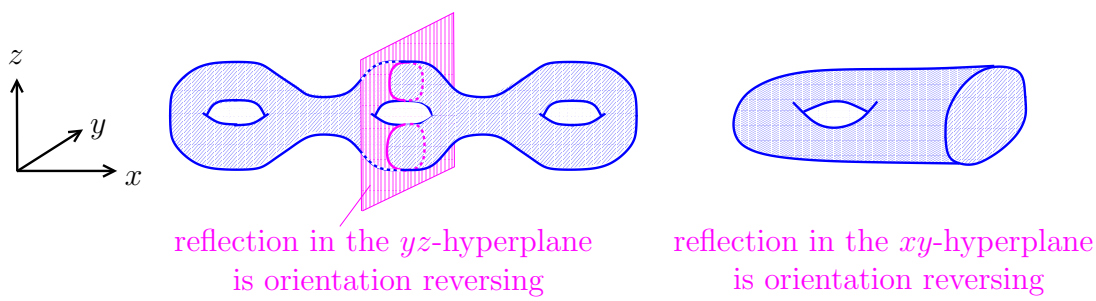

FIGURE 676.

(4) Example (2) can also be generalized as follows: if M is a compact oriented topological manifold, then its double $DM = (M \sqcup M')/\sim$ is amphichiral. Indeed, the map $f\colon DM \to DM$ that swaps the two copies of M is orientation-reversing. This follows immediately from the definition of the orientation of DM that we gave in Lemma 45.29.

The long list of examples of amphichiral manifolds raises the following question.

Question 47.6. *Are there compact oriented topological manifolds that are chiral?*

We end this chapter with a short discussion of lens spaces. Let $p \in \mathbb{N}$ and let $q \in \mathbb{N}$ be coprime to p. On page 266 we defined the lens space

$$L(p,q) \;=\; S^3/\mathbb{Z}_p \;=\; \big\{(z_1,z_2) \in \mathbb{C}^2 \,\big|\, |z_1|^2 + |z_2|^2 = 1\big\}/(z_1,z_2) \sim (e^{2\pi i/p} z_1, e^{2\pi i q/p} z_2).$$

Furthermore, on page 266 we had equipped $L(p,q)$ with the orientation which turns the obvious projection map $S^3 \to L(p,q)$ into an orientation-preserving map.

Now let $q, r \in \mathbb{Z}$ with $\gcd(p,q) = \gcd(p,r) = 1$. In Lemma 7.7 we showed that if $q \equiv \pm r^{\pm 1} \bmod p$, then $L(p,q)$ and $L(p,r)$ are diffeomorphic.[885] The following lemma is now a slight refinement of Lemma 7.7.

Lemma 47.7. *Let $p \in \mathbb{N}$ and let $q, r \in \mathbb{Z}$ with $\gcd(p,q) = \gcd(p,r) = 1$.*

[885] We still don't know whether the converse holds.

(1) *In the case that* $q \equiv r^{\pm 1} \bmod p$ *there exists an orientation-preserving diffeomorphism* $L(p,q) \to L(p,r)$.
(2) *On the other hand, if* $q \equiv -r^{\pm 1} \bmod p$, *then there exists an orientation-reversing diffeomorphism* $L(p,q) \to L(p,r)$.

Proof. Let $p \in \mathbb{N}$ and let $q, r \in \mathbb{Z}$ with $\gcd(p,q) = \gcd(p,r) = 1$. We suppose that $q \equiv \pm r^{\pm 1} \bmod p$. As in the proof of Lemma 7.7 we define a diffeomorphism

$$\Phi\colon S^3 \to S^3$$

as follows:

$$\begin{array}{llll}
\text{Case 1: } q \equiv r \bmod p. & (z_1, z_2) & \mapsto & (z_1, z_2) \\
\text{Case 2: } q \equiv -r \bmod p. & (z_1, z_2) & \mapsto & (z_1, \overline{z_2}) \\
\text{Case 3: } q \equiv r^{-1} \bmod p. & (z_1, z_2) & \mapsto & (z_2, z_1) \\
\text{Case 4: } q \equiv -r^{-1} \bmod p. & (z_1, z_2) & \mapsto & (z_2, \overline{z_1})
\end{array}$$

In all four cases it is straightforward to verify that the map descends to a diffeomorphism $L(p,q) \to L(p,r)$. It follows fairly easily from Lemma 32.16 and Proposition 47.3 that the diffeomorphism Φ is orientation-preserving in cases 1 and 3 and that it is orientation-reversing in cases 2 and 4.[886] The lemma now follows from the fact that the projection maps $S^3 \to L(p,q)$ and $S^3 \to L(p,r)$ are orientation-preserving. □

Example. Note that $-2^{-1} \equiv -3 \equiv 2 \bmod 5$. Thus we obtain from Lemma 47.7 that there exists an orientation-reversing diffeomorphism $L(5,2) \to L(5,2)$, i.e. the lens space $L(5,2)$ is amphichiral.

The argument of the previous example does not work for the lens space $L(3,1)$. So the following question arises:

Question 47.8. *Is the lens space* $L(3,1)$ *chiral?*

With our present knowledge we are not able to answer Questions 47.2, 47.6 and 47.8. The key to answering these three questions will be the cohomology groups that we introduce in the next chapter.

Exercises for Chapter 47.

Exercise 47.1. Why is the molecule shown in Figure 677 chiral? How can you show rigorously that the two molecules left and right cannot be turned into one another using a translation and a matrix in SO(3)?

Exercise 47.2.

[886] For example in case 3 the map is given by $(x_1, x_2, x_3, x_4) \mapsto (x_3, x_4, x_1, x_2)$ which is the composition of two reflections in hyperplanes, namely in the $x_1 = x_3$ and the $x_2 = x_4$ hyperplane.

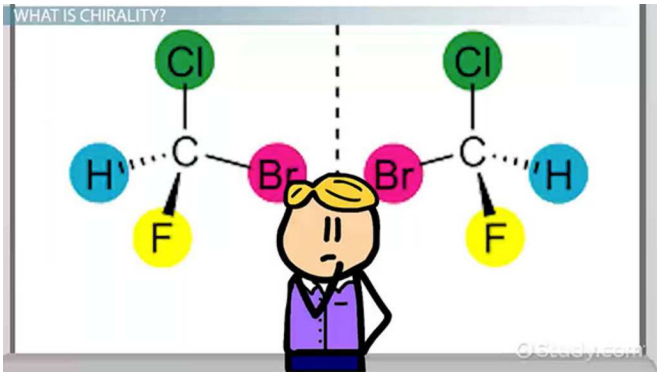

Figure 677.

(a) Give a rigorous proof for the statement that the surface of genus 3 is amphichiral. More precisely, give a precise description of the surface of genus 3 (e.g. as a dodecagon with appropriate identifications) and indicate carefully an orientation-reversing self-homeomorphism.
(b) Do the same exercise for the genus 2 surface with two open disks removed.

48. The cohomology groups of a topological space

48.1. **The Hom-functor.** We start out with the following obvious notation.

Notation. Given a group A and an abelian group G we write

$$\mathrm{Hom}(A,G) \;=\; \{\text{all group homomorphisms } A \to G\}.$$

The set of homomorphisms $\mathrm{Hom}(A,G)$ has the structure of an abelian group with the sum of two homomorphisms $\varphi,\psi\colon A \to G$ given by the group homomorphism that is defined by $(\varphi+\psi)(a) := \varphi(a)+\psi(a)$.

Example. We leave it as an exercise to show that for any $n \in \mathbb{N}$ and any abelian group G we have a natural isomorphism $\mathrm{Hom}(\mathbb{Z}_n, G) \cong \ker(G \xrightarrow{\cdot n} G)$. In particular for any $m \in \mathbb{N}$ we have $\mathrm{Hom}(\mathbb{Z}_n,\mathbb{Z}_m) \cong \mathbb{Z}_{\gcd(n,m)}$.

On several occasions we will implicitly and explicitly use the following lemma which is an immediate consequence of Lemma 11.1.

Lemma 48.1. $(*)$ *Let G be an abelian group. If S is a non-empty set, then the homomorphism*[887] [888] [889]

$$\begin{array}{rcl} \mathrm{Hom}(\mathbb{Z}^{(S)},G) & \to & \{\textit{all maps from the set } S \textit{ to } G\} \\ (\varphi\colon \mathbb{Z}^{(S)} \to G) & \mapsto & \left(\begin{array}{ccc} S & \to & G \\ s & \mapsto & \varphi(s) \end{array}\right) \end{array}$$

is an isomorphism. In particular the map

$$\begin{array}{rcl} \mathrm{Hom}(\mathbb{Z},G) & \to & G \\ \varphi & \mapsto & \varphi(1) \end{array}$$

is an isomorphism.

Let G be an abelian group and let $f\colon A \to B$ be a group homomorphism. Then f induces a homomorphism

$$\begin{array}{rcl} f^*\colon \mathrm{Hom}(B,G) & \to & \mathrm{Hom}(A,G) \\ (\varphi\colon B \to G) & \mapsto & \left(\begin{array}{ccc} A & \to & G \\ a & \mapsto & \varphi(f(a)) \end{array}\right). \end{array}$$

Example. Let G be an abelian group.

---

[887] Recall that on page 366, given a non-empty set S we defined

$$\mathbb{Z}^S \;:=\; \text{all maps from } S \text{ to } \mathbb{Z}.$$

and we defined the free abelian group generated by S to be the subgroup

$$\mathbb{Z}^{(S)} \;:=\; \text{all maps from } S \text{ to } \mathbb{Z} \text{ which are non-zero for only finitely many } s \in S.$$

Following the notation introduced on page 366 we view each $s \in S$ as an element in $\mathbb{Z}^{(S)}$.

[888] Why do we write $\mathbb{Z}^{(S)}$ in the lemma? Should it not be $\mathbb{Z}^S$?

[889] Note that the group structure on G turns both sides of the lemma into a group, so the given map clearly respects this group structure, i.e. the given map is a homomorphism.

(1) If A is a subgroup of a group B and if $i\colon A \to B$ is the inclusion map, then for each homomorphism $\varphi\colon B \to G$ the homomorphism $i^*\varphi\colon A \to G$ is just the restriction of φ to $A \subset B$.
(2) If S is a subset of a set T, then we have a natural inclusion $i\colon \mathbb{Z}^{(S)} \to \mathbb{Z}^{(T)}$ and it follows from Lemma 48.1 that the map $i^*\colon \operatorname{Hom}(\mathbb{Z}^{(T)}, G) \to \operatorname{Hom}(\mathbb{Z}^{(S)}, G)$ is an epimorphism. Indeed, we just extend the map $S \to G$ to a map $T \to G$ by assigning the trivial element in G to all elements in $T \setminus S$.

It follows immediately from the definitions that

$$(\mathrm{id}_A)_* = \mathrm{id}_{\operatorname{Hom}(A,G)}, \quad \text{for all groups } A$$

and

$$(g \circ f)^* = f^* \circ g^* \qquad \text{for all homomorphisms } f\colon A \to B \text{ and } g\colon B \to C.$$

Put differently, given an abelian group G the maps

$$\begin{array}{rcl} A & \mapsto & \operatorname{Hom}(A, G) \\ (f\colon A \to B) & \mapsto & (f^*\colon \operatorname{Hom}(B, G) \to \operatorname{Hom}(A, G)) \end{array}$$

define a *contravariant* functor from the category of groups to the category of abelian groups.

Remark. If R is a commutative ring, for example if $R = \mathbb{Z}_n, R = \mathbb{Z}, R = \mathbb{Q}$ or $R = \mathbb{R}$, then for any group C the set of homomorphisms $\operatorname{Hom}(C, R)$ forms an R-module in an obvious way. More precisely, given a homomorphism $\varphi\colon C \to R$ and $r \in R$ we define $r\varphi$ to be the homomorphism given by $c \mapsto r \cdot \varphi(c)$. Now we see easily that the above maps $A \mapsto \operatorname{Hom}(A, R)$ and $f \mapsto f^*$ define a contravariant functor from the category of groups to the category of R-modules.

The following lemma might be familiar from linear algebra. We refer to [Rot2, Theorem 2.32(i)] for more details.

Lemma 48.2. *Let $\{A_i\}_{i\in I}$ be a family of groups and let G be an abelian group. Then the map*

$$\begin{array}{rcl} \operatorname{Hom}\left(\bigoplus_{i\in I} A_i, G\right) & \to & \prod_{i\in I} \operatorname{Hom}(A_i, G) \\ f & \mapsto & \prod_{i\in I} f|_{A_i} \end{array}$$

is an isomorphism.

The following rather technical lemma will be used later on.

Lemma 48.3. *Let $\{\{A_i\}_{i\in\mathbb{N}}, \{\varphi_{ij}\colon A_i \to A_j\}_{i\le j}\}$ be a direct system of groups and let G be an abelian group. Then*

$$\{\{\operatorname{Hom}(A_i, G)\}_{i\in\mathbb{N}}, \{\varphi_{ij}^*\colon \operatorname{Hom}(A_j, G) \to \operatorname{Hom}(A_i, G)\}_{i\le j}\}$$

is an inverse system of abelian groups (or modules if G is a commutative ring), and we have a natural isomorphism

$$\operatorname{Hom}\left(\varinjlim A_i, G\right) \xrightarrow{\cong} \varprojlim \operatorname{Hom}(A_i, G)$$

of abelian groups (or modules if G is a commutative ring).

Proof. As so often for arguments regarding limits, the proof follows mostly from unraveling the definitions. We refer to [Rot2, Proposition 5.26] for more details. □

We continue with the following lemma which we will use on many occasions.

Lemma 48.4. *Let*

$$0 \to A \xrightarrow{i} B \xrightarrow{p} C \to 0$$

be a short exact sequence of abelian groups and let G be an abelian group. If C is free abelian, then the dual sequence

$$0 \to \operatorname{Hom}(C,G) \xrightarrow{p^*} \operatorname{Hom}(B,G) \xrightarrow{i^*} \operatorname{Hom}(A,G) \to 0$$

is also exact.

Proof. It follows from the hypothesis that C is a free abelian and from Lemma 33.1 that the initial short exact sequence splits. But this means that, according to Lemma 33.2, that there exists an isomorphism $\Phi\colon B \to A \oplus C$ such that the following diagram commutes:

$$\begin{tikzcd}
0 \arrow[r] & A \arrow[r, "i"] \arrow[d, "="] & B \arrow[r, "p"] \arrow[d, "\Phi", "\cong"'] & C \arrow[r] \arrow[d, "="] & 0 \\
0 \arrow[r] & A \arrow[r, "a\mapsto(a,0)"] & A \oplus C \arrow[r, "(a,c)\mapsto c"] & C \arrow[r] & 0.
\end{tikzcd}$$

By applying the contravariant $\operatorname{Hom}(-,G)$ functor we obtain the upper half of the following commutative diagram:

$$\begin{tikzcd}
0 & \operatorname{Hom}(A,G) \arrow[l] & \operatorname{Hom}(B,G) \cong \arrow[l, "i^*"'] & \operatorname{Hom}(C,G) \arrow[l, "p^*"'] & 0 \arrow[l] \\
0 & \operatorname{Hom}(A,G) \arrow[l] \arrow[u, "="] & \operatorname{Hom}(A\oplus C,G) \arrow[l, "(a\mapsto(a,0))^*"'] \arrow[u, "\Phi^*"] & \operatorname{Hom}(C,G) \arrow[l, "((a,c)\mapsto c)^*"'] \arrow[u, "="] & 0 \arrow[l] \\
0 & \operatorname{Hom}(A,G) \arrow[l] \arrow[u, "="] & \operatorname{Hom}(A,G)\oplus\operatorname{Hom}(C,G) \arrow[l, "f\oplus g\mapsto f"'] \arrow[u, "(f\oplus)\mapsto(a\oplus c\mapsto f(a)+g(c))"'] & \operatorname{Hom}(C,G) \arrow[l, "g\mapsto 0\oplus g"'] \arrow[u, "="] & 0. \arrow[l]
\end{tikzcd}$$

One can easily verify that the lower half of the diagram commutes. Furthermore it is evident that the bottom sequence is exact. Finally it is straightforward to see that the vertical maps are isomorphisms we obtain that the upper sequence is also exact. But that is exactly what we wanted to prove. □

48.2. **Cochain complexes.** Now we introduce the notion of a cochain complex and of its cohomology groups. A cochain complex is exactly the same as a chain complex except that the boundary map now increases the degree by one instead of lowering it by one.

Definition.

(1) A *cochain complex* is a sequence

$$\leftarrow D^n \xleftarrow{\delta_{n-1}} D^{n-1} \xleftarrow{\delta_{n-2}} \dots \xleftarrow{\delta_1} D^1 \xleftarrow{\delta_0} D^0 \leftarrow 0$$

of maps between abelian groups such that for all $i \in \mathbb{N}_0$ we have $\delta_{i+1} \circ \delta_i = 0$. We refer to the maps δ_* as *coboundary maps*.

(2) We define the *n-th cohomology group* of a cochain complex (D^*, δ_*) to be

$$H^n(D) \;:=\; \frac{\ker\{\delta_n \colon D^n \to D^{n+1}\}}{\operatorname{im}\{\delta_{n-1} \colon D^{n-1} \to D^n\}}.$$

Example. It follows from [Le2, Theorem 14.24] that the groups

$$\Omega_n(M) \;:=\; \{\text{all smooth } n\text{-forms on } M\}, \quad n \in \mathbb{N}_0$$

together with the differentials $d_n \colon \Omega_n(M) \to \Omega_{n+1}(M)$ define a cochain complex. The corresponding cohomology groups are called the de Rham cohomology groups of M. We will return to this example in more detail at a later stage.

Now we will see that most of the definitions and algebraic results for chain complexes can be generalized almost verbatim to cochain complexes.

Definition.

(1) A *cochain map* $f \colon C^* \to D^*$ between two cochain complexes consists of a family $\{f_n \colon C^n \to D^n\}_{n \in \mathbb{N}_0}$ of maps that commute with the coboundary maps, i.e. such that for all $n \in \mathbb{N}_0$ we have

$$\underset{\substack{\uparrow \\ \delta_n \colon D^n \to D^{n+1}}}{\delta_n} \circ f_n \;=\; f_{n+1} \circ \underset{\substack{\uparrow \\ \delta_n \colon C^n \to C^{n+1}}}{\delta_n} \colon C^n \;\to\; D^{n+1}.$$

(2) Let $f, g \colon C^* \to D^*$ be two cochain maps between two cochain complexes C^* and D^*. A *cochain homotopy* $P = \{P_n\}_{n \in \mathbb{N}_0}$ between the cochain maps f and g consists of a family $\{P_n \colon C^n \to D^{n-1}\}_{n \in \mathbb{N}_0}$ of maps such that for each $n \in \mathbb{N}_0$ we have

$$\delta_{n-1} \circ P_n + P_{n+1} \circ \delta_n \;=\; f_n - g_n.$$

If there exists a cochain homotopy between cochain maps f and g, then we say that f and g are *cochain homotopic*.

Remark. For orientation we summarize in the following diagram all objects arising in the definition of a cochain homotopy:

$$\begin{tikzcd}
{} & C^{n+1} \arrow[l, "\delta_{n+1}"'] \arrow[d, "f_{n+1}, g_{n+1}"] \arrow[dr, "P_{n+1}"] & C^n \arrow[l, "\delta_n"'] \arrow[d, "f_n, g_n"] \arrow[dr, "P_n"] & C^{n-1} \arrow[l, "\delta_{n-1}"'] \arrow[d, "f_{n-1}, g_{n-1}"] & {} \arrow[l, "\delta_{n-2}"'] \\
{} & D^{n+1} \arrow[l, "\delta_{n+1}"] & D^n \arrow[l, "\delta_n"] & D^{n-1} \arrow[l, "\delta_{n-1}"] & {} \arrow[l, "\delta_{n-2}"]
\end{tikzcd}$$

The statements of the next lemma surely do not come as much of a surprise.

Lemma 48.5.

(1) *If $f\colon C^* \to D^*$ is a cochain map between cochain complexes C^* and D^*, then the map*
$$\begin{array}{rcl} f_*\colon H^n(C) & \to & H^n(D) \\ [c] & \mapsto & [f_n(c)] \end{array}$$
is well-defined.

(2) *Two cochain maps that are cochain homotopic induce the same map on cohomology groups.*

(3) *Cochain complexes together with the cochain maps form a category, called the* category of cochain complexes.

Proof. The first statement is proved the same way as Lemma 29.7 and the second statement is proved the same way as Lemma 30.1. The last statement follows immediately from the definitions. □

One of the most important algebraic constructions in Algebraic Topology II was that we could associate to a short exact sequence of chain complexes a long exact sequence of homology groups. We have an almost identical construction for short exact sequences of cochain complexes and their cohomology groups. We will discuss this construction in detail. So let
$$0 \to C^* \xrightarrow{f} B^* \xrightarrow{g} A^* \to 0$$
be a short exact sequence of cochain complexes. In particular for each $n \in \mathbb{N}_0$ we have a commutative diagram
$$\begin{tikzcd} 0 \arrow[r] & C^{n+1} \arrow[r, "f_{n+1}"] & B^{n+1} \arrow[r, "g_{n+1}"] & A^{n+1} \arrow[r] & 0 \\ 0 \arrow[r] & C^n \arrow[r, "f_n"] \arrow[u, "\delta_n"] & B^n \arrow[r, "g_n"] \arrow[u, "\delta_n"] & A^n \arrow[r] \arrow[u, "\delta_n"] & 0 \end{tikzcd}$$
where the horizontal sequences are exact. Now we will define a *connecting homomorphism*
$$\delta\colon H^n(A) \to H^{n+1}(C).$$
The definition is almost verbatim the same as the definition on page 770 of the connecting homomorphism in homology. More precisely, we perform the following steps:

(1) Let $z \in H^n(A)$.
(2) We pick $\alpha \in A^n$ with $z = [\alpha]$.
(3) By the surjectivity of g_n we have $\alpha = g_n(\beta)$ for some $\beta \in B^n$.
(4) From the commutativity of the diagram and the exactness of the horizontal sequences we see that $\delta_n(\beta) = f_{n+1}(\gamma)$ for some uniquely determined $\gamma \in C^{n+1}$.
(5) We put $\delta_n(z) := [\gamma] \in H^{n+1}(C)$.

The following proposition is now the obvious analogue of Lemma 31.9 and Proposition 31.10. We leave the proof as an exercise to the reader.

Proposition 48.6.

(1) *The connecting homomorphisms are well-defined and they are indeed homomorphisms.*[890]

(2) *The connecting homomorphisms are natural in the sense that commuting diagrams of short exact sequences of cochain complexes give rise to commuting diagrams of cohomology groups involving the connecting homomorphisms.*

(3) *If*

$$0 \to C^* \xrightarrow{f} B^* \xrightarrow{g} A^* \to 0$$

is a short exact sequence of cochain complexes, then

$$\cdots \to H^n(C) \xrightarrow{f_*} H^n(B) \xrightarrow{g_*} H^n(A) \xrightarrow{\delta} H^{n+1}(C) \xrightarrow{f_*} H_{n+1}(B) \xrightarrow{g_*} \dots$$

forms an exact sequence.

Finally the following lemma says that cohomology commutes with direct sums and direct products. The proof of the lemma is identical to the proof of Lemma 29.12 that we did not give.

Lemma 48.7. *If $\{C_a\}_{a\in A}$ is a family of cochain complexes, then the family of inclusion maps $C_a \to \bigoplus_{a\in A} C_a$, $a \in A$, and $C_a \to \prod_{a\in A} C_a$, $a \in A$, induce isomorphisms*

$$\bigoplus_{a\in A} H^n(C_a) \xrightarrow{\cong} H^n\Big(\bigoplus_{a\in A} C_a\Big) \quad \textit{and} \quad \prod_{a\in A} H^n(C_a) \xrightarrow{\cong} H^n\Big(\prod_{a\in A} C_a\Big).$$

48.3. **Dual cochain complexes.** Now we will present the arguably most important source of cochain complex.

Definition. Let

$$(C_*, \partial_*)\colon \ \to C_{n+1} \xrightarrow{\partial_{n+1}} C_n \xrightarrow{\partial_n} \dots \xrightarrow{\partial_2} C_1 \xrightarrow{\partial_1} C_0 \to 0$$

be a chain complex and let G be an abelian group. For each $n \in \mathbb{N}_0$ we write

$$\delta_n := \partial_{n+1}^*\colon \operatorname{Hom}(C_n, G) \to \operatorname{Hom}(C_{n+1}, G).$$

We obtain the following cochain complex[891]

$$\leftarrow \operatorname{Hom}(C_{n+1}, G) \xleftarrow{\delta_n} \operatorname{Hom}(C_n, G) \xleftarrow{\delta_{n-1}} \dots \xleftarrow{\delta_1} \operatorname{Hom}(C_1, G) \xleftarrow{\delta_0} \operatorname{Hom}(C_0, G) \leftarrow 0.$$

We refer to it as *cochain complex dual to* (C_*, ∂_*) and we denote it by $\operatorname{Hom}(C_*, G)$. We define the *$n$-th cohomology group of the chain complex (C_*, ∂_*) with G-coefficients* as the cohomology of the cochain complex $(\operatorname{Hom}(C_*, G), \delta_*)$, i.e. we define

$$H^n(C; G) := \frac{\ker\{\delta_n\colon \operatorname{Hom}(C_n, G) \to \operatorname{Hom}(C_{n+1}, G)\}}{\operatorname{im}\{\delta_{n-1}\colon \operatorname{Hom}(C_{n-1}, G) \to \operatorname{Hom}(C_n, G)\}}.$$

[890]Furthermore, if the cochain complexes are cochain complexes over a commutative ring R, then the connecting homomorphism is in fact an R-module homomorphism.

[891]It follows the functoriality property of $\operatorname{Hom}(-, G)$ that $\delta_n \circ \delta_{n-1} = \partial_{n+1}^* \circ \partial_n^* = (\partial_n \circ \partial_{n+1})^* = 0$, i.e. this is indeed a cochain complex.

Remark.

(1) We had just defined $\delta_n := \partial^*_{n+1}$, i.e. the coboundary map in the cochain complex is the dual of the boundary map in the chain complex. This is the same definition that is used in most books on algebraic topology, see e.g. [Mun, p. 251] or [Hat, p. 189]. In the excellent book by Bredon [Bre, p. 321] the coboundary is defined as $\delta_n := (-1)^{n+1} \cdot \partial^*_{n+1}$.

The different conventions do not affect the definition of the cohomology groups, but they will affect the sign conventions in some formulas later on. In particular if one cites results from other books one needs to be careful about the sign conventions used.

(2) If R is a commutative ring and if (C_*, ∂_*) is a chain complex, then it follows immediately from the remark on page 1157 that the corresponding cohomology groups $H^n(C; R)$ come naturally with the structure of R-modules.

Many of the statements about chain complexes and their homology groups hold in a slightly modified version also for cohomology groups. For example we have the following purely algebraic lemma.

Lemma 48.8. *Let G be an abelian group.*

(1) *Let $f = \{f_n \colon C_n \to D_n\}_{n\in\mathbb{N}_0}$ be a chain map between chain complexes C_* and D_*, then for each $n \in \mathbb{N}_0$ the map*

$$\begin{array}{rcl} f^* \colon \operatorname{Hom}(D_n, G) & \to & \operatorname{Hom}(C_n, G) \\ (\varphi \colon D_n \to G) & \mapsto & \big(\underbrace{C_n \xrightarrow{f_n} D_n \xrightarrow{\varphi} G}_{=\varphi\circ f_n = f_n^*\varphi}\big) \end{array}$$

is a cochain map, in particular it induces a well-defined map

$$f^* \colon H^n(D; G) \to H^n(C; G).$$

(2) *For each $n \in \mathbb{N}_0$ the maps*

$$C_* \mapsto H^n(C; G) \quad \text{and} \quad f \mapsto f^*$$

define a contravariant *functor from the category of chain complexes to the category of abelian groups. (If G is a commutative ring, then this is in fact a functor to the category of G-modules.)*

(3) *Let $f, g \colon C_* \to D_*$ be two chain maps. If they are chain homotopic, then the induced cochain maps $f^*, g^* \colon \operatorname{Hom}(D_*, G) \to \operatorname{Hom}(C_*, G)$ are cochain homotopic and therefore the induced maps $f^*, g^* \colon H^n(D; G) \to H^n(C, G)$ are identical.*

(4) *If $f_* \colon C_* \to D_*$ is a chain homotopy equivalence, then for every $n \in \mathbb{N}_0$ the induced maps $f^* \colon H^n(D; G) \to H^n(C; G)$ are isomorphisms.*

Proof.

(1) Let $f = \{f_n \colon C_n \to D_n\}_{n\in\mathbb{N}_0}$ be a chain map. This means that for each $n \in \mathbb{N}_0$ we have
$$f_{n-1} \circ \partial_n \;=\; \partial_n \circ f_n$$
which implies by the fact that $A \mapsto \mathrm{Hom}(A, G)$ is a *contravariant* functor that
$$\underbrace{\partial_n^*}_{=\delta_{n-1}} \circ f_{n-1}^* \;=\; f_n^* \circ \underbrace{\partial_n^*}_{=\delta_{n-1}}.$$
We have thus shown that f^* is a cochain map. The second statement follows immediately from Lemma 48.5.

(2) This statement follows easily from the definitions.

(3) Let $\{P_n \colon C_n \to D_{n+1}\}_{n\in\mathbb{N}_0}$ be a chain homotopy $P = \{P_n\}_{n\in\mathbb{N}_0}$ between f and g. Recall that this means that for each $n \in \mathbb{N}_0$ we have
$$\partial_{n+1} \circ P_n + P_{n-1} \circ \partial_n \;=\; f_n - g_n.$$
We set $Q_n := P_{n-1}^* \colon \mathrm{Hom}(D_n, G) \to \mathrm{Hom}(C_{n-1}, G)$. It follows again from the fact that $A \mapsto \mathrm{Hom}(A, G)$ is a *contravariant* functor that
$$\underbrace{P_n^*}_{=Q_{n+1}} \circ \underbrace{\partial_{n+1}^*}_{=\delta_n} + \underbrace{\partial_n^*}_{=\delta_{n-1}} \circ \underbrace{P_{n-1}^*}_{=Q_n} \;=\; f_n^* - g_n^*.$$
This shows that the maps $Q_n, n \in \mathbb{N}_0$ form a cochain homotopy. It follows from Lemma 48.5 that the induced maps on cohomology groups agree.

(4) The last statement follows immediately from (2) and (3). □

In Lemma 42.7 we basically saw that for any chain complex C_* and any homomorphism $f \colon A \to B$ of abelian groups the maps
$$\begin{array}{rcl} f_* \colon C_* \otimes A & \to & C_* \otimes B \\ \Big[\sum\limits_{i=1}^k \sigma_i \otimes a_i\Big] & \mapsto & \Big[\sum\limits_{i=1}^k \sigma_i \otimes f(a_i)\Big] \end{array}$$
form a chain map, in particular for each $n \in \mathbb{N}_0$ we obtain an induced map
$$f_* \colon H_n(C_* \otimes A) \;\to\; H_n(C_* \otimes B).$$
Similarly, it is straightforward to check that the maps
$$\begin{array}{rcl} f_* \colon \mathrm{Hom}(C_n, A) & \to & \mathrm{Hom}(C_n, B) \\ \varphi & \mapsto & f \circ \varphi \end{array}$$
define a cochain map, in particular we get for each $n \in \mathbb{N}_0$ an induced map
$$f_* \colon H^n(C_*; A) \;\to\; H^n(C_*; B)$$
The following lemma basically says that these maps have all the properties one could possibly hope for. The lemma can be viewed as a cohomological analogue of Lemma 42.7.

Lemma 48.9. $(*)$

(1) *Given a chain complex C_* and $n \in \mathbb{N}_0$ the maps*

$$\begin{array}{rcl} A & \mapsto & H^n(C_*; A) \\ (f\colon A \to B) & \mapsto & (f_*\colon H^n(C_*; A) \to H^n(C_*; B)) \end{array}$$

form a covariant functor from the category of abelian groups to the category of abelian groups. In other words, "cohomology is covariant in the coefficients".

(2) *Given a group homomorphism $f\colon A \to B$ the maps f_* define a natural transformation from the contravariant functor $C_* \mapsto H^n(C_*; A)$ to the contravariant functor $C_* \mapsto H^n(C_*; B)$.*

Proof. The two statements follow basically immediately from the definitions. □

48.4. **The singular cohomology groups of topological spaces.** Now we apply the somewhat dry algebra from the last section to our favorite chain complex, namely the singular chain complex of a pair of topological spaces.

Definition. Let (X, A) be a pair of topological spaces and let G be an abelian group.

(1) For each $n \in \mathbb{N}_0$ we write

$$C^n(X, A; G) := \operatorname{Hom}(C_n(X, A), G) \quad \text{and} \quad \delta_n := \partial_{n+1}^*\colon C^n(X, A; G) \to C^{n+1}(X, A; G).$$

We use the following notation:

(a) We refer to the elements of $C^n(X, A; G)$ as *singular n-cochains*,

(b) we refer to the elements in the kernel of $\delta_n\colon C^n(X, A; G) \to C^{n+1}(X, A; G)$ as *singular n-cocycles* and

(c) we refer to the elements in the image of $\delta_{n-1}\colon C^{n-1}(X, A; G) \to C^n(X, A; G)$ as *singular n-coboundaries*.

When $n \in \mathbb{N}_0$ is understood then sometimes we just write δ instead of δ_n.

(2) We refer to the cochain complex

$$\cdots \leftarrow C^{n+1}(X, A; G) \xleftarrow{\delta_n} C^n(X, A; G) \xleftarrow{\delta_{n-1}} C^{n-1}(X, A; G) \leftarrow \ldots \xleftarrow{\delta_0} C^0(X, A; G) \leftarrow 0$$

as the *singular cochain complex of (X, A) with G-coefficients*. We define the *n-th singular cohomology group of (X, A) with G-coefficients*[892] as follows

$$H^n(X, A; G) := H^n(C_*(X, A); G) = \frac{\ker\{\delta_n\colon C^n(X, A; G) \to C^{n+1}(X, A; G)\}}{\operatorname{im}\{\delta_{n-1}\colon C^{n-1}(X, A; G) \to C^n(X, A; G)\}}.$$

(3) If $A = \varnothing$ then we just write $C^n(X; G) = C^n(X, \varnothing; G)$ and similar for cohomology groups.

(4) If $G = \mathbb{Z}$ then often we drop the coefficients from the notation, e.g. often we write $H^n(X, A) = H^n(X, A; \mathbb{Z})$.

[892] In most cases we drop the adjective "singular" and we just talk of the n-th cohomology group of (X, A) with coefficients in G. We only refer to it as singular cohomology when we want to distinguish it from de Rham cohomology.

Remark. As we had already pointed out on page 1162, if R is a commutative ring, e.g. if $R = \mathbb{Z}_n, \mathbb{Z}, \mathbb{Q}, \mathbb{R}$ or $R = \mathbb{C}$, then the cohomology groups $H^n(X, A; R)$ can in fact be viewed as R-modules and the coboundary maps are R-module homomorphisms.

In the following we first discuss the definition and examples of the absolute cohomology groups $H^*(X; G)$. A little later we will discuss the arguably even more confusing relative cohomology groups $H^*(X, A; G)$. We start this discussion of absolute cohomology groups with the following remark.

Remark. Let G be an abelian group.

(1) Let X be a topological space and let $n \in \mathbb{N}_0$. We denote by $S_n(X)$ the set of singular n-simplices. We then have natural identifications

$$C^n(X; G) \;=\; \mathrm{Hom}(C_n(X), G) \;\underset{\substack{\uparrow \\ \text{by definition } C_n(X) = \mathbb{Z}^{(S_n(X))}}}{=}\; \mathrm{Hom}\left(\mathbb{Z}^{(S_n(X))}, G\right) \;\underset{\substack{\uparrow \\ \text{identification given by Lemma 48.1}}}{=}\; \text{maps from } S_n(X) \text{ to } G.$$

Put differently, a singular n-cochain is precisely the same as assigning to each singular n-simplex an element in G. We will use this bijection throughout the course without explicitly referring to it.

(2) Let X be a topological space. We recall that, following the discussion on page 736, we can identify the singular 0-simplices in X with the points in X. According to the discussion in (1) we can now make the identification

$$C^0(X; G) \;=\; \{\text{all maps from } X \text{ to } G\}.$$

Before we develop the theory of cohomology groups in detail we first want to consider some explicit examples. As a starter we consider cochains and cocycles on the topological spaces $\mathbb{R}$ and S^1.

Examples.

(1) We start out with the topological space $X = \mathbb{R}$. We consider the two functions

$$\begin{array}{rcl} \alpha_{\mathbb{R}} \colon \mathbb{R} & \to & \mathbb{R} \\ x & \mapsto & x \end{array} \quad \text{and} \quad \begin{array}{rcl} \alpha_{\mathbb{Z}} \colon \mathbb{R} & \to & \mathbb{Z} \\ x & \mapsto & \lfloor x \rfloor := \max\{n \in \mathbb{Z} \,|\, n \leq x\}. \end{array}$$

As pointed out above, these two functions define singular 0-cochains. We denote these 0-cochains again by $\alpha_{\mathbb{R}}$ and $\alpha_{\mathbb{Z}}$. For any singular 1-simplex $\mu \colon \Delta^1 \to \mathbb{R}$ we have

$$(\delta\alpha_{\mathbb{R}})(\mu) \;\underset{\substack{\uparrow \\ \text{definition of } \delta}}{=}\; \alpha_{\mathbb{R}}(\partial\mu) \;\underset{\substack{\uparrow \\ \text{see page 738}}}{=}\; \alpha_{\mathbb{R}}(\mu(0,1) - \mu(1,0)) \;\underset{\substack{\uparrow \\ \text{definition of } \alpha_{\mathbb{R}}}}{=}\; \mu(0,1) - \mu(1,0)$$

and, slightly more interesting, it follows immediately from the above discussion and the definition of $\alpha_{\mathbb{Z}}$ that

$$(\delta\alpha_{\mathbb{Z}})(\mu) \;=\; \alpha_{\mathbb{Z}}(\partial\mu) \;=\; \begin{cases} \#\{n \in \mathbb{Z} \,|\, \mu(1,0) < n \leq \mu(0,1)\}, & \text{if } \mu(0,1) \geq \mu(1,0) \\ -\#\{n \in \mathbb{Z} \,|\, \mu(0,1) < n \leq \mu(1,0)\}, & \text{if } \mu(1,0) \geq \mu(0,1). \end{cases}$$

In a somewhat informal way we can say that the cochain $\delta\alpha_{\mathbb{Z}}\colon C_1(\mathbb{R}) \to \mathbb{Z}$ applied to a singular 1-simplex μ measures how many integers the simplex μ "crosses from left to right". We refer to Figure 678 for an illustration of $\delta\alpha_{\mathbb{Z}}$.

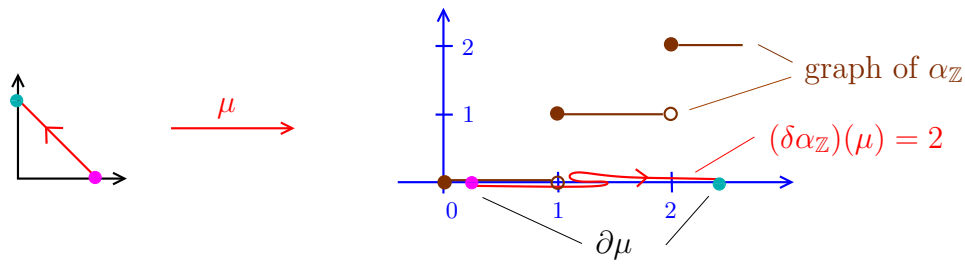

FIGURE 678.

(2) Now we consider the topological space $X = S^1$. As usual we denote by $p\colon \mathbb{R} \to S^1$, $t \mapsto e^{2\pi i t}$ the universal covering of S^1. Let $\sigma\colon \Delta^1 \to S^1$ be a singular 1-simplex. Since Δ^1 is simply connected it follows from Proposition 20.8 that σ lifts to a map $\widetilde{\sigma}\colon \Delta^1 \to \mathbb{R}$. The lift is not unique, but it is straightforward to see that any two lifts differ by addition by an integer. For a singular 1-simplex $\sigma\colon \Delta^1 \to S^1$ we pick a lift $\widetilde{\sigma}\colon \Delta^1 \to \mathbb{R}$ of σ and we define

$$\theta_{\mathbb{R}}(\sigma) \;:=\; \underset{\substack{\uparrow \\ \in C_1(\mathbb{R})}}{(\delta\alpha_{\mathbb{R}})(\widetilde{\sigma})} \;=\; \widetilde{\sigma}(0,1) - \widetilde{\sigma}(1,0)$$

and we also define

$$\theta_{\mathbb{Z}}(\sigma) \;:=\; (\delta\alpha_{\mathbb{Z}})(\widetilde{\sigma}) \;=\; \begin{cases} \#\{n \in \mathbb{Z} \,|\, \widetilde{\sigma}(1,0) < n \le \widetilde{\sigma}(0,1)\}, & \text{if } \widetilde{\sigma}(0,1) \ge \widetilde{\sigma}(1,0) \\ -\#\{n \in \mathbb{Z} \,|\, \widetilde{\sigma}(0,1) < n \le \widetilde{\sigma}(1,0)\}, & \text{if } \widetilde{\sigma}(1,0) \ge \widetilde{\sigma}(0,1). \end{cases}$$

Since any two lifts of σ differ by addition by an integer we see that $\theta_{\mathbb{R}}(\sigma)$ and $\theta_{\mathbb{Z}}(\sigma)$ are both well-defined, i.e. independent of the choice of the lift $\widetilde{\sigma}$. The definitions of $\theta_{\mathbb{R}}$ and $\theta_{\mathbb{Z}}$ are illustrated in Figure 679.[893]

As we had explained on page 1165, these two maps $\theta_{\mathbb{R}}$ and $\theta_{\mathbb{Z}}$ actually define singular 1-cochains in $C^1(S^1, \mathbb{R})$ and $C^1(S^1; \mathbb{Z})$.

[893]Here is an alternative description of the singular 1-cochain θ: We denote by $\Phi\colon [0,1] \to \Delta^1$ the homeomorphism that is given by $\Phi(t) = (1-t, t)$. Then for any singular 1-simplex $\sigma\colon \Delta^1 \to S^1$ we have

$$\theta_{\mathbb{R}}(\sigma) \;=\; \frac{1}{2\pi i} \int\limits_{\sigma\circ\Phi} \frac{1}{z}\, dz,$$

where the right-hand side denotes the path integral of the holomorphic function $\frac{1}{z}$ over the continuous path $\sigma \circ \Phi\colon [0,1] \to S^1$. We leave it as an amusing exercise to verify this equality using complex analysis.

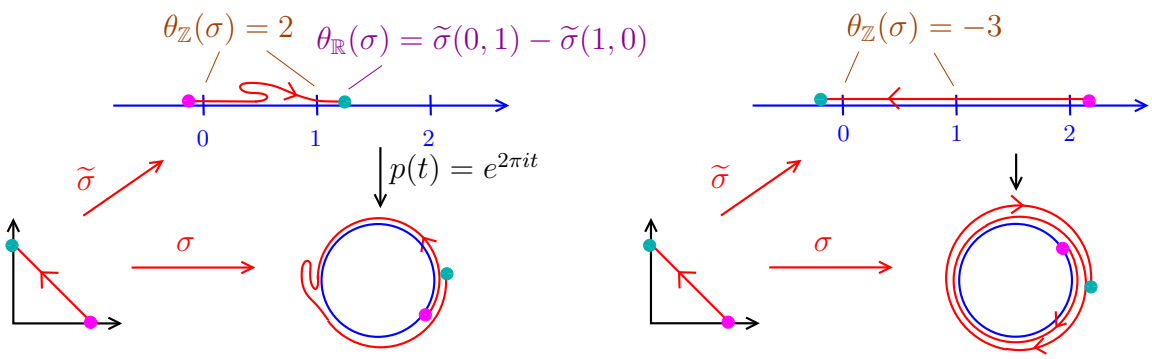

FIGURE 679.

As an example we consider the singular 1-simplex

$$\mu\colon \Delta^1 \;\to\; S^1 \quad \text{that is defined by} \quad \mu(1-t,t) \;=\; e^{2\pi i t}.$$

A lift of μ to the above universal covering $\mathbb{R} \to S^1$ is given by the singular 1-simplex

$$\widetilde{\mu}\colon \Delta^1 \;\to\; \mathbb{R} \quad \text{that is defined by} \quad \widetilde{\mu}(1-t,t) \;=\; t.$$

It follows immediately from the definitions that $\theta_{\mathbb{R}}(\mu) = \theta_{\mathbb{Z}}(\mu) = 1$.

The following lemma shows that $\theta_{\mathbb{R}}$ and $\theta_{\mathbb{Z}}$ are actually quite interesting singular 1-cochains.

Lemma 48.10. *We continue with the notation from the previous example.*

(1) *The singular 1-cochains $\theta_{\mathbb{R}}$ and $\theta_{\mathbb{Z}}$ are cocycles, in particular $\theta_{\mathbb{R}}$ defines an element in $H^1(S^1;\mathbb{R})$ and $\theta_{\mathbb{Z}}$ defines an element in $H^1(S^1;\mathbb{Z})$.*

(2) *The singular 1-cochain cochains $\theta_{\mathbb{R}}$ and $\theta_{\mathbb{Z}}$ are not the coboundary of a singular 0-cochain, i.e. the cohomology classes $[\theta_{\mathbb{R}}] \in H^1(S^1;\mathbb{R})$ and $[\theta_{\mathbb{Z}}] \in H^1(S^1;\mathbb{Z})$ are non-trivial.*

Proof.

(1) We will first prove that the singular 1-cochain $\theta_{\mathbb{R}}$ is a cocycle. Thus we have to show that $\delta_1\theta_{\mathbb{R}} = 0 \in C^2(S^1,\mathbb{R}) = \operatorname{Hom}(C_2(S^1),\mathbb{R})$. So let $\sigma\colon \Delta^2 \to S^1$ be a singular 2-simplex. We have to show that $(\delta_1\theta_{\mathbb{R}})(\sigma) = \theta_{\mathbb{R}}(\partial\sigma) = 0$.

As before we denote by $p\colon \mathbb{R} \to S^1$, $t \mapsto e^{2\pi i t}$ the universal covering of S^1. Since Δ^2 is simply connected we can apply Proposition 20.2 to obtain a lift of $\sigma\colon \Delta^2 \to S^1$ to a map $\widetilde{\sigma}\colon \Delta^2 \to \mathbb{R}$. We refer to Figure 680 for an illustration. Then

$$\theta_{\mathbb{R}}(\partial\sigma) \underset{\substack{\uparrow\\ \text{definition of } \partial}}{=} \theta_{\mathbb{R}}\Big(\sum_{j=0}^{2}(-1)^j\cdot\sigma\circ i_j^2\Big) \underset{\substack{\uparrow\\ \text{by definition of } \theta_{\mathbb{R}} \text{ and}\\ \text{since } \widetilde{\sigma}\circ i_j^2 \text{ is a lift of } \sigma\circ i_j^2}}{=} (\delta\alpha_{\mathbb{R}})\Big(\overbrace{\sum_{j=0}^{2}(-1)^j\cdot\widetilde{\sigma}\circ i_j^2}^{=\partial\widetilde{\sigma}}\Big) \underset{\substack{\uparrow\\ \text{by definition of } \delta\alpha_{\mathbb{R}} \text{ and } \partial\widetilde{\sigma}}}{=} \alpha_{\mathbb{R}}(\partial(\partial\widetilde{\sigma})) \underset{\substack{\uparrow\\ \text{since } \partial\circ\partial=0}}{=} 0.$$

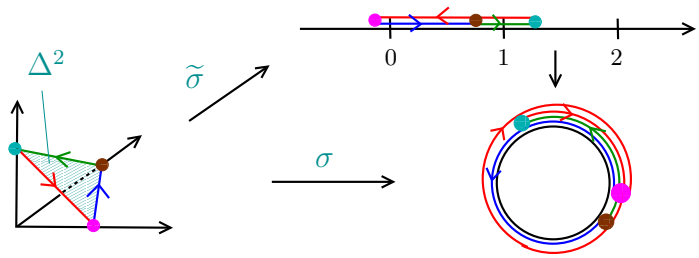

FIGURE 680.

Exactly the same argument applies to $\theta_{\mathbb{Z}}$.

(2) We still need to show that the singular 1-cochain cochains $\theta_{\mathbb{R}}$ and $\theta_{\mathbb{Z}}$ are not the coboundary of a singular 0-cochain. So let β be a singular 0-cochain. As usual we view β as a function $S^1 \to \mathbb{R}$. We consider again the singular 1-simplex $\mu\colon \Delta^1 \to S^1$ that is defined by $\mu(1-t,t) = e^{2\pi i t}$. Then

$$(\delta_0\beta)(\mu) \;=\; \beta(\,\partial(\mu)) \;=\; \beta\big(\underbrace{\mu(0,1)}_{=1\in S^1} - \underbrace{\mu(1,0)}_{=1\in S^1}\big) \;=\; 0.$$

But in the previous example we saw that $\theta_{\mathbb{R}}(\mu) = \theta_{\mathbb{Z}}(\mu) = 1$. □

Remark. In Lemma 48.10 we have just given a mysteriously simple proof that $H^1(S^1;\mathbb{R}) \neq 0$ and also that $H^1(S^1;\mathbb{Z}) \neq 0$.

We continue with another example of cochains.

Example. We return to the topological space $X = \mathbb{R}$. We fix a point $y \in \mathbb{R}$. We consider the cochain

$$\varphi_y\colon C_0(\mathbb{R}) \;\to\; \mathbb{Z}$$

that is determined by the function

$$\begin{array}{rcl} \mathbb{R} & \to & \mathbb{Z} \\ x & \mapsto & \begin{cases} 0, & \text{if } x \le y, \\ 1, & \text{else.} \end{cases} \end{array}$$

For any singular 1-simplex $d\colon \Delta^1 \to X = \mathbb{R}$ we have

$$(\delta_0\varphi_y)(d) \;=\; \varphi_y(\partial d) \;\underset{\substack{\uparrow \\ \text{since } \partial d = 1\cdot d(0,1) + (-1)\cdot d(1,0) \\ \text{and since } \varphi_y\colon C_0(\mathbb{R}) \to \mathbb{Z} \text{ is linear}}}{=}\; \varphi_y(d(0,1)) - \varphi_y(d(1,0)) \;=\; \begin{cases} 0, & \text{if } d(0,1), d(1,0) \le y, \\ 0, & \text{if } d(0,1), d(1,0) \ge y, \\ 1, & \text{if } d(1,0) \le y < d(0,1) \\ -1, & \text{if } d(0,1) \le y < d(1,0). \end{cases}$$

In a slightly informal way we can say that the homomorphism $\delta_0\varphi_y\colon C_1(\mathbb{R}) \to \mathbb{Z}$ applied to a singular 1-simplex d equals $+1$ if the simplex "crosses y from right to left" and it equals

-1 if the simplex "crosses y from left to right". We will make use of this singular 1-cochain on several occasions, hence we give it its own notation, namely we write

$$\gamma_y \ := \ \delta_0\varphi_y \ \in \ C^1(\mathbb{R};\mathbb{Z}).$$

We illustrate the singular 1-cochain $\gamma_y = \delta_0\varphi_y \in C^1(\mathbb{R};\mathbb{Z})$ in Figure 681.

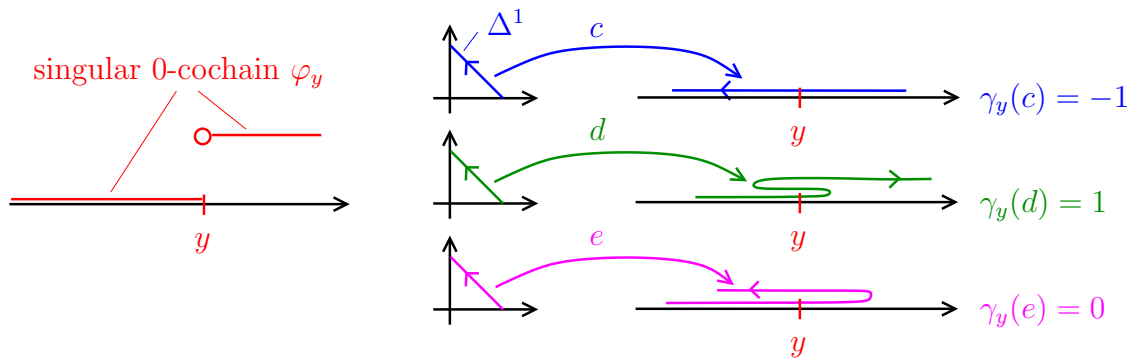

FIGURE 681.

After this long discussion of explicit cochains and cohomology classes we want to turn to more general results. The only two instances where we could compute homology groups without any problems was the 0-th homology group of a path-connected space, see Proposition 29.5, and the homology groups of a point, see Lemma 29.6. Not surprisingly we can also deal with the same situations with cohomology groups.

First of all we have the following analogue of Proposition 29.5.

Proposition 48.11. *Let X be a non-empty path-connected topological space and let G be an abelian group. Then the map*

$$\begin{array}{rcl} G & \to & H^0(X;G) \\ g & \mapsto & [\textit{0-cochain that assigns to each } x \in X \textit{ the value } g] \end{array}$$

is a well-defined map that is in fact an isomorphism. For any point $P \in X$ an inverse is given by the map

$$\begin{array}{rcl} H^0(X;G) & \to & G \\ [f] & \mapsto & f(P) \end{array}$$

Remark. At times we will use the isomorphism from Proposition 48.11 to identify the 0-th cohomology $H^0(X;G)$ of a path-connected topological space X with G.

Proof. We consider the "right-hand end" of the chain complex of $C_*(X)$ and of the cochain complex $\mathrm{Hom}(C_*(X),G)$:

$$C_1(X) \ \xrightarrow{\partial_1} \ C_0(X) \ \to \ 0 \quad \text{and} \quad \mathrm{Hom}(C_1(X),G) \ \xleftarrow{\delta_0=\partial_1^*} \ \mathrm{Hom}(C_0(X),G) \ \leftarrow \ 0.$$

Now we calculate that

$$\begin{aligned}
H^0(X;G) &= \ker\left\{\begin{array}{ccc} \mathrm{Hom}(C_0(X),G) & \to & \mathrm{Hom}(C_1(X),G) \\ (f\colon C_0(X)\to G) & \mapsto & (f\circ\partial_1\colon C_1(X)\to G)\end{array}\right\} \\
&\underset{\substack{\text{since the singular 1-simplices form a basis of } C_1(X)\\ \uparrow}}{=} \{\text{maps } f\colon X\to G \mid \underbrace{f(\partial_1(\sigma))}_{=f(\sigma(0,1))-f(\sigma(1,0))} = 0 \text{ for all singular 1-simplices } \sigma\colon \Delta^1\to X\} \\
&\underset{\substack{\text{by Lemma 48.1 we have the natural identification}\\ \mathrm{Hom}(C_0(X),G)=\text{maps from } X \text{ to } G\\ \uparrow}}{=} \text{all constant maps } X\to G \underset{\substack{\text{since } X \text{ is non-empty}\\ \uparrow}}{=} G.
\end{aligned}$$

since X is path-connected and since $\Delta^1\cong[0,1]$

The remaining statements of the proposition can be verified easily. □

In Exercise 48.1 we will prove the following lemma which can be viewed as an analogue of Lemma 29.6.

Lemma 48.12. *Let X be a topological space $X=\{x\}$ that consists of a single point x. For any abelian group G we have*

$$H^n(X;G) = \begin{cases} 0, & \text{if } n\geq 1,\\ G, & \text{if } n=0.\end{cases}$$

We want to conclude this section with a short discussion of relative cohomology classes. Before we do so we make the following observations:

Observation.

(1) Given an abelian group C, a subgroup D and an abelian group G we have a natural isomorphism

$$\begin{array}{rcl} \mathrm{Hom}(C/D,G) & \xrightarrow{\cong} & \text{all homomorphisms } C\to G \text{ that vanish on } D \\ (\varphi\colon C/D\to G) & \mapsto & (C\to C/D \xrightarrow{\varphi} G).\end{array}$$

We will use this isomorphism to identify the groups left and right.

(2) If S is a set and T is a subset, then for any abelian group G the identification

$$\mathrm{Hom}(\mathbb{Z}^{(S)},G) = \text{all maps from } S \text{ to } G$$

from Lemma 48.1 restricts to an isomorphism

$$\left\{f\in\mathrm{Hom}(\mathbb{Z}^{(S)},G)\,\middle|\, f \text{ vanishes on } \mathbb{Z}^{(T)}\right\} = \text{all maps } S\to G \text{ that are trivial on } T.$$

(3) It follows immediately from Lemma 48.1 and from (1) and (2) that given a pair of topological spaces (X,A) and an abelian group G we have for every $n\in\mathbb{N}_0$ a natural

isomorphism

$$\underbrace{\mathrm{Hom}(C_n(X,A),G)}_{=C^n(X,A;G)=\mathrm{Hom}(C_n(X)/C_n(A),G)} \;=\; \text{all maps } S_n(X)\to G \text{ that are trivial on } S_n(A).$$

We will often use this natural isomorphism to identify the left-hand side with the right-hand side.

Examples.

(1) In Exercise 48.2 we will modify the argument of Proposition 48.11 to show that for any path-connected topological space with non-empty subset A we have

$$H^0(X,A;G) \;=\; 0 \quad \text{for any abelian group } G.$$

(2) We write $I=[0,1]$. In this example we want to construct a non-trivial element in $H^1(I,\partial I)$. We consider the function

$$\begin{aligned} f\colon I &\to \mathbb{Z} \\ x &\mapsto \begin{cases} 0, & \text{if } x\in[0,\frac12) \\ 1, & \text{otherwise} \end{cases} \end{aligned}$$

which we use to define the singular 1-cochain

$$\begin{aligned} \rho\colon C_1(I) &\to \mathbb{Z} \\ (\sigma\colon \Delta^1\to I) &\mapsto f(\sigma(0,1))-f(\sigma(1,0)). \end{aligned}$$

Loosely speaking, similar to the singular 1-cochain φ_y from page 1169 the singular 1-cochain $\rho(\sigma)$ measures whether σ crosses $\frac12$, and if yes, in what direction. We refer to Figure 682 for an illustration. Since Δ^1 is connected and since $\{0,1\}$ is discrete it follows from Lemma 1.92 that any singular 1-simplex $\sigma\colon\Delta^1\to\partial I=\{0,1\}$ is constant. In particular in this case we have $\rho(\sigma)=0$. Thus we see, using the above observation, that ρ defines a map

$$\rho\colon C_1(I,\partial I) \;\to\; \mathbb{Z}.$$

In Exercise 48.5 we will see that ρ is a singular 1-cocycle and that it defines a non-trivial element in $H^1(I,\partial I;\mathbb{Z})$.

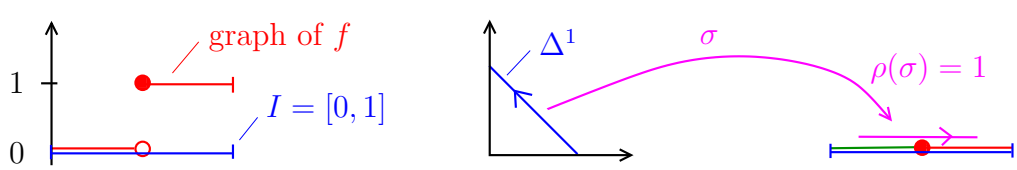

FIGURE 682.

48.5. **Basic properties of cohomology groups.** Now we will see that maps between pairs of topological spaces induce maps on cohomology groups.

Definition. Let G be an abelian group and let $f\colon (X,A) \to (Y,B)$ be a map between pairs of topological spaces. Recall that f induces a chain map $f_*\colon C_*(X,A) \to C_*(Y,B)$. For each $n \in \mathbb{N}_0$ we denote by

$$f^*\colon H^n(Y,B;G) \;\to\; H^n(X,A;G)$$

the induced map of cohomology groups that we obtain from Lemma 48.8 (1).

Example. We will see in Exercise 48.3 that any map $f\colon X \to Y$ between two path-connected non-empty topological spaces induces an isomorphism $f^*\colon H^0(Y;G) \to H^0(X;G)$. A very similar argument shows, that if Y is path-connected and X is non-empty, then $f^*\colon H^0(Y;G) \to H^0(X;G)$ is a monomorphism.

Notation. Let X be a topological space and let A be a subset. Furthermore let G be an abelian group. We denote by $i\colon A \to X$ the inclusion map. Sometimes we refer to $i^*\colon H^n(X;G) \to H^n(A;G)$ as the *restriction map.*

We summarize some basic properties of the induced maps in the following lemma.

Lemma 48.13. *Let G be an abelian group and let $n \in \mathbb{N}_0$.*

(1) *The maps*

$$\begin{array}{rcl} (X,A) & \mapsto & H^n(X,A;G) \\ (f\colon (X,A) \to (Y,B)) & \mapsto & (f^*\colon H^n(Y,B;G) \to H^n(X,A;G)) \end{array}$$

define a contravariant functor from the category of pairs of topological spaces to the category of abelian groups. (If G is a commutative ring, then this is in fact a functor to the category of G-modules.)

(2) *Let $f,g\colon (X,A) \to (Y,B)$ be maps between pairs of topological spaces. If f and g are homotopic, then they induce the same maps*

$$f^* \;=\; g^*\colon H^n(Y,B;G) \;\to\; H^n(X,A;G).$$

(3) *If $f\colon X \to Y$ is a homotopy equivalence between two topological spaces, then the induced map*

$$f^*\colon H^n(Y;G) \;\xrightarrow{\cong}\; H^n(X;G)$$

is an isomorphism. In particular the cohomology groups of homotopy equivalent topological spaces are isomorphic.

(4) *Let X be a topological space, let $A \subset B$ be subsets of X and let $n \in \mathbb{N}_0$. If A is a deformation retract of B, then the inclusion induced map*

$$H^n(X,B;G) \;\to\; H^n(X,A;G)$$

is an isomorphism. Similarly, if B is a deformation retract of X, then the inclusion induced map

$$H^n(X,A;G) \;\to\; H^n(B,A;G)$$

is an isomorphism.

Example. Lemma 48.13 (4), together with Lemma 48.12 and the discussion on page 308 implies that for any $n \geq 1$, any abelian group G and any $k \in \mathbb{N}_0$ we have

$$H^n(\mathbb{R}^k; G) \;=\; H^n\big(\overline{B}^k; G\big) \;=\; H^n\big(B^k; G\big) \;=\; H^n\big([0,1]^k; G\big) \;=\; H^n\big(\Delta^k; G\big) \;=\; 0.$$

Proof.

(1) This statement follows immediately from Lemma 48.8 (2) together with the fact that the map $(X, A) \mapsto C_*(X, A)$ defines a covariant functor from the category of pairs of topological spaces to the category of chain complexes.
(2) This statement is an immediate consequence of Proposition 31.15 together with Lemma 48.8 (3).
(3) This statement follows from (1) and (2).
(4) This statement is proved almost verbatim the same way as Corollary 31.16 (1) and (3). □

Many of the statements about homology groups can be modified to give corresponding statements about cohomology groups. For example we have the following lemma.

Lemma 48.14. *Let X be a topological space and let G be an abelian group.*

(1) *We denote by $\{X_j\}_{j\in J}$ the path-components of X. The inclusion maps $\iota_j \colon X_j \to X$, $j \in J$, induce an isomorphism*

$$\prod_{j\in J} \iota_j^* \colon H^n(X; G) \;\xrightarrow{\cong}\; \prod_{j\in J} H^n(X_j; G).$$

(2) *Suppose that X has finitely many path-components $X_1, \ldots, X_k$. If for $j = 1, \ldots, k$ we pick a point $P_j \in X_j$, then the map*

$$\begin{array}{rcl} H^0(X; G) & \to & G^k = \overbrace{G \times \cdots \times G}^{k \text{ times}} \\ [f] & \mapsto & (f(P_1), \ldots, f(P_k)) \end{array}$$

is an isomorphism.

Proof. Let X be a topological space with path-components $\{X_j\}_{j\in J}$ and let G be an abelian group. We have the following isomorphisms of cochain complexes:

$$\begin{array}{ccccc} \mathrm{Hom}(C_*(X), G) & \xrightarrow{\left(\bigoplus_{j\in J} \iota_{j*}\right)^*} & \mathrm{Hom}\Big(\bigoplus_{j\in J} C_*(X_j), G\Big) & \xrightarrow{\cong} & \prod_{j\in J} \mathrm{Hom}(C_*(X_j), G). \\ & \uparrow & & \uparrow & \\ & \text{Lemma 29.13} & & \text{Lemma 48.2} & \end{array}$$

The first statement now follows easily from this observation together with the fact that cohomology commutes with direct products, see Lemma 48.7.

The second statement follows from the first statement together with the calculation of 0-th cohomology groups of path-connected topological spaces in Proposition 48.11. □

The following lemma is the analogue of Proposition 31.13.

Lemma 48.15. *Given a triple (X, B, A) of topological spaces and an abelian group G we obtain a long exact sequence*

$$\dots \xrightarrow{\delta_{n-1}} H^n(X, B; G) \xrightarrow{p^*} H^n(X, A; G) \xrightarrow{i^*} H^n(B, A; G) \xrightarrow{\delta_n} H^{n+1}(X, B; G) \xrightarrow{p^*} \dots$$

hereby the maps are given as follows:

(1) *p^* is the map induced by the map $p\colon (X, A) \to (X, B)$,*
(2) *i^* is the map induced by the map $i\colon (B, A) \to (X, A)$,*
(3) *the connecting homomorphism $\delta_n\colon H^n(B, A; G) \to H^{n+1}(X, B; G)$ is natural and it is given by the map*

$$\begin{array}{rcl} H^n(B, A; G) & \to & H^{n+1}(X, B; G) \\ [f\colon C_n(B, A) \to G] & \mapsto & \left[\begin{array}{rcl} C_{n+1}(X, B) & \to & G \\ \sigma & \mapsto & f(q(\partial_n(\sigma))) \\ \uparrow & & \\ \text{with } \sigma \in C_{n+1}(X) & & \end{array}\right] \end{array}$$

here $q\colon C_n(X) \to C_n(B)$ is the map given by sending all singular simplices that do not lie in B to zero.

Remark.

(1) An equivalent approach to expressing the connecting homomorphism is given as follows:
   (a) take a cocycle $f \in C^n(B, A; G) = \mathrm{Hom}(C_n(B, A), G)$,
   (b) denote by $\pi\colon C_n(B) \to C_n(B, A)$ the projection map,
   (c) denote by $\widetilde{f}$ the result of extending $f \circ \pi\colon C_n(B) \to G$ to a map $C_n(X) \to G$ by sending all singular simplices that do not lie in B to zero (sometimes we call $\widetilde{f}$ the *trivial extension* of $f \circ \pi$),
   (d) then consider the coboundary $\delta\widetilde{f} \in C^{n+1}(X; G)$, since f is a cocycle it follows that $\delta\widetilde{f}$ actually defines an element in $C^{n+1}(X, B; G)$ that we also denote by $\delta\widetilde{f}$, and which turns out to be a cocycle,
   (e) then $\delta[f] = [\delta\widetilde{f}] \in H^{n+1}(X, B; G)$.
(2) One of the difficulties with the long exact sequence of cohomology groups is that all maps seem to point the wrong way. You should use the Lucky Luke approach to cohomology: if Rantanplan (i.e. your intuition) points one way, you should take the opposite direction.
(3) The most frequent application of Lemma 48.15 is that given a pair (X, B) of topological spaces, i.e. given the triple $(X, B, \varnothing)$ and given an abelian group G we obtain a natural long exact sequence

$$\dots \xrightarrow{\delta_{n-1}} H^n(X, B; G) \xrightarrow{p^*} H^n(X; G) \xrightarrow{i^*} H^n(B; G) \xrightarrow{\delta_n} H^{n+1}(X, B; G) \xrightarrow{p^*} \dots$$

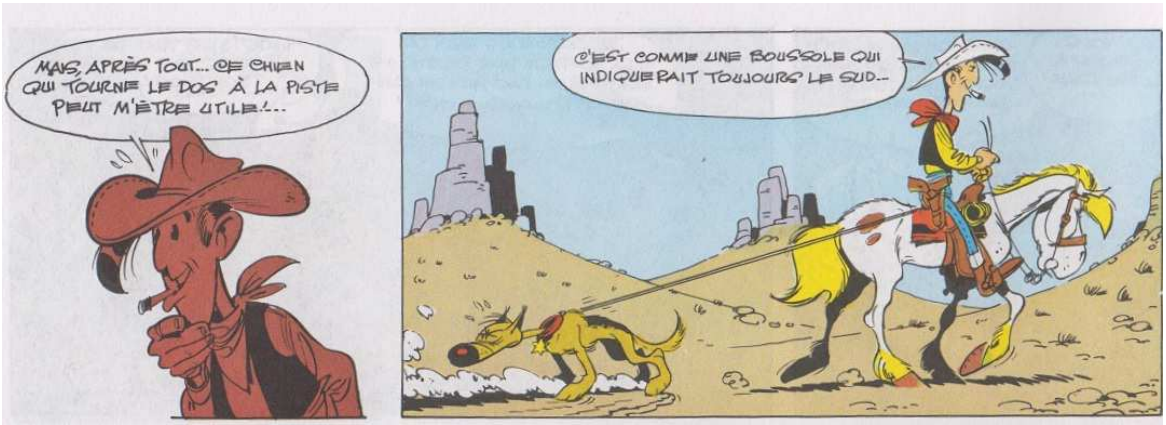

FIGURE 683. The Rantanplan rule.

Proof. Let (X, B, A) be a triple of topological spaces. As in the proof of Proposition 31.13 we note that

$$0 \;\to\; C_*(B, A) \;\xrightarrow{i_*}\; C_*(X, A) \;\xrightarrow{p_*}\; C_*(X, B) \;\to\; 0$$

is a short exact sequence of chain complexes. Now let G be an abelian group. Recall that we pointed out on page 775 that the chain groups $C_*(X, B)$ are free abelian groups. Thus we deduce from Lemma 48.4 that the following induced sequence of cochain complexes is also exact:

$$0 \;\to\; \mathrm{Hom}(C_*(X, B), G) \;\xrightarrow{p^*}\; \mathrm{Hom}(C_*(X, A), G) \;\xrightarrow{i^*}\; \mathrm{Hom}(C_*(B, A), G) \;\to\; 0.$$

The lemma now follows easily from Proposition 48.6 and the construction of the connecting homomorphism. We leave the details to the reader. □

Examples.

(1) Let X be a path-connected topological space and let A be any *non-empty* subset A of X. We denote by $i\colon A \to X$ the inclusion map. By the above remark we have a long exact sequence

$$0 \;\to\; H^0(X, A; G) \;\to\; H^0(X; G) \;\underset{\substack{\uparrow \\ \text{monomorphism, see page 1172}}}{\xrightarrow{i^*}}\; H^0(A; G) \;\to\; \dots$$

Thus it follows that $H^0(X, A; G) = 0$. In Exercise 48.2 we will provide an alternative proof for this fact using only the definitions of cohomology groups.

(2) Let $b \in \mathbb{R}_{>0}$. We consider the long exact sequence in cohomology with $\mathbb{Z}$-coefficients of the pair $(\mathbb{R}, \mathbb{R}\backslash[-b, b])$. Together with (1) and Lemma 48.14 we obtain the following

commutative diagram where the top horizontal sequence is exact:

$$\begin{tikzcd}
0 \arrow[r] & H^0(\mathbb{R};\mathbb{Z}) \arrow[r, "i^*"] \arrow[d, "{[f]\mapsto f(-b-1)}"] & H^0(\mathbb{R}\setminus[-b,b];\mathbb{Z}) \arrow[r, "\delta"] \arrow[d, "{[f]\mapsto (f(-b-1),f(b+1))}"] & H^1(\mathbb{R},\mathbb{R}\setminus[-b,b];\mathbb{Z}) \arrow[r] & H^1(\mathbb{R};\mathbb{Z}) \arrow[d, "="] \\
& \mathbb{Z} \arrow[r, "m\mapsto(m,m)"'] & \mathbb{Z}^2 & & 0.
\end{tikzcd}$$

The cokernel of the bottom horizontal map is easily seen to be isomorphic to $\mathbb{Z}$ and it is generated by the element $(0,1)\in\mathbb{Z}^2$. Put differently, the cokernel of the map $i^*\colon H^0(\mathbb{R};\mathbb{Z})\to H^0(\mathbb{R}\setminus[-b,b];\mathbb{Z})$ is represented by the singular 0-cochain given by

$$\begin{array}{rcl} \psi\colon \mathbb{R}\setminus[-b,b] & \to & \mathbb{Z} \\ x & \mapsto & \begin{cases} 0, & \text{if } x\le -b, \\ 1, & \text{if } x\ge b. \end{cases} \end{array}$$

Now we want to determine $\delta\psi\in H^1(\mathbb{R},\mathbb{R}\setminus[-b,b];\mathbb{Z})$. It is perhaps helpful to consider the following commutative diagram of short exact sequences:

$$\begin{tikzcd}
0 \arrow[r] & \mathrm{Hom}(C_1(\mathbb{R},\mathbb{R}\setminus[-b,b]),\mathbb{Z}) \arrow[r, "p^*"] & \mathrm{Hom}(C_1(\mathbb{R}),\mathbb{Z}) \arrow[r, "i^*"] & \mathrm{Hom}(C_1(\mathbb{R}\setminus[-b,b]),\mathbb{Z}) \arrow[r] & 0 \\
0 \arrow[r] & \mathrm{Hom}(C_0(\mathbb{R},\mathbb{R}\setminus[-b,b],\mathbb{Z}) \arrow[r, "p^*"] \arrow[u, "\delta_0"'] & \mathrm{Hom}(C_0(\mathbb{R}),\mathbb{Z}) \arrow[r, "i^*"] \arrow[u, "\delta_0"'] & \underbrace{\mathrm{Hom}(C_0(\mathbb{R}\setminus[-b,b],\mathbb{Z})}_{\text{contains } \psi} \arrow[r] \arrow[u, "\delta_0"'] & 0.
\end{tikzcd}$$

We start with the map $\psi\colon\mathbb{R}\setminus[-b,b]\to\mathbb{Z}$. We need to pick an extension to a map $\mathbb{R}\to\mathbb{Z}$. We might as well take the map $\varphi_0\colon\mathbb{R}\to\mathbb{Z}$ from page 1169. Then it follows from the discussion of the connecting homomorphism that the coboundary $\gamma_0:=\delta\varphi_0$ represents an element in $H^1(\mathbb{R},\mathbb{R}\setminus[-b,b];\mathbb{Z})$, and that $\delta\psi=[\gamma_0]$ is a generator of $H^1(\mathbb{R},\mathbb{R}\setminus[-b,b];\mathbb{Z})\cong\mathbb{Z}$.

48.6. **Reduced cohomology groups.** We saw on several occasions that the reduced homology groups $\widetilde{H}_k(X)$ of a a non-empty topological space can be convenient for expressing calculations and results. In this last section we quickly introduce the reduced cohomology groups.

Definition. Let X be a topological space. By Lemma 29.4 (1) we know that the following is a chain complex

$$\begin{array}{ccccccccc} \dots & \xrightarrow{\partial_3} & C_2(X) & \xrightarrow{\partial_2} & C_1(X) & \xrightarrow{\partial_1} & C_0(X) & \xrightarrow{\epsilon} & \mathbb{Z} & \to & 0. \\ & & & & & & \sum_{i=1}^k n_i\sigma_i & \mapsto & \sum_{i=1}^k n_i. & & \end{array}$$

Let G be an abelian group. In a fashion similar to reduced homology we now define the *k-th reduced cohomology group $\widetilde{H}^k(X;G)$ of X* to be the k-th cohomology group of the above chain complex.

The following lemma is the analogue of Lemma 31.1, and Lemma 31.12 (1) and Lemma 31.12 (2). We leave the proof as an exercise to the reader.

Lemma 48.16. *Let G be an abelian group.*

(1) *Let $f\colon X \to Y$ be a map between two topological spaces. For every $n \in \mathbb{N}_0$ the map f induces a map $f^*\colon \widetilde{H}^n(Y;G) \to \widetilde{H}^n(X;G)$ in the obvious way. For every $n \in \mathbb{N}_0$ the maps*

$$\begin{array}{rcl} X & \mapsto & \widetilde{H}^n(X;G) \\ (f\colon X \to Y) & \mapsto & (f^*\colon \widetilde{H}^n(Y;G) \to \widetilde{H}^n(X;G)) \end{array}$$

define a functor from the category of topological spaces to the category of abelian groups.

(2) *For each $n \in \mathbb{N}_0$ the maps*

$$\begin{array}{rcl} H^n(X;G) & \to & \widetilde{H}^n(X;G) \\ [\varphi] & \mapsto & [\varphi] \end{array}$$

define a natural transformation from the functor $X \mapsto H^n(X;G)$ to the functor $X \mapsto \widetilde{H}^n(X;G)$.

(3) *For every non-empty topological space X we have*

$$H^n(X;G) \;\cong\; \begin{cases} \widetilde{H}^0(X;G) \oplus G, & \text{if } n = 0, \\ \widetilde{H}^n(X;G), & \text{if } n \neq 0. \end{cases}$$

The isomorphism is natural for $n \geq 1$.

(4) *If X is a topological space with $n \in \mathbb{N}$ path-components, then $\widetilde{H}^0(X;G) \cong G^{n-1}$.*

(5) *Given a topological space X, a point $x_0 \in X$ and $n \in \mathbb{N}_0$ we consider the map*

$$H^n(X,\{x_0\};G) \longrightarrow H^n(X,\varnothing;G) \xrightarrow{=} H^n(X;G) \longrightarrow \widetilde{H}^n(X;G).$$

For any $n \in \mathbb{N}_0$ this map forms a natural isomorphism from the contravariant functor $(X,x_0) \mapsto \widetilde{H}_n(X;G)$ to the contravariant functor $(X,x_0) \mapsto H^n(X,x_0;G)$.

(6) *Any homotopy equivalence between two topological spaces induces isomorphisms of reduced cohomology.*

Finally the following lemma plays the role of Corollary 31.14.

Lemma 48.17. *Let X be a topological space and let $B \subset X$ be a non-empty subset. Then given any abelian group G there exists a natural long exact sequence*

$$\ldots \xrightarrow{\delta_{n-1}} H^n(X,B;G) \xrightarrow{p^*} \widetilde{H}^n(X;G) \xrightarrow{i^*} \widetilde{H}^n(B;G) \xrightarrow{\delta_n} H^{n+1}(X,B;G) \xrightarrow{p^*} \ldots$$

Proof. The lemma follows immediately from Lemma 48.15 applied to the triple $(X,B,\{P\})$ where P is a point in B, together with Lemma 48.16 (5). □

Exercises for Chapter 48.

Exercise 48.1. Let X be a topological space $X = \{x\}$ that consists of a single point x. Show that for any abelian group G we have

$$H^n(X;G) \;\cong\; \begin{cases} 0, & \text{if } n \geq 1, \\ G, & \text{if } n = 0. \end{cases}$$

Exercise 48.2. Let X be a path-connected topological space and let A be a non-empty subset of X. Show that

$$H^0(X,A;G) \;=\; 0,$$

using only the definitions of cohomology groups.

Exercise 48.3. Show that any map $f\colon X \to Y$ between two path-connected non-empty topological spaces induces an isomorphism $f^*\colon H^0(Y;G) \to H^0(X;G)$.

Exercise 48.4. Let X be a topological space. Is the 0-th homology group $H_0(X;\mathbb{Z})$ necessarily isomorphic to the 0-th cohomology group $H^0(X;\mathbb{Z})$?

Exercise 48.5. We write $I = [0,1]$. As on page 1171 we consider the function

$$\begin{array}{rcl} f\colon I & \to & \mathbb{Z} \\ x & \mapsto & \begin{cases} 0, & \text{if } x \in [0, \frac{1}{2}) \\ 1, & \text{otherwise.} \end{cases} \end{array}$$

This map gives rise to the following singular 1-cochain:

$$\begin{array}{rcl} \rho\colon C_1(I) & \to & \mathbb{Z} \\ (\sigma\colon \Delta^1 \to I) & \mapsto & f(\sigma(0,1)) - f(\sigma(1,0)). \end{array}$$

As we pointed out on page 1171, the map ρ actually defines a cochain $\rho\colon C_1(I,\partial I) \to \mathbb{Z}$.

(a) Show that $\rho \in C_1(I,\partial I)$ is a singular 1-cocycle.
(b) Show that ρ defines a non-trivial element in $H^1(I,\partial I;\mathbb{Z})$.

Exercise 48.6. Let $X = \mathbb{R}^2$. We consider the singular 2-cochain $\varphi\colon C_2(\mathbb{R}^2;\mathbb{F}_2)$ that is given by

$$\varphi(\sigma) \;:=\; \begin{cases} 1, & \text{if } (0,0) \text{ lies in the interior of the convex hull} \\ & \text{of the three points } \sigma(1,0,0), \sigma(0,1,0), \sigma(0,0,1), \\ 0, & \text{otherwise.} \end{cases}$$

Is φ a cocycle?

Exercise 48.7. Let $f\colon S^2 \to \mathbb{F}_2$ be a function such that $f(-x) = 1 - f(x)$ for all $x \in S^2$. Given a singular simplex $\tau\colon \Delta^1 \to S^2$ we write $\mu(\tau) = 0$ if f is constant on $\tau(\Delta^1)$ and otherwise we write $\mu(\tau) = 1$. We denote by $p\colon S^2 \to \mathbb{R}\mathrm{P}^2 = S^2/x \sim -x$ the projection map. We consider the following cochain

$$\begin{array}{rcl} \varphi\colon C^2(\mathbb{R}\mathrm{P}^2) & \to & \mathbb{F}_2 \\ (\sigma\colon \Delta^2 \to \mathbb{R}\mathrm{P}^2) & \mapsto & \begin{array}{c} \text{pick a lift } \widetilde{\sigma}\colon \Delta^2 \to S^2 \text{ of } \sigma \text{ and calculate} \\ \mu(\widetilde{\sigma} \circ i_0^2) + \mu(\widetilde{\sigma} \circ i_1^2) + \mu(\widetilde{\sigma} \circ i_2^2). \end{array} \end{array}$$

(a) Show that φ is well-defined, i.e. show that $\varphi(\sigma)$ does not depend on the choice of the lift $\widetilde{\sigma}$.
Remark: Note that if $\widetilde{\sigma}\colon \Delta^2 \to S^2$ is a lift of σ, then the only other one is given by $\nu \circ \widetilde{\sigma}$ where $\nu\colon S^2 \to S^2$ is the map defined by $\nu(x) = -x$ for all $x \in S^2$.

(b) Show that φ is a cocycle in $C^2(\mathbb{R}\mathrm{P}^2; \mathbb{F}_2)$.

(c) Does φ represent a non-zero cohomology class?

49. Chain complexes with isomorphic homology groups

In the following chapter we want to extend some of the deeper theorems and theories from the homological setup to the cohomological setting. Our goal will be to do so with as little effort as possible. To achieve this goal we will state and prove in this short chapter two purely algebraic propositions.

49.1. **Isomorphisms of homology groups are homotopy equivalences.** The goal of this chapter is to prove the following two propositions.

Proposition 49.1. *Suppose (C_*, ∂_*) and (C'_*, ∂'_*) are two chain complexes of free abelian groups. If $\gamma_n \colon H_n(C_*) \to H_n(C'_*)$, $n \in \mathbb{N}_0$, is a family of homomorphisms, then there exists a chain map $f \colon C_* \to C'_*$ such that for every $n \in \mathbb{N}_0$ we have*

$$f_* = \gamma_n \colon H_n(C_*) \ \to \ H_n(C'_*).$$

Remark. We consider the following commutative diagram

$$\begin{tikzcd}
0 \arrow[r] & \mathbb{Z} \arrow[r, "\cdot 2"] \arrow[d, "n \mapsto (0,n)"] & \mathbb{Z} \arrow[r] \arrow[d, "\mathrm{id}"] & 0 \\
0 \arrow[r] & \mathbb{Z} \oplus \mathbb{Z} \arrow[r, "(m,n) \mapsto m+2n"'] & \mathbb{Z} \arrow[r] & 0.
\end{tikzcd}$$

We view the top and bottom sequences as chain complexes C_* respectively D_* and we view the vertical maps as a chain map f. It is straightforward to see that f induces the zero map on homology but that it is not chain homotopic to the zero chain map. This shows that the chain map from Proposition 49.1 is in general *not* unique up to chain homotopy.

The second proposition can be viewed as a converse to Lemma 30.2.

Proposition 49.2. *Let $f \colon C_* \to C'_*$ be a chain map between chain complexes of free abelian groups. If f induces an isomorphism of all homology groups, then f is in fact a chain homotopy equivalence.*

Remark. Note that we had already promised the previous proposition in the remark after Proposition 31.21.

Before we give the proofs of the two propositions we point out several consequences.

Corollary 49.3. *Suppose (C_*, ∂_*) and (C'_*, ∂'_*) are two chain complexes of free abelian groups. Suppose that for each $n \in \mathbb{N}_0$ the homology groups $H_n(C_*)$ and $H_n(C'_*)$ are isomorphic. Then for each $n \in \mathbb{N}_0$ and any abelian group G the following statements hold:*

1. *the homology groups $H_n(C_* \otimes G)$ and $H_n(C'_* \otimes G)$ are isomorphic and*
2. *the cohomology groups $H^n(C; G)$ and $H^n(C'; G)$ are also isomorphic.*

Remark. The first statement also follows from the fact that the short exact sequence in the Algebraic Universal Coefficient Theorem 42.18 splits, see Proposition 42.22.

Proof. Suppose (C_*, ∂_*) and (C'_*, ∂'_*) are two chain complexes of free abelian groups. By our hypothesis there exist isomorphisms $\gamma_n \colon H_n(C_*) \to H_n(C'_*)$, $n \in \mathbb{N}_0$. By Proposition 49.1 these isomorphisms can be realized by a chain map $f \colon C_* \to C'_*$. But by Proposition 49.2 this chain map is a chain homotopy equivalence. Now we turn to the proofs of the two statements of the corollary.

(1) It is straightforward to see that $f \otimes \mathrm{id} \colon C_* \otimes G \to C'_* \otimes G$ is also a chain homotopy equivalence. Now the first statement follows from Corollary 30.3.
(2) The second statement follows immediately from Lemma 48.8. □

This corollary in turn gives us another, rather sobering corollary. It says that if our only goal is to distinguish (pairs of) topological spaces, then cohomology groups do not contain more information than homology groups.

Corollary 49.4. *Let (X, A) and (Y, B) be topological spaces and let G be an abelian group. Then*

$H_n(X, A)$ and $H_n(Y, B)$ are isomorphic for all $n \in \mathbb{N}_0$	$\Longrightarrow$	*the two groups $H_n(Y, B; G)$ and $H_n(X, A; G)$ and the two groups $H^n(Y, B; G)$ and $H^n(X, A; G)$ are isomorphic for all $n \in \mathbb{N}_0$.*

Remark. We will see later on in Exercise 51.7 that the analogous statement with the roles of homology and cohomology swapped does not hold. In particular there exist topological spaces X and Y such that $H^n(X; \mathbb{Z}) \cong H^n(Y; \mathbb{Z})$ for all $n \in \mathbb{N}_0$ but such that $H_1(X; \mathbb{Z})$ is not isomorphic to $H_1(Y; \mathbb{Z})$.

Proof. This corollary follows immediately from Corollary 49.3 and the observation from page 775 that relative singular chain groups are free abelian groups. □

The previous corollary does not specify how the isomorphism of the cohomology groups is given. If we already start out with a map $f \colon (X, A) \to (Y, B)$ that induces an isomorphism of homology groups, then we can be more precise.

Corollary 49.5. *Let $f \colon (X, A) \to (Y, B)$ be a map between pairs of topological spaces and let G be an abelian group. Then*

the induced map $f_* \colon H_n(X, A) \to H_n(Y, B)$ is an isomorphism for all $n \in \mathbb{N}_0$	$\Longrightarrow$	*the induced maps $f_* \colon H_n(X, A; G) \to H_n(Y, B; G)$ and $f^* \colon H^n(Y, B; G) \to H^n(X, A; G)$ are isomorphisms for all $n \in \mathbb{N}_0$.*

Proof. Let $f \colon (X, A) \to (Y, B)$ be a map between pairs of topological spaces and let G be an abelian group. If $f_* \colon H_n(X, A) \to H_n(Y, B)$ is an isomorphism for all $n \in \mathbb{N}_0$, then it follows from Proposition 49.2 that $f_* \colon C_*(X, A) \to C_*(Y, B)$ is already a chain homotopy equivalence. (Here, as in the previous proof we use that relative singular chain groups are free abelian groups.) Now we get the desired conclusion from the discussion on page 1009 and Lemma 48.8. □

Later on we will also use the following purely algebraic corollary to Proposition 49.2.

Corollary 49.6. *Let*

$$\begin{array}{ccccccccc} 0 & \longrightarrow & A_* & \longrightarrow & B_* & \longrightarrow & C_* & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & A'_* & \longrightarrow & B'_* & \longrightarrow & C'_* & \longrightarrow & 0 \end{array}$$

be a commutative diagram of short exact sequences of chain complexes. If two of the vertical maps are chain homotopy equivalences, then the third is also a chain homotopy equivalence.

Proof. By Proposition 31.10 we get a commutative diagram of long exact sequences

$$\begin{array}{ccccccccccccc} \dots & \longrightarrow & H_{n+1}(C_*) & \xrightarrow{\partial} & H_n(A_*) & \longrightarrow & H_n(B_*) & \longrightarrow & H_n(C_*) & \xrightarrow{\partial} & H_{n-1}(A_*) & \longrightarrow & \dots \\ & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \\ \dots & \longrightarrow & H_{n+1}(C'_*) & \xrightarrow{\partial} & H_n(A'_*) & \longrightarrow & H_n(B'_*) & \longrightarrow & H_n(C'_*) & \xrightarrow{\partial} & H_{n-1}(A'_*) & \longrightarrow & \dots \end{array}$$

By our hypothesis, together with Corollary 30.3, we know that always two out of three vertical maps are isomorphisms. But then it follows from the Five Lemma 31.11 that the third vertical map is also an isomorphism. Now Proposition 49.2 implies that the corresponding map of chain complexes is also a chain homotopy equivalence. □

As we pointed out above, the first time we had mentioned Proposition 49.2 was in the remark after Proposition 31.21. In fact Proposition 49.2 implies immediately that we can strengthen Proposition 31.21 to obtain the following result.

Proposition 49.7. *Let X be a topological space and let $\mathcal{U} = \{U_i\}_{i\in I}$ be a covering of X. Then the inclusion map*[894]

$$C_*^{\mathcal{U}}(X) \;\to\; C_*(X)$$

is a chain homotopy equivalence.

We conclude this discussion of the consequences of Proposition 49.1 and 49.2 with the following lemma which we will use on several occasions.

Lemma 49.8. *Let (C_*, c_*) be a free chain complex such that for each $k \in \mathbb{N}_0$ the homology group $H_k(C)$ is finitely generated. Then there exists a chain complex (D_*, ∂_*) with the following two properties:*

(1) *The chain complexes (C_*, ∂_*) and (D_*, ∂_*) are chain homotopy equivalent.*
(2) *Each chain group D_k is a free abelian group of* finite rank.

[894]Recall that a *covering of X* is a family $\mathcal{U} = \{U_i\}_{i\in I}$ of subsets of X such that the union of the interiors of the U_i equals X. On page 787 we defined

$$C_n^{\mathcal{U}}(X) \;=\; \Big\{ \sum_{j=1}^{k} a_j\sigma_j \;\Big|\; \text{for each } j \text{ there exists a } U_i \in \mathcal{U} \text{ such that the image of } \sigma_j \text{ lies in } U_i \Big\}$$

and we had observed that these groups form a subcomplex of $C_*(X)$. Note that these chain groups are free abelian groups generated by the union of the sets of singular n-simplices that lie in some U_i.

Proof. Let $k \in \mathbb{N}_0$. Recall that we assume that $H_k(C_*)$ is finitely generated. It follows immediately from the classification of finitely generated abelian groups, see Theorem 11.4, that there exists a chain complex D^k_* and an isomorphism $\varphi_k\colon H_k(D^k_*) \to H_k(C_*)$ such that only the chain groups D^k_k and D^k_{k+1} are non-zero and such that both chain groups are finitely generated free abelian groups.

We define $D_* = \bigoplus_{k\in\mathbb{N}_0} D^k_*$. It follows immediately from Proposition 49.1 and 49.2 that the chain complex D_* is chain homotopy equivalent to (C_*, c_*). □

49.2. **Proof of Propositions 49.1 and 49.2.** We start out with the proof of Proposition 49.1.

Proof of Proposition 49.1. Let (C_*, ∂_*) and (C'_*, ∂'_*) be two chain complexes of free abelian groups. Furthermore let $\gamma_n\colon H_n(C_*) \to H_n(C'_*)$, $n \in \mathbb{N}_0$ be a family of homomorphisms. We have to show that there exists a chain map $f\colon C_* \to C'_*$ such that for every $n \in \mathbb{N}_0$ we have

$$f_* = \gamma_n\colon H_n(C_*) \;\to\; H_n(C'_*).$$

We start out by recalling some of the usual notation and basic observations regarding chain complexes. More precisely, for each $n \in \mathbb{N}_0$ we write

$$Z_n \;:=\; \ker(\partial_n\colon C_n \to C_{n-1}), \quad B_n \;:=\; \operatorname{im}(\partial_{n+1}\colon C_{n+1} \to C_n) \quad \text{and} \quad H_n \;=\; Z_n/B_n.$$

Recall that these groups form the following two types of short exact sequences

$$\text{(a)} \qquad 0 \;\to\; Z_n \;\hookrightarrow\; C_n \;\xrightarrow{\partial_n}\; B_{n-1} \;\to\; 0,$$

and

$$\text{(b)} \qquad 0 \;\to\; B_n \;\hookrightarrow\; Z_n \;\to\; H_n \;\to\; 0.$$

Similarly we define Z'_n, B'_n and H'_n for the chain complex C'_*. Evidently these groups also form short exact sequences that we denote by (a′) and (b′).

Since all the chain groups are free abelian it follows from Lemma 11.2 that the subgroups Z_n, B_n, Z'_n and B'_n are also free abelian. In particular the sequences (b) and (b′) are free resolutions of H_n respectively H'_n. It follows from Lemma 42.13 that for each $n \in \mathbb{N}_0$ there exist homomorphisms β_n and ζ_n such that the following diagram commutes:

$$\begin{tikzcd}
0 \arrow[r] & B_n \arrow[r] \arrow[d, "\beta_n"] & Z_n \arrow[r] \arrow[d, "\zeta_n"] & H_n \arrow[r] \arrow[d, "\gamma_n"] & 0 \\
0 \arrow[r] & B'_n \arrow[r] & Z'_n \arrow[r] & H'_n \arrow[r] & 0.
\end{tikzcd}$$

Our goal is to extend the maps $\zeta_n\colon Z_n \to Z'_n$ to a chain map $f\colon C_n \to C'_n$. To do so we consider the following diagram

$$\begin{tikzcd}
0 \arrow[r] & Z_n \arrow[r, hook] \arrow[dr, hook] \arrow[dd, "\zeta_n"] & C_n \arrow[r, two heads, "\partial"] \arrow[d, dashed, "\psi_n"] & B_{n-1} \arrow[r] \arrow[dd, "\beta_{n-1}"] & 0 \\
& & Z_n \oplus B_{n-1} \arrow[ur, two heads] \arrow[d, "\zeta_n \oplus \beta_{n-1}"] & & \\
& & Z'_n \oplus B'_{n-1} \arrow[dr, two heads] & & \\
0 \arrow[r] & Z'_n \arrow[r, hook] \arrow[ur, hook] & C'_n \arrow[r, two heads, "\partial'"'] \arrow[u, dashed, "\psi'_n"'] & B'_{n-1} \arrow[r] & 0.
\end{tikzcd}$$

Here the top sequence is precisely the short exact sequence (a) and the bottom sequence is the short exact sequence (a′). Here the unlabeled maps are the obvious inclusion and projection maps. It follows immediately from Lemmas 33.1 and 33.2 that there exist isomorphisms $\psi_n\colon C_n \xrightarrow{\cong} Z_n \oplus B_{n-1}$ and $\psi'_n\colon C'_n \xrightarrow{\cong} Z'_n \oplus B'_{n-1}$ which make the diagram commute. Now we define $f_n\colon C_n \to C'_n$ to be vertical homomorphism given by the diagram, i.e. $f_n = (\psi'_n)^{-1} \circ (\zeta_n \oplus \beta_{n-1}) \circ \psi_n$.

Now we need to show that the maps f_n form a chain map. We consider the diagram

$$\begin{tikzcd}
C_n \arrow[r, "\partial"] \arrow[d, "f_n"] & B_{n-1} \arrow[r, hook] \arrow[d, "\beta_{n-1}"] & Z_{n-1} \arrow[r, hook] \arrow[d, "\zeta_{n-1}"] & C_{n-1} \arrow[d, "f_{n-1}"] \\
C'_n \arrow[r, "\partial'"'] & B'_{n-1} \arrow[r, hook] & Z'_{n-1} \arrow[r, hook] & C'_{n-1}
\end{tikzcd}$$

where all unlabeled maps are the obvious inclusion maps. The middle square commutes by the choice of β_{n-1} and ζ_{n-1}. We had arranged the maps f_n, f_{n-1} in such a way that the squares to the left and right commute. This shows that the rectangle commutes. But that was exactly what we needed to do to show that the maps f_n, $n \in \mathbb{N}_0$ form a chain map.

Finally note that it follows easily from the choice of ζ_n that the chain map f_n induces the given maps γ_n on homology. □

The remainder of this section will be occupied with the proof of Proposition 49.2. As we will see the proof is significantly trickier than the proof of Proposition 49.1. We start out with the following definition.

Definition. Let (C_n, c_n) and (D_n, d_n) be two chain complexes and let $\varphi\colon C_* \to D_*$ be a chain map. The *algebraic mapping cone of* φ is the chain complex $(M(\varphi), \partial_*)$ that is given by the chain groups

$$M(\varphi)_n \;:=\; \begin{matrix} C_{n-1} \\ D_n \end{matrix} \;:=\; C_{n-1} \oplus D_n$$

and the boundary maps[895]

$$\partial\colon \begin{array}{ccc} \overbrace{C_{n-1}}^{M(\varphi)_n} & \to & \overbrace{C_{n-2}}^{M(\varphi)_{n-1}} \\ D_n & & D_{n-1} \\ x & \mapsto & -c_{n-1}(x) \\ y & & \varphi_{n-1}(x)+d_n(y) \end{array} \qquad \text{which we write as block matrices} \qquad \begin{array}{cc} C_{n-1} & D_n \\ \end{array} \begin{array}{c} \\ \begin{pmatrix} -c_{n-1} & 0 \\ \varphi_{n-1} & d_n \end{pmatrix} \end{array} \begin{array}{c} C_{n-2} \\ D_{n-1} \end{array}$$

Remark. Let $f\colon A \to X$ be a map between topological spaces. Recall that on page 458 we defined the corresponding *mapping cone* as

$$\mathrm{Cone}(f\colon A \to X) \;:=\; (A \times [0,1] \sqcup X)/\sim$$

where $(a,1) \sim f(a)$ for all $a \in A$ and $(a,0) \sim (b,0)$ for all $a,b \in A$. As an application we showed on page 458 that for an inclusion map $i\colon A \to X$ there exists a natural isomorphism

$$\widetilde{H}_n(\mathrm{Cone}(i\colon A \to X)) \;\xrightarrow{\cong}\; H_n(X,A),$$

i.e. we can reinterpret relative homology groups as reduced homology groups of the corresponding mapping cone. Now suppose that A and X are finite CW-complexes and that f is a cellular map. By Corollary 26.24 (3) we can equip the mapping cone $\mathrm{Cone}(f\colon A \to X)$ with a natural CW-structure. In Exercise 49.4 we will show that the corresponding cellular chain complex is isomorphic to the algebraic mapping cone of the chain map $f_*\colon C_*^{\mathrm{CW}}(A) \to C_*^{\mathrm{CW}}(X)$.

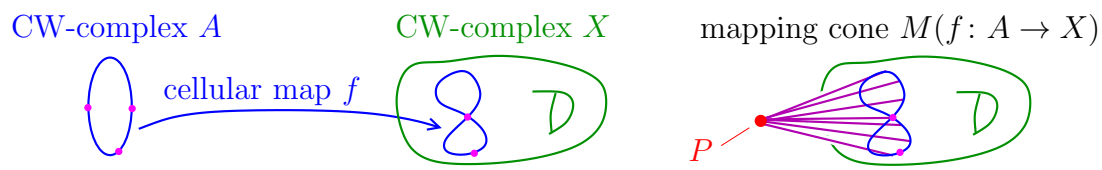

FIGURE 684.

Lemma 49.9. *Let $\varphi\colon C_* \to D_*$ be a chain map between two chain complexes (C_n, c_n) and (D_n, d_n). We denote by $i\colon D_n \to M(\varphi)_n = C_{n-1} \oplus D_n$ the obvious inclusion map and we denote by $p\colon M(\varphi)_n = C_{n-1} \oplus D_n \to C_{n-1}$ the obvious projection map. Then the following sequence is exact*

$$\ldots \to H_n(C_*) \xrightarrow{\varphi_*} H_n(D_*) \xrightarrow{i_*} H_n(M(\varphi)) \xrightarrow{p_*} H_{n-1}(C_*) \xrightarrow{\varphi_*} H_{n-1}(D_*) \to \ldots$$

[895]Note that

$$\partial_{n-1} \circ \partial_n \;=\; \begin{pmatrix} -c_{n-2} & 0 \\ \varphi_{n-2} & d_{n-1} \end{pmatrix} \begin{pmatrix} -c_{n-1} & 0 \\ \varphi_{n-1} & d_n \end{pmatrix} \;\underset{\uparrow}{=}\; \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}$$

since φ is a chain map and $c_{n-2} \circ c_{n-1} = 0$ and $d_{n-1} \circ d_n = 0$

This shows that we have indeed defined a chain complex.

Proof. For each $n \in \mathbb{N}_0$ we consider the following diagram

$$\begin{tikzcd}
0 \arrow[r] & D_n \arrow[r, "i_n"] \arrow[d, "d_n"] & \begin{matrix} C_{n-1} \\ D_n \end{matrix} \arrow[r, "p_n"] \arrow[d, "\partial_n"', "\begin{pmatrix} -c_{n-1} & 0 \\ \varphi_{n-1} & d_n \end{pmatrix}"] & C_{n-1} \arrow[r] \arrow[d, "c_{n-1}"] & 0 \\
0 \arrow[r] & D_{n-1} \arrow[r, "i_{n-1}"'] & \begin{matrix} C_{n-2} \\ D_{n-1} \end{matrix} \arrow[r, "p_{n-1}"'] & C_{n-2} \arrow[r] & 0.
\end{tikzcd}$$

We make the following observations:

(1) the horizontal sequences are exact,
(2) the left-hand square commutes, i.e. the maps i_* define a chain map,
(3) the right-hand square commutes up to a minus sign, i.e. we have

$$c_{n-1} \circ p_n \;=\; -p_{n-1} \circ \partial_n.$$

Fortunately this minus sign in the above equality does not change the fact that the maps p_n induce a map between homology groups.

Despite the minus sign in (3) we can use verbatim the same construction as on page 770 to obtain connecting homomorphisms $\partial_n \colon H_n(D_*) \to H_n(C_*)$, $n \in \mathbb{N}_0$, and verbatim the same proof as in Proposition 31.10 shows that these connecting homomorphisms give rise to a long exact sequence of the form

$$\ldots \;\to\; H_n(C_*) \;\xrightarrow{\partial_n}\; H_n(D_*) \;\xrightarrow{i_*} H_n(M(\varphi)) \;\xrightarrow{p_*} H_{n-1}(C_*) \;\xrightarrow{\partial_{n-1}}\; H_{n-1}(D_*) \;\to\; \ldots$$

It follows easily from the definition of the connecting homomorphism on page 770 that for each $n \in \mathbb{N}_0$ we have the equality

$$\partial_n \;=\; \varphi_* \colon H_n(C_*) \;\to\; H_n(D_*).$$

We have thus now shown that the sequence in the statement of the lemma is exact. □

The following lemma will be used in the proof of Proposition 49.2.

Lemma 49.10. *Let (C_*, ∂_*) be a chain complex of free abelian groups such that $H_n(C_*) = 0$ for all $n \in \mathbb{N}_0$. Then the identity map and the zero map of C_* to itself are chain homotopic.*

Proof. For each $n \in \mathbb{N}_0$ we write as usual

$$Z_n \;=\; \ker\{\partial_n \colon C_n \to C_{n-1}\} \quad \text{and} \quad B_n \;=\; \operatorname{im}\{\partial_{n+1} \colon C_{n+1} \to C_n\}.$$

By our hypothesis on the homology groups of C_* we have $B_n = Z_n$ for all $n \in \mathbb{N}_0$. Thus for each $n \in \mathbb{N}_0$ we have the short exact sequence

$$0 \;\to\; Z_n \;\to\; C_n \;\xrightarrow{\partial_n}\; Z_{n-1} \;\to\; 0.$$

The group $Z_{n-1} \subset C_{n-1}$ is a subgroup of a free abelian group, thus it is itself a free abelian group by Lemma 11.2. It follows immediately from Lemmas 33.1 and Lemma 33.2 that for each $n \in \mathbb{N}_0$ we can find a direct sum decomposition $C_n = Z_n \oplus A_n$ such that

$\partial_n\colon A_n \to B_{n-1} = Z_{n-1}$ is an isomorphism. We denote by $\varphi_n\colon Z_{n-1} \to A_n$ its inverse. Now we define

$$\begin{array}{rcl} P_n\colon C_n = Z_n \oplus A_n & \to & C_{n+1} = Z_{n+1} \oplus A_{n+1} \\ z \oplus a & \mapsto & 0 \oplus \varphi_{n+1}(z). \end{array}$$

Using the definitions one can now easily verify that for each $n \in \mathbb{N}_0$ we have

$$P_{n-1} \circ \partial_n + \partial_{n+1} \circ P_n \;=\; \mathrm{id}\colon \underbrace{Z_n \oplus A_n}_{=C_n} \;\to\; \underbrace{Z_n \oplus A_n}_{=C_n},$$

i.e. the maps $\{P_n\}_{n\geq 0}$ define the desired chain homotopy from the identity to the zero map. For orientation it might be convenient to keep in mind the following diagram:

$$\begin{tikzcd}
C_{n+1} = & Z_{n+1} \oplus A_{n+1} \arrow[d, shift right, "\partial_{n+1}"'] \\
C_n = & Z_n \oplus A_n \arrow[u, shift right, "P_n"'] \arrow[d, shift right, "\partial_n"'] \\
C_{n-1} = & Z_{n-1} \oplus A_{n-1} \arrow[u, shift right, "P_{n-1}"']
\end{tikzcd}$$

This concludes the proof of the lemma. □

Now we are finally fully prepared to provide the proof of Proposition 49.2.

Proof of Proposition 49.2. Let $\varphi\colon C_* \to D_*$ be a chain map between chain complexes (C_*, c_*) and (D_*, d_*) of free abelian groups which induces an isomorphism on all homology groups. We need to show that φ is in fact a chain homotopy equivalence.

As above we denote by $(M(\varphi)_*, \partial_*)$ the mapping cone of φ. We consider the long exact sequence from Lemma 49.9:

$$\ldots \to H_n(C_*) \xrightarrow{\varphi_*} H_n(D_*) \xrightarrow{i_*} H_n(M(\varphi)) \xrightarrow{p_*} H_{n-1}(C_*) \xrightarrow{\varphi_*} H_{n-1}(D_*) \to \ldots$$

By our hypothesis the maps φ induce isomorphisms of homology groups, thus we see that $H_n(M(\varphi)) = 0$ for all $n \geq 0$. By Lemma 49.10 this means that we have a chain homotopy $\{P_n\}_{n\geq 0}$ from the identity map to the zero map. (Note that here we use that by our hypothesis on C_* and D_* each $M(\varphi)_n = C_{n-1} \oplus D_n$ is a free abelian group.)

Recall that this means that for each $n \in \mathbb{N}_0$ we have the equality

$$(*) \qquad P_{n-1} \circ \partial_n + \partial_{n+1} \circ P_n \;=\; \mathrm{id}_{C_{n-1}\oplus D_n}\,.$$

Using the obvious matrix notation we write

$$P_n \;=\; \begin{pmatrix} P_n^{11} & P_n^{12} \\ P_n^{21} & P_n^{22} \end{pmatrix} : \underbrace{\begin{matrix} C_{n-1} \\ D_n \end{matrix}}_{=M(\varphi)_n} \;\to\; \underbrace{\begin{matrix} C_n \\ D_{n+1}. \end{matrix}}_{=M(\varphi)_{n+1}}$$

Now we can rewrite the above equality $(*)$ and we obtain that

$$\begin{pmatrix} P^{11}_{n-1} & P^{12}_{n-1} \\ P^{21}_{n-1} & P^{22}_{n-1} \end{pmatrix} \circ \begin{pmatrix} -c_{n-1} & 0 \\ \varphi_{n-1} & d_n \end{pmatrix} + \begin{pmatrix} -c_n & 0 \\ \varphi_n & d_{n+1} \end{pmatrix} \circ \begin{pmatrix} P^{11}_{n} & P^{12}_{n} \\ P^{21}_{n} & P^{22}_{n} \end{pmatrix} = \begin{pmatrix} \mathrm{id}_{C_{n-1}} & 0 \\ 0 & \mathrm{id}_{D_n} \end{pmatrix}.$$

Looking at the four entries separately we obtain the following four equalities:

$$\begin{array}{lrcl}
\text{(a)} & -P^{11}_{n-1} \circ c_{n-1} + P^{12}_{n-1} \circ \varphi_{n-1} - c_n \circ P^{11}_n & = & \mathrm{id}_{C_{n-1}}, \\
\text{(b)} & P^{12}_{n-1} \circ d_n - c_n \circ P^{12}_n & = & 0, \\
\text{(c)} & -P^{21}_{n-1} \circ c_{n-1} + P^{22}_{n-1} \circ \varphi_{n-1} + \varphi_n \circ P^{11}_n + d_{n+1} \circ P^{21}_n & = & 0, \\
\text{(d)} & P^{22}_{n-1} \circ d_n + \varphi_n \circ P^{12}_n + d_{n+1} \circ P^{22}_n & = & \mathrm{id}_{D_n}\,.
\end{array}$$

We make the following observation:

(1) equation (b) implies that the homomorphisms $\{P^{12}_n \colon D_n \to C_n\}_{n\in\mathbb{N}_0}$ define a chain map $D \to C$.

Now we claim that the chain map $\{P^{12}_n\}_{n\in\mathbb{N}_0}$ is a chain homotopy inverse to the chain map φ. We do so with the following two observations:

(2) equation (a) implies that $P^{12} \circ \varphi \simeq \mathrm{id}_{C_*}$ where the chain homotopy is given by the maps $P^{11}_n \colon C_{n-1} \to C_n$,
(3) whereas equation (d) implies that $\varphi \circ P^{12} \simeq \mathrm{id}_{D_*}$, where the chain homotopy is given by the maps $P^{22}_n \colon D_n \to D_{n+1}$,

The last two statements together imply that φ is indeed a chain homotopy equivalence. □

49.3. **Singular and cellular chain complexes.** In Chapter 35 we introduced the cellular chain complex and the cellular homology groups of a CW-complex. We saw that cellular homology groups are naturally isomorphic to singular homology groups. At that point we did not say anything about the relationship between the cellular chain complex and the singular chain complex. We will rectify this in this section. The extra information that we gain in this section will stand us in good stead in the next chapter when we explore the relationship between cellular cohomology and singular cohomology.

First we recall some definitions and some notation. Let X be a CW-complex.

(1) Recall that given $n \in \mathbb{N}_0$ we denote by X^n the n-skeleton of X, i.e. the union of all cells of dimension $\leq n$.
(2) We write $C^{\mathrm{CW}}_n(X) := H_n(X^n, X^{n-1})$ and we denote by $d_n \colon C^{\mathrm{CW}}_n(X) \to C^{\mathrm{CW}}_{n-1}(X)$ the cellular boundary map from page 882.
(3) We refer to

$$\ldots \xrightarrow{d_{n+2}} C^{\mathrm{CW}}_{n+1}(X) \xrightarrow{d_{n+1}} C^{\mathrm{CW}}_n(X) \xrightarrow{d_n} C^{\mathrm{CW}}_{n-1}(X) \xrightarrow{d_{n-1}} \ldots$$

as the *cellular chain complex*. The corresponding homology groups are denoted by $H^{\mathrm{CW}}_n(X)$.

In Proposition 35.4 we had seen that, given a CW-complex X the cellular homology groups $H^{\mathrm{CW}}_k(X)$ and the singular homology groups $H_k(X)$ are naturally isomorphic.

In the following we want to relate the cellular chain complex $C_*^{\mathrm{CW}}(X)$ to the singular chain complex $C_*(X)$. By the aforementioned Proposition 35.4, together with the newly acquired Propositions 49.1 and 49.2 we know that there exists a chain homotopy equivalence $C_*(X) \to C_*^{\mathrm{CW}}(X)$. But there is no obvious chain homotopy equivalence, in fact there is not even an obvious "interesting" chain map between these two chain complexes. But it turns out that there is a nice "'intermediate" chain complex which maps into both of the above chain complexes:

Definition. Given a CW-complex X and given $n \in \mathbb{N}_0$ we define the[896] *intermediate cellular chain complex*

$$C_n^{\mathrm{int}}(X) \;:=\; \ker\big\{C_n(X^n) \xrightarrow{\partial} C_{n-1}(X^n) \to C_{n-1}(X^n, X^{n-1})\big\}.$$

The following proposition shows that the intermediate cellular chain complex sits comfortably between the singular and the cellular chain complex.

Proposition 49.11. *Let X be a CW-complex. The two natural chain maps*

$$i\colon C_*^{\mathrm{int}}(X) \hookrightarrow C_*(X) \quad \textit{and} \quad p\colon C_*^{\mathrm{int}}(X) \twoheadrightarrow C_*^{\mathrm{CW}}(X),$$

which are given by obvious inclusion and the obvious projection, are chain homotopy equivalences.

Remark. The proof of the proposition is modelled on the proofs provided in [Schub2, p. 303] or alternatively [Lü3, Lemma 4.2] and [Lü6, p. 263].

Proof. By Proposition 49.2 it suffices to show that for each $n \in \mathbb{N}_0$ the maps

$$(1)\;\; i_*\colon H_n(C_*^{\mathrm{int}}(X)) \to \underbrace{H_n(C_*(X))}_{=H_n(X)} \quad \text{and} \quad (2)\;\; p_*\colon H_n(C_*^{\mathrm{int}}(X)) \to \underbrace{H_n(C_*^{\mathrm{CW}}(X))}_{=H_n^{\mathrm{CW}}(X)}$$

are isomorphisms. So let $n \in \mathbb{N}_0$. Before we start with showing that the two maps above are isomorphisms we recall that in Lemma 35.1 we proved the following two convenient facts:

(a) We have $H_{n-1}(X^{n-2}) = 0$ and $H_n(X^{n-1}) = 0$.
(b) The inclusion $k\colon X^n \to X$ induces an isomorphism $k_*\colon H_n(X^{n+1}) \xrightarrow{\cong} H_n(X)$.
(c) The inclusion $k\colon X^n \to X$ induces an epimorphism $k_*\colon H_n(X^n) \twoheadrightarrow H_n(X)$.

Claim 1. Let $n \in \mathbb{N}_0$.

(i) The map $i_*\colon H_n(C_*^{\mathrm{int}}) \to H_n(C_*(X)) = H_n(X)$ is a monomorphism.
(ii) The map $i_*\colon H_n(C_*^{\mathrm{int}}) \to H_n(C_*(X)) = H_n(X)$ is an epimorphism.

[896]It follows almost immediately from the definitions that $C_*^{\mathrm{int}}(X)$ is a subcomplex of $C_*(X)$, in particular it is a chain complex in its own right.

We consider the following two commutative diagrams

$$\begin{tikzcd} C_{n+1}^{\mathrm{int}}(X) \arrow[r, hook, "j"] \arrow[d, "\partial"] & C_{n+1}(X^{n+1}) \arrow[r, hook, "k"] \arrow[d, "\partial"] & C_{n+1}(X) \arrow[d, "\partial"] \\ C_n^{\mathrm{int}}(X) \arrow[r, hook, "j"] & C_n(X^{n+1}) \arrow[r, hook, "k"] & C_n(X) \end{tikzcd} \quad \text{and} \quad \begin{tikzcd} C_n^{\mathrm{int}}(X) \arrow[r, hook, "j"] \arrow[d, "\partial"] & C_n(X^n) \arrow[r, hook, "k"] \arrow[d, "\partial"] & C_n(X) \arrow[d, "\partial"] \\ C_{n-1}^{\mathrm{int}}(X) \arrow[r, hook, "j"] & C_{n-1}(X^n) \arrow[r, hook, "k"] & C_{n-1}(X). \end{tikzcd}$$

Both statements follow easily from the diagrams together with (b) and (c) above:

(i) Let $\sigma \in C_n^{\mathrm{int}}(X)$ be a cycle with the property that $i(\sigma)$ is null-homologous. It follows from (b) that $j(\sigma)$ is already null-homologous, i.e. there exists a $\tau \in C_{n+1}(X^{n+1})$ with $\partial\tau = j(\sigma)$. Note that $j(\sigma) = \sigma \in C_n(X^n)$. Thus we see that τ actually lies in $C_{n+1}^{\mathrm{int}}(X)$. But this implies that σ is null-homologous in $C_*^{\mathrm{int}}(X)$.

(ii) Let $[\sigma] \in H_n(X)$. By (c) we know that there exists a cycle $\tau \in C_n(X^n)$ with $[k(\tau)] = [\sigma]$. Since $\partial\tau = 0$ we see that $\tau \in C_n^{\mathrm{int}}(X)$. Since the bottom-left horizontal map is a monomorphism we see that $\tau \in C_n^{\mathrm{int}}(X)$ is also a cycle. But this shows that $[\sigma] = [i(\tau)]$.

This concludes the proof of the claim.

Claim 2. Let $n \in \mathbb{N}_0$.

(i) The map $p_*\colon H_n(C_*^{\mathrm{int}}) \to H_n(C_*^{\mathrm{CW}}(X))$ is a monomorphism.

(ii) The map $p_*\colon H_n(C_*^{\mathrm{int}}) \to H_n(C_*^{\mathrm{CW}}(X))$ is an epimorphism.

For orientation purposes we consider the following commutative diagram:

$$\begin{tikzcd} C_{n+1}^{\mathrm{int}}(X) \arrow[r, hook] \arrow[d, "\partial"] & C_{n+1}(X^{n+1}) \arrow[r, two heads] \arrow[d, "\partial"] & C_{n+1}(X^{n+1}, X^n) \arrow[d, "d"] \\ C_n^{\mathrm{int}}(X) \arrow[r, two heads, "p"] \arrow[d, "\partial"] & C_n(X^n) \arrow[r] \arrow[d, "\partial"] & C_n(X^n, X^{n-1}) \arrow[d, "d"] \\ C_{n-1}^{\mathrm{int}}(X) \arrow[r, two heads, "p"] & C_{n-1}(X^n) \arrow[r] & C_{n-1}(X^{n-1}, X^{n-2}). \end{tikzcd}$$

As we will see, the claim follows from (a) and some chasing around in the above diagram:

(i) Let $\sigma \in C_n^{\mathrm{int}}(X)$ be a cycle. Suppose that $p(\sigma) = 0 \in H_n^{\mathrm{CW}}(X)$. This means that there exists a $\mu \in C_{n+1}(X^{n+1}, X^n)$ with $\partial\mu = p(\sigma)$. We pick a $\tau \in C_{n+1}(X^{n+1})$ that represents σ. Note that $\partial\tau = \sigma + \alpha$ with $\alpha \in C_n(X^{n-1})$. Since $\partial(\partial\tau) = 0$ and since $\partial\sigma = 0$ we see that $\partial\alpha = 0$. From (a) we obtain that there exists a $\beta \in C_{n+1}(X^{n-1})$ with $\partial\beta = \alpha$. Note that $\partial(\tau - \beta) = \partial\tau - \partial\beta = \sigma$. Since $\sigma \in C_n(X^n)$ we conclude that $\tau - \beta \in C_{n+1}^{\mathrm{int}}(X)$. Thus we have shown that $[\sigma] = 0 \in H_n(C_*^{\mathrm{int}}(X))$.

(ii) Given a class in $H_n(C_*^{\mathrm{CW}}(X))$ we pick a representative in $C_n^{\mathrm{CW}}(X)) = C_n(X^n, X^{n-1})$ for which in turn we pick a lift $\sigma \in C_n(X^n)$. Note that $\partial\sigma \in C_{n-1}(X^{n-2})$. But by (a) we know that $H_{n-1}(X^{n-2}) = 0$. Hence there exists a $\mu \in C_n(X^{n-2})$ with

$\partial\mu = \partial\sigma$. Note that $\partial(\sigma - \mu) = 0$, in particular $\sigma - \mu$ is a cycle in $C_n^{\mathrm{int}}(X)$. Furthermore note that σ and $\sigma - \mu$ represent the same element in $C_n(X^n, X^{n-1})$.

This concludes the proof of the claim. □

Exercises for Chapter 49.

Exercise 49.1. We consider the following commutative diagram

$$\begin{tikzcd}
0 \arrow[r] & \mathbb{Z} \arrow[r, "\cdot 2"] \arrow[d, "n \mapsto (0,n)"] & \mathbb{Z} \arrow[r] \arrow[d, "\mathrm{id}"] & 0 \\
0 \arrow[r] & \mathbb{Z} \oplus \mathbb{Z} \arrow[r, "(m,n) \mapsto m+2n"'] & \mathbb{Z} \arrow[r] & 0.
\end{tikzcd}$$

We view the top and bottom sequences as chain complexes C_* respectively D_* and we view the vertical maps as a chain map f.

(a) Convince yourself that f induces the zero map on homology.
(b) Is the chain map f chain homotopic to the zero chain map?

Exercise 49.2. Suppose (C_*, ∂_*) and (C'_*, ∂'_*) are two chain complexes. We do *not* assume that the chain groups are necessarily free abelian groups. Suppose that for each $n \in \mathbb{N}_0$ the homology groups $H_n(C_*)$ and $H_n(C'_*)$ are isomorphic. Does it follow that for each $n \in \mathbb{N}_0$ and any abelian group G the cohomology groups $H^n(C_*; G)$ and $H^n(C'_*; G)$ are also isomorphic?

Exercise 49.3. Let X and Y are topological spaces. Suppose that $H_n(X; \mathbb{Z}) \cong H_n(Y; \mathbb{Z})$ for some $n \in \mathbb{N}_0$. Does it follow that $H^n(X; \mathbb{Z})$ and $H^n(Y; \mathbb{Z})$ are also isomorphic?

Exercise 49.4. Let $f\colon A \to X$ be a map between topological spaces. We defined the corresponding *mapping cone* as

$$M(f\colon A \to X) \;:=\; ((A \times [0,1]) \sqcup X)/\sim$$

where $(a,1) \sim f(a)$ for all $a \in A$ and $(a,0) \sim (b,0)$ for all $a, b \in A$. Now suppose that A and X are finite CW-complexes and that f is a cellular map.

We equip the mapping cone $M(f\colon A \to X)$ with the natural CW-structure of Corollary 26.24. Show that the corresponding cellular chain complex is isomorphic to the algebraic mapping cone of the chain map $f_*\colon C_*^{\mathrm{CW}}(A) \to C_*^{\mathrm{CW}}(X)$.

50. Properties of cohomology groups

After the disappointment of Corollary 49.4 one might be tempted to drop cohomology groups and move on to a different subject. But later on we will see that cohomology groups can be very interesting after all. The key, as we will see, is that cohomology is a contravariant functor whereas homology is a covariant functor.

Therefore we now persevere with the study of cohomology groups. In this chapter we want to extend the following deep theorems and theories from the homological setup to the cohomological setting:

(1) The Excision Theorem 31.17,
(2) the isomorphism between singular homology and cellular homology from Proposition 35.4,
(3) the Mayer-Vietoris Theorem 33.5.

These theorems will allow us in particular to give many more calculations of cohomology groups.

50.1. **Excision theorems for cohomology groups.** We start out with the analogue of the Excision Theorem 31.17.

Theorem 50.1. (Excision Theorem for Cohomology Groups) *Let X be a topological space and let $Z \subset A \subset X$ be subsets such that the closure of Z is contained in the interior of A. Then the inclusion*

$$i\colon (X \setminus Z, A \setminus Z) \quad \to \quad (X, A)$$

induces for each $n \in \mathbb{N}_0$ and every abelian group G an isomorphism

$$i^*\colon H^n(X, A; G) \quad \xrightarrow{\cong} \quad H^n(X \setminus Z, A \setminus Z; G).$$

Proof. In the original Excision Theorem 31.17 we showed that the inclusion induced map

$$i_*\colon H_n(X \setminus Z, A \setminus Z) \quad \to \quad H_n(X, A)$$

is an isomorphism for every $n \in \mathbb{N}_0$. But then it follows immediately from Corollary 49.5 that the inclusion induced maps

$$i^*\colon H^n(X, A; G) \quad \xrightarrow{\cong} \quad H^n(X \setminus Z, A \setminus Z; G).$$

are also isomorphisms. □

Remark. Using Corollary 49.5 we also obtain the "cohomological" versions of the various other excision theorems, e.g. Theorem 45.8 and Theorem 45.10. For example, let X be an m-dimensional topological manifold and let B be a compact m-dimensional submanifold of X. We write $\mathring{B} := B \setminus \partial_0 B$.[897] For every $n \in \mathbb{N}_0$ and any abelian group G the inclusion induced map

$$H^n(X, B; G) \xrightarrow{\cong} H^n\big(X \setminus \mathring{B}, \partial_0 B; G\big)$$

is an isomorphism.

[897] We refer to page 805 for the definition of $\partial_0 B$.

Psychologically it is often helpful to replace relative homology groups by the homology groups of a quotient space. In Proposition 31.19 we had seen that we can perform this switch for reasonable subsets. The following proposition does the same for cohomology groups.

Proposition 50.2. *Let G be an abelian group. Let X be a topological space and let $A \subset X$ be a non-empty subset. We denote by $p\colon (X,A) \to (X/A, A/A)$ the obvious projection map. We consider the following map:*

$$\begin{tikzcd} \widetilde{H}^n(X/A;G) \arrow[rr, bend right] & H^n(X/A, A/A; G) \arrow[l, "\text{Lemma 48.16 (5)}", "\cong"'] \arrow[r, "p^*"] & H^n(X,A;G) \end{tikzcd}$$

The following two statements hold:

1. *The above maps define a natural transformation from the contravariant functor $(X,A) \mapsto \widetilde{H}^n(X,A)$ to the contravariant functor $(X,A) \mapsto H^n(X,A;G)$.*
2. *If A is a non-empty good subset*[898]*, then the above map $\widetilde{H}^n(X/A;G) \to H^n(X,A;G)$ is an isomorphism.*

Proof. At this stage we have all the tools to rewrite the proof of Proposition 31.19. In particular we can use the above Excision Theorem 50.1 for Cohomology Groups to replace the Excision Theorem 31.17. We leave it to the reader to verify that nothing goes wrong. □

Example. Let G be an abelian group. From the calculation of the cohomology groups of finitely many points, see Lemmas 48.12 and 48.14, we obtain that

$$H^k(S^0;G) \quad \cong \quad \begin{cases} G^2, & \text{if } k=0, \text{ and} \\ 0, & \text{if } k \neq 0. \end{cases}$$

Similar to the proof of Proposition 31.3 we can use Proposition 50.2 to calculate, via an induction argument, that for $n \geq 1$ we have

$$H^k(S^n;G) \quad \cong \quad \begin{cases} G, & \text{if } k=0 \text{ or } k=n, \text{ and} \\ 0, & \text{if } k \neq 0, n. \end{cases}$$

We will give an alternative calculation of the cohomology groups of spheres in the next section using cellular cohomology.

50.2. **Cellular cohomology.** In Chapter 35 we introduced the cellular homology of a CW-complex. We saw that it is naturally isomorphic to singular homology and we saw that in many examples it is straightforward to compute cellular homology. Now we will repeat the trick and introduce cellular cohomology.

First we recall some definitions and some notation. Let X be a CW-complex.

1. Recall that given $n \in \mathbb{N}_0$ we denote by X^n the n-skeleton of X.
2. We write $C_n^{\mathrm{CW}}(X) := H_n(X^n, X^{n-1})$ and we denote by $d_n\colon C_n^{\mathrm{CW}}(X) \to C_{n-1}^{\mathrm{CW}}(X)$ the cellular boundary map from page 882.

[898]Recall according to the definition on page 763 this means that A is closed and that there exists an open neighborhood U of A in X such that A is a deformation retract of U.

(3) We refer to

$$\dots \xrightarrow{d_{n+1}} C_{n+1}^{\mathrm{CW}}(X) \xrightarrow{d_{n+1}} C_n^{\mathrm{CW}}(X) \xrightarrow{d_n} C_{n-1}^{\mathrm{CW}}(X) \xrightarrow{d_{n-1}} \dots$$

as the *cellular chain complex*.

(4) Let G be an abelian group. We remark that for a finite CW-complex we have

$$\mathrm{Hom}\left(C_n^{\mathrm{CW}}(X), G\right) \underset{\substack{\uparrow \\ \text{Lemmas 35.1 and 48.1}}}{\cong} \text{maps from the set of } n\text{-cells to } G \;=\; G^{\#\, n\text{-cells}}.$$

We refer to elements in $\mathrm{Hom}\left(C_n^{\mathrm{CW}}(X), G\right)$ as *cellular n-cochains*.

Example. Given a CW-complex X an integral cellular 1-cochain in $\mathrm{Hom}\left(C_1^{\mathrm{CW}}(X), \mathbb{Z}\right)$ assigns to *every* 1-cell an integer. We refer to Figure 685 for an illustration. In contrast an element in $C_1^{\mathrm{CW}}(X)$ can be viewed as a formal linear combination of 1-cells which is the same as saying that an element in $C_1^{\mathrm{CW}}(X)$ assigns a non-zero integer to only *finitely many* 1-cells.

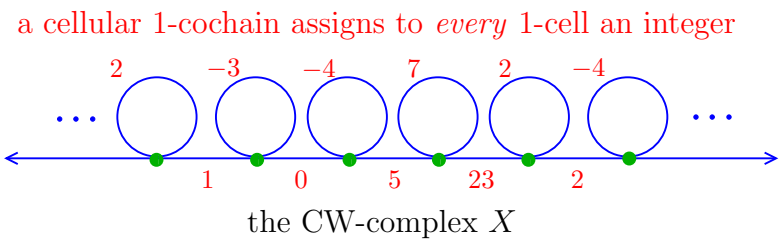

FIGURE 685.

Definition. Let G be an abelian group and let $n \in \mathbb{N}_0$.

(1) Let X be a CW-complex. We write $f_n := d_{n+1}^*$. We refer to

$$\dots \leftarrow \mathrm{Hom}\left(C_{n+1}^{\mathrm{CW}}(X), G\right) \xleftarrow{f_n} \mathrm{Hom}\left(C_n^{\mathrm{CW}}(X), G\right) \leftarrow \mathrm{Hom}\left(C_{n-1}^{\mathrm{CW}}(X), G\right) \xleftarrow{f_{n-1}} \dots$$

as the *cellular cochain complex*. We define the *n-th cellular cohomology group of X with G-coefficients* as

$$H_{\mathrm{CW}}^n(X;G) := H^n\left(C_*^{\mathrm{CW}}(X), G\right) = \frac{\ker\left\{f_n\colon \mathrm{Hom}(C_n^{\mathrm{CW}}(X), G) \to \mathrm{Hom}(C_{n+1}^{\mathrm{CW}}(X), G)\right\}}{\mathrm{im}\left\{f_{n-1}\colon \mathrm{Hom}(C_{n-1}^{\mathrm{CW}}(X), G) \to \mathrm{Hom}(C_n^{\mathrm{CW}}(X), G)\right\}}.$$

(2) If $f\colon X \to Y$ is a cellular map, then by Lemma 35.3 we get an induced chain map $f_*\colon C_*^{\mathrm{CW}}(X) \to C_*^{\mathrm{CW}}(Y)$ and thus we obtain from Lemma 48.8 (1) an induced map $f^*\colon H_{\mathrm{CW}}^n(Y;G) \to H_{\mathrm{CW}}^n(X;G)$.

For completeness' sake we jot down the following fairly self-evident lemma.

Lemma 50.3. $(*)$ *Let G be an abelian group and let $n \in \mathbb{N}_0$. The maps*

$$X \mapsto H^n_{\mathrm{CW}}(X) \quad \text{and} \quad (f\colon X \to Y) \mapsto (f^*\colon H^n_{\mathrm{CW}}(Y;G) \to H^n_{\mathrm{CW}}(X;G))$$

define a contravariant functor from the category of CW-complexes to the category of abelian groups.

Proof. This lemma follows immediately from Lemmas 35.3 and 48.8 (2). □

Perhaps not surprisingly we have the following theorem which plays a similar role as Proposition 35.4.

Proposition 50.4. *For every CW-complex X, any abelian group G and any $n \in \mathbb{N}_0$ there exists a natural isomorphism*[899]

$$H^n(X;G) \xrightarrow{\cong} H^n_{\mathrm{CW}}(X;G).$$

Remark. An alternative proof of this theorem is given in [Hat, p. 203].

First proof of Proposition 50.4. Let X be a CW-complex. Recall that on page 1189 we introduced the intermediate cellular chain complex that is given by

$$C^{\mathrm{int}}_n(X) := \ker\left\{C_n(X^n) \xrightarrow{\partial} C_{n-1}(X^n) \to C_{n-1}(X^n, X^{n-1})\right\} \quad \text{for } n \in \mathbb{N}_0.$$

We consider the two *natural* chain maps

$$i\colon C^{\mathrm{int}}_*(X) \hookrightarrow C_*(X) \quad \text{and} \quad p\colon C^{\mathrm{int}}_*(X) \twoheadrightarrow C^{\mathrm{CW}}_*(X),$$

which are given by the obvious inclusion and the obvious projection. In Proposition 49.11 we had seen that these two chain maps are chain homotopy equivalences. Thus it follows from Lemma 48.8 (4) that we get isomorphisms

$$H^n(X;G) = H^n(C_*(X);G) \xrightarrow[\cong]{i^*} H^n(C^{\mathrm{int}}_*(X);G) \xleftarrow[\cong]{p^*} H^n(C^{\mathrm{CW}}_*(X);G) = H^n_{\mathrm{CW}}(X;G).$$

As pointed out above, the two chain maps i and p are natural. Therefore we see that the above isomorphism $H^n(X;G) \to H^n_{\mathrm{CW}}(X;G)$ is in fact natural. □

Alternative proof of Proposition 50.4 without "natural". Let X be a CW-complex. We denote by $C_* = C_*(X)$ the singular chain complex and we denote by $D_* = C^{\mathrm{CW}}_*(X)$ the cellular chain complex. In Proposition 35.4 we showed that all the homology groups of the chain complexes C_* and D_* are isomorphic. It follows from Corollary 49.3 that for any abelian group G and any $n \in \mathbb{N}_0$ the cohomology groups $H^n(X;G) = H^n(C_*;G)$ and $H^n_{\mathrm{CW}}(X;G) = H^n(D_*;G)$ are isomorphic. This approach to proving Proposition 50.4 circumvents the use of Proposition 49.11. But it is not clear how this approach can be used to show that there exists a *natural* isomorphism. Of course for many applications this is not an issue. □

[899] Here "natural" means that there exists a natural transformation between the contravariant functors $X \mapsto H^n(X;G)$ and $X \mapsto H^n_{\mathrm{CW}}(X;G)$ from the category of CW-complexes to the category of abelian groups.

Examples. Let G be an abelian group.

(1) We use cellular cohomology to once again compute the cohomology groups of spheres. As we saw on page 648 we can view S^n, $n \geq 1$, as a CW-complex with one 0-cell and one other cell of dimension n. Furthermore the cellular boundary maps are the zero maps.[900] Thus we see that the cellular chain complex is of the form

$$0 \to \mathbb{Z} \xrightarrow{0} \cdots \xrightarrow{0} \mathbb{Z} \to 0.$$

The dual cochain complex is then given by

$$0 \leftarrow \underbrace{\mathrm{Hom}(\mathbb{Z}, G)}_{=G} \xleftarrow{0} \cdots \xleftarrow{0} \underbrace{\mathrm{Hom}(\mathbb{Z}, G)}_{=G} \leftarrow 0.$$

Summarizing, precisely as on page 1193 we obtain that

$$H^k(S^n; G) \cong \begin{cases} G, & \text{if } k = 0, n, \\ 0, & \text{otherwise.} \end{cases}$$

(2) If Γ is a connected, finite graph, then it follows from Proposition 9.21 that Γ is homotopy equivalent to a CW-complex X with one 0-cell and $\chi(\Gamma) + 1$ 1-cells, see Figure 686. The unique cellular boundary map in the cellular chain complex of X is zero by Lemma 35.7. Summarizing we see that for any $n \in \mathbb{N}_0$ we have

$$H^n(\Gamma; G) \underset{\substack{\uparrow \\ \text{Lemma 48.13}}}{\cong} H^n(X; G) \underset{\substack{\uparrow \\ \text{Proposition 50.4}}}{\cong} H^n_{\mathrm{CW}}(X; G) \underset{\substack{\uparrow \\ \text{since the coboundary map is zero}}}{\cong} \mathrm{Hom}(C_n^{\mathrm{CW}}(X); G) \cong \begin{cases} G, & \text{if } n = 0, \\ G^{\chi(\Gamma)+1}, & \text{if } n = 1, \\ 0, & \text{if } n \geq 2. \end{cases}$$

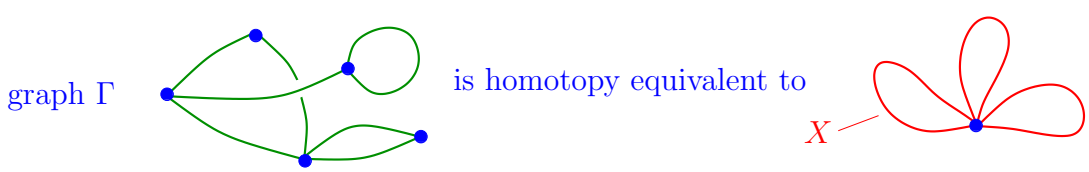

FIGURE 686.

(3) Given $g \in \mathbb{N}_0$ and $m \in \mathbb{N}_0$ we denote by $\Sigma_{g,m}$ the surface of genus g minus m open disks. On page 951 we had argued that for $m \geq 1$ the topological space $\Sigma_{g,m}$ is homotopy equivalent to the wedge of $2g + m - 1$ circles. The previous example, together with Lemma 48.13, thus gives us the calculation of the cohomology groups of $\Sigma_{g,m}$ for $m \geq 1$.

(4) Let Σ_g be the surface of genus g. In Figure 400 we showed that we can view Σ_g as a CW-complex with one 0-cell, $2g$ 1-cells and one 2-cell. On page 891 we saw that the

[900] For $n \geq 2$ this follows by definition, for $n = 1$ this is a consequence of Lemma 35.7.

cellular boundary maps are all zero. Hence for any abelian group G and any $n \in \mathbb{N}_0$ we have

$$H^n(\Sigma_g; G) \underset{\substack{\uparrow \\ \text{Proposition 50.4}}}{\cong} H^n_{\mathrm{CW}}(\Sigma_g; G) = \mathrm{Hom}\left(C^{\mathrm{CW}}_n(\Sigma_g); G\right) \cong \begin{cases} G, & \text{if } n = 0 \text{ or } n = 2, \\ G^{2g}, & \text{if } n = 1, \text{ and} \\ 0, & \text{if } n \neq 0, 1, 2. \end{cases}$$

In all the examples so far the cohomology groups are isomorphic to the corresponding homology groups that we had calculated earlier. Now we will see an example where the homology and cohomology groups differ.

Examples.

(1) We consider the n-dimensional projective space $\mathbb{R}\mathrm{P}^n$. In the proof of Proposition 35.11 we saw that there exists a CW-structure on $\mathbb{R}\mathrm{P}^n$ such that the corresponding cellular chain complex is of the following form:

$$0 \to \underset{\substack{\uparrow \\ \text{degree } n}}{\mathbb{Z}} \xrightarrow{\cdot(1+(-1)^n)} \mathbb{Z} \to \ldots \xrightarrow{0} \mathbb{Z} \xrightarrow{\cdot 2} \mathbb{Z} \xrightarrow{0} \mathbb{Z} \to 0$$

which allowed us to compute the homology groups of $\mathbb{R}\mathrm{P}^n$. Now let G be an abelian group. We dualize this chain complex, i.e. we apply the functor $\mathrm{Hom}(-, G)$. Using the isomorphism $\mathrm{Hom}(\mathbb{Z}, G) \to G$ from Lemma 48.1 we see that the cochain complex is isomorphic to the following cochain complex:

$$0 \leftarrow G \xleftarrow{\cdot(1+(-1)^n)} G \leftarrow \ldots \xleftarrow{0} G \xleftarrow{\cdot 2} G \xleftarrow{0} G \leftarrow 0.$$

For $G = \mathbb{Z}$ we thus obtain from Proposition 50.4 that for any $k \in \{0, \ldots, n\}$ we have

$$H^k(\mathbb{R}\mathrm{P}^n) \cong \begin{cases} \mathbb{Z}, & \text{if } k = 0, \\ \mathbb{Z}_2, & \text{if } k \text{ is even and } k \neq 0, \\ 0, & \text{if } k \text{ is odd and } k \neq n, \\ \mathbb{Z}, & \text{if } k = n \text{ and } n \text{ is odd} \end{cases} \quad \text{but } H_k(\mathbb{R}\mathrm{P}^n) \cong \begin{cases} \mathbb{Z}, & \text{if } k = 0, \\ \mathbb{Z}_2, & \text{if } k \text{ is odd and } k \neq n, \\ 0, & \text{if } k \text{ is even and } k \neq 0, \\ \mathbb{Z}, & \text{if } k = n \text{ and } n \text{ is odd} \end{cases}$$

where on the right-hand side we recall the calculation of the homology groups using the above cellular chain complex, see also Proposition 35.11. Therefore we see that for $n \geq 2$ the isomorphism types of the homology groups and the cohomology groups of $\mathbb{R}\mathrm{P}^n$ with $\mathbb{Z}$-coefficients do *not* coincide.

(2) To add to the confusion we also compute the cohomology of $\mathbb{R}\mathrm{P}^n$ with $\mathbb{F}_2$-coefficients. The corresponding dual cellular cochain complex is then given by

$$0 \to \mathbb{F}_2 \xleftarrow{0} \mathbb{F}_2 \leftarrow \ldots \leftarrow \mathbb{F}_2 \xleftarrow{\cdot 2 = 0} \mathbb{F}_2 \xleftarrow{0} \mathbb{F}_2 \to 0$$

and we see that

$$H^k(\mathbb{R}\mathrm{P}^n; \mathbb{F}_2) \cong \begin{cases} \mathbb{F}_2, & \text{if } k = 0, \ldots, n, \\ 0, & \text{otherwise.} \end{cases}$$

If we compare this result with the calculation on page 1011 of the homology of $\mathbb{R}\mathrm{P}^n$ with $\mathbb{F}_2$-coefficients we see that we get the same result. More precisely, the homology groups and the cohomology groups of $\mathbb{R}\mathrm{P}^n$ with $\mathbb{F}_2$-coefficients are isomorphic.

One can easily modify the above argument and apply it to $\mathbb{R}\mathrm{P}^\infty$, which we can view as a CW-complex with precisely one cell in each dimension, see 655. We then obtain easily that for each $k \in \mathbb{N}_0$ we have

$$H^k(\mathbb{R}\mathrm{P}^\infty; \mathbb{F}_2) \;\cong\; \mathbb{F}_2$$

(3) We recall that in Lemma 26.2 we showed that we can view $\mathbb{C}\mathrm{P}^n$ as a CW-complex which admits exactly one cell in dimensions $0, 2, \dots, 2n$ and which admits no odd-dimensional cells. It follows easily from Proposition 50.4 that

$$H^k(\mathbb{C}\mathrm{P}^n; \mathbb{Z}) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k = 0, 2, 4, \dots, 2n, \\ 0, & \text{otherwise.} \end{cases}$$

By Lemma 26.7 (2) we can view the infinite-dimensional complex projective space $\mathbb{C}\mathrm{P}^\infty$ as a CW-complex that has precisely one cell in each even dimension and no cells in odd dimensions. Using Proposition 50.4 we obtain that

$$H^k(\mathbb{C}\mathrm{P}^\infty; \mathbb{Z}) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k \text{ even,} \\ 0, & \text{if } k \text{ odd.} \end{cases}$$

Given $k < l \in \mathbb{N} \cup \{\infty\}$ we have an inclusion $\mathbb{C}\mathrm{P}^k \to \mathbb{C}\mathrm{P}^l$. Since the isomorphism of Proposition 50.4 is natural and since the cellular chain complexes of $\mathbb{C}\mathrm{P}^n$ and $\mathbb{C}\mathrm{P}^\infty$ agree up to the dimension $2n+1$ we see that the inclusion induced maps $H^k(\mathbb{C}\mathrm{P}^\infty; \mathbb{Z}) \to H^k(\mathbb{C}\mathrm{P}^n; \mathbb{Z})$ are actually isomorphisms up to dimension $2n$.

50.3. **Explicit generators of cohomology groups.** In the previous section we had used cellular cohomology to compute the isomorphism types of the cohomology groups of many different topological spaces. But this calculation of the isomorphism types does not give us any explicit generators of the cohomology groups. For example on page 1166 we introduced a singular 1-cochain $\theta_\mathbb{Z} \colon C_1(S^1) \to \mathbb{Z}$ and we showed in Lemma 48.10 that $\theta_\mathbb{Z}$ defines a non-zero cohomology class $[\theta_\mathbb{Z}] \in H^1(S^1; \mathbb{Z})$. By the discussion on page 1196 we now also know that $H^1(S^1; \mathbb{Z}) \cong \mathbb{Z}$, but we do not know whether $[\theta_\mathbb{Z}] \in H^1(S^1; \mathbb{Z})$ is a generator.

On the other hand in earlier chapters we had obtained a pretty good understanding of generators of homology groups. The idea now is to translate information on homology groups to information on cohomology groups. The key tool relating homology and cohomology is given by the Kronecker pairing that we now introduce.

Lemma 50.5. *Let C_* be a chain complex.*

(1) *Let G be an abelian group. The map*

$$\begin{array}{rcl} \langle\ ,\ \rangle \colon H^n(C; G) \times H_n(C) & \to & G \\ ([\varphi], [c]) & \mapsto & \langle [\varphi], [c] \rangle := \varphi(c) \\ & & \uparrow \end{array}$$

here $\varphi \in \mathrm{Hom}(C_n, G)$ and $c \in C_n$, so $\varphi(c) \in G$ is defined

is well-defined and bilinear.[901] *In particular, if (X, A) is a pair of topological spaces, then the map*

$$\begin{array}{rcl} \langle\ ,\ \rangle_X \colon H^n(X,A;G) \times H_n(X,A) & \to & G \\ ([\varphi],[c]) & \mapsto & \langle[\varphi],[c]\rangle_X := \varphi(c) \end{array}$$

is well-defined and bilinear. We refer to both pairings as the Kronecker pairing.[902][903]

(2) $(*)$ *If $\varphi\colon G_1 \to G_2$ is a group homomorphism then the following diagram commutes:*

$$\begin{tikzcd} H^n(C;G_1) \times H_n(C) \arrow[r, "\langle -,- \rangle"] \arrow[d, "\varphi_* \times \mathrm{id}"] & G_1 \arrow[d, "\varphi"] \\ H^n(C;G_2) \times H_n(C) \arrow[r, "\langle -,- \rangle"] & G_2. \end{tikzcd}$$

Proof. Let C_* be a chain complex.

(1) Let G be an abelian group. Let $\varphi \in \mathrm{Hom}(C_n, G)$ be a cocycle and let $c \in C_n$ be a cycle. Furthermore let $\alpha \in \mathrm{Hom}(C_{n-1}, G)$ and let $d \in C_{n+1}$. Then the following equalities hold in G:

$$\begin{array}{ccccccccc} (\varphi + \delta\alpha)(c) & = & \varphi(c) + \alpha(\partial c) & = & \varphi(c) & \text{and} & \varphi(c + \partial d) & = & \varphi(c) + (\delta\varphi)(d) & = & \varphi(c). \\ & \uparrow & & \uparrow & & & & \uparrow & & \uparrow & \\ & \text{definition of } \delta & & \text{since } c \text{ is a cycle} & & & & \text{definition of } \delta & & \text{since } \varphi \text{ is a cocycle} & \end{array}$$

This calculation shows that the definition of the Kronecker pairing does not depend on the choices of the representatives of the cohomology and the homology classes. Finally note that it is clear that the Kronecker pairing is bilinear.

(2) This statement follows immediately from the definitions. □

Even though we do not need the following lemma in the near future, we record it already for later on.

Lemma 50.6. *Let $f\colon C_* \to D_*$ be a chain map between two chain complexes and let G be an abelian group. Then for any $c \in H_n(C)$ and $\varphi \in H^n(D;G)$ we have*

$$\langle f^*(\varphi), c\rangle \ = \ \langle \varphi, f_*(c)\rangle.$$

In particular, suppose that $f\colon (X,A) \to (Y,B)$ is a map between two pairs of topological spaces. Let $c \in H_n(X,A)$ and let $\varphi \in H^n(Y,B;G)$. Then

$$\langle f^*(\varphi), c\rangle_X \ = \ \langle \varphi, f_*(c)\rangle_Y.$$

[901] In general, given a commutative ring R a map $\Theta\colon U \times V \to W$ between R-modules is called *bilinear*, if for all $u, u' \in U$, $v, v' \in V$ and $r \in R$ we have

$$\begin{array}{rclcrcl} \Theta(u+u',v) & = & \Theta(u,v) + \Theta(u',v) & \text{and} & \Theta(ru,v) & = & r\Theta(u,v), \quad \text{and} \\ \Theta(u,v+v') & = & \Theta(u,v) + \Theta(u,v') & \text{and} & \Theta(u,rv) & = & r\Theta(u,v). \end{array}$$

In our special case we consider the case of $\mathbb{Z}$-modules.

[902] Often we drop the subscript X in the notation.

[903] Leopold Kronecker (1823–1891) was a German mathematician who worked on number theory. I don't know how his name got attached to this pairing.

Proof. The statement follows immediately from the definitions. Indeed, if $[c] \in H_n(C)$ and $[\varphi] \in H^n(D;G)$, then

$$\langle f^*([\varphi]),[c]\rangle \;=\; \langle [f^*\varphi],[c]\rangle \;=\; (f^*\varphi)(c) \;=\; \varphi(f_*(c)) \;=\; \langle [\varphi],[f_*(c)]\rangle \;=\; \langle [\varphi], f_*([c])\rangle.$$

The statement regarding maps between pairs of topological spaces is an immediate consequence of the purely algebraic statement. □

Now we state the lemma which will allow us in many situations to show that given cocycles form a basis for cohomology groups.

Lemma 50.7. *Let X be a topological space and let $n \in \mathbb{N}_0$. Suppose that $H^n(X;\mathbb{Z})$ and $H_n(X;\mathbb{Z})$ are free abelian groups of rank k and suppose we are given $\varphi_1,\dots,\varphi_k \in H^n(X;\mathbb{Z})$ and $c_1,\dots,c_k \in H_n(X;\mathbb{Z})$. If*

$$\det\Big(\underbrace{\langle \varphi_i, c_j\rangle_{i,j=1,\dots,k}}_{=\,k\times k\text{-matrix}}\Big) \;=\; \pm 1,$$

then $\varphi_1,\dots,\varphi_k \in H^n(X;\mathbb{Z})$ and $c_1,\dots,c_k \in H_n(X;\mathbb{Z})$ are both bases.

Example. Let $X = S^1$. We denote by $\theta_{\mathbb{Z}}\colon C_1(S^1) \to \mathbb{Z}$ the singular 1-cocycle that we introduced on page 1166. We consider the singular cycle $\mu\colon \Delta^1 \to S^1$ that is given by $(1-t,t) \mapsto e^{2\pi i t}$. As on page 1167 we see that

$$\langle [\theta_{\mathbb{Z}}],[\mu]\rangle \;=\; \theta_{\mathbb{Z}}(\mu) \;=\; \alpha_{\mathbb{Z}}\left(\text{boundary of lift } \begin{array}{rcl} \widetilde{\mu}\colon \Delta^1 & \to & \mathbb{R} \\ (1-t,t) & \mapsto & t \end{array} \text{ of } \mu\right) \;=\; 1.$$

From Proposition 31.3 we know that $H_1(S^1;\mathbb{Z}) \cong \mathbb{Z}$ and by the discussion on page 1193 we know that $H^1(S^1;\mathbb{Z}) \cong \mathbb{Z}$. Therefore it follows from Lemma 50.7 that $[\theta_{\mathbb{Z}}] \in H^1(S^1;\mathbb{Z})$ is in fact a generator.[904] In particular we have an equality $H^1(S^1;\mathbb{Z}) = \mathbb{Z}\cdot[\theta_{\mathbb{Z}}]$.

Remark. Lemma 50.7 is really quite generous, it gives us as output that both sets are bases. In particular to apply the lemma we do not even have to verify that the c_i form a basis.

Lemma 50.7 is an immediate consequence of the following purely algebraic lemma.

Lemma 50.8. *Let A and B be two free abelian groups of rank k, let $a_1,\dots,a_k \in A$ and let $b_1,\dots,b_k \in B$. Furthermore let $\langle\ ,\ \rangle\colon A\times B \to \mathbb{Z}$ be a bilinear pairing. If*

$$\det(\langle a_i, b_j\rangle_{i,j=1,\dots,k}) \;=\; \pm 1,$$

then both $a_1,\dots,a_k$ and $b_1,\dots,b_k$ are bases.

Proof. We denote by S the free abelian group generated by the set $\{a_1,\dots,a_k\}$ and we denote by T the free abelian group generated by the set $\{b_1,\dots,b_k\}$. We denote by $i\colon S \to A$ and by $j\colon T \to B$ the obvious maps given by $a_i \mapsto a_i$ and $b_i \mapsto b_i$. We denote by

[904] It also follows from Lemma 50.7 that the singular 1-simplex $\mu\colon \Delta^1 \to S^1$ represents a generator for $H_1(S^1) \cong \mathbb{Z}$. We had obtained that result in Lemma 32.11.

$\Phi\colon A \to \mathrm{Hom}(B,\mathbb{Z})$ the homomorphism given by $a \mapsto (b \mapsto \langle a,b\rangle)$.[905] The claim follows from the following three observations:

(1) Let $\gamma\colon G \to H$ be a homomorphism between two finitely generated free abelian groups of the same rank. Lemma 11.8 (5) says that if γ is an epimorphism, then γ it is already an isomorphism.

(2) We consider the following sequence of homomorphisms

$$S \xrightarrow{i} A \xrightarrow{\Phi} \mathrm{Hom}(B,\mathbb{Z}) \xrightarrow{j^*} \mathrm{Hom}(T,\mathbb{Z}).$$

With respect to the basis $a_1,\dots,a_k$ of S and the dual basis $b_1^*,\dots,b_k^*$ of $\mathrm{Hom}(T,\mathbb{Z})$ this linear map is represented by the matrix $\langle a_i,b_j\rangle_{i,j=1,\dots,k}$. Thus by our hypotheses this map is an isomorphism. Furthermore by our hypotheses each of the individual groups is a free abelian group of rank k.

(3) Since the map in (2) is an isomorphism it is in particular an epimorphism. Starting from the right and using (1) three times in a row we see that all maps are in fact isomorphisms. In particular we have $S = A$. The same argument turned around shows that $T = B$. □

Now we will use Lemma 50.7 to determine explicit bases for the first cohomology groups of surfaces. We start out with the torus.

Lemma 50.9. *We consider the two projection maps*

$$\begin{array}{rcl} p\colon S^1\times S^1 & \to & S^1 \\ (v,w) & \mapsto & v \end{array} \quad \textit{and} \quad \begin{array}{rcl} q\colon S^1\times S^1 & \to & S^1 \\ (v,w) & \mapsto & w. \end{array}$$

Then $p^*([\theta_{\mathbb{Z}}])$ and $q^*([\theta_{\mathbb{Z}}])$ form a basis for $H^1(S^1\times S^1;\mathbb{Z}) \cong \mathbb{Z}^2$.

Proof. We denote as usual by $\mu\colon \Delta^1 \to S^1$ our favorite singular 1-cycle of S^1 that is given by $\mu(1-t,t) = e^{2\pi i t}$. For simplicity we write $\theta = \theta_{\mathbb{Z}}$. We denote by

$$\begin{array}{rcl} i\colon S^1 & \to & S^1\times S^1 \\ z & \mapsto & (z,1) \end{array} \quad \text{and} \quad \begin{array}{rcl} j\colon S^1 & \to & S^1\times S^1 \\ z & \mapsto & (1,z) \end{array}$$

the two obvious inclusion maps. We calculate that

$$\begin{pmatrix} \langle [p^*\theta],[i_*(\mu)]\rangle & \langle [p^*\theta],[j_*(\mu)]\rangle \\ \langle [q^*\theta],[i_*(\mu)]\rangle & \langle [q^*\theta],[j_*(\mu)]\rangle \end{pmatrix} \overset{\substack{\text{since } \langle [p^*\theta],[i_*(\mu)]\rangle = (p^*\theta)(i_*(\mu)) = \theta(p_*(i_*(\mu))) \text{ and similarly for the other terms} \\ \downarrow}}{=} \begin{pmatrix} \theta(p_*(i_*(\mu))) & \theta(p_*(j_*(\mu))) \\ \theta(q_*(i_*(\mu))) & \theta(q_*(j_*(\mu))) \end{pmatrix} \underset{\substack{\uparrow \\ \text{since } p\circ i = \mathrm{id} \text{ and } q\circ j = \mathrm{id} \text{ and since } p\circ j \equiv 1 \in S^1 \text{ and } q\circ i \equiv 1 \in S^1 \\ \text{here we denote by 1 also the constant singular 1-simplex given by } (1-t,t)\mapsto 1}}{=} \begin{pmatrix} \theta(\mu) & \theta(1) \\ \theta(1) & \theta(\mu) \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}.$$

We know from Lemma 33.12 that $H_1(S^1\times S^1;\mathbb{Z}) \cong \mathbb{Z}^2$ and we saw on page 1197 that $H^1(S^1\times S^1;\mathbb{Z}) \cong \mathbb{Z}^2$. The above calculation, together with Lemma 50.7 shows that $p^*([\theta_{\mathbb{Z}}])$ and $q^*([\theta_{\mathbb{Z}}])$ form a basis for $H^1(S^1\times S^1;\mathbb{Z})$. □

[905] The fact that $\langle\,,\,\rangle$ is bilinear implies that $b \mapsto \langle a,b\rangle$ is a homomorphism and that $\Phi\colon A \to \mathrm{Hom}(B,\mathbb{Z})$ is a homomorphism.

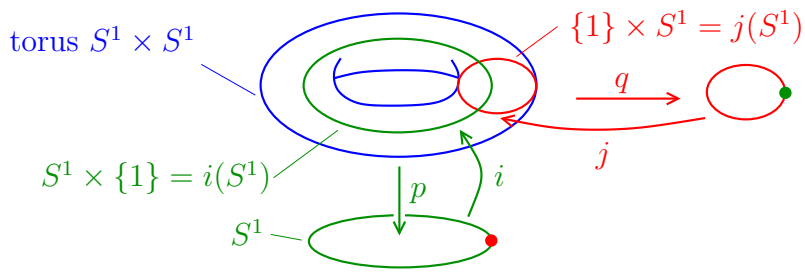

FIGURE 687.

Together with Proposition 48.11 we have now found explicit generators for the cohomology groups of the torus in dimensions 0 and 1. The following question arises:

Question 50.10. *Can we find an explicit generator of $H^2(S^1 \times S^1; \mathbb{Z}) \cong \mathbb{Z}$?*

Now we turn to surfaces of higher genus. As usual, given $g \in \mathbb{N}$ we denote by Σ_g the surface of genus g. In Figure 688 we show projection maps $p_i \colon \Sigma_g \to S^1 \times S^1$, $i = 1, \dots, g$.[906] The following lemma is a generalization of Lemma 50.9.

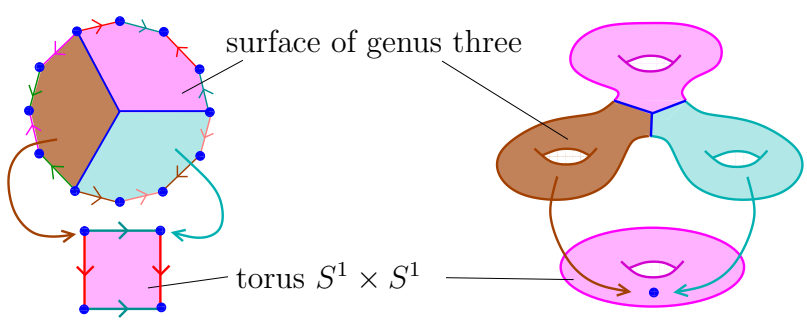

FIGURE 688.

Lemma 50.11. *We denote by $\alpha, \beta \in H^1(S^1 \times S^1; \mathbb{Z})$ the basis given by Lemma 50.9. A basis for $H^1(\Sigma_g; \mathbb{Z}) \cong \mathbb{Z}^{2g}$ is given by $p_i^*(\alpha), p_i^*(\beta)$, $i = 1, \dots, g$.*

Proof. The proof of the lemma is very similar to the proof of Lemma 50.9. For $i = 1, \dots, g$ we write $\varphi_i = p_i^*(\alpha)$ and $\psi_i := p_i^*(\beta)$. We consider the singular 1-cycles $x_1, \dots, x_g$ and $y_1, \dots, y_g$ that are indicated in Figure 689. As in the proof of Lemma 50.9 it follows easily from the definitions that (for $g = 2$) we have

$$\begin{pmatrix} \langle \varphi_1, x_1 \rangle & \langle \varphi_1, y_1 \rangle & \langle \varphi_1, x_2 \rangle & \langle \varphi_1, y_2 \rangle \\ \langle \psi_1, x_1 \rangle & \langle \psi_1, y_1 \rangle & \langle \psi_1, x_2 \rangle & \langle \psi_1, y_2 \rangle \\ \langle \varphi_2, x_1 \rangle & \langle \varphi_2, y_1 \rangle & \langle \varphi_2, x_2 \rangle & \langle \varphi_2, y_2 \rangle \\ \langle \psi_2, x_1 \rangle & \langle \psi_2, y_1 \rangle & \langle \psi_2, x_2 \rangle & \langle \psi_2, y_2 \rangle \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}.$$

[906] In fact for $g = 2$ we already saw this map in Figure 142.

The lemma now follows immediately from Lemma 50.7. □

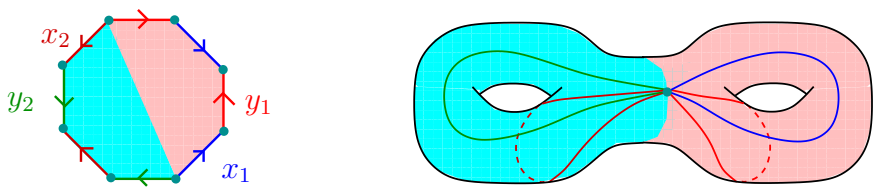

FIGURE 689. Illustration for the proof of Lemma 50.11.

50.4. **Excisive triads and the Mayer–Vietoris Theorem for cohomology groups.** Before we state and prove the Mayer–Vietoris Theorem for cohomology groups it is helpful to introduce the following definition.

Definition.

(1) A *triad of topological spaces* is a triple (X, A_1, A_2) where X is a topological space and where both A_1 and A_2 are subsets of X.[907]
(2) A map $f\colon (X, A_1, A_2) \to (Y, B_1, B_2)$ of triads is a map $f\colon X \to Y$ with $f(A_1) \subset B_1$ and $f(A_2) \subset B_2$.
(3) Given a triad (X, A_1, A_2) of topological spaces we consider the following subgroup of $C_n(A_1 \cup A_2)$:[908]

$$C_n^{\{A_1,A_2\}}(A_1 \cup A_2) := \left\{ \sum_{j=1}^{k} a_j \sigma_j \in C_n(A_1 \cup A_2) \;\middle|\; \begin{array}{l} \text{for each } j \text{ there exists an } i \in \{1,2\} \\ \text{such that the image of } \sigma_j \text{ lies in } A_i \end{array} \right\}.$$

The usual boundary map on the groups $C_*(A_1 \cup A_2)$ restricts to a boundary map on $C_*^{\{A_1,A_2\}}(A_1 \cup A_2)$, so we can view $C_*^{\{A_1,A_2\}}(A_1 \cup A_2)$ as a chain complex. We denote the corresponding homology groups by $H_*^{\{A_1,A_2\}}(A_1 \cup A_2)$.
(4) We say a triad (X, A_1, A_2) is *excisive* if the inclusion map

$$C_*^{\{A_1,A_2\}}(A_1 \cup A_2) \;\to\; C_*(A_1 \cup A_2)$$

is a chain homotopy equivalence of chain complexes.

Example. In Exercise 50.1 we will see that the triad $(X, A_1, A_2) := (\mathbb{R}, (-\infty, 0], (0, \infty))$ is *not* excisive.

After this negative example we want to collect some positive examples of excisive triads.

[907]This definition should not be confused with the definition of a *triple* of topological spaces, which was defined as a triple (X, B, A) where X is a topological space and $A \subset B \subset X$ are subsets. In a triad we do not demand that the third set is contained in the second set.

[908]The definition is basically the same as on page 787 except that this time we do not demand that the interiors of A_1 and A_2 cover all of X.

Proposition 50.12. *Let (X, A_1, A_2) be a triad of topological spaces. The triad is excisive if one of the following conditions is satisfied:*

(1) $A_1 \subset A_2$ *or* $A_2 \subset A_1$,
(2) $A_1 = \varnothing$ *or* $A_2 = \varnothing$ *or* $A_1 = A_2$,
(3) $A_1 \cup A_2 = \mathring{A}_1 \cup \mathring{A}_2$ *where we denote by* $\mathring{A}_1$ *and* $\mathring{A}_2$ *the interiors of* A_1 *and* A_2 *in* $A_1 \cup A_2$,
(4) A_1 *and* A_2 *are both open subsets of* $A_1 \cup A_2$,
(5) $A_1 \cup A_2$ *is a topological manifold and* A_1 *and* A_2 *are submanifolds such that each component of* $A_1 \cap A_2$ *is a boundary component of* A_1 *and a boundary component of* A_2, *and such that* A_1 *and* A_2 *are closed subsets,*
(6) X *is a CW-complex and* A_1 *and* A_2 *are both subcomplexes.*

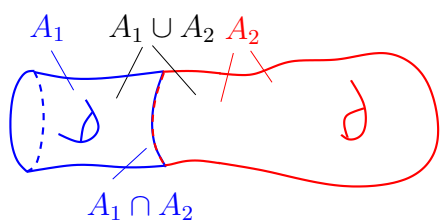

FIGURE 690. Illustration of Proposition 50.12 (5).

In the proof of Proposition 50.12 we will need the following lemma which gives us several criteria for a triad to be excisive.

Lemma 50.13. *Let (X, A_1, A_2) be a triad of topological spaces. The following statements are equivalent:*

(1) *the triad is excisive,*
(2) *for every $n \in \mathbb{N}_0$ the inclusion induced map*

$$H_n^{\{A_1, A_2\}}(A_1 \cup A_2) \;\to\; H_n(A_1 \cup A_2)$$

is an isomorphism,
(3) *for every $n \in \mathbb{N}_0$ the inclusion induced map*

$$H_n(A_1, A_1 \cap A_2) \;\to\; H_n(A_1 \cup A_2, A_2)$$

is an isomorphism.

Furthermore, if G is an abelian group and if the triad is excisive, then statements (2) *and* (3) *also hold for G-coefficients.*

Proof. Let (X, A_1, A_2) be a triad of topological spaces. The equivalence of (1) and (2) is an immediate consequence of Corollary 30.3 and Proposition 49.2.

Now we turn to the proof that (2) and (3) are equivalent. We write $Y = A_1 \cup A_2$. We consider the following sequences of chain complexes:

$$\begin{array}{ll} \text{(a)} & 0 \;\to\; C_*^{\{A_1,A_2\}}(Y) \;\to\; C_*(Y) \;\to\; C_*(Y)/C_*^{\{A_1,A_2\}}(Y) \;\to\; 0 \\ \text{(b)} & 0 \;\to\; \underbrace{C_*(A_1)/C_*(A_1\cap A_2)}_{=C_*(A_1,A_1\cap A_2)} \;\to\; \underbrace{C_*(Y)/C_*(A_2)}_{=C_*(Y,A_2)} \;\to\; C_*(Y)/C_*^{\{A_1,A_2\}}(Y) \;\to\; 0. \end{array}$$

The top sequence is exact by definition. It is easy to see that the bottom sequence is also exact. We can thus apply Proposition 31.10 to get the corresponding long exact sequences of homology groups:

$$\begin{array}{l} \text{(a)} \to H_n\big(C_*^{\{A_1,A_2\}}(Y)\big) \to H_n(Y) \to H_n\big(C_*(Y)/C_*^{\{A_1,A_2\}}(Y)\big) \xrightarrow{\partial} H_{n-1}\big(C_*^{\{A_1,A_2\}}(Y)\big) \to \\ \text{(b)} \to H_n(A_1, A_1\cap A_2) \to H_n(Y, A_2) \to H_n\big(C_*(Y)/C_*^{\{A_1,A_2\}}(Y)\big) \xrightarrow{\partial} H_{n-1}(A_1, A_1\cap A_2) \to \end{array}$$

But using these long exact sequences we see that

$$\text{(2) holds} \;\underset{\substack{\uparrow \\ \text{long exact sequence (a)}}}{\Longleftrightarrow}\; H_n\big(C_*(Y)/C_*^{\{A_1,A_2\}}(Y)\big) = 0 \text{ for all } n \in \mathbb{N}_0 \;\underset{\substack{\uparrow \\ \text{long exact sequence (b)}}}{\Longleftrightarrow}\; \text{(3) holds.}$$

Finally suppose that (X, A_1, A_2) is excisive and that G is an abelian group. The fact that the map in (2) is also an isomorphism with G-coefficients follows from basically the same argument as above. Furthermore, if (2) holds for G-coefficients, then again the same argument as above shows that also (3) holds with G-coefficients. □

Now we turn to the proof of Proposition 50.12.

Proof of Proposition 50.12. Let (X, A_1, A_2) be a triad of topological spaces.

(1) If $A_1 \subset A_2$, then $C_*^{\{A_1,A_2\}}(A_1 \cup A_2) = C_*(A_2) = C_*(A_1 \cup A_2)$, so the triad is excisive. The same argument applies if $A_2 \subset A_1$.
(2) This case is just a special case of (1).
(3) If $A_1 \cup A_2 = \mathring{A}_1 \cup \mathring{A}_2$, then the desired statement follows immediately from Proposition 49.7.
(4) The case that A_1 and A_2 are both open subsets of $A_1 \cup A_2$ is a special case of (3).
(5) Suppose that $A_1 \cup A_2$ is a compact topological manifold and that A_1 and A_2 are submanifolds such that each component of $A_1 \cap A_2$ is a boundary component of A_1 and a boundary component of A_2. The Excision Theorem 45.10 for topological manifolds implies that for every $n \in \mathbb{N}_0$ the inclusion induced map

$$H_n(A_1, A_1 \cap A_2) \;\to\; H_n(A_1 \cup A_2, A_2)$$

is an isomorphism. By Lemma 50.13 (3) ⇒ (1) this implies that the triad (X, A_1, A_2) is excisive.
(6) Suppose that X is a CW-complex and that A_1 and A_2 are both subcomplexes. The proof of the Excision Theorem 32.7 for Manifolds can easily be modified to give the corresponding statement for CW-complexes. More precisely, in the proof of the

Excision Theorem 32.7 for Manifolds we need to replace the Collar Neighborhood Theorem 10.10 by Proposition 26.11 (8). Furthermore we need to replace Proposition 3.21 (3) by Lemma 26.10 (3). We then proceed as in (5). We leave it to the reader to fill in the details. □

Now we can formulate the following theorem, which in view of Proposition 50.12 is a generalization of the various Mayer–Vietoris Theorems 33.5, 33.10, and 33.11 that we had formulated earlier.

Theorem 50.14. (Mayer–Vietoris Theorem) *Given any excisive triad (X, A, B) with $X = A \cup B$ there exists a natural*[909] *long exact sequence*

$$\cdots \to H_n(A \cap B) \xrightarrow{i_{A\cap B} \oplus -i_{A\cap B}} H_n(A) \oplus H_n(B) \xrightarrow{i_A + i_B} H_n(X) \xrightarrow{\partial_n} H_{n-1}(A \cap B) \to \dots$$

where the various maps denoted by i are the obvious inclusion induced maps. The same long exact sequence also exists for homology with coefficients in any abelian group G.

Proof. Let (X, A, B) be a triad with $X = A \cup B$. In the proof of the original Mayer–Vietoris Theorem 33.5 we showed that the sequence

$$0 \to C_*(A \cap B) \xrightarrow{i_{A\cap B} \oplus -i_{A\cap B}} C_*(A) \oplus C_*(B) \xrightarrow{i_A + i_B} C_*^{\{A,B\}}(X) \to 0$$

of chain maps is exact. We deduce from Proposition 31.10 that we get a long exact sequence of the form

$$\cdots \to H_n(A \cap B) \xrightarrow{i_{A\cap B} \oplus -i_{A\cap B}} H_n(A) \oplus H_n(B) \xrightarrow{i_A + i_B} H_n^{\{A,B\}}(X) \xrightarrow{p_n} H_{n-1}(A \cap B) \to \dots$$

This long exact sequence is natural by the remark on page 773. Now we suppose that (X, A, B) is in fact excisive. By definition, and since $X = A \cup B$, this means that the inclusion map

$$C_*^{\{A,B\}}(X) \to C_*(X)$$

is a chain homotopy equivalence, hence for every $n \in \mathbb{N}_0$ it induces a natural isomorphism

$$\Phi_n \colon H_n^{\{A,B\}}(X) \xrightarrow{\cong} H_n(X).$$

For each $n \in \mathbb{N}_0$ we now replace $H_n^{\{A,B\}}(X)$ by $H_n(X)$ and we write $\partial_n := p_n \circ \Phi_n^{-1}$ and we finally get the desired natural long exact sequence.

The argument for homology with G-coefficients is very similar, see also page 1010. We leave the details to the dedicated reader. □

[909] Here "natural" means that given a map $f \colon (X, A, B) \to (Y, C, D)$ of excisive triads with $X = A \cup B$ and $Y = C \cup D$ the following diagram commutes:

$$\begin{array}{ccccccccc}
\dots \longrightarrow & H_n(A \cap B) & \xrightarrow{i_{A\cap B} \oplus -i_{A\cap B}} & H_n(A) \oplus H_n(B) & \xrightarrow{i_A + i_B} & H_n(X) & \xrightarrow{\partial_n} & H_{n-1}(A \cap B) & \longrightarrow \dots \\
 & \downarrow f_* & & \downarrow f_* & & \downarrow f_* & & \downarrow f_* & \\
\dots \longrightarrow & H_n(C \cap D) & \xrightarrow{i_{C\cap D} \oplus -i_{C\cap D}} & H_n(C) \oplus H_n(D) & \xrightarrow{i_C + i_D} & H_n(Y) & \xrightarrow{\partial_n} & H_{n-1}(C \cap D) & \longrightarrow \dots
\end{array}$$

We also have the following analogue for cohomology groups.

Theorem 50.15. (Mayer–Vietoris Theorem for Cohomology Groups) *Let (X, A, B) be an excisive triad with $X = A \cup B$ and let G be an abelian group. Then there exists a natural*[910] *long exact sequence*

$$\cdots \to H^n(X;G) \xrightarrow{i^* \oplus i^*} H^n(A;G) \oplus H^n(B;G) \xrightarrow{i^* \oplus -i^*} H^n(A \cap B;G) \to H^{n+1}(X;G) \to \dots$$

where the maps i^* are the restrictions to the various subspaces.

Proof. Let (X, A, B) be an excisive triad with $X = A \cup B$ and let G be an abelian group. We start out with the following claim.

Claim. The inclusion map

$$C_*^{\{A,B\}}(X) \quad \to \quad C_*(X)$$

induces for each $n \in \mathbb{N}_0$ a natural isomorphism

$$H^n(X;G) \quad \to \quad H^n\big(C_*^{\{A,B\}}(X);G\big).$$

The claim follows immediately from the definition of an excisive triad together with Lemma 48.8 (3).

Now we turn to the actual proof of the Mayer–Vietoris Theorem for Cohomology Groups. Exactly as in the proof of the Mayer–Vietoris Theorem 50.14 we start out with the fact that the following sequence is exact:

$$0 \to C_*(A \cap B) \xrightarrow{i_{A\cap B} \oplus -i_{A \cap B}} C_*(A) \oplus C_*(B) \xrightarrow{i_A + i_B} C_*^{\{A,B\}}(X) \to 0.$$

The groups $C_*^{\{A,B\}}(X)$ are clearly free abelian groups. Thus we deduce from Lemma 48.4 and Proposition 48.6 that there exists a natural long exact sequence

$$\to \underbrace{H^n\big(C_*^{\{A,B\}}(X);G\big)}_{=H^n(X;G) \text{ by the claim}} \to H^n(A;G) \oplus H^n(B;G) \to H^n(A \cap B;G) \to \underbrace{H^{n+1}\big(C_*^{\{A,B\}}(X);G\big)}_{=H^{n+1}(X;G) \text{ by the claim}} \to$$

□

As an application of the Mayer–Vietoris Theorem 50.15 for Cohomology Groups we will determine the cohomology groups of the wedge of two topological spaces. We will not make use of this example.

Lemma 50.16. $(*)$ *Let X and Y be topological spaces and let $x \in X$ and $y \in Y$ be good points.*[911] *We use these points to define the wedge $X \vee Y$. Then $(X \vee Y, X, Y)$ is an excisive triad.*

---

[910] The meaning of "natural" is evidently totally analogous to the interpretation given in Footnote 909.

[911] Recall that according to the definition on page 387 we say that a point x in a topological space X is *good*, if $\{x\}$ is a closed subset and if there exists an open neighborhood U of x such that $\{x\}$ is a deformation retract of U.

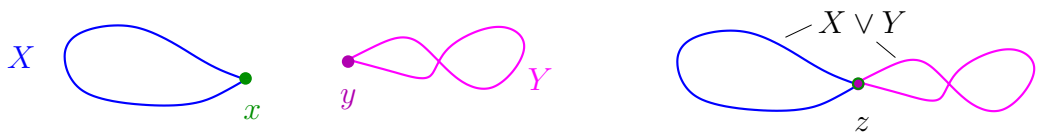

FIGURE 691.

Proof $(*)$. We denote by z the point in $X \vee Y$ that is given by identifying x with y. For each $k \in \mathbb{N}_0$ we consider the following diagram

$$\begin{array}{ccccccccc}
0 & \longrightarrow & H_k(Y,\{y\};\mathbb{Z}) & \longrightarrow & H_k(X,\{x\};\mathbb{Z}) \oplus H_k(Y,\{y\};\mathbb{Z}) & \longrightarrow & H_k(X,\{x\};\mathbb{Z}) & \longrightarrow & 0 \\
 & & \downarrow{=} & & \downarrow & & \downarrow & & \\
0 & \longrightarrow & H_k(Y,\{y\};\mathbb{Z}) & \longrightarrow & H_k(X \vee Y,\{z\};\mathbb{Z}) & \longrightarrow & H_k(X \vee Y, Y;\mathbb{Z}) & \longrightarrow & 0
\end{array}$$

where all the maps are the obvious maps. The top horizontal sequence is evidently exact. The bottom horizontal sequence is an excerpt from the long exact sequence of the triple $(\{y\} = \{z\}, Y, X \vee Y)$, see Proposition 31.13. The excerpt shown is also exact since $(Y, \{y\})$ is a retract of $(X \vee Y, \{z\})$, which implies that for any $l \in \mathbb{N}_0$ the inclusion induced map $H_l(Y,\{y\};\mathbb{Z}) \to H_l(X \vee Y,\{z\};\mathbb{Z})$ is a monomorphism.

The middle vertical map in the above diagram is an isomorphism by Proposition 34.8 and the left vertical map is the identity. It follows from the Five Lemma 31.11 that the right vertical hand map is an isomorphism. We obtain from Lemma 50.13 (3) $\Rightarrow$ (1) that $(X \vee Y, X, Y)$ is an excisive triad. $\square$

We can now prove the following proposition that is the analogue of Proposition 34.9.

Proposition 50.17. $(*)$ *Let $\{A_k\}_{k\in K}$ be a family of topological spaces. For each $k \in K$ suppose that we are given a good point $a_k \in A_k$. Let G be an abelian group. Given $j \in K$ we denote by*

$$i_j \colon A_j \to \bigvee_{k\in K} A_k \quad \textit{respectively} \quad p_j \colon \bigvee_{k\in K} A_k \to A_j$$

the natural inclusion map respectively the natural projection map that we introduced on page 317. Then for every $n \in \mathbb{N}_0$ the map

$$\prod_{k\in K} i_k^* \colon \widetilde{H}^n\Big(\bigvee_{k\in K} A_k; G\Big) \to \prod_{k\in K} \widetilde{H}^n(A_k;G)$$

is an isomorphism where the inverse is given by

$$\prod_{k\in K} p_k^* \colon \prod_{k\in K} \widetilde{H}^n(A_k;G) \to \widetilde{H}^n\Big(\bigvee_{k\in K} A_k; G\Big)$$

Proof $(*)$.

(1) First we consider the case we are given just two topological spaces. By Lemma 50.16 we can use the Mayer–Vietoris Theorem 50.15 for Cohomology Groups to prove, completely analogously to Proposition 34.8, the desired statement.

(2) The case that we are dealing with finitely many topological spaces follows from (1) by induction.
(3) The case that K is infinite is more tricky. There are two possible approaches:
   (a) In the proof of Proposition 34.9, that deals with the corresponding statement for homology groups, we gave two different proofs. The first proof generalizes to the present setting. It is not clear to me how the second proof can be generalized. But fortunately providing one proof is enough.
   (b) Alternatively we can consider the map

$$\bigoplus_{k\in K} i_{k*}\colon \bigoplus_{k\in K} \widetilde{C}_n(A_k) \;\to\; \widetilde{C}_n\Big(\bigvee_{k\in K} A_k\Big).$$

   By Proposition 34.9 this chain map induces an isomorphism of chain complexes. It follows from Proposition 49.2 that this map is in fact a chain homotopy equivalence. It follows from Lemma 48.8 that the above map induces an isomorphism of dual cochain complexes. The desired statement now follows from throwing Lemmas 48.2 and 48.7 into the bargain. The same logic applies to the projections. □

Recall that in Lemma 33.8 we showed that for any $k \in \mathbb{Z}$ and any topological space X we have a natural isomorphism

$$\Sigma_X\colon \widetilde{H}_k(X) \;\xrightarrow{\cong}\; \widetilde{H}_{k+1}(\Sigma(X)).$$

Not surprisingly we have a totally analogous statement in cohomology:

Lemma 50.18. $(*)$ *Let $k \in \mathbb{Z}$ and let G be an abelian group. Given any topological space X we have a natural isomorphism*

$$\Sigma_X\colon \widetilde{H}^k(\Sigma(X);G) \;\xrightarrow{\cong}\; \widetilde{H}^{k+1}(X;G)$$

which has the property that for any $\varphi \in H^k(X;G)$ and any $\sigma \in H_k(X)$ we have

$$\langle \Sigma_X(\varphi), \Sigma_X(\sigma)\rangle_{\Sigma(X)} \;=\; \langle \varphi, \sigma\rangle_X \;\in\; G.$$

Proof $(*)$. The construction of the isomorphism Σ_X is basically the same as the construction of the corresponding isomorphism in cohomology. In the Lemma 33.8 we just need to replace the Mayer–Vietoris Theorem 33.5 by the Mayer–Vietoris Theorem 50.15 for Cohomology Groups. We leave it to the reader to fill in the details. □

Example. Let $n \in \mathbb{N}$. Let $\Sigma(S^n) \to S^{n+1}$ be the homeomorphism from page 453. On page 819 we showed that

$$\Sigma_{S^n}([S^n]) \;=\; (-1)^{n+1}\cdot[S^{n+1}] \;\in\; H_{n+1}(S^{n+1};\mathbb{Z}).$$

From the equality in Lemma 50.18 we obtain the corresponding equality

$$\Sigma_{S^n}([S^n]^*) \;=\; (-1)^{n+1}\cdot[S^{n+1}]^* \;\in\; H^{n+1}(S^{n+1};\mathbb{Z}).$$

Exercises for Chapter 50.

Exercise 50.1. Show that the triad $(X, A_1, A_2) := (\mathbb{R}, (-\infty, 0], (0, \infty))$ is *not* excisive.

Exercise 50.2. Use cellular cohomology to determine the isomorphism types of the cohomology groups of the Klein bottle with $\mathbb{F}_2$-coefficients, with $\mathbb{F}_3$-coefficients and with $\mathbb{Z}$-coefficients.

Exercise 50.3. Let $\{A_k\}_{k\in K}$ be a family of CW-complexes. Suppose that for each $k \in K$ suppose that we are given a point in the 0-skeleton of A_k. Provide a proof for Proposition 50.17 using cellular cohomology. More precisely, provide a proof along the following lines:

(a) Equip $X := \bigvee_{k\in K} A_k$ with the CW-structure provided by Lemma 26.20.
(b) Determine the relationship between the reduced cellular chain complexes of X and of the A_i.
(c) Make use of Proposition 49.11.
(d) Make use of Lemmas 48.2 and 48.7.

51. The Universal Coefficient Theorems

51.1. **The Ext group.** One of the questions that arises from the last chapter is, how can we explain the erratic relationship between homology groups and cohomology groups that we saw on page 1197. Furthermore it would be interesting to know whether given a chain complex one can determine the cohomology groups with G-coefficients from the usual homology group.

These questions are purely in the realm of algebra. More precisely, let (C_*, ∂_*) be a chain complex of free abelian groups and let G an abelian group. We want to find a connection between the cohomology groups $H^*(C; G)$ and the homology groups $H_*(C)$. This problem, and later on its solution, is very similar to the problem we faced in Chapter 42 where we showed that we can determine homology groups of a chain complex with G-coefficients from the usual homology group of the chain complex.

As usual we denote by $\mathcal{A}$ the category of abelian groups. On page 1013 we defined what it means for a covariant functor $F\colon \mathcal{A} \to \mathcal{A}$ to be exact, left-exact and right-exact. The same way we can introduce these notions for contravariant functors $F\colon \mathcal{A} \to \mathcal{A}$.

Definition. A contravariant functor $F\colon \mathcal{A} \to \mathcal{A}$ is called *left-exact*[912] if for all exact sequences

$$A \xrightarrow{i} B \xrightarrow{j} C \longrightarrow 0$$

of abelian groups the sequence

$$0 \longrightarrow F(C) \xrightarrow{F(j)} F(B) \xrightarrow{F(i)} F(A)$$

is also exact. Furthermore a contravariant functor $F\colon \mathcal{A} \to \mathcal{A}$ is called *right-exact*, if for all exact sequences

$$0 \longrightarrow A \xrightarrow{i} B \xrightarrow{j} C$$

the sequence

$$F(C) \xrightarrow{F(j)} F(B) \xrightarrow{F(i)} F(A) \longrightarrow 0$$

is also exact.

In Lemma 42.10 we saw that the covariant functor $-\otimes G$ is right-exact but that in general it is not left-exact. With the contravariant functor $\mathrm{Hom}(-, G)$ the situation is precisely the converse. More precisely, in the next lemma we will show that this functor is left-exact and immediately afterwards we will give an example that shows that the contravariant functor $\mathrm{Hom}(-, G)$ is in general not right-exact.

Lemma 51.1. *For any abelian group G the contravariant functor* $\mathrm{Hom}(-, G)$ *is left-exact.*

[912] Admittedly one could also refer to this definition as "right"-exact, since the direction changes. But the definition we give is the one which is commonly used in the literature.

Proof $(*)$. Let G be an abelian group and let

$$A \xrightarrow{\alpha} B \xrightarrow{\beta} C \longrightarrow 0$$

be an exact sequence of abelian groups. We need to show that the sequence

$$0 \longrightarrow \mathrm{Hom}(C,G) \xrightarrow{\beta^*} \mathrm{Hom}(B,G) \xrightarrow{\alpha^*} \mathrm{Hom}(A,G)$$

is also exact. It is clear that β^* is injective and that $\alpha^* \circ \beta^* = (\beta \circ \alpha)^* = 0$, i.e. we have $\mathrm{im}(\beta^*) \subset \ker(\alpha^*)$. It remains to show that $\ker(\alpha^*) \subset \mathrm{im}(\beta^*)$. So let $f\colon B \to G$ be a homomorphism such that $\alpha^*(f) = 0$. This means that f vanishes on $\alpha(A)$, i.e. $f\colon B \to G$ can be written as $f = \overline{f} \circ \pi$ where $\pi\colon B \to B/\alpha(A)$ is the projection map and where $\overline{f}\colon B/\alpha(A) \to G$ is some homomorphism. But by the exactness of the original sequence the homomorphism β descends to an isomorphism $\psi\colon B/\alpha(A) \to C$. Now we see that $f = \overline{f} \circ \psi^{-1} \circ \beta$, i.e. we have $f = \beta^*(\overline{f} \circ \psi^{-1})$. $\square$

Now we give the example, promised above, that shows that the contravariant functor $\mathrm{Hom}(-,G)$ is in general not right-exact.

Example. We consider the chain complex

$$0 \to \mathbb{Z} \xrightarrow{\cdot 2} \mathbb{Z} \xrightarrow{p} \mathbb{Z}_2$$

where $p\colon \mathbb{Z} \to \mathbb{Z}_2$ denotes the obvious projection map. We apply the contravariant functor $\mathrm{Hom}(-,\mathbb{F}_2)$. The resulting cochain complex is of the form[913]

$$\mathbb{F}_2 \xrightarrow[\cong]{p^*} \mathbb{F}_2 \xrightarrow[=0]{(\cdot 2)^*} \mathbb{F}_2 \to 0.$$

Since this cochain complex is not exact it follows that the functor $\mathrm{Hom}(-,\mathbb{F}_2)$ is not right-exact.

In Chapter 42.4 we introduced the torsion groups $\mathrm{Tor}(H,G)$ which "measure" to what degree the functor $-\otimes G$ fails to be a left-exact functor. The same way we now introduce the so called Ext-groups $\mathrm{Ext}(H,G)$ which "measure" to what degree the functor $\mathrm{Hom}(-,G)$ fails to be right-exact.

Definition. Let G and H be abelian groups. We denote by

$$\ldots \to F_2 \xrightarrow{f_2} F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H \to 0$$

the canonical free resolution from page 1016. We define the *n-th G-Ext-group of H* as

$$\mathrm{Ext}_n(H,G) := H^n(F_*;G).$$

Remark. Let $n \in \mathbb{N}_0$. On page 1021 we saw that $\mathrm{Tor}_n(H,G)$ is covariantly functorial in both G and H. Now we will see that the groups $\mathrm{Ext}_n(H,G)$ are contravariantly functorial in H and covariantly functorial in G:

[913]Here we use the identification $\mathrm{Hom}(\mathbb{Z},G) = G$ from Lemma 48.1 and we use that multiplication by 2 is the zero endomorphism of $\mathbb{F}_2$.

(1) Let $\alpha\colon H \to H'$ be a homomorphism between abelian groups and let G be an abelian group. Then it follows from Lemmas 42.13 and 48.8 together with the definition of the G-Ext groups that α induces a homomorphism

$$\alpha^*\colon \operatorname{Ext}_n(H',G) \;\to\; \operatorname{Ext}_n(H,G).$$

It is now straightforward to show that

$$\begin{array}{rcl} H & \mapsto & \operatorname{Ext}_n(H,G) \\ (\alpha\colon H \to H') & \mapsto & (\alpha^*\colon \operatorname{Ext}_n(H',G) \to \operatorname{Ext}_n(H,G)) \end{array}$$

is a *contravariant* functor from the category of abelian groups to the category of abelian groups.

(2) On the other hand, if $\beta\colon G \to G'$ is a homomorphism between abelian groups then one sees easily that β induces a homomorphism

$$\beta_*\colon \operatorname{Ext}_n(H,G) \;\to\; \operatorname{Ext}_n(H,G')$$

Furthermore one can easily prove that

$$\begin{array}{rcl} G & \mapsto & \operatorname{Ext}_n(H,G) \\ (\beta\colon G \to G') & \mapsto & (\beta_*\colon \operatorname{Ext}_n(H,G) \to \operatorname{Ext}_n(H,G')) \end{array}$$

is a *covariant* functor from the category of abelian groups to the category of abelian groups.

The following proposition is the analogue of Proposition 42.12. The proof is almost the same as the proof of Proposition 42.12. We leave it to the reader to make the necessary changes.

Proposition 51.2. *Let G and H be abelian groups and let*

$$\ldots \;\to\; F_2 \xrightarrow{f_2} F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H \;\to\; 0$$

be a free resolution of H. Then for each $n \in \mathbb{N}_0$ there exists a canonical isomorphism

$$\operatorname{Ext}_n(H,G) \;\xrightarrow{\cong}\; H^n(F_*,G).$$

In particular if

$$0 \;\to\; F_1 \xrightarrow{f_1} F_0 \xrightarrow{f_0} H \;\to\; 0$$

is a free resolution of H of length one, then there exist canonical isomorphisms

$$\operatorname{Ext}_1(H,G) \;\xrightarrow{\cong}\; \operatorname{coker}\big\{\operatorname{Hom}(F_0,G) \xrightarrow{f_1^*} \operatorname{Hom}(F_1,G)\big\}$$

and

$$\operatorname{Ext}_0(H,G) \;\xrightarrow{\cong}\; \ker\big\{\operatorname{Hom}(F_0,G) \xrightarrow{f_1^*} \operatorname{Hom}(F_1,G)\big\}$$

In Lemma 42.16 we saw that the higher torsion groups of abelian groups vanish. The same statement, with basically the same proof, also holds for Ext groups. More precisely, we have the following corollary.

Corollary 51.3. *For every choice of abelian groups G and H we have* $\mathrm{Ext}_n(H,G)=0$ *for* $n\geq 2$.

Proof. As we pointed out in the proof of Lemma 42.16 any abelian group H admits a free resolution of length 2:

$$0 \;\to\; F_1 \;\xrightarrow{f_1}\; F_0 \;\xrightarrow{f_0}\; H \;\to\; 0.$$

The corollary now follows immediately from Proposition 51.2. □

In Lemma 42.15 we saw that the 0-th Torsion functor is an old acquaintance, namely we saw that for all abelian groups G and H there exists a natural isomorphism $\mathrm{Tor}_0(H,G)\xrightarrow{\cong} H\otimes G$. The following lemma gives us the analogous result for the 0-th Ext functor.

Lemma 51.4. *Let G and H be abelian groups, then there exists a natural*[914] *isomorphism*

$$\mathrm{Ext}_0(H,G) \;\xrightarrow{\cong}\; \mathrm{Hom}(H,G).$$

Proof $(*)$. The proof of Lemma 51.4 is, not surprisingly, rather similar to the proof of Lemma 42.15. Let G and H be abelian groups. Let

$$\cdots\to\; F_2 \;\xrightarrow{f_2}\; F_1 \;\xrightarrow{f_1}\; F_0 \;\xrightarrow{f_0}\; H \;\to\; 0$$

be the canonical free resolution of H. We know from Lemma 51.1 that the sequence

$$(*)\qquad 0 \;\to\; \mathrm{Hom}(H,G) \;\xrightarrow{f_0^*}\; \mathrm{Hom}(F_0,G) \;\xrightarrow{f_1^*}\; \mathrm{Hom}(F_1,G)$$

is exact. Now we obtain the following isomorphism

$$\begin{aligned}\mathrm{Ext}_0(H,G) \;&\overset{\text{by definition}}{\overset{\downarrow}{=}}\; H^0\big(\cdots\leftarrow \mathrm{Hom}(F_1,G)\xleftarrow{f_1^*}\mathrm{Hom}(F_0,G)\leftarrow 0\big)\\ &=\; \ker\big(\mathrm{Hom}(F_1,G)\xleftarrow{f_1^*}\mathrm{Hom}(F_0,G)\big)\;\underset{\substack{\uparrow\\ \text{isomorphism since }(*)\text{ is exact}}}{\xrightarrow{f_0^*}}\;\mathrm{Hom}(H,G).\end{aligned}$$

It is straightforward to verify that these isomorphisms are in fact natural. □

Definition. Given abelian groups G and H we refer to

$$\mathrm{Ext}(H,G) \;:=\; \mathrm{Ext}_1(H,G)$$

as *the* G-Ext-group of H.

[914]Here by "natural" we mean that these isomorphisms define a natural isomorphism from the contravariant functor $H\mapsto \mathrm{Ext}_0(H,G)$ to the contravariant functor $H\mapsto \mathrm{Hom}(H,G)$ and that they also define a natural transformation from the covariant functor $G\mapsto \mathrm{Ext}_0(H,G)$ to the covariant functor $G\mapsto \mathrm{Hom}(H,G)$.

Remark. Let G and H be two abelian groups. An *extension of H by G* is a short exact sequence of the form

$$0 \longrightarrow G \xrightarrow{\alpha} K \xrightarrow{\beta} H \longrightarrow 0.$$

We say that two such extensions given by K and K' are equivalent if there exists a homomorphism $\varphi\colon K \to K'$ that makes the following diagram commute

$$\begin{tikzcd} 0 \arrow[r] & G \arrow[r, "\alpha"] \arrow[d, "="] & K \arrow[r, "\beta"] \arrow[d, "\varphi"] & H \arrow[r] \arrow[d, "="] & 0 \\ 0 \arrow[r] & G \arrow[r, "\alpha'"] & K' \arrow[r, "\beta'"] & H \arrow[r] & 0. \end{tikzcd}$$

In [HS, Theorem II.3.4] it is shown that there is a natural bijection from the set of equivalence classes of extensions of H by G with the set $\mathrm{Ext}(H, G)$. This fact is the origin of the name "Ext-group".

In light of Corollary 51.3 and Lemma 51.4 the remaining task is to compute the Ext-group $\mathrm{Ext}(H, G) = \mathrm{Ext}_1(H, G)$. The following lemma allows us in particular to determine the Ext-group for all finitely generated abelian groups.

Lemma 51.5. *Let G, H and $G_1, \ldots, G_k, H_1, \ldots, H_k$ be abelian groups. The following statements hold:*

(1) *There exists a natural isomorphism*

$$\mathrm{Ext}\left(\bigoplus_{i=1}^{k} H_i, G\right) \;\cong\; \bigoplus_{i=1}^{k} \mathrm{Ext}(H_i, G).$$

(2) *There exists a natural isomorphism*

$$\mathrm{Ext}\left(H, \bigoplus_{i=1}^{k} G_i\right) \;\cong\; \bigoplus_{i=1}^{k} \mathrm{Ext}(H, G_i).$$

(3) *If H is a free abelian group, then* $\mathrm{Ext}(H, G) = 0$.
(4) *For all $n \in \mathbb{N}$ we have a natural isomorphism* $\mathrm{Ext}(\mathbb{Z}_n, G) \cong G/nG$.
(5) *If H is a finitely generated abelian group, then we have a natural isomorphism*

$$\mathrm{Ext}(H, \mathbb{Z}) \cong \textit{torsion subgroup of } H := \{h \in H \mid \textit{there exists an } n \in \mathbb{N} \textit{ with } nh = 0\}.$$

In particular $\mathrm{Ext}(H, \mathbb{Z})$ *is a finite group.*
(6) *For $n, m \in \mathbb{N}$ we have* $\mathrm{Ext}(\mathbb{Z}_n, \mathbb{Z}_m) \cong \mathbb{Z}_{\gcd(n,m)}$.

Remark.

(a) The first two statements of the lemma also generalize to the case of infinitely many groups, but some care needs to be taken. Indeed, some of the finite direct sums are secretly finite direct products and hence they generalize to infinite direct products. More precisely, the following holds:

(1') If $\{H_i\}_{i\in I}$ is a family of abelian groups and if G is an abelian group, then

$$\operatorname{Ext}\Big(\bigoplus_{i\in I} H_i, G\Big) \;\cong\; \prod_{i\in I} \operatorname{Ext}(H_i, G).$$

(2') If H is an abelian group and if $\{G_i\}_{i\in I}$ is a family of abelian groups, then

$$\operatorname{Ext}\Big(H, \prod_{i\in I} G_i\Big) \;\cong\; \prod_{i\in I} \operatorname{Ext}(H, G_i).$$

We refer to [Rot2, Propositions 7.21 and 7.22] for a proof. We will not make use of these more general statements.

(b) The statements of Lemma 51.5 look very similar to the statements of Lemma 42.17. But there are some differences:
   (i) In Lemma 42.17 we saw that for every abelian group we have $\operatorname{Tor}(H, \mathbb{Z}) = 0$ whereas we have now shown in Lemma 51.5 (5) that for every finite abelian group we have $\operatorname{Ext}(H, \mathbb{Z}) \cong H$.
   (ii) In Lemma 42.17 we saw that $\operatorname{Tor}(H, G) = 0$ not only whenever H is a free abelian group but also for all torsion-free abelian groups H. Here the situation is different, the statement of Lemma 51.5 (3) does not generalize to torsion-free abelian groups. For example in [Rot2, p. 428] it is shown that there exists an abelian group G such that $\operatorname{Ext}(\mathbb{Q}, G) \neq 0$. But this issue is of no concern to us.

Proof. The first three statements are proved almost the same way as we proved Lemma 42.17. We leave the details as an exercise to the reader. We turn to the final three statements.

(4) Let G be an abelian group and let $n \in \mathbb{N}$. We have

$$\operatorname{Ext}(\mathbb{Z}_n, G) \;\overset{\substack{\text{Proposition 51.2 applied to the free resolution } 0\to\mathbb{Z}\xrightarrow{\cdot n}\mathbb{Z}\to\mathbb{Z}_n\to 0}}{=}\; \operatorname{coker}\big\{\operatorname{Hom}(\mathbb{Z}, G) \xrightarrow{(\cdot n)^*} \operatorname{Hom}(\mathbb{Z}, G)\big\} \;\underset{\substack{\text{by the isomorphism } \operatorname{Hom}(\mathbb{Z},G)=G \text{ given by } f\mapsto f(1)}}{=}\; \operatorname{coker}\big\{G \xrightarrow{\cdot n} G\big\} \;=\; G/nG.$$

(5) This statement follows immediately from (1), (3) and (4) together with the classification of finitely generated abelian groups, see Theorem 11.4.

(6) This statement follows immediately from (4) and the calculation on page 1017. □

We have one more general result for calculating Ext-groups. Before we can state the result we need one more definition.

Definition. An abelian group G is called *divisible* if for any $g \in G$ and $n \in \mathbb{N}$ there exists an $h \in G$ with $n \cdot h = g$.

Examples.

(1) The groups $\mathbb{Q}, \mathbb{R}$ and $\mathbb{C}$ are divisible.

(2) Every quotient of a divisible group is divisible, for example the quotient group $\mathbb{Q}/\mathbb{Z}$ is also divisible.[915]
(3) The group $\mathbb{Z}$ is not divisible, and the only finite group that is divisible is the trivial group.

Proposition 51.6. *Let G and H be abelian groups. If G is divisible, then* $\mathrm{Ext}(H, G) = 0$.

In the proof of Proposition 51.6 it is useful to introduce the following notion.

Definition. An abelian group G is called *injective* if for all abelian groups A and B, every injective homomorphism $\varphi\colon B \to A$ and every homomorphism $\beta\colon B \to G$ there exists a homomorphism $\alpha\colon A \to G$ such that the following diagram commutes

$$\begin{tikzcd} 0 \arrow[r] & B \arrow[r, hook, "\varphi"] \arrow[d, "\beta"'] & A \arrow[dl, dashed, "\alpha"] \\ & G. & \end{tikzcd}$$

The following lemma shows why we are interested in injective groups.

Lemma 51.7. *Let G and H be abelian groups. If G is injective, then* $\mathrm{Ext}(H, G) = 0$.

Proof. Let H be an abelian group. As we pointed out in the proof of Lemma 42.16 the abelian group H admits a free resolution of length 2:

$$0 \to F_1 \xrightarrow{\varphi_1} F_0 \xrightarrow{\varphi_0} H \to 0.$$

By Proposition 51.2 the group $\mathrm{Ext}(H, G)$ is isomorphic to the cokernel of the map

$$\mathrm{Hom}\begin{pmatrix} F_1 \\ \downarrow \\ G \end{pmatrix} \xleftarrow{\varphi_1^*} \mathrm{Hom}\begin{pmatrix} F_0 \\ \downarrow \\ G \end{pmatrix}.$$

But by definition of G being injective this map φ_1^* is in fact an epimorphism. Thus we have shown that $\mathrm{Ext}(H, G) = 0$. □

To provide a proof for Proposition 51.6 it remains to prove the following proposition.

Proposition 51.8. *Every abelian group that is divisible is also injective.*

Remark. It is straightforward to prove the converse to Proposition 51.8, namely every injective abelian group is also divisible.

In the proof of Proposition 51.8 we will need Zorn's Lemma which we now recall for the reader's convenience.

Lemma 51.9. (Zorn's Lemma) *Suppose a partially ordered set $(P, \leq)$ has the property that every chain has an upper bound in P. Then the set P contains at least one maximal element.*

We also recall the definitions in the statement of Zorn's Lemma:

[915] Odd as it may sound, this example will actually be important later on.

(1) A *partially ordered set* $(P, \leq)$ is a set together with a preorder $\leq$ (see page 481) that has the property that $a \leq b$ and $b \leq a$ implies that $a = b$.
(2) A *chain* in P is a subset Q such that for any two elements $q, q' \in Q$ we have $q \leq q'$ or $q' \leq q$.
(3) An *upper bound* of a subset Q is an element $q \in Q$ such that $p \leq q$ for all $q \in Q$.
(4) A *maximal element* of a subset Q is an element $q \in Q$ such that there is no $r \in Q$ with $q < r$.[916]

We refer to [Ci, Theorem 4.3.4] for a proof of Zorn's Lemma. Perhaps it is more fun to look at Zorn's Lemma in "The Simpsons", see

`http://www.simonsingh.net/Simpsons_Mathematics/zorns-lemma/`

Now we can give the proof of Proposition 51.8.

Proof of Proposition 51.8 $(*)$. Let G be an abelian group that is divisible. Suppose we are given a diagram

$$\begin{tikzcd} 0 \arrow[r] & B \arrow[r, hook, "\varphi"] \arrow[d, "\beta"'] & A \arrow[dl, "?\,\alpha\,?"] \\ & G. & \end{tikzcd}$$

Since φ is a monomorphism we can assume that B is in fact a subgroup of A and that φ is the inclusion map.

We denote by P the set of all pairs (C_i, γ_i) where C_i is a subgroup of A which contains B and where $\gamma_i \colon C_i \to G$ is a homomorphism such that $\gamma_i|_B = \beta$. This family of pairs is non-empty since (B, β) satisfies the required conditions. We define $(C_i, \gamma_i) < (C_j, \gamma_j)$ if $C_i \subset C_j$ and if $\gamma_j|_{C_i} = \gamma_i$. Given a chain $(C_j, \gamma_j)_{j \in J}$ in P we get an upper bound by setting

$$C := \bigcup_{j \in J} C_j \quad \text{and} \quad \begin{array}{rcl} \gamma \colon C & \to & G \\ c & \mapsto & \gamma_j(c) \text{ if } j \in J \text{ with } c \in C_j. \end{array}$$

Since $(C_j, \gamma_j)_{j \in J}$ is a chain one can easily verify that C is in fact a subgroup of A which contains B and that γ is a homomorphism with $\gamma|_B = \beta$.

Therefore we can apply Zorn's Lemma to this family and we obtain a maximal pair (C_m, γ_m). It remains to prove the following claim.

Claim. We have $C_m = A$.

Suppose that this is not the case. Then there exists an $a \in A \setminus C_m$. We denote by $\langle\langle C_m, a \rangle\rangle$ the subgroup of A generated by C_m and a, i.e. $\langle\langle C_m, a \rangle\rangle$ is the smallest subgroup of A that contains C_m and a. To obtain a contradiction it suffices to show that there exists a homomorphism $\delta \colon \langle\langle C_m, a \rangle\rangle \to G$ that extends γ_m. We distinguish two cases:

(1) If there exists no $n \in \mathbb{N}$ such that $n \cdot a \in C_m$, then one can show easily that we have $\langle\langle C_m, a \rangle\rangle = C_m \oplus \langle a \rangle$. We extend γ_m to $\langle\langle C_m, a \rangle\rangle = C_m \oplus \langle a \rangle$ by setting $\delta(a) = 0$.

[916] Aren't "upper bound" and "maximal element" the same?

(2) Otherwise there exists a minimal $n \in \mathbb{N}$ such that $n \cdot a \in C_m$. We denote by $r \in \mathbb{N}_0$ the order of $n \cdot a \in C_m$. Here we say that the order is 0 if $n \cdot a \in C_m$ has infinite order. We consider the maps

$$\begin{array}{ccccccc} 0 & \to & \mathbb{Z}_r & \xrightarrow{\Phi} & C_m \oplus \mathbb{Z}_{nr} & \xrightarrow{\Psi} & \langle\langle C_m, a\rangle\rangle \to 0 \\ & & k & \mapsto & (k \cdot n \cdot a, -k \cdot n) & & \\ & & & & (c, l) & \mapsto & c + l \cdot a \end{array}$$

It is clear that Φ is injective and that $\Psi \circ \Phi = 0$. Note that the image of Ψ lies a priori in A, but it is straightforward to see that the image of Ψ is precisely $\langle\langle C_m, a\rangle\rangle$. By definition of n we have that $\ker(\Psi) \subset \operatorname{im}(\Phi)$. Put differently, the sequence is exact. Since G is divisible there exists an $h \in G$ such that $n \cdot h = \gamma(n \cdot a)$. We denote by $\alpha\colon C_m \oplus \mathbb{Z}_{nr} \to G$ the homomorphism that is given by setting $\alpha(c) = \gamma(c)$ for $c \in C_m$ and $\alpha(k) = k \cdot h$ for $k \in \mathbb{Z}$. One can easily verify that $\operatorname{im}(\Phi)$ is contained in $\ker(\alpha)$. It is now straightforward to show that the homomorphism

$$\begin{array}{ccccc} \delta\colon \langle\langle C_m, a\rangle\rangle & \to & (C_m \oplus \mathbb{Z}_{nr})/\operatorname{im}(\Phi) & \to & G \\ x & \mapsto & [\Psi^{-1}(x)] & & \\ & & [y] & \mapsto & \alpha(y) \end{array}$$

has the desired properties.

This concludes the proof of the claim and thus of the lemma. □

The following proposition gives arguably slightly weird example.

Proposition 51.10. *The group* $\operatorname{Ext}(\mathbb{Q}, \mathbb{Z})$ *is isomorphic to the additive group* $(\mathbb{R}, +)$.

Remark. Note that this proposition is not totally pointless, for example it follows from the existence of Moore spaces, see Proposition 34.11, that there exist topological spaces X with $H_n(X) \cong (\mathbb{Q}, +)$. Thus even unexpected abelian groups can appear in topology.

Proof. This proposition is proved in [Wie]. Alternatively the proposition is almost proved in [Bre2, Lemma 14.8]. □

This example also shows that Ext-groups can be quite large. In fact the following proposition holds.

Proposition 51.11. *Let G be an abelian group. If G is not finitely generated, then* $\operatorname{Hom}(G, \mathbb{Z})$ *is uncountable or* $\operatorname{Ext}(G, \mathbb{Z})$ *is uncountable.*

Proof. We will barely make use of this proposition, thus we refer to [Hat, Proposition 3.F.12] instead for a proof. □

51.2. **The Universal Coefficient Theorem for Cohomology Groups.** Finally we want to explore the connection between the cohomology groups of a chain complex C and the usual homology groups of the chain complex. The key to relating homology groups to cohomology groups is given by the following evaluation homomorphism.

Definition. Let (C_*, ∂_*) be a chain complex and let G be an abelian group. We refer to the map[917]

$$\begin{array}{rcl} \mathrm{ev}\colon H^n(C;G) & \to & \mathrm{Hom}(H_n(C),G) \\ [\varphi\colon C_n \to G] & \mapsto & \left(\begin{array}{rcl} H_n(C) & \to & G \\ [c] & \mapsto & \langle [\varphi],[c]\rangle = \varphi(c) \end{array} \right) \end{array}$$

as the *evaluation homomorphism.*

Remark. It follows immediately from Lemma 50.6 that the evaluation homomorphisms in natural in the chain complex C_* in the sense that if $f\colon C_* \to D_*$ is a chain map, then for any $n \in \mathbb{N}_0$ and any abelian group G the following diagram commutes

$$\begin{array}{ccc} H^n(C;G) & \xrightarrow{\mathrm{ev}} & \mathrm{Hom}(H_n(C),G) \\ {\scriptstyle f^*}\big\downarrow & & \big\downarrow{\scriptstyle (f_*)^*} \\ H^n(D;G) & \xrightarrow{\mathrm{ev}} & \mathrm{Hom}(H_n(D),G). \end{array}$$

Furthermore, it follows easily from the definitions that the evaluation map is natural in G, in the sense that if $\varphi\colon G_1 \to G_2$ is homomorphism of abelian groups, then for any $n \in \mathbb{N}_0$ and any chain complex C_* the following diagram commutes

$$\begin{array}{ccc} H^n(C;G_1) & \xrightarrow{\mathrm{ev}} & \mathrm{Hom}(H_n(C),G_1) \\ {\scriptstyle \varphi_*}\big\downarrow & & \big\downarrow{\scriptstyle \varphi_*} \\ H^n(C;G_2) & \xrightarrow{\mathrm{ev}} & \mathrm{Hom}(H_n(C),G_2). \end{array}$$

Here the map on the left is the one we had introduced on page 1163.

Recall that on page 845 we saw that $H_2(\mathbb{R}\mathrm{P}^2;\mathbb{Z}) = 0$ and that on page 1197 we showed that $H^2(\mathbb{R}\mathrm{P}^2;\mathbb{Z}) \cong \mathbb{Z}_2$. This implies that the evaluation homomorphism $\mathrm{ev}\colon H^n(X;G) \to \mathrm{Hom}(H_n(X);G)$ is in general not a monomorphism. The following theorem relates homology groups and cohomology groups via the evaluation homomorphism and the Ext-groups.

Theorem 51.12. (Universal Coefficient Theorem for Cohomology Groups) *Let (C_*, ∂_*) be a chain complex of free abelian groups and let G be an abelian group. Then for each $n \in \mathbb{N}_0$ there exists a short exact sequence*

$$0 \;\to\; \mathrm{Ext}(H_{n-1}(C),G) \;\to\; H^n(C;G) \;\xrightarrow{\mathrm{ev}}\; \mathrm{Hom}(H_n(C),G) \to 0$$

which is natural in the chain complex C_* and natural in the abelian group G. This short exact sequence splits and there exists therefore an isomorphism[918]

$$H^n(C;G) \;\cong\; \mathrm{Ext}(H_{n-1}(C),G) \oplus \mathrm{Hom}(H_n(C),G).$$

[917]This map is well-defined by Lemma 50.5.

[918]Once again the short exact sequence is natural, whereas the isomorphism is not natural. More precisely, the discussion on page 1033 can easily be modified to show that there exists no natural isomorphism

$$H^n(C;G) \;\cong\; \mathrm{Ext}(H_{n-1}(C),G) \oplus \mathrm{Hom}(H_n(C),G).$$

We will discuss this issue in Exercise 51.1.

Before we provide the proof of the above Universal Coefficient Theorem for Cohomology Groups 51.12 let us formulate the most important application, namely let us apply it to the chain complex of a pair of topological spaces.

Theorem 51.13. (Universal Coefficient Theorem for Cohomology Groups) *Let (X, A) be a pair of topological spaces and let G be an abelian group. Then for each $n \in \mathbb{N}_0$ there exists a short exact sequence*

$$0 \;\to\; \mathrm{Ext}(H_{n-1}(X,A),G) \;\to\; H^n(X,A;G) \;\xrightarrow{\mathrm{ev}}\; \mathrm{Hom}(H_n(X,A),G) \to 0$$

which is natural in the chain complex C_* and natural in the abelian group G. This short exact sequence splits and there exists therefore an isomorphism

$$H^n(X,A;G) \;\cong\; \mathrm{Ext}(H_{n-1}(X,A),G) \oplus \mathrm{Hom}(H_n(X,A),G).$$

Proof of Theorem 51.13 assuming Theorem 51.12. As the reader will have noticed there is really not much to say, except that we recall that we pointed out on page 775 that the chain groups $C_n(X,A)$, $n \in \mathbb{N}_0$ are free abelian groups. $\square$

Remark. Here is one straightforward but interesting consequence to the Universal Coefficient Theorem 51.13 for Cohomology Groups. Given any pair (X, A) of topological spaces we see that

$$\begin{array}{ccccccc} H^1(X;\mathbb{Z}) & \cong & \mathrm{Ext}(H_0(X,A),\mathbb{Z}) \oplus \mathrm{Hom}(H_1(X,A),\mathbb{Z}) & = & \mathrm{Hom}(H_1(X,A),\mathbb{Z}) & = & \text{torsion-free.} \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{Universal Coefficient Theorem 51.13} & & \text{by Lemma 51.5 and Corollary 29.14} & & \begin{array}{c}\text{since } \mathrm{Hom}(G,\mathbb{Z}) \text{ is} \\ \text{always torsion free}\end{array} & \end{array}$$

Now we turn to the proof of the purely algebraic Universal Coefficient Theorem 51.12 for Cohomology Groups. The proof is, perhaps not surprisingly, rather similar to the proofs of the Universal Coefficient Theorem 42.19 and Proposition 42.22.

Proof $(*)$. Let (C_*, ∂_*) be a chain complex of free abelian groups. For each $n \in \mathbb{N}_0$ we write as always $Z_n := \ker(\partial_n)$ and $B_n := \mathrm{im}(\partial_{n+1})$. Note that it follows from Lemma 11.2 that B_n and Z_n are free abelian groups.

As in the proof of the Universal Coefficient Theorem 42.19 we consider the following short exact sequence of vertical chain complexes:

$$\begin{tikzcd}
 & \vdots \arrow[d] & \vdots \arrow[d] & \vdots \arrow[d] & \\
0 \arrow[r] & Z_n \arrow[r] \arrow[d, "0"] & C_n \arrow[r, "\partial_n"] \arrow[d, "\partial_n"] & B_{n-1} \arrow[r] \arrow[d, "0"] & 0 \\
0 \arrow[r] & Z_{n-1} \arrow[r] \arrow[d] & C_{n-1} \arrow[r, "\partial_{n-1}"] \arrow[d] & B_{n-2} \arrow[r] \arrow[d] & 0 \\
 & \vdots & \vdots & \vdots &
\end{tikzcd}$$

Now let G be an abelian group. We apply the functor $\mathrm{Hom}(-,G)$ to the above short exact sequence of chain complexes and we obtain the following diagram:

$$\begin{tikzcd}
 & \vdots & \vdots & \vdots & \\
0 \arrow[r] & \mathrm{Hom}(B_{n-1},G) \arrow[r, "\partial_n^*"] \arrow[u] & \mathrm{Hom}(C_n,G) \arrow[r] \arrow[u] & \mathrm{Hom}(Z_n,G) \arrow[r] \arrow[u] & 0 \\
0 \arrow[r] & \mathrm{Hom}(B_{n-2},G) \arrow[r, "\partial_{n-1}^*"] \arrow[u, "0"] & \mathrm{Hom}(C_{n-1},G) \arrow[r] \arrow[u, "\partial_n^*"] & \mathrm{Hom}(Z_{n-1},G) \arrow[r] \arrow[u, "0"] & 0 \\
 & \vdots \arrow[u] & \vdots \arrow[u] & \vdots \arrow[u] &
\end{tikzcd}$$

This is again a sequence of cochain complexes. Since the Z_n are free abelian we obtain from Lemma 48.4 that the above horizontal sequences of cochain complexes are still exact. Therefore we can apply Proposition 48.6 to obtain the following long exact sequence

$$\to \mathrm{Hom}(Z_{n-1},G) \xrightarrow{d_n} \mathrm{Hom}(B_{n-1},G) \to H^n(C;G) \xrightarrow{\partial_n} \mathrm{Hom}(Z_n,G) \xrightarrow{d_{n-1}} \mathrm{Hom}(B_n,G) \to \dots$$

where the maps d_n are the connecting homomorphisms of the long exact sequence. One can show easily that the connecting homomorphism $d_n\colon \mathrm{Hom}(Z_n,G) \to \mathrm{Hom}(B_n,G)$ is the map $d_n = i_n^*$ where $i_n\colon B_n \to Z_n$ is the inclusion map. By Lemma 33.4 we obtain the following short exact sequence

$$0 \to \mathrm{coker}(\mathrm{Hom}(Z_{n-1},G) \to \mathrm{Hom}(B_{n-1},G)) \to H^n(C;G) \to \ker(\mathrm{Hom}(Z_n,G) \to \mathrm{Hom}(B_n,G)) \to 0.$$

We have to show that the expressions left and right coincide with the desired expressions. Both equalities follow immediately from Proposition 51.2 (together with Lemma 51.4 for the right-hand term) and the observation that for each $l \in \mathbb{N}_0$ a free resolution of $H_l(C)$ is given by $0 \to B_l \xrightarrow{i_l} Z_l \to H_l(C)$. We have thus shown the existence of the desired short exact sequence

$$0 \;\to\; \mathrm{Ext}(H_{n-1}(C),G) \;\to\; H^n(C;G) \;\xrightarrow{\mathrm{ev}}\; \mathrm{Hom}(H_n(C),G) \to 0.$$

The statement that the short exact sequence is natural follows easily from the definitions and Lemma 42.13 (2). We leave the verification of the details as an exercise to the reader.

It remains to show that the above short exact sequence splits. By definitions this means that we need to construct a homomorphism $\eta\colon \mathrm{Hom}(H_n(C),G) \to H^n(C;G)$ such that $\mathrm{ev} \circ \eta$ is the identity on $\mathrm{Hom}(H_n(C),G)$.

We consider again the short exact sequence

$$0 \;\to\; Z_n \;\hookrightarrow\; C_n \;\xrightarrow{\partial_n}\; B_{n-1} \;\to\; 0.$$

Since B_{n-1} is a free abelian group we obtain from Lemmas 33.1 and 33.2 that there exists a homomorphism $p_n\colon C_n \to Z_n$ such that p_n is the identity on $Z_n \subset C_n$.

In the proof of Proposition 42.22 we showed that the following diagram commutes:

$$\begin{tikzcd}
\dots \arrow[r] & C_{n+1} \arrow[r, "\partial_{n+1}"] \arrow[d, shift left, "p_{n+1}"] \arrow[dr, "\partial_{n+1}"] & C_n \arrow[r, "\partial_n"] \arrow[d, shift left, "p_n"] \arrow[dr, "\partial_n"] & C_{n-1} \arrow[r, "\partial_{n-1}"] \arrow[d, shift left, "p_{n-1}"] & \dots \\
& Z_{n+1} \arrow[u, hook, shift left] \arrow[d, two heads, "q_{n+1}"] & Z_n \arrow[u, hook, shift left] \arrow[d, two heads, "q_n"] & Z_{n-1} \arrow[u, hook, shift left] \arrow[d, two heads, "q_{n-1}"] & \\
\dots \arrow[r] & \underbrace{H_{n+1}(C)}_{=Z_{n+1}/B_{n+1}} \arrow[r, "0"] & \underbrace{H_n(C)}_{=Z_n/B_n} \arrow[r, "0"] & \underbrace{H_{n-1}(C)}_{=Z_{n-1}/B_{n-1}} \arrow[r, "0"] & \dots
\end{tikzcd}$$

where the maps q_n are just the obvious projection maps.

The top and the bottom horizontal sequences of the above diagram are chain complexes. Since the diagram commutes we see that the vertical maps from top to bottom are chain maps.

Now we apply the functor $\mathrm{Hom}(-, G)$ to the top and the bottom horizontal sequences and we obtain the following diagram of cochain complexes.

$$\begin{tikzcd}
\dots & \mathrm{Hom}(C_{n+1}, G) \arrow[l] & \mathrm{Hom}(C_n, G) \arrow[l, "\partial^*_{n+1}"'] & \mathrm{Hom}(C_{n-1}, G) \arrow[l, "\partial^*_n"'] & \dots \arrow[l] \\
\dots & \mathrm{Hom}(H_{n+1}(C), G) \arrow[l] \arrow[u, "(q_{n+1} \circ p_{n+1})^*"'] & \mathrm{Hom}(H_n(C), G) \arrow[l, "0"'] \arrow[u, "(q_n \circ p_n)^*"'] & \mathrm{Hom}(H_{n-1}(C), G) \arrow[l, "0"'] \arrow[u, "(q_{n-1} \circ p_{n-1})^*"'] & \dots \arrow[l]
\end{tikzcd}$$

The induced maps on the cohomology groups of these two cochain complexes give us a homomorphism

$$\eta\colon \mathrm{Hom}(H_n(C), G) = H^n(\text{lower sequence}) \ \to \ H^n(\text{upper sequence}) = H^n(C; G).$$

It remains to prove the following claim.

Claim. The composition $\mathrm{ev} \circ \eta$ is the identity on $\mathrm{Hom}(H_n(C), G)$.

Let $\varphi\colon H_n(C) \to G$ be homomorphism. We need to show that $(\mathrm{ev} \circ \eta)(\varphi) = \varphi$ in $\mathrm{Hom}(H_n(C), G)$. So let $[\sigma] \in H_n(C)$ with $\sigma \in Z_n$. Then

$$\big((\mathrm{ev} \circ \eta)(\varphi)\big)([\sigma]) \underset{\substack{\uparrow \\ \text{definition of ev}}}{=} \langle \overbrace{\eta(\varphi)}^{\in H^n(C;G)}, [\sigma] \rangle \underset{\substack{\uparrow \\ \text{definition of } \eta \text{ and } \langle\,,\,\rangle}}{=} (\overbrace{\varphi \circ q_n \circ p_n}^{\in \mathrm{Hom}(C_n, G)})(\sigma) \underset{\substack{\uparrow \\ \text{since } p_n = \mathrm{id} \text{ on } Z_n}}{=} (\varphi \circ q_n)(\sigma) \underset{\substack{\uparrow \\ \text{since } q_n(\sigma) = [\sigma]}}{=} \varphi([\sigma]).$$

This concludes the proof of the claim. $\square$

Remark. The Universal Coefficient Theorem 51.12 for Cohomology Groups also gives a new proof for Corollary 49.3 (2) which says that if two topological spaces have isomorphic homology groups, then they also have isomorphic cohomology groups.

Example. We consider again the projective space $P := \mathbb{R}\mathrm{P}^2$. As a reminder, we showed on page 846 that $H_2(P) = 0$, $H_1(P) \cong \mathbb{Z}_2$ and $H_0(P) \cong \mathbb{Z}$. It follows from the Universal Coefficient Theorem 51.13 and from the properties of the Ext-group that we had listed in Lemma 51.5 that

$$\begin{array}{lllll} H^2(P;\mathbb{Z}) & \cong \operatorname{Hom}(H_2(P),\mathbb{Z}) \oplus \operatorname{Ext}(H_1(P),\mathbb{Z}) & \cong \operatorname{Hom}(0,\mathbb{Z}) \oplus \operatorname{Ext}(\mathbb{Z}_2,\mathbb{Z}) & = 0 \oplus \mathbb{Z}_2 = \mathbb{Z}_2 \\ H^1(P;\mathbb{Z}) & \cong \operatorname{Hom}(H_1(P),\mathbb{Z}) \oplus \operatorname{Ext}(H_0(P),\mathbb{Z}) & \cong \operatorname{Hom}(\mathbb{Z}_2,\mathbb{Z}) \oplus \operatorname{Ext}(\mathbb{Z},\mathbb{Z}) & = 0 \oplus 0 = 0 \\ H^0(P;\mathbb{Z}) & \cong \operatorname{Hom}(H_0(P),\mathbb{Z}) & \cong \operatorname{Hom}(\mathbb{Z},\mathbb{Z}) & = \mathbb{Z} \end{array}$$

and

$$\begin{array}{lllll} H^2(P;\mathbb{Z}_2) & \cong \operatorname{Hom}(H_2(P),\mathbb{Z}_2) \oplus \operatorname{Ext}(H_1(P),\mathbb{Z}_2) & \cong \operatorname{Hom}(0,\mathbb{Z}_2) \oplus \operatorname{Ext}(\mathbb{Z}_2,\mathbb{Z}_2) & = 0 \oplus \mathbb{Z}_2 = \mathbb{Z}_2 \\ H^1(P;\mathbb{Z}_2) & \cong \operatorname{Hom}(H_1(P),\mathbb{Z}_2) \oplus \operatorname{Ext}(H_0(P),\mathbb{Z}_2) & \cong \operatorname{Hom}(\mathbb{Z}_2,\mathbb{Z}_2) \oplus \operatorname{Ext}(\mathbb{Z},\mathbb{Z}_2) & = \mathbb{Z}_2 \oplus 0 = \mathbb{Z}_2 \\ H^0(P;\mathbb{Z}_2) & \cong \operatorname{Hom}(H_0(P),\mathbb{Z}_2) & \cong \operatorname{Hom}(\mathbb{Z},\mathbb{Z}_2) & = \mathbb{Z}_2. \end{array}$$

Fortunately this coincides with the calculations from page 1197.

Example. We return to the study of lens spaces. In Lemma 40.12 we saw that

$$H_n(L(p,q);\mathbb{Z}) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } n = 0,3 \\ 0, & \text{if } n = 2 \text{ or } n > 3 \\ \mathbb{Z}_p, & \text{if } n = 1. \end{cases}$$

As in the previous example we can now use the Universal Coefficient Theorem 51.13 and Lemma 51.5 to compute the cohomology groups of $L(p,q)$. We leave it as an exercise to the reader to verify that[919]

$$H^n(L(p,q);\mathbb{Z}) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } n = 0,3 \\ 0, & \text{if } n = 1 \text{ or } n > 3 \\ \mathbb{Z}_p, & \text{if } n = 2. \end{cases}$$

This shows, as was already foreshadowed by Corollary 49.4, that cohomology groups also cannot distinguish between two lens spaces of the form $L(p,q)$ and $L(p,r)$. In particular we have not made any progress on Question 7.8 since the introduction of the fundamental group. All the extra invariants, namely higher homotopy groups, homology groups and cohomology groups (with any coefficients) have proved useless.

Proposition 51.14. *Let M be a connected n-dimensional topological manifold. Let G be an abelian group. Then the following statements hold:*

(1) *Let $x \in M \setminus \partial M$. For $i \neq n$ we have $H_i(M, M \setminus \{x\}; G) = 0$. Furthermore the map*
$$\operatorname{ev}\colon H^n(M, M \setminus \{x\}; G) \;\to\; \operatorname{Hom}(H_n(M, M \setminus \{x\}; \mathbb{Z}), G)$$
is an isomorphism.
(2) *If M is compact but not closed, then $H^n(M;G) = 0$.*
(3) *If M is closed, orientable and non-empty, then $H^n(M;G) \cong G$.*
(4) *If M is closed, non-orientable and non-empty, then $H^n(M;G) \cong G/2G$.*
(5) *For any $k > n$ we have $H^k(M;G) = 0$.*

[919]Note that the $\mathbb{Z}_p$ shifted from $n = 1$ in homology to $n = 2$ in cohomology.

Proof. Let M be a compact connected n-dimensional topological manifold and let G be an abelian group.

(1) This statement follows immediately from Lemma 45.16 and the Universal Coefficient Theorem 51.13.
(2) We suppose that M has non-empty boundary. Then

$$\begin{array}{ccccccc} H^n(M;G) & \cong & \mathrm{Hom}(H_n(M;\mathbb{Z}),G) \oplus \mathrm{Ext}(H_{n-1}(M;\mathbb{Z}),G) & = & \mathrm{Ext}(\mathbb{Z}^k,G) & = & 0. \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{Universal Coefficient Theorem 51.13} & & \begin{array}{c}\text{by Theorem 46.4 we have } H_n(M;\mathbb{Z})=0 \text{ and} \\ \text{by Proposition 46.21 (1) we have } H_{n-1}(M;\mathbb{Z})\cong\mathbb{Z}^k \\ \text{for some } k\in\mathbb{N}_0\end{array} & & \text{Lemma 51.5} & \end{array}$$

(3) Suppose that M is closed, orientable and non-empty. The argument is very similar to the proof of (2). We just need to use that we know from Theorem 46.2 that $H_n(M;\mathbb{Z}) \cong \mathbb{Z}$ and that from Proposition 46.21 (1) we know that $H_{n-1}(M;\mathbb{Z}) \cong \mathbb{Z}^k$ for some k.
(4) Next suppose that M is closed, non-orientable and non-empty. This time we use that we know from Theorem 46.2 and Proposition 46.21 (2) that $H_n(M;\mathbb{Z}) \cong 0$ and that $H_{n-1}(M;\mathbb{Z}) \cong \mathbb{Z}^k \oplus \mathbb{Z}_2$ for some k. Here we also use Lemma 51.5 (4) which says that $\mathrm{Ext}(\mathbb{Z}_2, G) \cong G/2G$.
(5) So let $k > n$. This time we use that by Theorem 46.4 we know that $H_k(M;\mathbb{Z}) = 0$ and that we know from Theorems 46.2 and 46.4 that $H_{k-1}(M;\mathbb{Z})$ is either zero or isomorphic to $\mathbb{Z}$. The desired statement follows again from the Universal Coefficient Theorem 51.13 and the fact that by Lemma 51.5 we have $\mathrm{Ext}(\mathbb{Z}, G) = 0$. □

Lemma 51.15. *Let M be a compact oriented connected n-dimensional non-empty topological manifold. Then we have $H^n(M,\partial M;\mathbb{Z}) \cong \mathbb{Z}$. Furthermore there exists a unique generator $[M]^* \in H^n(M,\partial M;\mathbb{Z})$ with $\langle [M]^*, [M]\rangle_M = 1$.*[920]

Proof (∗). Let M be a compact oriented connected n-dimensional non-empty topological manifold. We start out with the following claim.

Claim. The homology group $H_{n-1}(M,\partial M;\mathbb{Z})$ is a free abelian group.

The proof of the claim is basically identical to the proof of Proposition 46.21. For completeness' sake we give the details. First we note that by Propositions 32.1 (3) and 45.2 (3) we know that $H_{n-1}(M,\partial M;\mathbb{Z})$ is finitely generated. Therefore by Lemma 46.22 it suffices to show that $\mathrm{Tor}(H_{n-1}(M,\partial M;\mathbb{Z}),\mathbb{F}_p) = 0$ for all primes p.

[920]Here $[M] \in H_n(M,\partial M;\mathbb{Z})$ denotes the fundamental class provided by Corollary 46.5.

So let p be a prime. We have

$$\begin{array}{ccccc} & & \text{Universal Coefficient Theorem 42.23} & & \\ & & \downarrow & & \\ \mathbb{F}_p & \cong & H_n(M,\partial M;\mathbb{F}_p) & \cong & H_n(M,\partial M;\mathbb{Z})\otimes\mathbb{F}_p \oplus \operatorname{Tor}(H_{n-1}(M,\partial M;\mathbb{Z}),\mathbb{F}_p) \\ & & \uparrow & & \cong \mathbb{F}_p \oplus \operatorname{Tor}(H_{n-1}(M,\partial M;\mathbb{Z}),\mathbb{F}_p). \\ & & \text{by Proposition 46.20 (1),} & & \uparrow \\ & & \text{since by Lemma 45.25} & & \text{by Theorem 46.2 (3) we} \\ & & M \text{ is also } \mathbb{F}_p\text{-orientable} & & \text{have } H_n(M,\partial M;\mathbb{Z})\cong\mathbb{Z} \end{array}$$

It follows from Lemma 11.8 that $\operatorname{Tor}(H_{n-1}(M,\partial M;\mathbb{Z}),\mathbb{F}_p)=0$. This concludes the proof of the claim.

It follows from the Universal Coefficient Theorem 51.13 for Cohomology Groups together with the above claim that the map

$$H^n(M,\partial M;\mathbb{Z}) \xrightarrow{\text{ev}} \operatorname{Hom}(\underbrace{H_n(M,\partial M;\mathbb{Z})}_{=\mathbb{Z}\cdot[M]},\mathbb{Z})$$

is an isomorphism. By Corollary 46.5 (3) we have the equality $H_n(M,\partial M;\mathbb{Z})=\mathbb{Z}\cdot[M]$. Hence there exists a unique element $[M]^*\in H^n(M,\partial M;\mathbb{Z})$ with $\text{ev}([M]^*)([M])=1$, i.e. with $\langle [M]^*,[M]\rangle_M=1$. □

Definition.

(1) Given a compact oriented connected non-empty n-dimensional topological manifold M we refer to the uniquely determined element $[M]^*\in H^n(M,\partial M;\mathbb{Z})$ from Lemma 51.15 as the *dual fundamental class* of M.

(2) Given a compact oriented n-dimensional non-empty topological manifold M with finitely many components $M_1,\dots,M_k$ we define its *dual fundamental class* to be

$$[M]^* := [M_1]^*+\cdots+[M_k]^* \in \underbrace{H^n(M_1,\partial M_1;\mathbb{Z})\oplus\cdots\oplus H^n(M_k,\partial M_k;\mathbb{Z})}_{=H^n(M,\partial M;\mathbb{Z})}.$$

Example. We consider the manifold S^1 with the usual orientation. We saw on page 1118 that the singular simplex $\mu\colon\Delta^1\to S^1$ that is given by $(1-t,t)\mapsto e^{2\pi it}$ represents the fundamental class of S^1. On page 1167 we introduced a cocycle $\theta_{\mathbb{Z}}\in C^1(S^1;\mathbb{Z})$ and we had explicitly calculated that $\langle[\theta_{\mathbb{Z}}],[S^1]\rangle=\theta_{\mathbb{Z}}(\mu)=1$. This shows immediately that $[\theta_{\mathbb{Z}}]\in H^1(S^1;\mathbb{Z})$ is the dual fundamental class of S^1.

Later on we will need the following lemma.

Lemma 51.16. *Let $f\colon M\to N$ be a map between closed oriented connected non-empty n-dimensional topological manifolds. Then*

$$f^*([N]^*) = \deg(f)\cdot[M]^*.$$

Proof. Let $f\colon M\to N$ be a map between closed, oriented connected n-dimensional non-empty topological manifolds. It follows from Lemma 51.15 that any class in $\varphi=H^n(M;\mathbb{Z})$

is of the form $\varphi = k \cdot [M]^*$ for some $k \in \mathbb{Z}$ and it follows from $\langle [M]^*, [M] \rangle = 1$ and the bilinearity of the Kronecker pairing that $k = \langle \varphi, [M] \rangle_M$. In our case we have

$$\langle f^*([N]^*), [M] \rangle \underset{\substack{\uparrow \\ \text{Lemma 50.6}}}{=} \langle [N]^*, f_*([M]) \rangle \underset{\substack{\uparrow \\ \text{by definition of } \deg(f)}}{=} \langle [N]^*, \deg(f) \cdot [N] \rangle \underset{\substack{\uparrow \\ \text{since } \langle\, , \rangle \text{ is bilinear}}}{=} \deg(f) \cdot \underbrace{\langle [N]^*, [N] \rangle}_{=1} = \deg(f).$$

It follows from the above discussion that $f^*([N]^*) = \deg(f) \cdot [M]^*$. □

Next we record the following useful consequence of the Universal Coefficient Theorem 51.13 for Cohomology Groups:

Proposition 51.17. *Let X be a path-connected topological space, let $x_0 \in X$ and let G be an abelian group. Then the Hurewicz homomorphism $\pi_1(X, x_0) \to H_1(X)$ from page 924 and the evaluation homomorphism* $\mathrm{ev}\colon H^1(X; G) \to \mathrm{Hom}(H_1(X); G)$ *induce natural isomorphisms*

$$H^1(X; G) \xrightarrow{\cong} \mathrm{Hom}(H_1(X); G) \xrightarrow{\cong} \mathrm{Hom}(\pi_1(X, x_0), G).$$

One often uses the natural isomorphisms from Proposition 51.17 to identify these groups.

Proof. As we pointed out on page 1220 and Proposition 38.2 (4), both maps are natural. So it remains to show that both maps are isomorphisms.

We insert one extra map into the above sequence of maps to see that the maps are indeed isomorphisms":

$$H^1(X; G) \underset{\substack{\uparrow \\ \text{isomorphism by Theorem 51.13} \\ \text{since } H_0(X) \cong \mathbb{Z} \text{ by Proposition 29.5}}}{\xrightarrow{\mathrm{ev}}} \mathrm{Hom}(H_1(X); G) \underset{\substack{\uparrow \\ \text{Hurewicz Theorem 38.5}}}{\xrightarrow{\cong}} \mathrm{Hom}(\pi_1(X, x_0)_{\mathrm{ab}}, G) \underset{\substack{\uparrow \\ \text{by Proposition 13.10 (2)} \\ \text{since } G \text{ is abelian}}}{\xleftarrow{\cong}} \mathrm{Hom}(\pi_1(X, x_0), G).$$

□

Before we continue we introduce a slight variation of the Kronecker pairing defined in Lemma 50.5. More precisely, let C_* be a chain complex and let R be a commutative ring. We consider the map

$$\begin{aligned} \langle\, , \,\rangle\colon H^n(C; R) \times H_n(C; R) &\to R \\ \Big([\varphi], \Big[\sum_{i=1}^k c_i \otimes a_i\Big]\Big) &\mapsto \sum_{i=1}^k \varphi(c_i) \cdot a_i. \end{aligned}$$

We leave it as an exercise to verify that this map is well-defined and bilinear. We refer to this pairing also as the *Kronecker pairing*.

The next proposition relates homology and cohomology with coefficients in a field $\mathbb{F}$.

Proposition 51.18. *Let (X, A) be a pair of topological spaces and let $\mathbb{F}$ be a field. The map*

$$\begin{aligned} \mathrm{ev}\colon H^n(X, A; \mathbb{F}) &\to \mathrm{Hom}_{\mathbb{F}}(H_n(X, A; \mathbb{F}), \mathbb{F}) \\ \varphi &\mapsto \begin{pmatrix} H_n(X, A; \mathbb{F}) & \to & \mathbb{F} \\ \sigma & \mapsto & \langle \varphi, \sigma \rangle \end{pmatrix} \end{aligned}$$

is a natural isomorphism of $\mathbb{F}$*-vector spaces.*[921]

We postpone the proof of Proposition 51.18 to the next section. In most applications we are only interested in the following corollary to Proposition 51.18.

Corollary 51.19. *Let* X *be a topological space and let* $k \in \mathbb{N}_0$ *such that* $H_k(X;\mathbb{Z})$ *and* $H_{k-1}(X;\mathbb{Z})$ *are finitely generated. (By Proposition 45.2 we know that every compact topological manifold satisfies this condition.) Furthermore let* $\mathbb{F}$ *be a field. Then the homology and cohomology groups* $H_k(X;\mathbb{F})$ *and* $H^k(X;\mathbb{F})$ *are finite-dimensional* $\mathbb{F}$*-vector spaces with*

$$\dim_{\mathbb{F}}(H_k(X;\mathbb{F})) \;=\; \dim_{\mathbb{F}}(H^k(X;\mathbb{F})).$$

Remark. Note that in Corollary 51.19 we only claim that the homology and cohomology groups are abstractly isomorphic. We do not claim that there is a natural isomorphism. In fact it does not make sense to ask for a natural isomorphism since the homology groups of a topological space X with $\mathbb{F}$-coefficients are covariant in X whereas the cohomology groups of X with $\mathbb{F}$-coefficients are contravariant in X.

Proof. Let X be a topological space and let $k \in \mathbb{N}_0$ such that $H_k(X;\mathbb{Z})$ and $H_{k-1}(X;\mathbb{Z})$ are finitely generated. Let p be a prime number. By the classification of finitely generated abelian groups, see Theorem 11.4, we can make the identifications

$$H_{k-1}(X;\mathbb{Z}) \;=\; \mathbb{Z}^r \oplus \bigoplus_{i=1}^{\alpha}\mathbb{Z}_{a_i} \oplus \bigoplus_{i=1}^{\beta}\mathbb{Z}_{b_i} \quad \text{and} \quad H_k(X;\mathbb{Z}) \;=\; \mathbb{Z}^s \oplus \bigoplus_{i=1}^{\gamma}\mathbb{Z}_{c_i} \oplus \bigoplus_{i=1}^{\delta}\mathbb{Z}_{d_i}$$

where all the a_i, b_i, c_i and d_i are non-zero, and where each a_i and each c_i is divisible by p and none of the b_i and d_i are divisible by p. We start out with the following claim:

Claim. We have

$$\dim_{\mathbb{F}}(H_k(X,\mathbb{F})) \;=\; \begin{cases} s, & \text{if } \mathbb{F} \text{ is a field of characteristic zero,} \\ s+\alpha+\gamma, & \text{if } \mathbb{F} \text{ is a field of characteristic } p. \end{cases}$$

First assume that $\mathbb{F}$ is a field of characteristic zero. In this case we have

$$H_k(X;\mathbb{F}) \;\underset{\substack{\uparrow \\ \text{by Theorem 42.19 and Lemma 42.17 (4) since } \mathbb{F} \text{ is torsion-free}}}{\cong}\; H_k(X;\mathbb{Z}) \otimes \mathbb{F} \;=\; \Big(\mathbb{Z}^s \oplus \bigoplus_{i=1}^{\gamma}\mathbb{Z}_{c_i} \oplus \bigoplus_{i=1}^{\delta}\mathbb{Z}_{d_i}\Big) \otimes \mathbb{F} \;\underset{\substack{\uparrow \\ \text{see page 1004}}}{\cong}\; \mathbb{F}^s.$$

Now suppose that $\mathbb{F}$ is a field of characteristic p. We make the following observation. For any $n \in \mathbb{N}$ we have

$$\mathbb{Z}_n \otimes \mathbb{F} \underset{\substack{\uparrow \\ \text{Lemma 42.3 (3)}}}{=} \operatorname{coker}\big(\mathbb{F} \xrightarrow{\cdot n} \mathbb{F}\big) = \begin{cases} \mathbb{F}, & \text{if } p|n, \\ 0, & \text{else} \end{cases} \quad \text{and} \quad \operatorname{Tor}(\mathbb{Z}_n,\mathbb{F}) \underset{\substack{\uparrow \\ \text{Lemma 42.17 (6)}}}{=} \ker\big(\mathbb{F} \xrightarrow{\cdot n} \mathbb{F}\big) = \begin{cases} \mathbb{F}, & \text{if } p|n, \\ 0, & \text{else.} \end{cases}$$

[921]Note that "natural" makes sense since $(X,A) \mapsto H^k(X,A;\mathbb{F})$ and $(X,A) \mapsto \operatorname{Hom}_{\mathbb{F}}(H_k(X,A;\mathbb{F}),\mathbb{F})$ both define *contravariant* functors from the category of pairs of topological spaces to the category of $\mathbb{F}$-vector spaces.

Then

$$\begin{array}{ccccc} H_k(X;\mathbb{F}) & \cong & H_k(X;\mathbb{Z})\otimes\mathbb{F}\oplus\mathrm{Tor}(H_{k-1}(X;\mathbb{Z}),\mathbb{F}) & \cong & \mathbb{F}^s\oplus\mathbb{F}^\gamma\oplus\mathbb{F}^\alpha. \\ & \uparrow & & \uparrow & \\ & \text{by Theorem 42.19} & & \begin{array}{c}\text{by Lemma 42.17, the discussion on page 1004}\\ \text{and the above observations}\end{array} & \end{array}$$

This concludes the proof of the claim.

Now we have

$$\begin{array}{ccccc} \dim_{\mathbb{F}}(H^k(X;\mathbb{F})) & = & \dim_{\mathbb{F}}(\mathrm{Hom}(H_k(X;\mathbb{F}),\mathbb{F})) & = & \dim_{\mathbb{F}}(H_k(X;\mathbb{F})) \\ & \uparrow & & \uparrow & \\ & \text{Proposition 51.18} & & \text{since by the claim } H_k(X;\mathbb{F}) \text{ is finite dimensional} & \end{array}$$

We could also prove the equality $\dim_{\mathbb{F}}(H^k(X;\mathbb{F})) = \dim_{\mathbb{F}}(H_k(X;\mathbb{F}))$ without appealing to Proposition 51.18. Indeed, using Theorem 51.13, the fact that for any abelian group G we have $\mathrm{Hom}(\mathbb{Z}_n, G) \cong \ker(G \xrightarrow{\cdot n} G)$ and Proposition 51.6 one can easily compute $\dim_{\mathbb{F}}(H^k(X;\mathbb{F}))$ and one ends up with the same calculation as in the above claim. We leave it to the reader to fill in the details. □

51.3. **Proof of Proposition 51.18** $(*)$**.** In this section we give the proof of Proposition 51.18. Before we can provide the proof we need to prepare the ground.

Let $\mathbb{F}$ be a field. We define a *chain complex over* $\mathbb{F}$ to be a chain complex (V_*, v_*) where all chain groups are $\mathbb{F}$-vector spaces and all boundary maps are $\mathbb{F}$-homomorphisms. For example, if (C_*, ∂_*) is a chain complex of abelian groups, then $(C_*\otimes\mathbb{F}, \partial_*\otimes\mathrm{id})$ is easily seen to be a chain complex over $\mathbb{F}$.

Given a chain complex (V_*, v_*) over the field $\mathbb{F}$ and given $n\in\mathbb{N}_0$ its n-homology

$$H_n(V) \;:=\; \frac{\ker\{v_n\colon V_n\to V_{n-1}\}}{\mathrm{im}\{v_{n+1}\colon V_{n+1}\to V_n\}}.$$

is an $\mathbb{F}$-vector space in a natural way.

We also define cochain complexes and cochain maps over $\mathbb{F}$ in the obvious way. For example, if (C_*, c_*) is a chain complex, then the dual cochain complex $(\mathrm{Hom}(C_*(X,\mathbb{F})), c^*)$ is a cochain complex over $\mathbb{F}$.

Given a chain complex (V_*, v_*) over $\mathbb{F}$ we obtain a cochain complex by considering $(\mathrm{Hom}_{\mathbb{F}}(V_*;\mathbb{F}), v^*)$ and we define its n-th cohomology group to be the $\mathbb{F}$-vector space

$$H^n(V;\mathbb{F}) \;:=\; \frac{\ker\{v^*_{n+1}\colon \mathrm{Hom}_{\mathbb{F}}(V_n,\mathbb{F})\to\mathrm{Hom}_{\mathbb{F}}(V_{n+1},\mathbb{F})\}}{\mathrm{im}\{v^*_n\colon \mathrm{Hom}_{\mathbb{F}}(V_{n-1},\mathbb{F})\to\mathrm{Hom}_{\mathbb{F}}(V_n,\mathbb{F})\}}.$$

The proof of the Universal Coefficient Theorem 51.12 for Cohomology Groups can be modified fairly easily to provide the following theorem.

Theorem 51.20. *Let $\mathbb{F}$ be a field and let (V_*, v_*) be a chain complex over $\mathbb{F}$. Then the map*

$$\begin{array}{rcl} \mathrm{ev}_{\mathbb{F}}\colon H^k(V;\mathbb{F}) & \mapsto & \mathrm{Hom}_{\mathbb{F}}(H_k(V),\mathbb{F}). \\ (\varphi\colon V_k\to\mathbb{F}) & \mapsto & \left(\begin{array}{rcl} H_k(V) & \to & \mathbb{F} \\ {[c]} & \mapsto & \varphi(c)\end{array}\right) \end{array}$$

is well-defined and it is an isomorphism.

A proof of that theorem is provided by any self-respecting book on homological algebra, see e.g. [DK, Corollary 2.31].

We will also need the following lemma.

Lemma 51.21. *Let C be an abelian group and let $\mathbb{F}$ be a field. Then the map*[922]

$$\begin{array}{rcl} \Phi_C\colon \operatorname{Hom}_{\mathbb{Z}}(C,\mathbb{F}) & \to & \operatorname{Hom}_{\mathbb{F}}(C\otimes\mathbb{F},\mathbb{F}) \\ (\varphi\colon C\to\mathbb{F}) & \mapsto & \left(\begin{array}{ccc} C\otimes\mathbb{F} & \to & \mathbb{F} \\ \sum\limits_{i=1}^{k} c_i\otimes a_i & \mapsto & \sum\limits_{i=1}^{k}\varphi(c_i)\cdot a_i \end{array}\right) \end{array}$$

is an isomorphism.

Proof. It is straightforward to verify that an inverse map to Φ_C is given by the following homomorphism of $\mathbb{F}$-vector spaces:

$$\begin{array}{rcl} \Psi_C\colon \operatorname{Hom}_{\mathbb{F}}(C\otimes\mathbb{F},\mathbb{F}) & \to & \operatorname{Hom}_{\mathbb{Z}}(C,\mathbb{F}) \\ (\varphi\colon C\otimes\mathbb{F}\to\mathbb{F}) & \mapsto & \big(C \xrightarrow{c\mapsto c\otimes 1} C\otimes\mathbb{F} \xrightarrow{\varphi} \mathbb{F}\big). \end{array}$$

□

Corollary 51.22. *Let C_* be a chain complex and let $\mathbb{F}$ be a field. The maps*

$$\Phi_{C_k}\colon \operatorname{Hom}_{\mathbb{Z}}(C_k,\mathbb{F}) \to \operatorname{Hom}_{\mathbb{F}}(C_k\otimes\mathbb{F},\mathbb{F}) \quad \textit{with } k\in\mathbb{N}_0$$

from the previous lemma define an isomorphism of cochain complexes of $\mathbb{F}$-vector spaces, in particular for each $k\in\mathbb{N}_0$ they induce an isomorphism

$$\Phi\colon H^k(C;\mathbb{F}) \to H^k(C\otimes\mathbb{F};\mathbb{F})$$

of $\mathbb{F}$-vector spaces.

Proof. By Lemma 51.21 the maps Φ_{C_k}, $k\in\mathbb{N}_0$, are isomorphisms of the cochain vector spaces. It is straightforward to see that these maps are also cochain maps. □

Now we can finally provide the proof of Proposition 51.18.

Proof of Proposition 51.18. Let (X,A) be a pair of topological spaces and let $\mathbb{F}$ be a field. We write $C_*=C_*(X,A)$. Given $k\in\mathbb{N}_0$ we consider the diagram

$$\begin{tikzcd} & H^k(C\otimes\mathbb{F};\mathbb{F}) \arrow[dr, "\mathrm{ev}_{\mathbb{F}}"] & \\ H^k(C;\mathbb{F}) \arrow[ur, "\Phi"] \arrow[rr, "\mathrm{ev}"'] & & \operatorname{Hom}_{\mathbb{F}}(H_n(C\otimes\mathbb{F}),\mathbb{F}). \end{tikzcd}$$

It follows easily from the definitions that for any representative in $H^k(C;\mathbb{F})$ the image under the composition of the two diagonal maps agrees with the image under the map ev. This implies that ev is well-defined and that the diagram commutes.

[922]Note that to the left we consider homomorphisms of $\mathbb{Z}$-modules, i.e. homomorphisms of abelian groups whereas to the right we consider homomorphisms of $\mathbb{F}$-vector spaces.

Also note that the left diagonal map is an isomorphism by Corollary 51.22 whereas the right diagonal map is an isomorphism by Theorem 51.20. In particular the bottom map is an isomorphism. But that is exactly what we had wanted to show. □

51.4. **Change of coefficients in cohomology** $(*)$**.** Let (C_*, ∂_*) be a chain complex of free abelian groups and let G be an abelian group. By the Algebraic Universal Coefficient Theorem 42.18 we can relate the homology groups of $C_* \otimes G$ to the homology groups of C_*. Furthermore, by the Universal Coefficient Theorem for Cohomology Groups 51.12 we can relate the cohomology groups $H^n(C_*; G)$ to the homology groups $H_*(C)$. The following question arises.

Question 51.23. *Can we relate the cohomology groups $H^n(C; G)$ to the cohomology groups $H^n(C; \mathbb{Z})$?*

It turns out that the question is slightly subtle. To formulate the answer we need the following lemma.

Lemma 51.24. *Let G be an abelian group.*

(1) *For any abelian group H the map*

$$\begin{array}{rcl} \mu\colon \operatorname{Hom}(H,\mathbb{Z}) \otimes G & \to & \operatorname{Hom}(H,G) \\ \sum\limits_{i=1}^{m} \varphi_i \otimes g_i & \mapsto & \left(\begin{array}{ccc} H & \to & G \\ h & \mapsto & \sum\limits_{i=1}^{m} \varphi_i(h) \cdot g_i \end{array} \right) \end{array}$$

is a well-defined natural *homomorphism.*

(2) *Given a chain complex (C_*, ∂_*) the map*

$$\begin{array}{rcl} H^n(C;\mathbb{Z}) \otimes G & \xrightarrow{\mu} & H^n(C;G) \\ \sum\limits_{i=1}^{m} [\varphi_i] \otimes g_i & \mapsto & \sum\limits_{i=1}^{m} [\mu(\varphi_i \otimes g_i)] \end{array}$$

is well-defined.

Proof. The proof is elementary and is left to the reader. □

The following theorem gives an affirmative answer to Question 51.23, albeit only only under an extra hypothesis.

Theorem 51.25. (Universal Coefficient Theorem) *Let (C_*, ∂_*) be a chain complex of free abelian groups and let G be an abelian group. We suppose that all homology groups $H^n(C_*; \mathbb{Z})$ are finitely generated. Then for each $n \in \mathbb{N}_0$ there exists a short exact sequence of the form*

$$\begin{array}{ccccccccc} 0 & \to & H^n(C;\mathbb{Z}) \otimes G & \xrightarrow{\mu} & H^n(C;G) & \to & \operatorname{Tor}(H^{n+1}(C;\mathbb{Z}), G) & \to & 0. \\ & & [\varphi] \otimes g & \mapsto & [\mu(\varphi \otimes g)] & & & & \end{array}$$

Furthermore the short exact sequence splits.[923]

The key to proving the Universal Coefficient Theorem 51.25 is the following elementary but subtle lemma.

Lemma 51.26. *Let G be an abelian group. If H is a free abelian group of* finite rank*, then the map*

$$\mu\colon \operatorname{Hom}(H,\mathbb{Z})\otimes G \;\to\; \operatorname{Hom}(H,G)$$

is an isomorphism.

Proof. Let $v_1,\dots,v_n$ be a basis for the finitely generated free abelian group H. We denote by $\varphi_1,\dots,\varphi_n$ the dual basis of $\operatorname{Hom}(H,\mathbb{Z})$. In other words, these are the homomorphisms that are uniquely determined by $\varphi_i(v_j)=\delta_{ij}$. We leave it to the reader to verify that the map

$$\begin{array}{rcl} \nu\colon \operatorname{Hom}(H,G) & \to & \operatorname{Hom}(H,\mathbb{Z})\otimes G \\ \psi & \mapsto & \sum\limits_{i=1}^{n}\varphi_i\otimes\psi(v_i) \end{array}$$

is an inverse to the homomorphism μ. □

We will also need the following lemma.

Lemma 51.27. *Let (C_*,∂_*) be a chain complex of free abelian groups. If all cohomology groups $H^n(C_*;\mathbb{Z})$ are finitely generated, then all homology groups $H_n(C_*)$ are also finitely generated.*

Proof of Lemma 51.27. Let (C_*,∂_*) be a chain complex of free abelian groups such that all cohomology groups $H^n(C_*;\mathbb{Z})$ are finitely generated. By the Universal Coefficient Theorem 51.12 for Cohomology Groups there exists an isomorphism

$$H^n(C;\mathbb{Z}) \;\cong\; \operatorname{Ext}(H_{n-1}(C),\mathbb{Z})\oplus\operatorname{Hom}(H_n(C),\mathbb{Z}) \qquad \text{for every } n\in\mathbb{N}_0.$$

We see that all the groups $\operatorname{Ext}(H_{n-1}(C),\mathbb{Z})$ and $\operatorname{Hom}(H_n(C),\mathbb{Z})$ are finitely generated, in particular they are countable. But by Proposition 51.11 this implies that all the homology groups $H_n(C_*)$ are finitely generated. □

Proof of the Universal Coefficient Theorem 51.25. Let G be an abelian group. Furthermore let (C_*,∂_*) be a chain complex of free abelian groups such that all cohomology groups $H^n(C_*;\mathbb{Z})$ are finitely generated. It follows from Lemma 51.27 that all homology groups $H_n(C_*)$ are also finitely generated. Thus we obtain from Lemma 49.8 that there exists a chain homotopy equivalence $h\colon C_*\to D_*$ from (C_*,∂_*) to a chain complex (D_*,∂_*) such

[923]As always, the splitting is not natural. In fact in this theorem we do *not* even claim that the short exact sequence is natural. The reason is that the construction of the short exact sequence involves a choice of the chain complex D_* and we do not intend to discuss the question how that choice affects the map on the right hand side.

that each chain group D_n is a finitely generated free abelian group. Now we consider the following diagram:

$$\begin{tikzcd}
0 \arrow[r] & \overbrace{H_n(\mathrm{Hom}(D_*,\mathbb{Z}))}^{=H^n(D;\mathbb{Z}) \text{ by def.}} \otimes G \arrow[r, "{[\varphi]\otimes g \mapsto [\varphi\otimes g]}"] & H_n(\mathrm{Hom}(D_*,\mathbb{Z});G) \arrow[r] & \mathrm{Tor}(\overbrace{H_{n+1}(\mathrm{Hom}(D_*,\mathbb{Z}))}^{=H^{n+1}(D;\mathbb{Z}) \text{ by def.}}, G) \arrow[r] & 0. \\
& H^n(D;\mathbb{Z}) \otimes G \arrow[u, "="] \arrow[r, "\mu"] & H_n(\mathrm{Hom}(D_*,G)) \arrow[d, "\mu", "\cong"'] & \mathrm{Tor}(H^{n+1}(D;\mathbb{Z}),G) \arrow[u, "="] & \\
& H^n(D;\mathbb{Z}) \otimes G \arrow[u, "="] \arrow[r, "\mu"] \arrow[d, "h^*", "\cong"'] & H^n(D_*,G)) \arrow[u, "="] \arrow[d, "h^*", "\cong"'] & \mathrm{Tor}(H^{n+1}(D;\mathbb{Z}),G) \arrow[u, "="] \arrow[d, "h^*", "\cong"'] & \\
& H^n(C;\mathbb{Z}) \otimes G \arrow[r, "\mu"] & H^n(C,G) & \mathrm{Tor}(H^{n+1}(D;\mathbb{Z}),G). &
\end{tikzcd}$$

We make the following clarifications:

(1) The sequence on the top is the short exact sequence obtained from the Algebraic Universal Coefficient Theorem 42.18 applied to the chain complex $E_* = \mathrm{Hom}(D_{-*},\mathbb{Z})$. We need to invert the sign of the degrees twice, thus we end up with the degree $n+1 = -((-n)-1)$ on the right hand side. We know by Proposition 42.22 that the short exact sequence splits.
(2) The middle vertical map between the first two rows is an isomorphism by Lemma 51.26. Here we use that each chain group of D_* is a free abelian group of finite rank.
(3) One can easily verify that the diagram commutes.
(4) By Lemma 48.8 (4) the bottom vertical maps are isomorphisms.

It is now clear that we obtain the desired short exact sequence. □

The following theorem gives a practical "topological" version of the Universal Coefficient Theorem 51.25.

Theorem 51.28. (Universal Coefficient Theorem) *Let X be a topological space and let G be an abelian group. If all homology groups $H_n(X)$ of X are finitely generated (e.g. X could be a compact topological manifold or X could be a CW-complex that has only finitely many cells in each dimension*[924]*), then for each $n \in \mathbb{N}_0$ there exists a short exact sequence of the form*

$$\begin{array}{ccccccc} 0 & \to & H^n(X;\mathbb{Z}) \otimes G & \xrightarrow{\mu} & H^n(X;G) & \to & \mathrm{Tor}(H^{n+1}(X;\mathbb{Z}),G) \to 0. \\ & & [\varphi] \otimes g & \mapsto & [\mu(\varphi \otimes g)] & & \end{array}$$

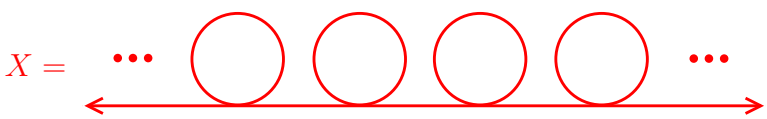
Furthermore the short exact sequence splits.

Proof. This theorem follows immediately from applying the Universal Coefficient Theorem 51.25 to the singular chain complex of X. □

Remark. In general the hypothesis on X that we put into the Universal Coefficient Theorem 51.28 cannot be dropped. For example consider the infinite string of circles X as

[924]By Proposition 45.2 (2) and Proposition 35.5 (1) such topological spaces qualify.

shown in Figure 692 and we take $G = \mathbb{Q}$. By Lemma 42.17 (4) we know that all Tor-groups $\mathrm{Tor}(H, \mathbb{Q})$ vanish. In Exercise 51.9 we will see that the groups $H^1(X;\mathbb{Z}) \otimes \mathbb{Q}$ and $H^1(X;\mathbb{Q})$ are not isomorphic. This shows that in this setting the sequence given in Universal Coefficient Theorem 51.28 is not exact.



the groups
$H^1(X;\mathbb{Z}) \otimes \mathbb{Q}$ and $H^1(X;\mathbb{Q})$
are not isomorphic

FIGURE 692.

The following lemma gives a convenient interpretation of the map μ appearing in the Universal Coefficient Theorem 51.28.

Lemma 51.29. *Let X be a topological space, let G be an abelian group and let $f\colon \mathbb{Z} \to G$ be a homomorphism. The following diagram commutes:*

$$\begin{tikzcd} H^n(X;\mathbb{Z}) \arrow[d, "a \mapsto a \otimes f(1)"'] \arrow[dr, "f_*"] & \\ H^n(X;\mathbb{Z}) \otimes G \arrow[r, "\mu"'] & H^n(X;G). \end{tikzcd}$$

Proof. The statement follows immediately from explicitly writing down the homomorphisms. □

Example. Let $n \in \mathbb{N} \cup \{\infty\}$. We denote by $f\colon \mathbb{Z} \to \mathbb{Z}_2$ the obvious group homomorphism. It follows from the Universal Coefficient Theorem 51.28, from Lemma 51.29, from the calculations of the cohomology groups $H^*(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$ on page 1198, and from the properties of Tor-groups, see Lemma 42.17, that for any $k \in \mathbb{N}_0$ the map $f_*\colon H_*(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \to H_*(\mathbb{C}\mathrm{P}^n;\mathbb{Z}_2)$ is an epimorphism.

We conclude this chapter with the following lemma which unwittingly gets used frequently.

Lemma 51.30. $(*)$ *We denote by $\varphi\colon \mathbb{Z} \to \mathbb{Q}$ the obvious inclusion. Let $n \in \mathbb{N}_0$.*

(1) *Let X be a topological space such that all homology groups are finitely generated. We suppose that $H^n(X;\mathbb{Z})$ is a finitely generated free abelian group. If $v_1, \dots, v_m$ is a basis of $H^n(X;\mathbb{Z})$, then $\varphi_*(v_1), \dots, \varphi_*(v_m)$ is a basis of $H^n(X;\mathbb{Q})$.*

(2) *Let $f\colon X \to Y$ be a map between topological spaces. We suppose that all homology groups of X and Y are finitely generated and we suppose that $H^n(X;\mathbb{Z})$ and $H^n(Y;\mathbb{Z})$ are free abelian groups. We consider the following commutative diagram:*

$$\begin{tikzcd} H^n(Y;\mathbb{Z}) \arrow[r, "f^*"] \arrow[d, "\varphi_*"'] & H^n(X;\mathbb{Z}) \arrow[d, "\varphi_*"] \\ H^n(Y;\mathbb{Q}) \arrow[r, "f^*"] & H^n(X;\mathbb{Q}). \end{tikzcd}$$

Suppose $v_1, \dots, v_r$ is a basis for $H^n(X;\mathbb{Z})$ and that $w_1, \dots, w_s$ is a basis for $H^n(Y;\mathbb{Z})$. The matrix that represents $f^*\colon H^n(Y;\mathbb{Z}) \to H^n(X;\mathbb{Z})$ with respect to the given bases also represents $f^*\colon H^n(Y;\mathbb{Q}) \to H^n(X;\mathbb{Q})$ with respect to the bases $\varphi_*(v_1), \dots, \varphi_*(v_r)$ and $\varphi_*(w_1), \dots, \varphi_*(w_s)$.

Proof $(*)$.

(1) This statement follows easily from the Universal Coefficient Theorem 51.28 together with Lemma 42.17 (4) and Lemma 51.29.
(2) The fact that the diagram commutes is an immediate consequence of Lemma 48.9. The remaining statement is just a psychologically helpful reinterpretation of the fact that the diagram commutes. □

Exercises for Chapter 51.

Exercise 51.1. Let C_* be a chain complex of free abelian groups and let $n \in \mathbb{N}$. Show that there does not exist a *natural* isomorphism

$$H^n(C;G) \;\cong\; \operatorname{Ext}(H_{n-1}(C), G) \oplus \operatorname{Hom}(H_n(C), G).$$

Exercise 51.2. Let $\{A_n\}_{n\in\mathbb{N}}$ be a sequence of finitely generated abelian groups. We assume that A_0 and A_1 are free abelian groups. Show that there exists a path-connected CW-complex X such that for any $n \in \mathbb{N}$ we have $H^n(X;\mathbb{Z}) \cong A_n$.
Hint: Use Proposition 34.10.

Exercise 51.3. Let $(P, \leq)$ be a partially ordered set and let Q be a subset. Is an upper bound necessarily a maximal element? And conversely, is a maximal element necessarily an upper bound?

Exercise 51.4. Redo Exercise 50.2. More precisely, use the Universal Coefficient Theorem 51.13 for Cohomology Groups to determine the isomorphism types of the cohomology groups of the Klein bottle with $\mathbb{F}_2$-coefficients, with $\mathbb{F}_3$-coefficients and with $\mathbb{Z}$-coefficients.

Exercise 51.5. Give an explicit example of a cocycle $\varphi\colon C_1(\mathbb{R}\mathrm{P}^2) \to \mathbb{F}_2$ that represents a generator of $H^1(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) \cong \mathbb{F}_2$.

Exercise 51.6. Let M be a compact oriented connected n-dimensional topological manifold with non-empty connected boundary. Show that $\delta([\partial M]^*) = [M]^* \in H^n(M, \partial M;\mathbb{Z})$ where δ denotes the connecting homomorphism in the long exact sequence of cohomology groups of the pair $(M, \partial M)$.
Hint: use Proposition 46.26.

Exercise 51.7.

(a) Let G and H be $\mathbb{Q}$-vector spaces. Let $\varphi\colon G \to H$ be a homomorphism of abelian groups. Show that φ is also a homomorphism of $\mathbb{Q}$-vector spaces.
(b) Show that the abelian groups $\mathbb{Q}$ and $\mathbb{Q}^2$ are not isomorphic.

(c) Show that the abelian groups $\mathbb{R}$ and $\mathbb{R}^2$ are isomorphic.
(d) Use (a) and (b), together with the existence of Moore spaces, see Proposition 34.11, and together with the Universal Coefficient Theorem 51.13 for Cohomology Groups and Proposition 51.10 to conclude that there exist topological spaces X and Y such that $H^n(X;\mathbb{Z}) \cong H^n(Y;\mathbb{Z})$ for all $n \in \mathbb{N}_0$ but such that $H_1(X;\mathbb{Z})$ is not isomorphic to $H_1(Y;\mathbb{Z})$.

Remark: This exercise shows that in Corollary 49.4 the roles of homology and cohomology are not symmetric.

Exercise 51.8. Let H be a free abelian group and let G be an abelian group. As in Lemma 51.26 we consider the map

$$\begin{array}{rcl} \mathrm{Hom}(H,\mathbb{Z}) \otimes G & \to & \mathrm{Hom}(H,G) \\ \sum\limits_{i=1}^{m} \varphi_i \otimes g_i & \mapsto & \left(\begin{array}{rcl} H & \to & G \\ h & \mapsto & \sum\limits_{i=1}^{m} \varphi_i(h) \cdot g_i \end{array} \right). \end{array}$$

Show that this map is in general not an isomorphism.

Exercise 51.9. We consider the topological space X shown in Figure 692. Show that the groups $H^1(X;\mathbb{Z}) \otimes \mathbb{Q}$ and $H^1(X;\mathbb{Q})$ are not isomorphic.

52. Cohomology groups and limits

52.1. **Direct limits of direct systems.** In the intermediate future direct limits of direct systems and inverse limits of inverse systems will play a large role. To fortify us for these discussions we recall the definitions and we prove some fairly elementary but useful lemmas regarding limits.

First we recall the following definition from page 481.

Definition. A *directed set* is a set I together with a relation $\leq$ on I which satisfies the following three conditions:

(1) the relation is reflexive, i.e. for any $i \in I$ we have $i \leq i$.
(2) the relation is transitive, i.e. for any $i, j, k \in I$ we have
$$i \leq j \text{ and } j \leq k \quad \Longrightarrow \quad i \leq k.$$
(3) for any $i, j \in I$ there exists a $k \in I$ with $i \leq k$ and $j \leq k$.

Examples.

(a) Evidently the natural numbers $\mathbb{N}$ together with the usual "$\leq$" relation form a directed set $(\mathbb{N}, \leq)$.
(b) Let M be a set. We denote by $\mathcal{P}(M)$ the power set of M, i.e. the set of all subsets of M. Then the relation given by "$\subseteq$" turns $\mathcal{P}(M)$ into a directed set. To prove this claim it only remains to verify (3). But this also holds, since for any $X, Y \in \mathcal{P}(M)$, i.e. for any subsets X, Y of M we can take $Z = X \cup Y$ and we then have $X \subseteq Z$ and $Y \subseteq Z$.

Next we recall the following definition from page 482.

Definition. Let $(I, \leq)$ be a directed set and let $\mathcal{C}$ be a category. A *direct system over the directed set*[925] $(I, \leq)$ is a family of objects $\{X_i\}_{i \in I}$ in $\mathcal{C}$, together with a family of morphisms $\{f_{ij} \colon X_i \to X_j\}$ for all $i, j \in I$ with $i \leq j$ such that the following two conditions are satisfied:

$$\begin{array}{lrcll} (1) & f_{ii} & = & \mathrm{id}_{X_i} & \text{for all } i \in I, \\ (2) & f_{ik} & = & f_{jk} \circ f_{ij} & \text{for all } i, j, k \in I \text{ with } i \leq j \leq k. \end{array}$$

Example. Let $\mathcal{C}$ be a category and let
$$X_1 \xrightarrow{g_1} X_2 \xrightarrow{g_2} X_3 \xrightarrow{g_3} X_4 \xrightarrow{g_4} \dots$$
be a sequence of morphisms in the category $\mathcal{C}$. For $i \in \mathbb{N}_0$ we set $f_{ii} = \mathrm{id}$ and for $i \leq j$ we set $f_{ij} = g_{j-1} \circ \dots \circ g_{i+1} \circ g_i \colon X_i \to X_j$. It is clear that $(\{X_i\}_{i \in \mathbb{N}}, \{f_{ij}\}_{i \leq j})$ is a direct system over the directed set $(\mathbb{N}, \leq)$. By a slight abuse of notation we refer to such a sequence $(\{X_i\}_{i \in \mathbb{N}}, \{g_i \colon X_i \to X_{i+1}\}_{i \in \mathbb{N}})$ also as a direct system.

Finally we also recall the definition of a direct limit from page 483.

[925] On page 482 we had also considered direct systems that are defined over preordered sets, but for the remainder of this course we are only interested in direct systems over directed sets.

Definition. Let $(I, \leq)$ be a directed set and let $\mathcal{C}$ be a category. Suppose we are given a direct system $(\{X_i\}_{i\in I}, \{f_{ij}\}_{i\leq j})$ in the category $\mathcal{C}$. A *direct limit* of the direct system is an object $\varinjlim X_i$ in $\mathcal{C}$ together with morphisms $h_i\colon X_i \to \varinjlim X_i, i \in I$ in the category $\mathcal{C}$ such that the following two conditions are satisfied:

(1) For all $k \leq l$ we have $h_l \circ f_{kl} = h_k\colon X_k \to \varinjlim X_i$, i.e. for all $k \leq l$ the following diagram commutes

$$\begin{tikzcd} X_l \arrow[r, "h_l"] & \\ X_k \arrow[u, "f_{kl}"] \arrow[r, "h_k"'] & \varinjlim X_i. \end{tikzcd}$$

(2) If we are given another object Y and morphisms $h'_i\colon X_i \to Y, i \in I$ that satisfy (1), then there exists a unique morphism $F\colon \varinjlim X_i \to Y$ such that for all $k \leq l$ the following diagram commutes

$$\begin{tikzcd} X_l \arrow[r, "h_l"] \arrow[rr, bend left, "h'_l"] & & \\ X_i \arrow[u, "f_{kl}"] \arrow[r, "h_k"] \arrow[rr, bend right, "h'_k"'] & \varinjlim X_k \arrow[r, dashed, "F", "\exists!"'] & Y. \end{tikzcd}$$

As we pointed out on page 484, the direct limit of direct system, if it exists, is in an appropriate sense unique up to isomorphism.

The following proposition is a variation of Proposition 16.1.

Proposition 52.1. *Let $(I, \leq)$ be a directed set and let $(\{X_i\}_{i\in I}, \{f_{ij}\}_{i\leq j})$ be a direct system over one of the following categories:*

(1) *the category of abelian groups,*
(2) *the category of R-modules, where R is a commutative ring,*
(3) *the category of chain complexes,*
(4) *the category of cochain complexes.*

Then[926]

$$\varinjlim X_i \;:=\; \Big(\bigsqcup_{i\in I} X_i\Big)/\sim \quad \textit{where } x \sim f_{ij}(x) \textit{ for all } i \leq j,\ x \in X_i$$

with the obvious maps $X_i \to \varinjlim X_i$ is a direct limit. Here we view $\varinjlim X_i$ as a group as follows: if we are given $a \in X_i$ and $b \in X_j$, then by definition of a directed set there exists

[926]The construction of the direct limit that we gave in Proposition 16.1 was different, and arguably more complicated, since there we had considered direct systems over arbitrary preordered sets.

a $k \in I$ with $i \leq k$ and $j \leq k$, and we define[927]

$$[a] + [b] \;:=\; \underbrace{\big[\underbrace{f_{ik}(a)}_{\in X_k} + \underbrace{f_{jk}(b)}_{\in X_k}\big]}_{\textit{addition in } X_k} \;\in\; \varinjlim X_i.$$

Depending on the category we are dealing with we can also equip $\varinjlim X_i$ with an R-module structure or we can equip it with (co) boundary maps.

Proof. This explicit construction of the direct limit was already given on page 487. The proof of the proposition is a not overly exciting exercise in going through all the definitions. We leave this task to the reader. □

Now we give three lemmas which will be helpful in getting direct limits "under control".

Lemma 52.2. *Let $(I, \leq)$ be a directed set and let $(\{X_i\}_{i\in I}, \{f_{ij}\colon X_i \to X_j\}_{i\leq j})$ be a direct system over I in one of the four categories that we had considered in Proposition 52.1. Then the following four statements hold:*

(1) *Every element in $\varinjlim X_i$ lies in the image of one of the maps $X_j \to \varinjlim X_i$.*
(2) *Let $a_j \in X_j$ and let $a_k \in X_k$. The images of a_j and a_k in $\varinjlim X_i$ agree if and only if there exists an $l \in I$ with $l \geq j$ and $l \geq k$ such that $f_{jl}(a_j) = f_{kl}(a_k) \in X_l$.*
(3) *Let $a_j \in X_j$. The image of a_j in $\varinjlim X_i$ is zero if and only if there exists a $k \geq j$ such that $f_{jk}(a_j) = 0 \in X_k$.*
(4) *If all maps $f_{ij}\colon X_i \to X_j$ are isomorphisms, then for any $j \in I$ the obvious map $X_j \to \varinjlim X_i$ is an isomorphism.*

Proof.

(1) The first statement follows immediately from the explicit description of the direct limit given in Proposition 52.1.
(2) The second statement will be proved in Exercise 52.1. For the exercise it is useful to note that the symbol "$\sim$" in the definition of $\varinjlim X_i$ in Proposition 52.1 is only a relation and we really have to work with the equivalence relation generated by this relation, see page 114 for more information.
(3) The third statement is a special case of the second statement.
(4) The last statement will be proved in Exercise 52.1. □

The second lemma is useful for simplifying calculations.

Lemma 52.3. *Let $(I, \leq)$ be a directed set and let $(\{X_i\}_{i\in I}, \{f_{ij}\colon X_i \to X_j\}_{i\leq j})$ be a direct system over I in one of the four categories that we had considered in Proposition 52.1. Let J be a subset of I such that $(J, \leq)$ is again a directed set.*

[927] It is straightforward to verify that this definition does not depend on the choice of k.

(1) *There exists a unique map*

$$\varinjlim_{j\in J} X_j \longrightarrow \varinjlim_{i\in I} X_i$$

such that for any $j \in J$ the following diagram commutes:

$$\begin{tikzcd} & X_j \arrow[dl] \arrow[dr] & \\ \varinjlim_{j\in J} X_j \arrow[rr] & & \varinjlim_{i\in I} X_i. \end{tikzcd}$$

(2) *If J has the property that given any $i \in I$ there exists a $j \in J$ with $i \leq j$, then the above map*

$$\varinjlim_{j\in J} X_j \longrightarrow \varinjlim_{i\in I} X_i$$

is an isomorphism.

The first part of the lemma is just an immediate consequence of the definition of the direct limit over the directed set J. As we will see, the second statement is a fairly straightforward consequence of the next lemma. But it is also a good exercise to prove the above second statement "by hand".

The following definition is a generalization of the definition on page 867.

Definition. Let $(I, \leq)$ and $(J, \leq)$ be directed sets.

(1) A *morphism* between the directed sets $(I, \leq)$ and $(J, \leq)$ is a map $\varphi\colon I \to J$ such that for any $i_1 \leq i_2$ in I we have $\varphi(i_1) \leq \varphi(i_2)$.
(2) A morphism $\varphi\colon I \to J$ is called *cofinal* if given any $j \in J$ there exists an $i \in I$ with $\varphi(i) \geq j$.
(3) Let $(\{K_i\}_{i\in I}, \{\chi_{i_1 i_2}\}_{i_1 \leq i_2})$ and $(\{L_j\}_{j\in J}, \{\lambda_{j_1 j_2}\}_{j_1 \leq j_2})$ be direct systems in one of the four categories that we had considered in Proposition 52.1. A *homomorphism between the direct systems* is a family $\{f_i\colon K_i \to L_{\varphi(i)}\}_{i\in I}$ of homomorphisms that has the property that for any $i_1 \leq i_2$ the following diagram commutes:

$$\begin{tikzcd} K_{i_2} \arrow[r, "f_{i_2}"] & L_{\varphi(i_2)} \\ K_{i_1} \arrow[u, "\chi_{i_1 i_2}"] \arrow[r, "f_{i_1}"] & L_{\varphi(i_1)} \arrow[u, "\lambda_{\varphi(i_1)\varphi(i_2)}"'] \end{tikzcd}$$

(4) The maps $K_i \xrightarrow{f_i} L_{\varphi(i)} \to \varinjlim L_j$ induce, by the universal property of a direct limit, a map

$$\varinjlim_{i\in I} K_i \to \varinjlim_{j\in J} L_j$$

which is uniquely determined by the property that for any $i \in I$ the following diagram commutes

$$\begin{tikzcd} K_i \arrow[r, "f_i"] \arrow[d] & L_{\varphi(i)} \arrow[d] \\ \varinjlim_{i\in I} K_i \arrow[r] & \varinjlim_{j\in J} L_j. \end{tikzcd}$$

Lemma 52.4. *Let $\{f_i\colon K_i \to L_{\varphi(i)}\}_{i\in I}$ be a homomorphism between two direct systems $(\{K_i\}_{i\in I}, \{\chi_{i_1 i_2}\}_{i_1\le i_2})$ and $(\{L_j\}_{j\in J}, \{\lambda_{j_1 j_2}\}_{j_1\le j_2})$ in one of the four categories that we had considered in Proposition 52.1. Suppose the following two conditions are satisfied:*

(1) *the morphism $\varphi\colon I \to J$ is cofinal, and*
(2) *for each $i \in I$ the map $f_i\colon K_i \to L_{\varphi(i)}$ is an isomorphism.*

Then the induced map

$$\varinjlim_{i\in I} K_i \ \to\ \varinjlim_{j\in J} L_j$$

is an isomorphism.

Sketch of proof. Let $j \in J$. Since $\varphi\colon I \to J$ is cofinal we can pick $i \in I$ with $f(i) \ge j$. We define

$$\begin{aligned} g_j\colon L_j &\to \varinjlim_{i\in I} K_i \\ x &\mapsto [f_i^{-1}(\lambda_{j,f(i)}(x))]. \end{aligned}$$

It is straightforward to verify that this map does *not* depend on the choice of i. Using this observation it is elementary to verify that for any $j_1 \le j_2$ the following diagram commutes:

$$\begin{tikzcd} L_{j_2} \arrow[dr, "g_{j_2}"] & \\ & \varinjlim_{i\in I} K_i. \\ L_{j_1} \arrow[uu, "\lambda_{j_1 j_2}"] \arrow[ur, "g_{j_1}"'] & \end{tikzcd}$$

But by the universal property of the direct limit this implies that we get an induced

$$\varinjlim_{j\in J} L_j \ \to\ \varinjlim_{i\in I} K_i.$$

We leave it as an exercise to verify that this map is an inverse to the map under consideration. □

52.2. **Inverse limits of inverse systems.** We recall the following definition from page 495.

Definition. Let $(I, \le)$ be a directed set and let $\mathcal{C}$ be a category. An *inverse system in the category $\mathcal{C}$ over I* is a family of objects $\{X_i\}_{i\in I}$ in $\mathcal{C}$, together with a family of morphisms

$\{f_{ji}\colon X_j \to X_i\}$ for all $i, j \in I$ with $i \leq j$[928] such that the following two conditions are satisfied:

$$\begin{array}{lrcll} (1) & f_{ii} & = & \mathrm{id}_{X_i} & \text{for all } i \in I, \\ (2) & f_{ki} & = & f_{ji} \circ f_{kj} & \text{for all } i, j, k \in I \text{ with } i \leq j \leq k. \end{array}$$

Example. Let $\mathcal{C}$ be a category and let

$$\ldots \xrightarrow{g_4} X_4 \xrightarrow{g_3} X_3 \xrightarrow{g_2} X_2 \xrightarrow{g_1} X_1$$

be a sequence of morphisms in the category $\mathcal{C}$. For $i \in \mathbb{N}$ we set $f_{ii} = \mathrm{id}$ and for $i \leq j$ we set $f_{ji} = g_i \circ \cdots \circ g_{j-1}\colon X_j \to X_i$. It is clear that $(\{X_i\}_{i\in I}, \{f_{ji}\}_{i\leq j})$ is an inverse system over the directed set $(\mathbb{N}, \leq)$. It is also clear that any inverse system over $(\mathbb{N}, \leq)$ arises that way. By a slight abuse of notation we refer to such a sequence $(\{X_i\}_{i\in\mathbb{N}}, \{g_i\colon X_{i+1} \to X_i\}_{i\in\mathbb{N}})$ also as an inverse system.

Using the convention from the previous example we can now reformulate in our context the original definition of an inverse limit from page 495.

Definition. Let $(\{X_i\}_{i\in\mathbb{N}}, \{g_i\colon X_{i+1} \to X_i\}_{i\in\mathbb{N}})$ be an inverse system in a category $\mathcal{C}$. An *inverse limit* of the inverse system is an object $\varprojlim X_i$ in $\mathcal{C}$ together with morphisms $h_i\colon \varprojlim X_i \to X_i$, $i \in I$, in the category $\mathcal{C}$ such that the following two conditions are satisfied:

(1) For all $i \in \mathbb{N}$ we have $g_i \circ h_{i+1} = h_i\colon \varprojlim X_i \to X_i$, i.e. for all $i \in \mathbb{N}$ the following diagram commutes

$$\begin{tikzcd} & X_{i+1} \arrow[d, "g_i"] \\ \varprojlim X_i \arrow[ur, "h_{i+1}"] \arrow[r, "h_i"'] & X_i. \end{tikzcd}$$

(2) If we are given another object Y and morphisms $h'_i\colon Y \to X_i$, $i \in \mathbb{N}$, that satisfy (1), then there exists a unique morphism $F\colon Y \to \varprojlim X_i$ such that for all $i \in \mathbb{N}$ the following diagram commutes

$$\begin{tikzcd} & & X_{i+1} \arrow[dd, "g_i"] \\ Y \arrow[urr, bend left, "h'_{i+1}"] \arrow[r, dashed, "F", "\exists!"'] \arrow[drr, bend right, "h'_i"'] & \varprojlim X_i \arrow[ur, "h_{i+1}"] \arrow[dr, "h_i"] & \\ & & X_i. \end{tikzcd}$$

[928] So in an inverse system, given $i \leq j$ we have a morphism $X_j \to X_i$, whereas in a direct system we had a morphism $X_i \to X_j$.

Throughout the reminder of this course we will only be interested in inverse systems over the directed set $(\mathbb{N}, \leq)$. In the following proposition we give an explicit description of inverse limits for this special case. The proposition can be viewed as a slight variation of Proposition 16.7.

Proposition 52.5. *Let $(\{X_i\}_{i\in\mathbb{N}}, \{g_i\colon X_{i+1} \to X_i\}_{i\in\mathbb{N}})$ be an inverse system over one of the following categories:*

1. *the category of abelian groups,*
2. *the category of R-modules, where R is a commutative ring,*
3. *the category of chain complexes,*
4. *the category of cochain complexes.*

Then

$$\varprojlim X_i \;:=\; \Big\{(x_i)_{i\in\mathbb{N}} \in \prod_{i\in\mathbb{N}} X_i \,\Big|\, g_i(x_{i+1}) = x_i \text{ for all } i \in \mathbb{N}\Big\}$$

with the obvious projection maps $\varprojlim X_i \to X_i$ is a direct limit.

Proof. This proposition is implicitly proved on page 501. □

Remark. Proposition 52.5 can be summarized as saying that, under the hypothesis of the proposition, we have

$$\varprojlim X_i \;=\; \text{all infinite sequences } (x_1, x_2, x_3, \dots) \text{ of the form } \begin{array}{ccc} x_3 & \in & X_3 \\ \downarrow & & \downarrow g_2 \\ x_2 & \in & X_2 \\ \downarrow & & \downarrow g_1 \\ x_1 & \in & X_1. \end{array}$$

Example. For each $i \in \mathbb{N}$ we define $X_i := \mathbb{Z}^i$ and we denote by

$$\begin{array}{rcl} g_i\colon \mathbb{Z}^{i+1} & \to & \mathbb{Z}^i \\ (x_1, \dots, x_{i+1}) & \mapsto & (x_1, \dots, x_i) \end{array}$$

the projection map. Then $(\{\mathbb{Z}^i\}_{i\in\mathbb{N}}, \{g_i\}_{i\in\mathbb{N}})$ forms an inverse system in the category of abelian groups. As we had already pointed out on page 501, using the description of the inverse limit provided in Proposition 52.5 one can show fairly easily that

$$\varprojlim_{i\in\mathbb{N}} \mathbb{Z}^i \;=\; \{(x_1, x_2, x_3, \dots) \mid x_j \in \mathbb{Z}\} \;\cong\; \mathbb{Z}^{\mathbb{N}}.$$

We conclude this section with the following analogue of Lemma 16.2.

Lemma 52.6. *Let $f_n\colon X_n \to X_{n+1}$ be a sequence of morphisms in any category. Suppose there exists an $N \in \mathbb{N}$ such that all f_n for $n \geq N$ are isomorphisms. Then $\varprojlim X_n$ exists and the natural map $\varprojlim X_n \to X_N$ is an isomorphism.*

Proof. We leave it to the reader to prove this elementary lemma. □

52.3. **Cohomology groups and inverse limits.** In Propositions 16.4 and 34.4 we saw that in favorable situations the fundamental group and the homology groups of a union of topological spaces are the direct limit of the corresponding fundamental groups and homology groups. In this section we will try to extend these results to cohomology groups. The results will not only be useful for computing cohomology groups, but they will also play an essential role in many proofs later on. For example the proof that de Rham cohomology is isomorphic to singular cohomology with real coefficients will build on the somewhat technical results of this section.

We recall that Proposition 34.4 was a consequence of the following two lemmas. The first lemma is of topological nature.

Lemma 34.5. *Let X be a topological space and let $X_1 \subset X_2 \subset X_3 \subset \dots$ be a sequence of subsets such that every compact subset of X is already contained in one of the X_i. Then the chain complexes $C_*(X_i), i \in \mathbb{N}$ together with the inclusion induced chain maps $C_*(X_i) \to C_*(X_j)$ for $i \leq j$ form a direct system of chain complexes. Furthermore the inclusion induced maps $C_*(X_i) \to C_*(X)$ induce an isomorphism*

$$\varinjlim C_*(X_i) \xrightarrow{\cong} C_*(X)$$

of chain complexes.

The second lemma is purely algebraic.

Lemma 34.6. *Let $(\{C_i\}_{i\in\mathbb{N}}, \{g_i \colon C_i \to C_{i+1}\}_{i\in\mathbb{N}})$ be a direct system of chain complexes. Then for each $n \in \mathbb{N}_0$ we obtain an induced direct system $(\{H_n(C_i)\}_{i\in\mathbb{N}}, \{g_{i*}\}_{i\in\mathbb{N}})$ of abelian groups. Furthermore, given any $n \in \mathbb{N}_0$ the maps $H_n(C_i) \to H_n\big(\varinjlim C_i\big)$ induce an isomorphism*

$$\varinjlim H_n(C_i) \xrightarrow{\cong} H_n\big(\varinjlim C_i\big).$$

Let $(\{C_i\}_{i\in\mathbb{N}}, \{g_i \colon C_i \to C_{i+1}\}_{i\in\mathbb{N}})$ be a direct system of chain complexes. The last lemma can be summarized as follows: for every $j \in \mathbb{N}$ and any $n \in \mathbb{N}_0$ we have the following diagram

$$\begin{tikzcd}
H_n(C_{j+1}) \arrow[dr] \arrow[drr, bend left] & & \\
& \varinjlim H_n(C_i) \arrow[r, "\cong"] & H_n\big(\varinjlim C_i\big) \\
H_n(C_j) \arrow[uu, "g_{j*}"] \arrow[ur] \arrow[urr, bend right] & &
\end{tikzcd}$$

Now we turn to cohomology groups. Let G be an abelian group. Whereas homology is a covariant functor, cohomology is a contravariant functor. This implies that from the above direct system of chain complexes we obtain for each $n \in \mathbb{N}_0$ an *inverse system*

$(\{H^n(C_i;G)\}_{i\in\mathbb{N}}, \{g_i^*\colon H^n(C_{i+1};G) \to H^n(C_i;G)\}_{i\in\mathbb{N}})$ of abelian groups. Furthermore the maps $C_i \to \varinjlim C_i$ induce maps $H^n(\varinjlim C_i;G) \to H^n(C_i;G)$. Put differently, for any $j \in \mathbb{N}$ we are in the following situation

$$\begin{tikzcd}
 & & H^n(C_{j+1};G) \arrow[dd, "g_j^*"] \\
H^n\big(\varinjlim C_i;G\big) \arrow[urr, bend left] \arrow[rr, dashed] \arrow[drr, bend right] & & \varprojlim H^n(C_i;G) \arrow[ur] \arrow[dr] & \\
 & & H^n(C_j;G)
\end{tikzcd}$$

where the dotted arrow exists by the definition of the inverse limit of the groups $H^n(C_i;G)$. The question is whether the dotted arrow is in fact an isomorphism, put differently, the following question arises.

Question 52.7. *Let $(\{C_i\}_{i\in\mathbb{N}}, \{g_i\colon C_i \to C_{i+1}\}_{i\in\mathbb{N}})$ be a direct system of chain complexes. Is the above map*

$$H^n\big(\varinjlim C_i;\mathbb{Z}\big) \;\to\; \varprojlim H^n(C_i;\mathbb{Z})$$

always an isomorphism?

It turns out that this is not necessarily the case. To formulate the relationship between the two sides of the above question it is useful to rewrite the inverse limit from Proposition 52.5. More precisely, given an inverse system $(\{D_i\}_{i\in\mathbb{N}}, \{g_i\colon D_{i+1} \to D_i\}_{i\in\mathbb{N}})$ of abelian groups we consider the map

$$\begin{array}{rcl}
\mu\colon \prod\limits_{i\in\mathbb{N}} D_i & \to & \prod\limits_{i\in\mathbb{N}} D_i \\
(x_i)_{i\in\mathbb{N}} & \mapsto & (x_i - g_i(x_{i+1}))_{i\in\mathbb{N}}.
\end{array}$$

Proposition 52.5 can be reformulated as saying that

$$\varprojlim D_i \;=\; \ker(\mu).$$

This leads us to the following definition.

Definition. Let $(\{D_i\}_{i\in\mathbb{N}}, \{g_i\colon D_{i+1} \to D_i\}_{i\in\mathbb{N}})$ be an inverse system of abelian groups. Using the above notation we define[929]

$$\varprojlim{}^1 D_i \;:=\; \operatorname{coker}(\mu).$$

Example. We consider the inverse system

$$D_*\colon\; \ldots \xrightarrow{0} \mathbb{Z} \xrightarrow{\cdot 2} \mathbb{Z} \xrightarrow{0} \mathbb{Z} \xrightarrow{\cdot 2} \mathbb{Z} \;\to\; 0.$$

[929]If R is a commutative ring and if $(\{D_i\}_{i\in\mathbb{N}}, \{g_i\colon D_{i+1} \to D_i\}_{i\in\mathbb{N}})$ is an inverse system of R-modules, then $\varprojlim^1 D_i$ is also an R-module in an obvious way.

In Exercise 52.2 we will see that $\varprojlim D_* = 0$ and $\varprojlim^1 D_* = 0$. Furthermore, we also consider the inverse system

$$E_*\colon\ \dots \xrightarrow{\cdot 5} \mathbb{Z} \xrightarrow{\cdot 4} \mathbb{Z} \xrightarrow{3} \mathbb{Z} \xrightarrow{\cdot 2} \mathbb{Z} \ \to 0.$$

In Exercise 52.2 we will see that $\varprojlim^1 E_* \neq 0$. Furthermore in Exercise 52.3 we will see that this inverse system arises "in nature", i.e. we will see that there exists a nested sequence of topological spaces X_i such that for each $i \in \mathbb{N}$ we have $H^1(X_i;\mathbb{Z}) \cong \mathbb{Z}$ and such that for each $i \in \mathbb{N}$ the map $H^1(X_{i+1};\mathbb{Z}) \to H^1(X_i;\mathbb{Z})$ is given by multiplication by $i+1$.

We cannot proceed without introducing the following somewhat technical definition.

Definition. We say an inverse system of abelian groups $(\{D_i\}_{i\in\mathbb{N}}, \{g_i\colon D_{i+1} \to D_i\}_{i\in\mathbb{N}})$ satisfies the *Mittag-Leffler condition* if given any $i \in \mathbb{N}$ there exists an $n \geq i$ such that for all $s \geq n$ we have

$$\operatorname{im}\{g_i \circ \dots \circ g_{s-1}\colon D_s \to D_i\} \ = \ \operatorname{im}\{g_i \circ \dots \circ g_{n-1}\colon D_n \to D_i\}.$$

.

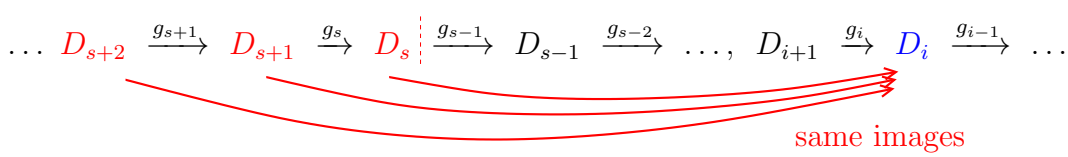


FIGURE 693.

Example. It is straightforward to verify that the above inverse system D_* satisfies the Mittag-Leffler condition whereas the above inverse system E_* does not satisfy the Mittag-Leffler condition.

In many situations one can ignore the precise definition of the Mittag-Leffler condition and instead one can appeal to the following lemma which in fact follows immediately from the definitions.

Lemma 52.8. *Let $(\{D_i\}_{i\in\mathbb{N}}, \{g_i\colon D_{i+1} \to D_i\}_{i\in\mathbb{N}})$ be an inverse system of abelian groups. If there exists an $m \in \mathbb{N}$ such that for all $i \in \mathbb{N}$ the map $g_i\colon D_{i+1} \to D_i$ is an epimorphism, then the inverse system satisfies the Mittag-Leffler condition.*

Our main interest in the Mittag-Leffler condition arises from the fact that if a direct system satisfies this condition, then the pesky $\varprojlim^1$-limit vanishes.

Lemma 52.9. *Let $(\{D_i\}_{i\in\mathbb{N}}, \{g_i\colon D_{i+1} \to D_i\}_{i\in\mathbb{N}})$ be an inverse system of abelian groups. If this inverse system satisfies the Mittag-Leffler condition, then*

$$\varprojlim^1 D_i \ = \ 0.$$

Proof $(*)$. Let $(\{D_i\}_{i\in\mathbb{N}}, \{g_i\colon D_{i+1} \to D_i\}_{i\in\mathbb{N}})$ be an inverse system of abelian groups that satisfies the Mittag-Leffler condition. This means that given given any $i \in \mathbb{N}$ there exists an $n(i) \geq i$ such that for all $s \geq n(i)$ we have

$$\operatorname{im}\{g_i \circ \cdots \circ g_{s-1}\colon D_s \to D_i\} \;=\; \operatorname{im}\{g_i \circ \cdots \circ g_{n(i)-1}\colon D_{n(i)} \to D_i\}.$$

Without loss of generality we can assume that $n(i)$ is monotonously increasing in i. We have to show that the map

$$\begin{array}{rcl} \mu\colon \prod\limits_{i\in\mathbb{N}} D_i & \to & \prod\limits_{i\in\mathbb{N}} D_i \\ (x_i)_{i\in\mathbb{N}} & \mapsto & (x_i - g_i(x_{i+1}))_{i\in\mathbb{N}} \end{array}$$

is an epimorphism.

Given $j \geq i$ we now write $f_{ji} := g_i \circ \cdots \circ g_{j-1}\colon D_j \to D_i$. First we consider $(a_i)_{i\in\mathbb{N}} \in \prod\limits_{i\in\mathbb{N}} D_i$ with the property that for all $i \in \mathbb{N}$ we have $a_i \in \operatorname{im}\{f_{n(i),i}\colon D_{n(i)} \to D_i\}$. To show that $\{a_i\}_{i\in\mathbb{N}}$ lies in the image of μ it suffices to prove the following claim.

Claim. There exist $b_i \in \operatorname{im}\{f_{n(i),i}\colon D_{n(i)} \to D_i\}$ with $i \in \mathbb{N}$ such that for each i we have $a_i = b_i - g_i(b_{i+1})$.

We define the b_i inductively. We set $b_0 = a_0$. Suppose $b_0, \ldots, b_k$ are already defined with the desired properties. By our hypothesis we have $a_k \in \operatorname{im}(f_{n(k),k})$ and by our choice of b_k we have $b_k \in \operatorname{im}(f_{n(k),k})$. By the Mittag-Leffler condition and since we arranged that $n(k+1) \geq n(k)$ we have $\operatorname{im}(f_{n(k+1),k}) = \operatorname{im}(f_{n(k),k})$. Thus can we pick $c \in D_{n(k+1)}$ with $f_{n(k+1),k}(c) = a_k - b_k$. Now we put

$$b_{k+1} \;=\; -f_{n(k+1),k+1}(c).$$

Then

$$b_k - g_{k+1}(b_{k+1}) = b_k + g_{k+1}(f_{n(k+1),k+1}(c)) = b_k + (\underbrace{g_{k+1} \circ f_{n(k+1),k+1}}_{=f_{(n(k+1),k)}})(c) = b_k + (a_k - b_k) = a_k.$$

We have thus shown that $b_0, \ldots, b_{k+1}$ have the desired properties. This concludes the proof of the claim.

Now let $(b_i)_{i\in\mathbb{N}} \in \prod\limits_{i\in\mathbb{N}} D_i$ be an arbitrary element. For each $i \in \mathbb{N}$ we set

$$c_i \;=\; b_i + \sum_{j=i+1}^{n(i)} f_{j,i}(b_j).$$

Claim. For each $i \in \mathbb{N}$ we have $b_i - (c_i - g_i(c_{i+1})) \in \operatorname{im}(f_{n(i),i})$.

Let $i \in \mathbb{N}$. We have

$$\begin{aligned} b_i - (c_i - g_i(c_{i+1})) \;&=\; b_i - b_i - \sum_{j=i+1}^{n(i)} f_{j,i}(b_j) + g_i\Big(b_{i+1} + \sum_{j=i+2}^{n(i+1)} f_{j,i+1}(b_j)\Big) \\ &=\; -\sum_{j=i+1}^{n(i)} f_{j,i}(b_j) + f_{i+1,i}(b_{i+1}) + \sum_{j=i+2}^{n(i+1)} f_{j,i}(b_j) \;=\; \sum_{j=n(i)+1}^{n(i+1)} f_{j,i}(b_j). \end{aligned}$$

But by definition of $n(i)$ we know that for each $j \in \{n(i)+1, \dots, n(i+1)\}$ we have $f_{j,i}(b_j) \in \operatorname{im}(f_{n(i),i})$. This concludes the proof of the claim.

It follows from the claim and the above discussion that $(b_i - (c_i - g_i(c_{i+1})))_{i\in\mathbb{N}}$ lies in the image of μ. Evidently $(c_i - g_i(c_{i+1}))_{i\in\mathbb{N}}$ lies in the image of μ. Since μ is a homomorphism we see that $(b_i)_{i\in\mathbb{N}}$ also lies in the image of μ. □

We continue with the following definition.

Definition. Let R be a commutative ring and let $(X_i, f_i)_{i\in\mathbb{N}}$ and $(Y_i, g_i)_{i\in\mathbb{N}}$ be inverse systems of R-modules. A *map of inverse systems* from (X_i, f_i) to (Y_i, g_i) consists of a sequence of module homomorphisms $u_i\colon X_i \to Y_i$, $i \in \mathbb{N}$ such that for each i we have $g_i \circ u_i = u_{i-1} \circ f_i$.

Remark. A map $u\colon (X_i, f_i) \to (Y_i, g_i)$ of inverse systems induces a map $u_*\colon \varprojlim X_i \to \varprojlim Y_i$ and also a map $u_*\colon \varprojlim^1 X_i \to \varprojlim^1 Y_i$ in the obvious way.[930]

Now we can formulate the following proposition.

Proposition 52.10. *Let $(\{C_i^*\}_{i\in\mathbb{N}}, \{f_i\colon C_{i+1}^* \to C_i^*\}_{i\in\mathbb{N}})$ be an inverse system of cochain complexes over $\mathbb{N}$. If for each $k \in \mathbb{N}_0$ the inverse system of cochain groups $\{C_i^k\}_{i\in\mathbb{N}}$ satisfies the Mittag-Leffler condition, then there exists a natural[931] short exact sequence of the form*

$$0 \;\to\; \varprojlim_{i\in\mathbb{N}}{}^1 H^{n-1}(C_i^*) \;\to\; H^n\big(\varprojlim_{i\in\mathbb{N}} C_i^*\big) \;\to\; \varprojlim_{i\in\mathbb{N}} H^n(C_i^*) \;\to\; 0$$

where the right-hand map is the obvious map.[932] *If R is a commutative ring and if the C_i^* are cochain complexes of R-modules, then the maps in the short exact sequence are natural R-module homomorphisms.*

Lemma 52.11. *Given any short exact sequence*

$$0 \;\to\; (X_i, f_i) \;\xrightarrow{u_i}\; (Y_i, g_i) \;\xrightarrow{v_i}\; (Z_i, h_i) \;\to\; 0$$

of inverse systems of abelian groups there exists a natural exact sequence

$$0 \to \varprojlim X_i \xrightarrow{u_*} \varprojlim Y_i \xrightarrow{v_*} \varprojlim Z_i \xrightarrow{\delta} \varprojlim{}^1 X_i \xrightarrow{u_*} \varprojlim{}^1 Y_i \xrightarrow{v_*} \varprojlim{}^1 Z_i \to 0.$$

If R is a commutative ring and if all cochain complexes and all maps are in the category of R-modules, then the maps in short exact sequence are natural R-module homomorphisms.

---

[930] Whatever obvious means.

[931] As so often it requires a few moments of pondering to figure out what "natural" is actually supposed to mean.

[932] Here it takes a little effort to figure out what the "obvious" map actually is supposed to be. By definition an inverse limit of cochain complexes comes with cochain maps $\varprojlim C_i^* \to C_i^*$. Since cohomology of cochain complexes is covariant in cochain maps we get induced maps $H^n(\varprojlim C_i) \to H^n(C_i^*)$ which then, by definition of the inverse limit, give rise to a map $H^n(\varprojlim C_i) \to \varprojlim H^n(C_i^*)$.

Proof. We consider the following commutative diagram

$$\begin{array}{ccccccccc}
0 & \longrightarrow & \prod_{i\in\mathbb{N}} X_i & \xrightarrow{u} & \prod_{i\in\mathbb{N}} Y_i & \xrightarrow{v} & \prod_{i\in\mathbb{N}} Z_i & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle\mu} & & \downarrow{\scriptstyle\mu} & & \downarrow{\scriptstyle\mu} & & \\
0 & \longrightarrow & \prod_{i\in\mathbb{N}} X_i & \xrightarrow{u} & \prod_{i\in\mathbb{N}} Y_i & \xrightarrow{v} & \prod_{i\in\mathbb{N}} Z_i & \longrightarrow & 0.
\end{array}$$

The horizontal sequences are evidently exact. We can view the rows as chain complexes. The desired natural exact sequence now follows from the snake lemma that we proved in Exercise 31.5. □

Now we can provide the proof of Proposition 52.10.

Proof of Proposition 52.10 (∗). Let $(\{C_i^*\}_{i\in\mathbb{N}}, \{f_i\}_{i\in\mathbb{N}})$ be an inverse system of cochain complexes such that for each $k \in \mathbb{N}_0$ the inverse system of cochain groups $\{C_i^k\}_{i\in\mathbb{N}}$ satisfies the Mittag-Leffler condition. Given $m \in \mathbb{N}_0$ and $i \in \mathbb{N}$ we denote by $B_i^m = \mathrm{im}\{C_i^{m-1} \to C_i^m\}$ the image of the $(m-1)$-st coboundary map and we denote by $Z_i^m = \ker\{C_i^m \to C_i^{m+1}\}$ the kernel of the m-th coboundary map. These give rise to the following two short exact sequences of inverse systems

$$\text{(i)} \qquad 0 \;\to\; B_i^m \;\to\; Z_i^m \;\to\; H^m(C_i) \;\to\; 0$$

and

$$\text{(ii)} \qquad 0 \;\to\; Z_i^m \;\to\; C_i^m \;\to\; B_i^{m+1} \;\to\; 0.$$

Let $m \in \mathbb{N}_0$. By our hypothesis the inverse systems $\{C_i^m\}_{i\in\mathbb{N}}$ satisfy the Mittag-Leffler condition. It is straightforward to see that then the inverse system $\{B_i^m\}_{i\in\mathbb{N}}$ also satisfies the Mittag-Leffler condition. It follows from Lemma 52.9 that

$$\varprojlim{}^1 B_i^{m+1} \;=\; 0 \quad \text{and} \quad \varprojlim{}^1 C_i^m \;=\; 0.$$

(Here and throughout the proof all limits are taken over $i \in \mathbb{N}$.) Using this data we obtain from Lemma 52.11, applied to the two short exact sequences (i) and (ii) of inverse systems above, the following two exact sequences

$$0 \to \varprojlim B_i^m \to \varprojlim Z_i^m \to \varprojlim H^m(C_i) \xrightarrow{\delta} \underbrace{\varprojlim{}^1 B_i^m}_{=0} \to \varprojlim{}^1 Z_i^m \to \varprojlim{}^1 H^m(C_i) \to 0$$

and

$$0 \to \varprojlim Z_i^m \to \varprojlim C_i^m \to \varprojlim B_i^{m+1} \xrightarrow{\delta} \varprojlim{}^1 Z_i^m \to \underbrace{\varprojlim{}^1 C_i^m}_{=0} \to \varprojlim{}^1 B_i^{m+1} \to 0$$

From these sequence we deduce that the maps

$$\text{(i)} \qquad \varprojlim{}^1 Z_i^m \;\to\; \varprojlim{}^1 H^m(C_i)$$

and

$$\text{(ii)} \qquad \varprojlim Z_i^m \;\to\; Z^m\big(\varprojlim C_i\big) := \ker\big(\varprojlim C_i^m \to \varprojlim B_i^{m+1}\big)$$

are isomorphisms and that the following sequences are exact

$$\text{(i')} \qquad 0 \;\to\; \varprojlim B_i^m \;\to\; \varprojlim Z_i^m \;\to\; \varprojlim H^m(C_i) \;\to\; 0.$$

and

$$\text{(ii')} \qquad 0 \;\to\; \underbrace{B^m\big(\varprojlim C_i\big)}_{=:\ker(\varprojlim C_i^m \to \varprojlim B_i^{m+1})} \;\to\; \varprojlim B_i^m \;\to\; \varprojlim{}^1 Z_i^{m-1} \;\to\; 0.$$

From (ii') and the isomorphism (ii) we obtain the inclusions

$$B^m\big(\varprojlim C_i\big) \;\subset\; \varprojlim B_i^m \;\subset\; \varprojlim Z_i^m \;=\; Z^m\big(\varprojlim C_i\big)$$

which gives rise to the short exact sequence[933]

$$0 \;\to\; \underbrace{\frac{\varinjlim B_i^m}{B^m(\varinjlim C_i)}}_{=\varinjlim{}^1 H^{m-1}(C_i)\ \text{by (ii') and (i)}} \;\to\; \underbrace{\frac{Z^m(\varinjlim C_i)}{B^m(\varinjlim C_i)}}_{=H^m(\varinjlim C_i)\ \text{by def.}} \;\to\; \underbrace{\frac{\varinjlim Z_i^m}{\varinjlim B_i^m}}_{=\varinjlim H^m(C_i)\ \text{by (i')}} \;\to\; 0.$$

□

52.4. **The cohomology group of an ascending sequence of topological spaces.** The following proposition can be viewed as the analogue of Proposition 34.4 for cohomology groups.

Proposition 52.12. *Let X be a topological space and let $X_1 \subset X_2 \subset X_3 \subset \dots$ be a sequence of subsets such that $X = \bigcup_{i\in\mathbb{N}} X_i$ and such that one the following three conditions holds:*

1. *every compact subset of X is contained in one of the X_i, or*
2. *each X_i is open in X, or*
3. *X is a CW-complex and each X_i is a subcomplex.*

Then for any $n \in \mathbb{N}_0$ and any abelian group R there exists a natural short exact sequence

$$0 \;\to\; \varprojlim_{i\in\mathbb{N}}{}^1 H^{n-1}(X_i;R) \;\xrightarrow{\tau}\; H^n(X;R) \;\to\; \varprojlim_{i\in\mathbb{N}} H^n(X_i;R) \;\to\; 0$$

where the right-hand map is induced by the restriction maps $H^n(X;R) \to H^n(X_i;R)$. If R is a commutative ring, then all maps are R-module homomorphisms.

[933] Here we use that a filtration $P \subset Q \subset R$ of three abelian groups induces a short exact sequence $0 \to Q/P \to R/P \to R/Q \to 0$.

Remark. In many situations the term $\varprojlim^1 H^{n-1}(X_i;R)$ will be zero. But it can be non-zero and one should view the proposition as a warning that in general it is not true that "limits commute with everything".

Proof. By Corollary 26.18 and Lemma 16.5 we only have to prove the proposition under the hypothesis (1). Therefore suppose that we are given a topological space X and subspaces $X_1 \subset X_2 \subset X_3 \subset \dots$ with $X = \bigcup_{i\in\mathbb{N}} X_i$ and such that the following condition holds:

(1) every compact subset of X is contained in one of the X_i.

Furthermore let R be a commutative ring.

For $i \in \mathbb{N}$ we now consider the cochain complex $D_i^* := \mathrm{Hom}(C_*(X_i), R)$ and for $i \in \mathbb{N}$ we denote by $f_i\colon D_{i+1}^* \to D_i^*$ the map that is induced by the inclusion $X_i \to X_{i+1}$.

Claim. For each $k \in \mathbb{N}$ the inverse system of cochain groups $(\{D_i^k\}_{i\in\mathbb{N}}, \{f_i\colon D_{i+1}^k \to D_i^k\}_{i\in\mathbb{N}})$ satisfies the Mittag-Leffler condition.

Let $k \in \mathbb{N}_0$. By Lemma 52.8 it suffices to show that for every $i \in \mathbb{N}$ the map

$$D_{i+1}^k \;=\; \mathrm{Hom}(C_n(X_{i+1});R) \;\xrightarrow{f_i}\; \mathrm{Hom}(C_n(X_i);R) \;=\; D_i^k$$

is an epimorphism. Since $X_i \subset X_{i+1}$ we know that the set of singular chains in X_i is a subset of the set of singular chains in X_{i+1}. It follows from the discussion on page 1157 that the map $\mathrm{Hom}(C_n(X_{i+1});R) \to \mathrm{Hom}(C_n(X_i);R)$ is indeed an epimorphism. This concludes the proof of the claim.

Let $n \in \mathbb{N}_0$. From Proposition 52.10 we obtain the short exact sequence

$$0 \;\to\; \varprojlim{}^1 H^{n-1}(D_i^*) \;\to\; H^n\big(\varprojlim D_i^*\big) \;\to\; \varprojlim H^n(D_i^*) \;\to\; 0$$

of R-modules. Let $i \in \mathbb{N}$. We make the following two observations:

(1) By definition we have $H^k(D_i^*) = H^k(X_i;R)$ for every $k \in \mathbb{N}_0$.
(2) We have natural isomorphisms

$$\varprojlim D_i^* \;\underset{\substack{\uparrow\\ \text{by definition of the } D_i}}{=}\; \varprojlim \mathrm{Hom}(C_*(X_i);R) \;\underset{\substack{\uparrow\\ \text{Lemma 48.3}}}{=}\; \mathrm{Hom}\big(\varinjlim C_*(X_i), R\big) \;\underset{\substack{\uparrow\\ \text{by Lemma 34.5 and hypothesis (1)}}}{=}\; \mathrm{Hom}(C_*(X),R).$$

Combining all of the above we obtain our desired short exact sequence

$$0 \;\to\; \varprojlim{}^1 H^{n-1}(X_i;R) \;\to\; H^n(X;R) \;\to\; \varprojlim H^n(X_i;R) \;\to\; 0.$$

□

We provide a few examples for the above proposition.

Examples.

(1) As in Lemma 34.7 we consider the real line with infinitely many 2-dimensional spheres attached, i.e. we consider

$$X \;:=\; (\mathbb{R} \cup S^2 \times \mathbb{Z})/\sim$$

where given $i \in \mathbb{Z}$ we identify $i \in \mathbb{R}$ with $((0,0,-1),i) \in S^2 \times \mathbb{Z}$. (See Figure 694 on the left.) Furthermore, given $k \in \mathbb{N}$ we consider the open subset

$$X_k \;:=\; \big(\big(-k-\tfrac{1}{2}, k+\tfrac{1}{2}\big) \cup S^2 \times \{-k,\dots,k\}\big)\big)/\sim .$$

We leave it as an exercise to verify that we can make the identifications[934]

$$H^n(X_k) \;=\; \begin{cases} \mathbb{Z}, & \text{if } n=0,\\ \mathbb{Z}^{2k+1}, & \text{if } n=2,\\ 0, & \text{else.}\end{cases}$$

such that for each $k \in \mathbb{N}$ the inclusion maps $X_k \to X_{k+1}$ induce the identity map on $\mathbb{Z} = H^0(X_{k+1}) \to H^0(X_k) = \mathbb{Z}$ and such that the inclusions induce the map

$$\begin{array}{rcl} \mathbb{Z}^{2k+3} = H^2(X_{k+1}) & \to & H^2(X_k) = \mathbb{Z}^{2k+1} \\ (a_1,\dots,a_{2k+3}) & \mapsto & (a_2,\dots,a_{2k+2}) \end{array}$$

It follows from Lemma 52.8 and the above calculations that for each $n \in \mathbb{N}_0$ the direct system of cohomology groups $\{H^n(X_k)\}_{k\in\mathbb{N}}$ satisfies the Mittag-Leffler condition. We obtain that

$$H^n(X) \;\underset{\substack{\uparrow\\ \text{Proposition 52.12 and Lemma 52.9}}}{=}\; \varprojlim H^n(X_k) \;=\; \varprojlim \begin{cases} \mathbb{Z}, & \text{if } n=0,\\ \mathbb{Z}^{2k+1}, & \text{if } n=2,\\ 0, & \text{else}\end{cases} \;\underset{\substack{\uparrow\\ \text{see page 1243}}}{=}\; \begin{cases} \mathbb{Z}, & \text{if } n=0,\\ \mathbb{Z}^{\mathbb{N}}, & \text{if } n=2,\\ 0, & \text{else.}\end{cases}$$

Here recall that $\mathbb{Z}^{\mathbb{N}} = \{(x_1,x_2,\dots) \mid x_i \in \mathbb{Z}\}$. In Lemma 34.7 we saw that $H_2(X) \cong \mathbb{Z}^{(\mathbb{N})}$. In this case we see that $H_2(X) \not\cong H^2(X)$ since the former group is countable whereas the latter group is uncountable.[935]

(2) We consider again the surface Σ_∞ of infinite genus that we had already encountered on pages 492 and 897. (See also Figure 694 on the right.) Using a variation of example (1) and the proof of Lemma 16.6 one can show that

$$H^n(\Sigma_\infty) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } n=0,\\ \mathbb{Z}^{\mathbb{N}}, & \text{if } n=1,\\ 0, & \text{if } n\geq 2.\end{cases}$$

We leave the details as an exercise to the valiant reader.

[934] One possible approach to showing these statements is to use the Mayer–Vietoris Theorem 50.15 for Cohomology Groups.

[935] Of course we could have obtained the same observation from the Universal Coefficient Theorem 51.13 for Cohomology Groups.

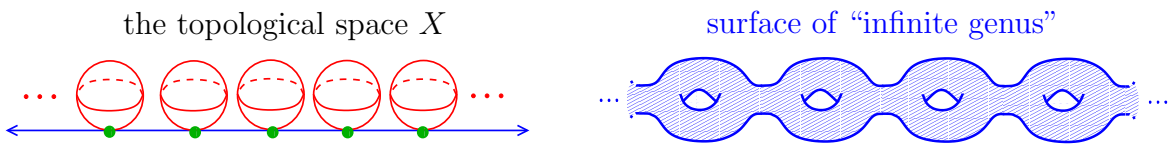

FIGURE 694.

We conclude this chapter with the following variation on Proposition 52.12. It can be viewed as the cohomological analogue of Lemma 35.1 (3).

Proposition 52.13. *Let X be a CW-complex and let $n \in \mathbb{N}$. For every $k > n$ and every abelian group G the inclusion $i\colon X^k \to X$ induces an isomorphism*

$$i^*\colon H^n(X;G) \;\to\; H^n(X^k;G).$$

Remark. We will give a very different proof of this proposition in Proposition **??**.

Proof. By Proposition 52.12 there exists a natural short exact sequence

$$0 \;\to\; \lim_{\substack{\leftarrow \\ j\in\mathbb{N}}}{}^1 H^{n-1}(X_j;G) \;\xrightarrow{\tau}\; H^n(X;G) \;\to\; \lim_{\substack{\leftarrow \\ j\in\mathbb{N}}} H^n(X_j;G) \;\to\; 0$$

where the right-hand map is induced by the restriction maps $H^n(X;G) \to H^n(X_i;G)$. It follows immediately from Lemmas 52.6 and Lemma 52.8 that is suffices to prove the following claim.

Claim. For any $j \geq k > n$ the inclusion induced map $H^n(X^j;G) \to H^n(X^k;G)$ is an isomorphism.

It follows from Lemma 35.1, the Universal Coefficient Theorem 51.13 for Cohomology Groups that for every $m \geq n$ we have $H^n(X^{m+1}, X^m; G) = 0$. Using the long exact sequence in cohomology of the pairs $(X^{m+1}, X^m), (X^{m+2}, X^m), \ldots$ one can now easily show that for any $j \geq k > n$ the inclusion induced map $H^n(X^j;G) \to H^n(X^k;G)$ is an isomorphism. This concludes the proof of the claim. □

Exercises for Chapter 52.

Exercise 52.1. Let $(I, \leq)$ be a directed set and let $(\{X_i\}_{i\in I}, \{f_{ij}\colon X_i \to X_j\}_{i\leq j})$ be a direct system of abelian groups over I.

(a) Let $a_j \in X_j$ and let $a_k \in X_k$. Prove the following statement: if the images of a_j and a_k in $\varinjlim X_i$ agree, then there exists an $l \in I$ with $l \geq j$ and $l \geq k$ such that $f_{jl}(a_j) = f_{kl}(a_k) \in X_l$.

(b) Show that if all maps $f_{ij}\colon X_i \to X_j$ are isomorphisms, then for any $j \in I$ the obvious map $X_j \to \varinjlim X_i$ is an isomorphism.

Exercise 52.2. We consider the inverse systems

$$D_*\colon\ \dots \xrightarrow{0} \mathbb{Z} \xrightarrow{\cdot 2} \mathbb{Z} \xrightarrow{0} \mathbb{Z} \xrightarrow{\cdot 2} \mathbb{Z} \ \to\ 0$$

and

$$E_*\colon\ \dots \xrightarrow{\cdot 5} \mathbb{Z} \xrightarrow{\cdot 4} \mathbb{Z} \xrightarrow{3} \mathbb{Z} \xrightarrow{\cdot 2} \mathbb{Z} \ \to\ 0.$$

(a) Show that $\varprojlim D_* = 0$,

(b) show that $\varprojlim^1 D_* = 0$,

(c) show that $\varprojlim^1 E_* \neq 0$.

Exercise 52.3. Show that there exists a nested sequence of topological spaces X_i such that for each $i \in \mathbb{N}$ we have $H^1(X_i;\mathbb{Z}) \cong \mathbb{Z}$ and such that for each $i \in \mathbb{N}$ the map $H^1(X_{i+1};\mathbb{Z}) \to H^1(X_i;\mathbb{Z})$ is given by multiplication by $i+1$.
Put differently, we want topological spaces and maps such that the inverse system

$$H^1(X_4) \ \to\ H^1(X_3) \ \to\ H^1(X_2) \ \to\ H^1(X_1)$$

is isomorphic to the inverse system E_* from Exercise 52.2.

53. Cohomology with compact support and bounded cohomology

53.1. **The definition of cohomology with compact support and basic properties.** In this section we introduce "cohomology with compact support", which is an interesting variation on the usual cohomology groups. Later on it will be a key tool in proving the Poincaré Duality Theorem, which is the most important result regarding homology and cohomology groups of topological manifolds.

We start out with the following definition.

Definition. Let X be a topological space and let G be an abelian group.

(1) Given a subset $A \subset X$ we say that a cochain $\varphi \in C^i(X;G) = \mathrm{Hom}(C_i(X), G)$ *vanishes on* A if $\varphi(c) = 0$ for all singular i-simplices $c\colon \Delta^i \to X$ in A, i.e. if φ vanishes on the image of $C_i(A) \to C_i(X)$.

(2) Given a subset $B \subset X$ we say that a cochain *vanishes outside* B if the cochain vanishes on $X \setminus B$.

(3) We say that a cochain $\varphi \in C^i(X;G) = \mathrm{Hom}(C_i(X), G)$ has *compact support* if there exists a compact set $K \subset X$ such that φ vanishes outside of K. We denote the set of all i-cochains with compact support by $C^i_c(X;G)$.

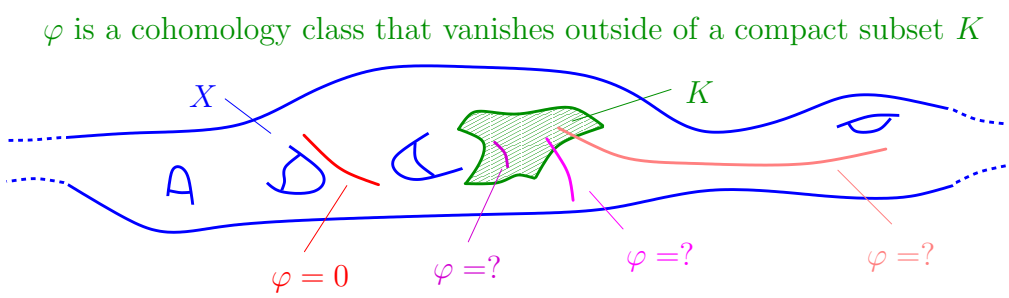

Figure 695.

Remark. Let X be a topological space and let G be an abelian group.

(1) Let A be a subset of X and let $n \in \mathbb{N}_0$. The inclusion $(X, \varnothing) \to (X, X \setminus A)$ induces an epimorphism $C_n(X) \to C_n(X, X \setminus A)$ and thus it also induces a monomorphism $C^n(X, X \setminus A; G) \to C^n(X;G)$. We have

$$\begin{aligned}\mathrm{im}(C^n(X, X\setminus A; G) \to C^n(X;G)) &= \text{all maps of the form } C_n(X) \to \overbrace{C_n(X, X\setminus A)}^{=C_n(X)/C_n(X\setminus A)} \to G \\ &= \{\varphi \in \mathrm{Hom}(C_n(X), G) \,|\, \varphi \text{ vanishes on } X \setminus A\ \} \\ &= \{\varphi \in \mathrm{Hom}(C_n(X), G) \,|\, \varphi \text{ vanishes outside } A\ \}.\end{aligned}$$

(2) On page 1165 we had made the identification

$$C^0(X;G) \;=\; \{\text{maps from } X \text{ to } G\}.$$

With this identification we can now write

$$C_c^0(X;G) = \{\text{maps } f\colon X \to G \mid \text{there exists a compact subset } K \text{ such that } f|_{X\setminus K} \equiv 0\}.$$

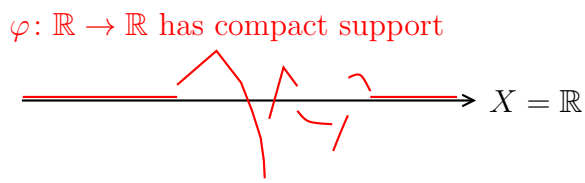

FIGURE 696.

The first question that arises is whether cochains with compact support give again rise to cohomology groups. The following lemma shows in particular that this is indeed the case.

Lemma 53.1. *Let X be a topological space and let G be an abelian group.*

(1) *A cochain $\varphi \in C^i(X;G)$ has compact support if and only if there exists a compact subset K such that φ lies in the image of the map $C^i(X, X\setminus K; G) \to C^i(X;G)$.*
(2) *The set of cochains that have compact support form a subcomplex $(C_c^*(X;G);\delta)$ of the cochain complex $(C^*(X;G);\delta)$.*
(3) *For any compact subset K of X the map $i_K\colon C^*(X, X\setminus K; G) \to C_c^*(X;G)$ from (1) is a cochain map.*

Proof. Let X be a topological space and let G be an abelian group. The first statement of the lemma follows immediately from the above remark.

We turn to the proof of the second statement.

Claim. Let $A, B \subset X$ be two subsets.

(a) If $\varphi \in C^i(X;G)$ vanishes outside A and if $\psi \in C^i(X;G)$ vanishes outside B, then for any $r, s \in \mathbb{Z}$ the linear combination $r\varphi + s\psi \in C^i(X;G)$ vanishes outside the union $A \cup B$.
(b) If $\varphi \in C^i(X;G)$ vanishes outside A, then $\delta\varphi \in C^{i+1}(X;G)$ also vanishes outside A.

The first statement is obvious. Now we turn to the proof of the second statement. Suppose we are given a cochain $\varphi \in C^i(X;G)$ that vanishes outside A. We need to show that $\delta\varphi \in C^{i+1}(X;G)$ also vanishes outside A. So let c be a singular $(i+1)$-simplex in $X \setminus A$. Then

$$(\delta\varphi)(c) \;=\; \varphi(\partial c) \;=\; \sum_{j=0}^{n} (-1)^j \cdot \varphi(c \circ i_j^n) \;\underset{\substack{\uparrow \\ \text{the image of each } c\circ i_j^n \text{ also lies in } X\setminus A \text{ and } \varphi \text{ vanishes outside } A}}{=}\; 0.$$

This concludes the proof of the claim.

The second statement is now an immediate consequence of the above claim and the observation that given two compact subsets $K, L \subset X$ the union $K \cup L$ is again a compact subset of X.

Finally the last statement is an immediate consequence of the definitions. $\square$

Definition. Let X be a topological space and let G be an abelian group. We define the *n-th cohomology group with compact support* $H_c^n(X;G)$ to be the cohomology of the cochain complex given by cochains with compact support, i.e. we define

$$H_c^n(X;G) \;:=\; \frac{\ker\{\delta_n\colon C_c^n(X;G) \to C_c^{n+1}(X;G)\}}{\operatorname{im}\{\delta_{n-1}\colon C_c^{n-1}(X;G) \to C_c^n(X;G)\}}.$$

Remark.

(1) If X is a compact topological space, then every cochain has compact support, in particular the cohomology groups with compact support are just the usual cohomology groups.

(2) Let X be a path-connected topological space. Then

$$H_c^0(X;G) \underset{\uparrow}{=} \left\{ f\colon X \to G \,\middle|\, \begin{array}{c} f \text{ is constant and there exists a} \\ \text{compact subset } K \text{ with } \varphi|_{X\setminus K} \equiv 0 \end{array} \right\} = \begin{cases} 0, & \text{if } X \text{ non-compact,} \\ G, & \text{if } X \text{ compact.} \end{cases}$$

see proof of Proposition 48.11 and description of $C_c^0(X;G)$ on page 1256.

Example. We consider the topological space $X = \mathbb{R}$. As on page 1169 we consider the singular 0-cochain

$$\varphi_0\colon C_0(X) \;\to\; \mathbb{Z}$$

that is uniquely determined by the property that for any singular 0-simplex $x \in X$ we have

$$x \;\mapsto\; \begin{cases} 0, & \text{if } x \leq 0, \\ 1, & \text{if } x > 0. \end{cases}$$

It is clear that this 0-cochain does *not have* compact support. As on page 1169 we also consider the coboundary $\gamma_0 := \delta\varphi_0 \in C^1(\mathbb{R};\mathbb{Z})$. Since γ_0 is a coboundary, it is in particular a cocycle. By definition $\gamma_0 = \delta\varphi_0$ is uniquely determined by the property that for any singular 1-simplex $d\colon \Delta^1 \to \mathbb{R}$ we have

$$(\delta\varphi_0)(d) \;=\; \varphi_0(\partial d) \;\underset{\uparrow}{=}\; \varphi_0(d(0,1)) - \varphi_0(d(1,0)).$$

see page 738

We claim that $\gamma_0 = \delta\varphi_0$ has compact support. In fact, we will now see that we can take K to be the compact set given by $K := \{0\}$. Indeed, if $d\colon \Delta^1 \to \mathbb{R} \setminus \{0\}$ is a singular 1-simplex, then it follows from the fact that Δ^1 is homeomorphic to the interval $[0,1]$ and the intermediate value theorem that either $d(0,1)$ and $d(1,0)$ both lie to the left of 0 or both lie to the right of 0. In both cases we obtain from the above formula that $\gamma_0(d) = (\delta\varphi_0)(d) = 0$. Thus we see that $\gamma_0 = \delta\varphi_0$ defines an element in $H_c^1(\mathbb{R})$.

Now we claim that $[\gamma_0] \in H^1_c(\mathbb{R};\mathbb{Z})$ is non-zero. This means that we have to show that there is no $\psi \in C^0_c(\mathbb{R};\mathbb{Z})$ with $\delta\psi = \gamma_0$. So let $\psi \in C^0_c(\mathbb{R};\mathbb{Z})$. Following the discussion on page 1256 we view ψ as a function $\mathbb{R} \to \mathbb{Z}$ which is zero outside of a compact subset of $\mathbb{R}$. This implies that there exists a $C \geq 0$ such that $\psi(x) = 0$ for all $x \notin [-C, C]$. Now we consider the singular 1-chain $d\colon \Delta^1 \to \mathbb{R}$ that is given by $d(1-t, t) = -2C + 4C \cdot t$ with $t \in [0,1]$. (See Figure 697 for an illustration.) Then we have

$$\gamma_0(d) \;=\; (\delta\varphi_0)(d) \;=\; \varphi_0(d(0,1)) - \varphi_0(d(1,0)) \;=\; \varphi_0(-2C) - \varphi_0(2C) \;=\; 0 - 1 \;=\; -1$$

but on the other hand we have

$$(\delta\psi)(d) \;=\; \psi(d(0,1)) - \psi(d(1,0)) \;=\; \psi(-2C) - \psi(2C) \;\underset{\substack{\uparrow \\ \text{since } \psi \text{ is zero outside } [-C,C]}}{=}\; 0 - 0 \;=\; 0.$$

This concludes the proof the $\gamma_0 = \delta\varphi_0$ is non-trivial in $H^1_c(\mathbb{R};\mathbb{Z})$.

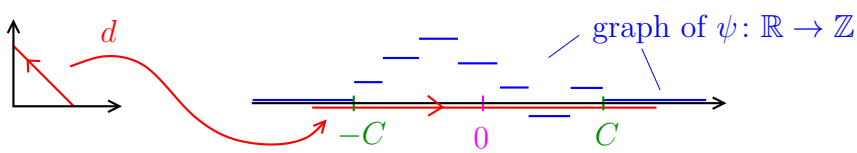

FIGURE 697.

The following lemma is an almost immediate consequence of Lemma 53.1 (1).

Lemma 53.2. *Let X be a topological space and let G be an abelian group. Given any $\varphi \in H^i_c(X;G)$ there exists a compact subset K such that φ lies in the image of the map $H^i(X, X \setminus K; G) \to H^i_c(X;G)$.*

Proof. Let $[\varphi] \in H^i_c(X;G)$. By Lemma 53.1 (1) there exists a compact subset K such that φ lies in the image of the map $C^i(X, X \setminus K; G) \to C^i_c(X;G)$. Since $C^*(X, X \setminus K; G)$ can be viewed as a subcomplex of $C^*_c(X;G)$ we see that φ is a also a cocycle in $C^*(X, X \setminus K; G)$, in particular φ lies in the image of the map $H^i(X, X \setminus K; G) \to H^i_c(X;G)$. $\square$

We conclude this section with the discussion of induced maps on cohomology groups with compact support.

If $f\colon X \to Y$ is a map between topological spaces and if G is any abelian group, then we saw that f induces a map $f^*\colon C^*(Y;G) \to C^*(X;G)$. But this map does in general *not* restrict to a map $f^*\colon C^*_c(Y;G) \to C^*_c(X;G)$. For example, if $f\colon \mathbb{R} \to \{P\}$ is the map that sends every point in $\mathbb{R}$ to the point P and if $\varphi\colon C_0(\{P\}) \to \mathbb{Z}$ is the map given by $P \mapsto 1$, then $f^*\varphi\colon C_0(\mathbb{R}) \to \mathbb{Z}$ corresponds to the map that takes the value 1 on all of $\mathbb{R}$, in particular it does not have compact support.

A moment of reflection shows, that if we want to get induced maps on cohomology groups with compact support, we have to restrict ourselves to "proper maps":

Definition. A map $f\colon X \to Y$ between topological spaces is called *proper* if the preimage of every compact subset of Y is a compact subset of X.

Examples.

(1) In Figure 698 we show graphs of functions $\mathbb{R} \to \mathbb{R}$, some of the functions are proper and some are not proper.

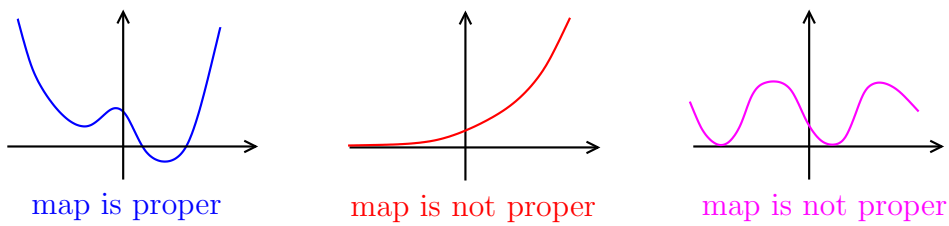

FIGURE 698.

(2) A map from a non-compact topological space to a compact topological space *cannot* be proper. In particular inclusion maps are not necessarily proper, for example the inclusion $i\colon (0,1) \to [-2,2]$ is not proper.
(3) Every homeomorphism is proper.
(4) Every map from a compact topological space to a Hausdorff space is proper. This statement follows immediately from Lemma 1.18 (1) and (2).

Remark. On page 330 we introduced the notion of a map from a compact topological manifold to some other topological manifold to be proper. As we pointed out in the last of the above examples, any such map is also proper in the above sense.

Lemma 53.3. *Let G be an abelian group.*

(1) *Let $f\colon X \to Y$ be a map between topological spaces. If f is a proper map, then the cochain map $f^*\colon C^*(Y;G) \to C^*(X;G)$ restricts to a cochain map*
$$f^*\colon C_c^*(Y;G) \quad \to \quad C_c^*(X;G).$$
In particular f^* induces a well-defined homomorphism
$$H_c^*(Y;G) \quad \to \quad H_c^*(X;G).$$
(2) *The maps $X \mapsto H_c^n(X;G)$ and $f \mapsto f^*$ define a contravariant functor*
$$\begin{array}{c}\textit{category where objects are topological spaces}\\ \textit{and morphisms are proper maps}\end{array} \quad \to \quad \textit{category of abelian groups.}$$
(3) *Homeomorphic topological spaces have isomorphic cohomology groups with compact support.*

Proof. Let $f\colon X \to Y$ be a proper map and let G be an abelian group. Let $\varphi\colon C_n(Y) \to G$ be a cocycle with compact support. We pick a compact subset K such that φ vanishes on $Y \setminus K$. Then $f^*\varphi$ vanishes on $f^{-1}(Y \setminus K) = X \setminus f^{-1}(K)$, i.e. $f^*\varphi$ vanishes outside of the

subset $f^{-1}(K)$. But $f^{-1}(K)$ is compact since f is proper. This concludes the proof of the first statement. The second statement and the third statement are obvious. $\square$

53.2. **Cohomology with compact support and direct limits.** Given a topological space X we consider the set $\mathcal{K}(X)$ of all compact subsets of X. The set $\mathcal{K}(X)$ together with the relation "$\subset$" defined by inclusion is a directed set since the union of two compact subsets is again compact. Furthermore, given any two compact subsets $K \subset L$ and any $i \in \mathbb{N}_0$ we get induced maps[936]

$$H^i(X, X \setminus K; G) \;\to\; H^i(X, X \setminus L; G).$$

Since cohomology groups are contravariantly functorial we see that these cohomology groups form a *direct* system over the directed set $(\mathcal{K}(X), \subset)$ and we can form the direct limit

$$\varinjlim_{K \in \mathcal{K}(X)} H^i(X, X \setminus K; G).$$

Recall that given any compact subset $K \subset X$ we have by Lemma 53.1 (3) a natural map $i_{K*}\colon H^i(X, X \setminus K; G) \to H^i_c(X; G)$. Given compact subsets $L \subset M$ these maps give rise to the following commutative diagram:

$$\begin{tikzcd}
H^i(X, X \setminus M; G) \arrow[dr, "\psi_M"'] \arrow[drr, bend left, "i_{M*}"] & & \\
& \varinjlim\limits_{K \in \mathcal{K}(X)} H^i(X, X \setminus K; G) \arrow[r, dashed, "\exists!", "\Phi"'] & H^i_c(X; G). \\
H^i(X, X \setminus L; G) \arrow[u] \arrow[ur, "\psi_L"] \arrow[urr, bend right, "i_{L*}"'] & &
\end{tikzcd}$$

Since this diagram commutes for all compact subsets $L \subset M$ we get the induced dotted arrow by the universal property of the direct limit.

The following proposition says that the above dotted arrow is in fact an isomorphism. This gives in particular an often convenient reformulation of the concept of cohomology with compact support.

Proposition 53.4. *Let X be a topological space and let G be an abelian group. Then the above map*

$$\Phi\colon \varinjlim_{K \in \mathcal{K}(X)} H^i(X, X \setminus K; G) \;\to\; H^i_c(X; G)$$

[936]The most confusing part about cohomology is to figure out which way the maps go. In this case $K \subset L$ implies $X \setminus L \subset X \setminus K$ which means that we have a map of pairs $(X, X \setminus L) \to (X, X \setminus K)$ given by inclusion, which by the discussion on page 1172 implies that we do indeed get an induced map $H^i(X, X \setminus K; G) \to H^i(X, X \setminus L; G)$.

defines a natural isomorphism.[937]

Proof. We need to show that the map Φ in the proposition is a bijection.

We first show that Φ is surjective. So let $\varphi \in H^i_c(X;G)$. By Lemma 53.2 there exists a compact subset L such that φ lies in the image of $H^i(X, X \setminus L; G) \to H^i(X;G)$. It follows immediately from the above commutative diagram that φ also lies in the image of $\Phi\colon \varinjlim H^i(X, X \setminus K; G) \to H^i_c(X;G)$.

Now we show that the map Φ is injective. In the subsequent discussion, given a subset A of X, we identify the image of the monomorphism $C^j(X, A; G) \to C^j(X;G)$ with $C^j(X, A; G)$, i.e. we view each $C^j(X, A)$ as a subgroup of $C^j(X)$.

Now suppose we are given an element c in the kernel of Φ. By Lemma 52.2 (1) the element c lies in the image of some $H^i(X, X \setminus L; G)$. We pick a representative $\varphi \in C^i(X, X \setminus L; G)$. Since φ represents the zero class in $H^i_c(X;G)$ there exists a compactly supported $(i-1)$-cocycle η with $\delta\eta = \varphi$. We pick a compact subset M of X such that η vanishes on $X \setminus M$, i.e. according to the above notation and the discussion on page 1255 we have $\eta \in C^{i-1}(X, X \setminus M)$. We consider the following commutative diagram:

$$\begin{tikzcd}
C^{i-1}(X;G) \arrow[rrr, "\eta\to\varphi", "\delta"'] & & & C^i(X;G) \\
& C^{i-1}(X, X\setminus(M\cup L);G) \arrow[ul, hook] \arrow[r, "\delta"] & C^i(X, X\setminus(M\cup L);G) \arrow[ur, hook] & \\
C^{i-1}(X, X\setminus M;G) \arrow[uu, hook] \arrow[ur, hook] & & & C^i(X, X\setminus L;G). \arrow[uu, hook] \arrow[ul, hook]
\end{tikzcd}$$

It follows immediately from the diagram that in $C^i(X, X\setminus(M\cup L);G)$ we have $\delta\eta = \varphi$, which shows that $[\varphi]$ represents the zero class in $H^i(X, X\setminus(M\cup L);G)$. It follows from Lemma 52.2 (2) or alternatively from the commutative diagram from page 1260 that $\psi_L([\varphi]) = c$ is zero. $\square$

[937]Here the term "natural" refers to the fact that both sides define a contravariant functor from the category where objects are topological spaces and morphisms are proper maps to the category of abelian groups.

Example. Now we turn to a key example, namely for each $k \in \mathbb{N}_0$ we consider the cohomology with compact support $H^k_c(\mathbb{R}^n;\mathbb{Z})$ of $\mathbb{R}^n$. We have

$$\begin{array}{ccccccc}
 & & & & & & \vdots \\
 & \text{Proposition 53.4} & & & \text{Lemma 52.3} & & H^k(\mathbb{R}^n, \mathbb{R}^n \setminus \overline{B}_2(0);\mathbb{Z}) \\
 & \downarrow & & & \downarrow & & \uparrow \\
H^k_c(\mathbb{R}^n;\mathbb{Z}) & = & \lim\limits_{\substack{\longrightarrow \\ K\in\mathcal{K}(\mathbb{R}^n)}} H^k(\mathbb{R}^n, \mathbb{R}^n \setminus K;\mathbb{Z}) & = & \lim\limits_{\substack{\longrightarrow \\ s\in\mathbb{N}}} & & H^k(\mathbb{R}^n, \mathbb{R}^n \setminus \overline{B}_1(0);\mathbb{Z}) \\
 & & & & & & \uparrow \\
 & & & & & & H^k(\mathbb{R}^n, \mathbb{R}^n \setminus \overline{B}_0(0);\mathbb{Z}) \\
 & \cong & H^k(\mathbb{R}^n, \mathbb{R}^n \setminus \overline{B}_0(0);\mathbb{Z}) & & \cong & & \begin{cases} \mathbb{Z}, & \text{if } k = n, \\ 0, & \text{otherwise.} \end{cases} \\
 & \uparrow & & & \uparrow & &
\end{array}$$

by Lemma 31.16 (4) all vertical maps in the direct system are isomorphisms, hence we can apply Lemma 52.2

same argument as in the proof of Lemma 45.16

We draw three interesting conclusions from this example:

(1) This example shows that cohomology with compact support can be used to show that the topological spaces $\mathbb{R}^n$ and $\mathbb{R}^m$ are not homeomorphic for $n \neq m$.
(2) The example also shows that cohomology with compact support, in contrast to basically all other invariants we have studied so far, is not the same for homotopy equivalent topological spaces.
(3) Finally we consider the case $n = 1$ in more detail. We consider again the singular 1-cochain $\gamma_0 := \delta\varphi_0$ from page 1169. On pages 1176 and 1257 we saw that γ_0 defines an element in each $H^1(\mathbb{R}, \mathbb{R} \setminus [-s, s];\mathbb{Z})$ and an element in $H^1_c(\mathbb{R};\mathbb{Z})$. Furthermore on page 1176 we saw that for each $s \in N$ the class $[\gamma_0] \in H^1(\mathbb{R}, \mathbb{R} \setminus [-s, s];\mathbb{Z})$ is a generator. The above argument now implies that $[\gamma_0] \in H^1_c(\mathbb{R};\mathbb{Z})$ is also a generator.

Example. In Exercise 53.2 we will use cohomology with compact support to show that the topological spaces

$$X \ := \ \overline{B}_1(0) \cup x\text{-axis} \quad \text{and} \quad Y \ := \ \overline{B}_1(0) \cup x\text{-axis} \cup y\text{-axis}$$

that are illustrated in Figure 699 are not homeomorphic.

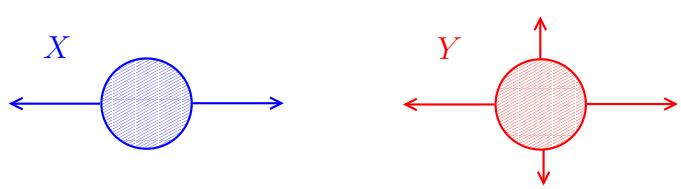

FIGURE 699.

In the previous examples cohomology with compact support turns out to be "bigger" than ordinary cohomology. On the other hand, Let us once again consider the topological space

$$X \;:=\; (\mathbb{R} \cup S^2 \times \mathbb{Z})/\sim$$

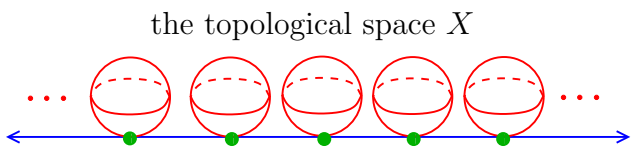
where given $i \in \mathbb{Z}$ we identify $i \in \mathbb{Z} \subset \mathbb{R}$ with $((0,0,-1),i) \in S^2 \times \mathbb{Z}$. (See Figure 53.2 for an illustration.) In Exercise 53.5 that

$$H^2_c(X) \;\cong\; \mathbb{Z}^{(\mathbb{N})},$$

in particular $H^2_c(X)$ is countable, whereas on page 1252 we saw that

$$H^2(X) \;\cong\; \mathbb{Z}^{\mathbb{N}}$$

is uncountable.



$H^2(X) \cong \mathbb{Z}^{\mathbb{N}}$ but $H^2_c(X) \cong \mathbb{Z}^{(\mathbb{N})}$

FIGURE 700.

In the following we will see the rather surprising fact that under fairly mild hypotheses an inclusion $U \to V$ of topological spaces induces for every $n \in \mathbb{N}_0$ a map $H^n_c(U) \to H^n_c(V)$ which "goes the same way".

We recall that given a topological space X we denote by $\mathcal{K}(X)$ the set of all compact subsets of X. Suppose U is an open subset of a topological space V and suppose that V is Hausdorff. We denote by $i_{UV*} = i_* \colon H^n_c(U) \to H^n_c(V)$ the composition of the following maps

$$H^n_c(U) \;\overset{\text{Proposition 53.4}}{=}\; \varinjlim_{K \in \mathcal{K}(U)} H^n(U, U \setminus K) \;\underset{\substack{\text{by the Excision Theorem 45.8 (2) the}\\ \text{map } H^n(V,V\setminus K) \to H^n(U,U\setminus K) \text{ is}\\ \text{an isomorphism for every compact subset } K \text{ of } U}}{\overset{\cong}{\longleftarrow}} \varinjlim_{K \in \mathcal{K}(U)} H^n(V, V \setminus K) \;\underset{\substack{\text{given by Lemma 52.3 (1) and the fact}\\ \text{that by Lemma 1.37 we have } \mathcal{K}(U) \subset \mathcal{K}(V)}}{\longrightarrow} \varinjlim_{K \in \mathcal{K}(V)} H^n(V, V \setminus K) \;\overset{\text{Proposition 53.4}}{=}\; H^n_c(V).$$

Note that, confusingly, the induced map on cohomology with compact support "goes the same direction" as the inclusion map $i \colon U \to V$.

Lemma 53.5. *Given a topological space X that is Hausdorff the above construction defines for each $n \in \mathbb{N}_0$ a* covariant *functor*

$$\begin{array}{c}\textit{category where the objects are open subsets}\\ \textit{of } X \textit{ and where the morphisms are inclusions}\end{array} \;\to\; \begin{array}{c}\textit{category of}\\ \textit{abelian groups.}\end{array}$$

Proof $(*)$. Let X be a topological space that is Hausdorff and let $U \subset V \subset W$ be open subsets. Let $n \in \mathbb{N}_0$. We have to show that $i_{UW*} = i_{VW*} \circ i_{UV*} \colon H^n_c(U) \to H^n_c(W)$. We consider the following diagram:

$$\begin{tikzcd}
\lim\limits_{\substack{\longrightarrow \\ K\in\mathcal{K}(U)}} H^n(U, U\setminus K) \arrow[rr, bend left, "i_{UV*}"] \arrow[drrr, bend right, "i_{UW*}"'] & & \lim\limits_{\substack{\longrightarrow \\ K\in\mathcal{K}(U)}} H^n(V, V\setminus K) \arrow[ll, "\cong"'] \arrow[r] & \lim\limits_{\substack{\longrightarrow \\ K\in\mathcal{K}(V)}} H^n(V, V\setminus K) \arrow[dd, bend left, "i_{VW*}"] \\
& & \lim\limits_{\substack{\longrightarrow \\ K\in\mathcal{K}(U)}} H^n(W, W\setminus K) \arrow[ull, "\cong"] \arrow[u, "\cong"] \arrow[r] \arrow[dr] & \lim\limits_{\substack{\longrightarrow \\ K\in\mathcal{K}(V)}} H^n(W, W\setminus K) \arrow[u, "\cong"'] \arrow[d] \\
& & & \lim\limits_{\substack{\longrightarrow \\ K\in\mathcal{K}(W)}} H^n(W, W\setminus K).
\end{tikzcd}$$

It follows from the explicit description of the direct limits in Proposition 52.1 and the uniqueness statement in the universal property of the direct limits that the two smaller triangles and the rectangle commute. Hence the diagram commutes and we get the desired statement. □

We conclude this section with the following proposition.

Proposition 53.6. *Let X be a topological space that is Hausdorff. Let $X_i, i \in \mathbb{N}$ be a sequence of subsets such that the following holds:*

1. *the sequence is nested, i.e. for each $i \in \mathbb{N}$ we have $X_i \subset X_{i+1}$,*
2. *each X_i is open in X,*
3. *and $X = \bigcup\limits_{i\in\mathbb{N}} X_i$.*

Then for any $n \in \mathbb{N}_0$ the above inclusion induced maps $H^n_c(X_i) \to H^n_c(X)$ induce an isomorphism

$$\lim_{\longrightarrow} \underbrace{H^n_c(X_i)}_{\substack{\uparrow \\ \text{by Lemma 53.5 this is a direct system with the above inclusion induced maps}}} \xrightarrow{\cong} H^n_c(X).$$

Proof $(*)$. Using Proposition 53.4 we see that we have to show that the map

$$\Phi \colon \lim_{\substack{\longrightarrow \\ i\in\mathbb{N}}} \lim_{\substack{\longrightarrow \\ K\in\mathcal{K}(X_i)}} H^n(X_i, X_i \setminus K) \xrightarrow{\cong} \lim_{\substack{\longrightarrow \\ K\in\mathcal{K}(X)}} H^n(X, X \setminus K)$$

is an isomorphism. We need to show that Φ is injective and surjective. The key to the proof of these two statements are the following observations:

(a) it follows from (1) and (2), together with Lemma 1.38, that every compact subset L of X is already contained in some X_i,

(b) it follows from the Excision Theorem 45.8 (2) that for each compact subset $L \subset X_i$ we get an inclusion induced isomorphism $H^n(X, X \setminus L) \to H^n(X_i, X_i \setminus L)$.

Now we prove that Φ is surjective, the proof that Φ is injective is fairly similar and we leave that part of the proof to the reader.

So let c be an element of the limit on the right-hand side. By Lemma 52.2 there exists a compact subset L of X and some $\varphi \in H^n(X, X \setminus L)$ such that c is the image of φ under the map $H^n(X, X \setminus L) \to \varinjlim H^n(X, X \setminus K)$. By (a) there exists an $i \in \mathbb{N}$ with $L \subset X_i$. We consider the following commutative diagram

$$\begin{tikzcd}
\varinjlim\limits_{i\in\mathbb{N}} \varinjlim\limits_{K\in\mathcal{K}(X_i)} H^n(X_i, X_i \setminus K) \arrow[r, "\Phi"] & \varinjlim\limits_{K\in\mathcal{K}(X)} H^n(X, X \setminus K) \\
H^n(X_i, X_i \setminus L) \arrow[u, "\beta"] & H^n(X, X \setminus L). \arrow[l, "\alpha", "\cong"'] \arrow[u]
\end{tikzcd}$$

The bottom horizontal map is an isomorphism by (b). Since the diagram is commutative we now see that $\Phi(\beta(\alpha(\varphi))) = c$. $\square$

53.3. **Bounded cohomology** $(*)$**.** We had just seen that with a modest modification of the original definition of cohomology we obtain a new invariant which for non-compact topological spaces behaves quite differently from the usual cohomology groups.

In this section we will introduce another variation on cohomology, namely bounded cohomology. We will not make use of it later on, but it does play an important role in topology. A much more detail discussion of bounded cohomology is for example provided in [Lö2].

Definition. Let X be a topological space.

(1) Let $C \in \mathbb{R}$. We say that a cochain $\rho \in C_n(X;\mathbb{R}) = \mathrm{Hom}(C_n(X), \mathbb{R})$ is *C-bounded* if for all singular n-simplices $\sigma\colon \Delta^n \to X$ we have $|\rho(\sigma)| \leq C$.
(2) We say that a cochain $\rho \in C_n(X;\mathbb{R}) = \mathrm{Hom}(C_n(X), \mathbb{R})$ is *bounded* if it is C-bounded for some $C \in \mathbb{R}$.
(3) Given $i \in \mathbb{N}_0$ we write

$$C_b^n(X;\mathbb{R}) \ := \ \{\text{all bounded cochains in } C^n(X;\mathbb{R})\}.$$

Examples.

(1) Let X be a topological space. The 0-cochain that assigns to each point $x \in X$ the same value $c \in \mathbb{R}$ is bounded.
(2) The singular 1-cochain $\theta_{\mathbb{R}} \in C^1(S^1;\mathbb{R})$ defined on page 1166 is *not* bounded. Indeed, given $n \in \mathbb{N}$ we denote by $\mu_n\colon \Delta^1 \to S^1$ the singular 1-simplex that is given by $(1-t, t) \mapsto e^{2\pi i n t}$. It follows easily from the definition of $\theta_{\mathbb{R}}$ that $\theta_{\mathbb{R}}(\mu) = n$.

Lemma 53.7. *Let X be a topological space. The bounded cochains $C_b^*(X)$ form a subcomplex of the cochain complex $(C^*(X), \delta)$.*

Proof. Suppose that $\rho \in C^n(X;\mathbb{R})$ is a cochain that is C-bounded. For any $\varphi\colon \Delta^{n+1} \to X$ we obtain that

$$|(\delta\rho)(\varphi)| \;=\; |\rho(\partial\varphi)| \;\underset{\substack{\uparrow \\ \text{definition of } \partial \text{ and linearity of } \rho}}{=}\; \Big|\sum_{j=0}^{n+1}(-1)^j\cdot\rho(\varphi\circ i_j^{n+1})\Big| \;\underset{\substack{\uparrow \\ \text{triangle inequality}}}{\le}\; \sum_{j=0}^{n+1}|\rho(\varphi\circ i_j^{n+1})| \;\underset{\substack{\uparrow \\ \text{since } \rho \text{ is } C\text{-bounded}}}{\le}\; (n+2)\cdot C.$$

This shows that $\delta\rho$ is $C\cdot(n+2)$-bounded, in particular it is bounded. This shows that bounded cochains $C_b^*(X)$ form a subcomplex of the cochain complex $(C^*(X),\delta)$. □

This lemma leads us straight to the following definition.

Definition. Let X be a topological space X and let $n \in \mathbb{N}_0$. The *n-th bounded cohomology group of X* is defined as

$$H_b^n(X;\mathbb{R}) \;:=\; \frac{\ker\{\delta_n\colon C_b^n(X;\mathbb{R}) \to C_b^{n+1}(X;\mathbb{R})\}}{\operatorname{im}\{\delta_{n-1}\colon C_b^{n-1}(X;\mathbb{R}) \to C_b^n(X;\mathbb{R})\}}.$$

Examples.

(1) The proof of Proposition 48.11 can be used, without any changes, to show that 0-th bounded cohomology of a path-connected topological space agrees with 0-th cohomology with real coefficients.[938]
(2) Every cochain on a topological space with finitely many points is bounded. Thus it follows from Lemma 48.12 that for a topological space $\{x_0\}$ consisting of a single point x_0 we have

$$H_b^n(\{x_0\};\mathbb{R}) \;=\; H^n(\{x_0\};\mathbb{R}) \;=\; \begin{cases} 0, & \text{if } n \ge 1, \\ \mathbb{R}, & \text{if } n = 0. \end{cases}$$

Proposition 53.8.

(1) *Let $f\colon X \to Y$ be a map between topological spaces. The map $f^*\colon C^*(Y;\mathbb{R}) \to C^*(X;\mathbb{R})$ on singular cochains restricts to a cochain map $f^*\colon C_b^*(Y;\mathbb{R}) \to C_b^*(X;\mathbb{R})$. In particular the map f^* induces a map*

$$f^*\colon H_b^n(Y;\mathbb{R}) \;\to\; H_b^n(X;\mathbb{R}).$$

(2) *For each $n \in \mathbb{N}_0$ the maps $X \mapsto H_b^n(X;\mathbb{R})$ and $f \mapsto f^*$ define a contravariant functor from the category of topological spaces to the category of real vector spaces.*
(3) *Homotopic maps induce the same maps on bounded cohomology.*
(4) *If $f\colon X \to Y$ is a homotopy equivalence, then the induced map*

$$f^*\colon H_b^n(Y;\mathbb{R}) \;\xrightarrow{\cong}\; H_b^n(X;\mathbb{R})$$

is in fact an isomorphism.

Proof.

[938] Is this statement also true for topological spaces that are not path-connected?

(1) It is obvious that the pull-back of a bounded cohomology class is again bounded. The first statement is an immediate consequence of this observation.
(2) This statement is obvious.
(3) Let $f, g\colon X \to Y$ be two maps between topological spaces X and Y. Furthermore let $F\colon X \times [0,1] \to Y$ be a homotopy between the maps f and g. As on page 758 we define

$$P_n\colon C_n(X) \;\to\; C_{n+1}(Y)$$

to be the map that is given by

$$(\sigma\colon \Delta^n \to X) \;\mapsto\; \sum_{j=0}^{n} (-1)^j \cdot F \circ (\sigma \times \mathrm{id}_{[0,1]}) \circ \underbrace{[v_0, \dots, v_j, w_j, \dots, w_n]}_{\Delta^{n+1} \to \Delta^n \times [0,1]}.$$

In the proof of Proposition 30.5 we saw that the maps P_n define a chain homotopy between f_* and g_*. It follows from this explicit description of P_n that for any cochain $\varphi \in C^{n+1}(Y;\mathbb{R})$ that is C-bounded the chain $P^*\varphi \in C^n(X;\mathbb{R})$ is $(n+1)\cdot C$-bounded, the map $P^*\colon C^{n+1}(Y;\mathbb{R}) \to C^n(X;\mathbb{R})$ restricts to a map $C_b^{n+1}(Y;\mathbb{R}) \to C_b^n(X;\mathbb{R})$. As in the proof of Lemma 48.8 (3) one sees easily that the maps P^* form a cochain homotopy between $f^*, g^*\colon C_b^*(Y;\mathbb{R}) \to C_b^*(X;\mathbb{R})$. The third statement now follows from Lemma 48.5.
(4) This statement follows immediately from (2) and (3). □

So far it seems like bounded cohomology might be quite similar to usual cohomology with real coefficients. It turns out that this guess is dramatically misguided.

For example the following theorem was proved by Mikhail Gromov [Grom2, p. 40], see also [Iv, Theorem 4.3].[939]

Theorem 53.9. *Let $f\colon X \to Y$ be a map between two connected CW-complexes. If the induced map $f_*\colon \pi_1(X) \to \pi_1(Y)$ is an epimorphism of fundamental groups such that the kernel* $\ker\{f_*\colon \pi_1(X) \to \pi_1(Y)\}$ *is an amenable group, then for any $n \in \mathbb{N}_0$ the induced map*

$$f^*\colon H_b^n(Y;\mathbb{R}) \;\xrightarrow{\cong}\; H_b^n(X;\mathbb{R})$$

is an isomorphism.

Remark. In the formulation of Theorem 53.9 we used the notion of an "amenable group". We will not give the definition of an "amenable group", instead we refer to [Pi] or [CSC, Section 4] for the definition. What matters to us are the following two facts:

(1) Groups that admit a finite index subgroup that is solvable are amenable, see [Pi, Propositions 13.3 and 13.4]. In particular finite groups and solvable groups are amenable.
(2) Groups that contain a free group on two generators are not amenable, see [Pi, Proposition 14.1].

[939]Mikhail Gromov (*1943) is a Russian-French mathematician who is easily one of the most influential geometers alive. He won the Abel prize in 2009.

Now we can formulate the following rather surprising corollary.

Corollary 53.10. *Let X be a connected CW-complex such that $\pi_1(X)$ is amenable, e.g. such that $\pi_1(X)$ is solvable. Then $H_b^n(X;\mathbb{R}) = 0$ for any $n \geq 1$.*

Example. If follows from Corollary 53.10 that the higher bounded cohomology groups of the n-tori $(S^1)^n$, the spheres S^n and lens spaces all vanish. In particular this new invariant is also not useful in our attempt to answer Question 7.8.

Proof. We consider the map $f\colon X \to \{x_0\}$ that is given by sending every point in X to the point x_0. Then for any $n \geq 1$ we have

$$\begin{array}{ccccc} H_b^n(X;\mathbb{R}) & \xrightarrow[\cong]{f^*} & H_b^n(\{x_0\};\mathbb{R}) & = & 0. \\ & \uparrow & & \uparrow & \\ & \text{by Theorem 53.9 since} & & \text{see above example} & \\ & \ker(f_*) = \pi_1(X) \text{ is amenable} & & & \end{array}$$

We have thus proved the desired result. □

The following vanishing result is in fact fairly easy to show, see e.g. [Frig, Chapter 2].

Lemma 53.11. *For any CW-complex X we have $H_b^1(X;\mathbb{R}) = 0$.*

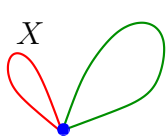
On the other hand, if the fundamental group is not amenable, then we also see some totally unexpected behavior as is shown in the following proposition.

Proposition 53.12. *Let X be the wedge of two circles. Then $H_b^2(X;\mathbb{R})$ and $H_b^3(X;\mathbb{R})$ are vector spaces of uncountable dimension.*

Proof. The statement regarding $H_b^2(X;\mathbb{R})$ is proved in [EF] and the statement regarding $H_b^3(X;\mathbb{R})$ is proved in [So, Theorem 3]. □

Somewhat shockingly the following question is still open:

Question 53.13. *Let X be the wedge of two circles. What are the bounded cohomology groups $H_b^k(X;\mathbb{R}) \neq 0$ for $k \geq 4$? Is any of the groups non-zero? Are all of them non-zero? Are all of them of uncountable dimension?*



$$\begin{aligned} \dim(H_b^1(X;\mathbb{R})) &= 0 \\ \dim(H_b^2(X;\mathbb{R})) &= \infty \\ \dim(H_b^3(X;\mathbb{R})) &= \infty \\ \dim(H_b^4(X;\mathbb{R})) &= ??? \end{aligned}$$

FIGURE 701.

Exercises for Chapter 53.

Exercise 53.1. We consider $X = \mathbb{R}$ and the singular 0-cochain

$$\varphi_0 \colon C_0(X) \ \to \ \mathbb{Z}$$

that is uniquely determined by the property that for any singular 0-simplex $x \in X = \mathbb{R}$ we have

$$x \ \mapsto \ \begin{cases} 1, & \text{if } x \leq 0, \\ 0, & \text{if } x > 0. \end{cases}$$

On page 1257 we saw that $\gamma_0 = \delta\varphi_0 \colon C_1(\mathbb{R}) \to \mathbb{Z}$ defines a class in $H^1_c(\mathbb{R};\mathbb{Z})$. Prove, only using the definitions, that this class is non-zero.

Exercise 53.2. What is the cohomology with compact support of the topological spaces

$$X \ := \ \overline{B}_1(0) \cup x\text{-axis} \quad \text{and} \quad Y \ := \ \overline{B}_1(0) \cup x\text{-axis} \cup y\text{-axis}$$

that are illustrated in Figure 699.

Exercise 53.3.

(a) Give an example of a path-connected topological space X such that $H^1(X) = 0$ but such that $H^1_c(X) \cong \mathbb{Z}^{(\mathbb{N})}$. You do not have to justify why your example has the correct properties.

(b) Give an example of a path-connected topological space X such that $H^2(X) = 0$ but such that $H^2_c(X) \cong \mathbb{Z}^3$. You do not have to justify why your example has the correct properties.

Exercise 53.4. Let M be a *compact* topological manifold. We write $\overset{\circ}{M} = M \setminus \partial M$. The cohomology group $H^n_c(\overset{\circ}{M})$ is homeomorphic to some other cohomology group that might look more familiar. What is it? You do not have to justify your answer.

Exercise 53.5. Let us once again consider the topological space

$$X \ := \ (\mathbb{R} \cup S^2 \times \mathbb{Z})/\sim$$

where given $i \in \mathbb{Z}$ we identify $i \in \mathbb{Z} \subset \mathbb{R}$ with $((0,0,-1),i) \in S^2 \times \mathbb{Z}$. On page 1252 we saw that $H^2(X) \cong \mathbb{Z}^{\mathbb{N}}$. Show that $H^2_c(X) \cong \mathbb{Z}^{(\mathbb{N})}$.

Exercise 53.6. Let $f, g \colon X \to Y$ be two maps between topological spaces. Show that if f and g are homotopic, then the induced maps on bounded cohomology are the same.

54. De Rham cohomology of manifolds

In this chapter we give a concise introduction to the de Rham cohomology groups of a manifold. In particular we will prove several statements for de Rham cohomology which are reminiscent of properties that we had already proved for singular cohomology. In the next chapter we will then explore the relationship between de Rham cohomology and singular cohomology.

54.1. **Alternating forms and the wedge-product.** An *alternating k-form* on a real vector space V is a map

$$\begin{array}{rcl} \omega\colon V^k & \to & \mathbb{R} \\ (v_1,\dots,v_k) & \mapsto & \omega(v_1,\dots,v_k) \end{array}$$

with the following properties:

(i) ω is linear in each argument, i.e. for all $v, v' \in V$ and $\lambda \in \mathbb{R}$ we have

$$\begin{array}{rcl} \omega(\dots, v+v', \dots) & = & \omega(\dots, v, \dots) + \omega(\dots, v', \dots) \\ \omega(\dots, \lambda v, \dots) & = & \lambda \cdot \omega(\dots, v, \dots), \end{array}$$

(ii) swapping two arguments flips the signs, i.e. for any $v, v' \in V$ we have

$$\omega(\dots, v, \dots, v', \dots) \;=\; -\omega(\dots, v', \dots, v, \dots).$$

We denote the vector space of alternating k-forms on V by $\wedge^k V^*$. A 0-form on V is by definition a real number, i.e. $\wedge^0 V^* = \mathbb{R}$.

Example.

(1) An alternating 1-form is by definition simply a linear map $V \to \mathbb{R}$. In particular $\wedge^1 V^* = V^* := \mathrm{Hom}(V, \mathbb{R})$ is the dual space of V.

(2) For $V = \mathbb{R}^n$ we denote by dx_i the 1-form which is given by

$$dx_i(v_1,\dots,v_n) \;=\; v_i.$$

Put differently, $dx_1, \dots, dx_n$ is the basis of $(\mathbb{R}^n)^*$ that is dual to the standard basis $e_1, \dots, e_n$ of $\mathbb{R}^n$.

(3) If $V = \mathbb{R}^n$, then for each $\lambda \in \mathbb{R}$ the map

$$\begin{array}{rcl} (\mathbb{R}^n)^n & \to & \mathbb{R} \\ (v_1,\dots,v_n) & \mapsto & \lambda \cdot \det(v_1 \;\dots\; v_n) \end{array}$$

is an alternating n-form. It follows easily from the uniqueness of the determinant, see e.g. [Lan2, Proposition XIII.4.6] that that each alternating n-form on $\mathbb{R}^n$ is of this form, i.e. $\wedge^n(\mathbb{R}^n)^* \cong \mathbb{R}$.

Now we recall the wedge product of 1-forms. In the following let V be an n-dimensional real vector space and let $\varphi_1, \dots, \varphi_k \in V^*$ be 1-forms. We consider the map

$$\begin{aligned} \varphi_1 \wedge \cdots \wedge \varphi_k \colon V^k &\to \mathbb{R} \\ (v_1, \dots, v_k) &\mapsto \det \begin{pmatrix} \varphi_1(v_1) & \dots & \varphi_1(v_k) \\ \vdots & & \vdots \\ \varphi_k(v_1) & \dots & \varphi_k(v_k) \end{pmatrix}. \end{aligned}$$

One can easily verify that this is an alternating k-form. We refer to this alternating k-form as the *wedge product* of $\varphi_1, \dots, \varphi_k$.

Next let $\varphi_1, \dots, \varphi_n$ be a basis for V^* and let $k \in \{0, \dots, n\}$. It follows from [Le2, Proposition 14.8] or [Loe, Chapter 20.13] that the wedge products

$$\varphi_{i_1} \wedge \cdots \wedge \varphi_{i_k} \quad \text{with} \quad i_1 < i_2 < \cdots < i_k$$

form a basis of $\wedge^k V^*$ and that $\wedge^k V^* = 0$ for $k > \dim(V)$.

Now we can introduce the wedge product of general alternating forms. Let $\omega \in \wedge^k V^*$ and $\sigma \in \wedge^l V^*$. Then by the above we can write

$$\omega = \sum_{i_1 < \cdots < i_k} a_{i_1, \dots, i_k} \cdot \varphi_{i_1} \wedge \cdots \wedge \varphi_{i_k}$$

and

$$\sigma = \sum_{j_1 < \cdots < j_l} b_{j_1, \dots, j_l} \cdot \varphi_{j_1} \wedge \cdots \wedge \varphi_{j_l}.$$

Finally we define

$$\omega \wedge \sigma := \sum_{i_1 < \cdots < i_k} \sum_{j_1 < \cdots < j_l} a_{i_1, \dots, i_k} b_{j_1, \dots, j_l} \cdot \varphi_{i_1} \wedge \cdots \wedge \varphi_{i_k} \wedge \varphi_{j_1} \wedge \cdots \wedge \varphi_{j_l}.$$

One can show easily that $\omega \wedge \sigma$ is an alternating $(k+l)$-form. The following lemma summarizes some of the key properties of the wedge product of alternating forms. The lemma is proved in [Le2, Proposition 14.11], but it is also straightforward to deduce the statements of the lemma from the definitions.

Lemma 54.1. *Let V be a real vector space.*

(1) *For any $\omega \in \wedge^k V^*$ and $\sigma \in \wedge^l V^*$ we have*

$$\omega \wedge \sigma = (-1)^{kl} \cdot \sigma \wedge \omega.$$

(2) *The map*

$$\wedge^k V^* \times \wedge^l V^* \to \wedge^{k+l} V^*$$

is bilinear and distributive.

(3) *For any $\omega \in \wedge^k V^*$, $\sigma \in \wedge^l V^*$ and $\tau \in \wedge^m V^*$ we have*

$$(\omega \wedge \sigma) \wedge \tau = \omega \wedge (\sigma \wedge \tau).$$

54.2. **The de Rham cohomology of a manifold.** What are cohomology groups good for? The universal coefficient theorem 51.13 for cohomology group says that the cohomology groups do not contain more information than the homology groups. Furthermore cohomology groups have the "disadvantage" that the induced maps go the "wrong" direction which often leads to total confusion.

In this chapter we want to sketch one answer: the cohomology groups with $\mathbb{R}$-coefficients of a manifold are isomorphic to the de Rham cohomology groups which are defined using differential forms.

Before we can show that such an isomorphism exists we first need to give the definition of de Rham cohomology groups and we need to state and prove some properties of de Rham cohomology groups.

Let M be an n-dimensional manifold.

(1) A *differential form k-form on M*assigns to each point $P \in M$ an alternating k-form on the tangent space $T_P M$. Using charts one can introduce the notions of continuity and smoothness of differential k-forms. We refer to [Le2, Chapter 14], [Tu, Chapter 18.3] or [Frie2] for details.

(2) One of the key reasons for studying differential forms on manifolds is that these are the "right" objects on a manifold that can be integrated. Somewhat more precisely, if M is a compact oriented k-dimensional manifold and if ω is a continuous differential k-form on M, then one can introduce the integral

$$\int_M \omega \ \in \ \mathbb{R}.$$

We refer to [Le2, Chapter 16] or to [Tu, Chapter 22.3] for details. The integral has the following simple, but nonetheless essential property: if M is a compact 0-dimensional manifold, i.e. $M = \{P_1, \dots, P_s\}$, where all points are given the positive orientation, then the integral of a differential 0-form, i.e. of a function $f\colon M \to \mathbb{R}$, is just the sum $f(P_1) + \dots + f(P_s)$.

(3) Let $k \in \mathbb{N}_0$. We define the k-th de Rham group as the real vector space[940][941]

$$C^k_{\mathrm{dR}}(M) \ := \ \{\text{smooth differential } k\text{-forms on } M\}.$$

[940]Georges de Rham (1903-1990) was a Swiss mathematician. The subscript "dR" in our notation $C^k_{\mathrm{dR}}(M)$ stands for de Rham. We use the subscript do distinguish it from the singular cochains $C^k(M;\mathbb{R})$.

[941]In most references, see e.g. [Le2, BT, Frie2] one writes $\Omega^k(M)$ for the set of all smooth differential k-forms on M. Since in a second we will view $C^k_{\mathrm{dR}}(M) = \Omega^k(M)$ as the groups in a cochain complex we prefer the notation $C^k_{\mathrm{dR}}(M)$.

If $f\colon M \to N$ is a smooth map between manifolds, then it follows from [Le2, p. 360] that f induces a homomorphism[942]

$$\begin{array}{rcl} f^*\colon C^k_{\mathrm{dR}}(N) & \to & C^k_{\mathrm{dR}}(M) \\ \omega & \mapsto & \text{the differential } k\text{-form } f^*\omega \text{ which at a point } P \in M \text{ is given by} \\ & & \begin{array}{rcl} (T_PM)^k & \to & \mathbb{R} \\ (v_1,\dots,v_k) & \mapsto & \omega_{f(P)}(Df_P(v_1),\dots,Df_P(v_k)) \end{array} \end{array}$$

(4) We refer to [Le2, p. 363] for the definition of the differential[943]

$$d_k\colon C^k_{\mathrm{dR}}(M) \ \to\ C^{k+1}_{\mathrm{dR}}(M).$$

Often, when the subscript k is understood from the context, we just write d instead of d_k. A smooth form ω with $d\omega = 0$ is called *closed*. A smooth form ω for which there exists a smooth form μ with $d\mu = \omega$ is called *exact*.

The following proposition summarizes some of the key properties of the integral of forms and of the differential.

Proposition 54.2.

(1) *Let $f\colon M \to N$ be a diffeomorphism between compact oriented connected k-dimensional manifolds and let ω be a smooth differential k-form on N. Then*

$$\int_M f^*\omega \ = \ \epsilon \cdot \int_N \omega \qquad \textit{where } \epsilon = \begin{cases} +1, & \textit{if } f \textit{ is orientation-preserving,} \\ -1, & \textit{if } f \textit{ is orientation-reversing.} \end{cases}$$

(2) *Let M be a compact oriented k-dimensional manifold and let ω be a smooth differential k-form on M. If $M = A \cup B$ where A and B are compact k-dimensional submanifolds such that $A \cap B$ is a $(k-1)$-dimensional submanifold, then*

$$\int_M f^*\omega \ = \ \int_A f^*\omega + \int_B f^*\omega.$$

(3) *Let M be a manifold. Then for any $k \in \mathbb{N}_0$ the map $d \circ d\colon C^k_{\mathrm{dR}}(M) \to C^{k+2}_{\mathrm{dR}}(M)$ is the zero map.*

---

[942]It is clear that $f^*\omega$ is a differential k-form on M, what one needs to show is that $f^*\omega$ is in fact a smooth differential k-form.

[943]Here is a quick summary of the definition. Using a partition of unity and charts it suffices to define the differential for differential k-forms on an open subset $U \subset \mathbb{R}^n$. We consider a differential k-form

$$\omega \ = \ \sum_{i_1<\cdots<i_k} f_{i_1\dots i_k} \cdot dx_{i_1} \wedge \cdots \wedge dx_{i_k}$$

where $f_{i_1\dots i_k}$ are real-valued smooth functions on U. The differential of ω is then defined as the differential $(k+1)$-form

$$d\omega \ := \ \sum_{i_1<\cdots<i_k} df_{i_1\dots i_k} \wedge dx_{i_1} \wedge \cdots \wedge dx_{i_k}.$$

(4) *Let $f\colon M \to N$ be a smooth map between two manifolds. Then for any smooth differential k-form ω on N we have*

$$d(f^*\omega) \;=\; f^*(d\omega).$$

Proof. The first statement is [Le2, Proposition 16.6]. The second statement follows fairly easily from the definitions and basic properties of the Lebesgue integral. We leave it to the reader to fill in the details. Finally the last two statements are proved in [Le2, Theorem 14.24 and Proposition 14.26]. □

The next theorem is one of the key results on differential forms. We refer to [Le2, Theorem 16.11] for a proof.

Theorem 54.3. (Stokes' Theorem) *If M is a compact oriented k-dimensional manifold with boundary ∂M and if $\omega \in C^{k-1}_{\mathrm{dR}}(M)$, then*[944]

$$\int_M d\omega \;=\; \int_{\partial M} \omega.$$

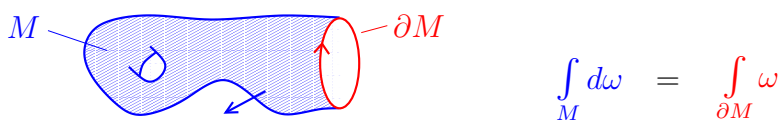


FIGURE 702.

Let M be a manifold. As we had just pointed out in Proposition 54.2 (3), the differentials $d_k\colon C^k_{\mathrm{dR}}(M) \to C^{k+1}_{\mathrm{dR}}(M)$ have the property that $d_{k+1} \circ d_k = 0$. Thus we obtain a cochain complex

$$0 \;\to\; C^0_{\mathrm{dR}}(M) \;\xrightarrow{d_0}\; C^1_{\mathrm{dR}}(M) \;\xrightarrow{d_1}\; C^2_{\mathrm{dR}}(M) \;\xrightarrow{d_2}\; \dots$$

in the sense of the discussion on page 1159. The *k–th de Rham cohomology group of M* is defined as the cohomology of this cochain complex, i.e. it is defined as

$$H^k_{\mathrm{dR}}(M) \;:=\; \frac{\ker\left\{d_k\colon C^k_{\mathrm{dR}}(M) \to C^{k+1}_{\mathrm{dR}}(M)\right\}}{\operatorname{im}\left\{d_{k-1}\colon C^{k-1}_{\mathrm{dR}}(M) \to C^k_{\mathrm{dR}}(M)\right\}}.$$

Note that $H^k_{\mathrm{dR}}(M)$ is the quotient of a real vector space by a subspace, in particular $H^k_{\mathrm{dR}}(M)$ is itself a real vector space.

The following proposition summarizes some basic properties of de Rham cohomology groups.

Proposition 54.4. *Let M be an n-dimensional manifold. Then the following hold:*

[944]Here the right-hand side is understood to be zero if $\partial M = \varnothing$.

(1) *If $f\colon M \to N$ is a smooth map to another manifold, then*

$$\begin{array}{rcl} f^*\colon H^k_{\mathrm{dR}}(N) & \to & H^k_{\mathrm{dR}}(M) \\ [\omega] & \mapsto & [f^*\omega] \end{array}$$

is a well-defined map.

(2) *If M is connected, then the map*

$$\begin{array}{rcl} \mathbb{R} & \to & H^0_{\mathrm{dR}}(M) \\ r & \mapsto & [\textit{constant function } x \mapsto r] \end{array}$$

is an isomorphism. We use this map to make the identification $H^0_{\mathrm{dR}}(M) = \mathbb{R}$.

(3) *If $f\colon M \to N$ is a smooth map between connected manifolds, then the induced map $f^*\colon H^0_{\mathrm{dR}}(N) \to H^0_{\mathrm{dR}}(M)$ is an isomorphism.*

(4) *$H^k_{\mathrm{dR}}(M) = 0$ for $k > n$.*

(5) *Suppose M consists of finitely many components $M_1, \dots, M_r$. Given $j \in \{1, \dots, r\}$ we denote by $i_j\colon M_i \to M$ the inclusion maps. Then for each $k \in \mathbb{N}_0$ the map*

$$\bigoplus_{j=1}^{r} i_j^*\colon H^k_{\mathrm{dR}}(M) \to \bigoplus_{j=1}^{r} H^k_{\mathrm{dR}}(M_j)$$

is an isomorphism.

(6) *If M has finitely many components, then $\dim_{\mathbb{R}}(H^0_{\mathrm{dR}}(M))$ equals the number of components of M.*

(7) *If M is closed and oriented, then the map*

$$\begin{array}{rcl} H^n_{\mathrm{dR}}(M) & \to & \mathbb{R} \\ [\omega] & \mapsto & \int_M \omega \end{array}$$

is well-defined. If M is non-empty, then the map is an epimorphism.

(8) *If M is closed orientable and non-empty, then $H^n_{\mathrm{dR}}(M) \neq 0$.*

Sketch of proof.

(1) The first statement is an immediate consequence of Proposition 54.2 (4) together with Lemma 48.5 (1).
(2) The second statement follows fairly easily from the definitions and elementary arguments.
(3) The third statement follows immediately from the second statement.
(4) The fourth statement is an immediate consequence of the fact that for any vector space V we have $\wedge^k V^* = 0$ for $k > \dim(V)$, see page 1271.
(5) The fifth statement follows easily from the definition.
(6) The sixth statement is an immediate consequence of (2) and (5).
(7) The seventh statement is a consequence of Stokes' Theorem and a straightforward calculation.
(8) Finally the last statement follows immediately from the seventh statement. □

Example. If $M = \{x\}$ is a manifold consisting of a single point x, then it follows immediately from Proposition 54.4 (2) and (4) that

$$H^k_{\mathrm{dR}}(\{x\}) \;=\; \begin{cases} \mathbb{R}, & \text{if } k = 0, \\ 0, & \text{otherwise.} \end{cases}$$

Now we denote by $\mathcal{M}$ the category of manifolds which is given by

$$\begin{aligned} \mathrm{Ob}(\mathcal{M}) &:= \text{all manifolds,} \\ \mathrm{Mor}(M,N) &:= \text{all smooth maps from } M \text{ to } N. \end{aligned}$$

It is straightforward to verify that for any $k \in \mathbb{N}_0$ the maps

$$\begin{aligned} M &\mapsto H^k_{\mathrm{dR}}(M) \\ (f\colon M \to N) &\mapsto (f^*\colon H^k_{\mathrm{dR}}(N) \to H^k_{\mathrm{dR}}(M)) \end{aligned}$$

define a contravariant functor from the category of manifolds to the category $\mathcal{V}$ of real vector spaces.

54.3. **Partitions of unity.** In this short section we have to introduce the notion of a "partition of unity". This is a key technical tool when studying functions and forms on manifolds.

Definition. Let X be a topological space.

(1) The *support* of a function $f\colon X \to \mathbb{R}$ is defined as

$$\mathrm{supp}(f) \;:=\; \overline{\{x \in X \mid f(x) \neq 0\}}.$$

The same way we also define the support of a differential k-form if X is a manifold.

(2) A *partition of unity* on X is a family of maps[945] $\{f_i\colon X \to [0,1]\}_{i\in I}$ with the following properties:
   (a) for each $x \in X$ there exists an open neighborhood U of x such that f_i vanishes on U for all but finitely many i. In particular for each i there exist only finitely many $i \in I$ such that $x \in \mathrm{supp}(f_i)$,
   (b) for every $x \in X$ we have[946]

$$\sum_{i\in I} f_i(x) \;=\; 1.$$

(3) Let $\{U_i\}_{i\in I}$ be an open covering. A *partition of unity subordinate to the open covering* is a partition of unity $\{f_j\}_{j\in J}$ such that for each $j \in J$ there exists an $i \in I$ with $\mathrm{supp}(f_j) \subset U_i$.

Example. In Figure 703 we consider the topological space $X = \mathbb{R}$ with the open covering given by the intervals $U_i = (i-1, i+1)$, $i \in \mathbb{Z}$. Also we illustrate a smooth partition of unity subordinate to this open covering.

The following theorem guarantees the existence of (smooth) partitions of unity.

[945] As always, all maps are assumed to be continuous.

[946] Note that by (1) there are only finitely many non-zero summands, hence the expression on the left-hand side makes sense even if I is infinite.

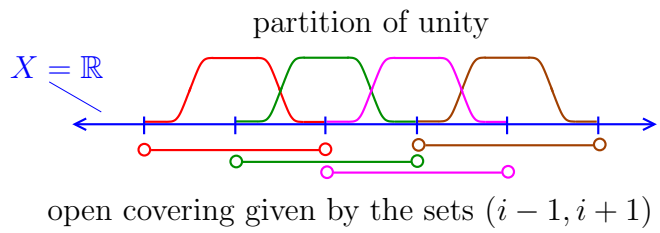

FIGURE 703.

Theorem 54.5. *Let M be a topological manifold. For any open covering of M there exists a partition of unity subordinate to the given open covering. If M is in fact a manifold, then the partition of unity can be chosen to be smooth.*

Proof. The theorem is proved for manifolds in [Tu, Theorem 13.7]. The proof for topological manifolds is basically the same. □

54.4. **The Poincaré Lemma.** In the following two sections we will see that de Rham cohomology has properties that are quite similar to singular cohomology with real coefficients.

For example, in Lemma 48.13 we saw that homotopic maps $f, g\colon X \to Y$ between topological spaces induce the same map on cohomology groups. Now we will obtain a similar result for de Rham cohomology groups, but we will have to restrict ourselves to *smooth homotopies*.

Proposition 54.6. *Let M be a manifold without boundary and let N be any manifold. Let f and g be two smooth maps between M and N. If there exists a smooth homotopy between f and g, then for any $k \in \mathbb{N}_0$ we have*

$$f^* = g^*\colon H^k_{\mathrm{dR}}(N) \;\to\; H^k_{\mathrm{dR}}(M).$$

The key to the proof of the proposition is the following lemma.

Lemma 54.7. *Let M be a manifold without boundary. We denote by $i_r\colon M \to M \times [0,1]$, $r = 0, 1$, the inclusion maps given by $i_r(z) = (z, r)$. Then for any $k \in \mathbb{N}_0$ we have*

$$i_0^* \;=\; i_1^*\colon H^k_{\mathrm{dR}}(M \times [0,1]) \;\to\; H^k_{\mathrm{dR}}(M).$$

We will first show that Lemma 54.7 implies Proposition 54.6.

Proof of Proposition 54.6 assuming Lemma 54.7. So suppose that $F\colon M \times [0,1] \to N$ is a smooth homotopy between two maps $f, g\colon M \to N$. Let $i_r\colon M \to M \times [0,1]$, $r = 0, 1$, be

the inclusion maps given by $i_r(z) = (z, r)$.[947] Then

$$\begin{array}{ccccccccc} f^* & = & (F \circ i_0)^* & = & i_0^* \circ F^* & = & i_1^* \circ F^* & = & (F \circ i_1)^* & = & g^*. \\ & & & \uparrow & & \uparrow & & \uparrow & & & \\ & & & \text{by functoriality} & & \text{by Lemma 54.7} & & \text{by functoriality} & & & \end{array}$$

We have thus shown that the two maps f^* and g^* agree. □

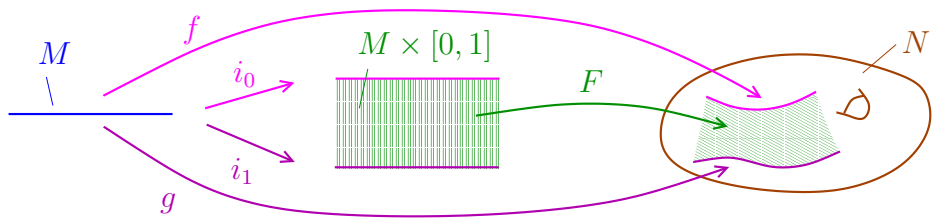

FIGURE 704. Illustration for the proof of Proposition 54.6.

Proof of Lemma 54.7. Let M be an m-dimensional manifold without boundary. By Lemma 48.5 it suffices to show that there exists a cochain homotopy

$$P_*\colon C^*_{\mathrm{dR}}(M \times [0,1]) \ \to\ C^{*-1}_{\mathrm{dR}}(M)$$

from i_0^* to i_1^*, i.e. we have to find maps $\{P_n\colon C^n_{\mathrm{dR}}(M \times [0,1]) \ \to\ C^{n-1}_{\mathrm{dR}}(M)\}_{n \in \mathbb{N}_0}$ such that for each $n \in \mathbb{N}_0$ we have

$$d_{n-1} \circ P_n + P_{n+1} \circ d_n \ = \ i_0^* - i_1^*\colon C^n_{\mathrm{dR}}(M \times [0,1]) \ \to\ C^n_{\mathrm{dR}}(M).$$

For orientation we summarize in the following diagram all objects arising in the definition of a cochain homotopy:

$$\begin{tikzcd}
\arrow[r, "d_{n+1}"'] & C^{n+1}_{\mathrm{dR}}(M \times [0,1]) \arrow[d, "i_0^*, i_1^*"] \arrow[dr, "P_{n+1}"] & C^n_{\mathrm{dR}}(M \times [0,1]) \arrow[l, "d_n"'] \arrow[d, "i_0^*, i_1^*"] \arrow[dr, "P_n"] & C^{n-1}_{\mathrm{dR}}(M \times [0,1]) \arrow[l, "d_{n-1}"'] \arrow[d, "i_0^*, i_1^*"] & \arrow[l, "d_{n-2}"'] \\
\arrow[r, "d_{n+1}"'] & C^{n+1}_{\mathrm{dR}}(M) & C^n_{\mathrm{dR}}(M) \arrow[l, "d_n"] & C^{n-1}_{\mathrm{dR}}(M) \arrow[l, "d_{n-1}"] & \arrow[l, "d_{n-2}"]
\end{tikzcd}$$

Given any $(x,t) \in M \times [0,1]$ we denote by $h \in T_{(x,t)}(M \times [0,1])$ the tangent vector that is represented by the "horizontal" curve $s \mapsto (x, t+s)$. Given any $t \in [0,1]$ we have the obvious inclusion map $M \to M \times [0,1]$. Given any $x \in M$ this map induces an inclusion $T_xM \to T_{(x,t)}(M \times [0,1])$. We use this map to view T_xM as a subspace of $T_{(x,t)}(M \times [0,1])$. Now we can write $T_{(x,t)}(M \times [0,1]) = T_xM \oplus \mathbb{R} \cdot h$.[948] This decomposition is illustrated in Figure 705. Given $n \in \mathbb{N}_0$ we consider the map

[947] Note that the smooth structure of the manifold $M \times [0,1]$ from Proposition 56.9 has the property that i_0 and i_1 are smooth maps. This implies that the maps i_0^* and i_1^* are actually defined.

[948] Why do we have this decomposition?

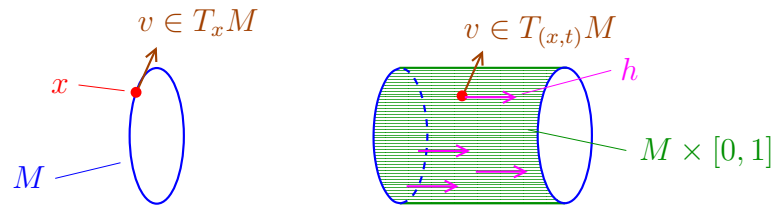

FIGURE 705.

$$\begin{aligned} P_n\colon C^n_{\mathrm{dR}}(M\times[0,1]) \;&\to\; C^{n-1}_{\mathrm{dR}}(M) \\ &\qquad \text{the } (n-1)\text{-form that at a point } x\in M \text{ is given by} \\ \omega \;&\mapsto\; \underbrace{(v_1,\ldots,v_{n-1})}_{(n\text{-}1)\text{ vectors in } T_xM} \mapsto (-1)^{n+1}\cdot\int_{t=0}^{t=1}\omega_{(x,t)}(\underbrace{v_1,\ldots,v_{n-1},h}_{n\text{ vectors in } T_{(x,t)}(M\times[0,1])})\,dt. \end{aligned}$$

It is straightforward to verify that this map is well-defined, i.e. the right-hand side is an $(n-1)$-form on M, and that this map is $\mathbb{R}$-linear. It remains to show that these maps P_n define a cochain homotopy, i.e. we have to verify that for all $n\in\mathbb{N}_0$ we have

$$(*)\qquad d_{n-1}\circ P_n + P_{n+1}\circ d_n \;=\; i_1^* - i_0^*\colon C^n_{\mathrm{dR}}(M\times[0,1]) \;\to\; C^n_{\mathrm{dR}}(M).$$

The idea of the proof is to first prove the equality $(*)$ for $M=\mathbb{R}^m$, and then to reduce the case of a general m-dimensional manifold to the case $M=\mathbb{R}^m$ via charts and a smooth partition of unity. So we start out with the following claim.

Claim. For any $n\in\mathbb{N}_0$ we have

$$d_{n-1}\circ P_n + P_{n+1}\circ d_n \;=\; i_1^* - i_0^*\colon C^n_{\mathrm{dR}}(\mathbb{R}^m\times[0,1]) \;\to\; C^n_{\mathrm{dR}}(\mathbb{R}^m).$$

We first prove the claim for $n\geq 1$. For any point in $\mathbb{R}^m\times[0,1]$ we can identify its tangent space with $\mathbb{R}^{m+1}$ and we equip its dual space with the basis given by $dx_1,\ldots,dx_m,dt$. It follows from the discussion of the basis of $\wedge^k(\mathbb{R}^{m+1})^*$ on page 1271 that for $n\geq 1$ every differential n-form on $\mathbb{R}^m\times[0,1]$ is a real linear combination of forms of the form

$$\eta \;=\; \varphi\cdot dx_{i_1}\wedge\cdots\wedge dx_{i_n} \qquad\text{and}\qquad \mu \;=\; \psi\cdot dx_{i_1}\wedge\cdots\wedge dx_{i_{n-1}}\wedge dt$$

where $\varphi,\psi\colon\mathbb{R}^n\times[0,1]\to\mathbb{R}$ are smooth functions. By the linearity of the terms in the claim it suffices to prove the claim for each such η and each such μ. It is straightforward to see that at each point $(x_1,\ldots,x_m)\in\mathbb{R}^m$ we have

$$P_n(\eta) \;=\; 0 \qquad\text{and}\qquad P_n(\mu) \;=\; (-1)^p\cdot\left(\int_{t=0}^{t=1}\psi(x_1,\ldots,x_m,t)\,dt\right)\cdot dx_{i_1}\wedge\cdots\wedge dx_{i_{n-1}}.$$

From this we obtain that $(d_{n-1} \circ P_n)(\eta) = 0$ and that

$$\begin{aligned}
(P_{n+1} \circ d_n)(\eta) &= P_{n+1}(d_0(\varphi) \wedge dx_{i_1} \wedge \cdots \wedge dx_{i_n}) \\
&= P_{n+1}\Big(\Big(\sum_{i=1}^{p} \tfrac{\partial \varphi}{\partial x_i} \cdot dx_i + \tfrac{\partial \varphi}{\partial t} \cdot dt\Big) \wedge dx_{i_1} \wedge \cdots \wedge dx_{i_n}\Big) \\
&= (-1)^n \cdot P_{n+1}\Big(\tfrac{\partial \varphi}{\partial t} \wedge dx_{i_1} \wedge \cdots \wedge dx_{i_m} \wedge dt\Big) \\
&= \Big(\int_0^1 \tfrac{\partial \varphi}{\partial t} dt\Big) \cdot dx_{i_1} \wedge \cdots \wedge dx_{i_m} \underset{\substack{\uparrow \\ \text{fundamental theorem of calculus}}}{=} (i_1^*)(\eta) - (i_0^*)(\eta).
\end{aligned}$$

We have thus proved the desired equality for η.

Now we turn to μ. We have $i_0^*(\mu) = i_1^*(\mu) = 0$ since $i_0^*(dt) = i_1^*(dt) = 0$. We obtain that

$$\begin{aligned}
(d_{n-1} \circ P_n)(\mu) &= (-1)^n \cdot \sum_{i=1}^{m} \Big(\int_{t=0}^{t=1} \frac{\partial \psi}{\partial x_i} dx_i\Big) \cdot dx_{i_1} \wedge \cdots \wedge dx_{i_{n-1}}, \\
(P_{n+1} \circ d_n)(\mu) &= (-1)^{n+1} \cdot \sum_{i=1}^{m} \Big(\int_{t=0}^{t=1} \frac{\partial \psi}{\partial x_i} dx_i\Big) \cdot dx_{i_1} \wedge \cdots \wedge dx_{i_{n-1}}.
\end{aligned}$$

We have thus proved the claim for μ and $n \geq 1$. It remains to prove the claim for $n = 0$. This follows immediately from the calculation that

$$(d_{-1} \circ P_0)(\varphi) + (P_1 \circ d_0)(\varphi) = 0 + P_1\Big(\sum_{i=1}^{m} \frac{\partial \varphi}{\partial x_i} \cdot dx_i + \frac{\partial \varphi}{\partial t} \cdot dt\Big) = \int_{t=0}^{t=1} \frac{\partial \varphi}{\partial t} dt \underset{\substack{\uparrow \\ \text{fundamental theorem of calculus}}}{=} (i_1^*)(\varphi) - (i_0^*)(\varphi).$$

This concludes the proof of the claim.

Now we return to the case that M is any m-dimensional manifold. We pick a smooth atlas $\{\Phi_j \colon U_j \to \mathbb{R}^m\}_{j \in J}$ for the manifold M.[949] By Theorem 54.5 we can pick a smooth partition of unity $\{f_j \colon M \to \mathbb{R}\}_{j \in J}$ that is subordinate to the open covering $\{U_j\}_{j \in J}$. We consider the diagram

$$\begin{tikzcd}
C^n_{\mathrm{dR}}(M \times [0,1]) \arrow[r, "(d_{n-1} \circ P_n + P_{n+1} \circ d_n) - (i_1^* - i_0^*)"] \arrow[d, hook, "\omega \mapsto \prod f_j \omega|_{U_j}"] & C^n_{\mathrm{dR}}(M) \arrow[d, hook, "\omega \mapsto \prod f_j \omega|_{U_j}"] \\
\prod_{j \in J} C^n_{\mathrm{dR}}(U_j \times [0,1]) \arrow[r, "\prod (d_{n-1} \circ P_n + P_{n+1} \circ d_n) - (i_1^* - i_0^*)"] \arrow[d, "\cong", "\omega_j \mapsto (\Phi_j^{-1})^*(\omega_j)"'] & \prod_{j \in J} C^n_{\mathrm{dR}}(U_j) \arrow[d, "\cong", "\omega_j \mapsto (\Phi_j^{-1})^*(\omega_j)"'] \\
\prod_{j \in J} C^n_{\mathrm{dR}}(\mathbb{R}^n \times [0,1]) \arrow[r, "\prod (d_{n-1} \circ P_n + P_{n+1} \circ d_n) - (i_1^* - i_0^*)"] & \prod_{j \in J} C^n_{\mathrm{dR}}(\mathbb{R}^n).
\end{tikzcd}$$

[949]Here by a smooth atlas for M we mean an atlas $\{\Phi_j \colon U_j \to \mathbb{R}^n\}_{j \in J}$ such that all maps are smooth with respect to the given smooth structure on M. Using the fact that any open ball is diffeomorphic to $\mathbb{R}^n$ one can easily show that such an atlas exists.

One can show easily that the maps P_n and i_0^* and i_1^* are natural, i.e. they commute with induced maps given by smooth maps between manifolds. This observation, together with Proposition 54.2 (4) implies that the horizontal maps are natural, i.e. they commute with smooth maps between manifolds. Therefore it follows that the diagram commutes. The top vertical maps are monomorphisms since the f_j form a smooth partition of unity. The bottom vertical maps are isomorphisms since the Φ_j are diffeomorphisms. We had just shown in the claim that the bottom map is the zero map. Hence the top map is also the zero map. But this is precisely what we had wanted to show. □

The following result is known as the Poincaré Lemma. This humble name belies the fact that it is an extremely useful statement.

Lemma 54.8. (Poincaré Lemma) *If $U \subset \mathbb{R}^n$ is an open star-shaped set, then*

$$H^k_{\mathrm{dR}}(U) \;=\; \begin{cases} \mathbb{R}, & \text{if } k = 0, \\ 0, & \text{otherwise.} \end{cases}$$

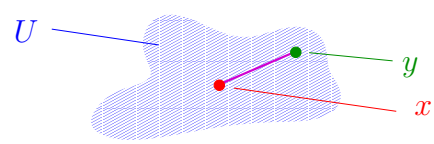

FIGURE 706.

Proof. By definition of a star-shaped subset of $\mathbb{R}^n$ there exists an $x \in U$ such that for every $y \in U$ the segment $\{xt + y(1-t) \,|\, t \in [0,1]\}$ lies in U. Let $i\colon \{x\} \to U$ be the inclusion map and let $p\colon U \to \{x\}$ the unique map from U to $\{x\}$. Evidently $p \circ i = \mathrm{id}_{\{x\}}$. Furthermore $i \circ p$ and id_U are smoothly homotopic, in fact a smooth homotopy is given by $F(y,t) = xt + y(1-t)$. It follows immediately from Proposition 54.6 and the functoriality of de Rham cohomology that $i^*\colon H^k_{\mathrm{dR}}(U) \to H^k_{\mathrm{dR}}(\{x\})$ and $p^*\colon H^k_{\mathrm{dR}}(\{x\}) \to H^k_{\mathrm{dR}}(U)$ are isomorphisms. The corollary now follows from the calculation of the de Rham cohomology groups for a point that we gave on page 1276. □

The following corollary is an immediate consequence of the Poincaré Lemma 54.8 and the functoriality of de Rham cohomology.

Corollary 54.9. *If M is an n-dimensional manifold that is diffeomorphic to an open star-shaped subset of $\mathbb{R}^n$, e.g. that is diffeomorphic to $\mathbb{R}^n$ or the open n-ball B^n, then*

$$H^k_{\mathrm{dR}}(M) \;=\; \begin{cases} \mathbb{R}, & \text{if } k = 0, \\ 0, & \text{otherwise.} \end{cases}$$

54.5. **Applications of the Poincaré Lemma to classical vector calculus** $(*)$**.** In this section we apply the Poincaré Lemma to classical vector calculus. Let $U \subset \mathbb{R}^3$ be an open set. We denote by

$$C^\infty(U) \;:=\; \text{all smooth maps } U \to \mathbb{R} \quad \text{and} \quad \mathcal{V}(U) \;:=\; \text{all smooth maps } U \to \mathbb{R}^3$$

the set of all smooth real-valued functions respectively smooth vector fields on U. We recall that there are three classical maps relating smooth functions and smooth vector fields:

$$\begin{aligned} \operatorname{grad}\colon C^\infty(U) &\to \mathcal{V}(U) & \operatorname{curl}\colon \mathcal{V}(U) &\to \mathcal{V}(U) & \operatorname{div}\colon \mathcal{V}(U) &\to C^\infty(U) \\ f &\mapsto \begin{pmatrix} \frac{\partial f}{\partial x} \\ \frac{\partial f}{\partial y} \\ \frac{\partial f}{\partial z} \end{pmatrix} & F = \begin{pmatrix} F_x \\ F_y \\ F_z \end{pmatrix} &\mapsto \begin{pmatrix} \frac{\partial F_z}{\partial y} - \frac{\partial F_y}{\partial z} \\ -\frac{\partial F_z}{\partial x} + \frac{\partial F_x}{\partial z} \\ \frac{\partial F_y}{\partial x} - \frac{\partial F_x}{\partial y} \end{pmatrix} & F = \begin{pmatrix} F_x \\ F_y \\ F_z \end{pmatrix} &\mapsto \tfrac{\partial F_x}{\partial x} + \tfrac{\partial F_y}{\partial y} + \tfrac{\partial F_z}{\partial z}. \end{aligned}$$

It is straightforward to verify that $\operatorname{curl} \circ \operatorname{grad} = 0$ and $\operatorname{div} \circ \operatorname{curl} = 0$. Put another way, the following sequence of maps is in fact a chain complex:

$$0 \;\to\; C^\infty(U) \;\xrightarrow{\text{grad}}\; \mathcal{V}(U) \;\xrightarrow{\text{curl}}\; \mathcal{V}(U) \;\xrightarrow{\text{div}}\; C^\infty(U) \;\to\; 0.$$

Now we will relate the above discussion to forms. A smooth function is by definition the same as a differential 0-form. A smooth function also gives rise to a 3-form, more precisely we have the following simple-minded isomorphism

$$\begin{aligned} \Theta\colon C^\infty(U) &\to C^3_{\mathrm{dR}}(U) \\ f &\mapsto f \cdot dx \wedge dy \wedge dz. \end{aligned}$$

More interestingly, a smooth vector field gives rise to a differential 1-form on U and also a 2-form on U. More precisely we have the following maps

$$\begin{aligned} \Phi\colon \mathcal{V}(U) &\to C^1_{\mathrm{dR}}(U) \\ &\quad \text{differential 1-form that} \\ &\quad \text{at } x \text{ is given by} \\ w &\mapsto T_xU = \mathbb{R}^3 \to \mathbb{R} \\ &\qquad\qquad v \mapsto \underbrace{v \cdot w}_{\text{scalar product}} \end{aligned} \qquad \begin{aligned} \Psi\colon \mathcal{V}(U) &\to C^2_{\mathrm{dR}}(U) \\ &\quad \text{differential 2-form that} \\ &\quad \text{at } x \text{ is given by} \\ w &\mapsto (T_xU)^2 = (\mathbb{R}^3)^2 \to \mathbb{R} \\ &\qquad\qquad (v_1, v_2) \mapsto \underbrace{(v_1 \times v_2)}_{\text{cross product}} \cdot w. \end{aligned}$$

It is straightforward to see that these maps are well-defined and that they are isomorphisms.

Summarizing we obtain the following diagram:

$$\begin{tikzcd} 0 \arrow[r] & C^\infty(U) \arrow[r, "\text{grad}"] \arrow[d, "\cong", "\text{id}"'] & \mathcal{V}(U) \arrow[r, "\text{curl}"] \arrow[d, "\cong", "\Phi"'] & \mathcal{V}(U) \arrow[r, "\text{div}"] \arrow[d, "\cong", "\Psi"'] & C^\infty(U) \arrow[r] \arrow[d, "\cong", "\Theta"'] & 0 \\ 0 \arrow[r] & C^0_{\mathrm{dR}}(U) \arrow[r, "d"] & C^1_{\mathrm{dR}}(U) \arrow[r, "d"] & C^2_{\mathrm{dR}}(U) \arrow[r, "d"] & C^3_{\mathrm{dR}}(U) \arrow[r] & 0. \end{tikzcd}$$

A heroic calculation, see e.g. [Wein, Theorem 3.8], shows that the diagram commutes.

If U is star-shaped then we showed in the Poincaré Lemma 54.8 that the cohomology of the lower sequence vanishes for $k = 1, 2, 3$. Since the diagram commutes and since all vertical maps are isomorphisms we have thus proved the following classical theorem.

Theorem 54.10. *Let U be a star-shaped open subset of $\mathbb{R}^3$.*

(1) *Every smooth vector field on U with vanishing rotation is the gradient of a smooth function.*
(2) *Every smooth vector field on U with vanishing divergence is the rotation of a smooth vector field.*
(3) *Every smooth function on U is the divergence of a smooth vector field.*

54.6. **More properties of the de Rham cohomology groups.** In this section we will continue the theme from the Section 54.4 and we will prove two more statements regarding de Rham cohomology groups that we had already proved for singular cohomology groups.

One of the key tools in computing singular homology and cohomology groups are the Mayer–Vietoris Theorems 33.5 and 50.15. The following theorem is the de Rham cohomology version of these two theorems.

Theorem 54.11. (Mayer–Vietoris Theorem for de Rham cohomology groups *Let M be a manifold and let U, V be open subsets with $M = U \cup V$. Let $j_U \colon U \to M$, $j_V \colon V \to M$, $i_U \colon U \cap V \to U$ and $i_V \colon U \cap V \to V$ be the inclusion maps. Then the following two statements hold:*

(1) *The following sequence of cochain complexes is exact*

$$0 \;\to\; C^*_{\mathrm{dR}}(M) \;\xrightarrow{j_U^* \oplus -j_V^*}\; C^*_{\mathrm{dR}}(U) \oplus C^*_{\mathrm{dR}}(V) \;\xrightarrow{i_U^* + i_V^*}\; C^*_{\mathrm{dR}}(U \cap V) \;\to\; 0.$$

(2) *There exists a natural long exact sequence of the form*

$$\cdots \to H^k_{\mathrm{dR}}(M) \xrightarrow{j_U^* \oplus -j_V^*} H^k_{\mathrm{dR}}(U) \oplus H^k_{\mathrm{dR}}(V) \xrightarrow{i_U^* + i_V^*} H^k_{\mathrm{dR}}(U \cap V) \xrightarrow{\delta} H^{k+1}_{\mathrm{dR}}(M) \to \dots$$

In the proof of Theorem 54.11 we will require the following lemma.

Lemma 54.12. *Let W be a manifold, let $U \subset W$ be an open subset and let φ be a smooth form on U. We define*

$$\epsilon(\varphi, W) \;:=\; \textit{the form on } W \textit{ that is given by } \varphi \textit{ on } U \textit{ and that is zero on } W \setminus U.$$

If $\operatorname{supp}(\varphi) \subset U$, *then $\epsilon(\varphi, M)$ is a smooth form on W.*

FIGURE 707.

Proof. To show that a form μ on a manifold W is smooth it suffices to show that there exists an open covering $\{W_i\}_{i\in I}$ such that the restriction of μ to each W_i is smooth. In our case we consider the open covering of U given by U and by $W \setminus \operatorname{supp}(\varphi)$. Note that this is indeed a covering since $\operatorname{supp}(\varphi) \subset U$. The restriction of the form $\epsilon(\varphi, W)$ to U equals φ, hence it is smooth. The restriction of $\epsilon(\varphi, W)$ to $W \setminus \operatorname{supp}(\varphi)$ is also smooth since it is by definition identically zero on $W \setminus \operatorname{supp}(\varphi)$. □

Now we can provide the proof of Theorem 54.11.

Proof of Theorem 54.11. Not surprisingly we first prove statement (1). Since $M = U \cup V$ it is clear that the left-hand map $j_U^* \oplus -j_V^*$ is a monomorphism. It is obvious that the composition of the two maps is zero and that the image of the left-hand map $j_U^* \oplus -j_V^*$ is the kernel of $i_U^* + i_V^*$. It remains to prove the following claim.

Claim. The map $i_U^* + i_V^* \colon C^*_{\mathrm{dR}}(U) \oplus C^*_{\mathrm{dR}}(V) \to C^*_{\mathrm{dR}}(U \cap V)$ is in fact an epimorphism.

Let $\eta \in C^*_{\mathrm{dR}}(U \cap V)$. By Theorem 54.5 there exists a smooth partition of unity φ_U, φ_V that is subordinate to the open covering of M given by U and V. We refer to Figure 708 for an illustration.

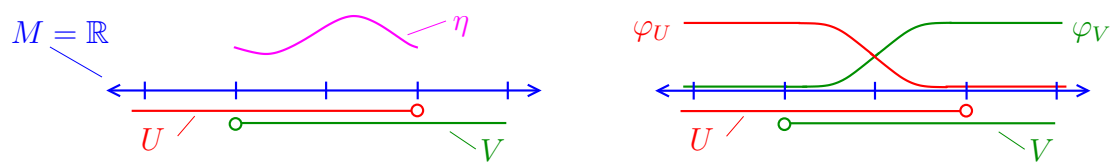

FIGURE 708.

We consider the forms $\epsilon(\eta\cdot\varphi_V, U)$ on U and $\epsilon(\eta\cdot\varphi_U, V)$. Both are smooth by Lemma 54.12. Now we have

$$(i_U^*+i_V^*)(\epsilon(\eta\cdot\varphi_V, U)+\epsilon(\eta\cdot\varphi_U, V)) \underset{\substack{\uparrow \\ \text{by definition of } i_U^* \text{ and } i_V^*}}{=} \epsilon(\eta\cdot\varphi_V, U)|_{U\cap V}+\epsilon(\eta\cdot\varphi_U, V)|_{U\cap V} \underset{\substack{\uparrow \\ \text{by definition of } \varphi_U \text{ and } \varphi_V}}{=} \eta\cdot\varphi_V + \eta\cdot\varphi_U \underset{\substack{\uparrow \\ \text{since } \varphi_U+\varphi_V \equiv 1}}{=} \eta.$$

This concludes the proof of the claim and thus also of statement (1).

The existence and naturality of the long exact sequence of statement (2) is an immediate consequence of statement (1) together with Proposition 48.6. □

Using the Mayer–Vietoris Theorem 54.11 for de Rham cohomology groups and some of our earlier results one can now compute many de Rham cohomology groups. The following lemma gives a sample calculation.

Lemma 54.13. *For any $n \geq 1$ we have*

$$H^k_{\mathrm{dR}}(S^n) \;\cong\; \begin{cases} \mathbb{R}, & \text{if } k = 0, n, \\ 0, & \text{otherwise.} \end{cases}$$

Proof. By induction we will prove the following statement: for any $n \geq 1$ we have

$$H^k_{\mathrm{dR}}(S^n) \;\cong\; \begin{cases} \mathbb{R}, & \text{if } k = 0, \\ 0, & \text{otherwise} \end{cases} \oplus \begin{cases} \mathbb{R}, & \text{if } k = n, \\ 0, & \text{otherwise.} \end{cases}$$

For $n = 0$ the statement holds by Proposition 54.4 (5) and the calculation of de Rham cohomology for a point that we gave on page 1276.

Given S^n with $n \geq 1$ we write

$$U := \{(x_1, \ldots, x_{n+1}) \in S^n \,|\, x_{n+1} \neq -1\} \quad \text{and } V = \{(x_1, \ldots, x_{n+1}) \in S^n \,|\, x_{n+1} \neq +1\}.$$

The stereographic projection that we defined in Lemma 1.41 gives diffeomorphisms from U and V to $\mathbb{R}^n$. We refer to Figure 709 for an illustration. In particular we know from Corollary 54.9 that

$$H^k_{\mathrm{dR}}(U) \;\cong\; H^k_{\mathrm{dR}}(V) \;\cong\; \begin{cases} \mathbb{R}, & \text{if } k = 0, \\ 0, & \text{otherwise.} \end{cases}$$

Using Proposition 54.6 it is also fairly straightforward to show that the inclusion map

$$\begin{aligned} \iota\colon S^{n-1} &\to U \cap V \\ P &\mapsto (P, 0) \end{aligned}$$

induces an isomorphism of de Rham cohomology groups.

Now we perform the induction step from $n = 0$ to $n = 1$. We consider the long exact Mayer–Vietoris sequence coming from Theorem 54.11 that corresponds to the decomposition $S^1 = U \cup V$:

$$0 \to \underbrace{H^0_{\mathrm{dR}}(S^1)}_{\cong\mathbb{R}} \to \underbrace{H^0_{\mathrm{dR}}(U)}_{\cong\mathbb{R}} \oplus \underbrace{H^0_{\mathrm{dR}}(V)}_{\cong\mathbb{R}} \to \underbrace{H^0_{\mathrm{dR}}(U \cap V)}_{\cong\mathbb{R}^2} \xrightarrow{\delta} H^1_{\mathrm{dR}}(S^1) \to \underbrace{H^1_{\mathrm{dR}}(U)}_{=0} \oplus \underbrace{H^1_{\mathrm{dR}}(V)}_{=0} \to \ldots$$

We recall that in Proposition 54.4 (3) we saw that inclusion induced maps between connected manifolds induce isomorphisms on 0-th de Rham cohomology. Using this observation and using the long exact sequence it is now straightforward to show that the de Rham cohomology of S^1 is precisely as predicted.[950]

The induction step for $n \geq 2$ from $n - 1$ to n is even easier, since one does not have to worry about 0-th de Rham cohomology. More precisely, for $k \geq 1$ the above Mayer–Vietoris sequence now looks as follows:

$$\begin{tikzcd} \ldots \arrow[r] & \underbrace{H^k_{\mathrm{dR}}(S^n)}_{\cong\mathbb{R}} \arrow[r] & \underbrace{H^k_{\mathrm{dR}}(U)}_{=0} \oplus \underbrace{H^k_{\mathrm{dR}}(V)}_{=0} \arrow[r] & H^k_{\mathrm{dR}}(U \cap V) \arrow[r, "\delta"] & H^{k+1}_{\mathrm{dR}}(S^n) \arrow[r] & \underbrace{H^{k+1}_{\mathrm{dR}}(U)}_{=0} \oplus \underbrace{H^{k+1}_{\mathrm{dR}}(V)}_{=0} \arrow[r] & \ldots \\ & & & H^k_{\mathrm{dR}}(S^{n-1}). \arrow[u, "\iota_*", "\cong"'] & & & \end{tikzcd}$$

It is now straightforward to prove the induction step. □

[950] Alternatively one can also use Lemma 40.4 to deduce that $H^1_{\mathrm{dR}}(S^1) \cong \mathbb{R}$.

FIGURE 709. Illustration for the proof of Lemma 54.13.

Using the calculation from Lemma 54.13 and the Mayer–Vietoris Theorem 54.11 for de Rham cohomology groups one can now fairly easily modify the arguments in Lemmas 33.9, 33.12 and 33.14 to compute the de Rham cohomology of the real projective plane $\mathbb{R}\mathrm{P}^2$, the torus $T = S^1 \times S^1$ and the Klein bottle K:

$$H^n_{\mathrm{dR}}(\mathbb{R}\mathrm{P}^2) \cong \begin{cases} 0, & \text{if } n \geq 1, \\ \mathbb{R}, & \text{if } n = 0 \end{cases} \quad H^n_{\mathrm{dR}}(T) \cong \begin{cases} \mathbb{R}, & \text{if } n = 0, 2, \\ \mathbb{R}^2, & \text{if } n = 1, \\ 0, & \text{otherwise} \end{cases} \quad H^n_{\mathrm{dR}}(K) \cong \begin{cases} \mathbb{R}, & \text{if } n = 0, \\ \mathbb{R}, & \text{if } n = 1, \\ 0, & \text{otherwise.} \end{cases}$$

We conclude this discussion of de Rham cohomology with the following proposition which is very similar in nature to Proposition 52.12 for singular cohomology.

Proposition 54.14. *Let M be a manifold and let $\{U_i\}_{i\in\mathbb{N}}$ be a sequence of open subsets of M that satisfy the following three conditions:*

(1) *for each $i \in \mathbb{N}$ the closure $\overline{U}_i$ of U_i is compact,*
(2) *for each $i \in \mathbb{N}$ we have $U_i \subset U_{i+1}$, and*
(3) $M = \bigcup_{i\in\mathbb{N}} U_i$.

Then for every $n \in \mathbb{N}_0$ there exists a natural short exact sequence

$$0 \;\to\; \varprojlim{}^1 H^{n-1}_{\mathrm{dR}}(U_i) \;\xrightarrow{\tau}\; H^n_{\mathrm{dR}}(M) \;\to\; \varprojlim H^n_{\mathrm{dR}}(U_i) \;\to\; 0$$

where the right-hand map is induced by the obvious maps $H^n_{\mathrm{dR}}(M) \to H^n_{\mathrm{dR}}(U_i)$.

Proof. For each $k \in \mathbb{N}_0$ we consider the inverse system

$$C^k_{\mathrm{dR}}(U_1) \;\leftarrow\; C^k_{\mathrm{dR}}(U_2) \;\leftarrow\; C^k_{\mathrm{dR}}(U_3) \;\leftarrow\; \dots$$

where all the maps are induced by the inclusion, put differently, they are all restriction maps.

Claim. The inverse system satisfies the Mittag-Leffler condition from page 1246.

Given any $j \geq i$ we denote by $\rho_{ji}\colon C^k_{\mathrm{dR}}(U_j) \to C^k_{\mathrm{dR}}(U_i)$ the restriction map. Now let $i \in \mathbb{N}$. We have to show that there exists an $n \geq i$ such that for all $r \geq n$ we have

$$\operatorname{im}\left\{\rho_{ri}\colon C^k_{\mathrm{dR}}(U_r) \to C^k_{\mathrm{dR}}(U_i)\right\} \;=\; \operatorname{im}\left\{\rho_{ni}\colon C^k_{\mathrm{dR}}(U_n) \to C^k_{\mathrm{dR}}(U_i)\right\}.$$

Since $\overline{U}_i$ is compact, since the U_j are nested and since $\overline{U}_i$ is contained in the union of all U_j there exists an n such that $\overline{U}_i \subset U_n$. We refer to Figure 710 for an illustration. We

claim that n has the desired property. So let $r \geq n$. We have to show that

$$\operatorname{im}\{\rho_{ri}\colon C^k_{\mathrm{dR}}(U_r) \to C^k_{\mathrm{dR}}(U_i)\} \;=\; \operatorname{im}\{\rho_{ni}\colon C^k_{\mathrm{dR}}(U_n) \to C^k_{\mathrm{dR}}(U_i)\}.$$

Clearly we have the inclusion "$\subset$". It remains to prove the reverse inclusion. So suppose $\eta \in C^k_{\mathrm{dR}}(U_i)$ is the restriction of some $\mu \in C^k_{\mathrm{dR}}(U_n)$. Note that U_n and $M \setminus \overline{U}_i$ form an open covering for M. It follows immediately from Theorem 54.5 that there exists a smooth function $\varphi\colon M \to \mathbb{R}$ with $\varphi|_{\overline{U}_i} \equiv 1$ and such that $\operatorname{supp}(\varphi) \subset U_n$. Let $r \geq n$. We see that

$$\eta \;=\; \mu|_{U_i} \;\underset{\substack{\uparrow \\ \text{since } \varphi \equiv 1 \text{ on } U_i}}{=}\; (\varphi \cdot \mu)|_{U_i} \;=\; \overbrace{\epsilon(\varphi \cdot \mu, U_r)}^{\text{smooth by Lemma 54.12}}\;|_{U_i}.$$

We have thus shown that η is also the restriction of some smooth form on U_r. This concludes the proof of the claim.

By the claim we can apply Proposition 52.10 to the inverse system $(\{C^*_{\mathrm{dR}}(U_i)\}_{i\in\mathbb{N}}, \{\rho_{ij}\}_{i\geq j})$ of cochain complexes over $\mathbb{N}$ and we obtain the short exact sequence

$$0 \;\to\; \varprojlim_{i\in\mathbb{N}}{}^{1} \underbrace{H^{n-1}(C^*_{\mathrm{dR}}(U_i))}_{=H^{n-1}_{\mathrm{dR}}(U_i)} \;\to\; \underbrace{H^n\Big(\overbrace{\varprojlim_{i\in\mathbb{N}} C^*_{\mathrm{dR}}(U_i)}^{=\,C^*_{\mathrm{dR}}(M),\ \text{see page 502}}\Big)}_{=H^n_{\mathrm{dR}}(M)} \;\to\; \varprojlim_{i\in\mathbb{N}} \underbrace{H^n(C^*_{\mathrm{dR}}(U_i))}_{=H^n_{\mathrm{dR}}(U_i)} \;\to\; 0.$$

We have thus obtained the desired short exact sequence. □

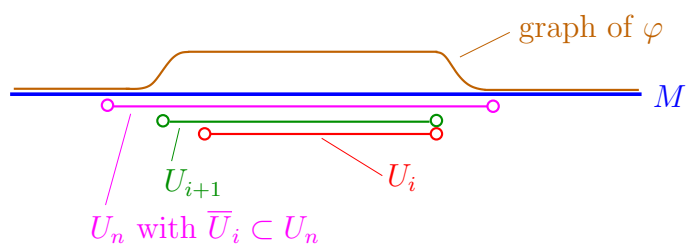

FIGURE 710. Illustration for the proof of Proposition 54.14.

Exercises for Chapter 54.

Exercise 54.1. Let Σ be the surface of genus 2 equipped with some orientation. Furthermore let $\gamma\colon S^1 \to \Sigma$ be an embedding. We write $C = \gamma(S^1)$ and we view C as an oriented curve on Σ. By the Tubular Neighborhood Theorem 10.19 we can pick a trivial tubular neighborhood $C \times [-2,2]$ for C. We denote by dt the usual differential 1-form on $[-2,2] \subset \mathbb{R}$. Let $f\colon [-2,2] \to \mathbb{R}_{\geq 0}$ be a smooth function with $\operatorname{supp}(f) \subset [-1,1]$ and

$\int_{t=0}^{t=1} f(t)\,dt = 1$. We denote by $p\colon C \times [-2,2] \to [-2,2]$ the projection. Finally denote by ω the smooth closed differential 1-form on Σ that is given by $p^*(f \cdot dt)$ on $C \times [-2,2]$ and that is extended to all of Σ by setting it zero outside of $C \times [-2,2]$. (Some of the objects are illustrated in Figure 711.)

Given a closed oriented curve $D \subset \Sigma$ we obtain the integral $\int_D \omega$.

(a) Show that the integral is an integer.
(b) What is the geometric interpretation of this integer?

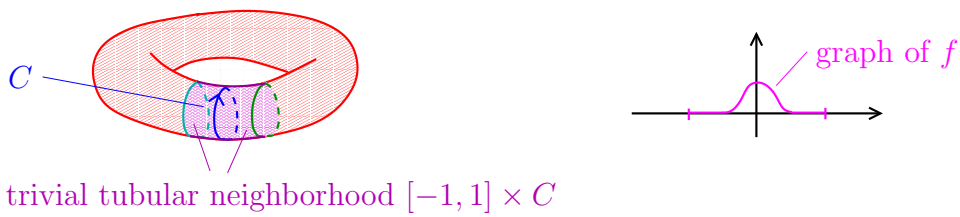

FIGURE 711.

Exercise 54.2. Let M be a manifold and let $\{U_i\}_{i\in\mathbb{N}}$ be a sequence of open subsets of M that satisfy the following three conditions:

(1) for each $i \in \mathbb{N}$ the closure $\overline{U}_i$ of U_i is compact,
(2) for each $i \in \mathbb{N}$ we have $U_i \subset U_{i+1}$, and
(3) $M = \bigcup_{i\in\mathbb{N}} U_i$.

In the proof of Proposition 54.14 we show that for each $k \in \mathbb{N}_0$ the inverse system

$$C^k_{\mathrm{dR}}(U_1) \;\leftarrow\; C^k_{\mathrm{dR}}(U_2) \;\leftarrow\; C^k_{\mathrm{dR}}(U_2) \;\leftarrow\; \dots$$

satisfies the Mittag-Leffler condition. Now let $i \in \mathbb{N}$. Does there exist an $n \geq i$ such that for all $r \geq n$ the map

$$C^k_{\mathrm{dR}}(U_r) \;\to\; C^k_{\mathrm{dR}}(U_i)$$

is an epimorphism?

55. The relationship between de Rham cohomology and singular cohomology

In this chapter we want to find the connection between the de Rham cohomology groups from the previous chapter and the singular cohomology groups that we defined earlier in Chapter 48.

To avoid a repetitive use of suffixes we will use the following convention.

Convention. In this chapter by a "manifold" we always mean a manifold *without boundary*, unless we say explicitly otherwise.

55.1. **Smooth cohomology theories.** To a manifold M we can associate the singular cohomology groups $H^i(M;\mathbb{R})$ and also the de Rham cohomology groups $H^i_{\mathrm{dR}}(M)$. In the last chapter we had in particular seen that these two cohomologies have many properties in common, for example they both satisfy a Mayer–Vietoris type theorem. Now we want to put both cohomologies in a common framework.

Definition. A *smooth cohomology theory* is a contravariant functor[951952]

$$\begin{array}{rcl} \mathcal{H}^*\colon \text{category of manifolds} & \to & \text{category of } \mathbb{N}_0\text{-graded real vector spaces} \\ M & \mapsto & \mathcal{H}^*(M) = \bigoplus\limits_{n\in\mathbb{N}_0} \mathcal{H}^n(M) \\ (f\colon M\to N) & \mapsto & \{f^* = \mathcal{H}^n(f)\colon \mathcal{H}^n(N)\to\mathcal{H}^n(M)\}_{n\in\mathbb{N}_0} \end{array}$$

that satisfies the following three axioms:

(1) (Smooth homotopy invariance) Let $f,g\colon M\to N$ be smooth maps between manifolds. If f and g are smoothly homotopic, then for all $n\in\mathbb{N}_0$ we have
$$\mathcal{H}^n(f) = \mathcal{H}^n(g)\colon \mathcal{H}^n(N) \;\to\; \mathcal{H}^n(M).$$

(2) (Mayer–Vietoris sequence) If M is a manifold and U and V are open subsets such that $M = U\cup V$, then there exists a natural long exact sequence of the form
$$\ldots \to \mathcal{H}^k(M) \xrightarrow{j_U^*\oplus -j_V^*} \mathcal{H}^k(U)\oplus\mathcal{H}^k(V) \xrightarrow{i_U^*+i_V^*} \mathcal{H}^k(U\cap V) \xrightarrow{\delta} \mathcal{H}^{k+1}(M) \to \ldots$$
where $j_U\colon U\to M$, $j_V\colon V\to M$, $i_U\colon U\cap V\to U$ and $i_V\colon U\cap V\to V$ denote the inclusion maps.

(3) (Limit property) Let M be a manifold and let $\{U_i\}_{i\in\mathbb{N}}$ be a sequence of open subsets that satisfy the following three conditions:
   (a) for each $i\in\mathbb{N}$ the closure $\overline{U}_i$ of U_i is compact,
   (b) for each $i\in\mathbb{N}$ we have $U_i\subset U_{i+1}$, and
   (c) $M = \bigcup\limits_{i\in\mathbb{N}} U_i$.

---

[951] Given a smooth map $f\colon M\to N$ the contravariant functor provides for each $n\in\mathbb{N}_0$ a morphism $\mathcal{H}^n(f)\colon \mathcal{H}^n(N)\to\mathcal{H}^n(M)$. As usual, when there is no danger of confusion we just write f^* instead of $\mathcal{H}^n(f)$.

[952] We refer to page 1037 for the definition of the category of $\mathbb{N}_0$-graded real vector spaces.

Then for every $n \in \mathbb{N}_0$ there exists a natural short exact sequence

$$0 \;\to\; \varprojlim{}^1 \mathcal{H}^{n-1}(U_i) \;\xrightarrow{\tau}\; \mathcal{H}^n(M) \;\to\; \varprojlim \mathcal{H}^n(U_i) \;\to\; 0$$

where the right-hand map is induced by the maps $\mathcal{H}^n(M) \to \mathcal{H}^n(U_i)$ which in turn are induced by the inclusions $U_i \to M$.

This time it is easy to give examples for our new definition.

Proposition 55.1.

(1) *Singular cohomology with real coefficients is a smooth cohomology theory.*
(2) *De Rham cohomology is a smooth cohomology theory.*

Proof.

(1) It follows from Lemma 48.13, Theorem 50.15, together with Proposition 50.12 and Proposition 52.12 (1), that singular cohomology with real coefficients is a smooth cohomology theory.
(2) It follows from Proposition 54.6, Theorem 54.11 and Proposition 54.14 that de Rham cohomology is a smooth cohomology theory. □

One might now be optimistic and hope that smooth cohomology theories are necessarily isomorphic. As it stands this thought though is too optimistic. For example other smooth cohomology theories are given by $\mathcal{H}^n(M) = 0$ for all $n \in \mathbb{N}_0$ or by $\mathcal{H}^n(M) = H^{n+5}(M;\mathbb{R})$ or by $\mathcal{H}^n(M) = H^n(M;\mathbb{R}) \oplus H^n(M;\mathbb{R})$. This shows that if we want to prove that smooth cohomology theories are isomorphic we have to add some extra hypotheses, for example we could demand that the 0-th cohomology groups of a point are isomorphic.

Notation. In the following $\star$ denotes the topological space consisting of a single point. Evidently $\star$ is a 0-dimensional manifold.

On page 251 we introduced the notion of a natural transformation between two *covariant* functors. Almost the same definition can also be applied to contravariant functors. For completeness' sake we write down the formal definition.

Definition. Let $\mathcal{C}$ and $\mathcal{D}$ be two categories and let $F, G\colon \mathcal{C} \to \mathcal{D}$ be two contravariant functors. A *natural transformation between the contravariant functors F and G* assigns to each object $X \in \mathrm{Ob}(\mathcal{C})$ a morphism $\Phi_X\colon F(X) \to G(X)$ in $\mathcal{D}$ such that for each morphism $f\colon X \to Y$ in $\mathcal{C}$ the following diagram commutes:

$$\begin{tikzcd} F(Y) \arrow[r, "F^*(f)"] \arrow[d, "\Phi_Y"'] & F(X) \arrow[d, "\Phi_X"] \\ G(Y) \arrow[r, "G^*(f)"] & G(X). \end{tikzcd}$$

If all the maps Φ_X are isomorphisms we also say it is a *natural isomorphism.*

Example. Given $n \in \mathbb{N}_0$ we consider the two contravariant functors $X \mapsto H^n(X;\mathbb{Z})$ and $X \mapsto \mathrm{Hom}(H_n(X),\mathbb{Z})$ from the category of topological spaces to the category of abelian groups. It follows from the discussion on page 1220 that the evaluation homomorphisms $\mathrm{ev}\colon H^n(X;\mathbb{Z}) \to \mathrm{Hom}(H_n(X),\mathbb{Z})$ define a natural transformation between the two contravariant functors, i.e. given any map $f\colon X \to Y$ between topological spaces the following diagram commutes:

$$\begin{tikzcd} H^n(Y;\mathbb{Z}) \arrow[r, "f^*"] \arrow[d, "\mathrm{ev}"'] & H^n(X;\mathbb{Z}) \arrow[d, "\mathrm{ev}"] \\ \mathrm{Hom}(H_n(Y),\mathbb{Z}) \arrow[r, "f^*"] & \mathrm{Hom}(H_n(X),\mathbb{Z}). \end{tikzcd}$$

With this notation and this definition we can now formulate the following theorem.

Theorem 55.2. *Let $\mathcal{H}^*$ and $\mathcal{K}^*$ be smooth cohomology theories and let $t\colon \mathcal{H}^* \to \mathcal{K}^*$ be a natural transformation. Suppose t has the following three properties:*

(i) *the natural transformation t is compatible with the connecting homomorphism in the Mayer-Vietoris sequence, i.e. with the obvious notation we always have a commutative diagram*

$$\begin{tikzcd} \dots \arrow[r] & \mathcal{H}^n(M) \arrow[r, "j_U^*\oplus -j_V^*"] \arrow[d, "t"] & \mathcal{H}^n(U)\oplus\mathcal{H}^n(V) \arrow[r, "i_U^*+i_V^*"] \arrow[d, "t\oplus t"] & \mathcal{H}^n(U\cap V) \arrow[r, "\delta"] \arrow[d, "t"] & \mathcal{H}^{n+1}(M) \arrow[r] \arrow[d, "t"] & \dots \\ \dots \arrow[r] & \mathcal{K}^n(M) \arrow[r, "j_U^*\oplus -j_V^*"] & \mathcal{K}^n(U)\oplus\mathcal{K}^n(V) \arrow[r, "i_U^*+i_V^*"] & \mathcal{K}^n(U\cap V) \arrow[r, "\delta"] & \mathcal{K}^{n+1}(M) \arrow[r] & \dots \end{tikzcd}$$

(ii) *the natural transformation t is compatible with the map τ appearing in the limit property, i.e. with the obvious notation we always have a commutative diagram*[953]

$$\begin{tikzcd} 0 \arrow[r] & \varprojlim^1 \mathcal{H}^{n-1}(U_i) \arrow[r, "\tau"] \arrow[d, "t"] & \mathcal{H}^n(M) \arrow[r] \arrow[d, "t"] & \varprojlim \mathcal{H}^n(U_i) \arrow[r] \arrow[d, "t"] & 0 \\ 0 \arrow[r] & \varprojlim^1 \mathcal{K}^{n-1}(U_i) \arrow[r, "\tau"] & \mathcal{K}^n(M) \arrow[r] & \varprojlim \mathcal{K}^n(U_i) \arrow[r] & 0, \end{tikzcd}$$

(iii) *for all $n \in \mathbb{N}_0$ the map $t^n(\star)\colon \mathcal{H}^n(\star) \to \mathcal{K}^n(\star)$ is an isomorphism.*

Then for every manifold M and every $n \in \mathbb{N}_0$ the map

$$t\colon \mathcal{H}^n(M) \;\to\; \mathcal{K}^n(M)$$

is an isomorphism.

Proof. Let $\mathcal{H}^*$ and $\mathcal{K}^*$ be smooth cohomology theories, which means they both satisfy

(α) smooth homotopy invariance,
(β) the Mayer-Vietoris sequence,
(γ) the limit property.

[953]Note that the left and right vertical maps are given by the remark on page 1248.

Furthermore let $t\colon \mathcal{H}^* \to \mathcal{K}^*$ be a natural transformation that has the above properties (i), (ii) and (iii). We need to prove the following statement:

Statement. Let $m \in \mathbb{N}_0$. For every m-dimensional manifold M and every $n \in \mathbb{N}_0$ the map

$$t^n(M)\colon \mathcal{H}^n(M) \ \to \ \mathcal{K}^n(M)$$

is an isomorphism.

We start out with the following two observations:

(A) Suppose M is an m-dimensional manifold and U and V are open subsets with $M = U \cup V$. If all t^n are isomorphisms for U, V and $U \cap V$, then it follows from (β), (i) and the Five Lemma 31.11 that all the t^n are also isomorphisms for M.

(B) Let M be an m-dimensional manifold and let $\{U_i\}_{i\in\mathbb{N}}$ be a sequence of open subsets that satisfy the following three conditions:
   (a) for each $i \in \mathbb{N}$ the closure $\overline{U}_i$ of U_i is compact,
   (b) for each $i \in \mathbb{N}$ we have $U_i \subset U_{i+1}$, and
   (c) $M = \bigcup\limits_{i\in\mathbb{N}} U_i$.

   If all the t^n are isomorphisms for all U_i, then it follows from (γ) and the Five Lemma 31.11 that all the t^n are also isomorphisms for M.

After these preparations we will prove the statement in four surprisingly easy steps:

(1) Let M be an open convex subset of $\mathbb{R}^m$. We pick an inclusion $f\colon \star \to M$. As in the proof of the Poincaré Lemma 54.8 we see that f is a smooth homotopy equivalence. Given $n \in \mathbb{N}_0$ we consider the diagram

$$\begin{array}{ccc} \mathcal{H}^n(M) & \xrightarrow{f^*} & \mathcal{H}^n(\star) \\ {\scriptstyle t}\downarrow & & \cong\downarrow{\scriptstyle t} \\ \mathcal{K}^n(M) & \xrightarrow{f^*} & \mathcal{K}^n(\star). \end{array}$$

The diagram commutes since t is a natural transformation. It follows easily from (α) that the horizontal maps are isomorphisms. By (iii) the right vertical map is also an isomorphism. It follows that the left vertical map is, as desired, an isomorphism

(2) We claim that t is an isomorphism for every subset M of $\mathbb{R}^m$ that is the union of k open convex subsets of $\mathbb{R}^m$. We prove this by induction on the number k of open convex subsets:
   (a) If $k = 1$, then M itself is an open convex subset of $\mathbb{R}^m$, hence the statement follows from (1).
   (b) Suppose the statement holds whenever M is the union of $k-1$ open convex subsets. Now let M be the union of k open convex subsets $U_1, \dots, U_k$. We write $V = U_1 \cup \dots \cup U_{k-1}$. By induction the statement holds for V and also for U_k. Furthermore since the intersection of two convex open subsets is again convex and open we see that $V \cap U_k = (U_1 \cap U_k) \cup \dots \cup (U_{k-1} \cap U_k)$ is the union

of $k-1$ open convex subsets, i.e. by induction the statement holds for $V \cap U_k$. But then it follows from (A) that the statement also holds for U.

(3) Let M be an open subset of $\mathbb{R}^m$. By Lemma 1.9 we can write M as the union of countably many open balls $B_i, i \in \mathbb{N}$. For $i \in \mathbb{N}$ we define $U_i := \bigcup_{j \le i} B_j$. By (2) the statement holds for each U_i, but then it follows from (B) that the statement holds for M.

(4) Finally let M be any m-dimensional manifold. We say a subset W of M is *small* if it is open, if $\overline{W}$ is compact and if W is contained in the domain of some chart for M. We make the following observations:
   (a) Since $\mathcal{H}$ and $\mathcal{K}$ are diffeomorphism invariants we obtain from (2) that the statement holds for every small subset of W (viewed as a manifold in its own right).
   (b) The same induction argument as in (2) shows that the statement holds for finite unions of small subsets (here the key observation is that the intersection of two small subsets is again small).[954]
   (c) Finally it follows easily from the fact that the manifold M is second-countable, the existence of charts around every point and Lemma 1.26 that there exist small sets $W_i, i \in \mathbb{N}$ which cover M. As in (3) we consider $U_i := \bigcup_{j \le i} W_j$. We had just seen in (b) that the statement holds for all the U_i. But then it follows from (B) that the statement holds for M. □

55.2. **Smooth singular cohomology.** One might think that it follows immediately from Proposition 55.1 and Theorem 55.2 (together with the calculations of the cohomology groups of a point in Lemma 48.12 and on page 1276) that the singular real valued cohomology and the de Rham cohomology groups of manifolds are always isomorphic.

But recall that to apply Theorem 55.2 we need to find a natural transformation

$$t\colon \text{de Rham cohomology} \quad \to \quad \text{real valued singular cohomology}$$

that has the property that

$$H^n_{\mathrm{dR}}(\star) \quad \xrightarrow{\cong} \quad H^n(\star;\mathbb{R}) \qquad \text{for all } n \in \mathbb{N}_0.$$

Here is an idea: on page 1272 we had mentioned that given a compact oriented n-dimensional manifold W and a smooth differential n-form ω on W there exists an

$$\int_W \omega \ \in \ \mathbb{R}$$

[954]Here we implicitly use the following statement: if A and B are subsets of M such that $\overline{A}$ and $\overline{B}$ are compact, then $\overline{A \cap B}$ and $\overline{A \cup B}$ are also compact. We will prove this statement in Exercise 55.2.

that has many good properties. So given some manifold M (with no restrictions on the dimension) we could try to define a map

$$\begin{array}{rcl} t\colon C^n_{\mathrm{dR}}(M) & \to & \mathrm{Hom}(C_n(M);\mathbb{R}) \\ \omega & \mapsto & \left(\begin{array}{ccc} C_n(M) & \to & \mathbb{R} \\ \sum\limits_{i=1}^k a_i\cdot(f_i\colon \Delta^n\to M) & \mapsto & \sum\limits_{i=1}^k a_i\cdot\int\limits_{\Delta^n} f_i^*\omega \end{array}\right). \end{array}$$

Unfortunately, there are several problems with this "definition":

(1) The first question that arises is the following: what does it mean to integrate a form over Δ^n? After all, it is not clear in what sense Δ^n is a manifold. With some luck that should not be too much of an issue, since Δ^n is clearly pretty close to being a manifold.
(2) Let us suppose that we have resolved (1). Now let $f\colon \Delta^n \to M$ be a singular n-chain. If the map f is not smooth, then $f^*\omega$ just does not make any sense.[955]
(3) After fixing the previous issues, why should t be a cochain map?

Arguably the most serious issue is (2). The only way around it is to only work with smooth singular simplices. This immediately leads us to the following definition:

Definition. Let $n \in \mathbb{N}_0$.

(1) We write
$$\widetilde{\Delta}^n \;:=\; \Big\{(t_1,\dots,t_n)\in\mathbb{R}^n_{\geq 0}\;\Big|\;\sum_{i=1}^n t_i\in[0,1]\Big\}.$$
(2) We denote by Θ_n the homeomorphism[956]
$$\begin{array}{rcl} \Theta_n\colon \widetilde{\Delta}^n & \to & \Delta^n \\ (t_1,\dots,t_n) & \mapsto & \Big(t_1,\dots,t_n,1-\sum\limits_{i=1}^n t_i\Big). \end{array}$$

FIGURE 712.

Now let M be a manifold.

[955]Recall that if $f\colon N\to M$ is a smooth map between manifolds and ω is a smooth differential n-form on M, then $f^*\omega$ is defined to be the differential n-form that for $v_1,\dots,v_n\in T_PN$ has the value
$$(f^*\omega)_P(v_1,\dots,v_n) \;=\; \omega_{f(P)}(Df_P(v_1),\dots,Df_P(v_n)).$$
But if f is not differentiable, then there is no differential $Df_P\colon T_PN\to T_{f(P)}M$.

[956]Put differently, Θ_n is the inverse of the obvious projecton map $\Delta^n\to\widetilde{\Delta}^n$.

(3) Recall that by the definition on page 184 a map $f\colon \widetilde{\Delta}^n \to M$ is *smooth* if given any $a \in \widetilde{\Delta}^n$ there exists an open neighborhood U in $\mathbb{R}^n$ of a and a smooth map $\widetilde{f}\colon U \to M$ which coincides with f on A. We define the differential of f at $a \in \widetilde{\Delta}^n$ to be the differential of $\widetilde{f}$.[957]

(4) We say a singular n-simplex $\sigma\colon \Delta^n \to M$ is *smooth* if the map $\sigma \circ \Theta_n\colon \widetilde{\Delta}^n \to M$ is smooth. We illustrate the definition in Figure 713.

(5) We write

$$C_n^{\text{smooth}}(M) \;=\; \begin{array}{c}\text{the free abelian group generated by the}\\ \text{set of smooth singular } n\text{-simplices in } M.\end{array}$$

This is a subgroup of $C_n(M)$ and it is straightforward to verify that the boundary map $\partial_n\colon C_n(M) \to C_{n-1}(M)$ restricts to a map $\partial_n\colon C_n^{\text{smooth}}(M) \to C_{n-1}^{\text{smooth}}(M)$.

(6) Given an abelian group G we write

$$C^n_{\text{smooth}}(M;G) \;:=\; \operatorname{Hom}\big(C_n^{\text{smooth}}(M), G\big)$$

and we define $\delta_n\colon C^n_{\text{smooth}}(M;G) \to C^{n+1}_{\text{smooth}}(M;G)$ as the map $\delta_n := \partial^*_{n+1}$.

(7) We define the *n-th smooth singular cohomology group of a manifold M with G-coefficients* as

$$H^n_{\text{smooth}}(M;G) \;:=\; \frac{\ker\big\{\delta_n\colon C^n_{\text{smooth}}(M;G) \;\to\; C^{n+1}_{\text{smooth}}(M;G)\big\}}{\operatorname{im}\big\{\delta_{n-1}\colon C^{n-1}_{\text{smooth}}(M;G) \;\to\; C^n_{\text{smooth}}(M;G)\big\}}.$$

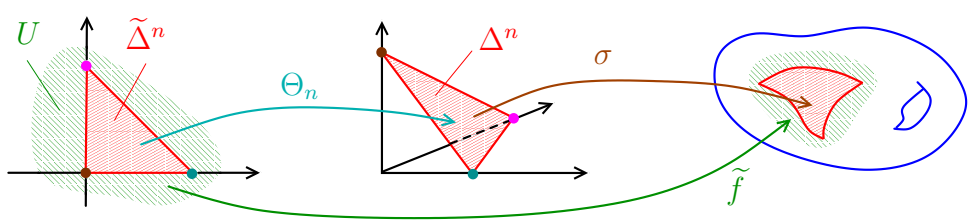

FIGURE 713.

Remark.

(1) Let $f\colon M \to N$ be a *smooth* map between two manifolds. Evidently the induced map $f_*\colon C^n(M) \to C^n(N)$ restricts to a map $f_*\colon C_n^{\text{smooth}}(M) \to C_n^{\text{smooth}}(N)$. In particular we get an induced map $f^*\colon C^n_{\text{smooth}}(N,G) \to C^n_{\text{smooth}}(M,G)$. Thus we obtain for each $n \in \mathbb{N}_0$ an induced map

$$f^*\colon H^n_{\text{smooth}}(N;G) \;\to\; H^n_{\text{smooth}}(M;G).$$

(2) Every map $\Delta^n \to \star$ is smooth, so there is no difference between ordinary singular cohomology and smooth singular cohomology for manifold $\star$.

[957] It is straightforward to verify that this definition does not depend on the choice of U and $\widetilde{f}$.

Proposition 55.3. *Smooth singular cohomology with real coefficients is a smooth cohomology theory.*

Sketch of proof. We need to verify that smooth singular cohomology with real coefficients satisfies the properties of a smooth cohomology theory.

(0) It is clear that smooth singular cohomology with real coefficients is a contravariant functor from the category of manifolds to the category of $\mathbb{N}_0$-graded real vector spaces.

(1) Suppose $f, g\colon M \to N$ are two smooth maps between two manifolds and suppose we are given a *smooth* homotopy F between f and g. Some thought shows that the chain homotopy

$$P_n\colon C_n(M) \;\to\; C_{n+1}(N), \quad n \in \mathbb{N}_0$$

from the proof of Proposition 30.5 restricts to a chain homotopy

$$C_n^{\text{smooth}}(M) \;\to\; C_{n+1}^{\text{smooth}}(N), \quad n \in \mathbb{N}_0.$$

Now we can once again appeal to Lemma 48.8 to conclude that the induced maps on smooth singular cohomology are the same.

(2) Let M be a manifold and let U and V be open subsets with $M = U \cup V$. The key to proving the existence of the Mayer–Vietoris sequence for ordinary singular cohomology was to show that the inclusion map

$$C_*^{\{U,V\}}(M) \;\to\; C_*(M)$$

is a chain homotopy equivalence. This in turn we showed using Proposition 31.21. In the proof of Proposition 31.21 we introduced the subdivision maps

$$u_n\colon C_n(M) \;\to\; C_n(M), \quad n \in \mathbb{N}_0.$$

It follows immediately from the definitions that these maps restrict to maps

$$u_n\colon C_n^{\text{smooth}}(M) \;\to\; C_n^{\text{smooth}}(M), \quad n \in \mathbb{N}_0.$$

Using this observation the proof of the existence of a Mayer–Vietoris sequence for smooth singular cohomology is otherwise identical to the proof for ordinary singular cohomology.

(3) The limit property is proved the same way as Proposition 52.12 (1). We only have to replace the fact, proved in Lemma 34.5 that $C_*(M) = \varinjlim C_*(U_i)$ by the observation that the same argument as in Lemma 34.5 shows that $C_*^{\text{smooth}}(M) = \varinjlim C_*^{\text{smooth}}(U_i)$.

□

Now we can easily show that smooth singular cohomology with real coefficients and ordinary singular cohomology with real coefficients are naturally isomorphic. More precisely, we have the following proposition.

Proposition 55.4. *There exists a natural isomorphism from smooth singular cohomology with real coefficients to ordinary singular cohomology with real coefficients. In particular*

for any manifold M and any $n \in \mathbb{N}_0$ we have a natural isomorphism

$$H^n(M;\mathbb{R}) \xrightarrow{\cong} H^n_{\text{smooth}}(M;\mathbb{R}).$$

Proof. For any manifold M we have the natural inclusion

$$C_*^{\text{smooth}}(M) \to C_*(M)$$

which evidently respects the boundary maps. These maps thus give rise to natural maps

$$C^*(M;\mathbb{R}) \to C^*_{\text{smooth}}(M;\mathbb{R})$$

which respect the coboundary maps. Thus we obtain a natural map

$$t(M)\colon H^*(M;\mathbb{R}) \to H^*_{\text{smooth}}(M;\mathbb{R}).$$

As we pointed out above, for $\star$ there is no difference between smooth and ordinary singular cohomology, i.e.

$$t(\star)\colon H^*(\star;\mathbb{R}) \to H^*_{\text{smooth}}(\star;\mathbb{R})$$

is an isomorphism. Since the natural transformation is induced by the inclusion map it follows easily that the natural transformation is compatible with the connecting homomorphism in the Mayer-Vietoris sequence and that it is compatible with the map τ appearing in the limit property. The proposition now follows immediately from Theorem 55.2. □

Now we also want to relate smooth singular cohomology to de Rham cohomology. The key for doing so is the following definition and the subsequent lemma.

Definition. Given a manifold M, given a smooth differential n-form ω on M and a smooth singular n-simplex $\sigma\colon \Delta^n \to M$ we define[958][959]

$$\int_\sigma \omega := (-1)^n \cdot \int_{\widetilde{\Delta}^n} (\sigma\circ\Theta_n)^*(\omega) := (-1)^n \cdot \int_{x\in\widetilde{\Delta}^n} \underbrace{\omega_{(\sigma\circ\Theta_n)(x)}(D(\sigma\circ\Theta_n)_x(e_1),\ldots,D(\sigma\circ\Theta_n)_x(e_n))}_{\text{continuous function in } x}.$$

We extend this definition linearly to define the integral of the smooth differential n-form ω over a smooth singular n-chain $\sum_{i=1}^k a_i \circ \sigma_i$.

Lemma 55.5. *Let M be a manifold, let ω be a smooth $(n-1)$-form and let $\sigma\colon \Delta^n \to M$ be a smooth singular n-simplex. Then*[960]

$$\int_\sigma d\omega = \int_{\partial\sigma} \omega.$$

[958]The Lebesgue integral is defined since $\widetilde{\Delta}^n$ is a compact subset of $\mathbb{R}^n$ and since the integrand is continuous.

[959]Recall that on page 935 we had equipped $\mathring{\Delta}^n$ with an orientation. The factor $(-1)^n$ is motivated by the fact that the restriction of the map $\Theta_n\colon \widetilde{\Delta}^n \to \Delta^n$ to the interiors is orientation-preserving if and only if n is even.

[960]Note that on the left we integrate a smooth differential n-form over a smooth singular n-simplex and that on the right we integrate a smooth $(n-1)$-form over a smooth singular $(n-1)$-chain.

In the following we provide a sketch of the proof of Lemma 55.5. A detailed proof is given in [War, p. 147].

Sketch of the proof. The idea of the proof is of course to use Stokes' Theorem 54.3. The fact that Δ^n, or equivalently $\widetilde{\Delta}^n$ are not manifolds in an obvious way is a slight nuisance. Here is one way how we can circumvent this problem. In [Le2, Chapter 16] or alternatively [Wall2, p. 30] the theory of manifolds with corner is developed. Prime examples are cubes $[0,1]^n$, half-balls $\{(x_1,\dots,x_n)\in \overline{B}^n \mid x_n \geq 0\}$ and most interestingly for us, the standard n-simplex Δ^n and equivalently also $\widetilde{\Delta}^n$. Furthermore there is a version of Stokes' Theorem 54.3 for manifolds with corner, see [Le2, Theorem 16.25].

In the following we provide the proof of Lemma 55.5 with an intuitive understanding of the concepts. All arguments can be made rigorous using the techniques developed in [Le2, Chapter 16].

Let M be a manifold, let ω be a smooth $(n-1)$-form and let $\sigma\colon \Delta^n \to M$ be a smooth singular n-simplex. Then

$$\int_\sigma d\omega \underset{\substack{\uparrow\\ \text{by definition}}}{=} (-1)^n\cdot\int_{\widetilde{\Delta}^n}(\sigma\circ\Theta)^*(d\omega) \underset{\substack{\uparrow\\ \text{Proposition 54.2 (4)}}}{=} (-1)^n\cdot\int_{\widetilde{\Delta}^n} d(\sigma\circ\Theta)^*(\omega) \underset{\substack{\uparrow\\ \text{Stokes Theorem for manifolds}\\ \text{with corner applied to } \widetilde{\Delta}^n}}{=} (-1)^n\cdot\int_{\partial\widetilde{\Delta}^n}(\sigma\circ\Theta_n)^*(\omega)$$

$$\underset{\substack{\uparrow\\ \text{since } \Theta_n^{-1}\circ i_j^n\circ\Theta_{n-1}\colon \widetilde{\Delta}^{n-1}\to\partial\widetilde{\Delta}^n \text{ is}\\ \text{orientation-reversing if and only if } j \text{ is even}\\ \text{(here we use Proposition 54.2 (1))}}}{=} \sum_{j=0}^n(-1)^j\cdot\int_{\widetilde{\Delta}^{n-1}}(-1)^{n-1}\cdot(\sigma\circ i_j^n\circ\Theta_{n-1})^*(\omega) \underset{\substack{\uparrow\\ \text{by definition of the integral}\\ \text{of a smooth } (n-1)\text{-form over a}\\ \text{smooth singular } (n-1)\text{-simplex}}}{=} \sum_{j=0}^n(-1)^j\cdot\int_{\sigma\circ i_j^n}\omega \underset{\substack{\uparrow\\ \text{by definition of } \partial\sigma}}{=} \int_{\partial\sigma}\omega.$$

We refer to Figure 714 for an illustration of the proof. □

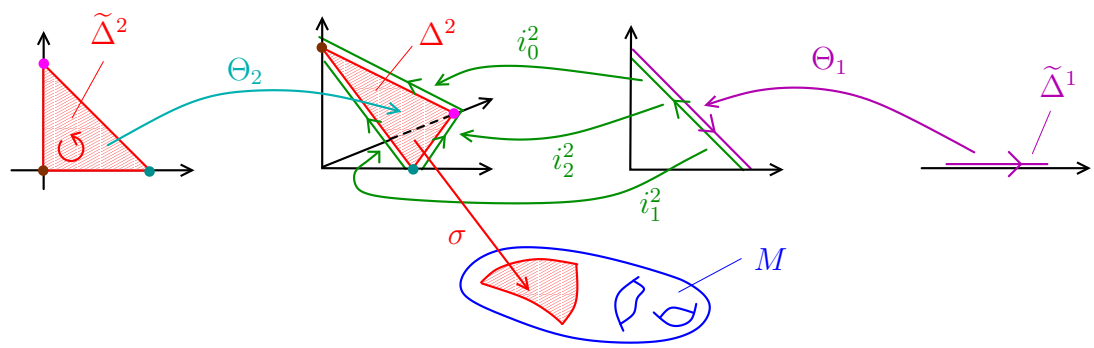

FIGURE 714. Illustration for the proof of Lemma 55.5.

55.3. **The isomorphism between singular and de Rham cohomology.** After the preparations in the previous sections we can now easily prove the theorem that we had been aiming for.

Theorem 55.6. (De Rham Theorem) *There exists a natural isomorphism u from de Rham cohomology to singular cohomology with real coefficients. In particular for any manifold M and any $k \in \mathbb{N}_0$ we have a natural isomorphism*

$$u\colon H^k_{\mathrm{dR}}(M;\mathbb{R}) \xrightarrow{\cong} H^k(M;\mathbb{R})$$

which has the property that for any closed differential k-form ω and any smooth singular k-chain σ that is a cycle we have

$$\langle \underbrace{u([\omega])}_{\in H^k(M;\mathbb{R})}, \underbrace{[\sigma]}_{\in H_k(M;\mathbb{Z})} \rangle_M = \int_\sigma \omega.$$

(*Here we stress, that according to the convention from page 1289 it is understood that the manifolds have empty boundary.*)

Remark.

(1) Let M be a closed oriented n-dimensional manifold and let $\omega \in \Omega_n(M)$ be an differential n-form. It follows quite easily from Proposition 39.3, the proof of Proposition 39.7, Lemma 46.7 and Theorem 55.6 that

$$\langle u([\omega]), [M]\rangle_M = \int_M \omega.$$

(2) A rather different proof for Theorem 55.6 is given in [War, p. 205] and [Ram, Chapte 4.6]. More precisely, in [War, Ram] the equivalence of de Rham cohomology and real valued singular cohomology is proved by relating both to another type of cohomology theory, namely sheaf cohomology. We also refer to [BT, Theorems 8.9 and 15.8] and [Dup, Theorem 1.15] for other proofs.

Proof. We denote by s the natural isomorphism from real-valued singular cohomology to real-valued smooth singular cohomology that we had constructed in the proof of Proposition 55.4.

Now we construct a natural isomorphism t from de Rham cohomology to real-valued smooth singular cohomology. For any manifold M and any $k \in \mathbb{N}_0$ we have, by the above discussion, a map

$$\begin{array}{rcl} C^k_{\mathrm{dR}}(M) & \to & C^k_{\mathrm{smooth}}(M;\mathbb{R}) \\ \omega & \mapsto & \left(\begin{array}{rcl} C^{\mathrm{smooth}}_k(M) & \to & \mathbb{R} \\ \sigma & \mapsto & \int_\sigma \omega \end{array}\right) \end{array}$$

Note that it follows basically immediately from the definitions that this map is natural in M. Also note that it is an immediate consequence of Lemma 55.5 that for given M all these maps together form a cochain map $C^*_{\mathrm{dR}}(M) \to C^*_{\mathrm{smooth}}(M;\mathbb{R})$. Summarizing we see that we have constructed a natural map

$$t(M)\colon H^*_{\mathrm{dR}}(M) \to H^*_{\mathrm{smooth}}(M;\mathbb{R}).$$

Furthermore, in the special case of $M = \star$ the map

$$t(\star)\colon H^*_{\mathrm{dR}}(\star) \to H^*_{\mathrm{smooth}}(\star;\mathbb{R})$$

is easily seen to be an isomorphism. Once one has unraveled all the definitions it becomes apparent that this natural transformation is compatible with the connecting homomorphism in the Mayer-Vietoris sequence and that it is compatible with the map τ appearing in the limit property. Now we obtain from Theorem 55.2 that t is a natural isomorphism from de Rham cohomology to real-valued smooth singular cohomology.

Finally we set $u := s^{-1} \circ t$. By the above u is a natural isomorphism from de Rham cohomology to singular cohomology with real coefficients. It follows easily from the definitions of s and t that for any closed differential k-form ω and any smooth singular k-chain σ that is a cycle we have

$$\langle \underbrace{u([\omega])}_{\in H^k(M;\mathbb{R})} , \underbrace{[\sigma]}_{\in H_k(M;\mathbb{Z})} \rangle_M = \int_\sigma \omega.$$

□

Theorem 55.6 allows us to transport information from de Rham cohomology to real-valued singular cohomology and vice-versa. For example the many computational techniques that we had developed, e.g. cellular cohomology, for singular cohomology can now be used to calculate isomorphism types of de Rham cohomology groups. In particular we can easily prove the following corollary.

Corollary 55.7. *If M is a closed, oriented connected, non-empty n-dimensional manifold, then the map*

$$\begin{array}{rcl} H^n_{\mathrm{dR}}(M) & \to & \mathbb{R} \\ [\omega] & \mapsto & \int_M \omega \end{array}$$

is an isomorphism.

Proof. By Proposition 54.4 (7) the map is well-defined and it is an epimorphism. On the other hand, by Proposition 51.14 and Theorem 55.6 we know that $H^n_{\mathrm{dR}}(M) \cong \mathbb{R}$, which implies that the map is an isomorphism. □

55.4. **Realizing cohomology classes by maps to S^1.** We start out this section with the following definition.

Definition. Let G be a group, let Y be a topological space and let $y_0 \in Y$ be a point with an identification $\pi_1(Y, y_0) = G$. Given another topological space X and $x_0 \in X$ we say that a homomorphism $\varphi\colon \pi_1(X, x_0) \to G = \pi_1(Y, y_0)$ is *realized by a map* $g\colon X \to Y$ if $g(x_0) = y_0$ and if $g_* = \varphi$. If there is no danger of confusion we will drop the base points from the notation.

In the following we will mostly discuss the case $G = \mathbb{Z}$ and $Y = S^1$. Before we can continue we introduce the following conventions.

Convention.

(1) We use the diffeomorphism $\mathbb{R}/\mathbb{Z} \to S^1$ given by $[t] \mapsto e^{2\pi i t}$ to make the identification $\mathbb{R}/\mathbb{Z} = S^1$.

(2) By Proposition 7.18 we have an isomorphism $\mathbb{Z} \to \pi_1(S^1, 1)$ given by sending 1 to the equivalence class of the loop $t \mapsto e^{2\pi i t}$. We use this isomorphism to make the identification $\pi_1(\mathbb{R}/\mathbb{Z}, 0) = \pi_1(S^1, 1) = \mathbb{Z}$.
(3) Let X be a path-connected topological space and let $x_0 \in X$. As shown in Proposition 51.17 we can use the Hurewicz homomorphism and the evaluation homomorphism to make the identifications $H^1(X; \mathbb{Z}) = \mathrm{Hom}(H_1(X); \mathbb{Z}) = \mathrm{Hom}(\pi_1(X, x_0), \mathbb{Z})$.

Now we can formulate the following question.

Question 55.8. *Let X be a path-connected topological space that is "reasonable", e.g. that is a manifold or a CW-complex. Let $x_0 \in X$ be a base point. Can every homomorphism $\varphi\colon \pi_1(X, x_0) \to \mathbb{Z} = \pi_1(S^1, 1)$ be realized by a map $(X, x_0) \to (S^1, 1)$?*

The following proposition gives an affirmative answer if X is a manifold.

Proposition 55.9. *Let M be a connected manifold (here for once we allow M to have boundary) and let P be a base point. Every $\phi \in H^1(M; \mathbb{Z}) = \mathrm{Hom}(\pi_1(M, P), \mathbb{Z})$ can be realized by a smooth map $g\colon M \to S^1$ with $g(P) = 1$.*

Remark. Sometimes the following reformulation of Proposition 55.9 is quite useful: Let M be a connected manifold and let P be a base point. Given any $\phi \in H^1(M; \mathbb{Z})$ there exists a smooth map $g\colon M \to S^1$ and a generator $\psi \in H^1(S^1; \mathbb{Z})$ with $\phi = g^*(\psi)$.

Examples.

(1) We consider the torus $T = S^1 \times S^1 = \mathbb{R}^2/\mathbb{Z}^2$ and we make the usual identification $H_1(T; \mathbb{Z}) = \mathbb{Z}^2$. We consider the cohomology classes in $H^1(T; \mathbb{Z}) = \mathrm{Hom}(H_1(T), \mathbb{Z})$ that are given by

$$\begin{array}{rcl} \phi\colon H_1(T;\mathbb{Z}) = \mathbb{Z}^2 & \to & \mathbb{Z} \\ (m,n) & \mapsto & m \end{array} \quad \text{and} \quad \begin{array}{rcl} \psi\colon H_1(T;\mathbb{Z}) = \mathbb{Z}^2 & \to & \mathbb{Z} \\ (m,n) & \mapsto & n. \end{array}$$

These two cohomology classes are evidently realized by the projection $S^1 \times S^1 \to S^1$ onto the first, respectively the second factor. In Exercise 55.3 the goal will be to give an example of an explicit map $g\colon T \to S^1$ that realizes the homomorphism $\varphi\colon H_1(T; \mathbb{Z}) = \mathbb{Z}^2 \to \mathbb{Z}$ given by $\varphi(m, n) = 6m + 4n$.
(2) In Figure 715 we consider the surface Σ of genus 2. As we saw on page 891, the oriented curves x_1, y_1, x_2, y_2 represent a basis for $H_1(\Sigma)$. We consider some random epimorphism $\phi\colon H_1(\Sigma) \to \mathbb{Z}$, e.g. we could consider the epimorphism $\phi\colon H_1(\Sigma) \to \mathbb{Z}$ that is given by $\phi(x_1) = 0$, $\phi(y_1) = 1$, $\phi(x_2) = -2$ and $\phi(y_2) = 1$. By Proposition 55.9 we know that ϕ can be realized by some map $g\colon \Sigma \to S^1$. But can one "visualize" such a map? We will return to this question at a later stage.

Proof. Let M be a connected manifold. We first assume that M has no boundary. We start out with the following definition. Let ω be a smooth differential 1-form on M and let

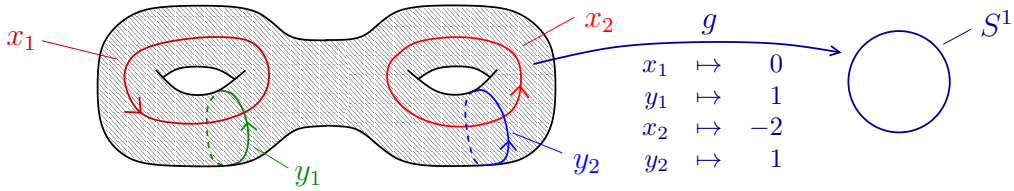

FIGURE 715.

$\gamma\colon [a,b] \to M$ be a piecewise smooth path. We pick $a = t_0 < t_1 < \cdots < t_n = b$ such that the restriction of γ to each subinterval $[t_i, t_{i+1}]$ is smooth. We define

$$\int_{[a,b]} \gamma^*\omega \;=\; \sum_{i=0}^{n-1} \int_{[t_i,t_{i+1}]} \gamma^*\omega.$$

It follows immediately from Proposition 54.2 (2) that this definition does not depend on the choice of the subdivision.

After this preparation we start with the actual proof of the proposition. We fix a base point $P \in M$. Furthermore let $\phi \in H^1(M;\mathbb{Z}) = \operatorname{Hom}(\pi_1(M,P),\mathbb{Z})$. We denote by u the natural isomorphism from de Rham cohomology to singular cohomology with real coefficients from Theorem 55.6. We pick a smooth closed differential 1-form ω on M with $u([\omega]) = \phi$.

Claim. Let $\delta\colon [0,1] \to M$ be a piecewise smooth loop in P. Then

$$\int_{[0,1]} \delta^*\omega \;=\; \phi\big(\underbrace{[\delta]}_{\in \pi_1(M,P)}\big) \;\in\; \mathbb{R}.$$

Let $\delta\colon [0,1] \to M$ be a piecewise smooth loop in P. One can show easily that after possibly performing an orientation-preserving reparametrization we can write $\delta = \delta_1 * \cdots * \delta_k$ as a product of smooth paths $\delta_i\colon [0,1] \to M$, $i = 1,\dots,k$. As in the definition of the Hurewicz homomorphism we use the map $t \mapsto (1-t,t)$ to make the identification $[0,1] = \Delta^1$. Using this identification we view each δ_i also as a smooth 1-simplex. In particular we have $\delta_1 + \cdots + \delta_k \in C_1^{\text{smooth}}(M)$. Then

$$\int_{[0,1]} \delta^*\omega \;\underset{\substack{\text{by the definitions and}\\ \text{by Proposition 54.2}\\ \text{(1) and (2)}}}{=}\; \int_{\delta_1+\cdots+\delta_k} \omega \;\underset{\substack{\text{by Theorem 55.6}\\ \text{since } u([\omega]) = \phi}}{=}\; \langle \phi, [\delta_1 + \cdots + \delta_k]\rangle \;\underset{\substack{\text{via the identification}\\ H^1(M;\mathbb{Z}) = \operatorname{Hom}(\pi_1(M,P),\mathbb{Z})}}{=}\; \phi([\delta]).$$

This concludes the proof of the claim.

We define

$$\begin{aligned} g\colon M &\to S^1 = \mathbb{R}/\mathbb{Z} \\ Q &\mapsto \Big[\int_{[0,1]} \gamma^*\omega\Big] \quad \text{where } \gamma \text{ is a smooth path}^{961} \text{ from } P \text{ to } Q. \end{aligned}$$

We claim that the map g has the required properties. It remains to prove the following four statements:

(1) The map g is well-defined.
(2) We have $g(P) = [0] \in \mathbb{R}/\mathbb{Z}$.
(3) The map g is smooth.
(4) We have $g_* = \phi\colon \pi_1(M, P) \to \pi_1(S^1, 1) = \mathbb{Z}$.

Now we turn to the proofs of the statements.

(1) Let Q in M. Suppose we are given two piecewise smooth paths β and γ from the base point P to Q. (See the left of Figure 716 for an illustration.) Then

$$\int_{[0,1]} \beta^*\omega - \int_{[0,1]} \gamma^*\omega \underset{\substack{\uparrow \\ \text{follows from the definitions} \\ \text{and Proposition 54.2 (1) and (2)}}}{=} \int_{[0,1]} (\beta * \overline{\gamma})^*\omega \underset{\substack{\uparrow \\ \text{by the above claim, since } \beta * \overline{\gamma} \\ \text{is a piecewise smooth loop}}}{=} \phi([\beta * \overline{\gamma}]) \in \mathbb{Z}.$$

This shows that g is indeed well-defined.

(2) We determine $g(P)$ by taking the constant path from P to P. It follows immediately from the definition of g that $g(P) = [0] \in \mathbb{R}/\mathbb{Z}$.

(3) Let $Q \in M$. We need to show that g is smooth in an open neighborhood of Q. We pick a path γ from P to Q. We pick a chart $\Phi\colon U \to B_r(0)$ around Q with $\Phi(Q) = 0$. Given a point $R \in U$ we denote by δ_R the piecewise smooth path that is given by the concatenation of the following two paths:
   (a) the path γ from P to Q,
   (b) the "radial path" from Q to R that corresponds, under the diffeomorphism Φ, to the radial path from 0 to $\Phi(R) \in B_r(0)$.

   (See the right of Figure 716 for an illustration.) Using these paths δ_R it is now relatively straightforward to show that g is smooth in U. We leave the verification of the details to the reader.

(4) Suppose we are given an element in $\pi_1(M, P)$. By Lemma 10.24 (1) we can represent this element by a smooth loop $\delta\colon [0,1] \to M$. We have the following equality:

$$\begin{aligned} g_*([\delta]) &\overset{\substack{\text{by Theorem 7.17} \\ \downarrow}}{=} \text{endpoint of the lift of } g \circ \delta\colon [0,1] \to \mathbb{R} \text{ to the universal covering } \mathbb{R} \text{ of } \mathbb{R}/\mathbb{Z} \\ &= \text{endpoint of the lift of the path } t \mapsto \Big[\int_{[0,t]} \delta^*\omega\Big] \text{ to the universal covering } \mathbb{R} \\ &= \text{endpoint of the path } t \mapsto \int_{[0,t]} \delta^*\omega = \text{the point } \int_{[0,1]} \delta^*\omega \underset{\substack{\uparrow \\ \text{by the above claim}}}{=} \phi([\delta]). \end{aligned}$$

We have thus shown that $g_* = \phi\colon \pi_1(M, P) \to \pi_1(S^1, 1) = \mathbb{Z}$.

[961] By Lemma 10.24 (2) any two points on a connected manifold, that do not lie on the boundary, can be connected by a smooth path. Here we again use that M has no boundary.

This concludes the proof of the theorem in the case that M has empty boundary.

Finally let M be a manifold with non-empty boundary. We consider $W := M \cup \partial M \times [0,1)$ where we make the obvious identification of $P = P \times \{0\}$ for $P \in \partial M$. Using the Collar Neighborhood Theorem 10.10 one can easily verify that W is a manifold such that M is a submanifold and such that W has no boundary. Evidently M is a deformation retract of W. It follows from Lemma 9.10 and Proposition 9.12 (1) that the induced map $i_*\colon \pi_1(M,P) \to \pi_1(W,P)$ is an isomorphism. Now let $\phi \in \mathrm{Hom}(\pi_1(M,P),\mathbb{Z})$. By the previously considered case we can realize $\phi \circ (i_*)^{-1}\colon \pi_1(W,P) \to \mathbb{Z}$ by a smooth map $g\colon W \to S^1$. The restriction of g to M has all the desired properties. $\square$

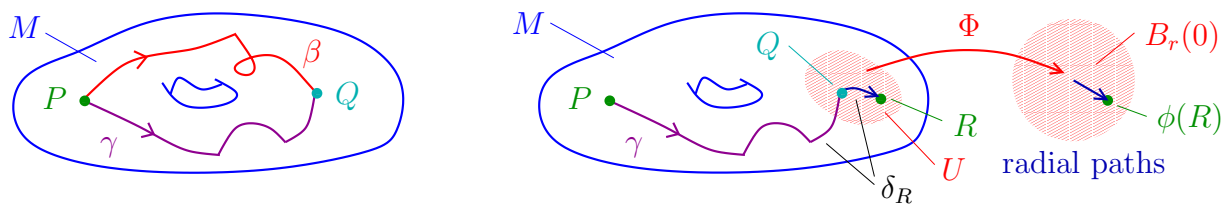

FIGURE 716.

Of course one can ask many variations on Question 55.8. Since arbitrary topological spaces can be quite weird we restrict ourselves in the following questions to CW-complexes.

Question 55.10. *Let X be a connected CW-complex.*

(1) *Let $g \geq 1$ and let Σ_g be the surface of genus $g \geq 1$. Can every homomorphism $\pi_1(X) \to \pi_1(\Sigma_g)$ be realized by a map $X \to \Sigma_g$?*

(2) *Can every homomorphism $\pi_1(X) \to \pi_1\Big(\bigvee_{i=1}^{k} S^1\Big) = \langle x_1, \dots, x_k \rangle$ be realized by a map $X \to \bigvee_{i=1}^{k} S^1$?*

(3) *Can every homomorphism $\pi_1(X) \to \mathbb{Z}_2 = \pi_1(\mathbb{R}\mathrm{P}^2)$ be realized by a map $X \to \mathbb{R}\mathrm{P}^2$?*

55.5. **The wedge product of differential forms** $(*)$**.** For a real vector space V we had already introduced on page 1271 the bilinear wedge product

$$\wedge^k V^* \times \wedge^l V^* \quad \to \quad \wedge^{k+l} V^*.$$

Given a manifold M we can define this wedge product for each tangent space $V = T_P M$. Using charts one can show that this wedge product sends smooth forms to smooth forms. More precisely, we have a bilinear map

$$\wedge\colon C^k_{\mathrm{dR}}(M) \times C^l_{\mathrm{dR}}(M) \quad \to \quad C^{k+l}_{\mathrm{dR}}(M).$$

We refer [Tu, p. 205] for details.

Lemma 55.11. *Let M be a manifold. For any $k, l \in \mathbb{N}_0$ the map*

$$\begin{array}{rcl} \wedge : H^k_{\mathrm{dR}}(M) \times H^l_{\mathrm{dR}}(M) & \to & H^{k+l}_{\mathrm{dR}}(M) \\ ([\omega],[\sigma]) & \mapsto & [\omega] \wedge [\sigma] := [\omega \wedge \sigma] \end{array}$$

is well-defined.

Proof. By [Tu, Proposition 4.7] we know that for any smooth differential k-form ω and any smooth differential l-form σ we have

$$(*) \qquad d(\omega \wedge \sigma) \;=\; d\omega \wedge \sigma + (-1)^k \cdot \omega \wedge d\sigma.$$

Now let $\omega \in C^k_{\mathrm{dR}}(M)$ and $\sigma \in C^l_{\mathrm{dR}}(M)$ be smooth forms.

(1) It follows immediately from $(*)$ that $\omega \wedge \sigma$ is again closed.
(2) If $\omega' = \omega + d\tau$ is another representative of $[\omega]$, then

$$\omega' \wedge \sigma - \omega \wedge \sigma \;\underset{\substack{\uparrow \\ \text{since “}\wedge\text{” is bilinear}}}{=}\; (\omega' - \omega) \wedge \sigma \;=\; d\tau \wedge \sigma \;\underset{\substack{\uparrow \\ \text{by } (*) \text{ and since } d\sigma = 0}}{=}\; d(\tau \wedge \sigma).$$

This shows that $\omega \wedge \sigma$ and $\omega' \wedge \sigma$ represent the same de Rham cohomology class, i.e. the wedge product does not depend on the choice of the representative of the de Rham cohomology class of the first entry.
(3) The proof that the wedge product does not depend on the choice of the representative of the second de Rham cohomology class is basically the same as the proof of (2). □

At this point it is helpful to introduce the following definition.

Definition.

(1) A *graded ring* is a ring[962] R together with a direct sum decomposition[963] $R = \bigoplus_{n \in \mathbb{N}_0} R_n$ into subgroups such that for any $m, n \in \mathbb{N}_0$ the multiplication map restricts to a map
$$R_m \times R_n \;\to\; R_{m+n}.$$
(2) A graded ring $R = \bigoplus_{n \in \mathbb{N}_0} R_n$ such that for any two homogeneous elements a and b the equality $a \cdot b = (-1)^{\deg(a) \cdot \deg(b)} \cdot b \cdot a$ holds is called a *superalgebra*.[964]
(3) Let $R = \bigoplus_{n \in \mathbb{N}_0} R_n$ and $S = \bigoplus_{n \in \mathbb{N}_0} S_n$ be two graded rings. A *morphism between the two graded rings* is a ring homomorphism $\varphi\colon R \to S$ such that for any $n \in \mathbb{N}_0$ we have $\varphi(R_n) \subset S_n$.
(4) We define the *category of graded rings* to be the category where the objects are graded rings and the morphisms are morphisms of graded rings. Similarly we define the category of graded superalgebras.

[962]Here we mean by a ring an abelian group together with a multiplicative structure which is associative, distributive and that admits a multiplicatively neutral element. We do not demand that a ring is commutative.

[963]In particular, R viewed as an abelian group is $\mathbb{N}_0$-graded.

[964]The word “algebra” in our context is justified by the fact that any ring is a $\mathbb{Z}$-algebra. We could also have referred to such an object as a superring, but this terminology seems to be uncommon.

Example. We consider the polynomial ring $R = \mathbb{Q}[x]$. We can view this ring as a graded ring by defining $R_n := \mathbb{Q} \cdot x^n$ for $n \in \mathbb{N}_0$.

Recall that for a given manifold M we write

$$H^*_{\mathrm{dR}}(M) \;=\; \bigoplus_{i=0}^{\infty} H^i_{\mathrm{dR}}(M).$$

We consider the following map

$$\begin{array}{rcl} \wedge\colon H^*_{\mathrm{dR}}(M) \times H^*_{\mathrm{dR}}(M) & \to & H^*_{\mathrm{dR}}(M) \\ \left(\sum\limits_{i=0}^{\infty} x_i, \sum\limits_{i=0}^{\infty} y_i\right) & \mapsto & \sum\limits_{i,j=0}^{\infty} x_i \wedge y_j. \end{array}$$

where it is understood that each x_i and y_i is homogeneous of degree i.

The following proposition summarizes the key features of the wedge product on de Rham cohomology.

Proposition 55.12. *The maps*

$$\begin{array}{rcl} M & \mapsto & (H^*_{\mathrm{dR}}(M), \wedge) \\ (f\colon M \to N) & \mapsto & (f^*\colon H^*_{\mathrm{dR}}(N) \to H^*_{\mathrm{dR}}(M)) \end{array}$$

define a contravariant functor from the category of manifolds to the category of graded superalgebras.

Proof.

(1) First note that it follows almost immediately from Lemma 54.1 that for a given manifold M the wedge product turns $H^*_{\mathrm{dR}}(M)$ into a graded superalgebra. The multiplicatively neutral element in de Rham cohomology is hereby the 0-dimensional cohomology class that is represented by the constant function $f\colon M \to \mathbb{R}$, $x \mapsto 1$.

(2) If $f\colon M \to N$ is a smooth map between manifolds, then it follows immediately from the definitions that for any choice of $\omega \in C^k_{\mathrm{dR}}(N)$ and $\sigma \in C^l_{\mathrm{dR}}(N)$ the following equality holds:

$$(f^*\omega \wedge f^*\sigma) \;=\; f^*(\omega \wedge \sigma).$$

Therefore the smooth map f induces a morphism $f^*\colon H^*_{\mathrm{dR}}(N) \to H^*_{\mathrm{dR}}(M)$ of graded rings. □

Example. We consider the differential 1-forms dx and dy on $\mathbb{R}^2$ which are given by[965] $dx(v,w) = v$ and $dy(v,w) = w$. Furthermore we identify the 2-torus T with the quotient space $\mathbb{R}^2/\mathbb{Z}^2$ and we denote the projection $\mathbb{R}^2 \to T = \mathbb{R}^2/\mathbb{Z}^2$ by p. It is straightforward to see that dx and dy induce differential 1-forms on T.[966] We denote these also by dx

[965] As always we identify $T_P\mathbb{R}^2$ with $\mathbb{R}^2$.

[966] Details are given in [Frie2, p. 248].

and dy.[967] The 1-forms dx and dy are closed, i.e. $d(dx) = d(dy) = 0$.[968] Thus they define cohomology classes $[dx], [dy] \in H^1_{\mathrm{dR}}(T)$. A straightforward calculation, see e.g. [Frie2, p. 248], shows that if we integrate the 2-form $dx \wedge dy$ on T with the standard orientation, then we obtain 1. It follows from Proposition 54.4 that $[dx \wedge dy] = [dx] \wedge [dy]$ is a non-trivial element in $H^2_{\mathrm{dR}}(T)$.

From the fact that $H^*_{\mathrm{dR}}(T)$ is a superalgebra we know that

$$[dx] \wedge [dy] \;=\; (-1)^{1\cdot 1} \cdot [dy] \wedge [dx] \;=\; -[dy] \wedge [dx].$$

Since this wedge product is non-zero we see that $(H^*_{\mathrm{dR}}(T), \wedge)$ is a non-commutative ring.

This discovery of a ring structure on de Rham cohomology raises the question whether one can also define such a ring structure using singular cohomology and whether such a ring structure exists on singular cohomology for more general spaces. We will answer these questions in the next chapter.

Exercises for Chapter 55.

Exercise 55.1. Let $\mathcal{H}^*$ be a smooth cohomology theory with $\mathcal{H}^n(\star) = 0$ for $n \geq 1$. We denote by $f\colon S^1 \to S^1$ the map that is given by $(x, y) \mapsto (x, -y)$. Show, only using the axioms of a smooth cohomology theory, that $f^*\colon \mathcal{H}^1(S^1) \to \mathcal{H}^1(S^1)$ is given by multiplication by -1.

Exercise 55.2. Let M be a manifold. Show that if A and B are subsets of M such that $\overline{A}$ and $\overline{B}$ are compact, then $\overline{A \cap B}$ and $\overline{A \cup B}$ are also compact.

Exercise 55.3. We make the usual identification $\pi_1(\mathbb{R}^2/\mathbb{Z}^2) = \mathbb{Z}^2$. We consider the homomorphism $\phi\colon \mathbb{Z}^2 = \pi_1(\mathbb{R}^2/\mathbb{Z}^2) \to \mathbb{Z}$ given by $\phi((1,0)) = 6$ and $\phi((0,1)) = 4$. Provide an *explicit* map $f\colon \mathbb{R}^2/\mathbb{Z}^2 \to S^1$ such that $f_* = \phi$.

Exercise 55.4. Let M be a manifold and let $\phi \in H^1(M; \mathbb{Z})$. Show that $\phi \cup \phi = 0$.

---

[967] More precisely, we showed that there exists a unique 1-form dx on T such that for each point $P \in \mathbb{R}^2$ and $v \in T_P\mathbb{R}^2$ we have $dx_P(v) = dx_{p(P)}(p_*(v))$. Of course the same statement also holds for dy.

[968] This is clear for dx and dy viewed as differential 1-forms on $\mathbb{R}^2$. But the projection map $p\colon \mathbb{R}^2 \to T = \mathbb{R}^2/\mathbb{Z}^2$ is a local diffeomorphism. Since the differential commutes with smooth maps, see Proposition 54.2 (4), we also see that $d(dx) = d(dy) = 0$ on $\mathbb{R}^2/\mathbb{Z}^2$.

56. The Eilenberg-Zilber theorem and the cross product

In Section 55.5 we saw that de Rham cohomology of a manifold carries a product structure which turns de Rham cohomology into a ring. It is therefore natural to try to find such a product structure in singular homology and/or in singular cohomology.

The key to doing so will be the Eilenberg-Zilber Theorem 43.4 that we had stated in algebraic topology II without providing a proof. In this chapter we will give a slightly more precise statement and we provide the proof. In this and the next chapter we will see how it can be used to find product structures on homology and cohomology groups.

56.1. **The Eilenberg-Zilber theorem.** We start out by recalling and introducing some definitions.

Definition.

(1) Let $\mathcal{C} = (C_*, \partial_*)$ and $\mathcal{C} = (C'_*, \partial'_*)$ be two chain complexes. On page 1041 we defined the tensor product $\mathcal{C} \otimes \mathcal{C}'$ of the chain complexes where the n-th chain group is defined as

$$(\mathcal{C} \otimes \mathcal{C}')_n \quad := \quad \bigoplus_{p+q=n} C_p \otimes C'_q$$

and where the boundary homomorphisms are given by

$$\begin{array}{rcl} \partial^{\otimes} \colon (\mathcal{C} \otimes \mathcal{C}')_n & \to & (\mathcal{C} \otimes \mathcal{C}')_{n-1} \\ c_p \otimes c'_q & \mapsto & \partial c_p \otimes c'_q + (-1)^p \cdot c_p \otimes \partial' c'_q. \end{array}$$

(2) Given a point x in a topological space X we denote by x also the singular 0-simplex given by sending the unique point of Δ^0 to x.

(3) Given two topological spaces X and Y we refer to the maps

$$\begin{array}{rcl} C_0(X) \otimes C_0(Y) & \to & C_0(X \times Y) \\ x \otimes y & \mapsto & (x, y) \end{array} \quad \text{and} \quad \begin{array}{rcl} C_0(X \times Y) & \to & C_0(X) \otimes C_0(Y) \\ (x, y) & \mapsto & x \otimes y \end{array}$$

as the *canonical maps*. We refer to the identity maps on $C_0(X) \otimes C_0(Y)$ and $C_0(X \times Y)$ also as the *canonical maps*.

The following theorem is a slightly more precise formulation of the original Eilenberg-Zilber Theorem 43.4.

Theorem 56.1. (Eilenberg-Zilber)

(1) *Given any topological spaces X and Y there exist natural chain maps*

$$\Upsilon \colon C_*(X) \otimes C_*(Y) \quad \to \quad C_*(X \times Y)$$

and

$$\Theta \colon C_*(X \times Y) \quad \to \quad C_*(X) \otimes C_*(Y),$$

which on the 0-level are the above canonical maps.

(2) *The maps* Υ *and* Θ *are unique up to natural chain homotopies*[969]
(3) *The maps* Υ *and* Θ *are naturally*[970] *chain homotopy inverses of one another.*

We refer to the maps Υ and Θ as *Eilenberg-Zilber* maps. In the notation and our discussions we will usually ignore the fact that these maps are well-defined only up to a natural homotopy. We will only work with the properties of Υ and Θ stated in the theorem, so a different choice of maps Υ and Θ does not affect anything we say afterwards.

56.2. **Proof of the Eilenberg-Zilber Theorem 56.1.** The proof of the Eilenberg-Zilber Theorem 56.1 breaks up into three parts: we first construct Υ, then we construct Θ and finally we show that these maps are unique in the above sense and that they have the desired properties.

We start out with the following definition.

Definition. A topological space X is called *acyclic* if $H_0(X;\mathbb{Z}) \cong \mathbb{Z}$ and if all higher homology groups are zero.

Example. In Corollary 30.8 we showed that every contractible topological space is acyclic. In particular every standard simplex Δ^n is contractible and thus acyclic. Furthermore, all products $\Delta^p \times \Delta^q$ of standard simplices are contractible and thus acyclic.[971]

We also fix some notation.

Notation. Let X be a topological space and let $x \in X$. If $\sigma\colon \Delta^n \to Y$ is a singular n-simplex in a topological space Y, then we denote by $x \times \sigma\colon \Delta^n \to X \times Y$ the singular n-simplex given by $v \mapsto (x, \sigma(v))$. We use the analogous notation for the roles of X and Y swapped.

Now we can formulate the following theorem.

Theorem 56.2. *Given any two topological spaces X and Y and any $p, q \in \mathbb{N}_0$ there exists a homomorphism*

$$\Upsilon_{p,q}\colon C_p(X) \otimes C_q(Y) \;\to\; C_{p+q}(X \times Y)$$

such that the following conditions are satisfied:

(1) *for $x \in X$ and $\sigma\colon \Delta^q \to Y$ we have $\Upsilon_{0,q}(x \otimes \sigma) = x \times \sigma$, the same statement also holds with the roles of X and Y swapped,*

[969]Here "natural chain homotopy" means that given two such maps Υ and Υ' there exists a choice of chain homotopies $(C_*(X) \otimes C_*(Y))_k \to C_{k+1}(X \times Y)$, which is natural in X and Y, between Υ and Υ'. An analogous statement holds for maps Θ and Θ'.

[970]Here "naturally" means that $\Upsilon \circ \Theta$ and $\Theta \circ \Upsilon$ are naturally homotopic to the identity maps, i.e. there exist natural chain homotopies from $\Upsilon \circ \Theta$ to the identity map and from $\Theta \circ \Upsilon$ to the identity map.

[971]This can be seen in many ways, for example pick points $x \in \Delta^p$ and $y \in \Delta^q$, it is straightforward to show that there exists a deformation retraction r from Δ^p to $\{x\}$ and that there exists a deformation retraction s from Δ^q to $\{y\}$. But these two deformation retractions also define a deformation retraction from $\Delta^p \times \Delta^q$ to (x, y).

(2) *the map* $\Upsilon_{p,q}$ *is natural, i.e. if* $f\colon X' \to X$ *and* $g\colon Y' \to Y$ *are maps between topological spaces, then for any* $a \in C_p(X')$ *and any* $b \in C_q(Y')$ *we have*

$$(f \times g)_*(\underbrace{\Upsilon_{p,q}(a \otimes b)}_{\in C_{p+q}(X' \times Y')}) \;=\; \underbrace{\Upsilon_{p,q}(f_*(a) \otimes g_*(b))}_{\in C_{p+q}(X \times Y)},$$

(3) *the maps* $\Upsilon_{p,q}$ *form a chain map, i.e. for any* $a \in C_p(X)$ *and any* $b \in C_q(Y)$ *we have*

$$\partial(\Upsilon_{p,q}(a \otimes b)) \;=\; \underbrace{\Upsilon_{p-1,q}(\partial a \otimes b) + (-1)^p \cdot \Upsilon_{p,q-1}(a \otimes \partial b)}_{=\Upsilon(\partial^{\otimes}(a \otimes b))}.$$

Proof. We prove the existence of the maps $\Upsilon_{p,q}$ by induction on $p \cdot q$. For clarity we henceforth suppress the subscript from $\Upsilon_{p,q}$.

Clearly for $p = 0$ or $q = 0$ the maps from (1) have the properties (2) and (3). So now suppose that we are given $p, q \in \mathbb{N}_0$ with $p \cdot q > 0$ such that the maps Υ have been defined for all p', q' with $p' \cdot q' < p \cdot q$.

Given any $n \in \mathbb{N}_0$ we denote by $\mathrm{id}_n\colon \Delta^n \to \Delta^n$ the identity map. We first want to come up with a reasonable definition of $\Upsilon(\mathrm{id}_p \otimes \mathrm{id}_q)$. If we want (3) to be satisfied we have to define $\Upsilon(\mathrm{id}_p \otimes \mathrm{id}_q) = z$ where $z \in C_{p+q}(\Delta^p \times \Delta^q)$ satisfies

$$(*) \qquad \partial z \;=\; \Upsilon(\partial\,\mathrm{id}_p \otimes \mathrm{id}_q) + (-1)^p \cdot \Upsilon(\mathrm{id}_p \otimes \partial\,\mathrm{id}_q) \;\in\; C_{p+q-1}(\Delta^p \times \Delta^q).$$

As we pointed out on page 1309, the product $\Delta^p \times \Delta^q$ is acyclic, in particular we have $H_{p+q-1}(\Delta^p \times \Delta^q) = 0$, which means that every singular $(p+q-1)$-chain *that is a cycle* is in fact the boundary of some $(p+q)$-chain z. So we have to show that the right-hand side of $(*)$ is indeed a cycle. We compute that

$$\begin{aligned}
&\overbrace{\partial(\Upsilon(\partial\,\mathrm{id}_p \otimes \mathrm{id}_q) + (-1)^p \cdot \Upsilon(\mathrm{id}_p \otimes \partial\,\mathrm{id}_q))}^{\text{boundary of our hypothetical } \Upsilon(\mathrm{id}_p \otimes \mathrm{id}_q)} \overset{\text{linearity of } \partial}{=} \partial(\Upsilon(\partial\,\mathrm{id}_p \otimes \mathrm{id}_q)) + (-1)^p \cdot \partial(\Upsilon(\mathrm{id}_p \otimes \partial\,\mathrm{id}_q)) \\
&= \Upsilon(\underbrace{\partial\partial\,\mathrm{id}_p}_{=0} \otimes \mathrm{id}_q) + (-1)^{p-1} \cdot \Upsilon(\partial\,\mathrm{id}_p \otimes \partial\,\mathrm{id}_q) \\
&\qquad\qquad + (-1)^p \cdot \Upsilon(\partial\,\mathrm{id}_p \otimes \partial\,\mathrm{id}_q) + (-1)^p \cdot (-1)^p \cdot \Upsilon(\mathrm{id}_p \otimes \underbrace{\partial\partial\,\mathrm{id}_q}_{=0}) = 0.
\end{aligned}$$

by our induction hypothesis we can apply the boundary formula (3) to $\Upsilon(\partial\,\mathrm{id}_p \otimes \mathrm{id}_q)$ and $\Upsilon(\mathrm{id}_p \otimes \partial\,\mathrm{id}_q)$

This discussion gives us the definition of $\Upsilon(\mathrm{id}_p \otimes \mathrm{id}_q) := z$.

Now let X and Y be topological spaces and let $\varphi\colon \Delta^p \to X$ and $\psi\colon \Delta^q \to Y$ be singular simplices. If we want (2) to be satisfied then we have to define

$$\Upsilon(\underbrace{\varphi \otimes \psi}_{\in C_p(X) \otimes C_q(Y)}) \;:=\; (\varphi \times \psi)_*(\underbrace{\Upsilon(\mathrm{id}_p \otimes \mathrm{id}_q)}_{\in C_{p+q}(\Delta^p \times \Delta^q)}) \;\in\; C_{p+q}(X \times Y).$$

We extend this map linearly to all of $C_p(X) \otimes C_q(Y)$. It follows almost immediately from the definition of Υ that the map Υ is natural in X and Y.

It remains to prove (3). This property holds basically by definition. But for completeness' sake we carry out the proof. So let $\varphi\colon \Delta^p \to X$ and $\psi\colon \Delta^q \to Y$ be singular simplices. We then have the following equality in $C_{p+q-1}(X \times Y)$:

$$\begin{aligned}
\partial(\Upsilon(\varphi \otimes \psi)) &= \partial\big((\varphi \times \psi)_*(\Upsilon(\mathrm{id}_p \otimes \mathrm{id}_q))\big) \overset{\text{since } (\varphi\times\psi)_* \text{ is a chain map}}{=} (\varphi \times \psi)_*(\partial(\overbrace{\Upsilon(\mathrm{id}_p \otimes \mathrm{id}_q)}^{=z})) \\
&= (\varphi \times \psi)_*(\Upsilon(\partial\,\mathrm{id}_p \otimes \mathrm{id}_q)) + (-1)^p \cdot (\varphi \times \psi)_*(\Upsilon(\mathrm{id}_p \otimes \partial\,\mathrm{id}_q)) \\
&\uparrow \\
&\text{by definition of } z \text{ and the linearity of } (\varphi \times \psi)_* \\
&= (\Upsilon(\varphi_*(\partial\,\mathrm{id}_p) \otimes \psi_*(\mathrm{id}_q))) + (-1)^p \cdot \Upsilon(\varphi_*(\mathrm{id}_p) \otimes \psi_*(\partial\,\mathrm{id}_q)) \\
&\uparrow \\
&\text{by induction we can apply the naturality of } \Upsilon \\
&= \Upsilon(\partial(\varphi) \otimes \psi) + (-1)^p \cdot \Upsilon(\varphi \otimes \partial\psi)) \\
&\uparrow \\
&\text{since } \varphi_* \text{ and } \psi_* \text{ are chain maps and since } \varphi_*(\mathrm{id}_p) = \varphi \text{ and } \psi_*(\mathrm{id}_q) = \psi
\end{aligned}$$

□

Now we turn to the construction of the second map in the Eilenberg-Zilber Theorem 56.1.

Theorem 56.3. *Given any two topological spaces X and Y and any $k \in \mathbb{N}_0$ there exists a homomorphism*

$$\Theta_k\colon C_k(X \times Y) \;\to\; (C_*(X) \otimes C_*(Y))_k \;=\; \bigoplus_{p+q=k} C_p(X) \otimes C_q(Y)$$

such that the following conditions are satisfied:

(1) *the map Θ_0 is the canonical map on the 0-level, i.e. for every $x \in X$ and $y \in Y$ we have $\Theta_0((x, y)) = x \otimes y$,*
(2) *the map Θ_k is natural in X and Y, i.e. for any two maps $f\colon X' \to X$ and $g\colon Y' \to Y$ of topological spaces and any $c \in C_k(X' \times Y')$ we have*

$$\Theta_k((f \times g)_*(c)) \;=\; (f_* \otimes g_*)(\Theta_k(c)),$$

(3) *the maps Θ_* form a chain map, i.e. for any $k \in \mathbb{N}_0$ we have*

$$\partial_k^{\otimes} \circ \Theta_k \;=\; \Theta_{k-1} \circ \partial_k.$$

In the proof of Theorem 56.3 we will need the following lemma.

Lemma 56.4. *Let X and Y be two acyclic topological spaces. For every $k \geq 1$ we have*

$$H_k(C_*(X) \otimes C_*(Y)) \;=\; 0.$$

Furthermore we have an isomorphism

$$\begin{aligned}
\epsilon\colon H_0(C_*(X) \otimes C_*(Y)) &\overset{\cong}{\to} \mathbb{Z} \\
\Big[\sum_{i=1}^{k} \underbrace{a_i}_{\in\mathbb{Z}} \cdot \underbrace{x_i}_{\in X} \otimes \underbrace{y_i}_{\in Y}\Big] &\mapsto \sum_{i=1}^{k} a_i.
\end{aligned}$$

Proof. The lemma is an immediate consequence of our hypotheses, Proposition 29.5 and the Künneth Theorem 43.7 for Chain Complexes. (Note that this Künneth Theorem is purely algebraic.) □

Proof of Theorem 56.3. As we will see the idea behind the proof of Theorem 56.3 is very similar to the idea of the proof of Theorem 56.2. We start out with the outline of proof:

(a) We use (1) to define Θ_0,
(b) we suppose the map $\Theta_0, \dots, \Theta_{k-1}$ are defined, we then use (3) to make an educated guess for $\Theta_k(d_k)$ where we consider
  (i) the topological spaces $X = Y = \Delta^k$ and
  (ii) the singular k-simplex $d_k\colon \Delta^k \to \Delta^k \times \Delta^k$ that is given by the diagonal map $d_k(x) = (x, x)$.
(c) we then use the naturality statement of (2) to define Θ_k for all topological spaces X and Y and all singular simplices in $C_*(X \times Y)$.

Now we carry out the above program. First of all, given a 0-simplex (x, y) in $X \times Y$ we define $\Theta_0((x, y)) = x \otimes y$. Then we extend this definition linearly to get the desired map $\Theta_0\colon C_0(X \times Y) \to C_0(X) \otimes C_0(Y)$.

Now suppose we have already constructed the maps $\Theta_0, \dots, \Theta_{k-1}$. We want to define Θ_k and we start out by defining $\Theta_k(d_k\colon \Delta^k \to \Delta^k \times \Delta^k)$. Since we need (3) to be satisfied we need to define $\Theta_k(d_k) := c$ where $c \in (C_*(\Delta^k) \otimes C_*(\Delta^k))_k$ satisfies $\partial_k^{\otimes}(c) = \Theta_{k-1}(\partial d_k)$. In the chain complex $C_*(\Delta^k) \otimes C_*(\Delta^k)$ we calculate that

$$\partial^{\otimes}(\overbrace{\Theta_{k-1}(\partial_k(d_k))}^{\text{defined by induction}}) \underset{\substack{\uparrow \\ \text{by induction we can apply (3)}}}{=} \Theta_{k-2}(\underbrace{\partial_{k-1}\partial_k}_{=0} d_k) = 0,$$

i.e. the chain $\Theta_{k-1}(\partial_k d_k) \in (C_*(\Delta^k) \otimes C_*(\Delta^k))_{k-1}$ is in fact a cycle. Since Δ^k is acyclic it follows immediately from Lemma 56.4 that this cycle is null-homologous. (For $k = 1$ one easily verifies, using the explicit description of Θ_0, that the cycle lies in the kernel of the isomorphism $\epsilon\colon H_0(C_*(\Delta^k) \otimes C_*(\Delta^k)) \to \mathbb{Z}$.) This means that there exists a singular chain $c \in (C_*(\Delta^k) \otimes C_*(\Delta^k))_k$ with $\partial^{\otimes}(c) = \Theta_{k-1}(\partial_k d_k)$. We define $\Theta_k(d_k) := c$.

Now we define Θ_k for arbitrary topological spaces X and Y and an arbitrary singular k-simplex $\sigma\colon \Delta^k \to X \times Y$. We denote by $p\colon X \times Y \to X$ and $q\colon X \times Y \to Y$ the obvious projection maps. Note that we have a commutative diagram

$$\begin{tikzcd} & \Delta^k \times \Delta^k \arrow[d, "(p\circ\sigma)\times(q\circ\sigma)"] \\ \Delta^k \arrow[ur, "d_k"] \arrow[r, "\sigma"'] & X \times Y, \end{tikzcd}$$

i.e. we have $\sigma = ((p \circ \sigma) \times (q \circ \sigma)) \circ d_k = ((p \circ \sigma) \times (q \circ \sigma))_*(d_k)$. For the naturality condition (2) to be satisfied we need to define

$$\Theta_k(\sigma) := ((p \circ \sigma)_* \otimes (q \circ \sigma)_*)(\Theta_k(d_k)) \in (C_*(X) \otimes C_*(Y))_k.$$

With this definition one readily verifies that the map Θ_k is natural in X and Y.

Finally we have to show that Θ_k satisfies the boundary formula (3). So as before let $\sigma\colon \Delta^k \to X \times Y$ be a singular k-simplex. Then

$$\begin{array}{rcl}
 & & \text{since } (p\circ\sigma)_* \otimes (q\circ\sigma)_*\colon C_*(\Delta^k)\otimes C_*(\Delta^k) \to C_*(X)\otimes C_*(Y) \\
\text{by definition of } \Theta_k(\sigma) & & \text{is a chain map by Lemma 43.3} \\
\downarrow & & \downarrow \\
\partial^{\otimes}\Theta_k(\sigma) & = & \partial^{\otimes}\big(((p\circ\sigma)_*\otimes(q\circ\sigma)_*)(\Theta_k(d_k))\big) \quad = \quad ((p\circ\sigma)_*\otimes(q\circ\sigma)_*)(\partial^{\otimes}\Theta_k(d_k)) \\
 & = & ((p\circ\sigma)_*\otimes(q\circ\sigma)_*)(\Theta_{k-1}(\partial d_k)) \quad = \quad \Theta_{k-1}\big(((p\circ\sigma)\times(q\circ\sigma))_*(\partial d_k)\big) \\
\uparrow & & \uparrow \\
\text{by definition of } \Theta_k(d_k) & & \text{by naturality of } \Theta_{k-1} \\
 & = & \Theta_{k-1}\partial\big(((p\circ\sigma)\times(q\circ\sigma))_*(d_k)\big) \quad = \quad \Theta_{k-1}\partial\sigma. \\
\uparrow & & \uparrow \\
\text{since } ((p\circ\sigma)\times(q\circ\sigma))_* \text{ is a chain map} & & \text{since } \sigma = ((p\circ\sigma)\times(q\circ\sigma))\circ d_k
\end{array}$$

We have now verified that Θ_k has all the desired properties. □

As we saw in the proofs of Theorem 56.2 and Theorem 56.3, the natural chain maps $\Upsilon\colon C_*(X)\otimes C_*(Y) \to C_*(X\times Y)$ and $\Theta\colon C_*(X\times Y) \to C_*(X)\otimes C_*(Y)$ depend on many choices. The next theorem says that different choices in the proofs lead to natural chain maps that are naturally homotopy equivalent to one another.

Theorem 56.5. *Let X and Y be topological spaces. Any two natural chain maps*

$$C_*(X\times Y) \;\to\; C_*(X)\otimes C_*(Y)$$

that are the canonical maps on the 0-level are in fact naturally chain homotopic. The same conclusion also holds for any two natural chain maps

$$C_*(X)\otimes C_*(Y)\to C_*(X)\otimes C_*(Y),\;\; C_*(X\times Y)\to C_*(X\times Y),\;\; C_*(X)\otimes C_*(Y)\to C_*(X\times Y)$$

that are the canonical maps on the 0-level.

Proof. The proof of this theorem is in many ways quite similar to the proofs of Theorem 56.2 and 56.3.

In the following we show the first statement. The proofs of the other three statements are very similar. So let

$$F, G\colon C_*(X\times Y) \;\to\; C_*(X)\otimes C_*(Y)$$

be two natural chain maps that are the canonical maps on the 0-chains, i.e. which satisfy $F((x,y)) = x\otimes y = G((x,y))$ for all $x\in X, y\in Y$. Given any $k\in\mathbb{Z}_{\geq -1}$ we have to define a map

$$P_k\colon C_k(X\times Y) \;\to\; (C_*(X)\otimes C_*(Y))_{k+1}$$

that satisfies the following three properties:

(1) the map P_{-1} is the zero map,
(2) the map P_k is natural in X and Y,
(3) we have $\partial^{\otimes}\circ P_k + P_{k-1}\circ\partial = F - G$.

So suppose we have already defined the maps $P_{-1}, \dots, P_{k-1}$ with $k \geq 0$. As before we denote by $d_k \colon \Delta^k \to \Delta^k \times \Delta^k$ the singular k-simplex that is given by the diagonal map $d_k(x) := (x, x)$. We first want to define $P_k(d_k) \in (C_*(\Delta^k) \otimes C_*(\Delta^k)_{k+1}$. In the chain complex $C_*(\Delta^k) \otimes C_*(\Delta^k)$ we calculate that

$$\begin{aligned}\partial^{\otimes}((F - G - P_{k-1}\partial)(d_k)) &= \partial^{\otimes} F(d_k) - \partial^{\otimes} G(d_k) - \partial^{\otimes} P_{k-1}(\partial d_k) \\ &= F(\partial d_k) - G(\partial d_k) - (F - G - P_{k-2}\partial)(\partial d_k) = P_{k-2}\partial\partial d_k = 0. \\ &\uparrow \\ &\text{since } F \text{ and } G \text{ are chain maps and since inductively we know that } \partial^{\otimes} \circ P_{k-1} + P_{k-1} \circ \partial = F - G\end{aligned}$$

It follows from Lemma 56.4 that there exists a $(k+1)$-chain $c \in (C_*(\Delta^k) \otimes C_*(\Delta^k))_{k+1}$ with $\partial^{\otimes}(c) = (F - G - P_{k-1}\partial)(d_k)$. (For $k = 0$ we need to show that $\epsilon((F - G)(d_0)) = 0$, to conclude this we need to use that F and G agree on 0-simplices.) We define $P_k(d_k) := c$.

Now let X and Y be two topological spaces and let $\sigma \in C_k(X \times Y)$. As in the proof of Theorem 56.2 we denote by $p \colon X \times Y \to X$ and $q \colon X \times Y \to Y$ the obvious projection maps and we set

$$P_k(\sigma) \ := \ ((p \circ \sigma)_* \otimes (q \circ \sigma)_*)(P_k(d_k)) \ \in \ (C_*(X) \otimes C_*(Y))_{k+1}.$$

Basically by definition this map is natural in X and Y. As in the proof of Theorem 56.2 one easily verifies that condition (3) is satisfied. □

Now we can easily provide the proof of the Eilenberg-Zilber Theorem 56.1.

Proof of the Eilenberg-Zilber Theorem 56.1. We pick natural chain maps

$$\Upsilon \colon C_*(X) \otimes C_*(Y) \ \to \ C_*(X \times Y)$$

and

$$\Theta \colon C_*(X \times Y) \ \to \ C_*(X) \otimes C_*(Y)$$

as provided by Theorems 56.2 and 56.3. These maps are the canonical maps on the 0-level. By Theorem 56.5 the maps Υ and Θ are thus unique up to a natural chain homotopy.

It remains to show that the maps Υ and Θ are naturally chain homotopy inverses of one another. The map $\Theta \circ \Upsilon \colon C_*(X) \otimes C_*(Y) \to C_*(X) \otimes C_*(Y)$ is a natural chain map that is the canonical map on the 0-level. But this is also the case for the identity map. It follows from Theorem 56.5 that $\Theta \circ \Upsilon$ is naturally chain homotopic to the identity. The same argument shows that $\Upsilon \circ \Theta$ is naturally chain homotopic to the identity. □

56.3. **The relative Eilenberg–Zilber map Υ.** In this short section we introduce a relative version of the Eilenberg–Zilber map Υ. We start out with the following elementary but essential remark.

Remark. Let X and Y be topological spaces and let $A \subset X$ and $B \subset Y$ be subsets. We denote by $i\colon A \to X$ and $j\colon B \to Y$ the inclusion maps. Then the diagram

$$\begin{tikzcd} C_*(A) \otimes C_*(B) \arrow[r, hook, "i_* \otimes j_*"] \arrow[d, "\Upsilon"] & C_*(X) \otimes C_*(Y) \arrow[d, "\Upsilon"] \\ C_*(A \times B) \arrow[r, hook, "(i \times j)_*"] & C_*(X \times Y) \end{tikzcd}$$

commutes by the naturality of Υ. In the following we do not explicitly mention the names of the various inclusion induced maps.

Proposition 56.6. *Let X and Y be topological spaces and let $A \subset X$ and $B \subset Y$ be subsets.*

(1) *The Eilenberg-Zilber map Υ induces a natural chain homotopy equivalence*[972]

$$\begin{array}{rcl} C_*(X,A) \otimes C_*(Y,B) & \to & C_*(X \times Y)/(C_*(A \times Y) + C_*(X \times B)) \\ \sum\limits_{i=1}^{n} [c_i] \otimes [d_i] & \mapsto & \sum\limits_{i=1}^{n} [\Upsilon(c_i \otimes d_i)]. \end{array}$$

(2) *The Eilenberg-Zilber map Υ descends to a well-defined chain map*

$$\begin{array}{rcl} C_*(X,A) \otimes C_*(Y,B) & \to & C_*(X \times Y, A \times Y \cup X \times B) \\ \sum\limits_{i=1}^{n} [c_i] \otimes [d_i] & \mapsto & \sum\limits_{i=1}^{n} \big[\Upsilon(c_i \otimes d_i)\big]. \end{array}$$

Proof. Let X and Y be topological spaces and let $A \subset X$ and $B \subset Y$ be subsets.

(1) We consider the following diagram

$$\begin{tikzcd} 0 \arrow[r] & C_*(A) \otimes C_*(Y) \arrow[r] \arrow[d, "\Upsilon"] & C_*(X) \otimes C_*(Y) \arrow[r] \arrow[d, "\Upsilon"] & C_*(X,A) \otimes C_*(Y) \arrow[r] \arrow[d, "\Upsilon"] & 0 \\ 0 \arrow[r] & C_*(A \times Y) \arrow[r] & C_*(X \times Y) \arrow[r] & C_*(X \times Y)/C_*(A \times Y) \arrow[r] & 0. \end{tikzcd}$$

The top sequence is given by tensoring a short exact sequence by the free abelian groups $C_*(Y)$, Lemma 42.9 implies that the resulting sequence is again exact. The bottom sequence is exact by definition. The two left vertical maps are homotopy equivalences by Theorem 56.1 and the diagram commutes by the naturality of Υ, as explained in the remark preceding the proposition. Finally note that it follows from Corollary 49.6 that the right vertical map is also a chain homotopy equivalence.

We consider the following diagram

$$\begin{tikzcd} 0 \arrow[r] & C_*(X,A) \otimes C_*(B) \arrow[r] \arrow[d, "\Upsilon"] & C_*(X,A) \otimes C_*(Y) \arrow[r] \arrow[d, "\Upsilon"] & C_*(X,A) \otimes C_*(Y,B) \arrow[r] \arrow[d, "\Upsilon"] & 0 \\ 0 \arrow[r] & C_*(X \times B)/C_*(A \times B) \arrow[r] & C_*(X \times Y)/C_*(A \times Y) \arrow[r] & \dfrac{C_*(X \times Y)}{C_*(A \times Y) + C_*(X \times B)} \arrow[r] & 0. \end{tikzcd}$$

[972]Note that $C_*(A \times Y) + C_*(X \times B)$ is in fact a subcomplex of the chain complex $C_*(X \times Y)$, so the right-hand side is indeed a chain complex.

As above, it follows from the fact that each $C_k(X,A)$ is a free abelian group and Lemma 42.9 that the top sequence is exact. It follows easily from[973]

$$C_*(X\times B)\cap C_*(A\times Y) \;=\; C_*((X\times B)\cap(A\times Y)) \;=\; C_*(A\times B)$$

that the bottom sequence is also exact. The middle vertical map is a chain homotopy equivalence by the above discussion. Exactly the same argument also shows that the left vertical map is a chain homotopy equivalence. The diagram commutes by the naturality of Υ. It follows from Corollary 49.6 that the right vertical map is also a homotopy equivalence.

(2) The second statement follows immediately from (1) together with the observation that $C_*(A\times Y)+C_*(X\times B)$ is a subcomplex of $C_*(A\times Y\cup X\times B)$. □

56.4. **The cross product on homology.** Recall that one of our goals is to find some type of product structure in homology or cohomology. We start our search for a product structure in homology, since we are more comfortable with homology groups.

The following definition already gives us some type of product structure on homology.

Definition. Let (X,A) and (Y,B) be two pairs of topological spaces. We refer to the map[974]

$$\begin{array}{rcl} \times\colon H_p(X,A)\otimes H_q(Y,B) & \xrightarrow{\times} & H_{p+q}(X\times Y, A\times Y\cup X\times B). \\ [c]\otimes[d] & \mapsto & [c]\times[d] := [\Upsilon(c\otimes d)] \end{array}$$

as the *cross product*.

In the following lemma we summarize some elementary properties of the cross product.

Lemma 56.7.

(1) *Let X and Y be two topological spaces and let $x\in X$ be a point. We denote by $f\colon Y\to X\times Y$ the map that is given by $y\mapsto(x,y)$ and we denote by $[x]\in H_0(X)$ the homology class defined by x. Then for any $q\in\mathbb{N}_0$ the maps*

$$H_q(Y) \underset{f_*}{\overset{\sigma\mapsto[x]\times\sigma}{\rightrightarrows}} H_q(X\times Y)$$

agree. The statement holds with the roles of X and Y reversed.

(2) *The cross product is natural, i.e. if $f\colon(X,A)\to(X',A')$ and $g\colon(Y,B)\to(Y',B')$ are maps between pairs of topological spaces, then for any $p,q\in\mathbb{N}_0$ the following*

[973]Why does this equality of chain complexes hold?

[974]Note that the map is well-defined by Lemmas 43.6 and 56.6 (2) and it is independent of the choice of Υ by Theorem 56.1 (2).

diagram commutes:

$$\begin{array}{ccc} H_p(X,A)\otimes H_q(Y,B) & \xrightarrow{\times} & H_{p+q}(X\times Y, A\times Y\cup X\times B) \\ {\scriptstyle f_*}\downarrow \quad \downarrow{\scriptstyle g_*} & & \downarrow{\scriptstyle (f\times g)_*} \\ H_p(X',A')\otimes H_q(Y',B') & \xrightarrow{\times} & H_{p+q}(X'\times Y', A'\times Y'\cup X'\times B'). \end{array}$$

Proof. The lemma follows immediately from the definitions and the properties of Υ given in Theorem 56.2 (1) and (2). □

We have the following variation of the Künneth Theorem 43.8 for topological spaces.

Theorem 56.8. (The Künneth Theorem) *Let (X,A) and (Y,B) be pairs of topological spaces. We assume that one of the following two statements holds:*

(1) *A and B are open subsets (note that A and B can possibly be empty), or*
(2) *(X,A) and (Y,B) are pairs of CW-complexes.*

Then for each $n\in\mathbb{N}$ there exists a natural short exact sequence

$$\begin{aligned} 0 \;\to\; \bigoplus_{p+q=n} H_p(X,A)\otimes H_q(Y,B) \;&\xrightarrow{\times}\; H_n(X\times Y, A\times Y\cup X\times B) \\ &\to\; \bigoplus_{p+q=n-1} \mathrm{Tor}(H_p(X,A),H_q(Y,B)) \;\to\; 0. \end{aligned}$$

Furthermore the above short exact sequence splits.

Examples.

(1) Let M be an m-dimensional topological manifold and let N be an n-dimensional topological manifold. Let $x\in M\setminus\partial M$ and let $y\in N\setminus\partial N$. Then it follows from the relative Künneth Theorem 56.8 (2), Lemma 45.16 and Lemma 42.17 that the cross product defines an isomorphism

$$H_m(M,M\setminus\{x\})\otimes H_n(N,N\setminus\{y\}) \xrightarrow{\times} H_{m+n}(M\times N, \underbrace{(M\setminus\{x\})\times N\cup M\times(N\setminus\{y\})}_{=(M\times N)\setminus\{(x,y)\}}).$$

(2) Let X and Y be path-connected topological spaces. Let $x\in X$ and let $y\in Y$. We denote by $i\colon X\to X\times Y$ the inclusion map that is given by $i(x)=(x,y)$ and similarly we denote by $j\colon Y\to X\times Y$ the inclusion map that is given by $j(y)=(x,y)$. It follows from Proposition 29.5, Lemma 56.7 (1) and the Künneth Theorem 56.8 that the map

$$i_*\oplus j_*\colon H_1(X;\mathbb{Z})\oplus H_1(Y;\mathbb{Z}) \;\to\; H_1(X\times Y;\mathbb{Z})$$

is an isomorphism. Let G be any abelian group. It follows easily from the above, the naturality of the Universal Coefficient Theorem 42.19 and Lemma 42.17 (3) that the map

$$i_*\oplus j_*\colon H_1(X;G)\oplus H_1(Y;G) \;\to\; H_1(X\times Y;G)$$

is also an isomorphism.

Proof. We consider the following maps

$$\begin{array}{c} 0 \to \bigoplus_{p+q=n} H_p(X,A)\otimes H_q(Y,B) \to H_n(C_*(X,A)\otimes C_*(Y,B)) \to \bigoplus_{p+q=n-1} \mathrm{Tor}(H_p(X,A),H_q(Y,B)) \to 0. \\ \downarrow \Upsilon \\ H_n(C_*(X\times Y)/(C_*(A\times Y)+C_*(X\times B))) \\ \downarrow \\ H_n(C_*(X\times Y)/C_*(A\times Y\cup X\times B)) \\ \downarrow = \\ H_n(X\times Y, A\times Y\cup X\times B) \end{array}$$

We first note that the top sequence is exact by the Künneth Theorem for Chain Complexes 43.7. (Here we use again that relative chain groups are free abelian groups.) Here the top vertical map is an isomorphism by Proposition 56.6. Recall that we assume that one of the following two statements holds:

(1) A and B are open subsets, or
(2) (X,A) and (Y,B) are pairs of CW-complexes.

We then know from Proposition 50.12 (4) respectively (6) that the inclusion induced map

$$\underbrace{C_*^{\{A\times Y, X\times B\}}(A\times Y\cup X\times B)}_{=C_*(A\times Y)+C_*(X\times B)} \;\to\; C_*(A\times Y\cup X\times B)$$

is a chain homotopy equivalence. The same argument as in the proof of Corollary 31.16 shows that this piece of information implies that the second vertical map is indeed an isomorphism. It follows immediately from the definition of the cross product that the induced "diagonal map"

$$\bigoplus_{p+q=n} H_p(X,A)\otimes H_q(Y,B) \;\to\; H_n(X\times Y, A\times Y\cup X\times B)$$

is precisely the cross product. □

56.5. **Product orientations.** In this second to last section we want to consider products of (topological) manifolds. We start out with the following, arguably slightly surprising proposition. It can be viewed as a generalization of Propositions 3.4, 3.42 and Proposition 32.1 (6).

Proposition 56.9.

(1) *Let M be an m-dimensional topological manifold and let N be an n-dimensional topological manifold. The topological space $M\times N$ is an $(m+n)$-dimensional topological manifold where the boundary is given by*

$$\partial(M\times N) \;=\; \partial M\times N \cup M\times \partial N.$$

(2) *Given any two manifolds M and N we can equip $M\times N$ with a natural smooth structure such that the following conditions are satisfied:*

(a) *If $\partial M = \varnothing$ or $\partial N = \varnothing$, then the smooth structure on $M \times N$ is the obvious smooth structure given by taking products of charts.*

(b) *For any two manifolds M and N the following statements hold:*

  (i) *the inclusion map $\overset{\circ}{M} \times \overset{\circ}{N} \to M \times N$ is smooth,*[975]

  (ii) *for any $P \in M$ and $Q \in N$ the inclusion maps*

$$\begin{array}{rcl} M & \to & M \times N \\ x & \mapsto & (x, Q) \end{array} \quad \text{and} \quad \begin{array}{rcl} N & \to & M \times N \\ y & \mapsto & (P, y) \end{array}$$

are smooth.

Example. Let $M = \overline{B}^2$ and $N = [0,1]$, then $M \times N = \overline{B}^2 \times [0,1]$ is the solid cylinder which is a 3-dimensional topological manifold with boundary

$$\partial\big(\overline{B}^2 \times [0,1]\big) \;=\; \partial\overline{B}^2 \times [0,1] \cup \overline{B}^2 \times \partial([0,1]) \;=\; S^1 \times [0,1] \cup \overline{B}^2 \times \{0,1\}.$$

We refer to Figure 717 for an illustration.

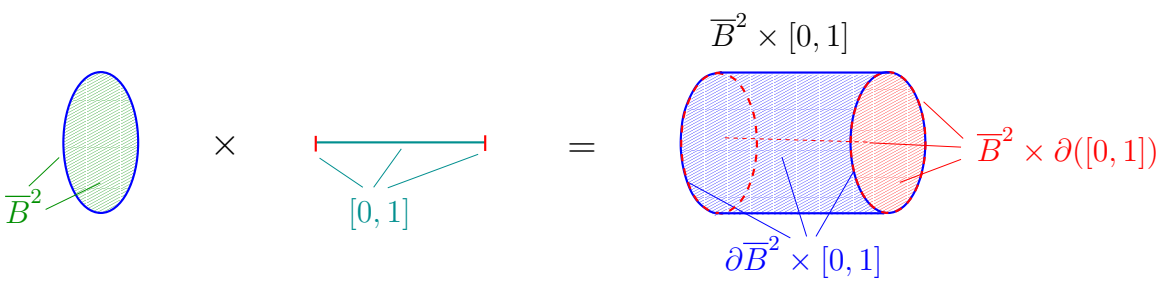

FIGURE 717.

Proof. Let M be an m-dimensional topological manifold and let N be an n-dimensional topological manifold. We consider the topological space $M \times N$. By Lemma 1.55 we remarked that the product of two Hausdorff spaces is again Hausdorff. Thus we see that $M \times N$ is Hausdorff. It follows from Lemma 3.1 that $M \times N$ is second-countable.

It remains to find charts for $M \times N$. More precisely, we have to find a chart of type (i) for each point in $(M \times N) \setminus (\partial M \times N \cup M \times \partial N)$ and we have to find a chart of type (ii) for each point in $\partial M \times N \cup M \times \partial N$. So let $(x, y) \in M \times N$. We distinguish three cases:

(1) If $x \in M \setminus \partial M$ and $y \in N \setminus \partial N$ then taking "product charts" it is straightforward to find a chart of type (i) for $(x, y) \in M \times N$.

(2) If $x \in M \setminus \partial M$ and $y \in \partial N$ or if $x \in \partial M$ and $y \in N \setminus \partial N$ then it is equally straightforward to find a chart of type (ii) for $(x, y) \in M \times N$.

[975]Note that it follows from Proposition 32.1 that $\overset{\circ}{M} = M \setminus \partial M$ and $\overset{\circ}{N} = N \setminus \partial N$ do not have boundary. Hence the smooth structure on $\overset{\circ}{M} \times \overset{\circ}{N}$ is given by the products of charts.

(3) Finally suppose that $x \in \partial M$ and $y \in \partial N$. We have to find a chart of type (ii) for $(x,y) \in M \times N$. It is straightforward to see that there exists an open neighborhood U of $(x,y) \in M \times N$ and a homeomorphism $\Phi\colon U \to \mathbb{R}^{m+n-2} \times \mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}$. We then compose this homeomorphism with the homeomorphism

$$\begin{array}{rcl} \Psi\colon \mathbb{R}^{m+n-2} \times \mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0} & \to & \mathbb{R}^{m+n-2} \times \mathbb{R} \times \mathbb{R}_{\geq 0} \\ (x_1, \dots, x_{m+n-2}, \underbrace{r\cos(\varphi), r\sin(\varphi)}_{=:z\in\mathbb{C}}) & \mapsto & (x_1, \dots, x_{m+n-2}, \underbrace{r\cos(2\varphi), r\sin(2\varphi)}_{=z^2}). \end{array}$$

It is straightforward to see that $\Psi \circ \Phi$ is a chart of type (ii) around (x,y).

If we start out with a smooth atlas for M and N then one can easily verify that the atlas that we have just constructed is also smooth and that it has the properties stated in (a) and (b). The statement that the smooth structure on $M \times N$ is natural is shown in [Wall2, Proposition 2.6.2]. □

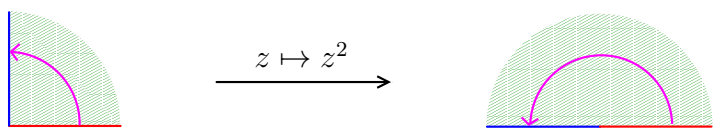

FIGURE 718. Illustration of the proof of Proposition 56.9.

The cross product now allows us to formulate the following proposition.

Proposition 56.10. *Let M be an m-dimensional topological manifold and let N be an n-dimensional topological manifold. Suppose M is equipped with an orientation $\{\mu_x\}_{x\in M\setminus\partial M}$ and that N is equipped with an orientation $\{\nu_y\}_{y\in N\setminus\partial N}$.*

(1) *Given $(x,y) \in (M \times N) \setminus \partial(M \times N)$ we denote by $\rho_{(x,y)}$ the image of $\mu_x \otimes \nu_y$ under the isomorphism*

$$H_m(M, M \setminus \{x\}) \otimes H_n(N, N \setminus \{y\}) \xrightarrow{\times} H_{m+n}(M \times N, (M \times N) \setminus \{(x,y)\})$$

from page 1317. Then these classes $\rho_{(x,y)}$ define an orientation on $M \times N$.

(2) *Suppose both M and N are compact and connected, then the map*

$$H_m(M, \partial M) \otimes H_n(N, \partial N) \xrightarrow{\times} H_{m+n}(M \times N, \partial(M \times N))$$

given by the cross product is an isomorphism and it has the property that

$$[M] \times [N] \;=\; [M \times N] \;\in\; H_{m+n}(M \times M, \partial(M \times N))$$

where $[M \times N]$ denotes the fundamental class of the compact topological manifold $M \times N$ equipped with the orientation defined in (1).

Proof. Let M be an m-dimensional topological manifold and let N be an n-dimensional topological manifold.

(1) The first statement of the proposition is a straightforward consequence of the definitions and the naturality of the cross product, see Lemma 56.7. For completeness' sake we sketch the proof. To simplify the notation we assume that $\partial M = \partial N = \varnothing$. Now let $(x, y) \in M \times N$. We pick an open neighborhood U of x and a class $\mu_U \in H_m(M, M\backslash U)$ and an open neighborhood V of y and a class $\nu_V \in H_n(N, N\backslash V)$ as given by the definition on page 1095. By the naturality of the cross product we obtain the following commutative diagram

$$\begin{tikzcd}
H_m(M, M\backslash U) \times H_n(N, N\backslash V) \arrow[r, "\times"] \arrow[d, "\mu_U \mapsto \mu_x"', "\nu_V \mapsto \nu_y"] & H_{m+n}(M \times N, M \times N\backslash(U \times V)) \arrow[d] \\
H_m(M, M\backslash\{x\}) \times H_n(N, N\backslash\{y\}) \arrow[r, "\times", "(\mu_x, \nu_y) \mapsto \rho_{(x,y)}"'] & H_{m+n}(M \times N, M \times N\backslash\{(x, y)\}).
\end{tikzcd}$$

It is now straightforward to verify that $\phi_{U\times V} := \mu_U \times \nu_V$ has the properties desired by the definition on page 1095.

(2) Now suppose that both M and N are compact. By Lemma 1.55, the product $M \times N$ is then also compact. Now let $x \in M \setminus \partial M$ and let $y \in N \setminus \partial N$. By Proposition 56.9 we have $(x, y) \in (M \times N) \setminus \partial(M \times N)$. Furthermore, by Lemma 56.7 we have the following commutative diagram

$$\begin{tikzcd}
H_m(M, \partial M) \otimes H_n(N, \partial N) \arrow[r, "\times"] \arrow[d] & H_{m+n}(M \times N, \partial(M \times N)) \arrow[d] \\
H_m(M, M \setminus \{x\}) \otimes H_n(N, N \setminus \{y\}) \arrow[r, "\times"] & H_{m+n}(M \times N, M \times N \setminus \{(x, y)\}).
\end{tikzcd}$$

The vertical maps are isomorphisms by Theorem 46.2. On page 1317 we saw that the bottom horizontal map is an isomorphism. It follows that, as claimed, the top horizontal map is also an isomorphism. The statement regarding the fundamental classes is an immediate consequence of the commutativity of the diagram and the definitions. □

Definition. Let M and N be oriented topological manifolds. We refer to the orientation on $M \times N$ defined in Proposition 56.10 (1) as the *product orientation.*

Remark. Recall that given any open subset $U \subset \mathbb{R}^k$, $k \in \mathbb{N}_0$, we introduced on page 1101 the standard orientation for U viewed as a topological manifold. (See also Figure 719 for a reminder.) The following lemma says that the above definition of the product orientation gives us the "expected" answer when we deal with open subsets of $\mathbb{R}^k$'s.

Proposition 56.11. *Let $U \subset \mathbb{R}^m$ and $V \subset \mathbb{R}^n$ be open non-empty subsets. We equip U and V with the standard orientation. Then the product orientation of $U \times V$, defined above, agrees with the standard orientation of $U \times V \subset \mathbb{R}^m \times \mathbb{R}^n = \mathbb{R}^{m+n}$.*

We postpone the proof of Proposition 56.11 to the next section.

Examples.

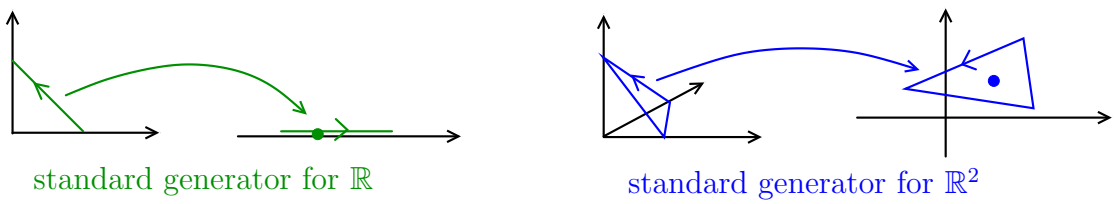

FIGURE 719.

(1) Let M and N be two oriented manifolds such that at most one of them has non-empty boundary. We have the following diagram

$$\begin{tikzcd}
\text{oriented manifolds } M, N \arrow[r, squiggly, "\text{Proposition 45.22}"] \arrow[d, squiggly, "\text{page 205}"] & \text{oriented topological manifolds } M, N \arrow[d, squiggly, "\text{see above}"] \\
\text{oriented manifold } M \times N \arrow[r, squiggly, "\text{Proposition 45.22}"] & \text{oriented topological manifold } M \times N.
\end{tikzcd}$$

It follows fairly easily from Proposition 56.11 that this diagram commutes.

(2) We write $I = [-1, 1]$. We view I as a 1-dimensional topological manifold and we equip I with the orientation coming from $\mathbb{R}$. Given $k \in \mathbb{N}_0$ we write

$$\partial I^k \;:=\; \{(x_1, \dots, x_k) \,|\, \text{there exists an } i \text{ with } x_i = -1 \text{ or } x_i = 1\}.$$

Given any $m, n \in \mathbb{N}$ one sees easily that

$$\partial(I^m \times I^n) \;=\; \partial I^m \times I^n \cup I^m \times \partial I^n \;=\; \partial(I^{m+n}).$$

(See also Figure 720 for an illustration.) It follows from Proposition 56.9 and the above discussion that we can view each $I^k = I \times \cdots \times I$ as a k-dimensional topological manifold with boundary given by the above subset ∂I^k. We equip I^k with the product orientation. It follows immediately from Proposition 56.11 that the orientation on the open subset $I^k \setminus \partial I^k \subset \mathbb{R}^k$ is the standard orientation.[976] As usual we denote by $[I^k] \in H_k(I^k, \partial I^k; \mathbb{Z})$ the fundamental class.

Now let $m, n \in \mathbb{N}_0$. We get a cross product

$$\overbrace{H_m(I^m, \partial I^m)}^{=\mathbb{Z}\cdot[I^m]} \otimes \overbrace{H_n(I^n, \partial I^n)}^{=\mathbb{Z}\cdot[I^n]} \;\to\; \overbrace{H_{m+n}(I^{m+n}, \partial I^{m+n})}^{=\mathbb{Z}\cdot[I^{n+n}]}$$

which by Proposition 56.10 (2) has the property that

$$[I^m] \times [I^n] \;=\; [I^{m+n}].$$

[976]Note that the homeomorphism

$$f\colon (I^k, \partial I^k) \;\to\; (\overline{B}^k, S^{k-1})$$

from Proposition 1.47 (2) has the property that the restriction to a dense open subset of $I^k \setminus \partial I^k \to B^k$ is an orientation-preserving diffeomorphism. In particular this homeomorphism is thus an orientation-preserving homeomorphism from the oriented topological manifold I^k to the oriented topological manifold $\overline{B}^k$.

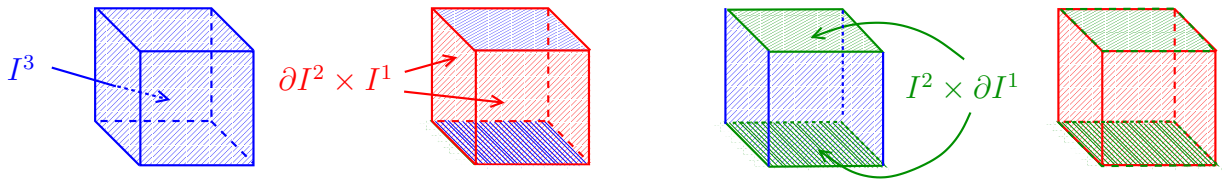

FIGURE 720.

56.6. **The shuffle product and the proof of Proposition 56.11** (∗)**.** In this section we will provide the proof of Proposition 56.11. The difficulty in the proof is that the definition of the cross product relies on the map Υ from Theorem 56.2. We gave a non-constructive proof of the existence of the map Υ. In this section we give an *explicit* description of a map ∇ which has all the properties that we had asked for in Theorem 56.2. We will then use this map ∇ to prove Proposition 56.11.

First we recall some notation from page 736.

Notation. For $i = 0, \dots, n$ we write

$$v_i \;:=\; (0, \dots, 1, 0, \dots, 0) \in \mathbb{R}^{n+1}.$$

Furthermore for $a_0, \dots, a_k \in \Delta^n$ we consider the map

$$\begin{aligned} [a_0, \dots, a_k] \colon \Delta^k &\to \Delta^n \\ \sum_{j=0}^{k} \lambda_j v_j &\mapsto \sum_{j=0}^{k} \lambda_j a_j. \end{aligned}$$

The map $[a_0, \dots, a_k]$ thus sends the standard k-simplex Δ^k to the simplex "spanned by $a_0, \dots, a_k$" in Δ^n.

Definition. Let $m, n \in \mathbb{N}_0$.

(1) An (m,n)-*shuffle* is a pair (μ, ν) of disjoint sets of integers

$$1 \le \mu_1 < \mu_2 < \dots < \mu_m \le m+n \quad \text{and} \quad 1 \le \nu_1 < \nu_2 < \dots < \nu_n \le m+n.$$

We denote by $\operatorname{sign}(\mu, \nu)$ the sign of the permutation $(\mu_1, \dots, \mu_m, \nu_1, \dots, \nu_n)$. We denote by $\eta^\mu \colon \Delta^{m+n} \to \Delta^m$ the unique affine linear map which satisfies $\eta^\mu(v_i) = v_j$ for $\mu_j \le i < \mu_{j+1}$.[977] The same way we define $\eta^\nu \colon \Delta^{m+n} \to \Delta^n$.

(2) Given two topological spaces X and Y we define

$$\begin{aligned} \nabla_{mn} \colon C_m(X) \otimes C_n(Y) &\to C_{m+n}(X \times Y) \\ (\sigma \otimes \tau) &\mapsto \sum_{(\mu,\nu)} \operatorname{sign}(\mu,\nu) \cdot \underbrace{(\overbrace{\sigma \circ \eta^\mu}^{\Delta^{m+n} \to X} \times \overbrace{\tau \circ \eta^\nu}^{\Delta^{m+n} \to Y})}_{\text{map } \Delta^{m+n} \to X \times Y} \end{aligned}$$

where we take the sum over all (m,n)-shuffles.

Examples.

[977] Here we implicitly use that $\mu_0 = 0$ and $\mu_{m+1} = m+n+1$.

(1) We consider the case $X = Y = \mathbb{R}$ and $m = n = 1$. There exist two $(1,1)$-shuffles, namely $\{\mu_1 = 1, \nu_1 = 2\}$ and $\{\mu_1 = 2, \nu_1 = 1\}$. Note that $\eta^1\colon \Delta^2 \to \Delta^1$ equals the map $[v_0, v_1, v_1]$ and that $\eta^2\colon \Delta^2 \to \Delta^1$ equals the map $[v_0, v_0, v_1]$. In Figure 721 we illustrate $\nabla_{11}(\sigma \otimes \tau)$ for two affine linear singular 1-simplices $\sigma\colon \Delta^1 \to X = \mathbb{R}$ and $\tau\colon \Delta^1 \to Y = \mathbb{R}$.

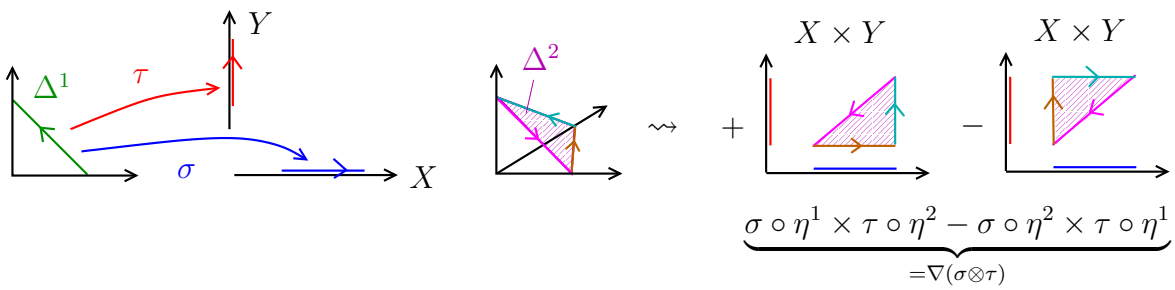

FIGURE 721. Illustration of the definition of the shuffle map.

(2) We consider the case $X = Y = S^1$ and $m = n = 1$. Furthermore we denote by $\mu\colon \Delta^1 \to S^1$ the singular 1-simplex that is given by $\mu(1-t, t) = e^{2\pi i t}$. On page 1118 we saw that μ represents the fundamental class of S^1 with the standard orientation. Comparing Figures 654 and 721 we see that the shuffle $\nabla(\mu \otimes \mu)$ is precisely the usual representative for the fundamental class of the 2-dimensional torus $S^1 \times S^1 = ([0,1] \times [0,1])/\sim$.

Proposition 56.12. *The maps ∇ that we had just defined have all the properties that we had mentioned in Theorem 56.2, i.e. the maps $\nabla\colon C_*(X) \otimes C_*(Y) \to C_*(X \times Y)$ are natural chain maps that on the 0-level equal the canonical maps that we introduced on page 1308.*

Proof. It follows immediately from the definition that the maps ∇_{mn} are natural and that on the 0-level they agree with the canonical maps. It is elementary (albeit rather painful) to verify that these maps are chain maps. We refer to [Dol, p. 184] and [EM2] for details and proofs. □

Now we can finally provide the proof of Proposition 56.11.

Proof of Proposition 56.11. It suffices to prove the statement for $U = \mathbb{R}^m$ and $V = \mathbb{R}^n$. Given any $k \in \mathbb{N}_0$ we consider the singular chain $\sigma_k = (-1)^k \cdot [v_0, \dots, v_k, 0]$. (In plain English the singular simplex $[v_0, \dots, v_k, 0]\colon \Delta^k \to \mathbb{R}^k$ is just given by the obvious projection.) We make the following observation:

(∗) Let $z \in \mathbb{R}^k$ be any point that lies in the interior of the image of σ_k. It follows from the discussion on page 1089 that the chain σ_k represents the standard generator of $H_k(\mathbb{R}^k, \mathbb{R}^k \setminus \{z\})$.

Next we consider the (m,n)-shuffle that is given by the sets $\mu_0 = \{1, \dots, m\}$ and by $\nu_0 = \{m+1, \dots, m+n\}$. It follows easily from the definitions that

$$\eta^{\mu_0} = [v_0, \dots, v_m, \dots, v_m]\colon \Delta^{m+n} \to \Delta^m \quad \text{and} \quad \eta^{\nu_0} = [v_m, \dots, v_m, \dots, v_{m+n}]\colon \Delta^{m+n} \to \Delta^n.$$

Also note that it is a straightforward consequence of the definitions that we have the following equality of singular $(m+n)$-chains in $\mathbb{R}^m \times \mathbb{R}^n = \mathbb{R}^{m+n}$:

$$(\sigma_m \circ \eta^{\mu_0}) \times (\sigma_n \circ \eta^{\nu_0}) \;=\; (-1)^m \cdot (-1)^n \cdot [v_0, \ldots, v_{m-1}, v_m, \ldots, v_{m+n-1}, 0] \;=\; \sigma_{m+n}.$$

We pick a point $(x, y) \in \mathbb{R}^m \times \mathbb{R}^n$ that lies in the interior of the image of σ_{m+n}. Note that x lies in the interior of the image of σ_m and that y lies in the interior of the image of σ_n.

It follows from the observation $(*)$, the definition of the product orientation on page 1321 and Proposition 45.17 (1) that it suffices to prove the following claim.

Claim. The following equality holds in $H_{m+n}(\mathbb{R}^{m+n}, \mathbb{R}^{m+n} \setminus \{(x,y)\})$:

$$[\sigma_m] \times [\sigma_n] \;=\; [\sigma_{m+n}].$$

We have

$$\begin{aligned}
[\sigma_m] \times [\sigma_n] \;&\underset{\substack{\uparrow \\ \text{Proposition 56.12 and Theorem 56.5}}}{=}\; [\nabla_{mn}(\sigma_m \otimes \sigma_n)] \;\underset{\substack{\uparrow \\ \text{by definition}}}{=}\; \Big[\sum_{(\mu,\nu)} \operatorname{sign}(\mu,\nu) \cdot (\sigma_m \circ \eta^\mu \times \sigma_n \circ \eta^\nu)\Big] \\
&\underset{\substack{\uparrow \\ \text{for all other shuffles } (\mu,\nu) \text{ the point } (x,y) \text{ does not lie in the image of } \sigma_m \circ \eta^\mu \times \sigma_n \circ \eta^\nu}}{=}\; \Big[\underbrace{\operatorname{sign}(\mu_0,\nu_0)}_{=1} \cdot \underbrace{(\sigma_m \circ \eta^{\mu_0} \times \sigma_n \circ \eta^{\nu_0})}_{=\sigma_{m+n}}\Big] \;=\; [\sigma_{m+n}].
\end{aligned}$$

This concludes the proof of the claim and thus of the proposition. □

56.7. **The Acyclic Model Theorem.** In this section we will prove two "Acyclic Model Theorems" which on many occasions will allow us to construct maps and homotopies. We start out with the following fairly friendly Acyclic Model Theorem. We will need this particular Acyclic Model Theorem later on when we construct Steenrod operations.

Theorem 56.13. (Acyclic Model Theorem) *Let $\mathcal{T}$ be the category of topological spaces and let $\mathcal{C}$ be the category of generalized*[978] *chain complexes. Let $G\colon \mathcal{T} \to \mathcal{C}$ be a coinvariant functor. Furthermore S be a natural transformation from the functor $X \mapsto C_*(X)$ to the functor $X \mapsto G(X)$. If $H_i(G(\Delta^k)) = 0$ for any $k \in \mathbb{N}_0$ and any $i \in \mathbb{N}_0$, then there exists a natural chain homotopy P from S to the zero map. In other words, for any topological space X and any $k \in \mathbb{N}$ there exists a natural map $P_X\colon C_k(X) \to G_{k+1}(X)$, such that for any $k \in \mathbb{N}_0$ we have*

$$\partial \circ P_X + P_X \circ \partial \;=\; S_X\colon C_k(X) \;\to\; G_k(X).$$

Sketch of proof. The proof of this theorem is very similar to the proof of Statement (2) of Theorem 56.5. First recall that the fact that S is a natural transformation means that for

[978] Here "generalized" just means, see page 745, that we also allow chain groups in negative degrees.

any topological space X we get a commutative diagram as follows:

$$\begin{tikzcd}
\dots \arrow[r] & C_2(X) \arrow[r, "\partial_2"] \arrow[d, "S"] & C_1(X) \arrow[r, "\partial_1"] \arrow[d, "S"] & C_0(X) \arrow[r] \arrow[d, "S"] & 0 \arrow[r] \arrow[d, "S"] & 0 \arrow[r] \arrow[d, "S"] & \dots \\
\dots \arrow[r] & G_2(X) \arrow[r, "\partial_2"] & G_1(X) \arrow[r, "\partial_1"] & G_0(X) \arrow[r, "\partial_0"] & G_{-1}(X) \arrow[r, "\partial_{-1}"] & G_{-2}(X) \arrow[r, "\partial_{-2}"] & \dots
\end{tikzcd}$$

Now we consider $\mathrm{id}_{\Delta^0} \in C_0(\Delta^0)$. It is a cycle in the chain complex $C_*(\Delta^0)$. Since the above diagram commutes we see that $S(\mathrm{id}_{\Delta^0})$ is also cycle in $G_0(\Delta^0)$. Since we assume that $H_0(G(\Delta^0)) = 0$ we see that there exists some $\mu_1 \in G_1(\Delta^0)$ with $\partial_1(\mu_1) = S(\mathrm{id}_{\Delta^0})$. Now, given any topological space X we define

$$\begin{array}{rcl}
P_0 \colon C_0(X) & \to & G_1(X) \\
\sum_{i=1}^m a_i \cdot \underset{\substack{\uparrow \\ \text{map } \Delta^0 \to X}}{f_i} & \mapsto & \sum_{i=1}^m a_i \cdot f_{i*}(\mu_1).
\end{array}$$

We iterate this procedure. Namely suppose that for $i = 0, \dots, k-1$ we have already constructed natural maps $P_i \colon C_i(X) \to G_{i+1}(X)$ such that $\partial \circ P_i + P_{i-1} \circ \partial = S_i$ for $i = 0, \dots, k-1$. For reference we consider the following diagram:

$$\begin{tikzcd}
\dots \arrow[r] & C_{k+1}(X) \arrow[r, "\partial_{k+1}"] \arrow[d, "S_{k+1}"] & C_k(X) \arrow[r, "\partial_k"] \arrow[d, "S_k"] \arrow[dl, dashed, "P_k"] & C_{k-1}(X) \arrow[r] \arrow[d, "S_{k-1}"] \arrow[dll, "P_k - 1"] & \dots \\
\dots \arrow[r] & G_{k+1}(X) \arrow[r, "\partial_{k+1}"'] & G_k(X) \arrow[r, "\partial_k"'] & G_{k-1}(X) \arrow[r, "\partial_{k-1}"] & \dots
\end{tikzcd}$$

Next we need to construct a suitable map P_k. We calculate that

$$\begin{aligned}
\partial_k((S_k - P_{k-1} \circ \partial)(\mathrm{id}_{\Delta_k})) &= \partial S_k(\mathrm{id}_{\Delta_k}) - \partial P_{k-1}(\partial\, \mathrm{id}_{\Delta_k}) \\
&\underset{\substack{\uparrow \\ \text{since } S \text{ is a chain map and since } \partial \circ P_{k-1} + P_{k-1} \circ \partial = S_i}}{=} S_k(\partial\, \mathrm{id}_{\Delta_k}) - (S_k - P_{k-2}\partial)(\partial\, \mathrm{id}_{\Delta_k}) = (P_{k-2} \circ \overbrace{\partial \circ \partial}^{=0})(\mathrm{id}_{\Delta_k}) = 0 \,.
\end{aligned}$$

Since we assume that $H_k(G(\Delta^k)) = 0$ we see that there exists some $\mu_{k+1} \in G_{k+1}(\Delta^k)$ with $\partial_{k+1}(\mu_{k+1}) = (S_k - P_{k-1} \circ \partial)(\mathrm{id}_{\Delta_k})$. Now, given any topological space X we define

$$\begin{array}{rcl}
P_k \colon C_k(X) & \to & G_{k+1}(X) \\
\sum_{i=1}^m a_i \cdot \underset{\substack{\uparrow \\ \text{map } \Delta^k \to X}}{f_i} & \mapsto & \sum_{i=1}^m a_i \cdot f_{i*}(\mu_{k+1}).
\end{array}$$

Using the fact that S is natural one can easily verify that P_k has the desired properties. $\square$

The above version of the Acyclic Model Theorem will not work for the situations that we need to deal with in the near future. There are two problems with the above Acyclic Model Theorem:

(1) On several occasions we will be interested in natural transformations of the form $C_*(X) \to C_*(X) \otimes C_*(X)$, but for $X = \Delta^k$ the chain complexes to the right does not satisfy the condition that the homology groups for $X = \Delta^k$ vanish in dimensions ≥ 0.
(2) We will also need to deal with situations where to the left we have more complicated chain complexes to the left, e.g. we might want to study natural transformations of the type $C_*(X) \times C_*(X) \to C_*(X \times X)$.

To formulate a version of the Acyclic Model Theorem that deals with the above two issues we need a few more definitions.

Definition.

(1) An *augmented chain complex* is a chain complex
$$(C_*, \partial_*) \;=\; \ldots \xrightarrow{\partial_3} C_2 \xrightarrow{\partial_2} C_1 \xrightarrow{\partial_1} C_0 \to 0$$
together with an epimorphism $\epsilon\colon C_0 \to \mathbb{Z}$ such that $\epsilon \circ \partial_1 \colon C_1 \to \mathbb{Z}$ is the zero map.
(2) We say that an augmented chain complex $((C_*, \partial_*), \epsilon\colon C_0 \to \mathbb{Z})$ is *acyclic* if the generalized chain complex
$$\begin{array}{ccccccccc} \ldots \xrightarrow{\partial_3} & C_2 & \xrightarrow{\partial_2} & C_1 & \xrightarrow{\partial_1} & C_0 & \xrightarrow{\epsilon} & \mathbb{Z} & \to 0 \\ & & & & & & & \uparrow & \\ & & & & & & & \text{degree } -1 & \end{array}$$
is acyclic, i.e. if all homology groups are zero.
(3) Let $((C_*, \partial_*), \epsilon)$ and $((C'_*, \partial'_*), \epsilon')$ be two augmented chain complexes. A *chain map of augmented chain complexes* is a chain map $f_*\colon C_* \to C'_*$ such that the following diagram commutes:
$$\begin{array}{ccc} C_0 & \xrightarrow{\epsilon} & \mathbb{Z} \\ {\scriptstyle f_*}\downarrow & & \downarrow{\scriptstyle =} \\ C'_0 & \xrightarrow{\epsilon'} & \mathbb{Z}. \end{array}$$
(4) We refer to the category $\mathcal{A}$ with
$$\begin{aligned} \mathrm{Ob}(\mathcal{A}) &= \text{augmented chain complexes} \\ \mathrm{Mor}((C,\epsilon),(C',\epsilon')) &= \begin{array}{c}\text{set of chain maps of augmented chain complexes} \\ \text{from } (C,\epsilon) \text{ to } (C',\epsilon')\end{array} \end{aligned}$$
as the *category of augmented chain complexes.*

Examples.

(1) Let X be a non-empty topological space. We denote by $\epsilon_X\colon C_0(X) \to \mathbb{Z}$ the augmentation that we introduced on page 742, i.e. ϵ_X is the map that sends each singular 0-simplex to 1. It follows from Lemma 29.4 (1) that $(C_*(X), \epsilon_X)$ is an augmented chain complex. If X is a contractible topological space, e.g. if $X = \Delta^k$, then it follows from Lemma 31.1 (7) that the corresponding augmented chain complex is acyclic.

(2) If (C_*, μ) and (D_*, ν) are two augmented chain complexes then the tensor product $C_* \otimes D_*$ of chain complexes, as defined in Lemma 43.2, together with the map

$$\begin{array}{rcl} \mu \otimes \nu \colon (C_* \otimes D_*)_0 = C_0 \otimes D_0 & \to & \mathbb{Z} \\ \sum\limits_{i=1}^{k} c_i \otimes d_i & \mapsto & \sum\limits_{i=1}^{k} \mu(c_i) \cdot \nu(d_i) \end{array}$$

is easily seen to be an augmented chain complex.[979]

Definition. We say a chain complex C_* is *almost acyclic* if $H_i(C_*) = 0$ for $i \geq 1$ and if $H_0(C_*) \cong \mathbb{Z}$.

Example. If X is a contractible topological space, then it follows from Corollary 30.8 that $C_*(X)$ is almost acyclic.

Proposition 56.14. *Let C_* and D_* be two chain complexes. If C_* and D_* are almost acyclic and if C_* is free, i.e. if each chain group C_k is a free abelian group, then $C_* \otimes D_*$ is also almost acyclic.*

Proof. Let $n \in \mathbb{N}_0$. Since C_* is free we can apply the Künneth Theorem for Chain Complexes 43.7 which gives us the following short exact sequence:

$$0 \to \bigoplus_{p+q=n} H_p(C_*) \otimes H_q(D_*) \xrightarrow{\Theta} H_n(C_* \otimes D_*) \to \bigoplus_{p+q=n-1} \operatorname{Tor}(H_p(C_*), H_q(D_*)) \to 0.$$

The proposition is an immediate consequence of this short exact sequence and of some very elementary statements regarding tensor products and torsion groups, see Lemma 42.3 and 42.17. □

The following lemma gives a convenient criterion for showing that augmented chain complexes are acyclic.

Lemma 56.15. *Let $((C_*, \partial_*), \epsilon)$ be an augmented chain complex. If the chain complex (C_*, ∂_*) is almost acyclic, then the augmented chain complex $((C_*, \partial_*), \epsilon)$ is acyclic.*

Proof $(*)$. We denote by $\widetilde{C}_*$ the generalized chain complex

$$\ldots \xrightarrow{\partial_3} C_2 \xrightarrow{\partial_2} C_1 \xrightarrow{\partial_1} C_0 \xrightarrow{\epsilon} \mathbb{Z} \longrightarrow 0.$$

We need to show that this chain complex is acyclic. It is clear that for $i \geq 1$ we have $H_i(\widetilde{C}_*) = H_i(C_*) = 0$. It remains to show that $H_0(\widetilde{C}_*) = 0$. Since $\mathbb{Z}$ is a free abelian group

[979] Indeed, by definition $(C_* \otimes D_*)_1$ is generated by elements $c_1 \otimes d_0$ with $C_1 \in C_1$ and $d_0 \in D_0$ and by elements $c_0 \otimes d_1$ with $C_0 \in C_0$ and $d_1 \in D_1$. We calculate that

$$((\mu \otimes \nu) \circ \partial_1)(c_1 \otimes d_0) = (\mu \otimes \nu)(\partial c_1 \otimes d_0 + (-1)^1 \cdot c_1 \otimes \underbrace{\partial d_0}_{=0}) = (\mu \otimes \nu)(\partial c_1 \otimes d_0) = \mu(\partial c_1) \cdot \nu(d_0) = 0 \cdot \nu(d_0) = 0.$$

The same argument shows that $((\mu \otimes \nu) \circ \partial_1)(c_0 \otimes d_1) = 0$.

and since $\epsilon C_0 \to \mathbb{Z}$ is an epimorphism we can pick a map $s\colon \mathbb{Z} \to C_0$ with $\epsilon \circ s = \mathrm{id}_{\mathbb{Z}}$. As in Lemma 31.1 (4) one can easily show that the map

$$\begin{array}{rcl} H_0(\widetilde{C}_*) \oplus \mathbb{Z} & \to & H_0(C_*) \\ [\sigma] \oplus n & \mapsto & [\sigma] + s(n) \end{array}$$

is an isomorphism. Since $H_0(C) \cong \mathbb{Z}$ it follows from Exercise 11.2 (b) (see also more generally Proposition 11.2) that $H_0(\widetilde{C}_*) = 0$. □

Definition. Let $\mathcal{K}$ be a category (in all applications $\mathcal{K}$ will be the category of non-empty topological spaces or the category of tuples of non-empty topological spaces) and let $F\colon \mathcal{K} \to \mathcal{A}$ be a covariant functor from $\mathcal{K}$ to the category $\mathcal{A}$ of augmented chain complexes. Let $\mathcal{M}$ be a collection of objects of $\mathcal{K}$.

(1) We say the functor F is *acyclic relative to* $\mathcal{M}$ if given any $X \in \mathcal{M}$ the augmented chain complex $F(X)$ is acyclic.
(2) We say the functor F is *free relative to* $\mathcal{M}$ if for each $k \in \mathbb{N}_0$ there exists $\mathcal{M}_k \subset \mathcal{M}$ and if for each $M \in \mathcal{M}_k$ there exists an element $\sigma_M \in F_k(M)$[980] such that given any $X \in \mathcal{K}$ the following two statements hold:
   (a) The set

$$\{\underbrace{F(f)}_{\substack{\uparrow \\ \text{the morphism } f\colon M \to X \text{ induces a homomorphism } F(f)\colon F_k(M) \to F_k(X)}}(\sigma_M) \in F_k(X) \mid \text{ with } M \in \mathcal{M}_k \text{ and } f \in \mathrm{Mor}(M, X)\}$$

   is a basis for the abelian group $F_k(X)$.[981]
   (b) The description of the set in (a) has no double elements, much more precisely, for $(M, f) \neq (M', f')$ we have $F(f)(\sigma_M) \neq F(f')(\sigma_{M'})$.

Remark. The objects in a collection $\mathcal{M}$ as in the previous definition are often called *models*.

The definition of "free relative to $\mathcal{M}$" is arguably somewhat intimidating. The following example should convince the reader that in practice it is not that bad.

Example. Let $\mathcal{K}$ be the category of non-empty topological spaces and let F be the covariant functor that assigns to each $X \in \mathcal{K}$ the augmented singular chain complex $(C_*(X), \epsilon_X)$. We consider

$$\mathcal{M} \ := \ \{\Delta^k \mid k \in \mathbb{N}_0\} \ = \ \text{the set of all standard simplices.}$$

We claim that F is acyclic and free relative to $\mathcal{M}$:

(1) By Lemma 31.1 (7) we know that for every $k \in \mathbb{N}_0$ we have $\widetilde{H}_*(\Delta^k) = 0$. But this just means that $\mathcal{M}$ is acyclic relative to F.

[980] Here $F_k(M)$ is the the k-chain group of the chain complex $F(M)$.
[981] In particular this implies that each $F_k(X)$ is a free abelian group.

(2) Let $k \in \mathbb{N}_0$. We set $\mathcal{M}_k = \{\Delta_k\}$ and we consider $\sigma_k = \mathrm{id}_{\Delta^k} \in C_k(\Delta_k)$. Now recall that given any topological space X and given any $k \in \mathbb{N}_0$ we have

$$\begin{array}{rcl} & \text{by definition of } C_k(X)\text{, see page 736} & \\ & \downarrow & \\ C_k(X) & = & \text{free abelian group generated by the set of singular } k\text{-simplices in } X \\ & = & \text{free abelian group generated by the set of all maps } \underbrace{f\colon \Delta^k \to X}_{=f_*(\mathrm{id}_{\Delta^k})}. \\ & \uparrow & \\ & \text{by definition of a singular } k\text{-simplex, see page 736} & \end{array}$$

But this means that the set $\{f_*(\mathrm{id}_{\Delta^k})\}_{f\colon \Delta^k \to X}$ is a basis for $C_k(X)$.

Now we can formulate the main theorem of this section.

Theorem 56.16. (Acyclic Model Theorem) *Let $\mathcal{K}$ be a category with a collection of objects $\mathcal{M}$. Furthermore let $F\colon \mathcal{K} \to \mathcal{A}$ be two covariant functors from $\mathcal{K}$ to the category of augmented chain complexes. If F is free relative to $\mathcal{M}$ and if G is acyclic relative to $\mathcal{M}$, then the following statements hold:*

(1) *There exists a natural transformation T from F to G. In other words, given any topological space X we have a chain map $T_X\colon F(X) \to G(X)$ of augmented chain complexes such that for any map $f\colon X \to Y$ between topological spaces the following diagram commutes:*[982]

$$\begin{tikzcd} F(X) \arrow[r, "F(f)"] \arrow[d, "T_X"'] & F(Y) \arrow[d, "T_Y"] \\ G(X) \arrow[r, "F(f)"] & G(Y). \end{tikzcd}$$

(2) *Given two natural transformations S_X and T_X from F to G there is a natural chain homotopy P_X between them.*

Proof. The proof is, ultimately very much the same as the proof of Theorem 56.5. We decline to provide a proof and we follow the lead given by Munkres [Mun, p. 185], namely like Munkres we assign the proof as an exercise to the reader. Alternatively the reader can find the proof in [Sp, p. 169], [Vic, Theorem 5.3] or [Dol2, p. 175]. □

As an example for the Acyclic Model Theorem 56.16 we will prove a statement that we will anyway need shortly. To formulate the application we need the following definition.

Definition. A *diagonal approximation* is a natural chain map

$$\varphi\colon C_*(X) \;\to\; C_*(X) \otimes C_*(X)$$

[982]Note that the zero map is *not* a chain map of augmented chain complexes, since it does not respect the augmentation.

such that for each $x \in X$, viewed as a singular 0-simplex, we have

$$\varphi(x) \;=\; x \otimes x \;\in\; \underbrace{C_0(X) \otimes C_0(X)}_{=(C_*(X)\otimes C_*(X))_0}.$$

Proposition 56.17. *Given any two diagonal approximations Φ and Ψ there exists a natural chain homotopy equivalence between Φ and Ψ.*

Proof. We let $\mathcal{K}$ be the category of non-empty topological spaces. As on page 1329 we consider the collection

$$\mathcal{M} \;:=\; \{\Delta^k \,|\, k \in \mathbb{N}_0\} \;=\; \text{the set of all standard simplices.}$$

We consider the covariant functors[983]

$$\begin{array}{rcl} F\colon \mathcal{K} & \to & \mathcal{A} \\ X & \mapsto & (C_*(X), \epsilon_X) \end{array} \qquad \text{and} \qquad \begin{array}{rcl} G\colon \mathcal{K} & \to & \mathcal{A} \\ X & \mapsto & (C_*(X) \otimes C_*(X), \epsilon_X \otimes \epsilon_X). \end{array}$$

Now let $\Phi, \Psi\colon C_*(X) \to C_*(X) \otimes C_*(X)$ be two diagonal approximations. By definition these are natural transformations from F to G. The hypothesis that Φ and Ψ are diagonal approximations implies that Φ and Ψ define chain maps of augmented chain complexes.

By the Acyclic Model Theorem 56.16 (2) it remains to prove the following claim.

Claim.

(1) The functor F is free relative to $\mathcal{M}$.
(2) The functor G is acyclic relative to $\mathcal{M}$.

We prove these two statements:

(1) Conveniently enough we showed on page 1330 that F is free relative to $\mathcal{M}$.
(2) We need to show that given any $k \in \mathbb{N}_0$ the corresponding augmented chain complex $(C_*(\Delta^k) \otimes C_*(\Delta^k), \epsilon_X \otimes \epsilon_X)$ is acyclic. By Lemma 56.15 it suffices to show that the chain complex $C_*(\Delta^k) \otimes C_*(\Delta^k)$ is almost acyclic. But this is a consequence of the fact that $C_*(\Delta^k)$ is almost acyclic, see page 1328, and Proposition 56.14.

This concludes the proof of the claim. □

[983] It follows from the discussion on page 1327 that both F and G are indeed functors to the category of augmented chain complexes.

57. The cup product

57.1. **A first definition of the cup product.** Let X be a topological space. The cross product from page 1316 applied to the same topological spaces $X = Y$ gives us in particular the cross product[984]

$$\begin{array}{rcl} \times\colon \overbrace{H_p(C_*(X)) \otimes H_q(C_*(X))}^{=H_p(X)\otimes H_q(X)} & \to & H_{p+q}(C_*(X) \otimes C_*(X)) \xrightarrow{\Upsilon_*} \overbrace{H_{p+q}(C_*(X \times X))}^{=H_{p+q}(X\times X)}. \\ [c] \otimes [d] & \mapsto & [c \otimes d]. \end{array}$$

This is very nice, but this construction does not give us a product on the homology groups of X itself, since we end up in the homology of a different topological space.

Now we try our luck with cohomology groups. Before we can study maps on cohomology groups we need a little bit of algebraic preparation.

Definition. Let $\mathcal{C}_*$ and $\mathcal{D}_*$ be chain complexes.

(1) Given $p, q \in \mathbb{N}_0$ we denote by

$$\Pi_{p,q}\colon (\mathcal{C}_* \otimes \mathcal{D}_*)_{p+q} = \bigoplus_{i+j=p+q} \mathcal{C}_i \otimes \mathcal{D}_j \ \to\ \mathcal{C}_p \otimes \mathcal{D}_q$$

the obvious projection map.

(2) Let R be a commutative ring. We denote by Ξ the map

$$\begin{aligned} \mathrm{Hom}(\mathcal{C}_p, R) \times \mathrm{Hom}(\mathcal{D}_q, R) &\to \mathrm{Hom}((\mathcal{C} \otimes \mathcal{D})_{p+q}, R) \\ (\varphi, \psi) &\mapsto \left((\mathcal{C}_* \otimes \mathcal{D}_*)_{p+q} \xrightarrow{\Pi_{p,q}} \mathcal{C}_p \otimes \mathcal{D}_q \xrightarrow{\varphi\otimes\psi} \begin{array}{rcl} R\otimes R & \to & R \\ a\otimes b & \mapsto & a\cdot b \end{array} \right). \end{aligned}$$

Lemma 57.1. *Let $\mathcal{C}_*$ and $\mathcal{D}_*$ be chain complexes. Furthermore let R be a commutative ring. The map*

$$\begin{array}{rcl} H^p(\mathcal{C}_*; R) \times H^q(\mathcal{D}; R) & \to & H^{p+q}(\mathcal{C}_* \otimes \mathcal{D}_*; R) \\ ([\varphi], [\psi]) & \mapsto & [\Xi(\varphi, \psi)] \end{array}$$

is well-defined.

Proof. We leave the verification of the lemma as an exercise to the reader. □

We return to topology. So let X be a topological space. We consider the map[985]

$$\begin{array}{rcl} \overbrace{H^p(C_*(X); \mathbb{Z}) \otimes H^q(C_*(X); \mathbb{Z})}^{=H^p(X;\mathbb{Z})\otimes H^q(X;\mathbb{Z})} & \xrightarrow{\Xi} & H^{p+q}(C_*(X) \otimes C_*(X); \mathbb{Z}) \xrightarrow{\Theta^*} \overbrace{H^{p+q}(C_*(X \times X); \mathbb{Z})}^{=H^{p+q}(X\times X;\mathbb{Z})}. \\ [\varphi] \otimes [\psi] & \mapsto & [\varphi \otimes \psi \circ \Pi_{p,q}]. \end{array}$$

Summarizing we get a map

$$H^p(X; \mathbb{Z}) \otimes H^q(X; \mathbb{Z}) \ \to\ H^{p+q}(X \times X; \mathbb{Z})$$

[984]Here $\Upsilon\colon C_*(X) \otimes C_*(Y) \to C_*(X \times Y)$ denotes the Eilenberg-Zilber map from Theorem 56.1.

[985]Here $\Theta\colon C_*(X \times Y) \to C_*(X) \otimes C_*(Y)$ denotes the Eilenberg-Zilber map from Theorem 56.1 (1). It follows from Theorem 56.1 (2) and Lemma 48.8 (3) that the definition below does not depend on the choice of Θ.

which is sometimes called the *cross product on cohomology*. Again, this is nice, but exactly as in the case of the cross product on homology, we end up in the cohomology of $X \times X$, but we really would like to end up in the cohomology of X.

Now we have to find a way how to go back from the topological space $X \times X$ to the original space X. In general there does not exist an "interesting"[986] map $X \times X \to X$. But, as we saw before, there does exist an interesting map in the opposite direction, namely the diagonal map

$$\begin{array}{rcl} d\colon X & \to & X \times X \\ x & \mapsto & (x, x). \end{array}$$

This diagonal map d induces a map

$$d_*\colon H_*(X;\mathbb{Z}) \;\to\; H_*(X \times X;\mathbb{Z})$$

on homology, and, much more interesting in our context, it also induces a map

$$d^*\colon H^*(X \times X;\mathbb{Z}) \;\to\; H^*(X;\mathbb{Z}).$$

on cohomology groups that goes in the "opposite direction". This discussion leads us to the following definition.

Definition. Let X be a topological space. We define the *cup product*[987] on the cohomology groups of X as the composition of the following maps:

$$H^p(X;\mathbb{Z}) \times H^q(X;\mathbb{Z}) \;\to\; H^p(X;\mathbb{Z}) \otimes H^q(X;\mathbb{Z}) \;\xrightarrow{\Theta^* \circ \Xi}\; H^{p+q}(X \times X;\mathbb{Z}) \;\xrightarrow{d^*}\; H^{p+q}(X;\mathbb{Z}).$$

For the resulting pairing we use the notation

$$\begin{array}{rcl} H^p(X;\mathbb{Z}) \times H^q(X;\mathbb{Z}) & \to & H^{p+q}(X;\mathbb{Z}) \\ (a, b) & \mapsto & a \smile b \end{array}$$

and we refer to $a \smile b$ as the *cup product of a and b*.

57.2. **An alternative definition of the cup product.** The definition of the cup product in the previous section was very natural and we could now develop the theory of the cup product using that definition. If one takes that route then one has to deal with the awkward fact that the Eilenberg-Zilber map Θ is not very explicit.

Now we give an alternative definition of the cup product which is more ad hoc, but which works surprisingly well in practice.

Definition. Let X be a topological space and let R be a commutative ring. Furthermore let $\varphi \in C^p(X;R)$ and $\psi \in C^q(X;R)$ be cochains. We define the *cup product* of φ and ψ to

[986]The projection from $X \times X$ onto one of the two factors does not count as "interesting", since it does not "mix" the two factors. In fact in Exercise 57.1 we will see that the map

$$H_*(X) \otimes H_*(X) \;\xrightarrow{\times}\; H_*(X \times X) \;\xrightarrow{p_*}\; H_*(X),$$

where $p\colon X \times X \to X$ denotes the projection on the first factor, is the zero map.

[987]The name "cup product" comes from the notation "$a \smile b$" for the composition since $\cup$ looks like a cup.

be the singular cochain[988]

$$\varphi \cup \psi \colon C_{p+q}(X) \quad \to \quad R$$

that is given by[989]

$$(\sigma \colon \Delta^{p+q} \to X) \quad \mapsto \quad \underbrace{\varphi(\sigma \circ [v_0, \dots, v_p])}_{\in R} \cdot \underbrace{\psi(\sigma \circ [v_p, \dots, v_{p+q}])}_{\in R}.$$

The[990] cup product thus defines a map

$$\cup \colon C^p(X;R) \times C^q(X;R) \;\to\; C^{p+q}(X;R).$$

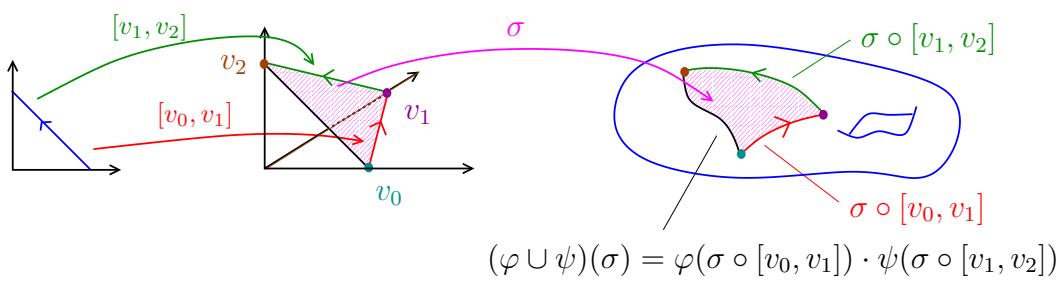

FIGURE 722. Illustration of the definition of the cup product.

Remark. The sign conventions for the cup product for cohomology classes $\varphi \in H^p(X;R)$ and $\psi \in H^q(X;R)$ differ in the literature. More precisely, given a topological space X and cochains $\varphi \in C^p(X;R)$ and $\psi \in C^q(X;R)$ the cup product $\varphi \cup \psi$, applied to a singular $(p+q)$-simplex $\sigma \colon \Delta^{p+q} \to X$ is defined as follows:

		$(\varphi \cup \sigma)(\sigma)$
(a)	Hatcher [Hat, p. 206]	$\varphi(\sigma \circ [v_0, \dots, v_p]) \cdot \psi(\sigma \circ [v_p, \dots, v_{p+q}])$
(b)	Bredon [Bre, p. 328]	$(-1)^{pq} \cdot \varphi(\sigma \circ [v_0, \dots, v_p]) \cdot \psi(\sigma \circ [v_p, \dots, v_{p+q}])$
(c)	Dold [Dol, p. 222]	$(-1)^{pq} \cdot \varphi(\sigma \circ [v_0, \dots, v_p]) \cdot \psi(\sigma \circ [v_p, \dots, v_{p+q}])$
(d)	Spanier [Sp, p. 251]	$\varphi(\sigma \circ [v_0, \dots, v_p]) \cdot \psi(\sigma \circ [v_p, \dots, v_{p+q}])$
(e)	Munkres [Mun, p. 288]	$\varphi(\sigma \circ [v_0, \dots, v_p]) \cdot \psi(\sigma \circ [v_p, \dots, v_{p+q}])$

So we see that our sign convention agrees with the conventions of Hatcher, Spanier and Munkres, but they differ by the sign $(-1)^{pq}$ from the conventions used in Bredon and Dold.

Example. Since the second definition of the cup product is initially strange and not very intuitive we consider an example in slightly more detail. In the following we consider the torus $T = S^1 \times S^1 = [0,1] \times [0,1]/\sim$ with the two singular 2-simplices σ_1 and σ_2 illustrated in Figure 723 which we already saw in Figure 654. We recall the following notation:

[988]Here, when we write $[v_0, \dots, v_p] \colon \Delta^p \to \Delta^{p+q}$ and $[v_p, \dots, v_{p+q}] \colon \Delta^q \to \Delta^{p+q}$, we use the notation from page 1323.

[990]In the literature, given a singular n-simplex $\sigma \colon \Delta^n \to X$ one often writes ${}_p\lfloor\sigma = \sigma \circ [v_0, \dots, v_p]$ and $\sigma\rfloor_p = \sigma \circ [v_{n-p}, \dots, v_n]$.

(1) we denote by p respectively q the projection $S^1 \times S^1 \to S^1$ onto the first respectively second factor,
(2) we denote by $\mu\colon \Delta^1 \to S^1$ the singular 1-simplex given by $\mu(1-t,t) = e^{2\pi i t}$,
(3) furthermore we denote by $\nu\colon \Delta^1 \to S^1$ the constant singular 1-simplex that is given by $\nu(1-t,t) = 1$.
(4) finally we recall that on page 1166 we introduced a cochain $\theta := \theta_{\mathbb{Z}} \in C^1(S^1;\mathbb{Z})$ and we showed that $\theta(\mu) = 1$, also note that $\theta(\nu) = 0$.

We want to determine the values of $p^*(\theta) \cup q^*(\theta) \in C^2(T;\mathbb{Z}) = \mathrm{Hom}(C_2(T),\mathbb{Z})$ on the singular 2-simplices σ_1 and σ_2. We have

$$\begin{aligned}(p^*(\theta) \cup q^*(\theta))(\sigma_1) &= p^*(\theta)(\sigma_1 \circ [v_0,v_1]) \cdot q^*(\theta)(\sigma_1 \circ [v_1,v_2]) \\ &= \theta(\underbrace{p \circ \sigma_1 \circ [v_0,v_1]}_{=\nu}) \cdot \theta(\underbrace{q \circ \sigma_1 \circ [v_1,v_2]}_{=\nu}) \quad = \quad 0 \cdot 0 \quad = \quad 0.\end{aligned}$$

Much more interestingly we have

$$\begin{aligned}(p^*(\theta) \cup q^*(\theta))(\sigma_2) &= p^*(\theta)(\sigma_2 \circ [v_0,v_1]) \cdot q^*(\theta)(\sigma_2 \circ [v_1,v_2]) \\ &= \theta(\underbrace{p \circ \sigma_2 \circ [v_0,v_1]}_{=\mu}) \cdot \theta(\underbrace{q \circ \sigma_2 \circ [v_1,v_2]}_{=\mu}) \quad = \quad 1 \cdot 1 \quad = \quad 1.\end{aligned}$$

To aid the reader we also recall in Figure 724 the notation that we had initially introduced on page 1117 and that we use in Figure 723.

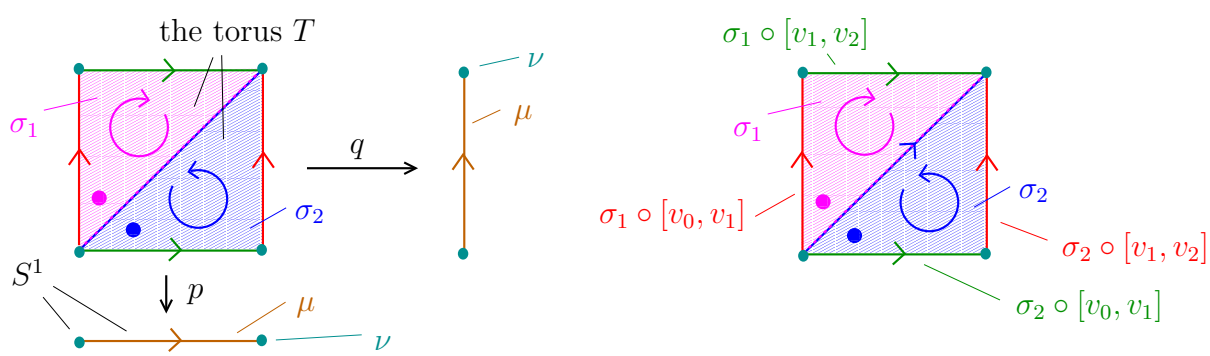

FIGURE 723.

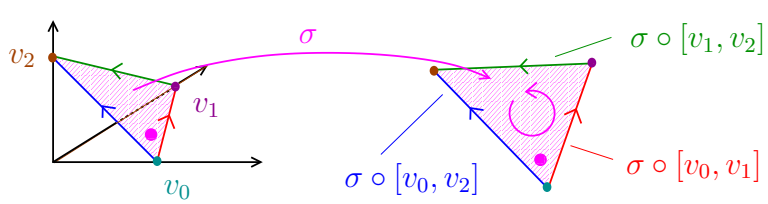

FIGURE 724. Notation of the "dotted triangle".

The definition of the cup product on cochains might look strange and arbitrary. But the following lemma shows that it behaves well with respect to coboundary maps.

Lemma 57.2. *Let X be a topological space and let R be a commutative ring. Furthermore let $\varphi \in C^p(X;R)$ and $\psi \in C^q(X;R)$. Then*

$$\delta(\varphi \cup \psi) \;=\; \delta\varphi \cup \psi \,+ (-1)^p \cdot \varphi \cup \delta\psi \;\in\; C^{p+q+1}(X;R).$$

Remark. A similar looking statement holds for differential forms. More precisely, given a manifold M and two differential forms $\omega \in \Omega^p(M)$ and $\eta \in \Omega^q(M)$ it follows from [Le2, Theorem 14.24 (ii)] that

$$d(\omega \wedge \eta) \;=\; d\omega \wedge \eta \,+\, (-1)^p \cdot \omega \wedge d\eta \;\in\; \Omega^{p+q+1}(M).$$

The (co-) boundary formula of Lemma 57.2 is of course also very similar to the definition of the boundary map in the tensor product of two chain complexes.

Proof $(*)$. The lemma follows from an elementary, albeit slightly confusing, calculation. Indeed, let $\varphi \in C^p(X;R)$ and $\psi \in C^q(X;R)$ be cochains. We have to prove the following equality:

$$\delta(\varphi \cup \psi) \;=\; \delta\varphi \cup \psi \,+ (-1)^p \cdot \varphi \cup \delta\psi \;\in\; C^{p+q+1}(X;R) = \mathrm{Hom}(C_{p+q+1}(X), R).$$

So let $\sigma\colon \Delta^{p+q+1} \to X$ be a singular $(p+q+1)$-simplex. Then we have the following three equalities in R:[991]

$$\begin{aligned}
\text{(a)}\quad (\delta(\varphi \cup \psi))(\sigma) &= (\varphi \cup \psi)\Big(\sum_{j=0}^{p+q+1} (-1)^j \cdot \sigma \circ i_j^{p+q+1}\Big) \\
&= (\varphi \cup \psi)\Big(\sum_{j=0}^{p} (-1)^j \cdot \sigma \circ i_j^{p+q+1}\Big) + (\varphi \cup \psi)\Big(\sum_{j=p+1}^{p+q+1} (-1)^j \cdot \sigma \circ i_j^{p+q+1}\Big) \\
&= \sum_{j=0}^{p} (-1)^j \cdot (\varphi \cup \psi)(\sigma \circ i_j^{p+q+1}) + (-1)^p \cdot \sum_{k=1}^{q+1} (-1)^k \cdot (\varphi \cup \psi)(\sigma \circ i_{k+p}^{p+q+1}) \\
&= \sum_{j=0}^{p} (-1)^j \cdot \varphi(\underbrace{\sigma \circ [v_0, \dots, v_{p+1}] \circ i_j^{p+1}}_{\text{map } \Delta^p \to X}) \cdot \psi(\underbrace{\sigma \circ [v_{p+1}, \dots, v_{p+q+1}]}_{\text{map } \Delta^q \to X}) \\
&\quad + (-1)^p \cdot \sum_{k=1}^{q+1} (-1)^k \cdot \varphi(\underbrace{\sigma \circ [v_0, \dots, v_p]}_{\text{map } \Delta^p \to X}) \cdot \psi(\underbrace{\sigma \circ [v_p, \dots, v_{p+q+1}] \circ i_k^{q+1}}_{\text{map } \Delta^q \to X}).
\end{aligned}$$

[991]Here in the argument we use on several occasions that for a singular n-cochain ϕ and a singular $(n+1)$-simplex μ we have by definition

$$(\delta\phi)(\mu) \;=\; \phi(\partial\mu) \;=\; \phi\Big(\sum_{l=0}^{n+1} (-1)^l \cdot \mu \circ i_l^{n+1}\Big).$$

$$\begin{aligned}
\text{(b)}\quad (\delta\varphi \cup \psi)(\sigma) &= (\delta\varphi)(\sigma \circ [v_0, \dots, v_{p+1}]) \cdot \psi(\sigma \circ [v_{p+1}, \dots, v_{p+q+1}]) \\
&= \varphi\Big(\sum_{j=0}^{p+1} (-1)^j \cdot \underbrace{\sigma \circ [v_0, \dots, v_{p+1}] \circ i_j^{p+1}}_{\text{map } \Delta^p \to X}\Big) \cdot \psi(\underbrace{\sigma \circ [v_{p+1}, \dots, v_{p+q+1}]}_{\text{map } \Delta^q \to X}) \\
&= \sum_{j=0}^{p+1} (-1)^j \cdot \varphi(\sigma \circ [v_0, \dots, v_{p+1}] \circ i_j^{p+1}) \cdot \psi(\sigma \circ [v_{p+1}, \dots, v_{p+q+1}])
\end{aligned}$$

and

$$\begin{aligned}
\text{(c)}\quad (-1)^p \cdot (\varphi \cup \delta\psi)(\sigma) &= (-1)^p \cdot \varphi(\sigma \circ [v_0, \dots, v_p]) \cdot (\delta\psi)(\sigma \circ [v_p, \dots, v_{p+q+1}]) \\
&= (-1)^p \cdot \varphi(\underbrace{\sigma \circ [v_0, \dots, v_p]}_{\text{map } \Delta^p \to X}) \cdot \psi\Big(\sum_{k=0}^{q+1} (-1)^k \cdot \underbrace{\sigma \circ [v_p, \dots, v_{p+q+1}] \circ i_k^{q+1}}_{\text{map } \Delta^q \to X}\Big) \\
&= (-1)^p \cdot \sum_{k=0}^{q+1} (-1)^k \cdot \varphi(\sigma \circ [v_0, \dots, v_p]) \cdot \psi(\sigma \circ [v_p, \dots, v_{p+q+1}] \circ i_k^{q+1}).
\end{aligned}$$

Now we observe that if we take the sum of (b) and (c), then the $(j = p+1)$-summand in (b) cancels with the $(k = 0)$-summand in (c). But after this observation it is obvious that the desired equality (b)+(c)=(a) holds. □

Lemma 57.3. *Let X be a topological space and let R be a commutative ring. Then the map*

$$\begin{array}{rcl}
\cup\colon H^p(X;R) \times H^q(X;R) & \to & H^{p+q}(X;R) \\
([\varphi],[\psi])] & \mapsto & [\varphi] \cup [\psi] := [\varphi \cup \psi]
\end{array}$$

is well-defined.

Definition. We refer to the pairing of Lemma 57.3 also as the *cup product*.

As we will see, the proof of Lemma 57.3 is basically identical to the proof of Lemma 55.11.

Proof. Let $\varphi \in C^p(X;R)$ and $\psi \in C^q(X;R)$ be cocycles.

(1) It follows immediately from Lemma 57.2 that $\varphi \cup \psi$ is again a cocycle.

(2) If $\varphi' = \varphi + \delta\tau$ is another representative of $[\varphi]$, then

$$\varphi' \cup \psi - \varphi \cup \psi \;\underset{\substack{\uparrow \\ \text{since “}\cup\text{” is clearly bilinear}}}{=}\; (\varphi' - \varphi) \cup \psi \;=\; \delta\tau \cup \psi \;\underset{\substack{\uparrow \\ \text{by Lemma 57.2 and since } \delta\psi = 0}}{=}\; \delta(\tau \cup \psi).$$

This shows that $\varphi \cup \psi$ and $\varphi' \cup \psi$ represent the same cohomology class, i.e. the cup product does not depend on the choice of the representative of the cohomology class of the first entry.

(3) The proof that the cup product does not depend on the choice of the representative of the second cohomology class is basically the same as the proof of (2). □

The following proposition now says that the original definition of the cup product and the new definition actually agree.

Proposition 57.4. *Let X be a topological space. Then for any $\varphi \in H^p(X;\mathbb{Z})$ and any $\psi \in H^q(X;\mathbb{Z})$ we have*

$$\varphi \,\tilde{\cup}\, \psi \;=\; \varphi \cup \psi \;\in\; H^{p+q}(X;\mathbb{Z}).$$

In the proof of Proposition 57.4 we need the following definition and the subsequent lemma.

Definition. A *diagonal approximation* consists of a natural chain map

$$\Phi\colon C_*(X) \;\to\; C_*(X)\otimes C_*(X)$$

for each topological space X, such that for each $x\in X$, viewed as a singular 0-simplex, the following equality holds in $(C_*(X)\otimes C_*(X))_0 = C_0(X)\otimes C_0(X)$:

$$\Phi(x) \;=\; x\otimes x.$$

Example. Given any topological space X we denote by $d\colon X\to X\times X$ the diagonal map given by $d(x)=(x,x)$. Then the induced chain maps

$$\Theta\circ d_*\colon C_*(X) \;\xrightarrow{d_*}\; C_*(X\times X) \;\underset{\substack{\uparrow\\ \text{Eilenberg-Zilber map from Theorem 56.1}}}{\xrightarrow{\Theta}}\; C_*(X)\otimes C_*(X)$$

form a diagonal approximation in the above sense.

The following lemma gives another diagonal approximation which will be very useful for doing actual calculations.

Lemma 57.5. *Given any topological space X we consider the map*

$$\Delta\colon C_*(X) \;\to\; C_*(X)\otimes C_*(X)$$

which for each singular n-simplex $\sigma\colon\Delta^n\to X$ is given by

$$\sigma \;\mapsto\; \sum_{p=0}^{n}\sigma\circ[v_0,\dots,v_p]\otimes\sigma\circ[v_p,\dots,v_n].$$

These maps form a diagonal approximation.

The diagonal approximation from Lemma 57.5 is called the *Alexander-Whitney diagonal approximation.* [992][993]

Proof. It follows almost immediately from the definition that the maps Δ are natural. Furthermore it is obvious that on the 0-chains the maps are of the desired form. It remains to show that for a given topological space X the maps actually form a chain map.

This follows from an elementary and uneventful calculation. For completeness' sake we provide the argument. Let $\mu\colon\Delta^n\to X$ be a singular n-simplex. Given $i_1,\dots,i_r$ we write $[i_1,\dots,i_r]:=\mu\circ[v_{i_1},\dots,v_{i_r}]$. We also use the convention that the empty singular simplex

[992]James Alexander (1888-1971) was an American mathematician whom we had already met on page 906.

[993]Hassler Whitney (1907–1989) was an American mathematician. We will encounter him again later on.

[ ] is 0. We calculate that

$$\begin{aligned}\Delta(\partial[0,\dots,n]) &= \Delta\Big(\sum_{i=0}^{n}(-1)^i\cdot[0,\dots,\widehat{i},\dots n]\Big)\\ &\underset{\uparrow}{=} \sum_{0\le p<i\le n}(-1)^i\cdot[0,\dots,p]\otimes[p,\dots,\widehat{i},\dots,n]+\sum_{0\le i<q\le n}(-1)^i\cdot[0,\dots,\widehat{i},\dots,q]\otimes[q,\dots,n]\end{aligned}$$

in the second sum we secretly used the substitution $q=p+1$

and

$$\begin{aligned}\partial(\Delta[0,\dots,n]) &= \partial\Big(\sum_{p=0}^{n}[0,\dots,p]\otimes[p,\dots,n]\Big)\\ &\underset{\uparrow}{=} \sum_{0\le i\le p\le n}(-1)^i\cdot[0,\dots,\widehat{i},\dots,p]\otimes[p,\dots,n]+\sum_{0\le p\le i\le n}(-1)^i\cdot[0,\dots,p]\otimes[p,\dots,\widehat{i},\dots,n].\end{aligned}$$

here we use the sign convention for the boundary in a tensor product

We see that the difference between the two terms equals

$$\begin{aligned}&\sum_{i=p}(-1)^i\cdot[0,\dots,\widehat{i},\dots,p]\otimes[p,\dots,n]+\sum_{i=p}(-1)^i\cdot[0,\dots,p]\otimes[p,\dots,\widehat{i},\dots,n]\\ &\underset{\uparrow}{=} \sum_{i=1}^{n}(-1)^i\cdot[0,\dots,i-1]\otimes[i,\dots,n]+\sum_{i=0}^{n-1}(-1)^i\cdot[0,\dots,i]\otimes[i+1,\dots,n]\end{aligned}$$

here we use that $[\ ]=0$

$$= \sum_{i=1}^{n}(-1)^i\cdot[0,\dots,i-1]\otimes[i,\dots,n]+\sum_{j=1}^{n}(-1)^{j-1}\cdot[0,\dots,j-1]\otimes[j,\dots,n] \;=\; 0.$$

We have thus shown that Δ is indeed a chain map. □

Proposition 57.6.

(1) *There exist diagonal approximations.*
(2) *Given any two diagonal approximations Φ and Ψ there exists a natural chain homotopy equivalence between Φ and Ψ.*

Proof.

(1) We had just given two examples of diagonal approximations.
(2) The uniqueness statement was proved in Proposition 57.6. □

Now we are ready to provide the proof of Proposition 57.4.

Proof of Proposition 57.4. We start out with the following claim.

Claim. For any two cochains $\varphi\in C^p(X;\mathbb{Z})$ and $\psi\in C^q(X;\mathbb{Z})$ we have[994]

$$\varphi\cup\psi \;=\; (\varphi\otimes\psi)\circ\Pi_{p,q}\circ\Delta \;\in\; C^{p+q}(X;\mathbb{Z})=\mathrm{Hom}(C_{p+q}(X),\mathbb{Z}).$$

[994]Here $\Delta\colon C_{p+q}(X)\to(C_*(X)\otimes C_*(X))_{p+q}$ denotes the above Alexander-Whitney diagonalization.

We have to show that the two sides are the same maps $C_{p+q}(X) \to \mathbb{Z}$. Therefore let $\sigma\colon \Delta^{p+q} \to X$ be a singular $(p+q)$-simplex. We calculate that

$$\begin{aligned}
(\varphi \otimes \psi \circ \Pi_{p,q} \circ \Delta)(\sigma) &\overset{\text{definition of the Alexander-Whitney diagonalization}}{=} (\varphi \otimes \psi)\big(\Pi_{p,q}\big(\sum_{i+j=p+q} \overbrace{\sigma \circ [v_0, \dots, v_i] \otimes \sigma \circ [v_i, \dots, v_{p+q}]}^{\in C_i(X) \otimes C_j(X)}\big)\big) \\
&= (\varphi \otimes \psi)(\sigma \circ [v_0, \dots, v_p] \otimes \sigma \circ [v_q, \dots, v_{p+q}]) \\
&= \varphi(\sigma \circ [v_0, \dots, v_p]) \cdot \psi(\sigma \circ [v_p, \dots, v_n]) \\
&= (\varphi \cup \psi)(\sigma).
\end{aligned}$$

This concludes the proof of the claim.

Now suppose that we are given cocycles $\varphi \in C^p(X;\mathbb{Z})$ and $\psi \in C^q(X;\mathbb{Z})$. We obtain the following equality in $H^{p+q}(X;\mathbb{Z})$:[995]

$$\begin{aligned}
[\varphi \widetilde{\cup} \psi] \overset{\text{by definition}}{=} [(\varphi \otimes \psi) \circ \Pi_{p,q} \circ (\Theta \circ d_*)] &= (\Theta \circ d_*)^*\big(\overbrace{[(\varphi \otimes \psi) \circ \Pi_{p,q}]}^{\in H^{p+q}(C_*(X) \otimes C_*(X))}\big) \\
&\underset{\substack{\uparrow \\ \text{by Proposition 57.6 the maps } \Theta \circ d_*, \Delta\colon C_*(X) \to C_*(X) \otimes C_*(X) \text{ are chain homotopic} \\ \text{so by Lemma 48.8 (3) they induce the same map on cohomology}}}{=} \Delta^*\big([(\varphi \otimes \psi) \circ \Pi_{p,q}]\big) = [(\varphi \otimes \psi) \circ \Pi_{p,q} \circ \Delta] \underset{\substack{\uparrow \\ \text{by the claim}}}{=} [\varphi \cup \psi].
\end{aligned}$$

We have thus obtained the desired equality of cohomology classes. □

Henceforth we will mostly work with the second definition of the cup product. In the following proposition we summarize some of the key properties of the cup product.

Proposition 57.7. *Let X be a topological space and let R be a commutative ring. Then the following statements hold:*

(1) *The cup product on $H^*(X;R)$ is R-bilinear and associative.*
(2) *The abelian group $H^*(X;R) = \bigoplus_{n \in \mathbb{N}_0} H^n(X;R)$ together with the map*

$$\cup\colon H^*(X;R) \times H^*(X;R) \to H^*(X;R)$$

is a ring[996] *where the multiplicatively neutral element is given by*

$$1_X \ := \ \big[\textit{constant map } X \to R \textit{ given by } x \mapsto 1\big] \ \in \ H^0(X;R).$$

Definition. Given a topological space X and a commutative ring R we refer to $(H^*(X;R), \cup)$ as the *R-cohomology ring of X*.

Proof. Let X be a topological space.

[995]Note that it follows from Lemma 57.1 that for two cocycles φ and ψ the composition $(\varphi \otimes \psi) \circ \Pi_{p,q}$ is indeed a cocycle, i.e. $(\varphi \otimes \psi) \circ \Pi_{p,q}$ defines an element in $H^{p+q}(C_*(X) \otimes C_*(X);\mathbb{Z})$.

[996]Recall that in Footnote 371 we had stated that in the lecture notes a ring is understood to be associative and it is understood to have a multiplicatively neutral element. We do not demand that a ring be commutative.

(1) It is clear from the second definition of the cup product that it is R-bilinear. It is also almost obvious, using the second definition, that the cup product is associative, but for completeness' sake we carry out the argument. Thus let $\alpha \in C^p(X;R)$, $\beta \in C^q(X;R)$ and $\gamma \in C^r(X;R)$ be cochains and let $\sigma\colon \Delta^{p+q+r} \to X$ be a singular simplex. Then

$$\begin{aligned}((\alpha \cup \beta) \cup \gamma)(\sigma) &= (\alpha \cup \beta)(\sigma \circ [v_0, \dots, v_{p+q}]) \cdot \gamma(\sigma \circ [v_{p+q}, \dots, v_{p+q+r}]) \\ &= \alpha(\sigma \circ [v_0, \dots, v_p]) \cdot \beta(\sigma \circ [v_p, \dots, v_{p+q}]) \cdot \gamma(\sigma \circ [v_{p+q}, \dots, v_{p+q+r}]) \\ &= (\alpha \cup (\beta \cup \gamma))(\sigma). \\ &\uparrow \\ &\text{same argument backwards}\end{aligned}$$

Thus we see that the cup product is already associative for cochains, so it is in particular associative for cohomology classes.

(2) Let $\eta\colon X \to R$ be the map that assigns to each point in X the value $1 \in R$. As usual we view η as a singular 0-cochain. It follows from Proposition 48.11 that η is a 0-cocycle and that we obtain an element $1_X := [\eta] \in H^0(X;R)$. It is clear from the definition that it is the neutral element with respect to the cup product. Together with (1) we have now shown that the cup product defines a ring structure on $H^*(X;R)$. □

Now that we have shown that $(H^*(X;R), \cup)$ is a ring the question arises whether it is commutative or whether it is not commutative. It turns out that the answer, as for the wedge product on de Rham cohomology, lies somewhere in between. More precisely, we have the following proposition.

Proposition 57.8. *Let X be a topological space and let R be a commutative ring. For any $a \in H^k(X;R)$ and $b \in H^l(X;R)$ we have*

$$a \cup b \;=\; (-1)^{kl} \cdot b \cup a.$$

Remark.

(1) If $R = \mathbb{F}_2$, then we are in the pretty situation that $-1 = 1$, i.e. the cup product is commutative. Put differently, the $\mathbb{F}_2$-cohomology ring $H^*(X;\mathbb{F}_2)$ of a topological space X is a commutative ring.

(2) The proof for Proposition 57.8 that we provide below is based on the second definition of the cup product. It is elementary but unfortunately unpleasant to read. In a later chapter we will provide a different, more conceptual proof based on the first definition of the cup product.

Proof $(*)$. We give a proof of the proposition following [Hat, p. 216-217]. In Hatcher's book more motivations for the steps in the proof are given.

So let $\varphi \in C^k(X;R)$ and $\psi \in C^l(X;R)$ be two cocycles. Given a singular n-simplex $\sigma\colon \Delta^n \to X$ we denote by $\overline{\sigma}$ the singular n-simplex obtained from σ by precomposing σ with the affine linear map $[v_n, \dots, v_0]\colon \Delta^n \to \Delta^n$ that reverses the order of the vertices.

Furthermore we write $\epsilon_n = (-1)^{n(n+1)/2}$. We note that for any $m, n \in \mathbb{N}_0$ an elementary calculation shows that $\epsilon_{m+n} = (-1)^{mn} \cdot \epsilon_m \epsilon_n$ and that $\epsilon_1 = -1$.

Claim. The maps

$$\begin{array}{rcl} \rho\colon C_n(X) & \to & C_n(X) \\ \sigma & \mapsto & \epsilon_n \cdot \overline{\sigma} \end{array}$$

form a chain map that is chain homotopic to the identity.

We first show that the claim implies the statement of the proposition. Let $[\varphi] \in H^k(X;R)$ and $[\psi] \in H^l(X;R)$. Since by the claim ρ is chain homotopic to the identity it follows from Lemma 48.8 that the induced map $\rho^*\colon C^*(X;R) \to C^*(X;R)$ induces the identity on cohomology groups. So to deduce the statement of the proposition it suffices to show that

$$\rho^*(\psi \cup \varphi) \;=\; (-1)^{kl} \cdot \rho^*\varphi \cup \rho^*\psi \;\in\; C^{k+l}(X;R).$$

Now let σ be a $(k+l)$-chain. Then

$$\begin{array}{rcl} (\rho^*(\psi \cup \varphi))(\sigma) & = & (\psi \cup \varphi)(\rho_*(\sigma)) \;=\; (\psi \cup \varphi)(\epsilon_{k+l} \cdot \sigma \circ [v_{k+l}, \dots, v_0]) \\ & = & \epsilon_{k+l} \cdot \psi(\sigma \circ [v_{k+l}, \dots, v_k]) \cdot \varphi(\sigma \circ [v_k, \dots, v_0]) \\ & = & (-1)^{kl} \cdot \varphi(\epsilon_k \cdot \sigma \circ [v_k, \dots, v_0]) \cdot \psi(\epsilon_l \cdot \sigma \circ [v_{k+l}, \dots, v_k]) \\ & \uparrow & \\ & \text{since } \epsilon_{k+l} = (-1)^{kl} \cdot \epsilon_k \cdot \epsilon_l \text{ and since } R \text{ is a } \textit{commutative} \text{ ring} & \\ & = & (-1)^{kl} \cdot (\rho^*\varphi \cup \rho^*\psi)(\sigma). \end{array}$$

We have thus shown the statement of the proposition modulo the claim.

We turn to the proof of the claim. It is straightforward to verify that ρ is a chain map, indeed, for any singular n-simplex σ we have

$$\begin{array}{rcl} \partial\rho(\sigma) & = & \partial(\epsilon_n \cdot \sigma \circ [v_n, \dots, v_0]) \;=\; \epsilon_n \cdot \sum_{i=0}^{n} (-1)^i \cdot \sigma \circ [v_n, \dots, \widehat{v_{n-i}}, \dots, v_0], \\ \rho\partial(\sigma) & = & \rho\Big(\sum_{i=0}^{n} (-1)^i \cdot \sigma \circ [v_0, \dots, \widehat{v_i}, \dots, v_n]\Big) \underset{\uparrow}{=} \epsilon_{n-1} \cdot \sum_{j=0}^{n} (-1)^{n-j} \cdot \sigma \circ [v_n, \dots, \widehat{v_{n-j}}, \dots, v_0]. \\ & & \text{definition of } \rho \text{ and substitution } j = n-i \end{array}$$

From $\epsilon_n = (-1)^n \cdot \epsilon_{n-1}$ we now obtain that $\partial\rho = \rho\partial$, i.e. we have shown that ρ is a chain map.

We still have to show that ρ is chain homotopic to the identity. We proceed with ideas similar to the ideas used in the proof of Proposition 30.5. As in that proof, given $i \in \{0, \dots, n\}$ we write

$$v_i \;:=\; (0, \dots, 1, 0, \dots, 0) \times \{0\} \;\in\; \mathbb{R}^{n+1} \times \{0\},$$

and

$$w_i \;:=\; (0, \dots, 1, 0, \dots, 0) \times \{1\} \;\in\; \mathbb{R}^{n+1} \times \{1\}.$$

We justify the reassignment of v_i to a different point by saying that we identify Δ^n with $\Delta^n \times \{0\} \in \mathbb{R}^{n+1} \times \mathbb{R}$. We denote by $\pi\colon \Delta^n \times [0,1] \to \Delta^n$ the projection map. We consider

the map

$$\begin{aligned} P\colon C_n(X) &\to C_{n+1}(X) \\ \sigma &\mapsto \sum_{i=0}^{n}(-1)^i\cdot\epsilon_{n-i}\cdot(\sigma\circ\pi)\circ[v_0,\dots,v_i,w_n,\dots,w_i]. \end{aligned}$$

Now we want to show that $\partial P + P\partial = \rho - \mathrm{id}$. We calculate

$$\begin{aligned} (P\partial)(\sigma) &= \sum_{i<j}(-1)^i(-1)^j\cdot\epsilon_{n-i-1}\cdot(\sigma\circ\pi)\circ[v_0,\dots,v_i,w_n,\dots,\widehat{w_j},\dots,w_i] \\ &\quad+\sum_{i>j}(-1)^{i-1}(-1)^j\cdot\epsilon_{n-i}\cdot(\sigma\circ\pi)\circ[v_0,\dots,\widehat{v_j},\dots,v_i,w_n,\dots,w_i], \end{aligned}$$

On the other hand we have

$$\begin{aligned} (\partial P)(\sigma) &= \sum_{j\le i}(-1)^i(-1)^j\cdot\epsilon_{n-i}\cdot(\sigma\circ\pi)\circ[v_0,\dots,\widehat{v_j},\dots,v_i,w_n,\dots,w_i] \\ &\quad+\sum_{j\ge i}(-1)^i(-1)^{i+1+n-j}\cdot\epsilon_{n-i}\cdot(\sigma\circ\pi)\circ[v_0,\dots,v_i,w_n,\dots,\widehat{w_j},\dots,w_i]. \end{aligned}$$

Now using that $\epsilon_{n-i} = (-1)^{n-i}\epsilon_{n-i-1}$ we see that the sum over the $j \neq i$ terms agrees precisely with $-P\partial$ calculated above (with the roles of i and j reversed). It remains to show that the sum over the $i = j$ terms equals $(\rho - \mathrm{id})(\sigma)$. This is indeed the case since

$$\begin{aligned} &\text{sum of the } i=j \text{ summands in the above formula for } (\partial P)(\sigma) \\ &= \epsilon_n\cdot(\sigma\circ\pi)\circ[w_n,\dots,w_0] + \sum_{i=1}^{n}\epsilon_{n-i}\cdot(\sigma\circ\pi)\circ[v_0,\dots,v_{i-1},w_n,\dots,w_i] \\ &\qquad+\sum_{i=0}^{n-1}(-1)^{n+i+1}\epsilon_{n-i}\cdot(\sigma\circ\pi)\circ[v_0,\dots,v_i,w_n,\dots,w_{i+1}] - (\sigma\circ\pi)\circ[v_0,\dots,v_n] \\ &= \epsilon_n\cdot(\sigma\circ\pi)\circ[w_n,\dots,w_0] - (\sigma\circ\pi)\circ[v_0,\dots,v_n] \;=\; (\rho-\mathrm{id})(\sigma). \\ &\uparrow \end{aligned}$$

in the second sum we substitute $j = i+1$, we obtain a new sign $(-1)^{n+j}\epsilon_{n-j+1} = -\epsilon_{n-j}$, thus we see that the two sums over i cancel

We have now completed the proof that $\partial P + P\partial = \rho - \mathrm{id}$, in particular we have shown the claim and thus also the proposition. □

Let $k \in \mathbb{N}$ be odd. It follows from Proposition 57.8 that given any topological space X and any $\varphi \in H^k(X;\mathbb{Z})$ we have $\varphi\cup\varphi = -(1)^{k\cdot k}\cdot\varphi\cup\varphi$, put differently, we have $2\cdot(\varphi\cup\varphi) = 0$. Thus we see that $\varphi\cup\varphi$ is 2-torsion. The next lemma makes the amusing observation that for $k = 1$ this "square" is in fact always zero.

Lemma 57.9. *Let X be a topological space. For any $\varphi \in H^1(X;\mathbb{Z})$ we have $\varphi\cup\varphi = 0$.*

Remark. There is no higher-dimensional analogue of Lemma 57.9, for example on [Hat, p. 403] it is shown that given any odd k with $k \ge 3$ there exists a class $\gamma \in H^k(\mathbb{R}\mathrm{P}^\infty \times \mathbb{R}\mathrm{P}^\infty;\mathbb{Z})$ with $\gamma^m \neq 0$ for all $m \in \mathbb{N}$.

Proof. Let X be a topological space and let $\varphi \in C^1(X;\mathbb{Z})$ be a cocycle. We need to show that $\varphi \cup \varphi \in C^2(X;\mathbb{Z})$ is a coboundary. We consider the 1-dimensional cochain

$$\mu\colon C_1(X) \;\to\; \mathbb{Z}$$

that is determined by

$$(\sigma\colon \Delta^1 \to X) \;\mapsto\; \tfrac{1}{2}\underbrace{(\varphi(\sigma) - \varphi(\sigma)^2)}_{\in 2\mathbb{Z}}.$$

It remains to prove the following claim.

Claim. We have $\varphi \cup \varphi = \delta\mu\colon C_2(X) \to \mathbb{Z}$.

We only need to prove this equality for singular 2-simplices. So suppose we are given $\tau\colon \Delta^2 \to X$. Given $j \in \{0,1,2\}$ we write $i_j = i_j^2\colon \Delta^1 \to \Delta^2$. Note that

$$(*) \qquad \varphi(\tau\circ i_0) - \varphi(\tau\circ i_1) + \varphi(\tau\circ i_2) \;=\; \varphi(\partial\tau) \underset{\substack{\uparrow \\ \text{definition of } \delta\varphi}}{=} (\delta\varphi)(\tau) \underset{\substack{\uparrow \\ \text{since } \varphi \text{ is a cocycle}}}{=} 0.$$

Now we compute that

$$\begin{aligned}
(\delta\mu)(\tau) \;&=\; \mu(\partial\tau) \;=\; \mu\big((\tau\circ i_0) - (\tau\circ i_1) + (\tau\circ i_0)\big)\\
&=\; \tfrac{1}{2}\big(\varphi(\tau\circ i_0) - \varphi(\tau\circ i_1) + \varphi(\tau\circ i_2) + \varphi(\tau\circ i_0)^2 - \varphi(\tau\circ i_1)^2 + \varphi(\tau\circ i_2)^2\big)\\
&=\; \tfrac{1}{2}\big(\varphi(\tau\circ i_0)^2 - (\varphi(\tau\circ i_0) + \varphi(\tau\circ i_2))^2 + \varphi(\tau\circ i_2)^2\big)\\
&\quad\uparrow \\
&\quad \text{by } (*) \text{ we have } \varphi(\tau\circ i_1) = \varphi(\tau\circ i_0) + \varphi(\tau\circ i_2)\\
&=\; \varphi(\tau\circ i_2)\cdot\varphi(\tau\circ i_0) \;=\; (\varphi\cup\varphi)(\tau).\\
&\quad\uparrow \qquad\qquad\qquad\qquad \uparrow \\
&\quad \text{elementary algebra} \qquad \text{definition of the cup-product}
\end{aligned}$$

This concludes the proof of the claim and thus of the lemma. □

We continue with the following lemma that shows that the cup product behaves well under maps between topological spaces.

Lemma 57.10. *Let R be a commutative ring.*

(1) *Let $f\colon X \to Y$ be a map between topological spaces. For any $c \in H^p(Y;R)$ and $d \in H^q(Y;R)$ we have*

$$f^*(c)\cup f^*(d) \;=\; f^*(c\cup d).$$

In particular the map

$$f^*\colon H^*(Y;R) \;\to\; H^*(X;R)$$

is a homomorphism of graded rings[997] *which satisfies $f^*(1_Y) = 1_X$.*

[997]Recall that a *graded ring* is a ring R together with a decomposition $R = \bigoplus_{n\in\mathbb{N}_0} R_n$ such that for any $m,n \in \mathbb{N}_0$ the multiplication map restricts to a map $R_m \times R_n \to R_{m+n}$. A homomorphism $f\colon R \to S$ between graded rings is a ring homomorphism with $f(R_n) \subset S_n$ for all $n \in \mathbb{N}_0$

(2) *The maps*

$$\begin{array}{rcl} X & \mapsto & (H^*(X;R),\cup) \\ (f\colon X\to Y) & \mapsto & (f^*\colon H^*(Y;R)\to H^*(X;R)) \end{array}$$

define a contravariant functor from the category $\mathcal{T}$ of topological spaces to the category $\mathcal{GR}$ of graded rings.

Proof. The lemma follows basically immediately from the definitions. But for completeness' sake we write down the proof. So let $c=[\varphi]\in H^p(Y;R)$ and let $b=[\psi]\in H^q(Y;R)$. Furthermore let $\sigma\colon \Delta^{p+q}\to X$ be a singular $(p+q)$-chain. Then

$$\begin{array}{rcl} (f^*\varphi\cup f^*\psi)(\sigma) & = & (f^*\varphi)(\sigma\circ[v_0,\dots,v_p])\cdot(f^*\psi)(\sigma\circ[v_p,\dots,v_{p+q}]) \\ & = & \varphi(f\circ(\sigma\circ[v_0,\dots,v_p]))\cdot\psi(f\circ(\sigma\circ[v_p,\dots,v_{p+q}])) \\ & = & \varphi((f\circ\sigma)\circ[v_0,\dots,v_p))\cdot\psi((f\circ\sigma)\circ[v_p,\dots,v_{p+q}]) \\ & = & (\varphi\cup\psi)(f\circ\sigma) \;=\; (f^*(\varphi\cup\psi))(\sigma). \end{array}$$

Finally note that it follows immediately from the definitions of 1_X, 1_Y and f^* that we have the equality $f^*(1_Y)=1_X$. Statement (2) follows immediately from statement (1) and the fact that cohomology groups with R-coefficients form a contravariant functor of abelian groups. □

We can use Lemma 57.10 to calculate the cup product of the wedge of finitely many spheres.

Lemma 57.11. *For any wedge of finitely many spheres all cup products in degrees ≥ 1 are zero.*

Proof. Let $S^{r_1}\vee\cdots\vee S^{r_k}$ be the wedge of finitely many spheres and let R be a commutative ring. For each $i\in\{1,\dots,k\}$ we denote by $p_i\colon S^{r_1}\vee\cdots\vee S^{r_k}\to S^{r_i}$ the obvious projection map. By Proposition 50.17 we know that for every $n\in\mathbb{N}$ the map

$$p_1^*\oplus\cdots\oplus p_k^*\colon H^n(S^{r_1};R)\oplus\cdots\oplus H^n(S^{r_k};R)\xrightarrow{\cong} H^n(S^{r_1}\vee\cdots\vee S^{r_k};R)$$

is an isomorphism. It remains to show that for any choice of $i,j\in\{1\dots,k\}$ with $r_i>0$ and $r_j>0$ we have $p_i^*([S^{r_i}]^*)\cup p_j^*([S^{r_j}]^*)=0$. We prove the statement for $i\neq j$. The proof of the statement for $i=j$ is basically the same. So suppose that $i\neq j$. We denote by $g\colon S^{r_1}\vee\cdots\vee S^{r_k}\to S^{r_i}\vee S^{r_j}$ the obvious projection map and we denote by $q_i\colon S^{r_i}\vee S^{r_j}\to S^{r_i}$ and $q_j\colon S^{r_j}\vee S^{r_j}\to S^{r_j}$ the obvious projection maps. Then

$$p_i^*([S^{r_i}]^*)\cup p_j^*([S^{r_j}]^*) \underset{\substack{\uparrow \\ \text{since } q_i\circ g=p_i \text{ and } q_j\circ g=p_j}}{=} g^*(q_i^*([S^{r_i}]^*))\cup g^*(q_j^*([S^{r_j}]^*)) \underset{\substack{\uparrow \\ \text{Lemma 57.10}}}{=} g^*(\overbrace{q_i^*([S^{r_i}]^*)\cup q_j^*([S^{r_j}]^*)}^{\in H^{r_i+r_j}(S^{r_i}\vee S^{r_j})=0}) = 0.$$

We have thus proved that all cup products in degrees ≥ 1 are zero. □

Later on, after we will have found methods for computing the cup product, we will often use the following corollary to show that certain topological spaces are not homotopy equivalent.

Corollary 57.12. *Let X and Y be topological spaces. If X and Y are homotopy equivalent, then for any commutative ring R there exists an isomorphism*

$$(H^*(Y;R),\cup) \xrightarrow{\cong} (H^*(X;R),\cup)$$

of graded rings.

Proof. Let $f\colon X \to Y$ be a homotopy equivalence. In Lemma 48.13 we saw that the induced maps $f^*\colon H^n(Y;R) \to H^n(X;R)$ on cohomology *groups* are isomorphisms. But it follows from Lemma 57.10 that these isomorphisms preserve the ring structure, i.e. the map f^* is in fact an isomorphism of graded rings. □

57.3. **The cup product of the torus.** Evidently our goal now is to determine the cup product of some of our favorite different topological spaces. We start out with two elementary observations regarding the cup product.

Observation 57.13. *Let R be a commutative ring.*

(1) *Let X be a path-connected topological space. Then it follows from Proposition 48.11 that $H^0(X;R) = R\cdot 1_X$. For any $r\cdot 1_X \in H^0(X;R)$ and $\varphi \in H^k(X;R)$ we have*

$$\begin{array}{ccccccc} (r\cdot 1_X)\cup\varphi & = & r\cdot(1_X\cup\varphi) & = & r\cdot\varphi & = & \varphi\cup(r\cdot 1_X). \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{since } \cup \text{ is } R\text{-bilinear} & & \text{Proposition 57.7} & & \text{the same argument backwards} & \end{array}$$

(2) *If M is an m-dimensional topological manifold, then for any p,q with $p+q>m$ the cup product $H^p(M;R)\times H^q(M;R)$ is zero, since it takes values in the group $H^{p+q}(M;R)$, which is zero by Theorem 46.4.*
(3) *By Proposition 57.7 the cup product is R-bilinear, so it suffices to determine the cup product on a generating system.*

In this section we want to determine the cup product on the torus $T = S^1\times S^1$. By Observation 57.13 it remains to determine the cup product

$$\cup\colon H^1(T;\mathbb{Z})\times H^1(T;\mathbb{Z}) \to H^2(T;\mathbb{Z}).$$

We first need to understand the cohomology groups $H^1(T;\mathbb{Z})$ and $H^2(T;\mathbb{Z})$ explicitly. We recall some notation and results from before:

(1) We denote by p respectively q the projection $S^1\times S^1 \to S^1$ onto the first respectively second factor. Furthermore, we recall that on page 1166 we introduced a cochain $\theta := \theta_{\mathbb{Z}} \in C^1(S^1;\mathbb{Z})$, we showed in Lemma 48.10 that θ is a cocycle and we showed on page 1200 that θ represents a generator of $H^1(S^1;\mathbb{Z})$.
(2) In Lemma 50.9 we showed that $H^1(T;\mathbb{Z}) \cong \mathbb{Z}^2$ and that the two cohomology classes $\alpha := p^*([\theta])$ and $\beta := q^*([\theta])$ form a basis for $H^1(S^1\times S^1;\mathbb{Z})$.

(3) On page 1118 we showed that the cycle $-\sigma_1+\sigma_2$, with the notation from Figure 654, represents the fundamental class of T.
(4) In Lemma 50.9 and 51.15 we showed that

$$\begin{array}{rcl} H^2(T;\mathbb{Z}) & \to & \mathbb{Z} \\ [\varphi] & \mapsto & \langle \varphi, [T]\rangle = \varphi(-\sigma_1+\sigma_2) \end{array}$$

is in fact an isomorphism. We will use this isomorphism to make the identification $H^2(T;\mathbb{Z}) = \mathbb{Z}$.

By Oberservation 57.13 (3) and the above discussion it suffices to determine all entries in the following matrix

$$\begin{pmatrix} \langle \alpha\cup\alpha, [T]\rangle & \langle \alpha\cup\beta, [T]\rangle \\ \langle \beta\cup\alpha, [T]\rangle & \langle \beta\cup\beta, [T]\rangle \end{pmatrix}.$$

Now we determine these four entries separately.

(1) We first consider the entry $\langle \alpha\cup\beta, [T]\rangle$. Fortunately we already did all the work on page 1335, more precisely, we have

$$\langle \alpha\cup\beta, [T]\rangle = (p^*\theta\cup q^*\theta)(-\sigma_1+\sigma_2) = (p^*\theta\cup q^*\theta)(-\sigma_1) + (p^*\theta\cup q^*\theta)(\sigma_2) \underset{\substack{\uparrow \\ \text{see calculations on page 1335}}}{=} 0+1 = 1.$$

(2) We could do the same argument as in (1) with α and β reversed. But it is easier to apply Proposition 57.8 which gives us that $\beta\cup\alpha = (-1)^{1\cdot 1}\cdot\alpha\cup\beta = -\alpha\cup\beta = -1$.
(3) There are many different ways for showing that $\alpha\cup\alpha = 0$:
  (a) We could do the calculation as in (1), but that is the least efficient approach.
  (b) We could use the symmetry from Proposition 57.8 to argue that $\alpha\cup\alpha = -\alpha\cup\alpha$, and hence $\alpha\cup\alpha = 0$ since $H^2(T;\mathbb{Z})$ is torsion-free.
  (c) We could just use Lemma 57.9 and remove all the fun.
  (d) We can also argue that

$$\langle \alpha\cup\alpha, [T]\rangle \;=\; \langle [p^*\theta]\cup[p^*\theta], [T]\rangle \underset{\substack{\uparrow \\ \text{by Lemma 57.10}}}{=} \langle p^*([\theta]\cup[\theta]), [T]\rangle \underset{\substack{\uparrow \\ \text{since } [\theta]\cup[\theta]\in H^2(S^1;\mathbb{Z})=0}}{=} 0.$$

(4) The same way as in (3) we see that $\beta\cup\beta = 0$.

Summarizing we have proved the following lemma.

Lemma 57.14. *Let T be the 2-dimensional torus. We use the above notation. The cup product $H^1(T;\mathbb{Z})\times H^1(T;\mathbb{Z}) \to H^2(T;\mathbb{Z})$ with respect to the basis α,β of $H^1(T;\mathbb{Z})$ and the identification $H^2(T;\mathbb{Z}) = \mathbb{Z}\cdot[T]^* = \mathbb{Z}$*[998] *is given by the matrix*

$$\begin{pmatrix} \alpha\cup\alpha & \alpha\cup\beta \\ \beta\cup\alpha & \beta\cup\beta \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

[998]Here $[T]^* \in H^2(T;\mathbb{Z})$ denotes the dual fundamental class that we introduced on page 1226, it is uniquely determined by $\langle [T]^*, [T]\rangle = 1$.

Thus we have shown that the cup product on cohomology is in general non-zero and that it is in general not commutative.

Remark.

(1) We have just shown that the 2-cocycle $p^*(\theta) \cup q^*(\theta) \in C^2(T;\mathbb{Z})$ represents a generator of $H^2(T;\mathbb{Z})$. We have thus answered Question 50.10.

(2) We have now performed enough calculations to see that the cohomology rings contain more information than the homology or the cohomology groups. More precisely, it follows from Lemma 33.12 and Propositions 31.3 and 34.8 that for the 2-dimensional torus $S^1 \times S^1$ and for $S^1 \vee S^1 \vee S^2$ we have

$$H_i(S^1 \times S^1;\mathbb{Z}) \;\cong\; H_i(S^1 \vee S^1 \vee S^2;\mathbb{Z}) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } i = 0,2, \\ \mathbb{Z}^2, & \text{if } i = 1, \\ 0, & \text{if } i \geq 3. \end{cases}$$

We deduce from the Universal Coefficient Theorem 51.13 for Cohomology Groups that $S^1 \times S^1$ and $S^1 \vee S^1 \vee S^2$ also have isomorphic cohomology groups. In Lemma 57.14 we saw that the cup product on $H^1(S^1 \times S^1;\mathbb{Z})$ is non-zero, whereas we showed in Lemma 57.11 that the cup product on $H^1(S^1 \vee S^1 \vee S^2;\mathbb{Z})$ is zero.[999]

In Exercise 57.2 we will use the above calculation of the cup product of the torus to prove the following slightly subtle lemma.

Lemma 57.15. *Let $f\colon T \to T$ be a homeomorphism of the torus $T = S^1 \times S^1$. If f is orientation-preserving, then*

$$\det\big(f_*\colon H_1(T;\mathbb{Z}) \to H_1(T;\mathbb{Z})\big) \;=\; \det\big(f^*\colon H^1(T;\mathbb{Z}) \to H^1(T;\mathbb{Z})\big) \;=\; +1.$$

Conversely, if f is orientation-reversing, then both determinants equal -1.

57.4. **The cup product of the surface of genus 2.** In this section we calculate the cup product for the surface Σ of genus 2. By Observation 57.13 it remains to determine the cup product

$$H^1(\Sigma;\mathbb{Z}) \times H^1(\Sigma;\mathbb{Z}) \;\to\; H^2(\Sigma;\mathbb{Z})$$

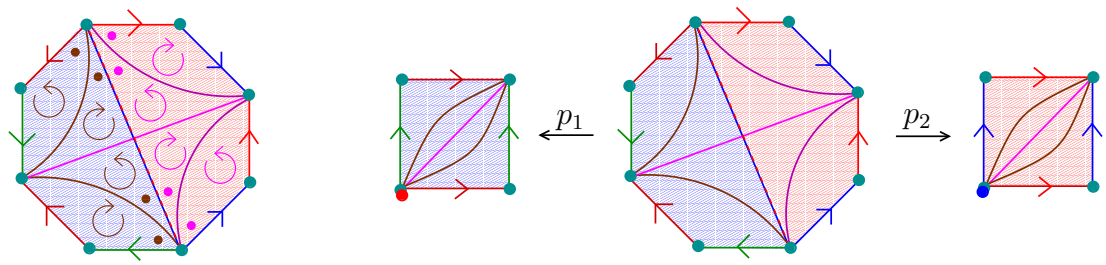
on a basis of $H^1(\Sigma;\mathbb{Z})$. We recall that on page 1202 we introduced maps $p_i\colon \Sigma \to T = S^1 \times S^1$ for $i = 1,2$. We refer to Figure 725 on the right for a reminder of the definition of the maps. We denote by $\alpha, \beta \in H^1(T;\mathbb{Z})$ the basis from Lemma 50.9 that we had also used in the previous section.

In Lemma 50.11 we saw that the map

$$p_1^* \oplus p_2^*\colon H^1(T;\mathbb{Z}) \oplus H^1(T;\mathbb{Z}) \;\to\; H^1(\Sigma;\mathbb{Z})$$

is an isomorphism. We deduce that a basis for $H^1(\Sigma;\mathbb{Z}) \cong \mathbb{Z}^4$ is given by $\alpha_i := p_i^*(\alpha)$, $\beta_i := p_i^*(\beta)$, $i = 1,2$. Now we can use the definition of the cup product and the explicit

[999]Of course we do not need to use cup products to distinguish the torus $S^1 \times S^1$ and the wedge $S^1 \vee S^1 \vee S^2$, this can already be done using fundamental groups. Nonetheless it is encouraging to see that we found a new way to prove this statement.



fundamental class of Σ projections from Σ to the torus

FIGURE 725.

description of a representative of the fundamental class $[\Sigma] \in H_2(\Sigma;\mathbb{Z})$ in Figure 725 on the left (see also Figure 657 for a more detailed discussion) to compute the cup product $H^1(\Sigma;\mathbb{Z}) \times H^1(\Sigma;\mathbb{Z}) \to H^2(\Sigma;\mathbb{Z}) = \mathbb{Z}$.

A not particularly exciting calculation leads us eventually to the following lemma.[1000]

Lemma 57.16. *Let Σ be the surface of genus 2. We use the above notation. The cup product $H^1(\Sigma;\mathbb{Z}) \times H^1(\Sigma;\mathbb{Z}) \to H^2(\Sigma;\mathbb{Z})$ with respect to the basis $\alpha_1, \beta_1, \alpha_2, \beta_2$ of $H^1(\Sigma;\mathbb{Z})$ and the identification $H^2(\Sigma;\mathbb{Z}) = \mathbb{Z} \cdot [\Sigma]^* = \mathbb{Z}$ is given by the matrix*

$$\begin{pmatrix} \alpha_1 \cup \alpha_1 & \alpha_1 \cup \beta_1 & \alpha_1 \cup \alpha_2 & \alpha_1 \cup \beta_2 \\ \beta_1 \cup \alpha_1 & \beta_1 \cup \beta_1 & \beta_1 \cup \alpha_2 & \beta_1 \cup \beta_2 \\ \alpha_2 \cup \alpha_1 & \alpha_2 \cup \beta_1 & \alpha_2 \cup \alpha_2 & \alpha_2 \cup \beta_2 \\ \beta_2 \cup \alpha_1 & \beta_2 \cup \beta_1 & \beta_2 \cup \alpha_2 & \beta_2 \cup \beta_2 \end{pmatrix} = \begin{pmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \end{pmatrix}$$

An analogous statement holds for any surface of genus $g \geq 1$, i.e. the cup product on the first cohomology of the surface of genus $g \geq 1$ can be represented by a block diagonal matrix consisting of g copies of $\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$.

Remark. In the next section we will obtain a more conceptual proof of Lemma 57.16.

Before we continue with more calculations of cup products we return to a question that we had asked in Algebraic Topology II.

Question 39.30.

(2) Let $g \geq 2$ and let $k \geq 2$. Does there exist a self-map $f\colon \Sigma_g \to \Sigma_g$ of degree k?[1001]

[1000] We have to evaluate the cup products of the explicit 1-cochains on the eight singular 2-simplices illustrated in Figure 725. It is straightforward to see that all 16 cup products evaluate to zero on the four central singular 2-simplices. For the remaining cup products the calculation is almost the same as for the torus on page 1335.

[1001] Recall that if $f\colon M \to N$ is a map between two closed, oriented connected, non-empty n-dimensional topological manifolds, then the degree $\deg(f) \in \mathbb{Z}$ is defined as the unique integer $\deg(f)$ that satisfies $f_*([M]) = \deg(f) \cdot [N]$.

Now we have the tools to answer this question. In this context it is useful to introduce the following definition.

Definition. A closed, oriented connected, non-empty topological manifold M is called *flexible* if given any $k \in \mathbb{Z}$ there exists a map $f\colon M \to M$ of degree k.

Example. In Lemma 32.15 we saw that S^1 is flexible. The combination of this fact with Lemma 32.18 showed that in fact any sphere S^n, $n \geq 1$ is flexible.

Now we can determine which closed oriented connected 2-dimensional manifolds are flexible. More precisely, we have the following proposition which gives a negative answer to Question 39.30 (2).

Proposition 57.17. *Let $g \geq 1$. We denote by Σ_g the surface of genus g.*

(1) *The torus $\Sigma_1 = S^1 \times S^1$ is flexible.*
(2) *For $g \geq 2$ the surface Σ_g is not flexible. In fact if $k \neq -1, 0, 1$, then there is no map $\Sigma_g \to \Sigma_g$ of degree k.*

Proof.

(1) We first show that the torus $S^1 \times S^1$ is flexible. So let $k \in \mathbb{Z}$. We consider the map $f\colon S^1 \to S^1$ that is given by $z \mapsto z^k$. We claim that $f \times \mathrm{id}\colon S^1 \times S^1 \to S^1 \times S^1$ has degree k. In fact by the naturality of the short exact sequence of the Künneth-Theorem 43.8 we have a commutative diagram

$$\begin{tikzcd} H_1(S^1) \otimes H_1(S^1) \arrow[r, "\Theta", "\cong"'] \arrow[d, "f_* \otimes \mathrm{id}"] & H_2(S^1 \times S^1) \arrow[d, "(f \times \mathrm{id})_*"] \\ H_1(S^1) \otimes H_1(S^1) \arrow[r, "\Theta", "\cong"'] & H_2(S^1 \times S^1) \end{tikzcd}$$

where the horizontal maps are isomorphisms. By Lemma 32.15 the map on the left is given by multiplication by k. Hence the map on the right is also given by multiplication by k.

(2) Now let $g \geq 2$ and let $f\colon \Sigma_g \to \Sigma_g$ be a map of degree $k \neq 0$. We have to show that $k \in \{\pm 1\}$. We write $\pi := \pi_1(\Sigma_g)$. We start out with the following claim.

Claim. The map $f_*\colon \pi \to \pi$ is an epimorphism.

First note that the argument in the proof of Proposition 39.26 shows that $f_*(\pi)$ is a finite-index subgroup of π. (Here we used that $k \neq 0$.) We denote by $n \in \mathbb{N}$ the index of the subgroup $f_*(\pi) \subset \pi$. In the proof of Proposition 40.11 we used the multiplicativity of the Euler characteristic under finite covers to show that the abelianization of $f_*(\pi)$ is isomorphic to $\mathbb{Z}^{2n\cdot(g-1)+2}$. On the other hand the epimorphism $\pi \to f_*(\pi)$ induces evidently an epimorphism of the abelianization of π onto the abelianization of $f_*(\pi)$, i.e. we have an epimorphism from $\mathbb{Z}^{2g}$ onto $\mathbb{Z}^{2n\cdot(g-1)+2}$. Since $g \geq 2$ this is only possible if $n = 1$. This concludes the proof of the claim.

Claim. The map $f^*\colon H^1(\Sigma_g; \mathbb{Z}) \to H^1(\Sigma_g; \mathbb{Z})$ is an isomorphism.

By the first claim we now that the map $f_*\colon \pi \to \pi$ is an epimorphism. It follows from the naturality of the Hurewicz Isomorphism, see Propositions 38.3 and 38.2 (4), that the map $f_*\colon H_1(\Sigma_g) \to H_1(\Sigma_g)$ is also an epimorphism. But any epimorphism from a finitely generated abelian group to itself is in fact an isomorphism[1002], so we see that $f_*\colon H_1(\Sigma_g;\mathbb{Z}) \to H_1(\Sigma_g;\mathbb{Z})$ is in fact an isomorphism. By Proposition 51.17 the evaluation homomorphism $\mathrm{ev}\colon H^1(\Sigma_g;\mathbb{Z}) \cong \mathrm{Hom}(H_1(\Sigma_g;\mathbb{Z}),\mathbb{Z})$ is a natural isomorphism, i.e. we have a commutative diagram

$$\begin{array}{ccc} H^1(\Sigma_g;\mathbb{Z}) & \xrightarrow[\cong]{\mathrm{ev}} & \mathrm{Hom}(H_1(\Sigma_g;\mathbb{Z}),\mathbb{Z}) \\ \downarrow{\scriptstyle f^*} & & \cong\downarrow{\scriptstyle (f_*)^*} \\ H^1(\Sigma_g;\mathbb{Z}) & \xrightarrow[\cong]{\mathrm{ev}} & \mathrm{Hom}(H_1(\Sigma_g;\mathbb{Z}),\mathbb{Z}). \end{array}$$

The right-hand map is an isomorphism, it follows from the commutative diagram that the left-hand map $f^*\colon H^1(\Sigma_g;\mathbb{Z}) \to H^1(\Sigma_g;\mathbb{Z})$ is also an isomorphism. This concludes the proof of the second claim.

By Lemma 57.16 we know that there exist $a, b \in H^1(\Sigma_g;\mathbb{Z})$ with $a \cup b = [\Sigma_g]^*$. Since $f^*\colon H^1(\Sigma_g;\mathbb{Z}) \to H^1(\Sigma_g;\mathbb{Z})$ is an isomorphism we can in particular find cohomology classes $c, d \in H^1(\Sigma_g;\mathbb{Z})$ with $f^*(c) = a$ and $f^*(d) = b$. Now we have

$$\begin{array}{ccccccccc} & & & & & \text{since } c\cup d \in H^2(\Sigma_g;\mathbb{Z}) \text{ and since } [\Sigma_g]^* \in H^2(\Sigma_g;\mathbb{Z}) \text{ is a generator such an } m \text{ exists} & & & \\ & & & & & \downarrow & & & \\ [\Sigma_g]^* & = & a\cup b & = & f^*(c)\cup f^*(d) & = & f^*(c\cup d) & = & f^*(m\cdot[\Sigma_g]^*) & = & \deg(f)\cdot m\cdot[\Sigma_g]^*. \\ & & & & & \uparrow & & & & \uparrow & \\ & & & & & \text{Lemma 57.10} & & & & \text{by Lemma 51.16 we have } f^*([\Sigma_g]^*) = \deg(f)\cdot[\Sigma_g]^* & \end{array}$$

Evidently this is only possible if $\deg(f) \in \{\pm 1\}$. □

57.5. **The cup product of the real projective plane** $(*)$**.** Now we want to understand the cup product in the $\mathbb{F}_2$-cohomology of the real projective plane $\mathbb{R}\mathrm{P}^2$. Recall that on page 1197 we saw that $H^i(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) = \mathbb{F}_2$[1003] for $i = 0, 1, 2$ and that the $\mathbb{F}_2$-cohomology vanishes in all other dimensions. By Observation 57.13 it remains to determine the cup product on the first cohomology.

To compute the cup product we need to get a good understanding of the cohomology groups. Recall that on 1121 we had seen that $(\sigma_1 + \sigma_2 + \tau_1 + \tau_2) \otimes 1 \in C_2(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2)$ is a representative of the $\mathbb{F}_2$-fundamental class $[\mathbb{R}\mathrm{P}^2]$ of $\mathbb{R}\mathrm{P}^2 = \overline{B}^2/\sim$.[1004] (See Figure 726 for the definition of $\sigma_1, \sigma_2, \tau_1$ and τ_2.) It follows from Proposition 51.18 and the above that the map

$$\begin{array}{rcl} \eta\colon H^2(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) & \to & \mathbb{F}_2 \\ [\varphi \in C^2(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2)] & \mapsto & [\varphi(\sigma_1) + \varphi(\sigma_2) + \varphi(\tau_1) + \varphi(\tau_2)] \end{array}$$

[1002]Why is that?

[1003]Why is it safe to write $H^i(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) = \mathbb{F}_2$? Would it not be much more appropriate to write $H^i(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) \cong \mathbb{F}_2$?

[1004]Here we use the identification $\mathbb{R}\mathrm{P}^2 = \overline{B}^2/\sim$ from page 113.

is an isomorphism.

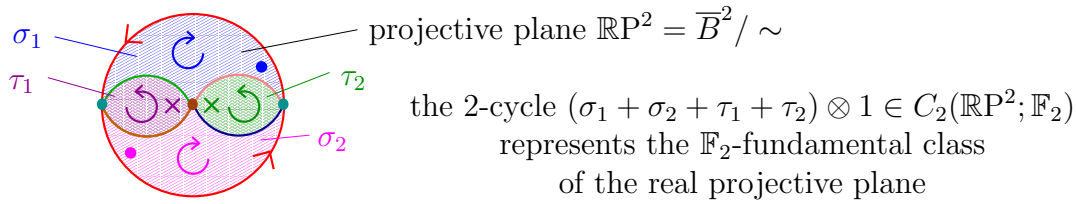


FIGURE 726.

Now we also need to find an explicit representative of $x \in H^1(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2)$. We will find such a representative in a similar fashion to the construction of the singular 1-cocycle $\theta_{\mathbb{Z}} \in H^1(S^1;\mathbb{Z})$ on page 1167. More precisely, we consider the map

$$\begin{array}{rcl} f\colon S^2 & \to & \mathbb{F}_2 \\ (x,y,z) & \mapsto & \begin{cases} 1, & \text{if } (z>0) \text{ or } (z=0 \text{ and } y>0) \text{ or } (z=y=0 \text{ and } x=1), \\ 0, & \text{otherwise.} \end{cases} \end{array}$$

Note that for any point $P \in S^2$ we have $f(-P) = 1 - f(P)$.[1005] For a singular 1-simplex $\sigma\colon \Delta^1 \to \mathbb{R}\mathrm{P}^2$ we pick a lift $\widetilde{\sigma}\colon \Delta^1 \to S^2$ of σ and we define

$$\varphi(\sigma) \ := \ f\big(\widetilde{\sigma}(0,1)\big) - f\big(\widetilde{\sigma}(1,0)\big) \ \in \ \mathbb{F}_2.$$

We refer to Figure 727.

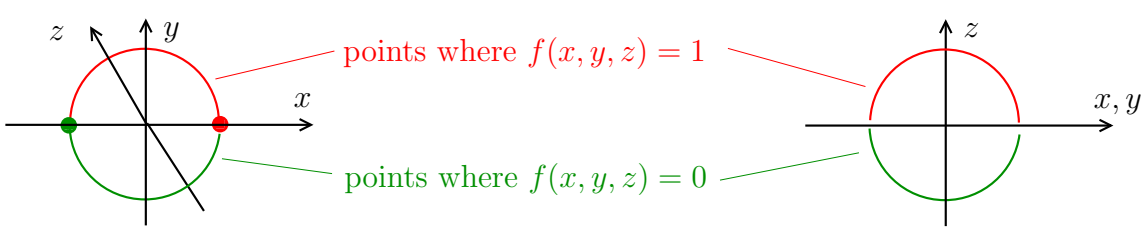

FIGURE 727.

Note that φ is well-defined since the only other lift of σ is given by multiplying $\widetilde{\sigma}$ by -1,[1006] but then it follows from $f(-P) = 1 - f(P)$ that the difference of the evaluations at the endpoints does not change. (Here we use that we work with $\mathbb{F}_2$-coefficients instead of $\mathbb{Z}$-coefficients.) The argument of Lemma 48.10 can easily be adapted to show that the singular 1-cochain $\varphi\colon C_1(\mathbb{R}\mathrm{P}^2) \to \mathbb{F}_2$ is a cocycle.

[1005] In fact for the subsequent discussion any map $f\colon S^2 \to \mathbb{F}_2$ with this property would work. We just picked this example for concreteness.

[1006] Why is that true?

Example. We consider the map $\mu\colon \Delta^1 \to \mathbb{R}\mathrm{P}^2 = S^2/\sim$ given by $\mu(1-t,t) = [e^{\pi i t}]$. Then $\mu \in C_1(\mathbb{R}\mathrm{P}^2)$. Thus we can apply the Kronecker pairing $H^1(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) \times H_1(\mathbb{R}\mathrm{P}^2) \to \mathbb{F}_2$ from Lemma 50.5 to $[\varphi] \in H^1(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2)$ and $[\mu] \in H_1(\mathbb{R}\mathrm{P}^2)$ and we calculate that

$$\langle [\varphi],[\mu]\rangle \;=\; \varphi(\mu) \;\underset{\substack{\uparrow \\ \text{since a lift of } \mu(1-t,t)=[e^{\pi i t}] \text{ to } S^2 \text{ is given by } \widetilde{\mu}(1-t,t)=e^{\pi i t}}}{=}\; f(e^{\pi i}) - f(e^0) \;=\; 1 \;\in \mathbb{F}_2.$$

Since this is non-zero we have now actually shown two statements at once: the cohomology class $[\varphi] \in H^1(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2)$ is non-zero and we have also certified that the homology class $[\mu] \in H_1(\mathbb{R}\mathrm{P}^2)$ is non-zero.[1007]

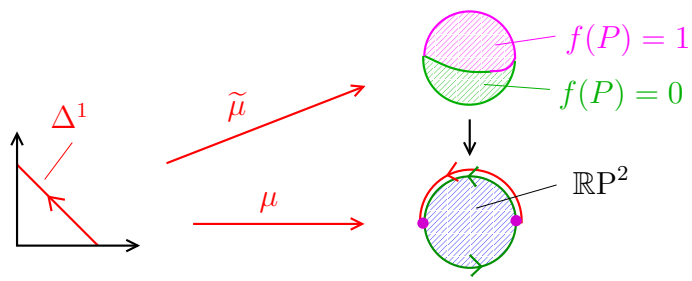

FIGURE 728.

Now we have the tools to prove the following lemma.

Lemma 57.18. *Under the identifications $H^i(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) = \mathbb{F}_2$ the cup product*

$$\cup\colon H^1(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) \times H^1(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) \;\to\; H^2(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2)$$

is given by

$$\begin{array}{rcl} \mathbb{F}_2 \times \mathbb{F}_2 & \to & \mathbb{F}_2 \\ (a,b) & \mapsto & a\cdot b. \end{array}$$

Remark. Note that the calculation in Lemma 57.18 that the statement of Lemma 57.9 does not hold for $\mathbb{F}_2$-coefficients.

Proof. By the discussion above it suffices to show that $\eta([\varphi]\cup[\varphi]) \neq 0$. Put differently, by definition of η we need to show that

$$(\varphi\cup\varphi)(\sigma_1) + (\varphi\cup\varphi)(\sigma_2) + (\varphi\cup\varphi)(\tau_1) + (\varphi\cup\varphi)(\tau_2) \;=\; 1 \;\in \mathbb{F}_2.$$

In Exercise 57.3 we will determine all four summands and we will see that the sum is indeed 1. □

The above calculation of the cup product of the real projective plane $\mathbb{R}\mathrm{P}^2$ is very explicit and hands on, but not very conceptual. Later on we will give a very different calculation of the cup product on $\mathbb{F}_2$-cohomology of all real projective spaces $\mathbb{R}\mathrm{P}^n$.

[1007] Do you know any other methods for showing that $[\mu] \neq 0 \in H_1(\mathbb{R}\mathrm{P}^2)$?

57.6. **The cup product and the wedge product** $(*)$**.** As a reminder, we denote by $\mathcal{M}$ the category of manifolds. As we already saw, the maps

$$\begin{array}{rcl} M & \mapsto & (H^k_{\mathrm{dR}}(M), \cup) \\ (f\colon M \to N) & \mapsto & (f^*\colon H^k_{\mathrm{dR}}(N) \to H^k_{\mathrm{dR}}(M)) \end{array}$$

define a contravariant functor from the category $\mathcal{M}$ of manifolds to the category of graded rings $\mathcal{GR}$.

If we assign to a manifold its k-th real cohomology groups, then we saw in Theorem 55.6 that it is naturally isomorphic to the k-th de Rham cohomology group. Now we can generalize Theorem 55.6.

Theorem 57.19. *The natural isomorphisms u from Theorem 55.6 are in fact ring homomorphisms, i.e. they define a natural isomorphism from the functor*

$$\begin{array}{rcl} \mathcal{M} & \to & \mathcal{GR} \\ M & \mapsto & (H^*_{\mathrm{dR}}(M), \wedge) \end{array} \quad \textit{to the functor} \quad \begin{array}{rcl} \mathcal{M} & \to & \mathcal{GR} \\ M & \mapsto & (H^*(M;\mathbb{R}), \cup). \end{array}$$

Example. As usual we denote by dt on $\mathbb{R}$ the 1-form that for every $v \in T_P\mathbb{R} = \mathbb{R}$ is given by $dt(v) = v$. We denote by $\pi\colon \mathbb{R} \to \mathbb{R}/\mathbb{Z} = S^1$ the obvious projection map. The closed 1-form dt descends to a closed 1-form on S^1, i.e. there exists a unique 1-form $\overline{dt}$ on $\mathbb{R}/\mathbb{Z} = S^1$ whose pull-back equals dt. Let $\sigma\colon \Delta^1 \to \mathbb{R}/\mathbb{Z} = S^1$ be a smooth singular 1-simplex. Since Δ^1 is simply-connected we can lift this singular 1-simplex, i.e. there exists a map (which is in fact smooth) $\widetilde{\sigma}\colon \Delta^1 \to \mathbb{R}$ with $\pi \circ \widetilde{\sigma} = \sigma$. We have

$$\int_\sigma \overline{dt} \underset{\substack{\uparrow \\ \text{see definition on page 1297}}}{=} -\int_{s=0}^{s=1} \overline{dt}(\sigma'(t, 1-t))ds \underset{\substack{\uparrow \\ \text{definition of } \overline{dt}}}{=} -\int_{s=0}^{s=1} \widetilde{\sigma}'(t, 1-t)ds \underset{\substack{\uparrow \\ \text{Fundamental Theorem} \\ \text{of Calculus}}}{=} -\widetilde{\sigma}(1,0) + \widetilde{\sigma}(0,1) \underset{\substack{\uparrow \\ \text{see page 1166}}}{=} \theta_{\mathbb{R}}(\sigma).$$

This little calculation shows that under the natural isomorphisms from Theorem 55.6 the class $[\overline{dt}] \in H^1_{\mathrm{dR}}(M)$ gets sent to our favorite generator $[\theta_{\mathbb{R}}] \in H^1(M;\mathbb{R})$, i.e. we have $u([\overline{dt}]) = [\theta_{\mathbb{R}}]$.

Next we consider the torus $M = S^1 \times S^1$. As before we denote $p\colon S^1 \times S^1 \to S^1$ respectively $q\colon S^1 \times S^1 \to S^1$ the projection onto the first, respectively the second factor. A direct calculation shows that, with the usual product orientation on $M = S^1 \times S^1$ we have

$$\int_{S^1 \times S^1} p^*(\overline{dt}) \wedge q^*(\overline{dt}) \;=\; +1.$$

On the other hand, by the naturality of u we have $u(p^*([\overline{dt}])) = p^*(u([\overline{dt}])) = p^*([\theta_{\mathbb{R}}])$ and similarly we also have $u(q^*([\overline{dt}]) = q^*([\theta_{\mathbb{R}}])$. The calculation of the above integral is now consistent with the calculation in Lemma 1347 where we had, implicitly, shown that $\langle p^*([\theta_{\mathbb{R}}]) \cup q^*([\theta_{\mathbb{R}}]), [S^1 \times S^1]\rangle = +1$.

Proof. It is shown in [Dup, Theorem 2.4], through a rather lengthy calculation, that the natural isomorphisms from Theorem 55.6 are ring homomorphisms. Unfortunately it is

rather difficult to make sure that all the different sign conventions match.[1008] The above example gives us at least some confidence that the signs are right. We also refer to [War, Theorem 5.45] for a proof of the theorem. □

Exercises for Chapter 57.

Exercise 57.1. Let X be a topological space. We consider the map

$$\Phi\colon H_*(X) \otimes H_*(X) \xrightarrow{\times} H_*(X \times X) \xrightarrow{p_*} H_*(X)$$

where $p\colon X \times X \to X$ denotes the projection on the first factor. Show that Φ is the trivial map.

Exercise 57.2. Let $f\colon T \to T$ be a homeomorphism of the torus $T = S^1 \times S^1$. Show that if f orientation-preserving, then the following two statements hold:

(a) $f_*\colon H_1(T;\mathbb{Z}) \to H_1(T;\mathbb{Z})$ has determinant one,
(b) $f^*\colon H^1(T;\mathbb{Z}) \to H^1(T;\mathbb{Z})$ has determinant one.

Exercise 57.3. We consider $\mathbb{R}\mathrm{P}^2 = S^2/\sim$ which we identify with $\overline{B}^2/\sim$ via the homeomorphism that is induced by the projection map $S^2 \to \overline{B}^2$. Let $\varphi \in C^1(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2)$ be the cocycle that we defined on page 1352. Determine *each of the four summands* in the sum

$$(\varphi \cup \varphi)(\sigma_1) + (\varphi \cup \varphi)(\sigma_2) + (\varphi \cup \varphi)(\tau_1) + (\varphi \cup \varphi)(\tau_2).$$

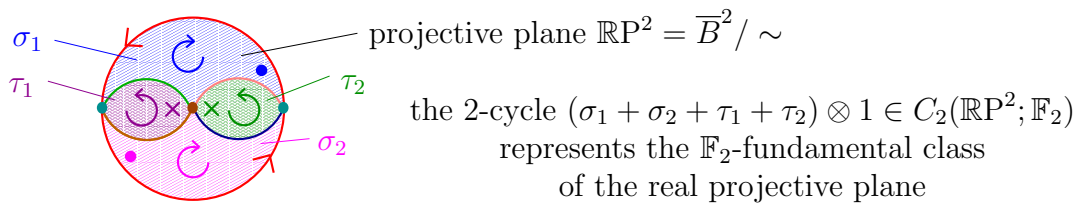

FIGURE 729.

Exercise 57.4. Let K be the Klein bottle.

(a) Is the cup product $H^1(K;\mathbb{Z}) \times H^1(K;\mathbb{Z}) \to H^2(K;\mathbb{Z})$ non-trivial?
(b) Is the cup product $H^1(K;\mathbb{F}_2) \times H^1(K;\mathbb{F}_2) \to H^2(K;\mathbb{F}_2)$ non-trivial?

[1008] For example, on [Dup, p. 20] it says "let $\cup$" be the usual cup-product", but as we had discussed on page 1334, it is not so clear what "usual cup-product" is supposed to mean.

58. The relative cup product

Our goal in this chapter is to introduce a relative version of the cup product. More precisely, given an excisive triad (X, A, B) and a commutative ring R we will introduce a cup product

$$H^p(X, A; R) \times H^q(X, B; R) \xrightarrow{\quad \cup \quad} H^{p+q}(X, A \cup B; R)$$

that is functorial in an appropriate sense and that equals the previous definition of the cup product for the special case that $A = B = \varnothing$. This relative cup product will help us in determining the cup products of wedges of topological spaces and of the suspension of a topological space. Also it will help us to determine the mysterious sounding Lusternik-Schnirelmann category.

58.1. **Definition of the relative cup product.** In this section we will work a lot with relative cochains. Before we do so we recall the following convention from page 1170.

Convention.

(1) Given an abelian group C, a subgroup D and an abelian group G we have a natural isomorphism

$$\begin{array}{rcl} \mathrm{Hom}(C/D, G) & \xrightarrow{\cong} & \{f\colon C \to G \,|\, f \text{ vanishes on } D\} \\ (\varphi\colon C/D \to G) & \mapsto & (C \to C/D \xrightarrow{\varphi} G). \end{array}$$

We will use this isomorphism to identify the groups left and right.

(2) In particular, given a pair of topological spaces (X, A), a commutative ring R and $n \in \mathbb{N}_0$ we make the identification

$$C^n(X, A; R) \xrightarrow{\cong} \{f\colon C_n(X) \to R \,|\, f(\sigma) = 0 \text{ for all } \sigma\colon \Delta^n \to A\}.$$

The definition of the relative cup product requires some preparation. We start out with the following definition.

Definition. Let (X, A, B) be a triad of topological spaces. As in the definition on page 1203 we write

$$C_n^{\{A,B\}}(A \cup B) \;:=\; \left\{ \sum_{j=1}^{k} n_j \sigma_j \in C_n(A \cup B) \;\middle|\; \begin{array}{c} \text{for each } j \text{ the image of } \sigma_j \\ \text{lies in } A \text{ or it lies in } B \end{array} \right\}$$

The usual boundary map on the groups $C_*(A \cup B)$ restricts to a boundary map on the groups $C_*^{\{A,B\}}(A \cup B)$. Given a commutative ring R we consider

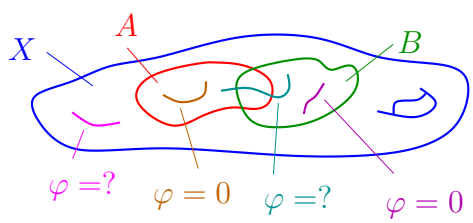
$$C^n(X, \{A, B\}; R) \;:=\; \ker\big\{C^n(X; R) \to \mathrm{Hom}\big(\underbrace{C_n^{\{A,B\}}(A \cup B)}_{\text{subgroup of } C_n(X)}, R\big)\big\}.$$

This is again a cochain complex and we denote the corresponding cohomology groups by $H^*(X, \{A, B\}; R)$.

Remark. With the above notation we could write that

$$C^n(X,\{A,B\};R) \;=\; \{\varphi\colon C_n(X)\to R \,|\, \varphi(\sigma)=0 \text{ for any } \sigma\colon \Delta^n\to A \text{ and any } \sigma\colon \Delta^n\to B\}.$$

The definition of $C^n(X,\{A,B\};R)$ is illustrated in Figure 730.



$\varphi \in H^1(X,\{A,B\};R)$

FIGURE 730.

Lemma 58.1. *Let (X,A,B) be an excisive triad of topological spaces. Given any commutative ring R the obvious*[1009] *map*

$$C^*(X,A\cup B;R) \quad\to\quad C^*(X,\{A,B\};R)$$

induces for every $n\in\mathbb{N}_0$ an isomorphism

$$H^n(X,A\cup B;R) \quad\xrightarrow{\cong}\quad H^n(X,\{A,B\};R).$$

Proof. We have the following commutative diagram of short exact sequences of chain complexes

$$\begin{array}{ccccccccc}
0 & \longrightarrow & C_*(A\cup B) & \longrightarrow & C_*(X) & \longrightarrow & C_*(X,A\cup B) & \longrightarrow & 0\\
 & & \downarrow & & \downarrow{=\mathrm{id}} & & \downarrow & & \\
0 & \longrightarrow & C_*^{\{A,B\}}(A\cup B) & \longrightarrow & C_*(X) & \longrightarrow & \dfrac{C_*(X)}{C_*^{\{A,B\}}(A\cup B)} & \longrightarrow & 0.
\end{array}$$

By our hypothesis the triad (X,A,B) is excisive. By definition this means that the left vertical map is a chain homotopy equivalence. The middle vertical map is the identity. It now follows from Corollary 49.6 that the right vertical map is also a chain homotopy equivalence.

Recall that by the convention on page 1356 we have an identification

$$\mathrm{Hom}\left(\frac{C_n(X)}{C_n^{\{A,B\}}(A\cup B)},R\right) \;=\; C^n(X,\{A,B\};R).$$

The lemma follows from the above vertical chain homotopy equivalence, the above observation and Lemma 48.8. □

The following lemma is the motivation for introducing the rather technical cohomology modules $H^*(X;\{A,B\};R)$.

[1009] What is the "obvious" map?

Lemma 58.2. *Let (X, A, B) be a triad of topological spaces and let R be a commutative ring. Then the map*

$$\begin{array}{rcl} C^p(X,A;R) \times C^q(X,B;R) & \to & C^{p+q}(X,\{A,B\};R) \\ (\varphi,\psi) & \mapsto & \left[\begin{array}{rcl} C_{p+q}(X) & \to & R \\ \sigma & \mapsto & \varphi(\sigma\circ[v_0,\dots,v_p])\cdot\psi(\sigma\circ[v_p,\dots,v_{p+q}]) \end{array}\right]. \end{array}$$

is well-defined and it induces an R-bilinear map

$$\cup\colon H^p(X,A;R) \times H^q(X,B;R) \to H^{p+q}(X,\{A,B\};R).$$

Proof. The lemma follows easily from the following claim.

Claim. Given $\varphi \in C^p(X,A;R)$ and $\psi \in C^q(X,B;R)$ the homomorphism

$$\begin{array}{rcl} C_{p+q}(X) & \to & R \\ (\sigma\colon \Delta^{p+q} \to X) & \mapsto & \varphi(\sigma\circ[v_0,\dots,v_p])\cdot\psi(\sigma\circ[v_p,\dots,v_{p+q}]) \end{array}$$

lies actually in $C^{p+q}(X,\{A,B\})$.

By the remark on page 1357 we have to show that the above cochain vanishes on all singular $(p+q)$-simplices that lie entirely in A or that lie entirely in B. But this is clear:

(1) given $\sigma\colon \Delta^{p+q} \to A$ the first factor $\varphi(\sigma\circ[v_0,\dots,v_p])$ is necessarily zero since we have $\varphi \in C^p(X,A;R)$, and similarly,
(2) given $\sigma\colon \Delta^{p+q} \to B$ the second factor $\psi(\sigma\circ[v_p,\dots,v_{p+q}])$ is necessarily zero since we have $\psi \in C^q(X,B;R)$.

This concludes the proof of the claim and thus also of the lemma. □

Definition. Let (X, A, B) be an excisive triad of topological spaces and let R be a commutative ring. We refer to the composition

$$H^p(X,A;R) \times H^q(X,B;R) \xrightarrow{(c,d)\mapsto c\cup d} H^{p+q}(X,\{A,B\};R) \xleftarrow{\cong} H^{p+q}(X,A\cup B;R)$$

$$\uparrow$$

isomorphism by Lemma 58.1

again as a *cup product* (or sometimes as a *relative cup product*) and we denote it as usual by the "$\cup$"-symbol.

Remark. Let X be a topological space, let $A, B \subset X$ be subsets and let R be a commutative ring. Suppose that $C_*^{\{A,B\}}(A\cup B) = C_*(A\cup B)$. (This is for example the case if $A = B = \varnothing$ or more generally, if A is a subset of B or if B is a subset of A.) Then the above definition of the cup product is just the "naive" definition given by

$$\begin{array}{rcl} C^p(X,A;R)\times C^q(X,B;R) & \to & C^{p+q}(X,A\cup B;R) \\ (\varphi,\psi) & \mapsto & \left(\begin{array}{rcl} C_{p+q}(X,A\cup B) & \to & R \\ \sigma & \mapsto & \underbrace{\varphi(\sigma\circ[v_0,\dots,v_p])}_{\in R}\cdot\underbrace{\psi(\sigma\circ[v_p,\dots,v_{p+q}])}_{\in R} \end{array}\right). \end{array}$$

The first part of following proposition is a generalization of Lemma 57.10.

Proposition 58.3.

(1) *Let (X, A, B) and (Y, C, D) be two excisive triads and let R be a commutative ring. Let $f\colon (X, A, B) \to (Y, C, D)$ be a map. Then for all $p, q \in \mathbb{N}_0$ the following diagram commutes:*

$$\begin{tikzcd} H^p(Y, C; R) \times H^q(Y, D; R) \arrow[r, "\cup"] \arrow[d, "f^* \times f^*"] & H^{p+q}(Y, C \cup D; R) \arrow[d, "f^*"] \\ H^p(X, A; R) \times H^q(X, B; R) \arrow[r, "\cup"] & H^{p+q}(X, A \cup B; R). \end{tikzcd}$$

(2) *Let (X, A, B) be an excisive triad. If $\varphi\colon R \to S$ is a homomorphism between commutative rings, then for all $p, q \in \mathbb{N}_0$ the following diagram commutes:*

$$\begin{tikzcd} H^p(X, A; R) \times H^q(X, B; R) \arrow[r, "\cup"] \arrow[d, "\varphi_* \times \varphi_*"] & H^{p+q}(X, A \cup B; R) \arrow[d, "\varphi_*"] \\ H^p(X, A; S) \times H^q(X, B; S) \arrow[r, "\cup"] & H^{p+q}(X, A \cup B; S). \end{tikzcd}$$

Here the vertical maps to the left are the maps defined on page 1163.

Proof.

(1) It follows easily from the definitions that the following diagram commutes:

$$\begin{tikzcd} H^p(Y, C; R) \times H^q(Y, D; R) \arrow[r, "\cup"] \arrow[d, "f^* \times f^*"] & H^{p+q}(Y, \{C, D\}; R) \arrow[d, "f^*"] & H^{p+q}(Y, C \cup D; R) \arrow[l, "\cong"'] \arrow[d, "f^*"] \\ H^p(X, A; R) \times H^q(X, B; R) \arrow[r, "\cup"] & H^{p+q}(X, \{A, B\}; R) & H^{p+q}(X, A \cup B; R). \arrow[l, "\cong"'] \end{tikzcd}$$

The desired statement follows immediately from this observation.

(2) This statement follows, similar to (1), basically immediately from the definitions. □

We record a particularly useful special case of Proposition 58.3 (1) as a corollary.

Corollary 58.4. *Let (X, A, B) be an excisive triad and let R be a commutative ring. Then the following diagram commutes:*

$$\begin{tikzcd} H^p(X, A; R) \times H^q(X, B; R) \arrow[r, "\cup"] \arrow[d] & H^{p+q}(X, A \cup B; R) \arrow[d] \\ H^p(X; R) \times H^q(X; R) \arrow[r, "\cup"] & H^{p+q}(X; R). \end{tikzcd}$$

In particular, if $\alpha \in H^p(X; R)$ lies in the image of $H^p(X, A; R)$ and if $\beta \in H^q(X; R)$ lies in the image of $H^q(X, B; R)$ and if $A \cup B = X$, then $\alpha \cup \beta = 0$.

Proof. The first part of the corollary follows immediately from Proposition 58.3 (1) applied to the obvious map $f\colon (X, \varnothing, \varnothing) \to (X, A, B)$ of excisive triads.

We turn to the proof of the second part. We denote by $\sigma\colon H^p(X, A; R) \to H^p(X; R)$, $\tau\colon H^p(X, B; R) \to H^p(X; R)$ and by $\upsilon\colon H^{p+q}(X, A \cup B; R) \to H^{p+q}(X; R)$ the obvious

maps. Let $\widehat{\alpha} \in H^p(X, A; R)$ and $\widehat{\beta} \in H^q(X, B; R)$. We write $\alpha = \sigma(\widehat{\alpha})$ and $\beta = \tau(\widehat{\beta})$. We suppose that $A \cup B = X$. Then

$$\alpha \cup \beta \;=\; \sigma(\widehat{\alpha}) \cup \tau(\widehat{\beta}) \;\underset{\substack{\uparrow \\ \text{by the commutative diagram}}}{=}\; \upsilon\big(\widehat{\alpha} \cup \widehat{\beta}\big) \;\underset{\substack{\uparrow \\ \text{since } \widehat{\alpha} \cup \widehat{\beta} \text{ lies in the group} \\ H^{p+q}(X, A \cup B; R) = H^{p+q}(X, X; R) = 0}}{=}\; \upsilon(0) \;=\; 0.$$

□

Before we state the next lemma we introduce one more convention.

Convention. Let A, B, C, D, X and Y be sets, let $f\colon C \to A$, $g\colon B \to D$ and $\mu\colon X \to Y$ be maps and let $\varphi\colon A \times B \to X$ and $\psi\colon C \times D \to Y$ be maps. We say that the diagram

$$\begin{tikzcd} A \times B \arrow[r, "\varphi"] \arrow[d, "g"] & X \arrow[d, "\mu"'] \\ C \times D \arrow[r, "\psi"] \arrow[u, "f"] & Y \end{tikzcd}$$

commutes, if for all $c \in C$ and $b \in B$ we have

$$\psi(c, g(b)) \;=\; \mu(\varphi(f(c), b)).$$

A similar convention holds with the directions of f and g reversed. Furthermore, if we are dealing with group homomorphisms, then there is an obvious notion of "commutes up to a given sign".

Later on, on one occasion we will need the following lemma.

Lemma 58.5. *Let (X, A) be a pair of topological spaces and let R be a commutative ring. For any $n, k \in \mathbb{N}_0$ the following diagram commutes:*

$$\begin{tikzcd} H^p(A; R) \times H^q(A; R) \arrow[r, "\cup"] \arrow[d, "\delta"] & H^{p+q}(A; R) \arrow[d, "\delta"] \\ H^p(X; R) \times H^{q+1}(X, A; R) \arrow[r, "\cup"] \arrow[u, "i^*"] & H_{p+q+1}(X, A; R) \end{tikzcd}$$

up to the sign $(-1)^p$. Here $i\colon B \to X$ denotes the inclusion map and δ denotes the connecting homomorphisms in the long exact sequence in cohomology corresponding to the pair (X, A).

Proof $(*)$. We pick cocyles $\varphi \in C^p(X; R)$ and $\psi \in C^q(A; R)$. We denote by $\widetilde{\psi}\colon C^q(X) \to R$ the extension of ψ that is defined to be zero on all singular k-simplices that do not lie in

the subset A. We have the following equalities:

$$\begin{array}{rcl}
\delta([i^*\varphi]\cup[\psi]) & = & \delta([i^*\varphi\cup\psi]) \\
 & & \underset{\substack{\text{by the discussion of the connecting homomorphism in the remark on page 1174 and} \\ \text{since } \varphi\cup\widetilde{\psi} \text{ is the trivial extension of } i^*\varphi\cup\psi\colon C_{p+q}(A)\to R \text{ to a homomorphism } C_{p+q}(X)\to R}}{\downarrow} \\
 & & = [\delta(\varphi\cup\widetilde{\psi})] \\
 & & \underset{\substack{\text{Lemma 57.2}}}{\uparrow} \\
 & & = [\delta\varphi\cup\widetilde{\psi}+(-1)^p\cdot(\varphi\cup\delta\widetilde{\psi})] \\
 & \underset{\substack{\text{since } \varphi \text{ is a cocycle}}}{\uparrow} & \\
 & = (-1)^p\cdot[\varphi\cup\delta\widetilde{\psi}] & = (-1)^p\cdot([\varphi]\cup[\delta\widetilde{\psi}]) \underset{\substack{\text{again by the remark on page 1174}}}{\uparrow} = (-1)^p\cdot([\varphi]\cup\delta[\psi]).
\end{array}$$

This equality implies that the diagram commutes up to the sign $(-1)^p$. □

We conclude this section with the definition of the cup product on cohomology with compact support. We will need this definition at a later stage.

Definition. Let X be a topological space and let $\varphi\in H^k_c(X)$ and let $\psi\in H^l_c(X)$. By Lemma 53.2 there exists a compact subset $K\subset X$ and a cohomology class $\widetilde{\varphi}\in H^k(X,X\backslash K)$ such that the image of $\widetilde{\varphi}$ in $H^k_c(X)$ equals φ. Analogously we find a compact set L and $\widetilde{\psi}\in H^l(X,X\setminus L)$. We define

$$\varphi\cup\psi \;:=\; \text{the image of } \varphi\cup\psi\in H^{k+l}(X,X\setminus(K\cup L)) \text{ in } H^{k+l}_c(X).$$

It follows easily from Corollary 58.4 that this definition does not depend on any of the choices. We refer to $\varphi\cup\psi$ as the *cup product in cohomology with compact support.*

58.2. **Calculations using the relative cup product.** In this section we will use Proposition 58.3 (1) to calculate cup products of several topological spaces. We start out with the suspension $\Sigma(X)=X\times[-1,1]/\sim$ of a topological space X. We refer to page 452 for the precise definition and we refer to Figure 731 for a reminder.

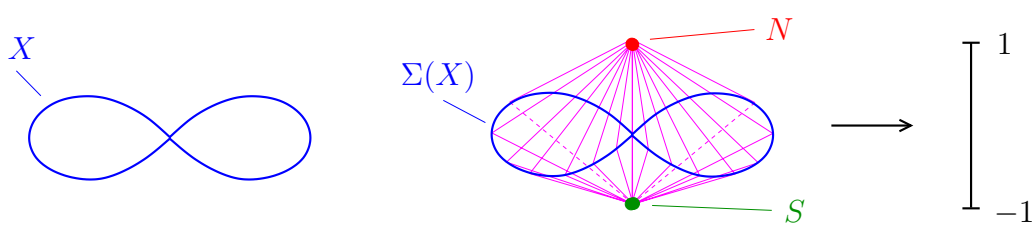


FIGURE 731.

The following lemma shows that the cup product of the suspension of a topological space is quite dull.

Lemma 58.6. *Let X be a path-connected topological space and let R be a commutative ring.*

(1) *We have*

$$H^k(\Sigma(X);R) \;\cong\; \begin{cases} R, & \text{if } k=0,\\ 0, & \text{if } k=1,\\ H^{k-1}(X;R), & \text{if } k\geq 2.\end{cases}$$

(2) *For any $k,l\geq 1$ the cup product*

$$H^k(\Sigma(X);R)\times H^l(\Sigma(X);R) \;\to\; H^{k+l}(\Sigma(X);R)$$

is the zero map.

Proof. We denote by $p\colon X\times[-1,1]\to\Sigma(X)$ the obvious projection map. We denote by $N:=[X\times\{1\}]$ the "North Pole" and we denote by $S:=[X\times\{-1\}]$ the "South Pole". We refer to Figure 731 for an illustration. We write $U=\Sigma(X)\setminus\{S\}$ and $V=\Sigma(X)\setminus\{N\}$. By the same argument as in Lemma 15.1 that U admits deformation retraction from U to the North Pole N. This shows that U is contractible. The same argument shows that V is contractible.

(1) Note that U and V are open subsets of $\Sigma(X)$.[1010] It follows from Proposition 50.12 (4) that $(\Sigma(X),U,V)$ is excisive. Therefore we can apply the Mayer–Vietoris Theorem 50.15 for Cohomology Groups and we obtain the following long exact sequence

$$\ldots\to H^i(\Sigma(X);R)\to H^i(U;R)\oplus H^i(V;R)\to H^i(U\cap V;R)\to H^{i+1}(\Sigma(X);R)\to\ldots$$

The desired isomorphism now follows easily from the above long exact sequence and the following:
   (a) above we had observed that U and V are contractible,
   (b) the intersection $U\cap V$ is homeomorphic to $X\times(-1,1)$, in particular it is homotopy equivalent to X,
   (c) Lemmas 48.14 and 48.12 and the discussion of induced maps on 0-th cohomology on page 1172.

(2) Now let $k,l\geq 1$. It follows immediately from the long exact sequence of cohomology groups corresponding to the pair $(\Sigma(X),U)$, the fact that U is homotopy equivalent to a point (together with Lemmas 48.12 and 48.13) that the inclusion induced map $H^k(\Sigma(X),U;R)\to H^k(\Sigma(X);R)$ is an isomorphism. Evidently the same also holds if we replace U by V.

By Corollary 58.4, and the fact that $(\Sigma(X),U,V)$ is excisive, we have the following commutative diagram

$$\begin{tikzcd}
H^k(\Sigma(X),U;R)\times H^l(\Sigma(X),V;R) \arrow[r, "\cup"] \arrow[d, "\cong"] & H^{k+l}(\Sigma(X),\overbrace{U\cup V}^{=\Sigma(X)};R) \arrow[d] \\
H^k(\Sigma(X);R)\times H^l(\Sigma(X);R) \arrow[r, "\cup"] & H^{k+l}(\Sigma(X);R).
\end{tikzcd}$$

[1010] Why is that?

Since $U \cup V = \Sigma(X)$ we see that the cohomology group on the top-right is zero. Furthermore, since the vertical map on the left is an isomorphism we see that the cup product on the bottom is zero. $\square$

Let X and Y be two topological spaces and let $x \in X$ and $y \in Y$ be good points. (See page 387 for the definition of a good point.) We use these points to define the wedge $X \vee Y$ of X and Y. Furthermore let R be a commutative ring. We denote by $p\colon X \vee Y \to X$ and $q\colon X \vee Y \to Y$ the obvious projection maps. By Proposition 50.17 we know that for every $n \in \mathbb{N}$ the map

$$p^* \oplus q^*\colon H^n(X;R) \oplus H^n(Y;R) \xrightarrow{\cong} H^n(X \vee Y;R)$$

is an isomorphism. The following lemma determines the cup product of $X \vee Y$ in terms of the cup products of X and Y. It can be viewed as a generalization of Lemma 57.11.

Lemma 58.7. *We continue with the above notation. Then for any $\alpha, \beta \in H^*(X;R)$ and $\varphi, \psi \in H^*(Y;R)$ in degrees ≥ 1 the following statements hold in $H^*(X \vee Y;R)$:*

$\cup$	$p^*(\beta)$	$q^*(\psi)$
$p^*(\alpha)$	$p^*(\alpha \cup \beta)$	0
$q^*(\varphi)$	0	$q^*(\varphi \cup \psi)$

Proof $(*)$. The statement regarding the "diagonal" terms of the table follows immediately from Lemma 57.10. It remains to prove that the off-diagonal terms are zero. We show that the top-right entry is zero. The proof that the bottom-left entry is zero is basically identical.

Thus let $\alpha \in H^k(X;R)$ and $\psi \in H^l(Y;R)$ with $k, l \geq 1$. We view X and Y as subsets of $X \vee Y$. We denote by $f\colon (X \vee Y, \varnothing) \to (X \vee Y, X)$ and $g\colon (X \vee Y, \varnothing) \to (X \vee Y, Y)$ the two inclusion maps of pairs of topological spaces.

Claim. There exist $\widetilde{\alpha} \in H^k(X \vee Y, Y;R)$ with $g^*(\widetilde{\alpha}) = p^*(\alpha)$ and $\widetilde{\psi} \in H^l(X \vee Y, X;R)$ with $f^*(\widetilde{\psi}) = q^*(\psi)$.

To prove the claim we consider the following two diagrams[1011]

$$\begin{tikzcd} H^k(X \vee Y;R) & H^k(X \vee Y, Y;R) \arrow[l, "g^*"'] \arrow[d] \\ H^k(X;R) \arrow[u, "p^*"] & H^k(X, \{x\};R) \arrow[l] \end{tikzcd} \quad \text{and} \quad \begin{tikzcd} H^l(X \vee Y;R) & H^l(X \vee Y, X;R) \arrow[l, "f^*"'] \arrow[d] \\ H^l(Y;R) \arrow[u, "q^*"] & H^l(Y, \{y\};R). \arrow[l] \end{tikzcd}$$

Here the maps that are unlabeled are induced by the obvious inclusions. It is easy to verify that the diagrams commute. It follows easily from the long exact sequence in cohomology of a pair of topological spaces that the two bottom horizontal maps are isomorphisms. Recall that in Lemma 50.16 we showed that the triad $(X \vee Y, X, Y)$ is excisive. Therefore

[1011] Recall that in $X \vee Y$ the points x and y get identified, so we can view x as an element in Y and we can view y as an element in X.

it follows from Lemma 50.13 that the vertical maps on the right are isomorphism. The claim is an immediate consequence of these observations.

Since, as we had just seen, the triad $(X \vee Y, X, Y)$ is excisive we can apply Corollary 58.4 and we obtain that

$$p^*(\alpha) \cup q^*(\psi) \;=\; g^*(\widetilde{\alpha}) \cup f^*(\widetilde{\psi}) \;\underset{\substack{\uparrow \\ \text{by Corollary 58.4 since } X \cup Y = X \vee Y}}{=}\; 0.$$

□

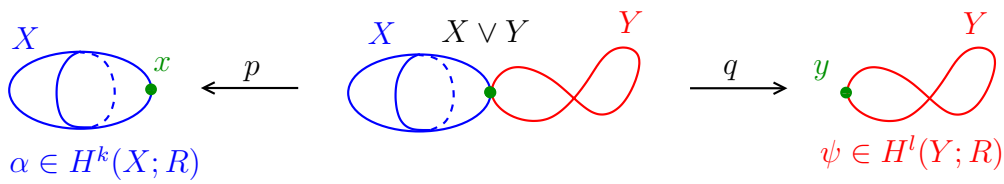

FIGURE 732. Illustration for the proof of Lemma 58.7.

Example. Now we can also give a new proof of Lemma 57.16, more precisely, we can give a new and somewhat more conceptual proof of the calculation of the cup product of the surface Σ of genus 2. First we recall that on page 1202 we introduced two projection maps $p_i \colon \Sigma \to T_i = S^1 \times S^1$ for $i = 1, 2$. It follows easily from Lemma 47.4 that these projection maps are degree-one maps, i.e. they send the fundamental class $[\Sigma]$ to the fundamental class $[T_i]$. In Lemma 50.11 we saw that the map

$$p_1^* \oplus p_2^* \colon H^1(T_1;\mathbb{Z}) \oplus H^1(T_2;\mathbb{Z}) \;\to\; H^1(\Sigma;\mathbb{Z})$$

is an isomorphism. We make the following observations:

(1) Let $\varphi, \psi \in H^1(T_i;\mathbb{Z})$, $i = 1, 2$. Then

$$\langle \varphi \cup \psi, [T_i]\rangle_{T_i} \;\underset{\substack{\uparrow \\ \text{since } p_i \text{ is of degree one}}}{=}\; \langle \varphi \cup \psi, p_{i*}([\Sigma])\rangle_{T_i} \;\underset{\substack{\uparrow \\ \text{Lemma 50.6}}}{=}\; \langle p_i^*(\varphi \cup \psi), [\Sigma]\rangle_{\Sigma} \;\underset{\substack{\uparrow \\ \text{Lemma 57.10}}}{=}\; \langle p_i^*(\varphi) \cup p_i^*(\psi), [\Sigma]\rangle_{\Sigma}.$$

(2) We denote by $q_i \colon T_1 \vee T_2 \to T_i$, $i = 1, 2$ the obvious projections. The two projection maps p_1, p_2 give rise to a map $p_1 \vee p_2 \colon \Sigma \to T_1 \vee T_2$ which has the property that $q_i \circ (p_1 \vee p_2) = p_i$, $i = 1, 2$. (See Figure 733 for an illustration.) Now let $\varphi_1 \in H^1(T_1;\mathbb{Z})$ and $\varphi_2 \in H^1(T_2;\mathbb{Z})$. Then

$$p_1^*(\varphi_1) \cup p_2^*(\varphi_2) \;\underset{\substack{\uparrow \\ \text{by Lemma 57.10, since } q_i \circ (p_1 \vee p_2) = p_i}}{=}\; (p_1 \vee p_2)^*(q_1^*(\varphi_1) \cup q_2^*(\varphi_2)) \;\underset{\substack{\uparrow \\ \text{Lemma 58.7}}}{=}\; (p_1 \vee p_2)^*(0) \;=\; 0.$$

Precisely the same proof shows also that $p_2^*(\varphi_2) \cup p_1^*(\varphi_1) = 0$.

These two claims, together with the previous calculation of the cup product on the torus $T = S^1 \times S^1$, see Lemma 57.14, give a new proof of Lemma 57.16.

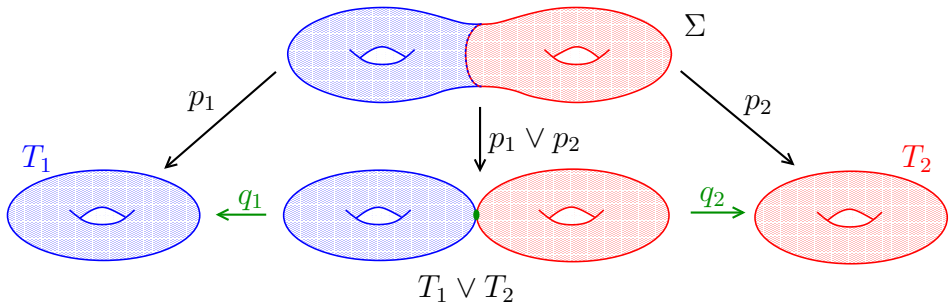

FIGURE 733.

58.3. **The Lusternik-Schnirelmann category.** We start out with the following definition.

Definition. Let M be an m-dimensional manifold.

(1) A *parametrization for* M is a smooth map $\Psi\colon V \to M$ with the following properties:
   (a) the domain V is either an open ball in $\mathbb{R}^m$, or an open rectangle, or all of $\mathbb{R}^m$,[1012]
   (b) the map Ψ is a diffeomorphism onto its image.
(2) We say a family $\{\Psi_i\colon V_i \to M\}_{i\in I}$ of parametrizations *covers* M if $\bigcup_{i\in I} \Psi_i(V_i) = M$.

The following slightly vague question arises:

Question 58.8. *For a given manifold M, how many parametrizations do we need to cover all of M?*

Examples.

(1) Let $N = (0, \dots, 0, 1)$ be the North Pole and let $S = (0, \dots, 0, -1)$ be the South Pole of the n-dimensional sphere S^n. We can cover S^n by the two open subsets $S^n \setminus \{N\}$ and $S^n \setminus \{S\}$. Stereographic projection, see Figure 23, gives rise to two diffeomorphisms $\Phi_1\colon S^n \setminus \{N\} \to \mathbb{R}^n$ and $\Phi_2\colon S^n \setminus \{S\} \to \mathbb{R}^n$. The inverses of these two maps define parametrizations that cover S^n.
   Since S^n is not diffeomorphic to any of the admissible domains of a parametrization we see that the above collection of parametrizations is optimal in the sense that we cannot parametrize S^n with fewer parametrizations.
(2) We consider the n-torus $(S^1)^n = \mathbb{R}^n/\mathbb{Z}^n$. We denote by $p\colon \mathbb{R}^n \to \mathbb{R}^n/\mathbb{Z}^n$ the projection map. We pick real numbers $0 < s_1 < s_2 < \cdots < s_{n+1} < 1$. For $i = 1, \dots, n+1$

[1012]The condition on V sounds slightly arbitrary, and it is, but it is reasonable that for practical purposes one prefers domains that are "easy to describe".

we consider the map

$$\begin{array}{rcl} \Psi_i\colon \overbrace{(s_i, s_i+1)\times\ldots\times(s_i, s_i+1)}^{=:V_i} & \to & \mathbb{R}^n/\mathbb{Z}^n \\ (t_1,\ldots,t_n) & \mapsto & p(t_1,\ldots,t_n). \end{array}$$

For $i = 1,\ldots,n+1$ we write $U_i = \Psi_i(V_i)$. It is straightforward to see that the maps $\Psi_1,\ldots,\Psi_{n+1}$ are parametrizations that cover $\mathbb{R}^n/\mathbb{Z}^n$.[1013] We illustrate the images of the parametrizations for the 2-torus in Figure 734.

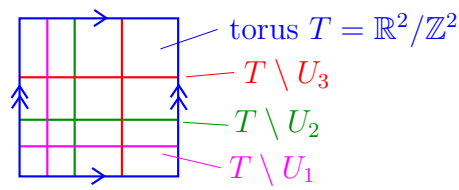

FIGURE 734.

(3) For $i = 1,\ldots,n+1$ we consider the map

$$\begin{array}{rcl} \Psi_i\colon \mathbb{R}^n & \to & \mathbb{R}\mathrm{P}^n = (\mathbb{R}^{n+1}\setminus\{0\})/\sim \\ (x_1,\ldots,x_n) & \mapsto & \underbrace{[x_1:\ldots:x_{i-1}:1:x_i:\ldots:x_n]}_{\text{point in } \mathbb{R}\mathrm{P}^n \text{ represented by } (x_1,\ldots,x_{i-1},1,x_i,\ldots,x_n)}. \end{array}$$

It is straightforward to see that the maps $\Psi_1,\ldots,\Psi_{n+1}$ are parametrizations that cover the real projective space $\mathbb{R}\mathrm{P}^n$.

(4) Almost the same construction as in (3) shows that we can cover the complex projective space $\mathbb{C}\mathrm{P}^n = (\mathbb{C}^{n+1}\setminus\{0\})/\sim$ by $n+1$ parametrizations such that the domain of each parametrization is diffeomorphic to $\mathbb{C}^n \cong \mathbb{R}^{2n}$.

The following question is now a more precise version of Question 58.8.

Question 58.9.

(1) *Can we cover $(S^1)^n$ by fewer than $n+1$ parametrizations?*
(2) *Can we cover $\mathbb{R}\mathrm{P}^n$ by fewer than $n+1$ parametrizations?*
(3) *Can we cover $\mathbb{C}\mathrm{P}^n$ by fewer than $n+1$ parametrizations?*

Now we will generalize this discussion to arbitrary topological spaces by introducing the following definition.

Definition.

(1) We say that a map $f\colon Y \to X$ between topological spaces is *null-homotopic* if it is homotopic to a constant map.

[1013] Hmm, why is it true that $U_1 \cup \cdots \cup U_{n+1} = \mathbb{R}^n/\mathbb{Z}^n$?

(2) The *Lusternik-Schnirelmann category* $\mathrm{cat}(X)$[1014] of a topological space X is defined as the smallest $n \in \mathbb{N}_0$ such that there exists an open covering $U_1, \ldots, U_{n+1}$ of X such that each inclusion map $U_i \to X$ is null-homotopic.[1015] If no such n exists, then we define $\mathrm{cat}(X) = \infty$.

Remark.

(1) Suppose that a given manifold M can be covered by $n+1$ parametrizations. Since the domain of a parametrization is contractible and since a parametrization is a diffeomorphism onto its image we see that $\mathrm{cat}(M) \leq n$.[1016]
(2) The sets U_i in the definition of the Lusternik-Schnirelmann category do not have to be contractible, for example if X itself is contractible, then for any subset $U \subset X$ the inclusion map $U \to X$ is null-homotopic.
(3) The Lusternik-Schnirelmann category plays an important role in topological robotics, see e.g. [Far] for more details.

Examples.

(1) For a non-empty topological space X we have $\mathrm{cat}(X) = 0$ if and only if $\mathrm{id}\colon X \to X$ is null-homotopic, i.e. if X is contractible.
(2) Statement (1) together with Figure 735 shows that for a wedge X of $n \geq 1$ circles we have $\mathrm{cat}(X) = 1$.

FIGURE 735.

(3) The above discussion of parametrizations of S^n together with statement (1) shows that $\mathrm{cat}(S^n) = 1$.
(4) The discussion preceding Question 58.9 gives us the inequalities $\mathrm{cat}((S^1)^n) \leq n$, $\mathrm{cat}(\mathbb{R}\mathrm{P}^n) \leq n$ and also $\mathrm{cat}(\mathbb{C}\mathrm{P}^n) \leq n$.
(5) For any $g \geq 2$ the surface Σ of genus g satisfies $\mathrm{cat}(\Sigma) \leq 2$, see Figure 736 for an illustration in the case $g = 2$.
(6) In [Hau, p. 147] or alternatively in [CLOT, Chapter 1.2] it is shown that for any n-dimensional connected CW-complex X the inequality $\mathrm{cat}(X) \leq n$ holds. This general statement generalizes all of the above statements (2) to (5).

[1014]The word "category" with its modern meaning was first used by Eilenberg-Maclane [EM] in 1945. On the other hand the term "Lusternik-Schnirelmann category" was already established by 1941, see [Fo].

[1015]Note the fairly well-hidden "+1" in the subscript of U_{n+1}. Sometimes, especially in the older literature the Lusternik-Schnirelmann category is defined without the adjustment given by the "+1".

[1016]Hmm, why is the image of a parametrization an open subset of the manifold?

(7) It follows from statement (6), together with Lemma 39.2 and Proposition 39.3 that for any compact connected n-dimensional manifold M we have $\operatorname{cat}(M) \leq n$. By the discussion on page 1075 the same statement also holds for closed connected n-dimensional topological manifolds, as long as $n \neq 4$.[1017]

(8) If X and Y are two path-connected CW-complexes with finite Lusternik-Schnirelmann categories, then $\operatorname{cat}(X \times Y) \leq \operatorname{cat}(X) + \operatorname{cat}(Y)$, see e.g. [Fo, Theorem 9] or [CLOT, Theorem 1.37]. The Ganea Conjecture from 1971 predicted that for any CW-complex X one has $\operatorname{cat}(X \times S^n) = \operatorname{cat}(X) + \operatorname{cat}(S^n) = \operatorname{cat}(X) + 1$. But this conjecture was eventually disproved by Norio Iwase [Iw, Iw2] in 1998.

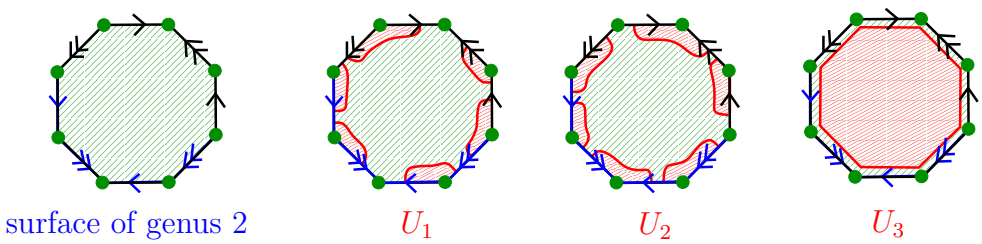

FIGURE 736.

As we saw in the above examples, one can obtain an upper bound on the Lusternik-Schnirelmann category of a given topological space by writing down explicit open subsets. To obtain lower bounds on the Lusternik-Schnirelmann category we introduce the following definition.

Definition. Given a topological space X we define its *cup length* $c(X) \in \mathbb{N}_0 \cup \{\infty\}$ as follows:

$$c(X) \;:=\; \max\left\{ n \in \mathbb{N}_0 \;\middle|\; \begin{array}{c} \text{there exists a commutative ring } R \text{ and } R\text{-cohomology} \\ \text{classes } x_1, \dots, x_n \text{ in degrees} \geq 1 \text{ with } x_1 \cup \dots \cup x_n \neq 0 \end{array} \right\}.$$

Examples.

(1) If X is an n-dimensional CW-complex, then it follows immediately from Proposition 50.4 that $c(X) \leq n$.

(2) In Lemma 57.14 and Lemma 57.16 we saw that for any surface Σ of genus $g \geq 1$ there exist $x, y \in H^1(\Sigma; \mathbb{Z})$ with $x \cup y \neq 0$, which together with (1) shows that $c(\Sigma) = 2$.

(3) In Lemma 57.18 we saw that there exists an $x \in H_1(\mathbb{R}\mathrm{P}^2; \mathbb{F}_2)$ with $x \cup x \neq 0$, which shows that $c(\mathbb{R}\mathrm{P}^2) = 2$.

The following proposition shows that the cup length is a lower bound on the Lusternik-Schnirelmann category.

[1017] I do not know whether the case of 4-dimensional topological manifolds is known.

Proposition 58.10. *For every topological space X we have*

$$c(X) \;\leq\; \mathrm{cat}(X).$$

Example. It follows immediately from Proposition 58.10 and the above examples that

$$\mathrm{cat}(S^1 \times S^1) \;=\; \mathrm{cat}(\text{surface of genus } g \geq 2) \;=\; \mathrm{cat}(\mathbb{R}\mathrm{P}^2) \;=\; 2.$$

Proof. Let X be a topological space, let R be a commutative ring and let $x_j \in H^{s_j}(X;R)$, $j = 1, \ldots, n$ be cohomology classes in dimensions $s_j \geq 1$ such that $x_1 \cup x_2 \cup \cdots \cup x_n \neq 0$. We have to show that $\mathrm{cat}(X) \geq n$.

Thus let $k \leq n$ and let $U_1, \ldots, U_k$ be open subsets in X with $U_1 \cup \cdots \cup U_k = X$ such that each inclusion map $U_i \to X$ is null-homotopic. We have to show that $U_1 \cup \cdots \cup U_k$ is a *proper* subset of X.

Claim. For any $j \in \{1, \ldots, k\}$ the obvious map $\rho_j \colon H^{s_j}(X, U_j; R) \to H^{s_j}(X;R)$ is in fact an isomorphism.

By our hypothesis the inclusion map $i_j \colon U_j \to X$ is null-homotopic, it follows that the restriction map $i_j^* \colon H^k(X;R) \to H^k(U_j;R)$ is the zero map for $k \geq 1$ and an epimorphism for $k = 0$.[1018] We deduce from this observation, the long exact sequence of cohomology groups corresponding to the pair (X, U_j) and the fact that $s_j \geq 1$ that the obvious map $\rho_j \colon H^{s_j}(X, U_j; R) \to H^{s_j}(X;R)$ is in fact an isomorphism. This concludes the proof of the claim.

Given $j \in \{1 \ldots, k\}$ we write $y_j := \rho_j^{-1}(x_j) \in H^{s_j}(X, U_j; R)$ and we set $s = s_1 + \cdots + s_k$. By Corollary 58.4[1019] we have the following commutative diagram

$$\begin{tikzcd}
H^{s_1}(X, U_1; R) \times \cdots \times H^{s_k}(X, U_k; R) \arrow[r, "\cup"] \arrow[d, "{(y_1, \ldots, y_k) \mapsto (x_1, \ldots, x_k)}"'] & H^s(X, U_1 \cup \cdots \cup U_k; R) \arrow[d] \\
H^{s_1}(X;R) \times \cdots \times H^{s_k}(X;R) \arrow[r, "\cup"] & H^s(X;R).
\end{tikzcd}$$

By our hypotheses the cup product $x_1 \cup \cdots \cup x_k$ is non-zero, which then implies, by the commutativity of the diagram, that the cup product $y_1 \cup \cdots \cup y_k$ is also non-zero. But this implies that the group $H^s(X, U_1 \cup \cdots \cup U_k; R)$ is non-zero, which in turn implies that $U_1 \cup \cdots \cup U_k$ is a proper subset of X. $\square$

Proposition 58.10 gives us a tool to attack Question 58.9. In fact we saw right after Proposition 58.10 that we can now answer the question for the 2-dimensional torus $(S^1)^2$ and the real projective plane $\mathbb{R}\mathrm{P}^2$.

The following questions naturally arise:

[1018] This can be seen as follows: the map $i_j \colon U_j \to X$ is homotopic to a constant map that takes the value $P_j \in X$. We denote by $c_j \colon U_j \to \{P_j\}$ the constant map and we denote by $k_j \colon \{P_j\} \to X$ the inclusion map. We statement now follows from $i_j^* = (k_j \circ c_j)^* = c_j^* \circ k_j^*$ and Lemmas 48.13 and 48.12.

[1019] Strictly speaking Corollary 58.4 was formulated for the cup product of two terms, but one can easily reduce the general case of k terms to the special case of 2 terms.

Question 58.11.

(1) *What is the* $\mathbb{Z}$*-cohomology ring of* $(S^1)^n$*?*
(2) *What is the* $\mathbb{F}_2$*-cohomology ring of* $\mathbb{R}\mathrm{P}^n$*?*
(3) *What is the* $\mathbb{Z}$*-cohomology ring of* $\mathbb{C}\mathrm{P}^n$*?*

We will answer these questions in the coming chapters.

Exercises for Chapter 58.

Exercise 58.1. Let X and Y be non-empty topological spaces. Show that

$$c(X \times Y) \ \geq \ \max\{c(X), c(Y)\}.$$

Here c denotes the cup length.

59. The cap product

In this chapter we introduce the cap product that relates the homology and the cohomology groups. It can be viewed as a generalization of the Kronecker pairing. Initially it might not be clear that the cap product is good for, but later on we will see that it plays an essential role in many calculations and in the formulation of the Poincaré Duality Theorem.

59.1. **The definition of the cap product and calculations.** We start out by introducing a convention that simplifies our notation later on.

Convention. Let R be a commutative ring and let S be a non-empty set. We consider

$$R^{(S)} \ := \ \text{all maps from } S \text{ to } R \text{ which are non-zero for only finitely many } s \in S$$

with the obvious R-module structure. We refer to $R^{(S)}$ as the *free R-module generated by S*. For example, the free $\mathbb{Z}$-module generated by S is precisely the same as the free abelian group generated by S. We use the same convention as on page 366 to identify elements in $R^{(S)}$ with finite formal linear combinations $r_1 s_1 + \cdots + r_k s_k$ where $r_1, \ldots, r_k \in R$ and $s_1, \ldots, s_k \in S$. By Lemma 42.3 the map

$$\begin{array}{rcl} \mathbb{Z}^{(S)} \otimes R & \to & R^{(S)} \\ \sum\limits_{i=1}^{n} n_i \cdot s_i \otimes r_i & \mapsto & \sum\limits_{i=1}^{n} \underbrace{n_i r_i}_{\in R} \cdot s_i \end{array}$$

is an isomorphism. We use this isomorphism to identify the left-hand side with the right-hand side. In particular, given a topological space X and $k \in N_0$ we write

$$C_k(X;R) \ := \ \mathbb{Z}^{S_k(X)} \otimes R \ = \ R^{S_k(X)} \ = \ \left\{ \sum_{i=1}^{n} r_i \cdot \sigma_i \,\middle|\, r_1, \ldots, r_n \in R \text{ and } \sigma_i \colon \Delta^k \to X \right\},$$

where $S_k(X)$ denotes the set of singular k simplices in X.

The following definition is inspired by the second definition of the cup product that we gave on page 1334.

Definition. Let X be a topological space and let R be a commutative ring. Given a singular cochain $\varphi \in C^k(X;R)$ and a singular simplex $\sigma \colon \Delta^l \to X$ with $k \leq l$ we define the *cap product* as[1020]

$$\varphi \cap \sigma \ := \ \underbrace{\varphi(\sigma \circ [v_0, \ldots, v_k])}_{\in R} \cdot \underbrace{\sigma \circ [v_k, \ldots, v_l]}_{\text{map } \Delta^{l-k} \to X}.$$

We extend this definition to singular R-chains and we obtain the cap product

$$\cap \colon C^k(X;R) \times C_l(X;R) \ \to \ C_{l-k}(X;R)$$

For $k > l$ we define the cap product to be the zero map.

[1020]Here we use, as usual, the notation from page 1323.

As for the cup product, the first thing we want to verify is that this map on the cochain and chain level defines a map on the level of cohomology groups and homology groups. The key to doing so is the following elementary lemma.

Lemma 59.1. *Let X be a topological space and let R be a commutative ring. Furthermore let $\varphi \in C^k(X;R)$ and let $\sigma \in C_l(X;R)$. Then*

$$\partial(\varphi \cap \sigma) \;=\; (-1)^k \cdot (-\delta\varphi \cap \sigma \,+\, \varphi \cap \partial\sigma) \;\in\; C_{l-k-1}(X;R).$$

In particular this implies that $\varphi \cap \partial\sigma$ and $\delta\varphi \cap \sigma$ are homologous.

Proof. For $k > l$ the statement is trivial. So assume that $k \leq l$. Clearly it suffices to prove the equality for the case that $\sigma\colon \Delta^l \to X$ is a singular l-simplex. This case follows from an elementary calculation. Indeed, we have

$$\begin{aligned}
&\text{(a)} & \varphi \cap \partial\sigma &= \sum_{i=0}^{k} (-1)^i \cdot \varphi(\sigma \circ [v_0, \dots, \widehat{v}_i, \dots, v_{k+1}]) \cdot \sigma \circ [v_{k+1}, \dots, v_l] \\
& & &\quad + \sum_{i=k+1}^{l} (-1)^i \cdot \varphi(\sigma \circ [v_0, \dots, v_k]) \cdot \sigma \circ [v_k, \dots, \widehat{v}_i, \dots, v_l] \\
&\text{(b)} & \delta\varphi \cap \sigma &= \sum_{i=0}^{k+1} (-1)^i \cdot \varphi(\sigma \circ [v_0, \dots, \widehat{v}_i, \dots, v_{k+1}]) \cdot \sigma \circ [v_{k+1}, \dots, v_l] \\
&\text{(c)} & (-1)^k \cdot \partial(\varphi \cap \sigma) &= \sum_{i=k}^{l} (-1)^i \cdot \varphi(\sigma \circ [v_0, \dots, v_k]) \cdot \sigma \circ [v_k, \dots, \widehat{v}_i, \dots, v_l].
\end{aligned}$$

Note that the summand of (b) corresponding to $i = k+1$ equals *minus* the summand of (c) corresponding to $i = k$. Adding (b) and (c) and comparing it to (a) we see that

$$\varphi \cap \partial\sigma \;=\; \delta\varphi \cap \sigma + (-1)^k \cdot \partial(\varphi \cap \sigma)$$

which gives the desired equality. □

The following lemma says that "$\cap$" descends to a map on homology and cohomology.

Lemma 59.2. *Let X be a topological space and let R be a commutative ring. Then for any $k, l \in \mathbb{N}_0$ the map*

$$\begin{array}{rcl} H^k(X;R) \times H_l(X;R) & \to & H_{l-k}(X;R) \\ ([\varphi],[\sigma]) & \mapsto & [\varphi \cap \sigma] \end{array}$$

is well-defined and R-bilinear.

We refer to the pairing from Lemma 59.2 as the *cap product.*[1021]

Proof. For $k > l$ the statement is trivial. So assume that $k \leq l$. The statement now follows easily from Lemma 59.1. Indeed, let $\varphi \in C^k(X;R)$ be a cocycle and let $\sigma \in C_l(X;R)$ be a cycle.

[1021]The name "cap product" comes from the notation "$a \cap b$" for the composition since $\cap$ looks like, just a little bit, like the "a" in cap. The other reason is that the cup product was first introduced, and mathematicians needed a different name for a somewhat related object. Also mathematicians are well-known for their great sense of humor.

(1) It follows from Lemma 59.1 that $\varphi \cap \sigma$ is a cycle, i.e. it represents a homology class.
(2) If $\sigma' = \sigma + \partial\tau$ is another representative of $[\sigma]$, then

$$\varphi \cap \sigma - \varphi \cap \sigma' \;=\; \varphi \cap (\sigma - \sigma') \;=\; \varphi \cap \partial\tau \;\underset{\substack{\uparrow \\ \text{by Lemma 59.1 and since } \delta\varphi = 0}}{=}\; \pm\partial(\varphi \cap \tau).$$

This shows that $\varphi \cap \sigma$ and $\varphi \cap \sigma'$ represent the same homology class, i.e. the cap product does not depend on the choice of the representative of the homology class.
(3) The proof that the cap product does not depend on the choice of representative of the cohomology class is basically the same as the proof of (2).

This shows that the map is well-defined. It is clear that the map is indeed R-bilinear. □

Remark. Rather depressingly there is an endless variety of definitions of the cap product in the literature. More precisely, given a cochain $\varphi \in C^k(X;R)$ and a singular simplex $\sigma\colon \Delta^l \to X$ the following definitions of $\varphi \cap \sigma$ can be found in the literature:

		$\varphi \cap \sigma$
(a)	Hatcher [Hat, p. 239]	$\varphi(\sigma \circ [v_0, \dots, v_k]) \cdot \sigma \circ [v_k, \dots, v_l]$
(b)	Bredon [Bre, p. 335]	$(-1)^{k(l-k)} \cdot \varphi(\sigma \circ [v_0, \dots, v_k]) \cdot \sigma \circ [v_k, \dots, v_l]$
(c)	Dold [Dol, p. 335]	$(-1)^{k(l-k)} \cdot \sigma \circ [v_0, \dots, v_{l-k}] \cdot \varphi(\sigma \circ [v_{l-k}, \dots, v_l])$
(d)	Spanier [Sp, p. 254]	$\sigma \circ [v_0, \dots, v_{l-k}] \cdot \varphi(\sigma \circ [v_{l-k}, \dots, v_l])$
(e)	Munkres [Mun, p. 389]	$\sigma \circ [v_0, \dots, v_{l-k}] \cdot \varphi(\sigma \circ [v_{l-k}, \dots, v_l])$

To the best of my understanding, see [Sp, p. 250] the singular chains

$$\varphi(\sigma \circ [v_0, \dots, v_k]) \cdot \sigma \circ [v_k, \dots, v_l] \quad \text{and } (-1)^{k(l-k)} \cdot \sigma \circ [v_0, \dots, v_{l-k}] \cdot \varphi(\sigma \circ [v_{l-k}, \dots, v_l])$$

are homologous. This shows that on the level of homology and cohomology groups the definition (a), which is also our definition, agrees with (c), but that the sign differs for (b), (d) and (e). For the most part this is not an issue, but one needs to be careful when one cites formulas from the literature. For example, as we had already mentioned on page 1162, Bredon [Bre] defined the coboundary map as

$$\delta_k^{\mathrm{Bre}} \;:=\; (-1)^{k+1} \cdot \partial_{k+1}^* \;=\; (-1)^{k+1} \cdot \delta_k$$

and as we saw above, the cap product is also defined differently. Thus our Lemma 59.1, which says that for $\varphi \in C^k(X;R)$ and $\sigma\colon \Delta^l \to X$ we have

$$\partial(\varphi \cap \sigma) \;=\; (-1)^k \cdot (\varphi \cap \partial\sigma \;-\; \delta\varphi \cap \sigma)$$

becomes the following equality in [Bre, Proposition VI.5.1]:[1022]

$$\partial(\varphi \cap \sigma) \;=\; (-1)^k \cdot \varphi \cap \partial\sigma \;+\; \delta^{\mathrm{Bre}}(\varphi) \cap \sigma.$$

The following lemma follows immediately from the definitions.

[1022]The lesson you should draw is that if you ever have to write algebraic topology lectures notes, stick to a single book and do not try to mix books.

Lemma 59.3. *Let X be a topological space and let R be a commutative ring. Then for any $\sigma \in H_k(X;R)$ we have*

$$1_X \cap \sigma \;=\; \sigma.$$

For future applications we state the special case $k = l$ in the cap product in the following lemma.

Lemma 59.4. *Let X be a topological space and let R be a commutative ring.*

(1) *The composition*

$$H^k(X;R) \times H_k(X;R) \;\xrightarrow{\cap}\; H_0(X;R) \;\xrightarrow[\text{from page 1009}]{\text{augmentation } \epsilon}\; R$$

is precisely the Kronecker pairing from pages 1199 and 1227.

(2) *If X is path-connected, and if we make the usual identification $H_0(X;R) = R$ given by the augmentation map, see Proposition 29.5, then for any $\varphi \in H^k(X;R)$ and $\sigma \in H_k(X;R)$ we have*

$$\varphi \cap \sigma \;=\; \langle \varphi, \sigma \rangle \;\in\; R.$$

Proof. Both statements follow immediately from recalling all the relevant definitions. □

Example. We consider some examples of the cap product in detail to get some feeling for what it does.

(1) Let $T = S^1 \times S^1 = [0,1] \times [0,1]/\sim$ be the torus. We recall the following notations and results that we have by now used on many occasions. (We refer to Figure 737 for some of the notation.)
   (a) We denote by σ_1, σ_2 the singular 2-simplices from Figure 737. As we pointed out on page 1118, the singular 2-chain $-\sigma_1 + \sigma_2$ is a representative of the fundamental class $[T]$.
   (b) We denote by p respectively q the projection $S^1 \times S^1 \to S^1$ onto the first respectively second factor.
   (c) We denote by $\theta := \theta_{\mathbb{Z}} \in C^1(S^1;\mathbb{Z})$ the singular 1-cocycle that we introduced on page 1166.
   (d) As before we denote by $\mu\colon \Delta^1 \to S^1$ the singular 1-simplex that is given by $\mu(1-t,t) = e^{2\pi i t}$. By the discussion on page 1118 we know that μ represents the fundamental class $[S^1]$ of S^1 equipped with the standard orientation. By a slight abuse of notation we also denote by $[1 \times S^1]$ the image of the fundamental class under the monomorphism $H_1(1 \times S^1;\mathbb{Z}) \to H_1(S^1 \times S^1;\mathbb{Z})$.

   We calculate that

$$p^*(\theta) \cap \sigma_1 \;=\; \underbrace{p^*(\theta)(\sigma_1 \circ [v_0,v_1])}_{=\theta(p\circ\sigma_1\circ[v_0,v_1])=0} \cdot \sigma_1 \circ [v_1,v_2] \;=\; 0$$

   and similarly we calculate that

$$p^*(\theta) \cap \sigma_2 \;=\; \underbrace{p^*(\theta)(\sigma_2 \circ [v_0,v_1])}_{=\theta(p\circ\sigma_2\circ[v_0,v_1])=1} \cdot \sigma_2 \circ [v_1,v_2] \;=\sigma_2\circ[v_1,v_2] = 1\times\mu.$$

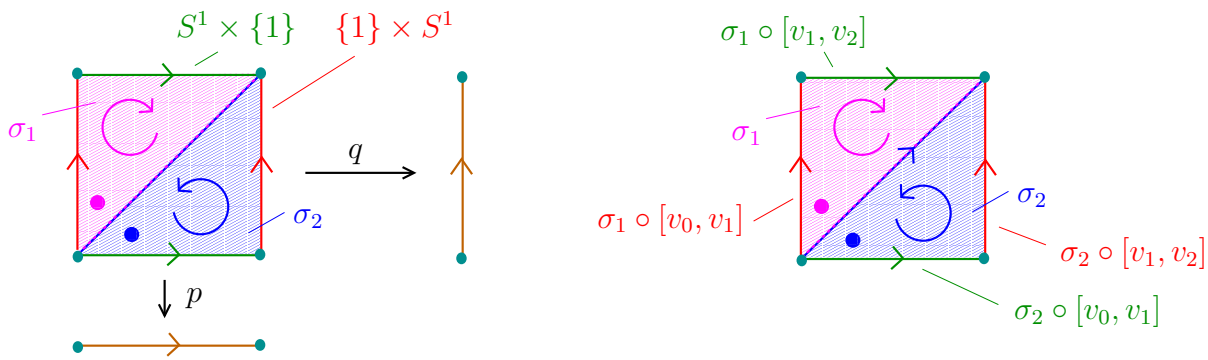

FIGURE 737.

Putting these calculations together we obtain that

$$[p^*(\theta)] \cap [T] \;=\; [p^*(\theta) \cap (-\sigma_1 + \sigma_2)] \;=\; [1 \times S^1].$$

Basically the same calculation shows that

$$[q^*(\theta)] \cap [T] \;=\; [q^*(\theta) \cap (-\sigma_1 + \sigma_2)] \;=\; -[S^1 \times 1].$$

So we see that the map

$$\cap[T] \colon H^1(T;\mathbb{Z}) \;\to\; H_1(T;\mathbb{Z})$$

is non-trivial, in fact we have just shown that this map satisfies

$$\begin{array}{rcr} [p^*(\theta)] & \mapsto & [1 \times S^1] \\ [q^*(\theta)] & \mapsto & -[S^1 \times 1] \end{array}$$

which shows that "capping with the fundamental class" is in this case an isomorphism.

(2) In Exercise 59.2 we will deal with the surface Σ of genus 2 and there we will also see that the map

$$\cap[\Sigma] \colon H^1(\Sigma;\mathbb{Z}) \;\to\; H_1(\Sigma;\mathbb{Z})$$

is an isomorphism.

(3) Finally we consider again the real projective plane $\mathbb{R}\mathrm{P}^2 = \overline{B}^2/\sim$. We introduce the following notation:
   (a) We denote by $\varphi \in C^1(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2)$ the cocycle that we introduced on page 1352.
   (b) We denote by $\gamma \colon \Delta^1 \to \mathbb{R}\mathrm{P}^2 = \overline{B}^2/\sim$ the singular 1-simplex that is given by $\gamma(t, 1-t) = [e^{\pi i t}]$. Note that γ is a cycle in $C_1(\mathbb{R}\mathrm{P}^2)$ and note that $\varphi(\gamma) = 1$.
   (c) In Figure 659 we already saw a representative for the $\mathbb{F}_2$-fundamental class, but we will work with a different one that is "smaller" and that is shown in Figure 738. In Figure 738 we see the singular 2-simplex σ that sends the face $[v_0, v_2]$ to a point P and the singular 2-simplex τ that sends all points on Δ^2 to P. It is straightforward to see that $(\sigma + \tau) \otimes 1 \in C_2(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2)$ is a cycle. Using Proposition 46.8 we see that it represents the $\mathbb{F}_2$-fundamental class of $\mathbb{R}\mathrm{P}^2$.

It is straightforward to see that

$$[\varphi]\cap[\mathbb{R}\mathrm{P}^2] \;=\; [\varphi]\cap[(\sigma+\tau)\otimes 1] \;=\; [\underbrace{\varphi\cap\sigma}_{=\gamma}\otimes 1+\underbrace{\varphi\cap\tau}_{=0}\otimes 1] \;=\; [\gamma\otimes 1]$$

We saw on page 1353 that $[\gamma\otimes 1]$ is the unique non-trivial element of $H_1(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2)$. Thus in this case we see that the map

$$\cap[\mathbb{R}\mathrm{P}^2]\colon H^1(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2) \;\to\; H_1(\mathbb{R}\mathrm{P}^2;\mathbb{F}_2)$$

is also an isomorphism.

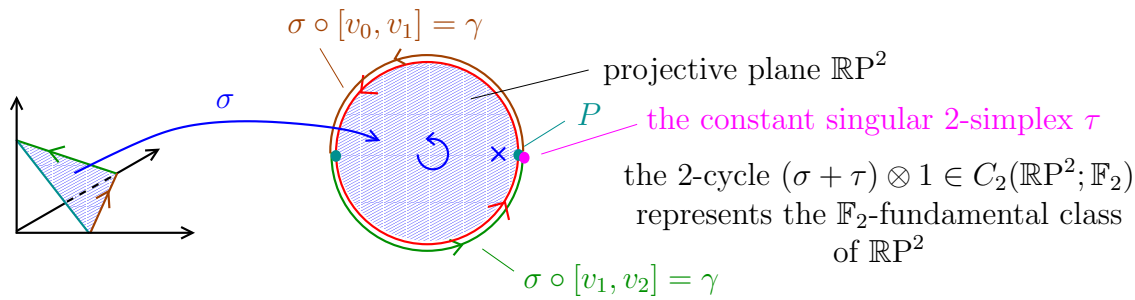

FIGURE 738.

Remark. In the last three examples we saw for the closed 2-dimensional manifolds $F = S^1\times S^1$, $F=\Sigma$, $F=\mathbb{R}\mathrm{P}^2$ and for $R=\mathbb{Z}$ respectively $R=\mathbb{F}_2$ that the map

$$-\cap[F]_R\colon H^1(F;R) \;\to\; H_1(F;R)$$

is an isomorphism. In the next chapter we will see that it is not a coincidence but that this observation can be generalized to all closed manifolds.

59.2. **The relative cap product and more properties of the cap product.** After considering the various examples of the cap product we continue with developing the theory.

Similar to the case of the cup product, we intend to extend the notion of cap product to relative homology and cohomology groups. As in the case of the cup product it requires some delicate footwork to get to the right notion of a relative cap product. We start out with the following rather technical definition.

Definition. Let (X,A,B) be a triad of topological spaces and let R be a commutative ring. We write

$$C_n(X,\{A,B\};R) \;:=\; \frac{C_n(X)\otimes R}{C_n^{\{A,B\}}(A\cup B)\otimes R}.$$

The boundary map on $C_*(X;R)$ descends to a boundary map on $C_*(X,\{A,B\};R)$ which we can thus view as a chain complex. We denote the corresponding homology groups by $H_*(X,\{A,B\};R)$.

This technical definition allows us to define a first version of a relative cap product.

Lemma 59.5. *Let (X, A, B) be a triad of topological spaces, let $k \leq l$ and let R be a commutative ring. Then the map*

$$\begin{array}{rcl} \cap\colon C^k(X, A; R) \times C_l(X, \{A, B\}; R) & \to & C_{l-k}(X, B; R) \\ (\varphi, [\sigma\colon \Delta^l \to X]) & \mapsto & \big[\underbrace{\varphi(\sigma \circ [v_0, \ldots, v_k])}_{\in R} \cdot \underbrace{\sigma \circ [v_k, \ldots, v_l]}_{\text{map } \Delta^{l-k} \to X}\big] \end{array}$$

is well-defined and it descends to a map

$$\cap\colon H^k(X, A; R) \times H_l(X, \{A, B\}; R) \;\to\; H_{l-k}(X, B; R)$$

that is R-bilinear.

Proof. We first show that the cap product on (co-) chains is well-defined. By definition of

$$C_n(X, \{A, B\}; R) \;:=\; \frac{C_n(X) \otimes R}{C_n^{\{A,B\}}(A \cup B) \otimes R} \;=\; \frac{C_n(X) \otimes R}{C_n(A) \otimes R + C_n(B) \otimes R}$$

we have to show that if we are given a singular l-simplex $\sigma\colon \Delta^l \to X$ such that

(1) the image of σ lies in A, or
(2) the image of σ lies in B,

then the product $\varphi(\sigma \circ [v_0, \ldots, v_k]) \cdot \sigma \circ [v_0, \ldots, v_k]$ is zero in $C_{l-k}(X, B; R)$. But this is indeed the case:

(1) first, if the image of σ lies in A, then it follows immediately from the hypothesis that φ lies in $C^k(X, A; R)$ that $\varphi(\sigma \circ [v_0, \ldots, v_k]) = 0$, and
(2) if the image of σ lies in B, then the image of $\sigma \circ [v_0, \ldots, v_k]$ also lies in B. Hence the term is zero in $C_{l-k}(X, B; R)$.

This concludes the proof of the first part of the lemma.

The argument that the map on (co-) chain complexes descends to a map on the level of homology and cohomology groups is the same as in the proof of Lemma 59.2. It is obvious that the map $\cap$ is R-bilinear. □

Evidently we are not very interested in the group $H_n(X, \{A, B\}; R)$. The following lemma allows us to replace this group by the much more agreeable group $H_n(X, A \cup B; R)$, at least for reasonable triads.

Lemma 59.6. *If (X, A, B) is an excisive triad of topological spaces, then given any commutative ring R the obvious map*

$$C_*(X, \{A, B\}; R) \;\to\; C_*(X, A \cup B; R)$$

induces for every $n \in \mathbb{N}_0$ an isomorphism

$$H_n(X, \{A, B\}; R) \;\xrightarrow{\cong}\; H_n(X, A \cup B; R).$$

Proof. In the proof of Lemma 58.1 we already showed that the map

$$C_*(X, \{A, B\}; \mathbb{Z}) \;\to\; C_*(X, A \cup B; \mathbb{Z})$$

on chain complexes is a chain homotopy equivalence. By tensoring all maps and chain homotopies with R we see that the map

$$C_*(X, \{A, B\}; R) \;\to\; C_*(X, A \cup B; R)$$

is also a chain homotopy equivalence. The second statement is then an immediate consequence of Corollary 30.3. □

Lemma 59.6 leads to the following definition.

Definition. Let (X, A, B) be an excisive triad of topological spaces, let $k \le l$ and let R again be a commutative ring. We refer to the map

$$\begin{array}{ccccc} H^k(X,A;R) \times H_l(X, A\cup B; R) & \overset{\cong}{\leftarrow} & H^k(X,A;R) \times H_l(X,\{A,B\};R) & \xrightarrow{\cap} & H_{l-k}(X,B;R) \\ & & \uparrow & & \uparrow \\ & & \text{isomorphism given by Lemma 59.6} & & \text{map from Lemma 59.5} \end{array}$$

as the *cap product* (sometimes we refer to it as the *relative cap product*) that we also denote by "$\cap$". For $k > l$ we define the cap product to be the zero map.

Remark. In many examples, e.g. if $A = \varnothing$, or $B = \varnothing$ or $A = B$, then the slightly mysterious first map in the definition of the cap product is just the identity. In particular, for any subset A of X we obtain cap products

$$H^k(X;R) \;\times\; H_l(X,A;R) \;\xrightarrow{\cap}\; H_{l-k}(X,A;R)$$

and

$$H^k(X,A;R) \;\times\; H_l(X,A;R) \;\xrightarrow{\cap}\; H_{l-k}(X;R)$$

and both of them are induced, on the (co-) chain level, by the formula

$$(\varphi, \sigma\colon \Delta^l \to X) \quad\mapsto\quad \varphi(\sigma\circ[v_0,\dots,v_k]) \cdot \sigma\circ[v_k,\dots,v_l].$$

This observation also shows that we can easily generalize Lemma 59.4 to the relative case in the obvious way. For example, if X is path-connected, and if we make the usual identification $H_0(X;\mathbb{Z}) = \mathbb{Z}$ given by the augmentation map, see Proposition 29.5, then for any $\varphi \in H^k(X,A;\mathbb{Z})$ and $\sigma \in H_k(X,A;\mathbb{Z})$ we have

$$\varphi \cap \sigma \;=\; \langle \varphi, \sigma \rangle \;\in\; \mathbb{Z}.$$

For the record we point out that it follows from this observation and Lemma 51.15 that if M is a compact oriented path-connected n-dimensional topological manifold, then for any point $P \in M$ we have

$$[M]^* \cap [M] \;=\; [P]$$

and $[M]^*$ is the only element in $H^n(M, \partial M; \mathbb{Z}) \cong \mathbb{Z}$ that has that property.

Example. Let $X = S^1 \times [0,1]$ be the annulus. In Figure 739 we show two singular 2-simplices σ_1, σ_2. It follows easily from Proposition 46.8 that $-\sigma_1 + \sigma_2$ represents the fundamental

class $[X] \in H_2(X, \partial X; \mathbb{Z})$ of the annulus X with the usual orientation. We denote by $p\colon X \to [0,1]$ the projection map. As on page 1171 we consider the function

$$\begin{array}{rcl} f\colon [0,1] & \to & \mathbb{Z} \\ x & \mapsto & \begin{cases} 0, & \text{if } x \in [0, \frac{1}{2}) \\ 1, & \text{otherwise} \end{cases} \end{array}$$

which we use to define the singular 1-cochain

$$\begin{array}{rcl} \rho\colon C_1([0,1]) & \to & \mathbb{Z} \\ (\sigma\colon \Delta^1 \to [0,1]) & \mapsto & f(\sigma(0,1)) - f(\sigma(1,0)). \end{array}$$

It follows from the discussion on page 1171 that $p^*(\rho) \in C^1(X, \partial X; \mathbb{Z})$ is a cochain, thus it represents an element in $H^1(X, \partial X; \mathbb{Z})$. We calculate that

$$\begin{array}{rclcl} [p^*(\rho)] \cap \sigma_1 & = & \underbrace{p^*(\sigma_1 \circ [v_0, v_1])}_{=1} \cdot \underbrace{\sigma_1 \circ [v_1, v_2]}_{=[S^1 \times 1]} & = & [S^1 \times 1] \\ [p^*(\rho)] \cap \sigma_2 & = & \underbrace{p^*(\sigma_2 \circ [v_0, v_1])}_{=0} \cdot \sigma_2 \circ [v_1, v_2] & = & 0. \end{array}$$

Adding up we see that

$$[p^*(\rho)] \cap [X] \;=\; [p^*(\rho) \cap (-\sigma_1 + \sigma_2)] \;=\; -[S^1 \times 1].$$

Since the inclusion $S^1 \times 1 \to X$ is a homotopy equivalence we see that $H_1(X; \mathbb{Z}) \cong \mathbb{Z}$ and that $[S^1 \times 1]$ is a generator. A straightforward argument, e.g. using the long exact sequence of the pair $(X, \partial X)$, shows that $H^1(X, \partial X; \mathbb{Z}) \cong \mathbb{Z}$. The above calculation thus shows that the map

$$\begin{array}{rcl} H^1(X, \partial X; \mathbb{Z}) & \to & H_1(X; \mathbb{Z}) \\ \varphi & \mapsto & \varphi \cap [X] \end{array}$$

is an epimorphism. Since both groups are isomorphic to $\mathbb{Z}$ we see that the map is in fact an isomorphism and as a bonus we obtain that $[\rho] \in H^1(X, \partial X; \mathbb{Z})$ is a generator. In Exercise 59.3 we will show that the map

$$\begin{array}{rcl} H^1(X; \mathbb{Z}) & \to & H_1(X, \partial X; \mathbb{Z}) \\ \varphi & \mapsto & \varphi \cap [X] \end{array}$$

is also an isomorphism.

The following lemma relates the cup product to the cap product.

Lemma 59.7. *Let X be a topological space and let R be a commutative ring.*

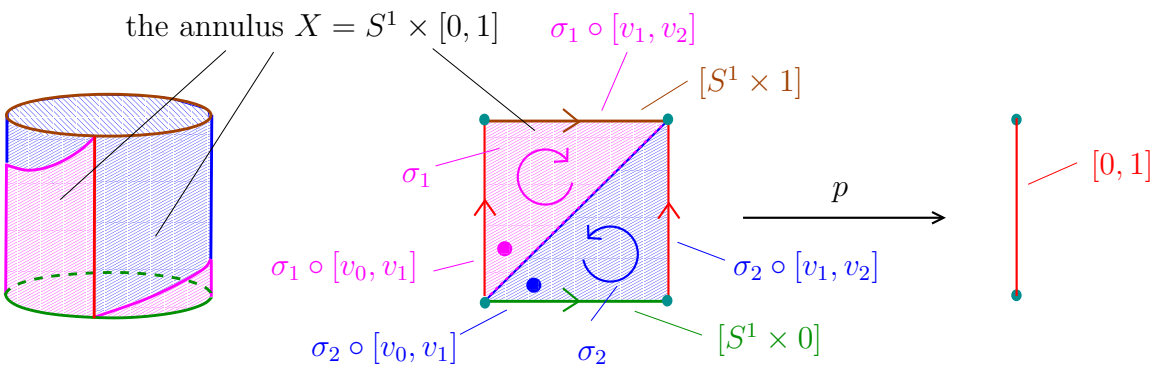

FIGURE 739.

(1) *Let* $\varphi \in C^k(X;R)$, $\psi \in C^l(X;R)$ *and let* $\sigma \in C_n(X;R)$. *Then*[1023]
$$\varphi \cap (\psi \cap \sigma) \;=\; (\psi \cup \varphi) \cap \sigma \;\in\; C_{n-k-l}(X;R).$$
(2) *If* $A \subset X$ *is a subset and* $C, D \in \{\varnothing, A\}$ *we have for any* $\varphi \in H^k(X,C;R)$, $\psi \in H^l(X,D;R)$ *and* $\sigma \in H_n(X, C \cup D;R)$ *that*
$$\varphi \cap (\psi \cap \sigma) \;=\; (\psi \cup \varphi) \cap \sigma \;\in\; H_{n-k-l}(X;R).$$

Proof. The case $k + l > n$ is trivial. So suppose that $k + l \leq n$.

(1) So let $\varphi \in C^k(X;R)$, $\psi \in C^l(X;R)$. It suffices to consider the case that $\sigma\colon \Delta^n \to X$ is a singular n-simplex. We have
$$\begin{aligned}
\varphi \cap (\psi \cap \sigma) &= \varphi \cap \big(\psi(\sigma \circ [v_0, \dots, v_l]) \cdot \sigma \circ [v_l, \dots, v_n]\big) \\
&= \psi(\sigma \circ [v_0, \dots, v_l]) \cdot \varphi \cap (\sigma \circ [v_l, \dots, v_n]) \\
&= \psi(\sigma \circ [v_0, \dots, v_l]) \cdot \varphi(\sigma \circ [v_l, \dots, v_{l+k}]) \cdot \sigma \circ [v_{l+k}, \dots, v_n] \\
&= (\psi \cup \varphi)(\sigma \circ [v_0, \dots, v_{l+k}]) \cdot \sigma \circ [v_{l+k}, \dots, v_n] \\
&= (\psi \cup \varphi) \cap \sigma.
\end{aligned}$$
(2) The statement regarding the (co-) homology classes follows almost immediately from the above result on (co-) chains obtained in (1). □

Now suppose we are given a map of excisive triads of topological spaces. We get induced maps on homology and cohomology and the following lemma tells us the relationship of these induced maps and the cap product.

Lemma 59.8. *Let R be a commutative ring.*

[1023]Note that on the right-hand side it says $(\psi \cup \varphi) \cap \sigma$ instead of $(\varphi \cup \psi) \cap \sigma$. In fact if one picks a different sign convention for the cap product this sign goes away. For example with the sign conventions used by Bredon, see [Bre, Chapter 5], the equation becomes
$$\varphi \cap (\psi \cap \sigma) \;=\; (\varphi \cup \psi) \cap \sigma$$
which looks much more appealing. Once we consider (co-) homology classes we obtain from Proposition 57.8 that the difference between these two expressions $(\psi \cup \varphi) \cap \sigma$ and $(\varphi \cup \psi) \cap \sigma$ is just a factor of $(-1)^{kl}$.

(1) *If* $f\colon (X,A,B) \to (\widetilde{X},\widetilde{A},\widetilde{B})$ *is a map between two excisive triads, then for any* $k,l \in \mathbb{N}_0$ *the following diagram commutes*[1024]

$$\begin{array}{ccccc} H^k(X,A;R) & \times & H_l(X,A\cup B;R) & \xrightarrow{\cap} & H_{l-k}(X,B;R) \\ {\scriptstyle f^*}\uparrow & & \downarrow{\scriptstyle f_*} & & \downarrow{\scriptstyle f_*} \\ H^k(\widetilde{X},\widetilde{A};R) & \times & H_l(\widetilde{X},\widetilde{A}\cup\widetilde{B};R) & \xrightarrow{\cap} & H_{l-k}(\widetilde{X},\widetilde{B};R), \end{array}$$

i.e. for any $\varphi \in H^k(\widetilde{X},\widetilde{A};R)$ *and any* $\sigma \in H_l(X,A\cup B;R)$ *we have*

$$\varphi \cap f_*(\sigma) \;=\; f_*(\underbrace{f^*(\varphi)\cap\sigma}_{\in H_{l-k}(X,B;R)}) \;\in\; H_{l-k}(\widetilde{X},\widetilde{B};R).$$

(2) *Let* X *and* $\widetilde{X}$ *be path-connected topological spaces and let* $B \subset X$ *and* $\widetilde{B} \subset \widetilde{X}$ *be subsets. If* $f\colon (X,B) \to (\widetilde{X},\widetilde{B})$ *is a map, then for any* $\varphi \in H^k(\widetilde{X},\widetilde{B};R)$ *and any* $\sigma \in H_k(X,B;R)$ *we have*

$$\varphi \cap f_*(\sigma) \;=\; f^*(\varphi)\cap\sigma \;\in\; \underbrace{H_0(X;R) = R = H_0(\widetilde{X};R)}_{\substack{\text{identification from}\\ \text{Proposition 29.5}}}.$$

Remark. By Lemma 59.4 (1) we can view the above as a generalization of Lemma 50.6.

Proof. The first statement follows immediately from the definitions. We leave the details to the skeptical reader. The second statement is an immediate consequence of the first statement. □

The next lemma says that cup and cap products behave in the obvious way with respect to the path-components. The statements in the lemma follow easily from the definitions. Therefore we leave the proof of the lemma to the reader.

Lemma 59.9. $(*)$ *Let* X *be a topological space and let* R *be a commutative ring. We denote by* $\{X_j\}_{j\in J}$ *the path-components of* X*. By Lemmas 29.13 and 48.14 the inclusion maps* $\iota_j\colon X_j \to X$*,* $j \in J$*, induce for any* $n \in \mathbb{N}_0$ *isomorphisms*

$$\Phi := \bigoplus_{j\in J}(\iota_j)_*\colon \bigoplus_{j\in J} H_n(X_j;G) \;\xrightarrow{\cong}\; H_n(X;G)$$

and

$$\Psi := \prod_{j\in J}\iota_j^*\colon H^n(X;G) \;\xrightarrow{\cong}\; \prod_{j\in J} H^n(X_j;G).$$

Then the following two statements hold:

(1) *For any* $i \neq j$ *and any* $\alpha \in H^m(X_i;R)$ *and* $\beta \in H^n(X_j;R)$ *we have*

$$\Psi^{-1}(\alpha) \,\cup\, \Psi^{-1}(\beta) \;=\; 0.$$

[1024]Here "the diagram commutes" is understood in the sense of the convention from page 1360.

(2) *For any $i \neq j$ and any $\alpha \in H^m(X_i; R)$ and $\beta \in H_n(X_j; R)$ we have*

$$\Psi^{-1}(\alpha) \cap \Phi(\beta) = 0.$$

The same type of statements hold for cup and cap products on relative (co-) homology groups.

In the next lemma of the chapter we relate the relative cap product to (co-) boundary maps on (co-) homology. More precisely, we have the following lemma which is similar in spirit to Lemma 58.5.

Lemma 59.10. *Let R be a commutative ring.*

(1) *Let (X, B, A) be a triple of topological spaces. For any $n, k \in \mathbb{N}_0$ the following diagram commutes:*

$$\begin{tikzcd}
H^k(B, A; R) \times H_{n-1}(B, A; R) \arrow[r, "\cap"] \arrow[d, "\delta"'] & H_{n-k-1}(B; R) \arrow[d, "i_*"] \\
H^{k+1}(X, B; R) \times H_n(X, B; R) \arrow[r, "\cap"] & H_{n-k-1}(X; R). \arrow[u, "\partial"']
\end{tikzcd}$$

Here $i\colon B \to X$ denotes the inclusion map and δ and ∂ denote the connecting homomorphisms in the long exact sequences in (co-) homology corresponding to the triple (X, B, A).

(2) *Let (X, A, B) be an excisive triad and let $n \in \mathbb{N}_0$. Note that by Lemma 50.13 the map $j_*\colon H_{n-1}(B, A \cap B; R) \to H_{n-1}(A \cup B, A; R)$ is an isomorphism. For any $k \in \mathbb{N}_0$ the following diagram commutes up to the sign $(-1)^{k+1}$:*

$$\begin{tikzcd}
H^k(X, A; R) \times H_n(X, A \cup B; R) \arrow[r, "\cap"] \arrow[d, "i^*"'] & H_{n-k}(X, B; R) \arrow[dd, "\partial"] \\
H^k(A \cup B, A; R) \times H_{n-1}(A \cup B, A; R) \arrow[d, "j^*"', "\cong"] & \\
H^k(B, A \cap B; R) \times H_{n-1}(B, A \cap B; R) \arrow[r, "\cap"] & H_{n-k-1}(B; R).
\end{tikzcd}$$

Here $i\colon (A \cup B, A) \to (X, A)$ and $j\colon (B, A \cap B) \to (A \cup B, A)$ denote the inclusion maps and ∂ denotes the connecting homomorphisms in the long exact sequences in homology corresponding to the triple $(X, A \cup B, A)$ respectively the pair (X, B).

Proof $(*)$.

(1) We pick $\psi \in H^k(B, A; R)$ and $\tau \in H_n(B, A; R)$. We make the following observations:
   (a) We can find $\sigma \in C_n(B; R)$ such that the image of σ in $C_n(B, A; R)$ is a cycle that represents τ.
   (b) We can pick a singular cochain $\varphi \in C^k(B; R) = \mathrm{Hom}(C_k(B), R)$ that vanishes on $C_k(A)$ and such that the corresponding element in $C^k(B, A; R)$ represents

ψ. We denote by $\widetilde{\varphi}\colon C_k(X) \to R$ the extension of φ that is defined to be zero on all singular k-simplices that do not lie in B.

We have the following equalities:

$$\delta\psi \cap \tau \underset{\substack{\uparrow \\ \text{see Lemma 48.15 and the} \\ \text{discussion on page 1174}}}{=} \big[\delta\widetilde{\varphi}\big] \cap [\sigma] \overset{\substack{\text{by the discussion of relative cap products on page 1378} \\ \downarrow}}{=} \big[\delta\widetilde{\varphi} \cap \sigma\big] \underset{\substack{\uparrow \\ \text{by Lemma 59.1 the classes } \delta\varphi \cap \sigma \\ \text{and } \varphi \cap \partial\sigma \text{ are homologous}}}{=} [\widetilde{\varphi} \cap \partial\sigma] = [\varphi \cap \partial\sigma] \overset{\downarrow}{=} [\varphi] \cap [\partial\sigma] \underset{\substack{\uparrow \\ \text{Proposition 31.13}}}{=} \psi \cap \partial\tau.$$

This equality implies that the diagram commutes.[1025]

(2) We pick $\psi \in H^k(X, A; R)$ and $\tau \in H_n(X, A \cup B; R)$. We make the following observations:

(a) It follows from our hypothesis that the triad (X, A, B) is excisive together with Lemma 59.6 that we can find $\sigma \in C_n(X; R)$ such that $\partial\sigma = \alpha + \beta$ with $\alpha \in C_{n-1}(A; R)$ and $\beta \in C_{n-1}(B; R)$ and such that the image of σ in $C_n(X, A \cup B; R)$ is a cycle that represents τ.

(b) As on page 1356 we make the identification

$$C^k(X, A; R) \xrightarrow{=} \text{all homomorphisms } C_k(X) \to R \text{ that vanish on } C_k(A).$$

We can pick a singular cochain $\varphi \in C^k(X; R) = \mathrm{Hom}(C_k(X), R)$ that vanishes on $C_k(A)$ and such that the corresponding element in $C^k(X, A; R)$ is a cocycle that represents ψ. Note that $\delta\varphi = 0$.

We have the following equalities:

$$\begin{aligned}
\partial(\psi \cap \tau) &\overset{\substack{\text{choice of } \sigma \text{ and definition} \\ \text{of relative cap product} \\ \downarrow}}{=} \partial([\varphi \cap \sigma]) \overset{\substack{\text{Proposition 31.13} \\ \downarrow}}{=} [\partial(\varphi \cap \sigma)] \overset{\substack{\text{Lemma 59.1} \\ \downarrow}}{=} (-1)^k \cdot [-\delta\varphi \cap \sigma + \varphi \cap \partial\sigma] \\
&\underset{\substack{\uparrow \\ \text{since } \delta\varphi = 0 \text{ and } \partial\sigma = \alpha + \beta}}{=} (-1)^k \cdot ([\varphi \cap \alpha + \varphi \cap \beta]) \underset{\substack{\uparrow \\ \text{since } \varphi \text{ vanishes on } C_k(A) \text{ and} \\ \text{since } \alpha \circ [v_0, \ldots, v_k] \in C_k(A)}}{=} (-1)^k \cdot ([\varphi \cap \beta]) \\
&\underset{\substack{\uparrow \\ \text{by Proposition 31.13 we have } j_*([\beta]) = \partial[\sigma]}}{=} (-1)^k \cdot ([j^* i^* \varphi] \cap j_*^{-1}(\partial[\sigma])).
\end{aligned}$$

This equality implies that the diagram commutes. □

As we had mentioned before, a frequently used trick in the study of topological manifolds is to replace a topological manifold with non-empty boundary by its double. When doing this trick the following lemma can at times be useful.

[1025] With the various quotient groups, lifts, extensions, inclusions and so on it is admittedly quite tricky to figure out in between where any of the equalities hold.

Lemma 59.11. *Let M be a topological manifold. We denote by $r\colon DM \to M$ the folding map from page 1086 and given $l \in \mathbb{N}_0$ we denote by $D\colon H_l(M,\partial M;\mathbb{Z}) \to H_l(DM;\mathbb{Z})$ the doubling homomorphism that we introduced in Lemma 45.13. Then for any $\phi \in H^k(M;\mathbb{Z})$ and any $\sigma \in H_l(M,\partial M;\mathbb{Z})$ we have*

$$r^*\phi \cap D(\sigma) \;=\; D(\phi \cap \sigma) \;\in\; H_{l-k}(DM;\mathbb{Z}).$$

Proof. We will show that the desired equality actually holds already on the (co-) chain level. So let $\phi \in C^k(M;\mathbb{Z})$ and let $\sigma\colon \Delta^l \to M$ be a singular l-simplex. If $k > l$, then both sides of the lemma are trivially zero. Hence we can assume that $k \le l$. For $i = 1, 2$ we denote by $j_i\colon M \to M \times \{i\} \subset DM$ the obvious map. Then

$$\begin{aligned}
r^*\phi \cap D(\sigma) \;&\overset{\text{by definition of } D(\sigma)}{=}\; r^*\phi \cap (j_1 \circ \sigma - j_2 \circ \sigma) \;\overset{\text{since } \cap \text{ is bilinear}}{=}\; r^*\phi \cap j_1 \circ \sigma - r^*\phi \cap j_2 \circ \sigma \\
&= \phi(\underbrace{r \circ j_1 \circ \sigma}_{=\sigma} \circ [v_0, \dots, v_k]) \cdot j_1 \circ \sigma \circ [v_k, \dots, v_l] - \phi(\underbrace{r \circ j_2 \circ \sigma}_{=\sigma} \circ [v_0, \dots, v_k]) \cdot j_2 \circ \sigma \circ [v_k, \dots, v_l] \\
&\uparrow \\
&\text{definition of cap product and definition of } r^*\phi \\
&= \phi(\sigma \circ [v_0, \dots, v_k]) \cdot j_1 \circ (\sigma \circ [v_k, \dots, v_l]) - \phi(\sigma \circ [v_0, \dots, v_k]) \cdot j_2 \circ (\sigma \circ [v_k, \dots, v_l]) \\
&= j_{1*}(\phi \cap \sigma) - j_{2*}(\phi \cap \sigma) \;=\; D(\phi \cap \sigma). \\
&\uparrow \\
&\text{definition of } j_{1*},\, j_{2*} \text{ and the cap product}
\end{aligned}$$

□

Exercises for Chapter 59.

Exercise 59.1. Let $X = S^1 \vee S^2$. We denote by $p\colon X \to S^1$ and $q\colon X \to S^2$ the obvious projection maps and we denote by $i\colon S^1 \to X$ and $j\colon S^2 \to X$ the obvious inclusion maps. Determine $p^*([\theta_{\mathbb{Z}}]) \cap j_*([S^2])$.

Exercise 59.2. We denote by Σ the surface of genus two. Furthermore we denote by $p_1, p_2\colon \Sigma \to T = S^1 \times S^1$ the two projection maps and we denote by $p, q\colon S^1 \times S^1 \to S^1$ the projection onto the first respectively the second factor. As usual we write $\alpha = p^*(\theta)$ and $\beta = q^*(\theta)$. We saw that $[p_1^*(\alpha)], [p_1^*(\beta)], [p_2^*(\alpha)], [p_2^*(\beta)]$ form a basis for $H^1(\Sigma;\mathbb{Z})$. Furthermore we denote by $x_1, y_1, x_2, y_2 \in H_1(\Sigma;\mathbb{Z})$ the standard basis. For each of the four basis elements of $H^1(\Sigma;\mathbb{Z})$ determine the cap product with $[\Sigma]$ in terms of the basis for $H_1(\Sigma;\mathbb{Z})$.
Remark: This exercise is not as bad as it might sound initially.

Exercise 59.3. We consider the annulus $X = S^1 \times [0,1]$. Determine the following map:

$$\begin{array}{rcl} H^1(X;\mathbb{Z}) & \to & H_1(X,\partial X;\mathbb{Z}) \\ \varphi & \mapsto & \varphi \cap [X] \end{array}$$

More precisely, give a basis for $H^1(X;\mathbb{Z})$ and $H_1(X,\partial X;\mathbb{Z})$ and express the map $- \cap [X]$ in terms of that basis.

60. The Product Theorem and the Künneth Theorem for cohomology

In this chapter we will deal with the cup and cap product of product topological spaces. In particular at the end of the chapter we will have determined the cup product of the product $S^m \times S^n$ of two spheres and of the n-dimensional torus $(S^1)^n$. Furthermore we will have determined the Lusternik-Schnirelmann category of the n-dimensional torus.

60.1. **The Product Theorem.** The following theorem relates the cross product to the cap product and the cup product.

Theorem 60.1. (Product Theorem) *Let (X, A) and (Y, B) be two pairs of topological spaces such that the triad $(X\times Y, A\times Y, X\times B)$ is excisive. We denote by $p\colon X\times Y \to X$ and $q\colon X \times Y \to Y$ the obvious projection maps. Furthermore let*[1026] *$A_1, A_2 \in \{\varnothing, A\}$ and let $B_1, B_2 \in \{\varnothing, B\}$. Then for any $\alpha \in H^k(X, A_1; \mathbb{Z})$, $\mu \in H_m(X, A_1\cup A_2; \mathbb{Z})$, $\beta \in H^l(Y, B_1; \mathbb{Z})$ and $\nu \in H_n(Y, B_1 \cup B_2; \mathbb{Z})$ we have the equality*[1027]

$$\big(p^*(\alpha) \ \cup \ q^*(\beta)\big) \ \cap (\mu \times \nu) \ = \ (-1)^{\deg(\alpha)\cdot\deg(\beta)+\deg(\beta)\cdot\deg(\mu)} \cdot (\alpha \cap \mu) \times (\beta \cap \nu)$$

in $H_{m+n-k-l}(X \times Y, X \times B_2 \cup A_2 \times Y; \mathbb{Z})$.

Remark. Even though the equality in the Product Theorem 60.1 is easy to write down, it is much harder to figure out in which (co-) homology groups the various objects actually live. In fact the equality is understood as follows:

$$\underbrace{\Big(\underbrace{p^*(\alpha)}_{\in H^k(X\times Y, A_1\times Y)} \ \cup \ \underbrace{q^*(\beta)}_{\in H^l(X\times Y, X\times B_1)}\Big)}_{\in H^{k+l}(X\times Y, A_1\times Y\cup X\times B_2)} \cap \overbrace{(\mu \times \nu)}^{\substack{\text{lies in } H_{m+n}(X\times Y, (A_1\cup A_2)\times Y \cup X\times(B_1\cup B_2))\\ \downarrow}} = (-1)^{\deg(\alpha)\cdot\deg(\beta)+\deg(\beta)\cdot\deg(\mu)} \cdot \underbrace{\underbrace{(\alpha \cap \mu)}_{\in H_{m-k}(X, A_2)} \times \underbrace{(\beta \cap \nu)}_{\in H_{n-l}(Y, B_2)}}_{\in H_{m+n-k-l}(X\times Y, X\times B_2\cup A_2\times Y)}.$$

In this formula we have to ensure that all products are in fact defined. This follows easily from Proposition 50.12, our hypothesis that $A_1, A_2 \in \{\varnothing, A\}$ and $B_1, B_2 \in \{\varnothing, B\}$ and our hypothesis that the triad $(X \times Y, A \times Y, X \times B)$ is excisive.

Remark.

(1) The condition in the Product Theorem 60.1 that the triad $(X \times Y, A \times Y, X \times B)$ needs to be excisive is arguably a little awkward. By Proposition 50.12 this condition is satisfied if we are in one of the following situations:
   (a) $A = \varnothing$ or $B = \varnothing$,
   (b) (X, A) and (Y, B) are pairs of CW-complexes,

[1026] By $A_1, A_2 \in \{\varnothing, A\}$ we mean that $A_1 = \varnothing$ or $A_1 = A$ and that $A_2 = \varnothing$ or $A_2 = A$.

[1027] Here, and throughout this section, we denote by p also the map of pairs $(X\times Y, A\times Y) \to (X, A)$ given by projection onto the first factor and similarly we denote by q the map of pairs $(X \times Y, X \times B) \to (Y, B)$ given by projection onto the second factor.

(c) $(X, A) = (X, \partial X)$ and $(Y, B) = (Y, \partial Y)$ where X and Y are topological manifolds,[1028]
(d) A and B are open subsets of X respectively Y.

(2) In fact a more general statement of the Product Theorem 60.1 holds if we deal with excisive triads (X, A_1, A_2) and (Y, B_1, B_2) and (co-) homology classes $\alpha \in H^k(X, A_1; \mathbb{Z})$, $\mu \in H_m(X, A_2; \mathbb{Z})$, $\beta \in H^l(Y, B_1; \mathbb{Z})$ and $\nu \in H_n(Y, B_2; \mathbb{Z})$. But some care needs to be taken to see which other triads need to be excisive to ensure that all the cap and cup products are defined. We will not attempt to formulate this more general statement and we will not make use of it. (See also [Dol, p. 240 and p. 244] for a few more details.)

(3) The cross product is defined the same way in all of the usual text books in algebraic topology. But we saw on pages 1334 and 1373 that in the literature different sign conventions are used for the cup product and the cap product. These also lead to different formulations of the Product Theorem 60.1. More precisely, given topological spaces X and Y and $\alpha \in H^k(X; \mathbb{Z})$, $\mu \in H_m(X; \mathbb{Z})$, $\beta \in H^l(Y; \mathbb{Z})$ and $\nu \in H_n(Y; \mathbb{Z})$ the following equations can be found in the literature:

$$\begin{array}{rrcl}
\text{[Bre, p. 337]} & (p^*(\alpha) \cup q^*(\beta)) \cap (\mu \times \nu) & = & (-1)^{\deg(\beta)\cdot\deg(\mu)} \cdot (\alpha \cap \mu) \times (\beta \cap \nu) \\
\text{[Dol, p. 240]} & (p^*(\alpha) \cup q^*(\beta)) \cap (\mu \times \nu) & = & (-1)^{\deg(\beta)\cdot\deg(\mu)} \cdot (\alpha \cap \mu) \times (\beta \cap \nu) \\
\text{[Sp, p. 255]} & (p^*(\alpha) \cup q^*(\beta)) \cap (\mu \times \nu) & = & (-1)^{\deg(\alpha)\cdot(\deg(\nu)-\deg(\beta))} \cdot (\alpha \cap \mu) \times (\beta \cap \nu).
\end{array}$$

With the aforementioned sign conventions the formulas of Dold and Spanier are consistent with our formula, whereas the formula of Bredon differs from the formula of Dold and Spanier by the term $(-1)^{\deg(\alpha)\cdot\deg(\nu)+\deg(\beta)\cdot\deg(\mu)}$.[1029]

(4) The conclusion of the Product Theorem 60.1 also holds, with verbatim the same proof, if throughout we replace $\mathbb{Z}$-coefficients by $\mathbb{F}_2$-coefficients.

The proof of the Product Theorem 60.1 is somewhat lengthy and technical. Therefore we first discuss some consequences of Theorem 60.1 which will then hopefully convince us that it is worth the effort to prove Theorem 60.1.

The following is one of the key calculations of the cup product and the cap product. As we will later see, many other calculations can be reduced to this calculation.

Proposition 60.2. *Let X be a compact oriented connected m-dimensional topological manifold and let Y be a compact oriented connected n-dimensional topological manifold. We denote by $p\colon X \times Y \to X$ and $q\colon X \times Y \to Y$ the obvious projection maps. Then the following two statements hold:*

[1028] Let X be an m-dimensional topological manifold and let Y be an n-dimensional manifold. It follows from Propositions 56.9 and 32.1 that $W := \partial(X \times Y) = \partial X \times Y \cup X \times \partial Y$ is an $(m+n-1)$-dimensional topological manifold. It is straightforward to verify that $\partial X \times Y$ and $X \times \partial Y$ are submanifolds of W such that

$$(\partial X \times Y) \cap (X \times \partial Y) \;=\; \partial X \times \partial Y = \partial(\partial X \times Y) \;=\; \partial(X \times \partial Y).$$

Therefore it follows from Proposition 50.12 (5) that the triad $(X \times Y, \partial X \times Y, X \times \partial Y)$ is excisive.

[1029] Mathematicians with a long experience of teaching cohomology groups sidestep all issues with signs by working with $\mathbb{F}_2$-coefficients, see [Hau].

(1)
$$\underbrace{p^*([X]^*)}_{\in H^m(X\times Y,\partial X\times Y)} \quad \cup \quad \underbrace{q^*([Y]^*)}_{\in H^n(X\times Y,X\times\partial Y)} \quad = \quad \underbrace{[X\times Y]^*}_{\in H^{m+n}(X\times Y,\partial(X\times Y))}.$$

(2) *If $P \in X$ and $Q \in Y$ are points, then*[1030]
$$\overbrace{p^*([X]^*)}^{\in H^m(X\times Y,\partial X\times Y)} \quad \cap \quad \overbrace{[X\times Y]}^{\in H_{m+n}(X\times Y,\partial(X\times Y))} \quad = \quad \overbrace{[\{P\}\times Y]}^{\in H_n(X\times Y,X\times\partial Y)}$$
and similarly
$$\underbrace{q^*([Y]^*)}_{\in H^n(X\times Y,X\times\partial Y)} \quad \cap \quad \underbrace{[X\times Y]}_{\in H_{m+n}(X\times Y,\partial(X\times Y))} \quad = \quad (-1)^{mn}\cdot \underbrace{[X\times\{Q\}]}_{\in H_m(X\times Y,\partial X\times Y)}.$$

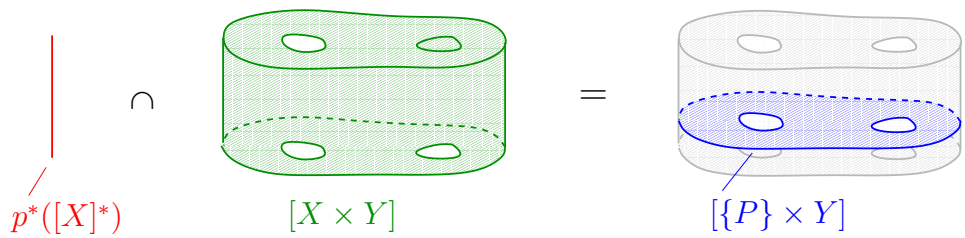

FIGURE 740.

Remark. As we pointed out above, the conclusion of the Product Theorem 60.1 also holds if we work with $\mathbb{F}_2$-coefficients. It follows easily that there is also an $\mathbb{F}_2$-coefficient analogue of Proposition 60.2.

Example. If we apply Proposition 60.2 (2) to $X = S^1$ and $Y = S^1$ we see that
$$p^*([S^1]^*)\cap[S^1\times S^1] = [1\times S^1] \quad \text{and} \quad q^*([S^1]^*)\cap[S^1\times S^1] = -[S^1\times 1].$$
This matches our down-to-earth calculation from page 1375.

Proof. Let X be a compact oriented connected m-dimensional topological manifold and let Y be a compact oriented connected n-dimensional topological manifold. Furthermore let P be a point in X and let Q be a point in Y. We start out with the following two observations:

(a) For any compact oriented connected topological k-dimensional manifold M and any point $R \in M$ we obtain from the discussion on page 1378 that $[M]^*\cap[M] = [R]$ and that $[M]^*$ is the unique element in $H^k(M,\partial M;\mathbb{Z}) \cong \mathbb{Z}$ with $[M]^*\cap[M] = [R]$ in $H_0(M;\mathbb{Z}) = \mathbb{Z}\cdot[R]$.

[1030]Here we use the following suggestive notation: We can view $\{P\}\times Y$ as a submanifold of $X\times Y$. It is canonically homeomorphic to Y, thus can view $\{P\}\times Y$ as a compact oriented topological manifold. We denote by $[\{P\}\times Y]$ its fundamental class, and by a slight abuse of notation we also denote by $[\{P\}\times Y]$ the image of the fundamental class under the inclusion $\{P\}\times Y \to X\times Y$.

(b) By Proposition 56.10 we have $[X \times Y] = [X] \times [Y]$.

Now we turn to the actual proof of the two statements.

(1) We perform the following calculation in $H_0(X \times Y; \mathbb{Z})$:

$$\begin{array}{rcl} & & \text{observation (b)} \\ & & \downarrow \\ (p^*([X]^*) \cup q^*([Y]^*)) \cap ([X \times Y]) & = & (p^*([X]^*) \cup q^*([Y]^*)) \cap ([X] \times [Y]) \\ = (-1)^{mn+mn} \cdot ([X]^* \cap [X]) \times ([Y]^* \cap [Y]) & = & [P] \times [Q] \quad = [(P,Q)]. \\ \uparrow & & \uparrow \qquad\qquad \uparrow \\ \text{by Theorem 60.1 applied} & & \text{observation (a)} \quad \text{see Lemma 56.7 (2)} \\ \text{to } (X, A_1, A_2) = (X, \partial X, \partial X) & & \\ \text{and } (Y, B_1, B_2) = (Y, \partial Y, \partial Y) & & \end{array}$$

This implies, by observation (a), that $p^*([X]^*) \cup q^*([Y]^*) = [X \times Y]^*$.

(2) Let $P \in X$. Then

$$\begin{array}{rcl} p^*([X]^*) \cap ([X \times Y]) & = & (p^*([X]^*) \cup q^*(1_Y)) \cap ([X] \times [Y]) \\ & \uparrow & \\ \text{by Proposition 58.3 (1) we have } q^*(1_Y) = 1_{X \times Y} & \text{and by observation (b) we have } [X \times Y] = [X] \times [Y] & \\ & = & ([X]^* \cap [X]) \times (1_Y \cap [Y]) \quad = [P] \times [Y] \quad = [\{P\} \times Y]. \\ & & \uparrow \qquad\qquad\qquad\qquad \uparrow \qquad\qquad \uparrow \\ & & \text{by Theorem 60.1 applied to } (Y, B_1, B_2) = (Y, \varnothing, \partial Y) \quad \text{by Lemma 59.3} \quad \text{Lemma 56.7 (2)} \\ & & \text{note that here we use that } 1_Y \text{ lies in } H^0(Y; \mathbb{Z}) \quad \text{and observation (a)} \end{array}$$

This proves the first equality of (2). Now let $Q \in Y$. Then, very similar to the above, we have

$$\begin{aligned} q^*([Y]^*) \cap ([X \times Y]) &= (p^*(1_X) \cup q^*([Y]^*)) \cap ([X] \times [Y]) \\ &= (-1)^{mn} \cdot (1_X \cap [X]) \times ([Y]^* \cap [Y]) \\ &= (-1)^{mn} \cdot [X] \times [Q] \;=\; (-1)^{mn} \cdot [X \times \{Q\}]. \end{aligned}$$

□

Using Proposition 60.2 (1) we can now easily compute the cup product of the product $S^m \times S^n$ of two spheres.

Lemma 60.3. *Let $m, n \in \mathbb{N}$. We denote by $p\colon S^m \times S^n \to S^m$ and by $q\colon S^m \times S^n \to S^n$ the two obvious projection maps. Let $1 \in H^0(S^m \times S^n; \mathbb{Z})$ be the neutral element from Proposition 57.7.*

(1) *The cohomology of $S^m \times S^n$ is given as follows:*

$$H^*(S^m \times S^n; \mathbb{Z}) \;=\; \mathbb{Z} \cdot 1 \oplus \mathbb{Z} \cdot p^*([S^m]^*) \oplus \mathbb{Z} \cdot q^*([S^n]^*) \oplus \mathbb{Z} \cdot [S^m \times S^n]^*.$$

(2) *The multiplication table for the cup product is given by*

$\cup$	1	$p^*([S^m]^*)$	$q^*([S^n]^*)$	$[S^m \times S^n]^*$
1	1	$p^*([S^m]^*)$	$q^*([S^n]^*)$	$[S^m \times S^n]^*$
$p^*([S^m]^*)$	$p^*([S^m]^*)$	0	$[S^m \times S^n]^*$	0
$q^*([S^n]^*)$	$q^*([S^n]^*)$	$(-1)^{mn} \cdot [S^m \times S^n]^*$	0	0
$[S^m \times S^n]^*$	$[S^m \times S^n]^*$	0	0	$0.$

Here the table shows the cup product of the term in the first column with the term in the first row (and not the other way round).

Remark.

(1) For $m = n = 1$, i.e. for the torus $S^1 \times S^1$ we had calculated the cup product in Lemma 57.14.
(2) If we use Proposition 60.2 (1) with $\mathbb{F}_2$-coefficients then we can also determine the cup product on $H^*(S^m \times S^n; \mathbb{F}_2)$ and we obtain basically the same result.

Proof.

(1) Using Proposition 31.3, the Künneth Theorem 43.8 for topological spaces and the Universal Coefficient Theorem 51.13 for Cohomology Groups one can easily determine the isomorphism type of $H^*(S^m \times S^n; \mathbb{Z})$. Furthermore, using Lemma 50.7 and the homology classes given by the fundamental classes of S^m, S^n and $S^m \times S^n$ it is straightforward to verify that the given cohomology classes do indeed form a basis for $H^*(S^m \times S^n; \mathbb{Z})$.
(2) By Observation 57.13 it remains to show that the red-colored and the blue-colored entries are correct.
   (a) First we consider the red-colored entries. We have
$$p^*([S^m]^*) \cup p^*([S^m]^*) \underset{\substack{\uparrow \\ \text{Lemma 57.10}}}{=} p^*([S^m]^* \cup [S^m]^*) \underset{\substack{\uparrow \\ \text{since } [S^m]^* \cup [S^m]^* \in H^{2m}(S^m;\mathbb{Z}) = 0}}{=} p^*(0) = 0.$$
   The same argument also shows that $q^*([S^n]^*) \cup q^*([S^n]^*) = 0$.
   (b) We turn to the blue-colored entries. We calculate that
$$(-1)^{mn} \cdot q^*([S^n]^*) \cup p^*([S^m]^*) \underset{\substack{\uparrow \\ \text{Proposition 57.8}}}{=} p^*([S^m]^*) \cup q^*([S^n]^*) \underset{\substack{\uparrow \\ \text{Proposition 60.2 (1)}}}{=} [S^m \times S^n]^*.$$
□

In the following we consider the wedge $X := S^2 \vee S^2 \vee S^4$ and the product $Y := S^2 \times S^2$. It follows from Lemma 33.12 and Propositions 31.3 and 34.8 and the Universal Coefficient Theorem 51.13 for Cohomology Groups that $X = S^2 \vee S^2 \vee S^4$ and $Y = S^2 \times S^2$ have isomorphic homology and cohomology groups. Furthermore one obtains easily from Propositions 5.14, 7.21 and 12.3 that both X and Y are simply connected.

It is quite easy to show that $X = S^2 \vee S^2 \vee S^4$ and $Y = S^2 \times S^2$ are not homeomorphic. Indeed, suppose there exists a homeomorphism $\phi\colon S^2 \vee S^2 \vee S^4 \to S^2 \times S^2$. We denote by P we wedge point of $X = S^2 \vee S^2 \vee S^4$ and we write $Q = f(P)$. Then $X \setminus \{P\}$ and $Y \setminus \{Q\}$ would also be homeomorphic. But the former topological space has three path-components whereas the latter has just one path-component.[1031] We refer to Figure 741 for a dimensionally reduced illustration.

The following lemma is much deeper than the above discussions.

[1031] How can you prove rigorously that given any point $Q \in S^2 \times S^2$ the complement $S^2 \times S^2 \setminus \{Q\}$ is still path-connected?

FIGURE 741.

Lemma 60.4. *The topological spaces $S^2 \vee S^2 \vee S^4$ and $S^2 \times S^2$ are not even homotopy equivalent.*

Proof. We had just seen in Lemma 60.3 that there exist cohomology classes α and β in $H^2(S^2 \times S^2; \mathbb{Z})$ with $\alpha \cup \beta \neq 0$. On the other hand in Lemma 57.11 we saw that the cup product

$$\cup\colon H^2(S^2 \vee S^2 \vee S^4; \mathbb{Z}) \times H^2(S^2 \vee S^2 \vee S^4; \mathbb{Z}) \;\to\; H^4(S^2 \vee S^2 \vee S^4; \mathbb{Z})$$

is the zero-map. It follows from Corollary 57.12 that the topological spaces $S^2 \vee S^2 \vee S^4$ and $S^2 \times S^2$ are not homotopy equivalent. □

In Proposition 39.21 we saw that there exists a degree-one map from $S^2 \times S^2$ onto the 4-dimensional sphere S^4. In Question 39.28 we had asked whether there exists a degree-one map from the 4-dimensional sphere S^4 to $S^2 \times S^2$. Now we can answer this question in the negative.

Lemma 60.5. *There is no map $f\colon S^4 \to S^2 \times S^2$ of non-zero degree.*

Proof. Let $f\colon S^4 \to S^2 \times S^2$ be a map. We have to show that $\deg(f) = 0$. By Lemma 51.16 it suffices to show that $f^*([S^2 \times S^2]^*) = 0$. In Lemma 60.3 we showed that there exist cohomology classes $a, b \in H^2(S^2 \times S^2; \mathbb{Z})$ such that $a \cup b = [S^2 \times S^2]^* \in H^4(S^2 \times S^2; \mathbb{Z})$. It follows that

$$\begin{array}{ccccccc} f^*([S^2 \times S^2]^*) & = & f^*(a \cup b) & = & f^*(a) \cup f^*(b) & = & 0 \cup 0 \;= 0. \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{since } [S^2 \times S^2]^* = a \cup b & & \text{Lemma 57.10} & & \text{since } f^*(a), f^*(b) \in H^2(S^4; \mathbb{Z}) = 0 & \end{array}$$

□

60.2. **Proof of the Product Theorem 60.1.** Now that we are fully convinced of the value of Theorem 60.1 it is time to actually provide a proof thereof.

Initially we introduced only the tensor product $C_* \otimes D_*$ of two chain complexes C_* and D_*. The definition of the boundary map in the tensor product $C_* \otimes D_*$ is *not* symmetric in the two terms. But it is straightforward to see that the tensor product of chain complexes is associative. More precisely, given chain complexes $C_*^1, \dots, C_*^k$ the boundary map on the tensor product $C_*^1 \otimes \cdots \otimes C_*^k$ is always determined by

$$\partial(c_1 \otimes c_2 \otimes \cdots \otimes c_k) \;=\; \sum_{i=1}^{k} (-1)^{\deg(c_1)+\cdots+\deg(c_{i-1})} \cdot c_1 \otimes \cdots \otimes \partial c_i \otimes \cdots \otimes c_k,$$

regardless of the way how one breaks the tensor product into the tensor product of pairs of two chain complexes.

The following lemma is basically the same as Lemma 43.3, but we state it here for the convenience of the reader.

Lemma 60.6. *Let $f_i\colon C_*^i \to D_*^i$, $i = 1, \dots, k$ be chain maps between chain complexes. Then the map*

$$f_1 \otimes \cdots \otimes f_k\colon C_*^1 \otimes \cdots \otimes C_*^k \quad \to \quad D_*^1 \otimes \cdots \otimes D_*^k$$

that is determined by

$$c_1 \otimes \cdots \otimes c_k \quad \mapsto \quad f(c_1) \otimes \cdots \otimes f(c_k)$$

is also a chain map.

Remark. Even the definition of $f_1 \otimes \cdots \otimes f_k$ is, oddly enough, not the same everywhere. For example [Bre, p. 315] adds a sign to the map.

Proof. Since in the proof of the Product Theorem 60.1 there are lots of steps later on which can make us nervous, let us convince ourselves that the statement is indeed correct. We have

$$\begin{aligned}
\partial\big((f_1 \otimes \ldots \otimes f_k)(c_1 \otimes \ldots \otimes c_k)\big) &= \partial(f_1(c_1) \otimes \ldots \otimes f_k(c_k)) \\
&= \sum_{i=1}^{k} (-1)^{\deg(f_1(c_1)) + \cdots + \deg(f_{i-1}(c_{i-1}))} \cdot f_1(c_1) \otimes \ldots \otimes \overbrace{f_i(\partial c_i)}^{=\partial f_i(c_i)} \otimes \ldots \otimes f_k(c_k) \\
&\underset{\substack{\uparrow \\ \text{since } \deg(f_i(c_i)) = \deg(c_i)}}{=} (f_1 \otimes \ldots \otimes f_k)\Big(\sum_{i=1}^{k} (-1)^{\deg(c_1) + \cdots + \deg(c_{i-1})} \cdot c_1 \otimes \ldots \partial c_i \otimes \ldots \otimes c_k\Big) \\
&= (f_1 \otimes \ldots \otimes f_k)(\partial(c_1 \otimes \ldots \otimes c_k)).
\end{aligned}$$

□

Note though that the naive swapping of two factors in the tensor product of two chain complexes is not necessarily a chain map. But we have the following lemma.

Lemma 60.7. *Let A_* and B_* be chain complexes. The unique map*

$$\tau\colon A_* \otimes B_* \quad \to \quad B_* \otimes A_*$$

that for $a \in A_k$ and $b \in B_l$ is given by

$$a \otimes b \quad \mapsto \quad (-1)^{kl} \cdot b \otimes a$$

is a chain map.

Remark. In Exercise 60.1 we will see that we can use Lemma 60.7 to give a new proof of Proposition 57.8, i.e. we can give a new proof that the cup product is (anti-) commutative.

Proof. The difficult bit about the lemma is coming up with the statement. The verification is now almost trivial. So let $a \in A_k$ and $b \in B_l$. Then we have

$$\begin{aligned}
\tau(\partial(a \otimes b)) &= \tau\big(\partial a \otimes b + (-1)^k \cdot a \otimes \partial b\big) &&= \tau(\partial a \otimes b) + (-1)^k \cdot \tau(a \otimes \partial b) \\
&= (-1)^{(k-1)l} \cdot b \otimes \partial a + (-1)^{k+k(l-1)} \cdot \partial b \otimes a &&= (-1)^{kl} \cdot \partial b \otimes a + (-1)^{l+kl} \cdot b \otimes \partial a \\
&= \partial((-1)^{kl} \cdot b \otimes a) \;=\; \partial(\tau(a \otimes b)).
\end{aligned}$$

□

Now we have to introduce a plethora of new definitions and notations.

Notation.

(1) We denote by $\mathbb{Z}$ also the chain complex given by the group $\mathbb{Z}$ in degree zero and where all other chain groups are zero.
(2) Given a chain complex C_* and $k \in \mathbb{N}_0$ we denote by $C_*[k]$ the chain complex which is the result of "shifting C_* by k to the left", i.e. it is the chain complex for which the m-th chain groups $(C_*[k])_m$ is given by C_{m-k}.[1032] For example, $\mathbb{Z}[3]$ is the following chain complex:

$$\begin{array}{ccccccccccc} \dots & \to & 0 & \to & \mathbb{Z} & \to & 0 & \to & 0 & \to & 0. \\ & & & & \uparrow & & & & & & \\ & & & & \text{degree } 3 & & & & & & \end{array}$$

(3) If $\alpha\colon C_* \to D_*$ is a chain map, then for any $k \in \mathbb{N}_0$ we denote by $\alpha[k]\colon C_*[k] \to D_*[k]$ the obvious shift of the chain map. Evidently this is again a chain map.
(4) Let C_* be a chain complex and let $k \in \mathbb{N}_0$.
   (a) Given a cocycle $\varphi\colon C_k \to \mathbb{Z}$ we denote by $\Pi_k(\varphi)\colon C_* \to \mathbb{Z}[k]$ the map that is given by φ on C_k and zero on all other chain groups.
   (b) Conversely, given a chain map $\psi\colon C_* \to \mathbb{Z}[k]$ we denote by $\psi_k\colon C_k \to \mathbb{Z}$ the map that is the k-th map of the chain map.

Lemma 60.8. *Let C_* be a chain complex and let $k \in \mathbb{N}_0$. The following statements hold:*

(1) *Let $\varphi\colon C_k \to \mathbb{Z}$ be a cocycle. The map $\Pi_k(\varphi)\colon C_* \to \mathbb{Z}[k]$ is a chain map.*
(2) *Let $\psi\colon C_* \to \mathbb{Z}[k]$ be a chain map. The map $\psi_k\colon C_k \to \mathbb{Z}$ is a cocycle.*
(3) *Let $\alpha, \beta\colon C_* \to \mathbb{Z}[k]$ be chain maps. If α and β are chain homotopic, then α_k and β_k are cohomologous.*

Proof.

(1) Let $\varphi\colon C_k \to \mathbb{Z}$ be a cocycle. We consider the following diagram:

$$\begin{array}{ccccccccc} \dots & \longrightarrow & C_{k+1} & \xrightarrow{\partial} & C_k & \xrightarrow{\partial} & C_{k-1} & \longrightarrow & \dots \\ & & \downarrow & & \downarrow{\scriptstyle\varphi} & & \downarrow & & \\ \dots & \longrightarrow & 0 & \longrightarrow & \mathbb{Z} & \longrightarrow & 0 & \longrightarrow & \dots. \end{array}$$

The hypothesis that φ is a cocycle means that $\delta\varphi = \varphi \circ \partial = 0$, which implies immediately that $\Pi_k(\varphi)$ is a chain map.
(2) The proof of statement (2) is almost the same as the proof of statement (1).
(3) Let $\alpha, \beta\colon C_* \to \mathbb{Z}[k]$ be chain maps and let $\{P_m\colon C_m \to \mathbb{Z}[k]_{m+1}\}_{m\in\mathbb{N}_0}$ be a chain homotopy between α and β. We summarize all relevant maps in the following

[1032] Once again, conventions in the literature differ. It is fairly common to define the boundary maps on $C_*[k]$ to be the boundary maps of C_* multiplied by $(-1)^k$, see e.g. [Weib, p. 10].

diagram:

$$\begin{tikzcd}
\dots \arrow[r] & C_{k+1} \arrow[r, "\partial"] \arrow[d] & C_k \arrow[r, "\partial"] \arrow[d, "\alpha_k-\beta_k"] \arrow[dl, "P_k"'] & C_{k-1} \arrow[r] \arrow[d] \arrow[dl, "P_{k-1}"'] & \dots \\
\dots \arrow[r] & 0 \arrow[r] & \mathbb{Z} \arrow[r] & 0 \arrow[r] & \dots.
\end{tikzcd}$$

By definition of a chain homotopy we obtain that $\alpha_k - \beta_k = P_{k-1} \circ \partial$. But this means that $\alpha_k - \beta_k = \delta P_{k-1}$, i.e. α_k and β_k are cohomologous. $\square$

Lemma 60.9. *Let C_* be a chain complex and let $k \in \mathbb{Z}$. The maps*

$$\begin{array}{rcl} \eta_m \colon (\mathbb{Z}[k] \otimes C_*)_m = \mathbb{Z} \otimes C_{m-k} & \to & (C_*[k])_m = C_{m-k} \\ a \otimes c_{m-k} & \mapsto & (-1)^{k(m-k)} \cdot a \cdot c_{m-k} \end{array}$$

form an isomorphism

$$\eta \colon \mathbb{Z}[k] \otimes C_* \xrightarrow{\cong} C_*[k]$$

of chain complexes.

Example. Let $k, l \in \mathbb{N}_0$. The chain map

$$\eta \colon \mathbb{Z}[k] \otimes \mathbb{Z}[l] \to \mathbb{Z}[k+l]$$

is determined by the fact that for $a \in (\mathbb{Z}[k])_k = \mathbb{Z}$ and $b \in (\mathbb{Z}[l])_l = \mathbb{Z}$ we have

$$\eta(a \otimes b) = (-1)^{kl} \cdot a \cdot b.$$

Proof. It follows from Lemma 42.3 (3) that each η_m is an isomorphism. But we still need to verify that the maps η_m form a chain map $\eta \colon \mathbb{Z}[k] \otimes C_* \to C_*[k]$. Thus let $k \in \mathbb{N}_0$, let $a \in (\mathbb{Z}[k])_k = \mathbb{Z}$ and let $c_{m-k} \in C_{m-k}$. Then

$$\begin{array}{rcl} & \text{since } a \text{ is of degree } k \text{ and since } \partial a = 0 & \text{since } \partial c_{m-k} \text{ is of degree } m-k-1 \\ & \downarrow & \downarrow \\ \eta_{m-1}(\partial(a \otimes c_{m-k})) & = & \eta_{m-1}((-1)^k \cdot a \otimes \partial c_{m-k}) \quad = \quad (-1)^k \cdot (-1)^{k(m-1-k)} \cdot a \cdot \partial c_{m-k} \\ & = & \partial((-1)^{k(m-k)} \cdot a \cdot c_{m-k}) \quad = \quad \partial(\eta_m(a \otimes c_{m-k})). \end{array}$$

It follows immediately that the maps η_m form a chain map. $\square$

Notation.

(1) Given topological spaces X and Y we denote by $\Upsilon \colon C_*(X) \otimes C_*(Y) \to C_*(X \times Y)$ and $\Theta \colon C_*(X \times Y) \to C_*(X) \otimes C_*(Y)$ the chain maps from the Eilenberg-Zilber Theorem 56.1.
(2) Given a topological space W we denote by $\Delta_W \colon C_*(W) \to C_*(W) \otimes C_*(W)$ the Alexander-Whitney diagonalization from page 1338. Recall that Δ_W is also a chain map.

In the following two lemmas we will reinterpret the cup product and the cap product as chain maps.

Lemma 60.10. *Let W be a topological space and let $\alpha \in C^k(W;\mathbb{Z})$ and $\beta \in C^l(W;\mathbb{Z})$ be cocycles. Then we have the following equality of chain maps:*

$$(-1)^{kl} \cdot \Pi_{k+l}\big(\underbrace{\alpha \cup \beta}_{\text{cocycle in } C^{k+l}(W;\mathbb{Z})}\big) \;=\; \eta \circ (\Pi_k(\alpha) \otimes \Pi_l(\beta)) \circ \Delta_W \colon C_*(W) \to \mathbb{Z}[k+l].$$

Proof. We introduce the following notation:

(1) We denote by $\mu\colon \mathbb{Z} \otimes \mathbb{Z} \to \mathbb{Z}$ the obvious isomorphism of abelian groups given by $\mu(a \otimes b) = a \cdot b$.
(2) We denote by $\Pi_{k,l}\colon (C_*(W) \otimes C_*(W))_{k+l} \to C_k(W) \otimes C_l(W)$ the obvious projection map.

In the proof of Proposition 57.4 on page 1339 we showed that

$$\alpha \cup \beta \;=\; \mu \circ (\alpha \otimes \beta) \circ \Pi_{k,l} \circ \Delta_W \colon C_{k+l}(W) \;\to\; \mathbb{Z}.$$

The lemma follows immediately from this equality and the following claim.

Claim. [1033]

$$(-1)^{kl} \cdot \mu \circ (\alpha \otimes \beta) \circ \Pi_{k,l} \;=\; \underbrace{(\eta \circ (\Pi_k(\alpha) \otimes \Pi_l(\beta)))_{k+l}}_{\substack{\text{the restriction to the } (k+l)\text{-th chain group of the} \\ \text{chain map } C_*(W) \otimes C_*(W) \to \mathbb{Z}[k] \otimes \mathbb{Z}[l] \to \mathbb{Z}[k+l] \\ a \otimes b \mapsto (-1)^{kl} \cdot ab}} \;\colon (C_*(W) \otimes C_*(W))_{k+l} \;\to\; \mathbb{Z}.$$

Let $\sigma_i \in C_i(W)$ and $\sigma_j \in C_j(W)$ with $i + j = k + l$. If $(i,j) \neq (k,l)$, then both maps are zero. So now suppose that $(i,j) = (k,l)$. Then it is clear that both maps send $\sigma_k \otimes \sigma_l$ to $(-1)^{kl} \cdot \alpha(\sigma_k) \cdot \beta(\sigma_l)$. (Note that the sign $(-1)^{kl}$ for the map on the right-hand side stems from the definition of the chain map η.) This concludes the proof of the claim. □

Given a topological space W and given $\varphi \in C^k(W;\mathbb{Z})$ we obtain for each $m \in \mathbb{N}_0$ a map

$$\begin{aligned} \varphi \cap -\colon C_m(W) &\;\to\; C_{m-k}(W) = (C_*(W)[k])_m \\ \sigma &\;\mapsto\; \varphi \cap \sigma. \end{aligned}$$

Unfortunately in general these maps do *not* form a chain map from the chain complex $C_*(W)$ to the chain chain complex $C_*(W)[k]$. This motivates introducing the following slight variation of the cap product.

Definition. Let W be a topological space. Given $\varphi \in C^m(W;\mathbb{Z})$ and given $\sigma \in C_n(W)$ we define[1034]

$$\varphi \,\widetilde{\cap}\, \sigma \;:=\; (-1)^{m(n-m)} \cdot \varphi \cap \sigma.$$

In particular for $m = n$ we have $\varphi \,\widetilde{\cap}\, \sigma = \varphi \cap \sigma$.

Lemma 60.11. *Let W be a topological space.*

[1033] Here, given two chain complexes $\mathcal{C}_*$ and $\mathcal{D}_*$ the map $\Pi_{k,l}\colon \mathcal{C}_* \otimes \mathcal{D}_* \to \mathcal{C}_k \otimes \mathcal{B}_l$ is the obvious projection map that we introduced on page 1332.

[1034] If we compare this definition with the discussion on page 1373 we see that the definition of $\widetilde{\cap}$ is precisely the definition of the cap product in Bredon [Bre] and Dold [Dol].

(1) *If $\varphi \in C^m(W;\mathbb{Z})$ is a cocycle, then the map*

$$\begin{array}{rcl} \varphi \mathbin{\widetilde{\cap}} -\colon C_*(W) & \to & C_*(W)[m] \\ \sigma & \mapsto & \varphi \mathbin{\widetilde{\cap}} \sigma \end{array}$$

is a chain map.

(2) *If $\varphi, \psi \in C^m(W;\mathbb{Z})$ are cohomologous cocycles, then the chain maps $\varphi \mathbin{\widetilde{\cap}} -$ and $\psi \mathbin{\widetilde{\cap}} -$ are chain homotopic.*

Proof. Let W be a topological space. We start out with the following claim.

Claim. For any cochain $\tau \in C^l(W;\mathbb{Z})$ and any chain $\mu \in C_n(W;\mathbb{Z})$ we have

$$\partial(\tau \mathbin{\widetilde{\cap}} \mu) \;=\; (-1)^{l+n} \cdot \delta\tau \mathbin{\widetilde{\cap}} \mu + \tau \mathbin{\widetilde{\cap}} \partial\mu.$$

The claim is an immediate consequence of Lemma 59.1. Since we are worried about signs we write down the detailed calculation. We have

$$\begin{array}{rcl} \partial(\tau \mathbin{\widetilde{\cap}} \mu) & \underset{\substack{\uparrow \\ \text{definition of } \widetilde{\cap}}}{=} & (-1)^{l(n-l)} \cdot \partial(\tau \cap \mu) \underset{\substack{\uparrow \\ \text{Lemma 59.1}}}{=} (-1)^{l(n-l)} \cdot (-1)^l \cdot (-\delta\tau \cap \mu + \tau \cap \partial\mu) \\ & = & (-1)^{l(n-l)+l} \cdot \big(-(-1)^{(l+1)\cdot(n-l-1)} \cdot \delta\tau \mathbin{\widetilde{\cap}} \mu + (-1)^{l\cdot(n-l-1)} \cdot \tau \mathbin{\widetilde{\cap}} \partial\mu \big) \\ & = & (-1)^{l+n} \cdot \delta\tau \mathbin{\widetilde{\cap}} \mu + \tau \mathbin{\widetilde{\cap}} \partial\mu. \end{array}$$

This concludes the proof of the claim.

Now we turn to the actual proof of the two statements.

(1) Let $\varphi \in C^m(W;\mathbb{Z})$ be a cocycle. Furthermore let $\sigma \in C_n(W)$. By the definition of the cap product and by definition of the shifting of chain complexes we have $\varphi \cap \sigma \in C_{n-m}(W) = (C_*(W)[m])_n$. This shows that $\varphi \mathbin{\widetilde{\cap}} -$ preserves degrees. It remains to show that the map $\varphi \mathbin{\widetilde{\cap}} -$ commutes with the boundary maps. But this is an immediate consequence of the above claim and the fact that φ is a cocycle.

(2) So let $\varphi, \psi \in C^m(W;\mathbb{Z})$ be cocycles. We assume they are cohomologous which means that there exists a $\tau \in C^{m-1}(W;\mathbb{Z})$ such that $\varphi = \psi + \delta\tau$. For any $k \in \mathbb{N}_0$ we consider the map

$$\begin{array}{rcl} P_k\colon C_k(W) & \to & (C_*(W)[m])_{k+1} = C_{k-m+1}(W) \\ \sigma & \mapsto & (-1)^{m+k} \cdot \tau \mathbin{\widetilde{\cap}} \sigma. \end{array}$$

We calculate that for any $\sigma \in C_k(W)$ we have

$$\begin{array}{rcl} \varphi \mathbin{\widetilde{\cap}} \sigma - \psi \mathbin{\widetilde{\cap}} \sigma \;=\; \delta\tau \mathbin{\widetilde{\cap}} \sigma & \underset{\substack{\text{by the claim} \\ \downarrow}}{=} & (-1)^{m+k} \cdot \partial(\tau \mathbin{\widetilde{\cap}} \sigma) + (-1)^{m+k-1} \cdot \tau \mathbin{\widetilde{\cap}} \partial\sigma \\ & = & (\partial \circ P_k)(\sigma) + (P_{k-1} \circ \partial)(\sigma). \end{array}$$

This shows that the maps $\{P_k\}_{k\in\mathbb{N}_0}$ form a chain homotopy between the chain maps $\varphi \mathbin{\widetilde{\cap}} -$ and $\psi \mathbin{\widetilde{\cap}} -$. □

In the proof of Theorem 60.1 we will also need the following reformulation of the cap product.

Proposition 60.12. *Let W be a topological space and let $\varphi \in C^m(W;\mathbb{Z})$ be a cocycle. Then we have the following equality of chain maps*

$$\varphi \,\widetilde{\cap}\, - \;=\; \eta \circ (\Pi_m(\varphi) \otimes \mathrm{id}) \circ \Delta_W \colon C_*(W) \;\to\; C_*(W)[m].$$

Proof. Let W be a topological space, let $\varphi \in C^m(W)$ be a cocycle and let $\sigma\colon \Delta^n \to W$ be a singular n-simplex. We have the following equalities in $C_*(W)[m]_n = C_{n-m}(W)$:

$$\begin{aligned}
\big(\eta \circ (\Pi_m(\varphi) \otimes \mathrm{id}) \circ \Delta_W\big)(\sigma) &\overset{\substack{\text{definition of the Alexander-Whitney diagonalization}\\ \downarrow}}{=} \eta\Big((\Pi_m(\varphi) \otimes \mathrm{id})\Big(\sum_{j=0}^{n} \sigma \circ [v_0,\dots,v_j] \otimes \sigma \circ [v_j,\dots,v_n]\Big)\Big) \\
&\underset{\substack{\uparrow \\ \text{by definition of the chain map } \Pi_m(\varphi)\otimes \mathrm{id}\colon C_*(W)\otimes C_*(W) \to \mathbb{Z}[m]\otimes C_*(W)}}{=} \eta\big(\underbrace{\varphi(\sigma \circ [v_0,\dots,v_m])}_{\in \mathbb{Z}[m]_m} \otimes \underbrace{\sigma \circ [v_m,\dots,v_n]}_{\in C_{n-m}}\big) \\
&\underset{\substack{\uparrow \\ \text{definition of } \eta \text{ in Lemma 60.9}}}{=} (-1)^{m(n-m)} \cdot \underbrace{\varphi(\sigma\circ[v_0,\dots,v_m])\cdot\sigma\circ[v_m,\dots,v_n]}_{=\varphi\cap\sigma} \underset{\substack{\uparrow \\ \text{definition of } \widetilde{\cap} \text{ on page 1394}}}{=} \varphi \,\widetilde{\cap}\, \sigma.
\end{aligned}$$

We have thus verified that the desired equality holds. □

The following statement is just the definition of the cross product.

Tautology 60.13. *Let X and Y two topological spaces. For any $[\mu] \in H_m(X;\mathbb{Z})$ and $[\nu] \in H_n(Y;\mathbb{Z})$ we have*

$$[\mu] \times [\nu] \;=\; [\Upsilon(\mu \otimes \nu)].$$

We need one more slightly delicate chain map before we can finally turn to the proof of the Product Theorem 60.1.

Lemma 60.14. *Let C_* and D_* be chain complexes and let $k, l \in \mathbb{N}_0$. The map*

$$\Psi_{k,l}\colon C_*[k] \otimes D_*[l] \;\to\; (C_* \otimes D_*)[k+l]$$

which is defined by the property that for $c_m \in C_m$ and $d_n \in D_n$ we have

$$c_m \otimes d_n \;\mapsto\; (-1)^{k(l+n)} \cdot c_m \otimes d_n.$$

is an isomorphism of chain complexes.

Proof. First note that it is clear that $\Psi_{k,l}$ preserves degrees and that on each degree it is an isomorphism. It remains to show that the map $\Psi_{k,l}$ is a chain map. Let $c_m \in C_m$ and

$d_n \in D_n$. We calculate that

$$\begin{aligned}
\Psi_{k,l}(\partial(c_m \otimes d_n)) &\overset{\substack{\text{since } c_m \text{ has degree } m+k \text{ in } C_*[k] \\ \downarrow}}{=} \Psi_{k,l}(\partial c_m \otimes d_n + (-1)^{m+k} \cdot c_m \otimes \partial d_n) \\
&= (-1)^{k(l+n)} \cdot \partial c_m \otimes d_n + (-1)^{m+k} \cdot (-1)^{k(l+n-1)} \cdot c_m \otimes \partial d_n \\
&= (-1)^{k(l+n)} \cdot (\partial c_m \otimes d_n + (-1)^m \cdot c_m \otimes \partial d_n) \underset{\substack{\uparrow \\ \text{since } c_m \text{ has degree } m \text{ in } C_*}}{=} (-1)^{k(l+n)} \cdot \partial(c_m \otimes d_n) \\
&= \partial((-1)^{k(l+n)} \cdot c_m \otimes d_n)) = \partial(\Psi_{k,l}(c_m \otimes d_n)).
\end{aligned}$$

This calculation implies that $\Psi_{k,l}$ is a chain map. □

The following theorem is the main technical result of this section. As we will see shortly, the Product Theorem 60.1 is a straightforward consequence of Theorem 60.15.

Theorem 60.15. *Let X and Y be topological spaces. We denote by $p\colon X \times Y \to X$ and $q\colon X \times Y \to Y$ the projection maps. Let $\alpha \in C^k(X;\mathbb{Z})$ and $\beta \in C^l(Y;\mathbb{Z})$ be cocycles. Then the chain maps*

$$(-1)^{kl} \cdot ((p^*\alpha \cup q^*\beta) \mathbin{\widetilde{\cap}} -) \circ \Upsilon \quad \text{and} \quad \Upsilon[k+l] \circ \Psi_{k,l} \circ (\alpha \mathbin{\widetilde{\cap}} - \otimes \beta \mathbin{\widetilde{\cap}} -)$$

from $C_*(X) \otimes C_*(Y)$ to $C_*(X \times Y)[k+l]$ are chain homotopic.

Proof. Let X and Y be topological spaces and let $\alpha \in C^k(X;\mathbb{Z})$ and $\beta \in C^l(Y;\mathbb{Z})$ be cocycles. We consider the following diagram of chain maps

$$\begin{tikzcd}
C_*X \otimes C_*Y \arrow[r, "\Upsilon"] \arrow[d, "\Delta_X \otimes \Delta_Y"] & C_*(X \times Y) \arrow[r, "\Delta_{X\times Y}"] & C_*(X \times Y) \otimes C_*(X \times Y) \arrow[d, "\Theta \otimes \mathrm{id}"] \\
C_*X \otimes C_*X \otimes C_*Y \otimes C_*Y \arrow[r, "\mathrm{id} \otimes \tau \otimes \mathrm{id}"] \arrow[d, "\Pi_k(\alpha) \otimes \mathrm{id} \otimes \Pi_l(\beta) \otimes \mathrm{id}"'] & C_*X \otimes C_*Y \otimes C_*X \otimes C_*Y \arrow[r, "\mathrm{id} \otimes \mathrm{id} \otimes \Upsilon"] \arrow[d, "\Pi_k(\alpha) \otimes \Pi_l(\beta) \otimes \mathrm{id} \otimes \mathrm{id}"] & C_*X \otimes C_*Y \otimes C_*(X \times Y) \arrow[d, "\Pi_k(\alpha) \otimes \Pi_l(\beta) \otimes \mathrm{id}"] \\
\mathbb{Z}[k] \otimes C_*X \otimes \mathbb{Z}[l] \otimes C_*Y \arrow[r, "\mathrm{id} \otimes \tau \otimes \mathrm{id}"] \arrow[dd, "\eta \otimes \eta"'] & \mathbb{Z}[k] \otimes \mathbb{Z}[l] \otimes C_*X \otimes C_*Y \arrow[r, "\mathrm{id} \otimes \mathrm{id} \otimes \Upsilon"] \arrow[d, "\eta \otimes \mathrm{id} \otimes \mathrm{id}"] & \mathbb{Z}[k] \otimes \mathbb{Z}[l] \otimes C_*(X \times Y) \arrow[d, "\eta \otimes \mathrm{id}"] \\
 & \mathbb{Z}[k+l] \otimes (C_*X \otimes C_*Y) \arrow[r, "\mathrm{id} \otimes \Upsilon"] \arrow[d, "\eta"] & \mathbb{Z}[k+l] \otimes C_*(X \times Y) \arrow[d, "\eta"] \\
C_*X[k] \otimes C_*Y[l] \arrow[r, "\Psi_{k,l}"] & (C_*X \otimes C_*Y)[k+l] \arrow[r, "\Upsilon[k+l]"] & C_*(X \times Y)[k+l].
\end{tikzcd}$$

Claim. The above diagram commutes up to chain homotopies.

To prove the claim we consider the various smaller squares and rectangles.

(1) The two paths along the top rectangle from the top-left corner to the bottom-right corner are both natural chain maps. Both have the property that for $x \in X$ and $y \in Y$ the element $x \otimes y \in C_*(X) \otimes C_*(Y)$ gets sent to $x \otimes y \otimes (x, y)$ in $C_*(X) \otimes C_*(Y) \otimes C_*(X \times Y)$. In particular both paths agree on the 0-level.

It follows from Acyclic Model Theorem 56.16 (2) that the rectangle commutes up to a chain homotopy. More precisely, we apply the Acyclic Model Theorem 56.16 as follows:

(a) We take $\mathcal{C}$ to be the category of tuples (X, Y) of topological spaces.
(b) We consider the two functors $F\colon (X,Y) \mapsto (C_*(X) \otimes C_*(Y), \epsilon_X \otimes \epsilon_Y)$ and $G\colon (X,Y) \mapsto (C_*(X \times Y), \epsilon_{X\times Y})$.
(c) We take $\mathcal{M} = \{\Delta^k \times \Delta^l\}_{k,l\in\mathbb{N}_0}$.
(d) We consider the two natural transformations that are given by the two extremal paths in the diagram (shifted downward in degrees).

(2) It is clear that the two squares between the second and the third row commute.
(3) It is straightforward to verify that the two squares at the bottom right commute.
(4) It remains to consider the big square to the bottom left of the diagram. Starting with $a \in (\mathbb{Z}[k])_k = \mathbb{Z}$, $b \in C_m(X)$, $c \in (\mathbb{Z}[l])_l = \mathbb{Z}$ and $d \in C_n(Y)$ and keeping in mind the sign conventions of Lemmas 60.7, 60.9 and 60.14 we get the following results for $a \otimes b \otimes c \otimes d$:
   (a) going down-right gives $(-1)^{km} \cdot (-1)^{ln} \cdot (-1)^{k(l+n)} \cdot ac \cdot (b \otimes d)$,
   (b) going right-down-down gives $(-1)^{ml} \cdot (-1)^{kl} \cdot (-1)^{(k+l)(m+n)} \cdot ac \cdot (b \otimes d)$.
   One easily verifies that the signs agree. So we see that the bottom left square also commutes.

This concludes the proof of the claim.

In light of the previous claim it suffices to prove the following claim.

Claim.

(1) the "left-bottom route" equals the chain map $\Upsilon[k+l] \circ \Psi_{k,l} \circ ((\alpha \mathbin{\widetilde{\cap}} -) \otimes (\beta \mathbin{\widetilde{\cap}} -))$,
(2) the "top-right route" is chain homotopic to $(-1)^{kl} \cdot ((p^*\alpha \cup q^*\beta) \mathbin{\widetilde{\cap}} -) \circ \Upsilon$.

We start out with the proof of statement (1). First we note that

$$\begin{aligned}(\alpha \mathbin{\widetilde{\cap}} -) \otimes (\beta \mathbin{\widetilde{\cap}} -) &\underset{\substack{\uparrow \\ \text{by Proposition 60.12}}}{=} (\eta \circ (\Pi_k(\alpha) \otimes \mathrm{id}) \circ \Delta_X) \otimes (\eta \circ (\Pi_l(\beta) \otimes \mathrm{id}) \circ \Delta_Y) \\ &\underset{\substack{\uparrow \\ \text{follows from the observation that for chain maps } a,b,c \text{ and } d \\ \text{we have } (a\circ b)\otimes(c\circ d) = (a\otimes b)\circ(c\otimes d)}}{=} (\eta \otimes \eta) \circ ((\Pi_k(\alpha) \otimes \mathrm{id} \otimes \Pi_l(\beta) \otimes \mathrm{id})) \circ (\Delta_X \otimes \Delta_Y).\end{aligned}$$

If we compose this equality with $\Upsilon[k+l] \circ \Psi_{k,l}$ then we obtain the "bottom left route" in the above diagram. This concludes the proof of statement (1).

We continue with the proof of statement (2). In that proof we will make use of the following subclaim.

Subclaim. The two cocycles[1035]

$$(\eta \circ (\Pi_k(\alpha) \otimes \Pi_l(\beta)) \circ \Theta)_{k+l} \quad \text{and} \quad (-1)^{kl} \cdot p^*(\alpha) \cup q^*(\beta)$$

in $C^{k+l}(X \times Y; \mathbb{Z})$ are cohomologous.

We consider the following diagram

$$\begin{tikzcd}
C_{k+l}(X \times Y) \arrow[r, hook] & C_*(X \times Y) \arrow[r, "\Theta"] \arrow[d, "\Delta_{X \times Y}"] & C_*(X) \otimes C_*(Y) \arrow[d, "\Pi_k(\alpha) \otimes \Pi_l(\beta)"] & \\
& C_*(X \times Y) \otimes C_*(X \times Y) \arrow[ur, "p_* \otimes q_*"] \arrow[r, "\Pi_k(p^*(\alpha)) \otimes \Pi_l(q^*(\beta))"'] & \mathbb{Z}[k] \otimes \mathbb{Z}[l] \arrow[r, "\eta"'] & \mathbb{Z}[k+l].
\end{tikzcd}$$

Note that by the above discussion all maps except for the top left map are chain maps. It follows immediately from the definitions that the bottom triangle of chain maps commutes "on the nose". The top triangle of chain maps commutes, up to a chain homotopy, by Theorem 56.5.[1036] It follows from Lemma 60.8 (3) that the restrictions of these two chain maps to maps $C_{k+l}(X \times Y) \to \mathbb{Z} = \mathbb{Z}[k+l]$ are cohomologous cochains. But the restriction of the "top route" equals evidently the left-hand side of the subclaim. On the other hand, by Lemma 60.10 the restriction of the "bottom route" equals the right-hand side of the subclaim. This concludes the proof of the subclaim.

[1035]Recall that $\eta \circ (\Pi_k(\alpha) \otimes \Pi_l(\beta)) \circ \Theta$ is a chain map $C_*(X \times Y) \to \mathbb{Z}[k+l]$. Furthermore recall that the map $(\eta \circ (\Pi_k(\alpha) \otimes \Pi_l(\beta)) \circ \Theta)_{k+l} \colon C_{k+l}(X \times Y) \to (\mathbb{Z}[k+l])_{k+l} = \mathbb{Z}$ is the $(k+l)$-th map of the chain map.

[1036]More precisely, given $x \in X$ and $y \in Y$ both routes along the triangle send (x, y) to $x \otimes y$. Furthermore both routes are natural chain maps. Thus we can apply Theorem 56.5.

Now we see that

$$
\begin{aligned}
(-1)^{kl}\cdot((p^*\alpha\cup q^*\beta)\,\widetilde{\cap}\,-)\circ\Upsilon \;&\overset{\substack{\text{the above subclaim and Lemma 60.11 (2)}\\ \downarrow}}{\simeq}\; \big((\eta\circ(\Pi_k(\alpha)\otimes\Pi_l(\beta))\circ\Theta)_{k+l}\,\widetilde{\cap}\,-\big)\circ\Upsilon\\
&= \eta\circ\big(\Pi_{k+l}((\eta\circ(\Pi_k(\alpha)\otimes\Pi_l(\beta))\circ\Theta)_{k+l})\otimes\mathrm{id}\big)\circ\Delta_{X\times Y}\circ\Upsilon\\
&\quad\uparrow\\
&\quad\text{Proposition 60.12 applied to the } (k+l)\text{-cocycle } (\eta\circ(\Pi_k(\alpha)\otimes\Pi_l(\beta))\circ\Theta)_{k+l}\\
&= \eta\circ\big(\Pi_{k+l}((\eta\circ(\Pi_k(\alpha)\otimes\Pi_l(\beta)))_{k+l})\circ\Theta\otimes\mathrm{id}\big)\circ\Delta_{X\times Y}\circ\Upsilon\\
&\quad\uparrow\\
&\quad\text{since for every chain map } \Omega\colon C_*(X)\times C_*(Y)\to\mathbb{Z}[k+l] \text{ we}\\
&\quad\text{have } \Pi_{k+l}((\Omega\circ\Theta)_{k+l}) = \Pi_{k+l}(\Omega_{k+l})\circ\Theta \text{ as maps } C_*(X\times Y)\to\mathbb{Z}[k+l],\\
&\quad\text{applies this observationc to } \Omega=\eta\circ(\Pi_k(\alpha)\otimes\Pi_l(\beta))\\
&= \eta\circ((\eta\circ(\Pi_k(\alpha)\otimes\Pi_l(\beta))\circ\Theta)\otimes\mathrm{id})\circ\Delta_{X\times Y}\circ\Upsilon\\
&\quad\uparrow\\
&\quad\text{here we use the equality of chain maps}\\
&\qquad\Pi_{k+l}((\eta\circ(\Pi_k(\alpha)\otimes\Pi_l(\beta)))_{k+l}) = \eta\circ(\Pi_k(\alpha)\otimes\Pi_l(\beta))\colon C_*(X)\otimes C_*(Y)\to\mathbb{Z}[k+l]\\
&\quad\text{which is obvious once one unravels the definitions}\\
&= \text{the “top right route” in the above diagram.}\\
&\quad\uparrow\\
&\quad\text{follows from } (f\otimes\mathrm{id})\circ(g\otimes\mathrm{id}) = (g\circ f)\otimes\mathrm{id}
\end{aligned}
$$

This concludes the proof of the claim and thus also of the theorem. □

Now we can finally provide the proof of Theorem 60.1.

Proof of Theorem 60.1. To simplify the notation we only consider the case $A = B = \varnothing$. For the general case one needs to take more care, we refer to [Dol, p. 240 and p. 244] for details. So let X and Y be two topological spaces. We denote by $p\colon X\times Y\to X$ and $q\colon X\times Y\to Y$ the projection maps. Let $[\alpha]\in H^k(X;\mathbb{Z})$, $[\beta]\in H^l(Y;\mathbb{Z})$ and let $[\mu]\in H_m(X;\mathbb{Z})$ and $[\nu]\in H_n(Y;\mathbb{Z})$. We have to show that

$$
\big(\underbrace{[p^*(\alpha)]}_{\in H^k(X\times Y)}\cup\underbrace{[q^*(\beta)]}_{\in H^l(X\times Y)}\big)\cap\underbrace{\big([\mu]\times[\nu]\big)}_{\in H_{m+n}(X\times Y)} = (-1)^{kl+lm}\cdot\underbrace{([\alpha]\cap[\mu])}_{\in H_{m-k}(X)}\times\underbrace{([\beta]\cap[\nu])}_{\in H_{n-l}(Y)}
$$

We have the following equality in $H_{m+n-k-l}(X \times Y)$:

$$\begin{aligned}
(p^*([\alpha]) \cup q^*([\beta])) \cap ([\mu] \times [\nu]) &\overset{\substack{\text{Tautology 60.13 and the definition of } \widetilde{\cap}\text{, see page 1394}\\ \downarrow}}{=} (-1)^{(k+l)(m+n-k-l)} \cdot ([p^*\alpha \cup q^*\beta]) \,\widetilde{\cap}\, [\Upsilon(\mu \otimes \nu)] \\
&= (-1)^{(k+l)(m+n-k-l)} \cdot (((p^*\alpha \cup q^*\beta) \,\widetilde{\cap}\, -) \circ \Upsilon)_*([\mu \otimes \nu]) \\
&= (-1)^{(k+l)(m+n-k-l)} \cdot ((-1)^{kl} \cdot \Upsilon[k+l] \circ \Psi_{k,l} \circ (\alpha \,\widetilde{\cap}\, - \otimes \beta \,\widetilde{\cap}\, -))_*([\mu \otimes \nu]) \\
&\underset{\substack{\uparrow\\ \text{by Theorem 60.15 and the fact that chain homotopic maps}\\ \text{induce the same map on homology groups}}}{=} \\
&= (-1)^{(k+l)(m+n-k-l)} \cdot (-1)^{kl} \cdot \Big[\Upsilon[k+l] \circ \Psi_{k,l} \circ \big(\underbrace{\underbrace{\alpha \,\widetilde{\cap}\, \mu}_{=(-1)^{k(m-k)} \cdot \alpha \cap \mu}}_{\in C_{m-k}(X)[k]} \otimes \underbrace{\underbrace{\beta \,\widetilde{\cap}\, \nu}_{=(-1)^{l(n-l)} \cdot \beta \cap \nu}}_{\in C_{n-l}(Y)[l]} \big)\Big] \\
&\underset{\substack{\uparrow\\ \text{definition of } \Psi_{k,l}\text{, see page 1396, and of the shifting from } \Upsilon \text{ to } \Upsilon[k+l]}}{=} (-1)^{(k+l)(m+n-k-l)} \cdot (-1)^{kl} \cdot (-1)^{k(l+n-l)} \cdot (-1)^{k(m-k)} \cdot (-1)^{l(n-l)} \cdot \big[\Upsilon(\alpha \cap \mu \otimes \beta \cap \nu)\big] \\
&\underset{\substack{\uparrow\\ \text{cleaning up signs and Tautology 60.13}}}{=} (-1)^{kl+lm} \cdot [\alpha \cap \mu \times \beta \cap \nu] = (-1)^{kl+lm} \cdot ([\alpha] \cap [\mu] \times [\beta] \cap [\nu]).
\end{aligned}$$

□

60.3. **The Künneth Theorem for cohomology groups.** Given two topological spaces X and Y the Künneth Theorem 56.8 for topological spaces determines the homology groups of $X \times Y$ in terms of the homology groups of X and Y. The following proposition gives us, under some mild hypothesis, a similar answer for cohomology groups.

Theorem 60.16. (The Künneth Theorem for cohomology groups) *Let X and Y be two topological spaces. We denote by $p\colon X \times Y \to X$ and $q\colon X \times Y \to Y$ the obvious projection maps. If all the homology groups of X are finitely generated*[1037]*, then given any $n \in \mathbb{N}_0$ there exists a short exact sequence*

$$0 \to \bigoplus_{k+l=n} H^k(X;\mathbb{Z}) \otimes H^l(Y;\mathbb{Z}) \to H^n(X \times Y;\mathbb{Z}) \to \bigoplus_{k+l=n+1} \operatorname{Tor}(H^k(X;\mathbb{Z}), H^l(Y;\mathbb{Z})) \to 0$$
$$\varphi \otimes \psi \mapsto p^*\varphi \cup q^*\psi$$

which is natural with respect to the topological spaces X and Y. If all the homology groups of Y are also finitely generated, then the short exact sequence splits (albeit not naturally).

Remark. Let X and Y be two topological spaces. In the literature the map

$$\begin{aligned} H^k(X;\mathbb{Z}) \times H^l(Y;\mathbb{Z}) &\to H^{k+l}(X \times Y;\mathbb{Z}) \\ (\varphi, \psi) &\mapsto p^*\varphi \cup q^*\psi \end{aligned}$$

is often referred to as the *cohomology cross product* and it is written as $\varphi \times \psi := p^*\varphi \cup q^*\psi$. We will not make use of this notation.

[1037] By this we mean that for every $k \in \mathbb{N}_0$ the abelian group $H_k(X;\mathbb{Z})$ is finitely generated.

The proof of the theorem rests on a purely algebraic theorem that, given two chain complexes $\mathcal{C}$ and $\mathcal{C}'$, relates the cohomology groups of $\mathcal{C}$ and $\mathcal{C}'$ to the cohomology groups of $\mathcal{C}\otimes\mathcal{C}'$. Before we can state the theorem we need to introduce one more definition, which is closely related to the definitions introduced on page 1332.

Definition. Let $\mathcal{C}$ and $\mathcal{C}'$ be two chain complexes and let $p,q\in\mathbb{N}_0$.

(1) We denote by

$$\Pi_{p,q}\colon (\mathcal{C}_*\otimes\mathcal{C}'_*)_{p+q}=\bigoplus_{i+j=p+q} C_i\otimes C'_j \;\to\; C_p\otimes C'_q$$

the obvious projection map.

(2) We denote by $\mu\colon \mathbb{Z}\otimes\mathbb{Z}\to\mathbb{Z}$ the obvious isomorphism given by $\mu(a\otimes b)=ab$.

(3) We consider the map:

$$\begin{aligned}\Xi_{p,q}\colon \operatorname{Hom}(C_p,\mathbb{Z})\otimes\operatorname{Hom}(C'_q,\mathbb{Z}) \;&\to\; \operatorname{Hom}\big((\mathcal{C}\otimes\mathcal{C}')_{p+q},\mathbb{Z}\big)\\ \varphi_p\otimes\varphi'_q \;&\mapsto\; \Bigg(\bigoplus_{i+j=p+q} C_i\otimes C'_j \xrightarrow{\Pi_{p,q}} C_p\otimes C'_q \xrightarrow{\varphi_p\otimes\varphi'_q} \mathbb{Z}\otimes\mathbb{Z}\xrightarrow{\mu}\mathbb{Z}\Bigg).\end{aligned}$$

(4) It is straightforward to verify that the map $\Xi_{p,q}$ induces a well-defined map on cohomology groups, i.e. that the map

$$\begin{aligned}\Xi_{p,q}\colon H^p(\mathcal{C};\mathbb{Z})\otimes H^q(\mathcal{C}';\mathbb{Z}) \;&\to\; H^{p+q}(\mathcal{C}\otimes\mathcal{C}';\mathbb{Z})\\ ([\varphi_p]\otimes[\varphi'_q]) \;&\mapsto\; [\Xi_{p,q}(\varphi_p\otimes\varphi'_q)]\end{aligned}$$

is well-defined. Furthermore it follows immediately from the definition that $\Xi_{p,q}$ is natural[1038] with respect to $\mathcal{C}$ and $\mathcal{C}'$.

Now we can state the promised purely algebraic theorem.

Theorem 60.17. (The Künneth Theorem for cochain complexes) *Let $\mathcal{C}$ and $\mathcal{C}'$ be chain complexes. If $\mathcal{C}$ is a free chain complex and if all homology groups of $\mathcal{C}$ are finitely generated, then for every $n\in\mathbb{N}_0$ there exists a short exact sequence*

$$0\to\bigoplus_{p+q=n} H^p(\mathcal{C};\mathbb{Z})\otimes H^q(\mathcal{C}';\mathbb{Z})\xrightarrow{\Xi_{p,q}} H^n(\mathcal{C}\otimes\mathcal{C}';\mathbb{Z})\to\bigoplus_{p+q=n+1}\operatorname{Tor}(H^p(\mathcal{C};\mathbb{Z}),H^q(\mathcal{C};\mathbb{Z}))\to 0$$

which is natural with respect to $\mathcal{C}$ and $\mathcal{C}'$. If all the chain groups of $\mathcal{C}'$ are also free abelian and all the homology groups of $\mathcal{C}'$ are also finitely generated, then the short exact sequence splits (albeit not naturally).

[1038] In this case this means that for chain maps $f\colon\mathcal{C}\to\mathcal{D}$ and $f'\colon\mathcal{C}'\to\mathcal{D}'$ the following diagram commutes:

$$\begin{array}{ccc} H^p(\mathcal{D};\mathbb{Z})\otimes H^q(\mathcal{D}';\mathbb{Z}) & \xrightarrow{\Xi_{p,q}} & H^{p+q}(\mathcal{D}\otimes\mathcal{D}';\mathbb{Z})\\ \big\downarrow{\scriptstyle f^*\otimes(f')^*} & & \big\downarrow{\scriptstyle (f\otimes f')^*}\\ H^p(\mathcal{C};\mathbb{Z})\otimes H^q(\mathcal{C}';\mathbb{Z}) & \xrightarrow{\Xi_{p,q}} & H^{p+q}(\mathcal{C}\otimes\mathcal{C}';\mathbb{Z}).\end{array}$$

In the proof of the Künneth Theorem 60.17 for cochain complexes we need one technical lemma. To state the lemma we recall that on page 1041 we introduced the tensor product of two chain complexes. Basically the same definition also allows us to define the tensor product of two cochain complexes. With this preamble we can formulate the next lemma.

Lemma 60.18. *Let $\mathcal{C}_*$ and $\mathcal{C}'_*$ be two chain complexes. We assume that all chain groups of $\mathcal{C}$ are finitely generated free abelian groups. Then the map*

$$\begin{array}{rcl} \Omega\colon \operatorname{Hom}(\mathcal{C}_*,\mathbb{Z})\otimes\operatorname{Hom}(\mathcal{C}'_*,\mathbb{Z}) & \to & \operatorname{Hom}(\mathcal{C}_*\otimes\mathcal{C}'_*,\mathbb{Z}) \\ (\varphi_p\colon C_p\to\mathbb{Z})\otimes(\varphi'_q\colon C'_q\to\mathbb{Z}) & \mapsto & (\mu\circ(\varphi_p\otimes\varphi'_q)\circ\Pi_{p,q}\colon (\mathcal{C}_*\otimes\mathcal{C}'_*)_{p+q}\to\mathbb{Z}) \end{array}$$

is an isomorphism of cochain complexes.

Proof $(*)$. We start out the proof of the lemma with the following elementary well-known observation:

$(*)$ For finitely many abelian groups $A_1,\dots,A_k$ we have a canonical isomorphism

$$\operatorname{Hom}(A_1\oplus\cdots\oplus A_k,\mathbb{Z}) = \operatorname{Hom}(A_1,\mathbb{Z})\oplus\cdots\oplus\operatorname{Hom}(A_k,\mathbb{Z}).$$

Now we turn to the actual proof of the lemma. It is elementary to verify that the map Ω is in fact a cochain map. So it remains to show that for every $n\in\mathbb{N}_0$ the map

$$\begin{array}{rcl} \bigoplus_{p+q=n}\operatorname{Hom}(C_p,\mathbb{Z})\otimes\operatorname{Hom}(C'_q,\mathbb{Z}) & \to & \operatorname{Hom}\Big(\bigoplus_{p+q=n}C_p\otimes C'_q,\mathbb{Z}\Big) \\ \varphi_p\otimes\varphi'_q & \mapsto & \mu\circ(\varphi_p\otimes\varphi'_q)\circ\Pi_{p,q} \end{array}$$

is an isomorphism. Applying $(*)$ to the right-hand side we see that it suffices to prove the following claim.

Claim. For every choice of $p,q\in\mathbb{N}_0$ the map

$$\begin{array}{rcl} \operatorname{Hom}(C_p,\mathbb{Z})\otimes\operatorname{Hom}(C'_q,\mathbb{Z}) & \to & \operatorname{Hom}(C_p\otimes C'_q,\mathbb{Z}) \\ \varphi_p\otimes\varphi'_q & \mapsto & \mu\circ(\varphi_p\otimes\varphi'_q) \end{array}$$

is an isomorphism.

Let $p,q\in\mathbb{N}_0$. By our hypothesis on $\mathcal{C}_*$ the chain group C_p is a finitely generated free abelian group. Therefore we can find a basis $a_1,\dots,a_k$ for C_p. We denote by $\widehat{a}_1,\dots,\widehat{a}_k$ the dual basis of $\operatorname{Hom}(C_p,\mathbb{Z})$. We can thus write

$$\operatorname{Hom}(C_p,\mathbb{Z}) = \bigoplus_{i=1}^{k}\mathbb{Z}\cdot\widehat{a}_i \quad\text{and}\quad C_p\otimes C'_q = \bigoplus_{i=1}^{k}\mathbb{Z}\cdot a_i\otimes C'_q.$$

Applying $(*)$ to the above decompositions and both sides of the claim one sees easily that the given homomorphism is an isomorphism. This concludes the proof. □

Now we can finally prove the Künneth Theorem 60.17 for cochain complexes.

Proof of the Künneth Theorem 60.17 for cochain complexes. We only provide an outline of the proof. Let $\mathcal{C}=(C_*,c_*)$ and $\mathcal{C}'=(C'_*,c'_*)$ be chain complexes such that all the chain groups C_n are free abelian groups and such that all the homology groups $H_k(\mathcal{C};\mathbb{Z})$ are finitely generated.

The idea is that one can turn any cochain complex into a chain complex by reversing the signs in the degrees. Thus one can try to reduce the theorem to the Künneth Theorem 43.7. Towards the end of the proof we need to insert Lemma 60.18 to make everything work.

The proof proceeds in three steps:

(1) Since $\mathcal{C}$ is a free chain complex and since all homology groups of $\mathcal{C}$ are finitely generated we can use Lemma 49.8 to replace $\mathcal{C}$ by a chain complex such that all chain groups are finitely generated free abelian groups.

(2) Given $n \in \mathbb{Z}_{\leq 0}$ we write $E_n := \operatorname{Hom}(C_{-n}, \mathbb{Z})$, $e_n := \partial^*_{-n+1} \colon E_n \to E_{n-1}$ and similarly we write $E'_n := \operatorname{Hom}(\mathcal{C}'_{-n}, \mathbb{Z})$ and $e'_n := \partial^*_{-n+1} \colon E'_n \to E'_{n-1}$. It follows immediately from the definitions that $\mathcal{E}_* := (E_*, e_*)$ and $\mathcal{E}'_* := (E'_*, e'_*)^*)$ form chain complexes in negative degrees. (We defined chain complexes to be given by chain groups indexed by $n \in \mathbb{N}_0$ but evidently the same theory also works for chain groups indexed by $\mathbb{Z}$ and $\mathbb{Z}_{\leq 0}$.) Since the groups E_n are free abelian we can apply the Künneth Theorem 43.7 (which also applies to chain complexes in non-positive degrees) to obtain for each $n \in \mathbb{Z}_{\leq 0}$ a natural short exact sequence

$$\begin{array}{ccccccccc} 0 & \to & \bigoplus\limits_{p+q=n} H_p(\mathcal{E}) \otimes H_q(\mathcal{E}') & \to & H_n(\mathcal{E} \otimes \mathcal{E}') & \to & \bigoplus\limits_{p+q=n-1} \operatorname{Tor}(H_p(\mathcal{E}), H_q(\mathcal{E}')) & \to & 0. \\ & & [\varphi] \otimes [\psi] & : & & & & & \end{array}$$

Put differently, for each $n \in \mathbb{N}_0$ we have a natural short exact sequence

$$0 \to \bigoplus_{-p-q=n} \underbrace{H_{-p}(\mathcal{E})}_{=H^p(\mathcal{C};\mathbb{Z})} \otimes \underbrace{H_{-q}(\mathcal{E}')}_{=H^q(\mathcal{E}';\mathbb{Z})} \to H_{-n}(\mathcal{E} \otimes \mathcal{E}') \to \bigoplus_{-p-q=n+1} \operatorname{Tor}(\underbrace{H_{-p}(\mathcal{E})}_{=H^p(\mathcal{C};\mathbb{Z})}, \underbrace{H_{-q}(\mathcal{E}')}_{=H^p(\mathcal{C};\mathbb{Z})}) \to 0.$$

(3) For each $n \in \mathbb{N}_0$ we have isomorphisms

$$\begin{array}{ccccc} H_{-n}(\mathcal{E}_* \otimes \mathcal{E}'_*) & = & H^n(\mathcal{E}_{-*} \otimes \mathcal{E}'_{-*}) & = & H^n\big(\overbrace{\operatorname{Hom}(\mathcal{C}_*, \mathbb{Z})}^{=\mathcal{E}_{-*}} \otimes \overbrace{\operatorname{Hom}(\mathcal{C}'_*, \mathbb{Z})}^{=\mathcal{E}'_{-*}}\big) \xrightarrow{\Omega} H^n(\mathcal{C}_* \otimes \mathcal{C}'_*; \mathbb{Z}). \\ & \uparrow & & \uparrow & \\ & \text{by definition} & & \text{by definition} & \text{by Lemma 60.18 and our hypothesis on } \mathcal{C}_* \end{array}$$

We use this isomorphism to replace the middle term of the second short exact sequence in (2) and we obtain the desired short exact sequence.

Finally suppose that all the chain groups of $\mathcal{C}'$ are also free abelian and that all the homology groups of $\mathcal{C}'$ are also finitely generated. As in (1) we can use Lemma 49.8 to replace $\mathcal{C}$ by a chain complex such that all chain groups are finitely generated free abelian groups. It follows that $\mathcal{E}_*$ is a free chain complex which implies, by the last statement of the Künneth Theorem 43.7, that the short exact sequence splits. □

Now we are in a position to prove the Künneth Theorem 60.16 for cohomology groups.

Proof of the Künneth Theorem 60.16 for cohomology groups $(*)$. Let X and Y be two topological spaces such that all the homology groups of X are finitely generated. We denote by $p \colon X \times Y \to X$ and $q \colon X \times Y \to Y$ the obvious projection maps. Throughout the proof we use all the definitions that we introduced in Section 60.2.

It follows from the Eilenberg-Zilber Theorem 56.1, together with comparing the conclusion of the Künneth Theorem 60.17 for cochain complexes with the desired statement of the Künneth Theorem 60.16 for cohomology groups, that it remains to prove the following claim.

Claim. For any $k, l \in \mathbb{N}_0$ the map

$$\begin{array}{rcl} H^k(X;\mathbb{Z}) \otimes H^l(Y;\mathbb{Z}) & \to & H^{k+l}(X \times Y;\mathbb{Z}) \\ [\alpha] \otimes [\beta] & \mapsto & [p^*\alpha \cup q^*\beta] \end{array}$$

agrees with the map that is given by

$$[\alpha] \otimes [\beta] \quad \mapsto \quad [(\alpha \otimes \beta) \circ \Pi_{k,l} \circ \Theta].$$

Let $\alpha \in C^k(X;\mathbb{Z})$ and $\beta \in C^l(Y;\mathbb{Z})$ be cocycles. We have to show that the two cocycles

$$\underbrace{p^*\alpha \cup q^*\beta}_{=:\aleph} \quad \text{and} \quad \underbrace{(\alpha \otimes \beta) \circ \Pi_{k,l}}_{=:\beth} \circ \Theta$$

are cohomologous.

As usual, given a topological space W we denote by $\epsilon_W \colon C_0(W) \to \mathbb{Z}$ the augmentation map. Clearly ϵ_W is a cocycle so by Lemma 60.8 (2) we can extend ϵ_W to a chain map $C_*(W) \to \mathbb{Z}$ which, by a slight abuse of notation, we also denote by ϵ_W. It follows from the Eilenberg-Zilber Theorem 56.1, Theorem 60.15 and Lemma 60.8 (2) that the maps

$$\underbrace{(-1)^{kl} \cdot \epsilon_{X\times Y}[k+l] \circ ((p^*\alpha \cup q^*\beta) \mathbin{\widetilde{\cap}} -)}_{=:\aleph'} \colon C_{k+l}(X \times Y) \to \mathbb{Z}[k+l] = \mathbb{Z}$$

and

$$\underbrace{\epsilon_{X\times Y}[k+l] \circ \Upsilon[k+l] \circ \Psi_{k,l} \circ (\alpha \mathbin{\widetilde{\cap}} - \otimes \beta \mathbin{\widetilde{\cap}} -)}_{=:\beth'} \circ \Theta \colon C_{k+l}(X \times Y) \to \mathbb{Z}[k+l] = \mathbb{Z}$$

are cocycles that are cohomologous. It remains to prove the following two subclaims.

Subclaim. We have

$$\aleph' = (-1)^{kl} \cdot \aleph \colon C_{k+l}(X \times Y) \ \to \ \mathbb{Z}.$$

Let $\sigma \in C_{k+l}(X \times Y)$. Then

$$\aleph'(\sigma) \ \underset{\substack{\uparrow \\ \text{under the identification } \mathbb{Z}[k+l] = \mathbb{Z} \text{ we} \\ \text{have } \epsilon_{X\times Y}[k+l] = \epsilon_{X\times Y}}}{=} \ (-1)^{kl} \cdot \epsilon_{X\times Y}((p^*\alpha \cup q^*\beta) \mathbin{\widetilde{\cap}} \sigma) \ \underset{\substack{\uparrow \\ \text{by definition of } \widetilde{\cap}\text{, see page 1394,} \\ \text{together with Lemma 59.4 (1)}}}{=} \ (-1)^{kl} \cdot (p^*\alpha \cup q^*\beta)(\sigma) \ = \ (-1)^{kl} \cdot \aleph(\sigma).$$

This concludes the proof of the subclaim.

Subclaim. We have

$$\beth' = (-1)^{kl} \cdot \beth \colon (C_*(X) \otimes C_*(Y))_{k+l} \ \to \ \mathbb{Z}.$$

We have to show that both sides take the same value on any tensor product of the form $\sigma_i \otimes \sigma_j$ with $i+j=k+l$ and $\sigma_i \in C_i(X)$ and let $\sigma_j \in C_j(Y)$. It follows easily from the definition that both sides are zero for $\sigma_i \otimes \sigma_j$ with $(i,j) \neq (k,l)$. So let $\sigma_k \in C_k(X)$ and let $\sigma_l \in C_l(Y)$. Then

$$\begin{aligned}
\beth'(\sigma_k \otimes \sigma_l) &= (\epsilon_{X\times Y} \circ \Upsilon)[k+l] \circ \Psi_{k,l} \circ (\alpha \mathbin{\widetilde{\cap}} \sigma_k \otimes \beta \mathbin{\widetilde{\cap}} \sigma_l) \\
&\quad \uparrow \\
&\quad \text{since } \epsilon_{X\times Y}[k+l] \circ \Upsilon[k+l] = (\epsilon_{X\times Y} \circ \Upsilon)[k+l] \\
&= (-1)^{kl} \cdot (\epsilon_X \otimes \epsilon_Y) \circ (\alpha \cap \sigma_k \otimes \beta \cap \sigma_l) && = (-1)^{kl} \cdot \alpha(\sigma_k) \cdot \beta(\sigma_l) \\
&\quad \uparrow && \uparrow \\
&\quad \text{we use } \epsilon_{X\times Y} \circ \Upsilon = \epsilon_X \otimes \epsilon_Y \colon (C_*(X) \otimes C_*(Y))_0 \to \mathbb{Z} \otimes \mathbb{Z} = \mathbb{Z}, && \text{by Lemma 59.4} \\
&\quad \text{the definition of } \Psi_{k,l} \text{ in Lemma 60.14 and the definition of } \widetilde{\cap} \text{ on page 1394} \\
&= (-1)^{kl} \cdot ((\alpha \otimes \beta) \circ \Pi_{k,l})(\sigma_k \otimes \sigma_l) && = (-1)^{kl} \cdot \beth(\sigma_k \otimes \sigma_l).
\end{aligned}$$

This concludes the proof of the second subclaim, thus also of the claim and therefore also of the theorem. □

60.4. **The cohomology ring of product topological spaces.** In this section we will determine the cohomology ring of the m-dimensional torus $(S^1)^m$ and more generally, under some mild technical hypothesis, we will determine the cohomology ring of a product $X \times Y$ of topological spaces in terms of the cohomology rings of X and Y.

We recall the following definition.

Definition.

(1) A *graded ring* is a ring R together with a decomposition $R = \bigoplus_{n\in\mathbb{N}_0} R_n$ such that for any $m,n \in \mathbb{N}_0$ the multiplication map restricts to a map $R_m \times R_n \to R_{m+n}$. We say that an element r of R that lies in some R_n is *homogeneous* and we refer to $\deg(r) := n$ as the degree of r.

(2) A homomorphism $\varphi\colon A \to B$ between graded rings is a ring homomorphism that preserves the gradings, i.e. that satisfies $\varphi(A_n) \subset B_n$ for all $n \in \mathbb{N}_0$.

(3) A graded ring $R = \bigoplus_{n\in\mathbb{N}_0} R_n$ such that for any two homogeneous elements a and b the equality $a \cdot b = (-1)^{\deg(a)\cdot\deg(b)} \cdot b \cdot a$ holds is called a *superalgebra*.

Examples.

(1) Proposition 57.8 says in particular that for any topological space X the cohomology ring $(H^*(X;\mathbb{Z}), \cup)$ is a superalgebra. Furthermore Lemma 57.10 implies that for any map $f\colon X \to Y$ the induced map $f^*\colon H^*(Y;\mathbb{Z}) \to H^*(X;\mathbb{Z})$ is a homomorphism of superalgebras.

(2) The polynomial ring $\mathbb{F}_2[a] = \bigoplus_{i\in\mathbb{N}_0} \mathbb{F}_2 \cdot a^i$ is a superalgebra if we equip the ring with the grading that is determined by setting $\deg(a^i) := i$.

(3) The polynomial ring $\mathbb{Z}[x] = \bigoplus_{i\in\mathbb{N}_0} \mathbb{Z} \cdot x^i$ is a superalgebra if we equip the ring with the grading that is determined by setting $\deg(x^i) := 2i$.

(4) More generally, the polynomial ring $\mathbb{Z}[x_1, \dots, x_k]$ in k variables $x_1, \dots, x_k$ can be viewed as a superalgebra by setting $\deg(x_1^{r_1} \cdot \dots \cdot x_k^{r_k}) = 2(r_1 + \dots + r_k)$.

(5) The ring $\mathbb{Z}[x]/(x^2) = \mathbb{Z} \oplus \mathbb{Z} \cdot x$ is a superalgebra by viewing elements in $\mathbb{Z}$ as elements of degree 0 and by viewing elements in $\mathbb{Z} \cdot x$ as elements of degree 1. Note that the map

$$\begin{array}{rcl} \mathbb{Z}[x]/(x^2) & \to & H^*(S^1; \mathbb{Z}) \\ a \cdot 1 + b \cdot x & \mapsto & a \cdot 1_{S^1} + b \cdot [S^1]^* \end{array}$$

is an isomorphism of superalgebras.

(6) We consider the ring

$$\Lambda[x_1, \dots, x_k] := \mathbb{Z}[x_1, \dots, x_k]/\text{ideal generated by } x_1^2, \dots, x_k^2, \{x_i x_j + x_j x_i\}_{i,j=1,\dots,k}.$$

In this ring we use the symbol "$\wedge$" for multiplication instead of "$\cdot$". For example for any $i, j \in \{1, \dots, k\}$ we have $x_i \wedge x_i = 0$ and $x_i \wedge x_j = -x_j \wedge x_i$. This ring can be viewed in a unique way as a superalgebra such that $\deg(x_j) = 1$ for $j = 1, \dots, k$. The ring $\Lambda[x_1, \dots, x_k]$ is often referred to as the *exterior algebra on generators* $x_1, \dots, x_k$, see e.g. [Hat, p. 217] and [Mac, p. 183].[1039] We leave it as an amusing exercise to verify that $\Lambda[x_1, \dots, x_k]$ is a free abelian group of rank 2^k where a basis is given by

$$\{x_{n_1} \wedge \dots \wedge x_{n_l} \,|\, n_1 < \dots < n_l\}.$$

In Exercise 51.2 we saw that any sequence $\{A_n\}_{n \geq 1}$ of finitely generated abelian groups, with A_1 torsion-free, can appear as the sequence of cohomology groups $H^*(X; \mathbb{Z})$ of some CW-complex. It is natural to ask whether any superalgebra structure can be realized as the cohomology ring of a topological space. More precisely, we have the following question, to which we will return later.

Question 60.19. *Let $R = \bigoplus_{n \in \mathbb{N}_0} R_n$ be superalgebra such that ${}_0 \cong \mathbb{Z}$, R_1 is torsion-free and such that all R_n are finitely generated. Does there exist a topological space X such that $(H^*(X; \mathbb{Z}), \cup)$ is isomorphic to R?*

Since there is not much to say right now about this question we continue with the next definition.

[1039] If we replace the $\mathbb{Z}$-coefficients by $\mathbb{R}$-coefficients we obtain a ring that we denote by $\Lambda_{\mathbb{R}}[x_1, \dots, x_k]$. This ring is isomorphic to the ring $\wedge^*(\mathbb{R}^k)^* = \bigoplus_{j=0}^{k} \wedge^j (\mathbb{R}^k)^*$ of alternating forms on $\mathbb{R}^k$, where the ring structure on $\wedge^*(\mathbb{R}^k)^*$ is given by the wedge product of alternating forms. More precisely a ring isomorphism is given by

$$\begin{array}{rcl} \Lambda_{\mathbb{R}}[x_1, \dots, x_k] & \to & \wedge^*(\mathbb{R}^k)^* \\ x_{i_1} \wedge \dots \wedge x_{i_r} & \to & dy_{i_1} \wedge \dots \wedge dy_{i_r} \end{array}$$

where $dy_i \colon \mathbb{R}^k \to \mathbb{R}$ is the projection onto the i-th coordinate.

Definition. The tensor product of two superalgebras $A = \bigoplus_{n\in\mathbb{N}_0} A_n$ and $B = \bigoplus_{n\in\mathbb{N}_0} B_n$ is defined as the graded abelian group

$$A \otimes B \;:=\; \bigoplus_{n\in\mathbb{N}_0} \underbrace{\bigoplus_{p+q=n} A_p \otimes B_q}_{=:(A\otimes B)_n}$$

where for $a_k \in A_k, a_l \in A_l, b_m \in B_m$ and $b_n \in B_n$ the multiplication is given by

$$(a_k \otimes b_l) \cdot (a_m \otimes b_n) \;=\; (-1)^{lm} \cdot a_k \cdot a_m \otimes b_l \cdot b_n.$$

Lemma 60.20.

(1) *The tensor product of two superalgebras is again a superalgebra.*
(2) *The tensor product of superalgebras is associative, i.e. for any three superalgebras A, B and C the map*

$$(A \otimes B) \otimes C \;\to\; A \otimes (B \otimes C)$$

that is induced by

$$(a \otimes b) \otimes c \;\mapsto\; a \otimes (b \otimes c)$$

is an isomorphism of superalgebras.

It follows immediately from Lemma 60.20 (2) that we can ignore parentheses when we consider the tensor product of several superalgebras.

Proof $(*)$. Let A, B and C be superalgebras and let $a_k \in A_k, a_l \in A_l, b_m \in B_m$ and $b_n \in B_n$.

(1) We have the following equalities:

$$\begin{aligned}(a_k \otimes b_l)\cdot(a_m \otimes b_n) \;&=\; (-1)^{lm}\cdot a_k\cdot a_m \otimes b_l\cdot b_n \;=\; (-1)^{lm+km+ln}\cdot a_m\cdot a_k \otimes b_n\cdot b_l\\ &=\; (-1)^{lm+km+ln+kn}\cdot(a_m \otimes b_n)\cdot(a_k \otimes b_l)\\ &=\; (-1)^{(m+n)(k+l)}\cdot(a_m \otimes b_n)\cdot(a_k \otimes b_l)\\ &=\; (-1)^{\deg(a_m\otimes b_n)\cdot\deg(a_k\otimes b_l)}\cdot(a_m \otimes b_n)\cdot(a_k \otimes b_l).\end{aligned}$$

It follows immediately that $A \otimes B$ is again a superalgebra.

(2) It suffices to show that the indicated map is a homomorphism of superalgebras. Thus let $c_r \in C_r$ and $c_s \in C_s$. Then

$$\begin{aligned}((a_k \otimes b_l) \otimes c_r)\cdot((a_m \otimes b_n) \otimes c_s) \;&=\; (-1)^{r(m+n)}\cdot((a_k \otimes b_l)\cdot(a_m \otimes b_n)) \otimes (c_r\cdot c_s)\\ &=\; (-1)^{r(m+n)+lm}\cdot(a_k\cdot a_m \otimes b_l\cdot b_n \otimes c_r\cdot c_s)\\ &=\; (-1)^{m(l+r)}\cdot(a_k\cdot a_m \otimes (b_l \otimes c_r)\cdot(b_n \otimes c_s))\\ &=\; (a_k \otimes (b_l \otimes c_r))\cdot(a_m \otimes (b_n \otimes c_s)).\end{aligned}$$

□

Examples.

(1) As above we view the polynomial rings $\mathbb{F}_2[a]$ and $\mathbb{F}_2[b]$ as superalgebras by setting $\deg(a^i) = \deg(b^i) = i$. We consider the map

$$\begin{aligned}\mathbb{F}_2[a] \otimes \mathbb{F}_2[b] \;&\to\; \mathbb{F}_2[a,b]\\ a^r \otimes b^s \;&\mapsto\; a^r \cdot b^s.\end{aligned}$$

Using Lemma 42.3 (1) it is straightforward to show that this map is an isomorphism of abelian groups. One can easily verify that the map is a homomorphism of superalgebras. Summarizing we have convinced ourselves that this map is in fact an isomorphism of superalgebras.

(2) As before we view the polynomial rings $\mathbb{Z}[x_j]$, $j = 1, \dots, k$ as superalgebras with $\deg(x_j^i) = 2i$. We consider the map

$$\begin{array}{rcl} \mathbb{Z}[x_1] \otimes \cdots \otimes \mathbb{Z}[x_k] & \to & \mathbb{Z}[x_1, \dots, x_k] \\ x_1^{r_1} \otimes \cdots \otimes x_k^{r_k} & \mapsto & x_1^{r_1} \cdot \dots \cdot x_k^{r_k}. \end{array}$$

The same argument as in (1) shows that this map is an isomorphism of superalgebras.

(3) As above we view the rings $\mathbb{Z}[x_j]/(x_j^2)$ as superalgebras with $\deg(x_j) = 1$. We leave it as an exercise to verify that the map

$$\begin{array}{rcl} \mathbb{Z}[x_1]/(x_1^2) \otimes \cdots \otimes \mathbb{Z}[x_k]/(x_k^2) & \to & \Lambda[x_1, \dots, x_k] \\ x_1^{r_1} \otimes \cdots \otimes x_k^{r_k} & \mapsto & x_1^{r_1} \wedge \cdots \wedge x_k^{r_k} \end{array}$$

is an isomorphism of superalgebras.

The following proposition explains our sudden interest in tensor products of superalgebras.

Proposition 60.21. *Let X and Y be two topological spaces. We denote by $p\colon X \times Y \to X$ and $q\colon X \times Y \to Y$ the obvious projection maps.*

(1) *The map*

$$\begin{array}{rcl} \Phi\colon H^*(X;\mathbb{Z}) \otimes H^*(Y;\mathbb{Z}) & \to & H^*(X \times Y;\mathbb{Z}) \\ \varphi \otimes \psi & \mapsto & p^*\varphi \cup q^*\psi \end{array}$$

is a homomorphism of superalgebras.

(2) *If all the homology groups of X are finitely generated and torsion-free, then the homomorphism from* (1) *is in fact an isomorphism.*

Proof. Let X and Y be two topological spaces.

(1) Let $\varphi_k \in H^k(X;\mathbb{Z})$, $\psi_l \in H^l(Y;\mathbb{Z})$, $\varphi_m \in H^m(X;\mathbb{Z})$ and $\psi_n \in H^n(Y;\mathbb{Z})$. Then

$$\begin{array}{rcl} \overbrace{\Phi\big((-1)^{lm}\cdot(\varphi_k \cup \varphi_m) \otimes (\psi_l \cup \psi_n)\big)}^{=\Phi((\varphi_k\otimes\psi_l)\cdot(\varphi_m\otimes\psi_n))} & & = (-1)^{lm}\cdot p^*(\varphi_k \cup \varphi_m) \cup q^*(\psi_l \cup \psi_n) \\ = (-1)^{lm}\cdot(p^*(\varphi_k) \cup p^*(\varphi_m) \cup q^*(\psi_l) \cup q^*(\psi_n)) & & = \underbrace{p^*(\varphi_k) \cup q^*(\psi_l) \cup p^*(\varphi_m) \cup q^*(\psi_n)}_{=\Phi(\varphi_k\otimes\psi_l)\cup\Phi(\varphi_m\otimes\psi_n))}. \\ \uparrow & & \uparrow \\ \text{Proposition 57.8} & & \text{Lemma 57.10} \end{array}$$

It follows immediately that Φ is a homomorphism of superalgebras.

(2) Now suppose that all the homology groups of X are finitely generated and torsion-free. This hypothesis allows us to apply the Künneth Theorem 60.16 for cohomology

groups and we obtain the following short exact sequence:

$$0 \to \bigoplus_{k+l=n} H^k(X;\mathbb{Z}) \otimes H^l(Y;\mathbb{Z}) \to H^n(X \times Y;\mathbb{Z}) \to \bigoplus_{k+l=n+1} \operatorname{Tor}(H^k(X;\mathbb{Z}), H^l(Y;\mathbb{Z})) \to 0.$$
$$\varphi \otimes \psi \mapsto p^*\varphi \cup q^*\psi$$

Since the homology groups of X are torsion-free we obtain from the Universal Coefficient Theorem 51.13 for Cohomology Groups that the cohomology groups $H^k(X;\mathbb{Z})$ are also torsion-free. But by Lemma 42.17 this implies that all the Tor-terms on the right-hand side of the short exact sequence vanish. □

The following proposition in particular provides an answer to Question 58.11 (1).

Proposition 60.22. *Let $n \in \mathbb{N}_0$. We denote by $T = (S^1)^n$ the n-dimensional torus. For $i = 1, \dots, n$ we denote by $p_i \colon T \to S^1$ the projection onto the i-th factor. Then there exists a unique isomorphism*

$$\psi \colon \Lambda[x_1, \dots, x_n] \quad \to \quad H^*(T;\mathbb{Z})$$

of superalgebras which has the property that for each $i \in \{1, \dots, n\}$ we have

$$\psi(x_i) \quad = \quad p_i^*([S^1]^*).$$

Proof. We consider the following isomorphism of superalgebras

$$\begin{array}{ccccccc} \Lambda[x_1, \dots, x_n] & \xleftarrow{\cong} & \mathbb{Z}[x_1]/(x_1^2) \otimes \dots \otimes \mathbb{Z}[x_k]/(x_k^2) & \xrightarrow{\cong} & H^*(S^1;\mathbb{Z}) \otimes \dots \otimes H^*(S^1;\mathbb{Z}) & \xrightarrow{\cong} & H^*((S^1)^n;\mathbb{Z}). \\ \uparrow & & \uparrow & & \uparrow & & \\ \text{isomorphism from page 1409} & & \text{isomorphism from page 1407} & & \text{Proposition 60.21} & & \end{array}$$

It is clear from the definitions of the various maps that the map from left to right sends each x_i to $p_i^*([S^1]^*)$. The composition of the isomorphisms thus gives us the desired isomorphism. The uniqueness follows immediately from the fact that the x_i generate $\Lambda[x_1, \dots, x_n]$ as a ring. □

The following corollary gives in particular a negative answer to Question 58.9.

Corollary 60.23. *For the n-dimensional torus $T = (S^1)^n$ the Lusternik-Schnirelmann category* $\operatorname{cat}(T)$ *equals n.*

Proof. On page 1367 we showed that $\operatorname{cat}(T) \leq n$. In the following we will show that the reverse inequality holds. Let $\psi \colon \Lambda[x_1, \dots, x_n] \to H^*(T;\mathbb{Z})$ be the isomorphism of graded rings provided by Proposition 60.22. By the discussion on page 1407 we know that $x_1 \wedge \dots \wedge x_n \neq 0$. Since ψ is an isomorphism we deduce that $\psi(x_1) \cup \dots \cup \psi(x_n) \neq 0$, i.e. the cup length $c(T)$ of T is at least n. We know from Proposition 58.10 that $\operatorname{cat}(T) \geq c(T)$. Thus we obtain that $\operatorname{cat}(T) \geq n$. □

We conclude this chapter with the following variation of Proposition 60.21.

Proposition 60.24. *Let X and Y be two topological spaces. We denote by $p \colon X \times Y \to X$ and $q \colon X \times Y \to Y$ the obvious projection maps. If all the homology groups of X are finitely*

generated, then the map

$$\begin{array}{rcl} \Phi\colon H^*(X;\mathbb{F}_2)\otimes H^*(Y;\mathbb{F}_2) & \to & H^*(X\times Y;\mathbb{F}_2) \\ \varphi\otimes\psi & \mapsto & p^*\varphi\cup q^*\psi \end{array}$$

is an isomorphism of superalgebras.

In the proof of Proposition 60.24 we will need the following theorem which is a variation of the Künneth Theorem 60.17 for cochain complexes.

Theorem 60.25. *Let $\mathcal{C}$ and $\mathcal{C}'$ be chain complexes. If $\mathcal{C}$ is a free chain complex and if all homology groups of $\mathcal{C}$ are finitely generated, then for every $n\in\mathbb{N}_0$ there exists a natural isomorphism*

$$\bigoplus_{k+l=n} H^k(\mathcal{C};\mathbb{F}_2)\otimes H^l(\mathcal{C}';\mathbb{F}_2) \xrightarrow{\Xi} H^n(\mathcal{C}\otimes\mathcal{C}';\mathbb{F}_2).$$

The proof of Theorem 60.25 is evidently very similar to the proof of the Künneth Theorem 60.17 for cochain complexes. We refer to [Mun, Theorem 60.6] for a proof.

Proof of Proposition 60.24. The proof is almost the same as the proof of Proposition 60.21. More precisely, we first note that if in the proof of the Künneth Theorem 60.16 for cohomology groups we replace the Künneth Theorem 60.17 for cochain complexes by Theorem 60.25 we obtain that the map

$$\begin{array}{rcl} \bigoplus_{k+l=n} H^k(X;\mathbb{F}_2)\otimes H^l(Y;\mathbb{F}_2) & \to & H^n(X\times Y;\mathbb{F}_2) \\ \varphi\otimes\psi & \mapsto & p^*\varphi\cup q^*\psi \end{array}$$

is an isomorphism. But the same argument as in the proof of Proposition 60.21 shows that this map is in fact a homomorphism of superalgebras. □

Exercises for Chapter 60.

Exercise 60.1. Let X be a topological space. Recall that Proposition 57.8 says that for any $a\in H^k(X;\mathbb{Z})$ and $b\in H^l(X;\mathbb{Z})$ we have

$$a\cup b \;=\; (-1)^{kl}\cdot b\cup a.$$

Provide a proof of this statement using the original definition of the cup product from page 1333 and using Lemma 60.7.

Exercise 60.2. Let $g\in\mathbb{N}$ and denote by Σ_g the surface of genus g. Show that the Lusternik-Schnirelmann category of $S^1\times\Sigma_g$ is greater or equal than three.

Exercise 60.3. Let Σ be the surface of genus 2, let $q\colon\Sigma\times S^1\to\Sigma$ be the projection map and let $p\colon\Sigma\to S^1$ be the map shown in Figure 742. Determine the cap product

$$q(p^*([S^1]^*))\cap[\Sigma\times S^1] \;\in\; H_2(\Sigma\times S^1;\mathbb{Z})$$

up to sign.

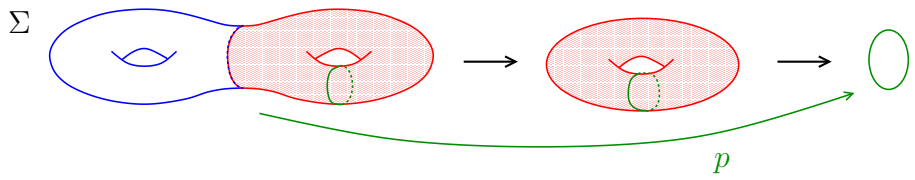

FIGURE 742.

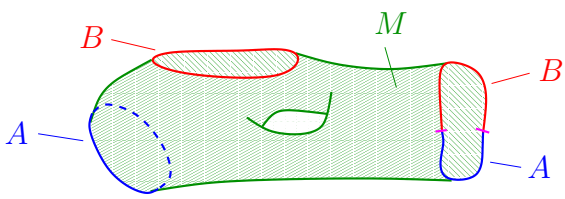
61. Poincaré-duality

61.1. **The Poincaré Duality Theorem.** The following theorem is by far the most important theorem regarding homology and cohomology groups of topological manifolds.[1040]

Theorem 61.1. (Poincaré Duality Theorem) *Let M be a compact, non-empty n-dimensional topological manifold and let R be a commutative ring. We suppose that M is R-oriented. We denote by $[M] \in H_n(M, \partial M; R)$ the R-fundamental class. Furthermore suppose that we are given a decomposition $\partial M = A \cup B$ where A and B are compact $(n-1)$-dimensional submanifolds of ∂M such that $A \cap B = \partial A = \partial B$. Then for each $k \in \mathbb{N}_0$ the map*[1041]

$$\begin{array}{rcl} H^k(M, A; R) & \xrightarrow{\cong} & H_{n-k}(M, B; R) \\ \sigma & \mapsto & \sigma \cap [M] \end{array}$$

is an isomorphism.



for all commutative rings R we have
$H^k(M, A; R) \xrightarrow{\cong} H_{2-k}(M, B; R)$

Figure 743. Illustration of the Poincaré Duality Theorem 61.1.

We proceed as follows: in this section and the next section we discuss several special cases and applications of the Poincaré Duality Theorem 61.1. In the subsequent section we will first provide a "pictorial" proof for closed manifolds and $\mathbb{F}_2$-coefficients. In the last two sections of the chapter we will then provide a rigorous, but arguably less intuitive proof, of the theorem. In the coming chapters we will then use the Poincaré Duality Theorem 61.1 to prove many more statements.

Notation. The isomorphism of the Poincaré Duality Theorem 61.1 is called the *Poincaré Duality isomorphism*. We denote it and its inverse both by PD_M, i.e. with the notation of

[1040]The theorem is named after the French mathematician Henri Poincaré whom we had already encountered twice before. He had formulated a simplified version of the theorem in 1895. But it took much longer to come up with a rigorous proof of the theorem as it is stated here.

[1041]Recall that Proposition 50.12 (5) implies that (M, A, B) is an excisive triad. In particular, following the definition of the relative cap product on page 1378, we obtain a relative cap product

$$H^k(M, A; R) \times \underbrace{H_n(M, \overbrace{A \cup B}^{=\partial M}; R)}_{\text{contains } [M]} \xrightarrow{\cap} H_{n-k}(X, B; R).$$

This shows that the map in the Poincaré Duality Theorem is in fact defined.

the Poincaré Duality Theorem 61.1 we have the isomorphism[1042]

$$\begin{array}{rcl} \mathrm{PD}_M\colon H^k(M,A;R) & \xrightarrow{\cong} & H_{n-k}(M,B;R) \\ \sigma & \mapsto & \sigma\cap[M] \end{array}$$

together with the inverse

$$\mathrm{PD}_M\colon H_{n-k}(M,B;R) \xrightarrow{\cong} H^k(M,A;R).$$

The isomorphisms PD_M thus allow us to go back and forth between homology and cohomology of an R-oriented manifold.

Remark. Let M be a compact n-dimensional topological manifold.

(1) Proposition 45.24 says that M is $\mathbb{F}_2$-orientable, i.e. the duality statement holds with $\mathbb{F}_2$-coefficients without any further assumptions on M.
(2) If M is in fact orientable, then it follows from Lemma 45.25 that M is R-orientable for any commutative ring R. In particular the duality statement holds for any commutative ring.
(3) The two most important instances of A and B are that we have either $A=\varnothing$ or $A=\partial M$. Under the hypothesis of the Poincaré Duality Theorem 61.1 we then get isomorphisms

$$\begin{array}{rcl} H^k(M;R) & \xrightarrow{\cong} & H_{n-k}(M,\partial M;R) \\ \sigma & \mapsto & \sigma\cap[M] \end{array} \quad \text{and} \quad \begin{array}{rcl} H^k(M,\partial M;R) & \xrightarrow{\cong} & H_{n-k}(M;R) \\ \sigma & \mapsto & \sigma\cap[M]. \end{array}$$

(4) For topological manifolds with non-empty boundary the Poincaré Duality Theorem is sometimes also called the *Poincaré-Lefschetz Duality Theorem.*
(5) Let P be a point in M and suppose that M is connected. As we pointed out on page 1378, we have $[M]^*\cap[M]=[P]\in H_0(M;\mathbb{Z})$. Therefore we obtain that $\mathrm{PD}_M([P])=[M]^*$.

Examples. Earlier we had already performed several explicit calculations:

(1) On page 1375 we saw that for any surface Σ the map

$$-\cap[\Sigma]\colon H^1(\Sigma;\mathbb{Z}) \to H_1(\Sigma;\mathbb{Z})$$

is an isomorphism. On page 1376 we had obtained similar results for $\mathbb{R}\mathrm{P}^2$ with $\mathbb{F}_2$-coefficients.
(2) On page 1379 we saw that for the annulus $X=S^1\times[0,1]$ the map

$$-\cap[X]\colon H^1(X;\mathbb{Z}) \to H_1(X,\partial X;\mathbb{Z})$$

is an isomorphism.

These calculations can be viewed as special case of the Poincaré Duality Theorem 61.1.

[1042]When M is understood, then we drop it from the notation.

It is also instructive to consider the cases $k = 0$ and $k = 1$ of the Poincaré Duality Theorem 61.1. For example, for $k = 0$ and the notation of the theorem we obtain for an compact, connected, non-empty n-dimensional topological manifold that

$$H_n(M, \partial M; \mathbb{Z}) \cong H^0(M; \mathbb{Z}) \underset{\substack{\uparrow \\ \text{Proposition 48.11}}}{\cong} \mathbb{Z} \text{ and } H_n(M; \mathbb{Z}) \cong H^0(M, \partial M; \mathbb{Z}) \underset{\substack{\uparrow \\ \text{Proposition 48.11 and page 1171}}}{\cong} \begin{cases} \mathbb{Z}, & \text{if } \partial M = \varnothing, \\ 0, & \text{if } \partial M \neq \varnothing. \end{cases}$$

This calculation is consistent with the results from Theorem 46.2 and Theorem 46.4 (1).

Next we consider the case $k = 1$ in the Poincaré Duality Theorem 61.1. As we will see, we obtain the following corollary which gives a new proof of Proposition 39.17 and Proposition 46.21 (1) and of the claim on page 1225.

Corollary 61.2. *Let M be a compact orientable n-dimensional topological manifold. Then the homology groups $H_{n-1}(M; \mathbb{Z})$ and $H_{n-1}(M, \partial M; \mathbb{Z})$ are free abelian groups.*

Proof. We have

$$\begin{aligned} H_{n-1}(M; \mathbb{Z}) &\underset{\substack{\uparrow \\ \text{Poincaré Duality Theorem 61.1}}}{\cong} H^1(M, \partial M; \mathbb{Z}) \underset{\substack{\uparrow \\ \text{Universal Coefficient Theorem 51.13}}}{\cong} \operatorname{Hom}(H_1(M, \partial M), \mathbb{Z}) \oplus \operatorname{Ext}(\overbrace{H_0(M, \partial M)}^{\cong \mathbb{Z}^r \text{ for some } r \in \mathbb{N}_0}, \mathbb{Z}) \\ &\underset{\substack{\uparrow \\ \text{Lemma 51.5 (3)}}}{\cong} \operatorname{Hom}(H_1(M, \partial M), \mathbb{Z}) \underset{\substack{\uparrow \\ \text{by Proposition 45.2 the group } H_1(M, \partial M) \text{ is finitely generated, hence} \\ \text{it is isomorphic to } \mathbb{Z}^k \oplus T \text{ for some } k \in \mathbb{N} \text{ and some finite group } T}}{\cong} \operatorname{Hom}(H_1(\mathbb{Z}^k \oplus T), \mathbb{Z}) \cong \mathbb{Z}^k. \end{aligned}$$

Basically the same argument also shows that $H_{n-1}(M, \partial M; \mathbb{Z})$ is a free abelian group. $\square$

The following theorem says that for a closed topological manifold the homology and cohomology groups with coefficients in a *field* are symmetric around the middle dimension.

Theorem 61.3. (Poincaré Duality Theorem with field coefficients) *Let M be a compact n-dimensional topological manifold and let $k \in \mathbb{N}_0$.*

(1) *We have*[1043]

$$\dim_{\mathbb{F}_2}(H_k(M; \mathbb{F}_2)) = \dim_{\mathbb{F}_2}(H_{n-k}(M, \partial M; \mathbb{F}_2))$$

and

$$\dim_{\mathbb{F}_2}(H^k(M; \mathbb{F}_2)) = \dim_{\mathbb{F}_2}(H^{n-k}(M, \partial M; \mathbb{F}_2)).$$

(2) *If M is orientable, then for any field $\mathbb{F}$ we have*

$$\dim_{\mathbb{F}}(H_k(M; \mathbb{F})) = \dim_{\mathbb{F}}(H_{n-k}(M, \partial M; \mathbb{F}))$$

and

$$\dim_{\mathbb{F}}(H^k(M; \mathbb{F})) = \dim_{\mathbb{F}}(H^{n-k}(M, \partial M; \mathbb{F})).$$

[1043]The statement implies of course that $H^k(M; \mathbb{F})$ and $H^{n-k}(M, \partial M; \mathbb{F})$ are isomorphic. We prefer to state the result in terms of dimensions to stress that the isomorphism is not natural.

Examples.

(1) We consider the real projective space $\mathbb{R}\mathrm{P}^n$. On page 1028 we had determined that

$$H_k(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2) \;\cong\; \begin{cases} \mathbb{F}_2, & \text{if } k=0,\dots,n,\\ 0, & \text{otherwise.}\end{cases}$$

So the homology groups with $\mathbb{F}_2$-coefficients are in particular symmetric, which is exactly what the above Poincaré Duality Theorem 61.3 with $\mathbb{F}_2$-coefficients predicts.

(2) Towards the end of the 19th century, when Henri Poincaré first developed what became known as Poincaré Duality he thought that for any closed orientable connected n-dimensional manifold the groups $H_k(M;\mathbb{Z})$ and $H_{n-k}(M;\mathbb{Z})$ are isomorphic. A Danish mathematician, Poul Heegaard, pointed out to him that this is not true in general, for example for the lens space $L(p,q)$ we have by Lemma 40.12 that

$$H_1(L(p,q);\mathbb{Z}) \;\cong\; \mathbb{Z}_p \quad \text{but} \quad H_2(L(p,q);\mathbb{Z}) \;=\; 0.$$

This shows that the homology groups with $\mathbb{Z}$-coefficients are *not* symmetric.

Proof. Let M be a compact n-dimensional topological manifold. We have

$$\begin{aligned}\dim_{\mathbb{F}_2}(H_k(M;\mathbb{F}_2)) \;&\underset{\substack{\uparrow\\ \text{Theorem 61.1}}}{=}\; \dim_{\mathbb{F}_2}(H^{n-k}(M,\partial M;\mathbb{F}_2)) \;\underset{\substack{\uparrow\\ \text{Proposition 51.18}}}{=}\; \dim_{\mathbb{F}_2}(\mathrm{Hom}(H_{n-k}(M,\partial M;\mathbb{F}_2),\mathbb{F}_2))\\ &\underset{\substack{\uparrow\\ \text{since Proposition 45.2 (3) says that } H_{n-k}(M,\partial M;\mathbb{F}_2) \text{ is finite-dimensional}}}{=}\; \dim_{\mathbb{F}_2}(H_{n-k}(M,\partial M;\mathbb{F}_2)).\end{aligned}$$

The proofs of all other statements are basically the same. □

Remark. Let M be a compact topological n-dimensional manifold and let $\mathbb{F}$ be a field. In Proposition 45.2 (2) we had mentioned that all homology groups $H_k(M;\mathbb{F})$ are finite-dimensional. But this proof relied on the slightly mysterious Theorem 45.1. Now we can give an alternative argument if M is closed and orientable. Indeed, we have

$$H_k(M;\mathbb{F}) \;\underset{\substack{\uparrow\\ \text{Theorem 61.1}}}{\cong}\; H^{n-k}(M;\mathbb{F}) \;\underset{\substack{\uparrow\\ \text{Proposition 51.18}}}{\cong}\; H_{n-k}(M;\mathbb{F})^* \;\underset{\substack{\uparrow\\ \text{Theorem 61.1}}}{\cong}\; H^k(M;\mathbb{F})^* \;\underset{\substack{\uparrow\\ \text{Proposition 51.18}}}{\cong}\; (H_k(M;\mathbb{F})^*)^*.$$

(Here, as always given an $\mathbb{F}$-vector space V we denote by $V^* = \mathrm{Hom}_{\mathbb{F}}(V,\mathbb{F})$ its dual vector space.) But by [Jacb, p. 244-248] (see also [DF, Chapter 11.4]) a vector space V is isomorphic to its double dual $(V^*)^*$ if and only if the vector space is finite dimensional.

61.2. **Consequences of the Poincaré Duality Theorem 61.1.** In this section we present a few fairly immediate consequences of the Poincaré Duality Theorem 61.1.

Proposition 61.4. *For every compact odd-dimensional topological manifold M we have*

$$\chi(M) \;=\; \tfrac{1}{2}\chi(\partial M).$$

In particular if M is closed, then $\chi(M)=0$.

Proof. Let M be a compact topological manifold of dimension $2n+1$. Then

$$\begin{aligned}
\chi(M) &\underset{\substack{\uparrow \\ \text{Proposition 45.7 (4)}}}{=} \sum_{i=0}^{2n+1}(-1)^i\cdot\dim_{\mathbb{F}_2}(H_i(M,\mathbb{F}_2)) \underset{\substack{\uparrow \\ \text{by Theorem 61.3}}}{=} \sum_{i=0}^{2n+1}(-1)^i\cdot\dim_{\mathbb{F}_2}(H_{2n+1-i}(M,\partial M,\mathbb{F}_2)) \\
&\underset{\substack{\uparrow \\ \text{follows from the substitution } j=2n+1-i \\ \text{together with the fact that } (-1)^{2n+1}=-1}}{=} -\sum_{j=0}^{2n+1}(-1)^j\cdot\dim_{\mathbb{F}_2}(H_j(M,\partial M,\mathbb{F}_2)) \underset{\substack{\uparrow \\ \text{Proposition 45.7 (4)}}}{=} -\chi(M,\partial M) \underset{\substack{\uparrow \\ \text{Proposition 45.7 (4)}}}{=} -\chi(M)+\chi(\partial M).
\end{aligned}$$

Summarizing we have shown that $\chi(M) = -\chi(M) + \chi(\partial M)$. The desired equality follows from solving for $\chi(M)$. □

Proposition 61.4 raises the question, what can we say about Euler characteristics of closed even-dimensional manifolds. By the classification of closed oriented connected 2-dimensional manifolds, see Theorem 14.10, we know that the Euler characteristic of such a manifold is even. In higher dimensions there is evidently much more freedom for constructing manifolds.

Question 61.5. *Let $n \geq 4$ be even. Is every integer the Euler characteristic of a closed oriented connected n-dimensional manifold?*

Using Proposition 61.4 we easily obtain the following surprising (?) corollary.

Corollary 61.6. *The 2-dimensional manifold $\mathbb{R}\mathrm{P}^2$ is not the boundary of a compact 3-dimensional manifold.*

Proof. Suppose there was a compact 3-dimensional manifold M with $\partial M = \mathbb{R}\mathrm{P}^2$. We would obtain that

$$\chi(M) \underset{\substack{\uparrow \\ \text{Proposition 61.4}}}{=} \tfrac{1}{2}\chi(\partial M) = \tfrac{1}{2}\chi(\mathbb{R}\mathrm{P}^2) \underset{\substack{\uparrow \\ \text{see page 966}}}{=} \tfrac{1}{2}.$$

But the Euler characteristic of a compact manifold is by definition an integer. □

Remark. In Exercise 61.4 we will study the question, whether the Klein bottle is the boundary of a compact 3-dimensional manifold M. It follows from the CW-structure on page 647 that the Euler characteristic of the Klein bottle K is zero, therefore Proposition 61.4 does not obstruct the existence of such an M.

Clearly non-orientable manifolds exhibit some unusual behavior. So the following question arises.

Question 61.7. *Is every closed* orientable *manifold the boundary of a compact manifold?*

Note that in Corollary 8.4 we showed that if N is a non-orientable manifold, then $\pi_1(N)$ admits an epimorphism onto $\mathbb{Z}_2$.[1044] It follows from the Hurewicz Theorem 38.5 that

[1044] If in the proof of Corollary 8.4 we replace Proposition 8.3 by Proposition 45.26 we see that the statement also holds for non-orientable topological manifolds.

there exists also an epimorphism $H_1(N;\mathbb{Z}) \to \mathbb{Z}_2$. For closed 3-dimensional manifolds the following Lemma 61.8 is thus a considerable strengthening of Corollary 8.4.

Lemma 61.8. *Let M be a connected closed 3-dimensional manifold. If M is non-orientable, then $H_1(M;\mathbb{Z})$ is infinite.*

Proof. Let M be a connected closed 3-dimensional manifold. We have

$$\begin{array}{ccccccccc} 0 & = & \chi(M) & = & \sum\limits_{n\in\mathbb{N}_0} (-1)^n \cdot b_n(M) & = & b_0(M) - b_1(M) + b_2(M) & = & 1 - b_1(M) + b_2(M). \\ & \uparrow & & \uparrow & & \uparrow & & \uparrow & \\ & \text{Proposition 61.4} & & \text{see page 1079} & & \text{Theorems 46.2 and 46.4} & & \text{by Proposition 29.5} & \end{array}$$

This equality can only hold if $b_1(M) > 0$, i.e. if $H_1(M;\mathbb{Z})$ is infinite. □

Definition. Let $f\colon M \to N$ be a map between closed, oriented connected non-empty n-dimensional topological manifolds. We consider the following diagram of maps:

$$\begin{tikzcd} H_k(M;\mathbb{Z}) \arrow[r, shift left, "\mathrm{PD}_M"] \arrow[d, "f_*"'] & H^{n-k}(M;\mathbb{Z}) \arrow[l, shift left, "\cap[M]"] \\ H_k(N;\mathbb{Z}) \arrow[r, shift left, "\mathrm{PD}_N"] & H^{n-k}(N;\mathbb{Z}). \arrow[l, shift left, "\cap[N]"] \arrow[u, "f^*"'] \end{tikzcd}$$

We refer to

$$\begin{array}{rcl} f^!\colon H_k(N;\mathbb{Z}) & \to & H_k(M;\mathbb{Z}) \\ \sigma & \mapsto & f^*(\mathrm{PD}_N(\sigma)) \cap [M] \end{array}$$

as the *Umkehr map* of f.[10451046]

The following lemma shows that in some circumstances the Umkehr map is just the transfer map that we introduced on page 1064.

Lemma 61.9. *Let $p\colon \widetilde{N} \to N$ be a finite cover of a closed, oriented, non-empty n-dimensional topological manifold. If we equip $\widetilde{N}$ with the orientation given by Lemma 45.28 (3), then for any $k \in \mathbb{N}_0$ the Umkehr map $p^!\colon H_k(N;\mathbb{Z}) \to H_k(\widetilde{N};\mathbb{Z})$ equals the transfer map p^*.*

Proof. We start our proof with the following claim.

Claim. Let $r \le s$. Given any singular simplex $\sigma\colon \Delta^s \to N$ and any cochain $\phi \in C^r(N;\mathbb{Z})$ we have

$$p^*(\phi) \cap p^*(\sigma) \;=\; p^*(\phi \cap \sigma).$$

[1045]This map is indeed called "Umkehr map" in English. The name stems from the fact that it is a map on homology that "goes the wrong way".

[1046]Wikipedia writes: "In category theory [...] certain unusual functors are denoted $f^!$ and $f_!$, with the exclamation mark used to indicate that they are exceptional in some way. They are thus accordingly sometimes called shriek maps, with "shriek" being slang for an exclamation mark [...]."

We write $m = [\widetilde{N} : N]$. We denote by $\widetilde{\sigma}_1, \dots, \widetilde{\sigma}_m$ the lifts of σ. Then

$$\begin{aligned} p^*(\phi) \cap p^*(\sigma) &= p^*(\phi) \cap \sum_{i=1}^m \widetilde{\sigma}_i = \sum_{i=1}^m p^*(\phi)(\widetilde{\sigma}_i \circ [v_0, \dots, v_r]) \cdot \widetilde{\sigma}_i \circ [v_r, \dots, v_s] \\ &= \sum_{i=1}^m \phi((p_* \circ \widetilde{\sigma}_i) \circ [v_0, \dots, v_r]) \cdot \widetilde{\sigma}_i \circ [v_r, \dots, v_s] \\ &= p^*\big(\phi(\sigma \circ [v_0, \dots, v_r]) \cdot \sigma \circ [v_r, \dots, v_s]\big) = p^*(\phi \cap \sigma) \\ &\uparrow \end{aligned}$$

since $p_* \circ \widetilde{\sigma}_i = \sigma$ and since $\widetilde{\sigma}_i \circ [v_0, \dots, v_r]$, $i = 1, \dots, m$ are the lifts of $\sigma \circ [v_0, \dots, v_r]$

This concludes the proof of the claim.

Now we turn to the actual proof of the lemma. We pick an n-cycle τ that is a representative for the fundamental class $[N] \in H_n(N; \mathbb{Z})$ of N. By Proposition 46.24 we know that $p^*(\tau)$ represents the fundamental class of $\widetilde{N}$. By definition of the Umkehr map it suffices to prove the following claim.

Claim. For any cocycle $\phi \in C^l(N; \mathbb{Z})$ we have

$$f^*(\phi) \cap p^*(\tau) = p^*(\phi \cap \tau).$$

The claim is an immediate consequence of the first claim. □

Finally we want to study degree-one maps between manifolds. We recall that on page 959 we defined the degree of a map $f\colon M \to N$ between closed, oriented connected non-empty n-dimensional topological manifolds to be the unique integer $\deg(f) \in \mathbb{Z}$ with $f_*([M]) = \deg(f) \cdot [N]$. We had obtained the following results:

(1) In Proposition 39.21 we showed that for any closed, oriented, non-empty n-dimensional manifold M there exists a degree-one map $M \to S^n$.[1047]
(2) In Proposition 39.26 we saw that if $\deg(f) = \pm 1$, then $f_*\colon \pi_1(M) \to \pi_1(N)$ is an epimorphism.
(3) In Lemma 60.5 we had used cup products to show that there does not exist a map $f\colon S^4 \to S^2 \times S^2$ of non-zero degree.

Now we add the following proposition to our list on results on the non-existence of degree-one maps.

Proposition 61.10. *Let $f\colon M \to N$ be a degree-one map between closed, oriented, non-empty n-dimensional topological manifolds. Then for every $k \in \mathbb{N}_0$ the following holds:*

(1) *the map $f_* \circ f^!$ is the identity, in particular the map $f^!\colon H_k(N; \mathbb{Z}) \to H_k(M; \mathbb{Z})$ splits,*
(2) *the image $f^!(H_k(N; \mathbb{Z}))$ is a subsummand of $H_k(M; \mathbb{Z})$, i.e. there exists a subgroup Q of $H_k(M; \mathbb{Z})$ such that $H_k(M; \mathbb{Z}) = f^!(H_k(N; \mathbb{Z})) \oplus Q$.*

[1047] Basically the same proof, together with say Theorem 46.2 (4) and an excision argument, shows that the same statement also holds for topological manifolds. We leave it to the reader to fill in the details.

Proof. Let $f\colon M \to N$ be a degree-one map between closed, oriented, non-empty n-dimensional topological manifolds. Let $\sigma \in H_k(N;\mathbb{Z})$. We have

$$(f_* \circ f^!)(\sigma) \underset{\substack{\uparrow \\ \text{definition of } f^!}}{=} f_*\big(f^*(\mathrm{PD}_N(\sigma)) \cap [M]\big) \underset{\substack{\uparrow \\ \text{Lemma 59.8}}}{=} \mathrm{PD}_N(\sigma) \cap f_*([M]) \underset{\substack{\uparrow \\ \text{since } \deg(f)=1}}{=} \mathrm{PD}_N(\sigma) \cap [N] \underset{\substack{\uparrow \\ \text{definition of } \mathrm{PD}_N}}{=} \sigma.$$

The second statement follows from combining the first statement with Lemma 33.2. □

It follows from remark (2) above that there is no degree-one map from $\mathbb{RP}^3$ to $S^1 \times S^2$. In Question 39.29 we had asked whether there exists a degree-one map from $S^1 \times S^2$ to $\mathbb{RP}^3$. Now we can give a negative answer.

Corollary 61.11. *There is no degree-one map from $S^1 \times S^2$ to $\mathbb{RP}^3$.*

Proof. The corollary follows immediately from Proposition 61.10 and the observation that the group $H_1(\mathbb{RP}^3;\mathbb{Z}) \cong \mathbb{Z}_2$ is not a subsummand of $H_1(S^1 \times S^2;\mathbb{Z}) \cong \mathbb{Z}$. □

61.3. **A geometric approach to the Poincaré Duality Theorem 61.1** (∗)**.** In this section we will provide a sketch of a geometric proof for the following weaker version of Poincaré Duality Theorem 61.1.

Theorem 61.12. (Poincaré Duality Theorem) *If M is a closed n-dimensional*[1048] *manifold, then for every $k \in \mathbb{N}_0$ there exists an isomorphism*

$$\mathrm{PD}_M\colon H_k(M;\mathbb{F}_2) \xrightarrow{\cong} H^{n-k}(M;\mathbb{F}_2).$$

The proof we provide for Theorem 61.12 has the great advantage that it is very pictorial and one "can see" what is happening. Also, much later, when we introduce a new invariant called Reidemeister torsion, the method of the proof of Theorem 61.12 will be useful. In the next two sections we will give a rigorous, more formal proof of Poincaré Duality Theorem 61.12, therefore we will take the liberty of skipping many steps in the following proof.

Sketch of the proof of Theorem 61.12. Before we start with the actual proof of Theorem 61.12 we want to recall and introduce several definitions for the standard simplex Δ^m:

(1) We denote by $B_m := (\frac{1}{m+1}, \dots, \frac{1}{m+1}) \in \Delta^m$ the *barycenter* of the standard m-simplex Δ^m.
(2) Given points $P_0, \dots, P_k$ in the simplex Δ^m we denote by

$$\begin{aligned} [P_0,\dots,P_k]\colon \Delta^k &\to \Delta^m \\ (t_0,\dots,t_k) &\mapsto \sum_{i=0}^k t_i \cdot P_i \end{aligned}$$

the singular k-simplex that sends each vertex v_i of Δ^k to P_i. We also write

$$\langle P_0,\dots,P_k\rangle := \text{image of } [P_0,\dots,P_k].$$

[1048]Note that here we do not allow topological manifolds.

(3) An r-*dimensional face* of Δ^m is defined as a subset of the form $\langle v_{n_1}, \dots, v_{n_r}\rangle$ where $0 \le n_1 < \cdots < n_r \le m$. We refer to the image of the barycenter B_r under the map $[v_{n_1}, \dots, v_{n_r}] \to \Delta^m$ as the *barycenter of the face*.
(4) The barycenter of a face τ is denoted by $\underline{\tau}$.

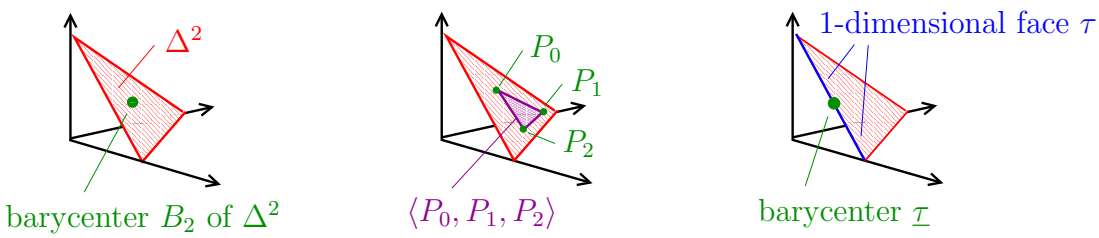


FIGURE 744.

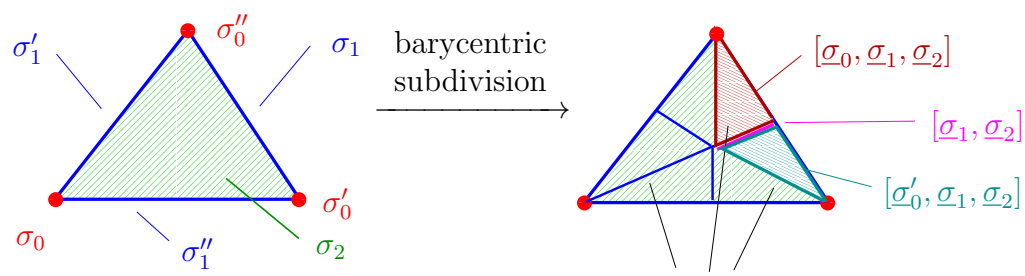
We continue with some new definitions.

(1) Let σ and τ be faces of Δ^m. If $\sigma \subset \tau$, then we write $\sigma \le \tau$. If $\sigma \ne \tau$, then we write $\sigma < \tau$.
(2) We refer to the set of singular simplices

$$[\underline{\sigma}_0, \dots, \underline{\sigma}_k] \quad \text{where } \sigma_0, \dots, \sigma_k \text{ are faces with } \sigma_0 < \sigma_1 < \cdots < \sigma_k \le \sigma$$

as the *barycentric subdivision of* Δ^m. The definition is illustrated in Figure 745.



2-dimensional simplex σ_2 with three 0-dimensional faces $\sigma_0, \sigma_0', \sigma_0''$ and three 1-dimensional faces $\sigma_1, \sigma_1', \sigma_1''$

barycentric subdivision of a 2-simplex σ_2.

FIGURE 745.

Now let M be a closed, oriented n-dimensional manifold. According to Proposition 39.3 the manifold M admits a simplicial structure $\{\varphi_i \colon \Delta^{n_i} \to M\}_{i \in I}$. We refer to pages 936 and 938 for the precise definition of a simplicial structure. In the following we summarize some of the key features and definitions of a simplicial structure.

(1) For each $i \in I$ the map $\varphi_i \colon \Delta^{n_i} \to M$ is injective.

(2) The image of $\varphi_i\colon \Delta^{n_i} \to M$ is called an *n_i-dimensional simplex*. We refer to it also by φ_i. We use the notation that we introduced above for the standard simplices in the obvious way for the simplices of M:
   (a) The image of the interior of Δ^{n_i} is called the interior of φ_i.
   (b) The image of a face of Δ^{n_i} is called a face of φ_i. Similarly we define the barycenter $\underline{\tau}$ of a face τ of φ_i.
   (c) Given points $P_0, \dots, P_k \in \varphi_i(\Delta^{n_i})$ we define

$$[P_0, \dots, P_k] := \sigma_i \circ [\varphi_i^{-1}(P_0), \dots, \varphi_i^{-1}(P_k)]\colon \Delta^k \to M.$$

   We denote the image of $[P_0, \dots, P_k]$ again by $\langle P_0, \dots, P_k\rangle$.

(3) For each $x \in M$ there exists a unique simplex such that x lies in the interior of the simplex.
(4) Every face of every simplex of M is again a simplex of M.
(5) If the images of φ_i and φ_j intersect, then there exist faces F_i of Δ^{n_i} and F_j of Δ^{n_j} such that the following two conditions are satisfied:
   (a) we have $\varphi_i(\Delta^{n_i}) \cap \varphi_j(\Delta^{n_j}) = \varphi_i(F_i) = \varphi_j(F_j)$,
   (b) the map $\varphi_j^{-1} \circ \varphi_i\colon F_i \to F_j$ is an affine homeomorphism.

Now we apply the barycentric subdivision to each simplex of M and we obtain a new set of singular simplices. We call this set *the barycentric subdivision of M*.[1049] For a k-simplex σ of M we define

$$\sigma^d := \bigcup_{\sigma=\sigma_0<\sigma_1<\dots<\sigma_s} \langle \underline{\sigma}_0, \underline{\sigma}_1, \dots, \underline{\sigma}_s\rangle.$$

We refer to σ^d as the *cell dual to σ* and we refer to $n-k$ as the dimension of the dual cell. Furthermore we define

$$\partial\sigma^d := \bigcup_{\sigma<\sigma_1<\dots<\sigma_s} \langle \underline{\sigma}_1, \dots, \underline{\sigma}_s\rangle \subset \sigma^d.$$

We illustrate σ^d and $\partial\sigma^d$ in Figure 746. We see in Figure 746 that in both examples the dual cell is a disk and that $\partial\sigma^d$ is the boundary of σ^d. The following claim says that this not a coincidence.

Claim 1. For each k-dimensional simplex σ the pair $(\sigma^d, \partial\sigma^d)$ is homeomorphic to the pair $(\overline{B}^{n-k}, S^{n-k})$.

In the proof of the claim one needs to use that M is a closed n-dimensional manifold. A proof of the claim can for example be found in [RS, Chapter 2].

In Figure 746 we see two simplices σ and τ, where $\sigma \subset \partial\tau$. In the dual cells this inclusion is reversed and we have $\tau^d \subset \partial\sigma^d$. Again this is not a coincidence, in fact the following claim holds in general.

[1049] It is straightforward to verify that the barycentric subdivision of M is again a simplicial structure for M. We will not make use of this fact.

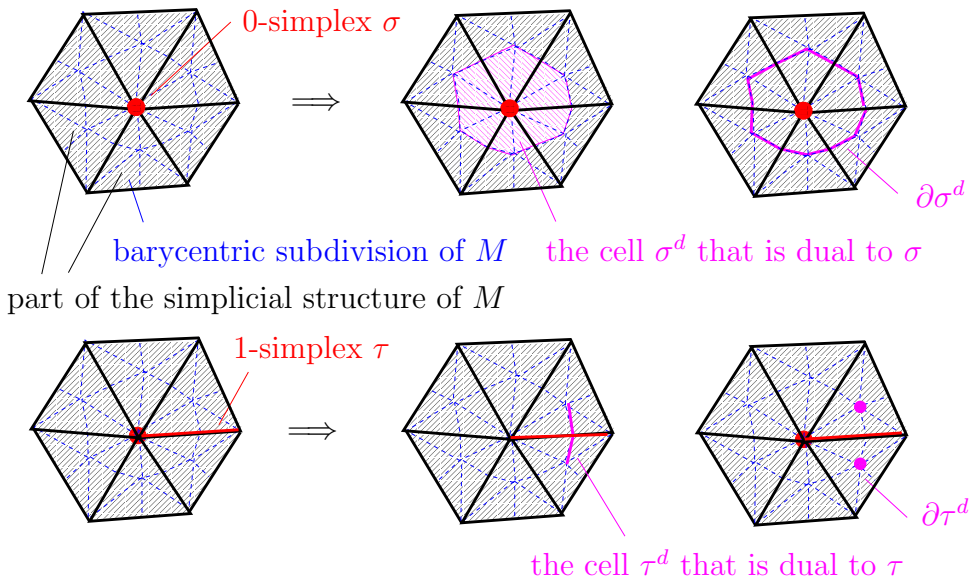


FIGURE 746. The dual cells of a 0-simplex and a 1-simplex.

Claim 2. Let σ and τ be two simplices of M. Then the following holds

$$\tau \text{ is a face of } \sigma \quad \Longleftrightarrow \quad \sigma^d \subset \tau^d.$$

Let τ be a face of σ. Then each sequence $\sigma = \sigma_0 < \sigma_1 \cdots < \sigma_k$ of faces can be extended to a sequence $\tau < \sigma = \sigma_0 < \sigma_1 \cdots < \sigma_k$. In particular we have $\langle \underline{\sigma}_0, \ldots, \underline{\sigma}_k \rangle \subset \langle \underline{\tau}, \underline{\sigma}_0, \ldots, \underline{\sigma}_k \rangle$, thus $\sigma^d \subset \tau^d$. The converse statement is proved exactly the same way. Thus we have proved the claim.

In the following we will equip M with two different CW-structures:

(1) Given $k \in \mathbb{N}_0$ we denote by $S_k(M)$ the set of k-simplices of M.
(2) In Lemma 39.2 we saw that the simplicial structure of M gives rise to a CW-structure X for M where the k-cells of X correspond precisely to the k-dimensional simplices of M. Put differently, we have a canonical identification

$$\text{set of the } k\text{-cells of } X \;=\; \{\sigma \,|\, \sigma \in S_k(M)\}.$$

(3) It follows fairly easily from the previous two claims that the dual cells form in fact a CW-structure for M. We denote the corresponding CW-complex by Y and refer to is as *the dual CW-complex structure*. Note that we have a canonical identification

$$\text{set of the } k\text{-cells of } Y \;=\; \{\sigma^d \,|\, \sigma \in S_{n-k}(M)\}.$$

(4) Given a k-cell y of Y we define its dual y^d to be the unique $(n-k)$-simplex τ with $y = \tau^d$.

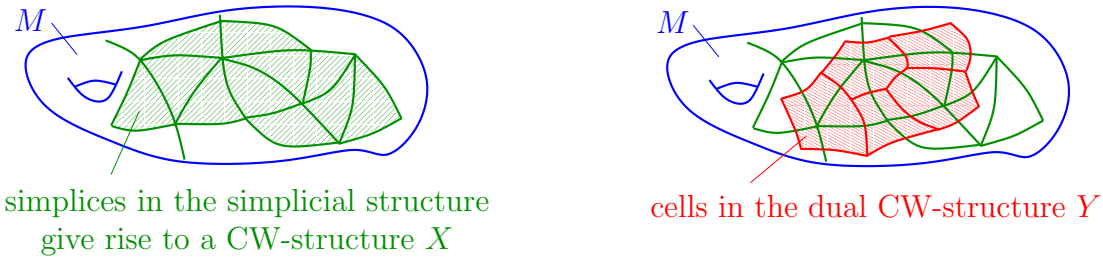

FIGURE 747.

Given $\sigma \in S_k(M)$ we define

$$\mathrm{PD}(\sigma)\colon C^{\mathrm{CW}}_{n-k}(Y) \ \to\ \mathbb{F}_2$$

to be the uniquely defined homomorphism that sends σ^d to one and that sends all other $(n-k)$-dimensional cells of Y to zero. The definition is illustrated in Figure 748.

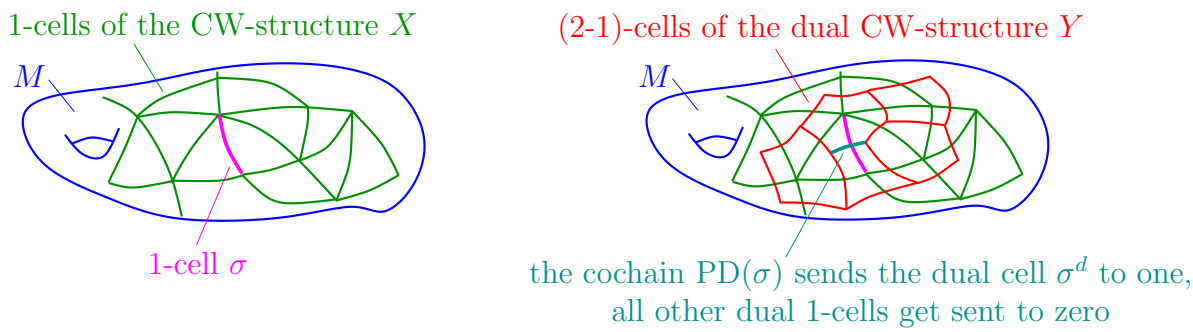

FIGURE 748.

Claim 3. The maps

$$\begin{array}{rcl} \mathrm{PD}\colon C^{\mathrm{CW}}_k(X)\otimes\mathbb{F}_2 & \to & \mathrm{Hom}\left(C^{\mathrm{CW}}_{n-k}(Y),\mathbb{F}_2\right) \\ \sum\limits_{i=1}^m a_i\cdot\sigma_i & \mapsto & \sum\limits_{i=1}^m a_i\cdot\mathrm{PD}(\sigma_i) \end{array}$$

induce isomorphisms

$$H^{\mathrm{CW}}_k(X;\mathbb{F}_2) \ \xrightarrow{\cong}\ H^{n-k}_{\mathrm{CW}}(Y;\mathbb{F}_2).$$

Before we provide the proof of the claim we note that we now obtain that

$$\begin{array}{ccccccc} H_k(M;\mathbb{F}_2) & \cong & H^{\mathrm{CW}}_k(X;\mathbb{F}_2) & \cong & H^{n-k}_{\mathrm{CW}}(Y;\mathbb{F}_2) & \cong & H^{n-k}(M;\mathbb{F}_2). \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{Proposition 35.4} & & \text{by the above claim} & & \text{Proposition 50.4} & \end{array}$$

We have thus proved the theorem, modulo the proof of the claim.

We turn to the proof of the claim. First note that it is straightforward to verify that the maps

$$\begin{array}{rcl} \mathrm{Hom}\left(C^{\mathrm{CW}}_{n-k}(Y), \mathbb{F}_2\right) & \to & C^{\mathrm{CW}}_k(X) \otimes \mathbb{F}_2 \\ f & \mapsto & \sum\limits_{\sigma \in S_k(M)} f(\sigma^d) \cdot \sigma \end{array}$$

are an inverse to the maps PD under consideration. It remains to show that the following diagram commutes:

$$\begin{array}{ccc} C^{\mathrm{CW}}_k(X; \mathbb{F}_2) & \xrightarrow{\ \mathrm{PD}\ } & \mathrm{Hom}\left(C^{\mathrm{CW}}_{n-k}(Y), \mathbb{F}_2\right) \\ \downarrow{\scriptstyle \partial} & & \downarrow{\scriptstyle \partial^*} \\ C^{\mathrm{CW}}_{k-1}(X; \mathbb{F}_2) & \xrightarrow{\ \mathrm{PD}\ } & \mathrm{Hom}\left(C^{\mathrm{CW}}_{n-(k-1)}(Y), \mathbb{F}_2\right). \end{array}$$

To show that the diagram commutes it suffices to show that for each k-simplex $\sigma \in S_k(M)$ and each $(k-1)$-simplex $\tau \in S_{k-1}(M)$ we have

$$(\mathrm{PD}(\partial\sigma))(\tau^d) \ = \ (\mathrm{PD}(\sigma))(\partial\tau^d) \ \in \ \mathbb{F}_2.$$

We denote by $y_1, \ldots, y_{n-k+2}$ the $(n-k)$-cells of Y that appear in the boundary of the $(n-k+1)$-cell τ^d. Then we have[1050]

$$\begin{array}{rcll} & & \text{by definition of the cellular boundary map and of PD} & \text{Claim 1} \\ & & \downarrow & \downarrow \\ (\mathrm{PD}(\partial\sigma))(\tau^d) = 1 & \iff & \tau \text{ is a face of } \sigma & \iff \sigma^d \subset \tau^d \\ & \iff & \text{there exists an } i \text{ with } y_i = \sigma^d & \\ & & \uparrow & \\ & & \text{since } y_1, \ldots, y_{n-k+2} \text{ are the only } (n-k)\text{-cells contained in } \tau^d & \\ & \iff & \text{there exists an } i \text{ with } (y_i)^d = \sigma \iff (\mathrm{PD}(\sigma))(\partial\tau^d) = 1. & \end{array}$$

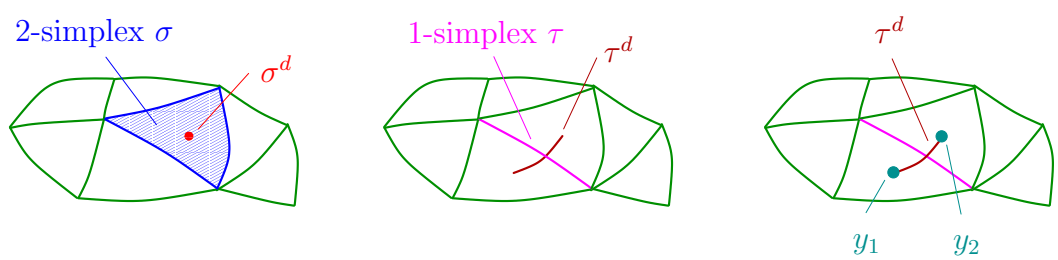

FIGURE 749.

Since $\mathbb{F}_2 = \{0, 1\}$ consists of precisely two elements the above equivalences prove that $(\mathrm{PD}(\partial\sigma))(\tau^d) = (\mathrm{PD}(\sigma))(\partial\tau^d)$. This concludes the proof of the claim. $\square$

[1050]Even though we justify the various equivalences one could argue that more details are required to turn the argument into a rigorous proof.

We only sketched the proof of Theorem 61.12, but it is not too difficult to turn the argument into a rigorous proof, see e.g. [SZ]. Nonetheless there are several issues with the statement and the proof of Theorem 61.12.

(1) Right now the proof only deals with closed manifolds. But this is not a big problem, with more care one can also prove a relative version. We refer to [SZ, Chapter 14.8] for details, at least in the special case that $A = \varnothing$ or $A = \partial M$.
(2) For closed orientable manifolds one would like to have isomorphisms of homology and cohomology groups with $\mathbb{Z}$-coefficients. In fact this can be arranged by a more careful discussion of orientations and signs. We refer to [Tur, p. 73], [Mun, Chapter 65] or [SZ, Chapter 14.2] for details on how to promote the above argument to a proof that deals with $\mathbb{Z}$-coefficients.
(3) We had stated Theorem 61.12 for manifolds. The only point where we used that we are working with a manifold was when we cited Proposition 39.3 to deduce that the manifold admits a simplicial structure. Put differently, the proof applies to any closed topological manifold that admits a simplicial structure. But it was shown by Ciprian Manolescu [Man, Man2] in 2013 that for every $n \geq 5$ there exists a closed orientable n-dimensional topological manifold that does not admit a simplicial structure.
(4) Even if one cares only about closed manifolds the proof of Theorem 61.12 is somewhat unsatisfactory. The proof relies on introducing a simplicial structure and the isomorphism between homology and cohomology groups relies on this choice. The statement of the Poincaré Duality Theorem 61.1 is much nicer since it states explicitly the isomorphism.

FIGURE 750. Ciprian Manolescu (on the right).

61.4. **The proof of Poincaré Duality for topological manifolds without boundary.** In this section we will prove the Poincaré Duality Theorem 61.1 for closed topological manifolds. More precisely, we will prove the following theorem.

Theorem 61.13. *Let M be a closed, non-empty n-dimensional topological manifold and let R be a commutative ring. We suppose that M is R-oriented. We denote by $[M] \in H_n(M; R)$*

the R-fundamental class. Then for each $k \in \mathbb{N}_0$ the map

$$\begin{array}{rcl} \mathrm{PD}_M \colon H^k(M;R) & \xrightarrow{\cong} & H_{n-k}(M;R) \\ \sigma & \mapsto & \sigma \cap [M] \end{array}$$

is an isomorphism.

In order to simplify the notation a little bit we will work throughout the section with $R = \mathbb{Z}$. The proof for other commutative rings is verbatim the same.

The key idea is somewhat similar to the strategy of the proof of Theorem 46.10. More precisely, using a Mayer–Vietoris argument and a limit argument we want to reduce the proof eventually to the fairly trivial case of an open ball in $\mathbb{R}^n$.

To carry out the above strategy we need a version of Poincaré Duality for every topological manifold (not necessarily compact) with empty boundary. Formulating this generalized Poincaré Duality Theorem requires some preparations. First we recall some definitions and results from earlier on:

(1) Given a topological space X we denote by $\mathcal{K}(X)$ the set of all compact subsets of X. Let $k \in \mathbb{N}_0$. By Proposition 53.4 we have an identification

$$\varinjlim_{K \in \mathcal{K}(X)} H^k(X, X \setminus K) \;=\; H^k_c(X).$$

(2) Let M be an n-dimensional topological manifold with empty boundary. If M is equipped with an orientation $\{\mu_x\}_{x \in M}$, then we saw in Theorem 46.10 (i) that given any compact subset K of M there exists a unique class $\mu_K^M \in H_n(M, M \setminus K)$ such that for any $x \in K$ the image of μ_K^M under the map

$$H_n(M, M \setminus K) \;\to\; H_n(M, M \setminus \{x\})$$

equals the given orientation μ_x at x. If M is understood, then we drop it from the notation, i.e. we just write μ_K instead of μ_K^M.

Lemma 61.14. *Let M be an oriented n-dimensional topological manifold with empty boundary.*

(1) *Let $K \subset L \subset M$ be compact subsets. We denote by $f_{KL} \colon (M, M \setminus L) \to (M, M \setminus K)$ the inclusion map of pairs.*
   (a) *The map $f_{KL*} \colon H_n(M, M \setminus L) \to H_n(M, M \setminus K)$ sends μ_L to μ_K.*
   (b) *For any $k \in \mathbb{N}_0$ the following diagram commutes:*

$$\begin{tikzcd} H^k(M, M \setminus K) \arrow[d, "f_{KL}^*"] \arrow[dr, "\cap \mu_K"] & \\ H^k(M, M \setminus L) \arrow[r, "\cap \mu_L"'] & H_{n-k}(M). \end{tikzcd}$$

(2) *For any $k \in \mathbb{N}_0$ there exists a unique map*

$$\mathrm{PD}_M \colon H^k_c(M) \to H_{n-k}(M)$$

such that for each compact subset $K \subset M$ the following diagram commutes[1051]

$$\begin{tikzcd} H^k(M, M \setminus K) \arrow[rr, "\cap \mu_K"] \arrow[dr] & & H_{n-k}(M). \\ & H^k_c(M) \arrow[ur, "\mathrm{PD}_M"'] & \end{tikzcd}$$

Proof. Let M be an oriented n-dimensional topological manifold with empty boundary.

(1) (a) This is precisely Lemma 46.11 (1).
(b) Let $\varphi \in H^k(M, M \setminus K)$. We see that

$$\varphi \cap \mu_K \underset{\substack{\uparrow \\ \text{part (1a)}}}{=} \varphi \cap f_{KL*}(\mu_L) \underset{\substack{\uparrow \\ \text{Lemma 59.8}}}{=} f^*_{KL}(\varphi) \cap \mu_L.$$

But this means precisely that the diagram under consideration commutes.

(2) This statement follows immediately from (1b) and the universal property of the direct limit. □

Throughout the remainder of this section we use the following notation.

Notation. Let $k \in \mathbb{N}_0$ and let X be a topological space.

(1) Given any subset A of X we denote by $i_*\colon H_k(A) \to H_k(X)$ and $i^*\colon H_k(X) \to H_k(A)$ the inclusion induced map.
(2) Suppose that X is Hausdorff and that U is an open subset of X. Then we denote by $i\colon H^k_c(U) \to H^k_c(X)$ the map defined by

$$H^n_c(U) = \varinjlim_{K \in \mathcal{K}(U)} H^n(U, U \setminus K) \xleftarrow{\cong} \varinjlim_{K \in \mathcal{K}(U)} H^n(X, X \setminus K) \to \varinjlim_{K \in \mathcal{K}(X)} H^n(X, X \setminus K) = H^n_c(X).$$

We refer to Lemma 53.5 for the proof that these inclusion maps are functorial with respect to compositions of inclusions.

We will prove the following generalization of Theorem 61.13.[1052] This more general version of Poincaré Duality will not only be useful for the divide-et-impera approach to the proof of Theorem 61.13, but it will also be of interest in its own right later on.

Theorem 61.15. *Let M be an oriented n-dimensional topological manifold with empty boundary. Then for each $k \in \mathbb{N}_0$ the map*

$$\mathrm{PD}_M\colon H^k_c(M) \xrightarrow{\cong} H_{n-k}(M)$$

from Lemma 61.14 is an isomorphism.

[1051] Note that for a class $\varphi \in H^k(M, M \setminus K)$ and $\mu_K \in H_n(M, M \setminus K)$ the cap product $\varphi \cap \mu_K$ does indeed lie in $H_{n-k}(M)$.

[1052] Why is it a generalization of Theorem 61.13?

Example. Let M be an oriented connected, non-empty n-dimensional topological manifold with empty boundary. Then

$$\begin{array}{ccccc} H_n(M;\mathbb{Z}) & \cong & H_c^0(M;\mathbb{Z}) & \cong & \begin{cases} \mathbb{Z}, & \text{if } M \text{ is compact,} \\ 0, & \text{if } M \text{ is non-compact.} \end{cases} \\ & \uparrow & & \uparrow & \\ & \text{Theorem 61.15} & & \text{see page 1257} & \end{array}$$

This calculation is consistent with the results obtained in Theorems 46.2 and 46.4.

Remark.

(1) Let M be an oriented connected, non-empty n-dimensional topological manifold with empty boundary. Following the convention introduced on page 1413 we denote the inverse of the isomorphism $\mathrm{PD}_M\colon H_c^k(M) \xrightarrow{\cong} H_{n-k}(M)$ also by PD_M.

(2) Given a possibly non-compact oriented manifold without boundary Theorem 61.15 allows us to relate singular homology to cohomology with compact support. There is also a different version of Poincaré Duality that relates singular cohomology to a different flavor of homology, namely Borel-Moore homology. We refer to [Gre], [Bre2, Chapter V.9] and [PS, p. 332] for details.

As a warm up for the proof of Theorem 61.15 we will deal with the case $M = B^n$ by hand.[1053] More precisely, we will prove the following lemma.

Lemma 61.16. *For each $k \in \mathbb{N}_0$ the map*

$$\mathrm{PD}_{B^n}\colon H_c^k(B^n) \xrightarrow{\cong} H_{n-k}(B^n)$$

is an isomorphism.

Proof. Let $k \in \mathbb{N}_0$. Given any $s \in (0,1)$ we write $\overline{B}_s^n := \{x \in \mathbb{R}^n \mid \|x\| \leq s\}$ and we also write $S_s^{n-1} := \partial\overline{B}_s^n$. For the remainder of the proof we fix $0 < r < s < 1$. We denote by $i\colon (\overline{B}_s^n, S_s^n) \to (B^n, B^n \setminus \overline{B}_r^n)$ the inclusion map of pairs.

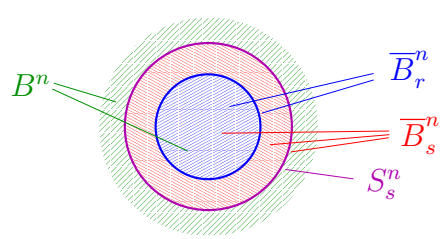

FIGURE 751. Illustration for the proof of Lemma 61.16.

[1053]We use the convention that any n-dimensional submanifold of $\mathbb{R}^n$ is equipped with the orientation induced from the standard orientation of $\mathbb{R}^n$, see Lemma 45.28.

We consider the following diagram:

$$\begin{tikzcd}
H^k\big(\overline{B}^n_s, S^n_s\big) \arrow[d, "\cap[\overline{B}^n_s]"] & H^k\big(B^n, B^n \setminus \overline{B}^n_r\big) \arrow[l, "i^*"'] \arrow[r] \arrow[d, "\cap\mu_{\overline{B}^n_r}"] & H^k_c(B^n) \arrow[d, "\mathrm{PD}_{B^n}"] \\
H_{n-k}\big(\overline{B}^n_s\big) \arrow[r, "i_*"] & H_{n-k}(B^n) \arrow[r, "="] & H_{n-k}(B^n).
\end{tikzcd}$$

The lemma is an immediate consequence of the following claim.

Claim.

(1) The diagram commutes,
(2) the left vertical map is an isomorphism, and
(3) all horizontal maps are isomorphisms.

We turn to the proof of the three statements.

(1) The square on the right commutes by definition of PD_{B^n}. So it remains to show that the square on the left commutes. Thus let $\varphi \in H^k(B^n, B^n \setminus \overline{B}^n_r)$. We have

$$i_*\big(i^*\varphi \cap [\overline{B}^n_s]\big) \underset{\substack{\uparrow \\ \text{Lemma 59.8}}}{=} \varphi \cap i_*([\overline{B}^n_s]) \underset{\substack{\uparrow \\ \text{since the images of } [\overline{B}^n_s] \text{ and } \mu_{\overline{B}^n_r} \\ \text{in } H_n(B^n, B^n \setminus \{0\}) \text{ agree}}}{=} \varphi \cap \mu_{\overline{B}^n_r} \in H_{n-k}(B^n).$$

(2) We consider the left vertical map of the diagram. Clearly both groups are zero for $k \neq n$. Evidently a generator for $H^n(\overline{B}^n_s, S^n_s)$ is given by the dual fundamental class $[\overline{B}^n_s]^*$. Since $\overline{B}^n_s$ is path-connected we see, following the discussion on page 1378, that $[\overline{B}^n_s]^* \cap [\overline{B}^n_s] = \langle [\overline{B}^n_s]^*, [\overline{B}^n_s] \rangle = 1 \in H_0(\overline{B}^n_s) = \mathbb{Z}$. In particular the left vertical map is an isomorphism.

(3) It follows easily from Corollary 31.16 and Lemma 48.13 that the left horizontal maps are isomorphisms. It remains to show that the top right horizontal map is an isomorphism. We consider the following commutative diagram

$$\begin{tikzcd}
H^k(B^n, B^n \setminus \overline{B}^n_r) \arrow[rr] \arrow[dr] & & \lim\limits_{\substack{\longrightarrow \\ K \in \mathcal{K}(B^n)}} H^k(B^n, B^n \setminus K) = H^k_c(B^n). \\
& \lim\limits_{\substack{\longrightarrow \\ t \in (0,1)}} H^k(B^n, B^n \setminus \overline{B}^n_t) \arrow[ur] &
\end{tikzcd}$$

We make the following two observations:

(a) Every compact subset of B^n is contained in a closed ball $\overline{B}^n_t$ with $t \in (0,1)$. Therefore it follows from Lemma 52.3 that the right diagonal map is an isomorphism.
(b) It follows easily from Lemmas 48.13 and 52.2 (4) that the left diagonal map is an isomorphism.

These two observations together imply that the horizontal map is also an isomorphism.

This concludes the proof of the claim. □

In the proof of Theorem 61.15 we will need the following two lemmas.

Lemma 61.17. *Let M be a topological manifold and let U, V be open subsets such that $M = U \cup V$. Then given any compact subset $C \subset M$ there exist compact subsets $K \subset U$ and $L \subset V$ such that $C = K \cup L$.*

FIGURE 752. Illustration of Lemma 61.17.

Proof (∗). Let M be an n-dimensional topological manifold and let U, V be open subsets with $M = U \cup V$. Furthermore let C be a compact subset of M. Using charts one can easily show that given any point $x \in C$ there exists a compact set A_x with the following properties:

(1) the point x lies in the interior of A_x,
(2) if $x \in U$ then the set A_x is contained in U,
(3) if $x \in V$ then the set A_x is contained in V.

It follows from (1), the fact that the sets A_x cover all of C together with the hypothesis that C is compact that there exist finitely many $y_1, \ldots, y_r \in C$ with $C \subset \mathring{A}_{y_1} \cup \cdots \cup \mathring{A}_{y_r}$. One can now easily verify that $K := \bigcup_{y_i \in U} (A_{y_i} \cap C)$ and $L := \bigcup_{y_i \in V} (A_{y_i} \cap C)$ have the desired properties. □

Lemma 61.18. *Let M be a compact oriented n-dimensional topological manifold and let U, V be open subsets such that $M = U \cup V$ and let $K \subset U$ and $L \subset V$ be compact subsets. Then there exist singular n-chains $\alpha_{U \setminus L}$, $\alpha_{U \cap V}$ and $\alpha_{V \setminus K}$ in $U \setminus L$, $U \cap V$ and $V \setminus K$ such that the following three equalities hold:*

$$\begin{array}{lrcll} \text{(a)} & \mu^M_{K \cup L} & = & [\alpha_{U \setminus L} + \alpha_{U \cap V} + \alpha_{V \setminus K}] & \textit{in } H_n(M, M \setminus (K \cup L)) \\ \text{(b)} & \mu^{U \cap V}_{K \cap L} & = & [\alpha_{U \cap V}] & \textit{in } H_n(U \cap V, U \cap V \setminus (K \cap L)) \\ \text{(c)} & \mu^U_K & = & [\alpha_{U \setminus L} + \alpha_{U \cap V}] & \textit{in } H_n(U, U \setminus K). \end{array}$$

Proof. We pick a representative $\alpha \in C_n(M)$ for $\mu^M_{K \cup L}$. Note that the open sets $U \setminus L, U \cap V$ and $V \setminus K$ cover M. It follows from Lemmas 31.25 and 31.28 that there exist singular chains $\alpha_{U \setminus L}$, $\alpha_{U \cap V}$ and $\alpha_{V \setminus K}$ in $U \setminus L$, $U \cap V$ and $V \setminus K$ such that α is homologous in $C_k(M)$

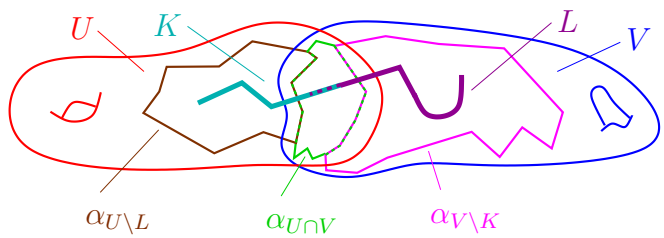

FIGURE 753. Illustration of Lemma 61.18.

to $\alpha_{U\setminus L} + \alpha_{U\cap V} + \alpha_{V\setminus K}$. The chains are in particular homologous in $C_k(M, M \setminus (K \cup L))$ which implies that (a) holds.[1054]

Next note that we have

$$\mu^M_{K\cap L} \underset{\substack{\uparrow \\ \text{Lemma 61.14}}}{=} \text{image of } \mu^M_{K\cup L} = [\alpha_{U\setminus L} + \alpha_{U\cap V} + \alpha_{V\setminus K}] \underset{\substack{\uparrow \\ \text{since } \alpha_{U\setminus L}, \alpha_{V\setminus K} \text{ lie in } C_n(M\setminus(K\cap L))}}{=} [\alpha_{U\cap V}] \in H_n(M, M \setminus (K \cap L)).$$

But $\alpha_{U\cap V}$ lies in $U \cap V$, therefore it follows from Lemma 46.11 (2) that $\mu^{U\cap V}_{K\cap L} = [\alpha_{U\cap V}]$ in $H_n(U \cap V, U \cap V \setminus (K \cap L))$. We have thus verified (b).

Finally the proof of equality (c) is basically the same as the proof of equality (b). □

We recall the following notation and convention:

Convention. Let X be a topological space, let A be a subset and let $k \in \mathbb{N}_0$. As on page 1356 we make the identification

$$C^k(X, A) \xrightarrow{=} \text{all homomorphisms } C_k(X) \to \mathbb{Z} \text{ that vanish on } C_k(A).$$

Furthermore, given another subset B of X we write

$$C^k(X, \{A, B\}) := \text{all homomorphisms } C_k(X) \to \mathbb{Z} \text{ that vanish on } C_k(A) \text{ and on } C_k(B).$$

If A and B are open subsets of X then we use the isomorphism

$$H^k(X, A \cup B) \xrightarrow{\cong} H^k(X, \{A, B\})$$

from Lemma 58.1 to identify the two groups.

In the proof of Theorem 61.15 we will also need the following "inverted" Mayer–Vietoris Theorem, which is very similar to Theorem 33.7.

Theorem 61.19. (The inverted Mayer–Vietoris Theorem for Cohomology groups) *Let X be a topological space and let A and B be open subsets.*

(1) *For every $n \in \mathbb{N}_0$ and every cochain $\varphi \in C^n(X, A \cup B)$ there exist $\varphi_A \in C^n(X, A)$ and $\varphi_B \in C^n(X, B)$ such that $\varphi_A + \varphi_B = \varphi$.*

[1054] Why is $\alpha_{U\setminus L} + \alpha_{U\cap V} + \alpha_{V\setminus K}$ a cycle in $C_*(M, M \setminus (K \cup L))$?

(2) *For all $n \in \mathbb{N}_0$ there exists a unique homomorphism*

$$\delta\colon H^n(X, A \cap B) \;\to\; H^{n+1}(X, A \cup B)$$

which has the following property: for every $\varphi_A \in C^n(X, A)$ and $\varphi_B \in C^n(X, B)$ such that $\varphi_A + \varphi_B$ is a cocycle in $C^n(X, A \cap B)$ we have

$$\delta([\varphi_A + \varphi_B]) \;=\; [\delta\varphi_A] \;=\; -[\delta\varphi_B] \;\in\; H^n(X, \{A, B\}) = H^n(X, A \cup B).$$

(3) *The sequence*

$$\ldots \to H^n(X, A \cup B) \xrightarrow{i^* \oplus -i^*} H^n(X, A) \oplus H_n(X, B) \xrightarrow{i^* \oplus i^*} H^n(X, A \cap B) \xrightarrow{\delta} H^{n+1}(X, A \cup B) \to \ldots$$

is exact.

Proof. We start out with the following two observations:

(1) It is straightforward to verify that the following sequence of cochain maps between cochain complexes is exact:

$$0 \;\to\; C^*(X, \{A, B\}) \;\xrightarrow{i^* \oplus -i^*}\; C^*(X, A) \oplus C^*(X, B) \;\xrightarrow{i^* \oplus i^*}\; C^*(X, A \cap B) \;\to\; 0.$$

(2) Since the subsets A and B are open we know from Proposition 50.12 (4) that the triad (X, A, B) is excisive. Therefore it follows from Lemma 58.1 that the obvious map $C^*(X, A \cup B) \to C^*(X, \{A, B\})$ induces for every $n \in \mathbb{N}_0$ an isomorphism $H^n(X, A \cup B) \xrightarrow{\cong} H^n(X, \{A, B\})$.

With these two observations it is straightforward to modify the proof of Theorem 33.5 to obtain the theorem. We leave it to the reader to fill in the details. □

The key to the proof of Theorem 61.15 is the following lemma.

Lemma 61.20. *Let M be an oriented n-dimensional topological manifold with empty boundary that is the union of two open sets U and V. Then there exists a diagram*

$$\begin{array}{ccccccccc}
\ldots \longrightarrow & H_c^k(U \cap V) & \xrightarrow{i \oplus -i} & H_c^k(U) \oplus H_c^k(V) & \xrightarrow{i + i} & H_c^k(M) & \longrightarrow & H_c^{k+1}(U \cap V) & \longrightarrow \ldots \\
& \downarrow{\scriptstyle \mathrm{PD}_{U \cap V}} & & \downarrow{\scriptstyle \mathrm{PD}_U \oplus \mathrm{PD}_V} & & \downarrow{\scriptstyle \mathrm{PD}_M} & & \downarrow{\scriptstyle \mathrm{PD}_{U \cap V}} & \\
\ldots \longrightarrow & H_{n-k}(U \cap V) & \xrightarrow{i \oplus -i} & H_{n-k}(U) \oplus H_{n-k}(V) & \xrightarrow{i + i} & H_{n-k}(M) & \longrightarrow & H_{n-k-1}(U \cap V) & \longrightarrow \ldots
\end{array}$$

with the following properties:

(1) *the first two squares commute, the third square commutes up to the sign $(-1)^{k+1}$,*
(2) *the lower exact sequence is the long exact Mayer–Vietoris sequence for $M = U \cup V$,*
(3) *the upper horizontal sequence is also exact.*

Proof. Let M be an oriented n-dimensional topological manifold with empty boundary. Throughout the proof, given any two subsets $X \subset Y$ and $i \in \mathbb{N}_0$ we write as before $H^i(Y|X) := H^i(Y, Y \setminus X)$. We note that if U is open and $K \subset U$ is compact we obtain a map

$$- \cap \mu_K^U\colon H^k(U|K) \;\to\; H_{n-k}(U).$$

Now let let U and V be open subsets with $M = U \cup V$. Furthermore let $K \subset U$ and $L \subset V$ be compact subsets. We consider the following diagram

$$\begin{array}{ccccccccc}
\dots \to & H^k(M|K\cap L) & \to & H^k(M|K) \oplus H^k(M|L) & \longrightarrow & H^k(M|K\cup L) & \xrightarrow{\delta} & H^{k+1}(M|K\cap L) & \to \dots \\
& \downarrow \cong & & \downarrow \cong & & & & \downarrow \cong & \\
& H^k(U\cap V|K\cap L) & & H^k(U|K) \oplus H^k(V|L) & & \downarrow \cap\mu^M_{K\cup L} & & H^{k+1}(U\cap V|K\cap L) & \\
& \downarrow \cap\mu^{U\cap V}_{K\cap L} & & \downarrow \cap\mu^U_K \oplus \cap\mu^V_L & & & & \downarrow \cap\mu^{U\cap V}_{K\cap L} & \\
\dots \longrightarrow & H_{n-k}(U\cap V) & \longrightarrow & H_{n-k}(U) \oplus H_{n-k}(V) & \longrightarrow & H_{n-k}(M) & \xrightarrow{\partial} & H_{n-k-1}(U\cap V) & \to \dots
\end{array}$$

which we now explain in more detail:

(1) We write $A = M \setminus K$ and $B = M \setminus L$. The upper horizontal sequence is the inverted Mayer–Vietoris Sequence for cohomology groups from Theorem 61.19.
(2) The lower horizontal sequence is the Mayer-Vietoris sequence coming from Theorem 33.5, corresponding to the decomposition $M = U \cup V$.
(3) The three vertical maps on the top are induced by inclusions of pairs of topological spaces, they are isomorphisms by the Excision Theorem 45.8 (2).

The following is the key claim of the proof.

Claim. The first two rectangles commute and the third rectangle commutes up to the sign $(-1)^{k+1}$.

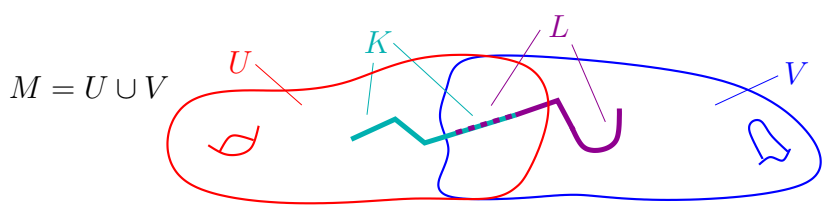

FIGURE 754.

Before we prove the claim we show that it implies Theorem 61.15. For each group appearing in the above diagram we take the direct limit over the directed set[1055]

$$I \;=\; \{(K, L) \mid K \text{ compact subset of } U \text{ and } L \text{ compact subset of } V\}$$

and we consider the induced maps of direct limits that were introduced on page 867. We make the following remarks regarding this new diagram:

[1055]We view I as a directed set given by the relation $(K, L) \le (K', L')$ if $K \subset K'$ and $L \subset L'$. It is clear that each of the groups in the diagram forms a direct system with respect to this directed set.

(1) Using Lemma 52.4 one can show that the groups that we obtain taking the direct limit over I are naturally isomorphic to the corresponding cohomology groups with compact support. We carry out the argument for two groups:

$$\varinjlim_{(K,L)\in I} H^k(U\cap V|K\cap L) \;=\; \varinjlim_{C\in\mathcal{K}(U\cap V)} H^k(U\cap V|C) \;=\; H^k_c(U\cap V).$$

we apply Lemma 52.4 to the cofinal morphism of directed sets given by $(K,L)\mapsto K\cap L$

and

$$\varinjlim_{(K,L)\in I} H^k(M|K\cup L) \;=\; \varinjlim_{C\in\mathcal{K}(M)} H^k(M|C) \;=\; H^k_c(M).$$

we apply Lemma 52.4 to the morphism of directed sets given by $(K,L)\mapsto K\cup L$, this morphism is cofinal by Lemma 61.17

All other cases are treated in a very similar fashion.

(2) By the functoriality of direct limits, and since the signs in the commutativity do not depend on K and L, the new diagram also commutes (up to the same signs).

(3) Using (2) and the definition of the "PD-maps" in Lemma 61.14 one can easily verify that the direct limit of the diagram does indeed give rise to the diagram specified in the statement of the lemma.

(4) Proposition 34.2 says that the direct limit of exact sequences is again exact.

All these remarks put together show that the direct limit of the above diagram gives rise precisely to the diagram that we claimed exists and that all claimed statements are satisfied. This concludes the proof that the claim implies the lemma.

We turn to the proof the claim. We show in three separate subclaims that the three rectangles commute. The proof of the first two subclaims consists of a clever usage of Lemma 59.8. The proof of the third subclaim is much more sophisticated since it relies on understanding the connecting homomorphisms in the Mayer-Vietoris sequences in (co-) homology.

Subclaim. The first rectangle of the diagram on page 1434 commutes.

So we need to show that the following diagram commutes:

$$\begin{tikzcd}
H^k(M, M\setminus K\cap L) \arrow[r, "i\oplus -i"] \arrow[d, "\cong"] \arrow[dr, "i\oplus -i"] & H^k(M, M\setminus K)\oplus H^k(M, M\setminus L) \arrow[d, "\cong"] \\
H^k(U\cap V, U\cap V\setminus K\cap L) \arrow[d, "\cap\mu^{U\cap V}_{K\cap L}"] & H^k(U, U\setminus K)\oplus H^k(V, V\setminus L) \arrow[d, "\cap\mu^U_K\oplus\cap\mu^V_L"] \\
H_{n-k}(U\cap V) \arrow[r, "i\oplus -i"] & H_{n-k}(U)\oplus H_{n-k}(V).
\end{tikzcd}$$

Evidently the triangle commutes. We note that the remaining pentagon breaks up into the "direct sum" of two diagrams. By symmetry reasons it suffices to consider the left-hand

summands. So let $\phi \in H^k(M, M \setminus K \cap L)$. We consider the following diagram of maps between pairs of topological spaces

$$\begin{tikzcd}
(U \cap V, U \cap V \setminus K \cap L) \arrow[r, "\alpha"] \arrow[d, "f \circ \alpha"] & (U, U \setminus K \cap L) \arrow[dl, "f"'] \\
(M, M \setminus K \cap L) & (U, U \setminus K). \arrow[l, "f \circ \beta"] \arrow[u, "\beta"]
\end{tikzcd}$$

With this notation we need to show that

$$\alpha_*\big((f \circ \alpha)^*(\phi) \cap \mu^{U \cap V}_{K \cap L}\big) \;=\; (f \circ \beta)^*(\phi) \cap \mu^U_K.$$

But this is indeed the case, since

$$\begin{array}{ccccc}
\alpha_*\big(\underbrace{(f \circ \alpha)^*}_{=\alpha^* \circ f^*}(\phi) \cap \mu^{U \cap V}_{K \cap L}\big) & = & f^*(\phi) \cap \alpha_*(\mu^{U \cap V}_{K \cap L}) & = & f^*(\phi) \cap \mu^U_{K \cap L} \\
 & & \uparrow & & \uparrow \\
 & & \text{Lemma 59.8} & & \text{by Lemma 46.11 we have } \alpha_*(\mu^{U \cap V}_{K \cap L}) = \mu^U_{K \cap L} \\
 & = & \beta_*\big((f \circ \beta)^*(\phi) \cap \mu^U_K\big) & = & (f \circ \beta)^*(\phi) \cap \mu^U_K \\
 & & \uparrow & & \uparrow \\
 & & \begin{array}{c}\text{same argument backwards} \\ \text{with the roles of } \alpha \text{ and } \beta \text{ exchanged}\end{array} & & \text{since } \beta \text{ on the first coordinate is the identity}
\end{array}$$

This concludes the proof of the subclaim.

Subclaim. The second rectangle of the diagram on page 1434 commutes.

The proof of that subclaim is very similar to the proof of the previous subclaim. We leave it as an exercise to the reader to fill in the details.

Subclaim. The third rectangle of the diagram on page 1434 commutes up to the sign $(-1)^{k+1}$.

As a reminder, we need to show that the following diagram commutes up to the sign $(-1)^{k+1}$:

$$\begin{tikzcd}
H^k(M, M \setminus K \cup L) \arrow[r, "\delta"] \arrow[d, "\cap \mu_{K \cup L}"] & H^{k+1}(M, M \setminus K \cap L) \arrow[r, "\cong"] & H^{k+1}(U \cap V, U \cap V \setminus K \cap L) \arrow[d, "\cap \mu_{K \cap L}"] \\
H_{n-k}(M) \arrow[rr, "\partial"] & & H_{n-k-1}(U \cap V).
\end{tikzcd}$$

So let $[\varphi] \in H^k(M, M \setminus K \cup L) = H^k(M, A \cap B)$. We start out with the following preparations:

(1) By Theorem 61.19 (1) we can find $\varphi_A \in C^k(M, A)$ and $\varphi_B \in C^k(M, B)$ such that $\varphi = \varphi_A + \varphi_B$.

(2) By Lemma 61.18 there exist singular chains $\alpha_{U\setminus L}$, $\alpha_{U\cap V}$ and $\alpha_{V\setminus K}$ in $U\setminus L$, $U\cap V$ and $V\setminus K$ such that the following three equalities hold:

$$\begin{array}{llcll}
\text{(2a)} & \mu_{K\cup L} & = & [\alpha_{U\setminus L}+\alpha_{U\cap V}+\alpha_{V\setminus K}] & \text{in } H_n(M, M\setminus(K\cup L)) \\
\text{(2b)} & \mu_{K\cap L}^{U\cap V} & = & [\alpha_{U\cap V}] & \text{in } H_n(U\cap V, U\cap V\setminus(K\cap L)) \\
\text{(2c)} & \mu_K^U & = & [\alpha_{U\setminus L}+\alpha_{U\cap V}] & \text{in } H_n(U, U\setminus K).
\end{array}$$

After these preparations we obtain the following equalities in $H_{n-k-1}(U\cap V)$:[1056]

$$\begin{array}{l}
\text{maps in the rectangle applied clockwise to } [\varphi] \;=\; \delta[\varphi]\cap\mu_{K\cap L}^{U\cap V} \overset{\substack{\text{Theorem 61.19 and (2b)}\\ \downarrow}}{=} [\delta\varphi_A\cap\alpha_{U\cap V}] \\
\underset{\substack{\uparrow\\ \text{Lemma 59.1}}}{=} [\varphi_A\cap\partial\alpha_{U\cap V}] \underset{\substack{\uparrow\\ \text{note that (2c) implies that } \partial(\alpha_{U\cap V}+\alpha_{U\setminus L}) \text{ is a singular chain in } U\setminus K,\\ \text{but } \varphi_A \text{ vanishes on singular chains in } A=M\setminus K}}{=} [\varphi_A\cap\partial\alpha_{U\cap V} - \underbrace{\varphi_A\cap\partial(\alpha_{U\cap V}+\alpha_{U\setminus L})}_{=0}] = [-\varphi_A\cap\partial\alpha_{U\setminus L}] \\
\underset{\substack{\uparrow\\ \text{since } \varphi_B \text{ vanishes on singular chains in } B=M\setminus L}}{=} [-\varphi_A\cap\partial\alpha_{U\setminus L} - \underbrace{\varphi_B\cap\partial\alpha_{U\setminus L}}_{=0}] = [-(\varphi_A+\varphi_B)\cap\partial\alpha_{U\setminus L}] \underset{\substack{\uparrow\\ \text{since } \varphi=\varphi_A+\varphi_B}}{=} [-\varphi\cap\partial\alpha_{U\setminus L}] \\
\underset{\substack{\uparrow\\ \text{by Lemma 59.1 and}\\ \text{since } \delta\varphi=0}}{=} [(-1)^{k+1}\cdot\partial(\varphi\cap\alpha_{U\setminus L})] \underset{\substack{\uparrow\\ \text{by the definition of the connecting homomorphism } \partial \text{ in the}\\ \text{Mayer–Vietoris sequence, see Theorem 33.5 (1)}}}{=} (-1)^{k+1}\cdot\partial[\underbrace{(\varphi\cap\alpha_{U\setminus L})}_{\in C_{n-k}(U)} + \underbrace{(\varphi\cap\alpha_{U\cap V}+\varphi\cap\alpha_{V\setminus K})}_{\in C_{n-k}(V)}] \\
\underset{\substack{\uparrow\\ \text{by equality (2a)}}}{=} (-1)^{k+1}\cdot\partial\big([\varphi]\cap\mu_{K\cup L}^M\big) = (-1)^{k+1}\cdot\text{maps in the rectangle applied counterclockwise to } [\varphi].
\end{array}$$

This concludes the proof of the claim and thus also of the lemma. □

Lemma 61.20 actually contains an interesting and useful statement which is worth jotting down separately.

Lemma 61.21. *Let M be an oriented n-dimensional topological manifold with empty boundary and let U be an open subset of M. We denote by $i\colon U\to M$ the inclusion. For any $k\in\mathbb{N}_0$ the following two diagrams commute:*

$$\begin{tikzcd}
H_c^k(U) \arrow[r, "i_*"] \arrow[d, "\mathrm{PD}_U"] & H_c^k(M) \arrow[d, "\mathrm{PD}_M"] \\
H_{n-k}(U) \arrow[r, "i_*"] & H_{n-k}(M)
\end{tikzcd}
\quad \textit{and} \quad
\begin{tikzcd}
H_k(U) \arrow[r, "i_*"] \arrow[d, "\mathrm{PD}_U"] & H_k(M) \arrow[d, "\mathrm{PD}_M"] \\
H_c^{n-k}(U) \arrow[r, "i_*"] & H_c^{n-k}(M).
\end{tikzcd}$$

Proof. The statement that the diagram on the left commutes for any k is contained in Lemma 61.20 (1). Since the maps PD_U and PD_M are isomorphisms the statement that the

[1056]The maps δ and ∂ written in blue are the connecting homomorphisms in the Mayer–Vietoris sequences.

diagram on the right commutes is just a reformulation of the fact that the diagrams on the left commutes. □

Now we turn to the actual proof of Theorem 61.15.

Proof of Theorem 61.15. We fix a dimension n. Throughout this proof by a "manifold" we mean an oriented n-dimensional topological manifold without boundary. We say *Poincaré Duality holds for a manifold M* if for each $k \in \mathbb{N}_0$ the map

$$\mathrm{PD}_M \colon H_c^k(M) \ \to \ H_{n-k}(M)$$

from Lemma 61.14 is an isomorphism. Our goal is to show that Poincaré Duality holds for all manifolds.

We start out with the following claim.

Claim. Let W be a manifold.

(A) If Poincaré Duality holds for W equipped with an orientation, then it also holds for any other orientation of W.
(B) If W is homeomorphic to a manifold for which Poincaré Duality holds, then Poincaré Duality also holds for W.
(C) Suppose that W is the union of two open subsets U and V. If Poincaré Duality holds for U, V and $U \cap V$, then it also holds for W.
(D) If W is the union of a nested sequence $U_1 \subset U_2 \subset \dots$ of open subsets such that Poincaré Duality holds for each U_i, then it also holds for W.

So let W be a manifold.

(A) Clearly it suffices to consider the case that W is path-connected. By Lemma 45.21 the path-oriented connected manifold W admits only one other orientation, namely the reverse orientation. Evidently Poincaré Duality also holds for that orientation.
(B) This statement is obvious.
(C) If all maps $\mathrm{PD}_U, \mathrm{PD}_V$ and $\mathrm{PD}_{U\cap V}$ are isomorphisms, then it follows immediately from Lemma 61.20 and the Five Lemma 31.11 that also each PD_W is an isomorphism, i.e. Poincaré Duality holds for $W = U \cup V$.
(D) Let $k \in \mathbb{N}_0$. We suppose that for every $i \in \mathbb{N}$ the map $\mathrm{PD}_{U_i} \colon H_c^k(U_i) \to H_{n-k}(U_i)$ is an isomorphism. Using Lemmas 59.8 and 61.14 it is straightforward to verify that for any $i \le j$ the following diagram commutes:

$$\begin{array}{ccc} H_c^k(U_i) & \xrightarrow{\mathrm{PD}_{U_i}} & H_{n-k}(U_i) \\ \downarrow & & \downarrow \\ H_c^k(U_j) & \xrightarrow{\mathrm{PD}_{U_j}} & H_{n-k}(U_j). \end{array}$$

We obtain isomorphisms

$$\begin{array}{ccccccc} H_c^k(W) & = & \varinjlim H_c^k(U_i) & \xrightarrow{\varinjlim \mathrm{PD}_{U_i}} & \varinjlim H_{n-k}(U_i) & = & H_{n-k}(W). \\ \uparrow & & \uparrow & & \uparrow & & \uparrow \\ \text{Proposition 53.6} & & \text{isomorphism by our hypothesis and since the above diagram commutes} & & & & \text{Proposition 34.4} \end{array}$$

We leave it as an exercise to verify that the map from left to right is indeed given by PD_W.

This concludes the proof of the claim.

The following claim completes the proof of the theorem.

Claim.

(1) Poincaré Duality holds for every open bounded convex subset of $\mathbb{R}^n$.
(2) For every $m \in \mathbb{N}$ Poincaré Duality holds for the union of m open bounded convex subsets of $\mathbb{R}^n$.
(3) Poincaré Duality holds for every open subset of $\mathbb{R}^n$.
(4) For every $m \in \mathbb{N}$ Poincaré Duality holds for all manifolds that admit an atlas with m charts.
(5) Poincaré Duality holds for all manifolds.

Now we provide the proof of the claim.

(1) Let M be an open bounded convex subset of $\mathbb{R}^n$. By Proposition 1.47 (1) there exists a homeomorphism $M \to B^n$. It follows from Lemma 61.16 and (B) that Poincaré Duality also holds for M.
(2) We prove the claim by induction on m. By (1) we know that the statement holds for $m = 1$. Now suppose it holds for all unions of $m - 1$ open bounded convex subsets of $\mathbb{R}^n$. Let M be the union of m open bounded convex subsets $U_1, \dots, U_m$. We set $V = U_1 \cup \dots \cup U_{m-1}$. By our hypothesis and by induction the statement holds for U_m, for V and also for $V \cap U_m = (U_1 \cap U_m) \cup \dots \cup (U_{m-1} \cap U_m)$, which is the union of $(m-1)$ open bounded convex subsets.[1057] Hence by (C) the statement also holds for
$$M = V \cup U_m = (U_1 \cup \dots \cup U_{m-1}) \cup U_m.$$
(3) Let M be an arbitrary open subset of $\mathbb{R}^n$. By Lemma 1.9 we can write M as the union of countably many open balls $B_i, i \in \mathbb{N}$. For $i \in \mathbb{N}$ we set $U_i := \bigcup_{j \le i} B_j$. By (2) Poincaré Duality holds for each $U_i \in \mathbb{N}$. But then it follows from (D) that Poincaré Duality also holds for M.
(4) We prove this statement by induction on m. The case $m = 1$ is taken care of by (3) and (B). Now suppose Poincaré Duality holds for all manifolds that admit an atlas with $m - 1$ charts. Let M be a manifold that admits an atlas $\{\phi_i \colon U_i \to V_i\}_{i=1,\dots,m}$ with m charts. We write $U = U_1 \cup \dots \cup U_{m-1}$ and $V = U_m$. Both are open

[1057] Here we once again use the convenient fact that the intersection of two convex sets is convex.

subsets of a manifold, hence they are also manifolds. Furthermore U and V are manifolds that admit an atlas with $m-1$ charts respectively one chart. Similarly $U \cap V = (U_1 \cap U_m) \cup \cdots \cup (U_{m-1} \cap U_m)$ is a manifold that admits an atlas with $m-1$ charts. By induction Poincaré Duality holds for U, V and $U \cap V$. Thus by (C) Poincaré Duality also holds for M itself.

(5) Finally let M be any manifold. We saw in Exercise 3.7 (1), using the fact that M is second-countable and using Lemma 1.26, that M admits a countable atlas $\{\Phi_j \colon U_j \to V_j\}_{j\in\mathbb{N}}$. For $i \in \mathbb{N}$ we set $X_i := \bigcup_{j\le i} U_j$. By (4) Poincaré Duality holds for each X_i. It follows from (D) that Poincaré Duality also holds for M. □

61.5. **The proof of Poincaré Duality for topological manifolds with boundary.** Now we will finally prove the general statement of the Poincaré Duality Theorem 61.1. For the reader's convenience we recall the statement.

Theorem 61.1. (Poincaré Duality Theorem) *Let M be a compact, non-empty n-dimensional topological manifold and let R be a commutative ring. We suppose that M is R-oriented. We denote by $[M] \in H_n(M, \partial M; R)$ the R-fundamental class. Furthermore suppose that we are given a decomposition $\partial M = A \cup B$ where A and B are compact $(n-1)$-dimensional submanifolds of ∂M such that $A \cap B = \partial A = \partial B$. Then for each $k \in \mathbb{N}_0$ the map*

$$\begin{array}{rcl} H^k(M, A; R) & \xrightarrow{\cong} & H_{n-k}(M, B; R) \\ \sigma & \mapsto & \sigma \cap [M] \end{array}$$

is an isomorphism.

Proof of Theorem 61.1 for $A = \partial M$ and $B = \varnothing$. In this proof we consider the case that $A = \partial M$ and $B = \varnothing$. To simplify the notation we will once again only consider the case that $R = \mathbb{Z}$. The proof of the general case is basically the same. We introduce the following objects:

(1) From the Topological Collar Neighborhood Theorem 45.3 we obtain a collar neighborhood $\partial M \times [-1, 0]$ of $\partial M = M \times \{0\}$. We refer to it as the "internal collar".

(2) We define

$$W := M \cup (\partial M \times [0, 1))/\sim \text{ with } x \sim (x, 0) \text{ for every } x \in \partial M.$$

Sometimes $\partial M \times [0, 1)$ is called an *external collar of M*. Furthermore, given any $t \in [-1, 1)$ we write

$$K_t := (M \setminus \partial M \times [-1, 0]) \cup (\partial M \times [-1, t])/\sim .$$

By elementary arguments and using Proposition 32.1 (1) one can easily show the following statements:

(A) W is an n-dimensional topological manifold with empty boundary,

(B) W admits an orientation such that M is a submanifold and such that $M \to W$ is orientation-preserving,

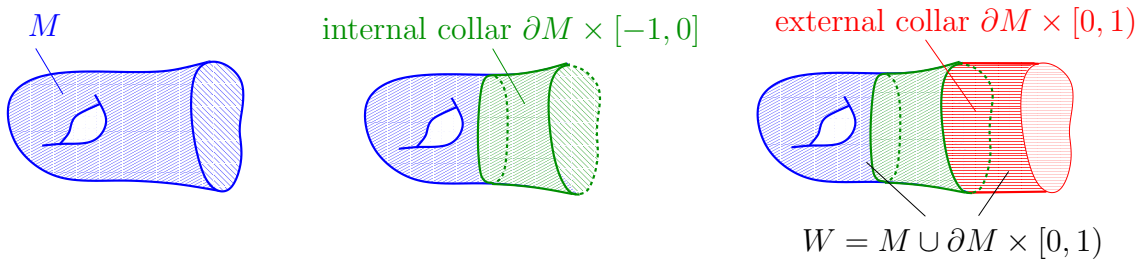

FIGURE 755.

(C) every K_t is a compact subset of W and given any compact subset K of W there exists a $t \in [-1,1)$ with $K \subset K_t$.

We denote by $i\colon (M, \partial M) \to (W, W \setminus K_{-1})$ the obvious inclusion map. We obtain the following diagram:

$$\begin{tikzcd}
H^k(M,\partial M) \arrow[d, "\cap[M]"] & H^k(W, W \setminus K_{-1}) \arrow[l, "i^*"'] \arrow[r] \arrow[d, "\cap \mu_{K_t}"] & H^k_c(W) \arrow[d, "\mathrm{PD}_W"] \\
H_{n-k}(M) \arrow[r, "i_*"] & H_{n-k}(W) \arrow[r, "="] & H_{n-k}(W).
\end{tikzcd}$$

It remains to prove the following claim which resembles closely the claim in the proof of Lemma 61.16.

Claim. The following three statements hold:

(1) the diagram commutes,
(2) the right vertical map is an isomorphism, and
(3) all horizontal maps are isomorphisms.

We turn to the proof of the claim.

(1) The right-hand square commutes by definition of PD_W. Using (B) we can apply the same argument as in the proof of the claim in Lemma 61.16 to show that the left-hand square commutes.
(2) Theorem 61.15 implies that the right vertical map is an isomorphism.
(3) It follows easily from Corollary 31.16 and Lemma 48.13 that the left horizontal maps are isomorphisms. It remains to show that the top right horizontal map is an isomorphism. Similar to the proof of Lemma 61.16 we consider the following

commutative diagram

$$\begin{tikzcd}
H^k(W, W \setminus K_{-1}) \arrow[rr] \arrow[dr] & & \lim\limits_{\substack{\longrightarrow \\ K \in \mathcal{K}(W)}} H^k(W, W \setminus K) = H^k_c(W). \\
& \lim\limits_{\substack{\longrightarrow \\ t \in [-1,1)}} H^k(W, W \setminus K_t) \arrow[ur] &
\end{tikzcd}$$

We make the following two observations:

(a) By (C) every compact subset of W is contained in some K_t. Therefore it follows from Lemma 52.3 that the right diagonal map is an isomorphism.

(b) It follows easily from Lemmas 48.13 and 52.2 (4) that the left diagonal map is an isomorphism.

These two observations together imply that the horizontal map is also an isomorphism.

This concludes the proof of the claim and it concludes the proof of Theorem 61.1 in the special case that $A = \partial M$ and $B = \varnothing$. □

Proof of Theorem 61.1 for the general case. Now we finally consider the general case of Theorem 61.1. So we suppose that we are given a decomposition $\partial M = A \cup B$ where A and B are compact $(n-1)$-dimensional submanifolds of ∂M such that $A \cap B = \partial A = \partial B$. We recall that by Proposition 50.12 (5) we know that the triad (M, A, B) is excisive. In this proof, once again we simplify the notation and we only work with $\mathbb{Z}$-coefficients.

We equip ∂M and then also B with the orientations coming from Proposition 45.30 and Lemma 45.28. We consider the following diagram

$$\begin{tikzcd}
\dots \arrow[r] & H^k(M, \partial M) \arrow[r] \arrow[d, "\cong"', "-\cap[M]"] & H^k(M, A) \arrow[r] \arrow[d, "-\cap[M]"] & H^k(\partial M, A) \arrow[r, "\delta"] \arrow[d, "\cong"', "i^*"] & H^{k+1}(M, \partial M) \arrow[r] \arrow[d, "\cong"', "-\cap[M]"] & \dots \\
\dots \arrow[r] & H_{n-k}(M) \arrow[r] & H_{n-k}(M, B) \arrow[r, "\partial"] & H^k(B, \partial B) \arrow[d, "\cong"', "-\cap[B]"] & & \\
& & & H_{n-k-1}(B) \arrow[r] & H_{n-k-1}(M) \arrow[r] & \dots
\end{tikzcd}$$

We make the following observations:

(1) The top horizontal sequence is the long exact sequence in cohomology of the triple $(M, \partial M, A)$ provided by Lemma 48.15.

(2) The bottom horizontal sequence is the long exact sequence in homology of the pair (M, B) provided by Corollary 31.14.

(3) The above vertical map $i^* \colon H^k(\partial M, A) \to H^k(B, \partial B)$ is induced by the inclusion $i \colon (B, \partial B) \to (\partial M, A)$. It is an isomorphism by Proposition 50.12 (5) together with Lemma 50.13 (3).

(4) The other maps decorated with "≅" are isomorphisms by the special case of the Poincaré Duality Theorem 61.1 that we have already dealt with.

By the Five Lemma 31.11 it remains to prove the following claim.

Claim. The above diagram commutes up to signs, more precisely:

(1) the first rectangle commutes,
(2) the second rectangle commutes up to the sign $(-1)^k$,
(3) the third rectangle commutes.

We consider the three rectangles separately.

(1) We consider the following diagram:

$$\begin{tikzcd}
H^k(M,\partial M) \times H_n(M,\partial M) \arrow[r] & H_{n-k}(M) \arrow[d] \\
H^k(M,\partial M) \times H_n(M,\partial M) \arrow[u, "="] \arrow[d] \arrow[r] & H_{n-k}(M,B) \\
H^k(M,A) \times H_n(M,\partial M) \arrow[u, "="] \arrow[r] & H_{n-k}(M,B) \arrow[u, "="]
\end{tikzcd}$$

We can convince ourselves that the diagram commutes by applying Lemma 59.8 to the maps $(M,\partial M,\varnothing) \to (M,\partial M,B)$ and $(M,A,B) \to (M,\partial M,B)$ of excisive triads. It follows easily from this observation that the first rectangle of the claim commutes.

Before we continue with the discussion of the other two rectangles we need to make one remark. We denote by $j\colon (B,\partial B) \to (\partial M, A)$ the inclusion map and we denote by $\partial\colon H_n(M,\partial M) \to H_{n-1}(\partial M, A)$ the connecting homomorphism in the long exact sequence of the triple $(M,\partial M,A)$. It follows from Proposition 46.26 (1), Lemma 46.23 and the remark on page 780 that the following equality holds

$$(*) \qquad i_*([B]) \;=\; \partial[M] \in H_{n-1}(\partial M, A).$$

Now we continue with the proof of the claim.

(2) We apply Lemma 59.10 (2) to the excisive triad (M,A,B). (Recall that $A \cup B = \partial M$ and $A \cap B = \partial B$.) We obtain that for any $k \in \mathbb{N}_0$ the following diagram commutes up to the sign $(-1)^k$:

$$\begin{tikzcd}
H^k(M,A) \times H_n(M,\partial M) \arrow[r, "\cap"] \arrow[d, "i^*"'] & H_{n-k}(M,B) \arrow[dd, "\partial"] \\
H^k(\partial M,A) \times H_{n-1}(\partial M,A) \arrow[d, "j^*"', "\cong"] & \\
H^k(B,\partial B) \times H_{n-1}(B,\partial B) \arrow[r, "\cap"] & H_{n-k-1}(B).
\end{tikzcd}$$

Together with $(*)$ we obtain that the second rectangle of the claim does indeed commute up to the sign $(-1)^k$.

(3) We consider the following diagram:

$$\begin{array}{ccc}
H^k(B,\partial B)\times H_{n-1}(B,\partial B) & \xrightarrow{\cap} & H_{n-k-1}(B) \\
{\scriptstyle i^*}\uparrow \quad \downarrow{\scriptstyle i_*} & & \downarrow{\scriptstyle i_*} \\
H^k(\partial M,A)\times H_{n-1}(\partial M,A) & \xrightarrow{\cap} & H_{n-k-1}(\partial M) \\
{\scriptstyle \delta}\downarrow \quad \uparrow{\scriptstyle \partial} & & \downarrow{\scriptstyle i_*} \\
H^{k+1}(M,\partial M)\times H_n(M,\partial M) & \xrightarrow{\cap} & H_{n-k-1}(M).
\end{array}$$

The upper part of this diagram commutes by Lemma 59.8 applied to the map $(B,\partial B,\varnothing)\to(\partial M,A,\varnothing)$ between excisive triads. The lower part commutes by Lemma 59.10 (1) applied to the triple $(M,\partial M,A)$. This discussion, together with $(*)$, implies that the third rectangle of the diagram in the claim commutes.

This concludes the proof of the claim and thus also of the Poincaré Duality Theorem 61.1. □

Remark. It follows from the Poincaré Duality Theorem 61.1 and Corollary 57.12 that if X is a topological space that is homotopy equivalent to a closed orientable connected n-dimensional manifold, then there exists a $\phi\in H^n(X;\mathbb{Z})$ such that for any $k\in\mathbb{N}_0$ the map

$$-\cap\phi\colon H^k(X;\mathbb{Z})\ \to\ H_{n-k}(X;\mathbb{Z})$$

is an isomorphism. (The same condition also has to hold for all finite covers of X.) One can ask to what degree the converse holds. But in [DP, p. 21] (see also [MM, p. 32]) it is shown that there exists a simply connected 5-dimensional CW-complex X such that the cohomology ring is isomorphic to the cohomology ring of $S^2\times S^3$ but such that X is not homotopy equivalent to a compact manifold.

If M is a compact topological n-dimensional manifold with non-empty boundary then the following proposition relates capping with the fundamental class of M to capping with the fundamental class of ∂M.

Proposition 61.22. *Let M be a compact, non-empty n-dimensional topological manifold and let R be a commutative ring. We suppose that M is R-oriented. As usual we denote by $[M]\in H_n(M,\partial M;R)$ the R-fundamental class. We consider the following diagram:*

$$\begin{array}{ccccccc}
\ldots\to H^k(M,\partial M;R) & \longrightarrow & H^k(M;R) & \longrightarrow & H^k(\partial M;R) & \xrightarrow{\delta} & H^{k+1}(M,\partial M;R)\to\ldots \\
\downarrow{\scriptstyle -\cap[M]} & & \downarrow{\scriptstyle -\cap[M]} & & \downarrow{\scriptstyle -\cap[\partial M]} & & \downarrow{\scriptstyle -\cap[M]} \\
\ldots\longrightarrow H_{n-k}(M;R) & \longrightarrow & H_{n-k}(M,\partial M;R) & \to & H_{n-k-1}(\partial M;R) & \longrightarrow & H_{n-k-1}(M;R)\xrightarrow{\partial}\ldots
\end{array}$$

where the horizontal sequences are the long exact sequences in (co-) homology of the pair $(M,\partial M)$. The first and the third square commute, furthermore the second square commutes up to the sign $(-1)^k$.

Proof. We had implicitly proved the proposition in the above proof of the Poincaré Duality Theorem 61.1 applied to the special case that $A=\varnothing$ and $B=\partial M$. □

Exercises for Chapter 61.

Exercise 61.1.

(a) Let M be a connected closed 3-dimensional manifold. Show that if M is non-orientable, then $H_1(M;\mathbb{Z})$ is infinite.
(b) Is the hypothesis in (a) that M is closed necessary? Justify your answer.

Exercise 61.2.

(a) Let M be an n-dimensional closed orientable connected topological manifold with $\pi_1(M) \cong S_5$. What can you say about $H^{n-1}(M;\mathbb{Z})$? Does the answer depend on whether or not M has boundary?
(b) Let M be a non-compact orientable topological manifold. Show that the group $H_{n-1}(M, \partial M; \mathbb{F}_2)$ is non-zero.

Exercise 61.3. Let $p\colon \widetilde{N} \to N$ be a finite covering of a closed, oriented n-dimensional topological manifold. We equip $\widetilde{N}$ with the orientation given by Lemma 45.28

(a) Let $r \leq s$. Show that given any singular simplex $\sigma\colon \Delta^s \to N$ and any cochain $\phi \in C^r(N;\mathbb{Z})$ we have
$$p^*(\phi) \cap p^*(\sigma) \;=\; p^*(\phi \cap \sigma).$$
Here p^* for homology classes denotes the transfer map.
(b) Show that for any $k \in \mathbb{N}_0$ the Umkehr map $p^!\colon H_k(N;\mathbb{Z}) \to H_k(\widetilde{N};\mathbb{Z})$ equals the transfer map p^*.
Hint: Proposition 46.24 might be useful.

Exercise 61.4. Is the Klein bottle the boundary of a compact 3-dimensional manifold? Justify your answer.

Exercise 61.5.

(a) Let M be a topological manifold and let U, V be open subsets such that $M = U \cup V$. Show that given any compact subset $C \subset M$ there exist compact subsets $K \subset U$ and $L \subset V$ such that $C = K \cup L$.
(b) Does statement (a) hold for any topological space?

Exercise 61.6. Let M be a closed connected 4-dimensional topological manifold that is simply connected and with $\chi(M) = 2$. What can you say about the homeomorphism type of M?

Exercise 61.7. Let W be a closed orientable topological 4-manifold with $\chi(W) = -3$. Show that W admits a finite covering $\widetilde{W}$ with $\chi(\widetilde{W}) < -27$.

Exercise 61.8. Let M be a closed 4-manifold.

(a) Show that if M is simply connected, then there exist at most finitely many isomorphism classes of finite groups which can act discretely on M.

(b) Is the hypothesis in (a) that M is simply connected necessary?

Exercise 61.9. Let M be a compact orientable 4-manifold with $\partial M = A \sqcup B$ where A and B are two connected 3-manifolds with $H_1(A;\mathbb{Z})$ finite. We suppose that the inclusion induced map $H_1(A;\mathbb{Z}) \to H_1(M;\mathbb{Z})$ is an epimorphism. Show that the inclusion induced map $H_1(B;\mathbb{Z}) \to H_1(M;\mathbb{Z})$ is a monomorphism.

62. The cup product of projective spaces

In this chapter we will use the Poincaré Duality Theorem 61.1 to determine the cup product on $H^*(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$ and $H^*(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2)$. These calculations will allow us to prove several interesting consequences which at first glance have very little to do with cup products.

62.1. **Non-singular pairings and the cup product.** Before we start drawing more conclusions from the Poincaré Duality Theorem 61.1 we need to introduce some purely algebraic definitions.

Definition. Let R be a commutative ring and let V, W and S be R-modules.

(1) A *pairing* on $V \times W$ is a map

$$V \times W \ \to \ S$$

that is R-bilinear, i.e. that is R-linear in V and that is R-linear in W.[1058]

(2) We say that a pairing $\langle\ ,\ \rangle\colon V \times W \to S$ is *non-singular* if the induced maps

$$\begin{array}{ccc} V & \to & \mathrm{Hom}_R(W,S) \\ v & \mapsto & \left(\begin{array}{ccc} W & \to & S \\ w & \mapsto & \langle v,w\rangle \end{array}\right) \end{array} \quad \text{and} \quad \begin{array}{ccc} W & \to & \mathrm{Hom}_R(V,S) \\ w & \mapsto & \left(\begin{array}{ccc} V & \to & S \\ v & \mapsto & \langle v,w\rangle \end{array}\right) \end{array}$$

are isomorphisms.

We start out with the following elementary lemma.

Lemma 62.1. *Let R be a commutative ring. Let V and W be free R-modules of the same rank and let*

$$\langle\ ,\ \rangle\colon V \times W \to R$$

be a pairing.

(1) *We denote by n the rank of V. Let $v_1,\dots,v_n$ be a basis for V and let $w_1,\dots,w_n$ be a basis for W. Then the following statement holds:*

$$\text{the pairing } \langle\ ,\ \rangle \text{ is non-singular} \quad\Longleftrightarrow\quad \det(\langle v_i,w_j\rangle)_{i,j=1,\dots,n}) \text{ is a unit of } R.$$

(2) *Suppose V and W are of rank one. If v and w are generators of V respectively W, then the following statement holds:*

$$\text{the pairing } \langle\ ,\ \rangle \text{ is non-singular} \quad\Longleftrightarrow\quad \langle v,w\rangle \text{ is a unit of the ring } R.$$

Proof. The second statement is evidently just a special case of the first statement. So it suffices to prove the first statement. Let $v_1,\dots,v_n$ be a basis for V and let $w_1,\dots,w_n$ be a basis for W. We denote by $v_1^*,\dots,v_n^* \in \mathrm{Hom}(V,R)$ and $w_1^*,\dots,w_n^* \in \mathrm{Hom}(W,R)$ the dual bases. We consider the maps

$$\begin{array}{ccc} V & \to & \mathrm{Hom}_R(W,R) \\ v & \mapsto & \left(\begin{array}{ccc} W & \to & R \\ w & \mapsto & \langle v,w\rangle \end{array}\right) \end{array} \quad \text{and} \quad \begin{array}{ccc} W & \to & \mathrm{Hom}_R(V,R) \\ w & \mapsto & \left(\begin{array}{ccc} V & \to & R \\ v & \mapsto & \langle v,w\rangle \end{array}\right) \end{array}.$$

[1058] In most examples we will be interested in $S = R$, but later on we will, oddly enough, also develop a fondness for $R = \mathbb{Z}$ and $S = \mathbb{Q}/\mathbb{Z}$.

Since $\langle\, ,\, \rangle$ is R-bilinear both maps are R-homomorphisms. Furthermore, it is straightforward to show that with respect to these bases both the R-homomorphisms are represented by the transpose of the matrix $(\langle v_i, w_j\rangle_{i,j=1,\dots,n})$. The lemma is an immediate consequence of this observation. $\square$

Remark. The proof of Lemma 62.1 shows that if V and W are free R-modules of finite rank, then the pairing is non-singular if and only if either of the two maps $V \to \operatorname{Hom}(W, R)$ or $W \to \operatorname{Hom}(V, R)$ is an isomorphism.[1059]

Now we return to topology.

Proposition 62.2. *Let M be a closed n-dimensional topological manifold and let $k \in \mathbb{N}_0$.*

(1) *Suppose M is oriented with fundamental class $[M]$. If $H_{k-1}(M;\mathbb{Z})$ and $H_{n-k-1}(M;\mathbb{Z})$ are torsion-free, then the cup product pairing*
$$\begin{array}{rcl} H^k(M;\mathbb{Z}) \times H^{n-k}(M;\mathbb{Z}) & \to & \mathbb{Z} \\ (\varphi, \psi) & \mapsto & \langle \varphi \cup \psi, [M]\rangle \end{array}$$
is non-singular.

(2) *Let $\mathbb{F}$ be a field. If M is $\mathbb{F}$-oriented with fundamental class $[M]$, then for any $k \in \mathbb{N}_0$ the cup product pairing*
$$\begin{array}{rcl} H^k(M;\mathbb{F}) \times H^{n-k}(M;\mathbb{F}) & \to & \mathbb{F} \\ (\varphi, \psi) & \mapsto & \langle \varphi \cup \psi, [M]\rangle \end{array}$$
is non-singular.

Proof. Let M be a closed n-dimensional topological manifold and let $k \in \mathbb{N}_0$.

(1) We suppose that M is oriented with fundamental class $[M]$ and we suppose that $H_{k-1}(M;\mathbb{Z})$ and $H_{n-k-1}(M;\mathbb{Z})$ are torsion-free. It follows from Proposition 45.2, our hypothesis on $H_{k-1}(M;\mathbb{Z})$ and $H_{n-k-1}(M;\mathbb{Z})$, the classification of finitely generated abelian groups, Lemma 51.5 (3) and the Universal Coefficient Theorem 51.13 that $H_{k-1}(M;\mathbb{Z})$, $H_{n-k-1}(M;\mathbb{Z})$, $H^k(M;\mathbb{Z})$ and $H^{n-k}(M;\mathbb{Z})$ are finitely generated free abelian groups. Therefore by the remark on page 1448 it suffices to show that the map
$$\begin{array}{rcl} \Omega\colon H^{n-k}(M;\mathbb{Z}) & \to & \operatorname{Hom}(H^k(M;\mathbb{Z}), \mathbb{Z}) \\ \psi & \mapsto & (\varphi \mapsto \langle \varphi \cup \psi, [M]\rangle) \end{array}$$
is an isomorphism. We start out with the following claim.

Claim. The following diagram commutes:[1060]
$$\begin{tikzcd} H^{n-k}(M;\mathbb{Z}) \arrow[rr, "\Omega"] \arrow[dr, "\mathrm{ev}"'] & & \operatorname{Hom}(H^k(M;\mathbb{Z}), \mathbb{Z}). \\ & \operatorname{Hom}_{\mathbb{Z}}(H_{n-k}(M;\mathbb{Z}), \mathbb{Z}) \arrow[ur, "(\cap[M])^*"'] & \end{tikzcd}$$

[1059] Is the hypothesis on V and W necessary to draw this conclusion?

[1060] The right diagonal is the dual map corresponding to the map $H^k(M;\mathbb{Z}) \xrightarrow{\cap[M]} H_{n-k}(M;\mathbb{Z})$.

We start out with the observation that for any $\psi \in H^{n-k}(M;\mathbb{Z})$ and $\varphi \in H^k(M;\mathbb{Z})$ the following equalities hold in $\mathbb{Z}$:

$$\Omega(\psi)(\varphi) \underset{\substack{\uparrow \\ \text{by definition of } \Omega \\ \text{and Lemma 59.4}}}{=} (\varphi \cup \psi) \cap [M] \underset{\substack{\uparrow \\ \text{Lemma 59.7}}}{=} \psi \cap (\varphi \cap [M]) \underset{\substack{\uparrow \\ \text{Lemma 59.4}}}{=} \langle \psi, \varphi \cap [M] \rangle = \mathrm{ev}(\psi)(\varphi \cap [M]).$$

But this observation immediately shows that the diagram commutes. This concludes the proof of the claim.

We need to show that in the above diagram the horizontal map is an isomorphism. By the claim it suffices to show that the two diagonal maps are isomorphisms. The left diagonal map is an isomorphism by the Universal Coefficient Theorem 51.13 for Cohomology Groups together with Lemma 51.5 (3) and the fact, pointed out above, that $H_{n-k-1}(M;\mathbb{Z})$ is free abelian. Furthermore the second map is an isomorphism by the Poincaré Duality Theorem 61.1.

(2) Now let $\mathbb{F}$ be a field. We suppose that M is $\mathbb{F}$-oriented with corresponding fundamental class $[M]$. By Proposition 51.18 the map

$$\begin{array}{rcl} \mathrm{ev}\colon H^k(M;\mathbb{F}) & \to & \mathrm{Hom}_{\mathbb{F}}(H_k(M;\mathbb{F}),\mathbb{F}) \\ \varphi & \mapsto & \left(\begin{array}{rcl} H_k(M;\mathbb{F}) & \to & \mathbb{F} \\ \sigma & \mapsto & \langle \varphi, \sigma \rangle \end{array} \right) \end{array}$$

is a natural isomorphism of $\mathbb{F}$-vector spaces. The proof of (2) is now basically the same as the proof of (1). □

The following corollary will be surprisingly effective in determining cup products on topological manifolds.

Corollary 62.3. *Let M be a closed, connected n-dimensional topological manifold and let $k \in \mathbb{N}_0$.*

(1) *Suppose that M is oriented and that $H_{k-1}(M;\mathbb{Z})$ and $H_{n-k-1}(M;\mathbb{Z})$ are torsion-free. Furthermore suppose that $H^k(M;\mathbb{Z}) \cong \mathbb{Z}$ and $H^{n-k}(M;\mathbb{Z}) \cong \mathbb{Z}$. If $\varphi \in H^k(M;\mathbb{Z})$ and $\psi \in H^{n-k}(M;\mathbb{Z})$ are generators, then*

$$\varphi \cup \psi \;=\; \epsilon \cdot [M]^* \;\in\; H^n(M;\mathbb{Z})$$

for some $\epsilon \in \{-1, 1\}$.

(2) *Let $\mathbb{F}$ be a field such that M is $\mathbb{F}$-orientable. Suppose that $H^k(M;\mathbb{F}) \cong \mathbb{F}$ and $H^{n-k}(M;\mathbb{F}) \cong \mathbb{F}$. If $\varphi \in H^k(M;\mathbb{F})$ and $\psi \in H^{n-k}(M;\mathbb{F})$ are non-zero, then $\varphi \cup \psi$ is non-zero in $H^n(M;\mathbb{F}) \cong \mathbb{F}$.*

Proof. Let M be a closed, connected n-dimensional topological manifold and let $k \in \mathbb{N}_0$.

(1) By our hypothesis and by Proposition 62.2 (1) the cup product pairing

$$\begin{array}{rcl} H^k(M;\mathbb{Z}) \times H^{n-k}(M;\mathbb{Z}) & \to & \mathbb{Z} \\ (\varphi, \psi) & \mapsto & \langle \varphi \cup \psi, [M] \rangle \end{array}$$

is non-singular. It follows from this fact and Lemma 62.1 (2) that $\langle \varphi \cup \psi, [M] \rangle = \pm 1$. But by Lemma 51.15 this just means that $\varphi \cup \psi \in H^n(M;\mathbb{Z})$ is a generator.

(2) This proof is almost identical to the proof of (1), we just need to replace Proposition 62.2 (1) by Proposition 62.2 (2). □

Example. Let $m \neq n \in \mathbb{N}$. As usual we denote by $p\colon S^m \times S^n \to S^m$ and by $q\colon S^m \times S^n \to S^n$ the two obvious projection maps. Let $1 \in H^0(S^m \times S^n;\mathbb{Z})$ be the neutral element from Proposition 57.7. In Lemma 60.3 we showed that the cohomology of $S^m \times S^n$ is given as follows:

$$H^*(S^m \times S^n;\mathbb{Z}) \;=\; \mathbb{Z}\cdot 1 \oplus \mathbb{Z}\cdot p^*([S^m]^*) \oplus \mathbb{Z}\cdot q^*([S^n]^*) \oplus \mathbb{Z}\cdot [S^m \times S^n]^*.$$

It follows from Corollary 62.3 (1)[1061] that $p^*([S^m]^*) \cup q^*([S^n]^*) = \pm[S^m \times S^n]^*$. This result recovers (up to the sign indeterminacy) the calculation of the non-trivial cup product on $S^m \times S^n$ that we had initially performed in Lemma 60.3 using the somewhat mysterious Product Theorem 60.1. In Exercise 62.3 we will see, that with slightly more effort, one can also prove the same type of result for $m = n$.

Next we consider the topological spaces $S^2 \vee S^4$ and $\mathbb{C}\mathrm{P}^2$. It follows from Propositions 5.14 and 12.3 and the discussion on page 697 that $S^2 \vee S^4$ and $\mathbb{C}\mathrm{P}^2$ are both simply connected. Furthermore it follows from Propositions 31.3 and 34.8, the calculation on page 884 and the Universal Coefficient Theorem 51.13 for Cohomology Groups that for any $k \in \mathbb{N}_0$ we have

$$H_k(S^2 \vee S^4;\mathbb{Z}) \;\cong\; H^k(S^2 \vee S^4;\mathbb{Z}) \;\cong\; H^k(\mathbb{C}\mathrm{P}^2;\mathbb{Z}) \;\cong\; H_k(\mathbb{C}\mathrm{P}^2;\mathbb{Z}) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k = 0,2,4, \\ 0, & \text{otherwise.} \end{cases}$$

We can thus view $S^2 \vee S^4$ as a (co-) homological doppelgänger to $\mathbb{C}\mathrm{P}^2$.

Using Corollary 62.3 (1) we can easily prove the following lemma which implies in particular that $S^2 \vee S^4$ is not homotopy equivalent to $\mathbb{C}\mathrm{P}^2$.

Lemma 62.4. *The topological space $S^2 \vee S^4$ is not homotopy equivalent to any closed topological manifold.*

Proof. Let X be a closed topological manifold whose homology and cohomology groups are isomorphic to the corresponding groups of $S^2 \vee S^4$. It follows from the above calculation of homology groups, our hypothesis that X is compact, from Propositions 29.5 and 46.21 and Theorems 46.2 and 46.4 that X is a closed oriented closed connected 4-dimensional topological manifold. But then Corollary 62.3 (1) implies that the cup product

$$H^2(X;\mathbb{Z}) \times H^2(X;\mathbb{Z}) \;\to\; H^4(X;\mathbb{Z})$$

is non-zero.

On the other hand in Lemma 57.11 we saw that the cup product

$$\cup\colon H^2(S^2 \vee S^4;\mathbb{Z}) \times H^2(S^2 \vee S^4;\mathbb{Z}) \;\to\; H^4(S^2 \vee S^4;\mathbb{Z})$$

[1061] Of course here we also use the fact, with which we are very familiar by now, that the homology groups of $S^m \times S^n$ are torsion-free.

is the zero-map. By Corollary 57.12 and the above calculation of the cup product of X this implies that $S^2 \vee S^4$ and X are not homotopy equivalent. $\square$

Remark. One can ask whether the adjective "closed" in Lemma 62.4 is necessary. It turns out that this is the case. In fact every wedge of finitely many spheres can be viewed as a deformation retract of an open subset of a sufficiently high-dimensional $\mathbb{R}^n$. For the wedge $S^1 \vee S^1$ we sketch the argument in Figure 756. With slightly more care one can also show that this wedge of finitely many spheres is also a deformation retract of some compact n-dimensional manifold of $\mathbb{R}^n$. We leave it as an exercise to provide a formal proof for these statements.

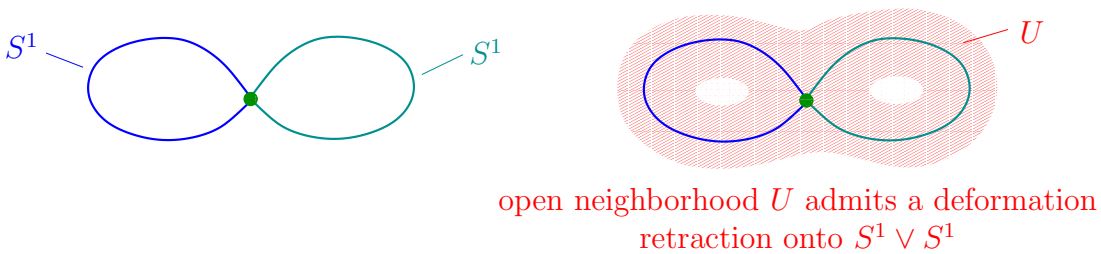

FIGURE 756.

We conclude this section with the following application to de Rham cohomology. We will not make use of it later on.

Corollary 62.5. *If M is a closed oriented n-dimensional manifold, then for any $k \in \mathbb{N}_0$ the pairing*

$$\begin{array}{rcl} H^k_{\mathrm{dR}}(M) \times H^{n-k}_{\mathrm{dR}}(M) & \to & \mathbb{R} \\ ([\varphi],[\psi]) & \mapsto & \int\limits_M \varphi \wedge \psi \end{array}$$

is non-singular.

Since there is no "de Rham homology" the above corollary is usually called the Poincaré Duality Theorem for de Rham cohomology.

Remark. Evidently there are also more direct proofs of Corollary 62.5 that take place within the setting of de Rham cohomology. We refer to [BT, p. 44] or alternatively [War, Theorem 6.13] for such a proof.

Proof. It is straightforward to see that it suffices to deal with the case that M is connected. Theorem 57.19 and the remark on page 1299 give us the following commutative diagram

with vertical isomorphisms:

$$\begin{array}{ccc} H^k_{\mathrm{dR}}(M) \times H^{n-k}_{\mathrm{dR}}(M) & \xrightarrow{(\varphi,\psi)\mapsto \int_M \varphi\wedge\psi} & \mathbb{R} \\ \cong\downarrow \qquad \downarrow\cong & & \downarrow= \\ H^k(M;\mathbb{R}) \times H^{n-k}(M;\mathbb{R}) & \xrightarrow{(\varphi,\psi)\mapsto\langle\varphi\cup\psi,[M]\rangle} & \mathbb{R}. \end{array}$$

By Proposition 62.2 (2) the pairing on the bottom is non-singular. Thus the pairing on the top is also non-singular. □

62.2. **The cup product of $\mathbb{C}\mathrm{P}^n$ and applications.** In this section we apply our acquired wisdom to the complex projective spaces $\mathbb{C}\mathrm{P}^n$. Recall that in Lemma 21.6 we showed that $\mathbb{C}\mathrm{P}^n$ is a closed $2n$-dimensional manifold that comes with a canonical orientation. Thus we will always view $\mathbb{C}\mathrm{P}^n$ as an *oriented* manifold. In particular $\mathbb{C}\mathrm{P}^n$ comes with a canonical fundamental class $[\mathbb{C}\mathrm{P}^n] \in H_{2n}(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$ and a canonical dual fundamental class $[\mathbb{C}\mathrm{P}^n]^* \in H^{2n}(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$.

An astute observer might already have noticed that Corollary 62.3 (1) can be used to compute the cup product on $H^*(\mathbb{C}\mathrm{P}^2;\mathbb{Z})$. In fact in this section we will use Corollary 62.3 (1) and the naturality of the cup product to compute the cohomology ring of any complex projective space $\mathbb{C}\mathrm{P}^n$. Throughout this section, given $m \le n$ we will view $\mathbb{C}\mathrm{P}^m$ as a submanifold of $\mathbb{C}\mathrm{P}^n$ via the embedding

$$\begin{array}{rcl} i\colon \mathbb{C}\mathrm{P}^m & \to & \mathbb{C}\mathrm{P}^n \\ [z_0 : \cdots : z_m] & \mapsto & [z_0 : \cdots : z_m : 0 : \cdots : 0]. \end{array}$$

We prepare the ground with the following elementary lemma.

Lemma 62.6.

(1) *For every $n \in \mathbb{N}$ and every $k \in \mathbb{N}_0$ we have*

$$H_k(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \;\cong\; H^k(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k = 0,2,4,\dots,2n, \\ 0, & \text{otherwise.} \end{cases}$$

(2) *Let $m \le n$. We denote by $i\colon \mathbb{C}\mathrm{P}^m \to \mathbb{C}\mathrm{P}^n$ the inclusion map. For any $k \le 2m$ the induced maps $i_*\colon H_k(\mathbb{C}\mathrm{P}^m;\mathbb{Z}) \to H_k(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$ and $i^*\colon H^k(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \to H^k(\mathbb{C}\mathrm{P}^m;\mathbb{Z})$ are isomorphisms.*

Proof $(*)$. First we recall that in Lemma 26.2 we showed that we can view $\mathbb{C}\mathrm{P}^n$ as a CW-complex which admits exactly one cell in dimensions $0,2,\dots,2n$ and which admits no cells in any other dimension. Furthermore we saw that the CW-structure can be chosen in such a way that for $k \in \{0,\dots,n\}$ the $(2k+1)$-skeleton on $\mathbb{C}\mathrm{P}^n$ equals $\mathbb{C}\mathrm{P}^k$.

Furthermore recall that by Propositions 35.4 we know that singular and cellular homology are *naturally* isomorphic. Together with the above discussion of the CW-structures it follows that for every $n \in \mathbb{N}$ and every $k \in \mathbb{N}_0$ we have

$$H_k(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \;\xrightarrow{\cong}\; H^{\mathrm{CW}}_k(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } k = 0,2,4,\dots,2n, \\ 0, & \text{otherwise} \end{cases}$$

and that for every $m \leq n$ the inclusion induced maps $i_*\colon H_k(\mathbb{C}\mathrm{P}^m;\mathbb{Z}) \to H_k(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$ are isomorphisms for $k \leq 2m$.

In Proposition 50.4 we had also seen that singular and cellular cohomology are naturally isomorphic. So the same logic applies to cohomology groups. □

We also introduce the following notation.

Notation.

(1) Let X be a topological space, let R be a commutative ring and let $\varphi \in H^k(X;R)$. We define $\varphi^0 = 1_X$ and given any $n \in \mathbb{N}$ we define

$$\varphi^n \;=\; \underbrace{\varphi \cup \cdots \cup \varphi}_{n \text{ times}} \;\in\; H^{kn}(X;R).$$

(2) Recall that we denote by $[\mathbb{C}\mathrm{P}^1]^* \in H^2(\mathbb{C}\mathrm{P}^1;\mathbb{Z})$ the dual fundamental class of $\mathbb{C}\mathrm{P}^1$. For any $n \geq 1$ we denote by $i\colon \mathbb{C}\mathrm{P}^1 \to \mathbb{C}\mathrm{P}^n$ the above inclusion map. By Lemma 62.6 we can define $x := (i^*)^{-1}([\mathbb{C}\mathrm{P}^1]^*) \in H^2(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$. We refer to $x \in H^2(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$ as the *standard generator*.

Now we have the tools to determine the cup product of all complex projective spaces.

Proposition 62.7. *Let $n \in \mathbb{N}$.*

(1) *For every $k \in \{0,\dots,n\}$ the k-th power $x^k \in H^{2k}(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \cong \mathbb{Z}$ is a generator.*
(2) *If we view $\mathbb{Z}[x]/(x^{n+1})$ as a superalgebra by equipping the ring with the grading determined by $\deg(x) = 2$, then the obvious map*

$$\mathbb{Z}[x]/(x^{n+1}) \;\to\; (H^*(\mathbb{C}\mathrm{P}^n;\mathbb{Z}), \cup)$$

is an isomorphism of superalgebras.

Proof. It follows immediately from the definitions and Proposition 57.8 that the map in (2) is a homomorphism of superalgebras. This observation, together with Lemma 62.6, shows that (2) is a consequence of (1). Thus it remains to prove (1)

We prove (1) by induction on n. Evidently the statement holds for $n = 1$. Now suppose it holds for some $n-1$ with $n \geq 2$. We denote by $i\colon \mathbb{C}\mathrm{P}^{n-1} \to \mathbb{C}\mathrm{P}^n$ the inclusion map. Note that $i^*(x) = x \in H^2(\mathbb{C}\mathrm{P}^{n-1};\mathbb{Z})$. It follows easily from Lemma 62.6 together with Lemma 57.10 and our induction hypothesis that for each $k \in \{1,\dots,n-1\}$ the cohomology class $x^k \in H^{2k}(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$ is a generator. It remains to show that $x^n \in H^{2n}(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$ is also a generator. This is an immediate consequence of Corollary 62.3 (1), applied to the generator $\varphi := x \in H^2(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \cong \mathbb{Z}$ and the generator $\psi := x^{n-1} \in H^{2(n-1)}(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \cong \mathbb{Z}$. □

The previous proof leaves it open whether nor not $x^n \in H^{2n}(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$ equals the dual fundamental class $[\mathbb{C}\mathrm{P}^n]^*$. We formulate this as a question which we will answer later on, when we will have obtained more tools for calculating cup products.

Question 62.8. *Let $n \in \mathbb{N}$. Does the n-th power $x^n \in H^{2n}(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$ equal the dual fundamental class $[\mathbb{C}\mathrm{P}^n]^*$?*

In Lemma 62.4 we had in particular shown that $\mathbb{C}\mathrm{P}^2$ is not homotopy equivalent to its (co-) homological doppelgänger $S^2 \vee S^4$. On page 1050 we pointed out that $S^2 \times S^4$ and $\mathbb{C}\mathrm{P}^3$ is another example of a pair of topological spaces that cannot be distinguished using the fundamental group and using homology groups. This motivated us to ask in Question 43.9 whether the topological spaces $S^2 \times S^4$ and $\mathbb{C}\mathrm{P}^3$ are homeomorphic. Now we can answer the question in the negative, in fact we can prove an even stronger result.

Corollary 62.9. *The topological spaces $S^2 \times S^4$ and $\mathbb{C}\mathrm{P}^3$ are not homotopy equivalent.*

Proof. In Lemma 60.3 we saw that the cup product

$$H^2(S^2 \times S^4; \mathbb{Z}) \times H^2(S^2 \times S^4; \mathbb{Z}) \quad \to \quad H^4(S^2 \times S^4; \mathbb{Z})$$

is zero, whereas we saw in Proposition 62.7 that the cup product

$$H^2(\mathbb{C}\mathrm{P}^3; \mathbb{Z}) \times H^2(\mathbb{C}\mathrm{P}^3; \mathbb{Z}) \quad \to \quad H^4(\mathbb{C}\mathrm{P}^3; \mathbb{Z})$$

is non-zero. It follows from Corollary 57.12 that $S^2 \times S^4$ and $\mathbb{C}\mathrm{P}^3$ are not homotopy equivalent. □

We recall the following definition from page 1149.

Definition. Let M be a compact oriented topological manifold. We say that M is *amphichiral* if M admits an orientation-reversing self-homeomorphism, otherwise we say that M is *chiral*.

On page 1152 we saw that many manifolds are amphichiral, for example we showed that all compact oriented 2-dimensional topological manifolds are amphichiral.

In Question 47.6 we had asked whether there exist compact oriented topological manifolds that are chiral. Now we will see that the complex projective space $\mathbb{C}\mathrm{P}^2$ is chiral which gives an affirmative answer to Question 47.6. Note that the following corollary also gives a negative answer to Question 39.30 (3).

Corollary 62.10. *The manifold $\mathbb{C}\mathrm{P}^2$ is chiral, i.e. there does not exist a self-homeomorphism $f\colon \mathbb{C}\mathrm{P}^2 \to \mathbb{C}\mathrm{P}^2$ with $f_*([\mathbb{C}\mathrm{P}^2]) = -[\mathbb{C}\mathrm{P}^2]$.*

Remark. In Exercise 62.4 we will discuss for which n the complex projective space $\mathbb{C}\mathrm{P}^n$ is chiral.

Proof. As usual we denote by $x \in H^2(\mathbb{C}\mathrm{P}^2; \mathbb{Z})$ the standard generator. By Proposition 62.7 we know that $x \cup x \in H^4(\mathbb{C}\mathrm{P}^2; \mathbb{Z})$ is a generator. This implies that $x \cup x = \epsilon \cdot [\mathbb{C}\mathrm{P}^2]^*$ for some $\epsilon \in \{-1, 1\}$.

Now let $f\colon \mathbb{C}\mathrm{P}^2 \to \mathbb{C}\mathrm{P}^2$ be a self-homeomorphism. Since we want to show that $\mathbb{C}\mathrm{P}^2$ is chiral we need to show that $f_*([\mathbb{C}\mathrm{P}^2]) = [\mathbb{C}\mathrm{P}^2] \in H_4(\mathbb{C}\mathrm{P}^2; \mathbb{Z})$, or equivalently, that $f^*([\mathbb{C}\mathrm{P}^2]^*) = [\mathbb{C}\mathrm{P}^2]^* \in H^4(\mathbb{C}\mathrm{P}^2; \mathbb{Z})$.

Now we see that

$$\begin{aligned} f^*([\mathbb{C}\mathrm{P}^2]^*) &= \epsilon \cdot f^*(x \cup x) \underset{\substack{\uparrow \\ \text{Lemma 57.10}}}{=} \epsilon \cdot (f^*(x) \cup f^*(x)) \underset{\substack{\uparrow \\ f^*(x) \text{ is also a generator of } H^2(\mathbb{C}\mathrm{P}^4;\mathbb{Z}), \\ \text{hence } f^*(x) = \eta \cdot x \text{ for some } \eta \in \{-1,1\}}}{=} \epsilon \cdot (\eta \cdot x \cup \eta \cdot x) \\ &\underset{\substack{\uparrow \\ \cup \text{ is bilinear}}}{=} \epsilon \cdot \eta^2 \cdot (x \cup x) \underset{\substack{\uparrow \\ \text{since } \eta \in \{-1,1\}}}{=} \epsilon \cdot (x \cup x) = [\mathbb{C}\mathrm{P}^2]^*. \end{aligned}$$

□

Next we turn to the calculation of the cohomology ring of the infinite-dimensional complex projective space $\mathbb{C}\mathrm{P}^\infty = \varinjlim \mathbb{C}\mathrm{P}^n$.

Lemma 62.11.

(1) *For every $k \in \mathbb{N}$ we have*

$$H^k(\mathbb{C}\mathrm{P}^\infty;\mathbb{Z}) \cong H_k(\mathbb{C}\mathrm{P}^\infty;\mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } k \text{ is even,} \\ 0, & \text{if } k \text{ is odd.} \end{cases}$$

(2) *Let $n \in \mathbb{N}$. We denote by $i\colon \mathbb{C}\mathrm{P}^n \to \mathbb{C}\mathrm{P}^\infty$ the inclusion map. For any $k \leq 2n$ the induced maps $i_*\colon H_k(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \to H_k(\mathbb{C}\mathrm{P}^\infty;\mathbb{Z})$ and $i^*\colon H^k(\mathbb{C}\mathrm{P}^\infty;\mathbb{Z}) \to H^k(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$ are isomorphisms.*

Proof. The statements in (1) and (2) regarding homology groups follow from the discussion on page 885. The statements in (1) and (2) regarding cohomology groups then follow from the Universal Coefficient Theorem 51.13 for Cohomology Groups. □

Remark. One could also prove the lemma using Lemma 62.6 and a suitable generalization of Proposition 52.12.

Notation. We denote by $i\colon \mathbb{C}\mathrm{P}^1 \to \mathbb{C}\mathrm{P}^\infty$ the inclusion map. By Lemma 62.11 we can set $x := (i^*)^{-1}([\mathbb{C}\mathrm{P}^1]^*) \in H^2(\mathbb{C}\mathrm{P}^\infty;\mathbb{Z})$. We refer to x as the *standard generator* of $H^2(\mathbb{C}\mathrm{P}^\infty;\mathbb{Z})$.

Proposition 62.12.

(1) *For every $k \in \mathbb{N}$ the k-th power $x^k \in H^{2k}(\mathbb{C}\mathrm{P}^\infty;\mathbb{Z}) \cong \mathbb{Z}$ is a generator.*
(2) *If we view $\mathbb{Z}[x]$ as a superalgebra by equipping the ring with the grading determined by $\deg(x) = 2$, then the obvious map*

$$\mathbb{Z}[x] \to (H^*(\mathbb{C}\mathrm{P}^\infty;\mathbb{Z}), \cup)$$

is an isomorphism of superalgebras.

Proof. Exactly as in the proof of Proposition 62.7 we see that (2) is a consequence of (1). Thus it remains to prove (1) So let $k \in \mathbb{N}$. We consider the inclusion map $j\colon \mathbb{C}\mathrm{P}^k \to \mathbb{C}\mathrm{P}^\infty$. By Proposition 62.7 and Lemma 57.10 we know that $j^*(x^k) = j^*(x)^k = x^k \in H^{2k}(\mathbb{C}\mathrm{P}^k;\mathbb{Z})$ is a generator. It follows from Lemma 62.11 that $x^k \in H^{2k}(\mathbb{C}\mathrm{P}^\infty;\mathbb{Z})$ is also a generator. □

Remark. It follows from Proposition 60.21 and the discussion on page 1409 that for each $k \in \mathbb{N}$ we also have an isomorphism

$$(H^*(\underbrace{\mathbb{C}\mathrm{P}^\infty \times \ldots \times \mathbb{C}\mathrm{P}^\infty}_{k \text{ copies}}; \mathbb{Z}), \cup) \;\cong\; \mathbb{Z}[x_1, \ldots, x_k]$$

of superalgebras. Here $x_1, \ldots, x_k$ are given by preimages of the standard generator of the group $H^2(\mathbb{C}\mathrm{P}^\infty; \mathbb{Z})$ under the k obvious projection maps.

The fact that so far we worked with $\mathbb{Z}$-coefficients was mostly irrelevant. In fact most of the results carry over, with obvious modifications, to the cohomology groups $H^*(\mathbb{C}\mathrm{P}^n; R)$ where R is an arbitrary commutative ring. For future reference we state the following proposition.

Proposition 62.13. *Let $n \in \mathbb{N}$.*

(1) *For every every $k \in \mathbb{N}_0$ we have*

$$H_k(\mathbb{C}\mathrm{P}^n; \mathbb{Z}_2) \;\cong\; H^k(\mathbb{C}\mathrm{P}^n; \mathbb{Z}_2) \;\cong\; \begin{cases} \mathbb{Z}_2, & \text{if } k = 0, 2, 4, \ldots, 2n, \\ 0, & \text{otherwise.} \end{cases}$$

(2) *We denote by $x \in H^2(\mathbb{C}\mathrm{P}^n; \mathbb{Z}_2)$ the unique non-trivial element. If we view the ring $\mathbb{Z}_2[x]/(x^{n+1})$ as a superalgebra by equipping the ring with the grading determined by $\deg(x) = 2$, then the obvious map*

$$\mathbb{Z}_2[x]/(x^{n+1}) \;\to\; (H^*(\mathbb{C}\mathrm{P}^n; \mathbb{Z}_2), \cup)$$

is an isomorphism of superalgebras.

The obvious analogues for $\mathbb{C}\mathrm{P}^\infty$ also hold.

Proof. This proposition can be proved in an almost identical way as Proposition 62.12. Alternatively we can deduce the proposition from Proposition 62.12, the Universal Coefficient Theorem 51.25, Lemma 51.29 and Proposition 58.3 (2). We leave it to the impeccably conscientious reader to fill in the details. □

Towards the end of this section we recall the definition of a retract. Thus let A be a subset of a topological space X. We denote by $i\colon A \to X$ the inclusion map. Recall that we say that A is a *retract* of X if there exists a map $r\colon X \to A$ such that $r \circ i = \mathrm{id}_A$. It follows immediately from the functoriality of homology groups and Lemma 33.2 that for each k the group $H_k(A; \mathbb{Z})$ is a subsummand of $H_k(X; \mathbb{Z})$.

Let $m < n$. In Question 38.12 we had asked whether $\mathbb{C}\mathrm{P}^m \subset \mathbb{C}\mathrm{P}^n$ is a retract of $\mathbb{C}\mathrm{P}^n$. Note that Lemma 62.6 shows that a study of homology groups does not preclude that for $m < n$ the complex projective space $\mathbb{C}\mathrm{P}^m$ is a retract of $\mathbb{C}\mathrm{P}^n$. Nonetheless, the final result of the section gives a negative answer to Question 38.12, i.e. we show that $\mathbb{C}\mathrm{P}^m$ is not a retract of $\mathbb{C}\mathrm{P}^n$.

Proposition 62.14. *If $1 \le m < n$, then $\mathbb{C}\mathrm{P}^m \subset \mathbb{C}\mathrm{P}^n$ is not a retract of $\mathbb{C}\mathrm{P}^n$.*

Proof. Let $1 \leq m < n$. We denote by $i\colon \mathbb{C}\mathrm{P}^m \to \mathbb{C}\mathrm{P}^n$ the inclusion map. Suppose there exists a retraction $r\colon \mathbb{C}\mathrm{P}^n \to \mathbb{C}\mathrm{P}^m$. We denote by $x \in H^2(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$ the standard generator. We have

$$\begin{array}{ccccccccc} x^n & = & (r^*(i^*(x)))^n & = & r^*(i^*(x)^n) & = & r^*(0) & = & 0 \in H^{2n}(\mathbb{C}\mathrm{P}^n;\mathbb{Z}). \\ & \uparrow & & \uparrow & & \uparrow & & & \\ & \begin{array}{c}\text{by Lemma 62.6 the map} \\ i^*\colon H^2(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \to H^2(\mathbb{C}\mathrm{P}^m;\mathbb{Z}) \\ \text{is an isomorphism, together} \\ \text{with } i^* \circ r^* = (r \circ i)^* = \mathrm{id} \\ \text{we obtain that } r^* \circ i^* = \mathrm{id}\end{array} & & \begin{array}{c}\text{Lemma 57.10}\end{array} & & \begin{array}{c}\text{note that } n > m \text{ implies that } i^*(x)^n \text{ lies} \\ \text{in the trivial group } H^n(\mathbb{C}\mathrm{P}^m;\mathbb{Z}) = 0\end{array} & & & & \end{array}$$

But this contradicts the fact shown in Proposition 62.7 that $x^n \neq 0$. □

62.3. **The cup product of $\mathbb{R}\mathbf{P}^n$ and applications.** In this section we intend to determine the cup product of the real projective space $\mathbb{R}\mathrm{P}^n$ with $\mathbb{F}_2$-coefficients. Evidently the approach will be very similar to the one taken in the previous section. First we recall that on page 192 we saw that the real projective space $\mathbb{R}\mathrm{P}^n$ is a closed n-dimensional manifold. Given $m \leq n$ we will view $\mathbb{R}\mathrm{P}^m$ as a submanifold of $\mathbb{R}\mathrm{P}^n$ via the embedding

$$\begin{array}{rcl} i\colon \mathbb{R}\mathrm{P}^m & \to & \mathbb{R}\mathrm{P}^n \\ [x_0 : \cdots : x_m] & \mapsto & [x_0 : \cdots : x_m : 0 : \cdots : 0]. \end{array}$$

The following lemma plays the role of Lemma 62.6.

Lemma 62.15.

(1) *For every $n \in \mathbb{N}$ we have*

$$H^k(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2) \;\cong\; H_k(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2) \;\cong\; \begin{cases} \mathbb{F}_2, & \text{if } k = 0, 1, \ldots, n, \\ 0, & \text{otherwise.} \end{cases}$$

(2) *Let $m \leq n$. For any $k \leq m$ the induced maps $i_*\colon H_k(\mathbb{R}\mathrm{P}^m;\mathbb{F}_2) \to H_k(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2)$ and $i^*\colon H^k(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2) \to H^k(\mathbb{R}\mathrm{P}^m;\mathbb{F}_2)$ are isomorphisms.*

Proof. The calculation of the isomorphism types of the (co-) homology groups and of the induced maps on homology is basically the same as in the proof of Lemma 62.15. The argument that determines the induced map on $\mathbb{F}_2$-cohomology is slightly different. This time we use Proposition 51.18 which gives us the following commutative diagram:

$$\begin{array}{ccc} H^k(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2) & \xrightarrow[\cong]{\mathrm{ev}} & \mathrm{Hom}(H_k(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2),\mathbb{F}_2) \\ \downarrow{\scriptstyle i^*} & & \downarrow{\scriptstyle i^*} \\ H^k(\mathbb{R}\mathrm{P}^m;\mathbb{F}_2) & \xrightarrow[\cong]{\mathrm{ev}} & \mathrm{Hom}(H_k(\mathbb{R}\mathrm{P}^m;\mathbb{F}_2),\mathbb{F}_2). \end{array}$$

As we had just pointed out, the maps on the right are isomorphisms for $k \leq m$. It follows that the maps on the left are also isomorphisms for $k \leq m$. □

Notation. Given $n \in \mathbb{N}$ we denote by $x \in H^1(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2)$ the unique non-trivial element.

The following proposition is the analogue of Propositions 62.7 and 62.12.

Proposition 62.16. *Let $n \in \mathbb{N}$.*

(1) *For every $k \in \{0, \dots, n\}$ the k-th power $x^k \in H^k(\mathbb{R}\mathrm{P}^n; \mathbb{F}_2) \cong \mathbb{F}_2$ is non-trivial.*
(2) *If we view $\mathbb{F}_2[x]/(x^{n+1})$ as a superalgebra by equipping the ring with the grading determined by $\deg(x) = 1$, then the obvious map*
$$\mathbb{F}_2[x]/(x^{n+1}) \ \to \ (H^*(\mathbb{R}\mathrm{P}^n; \mathbb{F}_2), \cup)$$
is an isomorphism of superalgebras.
(3) *If we view $\mathbb{F}_2[x]$ as a superalgebra by equipping the ring with the grading determined by $\deg(x) = 1$, then the obvious map*
$$\mathbb{F}_2[x] \ \to \ (H^*(\mathbb{R}\mathrm{P}^\infty; \mathbb{F}_2), \cup)$$
is an isomorphism of superalgebras.

Proof. First recall that Proposition 45.24 implies that any topological manifold, in particular $\mathbb{R}\mathrm{P}^n$, is $\mathbb{F}_2$-orientable. With this observation the proof of the proposition is basically identical to the proofs of Proposition 62.7 and 62.12. We just need to replace Lemma 62.6 by Lemma 62.15 and we need to replace Corollary 62.3 (1) by Corollary 62.3 (2). □

Remark.

(1) In principle one could have tried to compute the cup product on $\mathbb{R}\mathrm{P}^n$ using the same approach that we had taken in Section 57.5. More precisely, suppose one has found an explicit $\mathbb{F}_2$-fundamental class σ for $\mathbb{R}\mathrm{P}^n$. We denote by $\varphi \in C^1(\mathbb{R}\mathrm{P}^2; \mathbb{F}_2)$ the 1-cocycle from page 1352. Now we know from Proposition 62.16 that $\langle \varphi^n, \sigma \rangle = 1$. But more interestingly, if one shows with an explicit calculation that $\langle \varphi^n, \sigma \rangle = 1$, then this gives a new and elementary proof of Proposition 62.16.
(2) We have just computed the cup product on $H^*(\mathbb{R}\mathrm{P}^n; \mathbb{F}_2)$. We leave it as an exercise to use the same approach to determine the cup product on $H^*(\mathbb{R}\mathrm{P}^n; \mathbb{Z})$. This cup product is also determined, using a somewhat different approach, in [Hat, p. 214].
(3) In Corollary 61.11 we showed that there is no map $S^1 \times S^2$ to $\mathbb{R}\mathrm{P}^3$ of degree one, thus giving a negative answer to Question 39.29. On page 1389 and in Proposition 62.16 we had determined the cup product of $S^1 \times S^2$ and $\mathbb{R}\mathrm{P}^3$ on cohomology with $\mathbb{F}_2$-coefficients. Using an argument similar to the proof of Lemma 60.5 one can easily give an alternative proof of Corollary 61.11.

For completeness' sake we mention the following analogue of Proposition 62.14.

Proposition 62.17. *If $1 \le m < n$, then $\mathbb{R}\mathrm{P}^m \subset \mathbb{R}\mathrm{P}^n$ is not a retract of $\mathbb{R}\mathrm{P}^n$.*

Proof. The proof is totally analogous to the proof of Proposition 62.14. In the proof we just need to replace Lemma 62.6 by Lemma 62.15. □

Remark. We can also give an alternative proof of Proposition 62.17 using higher homotopy groups. More precisely, let $1 \le m < n$. By Proposition 28.9 together with Proposition 28.13 we know that $\pi_m(S^n) = 0$. Furthermore by Lemma 38.10 together with Proposition 28.13

we know that $\pi_m(S^m) \neq 0$. Since higher homotopy groups are functorial, see Proposition 28.6, we can use the standard argument, see e.g. the proof of Lemma 6.2, to show that $\mathbb{R}\mathrm{P}^m$ is not a retract of $\mathbb{R}\mathrm{P}^n$.

One of the many consequences of our calculations from this chapter is that we can now calculate the Lusternik-Schnirelmann category for $\mathbb{R}\mathrm{P}^n$ and $\mathbb{C}\mathrm{P}^n$. More precisely, we have the following proposition that gives a complete answer to Question 58.9.

Proposition 62.18. *For any $n \in \mathbb{N}_0$ we have* $\mathrm{cat}(\mathbb{R}\mathrm{P}^n) = \mathrm{cat}(\mathbb{C}\mathrm{P}^n) = n$.

Proof. By the discussion on page 1366 we know that $\mathrm{cat}(\mathbb{R}\mathrm{P}^n) \leq n$ and $\mathrm{cat}(\mathbb{C}\mathrm{P}^n) \leq n$. On the other hand it follows from Propositions 62.7, 62.16 and 58.10 that $\mathrm{cat}(\mathbb{R}\mathrm{P}^n) \geq n$ and $\mathrm{cat}(\mathbb{C}\mathrm{P}^n) \geq n$. □

We conclude this section with a new proof for the Borsuk-Ulam Theorem. First we recall the statement of the Borsuk-Ulam Theorem.

Theorem 44.16 (Borsuk-Ulam). *For every map $f\colon S^n \to \mathbb{R}^n$ there exists a pair of antipodal points x and $-x$ on S^n with $f(x) = f(-x)$.*

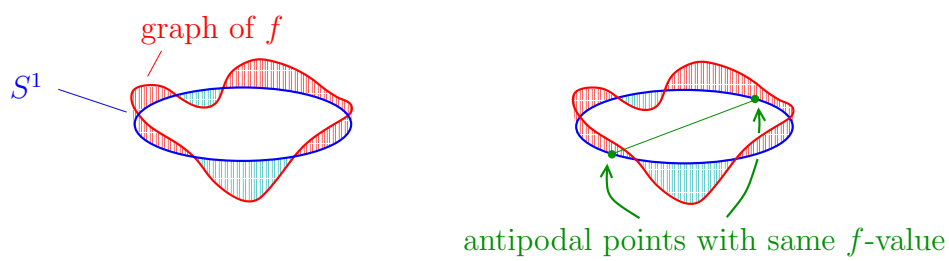

FIGURE 757. Illustration of the Borsuk-Ulam Theorem.

In the new proof of the Borsuk-Ulam Theorem below we will need the following Lemma.

Lemma 62.19.

(1) *Let $k \geq 2$. As usual we denote by $p\colon S^k \to \mathbb{R}\mathrm{P}^k$ the obvious projection map. If $\gamma\colon [0,1] \to S^k$ is a path with $\gamma(1) = -\gamma(0)$, then $p \circ \gamma$ represents the unique non-trivial element in $\pi_1(\mathbb{R}\mathrm{P}^k)$.*

(2) *Let $k, l \geq 2$. Furthermore let $h\colon \mathbb{R}\mathrm{P}^k \to \mathbb{R}\mathrm{P}^l$ be a map. If $h_*\colon \pi_1(\mathbb{R}\mathrm{P}^k) \to \pi_1(\mathbb{R}\mathrm{P}^l)$ has non-trivial image, then the induced maps $h_*\colon H_1(\mathbb{R}\mathrm{P}^k;\mathbb{F}_2) \to H_1(\mathbb{R}\mathrm{P}^l;\mathbb{F}_2)$ and $h^*\colon H^1(\mathbb{R}\mathrm{P}^l;\mathbb{F}_2) \to H^1(\mathbb{R}\mathrm{P}^k;\mathbb{F}_2)$ are also isomorphisms.*

Proof of Lemma 62.19. First we recall that for $k \geq 2$ we know from Corollary 7.19 that $\pi_1(\mathbb{R}\mathrm{P}^k) \cong \mathbb{Z}_2$.

(1) The first statement is an immediate consequence of Lemma 7.16 (1) and the fact that $\pi_1(\mathbb{R}\mathrm{P}^n) \cong \mathbb{Z}_2$.

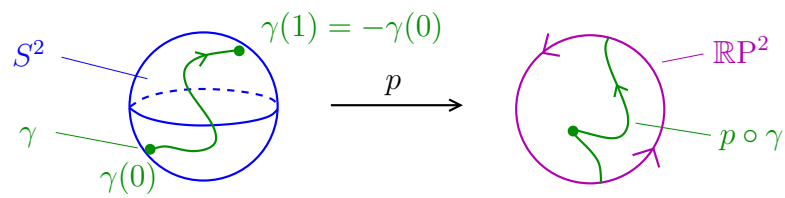

FIGURE 758. Illustration of Lemma 62.19.

(2) Since $k, l \geq 2$ both fundamental groups are isomorphic to $\mathbb{Z}_2$. In particular if $h_*\colon \pi_1(\mathbb{R}\mathrm{P}^k) \to \pi_1(\mathbb{R}\mathrm{P}^l)$ has non-trivial image, then this map is already an isomorphism. It follows from the naturality of the Hurewicz homomorphism, see Proposition 38.2 (4), together with the Hurewicz Theorem 38.5 that the induced map $h_*\colon H_1(\mathbb{R}\mathrm{P}^k;\mathbb{F}_2) \to H_1(\mathbb{R}\mathrm{P}^l;\mathbb{F}_2)$ is also an isomorphism. Finally it follows from the naturality of the isomorphisms in Proposition 51.17 that the induced map $h^*\colon H^1(\mathbb{R}\mathrm{P}^l;\mathbb{F}_2) \to H^1(\mathbb{R}\mathrm{P}^k;\mathbb{F}_2)$ is also an isomorphism. □

Proof of the Borsuk-Ulam 44.16 for $n \geq 2$. Suppose there exists a map $f\colon S^n \to \mathbb{R}^n$ such that for any $x \in S^n$ we have that $f(x) \neq f(-x)$. We consider the map

$$\begin{array}{rcl} g\colon S^n & \to & S^{n-1} \\ x & \mapsto & \frac{f(x)-f(-x)}{\|f(x)-f(-x)\|}. \end{array}$$

By our hypothesis this map is defined. It is clear that $g(-x) = -g(x)$ for all $x \in S^n$. Therefore this map g descends to a map

$$\begin{array}{rcl} h\colon \mathbb{R}\mathrm{P}^n & \to & \mathbb{R}\mathrm{P}^{n-1} \\ [x] & \mapsto & [g(x)] \end{array}$$

i.e. we get the following commutative diagram

$$\begin{array}{ccc} S^n & \xrightarrow{\quad g \quad} & S^{n-1} \\ \downarrow{\scriptstyle p} & & {\scriptstyle q}\downarrow \\ \mathbb{R}\mathrm{P}^n & \xrightarrow{[x]\mapsto h(x):=[g(x)]} & \mathbb{R}\mathrm{P}^{n-1} \end{array}$$

where p and q denote the obvious projection maps.[1062]

Claim. The map $h^*\colon H^1(\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2) \to H^1(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2)$ is an isomorphism.

By Lemma 62.19 (2) we only have to show that $h_*\colon \pi_1(\mathbb{R}\mathrm{P}^n) \to \pi_1(\mathbb{R}\mathrm{P}^{n-1})$ has non-trivial image. Let $\gamma\colon [0,1] \to S^n$ be a path with $\gamma(1) = -\gamma(0)$. Note that $p \circ \gamma\colon [0,1] \to \mathbb{R}\mathrm{P}^n$ is a

[1062]The map $q \circ g\colon S^n \to \mathbb{R}\mathrm{P}^{n-1}$ is continuous. It follows from Lemma 1.66 that the map h is also continuous.

loop. We calculate that

$$h_*([p\circ\gamma]) \;=\; [h\circ p\circ\gamma] \;\underset{\text{by the above commutative diagram}}{\overset{\downarrow}{=}}\; [q\circ(g\circ\gamma)] \;\underset{\text{by Lemma 62.19 (1) since } (g\circ\gamma)(1)=g(\gamma(1))=g(-\gamma(0))=-g(\gamma(0))=-(g\circ\gamma)(0)}{\overset{\uparrow}{\neq}}\; e \;\in \pi_1(\mathbb{R}\mathrm{P}^{n-1}).$$

This concludes the proof of the claim.

We denote by $y \in H^1(\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2)$ and $x \in H^1(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2)$ the unique non-trivial elements. We have the following equality in $H^n(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2)$:[1063]

$$0 \;\underset{\text{Proposition 62.16}}{\overset{\uparrow}{\neq}}\; x^n \;\underset{\text{by the claim}}{\overset{\uparrow}{=}}\; (h^*(y))^n \;\underset{\text{Lemma 57.10}}{\overset{\uparrow}{=}}\; h^*(y^n) \;\underset{\text{Proposition 62.16}}{\overset{\uparrow}{=}}\; h^*(0) \;=\; 0.$$

We have thus obtained the desired contradiction. □

62.4. **The cup product of quaternionic and octonion projective spaces** (∗)**.** In this very short section we discuss the cup product of the quaternionic projective spaces $\mathbb{H}\mathrm{P}^n$ that we introduced on page 1062. We will also calculate the cup product of the octonion projective plane $\mathbb{O}\mathrm{P}^2$ that we defined on page 1063. These calculations might not sound all that interesting, but later on we will use them to show that certain homotopy groups of spheres are non-trivial.

The following proposition is the only, and thus also the most interesting, result of this section. The statement is of course, in light of Proposition 62.7, entirely predictable.

Proposition 62.20.

(1) *Given any $n \in \mathbb{N}$ there exists an isomorphism*

$$\mathbb{Z}[z]/(z^{n+1}) \;\to\; (H^*(\mathbb{H}\mathrm{P}^n;\mathbb{Z}),\cup)$$

of superalgebras, where z is an element of degree 4.

(2) *There exists an isomorphism*

$$\mathbb{Z}[z]/(z^3) \;\to\; (H^*(\mathbb{O}\mathrm{P}^2;\mathbb{Z}),\cup)$$

of superalgebras, where z is an element of degree 8.

In both cases the obvious analogues with $\mathbb{Z}$ replaced by $\mathbb{Z}_2$ also hold.

Proof.

(1) Let $n \in \mathbb{N}_0$. By Lemma 44.10 we know that $\mathbb{H}\mathrm{P}^n$ is a $4n$-dimensional closed orientable manifold which admits a CW-structure that has exactly one cell in the dimensions $0, 4, 8, \ldots, 4n$. The proof of Proposition 62.7 can be used, with very minor modifications, to prove the desired result.

[1063] The argument is very similar to the argument in the proof of Proposition 62.14.

(2) In Proposition 44.11 we showed that the octonion projective plane $\mathbb{O}\mathrm{P}^2$ is a closed orientable 16-dimensional manifold which admits a CW-structure with precisely one cell in dimensions 0, 8 and 16, and which has no other cells. Once again the proof of Proposition 62.7 clinches the deal. □

Propositions 62.7 and 62.20 do raise a few questions, which can be viewed as a more specific versions of Question 60.19.

The first question asks whether we can realize polynomial rings in other degrees.

Question 62.21. *Let m be an even number and $n \in \mathbb{N}$. Does there exist a topological space X such that $(H^*(X;\mathbb{Z}), \cup)$ is isomorphic to $\mathbb{Z}[z]/(z^{n+1})$ where z is now an element of degree m?*

The following question is even more specific, it asks whether there exists a "cohomological $\mathbb{O}\mathrm{P}^3$.

Question 62.22. *Does there exist a topological space X such that $(H^*(X;\mathbb{Z}), \cup)$ is isomorphic to $\mathbb{Z}[z]/(z^4)$ where z is now an element of degree 8?*

It will note take the reader very long to see that a negative answer to Question 62.22 would also tragically give a negative answer to Question 44.12.

62.5. **Division algebras.** We recall that on page 1054 we defined a *real division algebra* to be an algebra over $\mathbb{R}$ such that for all $a \neq 0$ and $b \in A$ there exists an $x \in A$ with $a \cdot x = b$ and a $y \in A$ with $y \cdot a = b$. In Section 44.2 we gave several examples of real division algebras, namely $\mathbb{R}$, the complex numbers $\mathbb{C}$, the quaternions $\mathbb{H}$ (which are not commutative) and the Cayley Octonions $\mathbb{O}$ (which are neither commutative nor associative). These real division algebras are defined over $\mathbb{R}^n$ with $n = 1, 2, 4$ and 8.

These dimensions are powers of 2 and the following theorem, which was first proved by Heinz Hopf [Hopf2] in 1940, shows that this is not a coincidence.

Theorem 62.23. (Hopf 1940) *If $\mathbb{R}^n$ admits the structure of a real division algebra, then n is a power of 2.*

In the proof of Theorem 62.23 we will need the following lemma which is interesting in its own right.

Lemma 62.24. *Let $k \in \mathbb{N}$. We denote by $\varphi \in H^1(\mathbb{R}\mathrm{P}^k; \mathbb{F}_2)$ the unique non-trivial element. We denote by p and q the two obvious projection maps $\mathbb{R}\mathrm{P}^k \times \mathbb{R}\mathrm{P}^k \to \mathbb{R}\mathrm{P}^k$ and we write $\alpha = p^*(\varphi)$ and $\beta = q^*(\varphi)$. Then the obvious homomorphism*

$$\mathbb{F}_2[\alpha, \beta]/(\alpha^{k+1}, \beta^{k+1}) \;\to\; H^*(\mathbb{R}\mathrm{P}^k \times \mathbb{R}\mathrm{P}^k; \mathbb{F}_2)$$

of superalgebras is an isomorphism.

Proof. The lemma is an immediate consequence of Propositions 62.16 and Proposition 60.24 and the discussion on page 1409. □

Now we can provide the proof of Theorem 62.23.

Proof of Theorem 62.23. Let "$*$" be a real division algebra structure on $\mathbb{R}^n$. We want to show that n is a power of 2. Since 1 and 2 are powers of 2 we can assume that $n \geq 3$. As in the proof of Theorem 44.5 we consider the map

$$\begin{array}{rcl} \widetilde{f}\colon S^{n-1} \times S^{n-1} & \to & S^{n-1} \\ (x,y) & \mapsto & \widetilde{f}(x,y) := \dfrac{x*y}{\|x*y\|}. \end{array}$$

We make the following observations:

(1) In the proof of Theorem 44.5 we already showed, using the hypothesis that "$*$" defines a division algebra, that this map is well-defined, i.e. that we never divide by zero.
(2) In the proof of Theorem 44.5 we had also shown that the map $\widetilde{f}$ is continuous.
(3) Since "$*$" defines in particular an algebra we have

$$\widetilde{f}(-x,y) = -\widetilde{f}(x,y) \quad \text{and} \quad \widetilde{f}(x,-y) = -\widetilde{f}(x,y) \quad \text{for any } x,y \in S^{n-1}.$$

From (3) it follows that the above map $\widetilde{f}$ descends to a map[1064]

$$\begin{array}{rcl} f\colon \mathbb{R}\mathrm{P}^{n-1} \times \mathbb{R}\mathrm{P}^{n-1} & \to & \mathbb{R}\mathrm{P}^{n-1} \\ [\widetilde{x}], [\widetilde{y}] & \mapsto & [\widetilde{f}(x,y)]. \end{array}$$

We pick a point $z \in S^{n-1}$. We consider the inclusion maps

$$\begin{array}{rcl} i\colon \mathbb{R}\mathrm{P}^{n-1} & \to & \mathbb{R}\mathrm{P}^{n-1} \times \mathbb{R}\mathrm{P}^{n-1} \\ x & \mapsto & (x,[z]) \end{array} \quad \text{and} \quad \begin{array}{rcl} j\colon \mathbb{R}\mathrm{P}^{n-1} & \to & \mathbb{R}\mathrm{P}^{n-1} \times \mathbb{R}\mathrm{P}^{n-1} \\ x & \mapsto & ([z],x). \end{array}$$

Our first goal is to prove the following claim.

Claim 1. The map

$$(f \circ i)_*\colon H_1(\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2) \to H_1(\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2)$$

is an isomorphism. The same conclusion holds with i_* replaced by j_*.

We provide the proof for the first statement. The proof with i_* replaced by j_* is basically the same. By Lemma 62.19 (2) it suffices to show that the map

$$(f \circ i)_*\colon \pi_1(\mathbb{R}\mathrm{P}^{n-1}) \to \pi_1(\mathbb{R}\mathrm{P}^{n-1})$$

has non-trivial image. We introduce the following notation:

(1) We denote by $\pi\colon S^{n-1} \to \mathbb{R}\mathrm{P}^{n-1}$ the obvious projection map.
(2) We pick a path $\gamma\colon [0,1] \to S^{n-1}$ with $\gamma(1) = -\gamma(0)$. Note that $\pi \circ \gamma\colon [0,1] \to \mathbb{R}\mathrm{P}^{n-1}$ is a loop.
(3) We denote by $\widetilde{i}$ the inclusion map $S^{n-1} \to S^{n-1} \times S^{n-1}$ that is given by $\widetilde{i}(x) = (x,z)$.

[1064]The argument of Footnote 1062 shows that f is continuous.

Note that we get the following commutative diagram

$$\begin{array}{ccccccc}
[0,1] & \xrightarrow{\gamma} & S^{n-1} & \xrightarrow{\widetilde{i}} & S^{n-1}\times S^{n-1} & \xrightarrow{\widetilde{f}} & S^{n-1} \\
 & & \downarrow{\scriptstyle\pi} & & \downarrow{\scriptstyle\pi\times\pi} & & \downarrow{\scriptstyle\pi} \\
 & & \mathbb{R}\mathrm{P}^{n-1} & \xrightarrow{i} & \mathbb{R}\mathrm{P}^{n-1}\times\mathbb{R}\mathrm{P}^{n-1} & \xrightarrow{f} & \mathbb{R}\mathrm{P}^{n-1}.
\end{array}$$

Finally we note that

$$(f\circ i)_*([\pi\circ\gamma]) \;=\; [f\circ i\circ\pi\circ\gamma] \;\overset{\substack{\text{by the above commutative diagram}\\ \downarrow}}{=}\; \big[\pi\circ(\widetilde{f}\circ\widetilde{i}\circ\gamma)\big] \;\underset{\substack{\uparrow\\ \text{this follows from Lemma 62.19 (1) since the following equality holds:}\\ (\widetilde{f}\circ\widetilde{i}\circ\gamma)(1)=\widetilde{f}(\gamma(1),z)=\widetilde{f}(-\gamma(0),z)=-\widetilde{f}(\gamma(0),z)=-(\widetilde{f}\circ\widetilde{i}\circ\gamma)(0)}}{\neq}\; e \;\in \pi_1(\mathbb{R}\mathrm{P}^{n-1}).$$

This concludes the proof of the claim.

We denote by $\varphi\in H^1(\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2)$ the unique non-trivial element. Furthermore, as so often we denote by p and q the two obvious projection maps $\mathbb{R}\mathrm{P}^{n-1}\times\mathbb{R}\mathrm{P}^{n-1}\to\mathbb{R}\mathrm{P}^{n-1}$. Finally we write $\alpha=p^*(\varphi)$ and $\beta=q^*(\varphi)\in H^1(\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2)$.

Claim 2. The following equality holds

$$f^*(\varphi) \;=\; \alpha+\beta \;\in\; H^1(\mathbb{R}\mathrm{P}^{n-1}\times\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2).$$

We start out the proof of the claim with the following three observations:

(1) Proposition 51.18 says that for any topological space W the map

$$\begin{array}{rcl}
\mathrm{ev}\colon H^1(W;\mathbb{F}_2) & \to & \mathrm{Hom}(H_1(W;\mathbb{F}_2),\mathbb{F}_2) \\
\psi & \mapsto & (\sigma\mapsto\langle\psi,\sigma\rangle)
\end{array}$$

is an isomorphism.

(2) Let $x\in H_1(\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2)$ be the unique non-trivial element. By the discussion on page 1317 the map

$$\begin{array}{rcl}
H_1(\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2)\oplus H_1(\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2) & \to & H_1(\mathbb{R}\mathrm{P}^{n-1}\times\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2) \\
a\oplus b & \mapsto & i_*(a)\oplus j_*(b)
\end{array}$$

is an isomorphism. In particular we see that $H_1(\mathbb{R}\mathrm{P}^{n-1}\times\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2)$ is generated by $i_*(x)$ and $j_*(x)$.

(3) Since $H^1(\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2)$ and $H_1(\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2)$ both contain a unique non-trivial element, namely φ and x, we obtain from Observation (1) that $\mathrm{ev}(\varphi)(x)=\langle\varphi,x\rangle=1$.

It follows from (1) and (2) that it suffices to show that $\mathrm{ev}(f^*(\varphi))$ and $\mathrm{ev}(\alpha+\beta)$ agree on $i_*(x)$ and $j_*(y)$. In fact we have

$$\mathrm{ev}(f^*(\varphi))(i_*(x)) \underset{\substack{\uparrow \\ \text{by definition}}}{=} \langle f^*(\varphi), i_*(x)\rangle \underset{\substack{\uparrow \\ \text{Lemma 50.6}}}{=} \langle \varphi, f_*(i_*(x))\rangle \underset{\substack{\uparrow \\ \text{by Claim 1 since } x \text{ is the unique non-zero element of } H_1(\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2)}}{=} \langle \varphi, x\rangle \underset{\substack{\uparrow \\ \text{observation (3)}}}{=} 1.$$

We also calculate that

$$\mathrm{ev}(\alpha+\beta)(i_*(x)) \underset{\substack{\uparrow \\ \text{by definition}}}{=} \langle p^*\varphi + q^*\varphi, i_*(x)\rangle \underset{\substack{\uparrow \\ \text{Lemma 50.6}}}{=} \langle \varphi, p_*(i_*(x))\rangle + \langle \varphi, q_*(i_*(x))\rangle \underset{\substack{\uparrow \\ \text{since } p\circ i = \mathrm{id} \text{ and } q\circ i \text{ is a constant map}}}{=} \langle \varphi, x\rangle = 1.$$

We have thus shown that $\mathrm{ev}(f^*(\varphi))$ and $\mathrm{ev}(\alpha+\beta)$ agree on $i_*(x)$. The same argument also works with $i_*(x)$ replaced by $j_*(y)$. This concludes the proof of the claim.

Using Lemma 62.24 we can and will make the identification

$$H^*(\mathbb{R}\mathrm{P}^{n-1}\times\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2) = \mathbb{F}_2[\alpha,\beta]/(\alpha^n,\beta^n).$$

Using this identification we see that

$$0 = f^*(0) \underset{\substack{\uparrow \\ \text{by Proposition 62.16} \\ \text{since } \varphi\in H^1(\mathbb{R}\mathrm{P}^{n-1};\mathbb{F}_2)}}{=} f^*(\varphi^n) \underset{\substack{\uparrow \\ \text{Lemma 57.10}}}{=} (f^*(\varphi))^n \underset{\substack{\uparrow \\ \text{by the previous claim}}}{=} (\alpha+\beta)^n = \sum_{k=0}^{n}\binom{n}{k}\cdot\alpha^k\beta^{n-k} \underset{\substack{\uparrow \\ \text{since } \alpha^n=\beta^n=0}}{=} \sum_{k=1}^{n-1}\binom{n}{k}\cdot\alpha^k\beta^{n-k}.$$

This equality holds in the polynomial ring $\mathbb{F}_2[\alpha,\beta]/(\alpha^n,\beta^n)$. In this ring the $n-1$ monomials $\alpha\beta^{n-1}, \alpha^2\beta^{n-2}, \dots, \alpha^{n-1}\beta$ are linearly independent over the field $\mathbb{F}_2$. This implies that for $k = 1,\dots,n-1$ we have $\binom{n}{k} \equiv 0 \bmod 2$. Thus it remains to prove the following purely algebraic claim.

Claim. If $n\in\mathbb{N}$ satisfies that $\binom{n}{k}\equiv 0 \bmod 2$ for $k=1,\dots,n-1$, then n is a power of 2.

We can and will write n as a sum $n = n_1+\dots+n_r$ where each n_i is a power of 2 and with $n_1<\dots<n_r$. In the polynomial ring $\mathbb{F}_2[x]$ we obtain that

$$1+x^n \overset{\substack{\text{by our hypothesis} \\ \downarrow}}{=} \sum_{k=0}^{n}\binom{n}{k}x^k = (1+x)^n \overset{\substack{\text{since } n=n_1+\dots+n_r \\ \downarrow}}{=} (1+x)^{n_1}\cdot\dots\cdot(1+x)^{n_r}$$
$$\underset{\substack{\uparrow \\ \text{since each } n_i \text{ is a power of 2 and} \\ \text{since in } \mathbb{F}_2[x] \text{ we have } (a+b)^2=a^2+b^2}}{=} (1+x^{n_1})\cdot\dots\cdot(1+x^{n_r}) \underset{\substack{\uparrow \\ \text{since } n_1<\dots<n_r}}{=} 1+x^{n_1}+\text{higher powers}.$$

But this is only possible if $n=n_1$, i.e. if n itself is a power of 2. This concludes the proof of the claim. $\square$

In fact, with more fancy topological methods one can actually strengthen the previous theorem to obtain the following theorem which gives a complete answer to Question 44.8. Unfortunately the proof is well beyond the scope of these modest lecture notes.

Theorem 62.25. (Bott-Kervaire-Milnor 1958) *Every finite-dimensional division algebra over $\mathbb{R}$ is of dimension 1,2, 4 or 8.*

Proof. The theorem was first proved using topological methods by Michel Kervaire [Kerv] and John Milnor [Mi3, Corollary 1], building on the "Bott Periodicity Theorem" proved by Raoul Bott [Bot, Bot2].[1065] Full details for the proof can also be found in [Hat2, Theorem 2.16]. As of right now there is no purely algebraic proof for the statement. □

Remark. One might ask whether any finite-dimensional division algebra over $\mathbb{R}$ is isomorphic to $\mathbb{R}, \mathbb{C}, \mathbb{H}$ or $\mathbb{O}$. The statement holds under the stronger hypothesis that the algebra is "normed" or "alternative". We refer to [BD, p. 73], [EHHKMNPR, p. 262] and [Bae] for results in this direction. As is shown in [Hat, p. 59], [Bru, Os], without any extra hypotheses one cannot expect a uniqueness statement.

Exercises for Chapter 62.

Exercise 62.1. Let V and W be free $\mathbb{Z}$-modules of finite rank, i.e. V and W are free abelian groups. Furthermore let $\varphi\colon V \times W \to \mathbb{Z}$ be a pairing.

(a) Let $v_1, \dots, v_n$ be a basis for V. Show that the following two statements are equivalent:
  (a) There exists a basis $w_1, \dots, w_n$ for W such that $\lambda(v_i, w_j) = \delta_{ij}$ for all $i, j \in \{1, \dots, n\}$.[1066]
  (b) The pairing λ is non-singular.
(b) Suppose that λ is non-degenerate. Show that V and W have the same rank.
(c) Suppose that V and W are of rank n and suppose we are given $v_1, \dots, v_n \in V$ and $w_1, \dots, w_n \in W$ such that $\det(\lambda(v_i, w_j)) = \pm 1$. Show that $v_1, \dots, v_n$ is a basis for V and that $w_1, \dots, w_n$ is a basis for W.

Exercise 62.2. Let V be a free $\mathbb{Z}$-module of finite rank, i.e. V is a free abelian group. Let $\varphi\colon V \times V \to \mathbb{Z}$ be a form. Given a subgroup $U \subset V$ we write

$$U^\perp \;=\; \{v \in V \mid \varphi(u, v) = 0 \text{ for all } u \in U\}.$$

We suppose that the form φ is non-singular. Show that for any subgroup $U \subset V$ we have $\operatorname{rank}(U^\perp) = \operatorname{rank}(V) - \operatorname{rank}(U)$.

[1065] The Bott Periodicity Theorem says that for any $n \in \mathbb{N}$ we have $\pi_n(\mathrm{O}(\infty)) \cong \pi_{n+8}(\mathrm{O}(\infty))$. Here $\mathrm{O}(\infty)$ is defined as the direct limit of all orthogonal spaces $\mathrm{O}(n)$, $n \in \mathbb{N}$, where $\mathrm{O}(n) \to \mathrm{O}(n+1)$ is the obvious inclusion map. We refer to [Bot, Bot2] and also [Stro, Chapter 32.6] for a proof of this result.

[1066] The basis $w_1, \dots, w_n$ is in fact unique.

Exercise 62.3. Let $m, n \in \mathbb{N}$. We denote by $p\colon S^m \times S^n \to S^m$ and by $q\colon S^m \times S^n \to S^n$ the two obvious projection maps. Use Poincaré Duality to show that

$$p^*([S^m]^*) \cup q^*([S^n]^*) \;=\; \pm[S^m \times S^n]^*.$$

Put differently, you should show the equality without using the Product Theorem 60.1.

Exercise 62.4. For which $n \in \mathbb{N}$ is the complex projective space $\mathbb{C}\mathrm{P}^n$ chiral?

Exercise 62.5. Let $1 \leq m < n$. Show that $\mathbb{C}\mathrm{P}^m \subset \mathbb{C}\mathrm{P}^n$ is not a retract of $\mathbb{C}\mathrm{P}^n$.

Exercise 62.6. Does there exist a degree one map from $\mathbb{C}\mathrm{P}^2$ to $S^2 \times S^2$?

Exercise 62.7. Is $S^3 \vee \mathbb{R}\mathrm{P}^2$ homotopy equivalent to a manifold?

Exercise 62.8. Show that there exists a connected CW-complex X with base point x_0 and a homomorphism $\varphi\colon \pi_1(X, x_0) \to \mathbb{Z}_2 = \pi_1(\mathbb{R}\mathrm{P}^2, *)$ which cannot be realized by a map $g\colon X \to \mathbb{R}\mathrm{P}^2$, i.e. such that there is no map $f\colon X \to \mathbb{R}\mathrm{P}^2$ with $f(x_0) = *$ such that $f_* = \varphi$. Remark: This gives a negative answer to Question 55.10 (3).

63. The Hopf invariant

In the previous chapters we have seen that the introduction and the calculation of the cup product allowed us to answer many questions on topological spaces that we could not deal with before. In this section we want to use the cup product to address the following question that we formulated a long time ago.

Question 28.17. *Does the Hopf map $H\colon S^3 \to S^2$ represent a non-trivial element in the homotopy group $\pi_3(S^2)$?*

In this chapter we will use the calculation of the cup product of $\mathbb{C}\mathrm{P}^2$ to give an affirmative answer to this question. Furthermore we will use the quaternions and octonions to define higher dimensional analogues of the Hopf map which also represent non-trivial elements in homotopy groups of spheres.

63.1. **The Hopf map is not null-homotopic.** First we recall the definition of the Hopf map. On page 113 we gave an explicit identification $\mathbb{C}\mathrm{P}^1 = S^2$. Furthermore on page 726 we made the following definition.

Definition. We refer to the map[1067]

$$\begin{array}{rcl} H\colon S^3 = \{(z_1, z_2) \in \mathbb{C}^2 \,|\, |z_1|^2 + |z_2|^2 = 1\} & \to & S^2 = \mathbb{C}\mathrm{P}^1 \\ (z_1, z_2) & \mapsto & [z_1 : z_2] \end{array}$$

as the *Hopf map*.

Since the Hopf map is so much fun we will introduce two higher-dimensional analogues of the Hopf map. More precisely, we will repeat the trick with $\mathbb{C}$ replaced by the quaternions $\mathbb{H}$ and the octonions $\mathbb{O}$. First we note that we can use the homeomorphisms from Lemma 44.10 (2) and Proposition 44.11 (1) to make the identifications $\mathbb{H}\mathrm{P}^1 = S^4$ and $\mathbb{O}\mathrm{P}^1 = S^8$. Now we can introduce the quaternion and octonionic Hopf maps.

Definition. We refer to

$$\begin{array}{rcl} H_{\mathbb{H}}\colon S^7 = \{(z_1, z_2) \in \mathbb{H}^2 \,|\, |z_1|^2 + |z_2|^2 = 1\} & \to & S^4 = \mathbb{H}\mathrm{P}^1 \\ (z_1, z_2) & \mapsto & [z_1 : z_2] \end{array}$$

as the *quaternionic Hopf map* and we refer to

$$\begin{array}{rcl} H_{\mathbb{O}}\colon S^{15} = \{(z_1, z_2) \in \mathbb{O}^2 \,|\, |z_1|^2 + |z_2|^2 = 1\} & \to & S^8 = \mathbb{O}\mathrm{P}^1 \\ (z_1, z_2) & \mapsto & [z_1 : z_2] \end{array}$$

as the *octonionic Hopf map*.

The idea for answering Question 28.17 is to translate this question about maps to a question about topological spaces for which we can then bring our new invariants to bear. To carry out this approach we recall the following definitions from earlier on:

[1067]See also Figure 461 for an illustration of the map.

Definition.

(1) On page 450 we defined the *cone* of a topological space A to be the topological space $\mathrm{Cone}(A) := (A \times [0,1])/\sim$ where $(a,0) \sim (a',0)$ for all $a, a' \in A$.

(2) On page 458 we defined the *mapping cone* of a map $f\colon A \to X$ between topological spaces as
$$\mathrm{Cone}(f\colon A \to X) \;:=\; (\mathrm{Cone}(A) \cup X)/\sim$$
where $(a,1) \sim f(a)$ for all $a \in A$.

Both definitions are illustrated in Figure 759.

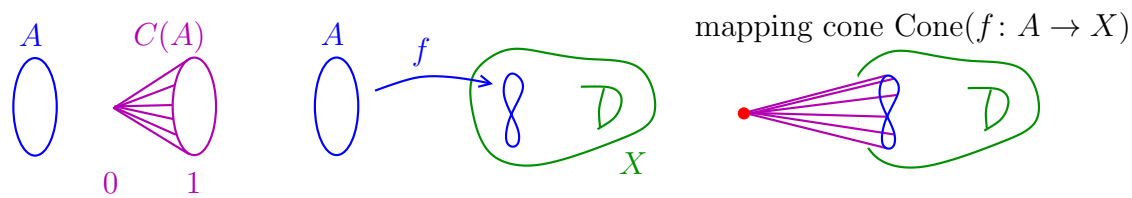

FIGURE 759.

Examples.

(1) It follows from Proposition 1.40 and Lemma 1.66 that the map
$$\begin{array}{rcl} \mathrm{Cone}(S^{n-1}) & \to & \overline{B}^n \\ [(P,t)] & \mapsto & t \cdot P \end{array}$$
is a homeomorphism. We use this homeomorphism to identify $\mathrm{Cone}(S^{n-1})$ with $\overline{B}^n$. In particular, if X is a topological space and if $f\colon S^{n-1} \to X$ is a map, then we get an identification
$$\mathrm{Cone}(f\colon S^{n-1} \to X) \;=\; \overline{B}^n \cup_f X.$$
It follows immediately from this observation that any finite CW-complex can be viewed as an iterated mapping cone (where we start out with a finite discrete set).

(2) In Exercise 63.1 we will see that the mapping cone of the map $f\colon S^1 \to S^1$ that is given by $f(z) = z^2$ is a topological space that we are very familiar with.

The next lemma gives us another elementary but oddly useful example.

Lemma 63.1. *If $f\colon S^k \to X$ is a constant map, then there exists a homeomorphism*
$$\mathrm{Cone}(f\colon S^k \to X) \;\xrightarrow{\cong}\; S^{k+1} \vee X,$$
where we perform the wedge for suitable points in S^{k+1} and X.

Proof. Suppose $f\colon S^k \to X$ is a constant map. It follows easily from the example on page 1469 and the homeomorphism $\overline{B}^{k+1}/S^k \cong S^{k+1}$ from page 99 that $\mathrm{Cone}(f\colon S^k \to X)$ is homeomorphic to a wedge $S^{k+1} \vee X$. We leave it to the reader to fill in the details. $\square$

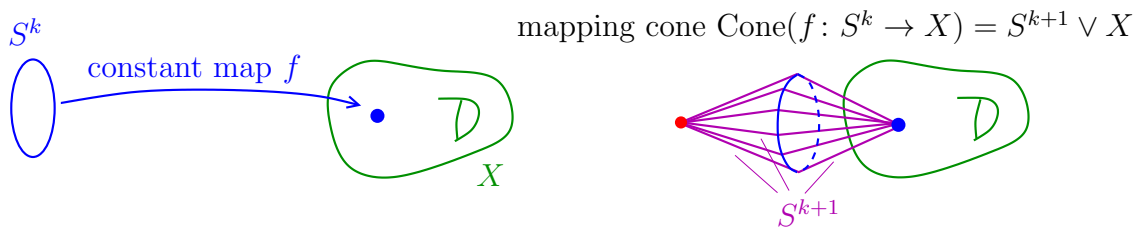

FIGURE 760. Illustration of Lemma 63.1.

The following lemma gives a particularly interesting example of a mapping cone.

Lemma 63.2. *There exist homeomorphisms*

$$\begin{array}{lrcl} (1) & \mathrm{Cone}(H\colon S^3 \to S^2) & \cong & \mathbb{C}\mathrm{P}^2 \\ (2) & \mathrm{Cone}(H_{\mathbb{H}}\colon S^7 \to S^4) & \cong & \mathbb{H}\mathrm{P}^2 \\ (3) & \mathrm{Cone}(H_{\mathbb{O}}\colon S^{15} \to S^8) & \cong & \mathbb{O}\mathrm{P}^2. \end{array}$$

Proof.

(1) In Lemma 26.2 we saw that $\mathbb{C}\mathrm{P}^2$ is a CW-complex that is obtained from the CW-complex $\mathbb{C}\mathrm{P}^1 = S^2$ by attaching a 4-cell. The attaching map $S^3 \to \mathbb{C}\mathrm{P}^1$ of the 4-cell is precisely the Hopf map. This observation, together with the discussion on page 1469, already implies the statement. For completeness' sake we give the argument more explicitly and in more detail. We consider the maps[1068]

$$\begin{array}{rcl} f\colon \mathrm{Cone}(S^3) & \to & \mathbb{C}\mathrm{P}^2 \\ [(z_0, z_1), r] & \mapsto & [(r \cdot z_0, r \cdot z_1, 1-r)] \end{array} \quad \text{and} \quad \begin{array}{rcl} g\colon \mathbb{C}\mathrm{P}^1 & \to & \mathbb{C}\mathrm{P}^2 \\ [z_0 : z_1] & \mapsto & [z_0 : z_1 : 0]. \end{array}$$

It follows immediately from the definitions that these two maps define a map

$$\underbrace{\mathrm{Cone}(H\colon S^3 \to S^2)}_{=(\mathrm{Cone}(S^3)\cup\mathbb{C}\mathrm{P}^1)/\sim} \to \mathbb{C}\mathrm{P}^2$$

which is easily seen to be a bijection. It follows from Lemma 1.66 that this map is continuous. Furthermore, using Proposition 1.40 and Lemma 1.81 one sees that the map is in fact a homeomorphism.

(2) The proof of (2) is basically identical to the proof of (1).

(3) The proof of (3) is similar to the proof of (1), we refer to [Lackm, p. 4] for details. □

Now we can finally answer Question 28.17 in the affirmative. More precisely we have the following theorem. The statement regarding the "classical" Hopf map was first proved by Heinz Hopf [Hopf] in 1931.

Theorem 63.3.

(1) *The Hopf map $H\colon S^3 \to S^2$ represents a non-trivial element in the homotopy group $\pi_3(S^2)$.*

[1068] It follows from Lemma 1.66 and Lemma 1.65 (3) that these two maps are continuous.

(2) *We have* $[H_{\mathbb{H}}] \neq 0 \in \pi_7(S^4)$.
(3) *We have* $[H_{\mathbb{O}}] \neq 0 \in \pi_{15}(S^8)$.

Proof. First we prove (1). Recall that for two topological spaces X and Y we write $X \simeq Y$ if they are homotopy equivalent. We have

$$\begin{array}{ccccccc} \text{Cone(Hopf map } H) & \cong & \mathbb{C}\mathrm{P}^2 & \not\simeq & S^2 \vee S^4 & \cong & \text{Cone(constant map)}. \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{Lemma 63.2 (1)} & & \text{Lemma 62.4} & & \text{Lemma 63.1} & \end{array}$$

But by Lemma 15.11 this means that the Hopf map is not homotopic to the constant map. In particular the Hopf map $H\colon S^3 \to S^2$ represents a non-trivial element in the homotopy group $\pi_3(S^2)$.

The proof of the other two statements is quite similar. We again use Lemma 63.2 and we use the calculations of the cup products of $\mathbb{H}\mathrm{P}^2$ and $\mathbb{O}\mathrm{P}^2$, see Proposition 62.20, to conclude that the mapping cones of the quaternion and octonionic Hopf maps are not homotopy equivalent to a wedge of spheres. □

63.2. **The Hopf invariant.** It is natural to ask how far we can push the methods of Theorem 63.3 to gain more insight into homotopy groups of spheres. In this section, given $n \geq 2$ we will introduce the Hopf invariant

$$\mathrm{Hopf}\colon \pi_{2n-1}(S^n) \ \to \ \mathbb{Z}$$

which satisfies $\mathrm{Hopf}(H) = \pm 1$, $\mathrm{Hopf}(H_{\mathbb{H}}) = \pm 1$ and $\mathrm{Hopf}(H_{\mathbb{O}}) = \pm 1$.

To introduce the Hopf invariant we need a careful study of the cohomology groups of a mapping cone. Recall that in Lemma 33.18 we saw that the homology groups of a mapping cone fit naturally into a long exact sequence of homology groups. The following lemma shows that the analogous statement also holds for the cohomology groups of a mapping cone.

Lemma 63.4. *Let R be a commutative ring.*

(1) *Let $f\colon A \to X$ be a map between topological spaces.*
   (a) *We denote by $j(f)\colon X \to \mathrm{Cone}(f) = (\mathrm{Cone}(A) \cup X)/\sim$ the obvious inclusion map.*
   (b) *We denote by U the image of $A \times [0, \frac{3}{4})$ in $\mathrm{Cone}(f)$ and we denote by V the complement of the image of $A \times [0, \frac{1}{4}]$. (See also Figure 761.) We consider the following diagram*

$$\begin{tikzcd} \dots \arrow[r] & H^{k-1}(U \cap V; R) \arrow[r, "\delta"] \arrow[d, "="] & H^k(\mathrm{Cone}(f); R) \arrow[r] & H^k(U; R) \oplus H^k(V; R) \arrow[r] & \dots \\ & H^{k-1}(A; R). \arrow[urr, "=:\delta^{k-1}(f)"'] & & & \end{tikzcd}$$

Here the top sequence is the long exact sequence arising from the Mayer–Vietoris Theorem 50.15 for Cohomology Groups[1069] *and the vertical map comes from the obvious identifications* $H^{k-1}(U \cap V; R) = H^{k-1}(A \times \frac{1}{2}; R) = H^{k-1}(A; R)$. *From the above diagram we obtain the map*

$$\delta^{k-1}(f)\colon H^{k-1}(A; R) \ \to \ H^k(\mathrm{Cone}(f); R).$$

The following sequence is exact

$$\ldots \to \widetilde{H}^k(\mathrm{Cone}(f); R) \xrightarrow{j(f)^*} H^k(X; R) \xrightarrow{f^*} H^k(A; R) \xrightarrow{\delta^k(f)} \widetilde{H}^{k+1}(\mathrm{Cone}(f); R) \to \ldots$$

(2) *The connecting homomorphism in* (1) *is natural. In particular given any commutative diagram*

$$\begin{array}{ccc} A & \xrightarrow{f} & X \\ {\scriptstyle\varphi}\downarrow & & \downarrow{\scriptstyle\psi} \\ \widetilde{A} & \xrightarrow{\widetilde{f}} & \widetilde{X} \end{array}$$

of maps between topological spaces the following diagram commutes:

$$\begin{array}{ccccccccc} \ldots \to & \widetilde{H}^k(\mathrm{Cone}(f); R) & \xrightarrow{j(f)^*} & H^k(X; R) & \xrightarrow{f^*} & H^k(A; R) & \xrightarrow{\delta^k(f)} & \widetilde{H}^{k+1}(\mathrm{Cone}(f); R) & \to \ldots \\ & \uparrow & & {\scriptstyle\psi^*}\uparrow & & {\scriptstyle\varphi^*}\uparrow & & \uparrow & \\ \ldots \to & \widetilde{H}^k(\mathrm{Cone}(\widetilde{f}); R) & \xrightarrow{j(\widetilde{f})^*} & H^k(\widetilde{X}; R) & \xrightarrow{\widetilde{f}^*} & H^k(\widetilde{A}; R) & \xrightarrow{\delta^k(\widetilde{f})} & \widetilde{H}^{k+1}(\mathrm{Cone}(\widetilde{f}); R) & \to \ldots \end{array}$$

Here the vertical maps between the cohomology groups of the mapping cones are induced by the maps from Lemma 15.9 (3).

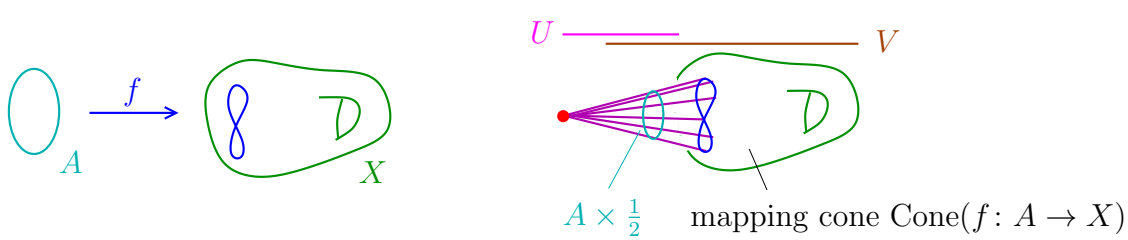

FIGURE 761. Illustration of Lemma 63.4.

Proof. The proof is basically identical to the proof of Lemma 33.18. The meticulous reader who filled in the details of the proof of Lemma 33.18 will have no troubles working out the details of the present proof. □

The following lemma is an immediate consequence of Lemma 63.4.

[1069]Note that U and V are open subsets of $\mathrm{Cone}(f)$. Thus it follows from Proposition 50.12 that we can in fact apply the theorem.

Lemma 63.5. *Let $f\colon S^m \to S^n$ be a map. If $m \geq n+1$ and $n \geq 1$, then the maps*

$$H^n(\mathrm{Cone}(f);\mathbb{Z}) \xrightarrow{j(f)^*} H^n(S^n;\mathbb{Z})$$

and

$$H^m(S^m;\mathbb{Z}) \xrightarrow{\delta^{2n-1}(f)} H^{m+1}(\mathrm{Cone}(f);\mathbb{Z})$$

are isomorphisms and all other reduced cohomology groups of $\mathrm{Cone}(f)$ *are zero. An analogous statement holds for homology groups. In particular we have isomorphisms*

$$H_k(\mathrm{Cone}(f\colon S^m \to S^n);\mathbb{Z}) \cong H^k(\mathrm{Cone}(f\colon S^m \to S^n);\mathbb{Z}) \cong \begin{cases} \mathbb{Z}, & \text{if } k = 0, n, m+1, \\ 0, & \text{otherwise.} \end{cases}$$

Throughout this section we use the notation that we had already introduced in the formulation of Lemma 63.4. More precisely, given a map $f\colon A \to X$ between two topological spaces we denote by $j(f)\colon X \to \mathrm{Cone}(f) = (\mathrm{Cone}(A) \cup X)/\sim$ the obvious inclusion map and furthermore we denote by $\delta^{k-1}(f)\colon H^{k-1}(A;\mathbb{Z}) \to H^k(\mathrm{Cone}(f);\mathbb{Z})$ the coboundary map in the long exact sequence in cohomology of Lemma 63.4.

Definition. Let $f\colon S^{2n-1} \to S^n$ be a map with $n \geq 2$. The *Hopf invariant* $\mathrm{Hopf}(f)$ is defined to be the unique integer that satisfies[1070]

$$\underbrace{(j(f)^*)^{-1}([S^n]^*)}_{\in H^n(\mathrm{Cone}(f);\mathbb{Z})} \cup \underbrace{(j(f)^*)^{-1}([S^n]^*)}_{\in H^n(\mathrm{Cone}(f);\mathbb{Z})} = \mathrm{Hopf}(f) \cdot \underbrace{\delta^{2n-1}(f)([S^{2n-1}]^*)}_{\in H^{2n}(\mathrm{Cone}(f);\mathbb{Z})}$$

in $H^{2n}(\mathrm{Cone}(f);\mathbb{Z}) \cong \mathbb{Z}$.

Remark. It follows immediately from the (anti-) commutativity of the cup product, see Proposition 57.8, that the Hopf invariant is zero for all odd n.

Example.

(1) As usual we denote by $H\colon S^3 \to S^2$ the Hopf map. In Lemma 63.2 we showed that the mapping cone $\mathrm{Cone}(H)$ is homeomorphic to $\mathbb{C}\mathrm{P}^2$. By Lemma 63.5 we know that $(j(H)^*)^{-1}([S^2]^*) \in H^2(\mathbb{C}\mathrm{P}^2;\mathbb{Z})$ and $\delta^3(f)([S^3]^*) \in H^4(\mathbb{C}\mathrm{P}^2;\mathbb{Z})$ are generators. It follows from the calculation of the cup product on $\mathbb{C}\mathrm{P}^2$, see Proposition 62.7, that $\mathrm{Hopf}(H) = -1$ or $\mathrm{Hopf}(H) = 1$.[1071]

(2) Using Proposition 62.20 one can show, by the same argument as in (1), that the Hopf invariants of the quaternionic Hopf map $H_{\mathbb{H}}\colon S^7 \to S^4$ and the octonionic Hopf map $H_{\mathbb{O}}\colon S^{15} \to S^8$ are equal to ± 1.

Lemma 63.6. *Let $n \geq 2$ and let $f_0, f_1\colon S^{2n-1} \to S^n$ be two maps. If f_0 and f_1 are homotopic, then* $\mathrm{Hopf}(f_0) = \mathrm{Hopf}(f_1)$.

[1070] Here we implicitly use that in Lemma 63.5 we showed that $j(f)^*$ and $\delta^{2n-1}(f)$ are isomorphisms.

[1071] With more care one can show that in fact $\mathrm{Hopf}(H) = 1$, but this is irrelevant for our purpose.

Proof $(*)$. Let $H\colon S^{2n-1}\times[0,1]\to S^n$ be a homotopy between f_0 and f_1. We denote by $i_0,i_1\colon S^{2n-1}\to S^{2n-1}\times[0,1]$ the two obvious inclusion maps. We obtain the following two commutative diagrams

$$\begin{tikzcd} S^{2n-1} \arrow[r, "f_0"] \arrow[d, "i_0"'] & S^n \arrow[d, "="] \\ S^{2n-1}\times[0,1] \arrow[r, "H"] & S^n \end{tikzcd} \quad \text{and} \quad \begin{tikzcd} S^{2n-1} \arrow[r, "f_1"] \arrow[d, "i_1"'] & S^n \arrow[d, "="] \\ S^{2n-1}\times[0,1] \arrow[r, "H"] & S^n. \end{tikzcd}$$

By Lemma 15.9 (3) the diagrams give rise to inclusion maps $\Xi_0\colon \operatorname{Cone}(f_0)\to\operatorname{Cone}(H)$ and $\Xi_1\colon \operatorname{Cone}(f_1)\to\operatorname{Cone}(H)$. From Lemma 63.4 we obtain the following commutative diagram of long exact sequences:

$$\begin{tikzcd} \dots \arrow[r] & \widetilde{H}^k(\operatorname{Cone}(f_0)) \arrow[r, "j(f_0)^*"] & H^k(S^n) \arrow[r, "f_0^*"] & H^k(S^{2n-1}) \arrow[r, "\delta"] & \widetilde{H}^{k+1}(\operatorname{Cone}(f_0)) \arrow[r] & \dots \\ \dots \arrow[r] & \widetilde{H}^k(\operatorname{Cone}(H)) \arrow[r, "j(H)^*"] \arrow[u, "\Xi_0^*"] \arrow[d, "\Xi_1^*"'] & H^k(S^n) \arrow[r, "H^*"] \arrow[u, "\mathrm{id}"] \arrow[d, "\mathrm{id}"'] & H^k(S^{2n-1}\times[0,1]) \arrow[r, "\delta"] \arrow[u, "\cong"', "i_0^*"] \arrow[d, "\cong"', "i_1^*"] & \widetilde{H}^{k+1}(\operatorname{Cone}(H)) \arrow[r] \arrow[u, "\Xi_0^*"] \arrow[d, "\Xi_1^*"'] & \dots \\ \dots \arrow[r] & \widetilde{H}^k(\operatorname{Cone}(f_1)) \arrow[r, "j(f_1)^*"] & H^k(S^n) \arrow[r, "f_1^*"] & H^k(S^{2n-1}) \arrow[r, "\delta"] & \widetilde{H}^{k+1}(\operatorname{Cone}(f_1)) \arrow[r] & \dots \end{tikzcd}$$

Note that the vertical maps between the cohomology groups of the mapping cones are isomorphisms. This can be shown using the Five Lemma 31.11, or alternatively, in a more fancy way using Lemma 15.11.

Next we consider the generator $\Theta := (i_0^*)^{-1}([S^{2n-1}]^*) = (i_1^*)^{-1}([S^{2n-1}]^*)$ of the group $H^{2n}(\operatorname{Cone}(H);\mathbb{Z})$. We define a number $\operatorname{Hopf}(H)$ via the equality

$$(j(H)^*)^{-1}([S^n]^*)\cup(j(H)^*)^{-1}([S^n]^*) \;=\; \operatorname{Hopf}(H)\cdot\delta^{2n-1}(H)(\Theta)$$

in $H^{2n}(\operatorname{Cone}(H);\mathbb{Z})\cong\mathbb{Z}$. We apply the above commutative diagram and we apply Lemma 57.10 to the maps $\Xi_0\colon \operatorname{Cone}(f_0)\to\operatorname{Cone}(H)$ and $\Xi_1\colon \operatorname{Cone}(f_1)\to\operatorname{Cone}(H)$ and we see that $\operatorname{Hopf}(f_0)=\operatorname{Hopf}(H)=\operatorname{Hopf}(f_1)$. □

It follows from Lemma 63.6 that the Hopf invariant descends to a well-defined map on homotopy groups:

Definition. It follows from Lemma 63.6 that for each $n\geq 2$ the map

$$\begin{array}{rcl} \pi_{2n-1}(S^n,*) & \to & \mathbb{Z} \\ [f] & \mapsto & \operatorname{Hopf}(f) \end{array}$$

is well-defined. This map is called the *Hopf invariant*.

Proposition 63.7. *For any $n\geq 2$ the Hopf invariant* $\operatorname{Hopf}\colon \pi_{2n-1}(S^n,*)\to\mathbb{Z}$ *is a homomorphism.*

Together with the calculation of the Hopf invariant for the Hopf maps H, $H_{\mathbb{H}}$ and $H_{\mathbb{O}}$ on page 1473 we obtain the following immediate corollary to Proposition 63.7.

Corollary 63.8. *The Hopf invariants*

$$\begin{array}{lrcl} (1) & \mathrm{Hopf}\colon \pi_3(S^2) & \to & \mathbb{Z} \\ (2) & \mathrm{Hopf}\colon \pi_7(S^4) & \to & \mathbb{Z} \\ (3) & \mathrm{Hopf}\colon \pi_{15}(S^8) & \to & \mathbb{Z} \end{array}$$

are epimorphisms.

The technically slightly dicey proof of Proposition 63.7 will require the remainder of this section. The reader is cordially invited to skip the argument and to jump to the much more entertaining content of the next section.

Our proof[1072] of Proposition 63.7 will require a few preparations. First of all, on several occasions we will need the following construction.

Construction 63.9. *Suppose we are given the following commutative diagram of topological spaces:*

$$\begin{tikzcd} X \arrow[r, "f"] \arrow[d, "\varphi"'] & Y \arrow[d, "\psi"] \\ \widetilde{X} \arrow[r, "\widetilde{f}"] & \widetilde{Y}. \end{tikzcd}$$

Then, as discussed in Lemma 15.9 (3), we obtain an induced map

$$\begin{array}{rcl} \mathrm{Cone}(f\colon X \to Y) & \to & \mathrm{Cone}(f\colon \widetilde{X} \to \widetilde{Y}) \\ [P] & \mapsto & \begin{cases} [(\varphi(x), t)], & \text{if } P = (x,t) \text{ with } x \in X,\ t \in [0,1], \\ [\psi(y)], & \text{if } P = y \text{ with } y \in Y \end{cases} \end{array}$$

By Lemma 15.9 (4) the map fits into the following commutative diagram:

$$\begin{tikzcd} Y \arrow[r, hook, "j"] \arrow[d, "\psi"'] & \mathrm{Cone}(f\colon X \to Y) \arrow[r, "p"] \arrow[d] & \Sigma(X) \arrow[d, "\Sigma(\varphi)"] \\ \widetilde{Y} \arrow[r, hook, "j"] & \mathrm{Cone}(\widetilde{f}\colon \widetilde{X} \to \widetilde{Y}) \arrow[r, "p"] & \Sigma(\widetilde{X}) \end{tikzcd}$$

where the horizontal maps to the left are the inclusions maps i introduced in Lemma 15.8 (1) and where the horizontal maps p on the right are given by the projection and the homeomorphism from Lemma 15.8 (2).

Finally we will need the following slight reinterpretation of the Hopf invariant.

Lemma 63.10. *Let $f\colon S^{2n-1} \to S^n$ be a map. We denote by $j\colon S^n \to \mathrm{Cone}(f)$ the inclusion map and we denote by $p\colon \mathrm{Cone}(f) \to \mathrm{Cone}(f)/S^n = \Sigma(S^{2n-1})$ the map given by the projection and homeomorphism from Lemma 15.8 (2). Then*

$$(j^*)^{-1}([S^n]^*) \cup (j^*)^{-1}([S^n]^*) \ = \ \mathrm{Hopf}(f) \cdot p^*(\Sigma([S^{2n-1}]^*)) \ \in \ H^{2n}(\mathrm{Cone}(f); \mathbb{Z}).$$

Proof of Lemma 63.10. The statement follows basically immediately from the discussion on page 1209[1073] and the cohomological analogue of Lemma 33.19. □

[1072] Our proof is based on the proof in [MTa, p. 35]. An alternative proof is sketched in [Stro, p. 557].

[1073] Note that here we use the convenient fact that $(-1)^{(2n-1)+1} = +1$. In reality the sign is largely irrelevant, as long as we can be sure that the sign depends only on n.

Proof of Proposition 63.7. We start out with a few preparations.

(1) Given a pointed topological space (X, x_0) we define $X \vee X$ by identifying two copies of X along the base point. We refer to the map $\varphi\colon X \vee X \to X$ which is given by the identity on either of the two copies as the *folding map*.

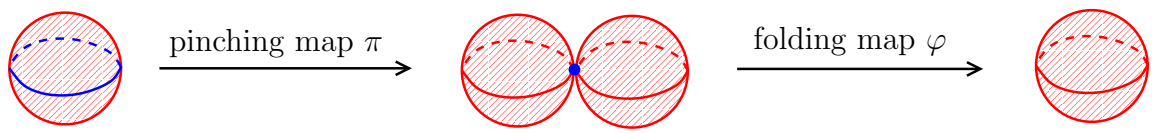

FIGURE 762.

(2) Let $k \in \mathbb{N}_{\geq 2}$. On page 715 we introduced a pinching map $\pi\colon S^k \to S^k \vee S^k$. The precise definition is rather irrelevant to us right now. What matters is that we saw on page 716 that given any pointed topological space (X, x_0) and given any two maps $f, g\colon (S^k, *) \to (X, x_0)$ we have

$$[f_1 * f_2] \;=\; \left[S^k \xrightarrow{\pi} S^k \vee S^k \xrightarrow{f_1 \vee f_2} X \vee X \xrightarrow{\varphi} X\right] \;\in\; \pi_k(X, x_0).$$

Now we turn to our actual situation. Let $n \in \mathbb{N}_{\geq 2}$. Suppose we are given two maps $f, g\colon (S^{2n-1}, *) \to (S^n, *)$. For $i = 1, 2$ we consider the following diagram

$$\begin{tikzcd}
S^n \arrow[r, "j"] & \mathrm{Cone}(\varphi \circ (f_1 \vee f_2) \circ \pi\colon S^{2n-1} \to S^n) \arrow[r, "p"] & \Sigma S^{2n-1} \\
S^n \vee S^n \arrow[u, "\varphi"] \arrow[d, "="'] \arrow[r, "j"] & \mathrm{Cone}((f_1 \vee f_2) \circ \pi\colon S^{2n-1} \to S^n \vee S^n) \arrow[u, "\varphi"'] \arrow[d, "\psi"] \arrow[r, "p"] & \Sigma S^{2n-1} \arrow[u, "="'] \arrow[d, "\Sigma(\pi)"] \\
S^n \vee S^n \arrow[d, "="'] \arrow[r, "j"] & \mathrm{Cone}(f_1 \vee f_2\colon S^{2n-1} \vee S^{2n-1} \to S^n \vee S^n) \arrow[r, "p"] & \Sigma(S^{2n-1} \vee S^{2n-1}) \\
S^n \vee S^n \arrow[u, "="] \arrow[d, "q_i"'] \arrow[r, "j \vee j"] & \mathrm{Cone}(f_1\colon S^{2n-1} \to S^n) \vee \mathrm{Cone}(f_2\colon S^{2n-1} \to S^n) \arrow[u, "\Xi"'] \arrow[d, "q_i"] \arrow[r, "p \vee p"] & \Sigma S^{2n-1} \vee \Sigma S^{2n-1} \arrow[u, "\Omega"'] \arrow[d, "q_i"] \\
S^n \arrow[r, "j"] & \mathrm{Cone}(f_i\colon S^{2n-1} \to S^n) \arrow[r, "p"] & \Sigma S^{2n-1}.
\end{tikzcd}$$

The top three vertical maps are illustrated in Figure 763. We make the following clarifications:

(1) The horizontal maps to the left are the inclusions maps j introduced in Lemma 15.8 (1) and the horizontal maps p on the right are given by the projection and the homeomorphism from Lemma 15.8 (2).

(2) The vertical maps between the first and the second and between the second and the third row are obtained from Construction 63.9 applied to the following two commutative diagrams

$$\begin{tikzcd}
S^{2n-1} \arrow[r, "(f_1 \vee f_2) \circ \pi"] \arrow[d, "="'] & S^n \vee S^n \arrow[d, "\varphi"] \\
S^{2n-1} \arrow[r, "\varphi \circ (f_1 \vee f_2) \circ \pi"] & S^n
\end{tikzcd}
\quad \text{and} \quad
\begin{tikzcd}
S^{2n-1} \arrow[r, "(f_1 \vee f_2) \circ \pi"] \arrow[d, "\pi"'] & S^n \vee S^n \arrow[d] \\
S^{2n-1} \vee S^{2n-1} \arrow[r, "f_1 \vee f_2"] & S^n \vee S^n.
\end{tikzcd}$$

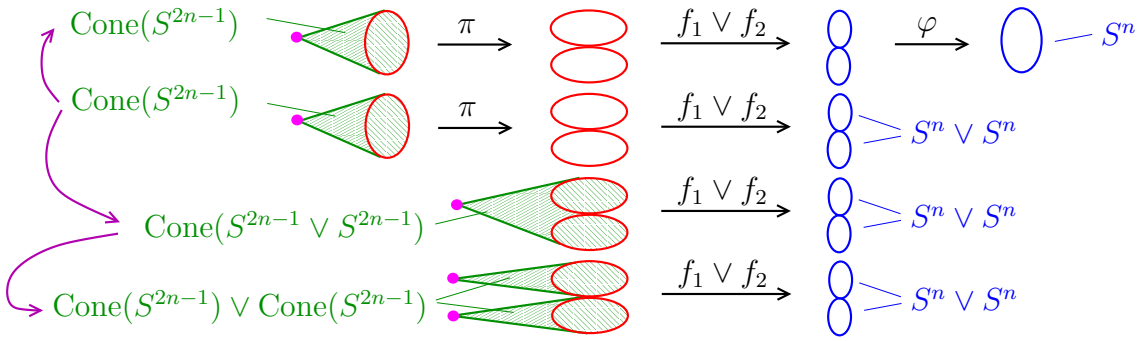

FIGURE 763. Illustration for the proof of Proposition 63.7.

In particular we see that the four upper squares commute.

(3) Next we consider the two diagrams

$$\begin{array}{ccc} S^{2n-1} & \xrightarrow{f_i} & S^n \\ \downarrow & & \downarrow \\ S^{2n-1} \vee S^{2n-1} & \xrightarrow{f_1 \vee f_2} & S^n \vee S^n \end{array}$$

which are given by the injections into the first respectively second factor. By Construction 63.9 these diagrams give rise to two sequences of maps. We "wedge" the two sequences and we obtain the vertical maps from the fourth to the third row.

(4) At the bottom, in each column the map q_i is the projections onto the first factor.

Next we apply the cohomology functor $X \mapsto H^k(X) = H^k(X;\mathbb{Z})$ with $k = n$ and $k = 2n$ to the above diagram (except that that at the bottom we consider both maps q_1 and q_2). We obtain the following commutative diagram:[1074]

$$\begin{array}{ccccc}
H^k(S^n) & \xleftarrow[\cong]{j^*} & H^k(\mathrm{Cone}(\varphi\circ(f_1\vee f_2)\circ\pi : S^{2n-1}\to S^n)) & \xleftarrow[\cong]{p^*} & H^k(\Sigma S^{2n-1}) \\
{\scriptstyle\varphi^*}\downarrow & & \downarrow{\scriptstyle\varphi^*} & & \downarrow{\scriptstyle =} \\
H^k(S^n\vee S^n) & \xleftarrow[\cong]{j^*} & H^k(\mathrm{Cone}((f_1\vee f_2)\circ\pi : S^{2n-1}\to S^n\vee S^n)) & \xleftarrow[\cong]{p^*} & H^k(\Sigma S^{2n-1}) \\
{\scriptstyle =}\uparrow & & \uparrow{\scriptstyle\psi^*} & & \uparrow{\scriptstyle\Sigma(\pi)^*} \\
H^k(S^n\vee S^n) & \xleftarrow[\cong]{j^*} & H^k(\mathrm{Cone}(f_1\vee f_2 : S^{2n-1}\vee S^{2n-1}\to S^n\vee S^n)) & \xleftarrow[\cong]{p^*} & H^k(\Sigma(S^{2n-1}\vee S^{2n-1})) \\
{\scriptstyle =}\downarrow & & \cong\downarrow{\scriptstyle\Xi^*} & & \cong\downarrow{\scriptstyle\Omega^*} \\
H^k(S^n\vee S^n) & \xleftarrow[\cong]{(j\vee j)^*} & H^k(\mathrm{Cone}(f_1)\vee\mathrm{Cone}(f_2)) & \xleftarrow[\cong]{(p\vee p)^*} & H^k(\Sigma S^{2n-1}\vee\Sigma S^{2n-1}) \\
{\scriptstyle q_1^*\oplus q_2^*}\uparrow\cong & & \cong\uparrow{\scriptstyle q_1^*\oplus q_2^*} & & \cong\uparrow{\scriptstyle q_1^*\oplus q_2^*} \\
H^k(S^n)\oplus H^k(S^n) & \xleftarrow[\cong]{j_1^*\oplus j_2^*} & H^k(\mathrm{Cone}(f_1))\oplus H^k(\mathrm{Cone}(f_2)) & \xleftarrow[\cong]{p_1^*\oplus p_2^*} & H^k(\Sigma S^{2n-1})\oplus H^k(\Sigma S^{2n-1}).
\end{array}$$

We make the following observations:

[1074] Any reader who knows of a program which can automatically turn the latex-code for a diagram of topological spaces into the latex-code for the corresponding diagram of cohomology groups should contact me urgently.

(1) It follows almost immediately from Lemma 63.4 that the horizontal maps to the left are isomorphisms in degree n. Since these isomorphisms are only in degree n they are colored in red.
(2) It follows easily from Lemma 63.4 and the cohomological analogue of Lemma 33.19 that the horizontal maps to the right are isomorphisms for $k = 2n$. Since these isomorphisms are only in degree $2n$ they are colored in green.
(3) Similar to the calculation in Exercise 34.3 we see that the map Ω^* is an isomorphism.
(4) It follows from (1), (2) and (3) that the map Ξ^* is an isomorphism.
(5) The vertical maps at the very bottom are induced by the obvious projection maps. The maps are isomorphisms by Proposition 50.17.

Next we denote by $\alpha = [S^n]^* \in H^n(S^n)$ the dual fundamental class. Furthermore we write $\beta = ([\Sigma([S^{2n-1}]^*)]) \in H^{2n}(\Sigma S^{2n-1})$.

Claim 1. We have $\varphi^*(\alpha) = q_1^*(\alpha) + q_2^*(\alpha)$ and $((\Sigma(\pi)^* \circ (\Omega^*)^{-1})(q_1^*(\beta) + q_2^*(\beta)) = \beta$.

We leave it to the reader to verify this claim.

The key calculation takes place in the fourth row. More precisely, we have the following claim.

Claim 2. The following equality holds in $H^{2n}(\mathrm{Cone}(f_1) \vee \mathrm{Cone}(f_2))$:

$$\big((j \vee j)^*)^{-1}(q_1^*(\alpha) + q_2^*(\alpha))\big)^2 \;=\; (\mathrm{Hopf}(f_1) + \mathrm{Hopf}(f_2)) \cdot (p \vee p)^*(q_1^*(\beta) + q_2^*(\beta)).$$

We calculate that

$$\begin{aligned}
&\big((j \vee j)^{*-1}(q_1^*\alpha + q_2^*\alpha)\big)^2 \overset{\substack{\text{since } j_i \circ q_i = q_i \circ (j \vee j)\colon S^n \vee S^n \to \mathrm{Cone}(f_i\colon S^{2n-1} \to S^n)\\ \downarrow}}{=} \big(q_1^*(j_1^{*-1}\alpha) + q_2^*(j_2^{*-1}\alpha)\big) \cup \big(q_1^*(j_1^{*-1}\alpha) + q_2^*(j_2^{*-1}\alpha)\big)\\
&\underset{\substack{\uparrow\\ \text{by Lemma 58.6 the “mixed” terms are zero}}}{=} q_1^*(j_1^{*-1}\alpha) \cup q_1^*(j_1^{*-1}\alpha) + q_2^*(j_2^{*-1}\alpha) \cup q_2^*(j_2^{*-1}\alpha) \underset{\substack{\uparrow\\ \text{since the cup product is natural, see Lemma 57.10}}}{=} q_1^*(j_1^{*-1}\alpha \cup j_1^{*-1}\alpha) + q_2^*(j_2^{*-1}\alpha \cup j_2^{*-1}\alpha)\\
&\underset{\substack{\uparrow\\ \text{by the reinterpretation of } \mathrm{Hopf}(f_1)\\ \text{and } \mathrm{Hopf}(f_2) \text{ given in Lemma 63.10}}}{=} q_1^*(\mathrm{Hopf}(f_1) \cdot p_1^*(\beta)) + q_2^*(\mathrm{Hopf}(f_2) \cdot p_2^*(\beta)) \underset{\substack{\uparrow\\ \text{since } p_i \circ q_i = q_i \circ (p \vee p)\colon\ \mathrm{Cone}(f_1) \vee \mathrm{Cone}(f_2) \to \Sigma S^{2n-1}}}{=} (\mathrm{Hopf}(f_1) + \mathrm{Hopf}(f_2)) \cdot (p \vee p)^*(q_1^*(\beta) + q_2^*(\beta)).
\end{aligned}$$

This concludes the proof of Claim 2.

It follows from $[f_1 * f_2] = [\varphi \circ (f_1 \vee f_2) \circ \pi]$, the definition of α and β and the reinterpretation of the Hopf invariant given in Lemma 63.10, that it remains to prove the following claim.

Claim 3. The following equality holds in the first row:

$$((j^*)^{-1}(\alpha))^2 \;=\; (\mathrm{Hopf}(f_1) + \mathrm{Hopf}(f_2)) \cdot p^*(\beta).$$

The idea is of course to push the equality from Claim 2 through the above commutative diagram towards the top. The key tool hereby is the naturality of the cup product, see Lemma 57.10. First we note that it follows from Lemma 57.10 and the fact that φ^* is an

isomorphism in degree $2n$ that it remains to prove that the following equality holds in the second row:

$$(*) \qquad (j^*)^{-1}(\varphi^*(\alpha))^2 \;=\; (\mathrm{Hopf}(f_1) + \mathrm{Hopf}(f_2)) \cdot p^*(\beta).$$

To prove this equality we note that it follows from Claims 1 and 2 together with Lemma 57.10 that the following equality holds in the third row:

$$((j^*)^{-1}(\varphi^*(\alpha)))^2 \;=\; (\mathrm{Hopf}(f_1) + \mathrm{Hopf}(f_2)) \cdot p^*((\Omega^*)^{-1}(q_1^*(\beta) + q_2^*(\beta))).$$

Again, using Lemma 57.10 we see that the following equality holds in the second row:

$$((j^*)^{-1}(\varphi^*(\alpha)))^2 \;=\; (\mathrm{Hopf}(f_1) + \mathrm{Hopf}(f_2)) \cdot p^*(\underbrace{\Sigma(\pi)^*((\Omega^*)^{-1}(q_1^*(\beta) + q_2^*(\beta)))}_{=\,\beta \text{ by Claim 1}}).$$

But using Claim 1 we see that this is precisely the desired equality that we formulated in $(*)$. This concludes the proof of Claim 3. □

63.3. **The Hopf invariant and multiplication maps.** By a *multiplication map* we mean any map of the form $f\colon S^k \times S^k \to S^k$. In this section we will see that such multiplication maps give rise to potentially interesting maps $\Theta_f\colon S^{2k+1} \to S^k$. In the key calculation of this section we show how we can determine the Hopf invariant $\mathrm{Hopf}(\Theta_f)$ directly in terms of homological data of the original map f.

We start out with the following not terribly inspired definition.

Definition. Let $n \in \mathbb{N}$ and let $f\colon S^n \times S^n \to S^n$ be a map. We pick $x_0, y_0 \in S^n$. We define the *bidegree* of f as[1075]

$$\mathrm{bideg}(f) := (p, q) \;\text{ where } p := \deg\begin{pmatrix} S^n & \to & S^n \\ x & \mapsto & f(x, y_0) \end{pmatrix} \text{ and } q := \deg\begin{pmatrix} S^n & \to & S^n \\ y & \mapsto & f(x_0, y) \end{pmatrix}.$$

Examples.

(1) The map $f\colon S^1 \times S^1 \to S^1$ that is given by complex multiplication has bidegree $(1, 1)$. This can be seen as follows: taking $x_0 = y_0 = 1$, we see that the two maps $S^1 \to S^1$ given by $z \mapsto f(z, 1)$ and $z \mapsto f(1, z)$ are in fact the identity.
(2) The same argument as in (1) shows that the quaternion multiplication $S^3 \times S^3 \to S^3$ is a map of bidegree $(1, 1)$ and that the octonion multiplication $S^7 \times S^7 \to S^7$ is also a map of bidegree $(1, 1)$.

The previous example shows that the division algebras $\mathbb{C}$, $\mathbb{H}$ and $\mathbb{O}$ give rise to maps of bidegree $(1, 1)$. This result can be generalized to all division algebras.

Lemma 63.11. *Let $n \in \mathbb{N}_{\geq 2}$. If $\mathbb{R}^n$ admits the structure of a division algebra*[1076]*, then there exists a map $S^{n-1} \times S^{n-1} \to S^{n-1}$ of bidegree (p, q) where both p and q are odd.*

[1075] Why does the definition not depend on the choice of x_0 and y_0?

[1076] Recall that by the definition on page 1054 a division algebra is an algebra that has left and right inverses. We do not assume that division algebras are associative and we do not assume that they preserve the scalar product.

Proof. Let $*$ be the multiplication map of a division algebra on $\mathbb{R}^n$. As in the proof of Theorem 44.5 we consider the map

$$\begin{array}{rcl} f\colon S^{n-1}\times S^{n-1} & \to & S^{n-1} \\ (x,y) & \mapsto & f(x,y) := \dfrac{x*y}{\|x*y\|}. \end{array}$$

In the proof of Theorem 44.5 we already showed, using the hypothesis that "$*$" defines a division algebra, that this map is well-defined and that it is continuous. Now we pick a point $* \in S^{n-1}$ and we consider the maps

$$\begin{array}{rcl} \varphi\colon S^{n-1} & \to & S^{n-1} \\ x & \mapsto & f(x,*) \end{array} \quad \text{and} \quad \begin{array}{rcl} \psi\colon S^{n-1} & \to & S^{n-1} \\ y & \mapsto & f(*,y). \end{array}$$

It follows easily from the fact that $*$ is the multiplication of a real algebra that for all $z \in S^{n-1}$ we have $\varphi(-z) = -\varphi(z)$ and $\psi(-z) = -\psi(z)$. By Proposition 44.17 this implies that $\deg(\varphi)$ and $\deg(\psi)$ are odd. Conveniently enough that is exactly what he had set out to show. $\square$

Before we continue we recall a few conventions that we had introduced along the way. Most of them are also illustrated in Figure 764.

(1) Given a topological space we consider the cone $\mathrm{Cone}(X)$, the suspension $\Sigma(X)$ and we consider the two copies $\mathrm{Cone}_\pm(X)$ of the cone in the suspension.[1077]
(2) Let $m \in \mathbb{N}_0$. By the discussion on page 450 we can make the identification $\mathrm{Cone}(S^m) = \overline{B}^{m+1}$ and by the discussion on page 453 we can make the identification $\Sigma(S^m) = S^{m+1}$.
(3) Let $m, n \in \mathbb{N}_0$. By the discussion on page 116 we can make the identification

$$(S^m \times \overline{B}^{n+1}) \sqcup_{\mathrm{id}_{S^m\times S^n}} (\overline{B}^{m+1} \times S^n) \xrightarrow{=} S^{m+n+1}.$$

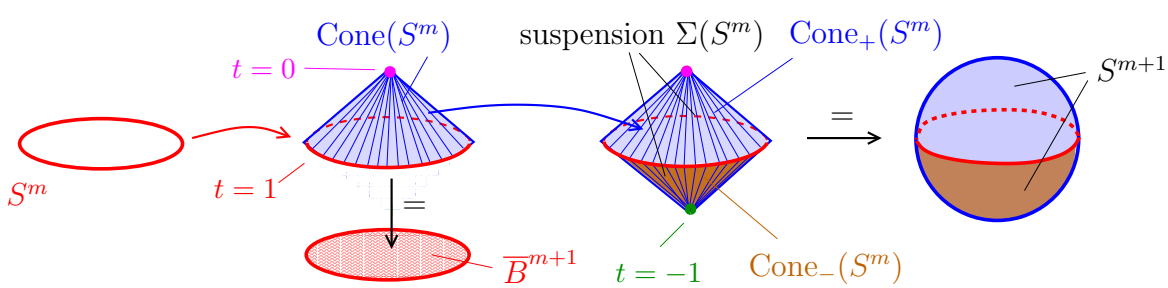

FIGURE 764.

Now we can move on to the promised construction of potentially interesting maps between spheres.

[1077] Here we implicitly use Lemma 15.2.

Definition. Let $f\colon S^p \times S^q \to S^r$ be a map. We consider the maps

$$\begin{array}{rcl} S^p \times \mathrm{Cone}(S^q) & \to & \mathrm{Cone}_+(S^r) \\ (P,[(Q,t)]) & \mapsto & [(f(P,Q),1-t)] \end{array} \quad \text{and} \quad \begin{array}{rcl} \mathrm{Cone}(S^p) \times S^q & \to & \mathrm{Cone}_-(S^r) \\ ([(P,t)],Q) & \mapsto & [(f(P,Q),t-1)]. \end{array}$$

We will see in Exercise 63.2 that these two maps are continuous. Evidently the two maps agree on the overlap $S^p \times S^q$. Thus by Lemma 1.83 (3) these two maps define a continuous map

$$\Theta_f\colon \underbrace{(S^p \times \mathrm{Cone}(S^q)) \sqcup_{S^p\times S^q} (\mathrm{Cone}(S^p) \times S^q) = S^{p+q+1}}_{=(S^p\times \overline{B}^{q+1})\sqcup_{S^p\times S^q}(\overline{B}^{p+1}\times S^q)} \to \underbrace{\Sigma(S^r)}_{=S^{r+1}}.$$

We refer to Figure 765 for a moderately successful attempt at illustrating the map Θ_f.

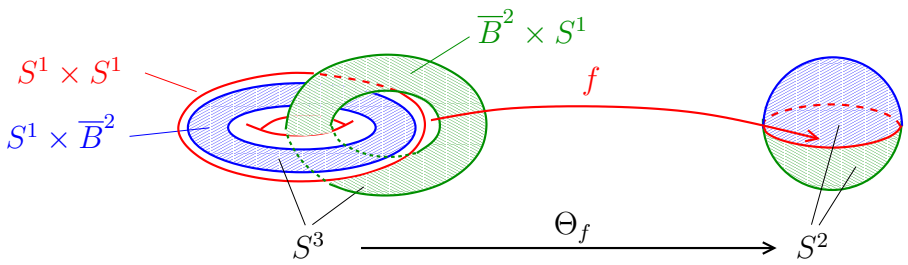

FIGURE 765.

Example.

(1) Again we consider the map $f\colon S^1 \times S^1 \to S^1$ that is given by complex multiplication. We obtain by the above construction a map $\Theta_f\colon S^3 \to S^2$. The heroically inclined reader will surely rise to the challenge of showing that this map is homotopic to the Hopf map.[1078]

(2) Similarly to (1) one can show that the quaternion multiplication $S^3 \times S^3 \to S^3$ gives rise to the quaternionic Hopf map $S^7 \to S^4$ and that the octonion multiplication $S^7 \times S^7 \to S^7$ gives rise to the quaternionic Hopf map $S^{15} \to S^8$.

Given a map $f\colon S^{n-1} \times S^{n-1} \to S^{n-1}$ the next proposition computes the Hopf invariant of Θ_f in terms of the bidegree of f.

Proposition 63.12. *Let $n \in \mathbb{N}_{\geq 2}$. If $f\colon S^{n-1} \times S^{n-1} \to S^{n-1}$ is a map of bidegree (r,s), then the induced map $\Theta_f\colon S^{2n-1} \to S^n$ has Hopf invariant $\pm rs$.*[1079]

Proof. We make the following preparations:

(1) Throughout the proof all cohomology groups are understood to be with $\mathbb{Z}$-coefficients.

(2) To simplify the notation we write $\mathrm{C}(\Theta_f)$ instead of $\mathrm{Cone}(\Theta_f)$.

[1078] To be on the safe side, let us more cautiously say that the map Θ_f is either homotopic to the Hopf map or that it is homotopic to the composition of the Hopf map with a reflection in a hyperplane.

[1079] We leave it to the sign aficionados to determine the correct sign.

(3) By Lemma 15.5 we know that the inclusion $S^n \to \mathrm{C}(\Theta_f\colon S^{2n-1} \to S^n)$ is actually a homeomorphism onto its image, thus we can identify S^n with its image in $\mathrm{C}(\Theta_f)$.
(4) We denote by $\overline{B}^n_+$ the upper hemisphere of S^n and we denote by $\overline{B}^n_+$ the lower hemisphere of S^n.
(5) By the discussion on page 450 we can make the identification

$$\overline{B}^n \times \overline{B}^n \;=\; \overline{B}^{2n} \;=\; \mathrm{Cone}\big(\underbrace{(S^{n-1} \times \overline{B}^n) \sqcup_{S^{n-1}\times S^{n-1}} (\overline{B}^n \times S^{n-1})}_{=S^{2n-1}}\big).$$

We denote by

$$F\colon \overline{B}^n \times \overline{B}^n \;\to\; \mathrm{C}(\Theta_f\colon S^{2n-1} \to S^n) \;=\; \underbrace{\mathrm{Cone}(S^{2n-1})}_{=\overline{B}^n\times\overline{B}^n=\overline{B}^{2n}} \sqcup_{\Theta_f} S^n$$

the obvious map which is given by the identification $\overline{B}^n \times \overline{B}^n = \mathrm{Cone}(S^{2n-1})$ followed by the projection.

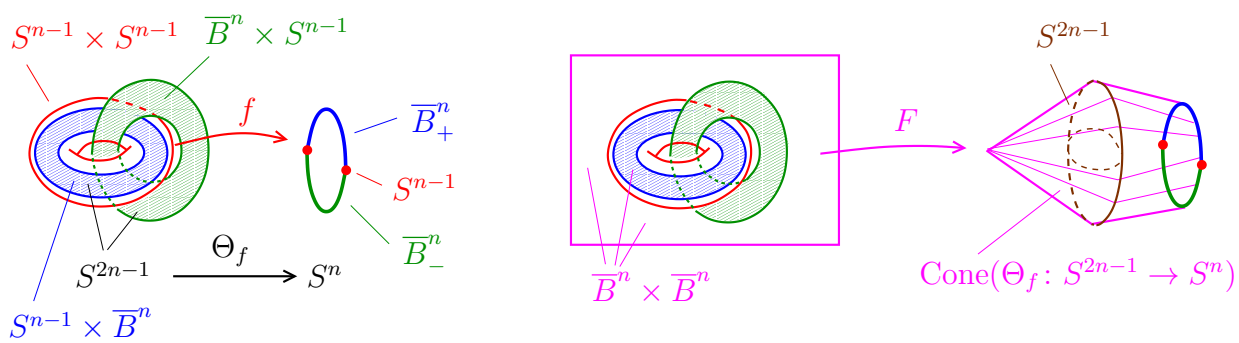

FIGURE 766. Illustration for the proof of Proposition 63.12.

Next we pick generators for various cohomology groups:
(1) We denote by $x \in H^n(\mathrm{C}(\Theta_f))$ and $z \in H^{2n}(\mathrm{C}(\Theta_f))$ the generators that are given in the definition of the Hopf invariant, see page 1473.
(2) The long exact sequence in cohomology of the pair $(\mathrm{C}(\Theta_f), \overline{B}^n_\pm)$ shows that the maps $H^n(\mathrm{C}(\Theta_f), \overline{B}^n_\pm) \to H^n(\mathrm{C}(\Theta_f)))$ are isomorphisms. Let $x_\pm \in H^n(\mathrm{C}(\Theta_f), \overline{B}^n_\pm)$ be the generators that correspond to x under the given isomorphisms.
(3) We denote by $[S^{n-1}]^* \in H^n(S^n)$ and $[\overline{B}^n]^* \in H^n(\overline{B}^n, S^{n-1})$ the standard dual generators. For $i = 1, 2$ we denote by $p_i\colon \overline{B}^n \times \overline{B}^n \to \overline{B}^n$ the projection onto the first respectively second coordinate. We write

$$\begin{aligned} y_1 &= p_1^*([\overline{B}^n]^*) \in H^n(\overline{B}^n \times \overline{B}^n, S^{n-1} \times \overline{B}^n) \quad \text{and} \\ y_2 &= p_2^*([\overline{B}^n]^*) \in H^n(\overline{B}^n \times \overline{B}^n, \overline{B}^n \times S^{n-1}). \end{aligned}$$

The following claim contains the key calculation of the proof.

Claim. The map F induces the following maps on relative cohomology:

$$\begin{array}{llcl} \text{(i)} & H^n(\mathrm{C}(\Theta_f), \overline{B}^n_+) & \xrightarrow{F^*} & H^n(\overline{B}^n \times \overline{B}^n, S^{n-1} \times \overline{B}^n) \\ & x_+ & \mapsto & \pm r \cdot y_1 \\ \text{(ii)} & H^n(\mathrm{C}(\Theta_f), \overline{B}^n_-) & \xrightarrow{F^*} & H^n(\overline{B}^n \times \overline{B}^n, \overline{B}^n \times S^{n-1}) \\ & x_- & \mapsto & \pm s \cdot y_2. \end{array}$$

Before we turn to the actual calculation we make the following two preparations:

(a) We point out that the restrictions of F to various subsets gives us the following commutative diagram

$$\begin{tikzcd} \overline{B}^n \times \overline{B}^n \arrow[r, "F"] & \mathrm{C}(\Theta_f) \\ \overline{B}^n \times S^{n-1} \arrow[u, hook] \arrow[r, "\Theta_f"] & \overline{B}^n_- \arrow[u, hook] \\ S^{n-1} \times S^{n-1} \arrow[u, hook] \arrow[r, "f"] & S^{n-1}. \arrow[u, hook] \end{tikzcd}$$

(b) We pick a point $* \in S^{n-1}$.

To provide the actual proof of the claim we consider the following diagram:

$$\begin{tikzcd} H^n(\mathrm{C}(\Theta_f)) \arrow[d, "\cong"] & & & H^n(\mathrm{C}(\Theta_f), \overline{B}^n_+) \arrow[lll, "\cong"'] \arrow[r, "F^*"] \arrow[dl] \arrow[d] & H^n(\overline{B}^n \times \overline{B}^n, S^{n-1} \times \overline{B}^n) \arrow[d, "\cong"] \\ H^n(S^n) & H^n(S^n, \overline{B}^n_+) \arrow[l, "\cong"'] \arrow[r, "\cong", "\text{exc.}"'] & & H^n(\overline{B}^n_-, S^{n-1}) \arrow[r, "\Theta_f^*"] & H^n(\overline{B}^n \times *, S^{n-1} \times *) \\ & & & H^{n-1}(S^{n-1}) \arrow[u, "\delta", "\cong"'] \arrow[r, "f^*", "{[S^{n-1}]^* \mapsto r \cdot [S^{n-1} \times *]^*}"'] & H^{n-1}(S^{n-1} \times *). \arrow[u, "\delta", "\cong"'] \end{tikzcd}$$

We make the following clarifications and observations:

(1) The maps that are not specified are induced by the obvious inclusions of (pairs) of topological spaces.
(2) The inclusion induced maps that are decorated by "$\cong$" are isomorphisms for the following reasons:
  (a) by the long exact sequence in cohomology for the corresponding pair,
  (b) the maps are induced by a homotopy equivalence,
  (c) by the long exact sequence provided by Lemma 63.4,
  (d) by an appropriate version of the Excision Theorem, see the remark on page 1192.
(3) The quadrilateral to the left commutes since all maps are induced by inclusions.
(4) It follows from (2) and (3) that the diagonal map is an isomorphism.
(5) The triangle towards the center commutes since all maps are induced by inclusions.
(6) It follows from (2), (4) and (5) that the middle vertical map is an isomorphism.
(7) The squares to the right commute by the commutative diagram shown in (a) and by the naturality of the connecting homomorphisms.

(8) The connecting homomorphisms δ are easily seen to be isomorphisms since the other groups in the corresponding long exact sequence are zero.
(9) Basically by the definition of the bidegree of the map f the bottom horizontal map is given by $[S^{n-1}]^* \mapsto r \cdot [S^{n-1} \times *]^*$.

The above arguments show that the vertical maps of the blue part of the diagram are isomorphisms. Since the bottom map is given by multiplication by r we see that the top map, with whatever choice of generators is also given by multiplication by $\pm r$. This concludes the proof of part (i) of the claim. The proof of part (ii) is evidently basically the same. This concludes the proof of the claim.

Finally we consider the following diagram

$$\begin{tikzcd}
H^n(\mathrm{C}(\Theta_f)) \times H^n(\mathrm{C}(\Theta_f)) \arrow[d, "\cup"', "(x,x)\mapsto x^2=\mathrm{Hopf}(\Theta_f))\cdot z"] & H^n(\mathrm{C}(\Theta_f), \overline{B}^n_-) \times H^n(\mathrm{C}(\Theta_f), \overline{B}^n_+) \arrow[l, "\substack{x\leftarrow\!\shortmid x_- \\ x\leftarrow\!\shortmid x_+}", "\cong"'] \arrow[r, "\substack{x_-\mapsto \pm r\cdot y_1 \\ x_+\mapsto \pm s\cdot y_2}", "F^*"'] \arrow[d, "\cup"] & H^n(\overline{B}^n \times \overline{B}^n, S^{n-1}\times \overline{B}^n) \times H^n(\overline{B}^n \times \overline{B}^n, \overline{B}^n \times S^{n-1}) \arrow[d, "\cup"', "(y_1,y_2)\mapsto y_1\cup y_2=[\overline{B}^n\times\overline{B}^n]^*"] \\
H^{2n}(\mathrm{C}(\Theta_f)) & H^{2n}(\mathrm{C}(\Theta_f), S^n) \arrow[l, "\cong"] \arrow[r, "F^*", "\cong"'] & H^{2n}(\overline{B}^n \times \overline{B}^n, \overline{B}^n \times S^{n-1} \cup S^{n-1} \times \overline{B}^n). \arrow[ll, bend left, "\pm z\leftarrow\!\shortmid [\overline{B}^n\times\overline{B}^n]^*"]
\end{tikzcd}$$

We make the following comments:

(1) It follows almost immediately from Proposition 50.12 (5) that $(\mathrm{C}(\Theta_f), \overline{B}^n_-, \overline{B}^n_+)$ and $(\overline{B}^n \times \overline{B}^n, S^{n-1} \times \overline{B}^n, \overline{B}^n \times S^{n-1})$ are excisive triads. Thus we see that the relative cup product in the center and to the right are actually defined.
(2) It follows from the naturality of the cup product, see Proposition 58.3, that the two squares commute.
(3) By Proposition 60.2 (1) we have $y_1 \cup y_2 = p_1^*([\overline{B}^n]) \cup p_2^*([\overline{B}^n]) = [\overline{B}^n \times \overline{B}^n]^*$.
(4) By the above claim we know that the top right horizontal map is in fact given by $x_- \mapsto \pm r \cdot y_1$ and $x_+ \mapsto \pm s \mapsto s \cdot y_2$.
(5) Since the bottom horizontal maps are isomorphisms we see that going right to left the generator $[\overline{B}^n \times \overline{B}^n]^*$ gets sent to $\pm z$.

It follows immediately from the above comments that $\mathrm{Hopf}(\Theta_f) = \pm r \cdot s$. □

Since the Hopf invariant gives us a homomorphism $\pi_{2n-1}(S^n) \to \mathbb{Z}$ we are now interested in finding interesting maps $S^{n-1} \times S^{n-1} \to S^{n-1}$. Perhaps somewhat surprisingly it is not that hard to find interesting maps.

Proposition 63.13. *If n is even, then there exists a map $S^{n-1} \times S^{n-1} \to S^{n-1}$ of bidegree (p, q) such that $p \cdot q$ is even.*

Proof. We consider the map

$$\begin{aligned} f\colon S^{n-1} \times S^{n-1} &\to S^{n-1} \\ (x, y) &\mapsto y - \langle x, y\rangle \cdot x = \text{reflection of } y \text{ in the hyperplane } x^\perp. \end{aligned}$$

We refer to Figure 767 for an illustration of the map f. $\square$

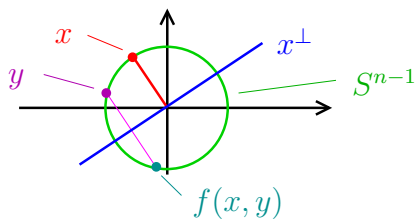

FIGURE 767. Illustration for the proof of Proposition 63.13.

The combination of Propositions 63.7 and 63.13 gives us the following interesting corollary.

Corollary 63.14. *Given any even $n \in \mathbb{N}$ there exists an epimorphism $\pi_{2n-1}(S^n) \to \mathbb{Z}$.*

As always in mathematics, every result opens up lots of new questions. Here are a few:

Question 63.15.

(1) *We have now seen that there exists an epimorphism $\pi_3(S^2) \to \mathbb{Z}$. Is this map an isomorphism?*
(2) *We have now seen that there exists an epimorphism $\pi_7(S^4) \to \mathbb{Z}$. Is this map an isomorphism?*

The previous question points to a problem: we have now developed some tools for showing that certain homotopy groups of spheres are non-trivial, but we have no tools yet for computing any interesting homotopy groups.

Here is another question.

Question 63.16. *Given any $n \in \mathbb{N}$ we know by Lemma 38.10 and Corollary 63.14 that $\pi_n(S^n)$ and $\pi_{4n-1}(S^{2n})$ admit an epimorphism onto $\mathbb{Z}$. Are there are any other homotopy groups of spheres that admit an epimorphism onto $\mathbb{Z}$?*

In light of Lemma 63.11 the following question becomes interesting:

Question 63.17. *For which $n \in \mathbb{N}_{\geq 2}$ does there exist a map $f\colon S^{2n-1} \to S^n$ such that $\mathrm{Hopf}(f) = 1$?*[1080]

[1080]Note that Propositions 63.7 and 63.13 tell us that this question is equivalent to the question, for which $n \in \mathbb{N}$ does there exist a map $f\colon S^{2n-1} \to S^n$ such that $\mathrm{Hopf}(f)$ is odd?

Initially one might not appreciate Question 63.17. But rather mysteriously it is not that hard to come up with maps of Hopf degree 2, but it is strikingly difficult to come up with maps of Hopf degree 1. To underline our point we conclude this chapter with another construction of a map of Hopf degree 2.

Example. Let $n \in \mathbb{N}$. We start out with the following two reminders:

(1) We can view S^n as a CW-complex with one 0-cell and one n-cell. In particular, if we denote by S^n_a and S^n_b two copies of S^n then we view S^n_a as a CW-complex with one 0-cell P and one n-cell that we denote by S^n_a. Similarly we view S^n_b as a CW-complex with one 0-cell Q and one n-cell S^n_b.

(2) Given two finite CW-complexes X and Y we introduced on page 669 the product CW-structure on $X \times Y$. Recall that the n-cells of $X \times Y$ correspond precisely to products $e_x \times f_y$ where e_x is a p-cell of X and f_y is an $(n-p)$-cell of Y.

It follows from (1) and (2) that we can view $S^n_a \times S^n_b$ as a CW-complex with one 0-cell (P, Q), two n-cells $S^n_a \times \{Q\}$ and $\{P\} \times S^n_b$ and one $2n$-cell $S^n_a \times S^n_b$. We consider the maps

$$S^{2n-1} \xrightarrow{\varphi} \overbrace{S^n_a \times \{Q\} \cup \{P\} \times S^n_b}^{=S^n_a \vee S^n_b} \xrightarrow{p} S^n.$$

φ: attaching map of the $2n$-cell to the $(2n-1)$-skeleton of $S^n_a \times S^n_b$ which is precisely $S^n_a \times \{Q\} \cup \{P\} \times S^n_b$

p: the obvious projection on $S^n_a \times \{Q\}$ and $\{P\} \times S^n_b$

The composition of the maps φ and p defines a map $f\colon S^{2n-1} \to S^n$. It is clear from

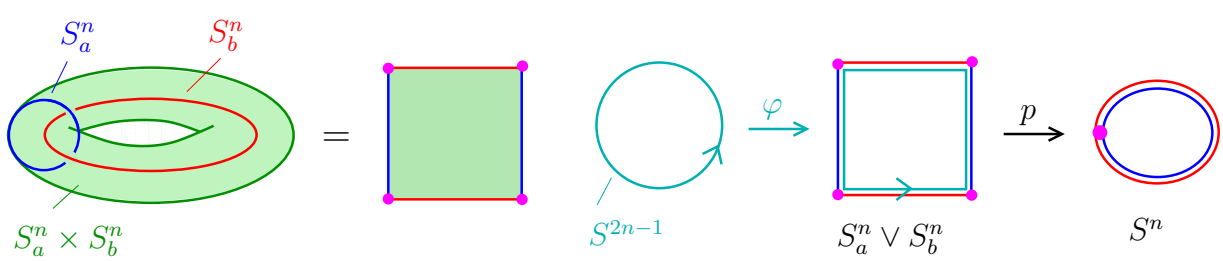

FIGURE 768.

Figure 768 that this map is not very interesting for $n = 1$. But using fairly elementary arguments one can show that for all even n we have $\mathrm{Hopf}(f) = \pm 2$. We refer to [Hat, p. 428] or [Vic, p. 138] for details. Alternatively we leave it as a brain teaser for the reader to perform this calculation.

Exercises for Chapter 63.

Exercise 63.1. What is the homeomorphism type of the mapping cone of the map $S^1 \to S^1$ given by $z \mapsto z^2$?
Hint: It is a topological space that we are quite familiar with.

Exercise 63.2. Let $f\colon S^p \times S^q \to S^r$ be a map. (As always, f is understood to be continuous.) Show that the map

$$\begin{array}{rcl} S^p \times \mathrm{Cone}(S^q) & \to & \mathrm{Cone}(S^r) \\ (P, [(Q,t)]) & \mapsto & [(f(P,Q),t)] \end{array}$$

is continuous.
Hint: Use Theorem 2.15 and Lemma 2.16 (2).

Exercise 63.3. Let $f\colon S^k \times S^k \to S^k$ be the projection onto the first factor. Show that the corresponding map $\Theta_f\colon S^{2k+1} \to S^{k+1}$, that is defined on page 1481, is homotopic to a constant map.
Hint: The exercise is very easy.

64. Differential topology II: Regular and Tubular Neighborhoods

Before we continue our long discussion of the impact of the Poincaré Duality Theorem 61.1 for manifolds it is useful to arm ourselves with several results regarding manifolds which will come in handy on many occasions. This arming process will happen in this and the subsequent chapter.

In this chapter we will introduce the notion of a regular neighborhood of a subset of a manifold and we will show that submanifolds admit tubular neighborhoods and we will show that tubular neighborhoods are regular. The results of this chapter can be viewed as a generalization of the Tubular Neighborhood Theorem 10.19. For the most part it might be OK to just skip this chapter and work with a naive understanding of regular and tubular neighborhoods. Nonetheless, the reader should be aware that these notions can be defined properly, that the definitions are not entirely self-evident, and that existence of such neighborhoods is non-trivial.

64.1. **Regular neighborhoods.** We start out with the following definition.

Definition. Let M be an n-dimensional topological manifold. We say a subset $W \subset M$ is a *k-dimensional submanifold with corner*[1081] if given any $P \in W$ there exists a chart of the type (α), (β) and (γ) from page 179 or if

(δ) there exists a chart $\Phi\colon U \to V$ of type (ii)[1082] for M such that

$$\Phi(U \cap W) \ \subset \ \{(0,\dots,0,x_1,\dots,x_k) \,|\, x_1,\dots,x_k \in \mathbb{R} \text{ with } x_{k-1} \geq 0 \text{ and } x_k \geq 0\}$$

and with $\Phi(P) \in \{(0,\dots,0,x_1,\dots,x_{k-2},0,0) \,|\, x_1,\dots,x_{k-2} \in \mathbb{R}\}$.

If M is an n-dimensional manifold, then we demand that the charts come from the maximal smooth atlas. We refer to the set of points in W that admit a chart of type (δ) as the *corner set of* W and we denote it by $\partial_c W$.

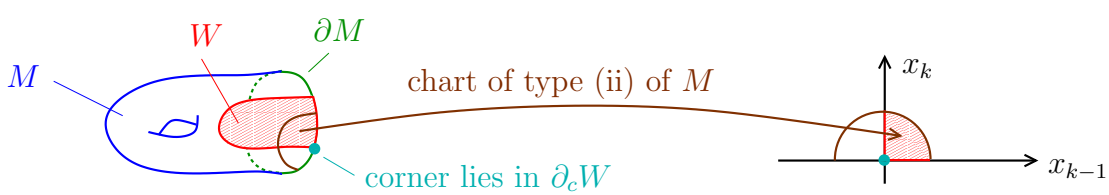

Figure 769.

The following lemma also introduces a notation that we will use throughout these notes.

[1081] Often in the literature such objects are called "submanifold with corners". Following [Wall, p. 30] we write "submanifold with corner" instead.

[1082] See page 171 for the definition of a chart of type (ii).

Lemma 64.1. *Let M be an n-dimensional (topological) manifold and let W be a compact n-dimensional submanifold with corner. We write*

$$\partial_0 W \ := \ W \cap \overline{M \setminus W} \quad \text{and } \partial_1 W \ := \ W \cap \partial M.$$

Then the following two statements hold:

(1) *The subset W itself is a (topological) manifold.*
(2) *The boundary of the (topological) manifold W equals $\partial_0 W \cup \partial_1 W$. Furthermore $\partial_0 W$ and $\partial_1 W$ are $(n-1)$-dimensional submanifolds of ∂W with $\partial_0 W \cap \partial_1 W = \partial_c W$.*
(3) *The set $\mathring{W} := W \setminus \partial_0 W$ is the interior of W in M, in particular $\mathring{W}$ is an open subset of M.*
(4) *The subset $M \setminus \mathring{W}$ is an n-dimensional submanifold of M with corner given by $\partial_c(M \setminus \mathring{W}) = \partial_c W$. Furthermore $\partial_0(M \setminus \mathring{W}) = \partial_0 W$.*

Remark.

(1) Note that if W is a compact submanifold "without corners", then the definition of $\partial_0 W$ and $\partial_1 W$ given in Lemma 64.1 coincides with the definition given on page 805. In particular Lemma 64.1 can be seen as a variation on Proposition 32.2.
(2) Given a manifold X the Excision Theorem for Manifolds 32.7 was initially formulated for a codimension zero submanifold B of X. We leave it as an exercise to verify that the conclusion of the theorem also holds if B is a codimension zero submanifold *with corner*.

Sketch of proof. In the proof that W itself is a (topological) submanifold we only have to worry about the corners. But for these we can use the approach taken in Proposition 56.9 to find a (smooth) atlas. The remaining statements follow fairly easily from Proposition 32.1 and the definitions. We leave it as an exercise to fill in the details. □

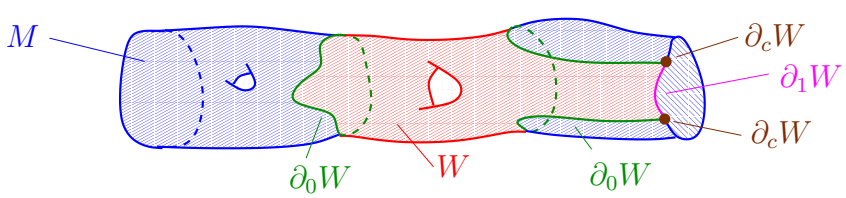

FIGURE 770. Illustration of Lemma 64.1.

We continue with a somewhat technical definition.

Definition. Let M be an m-dimensional topological manifold and let K be a compact subset. A *regular neighborhood* of K is an m-dimensional compact submanifold with corner N of M with the following properties:

(1) K is contained in the interior $\mathring{N}$ of N,
(2) K is a deformation retract of N,

(3) $\partial_0 N$ is a deformation retract of $N \setminus K$.

We refer to $\mathring{N}$ as an *open regular neighborhood of* K.

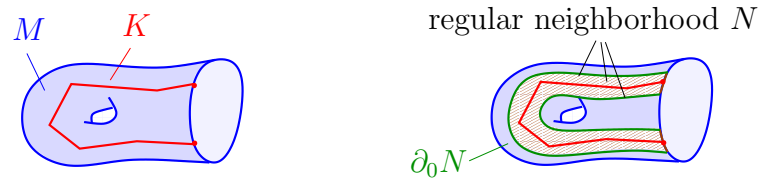

FIGURE 771.

Remark. The notion of a "regular neighborhood" is often used in the literature. For example Rourke–Sanderson [RS, p. 33] define a notion of "regular neighborhood" of a "compact polyhedron in a PL-manifold M" and in [RS, Theorem 3.24] they prove a uniqueness statement. Unfortunately from their definition it is not clear that what they call a regular neighborhood is indeed a regular neighborhood in the above sense. We also refer to [Hem, p. 7f] for a discussion of "regular neighborhoods".

Note that in the definition of a regular neighborhood we did not demand that K is a submanifold, in particular K could be any subset. In fact we have the following proposition.

Proposition 64.2. *Every finite spatial graph G in $\mathbb{R}^n$, in the sense of the definition on page 134, admits a regular neighborhood.*

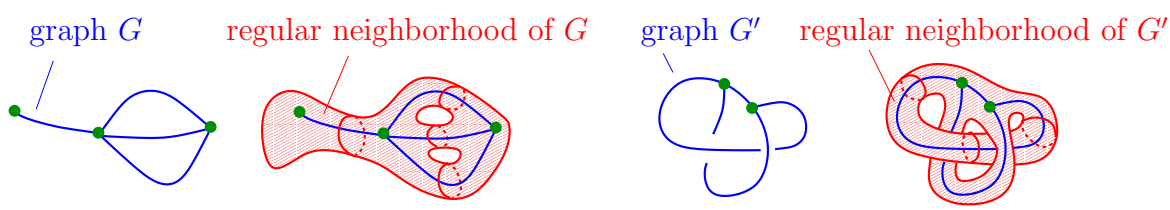

FIGURE 772. Regular neighborhoods for spatial graphs in $\mathbb{R}^3$.

Proof. This proposition is proved in [FH, FH2]. □

We continue this section with the following lemma which can be viewed as a generalization of Lemma 40.7 (3).

Lemma 64.3. *Let K be a compact subset of a topological manifold M. If N is a regular neighborhood of K, then the following statements hold:*

(1) *$M \setminus \mathring{N}$ is a deformation retract of $M \setminus K$,*
(2) *the inclusion $M \setminus \mathring{N} \to M \setminus K$ is a homotopy equivalence, in particular it induces an isomorphism of homotopy groups (for suitable base points) and homology groups,*

(3) *$M \setminus \mathring{N}$ is path-connected if and only if $M \setminus K$ is path-connected,*
(4) *the inclusion map $M \setminus \mathring{N} \to M \setminus K$ induces isomorphisms of fundamental groups and (co-) homology groups.*

Proof.

(1) By definition of a regular neighborhood there exists a deformation retraction r from $N \setminus K$ to $\partial_0 N$. We extend this deformation retraction to all of $M \setminus K$ in the obvious way. More precisely, we consider the map

$$\begin{array}{rcl} f\colon (M \setminus K) \times [0,1] & \to & M \setminus K \\ (P,t) & \mapsto & \begin{cases} P, & \text{if } P \notin N, \\ r(P,t), & \text{if } P \in N \setminus K. \end{cases} \end{array}$$

Using Lemma 1.32 (2) and Proposition 10.2 one can easily show that this map is indeed continuous. Once continuity is verified it is straightforward to show that f is indeed a deformation retraction from $M \setminus K$ to $M \setminus \mathring{N}$.

(2) It follows from (1) and Lemma 9.10 that the inclusion is a homotopy equivalence. The statement regarding homotopy groups and homology groups follow from Proposition 28.7 and Corollary 30.8.

(3) This statement follows from (2) and Lemma 9.9.

(4) This last statement follows from (2) together with Proposition 9.12 (1), Corollary 30.8 and Lemma 48.13 (3). □

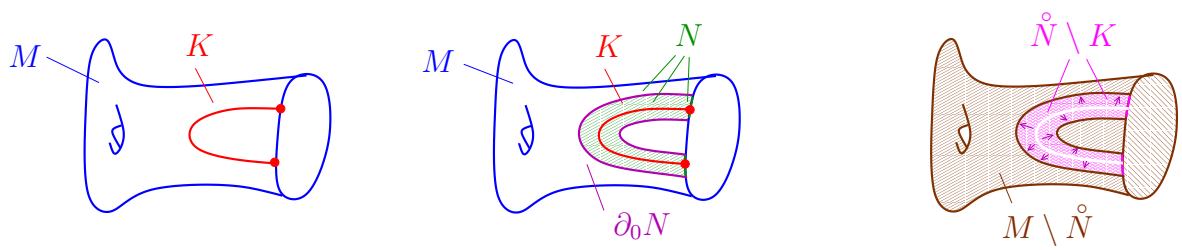

FIGURE 773. Illustration of Lemma 64.3.

The following corollary, which in the literature is often used implicitly or explicitly, gives one application of the theory of regular neighborhoods. In the next chapter we will see more applications.

Lemma 64.4. *Let M be a compact topological manifold and let $K \subset M$ be a compact subset. If K admits a regular neighborhood, then the following two statements hold:*

(1) *the fundamental group $\pi_1(M \setminus K)$ is finitely presented, and*
(2) *for each $k \in \mathbb{N}_0$ the homology group $H_k(M \setminus K; \mathbb{Z})$ is finitely generated.*

Proof. By Lemma 64.3 the topological space $M \setminus K$ is homotopy equivalent to $M \setminus \mathring{N}$. Since M is compact it follows from Lemma 64.1 (3) that $M \setminus \mathring{N}$ is also compact. Furthermore,

by Lemma 64.1 (4) we know that $M \setminus \mathring{N}$ is an n-dimensional manifold. Summarizing we have seen that $M \setminus \mathring{N}$ is a compact n-dimensional manifold. The lemma now follows from Proposition 45.2 and Lemma 64.3 (4). $\square$

In the Tubular Neighborhood Theorem 10.19 we showed that if M is an orientable manifold, then every closed 1-dimensional submanifold admits a trivial tubular neighborhood, which is easily seen to be a regular neighborhood. It is thus natural to guess that something similar should also hold for higher-dimensional submanifolds. In fact we have the following theorem.

Theorem 64.5. (Regular Neighborhood Theorem) *Let M be a manifold. Every compact proper submanifold of M admits a regular neighborhood.*

An outline of the proof will be sketched in the next section.

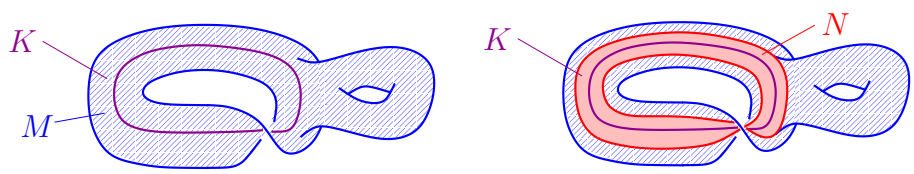

FIGURE 774. Illustration of the Regular Neighborhood Theorem 64.5.

64.2. **The Tubular Neighborhood Theorem II.** In Section 10.6 we introduced the notion of a "trivial tubular neighborhood" of a submanifold and we saw in Theorem 10.19 that some types of submanifolds admit trivial tubular neighborhoods.

In this section we will first introduce the general notion of a tubular neighborhood of a submanifold. We will then discuss existence and uniqueness, before we then show that tubular neighborhoods give rise to regular neighborhoods.

Definition. Let $m \in \mathbb{N}_0$.

(1) Let K be a manifold. A *smooth $\overline{B}^m$-bundle over K* is a manifold N together with a smooth map $p\colon N \to K$ with the following property: given any $x \in K$ there exists a *trivialization of p around x*, i.e. there exists an open neighborhood U of x and a diffeomorphism $\Phi\colon p^{-1}(U) \to \overline{B}^m \times U$ such that the following diagram commutes:

$$\begin{tikzcd} p^{-1}(U) \arrow[rr, "\Phi", "\cong"'] \arrow[dr, "p"'] & & \overline{B}^m \times U \arrow[dl, "(x,v)\mapsto x"] \\ & U. & \end{tikzcd}$$

A smooth $\overline{B}^1$-bundle is often called a *smooth interval bundle* and a smooth $\overline{B}^2$-bundle is often called a *smooth disk bundle*.

(2) An *isomorphism* between two smooth $\overline{B}^m$-bundles $p\colon M \to K$ and $q\colon N \to K$ is defined to be a diffeomorphism $\Phi\colon M \to N$ such that the following diagram commutes

$$\begin{tikzcd} M \arrow[rr, "\Phi"] \arrow[dr, "p"'] & & N \arrow[dl, "q"] \\ & K. & \end{tikzcd}$$

If such an isomorphism exists we say that the two smooth $\overline{B}^m$-bundles are *isomorphic*.

The following gives two trivial but nonetheless extremely important examples of constructions of smooth $\overline{B}^m$-bundles.

Example.

(1) Let K be a manifold and let $m \in \mathbb{N}_0$. We denote by $p\colon \overline{B}^m \times K \to K$ the obvious projection map. This map is evidently a smooth $\overline{B}^m$-bundle over K and we refer to it as the *trivial smooth $\overline{B}^m$-bundle over K*.

(2) Let $p\colon N \to K$ be a smooth $\overline{B}^m$-bundle. If $Y \subset K$ is a submanifold, then the restriction $p\colon p^{-1}(Y) \to Y$ is also a smooth $\overline{B}^m$-bundle.

Definition.

(1) Let W be a manifold and let $p\colon \overline{B}^m \times W \to W$ and $q\colon \overline{B}^m \times W \to W$ be two smooth $\overline{B}^m$-bundles. We say an isomorphism $\Phi\colon \overline{B}^m \times W \to \overline{B}^m \times W$ of smooth $\overline{B}$-bundles is *linear* if there exists a map $g\colon W \to \mathrm{O}(m)$ such that for any $(v, w) \in \overline{B}^m \times W$ we have

$$\Phi(v, w) \;=\; (g(w) \cdot v, w).$$

(2) A *linear $\overline{B}^m$-bundle* is a smooth $\overline{B}^m$-bundle $p\colon N \to K$ together with a family of trivializations $\{(U_i, \Phi_i\colon p^{-1}(U_i) \to \overline{B}^m \times U_i)\}_{i\in I}$ such that for any $i, j \in I$ the isomorphism $\Phi_j \circ \Phi_i^{-1}\colon \overline{B}^m \times (U_i \cap U_j) \to \overline{B}^m \times (U_i \cap U_j)$ of smooth $\overline{B}^m$-bundles over $U_i \cap U_j$ is linear. Henceforth, by a trivialization of a linear $\overline{B}^m$-bundle we always mean a trivialization from the above family.

(3) An *isomorphism of two linear $\overline{B}^m$-bundles* $p\colon M \to K$ and $q\colon N \to K$ is defined as an isomorphism $\Theta\colon M \to N$ of smooth $\overline{B}^m$-bundles such that for any trivializations $(U, \Phi\colon p^{-1}(U) \to \overline{B}^m \times U)$ of p and $(V, \Psi\colon q^{-1}(V) \to \overline{B}^m \times V)$ of q the isomorphism $\Phi \circ \Theta \circ \Psi^{-1}\colon \overline{B}^m \times (U \cap V) \to \overline{B}^m \times (U \cap V)$ of smooth $\overline{B}^m$-bundles over $U \cap V$ is linear.

The trivializations of a linear $\overline{B}^m$-bundle play a role similar to the smooth atlas of a manifold. In the case of a manifold we usually suppress the specific atlas from the notation. This leads us to the following convention.

Convention. In the following we will usually suppress the family of trivializations in the notation of a linear $\overline{B}^m$-bundle.

Examples.

(1) Any trivial $\overline{B}^m$-bundle is a linear $\overline{B}^m$-bundle in the obvious way.

(2) We consider the Möbius band $M = ([0,1] \times [-1,1])/(0,x) \sim (1,-x)$ together with the projection map

$$\begin{array}{rcl} p\colon M = ([0,1] \times [-1,1])/\sim & \to & [0,1]/0 \sim 1 \\ [(x,y)] & \mapsto & [x]. \end{array}$$

In Exercise 65.7 we will verify that this map defines a linear interval bundle. We refer to Figure 775 for an illustration.

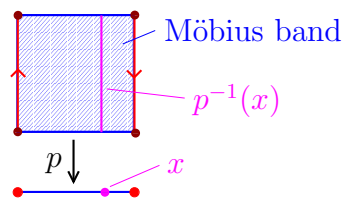

FIGURE 775.

For future reference we formulate the following lemma that classifies isomorphisms of some linear $\overline{B}^m$-bundles.

Lemma 64.6.

(1) *Let N be an oriented n-dimensional manifold and let $k \in \mathbb{N}$. The map*

$$\begin{array}{rcl} \{\textit{maps } N \to \mathrm{SO}(k)\}/\textit{homotopy} & \to & \left\{ \begin{array}{c} \textit{orientation-preserving} \\ \textit{isomorphisms of } \overline{B}^k \times N \end{array} \right\} \Big/ \textit{isotopy} \\ [f\colon N \to \mathrm{SO}(k)] & \to & \left(\begin{array}{rcl} \overline{B}^k \times N & \to & \overline{B}^k \times N \\ (v,P) & \mapsto & (\underbrace{f(P)}_{\in \mathrm{SO}(k)} \cdot v, P) \end{array} \right) \end{array}$$

is a bijection.

(2) *Let N be an oriented n-dimensional manifold. The identity is the only orientation-preserving linear $\overline{B}^1$-isomorphism of the trivial bundle $\overline{B}^1 \times N$.*

(3) *Up to isotopy every isomorphism of the linear bundle $\overline{B}^2 \times S^1$ is of the form*

$$\begin{array}{rcl} \overline{B}^2 \times S^1 & \to & \overline{B}^2 \times S^1 \\ (w,z) & \mapsto & (w \cdot z^k, w) \end{array}$$

for some $k \in \mathbb{Z}$.

Sketch of proof.

(1) This statement follows fairly easily from the definitions. We leave the details to the reader.

(2) This follows from (1) and the trivial observation that $\mathrm{SO}(1) = \{1\}$, thus there exists precisely one map from N to $\mathrm{SO}(1)$.
(3) This statement follows from (1) and the observation that any map $S^1 \to \mathrm{SO}(2) = S^1$ is homotopic to a map of the form $z \mapsto z^k$ for some $k \in \mathbb{Z}$. This in turn is a fairly straightforward consequence of the fact that $\pi_1(S^1, 1) \cong \mathbb{Z}$, see Proposition 7.18.[1083]

□

Now we can formulate the definition that we had been aiming for.

Definition. Let M be an n-dimensional manifold and let K be a compact proper k-dimensional submanifold. A *tubular neighborhood* for K is a pair $(N, p\colon N \to K)$ with the following properties:

(1) N is a compact codimension zero submanifold with corner.
(2) N is a neighborhood of K.
(3) The map $p\colon N \to K$ is a linear $\overline{B}^{n-k}$-bundle such that $p(x) = x$ for all $x \in K$.
(4) We have $\partial_1 N = p^{-1}(\partial K)$.[1084]

Remark. There are many books that introduce the notion of a tubular neighborhood, see e.g. [Kos, BJ, Bre, Lan4] and [Wall2]. The definitions and results tend to be subtly different and it requires some effort to go back and forth between these books. Our treatment is, by accident, very similar to the one given in [Wall2, Chapter 2.5].

Example.

(1) If K is a closed 1-dimensional manifold of an orientable n-dimensional manifold, then one can verify easily that the above concept of a tubular neighborhood is equivalent to the notion that we introduced in the Tubular Neighborhood Theorem 10.19.
(2) As above we consider the Möbius band $M = [0,1] \times [-1,1]/\sim$. Furthermore let $K = [0,1] \times \{0\} \subset M$ be the submanifold that is given by the central circle.[1085] In Figure 776 we illustrate a tubular neighborhood for K.

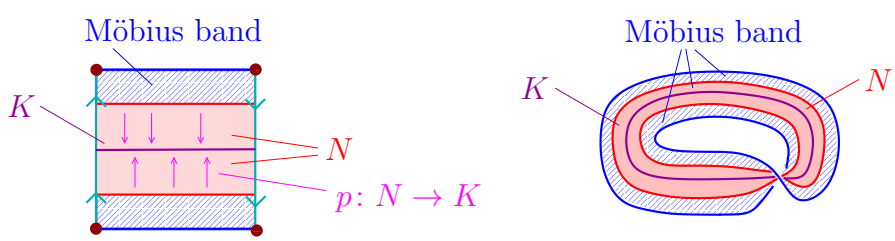

FIGURE 776.

[1083]So why don't we have to worry about base points?
[1084]Note that in Proposition 32.1 we showed that for the proper submanifold K we have $\partial K = \partial M \cap K$.
[1085]Could we not just take all of M to be a tubular neighborhood?

The following theorem is a generalization of the earlier Tubular Neighborhood Theorem 10.19.

Theorem 64.7. (General Tubular Neighborhood Theorem) *Let M be a manifold and let K be a proper submanifold. If K is compact, then K admits a tubular neighborhood.*

Proof. The sketch for the existence of a tubular neighborhood that we provided for the previous Tubular Neighborhood Theorem 10.19 is also valid in this more general context. As before a full proof is provided in [Wall2, Theorem 2.3.3]. Closely related and similar results are also proved in [Kos, Section III.2], [Bre, Theorem II.11.14], [Le2, Theorem 6.24], [BJ, Theorem 12.11] and [Lan4, Chapter IV]. □

In Theorem 10.19 we already saw that certain types of submanifolds admit a trivial tubular neighborhood. To this list we add one more example.

Proposition 64.8. $(*)$ *Let M be an orientable manifold and let K be a proper 2-dimensional submanifold. If each component of K has non-empty boundary, then K admits a trivial tubular neighborhood.*

Proof. By the General Tubular Neighborhood Theorem 64.7 it remains to show that a tubular neighborhood is already trivial. Note that with our hypothesis the topological space K admits a retraction onto a 1-dimensional CW-complex.[1086] Now it follows fairly easily from Propositions 9.1.1 and Proposition 9.2.3 of [Hau] that the tubular neighborhood is indeed trivial. □

The following proposition gives an appropriate uniqueness of tubular neighborhoods. The proposition can be viewed as a generalization of Proposition 10.20.

Proposition 64.9. (Uniqueness of tubular neighborhoods) *Let M be an n-dimensional manifold and let K be a compact proper k-dimensional submanifold. Furthermore let $p\colon U \to K$ and $q\colon V \to K$ be two tubular neighborhoods of K. Then there exists a diffeotopy $F\colon M \times [0,1] \to M$ with the following properties:*

1. *$F(P,0) = P$ for all $P \in M$,*
2. *$F(P,t) = P$ for all $P \in K$ and $t \in [0,1]$,*
3. *the diffeomorphism $\Phi = F_1\colon M \to M$ restricts to diffeomorphisms $\Phi\colon M \setminus \mathring{U} \to M \setminus \mathring{V}$ and $\Phi\colon U \to V$, and the latter map is an isomorphism of linear $\overline{B}^{n-k}$-bundles,*
4. *the diffeotopy F has compact support.*

Proof. As in the case of Proposition 10.20 a proof is provided in [Wall2, Chapter 2.5]. □

Convention. By the uniqueness of tubular neighborhoods that we had just proved in Proposition 64.9 we usually do not have to worry about the precise choice of a tubular neighborhood. Given a compact proper submanifold of a manifold M we usually denote by $N(K)$ some choice of a tubular neighborhood.

[1086] To be super-precise, this follows from the classification of 2-dimensional manifolds with boundary, see Theorem 14.15 and Lemma 14.20.

Remark. The General Tubular Neighborhood Theorem 64.7 is stated for manifolds instead of the more general context of topological manifolds. With slight modifications the definition of a tubular neighborhood also makes sense for a k-dimensional proper submanifold K of an n-dimensional topological manifold M.

(1) By [FHNOP, Theorem 4.6] tubular neighborhoods exist for any compact proper submanifold of a 4-dimensional topological manifold. If the submanifold is one-dimensional and the topological manifold is orientable, then there exists a trivial tubular neighborhood. Furthermore, by [FHNOP, Theorem 4.7] such a tubular neighborhood is unique in an appropriate sense.
(2) If $k = n - 2$, i.e. if K is a codimension 2 submanifold, then some type of tubular neighborhood seems to exist, see e.g. [DV, Theorem 6.8.1] and [FQ, p. 137] for details. We also refer to [Ped] and [Joha] for some positive results. Note though that when it comes to topological manifolds one should be very cautious with references. It is advisable to very carefully check the definitions used in papers on topological manifolds.
(3) If $k = n - 3$, i.e. if K is a codimension 3 submanifold, then, according to [DV, p. 347] and [Edw3, p. 9], a tubular neighborhood does not exist in general.

Fortunately for the most part we will not deal with topological manifolds and the General Tubular Neighborhood Theorem 64.7 will be good enough for our purposes.

Definition.

(1) A linear $\overline{B}^m$-bundle $p\colon N \to K$ is called *trivial* if it is isomorphic, as a linear $\overline{B}^m$-bundle, to the trivial $\overline{B}^m$-bundle $\overline{B}^m \times K \to K$.
(2) Let M be an m-dimensional manifold and let K be a k-dimensional submanifold. A tubular neighborhood $(N, p\colon N \to K)$ of K is called *trivial* if the linear $\overline{B}^m$-bundle $p\colon N \to K$ is trivial.

Example. As on page 1495 we consider again the Möbius band $M = [0,1] \times [-1,1]/\sim$ and the submanifold $K = [0,1] \times \{0\} \subset M$. At least from the picture it is pretty clear that K does not admit a trivial tubular neighborhood.[1087]

The following lemma gives some other instances where the tubular neighborhood is non-trivial.[1088]

Lemma 64.10. *Let M be an orientable manifold and let K be a proper submanifold. If K is non-orientable, then the tubular neighborhood is non-trivial.*

Sketch of proof. We prove the converse, if the K admits a trivial tubular neighborhood, then K is orientable. So suppose that K is a proper k-dimensional submanifold of an orientable m-dimensional manifold M and suppose that K admits a trivial neighborhood

[1087] What would be a rigorous proof for the statement that K does not admit a trivial tubular neighborhood?

[1088] To be more precise, we still need examples of say closed non-orientable manifolds that are embedded in orientable manifolds. We will shortly see that we can embed any real projective space $\mathbb{R}\mathrm{P}^n$ into $\mathbb{R}^{2n}$.

$\overline{B}^{m-k} \times K$. Let $P \in K \subset M$. We identify $T_P K$ and $T_0 \overline{B}^{m-k}$ with its images in $T_{(0,P)}M$ under the obvious inclusion maps $K \to \{0\} \times K \to M$ and $\overline{B}^{m-k} \to \overline{B}^{m-k} \times \{P\} \to P$. We define

$$\mathcal{B} \subset T_P K \text{ is a positive basis} \quad :\Longleftrightarrow \quad \begin{array}{l} \text{a positive basis of } \overbrace{T_0 \overline{B}^{m-k}}^{=\mathbb{R}^{m-k}} \text{ followed by } \mathcal{B} \\ \text{is a positive basis of } T_{(0,P)}M. \end{array}$$

One easily verifies that this defines an orientation for K. □

If we get away from the pesky non-orientable (sub-) manifolds we get some more positive results.

Proposition 64.11. *Let M be an oriented*[1089] *m-dimensional manifold and let K be a compact oriented proper submanifold.*

(1) *If K is of dimension one and $m \geq 2$, then there exists a trivial tubular neighborhood $N(K) = \overline{B}^{m-1} \times K$ such that the product orientation of $\overline{B}^{m-1} \times K$ matches the orientation of $N(K) \subset M$.*
(2) *If K is of codimension one, then there exists a trivial tubular neighborhood of the form $N(K) = [-1,1] \times K$ such that the product orientation of $[-1,1] \times K$ matches the orientation of M.*[1090]

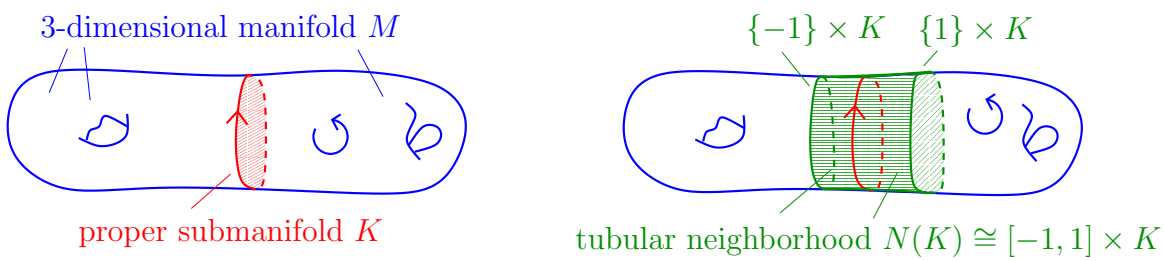

FIGURE 777. Illustration of Proposition 64.11.

Proof. In both cases it follows from the General Tubular Neighborhood Theorem 64.7 together with [Hau, Proposition 9.2.3] and [MiS, Axiom 3] that K admits a trivial neighborhood.[1091] The statement regarding the orientations can be achieved by possibly using an orientation reversing diffeomorphism of $\overline{B}^{m-1}$ or $[-1,1]$. □

[1089] Is the hypothesis that K is orientable, necessary? Put differently, is there an example of an orientable manifold and a compact proper codimension one submanifold such that the tubular neighborhood is non-trivial?

[1090] The reason why we prefer $[-1,1] \times K$ over $K \times [-1,1]$ will become apparent later.

[1091] We had mentioned the case $\dim(K) = 1$ explicitly in the original Tubular Neighborhood Theorem 10.19.

Proposition 64.11 raises the following question.

Question 64.12. *Let M be an orientable manifold and let K be a compact orientable proper submanifold. Is the tubular neighborhood $N(K)$ necessarily trivial?*

After this long discussion of tubular neighborhoods one can be excused for having lost track of what they are actually supposed to be good for. The following proposition finally implies Theorem 64.5.

Proposition 64.13. *Let M be a manifold and let K be a compact proper submanifold of M. Every tubular neighborhood of K is also a regular neighborhood of K.*

Proof. Let M be an n-dimensional manifold and let K be a compact proper k-dimensional submanifold of M. Let $(N, p\colon N \to K)$ be a tubular neighborhood of K. Recall that this means that the following three statements are satisfied:

(1) N is a compact codimension zero submanifold with corner of M that is a neighborhood of K.
(2) The map $p\colon N \to K$ is a linear $\overline{B}^{n-k}$-bundle such that for all $x \in K$ we have $p(x) = x$. We denote by $\{(U_i, \Phi_i\colon p^{-1}(U_i) \to \overline{B}^{n-k} \times U_i)\}_{i\in I}$ the corresponding family of trivializations.
(3) We have $\partial_1 N = p^{-1}(\partial K)$, put differently, we have $\partial M \cap N = p^{-1}(\partial M \cap K)$.

We start out the actual proof of the proposition with the following definition and construction. Let $v \in N$. We write $x := p(v)$. We pick an $i \in I$ with $p(v) \in U_i$ and we write $\Phi_i(v) = (w, x)$ where $w \in \overline{B}^m$.

(1) Given $s \in [0,1]$ we write $\varphi_s(v) := \Phi_i^{-1}(s \cdot w, x)$.
(2) Suppose $v \notin K$. This is equivalent to saying that $w \neq 0$. Then given $t \in [0,1]$ we write $\psi_t(v) := \Phi_i^{-1}\big((1-t)\cdot w + t \cdot \frac{w}{\|w\|}, x\big)$.

We leave it as an exercise to verify that these definitions are independent of the choice of the trivialization Φ_i.[1092] From this independence it also follows easily that the maps

$$\begin{array}{rcl} \Phi\colon N \times [0,1] & \to & N \\ (v,s) & \mapsto & \varphi_s(v) \end{array} \quad \text{and} \quad \begin{array}{rcl} \Psi\colon (N \setminus K) \times [0,1] & \to & N \setminus K \\ (v,t) & \mapsto & \psi_t(v) \end{array}$$

are continuous.[1093] We refer to Figure 778 for an illustration of the definition of Φ and Ψ. Finally recall that by definition of a regular neighborhood we have to prove the following claim.

Claim.

(1) K is contained in the interior of N,
(2) K is a deformation retract of N,

[1092] At this point it is essential that we work with a linear $\overline{B}^{n-k}$-bundle.

[1093] Evidently we only have to show continuity o-locally. So let $v \in N$. We can pick a trivialization that contains x and then it follows immediately from the definitions that the maps Φ and Ψ are continuous in the neighborhood of x corresponding to the trivialization.

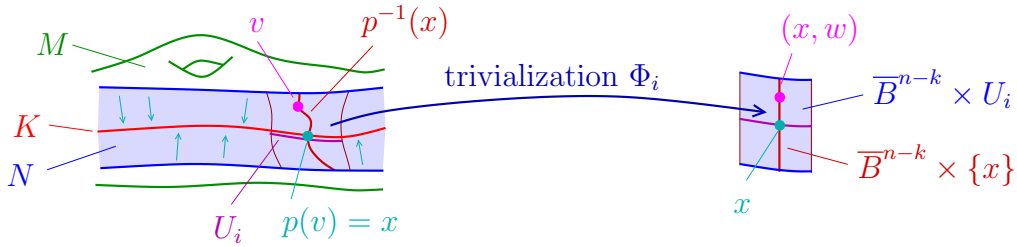

FIGURE 778. Illustration for the proof of Proposition 64.13.

(3) $\partial_0 N$ is a deformation retract of $N \setminus K$.

We turn to the proof of the claim.

(1) By definition of a neighborhood we know that K is contained in the interior of N.
(2) The above map $\Phi\colon N \times [0,1] \to N$ is easily seen to be a deformation retraction from N to K.
(3) The above map $\Psi\colon (N \setminus K) \times [0,1] \to N \setminus K$ is easily seen to be a deformation retraction from $N \setminus K$ to $\partial_0 N$.

This concludes the proof of the claim and thus also of the proposition. □

Remark. One of the frustrating aspects about tubular neighborhoods is that every book seems to work with a different definition. IMHO a tubular neighborhood should have the following two features:

(1) it should be a regular neighborhood, and
(2) it should satisfy a uniqueness statement.

By Propositions 64.9 and 64.13 our definition has these two properties. It is not always apparent that the definitions in the literature have these two features.

We conclude this chapter with a lemma which says that for transverse submanifolds one can find "transverse" tubular neighborhoods. We will not really make use of the lemma in these notes, but it seems to me that this lemma often gets used implicitly in the literature.

Lemma 64.14. $(*)$ *Let M be a manifold and let X and Y be proper submanifolds of M. If the submanifolds X and Y are compact and if they intersect transversally, then there exist tubular neighborhoods $p\colon U \to X$ and $q\colon V \to Y$ such that*[1094]

$$U \cap V \;=\; p^{-1}(V \cap X) = q^{-1}(U \cap Y).$$

Proof. I could not find a reference for the third statement in any of the standard books on differential topology [Le2, Wall2, Kos, GP]. But the standard proof for the existence of tubular neighborhoods can easily be adapted to prove the statement. The restriction to compact X and Y is almost certainly not necessary. □

[1094]From Figure 779 it should be pretty clear what we want to say. But does the statement of the lemma capture this idea? It is at times difficult to turn a picture into a precise mathematical statement.

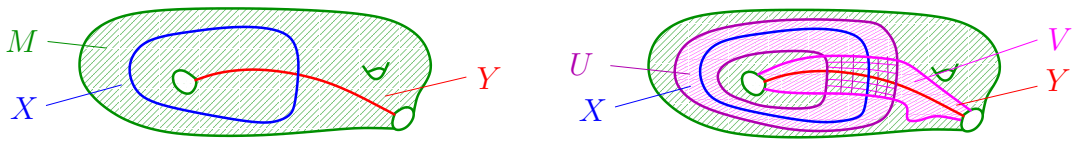

FIGURE 779. Illustration of Lemma 64.14.

Exercises for Chapter 64.

Exercise 64.1. Let G and G' be two spatial graphs in $\mathbb{R}^3$ with regular neighborhoods $N(G)$ and $N(G')$. Which of the following two implications is correct?

$$G \text{ and } G' \text{ are isotopic} \quad \Longleftrightarrow \quad N(G) \text{ and } N(G') \text{ are isotopic?}$$

Exercise 64.2. Let M be a 2-dimensional manifold. Furthermore let $f\colon [0,1] \to M$ be an embedding such that $f(0) \in \partial M$ and such that $f((0,1]) \subset M \setminus \partial M$. Show that the inclusion $M \setminus f([0,1]) \to M$ is a homotopy equivalence.
Hint: Use the Extension Theorem 10.26 and the General Tubular Neighborhood Theorem 64.7.

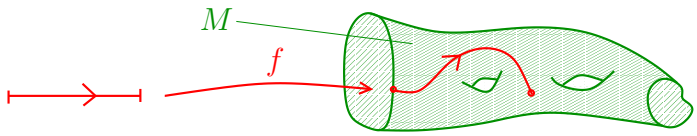

FIGURE 780.

65. Differential topology III: Whitney Approximation and Whitney Embedding

We continue with our attempt to expand our toolkit for dealing with manifolds.

65.1. **The Regular Value Theorem II** (∗)**.** In this section we formulate several refinements of the Regular Value Theorem 3.44. The refinements will play an important role later on, but perhaps it is best to skip the section at first reading.

Theorem 65.1. (Regular Value Theorem) *Let M be an m-dimensional manifold, let N be an n-dimensional manifold without boundary, let $f\colon M \to N$ be a smooth map and let $s \in N$ be a regular value of f. Then the following statements hold:*

1. *The preimage $X := f^{-1}(s)$ is a proper $(m-n)$-dimensional submanifold of M.*
2. *If M is orientable, then X is also orientable.*
3. *If M is compact, then X is also compact.*

For the last statement we assume that M is compact and orientable.

4. *There exists an open neighborhood U of s such that for any embedding $\varphi\colon \overline{B}^n \to U$ with $\varphi(0) = s$ there exists a tubular neighborhood $\Phi\colon \overline{B}^n \times X \to M$ such that the following two statements hold:*
   (a) *we have $f^{-1}(\varphi(\overline{B}^n)) = \Phi(\overline{B}^n \times X)$,*
   (b) *the following diagram commutes:*

$$\begin{tikzcd} \overline{B}^n \times X \arrow[r, "\Phi"] \arrow[d, "(p,x)\mapsto p"] & M \arrow[d, "f"] \\ \overline{B}^n \arrow[r, "\varphi"] & N. \end{tikzcd}$$

If M is oriented, then the orientation on X can be chosen such that Φ is orientation-preserving.

The first three statements of the above theorem are precisely the content of the original Regular Value Theorem 3.44.

Example. In Figure 113 we show the torus M as a submanifold of $\mathbb{R}^3$ and we consider the "height function" $f\colon M \to \mathbb{R}$ given by $f(x,y,z) = z$. This function has precisely four critical points which are indicated in Figure 113 on the left. On the right we show a regular value s and its preimage and we show a critical value t and its preimage $f^{-1}(t)$ which in this case is *not* a submanifold.

Sketch of proof. As mentioned above, the first three statements of the theorem form precisely the content of the original Regular Value Theorem 3.44. So it remains to deal with the final statement. This can be deduced quite easily from the Submersion Theorem 3.46. We leave it to the reader to fill in the details. □

For the reader's convenience we discuss the cases that $N = \mathbb{R}$ and $N = S^1$ separately. These two special cases also allow us to elucidate the somewhat confusing fourth statement of the Regular Value Theorem 65.1.

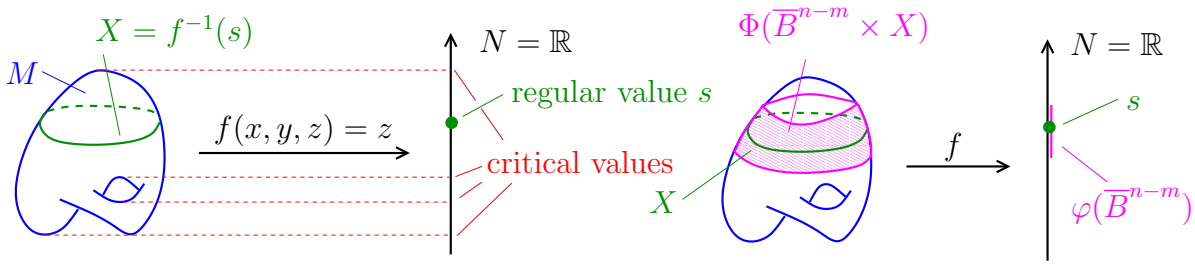

FIGURE 781. Illustration of the Regular Value Theorem 65.2.

Theorem 65.2. (Regular Value Theorem for $N = \mathbb{R}$) *Let M be an n-dimensional manifold, let $f\colon M \to \mathbb{R}$ be a smooth map and let $s \in \mathbb{R}$ be regular value of f. Then beyond statements (1), (2), (3) of the Regular Value Theorem 65.1 the following two statements hold:*

(4) *If M is compact and orientable, then there exists an $\epsilon > 0$ and a tubular neighborhood $[-\epsilon, \epsilon] \times X$ of X such that $f^{-1}([s-\epsilon, s+\epsilon]) = [-\epsilon, \epsilon] \times X$ and such that the following diagram commutes*

$$\begin{tikzcd} {[-\epsilon,\epsilon] \times X} \arrow[r, hook] \arrow[d, "(t,x)\mapsto t"] & M \arrow[d, "f"] \\ {[-\epsilon,\epsilon]} \arrow[r, "t\mapsto t+s"] & \mathbb{R}. \end{tikzcd}$$

If M is oriented, then the orientation on X can be chosen such that the embedding $[-\epsilon,\epsilon]\times \to M$ is orientation-preserving.

(5) *Suppose that $f^{-1}(s) \cap \partial M = \varnothing$. Then the preimage $W := f^{-1}((-\infty, s])$ is an n-dimensional submanifold of M with $\partial_0 W = f^{-1}(s)$.*

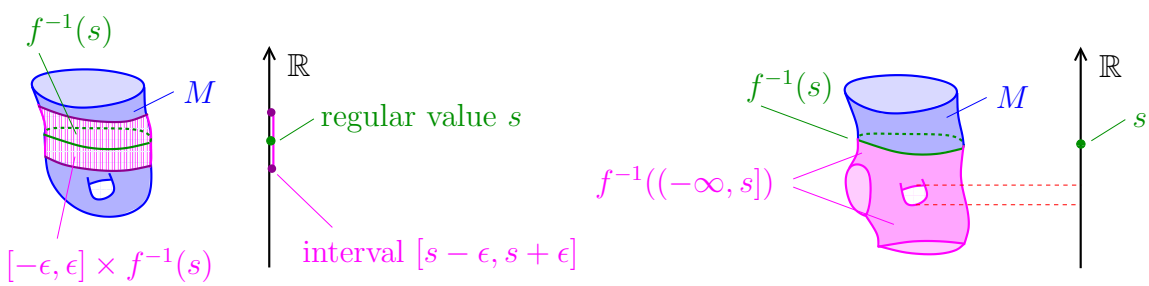

FIGURE 782. Illustration of the Regular Value Theorem 65.2.

Sketch of proof.

(4) Note that given any neighborhood U of $s \in \mathbb{R}$ there exists an $\epsilon > 0$ such that $[s-\epsilon, s+\epsilon] \subset U$. The statement now follows immediately from the Regular Value Theorem 65.1 (4) applied to the map $\varphi\colon [-\epsilon,\epsilon] \to \mathbb{R}$ given by $t \mapsto t+s$.

(5) If one takes a look at the proof of the Regular Value Theorem 65.1 (1) one sees that it actually provides submanifold charts of type (β) for $W := f^{-1}((-\infty, s])$ and any point on $f^{-1}(s)$. Also note that $f^{-1}((-\infty, s))$ is an open subset of M. We leave it to the reader to assemble from this observations the full proof of the statement. □

We also mention the following variation on the Regular Value Theorem 65.1.

Theorem 65.3. (Regular Value Theorem for $N = S^1$) *Let M be an n-dimensional manifold, let $f\colon M \to S^1$ be a smooth map and let $z = e^{2\pi i t} \in S^1$ be a regular value. Then beyond statements* (1), (2), (3) *of the Regular Value Theorem 65.1 the following statement holds:*

(4) *If M is compact and orientable, then there exists an $\epsilon > 0$ and a tubular neighborhood $[-\epsilon, \epsilon] \times X$ of X such that $f^{-1}(\{e^{2\pi i(t+s)} \mid t \in [-\epsilon, \epsilon]\}) = [-\epsilon, \epsilon] \times X$ and such that the following diagram commutes*

$$\begin{tikzcd} {[-\epsilon,\epsilon]\times X} \arrow[r, hook] \arrow[d, "(t,x)\mapsto t"] & M \arrow[d, "f"] \\ {[-\epsilon,\epsilon]} \arrow[r, "s\mapsto e^{2\pi i(t+s)}"] & S^1. \end{tikzcd}$$

If M is oriented, then the orientation on X can be chosen such that the embedding $[-\epsilon, \epsilon]\times \to M$ is orientation-preserving.

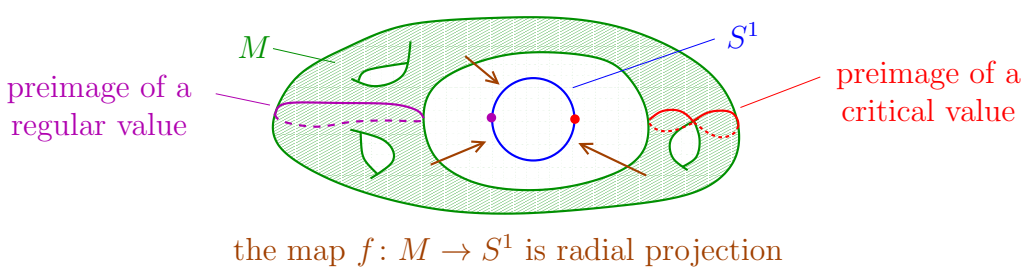

FIGURE 783. Illustration of the Regular Value Theorem 65.3.

Example. Let N be a manifold and let $\varphi\colon N \to N$ be a diffeomorphism. We consider the mapping torus $M := M(N, \varphi) = (N \times [0, 1])/(x, 0) \sim (\varphi(x), 1)$ together with the canonical projection $f\colon M \to S^1$ given by $f([p, x)]) = e^{2\pi i x}$. Then every $z = e^{2\pi i x} \in S^1$ is a regular value and the preimage $f^{-1}(z) = N \times \{x\}$ is just a "parallel" copy of N.

Proof. As in the case of Theorem 65.2 (4) this statement can be deduced easily from the Regular Value Theorem 65.1 (4). □

The following proposition often allows us to reduce a statement about non-compact manifolds to a statement about compact manifolds.

Proposition 65.4. *Let W be an n-dimensional manifold with compact boundary.*[1095] *There exists a sequence $X_1, X_2, \dots$ of n-dimensional submanifolds of W with the following three properties:*

(1) *the sequence is nested, i.e. for each $i \in N$ we have $X_i \subset X_{i+1}$,*
(2) *each X_i is compact and each X_i contains the boundary ∂W,*
(3) *we have $\bigcup_{i\in\mathbb{N}} \overset{\circ}{X}_i = W$.*

In the proof of Proposition 65.4 we will need the following useful lemma which is proved in [Le2, Proposition 2.28].

Lemma 65.5. *Let W be an n-dimensional manifold with compact boundary. There exists a smooth function $f\colon W \to \mathbb{R}_{\geq 0}$ with the property that for any $c \in \mathbb{R}_{\geq 0}$ the preimage $f^{-1}([0,c])$ is a compact subset of W.*

Examples.

(1) Let $W = [0,1)$ the half-open interval viewed as a 1-dimensional manifold. In this case the function defined by $f(x) = \frac{1}{1-x}$ has the desired properties
(2) We consider the surface of infinite genus illustrated in Figure 784. In this case the function $f(x,y,z) = x$ has the desired properties of Lemma 65.5. [1096]

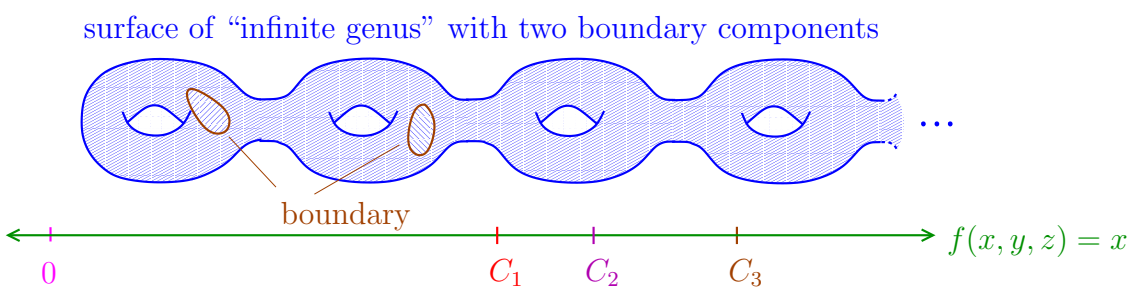

FIGURE 784. Illustration of the proof of Proposition 65.4

Proof of Proposition 65.4. Let W be an n-dimensional manifold with compact boundary. By Lemma 65.5 there exists a smooth function $f\colon W \to \mathbb{R}_{\geq 0}$ with the property that for any $c \in \mathbb{R}_{\geq 0}$ the preimage $f^{-1}([0,c])$ is a compact subset of W.

Since ∂W is compact it follows from Lemma 1.37 that there exists a $C \in \mathbb{R}_{\geq 0}$ such that $\partial W \subset f^{-1}([0,C])$. It follows from Sard's Theorem 3.48 and Proposition 3.47 (2) that there exists an increasing sequence $C \leq C_1 \leq C_2 \leq C_3 \leq \dots$ of regular values of f such that $\lim_{i\to\infty} C_i = \infty$. For each $i \in \mathbb{N}$ we set $X_i := f^{-1}((-\infty, C_i])$. By the Regular Value

[1095] Note that if the boundary is empty, it is also compact.

[1096] We consider the surface of infinite genus illustrated in Figure 784. Let us ignore the two boundary components so that we get a manifold without boundary. Is the result homeomorphic to the surface of infinite genus illustrated in Figure 297?

Theorem 65.2 (5) and by our choice of f each X_i is a compact n-dimensional submanifold of W with $\partial_0 X_i = f^{-1}(C_i)$. In particular we have by Lemma 64.1 that $\mathring{X}_i = f^{-1}((-\infty, C_i))$. By construction this sequence satisfies the desired conditions (1), (2) and (3). □

65.2. **The Whitney Approximation Theorem.** As we will see later on, there are many ways to construct interesting continuous maps between two manifolds. The following theorem allows us to "replace" such a continuous map by a smooth map.

Theorem 65.6. (Whitney Approximation Theorem) *Let M be manifold (with or without boundary) and let N be a manifold without boundary.*

(1) *Let $f\colon M \to N$ be a map that is smooth on a (possibly empty) closed subset A.*[1097] *There exists a homotopy $F\colon M \times [0,1] \to N$ with the following properties:*
   (a) *The homotopy is a homotopy rel A.*
   (b) *We have $F_0 = f$.*
   (c) *The map $F_1\colon M \to N$ is smooth.*

   Suppose that we are given a continuous function $\rho\colon M \to \mathbb{R}_{>0}$ and suppose that we are given a metric d on N. Then we can find a homotopy F as above that also satisfies the following extra condition:
   (d) *For every $(x,t) \in M \times [0,1]$ we have $d(F(x,t), f(x)) \leq \rho(x)$.*

(2) *Let $f, g\colon M \to N$ be two smooth maps that agree on a (possibly empty) closed subset A. If f and g are homotopic rel A, then there exists also a smooth homotopy between f and g that is constant on A.*

Remark. Suppose we are in the setting of the Whitney Approximation Theorem 65.6. Let $f\colon M \to N$ be a map that is injective (respectively surjective, bijective). We now know that we can find a homotopy from f to some smooth map $F_1 = g\colon M \to N$, but the theorem does not give us any control over whether the smooth map $F_1 = g$ is also injective (respectively surjective, bijective).

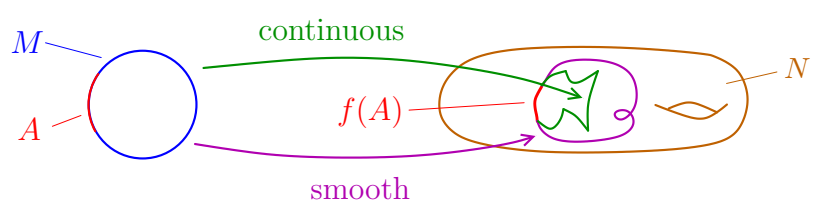

FIGURE 785. Illustration of Theorem 65.6 (1).

Proof.

[1097] Let M and N be manifolds and let $A \subset M$ be an arbitrary subset. On page 184 we defined what it means for a map $f\colon A \to N$ to be smooth.

(1) The first statement, without Condition (d), is the content of [Le2, Theorem 6.26]. The full statement including Condition (d) follows by almost the same argument as in the proof of [Le2, Theorem 6.26], one just needs o make full use of [Le2, Theorem 6.21]. We refer to [MTo, Lemma A.9] for a closely related argument. A weaker version of (1) is also proved in [Hirs, Lemma 5.1.5] and in [DFN, Theorem 10.1.2].
(2) The proof of Statement (2) can reduced to Statement (1) without too many problems. We refer to [Le2, Theorem 6.29] or alternatively to [DFN, Theorem 12.1.4] for details. □

We continue with the following pleasant corollary to the Whitney Approximation Theorem 65.6.

Corollary 65.7. *Let $n \in \mathbb{N}$. We pick a base point $*$ on S^n. Furthermore let M be a manifold without boundary. We pick a base point x_0. The obvious map*

$$\{\textit{all smooth maps } f\colon (S^n, *) \to (M, x_0) \textit{ up to smooth homotopies}\} \ \to \ \pi_n(M, x_0)$$

is an isomorphism.

Remark. In Exercise 65.1 we will use this isomorphism, together with Proposition 3.47 to give a quick proof of Proposition 28.9, i.e. we will reprove that for $k < n$ we have $\pi_k(S^n) = 0$.

Proof. Note that it follows immediately from the definition on page 184 that the restriction of any map $S^n \to M$ to any one-point subset $\{*\}$ is smooth. Thus the corollary follows immediately from the Whitney Approximation Theorem 65.6, applied to $A = \{*\}$. □

We conclude this section with two and a half more technical consequences of the Whitney Approximation Theorem 65.6. These results are interesting in their own right, but the reader might want to skip them initially.

Proposition 65.8. $(*)$ *Let M be manifold (with or without boundary) and let N be a manifold without boundary. Furthermore let $f\colon M \to N$ be a map. Finally let A and X be disjoint closed subsets such that the restriction of f to A is smooth and let $U \subset N$ be an open subset that contains $f(M \setminus X)$. If $X \neq \varnothing$, then there exists a homotopy $F\colon M \times [0,1] \to N$ with the following properties:*

(1) *The homotopy is a homotopy rel $X \cup A$.*
(2) *We have $F_0 = f$.*
(3) *The restriction of F_1 to the open subset $M \setminus X$ is smooth.*[1098]
(4) *For each $t \in [0,1]$ we have $F_t(M \setminus X) \subset U$.*

Proof. First we consider the case that $U = N$. By Theorem 3.10 we can pick a metric c on M such that the topology from the metric c agrees with the given topology on M. The

[1098]Since X is closed we see that $M \setminus X$ is an open subset of M, thus we can view $M \setminus X$ as a manifold in its own right.

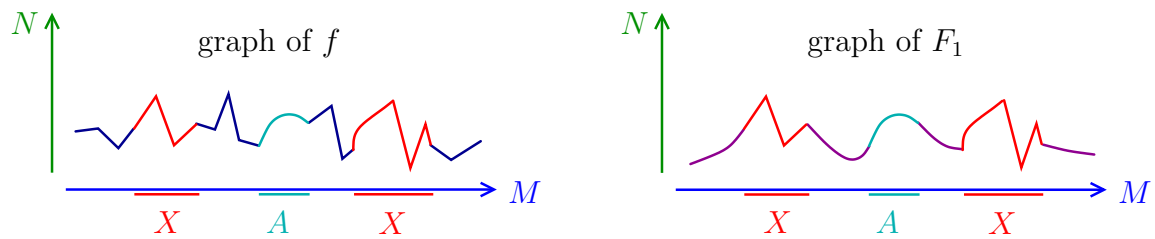

FIGURE 786. Illustration of Proposition 65.8.

same way we can pick a metric d on N. We consider the open subset $W := M \setminus X$ and we view it as a manifold. Since $X \neq \varnothing$ we can consider the function

$$\begin{array}{rcl} \rho\colon W & \to & \mathbb{R}_{\geq 0} \\ w & \mapsto & \rho(w) := c(w, X) = \inf\{c(w,x) \,|\, x \in X\}. \end{array}$$

Since X is closed and since the topology defined by c agrees with the topology on M we see that $\rho(w) > 0$ for every $w \in W$. By Lemma 1.57 we know that ρ is continuous. Since N is a manifold without boundary we can apply the Whitney Approximation Theorem 65.6 to the map $f\colon W \to N$ and we see that there exists a homotopy $G\colon W \times [0,1] \to N$ with the following properties:

(a) The homotopy is a homotopy rel A.
(b) We have $G_0 = f|_W$.
(c) The map $G_1\colon W \to N$ is smooth.
(d) For every $(w,t) \in W \times [0,1]$ we have $d(G(w,t), f(w)) \leq \rho(w)$.

It follows easily from (d) and the definition of ρ that the map

$$\begin{array}{rcl} F\colon M \times [0,1] & \to & N \\ (x,t) & \mapsto & \begin{cases} G(x,t), & \text{if } x \in W, \\ f(x), & \text{if } x \in X \end{cases} \end{array}$$

is continuous. Now it is straightforward to verify that this map has all the desired properties.

Finally we consider the case that $U \neq N$. In this case we consider the map

$$\begin{array}{rcl} \rho\colon W & \to & \mathbb{R}_{\geq 0} \\ w & \mapsto & \rho(w) := \min\{c(w,X), d(f(w), N \setminus U)\}. \end{array}$$

Since U is open and since $f(W) \subset U$ we see that ρ is again non-zero every. The rest of the argument is basically the same and it follows from (d) that for each $t \in [0,1]$ we have $F_t(M \setminus X) \subset U$. $\square$

Loosely speaking the following proposition says that a map $M \to X$ from a manifold to a topological space X can be made smooth with respect to open balls B^n contained in X.

Proposition 65.9. *Let M be a manifold and let $f\colon M \to X$ be a map to a topological space X that is Hausdorff. Let $\varphi\colon \overline{B}^n \to X$ be an injective map such that $\varphi(B^n)$ is an open subset of X. Given any $r \in (0,1)$ there exists a map $g\colon M \to X$ with the following properties:*

1. *g is homotopic to f rel the complement of $f^{-1}(\varphi(B^n_r))$ in M,*
2. *the map*
$$\begin{array}{rcl} f^{-1}(\varphi(B^n_r)) & \to & B^n_r \\ x & \mapsto & \varphi^{-1}(g(x)) \end{array}$$
is smooth.

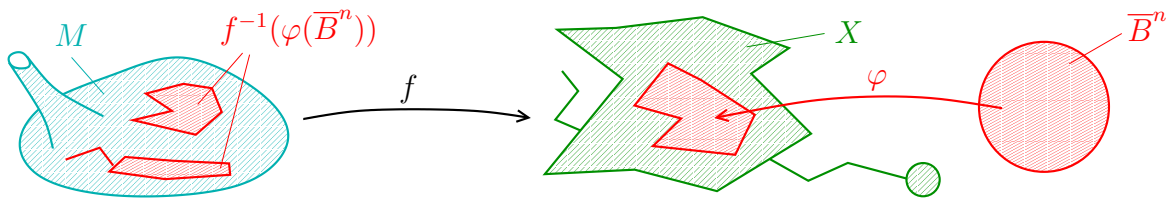

FIGURE 787.

Proof. Since $\overline{B}^n$ is compact, since X is Hausdorff and since $\varphi\colon \overline{B}^n \to X$ is injective we know by Proposition 1.40 that φ is a homeomorphism onto its image. Thus we might as well identify $\overline{B}^n$ with its image under the map $\varphi\colon \overline{B}^n \to X$. Now let $r \in \mathbb{R}_{>0}$. By Lemma 1.35 we know that B^n_r is also an open subset of X. Furthermore, note that it follows from the fact that X is Hausdorff, together with Lemma 1.18 (1), that $\overline{B}^n_r$ and $\overline{B}^n$ are a closed subsets of X. We consider the map

$$\begin{array}{rcl} \alpha\colon M & \to & \overline{B}^n/S^{n-1} \\ x & \mapsto & \begin{cases} f(x), & \text{if } x \in f^{-1}(B^n), \\ [S^{n-1}], & \text{if } x \in M \setminus f^{-1}(B^n). \end{cases} \end{array}$$

Note that α is continuous.[1099] As discussed on page 99 we can view $\overline{B}^n/S^{n-1}$ as a manifold such that B^n is a submanifold. Therefore we can apply Proposition 65.8 to the map $\alpha\colon M \to \overline{B}^n/S^{n-1}$ with $A = \varnothing$, with the closed subset $X = M \setminus f^{-1}(B^n_r)$[1100] and with the open subset $U = B^n_r \subset N$. We obtain a homotopy $F\colon M \times [0,1] \to \overline{B}^n/S^{n-1}$ with the following properties:

1. The homotopy is a homotopy rel $X = M \setminus f^{-1}(B^n_r)$.
2. We have $F_0 = \alpha$.
3. The restriction of F_1 to $M \setminus X = f^{-1}(B^n_r)$ is smooth.

[1099] Indeed, the restrictions of α to the closed subset $M \setminus f^{-1}(B^n)$ is a constant map and the restriction of α to the closed subset $f^{-1}(\overline{B}^n)$ is given by the composition of the map f with the projection map $\overline{B}^n \to \overline{B}^n/S^{n-1}$. Therefore we obtain from Lemma 1.32 (2) that α is indeed continuous.

[1100] Note the discrete subscript "r".

(4) For each $t \in [0,1]$ we have $F_t(f^{-1}(B^n_r)) \subset B^n_r$.

Finally we consider the map

$$\begin{array}{rcl} G\colon M \times [0,1] & \to & X \\ (x,t) & \mapsto & \begin{cases} F(x,t), & \text{if } x \in f^{-1}(B^n_r) \\ f(x), & \text{if } x \in M \setminus f^{-1}(B^n). \end{cases} \end{array}$$

Note that the restrictions of G to the closed subsets $(M \setminus f^{-1}(B^n_r)) \times [0,1]$ and $f^{-1}(\overline{B}^n_r) \times [0,1]$ are continuous.[1101] Thus we obtain from Lemma 1.32 (2) that G is continuous. It is now straightforward to verify that $g := G_1$ has all the desired properties. □

The following proposition is a slight variation on Proposition 65.9.

Proposition 65.10. *Let M be a manifold and let $f\colon M \to X$ be a map to a topological space X that is Hausdorff. Let $n \in \mathbb{N}$ and let $* \in S^n$ be a point. Finally let $\varphi\colon S^n \to X$ be an injective map such that $\varphi(S^n \setminus \{*\})$ is an open subset of X. There exists a map $g\colon M \to X$ with the following properties:*

(1) *g is homotopic to f rel the complement of $f^{-1}(\varphi(S^n \setminus \{*\}))$ in M,*
(2) *the map*

$$\begin{array}{rcl} f^{-1}(\varphi(S^n \setminus \{*\})) & \to & S^n \setminus \{*\} \\ x & \mapsto & \varphi^{-1}(g(x)) \end{array}$$

is smooth.

Proof. We leave it to the reader to modify the proof of Proposition 65.9 to obtain the desired result. As the reader will notice, in this case there is no need to work with some $r \in (0,1)$. In particular the conclusion we get is slightly more satisfactory. □

Example. Let $\bigvee_{i=1}^{k} S^{n_i}$ be a wedge of spheres. We denote by $*$ the wedge point. Let M be a manifold and let $f\colon M \to \bigvee_{i=1}^{k} S^{n_i}$ be a map. By iteratively applying Proposition 65.10 altogether k times we see that f is homotopic rel $f^{-1}(\{*\})$ to a map that is smooth on the open sets $f^{-1}(S^{n_i} \setminus \{*\})$, $i = 1, \dots, k$.

65.3. **Embeddings of (topological) manifolds into $\mathbb{R}^n$.** In this and the coming section we study the existence of embeddings of (topological) manifolds into some sufficiently high-dimensional $\mathbb{R}^n$. For the reader's convenience we recall the following definitions from page 330.

[1101] For nervous people, like the author, let us verify in slightly greater detail that the restriction of G to $f^{-1}(\overline{B}^n_r) \times [0,1]$ is indeed continuous. First note that by (4) the restriction of the map F to $f^{-1}(B^n_r) \times [0,1]$ takes values in B^n_r. It follows from Exercise 1.5 (3) and Exercise 1.25 that the restriction of the map F to $f^{-1}(\overline{B}^n_r) \times [0,1]$ takes values in the closure of B^n_r in $\overline{B}^n / S^{n-1}$. Since $r \in (0,1)$ we see that the closure equals $\overline{B}^n_r \subset B^n$. We now see that the restriction of the map G to $f^{-1}(\overline{B}^n_r) \times [0,1]$ equals the composition of the map $F\colon f^{-1}(\overline{B}^n_r) \times [0,1] \to \overline{B}^n_r$ with the inclusion $\overline{B}^n_r \to X$.

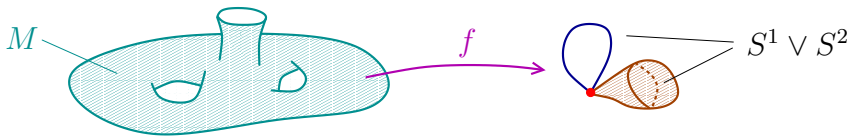

FIGURE 788.

Definition.

(1) A map $\varphi\colon N \to M$ between two topological manifolds is called a *topological embedding* if $\varphi\colon N \to \varphi(N)$ is a homeomorphism and if $\varphi(N)$ is a submanifold of M. (Here we view $\varphi(N)$ as a topological space equipped with the subspace topology coming from M.)

(2) A map $\varphi\colon N \to M$ between two manifolds is called an *immersion* if the following conditions are satisfied:
   (a) φ is smooth,
   (b) for each $P \in N$ the induced map $\varphi_*\colon T_PN \to T_{\varphi(P)}M$ is a monomorphism,
   (c) for each $P \in N \setminus \partial N$ we have $\varphi(P) \in M \setminus \partial M$,
   (d) for each $P \in \partial N$ with $\varphi(P) \subset \partial M$ the image $\varphi_*(T_PN)$ is *not* contained in $T_{\varphi(P)}(\partial M)$.[1102]

   An immersion that also satisfies the following extra condition
   (e) $\varphi\colon N \to \varphi(N)$ is a topological embedding,
   is called an *embedding*.

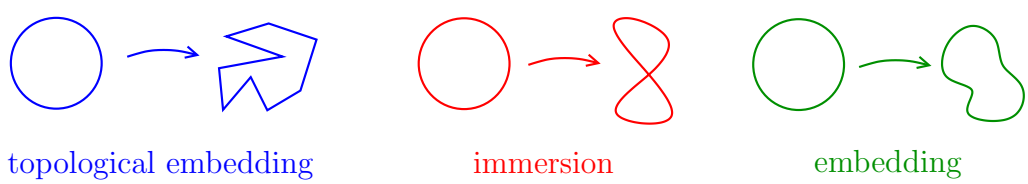

FIGURE 789.

Remark.

(1) Let $\varphi\colon N \to M$ be an injective map between topological manifolds. As is shown in Figure 790 such a map is not necessarily an embedding. But it follows from Lemma 1.37 that such a map is a topological embedding under the added hypothesis that N is compact. On several occasions we will use this observation without saying it explicitly.

(2) The super-meticulous reader will have noticed that the above definition of an embedding between manifolds differs slightly from the definition we gave on page 330.

[1102] Another way of expressing this condition is that the map $T_PN \to T_{\varphi(P)}M/T_{\varphi(P)}\partial M$ is an epimorphism.

In the original definition we had not demanded that the image of an embedding is (a topological) submanifold, but instead we saw in Proposition 10.1 that this property follows already from the a priori slightly weaker notion of an embedding that we had introduced on page 330. So any fears of incoherence in these notes just mercifully dissipated.

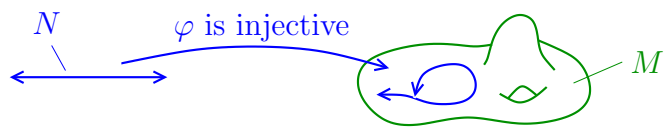

FIGURE 790.

Examples.

(1) It is straightforward to verify that the map

$$\begin{array}{rcl} S^1 \times S^1 & \to & \mathbb{R}^3 \\ (e^{i\theta}, e^{i\varphi}) & \mapsto & ((2+\sin(\theta))\cdot\cos(\varphi), (2+\sin(\theta))\cdot\sin(\varphi), \cos(\theta)) \end{array}$$

is an embedding of the 2-dimensional torus into $\mathbb{R}^3$.

(2) Let M be a closed non-empty n-dimensional topological manifold. In Corollary 36.8 we showed that there is no topological embedding of M into $\mathbb{R}^n$.

The question arises whether every (topological) manifold can be embedded into some $\mathbb{R}^n$. In the following proposition we give an affirmative answer for compact (topological) manifolds.

Proposition 65.11. *Given any compact (topological) manifold M there exists an $n \in \mathbb{N}$ and a (topological) embedding $M \to \mathbb{R}^n$. Furthermore, if M is an m-dimensional manifold*[1103]*, then we can arrange that $n = 2m+1$.*

The proof of the "furthermore" statement of Proposition 65.11 requires the following lemma, which is of interest in its own right.

Lemma 65.12. *Let M be an m-dimensional submanifold of $\mathbb{R}^n$. If $n > 2m+1$, then there exists a non-zero vector $v \in \mathbb{R}^n$ which does not lie in any tangent space*[1104] *T_PM and that is not secant to M, in other words, for any two distinct points $x, y \in M$ the difference $x - y$ is not parallel to v.*

[1103]Just to avoid any confusion, note that the second statement only refers to manifolds. The proof that we give does not apply to topological manifolds.

[1104]Here we use Proposition 3.32 to interpret the tangent space T_PM as a subvector space of $\mathbb{R}^n$.

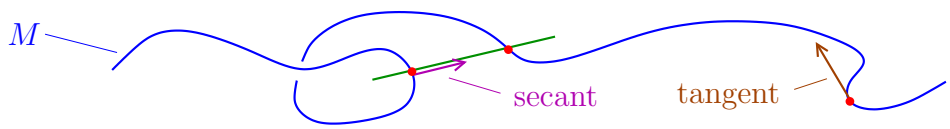

FIGURE 791. Illustration for Lemma 65.12.

Proof of Lemma 65.12. Let M be an m-dimensional submanifold of $\mathbb{R}^n$. We suppose that $n > 2m+1$. We consider the maps

$$\begin{array}{rcl} f\colon \{(P,w) \mid P \in M, w \in T_P M \setminus \{0\}\} & \to & \mathbb{R}\mathrm{P}^{n-1} \\ (P,w) & \mapsto & [w] \end{array}$$

and

$$\begin{array}{rcl} g\colon \{(x,y) \in M \times M \mid x \neq y\} & \to & \mathbb{R}\mathrm{P}^{n-1} \\ (x,y) & \mapsto & [x-y]. \end{array}$$

By the discussion on page 192 we can view $\mathbb{R}\mathrm{P}^{n-1}$ as an $(n-1)$-dimensional manifold. One can easily verify that the left-hand sides of both f and g are manifolds of dimension $2m$ and that the two maps are smooth. Since $2m < n-1$ we obtain from Proposition 3.47 that the complement of the images of f and g is dense, in particular non-empty. This means that there exists a $v \in \mathbb{R}\mathrm{P}^{n-1}$ such that the preimages of v under f and g are both the empty set. But that means that v has the desired properties. □

Now we turn to the proof of Proposition 65.11.

Proof of Proposition 65.11.

(a) First let M be a compact m-dimensional manifold. Since M is compact we can pick a finite smooth atlas $\{\Phi_i\colon U_i \to V_i\}_{i=1,\dots,s}$. By Theorem 54.5 we can find a smooth partition of unity subordinate to the open covering $\{U_i\}_{i=1,\dots,s}$ of M. Put differently, we can find smooth functions $\nu_i\colon M \to [0,1]$, $i = 1,\dots,s$ such that for each i we have $\operatorname{supp}(\nu_i) \subset U_i$ and such that for all $x \in M$ we have $\nu_1(x) + \cdots + \nu_s(x) = 1$. For $i = 1,\dots,s$ we define

$$\begin{array}{rcl} \widetilde{\Phi}_i\colon M & \to & \mathbb{R}^m \\ x & \mapsto & \begin{cases} \Phi_i(x) \cdot \nu_i(x), & \text{if } x \in U_i, \\ 0, & \text{otherwise.} \end{cases} \end{array}$$

It follows easily[1105] from Lemma 3.15 (1) that each of these maps $\widetilde{\Phi}_i$ is smooth. Finally note that the map

$$\begin{array}{rcl} \varphi\colon M & \to & \mathbb{R}^{s\cdot m+s} \\ x & \mapsto & (\widetilde{\Phi}_1(x),\dots,\widetilde{\Phi}_s(x),\nu_1(x),\dots,\nu_s(x)) \end{array}$$

[1105]Hmm, how does the smoothness of $\widetilde{\Phi}_i$ follow from Lemma 3.15 (1)?

is an embedding.[1106]

(b) The proof for topological manifolds is basically the same as in (a). The only difference is that from Theorem 54.5 we only obtain a continuous partition of unity subordinate to the open covering $\{U_i\}_{i=1,\dots,s}$ of M. In particular the map $\varphi\colon M \to \mathbb{R}^{s\cdot m+s}$ that we constructed in (a) is only a topological embedding.

(c) Finally assume that M is a compact m-dimensional manifold. We claim that we can can embed M into $\mathbb{R}^{2m+1}$. By (a) we can assume that M is already a submanifold of some $\mathbb{R}^n$. If $n \leq 2m+1$ there is nothing to prove, so we may assume that $n > 2m+1$. By Lemma 65.12 there exists a non-zero vector $v \in \mathbb{R}^n$ which does not lie in any tangent space T_PM and that is not secant to M, in other words, for any two distinct points $x, y \in M$ the difference $x - y$ is not parallel to v.

We consider the projection of $\mathbb{R}^n$ onto the orthogonal complement of v, i.e. we consider the map

$$\begin{array}{rcl} \mathbb{R}^n & \to & \{w \in \mathbb{R}^n \mid \langle w, v\rangle = 0\} \\ u & \mapsto & u - \langle u, v\rangle \cdot \frac{v}{\|v\|^2}. \end{array}$$

It follows easily from the claim that the restriction of the projection to M is an embedding. Thus we have embedded M into a real vector space of dimension $n-1$. Iterating this process we get an embedding of M into $\mathbb{R}^{2m+1}$. □

In the remainder of this section and in the subsequent chapter we will discuss refinements of Proposition 65.13 for manifolds. Many of the results also have more or less obvious analogues for topological manifolds, but to simplify the discussion we will not spell out the statements for topological manifolds.

Our first goal is to consider manifolds with boundary in greater detail. We recall the following definition and notation.

Definition.

[1106] For completeness' sake we provide the proof that $\varphi\colon M \to \mathbb{R}^{s\cdot m+s}$ is an embedding, even though the interest in the full details might be quite muted.

(a) First we show that φ is injective. Let $x, x' \in M$. We pick i with $\nu_i(x) \neq 0$. If $\nu_i(x') = 0$, then evidently $\varphi(x) \neq \varphi(x')$. If $\nu_i(x) \neq 0$, then $x, x' \in U_i$. Note that $\Phi_i(x) \neq \Phi_i(x')$, which is equivalent to $\nu_i(x)^{-1} \cdot \widetilde{\Phi}_i(x) \neq \nu_i(x')^{-1} \cdot \widetilde{\Phi}_i(x')$. But this means that $(\widetilde{\Phi}_i(x), \nu_i(x)) \neq (\widetilde{\Phi}_i(x'), \nu_i(x'))$, which implies that $\varphi(x) \neq \varphi(x')$.

(b) We need to show that for each $x \in M$ the differential $D\varphi_x\colon T_xM \to \mathbb{R}^{s\cdot m+s}$ is a monomorphism. We pick i with $\nu_i(x) \neq 0$. We consider the map

$$\begin{array}{rcccl} U_i & \to & \{(v,t) \in \mathbb{R}^m \times \mathbb{R} \mid t \neq 0\} & \to & \mathbb{R}^m \\ y & \mapsto & (\widetilde{\Phi}_i(y), \nu_i(y)) & & \\ & & (v,t) & \mapsto & \frac{1}{t} \cdot v. \end{array}$$

Note that the composition is just the diffeomorphism Φ_i, thus the differential at x is a monomorphism. But this implies that the differential of the first map at x is a monomorphism, which implies that the differential of φ at x is a monomorphism.

(1) Let N be a compact manifold and let M be any manifold. A map $\varphi\colon N \to M$ is called *proper* if $\varphi^{-1}(\partial M) = \partial N$.
(2) Given $n \in \mathbb{N}$ we write

$$H_n \;:=\; \{(x_1, \ldots, x_n) \in \mathbb{R}^n \,|\, x_n \geq 0\}.$$

For manifolds with boundary the following proposition refines the statement of Proposition 65.11.

Proposition 65.13. *Let M be a compact m-dimensional manifold.*

(1) *Given any $n \geq 2m+1$ there exists a proper embedding $M \to H_n$.*
(2) *Suppose we are given an embedding $f\colon \partial M \to \mathbb{R}^k$ of the boundary of M. Given any $n \geq 2m+k+1$ there exists a proper embedding $F\colon M \to H_n$ such that the following diagram commutes:*

$$\begin{tikzcd} \partial M \arrow[r, hook] \arrow[d, "f"'] & M \arrow[d, "F"] \\ \mathbb{R}^k \arrow[r, "x \mapsto (x,0)"] & H_n. \end{tikzcd}$$

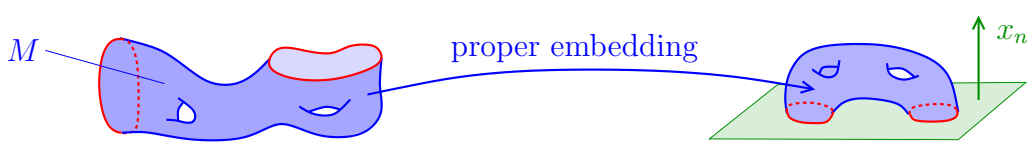

FIGURE 792. Illustration of Proposition 65.13 (1).

Proof $(*)$. Both statements of the proposition follow from the following claim.[1107]

Claim. Let M be a compact m-dimensional manifold and let Y be a (possibly empty) union of components of ∂M. Suppose we are given an embedding $f\colon Y \to \mathbb{R}^k$ of the boundary of M. Let $n \geq 2m+k+1$. Then there exists a proper embedding $F\colon M \to H_n$ such that the following diagram commutes:

$$\begin{tikzcd} Y \arrow[r, hook] \arrow[d, "f"'] & M \arrow[d, "F"] \\ \mathbb{R}^k \arrow[r, "x \mapsto (x,0)"] & H_n. \end{tikzcd}$$

Evidently the proof of the claim is quite similar to the proof of Proposition 65.11. Therefore we will only indicate in what ways the proof needs to be modified.

[1107]Indeed, the first statement of the proposition follows from $Y = \varnothing$ and $k = 0$. The second statement follows from setting $Y = \partial M$.

(a) By the Collar Neighborhood Theorem 10.10 we can pick a collar $\partial M \times [0,1]$. Note that using Lemma 3.12 one can easily construct a smooth non-decreasing function $\eta\colon [0,1] \to [0,1]$ with $\eta(t) = t$ for all $t \in [0, \frac{1}{4}]$ and with $\eta(t) = 1$ for all $t \in [\frac{1}{2}, 1]$. We define[1108]

$$\begin{array}{rcl} \mu\colon M & \to & [0,1] \\ P & \mapsto & \begin{cases} \eta(t), & \text{if } P = (Q,t) \text{ with } Q \in \partial M \text{ and } t \in [0,1], \\ 1, & \text{otherwise} \end{cases} \end{array}$$

and we define

$$\begin{array}{rcl} \widetilde{f}\colon M & \to & \mathbb{R}^k \\ P & \mapsto & \begin{cases} f(Q) \cdot (1 - \eta(t)), & \text{if } P = (Q,t) \text{ with } Q \in \partial M \text{ and } t \in [0,1], \\ 0, & \text{otherwise.} \end{cases} \end{array}$$

In the following we use the same notation and definitions as in the proof of Proposition 65.11. In particular we pick a finite atlas $\{\Phi_i\colon U_i \to V_i\}_{i=1,\dots,s}$, we pick a corresponding smooth partition of unity $\nu_i\colon M \to [0,1]$, $i = 1, \dots, s$ and we define $\widetilde{\Phi}_i\colon M \to \mathbb{R}^m$, $i = 1, \dots, s$ the same way as before. Similar to the proof of Proposition 65.11 one can verify that the map

$$\begin{array}{rcl} F\colon M & \to & \mathbb{R}^k \times \mathbb{R}^{s\cdot m+s} \times \mathbb{R}_{\geq 0} = H_{k+s\cdot m+s+1} \\ x & \mapsto & \big(\underbrace{\widetilde{f}(x)}_{\in\mathbb{R}^k}, \underbrace{\mu(x) \cdot \big(\widetilde{\Phi}_1(x), \dots, \widetilde{\Phi}_s(x), \nu_1(x), \dots, \nu_s(x)\big)}_{\in\mathbb{R}^{s\cdot m+s}}, \underbrace{\mu(x)}_{\in\mathbb{R}_{\geq 0}}\big) \end{array}$$

is a proper embedding. It is clear that the map F makes the diagram in the claim commute.

(b) To prove the claim it now remains to show that given such a proper embedding $F\colon M \to H_n$ with $n > 2m+k+1$ we can find a lower-dimensional proper embedding with the same properties. Without loss of generality we can assume that M is already a submanifold of H_n.

Similar to the proof of Proposition 65.11 we can find a non-zero vector $v \in \mathbb{R}^n$ with the following three properties:

(a) the vector does not lie in any tangent space T_xM,
(b) for any two distinct points $x, y \in M$ the difference $x - y$ is not parallel to v,
(c) the vector is orthogonal to $\mathbb{R}^k \times \{0\}$.[1109]

Note that projection onto the hyperplane that is orthogonal to v is the identity on $\mathbb{R}^k \times \{0\}$. Thus as in the proof of Proposition 65.11 we can lower the dimension by one without losing any of the desired properties. □

As happens so often in mathematics, the proof of a result immediately invites new questions. For example, in light of Propositions 65.11 and 65.13 the following question arises.

[1108] It follows from Lemma 3.15 (2) that these two maps are smooth.

[1109] Here we need that we have "extra k dimensions", i.e. we need that $n > 2m + 1 + k$.

Question 65.14. *For a given (topological) manifold M, e.g. $M = \mathbb{R}\mathrm{P}^n$, what is the minimal $k \in \mathbb{N}$ such that M admits a (topological) embedding into $\mathbb{R}^k$?*

We will address this question in the following chapter.

We conclude this section with a discussion of the uniqueness of embeddings of a given manifold M into some $\mathbb{R}^n$. Let us consider the three embeddings $f_0, f_1, f_2 \colon S^1 \to \mathbb{R}^3$ that are shown in Figure 793. The embeddings f_0, f_1 are "essentially the same", in the sense that they are isotopic. On the other hand it follows from Lemma 18.6, Exercise 12.6 and the Isotopy Extension Theorem 10.21 that the two embeddings f_0 and f_2 are not isotopic.

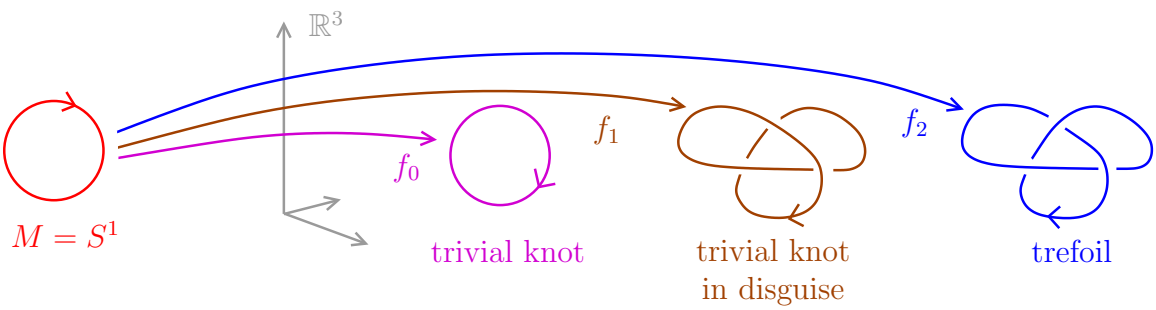

FIGURE 793.

Now we identify $\mathbb{R}^3$ with $\mathbb{R}^3 \times \{0\} \subset \mathbb{R}^4$. Therefore we can view the above embeddings f_0, f_1, f_2 as embeddings $f_0, f_2 \colon S^1 \to \mathbb{R}^4$. In Figure 794 we do our best to illustrate an isotopy $F \colon S^1 \times [0,1] \to \mathbb{R}^3 \times \mathbb{R}_{\geq 0} \subset \mathbb{R}^4$ from f_2 to f_1. The key to the understanding of the figure is that we use "pinkness" as the fourth coordinate, i.e. two points in $\mathbb{R}^3$ with different levels of "pinkness" differ in the fourth coordinate. With this convention the map $F \times S^1 \times [0,1] \to \mathbb{R}^3 \times \mathbb{R}_{\geq 0}$ shown in Figure 794 has the property that each F_t is an embedding. We have thus shown that f_2, f_1, viewed as embeddings into $\mathbb{R}^4$, are isotopic. In Exercise 65.5 we will in fact see that all embeddings of S^1 into $\mathbb{R}^3$ become isotopic once we view them as embeddings into $\mathbb{R}^4$.

In the above longish example we have seen that non-isotopic embeddings can become isotopic once we add extra dimensions. The following proposition shows that this phenomenon holds in general. More precisely, the proposition says that any two embeddings of a given closed manifold into some $\mathbb{R}^k$ become isotopic if we are allowed to increase the dimensions.

Proposition 65.15. *Let M be a closed manifold. Suppose we are given two embeddings $f_0, f_1 \colon M \to \mathbb{R}^k$. There exists a smooth isotopy $F \colon M \times [0,1] \to \mathbb{R}^{2k}$ such that for $i = 0, 1$*

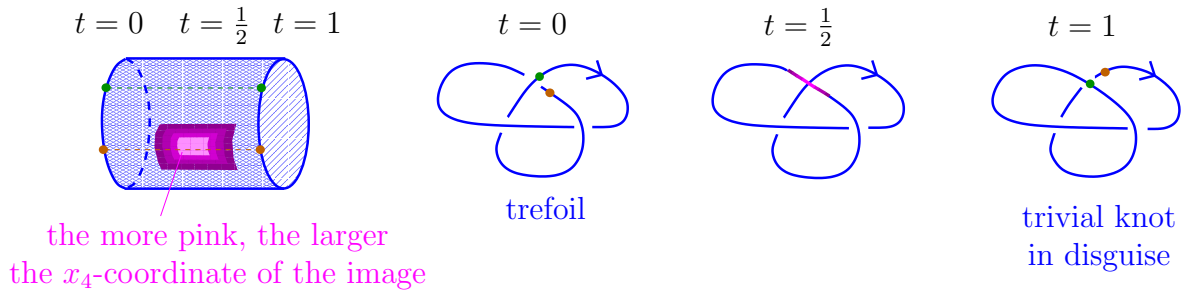

FIGURE 794.

the following diagram commutes

$$\begin{tikzcd} & M \arrow[dl, "f_i"'] \arrow[dr, "F_i"] & \\ \mathbb{R}^k \arrow[rr, "x\mapsto(x,0)"'] & & \mathbb{R}^{2k}. \end{tikzcd}$$

Proof. By Lemma 3.12 there exists a smooth function $\nu\colon [0,1]\to[0,1]$ with $\nu(t)=1$ for $t\in[0,\frac{1}{4}]$ and $\nu(t)=0$ for $t\in[\frac{3}{4},1]$. We consider the map

$$\begin{aligned} F\colon M\times[0,1] &\to \mathbb{R}^{2k} \\ (x,t) &\mapsto (\underbrace{f_0(x)\cdot\nu(t)+f_1(x)\cdot(1-\nu(t))}_{\in\mathbb{R}^k}, \underbrace{f_0(x)\cdot(1-\nu(t))\cdot\nu(t)}_{\in\mathbb{R}^k}). \end{aligned}$$

It is straightforward to verify that F is a smooth isotopy and that F makes the given diagram commute for $i=0,1$. □

The final proposition of this section is the "boundary version" of Proposition 65.15. This proposition will play an important role later on. But till then it is best to ignore it.

Proposition 65.16. $(*)$ *Let M be a compact manifold and let Y be a (possibly empty) union of boundary components of M. Suppose we are given two proper embeddings $f_0, f_1\colon M\to H_k$.*

(1) *If $f_0|_Y=f_1|_Y$, then there exists a proper smooth isotopy $F\colon M\times[0,1]\to H_{2k}$ rel Y such that for $i=0,1$ the following diagram commutes*

$$\begin{tikzcd} & M \arrow[dl, "f_i"'] \arrow[dr, "F_i"] & \\ H_k \arrow[rr, "x\mapsto(0,x)"'] & & H_{2k}. \end{tikzcd}$$

(2) *If $f_0(Y)=f_1(Y)$, then there exists a proper smooth isotopy $F\colon M\times[0,1]\to H_{2k}$ rel Y such that for $i=0,1$ the image of $f_i(M)$ under the obvious inclusion $H_k\to H_{2k}$ agrees with $F_i(M)$.*

The analogous statements also hold if we replace H_k by $[0,1]\times\mathbb{R}^{k-1}$ and if we replace H_{2k} by $[0,1]\times\mathbb{R}^{2k-1}$.

Proof $(*)$.

(1) We suppose that $f_0|_Y = f_1|_Y$. As in the proof of Proposition 65.15 we pick a smooth function $\nu\colon [0,1]\to[0,1]$ with $\nu(t)=1$ for $t\in[0,\frac{1}{4}]$ and $\nu(t)=0$ for $t\in[\frac{3}{4},1]$. Furthermore, as in the proof of Proposition 65.13 we pick a collar $\partial M\times[0,1]$, we pick a non-decreasing smooth function $\eta\colon[0,1]\to[0,1]$ with $\eta(t)=t$ for all $t\in[0,\frac{1}{4}]$ and with $\eta(t)=1$ for all $t\in[\frac{1}{2},1]$ and we consider the smooth functions

$$\begin{array}{rcl} \mu\colon M & \to & [0,1] \\ P & \mapsto & \begin{cases} \eta(t), & \text{if } P=(Q,t) \text{ with } Q\in Y \text{ and } t\in[0,1], \\ 1, & \text{otherwise} \end{cases} \end{array}$$

and

$$\begin{array}{rcl} \epsilon\colon M & \to & [0,1] \\ P & \mapsto & \begin{cases} \eta(t), & \text{if } P=(Q,t) \text{ with } Q\in \partial M \text{ and } t\in[0,1], \\ 1, & \text{otherwise.} \end{cases} \end{array}$$

Finally we consider the map

$$\begin{aligned} F\colon M\times[0,1] &\to \mathbb{R}^k\times H_k = H_{2k} \\ (x,t) &\mapsto (\underbrace{\mu(x)\cdot(f_0(x)\cdot(1-\eta(t))\cdot\eta(t))}_{\in\mathbb{R}^k}, \underbrace{f_0(x)\cdot\eta(t)+f_1(x)\cdot(1-\eta(t))+\epsilon(x)\cdot e_k}_{\in H_k}). \end{aligned}$$

It is straightforward to verify that F is a proper smooth isotopy rel Y and that F makes the given diagram commute for $i=0,1$.

(2) Now we only suppose that $f_0(Y)=f_1(Y)$. We consider the map $\varphi := f_1^{-1}\circ f_0\colon M\to M$. By Proposition 10.1 (2) we know that φ is a diffeomorphism of M. Note that the embeddings $f_0\colon M\to H_k$ and $f_1\circ\varphi\colon M\to H_k$ agree on Y. Thus we can apply (1). The proper smooth isotopy that we obtain this way evidently has the desired property.

The above proofs also apply, with minuscule modifications, if we replace H_k by $[0,1]\times\mathbb{R}^{k-1}$ and if we replace H_{2k} by $[0,1]\times\mathbb{R}^{2k-1}$. □

Example. We consider the two embeddings $f_0, f_1\colon M=[0,1]\to H_3$ shown in Figure 795. They agree on $Y=\{0\}$. By Proposition 65.16 these two embeddings become isotopic rel Y if we view f_0 and f_1 as embeddings into H_6.

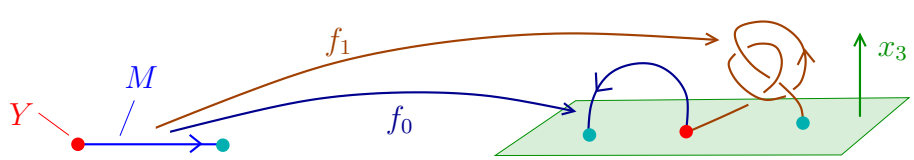

FIGURE 795.

65.4. **The Whitney Embedding Theorem** (∗)**.** In this section we state several propositions and theorems that generalize the results from the previous section to larger classes of manifolds and that give slightly improved bounds on the dimensions required to obtain (unique) embeddings. We will not make use of the results, therefore we will not provide any proofs.

The following proposition can be viewed as a moderately difficult generalization of Proposition 65.11.

Proposition 65.17.

(1) *Every n-dimensional manifold M without boundary admits a proper embedding $f\colon M \to \mathbb{R}^{2n+1}$ such that $f(M)$ is a closed subset of $\mathbb{R}^{2n+1}$.*
(2) *Every n-dimensional manifold M with non-empty boundary admits a proper embedding $f\colon M \to H_{2n+1}$ such that $f(M)$ is a closed subset of H_{2n+1}.*

Proof. As indicated above, it is an entertaining and slightly challenging exercise to modify the proofs of Proposition 65.11 and 65.13 to obtain the results. The argument is carried out in [Why, Theorem 1], [Bre, Theorem II.10.8], [Hirs, Theorems 1.3.5 and 1.4.3] and [Le2, Theorem 6.15]. □

Remark. Note that in Proposition 65.17 it is essential that manifolds are, by definition, second-countable. If we did not make this assumption, then any set with the discrete topology would be a 0-dimensional manifold, but there are sets whose cardinality is bigger than the cardinality of any $\mathbb{R}^n$. More precisely, by Cantor's Theorem, see page 255, the power set of $\mathbb{R}$ does not admit an injection into any $\mathbb{R}^n$.

In Propositions 65.11, 65.13 and 65.17 we had in particular seen that every n-dimensional manifold admits an embedding into $\mathbb{R}^{2n+1}$. The following theorem decreases the dimension by one. Even though this looks like a minor achievement, the proof of the Whitney Embedding Theorem is quite intricate.

Theorem 65.18. (Whitney Embedding Theorem) *Every n-dimensional manifold admits an embedding into $\mathbb{R}^{2n}$.*

Proof. This result was first proved by Hassler Whitney [Why2, p. 236] in 1944. For closed manifolds more recent accounts of the proof can be found in [Adac, Theorem II.2.11] or [Pra, Chapter 6.3]. □

Remark.

(1) By [Why3, p. 247] every n-dimensional manifold, with $n \geq 2$, can be immersed into $\mathbb{R}^{2n-1}$.
(2) Under some extra conditions one can obtain better results. For example we saw on page 210 that every closed orientable 2-dimensional manifold embeds into $\mathbb{R}^3$. Furthermore Hirsch [Hirs2] and Wall [Wall5] showed that every 3-dimensional manifold embeds into $\mathbb{R}^5$. Finally for $n > 4$ Haefliger-Hirsch [HH, Theorem 1.2] showed that every closed orientable n-dimensional manifold embeds into $\mathbb{R}^{2n-1}$.

(3) In [Mun3, p. 315] it is shown that every n-dimensional topological manifold admits a topological embedding into $\mathbb{R}^{2n+1}$. At least for compact topological manifolds one can actually find a topological embedding into $\mathbb{R}^{2n}$. We refer to [MeS, Corollary 4.14] and [BrM] for details.
(4) If M and N are two manifolds that can be embedded (respectively immersed) into $\mathbb{R}^n$, then the construction in [Hae, Chapter 1] [Hae2, Chapter 3] shows that the connected sum $M\#N$ can also be embedded in $\mathbb{R}^n$.

The following theorem is a refinement of Propositions 65.15 and 65.16.

Theorem 65.19.

(1) *Let M be a closed n-dimensional manifold. If $m \geq 2n+1$ and $m \geq n+3$, then any two embeddings $f_0, f_1 \colon M \to \mathbb{R}^m$ are smoothly isotopic.*
(2) *Let M be a compact n-dimensional manifold. If $m \geq 2n+1$ and $m \geq n+3$, then any two proper embeddings $f_0, f_1 \colon M \to H_m$ are related by a proper smooth isotopy.*

Proof. Both statements follow from [Hud, Theorem 4]. For connected manifolds the first statement also follows from [Hae, p. 47]. □

Remark.

(1) We consider again the two embeddings $f_0, f_2 \colon S^1 \to \mathbb{R}^3$ from Figure 793. As we pointed out on page 1517, these two embeddings are not isotopic. This shows that in Theorem 65.19 we not only need the condition that $m \geq 2n+1$ (which is satisfied in this example) but also the condition that $m \geq n+3$.
(2) The statements of Theorem 65.19 can be generalized considerably, in particular the target manifolds do not necessarily need to be $\mathbb{R}^m$ and H_m. We refer to [Hae, p. 47], [Hud] and [Sko] for many generalizations.

65.5. **Neighborhood retracts.** We recall two definitions from pages 307 and 130 and we introduce two related definitions.

Definition. Let X be a topological space.

(1) We say X is *contractible* if X is homotopy equivalent to a point.
(2) We say X is *locally contractible* if given any $Q \in X$ and any neighborhood U of Q there exists an open neighborhood V of Q that is contained in U and that is contractible.
(3) We say that a subset U of X is *contractible in X* if the inclusion map $U \to X$ is homotopic to a constant map.
(4) We say X is *weakly o-locally contractible* if given any $Q \in X$ and any neighborhood U of Q there exists an open neighborhood V of Q that is contained in U and that is contractible in U.

Examples.

(1) It follows almost immediately from the definitions that a topological space that is o-locally contractible is also weakly o-locally contractible.

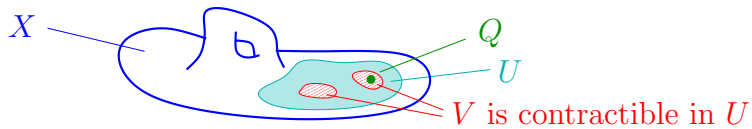

FIGURE 796.

(2) It is straightforward to verify that topological manifolds are o-locally contractible.
(3) In Proposition 26.11 (6) we showed that CW-complexes are o-locally contractible. In particular topological graphs and spatial graphs are o-locally contractible.
(4) It is easy to show that $\mathbb{R}^2 \setminus \{\frac{1}{n} \,|\, n \in \mathbb{N}\}$ is not weakly o-locally contractible.
(5) It is an amusing exercise to show that the topologist's sine curve

$$\big\{(0,y) \,\big|\, y \in [-1,1]\big\} \cup \big\{(x, \sin(\tfrac{1}{x})) \,\big|\, x \in (0,\pi]\big\} \;\subset\; \mathbb{R}^2,$$

which we had initially introduced on page 123, is not weakly o-locally contractible.
(6) It is an amusing (but not entirely trivial) exercise to come up with a subset of some $\mathbb{R}^n$ that is weakly o-locally contractible but not o-locally contractible.

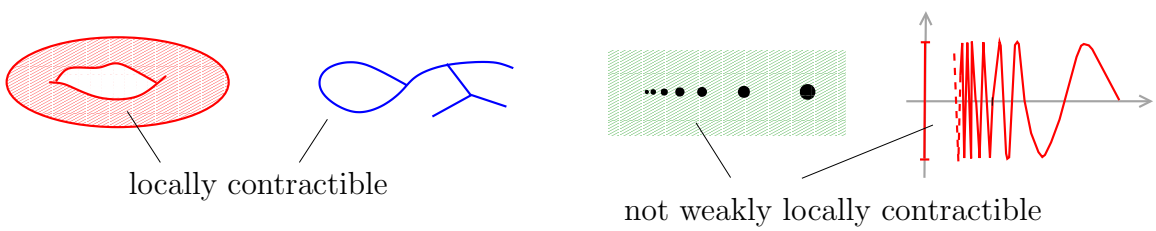

FIGURE 797.

Definition. Let X be a topological space and let A be a subset. We say A is a *neighborhood retract* if there exists a neighborhood N of A such that A is a retract of N.

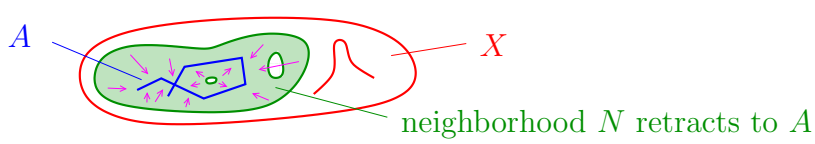

FIGURE 798.

Examples.

(1) It follows from Proposition 64.2 that every finite spatial graph in $\mathbb{R}^n$ is a neighborhood retract.

(2) Let M be a manifold. By the Regular Neighborhood Theorem 64.5 every compact proper submanifold of M is a neighborhood retract.
(3) We will see in Exercise 65.4 that $A = \{\frac{1}{n} \mid n \in \mathbb{N}\}$, viewed as a subset of $X = \mathbb{R}^2$, is not a neighborhood retract.

We continue with the following fairly elementary lemma.

Lemma 65.20. *Let X be a subset of $\mathbb{R}^n$. If X is a neighborhood retract, then it is also weakly o-locally contractible.*

Proof $(*)$. Let W be a neighborhood of X that admits a retraction $r\colon W \to X$. Let $Q \in X$ and let U be a neighborhood of Q in X. Since W is open there exists an $s > 0$ such that $B_s(Q) \subset r^{-1}(U)$. We denote by $F\colon B_r(Q) \times [0,1] \to B_r(Q)$ the obvious homotopy from the identity to the constant map. Then $r \circ F$ restricts to a homotopy $(B_s(Q) \cap X) \times [0,1] \to U$ from the identity to a constant map. In particular $V := B_s(Q) \cap X$ is contractible in U. $\square$

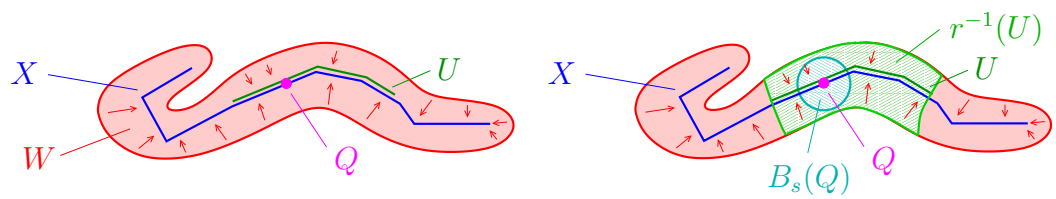

FIGURE 799. Illustration of the proof of Lemma 65.20.

It is rather stunning that for compact subsets the converse to Lemma 65.20 holds. More precisely, the following theorem was proved by Karol Borsuk [Bor] in 1932.[1110]

Theorem 65.21. (Borsuk Theorem *Let X be a compact subset of $\mathbb{R}^n$. If X is weakly o-locally contractible, then it is a neighborhood retract.*[1111]

Remark.

(1) It is fairly easy to modify the proof of Theorem 65.21 to show that the statement also holds for subsets of $\mathbb{R}^n$ that are weakly o-locally contractible and that are *locally* compact, see [Bre, Theorem E.3] for details. We will not make use of this more general statement.

[1110]Karol Borsuk (1905-1982) was a Polish mathematician. He lost his job at the university of Warsaw after the German invasion in 1939. To survive financially he developed a board game and produced and sold it during the war. Almost all copies of the game were lost during the Warsaw uprising in 1944, but in the 1990s one surviving copy was found and the game was republished. We refer to

`https://en.wikipedia.org/wiki/Animal_Husbandry_(game)`

for more details.

[1111]Is is worth stressing that the proposition does *not* claim that X is a *deformation retract* of a neighborhood of X.

(2) In the literature, see e.g. [Dol, Bre], a topological space X is called a *Euclidean neighborhood retract* if there exists a subset Y of some $\mathbb{R}^n$ which is homeomorphic to X and that is a neighborhood retract. In this language Theorem 65.21, with the slight strengthening of (1) says that every o-locally compact, weakly o-locally contractible topological space that admits a topological embedding into some $\mathbb{R}^n$ is a Euclidean neighborhood retract.

Before we provide the proof of Theorem 65.21 it is convenient to introduce one definition and to prove one lemma.

Definition. Let $k \in \mathbb{N}_0$ and let $n \in \mathbb{N}$. A $\frac{1}{2^k}$*-cube* is a subset C of $\mathbb{R}^n$ of the form

$$C \;=\; \left[\tfrac{a_1}{2^k}, \tfrac{a_1+1}{2^k}\right] \times \cdots \times \left[\tfrac{a_n}{2^k}, \tfrac{a_n+1}{2^k}\right] \quad \text{with } a_1, \dots, a_n \in \mathbb{Z}.$$

Put differently, a $\frac{1}{2^n}$-cube is a cube with side length $\frac{1}{2^k}$ and where the coordinates of all vertices lie in $\frac{1}{2^k} \cdot \mathbb{Z}$.

Lemma 65.22. *Let $x \in \mathbb{R}^n$ and let $r > 0$. If $k \in \mathbb{N}_0$ is chosen such that $\frac{1}{2^k} < \frac{1}{3\sqrt{n}} \cdot r$, then there exist finitely many $\frac{1}{2^k}$-cubes $W_1, \dots, W_m$ such that*

$$x \;\in\; \textit{interior of } W_1 \cup \cdots \cup W_m \;\subset\; W_1 \cup \cdots \cup W_m \;\subset\; B_r(x).$$

Proof. We write $x = (x_1, \dots, x_n)$ and we write $\epsilon = \frac{1}{2^k}$. For $i = 1, \dots, n$ we denote by y_i the result of rounding x_i down to the closest number in $\mathbb{Z} \cdot \epsilon$. Clearly we have

$$(x_1, \dots, x_k) \;\in\; \big[y_1, y_1{+}\epsilon\big] \times \cdots \times \big[y_n, y_n{+}\epsilon\big] \;\subset\; \text{interior of } \underbrace{\big[y_1{-}\epsilon, y_1{+}2\epsilon\big] \times \ldots \times \big[y_n{-}\epsilon, y_n{+}2\epsilon\big]}_{=:V}.$$

Since V is the union of finitely many ϵ-cubes it suffices to show that V is contained in $B_r(x)$. Thus let $y \in V$. We have

$$d(y,x) \;\underset{\substack{\uparrow \\ \text{since } x \in V}}{\leq}\; \text{diameter of } V \;\underset{\substack{\uparrow \\ \text{see page 137}}}{=}\; 3\sqrt{n} \cdot \epsilon \;=\; 3\sqrt{n} \cdot \tfrac{1}{2^k} \;\underset{\substack{\uparrow \\ \text{choice of } k}}{<}\; r$$

which means of course that $y \in B_r(x)$. Thus we have shown that $V \subset B_r(x)$. □

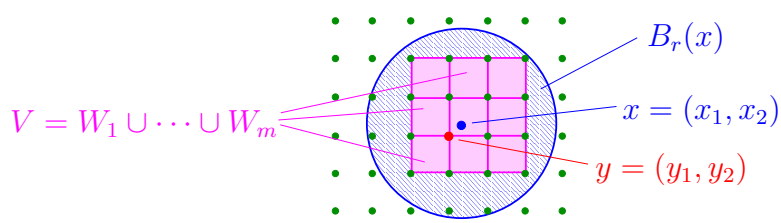

FIGURE 800. Illustration of the proof of Lemma 65.22.

Proof of Theorem 65.21. Let X be a compact, weakly o-locally contractible subset of $\mathbb{R}^n$. Evidently we only have to consider the case that X is non-empty. We introduce the following notation.

(1) We define C_1 to be the union of all 1-cubes that do not intersect X.
(2) We define C_2 to be the union of all $\frac{1}{2}$-cubes that do not intersect $\mathring{C}_1$ and that do not intersect X.
(3) We iterate this process, i.e. for any $k \geq 3$ we define C_k to be the union of all $\frac{1}{2^k}$-cubes that do not intersect the interior of $C_1 \cup \cdots \cup C_{k-1}$ and that do not intersect X.

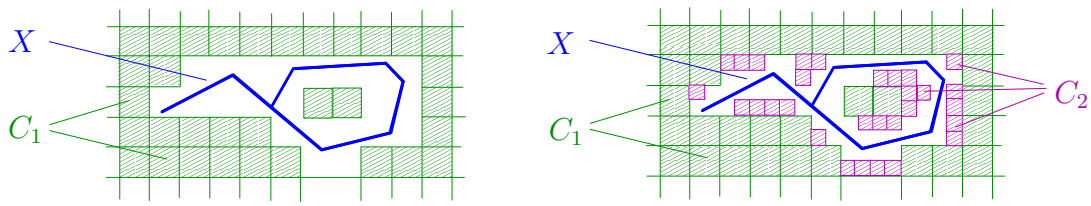

FIGURE 801.

Claim.

(1) We have $\bigcup_{k\in\mathbb{N}} C_k = \mathbb{R}^n \setminus X$.
(2) Given any $x_0 \in \mathbb{R} \setminus X$ there exists an open neighborhood U that intersects only finitely many cubes of $C_1, C_2, \ldots$.

Let $x_0 \in \mathbb{R}^n \setminus X$. Since X is compact we can apply Corollary 1.56 to find an $r > 0$ such that $B_r(x_0) \subset \mathbb{R}^n \setminus X$. We pick $k \in \mathbb{N}_0$ such that $\frac{1}{3\sqrt{n}\cdot 2^k} < r$. By Lemma 65.22 there exist finitely many $\frac{1}{2^k}$-cubes $W_1, \ldots, W_m$ such that

$$x_0 \in \underbrace{\text{interior of } W_1 \cup \cdots \cup W_m}_{:=U} \subset B_r(x).$$

This implies in particular that x_0 is contained in C_k or it is contained already in one of $C_1, \ldots, C_{k-1}$. Furthermore it is fairly easy to see that if U intersects a $\frac{1}{2^m}$-cube with $m \geq k$ it already intersects a $\frac{1}{2^k}$-cube. It follows from this observation and the iterative definition of the C_i that U intersects only finitely many cubes of $C_1, C_2, \ldots$. This concludes the proof of the claim.

We view each C_i as a CW-complex in the obvious way: the n-cells correspond precisely to the cubes and the lower dimensional cells correspond precisely to the faces of the cubes. For each k the union $C_1 \cup \cdots \cup C_k$ is also a CW-complex in an obvious way and finally we can also view the union $C := \bigcup_{k\in\mathbb{N}} C_k = \mathbb{R}^n \setminus X$ as a CW-complex. We leave it as an exercise to verify, using statement (2) of the claim, that the topology on this CW-complex, given by the weak topology defined on page 654, agrees with the usual subspace topology on $\mathbb{R}^n \setminus X$.

We continue with the following definition: given a cell σ of C and a map $f\colon \sigma \to X$ we define[1112]

$$\rho(f) \;:=\; \max\{d(z, f(z)) \,|\, z \in \sigma\}.$$

We start with the iterative definition of a subset of $\mathbb{R}^n$ together with a map to X.

(a) We denote by A_0 the 0-skeleton of C. Next we define a map $r_0\colon A_0 \to X$. Let $a \in A_0$. Since X is compact it follows from Corollary 1.56 that we can find a point $r_0(a) \in X$ with $d(a, r_0(a)) = d(a, X)$.

(b) Now suppose inductively that we have defined a map $r_i\colon A_i \to X$ on a union A_i of some of the i-cells of C. We define the next set A_{i+1} and the corresponding map $r_{i+1}\colon A_{i+1} \to X$ as follows:

(b$_1$) Let σ be an $(i+1)$-cell of C for which r_i is defined on $\partial\sigma$. Suppose that σ can be extended to a map $r_{i+1}\colon \sigma \to X$ that agrees with r_i on $\partial\sigma$. Then we pick a map $r_{i+1}\colon \sigma \to X$ with $r_{i+1}|_{\partial\sigma} = r_i$ such that

$$\rho(r_{i+1}) \;\le\; 2 \cdot \underbrace{\inf\{\rho(g) \,|\, g\colon \sigma \to X \text{ is a map with } g|_{\partial\sigma} = r_i|_{\partial\sigma}\}}_{\ge\, d(\sigma, X) \text{ which in turn is } > 0 \text{ by Corollary 1.56}}.$$

(b$_2$) We denote by A_{i+1} the union of all $(i+1)$-cells as in (b$_1$) and we define r_{i+1} on A_{i+1} as in (b$_1$).

(c) We set $A := \bigcup_{i\in\mathbb{N}} A_i \cup X$ and we define $r\colon A \to X$ to be the unique map that equals r_i on each A_i and that is the identity on X.

We refer to Figure 802 for an illustration. It remains to show that the set A is a neighbor-

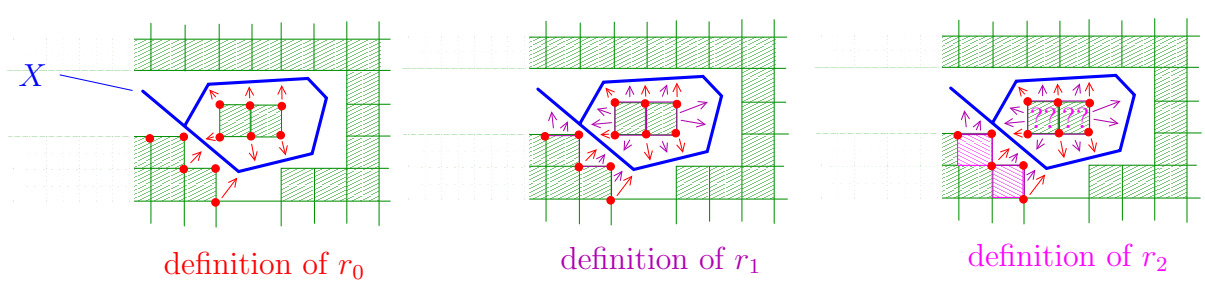

FIGURE 802.

hood of X and that the map $r\colon A \to X$ is continuous. Both statements follow from the following claim.

Claim. Given any $x \in X$ and any $\epsilon_0 > 0$ there exists an open neighborhood U that is contained in A and such that $|\underbrace{r(x)}_{=x} - r(y)| < \epsilon_0$ for all $y \in U$, i.e. such that $r(U) \subset B_{\epsilon_0}(x)$.

[1112]Note hat σ is compact, hence the maximum exists by Lemma 1.37 (2).

So let $x \in X$ and let $\epsilon_0 > 0$. We adopt the following notation: given $\mu > 0$ we write $W(\mu) = X \cap B_\mu(x)$.

Subclaim. We can find $\epsilon_1, \dots, \epsilon_{2n}$ with the following two properties:

(1) for each $i \in \{0, \dots, 2n-1\}$ we have $\epsilon_{i+1} < \frac{1}{3} \cdot \epsilon_i$,
(2) for every $i = 1, \dots, 2n$ the subset $W(\epsilon_i)$ is contractible in $W(\epsilon_{i-1})$.

So suppose that we have already found $\epsilon_0, \dots, \epsilon_i$ for some $i \in \{0, \dots, 2n-1\}$ with the desired properties. Since X is weakly o-locally contractible we can find an open neighborhood U of x in X that is contained in $W(\epsilon_i)$ and that is contractible in $W(\epsilon_i)$. Since U is open there exists an $\epsilon_{i+1} < \frac{1}{3}\epsilon_i$ such that $W(\epsilon_{i+1}) \subset U$. Since U is contractible in $W(\epsilon_i)$ the subset $W(\epsilon_{i+1})$ is also contractible in $W(\epsilon_i)$. We refer to Figure 803 for an illustration. This concludes the proof of the subclaim.

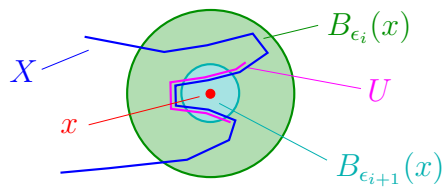

FIGURE 803.

We set $U := B_{\frac{1}{4}\epsilon_{2n}}(x)$. It suffices to prove the following two subclaims.

Subclaim 1. For each $i = 0, \dots, n$ the map r is defined for each i-cell σ of the CW-complex C that lies in U and for each such σ we have $r(\sigma) \subset W(\epsilon_{2n-2i})$.

Subclaim 2. The union of X with all cells of C that lie in U is a neighborhood of x.

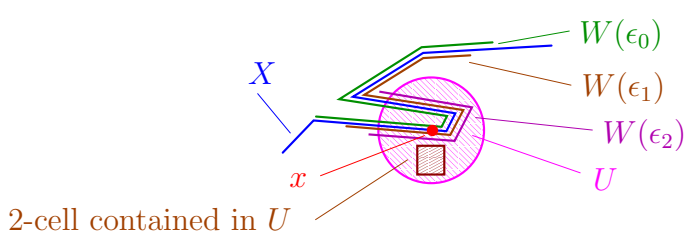

FIGURE 804.

First we prove Subclaim 1. We prove Subclaim 1 iteratively for $i = 0, 1, \dots, n$. We start out with $i = 0$. Thus we have to show that $r(U \cap A_0) \subset W(\epsilon_{2n})$. Therefore let $y \in U \cap A_0$. Then we have

$$d(x, r(y)) \underset{\substack{\uparrow \\ \text{triangle inequality and } r(y) = r_0(y)}}{\leq} d(x,y) + d(y, r_0(y)) \underset{\substack{\uparrow \\ \text{by (a) since } x \in X}}{\leq} d(x,y) + d(y,x) = 2d(x,y) \underset{\substack{\uparrow \\ \text{since } y \in U = B_{\frac{1}{4}\epsilon_{2n}}(x)}}{<} 2 \cdot \frac{1}{4} \cdot \epsilon_{2n} = \frac{1}{2} \cdot \epsilon_{2n}.$$

But since $r(y) \in X$ this means precisely that $r(y) \in W(\epsilon_{2n}) = X \cap B_{\epsilon_{2n}}(x)$. This shows that Subclaim 1 holds for $i = 0$.

Now suppose that Subclaim 1 holds for some $i \in \{0, \dots, n-1\}$. Let σ be an $(i+1)$-cell of the CW-complex C inside U. Since $r(\partial\sigma) \subset W(\epsilon_{2n-2i})$ and since $W(\epsilon_{2n-2i})$ is contractible in $W_{2n-2i-1}$ it follows from Proposition 1.47 and Proposition 28.7 (2) that we can extend $r|_{\partial\sigma} = r_i|_{\partial\sigma}$ to a map $s\colon \sigma \to W(\epsilon_{2n-2i-1})$. By definition of A_{i+1} this implies that $\sigma \subset A_{i+1}$. In particular r is defined on σ. It remains to show that $r(\sigma) \subset W(\epsilon_{2n-2i-2})$. Thus let $y \in \sigma$. We have

$$\begin{aligned}
d(x, r(y)) &\underset{\substack{\uparrow \\ \text{since } r(y) = r_{i+1}(y)}}{\leq} d(x, r_{i+1}(y)) \underset{\substack{\uparrow \\ \text{by definition}}}{\leq} \rho(r_{i+1}) \underset{\substack{\uparrow \\ \text{by } (\mathrm{b}_1)}}{\leq} 2 \cdot \inf\{\rho(g) \,|\, g\colon \sigma \to X \text{ and } g|_{\partial\sigma} = r_i|_{\partial\sigma}\}. \\
&\underset{\substack{\uparrow \\ \text{since } s \text{ is such a map}}}{\leq} 2\cdot\rho(s) = 2\cdot\max\{d(z, s(z)) \,|\, z \in \sigma\} \underset{\substack{\uparrow \\ \text{triangle inequality}}}{\leq} 2\cdot\max\{d(z, x) + d(x, s(z)) \,|\, z \in \sigma\} \\
&\underset{\substack{\uparrow \\ \text{since } \sigma \subset U = B_{\frac{1}{4}\epsilon_{2n}}(x) \text{ and since for each} \\ z \in \sigma \text{ we have } s(z) \in W(\epsilon_{2n-2i-1}) \subset B_{\epsilon_{2n-2i-1}}(x)}}{\leq} 2\cdot\left(\frac{1}{4}\epsilon_{2n} + \epsilon_{2n-2i-1}\right) = \frac{1}{2}\cdot\epsilon_{2n} + 2\cdot\epsilon_{2n-2i-1} \underset{\substack{\uparrow \\ \text{since for each } j \text{ we have } \epsilon_{j+1} \leq \frac{1}{3}\epsilon_j}}{\leq} \frac{2}{9}\cdot\epsilon_{2n-2i-2} + \frac{2}{3}\cdot\epsilon_{2n-2i-2} \leq \epsilon_{2n-2i-2}.
\end{aligned}$$

This concludes the proof that $r(\sigma) \subset W(\epsilon_{2n-2i-2})$. In particular this concludes the proof of Subclaim 1.

Finally it remains to prove Subclaim 2. We set $s = \frac{1}{4}\epsilon_{2n}$. As a reminder, we have to show that the union of X with all cells of C that lie in $B_s(x)$ is a neighborhood of x. Let W be a $\frac{1}{2^k}$-cube with $W \cap B_{\frac{s}{2}}(x) \neq \varnothing$ and $W \cap (\mathbb{R}^n \setminus B_s(x)) \neq \varnothing$. It follows that the diameter of W is at least $\frac{s}{2}$ which in turn implies that $\frac{\sqrt{n}}{2^k} \geq \frac{s}{2}$. We set $k_0 = \lfloor \ln_2(\frac{2\sqrt{n}}{s}) \rfloor$. We see that

$$\begin{aligned}
&\text{union of } X \text{ with all cells of } C \text{ that lie in } B_s(x) \\
&\supset \text{union of } X \text{ with all cubes of } C \text{ that lie in } B_s(x) \\
&\supset B_s(x) \setminus \text{union of all cubes of } C \text{ that are not contained in } B_s(x) \\
&\underset{\substack{\uparrow \\ \text{since } \mathbb{R}^n \setminus X = C}}{=} B_s(x) \setminus \text{union of all cubes of } C \text{ that are not contained in } B_s(x) \text{ but intersect } B_s(x) \\
&\underset{\substack{\uparrow \\ \text{definition of } k_0}}{\supset} B_s(x) \setminus \underbrace{\text{union of all } \tfrac{1}{2^k}\text{-cubes of } C \text{ with } k \leq k_0}_{\text{closed subset of } \mathbb{R}^n \text{ that does not contain } x}.
\end{aligned}$$

The last set is clearly an (open) neighborhood of x. But then the first set is also a neighborhood of x. This concludes the proof of Subclaim 2. □

The following proposition is a fairly straightforward consequence of Theorem 65.21. The proposition is a weak version of Theorem 45.1 that we had not proved.

Proposition 65.23. *Every compact topological manifold is a retract of a finite CW-complex.*

Using Proposition 65.23 we can now provide a proof for Proposition 45.2.

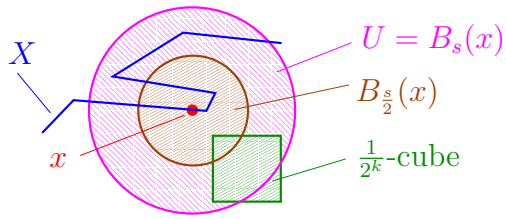

FIGURE 805. Illustration for the proof of Theorem 65.21.

Proof of Proposition 45.2. Let M be a compact, connected topological manifold. It follows from Proposition 65.23 that there exists a finite CW-complex X that contains M and which admits a retraction $r\colon X \to M$. If we denote by $i\colon M \to X$ the inclusion map, then $r \circ i = \mathrm{id}_X$. This implies that the map $r_*\colon \pi_1(X) \to \pi_1(M)$ is an epimorphism and it implies that for every abelian group G the maps $r_*\colon H_k(X;G) \to H_k(M;G)$ are epimorphisms. It follows from Proposition 27.12, Lemma 13.8, Proposition 35.5 and and the discussion on page 1010 that the fundamental group $\pi_1(M)$ is finitely presented and that the homology groups $H_k(M;G)$ are finitely generated. □

Before we prove Proposition 65.23 we make the following elementary observation.

Observation 65.24. *Let Z be a topological space and let K be a subset.*

(1) *Let $K \subset U \subset V \subset Z$ be subsets. If K is a retract of V, then K is also a retract of U.*
(2) *If K is a retract of a neighborhood it is also a retract of an open neighborhood.*

Proof. The first statement follows from the observation that the restriction of any retraction $r\colon V \to K$ to U is again a retraction. The second statement follows immediately from the first statement. □

Proof of Proposition 65.23. Let M be a compact topological manifold. It follows from Proposition 65.11 that there exists an $n \in \mathbb{N}$ and a topological embedding $M \to \mathbb{R}^n$. Since topological manifolds are weakly o-locally contractible we can apply Theorem 65.21. Together with Observation 65.24 (2) we obtain an open neighborhood U of $f(M)$ such that $f(M)$ is a retract of U. By the above, by Observation 65.24 (1) and by Lemma 1.37 it remains to prove the following claim.

Claim. Given any compact set K of an open subset U of $\mathbb{R}^n$ there exists a finite CW-complex X with $K \subset X \subset U$.

The idea is to define X to be the union of finitely many cubes. We set $r := d(K, \mathbb{R}^n \setminus U)$. Since K is compact and since U is open it follows easily[1113] from Corollary 1.56 that $r > 0$. We pick $k \in \mathbb{N}_0$ such that $\frac{1}{2^k} < \frac{1}{\sqrt{n}} \cdot r$. We denote by X the union of all $\frac{1}{2^k}$-cubes that intersect K. (See page 1524 for the definition of a $\frac{1}{2^k}$-cube.) Since K is compact we see

[1113] What is the "easy" argument?

that X is the union of finitely[1114] many $\frac{1}{2^k}$ cubes. The same argument as in the proof of Lemma 65.22 shows that each $\frac{1}{2^k}$-cube is contained in U. As in the proof of Theorem 65.21 we can view X as a finite CW-complex. This concludes the proof of the claim. □

FIGURE 806. Illustration of the proof of Proposition 65.23.

We conclude this chapter with the following proposition.

Proposition 65.25. *Let $f\colon M \to \mathbb{R}^n$ be a topological embedding of a compact topological manifold. There exists a compact n-dimensional submanifold X of $\mathbb{R}^n$ that contains $f(M)$ and such that $f(M)$ is a retract of X.*

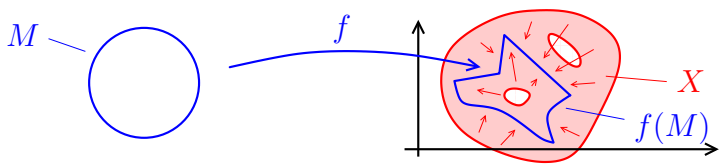

FIGURE 807. Illustration of Proposition 65.25.

Proof. Let $f\colon M \to \mathbb{R}^n$ be a topological embedding of a compact topological manifold. By Theorem 65.21 there exists an open neighborhood W of $f(M)$ such that $f(M)$ is a retract of W. Since W is an open subset of $\mathbb{R}^n$ it is in particular an n-dimensional manifold W. Therefore we can apply Proposition 65.4 and we obtain a sequence $X_1, X_2, \dots$ of subsets of W with the following three properties:

(a) the sequence is nested, i.e. for each $i \in N$ we have $X_i \subset X_{i+1}$,
(b) each X_i is a compact n-dimensional submanifold of W,
(c) we have $\bigcup_{i\in\mathbb{N}} \mathring{X}_i = W$ where $\mathring{X}_i := X_i \setminus \partial_0 X_i$.

We make the following observations:

(1) By Lemma 64.1 (3) each $\mathring{X}_i$ is an open subset of W and thus also of $\mathbb{R}^n$.
(2) It follows from (a), (c) and (1), the hypothesis that M is compact and Lemma 1.38 that there exists an $i \in \mathbb{N}$ such that $f(M) \subset X_i$.
(3) Since W is an open subset of $\mathbb{R}^n$ every submanifold of W is in fact also a submanifold of $\mathbb{R}^n$.

[1114]Why is that? Why do we need only finitely many such cubes?

It follows from this discussion and property (2) and Observation 65.24 (1) that $X := X_i$ has all the desired properties. $\square$

65.6. **Representing one-dimensional homology classes by submanifolds.** We start out with the following definition.

Definition. Let M be a manifold and let X be compact manifold. Let f and g be proper maps from X to M. A *proper homotopy* is a homotopy $F\colon [0,1] \times X \to M$ between f and g such that for each $t \in [0,1]$ the map $x \mapsto F(t,x)$ is a proper map. If such a proper homotopy exists, then we say that f and g are *properly homotopic*.

Now we can state the following theorem.

Theorem 65.26. *Let M be a manifold and let X be compact manifold. Furthermore let $f\colon X \to M$ be a proper map.*

(1) *The map f is properly homotopic to a proper smooth map $\widetilde{f}\colon X \to M$.*[1115]
(2) *If $\dim(M) = 2\cdot\dim(X)$, then the map f is properly homotopic to a proper immersion $\widetilde{f}\colon X \to M$ which has furthermore the property that there exist points $P_1, \dots, P_k$ in M with the following properties:*
   (a) *for each i the preimage $\widetilde{f}^{-1}(P_i)$ consists of precisely two points $Q_i^{\pm}$ which furthermore satisfy that $f_*(T_{Q_i^+}X) + f_*(T_{Q_i^-}X) = T_{P_i}(M)$,*
   (b) *the restriction of $\widetilde{f}$ to $X \setminus \{Q_1^{\pm}, \dots, Q_k^{\pm}\}$ is injective.*
(3) *If $\dim(M) \geq 2 \cdot \dim(X) + 1$, then the map f is properly homotopic to a proper embedding $\widetilde{f}\colon X \to M$.*[1116]

Furthermore, if f is already smooth on ∂X or if f is already an embedding on ∂X, then in (1) and (3) we can find a homotopy that is the identity on ∂X.

Example. In Figure 808 we consider $M = [-1,1] \times \mathbb{R}^2$ and a proper map $f\colon [-1,1] \to M$. We first see that f is homotopic to a proper smooth map and then we see that it is homotopic to a proper embedding.

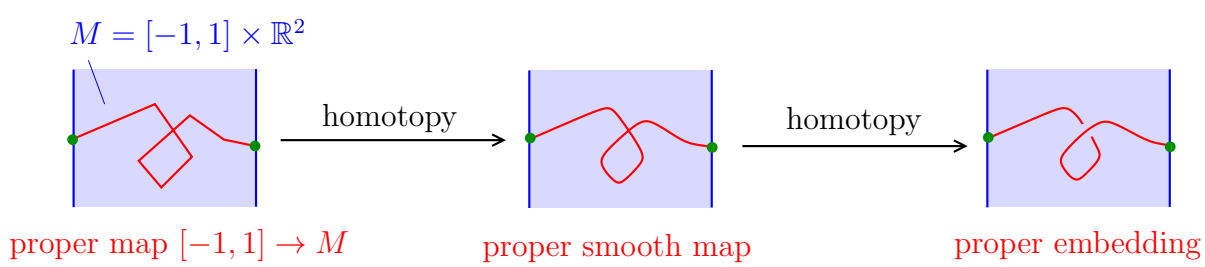

FIGURE 808. Illustration of Theorem 65.26.

[1115]This statement is very close to the statement of the Whitney Approximation Theorem 65.6.
[1116]Note that in general this statement is not true for $\dim(M) = 2 \cdot \dim(X)$. Why not?

Proof. The two statements are modest generalizations of [Hirs, Chapter 2, Theorem 2.6] and [Hirs, Chapter 2, Theorem 2.13]. □

We can now easily prove the following proposition.

Proposition 65.27. *Let M be an m-dimensional manifold with $m \geq 2$ and let A be a compact codimension zero submanifold of ∂M. Given any homology class in $\sigma \in H_1(M, A; \mathbb{Z})$ there exists an oriented proper 1-dimensional submanifold P with $\partial P \subset A$ such that $[P] = \sigma$.*

Sketch of proof. We only consider the case that $A = \varnothing$. We leave it to the reader to modify the proof to deal with the general case. Without loss of generality we can assume that M is connected. So let $x \in H_1(M; \mathbb{Z})$. By the Hurewicz Theorem 38.5, there exists a map $f\colon S^1 \to M$ such that $f_*([S^1]) = x$. Now we distinguish two cases.

(1) First we consider the case $m \geq 3$. Finally it follows from Theorem 65.26 (3) that f is homotopic to an embedding $g\colon S^1 \to M$. By Proposition 10.1 we know that the image $g(S^1)$ is a submanifold of M. It follows from Proposition 30.5 that $[g(S^1)] = g_*([S^1]) = f_*([S^1]) = x$.

(2) Now we consider the case $m = 2$. We apply Theorem 65.26 (2) to f to obtain a new map $\widetilde{f}\colon S^1 \to M$. This map is not an embedding but it has finitely many "transverse double points". We remove double points with the method shown in Figure 809. This way we obtain a submanifold of M. We leave it as an exercise to verify that it represents the homology class x, i.e. we leave it as an exercise to verify that this method from Figure 809 does not change the homology class. □

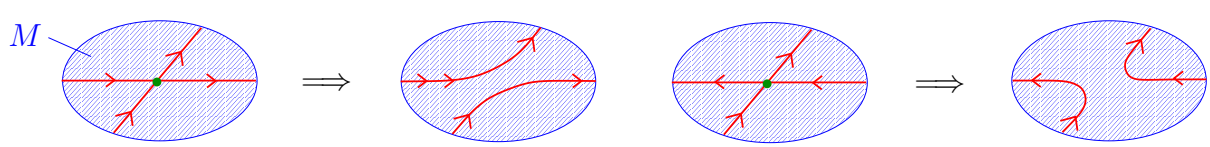

FIGURE 809.

We leave the proof of the following corollary to Proposition 65.27 as an exercise.

Corollary 65.28. *Let M be a connected manifold and let P, Q be two distinct points in M. Then there exists an embedding $\gamma\colon [0,1] \to M$ with $\gamma(0) = P$ and $\gamma(1) = Q$.*

Exercises for Chapter 65.

Exercise 65.1. Let $k < n$. Use the Whitney Approximation Theorem 65.6 and Proposition 3.47 to give a quick proof that $\pi_k(S^n) = 0$.

Exercise 65.2. Let M be a manifold and let V and W be two disjoint closed subsets. Show that for any $\epsilon > 0$ there exists a smooth function $f\colon M \to \mathbb{R}$ such that $f(V) \subset (-\epsilon, \epsilon)$ and $f(W) \subset (1-\epsilon, 1+\epsilon)$.
Hint: Use Urysohn's Lemma 1.45.

Exercise 65.3. Provide a proof for Proposition 65.10.

Exercise 65.4. We consider $\mathbb{Q}$ with the usual topology and we view it as a subset of $\mathbb{R}$. Show that there is no open neighborhood of $\mathbb{Q}$ that admits a retraction onto $\mathbb{Q}$.

Exercise 65.5. Let $f_0, f_1\colon S^1 \to \mathbb{R}^3$ be two embeddings. As usual we identify $\mathbb{R}^3$ with $\mathbb{R}^3 \times \{0\} \subset \mathbb{R}^4$. By Theorem 65.19 we know that $f_0, f_1\colon S^1 \to \mathbb{R}^4$ are isotopic. Show that f_0 and f_1 are also isotopic as maps $S^1 \to \mathbb{R}^3 \times \mathbb{R}_{\geq 0}$.
Hint: Consider Figure 794. Furthermore it might be useful to think of knots in terms of diagrams and to throw overboard any hopes of being 100% rigorous.

Exercise 65.6. Let M be a compact m-dimensional manifold. Show by hand that there exists an immersion $f\colon M \to \mathbb{R}^{2m}$.
Hint: Modify the proof of Proposition 65.11.

Exercise 65.7. We consider the Möbius band $M = ([0,1] \times [-1,1])/(0,x) \sim (1,-x)$ together with the projection map

$$\begin{array}{rcl} p\colon M = ([0,1] \times [-1,1])/\sim & \to & [0,1]/0 \sim 1 \\ [(x,y)] & \mapsto & [x]. \end{array}$$

Show that this map defines a linear interval bundle.

66. Alexander Duality

In this chapter we will study the Alexander Duality Theorem which, given a "reasonable" subset X of S^n relates the homology groups of $S^n \setminus X$ to the cohomology groups of X.

66.1. **The basic Alexander Duality Theorem.** We start out with the basic Alexander Duality Theorem which will be surprisingly easy to prove and which is already very helpful.

Theorem 66.1. (Alexander Duality Theorem) *Let K be a compact non-empty subset of S^n that admits a regular neighborhood. For any $i \in \mathbb{N}_0$ there exist isomorphisms*

$$\text{(a)} \qquad \widetilde{H}_i(S^n \setminus K; \mathbb{Z}) \;\cong\; \widetilde{H}^{n-i-1}(K; \mathbb{Z})$$

and

$$\text{(b)} \qquad \widetilde{H}^i(S^n \setminus K; \mathbb{Z}) \;\cong\; \widetilde{H}_{n-i-1}(K; \mathbb{Z}).$$

By the Regular Neighborhood Theorem 64.5 this conclusion holds for any closed non-empty submanifold of S^n. In this particular case the isomorphisms are natural.

Proof. Let K be a compact non-empty subset of S^n that admits a regular neighborhood N. We first consider statement (a) and the case that $i > 0$. In this case we have the following isomorphisms:

$$\begin{array}{ccccccc}
 & & & \text{Poincaré Duality Theorem 61.1 applied to } S^n \setminus \mathring{N}\text{, which is a compact manifold by Lemma 64.1 (4)} & & & \\
 & & & \downarrow & & & \\
\widetilde{H}_i(S^n \setminus K; \mathbb{Z}) & \xleftarrow{\cong} & \widetilde{H}_i(S^n \setminus \mathring{N}; \mathbb{Z}) & \xleftarrow{\cong} & H^{n-i}(S^n \setminus \mathring{N}, \partial N; \mathbb{Z}) & \xleftarrow{\cong} & H^{n-i}(S^n, N; \mathbb{Z}) \\
 & & \uparrow & & & & \uparrow \\
 & & \text{Lemmas 64.3 and 48.16 (6)} & & & & \text{Excision Theorem 45.8} \\
 & & \xleftarrow{\cong} \widetilde{H}^{n-i-1}(N; \mathbb{Z}) & & \xrightarrow{\cong} \widetilde{H}^{n-i-1}(K; \mathbb{Z}). & & \\
 & & \uparrow & & \uparrow & & \\
 & & \begin{array}{c}\text{by the long exact sequence in} \\ \text{reduced cohomology of the} \\ \text{pair } (S^n, N)\text{, see Lemma 48.17} \\ \text{here we use that } i > 0\end{array} & & \begin{array}{c}\text{by Lemma 48.16 (6) since } K \text{ is a} \\ \text{deformation retract of } N\end{array} & &
\end{array}$$

The case $i = 0$ is proved almost the same way. We leave it as an exercise to verify this case. This concludes the proof of (a). The proof of the existence of the isomorphism (b) is basically identical.

Finally suppose that K is a closed non-empty submanifold of S^n. It follows from the General Tubular Neighborhood Theorem 64.7 and Proposition 64.13 that we can take a tubular neighborhood as a regular neighborhood. By Proposition 64.9 tubular neighborhoods are unique in an appropriate sense which then allows us to get a natural isomorphism. □

Remark.

(1) The argument in the proof of the Alexander Duality Theorem 66.1 implies in particular that given any compact, non-empty n-dimensional submanifold W of S^n there

FIGURE 810. Illustration for the proof of the Alexander Duality Theorem 66.1.

exists an isomorphism

$$\widetilde{H}_i(S^n \setminus \mathring{W}; \mathbb{Z}) \;\cong\; \widetilde{H}^{n-i-1}(W; \mathbb{Z}).$$

(2) In Alexander Duality Theorem 66.1 we explicitly do not write "natural" isomorphism. The isomorphism that we construct in the proof depends on the choice of a regular neighborhood. It is not clear to me whether two regular neighborhoods are necessarily in any way "equivalent".

In practice we often like to consider objects that lie in $\mathbb{R}^n$ instead of S^n. The following variation of the Alexander Duality Theorem 66.1 deals with this situation.

Corollary 66.2. *Let K be a compact non-empty subset of $\mathbb{R}^n$. If K admits a regular neighborhood, then for any $i \in \mathbb{N}_0$ we have an isomorphism*

$$\widetilde{H}_i(\mathbb{R}^n \setminus K) \;\cong\; H^{n-i-1}(K).$$

By the Regular Neighborhood Theorem 64.5 this conclusion holds for any compact submanifold of $\mathbb{R}^n$.

Proof. Let K be a compact non-empty subset of $\mathbb{R}^n$ that admits a regular neighborhood N in $\mathbb{R}^n$. Recall that N is by definition compact. It follows easily that N is also a regular neighborhood for K in S^n. Now let $i \in \mathbb{N}_0$. Then

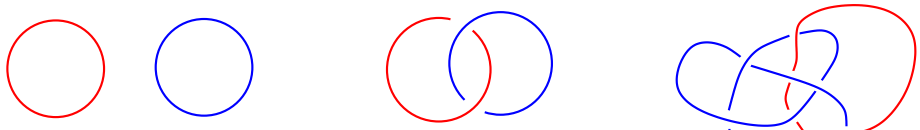
$$\begin{array}{ccccc} \widetilde{H}^{n-i-1}(K) & \cong & \widetilde{H}_i(S^n \setminus K) & \cong & \begin{cases} \widetilde{H}_i(\mathbb{R}^n \setminus K), & \text{if } i \neq n-1, \\ \widetilde{H}_{n-1}(\mathbb{R}^n \setminus K) \oplus \mathbb{Z}, & \text{if } i = n-1. \end{cases} \\ & & \uparrow & & \uparrow \\ & & \begin{array}{c}\text{Alexander Duality Theorem 66.1} \\ \text{which we can apply since } K \\ \text{admits a regular neighborhood in } S^n\end{array} & & \text{see Exercise 33.5} \end{array}$$

The corollary now follows from Lemmas 48.16 and 11.8 (1). □

In the remainder of this section we discuss a few applications of the Alexander Duality Theorem 66.1. The following definition generalizes the notion of a knot.

Definition. An *m-component link* is a 1-dimensional submanifold of S^3 that is diffeomorphic to the disjoint union of m circles.

The following lemma computes the homology groups of a link complement. It can be viewed as a generalization of Lemma 40.7 (5).



2-component trivial link Hopf link

FIGURE 811. Examples of 2-component links.

Lemma 66.3. *For any m-component link L in S^3 we have*

$$H_i(S^3 \setminus L; \mathbb{Z}) \;\cong\; \begin{cases} \mathbb{Z}^{m-1}, & \text{if } i = 2, \\ \mathbb{Z}^m, & \text{if } i = 1, \\ \mathbb{Z}, & \text{if } i = 0, \\ 0, & \text{otherwise.} \end{cases}$$

Proof. Let L be an m-component link. We calculate that

$$\widetilde{H}_i(S^3 \setminus L; \mathbb{Z}) \;\underset{\substack{\uparrow \\ \text{Alexander Duality Theorem 66.1}}}{\cong}\; \widetilde{H}^{2-i}(L; \mathbb{Z}) \;\cong\; \widetilde{H}^{2-i}(\underbrace{S^1 \sqcup \cdots \sqcup S^1}_{m\text{-copies}}; \mathbb{Z}) \;\cong\; \begin{cases} \mathbb{Z}^{m-1}, & \text{if } i = 2, \\ \mathbb{Z}^m, & \text{if } i = 1, \\ 0, & \text{otherwise.} \end{cases}$$

The lemma follows from this calculation together with Lemma 48.16 (3). □

For any 2-component link $L = K_1 \cup K_2$, for example for any of the links shown in Figure 811, we see that

$$H_1(S^3 \setminus L; \mathbb{Z}) \;\cong\; \mathbb{Z}^2 \quad \text{and} \quad H_2(S^3 \setminus L; \mathbb{Z}) \;\cong\; \mathbb{Z}.$$

The problem with this calculation is that we do not obtain any understanding of what the homology classes "look like". It seems reasonable to guess, along the lines of Lemma 40.7, that the first homology group is generated by the two meridians. But (a), we do not know how to prove it, and (b), we have no idea what a generator of the second homology group looks like. So the following question arises:

Question 66.4. *Given a link L, what are explicit bases for the homology groups of $S^3 \setminus L$?*

We will return to this question in a later chapter. We continue with another example.

Example. We consider the connected graph G with two vertices and three edges that is illustrated in Figure 812 on the left. On the right of Figure 812 we show a spatial graph G' in $S^3 = \mathbb{R}^3 \cup \{\infty\}$ that is homeomorphic to G. We have the following isomorphisms:

$$\widetilde{H}_i(S^3 \setminus G'; \mathbb{Z}) \;\underset{\substack{\uparrow \\ \text{by Proposition 64.2 we can apply} \\ \text{the Alexander Duality Theorem 66.1}}}{\cong}\; \widetilde{H}^{2-i}(G'; \mathbb{Z}) \;\cong\; \widetilde{H}^{2-i}(G; \mathbb{Z}) \;\underset{\substack{\uparrow \\ \text{similar to Lemma 40.17}}}{\cong}\; \begin{cases} \mathbb{Z}^2, & \text{if } i = 1, \\ 0, & \text{otherwise.} \end{cases}$$

In this case it is also rather unclear what a basis of $H_1(S^3 \setminus G; \mathbb{Z})$ should look like. Later on we will find an explicit basis for $H_1(S^3 \setminus G; \mathbb{Z})$.

graph G — the spatial graph G' in $S^3 = \mathbb{R}^3 \cup \{\infty\}$

FIGURE 812.

We conclude this section with the following variation on the above Alexander Duality Theorem 66.1. It will come in handy at times. But arguably it is best to study it only when it is actually needed.

Theorem 66.5. (Alexander Duality Theorem) $(*)$ *Let $n \in \mathbb{N}_0$ and let $j \in \{0, \dots, n\}$. Given any compact oriented n-dimensional manifold X with $H_j(X; \mathbb{Z}) = H_{j+1}(X; \mathbb{Z}) = 0$ and given any compact proper submanifold G of X there exist natural isomorphisms*

$$\alpha_G \colon H_j(X \setminus G; \mathbb{Z}) \xrightarrow{\cong} H^{n-j-1}(G, \partial G; \mathbb{Z}) \quad \text{and} \quad \alpha_G \colon H^j(X \setminus G; \mathbb{Z}) \xrightarrow{\cong} H_{n-j-1}(G, \partial G; \mathbb{Z})$$

such that the following conditions are satisfied:

(1) *If $X = S^n$, then the isomorphisms are precisely the isomorphisms from the Alexander Duality Theorem 66.1.*
(2) *The isomorphisms decompose in the obvious way if X is disconnected.*
(3) *If W is a compact oriented n-dimensional manifold with*

$$H_j(W; \mathbb{Z}) = H_{j+1}(W; \mathbb{Z}) = H_j(\partial W; \mathbb{Z}) = H_{j+1}(\partial W; \mathbb{Z}) = 0,$$

and if F is a compact proper submanifold of W, then we have commutative diagrams

$$\begin{array}{ccc} H_j(W \setminus F; \mathbb{Z}) & \xrightarrow[\alpha_F]{\cong} & H^{n-j-1}(F, \partial F; \mathbb{Z}) \\ {\scriptstyle i_*}\uparrow & & \uparrow{\scriptstyle \delta} \\ H_j(\partial W \setminus \partial F; \mathbb{Z}) & \xrightarrow[\alpha_{\partial F}]{\cong} & H^{n-j-2}(\partial F; \mathbb{Z}) \end{array} \quad \text{and} \quad \begin{array}{ccc} H^j(W \setminus F; \mathbb{Z}) & \xrightarrow[\alpha_F]{\cong} & H_{n-j-1}(F, \partial F; \mathbb{Z}) \\ {\scriptstyle i^*}\downarrow & & \downarrow{\scriptstyle \partial} \\ H^j(\partial W \setminus \partial F; \mathbb{Z}) & \xrightarrow[\alpha_{\partial F}]{\cong} & H_{n-j-2}(\partial F; \mathbb{Z}) \end{array}$$

where we denote by $i \colon \partial W \setminus \partial F \to W \setminus F$ the inclusion map and where the right-hand vertical maps are the connecting homomorphisms of the long exact sequences in (co-) homology of the pair $(F, \partial F)$.

Example. The above Alexander Duality Theorem 66.5 will be applied later on to the manifolds $W = [0,1] \times S^n$ and to $W = \overline{B}^n$. For example, suppose that F is a connected properly embedded surface in $\overline{B}^4$ such that $\partial F = K$ is a knot. We can apply the Alexander Duality Theorem 66.5 for $j = 1$. Together with Proposition 61.22 we obtain the following

commutative diagram:

$$\begin{tikzcd}
H_1(\overline{B}^4 \setminus F;\mathbb{Z}) \arrow[r, "\alpha_F", "\cong"'] & H^2(F,K;\mathbb{Z}) \arrow[r, "-\cap[F]", "\cong"'] & H_0(F;\mathbb{Z}) \arrow[d, "i_*"] \\
H_1(S^3 \setminus K;\mathbb{Z}) \arrow[u, "i_*"] \arrow[r, "\alpha_K", "\cong"'] & H^1(K;\mathbb{Z}) \arrow[u, "\delta"'] \arrow[r, "-\cap[K]", "\cong"'] & H_0(K;\mathbb{Z}).
\end{tikzcd}$$

The right hand vertical map is of course an isomorphism and both groups are isomorphic to $\mathbb{Z}$. We now see that both groups on the left are isomorphic to $\mathbb{Z}$ and that the inclusion induced map is an isomorphism.

Sketch of proof. Let $n \in \mathbb{N}_0$ and let $j \in \{0,\dots,n\}$. Let X be a compact orientable n-dimensional manifold with $H_j(X;\mathbb{Z}) = H_{j+1}(X;\mathbb{Z}) = 0$ and let G be a compact proper submanifold of X. We pick a tubular neighborhood N for G as provided by the General Tubular Neighborhood Theorem 64.7. Recall that N is a submanifold with corner. We define $\mathring{N}$ as in Lemma 64.1. We write $M := N \cap \partial X$. Note that M is a tubular neighborhood for $\partial F \subset \partial X$. We refer to Figure 813 for an illustration. We consider the following diagram

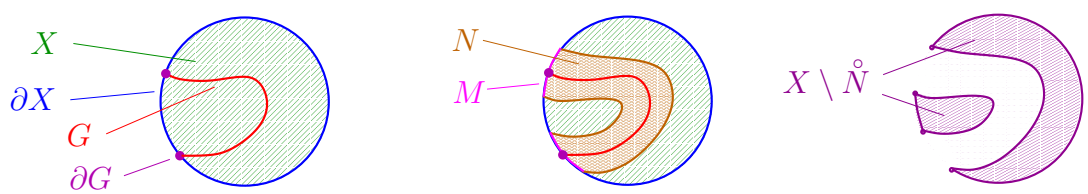


FIGURE 813.

$$\begin{tikzcd}
H_j(X\setminus\mathring{N}) \arrow[d, "\cong"'] & H^{n-j}(X\setminus\mathring{N},\partial(X\setminus\mathring{N})) \arrow[l, "\cong", "\mathrm{PD}"'] & H^{n-j}(X,N\cup\partial X) \arrow[l, "\cong", "\mathrm{exc}"'] & H^{n-j-1}(N\cup\partial X,\partial X) \arrow[l, "\cong", "\delta"'] \\
 & & & H^{n-j-1}(N,M) \arrow[u, "\mathrm{exc}", "\cong"'] \arrow[d, "\cong"] \\
H_j(X\setminus G) \arrow[rrr, dashed, "=:\alpha_G"] & & & H^{n-j-1}(G,\partial G).
\end{tikzcd}$$

We make the following comments:

(a) All maps where no map is specified are induced by inclusions. It follows from Proposition 64.13, together with Corollary 30.8 and Lemma 48.13 (4) that the vertical inclusion maps to the left and bottom right are isomorphisms.

(b) The two maps that are decorated with "exc" are inclusion induced maps that are isomorphisms by "excision". We leave it to the reader to verify that these inclusion maps are indeed isomorphisms. As an example, if $\partial X = \varnothing$, then it follows from the Excision Theorem 45.8 that the top "exc"-map is an isomorphism.

(c) The map on the top right indicated by "δ" is the connecting homomorphism of the long exact sequence in cohomology of the triple $(X, N\cup\partial X, \partial X)$. By our hypothesis we have $H_j(X;\mathbb{Z}) = H_{j+1}(X;\mathbb{Z}) = 0$. By the Poincaré Duality Theorem 61.1 this implies that $H^{n-j}(X,\partial X;\mathbb{Z}) = H^{n-j-1}(X,\partial X;\mathbb{Z}) = 0$, which in turn implies that the connecting homomorphism $\delta\colon H^{n-j-1}(N\cup\partial X,\partial X;\mathbb{Z}) \to H^{n-j}(X, N\cup\partial X;\mathbb{Z})$ is an isomorphism.

We have now seen that all maps in the diagram are isomorphisms. Thus we can define α_G to be the map on the bottom. A priori the definition of α_G depends on the choice of the tubular neighborhood N. But by Proposition 64.9 tubular neighborhoods are unique in an appropriate sense. This implies that isomorphisms do not depend on the choice of the tubular neighborhood. We have to verify that these homeomorphisms have the desired properties.

(1) This statement is basically clear once one compares the definitions.
(2) This statement follows from all the usual results for the behavior of invariants under the disjoint union.
(3) Let W be a compact oriented n-dimensional manifold with

$$(*) \qquad H_j(W;\mathbb{Z}) = H_{j+1}(W;\mathbb{Z}) = H_j(\partial W;\mathbb{Z}) = H_{j+1}(\partial W;\mathbb{Z}) = 0.$$

Furthermore let F be a compact proper submanifold of W. We pick a tubular neighborhood N for F. We define $\mathring{N}$ as above. We write $M := N\cap\partial W$. Note that M is a tubular neighborhood for ∂F. We consider the following diagram

$$\begin{tikzcd}
H_j(W\setminus\mathring{N}) \arrow[d, "\cong"'] & H^{n-j}(W\setminus\mathring{N},\partial(W\setminus\mathring{N})) \arrow[l, "\cong"', "\mathrm{PD}"] & H^{n-j}(W, N\cup\partial W) \arrow[l, "\cong"', "\mathrm{exc}"] & H^{n-j-1}(N\cup\partial W,\partial W) \arrow[l, "\cong"', "\delta"] \\
 & & & H^{n-j-1}(N,M) \arrow[u, "\mathrm{exc}"', "\cong"] \arrow[d, "\cong"] \\
H_j(W\setminus F) \arrow[rrr, blue, "\alpha_F"] & & & H^{n-j-1}(F,\partial F) \\
H_j(\partial W\setminus\partial F) \arrow[u, "i_*"] \arrow[rrr, blue, "\alpha_{\partial F}"] & & & H^{n-j-2}(\partial F) \arrow[u, "\delta"] \\
H_j(\partial W\setminus\mathring{M}) \arrow[u, "\cong"] & H^{n-j}(\partial W\setminus\mathring{M},\partial M) \arrow[l, "\cong"', "\mathrm{PD}"] & H^{n-j-1}(\partial W, M) \arrow[l, "\cong"', "\mathrm{exc}"] & H^{n-j-2}(M). \arrow[l, "\cong"', "\delta"] \arrow[u, "\cong"']
\end{tikzcd}$$

We make the following observations:
(a) By our hypothesis $(*)$ and the discussion above the horizontal maps α_G and $\alpha_{\partial G}$ are defined.
(b) One can easily see that the bottom "$\cup$" of the diagram is indeed the map $\alpha_{\partial F}$.
(c) If one ignores the blue arrows, then the brave reader can verify that the diagram does indeed commute.

Basically the same argument also provides the desired statements with the roles of homology and cohomology switched. □

66.2. **Immersions and embeddings of manifolds into $\mathbb{R}^n$.** In Question 1.85 we had asked whether the projective space $\mathbb{R}\mathrm{P}^2$ or the Klein bottle can be viewed as subsets of $\mathbb{R}^3$. We can reinterpret this question in three different ways:

Question 66.6.

(1) *Does* $\mathbb{R}\mathrm{P}^2$ (*respectively the Klein bottle*) *admit an immersion into* $\mathbb{R}^3$*?*
(2) *Does* $\mathbb{R}\mathrm{P}^2$ (*respectively the Klein bottle*) *admit an embedding into* $\mathbb{R}^3$*?*
(3) *Does* $\mathbb{R}\mathrm{P}^2$ (*respectively the Klein bottle*) *admit a topological embedding into* $\mathbb{R}^3$*?*

We start out with Question 66.6 (1).

(a) We saw in Figure 47 that there exists an immersion of the Klein bottle K into $\mathbb{R}^3$. In Figure 814 we show the images of two other immersions of the Klein bottle into $\mathbb{R}^3$. This gives a positive answer to Question 66.6 (1) for the Klein bottle.

Figure 814.

(b) The case of the real projective plane is much more interesting. In 1901 David Hilbert, arguably the greatest German mathematician of his generation, gave his PhD student Werner Boy [Boy][1117] the task to prove that there is no immersion of $\mathbb{R}\mathrm{P}^2$ into $\mathbb{R}^3$. To everyone's surprise Boy did the opposite, he showed that it was possible to immerse $\mathbb{R}\mathrm{P}^2$ into $\mathbb{R}^3$. In Figure 815 we give several illustrations of the image of the immersion. A detailed description of the immersion is given in [Kir5, Ap]. But perhaps it is more helpful to just watch the following video:

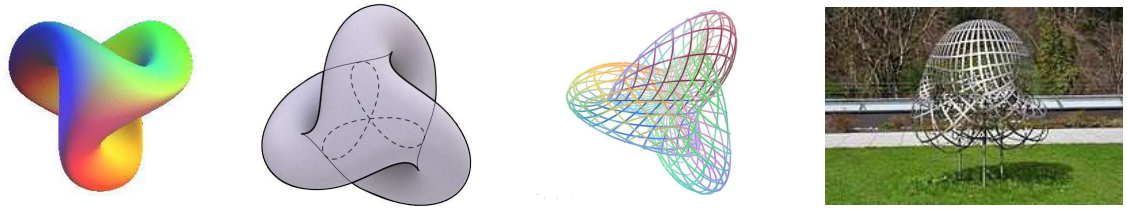
`https://www.youtube.com/watch?v=uiq-EcQz_uU`

A fun description of Boy's surface, and of many other concepts from topology, can also be found here:

`http://www.savoir-sans-frontieres.com/JPP/telechargeables/English/Topo_the_world_eng.pdf`

Lemma 3.39 says that the projective plane $\mathbb{R}\mathrm{P}^2$ and the Klein bottle are non-orientable. Therefore the following proposition gives in particular a negative answer to Question 66.6 (2).

[1117]Werner Boy (1879-1914) was a German mathematician who died in the first weeks of World War I.



Boy's surface at Oberwolfach

FIGURE 815.

Proposition 66.7. *Let N be a closed n-dimensional connected manifold. If N is non-orientable, then there is no embedding of N into $\mathbb{R}^{n+1}$.*

Proof. Let N be a closed n-dimensional connected non-orientable manifold. Suppose that N can be embedded into $\mathbb{R}^{n+1}$. We can thus view N as a submanifold of $\mathbb{R}^{n+1}$. We obtain that

$$\begin{array}{ccccccc} \mathbb{Z}_2 & \cong & H^n(N;\mathbb{Z}) & \cong & \widetilde{H}_0(\mathbb{R}^{n+1}\setminus N;\mathbb{Z}) & \cong & \mathbb{Z}^{\text{number of path-components of } \mathbb{R}^{n+1}\setminus N \text{ minus } 1}. \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{Proposition 51.14} & & \begin{array}{c}\text{Alexander Duality}\\ \text{Theorem 66.2}\end{array} & & \text{Proposition 29.5} & \end{array}$$

But this is absurd. We have thus obtained the desired contradiction. □

In the previous chapter we had also raised the following related question.

Question 65.14. *Given $n \in \mathbb{N}$, what is the minimal $k \in \mathbb{N}$ such that $\mathbb{R}\mathrm{P}^n$ admits a (topological) embedding into $\mathbb{R}^k$?*

Recall that it follows from Theorem 46.2 and the calculation of the homology groups of $\mathbb{R}\mathrm{P}^n$ in Proposition 35.11 that $\mathbb{R}\mathrm{P}^n$ is orientable if and only if n is odd. In particular it follows from Proposition 66.7 that for n even it is not possible to embed $\mathbb{R}\mathrm{P}^n$ into S^{n+1}. But this raises the question, whether for n odd one can embed $\mathbb{R}\mathrm{P}^n$ into S^{n+1}. It turns out that this is also not the case:

Proposition 66.8. *If $n \in \mathbb{N}_{\geq 2}$, then there is no embedding from $\mathbb{R}\mathrm{P}^n$ into S^{n+1}.*

In the proof of Proposition 66.8 we will need the following lemma which is interesting in its own right.

Lemma 66.9. *If K is a closed orientable connected $(n-1)$-dimensional submanifold of the manifold S^n, then there exist two compact n-dimensional submanifolds A and B of S^n such that $A \cap B = \partial A = \partial B = K$.*

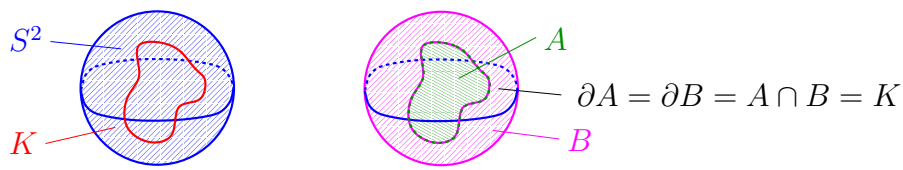


FIGURE 816.

Proof $(*)$. First we note that by Proposition 64.11 the submanifold K admits a tubular neighborhood $[-1,1] \times K$. Our hypothesis that K is connected implies that $[-1,0] \times K$ and $[0,1] \times K$ are also connected.

We first calculate that

$$\begin{array}{ccccccc} H_0(S^n \setminus K;\mathbb{Z}) & \cong & \widetilde{H}_0(S^n \setminus K;\mathbb{Z}) \oplus \mathbb{Z} & \cong & H^{n-1}(K;\mathbb{Z}) \oplus \mathbb{Z} & \cong & \mathbb{Z} \oplus \mathbb{Z}. \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{Lemma 31.1 (4a)} & & \text{Theorem 66.1} & & \text{Theorem 46.2} & \end{array}$$

It follows from Proposition 29.5 that $S^n \setminus K$ has precisely two path-components A' and B'. Since $[-1,0] \times K$ is connected and since it is contained in $S^n \setminus K = A' \cup B'$ it follows that $[-1,0] \times K$ is either contained in A' or it is contained in B'. Without loss of generality we can assume that $[-1,0] \times K$ is contained in A'.

Claim. The subset $[0,1] \times K$ is contained in B'.

We consider the set $A'' := A' \cup [-1,1] \times K$. Note that $S^n = A'' \cup B'$. Since both A'' and B' are open and since S^n is connected it follows that $A'' \cap B' \neq \varnothing$. But this implies that $[0,1] \times K \cap B' \neq \varnothing$. But since $[0,1] \times K$ is connected we see that $[0,1] \times K$ is contained in B'. This concludes the proof of the claim.

We set $A := A' \cup K = A' \cup [-1,0] \times K$ and $B := B' \cup K = B' \cup [0,1] \times K$. It is easy to show that A and B are compact submanifolds of S^n such that $A \cap B = \partial A = \partial B = K$. $\square$

Now we can provide the proof of Proposition 66.8.

Proof of Proposition 66.8. As we had discussed just before the proposition, it remains to deal with the case that n is odd. So suppose that $n \geq 3$ is odd and that there exists an embedding of $\mathbb{R}\mathrm{P}^n$ into S^{n+1}. We identify $\mathbb{R}\mathrm{P}^n$ with its image under the embedding, i.e. we view $\mathbb{R}\mathrm{P}^n$ as a submanifold of S^{n+1}. Note it follows from $n \geq 3$ and the discussion on page 1193 that $H^1(S^n;\mathbb{F}_2) = H^2(S^n;\mathbb{F}_2) = 0$.

Since n is odd we know that $\mathbb{R}\mathrm{P}^n$ is orientable. Thus we can apply Lemma 66.9 which tells us that there exist two compact $(n+1)$-dimensional submanifolds A and B of S^{n+1} with $A \cap B = \partial A = \partial B = K$. We denote by $i\colon \mathbb{R}\mathrm{P}^n \to A$ and by $j\colon \mathbb{R}\mathrm{P}^n \to B$ the inclusion maps. As usual we denote by $x \in H^1(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2) \cong \mathbb{F}_2$ the unique generator.

By Proposition 50.12 (5) we can apply the Mayer–Vietoris Theorem 50.15 for Cohomology Groups to $S^{n+1} = A \cup B$ and we obtain the long exact sequence

$$\cdots \to \underbrace{H^1(S^{n+1};\mathbb{F}_2)}_{=0 \text{ since } n\geq 3} \to H^1(A;\mathbb{F}_2) \oplus H^1(B;\mathbb{F}_2) \xrightarrow{i^*+j^*} \underbrace{H^1(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2)}_{=\mathbb{F}_2\cdot x} \to \underbrace{H^2(S^{n+1};\mathbb{F}_2)}_{=0 \text{ since } n\geq 3} \to \dots$$

Thus we see that the map $i^* + j^* \colon H^1(A;\mathbb{F}_2) \oplus H^1(B;\mathbb{F}_2) \to H^1(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2) \cong \mathbb{F}_2 \cdot x$ is an isomorphism. Without loss of generality we can assume that i^* is non-trivial which means that there exists an $a \in H^1(A;\mathbb{F}_2)$ with $i^*(a) = x$. We have

$$i^*(a^n) \underset{\substack{\uparrow \\ \text{Lemma 57.10}}}{=} (i^*(a))^n = x^n \underset{\substack{\uparrow \\ \text{Proposition 62.16}}}{\neq} 0 \in H^n(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2).$$

In particular the map $i^* \colon H^n(A;\mathbb{F}_2) \to H^n(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2)$ is non-zero. Now we consider the other end of the above Mayer-Vietoris sequence and we obtain the exact sequence

$$\begin{array}{ccccccc} H^n(A;\mathbb{F}_2) \oplus H^n(B;\mathbb{F}_2) & \xrightarrow{i^*+j^*} & \overbrace{H^n(\mathbb{R}\mathrm{P}^n;\mathbb{F}_2)}^{=\mathbb{F}_2\cdot x^n} & \to & \overbrace{H^{n+1}(S^{n+1};\mathbb{F}_2)}^{\cong\mathbb{F}_2} & \to & \underbrace{H^{n+1}(A;\mathbb{F}_2) \oplus H^{n+1}(B;\mathbb{F}_2)}_{\substack{\text{both are zero by Proposition 51.14,} \\ \text{since } A \text{ and } B \text{ are compact, connected} \\ (n+1)\text{-dimensional manifolds} \\ \text{with non-empty boundary}}} \\ a^n \oplus 0 & \mapsto & x^n & & & & \end{array}$$

Thus we see that the map on the left is an epimorphism and that the group on the right is trivial. But then the fact that $H^{n+1}(S^{n+1};\mathbb{F}_2) \neq 0$ shows that the sequence cannot possibly be exact. We have thus obtained the desired contradiction. □

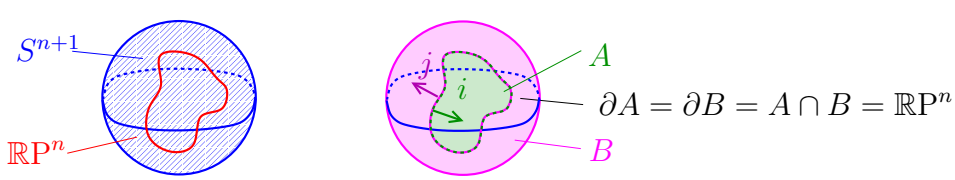

FIGURE 817. Illustration for the Proof of Proposition 66.8.

Remark. The above proposition does not give a complete answer to Question 65.14, we have only shown that $\mathbb{R}\mathrm{P}^n$ cannot embed into S^{n+1}. More lower bounds on the minimal dimension of some $\mathbb{R}^k$ into which we can embed $\mathbb{R}\mathrm{P}^n$ have been obtained by Michael Atiyah [At].

66.3. **The generalized Alexander Duality Theorem.** In a bout of optimism one might hope that the statement of Alexander Duality Theorem 66.1 holds for any (compact) subset of S^n. But this is not the case. More precisely, once again we consider the topologist's sine curve

$$X \;=\; \big\{(0,y)\,\big|\,y\in[-1,1]\big\}\cup\big\{(x,\sin(\tfrac{1}{x}))\,\big|\,x\in(0,\pi]\big\}\;\subset\;\mathbb{R}^2$$

that we had initially introduced on page 123. It is fairly straightforward to see that X is a closed subset of $\mathbb{R}^2$. Evidently X is bounded. Thus the Heine-Borel Theorem 1.21 implies that X is in fact a compact subset of $\mathbb{R}^2$ and thus of $S^2=\mathbb{R}^2\cup\{\infty\}$. Back on page 123 we saw that X is not path-connected, which by Proposition 48.11 and Lemma 48.14 implies that $\widetilde{H}^0(X;\mathbb{Z})\neq 0$. On the other hand, with some effort one can show that there exists a deformation retraction from $S^2\setminus X=(\mathbb{R}^2\setminus X)\cup\{\infty\}$ to ∞, which implies that $H_1(S^2\setminus X;\mathbb{Z})=0$. But this shows that $\widetilde{H}_1(S^2\setminus X;\mathbb{Z})\not\cong\widetilde{H}^0(X;\mathbb{Z})$.

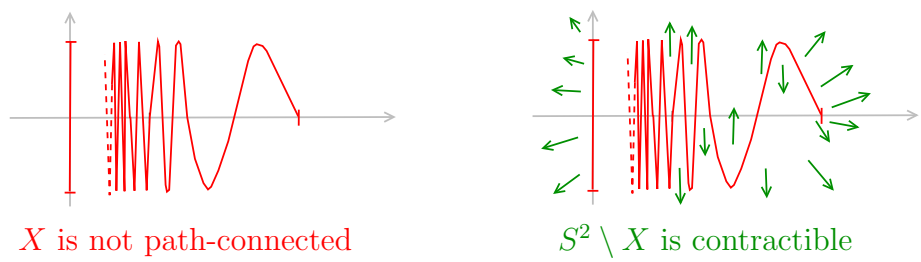

FIGURE 818.

Perhaps rather surprisingly one only needs a fairly modest hypothesis to ensure that Alexander Duality holds after all. More precisely, we have the following theorem which, by Lemma 65.20, is a significant generalization of the earlier Alexander Duality Theorem 66.1 (a).

Theorem 66.10. (Generalized Alexander Duality Theorem) *Let $n\geq 2$. If $X\neq S^n$ is a weakly o-locally contractible, non-empty compact subset of S^n, then for any $j\in\mathbb{N}_0$ we have a natural*[1118] *isomorphism*

$$\widetilde{H}_j(S^n\setminus X;\mathbb{Z})\;\xrightarrow{\cong}\;\widetilde{H}^{n-j-1}(X;\mathbb{Z}).$$

Example. In Figure 819 we show a subset X of $\mathbb{R}^3$ that is homeomorphic to the compact interval $[0,1]$. (We had already encountered this subset in Figure 550.) We leave it as an exercise to convince oneself that X does not admit a regular neighborhood. In particular this is a situation where the Generalized Alexander Duality Theorem 66.10 applies, even though our initial Alexander Duality Theorem 66.1 fails.

Remark. We leave it to the reader to determine whether the obvious generalization of Alexander Duality Theorem 66.1 (b) holds.

[1118] What does "natural" mean in this context? What are the categories? What are the functors?

weakly locally contracible compact subset of $\mathbb{R}^3$

FIGURE 819.

For most applications of Alexander Duality we will actually need the following straightforward consequence of the above theorem.

Theorem 66.11. (Alexander Duality Theorem for Manifolds) *Let $n \geq 2$ and let $k < n$. Furthermore let X be a compact, non-empty k-dimensional topological manifold. If $f\colon X \to S^n$ is an injective map, then for any $j \in \mathbb{N}_0$ we have a natural isomorphism*

$$\widetilde{H}_j(S^n \setminus f(X); \mathbb{Z}) \xrightarrow{\cong} \widetilde{H}^{n-j-1}(X; \mathbb{Z}).$$

Proof of the Alexander Duality Theorem 66.11 for Manifolds. Let $f\colon X \to S^n$ be an injective map from a compact, non-empty k-dimensional topological manifold to S^n where $k < n$. It is a consequence of Proposition 1.40 that $f\colon X \to f(X)$ is a homeomorphism. From $k < n$ and Proposition 32.5 it follows that $f(X) \neq S^n$. We have the following isomorphisms:

$$\widetilde{H}_j(S^n \setminus f(X); \mathbb{Z}) \underset{\substack{\uparrow \\ \text{we can apply the Generalized Alexander Duality Theorem 66.10} \\ \text{since } f(X) \text{ is weakly o-locally contractible and since } f(X) \neq S^n}}{\xrightarrow{\cong}} \widetilde{H}^{n-j-1}(f(X); \mathbb{Z}) \xrightarrow{\cong} \widetilde{H}^{n-j-1}(X; \mathbb{Z}).$$

□

Example. Let $n \geq 2$ and let $k < n$. Furthermore let $f\colon S^k \to S^n$ be an injective map. We obtain that

$$\widetilde{H}_j\big(S^n \setminus f(S^k); \mathbb{Z}\big) \underset{\substack{\uparrow \\ \text{Theorem 66.11}}}{\cong} \widetilde{H}^{n-j-1}(S^k; \mathbb{Z}) \underset{\substack{\uparrow \\ \text{see page 1196 and Lemma 48.16}}}{\cong} \begin{cases} \mathbb{Z}, & \text{if } j = n-k-1, \\ 0, & \text{otherwise.} \end{cases}$$

This calculation gives a new proof for Proposition 36.1 (2). Basically the same approach also gives a new proof of Proposition 36.1 (1).

Remark. The Generalized Alexander Duality Theorem 66.10 can be generalized even further. More precisely, an analogous statement also holds for any compact subset K of S^n, e.g. the topologist's sine curve. But hereby one needs to replace the usual singular cohomology on the right-hand side by the *Čech cohomology* of K. We refer to [Hat, p. 256] or [Pra, p. 271] for more details.

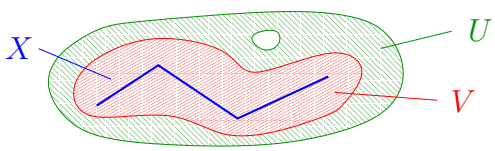
Proof of the Generalized Alexander Duality Theorem 66.10. Let $n \geq 2$ and let $X \neq S^n$ be a weakly o-locally contractible, non-empty compact subset of the sphere $S^n = \mathbb{R}^n \cup \{\infty\}$.

Without loss of generality we can assume that $X \subset \mathbb{R}^n \subset S^n$.[1119] We recall the following definition:

(1) Given a topological space Y we denote by $\mathcal{K}(Y)$ the set of all compact subsets of Y. Given $K, L \in \mathcal{K}(Y)$ we write $K \leq L$ if $K \subset L$. The set $\mathcal{K}(X)$ together with the relation "$\leq$" is a directed set since the union of two compact subsets is again compact.

We also introduce a new definition and notation:

(2) We denote by $\mathcal{N}(X)$ the set of all open neighborhoods of X. Given $U, V \in \mathcal{N}(X)$ we write $U \leq V$ if $V \subset U$. (Note the reversal of V and U.) The set $\mathcal{N}(X)$ together with the relation "$\leq$" is a directed set since the intersection of two open neighborhoods of X is again an open neighborhood of X.[1120]
(3) Given any subsets $A \subset B$ of S^n we denote by $i_{A,B}\colon A \to B$ the inclusion map.
(4) It follows from our definition of "$\leq$" on $\mathcal{N}(X)$ that for any $m \in \mathbb{N}_0$ the cohomology groups $\{\widetilde{H}^m(U)\}_{U \in \mathcal{N}(X)}$ together with the inclusion induced maps form a *direct* system of abelian groups.



we have $U \leq V$ and $i^*_{V,U}\colon \widetilde{H}^m(U) \to \widetilde{H}^m(V)$

FIGURE 820.

We continue with the key technical part of the theorem.

Claim. For any $m \in \mathbb{N}_0$ the map

$$\Phi\colon \varinjlim_{U \in \mathcal{N}(X)} \widetilde{H}^m(U) \;\to\; \widetilde{H}^m(X),$$

that is induced by the restriction maps $i^*_{X,U}\colon \widetilde{H}^m(U) \to \widetilde{H}^m(X)$, is an isomorphism.

By our hypothesis that X is compact and weakly o-locally contractible, Theorem 65.21 and Observation 65.24 (2) there exists an open neighborhood $W \subset \mathbb{R}^n$ of $X \subset \mathbb{R}^n$ for which there exists a retraction $r\colon W \to X$. (We refer to Figure 821 for an illustration.)

[1119]Indeed, by our hypothesis that $X \neq S^n$ there exists a point $P \in S^n$ that does not lie in X. By Lemma 1.73 (3) we know that the group $\mathrm{O}(n+1)$ acts transitively on S^n. In particular there exists a homeomorphism h of S^n with $h(P) = \infty$. Thus we can replace X by $h(X)$ which evidently lies in $\mathbb{R}^n$.

[1120]Here the idea is that the neighborhoods "approximate" X, in particular $U \leq V$ means that V is a "better approximation of X", which just means that $V \subset U$.

We consider the following commutative diagram

$$\begin{tikzcd}
 & \widetilde{H}^m(W) \arrow[dl] \arrow[dr, "i^*_{X,W}"] & \\
\lim\limits_{\substack{\longrightarrow \\ U\in\mathcal{N}(X)}} \widetilde{H}^m(U) \arrow[rr, "\Phi"'] & & \widetilde{H}^m(X). \arrow[ul, bend right, "r^*"']
\end{tikzcd}$$

From $(i^*_{X,W} \circ r^*) = (r \circ i_{X,W})^* = \mathrm{id}^*_X$ we deduce that the map $i^*_{X,W}$ is an epimorphism. It follows that the horizontal map Φ is also an epimorphism. It remains to show that Φ is a monomorphism.

By Lemma 52.2 (3) it remains to show that for any $U \in \mathcal{N}(X)$ there exists a $V \in \mathcal{N}(X)$ with $U \leq V$, i.e. with $V \subset U$, such that

$$\ker\left\{i^*_{X,U}\colon \widetilde{H}^m(U) \to \widetilde{H}^m(X)\right\} \ \subset\ \ker\left\{i^*_{V,U}\colon \widetilde{H}^m(U) \to \widetilde{H}^m(V)\right\}.$$

So let $U \in \mathcal{N}(X)$. After possibly replacing U by $U \cap W$ we can without loss of generality assume that $U \subset W$. We continue with the following subclaim.

Subclaim. There exists an open neighborhood V with $X \subset V \subset U$ such that the inclusion $i_{V,U}\colon V \to U$ and the retraction $r\colon V \to X \subset U$ are homotopic maps from V to U.

We consider the homotopy

$$\begin{array}{rcl} F\colon U \times [0,1] & \to & \mathbb{R}^n \\ (x,t) & \mapsto & (1-t)\cdot x + t \cdot r(x) \end{array}$$

from the identity id_U to the retraction $r\colon U \to X$. Note that $F(X \times [0,1]) = X$. Since X is compact and since F is continuous there exists an open neighborhood V of X, contained in U, such that $F(V \times [0,1]) \subset U$.[1121] But then the restriction of F to $F\colon V \times [0,1] \to U$ defines a homotopy from the inclusion $V \to U$ to the retraction $r\colon V \to X \subset U$. (We refer to Figure 821 for an illustration.) This concludes the proof of the subclaim.

We consider the following diagram

$$\begin{tikzcd}
\widetilde{H}^m(U) \arrow[rr, "i^*_{X,U}"] \arrow[dr, "i^*_{V,U}"'] \arrow[dr, bend left, "r^*"] & & \widetilde{H}^m(X) \arrow[dl, "r^*"'] \\
 & \widetilde{H}^m(V). &
\end{tikzcd}$$

The above subclaim says that the two maps $i_{V,U}\colon V \to U$ and $r\colon V \to X \subset U$ are homotopic. It follows from Lemma 48.13 that the two maps $i^*_{V,U}$ and r^* from $\widetilde{H}^m(U)$ to

[1121] This can be seen as follows. The set $W := F^{-1}(U) \subset U \times [0,1]$ is open and it evidently contains $X \times [0,1]$. Since X and $[0,1]$ are compact and since W is open one sees easily that there exists an $r > 0$ such that for any $z \in X$ we have $B_r(z) \times [0,1] \subset W$. But then $V := \bigcup\limits_{x\in X} B_r(x)$ has the property that $V \times [0,1] \subset W$.

$\widetilde{H}^m(V)$ agree. Since r is the identity on X we see that $r\colon U \to X \subset V$ equals the map $i_{X,U} \circ r\colon U \to X$. This shows that the diagram commutes. It follows immediately from these observations that V has the desired property. This concludes the proof of the claim.

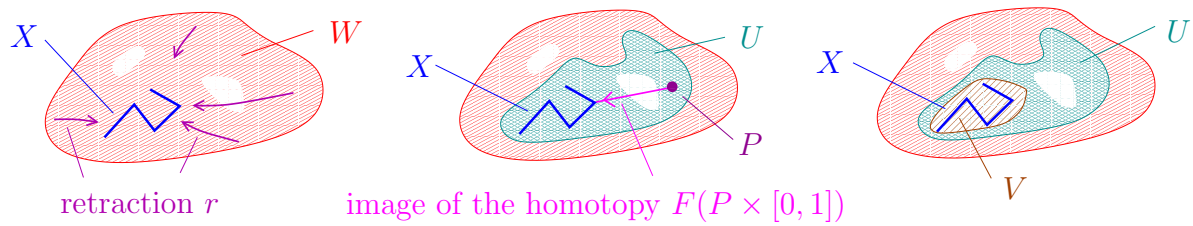


FIGURE 821.

We turn to the actual proof of the theorem. First let $j \neq 0$. The desired isomorphism will be given by a sequence of natural isomorphisms as follows:

$$H_j(S^n\setminus X) \underset{(1)}{\overset{\cong}{\Longleftarrow}} H_c^{n-j}(S^n\setminus X) \underset{(2)}{\overset{\cong}{\Longleftarrow}} \lim_{\substack{\longrightarrow \\ K\in\mathcal{K}(S^n\setminus X)}} H^{n-j}(S^n\setminus X, \overbrace{(S^n\setminus X)\setminus K}^{=(S^n\setminus K)\setminus X}) \underset{(3)}{\overset{\cong}{\Longleftarrow}} \lim_{\substack{\longrightarrow \\ U\in\mathcal{N}(X)}} H^{n-j}(S^n\setminus X, U\setminus X)$$
$$\underset{(4)}{\overset{\cong}{\Longleftarrow}} \lim_{\substack{\longrightarrow \\ U\in\mathcal{N}(X)}} H^{n-j}(S^n, U) \underset{(5)}{\overset{\cong}{\Longleftarrow}} \lim_{\substack{\longrightarrow \\ U\in\mathcal{N}(X)}} \widetilde{H}^{n-j-1}(U) \underset{(6)}{\overset{\cong}{\Longrightarrow}} \widetilde{H}^{n-j-1}(X).$$

We explain the natural isomorphisms in more detail:

(1) Since X is compact we know from Lemma 1.18 (2) that $S^n \setminus X$ is an open subset of $S^n \setminus X$. In particular it is also an n-dimensional manifold and via Lemma 45.28 it inherits an orientation from S^n. Also note that it follows from Proposition 32.1 that $S^n \setminus X$ has no boundary. After this preamble the first isomorphism is the Poincaré Duality isomorphism from Theorem 61.15 corresponding to the oriented manifold $S^n \setminus X$. By Lemma 61.21 this isomorphism is natural.

(2) The second isomorphism is provided by Proposition 53.4.

(3) The third isomorphisms comes from the straightforward observation that the map $\mathcal{N}(X) \to \mathcal{K}(S^n \setminus X)$ given by $U \mapsto S^n \setminus U$ is an isomorphism of directed sets which gives us an isomorphism of direct systems.

(4) For any open neighborhoods U and V of X with $U \leq V$, i.e. with $V \subset U$, we have a commutative diagram

$$\begin{array}{ccc} H^{n-j}(S^n\setminus X, V\setminus X) & \longleftarrow & H^{n-j}(S^n, V) \\ \uparrow & & \uparrow \\ H^{n-j}(S^n\setminus X, U\setminus X) & \longleftarrow & H^{n-j}(S^n, U) \end{array}$$

where all the maps are induced by the obvious inclusions of pairs of topological spaces. It follows from the Excision Theorem 50.1 for Cohomology Groups that the

horizontal maps are isomorphisms. The desired isomorphism of direct limits is now an immediate consequence of Lemma 52.4.

(5) For any open neighborhoods U and V of X with $U \leq V$, i.e. with $V \subset U$, we have a commutative diagram

$$\begin{array}{ccc} H^{n-j}(S^n, V) & \xleftarrow{\ \delta\ } & \widetilde{H}^{n-j-1}(V) \\ \uparrow & & \uparrow \\ H^{n-j}(S^n, U) & \xleftarrow{\ \delta\ } & H^{n-j-1}(U) \end{array}$$

where the vertical maps are induced by the obvious inclusions and where the horizontal maps are the connecting homomorphisms of the long exact sequences in reduced cohomology provided by Lemma 48.17. Since $j \geq 1$ we obtain from these long exact sequences and the calculation of the cohomology groups of S^n that the horizontal maps are in fact isomorphisms. As in (4) we appeal to Lemma 52.4 to obtain the desired isomorphism of direct limits.

(6) The last map is the isomorphism of the above claim.

It still remains to deal with the case $j = 0$. In this case all of the above maps are still isomorphisms, except for map (5). To address this issue we consider the following diagram:

$$\begin{array}{ccccccc} H_0(S^n \backslash X) & \xrightarrow[\cong]{(1)} & H^n_c(S^n \backslash X) & \xrightarrow[\cong]{(2),(3)} & \varinjlim\limits_{U \in \mathcal{N}(X)} H^n(S^n \backslash X, U \backslash X) & \xrightarrow[\cong]{(4)} & \varinjlim\limits_{U \in \mathcal{N}(X)} H^n(S^n, U) \\ \downarrow & & \downarrow & & \cong\downarrow & & \downarrow \\ H_0(S^n) & \xrightarrow[\cong]{(1)} & H^n_c(S^n) & \xrightarrow[\cong]{(2),(3)} & \varinjlim\limits_{U \in \mathcal{N}(X)} H^n(S^n, U) & \xrightarrow[\cong]{(4)} & \varinjlim\limits_{U \in \mathcal{N}(X)} H^n(S^n). \end{array}$$

Here the second vertical map is the inclusion induced map defined by Lemma 53.5. The first and the fourth vertical maps are the obvious inclusion induced maps. Furthermore the third vertical map is the inverse of the isomorphism which is induced by the isomorphisms $H^n(S^n, U) \to H^n(S^n \setminus X, U \setminus X)$ that are given by the Excision Theorem 50.1 for Cohomology Groups. The top horizontal maps are precisely the above maps (1), (2), (3) and (4). The bottom horizontal maps are defined completely analogously with $X = \varnothing$. Since the maps defined in (1), (2), (3) and (4) are natural we see that the diagram commutes. It follows that

$$\begin{array}{ccccc} & \text{follows easily from } H_0(S^n) \cong \mathbb{Z} & & \text{by the above commutative diagram} & \\ & \downarrow & & \downarrow & \\ \widetilde{H}_0(S^n \backslash X) & \cong & \ker\{H_0(S^n \backslash X) \to H_0(S^n)\} & \cong & \ker\left\{\varinjlim H^n(S^n, U) \to \varinjlim H^n(S^n)\right\} \\ & \cong & \varinjlim \ker\{H^n(S^n, U) \to H^n(S^n)\} & \cong & \varinjlim \widetilde{H}^{n-1}(U) \ \cong\ \widetilde{H}^{n-1}(X). \\ & \uparrow & & \uparrow & \uparrow \\ & \text{Corollary 34.3} & & \text{by the long exact sequence of Lemma 48.17 and since } n \geq 2 & \text{by the claim} \end{array}$$

□

The following proposition finally gives a negative answer to Question 66.6 (3).

Proposition 66.12. *Let M be a closed connected n-dimensional topological manifold. If M is not orientable, then there is no* topological *embedding of M into $\mathbb{R}^{n+1}$.*

Proof. The proof of Proposition 66.12 is verbatim the same as the proof of Proposition 66.7, we only need to replace the original Alexander Duality Theorem 66.1 by the Alexander Duality Theorem 66.11 for Manifolds.

We also give an alternative argument that does not require the slightly obscure Generalized Alexander Duality Theorem 66.10. Thus let M be a closed connected n-dimensional topological manifold which admits a topological embedding $f\colon M \to \mathbb{R}^{n+1}$. We have to show that M is orientable. As usual we view $\mathbb{R}^{n+1}$ as a subset of S^{n+1}. We make the following observations:

(1) By Proposition 65.25 there exists a compact $(n+1)$-dimensional submanifold X of $\mathbb{R}^{n+1}$ that contains $f(M)$ and such that there exists a retraction $r\colon X \to f(M)$. We denote by $i\colon f(M) \to X$ the inclusion map.
(2) Since $r \circ i = \mathrm{id}_{f(M)}$ we see that the map $r^*\colon H^n(f(M);\mathbb{Z}) \to H^n(X;\mathbb{Z})$, induced by the retraction, is a monomorphism.
(3) By the remark on page 1535 there is an isomorphism $H^n(X;\mathbb{Z}) \cong H_0(S^{n+1} \setminus X;\mathbb{Z})$. It follows in particular from Proposition 29.5 that $H^n(X;\mathbb{Z})$ is a free abelian group.
(4) It follows from (2) and (3) that $H^n(f(M);\mathbb{Z})$ is a torsion-free abelian group.
(5) Since $f\colon M \to f(M)$ is a homeomorphism we obtain from (4) that $H^n(M;\mathbb{Z})$ is a torsion-free abelian group.
(6) We deduce from (5) and Proposition 51.14 that the closed connected n-dimensional topological M is orientable. □

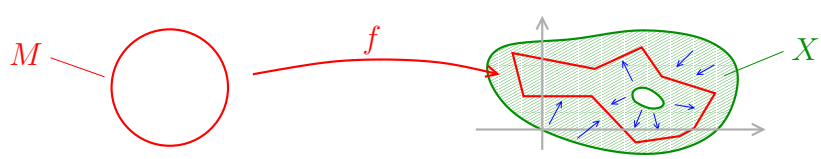

FIGURE 822. Illustration of the proof of Proposition 66.12.

The following proposition is a strengthening of Proposition 66.8.

Proposition 66.13. *If $n \in \mathbb{N}_{\geq 2}$, then there is no topological embedding of $\mathbb{R}\mathrm{P}^n$ into S^{n+1}.*

Proof. First let n be even. In this case $\mathbb{R}\mathrm{P}^n$ is not orientable and the result is an immediate consequence of Proposition 66.12.

Now let n be odd. This case is significantly harder and it was first proved by René Thom [Tho3, p. 180] in 1952. We cannot provide the argument. But it seems like the argument of Thom is somewhat reminiscent of the argument in the proof of Proposition 66.8. So suppose there exists a topological embedding $f\colon \mathbb{R}\mathrm{P}^n \to S^{n+1}$. It follows from Proposition 29.5, the Generalized Alexander Duality Theorem 66.10 and the fact that $H^n(\mathbb{R}\mathrm{P}^n;\mathbb{Z}) \cong \mathbb{Z}$ (here we use that n is odd), that $S^{n+1} \setminus f(\mathbb{R}\mathrm{P}^n)$ consists of two path

components. We denote the closures of the path components by A and B. The problem is that the triad (S^{n+1}, A, B) is in general not excisive so we cannot apply the Mayer–Vietoris Theorem 50.15 for Cohomology Groups. The idea in the proof is to replace usual singular cohomology by Alexander-Spanier cohomology for which the above triad is excisive. We refer to [Mas3, Chapter 8] or [Mas5] for an introduction to Alexander-Spanier cohomology and we refer to [Mas3, Theorem II.8.15] for the proof that in this setting the above triad is excisive. □

66.4. **The square-peg problem.** We start out with the following definition.

Definition.

(1) The image of an injective map $S^1 \to \mathbb{R}^2$ is called a *Jordan curve*.[1122]
(2) Given a Jordan curve C we say that a rectangle R is *inscribed in* C if all vertices of R belong to C.

The following question was asked by Otto Toeplitz [Toep] in 1911.[1123]

Question 66.14. *Does every Jordan curve admit an inscribed square?*

This question is known as the "inscribed square problem" or the "square-peg problem". Lev Schnirelmann [Schni][1124] gave a positive answer if the curve is smooth, in fact he gave a proof if the curve is C^2, i.e. if the map $S^1 \to \mathbb{R}^2$ is twice continuously differentiable. But the general case is still open.[1125] A detailed discussion of the question and its history is given in [Matsc].

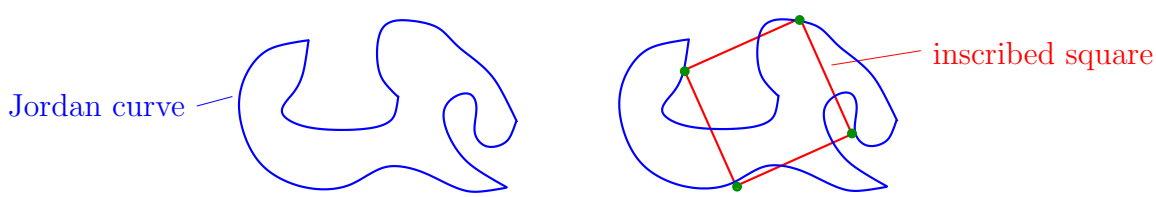

FIGURE 823.

We conclude this chapter with the following proposition.

Proposition 66.15. *Every Jordan curve admits an inscribed rectangle.*

[1122]Note that this definition is slightly different from the definition we gave on page 584 where we defined a Jordan curve to be an injective map $S^1 \to \overline{\mathbb{C}} = S^2$.

[1123]Otto Toeplitz (1881-1940) was a Jewish German mathematician who was forced to emigrate in 1939. He is mainly known for his contributions to analysis.

[1124]We had already encountered Lev Schnirelmann in Theorem 44.18.

[1125]Recently the Fields medalist Terence Tao [Tao] wrote a long paper in which he outlined an approach to the square-peg problem. See also the following video:

`https://www.youtube.com/watch?v=RGxnWgy5i80`

FIGURE 824. The more common square peg problem.

In [Mey] the subsequent ingenious proof of Proposition 66.15 is attributed to Herbert Vaughan. In preparation for the proof we need the following elementary lemma.

Lemma 66.16. *Let $T = S^1 \times S^1$ be the torus. Let $\sim$ be the equivalence relation on T generated by $(z, w) \sim (w, z)$. The quotient space $T/\sim$ is homeomorphic to the Möbius band and*

$$\partial(T/\sim) \;=\; \{[(z,z)] \,|\, z \in S^1\}.$$

Proof. The homeomorphism is illustrated in Figure 825. □

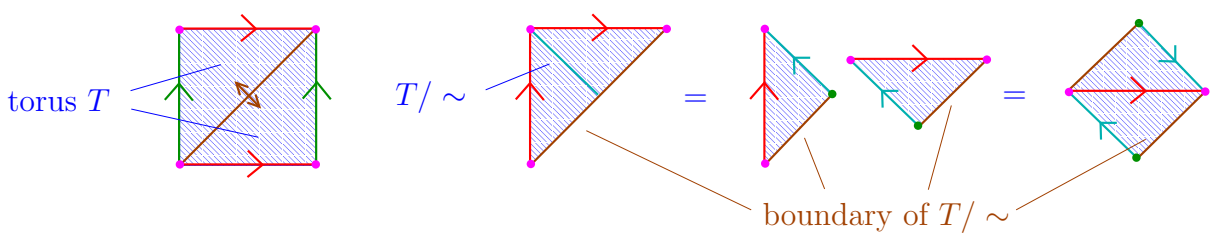

FIGURE 825.

Now we are already ready to prove Proposition 66.15.

Proof of Proposition 66.15. Let $\gamma\colon S^1 \to \mathbb{R}^2$ be an injective map. We have to show that $\gamma(S^1)$ admits an inscribed rectangle. We consider the map

$$\begin{aligned} \Phi\colon T := S^1 \times S^1 &\to \mathbb{R}^2 \times \mathbb{R}_{\geq 0} \\ (z,w) &\mapsto \left(\tfrac{\gamma(z)+\gamma(w)}{2}, |\gamma(z)-\gamma(w)|\right). \end{aligned}$$

Since for all $z, w \in S^1$ we have $\Phi(z,w) = \Phi(w,z)$ we see that Φ descends to a map

$$\Psi\colon T/\sim \;\to\; \mathbb{R}^3$$

where $\sim$ denotes of course the equivalence relation generated by $(z,w) \sim (w,z)$.

Claim. The map $\Psi\colon T/\sim \to \mathbb{R}^2 \times \mathbb{R}_{\geq 0}$ is not injective.

We first show that the claim implies the proposition. So now that we know that Ψ is not injective we know that there exist distinct pairs of points $\{z,w\}$ and $\{u,v\}$ with $\Phi(z,w) = \Phi(u,v)$. We consider the quadrilateral given by the points z, u, v, w. It follows

from $\Phi(z,w) = \Phi(u,v)$ that the diagonals bisect each other and that the diagonals have the same length. But such a quadrilateral is necessarily a rectangle.[1126] We refer to Figure 826 for an illustration.

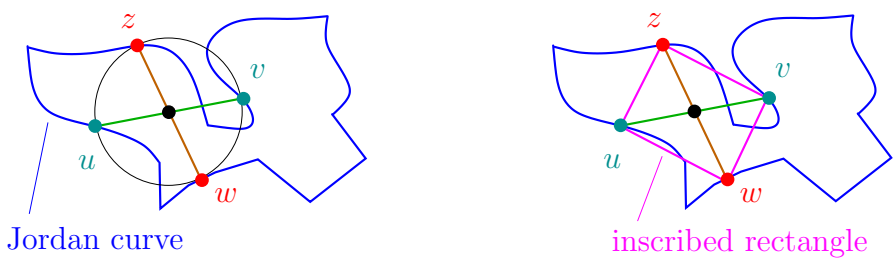

FIGURE 826.

It remains to prove the claim. Let us assume that $\Psi\colon T/\sim \to H := \mathbb{R}^2 \times \mathbb{R}_{\geq 0}$ is injective. By Lemma 66.16 the quotient $M := T/\sim$ is homeomorphic to the Möbius band and the boundary ∂M is given by $\{[(z,z)] \,|\, z \in S^1\}$. We see immediately from the definition of Ψ that for a point $[(z,w)] \in M = T/\sim$ we have $\Psi([(z,w)]) \in \partial H = \mathbb{R} \times \mathbb{R} \times \{0\}$ if and only if $[(z,w)] \in \partial M$. We denote by M_1 and M_2 two copies of M and we denote by $DM = M_1 \cup_{\partial M_1 = \partial M_2} M_2$ the double of M. It follows from the discussion on page 435 that DM is in fact homeomorphic to the Klein bottle, in particular DM is a closed, non-orientable 2-dimensional manifold.

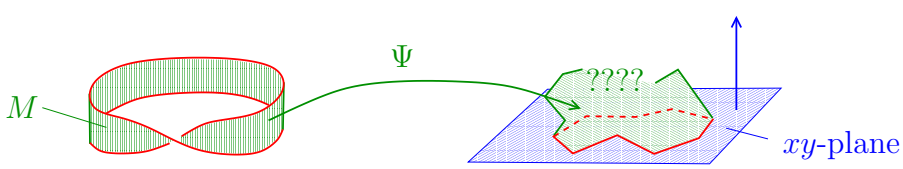

FIGURE 827.

We denote by $\rho\colon \mathbb{R}^3 \to \mathbb{R}^3$ the reflection in the xy-plane, i.e. ρ is the map that is given by $\rho(x,y,z) = (x,y,-z)$. We consider the map

$$DM = M_1 \cup_{\partial M_1 = \partial M_2} M_2 \quad \to \quad \mathbb{R}^3$$

that is given by

$$\begin{array}{rcll} P & \mapsto & \Psi(P), & \text{if } P \in M_1, \\ P & \mapsto & \rho(\Psi(P)), & \text{if } P \in M_2. \end{array}$$

It follows immediately from the above discussion that this map is well-defined and injective. Furthermore it follows from Lemma 1.66 that the map is in fact continuous. But now

[1126] Hmm, why is that?

we have constructed an injective map from the Klein bottle to $\mathbb{R}^3$. On page 1511 we pointed out that such a map is in fact a topological embedding. But we had just proved in Proposition 66.12 that such a topological embedding cannot exist. This concludes the proof of the claim. $\square$

Remark.

(1) The above proof of Proposition 66.15 is also explained in the following video:

`https://www.youtube.com/watch?v=AmgkSdhK4K8`

(2) There are many variations on Question 66.14. For example, given $r \neq 1$ one can ask whether every Jordan curve admits an inscribed rectangle with aspect ratio r. For $r \neq 1$ this is an open problem even for smooth curves. Arguably the best result is the recent observation of Cole Hugelmeyer [Hug] that a deep result in knot theory, due to Josh Batson [Bats], implies that every smooth Jordan curve admits an inscribed rectangle of aspect ratio $\sqrt{3}$. The key idea of [Hug] is rather similar to the proof of Proposition 66.15.

Exercises for Chapter 66.

Exercise 66.1. Let $X \subset S^3$ be a closed orientable connected 2-dimensional submanifold. We view S^3 as a subset of S^4 in the usual way.

(a) Determine the homology groups of $S^4 \setminus X$.
(b) Now let $X \subset S^3 = \mathbb{R}^3 \cup \{\infty\}$ be the surface shown in Figure 828. Give an example of a closed curve in $S^4 \setminus X$ that is not null-homotopic.

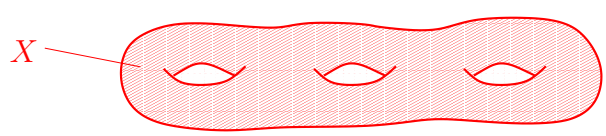

FIGURE 828.

Exercise 66.2. This exercise is a continuation of Exercise 66.1.

(a) Let $X \subset S^n$ be a closed submanifold. We view S^n as a subset of S^{n+1} in the usual way. Show that $S^{n+1} \setminus X$ is homotopy equivalent to $\Sigma(S^n \setminus X)$. (Here $\Sigma(S^n \setminus X)$ denotes the suspension of $S^n \setminus X$.)
Remark: You will need to use at some point that X is a "reasonable subset", e.g. that X is a closed submanifold. The statement does not hold for all subsets of S^n.
(b) Again let $X \subset S^3 = \mathbb{R}^3 \cup \{\infty\}$ be the surface shown in Figure 828. As above we view it as a submanifold of S^4. Determine $\pi_1(S^4 \setminus X)$.

Exercise 66.3.

(a) Let F be an orientable connected 2-dimensional manifold with non-empty boundary and let $i\colon F \to \mathbb{R}^3$ be an injective map. Is the complement $\mathbb{R}^3 \setminus F$ necessarily path-connected?

(b) Let F be an orientable connected surface non-compact 2-dimensional manifold with empty boundary and let $i\colon F \to S^3$ be an injective map. Is the complement $S^3 \setminus F$ necessarily path-connected?

67. The cup product and algebraic intersection numbers

In this chapter we will introduce the algebraic intersection number of two oriented submanifolds of a manifold M and we then relate this algebraic intersection number to the cup product of suitable cohomology classes of M.

67.1. **The Transversality Theorems.** The following definition is a harmless generalization of the definition from page 207.

Definition. Let M be a manifold and let Y be a proper submanifold of M. Let X be some other manifold and let $f\colon X \to M$ be a smooth map. We say f *intersects* Y *transversally* if for every $P \in X$ with $f(X) \in M$ the following two conditions are satisfied:

(1) We have $P \notin \partial X$ and $f(P) \notin \partial Y$.
(2) For every $P \in X$ with $f(P) \in Y$ we have the following equality[1127]

$$f_*(T_P X) + T_{f(P)} Y \;=\; T_P M.$$

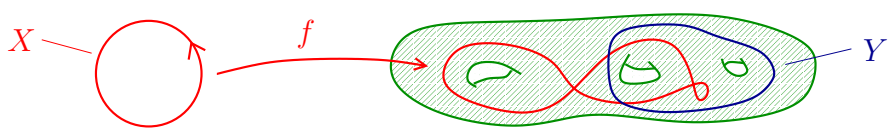

Figure 829.

Examples.

(1) Let M be a manifold and let X and Y be two proper submanifolds of M. We denote by $i\colon X \to M$ the inclusion map. It follows immediately from the definitions that i intersects Y transversally if and only if X intersects Y transversally in the sense of the definition on page 207.
(2) Let X be a manifold and let $f\colon X \to \mathbb{R}^n$ be a smooth map. Furthermore let $y \in \mathbb{R}^n$. By definition the map f is transverse to the 0-dimensional submanifold $\{y\}$ if and only if y is a regular value of f.

The following lemma might ring a bell. Considering the above examples we see that it is quite close to the statement of Lemma 67.1 and to the statement of the Regular Value Theorem 3.44.

Lemma 67.1. *Let M be a manifold and let Y be a proper submanifold of M of codimension l. Let X be some other manifold and let $f\colon X \to M$ be a smooth map. If f intersects Y transversely, then the following statements hold:*

(1) *The preimage $f^{-1}(Y)$ is a proper submanifold of X of codimension l.*
(2) *If M, X and Y are orientable, then $f^{-1}(Y)$ is orientable.*
(3) *If X is compact, then so is $f^{-1}(Y)$.*

[1127] Since Y is a submanifold of M we can view the tangent space $T_P Y$ as a subspace of $T_P M$.

Proof. The proof of this lemma is not overly hard. For space reasons we skip the proof and instead we refer to [Le2, Theorem 6.30] for a proof of (1). We leave the task of verifying the remaining statements to the reader. □

The following definition is a variation of the definition that we gave on page 334.

Definition. Let M be a manifold.

(1) Let W, W' be two proper submanifolds and let Z be (possibly empty) subset of W. We say that W and W' are (*smoothly*) *isotopic rel* Z, if there exists a (*smooth*) *isotopy from* W *to* W' *rel* Z, i.e. a map

$$\begin{array}{rcl} H\colon W \times [0,1] & \to & M \\ (z,t) & \mapsto & H(z,t) \end{array}$$

such that the following hold:
   (a) for each $P \in W$ we have $H(P,0) = P$,
   (b) for each $P \in Z$ and any $t \in [0,1]$ we have $H(P,t) = P$,
   (c) the map

$$\begin{array}{rcl} W & \to & M \\ z & \mapsto & H(z,1) \end{array}$$

   defines a homeomorphism (diffeomorphism) from W to W',
   (d) for each $t \in [0,1]$ the map $W \to M$ given by $P \mapsto H(P,t)$ is a proper homeomorphism onto its image (is a proper embedding).

   If W and W' are two oriented proper submanifolds, then we also want the following condition to be satisfied:
   (e) the diffeomorphism $W \to W'$ in (c) is orientation-preserving.

(2) Let X and Y be two submanifolds of M. We say X *and* Y *can be made transverse* (*respectively disjoint*) if there exist transverse (respectively disjoint) submanifolds X' and Y' of M such that X' is smoothly isotopic to X and Y' is smoothly isotopic to Y.

The next theorem says in particular that we can make any two proper submanifolds of a given manifold transverse.

Theorem 67.2. (Transversality Theorem) *Let M be a manifold and let Y be a proper submanifold of M.*[1128]

(1) *If X is a manifold and if $f\colon X \to M$ is a smooth map, then f is homotopic to a map that is transverse to Y.*
(2) *Let X be a proper submanifold of M. Given any neighborhood U of X there exists a smooth isotopy $F\colon X \times [0,1] \to U$ rel ∂X from X to a proper submanifold X' that is transverse to Y.*

Proof.

[1128]Note that the two statements are similar, but at least a priori they are independent in the sense that neither implies the other statement.

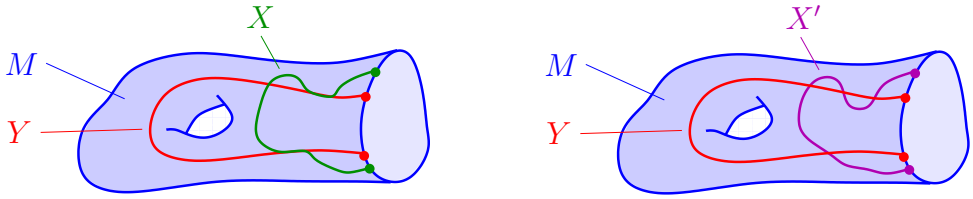

FIGURE 830. Illustration of Theorem 67.2 (2).

(1) This statement is proved in [Le2, Theorem 6.36]. A slightly less general statement is proved in [GP, p. 70].
(2) The theorem follows from Proposition 4.4.4, Theorem 4.5.6 and Proposition 4.5.7 of [Wall2].[1129] □

Example. Let M be a manifold. Furthermore let X and Y be two proper submanifolds. If $\dim(X) + \dim(Y) < \dim(M)$, then one deduces easily from the definitions that X and Y intersect transversally if and only if X and Y are disjoint. With this observation the Transversality Theorem 67.2 (2) says in particular that any two proper 1-dimensional submanifolds X and Y of the 3-dimensional ball $\overline{B}^3$ can be made disjoint after an isotopy rel boundary. This statement is illustrated in Figure 831.

FIGURE 831.

We conclude this section with a short discussion of self-transversal maps.

Definition. Let M and X be manifolds and let $\varphi\colon (X, \partial X) \to (M, \partial M)$ be a proper smooth map. We say φ *is self-transverse* if for any two points $P, Q \in X$ with $\varphi(P) = \varphi(Q)$ we have

$$\varphi_*(T_P X) + \varphi_*(T_P Y) \;=\; T_{\varphi(P)} M$$

and if for any two points $P, Q \in \partial X$ with $\varphi(P) = \varphi(Q)$ we have

$$\varphi_*(T_P X) + \varphi_*(T_P Y) \;=\; T_{\varphi(P)}(\partial M).$$

The proof of the following lemma is similar to the proof of Lemma 3.43. It is left as an exercise to the reader.

[1129] A first look at [Wall2, Theorem 4.5.6] might be slightly confusing since it demands that Y is a "submanifold of $J^r(M, N)$" for some $r \in \mathbb{N}_0$. But as is explained on page 101 of [Wall2], $J^0(M, X) = M \times X$, and $Y \times \{*\}$ is clearly a submanifold.

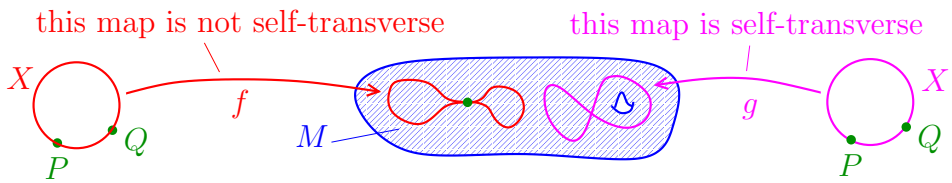

FIGURE 832.

Lemma 67.3. *Let M be an n-dimensional manifold and let a X be an m-dimensional manifold. Furthermore let $\varphi\colon (X, \partial X) \to (M, \partial M)$ be a proper smooth map. If φ is a self-transverse immersion, then the set*

$$\{P \in X \mid \textit{there exists a } Q \neq P \textit{ with } \varphi(P) = \varphi(Q)\}$$

is a proper submanifold of M of dimension $n - 2m$.

The following is a variation on the Transversality Theorem 67.2 (2).

Theorem 67.4. (Self-Transversality Theorem) *Let M be a manifold, let X be a manifold and let $\varphi\colon (X, \partial X) \to (M, \partial M)$ be an immersion. Given any neighborhood U of $\varphi(X)$ there exists a smooth isotopy $F\colon X \times [0,1] \to U$ from φ to a self-transverse immersion.*

Proof. The theorem is a straightforward consequence of [Wall2, Proposition 4.6.6]. □

67.2. **Algebraic intersection numbers of submanifolds.** In the following sections we want to study the question whether we can always make submanifolds disjoint. We start out with an example.

Example. We consider the three submanifolds X, Y and Z of the torus that are illustrated in Figure 833 on the left. As is shown in the same figure on the right, one can make X and Y disjoint.

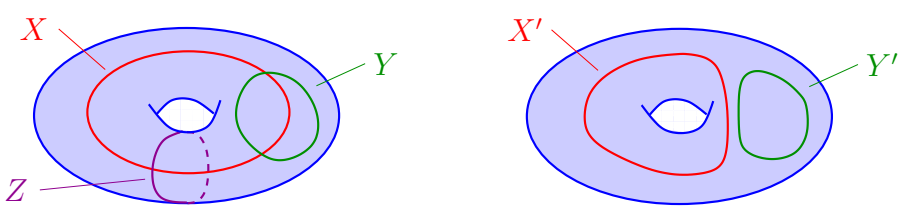

FIGURE 833.

It does not look like we can make the submanifolds X and Z disjoint. But how can we prove it? We will record this question for later.

Question 67.5. *Can we make the submanifolds X and Z, that are illustrated in Figure 833, disjoint?*

Lemma 67.6. *Let M be an m-dimensional manifold, let $X \subset M$ be a proper submanifold of dimension k and let $Y \subset M$ be a proper submanifold of the complementary dimension $m-k$. If X and Y intersect transversally and if X and Y are compact, then the intersection $X \cap Y$ consists of finitely many points.*

Proof. By Lemma 3.43 we know that $X \cap Y$ is a 0-dimensional submanifold of M. From our hypothesis we know that $X \cap Y$ is also compact. But any compact 0-dimensional submanifold of a manifold M is a finite set.[1130] □

Definition. Let M be an m-dimensional oriented manifold, let $X \subset M$ be a compact oriented proper submanifold of dimension k and let $Y \subset M$ be a compact oriented proper submanifold of the complementary dimension $m-k$. Suppose that X and Y intersect transversally.

(1) Let P be an intersection point of X and Y. We assign to P the sign $\sigma_P = 1$, if

$$\text{positive basis of } T_PX \text{ followed by positive basis of } T_PY \;=\; \text{positive basis of } T_PM.$$

Otherwise we put $\sigma_P = -1$.[1131]

(2) We define[1132]

$$\textit{geometric intersection number} \text{ of } X \text{ and } Y \;:=\; \#(X \cap Y)$$

and

$$\textit{algebraic intersection number} \text{ of } X \text{ and } Y \;:=\; X \cdot Y \;:=\; \sum_{P \in X \cap Y} \sigma_P \in \mathbb{Z}.$$

If X and Y do not intersect, then the algebraic intersection number of X and Y is of course zero.

Examples.

(1) In Figure 834 we show pieces of oriented submanifolds of the oriented manifold $\mathbb{R}^2$. On the left the sign of the intersection point is positive, on the right it is negative.

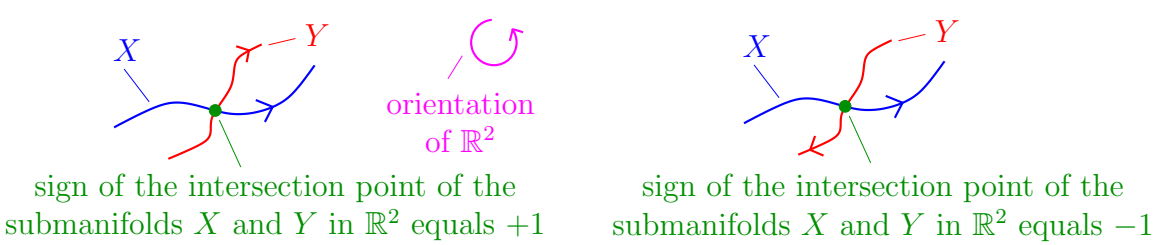

FIGURE 834.

[1130] Why is that?

[1131] It is a straightforward exercise in linear algebra to show that the definition of the sign σ_P does not depend on the choice of the positive bases of T_PU and T_PV.

[1132] It follows from Lemma 67.6 that the geometric intersection number is finite and that the algebraic intersection number is given by a finite sum.

(2) We consider the surface of genus 2 with the orientation where the normal vector "sticks outward" furthermore we consider the oriented submanifolds A, B, C, D and E that are illustrated in Figure 835. For the submanifolds A and B we have

$$\text{geometric intersection number of } A \text{ and } B \;=\; 1,$$

the sign of the intersection point is negative, hence

$$\text{algebraic intersection number of } A \text{ and } B \;=\; -1.$$

For the submanifolds A and C we have

$$\text{geometric intersection number of } A \text{ and } C \;=\; 2,$$

the intersection points have opposite signs, therefore

$$\text{algebraic intersection number of } A \text{ and } C \;=\; 0.$$

Finally for the submanifolds D and E we have

$$\text{geometric intersection number of } D \text{ and } E \;=\; 2,$$

here both intersection points have negative sign, thus

$$\text{algebraic intersection number of } D \text{ and } E \;=\; -2.$$

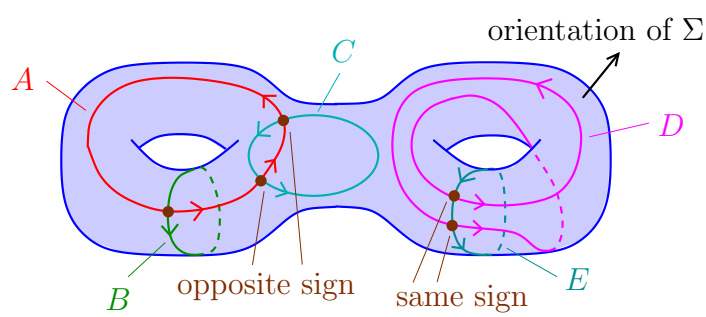

FIGURE 835.

(3) Now suppose that M and N are oriented manifolds of dimensions m respectively n. We assume that at most one of the two manifolds has non-empty boundary. We saw in Proposition 3.42 (1) that $M \times N$ is naturally[1133] a $(m+n)$-dimensional manifold. It is straightforward to show that for each $P \in M \setminus \partial M$ and $Q \in N \setminus \partial N$ the obvious map[1134]

$$T_P M \oplus T_Q N \;\to\; T_{(P,Q)}(M \times N)$$

[1133]What does he mean by "naturally"?
[1134]What is the obvious map?

is an isomorphism. If $\{v_1, \dots, v_m\}$ is a positive basis for $T_P M$ and $\{w_1, \dots, w_n\}$ is a positive basis for $T_Q N$, then we endow $T_{(P,Q)}(M \times N)$ with the orientation that makes the above isomorphism orientation-preserving.[1135]

Given $P \in M$ and $Q \in N$ it follows easily from the definitions that

$$\text{algebraic intersection number of } M \times \{Q\} \text{ and } \{P\} \times N \;=\; 1.$$

In Figure 836 we illustrate the statement that in the torus $S^1 \times S^1$ we have

$$\text{algebraic intersection number of } S^1 \times \{1\} \text{ and } \{1\} \times S^1 \;=\; 1.$$

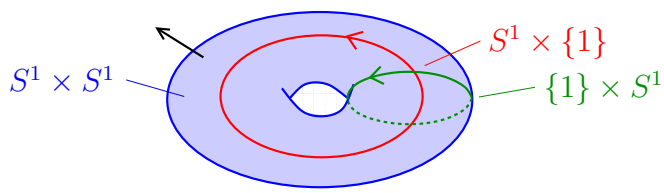

FIGURE 836.

(4) The above example (2) suggests that if two submanifolds have non-zero algebraic intersection number, then they cannot be made disjoint. This hunch is definitely not true if we allow *both* of the proper submanifolds to have boundary. More precisely in Figure 837 on the left we show the torus with one open disk removed and we show two proper submanifolds X and Y with boundary. The algebraic intersection number is $+1$, but as we see in Figure 837 on the right, these two submanifolds can be made disjoint. Therefore in the following discussion we will always assume that at least one of the two submanifolds is closed.[1136]

Before we continue, and in light of the last example, we introduce the following definition.

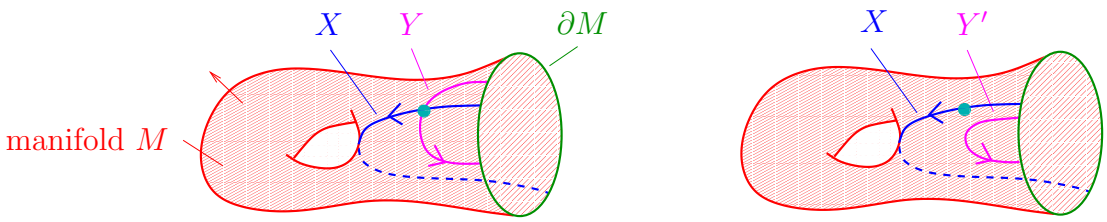
Definition. Let M be a compact oriented manifold and let X and Y be two submanifolds. We say X *and* Y *are complementary* if the following four conditions are satisfied:

(1) X is closed and Y is a proper submanifold,
(2) both X and Y are oriented,
(3) we have $\dim(X) + \dim(Y) = \dim(M)$,
(4) the submanifolds X and Y intersect transversally.

We would be able to answer Question 67.5 if we could prove the following statement.

[1135] One can easily verify that these orientations on the tangent spaces of $M \times N$ define an orientation on $M \times N$. In fact it follows fairly easily from Proposition 56.11 that this definition of the product orientation agrees with the definition we gave on page 1321.

[1136] Of course one could reformulate the question and consider only smooth isotopies rel the boundary of M. If we restrict ourselves to such isotopies then X and Y cannot be made disjoint.



the algebraic intersection number of X and Y equals $+1$

FIGURE 837.

Statement 67.7. *Let M be a compact oriented manifold and let $\{X, Y\}$ and $\{X', Y'\}$ be two pairs of complementary submanifolds of M. Then the following holds:*

$$X, X' \text{ are smoothly isotopic and } Y, Y' \text{ are smoothly isotopic} \quad \Longrightarrow \quad X \cdot Y \;=\; X' \cdot Y'.$$

But how can we prove such a statement? In Figure 838 we sketch an idea: We break the smooth isotopies from X to X' and from Y to Y' into "smaller isotopies" such that each smaller isotopy either does not change the type of intersection points, or two intersection points of opposite sign get created or erased. Even though the idea is fairly convincing, it is very hard to turn this idea into a proper proof.[1137][1138] So for the time being we will not attempt to provide a proof for Statement 67.7.

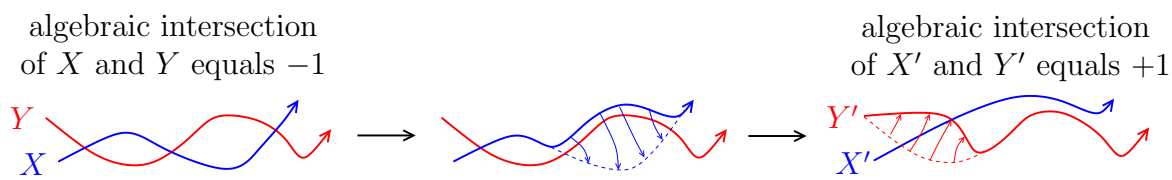


FIGURE 838.

We continue with developing the theory of algebraic intersection numbers a little further. We have the following elementary lemma which follows quite easily from the definitions and some basic linear algebra.

Lemma 67.8. *Let M be a compact oriented manifold. If X and Y are complementary submanifolds of M, then*

$$Y \cdot X \;=\; (-1)^{\dim(X)\cdot\dim(Y)} \cdot X \cdot Y.$$

[1137] You will see it is already hard to prove the statement in dimension 2, let alone in higher dimensions. In fact I am not aware of a direct geometric proof of Statement 67.7.

[1138] Even though we will not follow this approach, it was certainly this type of picture mathematicians had in mind when they developed the concept of algebraic intersection numbers in the early 20th century.

Sketch of proof. The statement follows easily from the definitions and the observation that the matrix that represents the linear homeomorphism that swaps the first k vectors with the last $(m-k)$ vectors of a basis of an m-dimensional vector space is represented by the matrix $\begin{pmatrix} 0 & \mathrm{id}_k \\ \mathrm{id}_{m-k} & 0 \end{pmatrix}$. One easily verifies that the determinant of this matrix equals $(-1)^{k(m-k)}$. □

The first part of the following definition dates back to page 579.

Definition.

(1) An *n-dimensional complex manifold* is a $2n$-dimensional manifold M without boundary together with a smooth atlas $\{\phi_i \colon U_i \to V_i\}_{i\in I}$ such that all transition maps are biholomorphisms.
(2) We define the *maximal complex atlas* of a complex manifold the same way as we defined the maximal smooth atlas of a manifold, see page 184.
(3) We say $W \subset M$ is a *k-dimensional complex submanifold* if for every point $P \in W$ there exists a chart $\phi_i \colon U_i \to V_i$ from the maximal complex atlas with $P \in U_i$ and which satisfies that $\phi_i(U_i \cap W) \subset \mathbb{C}^k \times \{0\}$.

Remark.

(1) Let M be a complex manifold. Note that every complex submanifold of M is a complex manifold in its own right.
(2) Proposition 21.4 shows that every complex manifold comes with a natural orientation. We will use this orientation throughout.

Now we can formulate this elementary but rather useful lemma.

Lemma 67.9. *Let M be a closed complex manifold and let X and Y be two closed complex submanifolds of M with $\dim(X) + \dim(Y) = \dim(M)$. Then the following hold:*

(1) *The sign at every transverse intersection point of X and Y is equal to $+1$.*
(2) *If X and Y intersect transversally, then the algebraic intersection number equals the geometric intersection number.*

Proof.

(1) We write $k = \dim(X)$ and $l = \dim(Y)$. Suppose that P is a transverse intersection point of X and Y. We pick a totally real basis $v_1, \dots, v_k$ for T_PX and we pick a totally real basis $w_1, \dots, w_l$ for T_PY. Then $v_1, \dots, v_k, w_1, \dots, w_l$ is evidently a totally real basis for $T_PX \oplus T_PY = T_PM$. We have
$$\underbrace{v_1, iv_1, \dots, v_k, iv_k}_{\text{positive basis for } T_PX}, \underbrace{w_1, iw_1, \dots, w_k, iw_k}_{\text{positive basis for } T_PY} = \underbrace{v_1, iv_1, \dots, v_k, iv_k, w_1, iw_1, \dots, w_l, iw_l}_{\text{positive basis for } T_PM}.$$
This shows that $\sigma_P = +1$. We have concluded the proof of the first statement.
(2) The second statement is an immediate consequence of the first statement. □

Example. We consider the complex projective plane $\mathbb{C}\mathrm{P}^n$. In Lemma 21.6 we saw that $\mathbb{C}\mathrm{P}^n$ is a complex manifold of complex dimension n. It follows easily from the definitions that for any $k \leq n$ the subset

$$X_k \;:=\; \{[z_0 : \ldots : z_k : 0 : \ldots : 0] \mid (z_0, \ldots, z_k) \in \mathbb{C}^{k+1} \setminus \{0\}\}$$

is a k-dimensional complex submanifold. Similarly

$$Y_k \;:=\; \{[0 : \ldots : 0 : z_{n-k} : \ldots : z_n] \mid (z_{n-k}, \ldots, z_n) \in \mathbb{C}^{k+1} \setminus \{0\}\}$$

is also a k-dimensional complex submanifold. Evidently both X_k and Y_k are biholomorphic to $\mathbb{C}\mathrm{P}^k$. Furthermore

$$X_k \cap Y_{n-k} \;=\; [0 : \ldots : 0 : \underset{\substack{\uparrow \\ \text{the } (k+1)\text{-st entry}}}{1} : 0 : \ldots : 0]$$

consists of a single point P. We leave it as an exercise to verify that X_k and Y_{n-k} intersect transversally at P. It follows from Lemma 67.9 that $X_k \cdot Y_{n-k} = 1$. The same way we also see that $Y_k \cdot X_{n-k} = 1$.

67.3. **The cup product and algebraic intersection numbers.** We recall the following notation.

Notation.

(1) Given a compact oriented n-dimensional topological manifold W we denote by $[W] \in H_n(W, \partial W; \mathbb{Z})$ its fundamental class. If W is a proper submanifold of some topological manifold M, then sometimes we denote by $[W] \in H_n(M, \partial M; \mathbb{Z})$ the image of $[W]$ under the inclusion induced map $H_n(W, \partial W; \mathbb{Z}) \to H_n(M, \partial M; \mathbb{Z})$.

(2) For the reader's convenience we recall the statement of the Poincaré Duality Theorem 61.1. Let M be a compact, non-empty n-dimensional topological manifold and suppose that we are given a decomposition $\partial M = A \cup B$ where A and B are compact $(n-1)$-dimensional submanifolds of ∂M such that $A \cap B = \partial A = \partial B$. Then for each $k \in \mathbb{N}_0$ the map

$$H^k(M, A; \mathbb{Z}) \;\xrightarrow{\cap [M]}\; H_{n-k}(M, B; \mathbb{Z})$$

is an isomorphism. We denote by

$$\mathrm{PD}_M \colon H_{n-k}(M, B; \mathbb{Z}) \;\longrightarrow\; H^k(M, A; \mathbb{Z})$$

its inverse. If M is understood from the context then often we just write PD instead of PD_M.

The following theorem relates the cup product on a manifold to algebraic intersection numbers. Or conversely, it expresses the algebraic intersection number of submanifolds as a cup product.

Theorem 67.10. *Let M be a compact oriented connected m-dimensional manifold. Let X and Y be a complementary pair of submanifolds of M. We write $k = \dim(X)$ and we*

denote by $i\colon X \to M$ and $j\colon Y \to M$ the obvious inclusion maps. Furthermore we denote by $[X] \in H_k(X)$ and $[Y] \in H_{m-k}(Y, \partial Y)$[1139] *the fundamental classes of X and Y. Then*

$$X \cdot Y \;=\; \Big\langle \overbrace{\underbrace{\mathrm{PD}_M(\underbrace{i_*([X])}_{\in H_k(M)})}_{\in H^{m-k}(M,\partial M)} \cup \underbrace{\mathrm{PD}_M(\underbrace{j_*([Y])}_{\in H_{m-k}(M,\partial M)})}_{\in H^k(M)}}^{\in H^m(M,\partial M)}, \overbrace{[M]}^{\in H_m(M,\partial M)} \Big\rangle \;\in\; \mathbb{Z}.$$

In particular with the abbreviation $[X] = i_*([X])$ and $[Y] := j_*([Y])$ we have the slightly more readable equality

$$X \cdot Y \;=\; \langle \mathrm{PD}_M([X]) \cup \mathrm{PD}_M([Y]), [M] \rangle.$$

Remark.

(1) Note that if in the setting of Theorem 67.10 the manifold M had non-empty boundary and if both X and Y were proper submanifolds with non-empty boundary, then the cohomological term in the statement of Theorem 67.10 would be

$$\underbrace{\mathrm{PD}_M(\underbrace{i_*([X])}_{\in H_k(M,\partial M)})}_{\in H^{m-k}(M)} \cup \underbrace{\mathrm{PD}_M(\underbrace{j_*([Y])}_{\in H_{m-k}(M,\partial M)})}_{\in H^k(M)}$$

but this is an element in $H^m(M)$ which is zero by Proposition 46.4 since M has non-empty boundary. After the informal discussion on page 1562 this is now a more formal reason why we cannot get any meaningful information if both X and Y have boundary.

(2) One easily verifies that the (anti-) commutativity of the algebraic intersection number of Lemma 67.8 corresponds precisely to the (anti-) commutativity of the cup product from Proposition 57.8.

(3) The following citation from [Kir4, p. 21] encapsulates the roles of algebraic intersection numbers and cup products:

> "Think with [algebraic] intersection [numbers], prove with cup products."

More precisely, algebraic intersection numbers are very intuitive and often they can be used to guess a statement. But when it comes to proving statements, e.g. why does the intersection number only depend on the isotopy type of a submanifold?, it is usually much easier to work with cup products.

Before we move on to the somewhat lengthy proof of Theorem 67.10 we want to convince ourselves that proving the theorem is worth the effort.

One application of Theorem 67.10 is that now we can provide a proof of a strengthened version of Statement 67.7. More precisely, we have the following proposition.

Proposition 67.11. *Let M be a compact oriented manifold.*

[1139] Recall that by definition of a complementary pair X is closed whereas Y is allowed to have boundary.

(1) *Let $\{X, Y\}$ and $\{X', Y'\}$ be pairs of complementary submanifolds of M. If X, X' are isotopic and if Y, Y' are isotopic, then $X \cdot Y = X' \cdot Y'$.*
(2) *If X and Y are two complementary submanifolds of M that can be made disjoint, then $X \cdot Y = 0$.*

Example. Now we can answer Question 67.5. The submanifolds X and Z, that are illustrated in Figure 833, cannot be made disjoint since their algebraic intersection number is non-zero.

Proof. Let M be a compact oriented manifold. We start out with the following claim.

Claim. If Z and Z' are isotopic compact oriented proper s-dimensional submanifolds of M, then $[Z] = [Z'] \in H_s(M, \partial M; \mathbb{Z})$.

We denote by $i\colon Z \to M$ and $i'\colon Z' \to M$ the inclusion maps. Since Z and Z' are isotopic there exists in particular an orientation-preserving homeomorphism $f\colon Z \to Z'$ such that the maps $i, i' \circ f\colon (Z, \partial Z) \to (M, \partial M)$ are homotopic. We obtain that

$$[Z] \;=\; i_*([Z]) \;\underset{\substack{\uparrow \\ \text{Proposition 31.15}}}{=}\; (i' \circ f)_*([Z]) = i'_*(f_*([Z])) \;\underset{\substack{\uparrow \\ \text{by Proposition 47.3 since } f \text{ is an} \\ \text{orientation-preserving homeomorphism}}}{=}\; i'_*([Z']) \;=\; [Z']$$

This concludes the proof of the claim.

Now let $\{X, Y\}$ and $\{X', Y'\}$ be two pairs of complementary submanifolds of M. We assume that the submanifolds X, X' are isotopic and that the manifolds Y, Y' are isotopic. We obtain that

$$X \cdot Y \;\underset{\substack{\uparrow \\ \text{Theorem 67.10}}}{=}\; \langle \mathrm{PD}_M([X]), \mathrm{PD}_M([Y]), [M] \rangle \;\underset{\substack{\uparrow \\ \text{by the claim}}}{=}\; \langle \mathrm{PD}_M([X']), \mathrm{PD}_M([Y']), [M] \rangle \;\underset{\substack{\uparrow \\ \text{Theorem 67.10}}}{=}\; X' \cdot Y'.$$

This concludes the proof of the first statement. The second statement is an immediate consequence of the first statement. □

Now we will use Theorem 67.10 "the other way", i.e. we will apply the theorem to use the algebraic intersection number to draw conclusions on (co-) homology classes and to determine cup products using our geometric understanding of submanifolds.

Example.

(1) Let M be the complement in S^3 of the two open 3-dimensional tori shown in Figure 839 on the left. On the right of that figure we show an annulus Y that is properly embedded in M. We will now see that $[Y] \in H_2(M, \partial M; \mathbb{Z})$ is non-trivial. Indeed, in the figure on the right we also see a closed 1-dimensional submanifold X of M. The two submanifolds X and Y are clearly transverse and they intersect in one point. So with whatever orientation, we have $X \cdot Y = \pm 1$. By Theorem 67.10 this implies in particular that $\mathrm{PD}_M([Y]) \neq 0$. But this in turn implies of course that $[Y]$ itself is non-zero.

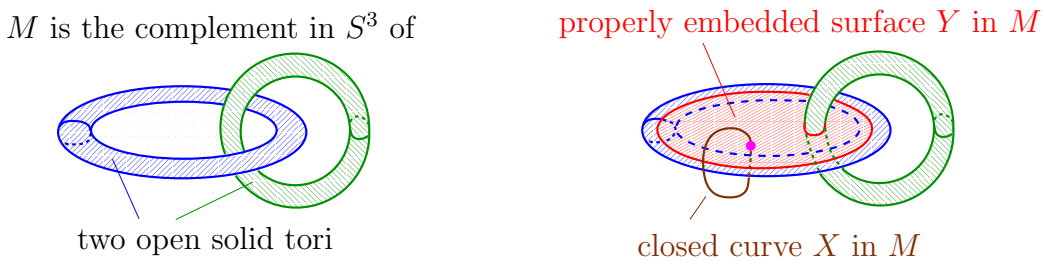

FIGURE 839.

(2) This time let M be the complement in S^3 of the two open 3-dimensional tori shown in Figure 840 on the left. Almost the same argument as in (1) shows that the surface X defines a non-trivial element in $H_2(M;\mathbb{Z})$.

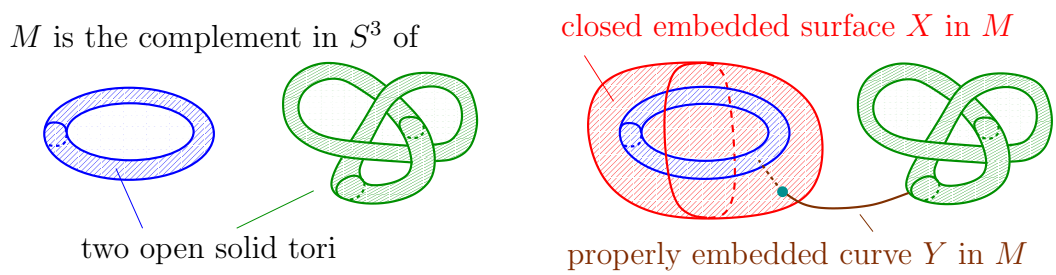

FIGURE 840.

Example. We consider the torus $T = S^1 \times S^1$ together with the submanifolds $X = S^1 \times \{1\}$ and $Y = \{1\} \times S^1$ which we endow with the usual orientations. By now we have many ways[1140] for showing that PD([X] and PD([Y]) form a basis for $H^1(T;\mathbb{Z})$. Thus if we want to understand the cup product on the torus, it suffices to understand the cup products involving these two cohomology classes. We calculate that

$$-\langle \mathrm{PD}([Y]) \cup \mathrm{PD}([X]), [S^1 \times S^1]\rangle \underset{\substack{\uparrow \\ \text{Proposition 57.8}}}{=} \langle \mathrm{PD}([X]) \cup \mathrm{PD}([Y]), [S^1 \times S^1]\rangle \underset{\substack{\uparrow \\ \text{Theorem 67.10}}}{=} X \cdot Y \underset{\substack{\uparrow \\ \text{Figure 841}}}{=} +1.$$

We denote by $X' = S^1 \times \{z\}$ with $z \neq 1$ a "parallel copy" of X and similarly we define Y'. We calculate that

$$\langle \mathrm{PD}([X]) \cup \mathrm{PD}([X]), [S^1 \times S^1]\rangle \underset{\substack{\uparrow \\ \text{by the claim in the proof of Proposition 67.11}}}{=} \langle \mathrm{PD}([X]) \cup \mathrm{PD}([X']), [S^1 \times S^1]\rangle \underset{\substack{\uparrow \\ \text{by Theorem 67.10, since } X \text{ and } X' \text{ are disjoint, in particular transverse}}}{=} X \cdot X' \underset{\substack{\uparrow}}{=} 0.$$

[1140]So, how many ways do you know?

and with the same argument we show that $\langle \mathrm{PD}([Y]) \cup \mathrm{PD}([Y]), [S^1 \times S^1] \rangle = 0$. We will now convince ourselves that these calculations match our previous calculations. To do so we denote by p_1 respectively p_2 the projection $S^1 \times S^1 \to S^1$ onto the first respectively the second factor and we denote by $\theta := \theta_{\mathbb{Z}} \in C^1(S^1; \mathbb{Z})$ the singular 1-cocycle that we introduced on page 1166. Now we see that

$$\begin{pmatrix} \mathrm{PD}([X]) \cup \mathrm{PD}([X]) & \mathrm{PD}([X]) \cup \mathrm{PD}([Y]) \\ \mathrm{PD}([Y]) \cup \mathrm{PD}([X]) & \mathrm{PD}([Y]) \cup \mathrm{PD}([Y]) \end{pmatrix} \underset{\substack{\text{on page 1374 we already showed that} \\ [p_1^*\theta] \cap [T] = [1 \times S^1] = [Y] \text{ and } [p_2^*\theta] \cap [T] = -[S^1 \times 1] = -[X]}}{=} \begin{pmatrix} [p_2^*\theta] \cup [p_2^*\theta] & -[p_2^*\theta] \cup [p_1^*\theta] \\ -[p_1^*\theta] \cup [p_2^*\theta] & [p_1^*\theta] \cup [p_1^*\theta] \end{pmatrix} \underset{\text{see page 1374}}{=} \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

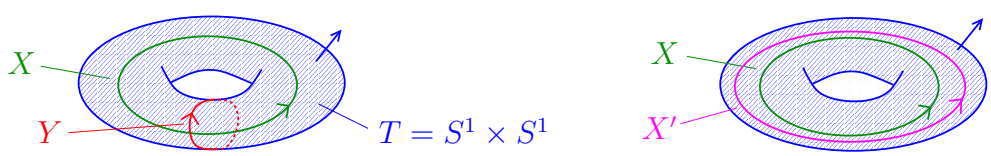

FIGURE 841.

We will do one more calculation of the cup product right after the proof of Theorem 67.10.

67.4. **Proof of Theorem 67.10.** In this section we will prove Theorem 67.10. Somewhat different proofs are given in [Bre, Theorem VI.11.9] or [DK, Theorem 10.32]. A quick outline of a proof is given in [GS, Proposition 1.2.5].

The proof of Theorem 67.10 will rely heavily on two lemmas that relate Poincaré duality in an oriented topological manifold M to Poincaré duality in a compact codimension 0 submanifold W.

The first lemma says that given a homology class in W we can apply Poincaré duality in M or W and essentially we end up with the same result:

Lemma 67.12. *Let M be a compact oriented m-dimensional topological manifold and let W be a compact m-dimensional submanifold with $M \cap \partial W = \varnothing$. We equip W with the induced orientation from Lemma 45.28. We write $\mathring{W} = W \setminus \partial W$.*[1141] *We fix the following notation:*

1. *We denote by w the inclusion map $W \to M$ and also the inclusion map of the pairs $(W, \partial W) \to (M, M \setminus \mathring{W})$,*
2. *we denote by $p\colon (M, \partial M) \to (M, M \setminus \mathring{W})$ the inclusion map of pairs.*

[1141] Recall that by Proposition 32.2 the set $\mathring{W} = W \setminus \partial W$ is indeed the interior of W in M.

Then for any $k \in \mathbb{N}_0$ the following diagram commutes[1142]

$$\begin{tikzcd}
H_k(W;\mathbb{Z}) \arrow[r, "\mathrm{PD}_W"] \arrow[d, "w_*"] & H^{m-k}(W,\partial W;\mathbb{Z}) \arrow[r, "(w^*)^{-1}", "\cong"'] & H^{m-k}(M, M\setminus \mathring{W};\mathbb{Z}) \arrow[d, "p^*"] \\
H_k(M;\mathbb{Z}) \arrow[rr, "\mathrm{PD}_M"] & & H^{m-k}(M,\partial M;\mathbb{Z}).
\end{tikzcd}$$

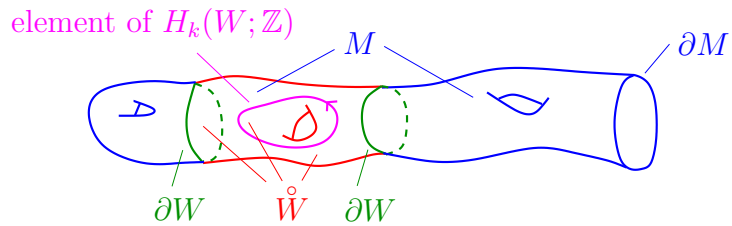

FIGURE 842. Illustration of Lemma 67.12.

Proof. By definition of the isomorphisms PD_W and PD_M, proving the lemma is equivalent to proving that the following diagram commutes:

$$\begin{tikzcd}
H_k(W;\mathbb{Z}) \arrow[d, "w_*"] & H^{m-k}(W,\partial W;\mathbb{Z}) \arrow[l, "\cap[W]"', "\cong"] & H^{m-k}(M, M\setminus \mathring{W};\mathbb{Z}) \arrow[l, "\cong", "w^*"'] \arrow[d, "p^*"] \\
H_k(M;\mathbb{Z}) & & H^{m-k}(M,\partial M;\mathbb{Z}). \arrow[ll, "\cap[M]", "\cong"']
\end{tikzcd}$$

So let $\beta \in H^{m-k}(M, M\setminus \mathring{W};\mathbb{Z})$. We have the following equality in $H_k(M;\mathbb{Z})$:

$$\begin{array}{ccccccc}
 & & \text{by Lemma 46.23 we have } p_*([M]) = w_*([W]) \in H_m(M, M\setminus\mathring{W}) & & & & \\
 & & \downarrow & & & & \\
w_*(w^*(\beta)\cap[W]) & = & \beta\cap w_*([W]) & = & \beta\cap p_*([M]) & = & p_*(\overbrace{p^*(\beta)\cap[M]}^{\in H_k(M)}) \quad = \quad p^*(\beta)\cap[M]. \\
 & & \uparrow & & \uparrow & & \uparrow \\
 & & \begin{array}{c}\text{Lemma 59.8 applied to}\\ w\colon (W,\partial W)\to(M, M\setminus\mathring{W})\end{array} & & \begin{array}{c}\text{Lemma 59.8 applied to}\\ p\colon (M,\partial M)\to(M, M\setminus\mathring{W})\end{array} & & \begin{array}{c}\text{since } p\colon M\to M \text{ is id}\\ \text{we have } p_* = \mathrm{id}_* = \mathrm{id}\end{array}
\end{array}$$

We have thus shown that the above diagram does indeed commute. □

We take a short rest from more technicalities and enjoy the fact that we can already prove Theorem 67.10 in the special case that M is closed and that the submanifolds *do not intersect*.

Proof of Theorem 67.10 for disjoint submanifolds. Let M be a closed oriented connected m-dimensional manifold and let X and Y be a complementary pair of *disjoint* submanifolds

[1142]Here we use that $w\colon (W,\partial W)\to(M, M\setminus\mathring{W})$ induces an isomorphism on cohomology by excision, see page 1192 for details.

of M. Since the submanifolds are disjoint it suffices to show that the cup product of the Poincaré duals of $[X]$ and $[Y]$ is also zero.

We write $k = \dim(X)$. We apply the General Tubular Neighborhood Theorem 64.7 to the submanifold $X \cup Y$ of M. We obtain disjoint tubular neighborhoods A for X and B for Y. We denote by $p\colon (M, \varnothing) \to (M, M \setminus \mathring{A})$ and $p\colon (M, \varnothing) \to (M, M \setminus \mathring{B})$ the obvious inclusion map of pairs of topological spaces.

We apply Lemma 67.12 to the codimension zero submanifold A and the homology class $[X] \in H_k(A; \mathbb{Z})$. We obtain an $\alpha \in H^{m-k}(M, M \setminus \mathring{A}; \mathbb{Z})$ with $p^*(\alpha) = \mathrm{PD}_M([X])$. Similarly we see that there exists a $\beta \in H^k(M, M \setminus \mathring{A}; \mathbb{Z})$ with $p^*(\beta) = \mathrm{PD}_M([Y])$.

We consider the following diagram

$$\begin{tikzcd}
H^{m-k}(M;\mathbb{Z}) \times H^k(M;\mathbb{Z}) \arrow[rr, "\cup"] & & H^m(M;\mathbb{Z}) \\
H^{m-k}(M, M\setminus\mathring{A};\mathbb{Z}) \times H^k(M, M\setminus\mathring{B};\mathbb{Z}) \arrow[rr, "\cup"] \arrow[u, "p^*\times p^*"'] \arrow[u, shift left=6, "(\mathrm{PD}_M([X]),\mathrm{PD}_M([Y]))"] \arrow[u, shift left=3, "\uparrow"] \arrow[u, shift left=1, "(\alpha,\beta)"] & & H^m(M, \underbrace{M\setminus\mathring{A} \cup M\setminus\mathring{B}}_{=M};\mathbb{Z}). \arrow[u]
\end{tikzcd}$$

The diagram commutes by Proposition 58.3 (1). It follows from the fact that the lower right group is zero that the cup product of $\mathrm{PD}_M([X])$ and $\mathrm{PD}_M([Y])$ is zero. $\square$

After this refreshing proof of the special case we continue with trying to prove the general case of Theorem 67.10. The following lemma also relates Poincaré Duality in a manifold M to Poincaré Duality in a compact submanifold W of codimension zero.

Lemma 67.13. *Let M be a compact oriented m-dimensional topological manifold and let W be a compact m-dimensional submanifold with corner. We equip W with the induced orientation from*[1143] *Lemma 45.28. We fix the following notation:*

1. *We write $\partial_1 W = W \cap \partial M$ and $\partial_0 W = \overline{\partial W \setminus \partial_1 W}$,*
2. *we write $\mathring{W} = W \setminus \partial_0 W$,*
3. *the inclusion maps $(W, \partial_0 W) \to (M, M \setminus \mathring{W})$ and $(W, \partial_1 W) \to (M, \partial M)$ are denoted by w, finally*
4. *we denote by $p\colon (M, \varnothing) \to (M, M \setminus \mathring{W})$ the obvious map.*

[1143]Lemma 45.28 was not formulated for submanifolds with corner, but the same construction as in Lemma 45.28 endows $W \setminus \partial W$ with an orientation.

Then for any $k \in \mathbb{N}_0$ the following diagram commutes[1144] [1145]

$$\begin{tikzcd}
H_k(M;\mathbb{Z}) \arrow[rr, "\mathrm{PD}_M"] \arrow[d, "p_*"] & & H^{m-k}(M,\partial M;\mathbb{Z}) \arrow[d, "w^*"] \\
H_k(M, M\setminus \mathring{W};\mathbb{Z}) \arrow[r, "(w_*)^{-1}", "\cong"'] & H_k(W,\partial_0 W;\mathbb{Z}) \arrow[r, "\mathrm{PD}_W"] & H^{m-k}(W,\partial_1 W;\mathbb{Z}).
\end{tikzcd}$$

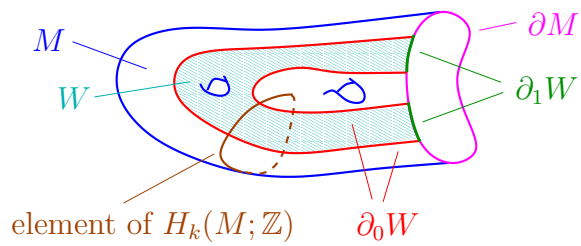

FIGURE 843. Illustration of Lemma 67.13.

Proof. In this proof we will twice use the full force of Lemma 59.8 applied to excisive triads. Since this can be seriously confusing we recall the general statement of the lemma. Let $f\colon (X,A,B) \to (\widetilde{X},\widetilde{A},\widetilde{B})$ be a map between two excisive triads. Then for any choice of $\varphi \in H^k(\widetilde{X},\widetilde{A};\mathbb{Z})$ and $\sigma \in H_m(X, A\cup B;\mathbb{Z})$ we have

$$\begin{array}{ccccc}
f_*\colon H_k(X,A\cup B) \to H_k(\widetilde{X},\widetilde{A}\cup\widetilde{B}) & & f^*\colon H^{m-k}(\widetilde{X},\widetilde{A}) \to H^{m-k}(X,A) & & \\
\downarrow & & \downarrow & & \\
\varphi \cap f_*(\sigma) & = & f_*(f^*(\varphi)\cap\sigma) & \in & H_k(\widetilde{X},\widetilde{B};\mathbb{Z}). \\
 & & \uparrow & & \\
 & & f_*\colon H_k(X,B) \to H_k(\widetilde{X},\widetilde{B}) & &
\end{array}$$

After this reminder we start out with the proof of the lemma in earnest. By definition of the isomorphisms PD_W and PD_M, proving the lemma is equivalent to proving that the following diagram commutes:

$$\begin{tikzcd}
H_k(M;\mathbb{Z}) \arrow[d, "p_*"] & & H^{m-k}(M,\partial M;\mathbb{Z}) \arrow[ll, "\cap[M]"', "\cong"] \arrow[d, "w^*"] \\
H_k(M, M\setminus \mathring{W};\mathbb{Z}) & H_k(W,\partial_0 W;\mathbb{Z}) \arrow[l, "w_*"', "\cong"] & H^{m-k}(W,\partial_1 W;\mathbb{Z}). \arrow[l, "\cap[W]"']
\end{tikzcd}$$

[1144]Here we use that by Lemma 64.1 we can apply the Poincaré Duality Theorem 61.1 to obtain that $\cap[W]\colon H^{m-k}(W,\partial_1 W;\mathbb{Z}) \to H_k(W,\partial_0 W;\mathbb{Z})$ is an isomorphism. We denote its inverse by PD_W.

[1145]Furthermore we use that $w\colon (W,\partial_0 W) \to (M, M\setminus\mathring{W})$ induces an isomorphism on cohomology by excision, see page 1192 for details.

So let $\beta \in H^{m-k}(M, \partial M; \mathbb{Z})$. We have the following equalities in $H_k(M, M \setminus \mathring{W}; \mathbb{Z})$:

$$\begin{array}{ccccccc} p_*(\beta \cap [M]) & = & \beta \cap p_*([M]) & = & \beta \cap w_*([W]) & = & w_*(w^*(\beta) \cap [W]). \\ & \uparrow & & \uparrow & & \uparrow & \end{array}$$

Lemma 59.8 applied to the map $p\colon (M, \partial M, \varnothing) \to (M, \partial M, M \setminus \mathring{W})$ of excisive triads

by Lemma 46.23 we have $p_*([M]) = w_*([W])$ in $H_m(M, M \setminus \mathring{W})$

Lemma 59.8 applied to the map $w\colon (W, \partial_1 W, \partial_0 W) \to (M, \partial M, M \setminus \mathring{W})$ of excisive triads □

In the proof of Theorem 67.10 we will need the following proposition.

Proposition 67.14. *Let M be a compact oriented manifold and let X and Y be two complementary proper submanifolds of dimensions k and l. We denote by $P_1, \dots, P_s$ the intersection points of X and Y. Then there exist*

(1) *compact submanifolds with corner A and B such that A is a neighborhood for X and B is a neighborhood for Y, and*
(2) *injective maps $\Psi_i\colon \overline{B}^k \times \overline{B}^l \to M$, $i = 1, \dots, s$*

such that the following statements hold:

(a) *For each $i \in \{1, \dots, s\}$ we have $\Psi_i((0,0)) = P_i$.*
(b) *The images $Q_i := \Psi_i\big(\overline{B}^k \times \overline{B}^l\big)$, $i = 1, \dots, s$ are disjoint.*
(c) *We have $Q_1 \cup \dots \cup Q_s = A \cap B$.*
(d) *For each $i \in \{1, \dots, s\}$ the following statements hold:*
  (d1) *the restriction of Ψ_i to $B^k \times B^l$ is a diffeomorphism onto its image,*
  (d2) *we have $Q_i \cap X = \Psi_i(\overline{B}^k \times \{0\})$ and the map $\Psi_i\colon \overline{B}^k \times \{0\} \to X$ is an orientation-preserving embedding,*
  (d3) *we have $Q_i \cap Y = \Psi_i(\{0\} \times \overline{B}^l)$ and the map $\Psi_i\colon \{0\} \times \overline{B}^l \to Y$ is an orientation-preserving embedding.*

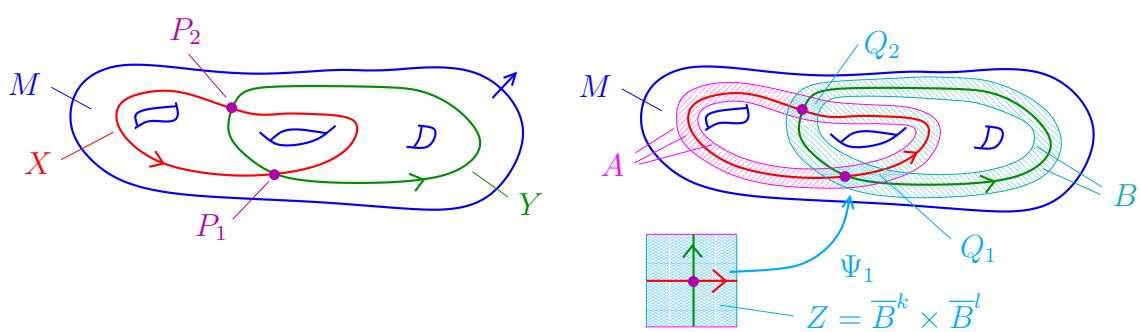

FIGURE 844. Illustration of Proposition 67.14.

Sketch of a proof. Let M be a compact oriented n-dimensional manifold and let X and Y be two complementary proper submanifolds of dimensions k and l. We denote by $P_1, \dots, P_s$

the intersection points of X and Y. For $i = 1, \dots, s$ we can and will pick embeddings $\Psi_i \colon \overline{B}^n \to M \setminus \partial M$ such that the following conditions are satisfies:

(1) the images are disjoint,
(2) for each $i \in \{1, \dots, s\}$ the map Ψ_i restricts to orientation-preserving diffeomorphisms $B^k \times \{0\} \to \Psi_i(B^n) \cap X$ and $\{0\} \times B^l \to \Psi_i(B^n) \cap Y$.

We consider $W := M \setminus \bigcup_{i=1}^{s} \Psi_i(B^n)$. Note that $X' := W \cap X$ and $Y' := W \cap Y$ are proper submanifolds of the compact manifold W. Thus we can apply the General Tubular Neighborhood Theorem 64.7 to obtain tubular neighborhoods for X' and Y'. Using Proposition 10.27 we can arrange the intersections of the tubular neighborhoods with $\Psi_i(S^{n-1})$ to be "standard $(n-1)$-dimensional balls". At this stage it is fairly straightforward to extend the tubular neighborhoods to the interiors of the $\Psi_i(B^n)$ and to obtain all the desired objects. We have faith in the unwavering enthusiasm of our readers for filling in the details. □

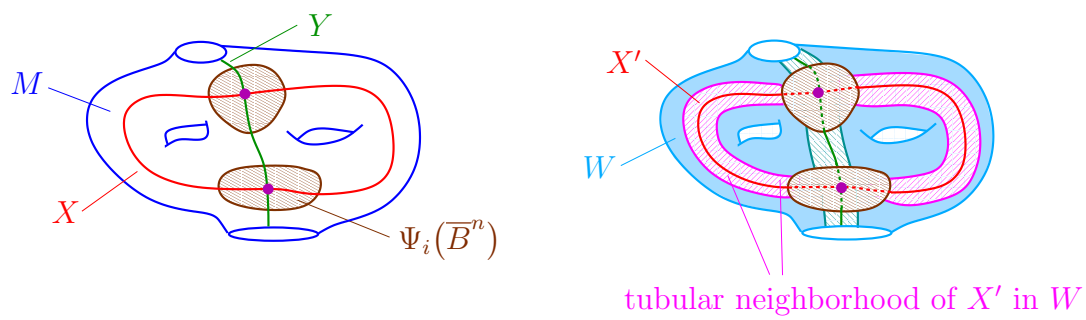

FIGURE 845. Illustration of the proof of Proposition 67.14.

Remark. An alternative approach to Proposition 67.14 would be to use tubular neighborhoods provided by Lemma 64.14.

Given the situation of Proposition 67.14 we can make one more statement.

Lemma 67.15. *We use the notation of Proposition 67.14. Let $i \in \{1, \dots, s\}$. We equip the topological manifold Q_i, which is a codimension zero submanifold of M, with the induced orientation coming from Lemma 45.28. Furthermore we equip the topological manifold $\overline{B}^k \times \overline{B}^l$ with the orientation coming from the standard orientation of $\mathbb{R}^k \times \mathbb{R}^l = \mathbb{R}^{k+l}$. With these choices the following statement holds:*

(g) *If we denote by σ_i the sign of the intersection point P_i, then*

$$\Psi_{i*}\big([\overline{B}^k \times \overline{B}^l]\big) \;=\; \sigma_i \cdot [Q_i].$$

Proof. Let $i \in \{1, \dots, s\}$. If follows from (e) and (f) that at the point $(0,0)$ the diffeomorphism $\Psi_i \colon B^k \times B^l \to \mathring{Q}_i$ is orientation-preserving if and only if $\sigma_i = 1$. Now the statement follows easily from the definition of σ_i, Proposition 47.3 and Lemma 45.23. □

The last preparation we need before we can provide the actual proof of Theorem 67.10 is the following variation of Proposition 60.2.

Proposition 67.16. *Let X be a compact oriented connected m-dimensional topological manifold and let Y be a compact oriented connected n-dimensional topological manifold. We denote by $p\colon X \times Y \to X$ and $q\colon X \times Y \to Y$ the obvious projection maps. If $P \in X$ and $Q \in Y$ are points, then*

$$\mathrm{PD}_{X\times Y}([X \times \{Q\}]) \cup \mathrm{PD}_{X\times Y}([\{P\} \times Y]) \;=\; [X \times Y]^*.$$

Proof. We calculate that

$$\begin{aligned}
\mathrm{PD}_{X\times Y}([X\times\{Q\}])\cup\mathrm{PD}_{X\times Y}([\{P\}\times Y]) &\overset{\text{Proposition 57.8}}{\underset{\text{by Proposition 60.2 (1) and the definition of } \mathrm{PD}_{X\times Y}}{=}} (-1)^{mn}\cdot\mathrm{PD}_{X\times Y}([\{P\}\times Y])\cup\mathrm{PD}_{X\times Y}([X\times\{Q\}]) \\
&= p^*([X]^*) \cup q^*([Y]^*) \;\underset{\text{by Proposition 60.2 (1)}}{=}\; [X\times Y]^*.
\end{aligned}$$

□

We turn to the actual proof of Theorem 67.10.

Proof of Theorem 67.10. Let M be a compact oriented connected m-dimensional manifold. To simplify the notation we assume that M is closed. The case that M has boundary is proved in a rather similar fashion.[1146]

Let X and Y be a complementary pair of submanifolds of M. We introduce the following notation:

(1) We write $k = \dim(X)$ and $l = m - k$.
(2) As usual we denote by $[X] \in H_k(X)$ and $[Y] \in H_l(Y)$ the fundamental classes of X and Y. By a slight abuse of notation we denote by $[X]$ respectively $[Y]$ also the images of these homology classes in any subset of M that contain X respectively Y.
(3) We denote the intersection points of X and Y by $P_1, \dots, P_s$ and we denote the corresponding signs by $\sigma_1, \dots, \sigma_s$.
(4) As usual, given a topological space X we denote by $\epsilon_X = \epsilon\colon H_0(X) \to \mathbb{Z}$ the augmentation map.

With the notation that we just introduced, and keeping in mind Lemma 59.4 (1), the statement of Theorem 67.10 can be reformulated as the following statement.

Statement.

$$\epsilon_M\big((\mathrm{PD}_M([X]) \cup \mathrm{PD}_M([Y])) \cap [M]\big) \;=\; \sum_{i=1}^{s} \sigma_i.$$

We introduce many more objects, notations and conventions:

[1146] Admittedly, the case that M has boundary also requires the generalization of Lemma 67.12 to the case that W is a codimension zero submanifold with corner. But that is not really a problem.

(5) We apply Proposition 67.14 to the submanifolds X and Y. In the remainder of the proof we use the notation that we introduced in that proposition. As a reminder, most of the relevant objects are illustrated in Figure 844.
(6) We denote by Z the "cylinder" $\overline{B}^k \times \overline{B}^l$.
(7) We write $\mathring{A} = A \setminus \partial A$ and $\mathring{B} = B \setminus \partial B$.
(8) We denote all of the inclusion maps $(M, \varnothing) \to (M, M \setminus \mathring{A})$, $(M, \varnothing) \to (M, M \setminus \mathring{B})$ and $(M, \varnothing) \to (M, M \setminus (\mathring{A} \cap \mathring{B}))$ by p.
(9) We write $C = A \cap B = Q_1 \cup \cdots \cup Q_s$. Furthermore we write $\partial_A C = \partial A \cap B$ and $\partial_B C = A \cap \partial B$. Note that $\partial C = \partial_A C \cup \partial_B C$. Also note that $(M \setminus \mathring{A}) \cup (M \setminus \mathring{B}) = M \setminus \mathring{C}$.
(10) We denote by $c\colon C \to M$ the inclusion map and we denote by c also all the corresponding inclusion maps of pairs where the first terms are C and M.
(11) Given $i \in \{1, \dots, s\}$ we write $\partial_A Q_i = \partial_A C \cap Q_i$ and $\partial_B Q_i = \partial_B C \cap Q_i$. Note that $\partial Q_i = \partial_A Q_i \cup \partial_B Q_i$.
(12) Given $i \in \{1, \dots, s\}$ we denote by $q_i\colon Q_i \to C$ the inclusion map and we denote by q_i also all the corresponding inclusion maps of pairs where the first terms are Q_i and C.
(13) Note that C and each Q_i is a codimension zero submanifold of M. We equip these submanifolds with the corresponding orientation introduced in Lemma 45.28.

We illustrate some of the definitions in Figure 846.

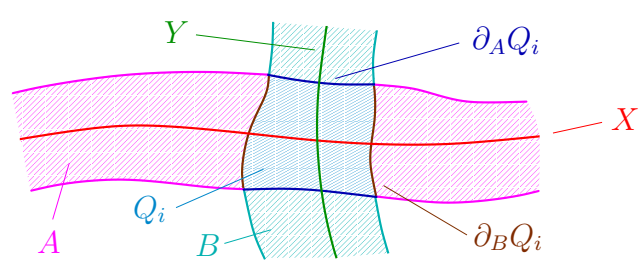

Figure 846.

Now we consider the following diagram:[1147]

$$\begin{tikzcd}
H^l(M) \times H^k(M) \arrow[r, "\cup"] & H^m(M) \arrow[r, "\cap[M]"] & H_0(M) \arrow[r, "\epsilon_M"] \arrow[d, "="] & \mathbb{Z} \arrow[d, "="'] \\
H^l(M, M\setminus \mathring{A}) \times H^k(M, M\setminus \mathring{B}) \arrow[r, "\cup"] \arrow[u, "p^*\times p^*"] \arrow[d, "c^*\times c^*"] & H^m(M, M\setminus \mathring{C}) \arrow[r, "\cap p_*([M])"] \arrow[u, "p^*"] \arrow[d, "c^*"] & H_0(M) \arrow[r, "\epsilon_M"] & \mathbb{Z} \\
H^l(C, \partial_A C) \times H^k(C, \partial_B C) \arrow[r, "\cup"] \arrow[d, "\bigoplus_{i=1}^s q_i^*\times q_i^*"] & H^m(C, \partial C) \arrow[r, "\cap[C]"] \arrow[d, "\bigoplus_{i=1}^s q_i^*"] & H_0(C) \arrow[r, "\epsilon_C"] \arrow[u, "c_*"] & \mathbb{Z} \arrow[u, "="] \\
\bigoplus_{i=1}^s H^l(Q_i, \partial_A Q_i) \times H^k(Q_i, \partial_B Q_i) \arrow[r, "\oplus\cup"] & \bigoplus_{i=1}^s H^m(Q_i, \partial Q_i) \arrow[r, "\bigoplus_{i=1}^s \cap[Q_i]"] & \bigoplus_{i=1}^s H_0(Q_i) \arrow[r, "\sum \epsilon_{Q_i}"] \arrow[u, "\sum_{i=1}^s q_{i*}"] & \mathbb{Z}. \arrow[u, "="]
\end{tikzcd}$$

Claim 1. The above diagram commutes.

In the following we deal with all of the nine squares of the diagram.

(a) The left squares in the first and second row commute by Proposition 58.3 (1).
(b) The left square in the third row commutes by Lemma 59.9 (1) together with the aforementioned Proposition 58.3 (1).
(c) The middle square in the first row commutes by Lemma 59.8 (1).
(d) It follows from our orientation conventions and Lemma 46.23 that $c_*([C]) = p_*([M])$. It follows from Lemma 59.8 (1) that the middle square in the second row commutes.
(e) It follows from the remark on page 1114 that $\sum_{i=1}^s q_{i*}([Q_i]) = [C]$. Now we obtain from Lemma 59.8 (1) and Lemma 59.9 (2) that the middle square in the third row commutes.
(f) The squares that involve the augmentation maps commute by the discussion on page 747.

This concludes the proof of the claim.

We introduce a few last pieces of notation:

(14) We denote by $a\colon (A, \partial A) \to (M, M \setminus \mathring{A})$ and $b\colon (B, \partial B) \to (M, M \setminus \mathring{B})$ the inclusion maps, note that a and b induce isomorphisms on cohomology by excision, see page 1192 for details.
(15) We write
$$\alpha = (a^*)^{-1}(\underbrace{\mathrm{PD}_A([X])}_{\in H^l(A,\partial A)}) \in H^l(M, M\setminus \mathring{A}) \text{ and } \beta = (b^*)^{-1}(\underbrace{\mathrm{PD}_B([Y])}_{\in H^k(B,\partial B)}) \in H^k(M, M\setminus \mathring{B}).$$
(16) Given $i \in \{1, \dots, s\}$ we write $X_i = X \cap Q_i$ and $Y_i = Y \cap Q_i$. It follows from Proposition 67.14 (e) and (f) that X_i and Y_i are codimension 0 submanifolds of X and Y. Since X and Y are oriented we can view X_i and Y_i also as oriented topological

[1147] Many of the vertical maps in the diagram are isomorphisms by excision, see page 1192 for details. But this is in fact irrelevant for our purpose.

manifolds. As usual we denote by $[X_i] \in H_k(X_i, \partial X_i)$ and $[Y_i] \in H_k(Y_i, \partial Y_i)$ the corresponding fundamental classes. With the same convention as before we denote by $[X_i]$ also the image under the inclusion induced map $H_k(X_i, \partial X_i) \to H_k(Q_i, \partial_B Q_i)$ and similarly we denote by $[Y_i]$ also the image under the inclusion induced map $H_k(Y_i, \partial Y_i) \to H_k(Q_i, \partial_A Q_i)$.

Claim 2. We have

(a) We have $p^*(\alpha) = \mathrm{PD}_M([X]) \in H^l(M)$ and $p^*(\beta) = \mathrm{PD}_M([Y]) \in H^k(M)$.

(b) For any $i \in \{1, \dots, s\}$ we have

$$(q_i^* \circ c^*)(\alpha) = \mathrm{PD}_{Q_i}([X_i]) \in H^l(Q_i, \partial_A Q_i) \text{ and } (q_i^* \circ c^*)(\beta) = \mathrm{PD}_{Q_i}([Y_i]) \in H^k(Q_i, \partial_B Q_i).$$

(c) For any $i \in \{1, \dots, s\}$ we have

$$\epsilon_{Q_i}\big((\mathrm{PD}_{Q_i}([X_i]) \cup \mathrm{PD}_{Q_i}([Y_i])) \cap [Q_i]\big) \;=\; \sigma_i.$$

We provide the proofs for the two statements of the claim.

(a) By Lemma 67.12 the following diagram commutes:

$$\begin{tikzcd}
H_k(A) \arrow[r, "\mathrm{PD}_A"'] \arrow[rr, bend left, "{[X]\mapsto\alpha}"] \arrow[d, "{[X]\mapsto[X]}"'] & H^l(A, \partial A) \arrow[r, "\cong", "(a^*)^{-1}"'] & H^l(M, M\setminus \mathring{A}) \arrow[d, "p^*"] \\
H_k(M) \arrow[rr, "\mathrm{PD}_M"] & & H^l(M).
\end{tikzcd}$$

We apply this commutative diagram to $[X] \in H_k(A)$ and we obtain immediately that $p^*(\alpha) = \mathrm{PD}_M([X])$. The same way one shows that $p^*(\beta) = \mathrm{PD}_M([Y])$.

(b) Let $i \in \{1, \dots, s\}$. We denote by $r_i \colon Q_i \to A$ the inclusion map. We consider the following diagram:

$$\begin{tikzcd}
H_k(A) \arrow[rr, "\mathrm{PD}_A"] \arrow[d] & & H^l(A, \partial A) \arrow[d, "r_i^*"] & H^l(M, M\setminus \mathring{A}) \arrow[l, "a^*"', "\cong"] \arrow[dl, "(q_i\circ c)^*"] \\
H_k(A, A\setminus \mathring{Q}_i) & H_k(Q_i, \partial_B Q_i) \arrow[l, "r_{i*}"', "\cong"] \arrow[r, "\mathrm{PD}_{Q_i}"] & H^l(Q_i, \partial_A Q_i). &
\end{tikzcd}$$

We make the following observations:

(α) The triangle on the right commutes since $a \circ r_i = c \circ q_i \colon Q_i \to M$ are both the inclusion map.

(β) It follows from Lemma 67.13, applied to the codimension zero submanifold Q_i of A, that the rectangle commutes.[1148]

(γ) By Lemma 46.23 we have $r_{i*}([X_i]) = [X] \in H_k(A, A \setminus \mathring{Q}_i)$.

[1148] One can easily convince oneself that $\partial_A Q_i = \partial_1 Q_i$ and $\partial_B Q_i = \partial_0 Q_i$ for Q_i viewed as a submanifold with corner of A.

(δ) It follows from a suitable variation of the excision theorem, see the remark on page 1489, that the map $r_{i*}\colon H_k(Q_i, \partial BQ_i) \to H_k(A, A \setminus \mathring{Q}_i)$ is an isomorphism.

The desired equality $(q_i^* \circ c^*)(\alpha) = \mathrm{PD}_{Q_i}([X_i])$ follows from the above commutative diagram applied to $[X] \in H_k(A)$. Exactly the same way we can also show that $(q_i^* \circ c^*)(\beta) = \mathrm{PD}_{Q_i}([Y_i])$.

(c) Let $i \in \{1, \dots, s\}$. We recall that $Z = \overline{B}^k \times \overline{B}^l$. We consider the following diagram:

$$\begin{tikzcd}
H^l(Q_i, \partial_A Q_i) \times H^k(Q_i, \partial_B Q_i) \arrow[r, "\cup"] \arrow[d, "\Psi_i^* \times \Psi_i^*"] & H^m(Q_i, \partial Q_i) \arrow[r, "\cap [Q_i]"] \arrow[d, "\Psi_i^*"] & H_0(Q_i) \arrow[r, "\epsilon_{Q_i}"] & \mathbb{Z} \\
H^l(Z, \overline{B}^k \times \partial\overline{B}^l) \times H^k(Z, \partial\overline{B}^k \times \overline{B}^l) \arrow[r, "\cup"] & H^m(Z, \partial Z) \arrow[r, "\cap \sigma_i \cdot [Z]"] & H_0(Z) \arrow[r, "\epsilon_Z"] \arrow[u, "\Psi_i^*"] & \mathbb{Z}. \arrow[u, "="']
\end{tikzcd}$$

As in the previous diagram, the squares to the left and right commute. The middle square is slightly more interesting. Lemma 67.15 says that $\Psi_{i*}([Q_i]) = \sigma_i \cdot [Z]$. Using this observation we obtain once again from Lemma 59.8 (1) that the middle square commutes.

We calculate that

$$\begin{aligned}
\epsilon_{Q_i}\big((\mathrm{PD}_{Q_i}([X_i]) \cup \mathrm{PD}_{Q_i}([Y_i])) \cap [Q_i]\big) &\overset{\text{by the above commutative diagram}}{=} \sigma_i \cdot \epsilon_Z\big((\Psi_i^*(\mathrm{PD}_{Q_i}([X_i])) \cup \Psi_i^*(\mathrm{PD}_{Q_i}([Y_i]))) \cap [Z]\big) \\
&= \sigma_i \cdot \epsilon_Z\big((\mathrm{PD}_Z([\overline{B}^k \times \{0\}]) \cup \mathrm{PD}_Z([\{0\} \times \overline{B}^l])) \cap [Z]\big) \\
&\underset{\text{Proposition 67.14 (d)}}{=} \sigma_i \cdot \epsilon_{\overline{B}^k \times \overline{B}^l}\big([\overline{B}^k \times \overline{B}^l]^* \cap [\overline{B}^k \times \overline{B}^l]\big) \underset{\text{definition of the dual fundamental class}}{=} \sigma_i.
\end{aligned}$$

Proposition 67.16

This concludes the proof of the claim.

After all these preparations we can prove the desired equality:

$$\begin{aligned}
\epsilon_M\big((\mathrm{PD}_M([X]) \cup \mathrm{PD}_M([Y])) \cap [M]\big) &\overset{\text{by the first row of the commutative diagram from Claim 1 and by Claim 2 (a)}}{=} \epsilon_M\big((\alpha \cup \beta) \cap p_*([M])\big) \\
&\underset{\text{by the second and third row of commutative diagram from Claim 1 and by Claim 2 (b)}}{=} \sum_{i=1}^s \epsilon_{Q_i}\big((\mathrm{PD}_{Q_i}([X_i]) \cup \mathrm{PD}_{Q_i}([Y_i])) \cap [Q_i]\big) \underset{\text{by Claim (2c)}}{=} \sum_{i=1}^s \sigma_i.
\end{aligned}$$

This concludes the proof of the theorem. □

Remark. Towards the end of the proof of the theorem we marked in red color that we used Proposition 67.16. Most of the other statements that we used in the proof were fairly straightforward lemmas regarding cup and cap products. But arguably the key ingredient

in the proof is Proposition 67.16 which was a variation of Proposition 60.2 and which in turn was a fairly straightforward consequence of the Product Theorem 60.1.

67.5. **Further applications of Theorem 67.10.** In this section we will give two more applications of Theorem 67.10.

Notation. Let $n \in \mathbb{N}$ and let $m \in \{0, \dots, n\}$.

(1) We consider the inclusion map

$$\begin{array}{rcl} i_{m,n}\colon \mathbb{C}\mathrm{P}^m & \to & \mathbb{C}\mathrm{P}^n \\ [z_0 : \dots : z_m] & \mapsto & [z_0 : \dots : z_m : 0 : \dots : 0]. \end{array}$$

When m and n are understood we write i instead of $i_{m,n}$. In Lemma 62.6 we showed that for any $k \le 2m$ the induced maps $i_*\colon H_k(\mathbb{C}\mathrm{P}^m;\mathbb{Z}) \to H_k(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$ and $i^*\colon H^k(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \to H^k(\mathbb{C}\mathrm{P}^m;\mathbb{Z})$ are isomorphisms.

(2) By a slight abuse of notation we abbreviate $(i_{m,n})_*([\mathbb{C}\mathrm{P}^m])$ to $[\mathbb{C}\mathrm{P}^m] \in H_{2m}(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$. Furthermore, again by a slight abuse of notation, we write $[\mathbb{C}\mathrm{P}^m]^* \in H^{2m}(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$ for the unique element with $\langle [\mathbb{C}\mathrm{P}^m]^*, [\mathbb{C}\mathrm{P}^m]\rangle = 1$. Finally we write $x = [\mathbb{C}\mathrm{P}^1]^*$.

In Proposition 62.7 we had used the Poincaré Duality Theorem 61.1 to show that for given $n \in \mathbb{N}$ and $k \in \{0, \dots, n\}$ the k-th power $x^k \in H^{2k}(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \cong \mathbb{Z}$ is a generator. In the following proposition we give a somewhat different proof for this statement, and more interestingly, we can precisely nail down the cohomology class x^k.

Proposition 67.17. *Let $n \in \mathbb{N}$. For every $k \in \{0, \dots, n\}$ we have*

$$(\underbrace{[\mathbb{C}\mathrm{P}^1]^*}_{=x})^k \;=\; [\mathbb{C}\mathrm{P}^k]^* \;\in\; H^{2k}(\mathbb{C}\mathrm{P}^n;\mathbb{Z}).$$

Remark.

(1) In contrast to Proposition 67.17 our earlier Proposition 62.7 only proves the equality $x^k = \pm[\mathbb{C}\mathrm{P}^k]^*$.

(2) Proposition 67.17 gives in particular an affirmative answer to Question 62.8.

The key to the proof of Proposition 67.17 is the following lemma.

Lemma 67.18. *Let $n \in \mathbb{N}$. For any $k \in \{0, \dots, n\}$ we have*

$$\mathrm{PD}_{\mathbb{C}\mathrm{P}^n}([\mathbb{C}\mathrm{P}^k]) \cup \mathrm{PD}_{\mathbb{C}\mathrm{P}^n}([\mathbb{C}\mathrm{P}^{n-k}]) \;=\; [\mathbb{C}\mathrm{P}^n]^* \;\in\; H^{2n}(\mathbb{C}\mathrm{P}^n;\mathbb{Z}).$$

Proof. Let $n \in \mathbb{N}$. For $k \in \{0, \dots, n\}$ we consider the inclusion map

$$\begin{array}{rcl} t_{k,n}\colon \mathbb{C}\mathrm{P}^k & \to & \mathbb{C}\mathrm{P}^n \\ [z_0 : \dots : z_k] & \mapsto & [0 : \dots : 0 : z_0 : \dots : z_k]. \end{array}$$

We also consider the map[1149]

$$\begin{array}{rcl} \Phi\colon \mathbb{C}\mathrm{P}^k \times [0,1] & \to & \mathbb{C}\mathrm{P}^n \\ ([z], t) & \mapsto & \big[\big(z \cdot \cos^2\big(t \cdot \frac{\pi}{2}\big), 0\big) + \big(0, z \cdot \sin^2\big(t \cdot \frac{\pi}{2}\big)\big)\big]. \end{array}$$

[1149]It is straightforward to verify that this map is well-defined, i.e. it does not depend on the choice of the representative $z \in \mathbb{C}^{k+1} \setminus \{0\}$ and $\big(z \cdot \cos^2\big(t \cdot \frac{\pi}{2}\big), 0\big) + \big(0, z \cdot \sin^2\big(t \cdot \frac{\pi}{2}\big)\big) \neq 0$ for all $t \in [0,1]$.

Then

$$\begin{aligned}
\langle \mathrm{PD}([\mathbb{C}\mathrm{P}^k]) \cup \mathrm{PD}([\mathbb{C}\mathrm{P}^{n-k}]), [\mathbb{C}\mathrm{P}^n]\rangle &= \langle \mathrm{PD}(i_{k,n*}([\mathbb{C}\mathrm{P}^k])) \cup \mathrm{PD}(i_{n-k,n*}([\mathbb{C}\mathrm{P}^{n-k}])), [\mathbb{C}\mathrm{P}^n]\rangle \\
&\underset{\substack{\uparrow \\ \text{by Proposition 30.5, since } \Phi \text{ is a homotopy from } i_{k,n} \text{ to } t_{k,n}}}{=} \langle \mathrm{PD}(t_{k,n*}([\mathbb{C}\mathrm{P}^k])) \cup \mathrm{PD}(i_{n-k,n*}([\mathbb{C}\mathrm{P}^{n-k}])), [\mathbb{C}\mathrm{P}^n]\rangle \\
&= \langle \mathrm{PD}([t_{k,n}(\mathbb{C}\mathrm{P}^k)]) \cup \mathrm{PD}([i_{n-k,n}(\mathbb{C}\mathrm{P}^{n-k})]), [\mathbb{C}\mathrm{P}^n]\rangle \\
&\underset{\substack{\uparrow \\ \text{by Theorem 67.10 since the submanifolds} \\ t_{k,n}(\mathbb{C}\mathrm{P}^k) \text{ and } i_{n-k,n}(\mathbb{C}\mathrm{P}^{n-k}) \text{ are transverse}}}{=} t_{k,n}(\mathbb{C}\mathrm{P}^k) \cdot i_{n-k,n}(\mathbb{C}\mathrm{P}^{n-k}) \underset{\substack{\uparrow \\ \text{see page 1565 for details}}}{=} 1.
\end{aligned}$$

By definition of the dual fundamental class this implies the desired result. □

We record the following fairly immediate corollary.

Corollary 67.19. *Let $n \in \mathbb{N}$. For any $k \in \{0, \dots, n\}$ we have*

$$\mathrm{PD}_{\mathbb{C}\mathrm{P}^n}([\mathbb{C}\mathrm{P}^k]) = [\mathbb{C}\mathrm{P}^{n-k}]^* \in H^{2n-2k}(\mathbb{C}\mathrm{P}^n; \mathbb{Z}).$$

Proof. Let $n \in \mathbb{N}$ and let $k \in \{0, \dots, n\}$. Then

$$\begin{aligned}
\langle \mathrm{PD}([\mathbb{C}\mathrm{P}^k]), [\mathbb{C}\mathrm{P}^{n-k}]\rangle &\underset{\substack{\downarrow \\ \text{by definition of } \mathrm{PD}([\mathbb{C}\mathrm{P}^{n-k}])}}{=} \langle \mathrm{PD}([\mathbb{C}\mathrm{P}^k]), \mathrm{PD}([\mathbb{C}\mathrm{P}^{n-k}]) \cap [\mathbb{C}\mathrm{P}^n]\rangle \\
&\underset{\substack{\uparrow \\ \text{Lemma 59.7 and Proposition 57.8}}}{=} \langle \mathrm{PD}([\mathbb{C}\mathrm{P}^k]) \cup \mathrm{PD}([\mathbb{C}\mathrm{P}^{n-k}]), [\mathbb{C}\mathrm{P}^n]\rangle \underset{\substack{\uparrow \\ \text{Lemma 67.18}}}{=} 1.
\end{aligned}$$

By definition of the dual fundamental class this implies the desired result. □

Now we can provide the proof of Proposition 67.17.

Proof of Proposition 67.17. We want show that for every $n \in \mathbb{N}$ and every $k \in \{0, \dots, n\}$ we have $([\mathbb{C}\mathrm{P}^1]^*)^k = [\mathbb{C}\mathrm{P}^k]^* \in H^{2k}(\mathbb{C}\mathrm{P}^n; \mathbb{Z})$. We start out with the following observation that follows immediately from the discussion on page 1580 and Lemma 57.10.

Observation. Let $m \in \mathbb{N}$ and let $k \in \{1, \dots, m\}$. If $([\mathbb{C}\mathrm{P}^1]^*)^k = [\mathbb{C}\mathrm{P}^k]^* \in H^{2k}(\mathbb{C}\mathrm{P}^m; \mathbb{Z})$, then for any $n \geq m$ we also have $([\mathbb{C}\mathrm{P}^1]^*)^k = [\mathbb{C}\mathrm{P}^k]^* \in H^{2k}(\mathbb{C}\mathrm{P}^n; \mathbb{Z})$

By the observation it suffices to prove the following claim.

Claim. For any $n \in \mathbb{N}$ we have $([\mathbb{C}\mathrm{P}^1]^*)^n = [\mathbb{C}\mathrm{P}^n]^* \in H^{2n}(\mathbb{C}\mathrm{P}^n; \mathbb{Z})$.

We prove the claim by induction on n. For $n = 1$ the statement holds by definition. So suppose that the statement holds for some $n - 1$ with $n \geq 2$. Then the following equality holds in $H^{2n}(\mathbb{C}\mathrm{P}^n; \mathbb{Z})$:

$$([\mathbb{C}\mathrm{P}^1]^*)^n = ([\mathbb{C}\mathrm{P}^1]^*)^{n-1} \cup [\mathbb{C}\mathrm{P}^1]^* \underset{\substack{\uparrow \\ \text{by induction and the observation}}}{=} [\mathbb{C}\mathrm{P}^{n-1}]^* \cup [\mathbb{C}\mathrm{P}^1]^* \underset{\substack{\uparrow \\ \text{Corollary 67.19}}}{=} \mathrm{PD}([\mathbb{C}\mathrm{P}^1]) \cup \mathrm{PD}([\mathbb{C}\mathrm{P}^{n-1}]) \underset{\substack{\uparrow \\ \text{Lemma 67.18}}}{=} [\mathbb{C}\mathrm{P}^n]^*.$$

This concludes the proof of the claim and thus of the proposition. □

Now we can answer Question 64.12 from an earlier chapter.

Proposition 67.20. *Every tubular neighborhood of* $\mathbb{C}\mathrm{P}^1 = i_{1,2}(\mathbb{C}\mathrm{P}^1)$ *in* $\mathbb{C}\mathrm{P}^2$ *is non-trivial.*[1150]

In Figure 102 we had implicitly seen that the tubular neighborhood of $\mathbb{R}\mathrm{P}^1$ in $\mathbb{R}\mathrm{P}^2$ is a Möbius band, and thus non-trivial. The above proposition is thus an analogue of this simpler, and more visual, observation.

Proof. Suppose that $\mathbb{C}\mathrm{P}^1$ admits a trivial tubular neighborhood in $\mathbb{C}\mathrm{P}^2$. By definition this means that there exists an embedding $\Phi\colon \mathbb{C}\mathrm{P}^1 \times \overline{B}^2 \to \mathbb{C}\mathrm{P}^2$ with $\Phi(P,0) = P$ for all $P \in \mathbb{C}\mathrm{P}^1$. We denote by $i = i_{1,2}\colon \mathbb{C}\mathrm{P}^1 \to \mathbb{C}\mathrm{P}^2$ the usual inclusion map and we denote by $f\colon \mathbb{C}\mathrm{P}^1 \to \mathbb{C}\mathrm{P}^2$ the embedding that is given by $P \mapsto \Phi(P,1)$. Then

$$\begin{aligned}
\pm 1 &\underset{\substack{\uparrow \\ \text{Proposition 67.17 or alternatively} \\ \text{Proposition 62.7}}}{=} \langle \mathrm{PD}(i_*([\mathbb{C}\mathrm{P}^1]) \cup \mathrm{PD}(i_*([\mathbb{C}\mathrm{P}^1])), [\mathbb{C}\mathrm{P}^2]\rangle \underset{\substack{\uparrow \\ \text{by Proposition 30.5 since } i,f\colon \mathbb{C}\mathrm{P}^1 \to \mathbb{C}\mathrm{P}^2 \text{ are homotopic} \\ \text{via the homotopy } (P,t)\mapsto \Phi(P,t)}}{=} \langle \mathrm{PD}(i_*([\mathbb{C}\mathrm{P}^1]) \cup \mathrm{PD}(f_*([\mathbb{C}\mathrm{P}^1])), [\mathbb{C}\mathrm{P}^2]\rangle \\
&\underset{\substack{\uparrow \\ \text{by Theorem 67.10}}}{=} i(\mathbb{C}\mathrm{P}^1)\cdot f(\mathbb{C}\mathrm{P}^1) \underset{\substack{\uparrow \\ \text{since } i(\mathbb{C}\mathrm{P}^1) \text{ and } f(\mathbb{C}\mathrm{P}^1) \text{ are disjoint}}}{=} 0.
\end{aligned}$$

We have thus obtained a contradiction. □

67.6. **Is the algebraic intersection number a complete invariant?** It is natural to ask whether the converse to Proposition 67.11 (2) holds. Playing around with curves on a surface shows that this looks dubious. More precisely, consider the oriented curves X and Y on the surface of genus 2 that are illustrated in Figure 847. Their algebraic intersection number is zero, but it is not clear how one can make them disjoint.[1151]

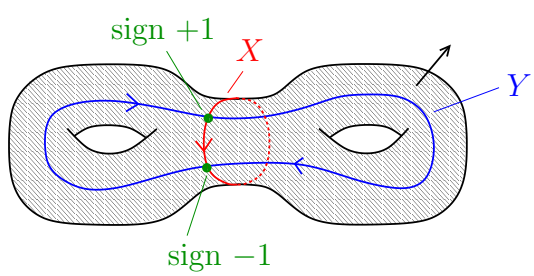

FIGURE 847.

[1150] We refer to page 1497 for the definition of a trivial tubular neighborhood.

[1151] Fun exercise: show that the curves cannot be made disjoint.

If one thinks for a while about the previous example, then one realizes that the issue in the example is that the manifold M is not simply connected. So it is more reasonable to demand some condition on the fundamental groups

Question 67.21. *Let M be an oriented m-dimensional manifold and let X and Y be complementary connected submanifolds of M. Suppose that $X \cdot Y = 0$ and that M is simply connected, does it follow that X and Y can be made disjoint?*

It turns out that the answer depends on the dimension of M.

Theorem 67.22. (Whitney) *Let M be an oriented simply connected manifold and let X and Y be complementary connected submanifolds of M.*

(1) *The answer to Question 67.21 is yes if* $\dim(X) \geq 3$ *and* $\dim(Y) \geq 3$.
(2) *The answer to Question 67.21 is yes if* $\dim(X) = 2$, $\dim(Y) \geq 3$ *and* $\pi_1(M \backslash Y) = 0$.

Remark. The fact that we have a positive answer to Question 67.21 in dimensions ≥ 6 turns out to be extremely useful, since, together with Theorem 67.10, it makes it possible to translate algebraic topological data, namely cup products, directly into geometric statements. This fact was a key ingredient in Hassler Whitney's proof that every n-dimensional manifold without boundary can be embedded into $\mathbb{R}^{2n}$, see Theorem 65.18. Furthermore, as explained in [Mi5], this fact played a crucial role in Steven Smale's proof of the Poincaré Conjecture in dimensions ≥ 5, see Theorem 28.22.

For dimensions ≥ 5 the theorem was proved by Hassler Whitney [Why2, Theorem 4] in 1944. An exposition of the proof is also given in [Kir3], [Sco, Chapter 1.5], [Mi5, Theorem 6.6], [GS, Theorem 9.2.7] or [RS, Theorem 5.12]. We only give a quick outline of the proof. Our main goal is to show where the restrictions on the dimensions enter.

Sketch of a proof of Theorem 67.22 (1). Let M be an oriented simply connected m-dimensional manifold and let X and Y be complementary connected submanifolds of M with $X \cdot Y = 0$ and with $\dim(X) \geq 3$ and $\dim(Y) \geq 3$. We do induction on the geometric intersection number $\#(X \cap Y)$. If $X \cap Y = \varnothing$, then there is nothing to prove. Now suppose that $X \cap Y \neq \varnothing$. Then there exist two intersection points P and Q of opposite signs. Since X is connected we obtain from Corollary 65.28 an embedded curve α on X from P to Q and since Y is connected we can similarly find an embedded curve β on Y from Q to P. Note that $\varphi := \alpha * \beta$ is in fact a loop. Since M is simply connected the curve $\varphi = \alpha * \beta \colon S^1 \to M$ is null-homotopic.

By Lemma 5.1 there exists a map $\Phi \colon \overline{B}^2 \to M$ with $\Phi|_{S^1} = \varphi$. Theorem 65.26 suggests[1152] that we can find a homotopy from Φ to a map $\Psi \colon \overline{B}^2 \to M$ such that $\Psi(S^1) = \Phi(S^1)$ and such that $\Psi \colon \overline{B}^2 \to M$ is an embedding.[1153] It follows from $\dim(X) \geq 3$ and $\dim(Y) \geq 3$ that $\dim(\Phi(\overline{B}^2)) + \dim(X) < \dim(M)$ and $\dim(\Phi(\overline{B}^2)) + \dim(Y) < \dim(M)$. Thus the

[1152]Here the exposition starts becoming rather vague.

[1153]Here there are some issues since the map $\alpha * \beta \colon S^1 \to M$ is not smooth at two points. In particular it is not quite clear what "embedding" is supposed to mean.
