Transversality Theorem 67.2 suggests that we can find a further isotopy so that we end up a with an embedded disk D with $\partial D = |\varphi| = |\alpha| \cup |\beta|$ and such that the interior of the disk intersects neither X nor Y. One can now use this disk to find an isotopy of X that removes the two intersection points P and Q without creating new intersection points. The precise construction of the isotopy is rather delicate. In fact, as the perspicacious reader might have noticed, so far we have not yet used that P and Q have opposite signs. We need it in finding this last isotopy. We refer to the aforementioned references for the details. □

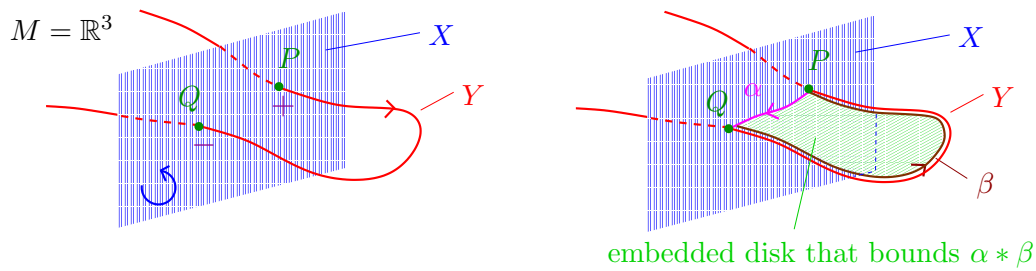

FIGURE 848. Illustration for the sketch of the proof of Theorem 67.22 (1).

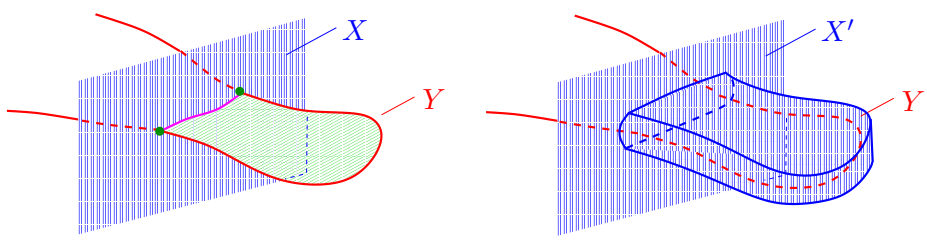

FIGURE 849. Second illustration for the sketch of the proof of Theorem 67.22 (1).

Remark. The approach taken in the proof of making submanifolds disjoint using embedded disks is often referred to as the "Whitney trick".

It turns out that we also have an affirmative answer to Question 67.21 in very low dimensions.

Theorem 67.23. *The answer to Question 67.21 is also yes if the dimension of the manifold is* ≤ 3.

Proof. The theorem is trivial for 1-dimensional manifolds. For 2-dimensional manifolds the proof is an amusing exercise using the fact, proved in Theorem 14.14, that every simply connected 2-dimensional manifold is diffeomorphic to S^2 or to $\overline{B}^2$.

For 3-dimensional manifolds the proof is similar to the proof in dimensions ≥ 5 except that one also needs to make use of the Loop Theorem (see [Pap] and [Hem]) to find the

embedded disk needed for the "Whitney trick". We leave it as a slightly challenging exercise to fill in the details in the 3-dimensional setting. □

So we are stilling missing 4-dimensional manifolds. Here the situation becomes tricky. It was known by 1961, see [KeM2], that the approach of the proof of Theorem 67.22, i.e. the Whitney trick, does not work for 4-dimensional manifolds. Later, see [Lacke], it was also shown that the Whitney trick does not work for topological 4-dimensional manifolds either.

In the 4-dimensional setting it is not only the case that the Whitney trick does not work. But more fundamentally, Question 67.21 has in fact a negative answer. For example it is known that there exist closed simply connected 4-manifolds and embedded spheres X, Y with zero intersection number that cannot be made disjoint by a smooth isotopy, in fact they cannot even be made disjoint by an isotopy that is not necessarily smooth, see e.g. [As, Theorem 1.2] for details. (More examples for the failure of the Whitney trick in dimension 4 are given in [Strl, Section 15.1] and [Gil].) As is pointed out in [As, Proposition 3.9], it is a consequence of the Freedman disk embedding theorem [FQ, Theorem 5.1.A] that under even stronger hypotheses the algebraic intersection number is in fact a complete invariant in the setting of topological manifolds.

The failure of the Whitney trick is at the heart of all the peculiar behavior of 4-dimensional manifolds which we had already encountered in Theorem 28.27.

67.7. **Higher dimensional analogue of Theorem 67.10.** We start out with the following definition which at first glance might look rather artificial.

Definition.

(1) An orientation for a 0-dimensional manifold M is a map $\epsilon\colon M \mapsto \{\pm 1\}$.
(2) Given an oriented 1-dimensional manifold W we define ∂W as the oriented 0-dimensional manifold given by the set ∂W and the sign $+1, -1$ assigned to the points depending on whether or not the orientation of W sticks "out" or "in" of W.[1154]
(3) The *fundamental class* of a compact oriented 0-dimensional manifold M consisting of points $\{P_1, \dots, P_k\}$ is defined as the homology class
$$\sum_{i=1}^{k} \epsilon(P_i) \cdot [P_i] \in H_0(M; \mathbb{Z}).$$
(4) Let N be an oriented k-dimensional topological manifold and let $M = \{P\}$ be a 0-dimensional manifold M consisting of a single point P that is equipped with an orientation $\epsilon \in \{-1, 1\}$. We equip the product topological manifolds $\{P\} \times N$ and $N \times \{P\}$ with the orientation that agrees with the orientation of N if $\epsilon(P) = +1$ and that is the opposite orientation if $\epsilon(P) = -1$. Similarly we define the product orientation of the product of any oriented topological manifold with any oriented 0-dimensional manifold.

[1154] We leave it to the reader to make this super-rigorous.

Example.

(1) The definition of the orientation of the boundary of an oriented 1-dimensional manifold is illustrated in Figure 850

FIGURE 850.

(2) The boundary of the 1-dimensional manifold $[0,1]$ with the usual orientation is given by $-\{0\} \cup \{1\}$.

(3) One can easily verify that the statement regarding product orientations from Proposition 3.42 (5) also holds in this context, i.e. given a 1-dimensional manifold M with boundary and a manifold N without boundary we have $\partial(M \times N) = (\partial M) \times N$ as *oriented* manifolds. In particular we have

$$\partial([0,1] \times N) \;=\; \underbrace{-\{0\} \times N}_{=\{0\}\times(-N)} \cup \{1\} \times N.$$

Let M be a compact oriented m-dimensional manifold, let $X \subset M$ be a closed oriented submanifold of codimension k and let Y be a compact oriented proper submanifold of the complementary dimension $m-k$. We suppose that X and Y are transverse. By assigning to each intersection point in $X \cap Y$ the sign introduced on page 1560 we can view $X \cap Y$ as a 0-dimensional oriented submanifold of M. With this convention we can reformulate the conclusion of Theorem 67.10 as follows:

Theorem 67.24. *With the above notation we have*

$$\mathrm{PD}_M([X]) \cup \mathrm{PD}_M([Y]) \;=\; \mathrm{PD}_M([X \cap Y]) \;\in\; H^{k+l}(M, \partial M; \mathbb{Z}).$$

Proof. Using Lemma 59.9 one can easily verify that it suffices to prove the theorem for each connected component of M separately. Put differently, without loss of generality we can assume that M is connected. We denote by $P_1, \dots, P_n$ the points in $X \cap Y$ and we denote by $\sigma_1, \dots, \sigma_n \in \{\pm 1\}$ the corresponding signs. Now we calculate that

$$\mathrm{PD}_M([X]) \cup \mathrm{PD}_M([Y]) \underset{\substack{\uparrow \\ \text{by Theorem 67.10 and since } M \text{ is connected}}}{=} (X \cdot Y) \cdot [M]^* = \sum_{i=1}^{n} \sigma_i \cdot [M]^* \underset{\substack{\uparrow \\ \text{see page 1414}}}{=} \sum_{i=1}^{n} \mathrm{PD}_M(\sigma_i \cdot [\{P_i\}]) = \mathrm{PD}_M([X \cap Y]).$$

□

The formulation of Theorem 67.24 has the nice feature that with some effort one can also generalize it to submanifolds that are not of complementary dimensions. Before we can formulate this generalization we need to formulate the following lemma.

Lemma 67.25. *Let M be an oriented m-dimensional manifold, let $X \subset M$ be an oriented proper submanifold and let Y be an oriented proper submanifold. Suppose that X and Y intersect transversally. By Lemma 3.43 we know that $X \cap Y$ is a submanifold. Given $P \in X \cap Y$ we have a natural short exact sequence induced by the various inclusion maps:*

$$0 \;\to\; T_P(X \cap Y) \;\to\; T_P X \oplus T_P Y \;\xrightarrow{\rho}\; T_P M \;\to\; 0.$$

We pick a set of vectors $\mathcal{C}$ in $T_P X \oplus T_P Y$ such that $\rho(\mathcal{C})$ is a positive basis for $T_P M$. We say that a basis $\mathcal{B}$ for $T_P(X \cap Y)$ is positive *if the basis $\{\mathcal{B}, \mathcal{C}\}$ is a positive basis for $T_P X \oplus T_P Y$. This definition is independent of the choices and it turns $X \cap Y$ into an oriented submanifold of M.*

Proof. We leave the elementary proof to the reader. □

Example. Let $n \in \mathbb{N}$ and let $0 \le k \le l \le n$. We consider $\mathbb{C}\mathrm{P}^n$ with the complex submanifolds

$$\begin{aligned} A &= \{[z_0 : \cdots : z_l : 0 : \cdots : 0] \,|\, (z_0, \ldots, z_l) \in \mathbb{C}^{l+1} \setminus \{0\}\} \\ B &= \{[0 : \cdots : 0 : z_k : \cdots : z_n] \,|\, (z_k, \ldots, z_n) \in \mathbb{C}^{n+1-k} \setminus \{0\}\} \end{aligned}$$

and

$$C = \{[0 : \cdots : 0 : z_k : \cdots : z_l : 0 : \cdots : 0] \,|\, (z_k, \ldots, z_l) \in \mathbb{C}^{l+1-k} \setminus \{0\}\}.$$

As usual we equip $\mathbb{C}\mathrm{P}^n$ and A, B, C with the natural orientations coming from Proposition 21.4. Then $A \cap B = C$ and one can easily show that the orientation of $A \cap B$ equals the orientation of C.

The following theorem is a generalization of Theorem 67.24 and thus also of Theorem 67.10.

Theorem 67.26. *Let M be a compact oriented m-dimensional manifold. Furthermore let $X \subset M$ be a closed oriented submanifold of codimension k and let Y be a compact oriented proper submanifold of codimension l. Then*[1155]

$$\underbrace{\mathrm{PD}_M([X])}_{\in H^k(M,\partial M)} \cup \underbrace{\mathrm{PD}_M([Y])}_{\in H^l(M)} \;=\; \mathrm{PD}_M([X \cap Y]) \;\in\; H^{k+l}(M, \partial M; \mathbb{Z}).$$

Proof. A proof is given in [Bre, Theorem VI.11.9]. □

Remark. Theorem 67.26 can be summarized as saying that cup products correspond to taking intersections of submanifolds. With this point of view, the symbol "$\cup$" for the cup product does not seem to be a great choice.

Examples.

[1155]The sign should be taken with a slight grain of salt. It is conceivable that the sign depends on the various dimensions.

(1) Let M be the manifold that is the complement in S^3 of the three open solid tori and the open ball that are shown in Figure 851. Furthermore let X and Y be the surfaces shown in that figure. Basically the same argument as on page 1568 shows that $[X]$ and $[Y]$ are non-trivial in $H_2(M;\mathbb{Z})$. On the other hand the class $[X \cap Y] \in H_1(M;\mathbb{Z})$ is clearly trivial. Therefore we deduce from Theorem 67.26 that $\mathrm{PD}_M([X]) \cup \mathrm{PD}_M([Y]) = 0$.

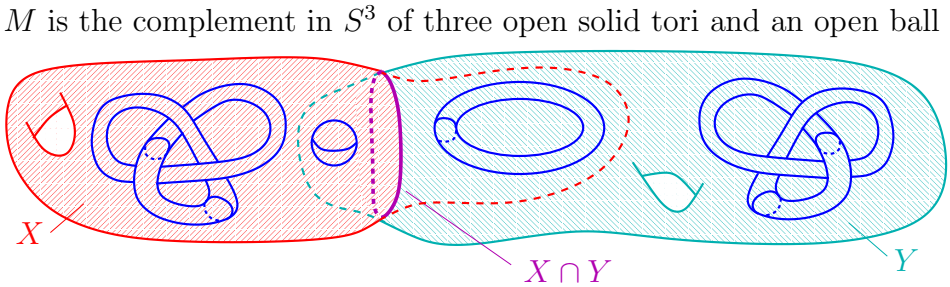

FIGURE 851.

(2) Using Theorem 67.26 and using the example preceding that theorem one can fairly easily give a completely geometric calculation of the cup product of $\mathbb{C}\mathrm{P}^n$.

Remark. Using Theorem 67.26 one can easily modify the proof of Proposition 67.20 to show that given any $n \geq 2$ every tubular neighborhood of $\mathbb{C}\mathrm{P}^{n-1}$ in $\mathbb{C}\mathrm{P}^n$ is non-trivial.

Exercises for Chapter 67.

Exercise 67.1. Let A, B be two 1-dimensional oriented submanifolds of S^2 with $A \cdot B = 0$. Sketch a proof for the claim that A and B can be made disjoint via isotopies of A and B.

Exercise 67.2. Let M be a closed oriented connected m-dimensional manifold. Furthermore let $p\colon \widetilde{M} \to M$ be a finite covering.

(a) Let X, Y be a complementary pair of submanifolds of M. We write $\widetilde{X} := p^{-1}(X)$ and $\widetilde{Y} := p^{-1}(Y)$. What is the relationship between $X \cdot Y$ and $\widetilde{X} \cdot \widetilde{Y}$? It suffices to give a short justification.
(b) Let X be a closed oriented submanifold of M. What is the relationship between $\mathrm{PD}_{\widetilde{M}}([\widetilde{X}])$ and $p^*(\mathrm{PD}_M([X])$? Justify your answer.
(c) Reprove (a) using (b) and Theorem 67.10.

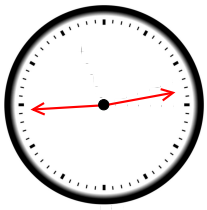
Exercise 67.3. Let M be an oriented m-dimensional manifold, let X be a k-dimensional oriented proper submanifold and let Y be an $(m-k)$-dimensional oriented proper submanifold of M. We suppose that $X \cap Y \cap \partial M = \varnothing$. What is the relationship between the algebraic intersection number $X \cdot Y$ in M and $DX \cdot DY$ in DM?
Here, as always, given a manifold N we denote by $DN = N \cup_{\partial N = \partial N'} N'$ the double of

N. We view DN as an oriented manifold where the orientation is chosen such that the orientation of DN agrees with the orientation on N.

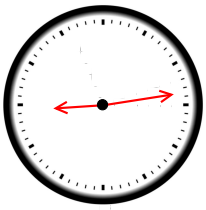
Exercise 67.4. Let $C \subset S^2 \times [1,2]$ be a closed surface. Suppose that there exists a $P \in S^2$ such that C intersects $\{P\} \times [1,2]$ transversally and that the intersection consists of a single point. Show that C intersects every path $\gamma\colon [0,1] \to S^2 \times [a,b]$ from a point in $S^2 \times \{a\}$ to a point in $S^2 \times \{b\}$.

Exercise 67.5. By accident you ended up buying a clock where both hands have the same length, so you can not distinguish the hand which shows the hour from the hand that indicates the minute. Fortunately, very often you can still tell the precise time. For example, in the configuration in Figure 852 it does not make sense for the hand that is indicating the hour to be just *before* 9 whereas the hand showing the minute is at 15.

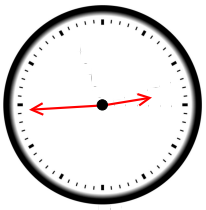
Of course there will be some configurations when it is indeed impossible to tell which hand is which. How many such confusions moments will there be in a 12 hour period? Hint: Consider a suitable map $\gamma\colon S^1 \to S^1 \times S^1$.



clock where both hands have the same length



this makes no sense



the time is 2:44

FIGURE 852.

Exercise 67.6. Let C and D be closed curves in $\mathbb{R}^2$ that intersect transversally. Give a rigorous proof that the number of intersection points between C and D is an even number.

68. Intersections of cycles and the cup product

In this chapter we generalize some of the results from the previous chapter. In particular we introduce the notion of "transverse cycles" in a topological manifold and we define the "algebraic intersection number" of transverse cycles. Afterwards we will show in Theorem 68.5 how this algebraic intersection number relates to the cup product. Later on we will see that this theorem greatly generalizes Theorem 67.10.

In the literature the pictorial "algebraic intersection number of transverse cycles" is often used as a substitute for the more forbidding cup product. This means that many authors implicitly use Theorem 68.5. To the best of my knowledge there is no published rigorous proof for Theorem 68.5, hence we decided to fill this gap in the literature.[1156]

Since the first part of the chapter is at times quite technical we start out with the following motivating question.

Question 68.1. *As shown in Figure 853 we consider the disk $\overline{B}^2$ together with the four points $P_\pm = (\pm 1, 0)$ and $Q_\pm = (0, \pm 1)$. Do there exist disjoint paths α and β such that α connects P_- to P_+ and β connects Q_- to Q_+?*

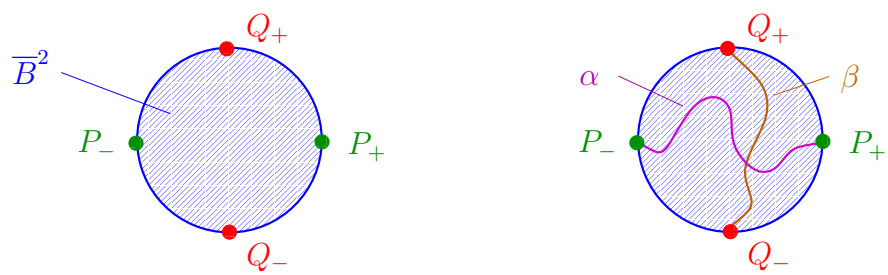


Figure 853.

It is pretty clear that the answer should be no. In fact once we have developed all the tools we will find it quite easy to answer Question 68.1 in the negative.

68.1. Intersections of cycles.

First we fix some notation.

Notation and Convention.

(1) Given a map $f\colon Y \to X$ between topological spaces we write $|f| = f(Y)$.
(2) We write $I = [-1, 1]$.
(3) Let M be an oriented topological manifold. We equip any codimension zero submanifold with the orientation coming from Lemma 45.28.

The following definition generalizes the concept of transversality from the last chapter.

[1156] In mathematics a statement that "everybody in a field knows", but for which no proof was ever written down, is called "folklore". It is a rather unfortunate aspect of mathematics that all too often statements which are very useful and which sound about right get used without bothering to write down a proof and without bothering to check whether a proof exists in the literature.

Definition. Let M be an m-dimensional topological manifold, let X be a k-dimensional topological manifold and let Y be an $(m-k)$-dimensional topological manifold. Furthermore let $f\colon X \to M$ and $g\colon Y \to M$ be maps. We say f and g *are transverse* at a point $P \in |f| \cap |g|$ if the following happens: there exists a compact submanifold Z of M and a homeomorphism $\Phi\colon Z \to I^k \times I^{m-k}$ such that:

(1) We have $P \in Z$ and we have $\Phi(P) = (0,0) \in I^k \times I^{m-k}$.
(2) The map Φ restricts to a homeomorphism $|f| \cap Z \to I^k \times \{0\} = I^k$,
(3) The map Φ restricts to a homeomorphism $|g| \cap Z \to \{0\} \times I^{m-k} = I^{m-k}$,
(4) the restriction of f to a map $f^{-1}(|f| \cap Z) \to |f| \cap Z$ is a homeomorphism, we write $X_P := f^{-1}(|f| \cap Z)$ and we denote the homeomorphism $X_P \to |f| \cap Z$ by $\widetilde{f}$,
(5) the restriction of g to a map $g^{-1}(|g| \cap Z) \to |g| \cap Z$ is a homeomorphism, we write $Y_P := g^{-1}(|g| \cap Z)$ and we denote the homeomorphism $Y_P \to |g| \cap Z$ by $\widetilde{g}$.

If these conditions are satisfied and if M, X, Y are oriented, then we refer to the degree of the map [1157] [1158] [1159] [1160] [1161]

$$\begin{array}{c}
\overbrace{H_k(X, X\setminus\{f^{-1}(P)\})}^{=\mathbb{Z}} \otimes \overbrace{H_{m-k}(Y, Y\setminus\{g^{-1}(P)\})}^{=\mathbb{Z}} \\
\cong \uparrow \\
H_k(X_P, X_P\setminus\{f^{-1}(P)\}) \otimes H_{m-k}(Y_P, Y_P\setminus\{g^{-1}(P)\}) \\
\cong \downarrow \widetilde{f}_* \otimes \widetilde{g}_* \\
H_k(|f|\cap Z, (|f|\cap Z)\setminus\{P\}) \otimes H_{m-k}(|g|\cap Z, (|g|\cap Z)\setminus\{P\}) \\
\cong \downarrow \Phi_* \otimes \Phi_* \\
H_k(I^k, I^k\setminus\{0\}) \otimes H_{m-k}(I^{m-k}, I^{m-k}\setminus\{0\}) \\
\cong \downarrow \times \\
H_m(I^m, I^m\setminus\{0\}) \\
\cong \downarrow (\Phi_*)^{-1} \\
H_m(Z, Z\setminus\{P\}) \\
\cong \downarrow \\
\underbrace{H_m(M, M\setminus\{P\})}_{=\mathbb{Z}}
\end{array}$$

as the *sign at* P. We refer to Figure 854 for an illustration. We say the maps f and g are *transverse* if they are transverse at all points in $|f| \cap |g|$.

On several occasions we will employ the following, almost self-explaining convention:

Convention. We continue with the notation from the previous definition. If X is a submanifold of M, then often we do not distinguish between X and the inclusion map. For example we will say that X is transverse to $g\colon Y \to M$ at a point P. The same convention applies to Y being a submanifold of M.

Lemma 68.2. *Let M be an oriented m-dimensional topological manifold, let X be an oriented k-dimensional topological manifold and let Y be an oriented $(m-k)$-dimensional topological manifold. Finally let $f\colon X \to M$ and $g\colon Y \to M$ be maps and let $P \in |f| \cap |g|$ be a transverse intersection point of f and g.*

[1157] It follows from (1) together with Proposition 32.1 that $P \in M \setminus \partial M$. Similarly it follows from (2) and (4) together with Proposition 32.1 that $f^{-1}(P)$ consists of a single point of X that lies in $X \setminus \partial X$. The analogous statement holds for $g^{-1}(P)$.

[1158] We use the orientations on X, Y and M and Footnote 1157 to identify the groups $H_k(X, X\setminus\{f^{-1}(P)\})$, $H_{m-k}(Y, Y\setminus\{g^{-1}(P)\})$ and $H_m(M, M\setminus\{P\})$ with $\mathbb{Z}$. Furthermore we identify $\mathbb{Z}\otimes\mathbb{Z}$ with $\mathbb{Z}$ via the natural isomorphism $m \otimes n \mapsto m \cdot n$.

[1159] Note that by the Excision Theorem 45.8 the first and the last map are inclusion induced isomorphisms.

[1160] The map $\times\colon H_k(I^k, I^k\setminus\{0\}) \times H_{m-k}(I^{m-k}, I^{m-k}\setminus\{0\}) \to H_m(I^m, I^m\setminus\{0\})$ denotes the cross product that we introduced on page 1316. This map is an isomorphism by the discussion on page 1317.

[1161] A priori this definition of the sign depends on the choice of the chart Φ. We leave it as a slightly lengthy exercise to show that the definition of the sign is independent of this choice.

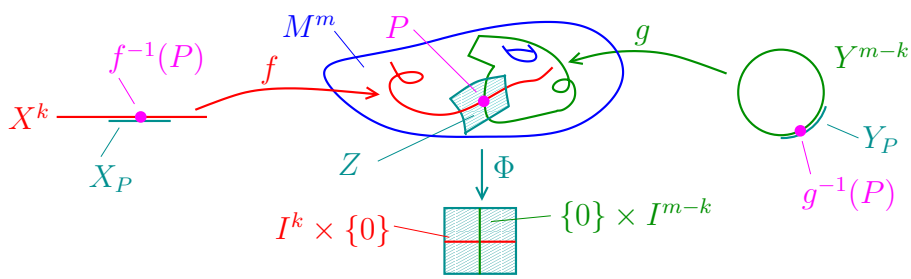

FIGURE 854.

(a) *We can find Z and Φ as in the above definition with the following two extra properties:*
  (6) *the homeomorphism $X_P \to I^k \times \{0\}$ is orientation-preserving, and*
  (7) *the homeomorphism $Y_P \to \{0\} \times I^{m-k}$ is orientation-preserving.*

(b) *If* (6) *and* (7) *are satisfied, then*

$$\Phi_*([Z]) \;=\; \textit{sign at } P \cdot [I^m] \;\in\; H_m(I^m, \partial I^m).$$

Proof.

(a) It is straightforward to see that it suffices to postcompose the homeomorphism $\Phi\colon Z \to I^k \times I^{m-k}$ from the definition of a transverse intersection point with the homeomorphism

$$(x_1, \ldots, x_k, y_1, \ldots, y_{m-k}) \;\mapsto\; (\epsilon \cdot x_1, x_2, \ldots, x_k, \mu \cdot y_1, y_2, \ldots, y_{m-k}),$$

for suitable signs $\epsilon, \mu \in \{-1, 1\}$, to obtain the desired homeomorphism. We leave it to the reader to fill in the details.

(b) This statement follows easily from the definitions together with Propositions 56.11 and 47.3. □

Lemma 68.3. *We continue with the above notation. If $f\colon X \to M$ and $g\colon Y \to M$ are transverse and if X and Y are compact, then $|f| \cap |g|$ is finite.*

Proof. A slight variation of the proof of Lemma 67.6 (2) shows that $|f| \cap |g|$ is indeed finite. We leave the details to the reader. □

Using Lemma 68.3 we can now introduce the following definition.

Definition. Let M be an oriented m-dimensional topological manifold. Let X be a compact oriented k-dimensional topological manifold and let Y be a compact oriented $(m-k)$-dimensional topological manifold. Furthermore let $f\colon X \to M$ and $g\colon Y \to M$ be maps. If f and g are transverse, then we define the *algebraic intersection number of f and g* to be

$$f \cdot g \;:=\; \sum_{P \in |f| \cap |g|} \text{sign at } P.$$

If X is actually a submanifold of M and if $f\colon X \to M$ is the inclusion map, then we write $X \cdot g$ instead of $f \cdot g$. The same way we proceed if Y is actually a submanifold of M.

The following lemma shows that the above definition is a generalization of the algebraic intersection number of submanifolds

Lemma 68.4. *Let M be an oriented m-dimensional manifold, let X be an oriented k-dimensional manifold and let Y be an oriented $(m-k)$-dimensional manifold. We denote by $i\colon X \to M$ and $j\colon Y \to M$ the inclusion maps. If the submanifolds are transverse in the sense of the definition on page 207, then the maps $i\colon X \to M$ and $j\colon Y \to M$ are transverse*[1162] *are and*

$$X \cdot Y \;=\; i \cdot j.$$

Sketch of proof. Suppose that the submanifolds X and Y are transverse. It follows almost immediately from Lemma 3.43 that the inclusion maps $i\colon X \to M$ and $j\colon Y \to M$ are transverse. Furthermore, after unraveling the definitions, it follows easily from Proposition 56.11 and the orientation conventions of Proposition 45.22 that $X \cdot Y = i \cdot j$. □

Now we turn to the study of singular chains in a topological manifold. To be on the safe side in our subsequent definitions we introduce the following convention.

Convention.

(1) Let X be a topological space. When we write "let $\sigma = c_1 \cdot \sigma_1 + \cdots + c_r \cdot \sigma_r$ be a singular m-chain in X" it is is understood that the σ_i are pairwise different and that all the c_i are non-zero. We write $|\sigma| = |\sigma_1| \cup \cdots \cup |\sigma_r|$.
(2) Given $n \in \mathbb{N}_0$ we equip the topological manifold Δ^n with the orientation given by the discussion on page 935 together with Proposition 45.22. In particular, given an oriented m-dimensional topological manifold M and singular simplices $\sigma\colon \Delta^k \to M$ and $\tau\colon \Delta^{m-k} \to M$ it makes sense to say that they are transverse, and if they are transverse, we have an algebraic intersection number $\sigma \cdot \tau$.

Definition. Let M be an oriented m-dimensional topological manifold. Furthermore let $\sigma = c_1 \cdot \sigma_1 + \cdots + c_r \cdot \sigma_r \in C_k(M)$ be a singular k-chain and $\tau = d_1 \cdot \tau_1 + \cdots + d_s \cdot \tau_s \in C_{m-k}(M)$ be a singular $(m-k)$-chain. We say σ and τ *are transverse* if the following two conditions are satisfied:

(1) for all $i \in \{1, \dots, r\}$ and $j \in \{1, \dots, s\}$ the maps $\sigma_i\colon \Delta^k \to M$ and $\tau_j\colon \Delta^{m-k} \to M$ are transverse, and
(2) for all $(i,j) \neq (i',j') \in \{1, \dots, r\} \times \{1, \dots, s\}$ we have
$$(|\sigma_i| \cap |\tau_j|) \cap (|\sigma_{i'}| \cap |\tau_{j'}|) \;=\; \varnothing.$$
Put differently, any intersection point is the intersection point of a unique pair of singular simplices.

[1162]Does the converse to this statement hold? More precisely, if the maps $i\colon X \to M$ and $j\colon Y \to M$ are transverse in the sense of the definition on page 1591, does it follows that the submanifolds transverse in the sense of the definition on page 207?

If this is the case, then we define the *algebraic intersection number of* σ *and* τ to be

$$\sigma \cdot \tau \ := \ \sum_{i,j} (c_i \cdot d_j) \cdot (\sigma_i \cdot \tau_j).$$

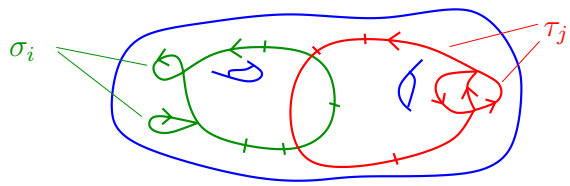

FIGURE 855.

Before we can state the main theorem of this chapter we recall the formulation of the Poincaré Duality theorem for (not necessarily compact) topological manifolds without boundary. Thus let W be an oriented m-dimensional topological manifold without boundary and let $K \subset W$ be a compact subset. By Theorem 46.10 there exists a unique lift of the orientation classes of W to a class in $H_m(W, W \setminus K)$. Given any $k \in \mathbb{N}_0$ we denote by

$$- \cap W \colon H^k(W, W \setminus K) \ \to \ H_{m-k}(W)$$

the map that is given by capping with this unique lift. Lemma 61.14 says that these maps define a well-defined map

$$- \cap W \colon H_c^k(W) \ \to \ H_{m-k}(W).$$

Furthermore the Poincaré Duality Theorem 61.15 says that this map is an isomorphism. We denote by

$$\mathrm{PD}_W \colon H_{m-k}(W) \ \to \ H_c^k(W)$$

the inverse map. Finally we remind the reader that given a topological space X we denote by $\epsilon_X = \epsilon \colon H_0(X) \to \mathbb{Z}$ the augmentation map.

Now we can formulate the main theorem of this chapter.

Theorem 68.5. *Let M be an oriented m-dimensional topological manifold without boundary. Let $\sigma \in C_k(M)$ and $\tau \in C_{m-k}(M)$ be two cycles. If σ and τ are transverse, then*[1163]

$$\epsilon_M\Big(\big(\overbrace{\mathrm{PD}_M([\sigma])}^{\in H_c^{m-k}(M)} \underbrace{\cup}_{\in H_c^m(M)} \overbrace{\mathrm{PD}_M([\tau])}^{\in H_c^k(M)}\big) \cap M\Big) \ = \ \sigma \cdot \tau.$$

[1163]We refer to page 1361 for the definition of the cup product on cohomology with compact support.

68.2. **Proof of Theorem 68.5.** Before we can provide the proof of Theorem 68.5 we need to prove several lemmas.

Definition. Let X be a topological space.

(1) Let A and B be disjoint subsets of X. We say U and V are *separating open neighborhoods for A and B* if U and V are disjoint, if U is an open neighborhood of A and if V is an open neighborhood of B.
(2) A topological space X is called *normal* if any two disjoint closed subsets A and B admit separating open neighborhoods.

Proposition 68.6.

(1) *Every topological manifold is normal.*
(2) *Let M be a topological manifold and let A and B be two closed disjoint subsets of M. If $U' \subset \partial M$ and $V' \subset \partial M$ are separating neighborhoods for $A \cap \partial M$ and $B \cap \partial M$, then there exist separating neighborhoods U and V of A and B such that $U \cap \partial M = U'$ and $V \cap \partial M = V'$.*

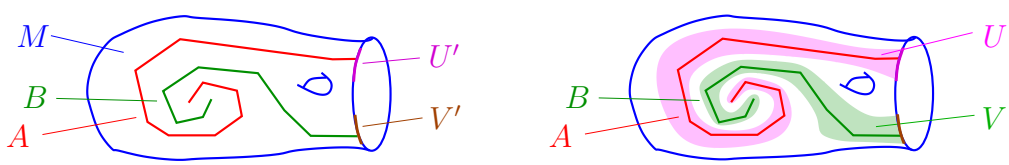

FIGURE 856. Illustration of Proposition 68.6.

Remark. For many situations it suffices to find separating open neighborhoods for *compact* subsets A and B of a Hausdorff space X. In this situation the existence of such open neighborhoods is an entertaining little exercise.

Sketch of proof.

(1) First note that by Theorem 3.10 the topological space M is metrizable, i.e. M admits a metric such that the topology from the metric agrees with the given topology. With some effort one can obtain the desired statement from this information. Alternatively we refer to [Wil, Theorems 20.9 and 20.10] for a proof that every metrizable topological space is normal.
(2) Let M be a topological manifold and let A and B be two closed disjoint subsets of M. We pick a collar neighborhood $\partial M \times [0,1]$ as given by the Topological Collar Neighborhood Theorem 45.3.

    Next suppose that we are given separating neighborhoods $U' \subset \partial M$ and $V' \subset \partial M$ for $A \cap \partial M$ and $B \cap \partial M$. By Proposition 32.1 the complement $M \setminus \partial M$ is again a manifold. By (1) it is normal. Thus there exist separating open neighborhoods $\widetilde{U}$ and $\widetilde{V}$ for the closed subsets $A \cap (M \setminus \partial M)$ and $B \cap (M \setminus \partial M)$. It follows from Lemma 3.6 (1) that $\widetilde{U}$ and $\widetilde{V}$ are open subsets of M. It is now straightforward

to verify that $U := \widetilde{U} \cup U' \times [0,1)$ and $V := \widetilde{V} \cup V' \times [0,1)$ have all the desired properties. $\square$

Lemma 68.7. *Let M be an oriented m-dimensional topological manifold without boundary and let $U \subset M$ be an open subset. Let $i\colon U \to M$ be the inclusion map. For any compact subset $K \subset U$ and any $k \in \mathbb{N}_0$ the map*

$$i^*\colon H^{m-k}(M, M \setminus K) \;\to\; H^{m-k}(U, U \setminus K)$$

is an isomorphism and the following diagram commutes:[1164]

$$\begin{tikzcd}
H_c^{m-k}(U) \arrow[rr, "\cap U = \mathrm{PD}_U^{-1}", "\cong"'] \arrow[d, "i_*"] & & H_k(U) \arrow[d, "i_*"] \\
 & H^{m-k}(U, U\setminus K) \arrow[ul] \arrow[ur, "\cap U"'] \arrow[d, "(i^*)^{-1}"] & \\
H_c^{m-k}(M) \arrow[rr, "\cap M = \mathrm{PD}_M^{-1}", "\cong"'] & & H_k(M). \\
 & H^{m-k}(M, M\setminus K) \arrow[ul] \arrow[ur, "\cap M"'] &
\end{tikzcd}$$

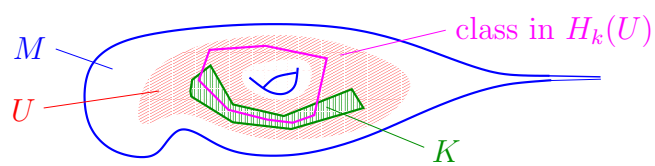

FIGURE 857. Illustration for Lemma 68.7.

Proof. We make the following comments and observations:

(i) By excision, see page 1192, the map $i^*\colon H^{m-k}(M, M \setminus K) \to H^{m-k}(U, U \setminus K)$ is an isomorphism.

(iii) The triangles on the top and the bottom commute by definition of PD_U and PD_M, see Lemma 61.14.

(iv) The square to the left commutes by definition of the map $i_*\colon H_c^{m-k}(U) \to H_c^{m-k}(M)$, see page 1263.

(v) It follows from Lemma 59.8 and Lemma 46.11 (2) that the square to the right commutes.

(vi) The rectangle in the back commutes by Lemma 61.21. $\square$

As in the case of Theorem 67.10 it is perhaps instructive to first prove Theorem 68.5 in the special case that the cycles do not intersect.

[1164] On page 135 we had mentioned that every finite graph can be realized by a spatial graph in $\mathbb{R}^3$. This has the helpful corollary that every finite diagram can in fact be drawn on paper together with indications for 3D-behavior.

Proof of Theorem 68.5 for disjoint cycles. Let M be an oriented m-dimensional topological manifold without boundary. Let $\sigma \in C_k(M)$ and $\tau \in C_{m-k}(M)$ be two cycles such that $|\sigma| \cap |\tau| = \varnothing$. We have to show that $\mathrm{PD}_M([\sigma]) \cup \mathrm{PD}_M([\tau]) = 0$.

By Proposition 68.6 we can find separating open neighborhoods U and V for $|\sigma|$ and $|\tau|$. Given a compact subset J of M and given $i \in \mathbb{N}_0$ we denote by $\varphi_J \colon H^i(M, M \setminus J) \to H^i_c(M)$ the natural map.

Claim.

(1) There exists a compact subset $K \subset U$ and some $\alpha \in H^{m-k}(M, M \setminus K)$ such that $\varphi_K(\alpha) = \mathrm{PD}_M([\sigma])$.
(2) There exists a compact subset $L \subset V$ and some $\beta \in H^k(M, M \setminus L)$ such that $\varphi_L(\beta) = \mathrm{PD}_M([\tau])$.

We consider $\mathrm{PD}_U([\sigma]) \in H^{m-k}_c(U)$. By definition of cohomology with compact support there exists a compact subset K of U such that $\mathrm{PD}_U([\sigma])$ lies in the image of the natural map $H^{m-k}(U, U \setminus K) \to H^{m-k}_c(U)$. The first statement of the claim now follows from Lemmas 68.7. The proof of the second statement is evidently basically the same. This concludes the proof of the claim.

We consider the following diagram

$$\begin{tikzcd}
H^{m-k}_c(M) \times H^k_c(M) \arrow[rr, "\cup"] & & H^m_c(M) \\
H^{m-k}(M, M\setminus K) \times H^k(M, M\setminus L) \arrow[u, "\varphi_K \times \varphi_L"] \arrow[rr, "\cup"] & & H^m(M, \underbrace{M\setminus K \cup M\setminus L}_{=M}). \arrow[u, "\varphi_M"] \\
& (\mathrm{PD}_M([\sigma]), \mathrm{PD}_M([\tau])) & \\
& (\alpha, \beta) \arrow[u, mapsto] &
\end{tikzcd}$$

The diagram commutes by the definition of the cup product on cohomology with compact support, see page 1361. It follows from the observation that the lower right group is zero that the cup product of $\mathrm{PD}_M([\sigma])$ and $\mathrm{PD}_M([\tau])$ is zero. $\square$

Convention. Let $n \in \mathbb{N}$. We use the homeomorphism from Proposition 1.47 (2) to make the identification $I^n = \overline{B}^n$ where $(\frac{1}{2}, \dots, \frac{1}{2})$ gets identified with the origin. Furthermore we use the homeomorphism from Lemma 29.1 to identify $\overline{B}^n$ with Δ^n. Summarizing we have canonical identifications $I^n = \overline{B}^n = \Delta^n$.

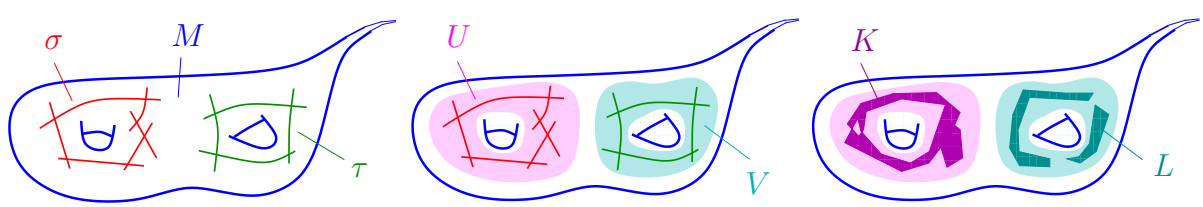

FIGURE 858. Illustration for the proof of Theorem 68.5 for disjoint cycles.

Lemma 68.8. *Let X be a compact oriented, n-dimensional topological manifold. Furthermore let $\varphi_i\colon I^n = \Delta^n \to X \setminus \partial X$, $i = 1, \dots, r$, be orientation-preserving topological embeddings such that the images are disjoint. We write $W = X \setminus (\varphi_1(\overset{\circ}{I}{}^n) \cup \dots \cup \varphi_r(\overset{\circ}{I}{}^n))$. Given any representative $\mu \in C_{n-1}(\partial X)$ of the fundamental class of ∂X there exists a singular n-chain $\sigma \in C_n(W)$ such that*

$$\partial(\sigma + \varphi_1 + \dots + \varphi_r) = \mu \quad \text{and with} \quad [\sigma + \varphi_1 + \dots + \varphi_r] \ = \ [X].$$

Example. We will employ Lemma 68.8 to the case that $X = \Delta^n$ itself is the standard n-simplex. This situation is illustrated in Figure 859.

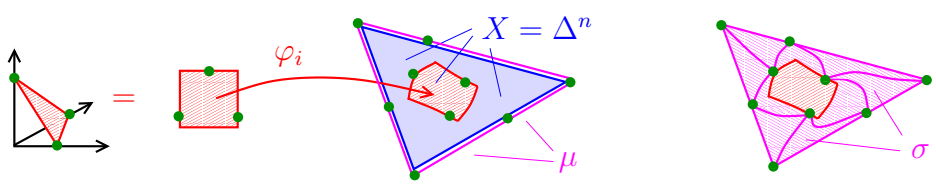

FIGURE 859.

Proof. Note that $\partial W = \varphi_1(\partial I^n) \cup \dots \cup \varphi_r(\partial I^n) \cup \partial X$. Since the φ_i are orientation-preserving we obtain from Proposition 46.26 that $-\partial\varphi_1 - \dots - \partial\varphi_r + \mu \in C_{n-1}(\partial W)$ represents the fundamental class of ∂W. Again by Proposition 46.26 we know that there exists a singular n-chain $\sigma \in C_n(W)$ with $\partial\sigma = -\partial\varphi_1 - \dots - \partial\varphi_r + \mu$. It follows from Proposition 46.8 that $\sigma + \varphi_1 + \dots + \varphi_r$ represents the fundamental class of X. □

The formulation of the following, rather technical lemma, might initially be somewhat intimidating. It can be viewed as a cousin to Lemma 67.12.

Lemma 68.9. *Let M be an oriented m-dimensional topological manifold, let Z be a compact codimension zero submanifold with a decomposition $\partial Z = A \cup B$ of the boundary into compact submanifolds with $\partial A = \partial B = A \cap B$. Let $U \subset M$ be an open subset with $U \cap \partial Z \subset A$ and let $K \subset U$ be a compact subset. We consider the three inclusion maps $p\colon (U, \varnothing) \to (U, U \setminus \overset{\circ}{Z})$, $g\colon (Z \cap U, A \cap U) \to (Z, A)$ and $z\colon (Z \cap U, A \cap U) \to (U, U \setminus \overset{\circ}{Z})$. We note that the induced map*

$$z_*\colon H_k(Z \cap U, A \cap U) \ \to \ H_k(U, U \setminus \overset{\circ}{Z})$$

is an isomorphism by the Excision Theorem 45.10 for topological manifolds. With this preparation the following diagram commutes

$$\begin{tikzcd}
 & H_k(M) & H^{m-k}(M, M\setminus K) \arrow[l, "\cap M"'] \arrow[dl] \arrow[dd] \\
H_k(U) \arrow[ur] \arrow[d, "p_*"] & H^{m-k}(U, U\setminus K) \arrow[l, "\cap U"'] & \\
H_k(U, U\setminus \mathring{Z}) \arrow[r, "(z_*)^{-1}"] & H_k(Z\cap U, A\cap U) \arrow[r, "g_*"] & H_k(Z, A) & H^{m-k}(Z, B). \arrow[l, "\cap [Z]"']
\end{tikzcd}$$

Here all the unmarked maps are induced by the obvious inclusion maps of (pairs) of topological spaces.

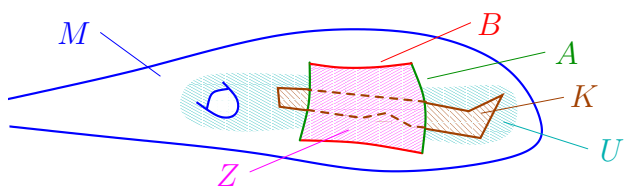

FIGURE 860. Illustration of Lemma 68.9.

Proof. We make the following preparations:

(a) We pick a representative $\nu_M \in H_m(M, M \setminus K)$ for the lift of the orientation of M and similarly we pick $\nu_U \in H_m(U, U \setminus K)$.

(b) We consider the two obvious inclusion maps $f\colon (Z, \partial Z) \to (Z, \overbrace{Z \setminus (\mathring{Z} \cap K)}^{=(\mathbb{Z}\setminus K)\cup A})$ and $g\colon (Z \cap U, (Z \cap U) \setminus (\mathring{Z} \cap K)) \to (Z, Z \setminus (\mathring{Z} \cap K))$. It follows from the Excision Theorem 31.17 that the map $g_*\colon H_m(Z\cap U, (Z\cap U)\setminus(\mathring{Z}\cap K)) \to H_m(Z, Z\setminus(\mathring{Z}\cap K))$ is an isomorphism. We write $\nu_Z := g_*^{-1}(f_*([Z]))$.

Next we consider the following expanded version of the above diagram:

$$\begin{tikzcd}
 & H_k(M) & & H^{m-k}(M, M\setminus K) \arrow[ll, "\cap\nu_M"'] \arrow[dl] \arrow[ddd] \\
H_k(U) \arrow[ur] \arrow[d] & & H^{m-k}(U, U\setminus K) \arrow[ll, "\cap\nu_U"'] \arrow[d] & \\
H_k(U, U\setminus \mathring{Z}) \arrow[r, "(z_*)^{-1}"] & H_k(Z\cap U, A\cap U) \arrow[dr] & H^{m-k}(Z\cap U, (Z\cap U)\setminus K). \arrow[l, "\cap\nu_Z"'] & \\
 & & H_k(Z, A) \arrow[d, "="] & H^{m-k}(Z, Z\setminus K) \arrow[l, "\cap f_*([Z])"] \arrow[ul] \arrow[d] \\
 & & H_k(Z, A) & H^{m-k}(Z, B). \arrow[l, "\cap[Z]"]
\end{tikzcd}$$

It suffices to show that all the five regions of the diagram commute:

(1) The parallelogram on the top of the diagram commutes by Lemma 59.8 applied to the map $h\colon (U, U\setminus K, \varnothing) \to (M, M\setminus K, \varnothing)$, together with the observation that Lemma 46.23 implies that $h_*(\nu_U) = \nu_M$.
(2) The 4-gon on the right commutes since all maps are induced by inclusions.
(3) For the lower parallelogram we obtain commutativity from applying Lemma 59.8 to the map $g\colon (Z\cap U, Z\cap U\setminus K, A\cap U) \to (Z, Z\setminus K, A)$.
(4) To show commutativity of the lower rectangle we apply Lemma 59.8 to the map $f\colon (Z, B, A) \to (Z, Z\setminus K, A)$.

Finally we turn to the upper rectangle. We need to show that the following rectangle commutes:

$$\begin{tikzcd}
H_k(U) \arrow[d, "p_*"] & & H^{m-k}(U, U\setminus K) \arrow[ll, "\cap\nu_U"'] \arrow[d, "z^*"] \\
H_k(U, U\setminus \mathring{Z}) & H_k(Z\cap U, A\cap U) \arrow[l, "z_*"'] & H^{m-k}(Z\cap U, (Z\cap U)\setminus K). \arrow[l, "\cap\nu_Z"']
\end{tikzcd}$$

Now let $\beta \in H^{m-k}(U, U\setminus K)$. We have the following equalities in $H_k(U, U\setminus \mathring{Z})$:

$$\begin{array}{ccccccc}
 & & \text{it follows from Lemma 46.30 that} & & & & \\
 & & \text{we have } p_*(\nu_U) = z_*(\nu_Z) \text{ in } H_m(U, U\setminus K\cup U\setminus \mathring{Z}) & & & & \\
 & & \downarrow & & & & \\
p_*(\beta\cap\mu) & = & \beta\cap p_*(\mu) & = & \beta\cap z_*(\nu) & = & z_*(z^*(\beta)\cap\nu). \\
 & & \uparrow & & \uparrow & & \\
 & & \text{Lemma 59.8 applied to the map} & & \text{Lemma 59.8 applied to the map} & & \\
 & & p\colon (U, U\setminus K, \varnothing) \to (U, U\setminus K, U\setminus \mathring{Z}) & & z\colon (Z\cap U, Z\cap U\setminus K, A\cap U) \to (U, U\setminus K, U\setminus \mathring{Z}) & &
\end{array}$$

We have thus shown that the diagram commutes. □

After all these preparations we can finally attack Theorem 68.5.

Proof of Theorem 68.5. Let M be an oriented m-dimensional topological manifold without boundary. Also let $\sigma = c_1 \cdot \sigma_1 + \cdots + c_r \cdot \sigma_r \in C_k(M)$ and $\tau = d_1 \cdot \tau_1 + \cdots + d_s \cdot \tau_s \in C_{m-k}(M)$ be two singular cycles that are transverse. We introduce some notation.

(1) We denote by $P_1, \dots, P_n$ the points in $\bigcup_{i,j} |\sigma_i| \cap |\tau_j|$. Furthermore we denote by $\nu_1, \dots, \nu_n \in \{-1, 1\}$ the corresponding signs.
(2) We denote by $X_1, X_2, \dots, X_n$ distinct copies of I^k and we denote by $Y_1, Y_2, \dots, Y_n$ distinct copies of I^{m-k}.
(3) Given $t \in (0,1)$ we write $X_i(t) = \{x \in X_i \mid \|x\| \le t\}$ and $\mathring{X}_i(t) = \{x \in X_i \mid \|x\| < t\}$. The same way we also define $Y_i(t)$ and $\mathring{Y}_i(t)$.
(4) For each $i \in \{1, \dots, n\}$ we pick, as in the definition of transverse intersection, a compact submanifold Z_i of M that is a neighborhood of P_i and a homeomorphism $\Phi_i \colon Z_i \to X_i \times Y_i$. It follows from Lemma 68.2 we can assume that the maps $\sigma_i \colon \Delta^k \cap \sigma_i^{-1}(Z_i) \to X_i \times \{0\}$ and $\tau_i \colon \Delta^{m-k} \cap \tau_i^{-1}(Z_i) \to \{0\} \times Y_i$ are orientation-preserving. After possibly shrinking the Z_i we can and will assume that the Z_i are disjoint.
(5) We use the homeomorphism $\Phi_i \colon Z_i \to X_i \times Y_i$ to identify Z_i with $X_i \times Y_i$ as *unoriented* topological manifolds. Under this identification we have an *orientation-preserving* identification $X \cap Z_i = X_i \times \{0\}$ and $Y \cap Z_i = \{0\} \times Y_i$ of oriented topological manifolds.
(6) We write $Z = Z_1 \cup \cdots \cup Z_n$.

For $i = 1, \dots, r$ we apply Lemma 68.8 to $X = \Delta^k$ with the cubes given by the preimages of the Z_i under the maps σ_i. Similarly we proceed with the τ_i. After some renaming we can assume that we are in the following situation:[1165]

(7) For $i = 1, \dots, n$ the singular simplex σ_i is an orientation-preserving homeomorphism $\sigma_i \colon \Delta^k \to X_i \times \{0\}$. Furthermore for $i = n+1, \dots, r$ the image of each σ_i lies in $(M \setminus Z) \cup (X_i \times \{0\})$.
(8) For $j = 1, \dots, n$ the singular simplex τ_j is an orientation-preserving homeomorphism $\tau_j \colon \Delta^{m-k} \to \{0\} \times Y_j$. Furthermore for $j = n+1, \dots, s$ the image of each τ_j lies in $(M \setminus Z) \cup (\{0\} \times Y_i)$.

We introduce the following notation:

(9) We write $\widetilde{\sigma} = c_{n+1} \cdot \sigma_{n+1} + \cdots + c_r \cdot \sigma_r$ and we denote by $|\widetilde{\sigma}|$ the union of the images of $\sigma_{n+1}, \dots, \sigma_r$. Similarly we define $\widetilde{\tau}$ and $|\widetilde{\tau}|$.

We refer to Figure 861 on the left for an illustration.

Claim 1. There exist open subsets U and V of M, compact subsets K and L of M and a $t \in (0,1)$ with the following properties:

[1165]Evidently a lot of details are packed into this sentence. In particular we use that this replacing process does not affect the algebraic intersection number of cycles. We leave this as a fairly elementary, albeit somewhat lengthy exercise to the reader.

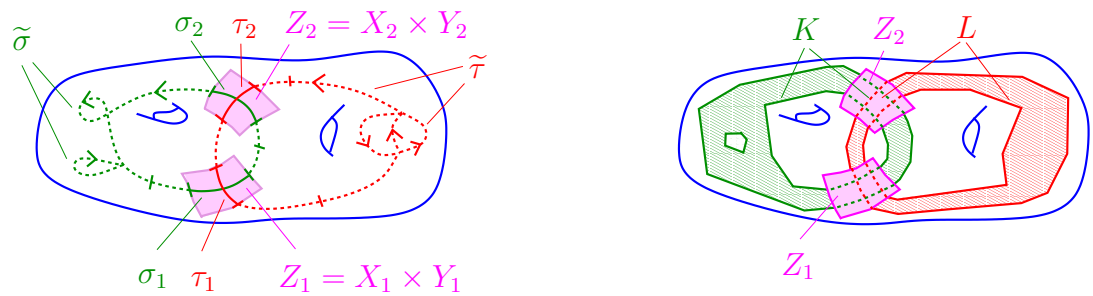

FIGURE 861.

(a) there exists a cohomology class $\varphi \in H^{m-k}(M, M \setminus K)$ such that the image of φ in $H_c^{m-k}(M)$ equals $\mathrm{PD}_M([\sigma])$,
(b) there exists a cohomology class $\psi \in H^k(M, M \setminus L)$ such that the image of ψ in $H_c^k(M)$ equals $\mathrm{PD}_M([\tau])$,
(c) we have $\widetilde{\sigma} \subset U$ and $\widetilde{\tau} \subset V$,
(d) we have $K \subset U$ and $L \subset V$,
(e) we have $K \cap L \cap (M \setminus Z) = \varnothing$,
(f) for each $i \in \{1, \ldots, n\}$ we have $U \cap Z_i = X_i \times \mathring{Y}_i(\frac{1}{2})$ and $V \cap Z_i = \mathring{X}_i(\frac{1}{2}) \times Y_i$,
(g) for each $i \in \{1, \ldots, n\}$ we have $K \cap Z_i = X_i \times Y_i(t)$ and $L \cap Z_i = X_i(t) \times Y_i$.

We refer to Figure 861 on the right for an illustration.

We consider the topological manifold $W := M \setminus \mathring{Z}$. Note that $|\widetilde{\sigma}| \cap \partial W = \partial X_i \times \{0\}$ and $|\widetilde{\tau}| \cap \partial W = \{0\} \times \partial Y_i$. It follows from Proposition 68.6 (2) that there exist disjoint open neighborhoods $\widetilde{U} \subset W$ of $|\widetilde{\sigma}|$ and $\widetilde{V} \subset W$ of $|\widetilde{\tau}|$ such that for each $i \in \{1, \ldots, n\}$ we have $\widetilde{U} \cap \partial Z_i = \partial X_i \times \mathring{Y}_i(\frac{1}{2})$ and $\widetilde{V} \cap \partial Z_i = \mathring{X}_i(\frac{1}{2}) \times \partial Y_i$. Finally we write $U = \widetilde{U} \cup \bigcup_{i=1}^{n} X_i \times \mathring{Y}_i(\frac{1}{2})$ and $V = \widetilde{V} \cup \bigcup_{i=1}^{n} \mathring{X}_i(\frac{1}{2}) \times \partial Y_i$. We refer to Figure 862 for an illustration.

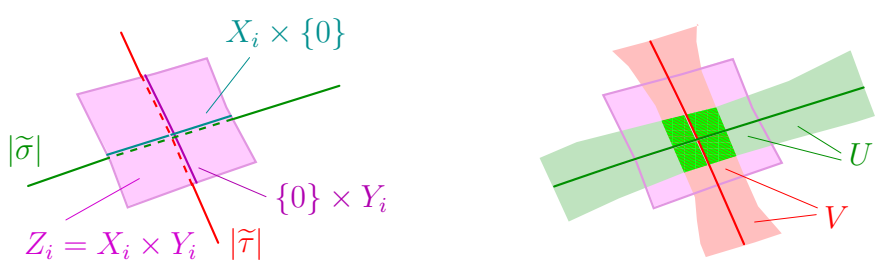

FIGURE 862.

We denote by $i \colon U \to M$ and $j \colon V \to M$ the inclusion maps. Since U is an open subset of M we can consider $\mathrm{PD}_U([\sigma]) \in H_c^{m-k}(U)$. By Lemma 53.2 there exists a compact subset

K' of U such that $\mathrm{PD}_U([\sigma])$ lies in the image of the map $H^{m-k}(U, U \setminus K') \to H_c^{m-k}(U)$. Similarly we can find a compact subset L' of V such that $\mathrm{PD}_V([\tau])$ lies in the image of the map $H^k(V, V \setminus L') \to H_c^k(V)$. Since each $K \cap Z_i$ and $L \cap Z_i$ is compact and since each $K \cap Z_i$ is contained in $U \cap Z_i = X_i \times \mathring{Y}_i(\frac{1}{2})$ and since each $L \cap Z_i$ is contained in $V \cap Z_i = \mathring{X}_i(\frac{1}{2}) \times Y_i$ we can and will pick a $t \in (0, \frac{1}{2})$ such that for all i we have $K' \cap Z_i \subset X_i \times Y_i(t)$ and $L' \cap Z_i \subset X_i(t) \times Y_i$. We set $K := K' \cup \bigcup_{i=1}^{n} X_i \times Y_i(t)$ and $L := L' \cup \bigcup_{i=1}^{n} X_i(t) \times Y_i$. Note that by construction the desired conditions (c), (d), (e), (f) and (g) are satisfied. It remains to prove (a) and (b). Since $K' \subset K$ we have the following commutative diagram

$$\begin{tikzcd}
 & H^{m-k}(U, U \setminus K') \arrow[dl] \arrow[dr] & \\
H^{m-k}(U, U \setminus K) \arrow[rr] & & H_c^{m-k}(U).
\end{tikzcd}$$

This shows that $\mathrm{PD}_U([\sigma])$ also lies in the image of $H^{m-k}(U, U \setminus K)$. The same way we see that $\mathrm{PD}_V([\tau])$ lies in the image of $H^{m-k}(V, V \setminus L)$. Statements (a) and (b) now follow directly from Lemma 68.7. This concludes the proof of the claim.

We continue with some more observations and notation.

(10) For $i = 1, \dots, n$ we write $K_i = K \cap Z_i$ and $L_i = L \cap Z_i$. By the above discussion we know that $K_i = X_i \times Y_i(t)$ and $L_i = X_i(t) \times Y_i$. Also note that by construction we have $K \cap L \subset \mathring{Z}$.

(11) Given any compact subset T of M we denote by $o\colon (M, \varnothing) \to (M, M \setminus T)$ the obvious map. Also we denote by $o^*\colon H^*(M, M \setminus T) \to H_c^*(M)$ the obvious map.

(12) We denote by $z\colon Z \to M$ the inclusion map and we denote by z also all the inclusion maps of pairs of topological spaces where the total spaces are Z and M.

(13) Given $i \in \{1, \dots, n\}$ we denote by $z_i\colon Z_i \to Z$ the inclusion map. We adopt the same convention as in (12) for pairs of topological spaces.

(14) We view Z as an m-dimensional submanifold of M and we equip Z with the orientation coming from Lemma 45.28. Given any subset $W \subset \mathring{Z}$ we denote by $[Z]$ also the image of the fundamental class of Z under the map $H_m(Z, \partial Z) \to H_m(Z, W)$. We adopt the same convention for $[Z_i]$.

(15) We refer to the map of pairs $(Z_i, X_i \times \partial Y_i) \to (Z_i, Z_i \setminus K_i)$ and also to the map $(Z_i, \partial X_i \times Y_i) \to (Z_i, Z_i \setminus L_i)$ as the canonical map c.

(16) By Theorem 46.10 there exists a unique lift $\mu \in H_m(M, M \setminus (K \cap L))$ of the orientation classes of M.

Next we consider the following diagram:

$$\begin{tikzcd}
H_c^{m-k}(M) \times H_c^k(M) \arrow[r, "\cup"] & H_c^m(M) \arrow[r, "\cap M"] & H_0(M) \arrow[r, "\epsilon_M"] \arrow[d, "="'] & \mathbb{Z} \arrow[d, "="'] \\
H^{m-k}(M, M\setminus K) \times H^k(M, M\setminus L) \arrow[r, "\cup"] \arrow[u, "o^*\times o^*"'] \arrow[d, "z^*\times z^*"] & H^m(M, M\setminus(K\cap L)) \arrow[r, "\cap\mu"] \arrow[u, "o^*"'] \arrow[d, "z^*"] & H_0(M) \arrow[r, "\epsilon_M"] & \mathbb{Z} \\
H^{m-k}(Z, Z\setminus K) \times H^k(Z, Z\setminus L) \arrow[r, "\cup"] \arrow[d, "\bigoplus_{i=1}^n z_i^*\times z_i^*"] & H^m(Z, Z\setminus K\cap L) \arrow[r, "\cap[Z]"] \arrow[d, "\bigoplus_{i=1}^n z_i^*"] & H_0(Z) \arrow[r, "\epsilon_Z"] \arrow[u, "z_*"'] & \mathbb{Z} \arrow[u, "="'] \\
\bigoplus_{i=1}^n H^{m-k}(Z_i, Z_i\setminus K_i) \times H^k(Z_i, Z_i\setminus L_i) \arrow[r, "\oplus\cup"] \arrow[d, "\bigoplus_{i=1}^n c^*\times c^*"] & \bigoplus_{i=1}^n H^m(Z_i, Z_i\setminus K_i\cap L_i) \arrow[r, "\oplus\cap[Z_i]"] \arrow[d, "\bigoplus_{i=1}^n c^*"] & \bigoplus_{i=1}^n H_0(Z_i) \arrow[r, "\sum\epsilon_{Z_i}"'] \arrow[u, "\sum_{i=1}^n z_{i*}"'] & \mathbb{Z} \arrow[u, "="'] \\
\bigoplus_{i=1}^n H^{m-k}(Z_i, X_i\times\partial Y_i) \times H^k(Z_i, \partial X_i\times Y_i) \arrow[r, "\oplus\cup"] & \bigoplus_{i=1}^n H^m(Z_i, \partial Z_i) \arrow[r, "\oplus\cap[Z_i]"] & \bigoplus_{i=1}^n H_0(Z_i) \arrow[r, "\sum\epsilon_{Z_i}"'] \arrow[u, "="'] & \mathbb{Z}. \arrow[u, "="']
\end{tikzcd}$$

Claim 2. The above diagram commutes.

In the following we deal with all of the twelve squares of the diagram.

(a) The square on the top left commutes by definition of the cup product on cohomology with compact support, see page 1361.
(b) The left squares in the second row and the fourth commute by Proposition 58.3 (1).
(c) The left square in the third row commutes by Lemma 59.9 (1) together with the aforementioned Proposition 58.3 (1).
(d) The middle square in the first row commutes by definition of the map $\cap M$.
(e) It follows from Lemma 46.11 that $z_*([Z]) = \mu \in H_m(M, M \setminus (K \cap L))$. Therefore we obtain from Lemma 59.8 (1) that the middle square in the second row commutes.
(f) It follows from the remark on page 1114 that $\sum_{i=1}^n z_{i*}([Z_i]) = [Z]$. Now we obtain from Lemma 59.8 (1) and Lemma 59.9 (2) that the middle square in the third row commutes.
(g) The squares that involve the augmentation maps commute by the discussion on page 747.
(h) It follows from Lemma 59.8 (1) and our conventions regarding the meaning of $[Z_i]$ that the middle square in the fourth row commutes.

This concludes the proof of the claim.

We introduce one last piece of notation:

(17) We denote by PD_{Z_i} and $\mathrm{PD}_{X_i\times Y_i}$ the isomorphisms from the Poincaré Duality 61.1 corresponding to the decomposition $\partial Z_i = \partial(X_i \times Y_i) = (\partial X_i \times Y_i) \cup (X_i \times \partial Y_i)$.

Claim 3. Let $i \in \{1, \ldots, n\}$.

(i) For the above $\varphi \in H^{m-k}(M, M \setminus K)$ we have $(c^* \circ z_i^* \circ z^*)(\varphi) = c_i \cdot \mathrm{PD}_{Z_i}([X_i \times \{0\}])$.
(ii) For the above $\psi \in H^k(M, M \setminus L)$ we have $(c^* \circ z_i^* \circ z^*)(\varphi) = d_i \cdot \mathrm{PD}_{Z_i}([\{0\} \times Y_i])$.

(iii) We have

$$\epsilon_{Z_i}\Big(\big((\mathrm{PD}_{Z_i}([X_i\times\{0\}])\cup \mathrm{PD}_{Z_i}([\{0\}\times Y_i])\big)\cap [Z_i]\Big) \;=\; \nu_i.$$

We provide the proof of the three statements:

(i) We introduce the following notation:

(α) We write $A=\partial X_i\times Y_i$ and $B=X_i\times\partial Y_i$.

(β) We denote by $p\colon (U,\varnothing)\to(U,U\setminus \mathring{Z}_i)$, $\widetilde{z}\colon (Z_i\cap U, A\cap U)\to(U,U\setminus\mathring{Z}_i)$ and $g\colon (Z_i\cap U, A\cap U)\to(Z_i,A)$ the obvious inclusion maps.

We make the following observation: We calculate that

$$(c^*\circ z_i^*\circ z^*)(\varphi)\cap[Z_i] \;\overset{\substack{\text{by Lemma 68.9 and since}\\ \varphi\cap M=[\sigma]\text{ with }|\sigma|\subset U}}{\overset{\downarrow}{=}}\; g_*(\widetilde{z}_*^{-1}(p_*([\sigma]))) \;\overset{\text{by (7) on page 1602}}{\overset{\downarrow}{=}}\; c_i\cdot g_*([X\cap Z_i]) \;\underset{\substack{\uparrow\\ \text{by the orientation-preserving identification } X\cap Z_i=X_i\times\{0\}}}{=}\; c_i\cdot[X_i\times\{0\}].$$

But by definition of the Poincaré duality isomorphism this is precisely what we had needed to show.

(ii) The proof of this statement is evidently the same as the proof of (2).

(iii) We recall that we made the identification $Z_i=X_i\times Y_i=I^k\times I^{m-k}=I^m$ as *unoriented* topological manifolds. The desired equality follows from the following observations:

(α) It is a consequence of our conventions and Lemma 68.2 that under the above identification we have $[Z_i]=\nu_i\cdot[X_i\times Y_i]$.

(β) By (i) and by the definition of the Poincaré Duality isomorphisms we have

$$\mathrm{PD}_{Z_i}([X_i\times\{0\}]) \;=\; \nu_i\cdot\mathrm{PD}_{X_i\times Y_i}([X_i\times\{0\}])$$

and

$$\mathrm{PD}_{Z_i}([\{0\}\times Y_i]) \;=\; \nu_i\cdot\mathrm{PD}_{X_i\times Y_i}([\{0\}\times Y_i]).$$

(γ) By Proposition 67.16 we have

$$\mathrm{PD}_{X_i\times Y_i}([X_i\times\{0\}])\cup\mathrm{PD}_{X_i\times Y_i}([\{0\}\times Y_i]) \;=\; [X_i\times Y_i]^*.$$

This concludes the proof of the claim.

After all these preparations we can prove the desired equality:

$$\epsilon_M\big((\mathrm{PD}_M([\sigma])\cup\mathrm{PD}_M([\tau]))\cap M\big) \;\overset{\substack{\text{by construction of }\varphi\text{ and }\psi\text{ in Claim 1 and the first row of the commutative diagram from Claim 2}\\ \downarrow}}{=}\; \epsilon_M((\varphi\cup\psi)\cap M)$$

$$\underset{\substack{\uparrow\\ \text{by the second, third and fourth row of the}\\ \text{commutative diagram from Claim 2}}}{=} \sum_{i=1}^n \epsilon_{Z_i}\Big(\big((c^*\circ z_i^*\circ z^*)(\varphi)\cup(c^*\circ z_i^*\circ z^*)(\psi)\big)\cap[Z_i]\Big) \;\underset{\substack{\uparrow\\ \text{by Claim 3}}}{=}\; \sum_{i=1}^n c_i\cdot d_i\cdot\nu_i \;=\; \sigma\cdot\tau.$$

This concludes the proof of the theorem. □

We conclude this section with the following variation of Theorem 68.5.

Theorem 68.10. *Let M be a compact orientable m-dimensional topological manifold. Let A and B be compact $(m-1)$-dimensional submanifolds of ∂M with $\partial A = \partial B = A \cap B$ and with $\partial M = A \cup B$. Let $\sigma \in C_k(M, A)$ and $\tau \in C_{m-k}(M, B)$ be two cycles. If σ and τ are transverse, then*

$$\epsilon_M\big(\big(\underbrace{\overbrace{\mathrm{PD}_M([\sigma])}^{\in H^{m-k}(M,B)} \cup \overbrace{\mathrm{PD}_M([\tau])}^{\in H^{k}(M,A)}}_{\in H^m(M,\partial M)}\big) \cap [M]\big) \;=\; \sigma \cdot \tau.$$

Sketch of proof. The proof of the theorem follows along the lines of the proof of Theorem 68.5. The key difference is that we need to use Poincaré Duality for non-compact topological manifolds with boundary. More precisely, let U be an oriented topological m-dimensional manifold with boundary. By Theorem 46.29, given any compact set K of U the orientation defines a natural homology class μ_K in $H_m(U, (U \setminus K) \cup \partial U)$. The same construction as in Lemma 61.14, this time using Lemma 46.30 instead of Lemma 46.11, shows that capping with these homology classes defines a well-defined map

$$\mathrm{PD}_U \colon H^k_c(U) \;\to\; H_{m-k}(U, \partial U).$$

A moderately heroic effort shows that the proof of the Poincaré Duality Theorem 61.1, as provided in Section 61.5 can be modified to show that the above map PD_U is an isomorphism. Once this is out of the way it is fairly straightforward to modify the proof of Theorem 68.5 to obtain a proof of Theorem 68.10. □

68.3. **Intersections of transverse maps of manifolds.** The following theorem is frequently used in the literature. I am not aware though of a published proof.

Theorem 68.11. *Let M be a compact oriented connected m-dimensional topological manifold. Furthermore let A and B be compact $(m-1)$-dimensional submanifolds of ∂M with $\partial A = \partial B = A \cap B$ and with $\partial M = A \cup B$. Let X be a compact oriented k-dimensional topological manifold and let Y be a compact oriented $(m-k)$-dimensional topological manifold. Finally let $f \colon X \to M$ and $g \colon Y \to M$ be two proper maps with $f(\partial X) \subset A$ and $g(\partial Y) \subset B$. If f and g are transverse, then*

$$f \cdot g \;=\; \langle \mathrm{PD}_M(f_*[X]) \cup \mathrm{PD}_M(g_*[Y]), [M] \rangle.$$

Remark. It follows immediately from Lemma 68.4 that Theorem 68.11 contains our earlier Theorem 67.10 as a special case.

Proof. It follows easily from Lemma 68.8 that there exists a k-cycle $\sigma \in C_k(M, A)$ and an $(m-k)$-cycle $\tau \in C_{m-k}(M, B)$ with the following properties:

(1) we have $[\sigma] = f_*([X])$ and $[\tau] = g_*([Y])$,
(2) the cycles σ and τ are transverse,

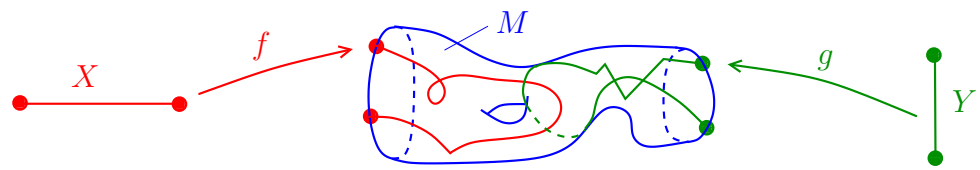

FIGURE 863. Illustration of Theorem 68.11.

(3) the equality $f \cdot g = \sigma \cdot \tau$ holds.

It follows that

$$f \cdot g \;=\; \sigma \cdot \tau \;\underset{\substack{\uparrow \\ \text{Theorem 68.10}}}{=}\; \langle \mathrm{PD}_M([\sigma]) \cup \mathrm{PD}_M([\tau]), [M] \rangle \;\underset{\substack{\uparrow \\ \text{since } [\sigma] = f_*([X]) \text{ and } [\tau] = g_*([Y])}}{=}\; \langle \mathrm{PD}_M(f_*[X]) \cup \mathrm{PD}_M(g_*[Y]), [M] \rangle.$$

□

As promised, we now find it quite easy to answer Question 68.1 in the negative.

Lemma 68.12. *We consider the disk $\overline{B}^2$ together with the four points $P_\pm = (\pm 1, 0)$ and $Q_\pm(0, \pm 1)$. If $\alpha\colon [-1,1] \to \overline{B}^2$ is a proper map with $\alpha(\pm 1) = P_\pm$ and if $\beta\colon [-1,1] \to \overline{B}^2$ is a proper map with $\beta(\pm 1) = Q_\pm$, then α and β intersect in at least one point.*

Proof. We write $I = [-1,1]$. Suppose that there exist proper maps $\alpha\colon I \to \overline{B}^2$ and $\beta\colon I \to \overline{B}^2$ with $\alpha(\pm 1) = P_\pm$ and with $\beta(\pm 1) = Q_\pm$ such that $|\alpha| \cap |\beta| = \varnothing$. We introduce the following notation:

(1) We consider the two "straight paths" $\alpha'\colon I \to \overline{B}^2$ given by $\alpha'(t) = (t, 0)$ and $\beta'\colon I \to \overline{B}^2$ given by $\beta'(t) = (0, t)$.
(2) We write $A = \left\{ e^{it} \,\middle|\, t \in \left[-\frac{\pi}{4}, \frac{\pi}{4}\right] \cup \left[\frac{3\pi}{4}, \frac{5\pi}{4}\right] \right\}$ and $B = \left\{ e^{it} \,\middle|\, t \in \left[-\frac{3\pi}{4}, -\frac{\pi}{4}\right] \cup \left[\frac{\pi}{4}, \frac{3\pi}{4}\right] \right\}$.
(3) We denote by PD_M the isomorphisms from the Poincaré Duality Theorem 61.1 corresponding to the decomposition $\partial \overline{B}^2 = A \cup B$.

We refer to Figure 864 for an illustration. We have

$$\begin{aligned} 0 \;\underset{\substack{\downarrow \\ \text{since } |\alpha| \cap |\beta| = \varnothing}}{=}\; \alpha \cdot \beta \;&\underset{\substack{\downarrow \\ \text{Theorem 68.11}}}{=}\; \left\langle \mathrm{PD}_M(\alpha_*([I])) \cup \mathrm{PD}_M(\beta_*([I]), [M] \right\rangle \\ &\underset{\substack{\uparrow \\ \text{by considering the long exact sequences in homology} \\ \text{of the pairs } (\overline{B}^2, A) \text{ and } (\overline{B}^2, B) \text{ we see that} \\ \alpha_*([I]) = \alpha'_*([I]) \text{ and } \beta_*([I]) = \beta'_*([I])}}{=}\; \left\langle \mathrm{PD}_M(\alpha'_*([I])) \cup \mathrm{PD}_M(\beta'_*([I]), [M] \right\rangle \underset{\substack{\uparrow \\ \text{Theorem 68.11}}}{=} \alpha' \cdot \beta' \underset{\substack{\uparrow \\ \alpha', \beta' \text{ intersect} \\ \text{transversely in} \\ \text{one point}}}{=} \pm 1. \end{aligned}$$

□

68.4. **The algebraic $\mathbb{F}_2$-intersection number** $(*)$**.** In this section we quickly discuss the "$\mathbb{F}_2$-analogue" of the results of the previous sections.

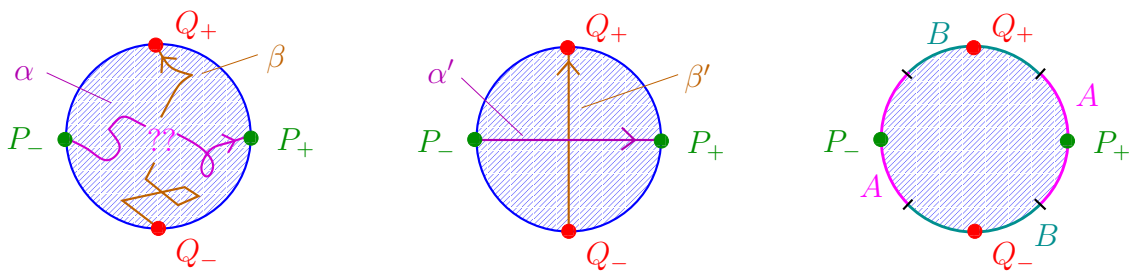

FIGURE 864.

Definition. Let M be an m-dimensional topological manifold, let X be a k-dimensional topological manifold and let Y be an $(m-k)$-dimensional topological manifold. Furthermore let $f\colon X \to M$ and $g\colon Y \to M$ be maps. If f and g are transverse, then we define

$$\text{the algebraic } \mathbb{F}_2\text{-intersection number of } f \text{ and } g \;:=\; f \cdot_{\mathbb{F}_2} g \;:=\; \#(|f| \cap |g|) \bmod 2.$$

If X and Y are in fact submanifolds and f and g are the inclusion map, then we write $X \cdot_{\mathbb{F}_2} Y := f \cdot_{\mathbb{F}_2} g$.

We recall the following notation.

Notation.

(1) In Corollary 46.6 we saw that any compact n-dimensional manifold W has a unique $\mathbb{F}_2$-fundamental class $[W]_{\mathbb{F}_2} \in H_n(W, \partial W; \mathbb{F}_2)$. If W is in fact a proper submanifold of some other topological manifold M, then often times we denote by $[W]_{\mathbb{F}_2} \in H_n(M, \partial M; \mathbb{F}_2)$ the image of $[W]_{\mathbb{F}_2}$ under the inclusion induced map $H_n(W, \partial W; \mathbb{F}_2) \to H_n(M, \partial M; \mathbb{F}_2)$.

(2) In this section, given a compact topological manifold we denote by PD_M the Poincaré Duality isomorphisms with $\mathbb{F}_2$-coefficients provided by the Poincaré Duality Theorem 61.1.

Now we can formulate the following theorem.

Theorem 68.13. *Let M be a compact connected m-dimensional topological manifold. Furthermore let A and B be compact $(m-1)$-dimensional submanifolds of ∂M such that $\partial A = \partial B = A \cap B$ and with $\partial M = A \cup B$. Let X be a compact k-dimensional topological manifold and let Y be a compact $(m-k)$-dimensional topological manifold. Furthermore let $f\colon X \to M$ and $g\colon Y \to M$ be two proper maps with $f(\partial X) \subset A$ and $g(\partial Y) \subset B$. If f and g are transverse, then*

$$f \cdot_{\mathbb{F}_2} g \;=\; \Big\langle \overbrace{\underbrace{\mathrm{PD}_M(\underbrace{f_*([X]_{\mathbb{F}_2})}_{\in H_k(M,A;\mathbb{F}_2)})}_{\in H^{m-k}(M,B;\mathbb{F}_2)} \cup \underbrace{\mathrm{PD}_M(\underbrace{g_*([Y]_{\mathbb{F}_2})}_{\in H_{m-k}(M,B;\mathbb{F}_2)})}_{\in H^{k}(M,A;\mathbb{F}_2)}}^{\in H^m(M,\partial M;\mathbb{F}_2)}, \overbrace{[M]_{\mathbb{F}_2}}^{\in H_m(M,\partial M;\mathbb{F}_2)} \Big\rangle \;\in\; \mathbb{F}_2.$$

In particular, if X and Y are already submanifolds of M, then

$$X \cdot_{\mathbb{F}_2} Y \;=\; \langle \mathrm{PD}_M([X]_{\mathbb{F}_2}) \cup \mathrm{PD}_M([Y]_{\mathbb{F}_2}), [M]_{\mathbb{F}_2} \rangle.$$

Proof. By Proposition 45.24 every topological manifold is $\mathbb{F}_2$-orientable. With this observation the proof of the theorem is a variation, and basically a simplification, of the proof of Theorem 67.10. We leave it to the skeptical reader to fill in the details. □

Example. Similar to the discussion on page 1567 we can use Theorem 68.13 to show that some homology classes are in fact non-zero. For example in Figure 865 we show the Klein bottle K together with two closed 1-dimensional submanifolds. These intersect in precisely one point, so their algebraic $\mathbb{F}_2$-intersection number is necessarily non-zero. Theorem 68.13 implies that $[X]_{\mathbb{F}_2}$ and $[Y]_{\mathbb{F}_2}$ are non-zero in $H_1(K;\mathbb{F}_2)$.

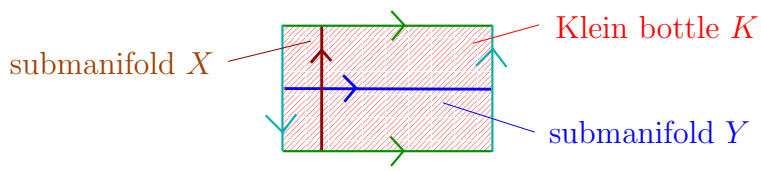

FIGURE 865.

Exercises for Chapter 68.

Exercise 68.1. Is every topological space that is Hausdorff also normal?

Exercise 68.2. We consider the definition of the sign of a transverse intersection point of two maps $f\colon X \to M$ and $g\colon Y \to M$ between oriented topological manifolds that we gave on page 1592. Did we implicitly assume that $\dim(X) > 0$ and $\dim(Y) > 0$, or does the definition also work for 0-dimensional topological manifolds?

Exercise 68.3. Can one use the Generalized Alexander Duality Theorem 66.10 to answer Question 68.1? Or some other of the earlier theorems? If yes, how would you do it? You could also try to restrict yourselves to the case that the map α is injective.

Exercise 68.4. Let M be a compact oriented connected n-dimensional topological manifold and let $N \subset M$ be a compact oriented proper submanifold of codimension one. Finally let $\gamma\colon S^1 \to M$ be a map that is transverse to N. Show that

$$\langle \mathrm{PD}_M([N]), \gamma_*([S^1]) \rangle \;=\; \gamma \cdot N.$$

69. Homology, cohomology and submanifolds

In this chapter, given an oriented, compact manifold M we will relate the following objects:

(1) Codimension one submanifolds of M,
(2) cohomology classes in $H^1(M;\mathbb{Z})$ of dimension one,
(3) homology classes in $H_{n-1}(M,\partial M;\mathbb{Z})$ of codimension one,
(4) maps $M \to S^1$.

69.1. **Codimension one submanifolds.** Let M be a compact oriented connected n-dimensional topological manifold. Every compact oriented proper submanifold $Y \subset M$ of *codimension* k gives rise to a homomorphism

$$\begin{array}{rcl} H_k(M;\mathbb{Z}) & \to & \mathbb{Z} \\ \sigma & \mapsto & \langle \underbrace{\mathrm{PD}_M([Y])}_{\in H^k(M;\mathbb{Z})}, \sigma\rangle. \end{array}$$

In many circumstances the next proposition gives an explicit description of this homomorphism $H_k(M;\mathbb{Z}) \to \mathbb{Z}$:

Proposition 69.1. *Let M be a compact oriented connected n-dimensional topological manifold and let $Y \subset M$ be a compact oriented proper submanifold of* codimension k. *Let $f\colon X \to M$ be a map from a closed k-dimensional topological manifold X to M. If f is transverse to Y, then*

$$\langle \underbrace{\mathrm{PD}_M([Y])}_{\in H^k(M;\mathbb{Z})}, \underbrace{f_*([X])}_{\in H_k(M;\mathbb{Z})} \rangle \;=\; f \cdot Y.$$

Remark. Let M be a compact oriented connected n-dimensional topological manifold and let $Y \subset M$ be a compact oriented proper submanifold of codimension one. In Proposition 64.11 we saw that Y admits a tubular neighborhood of the form $[-1,1] \times Y$ such that the product orientation of $[-1,1] \times Y$ matches the orientation of M. If $f\colon S^1 \to M$ is a map, then loosely speaking, the algebraic intersection number $f \cdot Y$ counts (with signs) how often f goes from from $Y \times \{\mp 1\}$ to $Y \times \{\pm 1\}$.

Proof. We have

$$\begin{array}{ll} f \cdot Y = \epsilon_M\big((\mathrm{PD}_M(f_*([X])) \cup \mathrm{PD}_M([Y]))\cap[M]\big) & = \epsilon_M\big(\mathrm{PD}_M([Y]) \cap (\mathrm{PD}_M(f_*([X]) \cap [M]))\big) \\ \uparrow & \uparrow \\ \text{by Theorem 68.11 since } f \text{ and } Y \text{ are transverse} & \text{by Lemma 59.7 and the discussion on page 1378} \\ = \epsilon_M(\mathrm{PD}_M([Y]) \cap f_*([X])) & = \langle \mathrm{PD}_M([Y]), f_*([X])\rangle. \\ \uparrow & \uparrow \\ \text{definition of } \mathrm{PD}_M(f_*([X])) & \text{Lemma 59.4} \end{array}$$

□

Now we can prove the following proposition which gives an easy criterion for showing that a codimension one submanifold represents a non-trivial class in homology.

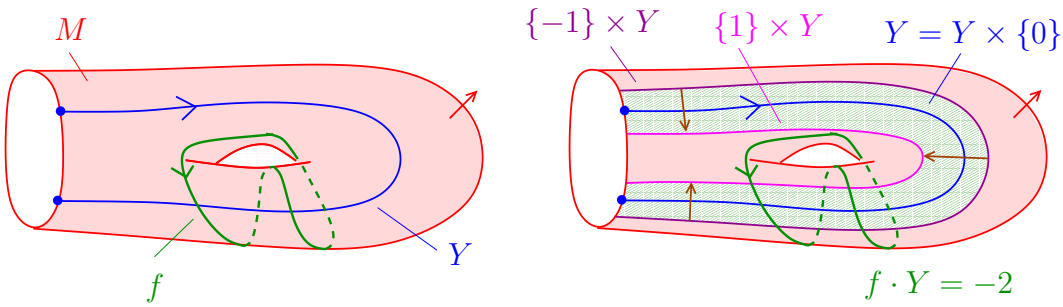

FIGURE 866.

Proposition 69.2. *Let M be a compact oriented n-dimensional manifold and let N be a compact orientable non-empty proper submanifold of codimension one. If the complement $M \setminus N$ is connected, then $[N] \in H_{n-1}(M, \partial M; \mathbb{Z})$ is a primitive*[1166] *element of infinite order.*

Example. Proposition 69.2 can in particular be seen as a generalization of the argument given on page 1567.

Remark. In any statement of a lemma, proposition or theorem it is always a good exercise to see whether the hypothesis stated are actually necessary. In the following we will discuss whether the conditions in Proposition 69.2 that M needs to be compact and oriented are necessary.

(1) We consider the real projective plane $\mathbb{R}\mathrm{P}^2$ and the 1-dimensional submanifold N that is illustrated in Figure 867 to the left. We see that $\mathbb{R}\mathrm{P}^2 \setminus N$ is connected, but since $H_1(\mathbb{R}\mathrm{P}^2; \mathbb{Z}) \cong \mathbb{F}_2$ we see that N cannot possibly represent an element of infinite order. On the other hand, an "$\mathbb{F}_2$-version" of Proposition 69.2, which by Proposition 45.24 also applies to non-orientable manifolds, shows that N represents a non-trivial element in $H_1(\mathbb{R}\mathrm{P}^2; \mathbb{F}_2)$.
(2) Let M be a non-compact oriented n-dimensional manifold and let N be a compact orientable non-empty proper submanifold of codimension one. If ∂M is compact, then we will see in Exercise 69.1 using Proposition 65.4 and 69.2, that the homology class $[N] \in H_{n-1}(M; \mathbb{Z})$ is still an element of infinite order.

Proof. Let M be a compact oriented n-dimensional manifold and let N be a compact orientable proper submanifold of codimension one such that $M \setminus N$ is connected. By Proposition 64.11 we can find a trivial tubular neighborhood $[-1, 1] \times N$ in M. By hypothesis $M \setminus N$ is connected. It follows from Proposition 64.13, Lemma 64.3 and Lemma 3.8 that $M \setminus (-1, 1) \times N$ is path-connected.

It follows from our hypothesis that N is non-empty, together with Corollary 32.4, that we can pick a point $P \in N \setminus \partial N$. We write $P_\pm = P \times \{\pm 1\} \in [-1, 1] \times N$. We denote

[1166]Recall that an element g of an additive abelian group G is called primitive if there does not exist an $h \in G$ and an $n \geq 2$ with $n \cdot h = g$.

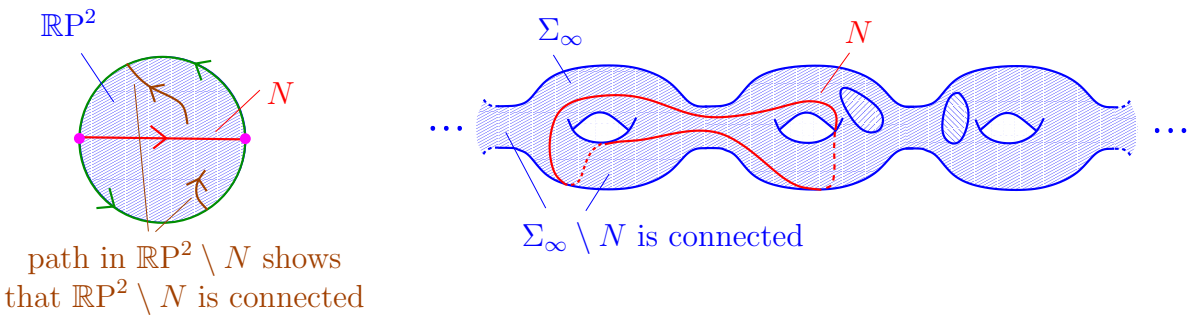

FIGURE 867.

by $\alpha\colon [0, \frac{1}{2}] \to [-1,1] \times N$ the "horizontal path" in $[-1,1] \times N$ from P_- to P_+. Since $M \setminus (-1,1) \times N$ is path-connected we can connect the two points P_+ to P_- via a path $\beta\colon [\frac{1}{2}, 1] \to M \setminus (-1,1) \times N$. We refer to Figure 868 for an illustration.

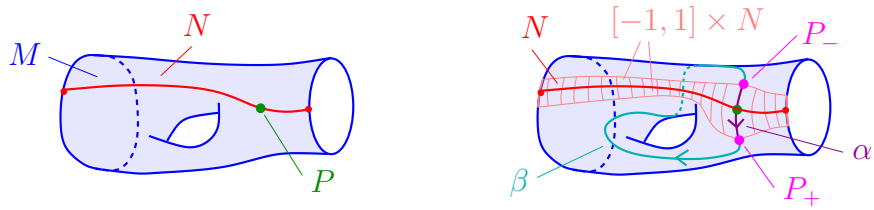

FIGURE 868. Illustration for the proof of Proposition 69.2.

We consider the map $\gamma\colon S^1 = [0,1] \to M$ that is defined by α on $[0, \frac{1}{2}]$ and that is given by β on $[\frac{1}{2}, 1]$. We consider the following homomorphism

$$\begin{aligned} \Psi\colon H_{n-1}(M, \partial M; \mathbb{Z}) &\to \mathbb{Z} \\ \sigma &\mapsto \langle \underbrace{\mathrm{PD}_M(\sigma)}_{\in H^1(M;\mathbb{Z})}, \underbrace{\gamma_*([S^1])}_{\in H_1(M;\mathbb{Z})} \rangle. \end{aligned}$$

We want to show that $[N] \in H_{n-1}(M, \partial M; \mathbb{Z})$ is a primitive element of infinite order. It suffices to show that $\Psi([N]) = \pm 1 \in \mathbb{Z}$. In fact we have

$$\begin{array}{ccccccc} \Psi([N]) & = & \langle \mathrm{PD}_M([N]), \gamma_*([S^1]) \rangle & = & \gamma \cdot N & = & \pm 1, \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{by definition} & & \begin{array}{c}\text{by Proposition 69.1 since} \\ \gamma \text{ and } N \text{ are clearly transverse}\end{array} & & \text{by construction of } \gamma & \end{array}$$

as desired. □

We conclude this section with the following lemma.

Lemma 69.3. $(*)$ *Let M be a compact orientable n-dimensional manifold with at most one boundary component and which furthermore satisfies $H_1(M;\mathbb{Z}) = 0$. (For example we could take $M = \overline{B}^n$ or $M = S^n$). Then for every connected submanifold N of codimension one with $N \cap \partial M = \varnothing$ there exists an n-dimensional compact submanifold W of M with $\partial W = N$.*

Proof $(*)$. By Proposition 64.11 we can find a trivial tubular neighborhood $[-1,1] \times N$ in M. It follows from the argument of the proof of Proposition 69.2 and our assumption that M is orientable and the fact that M is compact that $X := M \setminus (-1,1) \times N$ is disconnected. Furthermore it follows from Proposition 3.24 that X is a submanifold of M with $\partial X = \partial M \cup (\{-1\} \times N) \cup (\{1\} \times N)$. Since ∂M consists of at most one component, since M is connected and since X is disconnected we see that there exists a component Y of X with $\partial X = \{\epsilon\} \times N$ for some $\epsilon \in \{-1,1\}$. By adding "half" of the tubular neighborhood to Y we obtain a submanifold with $\partial Y = M$. □

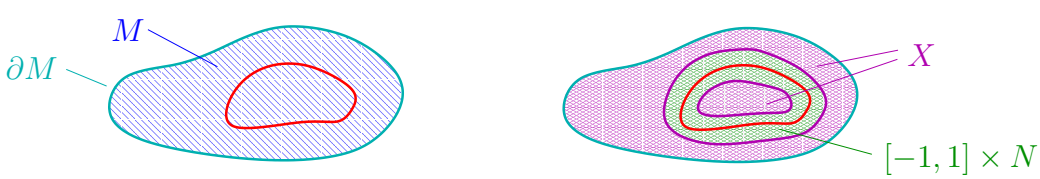

FIGURE 869. Illustration for the proof of Lemma 69.3.

69.2. **Representing homology classes by submanifolds.** The following definition is a slight generalization of the definition that we introduced on page 957.

Definition. Let M be a manifold and let A be a union of components of ∂M.

(1) If N is a compact oriented k-dimensional submanifold of M with $\partial N \subset A$, then, by a slight abuse of notation, we denote by $[N]$ the image of the fundamental class $[N]$ in $H_k(M,A;\mathbb{Z})$ under the inclusion induced map $H_k(N,\partial N;\mathbb{Z}) \to H_k(M,A;\mathbb{Z})$.
(2) We say that a homology class $z \in H_k(M,A;\mathbb{Z})$ *is represented by a submanifold* if there exists a compact oriented k-dimensional compact oriented proper submanifold N with $\partial N \subset A$ such that $[N] = z$.

Let M be an orientable, compact n-dimensional manifold. We saw in Theorem 67.10 that we can calculate the cup product of $\alpha \in H^k(M,\partial M;\mathbb{Z})$ and $\beta \in H^{n-k}(M;\mathbb{Z})$ if the Poincaré duals $\mathrm{PD}_M(\alpha) \in H_{n-k}(M;\mathbb{Z})$ and $\mathrm{PD}_M(\beta) \in H_k(M,\partial M;\mathbb{Z})$ are represented by transverse submanifolds. Thus the following question arises.

Question 69.4. *Let M be a manifold and let A be a union of components of ∂M. For which $k \in \mathbb{N}_0$ can homology classes in $H_k(M,A;\mathbb{Z})$ be represented by submanifolds?*

In Proposition 65.27 we already saw that we can always represent one-dimensional homology classes by submanifolds. We work our way up by one dimension.

Proposition 69.5. *Let M be an n-dimensional manifold with $n \geq 5$ and let $A \subset \partial M$ be a union of components of ∂M. Every class in $H_2(M, A; \mathbb{Z})$ is represented by a submanifold.*

Remark. Below we will deal with 2-dimensional homology classes for orientable manifolds of dimension ≤ 4.

Proof. Let M be an n-dimensional manifold with $n \geq 5$ and let $\sigma \in H_2(M, A; \mathbb{Z})$. The fairly elementary argument of [Cal, p. 3] shows that there exists a compact oriented 2-dimensional manifold Σ and a proper map $f\colon \Sigma \to M$ with $f(\partial\Sigma) \subset A$ such that $f_*([\Sigma]) = \sigma$. Since $n \geq 5$ we obtain from Theorem 65.26 that f is properly homotopic to a proper embedding $g\colon \Sigma \to M$. It follows from Proposition 30.5 that the submanifold Σ represents the same homology class as $f_*([\Sigma])$, namely σ. $\square$

Instead of moving on to the next highest dimension, we now actually consider homology class of *codimension one*. More precisely, we want to prove the following proposition.

Proposition 69.6. *If M is a compact orientable n-dimensional manifold, then every class in $H_{n-1}(M, \partial M; \mathbb{Z})$ can be represented by a submanifold.*

Proof. Let M be a compact orientable n-dimensional manifold and let $\sigma \in H_{n-1}(M, \partial M; \mathbb{Z})$. We write $\phi = \mathrm{PD}_M(\sigma) \in H^1(M; \mathbb{Z})$. By Proposition 55.9 there exists a smooth map $f\colon M \to S^1$ such that $\phi = f^*([S^1]^*)$ where $[S^1]^* \in H^1(S^1; \mathbb{Z})$ is the dual fundamental class.

By Sard's Theorem 3.48 and Proposition 3.47 (2) there exists a regular value $z \in S^1$. To simplify the notation we assume that in fact $z = 1$ is a regular value. We write $N := f^{-1}(1)$. By the Regular Value Theorem 65.3 (1), (2), (3) we know that N is a compact orientable $(n-1)$-dimensional manifold. Furthermore we know from Theorem 65.3 (4) that there exists an $\epsilon \in (0, \pi)$ and a tubular neighborhood $[-\epsilon, \epsilon] \times N$ of N such that the following diagram commutes

$$\begin{tikzcd}
{[-\epsilon, \epsilon] \times N} \arrow[r, hook] \arrow[d, "(s,x) \mapsto s"] & M \arrow[d, "f"] \\
{[-\epsilon, \epsilon]} \arrow[r, "s \mapsto e^{2\pi i s}"] & S^1.
\end{tikzcd}$$

We pick the orientation for N such that the inclusion map $[-\epsilon, \epsilon] \times N \to M$ is orientation-preserving. It remains to prove that $[N] = \sigma \in H_{n-1}(M, \partial M; \mathbb{Z})$. Recall that $\phi = \mathrm{PD}_M(\sigma)$, i.e. $\sigma = \phi \cap [M]$. Therefore it suffices to show that $[N] = \phi \cap [M] \in H_{n-1}(M, \partial M; \mathbb{Z})$.

We introduce the following notation:

(1) We write $I = [-\epsilon, \epsilon]$ and $\mathring{I} = (-\epsilon, \epsilon)$,
(2) we denote by $i\colon I \times N \to M$ the inclusion map and we denote by i also all maps of pairs where the first map is given by the inclusion map,
(3) we denote by q all maps of pairs of topological spaces where the first map is just the identity on M,
(4) finally we denote by $p\colon I \times N \to I$ the projection map.

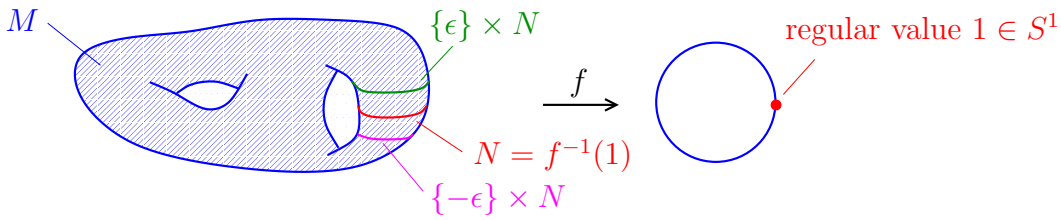

FIGURE 870. Illustration for the proof of Proposition 69.6.

We consider the following diagram[1167]

$$\begin{tikzcd}
H^1(M) & \times & H_n(M,\partial M) \arrow[r, "\cap"] \arrow[d, "q_*"] & H_{n-1}(M,\partial M) \arrow[d, "q_*"', "="] \\
H^1(M, M\setminus(\mathring{I}\times N)) \arrow[u, "q^*"] \arrow[d, "i^*"', "\cong"] & \times & H_n(M, M\setminus(\mathring{I}\times N)\cup\partial M) \arrow[r, "\cap"] & H_{n-1}(M,\partial M) \\
H^1(I\times N, \partial I\times N) \arrow[u, "p^*"] & \times & H_n(I\times N, \partial(I\times N)) \arrow[u, "i_*"'] \arrow[r, "\cap"] & H_{n-1}(I\times N, I\times\partial N) \arrow[u, "i_*"] \\
H^1(I,\partial I) \arrow[u, "p^*"] & \times & H_1(I,\partial I) \arrow[u, "-\times[N]"'] \arrow[r, "\cap"] & H_0(I). \arrow[u, "-\times[N]"]
\end{tikzcd}$$

The proposition follows from the following claim.

Claim.

(1) The diagram commutes.[1168]
(2) The map $i^*\colon H^1(M, M\setminus(\mathring{I}\times N)) \to H^1(I\times N, \partial I\times N)$ is an isomorphism.
(3) We have $(q^*\circ i_*^{-1}\circ p^*)([I]^*) = \phi$.
(4) We have $i_*([I]\times[N]) = q_*([M])$.

We turn to the proof of these four statements:

(1) The top two squares commute by Lemma 59.8 applied to the two maps

$$q\colon (M,\varnothing,\partial M) \;\to\; (M, M\setminus(\mathring{I}\times N), \partial M)$$

and

$$i\colon (I\times N, \partial I\times N, I\times\partial N) \;\to\; (M, M\setminus(\mathring{I}\times N), \partial M).$$

[1167]For completeness' sake we recall that the relative cap product is only defined for excisive triads, see page 1358. So one should think for a second about why the second cap product is in fact defined.

[1168]Note that here for the first three rows we use the convention of page 1360 for what "commutativity" actually means.

Finally regarding the bottom square, note that

$$p^*([I]^*) \cap ([I] \times [N]) \underset{\substack{\uparrow \\ \text{Proposition 56.10}}}{=} p^*([I]^*) \cap ([I \times N]) \underset{\substack{\uparrow \\ \text{Proposition 60.2 (2)}}}{=} [\{0\} \times N] = (\overbrace{[I]^* \cap [I]}^{=[\{0\}]}) \times [N].$$

Since $[I]^* \in H^1(I, \partial I)$ and $[I] \in H_1(I, \partial I)$ are generators it follows from this calculation that the bottom square commutes.

(2) It follows from excision for cohomology groups, see page 1192, that i^* is indeed an isomorphism. We leave it to the reader to verify the details.

(3) We identify the interval I with its image in S^1 under the orientation-preserving map defined by $s \mapsto e^{2\pi i s}$. We denote by $j\colon I \to S^1$ and $j\colon (I, \partial I) \to (S^1, S^1 \setminus \mathring{I})$ the inclusion maps. Furthermore we denote by $r\colon (S^1, \varnothing) \to (S^1, S^1 \setminus \mathring{I})$ the obvious map of pairs of topological spaces. We consider the following diagram

$$\begin{tikzcd}
H^1(S^1) \arrow[rr, "f^*"] & & H^1(M) \\
H^1(S^1, S^1 \setminus \mathring{I}) \arrow[u, "r^*"] \arrow[rr, "f^*"] \arrow[d, "j^*", "\cong"'] & & H^1(M, M \setminus (\mathring{I} \times N)) \arrow[u, "q^*"'] \arrow[d, "i^*"', "\cong"] \\
H^1(I, \partial I) \arrow[rr, "f^* = p^*"] & & H^1(I \times N, \partial I \times N).
\end{tikzcd}$$

Here the map j^* is an isomorphism by excision for cohomology groups. Also note that at the bottom horizontal map we have $f^* = p^*$ by the discussion on page 1615. Furthermore we note that by the functoriality of cohomology groups both squares commute. Finally note that it follows immediately from Lemma 46.23 that $r^*((j^*)^{-1}([I]^*)) = [S^1]^*$. The desired statement is a consequence of the observation that $\phi = f^*([S^1]^*)$.

(4) This statement follows immediately from Lemma 46.23. □

It is natural to ask what we can say about representing homology classes by submanifolds in the other dimensions. In the following two propositions we summarize what is known.

Proposition 69.7. *If M is a compact orientable n-dimensional manifold, then every class in $H_{n-2}(M, \partial M; \mathbb{Z})$ can be represented by a submanifold.*

Proof. The proof of this proposition is similar in spirit to the proof of Proposition 69.6. More precisely, given a class in $H_{n-2}(M, \partial M; \mathbb{Z}) = H^2(M; \mathbb{Z})$ one constructs a smooth map $M \to \mathbb{C}\mathrm{P}^1 = S^2$ and again one takes the preimage of a regular value. We will provide the full proof after we have developed much more theory, see Proposition 69.7. □

In contrast, for low-dimensional classes the following proposition was proved by René Thom. To the best of my knowledge the proof is much less constructive than the proofs of Propositions 69.6 and Proposition 69.7.

Proposition 69.8. *Let M be a compact orientable n-dimensional manifold and let $k \leq 6$ with $k < n$.*[1169] *Then every class in $H_k(M, \partial M; \mathbb{Z})$ can be represented by a submanifold.*

Remark. For $k \leq 5$ the statement can be found in [Tho4, Théorème 6][Tho, Théorème II.27]. The statement for $k = 6$ can be found in the footnote on page 173 of [Tho2].

As so often, the above references deal with "manifolds", without making it entirely clear whether or not this includes the case of manifolds with boundary. But using Lemma 45.11, Lemma 45.12 and the Transversality Theorem 67.2 one can reduce the case of a manifold with boundary to the case of a closed manifold. We leave it to the reader to fill in the details.

Finally note that by [BHK, Theorem 1], extending [Tho, p. 62f], there exists a 10-dimensional closed manifold and a class in $H_7(M; \mathbb{Z})$ that is not represented by a submanifold.

Remark. Propositions 69.6 and Proposition 69.7 also have analogues for topological manifolds. We refer to [FHNOP] for details.

69.3. **The basic Thom-Pontryagin Theory.** In the proof of Proposition 69.6 we saw that a map from a manifold N to S^1 gives rise to a codimension one submanifold. In this section we will go in the opposite direction.

Definition. Let M be a compact oriented n-dimensional manifold and let N be a proper oriented $(n-1)$-dimensional submanifold. By Proposition 64.11 there exists a trivial tubular neighborhood of the form $[-1, 1] \times N$ such that the product orientation of $[-1, 1] \times N$ matches the orientation of $[-1, 1] \times N$, viewed as a codimension zero submanifold of M. We refer to the map[1170]

$$\begin{array}{rcl} \rho_N \colon M & \to & S^1 \\ P & \mapsto & \begin{cases} e^{\pi i t}, & \text{if } P = (t, Q) \in [-1, 1] \times N, \\ -1, & \text{otherwise} \end{cases} \end{array}$$

as the *Thom-Pontryagin map.*[1171] The definition of ρ_N is illustrated in Figure 871.

Remark. The Thom-Pontryagin map ρ_N that we had just constructed depends on the choice of a tubular neighborhood. But it follows from the uniqueness of tubular neighborhoods, see Proposition 64.9, together with Lemma 64.6 (2) that any other choice of a tubular neighborhood $[-1, 1] \times N$ leads to a map $M \to S^1$ that is homotopic to the original map.

Lemma 69.9. *Let M be a compact oriented n-dimensional manifold and let N be a proper oriented proper $(n-1)$-dimensional submanifold. We have*

$$\rho_{N*} \;=\; \mathrm{PD}_M([N]) \;\in\; \mathrm{Hom}(H_1(N; \mathbb{Z}), \mathbb{Z}) \;\underset{\substack{\uparrow \\ \textit{identification from Proposition 51.17}}}{=}\; H^1(N; \mathbb{Z}).$$

[1169] Why do we exclude the case $k = n$?

[1170] It follows easily from Proposition 10.2 and Lemma 1.32 (2') that this map is indeed continuous.

[1171] Lev Pontryagin (1908-1988) was a Soviet topologist, he made many major contributions to topology, despite having lost his eyesight in an accident when he was 14.

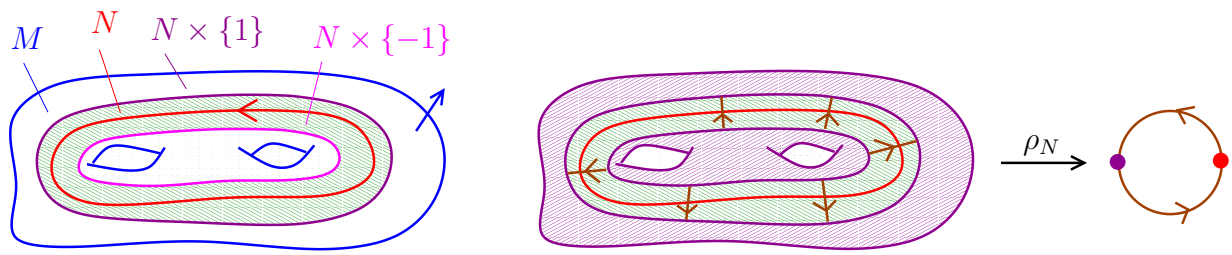

FIGURE 871.

Proof. We had implicitly verified this lemma in the above proof of Proposition 69.6. □

Example. We return to the example that we had discussed on page 1301. More precisely, let Σ be the surface of genus 2. The closed curves x_1, y_1, x_2, y_2 shown in Figure 872 represent a basis for $H_1(\Sigma;\mathbb{Z})$. We consider the epimorphism $\phi\colon H_1(\Sigma) \to \mathbb{Z}$ that is given by $\phi(x_1) = 0$, $\phi(y_1) = 1$, $\phi(x_2) = -2$ and $\phi(y_2) = 1$. By Proposition 55.9 we know that ϕ can be realized by some map $g\colon \Sigma \to S^1$. Now we will construct such a map explicitly.

We consider the closed curve C that is illustrated in Figure 872. We claim that the corresponding map $\rho_C\colon \Sigma \to S^1$ has the desired property. Put differently, we claim that $\rho_{C*} = \phi \in \operatorname{Hom}(H_1(N;\mathbb{Z}),\mathbb{Z})$. It suffices to show that the two homomorphisms agree on the basis $[x_1], [y_1], [x_2], [y_2]$ of $H_1(\Sigma;\mathbb{Z})$. For example we have

$$\begin{array}{ccccccccc} \rho_{C*}([x_2]) & = & \langle \mathrm{PD}_M([C]), [x_2]\rangle & = & x_2 \cdot C & = & -2 & = & \phi(x_2). \\ & \uparrow & & \uparrow & & \uparrow & & & \\ & \text{Lemma 69.9} & & \text{Proposition 69.1} & & \text{see Figure 872} & & & \end{array}$$

It is straightforward to verify that the same equalities hold for all the other basis elements.

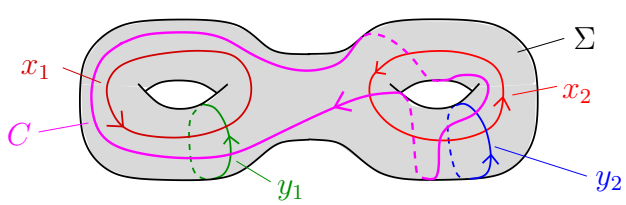

FIGURE 872.

In the remainder of this chapter we study an amusing generalization of the above Thom-Pontryagin map.

Definition. Let M be a compact oriented n-dimensional manifold and let $N_1, \dots, N_k$ be disjoint proper oriented $(n-1)$-dimensional submanifolds. As on page 1618 we pick a trivial tubular neighborhood of the form $[-1,1] \times (N_1 \cup \dots \cup N_k)$. We consider the wedge $\bigvee_{j=1}^{k} S^1_j$ given by identifying the points $-1 \in S^1_j$ to a single point $*$. We again refer to the

map

$$\begin{array}{rcl} \rho_{N_1,\dots,N_k}\colon M & \to & \bigvee_{j=1}^{k} S^1_j \\ P & \mapsto & \begin{cases} e^{\pi i t} \in S^1_j, & \text{if } P=(t,Q)\in[-1,1]\times N_j, \\ *, & \text{otherwise} \end{cases} \end{array}$$

as the *Thom-Pontryagin map*. The definition of ρ_N is illustrated in Figure 873.

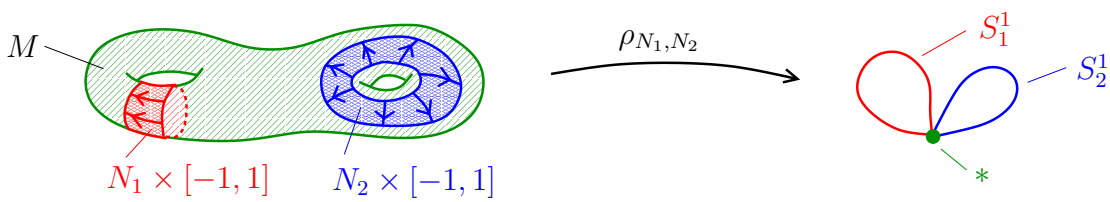

FIGURE 873.

Before we continue we recall that in Lemma 12.4 we gave an identification

$$\langle t_1,\dots,t_k\rangle \;=\; \pi_1\Big(\bigvee_{j=1}^{k} S^1_j, *\Big)$$

where each t_j is represented by a loop that goes once around the j-th circle S^1_j in a positive direction.

Proposition 69.10. *Let M be a compact oriented connected n-dimensional manifold and let $N_1,\dots,N_k$ be disjoint proper oriented non-empty $(n-1)$-dimensional submanifolds. If $M\setminus(F_1\cup\dots\cup F_k)$ is connected, then for any $x_0\in M$ the map*

$$\rho_{N_1,\dots,N_k}\colon \pi_1(M,x_0) \;\to\; \pi_1\Big(\bigvee_{j=1}^{k} S^1_j, *\Big) \;=\; \langle t_1,\dots,t_k\rangle$$

is an epimorphism.

Proof. We write $N=N_1\cup\dots\cup N_k$ and $\rho=\rho_{N_1,\dots,N_k}$. We pick a trivial tubular neighborhood of the form $[-1,1]\times N$. It follows from our hypothesis that $M\setminus N$ is connected, together with Proposition 64.13 and Lemma 64.3 that $M\setminus(-1,1)\times N$ is also connected. Since M is connected it follows from Exercise 6.4 that it suffices to consider a base point x_0 that lies in $M\setminus(-1,1)\times N$.

For $j=1,\dots,k$ we do the following:

(1) we pick a point $P_i\in N_i$,
(2) since $M\setminus(-1,1)\times N$ is connected we can pick a path α_j from x_0 to $(-1,P_j)$ and we can pick a path γ_j from $(1,P_j)$ to x_0,
(3) we denote by β_j the "horizontal" path in $[-1,1]\times\mathbb{N}_j$ from $(-1,P_j)$ to $(1,P_j)$,
(4) we write $\delta_j := \alpha_j * \beta_j * \gamma_j$.

It follows easily from the definitions that for $j = 1, \ldots, k$ we have $\rho_*([\delta_j]) = t_j$. We have thus shown that the generating set $\{t_1, \ldots, t_k\}$ lies in the image of ρ_*. In other words, ρ_* is indeed an epimorphism. $\square$

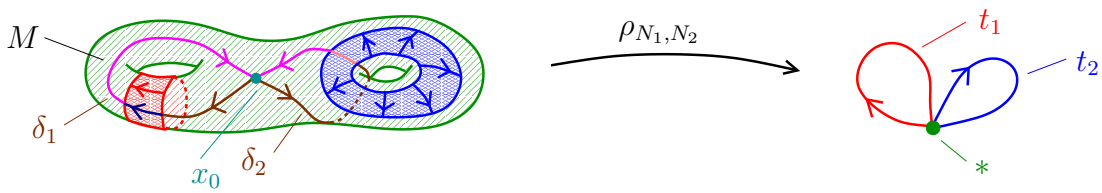

FIGURE 874. Illustration for the proof of Proposition 69.10.

Example. Let $g \in \mathbb{N}$ and let Σ_g be the surface of genus g. As should be pretty clear from considering Figure 875, the surface Σ_g contains g disjoint curves $N_1, \ldots, N_g$ such that the complement is connected. Thus it follows from Proposition 69.10 that there exists an epimorphism

$$\pi_1(\Sigma_g) \ \to \ \langle x_1, \ldots, x_g \rangle.$$

In fact, as we will see in Exercise 69.2, it is not difficult to show the existence of such an epimorphism on a more algebraic level.

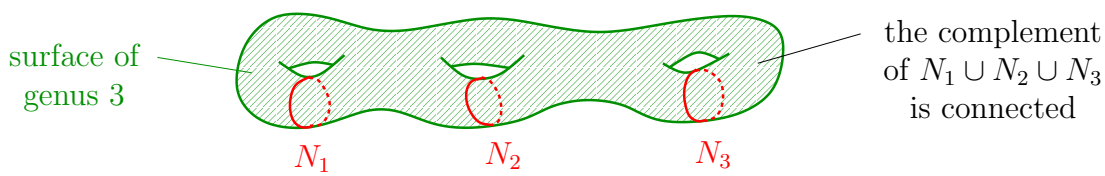

FIGURE 875.

The previous example raises the following thought-provoking question.

Question 69.11. *Let $g \in \mathbb{N}$ and let Σ_g be the surface of genus g.*

(1) *What is the maximal number $k = k(g) \in \mathbb{N}_0$ for which we can find k disjoint curves $F_1, \ldots, F_k$ on Σ_g such that $\Sigma_g \setminus (F_1 \cup \cdots \cup F_k)$ is connected?*
(2) *What is the maximal $l = l(g) \in \mathbb{N}_0$ for which there exists an epimorphism from $\pi_1(\Sigma_g)$ onto a free group of k generators?*

In summary, as of right now we know the following:

$$\begin{array}{ccccccc} g & \underset{\substack{\uparrow \\ \text{by the above} \\ \text{example}}}{\leq} & k(g) & \underset{\substack{\uparrow \\ \text{Proposition 69.10}}}{\leq} & l(g) & \underset{\substack{\uparrow \\ \text{Proposition 13.10}}}{\leq} & 2g. \end{array}$$

Exercises for Chapter 69.

Exercise 69.1. Let M be a *non-compact* oriented n-dimensional manifold with compact boundary. Furthermore let N be a compact orientable non-empty proper submanifold of codimension one such that $M \setminus N$ is connected. Show that $[N] \in H_{n-1}(M;\mathbb{Z})$ is an element of infinite order.
Hint: Use Propositions 65.4 and 69.2.

Exercise 69.2. Let $g \in \mathbb{N}$ and let Σ_g be the surface of genus g. By Proposition 14.3 we know that there exists an isomorphism

$$\pi_1(\Sigma_g) \;\cong\; \langle x_1, y_1, \dots, x_g, y_g \mid [x_1, y_1] \cdot \dots \cdot [x_g, y_g] \rangle.$$

Use this isomorphism to give a purely algebraic proof that $\pi_1(\Sigma_g)$ admits an epimorphism onto a free group on g generators.

Exercise 69.3. Here is one approach to answering Question 69.11 (1). Let $g \in \mathbb{N}$ and let Σ_g be the surface of genus g. Let $F_1, \dots, F_k$ be disjoint curves on Σ_g such that $\Sigma_g \setminus (F_1 \cup \dots \cup F_k)$ is connected. By the Tubular Neighborhood Theorem 10.19 we can pick a tubular neighborhood $\bigcup_{i=1}^{k} [-1,1] \times F_i$ for the submanifold $F_1 \cup \dots \cup F_k \subset \Sigma_g$. We consider the compact orientable 2-dimensional manifold $X := \Sigma_g \setminus \bigcup_{i=1}^{k} (-1,1) \times F_i$. What can you say about the Euler characteristic of X? What does the classification of compact orientable 2-dimensional manifolds tell you?

70. Applications to knot theory

After so much theory we want to practice what we have learned by applying our recent results to knot theory.

70.1. **Curves on 2-dimensional manifolds** $(*)$**.** We recall the following definition from page 306: A *closed oriented curve* C in a manifold M is a closed oriented connected 1-dimensional submanifold of M or of ∂M. In this section we want to study curves on 2-dimensional manifolds. Our main focus will be curves on the torus.

Before we state the results we recall that on page 853 we saw that a closed oriented curve C in a manifold M defines a homology class $[C] \in H_1(M;\mathbb{Z})$. We start out with the following lemma.

Lemma 70.1. *Let $T = S^1 \times S^1$ be the torus and let C be a closed oriented curve on T.*

(1) *If $T \setminus C$ is connected, then $[C]$ is a primitive element of $H_1(T;\mathbb{Z})$.*
(2) *If $T \setminus C$ is disconnected, then C is the boundary of an embedded disk.*

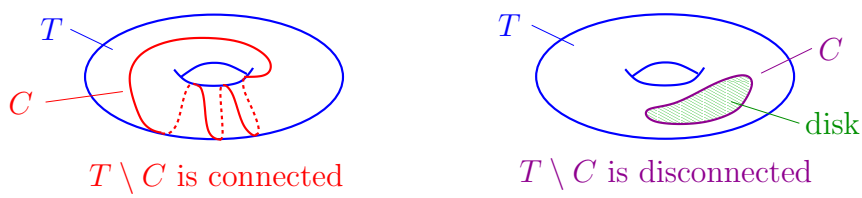

Figure 876. Illustration of Lemma 70.1.

Proof. If $T \setminus C$ is connected, then it follows from Proposition 69.2 that $[C]$ is a primitive element of $H_1(T;\mathbb{Z})$. Now suppose that $T \setminus C$ is disconnected. By the Tubular Neighborhood Theorem 10.19 there exists a tubular neighborhood $[-1,1] \times C$. From Lemma 64.3 and Proposition 64.13 we obtain that $T \setminus (-1,1) \times C$ is also disconnected. Since C is connected this implies that $T \setminus (-1,1) \times C$ has two components A and B, one of which contains $\{-1\} \times C$ and one which contains $\{1\} \times C$.[1172] By Proposition 3.24 we know that A and B are compact 2-dimensional manifolds, in particular they are finite CW-complexes. We have

$$\chi(A) + \chi(B) \underset{\substack{\uparrow \\ \text{Lemma 40.5}}}{=} \underbrace{\chi(T)}_{=0} + \underbrace{\chi(\{-1\} \times C)}_{=0} + \underbrace{\chi(\{1\} \times C)}_{=0} = 0.$$

Since A and B have boundary it follows from the classification of compact 2-dimensional manifolds and the calculation of Euler characteristics, see Lemma 40.6, that one of A or B is diffeomorphic to the disk $\overline{B}^2$. $\square$

[1172] Why is that?

Lemma 70.2. *Let $T = S^1 \times S^1$ be the torus. Let C and D be two closed oriented curves on T. If C and D are disjoint and if $[C]$ and $[D]$ are both non-zero*[1173] *in $H_1(T;\mathbb{Z})$, then $[C] = \pm[D]$.*

Proof. From Theorem 67.10 together with our hypothesis that $C \cap D = \varnothing$ we obtain that $\mathrm{PD}_T([C]) \cup \mathrm{PD}_T([D]) = 0$. It follows easily from the calculation of the cup product of the torus, see Lemma 57.14, that $\mathrm{PD}_T([C]) = k \cdot \mathrm{PD}_T([D])$ for some $k \in \mathbb{Z}$. We obtain from Lemma 70.1 that $k \in \{-1, 1\}$. □

Lemma 70.3. *Let $T = S^1 \times S^1$ be the torus. Let C and D be two closed oriented curves on T. Suppose that $[C] = [D] \neq 0$, then the following hold:*

1. *the two closed oriented curves are smoothly isotopic,*
2. *if C and D are furthermore disjoint, then there exists an embedded annulus $X \subset T$ with $\partial X = C \cup -D$.*

Furthermore, the same statements also hold if we replace the torus $T = S^1 \times S^1$ by the annulus $S^1 \times [-1, 1]$.

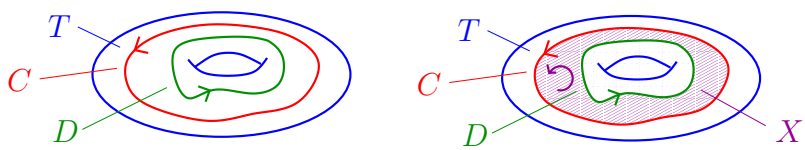

FIGURE 877. Illustration of Lemma 70.3 (2)

Sketch of proof. We provide a sketch of a proof for the various statements:

1. By the Transversality Theorem 67.2 (2) we can assume that C and D are already transverse. It follows from the calculation of the cup product of the torus and Theorem 67.10 that the algebraic intersection number is 0. The argument is now similar to the argument of the proof of Theorem 67.22, but this time we use Lemma 70.1 to find the desired embedded disks. We refer to Figure 878 for an illustration.

   It is a good, and not entirely trivial, mental exercise to fill in the details. The argument is sketched in more detail in [Rol, Lemma 5 of Chapter 2.C].
2. The proof of this statement is similar to the proof of Lemma 70.1 (2). We leave it to the reader to fill in the details.

The proof in the case that $T = S^1 \times [-1, 1]$ is easier. We will discuss it in Exercise 70.2. □

For completeness sake we state the following proposition, even though we will not make use of it.

Proposition 70.4. $(*)$ *Let F be a 2-dimensional manifold and let C and D be two closed oriented curves on F.*

[1173] Is this condition that $[C]$ and $[D]$ are both non-zero necessary?

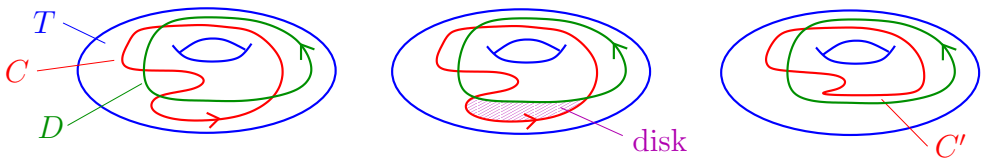

FIGURE 878.

(1) *If C and D are homotopic, then C and D are smoothly isotopic.*
(2) *if C and D are furthermore disjoint and if they are not null-homotopic, then there exists an embedded annulus $X \subset F$ with $\partial X = C \cup -D$.*

Proof.

(1) This statement is [FaM, Proposition 1.10]. (Closely related statements are also proved in [Baer], [Eps2, Theorem 2.1].) Unfortunately all the references are somewhat cavalier when it comes to distinguishing continuous and smooth maps, but with some effort one can see that all the references provide smooth isotopies.
(2) If F is orientable, then we will provide the proof in Exercise 70.5. The proof of the non-orientable case is not much harder. □

In Exercise 70.1 we will use Proposition 10.17 to prove the following corollary to Lemma 70.3.

Corollary 70.5. *Let $T = S^1 \times S^1$ be the torus and let C and D be two closed oriented 1-dimensional submanifolds of T. If $[C] = [D] \in H_1(T;\mathbb{Z})$, then there exists a compact oriented proper 2-dimensional submanifold Ω of $T \times [0,1]$ such that*

$$\partial\Omega \;=\; C \times \{0\} \cup -D \times \{1\}.$$

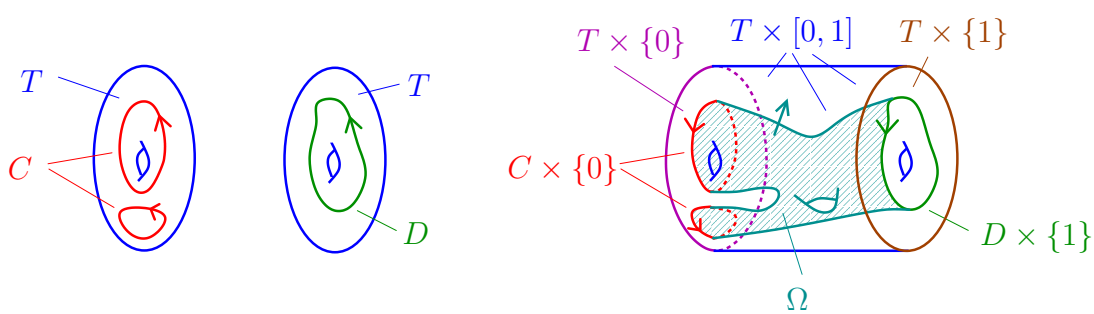

FIGURE 879. Illustration of Corollary 70.5.

70.2. **The longitude of a knot.** We start out our discussion of knots with the following definition.

Definition. Let $K \subset S^3$ be an oriented knot.

(1) A *fattening of* K is an orientation-preserving embedding $F\colon \overline{B}^2 \times K \to S^3$ such that $F(0,P) = P$ for all $P \in K$.
(2) Given a fattening F of K we refer to $X_K := S^3 \setminus F(B^2 \times K)$ as the *knot exterior*.
(3) Given a fattening F of K and given $* \in K$ we refer to the oriented submanifold $\mu_K := F(S^1 \times \{*\})$ of $S^3 \setminus K$ as the *meridian* of K.
(4) By Lemma 40.7 (5) the inclusion induced map $H_1(X_K;\mathbb{Z}) \xrightarrow{\cong} H_1(S^3 \setminus K;\mathbb{Z})$ is an isomorphism and we have $H_1(X_K;\mathbb{Z}) = \mathbb{Z}\cdot[\mu_K]$. We denote by ϕ_K the isomorphism

$$\begin{array}{rcl} \phi_K\colon H_1(S^3 \setminus K;\mathbb{Z}) = H_1(X_K;\mathbb{Z}) & \xrightarrow{\cong} & \mathbb{Z} \\ [\mu_K] & \to & 1. \end{array}$$

(5) Suppose we are given a fattening F for K. We define

$$\text{self-linking number of } F \ := \ \phi_K(\underbrace{F_*([\{1\} \times K])}_{\in H_1(X_K;\mathbb{Z})}).$$

Remark. It follows from the uniqueness of tubular neighborhoods, see Proposition 10.20, that the exterior X_K and the meridian μ_K are, in an appropriate sense, independent of the choice of the fattening. Therefore often we just say "the exterior" and "the meridian".

Lemma 70.6. *Let K be an oriented knot in S^3.*

(1) *Let $F\colon \overline{B}^2 \times S^1 \to S^3$ be a fattening of K and let $s \in \mathbb{Z}$. As in Lemma 64.6 we consider the homeomorphism*

$$\begin{array}{rcl} \Psi\colon \overline{B}^2 \times S^1 & \to & \overline{B}^2 \times S^1 \\ (w,z) & \mapsto & (w \cdot z^s, z). \end{array}$$

The map $F \circ \Psi$ is a fattening with

$$\textit{self-linking number of } F \circ \Psi \ = \ \textit{self-linking number of } F + s.$$

(2) *Given any $n \in \mathbb{Z}$ there exists a fattening of K with self-linking number n.*
(3) *If $F, F'\colon \overline{B}^2 \times K \to S^3$ are two fattenings with self-linking number n, then there exists a diffeotopy $H\colon S^3 \times [0,1] \to S^3$ rel K with $H_0 = \mathrm{id}$ and $H_1 \circ F = F'$.*

Given $K \subset \mathbb{R}^3 \subset S^3 = \mathbb{R}^3 \cup \{\infty\}$ the analogous statements hold if we consider fattenings that are contained in $\mathbb{R}^3$. Furthermore, in this setting the diffeotopy in (3) *of $\mathbb{R}^3$ can be assumed to have compact support.*

Remark. Given an oriented knot K and $n \in \mathbb{Z}$ sometimes we use the uniqueness statement of Lemma 70.6 to talk about *the fattening of K with self-linking number n*. Sometimes we shorten his cumbersome expression to *the n-fattening of K*.

Proof.

(1) We denote by m the self-linking number of F. We write $\lambda := F(\{1\} \times K)$ and $\mu := F(S^1 \times \{1\})$ and we view λ and μ as oriented 1-dimensional submanifolds with

the orientations given by K and S^1. We calculate that

$$\text{self-linking number of } F\circ\Psi = \phi_K(F_*(\Psi_*([\{1\}\times K])) \underset{\substack{\uparrow \\ \text{follows from Lemma 38.7 (2)}}}{=} \phi_K(s\cdot[\mu]+[\lambda]) \underset{\substack{\uparrow \\ \text{since } \phi_K(\mu)=1 \text{ and} \\ \text{by definition of } m}}{=} s+m.$$

(2) From the Tubular Neighborhood Theorem 10.19 we know that there exists a fattening $F\colon \overline{B}^2\times K\to S^3$. We denote by m the self-linking number of F. The desired statement now follows from (1) applied to $n-m$.

(3) The uniqueness statement is an immediate consequence of (1) together with Proposition 64.9 and Lemma 64.6 (3).

The same arguments as above also apply if we replace S^3 by $\mathbb{R}^3$. □

Definition. Let $K\subset S^3$ be an oriented knot. We pick a fattening $F\colon \overline{B}^2\times K\to S^3$ of self-linking number zero. We refer to $\lambda_K = F(\{1\}\times K)$ as *longitude* of K.[1174]

Examples.

(1) In Figure 880 we show the longitude and the meridian for the trivial knot and the Figure-8 knot.

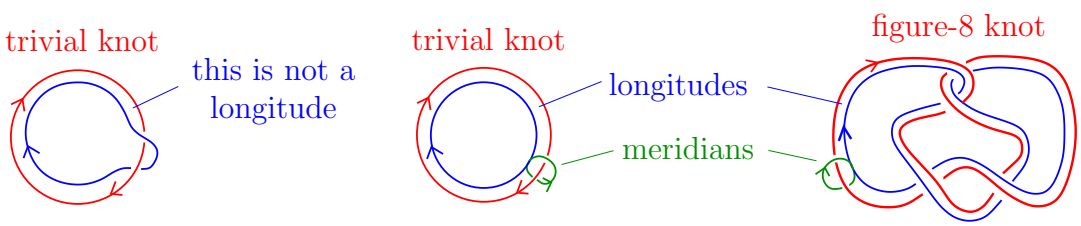

FIGURE 880.

(2) In Figure 881 we show the trefoil knot with three wannabe longitudes. It is not entirely clear which one is the right longitude. We will soon develop a tool with which it will be straightforward to settle this issue.

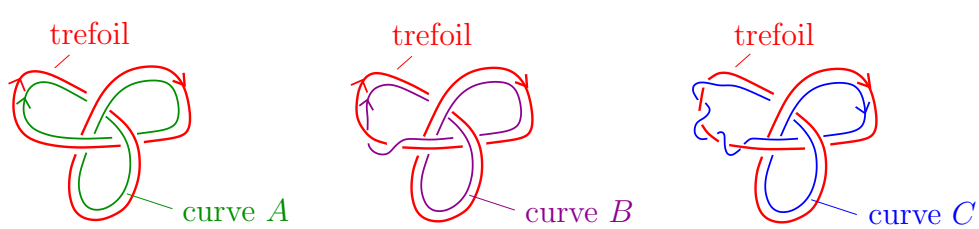

FIGURE 881.

[1174]It follows from Lemma 70.6 (3) that the longitude is in an appropriate way uniquely determined.

On several occasions the following lemma comes in handy.

Lemma 70.7. *Let K be an oriented knot and let $F\colon \overline{B}^2 \times K \to S^3$ be a fattening with self-linking number zero. We denote by $X_K = S^3 \setminus F(B^2 \times K)$ the corresponding knot exterior. Furthermore we denote as usual by $\mu_K = F(S^1 \times \{*\})$ and $\lambda_K = F(\{1\} \times K)$ the corresponding meridian and longitude.*

(1) *The classes $[\mu_K]$ and $[\lambda_K]$ form a basis for $H_1(\partial X_K; \mathbb{Z})$.*
(2) *There exists a short exact sequence of the following form*

$$\begin{array}{ccccccc} 0 & \to & H_2(X_K, \partial X_K; \mathbb{Z}) & \to & \overbrace{H_1(\partial X_K; \mathbb{Z})}^{=\mathbb{Z}\cdot[\mu_K]\oplus\mathbb{Z}\cdot[\lambda_K]} & \to & \overbrace{H_1(X_K; \mathbb{Z})}^{=\mathbb{Z}\cdot[\mu_K]} \to 0 \\ & & & & [\mu_K] & \mapsto & [\mu_K] \\ & & & & [\lambda_K] & \mapsto & 0. \end{array}$$

(3) *The longitude λ_K is the unique, up to smooth isotopy, closed oriented curve on the torus $F(S^1 \times K)$ that is homologous to $K = \{0\} \times K$ in $F(\overline{B}^2 \times K)$ and that is null-homologous in X_K.*
(4) *If we view μ_K and λ_K as closed oriented curves on the oriented torus $F(S^1 \times K)$, then the algebraic intersection number equals $\mu_K \cdot \lambda_K = +1$.*
(5) *If denote by $i\colon \mu_K \to \partial X_K$ the inclusion map, then*

$$i^*([\mu_K]) \cap [\partial X_K] \;=\; -[\lambda_K] \;\in\; H_1(\partial X_K; \mathbb{Z}).$$

Proof.

(1) This statement follows from Lemma 33.13.
(2) We consider the long exact sequence of homology groups of the pair $(X_K, \partial X_K)$:

$$\underbrace{H_2(X_K; \mathbb{Z})}_{=0 \text{ by Lemma 40.7 (5)}} \to H_2(X_K, \partial X_K; \mathbb{Z}) \to H_1(\partial X_K; \mathbb{Z}) \xrightarrow{\phi} H_1(X_K; \mathbb{Z}).$$

By definition we have $\phi([\lambda_K]) = 0$. Furthermore we know from Lemma 40.7 that the right-hand map is an epimorphism. The statement follows immediately from these observations.
(3) It follows from (1) that the kernel of $H_1(\partial X_K; \mathbb{Z}) \to H_1(X_K; \mathbb{Z})$ equals $\mathbb{Z} \cdot [\lambda_K]$. Since $H_1(F(\overline{B}^2 \times K); \mathbb{Z}) = \mathbb{Z} \cdot [K] = \mathbb{Z} \cdot [\lambda_K]$ we see that there exists a unique homology class that has the properties we are interested in. The desired statement now follows from Lemma 70.3 (1).
(4) This statement follows from the definitions and the easy observation that the oriented submanifolds $S^1 \times \{1\}$ and $\{1\} \times S^1$ of the oriented manifold $S^1 \times S^1$ have algebraic intersection number one.

(5) We calculate that

$$\begin{array}{rcl} i^*([\mu_K]) \cap [\partial X_K] & = & i^*([\mu_K]) \cap F_*(-[S^1 \times K]) \\ & \uparrow & \\ & \text{since } F_*([S^1 \times S^1]) = [\partial F(\overline{B}^2 \times K)] = -[\partial X_K] & \\ & = & -F_*([\{1\} \times K]) \\ & \uparrow & \\ & \text{see page 1374} & \end{array} \quad \begin{array}{rcl} & = & F_*\big([S^1 \times \{*\}]^* \cap (-[S^1 \times K])\big) \\ & \uparrow & \\ & \text{Lemma 59.8} & \\ & = & -[\lambda_K]. \\ & \uparrow & \\ & \text{by definition of } \lambda_K & \end{array}$$

□

70.3. **Seifert surfaces.**

Definition. Let $K \subset S^3$ be a knot. A *Seifert surface*[1175] *for* K is a compact orientable connected 2-dimensional submanifold F of S^3 such that $\partial F = K$. If K itself is oriented, then we equip a Seifert surface F with the orientation such that $\partial F = K$ as oriented manifold.

Examples.

(1) In Figure 882 we show Seifert surfaces for the trivial knot, the trefoil and the Figure-8 knot.

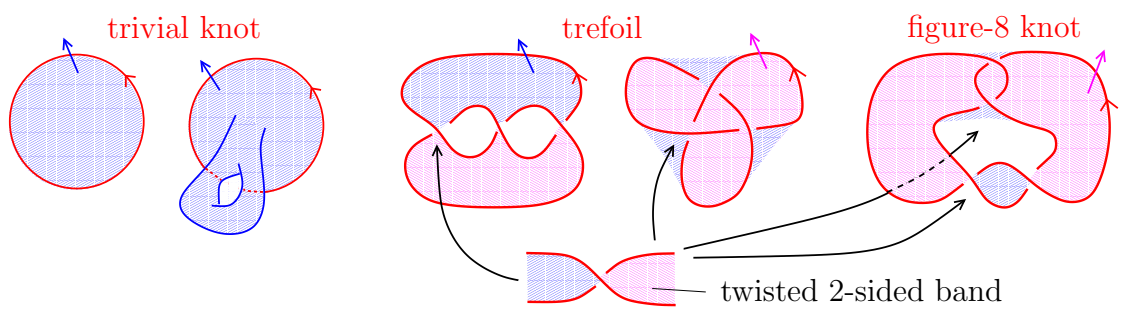

FIGURE 882.

(2) In Figure 883 we see two surfaces of minimal surface area that bound the trefoil, both were manufactured by Jürgen Neukirch. The one on the left is orientable, thus it is a Seifert surface. The one on the right is diffeomorphic to the Möbius band, thus it is not a Seifert surface.

The following proposition is arguably one of the most useful results in knot theory.

Proposition 70.8. *Every knot $K \subset S^3$ admits a Seifert surface.*

Remark.

[1175]Seifert surfaces are named after Herbert Seifert (1907-1996) whom we had already encountered at the Seifert-van Kampen Theorem 12.2.

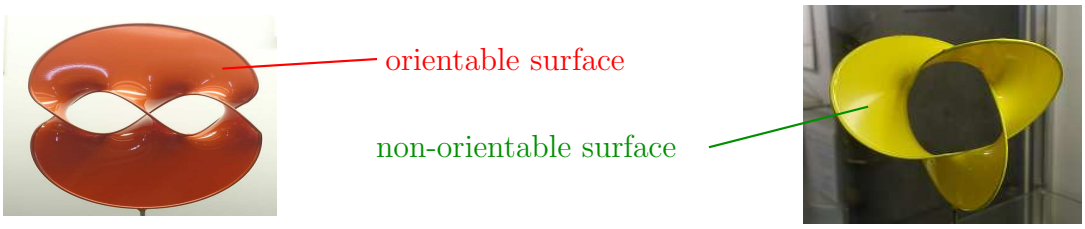

FIGURE 883.

(1) The proposition was first proved in 1930 by F. Frankl and Lev Pontryagin [FPo] in 1930. Shortly afterwards Herbert Seifert [Sei2] gave a different proof. More precisely Seifert found an algorithm that given a diagram for a knot produces an explicit Seifert surface for the knot. Seifert's algorithm is also described in most books on knot theory, see e.g. [Rol, p. 120] or [Lic3, Theorem 2.2].
(2) A slight generalization of the argument we give proves the following stronger statement: given any closed orientable n-dimensional manifold $V \subset S^{n+2}$ there exists a compact orientable $(n+1)$-dimensional submanifold $W \subset S^{n+2}$ such that $\partial W = V$. We refer to [Bre, Theorem VII.14.7], [Er, Lemma 2.2] and [BDR] for details. The proof in these two references is close to the approach taken in the proof of Proposition 70.8, but it circumvents the use of Proposition 69.6 by a more formal argument.

Proof. Let K be a knot. We need to show that there exists a compact orientable connected 2-dimensional submanifold F of S^3 such that $\partial F = K$.

By Lemma 70.6 (2) we can pick a fattening $2\overline{B}^2 \times K$ of the knot K with self-linking number zero. We denote by $X := S^3 \setminus (2B^2 \times K)$ the knot exterior. By Lemma 70.7 (2) we know that there exists a unique homology class $\sigma \in H_2(X, \partial X; \mathbb{Z})$ with $\partial\sigma = [\{2\} \times K] \in H_1(\partial X; \mathbb{Z})$. It follows from Proposition 69.6 that there exists a compact oriented proper 2-dimensional submanifold Σ of X such that $[\Sigma] = \sigma$. We then also have $[\partial\Sigma] = [\{2\} \times K] \in H_1(\partial X; \mathbb{Z})$.[1176]

We consider the torus $T = 2S^1 \times K$. Since $[\{2\} \times S^1] = [\partial\Sigma]$ we obtain from Corollary 70.5 a 2-dimensional submanifold Ω of

$$[1,2] \times S^1 \times K \;=\; (2\overline{B}^2 \setminus B^2) \times K \;=\; \{rz \,|\, r \in [1,2], z \in S^1\} \times K$$

[1176]Here is the argument for this claim. We denote by $i\colon \Sigma \to X$ the inclusion map. Recall that by definition of a proper submanifold we have $\partial\Sigma \subset \partial X$. We consider the following diagram

$$\begin{array}{ccc} H_2(\Sigma, \partial\Sigma; \mathbb{Z}) & \xrightarrow[{[\Sigma]\mapsto[\partial\Sigma]}]{\partial} & H_1(\partial\Sigma; \mathbb{Z}) \\ \downarrow{\scriptstyle i_*} & & \downarrow{\scriptstyle i_*} \\ H_2(X, \partial X; \mathbb{Z}) & \xrightarrow[{\sigma\mapsto[\{2\}\times K]}]{\partial} & H_1(\partial X; \mathbb{Z}) \end{array}$$

given by the connecting homomorphisms of the pairs $(X, \partial X)$ and $(\Sigma, \partial\Sigma)$. In the diagram we already used that by Proposition 46.26 we have $\partial([\Sigma]) = [\partial\Sigma] \in H_1(\partial X; \mathbb{Z})$. The statement now follows from the observation that this diagram commutes by Proposition 31.13 (3).

such that $\partial\Omega = (\{1\} \times K) \cup -\partial\Sigma$. We apply Proposition 10.17 twice to

$$([0,1] \times K) \cup \Omega \cup \Sigma \;\subset\; (\overline{B}^2 \times K) \cup (\{rz \,|\, r \in [1,2], z \in S^1\} \times K) \cup X = S^3$$

and we obtain a compact orientable 2-dimensional submanifold Z whose boundary equals K. This submanifold might not be connected, but the component of Z that contains K is the desired Seifert surface. $\square$

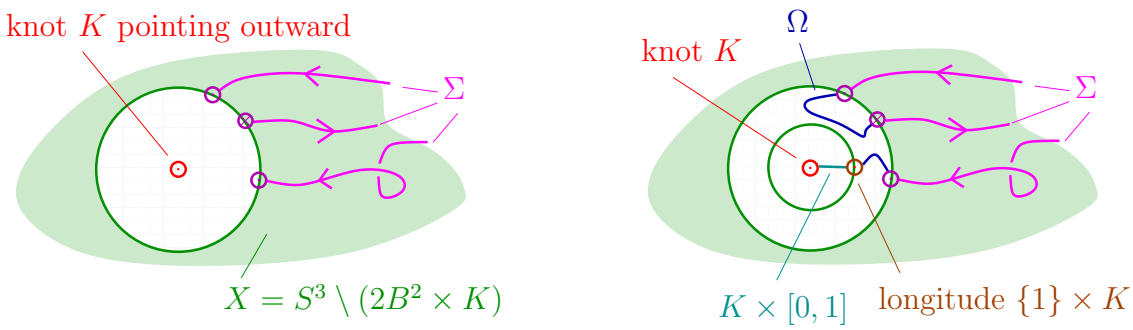

FIGURE 884. Illustration for the proof of Proposition 70.8.

Definition. Let F be a compact orientable connected 2-dimensional manifold with m boundary components. By Theorem 14.14 there exists a unique $g \in \mathbb{N}_0$ such that F is homeomorphic to the surface of genus g with m open disks removed. We refer to g as the *genus of* F.

Given a Seifert surface it is sometimes not entirely obvious how to determine the genus. The following lemma gives an easy criterion to determine the genus of a Seifert surface.

Lemma 70.9. *Let F be a compact orientable connected 2-dimensional submanifold with one boundary component. If $\Gamma \subset F$ is a graph that is a deformation retract of F, then*

$$\textit{genus of } F \;=\; \tfrac{1}{2}(1 - \chi(F)) \;=\; \tfrac{1}{2}(1 - \#\textit{vertices of } \Gamma + \#\textit{edges of } \Gamma).$$

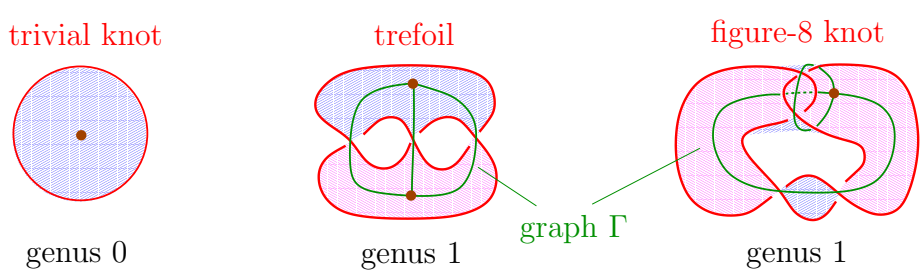

FIGURE 885.

Proof. We have

$$\text{genus of } F \underset{\substack{\uparrow \\ \text{by Proposition 35.10 we} \\ \text{have } \chi(F)=1-2g}}{=} \tfrac{1}{2}(1-\chi(F)) \underset{\substack{\uparrow \\ \text{by Corollary 40.2 since } \Gamma \text{ is a} \\ \text{deformation retract of } F}}{=} \tfrac{1}{2}(1-\chi(\Gamma)).$$

□

If a knot K bounds a Seifert surface of genus g, then the construction sketched in Figure 886 shows pretty convincingly that K also bounds Seifert surfaces of any genus $h \geq g$.

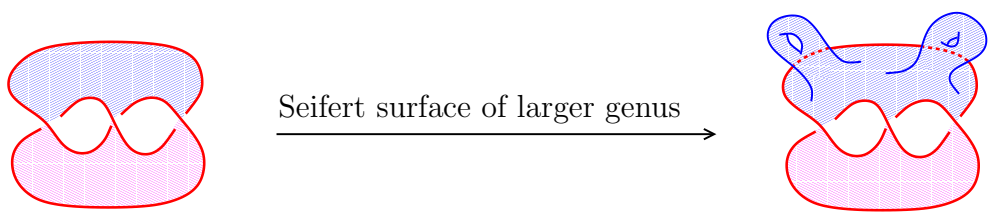

FIGURE 886.

So the interesting question is, what is the minimal genus of a Seifert surface for a given knot? This leads us to the following definition.

Definition. Given a knot $K \subset S^3$ we define

$$\text{genus}(K) := \text{minimal genus of a Seifert surface of } K.$$

As we have seen in Figure 885, the trivial knot has genus 0. The following lemma gives the converse to this observation.

Lemma 70.10. *Let K be a knot. If the genus of K is zero, then K is equivalent to the trivial knot.*

Sketch of proof. Let K be a knot with genus 0. This means that K bounds a disk, i.e. there exists an embedding $\varphi\colon \overline{B}^2 \to S^3 = \mathbb{R}^3 \cup \{\infty\}$ with $\varphi(S^1) = K$. We write $\mathbb{R}^3 = \mathbb{C} \times \mathbb{R}$ and we make the identification $\mathbb{C} = \mathbb{C} \times \{0\} \subset \mathbb{R}^3$. It suffices to show that there exists a smooth isotopy from φ to an embedding $\psi\colon \overline{B}^2 \to \mathbb{R}^3$ such that $\psi(S^1) = S^1 \subset \mathbb{C}$. We perform the following steps:

(0) Using that SO(4) is connected, see Lemma 1.96 (1), we can assume after a smooth isotopy that $\infty \notin \varphi(\overline{B}^2)$.
(1) Using that $\mathrm{SL}(3,\mathbb{R})$ is connected, see again Lemma 1.96 (2), we can find a smooth isotopy such that afterwards we have $\varphi(0) = 0$ and $(D_0\varphi)(T_0\overline{B}^2) = \mathbb{C} \times \{0\}$.
(2) We can shrink the disk such that the projection $\mathbb{R}^3 = \mathbb{C} \times \mathbb{R} \to \mathbb{C} \times \{0\}$ is injective on the disk.[1177]

[1177] At this point we could just apply Theorem 10.28 to conclude that K is equivalent to the trivial knot. Just for fun we indicate how one can prove the lemma "by hand".

(3) We can find a smooth isotopy to end up with an embedding $\varphi\colon \overline{B}^2 \to \mathbb{C}$ with $\varphi(0) = 0$ and $D_0\varphi = \mathrm{id}$.
(4) After possibly further shrinking the disk, the image of the embedding $\varphi\colon \overline{B}^2 \to \mathbb{C}$ is convex.
(5) The map

$$\begin{array}{rcl} F\colon \overline{B}^2 \times [0,1] & \to & \mathbb{C} \\ z & \mapsto & \varphi(z)\cdot(1-t) + z\cdot t \end{array}$$

is the final smooth isotopy that we were required to find.

We illustrate the steps (2) to (5) in Figure 887. We leave it to the reader to fill in all the technical details and to make all steps rigorous.[1178] □

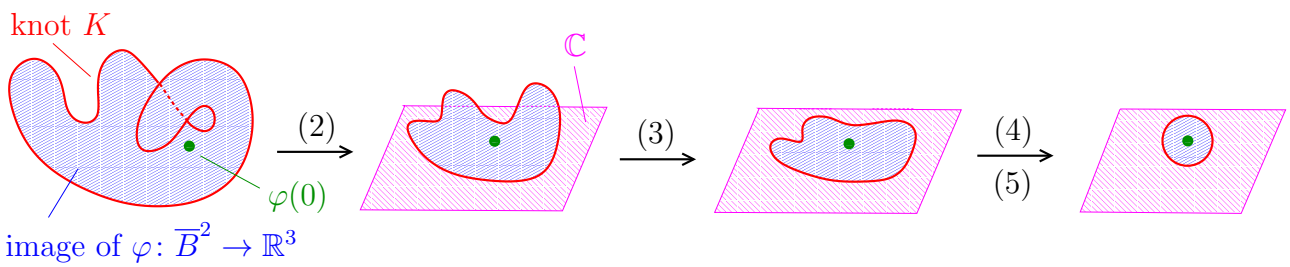

FIGURE 887.

Example. In Lemma 18.6 (2) we saw that the trefoil is not equivalent to the trivial knot. We had also just seen that the trefoil admits a Seifert surface of genus 1. It follows from Lemma 70.10 that

$$\mathrm{genus}(\text{trefoil}) \;=\; 1.$$

We conclude this section with the following question.

Question 70.11. *We consider the knot K in Figure 888. It admits a Seifert surface of genus two. Does it also admit a Seifert surface of genus one?*

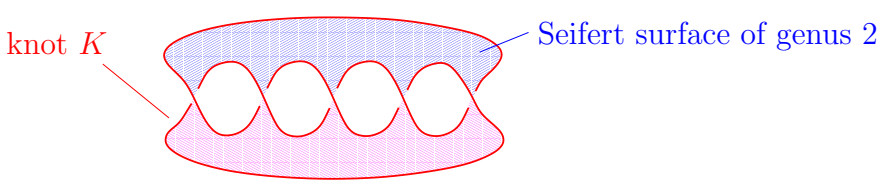

FIGURE 888.

[1178]It might be slightly painful, but it is not overly difficult to make all steps rigorous. Step (4) is a very nice exercise in real analysis.

70.4. **Linking numbers.** We recall the following definition from page 1535.

Definition. An *m-component link* is a closed 1-dimensional submanifold of S^3.

Remark. It follows from Proposition 3.53 that a link is the same as a 1-dimensional submanifold of S^3 that is diffeomorphic to the disjoint union of finitely many copies of S^1.

Convention. When we write, "let $L = L_1 \sqcup \cdots \sqcup L_m$ be an *m-component link*", then it is understood that each L_i is non-empty. In particular each L_i is a knot in its own right.

Definition. We say that *two m-component links $L = L_1 \sqcup \cdots \sqcup L_m$ and $J = J_1 \sqcup \cdots \sqcup J_m$ are equivalent* if there exists a smooth isotopy from L to J which preserves the ordering of the components. If L and J are oriented links, then we also demand that the isotopy is orientation-preserving.

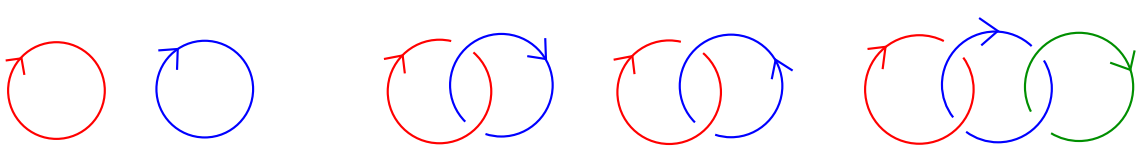
Examples.

(1) We say $L = L_1 \sqcup \cdots \sqcup L_m \subset S^3 = \mathbb{R}^3 \cup \{\infty\}$ is a *trivial link* if it lies in $\mathbb{R}^2 \times \{0\} \subset \mathbb{R}^3$ and[1179] if it bounds m disjoint disks in $\mathbb{R}^2 \times \{0\}$. Using Theorem 10.28 one can easily verify that all trivial links are in fact equivalent.

(2) In Figure 889 we show four examples of oriented links: the 2-component trivial link, two versions $H^\pm$ of the Hopf link and one further link. The Hopf link is in fact related to the Hopf map

$$\begin{array}{rcl} H\colon S^3 = \{(z_1, z_2) \in \mathbb{C}^2 \,|\, |z_1|^2 + |z_2|^2 = 1\} & \to & S^2 = \mathbb{C}\mathrm{P}^1 \\ (z_1, z_2) & \mapsto & [z_1 : z_2] \end{array}$$

from page 726. More precisely, if P, Q are two distinct points in S^2, then the preimage $H^{-1}(\{P, Q\})$ is a 2-component link that is equivalent to the Hopf links without orientation. This can be seen as follows: for $P = [1 : 0]$ and $Q = [0 : 1]$ one can verify "by hand" that the preimage is equivalent to a Hopf link. Given any two other distinct points P' and Q' in S^2 we can find disjoint smooth paths from P to P' and Q to Q', the preimages of these paths give rise to a smooth isotopy of links.



2-component trivial link $\quad H^-$ Hopf links H^+ $\quad$ chain link

FIGURE 889.

Our goal now is to distinguish inequivalent links. It follows immediately from the definition that if two links $L = L_1 \sqcup \cdots \sqcup L_m$ and $J = J_1 \sqcup \cdots \sqcup J_m$ are equivalent, then

[1179] Is the second condition necessary?

the components are equivalent knots. Therefore we are mostly interested in distinguishing links with equivalent components.

The following proposition generalizes Proposition 10.33. The proof is verbatim the same.

Proposition 70.12. *Let $L = L_1 \sqcup \cdots \sqcup L_m$ and $J = J_1 \sqcup \cdots \sqcup J_m$ be two m-component links. If they are equivalent, then the following two statements hold:*

(1) *There exists an orientation-preserving diffeomorphism $\Phi\colon S^3 \to S^3$ with $\Phi(L_i) = J_i$ for $i = 1, \dots, m$. If L and J are oriented, then there exists such a diffeomorphism Φ which for each $i \in \{1, \dots, m\}$ restricts to an orientation-preserving diffeomorphism $L_i \to J_i$.*

(2) *The link complements $S^3 \setminus L$ and $S^3 \setminus J$ are diffeomorphic, in particular homeomorphic.*

Remark. On page 361 we remarked that for knots the converse to Proposition 10.33 (2) holds. More precisely, if K and J are two knots such that there exists an orientation-preserving diffeomorphism between the knot complements $S^3 \setminus K$ and $S^3 \setminus J$, then K and J are equivalent. The analogous statement is no longer true for links. In Figure 890 we show two links $L = K \sqcup J$ and $L' = K' \sqcup J'$. In Exercise 70.7 we will see that $S^3 \setminus L$ and $S^3 \setminus L'$ are diffeomorphic. Even though we cannot prove it at the moment, it should be fairly clear that L and L' are not equivalent. This shows in particular that the problem of classifying links cannot be reduced to the problem of classifying the complements of links.

FIGURE 890.

To distinguish links with equivalent components we will now introduce an invariant of oriented links.

Definition. Let $K \subset S^3$ be an oriented knot. As before we denote by μ_K the meridian as defined on page 362 and as above we denote by ϕ_K the epimorphism $\phi_K\colon H_1(S^3 \setminus K; \mathbb{Z}) \to \mathbb{Z}$ that is given by $\phi_K([\mu_K]) = 1$. If $J \subset S^3$ is an oriented knot that is disjoint from K, then we define the *linking number of K and J* to be

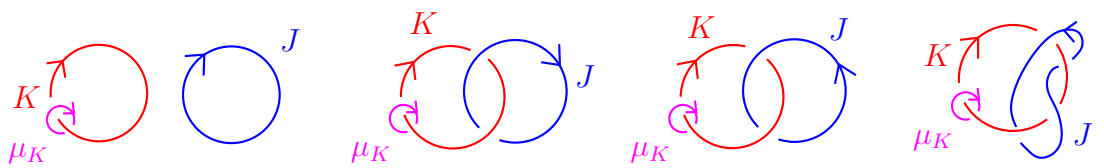
$$\operatorname{lk}(K, J) \;:=\; \phi_K([J])$$

where $[J] \in H_1(S^3 \setminus K; \mathbb{Z})$ denotes the image of the fundamental class of the oriented manifold J under the inclusion $J \to S^3 \setminus K$.

Remark. We continue with the above notation. If we denote by $[\mu_K^*] \in H^1(S^3 \setminus K; \mathbb{Z})$ the unique generator with $\langle [\mu_K^*], [\mu_K] \rangle = 1$, then it follows immediately from the definitions that for any oriented knot J disjoint from K we have

$$\mathrm{lk}(K, J) \;=\; \langle [\mu_K^*], [J] \rangle.$$

Example. If K is the trivial knot, then we saw in Proposition 18.4 that $S^3 \setminus K$ is diffeomorphic to the open solid torus $B^2 \times S^1$ and it is fairly straightforward to determine $\phi_K \colon H_1(S^3 \setminus K; \mathbb{Z}) \to \mathbb{Z}$ applied to a given curve. This allows us to determine the linking numbers of the oriented links shown in Figure 891.



$\mathrm{lk}(K, J) = 0$ $\mathrm{lk}(K, J) = -1$ $\mathrm{lk}(K, J) = 1$ $\mathrm{lk}(K, J) = 2$

FIGURE 891.

Proposition 70.13.

(1) *Let $L = L_1 \sqcup \cdots \sqcup L_m$ and $J = J_1 \sqcup \cdots \sqcup J_m$ be two m-component oriented links. If L and J are equivalent, then for all $r, s \in \{1, \dots, m\}$ we have*

$$\mathrm{lk}(L_r, L_s) \;=\; \mathrm{lk}(J_r, J_s).$$

(2) *Let $K \sqcup J$ be an oriented 2-component link. If we change the orientation of one of the components of the link, then the sign of the linking number flips.*

Proof. The first statement is an immediate consequence of Proposition 70.12 (1). The second statement follows easily from the definitions. □

Example. It follows from Proposition 70.13 together with the calculation of the linking numbers in Figure 891 that the two Hopf links H^- and H^+ are not equivalent.

The following proposition says that the linking number $\mathrm{lk}(K, J)$ is symmetric in the oriented knots K and J.

Proposition 70.14. *For any oriented 2-component link $L = J \sqcup K$ we have*

$$\mathrm{lk}(J, K) \;=\; \mathrm{lk}(K, J).$$

Proof $(*)$. We pick a fattening for the link $L = J \sqcup K$ and use it to define the exteriors X_L, X_K and X_J. Throughout the proof we consider the following inclusion maps

$$\begin{tikzcd} \partial X_K \arrow[dr, "f"] & & X_J \\ & X_L \arrow[ur, "j"] \arrow[dr, "k"] & \\ \partial X_J \arrow[ur, "g"] & & X_K. \end{tikzcd}$$

Furthermore, throughout the proof we use the isomorphisms from Proposition 29.5 and page 747 to make the identifications $H_0(\partial X_J;\mathbb{Z}) = H_0(X_L;\mathbb{Z}) = H_0(X_J;\mathbb{Z}) = \mathbb{Z}$. We start out with the following claim.

Claim. We have

$$\mathrm{lk}(K,J) \;=\; \big(\underbrace{k^*([\mu_K^*])}_{\in H^1(X_L;\mathbb{Z})} \cup \underbrace{j^*([\mu_J^*])}_{\in H^1(X_L;\mathbb{Z})}\big) \cap \underbrace{g_*([\partial X_J])}_{\in H_2(X_L;\mathbb{Z})}.$$

We denote by $[J] \in H_1(J;\mathbb{Z})$ the fundamental class. We have the following equalities:

$$\begin{array}{rcl} & & \text{Proposition 57.8} \\ & & \downarrow \\ (k^*([\mu_K^*]) \cup j^*([\mu_J^*])) \cap g_*([\partial X_J]) & = & -(j^*([\mu_J^*]) \cup k^*([\mu_K^*])) \cap g_*([\partial X_J]) \\ = \; -k^*([\mu_K^*]) \cap (j^*([\mu_J^*]) \cap g_*([\partial X_J])) & = & -k^*([\mu_K^*]) \cap g_*(g^*j^*[\mu_J^*] \cap [\partial X_J]) \\ \uparrow & & \uparrow \\ \text{Lemma 59.7} & & \text{Lemma 57.10 applied to } g \end{array}$$

$$\begin{array}{rcrcrcrcl} = & k^*([\mu_K^*]) \cap g_*([\lambda_J]) & = & \langle [\mu_K^*], k_*g_*([\lambda_J])\rangle & = & \langle [\mu_K^*], k_*g_*([J])\rangle & = & \mathrm{lk}(K,J). \\ \uparrow & & \uparrow & & \uparrow & & \uparrow & \\ \text{Lemma 70.7 (3)} & & \text{Lemmas 50.6 and 59.4} & & \text{since } [\lambda_J]=[J]\in H_1(X_K) & & \text{see page 1636} & \end{array}$$

This concludes the proof of the claim.

Now we conclude that

$$\begin{array}{rcl} \mathrm{lk}(K,J) & = & (j^*([\mu_J^*]) \cup k^*([\mu_K^*])) \cap g_*([\partial X_J]) \\ & \uparrow & \\ & \text{by the claim} & \end{array} \quad \begin{array}{rcl} & = & (-k^*([\mu_K^*]) \cup j^*([\mu_J^*])) \cap (-f_*([\partial X_K])) \\ & \uparrow & \\ & \text{by Proposition 57.8 and since by Corollary 46.27} & \\ & \text{we have } g_*([\partial X_J]) + f_*([\partial X_K]) = 0 \in H_2(X_L;\mathbb{Z}) & \end{array}$$

$$\begin{array}{rcl} & = & \mathrm{lk}(J,K). \\ & \uparrow & \\ & \text{by the claim} & \end{array}$$

□

To determine the linking number in more complicated cases it is helpful to have different ways to calculate the linking number.

Proposition 70.15. *Let $K \sqcup J$ be an oriented 2-component link. If F is a Seifert surface for K that is transverse to J, then*

$$\mathrm{lk}(K,J) \;=\; F \cdot J$$

where $F \cdot J$ denotes the algebraic intersection number of F and J.

Example. In Figure 892 we show an oriented link $K \sqcup J$ and a Seifert surface F for K. Clearly we have $F \cdot J = 0$, thus it follows from Proposition 70.15 that $\mathrm{lk}(K, J) = 0$.

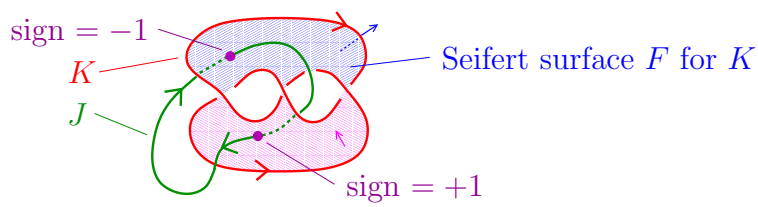


FIGURE 892.

Proof. Let $K \sqcup J$ be an oriented 2-component link. We pick a tubular neighborhood $\overline{B}^2 \times K$ for K. After possibly shrinking the tubular neighborhood we can and will assume that $S^1 \times K$ intersects F transversally in a single curve[1180] and that $\overline{B}^2 \times K$ does not intersect J. We write $X := S^3 \setminus (B^2 \times K)$ and we write $F' := F \cap X$. It follows from our choice of tubular neighborhood and from Lemma 3.43 that F' is a compact proper submanifold of F.

We start out with the following claim.

Claim. We have $\mathrm{PD}_X([F']) = [\mu_K^*] \in H^1(X; \mathbb{Z})$.

By definition of the Poincaré duality isomorphism PD_X the claim is equivalent to showing that $[\mu_K^*] \cap [X] = [F']$. From Lemma 70.7 (2) we know that the connecting homomorphism $\partial\colon H_2(X, \partial X; \mathbb{Z}) \to H_1(\partial X; \mathbb{Z})$ is a monomorphism. Therefore it suffices to show that $\partial([\mu_K^*] \cap [X]) = \partial[F']$. We denote by $i\colon \partial X \to X$ the inclusion map. We calculate that

$$\begin{array}{ccccccccc} \partial([\mu_K^*] \cap [X]) & \underset{\uparrow}{=} & -i^*([\mu_K^*]) \cap [\partial X] & \underset{\uparrow}{=} & [\lambda_K] & \underset{\uparrow}{=} & [\partial F'] & \underset{\uparrow}{=} & \partial([F']). \\ & & \text{Proposition 61.22} & & \text{Lemma 70.7 (5)} & & \text{Lemma 70.7 (4)} & & \text{Proposition 46.26} \end{array}$$

This concludes the proof of the claim.

Now we calculate that

$$\begin{array}{ccccccccc} & \text{Lemma 67.8} & & \text{since } J \subset X & & \text{Theorem 67.10} & & \text{Lemma 59.7} & \\ & \downarrow & & \downarrow & & \downarrow & & \downarrow & \\ F \cdot J & = & J \cdot F & = & J \cdot F' & = & (\mathrm{PD}_X([J]) \cup \mathrm{PD}_X([F'])) \cap [X] & = & \mathrm{PD}_X([F']) \cap (\mathrm{PD}_X([J]) \cap [X]) \\ & & & & & = & [\mu_K^*] \cap [J] \quad = \quad \langle [\mu_K^*], [J] \rangle & = & \mathrm{lk}(K, J). \\ & & & & & \uparrow & & \uparrow & \\ & & & & & \text{by the claim we have } \mathrm{PD}_X([F']) = [\mu_K^*] \text{ and} & & \text{see page 1636} & \\ & & & & & \text{by definition we have } \mathrm{PD}_X([J]) \cap [X] = [J] & & & \end{array}$$

We have thus proved the desired equality. □

[1180] This last statement requires a little bit of thought. We leave the technical details to the reader.

In practical situations the following proposition is often the most efficient way to compute linking numbers. We will formulate the proposition in a slightly informal way.

Proposition 70.16. *Let $K \sqcup J \subset S^3$ be an oriented 2-component link that is given by a diagram in the xy-plane.*[1181] *Then*

$$\mathrm{lk}(K,J) \;=\; \begin{array}{l} \tfrac{1}{2}\textit{number of positive crossings between } K \textit{ and } J \\ -\;\tfrac{1}{2}\textit{number of negative crossings between } K \textit{ and } J \end{array}$$

where a crossing P is called a positive (respectively negative) crossing if the direction of the upper strand together with the direction of the lower strand give a positive (respectively negative) basis for $\mathbb{R}^2$. We refer to Figure 893 for an illustration.

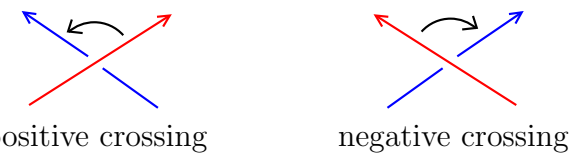

FIGURE 893.

Examples.

(1) In Figure 894 we show two oriented links and we compute the linking number using Proposition 70.16 by considering the signs of the crossings between K and J. As a reality check, on the left we consider the Hopf link that we had already considered in Figure 891. In both cases we obtain that the linking number equals -1.

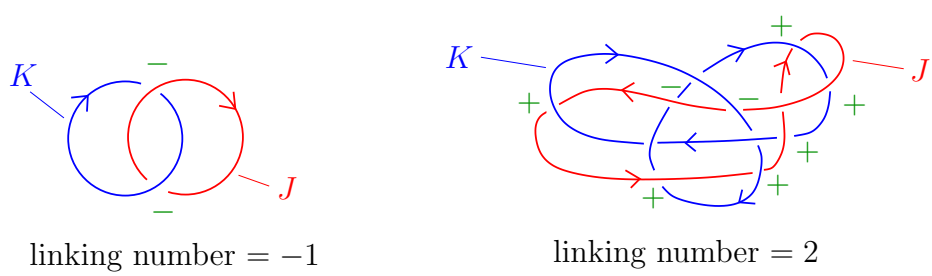

FIGURE 894.

(2) Now we can settle the question from page 1627, which of the three closed curves shown in Figure 895 is actually the longitude of the trefoil. More precisely, by definition the longitude λ_K satisfies $\phi_K([\lambda_K]) = 0$, but again by definition this means that $\mathrm{lk}(K, \lambda_K) = 0$. Conversely, loosely speaking any curve that runs "parallel to K"

[1181] We will not attempt to make the notion of a diagram precise and we work with a "naive" interpretation of the concept. We refer to the standard textbooks in knot theory, e.g. [**?**, Rol, BZH] for more details.

and that has linking number zero with K, is a longitude. Using Proposition 70.16 we calculate the linking numbers of the oriented knot K with the oriented curves A, B and C. We obtain that C is the only curve with linking number zero. Thus C is the longitude.

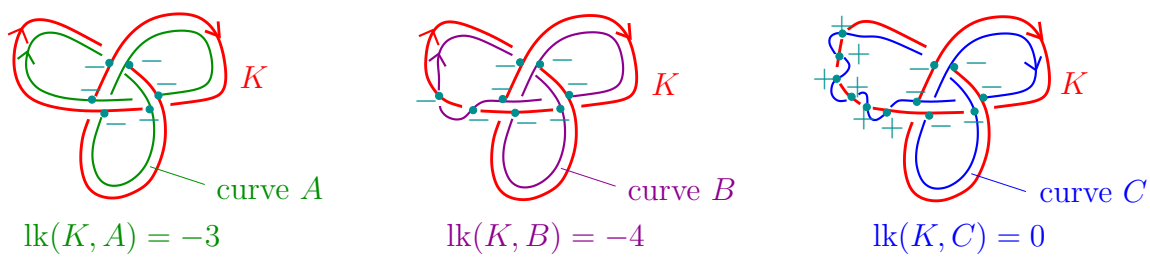

FIGURE 895.

Remark. Let $K \sqcup J \subset S^3$ be an oriented 2-component link that is given by a diagram in the xy-plane. An amusing exercise shows that

$$\begin{aligned} \operatorname{lk}(K,J) \;=\; & \text{number of positive crossings where } K \text{ crosses over } J \\ - \; & \text{number of negative crossings where } K \text{ crosses over } J. \end{aligned}$$

Sketch of proof. [1182] We introduce the following notation:

(1) Given $t \in \mathbb{R}$ we consider the map

$$\begin{aligned} \lambda_t \colon \mathbb{R}^3 &\to \mathbb{R}^3 \\ (x,y,z) &\mapsto (x,y,z+t). \end{aligned}$$

We extend this definition to a homeomorphism of S^3 by setting $\lambda_t(\infty) = \infty$.[1183]

(2) By Proposition 70.8 the knot J admits a Seifert surface F.

(3) We pick $r \in \mathbb{R}$ such that the minimal z-coordinate of any point on $\lambda_r(F)$ is greater than the maximal z-coordinate of any point in K.

(4) We write $F' = ((J \times [0,1]) \cup F)/\sim$ where we identify any point in $J \subset F$ with the corresponding point in $J \times \{1\}$. Note that F' is a compact 2-dimensional manifold that inherits an orientation from F.

(5) We consider the map[1184]

$$\begin{aligned} \Psi \colon F' = ((J \times [0,1]) \cup F)/\sim \;&\to\; \mathbb{R}^3 \\ Q \;&\mapsto\; \begin{cases} \lambda_{t\cdot r}(P) & \text{if } Q = (P,t) \in J \times [0,1], \\ \lambda_r(Q), & \text{if } Q \in F. \end{cases} \end{aligned}$$

[1182] A proof can evidently only be as precise as the input. Since we did not bother to completely rigorously formulate the statement we can also not expect a completely rigorous proof. But with some effort one can formulate both the statement and the proof rigorously.

[1183] Why is this map continuous?

[1184] Note that the map $\Psi \colon F' \to S^3$ is not necessarily injective. In particular the image is not necessarily a Seifert surface for J.

Then

$$\begin{array}{ccccc} \mathrm{lk}(K,J) & = & K\cdot\Psi & = & K\cdot\Psi|_{J\times[0,1]}. \\ & \uparrow & & \uparrow & \\ & \text{by the same argument} & & \text{by choice of } r \text{ we have} & \\ & \text{as in Proposition 70.15} & & K\cap\Psi(F)=\varnothing & \end{array}$$

The right-hand side can be computed easily, in fact the points in $K\cap\Psi(J\times[0,1])$ correspond precisely to the crossings of the diagrams where K crosses over J and one can easily convince oneself that the signs agree. The proposition now follows from the reformulation of the linking number in the remark preceding the proof. □

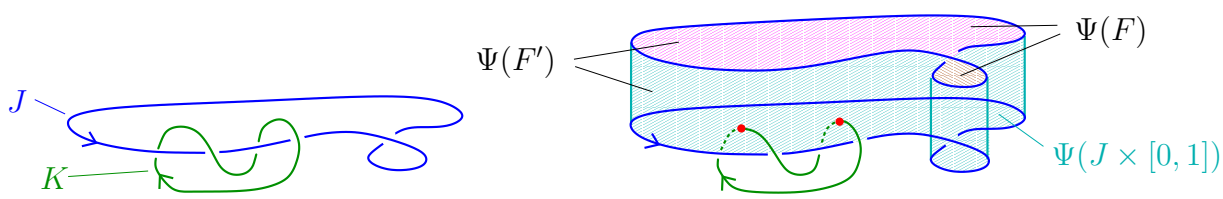

FIGURE 896. Illustration of the proof of Proposition 70.16.

In the following lemma we give a 4-dimensional interpretation of the linking number.

Lemma 70.17. *Let K, K' be two disjoint oriented knots.*

(1) *There exist oriented proper 2-dimensional submanifolds S and S' of $\overline{B}^4$ with $\partial S = K$ and $\partial S' = K'$ such that S and S' are transverse.*
(2) *Let S, S' be two oriented proper 2-dimensional submanifolds of $\overline{B}^4$ with $\partial S = K$ and $\partial S' = K'$. If S and S' are transverse, then*

$$\mathrm{lk}(K,K') \;=\; S\cdot_{\overline{B}^4} S'.$$

Sketch of proof. Let K, K' be two disjoint oriented knots.

(1) By Proposition 70.8 and the Transversality Theorem 67.2 (2) there exists a Seifert surface F for K that is transverse to K'. Furthermore let F' be a Seifert surface for K'. We pick a collar neighborhood $S^3\times[0,2]$ for $S^3=\partial\overline{B}^4$. We use the collar neighborhood $S^3\times[0,1]$ to define the push-in[1185] $\widetilde{F}$ of F and we use the collar neighborhood $S^3\times[0,2]$ to define the push-in $\widetilde{F}'$ of F'. It follows easily from Lemma 10.18 that $\widetilde{F}$ and $\widetilde{F}'$ have the desired properties.
(2) First we note that

$$\begin{array}{ccccccc} \mathrm{lk}(K,K') & = & F\cdot_{S^3}K' & = & \widetilde{F}\cdot_{\overline{B}^4}\widetilde{F}' & = & -(-\widetilde{F})\cdot_{-\overline{B}^4}(-\widetilde{F}'). \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{Proposition 70.15} & & \text{by inspection of the} & & \text{follows easily from the definitions} & \\ & & & \text{intersection points} & & & \end{array}$$

[1185] We refer to page 346 for the definition of push-ins.

Now let S, S' be two oriented proper 2-dimensional submanifolds of $\overline{B}^4$ with $\partial S = K$ and $\partial S' = K'$. We think of $S^4 = \overline{B}^4 \cup (-\overline{B}^4)$ as the union of two copies of $\overline{B}^4$ with opposite orientations, the first copy contains S, S' and the second contains $-\widetilde{F}, -\widetilde{F}'$. (See Figure 897 for an illustration.) It follows fairly easily from the Collar Neighborhood Theorem 10.15 that $S \cup -\widetilde{F}$ and $S' \cup -\widetilde{F}'$ are oriented submanifolds of S^4.[1186] We calculate that

$$S \cdot_{\overline{B}^4} S' - \operatorname{lk}(K, K') \underset{\substack{\uparrow \\ \text{by the above}}}{=} S \cdot_{\overline{B}^4} S' + (-\widetilde{F}) \cdot_{-\overline{B}^4} (-\widetilde{F}') \underset{\substack{\uparrow \\ \text{since } S \cap \widetilde{F}' = S' \cap \widetilde{F} = \varnothing}}{=} (S \cup -\widetilde{F}) \cdot_{S^4} (S' \cup -\widetilde{F}') \underset{\substack{\uparrow \\ \text{by Theorem 68.11 and} \\ \text{since } H^2(S^4;\mathbb{Z}) = 0}}{=} 0.$$

We have thus shown the desired equality $S \cdot_{\overline{B}^4} S' = \operatorname{lk}(K, K')$. □

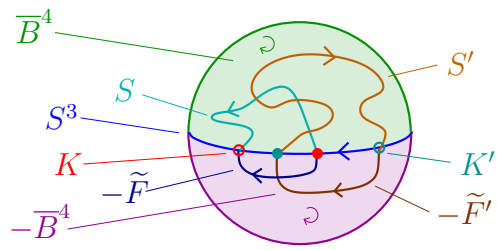

FIGURE 897. Illustration for the proof of Lemma 70.17.

The following proposition gives two more alternative ways to define or calculate or interpret the linking number.

Proposition 70.18. *Let $K \sqcup J \subset \mathbb{R}^3 \subset S^3 = \mathbb{R}^3 \cup \{\infty\}$ be an oriented 2-component link.*

(1) *If $\varphi\colon S^1 \to K$ and $\psi\colon S^1 \to J$ are two orientation-preserving diffeomorphisms, then*[1187]

$$\operatorname{lk}(K, J) = \deg \begin{pmatrix} S^1 \times S^1 & \to & S^2 \\ (z, w) & \mapsto & \frac{\varphi(z) - \psi(w)}{\|\varphi(z) - \psi(w)\|} \end{pmatrix}.$$

(2) *Let $f\colon [0, 2\pi] \to K$ and $g\colon [0, 2\pi] \to J$ be two maps such that f and g descend to orientation-preserving diffeomorphisms from $[0, 2\pi]/0 \sim 2\pi$ to K and J. Then*

$$\operatorname{lk}(K, J) = \frac{1}{4\pi} \int_{s=0}^{s=2\pi} \int_{t=0}^{t=2\pi} \frac{\det \overbrace{\big((f(s) - g(t)) \;\; f'(s) \;\; g'(t)\big)}^{3 \times 3\text{-matrix}}}{\|f(s) - g(t)\|^3}\, dt\, ds.$$

Remark.

[1186] The word "submanifold of S^4" is used in a slightly ambiguous way since it depends on whether we view S^4 as a topological manifold or a manifold. In this case we view S^4 only as a topological manifold.

[1187] Here we use the notion of "degree" that we introduced on page 959.

(1) The linking number of an oriented 2-component link was initially introduced by Gauss in 1833 by the integral in Proposition 70.18. We refer to Figure 898 for a scan of the relevant paragraphs in [Gau, p. 605]. The term *geometria situs* is hereby the earlier name for topology. We refer to [Epp, p. 73] for more information on the work of Gauss regarding the linking number.

Von der *Geometria Situs*, die Leibnitz ahnte und in die nur einem Paar Geometern (Euler und Vandermonde) einen schwachen Blick zu thun vergönnt war, wissen und haben wir nach anderthalbhundert Jahren noch nicht viel mehr wie nichts.

Eine Hauptaufgabe aus dem *Grenzgebiet* der *Geometria Situs* und der *Geometria Magnitudinis* wird die sein, die Umschlingungen zweier geschlossener oder unendlicher Linien zu zählen.

Es seien die Coordinaten eines unbestimmten Punkts der ersten Linie x, y, z; der zweiten x', y', z' und

$$\iint \frac{(x'-x)(\mathrm{d}y\,\mathrm{d}z'-\mathrm{d}z\,\mathrm{d}y')+(y'-y)(\mathrm{d}z\,\mathrm{d}x'-\mathrm{d}x\,\mathrm{d}z')+(z-z')(\mathrm{d}x\,\mathrm{d}y'-\mathrm{d}y\,\mathrm{d}x')}{[(x'-x)^2+(y'-y)^2+(z'-z)^2]^{\frac{3}{2}}} = V$$

dann ist dies Integral durch beide Linien ausgedehnt

$$= 4m\pi$$

und m die Anzahl der Umschlingungen.

Figure 898.

(2) It is not immediately clear why the integral in Proposition 70.14 is an invariant of the equivalence class of the link $K \sqcup J$. How would you prove this statement, without using Proposition 70.18 (2)?
(3) It is clear from the second reformulation of the linking number given in Proposition 70.18 that the linking number is symmetric. How does the symmetry follow from the first reformulation?

Proof. The proposition is proved in [RN, Section 5] or alternatively, with fewer details, in [Rol, p. 133]. See also [tD, p. 284]. □

Example. Given any topological invariant the question that arises is, how good is it at distinguishing objects. It is quite easy to find examples of links which show that the linking number is far from being a complete invariant. In Figure 899 we show the Whitehead link and the Borromean rings. Both are links with zero linking numbers and unknotted components but which are appear to be non-trivial. The Whitehead link is named after

John Henry Constantine Whitehead who also introduced the concept of CW-complexes. The Borromean rings are named after the Borromeo family that carries the Borromean rings in its coat of arms since medieval days.

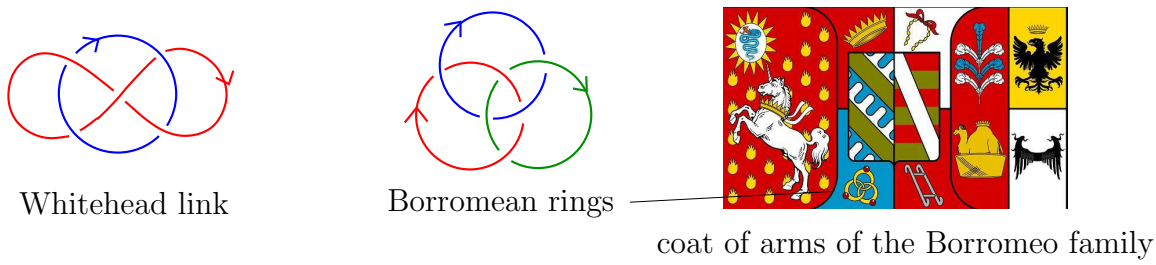

FIGURE 899.

We record the following question for later on.

Question 70.19. *How can we show that neither the Whitehead link nor the Borromean rings are equivalent to the trivial link?*

Remark. We can of course try to determine the fundamental groups of the complements of the trivial links and the Whitehead link and the Borromean rings. But then the question arises, how can we distinguish these groups?

70.5. **Alexander duality and linking numbers** $(*)$**.** Let Y be a compact non-empty subset of S^3 that admits a regular neighborhood. (For example, by Propositions 64.2, 64.11 and 64.13 the subset Y could be a link or a finite spatial graph.) We can compute the isomorphism types of the first homology group of the complement $S^3 \setminus Y$ as follows:

$$\begin{array}{ccccccc} H_1(S^3 \setminus Y;\mathbb{Z}) & \xrightarrow{\cong} & H^1(Y;\mathbb{Z}) & \xrightarrow{\cong} & \mathrm{Hom}(H_1(Y;\mathbb{Z}),\mathbb{Z}) & \cong & H_1(Y;\mathbb{Z})/\text{torsion}. \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{Alexander Duality} & & \text{Universal Coefficient} & & & \\ & \text{Theorem 66.1} & & \text{Theorem 51.13} & & \text{non-canonical isomorphism} & \end{array}$$

The catch with the Alexander Duality Theorem 66.1 is that it is quite hard to "see" the isomorphism. For example, suppose we are given a basis for $H_1(Y;\mathbb{Z})/\text{torsion}$, how do we get a basis for $H_1(S^3 \setminus Y;\mathbb{Z})$? In many situations the following lemma resolves that issue.

Lemma 70.20. *Let Y be a compact non-empty subset of S^3 that admits a regular neighborhood $N(Y)$. We suppose that $H_1(Y;\mathbb{Z})$ is a free abelian group*[1188] *of rank k. Let $C_1,\dots,C_k$ be oriented curves in $N(Y)$ and let $D_1,\dots,D_k$ be oriented curves in $S^3 \setminus N(Y)$. If*

$$\det\big(\underbrace{(\mathrm{lk}(C_i,D_j)_{i,j=1,\dots,k})}_{k\times k\text{-matrix}}\big) \;=\; \pm 1,$$

then $[D_1],\dots,[D_k]$ form a basis of $H_1(S^3 \setminus Y;\mathbb{Z})$.

[1188] Is it possible that $H_1(Y;\mathbb{Z})$ is not a free abelian group?

Proof. Let Y be a compact non-empty subset of S^3 that admits a regular neighborhood $N = N(Y)$. We denote by $\mathring{N}$ the interior of N. We consider the homomorphisms

$$\begin{array}{rcl} \Omega\colon \mathbb{Z}^k & \to & H_1(S^3\setminus\mathring{N};\mathbb{Z}) \\ (a_1,\dots,a_k) & \mapsto & \sum\limits_{i=1}^{k} a_i\cdot[D_i] \end{array} \quad \text{and} \quad \begin{array}{rcl} \Theta\colon H_1(S^3\setminus\mathring{N};\mathbb{Z}) & \to & \mathbb{Z}^k \\ \sigma & \mapsto & (\phi_{C_1}(\sigma),\dots,\phi_{C_k}(\sigma)). \end{array}$$

It follows from our hypothesis and the definition of linking numbers that $\Theta\circ\Omega$ is an epimorphism. Furthermore we know from the Alexander Duality Theorem 66.1 and the Universal Coefficient Theorem 51.13 that $H_1(S^3\setminus\mathring{N};\mathbb{Z})$ is also isomorphic to $\mathbb{Z}^k$. But by Lemma 11.8 (5) an epimorphism between two free abelian groups of the same rank is an isomorphism. Thus we see that Θ and Ω are isomorphisms.

Since $\{[D_1],\dots,[D_k]\}$ is the image under Ω of the standard basis of $\mathbb{Z}^k$ we see that $[D_1],\dots,[D_k]$ form a basis for $H_1(S^3\setminus\mathring{N};\mathbb{Z})$. But by Lemma 64.3 the inclusion induced map $H_1(S^3\setminus Y;\mathbb{Z})\to H_1(S^3\setminus\mathring{N};\mathbb{Z})$ is an isomorphism. Thus we see that $[D_1],\dots,[D_k]$ form a basis of $H_1(S^3\setminus Y;\mathbb{Z})$.[1189] □

Example. In Figure 900 we consider a spatial graph G together with a regular neighborhood N. By Lemma 40.17 we know that $H_1(G;\mathbb{Z})\cong\mathbb{Z}^2$. In Figure 900 we also see two oriented curves C_1 and C_2 in N and two oriented curves D_1 and D_2 in $S^3\setminus\mathring{N}$. Using Proposition 70.16 one can easily calculate that

$$\begin{pmatrix} \mathrm{lk}(C_1,D_1) & \mathrm{lk}(C_1,D_2) \\ \mathrm{lk}(C_2,D_1) & \mathrm{lk}(C_2,D_2) \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}.$$

It follows from Lemma 70.20 that $[D_1],[D_2]$ form a basis for $H_1(S^3\setminus G;\mathbb{Z})$.

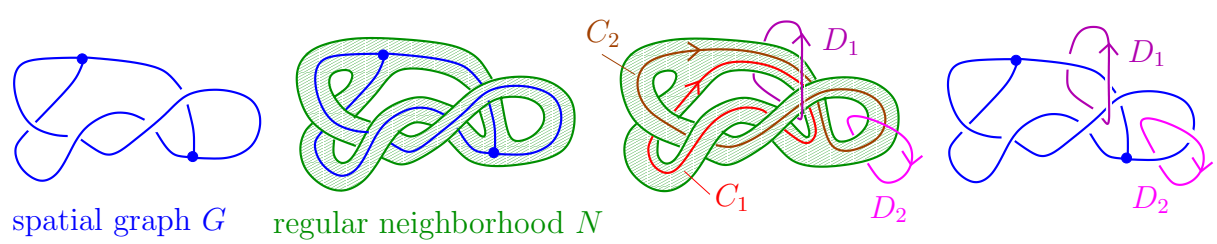

FIGURE 900.

In Lemma 66.3 we computed the homology groups of the complement of a link, but we could not determine explicit generators. The following lemma now solves that problem. In particular it gives an answer to Question 66.4.

Lemma 70.21. *Let $L = L_1\sqcup\cdots\sqcup L_m$ be an m-component link. We pick a fattening $\overline{B}^2\times L$ for L.*

[1189] The alert reader will have noticed that the proof resembles the argument given in Lemma 50.7.

(1) *A basis for* $H_1(S^3 \setminus L; \mathbb{Z}) \cong \mathbb{Z}^m$ *is given by the homology classes that are represented by the meridians* $\mu_1, \dots, \mu_m$.
(2) *A basis for* $H_2(S^3 \setminus L; \mathbb{Z}) \cong \mathbb{Z}^{m-1}$ *is given by considering the fundamental classes of all but one of the tori* $S^1 \times L$, $i \in \{1, \dots, m\}$. *More precisely, for any* $j \in \{1, \dots, m\}$ *a basis for* $H_2(S^3 \setminus L; \mathbb{Z}) \cong \mathbb{Z}^{m-1}$ *is given by*

$$[S^1 \times L_1], \dots, [S^1 \times L_{i-1}], [S^1 \times L_{i+1}], \dots, [S^1 \times L_m].$$

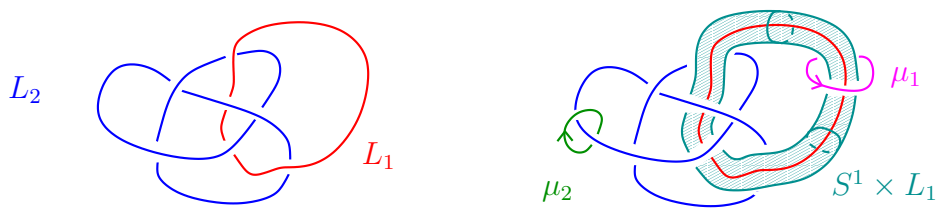

FIGURE 901.

Sketch of proof. Let $L = L_1 \sqcup \cdots \sqcup L_m$ be an m-component link. We know from Lemma 66.3 that $H_1(S^3 \setminus L; \mathbb{Z}) \cong \mathbb{Z}^m$ and that $H_2(S^3 \setminus L; \mathbb{Z}) \cong \mathbb{Z}^{m-1}$. We pick a fattening $\overline{B}^2 \times L$ for L. By the Collar Neighborhood Theorem 10.10 we can extend this fattening to a fattening $2\overline{B}^2 \times L$.

(1) The first statement follows from Lemma 70.20 applied to $C_i = \{0\} \times L_i$, $i = 1, \dots, m$ and $D_i := \mu_i$, $i = 1, \dots, m$.
(2) To simplify the notation we consider the case $j = m$. We write $X' := S^3 \setminus \frac{1}{2}B^2 \times L$. For $i = 1, \dots, m$ we write $T_i := S^1 \times L_i$. For $i = 1, \dots, m$ we pick a point P_i on $\frac{1}{2}S^1 \times L_i \subset \partial X'$. Since $S^3 \setminus (2B^2 \times L)$ is path-connected we can pick for each $i \in \{1, \dots, m-1\}$ a path γ_i from P_i to P_m that intersects T_i transversally in a single point and that does not intersect any of the T_j with $j \neq i, m$. Now we consider the map

$$\begin{array}{rcl} \Psi\colon H_1(X', \partial X'; \mathbb{Z}) \times H_2(X'; \mathbb{Z}) & \to & \mathbb{Z} \\ (\sigma, \tau) & \mapsto & \langle \mathrm{PD}_{X'}(\sigma) \cup \mathrm{PD}_{X'}(\tau), [X'] \rangle. \end{array}$$

It follows easily from Theorem 68.11 that for $i, j \in \{1, \dots, m-1\}$ we have the equality $\Psi([\gamma_i], [T_j]) = \delta_{ij}$. By Lemma 50.8 this implies that $[T_1], \dots, [T_{m-1}]$ do indeed form a basis of $H_2(X'; \mathbb{Z})$. □

Exercises for Chapter 70.

Exercise 70.1. Provide a proof for Corollary 70.5.

Exercise 70.2. Let $A = S^1 \times [-1, 1]$ be the annulus. Let C and D be two closed oriented curves on A. Suppose that $[C] = [D] \neq 0$. Show that the following two statements hold:

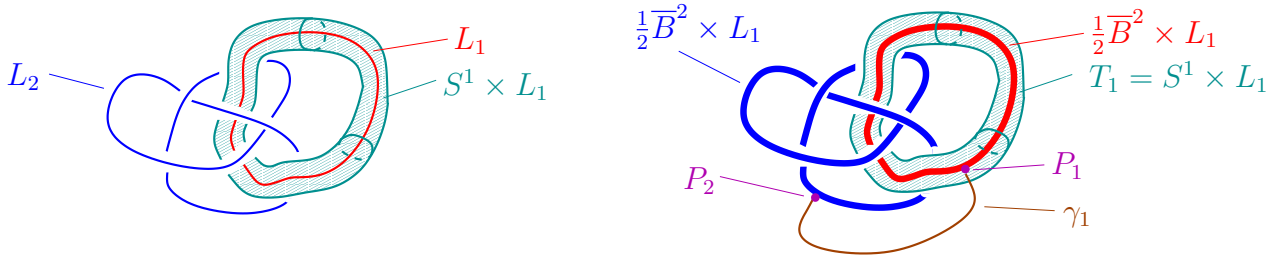

FIGURE 902.

(1) the two closed oriented curves are smoothly isotopic,
(2) if C and D are furthermore disjoint, then there exists an embedded annulus $X \subset A$ with $\partial A = C \cup -D$.

Hint: Using the fact that A is an annulus you can find a smooth isotopy that makes the curves disjoint. At that point it is perhaps better to first prove (2).

Exercise 70.3. Let F be an oriented connected 2-dimensional manifold and let C and D be distinct boundary curves. Suppose that C and D are homotopic. Show that F is diffeomorphic to the annulus $S^1 \times [-1, 1]$.

Exercise 70.4. Find explicit Seifert surfaces for the knots K_1 and K_2 shown in Figure 903. Remark: The answer to a question can only be as rigorous as the input. Since the input is a picture it suffices here of course to draw a convincing picture of a Seifert surface.

FIGURE 903.

Exercise 70.5. Let F be an oriented 2-dimensional manifold and let C and D be two closed oriented *disjoint* curves on F that are not null-homotopic. Assume that C and D are homotopic. Show that there exists an embedded annulus $X \subset F$ with $\partial X = C \cup -D$. Hint: Use Exercise 70.3. You might also want to use some of the ideas of the proof of Lemma 70.1.

Exercise 70.6. Let $\varphi\colon \overline{B}^3 \to S^3$ and $\psi\colon \overline{B}^3 \to S^3$ be two embeddings with disjoint images. Let $K \subset \varphi(\overline{B}^3)$ and $J \subset \psi(\overline{B}^3)$ be oriented knots. Show that $\mathrm{lk}(K, J) = 0$.

Exercise 70.7. We consider the two links shown in Figure 890. Show that the link complements are diffeomorphic.

FIGURE 904.

Exercise 70.8. The Borromean rings, shown in Figure 899, have the property that if you remove one component, then the remaining two knots form a trivial link. Does there exist a four component link with the property that if you remove any of the four components, then you get a three component trivial link?

Exercise 70.9. Let $L = K \sqcup J$ and $L' = K' \sqcup J'$ be two links such that the complements are diffeomorphic. Does it follow that $\operatorname{lk}(K, J) = \pm \operatorname{lk}(K', J')$?

Exercise 70.10. An m-component link $L = L_1 \sqcup \cdots \sqcup L_m \subset S^3$ is called *split link* if there exist disjoint closed balls $B_1, \dots, B_m$ such that each L_i is contained in B_i. Furthermore L is called a *boundary link* if there exist m disjoint Seifert surfaces $F_1, \dots, F_m$.

(a) A split link is easily seen to be a boundary link. Do there exist boundary links that are not split?

(b) Show that if $L = L_1 \sqcup \cdots \sqcup L_m$ is a boundary link, then there exists an epimorphism from $\pi_1(S^3 \setminus L)$ onto a free group of rank m.
Hint: You could try to find an interesting map from $S^3 \setminus L$ onto the wedge of m circles.

71. The intersection form of topological manifolds I: definition and calculations

In this chapter we will introduce and study the intersection form of compact oriented even-dimensional topological manifolds. Before we do so it is convenient to remind ourselves of a few basic notions and results in algebra.

71.1. **(Anti-) symmetric forms.** On page 1447 we introduced the notion of a pairing over a commutative ring R. We recall the definition and we introduce some new notions.

Definition. Let R be a commutative ring.

(1) A *pairing over* R is a pair (V, φ) where V is an R-module and φ is a map
$$\varphi\colon V \times V \ \to \ S$$
from $V \times V$ to some R-module S which has the property that φ is R-bilinear, i.e. that is R-linear in both arguments.

(2) We say that a pairing $\varphi\colon V \times V \to S$ is *symmetric* if $\varphi(v, w) = \varphi(w, v)$ for all $v, w \in V$. Furthermore we call the pairing *anti-symmetric* if $\varphi(v, w) = -\varphi(w, v)$ for all $v, w \in V$.

(3) We say that two pairings (V, φ) and (W, ψ) are *isometric*, written $(V, \varphi) \cong (W, \psi)$, if there exists an isometry, i.e. an isomorphism $\varphi\colon V \to W$ of R-modules such that $\varphi(v_1, v_2) = \psi(\varphi(v_1), \varphi(v_2))$ for all $v_1, v_2 \in V$.

(4) Given a pairing $\varphi\colon V \times V \to S$ we denote by $-\varphi$ the pairing that is given by $(-\varphi)(v, w) := -\varphi(v, w)$ for all $v, w \in V$.

(5) Given two pairings $\varphi\colon V \times V \to S$ and $\psi\colon W \times W \to S$ we define the *direct sum* of φ and ψ to be the pairing
$$\begin{array}{rcl} \varphi \oplus \psi\colon (V \oplus W) \times (V \oplus W) & \to & S \\ (v \oplus w), (v' \oplus w') & \mapsto & \varphi(v, v') + \psi(w, w'). \end{array}$$

(6) Given a pairing (V, g) and $n \in \mathbb{Z}$ we define
$$n \cdot (V, g) \ := \ \begin{cases} \overbrace{(V, g) \oplus \cdots \oplus (V, g)}^{n\text{-summands}}, & \text{if } n \geq 0, \\ \underbrace{(V, -g) \oplus \cdots \oplus (V, -g)}_{|n|\text{-summands}}, & \text{if } n \leq 0. \end{cases}$$

(7) Given a pairing (V, φ) and a submodule W we denote by $\varphi|_W$ the pairing that is given by restricting the map $\varphi\colon V \times V \to S$ to $W \times W \to S$.

In this chapter we will mostly be interested in the following special type of a pairing.

Definition. Let R be a commutative ring. A *form* is a finitely generated free R-module V together with a pairing $\varphi\colon V \times V \to R$ which is either symmetric or anti-symmetric. We refer to the rank of V also as the rank of the form.[1190]

[1190] The rank of a finitely generated free module over a commutative ring is well-defined, see e.g. [Lam, p. 4]. Note though that the rank of a finitely generated free module over a non-commutative ring is not

For the reader's convenience we recall the follow

Definition. Let R be a commutative ring. A form $\varphi\colon V \times V \to R$ is called *non-singular* if the two maps

$$\text{(a)} \quad \begin{array}{ccc} V & \to & \mathrm{Hom}_R(V,R) \\ v & \mapsto & \left(\begin{array}{ccc} V & \to & S \\ w & \mapsto & \varphi(v,w) \end{array} \right) \end{array} \quad \text{and} \quad \text{(b)} \quad \begin{array}{ccc} V & \to & \mathrm{Hom}_R(V,R) \\ w & \mapsto & \left(\begin{array}{ccc} V & \to & S \\ v & \mapsto & \varphi(v,w) \end{array} \right) \end{array}$$

are isomorphisms.

The following elementary lemma follows easily from the definitions and the fact that forms are by definition symmetric or anti-symmetric.

Lemma 71.1. *Let R be a commutative ring and let $\varphi\colon V \times V \to R$ be a pairing over R. if one of the two maps in the above definition is an isomorphism, then so is the other, hence the form is non-singular.*

In many situations it is convenient to represent a form by a matrix. We recall the relevant definition from the linear algebra courses.

Definition. Let R be a commutative ring and let $\varphi\colon V \times V \to R$ be a form. Given any basis $\{v_1, \dots, v_k\}$ of the free R-module V we refer to the $(k \times k)$-matrix

$$((\varphi(v_i, v_j))_{i,j=1,\dots,k}$$

as a *matrix representing the form φ.*

The following elementary lemma is usually proved in linear algebra. It is also straightforward to verify it using only the relevant definitions.[1191]

Lemma 71.2. *Let R be a commutative ring and let $\varphi\colon V \times V \to R$ be a form. Let $\{v_1, \dots, v_k\}$ and $\{w_1, \dots, w_k\}$ be bases of the free R-module V. We write*

$$A \ := \ ((\varphi(v_i, v_j))_{i,j=1,\dots,k}, \quad B \ := \ ((\varphi(w_i, w_j))_{i,j=1,\dots,k}.$$

If $P = (p_{ij})_{i,j=1,\dots,k} \in \mathrm{GL}(k, R)$ denotes the base change matrix that is uniquely defined by the property that $v_i = \sum_{j=1}^{k} p_{ij} w_j$ for $i = 1, \dots, k$, then

$$A \ = \ P^T B P.$$

The following lemma is even more elementary, it follows basically immediately from the definitions.

Lemma 71.3.

(1) *Let $\varphi\colon V \times V \to R$ be a form. If A is a matrix that represents φ, then the matrix $-A$ represents the form $-\varphi$.*

---

necessarily well-defined. More precisely, there exists a non-commutative ring R and $m \neq n \in \mathbb{N}$ such that R^m is isomorphic to R^n. We refer to [Lam, p. 4] for such examples.

[1191] It is easy though to get confused.

(2) *Let* $\varphi\colon V\times V \to R$ *and* $\psi\colon W\times W \to R$ *be two forms. If* A *is a matrix that represents* φ *and if* B *is a matrix that represents* ψ*, then the matrix* $A \oplus B := \begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix}$ *represents the form* $\varphi \oplus \psi$*.*

(3) *Let* $\varphi\colon V \times V \to R$ *be a form and let* $n \in \mathbb{N}_0$*. If* A *is a matrix that represents* φ*, then the matrix* $n \cdot A := \underbrace{A \oplus \cdots \oplus A}_{n\text{-times}}$ *represents the form* $n \cdot \varphi$*.*

Before we can turn to topology we need to introduce one last elementary mathematical object.

Definition.

(1) Given a finitely generated abelian group H we denote by $\mathrm{F}H := H/\text{torsion subgroup}$ the *maximal torsion-free quotient* of H.

(2) Given a homomorphism $\alpha\colon A \to B$ between two finitely generated abelian groups we denote the obvious induced map $\mathrm{F}A \to \mathrm{F}B$ by α as well.

Convention. On many occasions we do not distinguish in the notation between an element in an abelian group H and the element it represents in the maximal torsion-free quotient FH.

The following lemma summarizes everything we need to know about maximal torsion-free quotients.

Lemma 71.4.

(1) *The maps* $H \to \mathrm{F}H$ *and* $\alpha \mapsto \alpha$ *define a functor from the category of finitely generated abelian groups to the category of finitely generated free abelian groups.*

(2) *For every homomorphism* $\alpha\colon A \to B$ *between two finitely generated abelian groups the following diagram commutes:*[1192]

$$\begin{tikzcd} A \arrow[r, "\alpha"] \arrow[d] & B \arrow[d] \\ FA \arrow[r, "\alpha"] & FB. \end{tikzcd}$$

(3) *Any (anti-) symmetric pairing*

$$\varphi\colon H \times H \to \mathbb{Z}$$

over a finitely generated abelian group descends to a well-defined form

$$\begin{aligned} \mathrm{F}H \times \mathrm{F}H &\to \mathbb{Z}. \\ ([g],[h]) &\mapsto \varphi(g,h). \end{aligned}$$

[1192]In fancy speak this means that the projection maps $H \to \mathrm{F}H$ define a natural transformation from the identity functor to the functor $H \mapsto \mathrm{F}H$.

Proof. All the statements of the lemma are basically elementary. The only ingredient we need to use is that by Theorem 11.4 every finitely generated free abelian group is in fact a free abelian group.[1193] □

71.2. **The definition of the intersection form of topological manifolds.** Let M be a compact oriented non-empty m-dimensional topological manifold. Recall that by the Poincaré Duality Theorem 61.1 we know that for any $k \in \mathbb{N}_0$ the map

$$\begin{array}{rcl} H^{m-k}(M, \partial M; \mathbb{Z}) & \to & H_k(M; \mathbb{Z}) \\ \varphi & \mapsto & \varphi \cap [M] \end{array}$$

is an isomorphism. As before we denote by

$$\mathrm{PD}_M \colon H_k(M; \mathbb{Z}) \to H^{m-k}(M, \partial M; \mathbb{Z})$$

the inverse of this isomorphism. This leads us to the following definition.

Definition. Let M be a compact oriented non-empty topological manifold of the even dimension $2n$. We refer to the map[119411951196]

$$\begin{array}{rcl} Q_M \colon \mathrm{F}H_n(M; \mathbb{Z}) \times \mathrm{F}H_n(M; \mathbb{Z}) & \to & \mathbb{Z} \\ (a, b) & \mapsto & \langle \mathrm{PD}_M(a) \cup \mathrm{PD}_M(b), [M] \rangle \end{array}$$

as the *intersection form of M*.

Remark. Since $\mathrm{PD}_M \colon H_n(M; \mathbb{Z}) \to H^n(M, \partial M; \mathbb{Z})$ is an isomorphism it is clear that the intersection form is basically just a reformulation of the cup product pairing

$$\begin{array}{rcl} H^n(M, \partial M; \mathbb{Z}) \times H^n(M, \partial M; \mathbb{Z}) & \to & H^{2n}(M, \partial M; \mathbb{Z}) \\ (\alpha, \beta) & \mapsto & \alpha \cup \beta \end{array}$$

on cohomology groups in the middle dimension. The big psychological advantage of homology is that very often one can "see homology classes". For example, in many cases homology classes are represented by submanifolds and we can then use Theorem 67.10 to compute the intersection form of a manifold. Sometimes we can also represent homology classes by explicit cycles and we can use Theorem 68.5 to compute the intersection form.

In the following proposition we summarize some of the key properties of the intersection form. The proposition shows in particular that the intersection form is a form in the sense of the definition on page 1649.

[1193]It might sound silly to mention Theorem 11.4 explicitly, but it is worth noting that for more complicated commutative rings R there is usually no meaningful functor from the category of finitely generated R-modules to the category of free R-modules.

[1194]Note that $H_n(M; \mathbb{Z})$ is not necessarily torsion-free. For example $M = S^1 \times \mathbb{R}\mathrm{P}^3$ is orientable, but it follows easily from the Künneth Formula 43.8 and the calculation of the homology groups of $\mathbb{R}\mathrm{P}^3$ in Proposition 35.11 that $H_2(S^1 \times \mathbb{R}\mathrm{P}^3; \mathbb{Z}) \cong \mathbb{Z}_2$.

[1195]As mentioned above, in the notation usually we do not distinguish between an element in $H_n(M; \mathbb{Z})$ and the element it represents in $\mathrm{F}H_n(M; \mathbb{Z})$.

[1196]Note that $\mathrm{PD}(a)$ and $\mathrm{PD}(b)$ lie in $H^n(M, \partial M)$, hence the cup product lies in $H^{2n}(M, \partial M; \mathbb{Z})$. The fundamental class $[M]$ is an element in $H_{2n}(M, \partial M; \mathbb{Z})$, hence $\langle \mathrm{PD}(a) \cup \mathrm{PD}(b), [M] \rangle$ is indeed defined.

Proposition 71.5. *Let M be a compact oriented non-empty $2n$-dimensional topological manifold. Then the following hold:*

(1) *If n is even, then the intersection form Q_M is symmetric, otherwise it is antisymmetric.*
(2) *If M is closed, then the intersection form is non-singular.*

The proof of Proposition 71.5 (2) relies on the following reformulation of the intersection form, which will also be useful later on on a separate occasion.

Lemma 71.6. $(*)$ *Let M be a compact oriented connected $2n$-dimensional topological manifold. We denote by $i\colon (M,\varnothing) \to (M,\partial M)$ the inclusion map. We write*

$$\Phi\colon H_n(M;\mathbb{Z}) \xrightarrow{i_*} H_n(M,\partial M;\mathbb{Z}) \xrightarrow{\mathrm{PD}_M} H^n(M;\mathbb{Z}) \xrightarrow{\mathrm{ev}} \mathrm{Hom}(H_n(M;\mathbb{Z}),\mathbb{Z}).$$

For any $a,b \in \mathrm{F}H_{2n}(M;\mathbb{Z})$ we have

$$Q_M(a,b) \;=\; \Phi(b)(a).$$

Proof of Lemma 71.6 $(*)$. First we consider the following diagram:

$$\begin{tikzcd}
H_n(M;\mathbb{Z}) \times H_n(M;\mathbb{Z}) \arrow[r, "\mathrm{id}\times i_*"] \arrow[d, "\mathrm{PD}_M\times\mathrm{PD}_M"'] & H_n(M;\mathbb{Z}) \times H_n(M,\partial M;\mathbb{Z}) \arrow[d, "\mathrm{PD}_M\times\mathrm{PD}_M"] \\
H^n(M,\partial M;\mathbb{Z}) \times H^n(M,\partial M;\mathbb{Z}) \arrow[r, "\mathrm{id}\times i^*"] \arrow[d, "\cup"] & H^n(M,\partial M;\mathbb{Z}) \times H^n(M;\mathbb{Z}) \arrow[d, "\cup"] \\
H^{2n}(M,\partial M;\mathbb{Z}) \arrow[r, "="] & H^{2n}(M,\partial M;\mathbb{Z}).
\end{tikzcd}$$

By Proposition 61.22 we know that the upper square commutes. We obtain from Proposition 58.3, applied to the inclusion map $f\colon (M,\varnothing,\partial M) \to (M,\partial M,\partial M)$, that the lower square also commutes.

Now let $a,b \in H_{2n}(M;\mathbb{Z})$. We calculate that

$$\begin{array}{rcl}
Q_M(b,a) & = & \langle \mathrm{PD}_M(b)\cup\mathrm{PD}_M(a),[M]\rangle \\
 & \overset{\text{Lemma 59.4 (1)}}{=} & (\mathrm{PD}_M(b)\cup\mathrm{PD}_M(a))\cap[M] \\
 & = & (\mathrm{PD}_M(b)\cup\mathrm{PD}_M(i_*(a)))\cap[M] \\
 & \underset{\text{Lemma 59.7}}{=} & (\mathrm{PD}_M(i_*(a))\cap(\mathrm{PD}_M(b)\cap[M]) \\
 & \underset{\text{by the above commutative diagram}}{=} & \mathrm{PD}_M(i_*(a))\cap b \\
 & \underset{\text{Lemma 59.4 (1)}}{=} & \langle \mathrm{PD}_M(i_*(a)),b\rangle \\
 & \underset{\text{definition of }\mathrm{PD}_M(b)}{=} & \Phi(a)(b).
\end{array}$$

$\square$

Proof of Proposition 71.5.

(1) In Proposition 57.8 we showed that for a given topological space X the cup product

$$H^n(X;\mathbb{Z}) \times H^n(X;\mathbb{Z}) \;\to\; H^{2n}(X;\mathbb{Z})$$

is commutative if n is even and anti-commutative if n is odd. The same proof also applies verbatim to any relative cup product

$$H^n(X,A;\mathbb{Z}) \times H^n(X,A;\mathbb{Z}) \;\to\; H^{2n}(X,A;\mathbb{Z})$$

The first statement is an immediate consequence of this observation.

(2) Now suppose that M is closed. We consider the following diagram:

$$\begin{tikzcd}
\mathrm{F}H_k(M;\mathbb{Z}) \arrow[rr, "b\mapsto(a\mapsto Q_M(b,a))"] \arrow[dr, "\mathrm{PD}_M", "\cong"'] & & \mathrm{Hom}(\mathrm{F}H_k(M;\mathbb{Z}),\mathbb{Z}). \\
& \mathrm{F}H^k(M;\mathbb{Z}) \arrow[ur, "\mathrm{ev}"] &
\end{tikzcd}$$

We make the following observations:

(a) Since M is closed the map PD_M does indeed take values in the cohomology of M. Furthermore, by the Poincaré Duality Theorem 61.1 the map PD_M is an isomorphism.

(b) It follows from the Universal Coefficient Theorem 51.13 for Cohomology Groups together with Lemma 51.5 (5) and Proposition 45.2 (2) that the evaluation map

$$\mathrm{ev}\colon\; \mathrm{F}H^n(M;\mathbb{Z}) \;\to\; \mathrm{Hom}(\mathrm{F}H_n(M;\mathbb{Z}),\mathbb{Z})$$

is an isomorphism.

(c) The diagram commutes by Lemma 71.6.

(d) We have seen that the two diagonal maps are isomorphisms and that the diagram commutes. Thus we obtain that the top map is an isomorphism. Since we have seen in (1) that Q_M is symmetric that isomorphism takes care of all of our problems. □

In the next lemma we want to see to what degree the isometry type of the intersection form is an invariant of the homeomorphism type of the manifold.

Lemma 71.7. *Let $f\colon M \to N$ be a homeomorphism between two compact oriented non-empty even-dimensional topological manifolds. Then*

$$Q_M \;\cong\; \begin{cases} \;\;Q_N, & \text{if } f \text{ is orientation-preserving,} \\ -Q_N, & \text{if } f \text{ is orientation-reversing.} \end{cases}$$

Proof. [1197] Let $f\colon M \to N$ be a homeomorphism between two compact oriented $2n$-dimensional topological manifolds. We write $\varepsilon = +1$ if f is orientation-preserving and $\varepsilon = -1$ if f is orientation-reversing. We start out with the following claim.

Claim. For any $c \in H_n(M;\mathbb{Z})$ we have $\mathrm{PD}_N(f_*(c)) = \varepsilon \cdot (f^{-1})^*(\mathrm{PD}_M(c)) \in H^n(N,\partial N;\mathbb{Z})$.

[1197] The proof is perhaps slightly longer than one might expect. In a sense the statement of the lemma is basically trivial, but we have to pay a price for using the slightly awkward Poincaré Duality isomorphism $H_k(M;\mathbb{Z}) \to H^{2n-k}(M,\partial M;\mathbb{Z})$.

So let $c \in H_n(M;\mathbb{Z})$. We have

$$(f^{-1})^*(\mathrm{PD}_M(c)) \cap [N] \underset{\substack{\uparrow \\ \text{by Proposition 47.3 and the definition of } \varepsilon}}{=} (f^{-1})^*(\mathrm{PD}_M(c)) \cap (\varepsilon f_*([M])) \underset{\substack{\uparrow \\ \text{Lemma 59.8}}}{=} \varepsilon(f_*(\mathrm{PD}_M(c) \cap [M]) \underset{\substack{\uparrow \\ \text{definition of } \mathrm{PD}_M}}{=} \varepsilon f_*(c).$$

It follows from the definition of PD_N that we get the desired equality. This concludes the proof of the claim.

Now let $a, b \in \mathrm{F}H_n(M;\mathbb{Z})$. Then

$$\begin{aligned} Q_N(f_*(a), f_*(b)) &\underset{\substack{\downarrow \\ \text{by definition of } Q_N}}{=} \langle \mathrm{PD}_N(f_*(a)) \cup \mathrm{PD}_N(f_*(b)), [N]\rangle \\ &\underset{\substack{\uparrow \\ \text{by the claim and by Proposition 47.3}}}{=} \langle (\varepsilon \cdot (f^{-1})^*(\mathrm{PD}_M(a)) \cup \varepsilon \cdot (f^{-1})^*(\mathrm{PD}_M(b)), \varepsilon \cdot f_*([M])\rangle \\ &\underset{\substack{\uparrow \\ \text{by Propositition 58.3 (1) and since } \varepsilon^3 = \varepsilon}}{=} \varepsilon \cdot \langle (f^{-1})^*(\mathrm{PD}_M(a) \cup \mathrm{PD}_M(b)), f_*([M])\rangle \underset{\substack{\uparrow \\ \text{by Lemma 50.6 and the definition of } Q_M}}{=} \varepsilon \cdot Q_M(a,b). \end{aligned}$$

The lemma now follows from the fact that $f_*\colon \mathrm{F}H_n(M;\mathbb{Z}) \to \mathrm{F}H_n(N;\mathbb{Z})$ is an isomorphism. □

Examples.

(1) We first consider the $2n$-dimensional torus $M = S^n \times S^n$. By the Künneth Formula 43.8 we know that a basis for $H_n(S^n \times S^n;\mathbb{Z})$ is given by $a = [S^n \times \{0\}]$ and $b = [\{0\} \times S^n]$. We have two approaches for determining the intersection with respect to this basis:
   (a) We can use the Product Theorem 60.1 and its corollaries. More precisely, we first determine the Poincaré duals of $[S^n \times \{0\}]$ and $[\{0\} \times S^n]$ as in Proposition 60.2 (2) and then we can apply Lemma 60.3.
   (b) As on page 1568 we can use algebraic intersection numbers and Theorem 67.10 to determine the intersection form.

   In both cases we see that with respect to this basis the intersection form of $S^n \times S^n$ is represented by the matrix

$$\begin{pmatrix} Q_M(a,a) & Q_M(a,b) \\ Q_M(b,a) & Q_M(b,b) \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ (-1)^n & 0 \end{pmatrix}.$$

(2) We consider the surface Σ_3 of genus 3. In principle we could obtain the intersection form from the calculation of the cup product that we had performed in Lemma 57.16. But it is much more fun and instructive to use Theorem 67.10 instead. More precisely, we consider the surface Σ_3 that is illustrated in Figure 905. We give it the usual orientation. We already saw in the discussion on page 891 that the closed oriented curves $a_1, b_1, a_2, b_2, a_3, b_3$ illustrated in Figure 905 represent a basis for $H_1(\Sigma;\mathbb{Z})$. It

follows easily from Theorem 67.10 that with respect to this basis the intersection form is represented by the matrix

$$\begin{pmatrix} 0 & 1 & 0 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & -1 & 0 \end{pmatrix}.$$

An analogous statement holds of course for any surface of genus $g \geq 1$.[1198]

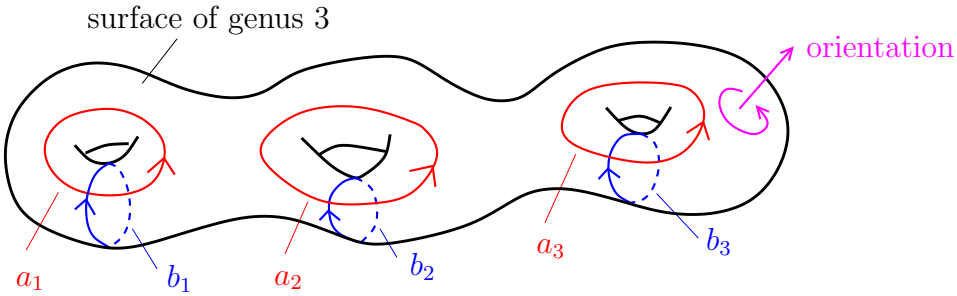

FIGURE 905.

(3) Next we consider the surface of genus two with three disks removed that is shown in Figure 906. By the discussion on page 896 we know that a basis for $H_1(\Sigma;\mathbb{Z})$ is represented by the curves a_1, b_1, a_2, b_2 together with two out of the three curve c_1, c_2, c_3. It follows from Theorem 67.10 that with respect to the basis $[a_1], [b_1], [a_2], [b_2], [c_1], [c_2]$ the intersection form is represented by the matrix

$$\begin{pmatrix} 0 & 1 & 0 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}.$$

(4) We consider the complex manifold $\mathbb{C}\mathrm{P}^2$. As always we equip $\mathbb{C}\mathrm{P}^2$ with the natural orientation coming from Proposition 21.4. It follows from Proposition 67.17 that the intersection form

$$Q_{\mathbb{C}\mathrm{P}^2}\colon H_2(\mathbb{C}\mathrm{P}^2;\mathbb{Z}) \times H_2(\mathbb{C}\mathrm{P}^2;\mathbb{Z}) \ \to\ \mathbb{Z}$$

is represented by the 1×1-matrix (1).

[1198]What do the curves a_i and b_i look like in the more precise description of the surface of genus 3 as a dodecagon with identified sides?

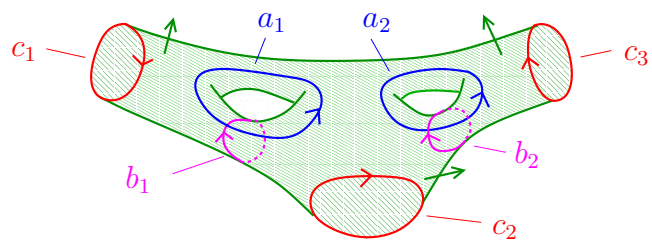

FIGURE 906.

(5) Let M be a closed oriented $2n$-dimensional topological manifold. As usual we denote by $-M$ the same manifold with the opposite orientation. It follows immediately from the definitions that $Q_{-M} = -Q_M$.

(6) For the complex projective space $\mathbb{C}\mathrm{P}^2$ we use the common notation that we write $\overline{\mathbb{C}\mathrm{P}}^2$ instead of $-\mathbb{C}\mathrm{P}^2$. With this notation it follows from (4) and (5) that the intersection form

$$Q_{\overline{\mathbb{C}\mathrm{P}}^2}\colon H_2(\overline{\mathbb{C}\mathrm{P}}^2;\mathbb{Z}) \times H_2(\overline{\mathbb{C}\mathrm{P}}^2;\mathbb{Z}) \ \to\ \mathbb{Z}$$

is represented by the 1×1-matrix (-1).

71.3. **The intersection form and degree-one maps.** As we remarked on page 1652 the intersection form of a compact oriented $2n$-dimensional manifold contains basically the same information as the cup product pairing

$$\begin{array}{rcl} H^n(M,\partial M;\mathbb{Z}) \times H^n(M,\partial M;\mathbb{Z}) & \to & H^{2n}(M,\partial M;\mathbb{Z}) \\ (\alpha,\beta) & \mapsto & \alpha \cup \beta. \end{array}$$

Given a map $f\colon X \to Y$ between topological spaces it follows from Lemma 57.10 that the cup product behaves well under the induced maps f^* on cohomology groups. It stands to reason that the intersection form should also behave well with respect to induced maps on homology.

So suppose we are given a degree-one map $f\colon X \to Y$ between closed oriented connected $2n$-dimensional topological manifolds. By the aforementioned Lemma 57.10 we know that for any $\alpha \in \mathrm{F}H^i(Y;\mathbb{Z})$ and $\beta \in \mathrm{F}H^j(Y;\mathbb{Z})$ we have $f^*\alpha \cup f^*\beta = f^*(\alpha \cup \beta)$. It seems reasonable to expect that given $\alpha \in H_n(X;\mathbb{Z})$ and $\beta \in H_n(X;\mathbb{Z})$ the following equality holds:

$$(*) \qquad Q_X(\alpha,\beta) \ = \ Q_Y(f_*(\alpha), f_*(\beta)).$$

In fact here is a diagram that looks awfully relevant:

$$\begin{tikzcd}
H_n(X;\mathbb{Z}) \times H_n(X;\mathbb{Z}) \arrow[r, "\mathrm{PD}\times\mathrm{PD}", "\cong"'] \arrow[d, "f_*\times f_*"] & H^n(X;\mathbb{Z}) \times H^n(X;\mathbb{Z}) \arrow[r, "\cup"] & H^{2n}(X;\mathbb{Z}) \arrow[r, "\langle -,[X]\rangle"] & \mathbb{Z} \arrow[d, "\mathrm{id}"'] \\
H_n(Y;\mathbb{Z}) \times H_n(Y;\mathbb{Z}) \arrow[r, "\mathrm{PD}\times\mathrm{PD}", "\cong"'] & H^n(Y;\mathbb{Z}) \times H^n(Y;\mathbb{Z}) \arrow[r, "\cup"] \arrow[u, "f^*\times f^*"] & H^{2n}(Y;\mathbb{Z}) \arrow[r, "\langle -,[Y]\rangle"] \arrow[u, "f^*", "\cong"'] & \mathbb{Z}.
\end{tikzcd}$$

If this diagram did commute, then $(*)$ would hold. One could now waste a lot of time trying to convince oneself that the diagram commutes. Or alternatively one might notice that $(*)$ just does not hold in general.

Example. We consider the map $f\colon S^1 \times S^1 \to S^2$ that is illustrated in Figure 907. It follows easily from Lemma 47.4 that this is a degree-one map. We consider the two homology classes α and β on the torus that are sketched in Figure 907. It follows easily from Theorem 67.10 that $Q_{S^1\times S^1}(\alpha,\beta) = +1$. On the other hand we have $f_*(\alpha) = f_*(\beta) = 0 \in H^1(S^2;\mathbb{Z})$, which evidently implies that $Q_{S^2}(f_*(\alpha), f_*(\beta)) = 0$. Thus in this case the equality $(*)$ does not hold.[1199]

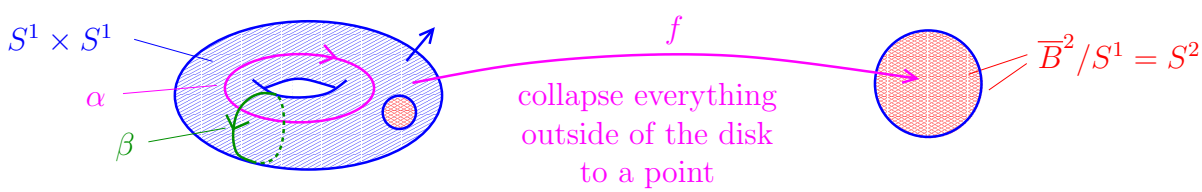

FIGURE 907.

Remark. With this discussion we also learned an interesting lesson:

Not every diagram commutes, not even up to sign.

71.4. **The connected sum of topological manifolds.** Recall that on page 355 we introduced the connected sum of two manifolds. In the following we generalize this definition to the connected sum of topological manifolds.

Definition. Let M and X be oriented n-dimensional topological manifolds. We say a map $\varphi\colon X \to M$ is *suitable* (respectively *anti-suitable*) if the following conditions are satisfied:

(1) we have $\varphi(X) \subset M \setminus \partial M$,
(2) the map φ is a topological embedding,
(3) the map φ is orientation-preserving (respectively orientation-reversing).[1200]

Now we can define the connected sum of two oriented topological manifolds.

Definition. Let $n \in \mathbb{N}$ and let M and N be two oriented non-empty n-dimensional topological manifolds. Given suitable a map $\varphi\colon \overline{B}^n \to M$ and given an anti-suitable map $\psi\colon \overline{B}^n \to N$ we define the *connected sum M and N* as

$$M\#N \;:=\; \big(M \setminus \varphi(B^n)\big) \sqcup \big(N \setminus \psi(B^n)\big) \,/\, \varphi(P) = \psi(P) \text{ for all } P \in S^{n-1}.$$

We refer to Figure 908 for an illustration.

We have the following proposition which in the following we will use without explicitly referring to it.

[1199] This still begs the question, in the above diagram, which of the squares does not commute?

[1200] We refer to page 1099 for the definition of "orientation-preserving" and "orientation-reversing".

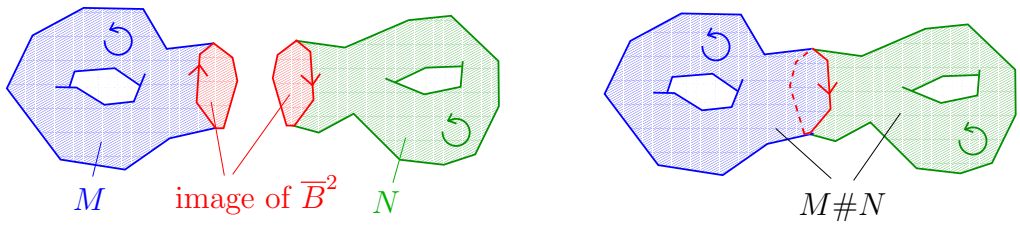

FIGURE 908.

Proposition 71.8. *Let $n \in \mathbb{N}$ and let M and N be two oriented connected n-dimensional topological manifolds.*

(1) *The homeomorphism type of $M\#N$ does not depend on the choice of (anti-) suitable maps.*
(2) *The connected sum $M\#N$ is an n-dimensional topological manifold.*
(3) *Given suitable maps $\varphi\colon \overline{B}^n \to M$ and $\psi\colon \overline{B}^n \to N$ we can equip the connected sum $M\#N$ with an orientation such that the two inclusion maps $M \setminus \varphi(B^n) \to M\#N$ and $M \setminus \psi(B^n) \to M\#N$ are orientation-preserving.*

Convention. We always equip the connected sum of two oriented connected n-dimensional topological manifolds with the orientation from Proposition 71.8 (3).

The proof of Proposition 71.8 (1) relies heavily on the following, surprisingly hard theorem which can be viewed as the topological analogue of Theorem 10.28

Theorem 71.9. *Let M be an oriented connected n-dimensional topological manifold. Let φ and ψ be two maps $\overline{B}^n_1 \sqcup \cdots \sqcup \overline{B}^n_s \to X$ from the disjoint union of s closed n-balls to X. Suppose the following statements hold:*

(1) *both φ and ψ are suitable or both are anti-suitable, and*
(2) *either $s = 1$ or $n \geq 2$,*

then there exists a homeomorphism F of M, isotopic to the identity, such that $F \circ \varphi = \psi$.

Proof. The theorem follows from combining the argument of [Rol, p. 42] together with the "annulus theorem" that was proved in 1969 by Rob Kirby [Kir] for $n \neq 4$ and that was proved in 1982 by Frank Quinn [Qu, Edw2] for $n = 4$. More details can be found in [FHNOP]. □

Now we can provide the proof of Proposition 71.8.

Proof of Proposition 71.8.

(1) The proof that the homeomorphism type of the connected sum of two oriented connected n-dimensional topological manifolds does not depend on the choice of (anti-) suitable maps is a fairly straightforward consequence of Theorem 71.9 applied twice with $s = 1$.

(2) It is fairly straightforward to show that the connected sum of two oriented connected topological manifolds is again a orientable connected topological manifold, see e.g. [Le3, Proposition 6.6] for details.
(3) The proof of the last statement is similar to the proof of Lemma 45.29. We leave the details as an exercise to the reader. □

Next we state how some of the key invariants behave under the connected sum operation.

Proposition 71.10. *Let $n \in \mathbb{N}$ and let M and N be two closed*[1201] *oriented connected n-dimensional topological manifolds and furthermore let $\varphi\colon \overline{B}^n \to M$ and $\psi\colon \overline{B}^n \to N$ be suitable maps. Then $H_0(M\#N;R) \cong H_n(M\#N;R) \cong R$. Furthermore, for any $i \neq 0, n$ and any commutative ring R the following inclusion induced maps are isomorphisms*

$$H_i(M\#N;R) \xleftarrow{\cong} H_i(M\backslash\varphi(B^n);R) \oplus H_i(N\backslash\psi(B^n);R) \xrightarrow{\cong} H_i(M;R) \oplus H_i(N;R).$$

Furthermore if $n \geq 3$, then the following inclusion induced maps are isomorphisms

$$\pi_1(M\#N) \xleftarrow{\cong} \pi_1(M \setminus \varphi(B^n)) * \pi_1(N \setminus \psi(B^n)) \xrightarrow{\cong} \pi_1(M) * \pi_1(N).$$

Proof. We proved the statements in Proposition 12.11 and Proposition 39.15 for manifolds. The proof for topological manifolds is very similar, we just need to make the following two modifications:

(1) The statement of the Seifert-van Kampen Theorem 12.9 also holds for topological manifolds, we just need to replace the Collar Neighborhood Theorem 10.10 by the Topological Collar Neighborhood Theorem 45.3.
(2) The Mayer–Vietoris argument in the proof of Lemma 39.16 works for topological manifolds by Proposition 50.12 (5) and the Mayer–Vietoris Theorem 50.14. □

71.5. **The intersection form and the connected sum operation.** The next proposition says that the isomorphism of homology groups from Proposition 71.10 induces an isometry of intersection forms.

Proposition 71.11. *Let $n \geq 1$, let M and N be closed oriented $2n$-dimensional topological manifolds and let $\varphi\colon \overline{B}^{2n} \to M$ and $\psi\colon \overline{B}^{2n} \to N$ be two suitable maps. The isomorphism $H_n(M\#N;\mathbb{Z}) \xrightarrow{\cong} H_n(M;\mathbb{Z}) \oplus H_n(N;\mathbb{Z})$ from Proposition 71.10 induces an isometry*

$$Q_{M\#N} \cong Q_M \oplus Q_N$$

of forms.

Example. We consider the surface Σ of genus two. In Figure 909 we recall that we can view Σ as the connected sum of two tori. It thus follows from Proposition 71.11, the discussion on page 1655 and Lemma 71.3 (2) that the intersection form on $H_1(\Sigma;\mathbb{Z}) \cong \mathbb{Z}^4$ is represented

[1201] How does the proposition change if we allow topological manifolds with boundary?

by the matrix

$$\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \oplus \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} = \begin{pmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \end{pmatrix}.$$

Not surprisingly this recovers the result from page 1656.

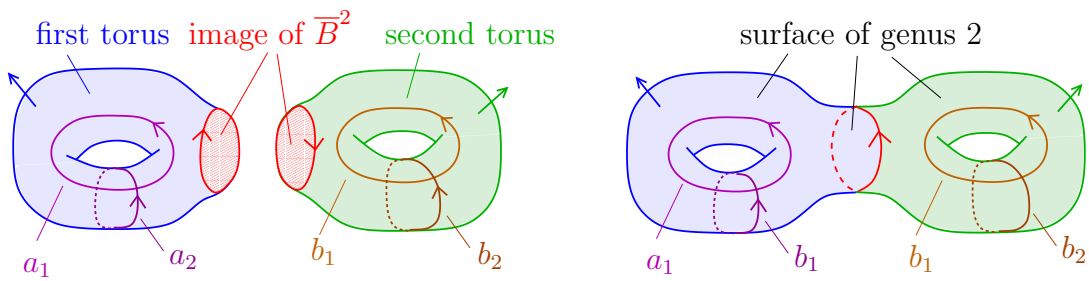

FIGURE 909.

Remark. Let $n \geq 1$, let M and N be closed oriented $2n$-dimensional topological manifolds and let $\varphi\colon \overline{B}^{2n} \to M$ and $\psi\colon \overline{B}^{2n} \to N$ be two suitable maps. Figure 909 suggests the following approach to proving Proposition 71.11:

(1) First we pick transverse n-dimensional cycles $a_1, \dots, a_k$ in $M \setminus \varphi(\overline{B}^{2n})$ such that $[a_1], \dots, [a_k]$ form a basis of $\mathrm{F}H_n(M; \mathbb{Z})$.
(2) Similarly we pick transverse n-dimensional cycles $b_1, \dots, b_l$ in $N \setminus \psi(\overline{B}^{2n})$ such that $[b_1], \dots, [b_l]$ form a basis of $\mathrm{F}H_n(N; \mathbb{Z})$.
(3) It follows immediately from Proposition 71.10 that $[a_1], \dots, [a_k], [b_1], \dots, [b_l]$ form a basis for $\mathrm{F}H_n(M\#N; \mathbb{Z})$.
(4) We use the basis from (3) to determine the intersection form of $M\#N$. Here we make the following observations:
   (a) By the orientation conventions from Proposition 71.8 (3) the algebraic intersection numbers of the a_i in M are the same as in $M\#N$,
   (b) similarly the algebraic intersection numbers of the b_i in N are the same as in $M\#N$,
   (c) the a_i do not intersect the b_j, hence $a_i \cdot b_j = 0$ for any i, j.

   Summarizing we obtain immediately from Theorem 68.5 that $Q_M \oplus Q_N \cong Q_{M\#N}$.

The above argument sounds very convincing. But there is a major catch: how can we find such $a_1, \dots, a_k$ and $b_1, \dots, b_l$? The problem is not that we need to avoid $\varphi(\overline{B}^{2n})$ and $\psi(\overline{B}^{2n})$.[1202] The problem is to find such classes that are transverse. Even though we have some tools, e.g. we have Theorem 65.26 and the Transversality Theorem 67.2, it is very hard to turn the above approach into a rigorous proof.

[1202] Why is this not a problem?

After the discussion in the previous remark we recall the advice from [Kir4, p. 21], see page 1566:

"Think with [algebraic] intersection [numbers], prove with cup products."

Thus we will use cup products to prove Proposition 71.11.

Proof of Proposition 71.11. Throughout the proof let $n \geq 1$. We start out with a lengthy preparation. Thus let X and Y be two oriented connected $2n$-dimensional topological manifolds with $\partial X \cong S^{2n-1}$ and $\partial Y \cong S^{2n-1}$. We equip ∂X and ∂Y with the orientation coming from Proposition 45.30. We identify ∂X and ∂Y via an orientation-reversing homeomorphism φ. We write $Z = X \cup_\varphi Y$. In the following we view X and Y as submanifolds of Z. We write $\mathring{X} = X \setminus \partial X$ and $\mathring{Y} = Y \setminus \partial Y$. Recall that by Proposition 71.8 we can equip Z with an orientation such that the induced orientations on X and Y are the given orientations.

We start out with the following claim.

Claim. The inclusions $i\colon X \to Z$ and $j\colon Y \to Z$ induce an isometry

$$Q_X \oplus Q_Y \xrightarrow{\cong} Q_Z.$$

As in Proposition 71.11 we see that the two inclusion maps i and j induce an isomorphism $H_n(X;\mathbb{Z}) \oplus H_n(Y;\mathbb{Z}) \to H_n(Z;\mathbb{Z})$. Evidently this isomorphism descends to an isomorphism $\mathrm{F}H_n(X;\mathbb{Z}) \oplus \mathrm{F}H_n(Y;\mathbb{Z}) \to \mathrm{F}H_n(Z;\mathbb{Z})$. Therefore it suffices to prove the following three statements.

(1) for $a, b \in \mathrm{F}H_n(X;\mathbb{Z})$ we have $Q_X(a,b) = Q_Z(i_*(a), i_*(b))$,
(2) for $a, b \in \mathrm{F}H_n(Y;\mathbb{Z})$ we have $Q_Y(a,b) = Q_Z(j_*(a), j_*(b))$,
(3) for $a \in \mathrm{F}H_n(X;\mathbb{Z})$ and $b \in \mathrm{F}H_n(Y;\mathbb{Z})$ we have $Q_Z(i_*(a), j_*(b)) = 0$.

We start out with the proof of the first statement. So let $a, b \in \mathrm{F}H_n(X;\mathbb{Z})$. We denote by $p\colon (Z, \partial Z) \to (Z, Z \setminus \mathring{X})$ and $i\colon (X, \partial X) \to (Z, Z \setminus \mathring{X})$ the two obvious inclusion maps of pairs of topological spaces. Note that it is a consequence of the Excision Theorem 45.8 for Topological Manifolds that $i_*\colon \mathrm{F}H_k(X, \partial X;\mathbb{Z}) \to \mathrm{F}H_k(Z, Z \setminus \mathring{X};\mathbb{Z})$ is an isomorphism for

every $k \in \mathbb{N}_0$. Then

$$\begin{aligned}
Q_X(a,b) &\underset{\substack{\uparrow \\ \text{by definition of } Q_X}}{=} \langle \mathrm{PD}_X(a) \cup \mathrm{PD}_X(b), [X] \rangle \underset{\substack{\uparrow \\ \text{Lemma 50.6 applied to } i\colon (X,\partial X) \to (Z, Z \setminus \mathring{X}), \\ \text{together with Proposition 58.3 (1)}}}{=} \big\langle (i^*)^{-1}(\mathrm{PD}_X(a)) \cup (i^*)^{-1}(\mathrm{PD}_X(b)), i_*([X]) \big\rangle \\
&\underset{\substack{\uparrow \\ \text{first note that by Lemma 46.23 we have, } i_*([X]) = p_*([Z]), \text{ next apply} \\ \text{Lemma 50.6 to } p, \text{ finally apply Proposition 58.3 (1) to } p}}{=} \big\langle p^*((i^*)^{-1}(\mathrm{PD}_X(a))) \cup p^*((i^*)^{-1}(\mathrm{PD}_X(b))), [Z] \big\rangle \\
&\underset{\substack{\uparrow \\ \text{by Lemma 67.12 we know that} \\ p^*(i^*)^{-1}(\mathrm{PD}_X(c)) = \mathrm{PD}_Z(i_*(c))}}{=} \big\langle \mathrm{PD}_Z(i_*(a)) \cup \mathrm{PD}_Z(i_*(b)), [Z] \big\rangle \underset{\substack{\uparrow \\ \text{definition of } Q_Z}}{=} Q_Z(i_*(a), i_*(b)).
\end{aligned}$$

The second statement is of course proved the same way. We turn to the proof of the third statement. So let $a \in \mathrm{F}H_n(X;\mathbb{Z})$ and $b \in \mathrm{F}H_n(Y;\mathbb{Z})$. The above argument shows that we can compute $Q_Z(i_*(a), j_*(b))$ in terms of the cup product in Z of an element in the image $H^n(Z, Z \setminus \mathring{X}) \to H^n(Z)$ and an element in the image of $H^n(Z, Z \setminus \mathring{Y}; \mathbb{Z}) \to H^n(Z;\mathbb{Z})$. But $(Z \setminus \mathring{X}) \cup (Z \setminus \mathring{Y}) = Z$. So it follows from Proposition 58.3 (1) that this cup product is zero. This concludes the proof of the claim.

After these preparations it is very easy to prove the actual statement of the proposition. Thus let M and N be closed oriented $2n$-dimensional topological manifolds and let $\varphi\colon \overline{B}^{2n} \to M$ and $\psi\colon \overline{B}^{2n} \to N$ be two suitable maps. We write $X = M \setminus \varphi(B^{2n})$ and $Y = N \setminus \psi(B^{2n})$. It follows from the definition of a topological embedding that X and Y are compact topological manifolds. With this notation we can write $M = X \cup \overline{B}^{2n}$ and $N = Y \cup \overline{B}^{2n}$. It follows from the claim and the fact that $H_n(\overline{B}^{2n};\mathbb{Z}) = 0$ that the inclusions induce isometries

$$Q_{M\#N} \xleftarrow{\cong} Q_X \oplus Q_Y \xrightarrow{\cong} Q_M \oplus Q_N.$$

We have thus proved the desired statement. □

We recall the following question.

Question 43.10. *Are the topological spaces* $\mathbb{C}\mathrm{P}^2\#\mathbb{C}\mathrm{P}^2$, $\mathbb{C}\mathrm{P}^2\#\overline{\mathbb{C}\mathrm{P}}^2$ *and* $S^2 \times S^2$ *homeomorphic?*

These topological spaces are hard to distinguish since we saw that they are simply connected and that their (co-) homology groups agree. Now we want to look at the intersection forms to see whether they can help us in distinguishing these three manifolds.

Example. On page 1656 we saw that the intersection form of $\mathbb{C}\mathrm{P}^2$ is represented by the 1×1-matrix (1) and we saw that the intersection form of $\overline{\mathbb{C}\mathrm{P}}^2$ is represented by the 1×1-matrix (-1). From Proposition 71.11 we thus obtain:

(1) the intersection form of $\mathbb{C}\mathrm{P}^2\#\mathbb{C}\mathrm{P}^2$ is represented by the matrix $\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$, whereas

(2) the intersection form of $\mathbb{C}\mathrm{P}^2\#\overline{\mathbb{C}\mathrm{P}}^2$ is represented by the matrix $\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$.

Finally we recall that on page 1655 we showed that

(3) the intersection form of $S^2 \times S^2$ is represented by the matrix $\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$.

Motivated by Question 43.10 and Lemma 71.7 the following question arises.

Question 71.12. *Are the forms over $\mathbb{Z}^2$ represented by the matrices*

$$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \quad \textit{and} \quad \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}.$$

isometric (*possibly up to a sign reversal*)*?*

In the next chapter we will develop the theory of non-singular forms to answer Question 71.12.

Exercises for Chapter 71.

Exercise 71.1. Let M be a compact oriented topological manifold. Recall that we say that M is *amphichiral* if M admits an orientation-reversing self-homeomorphism, otherwise we say that M is *chiral*. For which $k, l \in \mathbb{N}_0$ is the connected sum $k \cdot \mathbb{C}\mathrm{P}^2\#l \cdot \overline{\mathbb{C}\mathrm{P}}^2$ chiral? Justify your answer. More precisely:

(a) for the values that you exclude, show that $k \cdot \mathbb{C}\mathrm{P}^2\#l \cdot \overline{\mathbb{C}\mathrm{P}}^2$ is not chiral,

(b) for all the other values show explicitly that $k \cdot \mathbb{C}\mathrm{P}^2\#l \cdot \overline{\mathbb{C}\mathrm{P}}^2$ is chiral.

Exercise 71.2. Let R be a commutative ring. A form $\varphi\colon V \times V \to R$ is called *non-degenerate* if the two maps

$$\text{(a)} \quad \begin{array}{ccc} V & \to & \mathrm{Hom}_R(V,R) \\ v & \mapsto & \left(\begin{array}{ccc} V & \to & S \\ w & \mapsto & \varphi(v,w) \end{array} \right) \end{array} \quad \text{and} \quad \text{(b)} \quad \begin{array}{ccc} V & \to & \mathrm{Hom}_R(V,R) \\ w & \mapsto & \left(\begin{array}{ccc} V & \to & S \\ v & \mapsto & \varphi(v,w) \end{array} \right) \end{array}$$

are *monomorphisms*. Now let M be a compact oriented 4-dimensional topological manifold such that ∂M is a rational homology sphere. Show that the intersection form Q_M is non-degenerate.

72. The intersection form of topological manifolds II: Algebra and 4-dimensional manifolds

In the previous chapter we introduced the intersection form of compact oriented even-dimensional topological manifolds. Towards the end of the last chapter it became clear that we have to invest some time to study (anti-) symmetric forms as purely algebraic objects.

We start out with the following lemma.

Lemma 72.1. *Let R be a commutative ring.*

(1) *Let A be a (skew-) symmetric*[1203] *$n \times n$-matrix over R. We consider the map*

$$\begin{array}{rcl} \varphi(A)\colon R^n \times R^n & \to & R \\ (v,w) & \mapsto & v^T A w. \end{array}$$

Then the following hold:

(a) *$\varphi(A)$ is an (anti-) symmetric form over R,*

(b) *the form $\varphi(A)$ is non-singular if and only if A is invertible, i.e. if $\det(A)$ is a unit in R,*

(c) *if $P \in \mathrm{GL}(n,R)$ is an invertible matrix, then the forms $\varphi(P^T AP)$ and $\varphi(A)$ are isometric.*

(2) *Let (V,ψ) be an (anti-) symmetric form over R of rank n. If A is a matrix that represents ψ, then $(V,\psi) \cong (R^n, \varphi(A))$. In particular every (anti-) symmetric form over R is isometric to $\varphi(A)$ for some (skew-) symmetric $n \times n$-matrix A over R.*

Proof.

(1) (a) This statement follows almost immediately from the definitions and the observation that for any $v, w \in R^n$ we have

$$\varphi(A)(w,v) \;=\; w^T A v \;=\; (v^T A^T w)^T \;\underset{\substack{\uparrow \\ \text{for a } (1\times 1)\text{-matrix } (x) \text{ we have } (x)^T = (x)}}{=}\; v^T A^T w \;=\; \varphi(A^T)(v,w).$$

(b) The proof of this statement is an instructive exercise in linear algebra. We will not rob the reader of the joy of doing this exercise.

(c) We claim that that the isomorphism $v \mapsto Pv$ defines an isometry from the form $(R^n, \varphi(P^T AP))$ to the form $(R^n, \varphi(A))$. Indeed, for any $v, w \in R^n$ we have

$$\varphi(A)(Pv, Pw) \;=\; (Pv)^T APw \;=\; v^T (P^T AP) w \;=\; \varphi(P^T AP)(v,w).$$

(2) Let $\psi\colon V \times V \to R$ be an (anti-) symmetric form over R. Let $v_1, \dots, v_n$ be a basis of V. We denote by $A = (\psi(v_i, v_j))_{i,j=1,\dots,n}$ the corresponding matrix representing the form ψ. We consider the isomorphism

$$\begin{array}{rcl} \Theta\colon R^k & \to & V \\ (\lambda_1, \dots, \lambda_n) & \mapsto & \lambda_1 v_1 + \dots + \lambda_n v_n. \end{array}$$

[1203] Recall that a matrix A is called *skew-symmetric* if $A^T = -A$.

We claim that Θ is an isometry from the form $(R^n, \varphi(A))$ to the form (V, ψ). Indeed, if we denote by $e_1, \dots, e_n$ the standard basis for R^n, then for any $i, j \in \{1, \dots, n\}$ we have

$$\psi(\Theta(e_i), \Theta(e_j)) \;=\; \psi(v_i, v_j) \;=\; e_i^T A e_j \;=\; \varphi(A)(e_i, e_j).$$

By bilinearity of forms we obtain the corresponding statement for all pairs of vectors in R^n. □

Convention. Lemma 72.1 allows us to go back and forth between (anti-) symmetric forms and (skew-) symmetric matrices. Thus in the following discussion we will blur the distinction between these two concepts. For example, given a (skew-) symmetric matrix A over a commutative ring we will often just refer to the (anti-) symmetric form $\varphi(A)$ as the *form* A.

72.1. **Non-singular anti-symmetric forms.** In this section we will completely classify non-singular anti-symmetric forms over the real numbers and over the integers.

First we consider the matrix

$$S \;:=\; \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

It is skew-symmetric and it has determinant 1. From Lemma 72.1 we obtain an anti-symmetric form $\varphi(S)$. The following proposition shows that $\varphi(S)$ is in some sense the only example of a non-singular anti-symmetric form over the real numbers or over the integers.

Proposition 72.2. *If (V, φ) is a non-singular anti-symmetric form over $\mathbb{R}$ or over $\mathbb{Z}$, then there exists a $k \in \mathbb{N}_0$ such that*[1204] *$(V, \varphi) \cong k \cdot \varphi(S)$, i.e. φ is represented by the $2k \times 2k$-matrix*

$$\underbrace{\begin{pmatrix} 0 & 1 & \dots & 0 & 0 \\ -1 & 0 & \dots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \dots & 0 & 1 \\ 0 & 0 & \dots & -1 & 0 \end{pmatrix}}_{k \text{ diagonal blocks of } 2\times 2\text{-matrices}}.$$

In particular the rank of V is even.

Remark. Propositions 71.5 and 72.2 imply in particular that the isometry type of the intersection of a surface of genus g is determined by the formal properties of an intersection form. In particular we did not need to go through the discussion on page 1656 if we just need to know the *isomorphism type* of the intersection form.

Sketch of proof. First we remark that throughout the proof on many occasions we use Lemma 72.1 without saying so explicitly.

After this preamble, let (V, φ) be a non-singular anti-symmetric form over $\mathbb{R}$ of rank n. We pick an $(n \times n)$-matrix A that represents φ. Since φ is anti-symmetric we see that all

[1204] Here, when we write $k \cdot \varphi(S)$ we use the definition from page 1649.

terms of A on the diagonal are zero. We consider the following three types of elementary matrices:

$$D_\lambda := \begin{pmatrix} \mathrm{id} & 0 & 0 \\ 0 & \lambda & 0 \\ 0 & 0 & \mathrm{id} \end{pmatrix}, \lambda \neq 0, \quad P := \begin{pmatrix} \mathrm{id} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & \mathrm{id} & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \mathrm{id} \end{pmatrix} \quad \text{and} \quad Q_\lambda := \begin{pmatrix} \mathrm{id} & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & \lambda & 0 \\ 0 & 0 & \mathrm{id} & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & \mathrm{id} \end{pmatrix}.$$

We make the following elementary observations:

(i) Replacing a matrix B by $D_\lambda^T B D_\lambda$ means that first we multiply a column by λ, and then we multiply the corresponding row by λ.
(ii) Replacing a matrix B by $P^T B P$ means that first we exchange two columns, and then we exchange the corresponding two rows.
(iii) Replacing a matrix B by $Q_\lambda^T B Q_\lambda$ means that first we add λ-times one column to another column, and then we do the same operation for the corresponding rows.

Now we can perform the following sequence of operations to A:

$$A \overset{(1)}{=} \begin{pmatrix} 0 & * & * & \dots & * \\ * & 0 & * & \dots & * \\ * & * & 0 & * & * \\ \vdots & \vdots & * & \ddots & * \\ * & * & * & * & 0 \end{pmatrix} \overset{(2)}{\to} \begin{pmatrix} 0 & 1 & * & \dots & * \\ -1 & 0 & * & \dots & * \\ * & * & 0 & * & * \\ \vdots & \vdots & * & \ddots & * \\ * & * & * & * & 0 \end{pmatrix} \overset{(3)}{\to} \begin{pmatrix} 0 & 1 & 0 & \dots & 0 \\ -1 & 0 & * & \dots & * \\ 0 & * & 0 & * & * \\ \vdots & \vdots & * & \ddots & * \\ 0 & * & * & * & 0 \end{pmatrix} \overset{(4)}{\to} \begin{pmatrix} 0 & 1 & 0 & \dots & 0 \\ -1 & 0 & 0 & \dots & 0 \\ 0 & 0 & 0 & * & * \\ \vdots & \vdots & * & \ddots & * \\ 0 & 0 & * & * & 0 \end{pmatrix}$$

where we perform the following steps:

(1) We write out A, here and throughout the steps we use the convention that $*$ can mean any real number, the only condition being that all matrices are skew-symmetric.
(2) Since $\det(A) \neq 0$ there exists at least one entry on the first row which is non-zero. After operations of type (ii) and (i) we can arrange that the $(1,2)$-entry equals 1.
(3) Using operations of type (iii) we can "clean up" the remaining terms on the first row and column.
(4) Similarly, we can use operations of type (iii) to "clean up" the remaining terms on the second row and column.

At this stage we can continue with the same process, applied to the $(n-2)\times(n-2)$-matrix at the right bottom. Eventually we will have turned A into a matrix of the promised type.

Now suppose that (V, φ) is a non-singular anti-symmetric form over $\mathbb{Z}$. In Exercise 72.4 we will modify the above proof to deal with this new situation. □

Even though Proposition 72.2 is a little disappointing, it is just good enough to answer Question 61.5 where we had asked which integers appear as Euler characteristics of closed orientable connected even-dimensional manifolds. Now we can give a complete answer to this question.

Proposition 72.3. *Let $k \in \mathbb{N}_0$.*

(1) *Given any $n \in \mathbb{Z}$ there exists a closed orientable connected $4k$-dimensional manifold with Euler characteristic n.*
(2) *The Euler characteristic of any closed orientable connected topological manifold of dimension $4k+2$ is even. Conversely, any even number is the Euler characteristic of such a manifold.*

Proof. First we show that the Euler characteristic of a closed orientable topological manifold M of dimension $4k+2$ is even. Indeed, we have

$$\chi(M) \underset{\substack{\uparrow \\ \text{Proposition 45.7 (4)}}}{=} \sum_{i=0}^{4k+2}(-1)^i \cdot \dim_{\mathbb{R}}(H_i(M;\mathbb{R})) \underset{\substack{\uparrow \\ \text{by Theorem 61.3 we have } \dim_{\mathbb{R}}(H_i(M;\mathbb{R})) = \dim_{\mathbb{R}}(H_{4k+2-i}(M;\mathbb{R}))}}{=} \dim_{\mathbb{R}}(H_{2k+1}(M;\mathbb{R})) + \sum_{i=0}^{2k}(-1)^i \cdot 2\dim_{\mathbb{R}}(H_i(M;\mathbb{R}))$$

$$\underset{\substack{\uparrow \\ \text{by Proposition 71.5 and the facts that } M \text{ is closed and that } 2k+1 \text{ is odd we know} \\ \text{that the intersection on } H_{2k+1}(M;\mathbb{R}) \text{ is anti-symmetric and non-singular} \\ \text{by Proposition 72.2 we thus know that } \dim_{\mathbb{R}}(H_{2k+1}(M,\mathbb{R})) \text{ is even}}}{\equiv} 0 \mod 2.$$

Besides this restriction on the possible values of Euler characteristics, all other values can be realized. This follows easily from the following three facts:

(1) On page 966 we saw that

$$\chi(\mathbb{C}\mathrm{P}^n) = n+1 \equiv \begin{cases} 0 \bmod 2, & \text{if } n \text{ is odd.} \\ 1 \bmod 2, & \text{if } n \text{ is even.} \end{cases}$$

(2) Lemma 40.8 says that if M and N are two compact oriented connected *even-dimensional* manifolds, then $\chi(M\#N) = \chi(M) + \chi(N) - 2$.
(3) There is any number of reasons, e.g. we could use Lemma 40.9, why the Euler characteristic of the n-dimensional torus $(S^1)^n$ is zero.

Using these three facts one can show easily that any permissible value for an Euler characteristic of a $2k$-dimensional manifold is realized by an appropriate connected sum of copies of $\mathbb{C}\mathrm{P}^k$ and copies of the $2k$-dimensional torus. □

72.2. **Interlude: Sphere-packing.** In this short section we want to consider sphere packings. The relationship with our actual goal of dealing with symmetric forms is arguably tenuous but nonetheless fascinating.

Definition. Let $v_1, \dots, v_n$ be linearly independent vectors in $\mathbb{R}^n$. We refer to the group

$$\mathbb{Z} \cdot v_1 + \dots + \mathbb{Z} \cdot v_n = \left\{ \sum_{i=1}^n a_i \cdot v_i \,\middle|\, a_1, \dots, a_n \in \mathbb{Z} \right\}$$

as the *lattice spanned by* $v_1, \dots, v_n$.[1205]

We start out with the following theorem. The fact that strictly speaking we did not define all the terms will not bother us.

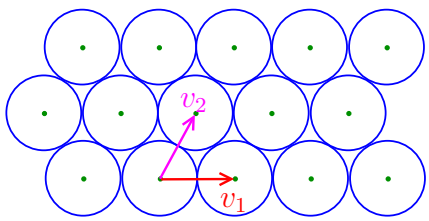
[1205] This is perhaps not the standard definition of a lattice, but who cares?

Theorem 72.4.

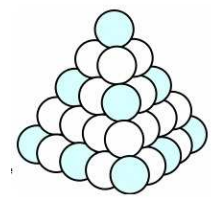
(1) *The densest packing of disks of radius* $\frac{1}{2}$ *in* $\mathbb{R}^2$ *is given by setting the centers on the "hexagonal" lattice spanned by* $v_1 = (1,0)$ *and* $v_2 = (\frac{1}{2}, \frac{\sqrt{3}}{2})$ *shown in Figure 910 on the left. The density equals* $\frac{\pi}{\sqrt{12}}$.

(2) *No packing of balls of the same radius in* $\mathbb{R}^3$ *has density greater than that of the "face-centered cubic packing" shown in Figure 910 in the middle and on the right. The density equals* $\frac{\pi}{\sqrt{18}}$.

Proof. The first statement was proved by L. Fejes Tóth [FT, FT2] in 1943. It is much harder to prove the second statement. This statement had been conjectured by Kepler in 1613 and it was finally proved by Thomas Hales [Hale, Hale2, Hale3] in 2005. □



densest circle packing



ball packings of highest density

FIGURE 910.

For a mathematician it is natural to wonder what are the highest densities of packings in higher dimensions. Not surprisingly this is a very problem. Astonishingly the next case that was dealt with is the 8-dimensional setting. More precisely, the following theorem was proved by Maryna Viazovska in 2016.

Theorem 72.5. *We consider the following matrix*

$$E_8 := \begin{pmatrix} 2 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 1 & 2 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 2 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 2 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 2 & 1 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 & 2 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 2 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 2 \end{pmatrix}.$$

No packing of unit balls in $\mathbb{R}^8$ *has density greater than that given by the lattice spanned by the eight column vectors of the* E_8*-matrix. Furthermore, this packing has density* $\frac{\pi^4}{384}$.

Remark. We also refer to [Bae2] for other interesting appearances of the E_8-matrix, for example its relationship to the regular icosahedron

Shortly afterwards the 24-dimensional case was settled in [CKMRV], in this case a densest packing is given by the "Leech lattice". OK, that was fun, but now let us return to our actual problem, and let us see whether this section was of any use.

72.3. **Non-singular symmetric forms over the real numbers.** In an earlier section we saw that non-singular *anti-symmetric* forms are almost depressingly boring mathematical objects. In this and the next section we will consider non-singular *symmetric* forms. These will, fortunately, turn out to be much more interesting.

Examples. We list some symmetric integral matrices with determinant equal to ± 1. By Lemma 72.1 these define in particular non-singular forms over $\mathbb{R}$ but also over $\mathbb{Z}$.

(1) The 1×1-matrices $(+1)$ and (-1).
(2) The slightly mysterious 8×8-matrix E_8 from the previous section.
(3) The matrix
$$H := \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$$
is symmetric and it has determinant -1.

It is natural to ask whether there is some type of analogue of Proposition 72.2 for symmetric forms. In fact using the methods of the proof of Proposition 72.2 one can prove the following statement.

Proposition 72.6. *If (V, φ) is a non-singular symmetric form over $\mathbb{R}$ of rank n, then there exists a $k \in \mathbb{N}_0$ such that $(V, \varphi) \cong k \cdot (+1) \oplus (n-k) \cdot (-1)$.*

Remark. Recall that Proposition 72.2 dealt with anti-symmetric forms over $\mathbb{R}$ and also with anti-symmetric forms over $\mathbb{Z}$. In contrast Proposition 72.6 only deals with symmetric forms over $\mathbb{R}$. It is a very instructive exercise to run through the proof of Proposition 72.6 and to determine where it breaks down if we work over $\mathbb{Z}$.

Sketch of proof. Let (V, φ) be a non-singular symmetric form over $\mathbb{R}$ of rank n. In the subsequent arguments below we use the conventions and notions we introduced in Proposition 72.2. In particular we will also use the operations of type (i), (ii) and (iii) that we introduced in that proof.

We pick an $(n \times n)$-matrix A that represents φ. Now we can perform the following sequence of operations to A:

$$A \overset{(1)}{=} \begin{pmatrix} * & * & \dots & * \\ * & * & \dots & * \\ \vdots & \vdots & \ddots & \vdots \\ * & * & \dots & * \end{pmatrix} \xrightarrow{(2)} \begin{pmatrix} \epsilon_1 & * & \dots & * \\ * & * & \dots & * \\ \vdots & \vdots & \ddots & \vdots \\ * & * & \dots & * \end{pmatrix} \xrightarrow{(3)} \begin{pmatrix} \epsilon_1 & 0 & \dots & 0 \\ 0 & * & \dots & * \\ \vdots & \vdots & \ddots & \vdots \\ 0 & * & \dots & * \end{pmatrix}$$

where we perform the following steps:

(1) We write out A, here and throughout the steps we use the convention that $*$ can mean anything, the only condition being that all matrices are symmetric.

(2) Since $\det(A) \neq 0$ there exists at least one entry on the first row which is non-zero. After operations of type (iii) and (i) we can arrange that the $(1,1)$-entry equals some $\epsilon_1 \in \{-1, 1\}$.
(3) Using operations of type (iii) we can "clean up" the remaining terms on the first row and column.

At this stage we can continue with the same process, applied to the $(n-1)\times(n-1)$-matrix at the right bottom. Eventually we will have turned A into a diagonal matrix where all entries lie in $\{-1, 1\}$. After operations of type (ii) we can arrange that the first diagonal entries are equal to $+1$ and the final ones are equal to -1. □

Let $n \in \mathbb{N}_0$. Proposition 72.6 raises the question whether or not the symmetric forms defined by $k \cdot (+1) \oplus (n-k) \cdot (-1)$ are isometric for different values of $k \in \{0, \ldots, n\}$. The following definition is the key to answering this question.

Definition. Let (V, φ) be a symmetric form over the real numbers.

(1) We say φ is *positive-definite* if $\varphi(v, v) > 0$ for all $v \neq 0$.
(2) We say φ is *negative-definite* if $\varphi(v, v) < 0$ for all $v \neq 0$.
(3) We say φ is *indefinite* if φ is neither positive-definite nor negative-definite.

Examples.

(1) The form $(+1)$ is positive-definite and the form (-1) is negative-definite.
(2) The form E_8 is positive-definite. Evidently one can show this by a brute force calculation. A more conceptual proof is given in [HGK, Theorem 1.16.14].
(3) The form H is indefinite, indeed, we have

$$\varphi(H)\left(\begin{pmatrix}1\\1\end{pmatrix}, \begin{pmatrix}1\\1\end{pmatrix}\right) \;=\; \begin{pmatrix}1 & 1\end{pmatrix}\begin{pmatrix}0 & 1\\1 & 0\end{pmatrix}\begin{pmatrix}1\\1\end{pmatrix} \;=\; 2$$

and

$$\varphi(H)\left(\begin{pmatrix}1\\-1\end{pmatrix}, \begin{pmatrix}1\\-1\end{pmatrix}\right) \;=\; \begin{pmatrix}1 & -1\end{pmatrix}\begin{pmatrix}0 & 1\\1 & 0\end{pmatrix}\begin{pmatrix}1\\-1\end{pmatrix} \;=\; -2.$$

To distinguish non-isometric forms we need to introduce some invariants of forms.

Definition. Let (V, φ) be a symmetric form over the real numbers. We define[1206]

$$\begin{aligned} b^+(\varphi) &:= \text{ maximal dimension of a subspace } W \text{ of } V \text{ such that } \varphi|_W \text{ is positive-definite,} \\ b^-(\varphi) &:= \text{ maximal dimension of a subspace } W \text{ of } V \text{ such that } \varphi|_W \text{ is negative-definite.} \end{aligned}$$

Furthermore we define the *signature* $\operatorname{sign}(\varphi)$ as

$$\operatorname{sign}(\varphi) \;:=\; b^+(\varphi) - b^-(\varphi).$$

The following lemma is an immediate consequence of the definitions.

[1206]Just to make sure there is no misunderstanding, by "subspace" we mean a "vector subspace". The set of all vectors $v \in V$ with $\varphi(v, v) > 0$ is *not* a subspace, but some open subset of V.

Lemma 72.7. *Let (V,φ) and (W,ψ) be two non-singular symmetric forms over $\mathbb{R}$. If (V,φ) and (W,ψ) are isometric, then*

$$\dim_{\mathbb{R}}(V) = \dim_{\mathbb{R}}(W), \quad b^{\pm}(\varphi) = b^{\pm}(\psi) \quad \text{and} \quad \operatorname{sign}(\varphi) = \operatorname{sign}(\psi).$$

In the following proposition we determine $b^{\pm}$ and the signature for a non-singular form that is given by a diagonal matrix.

Proposition 72.8. *If D is a diagonal $(n\times n)$-matrix where the diagonal entries $d_1,\dots,d_n$ are non-zero real numbers, then*

$$b^+(\varphi(D)) \;=\; \text{number of positive } d_i\text{'s} \quad \text{and} \quad b^-(\varphi(D)) \;=\; \text{number of negative } d_i\text{'s}.$$

In particular

$$\operatorname{sign}(\varphi(D)) \;=\; \text{number of positive } d_i\text{'s} \;-\; \text{number of negative } d_i\text{'s}.$$

Proof. After reordering the diagonal entries we can assume that the first k entries of D are positive and that the remaining $(n-k)$ entries are negative. We write

$$\begin{aligned} V^+ &:= \{(x_1,\dots,x_k,0,\dots,0)\in\mathbb{R}^n \mid x_1,\dots,x_k\in\mathbb{R}\} \quad \text{and} \\ V^- &:= \{(0,\dots,0,y_1,\dots,y_{n-k})\in\mathbb{R}^n \mid y_1,\dots,y_{n-k}\in\mathbb{R}\} \end{aligned}$$

It is clear that $\varphi(D)|_{V^+}$ is positive-definite and that $\varphi(D)|_{V^-}$ is negative-definite. Thus $b^+(\varphi(D))\ge k$ and $b^-(\varphi(D))\ge n-k$. If remains to prove the following claim.

Claim. For any symmetric form (W,ψ) over $\mathbb{R}$ we have $b^+(\psi)+b^-(\psi)\le\dim_{\mathbb{R}}(W)$.

Thus let W^+ be a positive-definite subspace of W and let W^- be a negative-definite subspace of W. The intersection $W^+\cap W^-$ is a subspace that is positive-definite and negative-definite. So for any non-zero vector $v\in W^+\cap W^-$ we have $\psi(v,v)>0$ and $\psi(v,v)<0$. This is only possible if no such v exists, i.e. we have shown that the intersection $W^+\cap W^-=\{0\}$. Now we see that

$$\dim(W^+)+\dim(W^-) \underset{\substack{\uparrow\\ \text{linear algebra}}}{=} \dim(W^++W^-)+\dim(W^+\cap W^-) \underset{\substack{\uparrow\\ W^+\cap W^-=\{0\}}}{=} \dim(W^++W^-) \underset{\substack{\uparrow\\ \text{since } W^++W^-\subset W}}{\le} \dim(W).$$

This concludes the proof of the claim. □

Corollary 72.9.

(1) *Let (V,φ) be a non-singular symmetric form over $\mathbb{R}$. We write $n=\dim_{\mathbb{R}}(V)$. The following statements hold:*
   (a) *we have $b^{\pm}(-\varphi)=b^{\mp}(\varphi)$, in particular we have $\operatorname{sign}(-\varphi)=-\operatorname{sign}(\varphi)$,*
   (b) *we have $b^+(\varphi)+b^-(\varphi)=\dim_{\mathbb{R}}(V)$,*
   (c) *we have $b^+(\varphi)=\frac{1}{2}(n+\operatorname{sign}(\varphi))$,*
   (d) *if we write $k=b^+(\varphi)$, then the form (V,φ) is isometric to $k\cdot(+1)\oplus(n-k)\cdot(-1)$.*

(2) *If (V,φ) and (W,ψ) are two non-singular symmetric forms over $\mathbb{R}$, then*

$$\operatorname{sign}(\varphi\oplus\psi) \;=\; \operatorname{sign}(\varphi)+\operatorname{sign}(\psi).$$

Proof.

(1) (a) This statement follows immediately from the definitions.
(b) By Proposition 72.6 and Lemma 72.7 it suffices to prove the statement for non-singular symmetric forms that are represented by diagonal matrices. But for those forms the statement follows immediately from Proposition 72.8.
(c) This statement is an immediate consequence of (b) and the definition of the signature.
(d) This statement follows from Proposition 72.6, Lemma 72.7 and Proposition 72.8.

(2) This statement follows immediately from statement (b), Proposition 72.6 applied to φ and ψ and Proposition 72.8. □

Example. Given a non-singular symmetric form φ on $\mathbb{R}^3$ one can visualize it by considering the "unit-sphere"

$$S(\varphi) \;:=\; \{v \in \mathbb{R}^3 \,|\, \varphi(v,v) = 1\}.$$

Corollary 72.9 (3) implies in particular that every non-singular symmetric form on $\mathbb{R}^3$ is isometric to one of the following four forms

(a) $3 \cdot (1)$, (b) $2 \cdot (1) \oplus (-1)$
(c) $2 \cdot (-1) \oplus (1)$ (d) $3 \cdot (-1)$.

In the last case the unit-sphere is the empty set. In the other cases the unit-spheres are sketched in Figure 911.

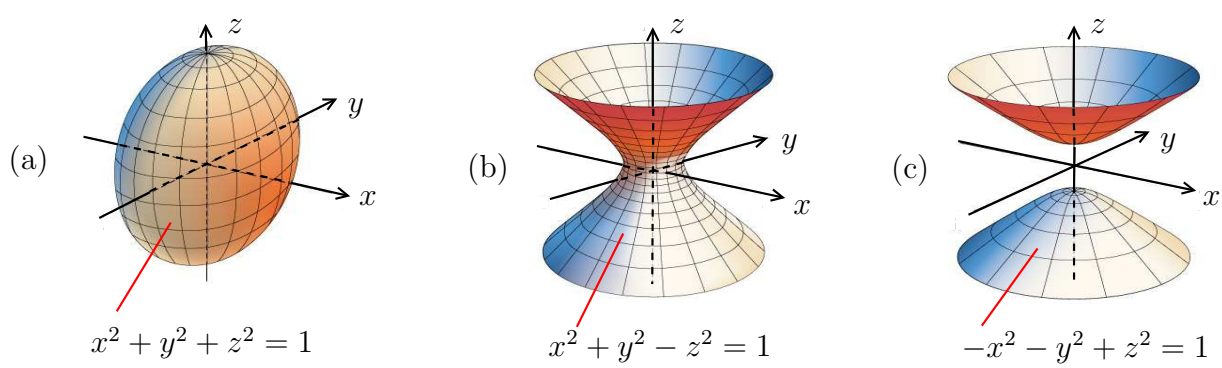


FIGURE 911.

The following theorem says that the dimension and the signature are a complete invariant for isometry types of non-singular symmetric forms over $\mathbb{R}$.

Theorem 72.10. (Sylvester's Theorem a. k. a. Sylvester's law of inertia) *Let* (V,φ) *and* (W,ψ) *be two non-singular symmetric forms over* $\mathbb{R}$. *Then*

$$(V,\varphi) \text{ and } (W,\psi) \text{ are isometric} \quad\Longleftrightarrow\quad \dim_{\mathbb{R}}(V) = \dim_{\mathbb{R}}(W) \text{ and } \operatorname{sign}(\varphi) = \operatorname{sign}(\psi).$$

Proof. The "⇒"-direction is precisely Lemma 72.7. It remains to prove the "⇐"-direction. So suppose we are given two non-singular symmetric forms (V,φ) and (W,ψ) over $\mathbb{R}$ with same dimension and same signature. It follows from our hypothesis together with Corollary 72.9 (c) and (d) that there exist $n,k \in \mathbb{N}_0$ such that (V,φ) and (W,ψ) are both isometric to $k\cdot(+1)\oplus(n-k)\cdot(-1)$. But this implies that (V,φ) and (W,ψ) are themselves isometric. □

Remark. It is also very easy to classify symmetric forms over $\mathbb{R}$ that are not necessarily non-singular. More precisely, given a symmetric form (V,φ) over $\mathbb{R}$ we define the *nullity* $\sigma(\varphi)$ as

$$\nu(\varphi) \;:=\; \text{maximal dimension of a subspace } W \text{ of } V \text{ such that } g|_W \text{ is the zero form.}$$

It is an amusing little exercise to modify the proof of Sylvester's Theorem 72.10 to show that two symmetric forms over $\mathbb{R}$ are isometric if and only if their dimensions, signatures and nullities agree.

Now it is time to apply our recently acquired knowledge to topology.

Definition.

(1) If (V,φ) is a symmetric form over the integers, then we define

$$\begin{array}{rcl} g\otimes\mathbb{R}\colon V\otimes\mathbb{R}\times V\otimes\mathbb{R} & \to & \mathbb{R} \\ (v\otimes r, w\otimes s) & \mapsto & r\cdot\varphi(v,w)\cdot s \end{array}.$$

Furthermore we define

$$\operatorname{sign}(\varphi) \;:=\; \operatorname{sign}(\varphi\otimes\mathbb{R}).$$

(2) Let $k\geq 1$. Let M be a closed oriented non-empty $4k$-dimensional topological manifold. We define the *signature of M* to be[1207]

$$\operatorname{sign}(M) \;:=\; \operatorname{sign}(Q_M).$$

For convenience we define the signature of the empty manifold to be zero.

Lemma 72.11. *Let $k\in\mathbb{N}$.*

(1) *Let M be a closed oriented non-empty $4k$-dimensional manifold. The form $Q_M\otimes\mathbb{R}$ is isometric to the form*

$$\begin{array}{rcl} H^{2k}(M;\mathbb{R})\times H^{2k}(M;\mathbb{R}) & \to & \mathbb{R} \\ (\varphi,\psi) & \mapsto & \langle\varphi\cup\psi,[M]\rangle. \end{array}$$

(2) *The signature is additive under the connected sum operation and under disjoint union.*

(3) *For any closed oriented non-empty $4k$-dimensional topological manifold we have*

$$\operatorname{sign}(-M) \;=\; -\operatorname{sign}(M).$$

[1207]Recall that by Proposition 71.5 the intersection form Q_M is indeed symmetric, so it makes sense to consider its signature.

(4) *Let M and N be two closed oriented non-empty $4k$-dimensional topological manifolds. If M and N are homeomorphic, then* $\operatorname{sign}(M) = \pm \operatorname{sign}(N)$.

Proof.

(1) This statement follows easily from the various definitions and Corollary 42.20.
(2) It follows easily from lemma 59.9 that the signature is additive under disjoint union. Furthermore it follows easily from Proposition 71.11 and Corollary 72.9 that the signature is additive under the connected sum operation.
(3) The second statement is an immediate consequence of Lemma 71.7 and Corollary 72.9.
(4) The last statement is also an immediate consequence of Lemma 71.7 and Corollary 72.9. □

Examples. We have

$$\begin{array}{ccccccccc}
\operatorname{sign}(\mathbb{C}\mathrm{P}^2\#\mathbb{C}\mathrm{P}^2) & = & \operatorname{sign}(\mathbb{C}\mathrm{P}^2) + \operatorname{sign}(\mathbb{C}\mathrm{P}^2) & = & \operatorname{sign}(1) + \operatorname{sign}(1) & = & 1+1 & = & 2 \\
 & \uparrow & & \uparrow & & & & & \\
 & \text{Lemma 72.11 (2)} & & \text{see page1656} & & & & & \\
 & \downarrow & & \downarrow & & & & & \\
\operatorname{sign}(\mathbb{C}\mathrm{P}^2\#\overline{\mathbb{C}\mathrm{P}}^2) & = & \operatorname{sign}(\mathbb{C}\mathrm{P}^2) - \operatorname{sign}(\mathbb{C}\mathrm{P}^2) & = & \operatorname{sign}(1) - \operatorname{sign}(1) & = & 1-1 & = & 0.
\end{array}$$

Furthermore we have

$$\operatorname{sign}(S^2 \times S^2) \underset{\substack{\uparrow \\ \text{see page 1655}}}{=} \operatorname{sign}\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \underset{\substack{\uparrow \\ \text{Lemma 72.1}}}{=} \operatorname{sign}\left(\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} \cdot \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \cdot \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}\right) = \operatorname{sign}\begin{pmatrix} 2 & 0 \\ 0 & -2 \end{pmatrix} \underset{\substack{\uparrow \\ \text{Proposition 72.8}}}{=} 0.$$

The above examples, together with Lemmas 71.7 and 72.11 (4) now allow us to give a partial answer to Question 43.10.

Corollary 72.12. *The topological space $\mathbb{C}\mathrm{P}^2\#\mathbb{C}\mathrm{P}^2$ is neither homeomorphic to $\mathbb{C}\mathrm{P}^2\#\overline{\mathbb{C}\mathrm{P}}^2$ nor to $S^2 \times S^2$.*

Remark. Corollary 72.12 shows in particular that in the definition of the connected sum of two orientable (topological) manifolds we needed to work with *oriented* (*topological*) *manifolds.*

Unfortunately we are not yet able to distinguish the two manifolds $S^2 \times S^2$ and $\mathbb{C}\mathrm{P}^2\#\overline{\mathbb{C}\mathrm{P}}^2$. In fact Sylvester's Theorem 72.10 might suggest that we are again at a dead end. But this is not the case since Sylvester's Theorem is a statement about *real* symmetric forms, but we are really dealing with symmetric forms defined over the integers. We will exploit this extra piece of information in the next section.

72.4. **Non-singular symmetric forms over the integers.** In this section we want to study symmetric forms over the integers. We start out with the following slightly silly looking definition.

Definition. A symmetric form (V, φ) over the integers is called *even* if

$$\varphi(v, v) \equiv 0 \mod 2 \quad \text{for all } v \in V,$$

otherwise the intersection form is called *odd*. We refer to the property of φ being even or odd as the *parity* of the form.

The following lemma summarizes some basic facts about the parity of symmetric forms.

Lemma 72.13.

(1) *Isometric forms have the same parity.*
(2) *For a symmetric form φ the parities of φ and $-\varphi$ agree.*
(3) *The direct sum of an odd form with any other form is also odd.*
(4) *If A is a symmetric square matrix over the integers, then*

$$\varphi(A) \text{ is even} \quad \Longleftrightarrow \quad \text{all diagonal entries of } A \text{ are even.}$$

Examples. It follows from Lemma 72.13 that the forms $(+1)$, (-1) and $\begin{pmatrix} \pm 1 & 0 \\ 0 & \pm 1 \end{pmatrix}$ are odd and that the forms E_8 and $H = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ are even.

Proof. The only statement which requires a little thought is the fact that if $A = (a_{ij})$ is a symmetric $(n \times n)$-matrix with even diagonal entries, then $\varphi(A)$ is even. Thus let $v = (v_1, \dots, v_n) \in \mathbb{Z}^n$. We calculate that

$$\varphi(A)(v, v) = v^T A v = \sum_{i=1}^{n} \sum_{j=1}^{n} v_i v_j \cdot a_{ij} \underset{\substack{\uparrow \\ \text{since } A \text{ is symmetric}}}{=} 2 \sum_{i=1}^{n} \sum_{j=1}^{i-1} v_i v_j \cdot a_{ij} + \sum_{i=1}^{n} v_i^2 a_{ii} \underset{\substack{\uparrow \\ \text{since the } a_{ii} \text{ are even}}}{\equiv} 0 \bmod 2. \qquad \square$$

It follows immediately from these examples and the earlier calculations of the intersection forms that the intersection form of $S^2 \times S^2$ is even whereas the intersection form of $\mathbb{C}\mathrm{P}^2 \# \overline{\mathbb{C}\mathrm{P}}^2$ is odd. This allows us to settle the remaining case of Question 43.10. More precisely, by Lemma 71.7 and Lemma 72.13 (1) and (2) we have the following proposition.

Proposition 72.14. *The topological space $S^2 \times S^2$ is not homeomorphic to $\mathbb{C}\mathrm{P}^2 \# \overline{\mathbb{C}\mathrm{P}}^2$.*

We consider the matrices

$$H = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \quad \text{and } D = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

It follows from Sylvester's Theorem 72.10 that the matrices give rise to *isometric forms over the real numbers*. On the other had we had just seen, using the parity, that the matrices give rise to *non-isometric forms over the integers*. The question arises, how much more complicated is the classification of non-singular symmetric forms over the integers than the classification of non-singular forms over the real numbers. In particular the following question arises.

Question 72.15. *Can we classify non-singular symmetric forms over the integers?*

The following is the key theorem in the classification of non-singular *indefinite* symmetric forms over $\mathbb{Z}$.

Theorem 72.16. *If φ_1 and φ_2 are two non-singular* indefinite *symmetric forms over the integers, then the following holds:*

$$\varphi_1 \text{ and } \varphi_2 \text{ are isometric} \quad \Longleftrightarrow \quad \varphi_1 \text{ and } \varphi_2 \text{ have the same rank, signature and parity.}$$

Example. Using the parity we had just seen that the intersection forms of the closed oriented 4-dimensional manifolds $M = S^2 \times S^2$ and $N = \mathbb{C}\mathrm{P}^2 \# \overline{\mathbb{C}\mathrm{P}}^2$ are not isometric, even up to sign. Now we consider the closed oriented 4-dimensional manifolds that we obtain from M and N by performing the connected sum with $\mathbb{C}\mathrm{P}^2$. In other words, we are considering $M \# \mathbb{C}\mathrm{P}^2 = (S^2 \times S^2) \# \mathbb{C}\mathrm{P}^2$ and $N \# \mathbb{C}\mathrm{P}^2 = \mathbb{C}\mathrm{P}^2 \# \overline{\mathbb{C}\mathrm{P}}^2 \# \mathbb{C}\mathrm{P}^2$. It follows from Proposition 71.11 that the intersection forms of these two manifolds are represented by the matrices

$$A \;=\; \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix} \quad \text{and} \quad B \;=\; \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$

Both forms are non-singular indefinite and odd. Thus it follows from Theorem 72.16 that the intersection forms are isometric. Thus we cannot distinguish $M \# \mathbb{C}\mathrm{P}^2 = (S^2 \times S^2) \# \mathbb{C}\mathrm{P}^2$ and $N \# \mathbb{C}\mathrm{P}^2 = \mathbb{C}\mathrm{P}^2 \# \overline{\mathbb{C}\mathrm{P}}^2 \# \mathbb{C}\mathrm{P}^2$ using their intersection forms. In fact, it turns out that there is a good reason why we have a hard time distinguishing them: as is shown in [GS, p. 151] the two manifolds are in fact diffeomorphic, in fact with good eyes one can write down an explicit diffeomorphism.

Proof. The proof of the theorem is provided in [MH, Theorem II.5.3] (see also [GS, Theorem 1.2.14] for an alternative summary). The proof relies crucially on a significant input from algebraic theory, namely the Hasse-Minkowski theorem. This theorem says that given $a_1, \ldots, a_n \in \mathbb{Q} \setminus \{0\}$ the equation

$$x_1^2 \cdot a_1 + \cdots + x_n^2 \cdot a_n \;=\; 0$$

has a non-trivial integral solution if and only if it has a non-trivial real solution and if for each prime p the equation has also has a non-trivial solution over the p-adic numbers $\mathbb{Q}_p$. A proof of the Hasse-Minkowski theorem is given in [Ser2, Chapter IV Theorem 8], [BSh, Section 7.1] or [Neuk, p. 385]. □

As an immediate corollary to Theorem 72.16 we obtain the classification of non-singular *indefinite odd* forms. More precisely, we have the following corollary.

Corollary 72.17. *If φ is a non-singular indefinite odd symmetric form over the integers, then*

$$\varphi \;\cong\; b^+(\varphi) \cdot (1) \oplus b^-(\varphi) \cdot (-1).$$

Proof. Let φ be a non-singular indefinite odd symmetric form. It follows from Proposition 72.8 that the rank, signature and parity of the two non-singular indefinite odd forms in the statement of the corollary agree. So these two forms are isometric by Theorem 72.16. $\square$

Now we turn to the study of even forms. We have the following, perhaps somewhat surprising proposition.

Proposition 72.18. *Let φ be a non-singular symmetric form over the integers. If φ is even, then* $\operatorname{sign}(\varphi) \equiv 0 \bmod 8$.

Example. As a reality check, the two even non-singular symmetric forms that we are acquainted with are $H = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ and E_8. These forms a non-singular even forms and the signatures are 0 and 8, so that matches Proposition 72.18.

Proof. Given a non-singular symmetric form (W, ψ) over $\mathbb{Z}$ we say that a vector $w \in W$ is *characteristic* if for all $u \in W$ we have

$$\varphi(u, w) \;\equiv\; \varphi(w, w) \mod 2.$$

We make the following observations:

(1) It follows easily from the definitions that (W, ψ) is even if and only if 0 is a characteristic vector.
(2) If $W = k \cdot (1) \oplus l \cdot (-1)$, then it is straightforward to show that a vector $u \in \mathbb{Z}^{k+l}$ is characteristic if and only if all its entries are odd.

It follows from Observation (1) that the following claim implies in particular the desired statement of Proposition 72.18.

Claim. Let (V, φ) be a non-singular symmetric form over $\mathbb{Z}$. If $v \in V$ is a characteristic vector, then

$$\varphi(v, v) \;\equiv\; \operatorname{sign}(\varphi) \mod 8.$$

Let $v \in V$ be a characteristic vector of (V, φ). It is straightforward to verify that $v + e_- + e_+$ is a characteristic vector in $(V \oplus \mathbb{Z} \oplus \mathbb{Z}, \varphi \oplus (1) \oplus (-1))$, where e_- and e_+ are generators of the first respectively the second $\mathbb{Z}$-summand. By Corollary 72.17 there exists an isometry[1208]

$$\Phi \colon \varphi \oplus (1) \oplus (-1) \;\xrightarrow{\cong}\; (b^+(\varphi) + 1) \cdot (1) \oplus (b^-(\varphi) + 1) \cdot (-1).$$

We write $u := \Phi(v + e_- + e_+)$. It is straightforward to verify that u is a characteristic vector for the form on the right-hand side. The above Observation (2) tells us that each

[1208]Note that both sides are non-singular odd indefinite forms, regardless of what non-singular symmetric form φ we actually consider.

entry of u is an odd number. Now we calculate that

$$\begin{aligned}
\varphi(v,v) &\overset{\substack{\text{straightforward calculation}\\ \downarrow}}{=} (\varphi \oplus (1) \oplus (-1))(v + e_- + e_+, v + e_- + e_+) \overset{\substack{\text{since } \Phi \text{ is an isometry}\\ \downarrow}}{=} \\
&= ((b^+(\varphi)+1)\cdot(1) \oplus (b^-(\varphi)+1)\cdot(-1))(u,u) \\
&= \sum_{i=1}^{b^+(\varphi)+1} (\underbrace{i\text{-th entry of } u}_{\text{odd integer}})^2 + \sum_{i=b^+(\varphi)+2}^{b^+(\varphi)+b^-(\varphi)+2} (-1)\cdot(\underbrace{i\text{-th entry of } u}_{\text{odd integer}})^2 \\
&\underset{\substack{\uparrow\\ \text{since for each odd number } k \text{ we have } k^2 \equiv 1 \bmod 8}}{\equiv} \sum_{i=1}^{b^+(\varphi)+1} 1 + \sum_{i=b^+(\varphi)+2}^{b^+(\varphi)+b^-(\varphi)+2} (-1) = (b^+(\varphi)+1) - (b_-(\varphi)+1) = \operatorname{sign}(\varphi) \bmod 8.
\end{aligned}$$

This concludes the proof of the claim. □

Now we can provide the classification of non-singular indefinite *even* symmetric forms.

Corollary 72.19. *If φ is a non-singular indefinite even symmetric form, then*

$$\varphi \cong \tfrac{\operatorname{sign}(\varphi)}{8} \cdot E_8 \oplus \tfrac{\operatorname{rank}(\varphi) - |\operatorname{sign}(\varphi)|}{2} \cdot H.$$

Proof. First note that it follows from Proposition 72.18 that $\operatorname{sign}(\varphi)$ is indeed divisible by 8. Furthermore it follows from $\operatorname{rank}(\varphi) = b_+(\varphi) + b_-(\varphi)$ and $\operatorname{sign}(\varphi) = b_+(\varphi) - b_-(\varphi)$ that $\operatorname{rank}(\varphi) - |\operatorname{sign}(\varphi)|$ is divisible by 2. So it makes sense to write down the right-hand side.

Next we recall that the two non-singular symmetric forms E_8 and H are even, that $\operatorname{rank}(E_8) = \operatorname{sign}(E_8) = 8$ and that $\operatorname{rank}(H) = 2$ and $\operatorname{sign}(H) = 0$. Now let φ be a non-singular indefinite even symmetric form. It follows from the above observation regarding E_8 and H that the rank, signature and parity of the two non-singular indefinite even forms in the statement of the corollary agree. So these two forms are isometric by Theorem 72.16. □

Now we turn to the study of non-singular definite symmetric forms over the integers. We start out with some more examples of such forms. The following lemma is proved in [MH, Lemmas 6.1 and 6.2] and [Ser2, p. 51].

Lemma 72.20. *We denote by $e_1, \dots, e_{4m}$ the standard basis for $\mathbb{Z}^{4m}$. We denote by Γ_{4m} the submodule of $\mathbb{Z}^{4m}$ spanned by the vectors $\{e_i + e_j\}_{i,j=1,\dots,4m}$ and $\frac{1}{2}(e_1 + \cdots + e_{4m})$. Then the following statements hold:*

1. *The restriction of the usual form $\langle\, ,\, \rangle$ on $\mathbb{Z}^{4m}$ to Γ_{4m} is a non-singular positive-definite symmetric form.*
2. *The form Γ_{4m} is odd if and only if m is odd.*
3. *The form Γ_8 is isometric to E_8.*
4. *The form Γ_{16} is not isometric to $E_8 \oplus E_8$.*

[1209] Why is it true that for each odd number k we have $k^2 \equiv 1 \bmod 8$?

It turns out that there are many more definite symmetric forms than indefinite symmetric forms and that there is no known classification of such forms. For example, by [MH, p. 28] and [Ser2, p. 55] we have the following table

dimension	8	16	24	32	40
number of isometry types of non-singular positive-definite even symmetric forms	1	2	24	$\geq 10^7$	$\geq 10^{51}$

Here in dimension 8, up to isometry, the unique example is $\Gamma_8 = E_8$ whereas in dimension 16 the unique examples are $\Gamma_8 \oplus \Gamma_8 = E_8 \oplus E_8$ and Γ_{16}.

Similar results are also known for the number of isometry classes of non-singular positive-definite odd symmetric forms of a given rank. We refer to [CS, p. 416] and [Kin, Table 2] for details.

72.5. **The intersection forms of 4-dimensional (topological) manifolds.** We have now introduced lots of invariants of topological spaces, namely the fundamental group, higher homotopy groups, homology groups and the cohomology groups together with the cup product. The question arises, whether we are done at some point, or whether this list of ever new invariants continues forever.

In an attempt to respond to this question we now want to consider simply connected 4-dimensional (topological) manifolds and their intersection forms. We are interested in the following two questions:

Question 72.21.

(1) *Is the intersection form a complete invariant of a simply connected 4-dimensional (topological) manifold?*[1210]
(2) *Which isometry types of non-singular symmetric forms are realized by simply connected 4-dimensional (topological) manifolds?*

In the remainder of this section we give a mostly chronological account of the developments regarding the two (or possibly four?) questions posed above.

In the previous section we introduced the initially rather unexpected form E_8. One might wonder whether a form as strange as E_8 can ever appear "in nature". As we will now see, somewhat surprisingly this is indeed the case.

Definition. We refer to

$$K3 \;:=\; \left\{[z_1 : z_2 : z_3 : z_4] \in \mathbb{C}\mathrm{P}^3 \,\middle|\, z_1^4 + z_2^4 + z_3^4 + z_4^4 = 0\right\}$$

as the *K3-surface*.

[1210]Note that for a simply connected 4-dimensional topological manifold M we have $H_1(M;\mathbb{Z}) = 0$ by the Hurewicz Theorem 38.5 and consequently we have $H_3(M;\mathbb{Z}) = 0$ by the Poincaré Duality Theorem 61.1. Thus we see that for simply connected 4-dimensional topological manifolds the intersection form contains all the (co-) homological data we could ask for.

Remark. The odd name "K3-surface" comes about as follows. First of all, as we will see in Proposition 72.22, K3 is a *2-dimensional* complex manifold, i.e. it is a complex surface. According to [OTL] the definition of the K3-surface is already implicit in the work of Srinivasa Ramanujan in the 1910s. The K3-surface was (re-) discovered by André Weil [Weil] who named it in honor of three algebraic geometers, Kummer, Kähler and Kodaira, and also the mountain K2 in Pakistan which is the second highest mountain on earth.[1211]

The following proposition summarizes some of the key aspects of the K3-surface.

Proposition 72.22. *The K3-surface is a closed simply connected complex manifold of complex dimension 2 or equivalently of real dimension 4. Furthermore we have*

$$\textit{intersection form of the K3-surface} \cong 2 \cdot E_8 \oplus 3 \cdot H.$$

Proof. All the statements are proved in [GS, Theorem 1.3.8] or alternatively [McS, p. 176]. The intersection form is also calculated in [Huy, Proposition 3.5]. The calculation of the intersection form, perhaps somewhat disappointingly, makes use of Corollary 72.19. □

The K3-surface plays a big role in (algebraic) geometry, as is indicated by the fact that a whole book [Huy] is dedicated to the study of the K3-surfaces. In the following we want to discuss one particular aspect. Namely, the calculation of the intersection form of the K3-surface, of the intersection form of $S^2 \times S^2$ and Proposition 71.11 raises the question whether one can split off copies of $S^2 \times S^2$ form the K3-surface. More precisely the following question arose almost immediately after the introduction of the K3-surface.

Question 72.23.

(1) *Does there exist a closed oriented 4-dimensional topological manifold M such that the K3-surface is homeomorphic to $M \# S^2 \times S^2$?*
(2) *Does there exist a closed oriented 4-dimensional manifold M such that the K3-surface is diffeomorphic to $M \# S^2 \times S^2$?*

We will return to the question shortly. But before we do so, we continue with our chronological discussion. The following theorem of Vladimir Rokhlin from 1952 was the first result to address Question 72.21 (2).

Theorem 72.24. (Rokhlin 1952) *Let X be a closed oriented 4-dimensional manifold. If the intersection form Q_X is even and if $H_1(X;\mathbb{Z})$ has no 2-torsion, then* $\operatorname{sign}(X)$ *is divisible by 16.*[1212]

[1211] More precisely, André Weil wrote: "Dans la seconde partie de mon rapport, il s'agit des varietés kähleriennes dites K3, ainsi nommées en l'honneur de Kummer, Kähler, Kodaira et de la belle montagne K2 au Cachemire".

[1212] Recall that from Proposition 72.18 we know, for purely algebraic reasons, that the signature of a non-singular even symmetric form is divisible by 8.

Remark. The slightly odd condition on $H_1(X;\mathbb{Z})$ is actually necessary. Indeed, by [Hab, FS] there exists a closed oriented 4-dimensional manifold X with 2-torsion in $H_1(X;\mathbb{Z})$ and with an even intersection form Q_X that satisfies $\operatorname{sign}(X) = 8$.

Outline of proof. Let X be a closed oriented 4-dimensional manifold such that the intersection form Q_X is even and such that $H_1(X;\mathbb{Z})$ has no 2-torsion. It follows from [GS, Corollary 5.7.6] that the manifold X admits a "spin structure". The definition of a "spin structure" is for example given in [GS, Chapter 1.4.2], but it is of no concern to us. What matters is that Rokhlin [Rok][Rok2, p. 21] showed that for any closed oriented 4-dimensional manifold that admits a spin structure, the signature is divisible by 16. More modern proofs of Rokhlin's Theorem are given in [FK] and [Sav2, Theorem 2.1]. □

The following theorem was the first noteworthy result towards an affirmative answer to Question 72.21 (1).

Theorem 72.25. (Milnor 1958) *Let X and Y be two closed oriented simply connected 4-dimensional topological manifolds. Then*

$$X \text{ and } Y \text{ are homotopy equivalent} \iff Q_X \text{ is isometric to } \pm Q_Y.$$

Proof. This theorem was proved for manifolds by John Milnor [Mi6, Theorem 3] in 1958, building on work of John Whitehead [Whd3]. Furthermore [GS, Theorem 1.2.25] sketches a proof that also works for topological manifolds. □

After these somewhat preliminary results by Vladimir Rokhlin and John Milnor the early 1980s saw two major breakthroughs by Michael Freedman and Simon Donaldson.

First, in 1981 Michael Freedman [Fre] gave a complete answer to Question 72.21 in the category of topological manifolds.[1213] More precisely, Michael Freedman [Fre] proved the following theorem.

Theorem 72.26. (Freedman 1981) *Let Q be a nonsingular symmetric form over the integers.*

(1) *If Q is even, then up to an orientation-preserving homeomorphism, there exists a unique closed oriented simply connected topological manifold whose intersection form is isometric to Q.*
(2) *If Q is odd, then up to orientation-preserving homeomorphisms, there exist precisely two closed oriented simply connected topological manifolds whose intersection forms are isometric to Q.*

Remark.

(1) Later we will see that for a simply connected topological space the Hurewicz homomorphism $\pi_2(X) \to H_2(X;\mathbb{Z})$ is an isomorphism. In particular, if $\pi_2(X)$ vanishes, then $H_2(X;\mathbb{Z}) = 0$. This fact shows that Theorem 72.26, applied to the form on the trivial group $\{0\}$, implies in particular Theorem 28.23.

[1213] Michael Freedman (*1951) is an American mathematician, in 1986 he was awarded the Fields medal for the proof of Theorem 72.26.

(2) On page 1656 we saw that the intersection form of $\mathbb{C}\mathrm{P}^2$ is represented by the (1×1)-matrix (1). Theorem 72.26 (2) says that there exists a closed oriented simply connected topological 4-manifold $\mathbb{C}\mathrm{P}^{2*}$ with the same intersection as $\mathbb{C}\mathrm{P}^2$ but that is not homeomorphic to $\mathbb{C}\mathrm{P}^2$. Furthermore $\mathbb{C}\mathrm{P}^{2*}$ is unique up to an orientation-preserving homeomorphism.
(3) The two homeomorphism types of Theorem 72.26 are distinguished by the Kirby-Siebenmann invariant, see [KSi2] or [Rudy2, Chapter 3.4]. This invariant is defined for any closed topological manifold X of any dimension and it takes values in $H^4(X;\mathbb{Z}_2)$.[1214] By [Rudy2, Theorem 3.4.3] this invariant vanishes if X admits a "piecewise linear structure". For manifolds of dimension ≤ 7 any manifold, i.e. any topological manifold with a smooth structure, also admits a "piecewise linear structure". We refer to [Cer, p. IX] and [Sco, p. 220] for more details.
(4) Freedman's Theorem also answers Question 72.23 (1) in the affirmative. More precisely, by the existence statement of Theorem 72.26 (1) there exists a closed oriented 4-dimensional topological manifold X with $Q_X \cong E_8$. Furthermore, by the uniqueness statement of Theorem 72.26 (1) there exists a homeomorphism of the K3-surface to $X\#X\#3\cdot(S^2\times S^2)$.

Among many other consequences we obtain the following rather surprising result.

Theorem 72.27. *There exist closed orientable 4-dimensional topological manifolds that do not admit a smooth structure.*

Proof. At this point we can combine the above results to give two types of examples of such manifolds:

(1) It follows from Theorem 72.26 (2) and the above Remark (3) that given any non-singular odd symmetric form Q there exists a closed oriented 4-dimensional topological manifold X with $Q_X \cong Q$ and non-trivial Kirby-Siebenmann invariant. As we pointed out above in Remark (3), this topological manifold does not admit a smooth structure.
(2) If we apply Freedman's Theorem 72.26 (1) to the non-singular positive-definite even form E_8 we obtain a certain 4-dimensional topological manifold which, by Rokhlin's Theorem 72.24, cannot admit a smooth structure. □

In a remarkable twist, shortly after Freedman proved his results on the intersection forms of topological 4-dimensional manifolds, Simon Donaldson[1215], see [Don, Theorem A] and

[1214]Here it is worth recalling that Proposition 51.14 (3) says that for a closed orientable 4-dimensional topological manifold we have $H^4(X;\mathbb{Z}_2)\cong\mathbb{Z}_2$.

[1215]Simon Donaldson (*1957) is an English mathematician. He proved Theorem 72.28 when he was a second year PhD student. The Fields medalist Michael Atiyah described in [At2] the work of Simon Donaldson as follows: "In 1982, when he was a second-year graduate student, Simon Donaldson proved a result that stunned the mathematical world." Simon Donaldson was awarded the Fields medal in 1986.

[Don2, Theorem 1], proved the following result regarding intersection forms of 4-dimensional manifolds.[1216]

Theorem 72.28. (Donaldson 1982) *Let X be a closed oriented 4-dimensional manifold. If Q_X is positive-definite, then Q_X is represented by the identity matrix.*

To understand the significance of Donaldson's Theorem, often referred to as *Donaldson's Theorem A*, recall that on page 1680 we saw that there are more than 10^{51} isometry classes of non-singular positive-definite symmetric forms of rank 40. By Freedman's Theorem 72.26 all of them arise as intersection forms of closed oriented connected topological 4-manifolds. By Donaldson's Theorem 72.28 the only one which appears as the intersection form of a closed oriented connected 4-dimensional manifold is the one represented by the identity matrix.[1217]

FIGURE 912. The Fields medalists Michael Freedman, Gerhard Faltings and Simon Donaldson at the ICM 1986 in Berkeley.

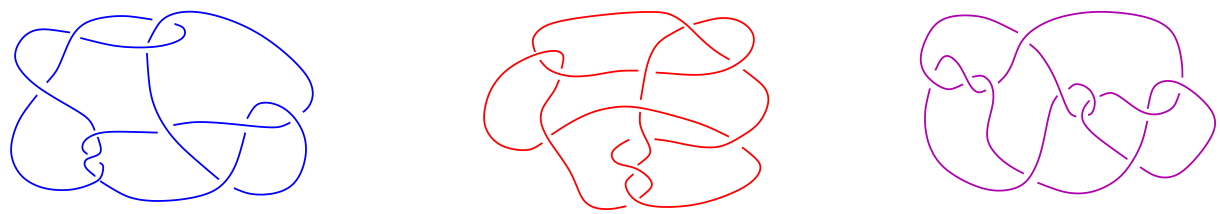
Remark. It is difficult to exaggerate the importance of Donaldson's Theorem in mathematics.[1218] For example it is at the heart of the proof of Theorem 28.27. But Donaldson's Theorem can also appear in totally unexpected situations. For example in 2017 Duncan McCoy [McC] used Donaldson's Theorem, and many other ingredients, to show that if K is an alternating knot that can be unknotted using a single crossing change, then such a crossing change can already be performed in an alternating diagram. For example, according to [CL] the three alternating knots shown in Figure 913 can be unknotted using a single crossing change in *some diagram*. By the aforementioned result we now know that we can turn these three knots into the trivial knot by changing a crossing in the alternating diagrams shown. Which crossings do you need to change?

Now that we have digested Donaldson's Theorem 72.28, the question arises, what can we say about *indefinite* intersection forms of closed oriented 4-dimensional manifolds? First recall that in Corollary 72.17 we saw that every non-singular indefinite odd symmetric form

[1216]An exposition of the proof is also given in [Law] and a different proof, using Seiberg-Witten invariants is given in [Ni2, Theorem 2.4.18] and a proof using Heegaard Floer homology is given in [OS, Theorem 9.1].

[1217]The identity matrix represents, by Proposition 71.11 and the discussion on page 1656, the intersection form of the connected sum of 40 copies of $\mathbb{C}P^2$.

[1218]Admittedly it is also hard to underestimate the role of Donaldson's Theorem outside of mathematics.



the knot $11a_{12}$ the knot $11a_{41}$ the knot $11a_{56}$

FIGURE 913.

is isometric to $m \cdot (1) \oplus n \cdot (-1)$ for some $m, n \in \mathbb{N}$. According to Proposition 71.11 and the discussion on page 1656 every such form is realized by the manifold $m \cdot \mathbb{CP}^2 \# n \cdot \overline{\mathbb{CP}}^2$.

Therefore, in the following we only need to discuss the realizability of non-singular indefinite *even* symmetric forms. Recall that in Corollary 72.19 we showed that every non-singular even indefinite symmetric form is isometric to $m \cdot H \oplus n \cdot E_8$ for some $m \in \mathbb{N}_0$ and $n \in \mathbb{Z} \setminus \{0\}$. The following theorem, proved by Mikio Furuta [Fu2] in 2001 gives some restrictions on the possible values of m and n.

Theorem 72.29. (Furuta's 10/8-Theorem) *If M is a closed oriented connected 4-dimensional manifold with* indefinite *even intersection form, then*

$$b_2(M) \ \geq \ \frac{10}{8} \cdot \operatorname{sign}(M) + 2.$$

In particular[1219] $Q_M \cong m \cdot H \oplus n \cdot E_8$ *with* $m \geq 2|n| + 1$.

Remark. Furuta's 10/8-Theorem allows us to answer Question 72.23 (2) in the negative. More precisely, suppose that we have a decomposition of the K3-surface as a connected sum $M \# N$. We make the following four observations:

(1) Without loss of generality we have $\operatorname{sign}(M) \geq \operatorname{sign}(N)$.
(2) It follows from Proposition 72.22, Lemma 72.13 (3) and Proposition 71.11 that Q_M and Q_N are even.
(3) From Lemma 72.11 (2) and Proposition 72.22 we obtain that $\operatorname{sign}(M) + \operatorname{sign}(N) = 16$.
(4) From Proposition 72.22 and Proposition 71.10 we know the equality $b_2(M) + b_2(N) = 22$.

If we combine these facts with Rokhlin's Theorem 72.24 we obtain easily that $\operatorname{sign}(M) = 16$. Furthermore, it follows from Donaldson's Theorem 72.28 that Q_M is indefinite. Now Furuta's 10/8-Theorem implies that $b_2(M) \geq \frac{10}{8} \cdot 16 + 2 = 22$, but by Proposition 72.22 this equals $b_2(K3)$. Thus we obtain from Proposition 71.10 that $b_2(N) = 0$.[1220] We can

[1219] This second statement follows from the first statement together with Corollary 72.19 and the calculation of the rank and signature of H and E_8.

[1220] By Proposition 71.10 and Proposition 72.22 we also know that $\pi_1(N) = 0$. As we will see later on, the Hurewicz Theorem shows that $\pi_1(N) = 0$ and $H_2(N; \mathbb{Z}) = 0$ implies that $\pi_2(N) = 0$. Thus it follows

conclude that we cannot split off a copy of $S^2 \times S^2$ from $K3$. This answers Question 72.23 (2) in the negative.

Furuta's 10/8 Theorem is not yet optimal since it does not quite close the gap between the forms which we can realize by manifolds and the forms which we can exclude. More precisely it follows from Proposition 71.11, the calculation of the intersection forms of the K3-surface, see Proposition 72.22, and of the intersection form of $S^2 \times S^2$ that for any $m \in \mathbb{Z}\setminus\{0\}$ and any $n \geq 3|m|$ there exists a closed oriented simply connected 4-dimensional manifold with intersection form isometric to $m \cdot E_8 \oplus n \cdot H$. More precisely, we have

$$\text{intersection form of } m \cdot \mathrm{K3} \,\#\, (n - 3|m|) \cdot (S^2 \times S^2) \;\cong\; m \cdot E_8 \oplus n \cdot H.$$

The following conjecture predicts that this result is optimal.

Conjecture 72.30. (11/8-Conjecture) *If M is a closed oriented 4-dimensional manifold with indefinite even intersection form, then*

$$b_2(M) \;\geq\; \tfrac{11}{8} \cdot \operatorname{sign}(M).$$

Equivalently, if $Q_M \cong m \cdot H \oplus n \cdot E_8$ with $n \neq 0$, then $n \geq 3|m|$.[1221]

Remark.

(1) A proof of the 11/8-Conjecture would imply, by Freedman's Theorem 72.26, that any closed oriented simply connected 4-dimensional manifold is *homeomorphic* to either a connected sum of the form $m \cdot \mathbb{C}\mathrm{P}^2 \# n \cdot \overline{\mathbb{C}\mathrm{P}}^2$ or alternatively to a connected sum of the form $m \cdot \mathrm{K3} \# n \cdot (S^2 \times S^2)$.

(2) For simply connected manifolds currently the best result is [HLSX, Corollary 1.13] which says that if M is a closed oriented simply-connected 4-manifold that is not homeomorphic to S^4, $S^2 \times S^2$ or the K3-surface and whose intersection form is indefinite and even, then $b_2(M) \geq \frac{10}{8} \cdot |\operatorname{sign}(M)| + 4$.

The other question which arises in this context is whether closed orientable 4-dimensional manifolds that are homeomorphic are also necessarily diffeomorphic. It turns out that in many cases the answer is very much no. For example the following theorem was proved in 1998 by Ron Fintushel and Ron Stern [FS2].

Theorem 72.31. *There exist closed orientable 4-dimensional manifolds X_i, $i \in \mathbb{N}$ such that each X_i is homeomorphic to the K3-surface, but such that the X_i are pairwise non-diffeomorphic.*

Similar results have been obtained for many other 4-dimensional manifolds, e.g. for $\mathbb{C}\mathrm{P}^2 \# k\overline{\mathbb{C}\mathrm{P}}^2$ with $k = 9$ by Simon Donaldson [Don2] in 1987, $k = 8$ by Dieter Kotschick [Kot]

from Theorem 28.23 that N is homeomorphic to S^4. Since Question 28.26 is still open, we do not know whether N is diffeomorphic to S^4.

[1221]As before, the fact that these two statements are equivalent follows from Corollary 72.19 and the calculation of the rank and signature of H and E_8.

in 1989 and $k = 7$ by Jongil Park [Par] in 2005, and since then also for $k = 6, 5, 4, 3, 2$, see e.g. [AP, AP2] for more details on the history of this problem.

The following question is perhaps the most important problem in the theory of 4-dimensional manifolds.

Question 72.32. *Does every closed oriented connected 4-dimensional manifold M admit infinitely many pairwise non-diffeomorphic smooth structures? Put differently, given any such M, do there always exist infinitely many manifolds M_i, $i \in \mathbb{N}$ which are homeomorphic to M but which are pairwise non-diffeomorphic?*

Note that an affirmative answer to Question 72.32 would also give a positive answer to Question 28.26.

The following theorem, proved by C. T. C. Wall [Wall7] in 1964 (see also [Sco, p. 149]) shows that in some sense homeomorphic simply connected manifolds are not that far from being diffeomorphic.

Theorem 72.33. *Let M and N be two closed oriented simply-connected 4-manifolds. If M and N are homeomorphic, then there exists a $k \in \mathbb{N}$ such that $M\#k \cdot (S^2 \times S^2)$ and $N\#k \cdot (S^2 \times S^2)$ are diffeomorphic.*

This raises the question, whether in the above theorem $k = 1$ suffices. More precisely the following question is still open.

Question 72.34. *Let M and N be two closed oriented simply-connected 4-manifolds that homeomorphic. Is $M\#(S^2 \times S^2)$ diffeomorphic to $N\#(S^2 \times S^2)$?*

There are some indications, see [JZ], that the answer to the above question should be no.

Remark. We conclude with a quick foray into the high-dimensional world. For $n \geq 3$ Wall [Wall3] (see also [Ran, p. 269]) classified diffeomorphism classes of pairs $(M, \partial M)$ where M is an orientable $(n-1)$-connected $2n$-dimensional manifold and where the boundary ∂M is a homotopy sphere. The classification goes via the intersection form and one extra invariant which lies in the homotopy group $\pi_{n-1}(\mathrm{SO}(n))$.

72.6. **Symmetric forms over $\mathbb{F}_2$.** Considering the power of the intersection form of a closed oriented even-dimensional topological manifold it is natural to ask, whether one can obtain similar results for non-orientable topological manifolds.

In fact, suppose we are given a closed $2n$-dimensional topological manifold M (not necessarily orientable). We denote by $[M]_{\mathbb{F}_2} \in H_{2n}(M; \mathbb{F}_2)$ the $\mathbb{F}_2$-fundamental class given by Corollary 46.6. Given $k \in \mathbb{N}_0$ we denote by

$$\mathrm{PD}_M^{\mathbb{F}_2} \colon H_k(M; \mathbb{F}_2) \;\to\; H^{2n-k}(M; \mathbb{F}_2)$$

the inverse of the isomorphism given by the Poincaré Duality Theorem 61.1. With these we define the $\mathbb{F}_2$-*valued intersection form*

$$\begin{array}{rcl} H_n(M; \mathbb{F}_2) \times H_n(M; \mathbb{F}_2) & \to & \mathbb{F}_2 \\ (a, b) & \mapsto & \big\langle \mathrm{PD}_M^{\mathbb{F}_2}(a) \cup \mathrm{PD}_M^{\mathbb{F}_2}(b), [M]_{\mathbb{F}_2} \big\rangle. \end{array}$$

The above definition is completely analogous to the definition on page 1652. Basically the same argument as in Proposition 71.5 shows that the $\mathbb{F}_2$-valued intersection form is symmetric and non-singular. Furthermore, as in Lemma 71.7 one can show easily that the $\mathbb{F}_2$-valued intersection forms of homeomorphic closed topological manifolds are isometric.

Examples.

(1) Similar to the discussion on page 1655 one can show that the $\mathbb{F}_2$-valued intersection form of the torus $S^1 \times S^1$ is represented by the matrx $\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$.

(2) Proposition 62.16, together with the obvious analogue of Proposition 71.11, implies that the $\mathbb{F}_2$-valued intersection form of $\mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2$ is represented by the matrx $\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$.

The question arises, whether we can classify non-singular symmetric forms over $\mathbb{F}_2$. For better or worse it turns out that there is a straightforward classification. To state the classification we need the following definition.

Definition. Let V be a finite-dimensional $\mathbb{F}_2$-vector space. We say a form $\lambda\colon V \times V \to \mathbb{F}_2$ is *even* if $\lambda(v, v) = 0 \in \mathbb{F}_2$ for all $v \in V$. Otherwise we say that the symmetric form is *odd*. We call the property of a form to be even or odd to be the *parity* of the form.

Example. As we had just seen, the $\mathbb{F}_2$-valued intersection form of the torus $S^1 \times S^1$ is even whereas the $\mathbb{F}_2$-valued intersection form of the torus $\mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2$ is odd. Thus we have found a new, and particularly complicated, proof that these two 2-dimensional manifolds are not homeomorphism.

The following proposition gives a complete classification of non-singular symmetric forms over $\mathbb{F}_2$ up to isometry.

Proposition 72.35. *Two non-singular symmetric forms (V, κ) and (W, λ) are isometric if and only if $\dim(V) = \dim(W)$ and if κ and λ have the same parity.*

Proof. The proposition is proved in [Hopk, Theorem 2.7]. It can also be deduced from [Szy, Corollary 6.3.1]. □

The proposition shows that, unfortunately, we extract only very little information from the $\mathbb{F}_2$-valued intersection form.

Exercises for Chapter 72.

Exercise 72.1. Let φ be a symmetric form on a finite-dimensional real vector space V. Prove the following statement: If φ is positive-definite, then φ is non-singular.

Exercise 72.2. Let M be a closed oriented $4k$-dimensional manifold and let N be a closed oriented $4l$-dimensional manifold. Show that $\operatorname{sign}(M \times N) = \operatorname{sign}(M) \cdot \operatorname{sign}(N)$.

Exercise 72.3. Let M be a closed non-orientable $4k$-dimensional manifold. Let $p\colon \widetilde{M} \to M$ be the orientation covering that we introduced on page 294. Show that $\operatorname{sign}(\widetilde{M}) = 0$.

Exercise 72.4.

(a) Explain how to modify the proof of Proposition 72.2 so that it also holds for the integers.
(b) Explain why the proof of Proposition 72.6 cannot be generalized to the integers.

Exercise 72.5. Let A and C be invertible real $k \times k$-matrices. We assume that C is symmetric.

(a) Show that the signature of the matrix $\begin{pmatrix} 0 & A \\ A^T & C \end{pmatrix}$ is zero.
(b) Does the conclusion of (a) still hold if A and C are not invertible?

Exercise 72.6. For which $k \in \mathbb{Z}$ does there exist a closed oriented 3-manifold N with $\operatorname{sign}(S^1 \times N) = k$?

Exercise 72.7. Show that the map

$$\begin{array}{rcl} \{A \in \mathrm{GL}(n, \mathbb{R}) \,|\, A = A^T\} & \to & \mathbb{Z} \\ A & \mapsto & \operatorname{sign}(A) \end{array}$$

is continuous.
Hint: You can work either with the definition of the signature or you could use Proposition 1.78.

73. Handlebodies and Heegaard splittings of 3-dimensional manifolds

Given coprime $p, q \in \mathbb{N}$ we introduced the lens spaces $L(p,q)$ on page 266. Using the fundamental groups it was very easy to see that homeomorphic lens spaces have the same p-parameter. But so far the more advanced invariants, i.e. higher homotopy groups, homology groups and cohomology groups failed miserably at providing us with more information.

In the next chapter we will cleverly apply cup products to obtain information on lens spaces $L(p,q)$ which goes beyond detecting the first parameter p. But before we do so we find it convenient to introduce several more general definitions regarding manifolds.

73.1. **The boundary connected sum operation.** The following definition gives us a new way to construct a manifold out of two given manifolds.

Definition. Let $n \in \mathbb{N}_{\geq 2}$. Let M and M' be two n-dimensional oriented manifolds with non-empty boundary. Let $\varphi\colon \overline{B}^{n-1} \to \partial M$ and $\varphi'\colon \overline{B}^{n-1} \to \partial M'$ be two embeddings where φ is orientation-preserving and φ' is orientation-reversing. We define the *boundary connected sum of M and M'* as[1222]

$$M \#_b M' \;:=\; (M \sqcup M')/\sim \qquad \text{where } \varphi(P) \sim \varphi'(P) \text{ for all } P \in \overline{B}^{n-1}.$$

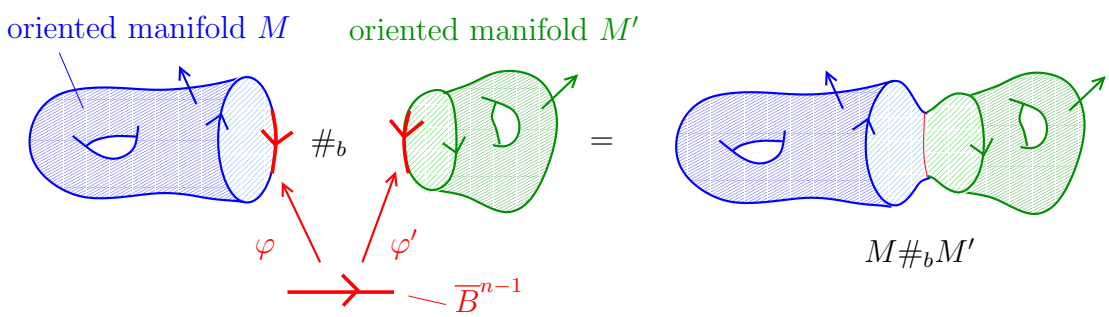


Figure 914.

In the following proposition we collect some basic facts on the boundary connected sum operation.

Proposition 73.1. *Let $n \in \mathbb{N}_{\geq 2}$. Let M and M' be two n-dimensional oriented manifolds with non-empty boundary and let A and A' be components of ∂M respectively $\partial M'$. Let $\varphi\colon \overline{B}^{n-1} \to A$ and $\varphi'\colon \overline{B}^{n-1} \to A'$ be two embeddings where φ is orientation-preserving and φ' is orientation-reversing.*

(1) *The boundary connected sum $M \#_b M'$ is naturally an n-dimensional manifold that contains M and M' as submanifolds with corner.*

[1222] Sometimes in the literature one also writes $M \sharp M'$ instead of $M \#_b M'$.

(2) *Given the boundary components A and A' the diffeomorphism type of the boundary connected sum $M\#_b M'$ does not depend on the choice of the two embeddings $\varphi\colon \overline{B}^{n-1} \to A$ and $\varphi'\colon \overline{B}^{n-1} \to A'$. In particular, if the boundary of M and M' is connected, then the diffeomorphism type of the boundary connected sum $M\#_b M'$ is well-defined.*

(3) *The boundary connected sum $M\#_b M'$ admits a unique orientation such that M and M' are oriented submanifolds with corner.*[1223]

(4) *We write $\partial M = A \sqcup B$ and $\partial M' = A' \sqcup B'$. Then*

$$\partial(M\#_b M') \;=\; A\#A' \;\sqcup\; B \sqcup B'.$$

In particular, if the boundary of M and M' is connected, then the boundary of $M\#_b M'$ is the connected sum of the boundaries of M and M'.

(5) *For any $i \geq 1$ and any commutative ring R the inclusion maps induce an isomorphism*

$$H_i(M;R) \oplus H_i(M';R) \;\xrightarrow{\cong}\; H_i(M\#_b M';R).$$

Furthermore, if M and M' are connected, then the inclusion maps induce an isomorphism

$$\pi_1(M) * \pi_1(M') \;\xrightarrow{\cong}\; \pi_1(M\#_b M').$$

Convention. We use Proposition 73.1 (3) to equip the boundary connected sum with an orientation.

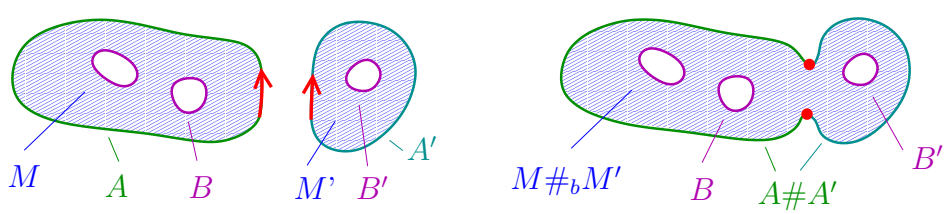

FIGURE 915. Illustration of Proposition 73.1.

Sketch of proof. Let M and M' be two oriented n-dimensional manifolds with non-empty connected boundary.

(1) This statement is a generalization of Proposition 10.27 (1). The tricky bit is to define the smooth atlas around the points given by $\varphi(S^{n-2}) = \varphi'(S^{n-2})$ in $M\#_b M'$. This is done by "smoothing the corners" as described for example in [Ni, p. 33] or in [Wall2, Proposition 2.6.2].

[1223]Basically the same construction as in Lemma 45.28 shows that given an oriented manifold, any codimension zero submanifold with corner inherits an orientation.

(2) This statement can be proved fairly easily using Theorem 10.28 and the Collar Neighborhood Theorem 10.10.[1224]
(3) This statement is proved in a very similar fashion as Proposition 10.27 (3).
(4) The final statement follows almost immediately from the definitions.
(5) It is pretty clear that both statements can be deduced from the Seifert-van Kampen 14.1 and the Mayer–Vietoris Theorem 33.5. The only technical issue that needs to be resolved is that we have to replace the subsets M and M' of $M\#_b M'$ by open subsets U and U' that admit M and M' as deformation retracts and such that $U \cap U'$ is a deformation retract of $M \cap M'$. This can be achieved using the Isotopy Extension Theorem 10.21 and the Collar Neighborhood Theorem 10.10.

We leave it as an exercise to provide full details for all of the above statements. See also [Kos, Theorem 3.1] for the same line of argument, given with more authority. □

Convention. In the following pages we will give many examples of boundary connected sums and related constructions. In many cases the objects we write down appear to be "manifolds with corner". There are two approaches to dealing with this problem:

(1) By "smoothing corners" we can turn any "manifold with corner" into a manifold, see e.g. [Wall2, Proposition 2.6.2] for details.
(2) Most of the examples that we discuss below are 3-dimensional manifolds. Theorem 28.24 says that every topological 3-dimensional manifold admits a unique smooth structure. Subsequently we apply this result as follows. We are given a topological space X that is homeomorphic to a 3-manifold M. By definition X is also a topological 3-dimensional manifold. Theorem 28.24 tells us that X admits a unique smooth structure, and that X, viewed as a manifold, is in fact diffeomorphic to M.[1225]

Examples.

(1) For any oriented n-dimensional manifold M with connected boundary we have a diffeomorphism $M\#_b\overline{B}^n \xrightarrow{\cong} M$ which is furthermore the identity outside of a collar neighborhood of ∂M. We refer to Figure 916 for an illustration and we refer to [Kos, p. 97] for a formal proof of this statement.
(2) We view the solid torus $S^1 \times \overline{B}^2$ as an oriented manifold where the orientation is given by the usual product orientation. Given $g \in \mathbb{N}$ we refer to

$$H_g \ := \ \text{boundary connected sum of } g \text{ copies of the solid torus } S^1 \times \overline{B}^2$$

as the *genus g handlebody*. As pointed out in the convention on page 1691, we view the genus g handlebody as an oriented manifold.

[1224]For this argument we need that ∂M and $\partial M'$ are connected.

[1225]We could also use a specific homeomorphism $f\colon X \to M$ to "transfer" a smooth atlas of M to X, but in most cases we are too lazy to write down a specific homeomorphism. Furthermore it is convenient to know that the smooth structure on X is independent of the choice of the homeomorphism f.

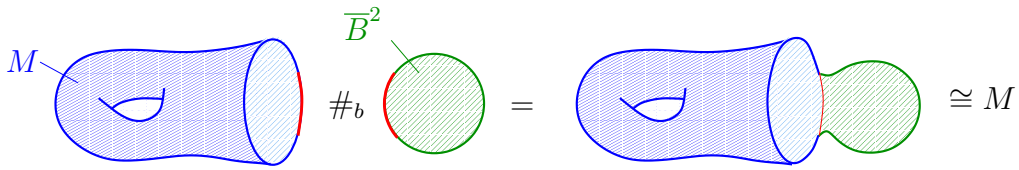

FIGURE 916.

By Proposition 73.1 (3) the boundary of H_g is the connected sum of g copies of the torus $S^1 \times S^1$. If we combine this fact with the discussion in Figure 224 we see that the boundary of the genus g handlebody is diffeomorphic to the surface of genus g. In the future we will at times identify ∂H_g with the surface of genus g. This discussion is illustrated in Figure 917.

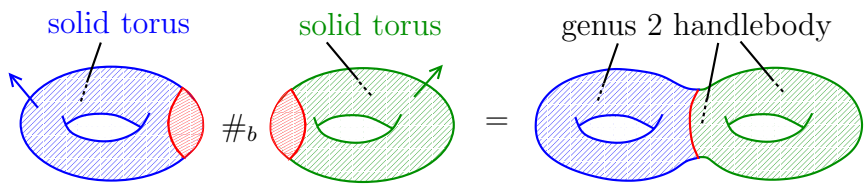

FIGURE 917.

(3) For "continuity reasons" we sometimes refer to the 3-ball $\overline{B}^3$ as a genus 0 handlebody.
(4) Handlebodies occur naturally in many contexts:
  (a) If we "thicken up" a spatial graph in S^3, then we obtain a topological space that is homeomorphic to a handlebody. We refer to Figure 918 for an illustration.

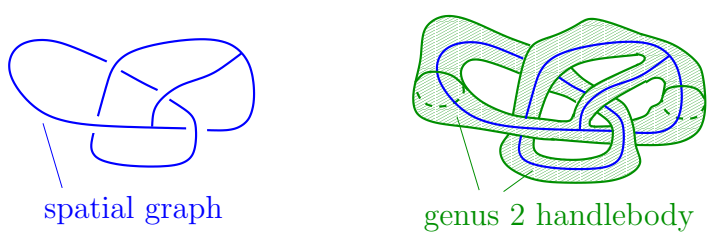

FIGURE 918.

  (b) One can obtain the genus g handlebody from the 3-ball $\overline{B}^3$ by either "attaching g handles" or by "drilling out g straight open tunnels". We refer to Figure 919 for an illustration.

We will not try to make either of the three constructions precise.

We conclude the discussion of handlebodies with the following elementary lemma.

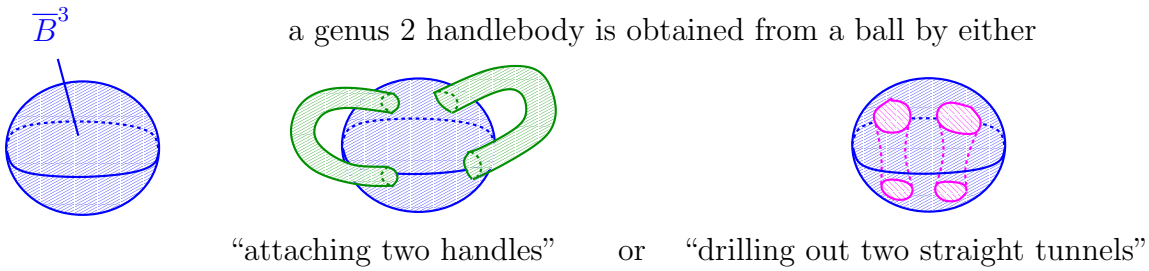

FIGURE 919.

Lemma 73.2. *The genus g handlebody H_g admits a deformation retraction to a connected graph Γ with $\chi(\Gamma) = 1-g$. In particular H_g is homotopy equivalent to the wedge of g circles and $\pi_1(H_g)$ is a free group on g generators.*

Remark. It follows from Lemma 73.2 that the Euler characteristic of the genus g handlebody H_g equals $1-g$. This is precisely half of the Euler characteristic of the surface Σ_g of genus g, which is consistent with Proposition 61.4.

Sketch of proof. Each solid torus in the construction of the genus g handlebody admits a deformation retraction to a circle such that the disks used in the definition of the boundary connected sum deformation retract to points on the circle. Thus we see that the genus g handlebody deformation retracts onto a graph G built out of g circles $C_1, \dots, C_g$ where for $i = 1, \dots, g-1$ the circle C_i is glued to C_{i+1} along a point. This is a graph of Euler characteristic $1-g$.[1226] We refer to Figure 920 for an illustration.

By Proposition 9.21 (3) the graph Γ is homotopy equivalent to the wedge of g circles. The statement regarding the fundamental groups follows from Lemma 12.5 and Proposition 9.12 (1). □

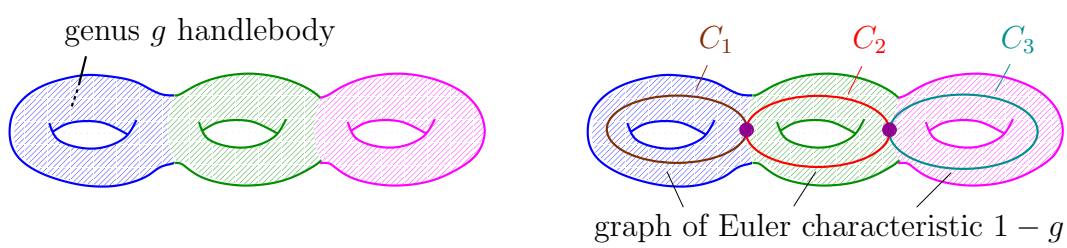

FIGURE 920.

Remark. We consider again the standard embedding of the surface Σ of genus three into $\mathbb{R}^3$ that is shown in Figure 921. Furthermore we consider the "obvious" genus 3 handlebody H that cobounds Σ and that is also shown in Figure 921. We already saw on page 891

[1226] Why is the Euler characteristic equal to $1-g$?

that the closed oriented curves $a_1, a_2, a_3, b_1, b_2, b_3$ form a basis for $H_1(\Sigma_3;\mathbb{Z})$. It follows from the proof of Lemma 73.2 that the closed oriented curves b_1, b_2, b_3 lie in the kernel of the inclusion induced map $H_1(\Sigma;\mathbb{Z}) \to H_1(H;\mathbb{Z})$ and that the oriented curves a_1, a_2, a_3 represent a basis for $H_1(H;\mathbb{Z})$.

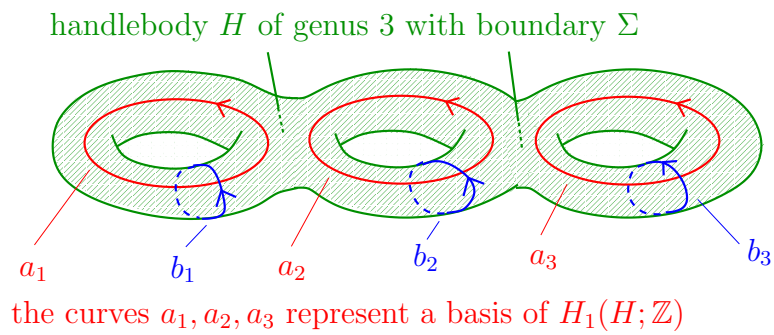

FIGURE 921.

73.2. **Heegaard splittings of 3-dimensional manifolds.**

Definition. Let M be a closed oriented connected 3-dimensional manifold.

(1) A *splitting of* M consists of a triple (X, Y, F) where X and Y are compact 3-dimensional submanifolds of M such that $M = X \cup Y$ and such that $F = X \cap Y = \partial X = \partial Y$. Given such a splitting we endow X and Y with the orientation coming from M and we endow F with the orientation coming from $F = \partial X$.[1227]

(2) A splitting (X, Y, F) of M is called a *Heegaard splitting* if X and Y are both diffeomorphic to handlebodies. We refer to the genus of the surface F as the *genus of the Heegaard splitting*.

Often, when there is no danger of confusion, we say "$M = X \cup Y$ is a splitting".

Remark. Heegaard splittings are named after the Danish mathematician Poul Heegaard (1871–1948) who proved the first important theorem regarding Heegaard splittings, see below. We had encountered Poul Heegaard before on page 1416.

Examples.

(1) Let $n \in \mathbb{N}$. On page 73 we saw that we can write the n-sphere as the union of the upper hemisphere $S^n_{\geq 0}$ and the lower hemisphere $S^n_{\leq 0}$, both of which are diffeomorphic[1228] to $\overline{B}^n$ and which intersect in an $(n-1)$-sphere. This observation gives us two examples of Heegaard splittings at once:

[1227] Note that the orientation coming from $F = \partial Y$ would be the opposite orientation.

[1228] Actually one has to think for a minute about why the hemispheres are *diffeomorphic* to $\overline{B}^n$. On page 73 we saw that the projection map from the hemispheres to $\overline{B}^n$ is a homeomorphism. But this is not a diffeomorphism (why not?). Fortunately stereographic projections, as defined in Lemma 1.41, can be used to give an explicit diffeomorphism.

(a) We obtain a genus 0 Heegaard splitting $S^3 = S^3_{\geq 0} \cup S^3_{\leq 0}$.
(b) We also obtain a genus 1 Heegaard splitting

$$S^1 \times S^2 \;=\; \underbrace{(S^1 \times S^2_{\geq 0})}_{\text{solid torus}} \cup \underbrace{(S^1 \times S^2_{\leq 0})}_{\text{solid torus}}.$$

(2) A 3-manifold can have many different Heegaard splittings. For example we consider $S^3 = \{(z,w) \in \mathbb{C}^2 \,|\, |w|^2 + |z|^2 = 1\}$ and the following two subspaces of S^3:

$$X \;:=\; \{(z,w) \in \mathbb{C}^2 \,|\, |w|^2 + |z|^2 = 1 \text{ and } |z|^2 \geq \tfrac{1}{2}\}$$

and

$$Y \;:=\; \{(z,w) \in \mathbb{C}^2 \,|\, |w|^2 + |z|^2 = 1 \text{ and } |w|^2 \geq \tfrac{1}{2}\}.$$

In Lemma 18.1 we showed that both X and Y are diffeomorphic to the solid torus $S^1 \times \overline{B}^2$. In particular Lemma 18.1 shows that $(X, Y, \partial X = \partial Y)$ is a genus 1 Heegaard splitting of S^3.

(3) The sphere S^3 admits in fact a Heegaard splitting of arbitrarily high genus. This can be seen as follows: we start out with the genus 0 Heegaard decomposition given by decomposing S^3 into two closed 3-balls X and Y. Now we we "drill g unknotted open tunnels" out of X and we add (the closure of) what we just drilled out to Y, which has the effect of "adding g handles to Y". In this construction we turned X and Y into genus g handlebodies. This example is illustrated in Figure 922. In fact

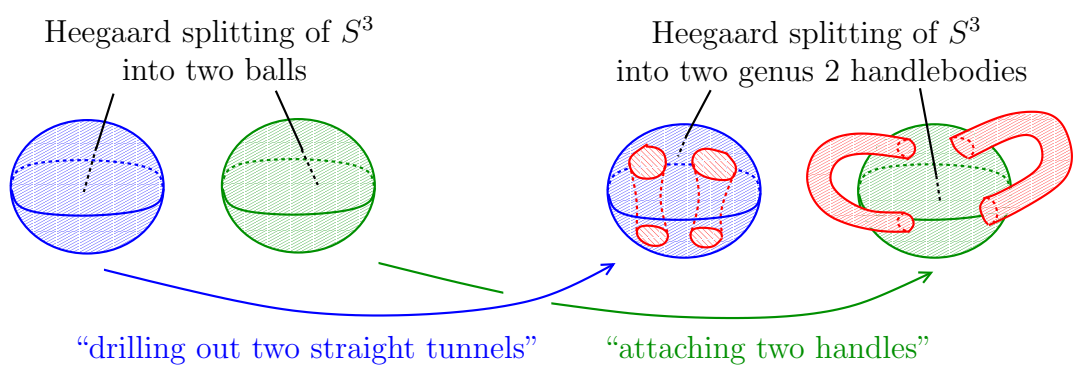

FIGURE 922.

we have now found all Heegaard splittings of S^3. More precisely, given a genus g Heegaard splitting (X, Y, F) of S^3 there exists a diffeomorphism f of S^3 which turns the Heegaard splitting into the Heegaard splittings of the same genus listed above. For $g = 0$ this statement is equivalent to the Generalized Smooth Schönflies Theorem 36.4 in dimension 3. For $g \geq 1$ the uniqueness of Heegaard splittings was shown in 1968 by Friedhelm Waldhausen [Wald, Schle].

(4) We consider the 3-dimensional cube $[0,1]^3$. We consider the equivalence relation $\sim$ that identifies the opposite sides of the cube. More precisely, on $[0,1]^3$ we denote by $\sim$ the equivalence relation that is generated by

$$(0,a,b) \sim (1,a,b), \quad (a,0,b) \sim (a,1,b) \quad \text{and} \quad (a,b,0) \sim (a,b,1) \quad \text{for } a,b \in [0,1].$$

It follows easily from Proposition 1.40 that the map $[0,1]^3/\sim \to S^1 \times S^1 \times S^1$ given by $(x,y,z) \mapsto (e^{2\pi i x}, e^{2\pi i y}, e^{2\pi i z})$ is a homeomorphism. We use this homeomorphism to identify $[0,1]^3/\sim$ with the 3-dimensional torus $S^1 \times S^1 \times S^1$. In Figure 923 we show the cube $[0,1]$ and we show the subset

$$X \;:=\; \big\{(x_1,x_2,x_3) \in [0,1]^3 \,\big|\, \text{at least two coordinates satisfy } \big|x_i - \tfrac{1}{2}\big| \le \tfrac{1}{4}\big\}.$$

We leave it as an exercise to show that $X/\sim$ is homeomorphic to the genus 3 handlebody and that $Y := \overline{([0,1]^3 \setminus X)/\sim}$ is also homeomorphic to the genus 3 handlebody. This shows that the 3-dimensional torus admits a genus 3 Heegaard splitting. It is natural to ask whether the 3-dimensional torus admits a Heegaard splitting of smaller genus. We study this question in Exercise 73.2

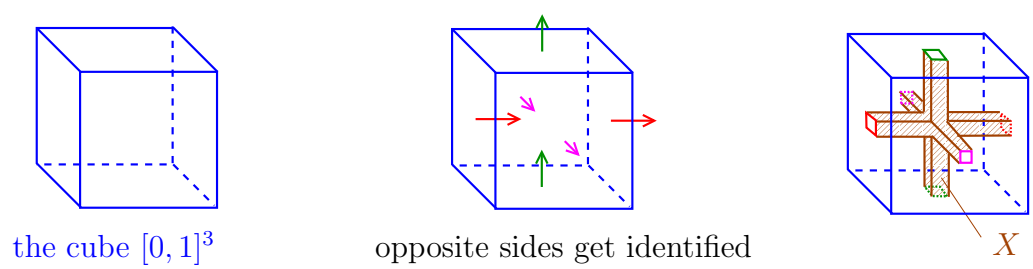

FIGURE 923.

(5) Let F be the surface of genus g and let $\varphi\colon F \to F$ be an orientation-preserving self-diffeomorphism. By Lemma 15.19 the mapping torus

$$M(F,\varphi) \;:=\; F \times [0,1] \,/\, (x,0) \sim (\varphi(x),1)$$

is a closed orientable 3-dimensional manifold. In Exercise 73.3 we will see that $M(F,\varphi)$ admits a Heegaard splitting of genus $2g+1$.

(6) Let X be a handlebody and let Y be a disjoint copy of the handlebody X. Furthermore let $\varphi\colon \partial X \to \partial Y$ be an orientation-reversing diffeomorphism. It follows from Proposition 10.12 that

$$M(X,Y,\varphi) \;:=\; (X \sqcup Y)/\sim \qquad \text{with } x \sim \varphi(x) \text{ for } x \in X$$

is a 3-dimensional manifold and that $M(X,Y,\varphi)$ admits a unique orientation such that the orientation of X, viewed as a codimension 0 submanifold of $M(X,Y,\varphi)$, agrees with the orientation of $M(X,Y,\varphi)$. Note that the images of X and Y in $M(X,Y,\varphi)$ define a Heegaard splitting.

In the following we want to consider Heegaard splittings of lens spaces in detail. Recall that given coprime $p, q \in \mathbb{N}$ the map

$$\begin{array}{rcl} \mathbb{Z}_p \times S^3 & \to & S^3 \\ (k + p\mathbb{Z}, (z, w)) & \mapsto & (e^{2\pi i k/p} \cdot z, e^{2\pi i k q/p} \cdot w) \end{array}$$

defines a free orientation-preserving action of the group $\mathbb{Z}_p$ on S^3. By definition we have $L(p, q) = S^3/\mathbb{Z}_p$ and, following the convention established on page 266, we equip $L(p, q)$ with the obvious orientation coming from S^3. It follows immediately from the definitions that this action by $\mathbb{Z}_p$ on $S^3 = X \cup Y$ preserves the solid tori X and Y from page 1696 setwise. In fact the quotients $X/\mathbb{Z}_p$ and $Y/\mathbb{Z}_p$ are again diffeomorphic to the solid torus. More precisely, we pick $r \in \mathbb{N}$ with $r \cdot q \equiv -1 \bmod p$. Similar to the proof of Lemma 18.1 it is fairly straightforward to verify that the maps

$$\begin{array}{rcl} \Phi\colon X/\mathbb{Z}_p = \left\{(z, w) \in \mathbb{C}^2 \,\middle|\, |w|^2 + |z|^2 = 1 \text{ and } |z|^2 \geq \frac{1}{2}\right\}/\mathbb{Z}_p & \to & S^1 \times \overline{B}^2 \\ [(z, w)] & \mapsto & \left(\frac{z^p}{|z^p|}, \frac{z^{-q} w}{|z^{1-q}|}\right) \end{array}$$

and

$$\begin{array}{rcl} \Psi\colon Y/\mathbb{Z}_p = \left\{(z, w) \in \mathbb{C}^2 \,\middle|\, |w|^2 + |z|^2 = 1 \text{ and } |w|^2 \geq \frac{1}{2}\right\}/\mathbb{Z}_p & \to & S^1 \times \overline{B}^2 \\ [(z, w)] & \mapsto & \left(\frac{w^p}{|w^p|}, \frac{z w^r}{|w^{1+r}|}\right) \end{array}$$

are well-defined diffeomorphisms and that Φ is orientation-preserving.[1229] This shows that

$$L(p, q) = X/\mathbb{Z}_p \cup Y/\mathbb{Z}_p$$

is a genus 1 Heegaard decomposition of the lens space $L(p, q)$. In the following lemma we describe this Heegaard splitting in greater detail.

Lemma 73.3. *Let $p \in \mathbb{N}$ and let $q \in \mathbb{Z}$ be coprime to p. We pick $r, s \in \mathbb{Z}$ such that $qr - ps = -1$. We write*

$$A = \begin{pmatrix} q & p \\ s & r \end{pmatrix} \quad \text{and we consider the orientation-reversing diffeomorphism} \quad \begin{array}{rcl} \varphi\colon \mathbb{R}^2/\mathbb{Z}^2 & \to & \mathbb{R}^2/\mathbb{Z}^2 \\ [v] & \mapsto & [Av]. \end{array}$$

If we make the usual identification $S^1 \times S^1 = \mathbb{R}^2/\mathbb{Z}^2$, then there exists an orientation-preserving diffeomorphism

$$L(p, q) \xrightarrow{\cong} M(S^1 \times \overline{B}^2, S^1 \times \overline{B}^2, \varphi).$$

Proof. In this proof we continue to use the notation that we introduced before stating the lemma. Now we write $U = X/\mathbb{Z}_p$ and $V = Y/\mathbb{Z}_p$ and as above we consider the two diffeomorphisms $\Phi\colon U \to S^1 \times \overline{B}^2$ and $\Psi\colon V \to S^1 \times \overline{B}^2$. We denote by $\gamma\colon S^1 \times S^1 \to S^1 \times S^1$ the diffeomorphism that is given by

$$S^1 \times S^1 = \partial(S^1 \times \overline{B}^2) \xleftarrow{\Phi} \partial U = \partial V \xrightarrow{\Psi} \partial(S^1 \times \overline{B}^2) = S^1 \times S^1.$$

[1229] To show that Φ is orientation-preserving it suffices by Proposition 47.3 to show that Φ is orientation-preserving at a single point. Using that $p > 0$ one can calculate explicitly that Φ is orientation-preserving at the point $[(1, 0)] \in X/\mathbb{Z}_p$.

Since Φ and Ψ are diffeomorphisms the two maps together give rise to a well-defined diffeomorphism

$$\begin{array}{rcl} L(p,q) = U \cup V & \to & M(S^1 \times \overline{B}^2, S^1 \times \overline{B}^2, \gamma) = (S^1 \times \overline{B}^2) \cup_\gamma (S^1 \times \overline{B}^2) \\ P & \mapsto & \begin{cases} \Phi(P) \text{ in the first solid torus,} & \text{if } P \in U, \\ \Psi(P) \text{ in the second solid torus,} & \text{if } P \in V. \end{cases} \end{array}$$

It follows from the orientation convention on page 1697, together with the fact that Φ is orientation-preserving, that this diffeomorphism is in fact orientation-preserving.

We consider the following diagram of diffeomorphisms:

$$\begin{tikzcd} S^1 \times S^1 \arrow[d, "="] & \partial(S^1 \times \overline{B}^2) \arrow[l, "="'] & \partial U \arrow[l, "\Phi"'] \arrow[r, "="] & \partial V \arrow[r, "\Psi"] & \partial(S^1 \times \overline{B}^2) \arrow[r, "="] & S^1 \times S^1 \arrow[d, "="] \\ \mathbb{R}^2/\mathbb{Z}^2 \arrow[rrrrr, "\varphi"] & & & & & \mathbb{R}^2/\mathbb{Z}^2. \end{tikzcd}$$

Starting from ∂U, it is straightforward to verify that the diagram commutes. But this just shows that, under the identification $S^1 \times S^1 = \mathbb{R}^2/\mathbb{Z}^2$, the two self-diffeomorphisms γ and φ of $S^1 \times S^1$ agree. $\square$

We have now given explicit Heegaard splittings of some basic examples of closed 3-manifolds. Perhaps somewhat surprisingly it is relatively straightforward to generalize these examples to all closed orientable 3-dimensional manifolds. More precisely, in 1898 Poul Heegaard proved the following theorem in his PhD thesis [Hee]. This result is one of the earliest results in the topology of 3-dimensional manifolds.

Theorem 73.4. *Every closed orientable connected 3-dimensional manifold admits a Heegaard splitting.*

Remark. As we had mentioned on page 1696, for each $g \geq 1$ the 3-sphere S^3 admits (up to diffeomorphism) a unique Heegaard splitting. In general though closed orientable connected 3-manifolds can admit inequivalent Heegaard splittings of a fixed genus, see e.g. [Engm, BGAM].

Sketch of proof. The idea of the proof of the theorem is quite simple. Let M be a closed orientable connected 3-dimensional manifold. By Proposition 39.3 the manifold M admits a triangulation, i.e. a simplicial structure. As usual we denote by M^1 the 1-skeleton of M. We pick a closed neighborhood C around the 1-skeleton M^1 such that the intersection of C with each 3-simplex is of the form shown in the middle of Figure 924. Furthermore we write $D = \overline{M \setminus C}$. The claim is that both C and D are handlebodies. The idea is that C and D are built out of pieces as sketched in Figure 924 and thus C and D are "obviously" handlebodies. But if one looks more carefully into the argument one sees that one needs the hypothesis that M is orientable to conclude that C and D are indeed handlebodies. We will not fill in the details of the argument. Unfortunately the proofs in the literature tend to be equally short on details, in particular the role of the orientability condition gets all

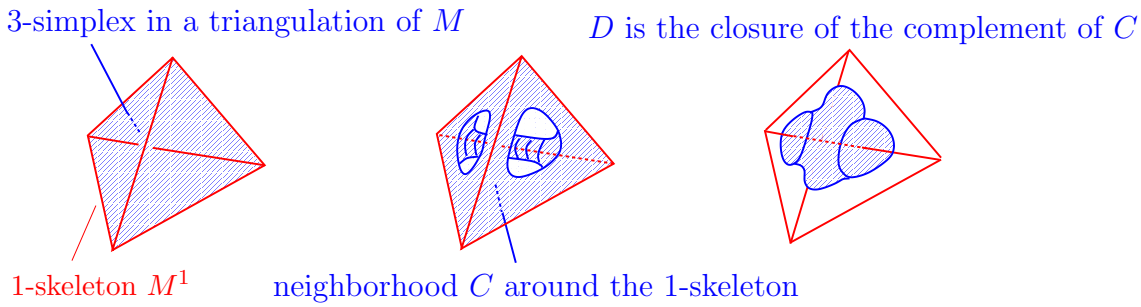

FIGURE 924.

too often swiped under the carpet. We refer to [Sav, Theorem 1.1], [Schar, p. 924] [Hem, Theorem 2.5] for proofs of the theorem which follow the above line of argumentations.

As so often in topology, there is another proof of the theorem, which might be less intuitive and less visual, but which is much more rigorous. This proof uses "Morse theory", which is a theory that explains how one can decompose a closed manifold of any dimension into "handles". We refer to [Mata, Mi4, Ni] for introductions to Morse theory, and we refer to [Johb, Theorem 4.29] or [Mata, Chapter 5.2] for details on how to obtain Heegaard splittings from Morse theory. □

Let $n \geq 4$. In Proposition 19.3 we saw that given any finitely presented group π there exists a closed orientable connected n-dimensional manifold with fundamental group isomorphic to π. Using Theorem 73.4 we will shortly see that the class of finitely presented groups that appear as fundamental groups of closed orientable connected 3-dimensional manifolds is much more restricted. Before we can state the result in detail we need to introduce the following group theoretic notion.

Definition. The *deficiency* of a finite presentation $\langle x_1, \dots, x_k \,|\, r_1, \dots, r_l \rangle$ is defined to be $k - l$.

Examples.

(1) The free group $\langle x_1, \dots, x_k \rangle$ on k generators admits, by definition, a presentation of deficiency k.
(2) Let $m \in \mathbb{N}$. On page 409 we saw that there exists an isomorphism
$$\langle x_1, \dots, x_m \mid [x_i, x_j] = e \text{ for all } i < j \in \{1, \dots, m\} \rangle \xrightarrow{\cong} \mathbb{Z}^m.$$
This shows that $\mathbb{Z}^m$ admits a presentation of deficiency $m - \frac{m(m-1)}{2}$.
(3) Let $r \in \mathbb{N}$ and $d_1, \dots, d_s \in \mathbb{N}$. It follows basically immediately from the above isomorphism in (2) that that there exists an isomorphism
$$\left\langle x_1, \dots, x_{r+s} \,\middle|\, \begin{array}{c} [x_i, x_j] = e \text{ for all } i < j \in \{1, \dots, r+s\} \\ \text{and } x_1^{d_1} = \dots = x_s^{d_s} = e \end{array} \right\rangle \xrightarrow{\cong} \mathbb{Z}^r \oplus \bigoplus_{i=1}^{s} \mathbb{Z}_{d_i}.$$

This shows that $\mathbb{Z}^r \oplus \bigoplus_{i=1}^{s} \mathbb{Z}_{d_i}$ admits a presentation of deficiency $r - \frac{(r+s)(r+s-1)}{2}$.

Given a finite presentation for a group π it is straightforward to find a finite presentation of smaller deficiency: we just add trivial relations to a given presentation. This observation naturally leads us to the following definition:

Definition. Let π be a finitely presented group. We define the *deficiency* $\mathrm{def}(\pi)$ *of* π as the maximal deficiency of a finite presentation for π.

The following lemma shows, in particular, that the deficiency is in fact a finite natural number.

Lemma 73.5.

(1) *If π is a finitely presented group, then*[1230]
$$\mathrm{def}(\pi) \ \leq \ \mathrm{rank}(\pi_{\mathrm{ab}}).$$
(2) *The deficiency of the free group $\langle x_1, \ldots, x_k \rangle$ equals k.*
(3) *The deficiency of $\mathbb{Z}^m$ equals $m - \frac{m(m-1)}{2}$.*
(4) *The deficiency of an abelian group is at most one. Furthermore, up to isomorphism, we have that*
   (a) *the only abelian groups of deficiency 1 are $\mathbb{Z}$ and $\mathbb{Z}^2$, and*
   (b) *the only abelian groups of deficiency 0 are $\mathbb{Z}_n$ and $\mathbb{Z} \oplus \mathbb{Z}_n$ with $n \neq 0$ and $\mathbb{Z}^3$.*

Proof.

(1) Let π be a finitely presented group and let $\langle x_1, \ldots, x_k \,|\, r_1, \ldots, r_l \rangle$ be a finite presentation. It follows from Proposition 13.10 (5) that there exists a short exact sequence of the form
$$0 \ \to \ A \ \to \ \mathbb{Z}^k \ \to \ \pi_{\mathrm{ab}} \ \to \ 0$$
where A is an abelian group that admits an epimorphism $\mathbb{Z}^l \to A$. We obtain that
$$k - l \ \underset{\substack{\uparrow \\ \text{Lemma 11.8 (6)}}}{\leq} \ k - \mathrm{rank}(A) \ \underset{\substack{\uparrow \\ \text{Lemma 11.6 (2)}}}{=} \ \mathrm{rank}(\pi_{\mathrm{ab}}).$$
It follows that $\mathrm{def}(\pi) \leq \mathrm{rank}(\pi_{\mathrm{ab}})$.
(2) Let $F = \langle x_1, \ldots, x_k \rangle$ be the free group on k generators. Evidently its deficiency is at least k. By Proposition 13.10 (4) we know that $F_{\mathrm{ab}} \cong \mathbb{Z}^k$. Thus it follows from (1) that the deficiency of F is also at most k.
(3) We had just seen that $\mathrm{def}(\mathbb{Z}^m) \geq m - \frac{m(m-1)}{2}$. It follows from [Eps, Lemma 1.3] that this inequality is in fact an equality.
(4) This statement also follows from from the above examples of presentations and [Eps, Lemma 1.3]. □

[1230]Here we denote by π_{ab} the abelianization of π that we introduced on page 415. Furthermore, given a finitely generated abelian group H we denote by $\mathrm{rank}(H)$ the rank that we introduced on page 371.

Now we have all the tools to state, and partially prove, the following theorem.

Theorem 73.6. *Let M be a closed orientable connected 3-dimensional manifold.*

(1) *We have* $\operatorname{def}(\pi_1(M)) \geq 0$,
(2) *If* $\pi_2(M) = 0$, *then* $\operatorname{def}(\pi_1(M)) = 0$.
(3) *If* $\pi_1(M)$ *is abelian, then* $\pi_1(M)$ *is either isomorphic to* $\mathbb{Z}^3$ *or to* $\mathbb{Z}_n$ *for some* $n \in \mathbb{N}_0$.

Remark. The list in (3) is complete, in the sense that all these abelian groups are realized by fundamental groups of closed orientable connected 3-dimensional manifolds. Indeed, given $n \in \mathbb{N}$, we obtain from Corollary 7.19 and Proposition 7.21 that

$$\pi_1(S^1 \times S^1 \times S^1) \cong \mathbb{Z}^3 \quad \pi_1(L(n,1)) \cong \mathbb{Z}_n, \qquad \text{and } \pi_1(S^1 \times S^2) \cong \mathbb{Z}.$$

Proof. Let M be a closed orientable connected 3-dimensional manifold.

(1) By Theorem 73.4 there exists a genus g Heegaard splitting $M = X \cup_F Y$ for M. We pick a base point $x_0 \in F = X \cap Y$. By Lemma 73.2 and Proposition 14.3 we can make identifications $\pi_1(X, x_0) = \langle x_1, \dots, x_g \rangle$, $\pi_1(Y, x_0) = \langle y_1, \dots, y_g \rangle$ and

$$\pi_1(F, x_0) \;=\; \langle a_1, \dots, a_{2g} \,|\, [a_1, a_2] \cdot \dots \cdot [a_{2g-1}, a_{2g}] \rangle.$$

We denote by $\varphi\colon \pi_1(F, x_0) \to \pi_1(X, x_0)$ and $\psi\colon \pi_1(F, x_0) \to \pi_1(Y, x_0)$ the inclusion induced maps. Now we have

$$\begin{array}{rcl} & \text{Seifert-van Kampen Theorem 14.2 for manifolds} & \\ & \downarrow & \\ \pi_1(M, x_0) & \cong & \pi_1(X, x_0) *_{\pi_1(F, x_0)} \pi_1(Y, x_0) \\ & = & \langle x_1, \dots, x_g, y_1, \dots, y_g \,|\, \varphi(a_1) = \psi(a_1), \dots, \varphi(a_{2g}) = \psi(a_{2g}) \rangle. \\ & \uparrow & \\ & \text{Lemma 13.13} & \end{array}$$

We have thus shown that $\pi_1(M)$ admits a presentation of deficiency zero.

(2) This statement is proved in [Eps, Lemma 3.1].
(3) It follows from (1) and Lemma 73.5 (4), that the only isomorphism types of abelian groups that can occur are $\mathbb{Z}_n$ for some $n \in \mathbb{N}_0$, $\mathbb{Z}^2$, $\mathbb{Z} \oplus \mathbb{Z}_n$ for some $n \geq 2$ and $\mathbb{Z}^3$. With somewhat more effort, see e.g. [Eps, Theorem 3.3] or [Rei, p. 28] one can also exclude the groups $\mathbb{Z}^2$ and $\mathbb{Z} \oplus \mathbb{Z}_n$ with $n \geq 2$ from the list. □

We conclude this discussion of Heegaard splittings with a particularly fascinating aspect of Heegaard splittings: they can be used to give a purely group theoretic formulation of the Poincaré Conjecture in dimension three. More precisely, the following theorem was proved by John Stallings [Sta3, Chapter 3] and William Jaco [Jaco, Theorem 6.3]. The origin of the theorem lies in the description of the fundamental group of a 3-manifold in terms of a Heegaard splitting that we gave in the proof of Theorem 73.6.

Theorem 73.7. *We introduce the following notation and language:*

(a) *Given* $g \in \mathbb{N}_0$ *we denote by* π_g *the fundamental group of the surface of genus* g *and we denote by* F_g *the free group of rank* g.

(b) *We say a homomorphism* $\beta\colon G \to A * B$ *from a group* G *to the free product of two groups* A *and* B *is* essential*, if there is no* $h \in A * B$ *such that* $h\beta(G)h^{-1}$ *is contained in* A *or* B*.*

The following two statements are equivalent:

(1) *Every 3-dimensional homotopy sphere is diffeomorphic to* S^3*.*
(2) *For any* $g \in \mathbb{N}$ *any epimorphism* $\alpha\colon \pi_g \to F_g \times F_g$ *factors through an essential monomorphism* $\beta\colon \pi_g \to A * B$ *from* π_g *to the free product of two groups* A *and* B*.*

Put differently, by Perelman's proof of Theorem 28.25 we now know that the first statement of Theorem 73.7 holds, thus the second statement also holds. This is the only known proof of that purely group theoretic statement. Conversely, any proof of the second statement of Theorem 73.7 would immediately reprove Theorem 28.25. Surely that is a quick and easy way to mathematical glory.

Remark.

(1) Perhaps by now it is no longer surprising that there is a huge literature on Heegaard splittings, see e.g. [Schle, Chapter 6] for an introduction.
(2) Recently the notion of a Heegaard splitting has been modified by David Gay and Rob Kirby [GK] to give the notion of a *trisection* of a closed orientable connected 4-dimensional manifold. One remarkable feature of trisections is that by recent work of Aarons Abrams, David Gay and Rob Kirby [AGK] they allow for a purely group theoretic reformulation of the smooth Poincaré Conjecture in dimension 4 that we had formulated as Question 28.26. This can be viewed as an analogue of Theorem 73.7.

73.3. **The mapping class group** $(*)$**.** In this section we will introduce the mapping class group of manifolds and we will study the mapping class groups of surfaces in more detail. We will use this discussion to show that every 3-manifold with a genus 1 Heegaard decomposition is in fact a lens space.

We start out with the following definition.

Definition. Let M be an oriented manifold.

(1) We write $\mathrm{Diff}(M)$ for the group of all self-diffeomorphisms of M.
(2) We denote by $\mathrm{Diff}_0(M)$ the set of all self-diffeomorphisms of M that are diffeotopic to the identity.
(3) We write $\mathrm{Diff}^+(M)$ for the group of all orientation-preserving self-diffeomorphisms of M.

We have the following useful lemma.

Lemma 73.8. *Let* M *be an oriented manifold. The set* $\mathrm{Diff}_0(M)$ *is contained in* $\mathrm{Diff}^+(M)$ *and it is a normal subgroup of* $\mathrm{Diff}(M)$*.*

Proof. It follows easily from Lemma 10.6 that $\mathrm{Diff}_0(M)$ is a normal subgroup of $\mathrm{Diff}(M)$. Furthermore it follows from Lemma 45.19 and Proposition 45.22 that $\mathrm{Diff}_0(M)$ is actually contained in $\mathrm{Diff}^+(M)$.[1231] □

We recall the following definition.

Definition. Let M and N be two manifolds. Two diffeomorphisms $f, g\colon M \to N$ are called *diffeotopic*, if there exists a *diffeotopy* from f to g, i.e. a smooth map[1232]

$$\begin{array}{rcl} H\colon M \times [0,1] & \to & N \\ (x,t) & \mapsto & H(x,t) \end{array}$$

such that the following hold:

(1) for all $x \in M$ we have $H(x,0) = f(x)$ and $H(x,1) = g(x)$, and
(2) for each $t \in [0,1]$ the map $M \to N$ given by $x \mapsto H(x,t)$ is a diffeomorphism.

In Lemmas 10.13 we already saw that for some constructions it does not make a difference if we modify a map by a diffeotopy.

In light of Lemma 73.8 it now makes sense to introduce the following definition.

Definition. Let M be an oriented manifold. The *mapping class group* $\mathrm{MCG}(M)$ of M is defined as

$$\mathrm{MCG}(M) \;:=\; \mathrm{Diff}(M)/\,\mathrm{Diff}_0(M)$$

and the *orientation-preserving mapping class group* $\mathrm{MCG}^+(M)$ of M is defined as

$$\mathrm{MCG}^+(M) \;:=\; \mathrm{Diff}^+(M)/\,\mathrm{Diff}_0(M).$$

Example. In this example we want to consider the orientation-preserving mapping class group of 1-dimensional manifolds. It is an amusing exercise to show that $\mathrm{MCG}^+(\mathbb{R})$, $\mathrm{MCG}^+([0,1]$ and $\mathrm{MCG}^+([0,1)$ are the trivial group. Furthermore, in Proposition 20.5 we showed that $\mathrm{MCG}^+(S^1)$ is also the trivial group.

For surfaces of genus 0 and 1, i.e. for the sphere S^2 and the torus $S^1 \times S^1 = \mathbb{R}^2/\mathbb{Z}^2$ the following theorem gives a complete description of the mapping class groups.

Theorem 73.9.

(1) $\mathrm{MCG}^+(S^2)$ *is the trivial group.*
(2) *The group* $\mathrm{MCG}(S^2)$ *contains two elements, one is represented by the identity and the other one is represented by any reflection in a hyperplane.*
(3) *Let* $T = \mathbb{R}^2/\mathbb{Z}^2$ *be the 2-dimensional torus. We use the generators from Lemma 33.13 to make the usual identification* $H_1(T;\mathbb{Z}) = \mathbb{Z}^2$ *and we use this identification to*

[1231] Sharp eyes will have noticed that this proof relies on going through the notion of $\mathbb{Z}$-orientability of a topological manifold. How can one proof this lemma only using the language of manifolds and their orientations?

[1232] See page 333 for the definition of what it means that a map on $M \times [0,1]$ is smooth.

make the corresponding identifications $\mathrm{Aut}(H_1(T;\mathbb{Z})) = \mathrm{Aut}(\mathbb{Z}^2) = \mathrm{GL}(2,\mathbb{Z})$ *and* $\mathrm{SAut}(H_1(T;\mathbb{Z})) = \mathrm{SAut}(\mathbb{Z}^2) = \mathrm{SL}(2,\mathbb{Z})$. *The maps*

$$\begin{aligned} \Phi\colon \mathrm{MCG}(T) &\mapsto \mathrm{GL}(2,\mathbb{Z}) \\ [f\colon T\to T] &\mapsto \underbrace{(f_*\colon H_1(T)\to H_1(T))}_{\in \mathrm{Aut}(H_1(T;\mathbb{Z}))=\mathrm{GL}(2,\mathbb{Z})} \end{aligned} \quad \textit{and} \quad \begin{aligned} \Psi\colon \mathrm{GL}(2,\mathbb{Z}) &\mapsto \mathrm{MCG}(T) \\ A &\mapsto \begin{bmatrix} \mathbb{R}^2/\mathbb{Z}^2 \mapsto \mathbb{R}^2/\mathbb{Z}^2 \\ [v] \mapsto [Av] \end{bmatrix} \end{aligned}$$

are inverses of one another.

(4) *The same statement as in* (3) *holds if we replace* $\mathrm{MCG}^+(\mathbb{R}^2/\mathbb{Z}^2)$ *by* $\mathrm{MCG}(\mathbb{R}^2/\mathbb{Z}^2)$ *and if we replace* $\mathrm{SL}(2,\mathbb{Z})$ *by* $\mathrm{GL}(2,\mathbb{Z})$.[1233]

Remark. In 1969 by Jean Cerf [Cer] (see also [Eli, Theorem 2.4.1] and [Hat7]) showed that the obvious analogues of the first two statements of Theorem 73.9 also hold for S^3. As is pointed out in [Hat5], it follows from the existence of exotic spheres, see page 730 and the h-cobordism theorem [Sma3, Mi5], that in most higher dimensions the analogues do not hold.

Proof. The first two statements were proved in 1959 by Stephen Smale [Sma2].[1234] It is an amusing exercise to show that $\Phi\circ\Psi = \mathrm{id}$ on $\mathrm{GL}(2,\mathbb{Z})$. The fact that $\Psi\circ\Phi = \mathrm{id}$ on $\mathrm{MCG}(\mathbb{R}^2/\mathbb{Z}^2)$ is somewhat harder. We refer to [FaM, Theorem 2.5] or alternatively to [Rol, Chapter 2.D] for proofs. The claim regarding the orientation-preserving mapping class group follows from the above result together with Lemma 57.15. □

Now we can give the following characterization of lens spaces.

Corollary 73.10. *If M is a closed orientable connected 3-dimensional manifold, then the following two statements are equivalent:*

$$M \text{ admits a genus 1 Heegaard splitting} \iff M \text{ is a lens space or } M \cong S^1\times S^2.$$

Proof. By Lemma 73.3 and the discussion on page 1696 we know that lens spaces and $S^1\times S^2$ admit genus 1 Heegaard splittings.

Now suppose that M is a closed orientable connected 3-dimensional manifold that admits a genus 1 Heegaard splitting $M = S^1\times\overline{B}^2 \cup_\varphi S^1\times\overline{B}^2$ where φ is an orientation-reversing self-diffeomorphism of $S^1\times S^1 = \mathbb{R}^2/\mathbb{Z}^2$. It is an immediate consequence of Theorem 73.9 (3), Lemma 57.15 and Lemma 10.13 that, after a diffeotopy, we can assume that φ is given by multiplication by a matrix $\begin{pmatrix} q & p \\ s & r\end{pmatrix} \in \mathrm{GL}(2,\mathbb{Z})$ with $qr - ps = -1$.

First assume that $p = 0$. We leave it as an amusing exercise to show that in this case M is diffeomorphic to $S^1\times S^2$. If $p > 0$, then it follows from Lemma 73.3 that M is diffeomorphic to $L(p,q)$. Finally we consider the case that $p < 0$. We denote by ψ the self-diffeomorphism

[1233] We showed in Lemma 57.15 that the map $\Phi\colon \mathrm{MCG}^+(T)\to\mathrm{GL}(2,\mathbb{Z})$ takes values in $\mathrm{SL}(2,\mathbb{Z})$.

[1234] We had already encountered Stephen Smale in the proof of the Poincaré Conjecture in dimensions ≥ 5, see Theorem 28.22.

of $\mathbb{R}^2/\mathbb{Z}^2$ that is given by multiplication by the matrix $\begin{pmatrix} q & -p \\ -s & r \end{pmatrix} \in \mathrm{GL}(2,\mathbb{Z})$. The map

$$S^1 \times \overline{B}^2 \cup_\varphi S^1 \times \overline{B}^2 \;\to\; S^1 \times \overline{B}^2 \cup_\psi S^1 \times \overline{B}^2,$$

given by reflection on both of the S^1 factors is easily seen to be a well-defined diffeomorphism. But as we had just shown, the right-hand side is diffeomorphic to the lens space $L(-p,q)$. □

We had just seen that the mapping class group of the 2-dimensional sphere and the torus are groups we are very familiar with. It is natural to ask, whether we can also understand the mapping class groups of higher genus surfaces.

Throughout the remainder of this section, given $g \geq 1$ we denote by Σ_g the surface of genus g. To facilitate the discussion, we equip $H_1(\Sigma_g;\mathbb{Z})$ with the standard basis $x_1,\dots,x_g,y_1,\dots,y_g$ shown in Figure 925 and we use this basis to make the identification $H_1(\Sigma_g;\mathbb{Z}) = \mathbb{Z}^{2g}$.

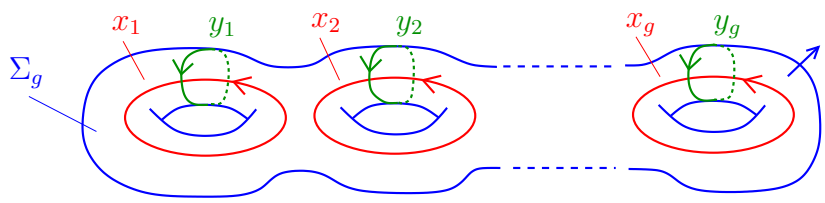

FIGURE 925.

Here is a somewhat optimistic interpretation of the above question.

Question 73.11. *Let $g \geq 2$. Is the map*

$$\begin{array}{rcl} \Phi_g\colon \mathrm{MCG}(\Sigma_g) & \mapsto & \mathrm{GL}(2g,\mathbb{Z}) \\ [f\colon \Sigma_g \to \Sigma_g] & \mapsto & \underbrace{\big(f_*\colon H_1(\Sigma_g;\mathbb{Z}) \to H_1(\Sigma_g;\mathbb{Z})\big)}_{\in \mathrm{Aut}(H_1(\Sigma_g;\mathbb{Z}))=\mathrm{GL}(2g,\mathbb{Z})} \end{array}$$

an isomorphism?

It turns out that the answer to Question 73.11 is no. In fact we have already developed all the tools to show that Φ_g is not an epimorphism. At this point it is useful to introduce the following definition.

Definition.

(1) Given $g \in \mathbb{N}$ we write $J_g := \begin{pmatrix} 0 & \mathrm{id}_g \\ -\mathrm{id}_g & 0 \end{pmatrix}$.

(2) We say a matrix $A \in \mathrm{GL}(2g,\mathbb{Z})$ is *symplectic*[1235] if $A^T J A = J$.

[1235]The origin of the word "symplectic" is explained in the following webpage

`http://jeff560.tripod.com/mathword.html`

which explores the earliest known uses of some of the words of mathematics.

(3) We define the *symplectic group* $\mathrm{Sp}(2g,\mathbb{Z})$ to be the group[1236] of all symplectic matrices.

Now we can formulate the following proposition.

Proposition 73.12. *Let $g \in \mathbb{N}$. The homomorphism $\Phi_g\colon \mathrm{MCG}^+(\Sigma_g) \to \mathrm{GL}(2g,\mathbb{Z})$ takes values in $\mathrm{Sp}(2g,\mathbb{Z})$.*

Proof. Recall that we use the homology classes represented by the curves $x_1,\dots,x_g,y_1,\dots,y_g$ shown in Figure 925 to make the identification $\mathbb{Z}^{2g} = H_1(\Sigma_g;\mathbb{Z})$. It follows from the calculation of the intersection form of Σ_g on page 1656 that we have a commutative diagram

$$\begin{tikzcd}
\mathbb{Z}^{2g} \times \mathbb{Z}^{2g} \arrow[r, "(v,w)\mapsto v^T J w"] \arrow[d, "="] & \mathbb{Z} \arrow[d, "="] \\
H_1(\Sigma_g;\mathbb{Z}) \times H_1(\Sigma_g;\mathbb{Z}) \arrow[r, "Q_{\Sigma_g}"] & \mathbb{Z}.
\end{tikzcd}$$

Now let f be an orientation-preserving self-homeomorphism of Σ_g. We denote by A the matrix that represents the induced map $f_*\colon H_1(\Sigma_g;\mathbb{Z}) \to H_1(\Sigma_g;\mathbb{Z})$ with respect to the above basis.

It is a consequence of Lemma 71.7 that the induced map f_* preserves the intersection form of Σ_g. Therefore we obtain from the commutative diagram that the induced map on $H_1(\Sigma_g;\mathbb{Z}) = \mathbb{Z}^{2g}$ also preserves the form on the top. But this means that for any two vectors $v,w \in \mathbb{Z}^g$ we have $v^T A^T J A w = (Av)^T J A w = v^T J w$. This in turn implies that $A^T J A = J$. □

The question now arises, how big is the symplectic group? The following proposition summarizes some known results:

Proposition 73.13. *Let $g \in \mathbb{N}$.*

(1) *We have $\mathrm{Sp}(2g,\mathbb{Z}) \subset \mathrm{SL}(2g,\mathbb{Z})$.*
(2) *We have $\mathrm{Sp}(2,\mathbb{Z}) = \mathrm{SL}(2,\mathbb{Z})$.*
(3) *For $g \geq 2$ the symplectic group $\mathrm{Sp}(2g,\mathbb{Z})$ is a proper subgroup of $\mathrm{SL}(2g,\mathbb{Z})$.*

Proof.

(1) The fact that every symplectic matrix has determinant equal to $+1$ is a somewhat non-trivial exercise in linear algebra. A proof is for example given in [Serd, Corollary 10.2] or [McS, Lemma 1.1.15].
(2) A short and amusing calculation (worth doing!) shows that every matrix in $\mathrm{SL}(2,\mathbb{Z})$ is in fact symplectic.

[1236] It is straightforward to verify that the set of all symplectic $(2g \times 2g)$-matrices is in fact a subgroup of $\mathrm{GL}(2g,\mathbb{Z})$.

(3) Let $g \geq 2$. Unless one is very unlucky, almost any randomly picked matrix in $\mathrm{SL}(2g, \mathbb{Z})$ will not lie in $\mathrm{Sp}(2g, \mathbb{Z})$. For example an elementary calculation shows that the matrix

$$A := \begin{pmatrix} 2 & 0 & 5 & 0 \\ 0 & 1 & 0 & 0 \\ 1 & 0 & 3 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

does not satisfy $A^T J A = J$, i.e. A does not lie in $\mathrm{Sp}(4, \mathbb{Z})$. A straightforward modification of this example shows that given any $g \geq 2$ there exist matrices in $\mathrm{SL}(2g, \mathbb{Z})$ that do not lie in $\mathrm{Sp}(2g, \mathbb{Z})$. □

In a last ditch effort to salvage Question 73.11 one could ask whether perhaps the map $\Phi_g \colon \mathrm{MCG}(\Sigma_g)^+ \to \mathrm{Sp}(2g, \mathbb{Z})$ is an isomorphism.

Now is perhaps a good moment to recall that we had already constructed diffeomorphisms of Σ_g. More precisely, recall that given an oriented curve C on Σ_g we introduced on page 472 the corresponding smooth Dehn twist $t_C \colon \Sigma_g \to \Sigma_g$. The following proposition shows that, in some sense, Dehn twists are all orientation-preserving diffeomorphisms we ever need.

Proposition 73.14. *The Dehn twists along the* $3g-1$ *curves shown in Figure 926 form a generating set for* $\mathrm{MCG}^+(\Sigma_g)$.

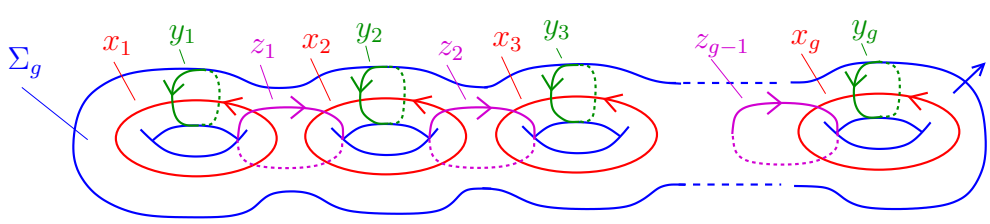

FIGURE 926.

Remark. It is significantly harder to show that $\mathrm{MCG}^+(\Sigma_g)$ admits a finite presentation, see [HT] and [Waj] for details.

Proof. This proposition proved in 1963 by Raymond Lickorish [Lic4], see also [FaM, Theorem 4.13] or [Bir, Theorem 4.3]. □

In fact this source of orientation-preserving diffeomorphisms is rich enough to prove the following proposition.

Proposition 73.15. *For any* $g \geq 1$ *the above map* $\Phi_g \colon \mathrm{MCG}^+(\Sigma_g) \to \mathrm{Sp}(2g, \mathbb{Z})$ *is an epimorphism.*

Proof. The result is proved in [FaM, Theorem 6.4]. □

This leads us to the following definition.

Definition. Given $g \geq 1$ we refer to

$$T_g \ := \ \ker\{\Phi_g \colon \ \mathrm{MCG}(\Sigma_g)^+ \to \mathrm{Sp}(2g, \mathbb{Z})\}$$

as the *Torelli group* of Σ_g.[1237]

The question now becomes, whether the Torelli group T_g is non-trivial. In fact the next proposition shows precisely that.

Proposition 73.16. *Let $g \in \mathbb{N}$.*

(1) *If C is an oriented curve on Σ_g that is not null-homotopic, then the Dehn twist t_C defines a non-trivial element in $\mathrm{MCG}(\Sigma_g)$.*
(2) *If C is an oriented curve on Σ_g that is null-homologous, then the Dehn twist t_C defines an element of the Torelli group T_g.*
(3) *For $g \geq 2$ the Dehn twist along the curve C shown in Figure 927 defines a non-trivial element in the Torelli group T_g.*

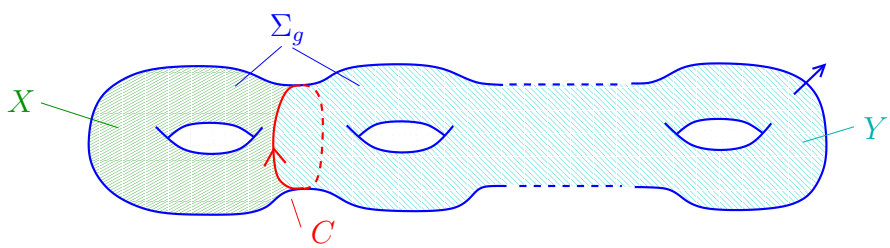

FIGURE 927.

Proof.

(1) The first statement is proved in [FaM, Proposition 3.1].
(2) This statement follows from [FaM, Proposition 3.2]. With some effort one could also prove this statement "by hand".
(3) By (1) and (2) it suffices to show that C is null-homologous but not null-homotopic. Note that C is the boundary of a submanifold X of Σ_g. We obtain from Corollary 46.27 (1) that $[C] = 0 \in H_1(X; \mathbb{Z})$, which implies that C is also null-homologous in Σ_g. On the other hand we saw on page 433 that C is not null-homotopic. $\square$

There are still lots of open questions regarding mapping class groups of surfaces. For example the following question is an interesting open problem.

Question 73.17. *Let Σ_g be the surface of genus $g \in \mathbb{N}_0$. Is the mapping class group $\mathrm{MCG}(\Sigma_g)$ linear, i.e. is it isomorphic to a subgroup of $\mathrm{GL}(n, \mathbb{C})$ for some large enough n?*

[1237] For slightly mysterious reasons this group is named after the Italian mathematician Ruggiero Torelli (1884–1915) who died in World War I.

We had just seen in Theorem 73.9 that the answer is yes for $g = 0$ and $g = 1$. Furthermore Stephen Bigelow and Ryan Budney [BB] showed in 2001 that the answer is yes for $g = 2$. The case $g \geq 3$ is still wide open.

As in almost any topic we have touched so far, there is again a tremendous amount of literature and work on mapping class groups. We refer to [Bir, FaM, Hat5] for more information regarding mapping class groups and diffeomorphism groups of manifolds in dimension 2 and in higher dimensions.

Exercises for Chapter 73.

Exercise 73.1. Let H_g be the genus g handlebody. Let $W = H_g \cup H_g$ be the double of H_g. This is a closed 3-dimensional manifold. Do we know what it is?

Exercise 73.2. In Chapter 65 we have seen that the 3-dimensional torus $S^1 \times S^1 \times S^1$ admits a Heegaard splitting of genus three. Does it also admit a Heegaard splitting of genus two?

Exercise 73.3. Let F be the surface of genus g and let $\varphi\colon F \to F$ be an orientation-preserving self-diffeomorphism. By Proposition 10.12 we know that the mapping torus

$$M(F, \varphi) \ := \ F \times [0,1] \,/\, (x, 0) \sim (\varphi(x), 1)$$

is a closed orientable connected 3-dimensional manifold. Show that $M(F, \varphi)$ admits a Heegaard splitting of genus $2g + 1$.

74. The linking pairing on rational homology spheres

74.1. **Rational homology spheres.** We recall the following lemma.

Lemma 7.7. *Let $p \in \mathbb{N}$ and furthermore let $q, r \in \mathbb{Z}$ with $\gcd(p,q) = \gcd(p,r) = 1$. If $q \equiv \pm r^{\pm 1} \bmod p$,*[1238] *then $L(p,q)$ and $L(p,r)$ are diffeomorphic.*

In Question 7.8 we had asked whether the converse to Lemma 7.7 holds. So far we have made little progress. On page 281 we saw, using fundamental groups, that if two lens spaces $L(p,q)$ and $L(\widetilde{p},\widetilde{q})$ are homeomorphic, then $p = \widetilde{p}$. Later on, on page 723 we saw that higher homotopy groups do not carry any additional information. In Lemma 40.12 we had determined the homology groups of lens spaces, more precisely we showed that

$$H_n(L(p,q);\mathbb{Z}) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } n = 0,3, \\ \mathbb{Z}_p, & \text{if } n = 1, \\ 0, & \text{otherwise.} \end{cases}$$

From the Universal Coefficient Theorem for Cohomology Groups 51.13 it follows that

$$H^n(L(p,q);\mathbb{Z}) \;\cong\; \begin{cases} \mathbb{Z}, & \text{if } n = 0,3, \\ \mathbb{Z}_p, & \text{if } n = 2, \\ 0, & \text{otherwise.} \end{cases}$$

This shows that homology groups and cohomology groups cannot be used to distinguish the lens spaces $L(p,q)$ and $L(p,q')$.

In Chapter 71 we had successfully applied the cup product to distinguish several manifolds that could not be distinguished just using cohomology groups. It is therefore tempting to try to use cup products to distinguish lens spaces. But here we immediately encounter the problem, that all non-trivial cup products are trivially trivial. More precisely, all cup products of cohomology classes in degree ≥ 1 are zero, since too many cohomology groups are zero. For example, the cup product on the non-trivial group $H^2(L(p,q);\mathbb{Z})$ with itself is zero since it takes values in $H^4(L(p,q);\mathbb{Z}) = 0$.

In this chapter we will develop an analogue of the intersection form, namely the *linking pairing*. This is an invariant defined for lens spaces, or more generally, for odd-dimensional rational homology spheres, which are defined as follows:

Definition. Let R be a commutative ring and let M be an n-dimensional topological manifold. We say M is an *R-homology sphere*, if for each $k \in \mathbb{N}_0$ we have $H_k(M;R) \cong H_k(S^n;R)$, i.e. we have

$$H_k(M;R) \;\cong\; \begin{cases} R, & \text{if } k = 0,n, \\ 0, & \text{otherwise.} \end{cases}$$

Instead of $\mathbb{Z}$-homology sphere we usually say *integral homology sphere* and instead of $\mathbb{Q}$-homology sphere we usually say *rational homology sphere*.

[1238] By our hypothesis we have $\gcd(p,r) = 1$. This implies that there exists a multiplicative inverse of r modulo p, i.e. there exists an s with $r \cdot s \equiv 1 \bmod p$. We write $r^{-1} := s$.

Examples.

(1) It follows from the aforementioned calculation of the homology groups of lens spaces and Corollary 42.20 (which is a straightforward consequence of the Universal Coefficient Theorem 42.18), that lens spaces are rational homology spheres.
(2) It follows from Proposition 71.10 that the connected sum of two n-dimensional R-homology spheres is again an n-dimensional R-homology sphere.

The following lemma gives an alternative description of rational homology spheres.

Lemma 74.1. *Let M be an n-dimensional topological manifold M. Then the following holds:*[1239]

$$M \text{ is a rational homology sphere} \iff \begin{array}{c} M \text{ is closed connected and orientable and} \\ H_i(M;\mathbb{Z}) \text{ is finite for } i = 1, \dots, \lfloor \frac{n-1}{2} \rfloor. \end{array}$$

Proof. The proof of the lemma is basically an exercise in combining all the standard facts on homology groups of topological manifolds that we have gathered so far. More precisely, the "$\Rightarrow$" direction follows from Corollary 42.20, Proposition 45.2 (2), Proposition 29.5 and Theorems 46.2 and 46.4. The proof of the "$\Leftarrow$" direction also requires the above ingredients, furthermore it also requires the Poincaré Duality Theorem 61.1. We leave it to the reader to connect the dots. □

74.2. **The Bockstein homomorphisms.** Before we can introduce the linking pairing of rational homology spheres we need to give some harmless extensions of our definitions and results from (co-) homology theory. We will do so in the coming two sections.

Let X be a topological space and let $f\colon A \to B$ be a homomorphism of abelian groups. We recall that in Lemma 42.7 we saw that the maps

$$\begin{array}{rcl} f_*\colon C_*(X;A) & \to & C_*(X;B) \\ \left[\sum_{i=1}^k \sigma_i \otimes a_i\right] & \mapsto & \left[\sum_{i=1}^k \sigma_i \otimes f(a_i)\right] \end{array}$$

form a chain map, in particular for each $n \in \mathbb{N}_0$ we obtain an induced map

$$f_*\colon H_n(X;A) \to H_n(X;B).$$

Similarly, it ifollows from the discussion on page 1163 that the maps

$$\begin{array}{rcl} f_*\colon C^n(X;A) = \mathrm{Hom}(C_n(X),A) & \to & C^n(X;B) = \mathrm{Hom}(C_n(X),B) \\ \varphi & \mapsto & f \circ \varphi \end{array}$$

define a cochain map, in particular we get for each $n \in \mathbb{N}_0$ an induced map

$$f_*\colon H^n(X;A) \to H^n(X;B)$$

In the following lemma we discuss one subtle example.

[1239]Here recall that given a real number r we denote by $\lfloor r \rfloor = \max\{n \in \mathbb{Z} \mid n \leq r\}$ the result of rounding r down.

Lemma 74.2. $(*)$ *Let $k \in \mathbb{Z}$. We denote by $f\colon \mathbb{Z} \to \mathbb{Z}$ the map that is given by multiplication by k. Given any pair (X, A) of topological spaces and given any $n \in \mathbb{N}_0$ the maps $f_*\colon H_n(X, A; \mathbb{Z}) \to H_n(X, A; \mathbb{Z})$ and $f_*\colon H^n(X, A; \mathbb{Z}) \to H^n(X, A; \mathbb{Z})$ are given by multiplication by m.*

Proof $(*)$. It is arguable whether this lemma actually needs a proof. Nonetheless, since at one point we will make use of the statement for cohomology, we provide the proof for the induced maps on cohomology. Thus let $\gamma\colon C_k(X, A) \to \mathbb{Z}$ be a cochain. We see that

$$f_*([\gamma]) = [f \circ \gamma] = \begin{bmatrix} C_k(X, A) \to \mathbb{Z} \\ \sigma \mapsto \underbrace{n \cdot f(\sigma)}_{=(f\circ\gamma)(\sigma)} \end{bmatrix} \underset{\substack{\uparrow \\ \text{this is the point where something happens}}}{=} \begin{bmatrix} C_k(X, A) \to \mathbb{Z} \\ \sigma \mapsto (n \cdot f)(\sigma) \end{bmatrix} = [n \cdot f] = n \cdot [\gamma].$$

□

These observations lead us to the definitions of the Bockstein homomorphisms.

Definition. Let X be a topological space and let $0 \to A \xrightarrow{i} B \xrightarrow{p} C \to 0$ be a short exact sequence of abelian groups. Let $n \in \mathbb{N}_0$. It follows from the fact that $C_n(X)$ is a free abelian group and from the natural isomorphisms of Lemma 42.3 that

$$0 \;\to\; C_n(X; A) \;\xrightarrow{i_*}\; C_n(X; B) \;\xrightarrow{p_*}\; C_n(X; C) \;\to\; 0$$

is also exact. Thus we obtain a short exact sequence

$$0 \;\to\; C_*(X; A) \;\xrightarrow{i_*}\; C_*(X; B) \;\xrightarrow{p_*}\; C_*(X; C) \;\to\; 0$$

of chain complexes. Furthermore, from Proposition 31.10 we obtain a long exact sequence

$$\ldots \;\xrightarrow[=:\beta_{n-1}]{\partial_{n-1}}\; H_n(X; A) \;\xrightarrow{i_*}\; H_n(X; B) \;\xrightarrow{p_*}\; H_n(X; C) \;\xrightarrow[=:\beta_n]{\partial_n}\; H_{n-1}(X; A) \;\to\; \ldots$$

which is called the *Bockstein sequence in homology.*[1240] Furthermore for each $n \in \mathbb{N}_0$ the connecting homomorphism $\beta = \partial_n\colon H_n(X; C) \to H_{n-1}(X; A)$ is called the *n-th Bockstein homomorphism in homology.*

The same setup also works in cohomology.

Definition. We continue with the notation from the previous definition. Since each $C_n(X)$ is a free abelian group one sees easily that

$$0 \;\to\; C^*(X; A) \;\xrightarrow{i}\; C^*(X; B) \;\xrightarrow{p_*}\; C^*(X; C) \;\to\; 0$$

is a short exact sequence of cochain complexes. From Proposition 48.6 we obtain a natural long exact sequence of cohomology groups

$$\ldots \;\xrightarrow[=:\beta_{n-1}]{\delta_{n-1}}\; H^n(X; A) \;\xrightarrow{i_*}\; H^n(X; B) \;\xrightarrow{p_*}\; H^n(X; C) \;\xrightarrow[=:\beta_n]{\delta_n}\; H^{n+1}(X; A) \;\to\; \ldots$$

[1240]The Bockstein homomorphism is named after the Russian mathematician Meyer Bockstein (1913-1990).

which is called the *Bockstein sequence in cohomology.* Furthermore for each $n \in \mathbb{N}_0$ the connecting homomorphism $\beta = \delta_n \colon H^n(X;C) \to H^{n+1}(X;A)$ is called the *n-th Bockstein homomorphism in cohomology.*

Examples. Let X be a topological space. The following two instances of the Bockstein homomorphisms are arguably the ones which are most frequently used:

(1) Let $k \in \mathbb{N}$. We consider the short exact sequence $0 \to \mathbb{Z}_k \xrightarrow{\cdot k} \mathbb{Z}_{k^2} \xrightarrow{p} \mathbb{Z}_k \to 0$ where p stands for the obvious projection map. Given a topological space X we obtain Bockstein homomorphisms $\beta_n \colon H_n(X;\mathbb{Z}_k) \to H_{n-1}(X;\mathbb{Z}_k)$, $n \in \mathbb{N}_0$. In Exercise 74.1 we will see that $\beta_{n-1} \circ \beta_n \colon H_n(X;\mathbb{Z}_k) \to H_{n-2}(X;\mathbb{Z}_k)$ is the zero map.
(2) Later on we will consider the short exact sequence $0 \to \mathbb{Z} \to \mathbb{Q} \to \mathbb{Q}/\mathbb{Z} \to 0$. It gives rise to Bockstein homomorphisms $\beta_n \colon H_n(X;\mathbb{Q}/\mathbb{Z}) \to H_{n-1}(X;\mathbb{Z})$ and $\beta_n \colon H^n(X;\mathbb{Q}/\mathbb{Z}) \to H^{n+1}(X;\mathbb{Z})$.

For completeness' sake we mention the following lemma.

Lemma 74.3. *Let $0 \to A \xrightarrow{i} B \xrightarrow{p} C \to 0$ be a short exact sequence of abelian groups.*

(1) *Let $n \in \mathbb{N}_0$. The n-th Bockstein homomorphisms β_n corresponding to the short exact sequence of abelian groups form a natural transformation from the contravariant functor $X \mapsto H^n(X;C)$ to the contravariant functor $X \mapsto H^{n+1}(X;A)$.*
(2) *Given a map $f \colon X \to Y$ between topological spaces the following diagram commutes:*

$$\begin{array}{ccccccccc}
\dots \xrightarrow{\beta_{n-1}} & H^n(Y;A) & \xrightarrow{i_*} & H^n(Y;B) & \xrightarrow{p_*} & H^n(Y;C) & \xrightarrow{\beta_n} & H^{n+1}(Y;A) & \longrightarrow \dots \\
 & \downarrow f^* & & \downarrow f^* & & \downarrow f^* & & \downarrow f^* & \\
\dots \xrightarrow{\beta_{n-1}} & H^n(X;A) & \xrightarrow{i_*} & H^n(X;B) & \xrightarrow{p_*} & H^n(X;C) & \xrightarrow{\beta_n} & H^{n+1}(X;A) & \longrightarrow \dots
\end{array}$$

Proof. The first statement is essentially a consequence of Lemma 31.9 (2). The second statement follows from the first statement together with Lemma 48.9. □

74.3. **The cup product and the cap product with coefficients.** On page 1333, given a topological space X, we introduced the cup product for the R-cohomology groups $H^*(X;R)$ provided the coefficients are given by a commutative ring R. In this section we will generalize the notion of the cup product where we no longer demand that the coefficients lie in a commutative ring R. Furthermore we also define a slight variation on the cap product. It is advisable to quickly look at the definitions and then move on to the next section. All the statements proved in this section are basically the obvious generalizations of earlier results.

Before we introduce the more general cup product, we recall the following notation from page 1323.

Notation. Given any $i \in \{0,\dots,n\}$ we write $v_i := (0,\dots,1,0,\dots,0) \in \mathbb{R}^{n+1}$ and secondly, given $a_0,\dots,a_s \in \Delta^n$ we denote by $[a_0,\dots,a_s]$ the unique affine linear map $\Delta^s \to \Delta^n$ that sends v_i to a_i for $i = 0,\dots,s$.

Now we can give the quite simple-minded definition of the more general cup product.

Definition. Let X be a topological space and let A and B be abelian groups. We define

$$\begin{aligned} C^p(X;A)\times C^q(X;B) \;&\to\; C^{p+q}(X;A\otimes B) \\ (\varphi,\psi) \mapsto &\left(\begin{array}{l} \varphi\cup_\otimes\psi\colon C_{p+q}(X)\to A\otimes B \\ \quad(\sigma\colon\Delta^{p+q}\to X)\mapsto \underbrace{\varphi(\sigma\circ[v_0,\ldots,v_p])}_{\in A}\otimes\underbrace{\psi(\sigma\circ[v_p,\ldots,v_{p+q}])}_{\in B} \end{array}\right). \end{aligned}$$

We have the following elementary lemma. The proof is basically verbatim the same as the proof of Lemma 57.2.

Lemma 74.4. *Let X be a topological space and let A and B be two abelian groups. If $\varphi\in C^p(X;A)$ and $\psi\in C^q(X;B)$, then*

$$\delta(\varphi\cup_\otimes\psi) \;=\; \delta\varphi\cup_\otimes\psi+(-1)^p\cdot\varphi\cup_\otimes\delta\psi \;\in\; C^{p+q+1}(X;A\otimes B).$$

Now we can easily prove the following lemma. The proof again is basically the same as the proof of Lemma 57.3, we just need to replace Lemma 57.2 by Lemma 74.4.

Lemma 74.5. *Let X be a topological space and let A and B be abelian groups. Then the map*

$$\begin{array}{rcl} \cup_\otimes\colon H^p(X;A)\times H^q(X;B) & \to & H^{p+q}(X;A\otimes B) \\ ([\varphi],[\psi]) & \mapsto & [\varphi\cup_\otimes\psi] \end{array}$$

is well-defined.

We refer to the pairing from Lemma 74.5 again as a *cup product*. The following lemma is an immediate consequence of the definitions.

Lemma 74.6. *Let X be a topological space.*

(1) *If $\alpha\colon A\to A'$ and $\beta\colon B\to B'$ are homomorphisms between two abelian groups, then for any $k,l\in\mathbb{N}_0$ the following diagram commutes*

$$\begin{array}{ccc} H^k(X;A)\times H^l(X;B) & \xrightarrow{\cup_\otimes} & H^{k+l}(X;A\otimes B) \\ \downarrow{\scriptstyle\alpha_*\times\beta_*} & & \downarrow{\scriptstyle(\alpha\otimes\beta)_*} \\ H^k(X;A')\times H^l(X;B') & \xrightarrow{\cup_\otimes} & H^{k+l}(X;A'\otimes B'). \end{array}$$

(2) *If $f\colon X\to X'$ is a map to another topological space X' and if A and B are two abelian groups, then for any $k,l\in\mathbb{N}_0$ the following diagram commutes*

$$\begin{array}{ccc} H^k(X';A)\times H^l(X';B) & \xrightarrow{\cup_\otimes} & H^{k+l}(X';A\otimes B) \\ \downarrow{\scriptstyle f^*\times f^*} & & \downarrow{\scriptstyle f^*} \\ H^k(X;A)\times H^l(X;B) & \xrightarrow{\cup_\otimes} & H^{k+l}(X;A\otimes B). \end{array}$$

To formulate the relationship to the earlier definition of the cup product we need to introduce the following definition.

Definition. Let R be a commutative ring. We refer to the homomorphism[12411242]

$$\begin{array}{rcl} \mu\colon R\otimes R & \to & R \\ \sum\limits_{i=1}^{n} \underbrace{a_i}_{\in\mathbb{Z}} \cdot \underbrace{r_i}_{\in R} \otimes \underbrace{s_i}_{\in R} & \mapsto & \sum\limits_{i=1}^{n} a_i \cdot \underbrace{(r_i \cdot s_i)}_{\in R} \end{array}$$

as the *multiplication induced map.*

Now we can formulate the relationship between the two cup products.

Lemma 74.7. *Let X be a topological space. If R is a commutative ring, then we have the following commutative diagram*

$$\begin{tikzcd} & H^p(X;R)\times H^q(X;R) \arrow[dl, "\cup_\otimes"'] \arrow[dr, "\cup"] & \\ H^{p+q}(X;R\otimes R) \arrow[rr, "\mu_*"] & & H^{p+q}(X;R) \end{tikzcd}$$

where $\mu\colon R\otimes R\to R$ denotes the multiplication induced map.

The proof of the following proposition is almost identical to the proof of the earlier Proposition 57.8.

Proposition 74.8. *Let X be a topological space and let A and B be abelian groups. Furthermore let $\varphi\in H^p(X;A)$ and $\psi\in H^q(X;B)$. If we denote by $\Theta\colon A\otimes B\to B\otimes A$ the natural isomorphism induced by $a\otimes b\mapsto b\otimes a$, see Lemma 42.3* (1)*, then*

$$\Theta_*\big(\underbrace{a\cup_\otimes b}_{\in H^{p+q}(X;A\otimes B)}\big) \;=\; (-1)^{p\cdot q}\;\cdot\;\underbrace{b\cup_\otimes a.}_{\in H^{p+q}(X;B\otimes A)}$$

We also need a barely visible variation on the cap product.

Definition. Let X be a topological space, let U be a subset of X and let G be an abelian group. Furthermore let $k\le l$. We define the *cap product*

$$\begin{array}{rcl} C^k(X;G)\times C_l(X,U) & \to & C_{l-k}(X,U;G) = C_{l-k}(X,U)\otimes G \\ (\varphi,[\sigma\colon\Delta^l\to X]) & \mapsto & \varphi\cap\sigma := \underbrace{\sigma\circ[v_k,\dots,v_l]}_{\in C_{l-k}(X,U)}\otimes\underbrace{\varphi(\sigma\circ[v_0,\dots,v_k])}_{\in G}. \end{array}$$

For $k>l$ we define the cap product to be the zero map.

The following lemma summarizes the key properties of the more general cap product.

Lemma 74.9. *Let X be a topological space, let U be a subset of X, let G be an abelian group and let $k,l\in\mathbb{N}_0$.*

[1241]Note that this is indeed a homomorphism of abelian groups.

[1242]Here on the right-hand side we implicitly use that any abelian group, in particular R, is a $\mathbb{Z}$-module.

(1) *The map*

$$\begin{array}{rcl} H^k(X;G) \times H_l(X,U;\mathbb{Z}) & \to & H_{l-k}(X,U;G) \\ ([\varphi],[\sigma]) & \mapsto & [\varphi] \cap [\sigma] \ := \ [\varphi \cap \sigma] \end{array}$$

is well-defined.

(2) *For any $\varphi \in H^k(X;G)$ and any $\sigma \in H_k(X;\mathbb{Z})$ we have*

$$\epsilon_X(\varphi \cap \sigma) \ = \ \langle \varphi, \sigma \rangle \ \in \ A,$$

where $\epsilon_X \colon H_0(X;G) \to G$ is the augmentation map and $\langle\ ,\ \rangle$ denotes the Kronecker pairing that we introduced in Lemma 50.5.

(3) *If $\rho \colon G \to B$ is a homomorphism of abelian groups, then for any $\varphi \in H^k(X;G)$ and any $\sigma \in H_l(X,U;\mathbb{Z})$ we have*

$$\rho_*(\varphi) \cap \sigma \ = \ \rho_*(\varphi \cap \sigma) \ \in \ H_{l-k}(X,U;B).$$

(4) *If $f \colon (X,U) \to (Y,V)$ is a map between pairs of topological spaces, then for any $\varphi \in H^k(Y;G)$ and any $\sigma \in H_l(X,U;\mathbb{Z})$ we have*

$$f_*(f^*(\varphi) \cap \sigma) \ = \ \varphi \cap f_*(\sigma) \ \in \ H_{l-k}(Y,V;G).$$

Note that here f^* denotes the induced map $f^* \colon H^k(Y;G) \to H^k(X;G)$ on absolute cohomology, whereas f_* denotes the induced maps $H_l(X,U;\mathbb{Z}) \to H_l(Y,V;\mathbb{Z})$ and $H_{l-k}(X,U;A) \to H_{l-k}(Y,V;A)$ on relative homology groups.

(5) *Let $\varphi \in H^k(X;\mathbb{Z})$, $\psi \in H^l(X;G)$ and furthermore let $\sigma \in H_n(X;\mathbb{Z})$. We denote by $c \colon G \otimes \mathbb{Z} \to G$ and $c \colon \mathbb{Z} \otimes G \to G$ the obvious isomorphisms given by Lemma 42.3. Then*

$$\varphi \cap (\psi \cap \sigma) \ = \ \underbrace{c_*(\overbrace{\psi \cup_\otimes \varphi}^{\in H^{k+l}(X;G\otimes\mathbb{Z})})}_{\in H^{k+l}(X;G)} \cap \sigma \ = \ (-1)^{kl} \cdot \underbrace{c_*(\overbrace{\varphi \cup_\otimes \psi}^{\in H^{k+l}(X;\mathbb{Z}\otimes G)})}_{\in H^{k+l}(X;G)} \cap \sigma \ \in \ H_{n-k-l}(X;G).$$

Proof. The proof of the first statement is entirely analogous to the proof of Lemma 59.2 or Lemma 43.6. The second statement and the third statement are an immediate consequence of the definitions. The fourth statement is a mild generalization of Lemma 59.8 and it is also a straightforward consequence of the definitions. Furthermore the first equality of the last statement is an equally mild generalization of Lemma 59.7. Finally the last equality of the last statement is a consequence of Proposition 74.8. □

Later on we will also need the following slight variation of the Poincaré Duality Theorem 61.1. The proof is verbatim the same as the proof of the Poincaré Duality Theorem 61.1.

Proposition 74.10. *Let M be a compact oriented non-empty n-dimensional topological manifold and let G be an abelian group. For each $k \in \mathbb{N}_0$ the map*

$$\begin{array}{rcl} H^k(M;G) & \xrightarrow{\cong} & H_{n-k}(M,\partial M;G) \\ \sigma & \mapsto & \sigma \cap [M] \end{array}$$

is an isomorphism.

The above proposition leads us to the following definition.

Definition. Let M be a closed oriented non-empty n-dimensional topological manifold and let G be an abelian group. We denote by

$$\mathrm{PD}_M^G\colon H_k(M;G) \xrightarrow{\cong} H^{n-k}(M;G)$$

the inverse of the isomorphism of the Poincaré Duality isomorphism given by Proposition 74.10.

The following lemma is an immediate consequence of the relevant definitions together with Lemma 74.9 (3).

Lemma 74.11. *Let M be a closed oriented non-empty n-dimensional topological manifold. If $\rho\colon G \to H$ is a homomorphism of abelian groups, then for every $k \in \mathbb{N}_0$ the following diagram commutes:*

$$\begin{array}{ccc} H_k(M;G) & \xrightarrow{\mathrm{PD}_M^G} & H^{n-k}(M;G) \\ {\scriptstyle\rho_*}\downarrow & & \downarrow{\scriptstyle\rho_*} \\ H_k(M;H) & \xrightarrow{\mathrm{PD}_M^H} & H^{n-k}(M;H). \end{array}$$

74.4. **The linking pairing on odd-dimensional rational homology spheres.** Now we return to the study of rational homology spheres. We start out with the following elementary lemma.

Lemma 74.12. *Let $n \geq 1$. For every $(2n+1)$-dimensional rational homology sphere M the Bockstein homomorphism $\beta\colon H^n(M;\mathbb{Q}/\mathbb{Z}) \to H^{n+1}(M;\mathbb{Z})$ corresponding to the short exact sequence $0 \to \mathbb{Z} \to \mathbb{Q} \to \mathbb{Q}/\mathbb{Z} \to 0$ is an isomorphism.*

Proof. It follows from our hypothesis together with Proposition 51.18 (or alternatively together with the Poincaré Duality Theorem 61.3), that for the rational homology sphere M we have $H^n(M;\mathbb{Q}) = H^{n+1}(M;\mathbb{Q}) = 0$. Thus it follows from the Bockstein sequence in cohomology that the Bockstein homomorphism $H^n(M;\mathbb{Q}/\mathbb{Z}) \to H^{n+1}(M;\mathbb{Z})$ is an isomorphism. □

We continue with the following purely algebraic definition.

Definition. A *linking pairing* on an abelian group H is a pairing that takes values in $\mathbb{Q}/\mathbb{Z}$, i.e. it is a bilinear map $\lambda\colon H \times H \to \mathbb{Q}/\mathbb{Z}$.

Example. Let $n \in \mathbb{N}$ and let $k \in \mathbb{Z}$. The map

$$\begin{array}{rcl} \lambda\colon \mathbb{Z}_n \times \mathbb{Z}_n & \to & \mathbb{Q}/\mathbb{Z} \\ (a,b) & \mapsto & \frac{k}{n} \cdot a \cdot b \end{array}$$

is a symmetric linking pairing. It is an amusing exercise to show that this linking pairing is non-singular, in the sense of the definition on page 1447, if and only if k is coprime to n.

The following lemma is a variation of Lemma 62.1. It gives another rich source of linking pairings.

Lemma 74.13. *If $A \in M(n \times n, \mathbb{Z})$ is a symmetric matrix with* $\det(A) \neq 0$*, then the map*

$$\begin{array}{rcl} \lambda(A)\colon \mathbb{Z}^n/A\mathbb{Z}^n \times \mathbb{Z}^n/A\mathbb{Z}^n & \to & \mathbb{Q}/\mathbb{Z} \\ ([v],[w]) & \mapsto & v^T A^{-1} w \end{array}$$

is well-defined and it defines a non-singular symmetric linking pairing.

Since we will not make use of Lemma 74.13 we will only provide a sketch of a proof.

Sketch of proof. It follows easily from the symmetry of A that the linking pairing is well-defined, i.e. that it is independent of the choice of the representatives v and w. Furthermore it is straightforward to see that the linking pairing is symmetric. It remains to show that the linking pairing is non-singular. By the symmetry of the linking pairing it suffices to show that the map

$$\begin{array}{rcl} \Phi\colon \mathbb{Z}^n/A\mathbb{Z}^n & \to & \mathrm{Hom}(\mathbb{Z}^n/A\mathbb{Z}^n, \mathbb{Q}/\mathbb{Z}) \\ [v] & \mapsto & ([w] \mapsto v^T A^{-1} w) \end{array}$$

is an isomorphism. We make the following three observations:

(1) From Lemma 11.7 and $\det(A) \neq 0$ we know that $\mathbb{Z}^n/A\mathbb{Z}^n$ is a torsion-group.
(2) It follows fairly easily from the classification of finitely generated abelian groups, see Theorem 11.4, that for any finite abelian group H the groups $\mathrm{Hom}(H, \mathbb{Q}/\mathbb{Z})$ and H have the same number of elements.
(3) By (1) and (2) the map Φ is a homomorphism between finite abelian groups with the same number of elements. Thus it suffices to show that Φ is a monomorphism.

Now let $v \in \mathbb{Z}^n$ such that $\Phi([v]) = 0$. This implies that for the i-th standard basis vector e_i the product $v^T A^{-1} e_i =: \mu_i$ lies in $\mathbb{Z}$. But this means that $v^T A^{-1} = (\mu_1 \ \dots \ \mu_n) \in \mathbb{Z}^n$, i.e. using the symmetry of A, we obtain that

$$v \ = \ A^T(\mu_1 \ \dots, \mu_n)^T \ = \ A(\mu_1 \ \dots \ \mu_n)^T \ \in \ A \cdot \mathbb{Z}^n. \qquad \square$$

Before we continue we fix some notation that we will use throughout the remainder of this chapter.

Notation. Let S be a commutative ring and let R be a subring of S. We adopt the following notations:

(1) We denote by $i\colon R \to S$ the inclusion map and we denote by $p\colon S \to R/S$ the projection map.
(2) Given a topological space X we denote by β the Bockstein homomorphism corresponding to the short exact sequence $0 \to R \xrightarrow{i} S \xrightarrow{p} S/R \to 0$.
(3) Similar to the discussion on page 1716 we can consider the multiplication induced homomorphisms

$$\begin{array}{rcl} R \otimes S/R & \to & S/R \\ \sum\limits_{i=1}^{k} r_i \otimes [s_i] & \mapsto & \sum\limits_{i=1}^{k} [r_i \cdot s_i] \end{array} \quad \text{and} \quad \begin{array}{rcl} S/R \otimes R & \to & S/R \\ \sum\limits_{i=1}^{k} [s_i] \otimes r_i & \mapsto & \sum\limits_{i=1}^{k} [s_i \cdot r_i]. \end{array}$$

We denote both homomorphisms by ν.

The following definition can be viewed as an odd-dimensional analogue of the definition of the intersection form on a compact oriented even-dimensional manifold that we gave on page 1652.

Definition. Let M be an oriented rational homology sphere of dimension $2n+1$ with $n \geq 1$. We refer to the map

$$\begin{array}{rcl} \lambda_M \colon H_n(M;\mathbb{Z}) \times H_n(M;\mathbb{Z}) & \to & \mathbb{Q}/\mathbb{Z} \\ (a,b) & \mapsto & \Big\langle \nu_*\big(\underbrace{\overbrace{\beta^{-1}(\mathrm{PD}(a))}^{\in H^{n+1}(M;\mathbb{Q}/\mathbb{Z})} \cup_\otimes \overbrace{\mathrm{PD}(b)}^{\in H^{n+1}(M;\mathbb{Z})}}_{\in H^{2n+1}(M;\mathbb{Q}/\mathbb{Z}\otimes\mathbb{Z})}\big), [M]\Big\rangle \end{array}$$

as the *linking pairing* λ_M *of* M.

Remark. With very minor efforts one can generalize the previous definition. More precisely, let M be a closed oriented $(2n+1)$-dimensional manifold. We denote by $TH_n(M;\mathbb{Z})$ the torsion subgroup of $H_n(M;\mathbb{Z})$. In an almost identical fashion to the above one can define a pairing

$$TH_n(M;\mathbb{Z}) \times TH_n(M;\mathbb{Z}) \ \to\ \mathbb{Q}/\mathbb{Z}.$$

Furthermore, with similar proofs one can generalize the subsequent Propositions 74.16 and Proposition 74.17 to this more general setup. But since we will not make use of this generalization we leave it to the reader to fill in the details.

Lemma 74.14. *Let $n \geq 1$ and let $f \colon M \to N$ be a homotopy equivalence between oriented $(2n+1)$-dimensional rational homology spheres. By Proposition 30.5 there exists an $\epsilon \in \{-1,1\}$ with $f_*([M]) = \epsilon \cdot [N] \in H_{2n+1}(N;\mathbb{Z})$. Then for any $x, y \in H_n(M;\mathbb{Z})$ the following equality holds:*

$$\lambda_N(f_*(x), f_*(y)) \ = \ \epsilon \cdot \lambda_M(x,y).$$

Proof. In the proof of Lemma 71.7 we had implicitly proved the following statement.[1243]

Statement 74.15. *For any $c \in H_k(M;\mathbb{Z})$ we have*

$$f^*(\mathrm{PD}_N^{\mathbb{Z}}(f_*(c))) \ = \ \varepsilon \cdot \mathrm{PD}_M^{\mathbb{Z}}(c) \in H^{2n+1-k}(M;\mathbb{Z}).$$

[1243]Strictly speaking, in the proof of Lemma 71.7 the map f was a homeomorphism, but that makes no difference.

Now we can prove the desired equality. More precisely, we have the following equalities in $\mathbb{Q}/\mathbb{Z}$:

$$\begin{aligned}
&\text{by definition of the linking pairing } \lambda_N \\
&\quad\downarrow \\
\lambda_M(x,y) &= \big\langle \beta^{-1}(\mathrm{PD}_M^{\mathbb{Z}}(x)) \cup_{\otimes} \mathrm{PD}_M^{\mathbb{Z}}(y), [M]\big\rangle \\
&= \big\langle f^*(\beta^{-1}(\mathrm{PD}_N^{\mathbb{Z}}(f_*(x)))) \cup_{\otimes} f^*(\mathrm{PD}_N^{\mathbb{Z}}(f_*(y))), \epsilon\cdot(f_*)^{-1}([N])\big\rangle \\
&\quad\uparrow \\
&\text{by the above statement, the convenient truth that } \epsilon^2 = 1 \text{ and the definition of } \epsilon \\
&\text{we also used the naturality of } \beta\text{, which is a consequence of Proposition 48.6 (2)} \\
&= \big\langle \beta^{-1}(\mathrm{PD}_N^{\mathbb{Z}}(f_*(x))) \cup_{\otimes} \mathrm{PD}_M^{\mathbb{Z}}(f_*(y)), \epsilon\cdot[N]\big\rangle \;=\; \epsilon\cdot\lambda_N(f_*(x), f_*(y)). \\
&\quad\uparrow \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \uparrow \\
&\text{by Lemma 50.6 and Lemma 74.6 (2)} \qquad\qquad\qquad\qquad \text{definition of } \lambda_N
\end{aligned}$$

□

In Proposition 71.5 we saw that the intersection form of a closed oriented even-dimensional topological manifold is (anti-) symmetric and non-singular. The following two propositions give us similar statements for linking pairings.

Proposition 74.16. *Let $n \geq 1$ and let M be an oriented $(2n+1)$-dimensional rational homology sphere. If n is odd, then the linking pairing λ_M on $H_n(M;\mathbb{Z})$ is symmetric otherwise it is anti-symmetric.*

Remark. Linking forms were initially introduced in 1933 by Herbert Seifert [Sei, p. 814] for oriented 3-dimensional rational homology spheres. He gave a somewhat informal argument why the linking pairing is symmetric. The fact that linking pairings are (anti-) symmetric is well-known and implicitly or implicitly used many times. But published proofs of this statement are few and far between. The subsequent proof of Proposition 74.16 first appeared in [CFH].

Proposition 74.17. *Let $n \geq 1$. The linking pairing λ_M of any oriented $(2n+1)$-dimensional rational homology sphere is non-singular.*

In these modest lecture notes we will not make use of Propositions 74.16 and 74.17. Since the proofs are somewhat technical we hide them in the next section.

74.5. **Proofs of Propositions 74.16 and 74.17.** We will see that Proposition 74.16 is a fairly straightforward consequence of the next lemma.

Lemma 74.18. *Let S be a commutative ring and let R be a subring of S. Let X be a topological space. For any $x \in H^k(X;S/R)$ and any $y \in H^l(X;S/R)$ we have*

$$\nu_*\big(\underbrace{\beta(x) \cup_{\otimes} y}_{\in H^{k+l+1}(X;R\otimes S/R)}\big) \;=\; (-1)^{k+1}\cdot\nu_*\big(\underbrace{x \cup_{\otimes} \beta(y)}_{\in H^{k+l+1}(X;S/R\otimes R)}\big) \;\in\; H^{k+l+1}(X;S/R).$$

Proof of Proposition 74.16 assuming Lemma 74.18. Let $n \geq 1$ and let M be an oriented $(2n+1)$-dimensional rational homology sphere. Furthermore let $a, b \in H_n(M;\mathbb{Z})$. We write

$x = \beta^{-1}(\mathrm{PD}(a)) \in H^n(M;\mathbb{Q}/\mathbb{Z})$ and $y = \beta^{-1}(\mathrm{PD}(b)) \in H^n(M;\mathbb{Q}/\mathbb{Z})$. Then

$$\begin{aligned}
\lambda_M(a,b) &\overset{\text{by definition of } \lambda_M}{=} \langle \nu_*(x \cup_\otimes \beta(y)), [M]\rangle \overset{\text{by Lemma 74.18}}{=} (-1)^{n+1}\cdot\langle \nu_*(\beta(x) \cup_\otimes y), [M]\rangle \\
&\underset{\text{by Proposition 74.8 since } n(n+1) \text{ is even}}{=} (-1)^{n+1}\cdot\langle \nu_*(y \cup_\otimes \beta(x)), [M]\rangle \underset{\text{by definition of } \lambda_M}{=} (-1)^{n+1}\cdot\lambda_M(b,a).
\end{aligned}$$

□

Proof of Lemma 74.18. First recall that we have a short exact sequence of cochain complexes:

$$0 \to C^*(X;R) \xrightarrow{i_*} C^*(X;S) \xrightarrow{p_*} C^*(X;S/R) \to 0.$$

In particular we can and will pick $f \in C^k(X;S)$ and $g \in C^l(X;S)$ such that $[p_*(f)] = x$ and such that $[p_*(g)] = y$. Next recall that the Bockstein homomorphisms in cohomology are the connecting homomorphisms corresponding to the above short exact sequence of cochain complexes. It follows immediately from the definition of the connecting homomorphism, see page 1160 and Proposition 48.6, that there exist unique cocycles $\beta(f) \in C^{k+1}(X;R)$ and $\beta(g) \in C^{l+1}(X;R)$ such that $i_*(\beta(f)) = \delta^k(f) \in C^{k+1}(X;S)$ and also such that $i_*(\beta(g)) = \delta^l(g) \in C^{l+1}(X;S)$. We have the following equality in $H^{k+l+1}(X;S\otimes S)$:

$$(*) \qquad \begin{aligned}
0 &\underset{\substack{\text{by definition}\\ \text{of cohomology}}}{=} [\delta(f \cup_\otimes g)] \overset{\text{see Lemma 74.4}}{=} [\delta(f) \cup_\otimes g + (-1)^k \cdot f \cup_\otimes \delta(g)] \\
&= \big[\underbrace{i_*(\beta(f)) \cup_\otimes g}_{\in C^{k+l+1}(X;R\otimes S)} + (-1)^k \cdot \underbrace{f \cup_\otimes i_*(\beta(g))}_{\in C^{k+l+1}(X;S\otimes R)}\big].
\end{aligned}$$

We consider the following diagram of group homomorphisms

$$\begin{tikzcd}
R\otimes S \arrow[r, "i\otimes\mathrm{id}"] \arrow[d, "\mathrm{id}\otimes p"'] & S\otimes S \arrow[d, "\mu"] & S\otimes R \arrow[l, "\mathrm{id}\otimes i"'] \arrow[d, "p\otimes\mathrm{id}"] \\
R\otimes S/R \arrow[dr, "\nu"] & S \arrow[d, "p"] & S/R\otimes R \arrow[dl, "\nu"'] \\
& S/R &
\end{tikzcd}$$

where, as usual, ν and μ stand for the obvious maps that are induced by multiplication in the ring S. It is straightforward to see that the diagram commutes. We have the following

equalities in $H^{k+l+1}(X;S/R)$:

$$\begin{aligned}
&\text{by the above equality } (*)\\
&\quad\downarrow\\
0 &= (p\circ\mu)_*\big(\big[i_*(\beta(f))\cup_\otimes g \;+\; (-1)^k\cdot f\cup_\otimes i_*(\beta(g))\big]\big)\\
&= \big[\nu_*\big(\beta(f)\cup_\otimes p_*(g)\big) \;+\; (-1)^k\cdot\nu_*\big(p_*(f)\cup_\otimes\beta(g)\big)\big]\\
&\quad\uparrow\\
&\text{by the above commutative diagram of group homomorphisms and some basic observations}\\
&\quad\text{regarding the functoriality of the cup product in the coefficients}\\
&= \nu_*\big([\beta(f)]\cup_\otimes[p_*(g)]\big) \;+\; (-1)^k\cdot\nu_*\big([p_*(f)]\cup_\otimes[\beta(g)]\big)\\
&\quad\uparrow\\
&\text{by definition of } \cup_\otimes \text{ and since } \beta(f), p_*(g), p_*(f) \text{ and } \beta(g) \text{ are cocycles}\\
&= \nu_*(\beta(x)\cup_\otimes y) \;+\; (-1)^k\cdot\nu_*(x\cup_\otimes\beta(y)).\\
&\quad\uparrow\\
&\text{since } [\beta(f)]=\beta([p_*(f)])=:\beta(x) \text{ and } [p_*(g)]=y \text{ and similar for the second summand}
\end{aligned}$$

This of course implies the desired statement. □

Before we give the proof of Proposition 74.17 we prove the following lemma which gives a slight reformulation of the linking pairing.

Lemma 74.19. *Let $n\geq 1$ and let M be an oriented $(2n+1)$-dimensional rational homology sphere. For any choice of $a,b\in H_n(M;\mathbb{Z})$ we have*

$$\lambda_M(a,b) \;=\; \epsilon_M\big(\beta^{-1}(\mathrm{PD}_M^{\mathbb{Z}}(a))\cap b\big) \;=\; \big\langle\beta^{-1}(\overbrace{\mathrm{PD}_M^{\mathbb{Z}}(a)}^{\in H^{n+1}(M;\mathbb{Z})}),b\big\rangle.$$

Proof. Let $a,b\in H_n(M;\mathbb{Z})$. We have the following equalities in $\mathbb{Q}/\mathbb{Z}$:

$$\begin{aligned}
&\text{by definition and Lemma 74.9 (2)}\\
&\quad\downarrow\\
\lambda_M(a,b) &= \epsilon_M\big(\overbrace{\nu_*\big(\underbrace{\beta^{-1}(\mathrm{PD}_M^{\mathbb{Z}}(a))}_{\in H^{n+1}(M;\mathbb{Q}/\mathbb{Z})}\cup_\otimes\underbrace{\mathrm{PD}_M^{\mathbb{Z}}(b)}_{\in H^n(M;\mathbb{Z})}\big)}^{\in H^{2n+1}(M;\mathbb{Q}/\mathbb{Z})}\cap[M]\big)\\
&= \epsilon_M\big(\underbrace{\beta^{-1}(\mathrm{PD}_M^{\mathbb{Z}}(a))}_{\in H^n(M;\mathbb{Q}/\mathbb{Z})}\cap\underbrace{(\mathrm{PD}_M^{\mathbb{Z}}(b)\cap[M])}_{\in H_n(M;\mathbb{Z})}\big) \qquad = \epsilon_M\big(\beta^{-1}(\mathrm{PD}_M^{\mathbb{Z}}(a))\cap b\big).\\
&\quad\uparrow \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \uparrow\\
&\text{by Lemma 74.9 (5) and the convenient fact} \qquad \text{definition of } \mathrm{PD}_M^{\mathbb{Z}}(b)\\
&\quad\text{that } n(n+1) \text{ is always even}\\
&= \big\langle\beta^{-1}(\mathrm{PD}_M^{\mathbb{Z}}(a)),b\big\rangle.\\
&\quad\uparrow\\
&\text{Lemma 74.9 (2)}
\end{aligned}$$

We have thus verified both desired equalities. □

We conclude this technical section with the proof of Proposition 74.17.

Proof of Proposition 74.17. Let M be an oriented $(2n+1)$-dimensional rational homology sphere. We need to show that the linking pairing $\lambda_M\colon H_n(M;\mathbb{Z}) \times H_n(M;\mathbb{Z}) \to \mathbb{Q}/\mathbb{Z}$ is non-singular. To do so we consider the map

$$\Phi_M\colon H_n(M;\mathbb{Z}) \xrightarrow{\mathrm{PD}_M^{\mathbb{Z}}} H^{n+1}(M;\mathbb{Z}) \xrightarrow[\cong]{\beta^{-1}} H^n(M;\mathbb{Q}/\mathbb{Z}) \xrightarrow{\mathrm{ev}} \mathrm{Hom}_{\mathbb{Z}}(H_n(M;\mathbb{Z}),\mathbb{Q}/\mathbb{Z}).$$

Here the first map is given by Poincaré Duality, the second map is the inverse of the Bockstein isomorphism given by Lemma 74.12 and the third map is given by the evaluation map.

In Proposition 74.16 we showed that the linking pairing is (anti-) symmetric. Therefore it suffices to prove that the map

$$\begin{array}{rcl} H_n(M;\mathbb{Z}) & \to & \mathrm{Hom}(H_n(M;\mathbb{Z}),\mathbb{Q}/\mathbb{Z}) \\ a & \mapsto & (b \mapsto \lambda_M(a,b)) \end{array}$$

is an isomorphism. But this in turn follows immediately from the following claim.

Claim.

(1) The map Φ_M is an isomorphism.
(2) For any $a, b \in H_n(M;\mathbb{Z})$ we have $\lambda_M(a,b) = \Phi_M(a)(b)$.

First note that the second statement is an immediate consequence of Lemma 74.19. For the first statement it remains to show that the third map in the definition of Φ_M is an isomorphism. Recall that by the Universal Coefficient Theorem 51.13 for Cohomology Groups we have a short exact sequence

$$0 \to \mathrm{Ext}(H_{n-1}(M;\mathbb{Z}),\mathbb{Q}/\mathbb{Z}) \to H^n(M;\mathbb{Q}/\mathbb{Z}) \xrightarrow{\mathrm{ev}} \mathrm{Hom}(H_n(M;\mathbb{Z}),\mathbb{Q}/\mathbb{Z}) \to 0.$$

On page 1217 we remarked that the abelian group $\mathbb{Q}/\mathbb{Z}$ is divisible. By Proposition 51.6 this implies that the Ext-term to the left is zero. But this shows that the evaluation homomorphism to the right is an isomorphism. This concludes the proof of the claim. □

74.6. **Linking forms of lens spaces.** In the next section we will prove the following proposition.

Proposition 74.20. *Let $p, q \in \mathbb{N}$ be coprime. The linking pairing of the lens space $L(p,q)$ is isometric to*[1244][1245]

$$\begin{array}{rcl} \mathbb{Z}_p \times \mathbb{Z}_p & \to & \mathbb{Q}/\mathbb{Z} \\ (x,y) & \mapsto & -\frac{q}{p}\cdot x \cdot y \mod \mathbb{Z}. \end{array}$$

[1244]Recall that we have $L(p,q) = S^3/\mathbb{Z}_p$ and, that following the convention established on page 266, we equip $L(p,q)$ with the obvious orientation coming from S^3.

[1245]By now I am fairly confident that the sign in the calculation of the linking pairing of the lens space $L(p,q)$ is correct. But the fact that, in my attempts to calculate the linking pairing, the sign flipped on numerous occasions means that one should take the result with a grain of salt.

Remark. There are many different approaches to calculating the linking pairing of lens spaces. The first calculation was given by Seifert [Sei, p. 824], see also [ST, p. 290] and [ST, p. 279]. Alternative calculations are given in [Hat, p. 306], [Mun, Chapter 69] and [Bre, p. 364]. The proof of Proposition 74.20 that we give is rather different from the previous proofs. The approach taken below has the advantage that it can also be used to determine the linking pairing of any oriented 3-dimensional rational homology sphere in terms of a Heegaard splitting. We refer to [CFH] for details.

Before we turn to the somewhat lengthy, and not overly enjoyable proof, we want to use this section to state and prove several corollaries of Proposition 74.20.

Corollary 74.21. *Let $L(p,q)$ and $L(p,\widetilde{q})$ be lens spaces. Suppose there exists a homotopy equivalence $f\colon L(p,q) \to (p,\widetilde{q})$. By Proposition 30.5 there exists an $\epsilon \in \{-1,1\}$ such that $f_*([L(p,q)]) = \epsilon \cdot [L(p,\widetilde{q})]$. Then there exists $r \in \mathbb{Z}$, coprime to p, such that*

$$q \;=\; \epsilon \cdot r^2 \cdot \widetilde{q} \bmod p.$$

Proof. We pick isomorphisms $\varphi\colon \mathbb{Z}_p \to H_1(L(p,q);\mathbb{Z})$ and $\widetilde{\varphi}\colon \mathbb{Z}_p \to H_1(L(p,\widetilde{q});\mathbb{Z})$ as provided by Proposition 74.20. The map $\widetilde{\varphi}^{-1} \circ f_* \circ \varphi\colon \mathbb{Z}_p \to \mathbb{Z}_p$ is an isomorphism, hence it is given by multiplication by some $r \in \mathbb{Z}$ that is coprime to p. Together with Lemma 74.14 we see that the following diagram commutes

$$\begin{tikzcd}
\mathbb{Z}_p \times \mathbb{Z}_p \arrow[r, "\varphi\times\varphi"] \arrow[rr, bend left, "(x,y)\mapsto -\frac{q}{p}\cdot x\cdot y"] \arrow[d, "(x,y)\mapsto(rx,ry)"] & H_1(L(p,q);\mathbb{Z}) \times H_1(L(p,q);\mathbb{Z}) \arrow[r, "\lambda_{L(p,q)}"] \arrow[d, "f_*\times f_*"] & \mathbb{Q}/\mathbb{Z} \arrow[d, "\cdot(-1)"] \\
\mathbb{Z}_p \times \mathbb{Z}_p \arrow[r, "\widetilde{\varphi}\times\widetilde{\varphi}"'] \arrow[rr, bend right, "(x,y)\mapsto -\frac{\widetilde{q}}{p}\cdot x\cdot y"'] & H_1(L(p,\widetilde{q});\mathbb{Z}) \times H_1(L(p,\widetilde{q});\mathbb{Z}) \arrow[r, "\lambda_{L(p,\widetilde{q})}"] & \mathbb{Q}/\mathbb{Z}.
\end{tikzcd}$$

If we start out with $(1,1) \in \mathbb{Z}_p \times \mathbb{Z}_p$ on the upper left corner and we compare the different routes to the lower right corner we obtain that $-\epsilon \cdot \frac{q}{p} = r^2 \cdot \frac{\widetilde{q}}{p}$. Multiplying by p we obtain the desired equality. □

Now we can give the classification of lens spaces up to homotopy equivalences:

Theorem 74.22. *Let $p \in \mathbb{N}$. If $q, \widetilde{q} \in \mathbb{N}$ are coprime to p, then*

the lens spaces $L(p,q)$ and $L(p,\widetilde{q})$ are homotopy equivalent	$\Longleftrightarrow$	*there exists an $r \in \mathbb{Z}$, coprime to p, such that $q = \pm r^2 \cdot \widetilde{q}^{\pm 1} \bmod p$.*

Proof. The "⇒"-direction is precisely the statement of Corollary 74.21. The "⇐"-direction was shown by Whitehead [Whd2, Theorem 10] (see also [Cohe, Chapter 29] or [DK, Theorem 11.1]), by writing down explicit homotopy equivalences. □

So, after a very long wait we have now finally made some serious progress towards answering Question 7.8. For example, one can easily verify, using Theorem 74.22 that the lens spaces $L(5,1)$ and $L(5,2)$ are not homotopy equivalent. Nonetheless, we have not yet completely answered Question 7.8. For example the lens spaces $L(7,1)$ and $L(7,4)$ are homotopy equivalent by Theorem 74.22. But it is not clear whether these two lens spaces are homeomorphic. We will look into this problem in Algebraic Topology IV.5.

Remark. For those who might get tired of chasing down lens spaces, I would like to quote from John F. Kennedy's speech at Rice University on September 12 1962, where he announced that the United States would attempt to land a man on the moon by the end of the decade:

> *But why, some say, the Moon? Why choose this as our goal? And they may well ask, why climb the highest mountain? Why, 35 years ago, fly the Atlantic? Why does Rice play Texas?*
>
> *We choose to go to the Moon! We choose to go to the Moon in this decade and do the other things, not because they are easy, but because they are hard; because that goal will serve to organize and measure the best of our energies and skills, because that challenge is one that we are willing to accept, one we are unwilling to postpone, and one we intend to win.*

John F. Kennedy speaking at Rice University in September 1962

Figure 928.

In Question 47.8 we had asked whether the lens space $L(3,1)$ is amphichiral, i.e. we had asked $L(3,1)$ admits an orientation-reversing self-homeomorphism.

Now we have the tools to address this question.

Proposition 74.23. *If there exists an* orientation-reversing *homeomorphism between two lens spaces $L(p,q)$ and $L(p,\widetilde{q})$, then there exists an $r \in \mathbb{Z}$ such that $q = -r^2 \cdot \widetilde{q}^{\pm 1} \bmod p$.*

Example. Note that $1 \neq -r^2 \bmod 3$ for any $r \in \mathbb{Z}$. Thus it follows from Proposition 74.23 that there is no orientation-reversing homeomorphism from the lens space $L(3,1)$ to itself, i.e. the lens space $L(3,1)$ is chiral. This now answers Question 47.8.

Proof. If $f\colon L(p,q) \to L(p,\widetilde{q})$ is an orientation-reversing homeomorphism, then we have $f_*([L(p,q)]) = -[L(p,\widetilde{q})]$, i.e. we have $\epsilon = -1$ in the statement of Corollary 74.21. The proposition now follows immediately from Corollary 74.21. $\square$

74.7. **The proof of Proposition 74.20.** This section is almost entirely dedicated to the proof of Proposition 74.20. Unless the reader suffers from an insatiable appetite for cup and cap products, it is recommended to skip this section.

We start out with the following lemma that relates the Bockstein homomorphisms in homology and cohomology via the Poincaré duality

Lemma 74.24. *Let M be a closed oriented m-dimensional topological manifold. If we are given a short exact sequence $0 \to P \xrightarrow{i} Q \xrightarrow{p} R \to 0$ of abelian groups, then for every $k \in \{0, \dots, m\}$ the two diagrams*

$$\begin{array}{ccc} H^k(M;R) & \xrightarrow{\cap[M]} & H_{m-k}(M;R) \\ \downarrow\beta & & \downarrow\beta \\ H^{k+1}(M;P) & \xrightarrow{\cap[M]} & H_{m-k-1}(M;P) \end{array} \quad \textit{and} \quad \begin{array}{ccc} H_{m-k}(M;R) & \xrightarrow{\mathrm{PD}_M^R} & H^k(M;R) \\ \downarrow\beta & & \downarrow\beta \\ H_{m-k-1}(M;P) & \xrightarrow{\mathrm{PD}_M^P} & H^{k+1}(M;P) \end{array}$$

commute up to the sign $(-1)^{k+1}$.

Proof. We pick a cycle $\sigma \in C_m(M;\mathbb{Z})$ that represents the fundamental class. Furthermore let $\psi \in C^k(M;R)$ be a cocycle. We pick $\varphi \in C^k(M;Q)$ with $p_*(\varphi) = \psi$. Then we have the following equalities in $H_{m-k-1}(M;P)$:[1246]

$$\beta([\psi]) \cap [M] \;\overset{\substack{\text{by definition of the connecting}\\ \text{homomorphism on page 1160}}}{=}\; [\delta(\varphi) \cap \sigma] \;\underset{\substack{\uparrow\\ \text{by Lemma 59.1 since } \sigma \text{ is a cycle}}}{=}\; [\partial(\varphi \cap \sigma)] \;\overset{\substack{\text{by definition of the connecting}\\ \text{homomorphism on page 770}}}{=}\; \beta([p_*(\varphi \cap \sigma)]) \;=\; \beta([\psi] \cap [M]).$$

But this implies that the left-hand diagram does indeed commute. The right-hand diagram is, by definition of the Poincaré duality isomorphisms, basically the same diagram. □

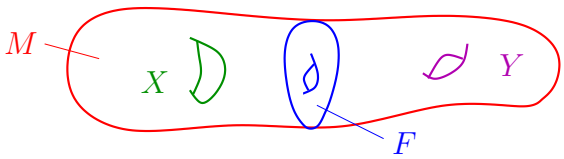
We continue with the following definition.

Definition. Let M be a 3-dimensional rational-homology sphere. Given a splitting (X, Y, F) of M, as defined on page 1695, we denote by $\Theta(X, Y, F)$ the homomorphism

$$H_1(M;\mathbb{Z}) \xrightarrow{\beta^{-1}} H_2(M;\mathbb{Q}/\mathbb{Z}) \to H_2(M,X;\mathbb{Q}/\mathbb{Z}) \underset{\substack{\uparrow\\ \text{isomorphism by the Excision Theorem 45.8 for manifolds}}}{\leftarrow} H_2(Y,F;\mathbb{Q}/\mathbb{Z}) \xrightarrow{\partial} H_1(F;\mathbb{Q}/\mathbb{Z}),$$

where "∂" denotes the connecting homomorphism of the long exact sequence of $\mathbb{Q}/\mathbb{Z}$-homology groups corresponding to the pair (Y, F). If the splitting (X, Y, F) is understood, then we just write Θ instead of $\Theta(X, Y, F)$.

[1246]The perspicacious reader will have noticed that the commutativity of the left-hand diagram has little to do with the hypothesis that we are capping with the fundamental class of a closed oriented topological manifold. Since we do not need the more general statements we leave the lemma as it is.



awfully schematic picture of a splitting of M

FIGURE 929.

The following lemma will allow us to compute the linking pairing of an oriented 3-dimensional rational homology sphere in terms of Poincaré duality on the surface F.

Lemma 74.25. *Let M be an oriented 3-dimensional rational homology sphere and let (X, Y, F) be a splitting of M, as defined on page 1695. We denote by $i\colon F \to M$ the inclusion map. Then the following diagram commutes:*

$$\begin{tikzcd}
H_1(M;\mathbb{Z}) \arrow[r, "\mathrm{PD}_M^{\mathbb{Z}}"] \arrow[d, "\Theta"] & H^2(M;\mathbb{Z}) \arrow[r, "\beta^{-1}"] & H^1(M;\mathbb{Q}/\mathbb{Z}) \arrow[d, "i^*"] \\
H_1(F;\mathbb{Q}/\mathbb{Z}) \arrow[rr, "\mathrm{PD}_F^{\mathbb{Q}/\mathbb{Z}}", "\cong"'] & & H^1(F;\mathbb{Q}/\mathbb{Z}).
\end{tikzcd}$$

Proof. First of all, we denote the inclusion map $F \to X$ by j. Furthermore we denote by $f\colon (M, \varnothing) \to (M, X)$ and $g\colon (Y, F) \to (M, X)$ the obvious maps between pairs of topological spaces. We write also $g\colon Y \to M$ for the inclusion of Y into M. We consider the following diagram:

$$\begin{tikzcd}
H_1(M;\mathbb{Z}) \arrow[dd, bend right=60, "\Theta"'] & & H^2(M;\mathbb{Z}) \arrow[ll, "\cap[M]", "\cong"'] \\
H_2(M;\mathbb{Q}/\mathbb{Z}) \arrow[u, "\beta", "\cong"'] \arrow[d, "f_*"] & & H^1(M;\mathbb{Q}/\mathbb{Z}) \arrow[ll, "\cap[M]", "\cong"'] \arrow[u, "\beta"'] \arrow[dd, "g^*"'] \arrow[ddd, bend left=60, "i^*"] \\
H_2(M,X;\mathbb{Q}/\mathbb{Z}) & & \\
H_2(Y,F;\mathbb{Q}/\mathbb{Z}) \arrow[u, "g_*"'] \arrow[d, "\partial"] & & H^1(Y;\mathbb{Q}/\mathbb{Z}) \arrow[ll, "\cap[Y]", "\cong"'] \arrow[d, "j^*"'] \\
H_1(F;\mathbb{Q}/\mathbb{Z}) \arrow[d, "="'] & & H^1(F;\mathbb{Q}/\mathbb{Z}) \arrow[ll, "\cap[Y]", "\cong"'] \arrow[d, "="] \\
H_1(F;\mathbb{Q}/\mathbb{Z}) & & H^1(F;\mathbb{Q}/\mathbb{Z}). \arrow[ll, "\cap[F]", "\cong"']
\end{tikzcd}$$

We consider the commutativity of the four rectangles in the diagram separately.

(1) The top rectangle commutes by Lemma 74.24. (Strictly speaking Lemma 74.24 says that the diagram commutes up to the sign $(-1)^{1+1} = 1$.)

(2) We turn to the second rectangle (or equivalently the first and only pentagon). Let $\varphi \in H^1(M;\mathbb{Q}/\mathbb{Z})$. We have the following equalities in $H_2(M,X;\mathbb{Q}/\mathbb{Z})$:

$$\begin{array}{ccccccc} & & & \text{by Lemma 46.23 we have } f_*([M]) = g_*([Y]) & & & \\ & & & \downarrow & & & \\ f_*(\varphi \cap [M]) & = & \varphi \cap f_*([M]) & = & \varphi \cap g_*([Y]) & = & g_*(g^*(\varphi) \cap [Y]). \\ & & \uparrow & & & \uparrow & \\ & & \begin{array}{c}\text{Lemma 74.9 (4) applied to} \\ f\colon (M,\varnothing) \to (M,X) \text{ where we use} \\ \text{that } f^* = \mathrm{id}\colon H^1(M;\mathbb{Q}/\mathbb{Z}) \to H^1(M;\mathbb{Q}/\mathbb{Z})\end{array} & & & \begin{array}{c}\text{Lemma 74.9 (4) applied} \\ \text{to } g\colon (Y,F) \to (M,X)\end{array} & \end{array}$$

(3) The third rectangle anti-commutes[1247] by the obvious extension of Proposition 61.22 from $\mathbb{Z}$-coefficients to $\mathbb{Q}/\mathbb{Z}$-coefficients.
(4) It follows from our orientation convention from page 1695 that $F = -\partial Y$ as oriented manifolds. By the discussion on page 1139 this implies $[F] = -\partial[Y]$. We obtain from this observation that the bottom rectangle anti-commutes.

Summarizing we see that the two approaches of going from $H^2(M;\mathbb{Z})$ to $H_1(F;\mathbb{Q}/\mathbb{Z})$ agree. The lemma follows from the observation, that by definition PD_M is the inverse of the top horizontal map and that similarly $\mathrm{PD}_F^{\mathbb{Q}/\mathbb{Z}}$ is the inverse of the bottom horizontal map. □

Now we turn to lens spaces. In the following we will use the description of lens spaces that we had obtained in Lemma 73.3. At this point it is convenient to recall and introduce some notation:

Notation.

(1) We write $F = S^1 \times S^1$. We write $a = [S^1 \times 1]$ and $b = [1 \times S^1]$ and we use this ordered basis of $H_1(F;\mathbb{Z})$ to make the usual identification $H_1(F;\mathbb{Z}) = \mathbb{Z}^2$. By a slight abuse of notation we also denote by a and b the corresponding elements in $H_1(F;\mathbb{Q}) = H_1(F;\mathbb{Z}) \otimes \mathbb{Q}$.
(2) Let $p, q \in \mathbb{N}$ be coprime. We pick $r, s \in \mathbb{N}$ such that $ps - qr = 1$. We write

$$A = \begin{pmatrix} q & p \\ s & r \end{pmatrix} \quad \text{and we consider the diffeomorphism} \quad \begin{array}{rcl} \varphi\colon F = \mathbb{R}^2/\mathbb{Z}^2 & \to & F = \mathbb{R}^2/\mathbb{Z}^2 \\ [v] & \mapsto & [Av]. \end{array}$$

By Lemma 38.7 (2) the induced map φ_* on the homology group $H_1(F;\mathbb{Z}) = \mathbb{Z}^2$ is given by multiplication by the matrix A.
(3) We write $X = S^1 \times \overline{B}^2$ and we denote by Y another disjoint copy of the solid torus $S^1 \times \overline{B}^2$. We equip X and Y with the usual product orientation. In Lemma 73.3 we gave an explicit orientation-preserving diffeomorphism

$$L(p,q) \xrightarrow{\cong} (X \sqcup Y)/x \sim \varphi(x) \quad \text{for } x \in F = \partial X$$

[1247]Here by "anti-commutes" we mean that the left-down path agrees with the down-left path except for a minus sign.

that we will use to identify $L(p,q)$ with the topological space to the right. By an abuse of notation we denote the images of the X and Y in $L(p,q)$ again by X and Y. Note that (X,Y,F) is a Heegaard splitting for $L(p,q)$.

(4) As usual, for want of a better notation, we denote by i the various inclusion maps $F \to X$, $X \to L(p,q)$ and $F \to L(p,q)$.
(5) We denote by $\rho\colon \mathbb{Q} \to \mathbb{Q}/\mathbb{Z}$ the obvious projection map.
(6) Finally we denote by $\Theta\colon H_1(L(p,q);\mathbb{Z}) \to H_1(F;\mathbb{Q}/\mathbb{Z})$ the map that we introduced on page 1727.

Lemma 74.26. *The following statements hold:*

(1) $i_*(a) \in H_1(L(p,q);\mathbb{Z})$ *is a generator,*
(2) *the equality* $\Theta(i_*(a)) = \rho_*(a - \frac{q}{p}\cdot b)$ *holds in* $H_1(F;\mathbb{Q}/\mathbb{Z})$.

Proof. By Proposition 50.12 we can apply the Mayer–Vietoris Theorem 50.14 to the decomposition $L(p,q) = X \cup Y$ and we obtain the following long exact sequence

$$H_1(F;\mathbb{Z}) \xrightarrow[\text{-}i_*]{i_*} \begin{matrix} H_1(X;\mathbb{Z}) \\ H_1(Y;\mathbb{Z}) \end{matrix} \to H_1(L(p,q);\mathbb{Z}) \to 0.$$

Recall that we denote by $a, b \in H_1(F;\mathbb{Z}) = H_1(S^1 \times S^1;\mathbb{Z})$ the standard basis. Since $S^1 \times S^1$ is the boundary of $S^1 \times \overline{B}^2$ we denote by a also the corresponding generator of $H_1(X;\mathbb{Z}) = H_1(S^1 \times \overline{B}^2;\mathbb{Z})$. Furthermore we denote by $a' \in H_1(Y;\mathbb{Z}) = H_1(S^1 \times \overline{B}^2;\mathbb{Z})$ the obvious generator. It follows from the above discussion and conventions, in particular the above description of φ_*, that with respect to our bases the above long exact sequence Mayer–Vietoris sequence becomes

$$\begin{matrix} \mathbb{Z}\cdot a \\ \mathbb{Z}\cdot b \end{matrix} \xrightarrow{\begin{pmatrix} 1 & 0 \\ q & p \end{pmatrix}} \begin{matrix} \mathbb{Z}\cdot a \\ \mathbb{Z}\cdot a' \end{matrix} \to H_1(L(p,q);\mathbb{Z}) \to 0.$$

At this stage it is an elementary linear algebra exercise to show that the image of a in $H_1(L(p,q);\mathbb{Z})$ is a generator.[1248]

We turn to the proof of the second statement. We denote by $h\colon (L(p,q),\varnothing) \to (L(p,q),X)$ and $j\colon (Y,F) \to (L(p,q),X)$ the obvious maps of pairs of topological spaces. We recall

[1248]This can be seen as follows. We consider the map

$$\operatorname{coker}\left\{\begin{pmatrix} 1 & 0 \\ q & p \end{pmatrix}\colon \begin{matrix} \mathbb{Z}\cdot a \\ \mathbb{Z}\cdot b \end{matrix} \to \begin{matrix} \mathbb{Z}\cdot a \\ \mathbb{Z}\cdot a' \end{matrix}\right\} \to \mathbb{Z}_p$$
$$ra + sa' \mapsto qr - s.$$

It is straightforward to see that this map is well-defined. It follows from Lemma 11.7 that the group on the left has order p. Since the map is an epimorphism and since both groups have the same order, we see that the map is in fact an isomorphism. Since the image of a on the right-hand side is a generator (here we use that q is coprime to p) we see that a also represents a generator on the left.

that Θ is defined as the composition of the following maps:

$$\begin{array}{ccccccc} H_1(L(p,q);\mathbb{Z}) & \xrightarrow{\beta^{-1}} & H_2(L(p,q);\mathbb{Q}/\mathbb{Z}) & \xrightarrow{h_*} & H_2(L(p,q),X;\mathbb{Q}/\mathbb{Z}) & \xleftarrow[\cong]{j_*} & H_2(Y,F;\mathbb{Q}/\mathbb{Z}) \\ & & & & & & \downarrow \partial \\ & & & & & & H_1(F;\mathbb{Q}/\mathbb{Z}). \end{array}$$

As before we denote by $i\colon F \to L(p,q)$ the inclusion map. For clarity we recall in the following diagram all the maps that play a role in the definition of the Bockstein homomorphism $\beta\colon H_2(L(p,q);\mathbb{Q}/\mathbb{Z}) \to H_1(L(p,q);\mathbb{Z})$:

$$\begin{array}{ccccccc} & & C_2(L(p,q);\mathbb{Q}) & \xrightarrow{\rho_*} & C_2(L(p,q);\mathbb{Q}/\mathbb{Z}) & \longrightarrow & 0 \\ & & \downarrow \partial & & & & \\ 0 \longrightarrow & C_1(L(p,q);\mathbb{Z}) & \longrightarrow & C_1(L(p,q);\mathbb{Q}). & & & \end{array}$$

Finally, we denote by $\widetilde{a}$ and $\widetilde{b}$ the obvious singular chains in F representing the homology classes a and b.

Now we turn to the actual proof of the equality $\Theta(i_*(a)) = \rho_*(a - \frac{q}{p}\cdot b)$ in $H_1(F;\mathbb{Q}/\mathbb{Z})$. We consider $a - \frac{q}{p}\cdot b \in H_1(F;\mathbb{Q})$. Note that

$$\varphi_*\big(a - \tfrac{q}{p}\cdot b\big) \underset{\substack{\uparrow \\ \text{by Lemma 38.7 and the naturality of the Universal Coefficient Theorem 42.19}}}{=} \begin{pmatrix} q & p \\ s & r \end{pmatrix} \cdot \begin{pmatrix} 1 \\ -\frac{q}{p} \end{pmatrix} = \begin{pmatrix} 0 \\ * \end{pmatrix} \in H_1(F;\mathbb{Q}) = \begin{matrix} \mathbb{Q}\cdot a \\ \mathbb{Q}\cdot b \end{matrix},$$

i.e. the image of $\varphi_*\big(a - \frac{q}{p}\cdot b\big)$ in $H_1(Y;\mathbb{Q})$ is zero.

This implies that there exists a singular 2-chain $\sigma \in C_2(Y;\mathbb{Q})$ with $\partial(\sigma) = \widetilde{a} - \frac{q}{p}\cdot\widetilde{b}$. Furthermore b represents the zero element in $H_1(X;\mathbb{Z})$, hence $\widetilde{b}$ is null-homologous in X, which implies that there exists a singular 2-chain $\mu \in C_2(X;\mathbb{Z})$ with $\partial(\mu) = \widetilde{b}$. Now we calculate that

$$\beta\big(\big[\underbrace{\rho_*(\overbrace{\sigma + \tfrac{q}{p}\cdot\mu}^{\in C_2(L(p,q);\mathbb{Q})})}_{\text{cycle in } C_2(L(p,q);\mathbb{Q}/\mathbb{Z})}\big]\big) \underset{\substack{\uparrow \\ \text{definition of } \beta}}{=} \big[\partial\big(\sigma + \tfrac{q}{p}\cdot\mu\big)\big] \underset{\substack{\uparrow \\ \text{since } \partial(\sigma) = a - \frac{q}{p}\cdot b}}{=} \big[\widetilde{a} - \tfrac{q}{p}\cdot\widetilde{b} + \tfrac{q}{p}\cdot\widetilde{b}\big] = i_*(a) \in H_1(L(p,q);\mathbb{Q}/\mathbb{Z}).$$

Since $\mu \in C_2(X;\mathbb{Z})$ and since $\sigma \in C_2(Y;\mathbb{Q})$ we have the equality

$$h_*\big(\rho_*\big(\sigma + \tfrac{q}{p}\mu\big)\big) = j_*(\rho_*(\sigma)) \in C_2(L(p,q),X;\mathbb{Q}/\mathbb{Z}).$$

We conclude that we have the following equalities in $H_1(F;\mathbb{Q}/\mathbb{Z})$:

$$\begin{array}{ccccccc}
 & & & \text{since } h_*(\rho_*(\sigma+\frac{q}{p}\mu)) = j_*(\rho_*(\sigma)) & & \text{by the above} \\
 & & & \downarrow & & \downarrow \\
\Theta(i_*(a)) & = & \partial\big(j_*^{-1}\big(h_*\big(\big[\rho_*\big(\sigma+\frac{q}{p}\mu\big)\big]\big)\big)\big) & = & \partial([\rho_*(\sigma)]) & = & [\rho_*(\partial(\sigma))] \;=\; \big[\rho_*\big(\widetilde{a}-\frac{q}{p}\cdot\widetilde{b}\big)\big] \\
 & \uparrow & & & \uparrow & & \\
 & \text{since } \beta([\rho_*(\sigma+\frac{q}{p}\cdot\mu)]) = i_*(a) & & & \text{since } \rho_*(\sigma) \text{ lives in } C_2(Y;\mathbb{Q}/\mathbb{Z}) \text{ we can calculate the} & & \\
 & & & & \text{connecting homomorphism of } [\rho_*(\sigma)] \text{ and we obtain } [\rho_*(\partial(\sigma))] & & \\
 & = & \rho_*\big(a-\frac{q}{p}\cdot b\big). & & & &
\end{array}$$

□

Now it is straightforward to provide the proof of Proposition 74.20.

Proof of Proposition 74.20. Let $p,q\in\mathbb{N}$ be coprime. We use the notation F,X,Y and a,b as above. We write $L=L(p,q)$. We denote by $\rho\colon\mathbb{Q}\to\mathbb{Q}/\mathbb{Z}$ the obvious projection map. To simplify the notation we use the convention that given any abelian group A we make the usual identification $H_0(L;A)=A$ and $H_0(F;A)=A$ from page 1009.

We start out this proof with the following claim.

Claim. If $x,y\in H_1(F;\mathbb{Z})$, then

$$\mathrm{PD}_F^{\mathbb{Z}}(x)\cap y \;=\; Q_F(y,x) \;\in\; H_0(F;\mathbb{Z})=\mathbb{Z}.$$

This claim follows from a calculation which by now is standard fare for us. For completeness' sake we carry out the details. We have

$$\begin{array}{ccccc}
 & & \text{by definition of } \mathrm{PD}_F^{\mathbb{Z}} & & \text{Lemma 59.7} \\
 & & \downarrow & & \downarrow \\
\mathrm{PD}_F^{\mathbb{Z}}(x)\cap y & = & \mathrm{PD}_F^{\mathbb{Z}}(x)\cap\big(\mathrm{PD}_F^{\mathbb{Z}}(y)\cap[F]\big) & = & \big(\mathrm{PD}_F^{\mathbb{Z}}(y)\cup\mathrm{PD}_F^{\mathbb{Z}}(x)\big)\cap[F] \\
 & = & \big\langle\mathrm{PD}_F^{\mathbb{Z}}(y)\cup\mathrm{PD}_F^{\mathbb{Z}}(x),[F]\big\rangle & = & Q_F(y,x). \\
 & & \uparrow & & \uparrow \\
 & & \text{Lemma 59.4} & & \text{by definition of } Q_F
\end{array}$$

This completes the proof of the claim.

From Lemma 74.26 we know that the map

$$\begin{array}{ccc}
\mathbb{Z}_p & \to & H_1(L(p,q);\mathbb{Z}) \\
x & \mapsto & x\cdot i_*(a)
\end{array}$$

is an isomorphism. Thus it remains to prove the following claim.

Claim.

$$\lambda_L(i_*(a),i_*(a)) \;=\; \frac{q}{p}\;\in\;\mathbb{Q}/\mathbb{Z}.$$

We calculate that

$$\begin{array}{rcl}
\lambda_L(i_*(a), i_*(a)) & = & \overbrace{\beta^{-1}(\mathrm{PD}_L^{\mathbb{Z}}(i_*(a)))}^{\in H^1(L;\mathbb{Q}/\mathbb{Z})} \cap \overbrace{i_*(a)}^{\in H_1(L;\mathbb{Z})} \\
& \uparrow & \\
& \text{Lemma 74.19} & \\
& = & \mathrm{PD}_F^{\mathbb{Q}/\mathbb{Z}}\big(\rho_*\big(a - \frac{q}{p}\cdot b\big)\big) \cap a \\
& \uparrow & \\
& \text{Lemmas 74.9 (4) and 74.26 (2)} & \\
& = & \rho\big(\mathrm{PD}_F^{\mathbb{Q}}\big(a - \frac{q}{p}\cdot b\big) \cap a\big) \\
& \uparrow & \\
& \text{Lemma 74.9 (3)} & \\
& = & \rho\big(Q_F(a,a) - \frac{q}{p} Q_F(a,b)\big) \\
& \uparrow & \\
& \text{by the claim} &
\end{array}
\qquad
\begin{array}{rcl}
& = & \overbrace{i^*\big(\mathrm{PD}_F^{\mathbb{Q}/\mathbb{Z}}(\Theta(i_*(a)))\big)}^{\in H^1(L;\mathbb{Q}/\mathbb{Z})} \cap \overbrace{i_*(a)}^{\in H_1(L;\mathbb{Z})} \\
& \uparrow & \\
& \text{Lemma 74.25 applied to } i_*(a) \in H_1(L;\mathbb{Z}) & \\
& = & \rho_*\big(\mathrm{PD}_F^{\mathbb{Q}}\big(a - \frac{q}{p}\cdot b\big)\big) \cap a \\
& \uparrow & \\
& \text{Lemma 74.11} & \\
& = & \rho\big(\mathrm{PD}_F^{\mathbb{Z}}(a) \cap a - \frac{q}{p}\cdot\big(\mathrm{PD}_F^{\mathbb{Z}}(b) \cap a\big)\big) \\
& \uparrow & \\
& \text{Lemma 74.11} & \\
& = & -\rho\big(\frac{q}{p}\big). \\
& \uparrow & \\
& \text{by page 1655 we have } Q_F(a,a) = 0 \text{ and } Q_F(a,b) = 1 &
\end{array}$$

□

74.8. **Computing the linking pairing by intersecting singular simplices.** Many working topologists would rather forgo the austere beauty of cup and cap products and they would rather work and calculate by "intersecting simplices". The following proposition shows that in many (most? all?) situations one can calculate linking pairings geometrically by determining algebraic intersection numbers of singular chains.

Proposition 74.27. *Let $n \geq 1$, let M be an oriented $(2n+1)$-dimensional rational homology sphere and let $x, y \in H_n(M;\mathbb{Z})$. Let σ and τ be cycles in $C_n(M;\mathbb{Z})$ that represent x and y. From Lemma 74.1 we know that $H_n(M;\mathbb{Z})$ is torsion, hence there exists a $d \in \mathbb{N}$ such that $d \cdot x = 0 \in H_n(M;\mathbb{Z})$ which means that $d \cdot \sigma$ is null-homologous. Suppose $\Sigma \in C_{n+1}(M;\mathbb{Z})$ is a singular chain with $\partial\Sigma = d \cdot \sigma$. If Σ and τ intersect transversally in the sense of the definition on page 1594, then*

$$\lambda_M(x,y) \;=\; (-1)^n \cdot \frac{1}{d} \cdot \underbrace{\Sigma \cdot \tau}_{\substack{\text{algebraic intersection} \\ \text{number as defined on page 1595}}} \;\in\; \mathbb{Q}/\mathbb{Z}.$$

Remark. Alas, all too often in the literature the right-hand side of Proposition 74.27 gets confused with the actual definition of the linking pairing, see e.g. [Frie, p. 899] for a typical example.

The proof of the proposition rests on a variation of Theorem 68.5. Before we can formulate that variation we make the following observation.

Observation. Let M be an oriented m-dimensional topological manifold and let A and B be abelian groups. Basically the same definitions as on page 1594 allow us to say that chains $\sigma \in C_k(M;A)$ and $\tau \in C_{m-k}(M;B)$ are *transverse* and they allow us to define the *algebraic intersection invariant* $\sigma \cdot_{\otimes} \tau \in A \otimes B$.

Now we can formulate the following slight variation of Theorem 68.5.

Proposition 74.28. *Let M be a closed oriented m-dimensional topological manifold, let A and B be abelian groups and let $\sigma \in C_k(M;A)$ and $\tau \in C_{m-k}(M;B)$ be two cycles. If σ and τ are transverse, then*

$$\epsilon_M\Big(\big(\underbrace{\overbrace{\mathrm{PD}_M^A([\sigma])}^{\in H^{m-k}(M;A)} \cup_\otimes \overbrace{\mathrm{PD}_M^B([\tau])}^{\in H^k(M;B)}}_{\in H^m(M;A\otimes B)}\big) \cap [M]\Big) \;=\; \sigma \cdot_\otimes \tau \;\in\; A\otimes B.$$

Proof. The proof of Theorem 68.5 generalizes without a hitch to give us this statement with more fancy coefficients. □

Now we can provide the proof of Proposition 74.27.

Proof of Proposition 74.27. As before we denote by $\nu\colon \mathbb{Q}/\mathbb{Z}\otimes\mathbb{Z} \to \mathbb{Q}/\mathbb{Z}$ the multiplication induced isomorphism. We perform the following calculation:

$$\begin{aligned}
\lambda_M(x,y) &\overset{\substack{\text{by the definition on page 1720, Lemma 74.9 (2) and Lemma 74.9 (3) applied to } \nu}}{=} \nu_*\big(\epsilon_M\big(\big(\beta^{-1}(\mathrm{PD}_M^{\mathbb{Z}}(x)) \cup_\otimes \mathrm{PD}_M^{\mathbb{Z}}(y)\big) \cap [M]\big)\big)\\
&= (-1)^n \cdot \nu_*\big(\epsilon_M\big(\big(\mathrm{PD}_M^{\mathbb{Q}/\mathbb{Z}}(\beta^{-1}(x)) \cup_\otimes \mathrm{PD}_M^{\mathbb{Z}}(y)\big) \cap [M]\big)\big)\\
&\overset{\substack{\text{Lemma 74.24}}}{=} (-1)^n \cdot \nu_*\big(\big(\tfrac{1}{d}\otimes\Sigma\big) \cdot_\otimes \tau\big) \underset{\substack{\text{follows immediately from the definitions}}}{=} (-1)^n \cdot \tfrac{1}{d}\cdot\Sigma\cdot\tau \;\in\; \mathbb{Q}/\mathbb{Z}.
\end{aligned}$$

by Proposition 74.28 and the observation that $\frac{1}{d}\otimes\Sigma$ represents $\beta^{-1}(x)$

□

74.9. **Linking forms and intersection forms** $(*)$**.** Before we turn to the relationship between linking forms and intersection forms we intend to introduce a variation on the intersection form. Recall that given a compact oriented connected $2n$-dimensional topological manifold M we introduced on page 1652 the intersection form

$$\begin{aligned}
Q_M\colon \mathrm{F}H_n(M;\mathbb{Z}) \times \mathrm{F}H_n(M;\mathbb{Z}) &\to \mathbb{Z}\\
(a,b) &\mapsto \big\langle \underbrace{\underbrace{\mathrm{PD}_M(v)}_{\in \mathrm{F}H^n(M,\partial M;\mathbb{Z})} \cup \underbrace{\mathrm{PD}_M(w)}_{\in \mathrm{F}H^n(M,\partial M;\mathbb{Z})}}_{\in \mathrm{F}H^{2n}(M,\partial M;\mathbb{Z})}, [M] \big\rangle.
\end{aligned}$$

Here, given an abelian group H we write $\mathrm{F}H := H/\text{torsion subgroup}$ the maximal free abelian quotient of H. Now we introduce a non-symmetric version of the intersection form.

Definition. Let M be a compact oriented connected $2n$-dimensional manifold. We refer to the pairing

$$\begin{array}{rcl} \widetilde{Q}_M\colon \mathrm{F}H_n(M;\mathbb{Z}) \times \mathrm{F}H_n(M,\partial M;\mathbb{Z}) & \to & \mathbb{Z} \\ (v,w) & \mapsto & \underbrace{\big\langle \underbrace{\mathrm{PD}_M(v)}_{\in \mathrm{F}H^n(M,\partial M;\mathbb{Z})} \cup \underbrace{\mathrm{PD}_M(w)}_{\in \mathrm{F}H^n(M;\mathbb{Z})}, [M] \big\rangle}_{\in \mathrm{F}H^{2n}(M,\partial M;\mathbb{Z})} \end{array}$$

as the *reduced intersection pairing of M.*

Example. Let M be the torus minus two open balls. We consider the four curves a, b, c, d on M that are shown in Figure 930. The curves a, b, c represent a basis for $H_1(M;\mathbb{Z})$, whereas the curves a, b, d represent a basis for $H_1(M,\partial M;\mathbb{Z})$.[1249] Using these bases and using Theorem 67.10 we see that

$$Q_M \text{ is represented by } \begin{array}{c} \\ a \\ b \\ c \end{array} \begin{array}{c} \begin{array}{ccc} a & b & c \end{array} \\ \begin{pmatrix} 0 & 1 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \end{array} \quad \text{and } \widetilde{Q}_M \text{ represented by } \begin{array}{c} \\ a \\ b \\ c \end{array} \begin{array}{c} \begin{array}{ccc} a & b & d \end{array} \\ \begin{pmatrix} 0 & 1 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix} \end{array}.$$

Note that the former matrix has determinant zero whereas the latter matrix has determinant. This calculation, together with Lemma 62.1 shows that the former pairing is degenerate whereas the latter pairing is non-singular.[1250] As we will see in the next proposition, it is not a coincidence that the reduced intersection pairing is non-singular.

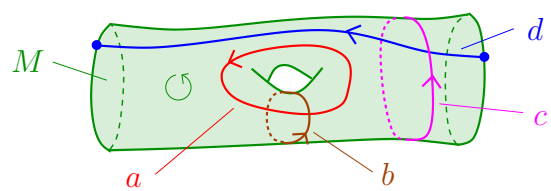


FIGURE 930.

Proposition 74.29. *Let M be a compact oriented connected $2n$-dimensional topological manifold. We denote by $p_*\colon H_n(M;\mathbb{Z}) \to H_n(M,\partial M;\mathbb{Z})$ the obvious map.*

(1) *The pairing $\widetilde{Q}_M\colon \mathrm{F}H_n(M;\mathbb{Z}) \times \mathrm{F}H_n(M,\partial M;\mathbb{Z}) \to \mathbb{Z}$ is non-singular.*
(2) *The following diagram commutes:*

$$\begin{tikzcd} \mathrm{F}H_n(M;\mathbb{Z}) \times \mathrm{F}H_n(M;\mathbb{Z}) \arrow[r, "Q_M"] \arrow[d, "\mathrm{id} \times p_*"] & \mathbb{Z} \arrow[d] \\ \mathrm{F}H_n(M;\mathbb{Z}) \times \mathrm{F}H_n(M,\partial M;\mathbb{Z}) \arrow[r, "\widetilde{Q}_M"] & \mathbb{Z}. \end{tikzcd}$$

[1249] Why is that?

[1250] In fact, using this observation and Exercise 62.1 (c) one can easily answer the previous footnote.

(3) *Let $v_1, \dots, v_m$ be a basis of the free abelian group $\mathrm{F}H_n(M;\mathbb{Z})$. By* (1) *together with Exercise 62.1* (a) *there exists a unique basis $w_1, \dots, w_m$ of the free abelian group $\mathrm{F}H_k(M, \partial M;\mathbb{Z})$ with $\widetilde{Q}_M(v_i, w_j) = \delta_{ij}$ for all $i, j \in \{1, \dots, m\}$. We denote by A the $(m \times m)$-matrix that represents the intersection form Q_M with respect to the basis $v_1, \dots, v_n$, i.e. we have $A = (a_{ij})$ with $a_{ij} = Q_M(v_i, v_j)$. This matrix represents the map $p_*\colon \mathrm{F}H_n(M;\mathbb{Z}) \to \mathrm{F}H_n(M, \partial M;\mathbb{Z})$ with respect to the bases $v_1, \dots, v_m$ and $w_1, \dots, w_m$.*

Proof.

(1) We consider the map

$$\Psi\colon \mathrm{F}H_n(M, \partial M;\mathbb{Z}) \xrightarrow{\mathrm{PD}_M} \mathrm{F}H^n(M;\mathbb{Z}) \xrightarrow{\mathrm{ev}} \mathrm{Hom}(\mathrm{F}H_n(M;\mathbb{Z}), \mathbb{Z}).$$

Basically the same argument as in the proof of Lemma 71.6 shows that for any $a \in \mathrm{F}H_n(M;\mathbb{Z})$ and any $b \in \mathrm{F}H_{2n}(M, \partial M;\mathbb{Z})$ we have $\widetilde{Q}_M(a, b) = \Psi(b)(a)$. Since PD_M and $\mathrm{ev}\colon \mathrm{F}H^n(M;\mathbb{Z}) \to \mathrm{Hom}(\mathrm{F}H_n(M;\mathbb{Z}), \mathbb{Z})$ are isomorphisms we obtain by the same argument as in Proposition 71.5 (together with the remark on page 1448) that $\widetilde{Q}_M$ is non-singular.

(2) This statement follows easily from the definitions and Proposition 61.22. Alternatively one can use the descriptions of Q_M and $\widetilde{Q}_M$ that are given in Lemma 71.6 and in (1).

(3) Let $i \in \{1, \dots, m\}$. We write $p_*(v_i) = \sum_{j=1}^{m} b_{ji} \cdot w_j$. Let $j \in \{1, \dots, m\}$. We see that

$$b_{ji} \underset{\substack{\uparrow \\ \text{since } \widetilde{Q}_M(v_j, w_k) = \delta_{jk}}}{=} \widetilde{Q}_M\Big(v_j, \sum_{k=1}^{m} b_{ki} \cdot w_k\Big) = \widetilde{Q}_M(v_j, p_*(v_i)) \underset{\substack{\uparrow \\ \text{follows from (2)}}}{=} Q_M(v_j, v_i) = a_{ji}.$$

Since by definition the matrix (b_{ij}) represents the map p_* with respect to the given bases we obtain the desired result. □

In the following let M be a compact oriented connected 4-dimensional topological manifold. We suppose that $Y = \partial M$ is a rational homology sphere. We want to study, in favorable situations, the relationship between the intersection form Q_M on M and the linking pairing λ_Y on Y. More precisely, we want to prove the following proposition.

Proposition 74.30. *Let M be a compact oriented connected 4-dimensional topological manifold such that $Y = \partial M$ is a rational homology sphere. We suppose that $H_1(M;\mathbb{Z}) = 0$. The following statements hold:*

(1) *The groups $H_2(M, Y;\mathbb{Z})$ and $H_2(M;\mathbb{Z})$ are free abelian groups of finite rank.*

(2) *By* (1) *we can pick a basis $v_1, \dots, v_m$ for the free abelian group $H_2(M;\mathbb{Z})$. By Proposition 74.29 together with Exercise 62.1* (a) *there exists a unique basis $w_1, \dots, w_m$ for the free abelian group $H_2(M, Y;\mathbb{Z})$ with $\widetilde{Q}_M(v_i, w_j) = \delta_{ij}$. We denote by $A = (Q_M(v_i, v_j))$ the $(m \times m)$-matrix that represents the intersection form with respect to the basis $v_1, \dots, v_m$. The following two statements hold:*

(a) *If we denote by* $\Psi\colon \mathbb{Z}^m \to H_2(M,Y;\mathbb{Z})$ *the isomorphism that is given by the basis* $w_1,\dots,w_m$*, then the map*

$$\begin{array}{rcl} \Theta\colon \mathbb{Z}^m/A\mathbb{Z}^m & \to & H_1(Y;\mathbb{Z}) \\ [u] & \mapsto & \partial(\Psi(u)) \\ & & \uparrow \\ & & \text{connecting homomorphism } \partial\colon H_2(M,Y;\mathbb{Z}) \to H_1(Y;\mathbb{Z}) \text{ of the pair } (M,Y) \end{array}$$

is well-defined and it is an isomorphism.

(b) *The matrix* A *is symmetric and if satisfies* $\det(A) \neq 0$.

(c) *The isomorphism* Θ *from* (a) *is in fact an isometry from*[1251]

$$\begin{array}{rcl} \mathbb{Z}^m/A\mathbb{Z}^m \times \mathbb{Z}^m/A\mathbb{Z}^m & \xrightarrow{\lambda(A)} & \mathbb{Q}/\mathbb{Z} \\ ([v],[w]) & \longmapsto & v^T A^{-1} w \end{array} \quad \text{to} \quad \underbrace{H_1(Y;\mathbb{Z}) \times H_1(Y;\mathbb{Z}) \xrightarrow{\lambda_Y} \mathbb{Q}/\mathbb{Z}}_{\text{linking pairing}}.$$

FIGURE 931. Illustration of Proposition 74.30.

Remark.

(1) We leave it to the reader to figure out what is a correct higher-dimensional analogue of Proposition 74.30. The reader will found out, that determining the correct sign is a never ending source of hilarious entertainment.

(2) Often it is (psychologically) easier to compute intersection forms of manifolds, thus on many occasions in the literature linking pairings are computed by calculating the intersection form of a suitable bounding manifold.

The following lemma is the key ingredient in the proof of Proposition 74.30.

Lemma 74.31. *We continue with the notation from Proposition 74.30. We denote by* $i\colon Y \to M$ *the inclusion and we denote by* $p\colon C_*(M) \to C_*(M,Y)$ *the projection map. The following diagram commutes up to a minus sign:*

$$\begin{tikzcd} H^2(M;\mathbb{Z}) \arrow[r, two heads, "i^*"] \arrow[d] & H^2(Y;\mathbb{Z}) \arrow[r, "\beta^{-1}", "\cong"'] & H^1(Y;\mathbb{Q}/\mathbb{Z}) \arrow[d, "\delta"] \\ H^2(M;\mathbb{Q}) \arrow[r, "(p^*)^{-1}", "\cong"'] & H^2(M,Y;\mathbb{Q}) \arrow[r] & H^2(M,Y;\mathbb{Q}/\mathbb{Z}). \end{tikzcd}$$

[1251]It follows from (b) and Lemma 74.13 that the form $\lambda(A)$ is in fact defined.

Remark. The encyclopedic reader will not have failed to notice that Lemma 74.31 is a special case of Exercise 31.6.

Proof of Lemma 74.31. Throughout the proof we adopt the following conventions:

(1) Given a cochain ψ that takes values in $\mathbb{Q}$ we denote by $\overline{\psi}$ the corresponding cochain that takes values in $\mathbb{Q}/\mathbb{Z}$.
(2) If ψ is a cochain that takes values in $\mathbb{Z}$, then we view it also as a cochain with values in $\mathbb{Q}$.

Now let $\phi \in C^2(M;\mathbb{Z}) = \mathrm{Hom}(C_2(M),\mathbb{Z})$ be a cochain. Note that the Poincaré Duality Theorem 61.1 implies that $H^i(Y;\mathbb{Q}) \cong H_i(Y;\mathbb{Q}) = 0$ for $i = 1, 2$. Thus we obtain from the long exact sequence of the pair (M, Y) that the map $p^*\colon H^2(M, Y;\mathbb{Q}) \to H^2(M;\mathbb{Q})$ is an isomorphism there exists a cochain $\psi \in C^2(M, Y;\mathbb{Q})$ such that $[\phi] = [p^* \circ \psi] \in H^2(M;\mathbb{Q})$. This means that there exists some $\alpha \in C^1(M;\mathbb{Q})$ such that $p^* \circ \psi - \phi = \delta\alpha$. We write $\varphi := \alpha|_{C_1(Y)}$. We calculate that

$$\begin{array}{ccccccccc}
\delta\overline{\varphi} & = & \overline{\delta\alpha}|_{C_2(Y)} & = & \overline{p^* \circ \psi - \phi}|_{C_2(Y)} & = & \overline{\phi}|_{C_2(Y)} & = & 0 \in C_2(Y;\mathbb{Q}/\mathbb{Z}). \\
 & \uparrow & & & & \uparrow & & \uparrow & \\
 & \text{restriction is a cochain map} & & & \text{since } p^* \circ \psi \text{ vanishes on } C_2(Y) & & & \text{since } \phi \text{ takes integral values.} &
\end{array}$$

In other words, $\overline{\varphi}$ represents an element in $H^2(Y;\mathbb{Q}/\mathbb{Z})$. The following claim computes the two possible connecting homomorphisms.

Claim. We have $\delta([\overline{\varphi}]) = [p^*(\psi)]$ and $\beta([\overline{\varphi}]) = -[i^*(\phi)]$.

The claim follows from considering the following two sequences of maps and elements:

$$\begin{array}{ccc}
\overset{(4)\ \overline{\psi}}{C^2(M,Y;\mathbb{Q}/\mathbb{Z})} & \xrightarrow{p^*} & \overset{(3)\ \overline{p^*\psi-\phi}=\overline{p^*\psi}}{C^2(M;\mathbb{Q}/\mathbb{Z})} \\
 & & \uparrow{\scriptstyle\delta} \\
 & & \underset{(2)\ \overline{\alpha}}{C^1(M;\mathbb{Q}/\mathbb{Z})} \xrightarrow{i^*} \underset{(1)\ \overline{\varphi}}{C^1(Y;\mathbb{Q}/\mathbb{Z})}
\end{array}
\quad \& \quad
\begin{array}{ccc}
\overset{(4)\ -i^*\phi}{C^2(Y;\mathbb{Z})} & \to & \overset{(3)\ \overbrace{i^*p^*}^{=0}\psi-i^*\phi}{C^2(Y;\mathbb{Q})} \\
 & & \uparrow{\scriptstyle\delta} \\
 & & \underset{(2)\ \varphi=i^*\alpha}{C^1(Y;\mathbb{Q})} \to \underset{(1)\ \overline{\varphi}}{C^1(Y;\mathbb{Q}/\mathbb{Z})}.
\end{array}$$

This concludes the proof of the claim.

Now we are basically done: Namely, if we go down and right, then the claim shows that $[\phi] \in H^2(M;\mathbb{Z})$ gets sent to $[\overline{\varphi}] \in H^2(M, Y;\mathbb{Q}/\mathbb{Z})$. On the other hand, if we go right and down, then the claim shows that $[\phi]$ is sent to $-[\overline{\varphi}]$. $\square$

Proof of Proposition 74.30. We consider the following maps:

$$\begin{tikzcd}
H_2(M;\mathbb{Z}) \arrow[r, "p_*"] \arrow[d, "\cong"', "\mathrm{PD}_M"] & H_2(M,Y;\mathbb{Z}) \arrow[r, "\partial"] \arrow[d, "\cong"', "\mathrm{PD}_M"] & H_1(Y;\mathbb{Z}) \arrow[r] & \overbrace{H_1(M;\mathbb{Z})}^{=0 \text{ by hypothesis}} \arrow[r] & H_1(M,Y;\mathbb{Z}) \arrow[r] & 0. \\
H^2(M,Y;\mathbb{Z}) \arrow[d, "\cong"', "\mathrm{ev}"] & H^2(M;\mathbb{Z}) \arrow[d, "\cong"', "\mathrm{ev}"] & & & & \\
\mathrm{Hom}(H_2(M,Y;\mathbb{Z}),\mathbb{Z}) & \mathrm{Hom}(H_2(M;\mathbb{Z}),\mathbb{Z}). & & & &
\end{tikzcd}$$

We make the following observations:

(a) The horizontal sequence is the long exact sequence in reduced homology of the pair (M,Y).
(b) By hypothesis we have $H_1(M;\mathbb{Z}) = 0$.
(c) It follows from (a) and (b) that $H_1(M,Y;\mathbb{Z}) = 0$.
(d) The vertical maps PD_M are the Poincaré duality isomorphisms given by the Poincaré Duality Theorem 61.1.
(e) It follows from (b), (c) and the Universal Coefficient Theorem 51.13 that both evaluation homomorphisms ev are isomorphisms.
(f) We obtain from the above discussion that $H_2(M;\mathbb{Z}) \cong \mathrm{Hom}(H_2(M,Y;\mathbb{Z}),\mathbb{Z})$ and that $H_2(M,Y;\mathbb{Z}) \cong \mathrm{Hom}(H_2(M;\mathbb{Z}),\mathbb{Z})$. It follows from Proposition 45.2 (2) together with the classification of finitely generated abelian groups, see Theorem 11.4, that $H_2(M;\mathbb{Z})$ and $H_2(M,Y;\mathbb{Z})$ are free abelian groups. In particular we have now shown statement (1) of the proposition.

We pick a basis $v_1,\dots,v_m$ for the free abelian group $H_k(M;\mathbb{Z})$. We denote by $w_1,\dots,w_m$ the unique basis for the free abelian group $H_2(M,Y;\mathbb{Z})$ with $\widetilde{Q}_M(v_i,w_j) = \delta_{ij}$. We denote by $A = (a_{ij})$ the $(n\times n)$-matrix that is given by $a_{ij} = Q_M(v_i,v_j)$. Note that it follows from Proposition 71.5 (1) that A is symmetric.

We denote by $\Phi\colon \mathbb{Z}^m \xrightarrow{\cong} H_2(M;\mathbb{Z})$ and $\Psi\colon \mathbb{Z}^m \xrightarrow{\cong} H_2(M,Y;\mathbb{Z})$ the isomorphisms that are given by the above bases. From the above long exact sequence together with Proposition 74.29 we obtain the following commutative diagram:

$$\begin{tikzcd}
\mathbb{Z}^m \arrow[r, "u\mapsto A\cdot u"] \arrow[d, "\Phi"', "\cong"] & \mathbb{Z}^m \arrow[r] \arrow[d, "\cong"', "\Psi"] & \mathbb{Z}^m/A\mathbb{Z}^m \arrow[r] \arrow[d, dotted, "\Theta"] & 0 \\
H_2(M;\mathbb{Z}) \arrow[r, "p_*"] & H_2(M,Y;\mathbb{Z}) \arrow[r, "\partial"] & H_1(Y;\mathbb{Z}) \arrow[r] & 0
\end{tikzcd}$$

Note that the lower sequence is exact by the discussion above. Furthermore note that the diagram commutes by Proposition 74.29 (2). It follows immediately that the map $\partial\circ\Psi\colon \mathbb{Z}^m \to H_1(Y;\mathbb{Z})$ descends to an isomorphism $\mathbb{Z}^m/A\mathbb{Z}^m \to H_1(Y;\mathbb{Z})$. This concludes the proof of statement (2a).

Next note that it follows from Proposition 71.5 (1) that A is symmetric. Furthermore note that it follows from (2a), the fact that $H_1(Y;\mathbb{Z})$ and Lemma 11.7 that $\det(A) \neq 0$. This concludes the proof of statement (2b).

The key to proving statement (2c) is the following claim:

Claim. There exists a pairing $\chi\colon H_2(M,Y;\mathbb{Z}) \times H_2(M,Y;\mathbb{Z}) \to \mathbb{Q}$ such that the following diagram commutes:

$$\begin{tikzcd}
H_2(M;\mathbb{Z}) \times H_2(M;\mathbb{Z}) \arrow[r, "Q_M"] \arrow[d, "p_* \times p_*"] & \mathbb{Z} \arrow[d, hook] \\
H_2(M,Y;\mathbb{Z}) \times H_2(M,Y;\mathbb{Z}) \arrow[r, "\chi"] \arrow[d, "\partial \times \partial"] & \mathbb{Q} \arrow[d] \\
H_1(Y;\mathbb{Z}) \times H_1(Y;\mathbb{Z}) \arrow[r, "\lambda_M"'] & \mathbb{Q}/\mathbb{Z}.
\end{tikzcd}$$

We first explain why the claim implies statement (2c). If we equip $H_2(M;\mathbb{Z})$ and $H_2(M,Y;\mathbb{Z})$ with the above bases, then we know by Proposition 74.29 (3) that the map p_* is represented by the matrix A. Furthermore, by definition A represents the intersection form Q_M. Now, for purely algebraic reasons we see that χ is represented by the rational matrx A^{-1}.[1252] Statement (2c) follows immediately from this observation, once we have proved the claim.

Thus it remains to prove the claim. In the following we denote by $\varphi\colon \mathbb{Z} \to \mathbb{Q}$ the inclusion. Next we consider the following diagram:

$$\begin{tikzcd}
H_2(M;\mathbb{Z}) \arrow[r, "p_*"] \arrow[d, "\cong", "\mathrm{PD}_M"'] & H_2(M,Y;\mathbb{Z}) \arrow[r, "\partial"] \arrow[d, "\cong", "\mathrm{PD}_M"'] & H_1(Y;\mathbb{Z}) \arrow[d, "\cong", "\mathrm{PD}_Y"'] \\
H^2(M,Y;\mathbb{Z}) \arrow[r, "p^*"] & H^2(M;\mathbb{Z}) \arrow[r, "i^*"] & H^2(Y;\mathbb{Z}).
\end{tikzcd}$$

By Proposition 61.22 the diagram commutes.[1253] The diagram with the vertical isomorphisms allows us to translate our above problem into a different taks. Namely it follows from the diagram and the definition of the intersection form Q_M that it suffices to show that there exists a pairing $\chi\colon H^2(M;\mathbb{Z}) \times H^2(M;\mathbb{Z}) \to \mathbb{Q}$ such that the following diagram

[1252]The purely algebraic reason is the following. Suppose we are given a commutative diagram of the form

$$\begin{tikzcd}
\mathbb{Z}^m \times \mathbb{Z}^m \arrow[r, "(x,y)\mapsto x^T P y"] \arrow[d, "(x,y)\mapsto(Cx,Dx)"] & \mathbb{Z} \arrow[d] \\
\mathbb{Z}^m \times \mathbb{Z}^m \arrow[r, "(x,y)\mapsto x^T Q y"] & \mathbb{Q}.
\end{tikzcd}$$

Then $P = C^T Q D$. If C and D are invertible over $\mathbb{Q}$, then $Q = (C^T)^{-1} P D^{-1}$. In our case we have $C = D = P = A$. Furthermore A is symmetric and we know that $\det(A) \neq 0$. Thus we see that $Q = A^{-1} A A^{-1} = A^{-1}$.

[1253]To be more precise, the square on the right commutes up to the $(-1)^2$, which happens to be $+1$.

commutes:

$$\begin{tikzcd}
H^2(M,Y\ \mathbb{Z}) \times H^2(M,Y;\mathbb{Z}) \arrow[r, "\cup"] \arrow[d, "p^*\times p^*"] & H^4(M,Y;\mathbb{Z}) \arrow[r, "\langle -,[M]\rangle"] & \mathbb{Z} \arrow[d, "\varphi"] \\
H^2(M;\mathbb{Z}) \times H^2(M;\mathbb{Z}) \arrow[rr, "\chi"] \arrow[d, "\mathrm{PD}_Y^{-1}\circ i^* \times \mathrm{PD}_Y^{-1}\circ i^*"] & & \mathbb{Q} \arrow[d] \\
H_1(Y;\mathbb{Z}) \times H_1(Y;\mathbb{Z}) \arrow[rr, "\lambda_M"'] & & \mathbb{Q}/\mathbb{Z}.
\end{tikzcd}$$

The key to proving the existence of such a pairing χ is the following daunting diagram:

$$\begin{tikzcd}
H^2(M,Y;\mathbb{Z})\times H^2(M,Y;\mathbb{Z}) \arrow[rr, "\cup"] \arrow[dr, "\varphi_*\times\mathrm{id}"] \arrow[ddd, "p^*\times p^*"] & & H^4(M,Y;\mathbb{Z}) \arrow[r, "\langle -,[M]\rangle"] \arrow[d, "\varphi_*"] \arrow[dl, phantom, "\text{(I)}"] & \mathbb{Z} \arrow[d, "\varphi"] \arrow[dl, phantom, "\text{(II)}"] \\
& H^2(M,Y;\mathbb{Q})\times H^2(M;\mathbb{Z}) \arrow[r, "\cup"'] \arrow[d, "\mathrm{id}"'] \arrow[d, shift left=6, "p^*"] \arrow[dr, phantom, "\text{(III)}"] & H^4(M,Y;\mathbb{Q}) \arrow[r, "\langle -,[M]\rangle"'] \arrow[d, "="] \arrow[dr, phantom, "\text{(IV)}"] & \mathbb{Q} \arrow[d, "="] \arrow[dr, phantom, "\text{(V)}"] \\
& H^2(M,Y;\mathbb{Q})\times H^2(M;\mathbb{Z}) \arrow[r, "\cup"'] \arrow[d, "p^*"'] \arrow[d, shift left=6, "\mathrm{id}"] & H^4(M,Y;\mathbb{Q}) \arrow[r, "\langle -,[M]\rangle"'] & \mathbb{Q} \arrow[ddd, "="] \\
\boxed{H^2(M;\mathbb{Z})\times H^2(M;\mathbb{Z})} \arrow[r, "\varphi_*\times\mathrm{id}"] \arrow[ddd, "i^*\times i^*"] & \boxed{H^2(M;\mathbb{Q})\times H^2(M;\mathbb{Z})} \arrow[d, "(p^*)^{-1}"'] \arrow[d, shift left=6, "\mathrm{id}"] \arrow[dr, phantom, "\text{(VI)}"] & & \\
& \boxed{H^2(M,Y;\mathbb{Q})\times H^2(M;\mathbb{Z})} \arrow[r, "\cup"] \arrow[d] \arrow[d, shift left=6, "\mathrm{id}"] \arrow[dr, phantom, "\text{(VII)}"] & \boxed{H^4(M,Y;\mathbb{Q})} \arrow[r, "\langle -,[M]\rangle"] \arrow[d] \arrow[dr, phantom, "\text{(VIII)}"] & \boxed{\mathbb{Q}} \arrow[d] \arrow[dr, phantom, "\text{(IX)}"] \\
& H^2(M,Y;\mathbb{Q}/\mathbb{Z})\times H^2(M;\mathbb{Z}) \arrow[r, "\cup"] \arrow[d, "i^*"] & H^4(M,Y;\mathbb{Q}/\mathbb{Z}) \arrow[r, "\langle -,[M]\rangle"] & \mathbb{Q}/\mathbb{Z} \arrow[d, "="] \\
H^2(Y;\mathbb{Z})\times H^2(Y;\mathbb{Z}) \arrow[r, "\beta^{-1}\times\mathrm{id}"] & H^1(Y;\mathbb{Q}/\mathbb{Z})\times H^2(Y;\mathbb{Z}) \arrow[r, "\cup"] \arrow[u, "\delta"] \arrow[dr, phantom, "\text{(X)}"] & H^3(Y;\mathbb{Q}/\mathbb{Z}) \arrow[r, "\langle -,[Y]\rangle"] \arrow[u, "\delta"] \arrow[dr, phantom, "\text{(XI)}"] & \mathbb{Q}/\mathbb{Z} \arrow[d, "="] \\
H_1(Y;\mathbb{Z}) \times H_1(Y;\mathbb{Z}) \arrow[u, "\mathrm{PD}_Y\times\mathrm{PD}_Y"] \arrow[rrr, "\lambda_M"'] & & \text{(XII)} & \mathbb{Q}/\mathbb{Z}.
\end{tikzcd}$$

The promised pairing χ is given by the traveling along the route that is traced out by the boxes. Thus it remains to prove that the diagram commutes. We make the following clarifications and observations:

(I) The lower cup product is the composition of the cup product as defined in Lemma 74.5 with the obvious map $\mathbb{Z}\otimes\mathbb{Q} \xrightarrow{\cong} \mathbb{Q}$. It follows basically immediately from the definitions that the square commutes, see also Proposition 58.3 (2).

(II) This square commutes by Lemma 50.5 (2).

(III) This square commutes since changing coefficients is a natural transformation, see Lemma 48.9.

(IV) This square commutes by a mild generalization of Proposition 58.3 (1).

(V) What a relief, there is nothing to show.
(VI) Note that the two vertical maps to the left of the square are inverses of one another. So we see that nothing happens in this square.
(VII) This recactangle commutes by Lemma 74.31.
(VIII) Similar to (I) the cup products are the composition of the cup product as defined in Lemma 74.5 with the obvious maps $\mathbb{Z}\otimes\mathbb{Q}\xrightarrow{\cong}\mathbb{Q}$ and $\mathbb{Z}\otimes\mathbb{Q}/\mathbb{Z}\xrightarrow{\cong}\mathbb{Q}/\mathbb{Z}$. As in (I) we see that the square commutes.
(IX) By the same argument as in (II) we see that the square commutes.
(X) A slight generalization of Lemma 58.5 to more general coefficients shows that the square icommutes up to the sign $(-1)^2 = 1$.
(XI) By Proposition 46.26 we have $\partial([M]) = [Y]$. It follows from a minute generalization of Lemma 59.10 (1) that this square commutes.
(XII) This rectangle commutes by definition of the linking pairing.

This concludes the proof of the claim. □

Exercises for Chapter 74.

Exercise 74.1. Let $k \in \mathbb{N}$. We consider the short exact sequence $0 \to \mathbb{Z}_k \xrightarrow{\cdot k} \mathbb{Z}_{k^2} \xrightarrow{p} \mathbb{Z}_k \to 0$ where p stands for the obvious projection map. Given a topological space X we obtain Bockstein homomorphisms $\beta_n\colon H_n(X;\mathbb{Z}_k) \to H_{n-1}(X;\mathbb{Z}_k)$, $n \in \mathbb{N}_0$. Show that

$$\beta_{n-1}\circ\beta_n\colon H_n(X;\mathbb{Z}_k) \;\to\; H_{n-2}(X;\mathbb{Z}_k)$$

is the zero map.

75. Branched coverings and chiral knots

After this long and technical, and basically picture free chapter, it is time to return to some more concrete topological questions. We recall the following question from some time ago.

Question 47.2. *Is the trefoil chiral, i.e. can the mirror of the trefoil be deformed into the trefoil itself? Put differently, are the two knots shown in Figure 75 smoothly isotopic in the sense of the definition on page 337?*

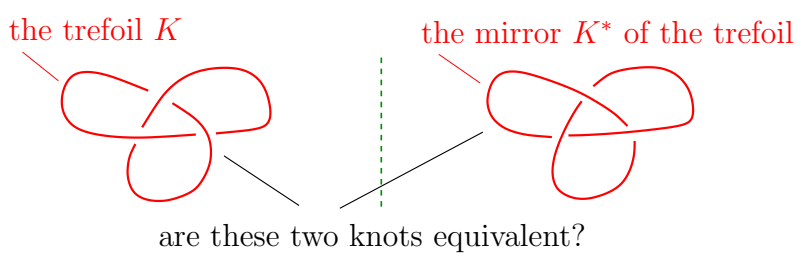

Figure 932.

In the last chapters we had developed several tools for showing that certain closed manifolds, e.g. the complex projective space $\mathbb{C}\mathrm{P}^2$ and the lens space $L(3,1)$, are chiral. In this section we will attack Question 47.2 by reducing it to a question that we had already dealt with. More precisely, the idea is to associate to a knot in S^3 an oriented rational homology sphere that retains at least some information on the knot. Then we will use the linking pairing of this rational homology sphere to draw conclusions on the chirality of the knot.

75.1. **Branched coverings.** In this section we will introduce branched coverings. We start out by recalling the following definition from page 1497.

Definition. Let M be a manifold and let $W \subset M$ be a proper codimension two submanifold. A *trivial tubular neighborhood* for W is an embedding

$$F\colon \overline{B}^2 \times W \;\to\; M$$

such that $F(0,P) = P$ for all $P \in W$ and such that $F(\overline{B}^2 \times \partial W) = \partial M \cap F(\overline{B}^2 \times W)$.

Examples.

(1) It is clear that every 0-dimensional submanifold of a 2-dimensional manifold admits a trivial tubular neighborhood.
(2) It follows from the Tubular Neighborhood Theorem 10.19 that every closed 1-dimensional submanifold of a closed orientable 3-dimensional manifold admits a trivial tubular neighborhood.
(3) In Proposition 67.20 we saw that the 2-dimensional submanifold $W = \mathbb{C}\mathrm{P}^1$ of the 4-dimensional manifold $M = \mathbb{C}\mathrm{P}^2$ does not admit a trivial tubular neighborhood.

Convention. Let $\overline{B}^2 \times W \to M$ be an embedding as above. On many occasions, by an abuse of notation, we will identify the image of the embedding $\overline{B}^2 \times W \to M$ with $\overline{B}^2 \times W$. Put differently, we often use the phrase let "$\overline{B}^2 \times W$ be a trivial tubular neighborhood".

Definition. Let M be a manifold and let $W \subset M$ be a compact proper submanifold of codimension two. We say a map $p\colon \widetilde{M} \to M$ is a *k-fold branched covering with branch locus W* if the following two conditions are satisfied:

(1) The restriction $p\colon \widetilde{M} \setminus p^{-1}(W) \to M \setminus W$ is a k-fold covering map in the usual sense.
(2) There exists a trivial tubular neighborhood $\overline{B}^2 \times W$ of W with the following property: for each component X of $p^{-1}(\overline{B}^2 \times W)$ there exists an $m \in \mathbb{N}_{\geq 2}$ and a diffeomorphism $\Psi\colon X \to \overline{B}^2 \times W$ such that the following diagram commutes[1254]

$$\begin{tikzcd} X \arrow[rr, "\Psi"] \arrow[dr, "p"'] & & \overline{B}^2 \times W \arrow[dl, "(z,w)\mapsto(z^m,w)"] \\ & \overline{B}^2 \times W. & \end{tikzcd}$$

We refer to m as the *branching degree of X*.

We say the branched covering is *simple* if $m = k$ throughout. Furthermore we say that the branched covering is *regular* if the covering map $p\colon \widetilde{M} \setminus p^{-1}(W) \to M \setminus W$ is regular in the sense of the definition on page 624. Otherwise we say that the branched covering is *irregular*.

Examples.

(1) The map $p\colon \widetilde{M} = \mathbb{C} \to M = \mathbb{C}$ given by $z \mapsto z^k$ is a simple k-fold branched covering with branch locus $W = \{0\}$. This is basically clear:
   (a) On page 260 we saw that the restriction of p to a map $\mathbb{C} \setminus \{0\} \to \mathbb{C} \setminus \{0\}$ is a k-fold covering map.
   (b) We take the obvious trivial tubular neighborhood $\overline{B}^2$ for 0 and we denote by Ψ the identity map. It is obvious that the above diagram commutes.
(2) The same argument as in (1) shows that the map

$$\begin{array}{rcl} \widetilde{M} = \mathbb{C} \setminus \{\{e^{2\pi i k/3} \,|\, k = 0,1,2\} & \to & \mathbb{C} \setminus \{1\} \\ z & \mapsto & z^3 \end{array}$$

that is illustrated in Figure 933 is a simple 3-fold branched covering with branch locus $W = \{0\}$.
(3) The projection map $\widetilde{M} = \mathbb{C} \to M := \mathbb{C}/z \sim -z$ is a simple 2-fold branched covering with branch locus $W = \{0\}$. To verify this statement we consider the

[1254]Here we view $\overline{B}^2 = \{z \in \mathbb{C} \,|\, |z| \leq 1\}$ as a subset of $\mathbb{C}$.

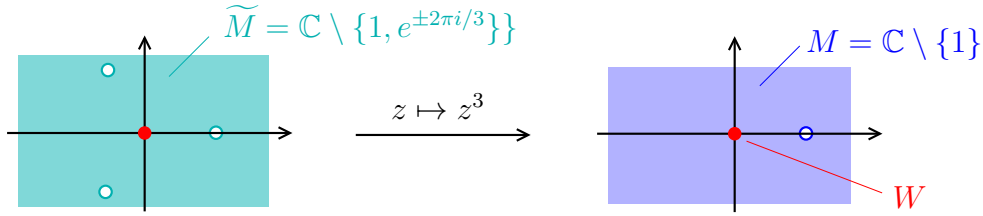

FIGURE 933.

following diagram

$$\begin{tikzcd} \mathbb{C} \arrow[rr, "z\mapsto[z]"] \arrow[dr, "z\mapsto z^2"'] & & \mathbb{C}/z \sim -z \arrow[dl, "{[z]\mapsto z^2}"] \\ & \mathbb{C}. & \end{tikzcd}$$

The diagram is clearly commutative and the right-hand diagonal map is easily seen to be a homeomorphism. We use this homeomorphism to equip $\mathbb{C}/z \sim -z$ with a smooth structure. In (1) we saw that the left diagonal map is a branched covering, thus the top horizontal map is also a branched covering.

(4) Let Σ be a closed complex 1-dimensional manifold (i.e. Σ is a closed 2-dimensional manifold with a complex structure) and let $f\colon \Sigma \to \mathbb{C}$ be a meromorphic non-constant function. We consider the map

$$\begin{array}{rcl} \Sigma & \to & \mathbb{C}\mathrm{P}^1 = S^2 \\ z & \mapsto & \begin{cases} [f(z):1], & \text{if } f(z) \neq \infty \\ [1:0], & \text{otherwise.} \end{cases} \end{array}$$

It is straightforward to see that this map is holomorphic. Using [Jä2, Satz 10] one can easily show that $f\colon \Sigma \to \mathbb{C}\mathrm{P}^1 = S^2$ is a branched covering.

Before we give more interesting examples of branched coverings we state and prove the following lemma that, given a simple branched covering $p\colon \widetilde{M} \to M$, relates the Euler characteristic of $\widetilde{M}$ to the Euler characteristic of M, the Euler characteristic of the branch locus and the degree of the branched covering.

The lemma carries a fancy name, even though it is quite elementary.

Lemma 75.1. (Riemann-Hurwitz formula) *Let M be a compact manifold and let W be a compact proper codimension 2 submanifold of M. If $p\colon \widetilde{M} \to M$ is a simple k-fold branched covering with branch locus W, then*

$$\chi\big(\widetilde{M}\big) \;=\; k \cdot \chi(M) + (1-k) \cdot \chi(W).$$

A similar statement also holds for non-simple branched coverings. The formulation becomes more messy, but the proof in this more general setting is equally trivial. Since we will not make use of this more general formula we decline to formulate it.

Proof. As usual, statements about Euler characteristics can be proved quite easily. First of all we pick a tubular neighborhood $\overline{B}^2 \times W$ and a diffeomorphism $\Psi\colon p^{-1}(\overline{B}^2 \times W) \to \overline{B}^2 \times W$ as in the definition of a branched covering. Now we calculate that

$$\begin{array}{rcl}
 & & \text{Proposition 45.7 (3) applied to } \widetilde{M} = \big(\widetilde{M} \setminus \Psi(B^2 \times W)\big) \cup \Psi\big(\overline{B}^2 \times W\big) \\
 & & \downarrow \\
\chi\big(\widetilde{M}\big) & = & \chi\big(\widetilde{M} \setminus \Psi(B^2 \times W)\big) + \chi\big(\Psi(\overline{B}^2 \times W)\big) - \chi\big(\Psi(S^1 \times W)\big) \\
 & = & k \cdot \chi(M \setminus (B^2 \times W)) + \chi(W) \\
 & & \uparrow \\
 & & \text{by Proposition 45.7 (5) since } p\colon \widetilde{M} \setminus \Psi(B^2 \times W) \to M \setminus (B^2 \times W) \text{ is a } k\text{-fold covering} \\
 & & \text{and using that Proposition 45.7 (2) implies that } \chi(\Psi(\overline{B}^2 \times W)) = \chi(W) \text{ and } \chi(\Psi(S^1 \times W)) = 0 \\
 & = & k \cdot \chi(M) - k \cdot \chi(\overline{B}^2 \times W) + k \cdot \chi(W \times S^1) + \chi(W) \;=\; k \cdot \chi(M) + (1-k) \cdot \chi(W). \\
 & & \uparrow \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \uparrow \\
 & & \text{by Proposition 45.7 (3) applied to } M = M \setminus (B^2 \times W) \cup \overline{B}^2 \times W \qquad \text{again by Proposition 45.7 (2)}
\end{array}$$

□

Remark. The concept of a map that is a covering outside of a sufficiently small subset also appears in other branches of mathematics. It is often also referred to as a "branched covering" or "ramified covering" or "ramification". In Figure 934 we show an extract of Neukirch's book on algebraic number theory [Neuk].

6. Extensions. Let $\mathcal{O}$ be a Dedekind domain with field of fractions K. Let $L|K$ be a finite separable extension, and $\mathcal{O}$ the integral closure of $\mathcal{O}$ in L. Let $Y = \operatorname{Spec}(\mathcal{O})$, $X = \operatorname{Spec}(\mathcal{O})$, and

$$f : X \longrightarrow Y$$

the morphism induced by the inclusion $\mathcal{O} \hookrightarrow \mathcal{O}$. If $\mathfrak{p}$ is a maximal ideal of $\mathcal{O}$ and

$$\mathfrak{p}\mathcal{O} = \mathfrak{P}_1^{e_1} \cdots \mathfrak{P}_r^{e_r}$$

the prime decomposition of $\mathfrak{p}$ in $\mathcal{O}$, then $\mathfrak{P}_1, \ldots, \mathfrak{P}_r$ are the different points of X which are mapped to $\mathfrak{p}$ by f. The morphism f is a "ramified covering." It is graphically represented by the following picture:

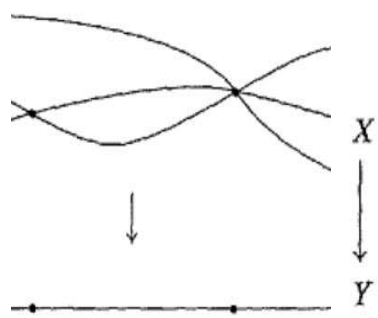

FIGURE 934.

75.2. **The hyperelliptic involution and branched coverings of surfaces.** Before we can provide the reader with new examples of branched coverings we need to introduce the following fun object.

Definition. As on page 967 we consider the surface Σ_g of genus g as the quotient of the regular $(4g+2)$-gon E_{4g+2} where we identify opposite sides by a translation. The map

$$\begin{array}{rcl}
\Theta\colon E_{4g+2}/\sim & \to & E_{4g+2}/\sim \\
[z] & \mapsto & [-z]
\end{array}$$

is called the *hyperelliptic involution*.[1255][1256] For $g = 2$ the surface $\Sigma_2 = E_{10}/\sim$ and the hyperelliptic involution are illustrated in Figure 935.

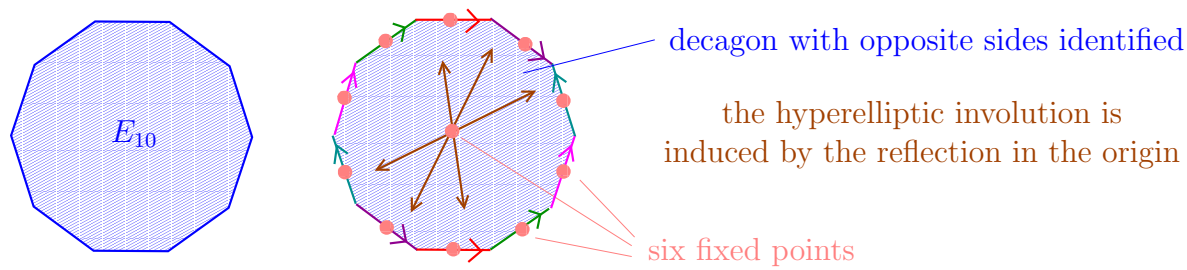

FIGURE 935.

The following lemma summarizes some properties of the hyperelliptic involution.

Lemma 75.2. *Let $g \in \mathbb{N}_0$.*

(1) *The hyperelliptic involution $\Theta\colon \Sigma_g \to \Sigma_g$ is orientation-preserving.*
(2) *The hyperelliptic involution $\Theta\colon \Sigma_g \to \Sigma_g$ has precisely $2g+2$ fixed points.*
(3) *The map $\Theta_*\colon H_1(\Sigma_g;\mathbb{Z}) \to H_1(\Sigma_g;\mathbb{Z})$ equals $-\operatorname{id}_{H_1(\Sigma_g;\mathbb{Z})}$.*
(4) *The quotient space $\Sigma_g/x \sim \Theta(x)$ is homeomorphic to the 2-sphere and it can be given a smooth structure such that the quotient map $\Sigma_g \to \Sigma_g/x \sim \Theta(x)$ is a 2-fold branched covering where the branch locus consists of $2g+2$ points.*

Sketch of proof.

(1) It follows easily from Proposition 47.3, applied to the origin, that the hyperelliptic involution Θ is orientation-preserving.
(2) It is straightforward to show that the fixed points of the hyperelliptic involution are given by the origin and the points that are represented by the $4g+2$ midpoints of the sides of the $(4g+2)$-gon. Since opposite midpoints get identified we see that we have precisely $1 + \frac{1}{2}(4g+2) = 2g+2$ fixed points.
(3) We equip E_{4g+2} with the obvious CW-structure with $2g+2$ 0-cells, $2g+2$ 1-cells and one 2-cell. Since the involution identifies cells with cells we can equip $\Sigma_g = E_{4g+2}/\sim$ with a corresponding quotient CW-structure. The hyperelliptic involution is a cellular map and one can easily compute that the induced map on $H_1^{\mathrm{CW}}(\Sigma_g;\mathbb{Z})$ is $-\operatorname{id}$. By Proposition 35.4 we know that singular homology is *naturally* isomorphic to cellular homology. In our setting this means that we have a commutative diagram

$$\begin{tikzcd} H_1(\Sigma_g;\mathbb{Z}) \arrow[r] \arrow[d, "f_*"'] & H_1^{\mathrm{CW}}(\Sigma_g;\mathbb{Z}) \arrow[d, "f_*"] \\ H_1(\Sigma_g;\mathbb{Z}) \arrow[r] & H_1^{\mathrm{CW}}(\Sigma_g;\mathbb{Z}), \end{tikzcd}$$

[1255]Recall that a map $f\colon X \to X$ is called an *involution* if $f \circ f = \operatorname{id}_X$.
[1256]I do not know where the fancy name "hyperelliptic" comes from.

where the horizontal maps are the same. Since the right vertical map is $-\mathrm{id}$ we now see that the left vertical map is also $-\mathrm{id}$.

(4) We leave it as an exercise to show that the quotient space $\Sigma_g/x \sim \Theta(x)$ is a closed orientable connected 2-dimensional manifold such that the quotient map $\Sigma_g \to \Sigma_g/x \sim \Theta(x)$ is a 2-fold branched covering with branch locus given by the images of the fixed points.[1257] Once we believe this fact we can calculate that

$$2-2g \;=\; \chi(\Sigma_g) \;\underset{\substack{\uparrow \\ \text{Lemma 75.1}}}{=}\; 2\cdot\chi(\Sigma_g/\sim) - \chi(\text{branch locus}) \;\underset{\substack{\uparrow \\ \text{by (1) there exist } 2g+2 \text{ fixed points}}}{=}\; 2\cdot\chi(\Sigma_g/\sim) - (2g+2).$$

Thus we see that $\chi(\Sigma_g/\sim) = 2$. It follows from Theorem 14.9 that $\Sigma_g/\sim$ is indeed diffeomorphic to the 2-dimensional sphere.[1258] □

More interestingly, the hyperelliptic involution is in some sense fully determined by being an orientation-preserving involution and satisfying Statement (2) or Statement (3) of Lemma 75.2. More precisely, the following proposition holds:

Proposition 75.3. *Let $g \in \mathbb{N}_0$ and let Ξ be an orientation-preserving involution of Σ_g. Suppose one of the following two conditions is satisfied:*

(1) *The map Ξ has precisely $2g+2$ fixed points.*
(2) *The map $\Xi_*\colon H_1(\Sigma_g;\mathbb{Z}) \to H_1(\Sigma_g;\mathbb{Z})$ equals $-\mathrm{id}$.*

Then Ξ and the hyperelliptic involution Θ represent conjugate elements in the orientation-preserving mapping class group $\mathrm{MCG}^+(\Sigma_g)$.

Proof. This statement is proved in Proposition 7.15 and the discussion on page 216 of [FaM]. □

Examples.

(1) Using Proposition 75.3 one can show easily that the maps

$$\begin{array}{ccc} \mathbb{R}^2/\mathbb{Z}^2 & \to & \mathbb{R}^2/\mathbb{Z}^2 \\ [(x,y)] & \mapsto & [(-x,-y)] \end{array} \quad \text{and} \quad \begin{array}{ccc} S^1\times S^1 & \to & S^1\times S^1 \\ (z,w) & \mapsto & (z^{-1},w^{-1}), \end{array}$$

under a suitable diffeomorphism between $\mathbb{R}^2/\mathbb{Z}^2 = S^1\times S^1$ and $E_6/\sim$, correspond to the hyperelliptic involution.[1259] In Lemma 1.58 we gave an explicit diffeomorphism between $S^1\times S^1$ and a specific submanifold of $\mathbb{R}^3$. Under this diffeomorphism the above hyperelliptic involution corresponds to rotation by π around a line in the xy-plane through the origin.

[1257] In the verification of this statement it can be useful to keep the second example on page 1744 in mind.

[1258] It always feels like cheating to use the calculation of Euler characteristics together with Theorem 14.9 to determine the diffeomorphism type of a given closed orientable connected 2-dimensional manifold. Can you find a more direct proof that $\Sigma_g/\sim$ is diffeomorphic to S^2?

[1259] Clearly both maps are orientation-preserving involutions. Thus it remains to show that these involutions of $\mathbb{R}^2/\mathbb{Z}^2$ and $S^1\times S^1$ have precisely four fixed points. What are they?

In Figure 936 we show the torus as a submanifold of $\mathbb{R}^3$ together with the hyperelliptic involution. We do our best to visualize that the quotient of the torus is indeed given by the sphere.

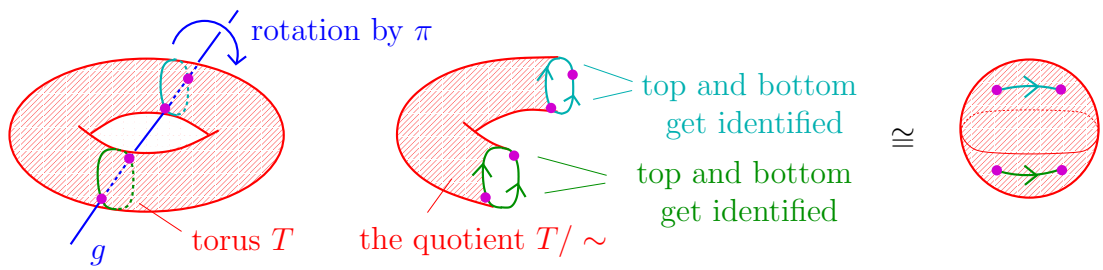

FIGURE 936.

(2) Using Proposition 75.3 we can now also visualize the hyperelliptic involution in our favorite "physical" model of the surface of genus g. More precisely, in Figure 937 on the right we show the surface of genus 2 as a submanifold of $\mathbb{R}^3$. Rotation by π around the x-axis is an orientation-preserving involution which has 6 fixed points. It follows from Proposition 75.3 that, under a suitable diffeomorphism to Σ_g, this involution corresponds to the hyperelliptic involution. For convenience we refer to this involution also as the hyperelliptic involution. In Figure 938 we indicate why the quotient is indeed the sphere.

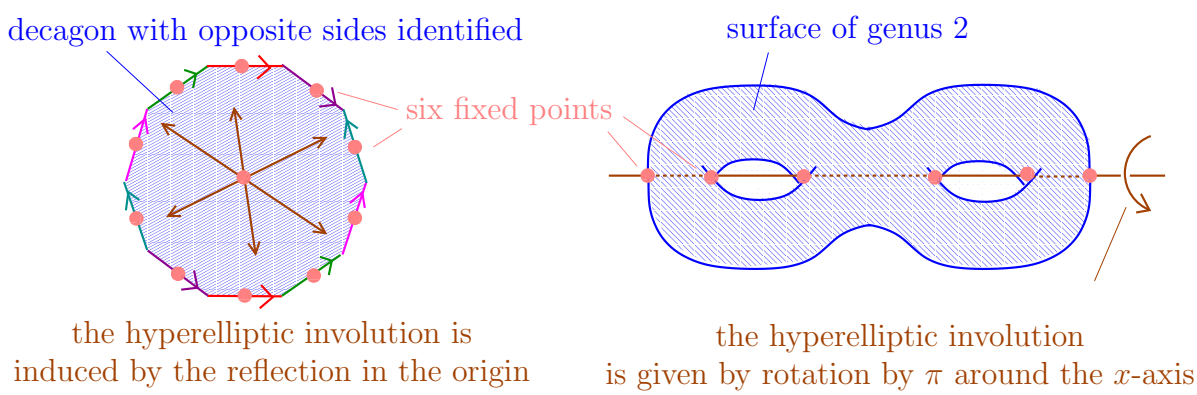

FIGURE 937.

75.3. **Branched coverings of 3-manifolds.** In this section we consider branched coverings of 3-manifolds. Before we start out with definitions and examples we provide a word of caution. Whenever one wants to deal with "real-life topological spaces" it is very hard to write down everything absolutely rigorously. In this chapter we will therefore take some liberties and we will not write down every argument in full detail.

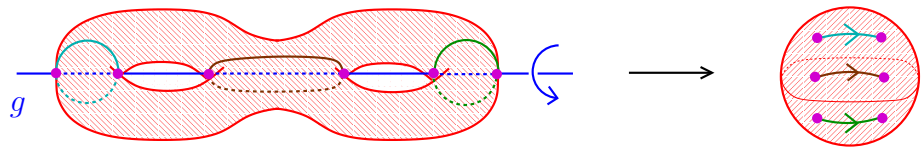

FIGURE 938.

As a balm to our mathematical conscience we recall that we pointed out on page 1692, topological 3-dimensional manifolds admit a unique smooth structure. Hence we do not need to distinguish between the concepts of being "homeomorphic" and "diffeomorphic".[1260]

Before we give a 3-dimensional example of a branched covering we need to introduce one more definition.

Definition.

(1) An *arc* in a 3-manifold M is a proper submanifold of M that is diffeomorphic to the interval $[0,1]$.

(2) We say arcs $A_1,\dots,A_m$ in $\overline{B}^3$ are *unknotted* if there exists a homeomorphism $f\colon \overline{B}^3 \to \overline{B}^2 \times [0,1]$ and distinct points $P_1,\dots,P_m$ such that for $i = 1,\dots,m$ we have $f(A_i) = P_i \times [0,1]$.

Example. In Figure 939 we show to the left an arc in the solid torus. To the right we show two arcs in $\overline{B}^3$ that are unknotted.

FIGURE 939.

Now we can give the promised examples of branched coverings of 3-dimensional manifolds.

Examples.

(1) We consider the map

$$\begin{array}{rcl} \Theta\colon \overline{B}^2 \times S^1 & \to & \overline{B}^2 \times S^1 \\ (re^{i\varphi}, z) & \mapsto & (re^{-i\varphi}, z^{-1}). \end{array}$$

[1260]This fact that by smoothing we can always replace a homeomorphism by a diffeomorphism should not be overgeneralized. For example, Bing [Bin2] gave an example of an involution f on S^3 that is not isotopic to a smooth involution. More precisely, we can isotope f to a smooth map, but we can no longer arrange that that map is an involution.

The map Θ is an involution that restricts to the hyperelliptic involution on the boundary. In Lemma 1.58 we had identified the solid torus $\overline{B}^2 \times S^1$ with a submanifold of $\mathbb{R}^3$. Under this identification the above involution Θ corresponds to the rotation by π around a line in the xy-plane. This map restricts to an involution on the solid torus $\overline{B}^2 \times S^1 \subset \mathbb{R}^3$. As is illustrated in Figure 940, the quotient $\overline{B}^2 \times S^1/x \sim \Theta(x)$ is the 3-ball and the quotient map $p\colon \overline{B}^2 \times S^1 \to \overline{B}^3$ is a 2-fold branched covering where the branch locus is given by two unknotted arcs.[1261]

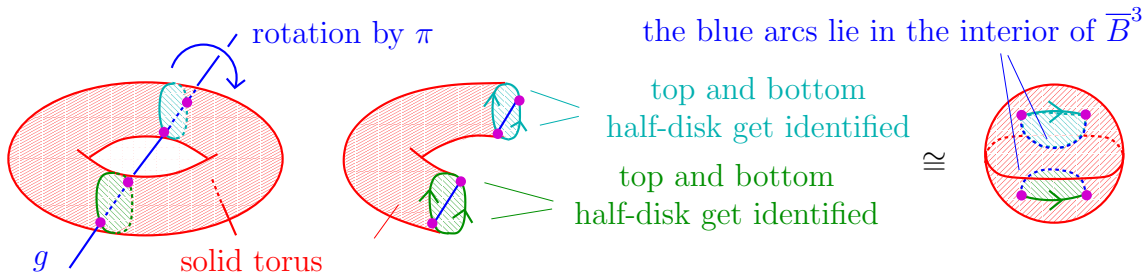

FIGURE 940.

(2) Above we saw that the surface of genus g is the branched covering of S^2 with branch locus given by $2g+2$ points. Similarly to (1) we can now replace the surface of genus g by the handlebody H_g of genus g and we obtain a branched covering of H_g over the 3-ball $\overline{B}^3$ where the branch locus is given by $g+1$ unknotted arcs.

It follows from the classification of closed connected 2-dimensional manifolds, see Theorem 14.10, together with discussion on page 1749 that every closed orientable connected 2-dimensional manifold Σ admits a simple branched covering over the 2-dimensional sphere. The following theorem says that a similar statement also holds in the 3-dimensional setting.

Theorem 75.4. (Hilden-Montesinos) *Every closed orientable connected 3-dimensional manifold M admits a map $p\colon M \to S^3$ which is a simple 3-fold branched covering (not necessarily regular) with branch locus a knot.*

Remark. The theorem has its origins in the work of James Alexander [Al3] from 1920. He had claimed that every closed orientable 3-dimensional manifold admits a map $p\colon M \to S^3$ which is a branched covering with branch locus a link. But the definition of a branched covering map in [Al3] is weaker than our notion and few details were provided in [Al3].

[1261] It is painful, but not impossible to prove this statement rigorously. Indeed, first of all we can replace $\overline{B}^2 \times S^1$ by $([-1,1]/-1 \sim 1) \times [0,2]^2$ where the involution is given by $(s,x,y) \sim (-s,x,2-y)$. The quotient space is then homeomorphic to $[0,1] \times [0,2]^2$ where $(0,x,y) \sim (0,x,2-y)$ and $(1,x,y) \sim (1,x,2-y)$. Using this description it is no longer that difficult to show that the quotient space is homeomorphic to $\overline{B}^2 \times [0,1]$ where the fixed point set is given by two arcs of the form $P_1 \times [0,1]$ and $P_2 \times [0,1]$. We leave it to the reader to fill in the details.

Proof. The theorem was independently proved by Hugh Hilden [Hild] and José Montesinos [Mon] in the early 1970s. An exposition of the proof is also given in [PrS, Theorem 23.1]. The definition of a branched covering used in the above references is slightly less restrictive, but it is clear from the proofs that they provide branched coverings in our sense. □

75.4. **Branched coverings defined by knots.** In the previous sections we saw that several maps $p\colon \widetilde{M} \to M$ between manifolds are branched coverings and we had determined the branch locus of those branched coverings.

In this section we go the other way round. We set $M = S^3$, we prescribe the branch locus as a given knot K and we describe a degree m. Given this data we will construct an essentially unique m-fold branched covering $p\colon \Sigma_m(K) \to S^3$ with branch locus K.

Definition. Let K be a knot in S^3 and let $m \in \mathbb{N}$.

(1) By Lemma 70.6 (2) we can pick a fattening $F\colon \overline{B}^2 \times K \to S^3$ with self-linking number 0.
   (a) As usual we write $X_K := S^3 \setminus F(B^2 \times K)$.
   (b) We equip X_K with the natural orientation coming from S^3.
   (c) We denote by $f\colon S^1 \times K \to \partial X_K = \partial F(\overline{B}^2 \times K)$ the diffeomorphism that is given by restricting F to the boundary torus $S^1 \times K$.
   (d) We denote by $\phi_K\colon \pi_1(X_K) \to H_1(X_K;\mathbb{Z}) \xrightarrow{\cong} \mathbb{Z}$ one of the two epimorphisms. (It will not matter which one we take.)

(2) By Proposition 20.8 there exists a connected covering $p\colon \widetilde{X_K} \to X_K$ that corresponds to $\ker\{\pi_1(X_K) \xrightarrow{\phi_K} \mathbb{Z} \to \mathbb{Z}_m\}$, i.e. that satisfies

$$p_*(\pi_1(\widetilde{X_K})) \;=\; \ker\left\{\pi_1(X_K) \xrightarrow{\phi_K} \mathbb{Z} \to \mathbb{Z}_m\right\}.$$

Furthermore, by Proposition 20.9 this covering is in an appropriate sense unique. We equip $\widetilde{X_K}$ with the orientation coming from Proposition 8.1 and coming from the above orientation on X_K.

(3) We consider the branched covering

$$\begin{array}{rcl} q\colon \overline{B}^2 \times K & \to & \overline{B}^2 \times K \\ (z,p) & \mapsto & (z^m,p). \end{array}$$

Since the self-linking number of F was chosen to be zero, and by the uniqueness statement of Proposition 20.9, we see that the restriction of q to the boundary $S^1 \times K$ can be identified with the m-fold covering corresponding to

$$\ker\left\{\pi_1(S^1 \times K) \xrightarrow{f_*} \pi_1(X_K) \to \mathbb{Z} \to \mathbb{Z}_m\right\}.$$

(4) It follows from (3) that f lifts to a diffeomorphism $\widetilde{f}\colon S^1 \times K \to \partial\widetilde{X_K}$ such that the following diagram commutes

$$\begin{array}{ccc} S^1 \times K & \xrightarrow{\widetilde{f}} & \partial\widetilde{X_K} \\ {\scriptstyle q}\downarrow & & \downarrow{\scriptstyle p} \\ S^1 \times K & \xrightarrow{f} & \partial X_K. \end{array}$$

(5) We define the *m-fold branched covering of K* to be the topological space

$$\Sigma_m(K) \ := \ \left(\overline{B}^2 \times K\right) \cup_{\widetilde{f}} \widetilde{X_K}.$$

The following proposition summarizes some basic properties of branched coverings of knots.

Proposition 75.5. *Let K be a knot and let $m \in \mathbb{N}$.*

(1) *The m-fold branched covering $\Sigma_m(K)$ is a closed orientable 3-dimensional topological manifold. It admits a unique smooth structure and a unique orientation such that $\widetilde{X_K}$ is a submanifold and such that the orientation on the submanifold $\widetilde{X_K}$ agrees with the orientation coming from Proposition 8.1 and the natural orientation on $X_K \subset S^3$.*

(2) *The oriented diffeomorphism type of $\Sigma_m(K)$ is independent of all of our choices.*

(3) *The map*

$$\begin{array}{ccccc} \Sigma_m(K) & = & \overline{B}^2 \times K & \cup_{\widetilde{f}} & \widetilde{X_K}. \\ \downarrow & & \downarrow q & & \downarrow p \\ S^3 & = & \overline{B}^2 \times K & \cup_f & X_K \end{array}$$

is well-defined and it is a regular simple m-fold branched covering with branch locus given by the knot K.

(4) *If two knots K and J are equivalent, then there exists an orientation-preserving diffeomorphism $\Sigma_m(K) \to \Sigma_m(J)$.*

(5) *Let K be a knot in $\mathbb{R}^3 \subset S^3 = \mathbb{R}^3 \cup \{\infty\}$. Let $K^* \subset \mathbb{R}^3$ be a mirror image, i.e. $K^* = \rho(K)$ where ρ is the reflection in a hyperplane of $\mathbb{R}^3$. There exists an* orientation-reversing *diffeomorphism from $\Sigma_m(K)$ to $\Sigma_m(K^*)$.*

(6) *If K is amphichiral, then $\Sigma_m(K)$ is amphichiral.*

(7) *We have isomorphisms*

$$H_1(\Sigma_m(K);\mathbb{Z}) \oplus \mathbb{Z} \cong H_1(\widetilde{X}_K;\mathbb{Z}) \cong H_1\left(\begin{matrix}\text{covering of } S^3 \setminus K \text{ corresponding to} \\ \text{the epimorphism } \pi_1(S^3 \setminus K) \to \mathbb{Z}_m\end{matrix};\mathbb{Z}\right).$$

(8) *If p is a prime number and $r \in \mathbb{N}$, then the homology group $H_1(\Sigma_{p^r}(K);\mathbb{Z})$ is finite.*

Sketch of proof.

(1) The first statement follows from Proposition 10.12.

(2) The second statement follows fairly easily from Propositions 20.9 and 64.9.

(3) The third statement follows easily from the definitions.

(4) Suppose that K and J are equivalent. This means that there exists a smooth isotopy from the knot K to the knot J. As we pointed out in the proof of Proposition 10.33, the smooth isotopy can be extended to a smooth isotopy of S^3 carrying K to J. It now follows easily from the definitions that there exists an orientation-preserving diffeomorphism $\Sigma_m(K) \to \Sigma_m(J)$.
(5) Let ρ be a reflection in a hyperplane of $\mathbb{R}^3$. From Exercise 1.19 we obtain that, by setting $\rho(\infty) = \infty$, the map ρ extends to a homeomorphism of $S^3 = \mathbb{R}^3 \cup \{\infty\}$. We denote this homeomorphism again by ρ. It follows from Proposition 47.3, say applied to the origin, that $\rho\colon S^3 \to S^3$ is orientation-reversing. It follows again easily from the definitions that ρ induces an orientation-reversing homeomorphism $\Sigma_m(K) \to \Sigma_m(K^*)$.
(6) This statement is an immediate consequence of (4) and (5).
(7) An amusing Meyer–Vietoris argument shows that there exists an isomorphism as stated on the left. The inclusion of the knot exterior into the knot complement is a homotopy equivalence, therefore it induces an isomorphism as stated on the right.
(8) The last statement is the only statement that is non-trivial. The case $p = 2$ and $r = 1$ is proved for example on [Rol, p. 213]. The general case is proved in [Gor, p. 362]. □

Now we can consider some examples of branched coverings of knots.

Examples.

(1) The 1-fold branched covering of a knot K is, basically by definition, given by S^3.
(2) For K the trivial knot it is an amusing exercise to verify that all branched coverings are again diffeomorphic to S^3.
(3) The following converse to (2) holds: If K is a knot and $m \in \mathbb{N}_{\geq 2}$ such that $\Sigma_m(K)$ is diffeomorphic to S^3, then K is equivalent to the trivial knot. This is a consequence of the *Smith Conjecture* which was proved in 1984, see [MB].[1262]
(4) More generally one can ask to what degree branched coverings remember the original knot K. The bad news is that by [Nak, Sak] there are many examples of triples (K, K', m) where K and K' are inequivalent "prime" knots and where $m \in \mathbb{N}_{\geq 2}$ such that $\Sigma_m(K)$ is diffeomorphic to $\Sigma_m(K')$. The good news is that it is shown in [Koj] that if K and K' are two "prime" knots such that $\Sigma_m(K)$ and $\Sigma_m(K')$ are diffeomorphic for infinitely many $m \in \mathbb{N}$, then K and K' are equivalent.

The idea now is of course to apply Proposition 75.5 to settle Question 47.2, namely to show that the trefoil is not amphichiral. Therefore we need to determine at least one interesting branched covering of the trefoil.

Definition. Let $J \subset S^3$ be a knot.

[1262]The Smith Conjecture, which was originally formulated in 1949 [Eil, Problem 36], says that if f is a diffeomorphism of S^3 of finite order, i.e. such that there exists an $n \in \mathbb{N}$ with $f^n = \mathrm{id}_{S^3}$, then the fixed point set of f cannot be a nontrivial knot. The conjecture was proved in 1984 [MB]. By [Gif] the analogous statement is wrong for 4-dimensional manifolds.

(1) We write

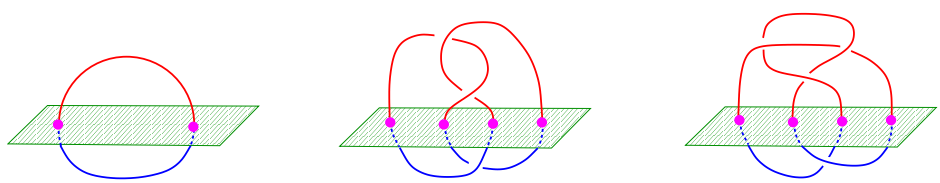
$$\begin{array}{rclcrcl} S^3_{\geq 0} & := & \{(x_1,x_2,x_3,x_4) \in S^3 \,|\, x_4 \geq 0\} & \text{and} & J_{\geq 0} & := & J \cap S^3_{\geq 0} \\ S^3_{\leq 0} & := & \{(x_1,x_2,x_3,x_4) \in S^3 \,|\, x_4 \leq 0\} & \text{and} & J_{\leq 0} & := & J \cap S^3_{\leq 0} \end{array}$$

and

$$S^3_{=0} := \{(x_1,x_2,x_3,x_4) \in S^3 \,|\, x_4 = 0\} \quad \text{and} \quad J_{=0} := J \cap S^3_{=0}.$$

(2) We say J is in *m-bridge position* if the following three conditions are satisfied:
   (a) J intersects the sphere $S^3_{=0} = \text{xy-plane} \cup \{\infty\}$ transversally,
   (b) the intersection $J_{\geq 0} = J \cap S^3_{\geq 0}$ consists of m trivial arcs in the 3-ball $S^3_{\geq 0}$,
   (c) the intersection $J_{\leq 0} = J \cap S^3_{\leq 0}$ consists of m trivial arcs in the 3-ball $S^3_{\leq 0}$.

Example. In Figure 941 we show three knots which are isotopic to the trivial knot, the trefoil and the figure-8 knot.[1263] The first knot is in 1-bridge position whereas the latter two knots are in 2-bridge position.



trivial knot the trefoil figure-8 knot

FIGURE 941.

Lemma 75.6. *Every knot K in S^3 is equivalent to a knot J that is in m-bridge position for some m.*

Sketch of proof. If a knot K is represented by a diagram with m crossings, then it is already in an m-bridge position. We refer to [BZH, Chapter 2.D] for more details. □

Definition. Given a knot $K \subset S^3$ we define its *bridge number* as

$$b(K) := \min\{m \in \mathbb{N} \,|\, K \text{ is equivalent to a knot in } m\text{-bridge position}\}.$$

If $b(K) = m$, then we also just say that K is an *m-bridge knot*.

Examples.

(1) If K is a knot with bridge number 1, then K is equivalent to the trivial knot. This sounds pretty convincing, but as so often, it is rather painful to write down a completely rigorous argument.
(2) It follows from (1) and Figure 941 that the trefoil and the figure-8 knot are 2-bridge knots.

[1263] We leave it as an exercise to verify that the knots pictured in Figure 941 are in fact isotopic to the knots shown in Figure 225.

Proposition 75.7. *Let K be a knot. The 2-fold branched covering $\Sigma_2(K)$ admits a Heegaard splitting of genus $b(K)-1$.*

Sketch of proof. By Proposition 75.5(4) we can assume that K itself is already in m-bridge position. We denote by $p\colon \Sigma_2(K) \to S^3$ the branched covering with branch locus K. The restriction of p to $p^{-1}(S^3_{\geq 0}) \to S^3_{\geq 0}$ is a 2-fold branched covering with branch locus $K_{\geq 0}$. Since $K_{\geq 0}$ are unknotted arcs this branched covering is essentially the same as the branched covering considered on page 1751.[1264] But this implies that $p^{-1}(S^3_{\geq 0})$ is a genus $m-1$ handlebody. Similarly we see that $p^{-1}(S^3_{\leq 0})$ is a genus $m-1$ handlebody and that the intersection of these two handlebodies, which is given by $p^{-1}(S^3_{=0})$ is a surface of genus $m-1$. But that means precisely that $\Sigma_2(K)$ admits a genus $m-1$ Heegaard splitting. □

Corollary 75.8. *If K is a knot with bridge number $b(K)=2$, then $\Sigma_2(K)$ is diffeomorphic to a lens space.*

Proof. Let K be a knot with bridge number $b(K)=2$. It follows from Proposition 75.7 that the 2-fold branched covering $\Sigma_2(K)$ admits a Heegaard splitting of genus one. It follows from Proposition 75.5 (1) and Corollary 73.10 that $\Sigma_2(K)$ is either diffeomorphic to a lens space or to $S^1 \times S^2$. In Proposition 75.5 (8) we saw that $H_1(\Sigma_2(K);\mathbb{Z})$ is finite, thus we can exclude the possibility that $\Sigma_2(K)$ is diffeomorphic to $S^1 \times S^2$. □

We had just seen that the trefoil and the figure-8 knot are 2-bridge knots. So their 2-fold branched coverings are lens spaces. The following proposition tells us what these 2-fold branched coverings are.

Proposition 75.9. [1265]

(1) *The 2-fold branched covering of the trefoil is diffeomorphic to the lens space $L(3,2)$.*
(2) *The 2-fold branched covering of the figure-8 knot is diffeomorphic to the lens space $L(5,2)$.*

Remark. Horst Schubert [Schub] showed in 1956 that every lens space is the 2-fold branched covering of a 2-bridge knot.

Proof. Let K be a 2-bridge knot. There is a general algorithm that determines the lens space which equals the 2-fold branched covering $\Sigma_2(K)$, see e.g. [BZH, Proposition 12.3]. The statement about the trefoil is then implied by [BZH, Example 12.16]. The statement about the figure-8 knot is implicit in [BZH, Section 12].

There are also several other proofs for the first statement:

(1) Let K be the trefoil. It follows from the calculation on page 542, the Hurewicz Theorem 38.5, Proposition 75.5 and Lemma 11.8 (1) that $H_1(\Sigma_2(K);\mathbb{Z}) \cong \mathbb{Z}_3$.

[1264] An argument similar to the proof of Proposition 75.5 (2) shows that all 2-fold branched coverings of the 3-ball with branch locus given by two unknotted arcs are homeomorphic.

[1265] Since it is exceedingly painful to keep track of orientation conventions we will not attempt to determine whether there exist orientation-preserving or orientation-reversing diffeomorphisms between the branched coverings and the lens spaces.

Furthermore, by Corollary 75.8 we know that $\Sigma_2(K)$ is a lens space. Thus we see that $\Sigma_2(K)$ is diffeomorphic to $L(3,1)$ or to $L(3,2)$. But these two lens spaces are diffeomorphic by Lemma 7.7.

(2) We also refer to [Sti, Section 7.2.2] and [Rol, p. 304] for two alternative proofs of the first statement. □

Finally we can answer Question 47.2 in the negative.

Proposition 75.10. *The trefoil is chiral.*

Proof. Let K be the trefoil. By Proposition 75.9 (9) we know that $\Sigma_2(K)$ is diffeomorphic to the lens space $L(3,2)$. We know from Proposition 74.23 that $L(3,2)$ is chiral. But by Proposition 75.5 (6) this implies that K is also chiral. □

We have now shown that the trefoil is not equivalent to its mirror image. Therefore one often distinguishes in the literature between the left-handed trefoil (which equals our trefoil from before) and the right-handed trefoil. The names stem from the observation that if we equip the right-handed trefoil with either of the two orientations the following holds: if the thumb of the right-hand points in the direction of the overcrossing-strand, then the fingers point in the direction of the undercrossing-strand. (It is a fun exercise to verify this statement.)

left-handed trefoil right-handed trefoil

FIGURE 942.

Remark. On page 1154 we saw that $L(5,2)$ is amphichiral. This is consistent with the fact, illustrated in Figure 673, that the figure-8 knot is amphichiral and Propositions 75.9 and 75.5 (6).

Remark. In this chapter we studied questions about embeddings of a given closed k-dimensional manifold W into a given closed $(k+2)$-dimensional manifold M, namely of embeddings of $W = S^1$ into $M = S^3$, by associating to an embedding a branched covering. The same approach can also be used in many other contexts, for example it can and is being used to study embeddings of surfaces into closed 4-manifolds, see e.g. [HsS].

Exercises for Chapter 75.

Exercise 75.1. The definition of the m-fold branched cover of a knot easily in S^3 generalizes to the notion of an m-fold branched cover of a link in S^3.

(a) We consider the trivial 2-component link L_2. What is the diffeomorphism type of the corresponding 2-fold branched cover?
(b) We consider the trivial 2-component link L_2. What is the diffeomorphism type of the corresponding 5-fold branched cover?
(c) We consider the trivial 2-component link L_3. What is the diffeomorphism type of the corresponding 2-fold branched cover?

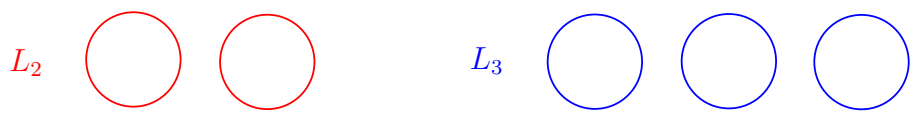


FIGURE 943.

76. Cobordisms

In Question 61.7 we had asked whether every closed orientable manifold is the boundary of a compact manifold. In this chapter we will see that the answer is very much no. In fact, we will "quantify" to what degree the answer is no by introducing the "cobordism group", which is an interesting object in its own right.

76.1. **The cobordism rings.** Given two closed n-dimensional manifolds M and N we obtain a new closed n-dimensional manifold by taking the disjoint union $M \sqcup N$. This operation has a neutral element, given by the empty manifold, and it looks abelian and associative.[1266] Thus it looks that all closed n-dimensional manifolds together with the operation "$\sqcup$" form a monoid.

For the reader's convenience we recall the definition of a monoid.

Definition. A *monoid* is a set S together with a map

$$\begin{array}{rcl} S \times S & \to & S \\ (x, y) & \mapsto & x \cdot y \end{array}$$

such that the following two conditions are satisfied:[1267]

(1) there exists a neutral element $e \in S$, i.e. an element which satisfies $e \cdot x = x \cdot e = x$ for all $x \in S$,
(2) the operation "$\cdot$" is associative, i.e. for all $x, y, z \in S$ we have $(x \cdot y) \cdot z = x \cdot (y \cdot z)$.

Careful comparison between the definition of a monoid and the discussion of manifolds above reveals a subtle problem: "all closed n-dimensional manifolds" do not form a set. As most mathematicians I have no intention of getting into the debate about what is a set. Instead we refer to [FPr] and [Halm] for details. Also, at this stage reading "Logicomix" [DoP], see Figure 944, is almost a must.

Fortunately, we are saved by the following lemma.

Lemma 76.1. *Let $n \in \mathbb{N}_0$. The diffeomorphism classes of n-dimensional manifolds form a set.*

Remark.

(1) Note that here it is essential that manifolds are assumed to be second-countable. If we did not make this assumption, then any set with the discrete topology would be a 0-dimensional manifold, but the bijection classes of sets do not form a set.
(2) In [CK] it is shown that in any dimension there exist only finitely many homeomorphism classes of compact topological manifolds. Thus homeomorphism classes of classes of compact topological manifolds form a set.

[1266] Very well-trained eyes will spot that purely set theoretically, $M \sqcup N$ and $N \sqcup M$ are not exactly the same, see the definition on page 83.

[1267] A *semi-group* is defined similarly, except that we do not demand the existence of a neutral element.

FIGURE 944.

Sketchy proof. In Proposition 65.11 and the Whitney Embedding Theorem 65.18 we saw that any n-dimensional manifold is diffeomorphic to a submanifold of $\mathbb{R}^{2n+1}$. Thus we can identify the "diffeomorphism classes of closed n-dimensional manifolds" with a subset of the power set of $\mathbb{R}^{2n+1}$, which is a set. $\square$

Definition.

(1) Given $n \in \mathbb{N}_0$ we denote by $\mathcal{M}_n$ the set of all diffeomorphism classes of closed oriented n-dimensional manifolds.[1268][1269]
(2) Given $S, T \in \mathcal{M}_n$ we say that S and T are *cobordant* if there exists a *cobordism between S and T*, i.e. a compact oriented $(n+1)$-dimensional manifold W such that[1270] ∂W admits an orientation-preserving diffeomorphism to $S \cup -T$. If S and T are cobordant, then we write $S \sim T$.

Convention. In the following we will often be slightly sloppy in our notation, meaning that we will not distinguish between a manifold and its diffeomorphism class. For example, given oriented manifolds W, S and T we often write $\partial M = S \sqcup T$, even though strictly speaking we have $\partial M = S' \sqcup T'$ where S' and T' are oriented manifolds that admit an orientation-preserving diffeomorphism to S respectively T.

[1268]Recall that the empty set is a closed oriented n-dimensional manifold.

[1269]Also recall that an orientation for a 0-dimensional manifold M consists of a choice of a sign in $\{\pm 1\}$ for each point in M, see the definition on page 1585.

[1270]Recall that each component of ∂W inherits an orientation from the orientation of W.

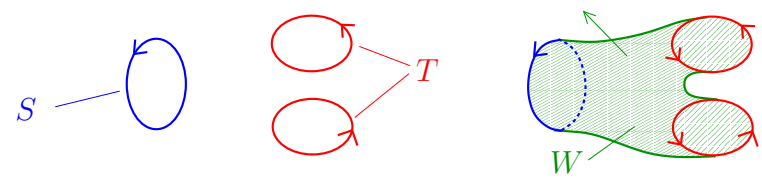

FIGURE 945.

Lemma 76.2. *Let $n \in \mathbb{N}_0$.*

(1) *The relation $\sim$ on $\mathcal{M}_n$ is an equivalence relation.*
(2) *The map*

$$\begin{array}{rcl} \mathcal{M}_n \times \mathcal{M}_n & \to & \mathcal{M}_n \\ ([S],[T]) & \mapsto & [S \sqcup T] \end{array}$$

is well-defined and it descends to an abelian group structure on the set $\mathcal{M}_n/\sim$[1271] *where the neutral element is given by the empty manifold.*

Proof.

(1) We first show that the relation $\sim$ on $\mathcal{M}_n$ is an equivalence relation.
   (a) Given $M \in \mathcal{M}_n$ we have $M \sim M$ since, by the discussion on page 1586, we have $\partial([0,1] \times M) = \{0\} \times (-M) \cup \{1\} \times M$.
   (b) Suppose that $S \sim T$, i.e. there exists a compact oriented $(n+1)$-dimensional manifold W with $\partial W = S \sqcup -T$. Then $\partial(-W) = -S \sqcup T = T \sqcup (-S)$ which shows that $T \sim S$.
   (c) Finally suppose that we have $R, S, T \in \mathcal{M}_n$ with $R \sim S$ and $S \sim T$. This means that there exist compact oriented $(n+1)$-dimensional manifolds X and Y with $\partial X = R \sqcup -S$ and $\partial Y = S \sqcup -T$. We set $Z := X \cup_S Y$. It follows from Proposition 10.12 that Z is a compact orientable $(n+1)$-dimensional manifold with $\partial Z = R \sqcup -T$. We refer to Figure 946 for an illustration.

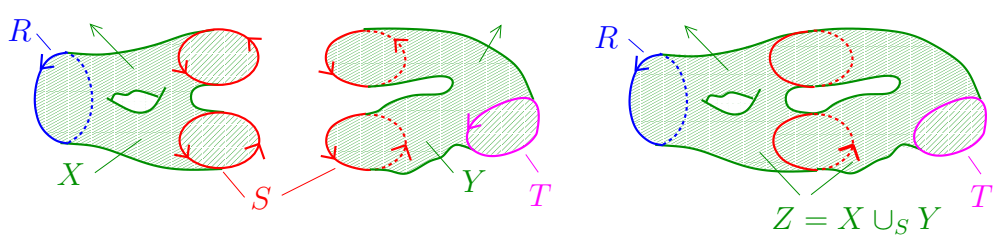

FIGURE 946.

(2) This statement follows from the following five observations:
   (a) One can easily verify that the definition does not depend on the choice of the representatives in $\mathcal{M}_n$.

[1271] By Lemma 76.1 we know that $\mathcal{M}_n$ and thus also $\mathcal{M}_n/\sim$ are a set.

(b) It is clear that the empty manifold is a neutral element for the above operation.
(c) We need to show that any $[M] \in \mathcal{M}_n$ has an inverse element. In fact this is represented by the oriented manifold $-M$, since by the discussion on page 1586, we have $\partial([0,1]\times M) = \{0\}\times(-M)\cup\{1\}\times M$, i.e. the manifold $[0,1]\times M$ defines a cobordism from $M \sqcup -M$ to the empty manifold. We refer to Figure 947 for an illustration.
(d) The product structure is commutative since $A \sqcup B$ and $B \sqcup A$ are naturally diffeomorphic, see Lemma 1.49 (4).[1272]
(e) The product structure is associative since $(A \sqcup B) \sqcup C$ and $A \sqcup (B \sqcup C)$ are naturally diffeomorphic, see Lemma 1.49 (5). □

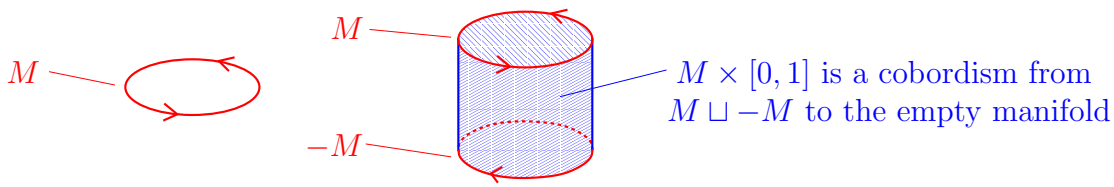

FIGURE 947.

Definition. Let $n \in \mathbb{N}_0$. We refer to

$$\Omega_n \ := \ (\mathcal{M}_n/\sim, \sqcup)$$

as the *n-th cobordism group.*

We have another natural operation on oriented connected manifolds, namely the connected sum operation. The following lemma says that up to cobordisms the connected sum operation is the same as the disjoint union.

Lemma 76.3. *Let $n \in \mathbb{N}$ and let M and N be two closed oriented connected n-dimensional manifolds, then*

$$M\#N \ = \ M \sqcup N \ \in \ \Omega_n.$$

Sketch of proof. Let M and N be two closed oriented connected n-dimensional manifolds. Let $\varphi\colon \overline{B}^n \to M \setminus \partial M$ and $\psi\colon \overline{B}^n \to N \setminus \partial N$ be embeddings such that φ is orientation-preserving and such that ψ is orientation-reversing.

We consider $[0,1]\times M$ and $[0,1]\times N$. Note that by the discussion on page 1586, we have $\partial([0,1]\times M) = (\{0\}\times(-M)) \cup (\{1\}\times M)$ and $\partial([0,1]\times N) = (\{0\}\times(-N)) \cup (\{1\}\times N)$. By a slight abuse of notation we denote by φ and ψ the obvious embeddings of $\overline{B}^n$ into $\{1\}\times M$ and $\{1\}\times N$. We use these two embeddings to form the boundary connected sum

$$W \ := \ ([0,1]\times M)\#_b([0,1]\times N) \ := \ ([0,1]\times M) \sqcup ([0,1]\times N)/\varphi(x) = \psi(x) \text{ for } x \in S^{n-1}$$

[1272]Strictly speaking Lemma 1.49 says that the two sides are naturally homeomorphic. But the same way we see that the two sides are diffeomorphic.

that we introduced on page 1690.

By Proposition 73.1 we know that W admits the structure of an $(n+1)$-dimensional orientable manifold such that

$$\partial W \;=\; \underbrace{(\{1\}\times M)\#(\{1\}\times N)}_{=M\#N} \sqcup \underbrace{(-\{0\}\times M)}_{=-M} \sqcup \underbrace{(-\{0\}\times N)}_{=-N}.$$

We have thus found the desired cobordism. □

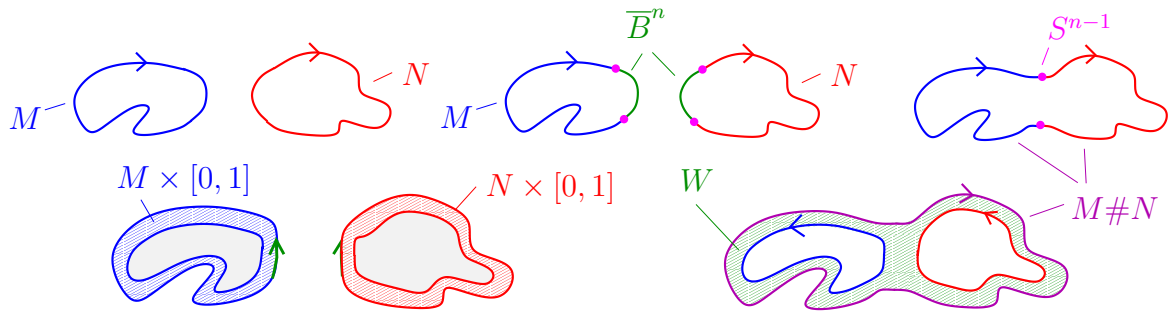

FIGURE 948.

Definition. If we use exactly the same definitions as before except that we drop the condition that the manifolds are orientable and we drop the condition that the cobordisms are orientable, then given $n\in\mathbb{N}_0$ we obtain the *unoriented cobordism group*

$$\mathcal{N}_n \;:=\; \{\text{closed } n\text{-dimensional manifolds}\}/\text{unoriented cobordisms}.$$

The following lemma summarizes a few basic facts about unoriented cobordism groups.

Lemma 76.4.

(1) *Let $n\in\mathbb{N}_0$. Every non-trivial element in $\mathcal{N}_n$ is of order two, i.e. given any $M\in\mathcal{N}_n$ we have $M\sqcup M=0\in\mathcal{N}_n$.*

(2) *Let $n\in\mathbb{N}$. Let M and N be two closed connected n-dimensional manifolds.*[1273] *Then*

$$M\#N \;=\; M\sqcup N \;\in\; \mathcal{N}_n.$$

Proof. Let $n\in\mathbb{N}_0$.

(1) Let $M\in\mathcal{N}_n$. We have

$$2\cdot M \;=\; M\sqcup M \;=\; (\{0\}\times M)\sqcup(\{1\}\times M) \;\underset{\uparrow}{=}\; \partial([0,1]\times M).$$

by Proposition 3.42 we have this equality of unoriented manifolds

[1273] If M and N are orientable, then the connected sum $M\#N$ is only well-defined once we pick an orientation for M and N. If M and N are orientable, then the equality is understood as holding for the definition of the connected sum for any choice of orientation for M and N.

(2) The proof of this statement is verbatim the same as in Lemma 76.3. □

In the following proposition we collect the computations of the low-dimensional (unoriented) cobordism groups.

Proposition 76.5. *We have the following table of isomorphism types of the (unoriented) cobordism groups for $n = 0, 1, 2, 3$:*

	$n=0$	$n=1$	$n=2$	$n=3$
Ω_n	$\mathbb{Z}$	0	0	0
$\mathcal{N}_n$	$\mathbb{Z}_2$	0	$\mathbb{Z}_2 \cdot [\mathbb{R}\mathrm{P}^2]$	0

Proof.

($n = 0$) Using the classification of compact 1-dimensional manifolds, see Proposition 3.53, one can easily see that the maps

$$\begin{array}{rcl} \Omega_0 & \to & \mathbb{Z} \\ \bigsqcup_{i=1}^{k} \{(P_i, \epsilon_i)\} & \mapsto & \sum_{i=1}^{k} \epsilon_i \end{array} \quad \text{and} \quad \begin{array}{rcl} \mathcal{N}_0 & \to & \mathbb{Z}_2 \\ \bigsqcup_{i=1}^{k} \{P_i\} & \mapsto & k \bmod 2 \end{array}$$

are isomorphisms.

($n = 1$) In Proposition 3.53 we saw that every closed connected 1-dimensional manifold is diffeomorphic to S^1. Evidently $S^1 = \partial \overline{B}^2$[1274], hence every generator, i.e. every (oriented) compact 1-dimensional manifold represents the trivial element in Ω_1 and in $\mathcal{N}_1$. Therefore we see that $\Omega_1 = 0$ and $\mathcal{N}_1 = 0$.

($n = 2$) In Theorem 14.10 we saw that every closed orientable 2-dimensional manifold is diffeomorphic to the surface of genus g for some g. By Proposition 73.1 (3) the surface of genus g is the boundary of the genus g handlebody. Thus we see that $\Omega_2 = 0$.

We turn to the calculation of $\mathcal{N}_2$. We want to prove the following claim.

Claim. The map

$$\begin{array}{rcl} \varphi\colon \mathbb{Z}_2 & \to & \mathcal{N}_2 \\ n & \mapsto & n \cdot \mathbb{R}\mathrm{P}^2 \end{array}$$

is an isomorphism.

We prove the claim in several steps:

(a) First we show that φ is a homomorphism. We denote by $\psi\colon \mathbb{Z} \to \mathcal{N}_2$ the map that is given by $n \mapsto n \cdot \mathbb{R}\mathrm{P}^2$. Since $\mathbb{Z}$ is a free group this is well-defined homomorphism. It remains to show that ψ factors through the projection $\mathbb{Z} \to \mathbb{Z}_2 = \mathbb{Z}/2\mathbb{Z}$. But that is an immediate consequence of Lemma 76.4 (1).

[1274]This is an equality of oriented manifolds if we equip S^1 and $\overline{B}^2$ with the usual orientation and also if we equip both manifolds with the opposite orientation.

(b) Next we show that $\varphi\colon \mathbb{Z}_2 \to \mathcal{N}_2$ is a monomorphism. We only need to show that $\varphi(1) = \mathbb{R}\mathrm{P}^2$ represents a non-trivial element in $\mathcal{N}_2$. In Corollary 61.6 we already saw, using the Euler characteristic and Poincaré Duality, that there is no compact 3-dimensional manifold whose boundary is homeomorphic to $\mathbb{R}\mathrm{P}^2$. Put differently, $\mathbb{R}\mathrm{P}^2$ represents a non-trivial element in $\mathcal{N}_2$.

(c) It remains to show that φ is an epimorphism. So let M be a compact 2-dimensional manifold representing an element in $\mathcal{N}_2$. Lemma 76.4 (2) shows that without loss of generality we can assume that M is connected. If M is orientable, then we already saw above that M is the boundary of a compact 3-manifold, hence $[M] = 0 \in \mathcal{N}_2$.
Finally we consider the case that M is non-orientable. We have

$$\begin{array}{ccccc} [M] & = & [\text{connected sum of } n \text{ copies of } \mathbb{R}\mathrm{P}^2] & = & n\cdot[\mathbb{R}\mathrm{P}^2] & = & (n \bmod 2)\cdot[\mathbb{R}\mathrm{P}^2]. \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{by Theorem 14.10 that there exists an } n \in \mathbb{N}_0 & & \text{Lemma 76.4 (2)} & & \text{Lemma 76.4 (1)} & \\ & \text{such that } M \text{ is diffeomorphic to the} & & & & & \\ & \text{connected sum of } n \text{ copies of } \mathbb{R}\mathrm{P}^2 & & & & & \end{array}$$

This completes the proof that φ is an epimorphism.

($n = 3$) It was first proved by René Thom [Tho, Tho2] in 1952 that $\Omega_3 = 0$ and by Albrecht Dold [Dol] in 1956 that $\mathcal{N}_3 = 0$. A fairly elementary proof for both statements was later was given by William Lickorish [Lic, Theorem 3] and [Lic2]. A particularly short proof that $\Omega_3 = 0$ is also given by Colin Rourke [Rou]. □

We have thus shown that the (unoriented) cobordism groups for $n = 0, 1, 2, 3$ are not particularly exciting. Our next goal is to study Ω_4. By the discussion on page 966 we know that $\chi(\mathbb{C}\mathrm{P}^2) = 3$. Thus the argument of Corollary 61.6 shows that $\mathbb{C}\mathrm{P}^2$ is a non-trivial element[1275] in Ω_4, but from Corollary 61.6 we cannot conclude whether or not $\mathbb{C}\mathrm{P}^2$ is an element of infinite order in Ω_4.

The following proposition is the key to showing that $\mathbb{C}\mathrm{P}^2$ is in fact an element of infinite order in Ω_4.

Proposition 76.6. *Let M be a closed oriented $4k$-dimensional topological manifold with $k \geq 0$.*[1276] *If there exists a compact orientable topological manifold X with $\partial X = M$, then* $\operatorname{sign}(M) = 0$.[1277]

It will take us a while to prove Proposition 76.6, therefore we first provide the following corollary.

Corollary 76.7. *For any $k \in \mathbb{N}$ the map*

$$\begin{array}{rcl} \operatorname{sign}\colon \Omega_{4k} & \to & \mathbb{Z} \\ [M] & \mapsto & \operatorname{sign}(M) \end{array}$$

[1275] In fact Corollary 61.6 also implies that $\mathbb{C}\mathrm{P}^2$ is a non-trivial element in $\mathcal{N}_4$.

[1276] Does the statement also hold for 0-dimensional manifolds?

[1277] We refer to page 1674 for the definition of the signature of M.

is an epimorphism.

Proof of Corollary 76.7. First we need to show that the map is well-defined. Thus suppose we are given closed oriented $4k$-dimensional manifolds M and N with $[M] = [N] \in \Omega_{4k}$. By definition there exists a compact oriented manifold X with $\partial X = M \sqcup -N$. We have

$$\begin{array}{ccccccccc} 0 & = & \operatorname{sign}(\partial X) & = & \operatorname{sign}(M \sqcup (-N)) & = & \operatorname{sign}(M) + \operatorname{sign}(-N) & = & \operatorname{sign}(M) - \operatorname{sign}(N). \\ & \uparrow & & & & \uparrow & & \uparrow & \\ & \text{Proposition 76.6} & & & & \text{Lemma 72.11 (2)} & & \text{Lemma 72.11 (3)} & \end{array}$$

This shows that $\operatorname{sign}\colon \Omega_{4k} \to \mathbb{Z}$ is well-defined. It follows from Lemma 72.11 (2) that this map is a homomorphism. Finally it follows immediately from Proposition 62.7 that $\operatorname{sign}(\mathbb{C}\mathrm{P}^{2k}) = \pm 1$,[1278] which shows that $\operatorname{sign}\colon \Omega_{4k} \to \mathbb{Z}$ is an epimorphism. □

The proof of Proposition 76.6 will rely on a purely algebraic lemma. Before we can formulate that lemma we have to introduce one more definition.

Definition. Given a form (V, g) and a subset $W \subset V$ we write

$$W^\perp := \{v \in V \mid g(v, w) = 0 \text{ for all } w \in W\}.$$

Example. We consider the form on $\mathbb{R}^2$ that is defined by the symmetric matrix

$$P := \begin{pmatrix} 0 & 1 \\ 1 & 2 \end{pmatrix}.$$

In this case for $H = \mathbb{R} \cdot (1, 0)$ we have $H^\perp = H$.

Lemma 76.8. *Let (V, g) be a non-singular symmetric form over the reals. If there exists a subspace W with $g|_W = 0$ and with $\dim(W) = \frac{1}{2}\dim(V)$, then $\operatorname{sign}(g) = 0$.*

Proof of Proposition 76.6. It follows from our hypothesis that $\dim(W) = \frac{1}{2}\dim(V)$ that we can find a basis $\{a_1, \dots, a_k, b_1, \dots, b_k\}$ for V such that $\{a_1, \dots, a_k\}$ is a basis for W. Since $g|_W = 0$ and since g is symmetric we see that with respect to this basis the form g is given by a matrix of the form

$$\begin{pmatrix} 0 & P \\ P^T & Q \end{pmatrix}$$

where Q is a symmetric matrix. It follows from the hypothesis that g is non-singular that $\det(P) \neq 0$, see e.g. Lemma 62.1. Now we consider the following three transformations

$$\begin{pmatrix} P^{-1} & 0 \\ 0 & \mathrm{id} \end{pmatrix} \begin{pmatrix} 0 & P \\ P^T & Q \end{pmatrix} \begin{pmatrix} (P^T)^{-1} & 0 \\ 0 & \mathrm{id} \end{pmatrix} = \begin{pmatrix} 0 & \mathrm{id} \\ \mathrm{id} & Q \end{pmatrix},$$

$$\begin{pmatrix} \mathrm{id} & 0 \\ -\frac{1}{2}Q & \mathrm{id} \end{pmatrix} \begin{pmatrix} 0 & \mathrm{id} \\ \mathrm{id} & Q \end{pmatrix} \begin{pmatrix} \mathrm{id} & -\frac{1}{2}Q \\ 0 & \mathrm{id} \end{pmatrix} = \begin{pmatrix} 0 & \mathrm{id} \\ \mathrm{id} & 0 \end{pmatrix}$$

and

$$\begin{pmatrix} \mathrm{id} & \mathrm{id} \\ \mathrm{id} & -\mathrm{id} \end{pmatrix} \begin{pmatrix} 0 & \mathrm{id} \\ \mathrm{id} & 0 \end{pmatrix} \begin{pmatrix} \mathrm{id} & \mathrm{id} \\ \mathrm{id} & -\mathrm{id} \end{pmatrix} = \begin{pmatrix} 2\,\mathrm{id} & 0 \\ 0 & -2\,\mathrm{id} \end{pmatrix}.$$

[1278] In fact the more fancy Lemma 67.18 says that $\operatorname{sign}(\mathbb{C}\mathrm{P}^{2k}) = +1$, but this is irrelevant for the proof.

It follows from Lemma 72.1 (1) that the three matrices to the right all define isometric forms. Considering the last matrix we obtain from Proposition 72.8 that the signature is zero. □

Lemma 76.9. *Let X be a compact orientable $(2n+1)$-dimensional topological manifold. We denote by $i\colon \partial X \to X$ the inclusion map. Then*

$$(1) \qquad \dim\big(\ker\{i_*\colon H_n(\partial X;\mathbb{R}) \to H_n(X;\mathbb{R})\}\big) \;=\; \tfrac{1}{2}\dim(H_n(\partial X;\mathbb{R}))$$

and

$$(2) \qquad \dim\big(\operatorname{im}\{i^*\colon H^n(X;\mathbb{R}) \to H^n(\partial X;\mathbb{R})\}\big) \;=\; \tfrac{1}{2}\dim(H^n(\partial X;\mathbb{R})).$$

The same statement also holds, regardless of whether or not X is orientable, if we replace $\mathbb{R}$-coefficients by $\mathbb{F}_2$-coefficients.

Remark. Given any homomorphism $\varphi\colon V \to W$ between finite-dimensional vector spaces the equality $\dim(\ker(\varphi)) + \dim(\operatorname{im}(\varphi)) = \dim(V)$ holds. Thus the first statement of the lemma can be reformulated as saying that

$$\dim\big(\ker\{i_*\colon H_n(\partial X;\mathbb{R}) \to H_n(X;\mathbb{R})\}\big) \;=\; \dim\big(\operatorname{im}\{i_*\colon H_n(\partial X;\mathbb{R}) \to H_n(X;\mathbb{R})\}\big).$$

This explains why the lemma is often referred to as the "half-live half-die lemma".

Examples.

(1) We consider the genus 3 handlebody X. In Figure 949 we show the usual basis $a_1, a_2, a_3, b_1, b_2, b_3$ for $H_1(\partial X;\mathbb{R})$. In this case the kernel of the inclusion induced map $H_1(\partial X;\mathbb{R}) \to H_1(X;\mathbb{R})$ is the three dimensional subspace generated by b_1, b_2 and b_3.

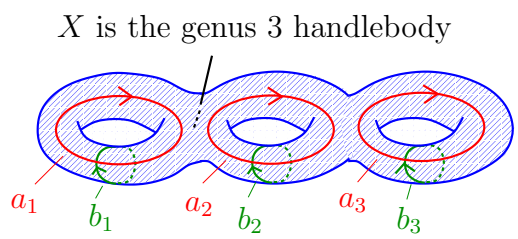

FIGURE 949.

(2) Let $K \subset S^3$ be a knot, we denote by X_K the knot exterior, see page 971. The boundary of X_K is a torus. By Lemma 70.7 (1) the meridian μ and the longitude λ form a basis for $H_1(X_K;\mathbb{R})$. have

$$\dim\big(\underbrace{\ker\{H_1(\partial X_K;\mathbb{R}) \to H_1(X_K;\mathbb{R})\}}_{=\,\mathbb{R}\cdot\lambda \text{ by Lemma 70.7 (1)}}\big) \;=1\;=\; \tfrac{1}{2}\cdot 2 \;=\; \tfrac{1}{2}\cdot\dim(H_1(\partial X_K;\mathbb{R})).$$

Proof of Lemma 76.9. Let X be a compact oriented $(2n+1)$-dimensional topological manifold. We denote by $i\colon \partial X \to X$ the inclusion map and we write $M = \partial X$. We first prove the first equality. Until further notice, we henceforth work with real coefficients for all (co-) homology groups. For space reasons we do not mention the real coefficients explicitly. We consider the long exact sequence in homology of the pair (X, M):

$$\to H_{n+1}M \to H_{n+1}X \to H_{n+1}(X,M) \xrightarrow{\partial} H_nM \xrightarrow{i_*} H_nX \to H_n(X,M) \to H_{n-1}M \to$$

The key observation is that this long exact sequence is "symmetric" around $H_n(M;\mathbb{R})$. More precisely, by the Poincaré Duality Theorem 61.3 (2)[1279] we have the following isomorphisms:

$$\to \overbrace{H_{n+1}M}^{\cong H_{n-1}M} \to \overbrace{H_{n+1}X}^{\cong H_n(X,M)} \to \overbrace{H_{n+1}(X,M)}^{\cong H_nX} \xrightarrow{\partial} H_nM \xrightarrow{i_*} H_nX \to H_n(X,M) \to H_{n-1}M \to$$

Therefore it suffices to prove the following purely algebraic claim.

Claim. If

$$0 \to A_k \xrightarrow{\beta_k} A_{k-1} \to \cdots \to A_2 \to A_1 \to B \xrightarrow{\gamma} A_1 \to A_2 \to \cdots \to A_{k-1} \xrightarrow{\alpha_k} A_k \to 0$$

is an exact sequence of finite-dimensional real vector spaces,[1280] then

$$\dim(\ker\{\gamma\colon B \to A_1\}) \;=\; \frac{1}{2}\cdot \dim B.$$

We prove the claim by induction on k. The case $k = 0$ is clear, since in this case $B = 0$. Now consider a symmetric sequence

$$0 \to A_k \xrightarrow{\beta_k} A_{k-1} \to \cdots \to A_2 \to A_1 \to B \xrightarrow{\gamma} A_1 \to A_2 \to \cdots \to A_{k-1} \xrightarrow{\alpha_k} A_k \to 0.$$

as above. It follows from Lemma 33.4 that the following sequence is also exact

$$0 \to A_{k-1}/\beta_k(A_k) \to \cdots \to A_2 \to A_1 \to B \xrightarrow{\gamma} A_1 \to A_2 \to \cdots \to \ker\{A_{k-1} \xrightarrow{\alpha_k} A_k\} \to 0.$$

But we have

$$\dim(A_{k-1}/\beta_k(A_k)) \;\underset{\substack{\uparrow \\ \text{since } \beta_k \text{ is injective}}}{=}\; \dim(A_{k-1}) - \dim(A_k) \;\underset{\substack{\uparrow \\ \text{since } \alpha_k \text{ is surjective}}}{=}\; \dim(\ker\{A_{k-1} \xrightarrow{\alpha_k} A_k\}).$$

So the new shorter sequence is also symmetric. So we can apply the induction hypothesis to get the desired equality. This concludes the proof of the claim and thus of the first equality of the lemma.

The proof of the second equality of the lemma is almost identical to the proof of the first equality. This concludes the proof of the lemma regarding $\mathbb{R}$-valued (co-) homology groups.

[1279] Even though it is irrelevant we would like to stress that the isomorphisms $H_k(M;\mathbb{R}) \cong H_{2n-k}(M;\mathbb{R})$, $H_k(X;\mathbb{R}) \cong H_{2n+1-k}(X,M;\mathbb{R})$ and $H_k(X,M;\mathbb{R}) \cong H_{2n+1-k}(X;\mathbb{R})$ are not natural.

[1280] Recall that by Proposition 45.2 we know that the real homology groups of X, M and (X,M) are finite-dimensional vector spaces.

Now let X be any compact $(2n+1)$-dimensional topological manifold, without any assumptions on orientability. In this case verbatim the same argument as above works, we just need to replace $\mathbb{R}$-coefficients by $\mathbb{F}_2$-coefficients and we need to replace the Poincaré Duality Theorem 61.3 (2) by the Poincaré Duality Theorem 61.3 (1). $\square$

Finally we can turn to the actual proof of Proposition 76.6.

Proof of Proposition 76.6. Let X be a compact oriented $(4k+1)$-dimensional topological manifold with $k \geq 1$. We write $M = \partial X$. We want to show that $\operatorname{sign}(M) = 0$. If $M = \varnothing$, then there is nothing to show. So suppose that $M \neq \varnothing$. We denote by g the form

$$\begin{array}{rcl} H^{2k}(M;\mathbb{R}) \times H^{2k}(M;\mathbb{R}) & \to & \mathbb{R} \\ (a,b) & \mapsto & \langle a \cup b, [M]\rangle_M. \end{array}$$

By Lemma 72.11 (1) we have $\operatorname{sign}(M) = \operatorname{sign}(g)$. We set

$$W \;:=\; \operatorname{im}\{i^*\colon H^{2k}(X;\mathbb{R}) \to H^{2k}(M;\mathbb{R})\}.$$

Note that by Proposition 71.5 we know that g is symmetric and non-singular. Therefore by Lemmas 76.8 and 76.9 (2) it suffices to show that $g|_W = 0$. Fortunately that is quite easy. Indeed, let $a, b \in H^{2k}(X;\mathbb{R})$. We have

$$\langle i^*(a) \cup i^*(b), [M]\rangle_M \;\underset{\substack{\uparrow \\ \text{Lemma 57.10}}}{=}\; \langle i^*(a \cup b), [M]\rangle_M \;\underset{\substack{\uparrow \\ \text{Lemma 50.6}}}{=}\; \langle a \cup b, i_*([M])\rangle_X \;\underset{\substack{\uparrow \\ \text{Corollary 46.27}}}{=}\; \langle a \cup b, 0\rangle_X \;=\; 0.$$

This concludes the proof that $g|_W \equiv 0$. $\square$

Before we continue with the determination of cobordism groups we prove the following elementary lemma.

Lemma 76.10. *For any $m, n \in \mathbb{N}_0$ the maps*

$$\begin{array}{rcl} \Omega_m \times \Omega_n & \to & \Omega_{m+n} \\ ([M],[N]) & \mapsto & [M \times N] \end{array} \qquad \textit{and} \qquad \begin{array}{rcl} \mathcal{N}_m \times \mathcal{N}_n & \to & \mathcal{N}_{m+n} \\ ([M],[N]) & \mapsto & [M \times N] \end{array}$$

are well-defined.

Proof $(*)$. We prove the statement regarding the Ω_k's, the proof for the $\mathcal{N}_k$'s is verbatim the same. So suppose that we have $[M] = [M'] \in \Omega_m$ and $[N] \in \Omega_n$. This means that there exists a compact oriented $(m+1)$-dimensional manifold W with $\partial W = M \sqcup (-M')$. But then we also have

$$\partial(W \times N) \;\underset{\substack{\uparrow \\ \text{by Proposition 3.42 (3) since } N \text{ closed}}}{=}\; \partial W \times N \;=\; (M \sqcup (-M')) \times N \;\underset{\substack{\uparrow \\ \text{since } (-M') \times N = -(M' \times N)}}{=}\; (M \times N) \sqcup -(M' \times N).$$

This shows that $[M \times N] = [M' \times N]$. The same argument shows that the map does not depend on the representative of $[N] \in \Omega_n$. $\square$

Definition. We define

$$\Omega_* := \bigoplus_{n\in\mathbb{N}_0} \Omega_n \quad \text{and} \quad \mathcal{N}_* := \bigoplus_{n\in\mathbb{N}_0} \mathcal{N}_n.$$

Together with the maps defined in Lemma 76.10 we can view these groups as commutative rings. We refer to Ω_* as the *cobordism ring* and we refer to $\mathcal{N}_*$ as the *unoriented cobordism ring*.

The following theorem summarizes some of the most important results on the cobordism ring Ω_*.

Theorem 76.11. (Thom)

(1) *The ring homomorphism*[1281] [12821283]

$$\mathbb{Q}[\{x_m\}_{m\in\mathbb{N}}] \to \Omega_* \otimes \mathbb{Q}$$

that is determined by

$$x_m \mapsto \mathbb{C}\mathrm{P}^{2m}$$

is an isomorphism.

(2) *For small n the isomorphism types of Ω_n are given by*

n	0	1	2	3	4	5	6	7	8	9	10	11
Ω_n	$\mathbb{Z}$	0	0	0	$\mathbb{Z}$	$\mathbb{Z}_2$	0	0	$\mathbb{Z}\oplus\mathbb{Z}$	$\mathbb{Z}_2\oplus\mathbb{Z}_2$	$\mathbb{Z}_2$	$\mathbb{Z}_2$

Hereby a generator for $\Omega_4 \cong \mathbb{Z}$ is given by $\mathbb{C}\mathrm{P}^2$ and a basis for $\Omega_8 \cong \mathbb{Z}^2$ is given by $\{\mathbb{C}\mathrm{P}^4, \mathbb{C}\mathrm{P}^2 \times \mathbb{C}\mathrm{P}^2\}$.[1284]

(3) *The group Ω_n is non-trivial for every $n \geq 8$.*

(4) *Every torsion element in Ω_n has order 2.*

Proof.

(1) The first statement was proved by René Thom [Tho2, Chapter IV], see also [Sto, p. 177].

(2) The calculation of the cobordism groups $\Omega_0, \dots, \Omega_3$ was given in Proposition 76.5, the values $\Omega_4, \dots, \Omega_7$ are given by René Thom in [Tho2, Theorem IV.13]. For $\Omega_8, \dots, \Omega_{11}$ we refer to [MiS, p. 203].

(3) This statement is proved in [Dol, p. 34].

(4) The last statement was proved by Terrence Wall [Wall4], see also [Sto, p. 182]. □

The following theorem, which is due to [Tho2, Theorem IV.12] and [Dol, p. 32], gives the complete calculation of the unoriented cobordism ring $\mathcal{N}_*$.

[1281] On the left-hand side $\mathbb{Q}[\{x_m\}_{m\in\mathbb{N}}]$ denotes the polynomial ring over $\mathbb{Q}$ with variables $\{x_m\}_{m\in\mathbb{N}}$.

[1282] Note that the tensor product of two commutative rings is again a commutative ring with the "naive multiplication". In particular the right-hand side $\Omega_* \otimes \mathbb{Q}$ is a commutative ring.

[1283] If we give each variable x_m the grading $4m$, and if we equip $\Omega_* \otimes \mathbb{Q}$ with the obvious grading, then this is an isomorphism of graded rings.

[1284] Note that in the ring homomorphism from (1) we have $x_1 \mapsto [\mathbb{C}\mathrm{P}^2]$ and $x_1^2 \mapsto [\mathbb{C}\mathrm{P}^2 \times \mathbb{C}\mathrm{P}^2]$ and also $x_2 \mapsto [\mathbb{C}\mathrm{P}^4]$.

Theorem 76.12. (Thom-Dold) *We let $I = \{n \in \mathbb{N} \,|\, n \neq 2^i - 1\} = \{2, 4, 5, 6, 8, 9, \dots\}$. There exists a ring isomorphism*

$$\mathbb{Z}_2[\{x_i\}_{i \in I}] \;\to\; \mathcal{N}_*$$

which is given by sending x_{2k} to $\mathbb{R}\mathrm{P}^k$ and given by sending x_i for odd i to an appropriate i-dimensional Dold manifold. Here a Dold manifold is a manifold of the form[1285]

$$P(m,n) \;:=\; (S^m \times \mathbb{C}\mathrm{P}^n)/(x,z) \sim (-x, \overline{z}) \qquad \text{for } x \in S^m \text{ and } z \in \mathbb{C}\mathrm{P}^n$$

for some $n, m \in \mathbb{N}_0$.

76.2. **The cobordism groups of rational homology spheres** $(*)$**.** First we recall the definition of an R-homology sphere from page 1711 and we introduce some, almost self-explanatory, related notions.

Definition. Let R be a commutative ring and let M be a compact orientable n-dimensional topological manifold.

(1) We say M is an *R-homology sphere*, if for each $k \in \mathbb{N}_0$ we have $H_k(M;R) \cong H_k(S^n;R)$.
(2) We say M is an *R-homology ball*, if for each $k \in \mathbb{N}_0$ we have $H_k(M;R) \cong H_k(\overline{B}^n;R)$.
(3) We say M is an *R-cylinder*, if for each $k \in \mathbb{N}_0$ we have $H_k(M;R) \cong H_k(S^{n-1} \times [0,1];R)$.

Instead of $\mathbb{Z}$-homology sphere we usually say *integral homology sphere* and instead of $\mathbb{Q}$-homology sphere we usually say *rational homology sphere*. The same convention holds also for balls and cylinders.

The following lemma will be proved in Exercise 76.4.

Lemma 76.13. *Let M be an n-dimensional topological manifold.*

(1) *If M is a rational homology n-ball, then ∂M is a rational homology $(n-1)$-sphere.*
(2) *Let M be a rational homology cylinder.*
   (a) *The boundary ∂M has precisely two components X and Y, each of which is a rational homology $(n-1)$-sphere.*
   (b) *The inclusion induced maps $H_*(X;\mathbb{Q}) \to H_*(M;\mathbb{Q})$ and $H_*(Y;\mathbb{Q}) \to H_*(M;\mathbb{Q})$ are isomorphisms.*
(3) *Let M be a rational homology ball. If $\varphi\colon \overline{B}^n \to M \setminus \partial M$ is an embedding, then $M \setminus \varphi(B^n)$ is a rational homology cylinder.*

The same statements also hold if we replace "rational" by "integral".

Now we can modify the cobordism groups Ω_n to obtain new and interesting groups.

[1285] It follows from Proposition 3.25 that each $P(m,n)$ is in fact a closed manifold.

Definition. Let $n \in \mathbb{N}$. We define

$$\Theta^n_{\mathbb{Q}} := \{\text{diffeomorphism classes of oriented } n\text{-dimensional rational homology spheres}\}/\sim_{\mathbb{Q}}$$

where we write $M \sim_{\mathbb{Q}} N$ if there exists an oriented cobordism W between M to N that is a rational homology cylinder. Similarly we define

$$\Theta^n_{\mathbb{Z}} := \{\text{diffeomorphism classes of oriented } n\text{-dimensional integral homology spheres}\}/\sim_{\mathbb{Z}}$$

where we write $M \sim_{\mathbb{Z}} N$ if there exists an oriented cobordism W between M and N that is an integral homology cylinder. Furthermore we define $\Theta^{\text{top},n}_{\mathbb{Q}}$ and $\Theta^{\text{top},n}_{\mathbb{Z}}$ the same way as above except that we "throw over board" all smooth structures. More precisely, we make the following two changes:

(1) We consider homeomorphism classes of oriented n-dimensional rational homology spheres.
(2) We no longer demand that the cobordism W is a manifold, we only assume that it is a topological manifold.

To simplify the discussion, and out of personal preference, henceforth we only consider the case $n = 3$ and we drop the decoration "3" from the notation. Recall that Theorem 28.24 says that in dimension *three* any topological manifold admits a smooth structure and two manifolds are homeomorphic if and only if they are diffeomorphic. Put differently, there is basically no difference between the study of topological 3-dimensional manifolds and the study of 3-dimensional manifolds. On the other hand, we saw in Theorem 72.27 that in dimension *four* there is a big difference between the theory of topological manifolds and the theory of manifolds. In particular the above notions of cobordisms might change depending on whether or not we consider topological 4-dimensional manifolds or 4-dimensional manifolds.

Proposition 76.14. *In all four cases the connected sum operation defines an abelian group structure where the neutral element is given by S^3 and where the inverse of a homology sphere Y is given by $-Y$.*

Example. Let Y be a 3-dimensional rational homology sphere. If Y is amphichiral, then we have the following equality in $\Theta_{\mathbb{Q}}$:

$$\begin{array}{ccccc} [Y]\#[Y] & \underset{\substack{\uparrow \\ \text{since } Y \text{ amphichiral}}}{=} & [Y]\#[-Y] & \underset{\substack{\uparrow \\ \text{Proposition 76.14}}}{=} & S^3 \in \Theta_{\mathbb{Q}} \end{array}$$

This implies that an amphichiral 3-dimensional rational sphere defines either the trivial element in $\Theta_{\mathbb{Q}}$ or an element of order 2.

Sketch of proof. In the following steps we verify all the statements that are implicit in the formulation of the proposition for $\Theta_{\mathbb{Q}}$.

(1) It follows from Proposition 39.15 that the connected sum of two rational homology spheres is again a rational homology sphere.

(2) We need to show that the connected sum operation descends to a well-defined operation on $\Theta_{\mathbb{Q}}$. Thus suppose that we are given oriented, rational homology spheres M and M' and also N and N' such that $M = M' \in \Theta_{\mathbb{Q}}$ and $N = N' \in \Theta_{\mathbb{Q}}$. We need to show that $M\#N = M'\#N' \in \Theta_{\mathbb{Q}}$. We pick compact oriented 4-dimensional manifolds X and Y with $\partial X = M \sqcup -M'$ and $\partial Y = N \sqcup -N'$ as in the definition of $\sim_{\mathbb{Q}}$.

By Proposition 65.27 we can pick an oriented proper connected 1-dimensional submanifold $[0,1] \cong \alpha \subset X$ which connects a point on M to a point on M'. Similarly we can pick a proper connected 1-dimensional submanifold $[0,1] \cong \beta \subset Y$ which connects a point on N to a point on N'. By the Tubular Neighborhood Theorem 10.19 we can thicken the submanifolds α and β to submanifolds $[0,1] \times \overline{B}^3 = \alpha \times \overline{B}^3$ and $[0,1] \times \overline{B}^3 = \beta \times \overline{B}^3$. We can and will pick the former map to be orientation-preserving and the latter orientation-reversing. We define

$$Z \ := \ \big((X \setminus (\alpha \times B^3)) \sqcup (Y \setminus (\beta \times B^3))\big)/\sim$$

where we identify a point on $\alpha \times S^2 = [0,1] \times S^2$ with the corresponding point on $\beta \times S^2 = [0,1] \times S^2$. After smoothing corners, see [Wall2, Proposition 2.6.2], we can view Z as a compact oriented manifold such that $\partial Z = (M\#N) \sqcup -(M'\#N')$. (This construction is illustrated in Figure 950.) Using that X and Y are rational homology cylinders one can fairly easily show that Z itself is also a rational homology cylinder.

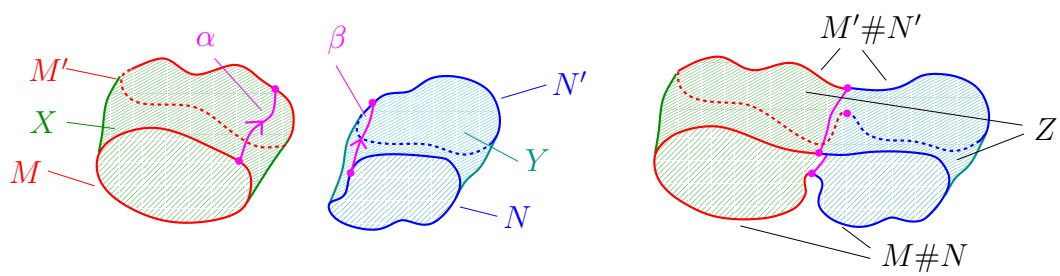

FIGURE 950.

(3) It follows from Lemma 10.30 that the connected sum operation is commutative and associative. Furthermore it follows from the discussion on page 355 that S^3 is the neutral element with respect to the connected sum operation.

(4) Let Y be a rational homology sphere. We have to show that $(Y\# - Y) \sim_{\mathbb{Q}} S^3$. We pick a closed 3-ball $\overline{B}^3$ in Y. We consider $W = ([0,1] \times Y) \setminus ([0,1] \times B^3)$. After smoothing corners we have $\partial W = Y\# - Y$. Finally we remove an open 4-ball from W and we obtain a 4-manifold Z with $\partial Z = (Y\# - Y) \sqcup S^3$. We leave it as an exercise to verify that Z is a rational homology cylinder. We illustrate this construction in Figure 951.

The proof that $\Theta_{\mathbb{Z}}$ forms a group is basically identical to the above proof. The proof that $\Theta_{\mathbb{Q}}^{\text{top}}$ and $\Theta_{\mathbb{Z}}^{\text{top}}$ form groups is in principle the same, except that we need to

replace the references dealing with manifolds by references that take care of topological manifolds. For example, we need to replace the Tubular Neighborhood Theorem 10.19 by the fact that compact 1-dimensional submanifolds of compact topological manifolds admit trivial tubular neighborhoods, see the discussion on page 1497.

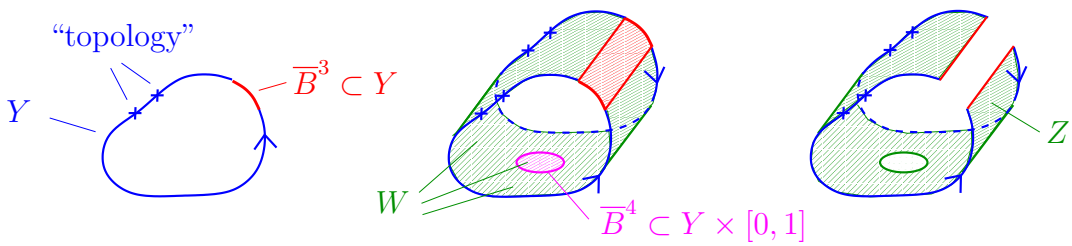

FIGURE 951.

□

The following lemma gives a characterization of manifolds representing the trivial element in the various groups that we just introduced.

Lemma 76.15. *Let Y be a 3-dimensional rational homology sphere. Then*

$$[Y] = 0 \in \Theta_{\mathbb{Q}} \quad \Longleftrightarrow \quad \begin{array}{l}\textit{there exists a 4-dimensional manifold } W \textit{ that} \\ \textit{is a rational homology ball } W \textit{ with } \partial W = Y.\end{array}$$

There are obvious analogues to this statement for the groups $\Theta_{\mathbb{Z}}$, $\Theta_{\mathbb{Q}}^{\text{top}}$ and $\Theta_{\mathbb{Z}}^{\text{top}}$.

Proof. Let Y be a 3-dimensional rational homology sphere.

"$\Rightarrow$" If Y represents the trivial element in $\Theta_{\mathbb{Q}}$, then by definition there exists a 4-dimensional rational homology cylinder Z with $\partial Z = Y \sqcup -S^3$. A straightforward argument, using Proposition 10.12, Lemma 76.13 and the Mayer–Vietoris Theorem for manifolds 33.10 shows that $W = Z \cup_{\partial Z = S^3} \overline{B}^4$ is a rational homology ball. Evidently we have $\partial W = Y$.

"$\Leftarrow$" Now suppose that there exists a 4-dimensional manifold W that is a rational homology ball W with $\partial W = Y$. We pick an embedding $\varphi\colon \overline{B}^4 \to W \setminus \partial W$. It follows from Lemma 76.13 (3) that $Z = Y \setminus \varphi(B^4)$ is a rational cylinder which then shows that $[Y] = [S^3] = 0 \in \Theta_{\mathbb{Q}}$. We refer to Figure 952 for an illustration. □

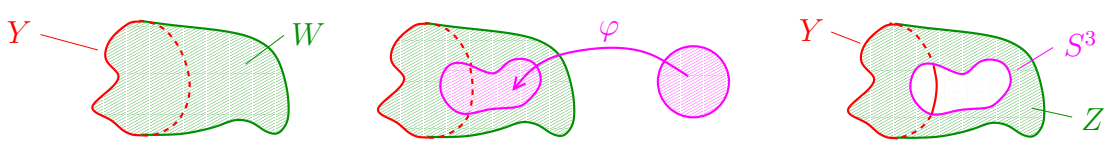

FIGURE 952.

We start out with the investigation of the group $\Theta_{\mathbb{Q}}^{\text{top}}$.

Proposition 76.16. *Let M be a 3-dimensional rational homology sphere. If $M = 0 \in \Theta^{\text{top}}_{\mathbb{Q}}$, then $|H_1(M;\mathbb{Z})|$ is a square.*

Proof. Let M be a 3-dimensional rational homology sphere which represents the trivial element in $\Theta^{\text{top}}_{\mathbb{Q}}$. By Lemma 76.15 there exists a 4-dimensional manifold W that is a rational homology ball W with $\partial W = M$. Thus the proposition follows from the following claim.

Claim. We have[1286]

$$|\ker\{H_1(M;\mathbb{Z}) \to H_1(W;\mathbb{Z})\}|^2 \;=\; |H_1(M;\mathbb{Z})|.$$

First we note that the fact that M is a rational homology sphere and that W is a rational homology ball implies, by the argument of Lemma 74.1, that the homology groups $H_1(M;\mathbb{Z})$, $H_2(M;\mathbb{Z})$ and also $H_1(W;\mathbb{Z})$, $H_2(W;\mathbb{Z})$ are finite.

We consider the long exact sequence in homology groups corresponding to the pair (W, M) with $\mathbb{Z}$-coefficients:

$$\begin{array}{l}
\text{isomorphic to } H^1(M;\mathbb{Z}) \cong \operatorname{Hom}(H_1(M;\mathbb{Z}),\mathbb{Z}) \text{ by the Poincaré Duality Theorem 61.1,}\\
\text{and Proposition 51.17, therefore zero since } H_1(M;\mathbb{Z}) \text{ is finite}\\
\qquad\qquad\downarrow\\
\ldots \to H_2(M;\mathbb{Z}) \to H_2(W;\mathbb{Z}) \to H_2(W,M;\mathbb{Z})\\
\quad \to H_1(M;\mathbb{Z}) \to H_1(W;\mathbb{Z}) \to H_1(W,M;\mathbb{Z}) \to H_0(M;\mathbb{Z}) \to H_0(W;\mathbb{Z}) \to 0.\\
\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\uparrow\\
\qquad\qquad\qquad\qquad\qquad\qquad\text{isomorphism by the discussion on page 747}
\end{array}$$

By Lemma 33.4 we now get the following exact sequence:

$$0 \to H_2(W;\mathbb{Z}) \to H_2(W,M;\mathbb{Z}) \to H_1(M;\mathbb{Z}) \to H_1(W;\mathbb{Z}) \to H_1(W,M;\mathbb{Z}) \to 0.$$

We consider the group on the left. We have

$$H_2(W,M;\mathbb{Z}) \underset{\substack{\uparrow\\ \text{Poincaré Duality}\\ \text{Theorem 61.1}}}{\cong} H^2(W;\mathbb{Z}) \underset{\substack{\uparrow\\ \text{Universal Coefficient}\\ \text{Theorem 51.13}}}{\cong} \overbrace{\operatorname{Hom}(H_2(W;\mathbb{Z}),\mathbb{Z})}^{=0 \text{ since } H_2(W;\mathbb{Z}) \text{ is finite}} \oplus \operatorname{Ext}(H_1(W;\mathbb{Z}),\mathbb{Z}) \underset{\substack{\uparrow\\ \text{by Lemma 51.5 (5)}\\ \text{since } H_1(W;\mathbb{Z}) \text{ is finite}}}{\cong} H_1(W;\mathbb{Z}).$$

Almost the same argument shows that $H_2(W;\mathbb{Z}) \cong H_1(W,M;\mathbb{Z})$. This shows that the above exact sequence is an exact sequence of finite abelian groups that is "symmetric" around $H_1(M;\mathbb{Z})$. Therefore it remains to prove the following claim.

Claim. If

$$0 \to A_k \to \ldots \to A_2 \to A_1 \to B \xrightarrow{\gamma} A_1 \to A_2 \to \ldots \to A_k \to 0$$

[1286]Put differently, we can say that $|\ker\{H_1(M;\mathbb{Z}) \to H_1(W;\mathbb{Z})\}| = \sqrt{|H_1(M;\mathbb{Z})|}$. With this formulation the statement of the claim is quite similar to the statement of Lemma 76.9. In fact we will see that the proof of the claim is a variation of the proof of Lemma 76.9.

is an exact sequence of finite abelian groups, then

$$|\ker\{\gamma\colon B \to A_1\}|^2 \;=\; |B|.$$

The claim is proved by induction on k, exactly the same way as we proved the claim on page 1768. We leave the details as an exercise to the reader. □

Corollary 76.17. *Let M and N be two 3-dimensional rational homology spheres. If we have $M = N \in \Theta^{\text{top}}_{\mathbb{Q}}$, then $|H_1(M;\mathbb{Z})| \cdot |H_1(N;\mathbb{Z})|$ is a square.*

Proof. Let M and N be 3-dimensional rational homology spheres with $[M] = [N] \in \Theta^{\text{top}}_{\mathbb{Q}}$. From Proposition 76.14 we obtain that $[M\#(-N)] = [M] - [N] = 0 \in \Theta^{\text{top}}_{\mathbb{Q}}$. Now Proposition 76.16 implies that $|H_1(M\#(-N);\mathbb{Z})|$ is a square. The corollary now follows from Proposition 39.15 which states that $H_1(M\#(-N);\mathbb{Z}) \cong H_1(M;\mathbb{Z}) \oplus H_1(N;\mathbb{Z})$. □

The following proposition shows that the groups $\Theta^{\text{top}}_{\mathbb{Q}}$ and $\Theta_{\mathbb{Q}}$ are very much non-trivial.

Proposition 76.18.

(1) *The groups $\Theta^{\text{top}}_{\mathbb{Q}}$ and $\Theta_{\mathbb{Q}}$ admit an epimorphism onto $\mathbb{Z}_2^\infty$.*
(2) *The groups $\Theta^{\text{top}}_{\mathbb{Q}}$ and $\Theta_{\mathbb{Q}}$ admit a subsummand isomorphic to $\mathbb{Z}_2^\infty$.*[1287]

Remark. It follows from [KK, Theorems 5.2 and 6.1] and a generalization of the arguments used in the proof of Proposition 76.18 (1) that the group $\Theta^{\text{top}}_{\mathbb{Q}}$ admits an epimorphism onto $\mathbb{Z}_2^\infty \oplus \mathbb{Z}_4^\infty \oplus \mathbb{Z}_4^\infty$.

The proof of Proposition 76.18 (2) relies on the following theorem from number theory. We refer to [IR, p. 251] for a proof.

Theorem 76.19. (Dirichlet's Theorem on Arithmetic Progressions) *For any coprime $a, n \in \mathbb{N}$ there exist infinitely many primes of the form $a + kn$ with $k \in \mathbb{N}$.*

Proof of Proposition 76.18.

(1) We have an obvious epimorphism $\Theta_{\mathbb{Q}} \to \Theta^{\text{top}}_{\mathbb{Q}}$, so it suffices to show that the group $\Theta^{\text{top}}_{\mathbb{Q}}$ admits an epimorphism onto $\mathbb{Z}_2^\infty$. For each prime p we consider the map

$$\begin{array}{rcl} \alpha_p\colon \Theta^{\text{top}}_{\mathbb{Q}} & \to & \mathbb{Z}_2 \\ M & \mapsto & \max\{n \in \mathbb{N}_0 \,|\, p^n \text{ divides } |H_1(M;\mathbb{Z})|\} \mod 2. \end{array}$$

It follows easily from Corollary 76.17, together with the uniqueness of the prime power decomposition of natural numbers and the fact that p is a prime, that this map is well-defined. Furthermore it follows from Proposition 39.15 that α_p is a group homomorphism.

[1287] Here we say that an abelian group G is a subsummand of an abelian group H if there exists an abelian group A such that $H \cong G \oplus A$.

It remains to show that the homomorphism

$$\begin{array}{rcl} \alpha\colon \Theta_{\mathbb{Q}}^{\mathrm{top}} & \to & \bigoplus\limits_{\text{prime } p} \mathbb{Z}_2 \\ M & \mapsto & \bigoplus\limits_{\text{prime } p} \alpha_p(M) \end{array}$$

is an epimorphism. But this follows immediately from considering lens spaces. More precisely, let p be a prime. By Corollary 38.6 we have $H_1(L(p,1);\mathbb{Z}) \cong \mathbb{Z}_p$, i.e. we have $\alpha_p(L(p,1)) = 1$ and $\alpha_q(L(p,1)) = 0$ for every prime $q \neq p$.

(2) By Dirichlet's Theorem 76.19 there exist infinitely many primes $p_i, i \in \mathbb{N}$ such that $p_i \equiv 1 \bmod 4$. By the calculation of the Legendre symbol, see e.g. [IR, p. 52], given any such prime p_i there exists an $a_i \in \{1, \dots, p_i - 1\}$ such that $a_i^2 \equiv -1 \bmod p_i$. It follows from Lemma 47.7 that the lens spaces $L(p_i, a_i)$ are amphichiral. It follows from the discussion on page 1772 and from (1) that we have well-defined homomorphisms

$$\begin{array}{rcccl} \mathbb{Z}_2^\infty & \to & \Omega_{\mathbb{Q}}^{\mathrm{top}} & \to & \mathbb{Z}_2^\infty \\ & & M & \mapsto & \sum\limits_i \alpha_{p_i}(M) \\ (x_1, x_2, \dots) & \mapsto & \#\limits_{\substack{i \text{ with} \\ x_i = 1}} L(p_i, a_i), & & \end{array}$$

furthermore we see easily that the composition of these two maps is the identity. This shows that the right-hand map splits. Therefore it follows from Lemma 33.2 that $\mathbb{Z}_2^\infty$ is in fact a subsummand of $\Omega_{\mathbb{Q}}^{\mathrm{top}}$. Exactly the same argument applies to $\Omega_{\mathbb{Q}}$. □

By definition any 3-dimensional integral homology sphere lies in the kernel of the epimorphism $\Omega_{\mathbb{Q}}^{\mathrm{top}} \to \mathbb{Z}_2^\infty$ that we had just constructed in the proof of Proposition 76.18.

In fact it was proved by Michael Freedman [Fre, Theorem 1.4'] in 1981 that every integral homology 3-dimensional sphere bounds a simply connected integral homology 4-dimensional ball.[1288] This result implies in particular the following theorem.

Theorem 76.20. *The group $\Theta_{\mathbb{Z}}^{\mathrm{top}}$ is trivial.*

It turns out that the situation is quite different if we consider the group $\Theta_{\mathbb{Z}}$ instead of the group $\Theta_{\mathbb{Z}}^{\mathrm{top}}$. In fact we have the following proposition.

Proposition 76.21. *Given a 3-dimensional integral homology sphere M we define*

$$\mu(M) \ := \ \frac{1}{8}\operatorname{sign}(W) \mod 2$$

where W is a compact oriented 4-dimensional manifold with $\partial W = M$, with $H_1(W;\mathbb{Z}) = 0$ and with even intersection form. Then the following statements hold:

[1288] The methods that Michael Freedman used in the proof of this result are closely related to the methods in Freedman's proof of the topological Poincaré Conjecture in dimension 4, see Theorem 28.23.

(1) *The number $\mu(M)$ is well-defined and it lies in $\mathbb{Z}_2$.*
(2) *The map*

$$\begin{array}{rcl} \mu\colon \Theta_{\mathbb{Z}} & \to & \mathbb{Z}_2 \\ M & \mapsto & \mu(M), \end{array}$$

is a well-defined homomorphism, it is called the Rokhlin homomorphism.
(3) *The Rokhlin homomorphism $\mu\colon \Theta_{\mathbb{Z}} \to \mathbb{Z}_2$ is an epimorphism, in particular $\Theta_{\mathbb{Z}}$ is non-trivial.*

Remark. The Rokhlin homomorphism is the starting point for many developments in the study of 3-dimensional and 4-dimensional manifolds. For example Andrew Casson showed in the mid 1980s that there exists a map

$$\lambda\colon \left\{ \begin{array}{c} \text{diffeomorphism classes of oriented} \\ \text{3-dimensional integral homology spheres} \end{array} \right\} \to \mathbb{Z}$$

that has the following properties:

(1) It is additive in the sense that for two 3-dimensional integral homology spheres M and N we have $\lambda(M\#N) = \lambda(M) + \lambda(N)$.
(2) For every 3-dimensional integral homology sphere we have $\mu(M) = \lambda(M) \bmod 2$.

More information on the Casson invariant λ can be found in [Sav2, AM].

Sketch of the proof of Proposition 76.21.

(1) Let M be a 3-dimensional integral homology sphere. The following arguments show that $\mu(M)$ is indeed defined, that it is well-defined and that it lies in $\mathbb{Z}_2$.
   (a) By [Kap], see also [Sav2, p. 38], there exists a compact oriented 4-dimensional manifold with $\partial W = M$, with $H_1(W;\mathbb{Z}) = 0$ and with even intersection form.[1289]
   (b) Since ∂W is an integral homology sphere and since $H_1(W;\mathbb{Z}) = 0$ one can easily adjust the argument of the proof of Proposition 71.5 to show that the intersection form Q_W is non-singular.
   (c) Since the intersection form Q_W is even and non-singular it follows from Proposition 72.18 that $\operatorname{sign}(W) = \operatorname{sign}(Q_W)$ is divisible by 8, i.e. $\frac{1}{8}\operatorname{sign}(W) \in \mathbb{Z}$.
   (d) Now suppose that we have another compact oriented 4-dimensional manifold W' with $H_1(W';\mathbb{Z}) = 0$, with $\partial W' = M$ and with even intersection form. We need to show that $\operatorname{sign}(W) \equiv \operatorname{sign}(W')$.
   We consider the closed oriented 4-dimensional manifold[1290]

$$X \;:=\; W \cup_{\partial W = \partial W'} (-W')$$

   that we obtain from gluing W and $-W'$ along the common boundary given by M. Since $H_1(W;\mathbb{Z}) = H_1(W';\mathbb{Z}) = 0$ and since M is an integral homology sphere one can easily adapt the proof of Proposition 39.15 to show that $H_1(X;\mathbb{Z}) = 0$ and

[1289] In fact in [Kap] it is shown that W can be chosen to be simply connected, which implies by the Hurewicz Theorem 38.5 that the first homology group vanishes.

[1290] Here we use Proposition 10.12 to conclude that X is indeed a closed oriented 4-dimensional manifold.

one can modify the proof of Proposition 71.11 to conclude that $Q_X \cong Q_W \oplus -Q_{W'}$, in particular Q_X is even. Now we can apply Rokhlin's Theorem 72.24 to conclude that $\operatorname{sign}(X) \equiv 0 \bmod 16$. But by the isomorphism $Q_X \cong Q_W \oplus -Q_{W'}$ this implies that $\operatorname{sign}(W) - \operatorname{sign}(W') \equiv 0 \bmod 16$, which gives us the desired result.

(2) Now we have to show that μ defines a well-defined homomorphism $\Theta_{\mathbb{Z}} \to \mathbb{Z}_2$.

(a) First we show that μ is additive. So let M and N be 3-dimensional integral homology spheres. We pick 4-dimensional manifolds X and Y with $\partial X = M$ and $\partial Y = N$ and the extra properties that are required in the definition of $\mu(M)$ and $\mu(N)$. We denote by $Z = X \#_b Y$ the boundary connected sum that we introduced on page 1690. It follows from Proposition 73.1 that Z as a 4-dimensional manifold with $\partial Z = M \# N$ and such that $H_1(Z;\mathbb{Z}) = 0$. Furthermore a modest modification of the proof of Proposition 71.11 shows that $Q_Z \cong Q_X \oplus Q_Y$. This means that we can use Z to calculate $\mu(M \# N)$ and we obtain that

$$\mu(M \# N) \;=\; \tfrac{1}{8}\operatorname{sign}(Z) \;=\; \tfrac{1}{8}\operatorname{sign}(X) + \tfrac{1}{8}\operatorname{sign}(Y) \;=\; \mu(M) + \mu(N).$$

We refer to Figure 953 for an illustration of the argument.

(b) It follows easily from the definitions that for any integral homology sphere M we have $\mu(-M) = \mu(M)$.

(c) It remains to show that μ is well-defined. By (a) and (b) it suffices to show that if M represents the trivial element in $\Theta_{\mathbb{Z}}$, then $\mu(M) = 0$. Let such M be given. It follows from Lemma 76.15 that M is the boundary of an integral homology sphere W. Since $H_2(W;\mathbb{Z}) = 0$ the intersection form is zero, in particular even. Since $H_1(W;\mathbb{Z}) = 0$ we can use W to determine $\mu(M)$ and we get immediately that $\mu(M) = \frac{1}{8}\operatorname{sign}(W) = 0$.

(3) Finally we want to show that there exists a 3-dimensional integral homology sphere M with $\mu(M) = 1$. Let M be the Poincaré homology sphere that we introduced on page 993. In [Sav2, p. 38] it is shown that M is the boundary of a compact oriented simply connected 4-dimensional manifold W with intersection form isometric to $-E_8$. As we saw on page 1671, the form $-E_8$ of rank 8 is negative definite, hence its signature is -8. By the definition of the Rokhlin homomorphism this implies that $\mu(M) = 1$. □

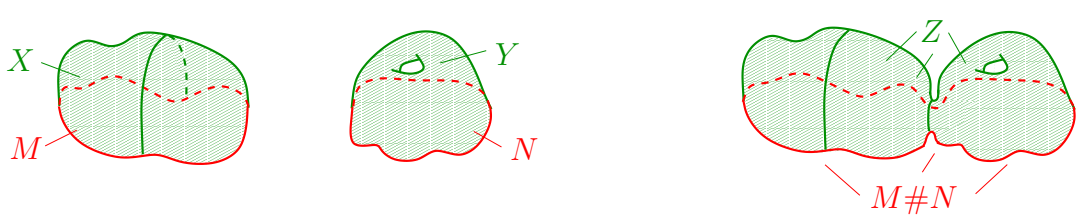

FIGURE 953.

In fact a much stronger statement than Proposition 76.21 holds. Building on the techniques developed by Simon Donaldson [Don, Don2] Mikio Furuta [Fu] proved in 1990 the following theorem.

Theorem 76.22. *The group $\Theta_{\mathbb{Z}}$ contains a subgroup that is isomorphic to $\mathbb{Z}^\infty$.*

Among the four groups that we have studied in this section, the trivial group $\Theta_{\mathbb{Z}}^{\text{top}}$ is the only one which has been fully calculated. At the moment we still know depressingly little about the remaining three groups. For example the following three questions are still open.

Question 76.23.

(1) *Is the group $\Theta_{\mathbb{Q}}^{\text{top}}$ isomorphic to $\mathbb{Z}_2^\infty \oplus \mathbb{Z}_4^\infty \oplus \mathbb{Z}_8^\infty$?*
(2) *Does the group $\Theta_{\mathbb{Q}}^{\text{top}}$ contain elements of infinite order?*
(3) *Let $n \neq 1, 2$ be a natural number. Does there exist an element in the groups $\Theta_{\mathbb{Z}}$ or $\Theta_{\mathbb{Q}}$ of order n?*

Exercises for Chapter 76.

Exercise 76.1. We consider the Klein bottle

$$K \;=\; (S^1 \times [0,1])/\sim \quad \text{where } (z,0) \;\sim\; (\overline{z},1) \text{ for all } z \in S^1.$$

On page 435 we showed that K is diffeomorphic to $\mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2$. Thus it follows from Lemma 76.4 that $[K] = [\mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2] = [\mathbb{R}\mathrm{P}^2 \sqcup \mathbb{R}\mathrm{P}^2] = 2 \cdot [\mathbb{R}\mathrm{P}^2] = 0 \in \mathcal{N}_2$. Write down an explicit compact 3-dimensional manifold M with $\partial M = K$.

Exercise 76.2. Provide a proof for Lemma 76.8 that does not uses bases.[1291] Let us elaborate. Let (V, g) be a non-singular symmetric form over $\mathbb{R}$ and suppose that there exists a subspace W of V with $g|_W = 0$ and with $\dim(W) = \frac{1}{2}\dim(V)$. Show that given any subspace A of V such that $g|_A$ is positive (respectively negative) definite there exists a subspace B of V such that $g|_B$ is negative (respectively positive) definite and which satisfies $\dim(A) = \dim(B)$. A proof of this statement implies that $\operatorname{sign}(g) = 0$.

Exercise 76.3. Let $L = L_1 \cup \cdots \cup L_m$ be an m-component link in S^3. We denote by X_L its exterior which is defined the same way as we defined the exterior of a knot on page 971. The boundary of X_L consists of m tori $T_1, \dots, T_m$. Let $k \in \{1, \dots, m\}$. We denote by $i\colon T_k \to X_L$ the inclusion map.

(a) Show that $\dim(\operatorname{im}\{i_*\colon H_1(T_k;\mathbb{R}) \to H_1(X_L;\mathbb{R})\}) \geq 1$.
(b) Do we necessarily have $\dim(\operatorname{im}\{i_*\colon H_1(T_k;\mathbb{R}) \to H_1(X_L;\mathbb{R})\}) = 1$?

Exercise 76.4. Provide a proof for Lemma 76.13.

[1291] As the reader surely knows, introducing bases is morally wrong and should be avoided at all costs.

Exercise 76.5. Let M be an oriented 3-dimensional rational homology sphere. We denote by $\lambda_M\colon H_1(M;\mathbb{Z})\times H_1(M;\mathbb{Z})\to\mathbb{Q}/\mathbb{Z}$ the linking pairing that we introduced on page 1720. Let W be a 4-dimensional rational homology ball with $\partial W = M$. We denote by $i\colon M\to W$ the inclusion and we write $K := \ker\{i_*\colon H_1(M;\mathbb{Z})\to H_1(W;\mathbb{Z})\}$. Show that λ_M vanishes on $K\times K$.

Exercise 76.6.

(a) Let M be an orientable n-dimensional manifold with $n\geq 4$ and let $C\cong S^1$ be a closed connected one-dimensional submanifold. By the Tubular Neighborhood Theorem 10.19 there exists a tubular neighborhood $\overline{B}^{n-1}\times C = \overline{B}^{n-1}\times S^1$. By Propositions 10.2 and 10.12

$$W \;:=\; (M\setminus(C\times B^{n-1}))\cup_{C\times S^{n-2}=S^1\times S^{n-2}}(\overline{B}^2\times S^{n-2})$$

is an n-dimensional manifold. Compute $\pi_1(W)$ in terms of $\pi_1(M)$ and C. (This approach to modifying the manifold M is sometimes called a *surgery*.)

(b) Let $n\geq 3$ and let X be a closed n-dimensional manifold. Suppose that there exists a compact orientable $(n+1)$-dimensional M with $\partial M = X$. Show that there exists also a compact orientable *simply connected* $(n+1)$-dimensional manifold N with $\partial N = X$.

(c) Does (b) also hold for $n=2$?

Exercise 76.7. Let Y_1 and Y_2 be two compact 3-dimensional manifolds with one torus boundary component. Let $Y = Y_1\cup Y_2$ be the result of gluing Y_1 and Y_2 along the boundary. Show that if $b_1(Y)=0$, then $b_1(Y_1)=1$ and $b_1(Y_2)=1$.

Exercise 76.8. Does there exist a compact simply-connected 3-dimensional manifold M such that ∂M has at least one boundary component that is a torus?

77. Vector bundles and Pontryagin classes

In this chapter we introduce vector bundles and their Pontryagin classes. This is only intended as a quick introduction. Therefore on many occasions we will only provide sketches of proofs or we will refer to the literature for the proofs. The best reference for this chapter is the classic book by Milnor-Stasheff [MiS] on characteristic classes. Other references are [Mi12, Hat2] and [Hus].

77.1. **Vector bundles.** In this section we introduce vector bundles and we give several constructions and examples. The definition of a vector bundle is fairly similar to the definition of a smooth $\overline{B}^m$-bundle that we gave on page 1492 and the definition of a linear $\overline{B}^m$-bundle that we gave on page 1493.

Loosely speaking, a vector bundle over a topological space X consists of a vector space for each $x \in X$, where the "vector spaces vary continuously with x". The following definition makes this idea precise.

Definition. An *n-dimensional vector bundle* over a topological space X is a topological space E together with a map $p\colon E \to X$ and a real vector space structure on each $p^{-1}(x)$, $x \in X$ such that for each $x \in X$ there exists an open neighborhood U of x and a homeomorphism $\varphi\colon p^{-1}(U) \to U \times \mathbb{R}^n$ such that the following two conditions are satisfied:

(1) the following diagram commutes

$$\begin{tikzcd} p^{-1}(U) \arrow[rr, "\varphi"] \arrow[dr, "p"'] & & U \times \mathbb{R}^n \arrow[dl, "(y,v)\mapsto y"] \\ & U & \end{tikzcd}$$

(2) for each $y \in U$ the map $\varphi\colon p^{-1}(y) \to \{y\} \times \mathbb{R}^n = \mathbb{R}^n$ is an isomorphism of vector spaces.

(The definition is illustrated in Figure 954.) A 1-dimensional vector bundle is often called a *line bundle*. We refer to the topological space E as the *total space* of the vector bundle and we refer to X as the *base space* of the vector bundle. Furthermore we refer to the map $p\colon E \to X$ as the *projection*.

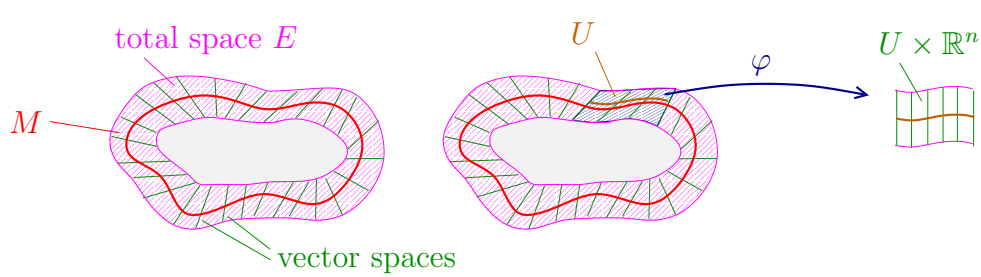

Figure 954.

Examples. In each of the following examples it is fairly elementary to verify that these are indeed vector bundles. For the sake of brevity[1292] we do not give all the details.

(1) For each topological space X the product $X \times \mathbb{R}^n$ together with the projection map $p\colon X \times \mathbb{R}^n \to X$ is an n-dimensional vector bundle over X. We refer to this vector bundle as the *trivial n-dimensional vector bundle over X*.

(2) Let M be an m-dimensional submanifold of $\mathbb{R}^k$.

(a) The map[1293]

$$\begin{array}{rcl} TM := \{(x,v) \in M \times \mathbb{R}^k \,|\, x \in M \text{ and } v \in V_xM\} & \to & M \\ (x,v) & \mapsto & x \end{array}$$

is an m-dimensional vector bundle over M. We refer to it as the *tangent bundle* of the submanifold M.

(b) The map

$$\begin{array}{rcl} NM := \{(x,v) \in M \times \mathbb{R}^k \,|\, x \in M \text{ and } v \in \mathbb{R}^k \text{ with } v \perp V_xM\} & \to & M \\ (x,v) & \mapsto & x \end{array}$$

is a $(k-m)$-dimensional vector bundle over M. We call it the *normal bundle* of M in $\mathbb{R}^k$.

The definition of the tangent bundle and the normal bundle are illustrated in Figure 955

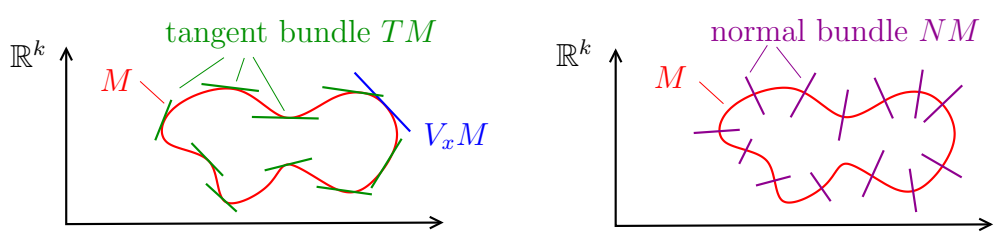

FIGURE 955.

(3) Recall that given $n \in \mathbb{N}_0$ we defined on page 104 the real projective space to be

$$\mathbb{R}\mathrm{P}^n \;:=\; (\mathbb{R}^{n+1} \setminus \{0\})/\sim$$

where $\sim$ denotes the equivalence relation on $\mathbb{R}^{n+1} \setminus \{0\}$ given by multiplication by an element in $\mathbb{R} \setminus \{0\}$. The map

$$\begin{array}{rcl} X = \{([v], \lambda v) \in \mathbb{R}\mathrm{P}^n \times \mathbb{R}^{n+1} \,|\, [v] \in \mathbb{R}\mathrm{P}^n, \lambda \in \mathbb{R}\} & \to & \mathbb{R}\mathrm{P}^n \\ ([v], w) & \mapsto & [v] \end{array}$$

defines a one-dimensional vector bundle over $\mathbb{R}\mathrm{P}^n$. We refer to it as the *tautological line bundle* over $\mathbb{R}\mathrm{P}^n$.

[1292] No snickering please.

[1293] We refer to page 196 for the definition of the "visual tangent spaces" $V_xM \subset \mathbb{R}^k$ of a submanifold $M \subset \mathbb{R}^k$.

(4) The real projective space $\mathbb{R}\mathrm{P}^n$ admits an obvious bijection with the set of all 1-dimensional subspaces of $\mathbb{R}^{n+1}$. This observation leads us to a generalization of the previous example. Given natural numbers $n, k \in \mathbb{N}$ we denote by $G(n,k)$ the set of all n-dimensional subspaces of $\mathbb{R}^{n+k}$. We have a surjection[1294]

$$\begin{array}{rcl} \overbrace{\left\{ \begin{array}{c} \text{all } k\text{-tuples } (v_1,\dots,v_k) \text{ of vectors in } \mathbb{R}^{n+k} \\ \text{that are linearly independent} \end{array} \right\}}^{\text{subset of } \mathbb{R}^{n(n+k)}} & \to & G(n,k) \\ (v_1,\dots,v_n) & \mapsto & \begin{array}{c} \text{subspace of } \mathbb{R}^{n+k} \\ \text{spanned by } v_1,\dots,v_n. \end{array} \end{array}$$

We equip $G(n,k)$ with the quotient topology. We refer to $G(n,k)$ as a *Grassmannian.*[1295][1296] With some modest effort one can show that

$$\begin{array}{rcl} F := \overbrace{\{(V,w) \mid [V] \in G(n,k) \text{ and } w \in V\}}^{\subset G(n,k)\times\mathbb{R}^n} & \to & G(n,k) \\ (V,w) & \mapsto & V \end{array}$$

is in fact an n-dimensional vector bundle. We point out that the obvious inclusions $\mathbb{R}^{n+k} \to \mathbb{R}^{n+k} \times \{0\} \subset \mathbb{R}^{n+k+1}$ induce inclusion maps $G(n,k) \to G(n,k+1)$ and we refer to the direct limit as an *infinite Grassmannian* $G(n)$. The n-dimensional vector bundles over $G(n,k)$ give rise to an n-dimensional vector bundle over $G(n)$. We refer to this vector bundle as the *tautological vector bundle* over the Grassmannian.

Before we introduce more examples we give the following, basically self-evident definition.

Definition. We say that two vector bundles $p\colon E \to X$ and $q\colon F \to X$ over a topological space X are *isomorphic* if there exists a homeomorphism $\varphi\colon E \to F$ such that for each $x \in X$ the map φ restricts to an isomorphism $p^{-1}(x) \to q^{-1}(x)$ of vector spaces.

We continue with a few more examples of vector bundles.

Examples.

(1) The map

$$\begin{array}{rcl} ([0,1]\times\mathbb{R})/(0,v)\sim(1,-v) & \to & S^1 \\ [(t,v)] & \mapsto & e^{2\pi i t} \end{array}$$

is a line bundle over S^1. The discussion on page 118 shows that the total space is homeomorphic to the open Möbius band. Therefore we refer to this bundle as the *Möbius bundle*. This bundle, and a bundle that is isomorphic to it, are illustrated in Figure 956.

[1294]The left-hand side is in fact an open subset of $\mathbb{R}^{n(n+k)}$. Why is that?

[1295]These objects are named after the German mathematician Hermann Grassmann (1809-1877).

[1296]It is shown in [MiS, p. 56] and [Hat2, p. 28 and 34] that one can equip $G(n,k)$ with a smooth atlas such that $G(n,k)$ becomes a closed nk-dimensional manifold. We will not make use of this fact.

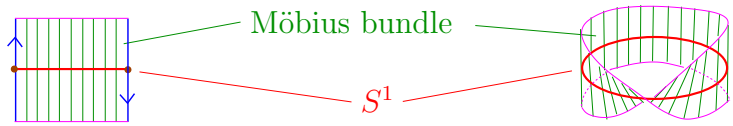

FIGURE 956.

(2) Let M be an n-dimensional manifold. We consider the map

$$\begin{array}{rcl} p\colon TM := \{(x,v)\,|\,x \in M \text{ and } v \in T_xM\} & \to & M \\ (x,v) & \mapsto & x. \end{array}$$

We would like to show that $p\colon TM \to M$ is an n-dimensional vector bundle. For each $x \in M$ the preimage $p^{-1}(x) = \{x\} \times T_xM$ admits an obvious vector space structure. Our next goal is to equip TM with a reasonable topology. For this we note that any chart $\Phi\colon U \to V$ for M induces a bijection

$$\begin{array}{rcl} \widetilde{\Phi}\colon p^{-1}(U) & \to & V \times \mathbb{R}^n \\ (x,v) & \mapsto & (\Phi(x), \underbrace{D\Phi_x(v)}_{\in T_{\Phi(x)}V = \mathbb{R}^n}). \end{array}$$

We say that a subset $W \subset TM$ is open if for every chart $\Phi\colon U \to V$ for M the image $\widetilde{\Phi}(W) \subset V \times \mathbb{R}^n$ is open. With this definition it is now reasonably easy to show that $p\colon TM \to M$ is an n-dimensional vector bundle over M. We refer to it as the *tangent bundle of* M.[1297]

If M is an n-dimensional submanifold of $\mathbb{R}^k$, then using the usual isomorphism $V_PM \cong T_PM$ from Proposition 3.32 one can show fairly easily that the two tangent bundles that we defined above are isomorphic. In practice we will not distinguish between these two notions.

(3) Let M be a connected manifold, let $x_0 \in M$ be a point and furthermore let $\alpha\colon \pi_1(M,x_0) \to \mathrm{GL}(n,\mathbb{R})$ be a representation. We denote by $p\colon \widetilde{M} \to M$ the universal covering. The group $\pi_1(M,x_0)$ acts on $\widetilde{M}$ via the action provided by Proposition 20.13. Furthermore $\pi_1(M,x_0)$ acts on $\widetilde{M} \times \mathbb{R}^n$ via $g \cdot (x,v) := (g \cdot x, \alpha(g) \cdot v)$. One can easily verify that the map

$$\begin{array}{rcl} (\widetilde{M} \times \mathbb{R}^n)/\pi_1(M,x_0) & \to & M \\ [(x,v)] & \mapsto & p(x) \end{array}$$

is an n-dimensional vector bundle over M. We refer to it as the *vector bundle defined by* α. One can show fairly easily that the bundle over S^1 corresponding to the representation $\pi_1(S^1,1) \to \mathrm{GL}(1,\mathbb{R})$ given by sending the standard generator of $\pi_1(S^1,1)$ to (-1) is isomorphic to the Möbius bundle.

[1297] It does not take too much effort to show that the total space TM of the tangent bundle is in fact a $2n$-dimensional manifold. We will not make use of this neat fact.

We throw in a few more definitions.

Definition.

(1) We say that an n-dimensional vector bundle $E \to X$ is *trivial*, if it is isomorphic to the trivial n-dimensional vector bundle $X \times \mathbb{R}^n \to X$.
(2) We say that a manifold M is *parallelizable* if its tangent bundle TM is trivial.
(3) A *section* of a vector bundle $p\colon E \to X$ is a continuous map $s\colon X \to E$ such that $p \circ s = \mathrm{id}_X$. We say a section is *non-vanishing* if $s(x) \neq 0$ for all $x \in X$.

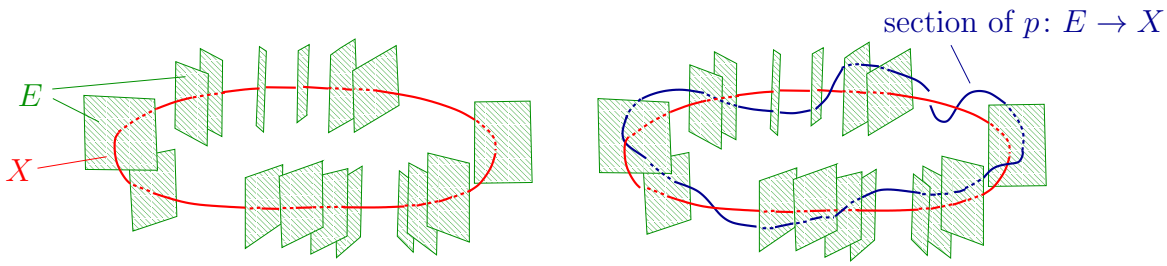

FIGURE 957.

Examples.

(1) Given a vector bundle $p\colon E \to X$ a section $s\colon X \to E$ is given by sending each $y \in E$ to the zero-element of the vector space $p^{-1}(y)$.[1298] This section is usually called the *zero-section* of p.
(2) Let M be a manifold. A *section* of the tangent bundle is usually called a *vector field* on M. If M is a submanifold of $\mathbb{R}^n$, then this is precisely the notion that we introduced on page 824.

Lemma 77.1.

(1) *Let $p\colon E \to X$ be an n-dimensional vector bundle. Then the following two statements are equivalent:*
   (a) *The vector bundle is trivial.*
   (b) *There exist n sections $s_1, \dots, s_n$ such that for every point $x \in X$ the vectors $s_1(x), \dots, s_n(x) \in p^{-1}(x)$ form a basis of the vector space $p^{-1}(x)$.*
(2) *A line bundle is trivial if and only if it admits a non-vanishing section.*
(3) *If M is an orientable 2-dimensional manifold, then its tangent bundle is trivial if and only if it admits a non-vanishing vector field.*

Sketch of proof.

[1298]It is a good exercise in practicing the definitions to convince oneself that this map $s\colon X \to E$ is indeed continuous.

(1) Let $p\colon E \to X$ be an n-dimensional vector bundle. If there exists an isomorphism $\varphi\colon X \times \mathbb{R}^n \to E$ of vector bundles, then the maps $s_i\colon x \mapsto \varphi(x, e_i)$, $i = 1, \dots, n$, define sections such that for each $x \in X$ the vectors $s_1(x), \dots, s_n(x) \in p^{-1}(x)$ form a basis of $p^{-1}(x)$. Conversely, if we are given such sections, then the map

$$\begin{array}{rcl} X \times \mathbb{R}^n & \to & E \\ (x, (\lambda_1, \dots, \lambda_n)) & \mapsto & \sum\limits_{i=1}^{n} s_i(x) \cdot \lambda_i \end{array}$$

is easily seen to be an isomorphism.

(2) This statement is an immediate consequence of (1).

(3) Let M be an orientable 2-dimensional manifold. By (1) we only have to show the following statement: if M admits a non-vanishing vector field v, then the tangent bundle is trivial. So suppose that v is a non-vanishing vector field on M. We pick an orientation for M. By [Le3, Proposition 13.3] the manifold M admits a Riemannian structure g.[1299] Since M is 2-dimensional and oriented we can now define

$$\begin{array}{rcl} w\colon M & \to & TM \\ x & \mapsto & \begin{array}{l} \text{unique vector } w(x) \in T_xM \text{ that has the following three properties:} \\ \text{(a)} \quad g(v(x), w(x)) = 0, \text{ i.e. } v(x) \text{ and } w(x) \text{ are orthogonal,} \\ \text{(b)} \quad g(w(x), w(x)) = 1, \text{ i.e. } w(x) \text{ has length one,} \\ \text{(c)} \quad v(x) \text{ and } w(x) \text{ form a positive basis for } T_xM \end{array} \end{array}$$

(We refer to Figure 958 for an illustration of the definition of $w(x)$.) It is fairly easy to see that this is a section of the tangent bundle. It has the property that for each $x \in M$ the vectors $v(x)$ and $w(x)$ form a basis for T_xM. Thus it follows from (1) that TM is a trivial bundle. □

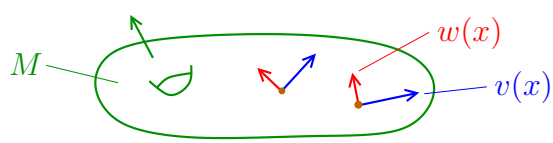

FIGURE 958. Illustration for the proof of Lemma 77.1.

Examples.

(1) By Lemma 77.1 (2) the normal bundle of $S^n \subset \mathbb{R}^{n+1}$ is trivial since it admits the non-vanishing section $P \mapsto (P, P)$. We illustrate this statement for $n = 1$ in Figure 959.

[1299] We refer to page 586 for the definition of a Riemannian structure.

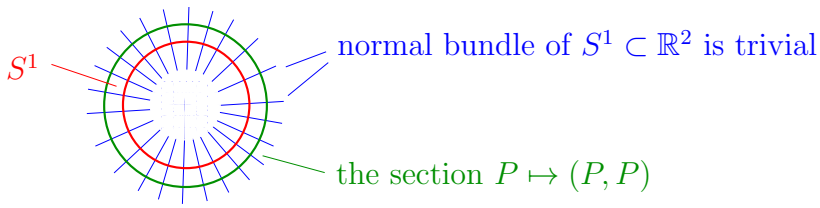

FIGURE 959.

(2) We can easily generalize the previous example. More precisely, let $n \in \mathbb{N}$ and let M be a closed oriented submanifold of $\mathbb{R}^n$ of codimension one. The map

$$\begin{array}{rcl} v\colon M & \to & NM \\ P & \mapsto & \begin{array}{c}\text{the unique vector } v(P) \in \mathbb{R}^n \text{ of length one that is normal to } V_PM \\ \text{and which, followed by a positive basis for } V_PM, \\ \text{forms a positive basis for } \mathbb{R}^n\end{array} \end{array}$$

is easily seen to be a section of the normal bundle. Since the normal bundle is one-dimensional we obtain from Lemma 77.1 (2) that the normal bundle of $M \subset \mathbb{R}^n$ is trivial. We refer to Figure 960 for an illustration.

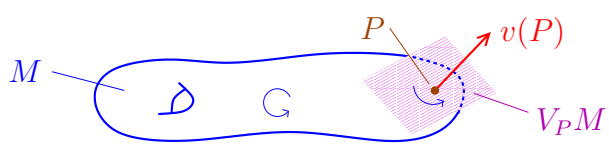

FIGURE 960.

(3) In Exercise 77.5 we will show that the Möbius bundle does not admit a non-vanishing section. It follows from Lemma 77.1 (2) that the Möbius bundle is non-trivial.
(4) It follows from the Hairy Ball Theorem 32.20 and Lemma 77.1 (1) that even-dimensional spheres are not parallelizable.
(5) For any $n \in \mathbb{N}$ the n-dimensional torus $(S^1)^n = \mathbb{R}^n/\mathbb{Z}^n$ is parallelizable, in fact if we denote by $q\colon \mathbb{R}^n \to \mathbb{R}^n/\mathbb{Z}^n$ the projection map, then an isomorphism of vector bundles is given by

$$\begin{array}{rcl} \varphi\colon (\mathbb{R}^n/\mathbb{Z}^n) \times \mathbb{R}^n & \mapsto & T(\mathbb{R}^n/\mathbb{Z}^n) \\ (q(x), v) & \mapsto & (q(x), Dq_x(v)) \\ & & \uparrow \\ & & Dq_x\colon \mathbb{R}^n = T_x\mathbb{R}^n \to T_{q(x)}(\mathbb{R}^n/\mathbb{Z}^n) \end{array}$$

(6) There are many proofs why for $g > 1$ the surface of genus g is not parallelizable, see for example [MiS, p. 313]. Note that together with Lemma 77.1 (3) this implies that such surfaces do not admit a nowhere vanishing vector field. We refer to Figure 961 for an illustration of a vector field on the surface of genus 2 that vanishes on precisely two points.

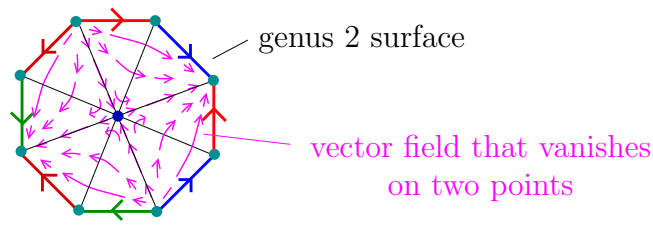

FIGURE 961.

(7) If a manifold is parallelizable, then evidently it is also orientable in the sense of Section 3.8. Put differently, a non-orientable manifold is not parallelizable.
(8) Every closed orientable 3-manifold is parallelizable. This was first proved by Eduard Stiefel [Stie] in 1935. An elementary proof for this statement is given in [BL]. Alternative proofs can be found in [DGGK] and [Kir4, p. 46].

77.2. **The pullback and the Whitney sum of vector bundles.** In this section we will introduce two constructions for obtaining new vector bundles out of given vector bundles.

Lemma 77.2. *Let $g\colon X \to Y$ be a map between topological spaces and let $q\colon F \to Y$ be an n-dimensional vector bundle. As in Lemma 16.8 (1) we consider the pullback*

$$g^*F \;:=\; \{(x,v)\,|\,x \in X \text{ and } v \in q^{-1}(g(x))\} \;\subset\; X \times F,$$

which is equipped with the subspace topology. Then the following statements hold:

(1) *The map*

$$\begin{array}{rcl} p\colon g^*F \;:=\; \{(x,v)\,|\,x \in X \text{ and } v \in q^{-1}(g(x))\} & \to & X \\ (x,v) & \mapsto & x \end{array}$$

is also an n-dimensional vector bundle where for each $x \in X$ the vector space structure on $p^{-1}(x) = \{x\} \times q^{-1}(g(x)) \subset X \times F$ is the vector space structure on the vector space $\{x\} \times q^{-1}(g(x)) = q^{-1}(g(x))$.

(2) *The following diagram commutes*

$$\begin{array}{ccc} g^*F & \xrightarrow{(x,v)\mapsto v} & F \\ \downarrow{\scriptstyle p} & & \downarrow{\scriptstyle q} \\ X & \xrightarrow{g} & Y. \end{array}$$

Proof.

(1) Let $x \in X$. If $V \subset Y$ is a neighborhood of $g(x)$ and $\varphi\colon q^{-1}(V) \to \mathbb{R}^n \times V$ has the desired properties (1) and (2) of the definition of a vector bundle, then the open

neighborhood $U := g^{-1}(V) \subset X$ of x together with the map

$$\begin{array}{rcl} \psi\colon p^{-1}(U) & \to & U \times \mathbb{R}^n \\ (z,v) & \mapsto & (p(z), \varphi(v)) \\ & & \uparrow \\ & & \text{note that } v \in q^{-1}(g(z)) \text{ and that } g(z) \in g(U) = V \end{array}$$

is easily seen to have the properties (1) and (2) of the definition of a vector bundle.

(2) It is straightforward to verify that the diagram commutes. Alternatively, the statement that the diagram commutes is part of the fact that g^*F is a pullback. □

Definition. Using the notation from Lemma 77.2 we refer to $g^*F \to X$ as the *pullback* of the vector bundle $q\colon F \to Y$ under the map $g\colon X \to Y$.

Example. Let $p\colon M \to S^1$ be the Möbius bundle. We denote by $g\colon S^1 \to S^1$ the map that is given by $g(z) = z^2$. In Exercise 77.8 we will see that the pullback of the Möbius bundle under g is a trivial bundle. We refer to Figure 962 for an illustration of the pullback of the Möbius bundle.[1300]

FIGURE 962.

The following proposition summarizes a few properties of the pullback of vector bundles.

Proposition 77.3.

(1) *The pullback of a trivial vector bundle is again trivial.*
(2) *If $q\colon Y\colon F \to Y$ is a vector bundle and if X is a subset of Y with inclusion map $i\colon X \to Y$, then i^*F is canonically isomorphic*[1301] *to the restriction of F to the vector bundle $q^{-1}(X) \to X$.*
(3) *Let $q\colon F \to Z$ be an n-dimensional vector bundle. The pullback $\mathrm{id}_Z^* F \to Z$ corresponding to the identity map id_Z is naturally isomorphic to $q\colon F \to Z$.*
(4) *Let $q\colon F \to Z$ be an n-dimensional vector bundle. If $f\colon X \to Y$ and $g\colon Y \to Z$ are maps between topological spaces, then the vector bundles $f^*(g^*F) \to X$ and $(g \circ f)^*F \to X$ are canonically isomorphic.*

Proof. All statements follow quite easily from the definitions. Thus we leave the verification of them to the industrious reader. □

[1300] The reader who is blessed with a good memory might recognize that this statement is quite similar to discussion on page 260 where we saw that the annulus is a 2-fold covering of the Möbius band.

[1301] One might initially expect that these two vector bundles are identical, but this is not the case. Nonetheless, a closer inspection of the definitions shows that there is an obvious isomorphism between these two vector bundles.

Later on we will need the following lemma.

Lemma 77.4.

(1) *If $f\colon M \to N$ is a local diffeomorphism between manifolds, then the map*

$$\begin{array}{rcl} TM & \to & f^*TN \\ (x,v) & \mapsto & (x, \underbrace{(f(x), Df_x(v))}_{\in TN}) \end{array}$$

is an isomorphism of vector bundles.

(2) *If $p\colon \widetilde{M} \to M$ is a covering of a manifold, then p^*TM is canonically isomorphic to $T\widetilde{M}$.*

Proof. We leave the straightforward verification of the first statement to the reader. The statement regarding the Pontryagin classes is now an immediate consequence of Theorem 77.9 (3). □

Proof. We rely on the never-ending energy of the reader to provide the proof of the first statement. The second statement is an immediate consequence of the first statement. □

Before we can formulate the next proposition we need to introduce the following definition.

Definition. A topological space X is called *paracompact* if it is Hausdorff and if given any open covering $\{U_i\}_{i\in I}$ there exists a partition of unity subordinate to the open covering.[1302]

Remark. In many textbooks, e.g. [Mun3, Chapter 41], [Kel, p. 156] or [Dug, Chapter VIII.2] an alternative definition for paracompactness is used. More precisely, a topological space X is often called paracompact if it is Hausdorff and if if each open covering $\{U_i\}_{i\in I}$ admits a locally finite open refinement, this means that there exists an open covering $\{V_j\}_{j\in J}$ such that each V_j is contained in some U_i and such that each $x \in X$ admits a neighborhood W that is contained in only finitely many V_j. We refer to [LW, Appendix I Proposition 6] or [Dug, Chapter VIII.4] for a proof that these two definitions of paracompactness are in fact equivalent. We will not make use of this alternative definition of paracompact.

We will never work directly with the definition of paracompact, instead we will use the following lemma to convince ourselves that most "reasonable" topological spaces are in fact paracompact.

Lemma 77.5.

(1) *Every topological manifold is paracompact.*
(2) *Every CW-complex is paracompact.*

Proof. The first statement is precisely the statement of Theorem 54.5. The second statement is [Hat2, Proposition 1.20]. □

[1302]See page 1276 for the definition of a partition of unity subordinate to a given open covering.

Example. Elementary topological psychology tells us that surely not every topological space is paracompact. Indeed, the "long line" from page 215 is not paracompact, we refer to [Kra, p. 66] for details.

Remark. Some books, see e.g. [Hat2, p. 77], make at some point the blanket assumption that all base spaces of vector bundles are paracompact.

Now we can formulate the proposition that we are actually interested in.

Proposition 77.6.

(1) *Let $q\colon F \to Y$ be a vector bundle, let X be a topological space and let $f_0, f_1\colon X \to Y$ be maps. If f_0 and f_1 are homotopic and if X is paracompact, then the vector bundles $f_0^*F \to X$ and $f_1^*F \to X$ are isomorphic.*
(2) *Let X and Y be two paracompact topological spaces. If $f\colon X \to Y$ is a homotopy equivalence, then the map f induces a bijection between the set of isomorphism classes of vector bundles over Y and the set of isomorphism classes of vector bundles over X.*
(3) *Let X be a topological space. If X is paracompact and contractible, then every vector bundle over X is trivial.*

Example. It follows immediately from Lemma 77.5 (1) and Proposition 77.6 (3) that every vector bundle over the topological spaces $\overline{B}^n, B^n$ and $\mathbb{R}^n$ is trivial.

Proof.

(1) This statement is [Hat2, Theorem 1.6].
(2) Let $g\colon Y \to X$ be a homotopy inverse to f. Recall that this means that $f \circ g$ is homotopic to id_Y and that $g \circ f$ is homotopic to id_X. Now the statement follows immediately from (1) and Proposition 77.3 (4).
(3) Let $F \to X$ be a vector bundle over a topological space that is paracompact and contractible. By definition of being contractible there exists a homotopy equivalence from the topological space X to the topological space $\{*\}$ consisting of a single point. Since every vector bundle over $\{*\}$ is trivial it follows from (2) and Proposition 77.3 (1) that every vector bundle over X is trivial. □

The following proposition says that every n-dimensional vector bundle is the pullback of the tautological bundle over the infinite Grassmannian $G(n)$ in an "essentially unique way".

Proposition 77.7. *Let $p\colon E \to X$ be an n-dimensional vector bundle over a paracompact topological space. We denote by $F \to G(n)$ the n-dimensional vector bundle over the infinite Grassmannian $G(n)$ that we introduced on page 1784. The following two statements hold:*

(1) *There exists a map $g\colon X \to G(n)$ such that g^*F is isomorphic to E.*
(2) *If $g_0, g_1\colon X \to G(n)$ are maps such that g_0^*F and g_1^*F are isomorphic to E, then g_0 and g_1 are homotopic.*

Sketch of proof. We only consider the case of the tangent bundle $p\colon TM \to M$ over some closed manifold M. By Proposition 65.11 we know that there exists a $k \in \mathbb{N}$ and an embedding $\varphi\colon M \to \mathbb{R}^{n+k}$.[1303] Now we consider the map

$$\begin{array}{rcl} g\colon M & \to & G(n, n+k) \subset G(n) \\ P & \mapsto & V_{\varphi(P)}(\varphi(M)). \end{array}$$

(We refer to Figure 963 for an illustration.) One can verify fairly easily that the pullback of the tautological vector bundle is indeed isomorphic to the original vector bundle. This concludes the proof of (1) for this particular case.

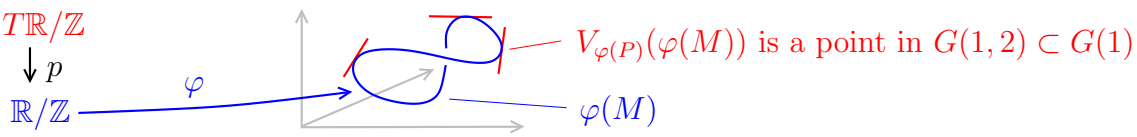

FIGURE 963. Illustration for the proof of Proposition 77.7.

Full details for the proofs of the two statements for any vector bundle over a paracompact topological space are provided by [MiS, Lemma 3.1 and Theorems 5.6 and 5.7]. □

We continue with our second construction of new vector bundles. The same way that we could obtain new vector spaces out of given vector spaces we can also obtain new vector bundles out of given vector bundles. For example we will now generalize the notion of the direct sum of two vector spaces to the notion of the direct sum of two vector bundles over a given topological space.

Definition. Let $p\colon E \to X$ be an m-dimensional vector bundle and let $q\colon F \to X$ be an n-dimensional vector bundle over a topological space X. The map

$$\begin{array}{rcl} E \oplus F := \{(v,w) \in E \times F \,|\, p(v) = q(w)\} & \to & X \\ (v,w) & \mapsto & p(v) \end{array}$$

is easily seen to be an $(m+n)$-dimensional vector bundle. It is called the *direct sum of the vector bundles E and F*.[1304]

Examples.

(1) Let $M \subset \mathbb{R}^n$ be a submanifold. Then for any point $P \in M$ we evidently have $V_P M \oplus (V_P M)^\perp = \mathbb{R}^n$. With this observation it follows that the map

$$\begin{array}{rcl} TM \oplus NM & \to & M \times \mathbb{R}^n \\ ((P,v),(P,w)) & \mapsto & (P, v+w) \end{array}$$

is an isomorphism of vector bundles. Put differently, the direct sum of the tangent bundle and the normal bundle is a trivial bundle.

[1303] Note that in the proof of that proposition we used implicitly that manifolds are paracompact.

[1304] The direct sum of two vector bundles is often also called the *Whitney sum*.

(2) We consider the sphere $S^2 \subset \mathbb{R}^3$. On page 1788 we saw that the tangent bundle TM is non-trivial and on page 1787 we saw that the normal bundle is trivial. Thus we see that the direct sum of a non-trivial vector bundle with a trivial vector bundle can be trivial.

We state the last example as a lemma.

Lemma 77.8. *Let M be an m-dimensional manifold and let N be an n-dimensional manifold. We denote by $p\colon M \times N \to M$ and $q\colon M \times N \to N$ the obvious projection maps. The map*[1305]

$$\begin{array}{rcl} T(M \times N) & \to & p^*(TM) \oplus q^*(TN) \\ ((x,y),v) & \mapsto & \big(((x,y),(x,p_*(v))),\ ((x,y),(y,q_*(v)))\big) \end{array}$$

is an isomorphism of $(m+n)$-dimensional vector bundles over $M \times N$.

Proof. The lemma is fairly elementary, a detailed proof is given in [Tu, p. 371]. □

77.3. **Pontryagin classes.** Given a topological space X and $i \in \mathbb{N}_0$ we define

$$\overline{H}^i(X;\mathbb{Z}) \ := \ H^i(X;\mathbb{Z})/\{a \in H^i(X;\mathbb{Z}) \,|\, 2a = 0\}.$$

It should be clear that these cohomology groups $\overline{H}$ are also contravariantly functorial and that all the results on usual cohomology groups have obvious analogues.

We can now formulate the following result that is one of the key theorems of this chapter. It was proved initially in about 1940 by Lev Pontryagin.[1306]

Theorem 77.9. *For each $i \in \mathbb{N}_0$ we can assign to every vector bundle $p\colon E \to X$ over a paracompact topological space a cohomology class $p_i(E) \in \overline{H}^{4i}(X;\mathbb{Z})$, called i-th* Pontryagin class*, such that the following conditions are satisfied:*

(1) *The 0-th Pontryagin class of any vector bundle over a topological space X is the unit element in $\overline{H}^0(X;\mathbb{Z})$.*
(2) *For any trivial vector bundle all Pontryagin classes p_i with $i \geq 1$ are zero.*
(3) *The Pontryagin class behaves well under pullbacks, i.e. if we are given a vector bundle $q\colon F \to Y$ and a map $g\colon X \to Y$ of topological spaces, then for any $i \in \mathbb{N}_0$ we have*

$$p_i(g^*F) \ = \ g^*(p_i(F)) \ \in \ \overline{H}^{4i}(X;\mathbb{Z}).$$

(4) *If $p\colon E \to X$ is an n-dimensional vector bundle, then $p_i(E) = 0$ for $i > \frac{n}{2}$.*

[1305]The map might appear slightly intimidating, but it is "the obvious" map. It looks somewhat complicated since the pullback vector bundles $p^*(TM)$ and $q^*(TM)$ are both defined to be pairs, where the first entry is a point in $M \times N$ and the second entry is also a pair.

[1306]Lev Pontryagin is also an old friend whom we had already encountered on page 1630.

(5) *We denote by* $x \in \overline{H}^2(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \cong \mathbb{Z}$ *the standard generator as introduced on page 1453 and in Proposition 67.17. Then for* $i = 0, \dots, n+1$ *we have*[1307]

$$p_i(T\mathbb{C}\mathrm{P}^n) \;=\; \binom{n+1}{i} \cdot x^{2i} \;\in\; \overline{H}^{4i}(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) \;=\; \mathbb{Z}[x]/(x^{n+1})$$

and all other Pontryagin classes are zero.

Given a vector bundle $p\colon E \to X$ *we refer to*

$$p(E) \;:=\; \underbrace{\bigoplus_{i=0}^{\infty} p_i(E)}_{\text{finite sum by Theorem 77.9 (4)}} \;\in\; \overline{H}^*(X;\mathbb{Z}) \;=\; \bigoplus_{i=0}^{\infty} \overline{H}^i(X;\mathbb{Z})$$

as the total Pontryagin class. *With this definition we can state the last property of Pontryagin classes:*

(6) *The total Pontryagin class is multiplicative with respect to the direct sum of vector bundles* up to 2-torsion. *More precisely, if* $e\colon E \to X$ *and* $f\colon F \to X$ *are two vector bundles, then*

$$p(E \oplus F) \;=\; p(E) \cup p(F) \;\in\; \overline{H}^*(X;\mathbb{Z}).$$

Remark.

(1) The above introduction to Pontryagin classes differs somewhat from the usual approach taken in [MiS, Hat2]. In particular Pontryagin classes are usually defined as elements in the usual cohomology groups.
(2) It is not entirely clear whether classes $p_i(E)$ are uniquely defined by the properties stated in Theorem 77.9. Similar uniqueness statements hold for "Stiefel-Whitney classes" and "Chern classes", see [Hat2, Theorems 3.1 and 3.2], but it is nonetheless not clear to me how to prove uniqueness for Pontryagin classes. Fortunately that is of no concern to us.
(3) For category aficionados one can squeeze some of the statements of Theorem 77.9 into the language of category theory:
   (a) Let $\mathcal{T}$ be the category of paracompact topological spaces, here the objects are paracompact topological spaces and the morphisms between two paracompact topological spaces X and Y are as usual all continuous maps from X to Y.
   (b) Let $\mathcal{S}$ be the category of sets, i.e. the objects are sets and the morphisms are just maps.
   (c) Given a paracompact topological space X we denote by $V_n(X)$ the *set* of isomorphism classes of n-dimensional vector bundles. This is indeed a set since by Proposition 77.7 we can view $V_n(X)$ as a subset of the set of homotopy classes of maps $X \to G(n)$. We write $V(X) = \bigcup_{n\in\mathbb{N}} V_n(X)$.

[1307]Note that for $i > \lfloor \frac{n}{2} \rfloor$ we have $x^{2i} = 0 \in H^{4i}(\mathbb{C}\mathrm{P}^n) = 0$. Nonetheless, for later it is convenient to write down this expression for all i up to n.

(d) For each $i \in \mathbb{N}_0$ we consider the following two contravariant functors:

$$\begin{array}{c} \mathcal{T} \to \mathcal{S} \\ X \mapsto H^{4i}(X;\mathbb{Z}) \\ \big(X \xrightarrow{f} Y\big) \mapsto \big(\overline{H}^{4i}(Y) \xrightarrow{f^*} \overline{H}^{4i}(X)\big) \end{array} \quad \text{and} \quad \begin{array}{c} \mathcal{T} \to \mathcal{S} \\ X \mapsto V(X) \\ \big(X \xrightarrow{f} Y\big) \mapsto \left(\begin{array}{c} V(Y) \to V(X) \\ [G \xrightarrow{p} Y] \mapsto [f^*G \to X] \end{array}\right). \end{array}$$

(e) In this language we can say that Pontryagin classes are a natural transformation between these two contravariant functors. This sentence now models property (3) of Pontryagin classes.

Sketchy sketch of a proof. Given $n \in \mathbb{N}$ we denote by $G(n)$ the infinite Grassmannian that we introduced on page 1784. In [Hat2, Proposition 3.16] it is shown that[1308][1309]

$$(\overline{H}^*(G(n);\mathbb{Z}), \cup) \;\cong\; \mathbb{Z}[q_1, \dots, q_k] \text{ for } n = 2k \text{ or } n = 2k+1$$

where each q_i has degree $4i$. Now let $p\colon E \to X$ be an n-dimensional vector bundle. We denote by $F \to G(n)$ the n-dimensional vector bundle over the infinite Grassmannian $G(n)$ that we introduced on page 1784. By Proposition 77.7 there exists a map $g\colon X \to G(n)$ such that g^*F is isomorphic to E. We define $p_i(E) := g^*(q_i) \in \overline{H}^{4i}(X;\mathbb{Z})$. It follows from Proposition 77.7 that this definition does not depend on the choice of the map g.

The proof that the Pontryagin classes have all the stated properties is given in [MiS, Chapter 15]. □

Example. Let $n \in \mathbb{N}$. Let M be a closed orientable submanifold of $\mathbb{R}^n$ of codimension one. For example we could take $M = S^{n-1} \subset \mathbb{R}^n$ or M could be the surface of some genus g which, by the discussion on page 210, we can view as a submanifold of $\mathbb{R}^3$.[1310] We want to determine the total Pontryagin class of the tangent bundle TM. As before we denote by NM the normal bundle of $M \subset \mathbb{R}^n$. Then

$$\begin{array}{ccccccc} p(TM) & = & p(TM) \cup p(NM) & = & p(TM \oplus NM) & = & p(\text{trivial bundle } M \times \mathbb{R}^n) \quad = \; 1. \\ & \uparrow & & \uparrow & & \uparrow & \qquad\qquad\qquad\qquad \uparrow \\ & \begin{array}{c}\text{by Theorem 77.9 (1) and (2)} \\ \text{since the vector bundle } NM \\ \text{is trivial, see page 1788}\end{array} & & \text{by Theorem 77.9 (6)} & & \text{see page 1793} & \qquad\qquad\qquad\qquad \text{Theorem 77.9 (2)} \end{array}$$

In the remainder of this chapter we are mostly interested in tangent bundles of manifolds, which leads us to the following definition.

[1308]The fact that the cohomology ring $(\overline{H}^*(G(n);\mathbb{Z}), \cup)$ is a polynomial algebra should ring a bell: When we introduced the (infinite) Grassmannian $G(n)$ we were saying that it should be viewed as a generalization of the (infinite) real projective spaces. Thus the calculation of the cup product mirrors our calculation that $(H^*(\mathbb{C}\mathrm{P}^\infty;\mathbb{Z}), \cup) \cong \mathbb{Z}[x]$, see Proposition 62.12, and our calculation that $(H^*(\mathbb{R}\mathrm{P}^\infty;\mathbb{F}_2), \cup) \cong \mathbb{F}_2[x]$, see Proposition 62.16 (3).

[1309]The calculation of the cohomology ring over the usual cohomology groups $H^*(G(n);\mathbb{Z})$ is somewhat more involved, see [Hat2, Theorem 3.9] for more information.

[1310]The Pontryagin classes for surfaces are zero for the stupid reason that they live in dimensions $4i$, but that is besides the point for this example.

Definition. Given a manifold M we define its Pontryagin classes as the Pontryagin classes of its tangent bundle, i.e. for $i \in \mathbb{N}_0$ we write $p_i(M) := p_i(TM) \in \overline{H}^{4i}(M;\mathbb{Z})$.

Example. With these definitions the statement of Theorem 77.9 (5) is equivalent to

$$\begin{array}{ccccccc} p(\mathbb{C}\mathrm{P}^n) & = \sum_{i=0}^{n} \binom{n+1}{i} \cdot x^{2i} & = & \overbrace{(1+x^2)^{n+1}}^{\text{higher terms are zero in the ring}} & \in \overline{H}^*(\mathbb{C}\mathrm{P}^n;\mathbb{Z}) & = & \mathbb{Z}[x]/(x^{n+1}). \\ & \uparrow & & \uparrow & & \uparrow & \end{array}$$

by Theorem 77.9 (2) and (5) since $T\mathbb{C}\mathrm{P}^n$ is $2n$-dimensional — general binomial formula, together with the fact that $x^j = 0$ for $j \geq n+1$ — see Proposition 67.17

For example we have

$$p(\mathbb{C}\mathrm{P}^1) = 1, \quad p(\mathbb{C}\mathrm{P}^2) = 1 + 3x^2, \quad p(\mathbb{C}\mathrm{P}^3) = 1 + 4x^2, \quad p(\mathbb{C}\mathrm{P}^4) = 1 + 5x^2 + 10x^4.$$

77.4. **Pontryagin classes as invariants of manifolds.** So far, throughout these lectures we have basically only studied invariants of topological spaces. Even the de Rham cohomology groups that we introduced in Section 54.2 were shown in Proposition 55.4 to be topological invariants, i.e. their isomorphism types depend only on the homeomorphism type of the underlying topological space.

The Pontryagin classes of a manifold M turn out to be more subtle invariants: they are defined using the tangent bundle of M. The definition of the tangent bundle in turn relies on the choice of the smooth structure. Put differently, a priori the Pontryagin classes $p_i(M) \in \overline{H}^{4i}(M;\mathbb{Z})$ depend on the smooth structure of the manifold.

The following lemma shows how diffeomorphisms interact with Pontryagin classes.

Lemma 77.10. *If $f\colon M \to N$ is a local diffeomorphism between two manifolds, then for any $i \in \mathbb{N}_0$ we have*

$$p_i(TM) = f^*(p_i(TN)) \in \overline{H}^{4i}(M;\mathbb{Z}).$$

Proof. The lemma is an immediate consequence of Lemma 77.4 (1) and Theorem 77.9 (3). □

In [Shar, Theorem 1.6] it is shown that the first Pontryagin class cannot detect the difference between different smooth structures. But the following theorem demonstrates that the higher Pontryagin classes contain information on smooth structures of manifolds.

Theorem 77.11. *For any $n \geq 2$ there exist two closed manifolds M and M' with the following properties:*

1. *the manifolds M and M' are homeomorphic,*
2. *the n-th Pontryagin class of M is trivial, whereas*
3. *the n-th Pontryagin class of M' is non-zero.*

In particular it follows from Lemma 77.10 that the manifolds M and M' are not diffeomorphic.

Proof. This theorem is proved in [KL, Theorem 4.8], see also [KL, Proof of Proposition 4.7]. Examples of non-compact manifolds M and M' with the same properties (1), (2) and (3) were given before by John Milnor [Mi8, p. 78] in 1964, see also [Rudy2, p. 87]. Furthermore, similar ideas had already been used before by John Milnor [Mi1] in the proof of Theorem 28.21 where he showed that there exists a manifold that is homeomorphic but not diffeomorphic to S^7. □

In fact the non-zero Pontryagin classes of the manifold M' in [Mi8, p. 78] and [KL, Theorem 4.8] happen to be torsion elements, so the Pontryagin classes of M and M' differ by some torsion element in cohomology. This leads us to the definition of the *rational Pontryagin* classes of a manifold.

Definition. Given a manifold M and $i \in \mathbb{N}_0$ we define the *i-th rational Pontryagin class* $p_i(M;\mathbb{Q})$ of M to be the image of $p_i(M)$ under the map $\overline{H}^{4i}(M;\mathbb{Z}) \to H^{4i}(M;\mathbb{Q})$.

The following theorem says that rational classes can *not* be used to find examples of manifolds that are homeomorphic but non-diffeomorphic. The theorem was proved by Sergei Novikov [No] in 1965.[1311]

Theorem 77.12. *Let $f\colon M \to M'$ be a homeomorphism between closed manifolds. We denote by $f^*\colon H^*(M';\mathbb{Q}) \to H^*(M;\mathbb{Q})$ the induced map on rational cohomology. Then for any $i \in \mathbb{N}_0$ we have*

$$p_i(M;\mathbb{Q}) \;=\; f^*(p_i(M';\mathbb{Q})).$$

77.5. **Pontryagin numbers and the signature.** We start out with the definition of the Pontryagin numbers of a manifold.

Definition.

(1) Let $n \in \mathbb{N}_0$. A *partition of n* is a set $I = \{i_1, \dots, i_r\}$ of numbers in $\mathbb{N}$ such that $n = i_1 + \cdots + i_r$. Often we just write, *$I = i_1 + \cdots + i_r$ is a partition of n.*[1312]

(2) Let $n \in \mathbb{N}_0$ and let $I = i_1 + i_2 + \cdots + i_r$ be a partition of n. Given a closed oriented $4n$-dimensional manifold we define its *I-Pontryagin class* as

$$p_I(M) \;:=\; p_{i_1}(M) \cup \cdots \cup p_{i_r}(M) \;\in\; \overline{H}^{4n}(M;\mathbb{Z})$$

and we define the corresponding *I-Pontryagin number* as

$$\widetilde{p}_I(M) \;:=\; \langle p_I(M), [M]\rangle \;\in\; \mathbb{Z}.$$

Remark. Let M and M' be two closed oriented $4n$-dimensional manifolds. If there exists an orientation-preserving diffeomorphism from M to M', then it follows easily from Lemma 77.10 that all of the Pontryagin numbers of M and M' agree.

The following proposition relates Pontryagin classes to the previous chapter on cobordisms. The proposition was first proved by Pontryagin.

[1311] Sergei Novikov (*1938) is a Russian mathematician who obtained a Fields medal in 1970.

[1312] Note that a partition is unordered, hence we view $4 = 3 + 1$ and $4 = 1 + 3$ as the same partition.

Proposition 77.13. *Let $n \in \mathbb{N}_0$ and let $I = i_1 + i_2 + \cdots + i_r$ be a partition of n.*

(1) *Let M be a closed oriented $4n$-dimensional manifold. If M is the boundary of a compact orientable manifold W, then $\widetilde{p}_I(M) = 0$.*

(2) *The map*

$$\begin{array}{rcl} \widetilde{p}_I \colon \Omega_{4n} & \to & \mathbb{Z} \\ M & \mapsto & \widetilde{p}_I(M) \end{array}$$

is a well-defined homomorphism.

Proof. Let W be a compact oriented $(4n+1)$-dimensional manifold. We set $M = \partial W$ and we denote by $i \colon M \to W$ the inclusion map. The subsequent calculation relies on the following claim.

Claim. If we denote by $TM \oplus \mathbb{R}$ the direct sum of TM and the one-dimensional trivial bundle over M, then $i^*(TW) \cong TM \oplus \mathbb{R}$.

By the Collar Neighborhood Theorem 10.10 we can find a neighborhood $M \times \{0\} \subset W$ for $M = M \times [0,1]$. We have

$$\begin{array}{ccccccc} i^*(TW) & \cong & i^*(T(M \times [0,1])) & \cong & TM \oplus i^*(T[0,1]) & \cong & TM \oplus \mathbb{R}. \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{Lemma 77.4 (1)} & & \text{Lemma 77.8} & & \text{Proposition 77.3 (1)} & \end{array}$$

This concludes the proof of the claim.

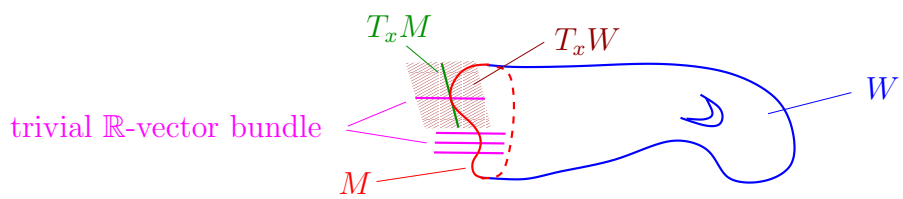

FIGURE 964. Illustration for the proof of Proposition 77.13

Let $I = i_1 + i_2 + \cdots + i_r$ be a partition of n. We turn to the proof of the first statement. We calculate that

$$\begin{array}{ccccccc} \widetilde{p}_I(M) & = & \langle p_I(TM), [M] \rangle & = & \langle p_I(TM \oplus \mathbb{R}), [M] \rangle & = & \langle p_I(i^*TW), [M] \rangle \\ & & & \uparrow & & \uparrow & \\ & & & \text{Theorem 77.9 (2) and (6)} & & \text{by the claim} & \\ & = & \langle i^* p_I(TW), [M] \rangle & = & \langle p_I(TW), i_*([M]) \rangle & = & 0. \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{Theorem 77.9 (3)} & & \text{Lemma 50.6} & & \text{Corollary 46.27} & \end{array}$$

Finally the second statement is an immediate consequence of the first statement and the trivial[1313] observation that for two closed oriented $4n$-dimensional manifolds M and N we

[1313] Why is this "trivial"? How can one prove this "obvious" equality?

have

$$\widetilde{p}_I(M \sqcup N) \;=\; \widetilde{p}_I(M) + \widetilde{p}_I(N). \qquad \square$$

The following theorem gives the converse to Proposition 77.13.

Theorem 77.14. *Let $n \in \mathbb{N}_0$. We denote by $\mathcal{I}$ the set of all partitions of n.*

(1) *The map*

$$\bigoplus_{I\in\mathcal{I}} \widetilde{p}_I \colon \Omega_{4n} \otimes \mathbb{Q} \;\to\; \bigoplus_{i\in\mathcal{I}} \mathbb{Q}\cdot i$$

is an isomorphism.

(2) *Let M be a closed oriented $4n$-dimensional manifold. If all Pontryagin numbers of M vanish, then $[M] = 0 \in \Omega_{4n}/\text{torsion}$.*

Sketch of proof. We consider the following diagram of homomorphisms:

$$\begin{tikzcd}
\Omega_{4n}/\text{torsion} \arrow[r, "\bigoplus_{I\in\mathcal{I}} \widetilde{p}_I"] \arrow[d, hook] & \bigoplus_{i\in\mathcal{I}} \mathbb{Z}\cdot i \arrow[d, hook] \\
\Omega_{4n}\otimes\mathbb{Q} \arrow[r, "\bigoplus_{I\in\mathcal{I}} \widetilde{p}_I"] & \bigoplus_{i\in\mathcal{I}} \mathbb{Q}\cdot i. \\
\bigoplus_{i_1+\dots+i_r=n\in\mathcal{I}} \mathbb{Q}\cdot(\mathbb{CP}^{2i_1}\times\dots\times\mathbb{CP}^{2i_r}) \arrow[u, "="] \arrow[ur, dashed, "\Psi"'] &
\end{tikzcd}$$

The left upper vertical map is a monomorphism by the discussion on page 1004. The right upper vertical map is evidently a monomorphism. It is clear that the diagram commutes. Thus we see that statement (2) of the theorem is an immediate consequence of statement (1).

Put differently, it remains to show that the bottom horizontal map is an isomorphism. Note that the lower vertical map is the identity by Theorem 76.11. Thus it suffices to show that the diagonal map is an isomorphism. As a reality check, note that the dimensions agree, in both cases the dimension is just given by the cardinality of $\mathcal{I}$.

In the following claim we carry out the arguments for $n = 1$ and $n = 2$ "by hand". The general case needs more clever arguments, for which we refer to [Tho2, Corollary IV.16].

Claim.

(1) Let $n = 1$. With respect to the bases $\{\mathbb{CP}^2\}$ and $\{p_1\}$ the diagonal map Ψ is represented by the matrix (3).

(2) Let $n = 2$. With respect to the bases $\{\mathbb{CP}^4, \mathbb{CP}^2\times\mathbb{CP}^2\}$ and $\{p_2, p_{1+1}\}$ the diagonal map Ψ is represented by the matrix $\begin{pmatrix} 10 & 9 \\ 25 & 18 \end{pmatrix}$.

In particular in both cases the matrix is invertible.

The case $n = 1$ is easy: We make the usual identification $pH^*(\mathbb{C}\mathrm{P}^2;\mathbb{Z}) = \mathbb{Z}[x]/(x^3)$, and we calculate that

$$\begin{array}{ccccccc} \widetilde{p}_1(\mathbb{C}\mathrm{P}^2) & = & \langle p_1(\mathbb{C}\mathrm{P}^2), [\mathbb{C}\mathrm{P}^2]\rangle & = & \langle 3x^2, [\mathbb{C}\mathrm{P}^2]\rangle & = & 3. \\ & & & \uparrow & & \uparrow & \\ & & & \text{Theorem 77.9 (5)} & & \text{Proposition 67.17} & \end{array}$$

The case $n = 2$ is slightly more involved. First note that by Theorem 77.9 (5) we have $p(\mathbb{C}\mathrm{P}^4) = 1 + 5x^2 + 10x^4 \in H^*(\mathbb{C}\mathrm{P}^4;\mathbb{Z}) = \mathbb{Z}[x]/(x^5)$. Thus as above we see that $\widetilde{p}_2(\mathbb{C}\mathrm{P}^4) = 10$. Furthermore, with similar arguments as above we have

$$\widetilde{p}_{1+1}(\mathbb{C}\mathrm{P}^4) \;=\; \langle p_1(\mathbb{C}\mathrm{P}^4) \cup p_1(\mathbb{C}\mathrm{P}^4), [\mathbb{C}\mathrm{P}^4]\rangle \;=\; \langle 5x^2 \cdot 5x^2, [\mathbb{C}\mathrm{P}^4]\rangle \;=\; 25.$$

This concludes the calculation of the first column of the matrix.

It remains to consider $\mathbb{C}\mathrm{P}^2 \times \mathbb{C}\mathrm{P}^2$. By Proposition 60.21 we can make the identification $H^*(\mathbb{C}\mathrm{P}^2 \times \mathbb{C}\mathrm{P}^2;\mathbb{Z}) = \mathbb{Z}[x,y]/(x^3,y^3)$ where x and y are the pullbacks of the standard generator of $H^2(\mathbb{C}\mathrm{P}^2;\mathbb{Z})$ under the two obvious projection maps. Using Lemma 77.8 and Theorem 77.9 (3), (5), (6) we see that $p(\mathbb{C}\mathrm{P}^2 \times \mathbb{C}\mathrm{P}^2) = (1 + 3x^2) \cdot (1 + 3y^2)$. In particular $p_1(\mathbb{C}\mathrm{P}^2 \times \mathbb{C}\mathrm{P}^2) = 3x^2 + 3y^2$ and $p_2(\mathbb{C}\mathrm{P}^2 \times \mathbb{C}\mathrm{P}^2) = 9x^2y^2$. Furthermore note that this implies that $p_{1+1}(\mathbb{C}\mathrm{P}^2 \times \mathbb{C}\mathrm{P}^2) = (3x^2 + 3y^2)^2 = 18x^2y^2$. The claim for $n = 2$ now follows from the observation that Proposition 60.2 tells us that $\langle x^2 \cdot y^2, [\mathbb{C}\mathrm{P}^2 \times \mathbb{C}\mathrm{P}^2]\rangle = 1$. $\square$

Our next goal is to use Theorem 77.14 to prove the following proposition. It says that the signature of a closed oriented manifold can be determined from its Pontryagin numbers.

Proposition 77.15. *Let $n \in \mathbb{N}_0$. We denote by $\mathcal{I}$ the set of all partitions of n. For each $I \in \mathcal{I}$ there exists $a_I \in \mathbb{Q}$ such that for any closed oriented $4n$-dimensional manifold M we have*

$$\mathrm{sign}(M) \;=\; \sum_{I \in \mathcal{I}} a_I \cdot \widetilde{p}_I(M).$$

Proof. Let $n \in \mathbb{N}_0$. We denote by $\mathcal{I}$ the set of all partitions of n. We consider the following diagram

$$\begin{tikzcd} \Omega_{4n} \arrow[r, "{[M]\mapsto[M]\otimes 1}"] \arrow[d, "\mathrm{sign}"'] & \Omega_{4n} \otimes \mathbb{Q} \arrow[r, "\bigoplus_{I\in\mathcal{I}} \widetilde{p}_I", "\cong"'] \arrow[d] & \bigoplus_{i\in\mathcal{I}} \mathbb{Q} \cdot i \arrow[dl, dashed, "\Phi"] \\ \mathbb{Z} \arrow[r, hook] & \mathbb{Q} & \end{tikzcd}$$

$$[M] \otimes r \mapsto \mathrm{sign}(M) \cdot r$$

Here the left-hand map is a homomorphism by Corollary 76.7. By Proposition 77.13 we know that the top right map is an isomorphism. Therefore there exists a diagonal homomorphism Φ that makes the diagram commute. Given $i \in I$ we set $a_i \in \mathbb{Q}$ to be the value

of Φ at $1 = 1 \cdot i \in \mathbb{Q} \cdot i \subset \bigoplus_{i \in I} \mathbb{Q} \cdot i$. In other words, the map

$$\bigoplus_{i \in \mathcal{I}} \mathbb{Q} \cdot i \quad \to \quad \mathbb{Q}$$

is given by

$$\bigoplus_{i \in \mathcal{I}} x_i \cdot i \quad \mapsto \quad \sum_{i \in \mathcal{I}} x_i \cdot a_i.$$

The desired equality $\operatorname{sign}(M) = \sum_{j=1}^{r} a_j \cdot \widetilde{p}_{I_j}(M)$ now follows immediately from the commutativity of the previous diagram. □

The coefficients in Proposition 77.15 had been completely determined by Friedrich Hirzebruch [Hirz]. The low-dimensional terms are given in the following theorem.

Theorem 77.16. (Hirzebruch Signature Theorem) *Let $n \in \{1, 2, 3, 4\}$ and let M be a closed oriented $4n$-dimensional manifold. Given $i \in \mathbb{N}_0$ we write $p_i := p_i(M) \in \overline{H}^{4i}(M; \mathbb{Z})$. The signature of M can be determined as follows:*

n	$\operatorname{sign}(M)$ *equals the Kronecker pairing of* $[M]$ *with the cohomology class*
1	$\frac{1}{3} p_1$
2	$\frac{1}{45}(7p_2 - p_1^2)$
3	$\frac{1}{945}(62p_3 - 13p_2 \cup p_1 + 2p_1^3)$
4	$\frac{1}{14175}(381p_4 - 71p_3 \cup p_1 - 19p_2^2 + 22p_2 \cup p_1^2 - 3p_1^4)$.

Proof. We carry out the case $n = 2$. We adopt the notation from the proof of Proposition 77.15. By Theorem 76.11 we have $\Omega_8 \otimes \mathbb{Q} = \mathbb{Q} \cdot [\mathbb{CP}^4] \oplus \mathbb{Q} \cdot [\mathbb{CP}^2 \times \mathbb{CP}^2]$. Now let M be a closed oriented 8-dimensional manifold. By the proof of Proposition 77.15 we have $\operatorname{sign}(M) = a_2 \cdot \widetilde{p}_2(M) + a_{1+1} \cdot \widetilde{p}_{1+1}(M)$ where

$$\begin{pmatrix} a_2 \\ a_{1+1} \end{pmatrix} = \begin{matrix} \text{matrix of sign applied to} \\ \text{the basis } \mathbb{CP}^4 \text{ and } \mathbb{CP}^2 \times \mathbb{CP}^2 \end{matrix} \cdot \begin{matrix} \text{inverse of the matrix that expresses } p_2, p_{1+1} \\ \text{for the manifolds } \mathbb{CP}^4 \text{ and } \mathbb{CP}^2 \times \mathbb{CP}^2 \end{matrix}$$

$$= \begin{pmatrix} 1 & 1 \end{pmatrix} \begin{pmatrix} 10 & 9 \\ 25 & 18 \end{pmatrix}^{-1} = \tfrac{-1}{45} \begin{pmatrix} 1 & 1 \end{pmatrix} \begin{pmatrix} 18 & -9 \\ -25 & 10 \end{pmatrix} = \tfrac{1}{45} \begin{pmatrix} 7 \\ -1 \end{pmatrix}.$$

$\uparrow$

by Lemma 67.18 and Exercise 72.2 we know that the signatures of these two manifolds are $+1$
for the second matrix we use the calculation from the proof of Theorem 77.14

This gives precisely the desired result for $n = 2$. The case $n = 1$ is evidently even easier.

The higher-dimensional cases are dealt with, more cleverly, in [Hirz] or alternatively in [MiS, p. 224]. These references also contain a precise formula for all $n \in \mathbb{N}_0$. □

Remark.

(1) The expressions in Theorem 77.16 might seem random, but they do arise in a cogent way from the coefficients of the power series $\frac{\sqrt{t}}{\tanh(t)}$. This connection is explained in [MiS, Chapter 19].
(2) The signature of a manifold is of course an integer. Thus we obtain from Theorem 77.16 the slightly mysterious statement that for any closed oriented 4-dimensional manifold the integer $\langle p_1(M), [M]\rangle$ is divisible by 3.

In Proposition 26.25 we saw that the Euler characteristic of a finite CW-complex is multiplicative under finite covers. In fact we saw that this statement follows almost immediately from the definition of a CW-complex. The following theorem gives the analogous statement that the signature of a closed oriented $4n$-dimensional manifold is multiplicative under finite covers.

Theorem 77.17. *Let $n \in \mathbb{N}_0$. Let M be a closed oriented $4n$-dimensional manifold and let $\widetilde{M} \to M$ be a finite covering. Then*

$$\operatorname{sign}\left(\widetilde{M}\right) \;=\; \left[\widetilde{M} : M\right] \cdot \operatorname{sign}(M).$$

Remark.

(1) Perhaps it is initially difficult to appreciate the significance of Theorem 77.17. If we only consider (co-) homological invariants, then there are basically only two statements that relate the invariants of a (reasonable) topological space X and an n-fold covering $p\colon \widetilde{X} \to X$ thereof:
   (a) as pointed out above, if X is a finite CW-complex, then $\chi(\widetilde{X}) = n \cdot \chi(X)$,
   (b) Proposition 44.14 shows that $p_*\colon H_*(\widetilde{X};\mathbb{Q}) \to H_*(X;\mathbb{Q})$ is an epimorphism.
   Besides these observations, (co-) homological invariants behave fairly erratically under finite covers. One example of such "random" behavior is given in Exercise 77.10.
(2) One might think that one should be able to prove Theorem 77.17 in a naive way. But this is not the case. This can be seen from the fact that our sketch of the proof of Theorem 77.17 works only for manifolds, the proof that we will sketch does not apply to topological manifolds.
(3) The statement of Theorem 77.17 does in fact hold for topological manifolds, but the proof is even harder, see e.g. [Schaf, Theorem 8].
(4) The fact that there is no proof of Theorem 77.17 that does not in an essential way make use of the fact that M is a (topological) manifold is highlighted by [Wall6, Corollary 5.4.1].
(5) For compact $4n$-dimensional manifolds with non-empty boundary the signature is in general *not* multiplicative under finite covers. We refer to [APS] for details.

Proof. Let $n \in \mathbb{N}_0$. By Proposition 77.15 there exist partitions $I_1, \ldots, I_r$ of $4n$ and rational numbers $a_1, \ldots, a_r$ such that for any closed oriented $4n$-dimensional manifold X the

following equality holds:

$$(*) \qquad \operatorname{sign}(X) \;=\; \sum_{j=1}^{r} a_j \cdot \langle p_{I_j}(X), [X]\rangle_X .$$

Now let M be a closed oriented $4n$-dimensional manifold and let $q\colon \widetilde{M} \to M$ be a finite covering. We have

$$\begin{aligned}
\operatorname{sign}\big(\widetilde{M}\big) &\underset{\substack{\uparrow \\ \text{by } (*)}}{=} \sum_{j=1}^{r} a_j \cdot \big\langle p_{I_j}\big(\widetilde{M}\big), \big[\widetilde{M}\big]\big\rangle_{\widetilde{M}} \underset{\substack{\uparrow \\ \text{by Theorem 77.9 (3), Lemma 57.10 and since } q^*TM = T\widetilde{M}\text{, see Lemma 77.4 (2)}}}{=} \sum_{j=1}^{r} a_j \cdot \big\langle q^*(p_{I_j}(M)), \big[\widetilde{M}\big]\big\rangle_{\widetilde{M}} \\
&\underset{\substack{\uparrow \\ \text{Lemma 50.6}}}{=} \sum_{j=1}^{r} a_j \cdot \big\langle p_{I_j}(M), q_*\big[\widetilde{M}\big]\big\rangle_M \underset{\substack{\uparrow \\ \text{Proposition 46.24}}}{=} \big[\widetilde{M}{:}M\big] \cdot \sum_{j=1}^{r} a_j \cdot \langle p_{I_j}(M), [M]\rangle_M \underset{\substack{\uparrow \\ \text{by } (*)}}{=} \big[\widetilde{M}{:}M\big] \cdot \operatorname{sign}(M).
\end{aligned}$$

□

We conclude this chapter with a short discussion of other characteristic classes.

(1) Loosely speaking, a *characteristic class* is a map that associates to a vector bundle a cohomology class in the base space. We had just discussed the Pontryagin classes in some detail. There are several other characteristic classes:
   (a) To a vector bundle $p\colon E \to X$ one can also associate the *Stiefel-Whitney classes* $w_i(E) \in \overline{H}^i(X;\mathbb{F}_2)$, $i \in \mathbb{N}_0$.
   (b) If $p\colon E \to X$ is an "oriented" n-dimensional vector bundle, then there exists the *Euler class* $e(E) \in \overline{H}^n(X;\mathbb{Z})$.
   (c) Finally, if $p\colon E \to X$ is a complex vector bundle, then the corresponding *Chern classes* $c_i(E) \in \overline{H}^{2i}(X;\mathbb{Z})$, $i \in \mathbb{N}_0$ are defined.

   The properties of Stiefel-Whitney classes and Chern classes are very similar to the properties stated in Theorem 77.9, in fact these characteristic classes are completely determined by the corresponding properties. Finally note that there are some relations between the various characteristic classes, for example given a vector bundle $p\colon E \to X$ the i-th Pontryagin class equals[1314]

$$p_i(E) \;:=\; c_{2i}(\text{the "complexification" } E \otimes \mathbb{C}) \;\in\; \overline{H}^{4i}(X;\mathbb{Z}).$$

   We refer to [MiS] and [Hat2] for more details on these characteristic classes.

(2) For complex vector bundles over a manifold M the images of the Chern classes in $\overline{H}^{2i}(M;\mathbb{R})$ can also be defined in the context of de Rham cohomology. Since Pontryagin classes are defined via Chern classes this shows in particular that the images of the Pontryagin classes in real cohomology can be defined via de Rham cohomology. We refer to [Ch, MiS] for details.

[1314] In fact, this usually the way Pontryagin classes are defined.

Exercises for Chapter 77.

Exercise 77.1. Does there exist a smooth vector field on S^2 with a single zero?

Exercise 77.2. Let W be a manifold and let M be a submanifold of W. We denote by $i\colon M \to W$ the inclusion map. Show that there exists a vector bundle $E \to M$ such that $TM \oplus E \cong i^*(TW)$.

Exercise 77.3. Show that S^3 and S^7 are parallelizable.

Exercise 77.4. Let $z \in \mathbb{R}\backslash\{0\}$. We denote by $\rho_z\colon \pi_1(S^1, 1) \to \mathrm{GL}(1, \mathbb{R})$ the representation that sends the standard generator of $\pi_1(S^1, 1) \cong \mathbb{Z}$ to the matrix (z). We denote by $E_z \to S^1$ the line bundle corresponding to this representation, see the definition on page 1785. For which z is this line bundle isomorphic to the trivial bundle and for which z is it isomorphic to the Möbius bundle?

Exercise 77.5. Show that the Möbius bundle does not admit a non-zero section.

Exercise 77.6. By Exercise 1.32 we can identify $\mathbb{R}\mathrm{P}^1$ with S^1. Let $p\colon E \to \mathbb{R}\mathrm{P}^1 = S^1$ be the tautological line bundle over $\mathbb{R}\mathrm{P}^1 = S^1$ from page 1783. Is this line bundle trivial? Is it isomorphic to the Möbius bundle?

Exercise 77.7. Let $g \geq 1$ and let Σ be the surface of genus g. Show that Σ admits a non-trivial line bundle.

Exercise 77.8. Let $p\colon M \to S^1$ be the Möbius bundle and let $g\colon S^1 \to S^1$ be the map that is given by $g(z) = z^2$. Show that the pullback of the Möbius bundle under g is a trivial bundle.

Exercise 77.9. Let M be a closed oriented manifold of dimension $4k + 3$. Show that $\mathrm{sign}(S^1 \times M) = 0$.

Exercise 77.10. Show that given any $n \in \mathbb{N}$ and $k \in \mathbb{N}_{\geq 2}$ there exists a CW-complex X with $H_k(X; \mathbb{Q}) = 0$ and that admits a 2-fold covering $\widetilde{X}$ with $H_k(\widetilde{X}; \mathbb{Q}) \cong \mathbb{Q}^n$.
Hint: You can take X to be a mapping torus of some high-dimensional torus. Use Proposition 33.20 to compute homology groups.

78. Steenrod operations

In this chapter we introduce the Steenrod operations. These are cohomology operations which satisfy several axioms. In the first three sections we will state the axioms and draw several interesting conclusions. Afterwards we will sketch a proof for the existence of the Steenrod operations.

78.1. **The axioms of Steenrod operations.**

Definition.

(1) Let A and B be abelian groups and let $m, n \in \mathbb{N}_0$. Any natural transformation from the contravariant functor

$$H^m(-;A)\colon \text{category of topological spaces} \quad \to \quad \text{category of sets}$$

to the contravariant functor

$$H^n(-;B)\colon \text{category of topological spaces} \quad \to \quad \text{category of sets}$$

is called a *cohomology operation of degree* $n-m$. In other words, a cohomology operation consists for any topological space X of a map $\Phi_X\colon H^m(X;A) \to H^n(X;B)$ of sets such that for any map $f\colon X \to Y$ between topological spaces the following diagram commutes:

$$\begin{tikzcd} H^m(Y;A) \arrow[r, "f^*"] \arrow[d, "\Phi_Y"'] & H^m(X;A) \arrow[d, "\Phi_X"] \\ H^n(Y;B) \arrow[r, "f^*"] & H^n(X;B). \end{tikzcd}$$

(2) A cohomology operation is called *additive* if each map $H^m(X;A) \to H^n(X;B)$ is a homomorphism.

(3) A cohomology operation is called *non-trivial* if there exists a topological space X such that the map $H^m(X;A) \to H^n(X;B)$ is non-trivial in the sense that the image is not just the trivial element.

With the obvious modifications the same definitions also apply to relative cohomology viewed as functors from the category of pairs of topological spaces to the category of sets.

Perhaps somewhat surprisingly we have already assembled a substantial list of non-trivial cohomology operations.

Examples.

(1) Let $n \in \mathbb{N}_0$ and let G be an abelian group. Given a pair of topological spaces (X, A) we consider the connecting homomorphism $H^n(X, A; G) \to H^{n+1}(X; G)$. It follows from Lemma 48.15 (3) that these homomorphisms define an additive cohomology operation of degree one.

(2) Let $\varphi\colon A \to B$ be a homomorphism between two abelian groups and let $n \in \mathbb{N}_0$. On page 1163 we saw that given any topological space X we obtain an induced

homomorphism $\varphi_*\colon H^n(X;A) \to H^n(X;B)$. By Lemma 48.9 we know that these maps define an additive cohomology operation of degree zero.

(3) Let $0 \to A \xrightarrow{i} B \xrightarrow{p} C \to 0$ be a short exact sequence of abelian groups. On page 1714 we introduced the n-th Bockstein homomorphism $\beta_n\colon H^n(X;C) \to H^{n+1}(X;A)$. In Lemma 74.3 we saw that the n-th Bockstein homomorphisms define an additive cohomology operation of degree one.

(4) Let $k \in \mathbb{N}$. It follows from Proposition 58.3 (1) that for any $m \in \mathbb{N}_0$ and any commutative ring R the maps[1315]

$$\begin{array}{rcl} H^m(X,A;R) & \to & H^{km}(X,A;R) \\ \varphi & \mapsto & \varphi^k = \underbrace{\varphi \cup \cdots \cup \varphi}_{k \text{ times}} \end{array}$$

define a cohomology operation of degree $km-m$. Note that this type of a cohomology operation is in general not additive. For example, if $k \geq 2$, then it follows easily from the calculation of the cup product of $\mathbb{C}\mathrm{P}^k$, see Proposition 62.7, that the map $H^2(\mathbb{C}\mathrm{P}^k;\mathbb{Z}) \to H^{2k}(\mathbb{C}\mathrm{P}^k;\mathbb{Z})$ given by $\varphi \mapsto \varphi^k$ is not a homomorphism.

(5) If R is a commutative ring with $1+1=0$, then the cohomology operation $\varphi \mapsto \varphi^2$ is in fact additive. Indeed for any $\varphi, \psi \in H^m(X,A;R)$ we have[1316]

$$\begin{array}{rcl} (\varphi+\psi)^2 & = & \varphi \cup \varphi + \varphi \cup \psi + \psi \cup \varphi + \psi \cup \psi \\ & = & \varphi \cup \varphi + (1+(-1)^{m^2}) \cdot \varphi \cup \psi + \psi \cup \psi \;=\; \varphi \cup \varphi + \psi \cup \psi \;=\; \varphi^2 + \psi^2. \\ & \uparrow & \qquad\qquad\qquad\qquad\qquad\qquad \uparrow \end{array}$$

by Proposition 57.8 we have $\psi \cup \varphi = (-1)^{m^2} \cdot (\varphi \cup \psi)$ since $1-1=0=1+1$ in R

Note that all of the cohomology operations that we have introduced above are of non-negative degree. This raises the following amusing question.

Question 78.1. *Does there exist a non-trivial cohomology operation of negative degree?*

We will come back to this question at a later point.

The following theorem gives us new and interesting cohomology operations. The theorem was first proved by Norman Steenrod [Ste] in 1947.

Theorem 78.2. *There exists a family*

$$\mathrm{Sq}^i\colon H^n(X,A;\mathbb{Z}_2) \;\to\; H^{n+i}(X,A;\mathbb{Z}_2) \qquad \textit{with } i \in \mathbb{N}_0 \textit{ and } n \in \mathbb{N}_0$$

of additive cohomology operations which satisfies the following axioms:

(1) $\mathrm{Sq}^0 = \mathrm{id}$.
(2) *For any* $\varphi \in H^i(X,A;\mathbb{Z}_2)$ *we have* $\mathrm{Sq}^i(\varphi) = \varphi^2 = \varphi \cup \varphi \in H^{2i}(X,A;\mathbb{Z}_2)$.
(3) *For any* $\varphi \in H^j(X,A;\mathbb{Z}_2)$ *with* $i > j$ *we have* $\mathrm{Sq}^i(\varphi) = 0$.

[1315] We refer to page 1358 for the definition of the relative cup product.

[1316] This can be viewed as the cohomological "freshman's dream". Perhaps it should called the incoming PhD student's dream.

(4) *Let (X, A, B) be an excisive triad of topological spaces. For any $\varphi \in H^r(X, A; \mathbb{Z}_2)$ any $\psi \in H^s(X, B; \mathbb{Z}_2)$ and any $k \in \mathbb{N}_0$ we have*[1317]

$$\mathrm{Sq}^k(\varphi \cup \psi) \;=\; \sum_{i=0}^{k} \underbrace{\mathrm{Sq}^i(\varphi)}_{\in H^{r+i}(X,A;\mathbb{Z}_2)} \;\cup\; \underbrace{\mathrm{Sq}^{k-i}(\psi)}_{\in H^{s+i}(X,B;\mathbb{Z}_2)} \;\in\; H^{r+s+k}(X, A \cup B; \mathbb{Z}_2).$$

This equality is often called the Cartan formula.

In the next two sections we will discuss some properties and applications of these cohomology operations. Only after these two sections, once we are convinced that Steenrod operations are indeed useful and interesting, will we provide a proof for Theorem 78.2.

Remark.

(1) The first three axioms of Theorem 78.2 can be summarized as follows: Given any $\varphi \in H^k(X, A; \mathbb{Z}_2)$ we obtain the following table

$\mathrm{Sq}^0(\varphi)$	$\mathrm{Sq}^1(\varphi)$	$\dots$	$\mathrm{Sq}^{k-1}(\varphi)$	$\mathrm{Sq}^k(\varphi)$	$\mathrm{Sq}^{k+1}(\varphi)$	$\dots$
φ	?	$\dots$	?	φ^2	0	$\dots$

(2) Throughout the remainder of this chapter we will almost invariably consider cohomology with $\mathbb{Z}_2$-coefficients. We point out that by Proposition 57.8 the cup product on the $\mathbb{Z}_2$-cohomology $H^*(X, A; \mathbb{Z}_2)$ of a given pair of topological spaces (X, A) is actually *commutative*.

The following theorem is [SE, Theorem VIII.3.10].

Theorem 78.3. *Any two families of additive cohomology operations that satisfy Axioms* (1) *to* (4) *are identical.*

This theorem allows us to give a name to the above cohomology operations.

Definition. We refer to the cohomology operations from Theorem 78.2 as the *Steenrod operations.*[1318]

The following theorem shows that the first Steenrod operation Sq^1 is actually an old acquaintance of ours.

Theorem 78.4. *The first Steenrod operation* Sq^1 *is the Bockstein homomorphism corresponding to the short exact sequence* $0 \to \mathbb{Z}_2 \xrightarrow{[a]\mapsto[2a]} \mathbb{Z}_4 \to \mathbb{Z}_2 \to 0$.

Proof. We will not make use of this theorem, thus we decline to provide a proof. The theorem is proved in [Bre, p. 418] or alternatively in [MTa, p. 23] [Hat, Theorem 4.L.12]. □

[1317] We refer to page 1203 for the definition of an excisive triad. By Proposition 50.12 most "reasonable" triads are in fact excisive. In fact we will only use the special cases that $A = B$, or that at least one of A or B is the empty set. We refer again to page 1358 for the definition of the relative cup product.

[1318] Sometimes they are also called Steenrod squares, and the term Steenrod operations is used for a more general concept.

Evidently our goal now is to compute Steenrod operations in specific examples. We start out with the following slightly disappointing lemma.

Lemma 78.5. *For any wedge of finitely many spheres all Steenrod operations in degrees ≥ 1 are zero.*

Proof. We will prove the lemma in Exercise 78.2. □

In remainder of this section we intend to compute the Steenrod operations for the real projective spaces $\mathbb{R}\mathrm{P}^n$ with $n \in \mathbb{N}_0$. Before we consider the real projective spaces in detail it is convenient to reformulate the Cartan formula.

For the reformulation we need the following notation:

Notation. Let (X, A) be a pair of topological spaces. Given $\varphi \in H^k(X, A; \mathbb{Z}_2)$ we write

$$\mathrm{Sq}(\varphi) \ := \ \mathrm{Sq}^0(\varphi) + \mathrm{Sq}^1(\varphi) + \cdots + \mathrm{Sq}^k(\varphi) \ \in \ H^*(X, A; \mathbb{Z}_2) = \bigoplus_{n \in \mathbb{N}_0} H^n(X, A; \mathbb{Z}_2).$$

Furthermore we extend the homomorphism Sq in the obvious way to a homomorphism $\mathrm{Sq}\colon H^*(X; \mathbb{Z}_2) \to H^*(X; \mathbb{Z}_2)$.

Remark. Let (X, A) be a pair of topological spaces and let $\varphi \in H^k(X, A; \mathbb{Z}_2)$. Recall that by Axiom (3) given $\varphi \in H^k(X, A; \mathbb{Z}_2)$ we have $\mathrm{Sq}^i(\varphi) = 0$ for $i > k$. Thus we can write

$$\mathrm{Sq}(\varphi) \ = \ \mathrm{Sq}^0(\varphi) + \mathrm{Sq}^1(\varphi) + \cdots + \mathrm{Sq}^k(\varphi) \ = \ \sum_{i \in \mathbb{N}_0} \mathrm{Sq}^i(\varphi).$$

With this notation we can formulate the following lemma.

Lemma 78.6. *Let (X, A) be a pair of topological spaces.*

(1) *Given any $\varphi, \psi \in H^*(X, A; \mathbb{Z}_2)$ we have*

$$\mathrm{Sq}(\varphi \cup \psi) \ = \ \mathrm{Sq}(\varphi) \cup \mathrm{Sq}(\psi).$$

(2) *Given any $\varphi \in H^*(X, A; \mathbb{Z}_2)$ and given any $k \in \mathbb{N}_0$ we have $\mathrm{Sq}^k(\varphi) = \mathrm{Sq}(\varphi)^k$.*

Proof. The first statement follows easily from the Cartan formula. Indeed, we see that

$$\begin{aligned} \mathrm{Sq}(\varphi \cup \psi) = \sum_{k \in \mathbb{N}_0} \mathrm{Sq}^k(\varphi \cup \psi) \ &\overset{\text{Cartan formula, i.e. Axiom (4)}}{=} \sum_{k \in \mathbb{N}_0} \sum_{i=0}^{k} \mathrm{Sq}^i(\varphi) \cup \mathrm{Sq}^{k-i}(\psi) \\ &= \sum_{r \in \mathbb{N}_0} \sum_{s \in \mathbb{N}_0} \mathrm{Sq}^r(\varphi) \cup \mathrm{Sq}^s(\psi) = \Big(\sum_{r \in \mathbb{N}_0} \mathrm{Sq}^r(\varphi) \Big) \cup \Big(\sum_{s \in \mathbb{N}_0} \mathrm{Sq}^s(\psi) \Big) = \mathrm{Sq}(\varphi) \cup \mathrm{Sq}(\psi). \end{aligned}$$

The second statement is an immediate consequences of the first statement. □

Before we state a corollary we introduce the following semi-obvious definition.

Definition. Let $r, s \in \mathbb{N}_0$. If $0 \leq r \leq s$, then we define $\binom{s}{r} = \frac{s!}{r!(s-r)!}$, otherwise we set $\binom{s}{r} = 0$.

Now we can state the promised corollary.

Corollary 78.7. *Let X be a topological space. For any cohomology class $\varphi \in H^1(X;\mathbb{Z}_2)$ of degree* one*, any $k \in \mathbb{N}$ and any $i \in \mathbb{N}$ we have*

$$\mathrm{Sq}^i(\varphi^k) \;=\; \binom{k}{i} \cdot \varphi^{k+i} \;\in\; H^{k+i}(X;\mathbb{Z}_2).$$

Examples.

(1) By Proposition 62.16 we know that given any $n \in \mathbb{N}_0$ we have a ring isomorphism $(H^*(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2),\cup) \cong \mathbb{Z}_2[x]/(x^{n+1})$, where $x \in H^1(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2)$, and we have a ring isomorphism $(H^*(\mathbb{R}\mathrm{P}^n;\mathbb{Z}_2),\cup) \cong \mathbb{Z}_2[x]$, where $x \in H^1(\mathbb{R}\mathrm{P}^\infty;\mathbb{Z}_2)$. Since Steenrod operations are additive we see that the result of Corollary 78.7 gives us the promised calculations of all Steenrod operations for the real projective spaces.

(2) In Exercise 78.3 we will use a similar argument to calculate the Steenrod operations on $H^*(\mathbb{C}\mathrm{P}^n;\mathbb{Z}_2)$.

Proof. We calculate that

$$\mathrm{Sq}(\varphi^k) \underset{\substack{\uparrow \\ \text{Lemma 78.6 (2)}}}{=} \mathrm{Sq}(\varphi)^k \underset{\substack{\uparrow \\ \text{by Axiom (3)} \\ \text{since } \varphi \in H^1(X;\mathbb{Z}_2)}}{=} (\mathrm{Sq}^0(\varphi) + \mathrm{Sq}^1(\varphi))^k \underset{\substack{\uparrow \\ \text{Axioms (1) and (2)}}}{=} (\varphi + \varphi^2)^k \underset{\substack{\uparrow \\ \text{since the ring } (H^*(X;\mathbb{Z}_2),\cup) \\ \text{is commutative}}}{=} \varphi^k \cup (1+\varphi)^k \;=\; \sum_{j=0}^{k} \binom{k}{j} \varphi^{k+j}.$$

The desired conclusion follows from comparing the terms in degree $k+i$ on both sides. □

78.2. **Steenrod operations and connecting homomorphisms.** This section is completely dedicated to the proof of the following proposition. In the subsequent section we will see that the proposition has powerful applications.

Proposition 78.8. *If (X,A) is a pair of topological spaces, then the Steenrod operations commute with the connecting homomorphisms in cohomology. More precisely, given any $i,n \in \mathbb{N}_0$ the following diagram commutes:*

$$\begin{tikzcd}
H^n(A;\mathbb{Z}_2) \arrow[r, "\delta"] \arrow[d, "\mathrm{Sq}^i"'] & H^{n+1}(X,A;\mathbb{Z}_2) \arrow[d, "\mathrm{Sq}^i"] \\
H^{n+i}(A;\mathbb{Z}_2) \arrow[r, "\delta"] & H^{n+i+1}(X,A;\mathbb{Z}_2).
\end{tikzcd}$$

In the proof of Proposition 78.8 we will make use of the cross product on cohomology which we now introduce.

Definition. Let R be a commutative ring, let X be a topological space and let (Y,B) be a pair of topological spaces. Furthermore let $\varphi \in H^m(X;R)$ and $\psi \in H^n(Y,B;R)$. We denote

by $p\colon X \times Y \to X$ and $q\colon X \times Y \to Y$ the projections. We define the *cross product*[1319]

$$\varphi \times \psi \;:=\; \underbrace{p^*(\varphi)}_{\substack{\uparrow \\ \text{lies in } H^m(X\times Y;R)}} \cup \underbrace{q^*(\psi)}_{\substack{\uparrow \\ \text{lies in } H^n(X\times Y, X\times B;R)}} \;\in\; H^{m+n}(X \times Y, X \times B; R).$$

The following proposition basically says that in Axiom (4), i.e. in the Cartan formula, we can replace the cup product by the cross product.

Proposition 78.9. *Let X be a topological space and let (Y, B) be a pair of topological spaces. For any $\varphi \in H^r(X; \mathbb{Z}_2)$, $\psi \in H^s(Y, B; \mathbb{Z}_2)$ and $n \in \mathbb{N}_0$ the following equality holds:*

$$\mathrm{Sq}^n(\varphi \times \psi) \;=\; \sum_{i=0}^{n} \mathrm{Sq}^i(\varphi) \times \mathrm{Sq}^{n-i}(\psi) \;\in\; H^{r+s+n}(X \times Y, X \times B; \mathbb{Z}_2).$$

Proof $(*)$. Let X be a topological space and let (Y, B) be a pair of topological spaces. Furthermore let $\varphi \in H^r(X; \mathbb{Z}_2)$ and $\psi \in H^s(Y, B; \mathbb{Z}_2)$. We denote by $p\colon X \times Y \to X$ and $q\colon X \times Y \to Y$ the projections. We start out with the following claim.

Claim. The following equalities hold in $H^{m+n}(X \times Y; \mathbb{Z}_2)$:[1320]

(a) $\quad p^*(\varphi) \;=\; \varphi \times 1_Y \quad$ and $\quad q^*(\psi) \;=\; 1_X \times \psi.$
(b) $\quad \varphi \times \psi \;=\; (\varphi \times 1_Y) \cup (1_X \times \psi).$

Let us provide the proof of the claim.

(a) We perform the following easy calculation:

$$\varphi \times 1_Y \;=\; p^*(\varphi) \cup q^*(1_Y) \;\underset{\substack{\uparrow \\ \text{by definition we have} \\ p^*(1_X) = q^*(1_Y) = 1_{X\times Y}}}{=}\; p^*(\varphi) \cup 1_{X\times Y} \;\underset{\substack{\uparrow \\ 1_{X\times Y} \text{ is multiplicatively neutral,} \\ \text{see Proposition 57.7}}}{=}\; p^*(\varphi).$$

Evidently the same argument also shows that $q^*(\psi) = 1_X \times \psi$.

(b) This statement follows immediately from (a) and the definition of the cross product.

This concludes the proof of the claim.

[1319]Recall that on page 1316, given two *homology* classes $\mu \in H_m(X; \mathbb{Z})$ and $\nu \in H_n(Y; \mathbb{Z})$ we defined the *cross product* $\mu \times \nu \in H_{m+n}(X \times Y; \mathbb{Z})$. It should usually be clear from the context whether in a given situation we mean the cross product on homology or on cohomology.

[1320]Recall that given a topological space W we denote by $1_Z \in H^0(W; \mathbb{Z}_2)$ the cohomology class that is represented by the cocycle that assigns to each singular 0-simplex the value $1 \in \mathbb{Z}_2$.

Now we turn to the proof of the actual statement of the proposition. We have the following equalities in $H^{r+s+n}(X \times Y; \mathbb{Z}_2)$:

$$\begin{aligned}
\mathrm{Sq}^n(\varphi \times \psi) &\overset{\text{part (b) of the claim}}{=} \mathrm{Sq}^n\big((\varphi \times 1_Y) \cup (1_X \times \psi)\big) &&\overset{\text{by the Cartan formula, i.e. by Axiom (4)}}{=} \sum_{i=0}^{n} \mathrm{Sq}^i(\varphi \times 1_Y) \cup \mathrm{Sq}^{n-i}(1_X \times \psi) \\
&\underset{\text{part (a) of the claim}}{=} \sum_{i=0}^{n} \mathrm{Sq}^i(p^*(\varphi)) \cup \mathrm{Sq}^{n-i}(q^*(\psi)) &&\underset{\text{since } \mathrm{Sq}^i \text{ and } \mathrm{Sq}^{n-2} \text{ are natural transformations}}{=} \sum_{i=0}^{n} p^*(\mathrm{Sq}^i(\varphi)) \cup q^*(\mathrm{Sq}^{n-i}(\psi)) \\
&\underset{\text{by definition of the cross product}}{=} \sum_{i=0}^{n} \mathrm{Sq}^i(\varphi) \times \mathrm{Sq}^{n-i}(\psi).
\end{aligned}$$

We have thus obtained the desired equality. □

The proof of Proposition 78.8 rests on the following lemma.

Lemma 78.10. *Let X be a topological space, let (Y, B) be a pair of topological spaces and let R be a commutative ring. If $\varphi \in H^m(X; R)$ and $\psi \in H^n(B; R)$, then*

$$\underset{\substack{\text{connecting homomorphism} \\ \text{in cohomology for the} \\ \text{pair } (X \times Y, X \times B)}}{\delta(\overbrace{\varphi \times \psi}^{\in H^{m+n}(X \times B; R)})} = (-1)^m \cdot \varphi \times \underset{\substack{\text{connecting homomorphism} \\ \text{in cohomology for the pair } (Y, B)}}{\overbrace{\delta\psi}^{\in H^{n+1}(Y, B; R)}} \in H^{m+n+1}(X \times Y, X \times B; R).$$

Proof of Lemma 78.10. This equality follows fairly easily from Lemma 57.2, the definition of the cross product via the cup product and the explicit description of the connecting homomorphism on page 1160. We leave it to the reader to fill in the details. □

Proof of Proposition 78.8. We start out with a warm-up case.

Claim. Let Z be a topological space and let $a < b$ be two real numbers. The conclusion of the proposition holds for the pair $(Z \times [a, b], Z \times \partial([a, b]))$ of topological spaces.

Let $\theta \in H^n(Z \times \partial([a, b]); \mathbb{Z}_2) = H^n(Z \times \{a, b\}; \mathbb{Z}_2)$. Recall that we need to show that $\mathrm{Sq}^i(\delta\theta) = \delta(\mathrm{Sq}^i(\theta))$. First note that θ can be written as $\theta = \varphi \times \psi$ for some $\varphi \in H^n(Z; \mathbb{Z}_2)$ and some $\psi \in H^0(\partial([a, b]); \mathbb{Z}_2) = H^0(\{a, b\}; \mathbb{Z}_2)$.[1321] Note that we have the following

[1321] This statement follows quite easily from the fact that $Z \times \partial([a, b]) = (Z \times \{a\}) \sqcup (Z \times \{b\})$, the observation that $H^0(\{a, b\}) = \mathbb{Z} \cdot 1_{\{a\}} \oplus \mathbb{Z} \cdot 1_{\{b\}}$, Proposition 57.7 and Lemma 59.9. We leave it to the assiduous reader to assemble these steps in the right logical order.

equalities in $H^{n+i+1}(Z \times [a,b], Z \times \partial([a,b]); \mathbb{Z}_2)$:

$$\begin{array}{ccccccc}
 & \text{since } \theta = \varphi \times \psi & & \text{by Lemma 78.10, we also use that } (-1)^n = 1 \in \mathbb{Z}_2 & & \text{Proposition 78.9} & \begin{array}{c}\text{since } \delta\psi \in H^1([a,b], \partial([a,b]); \mathbb{Z}_2) \\ \text{and since } H^i([a,b], \partial([a,b]); \mathbb{Z}_2) = 0 \\ \text{for every } i \geq 2 \text{ we know that} \\ \mathrm{Sq}^j(\delta\psi) = 0 \text{ for } j \geq 1\end{array} \\
 & \downarrow & & \downarrow & & \downarrow & \downarrow \\
\mathrm{Sq}^i(\delta\theta) & = \mathrm{Sq}^i(\delta(\varphi \times \psi)) & & = \mathrm{Sq}^i(\varphi \times \delta\psi) & & = \sum_{j=0}^{i} \mathrm{Sq}^{i-j}(\varphi) \times \mathrm{Sq}^j(\delta\psi) & = \mathrm{Sq}^i(\varphi) \times \mathrm{Sq}^0(\delta\psi) \\
 & = \mathrm{Sq}^i(\varphi) \times \delta\psi & & = \delta(\mathrm{Sq}^i(\varphi) \times \psi) & & = \delta(\mathrm{Sq}^i(\varphi \times \psi)) & = \delta(\mathrm{Sq}^i(\theta)). \\
 & \uparrow & & \uparrow & & \uparrow & \\
 & \begin{array}{c}\text{Axiom (1) says} \\ \text{that } \mathrm{Sq}^0 = \mathrm{id}\end{array} & & \text{Lemma 78.10} & & \begin{array}{c}\text{by Proposition 78.9 together with Axioms (1) and (3)} \\ \text{and the fact that } \psi \in H^0(\partial([a,b]); \mathbb{Z}_2)\end{array} &
\end{array}$$

This concludes the proof of the claim.

The remainder of the proof of the proposition consists in cleverly reducing the general case to the above special case. Thus let (X, A) be a pair of topological spaces. We denote by $i\colon A \to X$ the inclusion map. We set

$$\mathrm{Cyl}(i) = \begin{array}{c}\text{mapping cylinder of the} \\ \text{inclusion } i\colon A \to X\end{array} := ((A \times [0,1]) \sqcup X)/\sim \quad \text{where } (a,1) \sim a \text{ for all } a \in A.$$

We point out that by Exercise 15.5 and Lemma 15.5 we know that the obvious inclusions $A \times [0,1] \to \mathrm{Cyl}(i)$ and $X \to \mathrm{Cyl}(i)$ are homeomorphism onto their images. Thus we can view $A \times [0,1]$ and X as subsets of $\mathrm{Cyl}(i)$. Now we consider the following subsets of the mapping cylinder $\mathrm{Cyl}(i)$:

$$B := (A \times [0, \tfrac{1}{2}]) \cup X \quad \text{and} \quad C := A \times \{0\}.$$

We refer to Figure 965 for an illustration. The five statements in the following claim break

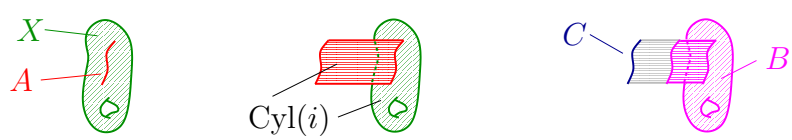

FIGURE 965.

the proof of the proposition into five manageable steps.

Claim.

(1) The conclusion of the proposition holds for $(A \times [0, \frac{1}{2}], A \times \partial([0, \frac{1}{2}]))$.
(2) The conclusion of the proposition holds for $(\mathrm{Cyl}(i), B \cup C)$.
(3) The conclusion of the proposition holds for $(\mathrm{Cyl}(i), C)$.
(4) The conclusion of the proposition holds for $(\mathrm{Cyl}(i), A \times [0,1])$.
(5) The conclusion of the proposition holds for (X, A).

The five statements of the claim are illustrated in Figure 966.

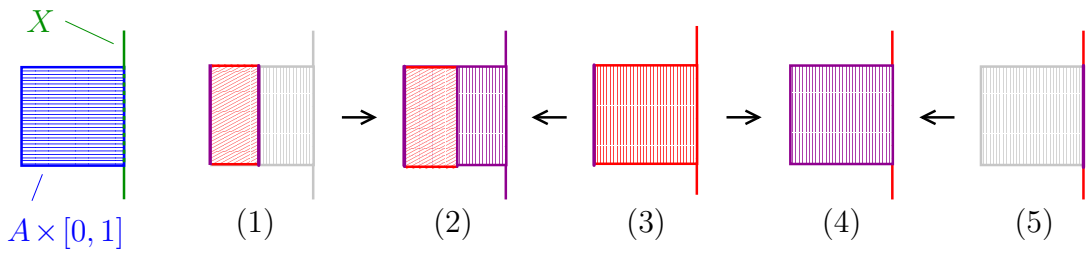

FIGURE 966.

Before we work our way through the five steps we need to make two related observations. Let $f\colon (X,A) \to (Y,B)$ be a map of pairs of topological spaces. We obtain the following cubical diagram:

$$\begin{tikzcd}
H^n(Y;\mathbb{Z}_2) \arrow[rr, "\delta"] \arrow[dr, "f^*"] \arrow[dd, "\mathrm{Sq}^i"'] & & H^{n+1}(Y,B;\mathbb{Z}_2) \arrow[dr, "f^*"] \arrow[dd, "\mathrm{Sq}^i"] & \\
& H^n(X;\mathbb{Z}_2) \arrow[rr, "\delta"] \arrow[dd, "\mathrm{Sq}^i"] & & H^{n+1}(X,A;\mathbb{Z}_2) \arrow[dd, "\mathrm{Sq}^i"] \\
H^{n+i}(B;\mathbb{Z}_2) \arrow[rr] \arrow[dr, "f^*"] & & H^{n+i+1}(Y,B;\mathbb{Z}_2) \arrow[dr, "f^*"] & \\
& H^{n+i}(A;\mathbb{Z}_2) \arrow[rr, "\delta"] & & H^{n+i+1}(X,A;\mathbb{Z}_2).
\end{tikzcd}$$

It follows from the naturality of the Steenrod operations that the parallelograms to the left and right commute. Furthermore, it follows from the naturality of the connecting homomorphism, see Lemma 48.15, that the top and bottom parallelograms commute. Using these facts we can make the following two observations:

(i) If the square in the front commutes and if the map f^* to the bottom right is an isomorphism, then it follows from a stroll through the cube, as indicated in Figure 967, that the square in the back also commutes.

(ii) If the square in the back commutes and if the map f^* to the top left is an isomorphism, then it follows as in (i) that the square in the front also commutes.

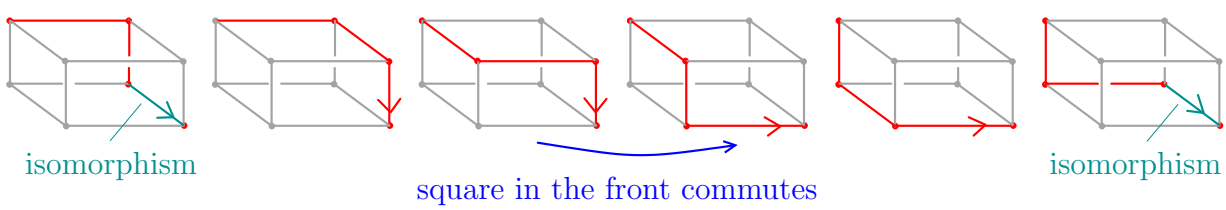

FIGURE 967.

Now we turn to the actual proof of the five steps in the claim.

(1) This statement follows immediately from the previous claim.
(2) We consider the inclusion map $f\colon (A \times [0, \frac{1}{2}], A \times \partial([0, \frac{1}{2}])) \to (\mathrm{Cyl}(i), B \cup C)$ and we consider the corresponding cube. By (1) we know that the square in the front commutes. We leave it to the reader to cleverly apply the Excision Theorem for Cohomology Groups 50.1 to show that the map f^* to the bottom right of the cube is an isomorphism. Thus we obtain from (i) that the square in the back commutes.
(3) We consider the inclusion map $f\colon (\mathrm{Cyl}(i), C) \to (\mathrm{Cyl}(i), B \cup C)$ and we consider the corresponding cube. By (2) we know that the square in the back commutes. Since on the first entry f is the identity we see that the top left map f^* is an isomorphism. Thus we obtain from (ii) that the square in the front also commutes.
(4) We consider the inclusion map $f\colon (\mathrm{Cyl}(i), A \times \{0\}) \to (\mathrm{Cyl}(i), \overbrace{A \times [0,1]}^{=C})$. By (3) we know that the square in the front commutes. Since $A \times \{0\}$ is a deformation retract of $A \times [0,1]$ we obtain from Lemma 48.13 (4) that the map f^* to the bottom right of the cube is an isomorphism. Thus we obtain from (i) that the square in the back also commutes.
(5) We consider the obvious inclusion

$$\begin{array}{rcl} f\colon X & \to & \mathrm{Cyl}(i) \\ x & \mapsto & [(x,1)]. \end{array}$$

It also defines a map $f\colon (X, A) \to (\mathrm{Cyl}(i), A \times [0,1])$ of pairs of topological spaces. We consider the corresponding cube. By (4) we know that the square in the back commutes. By Lemma 15.7 (1) the map $f\colon X \to \mathrm{Cyl}(i)$ is in fact a homotopy equivalence. Thus it follows from Lemma 48.13 that the top left f^* is an isomorphism. Therefore we obtain from (ii) that the square in the front commutes.

This concludes the proof of the claim. □

78.3. **Steenrod operations and suspensions.** In Proposition 78.8 we saw that Steenrod operations commute with connecting homomorphisms in cohomology. In this section we will use this fact to show that Steenrod operations behave well under taking suspensions. This fact will help us to obtain new information on homology groups of spheres.

First recall that in Proposition 32.14 we saw that taking the suspension $\Sigma(X)$ of a topological space shifts the reduced homology groups "upwards by one". The following proposition says that the same phenomenon occurs when we consider cohomology groups.

Proposition 78.11. *Let X be a non-empty topological space, let $n \in \mathbb{N}$[1322] and let G be an abelian group. As on page 818 we denote by C_-X and C_+X the "lower and upper half" of the suspension $\Sigma(X)$. We refer to Figure 968 for an illustration.*

[1322]Basically the same statement works for $n = 0$, the only nuisance is that in that case we need to work with reduced cohomology groups.

(1) *The following maps are isomorphisms:*[1323]

$$H^n(X;G) \xrightarrow{\delta} H^{n+1}(C_+X, X; G) \leftarrow H^{n+1}(\Sigma(X), C_-X; G) \to H^{n+1}(\Sigma(X); G).$$

Here the map to the left is the connecting homomorphism of the pair (C_+X, X) *from Lemma 48.15 The remaining two horizontal maps are induced by the obvious inclusion maps.*

(2) *The isomorphism*

$$\Sigma_X \colon H^n(X;G) \xrightarrow{\cong} H^{n+1}(\Sigma(X); G)$$

that is given by the maps in (1) *is in fact a natural isomorphism.*

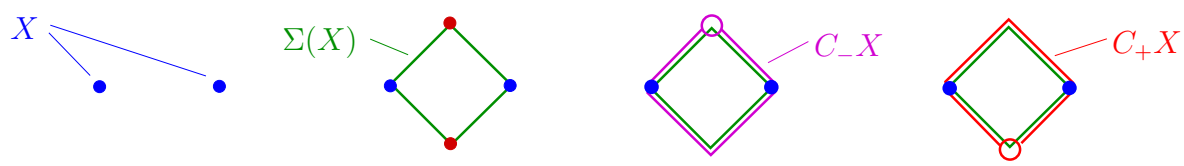

FIGURE 968. Illustration for Proposition 78.11.

Proof. The proof is a slight variation on the proof of Proposition 32.14. We leave it to the reader to fill in the details. □

The following proposition shows that Steenrod operations behave well under taking suspensions.

Proposition 78.12. *Given any topological space* X*, any* $n \in \mathbb{N}$ *and any* $i \in \mathbb{N}_0$ *the following diagram commutes:*

$$\begin{array}{ccc} H^n(X;\mathbb{Z}_2) & \xrightarrow[\cong]{\Sigma_X} & H^{n+1}(\Sigma(X);\mathbb{Z}_2) \\ \downarrow{\scriptstyle \mathrm{Sq}^i} & & \downarrow{\scriptstyle \mathrm{Sq}^i} \\ H^{n+i}(X;\mathbb{Z}_2) & \xrightarrow[\cong]{\Sigma_X} & H^{n+i+1}(\Sigma(X);\mathbb{Z}_2). \end{array}$$

Remark. The proposition says in particular that if there exists a non-trivial Steenrod operation on a topological space X, then its suspension inherits a non-trivial Steenrod operation. This is in so far interesting as we know by Lemma 58.6 that the cup product vanishes on suspensions. The fact that suspensions can have non-trivial Steenrod operations will allow us to prove several hitherto inaccessible results.

[1323]Here we use Lemma 15.2 (3) to identify X with the subset $C_-X \cap C_+X$ of $\Sigma(X)$.

Proof. We consider the following diagram

$$\begin{tikzcd}
H^n(X;\mathbb{Z}_2) \arrow[r, "\delta"'] \arrow[d, "\mathrm{Sq}^i"] \arrow[rrr, bend left, "\Sigma_X"] & H^{n+1}(C_+X, X;\mathbb{Z}_2) \arrow[d, "\mathrm{Sq}^i"] & H^{n+1}(\Sigma(X), C_-X;\mathbb{Z}_2) \arrow[l, "\cong"] \arrow[r, "\cong"'] \arrow[d, "\mathrm{Sq}^i"] & H^{n+1}(\Sigma(X);\mathbb{Z}_2) \arrow[d, "\mathrm{Sq}^i"] \\
H^{n+i}(X;\mathbb{Z}_2) \arrow[r, "\delta"] \arrow[rrr, bend right, "\Sigma_X"'] & H^{n+1+i}(C_+X, X;\mathbb{Z}_2) & H^{n+1+i}(\Sigma(X), C_-X;\mathbb{Z}_2) \arrow[l, "\cong"'] \arrow[r, "\cong"] & H^{n+1+i}(\Sigma(X);\mathbb{Z}_2).
\end{tikzcd}$$

The first square commutes by Proposition 78.8. The two other squares commute by the naturality of the Steenrod operation Sq^i. Thus we see that, as desired, the diagram commutes. $\square$

Next we recall that by the definitions on pages 726 and 1468 we have three different types of Hopf maps:

Definition. We consider the following maps

$$\underbrace{\begin{array}{rcl} H\colon S^3 & \to & S^2 = \mathbb{C}\mathrm{P}^1 \\ \underbrace{(z_1, z_2)}_{\in\mathbb{C}^2} & \mapsto & [z_1 : z_2] \end{array}}_{\text{the Hopf map}} \quad \underbrace{\begin{array}{rcl} H_{\mathbb{H}}\colon S^7 & \to & S^4 = \mathbb{H}\mathrm{P}^1 \\ \underbrace{(z_1, z_2)}_{\in\mathbb{H}^2} & \mapsto & [z_1 : z_2] \end{array}}_{\text{quaternionic Hopf map}} \quad \text{and} \quad \underbrace{\begin{array}{rcl} H_{\mathbb{O}}\colon S^{15} & \to & S^8 = \mathbb{O}\mathrm{P}^1 \\ \underbrace{(z_1, z_2)}_{\in\mathbb{O}^2} & \mapsto & [z_1 : z_2]. \end{array}}_{\text{octonionic Hopf map}}$$

In Theorem 63.3 we showed that the Hopf map $H\colon S^3 \to S^2$ is not null-homotopic. The key to doing so were the following two observations:

(1) The mapping cone $\mathrm{Cone}(H\colon S^3 \to S^2)$ is homeomorphic to $\mathbb{C}\mathrm{P}^2$.
(2) The cup product on $\mathbb{C}\mathrm{P}^2$ has the property that for a generator $\varphi \in H^2(\mathbb{C}\mathrm{P}^2;\mathbb{Z})$ the square φ^2 is non-zero.

Since the Steenrod operations are a generalization of the mod 2 "cup product square" and since Steenrod operations behave well with respect to suspensions it seems reasonable that we can use Steenrod operations to show that the suspensions of the Hopf maps are not null-homotopic.

Indeed, we can prove the following theorem.

Theorem 78.13.

(1) *For any $n \geq 2$ the $(n-2)$-fold suspension*

$$\Sigma^{n-2}(H)\colon \underbrace{\Sigma^{n-2}(S^3)}_{=S^{n+1}} \to \underbrace{\Sigma^{n-2}(S^2)}_{=S^n}$$

of the Hopf map defines a non-trivial element in $\pi_{n+1}(S^n)$. In particular for any $n \geq 2$ we have $\pi_{n+1}(S^n) \neq 0$.

(2) *For any $n \geq 4$ the $(n-4)$-fold suspension*

$$\Sigma^{n-4}(H_{\mathbb{H}})\colon \underbrace{\Sigma^{n-4}(S^7)}_{=S^{n+3}} \to \underbrace{\Sigma^{n-4}(S^4)}_{=S^n}$$

of the quaternionic Hopf map defines a non-trivial element in $\pi_{n+3}(S^n)$. In particular for any $n \geq 4$ we have $\pi_{n+3}(S^n) \neq 0$.

(3) *For any $n \geq 8$ the $(n-8)$-fold suspension*

$$\Sigma^{n-8}(H_{\mathbb{O}})\colon \underbrace{\Sigma^{n-8}(S^{15})}_{=S^{n+7}} \to \underbrace{\Sigma^{n-8}(S^8)}_{=S^n}$$

of the octonionic Hopf map defines a non-trivial element in $\pi_{n+7}(S^n)$. In particular for any $n \geq 8$ we have $\pi_{n+7}(S^n) \neq 0$.

Before we turn to the proof of Theorem 78.13 we recall, for the reader's convenience, the following, frequently overlooked, proposition which says that taking suspensions and taking mapping cones commutes.

Proposition 15.15. *If $f\colon X \to Y$ is a map between topological spaces, then there exists a homeomorphism*

$$g\colon \operatorname{Cone}(\Sigma(f)\colon \Sigma(X) \to \Sigma(Y)) \xrightarrow{\cong} \Sigma(\operatorname{Cone}(f\colon X \to Y)).$$

We also state the following lemma which we are already dimly aware of.

Lemma 78.14. *If a map $\varphi\colon S^m \to S^n$ is homotopic to a constant map, then the corresponding mapping cone* $\operatorname{Cone}(\varphi\colon S^m \to S^n)$ *is homotopy equivalent to $S^{m+1} \vee S^n$.*

Proof. We have

$$\operatorname{Cone}(\varphi\colon S^m \to S^n) \underset{\substack{\uparrow \\ \text{by Lemma 15.11, since } \varphi \text{ is homotopic to a constant map}}}{\simeq} \operatorname{Cone}(\text{constant map}\colon S^m \to S^n) \underset{\substack{\uparrow \\ \text{Lemma 63.1}}}{\cong} S^{m+1} \vee S^n.$$

□

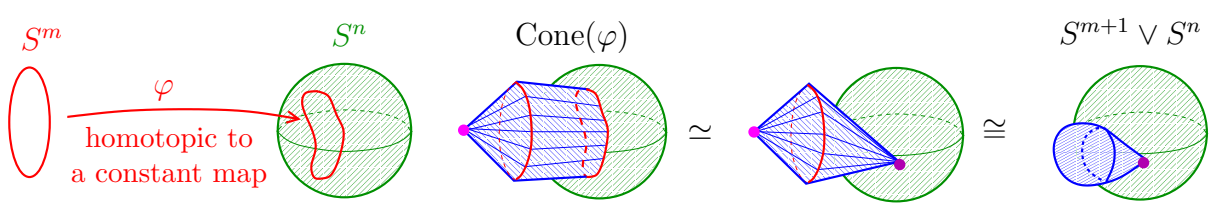

FIGURE 969. Illustration of Lemma 78.14.

Now we turn to the proof of Theorem 78.13. For clarity's sake we first provide a detailed proof of Theorem 78.13 (1). Afterwards we explain how to modify that proof to obtain statements (2) and (3) of Theorem 78.13.

Proof of Theorem 78.13 (1). In the following we will show that $\Sigma(H)\colon S^4 \to S^3$ is not homotopic to a constant map. The general statement regarding the $(n-2)$-fold suspension $\Sigma^{n-2}(H)$ follows easily from iterating the argument below.

For once we do a proof by contradiction. So let us assume that the map $\Sigma(H)\colon S^4 \to S^3$ is in fact homotopic to a constant map. We make the following preparations:

(1) To simplify the notation we denote the mapping cone of a map $f\colon X \to Y$ by $\mathrm{C}(f)$ instead of $\mathrm{Cone}(f)$. Furthermore we write $\mathbb{F} = \mathbb{Z}_2$.
(2) By Lemma 63.2 there exists a homeomorphism $f\colon\ \mathrm{C}(H\colon S^3 \to S^2) \xrightarrow{\cong} \mathbb{C}\mathrm{P}^2$.
(3) We denote by $g\colon \Sigma(\mathrm{C}(H)) \xrightarrow{\cong} \mathrm{C}(\Sigma(H))$ the homeomorphism from Proposition 15.15.
(4) Since we assume that the map H is homotopic to a constant map we obtain from Lemma 78.14 that there exists a homotopy equivalence $h\colon\ \mathrm{C}(\Sigma(H)) \to S^3 \vee S^5$.

Now we consider the following diagram:

$$\begin{tikzcd}
H^2(\mathbb{C}\mathrm{P}^2;\mathbb{F}) \arrow[r, "f^*", "\cong"'] \arrow[d, "x\mapsto x\cup x"'] \arrow[d, shift left=6, "\mathrm{Sq}^2"] & H^2(\mathrm{C}(H);\mathbb{F}) \arrow[r, "\Sigma", "\cong"'] \arrow[d, "\mathrm{Sq}^2"] & H^3(\Sigma(\mathrm{C}(H));\mathbb{F}) \arrow[r, "g^*", "\cong"'] \arrow[d, "\mathrm{Sq}^2"] & H^3(\mathrm{C}(\overbrace{\Sigma(H)}^{S^4\to S^3});\mathbb{F}) \arrow[d, "\mathrm{Sq}^2"] & H^3(S^5\vee S^3;\mathbb{F}) \arrow[l, "h^*"', "\cong"] \arrow[d, "\mathrm{Sq}^2"] \\
H^4(\mathbb{C}\mathrm{P}^2;\mathbb{F}) \arrow[r, "f^*", "\cong"'] & H^4(C(H);\mathbb{F}) \arrow[r, "\Sigma", "\cong"'] & H^5(\Sigma(\mathrm{C}(H));\mathbb{F}) \arrow[r, "g^*", "\cong"'] & H^5(\mathrm{C}(\Sigma(H));\mathbb{F}) & H^5(S^5\vee S^3;\mathbb{F}). \arrow[l, "h^*"', "\cong"]
\end{tikzcd}$$

We make the following observations:

(1) The maps Σ are the suspension isomorphisms given by Proposition 78.11.
(2) It follows from Axiom (2) that the two vertical maps on the left are actually the same.
(3) It follows from the naturality of Sq^2 that the first, third and the fourth square commute.
(4) It follows from Proposition 78.12 that the second square commutes.
(5) Since f and g are homeomorphism we see that the induced maps f^* and g^* are isomorphisms. Furthermore, since h is a homotopy equivalence we obtain from Lemma 48.13 (3) that the horizontal maps h^* are isomorphisms.
(6) By Proposition 62.13 we know that there exists a unique non-trivial $x \in H^2(\mathbb{C}\mathrm{P}^2;\mathbb{F})$ and that this element satisfies $x \cup x \neq 0 \in H^4(\mathbb{C}\mathrm{P}^2;\mathbb{F}) \cong \mathbb{F}$. In particular we see that the left vertical homomorphism is an isomorphism and that it is non-trivial.
(7) By Lemma 78.5 we know that the vertical homomorphism to the right is trivial.

In summary we have shown that the above diagram commutes, we have shown that all horizontal maps are isomorphisms, we have seen that the left vertical map is non-trivial and have pointed out that the right vertical map is trivial. But this is absurd. In other words, we have obtained a contradiction to our hypothesis that the map $\Sigma(H)\colon S^4 \to S^3$ is null-homotopic. $\square$

Proof of Theorem 78.13 (2) and (3). As we will see shortly, the proof for the quaternionic and octonionic Hopf maps is basically the same as the proof for the "classical" Hopf map.

Let us first consider the quaternionic Hopf. By Lemma 63.2 (2) there exists a homeomorphism $f\colon \mathrm{C}(H_{\mathbb{H}}) \xrightarrow{\cong} \mathbb{H}\mathrm{P}^2$. If $H_{\mathbb{H}}\colon S^7 \to S^4$ was null-homotopic we would, as in the proof of (1), obtain a commutative diagram of the following form:

$$\begin{tikzcd}
H^4(\mathbb{H}\mathrm{P}^2;\mathbb{F}) \arrow[r, "f^*", "\cong"'] \arrow[d, "x\mapsto x\cup x"'] \arrow[d, shift left, "\mathrm{Sq}^4"] & H^4(\mathrm{C}(H_{\mathbb{H}});\mathbb{F}) \arrow[r, "\Sigma"] \arrow[d, "\mathrm{Sq}^4"] & H^5(\Sigma(\mathrm{C}(H_{\mathbb{H}}));\mathbb{F}) \arrow[r, "g^*", "\cong"'] \arrow[d, "\mathrm{Sq}^4"] & H^5(\mathrm{C}(\overbrace{\Sigma(H_{\mathbb{H}})}^{S^8\to S^5});\mathbb{F}) \arrow[d, "\mathrm{Sq}^4"] & H^5(S^9\vee S^5;\mathbb{F}) \arrow[l, "h^*"', "\cong"] \arrow[d, "\mathrm{Sq}^4"] \\
H^8(\mathbb{H}\mathrm{P}^2;\mathbb{F}) \arrow[r, "f^*", "\cong"'] & H^8(C(H_{\mathbb{H}});\mathbb{F}) \arrow[r, "\Sigma"] & H^9(\Sigma(\mathrm{C}(H_{\mathbb{H}}));\mathbb{F}) \arrow[r, "g^*", "\cong"'] & H^9(\mathrm{C}(\Sigma(H_{\mathbb{H}}));\mathbb{F}) & H^9(S^9\vee S^5;\mathbb{F}) \arrow[l, "h^*"', "\cong"]
\end{tikzcd}$$

By Proposition 62.20 (1) the cup product on the left is non-trivial. Thus the same logic as in the proof of (1) leads to a contradiction.

The argument for the octonionic Hopf map is almost identical to the argument for the quaternionic Hopf map. We just need to work with Lemma 63.2 (3) and Proposition 62.20 (2). □

For the record we jot down the following proposition that we proved in the proof of Theorem 78.13. We will make use of it later on.

Proposition 78.15. $(*)$ *Given any $n \in \mathbb{N}_0$ the maps*

$$\begin{array}{lrcl}
(1) & \mathrm{Sq}^2\colon H^{2+n}(\mathrm{Cone}(\Sigma^n(H));\mathbb{Z}_2) & \to & H^{4+n}(\mathrm{Cone}(\Sigma^n(H));\mathbb{Z}_2) \\
(2) & \mathrm{Sq}^4\colon H^{4+n}(\mathrm{Cone}(\Sigma^n(H_{\mathbb{H}}));\mathbb{Z}_2) & \to & H^{8+n}(\mathrm{Cone}(\Sigma^n(H_{\mathbb{H}}));\mathbb{Z}_2) \\
(3) & \mathrm{Sq}^8\colon H^{8+n}(\mathrm{Cone}(\Sigma^n(H_{\mathbb{O}}));\mathbb{Z}_2) & \to & H^{16+n}(\mathrm{Cone}(\Sigma^n(H_{\mathbb{O}}));\mathbb{Z}_2)
\end{array}$$

are isomorphisms.

78.4. **Proof of Theorem 78.2 I.** In the final two sections we will give a partial proof of Theorem 78.2. More precisely, we will construct the Steenrod operations and we will provide the proof of some of the properties. The proof is split into two parts:

(1) The goal of this section is to construct a certain interesting sequence of natural maps $\Delta_n\colon C_*(X)\otimes C_*(X)\otimes C_*(X)$, $n\in\mathbb{N}_0$, where the zeroth map Δ_0 is a diagonal approximation.
(2) In the subsequent section we will show how this sequence of maps can be used to define the Steenrod operations.

In preparation for the construction of the sequence Δ_n we recall some definitions and results from earlier on. First recall that on page 1041 we introduced the tensor product $A_*\otimes B_*$ of two chain complexes A_* and B_*. We will make use of the following harmless lemma.

Lemma 60.7. *Let A_* and B_* be chain complexes. The unique map*

$$T\colon A_* \otimes B_* \;\to\; B_* \otimes A_*$$

that for $a \in A_k$ and $b \in B_l$ is given by

$$a \otimes b \;\mapsto\; (-1)^{kl} \cdot b \otimes a$$

is a chain map.

Since we will make use of this later on we point out that T is natural in A_* and B_* and we point out that $T^2 = \mathrm{id}$. Next we recall the following definition from page 1338.

Definition. A *diagonal approximation* consists of a natural chain map

$$\Phi\colon C_*(X) \;\to\; C_*(X) \otimes C_*(X)$$

for each topological space X, such that for each $x \in X$, viewed as a singular 0-simplex, the following equality holds in $(C_*(X) \otimes C_*(X))_0 = C_0(X) \otimes C_0(X)$:

$$\Phi(x) \;=\; x \otimes x.$$

Example. We will try to rise to the challenge of finding a suitable illustration for a diagonal approximation Φ. We start out with the following observation: if $\sigma\colon \Delta^1 \to X$ is a singular 1-simplex from a point P to a point Q, then $\Phi(\sigma) \in (C_*(X) \otimes C_*(X))_1$ needs to satisfy

$$\partial\Phi(\sigma) \;\underset{\substack{\uparrow \\ \text{since } \Phi \text{ is a chain map}}}{=}\; \Phi(\partial\sigma) \;=\; \Phi(P - Q) \;=\; \Phi(P) - \Phi(Q) \;\underset{\substack{\uparrow \\ \text{since } \Phi \text{ is determined on singular 0-simplices}}}{=}\; Q \otimes Q \;-\; P \otimes P.$$

For example $\Phi(\sigma) = (C_*(X) \otimes C_*(X))_1 = C_1(X) \otimes C_0(X) \oplus C_0(X) \otimes C_1(X)$ could be of the form $\alpha \otimes P + Q \otimes \beta$ where $\alpha\colon \Delta^1 \to X$ and $\beta\colon \Delta^1 \to X$ are singular simplices from P to Q. This situation is illustrated, with artistic liberties, in Figure 970.

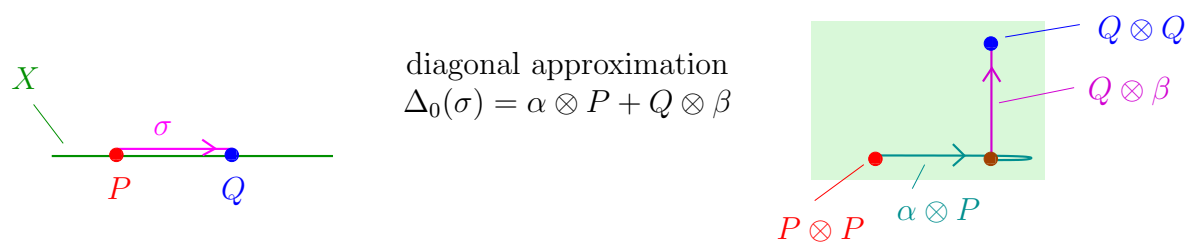

FIGURE 970.

The following proposition contains the two key results on diagonal approximations.

Proposition 57.6.

(1) *There exist diagonal approximations.*

(2) *Given any two diagonal approximations Φ and Ψ there exists a natural chain homotopy equivalence between Φ and Ψ.*

Proof. We gave an explicit example of a diagonal approximation in Lemma 57.5. In Proposition 56.17 we gave a proof of (2) using the Acyclic Model Theorem 56.16 (2). □

The following theorem shows that any diagonal approximation can be extended to a sequence of maps.

Theorem 78.16.

(1) *Given any topological space X there exists a sequence of natural maps*

$$\Delta_n \colon C_*(X) \;\to\; C_*(X) \otimes C_*(X), \quad n \in \mathbb{N}_0$$

of degree n[1324] *such that the following two conditions are satisfied:*
(a) *The map Δ_0 is a diagonal approximation.*
(b) *For every $n \in \mathbb{N}_0$ the following equality holds:*[1325]

$$\partial \circ \Delta_{n+1} + (-1)^n \cdot \Delta_{n+1} \circ \partial \;=\; (T + (-1)^{n+1} \cdot \mathrm{id}) \circ \Delta_n.$$

(2) *Given two sequences Δ_n, Δ'_n, $n \in \mathbb{N}_0$, as in (1) there exists a sequence of natural maps*

$$H_n \colon C_*(X) \;\to\; C_*(X) \otimes C_*(X), \quad n \in \mathbb{N}_0$$

of degree n such that the following two conditions are satisfied:
(a) *H_0 is the zero map.*
(b) *For every $n \in \mathbb{N}_0$ the following equality holds:*[1326]

$$\partial \circ H_{n+1} + (-1)^n \cdot H_{n+1} \circ \partial \;=\; \Delta_n - \Delta'_n - (T + (-1)^n \cdot \mathrm{id}) \circ H_n.$$

In the proof of Theorem 78.16 we will need the following innocuous variation on the definition of a chain map that we had given on page 745.

Definition.

(1) A *chain map $f \colon C_* \to D_*$ of degree d* between two chain complexes consists of a family $\{f_n \colon C_n \to D_{n+d}\}_{n \in \mathbb{N}_0}$ of maps such that for each $n \in \mathbb{N}_0$ the following equality holds:

$$f_{n-1} \circ \partial_n \;=\; \partial_{n+d} \circ f_n.$$

(2) An *anti-chain map $f \colon C_* \to D_*$ of degree d* is basically the same data as a chain map of degree d, except that for each $n \in \mathbb{N}_0$ the following equality holds:

$$f_{n-1} \circ \partial_n \;=\; -\partial_{n+d} \circ f_n.$$

[1324] By a map of degree n between chain complexes C_* and D_* we mean a collection of maps $C_k \to D_{k+n}$, $k \in \mathbb{N}_0$.

[1325] Note that both sides are maps $C_*(X) \to C_*(X) \otimes C_*(X)$ of degree n.

[1326] In other words, the map H_{n+1} is a chain homotopy between Δ_n and Δ'_n up to the "error term" $-(T + (-1)^n \cdot \mathrm{id}) \circ H_n$.

Remark. Given an anti-chain map $\{f_n\}_{n\in\mathbb{N}_0}$ of degree d one can easily see that the maps $\{(-1)^n \cdot f_n\}_{n\in\mathbb{N}_0}$ form a chain map of degree d. This little trick makes it possible to translate all kinds of statements about chain maps to anti-chain maps. For example, as in Lemma 29.7 we see that an anti-chain map induces a map on homology groups.

In the proof of Theorem 78.16 we will need the following consequence of the Acyclic Model Theorem 56.13.

Theorem 78.17. (Acyclic Model Theorem) *Let $\mathcal{T}$ be the category of topological spaces and let $\mathcal{C}$ be the category of generalized*[1327] *chain complexes.*

(1) *Let $S\colon C_*(X) \to C_*(X) \otimes C_*(X)$ be a natural chain map of degree d. If we have $d \geq 1$, then for any topological space X and any $k \in \mathbb{N}$ there exists a natural map $P_X\colon C_k(X) \to (C_*(X) \otimes C_*(X))_{k+d+1}$ such that for any $k \in \mathbb{N}_0$ we have*

$$\partial \circ P_X + P_X \circ \partial \;=\; S_X\colon C_k(X) \;\to\; (C_*(X) \otimes C_*(X))_{k+d}.$$

(2) *For a natural anti-chain map $S\colon C_*(X) \to C_*(X) \otimes C_*(X)$ of degree d the analogous data exists except that now we have*

$$\partial \circ P_X - P_X \circ \partial \;=\; S_X\colon C_k(X) \;\to\; (C_*(X) \otimes C_*(X))_{k+d}.$$

Proof of the Acyclic Model Theorem 78.17.

(1) Given any topological space X we consider $G(X) := (C_*(X) \otimes C_*(X))[-d]$. Here we use the notation introduced on page 1392, namely given a chain complex D_* we denote by $D_*[-d]$ the chain complex D_* "shifted by d to the right". This shift turns $G(X)$ into a generalized chain complex. Furthermore, this shift turns $S\colon C_*(X) \to G(X)$ into a natural chain map of degree 0.

Next note that for any $k \in \mathbb{N}_0$ and any $i \geq 0$ we have

$$\begin{array}{rclcl} H_i(G(\Delta^k)) & = & H_i((C_*(X) \otimes C_*(\Delta^k))[-d]) & = & H_{i+d}(C_*(\Delta^k) \otimes C_*(\Delta^k)) \\ & = & \bigoplus\limits_{p+q=i+d} H_p(\Delta^k) \otimes H_q(\Delta^k) & = & 0. \\ & \uparrow & & \uparrow & \\ & \text{by the Künneth Theorem 43.7} & & \text{by the calculation of } H_*(\Delta^k) & \\ & \text{for chain complexes} & & \text{and since } d \geq 1 & \end{array}$$

Thus we see that all the hypothesis of the Acyclic Model Theorem 56.13 are satisfied. Therefore we see that for any topological space X and any $k \in \mathbb{N}_0$ there exists a natural map $P_X\colon C_k(X) \to G_{k+1}(X)$ such that for any $k \in \mathbb{N}_0$ we have

$$\partial \circ P_X + P_X \circ \partial \;=\; S_X\colon C_k(X) \;\to\; G_k(X).$$

(2) Suppose we are given a natural anti-chain map S of degree d. As in the remark preceding the theorem, we can turn S into a natural chain map T by defining $T_k = (-1)^k \cdot S_k$, $k \in \mathbb{N}_0$. We apply (1) and we obtain natural maps Q_X. We

[1327] Recall that a generalized chain complex is like a chain complex except that we allow chain groups in negative degrees.

now define $P_k := (-1)^k \cdot \widetilde{P}_k$, $k \in \mathbb{N}_0$. One easily verifies that the desired equality holds. $\square$

Now, finally, we can turn to the actual proof of Theorem 78.16.

Proof of Theorem 78.16.

(1) We construct the maps $\Delta_n \colon C_*(X) \to C_*(X) \otimes C_*(X)$, $n \in \mathbb{N}_0$ iteratively.

(i) First of all, we know by the Proposition 57.6 (1) above that there exists a diagonal approximation $\Delta_0 \colon C_*(X) \to C_*(X) \otimes C_*(X)$.

(ii) Note that $T \circ \Delta_0 \colon C_*(X) \to C_*(X) \otimes C_*(X)$ is another diagonal approximation. It follows from Proposition 57.6 (2) that there exists a natural chain homotopy $\Delta_1 \colon C_*(X) \to C_*(X) \otimes C_*(X)$ between Δ_0 and $T \circ \Delta_0$. In other words, there exists a natural map $\Delta_1 \colon C_*(X) \to C_*(X) \otimes C_*(X)$ of degree one such that

$$\partial \circ \Delta_1 + \Delta_1 \circ \partial = \underbrace{T \circ \Delta_0 - \Delta_0}_{=(T-\mathrm{id})\circ\Delta_0}.$$

Thus we are done with the construction of the map Δ_1. This step is illustrated in Figure 971.

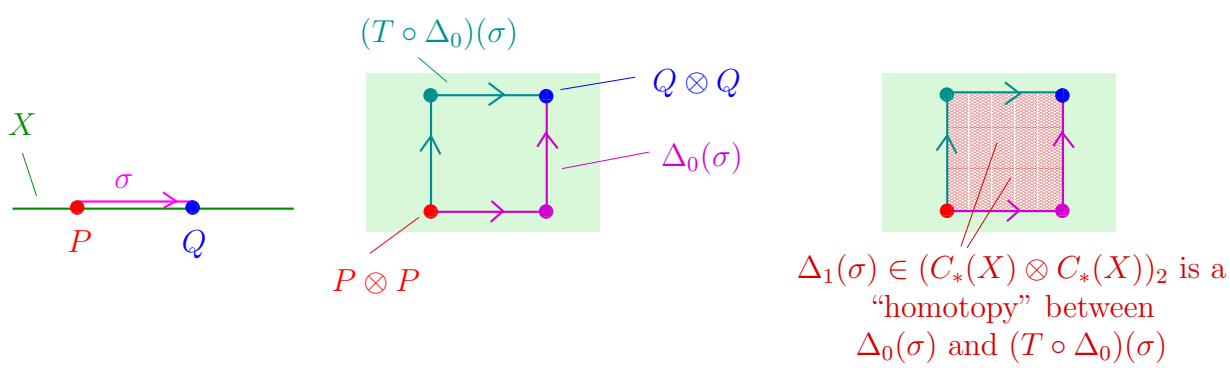

FIGURE 971.

(iii) The starting point for defining the next map Δ_2 is the following amusing little calculation:[1328]

$$\begin{aligned} 0 \overset{\text{since } T^2 = \mathrm{id}}{=} (T^2 - \mathrm{id}) \circ \Delta_0 &= (T + \mathrm{id}) \circ (T - \mathrm{id}) \circ \Delta_0 \overset{\text{by (ii)}}{=} (T + \mathrm{id}) \circ (\partial \circ \Delta_1 + \Delta_1 \circ \partial) \\ &\underset{\substack{\uparrow \\ \text{since } T \text{ and id are chain maps they commute with the boundary maps}}}{=} \partial \circ (T + \mathrm{id}) \circ \Delta_1 + (T + \mathrm{id}) \circ \Delta_1 \circ \partial. \end{aligned}$$

[1328]These are equalities of maps $C_*(X) \to C_*(X) \otimes C_*(X)$.

This shows that the map $(T+\mathrm{id})\circ\Delta_1\colon C_*(X)\to C_*(X)\otimes C_*(X)$ is a natural anti-chain map of degree one. By the Acyclic Model Theorem 78.17 (2) there exists a natural map $\Delta_2\colon C_*(X)\to C_*(X)\otimes C_*(X)$ of degree two such that

$$\partial\circ\Delta_2-\Delta_2\circ\partial \;=\; (T+\mathrm{id})\circ\Delta_1.$$

This conclude the construction of the map Δ_2.

(iv) Just for kicks we do the calculation for the next stage as well. We perform the following calculation:

$$\begin{aligned}
0 \;\overset{\substack{\text{since } T^2=\mathrm{id}\\ \downarrow}}{=}\; (T^2-\mathrm{id})\circ\Delta_1 \;&=\; (T-\mathrm{id})\circ(T+\mathrm{id})\circ\Delta_1 \;\overset{\substack{\text{by (iii)}\\ \downarrow}}{=}\; (T-\mathrm{id})\circ(\partial\circ\Delta_2-\Delta_2\circ\partial)\\
&\underset{\substack{\uparrow\\ \text{since } T \text{ and id are chain maps they commute with the boundary maps}}}{=}\; \partial\circ(T-\mathrm{id})\circ\Delta_2-(T-\mathrm{id})\circ\Delta_2\circ\partial.
\end{aligned}$$

This shows that the map $(T-\mathrm{id})\circ\Delta_2\colon C_*(X)\to C_*(X)\otimes C_*(X)$ is a natural chain map of degree two. By the Acyclic Model Theorem 78.17 (1) there exists a natural map $\Delta_3\colon C_*(X)\to C_*(X)\otimes C_*(X)$ of degree three such that

$$\partial\circ\Delta_3+\Delta_3\circ\partial \;=\; (T-\mathrm{id})\circ\Delta_2.$$

This conclude the construction of the map Δ_3.

(iv) We now iterate this procedure and we obtain the desired sequence of natural maps Δ_n.

(2) Given two sequences Δ_n,Δ_n' as in (1) we define the desired maps H_n, $n\in\mathbb{N}_0$ in a fashion that is quite similar to the approach taken in (1).

(i) We set $H_0=0$.

(ii) Nextwe point out that by definition Δ_0 and Δ_0' are diagonal approximations. Thus it follows from Proposition 57.6 (2) that there exist natural maps H_1 such that $\partial\circ H_1+H_1\circ\partial=\Delta_0-\Delta_0'$.

(iii) We calculate that

$$\begin{aligned}
&\partial\circ(\Delta_1-\Delta_1'-(T-\mathrm{id})\circ H_1)+(\Delta_1-\Delta_1'-(T-\mathrm{id})\circ H_1)\circ\partial\\
&\quad=\; (\partial\circ\Delta_1+\Delta_1\circ\partial)-(\partial\circ\Delta_1'+\Delta_1'\circ\partial)-\partial\circ(T-\mathrm{id})\circ H_1-(T-\mathrm{id})\circ H_1\circ\partial\\
&\quad\underset{\substack{\uparrow\\ \text{since } \partial\circ\Delta_1+\Delta_1\circ\partial=(T-\mathrm{id})\circ\Delta_0 \text{ (same for } \Delta_0',\Delta_1')\\ \text{and since } T \text{ and id are chain maps}}}{=}\; (T-\mathrm{id})\circ(\Delta_0-\Delta_0')-(T-\mathrm{id})\circ(\partial\circ H_1+H_1\circ\partial) \;\underset{\substack{\uparrow\\ \text{since } \partial\circ H_1+H_1\circ\partial=\Delta_0-\Delta_0'}}{=}\; 0.
\end{aligned}$$

This shows that $\Delta_1-\Delta_1'-(T-\mathrm{id})\circ H_1$ is an anti-chain map of degree one. By the Acyclic Model Theorem 78.17 (2) there exists a natural map H_2 with

$$H_2\circ\partial-\partial\circ H_2 \;=\; -(T-\mathrm{id})\circ H_1+\Delta_1-\Delta_1'.$$

(iv) Now we iterate this procedure to obtain the desired sequence of natural maps. One easily sees that we get the correct pattern for the signs involved. $\square$

Remark. If there did exist a diagonal approximation $\Delta_0\colon C_*(X) \to C_*(X) \otimes C_*(X)$ that is symmetric in the sense that $T \circ \Delta_0 = \Delta_0$, then we could take $\Delta_1 = 0$ and we could also take all higher Δ_n to be zero. Later on we will see that this is in general not the case. So even though diagonal approximations are symmetric on the degree 0 level, they cannot be chosen to be symmetric in higher degrees.

78.5. **Proof of Theorem 78.2 II.** In this section we will use the sequence of natural maps $\Delta_n\colon C_*(X) \to C_*(X) \otimes C_*(X)$, $n \in \mathbb{N}_0$, from Theorem 78.16 to define the Steenrod operations.

To get an inspiration for how to define the Steenrod operations we first recall the definition of the cup product. To do so we need the following lemma which is inspired by the definitions on from page 1332.

Lemma 78.18. *Let $\mathcal{C}_*$ and $\mathcal{D}_*$ be chain complexes and let R be a commutative ring. Given $p, q \in \mathbb{N}_0$ we consider the map*[1329]

$$\begin{aligned} \Xi_{p,q}\colon \operatorname{Hom}(\mathcal{C}_p, R) \otimes \operatorname{Hom}(\mathcal{D}_q, R) &\to \operatorname{Hom}((\mathcal{C} \otimes \mathcal{D})_{p+q}, R) \\ \varphi \otimes \psi &\mapsto \left(\begin{array}{rcl} (\mathcal{C}_* \otimes \mathcal{D}_*)_{p+q} \xrightarrow{\text{projection}} \mathcal{C}_p \otimes \mathcal{D}_q \xrightarrow{\varphi\otimes\psi} R \otimes R & \to & R \\ a \otimes b & \mapsto & a \cdot b \end{array} \right). \end{aligned}$$

The corresponding map

$$\Xi := \bigoplus_{p,q\in\mathbb{N}_0} \Xi_{p,q}\colon \operatorname{Hom}(\mathcal{C}_*, R) \otimes \operatorname{Hom}(\mathcal{D}_*, R) \quad \to \quad \operatorname{Hom}(\mathcal{C}_* \otimes \mathcal{D}_*, R)$$

is a cochain map.

Proof. The statement follows basically immediately from the definitions. □

The following lemma gives us a slight reformulation of the original definition of the cup product.

Lemma 78.19. *Let X be a topological space and let R be a commutative ring. Furthermore let $\Delta_0\colon C_*(X) \to C_*(X) \otimes C_*(X)$ be a diagonal approximation. We consider the cochain map*

$$\begin{tikzcd} \operatorname{Hom}(C_*(X), R) \otimes \operatorname{Hom}(C_*(X), R) \arrow[r, "\Xi"] \arrow[rr, bend right, "=:h_0"'] & \operatorname{Hom}(C_*(X) \otimes C_*(X), R) \arrow[r, "\Delta_0^*"] & \operatorname{Hom}(C_*(X), R). \end{tikzcd}$$

The corresponding map

$$\begin{array}{rcl} H^p(X;R) \times H^q(X;R) & \to & H^{p+q}(X;R) \\ ([\varphi],[\psi]) & \mapsto & [h_0(\varphi \otimes \psi)] \end{array}$$

equals the cup product as defined on page 1333.

[1329]The tensor product of cochain complexes is defined basically the same way as we defined the tensor product of chain complexes, see page 1041.

Proof $(*)$. Let $d\colon X \to X \times X$ be the diagonal map that is given by $d(x) = (x, x)$. Furthermore let $\Theta\colon C_*(X \times X) \to C_*(X) \otimes C_*(X)$ denote a Eilenberg-Zilber map from Theorem 56.1. For the purpose of this proof the only thing we need to know about the Eilenberg-Zilber map Θ is that, basically by definition, the map $\Theta \circ d\colon C_*(X) \to C_*(X \times X) \to C_*(X) \otimes C_*(X)$ is a diagonal approximation. We consider the following diagram:

$$\begin{tikzcd}
\mathrm{Hom}(C_*(X), R) \otimes \mathrm{Hom}(C_*(X), R) \arrow[r, "\Xi"] \arrow[rr, bend left, "=:h_0"] & \mathrm{Hom}(C_*(X) \otimes C_*(X), R) \arrow[r, "\Delta_0^*"] \arrow[d, "\Theta^*"] & \mathrm{Hom}(C_*(X), R) \\
& \mathrm{Hom}(C_*(X \times X), R). \arrow[ur, "d^*"'] &
\end{tikzcd}$$

The lower sequence of maps is at the heart of the definition of the cup product on page 1333. Since $\Theta \circ d$ is a diagonal approximation we obtain from Proposition 57.6 that Δ_0 and $\Theta \circ d$ are chain homotopic. But by Lemma 48.8 (4) this means that the two maps induce the same map on cohomology. The lemma follows almost immediately from the above observations. $\square$

Now we turn to the actual construction of the Steenrod operations. To do so we pick a sequence of natural maps

$$\Delta_n\colon C_*(X) \;\to\; C_*(X) \otimes C_*(X), \quad n \in \mathbb{N}_0$$

which satisfies the conditions set out in Theorem 78.16 (1). In light of Lemma 78.19 it is clear what we want to do next. Namely we want to replace Δ_0 by the "higher maps" Δ_n. This leads us straight to the following definition.

Definition. Let X be a topological space and let R be a commutative ring. Given $i \in \mathbb{N}_0$ we define

$$\begin{tikzcd}
\mathrm{Hom}(C_*(X), R) \otimes \mathrm{Hom}(C_*(X), R) \arrow[r, "\Xi"] \arrow[rr, bend right, "=:h_i"'] & \mathrm{Hom}(C_*(X) \otimes C_*(X), R) \arrow[r, "\Delta_i^*"] & \mathrm{Hom}(C_*(X), R).
\end{tikzcd}$$

Recall that Δ_i is a map of degree i. Since we dualize we see that Δ_i is a map of degree $-i$. For convenience we define $h_i := 0$ for $i \in \mathbb{Z}_{<0}$.

Now we can finally define the Steenrod operations.

Theorem 78.20. *Let X be a topological space, let $A \subset X$ be a subset and let R be a commutative ring. If $1 + 1 = 0$ in R, then for any $q \in \mathbb{N}_0$ and any $i \in \mathbb{N}_0$ the map*

$$\begin{array}{rcl}
\mathrm{Sq}^i\colon H^q(X, A; R) & \to & H^{q+i}(X, A; R) \\
[\underbrace{\varphi}_{\in C^q(X;R)}] & \mapsto & [h_{q-i}(\underbrace{\varphi \otimes \varphi}_{\in C^q \otimes C^q})]
\end{array}$$

is a well-defined natural homomorphism.

Remark. The proof of Theorem 78.20 that we give below is a long and winding calculation, with few interesting view points. Perhaps more interesting than the question, why the definition works, is the question, why does the map

$$\begin{array}{rcl} C^q(X,A;R)\otimes C^r(X,A;R) & \to & C^{q+r+j}(X,A;R) \\ \varphi\otimes\psi & \mapsto & h_j(\underbrace{\varphi\otimes\psi}_{\in C^q\otimes C^r}) \end{array}$$

not descend to a map on cohomology?

The proof of Theorem 78.20 requires some preparations. First of all, note that the equalities in Theorem 78.16 translate into the following lemma.

Lemma 78.21. *Let X be a topological space and let R be a commutative ring with $1+1=0$. For any $\alpha,\beta\in C^*(X;R)$ we have the following equality:*

$$h_{n+1}(\delta(\alpha\otimes\beta))+\delta(h_{n+1}(\alpha\otimes\beta)) \;=\; h_n(\alpha\otimes\beta+\beta\otimes\alpha) \;\in\; C^*(X;R).$$

Proof. Recall, see Theorem 78.16, that one of the defining properties of the sequence Δ_n is that for every $n\in\mathbb{N}_0$ the following equality holds:

$$\partial\circ\Delta_{n+1}+(-1)^n\cdot\Delta_{n+1}\circ\partial \;=\; (T+(-1)^{n+1}\cdot\mathrm{id})\circ\Delta_n.$$

We dualize this equality, we use the equality $1+1=0$, we use the fact, shown in Lemma 78.18 and that Ξ is a cochain map. After performing all these steps one obtains the desired equality. We leave it to the reader to fill in the few remaining details. □

For elements of the form $\alpha\otimes\alpha$ the following lemma shows how the maps h_n relate to coboundaries.

Lemma 78.22. *Let X be a topological space and let R be a commutative ring. If $1+1=0$ in R, then for any $\alpha\in C^q(X;R)$ we have*

$$h_{n+1}(\delta\alpha\otimes\delta\alpha) \;=\; \delta h_{n+1}(\alpha\otimes\delta\alpha)+\delta h_n(\alpha\otimes\alpha) \;\in\; C^{n+1}(X;R).$$

Proof. Since we assume that $1+1=0$ in R we can ignore conveniently enough ignore signs throughout the proof. Thus we compute

$$\begin{array}{rcl} & \text{since } \delta(c\otimes d)=\delta c\otimes d+c\otimes\delta d & \text{Lemma 78.21} \\ & \downarrow & \downarrow \\ h_{n+1}(\delta\alpha\otimes\delta\alpha) & = & h_{n+1}(\delta(\alpha\otimes\delta\alpha)) \\ & = & \delta h_{n+1}(\alpha\otimes\delta\alpha)+h_n(\delta(\alpha\otimes\alpha)) \\ & \uparrow & \uparrow \\ & \text{definition of } \delta \text{ on tensor product} & \text{by Lemma 78.21 and since } h_{n-1}(\underbrace{a\otimes a+a\otimes a}_{=0 \text{ since } 1+1=0})=0 \end{array}$$

$$\begin{array}{rcl} & \text{Lemma 78.21} \\ & \downarrow \\ h_{n+1}(\delta\alpha\otimes\delta\alpha) & = & \delta h_{n+1}(\alpha\otimes\delta\alpha)+h_n(\alpha\otimes\delta\alpha+\delta a\otimes\alpha) \\ & = & \delta h_{n+1}(\alpha\otimes\delta\alpha)+\delta h_n(\alpha\otimes\alpha). \\ & \uparrow & \end{array}$$

□

In the proof of Theorem 78.20 we will need the following little lemma.

Lemma 78.23. *Let X be a topological space and let R be a commutative ring with $1+1=0$. For any $\alpha,\beta\in C^q(X;R)$ the following equality holds:*

$$h_n((\alpha+\beta)\otimes(\alpha+\beta))=h_n(\alpha\otimes\alpha)+h_n(\beta\otimes\beta)+h_{n+1}(\delta(\alpha\otimes\beta))+\delta(h_{n+1}(\alpha\otimes\beta)).$$

Proof of Lemma 78.23. This follows from "multiplying out", the linearity of h_n and the equality

$$h_n(\alpha\otimes\beta+\beta\otimes\alpha) \underset{\substack{\uparrow \\ \text{by Lemma 78.21}}}{=} h_{n+1}(\delta(\alpha\otimes\beta))+\delta(h_{n+1}(\alpha\otimes\beta)).$$

□

Now, after these lengthy preparations we can provide the proof of Theorem 78.20.

Proof of Theorem 78.20. Let X be a topological space, let $A\subset X$ be a subset and let R be a commutative ring. First we consider the case that $A=\varnothing$. Let $\varphi\in C^q(X;R)$ be a representative of some element in $H^q(X;R)$.

(1) Note that $\varphi\otimes\varphi$ is of degree $2q$. Thus $h_{q-i}(\varphi\otimes\varphi)$ is of degree $2q-(q-i)=q+i$.
(2) Let $\varphi\in C^q(X;R)$ be a cocycle. We calculate that

$$\delta h_{q-i}(\varphi\otimes\varphi) \underset{\substack{\uparrow \\ \text{Lemma 78.21}}}{=} h_{q-i}(\delta(\varphi\otimes\varphi))+h_{q-i-1}(\overbrace{\varphi\otimes\varphi+\varphi\otimes\varphi}^{=0 \text{ since } 1+1=0}) \underset{\substack{\uparrow \\ \text{definition of } \delta \text{ on tensor product}}}{=} h_{q_i}(\delta\varphi\otimes\varphi+\varphi\otimes\delta\varphi) \underset{\substack{\uparrow \\ \text{since } \varphi \text{ is a coycle}}}{=} 0.$$

Thus we have shown that $h_{q-i}(\varphi\otimes\varphi)$ is a cocycle. In other words, we have shown that it defines an element in cohomology.
(3) Let $\psi\in C^{q-1}(X;R)$. We have the following equality in $H^{q+i}(X;R)$:

$$[h_{q-i}((\varphi+\delta\psi)\otimes(\varphi+\delta\psi))] \underset{\substack{\uparrow \\ \text{by Lemma 78.23, here we use that } \delta(\varphi\otimes\delta\psi)=\delta\varphi\otimes\delta\psi+\varphi\otimes\delta\delta\psi=0}}{=} [h_{q-i}(\varphi\otimes\varphi)+h_{q-i}(\delta\psi\otimes\delta\psi)] \underset{\substack{\uparrow \\ \text{Lemma 78.22}}}{=} [h_{q-i}(\varphi\otimes\varphi)].$$

This shows that the map Sq^i is well-defined, i.e. it does not depend on the choice of the representative of the cohomology class.
(4) It follows quite easily from Lemma 78.23 that Sq^i is in fact a homomorphism.

Finally we consider the case that $A\neq\varnothing$. Using the observation on page 1170 we make the identification

$$C^q(X,A;R) \;=\; \{\varphi\in C^q(X;R)=\mathrm{Hom}(C_q(X),R)\,|\,\varphi \text{ vanishes on } C_q(A)\subset C_q(X)\}.$$

It follows from the naturality of h_n that if $\varphi\in C_q(X)$ vanishes on $C_q(A)$, then $h_{q-i}(\varphi\otimes\varphi)$ vanishes on the subgroup $C_*(A)\otimes C_*(X)+C_*(X)\otimes C_*(A)$ of $C_*(X)\otimes C_*(X)$. Thus we see that the map

$$\begin{array}{rcl}\mathrm{Sq}^i\colon H^q(X,A;R) & \to & H^{q+i}(X,A;R)\\ [\underbrace{\varphi}_{\in C^q(X;R)}] & \mapsto & [h_{q-i}(\varphi\otimes\varphi)]\end{array}$$

is well-defined. □

We continue with the following proposition.

Proposition 78.24. *The definition of the maps* Sq^i *does not depend on the choice of the natural maps* Δ_n.

Proof. Suppose we are given another sequence of maps $\widetilde{\Delta}_n$ that have the properties described in Theorem 78.16 (1). We define $\widetilde{h}_i$ in the obvious way. By Theorem 78.16 (2) there exists a sequence of natural maps

$$H_n\colon C_*(X) \;\to\; C_*(X)\otimes C_*(X), \quad n\in\mathbb{N}_0$$

of degree n such that $H_0=0$ and such that for every $n\in\mathbb{N}_0$ the following equality holds:

$$(\,*\,) \qquad \partial\circ H_{n+1} + (-1)^n\cdot H_{n+1}\circ\partial \;=\; \Delta_n - \widetilde{\Delta}_n - (T+(-1)^n\cdot \mathrm{id})\circ H_n.$$

Given a cocycle $\varphi\in C^q(X,A;Z_2)$ and $i\in\mathbb{N}_0$ we see that we have the following equality in $H^{q+i}(X,A;R)$:

$$\begin{aligned}
[h_i(\varphi\otimes\varphi)] - [\widetilde{h}_i(\varphi\otimes\varphi)] \;&\overset{\text{definition of } h_i,\widetilde{h}_i}{=}\; [\Delta_i^*(\Xi(\varphi\otimes\varphi)) - \widetilde{\Delta}_i^*(\Xi(\varphi\otimes\varphi))]\\
&\underset{\substack{\text{by } (*) \text{ and since } 1+1=0\\ \text{since } \Xi \text{ is a cochain map and}\\ \text{since } \Xi \text{ commutes with } T}}{=}\; [H_{n+1}^*(\delta(\Xi(\varphi\otimes\varphi)) + \underbrace{\delta(H_{n+1}^*(\varphi\otimes\varphi))}_{\text{coboundary}} + H_n^*((T+\mathrm{id})^*(\Xi(\varphi\otimes\varphi)))]\\
&= [H_{n+1}^*(\Xi(\underbrace{\delta(\varphi\otimes\varphi)}_{=0 \text{ since } \varphi \text{ cocycle}})) + H_n^*(\Xi(\varphi\otimes\underbrace{\varphi+\varphi\otimes\varphi}_{=0}))] \;=\; 0.
\end{aligned}$$

We have thus shown that the two definitions using Δ_n and $\widetilde{\Delta}_n$ agree. □

By Proposition 78.24 the maps Sq^i are unambiguously defined. Thus we can make the following definition.

Definition. Given a pair of topological spaces (X,A) and $i\in\mathbb{N}_0$ we refer to each map

$$\mathrm{Sq}^i\colon H^q(X,A;\mathbb{Z}_2) \;\to\; H^{q+i}(X,A;\mathbb{Z}_2)$$

as the *i-th Steenrod operation.*

By Theorem 78.20 the Steenrod operations are additive cohomology operations. To complete the proof of Theorem 78.2 we need to verify that the maps Sq^i have all the other desired properties. In other words we need to prove the following theorem.

Theorem 78.25. *The Steenrod operations* Sq^i *have the following properties:*

(1) $\mathrm{Sq}^0=\mathrm{id}$.
(2) *For any* $\varphi\in H^i(X,A;\mathbb{Z}_2)$ *we have* $\mathrm{Sq}^i(\varphi)=\varphi^2$.
(3) *For any* $\varphi\in H^j(X,A;\mathbb{Z}_2)$ *with* $j<i$ *we have* $\mathrm{Sq}^i(\varphi)=0$.
(4) *For any* $\varphi\in H^r(X,A;\mathbb{Z}_2)$ *and* $\psi\in H^s(X,A;\mathbb{Z}_2)$ *we have*

$$\mathrm{Sq}^k(\varphi\cup\psi) \;=\; \sum_{i=0}^{k}\mathrm{Sq}^i(\varphi)\cup\mathrm{Sq}^{k-i}(\psi).$$

Proof.

(1) The notation might suggest that this statement is surely trivial, but that is not the case. For time and space reasons we will not give the, arguably not terribly enlightening proof, instead we refer to [Sp, p. 274] for details.

(2) First we deal with the absolute case. Thus let $\varphi \in C^i(X;R)$ be a cocycle. We calculate

$$\mathrm{Sq}^i(\varphi) \underset{\substack{\uparrow \\ \text{by definition}}}{=} [h_{i-i}(\varphi \otimes \varphi)] = [h_0(\varphi \otimes \varphi)] \underset{\substack{\uparrow \\ \text{Lemma 78.19}}}{=} [\varphi] \cup [\varphi].$$

The case that we are dealing with a cocycle $\varphi \in C^i(X,A;R)$ is proved basically the same way.

(3) Let $\varphi \in C^j(X,A;\mathbb{Z}_2)$ be a cocycle and suppose that $i > j$. We have

$$\mathrm{Sq}^i([\varphi]) \underset{\substack{\uparrow \\ \text{by definition}}}{=} [h_{j-i}(\varphi)] \underset{\substack{\uparrow \\ \text{since } j-i<0 \text{ we have } h_{j-i}=0}}{=} [0].$$

(4) This statement is proved in [Sp, p. 274]. □

Exercises for Chapter 78.

Exercise 78.1.

(a) Show that for any $k \in \mathbb{N}_{\geq 3}$ and $m \in \mathbb{N}$ the map $H^m(X;\mathbb{Z}_2) \to H^{mk}(X;\mathbb{Z}_2)$ given by $\varphi \mapsto \varphi^k$ is not an additive cohomology operation.

(b) Is the map $H^1(X;\mathbb{Z}_3) \to H^3(X;\mathbb{Z}_3)$ given by $\varphi \mapsto \varphi^3$ an additive cohomology operation?

Exercise 78.2. Let $X = S^m \vee S^n$ be the wedge of two spheres. Show that for $i \geq 1$ all Steenrod operations $\mathrm{Sq}^i\colon H^k(X;\mathbb{Z}_2) \to H^k(X;\mathbb{Z}_2)$ are zero.
Hint: Reread the proof of Lemma 57.11.

Exercise 78.3. Find a closed formula for the i-th Steenrod operation on $H^*(\mathbb{C}\mathrm{P}^\infty;\mathbb{Z}_2)$.
Hint: Use Proposition 62.13 (2).

79. The Adem relations

The following theorem was first proved by José Ádem [Ade, Ade2] in 1952.

Theorem 79.1. (Adem Relations) *For any $0 < a < 2b$ we have the following equality of cohomology operations:*[1330]

$$\mathrm{Sq}^a \circ \mathrm{Sq}^b \;=\; \sum_{j=0}^{\lfloor \frac{a}{2} \rfloor} \binom{b-1-j}{a-2j} \cdot \mathrm{Sq}^{a+b-j} \circ \mathrm{Sq}^j \,.$$

These equalities are called the Adem relations.

Remark. As is remarked on [SE, p. 2], the Adem relations are a consequence of the properties of Steenrod operations that were stated in Theorem 78.2. This observation also follows from the uniqueness result stated in Theorem 78.3.

Proof. Since the proof would consume too much of our valuable time we will not provide it. Instead we refer to the original paper by Adem [Ade, Ade2] or alternatively to [BuM], [SE, Theorem VIII.1.5], [MTa, p. 23] [Hat, Theorem 4.L.13] for a proof. □

Even though we will not prove the Adem relations, we will shamelessly exploit them in this chapter. Afterwards the conscientious reader will surely feel compelled to read the proof of the Adem relations.

Just to get a feeling for the Adem relations we determine for small values of a what the relations really look like.

Example. For $a = 1$ and for any $b \in \mathbb{N}$ we have

$$\mathrm{Sq}^1 \circ \mathrm{Sq}^b \;=\; \underbrace{\sum_{j=0}^{\lfloor \frac{a}{2} \rfloor} \binom{b-1-j}{a-2j} \cdot \mathrm{Sq}^{a+b-j} \circ \mathrm{Sq}^j}_{\text{with } a=1} \;=\; \underbrace{\binom{b-1}{1} \cdot \mathrm{Sq}^{1+b} \circ \mathrm{Sq}^0}_{j=0} \;\underset{\substack{\uparrow \\ \text{since } \mathrm{Sq}^0 = \mathrm{id}}}{=}\; (b-1) \cdot \mathrm{Sq}^{1+b} \,.$$

Furthermore, for $a = 2$ and any $b \in \mathbb{N}_{\geq 2}$ we have

$$\mathrm{Sq}^2 \circ \mathrm{Sq}^b \;=\; \underbrace{\binom{b-1}{2} \cdot \mathrm{Sq}^{2+b} \circ \mathrm{Sq}^0}_{j=0} + \underbrace{\binom{b-2}{0} \cdot \mathrm{Sq}^{1+b} \circ \mathrm{Sq}^1}_{j=1} \;\underset{\substack{\uparrow \\ \text{since } \mathrm{Sq}^0 = \mathrm{id}}}{=}\; \binom{b-1}{2} \cdot \mathrm{Sq}^{2+b} + \mathrm{Sq}^{1+b} \circ \mathrm{Sq}^1 \,.$$

In particular setting $b = 2$ we see that

$$\mathrm{Sq}^2 \circ \mathrm{Sq}^2 \;=\; \mathrm{Sq}^3 \circ \mathrm{Sq}^1 \,.$$

[1330] These are equalities of cohomology operations $H^n(X, A; \mathbb{Z}_2) \to H^{n+a+b}(X, A; \mathbb{Z}_2)$. In particular, since we work over $\mathbb{Z}_2$-coefficients, we only care about the binomial coefficient modulo 2. We will discuss the mod 2 reductions of binomial coefficients in Lemma 79.3.

79.1. **Application of the Adem relations to homotopy groups of spheres.** Recall that in Theorem 78.13 we used Steenrod operations to show that the three Hopf maps $H\colon S^3 \to S^2$, $H_{\mathbb{H}}\colon S^7 \to S^4$ and $H_{\mathbb{O}}\colon S^{15} \to S^8$ and their suspensions define non-trivial elements in the corresponding homotopy groups of spheres.

In this section we will use the Adem relations to show that the 2-fold iteration of these Hopf maps also define non-trivial elements in the homotopy groups of spheres. More precisely, we have the following theorem.

Theorem 79.2.

(1) *For any $n \geq 2$ the map*

$$\Sigma^{n-2}\big(\underbrace{\overbrace{H}^{S^3\to S^2} \circ \overbrace{\Sigma(H)}^{S^4\to S^3}}_{\text{map } S^4 \to S^2}\big)\colon S^{n+2} \to S^n$$

defines a non-trivial element in $\pi_{n+2}(S^n)$. In particular for any $n \geq 2$ we have $\pi_{n+2}(S^n) \neq 0$.

(2) *For any $n \geq 4$ the map*

$$\Sigma^{n-4}\big(\underbrace{\overbrace{H_{\mathbb{H}}}^{S^7\to S^4} \circ \overbrace{\Sigma^3(H_{\mathbb{H}})}^{S^{10}\to S^7}}_{\text{map } S^{10} \to S^4}\big)\colon S^{n+6} \to S^n$$

defines a non-trivial element in $\pi_{n+6}(S^n)$. In particular for any $n \geq 4$ we have $\pi_{n+6}(S^n) \neq 0$.

(3) *For any $n \geq 8$ the map*

$$\Sigma^{n-8}\big(\underbrace{\overbrace{H_{\mathbb{O}}}^{S^{15}\to S^8} \circ \overbrace{\Sigma^7(H_{\mathbb{O}})}^{S^{22}\to S^{15}}}_{\text{map } S^{22} \to S^8}\big)\colon S^{n+14} \to S^n$$

defines a non-trivial element in $\pi_{n+14}(S^n)$. In particular for any $n \geq 8$ we have $\pi_{n+14}(S^n) \neq 0$.

For the reader's convenience we recall the two lemmas which will play a key role in the proof of Theorem 79.2.

Lemma 63.4. *Let $f\colon A \to X$ be a map between two topological spaces. We denote by $j\colon X \to \mathrm{Cone}(f\colon A \to X)$ the obvious inclusion. Then there exists a natural long exact sequence of the form*

$$\ldots \to H^{k-1}(A;\mathbb{Z}_2) \xrightarrow{\delta} \widetilde{H}^k(\mathrm{Cone}(f\colon A \to X);\mathbb{Z}_2) \xrightarrow{j^*} H^k(X;\mathbb{Z}_2) \xrightarrow{f^*} H^k(A;\mathbb{Z}_2) \xrightarrow{\delta} \ldots$$

As an example for Lemma 63.4 let us consider the mapping cone of the iterated suspension of the Hopf map.

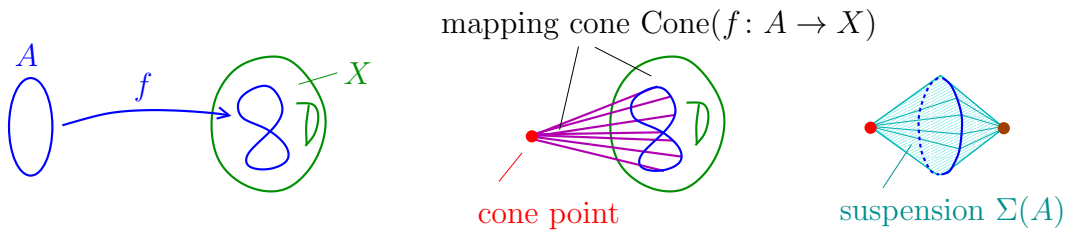

FIGURE 972.

Example. Let $k \in \mathbb{N}_0$. We consider $\Sigma^k(H)\colon S^{k+3} \to S^{k+2}$, i.e. we consider the k-fold suspension of the Hopf map $H\colon S^3 \to S^2$. As we saw in Lemma 63.5, it follows almost immediately from the long exact sequence of Lemma 63.4 that the maps

$$\widetilde{H}^{k+2}(\mathrm{Cone}(\Sigma^k(H)\colon S^{k+3} \to S^{k+2});\mathbb{Z}_2) \xrightarrow[\cong]{j^*} H^{k+2}(S^{k+2};\mathbb{Z}_2)$$

and

$$H^{k+3}(S^{k+3};\mathbb{Z}_2) \xrightarrow[\cong]{\delta} \widetilde{H}^{k+4}(\mathrm{Cone}(\Sigma^k(H)\colon S^{k+3} \to S^{k+2});\mathbb{Z}_2)$$

are isomorphisms, and that all the other reduced cohomology groups of the mapping cone vanish.

In the following we recall three statements of Lemma 15.8 which are at the moment relevant to us. It might be helpful to have a peek at Figure 972.

Lemma 15.8. *Let $f\colon A \to X$ be a map between topological spaces.*

(1) *The inclusion $X \to \mathrm{Cone}(f\colon A \to X)$ is a homeomorphism onto its image.*
(2) *The map*

$$\begin{array}{rcl} h\colon \mathrm{Cone}(f\colon A \to X)/X & \to & \Sigma(A) \\ [(a,t)] & \mapsto & [(a,1-2t)] \end{array}$$

is a homeomorphism.

(4) *The subset X is a deformation retract of the open neighborhood that is given by the complement of the cone point.*

Now we turn to the proof of Theorem 79.2. As in the proof of Theorem 78.13 we first consider the case of the classical Hopf map, i.e. we first prove Statement (1).

Proof of Theorem 79.2 (1). Let $n \in \mathbb{N}_{\geq 2}$. We write

$$\Sigma^{n-2}(H \circ \Sigma(H)) \underset{\substack{\uparrow \\ \text{Lemma 15.4 (2)}}}{=} \overbrace{\underbrace{\Sigma^{n-2}(H)}_{=:g}}^{S^{n+1}\to S^n} \circ \overbrace{\underbrace{\Sigma^{n-1}(H)}_{=:f}}^{S^{n+2}\to S^{n+1}}\colon S^{n+2} \to S^n.$$

We need to show that $g \circ f\colon S^{n+2} \to S^n$ defines a non-trivial element in $\pi_{n+2}(S^n)$. As in the proof of Theorem 78.13 we do a proof by contradiction. Thus suppose that there exists a homotopy from $g \circ f\colon S^{n+2} \to S^n$ to a constant map. By Lemma 28.4 we can use this homotopy to construct a map[1331] $\varphi\colon \operatorname{Cone}(S^{n+2}) = \overline{B}^{n+3} \to S^n$ such that $\varphi|_{S^{n+2}} = g \circ f$. We consider the map[1332]

$$\begin{array}{rcl} \phi\colon \overbrace{(\operatorname{Cone}(S^{n+2}) \sqcup S^{n+1})/\sim}^{=\operatorname{Cone}(f\colon S^{n+2}\to S^{n+1})} & \to & S^n \\ [P] & \mapsto & \begin{cases} g(P), & \text{if } P \in S^{n+1}, \\ \varphi(P), & \text{if } P \in \operatorname{Cone}(S^{n+2}) = \overline{B}^{n+3}. \end{cases} \end{array}$$

Our main object of interest is now, perhaps rather confusingly, the mapping cone of ϕ. This mapping cone comes with two interesting maps:

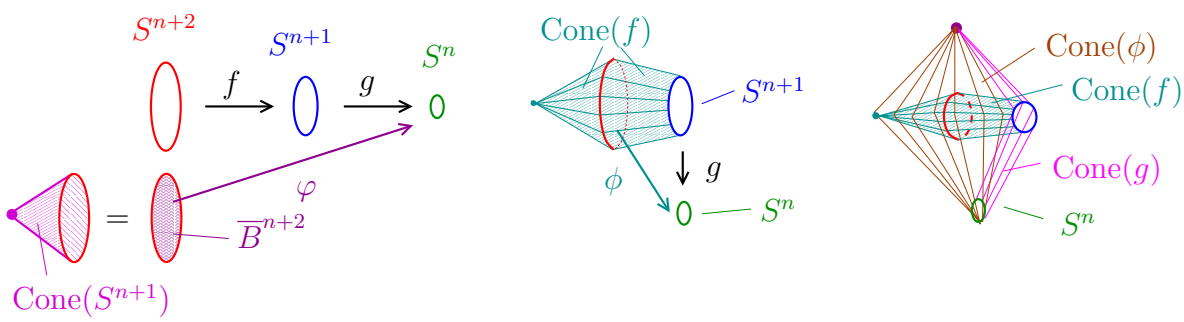

FIGURE 973. Illustration for the proof of Theorem 79.2.

(1) Since we have an inclusion $S^{n+1} \to \operatorname{Cone}(f)$ and since $\phi|_{S^{n+1}} = g$ we obtain, see Lemma 15.9 (3), also an inclusion map

$$i\colon \operatorname{Cone}(g\colon S^{n+1} \to S^n) \;\to\; \operatorname{Cone}(\phi\colon \operatorname{Cone}(f) \to S^n).$$

(2) We also consider the projection map

$$p\colon \operatorname{Cone}(\phi\colon \operatorname{Cone}(f) \to S^n) \;\to\; \operatorname{Cone}(\phi\colon \operatorname{Cone}(f) \to S^n)/S^n.$$

In the following two claims we will study the maps on cohomology induced by the inclusion i and the projection p.

Claim 1.

[1331]As we discussed on page 450, given any $m \in \mathbb{N}_0$ the map $\operatorname{Cone}(S^m) \to \overline{B}^{m+1}$ given by $[(v,t)] \mapsto v \cdot t$ is a homeomorphism. We will use this map to make the identification $\overline{B}^{m+1} = \operatorname{Cone}(S^m)$.

[1332]It follows from $\varphi|_{S^{n+2}} = g \circ f$ that this map is well-defined. Furthermore we obtain from Lemma 1.83 (3) that this map is continuous.

(a) The induced map

$$i^*\colon H^k(\mathrm{Cone}(\phi);\mathbb{Z}_2) \;\to\; H^k(\mathrm{Cone}(g);\mathbb{Z}_2)$$

is an isomorphism for $k \neq n+1$.

(b) We have $H^{n+1}(\mathrm{Cone}(\phi);\mathbb{Z}_2) = 0$.

We consider the following diagram:

$$\begin{tikzcd}
H^{k-2}(S^{n+2};\mathbb{Z}_2) \arrow[d] & & & & H^{k-1}(S^{n+2};\mathbb{Z}_2) \arrow[d] \\
\to H^{k-1}(\mathrm{Cone}(f);\mathbb{Z}_2) \arrow[r] \arrow[d] & H^k(\mathrm{Cone}(\phi\colon \mathrm{Cone}(f)\to S^n);\mathbb{Z}_2) \arrow[r] \arrow[d, "i^*"] & H^k(S^n;\mathbb{Z}_2) \arrow[r, "\phi^*"] \arrow[d, "\mathrm{id}"] & H^k(\mathrm{Cone}(f);\mathbb{Z}_2) \to \arrow[d] \\
\longrightarrow H^{k-1}(S^{n+1};\mathbb{Z}_2) \arrow[r] \arrow[d, "f^*"] & H^k(\mathrm{Cone}(g\colon S^{n+1}\to S^n);\mathbb{Z}_2) \arrow[r] & H^k(S^n;\mathbb{Z}_2) \arrow[r, "f^*"] & H^k(S^{n+1};\mathbb{Z}_2) \longrightarrow \arrow[d, "f^*"] \\
H^{k-1}(S^{n+2};\mathbb{Z}_2) & & & H^k(S^{n+2};\mathbb{Z}_2)
\end{tikzcd}$$

Here the two horizontal and the two vertical sequences are obtained from Lemma 63.4. The diagram commutes by the naturality of the long exact sequence. The two statements of the claim follow easily from the above diagram (see also the discussion on page 1834) and the calculation of the cohomology groups of spheres with $\mathbb{Z}_2$-coefficients. This concludes the proof of Claim 1.

Claim 2. The map

$$p^*\colon H^k(\mathrm{Cone}(\phi)/S^n;\mathbb{Z}_2) \;\to\; H^k(\mathrm{Cone}(\phi);\mathbb{Z}_2)$$

is an isomorphism for $k \neq n, n+1$.

We consider the following diagram:

$$\begin{tikzcd}
\ldots \arrow[r] & H^{k-1}(S^n;\mathbb{Z}_2) \arrow[r, "\delta"] & H^k(\mathrm{Cone}(\phi), S^n;\mathbb{Z}_2) \arrow[r] \arrow[d] & H^k(\mathrm{Cone}(\phi);\mathbb{Z}_2) \arrow[r] & H^k(S^n;\mathbb{Z}_2) \arrow[r] & \ldots \\
& & H^k(\mathrm{Cone}(\phi)/S^n;\mathbb{Z}_2) \arrow[ur, "p^*"'] & & &
\end{tikzcd}$$

Here on top we see the long exact sequence in cohomology of the pair $(\mathrm{Cone}(\phi), S^n)$. Furthermore the vertical map is the natural map from Proposition 50.2 which has in particular the property that it makes the diagram commute. Furthermore, it follows from Proposition 50.2 (2) and Lemma 15.8 (4) that the vertical map is an isomorphism. The desired statement follows immediately from this discussion and the calculation of the cohomology groups of S^n. This concludes the proof of Claim 2.

Next we consider the following diagram.

$$
\begin{tikzcd}
H^n(\mathrm{Cone}(\Sigma^{n-2}(H));\mathbb{Z}_2) \arrow[r, "\mathrm{Sq}^2", "\cong"'] \arrow[d, "="] & H^{n+2}(\mathrm{Cone}(\Sigma^{n-2}(H));\mathbb{Z}_2) \arrow[d, "="'] & \\
H^n(\mathrm{Cone}(g);\mathbb{Z}_2) \arrow[r, "\mathrm{Sq}^2", "\cong"'] & H^{n+2}(\mathrm{Cone}(g);\mathbb{Z}_2) & \\
H^n(\mathrm{Cone}(\phi);\mathbb{Z}_2) \arrow[u, "i^*", "\cong"'] \arrow[r, "\mathrm{Sq}^2"] & H^{n+2}(\mathrm{Cone}(\phi);\mathbb{Z}_2) \arrow[u, "\cong", "i^*"'] \arrow[r, "\mathrm{Sq}^2"] & H^{n+4}(\mathrm{Cone}(\phi);\mathbb{Z}_2) \\
& H^{n+2}(\mathrm{Cone}(\phi)/S^n;\mathbb{Z}_2) \arrow[u, "p^*", "\cong"'] \arrow[r, "\mathrm{Sq}^2"] & H^{n+4}(\mathrm{Cone}(\phi)/S^n;\mathbb{Z}_2) \arrow[u, "\cong", "p^*"'] \\
& H^{n+2}(\Sigma(\mathrm{Cone}(f));\mathbb{Z}_2) \arrow[u, "h^*", "\cong"'] \arrow[r, "\mathrm{Sq}^2", "\cong"'] & H^{n+4}(\Sigma(\mathrm{Cone}(f));\mathbb{Z}_2) \arrow[u, "\cong", "h^*"'] \\
& H^{n+2}(\mathrm{Cone}(\Sigma(f));\mathbb{Z}_2) \arrow[d, "\theta^*", "\cong"'] \arrow[r, "\mathrm{Sq}^2", "\cong"'] & H^{n+4}(\mathrm{Cone}(\Sigma(f));\mathbb{Z}_2) \arrow[d, "\cong", "\theta^*"'] \\
& H^{n+2}(\mathrm{Cone}(\Sigma^n(H));\mathbb{Z}_2) \arrow[r, "\mathrm{Sq}^2", "\cong"'] & H^{n+4}(\mathrm{Cone}(\Sigma^n(H));\mathbb{Z}_2). \arrow[d, "="] \\
& & {}
\end{tikzcd}
$$

We make the following clarifications and observations:

(1) At the top and bottom we use that by definition $f = \Sigma^{n-1}(H)\colon S^{n+2} \to S^{n+1}$ and $g = \Sigma^{n-2}(H)\colon S^{n+1} \to S^n$.
(2) We obtain from Proposition 78.15 (1) that the top and bottom horizontal maps Sq^2 are isomorphisms.
(3) It follows from the above two claims that the vertical maps i^* and p^* are isomorphisms.
(4) The map $h\colon \mathrm{Cone}(\phi\colon \mathrm{Cone}(f) \to S^n)/S^n \to \Sigma(\mathrm{Cone}(f))$ is the homeomorphism from Lemma 15.8 (2).
(5) The map $\theta\colon \mathrm{Cone}(\Sigma(f)\colon \Sigma(X) \to \Sigma(Y)) \to \Sigma(\mathrm{Cone}(f\colon X \to Y))$ is the homeomorphism from Proposition 15.15.
(6) It follows from the naturality of the Steenrod operations that all the squares commute.
(7) The combination of the above arguments implies that both of the maps Sq^2 in the third row are isomorphisms.

Finally we consider the following diagram.

$$
\begin{tikzcd}
\overbrace{H^n(\mathrm{Cone}(\phi);\mathbb{Z}_2)}^{\neq 0} \arrow[r, "\mathrm{Sq}^2", "\cong"'] \arrow[dr, "\mathrm{Sq}^1"'] & H^{n+2}(\mathrm{Cone}(\phi);\mathbb{Z}_2) \arrow[r, "\mathrm{Sq}^2", "\cong"'] & H^{n+2}(\mathrm{Cone}(\phi);\mathbb{Z}_2). \\
& \underbrace{H^{n+1}(\mathrm{Cone}(\phi);\mathbb{Z}_2)}_{=0} \arrow[ur, "\mathrm{Sq}^3"'] &
\end{tikzcd}
$$

We make the following observations:

(1) By the discussion preceding the diagram we know that the two maps on the top are isomorphisms.
(2) As we saw on page 1832, we have the Adem relation $\mathrm{Sq}^2 \circ \mathrm{Sq}^2 = \mathrm{Sq}^3 \circ \mathrm{Sq}^1$. This implies that the diagram commutes.
(3) We have

$$\begin{array}{ccccc} H^n(\mathrm{Cone}(\phi);\mathbb{Z}_2) & \cong & H^n(\mathrm{Cone}(\overbrace{\Sigma^{n-2}(H)}^{=g});\mathbb{Z}_2) & \cong & H^n(S^n;\mathbb{Z}_2) \;\cong\; \mathbb{Z}_2. \\ & \uparrow & & \uparrow & \\ & \text{Claim 1 (a)} & & \text{see the example on page 1834} & \end{array}$$

(4) In Claim 1 (b) we had shown that the group $H^{n+1}(\mathrm{Cone}(\phi);\mathbb{Z}_2)$ is trivial.

By (1) and (3) the two horizontal maps in the diagram give us an isomorphism of a non-trivial group. On the other hand, by (2) and (4) this isomorphism factors through a trivial group. This is absurd. We have thus obtained a contradiction. □

Now we turn to the proof of the remaining two statements of Theorem 79.2.

Proof of Theorem 79.2 (2) and (3). The proof for the quaternionic Hopf map $H_{\mathbb{H}}$ and the octonion Hopf map $H_{\mathbb{O}}$ is almost the same as the above proof that deals with the classical Hopf map H. We just need to replace Proposition 78.15 (1) by Proposition 78.15 (2) and (3) and we need to use the following Adem relations:

$$\begin{aligned} \mathrm{Sq}^4 \circ \mathrm{Sq}^4 &= \mathrm{Sq}^6 \circ \mathrm{Sq}^2 + \mathrm{Sq}^7 \circ \mathrm{Sq}^1 \\ \mathrm{Sq}^8 \circ \mathrm{Sq}^8 &= \mathrm{Sq}^{12} \circ \mathrm{Sq}^4 + \mathrm{Sq}^{14} \circ \mathrm{Sq}^2 + \mathrm{Sq}^{15} \circ \mathrm{Sq}^1 . \end{aligned}$$

These relations can be obtained easily by hand from Theorem 79.1. Alternatively one can use the Adem relations calculator:

`https://math.berkeley.edu/~kruckman/adem/`

As in the proof for the Hopf maps one sees that the initial Steenrod operations on the right hand side all end up in a cohomology group which is zero. Thus one obtains again a contradiction to the hypothesis that the maps are $\Sigma^{n-4}(H_{\mathbb{H}} \circ \Sigma^3(H_{\mathbb{H}})) \colon S^{n+6} \to S^n$ and $\Sigma^{n-8}(H_{\mathbb{O}} \circ \Sigma^7(H_{\mathbb{O}})) \colon S^{n+14} \to S^n$ are null-homotopic. □

79.2. **Decomposing Steenrod operations and the Hopf invariant revisited.** The key to extracting extra mileage out of Steenrod operations is the following innocuous lemma from elementary number theory.

Lemma 79.3. *Let $n, k \in \mathbb{N}_0$. If we write $n = \sum_{i\in\mathbb{N}_0} n_i \cdot 2^i$ and $k = \sum_{i\in\mathbb{N}_0} k_i \cdot 2^i$ with $n_i, k_i \in \{0,1\}$, then*

$$\binom{n}{k} = \prod_{i\in\mathbb{N}_0} \binom{n_i}{k_i} \mod 2.$$

Remark.

(1) Note that for $r, s \in \{0, 1\}$ it follows easily from the definition on page 1809 that

$$\binom{s}{r} = \begin{cases} 1, & \text{if } r \leq s, \\ 0, & \text{otherwise.} \end{cases}$$

(2) Let $n \in \mathbb{N}$ and let $k \in \{0, \ldots, d\}$. We define n_i, k_i as above. It follows from Lemma 79.3 and (1) that $\binom{n}{k}$ is odd if and only if for each i we have $k_i \leq n_i$. If we draw the usual Pascal triangle, then by shading odd and even terms in different colors we obtain a Sierpinski triangle. We refer to Figure 974 for an illustration.[1333]

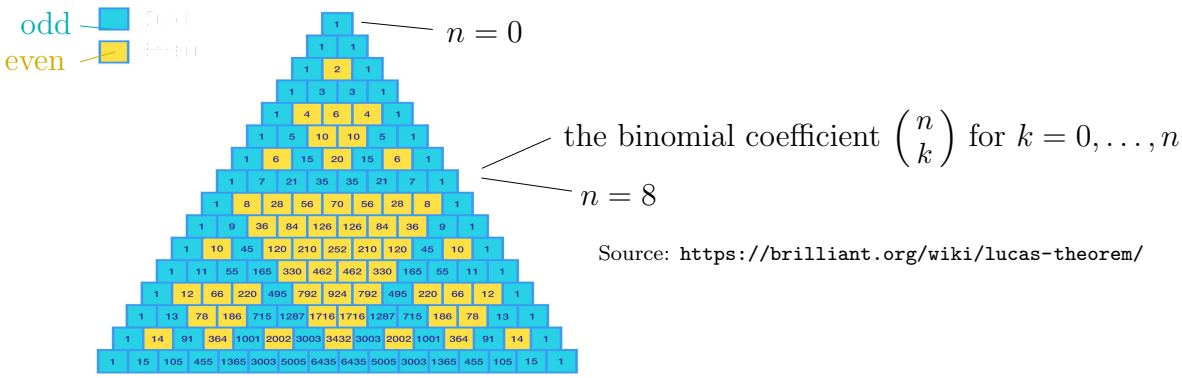

FIGURE 974.

(3) In fact the obvious analogue of Lemma 79.3 holds with the prime 2 replaced by any prime p. This more general statement is known as Lucas' Theorem, a proof is for example provided in [Fi].

Proof. Let $n, k \in \mathbb{N}_0$. We write $n = \sum_{i \in \mathbb{N}_0} n_i \cdot 2^i$ and $k = \sum_{i \in \mathbb{N}_0} k_i \cdot 2^i$ with $n_i, k_i \in \{0, 1\}$ In the polynomial ring $\mathbb{Z}_2[x]$ we have the following equalities[1334]

$$\sum_{i=0}^{n} \binom{n}{i} x^i \underset{\substack{\uparrow \\ \text{binomial formula}}}{=} (1+x)^n = (1+x)^{\sum n_i 2^i} = \prod_{i \in \mathbb{N}_0} (1+x)^{2^i n_i} \underset{\substack{\uparrow \\ \text{since in } \mathbb{Z}_2[x] \text{ we have } (a+b)^2 = a^2 + b^2}}{=} \prod_{i \in \mathbb{N}_0} (1+x^{2^i})^{n_i} \underset{\substack{\uparrow \\ \text{binomial formula}}}{=} \prod_{i \in \mathbb{N}_0} \sum_{j_i=0}^{n_i} \binom{n_i}{j_i} x^{j_i \cdot 2^i}.$$

[1333] A more elaborate version of this figure can be found here:

https://upload.wikimedia.org/wikipedia/commons/8/87/Sierpinski_Pascal_triangle.svg

[1334] The argument has some similarities with the proof of the claim on page 1465.

Now we compare the x^k-coefficients, we see that[1335]

$$\binom{n}{k} = x^k\text{-coefficient of } \sum_{i=0}^{n}\binom{n}{i}x^i \underset{\substack{\uparrow \\ \text{by the above equality}}}{=} x^k\text{-coefficient of } \prod_{i\in\mathbb{N}_0}\sum_{j_i=0}^{n_i}\binom{n_i}{j_i}x^{j_i\cdot 2^i} \underset{\substack{\uparrow \\ \text{by the uniqueness of the 2-adic description} \\ \text{of a natural number we only get } x^k \\ \text{if each variable } j_i \text{ equals } k_i}}{=} \prod_{i\in\mathbb{N}_0}\binom{n_i}{k_i}.$$

We have thus proved the desired equality. □

This lemma allows us to prove the following theorem.

Theorem 79.4. *Let $i \in \mathbb{N}_0$. If i is not a power of 2, then Sq^i is decomposable, in the sense that it can be written as the sum of compositions of Steenrod operations of smaller degree.*

Example. By the discussion on page 1832 we know that for any $k \in \mathbb{N}_0$ we have

$$\mathrm{Sq}^{2k+1} = \mathrm{Sq}^1 \circ \mathrm{Sq}^{2k} \quad \text{and} \quad \mathrm{Sq}^{4k+2} = \mathrm{Sq}^2 \circ \mathrm{Sq}^{4k} + \mathrm{Sq}^{4k+1} \circ \mathrm{Sq}^1 .$$

In particular we see that

$$\mathrm{Sq}^3 = \mathrm{Sq}^1 \circ \mathrm{Sq}^2, \quad \mathrm{Sq}^5 = \mathrm{Sq}^1 \circ \mathrm{Sq}^4, \quad \mathrm{Sq}^6 = \mathrm{Sq}^2 \circ \mathrm{Sq}^4 + \mathrm{Sq}^5 \circ \mathrm{Sq}^1 \quad \text{and } \mathrm{Sq}^7 = \mathrm{Sq}^1 \circ \mathrm{Sq}^6 .$$

Proof. Suppose that we are given $i \in \mathbb{N}_0$ that is not a power of two. This means that we can write $i = a + b$ where $b = 2^k$ and $a \in \{1, \dots, 2^k - 1\}$. Since $0 < a < 2b$ we obtain an Adem relation for $\mathrm{Sq}^a \circ \mathrm{Sq}^b$ from Theorem 79.1. This relation can be rewritten as follows:

$$\binom{b-1}{a} \cdot \mathrm{Sq}^{a+b} = \underbrace{\mathrm{Sq}^a \circ \mathrm{Sq}^b + \sum_{j=1}^{\lfloor \frac{a}{2} \rfloor} \binom{b-1-j}{a-2j} \cdot \mathrm{Sq}^{a+b-j} \circ \mathrm{Sq}^j}_{\text{compositions of Steenrod operations of degree} < a+b} .$$

It remains to show that $\binom{b-1}{a} = 1 \bmod 2$. We calculate

$$\binom{b-1}{a} \underset{\substack{\downarrow \\ \text{by Lemma 79.3 where } b-1 = \sum_{i\in\mathbb{N}_0} d_i \cdot 2^i \text{ and } 2a = \sum_{i\in\mathbb{N}_0} c_i \cdot 2^i \text{ with } c_i, d_i \in \{0,1\}}}{=} \prod_{i\in\mathbb{N}_0}\binom{d_i}{c_i} \underset{\substack{\uparrow \\ \text{since } b-1 = 2^k - 1 = 1 + 2 + \cdots + 2^{k-1} \text{ we have } d_0 = \cdots = d_{k-1} = 1 \text{ and } d_k = d_{k+1} = \cdots = 0 \\ \text{furthermore, since } a < 2^k - 1 \text{ we have } c_k = c_{k+1} = \cdots = 0}}{=} \prod_{i=0}^{k-1}\binom{1}{c_i} \cdot \prod_{i=k}^{\infty}\binom{0}{0} = 1 \mod 2.$$

□

Corollary 79.5. *Let X be a topological space and let $n \in \mathbb{N}_0$. We consider the Steenrod operation*

$$\mathrm{Sq}^i \colon H^n(X;\mathbb{Z}_2) \to H^{n+i}(X;\mathbb{Z}_2).$$

If the cohomology groups inbetween vanish, i.e. if $H^{k+1}(X;\mathbb{Z}_2) = \ldots = H^{n+k-1}(X;\mathbb{Z}_2) = 0$, and if i is not a power of 2, then the Steenrod operation is the zero map.

[1335]Note that the equalities also make sense for $k > n$. In this setting one sees easily that all terms are in fact zero.

Proof. Since i is not a power of 2 we know by Theorem 79.4 that Sq^i can be written as the sum of compositions of Steenrod operations of smaller degree. But by our hypothesis for any $j \in \{1, \dots, n-1\}$ we have $H^{n+j}(X; \mathbb{Z}_2) = 0$. But this implies in particular that for any such j we have $\mathrm{Sq}^j \colon H^n(X; \mathbb{Z}_2) \to H^{n+j}(X; \mathbb{Z}_2) = 0$. $\square$

$$\begin{tikzcd}
H^n(X;\mathbb{Z}_2) \arrow[rrrrrrr, bend left, "\mathrm{Sq}^i"] \arrow[rrrr, bend right, "\mathrm{Sq}^j"'] & 0 & 0 & 0 & 0 & 0 & 0 & H^{n+i}(X;\mathbb{Z}_2)
\end{tikzcd}$$

FIGURE 975. Illustration for the proof of Corollary 79.5.

In Question 60.19 we asked whether all (reasonable) superalgebras can be realized as cohomology rings. We will now see that this is not the case. Before we can state the corresponding proposition we need to introduce the following definition.

Definition. Let $m \in \mathbb{N}$ be an even number and let $s \in \mathbb{N}$. We define $R_m(s)$ to be the superalgebra which is given by the groups[1336]

$$R_m(s) \;=\; \begin{cases} \mathbb{Z} \cdot 1, & \text{in degree } 0, \\ \mathbb{Z} \cdot x, & \text{in degree } m, \\ \mathbb{Z} \cdot y, & \text{in degree } 2m, \\ 0, & \text{in all other degrees} \end{cases}$$

and where the multiplication is given by $x \cdot x = s \cdot y$. In other words, the multiplication table is given as follows

	1	x	y
1	1	x	y
x	x	$s \cdot y$	0
y	y	0	0.

Example.

(1) For any m the superalgebra $R_m(1)$ is evidently isomorphic to $\mathbb{Z}[x]/(x^3)$ where x is of degree m.
(2) By (1) together with Proposition 62.7 and Proposition 62.20 we have isomorphisms $(H^*(\mathbb{C}\mathrm{P}^2; \mathbb{Z}), \cup) \cong R_2(1)$, $(H^*(\mathbb{H}\mathrm{P}^2; \mathbb{Z}), \cup) \cong R_4(1)$ and $(H^*(\mathbb{O}\mathrm{P}^2; \mathbb{Z}), \cup) \cong R_8(1)$.

We can now prove the following proposition which gives a negative answer to Questions 60.19 and Question 62.21.

Proposition 79.6. *Let m be an even number and let s be an odd number. If m is not a power of 2, then there is no topological space X such that $(H^*(X; \mathbb{Z}), \cup)$ is isomorphic to $R_m(s)$.*

[1336] It follows from the fact that m is even that this is indeed a superalgebra.

In the proof of Proposition 79.6 we will need the following lemma.

Lemma 79.7. *Let $m \in \mathbb{N}$. We denote by $\varphi\colon \mathbb{Z} \to \mathbb{Z}_m$ the canonical map. Given any topological space X there exists a long exact sequence*

$$\ldots \to H^k(X;\mathbb{Z}) \xrightarrow{\cdot m} H^k(X;\mathbb{Z}) \xrightarrow{\varphi_*} H^k(X;\mathbb{Z}_2) \xrightarrow{\delta} H^{k+1}(X;\mathbb{Z}) \to \ldots$$

Proof of Lemma 79.7. We denote by $\psi\colon \mathbb{Z} \to \mathbb{Z}$ the map that is given by multiplication by m. We have the short exact sequence

$$0 \to \mathbb{Z} \xrightarrow{\psi} \mathbb{Z} \xrightarrow{\varphi} \mathbb{Z}_m \to 0.$$

By the discussion on page 1714 we have the corresponding Bockstein sequence in cohomology which looks as follows:

$$\ldots \xrightarrow{\delta} H^k(X;\mathbb{Z}) \xrightarrow{\psi_*} H^k(X;\mathbb{Z}) \xrightarrow{\varphi_*} H^k(X;\mathbb{Z}_2) \xrightarrow{\delta} H^{k+1}(X;\mathbb{Z}) \to \ldots$$

By the almost, but not entirely trivial Lemma 74.2 we know that φ_* is indeed multiplication by m. □

Proof of Proposition 79.6. Let m be an even number. Furthermore let X be a topological space such that $(H^*(X;\mathbb{Z}), \cup) = R_m(s)$ for some odd number s. We need to show that m is a power of 2. We denote by $\varphi\colon \mathbb{Z} \to \mathbb{Z}_2$ the canonical map. We consider the following diagram

$$\begin{array}{ccc}
H^m(X;\mathbb{Z}) & \xrightarrow{x \mapsto x^2 = x \cup x = s \cdot y} & H^{2m}(X;\mathbb{Z}) \\
\downarrow{\scriptstyle \varphi_* \times \varphi_*} & & \downarrow{\scriptstyle \varphi_*} \\
H^m(X;\mathbb{Z}_2) & \xrightarrow{z \mapsto z^2 = z \cup z} & H^{2m}(X;\mathbb{Z}_2) \\
\downarrow & & \downarrow \\
H^m(X;\mathbb{Z}_2) & \xrightarrow{z \mapsto \mathrm{Sq}^m(z)} & H^{2m}(X;\mathbb{Z}_2).
\end{array}$$

We make the following clarifications and observations:

(1) It follows from Proposition 58.3 (2) that the upper square commutes.
(2) It follows from Lemma 79.7 and our hypothesis on the topological space X that the map $\varphi_*\colon H^{2m}(X;\mathbb{Z}) \to H^{2m}(X;\mathbb{Z}_2)$ is an epimorphism and that $H^{2m}(X;\mathbb{Z}_2) \cong \mathbb{Z}_2$. In particular we see that $\varphi_*(y) \in H^{2m}(X;\mathbb{Z}_2)$ is a non-trivial element of order 2.
(3) Since s is odd we obtain from (2) that $\varphi_*(s \cdot y) = s \cdot \varphi_*(y)$ is a non-trivial element of $H^{2m}(X;\mathbb{Z}_2)$.
(4) The lower square commutes by Axiom (2) of Steenrod operations, see Theorem 78.2 (2).
(5) By our hypothesis on X we know that the intermediate cohomology groups vanish, ie. we have $H^{m+1}(X;\mathbb{Z}_2) = \cdots = H^{2m-1}(X;\mathbb{Z}_2) = 0$.

It follows from (3) and (4) that the bottom horizontal map has non-trivial image. But by Corollary 79.5 together with (5) this is only possible if m is indeed a power of 2. □

As promised in the title of the section, we now return to the Hopf invariant. Let $f\colon S^{2n-1} \to S^n$ be a map where $n \geq 2$. Recall that on page 1473 we introduced the Hopf invariant $\mathrm{Hopf}(f) \in \mathbb{Z}$. The following lemma translates the Hopf invariant into the language of the above discussion. The lemma can also be viewed as an alternative definition of the Hopf invariant, at least up to sign.

Lemma 79.8. *Let $n \geq 2$. If $f\colon S^{2n-1} \to S^n$ is a map, then there exists an isomorphism*

$$(H^*(\mathrm{Cone}(f);\mathbb{Z}), \cup) \;\cong\; R_n(\mathrm{Hopf}(f))$$

of superalgebras.

Proof. This statement follows immediately from Lemma 63.5 and the definition of the Hopf invariant, see page 1473. □

The following proposition is the summary of our previous discussion of the Hopf invariant.

Proposition 79.9. *Let $n \geq 2$.*

(1) *The Hopf invariant* $\mathrm{Hopf}\colon \pi_{2n-1}(S^n) \to \mathbb{Z}$ *is a homomorphism.*
(2) *The Hopf invariant* $\mathrm{Hopf}\colon \pi_{2n-1}(S^n) \to \mathbb{Z}$ *is zero for odd n.*
(3) *If $\mathbb{R}^n$ can be equipped with the structure of a division algebra, then there exists a map $f\colon S^{2n-1} \to S^n$ with* $\mathrm{Hopf}(f) = 1$.
(4) *For $k = 1, 2, 4$ the Hopf maps $H, H_{\mathbb{H}}$ and $H_{\mathbb{O}}$ give elements in $\pi_{4k-1}(S^{2k})$ with Hopf invariant* 1.
(5) *Given any $k \in \mathbb{N}$ there exists a map $f\colon S^{4k-1} \to S^{2k}$ with* $\mathrm{Hopf}(f) = 2$.

Proof. The proof follows from Proposition 63.7, Corollary 63.8, Lemma 63.11 and Propositions 63.13 and 63.12. □

We recall the following question that we asked a while ago.

Question 63.17. *For which $n \in \mathbb{N}_{\geq 2}$ does there exist a map $f\colon S^{2n-1} \to S^n$ with* $\mathrm{Hopf}(f) = 1$*?*

The following theorem is an immediate consequence of Proposition 79.6 and Lemma 79.8.

Theorem 79.10. *Let $n \geq 2$. If there exists a map $f\colon S^{2n-1} \to S^n$ with* $\mathrm{Hopf}(f) = 1$*, then n is a power of* 2.

The combination of Proposition 79.9 (3) and Theorem 79.10 gives us an alternative proof of the following theorem.

Theorem 62.23. (Hopf 1940) *If $\mathbb{R}^n$ admits the structure of a real division algebra, then n is a power of 2.*

It is an amusing mental exercise, left to the reader, to compare the two proofs of Theorem 62.23. The first one relies on the calculation of the cup product of $\mathbb{R}\mathrm{P}^n \times \mathbb{R}\mathrm{P}^n$ with

$\mathbb{Z}_2$-coefficients and a fact in elementary number theory that is proved on page 1465. The second proof uses Steenrod operations and a different input from elementary number theory, namely Lemma 79.3. Note that in some sense the former proof is more satisfactory since we could provide full details, whereas the latter proof relies on the Adem relations that we did not prove.

For completeness we remark that in 1960 Frank Adams [Adam] (see also [AdA], [May, Chapter 24.6] and [Hus, Theorem 15.4.3]) proved the following strengthening of Theorem 79.10.

Theorem 79.11. *Let $n \geq 2$. If there exists a map $f\colon S^{2n-1} \to S^n$ with* $\operatorname{Hopf}(f) = 1$*, then $n = 2, 4$ or $n = 8$.*

The combination of Proposition 79.9 (3) and Theorem 79.11 gives us an alternative proof of the following beautiful theorem.

Theorem 62.25. *Every finite-dimensional division algebra over $\mathbb{R}$ is of dimension 1,2, 4 or 8.*

79.3. **The Steenrod cyclic reduced powers** $(*)$**.** The Steenrod operations Sq^i are cohomology operations on cohomology groups with $\mathbb{Z}_2$-coefficients. It turns out that there exist also analogous cohomology operations for cohomology with $\mathbb{Z}_p$-coefficients. More precisely, the following theorem holds:

Theorem 79.12. *Let p be an odd prime. There exists a family*[1337]

$$P^i\colon H^n(X, A; \mathbb{Z}_p) \;\to\; H^{n+2i(p-1)}(X, A; \mathbb{Z}_p) \qquad \text{with } i \in \mathbb{N}_0 \text{ and } n \in \mathbb{N}_0$$

of additive cohomology operations which satisfies the following axioms:

(1) $P^0 = \mathrm{id}$.
(2) *For any $\varphi \in H^{2i}(X, A; \mathbb{Z}_p)$ we have $P^i(\varphi) = \varphi^p \in H^{2pi}(X, A; \mathbb{Z}_p)$.*
(3) *For any $\varphi \in H^j(X, A; \mathbb{Z}_p)$ with $i > j$ we have $P^i(\varphi) = 0$.*
(4) *Let (X, A, B) be an excisive triad of topological spaces. For any $\varphi \in H^r(X, A; \mathbb{Z}_p)$ any $\psi \in H^s(X, B; \mathbb{Z}_p)$ and any $k \in \mathbb{N}_0$ we have*[1338]

$$P^k(\varphi \cup \psi) \;=\; \sum_{i=0}^{k} \underbrace{P^i(\varphi)}_{\in H^{r+2i(p-1)}(X,A;\mathbb{Z}_p)} \;\cup\; \underbrace{P^{k-i}(\psi)}_{\in H^{s+2i(p-1)}(X,B;\mathbb{Z}_p)} \;\in\; H^{r+s+2k(p-1)}(X, A \cup B; \mathbb{Z}_p).$$

This equality is often called the Cartan formula.

[1337]Note that if for argument's sake one plugs $p = 2$ into the statements of Theorem 79.12, then one does *not* get the statements of Theorem 78.2 since the degree formulas are different. In other words there is no easy way to combine Theorems 78.2 and 79.12 into a single statement.

[1338]We refer to page 1203 for the definition of an excisive triad. By Proposition 50.12 most "reasonable" triads are in fact excisive. In fact we will only use the special cases that $A = B$, or that at least one of A or B is the empty set. We refer again to page 1358 for the definition of the relative cup product.

Proof. This theorem is proved in [SE, Chapter VI]. A very different proof is given in [Hat, Theorem 4.L.16]. □

The following theorem plays the role of Theorem 79.1.

Theorem 79.13. (Adem Relations) *Let p be an odd prime.*

(1) *For any $0 < a < pb$ we have the following equality of cohomology operations:*

$$P^a \circ P^b \;=\; \sum_{j=0}^{\lfloor \frac{a}{p} \rfloor} (-1)^{a+j} \cdot \binom{(p-1)(b-j)-1}{a-pj} \cdot P^{a+b-j} \circ P^j.$$

(2) *Given $i \in \mathbb{N}_0$ we denote by $\beta\colon H^i(X;\mathbb{Z}_p) \to H^{i+1}(X;\mathbb{Z}_p)$ the Bockstein homomorphism that corresponds to the short exact sequence $0 \to \mathbb{Z}_p \to \mathbb{Z}_{P^2} \to \mathbb{Z}_p \to 0$. For any $0 < a \leq pb$ the following mystifying equality holds:*

$$\begin{aligned} P^a \circ \beta \circ P^b \;=\; & \sum_{j=0}^{\lfloor \frac{a}{p} \rfloor} (-1)^{a+j} \cdot \binom{(p-1)(b-j)}{a-pj} \cdot \beta \circ P^{a+b-j} \circ P^j \\ & - \sum_{j=0}^{\lfloor \frac{a-1}{p} \rfloor} (-1)^{a+j} \cdot \binom{(p-1)(b-j)-1}{a-pj-1} \cdot P^{a+b-j} \circ \beta \circ P^j. \end{aligned}$$

These equalities are called the Adem relations.

Example. Let us consider the case of the prime $p = 3$. In this case the corresponding reduced Steenrod operations are additive cohomology operations of the form

$$P^i\colon H^n(X,A;\mathbb{Z}_3) \;\to\; H^{n+4i}(X,A;\mathbb{Z}_3).$$

For $a = 1$ and $b = 3$ we obtain the Adem relation

$$P^1 \circ P^3 \underset{\substack{\uparrow \\ \text{Theorem 79.13 (1)}}}{=} \sum_{j=0}^{\lfloor \frac{1}{3} \rfloor} (-1)^{1+j} \binom{2\cdot(3-j)-1}{1-3\cdot j} \cdot P^{4-j} \circ P^j \underset{\substack{\uparrow \\ \text{only one summand, namely for } j=0}}{=} (-1) \cdot \binom{5}{1} \cdot P^4 \;=\; -5 \cdot P^4 \underset{\substack{\uparrow \\ \text{we work in } \mathbb{Z}_3}}{=} P^4.$$

The Steenrod cyclic reduced powers can, not surprisingly, be used to give more information on homotopy groups of spheres. We refer to [SE, Chapter VI.5] and [Hat, Example 4.L.6] for details.

Instead of providing more results on homotopy groups of spheres we want to give a different application of the Steenrod cyclic reduced powers, namely we want to prove the following proposition which gives a negative answer to Question 62.22.

Proposition 79.14. *There is no topological space X such that $H^*(X;\mathbb{Z}_3)$ is isomorphic to $\mathbb{Z}_3[\varphi]/(\varphi^4)$ with $\varphi \in H^8(X;\mathbb{Z}_3)$.*

Proof. We provide a proof by contradiction. So suppose there exists a topological space X such that $H^*(X;\mathbb{Z}_3)$ is isomorphic to $\mathbb{Z}_3[\varphi]/(\varphi^4)$ with $\varphi \in H^8(X;\mathbb{Z}_3)$. We see that

$$\begin{array}{ccccccccccc} & & & \text{Theorem 79.12 (2)} & & & & & & & \\ & & & \downarrow & & & & & & & \\ 0 & \neq & \varphi^3 & = & P^4(\varphi) & = & (P^1 \circ P^3)(\varphi) & = & P^1(\overbrace{P^3(\varphi)}^{\in H^{8+3\cdot 4}(X;\mathbb{Z}_3)}) & = & 0. \\ & \uparrow & & & & \uparrow & & & & \uparrow & \\ & \text{since we assume that} & & & & \text{since } P^4 = P^1 \circ P^3 & & & & \text{since } H^{20}(X;\mathbb{Z}_3) = 0 & \\ & H^*(X;\mathbb{Z}_3) \cong \mathbb{Z}_3[\varphi]/(\varphi^4) & & & & & & & & & \end{array}$$

We have thus obtained a contradiction. □

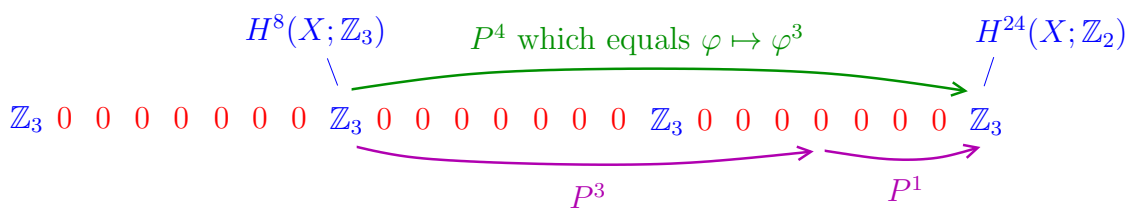

FIGURE 976. Illustration for the proof of Proposition 79.14.

Remark. In Exercise 79.2 we will use Proposition 79.14 to give a negative answer to Question 44.12. So with most reasonable interpretations it is fair to say that there is no manifold that deserves the name $\mathbb{O}\mathrm{P}^n$ with $n \geq 3$.

Exercises for Chapter 79.

Exercise 79.1. Let X be a topological space and let $\varphi \in H^1(X;\mathbb{Z}_2)$ be a cohomology class of degree *one*. Show that for any $k \in \mathbb{N}$ and any $i \in \mathbb{N}$ we have

$$\mathrm{Sq}^i(x^{2k}) = \begin{cases} x^{2k}, & \text{if } i = 0, \\ x^{2^{k+1}}, & \text{if } i = 2^k, \\ 0, & \text{otherwise.} \end{cases}$$

Exercise 79.2. Let $n \geq 3$. Show that there is no closed orientable $8n$-dimensional manifold that admits a CW-structure with precisely one cell in dimensions $0, 8, 16, \dots, 8n$.
Remark: This exercise gives a negative answer to Question 44.12.

80. The Hurewicz Theorem in higher dimensions

After a very long hiatus we now return to the study of higher homotopy groups that we had initiated in Chapter 28. The goal of this chapter is to formulate and prove the high-dimensional analogue of the original Hurewicz Theorem 38.5. Furthermore we will discuss several applications of the higher-dimensional Hurewicz Theorem.

80.1. **The group structure on $\pi_n(X, x_0)$.** Before we turn to the formulation of the high-dimensional Hurewicz Theorem we want to recall some conventions regarding higher homotopy groups and we want to introduce a useful approach to understanding the sum operation in the higher homotopy groups.

First we recall some conventions and notations that apply to any $n \in \mathbb{N}$.

(1) We write $* = (-1, 0, \ldots, 0) \in S^n$.
(2) We write $I = [0, 1]$.
(3) We denote by $I^n \subset \mathbb{R}^n$ the cube in $\mathbb{R}^n$.
(4) We denote by ∂I^n the boundary of I^n viewed as a subset of $\mathbb{R}^n$.
(5) Let $\varphi\colon (I^n, \partial I^n) \to (\overline{B}^n, S^{n-1})$ be the homeomorphism from page 80.
(6) Let $\psi\colon (\overline{B}^n, S^{n-1}) \to (S^n, *)$ be the map from page 99 that induces the usual identification $\overline{B}^n/S^{n-1} \to S^n$.
(7) As on page 715 we use φ and ψ to make the identifications

$$\pi_n(X, x_0) = \begin{array}{c}\text{set (of homotopy classes)}\\ \text{of maps } (I^n, \partial I^n) \to (X, x_0)\\ \|\\ \text{set (of homotopy classes)}\\ \text{of maps } (\overline{B}^n, S^{n-1}) \to (X, x_0).\end{array} = \begin{array}{c}\text{set (of homotopy classes)}\\ \text{of maps } (S^n, *) \to (X, x_0)\end{array}$$

The maps φ and ψ are illustrated in Figure 977.

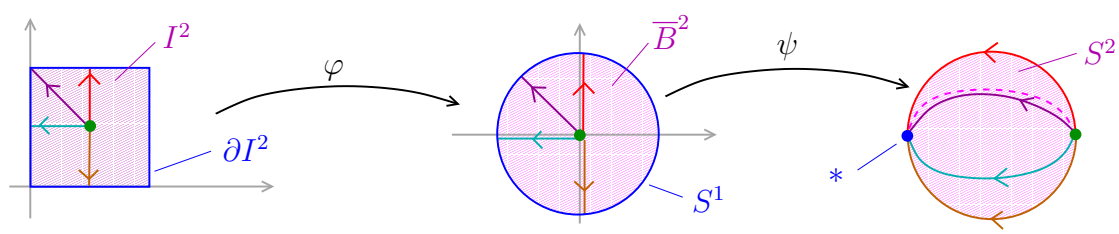

Figure 977.

Now let (X, x_0) be a pointed topological space and let $n \in \mathbb{N}$. Recall that on page 710 we defined the group structure on $\pi_n(X, x_0)$ by considering elements in the homotopy groups as homotopy classes of maps $(I^n, \partial I^n) \to (X, x_0)$. Under the above identifications it is at times difficult to see what the group structure actually looks like. We start out with considering inverses of homotopy classes.

Lemma 80.1. *Let $n \in \mathbb{N}$ and let (X, x_0) be a pointed topological space.*

(1) *Let* $f\colon (\overline{B}^n, S^{n-1}) \to (X, x_0)$ *be a map. If* $\rho\colon \overline{B}^n \to \overline{B}^n$ *is the reflection in some hyperplane of* $\mathbb{R}^n$*, then* $-[f] = [f \circ \rho] \in \pi_n(X, x_0)$.
(2) *Let* $f\colon (S^n, *) \to (X, x_0)$ *be a map. If* $\rho\colon S^n \to S^n$ *is the reflection in some hyperplane of* $\mathbb{R}^{n+1}$ *that contains the line* $\mathbb{R} \cdot (-1, 0, \dots, 0)$*, then we have the equality* $-[f] = [f \circ \rho] \in \pi_n(X, x_0)$.[1339]

Proof $(*)$.

(1) Let $\varphi\colon (I^n, \partial I^n) \to (\overline{B}^n, S^{n-1})$ be the homeomorphism from page 80 that we use to identify the two different points of view regarding the homotopy group $\pi_n(X, x_0)$. It follows from Proposition 28.1 (2) and from considering the definition of ρ that if ρ is the reflection in the $(x_2 = 0)$-hyperplane, then $-[f] = [f \circ \rho]$. If ψ is the reflection in some other hyperplane, then it follows from Lemma 9.4 that ψ and ρ are homotopic as maps $(\overline{B}^n, S^{n-1}) \to (\overline{B}^n, S^{n-1})$. But this observation implies $[f \circ \psi] = [f \circ \rho]$ and thus we see that $[f \circ \psi] = -[f]$.
(2) This statement follows easily from statement (1) and from considering the map $\psi\colon (\overline{B}^n, S^{n-1}) \to (S^n, *)$ from page 99 that we use to identify the two different points of view regarding the homotopy group $\pi_n(X, x_0)$. □

To consider the group structure on the higher homotopy groups we need the following new and fairly harmless definition.

Definition. Let $n \in \mathbb{N}$ and let M be an n-dimensional topological manifold.

(1) We say topological embeddings[1340] $\alpha_1, \dots, \alpha_m\colon \overline{B}^n \to M$ are (*weakly*) *disjoint* if the images (of the interiors) do not intersect.
(2) Let X be a topological space and let $x_0 \in X$. Given weakly disjoint topological embeddings $\alpha_1, \dots, \alpha_m\colon \overline{B}^n \to M$ and maps $f_1, \dots, f_m\colon (\overline{B}^n, S^{n-1}) \to (X, x_0)$ we define[1341]
$$\begin{array}{rcl} \Phi(\alpha_1, \dots, \alpha_m, f_1, \dots, f_m)\colon M & \to & X \\ y & \mapsto & \begin{cases} f_i(z), & \text{if } y = \alpha_i(z) \text{ with } z \in \overline{B}^n, \\ x_0, & \text{otherwise.} \end{cases} \end{array}$$
The definition of this map is illustrated in Figure 978.

The following proposition gives a versatile tool for dealing with the group structure.

Proposition 80.2. *Let* (X, x_0) *be a pointed topological space and let* $n \in \mathbb{N}_{\geq 2}$*. Suppose we are given weakly disjoint embeddings*[1342] $\alpha_1, \dots, \alpha_m\colon \overline{B}^n \to S^n$ *such that the images of the* B^n *lie in* $S^n \setminus \{*\}$*. Also suppose we are given maps* $f_1, \dots, f_m\colon (\overline{B}^n, S^{n-1}) \to (X, x_0)$*.*

[1339] Note that $\rho(*) = *$, hence $(f \circ \rho)(*) = x_0$.

[1340] We refer to page 1511 for the definition of a topological embedding. As discussed on page 1512, an embedding of a manifold in the sense of the definition on page 330 is indeed a topological embedding.

[1341] It follows from Lemmas 1.37 and 1.18, Proposition 32.2 and Lemma 1.32 (2) that this map is indeed continuous.

[1342] Note that here we work on purpose with "embeddings" instead of "topological embeddings".

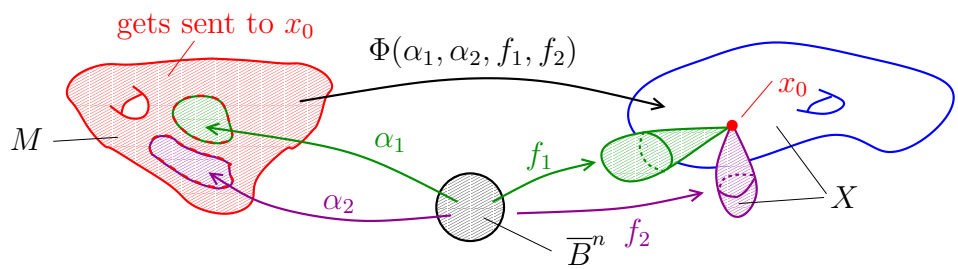

FIGURE 978.

Given $i \in \{1, \dots, m\}$ we write $\epsilon_i = 1$ if α_i is orientation-preserving otherwise we write $\epsilon_i = -1$. Then we have the following equality in $\pi_n(X, x_0)$:

$$\big[\underbrace{\Phi(\alpha_1, \dots, \alpha_m, f_1, \dots, f_m)\colon (S^n, *) \to (X, x_0)}_{\in \pi_n(X, x_0)}\big] = \sum_{i=1}^{m} \epsilon_i \cdot \big[\underbrace{f_i\colon (\overline{B}^n, S^{n-1}) \to (X, x_0)}_{\in \pi_n(X, x_0)}\big].$$

Example. A slight modification of the map $\overline{B}^n \to S^n$ given on page 99 provides us with an orientation-preserving embedding $\alpha_1\colon \overline{B}^2 \to S^2$ that sends the disk to the "left hemisphere". Similarly we obtain an orientation-preserving embedding $\alpha_2\colon \overline{B}^2 \to S^2$ that sends the disk to the "right hemisphere". It follows from Proposition 80.2 that for any two maps $f_1, f_2\colon (\overline{B}^2, S^1) \to (X, x_0)$ we have

$$[\Phi(\alpha_1, \alpha_2, f_1, f_2)\colon (S^2, *) \to (X, x_0)] = [f_1\colon (\overline{B}^2, S^1) \to (X, x_0)] + [f_2\colon (\overline{B}^2, S^1) \to (X, x_0)].$$

This situation is illustrated in Figure 979. We obtain basically the same picture as we had already obtained on page 716.

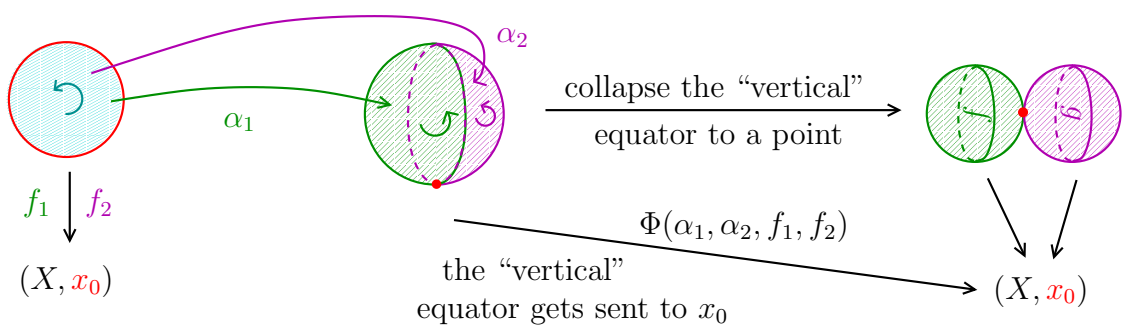

FIGURE 979.

Remark. The statement of Proposition 80.2 also holds for topological embeddings. But in that case, in the proof below, one needs to replace the mainstream Theorem 10.28 by the surprisingly difficult Theorem 71.9. In particular it is not clear to me what goes into the

proof of Theorem 71.9 (does it require the Hurewicz Theorem, are we in danger of using circular logic?). Therefore I prefer to stick to embeddings.[1343]

In the proof of Proposition 80.2 we need the following lemma which basically says the following: if we isotope the topological embeddings α_i, then the resulting Φ-maps are homotopic.

Lemma 80.3. $(*)$ *Let $n \in \mathbb{N}$, let M be an n-dimensional manifold and let Z be a subset of M. Furthermore suppose we are given a topological space X, a base point $x_0 \in X$ and maps $f_1, \dots, f_m \colon (\overline{B}^n, S^{n-1}) \to (X, x_0)$. Finally suppose that for $i = 1, \dots, m$ we are given homotopies*

$$\Omega_i \colon \overline{B}^n \times [0,1] \ \to \ M \setminus Z$$

such that for each $t \in [0,1]$ the maps $\Omega_{1,t}, \dots, \Omega_{m,t} \colon \overline{B}^n \to M$ are weakly disjoint topological embeddings, then the maps

$$\Phi(\underbrace{\Omega_{1,0}, \dots, \Omega_{m,0}}_{\Omega \text{ at } t=0}, f_1, \dots, f_m), \Phi(\underbrace{\Omega_{1,1}, \dots, \Omega_{m,1}}_{\Omega \text{ at } t=1}, f_1, \dots, f_m) \colon (M, Z) \ \to \ (X, x_0)$$

are homotopic as maps of pairs of topological spaces.

Proof $(*)$. As before it follows from Lemmas 1.37 and 1.18, Proposition 32.2 and Lemma 1.32 (2) that the map

$$\begin{array}{rcl} H \colon M \times [0,1] & \to & X \\ (P,t) & \mapsto & \Phi(\Omega_{1,t}, \dots, \Omega_{m,t}, f_1, \dots, f_m)(P) \end{array}$$

is continuous. This map is then the desired homotopy. □

Sketch of a proof of Proposition 80.2 $(*)$. Let (X, x_0) be a pointed topological space and let $n \in \mathbb{N}_{\geq 2}$. Furthermore suppose we are given maps $f_1, \dots, f_m \colon (\overline{B}^n, S^{n-1}) \to (X, x_0)$. Finally let $\alpha_1, \dots, \alpha_m \colon \overline{B}^n \to S^n$ be weakly disjoint embeddings such that the images of the B^n lie in $S^n \setminus \{*\}$. We start out with the following observations:

(1) Let $\rho \colon \overline{B}^n \to \overline{B}^n$ be the reflection in some hyperplane of $\mathbb{R}^n$. We replace every pair (α_i, f_i) for which α_i is orientation-reversing by the pair $(\alpha_i \circ \rho, f_i \circ \rho)$. It follows immediately from Lemma 80.1 that the desired equality holds for the new data if and only if it holds for the old data.

(2) If the α_i are not disjoint we make them disjoint by shrinking. More precisely, we consider the isotopies

$$\begin{array}{rcl} F_i \colon \overline{B}^n \times [0,1] & \to & M \\ (P,t) & \mapsto & \alpha_i(P \cdot (1 - \frac{t}{2})). \end{array}$$

Since the α_i were weakly disjoint we see that the resulting topological embeddings are now disjoint.

[1343] Recall that the absence of the word "topological" implies in our setup that embeddings are smooth maps.

(3) The map $(\overline{B}^n, S^{n-1}) \to (S^n, \{*\})$ that we gave on page 99 restricts to a diffeomorphism $B^n \to S^n \setminus \{*\}$.

Keeping the above three observations in mind we obtain from Lemma 80.3 that it suffices to prove the following statement.

Statement. For any disjoint orientation-preserving embeddings $\alpha_1, \dots, \alpha_m \colon \overline{B}^n \to B^n$ we have the following equality in $\pi_n(X, x_0)$:

$$\big[\underbrace{\Phi(\alpha_1, \dots, \alpha_m, f_1, \dots, f_m) \colon (\overline{B}^n, S^{n-1}) \to (X, x_0)}_{\in \pi_n(X, x_0)}\big] = \sum_{i=1}^{m} \big[\underbrace{f_i \colon (\overline{B}^n, S^{n-1}) \to (X, x_0)}_{\in \pi_n(X, x_0)}\big].$$

Perhaps the key observation in the proof is that Theorem 10.28 (where we use our hypothesis that $n \geq 2$ and here we use that work with embeddings not just topological embeddings of balls) together with Lemma 80.3 implies that we only need to prove the statement for a single choice of disjoint orientation-preserving embeddings $\alpha_1, \dots, \alpha_m$. Put differently, it remains to prove the following claim.

Claim. There exist disjoint orientation-preserving embeddings $\alpha_1, \dots, \alpha_m \colon \overline{B}^n \to B^n$ such that

$$\big[\underbrace{\Phi(\alpha_1, \dots, \alpha_m, f_1, \dots, f_m) \colon (\overline{B}^n, S^{n-1}) \to (X, x_0)}_{\in \pi_n(X, x_0)}\big] = \sum_{i=1}^{m} \big[\underbrace{f_i \colon (\overline{B}^n, S^{n-1}) \to (X, x_0)}_{\in \pi_n(X, x_0)}\big].$$

By induction it suffices prove the claim for $m = 2$. Even your famously verbose author does not feel like spelling out all the details. We leave it to the reader to piece together the argument using Figure 980 and the following observations:

(a) by Proposition 80.2 (or alternatively Lemma 28.2) we can "move cubes" in I^n,
(b) by Lemma 9.1 the map $\varphi^{-1} \colon \overline{B}^n \to I^n$ is isotopic to the identity,
(c) the restriction of the map $\varphi \colon I^n \to \overline{B}^n$ to each open cone on one of the sides of the cube I^n is smooth.

Using Lemma 80.3 these moves translate into homotopies of the corresponding maps. □

80.2. **The statement of the Hurewicz Theorem and applications.** We recall the following definition from page 932.

Definition. Let (X, x_0) be a pointed topological space and let $n \geq 1$. We denote by $[S^n] \in H_n(S^n; \mathbb{Z}) \cong \mathbb{Z}$ the fundamental class of the oriented manifold S^n.[1344] We refer to the map

$$\begin{array}{rcl} \Phi_{(X,x_0)} \colon \pi_n(X, x_0) & \to & H_n(X; \mathbb{Z}) \\ [f \colon (S^n, *) \to (X, x_0)] & \mapsto & f_*([S^n]) \end{array}$$

as the *Hurewicz homomorphism.*

[1344]Earlier on we also called it the standard generator, see page 814.

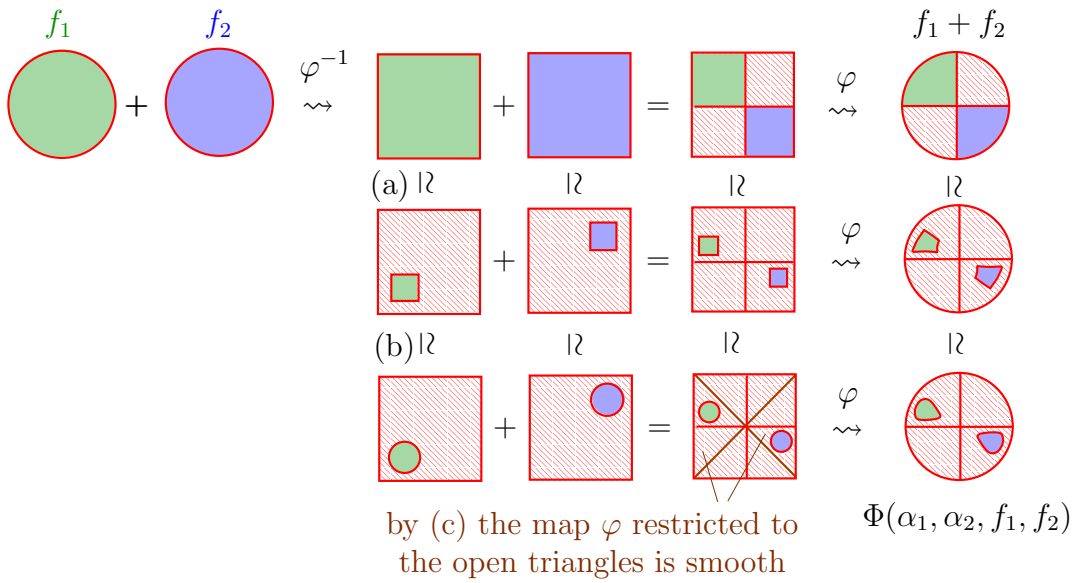

FIGURE 980. Illustration of the proof of Proposition 80.2.

Remark. Let (X, x_0) be a pointed topological space and let $n \geq 1$. If we think of elements of $\pi_n(X, x_0)$ as homotopy classes of maps $(I^n, \partial I^n) \to (X, \{x_0\})$, then it follows easily from the fact that the above diffeomorphism $I^n \setminus \partial I^n \to S^n \setminus \{*\}$ is orientation-preserving, that the Hurewicz homomorphism is also given by the map

$$\begin{array}{rcl} \Phi_{(X,x_0)} \colon \pi_n(X, x_0) & \to & H_n(X; \mathbb{Z}) \\ [f \colon (I^n, \partial I^n) \to (X, x_0)] & \mapsto & f_*([I^n]) \end{array}$$

In the following proposition we collect same basic facts about the Hurewicz homomorphism. In particular we will justify why it is called the Hurewicz *homomorphism*.

Proposition 80.4. *Let $n \in \mathbb{N}$.*

(1) *For any pointed topological space (X, x_0) the Hurewicz homomorphism*

$$\Phi_{(X,x_0)} \colon \pi_n(X, x_0) \to H_n(X; \mathbb{Z})$$

is a homomorphism.

(2) *The Hurewicz homomorphisms define a natural transformation from n-th homotopy groups to n-th homology groups. In plain English this means that for a map $f \colon (X, x_0) \to (Y, y_0)$ of pointed topological spaces we have a commutative diagram*

$$\begin{tikzcd} \pi_n(X, x_0) \arrow[r, "f_*"] \arrow[d, "\Phi_{(X,x_0)}"'] & \pi_n(Y, y_0) \arrow[d, "\Phi_{(Y,y_0)}"] \\ H_n(X; \mathbb{Z}) \arrow[r, "f_*"] & H_n(Y; \mathbb{Z}). \end{tikzcd}$$

(3) *If X is path-connected, then the Hurewicz homomorphism induces an isomorphism*[1345]

$$\Phi_{(X,x_0)}\colon \pi_1(X,x_0)_{\mathrm{ab}} \;\to\; H_1(X;\mathbb{Z}).$$

Proof. These statements are precisely the contents of Lemma 38.9 and Hurewicz Theorem 38.5. □

The goal of this chapter is to prove the following theorem which can be viewed as the high-dimensional analogue of Proposition 80.4 (3), i.e. of the original Hurewicz Theorem 38.5.

Theorem 80.5. (Hurewicz Theorem) *Let (X,x_0) be a pointed topological space. Furthermore let $n \in \mathbb{N}_{\geq 2}$. If X is $(n-1)$-connected*[1346]*, then the following two statements hold:*

(1) *we have $\widetilde{H}_k(X;\mathbb{Z}) = 0$ for $k = 0,\dots,n-1$, and*
(2) *the Hurewicz homomorphism $\Phi_{(X,x_0)}\colon \pi_n(X,x_0) \to H_n(X;\mathbb{Z})$ is an isomorphism.*

Remark. On page 933 we already saw that in general the hypothesis in the Hurewicz Theorem 80.5 that X is $(n-1)$-connected cannot be dropped.

Using the Hurewicz Theorem 80.5 we can now determine some homotopy groups that had been eluding us for a long time.

Corollary 80.6.

(1) *For any $n \in \mathbb{N}$ we have $\pi_n(S^n) \cong \mathbb{Z}$, in fact $\pi_n(S^n,*) = \mathbb{Z}\cdot[\mathrm{id}_{S^n}]$.*
(2) *For any $n \in \mathbb{N}\cup\{\infty\}$ we have $\pi_2(\mathbb{C}\mathrm{P}^n) \cong \mathbb{Z}$. In fact, if we make the identification $\mathbb{C}\mathrm{P}^1 = S^2$ from page 113 and if we use the convention from page 111 to view $\mathbb{C}\mathrm{P}^1 = S^2$ as a subset of $\mathbb{C}\mathrm{P}^n$, then $\pi_2(\mathbb{C}\mathrm{P}^n,*) = \mathbb{Z}\cdot[\mathrm{id}_{\mathbb{C}\mathrm{P}^1}]$.*

Proof.

(1) Let $n \in \mathbb{N}$. By Proposition 28.9 we know that S^n is $(n-1)$-connected. Thus the statement follows immediately from the Hurewicz Theorems 38.5 and 80.5 and the fact that $H_n(S^n;\mathbb{Z}) = \mathbb{Z}\cdot[S^n]$.
(2) Let $n \in \mathbb{N}\cup\{\infty\}$. We denote by $i\colon \mathbb{C}\mathrm{P}^1 \to \mathbb{C}\mathrm{P}^n$ the obvious inclusion. From Proposition 80.4 (2) we obtain the following commutative diagram

$$\begin{tikzcd}
\pi_2(\mathbb{C}\mathrm{P}^1,*) \arrow[r, "i_*"] \arrow[d, "\Phi_{(\mathbb{C}\mathrm{P}^1,*)}"'] & \pi_2(\mathbb{C}\mathrm{P}^n,*) \arrow[d, "\Phi_{(\mathbb{C}\mathrm{P}^n,*)}"] \\
H_2(\mathbb{C}\mathrm{P}^1;\mathbb{Z}) \arrow[r, "i_*"] & H_2(\mathbb{C}\mathrm{P}^n;\mathbb{Z}).
\end{tikzcd}$$

If $n \in \mathbb{N}$, then it follows immediately from Lemma 62.6 that the inclusion induced map $H_2(\mathbb{C}\mathrm{P}^1;\mathbb{Z}) \to H_2(\mathbb{C}\mathrm{P}^n;\mathbb{Z})$ is an isomorphism. For $n = \infty$ we need to appeal to the discussion on page 885 to draw the same conclusion. Finally, since $[\mathbb{C}\mathrm{P}^1] = [S^2]$ is a generator of $H_2(\mathbb{C}\mathrm{P}^1;\mathbb{Z}) = H_2(S^2;\mathbb{Z})$ we obtain that $\pi_2(\mathbb{C}\mathrm{P}^n,*) = \mathbb{Z}\cdot[\mathrm{id}_{\mathbb{C}\mathrm{P}^1}]$ from the above commutative diagram. □

[1345] Recall that given a group π we denote by π_{ab} its abelianization, as defined on page 415.

[1346] Recall that by the definition on page 728 this means that $\pi_i(X) = 0$ for $i = 0,\dots,n-1$.

On several occasions we will also need the following straightforward corollary to the Hurewicz Theorem 80.5.

Corollary 80.7. *Let (X, x_0) be a pointed topological space and let $n \in \mathbb{N}$. We suppose that X is simply connected. If given every $k \in \{2, \dots, n\}$ we have $\pi_k(X, x_0) = 0$ or $H_k(X; \mathbb{Z}) = 0$, then the following two statements hold:*

1. *for $k = 1, \dots, n$ we have $\pi_k(X, x_0) = H_k(X; \mathbb{Z}) = 0$,*
2. *the Hurewicz homomorphism $\pi_{n+1}(X, x_0) \to H_{n+1}(X; \mathbb{Z})$ is an isomorphism.*

Proof. We prove the corollary by induction on n. First consider the case $n = 1$. Since X is simply connected we obtain from the Hurewicz Theorem 38.5 that $H_1(X; \mathbb{Z}) = 0$. Furthermore it follows from the Hurewicz Theorem 80.5 that $\Phi_{(X,x_0)} \colon \pi_2(X, x_0) \to H_2(X; \mathbb{Z})$ is an isomorphism.

Now suppose the statement holds for $n - 1$ with $n \geq 2$. Suppose that for every $k \in \{2, \dots, n\}$ we have $\pi_k(X) = 0$ or $H_k(X; \mathbb{Z}) = 0$. By induction we know that the homotopy and homology groups vanish up to degree $n - 1$. Thus we can apply the Hurewicz Theorem 80.5 which says that $\pi_n(X)$ and $H_n(X; \mathbb{Z})$ are isomorphic. Since one is zero, both are zero. Hence we can apply the Hurewicz Theorem 80.5 once more to see that the Hurewicz homomorphism $\pi_{n+1}(X, x_0) \to H_{n+1}(X; \mathbb{Z})$ is an isomorphism. □

Example. Let M be the Poincaré homology sphere that we introduced on page 993. Recall that M is a 3-dimensional homology sphere with non-trivial fundamental group. We denote by $\Sigma(M)$ its suspension as defined on page 452. By Lemma 15.3 we know that $\Sigma(M)$ is simply connected. Furthermore we have

$$\widetilde{H}_k(\Sigma(M); \mathbb{Z}) \underset{\substack{\uparrow \\ \text{Proposition 32.14}}}{\cong} \widetilde{H}_{k-1}(M; \mathbb{Z}) \underset{\substack{\uparrow \\ \text{since } M \text{ is a 3-dimensional} \\ \text{homology sphere}}}{\cong} \begin{cases} 0, & \text{if } k \neq 4, \\ \mathbb{Z}, & \text{if } k = 4. \end{cases}$$

With this information we obtain from Corollary 80.7 that $\pi_2(\Sigma(M)) = \pi_3(\Sigma(M)) = 0$ and that $\pi_4(\Sigma(M)) \cong \mathbb{Z}$. As a side remark we point out that we saw in Exercise 28.7 that $\Sigma(M)$ is not a topological manifold.

We recall the following definition from page 728.

Definition. Let $n \in \mathbb{N}$. An n-dimensional topological manifold X that is closed and that is $\lfloor \frac{n}{2} \rfloor$-connected is called an *n-dimensional homotopy sphere.*

Example. A closed 3-dimensional topological manifold is by definition a 3-dimensional homotopy sphere if it is 1-connected, i.e. if it is simply connected.

We have now the following characterizations of n-dimensional homotopy spheres.

Proposition 80.8. *Let $n \geq 2$. If X is a closed connected n-dimensional topological manifold, then the following statements are equivalent:*

1. *X is a homotopy sphere,*

(2) *X is $(n-1)$-connected,*
(3) *$\pi_1(X)$ is trivial and $H_i(X;\mathbb{Z}) = 0$ for $i = 2, \ldots, n-1$,*
(4) *$\pi_1(X)$ is trivial and $H_i(X;\mathbb{Z}) = 0$ for $i = 2, \ldots, \lfloor \frac{n}{2} \rfloor$.*

Remark. The reader might wonder why we defined a homotopy sphere the way we did, after all the characterization of Proposition 80.8 (2) seems much more natural. The purely didactical reason is that, as pointed out in the example before the proposition, in the 3-dimensional setting we only have to take the fundamental group into account and not the second homotopy group.

Proof. We have (1) $\Rightarrow$ (4) by Corollary 80.7. We can easily show that (4) $\Rightarrow$ (3) by applying the Poincaré Duality Theorem 61.1 (here we use that X is orientable by Corollary 45.27) and the Universal Coefficient Theorem 51.13 for Cohomology Groups.[1347] The conclusion (3) $\Rightarrow$ (2) is again Corollary 80.7 and finally (2) $\Rightarrow$ (1) is trivial. $\square$

We conclude this section with the following proposition.

Proposition 80.9. *Let $n \in \mathbb{N}$ and let $f\colon S^n \to S^n$ be a homeomorphism with $f(*) = *$. Then the following equality holds in $\pi_n(S^n, *)$:*

$$[f] \;=\; \begin{cases} \;\;[\mathrm{id}_{S^n}], & \text{if } f \text{ is orientation-preserving,} \\ -[\mathrm{id}_{S^n}], & \text{if } f \text{ is orientation-reversing.} \end{cases}$$

Remark. Let $n \in \mathbb{N}$. Proposition 80.9 says that every orientation-preserving self-homeomorphism f of S^n with $f(*) = *$ is *homotopic*, rel the base point $*$, to the identity. It is not clear to me whether f is *isotopic*, rel the base point $*$, to the identity. Put differently, can one find a homotopy F from f to id such that each $F_t\colon S^n \to S^n$ is also a homeomorphism?

Proof. Let $n \in \mathbb{N}$ and let $f\colon S^n \to S^n$ be a homeomorphism with $f(*) = *$. By the naturality of the Hurewicz homomorphism, see Proposition 80.4 (2), we have the following commutative diagram

$$\begin{tikzcd} \pi_n(S^n, *) \arrow[r, "f_*"] \arrow[d, "\Phi_{(S^n,*)}"'] & \pi_n(S^n, *) \arrow[d, "\Phi_{(S^n,*)}"] \\ H_n(S^n;\mathbb{Z}) \arrow[r, "f_*"] & H_n(S^n;\mathbb{Z}). \end{tikzcd}$$

By Proposition 28.9 we know that S^n is $(n-1)$-connected. Therefore the vertical maps are isomorphisms by the Hurewicz Theorems 38.5 and 80.5. The corollary now follows from Proposition 47.3 and the simple observation that $[f] = f_*([\mathrm{id}_{S^n}]) \in \pi_n(S^n, *)$. $\square$

Now that we are fully convinced of the value of the Hurewicz Theorem 80.5 we turn to the proof thereof. We will discuss more applications in the next chapter.

[1347] Note that the proof of (4) $\Rightarrow$ (3) is almost identical to the proof of Lemma 74.1.

80.3. **The proof of the Hurewicz Theorem 80.5.** The proof of the Hurewicz Theorem 80.5 requires some preparations.

Convention. Let $k \in \mathbb{N}_0$. We view Δ^k as a CW-complex in the following way. Given $m \in \{0, \dots, k\}$ the m-cells correspond precisely to all the maps

$$\begin{array}{rcl} \overline{B}^m = \Delta^m & \to & \Delta^k \\ (t_0, \dots, t_m) & \mapsto & \sum\limits_{i=0}^{m} t_i e_{\varphi(i)} \end{array}$$

where φ is a strictly increasing map $\varphi\colon \{0, \dots, m\} \to \{0, \dots, k\}$. Note that the $(k-1)$-skeleton of Δ^k is given by $\partial\Delta^k$.

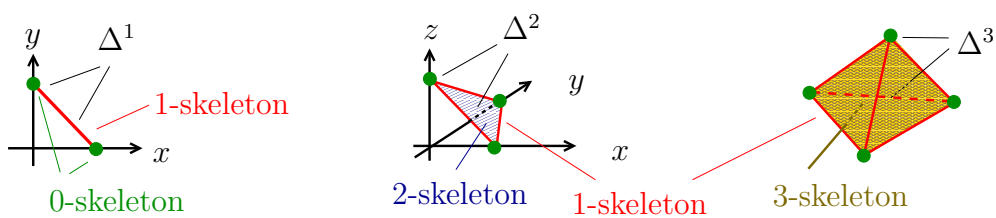

FIGURE 981.

Definition. Let (X, x_0) be a pointed topological space and let $n \in \mathbb{N}_0$. Given $k \in \mathbb{N}_0$ we define[1348]

$$C_k^{(n)}(X, x_0) \ := \ \begin{array}{c} \text{the subgroup of the relative chain group } C_k(X, \{x_0\}) \text{ generated} \\ \text{by all singular simplices } \sigma\colon \Delta^k \to X \text{ with } \sigma(n\text{-skeleton of } \Delta^k) \subset \{x_0\}. \end{array}$$

These groups define a subcomplex of $C_*(X, \{x_0\})$. In particular we obtain corresponding homology groups $H_k^{(n)}(X, x_0)$ and the inclusion $C_*^{(n)}(X, x_0) \to C_*(X, \{x_0\})$ defines natural maps $H_k^{(n)}(X, x_0) \to H_k(X, \{x_0\})$.

Example. In Figure 982 we show a pointed topological space (X, x_0) and we consider an element $\sigma \in C_1^{(0)}(X, x_0)$ and an element $\tau \in C_2^{(1)}(X, x_0)$. From the pictures it becomes apparent that elements in $C_n^{(n-1)}(X, x_0)$ are "close" to elements in $\pi_n(X, x_0)$. In particular it seems reasonable to expect that $H_n^{(n-1)}(X, x_0)$ is a group that "sits between" $H_n(X; \mathbb{Z})$ and $\pi_n(X, x_0)$.

In the following lemma we summarize a few basic facts about these new chain groups.

Lemma 80.10. *Let (X, x_0) be a pointed topological space and let $n \in \mathbb{N}_0$. Furthermore let $k \in \{0, \dots, n\}$. The following statements hold:*

(1) *We have $C_k^{(n)}(X, x_0) = 0$,*
(2) *we have $H_k^{(n)}(X, x_0) = 0$,*

[1348]Note that the notation $C_k^{(n)}(X, x_0)$ instead of $C_k^{(n)}(X, \{x_0\})$ is on purpose.

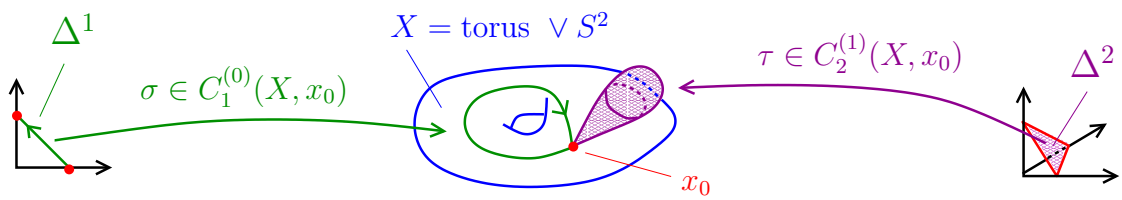

FIGURE 982.

(3) *any element in* $C_{k+1}^{(n)}(X, x_0)$ *is a cycle.*

Proof. Let $k \in \{0, \ldots, n\}$. Put differently, we have k with $n \geq k$. Note that this implies that Δ^k is the n-skeleton of Δ^k. In particular, by definition, $C_k^{(n)}(X, x_0)$ is the subgroup of $C_k(X, \{x_0\})$ generated by the constant maps $\Delta^k \to \{x_0\}$, but these are zero in the relative chain group $C_k(X, \{x_0\})$. This concludes the proof of (1). The remaining two statements are immediate consequences of (1). □

The following lemma is one of the key ingredients in the proof of the Hurewicz Theorem 80.5

Lemma 80.11. *Let* (X, x_0) *be a pointed topological space and let* $n \in \mathbb{N}$. *If* X *is* n*-connected, then the inclusion map*

$$C_*^{(n)}(X, x_0) \quad \to \quad C_*(X, \{x_0\})$$

is a chain homotopy equivalence. In particular for any $k \in \mathbb{N}_0$ *the induced map*

$$H_k^{(n)}(X, x_0) \quad \to \quad H_k(X, \{x_0\})$$

is an isomorphism.

Proof. Let (X, x_0) be a pointed topological space and let $n \in \mathbb{N}$. We suppose that X is n-connected. We recall the following notation from Lemma 30.6: given $t = 0$ and $t = 1$ and $k \in \mathbb{N}_0$ we denote by

$$\begin{aligned} \eta_t \colon \Delta^k &\to \Delta^k \times [0, 1] \\ x &\mapsto (x, t) \end{aligned}$$

the obvious inclusion map. We start out with the following claim which basically says that any singular simplices $\Delta^k \to X$ can be homotoped consistently to a singular simplices that lie in $C_k^{(n)}(X, x_0)$.

Claim. Given any $k \in \mathbb{N}_0$ and given any singular simplex $\sigma \colon \Delta^k \to X$ we can choose a map $P(\sigma) \colon \Delta^k \times [0, 1] \to X$ such that the following four statements are satisfied:

(a) we have $P(\sigma) \circ \eta_0 = \sigma \colon \Delta^k \to X$,
(b) the singular k-simplex $P(\sigma) \circ \eta_1 \colon \Delta^k \to X$ lies in $C_k^{(n)}(X, x_0)$,
(c) if $\sigma \in C_k^{(n)}(X, x_0)$, then $P(\sigma) = \sigma \circ \pi$ where $\pi \colon \Delta^k \times [0, 1] \to \Delta^k$ is the projection map, and

(d) for any $j \in \{0, \dots, k\}$ we have

$$P(\sigma) \circ \underbrace{(i_j^k \times \mathrm{id}_{[0,1]})}_{\Delta^{k-1}\times[0,1]\to\Delta^k\times[0,1]} = P(\underbrace{\sigma \circ i_j^k}_{\Delta^{k-1}\to X}) \colon \Delta^{k-1} \times [0,1] \to X.$$

We turn to the proof of the claim. Property (d) already suggests that we should prove the claim by induction on k. It is convenient to view $k = -1$ as the (trivial) base case. Now let $k \in \mathbb{N}_0$ and suppose that we have proved the claim for all singular i-simplices with $i < k$. Now let $\sigma \colon \Delta^k \to X$ be a singular simplex. If $\sigma \in C_k^{(n)}(X, x_0)$, then we set $P(\sigma) = \sigma \circ \pi$. In this case it is straightforward to verify that the conditions (a), (b) and (d) are satisfied.

Now consider the case that $\sigma \notin C_k^{(n)}(X, x_0)$. We distinguish two cases.

(1) First we consider the case that $k \le n$. By induction the maps $P(\sigma \circ i_j^k)$ have been defined for all j. We set $\partial(\Delta^k \times [0,1]) := (\partial\Delta^k \times [0,1]) \cup (\Delta^k \times \{0,1\})$ and we consider the map

$$Q \colon \partial(\Delta^k \times [0,1]) \to X$$

which is defined via σ on $\Delta^k \times \{0\}$, via the maps $P(\sigma \circ i_j^k)$ on $\partial\Delta^k \times [0,1]$[1349] and which sends all points in $\Delta^k \times \{1\}$ to x_0.[1350] (We refer to Figure 983 for an illustration of this map.) It follows almost immediately from Proposition 1.47 (2) that the pair $(\Delta^k \times [0,1], \partial(\Delta^k \times [0,1]))$ is homeomorphic to $(\overline{B}^{k+1}, S^k)$. Since $k \le n$ and since X is n-connected we obtain from Lemma 28.4 that there exists an extension of Q to a map $\Delta^k \times [0,1] \to X$. We define $P(\sigma)$ to be any such extension. We obtain a map $P(\sigma)$ which is easily seen to have all the desired properties.

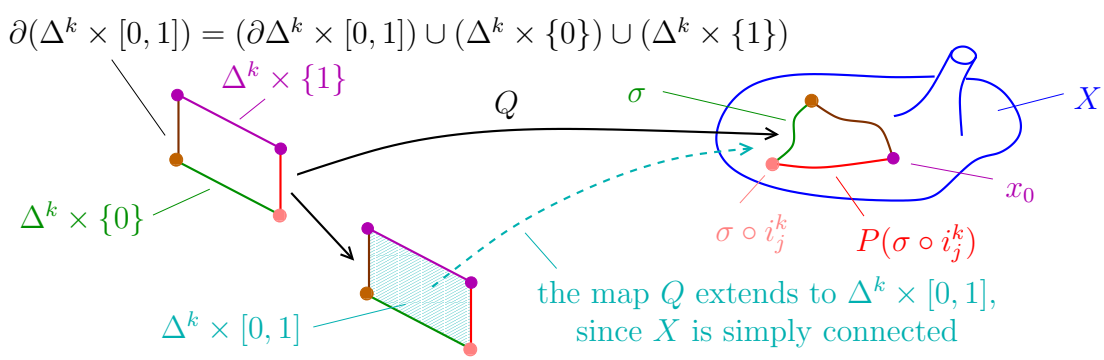

FIGURE 983.

(2) Now we consider the case that $k > n$. Note that in this case condition (b) is satisfied "for free" by any map $\Delta^k \times [0,1] \to X$ that satisfies (d). Thus we only have to find

[1349] Here we use that we assume that the maps $P(\mu)$ are defined for simplices of dimension $< k$.

[1350] It follows from Lemma 1.32 (2') that this map is indeed continuous.

a map $P(\sigma)$ that satisfies (a), (c) and (d). This is much easier than in (1). Indeed, similar to (1) we consider the map

$$G\colon (\Delta^k \times \{0\}) \cup (\partial\Delta^k \times [0,1]) \;\to\; X$$

that is defined via σ on $\Delta^k \times \{0\}$ and via the maps $P(\sigma \circ i_j^k)$ on $\partial\Delta^k \times [0,1]$. (We refer to Figure 984 for an illustration.) Note that by Lemma 27.6 (together with the homeomorphism $\overline{B}^k \cong \Delta^k$) there exists a retraction r from $\Delta^k \times [0,1]$ to the domain of G. Thus combining this retraction r with Q we obtain an extension of Q to map $\Delta^k \times [0,1] \to X$. We define $P(\sigma)$ to be this extension. It follows basically by construction that all the statements are satisfied.

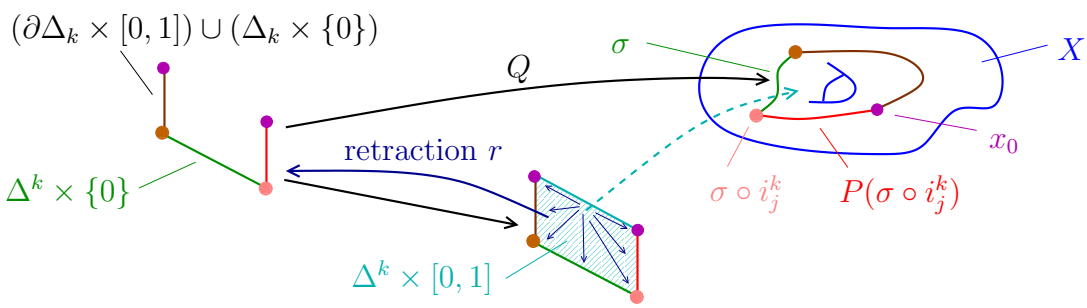

FIGURE 984.

This concludes the proof of the claim.

Now we turn to the actual proof of the statement that the inclusion map[1351]

$$\iota\colon C_*^{(n)}(X, x_0) \;\to\; C_*(X, \{x_0\})$$

is a chain homotopy equivalence. To do so we consider the map

$$\phi\colon C_*(X, \{x_0\}) \;\to\; C_*^{(n)}(X, x_0)$$

that is determined by

$$(\sigma\colon \Delta^n \to X) \;\mapsto\; \phi(\sigma) := \underbrace{P(\sigma) \circ \eta_1}_{\Delta^k \to \Delta^k \times [0,1] \to X}.$$

It follows from (b) that ϕ does indeed take values in $C_*^{(n)}(X, x_0)$ and it follows easily from (d) that ϕ is in fact a chain map. We want to show that ϕ is a chain homotopy inverse to ι. By (c) we have $\phi \circ \iota = \mathrm{id}$. Thus it remains to prove the following claim.

Claim. There exists a chain homotopy from $\iota \circ \phi$ to the identity of $C_*(X, \{x_0\})$.

[1351]Here and throughout the proof we do not distinguish in the notation between a singular chain in $C_k(X)$ and the element it represents in $C_k(X, \{x_0\})$.

Let $k \in \mathbb{N}_0$. We recall that on page 756 we introduced the singular $(k+1)$-chain

$$\Omega_k \;:=\; \sum_{j=0}^{k} (-1)^j \cdot \underbrace{[v_0, \dots, v_j, w_j, \dots, w_k]}_{\Delta^{k+1} \to \Delta^k \times [0,1]} \;\in\; C_{k+1}(\Delta^k \times [0,1])$$

where $v_0, \dots, v_k, w_0, \dots, w_k$ denote the vertices of $\Delta^k \times [0,1]$, see page 755 for details. The key property of these singular chains is that Lemma 30.6 says that for any $k \in \mathbb{N}_0$ we have

$$(*) \qquad \partial_{k+1}(\Omega_k) + \sum_{j=0}^{k} (-1)^j \cdot \underbrace{(i_j^k \times \mathrm{id}_{[0,1]})_*}_{C_*(\Delta^{k-1} \times [0,1]) \to C_*(\Delta^k \times [0,1])} (\Omega_{k-1}) \;=\; \eta_1 - \eta_0 \;\in\; C_k(\Delta^k \times [0,1]).$$

For any $k \in \mathbb{N}_0$ we consider the map

$$D_k \colon C_k(X, \{x_0\}) \;\to\; C_{k+1}(X, \{x_0\})$$

that is determined by

$$(\sigma \colon \Delta^k \to X) \;\mapsto\; \underbrace{P(\,\sigma\,)_*}_{C_*(\Delta^k \times [0,1]) \to C_*(X, \{x_0\})} \;(\; \underbrace{\Omega_k}_{\in C_{k+1}(\Delta^k \times [0,1])}\;).$$

We claim that these maps define a chain homotopy from $\iota \circ \phi$ to the identity of $C_*(X, \{x_0\})$. Thus let $\sigma \colon \Delta^k \to X$ be a singular k-simplex. We need to show that $\partial D\sigma + D\partial\sigma = \phi(\sigma) - \sigma$. Indeed we have

$$\begin{aligned}
\partial_{k+1}(D_k(\sigma)) + D_{k-1}(\partial_k(\sigma)) \;&=\; \partial_{k+1}(D_k(\sigma)) + D_{k-1}\Big(\sum_{j=0}^{k} (-1)^j \cdot \sigma \circ i_j^k\Big) \\
&=\; \partial_{k+1}(P(\sigma)_*(\Omega_k)) + \sum_{j=0}^{k} (-1)^j \cdot P(\sigma \circ i_j^k)_*(\Omega_{k-1}) \\
&=\; P(\sigma)_*\Big(\partial_{k+1}(\Omega_k) + \sum_{j=0}^{k} (-1)^j \cdot (i_j^k \times \mathrm{id}_{[0,1]})_*(\Omega_{k-1})\Big) \\
&\quad\uparrow \\
&\quad \text{in the first summand we used that } P(\sigma)_* \text{ is a chain map and} \\
&\quad \text{in the second summand we used that by (d) we have } P(i_j^k \circ \sigma) = P(\sigma) \circ (i_j^k \times \mathrm{id}_{[0,1]}) \\
&=\; P(\sigma)_*(\eta_1 - \eta_0) \;=\; P(\sigma) \circ \eta_1 - P(\sigma) \circ \eta_0 \;=\; \phi(\sigma) - \sigma. \\
&\quad\uparrow \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \uparrow \\
&\quad \text{by the above equality } (*) \qquad\qquad\qquad \text{by (a) and definition of } \phi
\end{aligned}$$

This concludes the proof of the claim. □

Before we can continue with the proof of the Hurewicz Theorem 80.5 we need to introduce another, slightly different point of view, regarding higher homotopy groups.

So let $n \in \mathbb{N}$. We consider the homeomorphism $\eta_n \colon (\Delta^n, \partial\Delta^n) \to (\overline{B}^n, S^{n-1})$ that is given by the composition of the following three maps:[1352]

$$\begin{aligned} \eta_n \colon \Delta^n &\xrightarrow{\cong} \left\{ (x_1, \dots, x_n) \in [0,1]^n \;\middle|\; \sum_{i=1}^n x_i \in [0,1] \right\} \xrightarrow[\text{with } Q = (\frac{1}{n+1}, \dots, \frac{1}{n+1})]{\text{Proposition 1.48 (2)}} \overline{B}^n \xrightarrow[\text{by } A_n]{\text{multiplication}} \overline{B}^n. \\ (t_0, \dots, t_n) &\mapsto (t_0, \dots, t_{n-1}) \end{aligned}$$

where $A_n \in \mathrm{O}(n)$ is a matrix which is chosen in such a way that we have the equality $\eta_n((1,0,\dots,0)) = * := (-1,0,\dots,0)$.[13531354] We sketch the definition of η_n in Figure 985.

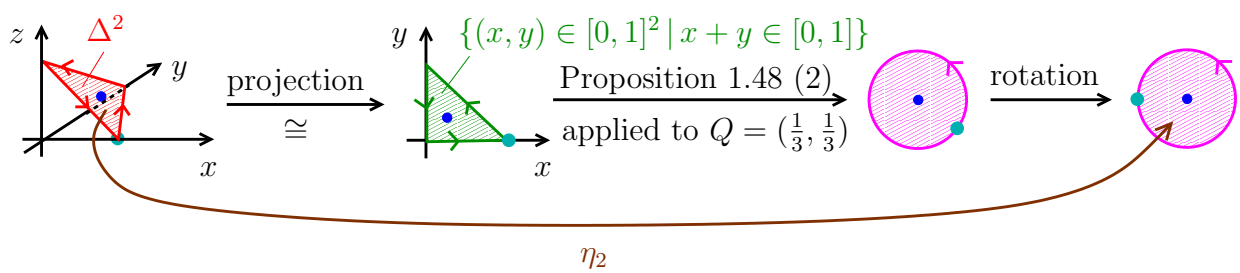

FIGURE 985.

We use the homeomorphism $\eta_n \colon (\Delta^n, \partial\Delta^n) \to (\overline{B}^n, S^{n-1})$ to identify these two pairs of topological spaces. In particular we use it to make the identification $\partial\Delta^n = S^{n-1}$. By a slight abuse of notation we write write $* := (1,0,\dots,0) \in \Delta^n$. In particular for any $n \in \mathbb{N}_0$ we can extend the identifications from page 1847 to obtain the following identifications

$$\begin{array}{ccccc} \pi_n(X, x_0) & = & \begin{array}{c} \text{set (of homotopy classes)} \\ \text{of maps } (I^n, \partial I^n) \to (X, x_0) \\ \| \\ \text{set (of homotopy classes)} \\ \text{of maps } (\overline{B}^n, S^{n-1}) \to (X, x_0) \\ \| \\ \text{set (of homotopy classes)} \\ \text{of maps } (\Delta^n, \partial\Delta^n) \to (X, x_0). \end{array} & = & \begin{array}{c} \text{set (of homotopy classes)} \\ \text{of maps } (S^n, *) \to (X, x_0) \\ \| \\ \text{set (of homotopy classes)} \\ \text{of maps } (\partial\Delta^{n+1}, *) \to (X, x_0) \end{array} \end{array}$$

As above we will use these identifications to pick at each given moment our most convenient point of view.

As an illustration, under the above identifications Lemma 28.4 translates into the following lemma.

[1352]Note that the composition of the first two homeomorphisms is precisely the homeomorphism from Lemma 29.1.

[1353]It follows from Lemma 1.73 (3) that such a matrix exists.

[1354]The map η_n depends on the choice of the matrix A_n, this will not affect us at all.

Lemma 80.12. *Let (X, x_0) be a pointed topological space and let $n \geq 1$. Furthermore let $f\colon (\partial\Delta^{n+1}, *) \to (X, x_0)$ be a map. Then f represents the trivial element in $\pi_n(X, x_0)$ if and only if there exists a map $F\colon \Delta^{n+1} \to X$ so that $F|_{\partial\Delta^{n+1}} = f$.*

The following lemma is the other key technical ingredient in the proof of the Hurewicz Theorem 80.5.

Lemma 80.13. *Let (X, x_0) be a pointed topological space and let $n \in \mathbb{N}_{\geq 2}$. Furthermore let $\sigma\colon \partial\Delta^{n+1} \to X$ be a map that sends the $(n-1)$-skeleton of $\partial\Delta^{n+1}$ to x_0. Then*[1355][1356]

$$[\sigma\colon (\partial\Delta^{n+1}, *) \to (X, x_0)] \;=\; \sum_{j=0}^{n+1} (-1)^j \cdot [\sigma \circ i_j^{n+1}\colon (\Delta^n, \partial\Delta^n) \to (X, x_0)] \;\in\; \pi_n(X, x_0).$$

We refer to Figure 986 for an illustration for $n = 1$, even though this case is strictly speaking not allowed.

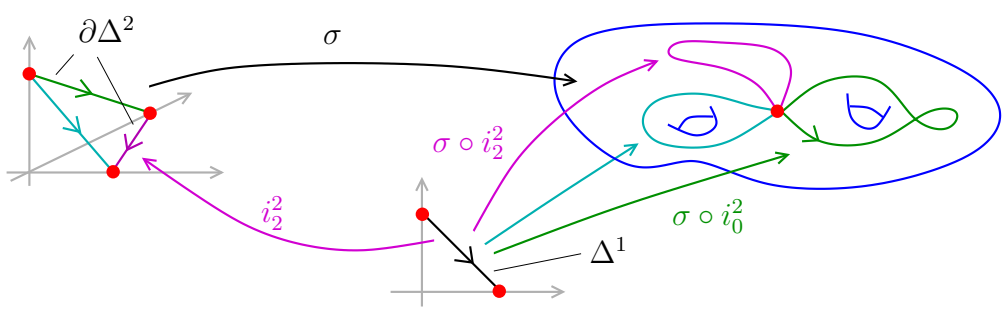

FIGURE 986. Illustration of Lemma 80.13.

Proof $(*)$. The reader might already have noticed that the statement of the lemma resembles the statement of Proposition 80.2. Indeed, after some massaging we will be able to deduce the desired statement from Proposition 80.2.

Given any $k \in \mathbb{N}_0$, let $\eta_k\colon (\Delta^k, \partial\Delta^k) \to (\overline{B}^k, S^{k-1})$ the homeomorphism from page 1861. Using our identifications the desired statement is now equivalent to the following statement.

Statement. Given $j \in \{0, \dots, n+1\}$ we write $\alpha_i = \eta_{n+1} \circ i_j^{n+1} \circ \eta_n^{-1}\colon \overline{B}^n \to S^n = \partial\overline{B}^{n+1}$ and furthermore we write $f_j = \sigma \circ i_j^{n+1} \circ \eta_n^{-1}\colon \overline{B}^n \to X$. Then we have the following equality in $\pi_n(X, x_0)$:

$$\big[\underbrace{\Phi(\alpha_0, \dots, \alpha_n, f_0, \dots, f_n)\colon (S^n, *) \to (X, x_0)}_{\in \pi_n(X, x_0)}\big] \;=\; -\sum_{j=0}^{n+1} (-1)^j \cdot \big[\underbrace{f_j\colon (\overline{B}^n, S^{n-1}) \to (X, x_0)}_{\in \pi_n(X, x_0)}\big].$$

[1355]Note that our hypothesis that σ sends the $(n-1)$-skeleton of $\partial\Delta^{n+1}$ to x_0 implies in particular that for all $j \in \{0, \dots, n+1\}$ we have $(\sigma \circ i_j^{n+1})(\partial\Delta^n) = \{x_0\}$.

[1356]Also note that by our base point $*$ is chosen in such a way that it lies on the $(n-1)$-skeleton of $\partial\Delta^{n+1}$.

We refer to Figure 987 for an illustration.

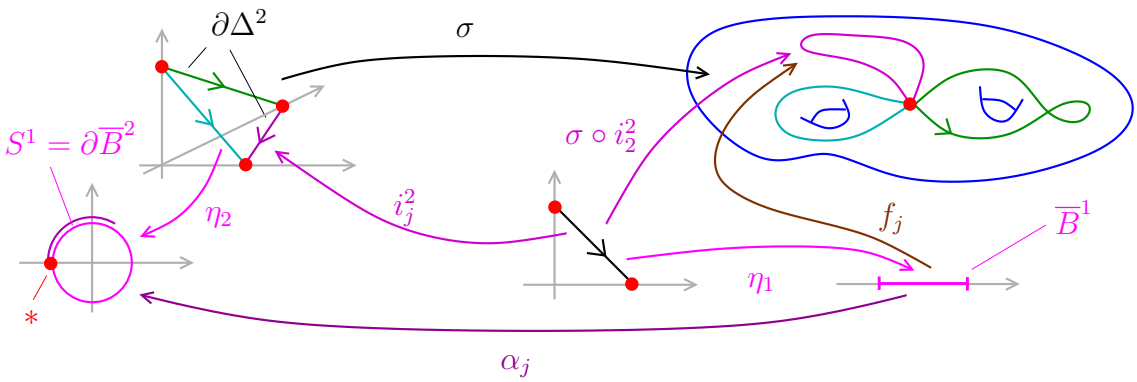

FIGURE 987. Illustration of the proof of Lemma 80.13.

First note that it follows from the discussion on page 1089 that the maps η_k is orientation-preserving if and only if k is even. Furthermore it is fairly straightforward to see that the maps i_j^{n+1} are orientation-preserving if and only if j is even. In summary, the topological embedding α_j is orientation-preserving if and only if j is odd.[1357]

The only reason why we cannot apply Proposition 80.2 immediately is that the maps α_j are topological embeddings but they are not smooth, so they are not embeddings. Keeping Lemma 80.1 in mind we see that it suffices to prove the following claim.

Claim. The maps $\alpha_0, \ldots, \alpha_{n+1} \colon \overline{B}^n \to S^n$ are isotopic, through weakly disjoint topological embeddings, to embeddings $\beta_0, \ldots, \beta_{n+1}$.

For $j = 0, \ldots, n+1$ we write $F_j = i_j^{n+1}(\mathring{\Delta}^n)$ and we write $\overline{F}_j = i_j^{n+1}(\Delta^n)$. Note that F_j is an n-dimensional submanifold of $\mathbb{R}^{n+1}$, we endow it with the usual orientation where the "normal vector sticks outward". Now this claim can be proved using the following observations:

(1) similar to the discussion on page 1850 we can shrink the weakly disjoint topological embeddings $\alpha_j \colon \overline{B}^n \to \overline{F}_j$ to disjoint topological embeddings $\beta_j \colon \overline{B}^n \to F_j$,
(2) using Lemma 9.1 we can isotope these topological embeddings $\beta_j \colon \overline{B}^n \to F_j$ to embeddings[1358] $\gamma_i \colon \overline{B}^n \to F_j$
(3) for each $j \in \{0, \ldots, n+1\}$ the restriction of $\eta_{n+1} \colon \partial\Delta^{n+1} \to S^n$ to the map $\eta_{n+1} \colon F_j \to S^n$ is smooth and orientation-preserving.

Together with Figure 988 the reader should have no troubles assembling a full proof of the claim and the lemma using the above observations. □

Now we can turn to the proof of the Hurewicz Theorem 80.5.

[1357]Here we used the deep fact that precisely one out of the numbers n, $n+1$ is odd.
[1358]Recall that an embedding is by definition smooth.

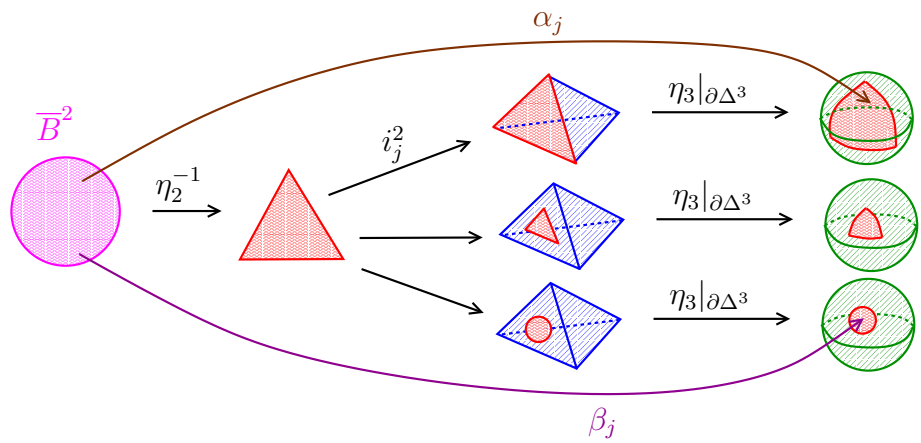

FIGURE 988. Illustration of the proof of Lemma 80.13.

Proof of the Hurewicz Theorem 80.5. Let $n \in \mathbb{N}_{\geq 2}$ and let (X, x_0) be a pointed topological space. We suppose that X is $(n-1)$-connected.

Statement (1) of the theorem can be proved easily. Indeed, let $k \in \{0, \dots, n-1\}$. We have

$$\begin{array}{ccccccc} \widetilde{H}_k(X;\mathbb{Z}) & \cong & H_k(X, \{x_0\};\mathbb{Z}) & = & H_k^{(n-1)}(X, x_0) & = & 0. \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{Lemma 31.12} & & \begin{array}{c}\text{by Lemma 80.11 since} \\ X \text{ is } (n-1)\text{-connected}\end{array} & & \begin{array}{c}\text{by Lemma 80.10 (2)} \\ \text{since } k \leq n-1\end{array} & \end{array}$$

We turn to the much more interesting proof of statement (2). As a reminder, we want to show that the map

$$\pi_n(X, x_0) \xrightarrow{\Phi_{(X,x_0)}} H_n(X;\mathbb{Z})$$

is an isomorphism. The goal again is to bring the homology groups $H_n^{(n-1)}(X, x_0)$ into the game. This leads us to the following claim.

Claim.

(1) The map

$$\begin{array}{rcl} \Psi_{(X,x_0)} \colon \pi_n(X, x_0) & \to & H_n^{(n-1)}(X, x_0) \\ [f \colon (\Delta^n, \partial\Delta^n) \to (X, x_0)] & \mapsto & [\underbrace{f \colon \Delta^n \to X}_{\in C_n^{(n-1)}(X,x_0)}] \end{array}$$

is well-defined and it is a homomorphism.

(2) The following diagram commutes up to the sign $(-1)^n$:

$$\begin{tikzcd}
\pi_n(X,x_0) \arrow[r, "\Phi_{(X,x_0)}", "{[f]\mapsto f_*([S^n])}"'] \arrow[d, "\Psi_{(X,x_0)}"'] & H_n(X;\mathbb{Z}) \arrow[d, "\cong"] \\
H_n^{(n-1)}(X,x_0) \arrow[r, "\cong", "\iota"'] & H_n(X,\{x_0\};\mathbb{Z})
\end{tikzcd}$$

where ι is induced by the inclusion $C_*^{(n-1)}(X,x_0) \to C_n(X,\{x_0\})$.

(3) The right-vertical and the bottom-horizontal maps of the diagram in (2) are isomorphisms.

We prove the claim using a somewhat convoluted logic.[1359] We consider the following diagram

$$\begin{tikzcd}
\{\text{set of maps } (\Delta^n,\partial\Delta^n) \to (X,x_0)\} \arrow[rr, "f\mapsto f_*([\Delta^n])"] \arrow[dr, two heads] \arrow[dd, "f\mapsto[f]"'] & & H_n(X;\mathbb{Z}) \arrow[dd, "\cong"] \\
& \pi_n(X,x_0) \arrow[ur, "\Phi_{(X,x_0)}"'] \arrow[dl, dashed, "\Psi_{(X,x_0)}"'] & \\
H_n^{(n-1)}(X,x_0) \arrow[rr, "\cong", "\iota"'] & & H_n(X,\{x_0\};\mathbb{Z})
\end{tikzcd}$$

We make the following observations:

(a) It follows from $n \geq 2$ and from the long exact sequence of homology groups of the pair $(X,\{x_0\})$, see Corollary 31.14, that the right-hand vertical map of both diagrams is an isomorphism.

(b) It follows from Lemma 80.11 and our hypothesis that X is $(n-1)$-connected that the bottom horizontal map ι of both diagrams is an isomorphism.

(c) Let $f\colon (\Delta^n,\partial\Delta^n) \to (X,x_0)$ be a map. The $(n-1)$-skeleton of Δ^n equals $\partial\Delta^n$, thus the map $f\colon \Delta^n \to X$ does indeed define an element in $C_n^{(n-1)}(X,x_0)$. Furthermore by Lemma 80.10 (3) we know that every element in $C_n^{(n-1)}(X,x_0)$ is a cycle, thus f defines an element in $H_n^{(n-1)}(X,x_0)$. This shows that in the above diagram the left vertical map is well-defined.

(d) Let $f\colon (\Delta^n,\partial\Delta^n) \to (X,x_0)$ be a map. It follows from Lemma 32.12 that going down-right and going right-down leads to the same element in $H_n(X,\{x_0\};\mathbb{Z})$, up to the sign $(-1)^n$. Thus in the above diagram the rectangle commutes up to sign.

(e) Evidently the top small triangle in the above diagram commutes.

(f) We want to show that $\Psi_{(X,x_0)}$ is well-defined and that it is a homomorphism. By (b) we know that ι is an isomorphism. Thus it suffices to show these statements for $\iota \circ \Psi_{(X,x_0)}$. But these now follow from (d) and (e) and the fact, see Proposition 80.4 (1), that the Hurewicz homomorphism $\Phi_{(X,x_0)}$ is well-defined and a homomorphism.

[1359] The convoluted logic is forced upon us since proving (1) as a stand-alone statement is actually slightly tricky.

This concludes the proof of the claim.

By the claim it suffices to show that the homomorphism

$$\begin{array}{rcl} \Psi_{(X,x_0)}\colon \pi_n(X,x_0) & \to & H_n^{(n-1)}(X,x_0) \\ [f\colon (\Delta^n,\partial\Delta^n)\to(X,x_0)] & \mapsto & [f\colon \Delta^n\to X] \end{array}$$

is in fact an isomorphism. We will do so by defining an explicit inverse.

Claim.

(1) The map

$$\Xi_{(X,x_0)}\colon C_n^{(n-1)}(X,x_0) \ \to\ \pi_n(X,x_0)$$

that is induced by

$$(\sigma\colon (\Delta^n,\partial\Delta^n)\to(X,x_0)) \ \mapsto\ [\sigma\colon (\Delta^n,\partial\Delta^n)\to(X,x_0)]$$

is well-defined.

(2) The map $\Xi_{(X,x_0)}$ from (1) descends to a well-defined map

$$H_n^{(n-1)}(X,x_0) \ \to\ \pi_n(X,x_0).$$

(3) The map $\Xi_{(X,x_0)}$ is an inverse to $\Psi_{(X,x_0)}$.

Since the end is near we set out with renewed vigor to prove the claim.

(1) Recall that we know from Proposition 28.3 and our hypothesis $n\geq 2$ that the group on the right is abelian. Therefore it follows from Lemma 11.1 that the map is well-defined.[1360]

(2) Let $\sigma\colon \Delta^{n+1}\to X$ be a singular $(n+1)$-simplex that defines an element in the group $C_{n+1}^{(n-1)}(X,x_0)$. We need to show that $\Xi_{(X,X_0)}(\partial\sigma)=0$. We calculate that we have the following equality in $\pi_n(X,x_0)$:

$$\Xi_{(X,X_0)}(\partial\sigma)=\Xi_{(X,X_0)}\Big(\sum_{j=0}^{n+1}(-1)^j\cdot\sigma\circ i_j^n\Big)\underset{\substack{\uparrow\\ \text{by definition of }\Xi_{(X,x_0)}}}{=}\sum_{j=0}^{n+1}(-1)^j\cdot[\overbrace{\sigma\circ i_j^{n+1}}^{(\Delta^n,\partial\Delta^n)\to(X,x_0)}]\underset{\substack{\uparrow\\ \text{Lemma 80.13}}}{=}-[\overbrace{\sigma|_{\partial\Delta^{n+1}}}^{(\partial\Delta^{n+1},*)\to(X,x_0)}]\underset{\substack{\uparrow\\ \text{Lemma 80.12}}}{=}0.$$

(3) It follows immediately from the definitions that $\Xi_{(X,x_0)}\circ\Psi_{(X,x_0)}$ is the identity on $\pi_n(X,x_0)$. Furthermore it follows easily from Lemma 80.10 and the definitions that $\Psi_{(X,x_0)}\circ\Xi_{(X,x_0)}$ is the identity on a generating set for $H_n^{(n-1)}(X,x_0)$. But by the claim and Proposition 80.4 (1) we know that $\Psi_{(X,x_0)}$ and $\Xi_{(X,x_0)}$ are both homomorphisms. Thus we see that $\Psi_{(X,x_0)}\circ\Xi_{(X,x_0)}$ is actually the identity on all of $H_n^{(n-1)}(X,x_0)$.

This concludes the proof of the claim and thus we are done with the proof of the Hurewicz Theorem 80.5. □

[1360]Put differently, it would be a serious dereliction of duty to use the additive notation for a group structure, if the group was not known to be additive.

Remark. The most awkward aspect of the proof of the Hurewicz Theorem 80.5 is that one needs to go back and forth between the different points of view regarding elements in higher homotopy groups, in particular the fact that we need Proposition 80.2 and Lemma 80.13 is arguably aesthetically somewhat unpleasant.

In fact there is, in principle, an elegant way around this problem: One could prove the Hurewicz Theorem 80.5 using "cubical singular homology" instead of the usual singular homology. As the name suggests, in this theory the "building blocks" are singular cubes, i.e. maps from $[0,1]^n$ to a topological space X. (This theory is developed in [Mas2, Chapter VII.2].) Since cubes are also used in the definition of the product structure on higher homotopy groups I would expect that many of the technical issues we had to deal with vanish magically.

The downside is that one still needs to show that "cubical singular homology" is naturally isomorphic to the usual singular homology. This can be shown using the Acyclic Model Theorem 56.16.

Exercises for Chapter 80. In the following two exercises we need the following definition.

Definition. A topological space X is called *aspherical* if it is path-connected and if all higher homotopy groups $\pi_n(X)$, $n \geq 2$, vanish.

Exercise 80.1. Let X be a connected 2-dimensional CW-complex with $\pi_2(X) = 0$. Show that X is aspherical.

Exercise 80.2. Let X be a CW-complex and let U and V be path-connected subcomplexes of X. Suppose that $U \cap V$ is path-connected and furthermore suppose that the inclusion induced maps $\pi_1(U \cap V) \to \pi_1(U)$ and $\pi_1(U \cap V) \to \pi_1(V)$ are monomorphisms. Finally suppose that U, V and $U \cap V$ are aspherical. Show that X is also aspherical.
Hint: You might want to use Propositions 13.14, 20.15 and Proposition 50.12 (6).

Exercise 80.3. Let M and N be two closed oriented n-dimensional manifolds. Suppose there exists a $k \in \mathbb{N}$ such that M and N are k-connected. Show that the connected sum $M \# N$ is also k-connected.

Exercise 80.4. Let X be an n-dimensional CW-complex and let Y be a subcomplex of X that is homotopy equivalent to S^n. Show that the inclusion induced map $\pi_n(Y) \to \pi_n(X)$ is a monomorphism.

Exercise 80.5. We denote by $*$ suitable base points of the spheres. Now let $f\colon S^n \to S^n$ be a map with $f(*) = *$. We suppose that f is a map of degree $k \in \mathbb{Z}$, i.e. f is a map such that the induced map $f_*\colon H_n(S^n;\mathbb{Z}) \to H_n(S^n;\mathbb{Z})$ is given by multiplication by k.

(a) Let $g\colon S^n \to S^m$ be a map. Show that $[g \circ f] = k \cdot [g] \in \pi_n(S^m)$.
(b) Show that if $g\colon S^m \to S^n$ is a map, then it is not necessarily the case that the equality $[f \circ g] = k \cdot [g] \in \pi_m(S^n)$ holds.

Hint: We view S^3 as a subset of $\mathbb{C}^2$ and we make the usual identification $\mathbb{C}\mathrm{P}^1 = S^1$. Now consider the following commutative diagram:

$$\begin{tikzcd} S^3 \arrow[r, "(z,w)\to[(z,w)]"] \arrow[d, "(z,w)\mapsto(\overline{z},\overline{w})"'] & S^2 \arrow[d, "{[(z,w)]\mapsto[(\overline{z},\overline{w})]}"] \\ S^3 \arrow[r, "(z,w)\to[(z,w)]"] & S^2. \end{tikzcd}$$

81. Applications of the Hurewicz Theorem

In this chapter we want to spend some more time with the Hurewicz Theorem and we want to discuss some applications thereof.

81.1. **Paths acting on homotopy groups.** In Propositions 5.11 and 28.5 we already saw that for path-connected topological spaces the *isomorphism types* of the homotopy groups do not depend on the choice of the base point.

In this section we want to discuss this statement in greater detail. We recall the following definition which appeared already in the proof of Proposition 28.5.

Definition. Let X be a topological space and let $n \in \mathbb{N}$. Let $\gamma\colon [0,1] \to X$ be a path from a point x_0 to a point x_1. Given a map $f\colon (I^n, \partial I^n) \to (X, x_1)$ we define the map

$$\begin{array}{rcl} f^\gamma\colon (I^n, \partial I^n) & \to & (X, x_0) \\ (t_1, \dots, t_n) & \to & \begin{cases} f\big(2t_1 - \frac{1}{2}, \dots, 2t_n - \frac{1}{2}\big), & \text{if } (t_1, \dots, t_n) \in \big[\frac{1}{4}, \frac{3}{4}\big]^n, \\ \gamma(t), & \text{if } (t_1, \dots, t_n) \in \partial\big(\big[\frac{t}{4}, \frac{4-t}{4}\big]^n\big) \text{ for } t \in [0,1]. \end{cases} \end{array}$$

The definition of f^γ is illustrated in Figure 989.

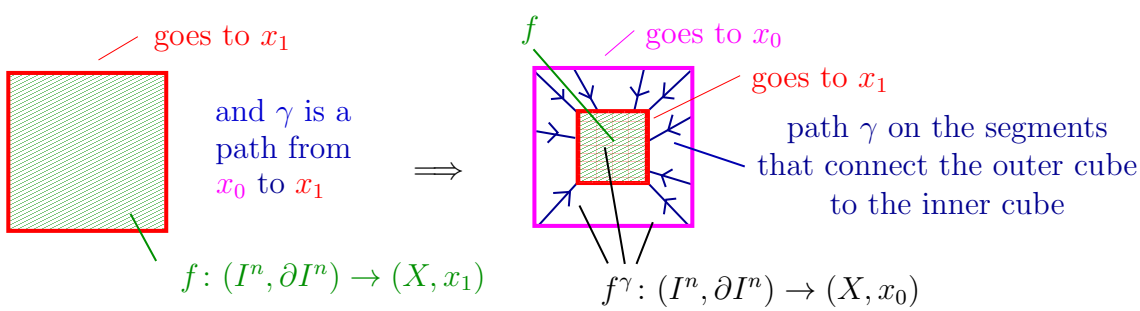

Figure 989.

Example. We consider the case $n = 1$ in the above definition. In this situation the map $f\colon (I, \partial I) \to (X, x_1)$ is a loop. It follows almost immediately from the definitions that the new loop $f^\gamma\colon (I, \partial I) \to (X, x_0)$ equals, up to an orientation-preserving reparametrization, the loop $\gamma * f * \overline{\gamma}$ that is given by the product of the three paths γ, f and $\overline{\gamma}$. We refer to Figure 990 for an illustration.

Figure 990.

Remark. Recall that on pages 715 and 1847 we saw that we can also interpret elements in a homotopy group $\pi_n(X, x_0)$ as homotopy classes of maps $(S^n, *) \to (X, x_0)$. Let $\gamma\colon [0,1] \to X$ be a path from x_0 to x_1 and let $f\colon (S^n, *) \to (X, x_1)$ be a map. We define[1361]

$$\begin{array}{rcl} f^\gamma\colon S^n & \to & X \\ \underbrace{\cos(\varphi)\cdot(1,0,\dots,0)+\sin(\varphi)\cdot(0,v)}_{\varphi\in[0,\pi], v\in\mathbb{R}^{n-1}} & \mapsto & \begin{cases} f(\cos(2\varphi)\cdot(1,0,\dots,0)+\sin(2\varphi)\cdot(0,v)), & \text{if } \varphi\in[0,\frac{\pi}{2}] \\ \gamma(2-\frac{2}{\pi}t), & \text{if } \varphi\in[\frac{\pi}{2},\pi]. \end{cases} \end{array}$$

Of course one should only work with the formula if one is forced to at gun point. It is much more illuminating to look at Figure 991 where we try our best to visualize the map $f^\gamma\colon (S^n, *) \to (X, x_0)$. One can easily verify that, under the various identifications, the map f^γ corresponds to the construction on page 1869.

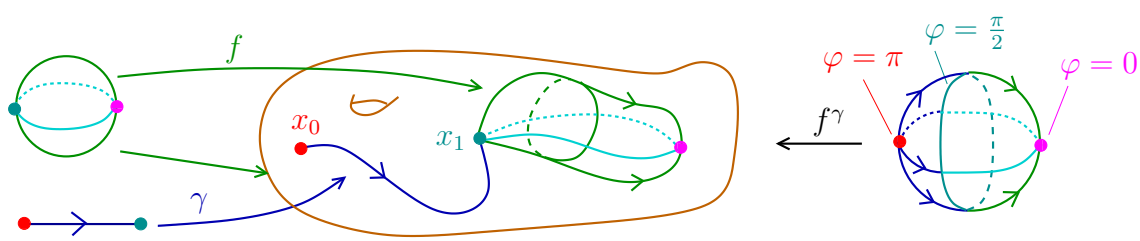

FIGURE 991.

Before we continue we introduce the following basically self-explanatory definition.

Definition. Let G be a group and let A be a group (or module or vector space). An *action of G on the group A* (respectively module or vector space) is a an action $G \times A \to A$ in the sense of the definition on page 102 such that for each $g \in G$ the map

$$\begin{array}{rcl} A & \to & A \\ a & \mapsto & g\cdot a \end{array}$$

is a group homomorphism (respectively module or vector space homomorphism).[1362]

The following proposition can be viewed as a more precise version of Proposition 28.5.

Proposition 81.1. *Let X be a topological space and let $n \in \mathbb{N}$.*

(1) *If $\gamma\colon [0,1] \to X$ is a path from x_0 to x_1, then the map*

$$\begin{array}{rcl} \gamma_*\colon \pi_n(X, x_1) & \to & \pi_n(X, x_0) \\ [f] & \mapsto & [f^\gamma] \end{array}$$

is a well-defined isomorphism.

(2) *If x_0 and x_1 are two points in X which lie in the same path-component of X, then $\pi_n(X, x_0)$ is isomorphic to $\pi_n(X, x_1)$.*

[1361]It follows easily from Lemma 1.32 (2') that this map is continuous.

[1362]In fact, since multiplication by g^{-1} is an inverse we see that these maps are actually isomorphisms.

(3) *Let $\varphi\colon X \to Y$ be a map between topological spaces.*
   (a) *If $\gamma\colon [0,1] \to X$ is a path from x_0 to x_1, then the following diagram commutes*

$$\begin{tikzcd} \pi_n(X,x_1) \arrow[r, "\gamma_*"] \arrow[d, "\varphi_*"'] & \pi_n(X,x_0) \arrow[d, "\varphi_*"] \\ \pi_n(Y,\varphi(x_1)) \arrow[r, "(\varphi\circ\gamma)_*"] & \pi_n(Y,\varphi(x_0)). \end{tikzcd}$$

   (b) *If $\varphi_*\colon \pi_n(X,x_0) \to \pi_n(Y,\varphi(x_0))$ is an isomorphism (epimorphism, monomorphism) for some base point $x_0 \in X$, then for any other base point x_1 in the same path component of X the map $\varphi_*\colon \pi_n(X,x_1) \to \pi_n(Y,\varphi(x_1))$ is also an isomorphism (epimorphism, monomorphism).*[1363]

(4) *Let γ and δ be two paths in X from x_0 to x_1. If γ and δ are path-homotopic in X, then the corresponding maps γ_* and δ_* from $\pi_n(X,x_1)$ to $\pi_n(X,x_0)$ agree.*

(5) *If γ is a path in X from x_0 to x_1 and if δ is a path in X from x_1 to x_2, then*[1364]

$$(\underbrace{\gamma * \delta}_{\text{path from } x_0 \text{ to } x_2})_* = \gamma_* \circ \delta_*\colon \pi_n(X,x_2) \ \to\ \pi_n(X,x_0).$$

(6) *The map*

$$\begin{array}{rcl} \pi_1(X,x_0) \times \pi_n(X,x_0) & \to & \pi_n(X,x_0) \\ ([\gamma],[f]) & \mapsto & [\gamma]\cdot[f] := [f^\gamma] \end{array}$$

defines an action (in the sense of the definition on page 102) of the group $\pi_1(X,x_0)$ on the group $\pi_n(X,x_0)$.

(7) *Let $f_0, f_1\colon S^n \to X$ be two maps. We write $x_0 = f_0(1)$ and $x_1 = f_1(1)$. The following statement holds:*

$$f_0 \text{ and } f_1 \text{ are homotopic} \quad\Longleftrightarrow\quad \begin{array}{c}\text{there exists a path } \gamma \text{ from } x_0 \text{ to } x_1 \\ \text{such that } [f_1^\gamma] = [f_0] \in \pi_n(X,x_0).\end{array}$$

Remark. Let X be a topological space, let x_0, x_1 be two points in X and let γ and δ be two paths from x_0 to x_1. If X is simply connected, then Lemma 5.13 tells us that the two paths γ and δ are in fact homotopic. Therefore it follows from Proposition 81.1 (4) that $\gamma_* = \delta_*\colon \pi_n(X,x_0) \to \pi_n(X,x_1)$. In other words, if X is simply connected, then given any two base points x_0 and x_1 there exists in fact a natural[1365] isomorphism $\pi_n(X,x_0) \xrightarrow{\cong} \pi_n(X,x_1)$. In particular in this case it is almost always entirely safe to suppress the base point in the notation. By Proposition 5.14 this observation applies in particular to $X = S^k$ for $k \geq 2$.

Proof.

[1363] For $n = 1$ this is basically the content of Exercise 6.4.

[1364] Here it is worth remembering that by definition, see page 231, the product path $\gamma * \delta$ is given by first traversing γ and then traversing δ.

[1365] As always, when the adjective "natural" gets used it is an amusing exercise to figure out what categories and functors are involved.

(0) Let $\gamma\colon [0,1] \to X$ be a path from x_0 to x_1. It is straightforward to see that the map

$$\begin{array}{rcl} \gamma_*\colon \pi_n(X,x_1) & \to & \pi_n(X,x_0) \\ [f] & \mapsto & [f^\gamma] \end{array}$$

is well-defined. It is also elementary, albeit potentially slightly painful, to see that γ_* is a group homomorphism. (See the corresponding discussion in the proof of Proposition 28.5.)

(4),(5) These two statements are elementary to verify. It is worth spending a second to convince oneself that in (5) we have the equality $(\gamma * \delta)_* = \gamma_* \circ \delta_*$ instead of $(\gamma * \delta)_* = \delta_* \circ \gamma_*$.

(1) Recall that in Proposition 5.6 (3) we saw that for any path δ the composition $\delta * \overline{\delta}$ is path-homotopic to the constant path. It follows easily from this observation together with (4) and (5) that γ_* is a bijection. Together with (0) we see that for any path $\gamma\colon [0,1] \to X$ from x_0 to x_1 the induced map $\gamma_*\colon \pi_n(X,x_1) \to \pi_n(X,x_0)$ is an isomorphism.

(2) This is an immediate consequence of (1)

(3) Statement (a) follows immediately from the definitions. Statement (b) is a consequence of the commutative diagram of (a) and the fact that the horizontal maps are isomorphisms by (1).

(6) It follows immediately from (4) and (5) that the map defines an action of $\pi_1(X,x_0)$ on the set $\pi_n(X,x_0)$. Furthermore (1) implies that this action is in fact an action on the group $\pi_n(X,x_0)$.

(7) The proof of this statement is a moderately complicated generalization of the proof of Proposition 9.22. We leave it to the reader to fill in the details. □

81.2. **Group rings.** Before we continue with our study of higher homotopy groups it is convenient to introduce the purely algebraic concept of a group ring.

Definition. Let G be a group and let R be a commutative ring. We denote the free R-module generated by the set G by $R[G]$. Put differently, with the notation from page 366 we have

$$R[G] \;=\; \Big\{ \sum_{i=1}^m r_i g_i \,\Big|\, r_1,\dots,r_m \in R \text{ and } g_1,\dots,g_m \in G \Big\}.$$

We equip $R[G]$ with the multiplication that is given by[1366]

$$\Big(\sum_{i=1}^m r_i g_i\Big) \cdot \Big(\sum_{j=1}^n s_j h_j\Big) \;:=\; \sum_{i=1}^m \sum_{j=1}^n \underbrace{r_i s_j}_{\in R} \cdot \underbrace{(g_i h_j)}_{\in G}.$$

We refer to $R[G]$ as the *group ring of G with R-coefficients.* (For $R = \mathbb{Z}$ we refer to $\mathbb{Z}[G]$ as *the group ring of G.*)

The following lemma summarizes a few basic facts about group rings.

Lemma 81.2. *Let G be a group and let R be a commutative ring.*

[1366]The multiplication is basically given by naive "multiplying out".

(1) *The group ring $R[G]$ is an associative ring with a multiplicatively neutral element, namely $1 \cdot e$ where e denotes the trivial element in G.*
(2) *The group ring $R[G]$ is commutative if and only if G is an abelian group.*
(3) *If R is a field, then $R[G]$ is evidently an algebra over the field R.*
(4) *Given a unit $r \in R$ and an element $g \in G$ the product $r \cdot g$ is a unit in $R[G]$.*
(5) *If G has a torsion element, i.e. if there exists a non-trivial $g \in G$ such that $g^k = e$ for some $k \in \mathbb{N}$, then $R[G]$ has zero divisors.*

Proof. All the statements are verified easily. Perhaps the most interesting statement is (5). We will not rob the reader of the pleasure of proving this in Exercise 81.2. □

Examples. Let R be a commutative ring.

(1) We consider the infinite cyclic group $\langle t \rangle$. In this case the group ring $R[\langle t \rangle]$ is isomorphic to the ring $R[t^{\pm 1}]$ of Laurent polynomials, more precisely the "obvious" map
$$\begin{array}{ccc} R[t^{\pm 1}] & \to & R[\langle t \rangle] \\ \sum\limits_{i=r}^{i=s} a_i t^i & \mapsto & \sum\limits_{i=r}^{i=s} a_i t^i \end{array}$$
is a ring isomorphism.
(2) More generally, if H is a free abelian group of rank m, then any choice of a basis $t_1, \ldots, t_m$ for H gives rise to a natural isomorphism from the multivariable Laurent polynomial ring $R[t_1^{\pm 1}, \ldots, t_m^{\pm 1}]$ to the group ring $R[H]$.

The group rings of free groups are particularly interesting. Therefore we dedicate a lemma to them.

Lemma 81.3. *Let $\langle T \rangle$ be the free group on a generating set T. Given any ring S and given any map $g\colon T \to S$ there exists a unique ring homomorphism $\varphi\colon \mathbb{Z}[\langle T \rangle] \to S$ with $\psi(t) = g(t)$ for all $t \in T$.*

Remark. Given a commutative ring R the group ring $R[\langle T \rangle]$ is sometimes called the *free ring on the set S over the ring R.*

Proof. It follows immediately from Lemma 11.13 that there exists a unique group homomorphism $\varphi\colon \langle T \rangle \to S^* := \{\text{units of } S\}$ that extends the given map g. It is now straightforward to verify that the map
$$\begin{array}{ccc} \mathbb{Z}[\langle T \rangle] & \to & S \\ \sum\limits_{i=1}^{m} r_i g_i & \mapsto & r_i \cdot \varphi(g_i) \end{array}$$
is a ring homomorphism that extends g and that it is the unique ring homomorphism with this desirable property. □

As a side remark we mention the following beautiful conjectures. These say in particular that in some sense the statements of Lemma 81.2 (4) and (5) are optimal.

Conjecture 81.4. (Kaplansky Conjectures) *Let G be a torsion-free group and let $\mathbb{F}$ be a field.*

(1) *The elements* 0 *and* 1 *are the only idempotents of* $\mathbb{F}[G]$*, i.e. they are the only elements in* $\mathbb{F}[G]$ *with* $x^2 = x$*.*
(2) *The group ring* $\mathbb{F}[G]$ *is a domain, i.e. it has no non-trivial zero divisors.*
(3) *The only units in* $\mathbb{F}[G]$ *are the elements of the form* $f \cdot g$ *with* $f \in \mathbb{F} \setminus \{0\}$ *and* $g \in G$*.*
(4) *The group ring* $\mathbb{C}[G]$ *can be embedded in a skew field.*

Remark.

(1) The conjectures are named after the Canadian mathematician Irving Kaplansky (1917-2006). The first conjecture is often also referred to as the *zero divisor conjecture*. They are formulated in [Lü2, Conjecture 10.14], [Lam2, p. 95] and [FG, p. 729]. As is pointed out in [Lam2, p. 95], Conjecture (3) implies Conjecture (2). It is elementary to to see that Conjecture (4) implies Conjecture (2) and that Conjecture (2) implies Conjecture (1).
(2) The Kaplansky Conjectures are very attractive since they are easy to state. But it is usually very very hard to prove non-trivial group-theoretic statements that are valid for all (torsion-free) groups. In particular all of the Kaplansky Conjectures are still wide open. We refer to [Lü5, Chapter 4.5] for a summary of what is known regarding these conjectures.

We continue with the following elementary lemma.

Lemma 81.5. *Let* G *be a group and let* A *be an abelian group (with additive notation for the group structure). Suppose we are given a* G*-action on the group* A*. Then the map*[1367]

$$\begin{array}{ccc} \mathbb{Z}[G] \times A & \to & A \\ \left(\sum\limits_{i=1}^{m} r_i g_i, a \right) & \mapsto & \sum\limits_{i=1}^{m} r_i \cdot (\underbrace{g_i \cdot a}_{\in A}) \end{array}$$

defines a natural $\mathbb{Z}[G]$*-left module structure on* A*.*[1368]

Proof. The lemma is indeed elementary and trivial. We leave it to the reader to ponder what "natural" might mean in this context. □

Before we continue we introduce or recall the following convention:

Convention. If a homotopy group is abelian, then sometimes we use additive notation for the group multiplication instead of the multiplicative notation.

[1367]Here we use a somewhat perilous notation, namely we use the symbol "$\cdot$" with two different meanings. First of all, for $g \in G$ and $a \in A$ we denote by $g \cdot a \in A$ the element defined by the G-action on A. Secondly, for $r \in \mathbb{Z}$ and $b \in A$ we write, as usual, $r \cdot b = \underbrace{b + \cdots + b}_{r\text{-times}}$ for $r \geq 0$ and $r \cdot b = \underbrace{-b - \cdots - b}_{(-r)\text{-times}}$ for $r < 0$.

[1368]If R is a non-commutative ring, then one needs to be a little careful when one talks about "R-modules". More precisely, there are now two different concepts one can consider: Given an abelian group M one can demand that for any $r, s \in R$ and $m \in M$ one has $(rs) \cdot m = r \cdot (s \cdot m)$ in which case one says that M is an "R-left module". Alternatively one could demand that for any $r, s \in R$ and $m \in M$ one has $(rs) \cdot m = s \cdot (r \cdot m)$ in which case one says that M is an "R-right module". This discussion is the analogue of the discussion on page 102.

This convention, Lemma 81.5, Propositions 28.3 and Proposition 81.1 lead us to the following lemma.

Lemma 81.6. *Let (X, x_0) be a pointed topological space. If $n \geq 2$, then the map*

$$\begin{aligned} \mathbb{Z}[\pi_1(X, x_0)] \times \pi_n(X, x_0) &\to \pi_n(X, x_0) \\ ([\gamma], [f]) &\mapsto [f^\gamma] \end{aligned}$$

induced by

defines a natural $\mathbb{Z}[\pi_1(X, x_0)]$-left module structure on $\pi_n(X, x_0)$.

81.3. **Homotopy groups of $S^1 \vee S^2$.** In this section we want to consider the homotopy groups of $S^1 \vee S^2$ since they are quite instructive. On page 933 we already saw that $\pi_2(S^1 \vee S^2)$ is very big, more precisely, we saw that it admits an epimorphism onto $\mathbb{Z}^\infty$. We will now see that if we take the view of Lemma 81.6, i.e. if we view $\pi_2(S^1 \vee S^2)$ as a module over the group ring $\mathbb{Z}[\pi_1(S^1 \vee S^2)]$, then the apparently messy group $\pi_2(S^1 \vee S^2)$ suddenly gets a simple description.

We explicitly construct $X = S^1 \vee S^2$ by identifying the point $i \in S^1$ with the point $(0, 0, -1) \in S^2$. In the following we evidently use the wedge point as the base point of $X = S^1 \vee S^2$. We refer to it by x_0. Finally we denote by $\gamma\colon [0, 1] \to S^1 \subset X$ the obvious counterclockwise loop that starts at i. Furthermore we denote by $\mathrm{id}_{S^2}\colon S^2 \to S^2 \subset X$ the obvious inclusion map.

Now we can formulate the following proposition which delivers the promised concise description of $\pi_2(S^1 \vee S^2)$.

Proposition 81.7. *The ring homomorphism*[1369]

$$\begin{aligned} \Psi\colon \mathbb{Z}[t^{\pm 1}] &\to \pi_2(S^1 \vee S^2, x_0) \\ t &\mapsto \left[(\mathrm{id}_{S^2})^\gamma\right] \end{aligned}$$

that is uniquely determined by

is an isomorphism.

Proof. For aesthetic reasons for once we use the base point $* = (0, 0, -1)$ for S^2 and we use this base point to define the second homotopy groups of X and $\widetilde{X}$. As on page 568 we see that the universal covering of $X = S^1 \vee S^2$ is given by the map

$$\begin{aligned} p\colon \overbrace{\big(\mathbb{R} \cup (\mathbb{Z} \times S^2)\big) / n \sim (n, (0, 0, -1))}^{=:\widetilde{X}} &\to S^1 \vee S^2 \\ P &\mapsto \begin{cases} e^{2\pi i (P + \frac{1}{4})}, & \text{if } P \in \mathbb{R} \\ Q, & \text{if } P = (n, Q) \text{ with } n \in \mathbb{Z}, Q \in S^2. \end{cases} \end{aligned}$$

We pick the base points $x_0 = i \in S^1 \subset X$ and $\widetilde{x}_0 = 0 \in \mathbb{R} \subset \widetilde{X}$. Even though we have seen this covering map on numerous occasions we show it again in Figure 992. We consider the

[1369]It follows from Lemma 81.3 that there is indeed a unique such ring homomorphism.

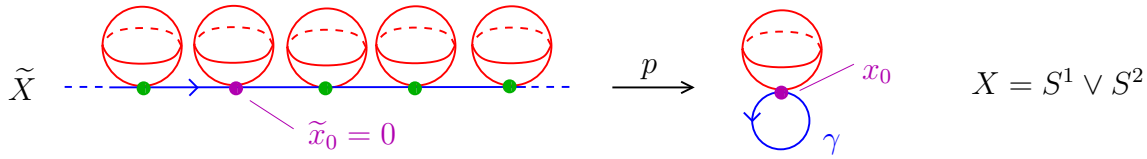

FIGURE 992. First illustration for the proof of Proposition 81.7.

following sequence of maps

$$(*) \qquad \mathbb{Z}[t^{\pm 1}] \xrightarrow{\Psi} \pi_2(X, x_0) \xrightarrow{\Xi} \pi_2(\widetilde{X}, \widetilde{x}_0) \xrightarrow{\Phi_{(\widetilde{X},\widetilde{x}_0)}} H_2(\widetilde{X}; \mathbb{Z}) \xleftarrow{\Omega} \mathbb{Z}[t^{\pm 1}].$$

Here $\Phi_{(X,x_0)}$ denotes the Hurewicz homomorphism. Since $\widetilde{X}$ is simply connected we obtain from the Hurewicz Theorem 80.5 that it is an isomorphism. The reader will not have failed to notice that we did not define the two maps Ξ and Ω yet. We will do so now.

(1) First we recall that given a map $g\colon (S^2, *) \to (X, x_0)$ there exists by Proposition 20.2 a unique lift $\widetilde{g}\colon (S^2, *) \to (\widetilde{X}, \widetilde{x}_0)$. Now we consider the map

$$\begin{array}{rcl} \Xi\colon \pi_2(X, x_0) & \to & \pi_2(\widetilde{X}, \widetilde{x}_0) \\ [g\colon (S^2, *) \to (X, x_0)] & \to & \big[\widetilde{g}\colon (S^2, *) \to (\widetilde{X}, \widetilde{x}_0)\big]. \end{array}$$

By Proposition 28.13 we know that Ξ is well-defined and that it is an isomorphism.

(2) Given $i \in \mathbb{Z}$ we denote by $f_i\colon S^2 \to X$ the "obvious" i-th inclusion map. In Lemma 34.7 we saw that the map

$$\begin{array}{rcl} \Omega\colon \mathbb{Z}[t^{\pm 1}] & \to & H_2(\widetilde{X}; \mathbb{Z}) \\ \sum\limits_{i=r}^{s} a_i \cdot t^i & \mapsto & \sum\limits_{i=r}^{s} a_i \cdot f_i([S^2]). \end{array}$$

is an isomorphism.

We see in particular that in $(*)$ the three maps to the right are isomorphisms. Therefore it suffices to show that the maps $\Omega^{-1} \circ \Phi_{(X,x_0)} \circ \Xi \circ \Psi$ is the identity. In other words, it suffices to show the following claim.

Claim. For any $n \in \mathbb{Z}$ we have

$$(\Phi_{(X,x_0)} \circ \Xi \circ \Psi)(t^n) \;=\; \Omega(t^n) \;\in\; H_2(\widetilde{X}; \mathbb{Z}).$$

So let $n \in \mathbb{Z}$. It follows immediately from the definitions of the various maps that the desired statement is equivalent to the statement that

$$\underbrace{\big(\widetilde{(\mathrm{id}_{S^2})^{\gamma^n}}\big)}_{\text{map } S^2 \to \widetilde{X}}{}_*[S^2] \;=\; \underbrace{f_n}_{\text{map } S^2 \to \widetilde{X}}([S^2]) \;\in\; H_2(\widetilde{X}; \mathbb{Z}).$$

Thus by Proposition 30.5 it suffices to show that the two maps $(\mathrm{id}_{S^2})^{\gamma^n}$ and f_n are homotopic maps from S^2 to $\widetilde{X}$. For those readers who are still awake this should be basically obvious.[1370] As a digestion aid we illustrate both maps in Figure 992. $\square$

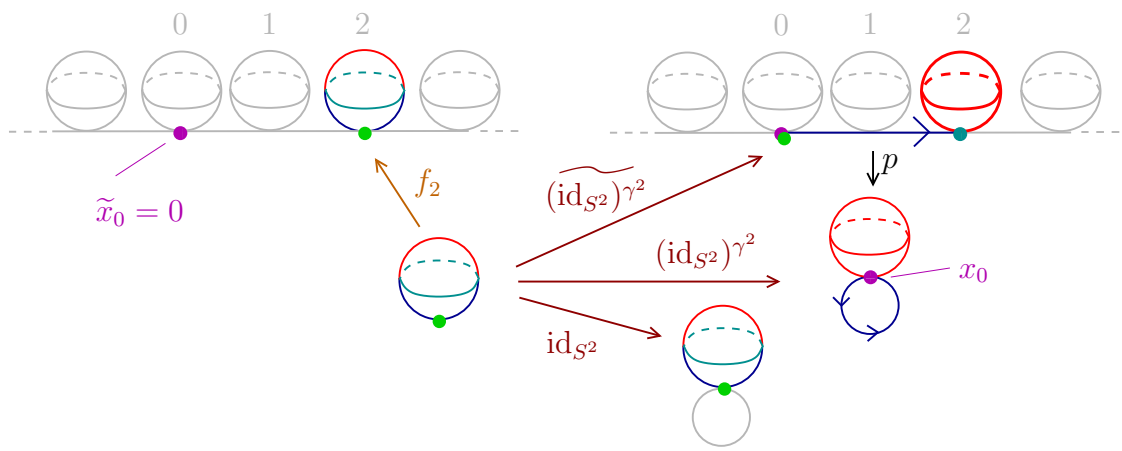

FIGURE 993. Second illustration for the proof of Proposition 81.7.

In Proposition 35.5 we saw that the homology groups of a finite CW-complex are finitely generated abelian groups. Since the discussion on page 933 we had known that the corresponding statement is not true for homotopy groups. But we now also know that one should really view the homotopy groups of a pointed topological space (X, x_0) as modules over the group ring $\mathbb{Z}[\pi_1(X, x_0)]$. Thus the following question arises.

Question 81.8. *Let X be a finite CW-complex. Are the homotopy groups $\pi_n(X, x_0)$, $n \geq 2$, finitely generated $\mathbb{Z}[\pi_1(X, x_0)]$-modules?*

It turns out that the answer is yes if X is simply connected. More precisely, Jean-Pierre Serre [Ser3][1371] proved the following theorem.

Theorem 81.9. (Serre) *If X is a simply-connected topological space such that all homology groups are finitely generated (for example X could be a compact topological manifold or a finite CW-complex), then all homotopy groups are also finitely generated abelian groups.*[1372]

Example. It follows in particular from Serre's Theorem 81.9 that the homotopy groups of spheres are finitely generated. Even this statement is highly non-trivial.

[1370] In fact this follows from the "$\Leftarrow$"-direction of Proposition 81.1 (7).

[1371] Jean-Pierre Serre (*1926) is a French mathematician. He was, and remains, the youngest person ever to be awarded the Fields Medal.

[1372] It follows immediately from the Hurewicz Theorem 80.5 that $\pi_2(X)$ is finitely generated. The fact that the higher homotopy groups are also finitely generated is much stronger.

Nonetheless, it turns out that the answer to Question 81.8 is negative. In fact, one does not need to wander off particularly far to find such an example:

Proposition 81.10. *The group $\pi_3(S^1 \vee S^2)$ is not finitely generated over the group ring $\mathbb{Z}[\pi_1(S^1 \vee S^2)] = \mathbb{Z}[t^{\pm 1}]$.*

A proof for the proposition is for example sketched in [Hat, Chapter 4.2, Exercise 38].

Remark. The Hilton-Milnor theorem, see [Hilt, Theorem A],[Mi11] or [Whda, Chapter XI], gives a calculation of the homotopy groups of a finite wedge of spheres, more precisely, these homotopy groups are computed in terms of the homotopy groups of the spheres involved. Unfortunately, at least at a first glance, it is not so clear how the module structure over the group ring can be read off from the Hilton-Milnor theorem.

81.4. **The Connected Sum Decomposition Theorem** $(*)$**.** We conclude this chapter with the study of connected sum decompositions of closed oriented topological manifolds.

Definition. Let M be a closed oriented n-dimensional topological manifold.

(1) A *connected sum decomposition of* M is a homeomorphism $M \cong X \# Y$ where X and Y are closed oriented n-dimensional topological manifolds. We say a connected sum decomposition is *non-trivial* if neither X nor Y is homeomorphic to S^n.
(2) We say M is *irreducible* if it does not admit a non-trivial connected sum decomposition.

Example. It follows easily from Proposition 71.10 and the classification of closed 2-dimensional topological manifolds, see Theorem 14.9, that the 2-sphere S^2 is irreducible. We will see shortly that in fact all spheres are irreducible.

The following theorem says that any closed oriented topological manifold can be decomposed into irreducible manifolds.

Theorem 81.11. (Connected Sum Decomposition Theorem) *Given any closed oriented connected n-dimensional topological manifold M there exists a homeomorphism $M \cong N_1 \# \dots \# N_k$ where $N_1, \dots, N_k$ are closed oriented irreducible n-dimensional topological manifolds.*

Remark. For 3-dimensional manifolds the statement of Theorem 81.11 was first proved in 1929 by Hellmuth Kneser [Kn]. In our proof of Theorem 81.11 we will make use of the proof of the Poincaré Conjecture which for 3-dimensional topological manifolds was settled by Grigori Perelman only in 2002. The proof of Hellmuth Kneser relied on a different complexity argument and did not make use of the Poincaré Conjecture.

The idea behind the proof of Theorem 81.11 is quite simple: We want to show that if a closed oriented topological manifold M admits a non-trivial connected sum decomposition $X \# Y$, then X and Y should both be "smaller" than M, e.g. they should have "smaller" algebraic invariants. So the process of decomposing a closed oriented topological manifold should stop after finitely many steps. To carry out this idea we need some group theoretic input.

Definition. Let A be a finitely generated abelian group.

(1) The *rank of* A is defined as $\operatorname{rank}(A) := \dim_{\mathbb{Q}}(A \otimes \mathbb{Q})$.[1373]
(2) As on page 372 we refer to
$$\operatorname{tor}(A) \;=\; \{a \in A \mid \text{ there exists an } n \in \mathbb{N} \text{ with } na = 0\}$$
as the *torsion subgroup of* A.[1374]
(3) We define $t(A) = \#\operatorname{tor}(A)$, i.e. $t(A)$ is the number of elements in the torsion subgroup $\operatorname{tor}(A)$.

We continue with the following elementary lemma.

Lemma 81.12. *If A and B are finitely generated abelian groups, then*
$$\operatorname{rank}(A \oplus B) \;=\; \operatorname{rank}(A) + \operatorname{rank}(B) \quad \textit{and} \quad t(A \oplus B) = t(A) \cdot t(B).$$

Proof. The first statement is an immediate consequence of the additivity of dimensions under the direct sum operation or alternatively it is a consequence of Lemma 11.6. The second statement follows from the observation that $\operatorname{tor}(A \oplus B) = \operatorname{tor}(A) \oplus \operatorname{tor}(B)$. □

We also recall the following definition from page 382.

Definition. Let G be a finitely generated group. We denote by $d(G) \in \mathbb{N}_0$ the minimal number of elements in a generating set for G.

Remark. It is an unfortunate fact of life that in the literature the number $d(G)$ is usually referred to as the rank of the group G. But for abelian groups the invariants $\operatorname{rank}(G)$ and $d(G)$ can differ quite dramatically. For example for $G = (\mathbb{Z}_2)^n$ we have $\operatorname{rank}(G) = 0$ but $d(G) = n$.

For the reader's convenience we also recall the Grushko-Neumann Theorem 11.18. It can be viewed as an analogue of Lemma 81.12.

Theorem 81.13. (Grushko-Neumann Theorem) *Given any two finitely generated groups A and B we have*
$$d(A * B) \;=\; d(A) + d(B).$$

Now we can provide the proof of Theorem 81.11.

Proof of Theorem 81.11. Let $n \in \mathbb{N}$. Let M be a closed oriented connected n-dimensional topological manifold. In Proposition 45.2 we saw that the fundamental group $\pi_1(M)$ and the homology groups $H_i(M;\mathbb{Z})$ are finitely generated groups. Thus we can define
$$c(M) \;:=\; d(\pi_1(M)) \,+\, \operatorname{rank}\Big(\bigoplus_{i=1}^{n-1} H_i(M;\mathbb{Z})\Big) \,+\, t\Big(\bigoplus_{i=1}^{n-1} H_i(M;\mathbb{Z})\Big) \,\in\, \mathbb{N}_0.$$
We make two observations:

[1373] As we had discussed on page 1006, this definition agrees with the earlier definition that we gave on page 371.

[1374] It follows from the classification of finitely generated abelian groups, see Theorem 11.4, that $\operatorname{tor}(A)$ is in fact a finite subgroup.

(1) It follows from the proof of the Poincaré Conjecture in all dimensions, see Section 28.6 together with Proposition 80.8 that $c(M) = 0$ if and only if M is homeomorphic to S^n.
(2) If $M = X\#Y$ is a non-trivial connected sum decomposition, then it follows immediately from Proposition 71.10, Lemma 81.12 and the Grushko-Neumann Theorem 81.13 that $c(X) < c(M)$ and $c(Y) < c(M)$.

Theorem 81.11 now follows from an elementary induction argument. □

Remark. Note that the argument used in the above proof of Theorem 81.11 also shows that spheres are irreducible.

In dimension 3 the decomposition of Theorem 81.11 is essentially unique. More precisely John Milnor [Mi7] (see also [Hem, Chapter 3] and [Schul, Proposition 5.5.3]) proved in 1962 the following theorem.

Theorem 81.14. *Let M be a closed oriented connected 3-dimensional topological manifold. If $M \cong N_1\#\dots\#N_r$ and $M \cong N_1'\#\dots\#N_s'$ where the topological 3-manifolds N_i and N_i' are oriented irreducible 3-manifolds and such that none of the N_i and N_i' are homeomorphic to S^3, then $r = s$ and (possibly after reordering) there exists an orientation-preserving homeomorphism $N_i \to N_i'$ for each i.*

Remark.

(1) In the 3-dimensional setting our language unfortunately diverges slightly from standard parlance. More precisely, what we call an irreducible 3-dimensional topological manifold is usually in the literature (see e.g. [Hem, p. 27]) referred to as a "prime 3-dimensional topological manifold". Furthermore in the literature there is a different notion of a 3-dimensional manifold being irreducible. Namely, in the literature (see e.g. [Hem, p. 28]) a 3-dimensional manifold is usually called irreducible if every embedded 2-dimensional sphere bounds an embedded 3-dimensional ball. Fortunately, as is shown in [Hem, Lemma 3.13] for orientable 3-dimensional topological manifolds the two notions of "irreducible" only differ for $S^1 \times S^2$.
(2) In Theorem 81.14 we cannot drop the condition that M is oriented. For example in Exercise 81.10 we will see that $\mathbb{R}\mathrm{P}^3\#\mathbb{R}\mathrm{P}^3$ is homeomorphic to $\mathbb{R}\mathrm{P}^3\#(S^1 \times S^2)$.

The following proposition says that the analogous statement does not hold in dimension four.

Proposition 81.15. *The closed oriented topological manifolds $\mathbb{C}\mathrm{P}^2, \overline{\mathbb{C}\mathrm{P}}^2$ and $S^2 \times S^2$ are irreducible and $(S^2 \times S^2)\#\mathbb{C}\mathrm{P}^2$ is homeomorphic*[1375] *to $\mathbb{C}\mathrm{P}^2\#\overline{\mathbb{C}\mathrm{P}}^2\#\mathbb{C}\mathrm{P}^2$.*

Proof. We use the notation from the proof of Theorem 81.11. The calculation of the invariants of $\mathbb{C}\mathrm{P}^2$, $\overline{\mathbb{C}\mathrm{P}}^2$ and $S^2 \times S^2$ shows that $c(\mathbb{C}\mathrm{P}^2) = c(\overline{\mathbb{C}\mathrm{P}^2}) = 1$ and $c(S^2 \times S^2) = 2$.

[1375] In fact the two topological manifolds are diffeomorphic if we equip them with the obvious smooth structure.

Thus the argument of the proof of Theorem 81.11 shows that $\mathbb{C}\mathrm{P}^2$ and $\overline{\mathbb{C}\mathrm{P}}^2$ are prime. Next recall that on page 1655 we showed that the intersection form of $S^2 \times S^2$ is represented by the matrix $\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$. Using this piece of information and using Proposition 71.11 one can fairly easily show that $S^2 \times S^2$ is prime. The full details will be carried out in Exercise 81.9.

Finally note that on page 1677 we pointed out that the manifolds $(S^2 \times S^2)\#\mathbb{C}\mathrm{P}^2$ and $\mathbb{C}\mathrm{P}^2\#\overline{\mathbb{C}\mathrm{P}}^2\#\mathbb{C}\mathrm{P}^2$ are diffeomorphic, in particular they are homeomorphic. $\square$

We turn our gaze to all dimensions ≥ 4 and quote the following result from [ICFHLN], which extends earlier work in [KrS, Theorem 1.1].

Proposition 81.16. *Let $n \in \mathbb{N}_{\geq 4}$. We write $n = 2k + \epsilon$ with $\epsilon \in \{0, 1\}$. There exist closed oriented connected topological n-dimensional manifolds M and N that are not homotopy equivalent but such that $M\#(S^k \times S^{k+\epsilon})$ and $N\#(S^k \times S^{k+\epsilon})$ are diffeomorphic.*

Since the connected sum operation is well-defined up to homeomorphism we see that $M\#(S^k \times S^{k+\epsilon})$ admits two non-equivalent decompositions into irreducible topological manifolds.

Remark. In the above exposition we worked throughout with topological manifolds up to homeomorphisms. Of course one could also work with manifolds and diffeomorphisms. This leads us to the notion of a "smoothly prime" manifold. As we pointed out in Theorem 28.24, in the 3-dimensional setting there is essentially no difference between these two approaches. But in the higher-dimensional setting it is not even true any more that spheres are necessarily smoothly prime. More precisely, by [KeM, Theorem 1.2] there exists a closed oriented 7-dimensional manifold X that is not diffeomorphic to S^7 but such that $X\#X$ is diffeomorphic to S^7. As we remarked on on page 355, given any closed oriented n-dimensional manifold the connected sum $M\#S^n$ is diffeomorphic to M. The above discussion implies that no closed oriented connected 7-dimensional manifold is smoothly prime.

Exercises for Chapter 81.

Exercise 81.1. Let (X, x_0) be a pointed topological space and let $n \in \mathbb{N}_{\geq 2}$. We consider the Hurewicz homomorphism $\Phi\colon \pi_n(X, x_0) \to H_n(X; \mathbb{Z})$. Show that for any $g \in \pi_1(X, x_0)$ and any $\sigma \in \pi_n(X, x_0)$ we have

$$\Phi(g \cdot \sigma) \;=\; \Phi(\sigma) \in H_n(X; \mathbb{Z}).$$

Exercise 81.2. Let G be a group and let R be a commutative ring. Suppose there exists a non-trivial $g \in G$ such that $g^k = e$ for some $k \in \mathbb{N}$. Show that $R[G]$ has a zero divisor, i.e. show that there exist non-zero elements $p, q \in R[G]$ with $p \cdot q = 0$.
Hint: First consider the case that $G = \langle t \,|\, t^n \rangle$ is a finite cyclic group with $n \geq 2$ elements.

Exercise 81.3. Is the ring $M(3 \times 3, \mathbb{R})$ of real (3×3)-matrices isomorphic, as a ring, to the real group ring $\mathbb{R}[G]$ of some group G?

Exercise 81.4. Let G be a finite group. We view $\mathbb{Q}[G]$ as a $\mathbb{Q}[G]$-left module via left multiplication. Show that $\mathbb{Q}[G]$ admits a submodule $V \neq 0$ with $V \neq \mathbb{Q}[G]$ that is isomorphic to the trivial $\mathbb{Q}[G]$-module $\mathbb{Q}$ where every $g \in G$ acts via the identity on $\mathbb{Q}$.

Exercise 81.5. Let G be a finite group. Show that there exists a monomorphism from G to some unitary group $\mathrm{U}(n)$.

Exercise 81.6. We consider the ring $M(2, \mathbb{R})$. Does there exist a finite set T and an epimorphism from the free ring $\mathbb{R}[\langle T \rangle]$ onto $M(2, \mathbb{R})$?

Exercise 81.7. Let G be a group that acts on an abelian group A. Show that the set

$$\{g \cdot a - a \,|\, g \in G \text{ and } a \in A\} \;\subset\; A$$

is in fact a subgroup of A.

Exercise 81.8. Let X be a simply connected topological space and let $f\colon X \to X$ be a self-homeomorphism. Recall that on page 469 we introduced the mapping torus

$$M \;:=\; (X \times [0,1])/(x,0) \sim (f(x),1).$$

Express the $\mathbb{Z}[\pi_1(M)]$-module $\pi_2(M)$ in terms of the homology groups of X and the action by f on the homology groups of X.

Exercise 81.9. Show that the topological manifold $S^2 \times S^2$ is prime.
Hint: Consider the proof of Theorem 81.11 and use Proposition 71.11. Also make use of the fact that on page 1655 we showed that the intersection form of $S^2 \times S^2$ is represented by the matrix $\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$.

Exercise 81.10. Show that $\mathbb{R}\mathrm{P}^3 \# \mathbb{R}\mathrm{P}^3$ is homeomorphic to $\mathbb{R}\mathrm{P}^3 \#(S^1 \times S^2)$.

82. Relative homotopy groups

82.1. **The definition of relative homotopy groups.** While studying homology groups we saw at some point that it was convenient to introduce the relative homology groups $H_k(X, A)$ corresponding to a pair of topological spaces (X, A). In our latest attempt to understand homotopy groups we will now, perhaps not surprisingly, introduce relative homotopy groups. We start out with introducing the following notation.

Notation. Throughout this chapter we write $I = [0, 1]$ for the unit interval. Furthermore, given $n \in \mathbb{N}$ we use the following notation:

(1) we denote by $I^n \subset \mathbb{R}^n$ the cube in $\mathbb{R}^n$,
(2) we denote by ∂I^n the boundary of I^n viewed as a subset of $\mathbb{R}^n$,
(3) by a slight abuse of notation we make the identification $I^{n-1} = I^{n-1} \times \{0\}$,
(4) we write $J^{n-1} = \overline{\partial I^n \setminus I^{n-1}}$.

We refer to Figure 994 for an illustration.

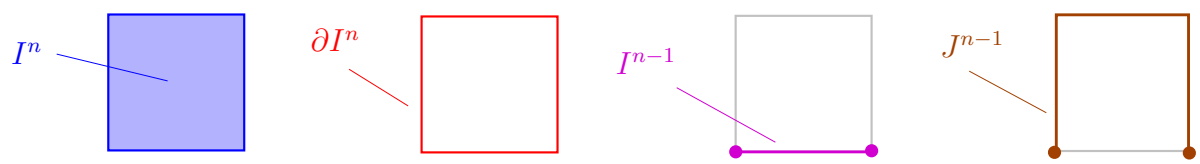

Figure 994.

The following definition is a variation on the notion of a pointed topological space that we introduced on page 242.

Definition. A *pointed pair of topological spaces* is a triple (X, A, x_0), where X is a topological space, A is a subset of X and x_0 is a point in A. A *morphism* between pointed pairs of topological spaces (X, A, x_0) and (Y, B, y_0) is a map $f\colon X \to Y$ with $f(A) \subset B$ and $f(x_0) = y_0$. We refer to the corresponding category as the *category of pointed pairs of topological spaces*.

Definition. Let (X, A, x_0) be a pointed pair of topological spaces. Given $n \geq 1$ we define the *n-th relative homotopy group of* (X, A, x_0) to be[1376]

$$\pi_n(X, A, x_0) \ := \ \text{homotopy classes of maps } (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\}).$$

The definition is illustrated in Figure 995.

Examples.

[1376]On page 641 we defined the notion of maps between pairs of topological spaces and we defined the notion of a homotopy between such maps. These notions extend in an obvious way to triples of topological spaces.

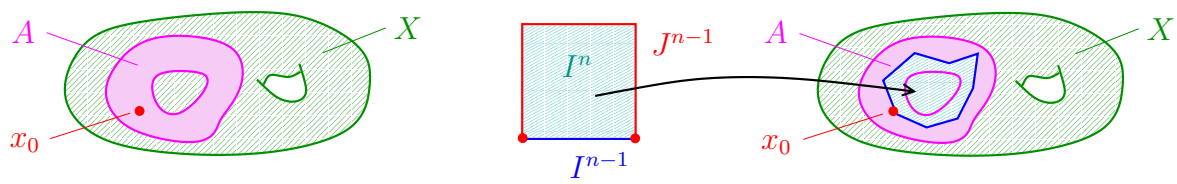

FIGURE 995.

(1) Let (X, A, x_0) be a pointed pair of topological spaces. We want to get a better understanding of elements in $\pi_1(X, A, x_0)$. For $n = 1$ we have $I^1 = [0, 1]$, $\partial I^1 = \{0, 1\}$ and $J^0 = \{1\}$. A map $(I^1, \partial I^1, J^0) \to (X, A, \{x_0\})$ is thus the same as a path in X that starts at a point in A and that ends in x_0. We refer to Figure 996 and 997 for an illustration.

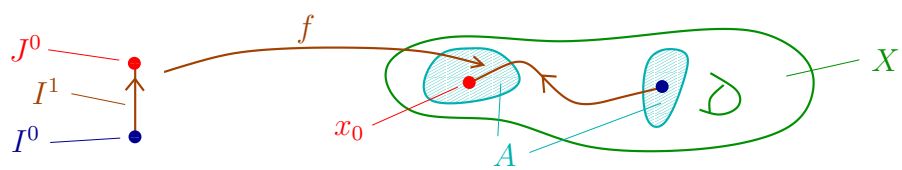

FIGURE 996.

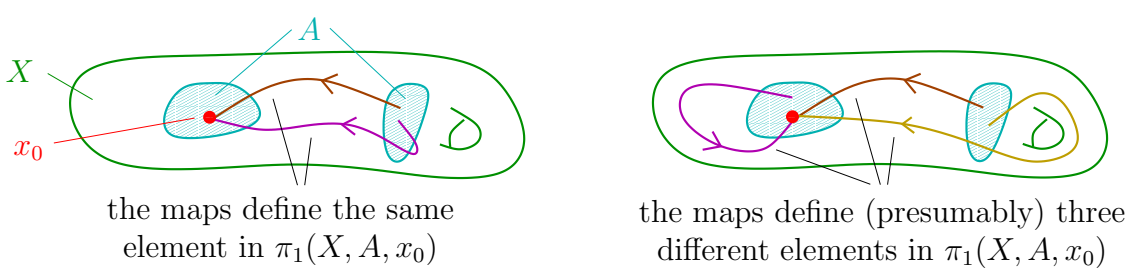

FIGURE 997.

(2) Let (X, x_0) be a pointed topological space. For any $n \geq 1$ the map

$$\begin{array}{rcl} \pi_n(X, x_0) & \to & \pi_n(X, \{x_0\}, x_0) \\ [f\colon (I^n, \partial I^n) \to (X, \{x_0\})] & \to & [f\colon (I^n, \partial I^n, J^{n-1}) \to (X, \{x_0\}, \{x_0\})] \end{array}$$

defines, basically by definition, a natural bijection. In the following we will use this natural bijection to make the identification $\pi_n(X, x_0) = \pi_n(X, \{x_0\}, x_0)$.

(3) Let X be a topological space, let A be a subset of X and let $x_0 \in A$ be a point. For any $n \geq 1$ the map

$$\begin{array}{rcl} \pi_n(X, x_0) & \to & \pi_n(X, A, x_0) \\ [f\colon (I^n, \partial I^n) \to (X, \{x_0\})] & \to & [f\colon (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})] \end{array}$$

is a natural map from absolute homotopy groups to relative homotopy groups.

In the previous discussion we already referred to $\pi_n(X, A, x_0)$ as a "relative homotopy group". This was slightly premature, but now we will actually deliver the goods and provide a group structure.

Definition. Let (X, A, x_0) be a pointed pair of topological spaces and let $n \geq 2$.[1377] Given two maps $f, g\colon (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})$ we define[1378]

$$\begin{array}{rcl} f * g\colon I^n & \to & X \\ (t_1, \ldots, t_n) & \mapsto & \begin{cases} f(2t_1, t_2, \ldots, t_n), & \text{if } t_1 \in [0, \frac{1}{2}], \\ g(2t_1 - 1, t_2, \ldots, t_n) & \text{if } t_1 \in [\frac{1}{2}, 1]. \end{cases} \end{array}$$

Note that $f * g$ is again a map $(I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})$ of triples. The definition of $f * g$ is illustrated in Figure 998.

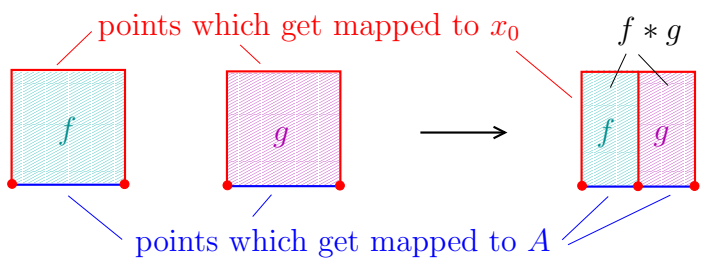

FIGURE 998.

The following proposition finally gives the justification for the name *relative homotopy group*.

Proposition 82.1. *Let (X, A, x_0) be a pointed pair of topological spaces.*

(1) *Let $n \geq 2$. The map*

$$\begin{array}{rcl} \pi_n(X, A, x_0) \times \pi_n(X, A, x_0) & \to & \pi_n(X, A, x_0) \\ ([f], [g]) & \mapsto & [f * g] \end{array}$$

is well-defined and it defines a group structure on $\pi_n(X, A, x_0)$. Furthermore the following two statements hold:

(a) *the trivial element in $\pi_n(X, A, x_0)$ is represented by the constant map $I^n \to X$ that sends every point in I^n to x_0,*

(b) *the inverse of the relative homotopy class $[f\colon (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})]$ is represented by the map*

$$\begin{array}{rcl} (I^n, \partial I^n, J^{n-1}) & \to & (X, A, \{x_0\}) \\ (t_1, t_2, \ldots, t_n) & \mapsto & (1 - t_1, t_2, \ldots, t_n). \end{array}$$

[1377] What, if anything, goes wrong for $n = 1$?

[1378] This map is continuous by Lemma 1.32 (2).

(2) *For $n \geq 2$ the above natural bijection $\pi_n(X, x_0) \xrightarrow{=} \pi_n(X, \{x_0\}, x_0)$ is in fact a group isomorphism.*
(3) *For $n \geq 2$ the above natural map $\pi_n(X, x_0) \to \pi_n(X, A, x_0)$ is a group homomorphism.*
(4) *For $n \geq 3$ the group $\pi_n(X, A, x_0)$ is abelian.*
(5) *Let $n \in \mathbb{N}$. Given a morphism $f\colon (X, A, x_0) \to (Y, B, y_0)$ of pointed pairs of topological spaces the map*

$$\begin{array}{rcl} f_*\colon \pi_n(X, A, x_0) & \to & \pi_n(Y, B, y_0) \\ [\varphi] & \mapsto & [f \circ \varphi] \end{array}$$

is well-defined. Furthermore the following four statements hold:
(a) *For $n \geq 2$ the induced map f_* is a group homomorphism.*
(b) *The maps f_* define a functor from the category of pointed pairs of topological spaces to the category of sets (respectively groups for $n \geq 2$).*
(c) *Let $n \geq 1$ and let $f, g\colon (X, A) \to (Y, B)$ be two maps between pairs of topological spaces. If $f_*\colon \pi_n(X, A, x_0) \to \pi_n(Y, B, f(x_0))$ is a bijection for all $x_0 \in A$ and if g is homotopic[1379] to f, then $g_*\colon \pi_n(X, A, x_0) \to \pi_n(Y, B, g(x_0))$ is also a bijection for all $x_0 \in A$.*
(d) *Let $f\colon (X, A) \to (Y, B)$ be a map between pairs of topological spaces and let $x_0 \in A$. If f is a homotopy equivalence, then the map*

$$f_*\colon \pi_n(X, A, x_0) \to \pi_n(Y, B, f(x_0))$$

is a bijection (in particular it is an isomorphism if $n \geq 2$).

Sketch of proof.
(1) The proof of the first statement is quite similar to the proof of Proposition 28.1. We leave it to the reader to fill in the details.
(3) This statement requires just slightly more thought than one might think. More precisely, given two maps f and g from $(I^n, \partial I^n, J^{n-1})$ to $(X, \{x_0\}, \{x_0\})$, the "product maps" $f * g$ considered on page 710 for $\pi_n(X, \{x_0\})$ (and illustrated in Figure 448) and in the above proposition for $\pi_n(X, A, x_0)$ are not identical. Nonetheless, using Lemma 28.2 or Proposition 80.2 it is straightforward to show that they are homotopic. This observation shows that the above identification of sets is in fact an identification of groups.
(2) We already know that the map is a bijection. Thus it suffices to show that it is a group homomorphism. But this follows from (3) applied to $A = \{x_0\}$.
(4) The proof of this statement is an entertaining variation of the proof of Proposition 28.3. The proof is the content of Exercise 82.2.
(5) Statements (a) and (b) follow basically immediately from the definitions. Statement (c) and (d) are proved in a similar fashion to Proposition 28.7. □

Remark.

[1379] Here we mean of course, "homotopic as a map between pairs of topological spaces".

(1) We will see shortly that the relative homotopy group $\pi_2(X, A, x_0)$ is in general not abelian.
(2) For want of a better idea, given a pointed pair of topological spaces (X, A, x_0) we refer to $\pi_1(X, A, x_0)$ also as a *relative homotopy group* even though strictly speaking we did not define a group structure on $\pi_1(X, A, x_0)$.

In light of Proposition 82.1 we adopt the following convention:

Convention. For $n \geq 3$ we usually use additive notation for the group structure on the relative homotopy groups $\pi_n(X, A, x_0)$.

Let X be a topological space and let $A \subset B \subset X$ be two subsets. In Proposition 31.13 we saw that this data gives rise to a long exact sequence of homology groups. Shortly we will see that a similar statement holds for relative homotopy groups. We did not define a group structure on $\pi_1(X, A, x_0)$ and we did not define a group structure on $\pi_0(X, x_0)$. (In fact we will see in Exercise 82.3 that there is no natural way to turn these sets into groups.) Nonetheless we would like to include these objects at the lower end of the long exact sequence of (relative) homotopy groups. In fact, as it turns out, $\pi_1(X, A, x_0)$ and $\pi_0(X, x_0)$ have ever so slightly more structure than just the structure of a set.

Definition.

(1) A *pointed set* is a pair (S, s_0) where S is a set and $s_0 \in S$ is a point. We call s_0 the *trivial element* in S.
(2) A *morphism* from a pointed set (S, s_0) to a pointed set (T, t_0) is a map $f\colon S \to T$ with $f(s_0) = t_0$. Furthermore we adopt the following language:
   (a) Given a morphism $f\colon (S, s_0) \to (T, t_0)$ we refer to $\ker(f) := f^{-1}(t_0)$ as the *kernel of* f.
   (b) We say a morphism $f\colon (S, s_0) \to (T, t_0)$ is *trivial* if $\ker(f) = S$, put differently, if all elements in S get sent to t_0.
   (c) We say a morphism $f\colon (S, s_0) \to (T, t_0)$ is a *monomorphism* if $\ker(f) = \{s_0\}$.
   (d) We say a morphism $f\colon (S, s_0) \to (T, t_0)$ is an *epimorphism* if f is surjective.
(3) We say that a sequence

$$\ldots \xrightarrow{f_{n+2}} (S_{n+1}, s_{n+1}) \xrightarrow{f_{n+1}} (S_n, s_n) \xrightarrow{f_n} (S_{n-1}, s_{n-1}) \xrightarrow{f_{n-1}} \ldots$$

of morphisms of pointed sets is *exact* if for every $n \in \mathbb{N}_0$ we have the usual equality $\ker(f_n) = \operatorname{im}(f_{n+1})$.

Examples.

(1) Any group G gives rise to the pointed set $(G, \{e\})$ where $e \in G$ evidently denotes the trivial element. We will thus always view a group as a pointed set. Any group homomorphism is also a morphism of the corresponding pointed sets. Furthermore an exact sequence of homomorphisms of groups is also an exact sequence of pointed sets.

(2) If G is a group and H is a subgroup, then the set of right cosets G/H is a pointed set with trivial element given by $H \in G/H$. The obvious projection map $G \to G/H$ is a morphism of pointed sets.

The following little lemma will be proved in Exercise 82.4.

Lemma 82.2. *Let $\varphi\colon G \to H$ be a group homomorphism. Furthermore let (S, s_0) be a pointed set which is equipped with an H-action. Suppose that we have an exact sequence*

$$\{e\} \;\to\; G \;\xrightarrow{\varphi}\; H \;\xrightarrow{\psi}\; (S, s_0) \;\to\; \{e\}$$

where ψ is a morphism of pointed sets that preserves the H-action. Then $\varphi(G)$ is a subgroup of H whose index equals the cardinality of the set S.

Example. The previous lemma might sound rather artificial. But we have seen it before in group theory: suppose that H is a group and G is a subgroup. As above we view the set of right cosets G/H as a pointed set. Left-multiplication by G defines an action on G/H. Evidently the projection $G \to G/H$ preserves the right action and we get a short exact sequence $\{e\} \to G \to H \to G/H \to \{e\}$ as in Lemma 82.2.

We continue with pointed sets that arise in topology.

Examples.

(1) Let (X, x_0) be a pointed topological space. On page 710 we defined $\pi_0(X, x_0)$ to be the set of homotopy classes of maps from the point I^0 to X. In other words, $\pi_0(X, x_0)$ is the set of path-components of X. We view $\pi_0(X, x_0)$ as a pointed set where the trivial element is given by the map that sends the unique point in I^0 to x_0. A map $f\colon X \to Y$ between topological spaces defines a morphism $f_*\colon \pi_0(X, x_0) \to \pi_0(Y, f(x_0))$ of pointed sets in the obvious way. Sometimes, by an unfortunate abuse of language, we refer to $\pi_0(X, x_0)$ as a homotopy group of X.

(2) Similarly to the above, given a pointed pair of topological spaces (X, A, x_0) we view $\pi_1(X, A, x_0)$ as pointed set where the trivial element is once again represented by the constant path $I \to X$ given by sending all points to x_0.

We conclude this section with the following elementary lemma that will be proved in Exercise 82.6.

Lemma 82.3. *Let (X, A, x_0) be a pointed pair of topological spaces and let $n \geq 1$. Let $f\colon (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})$ be a map. If $f(I^n) \subset A$, then f represents the trivial element in $\pi_n(X, A, x_0)$.*[1380][1381]

Since it is much easier to convince oneself of a statement if one sees an explicit example, we show such a map with $f(I^n) \subset A$ in Figure 999.

[1380] Put differently, as for relative homology groups, all objects that "land in A" are in fact trivial in the relative homotopy group.

[1381] Note that by the above discussion of pointed sets the statement of Lemma 82.3 is also meaningful for $n = 1$.

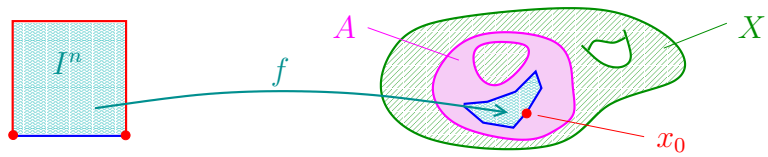

FIGURE 999.

82.2. **The long exact homotopy sequence of a pair.** In Proposition 31.13 we saw that we can associate to a pair (X, A) of topological spaces a long exact sequence of (relative) homology groups. The goal of this section is to do the same for homotopy groups. More precisely we will associate to a pointed pair (X, A, x_0) of topological spaces a long exact sequence of (relative) homotopy groups.

Proposition 82.4. *Let (X, A, x_0) be a pointed pair of topological spaces.*

(1) *For any $n \geq 1$ the map*

$$\begin{array}{rcl} \partial_n \colon \pi_n(X, A, x_0) & \to & \pi_{n-1}(A, x_0) \\ [f \colon (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})] & \to & \left[\begin{array}{rcl} (I^{n-1}, \partial I^{n-1}) & \to & (A, \{x_0\}) \\ (x_1, \ldots, x_{n-1}) & \mapsto & f(x_1, \ldots, x_{n-1}, 0) \end{array} \right] \end{array}$$

is well-defined. (See Figure 1000 for an illustration.) We refer to it as the connecting morphism*. It has the following two properties:*

(a) *The connecting morphism is a morphism of pointed sets and it is a group homomorphism for $n \geq 2$.*

(b) *The connecting morphism is a natural transformation from $\pi_n(X, A, x_0)$ to $\pi_{n-1}(A, x_0)$. In everyday language this just simply means that for a map $f \colon (X, A, x_0) \to (Y, B, y_0)$ between pointed pairs of topological spaces the following diagram commutes:*

$$\begin{array}{ccc} \pi_n(X, A, x_0) & \xrightarrow{\partial} & \pi_{n-1}(A, x_0) \\ \downarrow{\scriptstyle f_*} & & \downarrow{\scriptstyle f_*} \\ \pi_n(Y, B, y_0) & \xrightarrow{\partial} & \pi_{n-1}(B, y_0). \end{array}$$

(2) *The following sequence is exact*

$$\cdots \to \pi_n(A, x_0) \xrightarrow{i_*} \pi_n(X, x_0) \to \pi_n(X, A, x_0) \xrightarrow{\partial_n} \pi_{n-1}(A, x_0) \to \cdots \to \pi_0(X, x_0).$$

Here $i \colon A \to X$ is the inclusion map and the map $\pi_n(X, x_0) \to \pi_n(X, A, x_0)$ is the natural map introduced on page 1885.

Examples.

(1) We consider $X = \mathbb{R}^2$ and we consider $A = A_0 \sqcup A_1$ which is the union of disjoint closed disks A_0 and A_1 in $X = \mathbb{R}^2$. We denote by $x_0 \in A_0$ and $x_1 \in A_1$ the centers of the two disks. Furthermore we denote by $f \colon I = [0, 1] \to X$ a map with $f(0) = x_1$

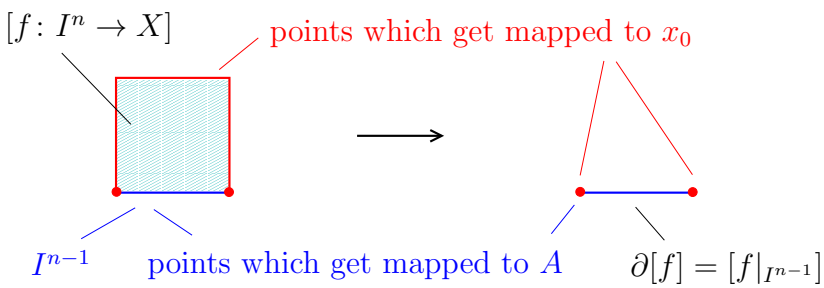

FIGURE 1000.

and $f(1) = x_0$. (We refer to Figure 1001 for an illustration.) Finally, for any $n \in \mathbb{N}_0$ and any $i \in \{0,1\}$ we denote by $c_{x_i}\colon I^n \to A_i$ the constant map that sends all points to x_i. It follows from Lemma 9.10 together with Lemma 9.9 and Propositions 9.12 (1) and 28.7 that all the homotopy groups of A and X are generated by $[c_{x_0}]$ except for $\pi_0(A, x_0)$ that equals the set $\{[c_{x_0}], [c_{x_1}]\}$.

As discussed on page 1884, f defines an element in $\pi_1(X, A, x_0)$. Using the definitions one sees almost immediately that $\partial[f] = [c_{x_1}] \in \pi_0(A, x_0)$. It follows easily from this data and Proposition 82.4 (2) that $\pi_1(X, A, x_0)$ consists of precisely two elements, namely $[c_{x_0}]$ and $[f]$.

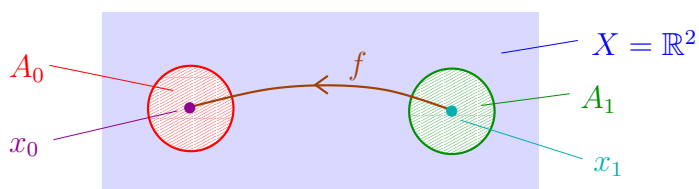

FIGURE 1001.

(2) Let $X = \mathbb{R}^2$. We denote by A the wedge of two circles, viewed as a subset of $X = \mathbb{R}^2$. Furthermore we denote by x_0 the wedge point. It follows from Proposition 82.4 (2) that $\pi_2(X, A, x_0) \xrightarrow{\cong} \pi_1(A, x_0)$. In Lemma 14.4 we saw that $\pi_1(A, x_0)$ is non-abelian, thus $\pi_2(X, A, x_0)$ is also non-abelian.

In fact we can identify two elements in $\pi_2(X, A, x_0)$ that do not commute. We consider the two maps $f, g\colon (I^2, \partial I^2, J^1) \to (X, A, \{x_0\})$ that are illustrated in Figure 1002. It follows easily from the definitions that $\partial[f], \partial[g]$ are the standard generators of the free group[1382] $\pi_1(S^1 \vee S^1, x_0)$. Since these do not commute we see that $[f]$ and $[g]$ do not commute either.

Proof. We start out with the proof of statement (1). In fact this statement follows mostly easily from the definitions. One only needs to think for a minute about the question why the connecting homomorphism is in fact a homomorphism.

[1382]We refer to page 390 for the calculation of the fundamental group of $S^1 \vee S^1$.

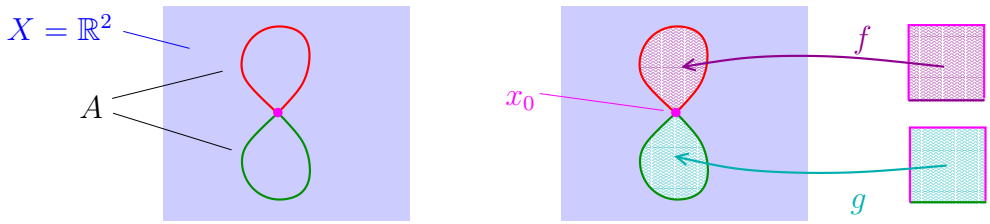

FIGURE 1002.

We turn to the proof of statement (2). In fact we prove a slight variation of the second statement. More precisely, let X be a topological space, let A be a subset of X and let B be a subset of A. Finally let $x_0 \in B$. For any $n \geq 2$ the map

$$\begin{array}{rcl} \partial_n \colon \pi_n(X, A, x_0) & \to & \pi_{n-1}(A, B, x_0) \\ [f \colon (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})] & \to & \left[\begin{array}{rcl} (I^{n-1}, \partial I^{n-1}, J^{n-2}) & \to & (A, B, \{x_0\}) \\ (x_1, \ldots, x_{n-1}) & \mapsto & f(x_1, \ldots, x_{n-1}, 0) \end{array} \right] \end{array}$$

is easily seen to be a well-defined morphism of pointed sets. Our goal is to prove the following claim.

Claim. The following sequence is exact[1383]

$$\ldots \to \pi_n(A, B, x_0) \xrightarrow{i_*} \pi_n(X, B, x_0) \xrightarrow{j_*} \pi_n(X, A, x_0) \xrightarrow{\partial_n} \pi_{n-1}(A, B, x_0) \to \ldots \to \pi_1(X, A, x_0).$$

where $i \colon (A, B) \to (X, B)$ and $j \colon (X, B) \to (X, A)$ are the obvious morphisms of pointed pairs of topological spaces.

Note that this claim, applied to $B = \{x_0\}$ together with Proposition 82.1 (2) almost implies that the sequence of the proposition is exact. The only problem is that the sequence of the claim stops slightly earlier, more precisely it stops at the subindex one instead of subindex zero. Thus the only piece missing is the exactness of the sequence of the proposition at the last three pointed sets. We leave the verification of exactness at these three spots as an elementary exercise to the conscientious reader.

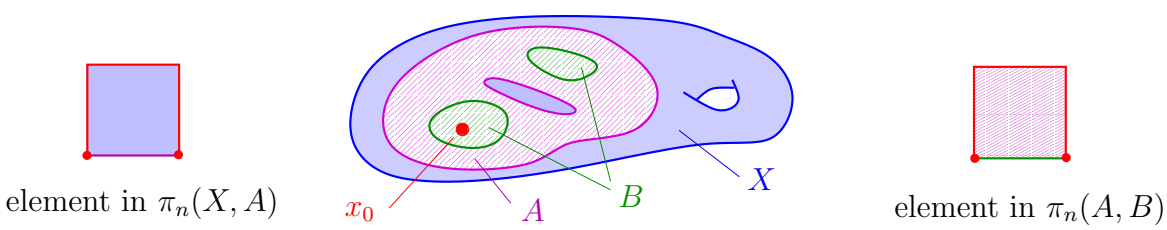

FIGURE 1003. First illustration for the proof of Proposition 82.4.

[1383]This sequence plays of course the role of the long exact sequence in homology groups of a triple of topological spaces, see Proposition 31.13.

Now we turn to the proof of the claim. Not surprisingly the proof of the claim breaks up into three separate proofs, namely we need to verify exactness at the three different groups.
Exactness at $\pi_n(X, B, x_0)$. It follows easily from Lemma 82.3 that $j_* \circ i_* = (j \circ i)_*$ is the trivial morphism. We leave it as an exercise to the reader to verify that $\ker(j_*) \subset \operatorname{im}(i_*)$.
Exactness at $\pi_n(X, A, x_0)$. It follows again easily from Lemma 82.3 and the definition of the connecting homomorphism ∂ that $\partial \circ j_*$ is the trivial morphism. Now suppose we are given $f\colon (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})$ such that the restriction of f to $I^{n-1} \times \{0\}$ represents the trivial element in $\pi_{n-1}(A, B, x_0)$. This means that there exists a homotopy $H\colon I^{n-1} \times I \to A$ (with all the required restrictions) from $f|_{I^n \times \{0\}}$ to the constant map. The map

$$\begin{array}{rcl} I^n \times [0,1] & \to & X \\ (x_1, \dots, x_n, t) & \mapsto & \begin{cases} f\big(x_1, \dots, x_{n-1}, \frac{t}{2} \cdot x_n + (1 - x_n)\big), & \text{if } x_n \in \big[\frac{t}{2}, 1\big] \\ H\big(x_1, \dots, x_{n-1}, 2x_n - t\big), & \text{if } x_n \in \big[0, \frac{t}{2}\big] \end{cases} \end{array}$$

is continuous by Lemma 5.3 and it defines a homotopy (again with all the desired extra properties) from f to a map that represents an element in $\pi_n(X, B, x_0)$. The definition of the homotopy is sketched, to the best of my abilities, in Figure 1004.

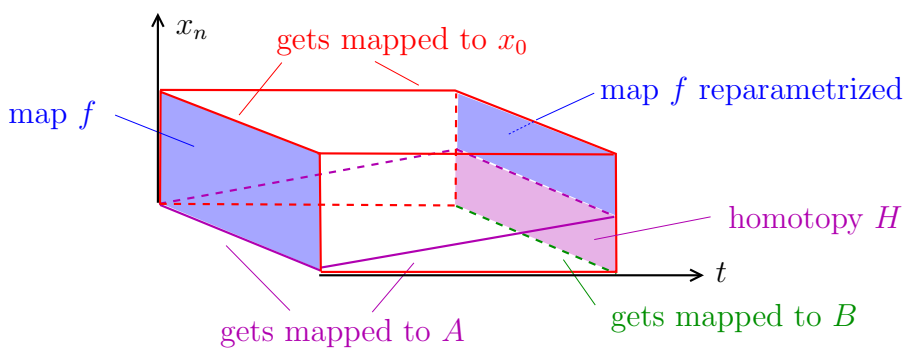

FIGURE 1004.

Exactness at $\pi_n(A, B, x_0)$. First note that $i_* \circ \partial$ is the trivial morphism. Indeed, if $f\colon (I^{n+1}, \partial I^{n+1}, J^n) \to (X, A, \{x_0\})$ is a map, then $f\colon (I^n \times [0,1], \partial I^n \times [0,1]) \to (X, x_0)$ defines a homotopy from $\partial f = f|_{I^n \times \{0\}}$ to the constant map c_{x_0}. Thus $(i_* \circ \partial)[f] = [i_* \circ \partial f]$ is the trivial element in $\pi_n(X, B, x_0)$.

Now suppose that we are given a map $f\colon (I^n, \partial I^n, J^{n-1}) \to (A, B)$ such that $j \circ f$ represents the trivial element in $\pi_n(X, B, x_0)$. This means that there exists a homotopy H (with all the obvious conditions) from $j \circ f$ to the constant map c_{x_0}. We define

$$\begin{array}{rcl} g\colon I^n & \to & B \\ (x_1, \dots, x_n) & \mapsto & H(x_1, \dots, x_{n-1}, 0, x_n). \end{array}$$

We pick a homeomorphism $\Psi\colon I^2 \to I^2$ with the properties as illustrated in Figure 1005.[1384] (Here it is psychologically convenient to think of I^2 as the square in the plane with x_n and x_{n+1}-coordinates.) It follows immediately from the definitions that the map

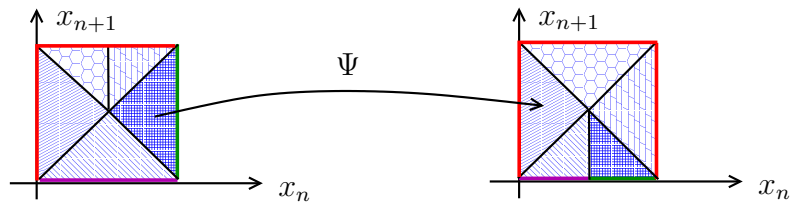

FIGURE 1005.

$$\begin{array}{rcl} I^{n+1} & \to & X \\ (x_1,\dots,x_n,x_{n+1}) & \to & H(x_1,\dots,x_{n-1},\Psi(x_n,x_{n+1})) \end{array}$$

defines an element in $\pi_{n+1}(X,A,x_0)$ such that the connecting morphism sends it to the element in $\pi_n(A,B,x_0)$ represented by the map[1385]

$$\begin{array}{rcl} f*g\colon I^n & \to & X \\ (t_1,\dots,t_n) & \mapsto & \begin{cases} f(t_1,\dots,t_{n-1},2t_n), & \text{if } t_n\in[0,\frac12], \\ g(t_1,\dots,t_{n-1},2t_n-1), & \text{if } t_n\in[\frac12,1] \end{cases} \end{array}$$

It remains to show that $f*g$ and f represent the same element in $\pi_n(A,B,x_0)$. This can be done in a fashion similar to the above proof of exactness. More precisely, a homotopy between f and $f*g$, again with all the desired properties, is given by

$$\begin{array}{rcl} I^n\times[0,1] & \to & X \\ (x_1,\dots,x_n,t) & \mapsto & \begin{cases} f\big(x_1,\dots,x_{n-1},\frac{t}{2}\cdot x_n+(1-x_n)\big), & \text{if } x_n\in\big[\frac{t}{2},1\big] \\ H\big(x_1,\dots,x_{n-1},2x_n-t\big), & \text{if } x_n\in\big[0,\frac{t}{2}\big] \end{cases} \end{array}$$

□

82.3. **Paths acting on relative homotopy groups.** Let (X,x_0) be a pointed topological space. In Section 81.1 we saw that the fundamental group $\pi_1(X,x_0)$ of X acts on any homotopy group $\pi_n(X,x_0)$. In this section we will discuss an analogous construction for relative homotopy groups. In particular, given a pointed pair (X,A,x_0) of topological spaces we will see that the fundamental group $\pi_1(A,x_0)$ of A (let us stress that here we write A instead of X) acts on any relative homotopy group $\pi_n(X,A,x_0)$.

The following definition is quite similar to the definition on page 1869.

[1384] The triangles in Figure 1005 indicate how one could write down an explicit homeomorphism.

[1385] Strictly speaking this definition of $f*g$ differs from the definition on page 1885 since we use a different coordinate to perform the product. But it is convenient to use the same notation.

Definition. Let X be a topological space, let A be a subset of X and let $n \in \mathbb{N}_{\geq 2}$.[1386] Furthermore let $\gamma\colon [0,1] \to A$ be a path in the subset A[1387] from a point x_0 to a point x_1. Finally let

$$f\colon (I^n, \partial I^n, J^{n-1}) \quad \to \quad (X, A, \{x_1\})$$

be a map. We define

$$f^\gamma\colon (I^n, \partial I^n, J^{n-1}) \quad \to \quad (X, A, \{x_0\})$$

to be the map that is illustrated in Figure 1006. For our particularly pedantic readers we now also give a super-rigorous definition of f^γ: First of all, given $t \in [0,1]$ we define $C_t = \left[\frac{t}{4}, \frac{4-t}{4}\right]^{n-1} \times [0, 1-\frac{t}{2}]$. Now we define

$$\begin{aligned} f^\gamma\colon (I^n, \partial I^n, J^{n-1}) &\to (X, A, x_0) \\ (x_1, \dots, x_n) &\to \begin{cases} f\big(2x_1 - \frac{1}{2}, \dots, 2x_n\big), & \text{if } (x_1, \dots, x_n) \in C_1 = \left[\frac{1}{4}, \frac{3}{4}\right]^{n-1} \times [0, \frac{1}{2}], \\ \gamma(t), & \text{if } (x_1, \dots, x_n) \in \partial C_t \text{ for } t \in [0,1]. \end{cases} \end{aligned}$$

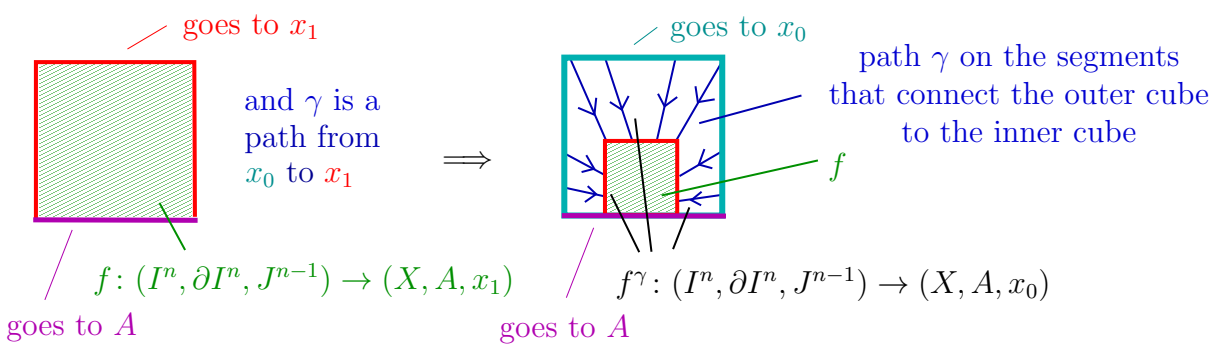

FIGURE 1006.

The following proposition can be viewed as the "relative analogue" of Proposition 28.5.

Proposition 82.5. *Let X be a topological space, let A be a subset of X and let $n \in \mathbb{N}_{\geq 2}$.*

(1) *If $\gamma\colon [0,1] \to A$ is a path from x_0 to x_1, then the map*

$$\begin{aligned} \gamma_*\colon \pi_n(X, A, x_1) &\to \pi_n(X, A, x_0) \\ [f] &\mapsto [f^\gamma] \end{aligned}$$

is a well-defined map that is a group homomorphism.

(2) *If x_0 and x_1 are two points in A which lie in the same path-component of A, then $\pi_n(X, A, x_0)$ is isomorphic to $\pi_n(X, A, x_1)$.*

(3) *Let $\varphi\colon (X, A) \to (Y, B)$ be a map between pairs of topological spaces.*

[1386] What is wrong with $n = 1$?

[1387] Note that in contrast to the definition on page 1869 we only consider paths in A. At this point we do not allow paths in X.

(a) *If* $\gamma\colon [0,1] \to A$ *is a path from* x_0 *to* x_1*, then the following diagram commutes*

$$\begin{array}{ccc} \pi_n(X,A,x_1) & \xrightarrow{\gamma_*} & \pi_n(X,A,x_0) \\ \downarrow{\scriptstyle \varphi_*} & & \downarrow{\scriptstyle \varphi_*} \\ \pi_n(Y,B,\varphi(x_1)) & \xrightarrow{(\varphi\circ\gamma)_*} & \pi_n(Y,B,\varphi(x_0)). \end{array}$$

(b) *If* $\varphi_*\colon \pi_n(X,A,x_0) \to \pi_n(Y,B,\varphi(x_0))$ *is an isomorphism (epimorphism, monomorphism) for some base point* $x_0 \in A$*, then for any other point* x_1 *in the same path component of* A *the map* $\varphi_*\colon \pi_n(X,A,x_1) \to \pi_n(Y,B,\varphi(x_1))$ *is also an isomorphism (epimorphism, monomorphism).*

(4) *Let* γ *and* δ *be two paths in* A *from* x_0 *to* x_1*. If* γ *and* δ *are path-homotopic in* A*, then the corresponding maps* γ_* *and* δ_* *from* $\pi_n(X,A,x_1)$ *to* $\pi_n(X,A,x_0)$ *agree.*

(5) *If* γ *is a path in* A *from* x_0 *to* x_1 *and if* δ *is a path in* A *from* x_1 *to* x_2*, then*[1388]

$$(\underbrace{\gamma * \delta}_{\text{path in } A \text{ from } x_0 \text{ to } x_2})_* = \gamma_* \circ \delta_*\colon \pi_n(X,A,x_2) \ \to\ \pi_n(X,A,x_0).$$

(6) *The map*

$$\begin{array}{rcl} \pi_1(A,x_0) \times \pi_n(X,A,x_0) & \to & \pi_n(X,A,x_0) \\ ([\gamma],[f]) & \mapsto & [\gamma]\cdot[f] := [f^\gamma] \end{array}$$

defines an action (in the sense of the definition on page 102) of the group $\pi_1(A,x_0)$ *on the group* $\pi_n(X,A,x_0)$*.*

(7) *We denote by* $i\colon A \to X$ *the inclusion map and by* $\varphi\colon \pi_n(X,x_0) \to \pi_n(X,A,x_0)$ *the natural map. Then, with the convention from page 1360, the following diagram commutes*

$$\begin{array}{ccc} \pi_1(X,x_0) \times \pi_n(X,x_0) & \longrightarrow & \pi_n(X,x_0) \\ {\scriptstyle i_*}\uparrow \quad \downarrow{\scriptstyle \varphi_*} & & {\scriptstyle \varphi_*}\downarrow \\ \pi_1(A,x_0) \times \pi_n(X,A,x_0) & \longrightarrow & \pi_n(X,A,x_0). \end{array}$$

(8) *If* $\gamma\colon [0,1] \to A$ *is a path from* x_0 *to* x_1*, then the following diagram commutes:*

$$\begin{array}{ccc} \pi_n(X,A,x_1) & \xrightarrow{[f]\mapsto[f^\gamma]} & \pi_n(X,A,x_0) \\ \downarrow{\scriptstyle \partial} & & {\scriptstyle \partial}\downarrow \\ \pi_{n-1}(A,x_1) & \xrightarrow{[f]\mapsto[f^\gamma]} & \pi_{n-1}(A,x_0). \end{array}$$

Proof. The proof of the first six statements of the proposition is basically identical to the proof of Proposition 81.1. The last two statements follow easily from the definitions. To protect the trees we will not carry out the details. □

[1388]Here it is worth remembering that by definition, see page 231, the product path $\gamma * \delta$ is given by first traversing γ and then traversing δ.

Remark. Let X be a topological space, let A be a non-empty subset and let $n \in \mathbb{N}_{\geq 2}$. If A is path-connected, then it follows from Proposition 82.5 (2) that the isomorphism type of the relative higher homotopy groups $\pi_n(X, A, x_0)$ does not depend on the choice of a base point in A. Thus if we are only interested in the isomorphism type of the n-th relative homotopy group of (X, A), then sometimes we just write $\pi_n(X, A)$, i.e. we suppress the base point from the notation.

Recall that for the relative homotopy groups $\pi_n(X, A, x_0)$ with $n \geq 3$ we use the additive notation for the group structure. Thus Lemma 81.5, Propositions 28.3, 82.1 (4) and 82.5 lead us to the following observation:

Observation. Let (X, A, x_0) be a pointed pair of topological spaces. If $n \geq 3$, then the abelian group $\pi_n(X, A, x_0)$ admits a natural $\mathbb{Z}[\pi_1(A, x_0)]$-left module structure.

Example. We consider the wedge $X = S^1 \vee S^2$ where we identify $i \in S^1$ with $(0, 0, -1) \in S^2$. We denote by x_0 the wedge point. Furthermore let $A = S^1 \subset X$. We denote by $t \in \pi_1(S^1, i)$ the standard generator. (We refer to Figure 1007 for an illustration.) By Proposition 12.3 we know that the inclusion $A \to X$ induces an isomorphism $\pi_1(A, x_0) \to \pi_1(X, x_0)$. We use this isomorphism to make the identification $\pi_1(A, x_0) = \pi_1(X, x_0) = \langle t \rangle$. It follows from Proposition 82.4 and Proposition 82.5 (7) that the natural map $\pi_2(X, x_0) \to \pi_2(X, A, x_0)$ is an isomorphism of $\mathbb{Z}[t^{\pm 1}]$-modules. In particular, by Proposition 81.7, we have

$$\pi_2(X, A, x_0) \overset{\cong}{\leftarrow} \pi_2(S^1 \vee S^2) \overset{\cong}{\rightarrow} \mathbb{Z}[t^{\pm 1}].$$

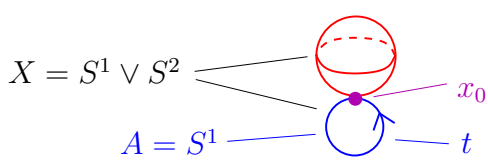

FIGURE 1007.

82.4. **Alternative description of relative homotopy groups.** Let (X, x_0) be a pointed topological space. Recall that on page 715 we had in particular introduced the following identifications:

$$\pi_n(X, x_0) \quad = \quad \begin{array}{c}\text{set (of homotopy classes)}\\ \text{of maps } (I^n, \partial I^n) \to (X, x_0)\end{array} \quad = \quad \begin{array}{c}\text{set (of homotopy classes)}\\ \text{of maps } (S^n, *) \to (X, x_0).\end{array}$$

These identifications allowed us to go back and forth between different view points regarding homotopy groups.

Before we continue with our discussion of relative homotopy groups we also want to introduce a second view point regarding relative homotopy groups. The key to doing so is the following elementary lemma.

Lemma 82.6. *Let $n \in \mathbb{N}$. There exists an explicit*[1389] *map $\varphi\colon I^n \to \overline{B}^n$ with the following three properties:*

(1) *we have $\varphi(J^{n-1}) = * := (-1, 0, 0, \ldots, 0)$ and $\varphi(I^{n-1}) = S^{n-1}$,*
(2) *the map φ descends to a homeomorphism $(I^n/J^{n-1}, I^{n-1}/\partial I^{n-1}) \xrightarrow{\cong} (\overline{B}^n, S^{n-1})$,*
(3) *the restriction of φ to the map $I^n \setminus \partial I^n \to B^n$ is an orientation-preserving diffeomorphism.*

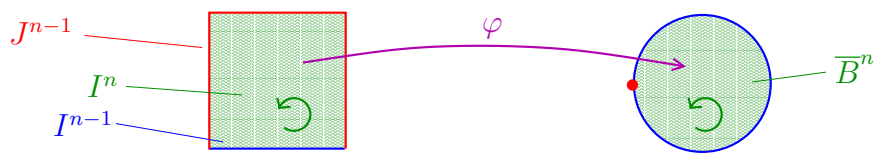

FIGURE 1008.

Sketch of a proof for Lemma 82.6 $(*)$. We write $Q = (\frac{1}{2}, \ldots, \frac{1}{2}, 0) \in I^n$. Given any point $x \in I^n \setminus \{Q\}$ we define

$$\rho(x) \ := \ \sup\big\{\|rx\| \,\big|\, r \in \mathbb{R}_{>0} \text{ and } r(x-Q)+Q \in I^n\big\}.$$

We consider the map

$$\begin{array}{rcl} \alpha\colon I^n/J^{n-1} & \to & \overbrace{\{(x_1,\ldots,x_n) \in \mathbb{R}^n \,|\, x_n \geq 0\}}^{=H_n} \cup \{\infty\} \\ [x] & \mapsto & \begin{cases} \frac{x-Q}{\|x-Q\|} \cdot \tan\left(\frac{\pi}{2} \cdot \frac{\|x-Q\|}{\rho(x)}\right), & \text{if } x \neq Q, \\ 0, & \text{if } x = Q. \end{cases} \end{array}$$

This map stretches each of the segments from Q to a point on J^{n-1} to an infinite ray emanating from the origin. In particular all points in J^{n-1} get sent to infinity, i.e. the map is well-defined. We refer to Figure 1009 for an illustration.

Similar to the proof of Proposition 1.48 we see that the map α is a homeomorphism that restricts to a homeomorphism $I^{n-1}/\partial I^{n-1} \to (\mathbb{R}^{n-1} \times \{0\}) \cup \{\infty\}$. Let $\beta\colon \mathbb{R}^n \cup \{\infty\} \to S^n$ be the inverse of the stereographic projection that we introduced in Lemma 1.41. Note that $\beta(\infty) = (0, \ldots, 0, 1)$. Furthermore note that the homeomorphism β restricts to a homeomorphism[1390]

$$\beta\colon H^n \cup \{\infty\} \ \to \ S^n_{\geq 0} \ := \ \{(x_1, \ldots, x_{n+1}) \in S^n \,|\, x_n \geq 0\}.$$

[1389] "Explicit" means that in the proof we explicitly write down such a map that does not depend on any choices. No reader will ever want to see the precise definition, but the fact that the map is explicitly given implies that there is no ambiguity involved when we write "let φ be the map from Lemma 82.6."

[1390] Note that the condition $x_n \geq 0$ is not a typo.

Finally we consider the following map:

$$\begin{array}{ccccccc} I^n & \to & I^n/J^{n-1} & \xrightarrow{\alpha} & H_n \cup \{\infty\} & \xrightarrow{\beta} & S^n_{\geq 0} & \to & \overline{B}^n \\ & & & & & & (x_1, \dots, x_n, x_{n+1}) & \mapsto & (-x_{n+1}, x_2, \dots, x_{n-1}, (-1)^n \cdot x_1). \end{array}$$

Using Exercise 3.5 one can easily verify that this map has all the desired properties.[1391] □

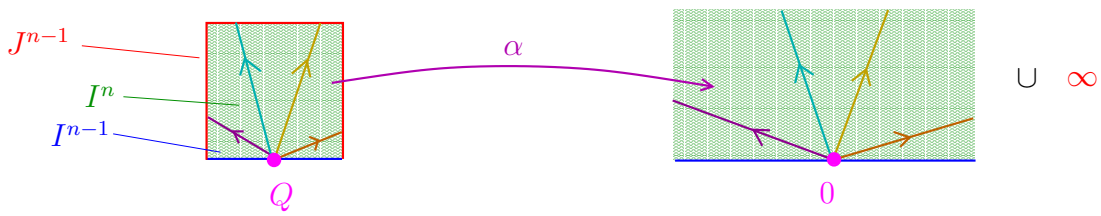

FIGURE 1009.

Convention. Using the map

$$\varphi\colon (I^n, \partial I^n, J^{n-1}) \to (\overline{B}^n, S^{n-1}, *)$$

from Lemma 82.6 we make the following identifications

$$\pi_n(X, A, x_0) = \begin{array}{c}\text{set (of homotopy classes) of} \\ \text{maps } (I^n, \partial I^n, J^{n-1}) \to (X, A, x_0)\end{array} = \begin{array}{c}\text{set (of homotopy classes) of} \\ \text{maps } (\overline{B}^n, S^{n-1}, *) \to (X, A, x_0).\end{array}$$

We refer to Figure 1010 for an illustration.

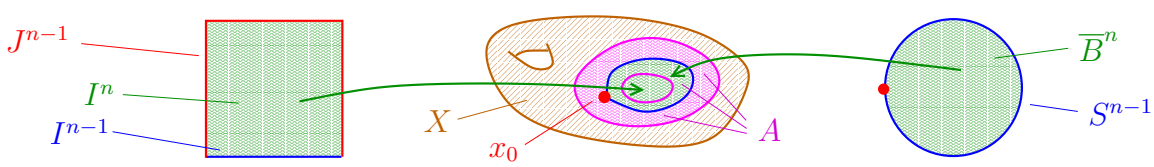

FIGURE 1010.

Remark. Let (X, A, x_0) be a pointed pair of topological spaces and let $n \in \mathbb{N}$. As above we make the identifications

$$\pi_n(X, A, x_0) = \left\{ \begin{array}{c}\text{homotopy classes of maps} \\ (\overline{B}^n, S^{n-1}, *) \to (X, A, x_0)\end{array} \right\} \text{ and } \pi_{n-1}(A, x_0) = \left\{ \begin{array}{c}\text{homotopy classes of maps} \\ (S^{n-1}, *) \to (A, x_0)\end{array} \right\}.$$

We leave it as an exercise to the ever-vigilant reader to verify that the connecting homomorphism $\pi_n(X, A, x_0) \to \pi_{n-1}(A, x_0)$ from Proposition 82.4 is given by the map

$$\begin{array}{rcl} \partial_n\colon \pi_n(X, A, x_0) & \to & \pi_{n-1}(A, x_0) \\ [f\colon (\overline{B}^n, S^{n-1}, *) \to (X, A, x_0)] & \mapsto & [f|_{S^{n-1}}\colon (S^{n-1}, *) \to (A, x_0)]. \end{array}$$

[1391] More precisely, the author is somewhat optimistic that the signs are right and that the map is indeed orientation-preserving.

82.5. **Connected (pairs of) topological spaces.** For convenience we recall the following definition from page 728.

Definition. Let $k \in \mathbb{N}_0$. We say a topological space X is *k-connected*, if $\pi_i(X) = 0$ for $i = 0, \dots, k$.

This definition has the following obvious "relative" analogue.

Definition. Let X be a topological space, let $A \subset X$ and let $k \in \mathbb{N}$. We say (X, A) *is k-connected* if every path-component of X contains a point of A and if for every $i \in \{1, \dots, k\}$ and every $x_0 \in A$ we have $\pi_i(X, A, x_0) = 0$.

The following lemma provides a convenient reformulation of the previous definition.

Lemma 82.7. *Let X be a topological space, let $A \subset X$ and let $k \in \mathbb{N}$. The following two statements are equivalent:*

(1) *The pair (X, A) is k-connected.*
(2) *Every path-component of X contains a point of A, for every $a \in A$ and every $j \in \{1, \dots, k-1\}$ the inclusion induced map $\pi_j(A, a) \to \pi_j(X, a)$ is an isomorphism and the inclusion induced map $\pi_k(A, a) \to \pi_k(X, a)$ is an epimorphism.*

Example. Let X be a topological space and let $A \subset X$ be a deformation retract. It follows from Proposition 28.7 (1) that for any $x_0 \in A$ and any $i \in \mathbb{N}_0$ the inclusion induced map $\pi_i(A, x_0) \to \pi_i(X, x_0)$ is an isomorphism. It follows from Lemma 82.7 that (X, A) is k-connected for every $k \in \mathbb{N}$.

Proof. We denote by $i \colon A \to X$ the inclusion map. Let $a \in A$. By Proposition 82.4 we have the following long exact sequence of homotopy groups:

$$\dots \to \pi_k(A, a) \xrightarrow{i_*} \pi_k(X, a) \to \pi_k(X, A, a) \xrightarrow{\partial} \pi_{k-1}(A, a) \xrightarrow{i_*} \pi_{k-1}(X, a) \to \dots$$

The lemma is an immediate consequence of the existence of this long exact sequence. □

The following proposition gives a convenient characterization of the vanishing relative homotopy groups.

Proposition 82.8. *Let X be a topological space and let $A \subset X$. For any $n \in \mathbb{N}$ the following two statements are equivalent:*

(1) *Every map $(\overline{B}^n, S^{n-1}) \to (X, A)$ is homotopic rel S^{n-1} to a map $\overline{B}^n \to A$,*
(2) *for every $x_0 \in A$ we have $\pi_n(X, A, x_0) = 0$.*

Furthermore, for $n = 0$ the above statement (1) is equivalent to

(2') *every path-component of X contains a point of A.*

Example. We consider the infinite cylinder $X = S^1 \times \mathbb{R}$ and the annulus $A = S^1 \times [-1, 1]$. Evidently A is a deformation retract of X. Thus, by the previous example the pair (X, A) is k-connected for every $k \in \mathbb{N}_0$. In Figure 1011 we show a map $f \colon (\overline{B}^2, S^1) \to (X, A)$. Furthermore we show a map $g \colon \overline{B}^2 \to A$ that is homotopic, rel S^1, to f.

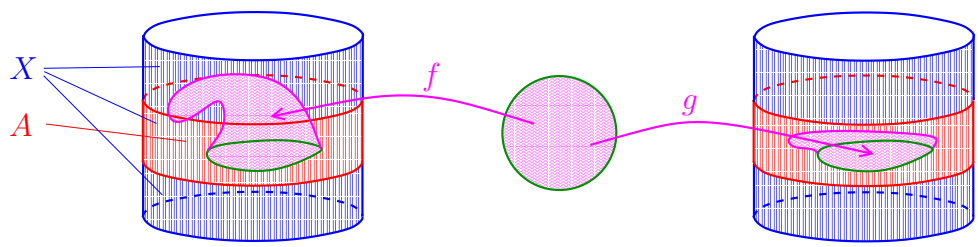

FIGURE 1011.

Proof of Proposition 82.8. First note that it is elementary to see that for $n = 0$ the statements (1) and (2') are equivalent. Now let $n \geq 1$. The implication (1) $\Rightarrow$ (2) is an immediate consequence of Lemma 82.3 and the by now well-known fact that there exists a homeomorphism $(I^n, \partial I^n) \xrightarrow{\cong} (\overline{B}^n, S^{n-1})$.

The most interesting statement of the proposition is the implication (2) $\Rightarrow$ (1). Thus we now assume that $\pi_n(X, A, x_0) = 0$ for every $x_0 \in A$. Let $f\colon (\overline{B}^n, S^{n-1}) \to (X, A)$ be a map. We need to show that f is homotopic rel S^{n-1} to a map that takes values only in A. Let $\varphi\colon I^n \to \overline{B}^n$ be the map from Lemma 82.6 with $\varphi(J^{n-1}) = (-1, 0, \dots, 0)$. We set $x_0 := f(-1, 0, \dots, 0)$. Note that the map $f \circ \varphi\colon I^n \to X$ is actually a map

$$f \circ \varphi\colon (I^n, \partial I^n, J^{n-1}) \;\to\; (X, A, \{x_0\})$$

of triples. Since $\pi_n(X, A, x_0) = 0$ we see that there exists a homotopy

$$F\colon (I^n, \partial I^n, J^{n-1}) \times [0,1] \;\to\; (X, A, \{x_0\})$$

which satisfies $F_0 = f \circ \varphi$ and $F_1 = c_{x_0}$. Now we consider the map

$$\begin{array}{rcl} I^n \times [0,1] & \to & X \\ (x_1, \dots, x_n, t) & \mapsto & \begin{cases} F\big(x_1, \dots, x_{n-1}, \frac{1}{1-\frac{t}{2}} \cdot (x_n - \frac{t}{2}), t\big), & \text{if } x_n \in \big[\frac{t}{2}, 1\big] \\ F\big(x_1, \dots, x_{n-1}, 0, 2 \cdot x_n\big), & \text{if } x_n \in \big[0, \frac{t}{2}\big]. \end{cases} \end{array}$$

The definition of the homotopy is sketched, with moderate success, in Figure 1012. This

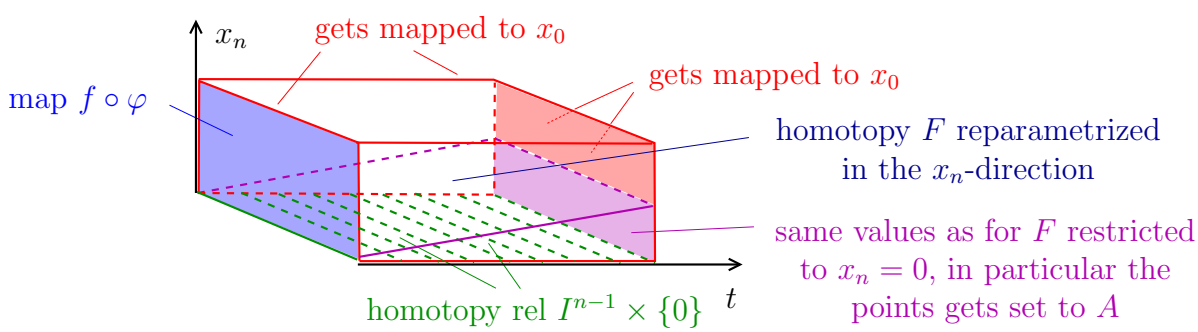

FIGURE 1012.

map has the following properties:

(0) the map is continuous by Lemma 5.3,
(1) the map is a homotopy rel $I^{n-1} \times \{0\}$,
(2) the map is a homotopy from $f \circ \varphi$ to a map that takes values in A,
(3) the map sends $J^{n-1} \times [0,1]$ to x_0.

It follows from Property (3), and using the above map $\varphi\colon (I^n, J^{n-1}) \to (\overline{B}^n, (-1, 0, \dots, 0))$, that F defines a homotopy $G\colon \overline{B}^n \times [0,1] \to X$. Property (1) implies that G is a homotopy rel S^{n-1}. Furthermore Property (2) says that G is a homotopy from f to a map that takes values in A. Thus G is the desired a homotopy. □

The following proposition gives us an important example of a k-connected pair of topological spaces.

Proposition 82.9. *Let X be a CW-complex and let $k \in \mathbb{N}_0$.*

(1) *If A is a subcomplex such that all cells in $X \setminus A$ have dimension greater than k, then the pair (X, A) is k-connected.*
(2) *The pair (X, X^k) is k-connected.*[1392]

Proof.

(1) Let X be a CW-complex, let A be a subcomplex and let $k \in \mathbb{N}_0$. Suppose that all cells in $X \setminus A$ have dimension greater than k. This implies in particular that every path-component of X contains at least one point in A. The remainder of the proof is almost the same as the proof of Proposition 28.10. The key difference is that we need to replace the Cellular Approximation Theorem 27.15 by the Cellular Approximation Theorem 27.16 for Pairs of CW-complexes and that now we use the (1) ⇒ (2) implication of Proposition 82.8. We leave it to the reader to carry out the modest modifications of the proof of Proposition 28.10.
(2) This statement is of course an immediate consequence of the first statement. □

The following corollary is an extremely useful consequence of Lemma 82.7 and Proposition 82.9 (2).

Corollary 82.10. *Let X be a CW-complex, let $k \in \mathbb{N}_0$ and let $x \in X^k$. The following two statements hold:*

(1) *For $j = 1, \dots, k-1$ the inclusion induced map $\pi_j(X^k, x) \to \pi_j(X, x)$ is an isomorphism.*
(2) *The inclusion induced map $\pi_k(X^k, x) \to \pi_k(X, x)$ is an epimorphism.*

82.6. **The relative Hurewicz Theorem.** In this section we state the "Relative Hurewicz Theorem" that generalizes the original Hurewicz Theorem 80.5 to the relative setting.

[1392]Recall that X^k denotes the k-skeleton of X, i.e. the union of all cells of dimension $\leq k$.

Definition. Let (X, A, x_0) be a pointed pair of topological spaces and let $n \in \mathbb{N}$. We denote by $[I^n] \in H_n(I^n, \partial I^n; \mathbb{Z})$ the fundamental class of I^n.[1393] We refer to the map

$$\begin{array}{rcl} \Phi_{(X,A,x_0)} \colon \pi_n(X, A, x_0) & \to & H_n(X, A; \mathbb{Z}) \\ [f \colon (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})] & \mapsto & f_*([I^n]) \end{array}$$

as the *relative Hurewicz homomorphism.*

The following lemma summarizes some elementary properties of the relative Hurewicz homomorphism.

Lemma 82.11.

(1) *Let (X, A, x_0) be a pointed pair of topological spaces and let $n \in \mathbb{N}_{\geq 2}$. The map*

$$\begin{array}{rcl} \Phi_{(X,A,x_0)} \colon \pi_n(X, A, x_0) & \to & H_n(X, A; \mathbb{Z}) \\ [f \colon (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})] & \mapsto & f_*([I^n]) \end{array}$$

is well-defined and it is a homomorphism.

(2) *Let (X, x_0) be a pointed topological space and let $n \geq 2$. The following diagram commutes*

$$\begin{array}{ccc} \pi_n(X, x_0) & \xrightarrow{\Phi_{(X,x_0)}} & H_n(X; \mathbb{Z}) \\ \cong \big\downarrow & & \big\downarrow \cong \\ \pi_n(X, \{x_0\}, x_0) & \xrightarrow{\Phi_{(X,\{x_0\},x_0)}} & H_n(X, \{x_0\}; \mathbb{Z}). \end{array}$$

Here the left-hand vertical map is given by the identification from page 1884 and the right-hand vertical map is the obvious map from absolute to relative homology groups.

(3) *Let (X, A, x_0) be a pointed pair of topological spaces. The following diagram commutes*

$$\begin{array}{ccccccccccc} \ldots \longrightarrow & \pi_n(A, x_0) & \longrightarrow & \pi_n(X, x_0) & \longrightarrow & \pi_n(X, A, x_0) & \xrightarrow{\partial} & \pi_{n-1}(A, x_0) & \longrightarrow \ldots \to & \pi_1(X, x_0) \\ & \big\downarrow & & \big\downarrow & & \big\downarrow & & \big\downarrow & & \big\downarrow \\ \ldots \longrightarrow & H_n(A; \mathbb{Z}) & \longrightarrow & H_n(X; \mathbb{Z}) & \longrightarrow & H_n(X, A; \mathbb{Z}) & \xrightarrow{\partial} & H_{n-1}(A; \mathbb{Z}) & \longrightarrow \ldots \to & H_1(X; \mathbb{Z}). \end{array}$$

Here the horizontal sequences are the long exact sequences given by Corollary 31.14 and by Proposition 82.4 and the vertical maps are the Hurewicz homomorphisms.

Sketch of proof.

(1) The proof of the first statement is evidently just a straightforward variation of the proof of Lemma 38.9. We refer to [Bre, Lemma VII.10.2] or [Hat, Proposition 4.36] for details.

(3) We have to show that each of the three squares commutes.

  (a) The first square commutes basically by definition, see also Lemma 38.9 (2).

[1393] Here we endow $I^n \subset \mathbb{R}^n$ with the usual orientation coming from $\mathbb{R}^n$.

(b) The fact that the second square commutes is an immediate consequence of the description of the Hurewicz homomorphism $\pi_n(X, x_0) \to H_n(X; \mathbb{Z})$ that is given on page 1852.

(c) Finally it follows fairly easily from the aforementioned discussion on page 1852 together with Lemma 46.23 and Proposition 46.26 that the third square commutes.

(2) This is just a special case of the second square considered in (3). □

Again the following question arises: to what degree is the relative Hurewicz homomorphism in fact an isomorphism? One might hope that if a pair (X, A) is $(n-1)$-connected, then the Hurewicz homomorphism $\Phi_{(X,A,x_0)} \colon \pi_n(X, A, x_0) \to H_n(X, A; \mathbb{Z})$ is an isomorphism. But the following example shows that this is *not* the case.

Example. We consider again $X = S^1 \vee S^2$ and $A = S^1 \subset X$. We denote by x_0 the wedge point. It follows easily from the long exact sequence of homotopy groups provided by Proposition 82.4 that (X, A) is 1-connected.[1394] We see that in this case the map

$$\Phi_{(X,A,x_0)} \colon \underbrace{\pi_2(X, A, x_0)}_{\cong \mathbb{Z}^\infty,\ \text{see page 1896}} \to \underbrace{H_2(X, A; \mathbb{Z})}_{\cong \mathbb{Z}}$$

is *not* an isomorphism.

The following lemma is the key to understanding why the relative Hurewicz homomorphism fails to be a monomorphism.

Lemma 82.12. *Let (X, A, x_0) be a pointed pair of topological spaces and let $n \in \mathbb{N}_{\geq 2}$. Furthermore let $\sigma \in \pi_n(X, A, x_0)$. For any $g \in \pi_1(A, x_0)$ we have*

$$\Phi_{(X,A,x_0)}(g \cdot \sigma) \;=\; \Phi_{(X,A,x_0)}(\sigma).$$

Proof. Let (X, A, x_0) be a pointed pair of topological spaces and let $n \in \mathbb{N}_{\geq 2}$. Furthermore let $[f] \in \pi_n(X, A, x_0)$ and let $[\gamma] \in \pi_1(A, x_0)$. As in Proposition 81.1 (7) we see that the maps $f \colon (I^n, \partial I^{n-1}) \to (X, A)$ and $f^\gamma \colon (I^n, \partial I^{n-1}) \to (X, A)$ are homotopic. We obtain that

$$\Phi_{(X,A,x_0)}([\gamma] \cdot [f]) \;=\; \Phi_{(X,A,x_0)}([f^\gamma]) \;=\; (f^\gamma)_*([I^n]) \;\underset{\substack{\uparrow \\ \text{by Proposition 31.15, since } f \text{ and } f^\gamma \text{ are homotopic as maps } (I^n, \partial I^n) \to (X, A)}}{=}\; f_*([I^n]) \;=\; \Phi_{(X,A,x_0)}([f]).$$

□

The above lemma leads us to the following definition.

Definition. Let (X, A, x_0) be a pointed pair of topological spaces.[1395]

[1394] Alternatively we could view X as a CW-complex in the usual way. Then we obtain from Proposition 82.9 that the pair (X, A) is 1-connected.

[1395] Here we use the common, but sometimes confusing, convention that we write the group structure on the abelian group $\pi_n(X, A, x_0)$, $n \geq 3$, additively whereas we write the group structure on $\pi_2(X, A, x_0)$ multiplicatively. Evidently there is no rule without an exception, hence, if $\pi_2(X, A, x_0)$ happens to be abelian after all, then we also like to use additive notation for $\pi_2(X, A, x_0)$.

(1) For $n \in \mathbb{N}_{\geq 3}$ we define $\pi'_n(X, A, x_0)$ to be the quotient group[1396]

$$\pi'_n(X, A, x_0) \ := \ \pi_n(X, A, x_0)/\{g \cdot \sigma - \sigma \,|\, g \in \pi_1(A, x_0) \text{ and } \sigma \in \pi_n(X, A, x_0)\}.$$

(2) We define[1397]

$$\pi'_2(X, A, x_0) \ := \ \pi_2(X, A, x_0)/\langle\langle\{(g\cdot\sigma)\cdot\sigma^{-1} \,|\, g \in \pi_1(A, x_0), \sigma \in \pi_2(X, A, x_0)\}\rangle\rangle.$$

(3) By Lemma 82.12 the Hurewicz homomorphism

$$\Phi_{(X,A,x_0)} \colon \pi_n(X, A, x_0) \ \to \ H_n(X, A; \mathbb{Z})$$

descends to a homomorphism

$$\Phi_{(X,A,x_0)} \colon \pi'_n(X, A, x_0) \ \to \ H_n(X, A; \mathbb{Z}).$$

We refer to this homomorphism again as the *Hurewicz homomorphism.*

Remark. Let (X, A, x_0) be a pointed pair of topological spaces. It is a fun exercise to show "by hand" that $\pi'_2(X, A, x_0)$ is an abelian group. We refer to [Hat, Lemma 4.39] for details.

Example. Once again we consider $X = S^1 \vee S^2$ and $A = S^1 \subset X$. We denote by x_0 the wedge point. As usual we write $\pi_1(A, x_0) = \langle t \rangle$. On page 1896 we already saw that $\pi_2(X, A, x_0) \cong \mathbb{Z}[t^{\pm 1}]$ as $\mathbb{Z}[\pi_1(A, x_0)] = \mathbb{Z}[t^{\pm 1}]$-modules. Thus we have an isomorphism

$$\pi'_2(X, A, x_0) \ \cong \ \mathbb{Z}[t^{\pm 1}]/\{(t^k - 1) \cdot f \,|\, f \in \mathbb{Z}[t^{\pm 1}] \text{ and } k \in \mathbb{Z}\}.$$

It is an amusing algebra exercise to show that the group on the right-hand side is isomorphic to $\mathbb{Z}$.

The following theorem is a generalization of the Hurewicz Theorem 80.5 to the relative case.

Theorem 82.13. (Relative Hurewicz Theorem) *Let (X, A, x_0) be a pointed pair of topological spaces such that X and A are path-connected. Let $n \geq 2$. If the pair (X, A) is $(n-1)$-connected, then the following two statements hold:*

(1) *We have $H_k(X, A; \mathbb{Z}) = 0$ for $k = 1, \dots, n-1$.*
(2) *The Hurewicz homomorphism*

$$\Phi_{(X,A,x_0)} \colon \pi'_n(X, A, x_0) \ \to \ H_n(X, A; \mathbb{Z})$$

is an isomorphism.

Proof. We will not provide a proof of the Relative Hurewicz Theorem. A full proof is given in [Bre, Theorem VII.10.7] or alternatively in [Hat, Theorem 4.37] and [Sp, Proposition 7.5.1]. If A is simply connected, then it is a great exercise to figure out to what degree the proof of the Hurewicz Theorem 80.5 can be modified to deal with the relative case. □

[1396] Let $n \in \mathbb{N}_{\geq 3}$. By Proposition 82.1 (4) we know that $\pi_n(X, A, x_0)$ is abelian. Therefore it follows from Exercise 81.7 that $\{g\cdot\sigma - \sigma \,|\, g \in \pi_1(A, x_0) \text{ and } \sigma \in \pi_n(X, A, x_0)\}$ is in fact a subgroup of $\pi_n(X, A, x_0)$.

[1397] Recall that given a group π and a subset $X \subset \pi$ we denote by $\langle\langle X \rangle\rangle$ the subgroup of π normally generated by X. We refer to page 407 for details.

The following theorem, which can be viewed as a corollary to the Relative Hurewicz Theorem 82.13, is a nice illustration of the usefulness of relative homotopy groups.

Theorem 82.14. *Let X and Y be two topological spaces and furthermore let $f\colon X \to Y$ be a map. We pick a base point $x_0 \in X$ and we write $y_0 = f(x_0)$.*

(1) *If for every $i \in \mathbb{N}_{\geq 2}$ the induced map*

$$f_*\colon \pi_i(X, x_0) \xrightarrow{\cong} \pi_i(Y, y_0)$$

is an isomorphism, then for every $i \in \mathbb{N}_{\geq 2}$ the induced map

$$f_*\colon H_i(X;\mathbb{Z}) \xrightarrow{\cong} H_i(Y;\mathbb{Z})$$

is also an isomorphism.

(2) *If X and Y are simply connected, then the converse to (1) holds. More precisely, in this case, if for every $i \in \mathbb{N}_{\geq 2}$ the induced map*

$$f_*\colon H_i(X;\mathbb{Z}) \xrightarrow{\cong} H_i(Y;\mathbb{Z})$$

is an isomorphism, then for every $i \in \mathbb{N}_{\geq 2}$ the induced map

$$f_*\colon \pi_i(X, x_0) \xrightarrow{\cong} \pi_i(Y, y_0)$$

is also an isomorphism.

Remark. In some textbooks, see e.g. [Bre, p. 481], [DK, p. 162] and [Sp, p. 399], this theorem is referred to as the "Whitehead Theorem". We will reserve the "Whitehead Theorem" for a later result.

Proof. The idea is to "replace" the map $f\colon X \to Y$ by an inclusion map so that we can apply the commutative diagram from Lemma 82.11. The key to doing so is the notion of the mapping cylinder that we introduced on page 455. Recall that the mapping cylinder corresponding to f is defined as the topological space

$$\mathrm{Cyl}(f) \;:=\; ((X \times [0,1]) \sqcup Y)/\sim \;\text{ where } (x,1) \sim f(x) \text{ for all } x \in X.$$

We consider the maps

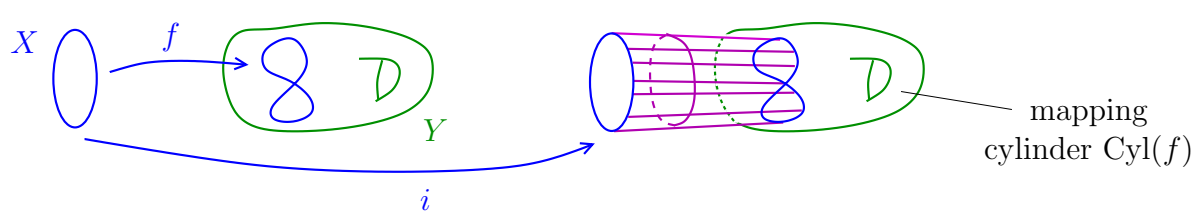

FIGURE 1013.

$$\begin{aligned} i\colon X &\to \mathrm{Cyl}(f) \\ x &\mapsto (x,0) \end{aligned} \quad \text{respectively} \quad \begin{aligned} r\colon \mathrm{Cyl}(f) &\to Y \\ P &\mapsto \begin{cases} P, & \text{if } P \in Y, \\ f(Q), & \text{if } P = [(Q,t)] \text{ with } Q \in X, t \in [0,1]. \end{cases} \end{aligned}$$

Note that we have $r \circ i = f\colon X \to Y$. Also note that in Lemma 15.7 (2b) we showed that the retraction $r\colon \mathrm{Cyl}(f) \to Y$ is a homotopy equivalence. We use the inclusion $i\colon X \to \mathrm{Cyl}(f)$ to identify X with $i(X)$, i.e. we view X as a subset of $\mathrm{Cyl}(f)$.

In the following we prove Statement (2) of the theorem. Thus we assume that X and Y are simply connected and we assume that for every $i \in \mathbb{N}_{\geq 2}$ the induced map

$$f_*\colon H_i(X;\mathbb{Z}) \xrightarrow{\cong} H_i(Y;\mathbb{Z})$$

is an isomorphism. We need to show that for every $i \in \mathbb{N}_{\geq 2}$ the induced map

$$f_*\colon \pi_i(X,x_0) \xrightarrow{\cong} \pi_i(Y,y_0)$$

is also an isomorphism. We consider the following maps

$$\begin{tikzcd}
 & & & \pi_2(Y,y_0) & & \\
\dots \arrow[r] & \pi_3(\mathrm{Cyl}(f),X,x_0) \arrow[r, "\partial"] \arrow[d] & \pi_2(X,x_0) \arrow[r, "i_*"] \arrow[d] \arrow[ur, "f_*"] & \pi_2(\mathrm{Cyl}(f),x_0) \arrow[r] \arrow[d] \arrow[u, "r_*"'] & \pi_2(\mathrm{Cyl}(f),X,x_0) \arrow[r] \arrow[d] & 0 \\
\dots \arrow[r] & H_3(\mathrm{Cyl}(f),X;\mathbb{Z}) \arrow[r, "\partial"] & H_2(X;\mathbb{Z}) \arrow[r, "i_*"] \arrow[dr, "f_*"'] & H_2(\mathrm{Cyl}(f);\mathbb{Z}) \arrow[r] \arrow[d, "r_*"] & H_2(\mathrm{Cyl}(f),X;\mathbb{Z}) \arrow[r] & 0 \\
 & & & H_2(Y;\mathbb{Z}) & &
\end{tikzcd}$$

where the vertical maps between the second and the third row are the Hurewicz homomorphisms. The desired statement follows from the following observations:

(a) The triangles commute since $f = r \circ i$. Furthermore the squares commute by Lemma 82.11.
(b) By our hypothesis the maps $f_*\colon H_*(X;\mathbb{Z}) \to H_*(Y;\mathbb{Z})$ are isomorphisms. Furthermore, since r is a deformation retraction we obtain from Corollary 30.8 that the maps $r_*\colon H_*(\mathrm{Cyl}(f);\mathbb{Z}) \to H_*(Y;\mathbb{Z})$ are isomorphisms.
(c) Since $f_* = (r \circ i)_* = r_* \circ i_*$ we obtain immediately from (b) that the maps $i_*\colon H_*(X;\mathbb{Z}) \to H_*(\mathrm{Cyl}(f);\mathbb{Z})$ are also isomorphisms.
(d) It follows from (c) and the bottom long exact sequence that all the relative homology groups $H_*(\mathrm{Cyl}(f),X;\mathbb{Z})$ vanishes.
(e) It follows easily from (d), the hypothesis that X is simply connected and the Relative Hurewicz Theorem 82.13 that all the relative homotopy groups $\pi_*(\mathrm{Cyl}(f),X,x_0)$ vanish.
(f) Using (e) we obtain immediately from the top long exact sequence that the maps $i_*\colon \pi_*(X,x_0) \to \pi_*(\mathrm{Cyl}(f),x_0)$ are isomorphisms.

(g) By Proposition 28.7 we know that the maps $r_*\colon \pi_*(\mathrm{Cyl}(f), x_0) \to \pi_*(Y, y_0)$ are isomorphisms.
(h) Finally it follows from $f_* = r_* \circ i_*$ together with (f) and (g) that the maps $f_*\colon \pi_*(X, x_0) \to \pi_*(Y, y_0)$ are indeed isomorphisms.

The proof of Statement (1) is very similar to the above argument. We leave it to fill in the details. □

We conclude this section with a discussion of homotopy spheres. Recall that by the definition on page 728 an n-dimensional homotopy sphere Σ is a closed n-dimensional topological manifold that is $\lfloor \frac{n}{2} \rfloor$-connected. In Proposition 80.8 we saw that the n-dimensional homotopy sphere Σ is in fact $(n-1)$-connected, i.e. the homotopy groups of Σ agree with the homotopy groups of S^n up to degree $n-1$.

The following pleasant corollary shows that in fact all homotopy groups of Σ are isomorphic to the corresponding homotopy groups of S^n.

Corollary 82.15. *Let $n \in \mathbb{N}_{\geq 2}$. If Σ is an n-dimensional homotopy sphere, then for every $i \in \mathbb{N}_0$ we have $\pi_i(\Sigma) \cong \pi_i(S^n)$.*

Proof. Let Σ be an n-dimensional homotopy sphere. By Theorem 82.14 (2) it suffices to find a map $f\colon S^n \to \Sigma$ such that for every $i \in \mathbb{N}_{i\geq 2}$ the induced map $f_*\colon H_i(S^n;\mathbb{Z}) \to H_i(\Sigma;\mathbb{Z})$ is an isomorphism.

So let us try to find such a map f. We pick a base point $x_0 \in \Sigma$. By the definition and Proposition 80.8 we know that Σ is a non-empty closed connected n-dimensional topological manifold with $H_i(\Sigma;\mathbb{Z}) \cong \pi_i(\Sigma, x_0) = 0$ for $i = 1, \dots, n-1$. It follows from the Hurewicz Theorem 80.5 that the Hurewicz homomorphism

$$\begin{array}{rcl} \Phi\colon \pi_n(\Sigma, x_0) & \to & H_n(\Sigma;\mathbb{Z}) \\ [f\colon (S^n, *) \to (\Sigma, x_0)] & \mapsto & f_*([S^n]) \end{array}$$

is an isomorphism. Note that the fact that $\pi_1(\Sigma, x_0) = 0$ together with Corollary 45.27 implies that Σ is orientable. Therefore by Theorem 46.2 we know that $H_n(\Sigma;\mathbb{Z}) \cong \mathbb{Z}$. Since the Hurewicz homomorphism is an isomorphism we can pick a map $f\colon S^n \to \Sigma$ such that $f_*([S^n]) \in H_n(\Sigma;\mathbb{Z}) \cong \mathbb{Z}$ is a generator.

We claim that f has the desired properties. By choice of f we know that the map $f_*\colon H_n(S^n;\mathbb{Z}) \to H_n(\Sigma;\mathbb{Z})$ is an epimorphism. But since both groups are isomorphic to $\mathbb{Z}$ we see that the map is in fact an isomorphism. Since S^n and Σ are path-connected we obtain from the discussion on page 747 that $f_*\colon H_0(S^n;\mathbb{Z}) \to H_0(\Sigma;\mathbb{Z})$ is also an isomorphism. Furthermore for all other dimensions f_* induces an isomorphism of homology groups for the rather banal reasons that all other homology groups of S^n and Σ are zero. (Indeed, we saw above that the homology groups in dimension less than n vanish and it follows from Theorem 46.4 that the homology groups vanish in dimension greater than n.) □

82.7. **Excision for relative homotopy groups?** We have now seen that the (relative) homotopy groups and (relative) homology groups have some properties in common:

(1) both invariants are functorial,

(2) in both cases homotopic maps induce the same maps on the invariants,
(3) a (pointed) pair of topological spaces gives rise to a long exact sequence.

These formal similarities between (relative) homotopy and (relative) homology groups makes one wonder whether an analogue of the Excision Theorem 31.17 holds for relative homotopy groups.

For better or worse this is not the case. More precisely, the next lemma shows that a naive analogue of the Excision Theorem 31.17 fails even in very simple situations.

Lemma 82.16. *We consider the 2-dimensional sphere $X = S^2$ together with the subset $A := S^2_{\leq 0} = \{(x, y, z) \in S^2 \,|\, z \leq 0\}$ given by the lower hemisphere and together with the subset $Z = \{(0, 0, -1)\}$ that is given by the "South Pole". Then*[1398]

$$\pi_3(X, A) \ \not\cong \ \pi_3(X \setminus Z, A \setminus Z).$$

Figure 1014.

Proof. We start out with the following observations:

(1) On page 73 we saw that $A = S^2_{\leq 0}$ is homeomorphic to $\overline{B}^2$. In particular A is contractible which implies by Proposition 28.7 that $\pi_2(A) = \pi_3(A) = 0$.
(2) The above homeomorphism also shows that $A \setminus Z$ is homeomorphic to $\overline{B}^2 \setminus \{(0)\}$ which is homotopy equivalent to S^1. This implies that $\pi_2(A \setminus Z) = \pi_3(A \setminus Z) = 0$.
(3) Finally in Lemma 1.41 we saw that $X \setminus Z = S^2 \setminus \{(0, 0, -1)\}$ is homeomorphic to $\mathbb{R}^2$ which implies that $\pi_2(X \setminus Z) = \pi_3(X \setminus Z) = 0$.

It follows from these observations and the long exact sequence of homotopy groups, provided by Proposition 82.4, that $\pi_3(X \setminus Z, A \setminus Z) \cong \pi_2(A \setminus Z) \cong \pi_2(S^1) = 0$ and furthermore that $\pi_3(X, A) \cong \pi_3(S^2)$. But in Theorem 63.3 we saw that $\pi_3(S^2)$ is non-trivial. We have thus shown that $\pi_3(X, A)$ is not isomorphic to $\pi_3(X \setminus Z, A \setminus Z)$. □

Remark. We just used the fact that $\pi_3(S^2) \neq 0$ to show that relative homotopy groups do not satisfy excision. It is a good moment to remind ourselves of Theorem 42.29. The theorem suggests that if relative homotopy groups did satisfy excision, then it would follow from Proposition 82.4 that, at least morally, (abelianized) homotopy groups would agree with homology groups.[1399] But the calculations $\pi_3(S^2) \neq 0$ and $H_3(S^2) = 0$ show that this is not the case.

[1398] Here evidently the closure of Z is contained in the interior of A, i.e. the hypotheses for the Excision Theorem 31.17 for homology groups are satisfied.

[1399] To turn this logic into a proper argument might be a little tricky because of base point issues.

In much more restricted circumstances there is in fact an excision theorem. For the record we state the following theorem. We will not make use of it and therefore we will not provide the proof (which by all accounts seems to be somewhat messy.)

Theorem 82.17. (Blakers-Massey Theorem)

(1) *Let X be a topological space and let A and B be subsets such that $X = \mathring{A} \cup \mathring{B}$. If $(A, A \cap B)$ is n-connected and if $(B, A \cap B)$ is m-connected, then the inclusion induced map*

$$\pi_k(A, A \cap B) \ \to \ \pi_k(X, B)$$

is an isomorphism for $k < m + n$ and it is an epimorphism for $k = m + n$.

(2) *The conclusion of (1) also holds if X is a CW-complex and A and B are two subcomplexes of X with $X = A \cup B$ such that $A \cap B$ is non-empty and connected.*

Proof. The first statement was originally proved in 1952 by Albert Blakers and William Massey [BlM]. Proofs can also be found in [Gra, Corollary 16.27], [tD2, Theorem 6.4.1] or [tDKP, p. 211]. The second statement can presumably be deduced from the first statement. Alternatively see [Hat, Theorem 4.23]. □

Exercises for Chapter 82.

Exercise 82.1. Show that the three paths to the right of Figure 997 define three different elements in $\pi_1(X, A, x_0)$.

Exercise 82.2. Let (X, A, x_0) be a pointed pair of topological spaces. Show that if $n \geq 3$, then the relative homotopy group $\pi_n(X, A, x_0)$ is abelian.

Exercise 82.3. Let X be a topological space and $x_0 \in X$. We consider the set $\pi_0(X, x_0)$. We all know that $\pi_0(X, x_0)$ is "not a group". But why not? After all, every non-empty set can be equipped with a group structure (why is that?). So why is not possible to equip $\pi_0(X, x_0)$ with a group structure in a "meaningful way"? More precisely, if we could equip it with a group structure in a reasonable sense, what properties would we demand? Why can these not be satisfied?

Exercise 82.4. Let $\varphi\colon G \to H$ be a group homomorphism. Furthermore let (S, s_0) be a pointed set which is equipped with an H-action. Suppose that we have an exact sequence

$$\{e\} \ \to \ G \ \xrightarrow{\varphi} \ H \ \xrightarrow{\psi} \ (S, s_0) \ \to \ \{e\}$$

where ψ is a morphism of pointed sets that preserves the H-action. Show that $\varphi(G)$ is a subgroup of H whose index equals the cardinality of the set S.

Exercise 82.5. Is a monomorphism of pointed sets necessarily injective?

Exercise 82.6. Provide a proof for Lemma 82.3.

Exercise 82.7. Let (X, A, x_0) be a pointed pair of topological spaces and let $n \in \mathbb{N}$. By the convention of page 1898 we can view elements in $\pi_n(X, A, x_0)$ as homotopy classes of maps $(\overline{B}^n, S^{n-1}, *) \to (X, A, \{x_0\})$. Using this point of view, how can we visualize the action of $\pi_1(A, x_0)$ on $\pi_n(X, A, x_0)$?

Exercise 82.8. Give an example of a connected CW-complex X, a connected subcomplex $A \subset X$ and an $n \in \mathbb{N}$ such that the homotopy group $\pi_n(X/A)$ is not isomorphic to the relative homotopy group $\pi_n(X, A)$.

83. Fibrations

In this chapter we introduce fibrations and we show that fibrations give rise to a long exact sequence of homotopy groups. In the subsequent two chapters we will give many more examples of fibrations and we will see that fibrations allow us to compute various interesting higher homotopy groups.

83.1. **Definition and examples of fibrations.** The following is the key definition of this chapter.

Definition. Let $p\colon Y \to B$ be a map between topological spaces.

(1) Let X be a topological space. We say that the map $p\colon Y \to B$ has the *homotopy lifting property with respect to* X if given any map $F\colon X \times [0,1] \to B$ and given any map $\widetilde{f}\colon X \times \{0\} \to Y$ with $p \circ \widetilde{f} = F \circ i$ there exists a map $\widetilde{F}\colon X \times [0,1] \to Y$ such that the following diagram commutes:

$$\begin{tikzcd} X \times \{0\} \arrow[r, "\widetilde{f}"] \arrow[d, "i"] & Y \arrow[d, "p"] \\ X \times [0,1] \arrow[r, "F"'] \arrow[ur, dashed, "\widetilde{F}", "??"'] & B. \end{tikzcd}$$

Sometimes we refer to $\widetilde{F}\colon X \times [0,1] \to Y$ as a *lift* of $F\colon X \times [0,1] \to B$. (Note that we do *not* demand that the lift $\widetilde{F}$ is any way unique.) We refer to Figure 1015 for an illustration of the definition.

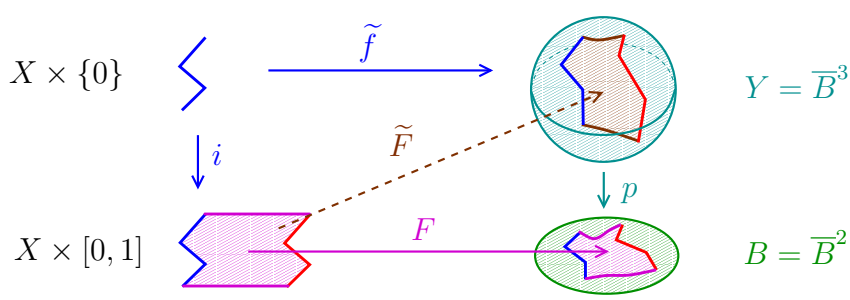

Figure 1015.

(2) We say that the map $p\colon Y \to B$ is a *fibration* if p has the homotopy lifting property with respect to all topological spaces.

(3) We say that the map $p\colon Y \to B$ is a *Serre fibration* if p has the homotopy lifting property with respect to all closed balls $\overline{B}^n$, $n \in \mathbb{N}_0$. So perhaps somewhat confusingly a Serre fibration is not necessarily a fibration.

Remark. Different textbooks mean different objects when they talk about "fibrations". Out definition coincides with the language used in [Hat, Rot, DK]. In [Bre], what we call a "fibration" is called a "Hurewicz fibration".

Examples.

(1) In Proposition 7.13 we already showed that every covering $p\colon Y \to B$ has the homotopy lifting property (in fact with a unique lift) with respect to every topological manifold, in particular with respect to any closed ball $\overline{B}^n$. This implies in particular that every covering is a Serre fibration.

(2) Let B and G be topological spaces. We denote by $p\colon B\times G \to B$ and $q\colon B\times G \to G$ the two obvious projections. In the following we show that the projection map $p\colon B \times G \to B$ is a fibration. Indeed, in the setting above the map

$$\begin{array}{rcl} \widetilde{F}\colon X \times [0,1] & \to & B \times G \\ (x,t) & \mapsto & \big(F(x,t), q\big(\underbrace{\widetilde{f}(x,0)}_{\in B\times G}\big)\big) \end{array}$$

makes the diagram commute. As is shown in Figure 1016, in contrast to the first example, the lift $\widetilde{F}$ is in general not unique.

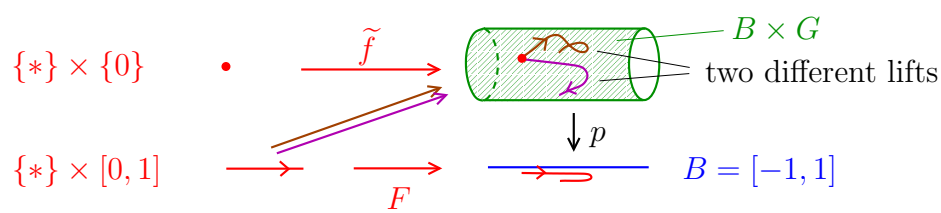

FIGURE 1016.

(3) For any $n \in \mathbb{N}$ the map

$$\begin{array}{rcl} \overline{B}^{n+1} & \to & \overline{B}^n \\ (x_1,\dots,x_n,x_{n+1}) & \mapsto & (x_1,\dots,x_n) \end{array}$$

is a Serre fibration. With some effort this statement can be proved "by hand". The case $n = 1$ is precisely the content of Exercise 83.1.

We conclude the list of examples with a "non-example". To make this example more readable we package it is as a lemma.

Lemma 83.1. *The map $p\colon S^1 \to [-1,1]$ that is given by the projection onto the x-coordinate is not a Serre fibration.*

Proof. We consider the topological space $X = \overline{B}^1 = [-1,1]$ and the maps $\widetilde{f}\colon X \times \{0\} \to S^1$ and $F\colon [-1,1] \times [0,1] \to [-1,1]$ that are illustrated in Figure 1017. We claim that there is no lifting $\widetilde{F}\colon X \times [0,1] \to S^1$. More precisely, we prove the following claim.

Claim. If $\widetilde{F}\colon X \times [0,1] \to S^1$ is a map with $p \circ \widetilde{F} = F$, then $\widetilde{F}|_{X\times\{0\}}$ does not agree with $\widetilde{f}$.

Thus let $\widetilde{F}\colon X\times[0,1] \to S^1$ be a map with $p\circ\widetilde{F} = F$. We make the following observations:

(1) The preimage $F^{-1}(0)$ is connected by the definition of F.
(2) We obtain from (1) and Lemma 1.88 that the image $\widetilde{F}(F^{-1}(0))$ is also connected.
(3) The fact that $p \circ \widetilde{F} = F$ implies that $\widetilde{F}(F^{-1}(0)) \subset p^{-1}(0)$.[1400]
(4) By definition of the map p we have $p^{-1}(0) = \{(0, \pm 1)\}$.
(5) It follows from (2), (3) and (4) that $\widetilde{F}$ restricted to $F^{-1}(0)$ is constant.
(6) The map $\widetilde{f}$ is not constant on $F^{-1}(0)$.

The combination of (5) and (6) proves our claim. □

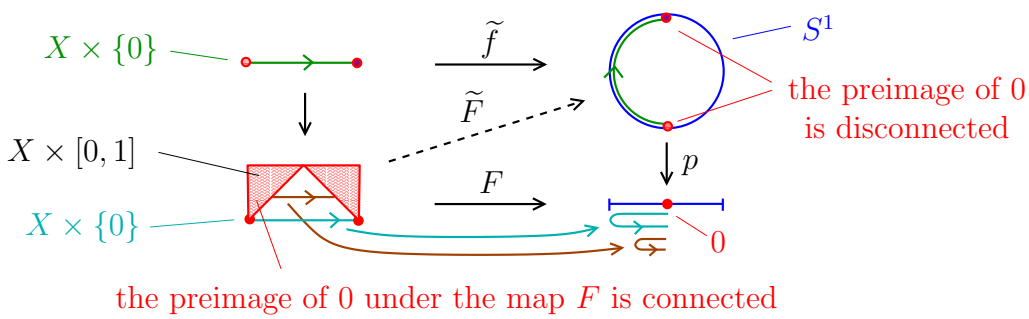

FIGURE 1017.

We continue with introducing some language and notation.

Notation.

(1) Given a fibration or a Serre fibration $p\colon Y \to B$ we sometimes refer to B as the *base space* and to Y as the *total space*.[1401]

Furthermore, given a point $* \in B$ we refer to $F := p^{-1}(*)$ as a *fiber*. The last definition is somewhat dangerous since, as we see in the last of the above examples, the homeomorphism type $p^{-1}(*)$ depends on the choice of $*$. We will shortly discuss "uniqueness" of the fiber. Finally throughout this chapter we denote by $i\colon F \to Y$ the inclusion map.

(2) Given $n \in \mathbb{N}_0$ we define I, I^n and J^n as on page 1883.

Before we can formulate the main theorem of this chapter we need to make some preparations.

Lemma 83.2.

[1400]Since I always find these arguments confusing let me give the argument: Let $y \in \widetilde{F}(F^{-1}(0))$. This means that there exists a $P \in F^{-1}(0)$ with $y = \widetilde{F}(P)$. We have $p(y) = p(\widetilde{F}(P)) = F(P)$, but $P \in F^{-1}(0)$, thus $p(y) = 0$. In other words, we have $y \in p^{-1}(0)$.

[1401]This mirrors the language that we introduced on page 1782 for vector bundles.

(1) *For each $n \in \mathbb{N}$ there exists an orientation-preserving homeomorphism*

$$\left(\overline{B}^n \times [0,1], \overline{B}^n \times \{0\} \cup S^{n-1} \times [0,1]\right) \xrightarrow{\cong} \left(\overline{B}^n \times [0,1], \overline{B}^n \times \{0\}\right)$$

of pairs of topological spaces. (*This statement is illustrated in Figure 1018 on the left.*)

(2) *For each $n \in \mathbb{N}$ there exists a homeomorphism*

$$(I^n, J^{n-1}) \xrightarrow{\cong} (I^n, I^{n-1} \times \{0\}).$$

of pairs of topological spaces. (*This statement is illustrated in Figure 1018 on the right.*)

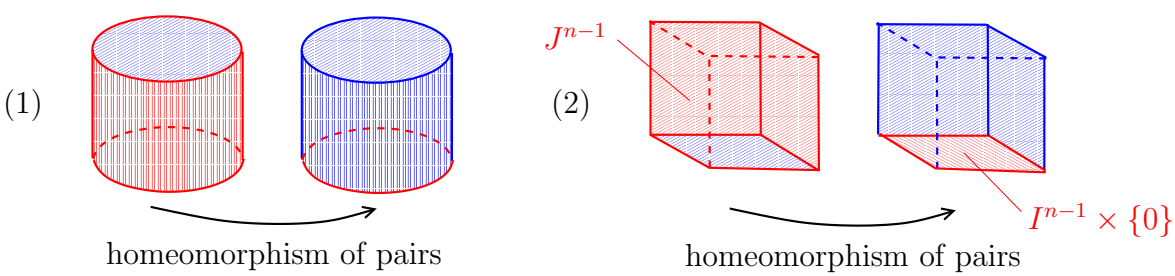

FIGURE 1018. Illustration of Lemma 83.2.

Sketch of proof (∗).

(1) For $n = 1$ such a homeomorphism is illustrated in Figure 1019. The general case is

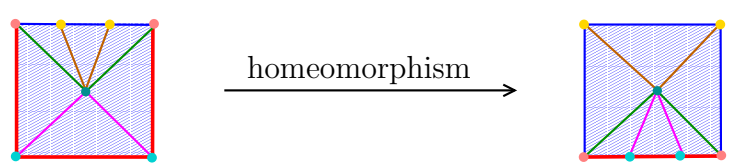

FIGURE 1019. Illustration for the proof of Lemma 83.2.

given by "rotating this homeomorphism around the $x_1 = 0$-axis in $\mathbb{R}^n$".

(2) Using the homeomorphism $\overline{B}^{n-1} \cong I^{n-1}$ from Proposition 1.48 (2) one can easily reduce the proof of (2) to the statement that we had just proved in (1). □

We will also soon need the following elementary lemma.

Lemma 83.3. *Let $p\colon Y \to B$ be a Serre fibration. Let $y_0 \in Y$. We write $b_0 = p(y_0)$. Furthermore let $n \in \mathbb{N}$. Given any map $\varphi\colon (I^n, \partial I^n) \to (B, \{b_0\})$ there exists a map*

$\widetilde{\varphi}\colon (I^n, J^{n-1}) \to (Y, \{y_0\})$ *such that the following diagram commutes:*

$$\begin{tikzcd} & Y \arrow[d, "p"] \\ I^n \arrow[ur, dashed, "\widetilde{\varphi} \text{ with } J^{n-1} \mapsto y_0"] \arrow[r, "\varphi \text{ with } \partial I^n \mapsto b_0"'] & B. \end{tikzcd}$$

We refer to Figure 1020 for an illustration.

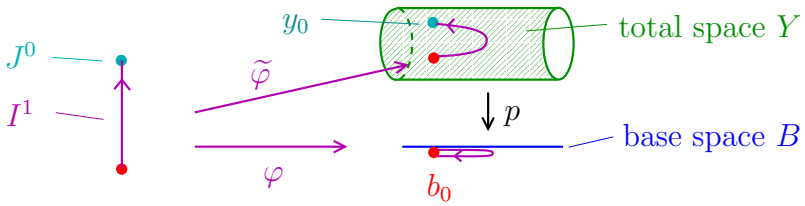

FIGURE 1020. Illustration of Lemma 83.3.

Proof. Let $\Psi\colon (I^n, J^{n-1}) \xrightarrow{\cong} (I^n, I^{n-1} \times \{0\})$ be a homeomorphism as in Lemma 83.2 (2). We consider the diagram

$$\begin{tikzcd} I^{n-1} \times \{0\} \arrow[r, "\Psi^{-1}"] \arrow[d, hook] & J^{n-1} \arrow[r, "\text{constant map } y_0"] \arrow[d, hook] & Y \arrow[d, "p"] \\ I^{n-1} \times [0,1] \arrow[r, "\Psi^{-1}"'] \arrow[urr, dashed, "G"] & I^n \arrow[r, "\varphi"'] & B. \end{tikzcd}$$

Note that the diagram without the red dashed arrow commutes. Since p is a Serre fibration and since I^{n-1} is homeomorphic to the $(n-1)$-ball, see Proposition 1.47 (2), it follows that a map $G\colon I^{n-1} \times I \to Y$ exists that makes the diagram commute. It is now straightforward to verify that $G \circ \Psi\colon I^n \to B$ has the desired properties. $\square$

83.2. **The homotopy fiber of a fibration.** First we introduce the following, arguably long overdue notation.

Notation. Given two topological spaces X and Y we define $[X, Y]$ to be the set of homotopy equivalence classes of maps from X to Y.[1402]

The following lemma is a reformulation of Lemma 9.5.

Lemma 83.4. *Let X, Y and Z be topological spaces. The map*

$$\begin{array}{rcl} [Y, Z] \times [X, Y] & \mapsto & [X, Z] \\ ([g], [f]) & \mapsto & [g \circ f] \end{array}$$

is well-defined.

[1402]Recall that in Lemma 9.3 we saw that "being homotopic" is an equivalence relation.

Now we can formulate the key technical proposition of this section.

Proposition 83.5. *Let $p\colon Y \to B$ be a fibration. Given $b \in B$ we write $F_b := p^{-1}(b)$. Let $\alpha\colon [0,1] \to B$ be a path from a point b_0 to a point b_1. We consider the following diagram*

$$\begin{tikzcd} F_{b_0} \times \{0\} \arrow[r, "(x,0)\mapsto x"] \arrow[d, "i"] & Y \arrow[d, "p"] \\ F_{b_0} \times [0,1] \arrow[r, "(x,t)\mapsto \alpha(t)"'] \arrow[ur, "H(\alpha)"'] & B. \end{tikzcd}$$

Since $p\colon Y \to B$ is a fibration there exists a diagonal map $H(\alpha)\colon F_{b_0} \times [0,1] \to Y$.[1403] *(We refer to Figure 1021 for an illustration.) We define $\Theta(\alpha) := H(\alpha)_1$. The following statements hold:*

(1) *The map $\Theta(\alpha)$ goes from F_{b_0} to F_{b_1}.*
(2) *The map $\Theta(\alpha)$, viewed as an element in $[F_{b_0}, F_{b_1}]$, is well-defined.*
(3) *The map $\Theta(\alpha)\colon F_{b_0} \to F_{b_1}$ is a homotopy equivalence.*
(4) *If two paths $\alpha, \beta\colon [0,1] \to B$ from b_0 to b_1 are path-homotopic, then $[\Theta(\alpha)] = [\Theta(\beta)]$.*
(5) *If c_b is the constant path at $b \in B$, then $[\Theta(c_b)] = [\mathrm{id}_{F_b}] \in [F_b, F_b]$.*
(6) *If α is a path in B from b_0 to b_1 and β is a bath in B from b_1 to b_2, then*

$$\underbrace{[\Theta(\alpha * \beta)]}_{\in [F_{b_0}, F_{b_2}]} = \underbrace{[\Theta(\beta)]}_{\in [F_{b_1}, F_{b_2}]} \circ \underbrace{[\Theta(\alpha)]}_{\in [F_{b_0}, F_{b_1}]}.$$

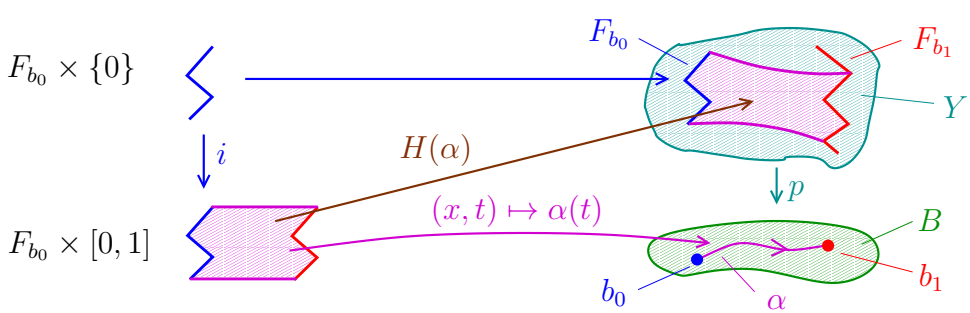

FIGURE 1021. Illustration of Proposition 83.5.

Remark. The picture behind the statement of Proposition 83.5 is that while walking along B we can drag the fiber along. Thus any path defines a map between the corresponding fibers.

[1403] Recall that in general $H(\alpha)$ is not uniquely determined by the data, i.e. there might be many such maps.

Proof $(*)$. Let $p\colon Y \to B$ be a fibration over a topological space B. Given $b \in B$ we write $F_b := p^{-1}(b)$. Let $\alpha\colon [0,1] \to B$ be a path from a point b_0 to a point b_1. We consider the following diagram

$$\begin{tikzcd} F_{b_0} \times \{0\} \arrow[r, "(p,0)\mapsto p"] \arrow[d, "i"] & Y \arrow[d, "p"] \\ F_{b_0} \times [0,1] \arrow[r, "(x,t)\mapsto\alpha(t)"'] \arrow[ur, "H(\alpha)"] & B. \end{tikzcd}$$

Since $p\colon Y \to B$ is by hypothesis a fibration there exists in fact such a diagonal map $H(\alpha)\colon F_{b_0} \times [0,1] \to Y$. Note that the map $H(\alpha)_0\colon F_{b_0} \to B$ is just the obvious inclusion. We turn to the proofs of the statements, albeit perhaps in an unexpected order:

(1) Since the above diagram commutes we see immediately that the map $H(\alpha)_1$ is a map from $F_{b_0} \to F_{b_1}$.

(4) Let $\alpha, \beta\colon [0,1] \to B$ be two paths from b_0 to b_1. We pick maps $H(\alpha)$ and $H(\beta)$ as above, keeping in mind that $H(\alpha)$ and $H(\beta)$ are not uniquely determined. Now we assume that α and β are path-homotopic. We need to show the following claim.

Claim. The maps $H(\alpha)_1, H(\beta)_1\colon F_{b_0} \to F_{b_1}$ are homotopic.

We start out the proof of the claim with the following observation. It follows immediately from Lemma 83.2 (2), applied to $n = 2$, that there exists a self-homeomorphism

$$\Psi\colon [0,1] \times [0,1] \quad \to \quad [0,1] \times [0,1]$$

that restricts to a homeomorphism

$$\underbrace{([0,1] \times \{0,1\}) \cup (\{0\} \times [0,1])}_{=:U} \quad \to \quad [0,1] \times \{0\}.$$

For reassurance the construction of such a map is also sketched in Figure 1022. Now

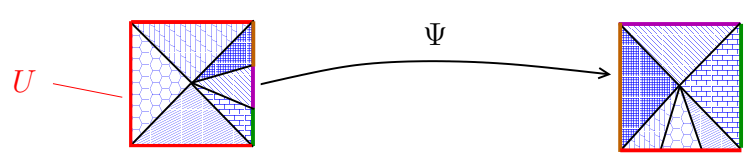

FIGURE 1022.

we pick a homotopy $G\colon [0,1] \times [0,1] \to B$ rel $\{0,1\}$ from α to β. We consider the

following diagram

$$\begin{tikzcd}
F_{b_0}\times[0,1]\times\{0\} \arrow[r, "\mathrm{id}_{F_{b_0}}\times\Psi^{-1}"] \arrow[d, hook] & \overbrace{(F_{b_0}\times[0,1]\times\{0,1\})\cup(F_{b_0}\times\{0\})\times[0,1]}^{=F_{b_0}\times U} \arrow[r, "\Omega"] \arrow[d, hook] & Y \arrow[d, "p"] \\
F_{b_0}\times[0,1]\times[0,1] \arrow[r, "\mathrm{id}_{F_{b_0}}\times\Psi^{-1}"'] \arrow[urr, dashed, "\Xi"] & F_{b_0}\times[0,1]\times[0,1] \arrow[r, "(P,s,t)\mapsto G(s,t)"'] \arrow[ur, dashed, "\Xi\circ(\mathrm{id}_{F_{b_0}}\times\Psi)"'] \arrow[l, bend left, "\mathrm{id}_{F_{b_0}}\times\Psi"] & B.
\end{tikzcd}$$

We make the following clarifications and observations:

(a) The map Ω is defined as follows:[1404]
  (i) on $F_{b_0}\times[0,1]\times\{0\}=F_{b_0}\times[0,1]$ the map Ω is given by $H(\alpha)$,
  (ii) on $F_{b_0}\times[0,1]\times\{1\}=F_{b_0}\times[0,1]$ the map Ω is given by $H(\beta)$,
  (iii) on $F_{b_0}\times\{0\}\times[0,1]$ the map Ω is given by the projection onto F_{b_0} followed by the inclusion into Y.

(b) It follows immediately from the definitions that the diagram commutes.

(c) Since $p\colon Y\to B$ is a fibration we see that there exists a map Ξ that makes the outer diagram commute.

(d) The map $\Xi\circ(\mathrm{id}_{F_{b_0}}\times\Psi)\colon F_{b_0}\times[0,1]\times[0,1]\to Y$ is a homotopy between $H(\alpha)$ and $H(\beta)$. In particular the map $(\Xi\circ(\mathrm{id}_{F_{b_0}}\times\Psi))_1\colon F_{b_0}\times[0,1]\to Y$ is the desired homotopy between $H(\alpha)_1$ and $H(\beta)_1$.

This concludes the proof of the claim.

(5) This statement follows from the observation that for the constant path c_b at a point $b\in B$ we can choose $H(c_b)\colon F_b\times[0,1]\to F_b$ to be the projection. Evidently we obtain that $\Theta(c_b)=H(c_b)_1=\mathrm{id}_{F_b}$.

(6) Let α be a path in B from b_0 to b_1 and let β be a bath in B from b_1 to b_2. Almost the same way that we define the product $\alpha*\beta$ we combine $H(\alpha)$ and $H(\beta)$. More precisely, we consider the map[1405]

$$\begin{aligned} H(\alpha*\beta)\colon F_{b_0}\times[0,1] &\to X \\ (P,t) &\mapsto \begin{cases} H(\alpha)(P,2t), & \text{if } t\in[0,\tfrac12], \\ H(\beta)\big(\underbrace{H(\alpha(P),1)}_{\in F_{b_1}},2t-1\big), & \text{if } t\in[\tfrac12,1]. \end{cases}\end{aligned}$$

One can easily verify that this map has all the properties that we expect from a map that is called $H(\alpha*\beta)$. The desired statement is now an immediate consequence of the observation that $H(\alpha*\beta)_1=H(\beta)_1\circ H(\alpha)_1$.

[1404]As on so many other occasions we can use Lemma 1.32 (2) to show that the map Ω is indeed continuous.

[1405]It follows again from Lemma 5.3 that this map is continuous.

(3) Let $\alpha\colon [0,1] \to B$ be a path from b_0 to b_1. We pick a map $H(\alpha)\colon F_{b_0} \times [0,1] \to X$ as above. We want to show that the corresponding map $H(\alpha)_1\colon F_{b_0} \to F_{b_1}$ is a homotopy equivalence. We denote by $\overline{\alpha}\colon [0,1] \to B$ the inverse path of α, i.e. the path from b_1 to b_0 that is given by $\overline{\alpha}(t) = \alpha(1-t)$. We pick a map $H(\overline{\alpha})\colon F_{b_1} \times [0,1] \to X$ as above. It remains to prove the following claim.

Claim.
(a) The map $H(\overline{\alpha})_1 \circ H(\alpha)_1\colon F_{b_0} \to F_{b_0}$ is homotopic to the identity of F_{b_0}.
(b) The map $H(\alpha)_1 \circ H(\overline{\alpha})_1\colon F_{b_1} \to F_{b_1}$ is homotopic to the identity of F_{b_1}.

We prove the first statement. The proof of the second statement is verbatim the same. We have

$$\begin{array}{ccccccc} [\,H(\overline{\alpha})_1 \circ H(\alpha)_1\,] & = & [\,H(\alpha * \overline{\alpha})\,] & = & [\,H(c_{b_0})\,] & = & [\,\mathrm{id}_{F_{b_0}}\,]. \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{by (6)} & \text{by (4) and Proposition 5.6 (3)} & & & \text{by (5).} & \end{array}$$

This concludes the proof of the claim.

(2) We apply the argument from (4) to $\beta = \alpha$ together with two maps $H(\alpha)$ and $H(\beta)$ that make the diagram commute. We obtain by (3) that $H(\alpha)$ and $H(\beta)$ are homotopic, i.e. we see that $[H(\alpha)] \in [F_{b_0}, F_{b_1}]$ is well-defined. □

Using Proposition 83.5, and the proof thereof, we almost immediately obtain the following proposition.

Proposition 83.6. *Let $p\colon Y \to B$ be a map between topological spaces. We assume that B is path-connected.*

(1) *If $p\colon Y \to B$ is a fibration, then for any two points $b_0, b_1 \in B$ the fibers $p^{-1}(b_0)$ and $p^{-1}(b_1)$ are homotopy equivalent.*
(2) *If $p\colon Y \to B$ is a Serre fibration, then for any two points $b_0, b_1 \in B$ such that the fibers $p^{-1}(b_0)$ and $p^{-1}(b_1)$ are discrete subsets, the fibers $p^{-1}(b_0)$ and $p^{-1}(b_1)$ are homotopy equivalent.*

Proof.

(1) This statement follows immediately from Proposition 83.5 (3) and the hypothesis that B is path-connected.
(2) Let $p\colon Y \to B$ be a Serre fibration with B a path-connected topological space. Let $b_0, b_1 \in B$ such that the fibers $F_{b_0} := p^{-1}(b_0)$ and $F_{b_1} := p^{-1}(b_1)$ are discrete subsets. In the proof of Proposition 83.5 (3) we used the homotopy lifting property for the topological spaces $X = F_{b_i} \times [0,1]^n$ with $i \in \{0,1\}$ and $n \in \{1,2\}$. Since F_{b_0} and F_{b_1} are discrete we see that each component of $X = F_{b_i} \times [0,1]^n$ is homeomorphic to $[0,1]^n$, i.e. each component is homeomorphic to $\overline{B}^n$. Since we can do the lifting component-wise it suffices in our context that we are given a Serre fibration. We leave it to the reader to fill in the details. □

Proposition 83.6 (1) allows us to make the following definition.

Definition. Let $p\colon Y \to B$ be a fibration over a path-connected topological space B. We refer to the homotopy type of the fibers as the *homotopy fiber* of the fibration.

Remark. A more precise statement of Proposition 83.6 (1) holds: any path $\gamma\colon [0,1] \to B$ from b_0 to b_1 defines naturally a homotopy equivalence between the fibers $p^{-1}(b_0)$ and $p^{-1}(b_1)$. We refer to [DK, Theorem 6.12] for the precise formulation and proof of this statement.

Examples.

(1) Let $p\colon \widetilde{X} \to X$ be a covering map over a path-connected topological space. As discussed on page 1912 such a map is a Serre fibration. It follows immediately from the definition of a covering map that for each $x \in X$ the fiber $p^{-1}(x)$ is a discrete subset of $\widetilde{X}$. Therefore it follows from Lemma 9.9 and Proposition 83.6 (2) that given any two points $x_0, x_1 \in X$ there exists a bijection $p^{-1}(x_0) \to p^{-1}(x_1)$. In other words, we have found a new proof for Lemma 7.2.

(2) Let us consider again the "non-example" from Lemma 83.1, i.e. we consider the map

$$\begin{array}{rcl} p\colon Y = S^1 = \{(x,y) \in \mathbb{R}^2 \,|\, x^2+y^2=1\} & \to & B = [-1,1] \\ (x,y) & \mapsto & x. \end{array}$$

In this case $p^{-1}(-1) = \{(-1,0)\}$ and $p^{-1}(0) = \{(0,\pm 1)\}$ are discrete subsets, but the number of components is different. From Lemma 9.9 we deduce that $p^{-1}(-1)$ is not homotopy equivalent to $p^{-1}(0)$. Thus Proposition 83.6 (2) gives a new proof (after the more hands-on proof provided by Lemma 83.1) that p is not a Serre fibration.

(3) We consider the map $p\colon Y \to B$ given by the total space

$$Y \;:=\; \{\underbrace{(x,y)}_{\in\mathbb{R}^2} \,\big|\, y = 1-x \text{ and } x \in [0,1]\} \cup \bigcup_{n\in\mathbb{N}} \{\underbrace{(x,y)}_{\in\mathbb{R}^2} \,|\, x \in [0,1] \text{ and } y = 1+\tfrac{1}{n}\}$$

the base space $B = [0,1]$ and the obvious projection $p\colon Y \to X$. (This example is illustrated in Figure 1023.) It is an amusing exercise to show that $p\colon Y \to B$ is a Serre fibration. We saw in Exercise 9.9 that the fibers $p^{-1}(0)$ and $p^{-1}(1)$ are not homotopy equivalent. It follows from Proposition 83.6 (1) that $p\colon Y \to B$ is not a fibration.[1406]

We can also show more directly that p is not a fibration: We consider $X = p^{-1}(1)$, the usual projection map $f\colon X \times [0,1] \to B = [0,1]$ together with the obvious inclusion $\widetilde{f}\colon X \times \{0\} \to Y$. It is once again an amusing elementary exercise to show that there is no map $\widetilde{F}\colon X \times [0,1] \to B$ with all the desired properties. This shows that $p\colon Y \to B$ is not a fibration.

[1406]The discussion of this example would be more intelligible if we followed the convention of [Bre, p. 450] and if we referred to "fibrations" as "Hurewicz fibrations" to better distinguish them from "Serre fibrations".

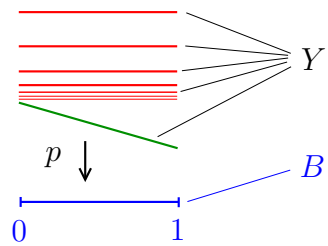

FIGURE 1023.

83.3. **The long exact homotopy sequence of a Serre fibration.** For us the most interesting aspect of fibrations is that they give rise to long exact sequences of homotopy groups. More precisely, we have the following theorem.

Theorem 83.7. *Let $p\colon Y \to B$ be a Serre fibration. Let $y_0 \in Y$. We write $b_0 = p(y_0)$ and $F = p^{-1}(b_0)$.*

(1) *Given any $n \in \mathbb{N}$ the following map is well-defined:*

$$\begin{aligned} \partial_n\colon \pi_n(B, b_0) &\to \pi_{n-1}(F, y_0) \\ [\varphi\colon (I^n, \partial I^n) \to (B, b_0)] &\mapsto \left[\begin{array}{c} \textit{pick a map } \widetilde{\varphi}\colon (I^n, J^{n-1}) \to (Y, \{y_0\}) \textit{ with } p \circ \widetilde{\varphi} = \varphi \\ (\textit{we know from Lemma 83.3 that such a map exists}) \\ \textit{and then restrict the map } \widetilde{\varphi} \textit{ to } I^{n-1} = I^{n-1} \times \{0\} \end{array}\right]. \end{aligned}$$

(*The definition of ∂_n is moderately successfully illustrated in Figure 1024.*) *Furthermore, these maps ∂_n have the following properties:*

(a) *The maps are morphisms of groups (if $n \geq 2$) and of pointed sets (if $n = 1$).*

(b) *The maps are natural in the following two senses: Suppose we are given another Serre fibration $p'\colon Y' \to B'$ and suppose we are given a commutative diagram*

$$\begin{tikzcd} Y \arrow[r, "p"] \arrow[d, "\Phi"'] & B \arrow[d, "\phi"] \\ Y' \arrow[r, "p'"] & B'. \end{tikzcd}$$

If we write $y_0' = \Phi(y_0), b_0' = \phi(b_0)$ and $F' = (p')^{-1}(b_0')$, then for any $n \in \mathbb{N}$ the following diagram commutes

$$\begin{tikzcd} \pi_n(B, b_0) \arrow[r, "\partial_n"] \arrow[d, "\phi_*"'] & \pi_{n-1}(F, y_0) \arrow[d, "(\Phi|_F)_*"] \\ \pi_n(B', b_0') \arrow[r, "\partial_n"] & \pi_{n-1}(F', y_0'). \end{tikzcd}$$

(c) *Let $\alpha\colon [0,1] \to B$ be a path from b_0 to some point b_1.*[1407] *We write $F_1 = p^{-1}(b_1)$. If $\Theta(\alpha)\colon F \to F_1$ is a map as in Proposition 83.5, then the following diagram*

[1407] Here we allow of course that $b_1 = b_0$.

commutes

$$\begin{array}{ccc} \pi_n(B,b_0) & \xrightarrow{\partial_n} & \pi_{n-1}(F,y_0) \\ {\scriptstyle \alpha_*}\downarrow & & \downarrow{\scriptstyle \Theta(\alpha)_*} \\ \pi_n(B,b_1) & \xrightarrow{\partial_n} & \pi_{n-1}(F_1,y_1) \end{array}$$

where $y_1 = \Theta(\alpha)(y_0)$.

(2) *The following sequence is exact:*[1408]

$$\begin{aligned} \ldots &\xrightarrow{\partial_{n+1}} \pi_n(F,y_0) \xrightarrow{i_*} \pi_n(Y,y_0) \xrightarrow{p_*} \pi_n(B,b_0) \xrightarrow{\partial_n} \\ &\xrightarrow{\partial_n} \pi_{n-1}(F,y_0) \xrightarrow{i_*} \ldots\ldots\ldots \xrightarrow{p_*} \pi_1(B,b_0) \xrightarrow{\partial_1} \\ &\xrightarrow{\partial_1} \pi_0(F,y_0) \xrightarrow{i_*} \pi_0(Y,y_0) \xrightarrow{p_*} \pi_0(B,b_0). \end{aligned}$$

(3) *If the inclusion map* $i\colon F \to Y$ *is homotopic rel* y_0 *to the constant map* $c_{y_0}\colon F \to \{y_0\}$, *then for any* $n \in \mathbb{N}_{\geq 2}$ *the above long exact sequence breaks into a short exact sequence*

$$0 \;\to\; \pi_n(Y,y_0) \xrightarrow{p_*} \pi_n(B,b_0) \xrightarrow{\partial_n} \pi_{n-1}(F,y_0) \;\to\; 0.$$

Furthermore the short exact sequence splits, which implies that for any $n \in \mathbb{N}_{\geq 2}$ *we have an isomorphism*

$$\pi_n(B,b_0) \;\cong\; \pi_n(Y,y_0) \oplus \pi_{n-1}(F,y_0).$$

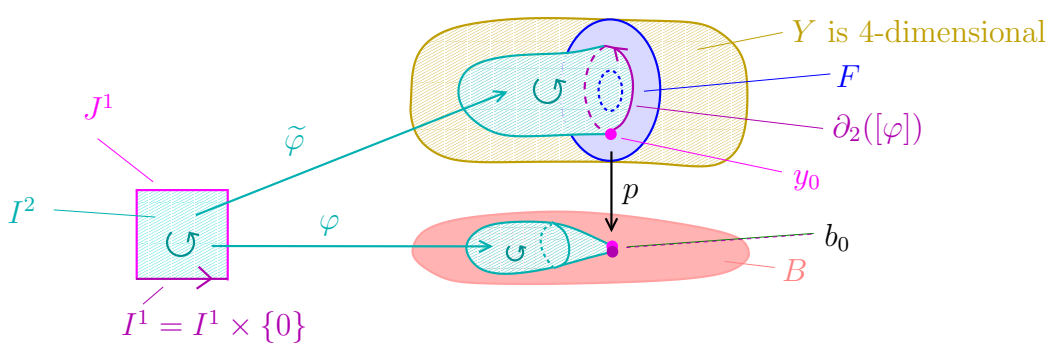

FIGURE 1024.

Before we head towards the proof of Theorem 83.7 we want to see what the theorem tells us in two types of fibrations that we had considered above, namely for coverings and products.

Example. Let $p\colon Y \to B$ be a covering of path-connected topological spaces. As mentioned above, by Proposition 7.13 we know that p is a Serre fibration. We pick $y_0 \in Y$ and we write $b_0 = p(y_0)$ and $F = p^{-1}(b_0)$. It follows immediately from the definition of a covering

[1408]Here, at the lower end, we mean "exact" in the sense of the definition on page 1887.

map that F, equipped with the subspace topology coming from Y, is a discrete topological space, in particular $\#\pi_0(F,y_0) = \#F$ and $\pi_i(F,y_0) = 0$ for $i \geq 1$. From the long exact sequence provided by Theorem 83.7 we obtain the following two pieces of information:

(1) At the lower end the long exact sequence looks as follows:

$$\underbrace{\pi_1(F,y_0)}_{=\{e\}} \to \pi_1(Y,y_0) \xrightarrow{p_*} \pi_1(B,b_0) \xrightarrow{\partial} \underbrace{\pi_0(F,y_0)}_{\#\pi_0(F,y_0)=\#F} \to \underbrace{\pi_0(Y,y_0)}_{=\{e\}} \to \underbrace{\pi_0(B,b_0)}_{=\{e\}}.$$

In other words we obtain the short exact sequence

$$\{e\} \to \pi_1(Y,y_0) \xrightarrow{p_*} \pi_1(B,b_0) \xrightarrow{\partial} \pi_0(F,y_0) \to \{e\}.$$

We draw the following two conclusions:

(a) The map $p_*\colon \pi_1(Y,y_0) \to \pi_1(B,b_0)$ is a monomorphism.

(b) With a little bit of extra thought[1409] we obtain from the short exact sequence, Proposition 83.5, Theorem 83.7 (1c) and Lemma 82.2 that $p_*(\pi_1(Y,y_0))$ is a subgroup of $\pi_1(B,b_0)$ of index $\#\pi_0(F,y_0) = \#F = [Y:B]$.

These two statements are precisely the content of Lemma 6.4 and Lemma 7.16 (3).

(2) Since all other homotopy groups of F vanish we see that for any $n \geq 2$ the map $p_*\colon \pi_n(Y,x_0) \to \pi_n(B,b_0)$ is an isomorphism. This result recovers Proposition 28.13.

We move on to the next application. More precisely we want to apply Theorem 83.7 to the case of a Serre fibration of the form $X \times Y \to X$. This leads to a new proof of Propositions 7.21 and 28.8.

Proposition 28.8. *Let X and Y be two topological spaces and let $x_0 \in X$ and $y_0 \in Y$. We consider the maps*

$$\begin{array}{rcl} i\colon X & \to & X \times Y \\ x & \mapsto & (x,y_0) \end{array} \quad \text{and} \quad \begin{array}{rcl} j\colon Y & \to & X \times Y \\ y & \mapsto & (x_0,y). \end{array}$$

For any $n \in \mathbb{N}$ the map[1410]

$$\begin{array}{rcl} \Phi\colon \pi_n(X,x_0) \times \pi_n(Y,y_0) & \to & \pi_n(X \times Y,(x_0,y_0)) \\ (\varphi,\psi) & \to & i_*(\varphi) \cdot j_*(\psi) \end{array}$$

is an isomorphism.

Proof. We denote by $p\colon X \times Y \to X$ and $q\colon X \times Y \to Y$ the two obvious projections. On page 1912 we saw that both projections are fibrations. We concentrate on the first projection map $p\colon X \times Y \to X$. It is a fibration with fiber $p^{-1}(x_0) = \{x_0\} \times Y$. Using

[1409] We leave this extra thinking as a mental exercise to the reader.

[1410] Note that for $n \geq 2$ the map is a group homomorphism since in this case the group on the right-hand side is abelian. It is a priori not completely clear that the map is also a homomorphism for $n = 1$, but we will see in the proof that the map is indeed a homomorphism.

the obvious homeomorphism $Y \to \{x_0\} \times Y$ we obtain from Theorem 83.7 the long exact sequence

$$\ldots \;\to\; \pi_n(Y, y_0) \;\xrightarrow{j_*}\; \pi_n(X \times Y, (x_0, y_0)) \;\xrightarrow{p_*}\; \pi_n(X, x_0) \;\to\; \pi_{n-1}(Y, y_0)) \;\xrightarrow{j_*}\; \ldots .$$

Evidently we have $q \circ j = \mathrm{id}_Y$ which implies that $q_* \circ j_* = \mathrm{id}_{\pi_1(Y,y_0)}$. It follows that for every $n \in \mathbb{N}_0$ the map $j_* \colon \pi_n(F, (x_0, y_0)) \to \pi_n(X \times Y, (x_0, y_0))$ is a monomorphism. Thus for each $n \in \mathbb{N}$ we see that

$$0 \;\to\; \pi_n(Y, y_0) \;\xrightarrow{j_*}\; \pi_n(X \times Y, (x_0, y_0)) \;\xrightarrow{p_*}\; \pi_n(X, x_0) \;\to\; 0$$

is exact. Once again using that $q_* \circ j_* = \mathrm{id}$ we obtain from Lemma 33.2 (and the remark on page 838) that the given map

$$\begin{array}{rcl} \Phi \colon \pi_n(X, x_0) \times \pi_n(Y, y_0) & \to & \pi_n(X \times Y, (x_0, y_0)) \\ (\varphi, \psi) & \to & i_*(\varphi) \cdot j_*(\psi) \end{array}$$

is indeed an isomorphism. □

Even these modest applications should already convince the reader that it is worth proving Theorem 83.7. After the proof we will give many more examples of fibrations and we will find many more interesting applications.

83.4. **Proof of Theorem 83.7.** The proof of Theorem 83.7 requires some preparations, i.e. we first need to prove some propositions.

Proposition 83.8. *Let $p \colon Y \to B$ be a Serre fibration and let (K, L) be a pair of CW-complexes. We denote by $i \colon K \times \{0\} \cup L \times [0,1] \to K \times [0,1]$ the inclusion map. Given any map $F \colon K \times [0,1] \to B$ and given any map $\widetilde{f} \colon K \times \{0\} \cup L \times [0,1] \to Y$ with $p \circ \widetilde{f} = F \circ i$ there exists a map $\widetilde{F} \colon K \times [0,1] \to Y$ such that the following diagram commutes:*

$$\begin{tikzcd} K \times \{0\} \cup L \times [0,1] \arrow[r, "\widetilde{f}"] \arrow[d, hook, "i"] & Y \arrow[d, "p"] \\ K \times [0,1] \arrow[r, "F"'] \arrow[ur, dashed, "\widetilde{F}", "??"'] & B. \end{tikzcd}$$

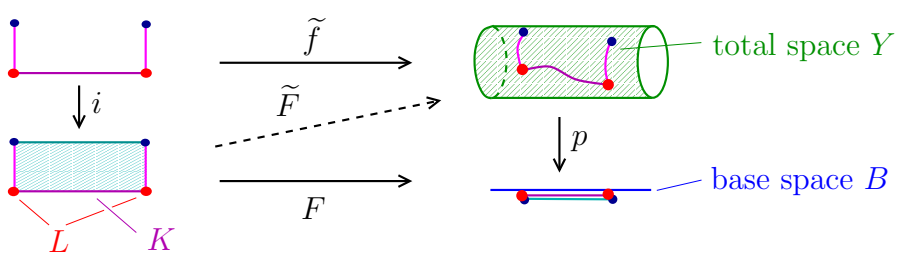

FIGURE 1025. Illustration of Proposition 83.8.

Proof. We start out with a reformulation of our task: Given $n = 0, 1, 2, 3, \dots$ we need to define maps

$$\widetilde{F}^n \colon (K \times \{0\}) \cup (K^n \cup L) \times [0,1] \;\to\; Y$$

that make the above diagram commute and which have the property that for $n < m$ the maps $\widetilde{F}^n$ and $\widetilde{F}^m$ agree on the common domain.

We set $\widetilde{F}^{-1} = \widetilde{f}$. Suppose we have already defined maps $\widetilde{F}^{-1}, \dots, \widetilde{F}^{n-1}$ as above. Let $\{\Phi_i \colon (\overline{B}^n, S^{n-1}) \to (K^n, L^{n-1})\}_{i \in I}$ be the characteristic maps of the n-cells of K that do not lie in L. Recall that by Lemma 83.2 (1) there exists a homeomorphism

$$\Psi \colon \big(\overline{B}^n \times [0,1], (\overline{B}^n \times \{0\}) \cup (S^{n-1} \times [0,1])\big) \;\overset{\cong}{\to}\; \big(\overline{B}^n \times [0,1], \overline{B}^n \times \{0\}\big).$$

For each $i \in I$ we consider the following diagram

$$\begin{tikzcd}
\overline{B}^n \times \{0\} \arrow[r, "\Psi^{-1}"] \arrow[d, hook] & \overline{B}^n \times \{0\} \cup S^{n-1} \times \{1\} \arrow[r, "\widetilde{F}^{n-1} \circ \Phi_i"] \arrow[d, hook] & Y \arrow[d, "p"] \\
\overline{B}^n \times [0,1] \arrow[r, "\Psi^{-1}"'] \arrow[urr, dashed, "\Xi_i"] & \overline{B}^n \times [0,1] \arrow[r, "F \circ \Phi_i"'] & B.
\end{tikzcd}$$

One can easily verify that the two rectangles commute. Since $p \colon Y \to B$ is a Serre fibration there exists a map $\Xi_i \colon \overline{B}^n \times [0,1] \to Y$ that makes the diagram commute. These maps $\{\Xi_i\}_{i \in I}$ can now be used to extend $\widetilde{F}^{n-1}$ to the desired map $\widetilde{F}^n$. $\square$

Proposition 83.9. *Let $p \colon Y \to B$ be a Serre fibration and let (K, L) be a pair of CW-complexes such that L is a deformation retract of K. We denote by $i \colon L \to K$ the inclusion map. Given any map $f \colon K \to B$ and given any map $g \colon L \to Y$ with $f \circ i = p \circ g \colon L \to B$ there exists a map $\widetilde{f} \colon K \to Y$ such that the following diagram commutes:*

$$\begin{tikzcd}
L \arrow[r, "g"] \arrow[d, hook, "i"'] & Y \arrow[d, "p"] \\
K \arrow[r, "f"'] \arrow[ur, dashed, "\widetilde{f}"] & B.
\end{tikzcd}$$

Example. Later on we will apply Proposition 83.9 to the special case that $K = \overline{B}^n$ and that $L = \{(-1, 0, \dots, 0)\}$. We refer to Figure 1026 for an illustration.

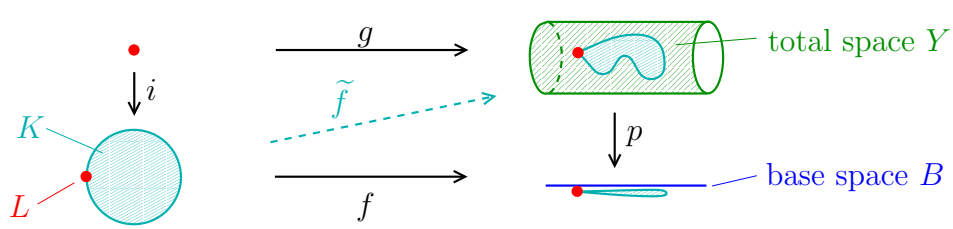

FIGURE 1026.

Proof. We make the following preparations:

(1) Since L is a deformation retract of K there exists by definition of a deformation retraction, see page 308, a homotopy $H\colon K \times [0,1] \to K$ rel L such that $H_0 = \mathrm{id}_K$ and $H_1(K) \subset L$. We denote by $r = H_1\colon K \to L$ the corresponding retraction.

(2) We denote by $\mathrm{proj}\colon L \times [0,1] \to L$ the obvious projection.

Now we consider the following commutative diagram

$$\begin{tikzcd}
L \times \{0\} \arrow[r, hook] \arrow[d, hook] & K \times \{1\} \cup L \times [0,1] \arrow[r, "r \cup \mathrm{proj}"] \arrow[d, hook] & L \arrow[r, "g"] \arrow[d, hook] & Y \arrow[d, "p"] \\
K \times \{0\} \arrow[r, hook] & K \times [0,1] \arrow[r, "H"'] \arrow[urr, dashed, "\Phi"] & K \arrow[r, "f"'] & B.
\end{tikzcd}$$

To be somewhat more precise, the map $r \cup \mathrm{proj}\colon K \times \{1\} \cup L \times [0,1]$ is defined via the retraction r on $K = K \times \{1\}$ and the projection $L \times [0,1] \to L$. The right-hand square commutes by our hypothesis. One easily verifies that the middle square commutes. It follows from Proposition 83.8 that there exists a map $\Phi\colon K \times [0,1] \to Y$ that makes the diagram commute. For any $k \in K$ we have

$$(p \circ \Phi)(k,0) \;=\; f(H(k,0)) \;=\; f(H_0(k)) \;=\; f(k)$$

and for any $l \in L$ we have

$$\Phi(l,0) \;=\; (g \circ \mathrm{proj})(l,0) \;=\; g(\mathrm{proj}(l,0)) \;=\; g(l).$$

This shows that the restriction of Φ to $K = K \times \{0\}$ has the desired properties. □

Proposition 83.10. *Let $p\colon Y \to B$ be a Serre fibration. Let $y_0 \in Y$. We write $b_0 = p(y_0)$. Let $B' \subset B$ be any subset with $b_0 \in B'$. We set $Y' := p^{-1}(B')$. Then*

$$p_*\colon \pi_n(Y, Y', y_0) \;\to\; \pi_n(B, B', b_0)$$

is an isomorphism for all $n \in \mathbb{N}$. (We refer to Figure 1027 for an illustration.)

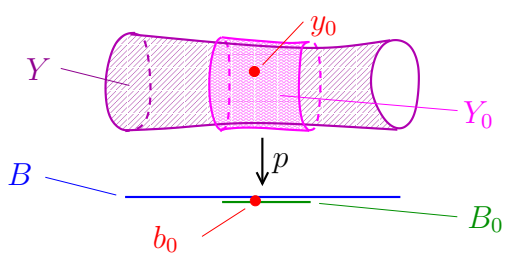

FIGURE 1027. Illustration of Proposition 83.10.

In the proof of Proposition 83.10 we will need the following elementary lemma.

Lemma 83.11. *Let $n \in \mathbb{N}$. If $x \in S^{n-1}$, then $(\overline{B}^n \times \partial[0,1]) \cup (\{x\} \times [0,1])$ is a deformation retract of $\overline{B}^n \times [0,1]$.*

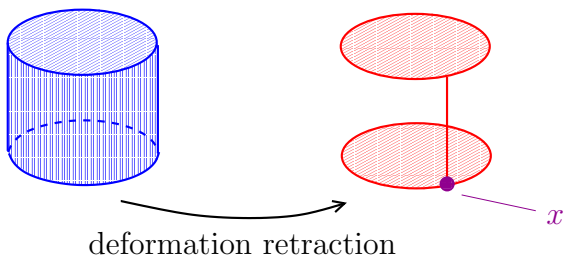

FIGURE 1028.

Proof of Lemma 83.11 $(*)$. As usual we write $I = [0,1]$. Given $k \in \{1, \ldots, n\}$ we consider

$$X_k \ := \ (I^{n-1} \times \partial I) \ \cup \ (\{\underbrace{(1,1,\ldots,1)}_{\in \mathbb{R}^{n-k}}\} \times I^k).$$

(We refer to Figure 1029 for an illustration.) Using Proposition 1.47 (2) and Lemma 1.73 (3) one can show easily that there exists a homeomorphism

$$(\overline{B}^n \times [0,1], (\overline{B}^n \times \{0,1\}) \cup (\{x\} \times [0,1])) \ \stackrel{\cong}{\to} \ (X_n, X_1).$$

Thus it suffices to show that each X_i is a deformation retract of X_{i+1}. But such deformation retractions one can actually write down by hand. $\square$

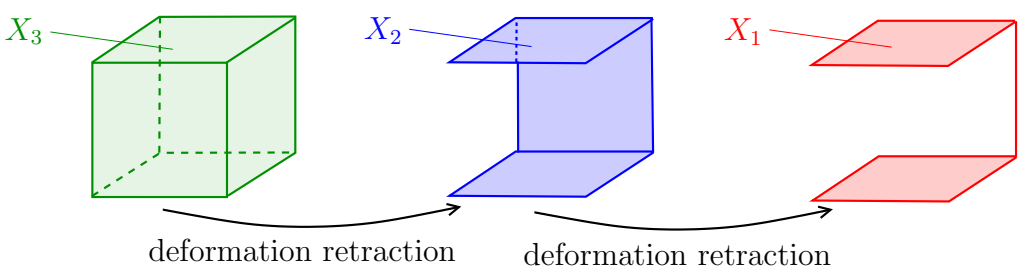

FIGURE 1029.

Now we can provide the proof of Proposition 83.10.

Proof of Proposition 83.10. Let $p\colon Y \to B$ be a Serre fibration and let $n \in \mathbb{N}$. Furthermore let $y_0 \in Y$. We write $b_0 = p(y_0)$. Finally let $B' \subset B$ be any subset with $b_0 \in B'$. We set $Y' := p^{-1}(B')$. Throughout this proof we use the identification from page 1898, i.e. we view elements in a relative homotopy group $\pi_n(X, A, x_0)$ as homotopy classes of maps $(\overline{B}^n, S^{n-1}, *) \to (X, A, x_0)$.

First we show that $p_*\colon \pi_n(Y,Y',y_0) \to \pi_n(B,B',b_0)$ is an epimorphism. Thus suppose we are given a map $f\colon (\overline{B}^n, S^{n-1}, *) \to (B,B',b_0)$. It follows from Proposition 83.9, applied to $(K,L) = (\overline{B}^n, *)$, that there exists a map $g\colon \overline{B}^n \to Y$ such that the following diagram commutes:

$$\begin{tikzcd}
\{*\} \arrow[r, "*\mapsto y_0"] \arrow[d, hook] & Y \arrow[d, "p"] \\
\overline{B}^n \arrow[r, "f"'] \arrow[ur, dashed, "g"] & B.
\end{tikzcd}$$

Basically by definition g is a map $(\overline{B}^n, S^{n-1}, *) \to (Y,Y',y_0)$. Since $f = p \circ g$ we have $[f] = p_*([g])$.

Next we show that $p_*\colon \pi_n(Y,Y',y_0) \to \pi_n(B,B',b_0)$ is also a monomorphism. Therefore suppose that we are given two maps $g_0, g_1\colon (\overline{B}^n, S^{n-1}, *) \to (Y,Y',y_0)$ such that the equality $p_*([g_0]) = p_*([g_1]) \in \pi_n(B,B',b_0)$ holds. This equality means that $p \circ g_0$ is homotopic to $p \circ g_1$ via a homotopy $F\colon (\overline{B}^n, S^{n-1}, *) \times [0,1] \to (B,B',b_0)$. We consider the following commutative diagram (first without the dashed arrow):

$$\begin{tikzcd}
(\overline{B}^n \times \{0,1\}) \cup (\{*\} \times [0,1]) \arrow[r, "\text{via } g_0, g_1"] \arrow[d, hook] & Y \arrow[d, "p"] \\
\overline{B}^n \times [0,1] \arrow[r, "F"'] \arrow[ur, dashed, "\widetilde{F}"] & B.
\end{tikzcd}$$

By Proposition 83.9 and Lemma 83.11 there exists a map $\widetilde{F}\colon \overline{B}^n \times [0,1] \to Y$ such that the above diagram commutes. This map $\widetilde{F}\colon \overline{B}^n \times [0,1] \to Y$ is easily seen to be a homotopy between g_0 and g_1 which shows that $[g_0] = [g_1] \in \pi_n(Y,Y',y_0)$. □

With these preparations it is surprisingly easy to provide a proof of Theorem 83.7 (1) and (2).

Proof of Theorem 83.7 (1) and (2). Let $p\colon Y \to B$ be a Serre fibration. Furthermore let $y_0 \in Y$. We write $b_0 = p(y_0)$ and $F = p^{-1}(b_0)$. We denote by $i\colon F \to Y$ the inclusion map. We consider the following diagram of maps

$$\begin{tikzcd}
\dots \arrow[r] & \pi_n(F,y_0) \arrow[r, "i_*"] & \pi_n(Y,y_0) \arrow[r] \arrow[dr, bend right, "p_*"'] & \pi_n(Y,F,y_0) \arrow[r, "\partial_n"] \arrow[d, "\cong"', "p_*"] & \pi_{n-1}(F,y_0) \arrow[r, "i_*"] & \dots \\
& & & \pi_n(B,\{b_0\},b_0) \arrow[d, "="] & & \\
& & & \pi_n(B,b_0). \arrow[uur, bend right, "\partial_n \circ p_*^{-1}"'] & &
\end{tikzcd}$$

We make the following comments:

(a) The top sequence of maps is the long exact sequence of homotopy groups of the pointed pair of topological spaces (Y,F,y_0), see Proposition 82.4 for details.

(b) The top vertical map is an isomorphism by Proposition 83.10.
(c) The bottom vertical map is the identification given on page 1884.
(d) It follows immediately from the definitions that the left-hand triangle commutes.
(e) The right-hand triangle commutes by definition of the diagonal map.

It follows immediately from the definition of p_* that given any $n \in \mathbb{N}$ the map

$$\partial_n \circ p_*^{-1} \colon \pi_n(B, b_0) \quad \to \quad \pi_{n-1}(F, y_0)$$

is given by

$$[\varphi \colon (I^n, \partial I^n) \to (B, b_0)] \quad \mapsto \quad \left[\begin{array}{c} \text{the restriction of } \widetilde{\varphi} \text{ to } I^{n-1} = I^{n-1} \times \{0\} \\ \text{where } \widetilde{\varphi} \text{ is a map } (I^n, J^{n-1}) \to (Y, \{y_0\}) \\ \text{with } p \circ \widetilde{\varphi} = \varphi \end{array} \right].$$

This observation shows that the map given in statement (1) of the theorem is well-defined and that it is a homomorphism (respectively a morphism of pointed sets). We leave it to the few readers who made it that far to verify that the maps ∂_n have the two properties stated in (1b) and (1c).

Furthermore, since the top sequence is exact and since the vertical maps are isomorphisms we see that the sequence given in statement (2) of the theorem is indeed exact. □

Proof of Theorem 83.7 (3). Let $p \colon Y \to B$ be a Serre fibration. Furthermore let $y_0 \in Y$. We write $b_0 = p(y_0)$ and $F = p^{-1}(b_0)$. We denote by $i \colon F \to Y$ the inclusion map. Now we suppose that the inclusion map $i \colon F \to Y$ is homotopic rel y_0 to the constant map $c_{y_0} \colon F \to \{y_0\}$. Put differently, we suppose that there exists a homotopy $G \colon F \times [0,1] \to Y$ rel y_0 such that $G_0 = i$ and $G_1(f) = y_0$ for every $f \in F$.

It follows almost immediately from Lemmas 33.2 and 33.4 that it suffices to show that for any $n \in \mathbb{N}_{\geq 2}$ there exists a homomorphism $\lambda \colon \pi_{n-1}(F, y_0) \to \pi_n(B, b_0)$ such that $\partial_n \circ \lambda = \mathrm{id}_{\pi_{n-1}(F, y_0)}$. We consider the map[1411]

$$\begin{array}{rcl} \lambda \colon \pi_{n-1}(F, y_0) & \to & \pi_n(Y, F, y_0) \xrightarrow{p_*} \pi_n(B, \{b_0\}, b_0) = \pi_n(B, b_0) \\ [\varphi \colon (I^{n-1}, \partial I^{n-1}) \to (F, y_0)] & \mapsto & \left[\begin{array}{c} (I^n, \partial I^n, J^{n-1}) \to (Y, F, \{y_0\}) \\ (x,t) \mapsto G(\varphi(x), t) \end{array} \right] \end{array}$$

It is elementary to verify that λ is in fact a homomorphism. It follows almost immediately from the definitions that $\partial_n \circ \lambda = \mathrm{id}_{\pi_{n-1}(F, y_0)}$. □

83.5. **The path space fibration.** We recall the following, long dormant, definition from page 150.

Definition. Let X and Y be topological spaces.

(1) We denote by $X^Y = C(Y, X)$ the set of all maps[1412] from Y to X.

[1411] It takes a second to actually verify that the map $(x,t) \mapsto G(\varphi(x), t)$ defines in fact a map $(I^n, \partial I^n, J^{n-1}) \to (Y, F, \{y_0\})$.

[1412] Of course here we mean "all continuous maps".

(2) The *compact-open topology* on X^Y is the topology generated, in the sense of the definition on page 63, by all the sets of the form

$$M(K,U) \;:=\; \{f \in X^Y \mid f(K) \subset U\}$$

where $K \subset Y$ is compact and where $U \subset X$ is open.

In the following we state slightly simplified versions of two technical results which we proved a long time ago.

Proposition 2.4. *Let X be a topological space.*

(1) *The evaluation map*

$$\begin{array}{rcl} e\colon X^{[0,1]} \times [0,1] & \to & X \\ ((f\colon [0,1] \to X), y) & \mapsto & f(y) \end{array}$$

is continuous.

(2) *For each $y \in [0,1]$ the evaluation map*

$$\begin{array}{rcl} e\colon X^{[0,1]} & \to & X \\ (f\colon [0,1] \to X) & \mapsto & f(y) \end{array}$$

is continuous.

Proposition 2.6. *Let X and T be two topological spaces. Let $H\colon T \times [0,1] \to X$ be a map. Given $t \in T$ we denote by $H_t\colon [0,1] \to X$ the map defined by $H_t(y) = H(t,y)$. Then*

$$H\colon T \times [0,1] \to X \text{ is continuous } \Leftrightarrow \begin{array}{l} (1) \text{ each } H_t\colon [0,1] \to X \text{ is continuous, and} \\ (2) \text{ the map } T \to X^{[0,1]} \text{ given by } t \mapsto H_t \text{ is continuous.} \end{array}$$

This reminder allows us to introduce our latest best friends.

Definition. Let X be a topological space.

(1) We define

$$\textit{free path space } X^{[0,1]} \;:=\; \text{set of all maps } [0,1] \to X$$

where $X^{[0,1]}$ is as usual equipped with the compact-open topology. Furthermore we introduce the

$$\textit{free loop space } \Omega(X) \;:=\; \{f \in X^{[0,1]} \mid f(0) = f(1)\}.$$

We equip the free loop space with the compact-open topology coming from $X^{[0,1]}$.

(2) Suppose we are also given a base point $x_0 \in X$. We introduce the

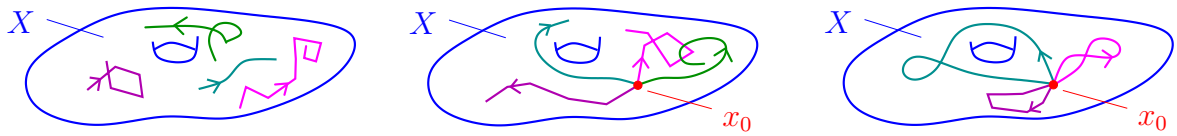
$$\textit{path space } P(X,x_0) \;:=\; \{f \in X^{[0,1]} \mid f(0) = x_0\}$$

and the

$$\textit{loop space } \Omega(X,x_0) \;:=\; \{f \in X^{[0,1]} \mid f(0) = f(1) = x_0\}.$$

We equip both sets with the compact-open topology coming from $X^{[0,1]}$.

(3) We denote by $c_{x_0}\colon [0,1] \to X$ the constant path given by sending all t's to x_0.



elements in the free path space $X^{[0,1]}$ | elements in the path space $P(X, x_0)$ | elements in the loop space $\Omega(X, x_0)$

FIGURE 1030.

Examples.

(1) Let (X, x_0) be a pointed topological space and let $\alpha, \beta \in \Omega(X, x_0)$. It follows from Proposition 2.6 that a path in $\Omega(X, x_0)$ from α to β is basically the same as a homotopy between the maps α and β viewed as loops in (X, x_0). Thus we see that we have a natural identification

$$\pi_0(\Omega(X, x_0)) \;=\; \pi_1(X, x_0).$$

(2) Let (X, x_0) be a pointed topological space. It follows from Proposition 2.4 that the map

$$\begin{array}{rcl} e\colon P(X, x_0) & \to & X \\ f & \mapsto & f(1) \end{array}$$

is continuous. We can ask whether this map has a left-inverse. More precisely, the question is whether there exists a continuous map $s\colon X \to P(X, x_0)$ such that $e(s(x)) = x$ for all $x \in X$. This sounds like a rather random question, so let us reformulate it. The question is, can we *continuously* assign to each $x \in X$ a path from x_0 to x? Clearly that is possible say for $(X, x_0) = (\mathbb{R}^2, 0)$, we just assign to each $x \in \mathbb{R}^2$ the direct path $e(x)$ that is given by $t \mapsto t \cdot x$. But can we do so say for $X = S^1$ or $X = S^2$?[1413] We will answer this question in Exercise 83.2.

For the record we state the following lemma.

Lemma 83.12. *The maps*

$$\begin{array}{rcl} (X, x_0) & \mapsto & (\Omega(X, x_0), c_{x_0}) \\ (f\colon (X, x_0) \to (Y, y_0)) & \mapsto & \left(\begin{array}{rcl} \Omega(X, x_0) & \to & \Omega(Y, y_0) \\ (\gamma\colon [0,1] \to X) & \mapsto & (f \circ \gamma\colon [0,1] \to Y) \end{array} \right) \end{array}$$

define a covariant functor from the category of pointed topological spaces to the category of pointed topological spaces. We refer to this functor as the loop space functor*.*

[1413]This question is somewhat similar to Question 37.7 and it also falls into the vaguely defined realm of "topological robotics".

Proof. Let $f\colon (X,x_0) \to (Y,y_0)$ be a map between pointed topological spaces. It follows from Lemma 2.5 (1) that the map

$$\begin{array}{rcl} \Omega(X,x_0) & \to & \Omega(Y,y_0) \\ (\gamma\colon [0,1] \to X) & \mapsto & (f\circ\gamma\colon [0,1]\to Y) \end{array}$$

is actually continuous. With this observation out of the way it is straightforward to prove the lemma. □

The following lemma says that in some sense (free) path spaces, in isolation, are not particularly interesting examples of topological spaces.

Lemma 83.13.

(1) *Let X be a topological space. We view X as a subset of the free path space $X^{[0,1]}$ via the inclusion $x \mapsto c_x$.*[1414] *Then X is a deformation retract of the free path space $X^{[0,1]}$.*

(2) *If (X,x_0) is a pointed topological space, then $\{c_{x_0}\}$ is a deformation retract of the path space $P(X,x_0)$, in particular the path space $P(X,x_0)$ is contractible.*

FIGURE 1031. Illustration of Lemma 83.13 (2).

Proof. We prove statement (2). The proof of statement (1) is basically identical. Thus let (X,x_0) be a pointed topological space. We consider the "obvious" deformation retraction given by

$$\begin{array}{rcl} F\colon P(X,x_0)\times[0,1] & \to & P(X,x_0) \\ ((f\colon [0,1]\to X),t) & \mapsto & \left(\begin{array}{rcl} [0,1] & \to & X \\ s & \mapsto & f(s\cdot(1-t)) \end{array}\right) \end{array}$$

The only reason why we are not already done is that we still need to verify that F is in fact continuous. As we will see this is slightly delicate. We consider the map

$$G\colon \underbrace{X^{[0,1]}\times[0,1]}_{=:T} \to X^{[0,1]}$$

that is defined in exactly the same way as F. Since $F = G|_{P(X,x_0)\times[0,1]}$ it suffices to show that G is continuous. By the "⇒"-direction of Proposition 2.6 applied to $T = X^{[0,1]}\times[0,1]$

[1414]Note that this inclusion $X \to X^{[0,1]}$ is continuous by Lemma 2.3.

it suffices to show that the map

$$\begin{array}{rcl} H\colon [0,1] \times \overbrace{(X^{[0,1]} \times [0,1])}^{=T} & \to & X \\ (s, ((g\colon [0,1] \to X), x)) & \mapsto & g(s \cdot x) \end{array}$$

is continuous. But the map H can be written as the composition

$$\begin{array}{rcccl} H\colon [0,1] \times X^{[0,1]} \times [0,1] & \to & X^{[0,1]} \times [0,1] & \to & X \\ (s, g, x) & \mapsto & (g, s \cdot (1-x)) & & \\ & & (g, t) & \mapsto & g(t). \end{array}$$

The first map is continuous by Lemma 1.53 and the second map is continuous by Proposition 2.4 (1). Thus we see that H itself is continuous. □

In contrast to the previous proposition the following theorem shows that (free) path spaces give rise to interesting *maps*.

Theorem 83.14.

(1) *Let X be a topological space. The evaluation map*

$$\begin{array}{rcl} p\colon X^{[0,1]} & \to & X \\ (f\colon [0,1] \to X) & \mapsto & f(1) \end{array}$$

is a fibration. Furthermore, given any $x_0 \in X$ the fiber $p^{-1}(x_0)$ is the topological space of all paths $[0,1] \to X$ that end *in x_0.*

(2) *Let (X, x_0) be a pointed topological space. The evaluation map*

$$\begin{array}{rcl} p\colon P(X, x_0) & \to & X \\ (f\colon [0,1] \to X) & \mapsto & f(1) \end{array}$$

is a fibration with fiber $p^{-1}(x_0) = \Omega(X, x_0)$.

Theorem 83.14 leads us to the following definition.

Definition.

(1) Let X be a topological space. We refer to the above fibration $p\colon X^{[0,1]} \to X$ as the *free path space fibration of X*.

(2) Let (X, x_0) be a pointed topological space. In the following we refer to the above fibration $p\colon P(X, x_0) \to X$ as the *path space fibration of (X, x_0)*.

Proof. We prove statement (2). The proof of statement (1) is basically identical and is thus left to the reader. Thus let (X, x_0) be a pointed topological space. First note that the map $p\colon P(X, x_0) \to X$ is continuous by Proposition 2.4 (2). Next recall that we need to solve

the following type of extension problem for some topological space W and $c > 0$: [1415]

$$\begin{tikzcd}
W \times \{0\} \arrow[r, "\widetilde{f}"] \arrow[d, hook] & P(X, x_0) \subset X^{[0,1]} \arrow[d, "p"', "\gamma \mapsto \gamma(1)"] \\
W \times [0, c] \arrow[r, "F"'] \arrow[ur, dashed, "\widetilde{F}"] & X.
\end{tikzcd}$$

We refer to Figure 1032 for an illustration.

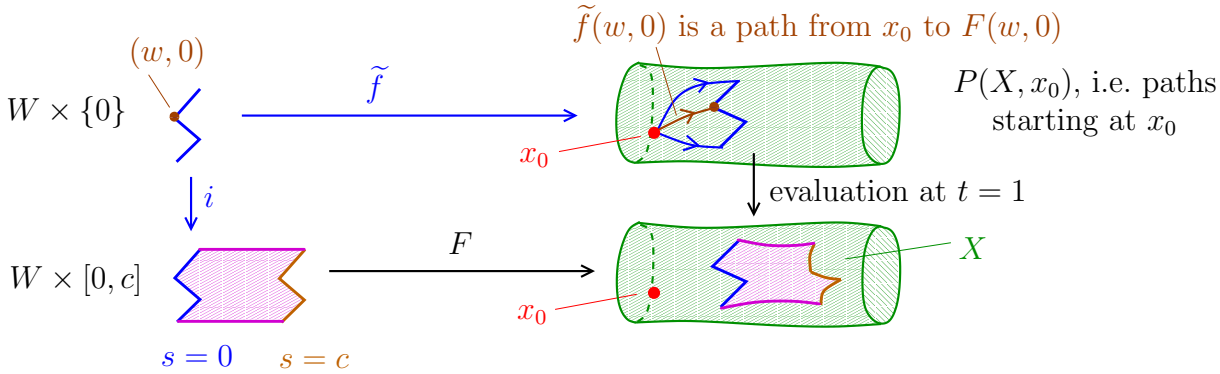


FIGURE 1032. Illustration for the proof of Theorem 83.14.

The idea for the proof is quite simple: Given $(w, s) \in W \times [0, c]$ we have to "systematically" find an element $\gamma \in P(X, x_0)$ with $p(\gamma) = F(w, s)$, i.e. we have to find a path $\gamma\colon [0, 1] \to X$ from x_0 to $F(w, s)$. But there is an obvious path, namely we first travel along $\widetilde{f}(w, 0)$ from x_0 to $F(w, 0)$ and then we use the path $t \mapsto F(w, t)$ to get from $F(w, 0)$ to $F(w, s)$. That is exactly what we will do, except that we need to be a little careful with our parametrizations.

Now we have to turn this idea into a proper proof. We consider the map

$$\begin{array}{rcl}
\widetilde{F}\colon W \times [0, c] & \to & P(X, x_0) \\
(w, s) & \mapsto & \left(\begin{array}{rcl} [0,1] & \to & X \\ t & \mapsto & \begin{cases} \widetilde{f}(w,0)\big(\frac{t}{1-\frac{s}{2c}}\big), & \text{if } t \in [0, 1-\frac{s}{2c}], \\ F(w, 2\cdot(t-1+\frac{s}{2})), & \text{if } t \in [1-\frac{s}{2c}, 1] \end{cases} \end{array} \right).
\end{array}$$

We claim that this map has all the desired properties:

(1) Let $(w, s) \in W \times [0, c]$. We make the following observations:
  (a) The given map $[0, 1] \to X$ starts at x_0.

[1415] In the diagram we write $W \times [0, c]$ instead of the more customary $W \times [0, 1]$ for purely psychological reasons, it makes it easier to distinguish the two types of intervals which arise throughout the proof and which play very different roles.

(b) It follows easily from Lemma 1.32 (2) that the given map $[0,1] \to X$ is indeed continuous.

In other words, the given map $[0,1] \to X$ does indeed define an element in $P(X, x_0)$.

(2) For each $(w,s) \in W \times [0,c]$ we have by construction that $\widetilde{F}(w,s)(t=1) = F(w,s)$. In other words, we have $p \circ \widetilde{F} = F$.

Thus it remains to prove the following claim:

Claim. The map $\widetilde{F}\colon W \times [0,c] \to P(X, x_0)$ is continuous.

We consider the map

$$\begin{array}{rcl} \widetilde{G}\colon W \times [0,c] \times [0,1] & \to & X \\ (w,s,t) & \mapsto & \widetilde{F}(w,s)(t) = \begin{cases} \widetilde{f}(w,0)\big(\frac{t}{1-\frac{s}{2c}}\big), & \text{if } t \in [0, 1-\frac{s}{2c}], \\ F(w, 2\cdot(t-1+\frac{s}{2})), & \text{if } t \in [1-\frac{s}{2c}, 1]. \end{cases} \end{array}$$

It follows easily from the fact that F and $\widetilde{f}$ are continuous that the restrictions of $\widetilde{G}$ to the closed subsets

$$A_1 \;:=\; W \times \{(s,t) \in [0,c] \times [0,1] \,|\, t \in [0, 1-\tfrac{s}{2c}]\},$$

and

$$A_2 \;:=\; W \times \{(s,t) \in [0,c] \times [0,1] \,|\, t \in [1-\tfrac{s}{2c}, 1]\}$$

are continuous. Therefore it follows from Lemma 1.32 (2) that $\widetilde{G}$ is continuous. Finally we deduce from the "$\Rightarrow$"-direction of Proposition 2.6 applied to $T = W \times [0,c]$, $Y = [0,1]$ and $H = \widetilde{G}$ that $\widetilde{F}$ is also continuous. This concludes the proof of the claim. $\square$

We obtain the following amusing corollary which later on will turn out to play an important role.

Corollary 83.15. *Given any pointed topological space (X, x_0) and any $n \geq 1$ there exists a natural isomorphism*

$$\partial_n\colon \pi_n(X, x_0) \;\overset{\cong}{\to}\; \pi_{n-1}(\Omega(X, x_0), c_{x_0}).$$

Remark. For $n = 1$ the statement of Corollary 83.15 recovers the result from page 1931 where we saw that there exists a natural identification

$$\pi_0(\Omega(X, x_0), c_{x_0}) \;=\; \pi_1(X, x_0).$$

Proof. Let $f\colon (X, x_0) \to (Y, y_0)$ be a map between pointed topological spaces. It is clear that we obtain a commutative diagram

$$\begin{array}{ccc} P(X, x_0) & \xrightarrow{\gamma \mapsto f \circ \gamma} & P(Y, y_0) \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle p} \\ X & \xrightarrow{\quad f \quad} & Y. \end{array}$$

It follows from Theorems 83.14 (1) and (2) and 83.7 that we have commutative diagram of long exact sequences

$$\begin{array}{ccccccccc}
\cdots \to & \pi_n(P(X,x_0),c_{x_0}) & \to & \pi_n(X,x_0) & \xrightarrow{\partial} & \pi_{n-1}(\Omega(X,x_0),c_{x_0}) & \to & \pi_{n-1}(P(X,x_0),c_{x_0}) & \to \dots \\
& \downarrow & & \downarrow & & \downarrow & & \downarrow & \\
\cdots \to & \pi_n(P(Y,y_0),c_{y_0}) & \to & \pi_n(Y,y_0) & \xrightarrow{\partial} & \pi_{n-1}(\Omega(Y,y_0),c_{y_0}) & \to & \pi_{n-1}(P(Y,y_0),c_{y_0}) & \to \dots
\end{array}$$

We obtain from Lemma 83.13 and Proposition 28.7 that the homotopy groups of the path spaces $P(X,x_0)$ and $P(Y,y_0)$ are trivial. Thus the connecting homomorphisms are the desired *natural* isomorphisms. □

Example. We consider the loop space of the 2-dimensional sphere with the base point given by the North Pole $N=(0,0,1)$. We calculate that

$$\begin{array}{ccccc}
\pi_1(\Omega(S^2,N),c_N) & \xleftarrow{\cong} & \pi_2(S^2,N) & \xrightarrow{\cong} & \mathbb{Z}. \\
& \uparrow & & \uparrow & \\
& \text{Corollary 83.15} & & \text{Corollary 80.6 (1)} &
\end{array}$$

In Figure 1033 we see a loop $\{\gamma_z\}_{z\in S^1}$ of loops in the pointed topological space (S^2,N). Put differently, we see a loop in the pointed topological space $(\Omega(S^2,N),c_N)$. It is an amusing and instructive exercise to run through the above two isomorphisms to verify that our loop in the pointed topological space $(\Omega(S^2,N),c_N)$ is actually a generator of $\pi_1(\Omega(S^2,N),c_N)$.

So what does this example actually really mean? It means that even though each individual loop γ_z is null-homotopic in S^2, we cannot continuously deform all the loops γ_z altogether into the constant loop. It is a good idea to think about what it would mean for $[z\mapsto\gamma_z]\in\pi_1(\Omega(S^2,N),c_N)$ to be null-homotopic and why, pictorially, this is not the case in our situation.

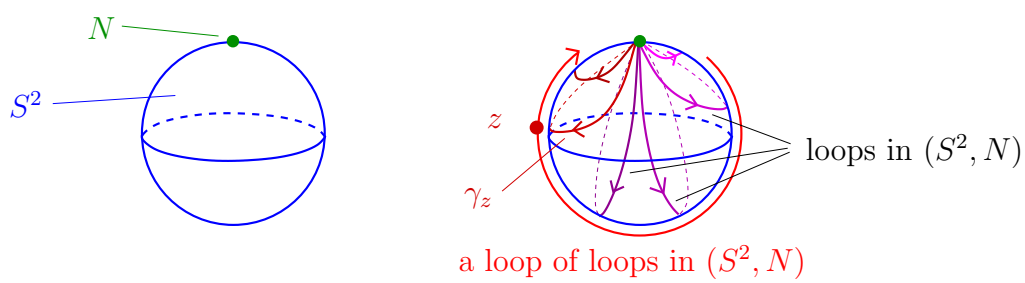

FIGURE 1033.

Note that the statement of Corollary 83.15 can be summarized as follows: The loop space functor

$$\begin{array}{rcl}
\Omega\colon \text{category of pointed topological spaces} & \to & \text{category of pointed topological spaces} \\
(X,x_0) & \mapsto & (\Omega(X,x_0),c_{x_0})
\end{array}$$

shifts homotopy groups down by one degree, i.e. for every pointed topological space (X, x_0) and every $n \in \mathbb{N}$ we have a natural isomorphism

$$\pi_n(X, x_0) \xrightarrow{\cong} \pi_{n-1}(\Omega(X, x_0), c_{x_0}).$$

This should be compared to the fact that in Proposition 32.14 we saw that the suspension functor

$$\begin{array}{rcl} \Sigma\colon \text{category of topological spaces} & \to & \text{category of topological spaces} \\ X & \mapsto & \Sigma(X) \end{array}$$

shifts reduced homology groups up by one degree, i.e. for every topological space X and any $n \in \mathbb{N}$ we have a natural isomorphism

$$\widetilde{H}_n(X) \xrightarrow{\cong} \widetilde{H}_{n+1}(\Sigma(X)).$$

In Exercise 83.7 we will discuss whether we can also shift homotopy groups *upwards* and whether we can shift reduced homology groups *downwards* in a functorial way.

83.6. **Every map can be replaced by a fibration.** In this section we will see that one can "replace" any map $f\colon X \to Y$ between topological spaces by a fibration $P_f \to Y$ that has very similar properties to the map f.

We start out with the notion of the pullback of a fibration. Perhaps not surprisingly the definition is almost identical to the definition of the pullback of a vector bundle that we gave on page 1790.

Lemma 83.16. *Let $f\colon A \to B$ be a map between topological spaces and let $q\colon Z \to B$ be a fibration. As in Lemma 16.8 (1) we consider the pullback*

$$f^*Z \;:=\; \{(a, z) \,|\, a \in A \text{ and } \overbrace{z \in q^{-1}(f(a))}^{\text{i.e. } q(z) = f(a)}\} \;\subset\; A \times Z.$$

Then the following statements hold:

(1) *The pullback map*

$$\begin{array}{rcl} p\colon f^*Z \;:=\; \{(a, z) \,|\, a \in A \text{ and } z \in q^{-1}(f(a))\} & \to & A \\ (a, z) & \mapsto & a \end{array}$$

is also a fibration. Furthermore for any $a \in A$ the fiber $p^{-1}(a)$ is homeomorphic to the fiber $q^{-1}(f(a))$.

(2) *The following diagram commutes*

$$\begin{tikzcd} f^*Z \arrow[r, "(a,z)\mapsto z"] \arrow[d, "p"] & Z \arrow[d, "q"] \\ A \arrow[r, "f"] & B. \end{tikzcd}$$

Proof.

(2) It is straightforward to verify that the diagram commutes.

(1) Let X be any topological space. We consider the following diagram where initially we ignore the diagonal arrows:

$$\begin{tikzcd}
X \times \{0\} \arrow[r, "\widetilde{g}"] \arrow[d, "i"] & f^*Z \arrow[r, "(a,z)\mapsto z"] \arrow[d, "p"] & Z \arrow[d, "q"] \\
X \times [0,1] \arrow[r, "G"'] \arrow[ur, dashed, "?\widetilde{G}?"] \arrow[urr, "\widetilde{f\circ G}"] & A \arrow[r, "f"'] & B.
\end{tikzcd}$$

Here the maps $G\colon X \times [0,1] \to A$ and $\widetilde{g}\colon X \times \{0\} \to f^*Z$ are "the challenge" we have to deal with in the definition of a fibration. Since $q\colon Z \to B$ is a fibration there exists a map $\widetilde{f \circ G}\colon X \times [0,1] \to Z$ that makes the diagram commute. It is now straightforward to verify that the map

$$\begin{array}{rcl} X \times [0,1] & \to & f^*Z = \{(a,z) \,|\, a \in A \text{ and } z \in q^{-1}(f(a))\} \\ (x,t) & \mapsto & \big(G(x,t), \big(\widetilde{f \circ G}\big)(x,t)\big) \end{array}$$

makes the above diagram commute. We have thus shown that $p\colon f^*Z \to A$ is also a fibration.

Finally we have to prove the statement regarding the fibers. Thus let $a \in A$. It follows immediately from the definitions that $p^{-1}(a) = \{a\} \times q^{-1}(f(a)) \subset A \times Z$. It follows from Lemma 1.53 (3b) that the fiber $p^{-1}(a)$ is homeomorphic to the fiber $q^{-1}(f(a))$. □

Definition. Using the notation from Lemma 83.16 we refer to $f^*Z \to A$ as the *pullback* of the fibration $q\colon Z \to B$ under the map $f\colon A \to B$.

Now we turn to the actual problem that we had stated in the beginning of this section.

Definition. Let $f\colon X \to Y$ be a map between topological spaces. Similar to the free path space fibration we now consider the fibration[1416]

$$\begin{array}{rcl} q\colon Y^{[0,1]} & \to & Y \\ \gamma & \mapsto & \gamma(0). \end{array}$$

We refer to the map

$$\begin{array}{rcl} p\colon P_f := f^*(Y^{[0,1]}) = \{(x, \gamma\colon [0,1] \to Y) \in X \times Y^{[0,1]} \,|\, \gamma(0) = f(x)\} & \to & Y \\ (x,\gamma) & \mapsto & \gamma(1) \end{array}$$

as the *mapping path fibration.*[1417]

The following proposition in particular justifies the name "mapping path *fibration*".

Proposition 83.17. *Let $f\colon X \to Y$ be a map between topological spaces. We denote by $p\colon P_f \to Y$ the corresponding mapping path fibration.*

[1416]This map is basically the same as the free path space fibration except that now we consider the evaluation $\gamma(0)$ instead of the evaluation $\gamma(1)$.

[1417]Note that it follows from Proposition 2.4 (2) that this map is in fact continuous.

(1) *The map*

$$\begin{array}{rcl} h\colon X & \to & P_f \\ x & \mapsto & (x, \text{constant path } c_{f(x)}) \end{array}$$

is a homotopy equivalence and it has the property that it makes the following diagram commute:

$$\begin{tikzcd} X \arrow[rr, "h"] \arrow[dr, "f"'] & & P_f \arrow[dl, "p"] \\ & Y. & \end{tikzcd}$$

(2) *The map $p\colon P_f \to Y$ is a fibration. Given any $y \in Y$ the fiber is given by*

$$\{(x,\gamma) \,|\, x \in X \text{ and } \gamma\colon [0,1] \to Y \text{ is a path from } f(x) \text{ to } y\}.$$

Definition. Let $f\colon X \to Y$ be a map between topological spaces. We suppose that Y is path-connected. We refer to the homotopy type of the fiber of the corresponding mapping path fibration $P_f \to Y$[1418] as the *homotopy fiber of f*.

Remark. If $f\colon X \to Y$ is a fibration, then it is shown in [DK, Theorem 6.18] that the map $h\colon X \to P_f$ in Proposition 83.17 (1) is a "fiber homotopy equivalence", thus, loosely speaking, the original fibration $f\colon X \to Y$ and the new fibration $p\colon P_f \to Y$ are essentially the same. We will not make use of this fact.

Example. Proposition 83.17 thus says that any map $f\colon X \to Y$ between topological spaces can be "replaced" by a fibration. As a reality check let us consider again the "non-example" from Lemma 83.1, i.e. we consider the map $f\colon S^1 \to [-1,1]$ that is given by the projection onto the x-coordinate. Lemma 83.1 says that f is not a fibration. Let us see what the above construction does in this case.

As pointed out in Proposition 83.17 (2), given any $y \in [-1,1]$ the preimage of y under the map $p\colon P_f \to Y = [-1,1]$ is given by

$$p^{-1}(y) \;=\; \{(x,\gamma) \,|\, x \in S^1 \text{ and } \gamma\colon [0,1] \to [-1,1] \text{ is a path from } f(x) \text{ to } y\}.$$

In Figure 1034 we strive to illustrate three points in the preimage of a point $y \in [-1,1]$. In Exercise 83.3 we will see that for each $y \in [-1,1]$ the preimage $p^{-1}(y)$ is homotopy equivalent to S^1. In particular this shows that the homotopy fiber of $f\colon S^1 \to [-1,1]$ is S^1. This exercise does not quite show yet that the map $p\colon P_f \to [-1,1]$ is a fibration, but at the very least it is consistent with Proposition 83.6 (1).

Proof of Proposition 83.17. Let $f\colon X \to Y$ be a map between topological spaces. We consider the map

$$\begin{array}{rcl} p\colon P_f = f^*(Y^{[0,1]}) = \{(x, \gamma\colon [0,1] \to Y) \in X \times Y^{[0,1]} \,|\, \gamma(0) = f(x)\} & \to & Y \\ (x,\gamma) & \mapsto & \gamma(1). \end{array}$$

We turn to the proof of the two statements:

[1418]Recall that Proposition 83.6 (1) says that the homotopy type of the fiber of a fibration over a path-connected topological space is well-defined.

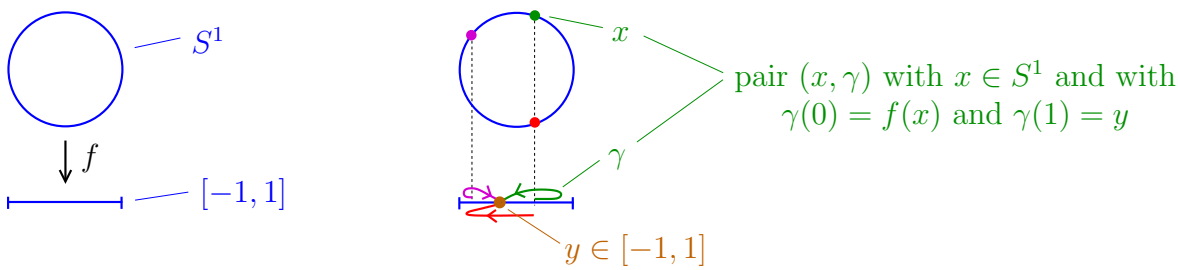

FIGURE 1034.

(1) Given $y \in Y$ we denote, as usual, by $c_y\colon [0,1] \to Y$ the constant path given by $c_y(t) = y$ for all $t \in [0,1]$. We consider the map $h\colon X \to P_f$ that is given by $x \mapsto (x, c_{f(x)})$.[1419] We claim it has the desired properties. It is obvious that $p \circ h = f$, i.e. the diagram given in the proposition commutes. So it remains to show that h is a homotopy equivalence. We consider the map $g\colon P_f \to X$ given by $g(x,\gamma) = x$. Evidently we have $g \circ h = \mathrm{id}_X$. We are done once we have shown that $h \circ g$ is homotopic to id_{P_f}. In fact such a homotopy is given by[1420]

$$\begin{array}{rcl} H\colon P_f \times [0,1] & \to & P_f \\ ((x,\gamma),t) & \mapsto & \left(x, \left(\begin{array}{rcl} [0,1] & \to & Y \\ s & \mapsto & \gamma(s \cdot t) \end{array} \right)\right). \\ \uparrow & & \\ \gamma\colon [0,1] \to Y \text{ is a path with } \gamma(0) = f(x) & & \end{array}$$

One easily verifies that $H_0 = h \circ g$ and that $H_1 = \mathrm{id}_{P_f}$.

(2) We want to show that the map $p\colon P_f \to Y$ is a fibration. Thus let A be any topological space. Let $c > 0$. We consider the following "challenge diagram":[1421]

$$\begin{tikzcd} A \times \{0\} \arrow[r, "\widetilde{g}"] \arrow[d, "i"] & P_f = \{(x, \gamma\colon [0,1] \to Y) \in X \times Y^{[0,1]} \mid \gamma(0) = f(x)\} \arrow[d, "p"', "(x,\gamma) \mapsto \gamma(1)"] \\ A \times [0,c] \arrow[r, "G"'] \arrow[ur, dashed, "\widetilde{G}", "??"'] & Y. \end{tikzcd}$$

To define $\widetilde{G}$ we first split up the map $\widetilde{g}$ into its components. More precisely, we define maps $\widetilde{g}_1\colon A \to X$ and $\widetilde{g}_2\colon A \to Y^{[0,1]}$ via the equality

$$\widetilde{g}(a,0) \;=\; \big(\widetilde{g}_1(a), \widetilde{g}_2(a)\big) \;\in\; P_f \subset X \times Y^{[0,1]} \quad \text{for all } a \in A.$$

[1419] It follows from Lemma 1.53 (3c) and Lemma 2.3 that this map is continuous.

[1420] An argument as in the proof of Lemma 83.13 (2) shows that the map H is indeed continuous.

[1421] As in the proof of Theorem 83.14 we prefer to work, for purely psychological reasons, with $A \times [0,c]$ instead of $A \times [0,1]$.

Note that by definition of P_f the path $\widetilde{g}_2(a) \in Y^{[0,1]}$ is a path from $f(\widetilde{g}_1(a))$ to $G(a,0)$. We need to define a suitable map $\widetilde{G}\colon A \times [0,c] \to P_f \subset X \times Y^{[0,1]}$. We consider the two factors separately:

(a) We already have the map $A \times [0,c] \to A \xrightarrow{\widetilde{g}_1} X$.

(b) To each $(a,s) \in A \times [0,c]$ we need to assign "systematically" a path $[0,1] \to Y$ from $f(x)$ to $G(a,s)$. The idea is quite simple: Given $(a,s) \in A \times [0,c]$ we consider the path $[0,1] \to Y$ that is given by first traveling along the path $\widetilde{g}_2(a)$ from $f(\widetilde{g}_1(a))$ to $G(a,0)$ and then we travel along the path $t \mapsto G(a,t)$ from $G(a,0)$ to $G(a,s)$. More precisely, similar to the proof of Theorem 83.14 we consider the map[1422]

$$\begin{array}{rcl} \widetilde{G}_2\colon A \times [0,c] & \to & Y^{[0,1]} \\ (a,s) & \mapsto & \left(\begin{array}{rcl} [0,1] & \to & Y \\ t & \mapsto & \begin{cases} \widetilde{g}_2(a)\big(\frac{t}{1-\frac{s}{2c}}\big), & \text{if } t \in [0, 1-\frac{s}{2c}], \\ G(a, 2\cdot(t-1+\frac{s}{2})), & \text{if } t \in [1-\frac{s}{2c}, 1] \end{cases} \end{array} \right). \end{array}$$

We refer to Figure 1035 for an illustration of the definition of $\widetilde{G}_2$.

Finally we consider the following map:

$$\begin{array}{rcl} \widetilde{G}\colon A \times [0,c] & \to & P_f \\ (a,s) & \mapsto & \big(\widetilde{g}_1(a), \widetilde{G}_2(a,s)\big). \end{array}$$

We make the following observations:

(a) It follows easily from the definitions that $\widetilde{G}$ takes values in P_f.

(b) It follows from the above and Lemma 1.53 (3c) that $\widetilde{G}$ is continuous.

(c) It is straightforward to verify that $\widetilde{G}$ makes the diagram commute.

We have thus verified that $\widetilde{G}$ has all the desired properties. □

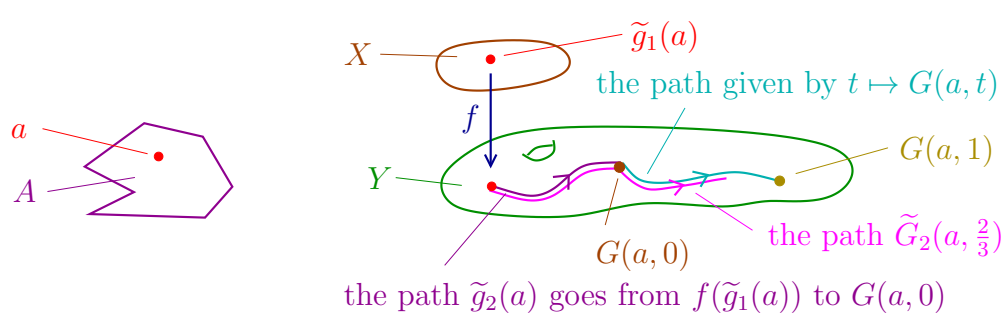

FIGURE 1035. Illustration for the proof of Proposition 83.17.

[1422]The argument in the proof of Theorem 83.14 also shows that the map $\widetilde{G}_2$ does indeed take values in $Y^{[0,1]}$ and that the map $\widetilde{G}_2\colon A \times [0,c] \to Y^{[0,1]}$ is continuous.

The statement of Proposition 83.17 that any map $f\colon X \to Y$ between topological spaces can be "replaced" by a fibration is quite surprising and perhaps also somewhat puzzling. Therefore we want to consider one more example.

Example. We denote by Σ the surface of genus 2 and we denote by T the torus. We consider the map $f\colon \Sigma \to T$ that is illustrated in Figure 1036. We denote by $p\colon P_f \to T$ the mapping path fibration and we denote by F the corresponding homotopy fiber. So what can we say about the mysterious homotopy fiber F?

We have the following diagram

$$\begin{tikzcd}
\dots \arrow[r] & \pi_2(F) \arrow[r] & \pi_2(P_f) \arrow[r, "p_*"] & \pi_2(T) \arrow[r, "\partial"] & \pi_1(F) \arrow[r] & \pi_1(P_f) \arrow[r, "p_*"] & \pi_1(T) \arrow[r] & \dots \\
& & \pi_2(\Sigma) \arrow[u, "h_*"', "\cong"] \arrow[ur, "f_*"'] & & & \pi_1(\Sigma). \arrow[u, "h_*"', "\cong"] \arrow[ur, "f_*"'] & &
\end{tikzcd}$$

We make the following explanations and observations:

(1) The top sequence is the long exact sequence coming from Theorem 83.7. The vertical maps are induced by the homotopy equivalence $h\colon \Sigma \to P_f$ from Proposition 83.17 (1). In particular the vertical maps are isomorphisms by Proposition 28.7.
(2) Since $p \circ h = f$ we see that the diagram commutes.
(3) By the discussion on page 724 we know that $\pi_n(T) = \pi_n(\Sigma) = 0$ for $n \geq 2$.
(4) It is pretty clear that the map $f_*\colon \pi_1(\Sigma) \to \pi_1(T)$ is an epimorphism.
(5) We obtain from the above discussion and from Proposition 39.13 that F is path-connected, that $\pi_n(F) = 0$ for $n \geq 2$ and that $\pi_1(F)$ is an *infinitely generated* free group.

Thus we see that the homotopy groups of F are isomorphic to the homotopy groups of an infinite wedge of circles.

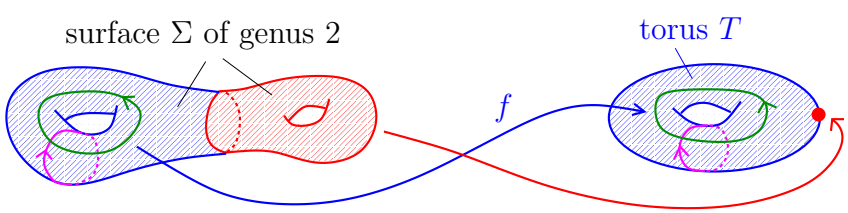

FIGURE 1036. A degree-one map from the surface of genus 2 to the torus.

Exercises for Chapter 83.

Exercise 83.1. Show that the projection map

$$\begin{array}{rcl} \overline{B}^2 & \to & \overline{B}^1 = [-1,1] \\ (x,y) & \mapsto & x \end{array}$$

is a Serre fibration.

Exercise 83.2. . Let $n \in \mathbb{N}_0$ and let x_0 be a point on S^n. It follows from Proposition 2.4 that the map

$$\begin{array}{rcl} e\colon P(S^n, x_0) & \to & S^n \\ \{f\colon [0,1] \to S^n \mid f(0) = x_0\} & \mapsto & f(1) \end{array}$$

is continuous. For which $n \in \mathbb{N}_0$ does e admit a left-inverse?

Exercise 83.3. We consider the map $f\colon S^1 \to [-1,1]$ that is given by the projection onto the x-coordinate. We define the mapping path fibration $q\colon P_f \to [-1,1]$ as in Proposition 83.17. Show that for each $y \in [-1,1]$ the preimage $q^{-1}(y)$ admits a deformation retraction to a circle.
Remark: See Figure 1034 for an illustration of the mapping path fibration.

Exercise 83.4. Let (X, x_0) be a pointed topological space. In Corollary 83.15 we wrote that for any $n \geq 1$ there exists a natural isomorphism

$$\pi_n(X, x_0) \xrightarrow{\cong} \pi_{n-1}(\Omega(X, x_0), c_{x_0}).$$

What does this statement mean for $n = 1$? It seems to say that $\pi_0(\Omega(X, x_0), c_{x_0})$ admits a natural group structure. Can you define such a natural group structure without using the above isomorphism?

Exercise 83.5. Convince yourself, without using Corollary 83.15, that the loop in the pointed topological space $(\Omega(S^2, N), c_N)$ that is shown in Figure 1033 is not null-homotopic.

Exercise 83.6. Let X be a topological space and let $x_0 \in X$ be a base point. Recall that the loop space $\Omega(X, x_0)$ is defined as the set $\Omega(X, x_0) = \{f \in X^{[0,1]} \mid f(0) = f(1) = x_0\}$ together with the compact-open topology. We denote by $\sim$ the equivalence relation on $\Omega(X, x_0)$ given by homotopy of paths. By definition we have $\pi_1(X, x_0) = \Omega(X, x_0)/\sim$. We equip $\pi_1(X, x_0)$ with the quotient topology. We can thus view $\pi_1(X, x_0)$ as a topological space. Show that $\pi_1(S^1, 1)$ is a discrete topological space.
Hint: It is possibly easier to show that for any pointed topological space (X, x_0) that admits a universal covering the fundamental group $\pi_1(X, x_0)$ is a discrete topological space.
Remark: There are examples of pointed topological spaces for which $\pi_1(X, x_0)$ is not a discrete topological space. For example the fundamental group of the Hawaiian Earrings, introduced in Exercise 26.6, is not a discrete topological space. We refer to [Fab, Fab2] for details.

Exercise 83.7.

(a) Show that there is no functor

$$\Phi\colon \text{category of pointed topological spaces} \to \text{category of pointed topological spaces}$$

which admits for every $n \in \mathbb{N}$ a natural isomorphism

$$\pi_n(X, x_0) \xrightarrow{\cong} \pi_{n+1}(\Phi(X, x_0)).$$

(b) Show that there is no functor

$$\Psi\colon \text{category of topological spaces} \;\to\; \text{category of topological spaces}$$

which admits for every $n \in \mathbb{N}$ a natural isomorphism

$$\widetilde{H}_n(X) \;\overset{\cong}{\to}\; \widetilde{H}_{n-1}(\Psi(X)).$$

Hint: In Exercise 31.2 (b) we proved the following statement. If X is a topological space with $\widetilde{H}_0(X) \cong \mathbb{Z}$, then given any map $f\colon X \to X$ the induced map f_* on $\widetilde{H}_0(X)$ is given by multiplication by some $\epsilon \in \{-1, 0, 1\}$.

84. Cofibrations (∗)

In this chapter we introduce the notion of a cofibration. As of right now we will make little use of them later on. Nonetheless we intend to introduce them since they get used frequently in various branches of algebraic topology.

As the name suggests, the concept of a cofibration is connected to the notion of a fibration. Towards the end of this chapter we will explain the formal relationship between fibrations and cofibrations.

Throughout this chapter we will on numerous occasions make use of the notion of a mapping cylinder and of a mapping cone. We start out by recalling the definition of a mapping cylinder that we had initially given on page 455.

Definition. Let $f\colon X \to Y$ be a map between topological spaces. We define the corresponding *mapping cylinder* to be the topological space

$$\mathrm{Cyl}(f) \;:=\; ((X \times [0,1]) \sqcup Y)/\sim \;\text{ where } (x,1) \sim f(x) \text{ for all } x \in X.$$

We refer to the maps

$$\begin{array}{l} X \xrightarrow{i} \mathrm{Cyl}(f) \\ x \mapsto (x,0) \end{array} \quad \text{respectively} \quad \begin{array}{l} \mathrm{Cyl}(f) \xrightarrow{r} Y \\ P \mapsto \begin{cases} P, & \text{if } P \in Y, \\ f(Q), & \text{if } P = [(Q,t)] \text{ with } Q \in X, t \in [0,1]. \end{cases} \end{array}$$

as the *natural inclusion* respectively the *natural retraction*.

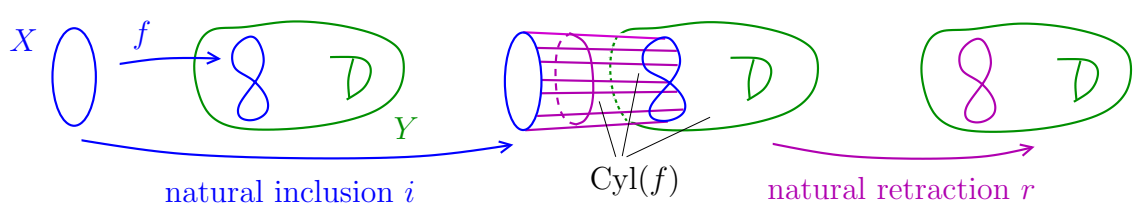

Figure 1037.

We also recall the definition of a mapping cone that we gave on page 458.

Definition. Given a map $f\colon A \to X$ between topological spaces the corresponding *mapping cone* is defined as

$$\mathrm{Cone}(f\colon A \to X) \;:=\; (A \times [0,1]) \sqcup X/\sim \qquad \text{where} \quad \begin{array}{l} (a,0) \sim (b,0) \text{ for all } a,b \in A \text{ and} \\ (a,1) \sim f(a) \text{ for all } a \in A. \end{array}$$

We refer to the point $[A \times \{0\}] \in \mathrm{Cone}(f)$ as the *cone point*. We illustrate the definition for an inclusion map $i\colon A \to X$ in Figure 1038.

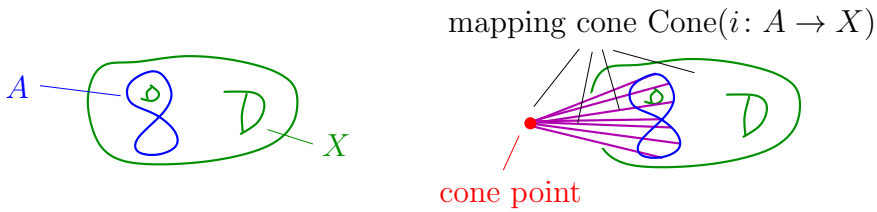

FIGURE 1038.

84.1. **Cofibrations: definition and examples.** Now we can finally introduce the leading contender for our attention in this chapter.

Definition. A map $i\colon A \to X$ between topological spaces is called a *cofibration* if it has the homotopy extension property, i.e. if given any topological space Y and any two maps $f\colon X \times \{0\} \to Y$ and $G\colon A \times [0,1] \to Y$ with $f(i(a),0) = G(a,0)$ for all $a \in A$ there exists a map $F\colon X \times [0,1] \to Y$ such that the following diagram commutes:

$$\begin{tikzcd}
A \times \{0\} \arrow[r, hook] \arrow[d, "i"'] & A \times [0,1] \arrow[dl, "G"'] \arrow[d, "i\times\mathrm{id}"] \\
X \times \{0\} \arrow[r, hook] \arrow[ur, "f"] & X \times [0,1]. \arrow[ul, dashed, "F"']
\end{tikzcd}$$

Remark. As we will see in a minute, in most cases of interest the map $i\colon A \to X$ is for all intents and purposes an inclusion. For such situations the definition of the homotopy extension property is illustrated in Figure 1039.

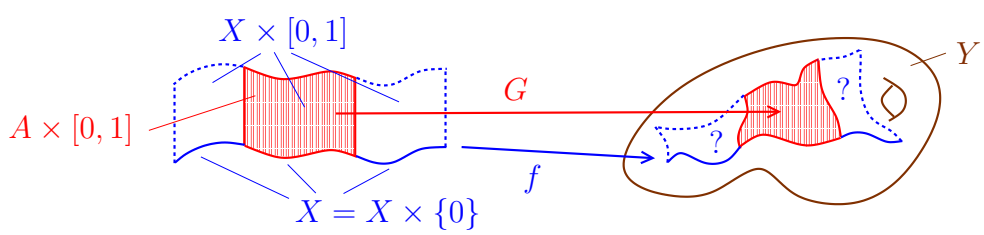

FIGURE 1039.

Example. Let X be a CW-complex and let A be a subcomplex. The Homotopy Extension Theorem 27.4 says that the inclusion $i\colon A \to X$ has the homotopy extension property, i.e. the map $i\colon A \to X$ is a cofibration.

The following lemma gives a useful characterization of cofibrations.

Lemma 84.1. *If $i\colon A \to X$ is a map between two topological spaces, then the following three statements are equivalent:*

(1) *The map* $i\colon A \to X$ *is a cofibration.*
(2) *The map*[1423]

$$\begin{array}{rcl} s\colon \mathrm{Cyl}(i) & \to & X \times [0,1] \\ P & \mapsto & \begin{cases} (i(a), 1-t), & \text{if } P = [(a,t)] \text{ with } a \in A \text{ and } t \in [0,1], \\ (P, 0), & \text{if } P \in X \end{cases} \end{array}$$

admits a left-inverse, in other words, there exists a map $r\colon X \times [0,1] \to \mathrm{Cyl}(i)$ *such that* $r \circ s = \mathrm{id}_{\mathrm{Cyl}(i)}$.
(3) *The set* $(X \times \{0\}) \cup (A \times [0,1])$ *is a retract of* $X \times [0,1]$.

Proof. First we prove the "(1) ⇒ (2)"-direction. Thus we suppose that the map $i\colon A \to X$ is a cofibration. We consider the inclusion map $j\colon X \times \{0\} \to \mathrm{Cyl}(i)$ which is given by $j(x,0) = x$ and we consider the map

$$\begin{array}{rcl} G\colon A \times [0,1] & \to & \mathrm{Cyl}(i) \\ (a,s) & \mapsto & [(a, 1-s)]. \end{array}$$

We obtain the following diagram:

$$\begin{tikzcd} A \times \{0\} \arrow[rr, hook] \arrow[d, hook, "i"'] & & A \times [0,1] \arrow[dl, "G"'] \arrow[d, hook, "i \times \mathrm{id}"] \\ & \mathrm{Cyl}(i) & \\ X \times \{0\} \arrow[rr, hook] \arrow[ur, hook, "j"] & & X \times [0,1]. \arrow[ul, dashed, "r"] \end{tikzcd}$$

One easily verifies that the black diagram commutes. Since $i\colon A \to X$ is a cofibration we obtain a map $r\colon X \times [0,1] \to \mathrm{Cyl}(i)$ which makes the diagram commute. It is straightforward to verify that $r \circ s = \mathrm{id}_{\mathrm{Cyl}(i)}$.

The proof of the converse, i.e. the proof of the "(2) ⇒ (1)"-direction is also quite straightforward. We will provide the proof in Exercise 84.2.

Now we turn to the equivalence of (2) and (3). This turns out to be quite subtle. First note that the image of $\mathrm{Cyl}(i)$ in $X \times [0,1]$ under the map s is precisely $(X \times \{0\}) \cup (A \times [0,1])$. Thus we have the following commutative diagram

$$\begin{tikzcd} \mathrm{Cyl}(i) \arrow[rr, "s"] \arrow[dr, "s"'] & & (X \times \{0\}) \cup (A \times [0,1]) \arrow[dl, hook] \\ & X \times [0,1]. & \end{tikzcd}$$

To show that (2) and (3) are equivalent it would suffice to show that the top horizontal map is a homeomorphism.

It is basically clear that the top horizontal map is a bijection. Furthermore it follows easily from Lemma 1.83 (3) that the map is continuous. Actually in Lemma 15.6 (1) we

[1423]It follows from Lemma 1.83 (3) that this map is continuous.

showed that the map is a homeomorphism if A is a *closed* subset. On the other hand we saw in Lemma 15.6 (3) that in general the map is *not* a homeomorphism.

Rather surprisingly it is nonetheless true that (2) and (3) are equivalent. This delicate argument is given in to [Strø, Lemma 4] or alternatively to [Hat, Proposition A.18]. □

Lemma 84.1 allows us to prove the following proposition which gives us many more examples of cofibrations.

Proposition 84.2. *Let M be a manifold. If N is a compact and proper submanifold, then the inclusion $i\colon N \to M$ is a cofibration.*

In the proof of Proposition 84.2 we will need the following elementary lemma.

Lemma 84.3. *There exists a retraction*

$$\rho\colon [0,1]\times[0,1] \;\to\; (\{0\}\times[0,1])\cup([0,1]\times\{0\})$$

that has the property that $\rho(\{1\}\times[0,1]) = \{(1,0)\}$.

Proof. In Figure 1040 we show how such a retraction ρ can be constructed. □

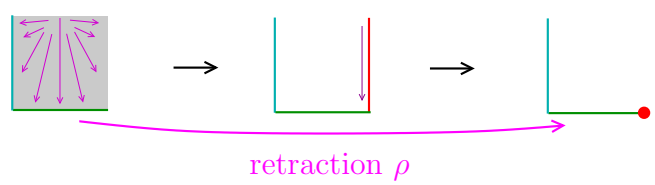

FIGURE 1040. Second illustration for the proof of Proposition 84.5.

Sketch of a proof of Proposition 84.2. Let M be an m-dimensional manifold and let N be a compact proper n-dimensional submanifold. We want to show that the inclusion $i\colon N \to M$ is a cofibration. By the General Tubular Neighborhood Theorem 64.7 the submanifold N admits a tubular neighborhood. To simplify the discussion we will only treat the case that N admits a trivial tubular neighborhood $\overline{B}^{m-n}\times N$. The general case is notationally more messy since we have to work with a trivialization of the tubular neighborhood, similar to the argument in the proof of Proposition 64.13. We leave it to the doubting Thomases among the readership to deal with the general case.

Now we recall that in Lemma 84.3 we saw that there exists a retraction

$$\varphi = (\varphi_1,\varphi_2)\colon [0,1]\times[0,1] \;\to\; (\{0\}\times[0,1])\cup([0,1]\times\{0\})$$

that has the property that $\varphi(\{1\} \times [0,1]) = \{(1,0)\}$. We consider the map[1424]

$$\begin{aligned} r\colon M \times [0,1] \ &\to\ \mathrm{Cyl}(i) = ((N \times [0,1]) \sqcup M)/\sim \ \text{ where } (x,1) \sim x \text{ for } x \in N \\ (P,t) \ &\mapsto \begin{cases} (\underbrace{(z \cdot \varphi_1(|z|,t), Q)}_{\in \overline{B}^{m-n} \times N}, \varphi_2(|z|,t)), & \text{if } P = (z,Q) \text{ with } z \in \overline{B}^{m-n} \text{ and } Q \in N, \\ P, & \text{if } P \notin \overline{B}^{m-n} \times N. \end{cases} \end{aligned}$$

(We refer to Figure 1041 for an illustration of the map r.) One can easily verify that r is a left-inverse to the map $s\colon \mathrm{Cyl}(i) \to M \times [0,1]$ that we had considered in Lemma 84.1 (2). Thus it follows from Lemma 84.1 that $i\colon N \to M$ is a cofibration. □

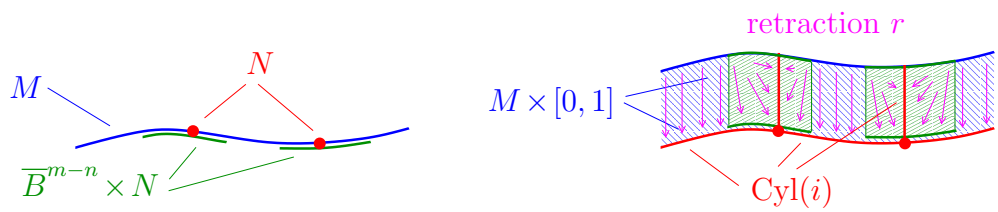

FIGURE 1041. Illustration of the proof of Proposition 84.2.

The next proposition gives another rich source of examples of cofibrations.

Proposition 84.4. *Let $f\colon X \to Y$ be a map between topological spaces. The natural inclusion $i\colon X \to \mathrm{Cyl}(f)$ is a cofibration.*

Proof. So suppose we are given the following "challenge diagram":

$$\begin{tikzcd} X \times \{0\} \arrow[r, hook] \arrow[d, hook, "i"] & X \times [0,1] \arrow[dl, "H"'] \arrow[d, hook, "i \times \mathrm{id}"] \\ Z & \\ \mathrm{Cyl}(f) \times \{0\} \arrow[r, hook] \arrow[uur, "g"] & \mathrm{Cyl}(f) \times [0,1]. \arrow[ul, dashed, "G", "??"'] \end{tikzcd}$$

This situation is illustrated in Figure 1042.

The key to finding the desired map G is the following claim.

Claim. There is a retraction r from $\mathrm{Cyl}(f) \times [0,1]$ to its subset $(\mathrm{Cyl}(f) \times \{0\}) \cup (X \times [0,1])$.

In Figure 1043 we do our best to illustrate the objects involved. To construct the desired retraction r we recall that in Lemma 84.3 we saw that there exists a retraction

$$s\colon [0,1] \times [0,1] \ \to\ (\{0\} \times [0,1]) \cup ([0,1] \times \{0\})$$

[1424]It follows from the definition of a tubular neighborhood, see page 1495, together with Lemma 1.32 (2) and Lemma 64.1 that the map is indeed continuous.

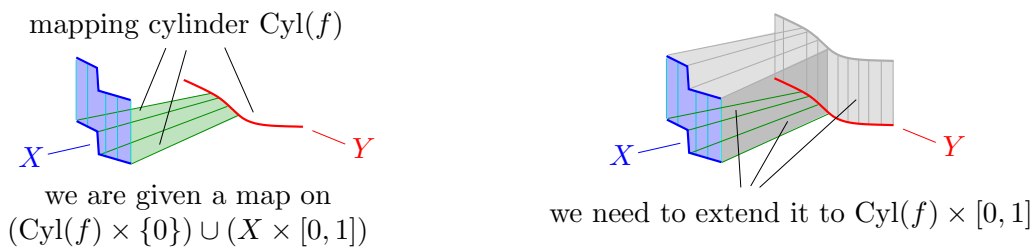

FIGURE 1042. Illustration for the proof of Proposition 84.4.

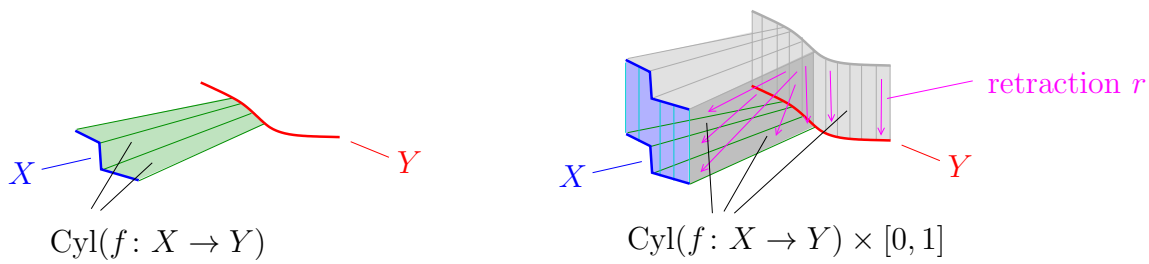

FIGURE 1043. Illustration for the proof of Proposition 84.4.

that has the property that $s(\{1\} \times [0,1]) = \{(1,0)\}$. Now the desired retraction is given by the map[1425]

$$\begin{array}{rcl} r\colon \operatorname{Cyl}(f) \times [0,1] & \to & (\operatorname{Cyl}(f) \times \{0\}) \cup (X \times [0,1]) \\ P & \mapsto & \begin{cases} [(x, s(t,u))], & \text{if } P = [(x,t,u)] \text{ with } x \in X \text{ and } t,u \in [0,1], \\ [(y,0)], & \text{if } P = [(y,u)] \text{ with } y \in Y \text{ and } u \in [0,1]. \end{cases} \end{array}$$

This concludes the proof of the claim.

Next we note that the fact that the above "challenge diagram" commutes, together with Lemma 1.32 (2), implies that the following map is well-defined and continuous:

$$\begin{array}{rcl} \Phi\colon (\operatorname{Cyl}(f) \times \{0\}) \cup_{X \times \{0\}} (X \times [0,1]) & \to & Z \\ P & \mapsto & \begin{cases} H(P), & \text{if } P \in X \times [0,1] \\ g(P), & \text{if } P \in \operatorname{Cyl}(f) \times \{0\}. \end{cases} \end{array}$$

It is now clear that the map $G := \Phi \circ r\colon \operatorname{Cyl}(f) \times [0,1] \to Z$ has the desired properties. □

In Proposition 83.17 we saw that any map $f\colon X \to Y$ between topological spaces can be "replaced" by a fibration $P_f \to Y$. The following proposition is the analogue of Proposition 83.17 for cofibrations.

Proposition 84.5. *Let $f\colon X \to Y$ be a map between topological spaces. We denote by $i\colon X \to \operatorname{Cyl}(f)$ the natural inclusion. The natural retraction $r\colon \operatorname{Cyl}(f) \to Y$ is a homotopy*

[1425]This map is continuous by Lemma 1.32 (2).

equivalence and the following diagram commutes:

$$\begin{tikzcd} & X \arrow[dl, "i"'] \arrow[dr, "f"] & \\ \mathrm{Cyl}(f) \arrow[rr, "r"] & & Y. \end{tikzcd}$$

By Proposition 84.4 we know that the left diagonal map $i\colon X \to \mathrm{Cyl}(f)$ is a cofibration.

Proof. We showed in Lemma 15.7 (2b) that the natural retraction $r\colon \mathrm{Cyl}(f) \to Y$ is a homotopy equivalence. It is clear that the given diagram commutes. Thus we are done by Proposition 84.4. That was quick. □

84.2. **Properties of cofibrations.** The following lemma summarizes a few key properties of cofibrations.

Lemma 84.6. *If $i\colon A \to X$ is a cofibration, then the following three statements hold:*
(1) *the map $i\colon A \to X$ is injective,*
(2) *the map $i\colon A \to X$ is a homeomorphism onto its image,*
(3) *if X is Hausdorff, then $i(A)$ is a closed subset of X.*

Remark. In Exercise 84.3 we will see that in Lemma 84.6 (3) we cannot drop the hypothesis that X is Hausdorff.

Proof. Let $i\colon A \to X$ be a cofibration.

(1) Similar to the proof of Lemma 84.1 we consider the inclusion map $j\colon X \times \{0\} \to \mathrm{Cyl}(i)$ which is given by $j(x, 0) = x$ and we consider the map

$$\begin{array}{rcl} G\colon A \times [0,1] & \to & \mathrm{Cyl}(i) \\ (a, s) & \mapsto & [(a, 1-s)]. \end{array}$$

We obtain the following diagram:

$$\begin{tikzcd} A \times \{0\} \arrow[rr, hook] \arrow[dd, hook, "i"'] & & A \times [0,1] \arrow[dl, "G"'] \arrow[dd, hook, "i \times \mathrm{id}"] \\ & \mathrm{Cyl}(i) & \\ X \times \{0\} \arrow[rr, hook] \arrow[ur, hook, "j"] & & X \times [0,1]. \arrow[ul, dashed, "F"'] \end{tikzcd}$$

One easily verifies that the black diagram commutes. Since i is a cofibration we obtain a map $F\colon X \times [0,1] \to \mathrm{Cyl}(i)$ which makes the diagram commute. Note that by design for any $t \in (0,1]$ the map $G\colon A \times \{t\} \to \mathrm{Cyl}(i)$ is injective. Since the diagram commutes this implies that $i \times \mathrm{id}_{\{t\}}\colon A \times \{t\} \to X \times \{t\}$ is also injective, i.e. $i\colon A \to X$ is injective.

(2) We continue with the argument and the notation in (1). Let $t \in (0,1]$. The map $G|_{A \times \{t\}}\colon A \times \{t\} \to A \times \{1-t\}$ is evidently a homeomorphism. Thus we see that

$$(G|_{A \times \{t\}})^{-1} \circ F|_{X \times \{t\}}\colon i(A) \times \{t\} \ \to \ A \times \{t\}$$

is an inverse to the map $i \times \mathrm{id}_{\{t\}} \colon A \times \{t\} \to X \times \{t\}$. This implies that the map $i \times \mathrm{id}_{\{t\}} \colon A \times \{t\} \to X \times \{t\}$ is a homeomorphism onto its image, but this also implies that the map $i \colon A \to X$ is a homeomorphism onto its image.

(3) It follows from (1) that we can assume that A is a subset of X and that $i \colon A \to X$ is the inclusion map. Thus we can make the identification $\mathrm{Cyl}(i) = (A \times [0,1]) \cup (X \times \{0\})$ and we can view $\mathrm{Cyl}(i)$ as a subset of $X \times [0,1]$. The discussion in (1) shows that $F \colon X \times [0,1] \to \mathrm{Cyl}(i)$ is a retraction. We see that

$$\begin{array}{rcl} & \text{for } x \in A \text{ we have } F(x,0) = (x,0) \text{ by construction of } F\text{, furthermore} \\ & \text{for } x \notin A \text{ the point } (x,0) \text{ does not lie in } \mathrm{Cyl}(i)\text{, thus it does not lie in the image of } F \\ & \downarrow & \\ A & = & \{x \in X \mid F(x,0) = (x,0)\} \\ & = & \left\{ \begin{array}{c} \text{the points in } X \text{ on} \\ \text{which the maps} \end{array} \begin{array}{rcl} X & \to & X \times [0,1] \\ x & \mapsto & F(x,0) \end{array} \text{ and } \begin{array}{rcl} X & \to & X \times [0,1] \\ x & \mapsto & (x,0) \end{array} \text{ agree} \right\}. \end{array}$$

It follows from this description of A, our hypothesis that X is Hausdorff (which implies by Lemma 1.55 (1) that $X \times [0,1]$ is also Hausdorff) and Exercise 1.31 that A is indeed a closed subset of X. □

The following lemma shows that inclusion maps that are cofibrations are particularly nicely behaved.

Lemma 84.7. *Let X be a topological space and let $A \subset X$ be a subset. We denote by $i \colon A \to X$ the inclusion map. If i is a cofibration and if A is a closed subset, then the following three statements hold:*

(1) *The map*[1426]

$$\begin{array}{rcl} \varphi \colon \mathrm{Cone}(i \colon A \to X) & \to & X/A \\ P & \mapsto & \left\{ \begin{array}{ll} [P], & \text{if } P \in X, \\ [A], & \text{if } P = [(a,t)] \text{ with } a \in A \text{ and } t \in [0,1] \end{array} \right. \end{array}$$

is a homotopy equivalence.

(2) *If A is contractible, then the projection map $X \to X/A$ is a homotopy equivalence.*

(3) *If $a_0 \in A$ is a deformation retract of A, then the projection map $X \to X/A$ is a homotopy equivalence between the pointed topological spaces (X, a_0) and $(X/A, [A])$.*

(4) *For any $n \in \mathbb{N}_0$ the map $H_n(X,A) \to \widetilde{H}_n(X/A)$ from page 783 is an isomorphism.*

Proof. Let X be a topological space and let $A \subset X$ be a subset.

(1) Similar to the proof of Lemma 84.6 (1) we consider the following two maps:

(a) First of all we consider the obvious inclusion map $j \colon X \times \{0\} \to \mathrm{Cone}(i)$ which is given by $j(x,0) = x$.

[1426]It follows from the ever popular Lemma 1.32 (2) and the fact that A is a closed subset of X that the map φ is continuous.

(b) We consider the map

$$\begin{array}{rcl} G\colon A\times[0,1] & \to & \mathrm{Cone}(i) \\ (a,s) & \mapsto & [(a,1-s)]. \end{array}$$

Note that G_1 sends all points in A to the cone point.
We obtain the following diagram:

$$\begin{tikzcd} A\times\{0\} \arrow[rr, hook] \arrow[d, hook, "i"'] & & A\times[0,1] \arrow[dl, "G"'] \arrow[d, hook, "i\times\mathrm{id}"] \\ & \mathrm{Cone}(i) & \\ X\times\{0\} \arrow[rr, hook] \arrow[ur, hook, "j"] & & X\times[0,1]. \arrow[ul, dashed, "F"'] \end{tikzcd}$$

One easily verifies that the diagram commutes. Since i is a cofibration we obtain a map $F\colon X\times[0,1]\to\mathrm{Cone}(i)$ which makes the diagram commute. Note that the map $F_1\colon X\to\mathrm{Cone}(i)$ sends all points in A to the cone point. Thus F_1 descends to a map $\psi\colon X/A\to\mathrm{Cone}(i)$. It remains to prove the following claim.

Claim. The maps $\varphi\colon\ \mathrm{Cone}(i)\to X/A$ and $\psi\colon X/A\to\mathrm{Cone}(i)$ are homotopy inverses of one another.

Note that $F(A\times[0,1])=G(A\times[0,1])\subset A$. Therefore it follows from Lemma 9.14 that the map

$$H\colon (X/A)\times[0,1] \xrightarrow{([x],t)\mapsto[(x,t)]} (X\times[0,1])/(A\times[0,1]) \xrightarrow{[(x,t)]\mapsto[F(x,t)]} X/A$$

is continuous. It follows immediately from the definitions that H is a homotopy between $\mathrm{id}_{X/A}$ and $\varphi\circ\psi$.

Conversely we consider the map

$$\begin{array}{rcl} H\colon\ \mathrm{Cone}(i)\times[0,1] & \to & \mathrm{Cone}(i) \\ (P,s) & \mapsto & \begin{cases} F(P,s), & \text{if } P\in X, \\ [a,(1-s)\cdot t], & \text{if } P=[(a,t)] \text{ with } a\in A \text{ and } t\in[0,1]. \end{cases} \end{array}$$

One easily verifies that this is a homotopy from $\mathrm{id}_{\mathrm{Cone}(i)}$ to $\psi\circ\varphi$. This concludes the proof of the claim.

(2) We consider the following diagram

$$\begin{tikzcd} X \arrow[rr, hook] \arrow[dr] & & \mathrm{Cone}(i\colon A\to X) \arrow[dl, "\varphi"] \\ & X/A. & \end{tikzcd}$$

It follows immediately from the definition of φ that this diagram commutes. Now suppose that A is contractible. By Proposition 15.14 (1) there exists a deformation retraction G from $\mathrm{Cone}(i\colon A\to X)$ to X. By statement (1) we know that φ is a

homotopy equivalence. Thus it follows from Lemma 9.8 (1) that the map $X \to X/A$ is a homotopy equivalence.

(3) Now assume that $a_0 \in A$ is a deformation retract. By Proposition 15.14 (2) there exists a deformation retraction G from $\mathrm{Cone}(i\colon A \to X)$ to X such that for any $t \in [0,1]$ we have $G_1([(a_0,t)]) = a_0$. Also note that the homotopy equivalence H from (1) has the property that $H(a_0,t) = [(a_0, 1-t)]$. If one combines these observations with the argument in (2) it is not difficult to see that the projection map is in fact a homotopy equivalence of the pointed topological spaces (X, a_0) and $(X/A, [a_0])$.

(4) Now we suppose that A is non-empty. Let $n \in \mathbb{N}_0$. We consider the following diagram

$$\begin{tikzcd} H_n(X,A) \arrow[rr] \arrow[dr, "\cong"'] & & \widetilde{H}_n(X/A) \\ & \widetilde{H}_n(\mathrm{Cone}(i)). \arrow[ur, "\varphi"'] & \end{tikzcd}$$

Here the top map is the natural homomorphism that we introduced on page 783 and the left diagonal map is the natural *isomorphism* of Lemma 33.7. We leave it to the reader to verify that the diagram commutes. We had just seen in (1) that φ is a homotopy equivalence. Therefore we obtain from Corollary 30.8 that the right diagonal map is also an isomorphism. Putting everything together we see that the top map is indeed an isomorphism. □

The following corollary is quite useful.

Corollary 84.8. *Let X be a CW-complex and let $A \subset X$ be a subcomplex.*

(1) *If A is contractible, then the projection map $X \to X/A$ is a homotopy equivalence.*
(2) *If $a_0 \in A$ is a deformation retract of A, then the projection map $X \to X/A$ is a homotopy equivalence between the pointed topological spaces (X, a_0) and $(X/A, [A])$.*

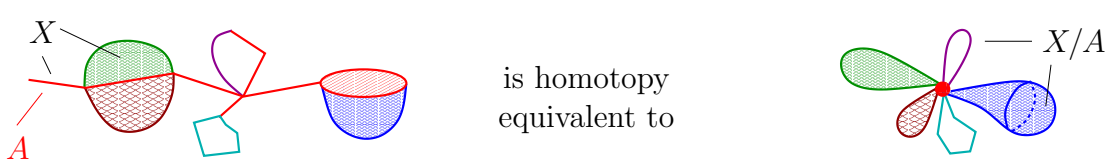

FIGURE 1044. Illustration of Corollary 84.8.

Proof. On page 1946 we pointed out that the inclusion $A \to X$ is a cofibration. The two statements now follow immediately from the corresponding statements in Lemma 84.7. □

84.3. **Adjoint functors.** In this section we will discuss the relationship between fibrations and cofibrations. First we point out a formal similarity between fibrations and cofibrations, namely they both give rise to long exact sequences:

(1) Let $p\colon Y \to B$ be a fibration. Let $y_0 \in Y$. We write $b_0 = p(y_0)$ and we denote by $F = p^{-1}(b_0)$ the homotopy fiber of p. Let $i\colon F \to Y$ be the inclusion map. By Theorem 83.7 we obtain the following long exact sequence of homotopy groups:

$$\ldots \xrightarrow{\partial} \pi_n(F, y_0) \xrightarrow{i_*} \pi_n(Y, y_0) \xrightarrow{p_*} \pi_n(B, b_0) \xrightarrow{\partial} \pi_{n-1}(F, y_0) \xrightarrow{i_*} \ldots.$$

(2) Let $i\colon A \to X$ be a cofibration. We refer to the mapping cone $C := \mathrm{Cone}(i)$ as the *cofiber*. If $i(A)$ is a closed non-empty subset of X, then it follows easily from Corollary 31.14 and Lemma 84.7 (4) that we obtain a long exact sequence of reduced homology groups of the following form:

$$\ldots \xrightarrow{\partial} \widetilde{H}_n(A) \xrightarrow{i_*} \widetilde{H}_n(X) \xrightarrow{p_*} \widetilde{H}_n(C) \xrightarrow{\partial} \widetilde{H}_{n-1}(A) \xrightarrow{i_*} \ldots.$$

This basically recovers the statement of Lemma 33.18.

Here is another similarity between fibrations and cofibrations:

(1) Let $p\colon Y \to B$ be a fibration and let $f\colon A \to B$ be a map. As in Lemma 16.8 (1) we consider the pullback

$$\begin{tikzcd} f^*Y \arrow[r] \arrow[d] & Y \arrow[d, "p"] \\ A \arrow[r, "f"'] & B \end{tikzcd}$$

where $f^*Y = \{(a, y) \in A \times Y \mid f(a) = p(y)\}$. In Lemma 83.16 we saw that the pullback $f^*Y \to A$ is also a fibration.

(2) Now let $i\colon A \to X$ be a cofibration and let $f\colon A \to B$ be a map to another topological space. As on page 486 we consider the pushout

$$\begin{tikzcd} A \arrow[r, "f"] \arrow[d, "i"'] & B \arrow[d] \\ X \arrow[r] & f_*X \end{tikzcd}$$

where $f_*X = (X \sqcup B)/i(a) \sim f(a)$ for all $a \in A$. In Exercise 84.6 we will see that the pushout $B \to f_*X$ is again a cofibration.

So, to summarize: *the pullback of a fibration is again a fibration* and *the pushout of a cofibration is again a cofibration.*

The main goal of this section though is to formulate an arguably more direct relationship between the notions of a fibration and a cofibration. The key to doing so is the following definition from category theory.

Definition. We say that two covariant functors $F\colon \mathcal{C} \to \mathcal{D}$ and $G\colon \mathcal{D} \to \mathcal{C}$ between categories $\mathcal{C}$ and $\mathcal{D}$ form an *adjoint pair* if given any $c \in \mathrm{Ob}(\mathcal{C})$ and $d \in \mathrm{Ob}(\mathcal{D})$ there exists a bijection

$$\mathrm{Mor}_{\mathcal{D}}(F(c), d) \to \mathrm{Mor}_{\mathcal{C}}(c, G(d))$$

that is natural in c and d.[1427] We also say that the functor F is the *left adjoint of* G and that G is the *right adjoint of* F.

Examples.

(1) Let $\mathcal{S}$ be the category of sets and let $\mathcal{G}$ be the category of groups. We consider the two functors

$$\begin{array}{rcl} F\colon \mathcal{S} & \to & \mathcal{G} \\ S & \mapsto & \langle S\rangle \end{array} \qquad \text{and} \qquad \begin{array}{rcl} G\colon \mathcal{G} & \to & \mathcal{S} \\ (\pi,\ \cdot\ ) & \mapsto & \pi. \end{array}$$

In other words, F associates to a set S the free group $\langle S\rangle$ generated by S that we defined on page 377.[1428] Furthermore, G assigns to a group $(\pi,\ \cdot\ )$ the underlying set π.[1429] Using Lemma 11.13 one sees that for a set S and a group π the map

$$\begin{array}{rcl} \mathrm{Mor}_{\mathcal{S}}(S,\ \overbrace{\pi}^{=G(\pi,\ \cdot\ )}\ ) & \to & \mathrm{Mor}_{\mathcal{G}}(\overbrace{\langle S\rangle}^{=F(S)}, (\pi,\ \cdot\ )) \\ (\text{map } h\colon S\to\pi \text{ of sets}) & \mapsto & \begin{array}{l}\text{the unique homomorphism } \langle S\rangle\to(\pi,\ \cdot\ ) \\ \text{that restricts to } h \text{ on the subset } S\subset\langle S\rangle\end{array} \end{array}$$

is a natural bijection. Thus we see that the functors F and G are adjoint.

(2) Let $\mathcal{A}$ be the category of abelian groups and let A be an abelian group. We consider the two functors

$$\begin{array}{rcl} F\colon \mathcal{A} & \to & \mathcal{A} \\ B & \mapsto & A\otimes B \end{array} \qquad \text{and} \qquad \begin{array}{rcl} G\colon \mathcal{A} & \to & \mathcal{A} \\ B & \mapsto & \mathrm{Hom}(A,B). \end{array}$$

Now let $B, C\in\mathcal{A}$. We consider the map[1430]

$$\begin{array}{rcl} \mathrm{Mor}_{\mathcal{A}}(\overbrace{A\otimes B}^{=F(B)}, C) & \to & \mathrm{Mor}_{\mathcal{A}}(B, \overbrace{\mathrm{Hom}(A,C)}^{=G(C)}) \\ (f\colon A\otimes B\to C) & \mapsto & \left(\begin{array}{rcl} B & \to & \mathrm{Hom}(A,C) \\ b & \mapsto & \left(\begin{array}{rcl} A & \to & Y \\ a & \mapsto & f(a\otimes b)\end{array}\right)\end{array}\right). \end{array}$$

Using Lemma 42.2 (3) one can easily show that this map is a bijection. This shows that F and G form an adjoint pair.

(3) Let $\mathcal{T}$ be the category of topological spaces. Rather similarly to the previous example we consider the two functors[1431]

$$\begin{array}{rcl} F\colon \mathcal{T} & \to & \mathcal{T} \\ X & \mapsto & X\times[0,1] \end{array} \qquad \text{and} \qquad \begin{array}{rcl} G\colon \mathcal{T} & \to & \mathcal{T} \\ X & \mapsto & X^{[0,1]}. \end{array}$$

[1427] We leave it to our reader to figure out what "natural in c and d" means.

[1428] In what sense is this a functor?

[1429] Such a functor, where we "forget" some of the given structure is often called a *forgetful functor*.

[1430] For abelian groups X and Y we have by definition that $\mathrm{Mor}_{\mathcal{A}}(X,Y)=\mathrm{Hom}(X,Y)$.

[1431] Here we equip $X\times[0,1]$ with the product topology and we equip $X^{[0,1]}$ with the compact-open topology.

Now let $X, Y \in \mathrm{Ob}(\mathcal{T})$, i.e. let X and Y be topological spaces. We consider the map

$$\begin{array}{rcl} \mathrm{Mor}_{\mathcal{T}}(\overbrace{X \times [0,1]}^{=F(X)}, Y) & \to & \mathrm{Mor}_{\mathcal{T}}(X, \overbrace{Y^{[0,1]}}^{=G(Y)}) \\ (f\colon X \times [0,1] \to Y) & \mapsto & \left(\begin{array}{rcl} X & \to & Y^{[0,1]} \\ x & \mapsto & \left(\begin{array}{rcl} [0,1] & \to & Y \\ t & \mapsto & f(x,t) \end{array} \right) \end{array} \right). \end{array}$$

It follows from Proposition 2.6 that this map is well-defined and that it is a bijection.[1432] We have thus shown that F and G form an adjoint pair.

(4) The following example is a slight, but important modification of the previous example. We consider the two functors

$$\begin{array}{rcl} F\colon \mathcal{T} & \to & \mathcal{T} \\ X & \mapsto & \Sigma(X) = \underbrace{(X \times [-1,1])/\sim}_{=\text{suspension of } X} \end{array} \qquad \text{and} \qquad \begin{array}{rcl} G\colon \mathcal{T} & \to & \mathcal{T} \\ X & \mapsto & \underbrace{\Omega(X)}_{=\text{free loop space}}. \end{array}$$

Now let $X, Y \in \mathrm{Ob}(\mathcal{T})$. We consider the map

$$\begin{array}{rcl} \mathrm{Mor}_{\mathcal{T}}(\overbrace{\Sigma(X)}^{=F(X)}, Y) & \to & \mathrm{Mor}_{\mathcal{T}}(X, \overbrace{\Omega(Y)}^{=G(Y)}) \\ \left(\begin{array}{rcl} f\colon \Sigma(X) & \to & Y \\ [(x,t)] & \mapsto & f([(x,t)]) \end{array} \right) & \mapsto & \left(\begin{array}{rcl} X & \to & \Omega(Y) \\ x & \mapsto & \left(\begin{array}{rcl} [0,1] & \to & Y \\ t & \mapsto & f([(x,2t-1)]) \end{array} \right) \end{array} \right). \end{array}$$

It follows quite easily from Proposition 2.6 and Lemma 1.68 that this map is well-defined and that it is a bijection. We have thus shown that F and G form an adjoint pair.

Now we can explain the formal relationship between fibrations and cofibrations. Let E and B be topological spaces and let $p\colon E \to B$ be a map. Recall that by definition $p\colon E \to B$ is a fibration if we can always complete the following diagram:

$$\begin{tikzcd} Y \arrow[r, "\widetilde{f}"] \arrow[d, hook, "y \mapsto (y,0)"'] & E \arrow[d, "p"] \\ Y \times [0,1] \arrow[r, "F"] \arrow[ur, dashed, "\widetilde{F}"] & B. \end{tikzcd}$$

We now "dualize" this diagram as follows:

(1) we reverse the orientation of each arrow,
(2) we replace monomorphisms by epimorphisms,

[1432]More precisely, if we consider this map in the category of sets, then it is obviously a bijection. Proposition 2.6 shows that the map f on the left is continuous if and only if the corresponding map on the right is continuous. This shows that we also have a bijection between the sets of continuous maps, i.e. between the sets of morphisms in the category of topological spaces.

(3) we replace $Y \times [0,1]$ by $Y^{[0,1]}$,
(4) for purely psychological reasons we replace $p\colon E \to B$ by $i\colon A \to X$.

We obtain the following diagram:

$$\begin{tikzcd}
Y & & X \arrow[ll, "\widetilde{f}"'] \arrow[dll, dashed, "\widetilde{F}"'] \\
Y^{[0,1]} \arrow[u, two heads, "f \mapsto f(0)"] & & A. \arrow[ll, "f"'] \arrow[u, "i"']
\end{tikzcd}$$

Finally recall that we had just shown in Example (3) that given two topological spaces A and B we have a natural identification

$$\mathrm{Mor}(A \times [0,1], B) \;=\; \mathrm{Mor}(A, B^{[0,1]}).$$

Thus (with a few other more or less mysterious changes) the previous challenge diagram translates into the following challenge diagram:

$$\begin{tikzcd}
X \arrow[r, "x \mapsto (x,0)"] \arrow[d, "\widetilde{f}"'] & X \times [0,1] \arrow[dl, dashed, "\widetilde{F}"'] \\
Y & A \times [0,1]. \arrow[l, "f"'] \arrow[u, "i"']
\end{tikzcd}$$

But this challenge diagram looks familiar: it is precisely the diagram that appears in the definition of a cofibration.

We conclude this chapter with three quotes:

(1) "In the mathematical disciplines of algebraic topology and homotopy theory, Eckmann–Hilton duality in its most basic form, consists of taking a given diagram for a particular concept and reversing the direction of all arrows [...]."[1433] [1434]
(2) "Eckmann–Hilton duality can be extremely helpful as an organizational principle, reducing significantly what one has to remember, and providing valuable hints on how to proceed in various situations." [Hat, p. 464]
(3) "In mathematics [...] currying[1435] is the technique of translating the evaluation of a function that takes multiple arguments into evaluating a sequence of functions, each with a single argument. For example, a function that takes two arguments, one from X and one from Y, and produces outputs in Z, by currying is translated into a function that takes a single argument from X and produces as outputs functions from Y to Z."[1436]

[1433] `https://en.wikipedia.org/wiki/Eckmann-Hilton_duality`

[1434] Note that the notion of pullback and pushout are related by Eckmann-Hilton duality.

[1435] This notion is named after the American mathematician Haskell Brooks Curry (1900-1982) who was an American mathematician and logician. There are three programming languages named after him, namely Haskell, Brook and Curry.

[1436] `https://en.wikipedia.org/wiki/Currying#Algebraic_topology`

So we see that in the above discussion we performed Eckmann-Hilton duality combined with some currying.

Exercises for Chapter 84.

Exercise 84.1. Solve the following problems "by hand", i.e. without making use of any of above results. For example you should not use Lemma 84.6.

(a) Let $A = [a, b]$ be a compact interval and let $X = \mathbb{R}$. Show that the inclusion $i\colon A \to X$ is a cofibration.
(b) Let $A = \mathbb{R} \setminus \{0\}$ and $X = \mathbb{R}$. Show that the inclusion $i\colon A \to X$ is not a cofibration.
(c) Let $A = (-1, 1)$ and $X = \mathbb{R}$. Show that the inclusion $i\colon A \to X$ is not a cofibration.

Exercise 84.2. Prove the "(2) $\Rightarrow$ (1)"-direction of Lemma 84.1.

Exercise 84.3. Let $X = \{x, y\}$ be a set with two elements and the trivial topology furthermore let $A = \{x\}$. Show that the inclusion $A \to X$ is a cofibration.

Exercise 84.4. Let M be a manifold. Show that the inclusion $i\colon \partial M \to M$ is a cofibration. Hint: The proof is not that different from the proof of Proposition 84.2.

Exercise 84.5. Let X be a topological space and let $x_0 \in X$. We suppose that the inclusion map $\{x_0\} \to X$ is a cofibration. Show that there exists an open neighborhood U of x_0 and a homotopy $H\colon U \times [0, 1] \to X$ rel $\{x_0\}$ from id_U to the constant map c_{x_0}.
Remark: This statement almost implies that the point $x_0 \in X$ is good in the sense of the definition on page 387.

Exercise 84.6. Let $i\colon A \to X$ be a cofibration and let $f\colon A \to B$ be a map to another topological space B. Show that the map

$$\begin{array}{rcl} B & \to & f_*X = (X \sqcup B)/\sim \ \text{ with } i(a) \sim f(a) \text{ for all } a \in A \\ b & \mapsto & [b] \end{array}$$

is a cofibration.

85. Fiber bundles

In this chapter we will introduce fiber bundles. For us they will be the most important source of fibrations. In this and the following chapter one of our favorite games will be to find more and more fiber bundles to obtain lots of non-trivial information on homotopy groups of various topological spaces.

85.1. **The definition of fiber bundles.**

The following proposition says that being a Serre fibration is a "local property".

Proposition 85.1. *Let $p\colon Y \to B$ be a map between topological spaces. If for every $b \in B$ there exists an open neighborhood U of b such that $p\colon p^{-1}(U) \to U$ is a Serre fibration, then $p\colon Y \to B$ itself is a Serre fibration.*

Proof. Let $p\colon Y \to B$ be a map between topological spaces. In this proof we say $U \subset B$ is *small* if $p\colon p^{-1}(U) \to U$ is a Serre fibration.

Now assume that $p\colon Y \to B$ has the property that B can be covered by small sets. We want to show that this hypothesis implies that the map $p\colon Y \to B$ is a Serre fibration. Therefore let $n \in \mathbb{N}_0$, let $F\colon \overline{B}^n \times [0,1] \to B$ and let $\widetilde{f}\colon \overline{B}^n \times \{0\} \to Y$ be maps such that the rectangle in the following diagram commutes:

$$\begin{tikzcd}
\overline{B}^n \times \{0\} \arrow[r, "\widetilde{f}"] \arrow[d, hook] & Y \arrow[d, "p"] \\
\overline{B}^n \times [0,1] \arrow[r, "F"'] \arrow[ur, dashed, "\widetilde{F}"] & B.
\end{tikzcd}$$

We need to show that there exists a diagonal map $\widetilde{F}\colon \overline{B}^n \times [0,1] \to Y$ such that the above diagram commutes.

Claim. There exists a CW-structure X on $\overline{B}^n$ and real numbers $0 = s_0 < s_1 < \cdots < s_k = 1$ such for each cell e of X and each $i \in \{0, \dots, k-1\}$ the image $F(e \times [s_i, s_{i+1}])$ is small.

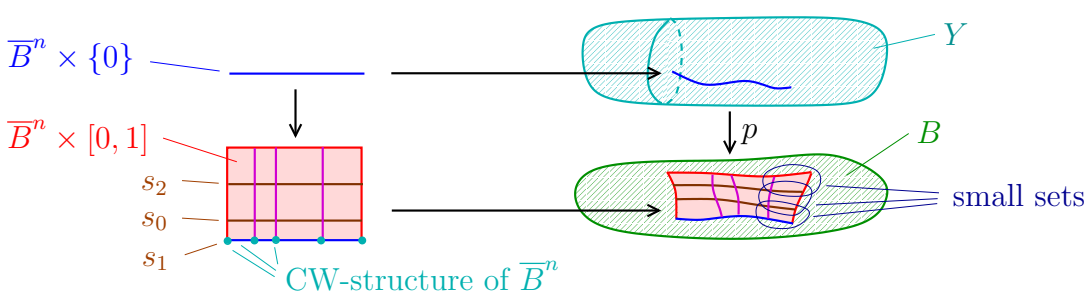

Figure 1045.

By Lemma 29.1 we can identify $\overline{B}^n$ with $[0,1]^n$. Since B is by hypothesis covered by small open subsets and since any subset of a small set is again small we obtain from Corollary 1.106 that there exists a $k \in \mathbb{N}$ such that each

$$F\Big(\underbrace{\Big[\tfrac{a_1}{k}, \tfrac{a_1+1}{k}\Big] \times \ldots \Big[\tfrac{a_n}{k}, \tfrac{a_n+1}{k}\Big]}_{\subset [0,1]^n = \overline{B}^n} \times \underbrace{\Big[\tfrac{a_{n+1}}{k}, \tfrac{a_{n+1}+1}{k}\Big]}_{\subset [0,1]}\Big)$$

is small for all $a_1, \ldots, a_{n+1} \in \{0, \ldots, k-1\}$. We equip $[0,1]^n = \overline{B}^n$ with the CW-structure defined on page 670 given by the "subcubes" of side length $\frac{1}{k}$. Furthermore we set $s_i = \frac{i}{k}$, $i = 0, \ldots, k$. By design this CW-structure and this choice of s_i has the desired properties. This concludes the proof of the claim.

We continue with the following claim.

Claim. Let $i \in \{0, \ldots, k-1\}$. Given a map $\widetilde{F}_i \colon \overline{B}^n \times \{s_i\} \to Y$ with $p \circ \widetilde{F}_i = F|_{\overline{B}^n \times \{s_i\}}$ there exists a map $\widetilde{F}_{i+1} \colon \overline{B}^n \times [s_i, s_{i+1}] \to Y$ such that the following diagram commutes:

$$\begin{tikzcd}
\overline{B}^n \times \{s_i\} \arrow[r, "\widetilde{F}_i"] \arrow[d, hook] & Y \arrow[d, "p"] \\
\overline{B}^n \times [s_i, s_{i+1}] \arrow[r, "F"'] \arrow[ur, dashed, "\widetilde{F}_{i+1}"'] & B.
\end{tikzcd}$$

In fact the claim follows immediately from the argument of the proof of Proposition 83.8 applied to the CW-complex $K := X = \overline{B}^n$ and the subcomplex $L = \varnothing$. Indeed, in the proof of Proposition 83.8 we did not need to assume that $p \colon Y \to B$ is a Serre fibration, all we ever used is that for every cell e of B the image $F(e)$ is small in the above sense. But in our present setting this is guaranteed by our choice of the CW-structure on $\overline{B}^n$. This concludes the proof of the claim.

We set $\widetilde{F}_0 = \widetilde{f}_0 \colon \overline{B}^n \times \{0\} \to Y$. Iteratively applying the previous claim we obtain maps $\widetilde{F}_i \colon \overline{B}^n \times [s_i, s_{i+1}] \to Y$ that agree on the overlaps of the domains. By Lemma 5.3 all these maps together define a continuous map $\widetilde{F} \colon \overline{B}^n \times [0,1] \to Y$ which by construction has the desired properties. $\square$

As we saw on page 1912, every projection $p \colon B \times F \to B$ is a (Serre) fibration. This observation, together with Proposition 85.1 leads us naturally to the following definition.

Definition. Let F be a topological space.

(1) A map $p \colon Y \to B$ between two topological spaces is called an *F-bundle over B* if given any $b \in B$ there exists an open neighborhood U of b and a homeomorphism $\Phi \colon p^{-1}(U) \to U \times F$ such that the following diagram commutes:

$$\begin{tikzcd}
p^{-1}(U) \arrow[rr, "\Phi"] \arrow[dr, "p"'] & & U \times F \arrow[dl, "(x,f) \mapsto x"] \\
& U. &
\end{tikzcd}$$

Alternatively we call such a map $p\colon Y \to B$ a *bundle projection* with *fiber* F. As for fibrations we sometimes refer to B as the *base space* and to Y as the *total space*. Furthermore we refer to the map $p\colon Y \to B$ as the *projection*.

(2) We say that two F-bundles $p\colon Y \to B$ and $q\colon Z \to B$ are *equivalent* if there exists a homeomorphism $f\colon Y \to Z$ such that the following diagram commutes:

$$\begin{tikzcd} Y \arrow[rr, "f"] \arrow[dr, "p"'] & & Z \arrow[dl, "q"] \\ & B. & \end{tikzcd}$$

The following proposition will be the incarnation of Theorem 83.7 that we will use most often.

Proposition 85.2. *Let $p\colon Y \to B$ be a fiber bundle with fiber F.*

(1) *The map $p\colon Y \to B$ is a Serre fibration.*

(2) *We pick $y_0 \in Y$ and we write $b_0 = p(y_0)$. We pick an identification $F \xrightarrow{\cong} p^{-1}(b_0)$. We denote by $i\colon F = p^{-1}(b_0) \to Y$ the inclusion. We use the fact from (1) that $p\colon Y \to B$ is a Serre fibration to define maps $\partial_n\colon \pi_n(B, b_0) \to \pi_{n-1}(F, y_0)$, $n \in \mathbb{N}$, as in Theorem 83.7. The following sequence is exact:*

$$\begin{aligned} \dots &\xrightarrow{\partial_{n+1}} \pi_n(F, y_0) \xrightarrow{i_*} \pi_n(Y, y_0) \xrightarrow{p_*} \pi_n(B, b_0) \xrightarrow{\partial_n} \\ &\xrightarrow{\partial_n} \pi_{n-1}(F, y_0) \xrightarrow{i_*} \dots\dots\dots \xrightarrow{p_*} \pi_1(B, b_0) \xrightarrow{\partial_1} \\ &\xrightarrow{\partial_1} \pi_0(F, y_0) \xrightarrow{i_*} \pi_0(Y, y_0) \xrightarrow{p_*} \pi_0(B, b_0). \end{aligned}$$

(3) *If we are given a commutative diagram*

$$\begin{tikzcd} Y' \arrow[r, "g"] \arrow[d, "p'"'] & Y \arrow[d, "p"] \\ B' \arrow[r, "f"] & B \end{tikzcd}$$

where $p'\colon Y' \to B'$ is a fiber bundle with fiber F', then given any base point $y_0' \in Y'$ the obvious diagram of the long exact sequences of homotopy groups corresponding to the fiber bundles $p\colon Y \to B$ and $p'\colon Y' \to B'$ is commutative.

(4) *If the fiber F and the base space B are path-connected, then the total space Y is also path-connected.*

Proof.

(1) This part of the proposition is an immediate consequence of the definitions, Proposition 85.1 and the discussion on page 1912.

(2) The second statement follows immediately from (1) and Theorem 83.7 (2).

(3) This statement follows easily from Theorem 83.7 (1b).

(4) This statement follows immediately from (2). □

Proposition 85.2 sparks our interest in fiber bundles. Fortunately, in the following discussion we will see that fiber bundles are ubiquitous and can be found throughout the notes.

Examples.

(1) For any two topological spaces B and F the projection map $p\colon B \times F \to B$ onto the first factor is evidently a fiber bundle with fiber F. Any F-bundle that is equivalent to such a bundle is called *trivial*, otherwise it is called non-trivial.

(2) The "obvious projection map" from the Möbius band to the circle S^1, i.e. the map

$$\begin{array}{rcl} Y = ([0,1] \times [-1,1])/(0,y) \sim (1,-y) & \to & S^1 \\ (x,y) & \mapsto & e^{2\pi i x} \end{array}$$

is easily seen to be a fiber bundle with fiber $[-1,1]$. Since the Möbius band is not homeomorphic to the trivial bundle $S^1 \times [-1,1]$ we see that the bundle is non-trivial.

(3) The same argument as in (2) shows that the Klein bottle is a non-trivial S^1-bundle over S^1. On page 435 we saw that the connected sum $\mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2$ is homeomorphic to the Klein bottle. We have thus shown that $\mathbb{R}\mathrm{P}^2 \# \mathbb{R}\mathrm{P}^2$ is a non-trivial S^1-bundle over S^1. Amusingly an analogous statement holds in dimension four, namely the connected sum $\mathbb{C}\mathrm{P}^2 \# \overline{\mathbb{C}\mathrm{P}^2}$ is a non-trivial S^2-bundle over S^2. It is a challenging exercise to prove this fact by hand, alternatively a proof can be found in [GS, p. 107] or [Sco, p. 124]. Similarly, one can show that the connected sum $\mathbb{H}\mathrm{P}^2 \# \overline{\mathbb{H}\mathrm{P}^2}$ is a non-trivial S^4-bundle over S^4.

(4) An n-dimensional vector bundle $p\colon W \to B$, in the sense of the definition on page 1782, is by definition an $\mathbb{R}^n$-bundle over B.

We consider the next example in greater detail.

Lemma 85.3.

(1) *Let X be a topological space and let $f\colon X \to X$ be a homeomorphism. The natural projection*

$$\begin{array}{rcl} \overbrace{M(X,f) = ([0,1] \times X)/(0,x) \sim (1,f(x))}^{\text{basically the mapping torus of } (X,f)} & \to & [0,1]/0 \sim 1 = S^1 \\ [(t,x)] & \mapsto & [t] = e^{2\pi i t} \end{array}$$

is an X-bundle over S^1.

(2) *Let X be a topological space and let $f_0, f_1\colon X \to X$ be two homeomorphisms. If f_0 and f_1 are isotopic, then the two X-bundles $M(X,f_0) \to S^1$ and $M(X,f_1) \to S^1$ are equivalent.*

(3) *Let V be an n-dimensional real vector space and let $\varphi\colon V \to V$ be an isomorphism of vector spaces. We equip V with the topology given on page 73. For each $t \in [0,1)$ we equip $\{t\} \times V \subset M(V,\varphi)$ with the obvious vector space structure. This turns the projection map $M(V,\varphi) \to S^1$ into an n-dimensional vector bundle.*

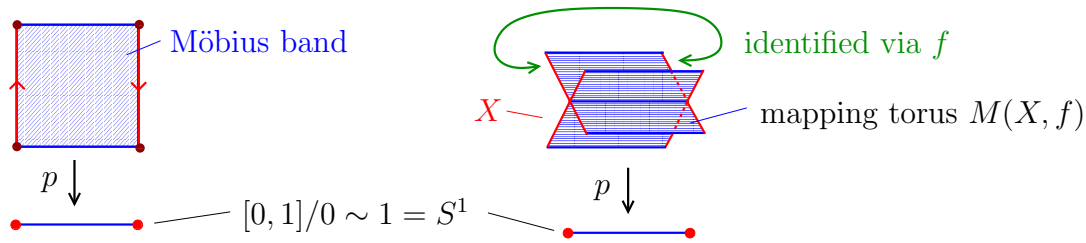

FIGURE 1046.

Proof.

(1) We denote by $\pi\colon [0,1] \to [0,1]/0 \sim 1$ the obvious projection map. We consider the two open sets $U_1 := \pi((\frac{1}{4}, \frac{3}{4}))$ and $U_2 := \pi([0, \frac{1}{3}) \cup (\frac{2}{3}, 1])$ in $[0,1]/0 \sim 1$. Furthermore we consider the maps

$$\begin{array}{ccc} p^{-1}(U_1) & \xrightarrow{\Phi_1} & U_1 \times X \\ [(t,x)] & \mapsto & (t,x) \end{array} \quad \text{and} \quad \begin{array}{ccc} p^{-1}(U_2) & \xrightarrow{\Phi_2} & U_2 \times X \\ [(t,x)] & \mapsto & \begin{cases} (t, f(x)), & \text{if } t \in [0, \frac{1}{3}), \\ (t,x) & \text{if } t \in (\frac{2}{3}, 1]. \end{cases} \end{array}$$

Note that the map on the right is indeed well-defined. Using Lemmas 1.66 and 5.3 one can show quite easily that both maps are homeomorphisms. Furthermore it is basically clear that Φ_1 and Φ_2 respect the projections onto U_1 and U_2. Therefore, since the two open subsets U_1 and U_2 cover all of $[0,1]/0 \sim 1$, we have shown that $p\colon M(X,f) \to [0,1]/0 \sim 1$ is indeed an X-bundle.

(2) This statement will be proved in Exercise 85.3.

(3) The proof of this statement is basically the same as the proof of (1). We only have to make the extra observation that for each $i \in \{1,2\}$ and each $t \in U_i$ the map

$$\Phi_i\colon V = [\{t\} \times V] = p^{-1}(t) \ \to \ \{t\} \times V = V$$

is either given by id or ϕ. Thus in either case the map is given by an *isomorphism* of vector spaces. □

Remark. The previous lemma shows that any self-homeomorphism of $\mathbb{R}^n$ gives rise to an $\mathbb{R}^n$-bundle over S^1, whereas any isomorphism of $\mathbb{R}^n$ gives rise to an n-dimensional vector bundle over S^1. The question arises whether every $\mathbb{R}^n$-bundle is secretly a vector bundle. More precisely, the question arises whether every $\mathbb{R}^n$-bundle is equivalent to an n-dimensional vector bundle. In Exercise 85.4 we will answer this question in the affirmative if $f\colon \mathbb{R}^n \to \mathbb{R}^n$ is a diffeomorphism.[1437]

It follows from the discussion on page 471 and Lemma 85.3 that the complement of the trefoil knot and the complement of the figure-8 knot are fiber bundles over S^1. Of course there are many other knots, for example consider the stevedore knot shown in Figure 1047. The following question arises:

[1437] Frankly, I am not sure whether the same statement holds if f is a homeomorphism.

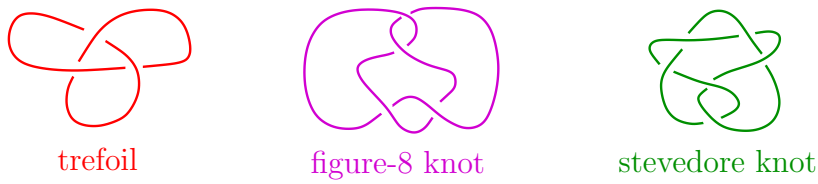

FIGURE 1047.

Question 85.4. *Is the complement of the stevedore knot a fiber bundle over S^1?*

We continue with more examples of fiber bundles.

Examples.

(1) As we pointed out above, any n-dimensional vector bundle $p\colon W \to B$ is by definition an $\mathbb{R}^n$-bundle over B. In fact p gives rise to two other bundles which are much more interesting topological objects:

(a) We denote by $s\colon B \to W$ the zero-section, i.e. the map given by sending each $b \in B$ to the zero-element of the vector space $p^{-1}(y)$. We write $W^* := W \backslash s(B)$. It follows easily from the definitions that $p\colon W^* \to B$ is a fiber bundle with fiber $\mathbb{R}^n \setminus \{0\}$.

(b) Let $\lambda \in \mathbb{R}$. By definition of a vector bundle we have a well-defined multiplication by λ on each fiber. We define

$$SW \;:=\; W^*/\sim \qquad \text{where } v \sim w \text{ if } p(v) = p(w) \text{ and if there exists a } \lambda > 0 \text{ with } \lambda v = w.$$

The map $p\colon W^* \to B$ descends to a map $p\colon SW \to B$. We leave it as an entertaining exercise to verify that $p\colon SW \to B$ is an S^{n-1}-bundle.

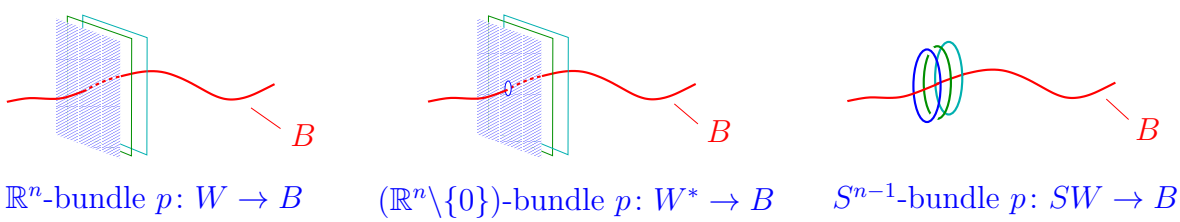

FIGURE 1048.

(2) A smooth $\overline{B}^n$-bundle $p\colon W \to M$ over a manifold M, in the sense of the definition on page 1492, is by definition an $\overline{B}^n$-bundle in the above sense. Slightly more interesting, if M has no boundary and if we restrict p to a map $\partial W \to M$, then it follows easily from Proposition 56.9 (1) that the restriction of p to ∂W defines an S^{n-1}-bundle $p\colon \partial W \to M$.

The following lemma is almost verbatim the same as Lemma 77.2.

Lemma 85.5. *Let $g\colon C \to B$ be a map between topological spaces and let $p\colon Y \to B$ be a fiber bundle with fiber F. As in Lemma 16.8 (1) we consider the pullback*

$$g^*Y \;:=\; \{(c,f)\,|\,c \in C \text{ and } f \in p^{-1}(g(c))\} \;\subset\; C \times Y,$$

which is equipped with the subspace topology. Then the map

$$\begin{array}{rcl} q\colon g^*Y \;:=\; \{(c,f)\,|\,c \in C \text{ and } f \in p^{-1}(g(c))\} & \to & C \\ (c,f) & \mapsto & c \end{array}$$

is also an F-bundle.

Proof. The proof is, not surprisingly, also almost identical to the proof of Lemma 77.2. □

Remark. The pullback of bundles satisfies basically the same statements as the pullback of vector bundles, see Proposition 77.3. There is surely no need to spell out these properties again.

The following lemma classifies bundles over compact intervals $[a,b]$ and also over the circle S^1.

Lemma 85.6.

(1) *Every bundle over a compact interval $[a,b]$ is trivial.*
(2) *If $p\colon Y \to S^1$ is a fiber bundle with fiber X, then there exists a homeomorphism $f\colon X \to X$ such that p is equivalent to the above fiber bundle $M(X,f) \to S^1$.*

Sketch of proof.

(1) This statement will be proved in Exercise 85.2.
(2) Suppose we are given a fiber bundle $p\colon Y \to S^1$ with fiber X. Let $\varphi\colon [0,2\pi] \to S^1$ be the map that is given by $\varphi(t) = e^{it}$. It follows from (1) that the pullback bundle

$$q\colon \varphi^*Y = \{(t,v) \in [0,2\pi] \times Y \,|\, v \in p^{-1}(\varphi(t))\} \;\to\; [0,2\pi]$$

is trivial, i.e. there exists a homeomorphism $\Phi\colon [0,2\pi] \times X \to \varphi^*Y$ such that the following diagram commutes

$$\begin{tikzcd} {[0,2\pi] \times X} \arrow[rr, "\Phi"] \arrow[dr, "(t,x)\mapsto t"'] & & \varphi^*Y \arrow[dl, "q"] \\ & {[0,2\pi].} & \end{tikzcd}$$

We define $f\colon X \to X$ to be the homeomorphism that is given by

$$\begin{array}{ccccccccccc} & & & & \varphi(0) = 1 = \varphi(2\pi) & & & & & & \\ & & & & \downarrow & & & & & & \\ X & \xrightarrow{x\mapsto(0,x)} & \{0\}\times X & \xrightarrow{\Phi} & q^{-1}(0) & \to & p^{-1}(1) & \leftarrow & q^{-1}(2\pi) & \xleftarrow{\Phi} & \{2\pi\}\times X \xrightarrow{(2\pi,x)\mapsto x} X. \\ & & & & (0,v) & \mapsto & v & & & & \\ & & & & & & v & \leftarrow\!\shortmid & (2\pi,v). & & \end{array}$$

We leave it as a mildly interesting exercise to the reader to verify that $p\colon Y \to S^1$ is equivalent to the fiber bundle $M(X,f) \to S^1$. □

For the record we mention the following generalization of Lemma 85.6 (1).

Proposition 85.7. *Let X be a topological space. If X is paracompact and contractible, then every bundle over X is trivial.*

Proof. The statement of the proposition is almost the same as the statement of Proposition 77.6 (3) for vector bundles. The reference we gave for vector bundles, namely [Hat2, Theorem 1.6], also applies to general bundles. □

We conclude this section with an example that shows how the above results can be used in practice. Thus let $n \in \mathbb{N}$ and K be a closed k-dimensional submanifold of the manifold S^n. We calculate that for $i = 1, \dots, n-k-2$ we have

$$\begin{array}{ccccc} H_i(S^n \setminus K; \mathbb{Z}) & \cong & H^{n-i-1}(K; \mathbb{Z}) & = & 0. \\ & \uparrow & & \uparrow & \\ & \text{Alexander Duality Theorem 66.1} & & \text{by Proposition 51.14 (5) and the fact that } n-i-1 > k = \dim(K) & \end{array}$$

The following proposition shows that not only do the first $n-k-2$ homology vanish, but the first $n-k-2$ homotopy groups also vanish.

Proposition 85.8. $(*)$ *Let $n \in \mathbb{N}$ and let K be a closed k-dimensional submanifold of the manifold S^n. For $i = 1, \dots, n-k-2$ we have $\pi_i(S^n \setminus K) = 0$.*

Example. Let K be the trefoil in $\mathbb{R}^3$ and let $\mu \subset \mathbb{R}^3$ be a meridian as defined on page 362. (See also Figure 1049 to the left.) In Lemma 33.15 we saw that μ represents a non-zero element in $H_1(S^3 \setminus K)$. It follows from the naturality of the Hurewicz homomorphism, see Proposition 38.2 (4), that μ also represents a non-trivial element in $\pi_1(S^3 \setminus K)$. Via the usual embedding $\mathbb{R}^3 \to \mathbb{R}^3 \times \{0\} \to \mathbb{R}^4$ we can view K and μ as submanifolds of $S^4 = \mathbb{R}^4 \cup \{\infty\}$. By Proposition 85.8 we have $\pi_1(S^4 \setminus K) = 0$. In particular we obtain that μ is trivial in $\pi_1(S^4 \setminus K)$. In fact in Figure 1049 we show an embedded disk D in $\mathbb{R}^4 \subset S^4$ whose boundary is given by μ and that does not intersect K. Here we use the convention from page 1517, i.e. "pinkness" of a point measures how large is the fourth coordinate.

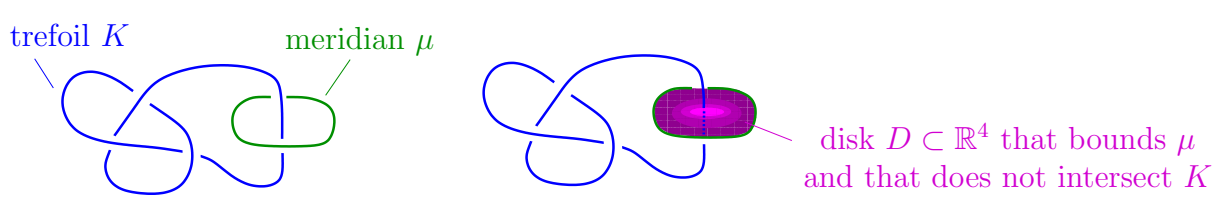

FIGURE 1049.

Proof $(*)$. Let $n \in \mathbb{N}$ and K be a closed k-dimensional submanifold of the manifold S^n. If $n-k-2 \leq 0$, then there is nothing to prove. Thus we assume that $n-k-2 \geq 1$, i.e. we assume that $n \geq k+3$.

We want to show that $\pi_i(S^n \setminus K) = 0$ for $i = 1, \dots, n-k-2$. We already know that the corresponding homology groups vanish. Thus by Corollary 80.7 it suffices to show that $\pi_1(S^n \setminus K) = 0$. That is precisely what we will do in the remainder of this proof.

In the following we consider the case that K is connected. We leave it to the reader to modify the proof to deal with the case that K is disconnected. By the General Tubular Neighborhood Theorem 64.7 the closed submanifold K admits a tubular neighborhood $p\colon W \to K$. Recall that W is a compact n-dimensional submanifold of S^n and that p is in particular a $\overline{B}^{n-k}$-bundle over K. As we pointed out on page 1965, the projection $p\colon \partial W \to K$ is an S^{n-k-1}-bundle.

We write $X = S^n \setminus \mathring{W}$. By Proposition 64.13 and Lemma 64.3 we know that $\pi_1(S^n \setminus K)$ is isomorphic to $\pi_1(X)$. Thus it suffices to show that X is simply connected.

By Proposition 3.24 we know that X is a compact n-dimensional submanifold of S^n with $W \cap X = \partial W = \partial X$. From Proposition 85.2 (4) we know that ∂W is connected. We pick a base point $x_0 \in \partial W$. By the Seifert-van Kampen Theorem 14.2 for manifolds we know that the inclusion induced map

$$\pi_1(X, x_0) *_{\pi_1(\partial W, x_0)} \pi_1(W, x_0) \ \to \ \underbrace{\pi_1(S^n, x_0)}_{=0}$$

is an isomorphism. We recall that Lemma 13.12 says that $A *_G G \cong A$. Thus, if we want to show that $\pi_1(X, x_0) = 0$ it follows from Lemma 13.12 that it suffices to prove the following claim.

Claim. The inclusion induced map $\pi_1(\partial W, x_0) \to \pi_1(W, x_0)$ is an isomorphism.

We denote both of the inclusions $\partial W \to W$ and $S^{n-k-1} \to \overline{B}^{n-k}$ by i. We have a commutative diagram

$$\begin{tikzcd}
\partial W \arrow[rr, "i"] \arrow[dr] & & W \arrow[dl] \\
& K &
\end{tikzcd}$$

of fiber bundles with fibers S^{n-k-1} and $\overline{B}^{n-k}$. From Proposition 85.2 (3) we obtain the following commutative diagram of long exact sequences of morphisms between pointed sets:

$$\begin{tikzcd}
\dots \arrow[r] & \pi_2(K) \arrow[r, "\partial"] \arrow[d, "="] & \pi_1(S^{n-k-1}) \arrow[r] \arrow[d, "i_*"] & \pi_1(\partial W) \arrow[r] \arrow[d, "i_*"] & \pi_1(K) \arrow[r, "\partial"] \arrow[d, "="] & \pi_0(S^{n-k-1}) \arrow[r] \arrow[d, "i_*"] & \dots \\
\dots \arrow[r] & \pi_2(K) \arrow[r, "\partial"] & \pi_1(\overline{B}^{n-k}) \arrow[r] & \pi_1(W) \arrow[r] & \pi_1(K) \arrow[r, "\partial"] & \pi_0(\overline{B}^{n-k}) \arrow[r] & \dots
\end{tikzcd}$$

Since $n-k \geq 3$ we have $n-k-1 \geq 2$, thus $\pi_1(S^{n-k-1}) = 0$ by Proposition 5.14. It follows from a slight generalization[1438] of the Five Lemma 31.11 that the middle vertical map $i_*\colon \pi_1(\partial W) \to \pi_1(W)$ is an isomorphism. This concludes the proof of the claim. $\square$

Remark. We want to sketch an alternative approach to proving Proposition 85.8. Thus let $n \in \mathbb{N}$, let K be a closed k-dimensional submanifold of the manifold S^n and finally let $i \in \{1, \dots, n-k-2\}$. We want to show that $\pi_i(S^n \setminus K, x_0) = 0$ for some base point $x_0 \in S^n \setminus K$. Let $[\varphi\colon (S^i, *) \to (S^n \setminus K, x_0)] \in \pi_i(S^n \setminus K, x_0)$ be a random element. We make the following observations:

(1) By the Whitney Approximation Theorem 65.6 we can assume that φ is smooth.
(2) Since $i < n$ we know that $\pi_i(S^n, x_0) = 0$. It follows from Lemma 28.4 that there exists a map $\psi\colon \overline{B}^{i+1} \to S^n$ with $\psi|_{S^i} = \varphi$.
(3) Once again, by the Whitney Approximation Theorem 65.6 we can assume that ψ is also smooth.
(4) Since $k+i+1 < n$ one would like to argue, similar to the Transversality Theorem 67.2, that we can homotop ψ rel S^i to a map that does not intersect K, i.e. we would like to homotop ψ rel S^i to a map $\overline{B}^{i+1} \to S^n \setminus K$. By Lemma 28.4 this would then imply that $[\varphi] = 0 \in \pi_i(S^n \setminus K, x_0)$.

This approach can be turned into a proper proof, but we will not do so.

85.2. **Hopf fibrations arising from complex and quaternionic projective spaces.** In this section we will see that the complex projective spaces $\mathbb{C}\mathrm{P}^n$ and the quaternionic projective spaces[1439] $\mathbb{H}\mathrm{P}^n$ give rise to interesting fiber bundles. In particular we will see that the Hopf map $S^3 \to S^2$ that we introduced on page 726 is in fact an S^1-bundle.

In the following we introduce two straightforward higher-dimensional analogues of the original Hopf map.

Definition. Let $n \in \mathbb{N}$. We refer to the maps

$$\begin{aligned} p\colon S^{2n+1} = \{(z_0, \dots, z_n) \in \mathbb{C}^{n+1} \mid |z_0|^2 + \dots + |z_n|^2 = 1\} &\to \mathbb{C}\mathrm{P}^n \\ (z_0, \dots, z_n) &\mapsto [z_0 : \dots : z_n] \end{aligned}$$

and[1440]

$$\begin{aligned} q\colon S^{4n+3} = \{(h_0, \dots, h_n) \in \mathbb{H}^{n+1} \mid |h_0|^2 + \dots + |h_n|^2 = 1\} &\to \mathbb{H}\mathrm{P}^n \\ (h_0, \dots, h_n) &\mapsto [h_0 : \dots : h_n] \end{aligned}$$

as *Hopf maps*.

[1438] More precisely, if one goes through the proof of the Five Lemma 31.11, then one realizes that it suffices that the right most vertical map is an injective morphism of pointed sets, i.e. the right most vertical map does not need to be a homomorphism of groups.

[1439] We refer to page 1062 for the slightly subtle definition of the quaternionic projective spaces.

[1440] Recall that on page 1056 we defined the norm of a quaternion $h = a \cdot 1 + b \cdot i + c \cdot j + d \cdot k$ as $|h| = \sqrt{a^2 + b^2 + c^2 + d^2}$.

The following proposition, together with Proposition 85.2, explains our interest in the Hopf maps.[1441]

Proposition 85.9. *Let $n \in \mathbb{N}$.*

(1) *The Hopf map $p\colon S^{2n+1} \to \mathbb{C}\mathrm{P}^n$ is an S^1-bundle.*
(2) *The Hopf map $q\colon S^{4n+3} \to \mathbb{H}\mathrm{P}^n$ is an S^3-bundle.*

Proof. We only provide the proof of (2). The proof of (1) is a straightforward modification of the proof of (2). Given $j \in \{0, \dots, n\}$ we define

$$V_j \ := \ \{[h_0 : \cdots : h_n] \in \mathbb{H}\mathrm{P}^n \mid h_j \neq 0\}.$$

The same argument as in the proof of Lemma 21.6 shows that V_j is an open subset of $\mathbb{H}\mathrm{P}^n$.

Claim. The map

$$\begin{aligned} \Phi_j\colon q^{-1}(V_j) = \Big\{(h_0, \dots, h_n) \in \mathbb{H}^{n+1} \,\Big|\, \textstyle\sum_{i=0}^n |h_i|^2 = 1 \text{ and } h_j \neq 0\Big\} \ &\to \ V_j \times S^3 \\ (h_0, \dots, h_n) \ &\mapsto \ \big([h_0 : \cdots : h_n], \tfrac{1}{|h_j|} \cdot h_j\big) \end{aligned}$$

is a homeomorphism.

We consider the map

$$\begin{aligned} \Psi_j\colon V_j \times S^3 \ &\to \ q^{-1}(V_j) \\ ([h_0 : \cdots : \underbrace{h_j}_{\neq 0} : \cdots : h_n], u) \ &\mapsto \ \begin{array}{c}\text{the normalization to length one of the non-zero vector} \\ \big(u \cdot h_j^{-1} \cdot h_0, \dots, \underbrace{u \cdot h_j^{-1} \cdot h_j}_{=u}, \dots, u \cdot h_j^{-1} \cdot h_n\big) \in \mathbb{H}^{n+1}.\end{array} \end{aligned}$$

This map Ψ_j is well-defined. Indeed, a short calculation shows that if we pick a different representative for $[h_0 : \cdots : h_n]$, i.e. if we plug in $[\lambda \cdot h_0 : \cdots : \lambda \cdot h_n]$ for some $\lambda \in \mathbb{H} \setminus \{0\}$ then we obtain the same result.[1442] Using Lemma 1.66 one can show that the map Ψ_j is continuous. One easily verifies that Ψ_j and Φ_j are inverses of one another. This concludes the proof of the claim.

It is clear that the open sets V_j cover all of $\mathbb{H}\mathrm{P}^n$ and that the triangles

$$\begin{tikzcd} q^{-1}(V_j) \arrow[rr, "\Phi_j"] \arrow[dr, "q"'] & & V_j \times S^3 \arrow[dl, "(v,h)\mapsto h"] \\ & S^3 & \end{tikzcd}$$

commute. This shows, according to the definition on page 1961, that $q\colon S^{4n+3} \to \mathbb{H}\mathrm{P}^n$ is an S^3-bundle. $\square$

Proposition 85.9, combined with Proposition 85.2 gives us two interesting theorems.

[1441]For mysterious reasons the Hopf maps are almost invariably called "Hopf fibrations", even though the name "Hopf fiber bundle" would be more precise.

[1442]Note though that the order of the factors in the definition of Ψ_j is important since $\mathbb{H}$ is not commutative.

Theorem 85.10.

(1) *For all $n \geq 3$ we have $\pi_n(S^3) \cong \pi_n(S^2)$.*
(2) *We have $\pi_3(S^2) \cong \mathbb{Z}$ and $\pi_3(S^2)$ is generated by the Hopf map $S^3 \to S^2$.*

The second statement gives in particular an answer to Question 63.15 (1).

Proof.

(1) On page 113 we gave an identification of $\mathbb{C}\mathrm{P}^1$ with S^2. Thus Proposition 85.9 (1), applied to $n = 1$, tells us that the Hopf map $p\colon S^3 \to S^2 = \mathbb{C}\mathrm{P}^1$ defines an S^1-bundle. Proposition 85.2 gives us the long exact sequence[1443]

$$\ldots \to \pi_n(S^1) \to \pi_n(S^3) \xrightarrow{p_*} \pi_n(S^2) \xrightarrow{\partial} \pi_{n-1}(S^1) \to \pi_{n-1}(S^3) \to \ldots$$

The desired statement now follows from the example on page 723 where we saw that $\pi_k(S^1) = 0$ for $k \geq 2$.

(2) In Corollary 80.6 (1) we saw that $\pi_3(S^3) = \mathbb{Z} \cdot [\mathrm{id}_{S^3}]$. By (1) the Hopf map $p\colon S^3 \to S^2 = \mathbb{C}\mathrm{P}^1$ induces an isomorphism $p_*\colon \pi_3(S^3) \xrightarrow{\cong} \pi_3(S^2)$. The image of $[\mathrm{id}_{S^3}]$ under p_* is by definition precisely the class in $\pi_3(S^2)$ represented by the Hopf map. Thus we see that $\pi_3(S^2) \cong \mathbb{Z}$ and that $\pi_3(S^2)$ is generated by the Hopf map. □

Theorem 85.11.

(1) *For all $n \geq 2$ we have $\pi_n(S^4) \cong \pi_n(S^7) \oplus \pi_{n-1}(S^3)$.*
(2) *For $n \in \{1, \ldots, 6\}$ we have $\pi_n(S^4) \cong \pi_{n-1}(S^3)$.*

Remark. From Corollary 80.6 (1) we know that $\pi_7(S^7) \cong \mathbb{Z}$. Thus it follows from Theorem 85.11 (1) that $\pi_7(S^4) \cong \pi_7(S^7) \oplus \pi_6(S^3)$ admits an epimorphism onto $\mathbb{Z}$. In fact in Corollary 63.8 we already saw that the Hopf invariant is an epimorphism $\pi_7(S^4) \to \mathbb{Z}$.

Proof.

(1) By Lemma 44.10 (2) we can identify the quaternionic projective space $\mathbb{H}\mathrm{P}^1$ with S^4. Therefore if we apply Proposition 85.9 (2) with $n = 1$ we obtain an S^3-bundle $q\colon S^7 \to \mathbb{H}\mathrm{P}^1 = S^4$. We pick $y_0 \in S^7$ and we write $b_0 = q(y_0)$. We pick an identification $S^3 = q^{-1}(b_0)$ and we denote by $i\colon S^3 \to S^7$ the map that is given by the inclusion of the fiber $F = S^3$ into S^7. From Proposition 85.2 we obtain the following long exact sequence

$$\cdots \to \pi_n(S^3, y_0) \xrightarrow{i_*} \pi_n(S^7, y_0) \xrightarrow{q_*} \pi_n(S^4, b_0) \xrightarrow{\partial} \pi_{n-1}(S^3, y_0) \xrightarrow{i_*} \pi_{n-1}(S^7, y_0) \to \ldots.$$

By Proposition 28.9 we know that $\pi_3(S^7, y_0) = 0$. By definition this implies that the map $i\colon S^3 \to S^7$ is homotopic rel y_0 to the constant map $c_{y_0}\colon S^3 \to \{y_0\}$. By

[1443] It is actually worth having a glance at the lower end of this sequence. We have the exact sequence

$$\pi_2(S^3) \xrightarrow{p_*} \pi_2(S^2) \xrightarrow{\partial} \pi_1(S^1) \to \pi_1(S^3).$$

From Proposition 28.9 we know that $\pi_1(S^3) = \pi_2(S^3) = 0$ and Proposition 7.18 we know that $\pi_1(S^1) \cong \mathbb{Z}$. Thus we obtain that $\pi_2(S^2) \cong \mathbb{Z}$. In Exercise 85.11 we will see that using this exact sequence we can obtain a new proof that id_{S^2} is a generator of $\pi_2(S^2)$.

Theorem 83.7 (3) this implies that the above long exact sequence splits into short exact sequences

$$0 \to \pi_n(S^7, y_0) \xrightarrow{q_*} \pi_n(S^4, b_0) \xrightarrow{\partial} \pi_{n-1}(S^3, y_0) \to 0.$$

Furthermore Theorem 83.7 (3) says that these short exact sequences split, therefore we obtain the promised isomorphisms $\pi_n(S^4, b_0) \cong \pi_n(S^7, y_0) \oplus \pi_{n-1}(S^3, y_0)$.

(2) The statement holds trivially Proposition 28.9 for $n = 1$. For $n \geq 2$ this statement follows from (1) and Proposition 28.9 which says in this context that $\pi_n(S^7) = 0$ for $n = 1, \dots, 6$. □

As we will see, Proposition 85.2 is a goose that just cannot stop laying golden eggs. For example we have the following theorem.

Theorem 85.12. *We use the homeomorphism from page 113 to make the identification $\mathbb{C}\mathrm{P}^1 = S^2$ and as on page 111 we view $\mathbb{C}\mathrm{P}^1$ as a subset of each $\mathbb{C}\mathrm{P}^n$ and of $\mathbb{C}\mathrm{P}^\infty$.*

(1) *Let $n \in \mathbb{N}$. We have*

$$\pi_k(\mathbb{C}\mathrm{P}^n) = \begin{cases} \mathbb{Z} \cdot [\mathrm{id}_{\mathbb{C}\mathrm{P}^1}], & \text{if } k = 2, \\ 0, & \text{if } k = 1, 3, 4, 5, \dots, 2n, \\ \mathbb{Z}, & \text{if } k = 2n + 1. \end{cases}$$

(2) *We have*

$$\pi_k(\mathbb{C}\mathrm{P}^\infty) = \begin{cases} \mathbb{Z} \cdot [\mathrm{id}_{\mathbb{C}\mathrm{P}^1}], & \text{if } k = 2, \\ 0, & \text{if } k = 1, 3, 4, 5, 6, \dots. \end{cases}$$

Remark. Let $k < l$. In Question 38.12 we had asked whether the complex projective space $\mathbb{C}\mathrm{P}^k$ is a retract of $\mathbb{C}\mathrm{P}^l$. In Proposition 62.14 we used the calculation of the cup product to give a negative answer. Now we can also use homotopy groups for the same purpose. More precisely, from Theorem 85.12, we obtain that $\pi_{2k+1}(\mathbb{C}\mathrm{P}^k) \cong \mathbb{Z}$ but that $\pi_{2k+1}(\mathbb{C}\mathrm{P}^l) = 0$. The usual argument, see Lemma 6.2 implies that once again we obtain a negative answer to Question 38.12, i.e. $\mathbb{C}\mathrm{P}^k$ is not a retract of $\mathbb{C}\mathrm{P}^l$.

Proof.

(1) By Proposition 85.9 (1) we know that for every $n \in \mathbb{N}$ the Hopf map $p\colon S^{2n+1} \to \mathbb{C}\mathrm{P}^n$ is an S^1-bundle. Thus we obtain from Proposition 85.2 the following long exact sequence of homotopy groups:

$$\dots \to \pi_k(S^1) \to \pi_k(S^{2n+1}) \xrightarrow{p_*} \pi_k(\mathbb{C}\mathrm{P}^n) \xrightarrow{\partial} \pi_{k-1}(S^1) \to \dots$$

We remind ourselves of the facts that $\pi_k(S^{2n+1}) = 0$ for $k = 1, \dots, 2n$, that $\pi_{2n+1}(S^{2n+1}) \cong \mathbb{Z}$ and that $\pi_k(S^1) = 0$ for $k \geq 2$. Putting everything together implies immediately that $\pi_k(\mathbb{C}\mathrm{P}^n) = 0$ for $k = 3, \dots, 2n$ and that $\pi_{2n+1}(\mathbb{C}\mathrm{P}^n) \cong \mathbb{Z}$. Only the lower end of the long exact sequence requires slightly more thought. More

precisely, we have the exact sequence

$$\underbrace{\pi_2(S^{2n+1})}_{=0} \to \pi_2(\mathbb{C}\mathrm{P}^n) \xrightarrow{\partial} \pi_1(S^1) \to \underbrace{\pi_1(S^{2n+1})}_{=0} \to \pi_1(\mathbb{C}\mathrm{P}^n) \to \pi_0(S^1) \to \pi_0(S^{2n+1}).$$

Since S^1 and S^{2n+1} are path-connected we see that the map on the right is an isomorphism of pointed sets. It follows that $\pi_2(\mathbb{C}\mathrm{P}^n) \xrightarrow{\cong} \pi_1(S^1) \cong \mathbb{Z}$ and that $\pi_1(\mathbb{C}\mathrm{P}^n) = 0$. (We had of course known the latter statement for a long time, see e.g. page 697.) The only thing which is not entirely clearly from this argument is why $\mathrm{id}_{\mathbb{C}\mathrm{P}^1}$ represents a generator of $\pi_2(\mathbb{C}\mathrm{P}^n)$. One could either heroically fight one's way through the above isomorphism, in the same vein as in Exercise 85.11, and use that we know explicitly the generator of $\pi_1(S^1)$.

But fortunately we do not have to go down that route since in Corollary 80.6 (2) we already saw that $\mathrm{id}_{\mathbb{C}\mathrm{P}^1}$ represents a generator of $\pi_2(\mathbb{C}\mathrm{P}^n)$.

(2) We calculate that

$$\pi_k(\mathbb{C}\mathrm{P}^\infty) \;=\; \pi_k\Big(\bigcup_{k\in\mathbb{N}} \mathbb{C}\mathrm{P}^n\Big) \;\underset{\substack{\uparrow \\ \text{by Proposition 28.11 since, see Lemma 26.7,} \\ \text{we can view } \mathbb{C}\mathrm{P}^\infty \text{ as a CW-complex where} \\ \text{each } k\text{-skeleton is given by } \mathbb{C}\mathrm{P}^n \subset \mathbb{C}\mathrm{P}^\infty}}{=} \lim_{\longrightarrow} \pi_k(\mathbb{C}\mathrm{P}^n) \;\underset{\substack{\uparrow \\ \text{by (1)}}}{=} \begin{cases} \mathbb{Z}\cdot[\mathrm{id}_{\mathbb{C}\mathrm{P}^1}], & \text{if } k=2, \\ 0, & \text{if } k = 1,3,4,5,\ldots. \end{cases}$$

□

85.3. **The Hopf fibration arising from the octonions** (∗)**.** In Proposition 85.9 we had in particular seen that the Hopf map $p\colon S^3 \to \mathbb{C}\mathrm{P}^1 = S^2$ is an S^1-bundle and that the Hopf map $q\colon S^7 \to \mathbb{H}\mathrm{P}^1 = S^4$ is an S^3-bundle. We exploited these fiber bundles in Theorems 85.10 and 85.11 to obtain non-trivial information on higher homotopy groups of spheres.

In our discussion of division algebras in Section 44.2 we gave the quaternions as a first example of a non-commutative division algebra. The algebra structure on the quaternions is still nonetheless quite reasonable, in particular the algebra structure is associative which was enough to define the quaternionic projective spaces on page 1062.

Next on the list of ever weirder division algebras were the octonions $\mathbb{O}$ that we introduced on page 1057. Recall that the underlying vector space of the octonions is $\mathbb{R}^8$ but that this time the algebra structure is neither commutative nor associative. The only redeeming feature is that $\mathbb{O}$ is still a division algebra.

Since the octonions are no longer associative one cannot just copy-paste the definition of the quaternionic projective spaces on page 1062 to define octonionic projective spaces in any obvious way. But we can make a prediction: If there was a first octonionic projective space, then it would presumably give rise to a Hopf fibration $r\colon S^{15} \to \mathbb{O}P^1 = S^8$ with fiber S^7. Alas, octonionic projective spaces do not exist. But as we will see, we can still use octonions to produce such a fiber bundle. More precisely, our goal in this section is to prove the following proposition.

Proposition 85.13. *There exists a fiber bundle $p\colon S^{15} \to S^8$ with fiber S^7.*

The proof of Proposition 85.13 is rather longish, thus we will first point out that it allows us to prove the following theorem.

Theorem 85.14.

(1) *For all* $n \geq 2$ *we have* $\pi_n(S^8) \cong \pi_n(S^{15}) \oplus \pi_{n-1}(S^7)$.
(2) *For* $n \in \{1, \dots, 14\}$ *we have* $\pi_n(S^8) \cong \pi_{n-1}(S^7)$.

Proof. The proof is basically the same as the proof of Theorem 85.11. We just need to replace Proposition 85.9 (2) by Proposition 85.13. □

We can copy-paste the remark after Theorem 85.11:

Remark. From Corollary 80.6 (1) we know that $\pi_{15}(S^{15}) \cong \mathbb{Z}$. Thus it follows from Theorem 85.11 (1) that $\pi_{15}(S^8)$ admits an epimorphism onto $\mathbb{Z}$. In fact in Corollary 63.8 we already saw that the Hopf invariant is an epimorphism $\pi_{15}(S^8) \to \mathbb{Z}$.

The remainder of this chapter is occupied with providing a proof of Proposition 85.13. The proof requires several preparations. In particular we need the notion of the join of two topological spaces X and Y. Loosely speaking the join $X * Y$ is obtained by connecting each point in X to each point in Y via an interval. The following definition makes this idea precise.

Definition. Let X and Y be two topological spaces. We define the *join* $X * Y$ to be the topological space obtained from $X \times Y \times [0, 1]$, equipped with the product topology, by performing the following two types of identifications:

(1) for every $x \in X$ we identify all points in $\{x\} \times Y \times \{0\}$ to a single point and
(2) for every $y \in Y$ we identify all points in $X \times \{y\} \times \{1\}$ to a single point.

Remark. The join $X * Y$, viewed as a set, can be equipped with another reasonable topology, namely the "initial topology", see [BrownR2, Chapter 5.7]. By [BrownR2, Corollary 5.7.2] these two topologies agree if X and Y are compact and Hausdorff. When dealing with joins it seems that it is safest to stick to the case that X and Y are compact and Hausdorff. For example, if X, Y and Z are topological spaces that are compact and Hausdorff, then the join is "associative", i.e. there exists a natural homeomorphism $(X * Y) * Z \cong X * (Y * Z)$. This statement is not true for all topological spaces. We refer to [Cohe3], [BrownR2, Chapter 5.7] and [FF, Chapter 2.4] for details.[1444]

Before we deal with a few examples we give a criterion for showing that a map of the form $f\colon X * Y \to Z$ is a homeomorphism.

Lemma 85.15. *If* X *and* Y *are compact topological spaces, then the following two statements hold:*

(1) *The join* $X * Y$ *is compact.*

[1444] As we saw in Lemma 2.13, products and quotients of topological spaces do not mix well. It is easy to write down "continuous looking" maps that are not continuous.

(2) *Let $f\colon X \times Y \times [0,1] \to Z$ be a map to a topological space Z such that for any $x, x_1, x_2 \in X$ and $y, y_1, y_2 \in Y$ we have the equalities $f(x, y_1, 0) = f(x, y_2, 0)$ and $f(x_1, y, 1) = f(x_2, y, 1)$. If Z is Hausdorff and if the induced map*[1445]

$$\begin{array}{rcl} \Psi\colon X * Y & \to & Z \\ [(x,y,t)] & \mapsto & f(x,y,t) \end{array}$$

is a bijection, then the map Ψ is a homeomorphism.

Proof.

(1) It follows immediately from our hypothesis and Lemmas 1.37 and 1.55 that the join $X * Y = (X \times Y \times [0,1])/\sim$ is compact.
(2) The map $\Psi\colon X * Y \to Z$ is continuous by Lemma 1.66. Thus we obtain from our hypotheses on Ψ and Z together with Proposition 1.40 that Ψ is indeed a homeomorphism. □

In the following examples we will see that the join operation sometimes produces well-known topological spaces.

Examples.

(1) We start out with the join of the two intervals $X = [0,1]$ and $Y = [0,1]$. First let us consider Figure 1050. The figure suggests that the join $X * Y = [0,1] * [0,1]$ should be homeomorphic to the 3-dimensional standard simplex Δ^3. In fact let us consider the map

$$\begin{array}{rcl} \overbrace{([0,1] \times [0,1] \times [0,1])/\sim}^{=[0,1]*[0,1]} & \to & \Delta^3 = \{(t_0,t_1,t_2,t_3) \in (\mathbb{R}_{\geq 0})^4 \,|\, t_0 + t_1 +_2 + t_3 = 1\} \\ [(x,y,t)] & \mapsto & \frac{1}{2} \cdot \big(x \cdot t, y \cdot (1-t), t, 2 - (x \cdot t + y \cdot (1-t) + t)\big). \end{array}$$

It follows easily from Lemma 85.15 (2) that this map is a homeomorphism.

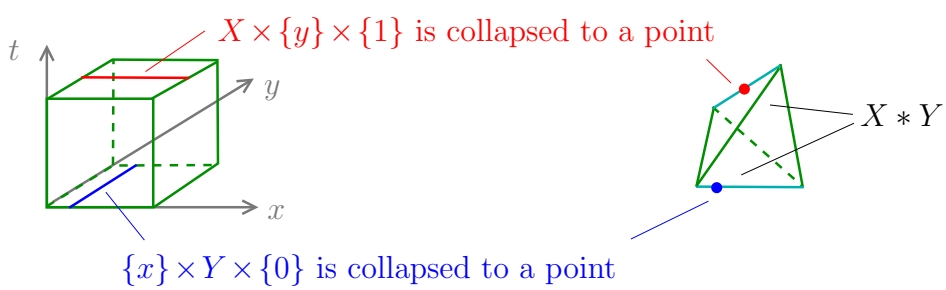

FIGURE 1050.

[1445]It follows from our hypothesis on f that the map f descends to a map on $X * Y = (X \times Y \times [0,1])/\sim$.

(2) Let X be a topological space that is compact and that is Hausdorff. Furthermore let $Y = \{-1, 1\}$ be the topological space given by the set with two elements ± 1 and the discrete topology. As usual we denote by $\Sigma(X)$ the suspension of X. For the reader's convenience we recall that it is defined as

$$\Sigma(X) \ := \ (X \times [-1, 1])/\sim$$

where we squash all points in $X \times \{-1\}$ to a single point and where we squash all points in $X \times \{1\}$ to a single point. We consider the map

$$\begin{array}{rcl} X * \{-1, 1\} = (X \times \{-1, 1\} \times [0, 1])/\sim & \mapsto & \Sigma(X) = (X \times [-1, 1])/\sim \\ [(x, \epsilon, t)] & \mapsto & [(x, \epsilon \cdot t)]. \end{array}$$

By Lemma 15.2 (2) and our hypothesis that X is Hausdorff we know that $\Sigma(X)$ is Hausdorff. Now it follows easily from Lemma 85.15 (2) that the map is in fact a homeomorphism. This homeomorphism is sketched in Figure 1051 for $X = S^1$.[1446]

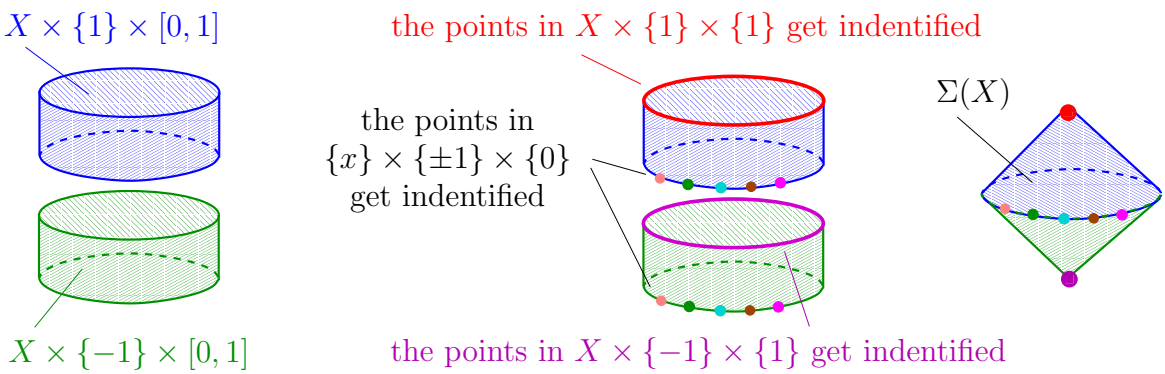

FIGURE 1051.

We record the next example of joins as a lemma.

Lemma 85.16. *Given any $m, n \in \mathbb{N}_0$ the map*

$$\begin{array}{rcl} S^m * S^n & \to & S^{m+n+1} \\ [(x, y, t)] & \mapsto & \underbrace{\left(x \cdot \cos\left(\frac{\pi t}{2}\right), y \cdot \sin\left(\frac{\pi t}{2}\right)\right)}_{\in \mathbb{R}^{m+1} \times \mathbb{R}^{n+1} = \mathbb{R}^{m+n+2}} \end{array}$$

is a homeomorphism.

Proof. Using Lemma 15.2 (2) one can fairly easily verify that the given map is a homeomorphism. □

By now the reader can be excused for thinking that we veered off-topic. But the following proposition explains our sudden interest in the join of two topological spaces.

[1446] I do not know whether it is true that given any topological space the join $X * \{-1, 1\}$ is homeomorphic to the suspension $\Sigma(X)$.

Proposition 85.17. *Let X be a topological space that is compact and Hausdorff. Furthermore let $\varphi\colon X \times X \to X$ be a map. Given $x \in X$ we consider the maps*[1447]

$$\begin{array}{rcl} L_x\colon X & \to & X \\ a & \mapsto & \varphi(x,a) \end{array} \qquad \text{and} \qquad \begin{array}{rcl} R_x\colon X & \to & X \\ a & \mapsto & \varphi(a,x). \end{array}$$

If each map $L_x\colon X \to X$ and each map $R_x\colon X \to X$ is a homeomorphism, then the map

$$\begin{array}{rcl} h_\varphi\colon X * X & \to & \Sigma(X) \\ [(x,y,t)] & \mapsto & [(\varphi(x,y), 2t-1)] \end{array}$$

is a fiber bundle with fiber X.[1448]

Example. We write $S^3 = \{z \in \mathbb{H} \,|\, |z| = 1\}$. By Lemma 44.1 we know that for any $w, z \in \mathbb{H}$ we have $|w \cdot z| = |w| \cdot |z|$. Thus multiplication of quaternions defines a map $\varphi\colon S^3 \times S^3 \to S^3$. Given any $z \in S^3$ the map L_z is a homeomorphism. In fact an inverse is given by $L_{z^{-1}}$ since for any $x \in S^3$ we have

$$(L_{z^{-1}} \circ L_z)(x) \;=\; z^{-1} \cdot (z \cdot x) \;\underset{\substack{\uparrow \\ \text{since } \mathbb{H} \text{ is associative}}}{=}\; (z^{-1} \cdot z) \cdot x \;=\; x,$$

and similarly we have $L_z \circ L_{z^{-1}} = \mathrm{id}_{S^3}$. The same argument shows that R_z is also a homeomorphism. Thus we obtain from Proposition 85.17 and Lemma 85.16 a fiber bundle $p\colon S^7 \to S^4$ with fiber S^3. We leave it to the heroically inclined reader to verify that this S^3-bundle is equivalent to the S^3-bundle $q\colon S^7 \to \mathbb{H}\mathrm{P}^1 = S^4$ that we had constructed in the proof of Proposition 85.9.

Proof. We consider the following two subsets of $\Sigma(X)$:

$$C \;:=\; (X \times [-1, \tfrac{1}{2}]) \,/\, X \times \{-1\} \quad \text{and} \quad D \;:=\; (X \times [-\tfrac{1}{2}, 1]) \,/\, X \times \{1\}.$$

We refer to Figure 1052 for an illustration. Since the interiors of these two sets cover $\Sigma(X)$ it suffices to find trivializations of the map $h_\varphi\colon X * X \to \Sigma(X)$ with fiber X over C and over D.

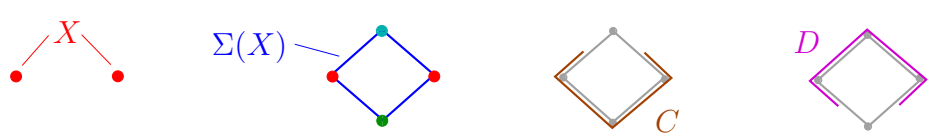

FIGURE 1052.

We start out with finding a trivialization over C.

[1447]Here the mnemonic device is that "L" should suggest "left-multiplication" and "R" should suggest "right-multiplication".

[1448]It is a good exercise to first verify that the map is actually well-defined.

Claim. The map

$$\begin{array}{rcl} \Psi\colon X\times C & \to & X*X \\ (x,[(y,t)]) & \mapsto & [(x,L_x^{-1}(y),\tfrac{1}{2}(t+1))] \end{array}$$

is continuous and it restricts to a homeomorphism onto $h_\varphi^{-1}(C)$.

By now the reader is surely aware of the fact that whenever we mix quotients with products we need to tread carefully. Thus let us first consider the maps

$$\begin{array}{rcl} \alpha\colon X\times X & \to & X\times X \\ (x,y) & \mapsto & (x,\varphi(x,y))=(x,L_x(y)) \end{array} \quad \text{and} \quad \begin{array}{rcl} \beta\colon X\times X & \to & X\times X \\ (x,y) & \mapsto & (x,L_x^{-1}(y)). \end{array}$$

Note that these two maps are inverses of one another. Also note that α is continuous by Lemma 1.53 (3). Furthermore note that α is a bijection, in fact the inverse is given by β. Since X is compact and Hausdorff we obtain from Lemma 1.55 and Proposition 1.40 that α is a homeomorphism. In particular $\beta=\alpha^{-1}$ is also continuous.

Next we consider the map

$$\begin{array}{rcl} \psi\colon X\times(X\times[-1,\tfrac{1}{2}]) & \to & X\times X\times[0,1] \\ (x,y,t) & \mapsto & (x,L_x^{-1}(y),\tfrac{1}{2}(t+1))=(\beta(x,y),\tfrac{1}{2}(t+1)). \end{array}$$

Since β is continuous we see that ψ is also continuous. Finally we consider the following commutative diagram

$$\begin{tikzcd} X\times X\times[-1,\tfrac{1}{2}] \arrow[r, "(x,y,t)\mapsto(x,[(y,t)])"] \arrow[d, "\psi"'] \arrow[dr, "f:=p\circ\psi"] & \overbrace{X\times\big((X\times[-1,\tfrac{1}{2}])\,/\,(X\times\{-1\})\big)}^{=X\times C} \arrow[d, "\Psi"] \\ X\times X\times[0,1] \arrow[r, two heads, "p(x,y,t):=[(x,y,t)]"'] & X*X. \end{tikzcd}$$

Claim. The map Ψ is continuous.

We had just seen that $f=p\circ\psi$ is continuous. Note that by Lemma 2.14 (1) the projection map $q\colon X\times[-1,\tfrac{1}{2}]\to(X\times[-1,\tfrac{1}{2}])\,/\,(X\times\{-1\})$ is a quotient map. Since X is compact and Hausdorff we know by Lemma 1.103 that X is locally compact.[1449] Thus it follows from Theorem 2.15 that the top horizontal map $\mathrm{id}_X\times q$ is a quotient map. Thus it follows from Lemma 2.16 (2) that f is continuous. This concludes the proof of the claim.

One easily verifies that Ψ defines a bijection

$$\Psi\colon \underbrace{X\times C}_{\subset X*X} \to \underbrace{h_\varphi^{-1}(C)}_{\subset\Sigma(X)}.$$

Since X is compact we know by Lemma 85.15 that the left-hand side is compact. By Lemma 15.2 (2) and our hypothesis that X is Hausdorff we know that the right-hand

[1449]If the reader is unhappy about using Lemma 1.103 we point out that in our application of the proposition the topological space will be $X=S^n$ and thus obviously locally compact.

side is Hausdorff. Therefore it follows from Proposition 1.40 that the continuous bijection $\Psi\colon X \times C \to h_\varphi^{-1}(C)$ is indeed a homeomorphism. This concludes the proof of the claim.

We consider the following diagram

$$\begin{tikzcd} X \times C \arrow[rr, "\Psi"] \arrow[dr, "(x,c)\mapsto c"'] & & h_\varphi^{-1}(C) \arrow[dl, "h_\varphi"] \\ & C. & \end{tikzcd}$$

It is straightforward to verify that this diagram commutes. Since the top map is homeomorphism by the previous claim we have found a trivialization of h_φ over C. We leave it as an exercise to the reader to make the minor modifications needed to find a trivialization of h_φ over D.[1450] □

Evidently the idea now is to replace the quaternions in the example on page 1977 by the octonions. In the following we recall the most salient bits from the discussion of octonions on page 1057. The octonions $\mathbb{O}$ are $\mathbb{R}^8$ together with an algebra structure over $\mathbb{R}$ that has the following properties:

(1) The octonions $\mathbb{O}$ are a division algebra, i.e. for all $a \neq 0$ and $b \in \mathbb{O}$ there exists an $x \in \mathbb{O}$ with $a \cdot x = b$ and a $y \in \mathbb{O}$ with $y \cdot a = b$.
(2) The algebra structure is neither commutative nor associative.
(3) Multiplication on $\mathbb{O}$ respects the euclidean norm, more precisely, given $a, b \in \mathbb{O}$ we have $\|a \cdot b\| = \|a\| \cdot \|b\|$.

It follows from (3) that the algebra multiplication induces a map $\varphi\colon S^7 \times S^7 \to S^7$.

Lemma 85.18. *Given any $z \in S^7$ the maps $L_z\colon S^7 \to S^7$ and $R_z\colon S^7 \to S^7$, as defined in Proposition 85.17, are homeomorphisms.*

Proof. First note that we can *not* recycle the argument from page 1977 since there we used that the quaternions are associative.

By Corollary 36.8 (2) it suffices to show that the maps L_z and R_z are injective. First we show that given any $z \in S^7$ the map $L_z\colon S^7 \to S^7$ is injective. So suppose that we have $a, b \in S^7$ with $L_z(a) = L_z(b)$. We obtain that

$$\begin{array}{ccccccccc} \|a-b\| & = & \|z\| \cdot \|a-b\| & = & \|z \cdot (a-b)\| & = & \|z \cdot a - z \cdot b\| & = & \|L_z(a) - L_z(b)\| & = & 0. \\ & \uparrow & & \uparrow & & \uparrow & & \uparrow & & \uparrow & \\ & \text{since } z \in S^7 & & \text{by (3)} & & \text{since } \mathbb{O} \text{ is an algebra} & & \text{by definition of } L_z & & \text{since } L_z(a) = L_z(b) & \end{array}$$

Thus we see that $a = b$. Almost the same argument shows that R_z is injective.[1451] □

Now we are basically done with the proof of Proposition 85.13.

[1450] Note that in this second part we will need to use that the maps $R_x\colon X \to X$ are homeomorphisms.

[1451] At first glance it might appear odd that we never used that the octonions are a division algebra, we only used the innocuous looking third property. But it is clear that (3) already implies that $\mathbb{O}$ has no zero-divisors. By Lemma 44.6 this forces $\mathbb{O}$ to be a division algebra.

Proof of Proposition 85.13. It follows immediately from Lemma 85.18, Proposition 85.17 and Lemma 85.16 that there exists a fiber bundle $p\colon S^{15} \to S^8$ with fiber S^7. $\square$

Exercises for Chapter 85.

Exercise 85.1. Let F be a topological space and let $p\colon Y \to B$ be an F-bundle. Suppose that the fiber F and the base space B are path-connected. Show directly, without making use of Proposition 85.2 (2), that the total space Y is also path-connected.

Exercise 85.2. Let $p\colon Y \to [0,1]$ be a bundle with fiber F. Show with your bare hands (i.e. without using Proposition 85.7) that p is trivial, i.e. show that p is equivalent to the trivial bundle $F \times [0,1] \to [0,1]$.

Exercise 85.3. Let X be a topological space and let $f_0, f_1\colon X \to X$ be homeomorphisms. Suppose that f_0 and f_1 are isotopic. Show that the two X-bundles $M(X, f_0) \to S^1$ and $M(X, f_1) \to S^1$ are equivalent.

Exercise 85.4. Let $f\colon \mathbb{R}^n \to \mathbb{R}^n$ be a diffeomorphism. Show that the corresponding $\mathbb{R}^n$-bundle $M(\mathbb{R}^n, f) \to S^1$ is equivalent to an n-dimensional vector bundle.
Hint: Use Lemma 32.25 and Lemma 85.3 (2), the latter is a. k. a. Exercise 85.3.

Exercise 85.5. The Ehresmann Fibration Theorem says the following:
Let $f\colon M \to N$ be a smooth map between closed manifolds. We suppose that N is connected. If f is a submersion, i.e. if given any $P \in M$ the map $Df_P\colon T_PM \to T_{f(P)}N$ is an epimorphism, then f is a fiber bundle. Provide a proof using the Submersion Theorem 3.46.

Exercise 85.6. Use the Ehresmann Fibration Theorem, see Exercise 85.5, to give an alternative proof of the fact that the Hopf map $S^3 \to \mathbb{C}\mathrm{P}^1$ defines an S^1-bundle over $\mathbb{C}\mathrm{P}^1 = S^2$.

Exercise 85.7. Let $n \in \mathbb{N}$. We consider the map

$$\begin{array}{rcl} \varphi\colon\ \mathrm{U}(n) = \{A \in M(n \times n, \mathbb{C}) \,|\, A \cdot \overline{A}^T = \mathrm{id}\} & \to & \mathbb{C} \setminus \{0\} \\ A & \mapsto & \det(A). \end{array}$$

(a) Show that φ takes values in S^1.
(b) Show that the map $\varphi\colon \mathrm{U}(n) \to S^1$ is a fiber bundle.
Hint: You can use the Ehresmann Fibration Theorem from Exercise 85.5.

Exercise 85.8. Let X be a topological space and let $f\colon X \to X$ be a homeomorphism. By the discussion on page 1963 and Proposition 85.2 we know that the map

$$\begin{array}{rcl} M(X,f) = X \times [0,1]/(x,0) \sim (f(x),1) & \to & S^1 \\ [(x,t)] & \mapsto & e^{2\pi i t} \end{array}$$

is a fibration. We make the obvious identification $X = X \times \{0\} \subset M(X, f)$. Let $k \in \mathbb{N}_0$ and let $\alpha\colon [0,1] \to S^1$ be the usual loop given by $\alpha(t) = e^{2\pi i t}$. By Proposition 83.5 and Lemma 30.2 we get a well-defined map

$$\Theta(\alpha)_*\colon H_k(X;\mathbb{Z}) \ \to \ H_k(X;\mathbb{Z}).$$

Show that $\Theta(\alpha)_* = (f_*)^{-1}$.

Exercise 85.9. Let W be an n-dimensional manifold and let K be a compact proper connected k-dimensional submanifold with $k \leq n-3$. Show that the inclusion induced map $\pi_1(W \setminus K) \to \pi_1(W)$ is an isomorphism.
Hint: Use Lemma 13.12 (3).

Exercise 85.10. The same way that we defined the infinite complex projective space $\mathbb{C}\mathrm{P}^\infty$, see page 655, we define the infinite quaternionic projective space $\mathbb{H}\mathrm{P}^\infty$ as the direct limit of the finite dimensional quaternionic projective spaces $\mathbb{H}\mathrm{P}^k$. Show that for any $i \in \mathbb{N}_{\geq 2}$ we have an isomorphism $\pi_i(\mathbb{H}\mathrm{P}^\infty) \cong \pi_{i-1}(S^3)$.

Exercise 85.11. Let $p\colon S^3 \to S^2$ the Hopf fibration. In Proposition 85.9 we saw that it is an S^1-fiber bundle. We consider the connecting homomorphism $\partial\colon \pi_2(S^2) \to \pi_1(S^1)$ of the long exact sequence of homotopy groups from Proposition 85.2 (2). Show, just using the definition of the connecting homomorphism, that $\partial([\mathrm{id}_{S^2}]) = [\mathrm{id}_{S^1}]$.

Exercise 85.12. Show that for any choice of $m, n \in \mathbb{N}_0$ there exists a homeomorphism $\overline{B}^m * \overline{B}^n \xrightarrow{\cong} \overline{B}^{m+n+1}$.

Exercise 85.13. We let $X = S^1$ be the standard circle in the xy-plane of $\mathbb{R}^3$ and we let Y be the circle in $S^3 = \mathbb{R}^3 \cup \{\infty\}$ that is given by the z-axis together with the point $\{\infty\}$. (See Figure 1053 for a simple illustration.) Show that we can "continuously" connect every point on X to every point Y such that the paths fill out S^3. In other words, try to visualize the fact that $S^1 * S^1 \cong X * Y$ is homeomorphic to S^3.

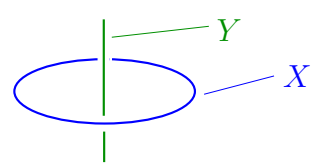

FIGURE 1053.

Exercise 85.14. Show that the homotopy groups of S^2 and $S^3 \times \mathbb{C}\mathrm{P}^\infty$ are isomorphic.

86. Homotopy groups of Lie groups

In this chapter our focus will lie on the study of the homotopy groups of the matrix groups $\mathrm{O}(n)$ and $\mathrm{U}(n)$. Later on in the section we will see that we should also define a third type of groups, namely the groups $\mathrm{Sp}(n)$ which can be viewed as the quaternion analogue of $\mathrm{O}(n)$ and $\mathrm{U}(n)$.

Since these groups are Lie groups and since this structure is helpful in our study of $\mathrm{O}(n)$ and $\mathrm{U}(n)$ we first give a short introduction to Lie groups.

86.1. **Topological groups and Lie groups.** First we recall the following definition from page 139.

Definition. A *topological group* is a topological space X together with a group structure such that the two maps

$$\begin{array}{rcl} X\times X & \to & X \\ (x,y) & \mapsto & x\cdot y \end{array} \quad \text{and} \quad \begin{array}{rcl} X & \to & X \\ x & \mapsto & x^{-1} \end{array}$$

are continuous. A *morphism between topological groups* X and Y is a homomorphism $f\colon X\to Y$ that is furthermore continuous.

Examples.

(1) On page 140 we already saw that for any $n\in\mathbb{N}$ the matrix groups $\mathrm{SL}(n,\mathbb{R})$, $\mathrm{O}(n)$, $\mathrm{SO}(n)$, $\mathrm{GL}(n,\mathbb{C})$, $\mathrm{U}(n)$ and $\mathrm{SU}(n)$ are topological groups.

(2) Let X be a topological space and let $x_0\in X$ be a base point. We consider the loop space $\Omega(X,x_0)$, i.e. the set

$$\Omega(X,x_0) \;=\; \{\gamma\colon [0,1]\to X \mid \gamma(0)=\gamma(1)=x_0\}/\text{homotopy}$$

equipped with the compact-open topology. As in Exercise 83.6 we equip the set $\pi_1(X,x_0)=\Omega(X,x_0)/\sim$ with the quotient topology, i.e. we view $\pi_1(X,x_0)$ as a topological space. Evidently $\pi_1(X,x_0)$ admits a group structure, but somewhat surprisingly, the multiplication map $\pi_1(X,x_0)\times\pi_1(X,x_0)\to\pi_1(X,x_0)$ is in general *not* continuous. In fact such an example is given by the Hawaiian Earrings, introduced in Exercise 26.6. We refer to [Fab2] for details.[1452]

We leave the elementary proof of the following lemma to the reader.

Lemma 86.1. *Let G be a topological group and let H be a subgroup of G. The map*

$$\begin{array}{rcl} G\times H & \to & G \\ (g,h) & \mapsto & g\cdot h \end{array}$$

defines a right-action of H on G that is free and continuous.

To avoid any misunderstanding we introduce the following convention.

[1452]In fact, as is pointed out in [Fab2], the failure of $\pi_1(X,x_0)$ to be a topological group is another instance of the phenomenon, discussed in Section 2.2, that in general product and quotient topologies do not mix well.

Convention. Let G be a topological group and let H be a subgroup. We denote by G/H the topological space that is given by the equivalence relation[1453]

$$g_1 \sim g_2 \quad \Longleftrightarrow \quad \text{there exists an } h \in H \text{ with } g_1 \cdot h = g_2.$$

The following definition of a Lie group is quite similar to the above definition of a topological group.

Definition. A *Lie group* is a manifold X with empty boundary together with a group structure such that the two maps[1454]

$$\begin{array}{rcl} X \times X & \to & X \\ (x,y) & \mapsto & x \cdot y \end{array} \quad \text{and} \quad \begin{array}{rcl} X & \to & X \\ x & \mapsto & x^{-1} \end{array}$$

are smooth.

Remark.

(1) It follows immediately from Lemma 3.15 (2) that a Lie group is also a topological group.
(2) As we will see in Exercise 86.2, strictly speaking one does not need to demand that the map $x \mapsto x^{-1}$ is smooth, since it follows already from the other properties.

Examples.

(1) It is straightforward to see that the manifold $\mathbb{R}$ with the group structure given by addition and the manifold S^1 with the group structure given by multiplication are Lie groups.
(2) The product $G_1 \times G_2$ of two Lie groups G_1 and G_2 admits a canonical manifold structure by Proposition 3.42 and the group structures on G_1 and G_2 define a group structure on $G_1 \times G_2$. One can easily verify that $G_1 \times G_2$ is again a Lie group. In particular the torus $S^1 \times S^1$ is a Lie group.

As mentioned in the beginning of this chapter, we are now interested in the homotopy groups of the groups

$$\begin{aligned} \mathrm{O}(n) &= \{A \in M(n \times n, \mathbb{R}) \,|\, A^T A = \mathrm{id}\} \\ \mathrm{U}(n) &= \{A \in M(n \times n, \mathbb{C}) \,|\, \overline{A}^T A = \mathrm{id}\}. \end{aligned}$$

As we will see later on, even if we are only interested in these groups it makes sense to extend our gaze and to consider the quaternion analogue of $\mathrm{O}(n)$ and $\mathrm{U}(n)$:

Definition. Let $n \in \mathbb{N}$. We define.[1455]

$$\mathrm{Sp}(n) = \{A \in M(n \times n, \mathbb{H}) \,|\, \overline{A}^T A = \mathrm{id}\}.$$

[1453]The point of this convention is that in principle G/H could mean the quotient of the topological space G by the subset H.

[1454]Here we equip $X \times X$ with the product manifold structure introduced in Proposition 3.42.

[1455]Recall that the conjugate of a quaternion $h = a \cdot 1 + b \cdot i + c \cdot j + d \cdot k$ is defined as $\overline{h} = a \cdot 1 - b \cdot i - c \cdot j - d \cdot k$. Given a matrix $A = (a_{ij})$ over $\mathbb{H}$ we define $\overline{A} = (\overline{a}_{ij})$.

We will first discuss $\mathrm{Sp}(n)$ a little bit before we settle on a name for it:

Lemma 86.2.

(1) *We have* $\mathrm{Sp}(1) = S^3$.
(2) *Let* $n \in \mathbb{N}$. *Matrix multiplication turns* $\mathrm{Sp}(n)$ *into a group.*
(3) *Let* $n \in \mathbb{N}$. *We write* $J = \begin{pmatrix} 0 & \mathrm{id}_n \\ -\mathrm{id}_n & 0 \end{pmatrix}$. *The map*

$$\begin{array}{rcl} \Phi\colon \mathrm{Sp}(n) & \to & \{X \in \mathrm{U}(2n) \mid JXJ^{-1} = \overline{X}\} \\ P & \mapsto & \begin{pmatrix} A & B \\ -\overline{B} & \overline{A} \end{pmatrix} \quad \textit{where } A, B \in M(n \times n; \mathbb{C}) \textit{ with}^{1456} P = A + Bj \end{array}$$

is a group isomorphism.

Proof.

(1) In Lemma 44.1 we saw that for any quaternion $h \in \mathbb{H}$ we have $h \cdot \overline{h} = \|h\|^2$. It follows immediately that $\mathrm{Sp}(1) = S^3$.
(2) We start out with the following observation: A straightforward calculation[1457] shows that for any two matrices $A, B \in M(n \times n, \mathbb{H})$ we have $\overline{(AB)}^T = \overline{B}^T \overline{A}^T$. Now we turn to the proof that $\mathrm{Sp}(n)$ is a group:
   (a) The fact that $\mathbb{H}$ is associative implies that the multiplication of matrices in $M(n \times n, R)$ is associative.
   (b) The identity matrix is as usual a neutral element.
   (c) Given $A \in \mathrm{Sp}(n)$ we have by definition that $\overline{A}^T A = \mathrm{id}$, i.e. $\overline{A}^T$ is a left-inverse. The above observation implies that $\overline{A}^T$ is also a right-inverse.
   (d) It follows from the above observation that $\mathrm{Sp}(n)$ is closed under matrix multiplication and taking inverses.

   We have thus shown that $\mathrm{Sp}(n)$ is indeed a group.
(3) We will only use this isomorphism to justify the name for $\mathrm{Sp}(n)$, otherwise it will not play a role. Therefore we will not provide the fairly elementary proof of this statement, instead we refer to [Bre, p. 103] for the proof. □

Not surprisingly we will now see that $\mathrm{O}(n)$, $\mathrm{U}(n)$ and $\mathrm{Sp}(n)$ are Lie groups.

Lemma 86.3.

(1) *Let* $n \in \mathbb{N}$.
   (a) *The set* $\mathrm{O}(n)$ *is a submanifold of* $M(n \times n, \mathbb{R}) = \mathbb{R}^{n^2}$ *of dimension* $\frac{1}{2}n(n-1)$.
   (b) *The set* $\mathrm{U}(n)$ *is a submanifold of* $M(n \times n, \mathbb{C}) = \mathbb{C}^{n^2} = \mathbb{R}^{2n^2}$ *of dimension* n^2.

[1456] It follows from $i \cdot j = k$ that any quaternion $a \cdot 1 + b \cdot i + c \cdot j + d \cdot k$ can be uniquely written as $(a \cdot 1 + b \cdot i) + (c \cdot 1 + d \cdot i) \cdot j$ where $a \cdot 1 + b \cdot i$ and $c \cdot 1 + d \cdot i$ are complex numbers. The same statement applies to matrices.

[1457] In the calculation we need to use the fact, mentioned in Lemma 44.1 (3), that for quaternions $w, z \in \mathbb{H}$ we have $\overline{z \cdot w} = \overline{w} \cdot \overline{z}$.

(c) *The set* $\mathrm{Sp}(n)$ *is a submanifold of* $M(n \times n, \mathbb{H}) = \mathbb{H}^{n^2} = \mathbb{R}^{4n^2}$ *of dimension* $2n^2 + n$.

Furthermore, if we view $\mathrm{O}(n)$ *as a subspace of* $\mathrm{O}(n+1)$ *in the obvious way, then* $\mathrm{O}(n)$ *is a submanifold of* $\mathrm{O}(n+1)$. *The same statements apply to* $\mathrm{U}(n)$ *and* $\mathrm{Sp}(n)$.

(2) $\mathrm{O}(n)$, $\mathrm{U}(n)$ *and* $\mathrm{Sp}(n)$, *viewed as manifolds in their own right, are closed, in particular they are compact.*

(3) *The usual matrix multiplication turns* $\mathrm{O}(n)$, $\mathrm{U}(n)$ *and* $\mathrm{Sp}(n)$ *into Lie groups.*

Remark.

(1) Recall that on page 1707 we defined the symplectic group $\mathrm{Sp}(2g, \mathbb{Z})$ as follows:

$$\mathrm{Sp}(2g, \mathbb{Z}) \;=\; \{A \in \mathrm{GL}(2g, \mathbb{Z}) \,|\, A^T J A = A\} \quad \text{where} \quad J \;=\; \begin{pmatrix} 0 & \mathrm{id}_g \\ -\mathrm{id}_g & 0 \end{pmatrix}.$$

This definition, together with Lemmas 86.2 and 86.3, leads us to calling $\mathrm{Sp}(n)$ the *n-th compact symplectic group.*

(2) The statements regarding the groups $\mathrm{O}(n)$ and $\mathrm{U}(n)$ are mostly already contained in Lemma 3.45.

Proof. In Lemma 3.45 we had basically proved statements (1) and (2) for the groups $\mathrm{O}(n)$ and $\mathrm{U}(n)$. The only aspect that we did not mention explicitly so far is that $\mathrm{O}(n)$ is a submanifold of $\mathrm{O}(n+1)$. We leave it to the reader to verify that this statement holds. The proof of (1) and (2) for $\mathrm{Sp}(n)$ is basically the same.

In Lemma 1.108 we showed that $\mathrm{O}(n)$ and $\mathrm{U}(n)$ are topological groups. Almost the same argument given in that proof shows that matrix multiplication and taking inverses are smooth maps. This implies that $\mathrm{O}(n)$ and $\mathrm{U}(n)$ are Lie groups. Furthermore it is clear that multiplication in $\mathrm{Sp}(n)$ is smooth. It remains to show that the map

$$\begin{array}{rcl} \mathrm{Sp}(n) & \to & \mathrm{Sp}(n) \\ A & \mapsto & A^{-1} \end{array}$$

is smooth. We will show this fact in Exercise 86.4. □

Basically by definition we have $\mathrm{O}(1) = S^0$ and $\mathrm{U}(1) = S^1$, furthermore by Lemma 86.2 (1) we have $\mathrm{Sp}(1) = S^3$. Thus it follows from Lemma 86.3 that these three spheres can be viewed as Lie groups. The question arises, whether perhaps other (all?) spheres can be equipped with the structure of a Lie group. The following lemma gives an easy way to rule out the existence of Lie group structures on some manifolds.

Lemma 86.4. *Every Lie group is parallelizable.*[1458]

Examples. Recall that on page 1788 we saw that $2n$-dimensional spheres with $n \geq 1$ are not parallelizable. Furthermore t on page 1788 we showed that for $g \neq 1$ the surface of genus g is not parallelizable. Thus it follows from Lemma 86.4 that these spheres and surfaces cannot be equipped with a Lie group structure.

[1458]Recall that according to the definition on page 1786 a manifold is called parallelizable if its tangent bundle is trivial.

Sketch of proof. Let G be an n-dimensional Lie group with trivial element e. We denote by $R_g\colon G \to G$ the map that is given by right-multiplication by g. Since G is a Lie group this map is in fact a diffeomorphism. The map

$$\begin{array}{rcl} G \times T_eG & \to & TG = \{(g,h) \,|\, g \in G \text{ and } w \in T_hG\} \\ (g,v) & \mapsto & (g,(R_g)_*(v)) \end{array}$$

is an isomorphism of vector bundles. (This statement is basically obvious, except that perhaps it is not completely clear why the map is continuous, we refer to [Le2, Corollary 8.39] for more details.) But this shows that G is parallelizable. □

The following lemma gives us more examples of Lie groups.

Lemma 86.5. *Let G be a Lie group and let K be a finite normal subgroup. Then the quotient G/K admits a unique manifold structure such that the projection $G \to G/K$ is a local diffeomorphism. Furthermore the group structure on the quotient group G/K defines a Lie group structure on G/K.*

Example. It follows from Lemma 86.5 that for any $n \in \mathbb{N}$ the quotients $\mathrm{SU}(n)/\{\pm \mathrm{id}\}$ and $(\mathrm{SU}(n) \times \mathrm{SU}(n))/\{\pm(\mathrm{id},\mathrm{id})\}$ are Lie groups.

Proof. In Lemma 86.1 we already saw that the action of K on G is free and continuous. Since G is a Lie group one also sees that the action is smooth. Finally, since G is finite we get for free that the action is proper. Thus we obtain from Proposition 3.25 that G/K admits a unique manifold structure (without boundary) such that the projection $G \to G/K$ is a local diffeomorphism. We leave it to the reader to verify that the induced multiplication map $G/K \times G/K \to G/K$ is again smooth. □

Above we have seen that subgroups of matrix groups often give rise to Lie groups. Perhaps somewhat surprisingly, in a sense, all compact Lie groups arise that way. More precisely, the following theorem holds:[1459]

Theorem 86.6. *Any compact Lie group is isomorphic (in the obvious sense) to a Lie subgroup of $\mathrm{GL}(n,\mathbb{R})$ for some $n \in \mathbb{N}$.*

The theorem is a consequence of the so-called Peter-Weyl Theorem. We only stated the theorem for "general culture". We will not make use of it and thus we refer to [BtD, Theorem III.4.1] or alternatively to [Sep, Theorem 3.28] for a proof.

86.2. **The homotopy groups of $\mathrm{O}(n)$, $\mathrm{U}(n)$ and $\mathrm{Sp}(n)$.** In this chapter we want to see what we can say about the homotopy groups of $\mathrm{O}(n)$, $\mathrm{U}(n)$ and $\mathrm{Sp}(n)$.

Convention.

[1459] One could view Theorem 86.6 as an analogue of Proposition 65.11 or of the Whitney Embedding Theorem 65.18.

(1) Given $n \in \mathbb{N}$ we have the obvious monomorphism

$$\begin{array}{rcl} \mathrm{O}(n) & \to & \mathrm{O}(n+1) \\ A & \mapsto & \begin{pmatrix} A & 0 \\ 0 & 1 \end{pmatrix} \end{array}$$

Often we will use it to identify $\mathrm{O}(n)$ with its image in $\mathrm{O}(n+1)$. Similarly we view $\mathrm{U}(n)$ as a subgroup of $\mathrm{U}(n+1)$ and we view $\mathrm{Sp}(n)$ as a subgroup of $\mathrm{Sp}(n+1)$.

(2) We will view any subgroup of $\mathrm{GL}(n,\mathbb{R})$, $\mathrm{GL}(n,\mathbb{C})$ or $\mathrm{GL}(n,\mathbb{H})$ as a topological space that is equipped with the base point given by the identity matrix. Thus in the remainder of this chapter we will suppress the base point in the discussion of fundamental groups.

The following lemma evidently uses the convention from page 1983.

Lemma 86.7. *Let $n \in \mathbb{N}$. The maps*

$$\begin{array}{r} \mathrm{O}(n+1)/\mathrm{O}(n) \xrightarrow{p} S^n \\ [(v_1 \ldots v_{n+1})] \mapsto v_{n+1} \end{array} \qquad \begin{array}{r} \mathrm{U}(n+1)/\mathrm{U}(n) \xrightarrow{q} S^{2n+1} \\ [(v_1 \ldots v_{n+1})] \mapsto v_{n+1} \end{array} \quad \textit{and} \quad \begin{array}{r} \mathrm{Sp}(n+1)/\mathrm{Sp}(n) \xrightarrow{r} S^{4n+3} \\ [(v_1 \ldots v_{n+1})] \mapsto v_{n+1} \end{array}$$

are well-defined and they are homeomorphisms.

Proof.

(1) First we show that the given map $p\colon \mathrm{O}(n+1)/\mathrm{O}(n) \to S^n$ is well-defined. To do so we consider the map[1460]

$$\begin{array}{rcl} \mathrm{O}(n+1) & \to & S^n \\ V := (v_1 \ldots v_{n+1}) & \mapsto & v_{n+1} = V \cdot e_{n+1}. \end{array}$$

Note that if we multiply V on the right by a matrix of the form $\begin{pmatrix} A & 0 \\ 0 & 1 \end{pmatrix}$, then the multiplication with e_{n+1} is not affected. Therefore the above map $\mathrm{O}(n+1) \to S^n$ descends to a map $\mathrm{O}(n+1)/\mathrm{O}(n) \to S^n$ which is exactly the map p we consider in the lemma. This shows that p is well-defined.

Also note that basic linear algebra tells us that given any point $v_{n+1} \in S^n$ there exist vectors $v_1, \ldots, v_n \in \mathbb{R}^n$ such that $v_1, \ldots, v_n, v_{n+1}$ form an orthonormal basis $\mathbb{R}^{n+1}$. This shows that the given map p is a surjection. Similarly, elementary linear algebra shows that p is injective. Finally note that S^n is Hausdorff and note that Lemmas 86.3 and 1.37 imply that $\mathrm{O}(n+1)/\mathrm{O}(n)$ is compact. Therefore it follows from Proposition 1.40 that the map p is indeed a homeomorphism.

(2),(3) The proof for (2) and (3) is basically identical to the proof in (1), except that the linear algebra aspects require slightly more thought. □

The following proposition gives us new interesting examples of fiber bundles.

[1460] It follows easily from $A^T A = \mathrm{id}$ that every column v of A satisfies $\|v\| = 1$, i.e. every column lies in S^n.

Proposition 86.8. *Let $n \in \mathbb{N}$. The maps*

$$\begin{array}{rcl} \mathrm{O}(n+1) & \to & S^n \\ (v_1 \ldots v_{n+1}) & \mapsto & v_{n+1} \end{array} \qquad \begin{array}{rcl} \mathrm{U}(n+1) & \to & S^{2n+1} \\ (v_1 \ldots v_{n+1}) & \mapsto & v_{n+1} \end{array} \quad \textit{and} \quad \begin{array}{rcl} \mathrm{Sp}(n+1) & \to & S^{4n+3} \\ (v_1 \ldots v_{n+1}) & \mapsto & v_{n+1} \end{array}$$

are bundle projections with fibers given by $\mathrm{O}(n)$, $\mathrm{U}(n)$ *and* $\mathrm{Sp}(n)$ *respectively.*

Remark. Without too much effort one can show that the bundle projections $\mathrm{O}(n+1) \to S^n$ with fiber $\mathrm{O}(n)$ and $\mathrm{U}(n+1) \to S^{2n+1}$ with fiber $\mathrm{U}(n)$ from the proposition restrict to bundle projections $\mathrm{SO}(n+1) \to S^n$ with fiber $\mathrm{SO}(n)$ and $\mathrm{SU}(n+1) \to S^{2n+1}$ with fiber $\mathrm{SU}(n)$.

We will outline two approaches to proving Proposition 86.8. The first approach relies on the following proposition that shows more generally that Lie groups (and sometimes topological groups) give rise to fiber bundles.

Proposition 86.9. $(*)$

(1) *Let G be a Lie group. If H is a closed subgroup of G, then the projection $G \to G/H$ is a bundle projection with fiber H.*
(2) *Let G be a topological group and H be a closed subgroup of G. If H admits the structure of a Lie group, then the projection $G \to G/H$ is a bundle projection with fiber H.*

Remark. One might hope that Proposition 86.9 (1) generalizes to all topological groups and subgroups. But as shown in [Karu, p. 347], there exists a topological group G and a closed subgroup H such that the projection $G \to G/H$ is not a bundle projection.

Proof of Proposition 86.9 $(*)$.

(1) This statement is proved in [Kiri, Theorem 2.11]. Alternatively, if G is a closed subgroup of some $\mathrm{GL}(n, \mathbb{C})$, then the proposition is proved in [Bre, p. 110].
(2) This statement is proved in [Pal4, Corollary 4.1]. □

First proof of Proposition 86.8 $(*)$. These three statements are an immediate consequence of Lemma 86.7 and Proposition 86.9 (1). □

Second proof of Proposition 86.8. In the following we give an outline of a "bare hands only" proof that the first projection map $p\colon \mathrm{O}(n+1) \to S^n$ is indeed a bundle projection with fiber $\mathrm{O}(n)$. We leave it to the reader to modify the proof to deal with the two other cases.[1461]

Thus let $n \in \mathbb{N}$. As usual we equip $\mathbb{R}^{n+1}$ with the euclidean inner product $\langle\, , \rangle$. In this proof we identify $\mathrm{O}(n+1)$ with the group of isometries of $(\mathbb{R}^{n+1}, \langle\, , \rangle)$. More precisely, we do not distinguish in the notation between an isometry of $(\mathbb{R}^{n+1}, \langle\, , \rangle)$ and the matrix it represents with respect to the standard basis of $\mathbb{R}^{n+1}$.

We consider the two compact subsets

$$V \;=\; \{(x_1, \ldots, x_{n+1}) \in S^n \,|\, x_{n+1} \leq \tfrac{1}{2}\} \quad \text{and } W \;=\; \{(x_1, \ldots, x_{n+1}) \in S^n \,|\, x_{n+1} \geq -\tfrac{1}{2}\}.$$

[1461] Alternatively the reader can look up the proof of Proposition 86.9 (1).

We continue with the following claim.

Claim. Let $P \in V$. We write $W(P) := \operatorname{span}\{e_{n+1}, P\}$. There exists a unique orientation-preserving isometry $\alpha(P)$ of $\mathbb{R}^{n+1} = W(P) \oplus W(P)^\perp$ that satisfies the following two conditions:

(1) the restriction of $\alpha(P)$ to $W(P)$ is an orientation-preserving isometry of $W(P)$ that sends e_{n+1} to P,
(2) it equals the identity on $W(P)^\perp$.

We illustrate the definition of $\alpha(P)$ in Figure 1054. In the 3-dimensional setting the isometry $\alpha(P)$ is the unique rotation around "the $W(P)^\perp$-axis" that sends e_{n+1} to P.

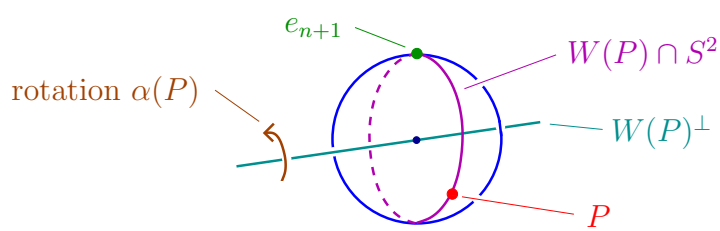

FIGURE 1054.

Note that $(W(P), \langle\,,\,\rangle)$ and $(\mathbb{R}^2, \langle\,,\,\rangle)$ are both positive-definite and symmetric forms. Thus it follows from Exercise 72.1 that both forms are also non-singular. Therefore we obtain from Sylvester's Theorem 72.10 that the two forms $(W(P), \langle\,,\,\rangle)$ and $(\mathbb{R}^2, \langle\,,\,\rangle)$ are isometric. In the latter case the orientation-preserving isometries are given by $\mathrm{SO}(2)$. Since $\mathrm{SO}(2) = S^1$ acts freely and transitively on S^1 we see that given any two points $X, Y \in \mathbb{R}^2$ with $\|X\| = \|Y\|$ there exists a unique orientation-preserving isometry β of $(\mathbb{R}^2, \langle\,,\,\rangle)$ with $\beta(X) = Y$. Since $(W(P), \langle\,,\,\rangle)$ is isometric to $(\mathbb{R}^2, \langle\,,\,\rangle)$ the same uniqueness statement applies to $W(P)$ and the two points $e_{n+1}, P \in W(P)$. The claim immediately follows from this observation.

We leave it as an exercise to verify that the map $\alpha\colon V \to \mathrm{O}(n+1)$ that we had just defined is indeed continuous. Next we consider the map

$$\begin{aligned} f\colon V \times \mathrm{O}(n) &\to \mathrm{O}(n+1) \\ (P, A) &\mapsto \alpha(P) \circ \begin{pmatrix} A & 0 \\ 0 & 1 \end{pmatrix}. \end{aligned}$$

An entertaining exercise in linear algebra shows that the map f restricts to a bijection $V \times \mathrm{O}(n) \to p^{-1}(V)$. Since V and $\mathrm{O}(n)$ are compact we obtain from Proposition 1.40 that f defines a homeomorphism $V \times \mathrm{O}(n) \to p^{-1}(V)$.

Now recall that for any $P \in V$ we have, by design, that $\alpha(P)(e_{n+1}) = P$. Using this observation we see almost immediately that the following diagram commutes:

$$\begin{tikzcd} V \times \mathrm{O}(n) \arrow[rr, "f", "\cong"'] \arrow[dr, "(P,A)\mapsto P"'] & & p^{-1}(V) \arrow[dl, "p", "B\mapsto B\cdot e_{n+1}"'] \\ & V. & \end{tikzcd}$$

This shows that we have found a trivialization of p over V. With very minor modifications one can also find a trivialization of p over W. Since the interiors of V and W cover all of S^n we see that these two trivializations show that $p\colon \mathrm{O}(n+1) \to S^n$ is indeed a fiber bundle with fiber $\mathrm{O}(n)$. □

Now we can continue with the actual study of the homotopy groups of $\mathrm{O}(n)$, $\mathrm{U}(n)$ and $\mathrm{Sp}(n)$.

Proposition 86.10. *Let $n \in \mathbb{N}$.*

(1) *The inclusion induced map*[1462]

$$\pi_k(\mathrm{O}(n)) \;\to\; \pi_k(\mathrm{O}(n+1)) \quad \textit{is an} \quad \begin{cases} \textit{isomorphism for } k < n-1, \\ \textit{epimorphism for } k = n-1. \end{cases}$$

(2) *The inclusion induced map*

$$\pi_k(\mathrm{U}(n)) \;\to\; \pi_k(\mathrm{U}(n+1)) \quad \textit{is an} \quad \begin{cases} \textit{isomorphism for } k < 2n, \\ \textit{epimorphism for } k = 2n. \end{cases}$$

(3) *The inclusion induced map*

$$\pi_k(\mathrm{Sp}(n)) \;\to\; \pi_k(\mathrm{Sp}(n+1)) \quad \textit{is an} \quad \begin{cases} \textit{isomorphism for } k < 4n+2, \\ \textit{epimorphism for } k = 4n+2. \end{cases}$$

Example.

(1) We know that $\mathrm{U}(1) = S^1$. Thus we obtain from Proposition 86.10 (2) that all unitary groups $\mathrm{U}(n)$ are path-connected.
(2) Recall that in Lemma 86.2 (1) we pointed out that $\mathrm{Sp}(1) = S^3$. Thus we obtain from Proposition 86.10 (3) that all compact symplectic groups $\mathrm{Sp}(n)$ are simply connected.

Proof. We prove the first statement. The proofs of the remaining two statements are almost identical.[1463] By Proposition 86.8 we have a bundle projection $p\colon \mathrm{O}(n+1) \to S^n$ with fiber

[1462]Recall that in Lemma 1.96 (1) we saw that $\mathrm{O}(n)$ is disconnected. Thus in principle it is not completely clear what we mean by $\pi_k(\mathrm{O}(n))$. But, as we pointed out on page 1987, we always consider $\mathrm{O}(n)$ as equipped with the base point that is given by the identity. Also note that it follows easily from Lemma 1.110 that for a topological group the isomorphism type of the homotopy groups does not depend on the choice of a base point.

[1463]The only catch is that one needs to be careful about the degrees involved.

$\mathrm{O}(n)$. From Proposition 85.2 we obtain a long exact sequence of the form

$$\ldots \to \pi_{k+1}(S^n) \xrightarrow{\partial} \pi_k(\mathrm{O}(n)) \to \pi_k(\mathrm{O}(n+1)) \to \pi_k(S^n) \xrightarrow{\partial} \ldots$$

The desired statement now follows from the familiar fact that by Proposition 28.9 we have $\pi_i(S^k) = 0$ for $i < k$. □

As a corollary to Proposition 86.10 (1) we can now finally answer Question 37.5. More precisely, we have the following proposition.

Proposition 86.11.

(1) *For any $n \in \mathbb{N}$ the inclusions $i\colon \mathrm{SO}(n) \to \mathrm{SL}(n,\mathbb{R})$ and $j\colon \mathrm{SL}(n,\mathbb{R}) \to \mathrm{GL}_+(n,\mathbb{R})$*[1464] *are homotopy equivalences.*

(2) *For any $n \geq 3$ we have isomorphisms*

$$\mathbb{Z}_2 \cong \pi_1(\mathrm{SO}(n)) \xrightarrow[i_*]{\cong} \pi_1(\mathrm{SL}(n,\mathbb{R})) \xrightarrow[j_*]{\cong} \pi_1(\mathrm{GL}_+(n,\mathbb{R})).$$

(3) *In each of the three fundamental groups of (2) the unique non-trivial element is represented by the loop*

$$\begin{array}{rcl} S^1 & \to & \mathrm{SO}(n) \\ e^{i\varphi} & \mapsto & \begin{pmatrix} \cos(\varphi) & -\sin(\varphi) & 0 \\ \sin(\varphi) & \cos(\varphi) & 0 \\ 0 & 0 & \mathrm{id}_{n-2} \end{pmatrix}. \end{array}$$

Proof.

(1) We proved this statement in Lemma 10.7.

(2) Let $n \geq 3$. We have isomorphisms

$$\begin{array}{ccccccc} \mathbb{Z}_2 & \cong & \pi_1(\mathrm{SO}(3),\mathrm{id}) & \cong & \pi_1(\mathrm{SO}(n),\mathrm{id}) & \xrightarrow[i_*]{\cong} & \pi_1(\mathrm{SL}(n,\mathbb{R}),\mathrm{id}) \xrightarrow[j_*]{\cong} \pi_1(\mathrm{GL}_+(n,\mathbb{R}),\mathrm{id}). \\ \uparrow & & \uparrow & & \uparrow & & \uparrow \\ \text{Corollary 37.4} & & \text{by Proposition 86.10 and the fact that by Lemma 1.96 (1) SO}(k) \text{ is the path-component of O}(k) \text{ that contains id} & & & & \text{by (1) and Proposition 9.12 (1)} \end{array}$$

(3) We consider the loop

$$\begin{array}{rcl} \gamma\colon S^1 & \to & \mathrm{SO}(2) \\ e^{i\varphi} & \mapsto & \begin{pmatrix} \cos(\varphi) & -\sin(\varphi) \\ \sin(\varphi) & \cos(\varphi) \end{pmatrix}. \end{array}$$

Since $\mathrm{SO}(2) = S^1$ we know by Proposition 7.18 that γ represents a generator of $\pi_1(\mathrm{SO}(2))$. By Proposition 86.10 we know that the inclusion $\mathrm{SO}(2) \to \mathrm{SO}(n)$ induces an epimorphisms of fundamental groups. It follows immediately that the loop given in (3) is indeed a generator of $\pi_1(\mathrm{SO}(n))$. Since the inclusions i and j induce

[1464] Recall that we write $\mathrm{GL}_+(n,\mathbb{R}) = \{A \in \mathrm{GL}(n,\mathbb{R}) \mid \det(A) > 0\}$.

isomorphisms of fundamental groups we see that the given loop also represents a generator of $\pi_1(\mathrm{SL}(n,\mathbb{R}))$ and $\pi_1(\mathrm{GL}(n,\mathbb{R}))$. $\square$

86.3. **Spin groups.** Let $n \geq 3$. Recall that in Lemma 1.96 (1) we showed that $\mathrm{SO}(n)$ is path-connected and in Corollary 86.11 (2) we had just seen that $\pi_1(\mathrm{SO}(n)) \cong \mathbb{Z}_2$. By Lemma 7.16 this implies that the universal covering, as defined on page 567, of $\mathrm{SO}(n)$ is a 2-fold covering of $\mathrm{SO}(n)$.[1465] For example in Theorem 37.2 we showed that the 2-fold covering of $\mathrm{SO}(3)$ is diffeomorphic to $\mathrm{SU}(2)$.

Thus the following question arises:

Question 86.12. *Let $n \geq 3$.*

(1) *Is the universal covering of $\mathrm{SO}(n)$ a group?*
(2) *If yes, is it a group "we already know"?*

It turns out that the answer to Question 86.12 (1) is yes. In fact, the following, initially perhaps somewhat surprising proposition holds. The proof turns out to be almost disappointingly easy.

Proposition 86.13. *Let G be a connected Lie group and let $p\colon \widetilde{G} \to G$ be the universal covering. We denote by 1_G the neutral element in G. We pick a point $1_{\widetilde{G}} \in p^{-1}(1_G)$. Then $\widetilde{G}$ admits a unique Lie group structure such that $p\colon \widetilde{G} \to G$ is a smooth map and a homomorphism and such that $1_{\widetilde{G}}$ is the neutral element in $\widetilde{G}$.*

Remark. Let $k \in \mathbb{N}_{\geq 2}$. By Proposition 86.13 the universal covering $\widetilde{\mathrm{SL}(k,\mathbb{R})}$ of the Lie group $\mathrm{SL}(k,\mathbb{R})$ is again Lie group. In [HallB, Theorem C.12] it is shown that $\widetilde{\mathrm{SL}(k,\mathbb{R})}$ is *not* isomorphic to any subgroup of $\mathrm{GL}(n,\mathbb{R})$ for any $n \in \mathbb{N}$. This shows that Theorem 86.6 does not extend to non-compact Lie groups.

Sketch of the proof. First note that we saw in Proposition 8.1 that $\widetilde{G}$ is a topological manifold that admits a unique smooth structure such that $p\colon \widetilde{G} \to G$ is a smooth map. Now we turn towards defining the Lie group structure on the manifold $\widetilde{G}$. In fact we will give two equivalent definitions of the group structure on $\widetilde{G}$:

(1) First note that by Proposition 7.21 we know that $\widetilde{G} \times \widetilde{G}$ is also simply connected. We consider the maps

$$\begin{tikzcd} & \widetilde{G} \arrow[d, "p"] \\ \widetilde{G} \times \widetilde{G} \arrow[r, "(x,y)\mapsto p(x)\cdot p(y)"'] & G. \end{tikzcd}$$

It follows from Proposition 20.2 that there exists a unique lift

$$\begin{tikzcd} & \widetilde{G} \arrow[d, "p"] \\ \widetilde{G} \times \widetilde{G} \arrow[r, "(x,y)\mapsto p(x)\cdot p(y)"'] \arrow[ur, dashed, "(1_{\widetilde{G}},1_{\widetilde{G}})\mapsto 1_{\widetilde{G}}"] & G. \end{tikzcd}$$

[1465]Note that here we use that $\mathrm{SO}(n)$ is a manifold, which implies by the discussion on page 567 that the universal covering does indeed exist.

(2) By Proposition 20.8 and Corollary 20.11 we can assume that

$$\widetilde{G} \;=\; \{\text{paths in } G \text{ starting at } 1_G\}/\text{ homotopies that fix the starting point and the endpoint}$$

With that explicit description we define

$$\begin{array}{rcl} \widetilde{G}\times\widetilde{G} & \to & \widetilde{G} \\ ([a(t)],[b(t)]) & \mapsto & \left[\begin{array}{rcl} [0,1] & \to & G \\ t & \mapsto & a(t)\cdot b(t) \end{array}\right]. \end{array}$$

Using the fact that the multiplication map $\widetilde{G}\times\widetilde{G}\to\widetilde{G}$ is continuous one can show fairly easily that this map is well-defined.

We leave it as an exercise to show that the two given definitions of the group structure agree and that in both cases we defined a Lie group structure on $\widetilde{G}$.[1466]

It remains to show that the group structure on $\widetilde{G}$ is the unique Lie group structure on the manifold $\widetilde{G}$ for which $1_{\widetilde{G}}$ is the neutral element and that turns p into a homomorphism. Suppose we are given a smooth map $\varphi\colon \widetilde{G}\times\widetilde{G}\to\widetilde{G}$ that has the same properties. We obtain the following commutative diagram:

$$\begin{tikzcd} \widetilde{G}\times\widetilde{G} \arrow[r, "\varphi"] \arrow[d, "p\times p"'] \arrow[dr, "(x,y)\mapsto p(x)\cdot p(y)"] & \widetilde{G} \arrow[d, "p"] \\ G\times G \arrow[r, "(x,y)\mapsto x\cdot y"'] & G. \end{tikzcd}$$

Since the diagram commutes we see that $\varphi\colon \widetilde{G}\times\widetilde{G}\to\widetilde{G}$ is precisely a lift of the blue map $\widetilde{G}\times\widetilde{G}\to G$ that sends $(1_{\widetilde{G}},1_{\widetilde{G}})$ to $1_{\widetilde{G}}$. Thus by the uniqueness of the lift we see that the Lie group structure on $\widetilde{G}$ is uniquely determined by our wish list. □

This proposition leads us to the following definition.

Definition. Let $n\geq 3$. We refer to the universal covering of $\mathrm{SO}(n)$ as the *spin group* $\mathrm{Spin}(n)$.

The combination of Propositions 86.11 (2) and 86.13 and Corollary 20.11 shows that $\mathrm{Spin}(n)$ is indeed a Lie group and that $p\colon \mathrm{Spin}(n)\to\mathrm{SO}(n)$ is a 2-fold covering that is a group homomorphism.

Remark. By Corollary 20.11 the universal covering of a manifold, even if it is equipped with a base point, is only well-defined up to "equivalence". This slightly awkward issue can be circumvented in two different ways:

(1) either we use the explicit model of the universal covering of a based manifold in terms of equivalence classes of paths, or

[1466]The smoothness of the group multiplication is perhaps easier to prove with the first point of view, the fact that it is a group structure is possibly less confusing to verify with the second point of view.

(2) in this particular situation there is a more elegant solution, one can give a purely algebraic explicit description of $\mathrm{Spin}(n)$. We refer to [Mei, Chapter 3.1] for details.

It is harder to give an answer to Question 86.12 (2). For reasonably low dimensions the following proposition gives a positive answer.

Proposition 86.14.

(1) *There exist Lie group isomorphisms*[1467]

$$\begin{array}{lrcl} \text{(a)} & \mathrm{SO}(3) & \cong & \mathrm{SU}(2)/\{\pm\,\mathrm{id}\} \\ \text{(b)} & \mathrm{SO}(4) & \cong & (\mathrm{SU}(2)\times\mathrm{SU}(2))/\{\pm(\mathrm{id},\mathrm{id})\} \\ \text{(c)} & \mathrm{SO}(5) & \cong & \mathrm{Sp}(2)/\{\pm\,\mathrm{id}\}. \end{array}$$

(2) *There exist Lie group isomorphisms*

$$\begin{array}{lrcl} \text{(a)} & \mathrm{Spin}(3) & \cong & \mathrm{SU}(2) \\ \text{(b)} & \mathrm{Spin}(4) & \cong & \mathrm{SU}(2)\times\mathrm{SU}(2) \\ \text{(c)} & \mathrm{Spin}(5) & \cong & \mathrm{Sp}(2) \\ \text{(d)} & \mathrm{Spin}(6) & \cong & \mathrm{SU}(4). \end{array}$$

Proposition 86.14 (b) thus says that for $n = 3, 4, 5, 6$ the spin group $\mathrm{Spin}(n)$ is isomorphic to Lie groups that we are already familiar with. But according to [Mei, p. 53] "for $n \geq 7$, there are no further accidental isomorphisms of this type." In other words, in general the answer to Question 86.12 (2) is negative.

Proof.

(1) (a) This statement follows immediately from Lemma 37.1 and Theorem 37.2.

(b) In Proposition 44.2 we saw that the quaternion multiplication defines a group structure on $S^3 = \{h \in \mathbb{H} \,|\, |h| = 1\}$ where the trivial element is given by $1 \in \mathbb{H}$. Furthermore in Proposition 44.2 we had also seen that the Lie groups SU(2) and S^3 are isomorphic. Thus it suffices to show that the Lie groups $(S^3 \times S^3)/\{\pm(1,1)\}$ and SO(4) are diffeomorphic. We consider the following map:

$$\begin{array}{rcl} \Phi\colon S^3\times S^3 & \to & \mathrm{SO}(4) \\ (q_1,q_2) & \mapsto & \left(\begin{array}{rcl} \mathbb{R}^4=\mathbb{H} & \to & \mathbb{R}^4=\mathbb{H} \\ z & \mapsto & q_1 z q_2^{-1} \end{array}\right). \end{array}$$

We make the following observations:

(i) In Exercise 44.1 we showed that the map $z \mapsto q_1 z q_2^{-1}$ does indeed define an element in SO(4).

(ii) One can easily verify that the map Φ is smooth and that it is a homomorphism.

(iii) We leave it to the energetic reader to verify that the differential of Φ at each point is invertible.

[1467] Note that it follows from Lemma 86.5 that the groups on the right-hand side are indeed Lie groups.

(iv) We note that the kernel of this homomorphism is given by $\{\pm(1,1)\}$. Indeed, the kernel of this homomorphism is given by the set of all $(q_1, q_2) \in S^3 \times S^3$ such that $q_1 z q_2^{-1} = z$ for all $z \in \mathbb{H}$. By setting $z = 1$ we obtain that $q_1 = q_2$. Furthermore, since $q_1 z q_1^{-1} = z$ for all $z \in S^3$ we see that $q_1 = q_2$ lies in the center of the group S^3. An elementary calculation shows that the center of S^3 is given by ± 1. Thus the kernel of Φ contains precisely the two elements $(1,1)$ and $(-1,-1)$.

It follows from the above, Lemmas 1.66 and 86.5 and elementary group theory[1468] that the above map Φ descends to a smooth and injective map

$$\overline{\Phi}\colon (S^3 \times S^3)/\{\pm(1,1)\} \;\to\; \mathrm{SO}(4)$$

such that the differential at each point is invertible. By Lemmas 86.3 and 86.5 both sides are closed connected 6-dimensional manifolds. Thus it follows from Corollary 36.8 (2) that the map $\overline{\Phi}$ is also surjective. It follows from the above results and the Inverse Mapping Theorem 3.33 (2) that $\overline{\Phi}$ is in fact a diffeomorphism.

(c) Let V be the real vector space of quaternionic Hermitian 2×2-matrices with trace 0. In other words we consider

$$V \;=\; \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in M(2 \times 2, \mathbb{H}) \,\middle|\, a + d = 0, a, d \in \mathbb{R} \text{ and } b = \overline{c} \right\}.$$

Note that V is a 5-dimensional real vector space. The group $\mathrm{Sp}(2)$ acts by conjugation on V.[1469] One easily verifies that the kernel is given by $\{\pm\,\mathrm{id}\}$. Furthermore by [Pro, Chapter 4.5.3] there exists a positive-definite symmetric form on V that is preserved by this action. Thus, by Sylvester's Theorem 72.10 this action defines a homomorphism $\mathrm{Sp}(2) \to \mathrm{SO}(5)$. Similar to (b) we obtain a diffeomorphism $\mathrm{Sp}(2)/\{\pm\,\mathrm{id}\} \xrightarrow{\cong} \mathrm{SO}(5)$.

(2) (a) By (2a) we can make the identification $\mathrm{SO}(3) = \mathrm{SU}(2)/\{\pm\,\mathrm{id}\}$ of Lie groups. By Theorem 37.2 we know that $\mathrm{SU}(2)$ is homeomorphic to S^3, in particular we see that $\mathrm{SU}(2)$ is simply connected. By Lemma 86.5 the quotient map $\mathrm{SU}(2) \to \mathrm{SU}(2)/\{\pm 1\}$ is a covering map, it is smooth and it is a homomorphism. Thus we see that $\mathrm{SU}(2)$ is in fact the universal covering of $\mathrm{SU}(2)/\{\pm\,\mathrm{id}\} = \mathrm{SO}(3)$ and we deduce from Proposition 86.13 that $\mathrm{Spin}(3) \cong \mathrm{SU}(2)$.

(b) By the same argument as in (2a) this statement can be deduced from (1b).

(c) By the same argument as in (2a) this statement can be deduced from (1c).

(d) We will not make use of this results, hence we will not provide a proof, instead we refer to [Mei, p. 84] for details. □

[1468] More precisely, we use the elementary fact that if $\alpha\colon G \to H$ is a group homomorphism, then the induced map $G/\ker(\alpha) \to H$ is injective.

[1469] The group $\mathrm{Sp}(2)$ acts evidently by conjugation on all quaternionic 2×2-matrices, in principle one now needs to verify that this action restricts to an action on V.

Remark. Initially the spin groups might appear as amusing curiosities. In fact they arise naturally in many parts of mathematics and physics. We refer to [LM, Mor, Mei] for more details.

86.4. **The Bott Periodicity Theorem.** We continue with the following definition.

Definition. We define[1470]

$$\mathrm{O} \;=\; \varinjlim \mathrm{O}(n) \;=\; \left\{ A = (a_{ij})_{i,j\in\mathbb{N}} \;\middle|\; \begin{array}{l}\text{there exists an } n\in\mathbb{N}\\ \text{and a } B\in \mathrm{O}(n) \text{ with}\end{array} A = \begin{pmatrix} B & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & \ddots \end{pmatrix} \right\}$$

where O has the obvious group structure and where O has the topology that is defined by the condition that subset $U \subset \mathrm{O}$ is open if and only if for each n the intersection $U \cap \mathrm{O}(n)$ is open. Similarly we define

$$\mathrm{U} \;=\; \varinjlim \mathrm{U}(n), \quad \mathrm{Sp} \;=\; \varinjlim \mathrm{Sp}(n)$$

In Proposition 16.1 we saw that every direct system $\{G_i\}_{i\in I}$ of groups admits a direct limit $\varinjlim G_i$. In fact for the above direct limit $\mathrm{O} = \varinjlim \mathrm{O}(n)$ the group structure is the "obvious" one given above. The following shows that these group structure are continuous, i.e. O, U and Sp are topological groups.

Lemma 86.15. *The above group structures on* O*,* U *and* Sp *are continuous.*

Remark. Initially one might be tempted to dismiss Lemma 86.15 as obvious. But in general there is a subtle issue. If $\{G_i\}_{i\in I}$ is a direct system of topological groups, then the above multiplication on the direct limit $\varinjlim G_i$ might not be continuous. Such examples are for example provided in [TSH]. If one thinks about it for a while one realizes that this failure for the multiplication map to be continuous is another instance of the observation made in Section 2.2, that mixing product and quotient topologies is fraught with dangers.

Proof. This lemma can surely be proved, with a little effort, "by hand". Alternatively one can use [TSH, Theorem 2.7] which shows that for a direct system $\{X_i\}_{i\in\mathbb{N}}$ of compact topological groups the above multiplication on $\varinjlim X_i$ is indeed continuous. □

For later usages of O, U and Sp we have to get the following technical lemma out of the way.

Lemma 86.16. $(*)$ *The topological spaces* O*,* U *and* Sp *admit CW-structures such that each* $\mathrm{O}(n) \subset \mathrm{O}$*,* $\mathrm{U}(n) \subset \mathrm{U}$ *and* $\mathrm{Sp}(n) \subset \mathrm{Sp}$ *is a subcomplex.*

[1470]When we talk about the direct limit we have to say what category we consider. Here we want to consider the category of groups and of topological spaces at the same time. Since we have obvious inclusions maps $\mathrm{O}(n) \to \mathrm{O}(n+1)$ we obtain from the discussion on page 488 that in both settings we obtain the same underlying set, which we can then equip with a group structure and a topology.

Proof. In [Whd9] it is shown that we can equip the $\mathrm{O}(n)$ with CW-structures such that for each n the subset $\mathrm{O}(n) \subset \mathrm{O}(n+1)$ is actually a subcomplex. Analogous statements for $\mathrm{U}(n)$ and $\mathrm{Sp}(n)$ are proved in [Yo, Theorem 5.3 and 5.5] or alternatively in [Stro, Chapter 9.3.3]. It follows from Lemma 26.22 that O is a CW-complex. □

Now we turn to the study of the homotopy groups of O, U and Sp.

Lemma 86.17. *Given any $k \in \mathbb{N}$ we have*

$$\begin{array}{llllll}
(1) & \pi_k(\mathrm{O}) & = & \varinjlim \pi_k(\mathrm{O}(n)) & \xleftarrow{\cong} & \pi_k(\mathrm{O}(N)) \quad \textit{for any } N \in \mathbb{N} \textit{ with } N > k+1, \\
(2) & \pi_k(\mathrm{U}) & = & \varinjlim \pi_k(\mathrm{U}(n)) & \xleftarrow{\cong} & \pi_k(\mathrm{U}(N)) \quad \textit{for any } N \in \mathbb{N} \textit{ with } 2N > k, \\
(3) & \pi_k(\mathrm{Sp}) & = & \varinjlim \pi_k(\mathrm{Sp}(n)) & \xleftarrow{\cong} & \pi_k(\mathrm{Sp}(N)) \quad \textit{for any } N \in \mathbb{N} \textit{ with } 4N > k-2.
\end{array}$$

Proof $(*)$. We prove (1). The proofs of (2) and (3) are almost identical. We start out with the following claim.

Claim. Given any compact subset K of O there exists an $n \in \mathbb{N}$ with $K \subset \mathrm{O}(n)$.

Let K be a compact subset of O. Given $n \in \mathbb{N}$ we write $X_n := \{1, \dots, n\} \times \{1, \dots, n\}$. First recall that $\mathrm{O}(n)$ is equipped with the subspace topology coming from the inclusion map $g_n \colon \mathrm{O}(n) \subset M(n \times n, \mathbb{R}) = \mathbb{R}^{X_n} = \mathbb{R}^{n^2}$. Given $n \in \mathbb{N}$ we denote by $f_n \colon \mathbb{R}^{X_n} \to \mathbb{R}^{X_{n+1}}$ the obvious inclusion map. These have the property that for any $n \in \mathbb{N}$ the following diagram commutes:

$$\begin{tikzcd}
\mathrm{O}(n) \arrow[r, "g_n"] \arrow[d, hook] & \mathbb{R}^{X_n} \arrow[d, hook, "f_n"] \\
\mathrm{O}(n+1) \arrow[r, "g_{n+1}"] & \mathbb{R}^{X_{n+1}}.
\end{tikzcd}$$

The above inclusion maps $g_n \colon \mathrm{O}(n) \to \mathbb{R}^{X_n}$ induce a map $g \colon \mathrm{O} = \varinjlim \mathrm{O}(n) \hookrightarrow \varinjlim \mathbb{R}^{X_n}$. By our hypothesis that K is compact and Lemma 1.37 we know that $g(K) \subset \varinjlim \mathbb{R}^{X_n}$ is also compact. Basically the same argument as in the proof of Lemma 26.5 shows that there exists an $n \in \mathbb{N}$ with $g(K) \subset \mathbb{R}^{X_n}$. But this implies that $K \subset \mathrm{O}(n)$. This concludes the proof of the claim.

Now let $N \in \mathbb{N}$ with $N > k+1$. We have

$$\begin{array}{ccccc}
\pi_k(\mathrm{O}) & = & \varinjlim \pi_k(\mathrm{O}(n)) & = & \pi_k(\mathrm{O}(N)). \\
 & \uparrow & & \uparrow & \\
 & \text{by Proposition 28.11 and the claim} & & \text{Proposition 86.10 (1) and Lemma 16.2} &
\end{array}$$

□

We will now state two versions of the Bott Periodicity Theorem which implies in particular that the homotopy groups of O, U and Sp are periodic.

The first theorem requires just a little bit of preparation.

(1) As above we equip U, Sp and O with the base point given by the infinite identity matrix. We use these base points to form the loop spaces ΩU, $\Omega\,\mathrm{Sp}$ and ΩO.

(2) Given a point x in a topological space X we denote by c_x the corresponding constant path.
(3) We use notation (2) to equip each loop space $\Omega(X, x_0)$ with the base c_{x_0} and we can thus iterate the loop space construction.
(4) The obvious isomorphism $\mathbb{H} \xrightarrow{\cong} \mathbb{R}^4$ of real vector spaces defines inclusion maps $\mathrm{Sp}(n) \to \mathrm{O}(4n)$ and $\mathrm{Sp} \to \mathrm{O}$.
(5) The inclusion $\mathbb{R} \to \mathbb{H}$ defines inclusions $\mathrm{O}(n) \to \mathrm{Sp}(n)$ and thus $\mathrm{O} \to \mathrm{Sp}$.

Theorem 86.18. (Bott Periodicity Theorem) *There exist homotopy equivalences*

$$(1) \quad \mathrm{U} \to \Omega^2 \mathrm{U} \qquad (2) \quad \mathrm{Sp} \to \Omega^4 \mathrm{O} \qquad \textit{and} \qquad (3) \quad \mathrm{O} \to \Omega^4 \mathrm{Sp}\,.$$

Before we talk about the proof of the Bott Periodicity Theorem 86.18 let us move on to the following direct consequence.

Theorem 86.19. (Bott Periodicity Theorem) *For any $i \in \mathbb{N}_0$ we have*[1471]

$$\begin{aligned} &(1) & \pi_{i+2}(\mathrm{U}) &\cong \pi_i(\mathrm{U}), \\ &(2) & \pi_{i+4}(\mathrm{Sp}) &\cong \pi_i(\mathrm{O}), \\ &(3) & \pi_{i+4}(\mathrm{O}) &\cong \pi_i(\mathrm{Sp}). \end{aligned}$$

In particular, combining (2) *and* (3) *we have for any $i \in \mathbb{N}_0$ that*

$$\begin{aligned} &(4) & \pi_{i+8}(\mathrm{O}) &\cong \pi_i(\mathrm{O}), \\ &(5) & \pi_{i+8}(\mathrm{Sp}) &\cong \pi_i(\mathrm{Sp}). \end{aligned}$$

Proof of the Bott Periodicity Theorems 86.18 and 86.19. First note that Theorem 86.19 follows immediately from Theorem 86.18 together with Corollary 83.15. All the known proofs are non-trivial and go well-beyond what we can do in these modest notes.

Theorem 86.18 was first proved by Raoul Bott [Bot, Bot2, Bot3] in 1957. Another proof is given in [Mi4, p. 129, 142]. There explicit maps that give these homotopy equivalences, they are described well in [DL]. Nonetheless the description is too long for us to write down at this point.

There are many proofs of Theorem 86.19 which use a slightly different language, in particular it is at first glance not entirely clear whether they also imply Theorem 86.18. We refer to [Stro, Chapter 32.6], [AGP, Chapter 9.5], [APr] and [Hat2] for a discussions and proofs of Theorem 86.19. □

Using the Bott Periodicity Theorem 86.19 we can completely determine the homotopy groups of O, U and Sp.

Proposition 86.20. *The homotopy groups of* O, U *and* Sp *are as follows:*

$i \bmod 8$	0	1	2	3	4	5	6	7
$\pi_i(\mathrm{U})$	0	$\mathbb{Z}$	0	$\mathbb{Z}$	0	$\mathbb{Z}$	0	$\mathbb{Z}$
$\pi_i(\mathrm{O})$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	0	$\mathbb{Z}$	0	0	0	$\mathbb{Z}$
$\pi_i(\mathrm{Sp})$	0	0	0	$\mathbb{Z}$	$\mathbb{Z}_2$	$\mathbb{Z}_2$	0	$\mathbb{Z}$.

[1471] For $i = 0$ we actually have an isomorphism of pointed sets.

Proof. The homotopy groups of U are straightforward to determine. More precisely, let $i \in \mathbb{N}_0$. We have

$$\begin{array}{ccccccccc} \pi_i(\mathrm{U}) & = & \pi_{i \bmod 2}(\mathrm{U}) & \overset{\cong}{\leftarrow} & \pi_{i \bmod 2}(\mathrm{U}(1)) & = & \pi_{i \bmod 2}(S^1) & \cong & \begin{cases} 0, & \text{if } i = 0 \bmod 2, \\ \mathbb{Z}, & \text{if } i = 1 \bmod 2. \end{cases} \\ & \uparrow & & \uparrow & & \uparrow & & \uparrow & \\ & \text{Bott Periodicity Theorem 86.19} & & \text{Lemma 86.17 (2)} & & \text{since } \mathrm{U}(1) = S^1 & & \begin{array}{c}\text{see Lemma 1.96} \\ \text{Proposition 7.18}\end{array} & \end{array}$$

Now we consider the homotopy groups of O and Sp. By the Bott Periodicity Theorem 86.19 it suffices to compute the homotopy groups $\pi_i(\mathrm{O})$ and $\pi_i(\mathrm{Sp})$ for $i = 0, 1, 2, 3$.[1472] So let $i \in \{0, 1, 2, 3\}$. We have

$$\begin{array}{ccccccc} \pi_i(\mathrm{Sp}) & \overset{\cong}{\leftarrow} & \pi_i(\mathrm{Sp}(1)) & = & \pi_i(S^3) & \cong & \begin{cases} 0, & \text{if } i = 0, 1, 2, \\ \mathbb{Z}, & \text{if } i = 3. \end{cases} \\ & \uparrow & & \uparrow & & \uparrow & \\ & \text{Lemma 86.17 (3)} & & \text{since } \mathrm{Sp}(1) = S^3 & & \text{Proposition 28.9 and Corollary 80.6 (1)} & \end{array}$$

We turn to the calculation of the homotopy groups of O. First we note that for any $i \geq 1$ we have

$$\begin{array}{ccccc} \pi_i(\mathrm{O}) & \overset{\cong}{\leftarrow} & \pi_i(\mathrm{O}(i+2)) & \cong & \pi_i(\mathrm{SO}(i+2)). \\ & \uparrow & & \uparrow & \\ & \text{Lemma 86.17 (3)} & & \text{Lemmas 1.96 and 1.110} & \end{array}$$

Thus it remains to prove the following claim.

Claim.

(a)	$\pi_0(\mathrm{O}(2))$	$\cong$	$\mathbb{Z}_2$	(c)	$\pi_2(\mathrm{SO}(4))$	$\cong$	0
(b)	$\pi_1(\mathrm{SO}(3))$	$\cong$	$\mathbb{Z}_2$	(d)	$\pi_3(\mathrm{SO}(5))$	$\cong$	$\mathbb{Z}$.

We turn to the proof of these four separate claims.

(a) By Lemma 1.96 (1) we know that O(2) consists of two path components, thus $\pi_0(\mathrm{O}(2))$ is by definition a pointed set with two elements.
(b) By Proposition 86.11 we know that $\pi_1(\mathrm{SO}(3)) \cong \mathbb{Z}_2$.
(c) We have the following isomorphisms:

$$\begin{array}{ccccccccc} \pi_2(\mathrm{SO}(4)) & \cong & \pi_2((S^3 \times S^3)/\mathbb{Z}_2) & \cong & \pi_2(S^3 \times S^3) & \cong & \pi_2(S^3) \oplus \pi_2(S^3) & = & 0. \\ & \uparrow & & \uparrow & & \uparrow & & \uparrow & \\ & \begin{array}{c}\text{by Proposition 86.14 (1b)} \\ \text{and Proposition 44.2}\end{array} & & \begin{array}{c}\text{by Lemma 86.5} \\ \text{and Proposition 28.13}\end{array} & & \text{Proposition 28.8} & & \text{Proposition 28.9} & \end{array}$$

[1472] We will see that $\pi_0(\mathrm{O})$ is the pointed set with two elements. It follows from the Bott Periodicity Theorem 86.19 that $\pi_{4+8k}(\mathrm{Sp})$ and $\pi_{8k}(\mathrm{O})$, $k \geq 1$, are also pointed sets with two elements. But these pointed sets are also groups. Since there is only one group structure on a pointed set with two elements we see that all these groups are isomorphic to $\mathbb{Z}_2$.

(d) We have the following isomorphisms:

$$\begin{array}{ccccccccc} \pi_3(\mathrm{SO}(5)) & \cong & \pi_3(\mathrm{Sp}(2)/\{\pm\,\mathrm{id}\}) & \cong & \pi_3(\mathrm{Sp}(2)) & \cong & \pi_3(\mathrm{Sp}) & \cong & \mathbb{Z}. \\ & \uparrow & & \uparrow & & \uparrow & & \uparrow & \\ & \text{Proposition 86.14 (1c)} & & \text{by Lemma 86.5 and Proposition 28.13} & & \text{Proposition 86.10} & & \text{see above} & \end{array}$$

This concludes the proof of the claim. □

86.5. **H-spaces** (∗)**.** In this final section of this chapter we want to state two general statements about homotopy groups of Lie groups. In fact these statements hold for a much wider class of topological spaces that we introduce now:

Definition. We say a topological space X is an *H-space*[1473] if there exists a map[1474]

$$\mu\colon X \times X \;\to\; X$$

and an element $e \in X$ such that $\mu(e,e) = e$ and such that the maps

$$\begin{array}{rcl} (X,e) & \mapsto & (X,e) \\ x & \mapsto & \mu(x,e) \end{array} \quad \text{and} \quad \begin{array}{rcl} (X,e) & \mapsto & (X,e) \\ x & \mapsto & \mu(e,x) \end{array}$$

of pairs of topological spaces are homotopic to the identity.

Examples.

(1) Evidently Lie groups and more generally, topological groups are H-spaces, where μ is given by the group structure and e is the trivial element of the group.

(2) The topological space S^7 together with the multiplication given by the octonion structure on $\mathbb{O} = \mathbb{R}^8$ and with $e = 1 = (1,0,\dots,0) \in S^7$ is an H-space.[1475] Since octonion multiplication is not associative we see that, at least with this multiplication, S^7 is not a topological group.

(3) Given a non-zero polynomial $p(t) = \sum_{i=0}^{n} a_i t^i \in \mathbb{C}[t]$ we define

$$[p(t)] \;:=\; [a_0 : a_1 : \dots : a_n : 0 : \dots] \;\in\; \mathbb{C}\mathrm{P}^\infty.$$

Evidently every element in $\mathbb{C}\mathrm{P}^\infty$ is of that form. We consider the "multiplication" map

$$\begin{array}{rcl} \mu\colon \mathbb{C}\mathrm{P}^\infty \times \mathbb{C}\mathrm{P}^\infty & \to & \mathbb{C}\mathrm{P}^\infty \\ ([p(t)],[q(t)]) & \mapsto & [\underbrace{p(t)\cdot q(t)}_{\in\mathbb{C}[t]}]. \end{array}$$

We leave it to the reader to verify that μ is continuous. It is clear that left and right "multiplication" by $e = [1] = [1 : 0 : \dots]$ is the identity. This shows that $\mathbb{C}\mathrm{P}^\infty$

[1473] According to [Hub, p. 747] the term H-space was coined by Jean-Pierre Serre to honor the work of Heinz Hopf.

[1474] As usual, whenever we deal with topological spaces, all maps are understood to be continuous.

[1475] Recall that by the discussion on page 1057 we know that for octonions $w, z \in \mathbb{O} = \mathbb{R}^8$ we have $\|w \cdot z\| = \|w\| \cdot \|z\|$, in particular the multiplication restricts to a map on S^7. Also note that multiplication by $e = 1$ is the identity.

together with μ and e is an H-space. Note that this multiplication μ is commutative and associative, but it does not have inverses[1476], thus μ does not define a group structure on $\mathbb{C}\mathrm{P}^\infty$.

We formulate the last example as a lemma.

Lemma 86.21. *Let (X, x_0) be a pointed topological space. We denote by $\Omega(X, x_0)$ the loop space as defined on page 1930.*

(1) *The map*

$$\begin{array}{rcl} \mu\colon \Omega(X,x_0)\times\Omega(X,x_0) & \to & \Omega(X,x_0) \\ (f\colon [0,1]\to X, g\colon [0,1]\to X) & \mapsto & (\underbrace{f * g}_{\substack{\text{multiplication of loops}\\ \text{as defined on page 231}}} : [0,1]\to X) \end{array}$$

is continuous.

(2) *The map $\mu\colon \Omega(X,x_0)\times\Omega(X,x_0)\to\Omega(X,x_0)$ from (1) together with the constant loop given by $e(t)\equiv x_0$, turns $\Omega(X,x_0)$ into an H-space.*

Remark.

(1) Note that for the H-space $\Omega(X,x_0)$ "multiplication" by e is not the identity, it is only homotopy equivalent to the identity.
(2) We had hinted at the existence of a multiplication map on $\Omega(X,x_0)$ in Exercise 83.4.

Proof $(*)$. Let (X,x_0) be a pointed topological space. To simplify the notation we write ΩX instead of $\Omega(X,x_0)$.

(1) We need to show that the map $\mu\colon \Omega X\times\Omega X\to\Omega X$ is in fact continuous. By the "$\Rightarrow$"-direction of Proposition 2.6, applied to $T=\Omega X\times\Omega X$ and the locally compact topological space $Y=[0,1]$, it suffices to show that the following map is continuous:

$$\Phi\colon (\Omega X\times\Omega X)\times[0,1] \xrightarrow{\mu\times\mathrm{id}} \Omega X\times[0,1] \xrightarrow{(f,t)\mapsto f(t)} X.$$

On the subset $(\Omega X\times\Omega X)\times[0,\frac{1}{2}]$ this map is equal to

$$(\Omega X\times\Omega X)\times[0,\tfrac{1}{2}] \xrightarrow{((f,g)\mapsto f)\times(t\mapsto 2t))} \Omega X\times[0,1] \xrightarrow{(f,t)\mapsto f(t)} X.$$

The first map is evidently continuous. Furthermore, the second map is continuous by Proposition 2.4. Thus we have shown that the restriction of Φ to the subset $(\Omega X\times\Omega X)\times[0,\frac{1}{2}]$ is continuous. Basically the same argument shows that the restriction of Φ to $(\Omega X\times\Omega X)\times[\frac{1}{2},1]$ is continuous. it follows from Lemma 5.3 that Φ itself is continuous.

[1476] Why are there elements in $\mathbb{C}\mathrm{P}^\infty$ which do not have multiplicative inverses?

(2) Let $e \in \Omega(X, x_0)$ be the constant loop given by $e(t) \equiv x_0$. It is clear that $\mu(e, e) = e$. Thus it remains to show that the maps

$$\begin{array}{rcl} (\Omega(X,x_0),e) & \mapsto & (\Omega(X,x_0),e) \\ f & \mapsto & \mu(f,e) \end{array} \quad \text{and} \quad \begin{array}{rcl} (\Omega(X,x_0),e) & \mapsto & (\Omega(X,x_0),e) \\ f & \mapsto & \mu(e,f) \end{array}$$

of pairs of topological spaces are homotopic to the identity. We consider the map

$$\begin{array}{rcl} H\colon \Omega(X,x_0)\times[0,1] & \to & \Omega(X,x_0) \\ ((f\colon [0,1]\to X),t) & \mapsto & \left(\begin{array}{rcl} [0,1] & \to & X \\ s & \mapsto & \begin{cases} f(\frac{2s}{t+1}), & \text{if } s\in[0,\frac{t+1}{2}], \\ x_0, & \text{otherwise.} \end{cases} \end{array} \right) \end{array}$$

We leave it to the underchallenged reader to show, using the "$\Rightarrow$"-direction of Proposition 2.6, that this map H is in fact continuous. Note that we have $H(e,t) = e$ for all $t \in [0,1]$. With these observations it is basically clear that it is the desired homotopy between the map $f \mapsto \mu(f,e)$ and the identity.

Almost exactly the same way we deal with the second map $f \mapsto \mu(e,f)$. □

The following lemma is the only statement on H-spaces that we can prove with our limited space resources.

Lemma 86.22. *If X is a path-connected H-space, then $\pi_1(X)$ is abelian.*

Remark. Let (X, x_0) be a pointed topological space. As we pointed out above the loop space $\Omega(X, x_0)$ is an H-space which implies by Lemma 86.22 that $\pi_1(\Omega(X, x_0))$ is abelian. Now recall that in Corollary 83.15 we saw that there exists an isomorphism $\pi_1(\Omega(X, x_0)) \xrightarrow{\cong} \pi_2(X)$, which is abelian by Proposition 28.3. So we now have two different (?) proofs for the statement that $\pi_1(\Omega(X, x_0))$ is abelian.

Proof $(*)$. We denote by $\mu\colon X \times X \to X$ and $e \in X$ the objects in the definition of an H-space. Let $f, g\colon [0,1] \to X$ be loops in e. We need to show that the path $f * g$ is path-homotopic to the path $g * f$.

We denote by by $\mu(f, e)$ the path $t \mapsto \mu(f(t), e)$ and similarly we define $\mu(e, g)$. We consider the map

$$\begin{array}{rcl} F\colon [0,1]\times[0,1] & \to & X \\ (s,t) & \mapsto & \mu(f(s),g(t)). \end{array}$$

Note that this map is continuous by Lemma 1.53 (3) and the fact that μ is continuous. Furthermore we consider the following path-homotopy:[1477]

$$\begin{array}{rcl} H\colon [0,1]\times[0,1] & \to & X \\ (s,t) & \mapsto & \begin{cases} F(2s\cdot(1-t,t)), & \text{if } s\le\frac12 \\ F((2-2s)\cdot(1-t,t)+(2s-1)\cdot(1,1)), & \text{if } s>\frac12. \end{cases} \end{array}$$

By carefully plugging in $t = 0$ and $t = 1$ we see that H is a path-homotopy from the loop $\mu(f, e) * \mu(e, g)$ to the loop $\mu(e, g) * \mu(f, e)$.

[1477] It follows easily from Lemma 1.32 (2') that this map is continuous.

Next we recall that by definition of an H-space there exists a homotopy $A\colon X\times[0,1]\to X$ rel $\{e\}$ with $A_0=\mathrm{id}$ and $A_1=\mu(-,e)$ and there exists a homotopy $B\colon X\times[0,1]\to X$ rel $\{e\}$ with $B_0=\mathrm{id}$ and $B_1=\mu(e,-)$. We consider the maps

$$\begin{array}{rcl} A_f\colon [0,1]\times[0,1] & \to & X \\ (s,t) & \mapsto & A(\underbrace{f(s)}_{\in X},t) \end{array} \quad \text{and} \quad \begin{array}{rcl} B_g\colon [0,1]\times[0,1] & \to & X \\ (s,t) & \mapsto & B(\underbrace{g(s)}_{\in X},t). \end{array}$$

Note that A_f is a path-homotopy from the loop f to the loop $\mu(f,e)$ and B_g is a path-homotopy from the loop g to the loop $\mu(e,g)$. The path-homotopy between the loops $f*g$ and $g*f$ is given by combining H with A_f and B_g as indicated in Figure 1055. We leave it to the reader to conscientiously write down the precise homotopy. □

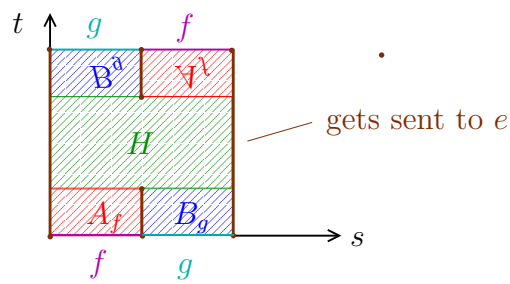

FIGURE 1055. Illustration for the proof of Lemma 86.22.

The following theorem was proved by William Browder [Browd, Theorem 2] [Browd2, Theorem 6.11] in 1961.

Theorem 86.23. *Let X be a path-connected H-space. If the group $\bigoplus_{i=0}^{\infty} H_i(X;\mathbb{Z})$ is finitely generated, then*

$$\min\{m\in\mathbb{N}_{\geq 2}\,|\,\pi_m(X)\neq 0\}$$

is odd. In particular we have $\pi_2(X)=0$.

Example. On page 2000 we saw that $\mathbb{C}\mathrm{P}^\infty$ is an H-space. Furthermore in Corollary 80.6 (2) we saw that $\pi_2(\mathbb{C}\mathrm{P}^\infty)\neq 0$. Thus we see that in the statement of Theorem 86.23 we cannot drop the hypothesis that $\bigoplus_{i=0}^{\infty} H_i(X;\mathbb{Z})$ is a finitely generated group.

We conclude this chapter with a corresponding theorem for Lie groups.

Theorem 86.24. *If G is a path-connected Lie group, then*

$$\min\{m\in\mathbb{N}_{\geq 2}\,|\,\pi_m(G)\neq 0\}$$

is odd. In particular $\pi_2(G)=0$.

Remark. There are many direct proofs in the literature for the statement that given a path-connected Lie group G the second homotopy group $\pi_2(G)$ vanishes, see e.g. [Cart] or [Mi4, Theorem 21.7] or [BtD, Proposition V.7.5].

Note that Theorem 86.24 has no conditions on the Lie group except that it needs to be path-connected. The reason why we can get away with so few conditions is given by the following proposition.

Proposition 86.25. *Let G be a Lie group. There exists a compact Lie subgroup K*[1478] *such that G is homeomorphic to $K \times \mathbb{R}^n$ for some $n \in \mathbb{N}_0$.*

Proof of Proposition 86.25. Like many other foundational results on Lie groups this proposition has its origins in the work of Henri Cartan [Cart]. A full proof is given in [Mal, Theorem 11] or [Mos, Theorem 2]. A sketch of the proof is provided in [Sam, Chapter 7]. □

Example. We consider the group $\mathrm{Isom}(\mathbb{R}^n)$ of isometries of the vector space $\mathbb{R}^n$ equipped with the usual inner product. It is an elementary, but not totally trivial fact, see [Ree, p. 11], that

$$\mathrm{Isom}(\mathbb{R}^n) \;=\; \{\text{all maps of the form } x \mapsto Ax + v \text{ where } A \in \mathrm{O}(n) \text{ and } v \in \mathbb{R}^n\}.$$

The maps

$$\begin{array}{rcl} \mathrm{O}(n) \times \mathbb{R}^n & \to & \mathrm{Isom}(\mathbb{R}^n) \\ (A, v) & \mapsto & (x \mapsto Ax + v) \end{array} \quad \text{and} \quad \begin{array}{rcl} \mathrm{Isom}(\mathbb{R}^n) & \to & \mathrm{O}(n) \times \mathbb{R}^n \\ f & \mapsto & (\underbrace{(x \mapsto (f(x) - f(0))}_{\text{represented by matrix in } \mathrm{O}(n)}, f(0)) \end{array}$$

are inverses of one another. Thus we can use the manifold structure on $\mathrm{O}(n) \times \mathbb{R}^n$ to turn $\mathrm{Isom}(\mathbb{R}^n)$ into a manifold and it is quasi-obvious to see that this turns $\mathrm{Isom}(\mathbb{R}^n)$ into a Lie group. We can view $\mathbb{R}^n$ and $\mathrm{O}(n)$ as subgroups of $\mathrm{Isom}(\mathbb{R}^n)$ in an obvious way. But one easily verifies that the map $\mathrm{O}(n) \times \mathbb{R}^n \to \mathrm{Isom}(\mathbb{R}^n)$ is not an isomorphism. In other words, as predicted by Proposition 86.25 the Lie group $\mathrm{Isom}(\mathbb{R}^n)$ splits topologically into a product. But the Lie group does not split as a Lie group.

Proof of Theorem 86.24. Let G be a path-connected Lie group. By Proposition 86.25 we know that G is homotopy equivalent to a compact path-connected Lie group K. By Proposition 28.7 it suffices to prove the desired statement for K. Since K is in particular a compact manifold we obtain from Proposition 45.2 that $\bigoplus_{i=0}^{\infty} H_i(X; \mathbb{Z})$ is a finitely generated abelian group. Thus we can conclude the proof by appealing to Theorem 86.23. □

[1478] In fact a Lie group contains a maximal compact Lie subgroup which is furthermore unique up to conjugation. We will not make use of this fact.

Exercises for Chapter 86.

Exercise 86.1. Let X be the torus minus one open disk. Does X admit the structure of a topological group?

Exercise 86.2. Let M be manifold without boundary and let $g\colon M \times M \to M$ be a map that is smooth and that defines a group structure on M. Show that (M, g) is a Lie group. In other words, show that the map $M \to M$ given by $x \mapsto x^{-1}$ is smooth.
Hint: Use the Implicit Function Theorem, see e.g. [Le2, p. 661].

Exercise 86.3. Let $n \in \mathbb{N}$. We define

$$\mathrm{GL}(n, \mathbb{H}) \;=\; \left\{ A \in M(n \times n, \mathbb{H}) \;\middle|\; \begin{array}{c} \text{there exist matrices } X, Y \in M(n \times n, \mathbb{H}) \\ \text{such that } AX = YA = \mathrm{id} \end{array} \right\}.$$

Is $\mathrm{GL}(n, \mathbb{H})$ an open subset of $M(n \times n, \mathbb{H})$?

Exercise 86.4. Let $n \in \mathbb{N}$. In the proof of Lemma 86.3 we already saw that $\mathrm{Sp}(n)$ is a manifold and that matrix multiplication turns $\mathrm{Sp}(n)$ into a group. Show that the map

$$\begin{array}{rcl} \mathrm{Sp}(n) & \to & \mathrm{Sp}(n) \\ A & \mapsto & A^{-1} \end{array}$$

is a smooth map.
Note: The argument in the proof of Lemma 1.108 can be used to show that taking inverses in $\mathrm{GL}(n, \mathbb{R})$ and $\mathrm{GL}(n, \mathbb{C})$ is smooth. Does this help us in any way?
Remark: In principle one could use Exercise 86.2. But what do readers do who are still traumatized by the Implicit Function Theorem?

Exercise 86.5. Use the Ehresmann Fibration Theorem that we had stated in Exercise 85.5 to give a third proof that the map $p\colon\ \mathrm{O}(n+1) \to S^n$ from Proposition 86.8 is a fiber bundle.

Exercise 86.6. Determine all closed non-orientable 2-dimensional manifolds that admit a Lie group structure.

Exercise 86.7. We define $\mathrm{SU} = \varinjlim \mathrm{SU}(n)$ the same way as we defined U. Determine the homotopy groups of SU.
Remark: You might want to use Exercise 85.7.

87. The Thom-Pontryagin Theory

In this chapter we will introduce the Thom-Pontryagin approach to calculating homotopy groups of spheres. Furthermore we will see that it allows us to reprove several earlier results. In the subsequent chapter we will use the Thom-Pontryagin approach to obtain new results.

Before we start with discussing the Thom-Pontryagin theory we fix some notations and conventions.

Notation and Convention. Let $n \in \mathbb{N}_0$.

(1) We denote by $*$ the point in $\overline{B}^n/S^{n-1}$ that is given by $[S^{n-1}]$.
(2) We denote by $*$ the "North Pole" $(0,\dots,0,1) \in S^n$.

We make the following identifications:

(a) We use the homeomorphism $S^n \to \mathbb{R}^n \cup \{\infty\}$ from Lemma 1.41, which is given by stereographic projection, that sends the North Pole $*$ to ∞ to make the identification $S^n = \mathbb{R}^n \cup \{\infty\}$.
(b) On page 99 we wrote down an explicit homeomorphism $\overline{B}^n/S^{n-1} \to S^n$. This homeomorphism sends $*$ to $(-1,0,\dots,0)$. Thus we postcompose it with the diffeomorphism of S^n that is given by[1479] $(x_1,\dots,x_{n+1}) \mapsto (x_{n+1},x_2,\dots,x_n,-x_1)$. This way we obtain a homeomorphism $\overline{B}^n/S^{n-1} \to S^n$ that sends $*$ to $(0,\dots,0,1)$.
(c) Putting the two homeomorphisms from (a) and (b) together we obtain a homeomorphism
$$\varphi\colon \overline{B}^n/S^{n-1} \quad \to \quad \mathbb{R}^n \cup \{\infty\}.$$
It follows fairly easily from the definitions of the two maps in (a) and (b) that φ restricts to a diffeomorphism $B^n \to \mathbb{R}^n$ and that φ is of the form
$$x \quad \mapsto \quad \begin{cases} \eta(\|x\|)\cdot x, & \text{if } x \in B^n, \\ \infty, & \text{if } x = *, \end{cases}$$
where $\eta\colon [0,1) \to [0,\infty)$ is a strictly monotonously increasing function with $\eta(0)=0$ and $\lim\limits_{t\to 1}\eta(t)=\infty$.

Summarizing we have the identifications $S^n = \mathbb{R}^n \cup \{\infty\} = \overline{B}^n/S^{n-1}$ and under these identifications the points $* \in S^n$, ∞ and $* \in \overline{B}^n/S^{n-1}$ get identified. We refer to Figure 1056 for an illustration.

87.1. **The generalized Thom-Pontryagin construction.** On page 1618 we saw that a proper oriented codimension one submanifold of a compact oriented manifold M gives rise, via the Thom-Pontryagin construction, to a map $M \to S^1$. In this section we will generalize this construction.

The key objects in the more general construction of Thom-Pontryagin maps are "fattened" submanifolds:

[1479] Note that this map is given by multiplication by a matrix in $\mathrm{SO}(n+1)$. In Lemma 10.4 we showed that such a diffeomorphism is diffeotopic to the identity. In particular it is orientation-preserving.

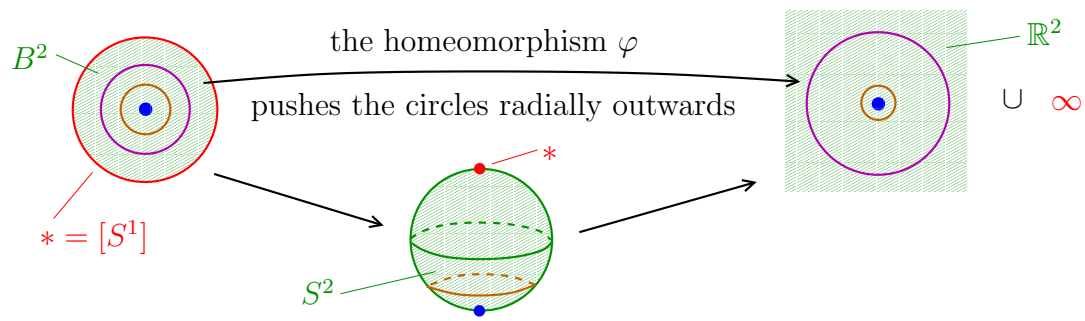

FIGURE 1056.

Definition. Let M be an orientable n-dimensional manifold.

(1) Let N be a compact orientable proper k-dimensional submanifold of M. A *fattening of* N is an injective map $g\colon \overline{B}^{n-k} \times N \to M$ with the following properties:[1480][1481][1482]
   (a) for all $P \in N$ we have $g(0, P) = P$,
   (b) the image $g(\overline{B}^{n-k} \times N)$ is a submanifold with corner of M,
   (c) we have $g(\overline{B}^{n-k} \times N) \cap \partial M = g(\overline{B}^{n-k} \times \partial N)$.
   We refer to Figure 1057 for an illustration.

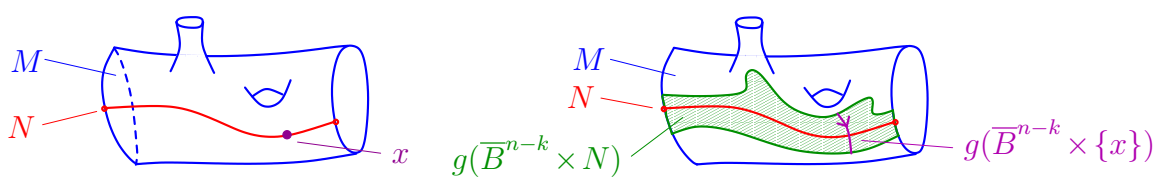

FIGURE 1057.

(2) A *fattened submanifold* of M is a pair (N, g) where N is a compact orientable proper[1483] submanifold of M and g is a fattening for N.
(3) Let $\varphi\colon M \to W$ be an embedding of M into a manifold W of the same dimension. Given a fattened k-dimensional submanifold $(N, g\colon \overline{B}^{n-k} \times N)$ of $M \setminus \partial M$ we equip

[1480]Here one really would like to say that $g\colon \overline{B}^{n-k} \times N \to M$ is an "embedding", but if N has boundary, then it is not entirely clear in what sense $\overline{B}^{n-k} \times N$ is a manifold and what "embedding" is supposed to mean.

[1481]The definition looks very similar to the definition of a tubular neighborhood. In fact a fattening is the same data as a trivial tubular neighborhood, it is just phrased in slightly different words.

[1482]On page 1626 we introduced the fattening of an *oriented* knot. For knots the present definition is the same as before, except that we no longer demand that the knot is oriented.

[1483]Note that here, in the definition of a fattened submanifold, we sneaked in the adjectives "compact", "orientable" and "proper", so that we will not have to carry them around all the time.

$\varphi(N)$ with the "obvious fattening", namely with the fattening that is given by

$$\begin{array}{rcl} \varphi_*(g)\colon \overline{B}^{n-k} \times \varphi(N) & \to & W \\ (v,P) & \mapsto & g(v,\varphi^{-1}(P)). \end{array}$$

Evidently $(\varphi(N), \varphi_*(g))$ is a fattened submanifold of W.

The following definition can be viewed as a generalization of the Thom-Pontryagin map introduced on page 1618.

Definition. Let M be an orientable n-dimensional manifold. Given a fattened k-dimensional submanifold $(N, g\colon \overline{B}^{n-k} \times N \to M)$ we refer to the map[1484]

$$\begin{array}{rcl} \rho_{(N,g)}\colon M & \to & S^{n-k} = \overline{B}^{n-k}/S^{n-k-1} \\ P & \mapsto & \begin{cases} [x], & \text{if } P = g(x,y) \text{ with } (x,y) \in \overline{B}^{n-k} \times N, \\ *, & \text{otherwise} \end{cases} \end{array}$$

as the *Thom-Pontryagin map.* (We refer to Figure 1058 for an illustration.) Sometimes we refer to this approach of assigning to a fattened k-dimensional submanifold a map $M \to S^{n-k}$ as the *Thom-Pontryagin construction.*

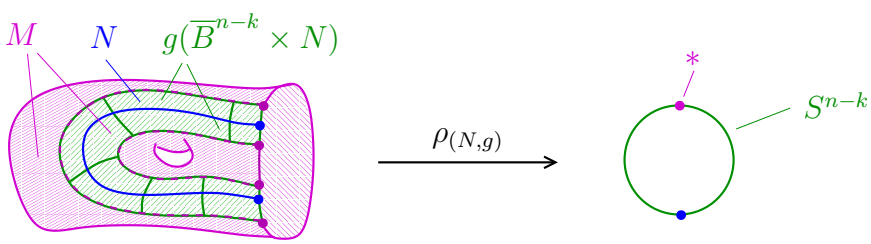

FIGURE 1058.

Remark.

(1) Let N be a compact *oriented* proper codimension one submanifold of an *oriented* manifold M. It follows immediately from Proposition 64.11 that N admits a fattening $[-1,1]\times N$ such that the inclusion $(-1,1)\times N \to M$ is orientation-preserving.[1485] The map $\rho_N\colon M \to S^1$ that we defined on page 1618 is basically the same as the above map $\rho_{(N,g)}\colon M \to S^1$. The only difference is that the two maps differ by multiplication by $i \in S^1$.

(2) We saw in Proposition 67.20 that the submanifold $\mathbb{C}\mathrm{P}^1$ of $\mathbb{C}\mathrm{P}^2$ does *not* admit a trivial tubular neighborhood, in particular it does not admit a fattening.

[1484] It follows easily from Lemma 64.1 and Lemma 1.32 (2) that this map is indeed continuous.

[1485] Furthermore we saw in Proposition 64.9 that this fattening is essentially unique.

Example. Let $n \in \mathbb{N}$ and let M be a closed orientable n-dimensional manifold together with a 0-dimensional submanifold $N = \{P_1, \ldots, P_m\}$. Suppose N is equipped with a fattening

$$g = g_1 \sqcup \cdots \sqcup g_m \colon (\overline{B}^n \times \{P_1\}) \sqcup \cdots \sqcup (\overline{B}^n \times \{P_m\}) \ \to \ M.$$

From the Thom-Pontryagin construction we obtain a map $\rho_{(N,g)} \colon M \to S^n$. It might not be clear what this is good for, but it is kind of fun. This example is illustrated in Figure 1059.

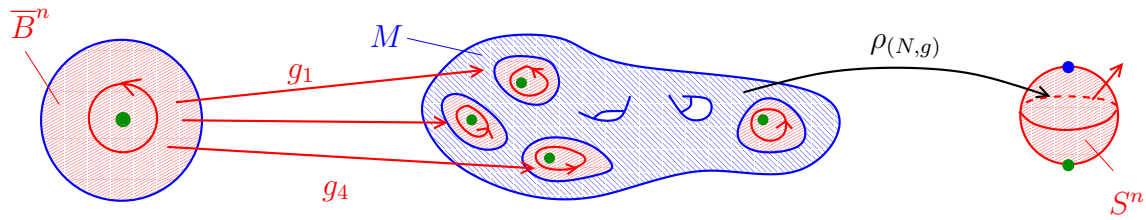

FIGURE 1059.

The following lemma gives us a first interesting example of a Thom-Pontryagin map.

Lemma 87.1. *Let $n \in \mathbb{N}$ and let $P \in B^n$. We equip the 0-dimensional manifold $\{P\}$ with any fattening $g \colon \overline{B}^n \times \{P\} \to B^n$ that is orientation-preserving*[1486]*. The corresponding map*

$$\rho_{(\{P\},g)} \colon \overline{B}^n / S^{n-1} \ \to \ \overline{B}^n / S^{n-1}$$

is homotopic rel $*$ to the identity map of $\overline{B}^n / S^{n-1}$.

The proof of Lemma 87.1 relies on the following lemma which we will use on several occasions.

Lemma 87.2. *Let $m \in \mathbb{N}$. Given any real number $r \in (0,1)$ there exists a homotopy $F \colon \overline{B}^m / S^{m-1} \times [0,1] \to \overline{B}^m / S^{m-1}$ rel $*$ with the following three properties:*

(1) *$F_0 = \mathrm{id}$,*
(2) *the restriction of F_1 to B^m_r is given by multiplication by $\frac{1}{r}$,*
(3) *for any point $x \notin B^m_r$ we have $F_1(x) = *$.*

Proof. Let $r \in (0,1)$. We consider the map

$$\begin{array}{rcl} (\overline{B}^m / S^{m-1}) \times [0,1] & \to & \overline{B}^m / S^{m-1} \\ ([x], t) & \mapsto & \begin{cases} [x \cdot (1 - t + t \cdot \frac{1}{r})], & \text{if } x \in B^m \text{ and } t < \frac{1 - \|x\|}{(\frac{1}{r} - 1) \cdot \|x\|} \\ *, & \text{otherwise.} \end{cases} \end{array}$$

We leave as an exercise to the engaged reader to verify that this map is indeed continuous. It is clear that F has the desired properties. $\square$

Now we can easily prove Lemma 87.1.

[1486] We equip $\overline{B}^n$ and B^n with the usual orientation.

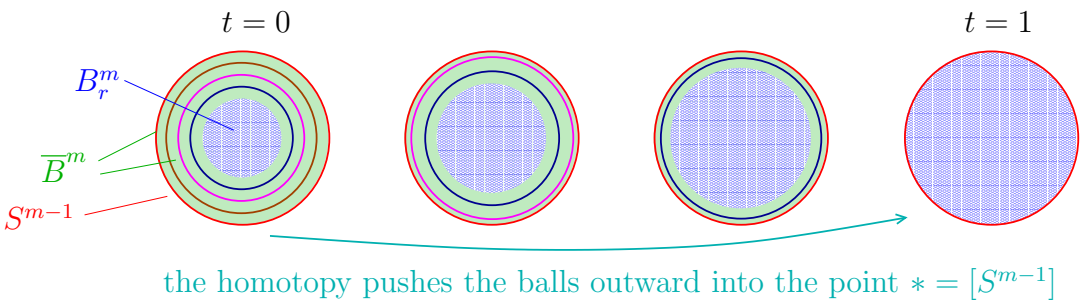

FIGURE 1060. Illustration of Lemma 87.2 (1).

Sketch of proof of Lemma 87.1. It follows quite easily[1487] from Theorem 10.28 that we can assume without loss of generality that $P = 0$ and that we can assume that g is the fattening $g\colon \overline{B}^n \times \{0\} \to B^n$ given by $g(v,0) = \frac{1}{2}v$. By Lemma 87.2 there exists a homotopy $F\colon (\overline{B}^n/S^{n-1}) \times [0,1] \to \overline{B}^n/S^{n-1}$ rel $*$ with the following three properties:

(1) $F_0 = \mathrm{id}$,
(2) the restriction of F_1 to $B^n_{\frac{1}{2}}$ is given by the map $x \mapsto 2 \cdot x$,
(3) for any point $x \notin B^n_{\frac{1}{2}}$ we have $F_1(x) = *$.

If one thinks about it for a second, then one realizes that F_1 equals $\rho_{(0,g)}$ "on the nose". Thus we have found the desired homotopy. □

87.2. **The Thom-Pontryagin construction and homotopy groups.** The following is the key observation which justifies our renewed interest in the Thom-Pontryagin construction.

Observation. Let $n, k \in \mathbb{N}_0$ and let $(N, g\colon \overline{B}^n \times N \to \mathbb{R}^{n+k})$ be a fattened k-dimensional submanifold of $\mathbb{R}^{n+k}$. We can view $(N, g\colon \overline{B}^n \times N \to \mathbb{R}^{n+k})$ also as a fattened submanifold of $\mathbb{R}^{n+k} \cup \{\infty\}$.[1488] Note that the corresponding Thom-Pontryagin map

$$\begin{aligned} \rho_{(N,g)}\colon S^{n+k} = \mathbb{R}^{n+k} \cup \{\infty\} &\to \overline{B}^n/S^{n-1} = S^n \\ P &\mapsto \begin{cases} [x], & \text{if } P = g(x,y) \text{ with } (x,y) \in \overline{B}^n \times N, \\ *, & \text{otherwise,} \end{cases} \end{aligned}$$

sends ∞ to $*$. In particular $\rho_{(N,g)}$ defines an element in $\pi_{n+k}(S^n, *)$. It is worth repeating this observation:

fattened k-dimensional submanifolds of $\mathbb{R}^{n+k}$ give rise to elements in $\pi_{n+k}(S^n, *)$.

The following questions immediately arise:

Question 87.3. *Let $n, k \in \mathbb{N}_0$.*

[1487] The slightly hesitant "quite easily" refers to the fact that, if one thinks about it, we need that the diffeotopy of $\mathbb{R}^{m+k}$ given by Theorem 10.28 has compact support.

[1488] Why can we do so?

(1) *Which elements in $\pi_{n+k}(S^n, *)$ can be realized by Thom-Pontryagin maps?*
(2) *When do two fattened k-dimensional submanifolds of $\mathbb{R}^{n+k}$ give rise to the same element in $\pi_{n+K}(S^n, *)$.*

Before we address this question we intend to discuss two examples in greater detail:

(1) the case of fattened 0-dimensional submanifolds of some $\mathbb{R}^n$, and
(2) the case of fattened 1-dimensional submanifolds of $\mathbb{R}^3$.

We start out with the first case. Dealing with this case requires one definition.

Definition. Let $P \in \mathbb{R}^n$ be a point and let $g\colon \{P\} \times \overline{B}^n \to \mathbb{R}^n$ be a fattening of P. We equip $\{P\} \times \overline{B}^n = \overline{B}^n$ and $\mathbb{R}^n$ with the standard orientations. We define

$$\operatorname{sign}(g) \ := \ \begin{cases} +1, & \text{if } g \text{ is orientation-preserving,} \\ -1, & \text{if } g \text{ is orientation-reversing.} \end{cases}$$

Now we can discuss the case of fattened 0-dimensional submanifolds.

Example. Let $N = \{P_1, \ldots, P_m\}$ be a 0-dimensional submanifold of some $\mathbb{R}^n$ and suppose N is equipped with a fattening

$$g = g_1 \sqcup \cdots \sqcup g_m \colon (\overline{B}^n \times P_1) \sqcup \cdots \sqcup (\overline{B}^n \times P_m) \ \to \ \mathbb{R}^n.$$

It follows almost immediately from Proposition 80.2 that

$$[\rho_{(N,g)}] \ = \ \sum_{i=1}^{m} \operatorname{sign}(g_i) \cdot [\mathrm{id}_{S^n}] \ \in \ \pi_n(S^n, *).$$

We continue our discussion of examples of the Thom-Pontryagin construction with knots and links. By the above discussion every fattened knot or link in $\mathbb{R}^3$, i.e. every fattened 1-dimensional submanifold of $\mathbb{R}^3$, gives rise to an element in $\pi_3(S^2, *)$. For the trefoil together with some fattening we illustrate the corresponding map $S^3 \to S^2$ in Figure 1061.

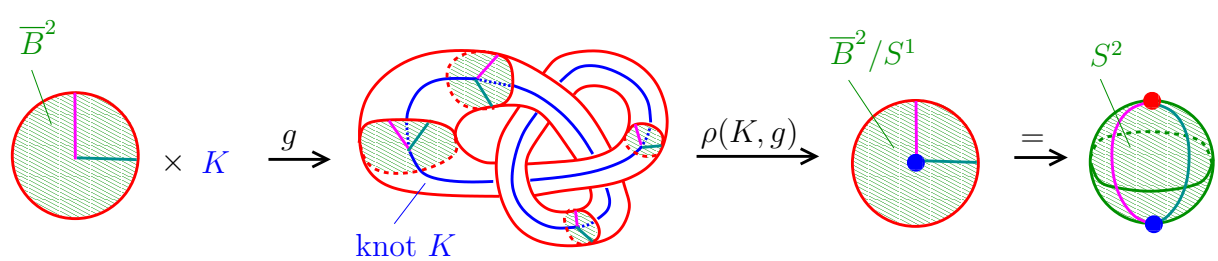

FIGURE 1061.

Before we continue we need to introduce the following slight variation on a definition from page 1626.

Definition. Let K be a knot and let $g\colon \overline{B}^2 \times K \to S^3$ be a fattening. We pick an orientation for K and we equip $g(\{1\} \times K)$ with the corresponding definition. We define[1489]

$$\text{self-linking number of } g \ := \ \mathrm{lk}(K, g(\{1\} \times K)).$$

It follows from Proposition 70.13 (2) that this definition does not depend on the choice of the orientation of K.

The following lemma deals with two basic, but important examples. Later on both examples will follow (at least up to sign) from a more general result, but for the geometrically inclined person it can be fun to consider the more direct arguments provided in the proof of the lemma.

Lemma 87.4. *Let K be the trivial knot and let $g\colon \overline{B}^2 \times K \to \mathbb{R}^3$ be a fattening.*

(1) *If g is a fattening with self-linking number zero, then $[\rho_{(K,g)}] = 0 \in \pi_3(S^2, *)$.*
(2) *If g is a fattening with self-linking number one, then*[1490] *$[\rho_{(K,g)}] = [H] \in \pi_3(S^2, *)$ where $H\colon (S^3, *) \to (S^2, *)$ denotes the Hopf map, that we defined on page 726.*

Sketch of proof $(*)$. It follows easily from Lemma 70.6[1491] that any two fattenings with the same self-linking number give rise to the same element in $\pi_3(S^2, *)$. Furthermore it follows almost immediately from Lemma 18.1 that we can make the identification

$$S^3 \ = \ (\overline{B}^2 \times S^1) \sqcup_{S^1 \times S^1} (S^1 \times \overline{B}^2)$$

such that $K = \{0\} \times S^1$. Furthermore it follows from Lemma 18.2 that the obvious inclusion of $\overline{B}^2 \times S^1$ into the above decomposition of S^3 is a fattening of the trivial knot $K = S^1$ with fattening number zero.

(1) Let g be the fattening of the trivial knot K with self-linking number zero. We want to show that $[\rho_{(K,g)}] = 0 \in \pi_3(S^2, *)$. By Proposition 81.1 it suffices to show that the map $\rho_{(K,g)}\colon S^3 \to S^2$ is homotopic to a constant map. (More precisely, Proposition 81.1 (7) says that in this context we do not need to worry about base points since S^2 is path-connected.) Using the above preparations we will prove in Exercise 87.1 that the map $\rho_{(K,g)}\colon S^3 \to S^2$ is indeed homotopic to a constant map.

[1489] We refer to page 1635 for the definition of the linking number $\mathrm{lk}(K, J)$ of two disjoint oriented knots K and J.

[1490] The sign should be correct. Hopefully. Perhaps.

[1491] Note that here we need that in the statement of Lemma 70.6 for $\mathbb{R}^3$ we stated that there exists a diffeotopy of $\mathbb{R}^3$ with compact support.

(2) First we note that under the above identification of S^3 the Hopf map is given as follows:[1492]

$$\begin{array}{rcl} H\colon \overbrace{(\overline{B}^2 \times S^1) \sqcup_{S^1\times S^1} (S^1 \times \overline{B}^2)}^{=S^3} & \to & \mathbb{C}\mathrm{P}^1 \\ [(z,w)] & \mapsto & \begin{cases} [1 : \frac{z}{w}], & \text{if } z \in \overline{B}^2 \text{ and } w \in S^1, \\ [\frac{w}{z} : 1], & \text{if } z \in S^1 \text{ and } w \in \overline{B}^2. \end{cases} \end{array}$$

Now note that it follows from Lemma 70.6 (1) that the map

$$\begin{array}{rcl} g\colon \overline{B}^2 \times S^1 & \to & \overline{B}^2 \times S^1 \subset S^3 = (\overline{B}^2 \times S^1) \sqcup_{S^1\times S^1} (S^1 \times \overline{B}^2) \\ (z,w) & \mapsto & (z\cdot w, w) \end{array}$$

is a fattening of the trivial knot of self-linking number one. Furthermore by definition the corresponding map $\rho_{(K,g)}$ is easily seen to be the map[1493]

$$\begin{array}{rcl} \rho_{(K,g)}\colon (\overline{B}^2 \times S^1) \sqcup_{S^1\times S^1} (S^1 \times \overline{B}^2) & \to & \overline{B}^2/S^1 \\ [(z,w)] & \mapsto & \begin{cases} [\frac{z}{w}], & \text{if } z \in \overline{B}^2 \text{ and } w \in S^1, \\ \infty = [S^1], & \text{if } z \in S^1 \text{ and } w \in \overline{B}^2. \end{cases} \end{array}$$

Comparing the definitions of the Hopf map H and the map $\rho_{(K,g)}$ on $\overline{B}^2 \times S^1$ we see that we are perhaps not that far off.

Next we need to relate the targets $\mathbb{C}\mathrm{P}^1$ and $\overline{B}^2/S^1$. To do so we consider the map $\Theta\colon \mathbb{C}\mathrm{P}^1 \to \overline{B}^2/S^1$ that is given by $\Theta([1:z]) = \frac{z}{1+|z|}$ and $\Theta([0:1]) = [S^1] = * \in \overline{B}^2/S^1$. It follows easily from Proposition 1.40 that Θ is a homeomorphism. The particularly audacious reader can verify that this map is homotopic to the "official" identification $\mathbb{C}\mathrm{P}^1 = \overline{B}^2/S^1$ which is given by the identification $\mathbb{C}\mathrm{P}^1 = S^2$ from page 113 and the above identification $S^2 = \overline{B}^2/S^1$. Note that the image of the first solid torus $\overline{B}^2 \times S^1$ under the map $\Theta \circ H$ equals the disk of radius $\frac{1}{2}$, i.e. it equals $\overline{B}^2_{\frac{1}{2}} \subset \overline{B}^2/S^1$.

We apply Lemma 87.2 to obtain a homotopy F of $\overline{B}^2/S^1$ with the following properties:

(a) $F_0 = \mathrm{id}$,
(b) the restriction of F_1 to $B^2_{\frac{1}{2}}$ is given by multiplication by 2,
(c) for any point $x \notin B^2_{\frac{1}{2}}$ we have $F_1(x) = *$.

The map $F_0 \circ \Theta \circ H = \Theta \circ H$ is homotopic rel $*$ to $F_1 \circ \Theta \circ H$. It is now straightforward to show that $F_1 \circ \Theta \circ H$ is homotopic rel $*$ to $\rho_{(K,g)}$. We leave it to the reader to fill in the details. □

[1492] As a reality check one can verify that the map is well-defined, i.e. for $[(z,w)]$ with $(z,w) \in S^1 \times S^1$ we get consistent answers.

[1493] Why does it say $[\frac{z}{w}]$ instead of $[z \cdot w]$, which might look more natural?

We conclude this list of basic examples of the Thom-Pontryagin construction with the following lemma.

Lemma 87.5. *Let $n, k \in \mathbb{N}_0$ with $n + k \geq 2$. Let (N_i, g_i), $i = 1, \dots, m$ be fattened k-dimensional submanifolds of $\mathbb{R}^{n+k}$. If the images $g_i(\overline{B}^n \times N_i)$ are contained in m disjoint closed smooth $(n+k)$-dimensional balls*[1494]*, then*

$$\rho_{(N_1 \sqcup \dots \sqcup N_m, g_1 \sqcup \dots \sqcup g_m)} \;=\; \rho_{(N_1, g_1)} + \dots + \rho_{(N_m, g_m)} \;\in\; \pi_{n+k}(S^n, *).$$

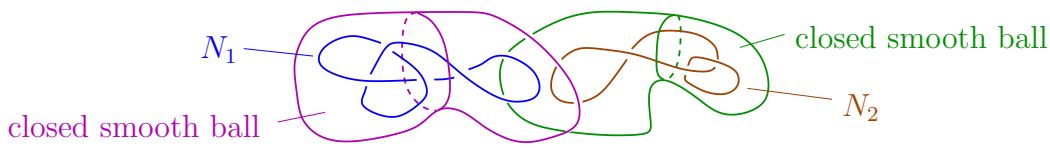

FIGURE 1062.

Proof. This lemma follows easily from Proposition 80.2. We leave it to the reader to fill in the details. □

The following proposition gives an affirmative answer to Question 87.3.

Proposition 87.6. *Let $k, n \in \mathbb{N}_0$. Given any $\varphi \in \pi_{n+k}(S^n, *)$ there exists a fattened k-dimensional submanifold (N, g) of $\mathbb{R}^{n+k}$ with $[\rho_{(N,g)}] = \varphi$.*

Proof. Throughout this proof we find it convenient to view each m-dimensional sphere as the quotient $\overline{B}^m / S^{m-1}$. So suppose we are given a map $\varphi \colon \overline{B}^{n+k}/S^{n+k-1} \to \overline{B}^n/S^{n-1}$ with $\varphi(*) = *$. As we pointed out in Corollary 65.7, it is a consequence of the Whitney Approximation Theorem 65.6 that we can arrange that φ is in fact a smooth map. It follows immediately from Sard's Theorem 3.48 and Proposition 3.47 (2) that there exists a regular value $z \in \overline{B}^n/S^{n-1}$ such that $\varphi^{-1}(z)$ does not contain the point $*$. By Proposition 10.23 (2)[1495] we can without loss of generality assume that the origin 0 is a regular value. By the Regular Value Theorem 65.1 we know that the preimage $N := \varphi^{-1}(0)$ is a closed orientable k-dimensional submanifold of B^{n+k}. Furthermore by statement (4) of the Regular Value Theorem 65.1 we know that there exists an $\epsilon > 0$ and a fattening $g \colon \overline{B}^n \times N \to B^{n+k}$ such

[1494]Here a "closed smooth $(n+k)$-dimensional ball" is shorthand for the image of an embedding of $\overline{B}^{n+k}$ in $\mathbb{R}^{n+k}$.

[1495]To be more precise, we apply Proposition 10.23 to the manifold $\overline{B}^n/S^{n-1} = \mathbb{R}^n \cup \{\infty\}$ with $P_1 = z$, $P_2 = \infty$ and $Q_1 = 0$ and $Q_2 = \infty$.

that $\varphi^{-1}(\overline{B}^n_\epsilon) = g(\overline{B}^n \times N)$ and such that the following diagram commutes[1496][1497]

$$\begin{tikzcd} \overline{B}^n \times N \arrow[r, "g"] \arrow[d, "(p,x)\mapsto \epsilon\cdot p"] & B^{n+k} \arrow[d, "\varphi"] \\ \overline{B}^n_\epsilon \arrow[r, hook] & \overline{B}^n/S^{n-1}. \end{tikzcd}$$

This fattening g allows us to consider the map $\rho_{(N,g)}\colon \overline{B}^{n+k}/S^{n+k-1} \to \overline{B}^n/S^{n-1}$. Note that in general φ and $\rho_{(N,g)}$ are quite different maps. (We refer to Figure 1063 for an illustration of the two maps φ and $\rho_{(N,g)}$.) But that does not bother us too much, since it suffices to prove the following claim.

Claim. The maps φ and $\rho_{(N,g)}$ from $\overline{B}^{n+k}/S^{n+k-1}$ to $\overline{B}^n/S^{n-1}$ are homotopic rel $*$.

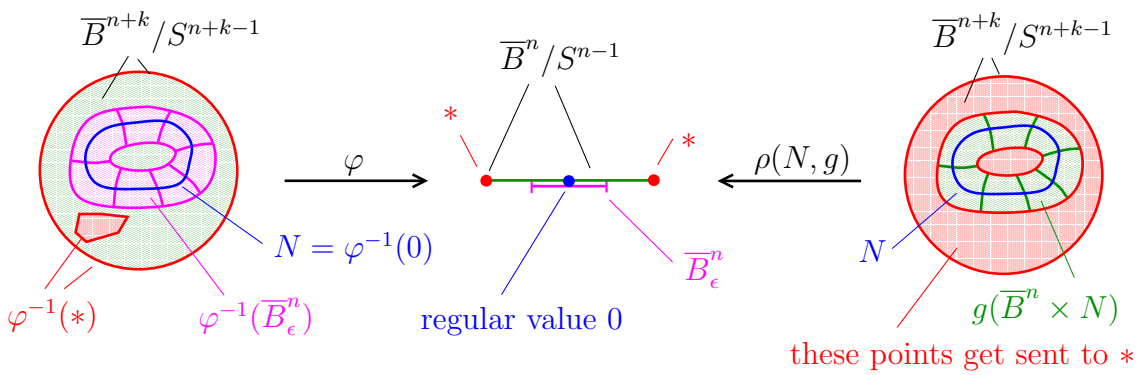

FIGURE 1063.

First we remind the reader that in Lemma 87.2 (1) we showed that there exists a homotopy $F\colon (\overline{B}^n/S^{n-1}) \times [0,1] \to \overline{B}^n/S^{n-1}$ rel $*$ with the following properties:

(1) $F_0 = \mathrm{id}$,
(2) the restriction of F_1 to B^n_ϵ is given by multiplication by $\frac{1}{\epsilon}$,
(3) for any point $x \notin B^n_\epsilon$ we have $F_1(x) = *$.

We define $\psi = F_1 \circ \varphi$. It follows from (1) that ψ is homotopic rel $*$ to φ. Therefore we are done once we have shown that ψ in fact equals $\rho_{(N,g)}$. As a reminder, see the definition on

[1496]Note the discretely hidden multiplication by ϵ in the left-vertical map.
[1497]Note that the above information implies in particular that $\varphi^{-1}(B^n_\epsilon) = g(B^n \times N)$.

page 2008, the map $\rho_{(N,g)}$ is given as follows:[1498]

$$\begin{array}{rcl} \rho_{(N,g)}\colon \overline{B}^{n+k}/S^{n+k-1} & \to & S^n = \overline{B}^n/S^{n-1} \\ P & \mapsto & \begin{cases} x, & \text{if } P = g(x,y) \text{ with } (x,y) \in B^n \times N, \\ *, & \text{otherwise.} \end{cases} \end{array}$$

We now verify that ψ does indeed agree with $\rho_{(N,g)}$. Thus first suppose we are given a point $P = g(x,y)$ with $(x,y) \in B^n \times N$. We have

$$\psi(P) \underset{\substack{\uparrow \\ \text{definition of } \psi}}{=} F_1(\varphi(g(x,y))) \underset{\substack{\uparrow \\ \text{by the above} \\ \text{commutative diagram}}}{=} F_1(\epsilon \cdot x) \underset{\substack{\uparrow \\ \text{by Property (2) of } F_1 \\ \text{and since } \epsilon \cdot x \in B^n_\epsilon}}{=} \tfrac{1}{\epsilon} \cdot \epsilon \cdot x = x = \rho_{(N,g)}(g(x,y)) = \rho_{(N,g)}(P).$$

Finally suppose that we are given a point $P \in \overline{B}^{n+k}/S^{n+k-1}$ that does not lie in the subset $g(B^n \times N)$. In this case we calculate that

$$\psi(P) \underset{\substack{\uparrow \\ \text{definition of } \psi}}{=} F_1(\varphi(P)) \underset{\substack{\uparrow \\ \text{since } \varphi^{-1}(B^n_\epsilon) = g(B^n \times N) \\ \text{and by choice of } P}}{=} F_1(\text{point that does not lie in } B^n_\epsilon) \underset{\substack{\uparrow \\ \text{by Property (3) of } F_1}}{=} * = \rho_{(N,g)}(P).$$

This concludes the proof of the claim. □

87.3. **The fattened cobordism groups and the Thom-Pontryagin Theorem.** Recall that the Thom-Pontryagin construction from page 2008 makes the assignment

$$\text{fattened } k\text{-dimensional submanifold of } \mathbb{R}^{n+k} \quad \rightsquigarrow \quad \text{map } (S^{n+k}, *) \to (S^n, *).$$

We now would like to answer Question 87.3 (2), i.e. we would like to determine when do two fattened k-dimensional submanifolds give rise to the same homotopy class of maps $(S^{n+k}, *) \to (S^n, *)$. Loosely speaking we would like to fill in the left-hand side of

$$?? \quad \rightsquigarrow \quad \text{map } (S^{n+k} \times [0,1], * \times [0,1]) \to (S^n, *).$$

A quick look at the Thom-Pontryagin construction suggests that the left-hand side should be filled in with a suitable fattened $(k+1)$-dimensional submanifold of $\mathbb{R}^{n+k} \times [0,1]$.

This makes sense, except that in Proposition 3.42 we saw that for products of two manifolds it is advisable to have the manifold with boundary as a first factor. Thus we will consider submanifolds of $[0,1] \times \mathbb{R}^{n+k}$.[1499]

Before we continue we introduce the following straightforward convention.

Convention. Given a topological space X and an interval I and some $t \in I$ we make at times the identification $X = \{t\} \times X$ via the obvious bijection.

[1498] Eyes which profited from a carrot-rich diet might notice that the description is not verbatim the same as on page 2008. But with either description of the map the points $P = g(x,y)$ with $x \in S^{n-1}$ and $y \in N$ get sent to $*$. So we really do consider the same map as before.

[1499] Perhaps in hindsight we should have defined homotopies as maps $[0,1] \times X \to Y$ instead of defining them as maps $X \times [0,1] \to Y$?

The above observation leads us to the following definition which looks awfully similar to the definition of the notion of a cobordism of manifolds that we introduced on page 1760.

Definition. Let $k, m \in \mathbb{N}_0$.

(1) Let N_0 and N_1 be two closed orientable k-dimensional submanifolds of $\mathbb{R}^m$. A *cobordism between* N_0 *and* N_1 is a compact orientable proper $(k+1)$-dimensional submanifold W of $[0,1] \times \mathbb{R}^m$ with $\partial W = (\{0\} \times N_0) \cup (\{1\} \times N_1)$.[1500]

(2) Let (N_0, g_0) and (N_1, g_1) be two fattened k-dimensional submanifolds of $\mathbb{R}^m$. A *fattened cobordism between* (N_0, g_0) *and* (N_1, g_1) is a fattened $(k+1)$-dimensional submanifold (W, G) of $[0,1] \times \mathbb{R}^m$ where W is a cobordism between N_0 and N_1 and G is a fattening of W with the following two properties:[1501]
   (a) $G|_{\{0\}\times\overline{B}^m} = g_0$ under the identification $\{0\} \times \overline{B}^m = \overline{B}^m$,
   (b) $G|_{\{1\}\times\overline{B}^m} = g_1$ under the identification $\{1\} \times \overline{B}^m = \overline{B}^m$.
   If such a fattened cobordism exists, then we say that (N_0, g_0) and (N_1, g_1) are *cobordant*.[1502] If (N, g) is cobordant to the empty submanifold, then we say N is a *fattened null-cobordism* and we say that (N, g) is *null-cobordant*. The definition of a fattened cobordism is illustrated in Figure 1064.

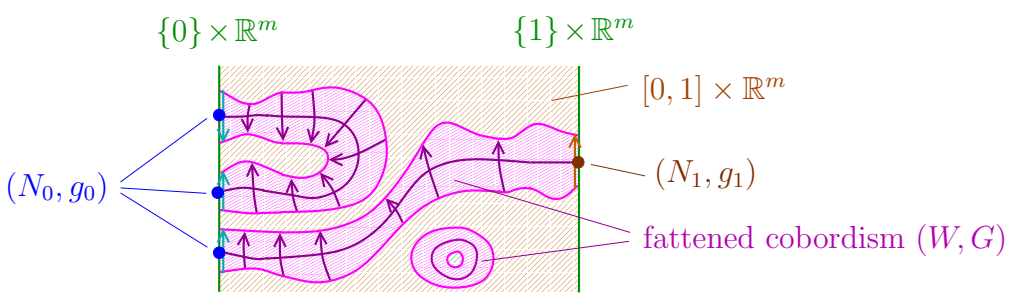

FIGURE 1064.

The following lemma shows that diffeotopies give rise to fattened cobordisms.

Lemma 87.7. *Let (M, g) be a fattened submanifold of $\mathbb{R}^m$ and let φ be a diffeomorphism of $\mathbb{R}^m$. If φ is diffeotopic to the identity, then $(\varphi(M), \varphi_*(g))$ is cobordant to (M, g).*

Example. Let $m \in \mathbb{N}$. Any map $\mathbb{R}^m \to \mathbb{R}^m$ of the form $x \mapsto r \cdot x + P$ for some $r > 0$ and $P \in \mathbb{R}^m$ is clearly diffeotopic to the identity. Thus Lemma 87.7 says that given a fattened submanifold (M, g) we can translate and shrink it without changing the fattened cobordism class.

[1500] Note that we work with submanifolds that are orientable, but we do not assume that they are equipped with an orientation.

[1501] Note that it follows from property (d) of a fattened submanifold, see page 2007, that we know that in fact $G|_{\{0\}\times\overline{B}^m} \subset \{0\} \times \mathbb{R}^m$ and $G|_{\{1\}\times\overline{B}^m} \subset \{1\} \times \mathbb{R}^m$.

[1502] We spare the reader the even more logical name "fattened cobordant".

Proof. Let $(M, g\colon \overline{B}^{m-k} \times M \to \mathbb{R}^m)$ be a fattened k-dimensional submanifold of $\mathbb{R}^m$ and furthermore let $F\colon \mathbb{R}^m \times [0,1] \to \mathbb{R}^m$ be a diffeotopy from the identity to a diffeomorphism φ. It is straightforward to verify that the map

$$\begin{array}{rcl} [0,1] \times M & \to & [0,1] \times \mathbb{R}^m \\ (t, P) & \mapsto & (t, F(P,t)) \end{array}$$

is an embedding. We write $W := F([0,1] \times M)$. It is straightforward to verify that W together with the fattening given by

$$\begin{array}{rcl} \overline{B}^{m-k} \times W & \to & [0,1] \times \mathbb{R}^m \\ (v, (t, F(P,t))) & \mapsto & (t, F(g(v,P), t)) \end{array}$$

is a fattened cobordism between (M, g) and $(\varphi(M), \varphi_*(g))$. □

Lemma 87.8. *"Being cobordant" is an equivalence relation on the set of fattened k-dimensional submanifolds of $\mathbb{R}^m$.*

Sketch of proof. To simplify the discussion we ignore throughout the proof the fattenings. The reader should have no major troubles modifying the proof to also include the fattenings.

It is straightforward to see that "being cobordant" is reflexive and symmetric: Indeed, given a closed k-dimensional submanifold N a cobordism from N to itself is given by $[0,1] \times N \subset [0,1] \times \mathbb{R}^m$. Furthermore, suppose there exists a cobordism W between N_0 and N_1. "Flipping" W along $\mathbb{R}^m \times \{\frac{1}{2}\}$ we obtain a cobordism between N_1 and N_0.

The proof of transitivity takes more efforts. Initially the idea is quite simple. Given a cobordism V from N_0 to N_1 and another cobordism W from N_1 to N_2 one would like to stick them together to obtain a cobordism from N_0 to N_2. Unfortunately, as we had discussed on page 342, the resulting object is in general not a (smooth) submanifold of the manifold $\mathbb{R}^m$.

Fortunately we had already developed all the tools to deal with the situation. More precisely, in Proposition 10.16 we saw that we can modify the cobordisms V and W to obtain cobordisms V' and W' that are products on $[0, \epsilon] \times \mathbb{R}^m$ and $[1-\epsilon, 1] \times \mathbb{R}^m$ for a suitable $\epsilon \in (0, \frac{1}{2})$. Now we can stick V' and W' together to obtain the desired cobordism X. We refer to Figure 1065 for an illustration. □

The previous lemma allows us to make the following definition.

Definition. We denote by $\Omega_k^{\text{fat}}(\mathbb{R}^m)$ the set of fattened cobordism classes of fattened k-dimensional submanifolds of $\mathbb{R}^m$. In light of the subsequent Proposition 87.9 we refer to $\Omega_k^{\text{fat}}(\mathbb{R}^m)$ as a *fattened cobordism group.*

The definition of $\Omega_k^{\text{fat}}(\mathbb{R}^m)$ is reminiscent of the definition of the cobordism group Ω_k that we gave on page 1762. The group structure on Ω_k that we had introduced in Lemma 76.2 is given by "disjoint union". We will now see that $\Omega_k^{\text{fat}}(\mathbb{R}^m)$ also admits a group structure that is defined quite similarly.

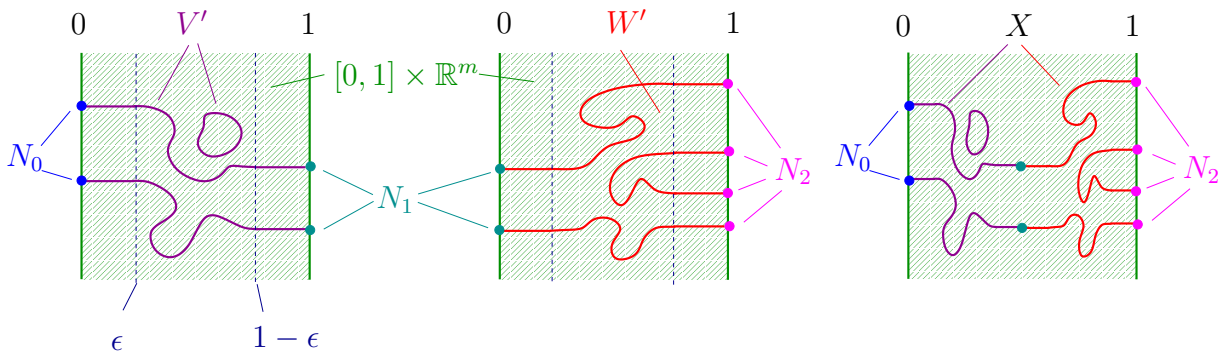

FIGURE 1065. Illustration for the proof of Lemma 1065.

Proposition 87.9. *Let $k \in \mathbb{N}_0$ and let $m \in \mathbb{N}_{\geq 2}$. Let (M, g) and (N, h) be two fattened k-dimensional submanifolds of $\mathbb{R}^m$. Since M and N are compact we can pick $r, s \in \mathbb{R}_{>0}$ with $g(\overline{B}^{m-k} \times M) \subset B^m_r(0)$ and $h(\overline{B}^{m-k} \times N) \subset B^m_s(0)$. Furthermore we pick two orientation-preserving embeddings $\varphi\colon \overline{B}^m_r(0) \to \mathbb{R}^m$ and $\psi\colon \overline{B}^m_s(0) \to \mathbb{R}^m$ with disjoint images. We define*

$$[(M, g)] + [(N, h)] \;:=\; [(\varphi(M) \sqcup \psi(N), \varphi_*(g) \sqcup \psi_*(h))] \;\in\; \Omega^{\text{fat}}_k(\mathbb{R}^m).$$

(The definition of the operation "+" is illustrated in Figure 1066.)

(1) *The definition of "+" on $\Omega^{\text{fat}}_k(\mathbb{R}^m)$ is well-defined and commutative.*
(2) *The operation "+" defines a group structure on $\Omega^{\text{fat}}_k(\mathbb{R}^m)$. Here the following two statements hold:*
   (a) *The neutral element is represented by the empty submanifold.*[1503]
   (b) *Let $\rho\colon \mathbb{R}^m \to \mathbb{R}^m$ be the reflection in a hyperplane. The inverse of $[(M, g)]$ is given by $[(\rho(M), \rho_*(g))]$.*

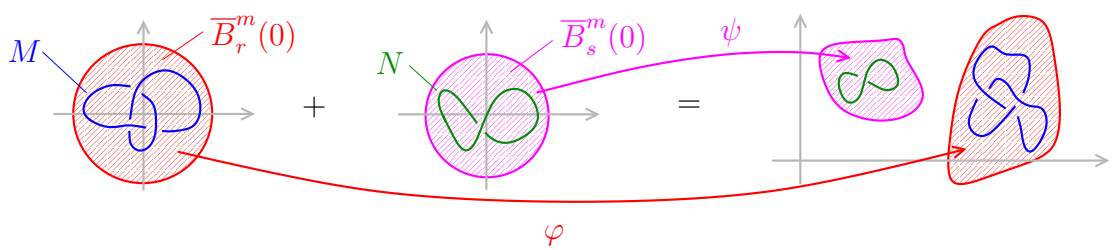

FIGURE 1066.

Proof.

(1) It follows from Theorem 10.28 and Lemma 87.7 that "+" is well-defined and commutative. Note that here we use that $m \geq 2$.

[1503]It is worth remembering that the empty set is a submanifold of any dimension.

(2) It is basically obvious that "+" is associative and that the empty submanifold is a neutral element. Thus it remains to prove the statement regarding the inverse. It follows from Lemmas 87.7 and 9.4 that without loss of generality we can assume that the reflection $\rho\colon \mathbb{R}^m \to \mathbb{R}^m$ is the reflection in the $(x_m = 0)$-hyperplane. So let $(M, g\colon \overline{B}^{m-k} \times M \to \mathbb{R}^m)$ be a fattened k-dimensional submanifold of $\mathbb{R}^m$. We set $\epsilon = \frac{1}{4}$. It follows immediately from the discussion on page 2017 that we can assume that $g(\overline{B}^{m-k} \times M)$ is contained in the ball $\overline{B}^m_\epsilon(\underbrace{(0,\dots,0,2\epsilon)}_{\in\mathbb{R}^m})$. We consider the map

$$\begin{array}{rcl} \varphi\colon \overline{B}^{m-k} \times (M \times [0,\pi]) & \to & [0,1] \times \mathbb{R}^m \\ (v,(P,\gamma)) & \mapsto & \begin{pmatrix} \cos(\gamma) & \sin(\gamma) & 0 \\ -\sin(\gamma) & \cos(\gamma) & 0 \\ 0 & 0 & \mathrm{id}_{m-1} \end{pmatrix} \cdot \underbrace{\begin{pmatrix} 0 \\ g(v,P) \end{pmatrix}}_{\in\mathbb{R}^{m+1}}. \end{array}$$

Using that $g(\overline{B}^{m-k} \times M)$ is contained $\overline{B}^m_\epsilon((0,\dots,0,2\epsilon))$ we can make the following three observations:

(a) The image of φ does indeed lie in $[0,1] \times \mathbb{R}^m$.
(b) The restriction to $\{0\} \times M \times [0,\pi]$ is a proper embedding. Therefore we can now consider the compact orientable proper $(k+1)$-dimensional submanifold $W = \varphi(\{0\} \times M \times [0,\pi])$ of $[0,1] \times \mathbb{R}^m$.
(c) The map φ gives rise to a fattening for W.

It is now basically clear that we have constructed a fattened cobordism from the fattened submanifold $(M \sqcup \rho(M), g \sqcup \rho_*(g))$ to the empty submanifold. (We refer to Figure 1067 for an illustration.) But by the definition of "+" this implies that $(\rho(M), \rho_*(g))$ represents the inverse of (M, g). □

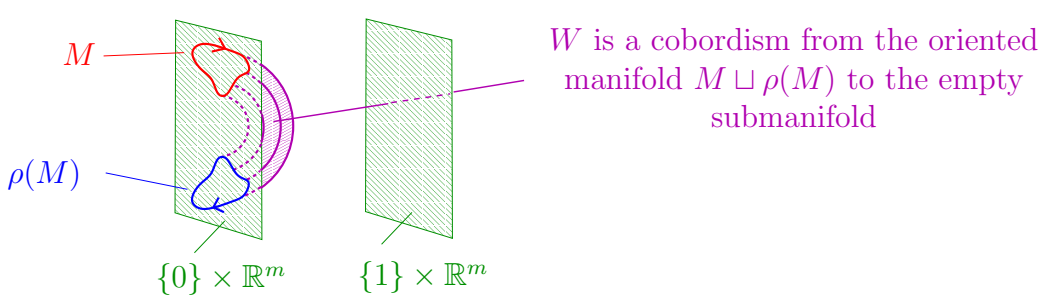

FIGURE 1067.

Evidently our challenge now is to compute the groups $\Omega_k^{\mathrm{fat}}(\mathbb{R}^m)$ for suitable values of m and k. In general this might be quite difficult, but the following proposition gives a reasonably amusing calculation.

Proposition 87.10. *Let $m \geq 2$. The map*[1504]

$$\begin{array}{rcl} \varphi\colon \Omega_0^{\mathrm{fat}}(\mathbb{R}^m) & \to & \mathbb{Z} \\ [(\{P_1\}, g_1) \sqcup \cdots \sqcup (\{P_k\}, g_k)] & \mapsto & \sum_{i=1}^{k} \operatorname{sign}(g_i) \end{array}$$

is well-defined and it is an isomorphism.

Sketch of proof. First we need to show that $\varphi\colon \Omega_0^{\mathrm{fat}}(\mathbb{R}^m) \to \mathbb{Z}$ is well-defined. It suffices to show that for any *connected* fattened 1-dimensional cobordism $(Z, V) \subset [0,1] \times \mathbb{R}^m$ between two 0-dimensional fattened submanifolds (N_0, g_0) and (N_1, g_1) we have the equality $\varphi([(N_0, g_0)]) = \varphi([(N_1, g_1)])$. This statement follows from the classification of compact 1-dimensional manifolds, see Proposition 3.53, and some orientation considerations. Since writing down the precise arguments regarding the orientations will only obfuscate the argument we refer to Figure 1068 for convincing pictures, and we leave it to the reader to fill in the details.

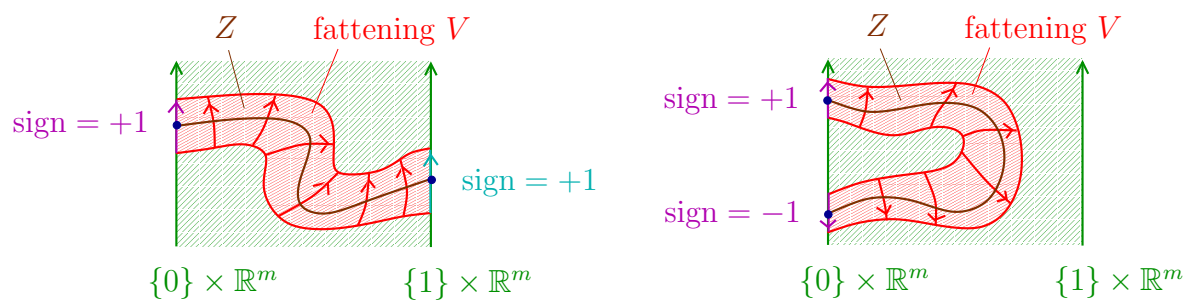

FIGURE 1068. Illustration for the proof of Proposition 87.10.

Next note that the map $\varphi\colon \Omega_0^{\mathrm{fat}}(\mathbb{R}^m) \to \mathbb{Z}$ is, basically by definition, a homomorphism. Finally note that it is clear that φ is an epimorphism. Thus it remains to show that φ is a monomorphism. A straightforward induction argument shows that it suffices to prove the following claim.

Claim. For points $P, Q \in \mathbb{R}^m$ and fattenings g and h of P and Q with $\operatorname{sign}(g) = -\operatorname{sign}(h)$ we have $[(P, g)] + [(Q, h)] = 0 \in \Omega_0^{\mathrm{fat}}(\mathbb{R}^m)$.

In the following let $\rho\colon \mathbb{R}^m \to \mathbb{R}^m$ be the reflection in a hyperplane. By the discussion on page 2017 we can assume, after possibly applying a translation, that $Q = \rho(P)$. Since ρ is orientation-reversing we see that $\operatorname{sign}(\rho_*(g)) = -\operatorname{sign}(g) = \operatorname{sign}(h)$. Now we calculate that

$$\begin{array}{ccccccc} [(P,g)] + [(Q,h)] & = & [(P,g)] + [(\rho(P),h)] & \underset{\uparrow}{=} & [(P,g)] + [(\rho(P),\rho_*(g))] & \underset{\uparrow}{=} & 0 \in \Omega_0^{\mathrm{fat}}(\mathbb{R}^m). \\ & & & \text{by } \operatorname{sign}(h) = \operatorname{sign}(\rho_*(g)), \text{ Theorem 10.28 and Lemma 87.7} & & \text{by Proposition 87.9 (2b)} & \end{array}$$

This concludes the proof of the claim. □

[1504]We refer to page 2011 for the definition of the sign of a fattening of a point.

Considering the discussion on page 2016, the following theorem does not come as a big surprise. It justifies our interest in the groups $\Omega_k^{\text{fat}}(\mathbb{R}^m)$.

Theorem 87.11. (Thom-Pontryagin Theorem) *Let $n, k \in \mathbb{N}_0$ with $n + k \geq 2$. The map*

$$\begin{array}{rcl} \Psi\colon \Omega_k^{\text{fat}}(\mathbb{R}^{n+k}) & \to & \pi_{n+k}(S^n, *) \\ [(N, g)] & \mapsto & [\rho_{(N,g)}] \end{array}$$

is well-defined and it is an isomorphism.

Sketch of proof. Fortunately we have already done basically all the work:

(1) First we argue that Ψ is well-defined. Thus suppose that we are given fattened k-dimensional submanifolds (M, g) and (N, h) of $\mathbb{R}^{n+k}$ that are cobordant. We pick a fattened cobordism $(W, F\colon \overline{B}^n \times W \to [0, 1] \times \mathbb{R}^{n+k})$ in $[0, 1] \times \mathbb{R}^{n+k}$. The corresponding map

$$\rho_{(W,F)}\colon [0, 1] \times \mathbb{R}^{n+k} \to S^n$$

has the property that it sends a neighborhood of $[0, 1] \times \{\infty\}$ to $*$. Therefore it follows easily from Lemma 1.32 (2) that the following map is continuous:

$$\begin{array}{rcl} S^{n+k} \times [0, 1] = (\mathbb{R}^{n+k} \cup \{\infty\}) \times [0, 1] & \to & S^n \\ (P, t) & \mapsto & \begin{cases} \rho_{(W,F)}(t, P), & \text{if } P \in \mathbb{R}^{n+k}, \\ *, & \text{if } P = \infty. \end{cases} \end{array}$$

It follows from the above that this map is in fact a homotopy rel $*$ between the map $\rho_{(M,g)}\colon (S^{n+k}, *) \to (S^n, *)$ and the map $\rho_{(N,h)}\colon (S^{n+k}, *) \to (S^n, *)$. In particular we have $[\rho_{(M,g)}] = [\rho_{(N,h)}] \in \pi_{n+k}(S^n, *)$.

(2) It follows immediately from Lemma 87.5 that Ψ is a homomorphism.

(3) The statement of Proposition 87.6 is equivalent to saying that Ψ is an epimorphism.

(4) Finally it remains to show that Ψ is in fact a monomorphism. So suppose that we are given two fattened k-dimensional submanifolds (M, g) and (N, h) of $\mathbb{R}^{n+k}$ such that $[\rho_{(M,g)}] = [\rho_{(N,h)}] \in \pi_{n+k}(S^n, *)$, i.e. such that there exists a homotopy $F\colon S^{n+k} \times [0, 1] \to S^n$ rel $*$ from $\rho_{(M,g)}$ to $\rho_{(N,h)}$.

The proof of Proposition 87.6 can be modified without too many problems to show that the homotopy F gives rise to a fattened cobordism between (M, g) and (N, h). We leave it to the reader to fill in the details. See also [Kos, Theorem 9.5.5] or [Bre, Chapter 16] for similar claims stated with more authority. □

From our above results we obtain the following corollary. Of course we proved this result earlier in Corollary 80.6, using very different methods.

Corollary 87.12. *For any $m \geq 2$ the map*

$$\begin{array}{rcl} \mathbb{Z} & \to & \pi_m(S^m, *) \\ n & \mapsto & n \cdot [\mathrm{id}_{S^m}] \end{array}$$

is an isomorphism.

Proof. Let $P \in \mathbb{R}^m$ and let g be a fattening for the submanifold $\{P\}$. We consider the two maps

$$\begin{array}{rcl} \mathbb{Z} & \to & \Omega_0^{\mathrm{fat}}(\mathbb{R}^m) \\ n & \mapsto & n \cdot [(\{0\}, g \text{ with } \mathrm{sign}(g) = 1)] \end{array} \quad \text{and} \quad \begin{array}{rcl} \Omega_0^{\mathrm{fat}}(\mathbb{R}^m) & \to & \pi_m(S^m, *) \\ [(N, g)] & \mapsto & [\rho_{(N,g)}]. \end{array}$$

The first map is an isomorphism by Proposition 87.10 and the second map is an isomorphism by the Thom-Pontryagin Theorem 87.11, applied to $k = 0$ and $m \geq 2$. Thus the composition of the two maps is an isomorphism. Finally it follows from Lemma 87.1 that the composition of these two maps sends n to $n \cdot [\mathrm{id}_{S^m}]$. □

87.4. **The calculation of the fattened cobordism group $\Omega_1^{\mathrm{fat}}(\mathbb{R}^3)$.** Surely the most interesting calculation of a higher homotopy group that we have performed so far is that in Theorem 85.10 (2) we saw $\pi_3(S^2) \cong \mathbb{Z}$. Our goal now is to give a new proof of this fact using the Thom-Pontryagin Theorem 87.11. Thus we need to show that $\Omega_1^{\mathrm{fat}}(\mathbb{R}^3) \cong \mathbb{Z}$.

We start out with the following slightly subtle definition.

Definition. Let $m \in \mathbb{N}$.

(1) Let $(M, v\colon \overline{B}^{m-k} \times \mathbb{R}^m)$ be a fattened $(m-k)$-dimensional submanifold of $\mathbb{R}^m$. The *natural orientation of M* is the unique orientation that turns v into an orientation-preserving map.[1505]
(2) Similarly we define the natural orientation of a fattened cobordism.

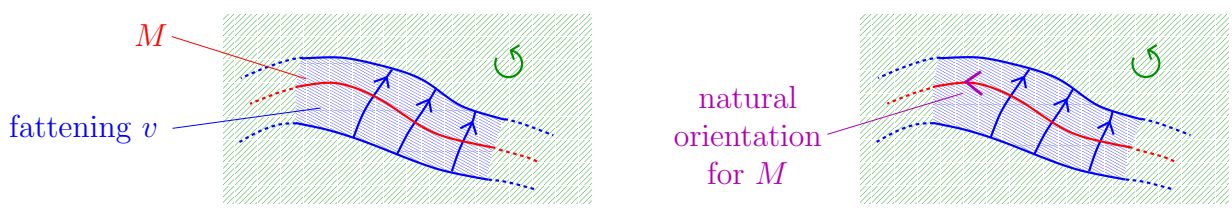

FIGURE 1069.

This definition leads us to the following convention.

Convention. In this section we equip any fattened submanifold and any fattened cobordism with the natural orientation.

Before we write down an explicit isomorphism we introduce the following definition which generalizes the definition of the self-linking number of a fattened knot that we introduced on page 1626.

Definition.

[1505]Recall that M is assumed to be orientable, but a priori it does not come with an orientation. It is not difficult to see that there exists a unique orientation on M such that, if we equip $\overline{B}^{m-k} \times M$ with the product orientation, v becomes orientation-preserving.

(1) Let $K = K_1 \sqcup \cdots \sqcup K_m$ and $L = L_1 \sqcup \cdots \sqcup L_n$ be two disjoint oriented links. We define the *linking number of K and L* as
$$\mathrm{lk}(K, L) \;=\; \sum_{i=1}^{m} \sum_{j=1}^{n} \mathrm{lk}(K_i, L_j).$$

(2) Let (L, g) be a fattened link. We write $L' = g(\{1\} \times L)$. We define the *self-linking number of* (L, g) as $\mathrm{slk}(L, g) := \mathrm{lk}(L, L')$.[1506]

The following elementary lemma is at times useful for determining self-linking numbers of fattened links.

Lemma 87.13. *If $(L, g) = (L_1 \sqcup \cdots \sqcup L_m, g_1 \sqcup \cdots \sqcup g_m)$ is a fattened link, then*
$$\mathrm{slk}(L, g) \;:=\; \sum_{i \neq j} \mathrm{lk}(L_i, L_j) \;+\; \sum_{i=1}^{m} \mathrm{slk}(L_i, g_i).$$

Proof. We will prove the lemma in Exercise 87.2. □

Now we can give the promised isomorphism.

Theorem 87.14. *The map*
$$\begin{array}{rcl} \Psi\colon \Omega_1^{\mathrm{fat}}(\mathbb{R}^3) & \to & \mathbb{Z} \\ [(L, g)] & \mapsto & \textit{self-linking number } \mathrm{slk}(L, g) \end{array}$$
is well-defined and it is an isomorphism. In particular we have $\pi_3(S^2) \cong \mathbb{Z}$.

Examples.

(1) We consider the trivial knot K with a fattening g of self-linking number $+1$. By Theorem 87.14 the fattened knot (K, g) defines a generator of $\Omega_1^{\mathrm{fat}}(\mathbb{R}^3)$. It follows from the isomorphism provided by the Thom-Pontryagin Theorem 87.11 that $\rho_{(K,g)}\colon S^3 \to S^2$ represents a generator of $\pi_3(S^2, *)$. In Lemma 87.4 we saw that $\rho_{(K,g)}$ represents the same element of $\pi_3(S^2, *)$ as the Hopf map $H\colon S^3 \to S^2$. Thus we see once again that the Hopf map represents a generator of $\pi_3(S^2)$.

(2) We consider the Hopf link $L = L_1 \sqcup L_2$ with the orientations shown in Figure 1070. We equip $L = L_1 \sqcup L_2$ with a "trivial fattening" $g_1 \sqcup g_2$, i.e. where the fattening g_i of each component L_i has self-linking number 0. We see that
$$\mathrm{slk}(L_1 \sqcup L_2, g_1 \sqcup g_2) \underset{\substack{\uparrow \\ \text{Lemma 87.13}}}{=} \mathrm{lk}(L_1, L_2) + \mathrm{lk}(L_2, L_1) + \overbrace{\mathrm{slk}(L_1, g_1)}^{=0} + \overbrace{\mathrm{slk}(L_2, g_2)}^{=0} \underset{\substack{\uparrow \\ \text{pick your favorite method from Section 70.4}}}{=} 1 + 1 = 2.$$
This shows that the Hopf link, perhaps slightly counter-intuitively, gives rise to *twice* the generator of $\pi_3(S^2, *)$.

[1506] Here we use the above convention to view L as an *oriented* submanifold, and we equip $L' = g(\{1\} \times L)$ with the obvious corresponding orientation.

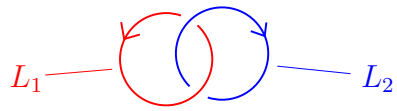

FIGURE 1070.

Since we already have an independent proof of Theorem 87.14 we will take the liberty to cut a few corners in the new proof of the theorem. The new proof of Theorem 87.14 will build on the following four lemmas. The first two lemmas generalize Proposition 70.8 and Lemma 70.17 from knots to links. They are perhaps interesting in their own right.

Lemma 87.15. *Given any oriented link $L \subset S^3$ there exists a compact oriented connected surface $F \subset S^3$ such that $\partial F = L$.*[1507]

Proof of Lemma 87.15. Let $L \subset S^3$ be an oriented link. A modest generalization of Proposition 70.8 shows that there exists a compact oriented surface $G \subset S^3$ with $\partial G = L$. In Exercise 87.5 we will show that we can turn G into a compact oriented *connected* surface F with $\partial F = L$.[1508] □

Lemma 87.16. *If $K = K_1 \sqcup \cdots \sqcup K_m$ and $L = L_1 \sqcup \cdots \sqcup L_n$ are two oriented links, then the following statements hold:*

(1) *There exist compact oriented proper 2-dimensional submanifolds S and T of $\overline{B}^4$ with $\partial S = K$ and $\partial T = L$ such that S and T are transverse.*
(2) *Let S, T be two oriented proper 2-dimensional submanifolds of $\overline{B}^4$ with $\partial S = K$ and $\partial T = L$. If S and T are transverse, then*[1509]

$$\mathrm{lk}(K, L) \;=\; S \cdot_{\overline{B}^4} T.$$

Example. As on page 965 we consider the Hopf link that is illustrated in Figure 1071 on the left. On the right of Figure 1071 we show a compact oriented connected surface whose boundary equals the Hopf link.

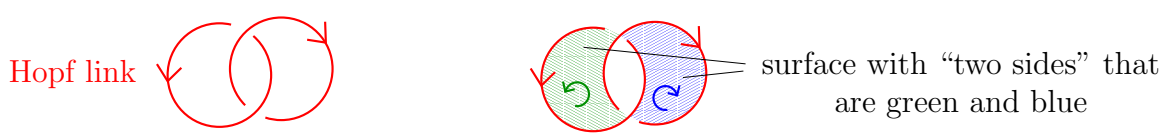

FIGURE 1071.

[1507]Here the equality $\partial F = L$ is understood to be an equality of *oriented* submanifolds.

[1508]Frankly it can be slightly annoying to give a completely rigorous proof that such a surface F exists. This is one of the main reasons why we made the caveat above that we are going to cut a few corners in the argument.

[1509]Here $S \cdot_{\overline{B}^4} T$ denotes the algebraic intersection number of the oriented transverse surfaces S and T in the oriented manifold $\overline{B}^4$. We refer to page 1560 for the definition of the algebraic intersection number.

Proof of Lemma 87.16.

(1) The proof of this statement is virtually the same as the proof of Lemma 70.17, we just need to replace Proposition 70.8 by Lemma 87.15.
(2) We leave it to the reader to verify that the proof of Lemma 70.17 (2) can be modified to deal not only with knots but also with links. □

The following two lemmas that we need for the proof of Theorem 87.14 are arguably more technical.

Lemma 87.17. *Let K be an oriented* knot *in $\mathbb{R}^3$ and let g and h be two fattenings for K in $\mathbb{R}^3$. If $\operatorname{slk}(K,g)=\operatorname{slk}(K,h)$, then $[(K,g)]=[(K,h)]\in\Omega_1^{\text{fat}}(\mathbb{R}^3)$.*

Proof of Lemma 87.17(∗). Since $\operatorname{slk}(K,g)=\operatorname{slk}(K,h)$ it follows from Lemma 70.6 that there exists a smooth isotopy $F\colon(\overline{B}^2\times K)\times[0,1]\to\mathbb{R}^3$ between g and h which has compact support and which has the property that $F(0,k,t)=k$ for all $k\in K$ and all $t\in[0,1]$. We consider $W=[0,1]\times K$ with the fattening given by

$$\begin{array}{rcl} j\colon\overline{B}^2\times([0,1]\times K) & \to & [0,1]\times\mathbb{R}^3\\ (v,(t,x)) & \mapsto & (t,F((v,x),t)).\end{array}$$

The fattened manifold (W,j) is a fattened cobordism between (K,g) and (K,h). □

Lemma 87.18. *Let W be a compact oriented proper connected 2-dimensional submanifold of $\mathbb{R}^3\times[0,1)$ with boundary components $L_1,\dots,L_m$. Given $s_1,\dots,s_{m-1}\in\mathbb{Z}$ there exists a fattening h for W such that for $i=1,\dots,m-1$ we have $\operatorname{slk}(L_i,h|_{L_i})=s_i$.*

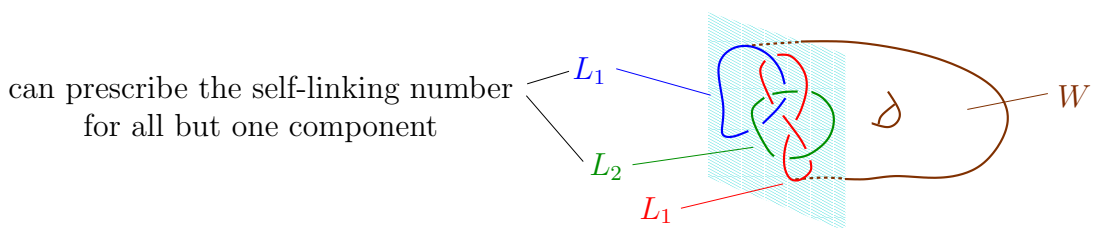

FIGURE 1072.

Proof. Evidently we can assume that $m\geq 1$. In this case W is a compact oriented proper connected 2-dimensional submanifold with non-empty boundary. Thus by Proposition 64.8 there exists a fattening $f\colon\overline{B}^2\times W\to\mathbb{R}^3\times[0,1)$ for W. For $i=1,\dots,m-1$ we write $r_i:=\operatorname{slk}(L_i,g|_{L_i})$.

By Lemma 14.20 there exists a map $\varphi\colon W\to L_1\vee\dots\vee L_{m-1}$[1510] that is the identity on each L_i. We pick a map $\psi\colon L_1\vee\dots\vee L_{m-1}\to\mathrm{SO}(2)=S^1$ with the following property:

[1510]Here, as a reminder, $L_1\vee\dots\vee L_{m-1}$ denotes the wedge of the topological spaces $L_1,\dots,L_{m-1}$.

under a orientation-preserving identification $L_i = S^1$ the restriction of ψ to L_i is given by $z \mapsto z^{s_i - r_i}$. Now we consider the fattening

$$\begin{aligned} h\colon \overline{B}^2 \times W &\to W \\ (v, P) &\mapsto f(\underbrace{(\overbrace{\psi \circ \varphi)(P)}^{\in \mathrm{SO}(2)} \cdot v, P)}_{\in \overline{B}^2 \times W}). \end{aligned}$$

By Lemma 70.6 (1) we know that for any $i \in \{1, \dots, m-1\}$ we added $s_i - r_i$ to the self-linking number of L_i. Thus the fattening h has all the desired properties. $\square$

Now we are in a position to provide the proof of Theorem 87.14.

Sketch of proof of Theorem 87.14.

(1) First we need to show that $\Psi\colon \Omega_1^{\mathrm{fat}}(\mathbb{R}^3) \to \mathbb{Z}$ is well-defined. In the proof of this fact we borrow some ideas from the proof of Lemma 70.17 (2). So let (W, F) be a fattened cobordism between (K, g) and (L, h). We write $W' = F(\{1\} \times W)$, $K' = g(\{1\} \times K)$ and $L' = h(\{1\} \times L)$. By Lemma 87.16 (1) there exist oriented proper 2-dimensional submanifolds S and S' of $\overline{B}^4$ with $\partial S = K$ and $\partial S' = K'$ such that S and S' are transverse. Similarly there exist T, T' for L and L'.

We can make the identification $S^4 = (-\overline{B}^4) \cup [0,1] \times S^3 \cup \overline{B}^4$[1511] (See Figure 1073 for an illustration.) Using Proposition 10.17 we can arrange that both $(-S) \cup W \cup T$ and $(-S') \cup W' \cup T'$ are oriented submanifolds of the manifold S^4. We calculate that

$$\begin{aligned} -\operatorname{slk}(K,g) + \operatorname{slk}(L,h) &\overset{\substack{\text{by definition of slk} \\ \downarrow}}{=} -\operatorname{lk}(K,K') + \operatorname{lk}(L,L') \overset{\substack{\text{Lemma 87.16 (2)} \\ \downarrow}}{=} (-S) \cdot_{\overline{B}^4} S' + T \cdot_{\overline{B}^4} T' \\ = (-S) \cdot_{-\overline{B}^4} (-S') + T \cdot_{\overline{B}^4} T' &\underset{\substack{\uparrow \\ \text{since the only intersections appear} \\ \text{between } S, S' \text{ and } T, T', \text{ here we use that} \\ W \text{ and } W' \text{ are disjoint}}}{=} (-S \cup W \cup T) \cdot_{S^4} (-S' \cup W' \cup T') \underset{\substack{\uparrow \\ \text{by Theorem 68.11 and} \\ \text{since } H_2(S^4;\mathbb{Z}) = 0}}{=} 0. \end{aligned}$$

We have thus shown that the self-linking numbers of (K, g) and (L, h) agree. This shows that the map $\Psi\colon \Omega_1^{\mathrm{fat}}(\mathbb{R}^3) \to \mathbb{Z}$ is indeed well-defined.

(2) It follows easily from Exercise 70.6 that Ψ is a homomorphism.

(3) By Lemma 70.6 there exists a knot in $\mathbb{R}^3$ with a fattening in $\mathbb{R}^3$ with self-linking number one, thus Ψ is an epimorphism.

(4) It remains to show that $\Psi\colon \Omega_1^{\mathrm{fat}}(\mathbb{R}^3) \to \mathbb{Z}$ is a monomorphism. So suppose we are given a fattened m-component link $(L, g) = \bigsqcup_{i=1}^{m} (L_i, g_i)$ with $\Psi([(L, g)]) = 0$.

[1511] If the reader does not feel like making this identification, then we point out that we only need that the right-hand side is a manifold and that the second homology vanishes.

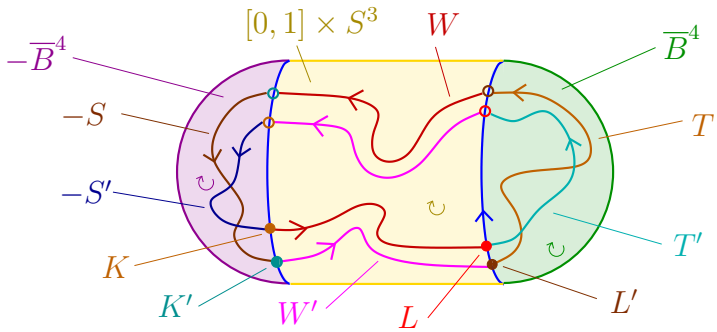

FIGURE 1073. Illustration for the proof of Theorem 87.14.

By Lemma 87.15 there exists a compact oriented connected surface W in $\mathbb{R}^3\times[0,1)$ whose boundary equals $L\subset\mathbb{R}^3=\mathbb{R}^3\times\{0\}$. By Lemma 87.18 we can equip W with a fattening h such that for $i=1,\dots,m-1$ we have $\operatorname{slk}(L_i,h|_{L_i})=\operatorname{slk}(L_i,g_i)$.

Claim. We also have $\operatorname{slk}(L_m,h|_{L_m})=\operatorname{slk}(L_m,g_m)$.

Note that (W,h) is a fattened cobordism between $(L,h|_L)$ and the empty link. In particular we obtain from (1) that $\operatorname{slk}(L,h|_L)=0$. By our hypothesis on (L,g) we also have $\operatorname{slk}(L,g)=0$. We had already arranged that for $i=1,\dots,m-1$ we have $\operatorname{slk}(L_i,h|_{L_i})=\operatorname{slk}(L_i,g_i)$. It now follows immediately from Lemma 87.13 that $\operatorname{slk}(L_m,h|_{L_m})=\operatorname{slk}(L_m,g_m)$. This concludes the proof of the claim.

Now we are done, since

$$\begin{array}{ccccccc}[(L,g)] & = & [(L,h|_g)] & = & 0 & \in & \Omega_1^{\text{fat}}(\mathbb{R}^3).\\ & \uparrow & & \uparrow & & & \\ & \text{Lemma 87.17} & & \text{since } (W,h) \text{ is a null-cobordism for } (L,h|_g) & & & \end{array}$$

□

87.5. **The fattened cobordism group $\Omega_{2n-1}^{\text{fat}}(\mathbb{R}^{4n-1})$.** In Corollary 63.14 we had sketched a proof that given any $n\in\mathbb{N}$ there exists an epimorphism $\pi_{4n-1}(S^{2n})\to\mathbb{Z}$. By the Thom-Pontryagin Theorem 87.11 this statement is equivalent to saying that there exists an epimorphism $\Omega_{2n-1}^{\text{fat}}(\mathbb{R}^{4n-1})\to\mathbb{Z}$.

In this section we will give an alternative proof that such an epimorphism exists. Since we already have a proof for this statement we will only prove the most salient statements. In other words, this section is stuffed with entertaining exercises for the reader.

First of all we work with the same convention as in the last section.

Convention. In this section we equip any fattened submanifold and any fattened cobordism with the natural orientation that we introduced on page 2023.

We continue with the following notation that is germane to this section.

Notation. Let $n\in\mathbb{N}$.

(1) Given a closed oriented m-dimensional submanifold K of S^{2m+1} we denote by
$$\beta_K\colon H_m(K;\mathbb{Z}) \;\to\; H^m(S^{2m+1}\setminus K;\mathbb{Z})$$
the inverse of the isomorphism given by the Alexander Duality Theorem 66.5.

(2) Given a compact oriented proper $(m+1)$-dimensional submanifold W of $[0,1]\times S^{2m+1}$ we denote by
$$\beta_W\colon H_{m+1}(W,\partial W;\mathbb{Z}) \;\to\; H^m(([0,1]\times S^{2m+1})\setminus W;\mathbb{Z})$$
the inverse of the isomorphism given by the Alexander Duality Theorem 66.5.

With this notation we can introduce the following definition.

Definition. Let $m\in\mathbb{N}$ and let K and L be two disjoint closed oriented m-dimensional submanifolds of S^{2m+1}. We define the *linking number of K and L* as
$$\mathrm{lk}(K,L) \;=\; \langle\beta_K([K]),[L]\rangle \;\in\; \mathbb{Z}$$
where we view the fundamental class $[L]$ of L as a homology class in $H_m(S^{2m+1}\setminus K;\mathbb{Z})$.

Remark. The vigilant reader will not have failed to notice that in the 3-dimensional setting it is a priori not clear that the above definition of the linking number agrees with the definition given on page 1635. In Exercise 87.6 we will prove that in the 3-dimensional setting the two competing notions of linking numbers agree.

Proposition 87.19. *Let $n\in\mathbb{N}$ and let $*\in\overline{B}^{2n}$. The map*
$$\begin{aligned}\Psi\colon \Omega^{\mathrm{fat}}_{2n-1}(\mathbb{R}^{4n-1}) &\;\to\; \mathbb{Z}\\ [(N,g\colon \overline{B}^{2n}\times N\to\mathbb{R}^{4n-1})] &\;\mapsto\; \mathrm{lk}(N,g(*\times N))\end{aligned}$$
is a well-defined homomorphism.

Remark. Let $n\in\mathbb{N}$. We recall that on page 1473 we used the cup product to define the Hopf invariant
$$\mathrm{Hopf}\colon \pi_{4n-1}(S^{2n},*) \;\to\; \mathbb{Z}$$
which is, as shown in Proposition 63.7, in fact a homomorphism. The audacious reader can attempt to show that, under the above isomorphism $\Omega^{\mathrm{fat}}_{2n-1}(\mathbb{R}^{4n-1})\xrightarrow{\cong}\pi_{4n-1}(S^{2n},*)$, the Hopf invariant and the homomorphism $\Psi\colon\Omega^{\mathrm{fat}}_{2n-1}(\mathbb{R}^{4n-1})\to\mathbb{Z}$ from Proposition 87.19 agree up to sign.[1512]

Proof. In Exercise 87.7 we will verify that Ψ is a homomorphism. Now let us actually show that Ψ is well-defined. Thus suppose that we are given fattened $(2n-1)$-dimensional submanifolds (N_0,g_0) and (N_1,g_1) of $\mathbb{R}^{4n-1}$ that are cobordant via a fattened cobordism (W,G). We denote by $i_0\colon\{0\}\times S^{4n-1}\to[0,1]\times S^{4n-1}$ the inclusion. Similarly we define i_1. We also use i_0,i_1 in a rather obvious way for restrictions of the above inclusion maps

[1512]Attempting to determine the correct sign with confidence might have negative effects on one's mental health.

to suitable subsets. It follows immediately from the Alexander Duality Theorem 66.5 that we have the following commutative diagram

$$\begin{array}{ccc}
H_{2n}(W,\partial W;\mathbb{Z}) & \xrightarrow[\beta_W]{\cong} & H^{2n-1}(([0,1]\times S^{4n-1})\setminus W;\mathbb{Z}) \\
\Big\downarrow \partial & & \begin{matrix} i_0^* \\ i_1^* \end{matrix} \Big\downarrow \\
\begin{matrix} H_{2n-1}(\{0\}\times N_0;\mathbb{Z}) \\ H_{2n-1}(\{1\}\times N_1;\mathbb{Z}) \end{matrix} & \xrightarrow[\cong]{\begin{pmatrix} \beta_{N_0} & 0 \\ 0 & \beta_{N_1}\end{pmatrix}} & \begin{matrix} H^{2n-1}(\{0\}\times (S^{4n-1}\setminus N_0);\mathbb{Z}) \\ H^{2n-1}(\{1\}\times (S^{4n-1}\setminus N_1);\mathbb{Z}) \end{matrix}
\end{array}$$

where all horizontal maps are isomorphisms and where the left-hand vertical map is the connecting homomorphism of the long exact sequence in homology of the pair $(W,\partial W)$.

It follows that

$$\begin{array}{rcl}
\mathrm{lk}(N_0, g_0(*\times N_0)) & = & \langle \beta_{N_0}([N_0]), [g_0(*\times N_0)]\rangle \\
& = & \langle \beta_W([W]), (i_0)_*([g_0(*\times N_0)])\rangle \\
& \uparrow & \\
& \text{Lemma 50.6} & \text{it follows from } \partial(G(*\times W)) = g_0(*\times N_0)\cup g_1(*\times N_1) \text{ together with} \\
& & \text{Corollary 46.27 (2) that } (i_0)_*([g_0(*\times N_0)]) = (i_1)_*([g_1(*\times N_1)]) \\
& = & \mathrm{lk}(N_1, g_1(*\times N_1)). \\
& \uparrow & \\
& \text{same argument backwards} &
\end{array}$$

$$\begin{array}{rcl}
& & \text{follows from the above diagram and the fact} \\
& & \text{that } [\partial W] = [\{0\}\times N_0] + [\{1\}\times N_1], \text{ see Proposition 46.26} \\
& & \downarrow \\
& = & \langle i_0^*(\beta_W([W])), [g_0(*\times N_0)]\rangle \\
& = & \langle \beta_W([W]), (i_1)_*([g_1(*\times N_1)])\rangle \\
& & \uparrow
\end{array}$$

We have thus shown that Ψ is indeed well-defined. □

Of course an invariant is only interesting if we can show that it assumes non-trivial values. If $n=1$, then we already know[1513] that the trivial knot K together with the fattening g of self-linking number one satisfies $\Psi([(N,g)]) = 1$. In particular we see that $\Psi\colon \Omega_1^{\mathrm{fat}}(\mathbb{R}^3)\to\mathbb{Z}$ is an epimorphism.

Recall that the combination of Propositions 63.7 and 63.13 shows that that given any $n\in\mathbb{N}$ there exists a map $f\colon S^{4n-1}\to S^{2n}$ such that the Hopf invariant equals 2. The following proposition that can be viewed as an analogue of this fact.

Proposition 87.20. *For any $n\in\mathbb{N}$ there exists a fattened $(2n-1)$-dimensional submanifold (N,g) in $\mathbb{R}^{4n-1}$ with $\Psi([(N,g)]) = 2$.*

Sketch of proof. We consider the "trivial $(2n-1)$-dimensional knot"

$$K \;=\; S^{2n-1}\times\{0\} \;=\; \{(z_1,\dots,z_{2n},0,\dots,0)\in\mathbb{R}^{4n-1} \mid z_1^2+\dots+z_{2n}^2 = 1\}$$

[1513]Here we assume for convenience that we already know that the two different definitions of the linking pairing in the 3-dimensional setting agree.

together with the map[1514]

$$\begin{array}{rcl} g\colon \overline{B}^{2n} \times K & \to & \mathbb{R}^{4n-1} \\ \big((x, \underbrace{(y_1, \dots, y_{2n-1})}_{=:y\in\mathbb{R}^{2n-1}}), \underbrace{(z,0)}_{\in K}\big) & \mapsto & (z + \frac{1}{4}x \cdot z, y). \end{array}$$

One can easily verify that, with a suitable orientation for K, the pair (K, g) is a fattened $(2n-1)$-dimensional submanifold of $\mathbb{R}^{4n-1}$. It is not particularly difficult to show that $[g(* \times K)] = 0 \in H_{2n-1}(\mathbb{R}^{4n-1} \setminus K)$. Unfortunately this implies that $\operatorname{lk}(K, g(* \times K)) = 0$.

The first idea would be to modify the fattening g in a similar vein as in Lemma 70.6. This might work in principle, but at least your author does not know how to make this work in general.[1515] Instead we will recycle the example from page 2024 where we saw that the Hopf link gives rise to a non-trivial element in $\Omega_1^{\text{fat}}(\mathbb{R}^3)$. More precisely, we consider the diffeomorphism

$$\begin{array}{rcl} \Theta\colon \mathbb{R}^{4n-1} & \to & \mathbb{R}^{4n-1} \\ (\underbrace{x_1, \dots, x_{2n}}_{=x}, \underbrace{y_1, \dots, y_{2n-1}}_{=y}) & \mapsto & (y, x) + (0, \dots, 0, \underset{\substack{\uparrow \\ 2n\text{-th coordinate}}}{1}, 0, \dots, 0). \end{array}$$

Similar to the discussion on page 2024 one can now fairly easily show (voluntary exercise!) that $\Psi([K \sqcup \Theta(K), g \sqcup \Theta_*(g)]) = \pm 2$. Since Ψ is a homomorphism we see that there exists a fattened $(2n-1)$-dimensional submanifold (N, g) in $\mathbb{R}^{4n-1}$ with $\Psi([(N, g)]) = 2$. $\square$

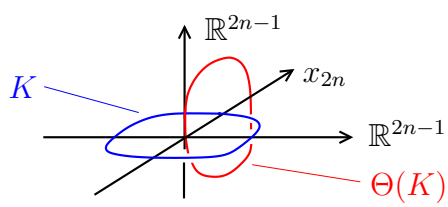

FIGURE 1074.

Remark. In Theorem 79.11 we saw that, unless $n = 2, 4, 8$, there does not exist a map $f\colon S^{2n-1} \to S^n$ with $\operatorname{Hopf}(f) = 1$. If we believe for a second that the Hopf invariant corresponds to the above homomorphisms Ψ, then this shows that Proposition 87.20 is optimal for $n \notin \{1, 2, 4\}$.

In summary, the Thom-Pontryagin Theorem 87.11 together with Propositions 87.19 and 87.20 give us the following result, which is precisely the content of Corollary 63.14.

Proposition 87.21. *Given any* even $n \in \mathbb{N}$ *there exists an epimorphism* $\pi_{2n-1}(S^n) \to \mathbb{Z}$.

[1514] This map g is basically just the "obvious" fattening of $S^{2n-1} \subset \mathbb{R}^{2n}$ extended to higher dimensions.

[1515] Also the remark after the proof might temper one's optimism.

Exercises for Chapter 87.

Exercise 87.1. We consider the map

$$\begin{array}{rcl} f\colon (\overline{B}^2 \times S^1) \sqcup_{S^1\times S^1} (S^1 \times \overline{B}^2) & \to & \overline{B}^2/S^1 \\ P & \mapsto & \begin{cases} [Q], & \text{if } P = [(Q,z)] \text{ with } Q \in \overline{B}^2 \text{ and } z \in S^1, \\ [S^1], & \text{if } P = [(z,Q)] \text{ with } z \in S^1 \text{ and } Q \in \overline{B}^2. \end{cases} \end{array}$$

Show that f is null-homotopic.

Exercise 87.2. Let $(L = L_1 \sqcup \cdots \sqcup L_m, g = g_1 \sqcup \cdots \sqcup g_m)$ be a fattened link. Show that

$$\operatorname{slk}(L,g) \ := \ \sum_{i\neq j} \operatorname{lk}(L_i, L_j) \ + \ \sum_{i=1}^{m} \operatorname{slk}(L_i, g_i).$$

Exercise 87.3. Let $m \geq 2$. The Thom-Pontryagin Theorem 87.11 implies in particular that $\Omega^{\text{fat}}_{m-1}(\mathbb{R}^m) \cong \pi_1(S^m) = 0$. This implies that every fattened submanifold of $\mathbb{R}^m$ of codimension one is null-cobordant. Prove this statement without making use of the Thom-Pontryagin Theorem 87.11.
Hint: Use Lemma 69.3.

Exercise 87.4. We consider the Hopf link H as shown in Figure 1075. Draw an explicit oriented connected compact surface whose boundary equals the oriented link H.
Remark: Note that the orientation of one of the components is different from the Hopf link that we had considered above in Figure 1071.

FIGURE 1075.

Exercise 87.5. Let $L \subset S^3$ be an oriented link and let $G \subset S^3$ be a compact oriented surface with $\partial G = L$. We assume that G has no closed components.

(a) Show that $S^3 \setminus G$ is path-connected.
(b) Give an outline of an argument why there exists a compact oriented *connected* surface F with $\partial F = L$.

Exercise 87.6. Let K and J be two oriented disjoint knots in S^3. Show that the two definitions of the linking number $\operatorname{lk}(K,J)$ given on pages 1635 and 2029 agree.

Exercise 87.7. Show that the map

$$\begin{array}{rcl} \Psi\colon \Omega^{\text{fat}}_{2n-1}(\mathbb{R}^{4n-1}) & \to & \mathbb{Z} \\ [(N, g\colon \overline{B}^{2n} \times N \to \mathbb{R}^{4n-1})] & \mapsto & \operatorname{lk}(N, g(* \times N)) \end{array}$$

considered in Proposition 87.19 is a homomorphism.

Exercise 87.8. In Section 87.5 we had just seen that given any even $n \in \mathbb{N}$ there exists an epimorphism $\Omega_{n-1}^{\text{fat}}(\mathbb{R}^{2n-1}) \to \mathbb{Z}$. What about the group $\Omega_{n-1}^{\text{fat}}(\mathbb{R}^{2n-1})$ if n is odd? Can we use linking numbers to define a homomorphism to $\mathbb{Z}$? Can we use them to find an epimorphism from $\Omega_{n-1}^{\text{fat}}(\mathbb{R}^{2n-1})$ to $\mathbb{Z}$?

88. Thom-Pontryagin Theory II: The Freudenthal Suspension Theorem

88.1. **The framed cobordism group.** In the previous chapter we introduced the fattened cobordism groups $\Omega_k^{\text{fat}}(\mathbb{R}^{n+k})$ and we showed that they are isomorphic to $\pi_{n+k}(S^n, *)$. Furthermore we computed that $\Omega_0^{\text{fat}}(\mathbb{R}^n) \cong \mathbb{Z}$ and $\Omega_1^{\text{fat}}(\mathbb{R}^3) \cong \mathbb{Z}$. Finally we showed that given any $n \in \mathbb{N}$ there exists an epimorphism $\Omega_{2n-1}^{\text{fat}}(\mathbb{R}^{4n-1}) \to \mathbb{Z}$. These calculations gave us new proofs for Corollary 80.6, Theorem 85.10 (2) and Corollary 63.14.

Even though these new proofs were very pleasant, it is now time for some new results. In this section we will prove the Freudenthal Suspension Theorem and we will calculate the homotopy groups $\pi_{n+1}(S^n)$ for $n \geq 3$. For the subsequent calculations it is better though to work with the "framed cobordism groups" $\Omega_k^{\text{fr}}(\mathbb{R}^n)$ that we introduce in this section. As we will see, the framed cobordism groups are isomorphic to the fattened cobordism group, but at times they are easier to calculate since they allow us to reduce many issues to linear algebra.

First we introduce the following definitions in linear algebra.

Definition. Given $m, k \in \mathbb{N}_0$ we write

$$\begin{aligned} \mathrm{GL}(m,k) &:= \text{ set of } k\text{-tuples of linearly independent vectors of } \mathbb{R}^m \\ \mathrm{O}(m,k) &:= \text{ set of } k\text{-tuples of orthonormal vectors of } \mathbb{R}^m. \end{aligned}$$

We adopt the following conventions:

(1) Given $v \in \mathrm{GL}(m,k)$ we denote by $v_1, \dots, v_k$ the corresponding column vectors.
(2) We view $\mathrm{GL}(m,k)$ and $\mathrm{O}(m,k)$ as subsets of the manifold $M(m \times k, \mathbb{R}) = \mathbb{R}^{mk}$.

Now we can give the topological definition we are really interested in.

Definition. Let $m \in \mathbb{N}_0$ and let N be an m-dimensional submanifold of $\mathbb{R}^m$. (Later on we will only be interested in $N = \mathbb{R}^m$, $N = [0,1] \times \mathbb{R}^{m-1}$ and the case that $N = \overline{B}_r^m(P)$ is a closed m-dimensional ball.)

(1) Let M be a compact orientable proper k-dimensional submanifold of N.
   (a) Let $P \in M$. We say $v = (v_1, \dots, v_{m-k}) \in \mathrm{GL}(m, m-k)$ is a *frame* of M at P if the vectors $v_1, \dots, v_{m-k}$, together with $T_P M$[1516] spans $\mathbb{R}^m$.
   (b) A *framing for M* is a smooth[1517] map $v\colon M \to \mathrm{GL}(m, m-k)$ such that for each $P \in M$ the vectors $v_1(P), \dots, v_{m-k}(P)$ are a frame of M at P.
   (c) We say that a framing $v = (v_1, \dots, v_{m-k})$ is *perpendicular* if for each $P \in M$ the vectors $v_1(P), \dots, v_{m-k}(P)$ lie in the orthogonal complement of $T_P M$, i.e. if they lie in the vector space

$$(T_P M)^\perp \;=\; \{v \in \mathbb{R}^m \mid \langle v, w\rangle = 0 \text{ for all } w \in T_P M\}.$$

[1516]Here we use the isomorphism from Proposition 3.32 to identify $T_P M$ with the subvector space $V_P M$ of $\mathbb{R}^m$.

[1517]Since we view $\mathrm{GL}(m, m-k)$ as a subset of the manifold $M(m \times (m-k), \mathbb{R}) = \mathbb{R}^{m\cdot(m-k)}$ it makes sense to say that a map $M \to \mathrm{GL}(m, m-k)$ is smooth.

If the framing is perpendicular and if all the vectors are orthonormal, then we that the framing is *orthonormal*.

(2) A *framed k-dimensional submanifold* of N is a pair (M, v) where M is a compact orientable proper k-dimensional submanifold of N and v is a framing for M.

(3) Let (M, v) be a framed k-dimensional submanifold of N and let $\varphi\colon N \to W$ be an embedding of N into a manifold of the same dimension. We consider the map

$$\begin{array}{rcl} \varphi_*(v)\colon \varphi(M) & \to & \mathrm{GL}(m, m-k) \\ P & \mapsto & (\varphi_*(v_1(\varphi^{-1}(P))), \ldots, \varphi_*(v_{m-k}(\varphi^{-1}(P)))). \end{array}$$

The pair $(\varphi(M), \varphi_*(v))$ is a framed submanifold of W.

Some of the above definitions are illustrated in Figure 1076.

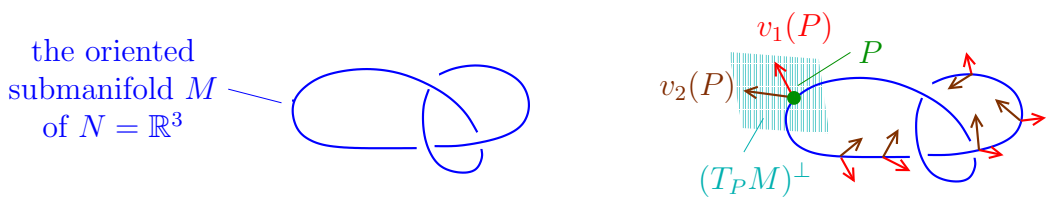

FIGURE 1076.

Definition. Let $k, m \in \mathbb{N}_0$ and let (N_0, v_0) and (N_1, v_1) be two framed k-dimensional submanifolds of $\mathbb{R}^m$. A *framed cobordism between* (N_0, v_0) *and* (N_1, v_1) is a framed $(k+1)$-dimensional submanifold (W, V) of $[0, 1] \times \mathbb{R}^m$ such that the following three conditions are satisfied:

(1) $\partial W = (\{0\} \times N_0) \cup (\{1\} \times N_1)$,
(2) $V|_{\{0\}\times N_0} = v_0$ under the identification $\{0\} \times \mathbb{R}^m = \mathbb{R}^m$,
(3) $V|_{\{1\}\times N_1} = v_1$ under the identification $\{1\} \times \mathbb{R}^m = \mathbb{R}^m$,

If such a framed cobordism exists, then we say that (N_0, v_0) and (N_1, v_1) are *cobordant*. The definition of a framed cobordism is illustrated in Figure 1077.

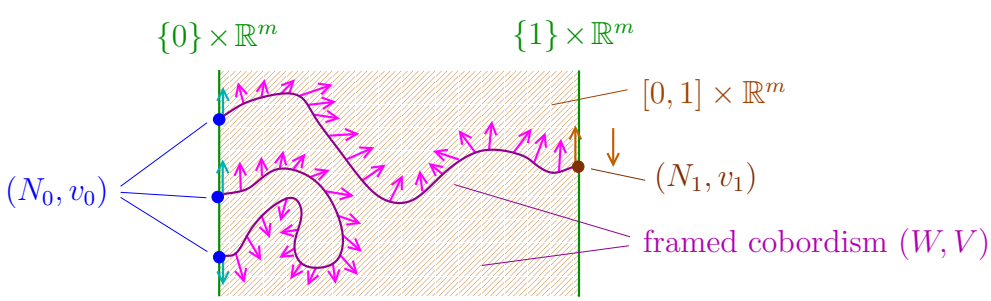

FIGURE 1077.

Basically the same proof as in Lemma 87.8 gives us the following lemma.

Lemma 88.1. *The property of "being cobordant" is an equivalence relation on the set of framed k-dimensional submanifolds of $\mathbb{R}^m$.*

This lemma leads us, not surprisingly, to the following definition.

Definition. We denote by $\Omega_k^{\mathrm{fr}}(\mathbb{R}^m)$ the set of cobordism classes of framed k-dimensional submanifolds of $\mathbb{R}^m$. We refer to $\Omega_k^{\mathrm{fr}}(\mathbb{R}^m)$ as a *framed cobordism group.*

The following proposition, which is the analogue of Proposition 87.9, justifies the name "framed cobordism group".

Proposition 88.2. *Let $k \in \mathbb{N}$ and let $m \in \mathbb{N}_{\geq 2}$. Let (M, v) and (N, w) be two framed k-dimensional submanifolds of $\mathbb{R}^m$. Since M and N are compact we can pick $r, s \in \mathbb{R}_{>0}$ with $M \subset B_r^m(0)$ and $N \subset B_s^m(0)$. Furthermore we pick two orientation-preserving embeddings $\varphi\colon \overline{B}_r^m(0) \to \mathbb{R}^m$ and $\psi\colon \overline{B}_s^m(0) \to \mathbb{R}^m$ with disjoint images. We define*

$$[(M, v)] + [(N, w)] := [(\varphi(M) \sqcup \psi(N), \varphi_*(v) \sqcup \psi_*(w))] \in \Omega_k^{\mathrm{fr}}(\mathbb{R}^m).$$

This operation "+" has the following properties:

1. *The definition of "+" on $\Omega_k^{\mathrm{fr}}(\mathbb{R}^m)$ is well-defined and commutative.*
2. *The operation "+" defines a group structure on $\Omega_k^{\mathrm{fr}}(\mathbb{R}^m)$. The following two statements hold:*
   (a) *The neutral element is represented by the empty submanifold.*
   (b) *Let $\rho\colon \mathbb{R}^m \to \mathbb{R}^m$ be the reflection in a hyperplane. The inverse of $[(M, v)]$ is given by $[(\rho(M), \rho_*(v))]$.*

Proof. The proof is basically identical to the proof of Proposition 87.9. We leave it to the reader to carry out the minor adjustments that are necessary to make the transition from fattened cobordisms groups to framed cobordism groups. □

Lemma 88.3. *Let $m \in \mathbb{N}_{\geq 2}$ and $k \in \{0, \dots, m\}$.*

1. *Every framed k-dimensional submanifold (M, v) of $\mathbb{R}^m$ is cobordant to (M, w) where w is an orthonormal framing.*
2. *Let (W, V) be a framed cobordism between two framed k-dimensional submanifolds (M_0, v_0) and (M_1, v_1) of $\mathbb{R}^m$. If v_0 and v_1 are orthonormal, then there exist an orthonormal framing V' for W such that (W, V') is a framed cobordism between (M_0, v_0) and (M_1, v_1).*

Proof $(*)$. We prove statement (1) of the lemma. The proof of statement (2) is a mild variation on the proof of statement (1). Thus let (M, u) be a framed k-dimensional submanifold of $\mathbb{R}^m$. Using the fact that being cobordant is transitive, the proof of the lemma can be broken up into two stages:

1. First we show that there exists a perpendicular framing v such that (M, u) is cobordant to (M, v).
2. Then we show that there exists an orthonormal framing w such that (M, v) is cobordant to (M, w).

We carry out the two steps:

(1) Let $(M, u\colon M \to \mathrm{GL}(m, m-k))$ be a framed k-dimensional submanifold of $\mathbb{R}^m$. Given $P \in M$ we write $U_P M := \mathrm{span}\{u_1(P), \dots, u_k(P)\}$ and furthermore we write $Z_P M := (T_P M)^\perp$. For each $P \in M$ the decomposition $\mathbb{R}^m = T_P M \oplus Z_P M$ defines a projection of $\mathbb{R}^m$ onto $Z_P M$. We denote the restriction of this projection to $U_P M$ by $\rho_P\colon U_P M \to Z_P M$. By definition of a framing this map is an isomorphism. We consider the product cobordism $W = [0,1] \times M$ equipped with the framing[1518]

$$\begin{array}{rcl} V\colon W = [0,1] \times M & \to & \mathrm{GL}(m, m-k) \\ (t, P) & \mapsto & (u(P) \cdot (1-t) + \rho_P(u(P)) \cdot t). \end{array}$$

Basically by definition this is a framed cobordism from (M, u) to (M, v) where $v = V_1$ is a perpendicular framing.

(2) In Lemma 10.7 (1) we showed that there exists a smooth deformation retraction $R\colon \mathrm{GL}(m, m-k) \times [0,1] \to \mathrm{O}(m, m-k)$ from $\mathrm{GL}(m, m-k)$ to $\mathrm{O}(m, m-k)$ which has the following extra property:

($*$) For any $v = (v_1, \dots, v_{m-k}) \in \mathrm{GL}(m, m-k)$ and any $t \in [0,1]$ we have

$$\text{span of } R_t(v_1), \dots, R_t(v_{m-k}) \;=\; \text{span of } v_1, \dots, v_{m-k}.$$

Now let (M, v) be a framed k-dimensional submanifold. We consider the product cobordism $W = [0,1] \times M$ equipped with the framing

$$\begin{array}{rcl} V\colon W = [0,1] \times M & \to & \mathrm{GL}(m, m-k) \\ (t, P) & \mapsto & R_t(v(P)). \end{array}$$

It follows from the fact that R is smooth and that ($*$) holds that this is a framed cobordism from (M, v) to (M, w) where $w = V_1$ is an orthonormal framing. □

The following proposition shows that the two types of cobordism groups that we introduced in this and the last chapter are in fact isomorphic.

Proposition 88.4. *Let $m \in \mathbb{N}_{\geq 2}$ and let $k \in \{0, \dots, m\}$. The map*

$$\begin{array}{rcl} \Phi\colon \Omega_k^{\mathrm{fat}}(\mathbb{R}^m) & \to & \Omega_k^{\mathrm{fr}}(\mathbb{R}^m) \\ [(N, g\colon \overline{B}^{m-k} \times N)] & \to & \left[\begin{array}{l} N \textit{ equipped with the framing that associates to } P \in N \\ \textit{the frame } Dg_{(0,P)}(e_1), \dots, Dg_{(0,P)}(e_{m-k}) \end{array}\right] \end{array}$$

is well-defined and it is an isomorphism.

Convention. Let $n, k \in \mathbb{N}_0$ with $n + k \geq 2$. We use the isomorphisms from the Thom-Pontryagin Theorem 87.11 and Proposition 88.4 to make the identifications

$$\pi_{n+k}(S^n, *) \;=\; \Omega_k^{\mathrm{fat}}(\mathbb{R}^{n+k}) \;=\; \Omega_k^{\mathrm{fr}}(\mathbb{R}^{n+k}).$$

Sketch of proof.

[1518] It takes a little bit of thought to show that this is indeed a smooth map.

(1) It follows basically from the definitions that the framing associated to a fattened submanifold is indeed a framing. Applying the same procedure to a fattened cobordism between fattened submanifolds we obtain a framed cobordism between framed submanifolds. This shows that Φ is well-defined.
(2) It follows immediately from the definitions of the group structures that Φ is a homomorphism.
(3) We sketch the construction of the inverse to Φ. Let $(N, \{v_1, \dots, v_{m-k}\})$ be a framed k-dimensional submanifold of $\mathbb{R}^m$. We consider the map

$$\begin{array}{rcl} g(v)\colon \mathbb{R}^{m-k} \times N & \to & \mathbb{R}^m \\ ((t_1, \dots, t_{m-k}), P) & \mapsto & P + t_1 \cdot v_1(P) + \dots + t_{m-k} \cdot v_{m-k}(P). \end{array}$$

The same argument as in the proof of Theorem 10.19 shows that there exists an $\epsilon > 0$ such that $g(v)$ restricts to an embedding $\overline{B}^k_\epsilon(0) \times N \to \mathbb{R}^m$. After rescaling the ball we thus get a fattening $\overline{B}^k \times N \to \mathbb{R}^m$ of N. It is straightforward to see that the class $[(N, g(v)] \in \Omega^{\text{fat}}_k(\mathbb{R}^m)$ does not depend on the choice of $\epsilon > 0$. Since the same approach also works for cobordisms we obtain a well-defined map

$$\Psi\colon \Omega^{\text{fr}}_k(\mathbb{R}^m) \ \to \ \Omega^{\text{fat}}_k(\mathbb{R}^m).$$

It remains to show that Φ and Ψ are inverses of one another. It follows basically immediately from the definitions and Lemma 88.3 (1) that $\Phi \circ \Psi$ is the identity on $\Omega^{\text{fr}}_k(\mathbb{R}^m)$. The fact that $\Psi \circ \Phi$ is the identity on $\Omega^{\text{fat}}_k(\mathbb{R}^m)$ follows fairly immediately from the uniqueness of tubular neighborhoods, see Proposition 64.9, together with Lemma 64.6. □

Definition. Let N be an orientable k-dimensional submanifold of $\mathbb{R}^m$ and let $n \geq m$.

(1) We write $N_n := N \times \{0\} \subset \mathbb{R}^n$.

Now suppose we are given a framing $v\colon N \to \mathrm{GL}(m, m-k)$ for N.

(2) We define

$$\begin{array}{rcl} v_n\colon N_n & \to & \mathrm{GL}(n, n-k) \\ (P, 0) & \mapsto & \begin{pmatrix} v(P) & 0 \\ 0 & \mathrm{id}_{n-m} \end{pmatrix}. \end{array}$$

It is clear that v_n is a framing for N_n. Note that $N_m = N$ and $v_m = v$.
(3) We refer to (N_n, v_n) as the $(n-m)$*-fold suspension of* (N, v). In particular we refer to (N_{m+1}, v_{m+1}) as *the suspension of* (N, v).

The same notation applies in an obvious way to (framed) submanifolds of $[0, 1] \times \mathbb{R}^m$.

The following lemma justifies the name "suspension" that we had used in the above definition.

Lemma 88.5. *Let $m \in \mathbb{N}_{\geq 2}$ and let $k \in \{0, \dots, m\}$.*

(1) *The map*

$$\begin{array}{rcl} \Omega^{\text{fr}}_k(\mathbb{R}^m) & \to & \Omega^{\text{fr}}_k(\mathbb{R}^{m+1}) \\ [(N, v)] & \mapsto & [\textit{the suspension of } (N, v)] \end{array}$$

is well-defined and it is a homomorphism. We refer to it as the suspension homomorphism.

(2) *Under the identification from the convention on page 2037 the suspension homomorphisms on $\pi_{n+k}(S^n, *)$ and $\Omega_k^{\mathrm{fr}}(\mathbb{R}^{n+k})$ agree up to sign,*[1519] *in other words, the following diagram commutes up to sign:*

$$\begin{tikzcd} \Omega_k^{\mathrm{fr}}(\mathbb{R}^{n+k}) \arrow[r, "\textit{suspension}"] \arrow[d, "\cong"] & \Omega_k^{\mathrm{fr}}(\mathbb{R}^{n+k+1}) \arrow[d, "\cong"] \\ \pi_{n+k}(S^n, *) \arrow[r, "\textit{suspension}"] & \pi_{n+k+1}(S^{n+1}, *). \end{tikzcd}$$

Proof.

(1) The first statement is almost obvious.
(2) We leave it to the reader to go through all the definitions to verify this statement. □

88.2. **The Freudenthal Suspension Theorem.** In this section we will prove the following theorem that was first proved in 1937 by Hans Freudenthal [Freu, p. 300].

Theorem 88.6. (Freudenthal Suspension Theorem) *Let $n, k \in \mathbb{N}_0$. We suppose that $n + k \geq 2$. The suspension homomorphism $\pi_{n+k}(S^n) \to \pi_{n+k+1}(S^{n+1})$ from Lemma 28.18 is an isomorphism if $n > k + 1$ and it is an epimorphism if $n = k + 1$.*

Remark.

(1) The Freudenthal Suspension Theorem 88.6 can be reformulated as follows: given $n \in \mathbb{N}$ the suspension homomorphism $\pi_m(S^n) \to \pi_{m+1}(S^{n+1})$ is an isomorphism if $m < 2n-1$ and that it is an epimorphism if $m = 2n-1$. We consider two situations in slightly more detail:
   (a) The Freudenthal Suspension Theorem 88.6 says that the suspension homomorphism $\pi_3(S^2) \to \pi_4(S^3)$ is an epimorphism and it says that for any $n \geq 3$ the suspension homomorphism $\pi_{n+1}(S^n) \to \pi_{n+2}(S^{n+1})$ is an isomorphism. This special case will play an important role shortly.
   (b) The Freudenthal Suspension Theorem 88.6 almost recovers Theorems 85.11 (2) and 85.14 (2). These theorems stated that for $m \in \{0, \ldots, 5\}$ we have $\pi_m(S^3) \cong \pi_{m+1}(S^4)$ and that for $m \in \{0, \ldots, 13\}$ we have $\pi_m(S^7) \cong \pi_{m+1}(S^8)$.
(2) Let $n \in \mathbb{N}_0$. Recall that on page 453 we saw that the suspension $\Sigma(S^n)$ is homeomorphic to S^{n+1}. Thus we see that the Freudenthal Suspension Theorem 88.6 is a consequence of the following stronger statement: Let X be an $(n-1)$-connected topological space and let $* \in X$ be a good base point.[1520] Then the suspension homomorphism $\pi_{n+k}(X, *) \to \pi_{n+k+1}(\Sigma(X), *)$ is an isomorphism for all $n > k + 1$

[1519] To be more precise, they might agree on the nose, but we will not spend valuable time on figuring out the sign.

[1520] We refer to page 387 for the definition of a good point.

and it is an epimorphism for $n = k+1$. This statement is proved in most textbooks on homotopy theory, see e.g. [Gra, Theorem 16.34], [Whda, Theorem VII.7.13] or [DK, Theorem 8.7 and Chapter 10.3]. If X is a CW-complex, then the statement is also proved in [Hat, Corollary 4.24]. The proof of [Hat, Corollary 4.24] is actually a corollary to the Blakers-Massey Theorem 82.17 that we had stated but not proved.

It follows from Lemma 88.5 that the Freudenthal Suspension Theorem 88.6 is equivalent to the following theorem.

Theorem 88.7. *Let $n, k \in \mathbb{N}$.*

(1) *The suspension homomorphism $\Omega_k^{\mathrm{fr}}(\mathbb{R}^{n+k}) \to \Omega_k^{\mathrm{fr}}(\mathbb{R}^{n+k+1})$ is an epimorphism whenever $n \geq k+1$.*
(2) *The suspension homomorphism $\Omega_k^{\mathrm{fr}}(\mathbb{R}^{n+k}) \to \Omega_k^{\mathrm{fr}}(\mathbb{R}^{n+k+1})$ is a monomorphism whenever $n > k+1$.*

The basic behind the proof of Theorem 88.7 (1) is quite simple: given a framed k-dimensional submanifold of $\mathbb{R}^{n+k+1}$ we want to use the "room provided by a large enough n" to show that it is cobordant to a framed submanifold coming from $\mathbb{R}^{n+k} = \mathbb{R}^{n+k} \times \{0\}$. This idea is for the most part carried out in the following two lemmas.

Lemma 88.8. *Let (M, v) be a framed k-dimensional submanifold of $\mathbb{R}^{n+k+1}$. If $n \geq k+1$, then there there exists a framed cobordism from (M, v) to a framed k-dimensional submanifold (N, w) of $\mathbb{R}^{n+k+1}$ with $N \subset \mathbb{R}^{n+k} \times \{0\}$.*

Proof. Let $(M, v\colon M \to \mathrm{GL}(n+k+1, n+1))$ be a framed k-dimensional submanifold of $\mathbb{R}^{n+k+1}$. We point out that by Lemma 88.3 (1) we can assume that v is an orthonormal framing.

It follows from $n \geq k+1$ and Lemma 65.12 that there exists a vector $\nu \in \mathbb{R}^{n+k+1}$ which satisfies the following condition:

($*$) the vector ν does not lie in any tangent space $T_P M$[1521] and ν is not secant to M, i.e. for any two distinct points $x, y \in M$ the difference $x - y$ is not parallel to ν.

By Lemma 1.73 (4) there exists a matrix $A \in \mathrm{SO}(n+k+1)$ with $A\nu = e_{n+k+1}$. By Lemma 10.4 there exists a diffeotopy of $\mathbb{R}^{n+k+1}$ from $\mathrm{id}_{\mathbb{R}^{n+k+1}}$ to the diffeomorphism given by multiplying by A. Therefore, by the obvious analogue of Lemma 87.7 for the framed cobordism group, we can assume without loss of generality that $\nu = e_{n+k+1}$.

Claim. The map

$$\begin{array}{rcl} \Psi\colon [0,1] \times M & \to & [0,1] \times \mathbb{R}^{n+k+1} \\ (t, \underbrace{(x_1, \dots, x_{n+k+1})}_{\in M}) & \mapsto & (t, \underbrace{x_1, \dots, x_{n+k}, (1-t) \cdot x_{n+k+1}}_{\in \mathbb{R}^{n+k+1}}) \end{array}$$

is a proper embedding. The definition of Ψ is illustrated in Figure 1078.

[1521]Here and throughout this proof we use Proposition 3.32 to view the tangent spaces of submanifolds of some $\mathbb{R}^m$ as subvector spaces of $\mathbb{R}^m$.

It follows from the fact that for any two distinct points $x, y \in M$ the difference $x - y$ is not parallel to $\nu = e_{n+k+1}$ that the map is injective. Furthermore note that the map Ψ is the composition of the inclusion $i\colon [0,1] \times M \to [0,1] \times \mathbb{R}^{n+k+1}$ with the map

$$\begin{array}{rcl} \Theta\colon [0,1] \times \mathbb{R}^{n+k+1} & \to & [0,1] \times \mathbb{R}^{n+k+1} \\ (t, (x_1, \ldots, x_{n+k+1})) & \mapsto & (t, x_1, \ldots, x_{n+k}, (1-t) \cdot x_{n+k+1}). \end{array}$$

A straightforward calculation shows that

$$D\Theta_{(t,x_1,\ldots,x_{n+k+1})} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \mathrm{id}_{n+k} & 0 \\ -x_{n+k+1} & 0 & 1-t \end{pmatrix}.$$

It follows immediately from this calculation and the fact that e_{n+k+1} is not contained in any tangent space $T_P M$ that $\Psi = \Theta \circ i$ is an immersion. Together with the injectivity of Θ, the fact that M is compact and the ever-popular Proposition 1.40 we obtain that $\Psi = \Theta \circ i$ is in fact an embedding. It is also clear that the embedding is proper. We are thus done with the proof of the claim.

We set $W := \Psi([0,1] \times M)$. By the claim together with Proposition 10.1 (2) we know that W is a proper $(k+1)$-dimensional submanifold of $[0,1] \times \mathbb{R}^{n+k+1}$. Basically by definition W is a cobordism between $M \subset \mathbb{R}^{n+k+1}$ and some submanifold $N \subset \mathbb{R}^{n+k} \times \{0\}$.

It remains to extend the orthonormal framing $v\colon M \to \mathrm{GL}(n+k+1, n+1)$ of M to a framing of W. In fact, we obtain a framing of $W = \Psi([0,1] \times M)$ by using the "same vectors" as for M. More precisely, we consider the map

$$\begin{array}{rcl} V\colon W = \Psi([0,1] \times M) & \to & \mathrm{GL}(n+k+2, n+1) \\ \Psi(t, P) & \mapsto & \begin{pmatrix} 0 \\ v(P) \end{pmatrix}. \end{array}$$

Evidently under the identification $\{0\} \times \mathbb{R}^{n+k+1} = \mathbb{R}^{n+k+1}$ we have $V|_M = v$. Thus it remains to show that V is indeed a framing. A short moment's thought shows that V is smooth. The definition of W and V are illustrated in Figure 1078. Therefore it suffices to

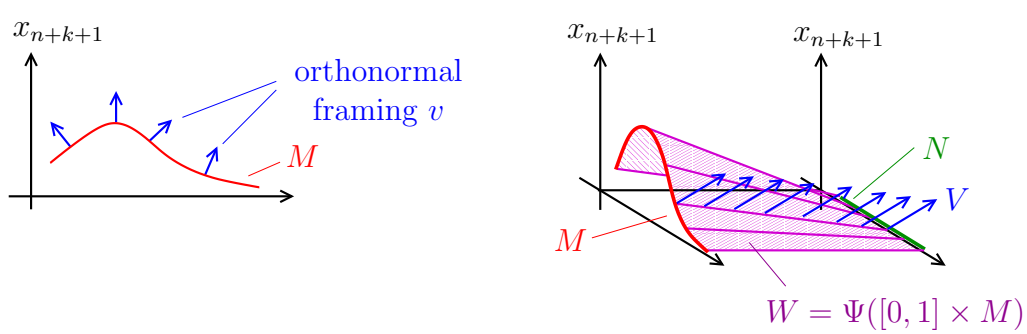

FIGURE 1078. Illustration for the proof of Lemma 88.8.

prove the following claim.

Claim. For any $t \in [0,1]$ and any $P \in M$ the matrix $V(\Psi(t,P)) \in \mathrm{GL}(n+k+2, n+1)$ is a frame for $W = \Psi([0,1] \times M)$ at $\Psi(t,P)$.

Let $t \in [0,1]$ and let $P \in M$. Note that the columns of $V(\Psi(t,P))$ span an $(n+1)$-dimensional subvector space of $\mathbb{R}^{n+k+2}$. Since $T_{\Psi(t,P)}(W)$ is a subvector space of the complementary dimension $k+1$ it suffices to show that the intersection of these two subvector spaces is trivial.

We note that

$$\underbrace{T_{\Psi(t,P)}(W) \cap \begin{array}{c}\text{span of the}\\ \text{columns of}\\ V(\Psi(t,P))\end{array}}_{\subset \mathbb{R}^{1+n+k+1}} \overset{\substack{\text{by definition of } W = \Psi([0,1]\times M) = (\Theta \circ i)([0,1]\times M) \text{ and the calculation of } D\Theta \\ \downarrow}}{=} \underbrace{\begin{pmatrix} 1 & 0 & 0 \\ 0 & \mathrm{id}_{n+k} & 0 \\ -x_{n+k+1} & 0 & 1-t \end{pmatrix} \cdot \begin{pmatrix} \mathbb{R} \\ \oplus \\ T_P(M) \end{pmatrix} \cap \begin{array}{c}\text{span of the}\\ \text{columns of}\\ V(\Psi(t,P))\end{array}}_{\subset \mathbb{R}^{1+n+k+1}}$$

$$\underset{\substack{\uparrow \\ \text{since the first row of } V \text{ is zero we can} \\ \text{“ignore” the first coordinate}}}{\cong} \underbrace{\begin{pmatrix} \mathrm{id}_{n+k} & 0 \\ 0 & 1-t \end{pmatrix} \cdot T_P(M) \cap \begin{array}{c}\text{span of the}\\ \text{columns of } v(P)\end{array}}_{\subset \mathbb{R}^{n+k+1}} \underset{\substack{\uparrow \\ \text{since } v \text{ is an orthonormal framing}}}{=} \begin{pmatrix} \mathrm{id}_{n+k} & 0 \\ 0 & 1-t \end{pmatrix} \cdot T_P(M) \cap (T_P M)^\perp.$$

Now let $u \in T_P M$ be a non-zero vector. We write $u = \begin{pmatrix} u' \\ u_{n+k+1} \end{pmatrix}$ with $u' \in \mathbb{R}^{n+k}$ and $u_{n+k+1} \in \mathbb{R}$. Note that u' is non-zero since we had arranged that $e_{n+k+1} \notin T_P M$. Now we calculate that

$$\left\langle \begin{pmatrix} \mathrm{id}_{n+k} & 0 \\ 0 & 1-t \end{pmatrix} \begin{pmatrix} u' \\ u_{n+k+1} \end{pmatrix}, \underbrace{\begin{pmatrix} u' \\ u_{n+k+1} \end{pmatrix}}_{=u \in T_P M} \right\rangle = \langle u', u' \rangle + (1-t) \cdot u_{n+k+1}^2 \underset{\substack{\uparrow \\ \text{since } u' \neq 0 \text{ and } (1-t) \geq 0}}{>} 0.$$

But this shows that $\begin{pmatrix} \mathrm{id}_{n+k} & 0 \\ 0 & 1-t \end{pmatrix} \cdot u$ is not orthogonal to $T_P M$, in other words, this vector does not lie in $(T_P M)^\perp$. This concludes the proof of the claim. □

Lemma 88.9. *Let (M, v) be a framed k-dimensional submanifold in $\mathbb{R}^{n+k} \times \{0\} \subset \mathbb{R}^{n+k+1}$. If $n \geq k+1$, then there exists a framed cobordism to $(M, w = (w_1, \dots, w_{n+1}))$ where we have $w_{n+1}(P) = e_{n+k+1}$ for all $P \in M$.*

Proof. Let $(M, u = (u_1, \dots, u_{n+1}) \colon M \to \mathrm{GL}(n+k+1, n+1))$ be a framed k-dimensional submanifold that is contained in $\mathbb{R}^{n+k} \times \{0\} \subset \mathbb{R}^{n+k+1}$. By Lemma 88.3 (1) and Lemma 88.1 we can assume that u is orthonormal. We write $e := e_{n+k+1}$.

Claim. There exists an orthonormal framing $v = (v_1, \dots, v_{n+1})$ for M such that (M, u) is cobordant to (M, v) and such that for every $P \in M$ we have $v_{n+1}(P) \neq -e$.

Let $x \in M$. Since M is contained in $\mathbb{R}^{n+k} \times \{0\}$ we know that e is orthogonal to $T_x M$. Therefore we can uniquely write $e = \sum_{i=1}^{n+1} \lambda_i(x) \cdot u_i(P)$. Since $\|e\| = 1$ and since u is an

orthonormal framing we actually have $\sum_{i=1}^{n+1} \lambda_i^2(P) = 1$. Thus we obtain a map

$$\begin{array}{rcl} \lambda\colon M & \to & S^n \\ x & \mapsto & (\lambda_1(x), \dots, \lambda_{n+1}(x)) \end{array}$$

which is fairly easily seen to be smooth. If $(0, \dots, 0, -1) \notin \lambda(M)$, then we can just take $u = v$ and we are done.[1522] If not we proceed as follows. Since $\dim(M) = k < n$ it follows from Proposition 3.47 that there exists a $\nu \in S^n$ with $\nu \notin \lambda(M)$. By Lemma 1.73 (4) there exists a matrix $A \in \mathrm{SO}(n+1)$ with $\nu = A \cdot (-e) \in S^n$. By Lemma 1.96 and Exercise 10.11 there exists a smooth path $\gamma\colon [0,1] \to \mathrm{SO}(n+1)$ from id to A. The desired framed cobordism is now given by the manifold $[0,1] \times M$ together with the framing[1523]

$$\begin{array}{rcl} [0,1] \times M & \to & \mathrm{GL}(n+k+2, n+1) \\ (t,x) & \mapsto & \underbrace{\begin{pmatrix} 0 \\ u(x) \end{pmatrix}}_{\in \mathrm{GL}(n+k+2,n+1)} \cdot \gamma(t). \end{array}$$

This concludes the proof of the claim.

As a final step we want to "rotate v_{n+1} into e". To do this smoothly for every point we need to introduce two maps. Given $u \in \mathbb{R}^{n+1} \setminus \{0\}$ we write

$$\underbrace{\begin{array}{rcl} T_u\colon \mathbb{R}^{n+k+1} & \mapsto & \mathbb{R}^{n+k+1} \\ y & \to & 2 \cdot \langle y, u \rangle \cdot u - y \end{array}}_{\text{reflection in the line } \mathbb{R} \cdot u} \quad \text{and} \quad \underbrace{\begin{array}{rcl} R_u\colon \mathbb{R}^{n+k+1} & \to & \mathbb{R}^{n+k+1} \\ y & \mapsto & T_e(T_u(y)). \end{array}}_{\text{orientation-preserving diffeomorphism}}$$

We will need the following elementary observation from linear algebra.

Claim. Let $w \in \mathbb{R}^{n+k+1}$ with $\|w\| = 1$. Let $u = \frac{w+e}{\|w+e\|}$ be the normalized midpoint between w and e. Then $R_u(w) = e$.

We have

$$R_u(w) \;=\; T_e(T_u(w)) \;=\; T_e\Big(2 \cdot \Big\langle w, \tfrac{w+e}{\|w+e\|} \Big\rangle \cdot \tfrac{w+e}{\|w+e\|} - w\Big) \;\underset{\substack{\uparrow \\ \text{short calculation using } \langle w,w\rangle = \langle e,e\rangle}}{=}\; T_e(e) \;=\; e.$$

This concludes the proof of the claim.

[1522] Indeed, if $v_{n+1}(x) = -e$, then $e = -v_{n+1}(x)$, i.e. $\lambda(x) = (0, \dots, 0, -1)$.

[1523] That this framing has the correct properties can be seen as follows. Let v be the new framing at $\{1\} \times M$. If we denote by $\lambda_u, \lambda_v\colon M \to S^n$ the corresponding maps, then one easily sees that for each $x \in M$ we have $\lambda_v(x) = A^{-1} \cdot \lambda_u(x)$. Thus the fact that ν does not lie in the image of λ_u implies that $-e = A^{-1}\nu$ does not lie in the image of λ_v.

The above claim now allows us to come to the denouement of the argument. More precisely, given $t \in [0,1]$ and $x \in M$ we write

$$z(x) \;:=\; \underbrace{\frac{v_{n+1}(x)+e}{\|v_{n+1}(x)+e\|}}_{\text{note that } v_{n+1}(x)+e \neq 0} \quad \text{and} \quad z_t(x) \;=\; \underbrace{\frac{(1-t)\cdot e+t\cdot z(x)}{\|(1-t)\cdot e+t\cdot z(x)\|}}_{\text{note that } t\cdot e+(1\text{-}t)\cdot z(x) \neq 0}.$$

Note that $z_0 = e$ and $R_{z_0} = \mathrm{id}$. Furthermore note that $z_1 = z(x)$. Thus we obtain from the above claim that $R_{z_1(x)}(v_{n+1}(x)) = e$. Finally we consider the framed cobordism that is given by the submanifold $Z = [0,1] \times M$ of $[0,1] \times \mathbb{R}^{n+k+1}$ together with the framing

$$\begin{aligned} W\colon Z = [0,1]\times M &\to \mathrm{GL}(n+k+2, n+1) \\ (t,x) &\mapsto \begin{pmatrix} 0 \\ R_{z_t(x)} \circ v(x) \end{pmatrix}. \end{aligned}$$

We leave it to the reader to verify that the map W is indeed a framing for the cobordism $Z = [0,1] \times M \subset [0,1] \times \mathbb{R}^{n+k+1}$. The discussion above shows that $(Z = [0,1] \times M, W)$ is a framed cobordism from (M, v) to a framed manifold $(M, w = w_1, \dots, w_n, e)$. $\square$

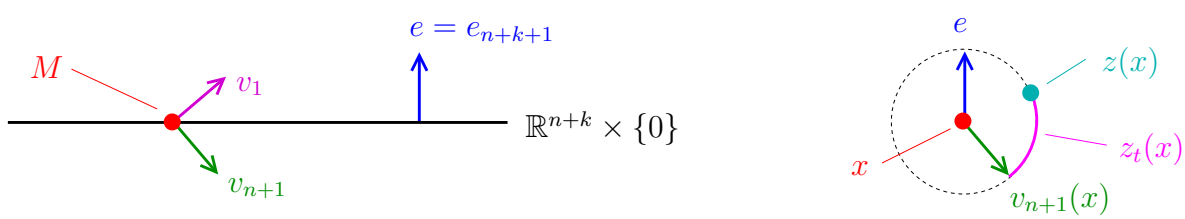

FIGURE 1079. Illustration for the proof of Lemma 88.9.

Now we turn to the actual proof of Theorem 88.7 and thus of the Freudenthal Suspension Theorem 88.6.

Proof. Let $n, k \in \mathbb{N}_0$ with $n + k \geq 2$.

(1) Suppose that $n \geq k+1$. We want to show that the suspension homomorphism $\Omega_k^{\mathrm{fr}}(\mathbb{R}^{n+k}) \to \Omega_k^{\mathrm{fr}}(\mathbb{R}^{n+k+1})$ is an epimorphism. Thus let (M, v) be a framed k-dimensional submanifold of $\mathbb{R}^{n+k+1}$. It follows immediately from Lemmas 88.8 and 88.9 that (M, v) is cobordant to a k-dimensional framed submanifold (N, w) with $N \subset \mathbb{R}^{n+k} \times \{0\}$ and such that $w_{n+1}(P) = e_{n+k+1}$ for all $P \in N$. But this means that $[(M, v])] = [(N, w)]$ lies in the image of the suspension homomorphism. Thus the suspension homomorphism $\Omega_k^{\mathrm{fr}}(\mathbb{R}^{n+k}) \to \Omega_k^{\mathrm{fr}}(\mathbb{R}^{n+k+1})$ is an epimorphism.

(2) Suppose that $n > k+1$. We want to show that the suspension homomorphism $\Omega_k^{\mathrm{fr}}(\mathbb{R}^{n+k}) \to \Omega_k^{\mathrm{fr}}(\mathbb{R}^{n+k+1})$ is an monomorphism. Thus let (M, v) and (N, w) be two framed k-dimensional submanifolds of $\mathbb{R}^{n+k}$. Suppose there exists a framed cobordism (W, V) in $[0,1] \times \mathbb{R}^{n+k+1}$ between the suspensions of (M, v) and (N, w). Since $n > k+1$, then an argument as in Lemmas 88.8 and 88.9 shows that we can

turn (W, V) into a cobordism (W', V') with $W' \subset [0,1] \times \mathbb{R}^{n+k} \times \{0\}$ and such that $V'(P) = e_{n+k+1}$ for all $P \in W'$. But this shows that (M, v) and (N, w) are already cobordant. Thus we have shown that for $n > k+1$ the suspension homomorphism $\Omega_k^{\mathrm{fr}}(\mathbb{R}^{n+k}) \to \Omega_k^{\mathrm{fr}}(\mathbb{R}^{n+k+1})$ is a monomorphism. □

88.3. **The calculation of the framed cobordism groups $\Omega_1^{\mathrm{fr}}(\mathbb{R}^{n+1})$ for $n \geq 3$.** In Theorem 85.10 (2) (and alternatively in Theorem 87.14) we saw that $\pi_3(S^2) \cong \mathbb{Z}$ and we saw that the Hopf map represents a generator of $\pi_3(S^2)$. Furthermore, by the Freudenthal Suspension Theorem 88.6 we know that for every $n \geq 3$ the suspension homomorphism $\pi_3(S^2) \to \pi_{n+1}(S^n)$ is an epimorphism. Thus we know that $\pi_{n+1}(S^n)$ is isomorphic to a quotient of $\mathbb{Z}$ and that $\pi_{n+1}(S^n)$ is generated by the $(n-2)$-fold suspension of the Hopf map. The goal of this section is to prove the following theorem which determines this quotient.

Theorem 88.10. *For every $n \geq 3$ there exists an isomorphism $\pi_{n+1}(S^n) \cong \mathbb{Z}_2$.*

Remark.

(1) In Theorem 78.13 we already saw that for every $n \geq 3$ we have $\pi_{n+1}(S^n) \neq 0$. The proof of Theorem 88.10 below is independent of Theorem 78.13. In particular we will not make use of Steenrod operations.
(2) By the Thom-Pontryagin Theorem 87.11 and Proposition 88.4 the theorem is equivalent to showing that for every $n \geq 3$ we have an isomorphism $\Omega_1^{\mathrm{fr}}(\mathbb{R}^{n+1}) \cong \mathbb{Z}_2$. This is exactly what we will do below. The approach that we take below to calculate $\Omega_1^{\mathrm{fr}}(\mathbb{R}^{n+1})$ differs, to the best of my knowledge, from the other proofs in the literature. We refer to [Po3, Chapter 14] for Pontryagin's original proof, which makes for challenging reading for the modern reader. A third, quite readable approach is presented in [Put].
(3) There are various alternative proofs of Theorem 88.10. The first proof was given by Hans Freudenthal [Freu, p. 301] in 1937. Another proof is given in [Hat6, p. 549] using "spectral sequences".
(4) The discussion preceding the theorem shows that the suspension of the Hopf map defines a non-trivial element in $\pi_4(S^3)$. This gives in particular an affirmative answer to Question 28.19.

As we had just mentioned above, proving Theorem 88.10 is equivalent to showing that for every $n \geq 3$ there exists an isomorphism $\Omega_1^{\mathrm{fr}}(\mathbb{R}^{n+1}) \cong \mathbb{Z}_2$. We will perform this calculation in the remainder of this section.

We start out our calculation of $\Omega_1^{\mathrm{fr}}(\mathbb{R}^{n+1})$ for $n \geq 3$ with the following definition.

Definition.

(1) We refer to $C := S^1$ as the *standard circle in* $\mathbb{R}^2$.

(2) We refer to the framing of $C \subset \mathbb{R}^2$ that is given by

$$\begin{array}{rcl} t\colon C & \to & \mathbb{R}^2 \\ \begin{pmatrix} x \\ y \end{pmatrix} & \mapsto & \begin{pmatrix} x \\ y \end{pmatrix} \end{array}$$

as the *trivial framing* t *of* C.

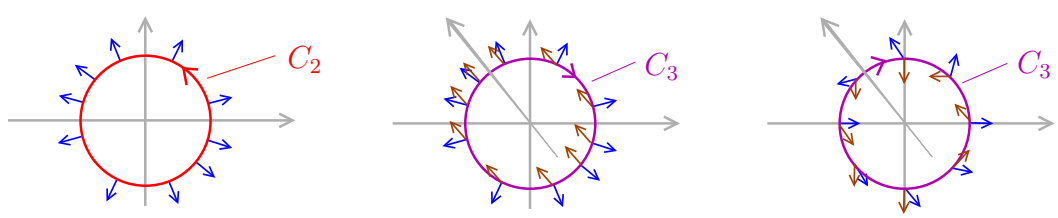
(3) Let $n \in \mathbb{N}_{\geq 2}$. We adopt the convention from page 2038 to define the *standard standard circle* C_n in $\mathbb{R}^n$. Furthermore, using the definition from page 2038 we define the *trivial framing* t_n *for* C_n.

(4) We refer to the framing of $C_3 \subset \mathbb{R}^3$ that is given by the map[1524]

$$\begin{array}{rcl} h\colon C_3 & \to & \mathbb{R}^3 \\ \begin{pmatrix} \cos(\varphi) \\ \sin(\varphi) \\ 0 \end{pmatrix} & \mapsto & \underset{\substack{\uparrow \\ \text{don't overlook the } t_3}}{t_3} \begin{pmatrix} \cos(\varphi) \\ \sin(\varphi) \\ 0 \end{pmatrix} \cdot \begin{pmatrix} \cos(\varphi) & -\sin(\varphi) \\ \sin(\varphi) & \cos(\varphi) \end{pmatrix} = \begin{pmatrix} \cos(\varphi) & 0 \\ \sin(\varphi) & 0 \\ 0 & 1 \end{pmatrix} \cdot \begin{pmatrix} \cos(\varphi) & -\sin(\varphi) \\ \sin(\varphi) & \cos(\varphi) \end{pmatrix} \end{array}$$

as the *Hopf framing* h *of* C_3.

(5) Let $n \in \mathbb{N}_{\geq 3}$. As in (3) we use the convention from page 2038 to define the *Hopf framing* h_n *of* C_n. These definitions are illustrated in Figure 1080.



trivial framing t_2 trivial framing t_3 Hopf framing h_3

FIGURE 1080.

Throughout this section we also use the following notation:

Notation.

(1) Given $g \in \mathbb{N}_0$ we denote by $\Sigma_{g,1}$ the surface of genus g minus one open disk. We pick once and for all an orientation for $\Sigma_{g,1}$.

(2) For any $n \in \mathbb{N}_{\geq 2}$ we denote by

$$\begin{array}{rcl} \rho\colon \mathbb{R}^n & \to & \mathbb{R}^n \\ (x_1, x_2, x_3, \dots, x_n) & \mapsto & (x_1, -x_2, x_3, \dots, x_n) \end{array}$$

the reflection in the $(x_2 = 0)$-hyperplane.

(3) Given $n \in \mathbb{N}_0$ we make the identification $\mathbb{R}^n = \{0\} \times \mathbb{R}^n \subset [0,1] \times \mathbb{R}^n$.

[1524] We leave the task of showing that this map is smooth to the every-ready reader.

The following two lemmas justify the names "trivial framing" and "Hopf framing".

Lemma 88.11.

(1) *Let $g \in \mathbb{N}_0$. Given any $g \in \mathbb{N}$ there exists a proper embedding $\psi\colon \Sigma_{g,1} \to [0,1] \times \mathbb{R}^2$ and a framing w for $\psi(\Sigma_{g,1})$ such that $\partial\psi(\Sigma_{g,1}) = C_2$ and such that the restriction of w to C_2 equals t.*

(2) *For any $n \geq 2$ we have $[(C_n, t_n)] = 0 \in \Omega_1^{\mathrm{fr}}(\mathbb{R}^n)$.*

Sketch of proof.

(1) By now the seasoned reader should be fairly convinced that there exists a proper embedding $\psi\colon \Sigma_{g,1} \to [0,1] \times \mathbb{R}^2$ with $\psi(\partial\Sigma_{g,1}) = C_2$ and such that the embedding is a "product near the boundary". More precisely, such that for some $\epsilon \in (0,1)$ we have the equality $\psi(\Sigma_{g,1}) \cap ([0,\epsilon] \times \mathbb{R}^2) = [0,\epsilon] \times C_2$. Since $\psi(\Sigma_{g,1})$ is a oriented connected submanifold of $[0,1] \times \mathbb{R}^2$ of codimension two we see that $\psi(\Sigma_{g,1})$ has precisely two normal vector fields of length one. We refer to Figure 1081 for an illustration.

It follows almost immediately from the fact that $\psi(\Sigma_{g,1})$ is a product near $\{0\} \times \mathbb{R}^2$ that one of the above two normal vectors fields agrees with t on $\{0\} \times S^1$.

(2) It follows from (1) that $[(C_2, t_2)] = 0 \in \Omega_1^{\mathrm{fr}}(\mathbb{R}^2)$. From Lemma 88.5 we obtain that $[(C_n, t_n)] = 0 \in \Omega_1^{\mathrm{fr}}(\mathbb{R}^n)$ for any $n \in \mathbb{N}_{\geq 2}$. □

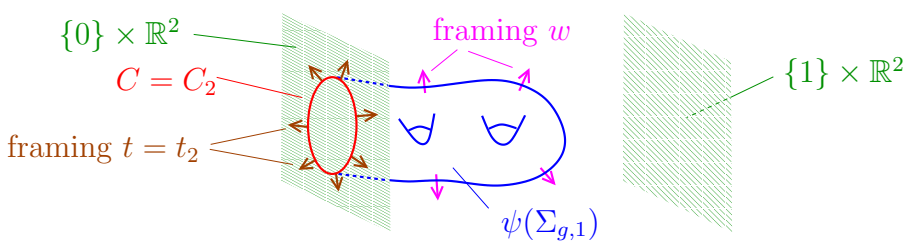


FIGURE 1081. Illustration of Lemma 88.11.

Lemma 88.12.

(1) *Under the isomorphism $\Omega_1^{\mathrm{fr}}(\mathbb{R}^3) \cong \pi_3(S^2, *)$ the element $[(C_3, h_3)]$ corresponds, up to a sign, to the element represented by the Hopf map $S^3 \to S^2$.*

(2) *Let $n \geq 4$. Under the isomorphism $\Omega_1^{\mathrm{fr}}(\mathbb{R}^n) \cong \pi_n(S^{n-1}, *)$ the element $[(C_n, h_n)]$ corresponds, up to a sign, to the element represented by the $(n-3)$-fold suspension of the Hopf map $S^3 \to S^2$.*

Proof. The first statement follows easily from Lemma 87.4. The second statement is a straightforward consequence of Lemma 88.5 (2). □

The following proposition is the first key ingredient in the calculation of $\Omega_1^{\mathrm{fr}}(\mathbb{R}^n)$ for $n \geq 4$.

Proposition 88.13. *Let $n \in \mathbb{N}_{\geq 4}$. The map*

$$\begin{array}{rcl} \mathbb{Z}_2 & \to & \Omega_1^{\mathrm{fr}}(\mathbb{R}^n) \\ [k] & \mapsto & k \cdot [(C_n, h_n)] \end{array}$$

is well-defined and it is an epimorphism.

Our proof of Proposition 88.13 requires one definition and two lemmas.

Definition. Let $n \in \mathbb{N}_{\geq 2}$, let $\gamma\colon S^1 \to \mathbb{R}^n$ be an embedding and let $f\colon \gamma(S^1) \to \mathrm{GL}(n, n-1)$ be a framing for $\gamma(S^1)$. Given a smooth map $\alpha\colon S^1 \to \mathrm{GL}_+(n-1, \mathbb{R})$ we define

$$\begin{array}{rcl} f(\alpha)\colon \gamma(S^1) & \to & \mathrm{GL}(n, n-1) \\ \gamma(z) & \mapsto & \underbrace{f(\gamma(z))}_{\in \mathrm{GL}(n,n-1)} \cdot \underbrace{\alpha(z)}_{\in \mathrm{GL}(n-1,\mathbb{R})}. \end{array}$$

It follows easily from the fact that α takes values in $\mathrm{GL}_+(n-1, \mathbb{R})$ that $f(\alpha)$ is again a framing of $\gamma(S^1)$.

The first lemma that goes into the proof of Proposition 88.13 is really just a crucial example masquerading as a lemma.

Lemma 88.14. *Let $n \in \mathbb{N}_{\geq 3}$ and let $\gamma\colon S^1 \to C_n$ be the obvious diffeomorphism. We consider the loop*

$$\begin{array}{rcl} \alpha\colon S^1 & \to & \mathrm{GL}_+(n-1, \mathbb{R}) \\ z = e^{i\varphi} & \mapsto & \begin{pmatrix} \cos(\varphi) & -\sin(\varphi) & 0 \\ \sin(\varphi) & \cos(\varphi) & 0 \\ 0 & 0 & \mathrm{id}_{n-3} \end{pmatrix}. \end{array}$$

As above let t_n be the trivial framing for C_n and let h_n be the Hopf framing for C_n. We have the following two equalities of framings of C_n:

1. *We have $t_n(\alpha) = h_n$.*
2. *We have $t_n(\overline{\alpha}) = \rho_*(h_n)$.*[1525]

Proof $(*)$. The first statement follows immediately from the definitions. We turn to the proof of the second statement. As we will see, the proof of the second statement is given by a slightly tedious calculation. To simplify the notation we only deal with the case $n = 3$.

[1525]Here $\overline{\alpha}$ is the "inverse of the loop α", i.e. it is the loop given by $\overline{\alpha}(e^{i\varphi}) = \alpha(e^{-i\varphi})$. As above $\rho\colon \mathbb{R}^n \to \mathbb{R}^n$ is the reflection in the $(x_2 = 0)$-hyperplane. Finally the framing $\rho_*(h_n)$ is defined as on page 2035.

At a given point $P = \gamma(e^{i\varphi}) = \begin{pmatrix} \cos(\varphi) \\ \sin(\varphi) \\ 0 \end{pmatrix} \in C_3$ we have

$$\begin{aligned} t_n(\overline{\alpha}) \begin{pmatrix} \cos(\varphi) \\ \sin(\varphi) \\ 0 \end{pmatrix} &= t_n \begin{pmatrix} \cos(\varphi) \\ \sin(\varphi) \\ 0 \end{pmatrix} \cdot \underbrace{\alpha(e^{-i\varphi})}_{=\overline{\alpha}(e^{i\varphi})} = \begin{pmatrix} \cos(\varphi) & 0 \\ \sin(\varphi) & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} \cos(-\varphi) & -\sin(-\varphi) \\ \sin(-\varphi) & \cos(-\varphi) \end{pmatrix} \\ &\underset{\substack{\uparrow \\ \text{since } \rho \text{ is reflection in the second coordinate} \\ \text{together with the symmetries of sin and cos}}}{=} \rho \left(\begin{pmatrix} \cos(-\varphi) & 0 \\ \sin(-\varphi) & 0 \\ 0 & 1 \end{pmatrix} \cdot \begin{pmatrix} \cos(-\varphi) & -\sin(-\varphi) \\ \sin(-\varphi) & \cos(-\varphi) \end{pmatrix} \right) \underset{\substack{\uparrow \\ \text{definition of } h_n, \text{ see page 2046}}}{=} \rho \left(h_n \begin{pmatrix} \cos(-\varphi) \\ \sin(-\varphi) \\ 0 \end{pmatrix} \right) \\ &\underset{\substack{\uparrow \\ \text{definition of } \rho}}{=} \rho \left(h_n \left(\rho^{-1} \begin{pmatrix} \cos(\varphi) \\ \sin(\varphi) \\ 0 \end{pmatrix} \right) \right) \underset{\substack{\uparrow \\ \rho_*(h_n) \text{ as defined on page 2035}}}{=} \rho_*(h_n) \begin{pmatrix} \cos(\varphi) \\ \sin(\varphi) \\ 0 \end{pmatrix}. \end{aligned}$$

This concludes the mind-numbing verification of the second statement. □

Lemma 88.15. *Let $n \in \mathbb{N}_{\geq 2}$ and let $\gamma\colon S^1 \to \mathbb{R}^n$ be an embedding. Furthermore let $f\colon \gamma(S^1) \to \mathrm{GL}(n, n-1)$ be a framing for $\gamma(S^1)$. Finally let $\alpha, \beta\colon S^1 \to \mathrm{GL}_+(n-1, \mathbb{R})$ be two smooth maps. If α and β are smoothly homotopic, then*

$$[(\gamma(S^1), f(\alpha))] \;=\; [(\gamma(S^1), f(\beta))] \;\in\; \Omega_1^{\mathrm{fr}}(\mathbb{R}^n).$$

Proof of Lemma 88.15 (∗). We write $M = \gamma(S^1)$. Since $\alpha, \beta\colon S^1 \to \mathrm{GL}_+(n-1, \mathbb{R})$ are smoothly homotopic we can pick a smooth homotopy $H\colon S^1 \times [0,1] \to \mathrm{GL}_+(n-1, \mathbb{R})$ with $H_0 = \alpha$ and $H_1 = \beta$. We consider the product cobordism $[0,1] \times M$ equipped with the framing

$$\begin{aligned} V\colon [0,1] \times M &\to \mathrm{GL}(n+1, n) \\ (t, \gamma(z)) &\mapsto \begin{pmatrix} 1 & 0 \\ 0 & f(\gamma(z)) \cdot H(z,t) \end{pmatrix} \end{aligned}$$

It is clear that $([0,1] \times M, V)$ is a framed cobordism between $(\gamma(S^1), f(\alpha))$ and $(\gamma(S^1), f(\beta))$. □

Now we can provide the proof of Proposition 88.13.

Proof of Proposition 88.13. Let $n \in \mathbb{N}_{\geq 4}$. We consider the following diagram

$$\begin{tikzcd} \mathbb{Z} \arrow[r, "k \mapsto k \cdot [(C_3, h_3)]", "\cong"'] \arrow[d, two heads] \arrow[dr, two heads, "k \mapsto k \cdot [(C_n, h_n)]"'] & \Omega_1^{\mathrm{fr}}(\mathbb{R}^3) \arrow[d, two heads, "(n\text{-}3)\text{-fold suspension homomorphism}"] \\ \mathbb{Z}_2 \arrow[r, dashed] & \Omega_1^{\mathrm{fr}}(\mathbb{R}^n). \end{tikzcd}$$

We make the following observations:

(1) It follows quite easily from Theorem 87.14, Lemma 88.12 and Proposition 88.4 that the top horizontal map is an isomorphism.
(2) The right vertical map is given by the $(n-3)$-fold application of the suspension homomorphism defined on page 2038. Note that the right vertical map is an epimorphism by the Freudenthal Suspension Theorem 88.7.
(3) The top right triangle commutes by definition of the suspension homomorphism and by definition of (C_n, h_n).

The above diagram and the above discussion show that it remains to prove the following claim.

Claim. The element $2 \cdot [(C_n, h_n)]$ is trivial in $\Omega_1^{\mathrm{fr}}(\mathbb{R}^n)$.

We consider the loop

$$\begin{array}{rcl} \alpha\colon S^1 & \to & \mathrm{GL}_+(n-1,\mathbb{R}) \\ z = e^{i\varphi} & \mapsto & \begin{pmatrix} \cos(\varphi) & -\sin(\varphi) & 0 \\ \sin(\varphi) & \cos(\varphi) & 0 \\ 0 & 0 & \mathrm{id}_{n-3} \end{pmatrix}. \end{array}$$

We have the following equalities in $\Omega_1^{\mathrm{fr}}(\mathbb{R}^n)$:

$$\begin{array}{rcl} 2 \cdot [(C_n, h_n)] & \underset{\uparrow}{=} & [(C_n, h_n)] + [(C_n, t_n(\alpha))] \underset{\uparrow}{=} [(C_n, h_n)] + [(C_n, t_n(\overline{\alpha}))] \\ & & \text{Lemma 88.14 (1)} \quad \begin{array}{l} \text{since } n \geq 4 \text{ we know by Proposition 86.11 (2) that } \pi_1(\mathrm{GL}_+(n-1,\mathbb{R})) \cong \mathbb{Z}_2, \\ \text{therefore we see that } [\alpha] \cdot [\alpha] = 0 \in \pi_1(\mathrm{GL}_+(n-1,\mathbb{R})), \\ \text{this implies by Proposition 5.7 that } \alpha \text{ is path-homotopic to } \overline{\alpha}, \\ \text{in fact, by the Whitney Approximation Theorem 65.6} \\ \text{we see that } \alpha \text{ is actually smoothly homotopic to } \overline{\alpha}, \\ \text{by Lemma 88.15 this gives us the equality } [(C_n, t_n(\alpha))] = [(C_n, t_n(\overline{\alpha}))] \end{array} \\ & \underset{\uparrow}{=} & [(C_n, h_n)] + [(\rho_*(C_n), \rho_*(h_n))] \underset{\uparrow}{=} [(C_n, h_n)] + (-[(C_n, h_n)]) = 0. \\ & & \text{Lemma 88.14 (2)} \qquad\qquad \text{Proposition 88.2} \end{array}$$

This concludes the proof of the claim. □

Let $n \geq 4$. By Proposition 88.13 we now know that there exists an epimorphism $\mathbb{Z}_2 \to \Omega_1^{\mathrm{fr}}(\mathbb{R}^n) \cong \pi_n(S^{n-1})$. In Theorem 78.13 we showed that $\pi_{n+1}(S^n)$ is non-trivial. Therefore it follows that $\pi_{n+1}(S^n) \cong \mathbb{Z}_2$, which means we have proved Theorem 88.10. The readers who studied Steenrod operations *and* who happen to be tired of Thom-Pontryagin theory can thus move on to next section.

For all others we provide a proof of Theorem 88.10 that does not rely on Theorem 78.13. More precisely, we prove the following proposition which is the main technical result of this section.

Proposition 88.16. *For any $n \in \mathbb{N}_{\geq 4}$ the map*

$$\begin{array}{rcl} \mathbb{Z}_2 & \to & \Omega_1^{\mathrm{fr}}(\mathbb{R}^n) \\ [k] & \mapsto & k \cdot [(C_n, h_n)] \end{array}$$

is an isomorphism.

As we had mentioned many times, Theorem 88.10 is an immediate consequence of the Thom-Pontryagin Theorem 87.11 and Proposition 88.4 together with Proposition 88.16.

Proof. Let $n \in \mathbb{N}_{\geq 4}$. By Proposition 88.13 it remains to show that (C_n, h_n) represents a non-trivial element in $\Omega_1^{\mathrm{fr}}(\mathbb{R}^n)$.

We start out with a more general discussion. Given any $m \in \mathbb{N}_{\geq 2}$ we make the identification $C_m = \{0\} \times C_m \subset [0,1] \times \mathbb{R}^m$. The following claim applies to all dimensions.

Claim. Let $m \in \mathbb{N}_{\geq 2}$. Let F be a compact orientable connected proper 2-dimensional manifold in $[0,1] \times \mathbb{R}^m$ with $\partial F = C_m$. At most one of the two framings t_m and h_m can be extended to a framing of F.

Suppose there exist framings T and H on F with $T|_{C_m} = t_m$ and $H|_{C_m} = h_m$. It follows from Lemma 88.3 that we can assume that T and H are orthonormal. We consider the map[1526]

$$\begin{array}{rcl} \Psi\colon F & \to & \mathrm{GL}(m-1,\mathbb{R}) \\ P & \mapsto & \text{the unique matrix } \Psi(P) \in \mathrm{GL}(m-1,\mathbb{R}) \text{ with } T(P)\cdot\Psi(P) = H(P). \end{array}$$

We denote by $i\colon C_m \to F$ the inclusion map and we denote by $\gamma\colon S^1 \to C_m$ the usual diffeomorphism given by $\gamma(e^{i\varphi}) = (\cos(\varphi), \sin(\varphi), 0, \dots, 0)$. We make the following key observation: it follows immediately from the definitions and Lemma 88.14 that the map $\Psi \circ i \circ \gamma\colon S^1 \to \mathrm{GL}(m-1,\mathbb{R})$ is precisely, on the nose, given by the map

$$\begin{array}{rcl} \alpha\colon S^1 & \to & \mathrm{GL}(m-1,\mathbb{R}) \\ e^{i\varphi} & \mapsto & \begin{pmatrix} \cos(\varphi) & -\sin(\varphi) & 0 \\ \sin(\varphi) & \cos(\varphi) & 0 \\ 0 & 0 & \mathrm{id}_{m-3} \end{pmatrix}. \end{array}$$

Now we consider the following diagram

$$\begin{tikzcd} H_1(\partial F;\mathbb{Z}) \arrow[d, "i_*"'] & H_1(S^1;\mathbb{Z}) \arrow[l, "\gamma_*"'] \arrow[d, "\alpha_*"'] & \pi_1(S^1,1) \arrow[l, "\text{Hurewicz isom.}", "\cong"'] \arrow[d, "\alpha_*"'] \\ H_1(F;\mathbb{Z}) \arrow[r, "\Psi_*"] & H_1(\mathrm{GL}(m-1,\mathbb{R})) & \pi_1(\mathrm{GL}(m-1,\mathbb{R}),\mathrm{id}). \arrow[l, "\cong", "\text{Hurewicz isom.}"'] \end{tikzcd}$$

We make the following observations:

(1) The left-hand square commutes by the above equality $\alpha = \Psi \circ i \circ \gamma$.
(2) The two horizontal maps to the right are the Hurewicz homomorphisms that we introduced on page 924. The Hurewicz homomorphisms are isomorphisms by the Hurewicz Theorem 38.5 together with the fact that the fundamental groups on the right are both abelian.

[1526]Let $P \in F$. The fact that T and H are orthonormal means that the columns of $T(P)$ and $H(P)$ are bases for the same vector space, namely $(T_P F)^\perp$. Therefore there exists a matrix $\Psi(P) \in \mathrm{GL}(m-1,\mathbb{R})$ such that $T(P)\cdot\Psi(P) = H(P)$. The fact that $P \mapsto \Psi(P)$ is continuous is left as an exercise.

(3) The right-hand square commutes by the naturality of the Hurewicz homomorphisms, see Proposition 38.2 (4).
(4) By Proposition 86.11 (2) and (3) we know that the loop $\alpha\colon S^1 \to \mathrm{GL}(m-1,\mathbb{R})$ represents a non-trivial element in $\pi_1(\mathrm{GL}(m-1,\mathbb{R}),\mathrm{id})$. This implies that the right vertical map $\alpha_*\colon \pi_1(S^1,1) \to \pi_1(\mathrm{GL}(m-1,\mathbb{R}),\mathrm{id})$ is non-trivial.
(5) It follows from (1) – (4) that the left vertical map is also non-trivial. But this contradicts Lemma 35.9 (1).

This concludes the proof of the claim.

Now we start out with the actual proof of the theorem. Thus let $n \in \mathbb{N}_{\geq 4}$. As we pointed out above, we need to show that (C_n, h_n) represents a non-trivial element in $\Omega_1^{\mathrm{fr}}(\mathbb{R}^n)$. Suppose that that (C_n, h_n) represents in fact the trivial element in $\Omega_1^{\mathrm{fr}}(\mathbb{R}^n)$. This means that there exists a framed cobordism $(F, v) = (F_n, v_n)$ in $[0,1] \times \mathbb{R}^n$ from (C_n, h_n) to the empty manifold. In other words, $F = F_n$ is a compact orientable proper 2-dimensional submanifold of $[0,1] \times \mathbb{R}^n$ with $\partial F_n = C_n$ and $v = v_n$ is a framing with $v|_{C_n} = h_n$. By throwing away all closed components of F_n we can assume that F_n is connected.

By the classification of compact orientable connected 2-dimensional manifolds, see Theorem 14.14, we know that there exists a $g \in \mathbb{N}_0$ such that F is diffeomorphic to $\Sigma := \Sigma_{g,1}$. In other words, there exists a proper embedding $\varphi\colon \Sigma \to [0,1] \times \mathbb{R}^n$ with $\varphi(\Sigma) = F_n$. Given any $m \geq n$ we denote by $\varphi_m\colon \Sigma \to [0,1] \times \mathbb{R}^m$ the embedding that is given by the composition of the embedding φ with the obvious embedding $[0,1] \times \mathbb{R}^n \to [0,1] \times \mathbb{R}^m$.

By Lemma 88.11 (1) we know that there exists a proper embedding $\psi\colon \Sigma \to [0,1] \times \mathbb{R}^2$ and a framing $w_2 = w$ for $G_2 = G := \psi(\Sigma)$ such that $\partial\psi(\Sigma) = C_2$ and such that the restriction of $w_2 = w$ to C_2 equals t_2. Given $m \geq 2$ we denote by $\psi_m\colon \Sigma \to [0,1] \times \mathbb{R}^m$ the embedding that is given by the composition of the embedding ψ with the obvious embedding $[0,1] \times \mathbb{R}^2 \to [0,1] \times \mathbb{R}^m$.

Now we consider the two proper embeddings $\psi_n, \varphi_n\colon \Sigma \to [0,1] \times \mathbb{R}^n$. We can arrange[1527] that $\psi_n|_{\partial\Sigma} = \varphi_n|_{\partial\Sigma}$.

It follows from Proposition 65.16 (2) and the Isotopy Extension Theorem 10.21 that there exists an $m \geq n$ and a diffeomorphism Ψ of the manifold $[0,1] \times \mathbb{R}^m$ such that $\Psi(F_m) = G_m$ and such that the restriction of Ψ to $\{0\} \times \mathbb{R}^m$ is the identity. We refer to Figure 1082 for an illustration.

Since (F_m, v_m) is an extension of (C_m, h_m) and since the restriction of Ψ to $\{0\} \times \mathbb{R}^m$ is the identity we see that $(\Psi(F_m), \Psi_*(v_m)) = (G_m, \Psi_*(v_m))$ is an extension of (C_m, h_m). On the other hand we saw (G_m, w_m) is an extension of (C_m, t_m). Thus both h_m and t_m can be extended over G_m. But this contradicts the above claim. □

[1527]This sentence contains a slight technical nuisance which we cleverly hide in a footnote. First of all, it should be pretty clear by now that Σ admits an orientation-reversing self-diffeomorphism. Thus, after possibly precomposing φ_n with such a diffeomorphism we can assume that $\psi_n^{-1} \circ \varphi_n$ is orientation-preserving. Using Corollary 20.6 and using the Collar Neighborhood Theorem 10.10 we can then arrange, after possibly precomposing φ_n by another diffeomorphism, that $\psi_n|_{\partial\Sigma} = \varphi_n|_{\partial\Sigma}$.

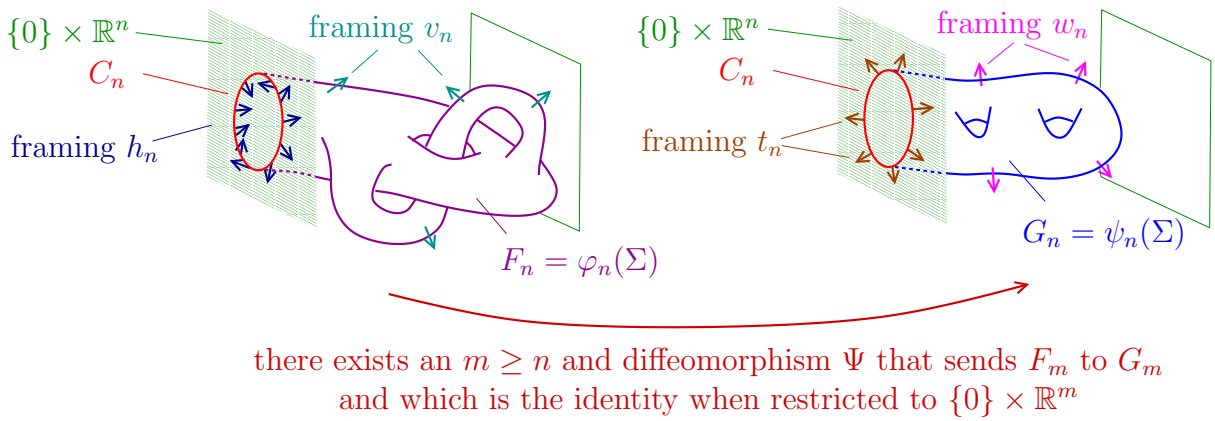

FIGURE 1082. Illustration for the proof of Proposition 88.16.

88.4. **Further results obtained using the Thom-Pontryagin approach.** In this final section we summarize a few more results that have been proved using the Thom-Pontryagin approach. First of all, using the Thom-Pontryagin method Pontryagin [Po2] proved in 1950 the following theorem.

Theorem 88.17. *For any $n \geq 2$ we have $\pi_{n+2}(S^n) \cong \mathbb{Z}_2$.*

Remark.

(1) By Theorem 85.10 (1) we know that for every $n \geq 3$ we have an isomorphism $\pi_n(S^3) \cong \pi_n(S^2)$. Furthermore we know by Theorem 88.10 that for every $n \geq 3$ we have $\pi_{n+1}(S^n) \cong \mathbb{Z}_2$. Putting these two results together shows that $\pi_4(S^2) \cong \mathbb{Z}_2$.
(2) In Theorem 79.2 we used Steenrod operations to show that $\pi_{n+2}(S^n) \neq 0$ for all $n \geq 2$.
(3) By the Freudenthal Suspension Theorem 88.6 we know that the suspension homomorphism $\pi_5(S^3) \to \pi_6(S^4)$ is an epimorphism and we know that for $n > k+1$ the suspension homomorphism $\pi_{n+2}(S^n) \to \pi_{n+3}(S^{n+1})$ if an isomorphism for $n \geq 5$.
(4) Unfortunately (1), (2) and (3) are *not* strong enough to give an alternative proof of Theorem 88.17.

Proof.

(1) As mentioned before, the theorem was proved by Lev Pontryagin [Po2, Po3]. See also [Sco, p. 233] and [WX2, Chapter 2.5] for outlines of the proof. The most readable account of the Thom-Pontryagin approach to proving the theorem is surely [Put].
(2) At the same time as Pontryagin two very different proofs that $\pi_{n+2}(S^n) \cong \mathbb{Z}_2$ for $n \geq 2$ were given by George W. Whitehead [Whda2] and Jean-Pierre Serre [Ser3, Proposition 10]. We also refer to [Hat6, Theorem 1.40 (a)] for a proof using spectral sequences and Steenrod operations. Alternatively see also [Hu2, Theorem XI.15.2].

□

Finally Rokhlin [Rok, Rok2] used the Thom-Pontryagin approach to prove the following theorem.

Theorem 88.18.

(1) *We have*[1528] $\pi_5(S^3) \cong \mathbb{Z}_2$, $\pi_6(S^3) \cong \mathbb{Z}_{12}$, $\pi_7(S^4) \cong \mathbb{Z} \oplus \mathbb{Z}_{12}$.
(2) *For any* $n \geq 5$ *we have* $\pi_{n+3}(S^n) \cong \mathbb{Z}_{24}$.

Remark.

(1) In Theorem 78.13 we used Steenrod operations to show the weaker statement that $\pi_{n+3}(S^n) \neq 0$ for all $n \geq 2$.
(2) Note that Theorem 88.18 (1) gives a negative answer to Question 63.16.

Proof.

(a) The theorem was proved by Vladimir Rokhlin [Rok][Rok2, p. 21] in 1952, using the above Thom-Pontryagin approach.[1529]
(b) A somewhat different proof is sketched in [WX2, Chapter 2.6]. Some of the results can also be found in [Ser3, Proposition 10]. Other proofs are given in [Hat6, Theorem 1.40 (b)] and [Hu2, Chapter XI.16]. □

The results of the last two chapters summarize most (or all?) of the calculations of homotopy groups of spheres that have been obtained using the Thom-Pontryagin approach.

Exercises for Chapter 88.

Exercise 88.1. In the proof of Proposition 88.13 we used the Freudenthal Suspension Theorem 88.6 to show that the map

$$\begin{array}{rcl} \mathbb{Z} & \to & \Omega_1^{\mathrm{fr}}(\mathbb{R}^4) \\ [k] & \mapsto & k \cdot [(C_4, h_4)] \end{array}$$

is an epimorphism. Use Exercise 65.5 to give an alternative argument, which does not rely on the Freudenthal Suspension Theorem 88.6.

Exercise 88.2. Let $n \in \mathbb{N}_{\geq 2}$. We consider the loops

$$\begin{array}{rcl} \alpha\colon S^1 & \to & \mathrm{GL}_+(n,\mathbb{R}) \\ z = e^{i\varphi} & \mapsto & \begin{pmatrix} \cos(\varphi) & -\sin(\varphi) & 0 \\ \sin(\varphi) & \cos(\varphi) & 0 \\ 0 & 0 & \mathrm{id}_{n-2} \end{pmatrix} \end{array} \quad \text{and} \quad \begin{array}{rcl} \overline{\alpha}\colon S^1 & \to & \mathrm{GL}_+(n,\mathbb{R}) \\ z = e^{i\varphi} & \mapsto & \begin{pmatrix} \cos(\varphi) & \sin(\varphi) & 0 \\ -\sin(\varphi) & \cos(\varphi) & 0 \\ 0 & 0 & \mathrm{id}_{n-2} \end{pmatrix} \end{array}.$$

Recall that in the proof of Lemma 88.15 we used the fact, proved in Proposition 86.11 (2), that $\pi_1(\mathrm{GL}_+(n-1,\mathbb{R})) \cong \mathbb{Z}_2$, to show that α is path-homotopic to $\overline{\alpha}$. Give a direct proof that the loop α is path-homotopic to the loop $\overline{\alpha}$.

[1528] In fact the first isomorphism $\pi_5(S^3) \cong \mathbb{Z}_2$ is a consequence of Theorem 85.10 and Theorem 88.17.

[1529] In fact Rokhlin [Rok3] initially thought that for $n \geq 5$ the groups $\pi_{n+3}(S^n)$ are isomorphic to $\mathbb{Z}_{12}$. The key to fixing the mistake is Rokhlin's Theorem 72.24 regarding signatures of certain 4-manifolds.

89. Summary of homotopy groups of spheres

The results from last chapter conclude our calculations of homotopy groups of spheres. Throughout the course we employed a long and varied list of tools to compute homotopy groups of spheres:

(1) Covering theory, see page 723.
(2) The Cellular Approximation Theorem 27.15, see Proposition 28.9.
(3) Homology theory and the Hurewicz Theorem 80.5, see Corollary 80.6.
(4) The cup product, see Corollary 63.14.
(5) Steenrod operations, see Theorems 78.13 and 79.2.
(6) The long exact sequence of a fibration, see Theorem 85.10.
(7) The Thom-Pontryagin Theory, see the Freudenthal Suspension Theorem 88.6 and Theorem 88.10.

In the following we summarize the results we have obtained on homotopy groups of spheres:

(1) On page 723 we saw that $\pi_n(S^1) = 0$ for $n \geq 2$.
(2) Proposition 28.9 says that for any $n \in \mathbb{N}$ we have $\pi_1(S^n) = \cdots = \pi_{n-1}(S^n) = 0$.
(3) Corollary 80.6 (or alternatively by Corollary 87.12) we know that for any $n \in \mathbb{N}$ we have $\pi_n(S^n) \cong \mathbb{Z}$.
(4) By Theorem 85.10 (1) we know that for every $n \geq 3$ we have an isomorphism $\pi_n(S^3) \cong \pi_n(S^2)$. In particular, together with (3) we know that $\pi_3(S^2) \cong \mathbb{Z}$. An alternative proof of the fact that $\pi_3(S^2) \cong \mathbb{Z}$ is given by the combination of the Thom-Pontryagin Theorem 87.11 and Theorem 87.14.
(5) In Corollary 63.14, and alternatively in Proposition 87.21 we saw that given any even $n \in \mathbb{N}$ there exists an epimorphism $\pi_{2n-1}(S^n) \to \mathbb{Z}$.
(6) By Theorem 85.11 (1) we know that for every $n \geq 2$ we have an isomorphism $\pi_n(S^4) \cong \pi_n(S^7) \oplus \pi_{n-1}(S^3)$. Furthermore, by Theorem 85.11 (1) we know that for every $n \geq 2$ we have an isomorphism $\pi_n(S^8) \cong \pi_n(S^{15}) \oplus \pi_{n-1}(S^7)$.
(7) By the Freudenthal Suspension Theorem 88.6 we know that for $n = k+1$ we have an epimorphism $\pi_{n+k}(S^n) \cong \pi_{n+k+1}(S^{n+1})$ and we know that for $n > k+1$ we have an isomorphism $\pi_{n+k}(S^n) \cong \pi_{n+k+1}(S^{n+1})$.
(8) By Theorem 85.11 (2) we know that $\pi_6(S^4) \cong \pi_5(S^3)$ and by Theorem 85.14 (3) we know that $\pi_{14}(S^8) \cong \pi_{13}(S^7)$.
(9) In Theorem 78.13 we proved the following three statements:
    (a) for any $n \geq 2$ the group $\pi_{n+1}(S^n)$ is non-trivial,
    (b) for any $n \geq 4$ the group $\pi_{n+3}(S^n)$ is non-trivial,
    (c) for any $n \geq 8$ the group $\pi_{n+7}(S^n)$ is non-trivial.
(10) By Theorem 88.10 we know that for every $n \geq 3$ we have $\pi_{n+1}(S^n) \cong \mathbb{Z}_2$. This is a refinement of statement (9a). Note that it follows from this fact together with (4) that $\pi_4(S^2) \cong \mathbb{Z}_2$.
(11) In Theorem 79.2 we proved the following three statements:
    (a) for any $n \geq 2$ the group $\pi_{n+2}(S^n)$ is non-trivial,

(b) for any $n \geq 4$ the group $\pi_{n+6}(S^n)$ is non-trivial,
(c) for any $n \geq 8$ the group $\pi_{n+14}(S^n)$ is non-trivial.

We recall that Serre's Theorem 81.9 says that all homotopy groups of spheres are finitely generated abelian groups. In the discussion above we saw that some of the homotopy groups of spheres are infinite.

The following theorem can be summarized as saying that we have picked up all elements of infinite order. In particular the theorem gives a complete answer to Question 63.16. This theorem can also be viewed as a strengthening of Serre's Theorem 81.9. In fact, the strengthening is also due to Jean-Pierre Serre.

Theorem 89.1.

(1) *If n is odd, then $\pi_k(S^n)$ is finite for $k \geq n+1$.*
(2) *If n is even, then the following two statements hold:*
  (a) *The group $\pi_k(S^n)$ is finite for $k \geq n+1$ and $k \neq 2n-1$.*
  (b) *The group $\pi_{2n-1}(S^n)$ is isomorphic to the direct sum of $\mathbb{Z}$ with a finite group.*

Proof. The theorem was first proved by Serre [Ser3] using "spectral sequences". Expositions of the proof are also given in [Hat6, Theorem 1.21] and [Sp, p. 515f]. □

The following table, obtained from [Tod, Chapter XIV], shows the low-dimensional homotopy groups of low-dimensional spheres. The entries colored in blue have been proved in these lecture notes.

	π_1	π_2	π_3	π_4	π_5	π_6	π_7	π_8	π_9	π_{10}	π_{11}	π_{12}	π_{13}	π_{14}	π_{15}

Note that we showed in Theorem 85.10 (1) that the second and the third row, starting with π_3, are the same.

Recall that the Freudenthal Suspension Theorem 88.6 says that for any $n, k \in \mathbb{N}_0$ with $n > k+1$ the suspension homomorphism $\pi_{n+k}(S^n) \to \pi_{n+k+1}(S^{n+1})$ is an isomorphism. Thus we see that the groups $\pi_{n+k}(S^n)$ "stabilize" as $n \to \infty$. It is therefore perhaps more instructive to shift in the above diagram the i-th row leftward by $i-1$ terms. This way the diagonal lines become vertical. In other words we consider the following diagram where

π_{n+k} is short for $\pi_{n+k}(S^n)$.

n	π_{n+0}	π_{n+1}	π_{n+2}	π_{n+3}	π_{n+4}	π_{n+5}	π_{n+6}	π_{n+7}	π_{n+8}	π_{n+9}	π_{n+10}

Here for convenience we colored the "diagonal" $\pi_n(S^{2n})$ in red, since the Freudenthal Suspension Theorem 88.6 implies that below the diagonal the groups on each column are the same.

We conclude this discussion of the precise homotopy groups of spheres with the following sobering fact:

Fact 89.2. *There is no sphere S^n with $n \geq 2$ for which we*[1530] *know the isomorphism types of all homotopy groups.*

As we had mentioned above, the Freudenthal Suspension Theorem 88.6 says that homotopy groups of spheres "stabilize". This leads us to the following definition.

Definition. Let $k \in \mathbb{N}_0$. We refer to[1531]

$$\pi_k^s \;:=\; \varinjlim \pi_{n+k}(S^n)$$

as the *k-th stable homotopy group of spheres.*[1532]

Note that it follows from Theorem 89.1 that for any $k \geq 1$ the k-th stable homotopy group π_k^s is finite. The following table obtained from [Wiki] gives the stable homotopy groups up to $k = 63$. It seems like 64 is the first dimension for which we do not know the

[1530]Here "we" is defined as members of our species.

[1531]Given $k \in \mathbb{N}_0$ the groups $\{\pi_{n+k}(S^n)\}_{n\in\mathbb{N}}$ together with the suspension homomorphisms form a direct system. Thus it makes sense to consider the direct limit.

[1532]Note that for any n, k with $n > k + 1$ the Freudenthal Suspension Theorem 88.6, together with Lemma 52.2 (4) and Lemma 52.3, says that the natural map $\pi_{n+k}(S^n) \to \pi_k^s$ is an isomorphism.

corresponding stable homotopy groups.

π^s_{56+n}	$\mathbb{Z}_2^2$	$\mathbb{Z}_2^4$	$\mathbb{Z}_2^2$	$\mathbb{Z}_2^2\,\mathbb{Z}_{8\cdot 9\cdot 7\cdot 11\cdot 31}$	$\mathbb{Z}_4$	0	$\mathbb{Z}_2^2\,\mathbb{Z}_{4\cdot 3}$	$\mathbb{Z}_2^3\,\mathbb{Z}_{128\cdot 3\cdot 5\cdot 17}$

This concludes our discussion of the homotopy groups of spheres. We refer to [May, WX2, Wiki] and [Hat, Chapter 4] for a more detailed discussion.

extension of abelian groups, 1215
exterior algebra, 1407
exterior of a knot, 971, 1151, 1626

face map, 736
face of the standard simplex, 735
fattened cobordism group, 2018
fattened submanifold, 2007
fattening of a knot, 1625
fattening of a submanifold, 2007
fiber, 1913, 1962
fiber bundle, 1962
  non-trivial, 1963
  trivial, 1963
fibration, 1911
flag of a polyhedron, 988
folding map, 1086
form, 1649
  even, 1676
  indefinite, 1671
  negative-definite, 1671
  non-degenerate, 1664
  non-singular, 1650
  odd, 1676
  positive-definite, 586, 1671
framed cobordism group, 2036
framing
  orthonormal, 2035
  perpendicular, 2034
free R-module, 1371
free abelian group, 366, 367
free group, 377, 378
free loop space, 1930
free path space, 1930
free path space fibration, 1933
free product of groups, 374
free resolution of an abelian group, 1015
functor
  acyclic relative to $\mathcal{M}$, 1329

contravariant, 245
covariant, 243
fundamental class, 947, 1113
fundamental class of oriented 0-dimensional manifold, 1585
fundamental group, 234

Galois extension, 639
Galois group, 639
generating set, 368
generating set of a group, 378
generators of a group, 378
generators of a presentation, 408
geodesic, 597
girth of a graph, 997
gluing of topological spaces, 114
graded module, 1037
graded ring, 1305, 1406
graph
simple, 999
graph of an equivalence relation, 100
Grassmannian, 1784
group
finitely generated, 378, 410
finitely presented, 410
free, 378
Hopfian, 975
indecomposable, 382
locally free, 383
group ring, 1872

H-space, 2000
handlebody, 1692
Hawaiian earrings, 680
Heegaard splitting, 1695
HNN-extension, 510
homeomorphism, 72
homogeneous element of a graded module, 1037
homologous, 740
homology class represented by a submanifold, 957, 1614
homology group of a chain complex, 744
homology groups with coefficients, 1007
homology manifold, 1094
homology sphere, 992
homotopy, 641
proper, 1531
rel a subset, 301, 641
homotopy between maps, 299
homotopy between pairs of topological spaces, 641
homotopy category, 305, 760
homotopy equivalence, 307, 759
homotopy equivalence between pairs of topological spaces, 642
homotopy fiber, 1920, 1939
homotopy group, 709
homotopy inverse, 307
homotopy lifting property, 1911
homotopy sphere, 728, 1854
Hopf invariant, 1473, 1474
Hopf link, 965
Hopf map, 726, 1468, 1817, 1969
octonion, 1468, 1817
quaternion, 1817
quaternionic, 1468
Hurewicz homomorphism, 924, 932, 1851, 1904
hyperbolic disk, 588
hyperbolic half-plane, 586
hyperbolic line, 591
hyperelliptic involution, 1747

immersion, 1511
inductive limit, 496
infinite Grassmannian, 1784
integral homology sphere, 1711, 1771
interior, 50
intermediate cellular chain complex, 1189
intersection form
$\mathbb{F}_2$-valued, 1687
$\mathbb{Z}$-valued, 1652
intersection number

algebraic, 1560
geometric, 1560
inverse limit, 496, 1242
inverse path, 226
inverse system, 495, 1241
isometry, 589
isomorphism problem, 546
isotopy, 301, 473

join of topological spaces, 1974
Jordan curve, 584, 1551

K3-surface, 1680
Klein bottle, 118, 435
knot, 360, 853
amphichiral, 1148
chiral, 1148
oriented, 360
trivial knotted, 361
Kronecker pairing, 1199, 1227
Krull topology, 640

Lebesgue number, 137
length of a curve, 594
length of a free resolution, 1015
lens space, 266
Lie group, 1983
lift of a map, 272, 550
lift of a path, 269
limit, 496
line bundle, 1782
line with a point at infinity, 53
line with two zeros, 53
linear $\overline{B}^m$-bundle, 1493
link, 1535, 1634
boundary link, 1648
split, 1648
linking number, 1635, 2029
linking pairing, 1718, 1720
local degree, 827
local homology of a topological manifold, 1088
local property of a map, 132
local property of a topological space, 130, 549
long exact sequence in homology, 772
long exact sequence in homology of a pair, 780
long exact sequence of a triple, 778
longitude, 1627
loop, 223, 226, 234
null-homotopic, 223, 226
loop space, 1930
Lusternik-Schnirelmann category, 1367

Möbius band, 105
Möbius bundle, 1784
Möbius isomorphism, 613
Möbius manifold, 602
Möbius map, 613
Möbius structure, 602
Möbius transformation, 586, 588
manifold, 182
amphichiral, 1149
chiral, 1149
irreducible, 1878
orientable, 200
parallelizable, 1786, 1985
manifolds
cobordant, 1760
commensurable, 576
map
bilinear, 1002, 1199
cellular, 697, 883
closed, 70
continuous, 65
covering, 257
holomorphic, 578, 579, 582
immersion, 330
induced, 246
of bounded displacement, 801
open, 70
orientation-preserving, 199, 200, 1099
orientation-reversing, 1100

piecewise linear, 703
proper, 330, 1259, 1515
quotient map, 162
self-transverse, 1558
smooth, 181
submersion, 211
uniformly continuous, 139
mapping class group, 1704
mapping cone, 458, 855, 1469, 1945
mapping cylinder, 455, 456, 1945
mapping path fibration, 1938
mapping torus, 469, 859
maps
diffeotopic, 335
homotopic, 299, 642, 754
homotopy equivalent, 759
isotopic, 302, 473
path-homotopic, 277
smoothly homotopic, 334
transverse, 1592
matrix
symplectic, 1706
maximal elemen of a partially ordered set, 1218
maximal smooth atlas, 184
meridian, 362, 853, 1626
metric
Euclidean metric, 43
maximum's metric, 61
Paris metric, 327
metric space, 43
complete, 599
minus n open disks, 440
mirror of a knot, 1147
Mittag-Leffler condition, 1246
monodromy, 469
monoid, 1759
Moore space of type $M(\pi, n)$, 875
morphism of a category, 241

natural isomorphism, 251, 1290
natural transformation, 251, 1290
neighborhood, 48
neighborhood retract, 1522
nice neighborhood, 827
normal bundle, 1783
normal core of a subgroup, 635
normalizer of a subgroup, 628
null-homologous cycle, 740, 745
nullity of a form, 1674

o-local property of a topological space, 130
object of a category, 241
octonion projective plane, 1063
octonions, 1057
open annulus, 117
open cell, 643
open collar neighborhood, 338
open covering, 54
open cylinder, 117
open Möbius band, 105
open neighborhood, 48
open regular neighborhood, 1490
open solid torus, 91
orientation covering, 294, 1104
orientation of a manifold, 200
orientation of a topological manifold, 1099
orientation of a vector space, 199
orientation-preserving mapping class group, 1704
oriented curve, 306
oriented manifold, 200

pair of CW-complexes, 699
pairing, 1447, 1649
anti-symmetric, 1649
non-singular, 1447
symmetric, 1649
parametrization of a manifold, 1365
parity of a form, 1676
partially ordered set, 1218
partition of a natural number, 1798

partition of unity, 1276
path, 223, 226
  orientation-preserving, 297
  orientation-reversing, 297
  piecewise smooth, 365
path space, 1930
path space fibration, 1933
path-component, 127
path-homotopy between paths, 226
paths
  path-homotopic, 223, 226
pinching map, 715
planar linkage, 919
Platonic solid, 990
Poincaré Duality isomorphism, 1413
Poincaré homology sphere, 993
Poincaré model for hyperbolic space, 588
point
  critical, 208
  good, 387
  isolated, 95
  regular, 208
pointed pair of topological spaces, 1883
pointed set, 1887
pointed topological space, 242
polygon
  regular, 985
polyhedron, 703
  regular, 988
Pontryagin class, 1794
preorder, 481
preordered set, 481
presentation, 410
presentation for a group, 410
product of paths, 231
product orientation, 205, 1321
profinite completion of a group, 505
profinite integers, 502
projective limit, 483
proper smooth isotopy, 334
pullback, 503
pullback fibration, 1938
pullback of a bundle, 1966
pullback of a vector bundle, 1790
pullback system, 503
punctured surface, 612
push-in, 346
push-pull set, 481
pushout, 485
pushout system, 483

quaternions, 1055

rank of a finitely generated abelian group, 371, 966
rank of a free abelian group, 366
rank of a free group, 674
rank of an abelian group, 1879
rational homology sphere, 1711, 1771
rational Pontryagin class, 1798
ray, 593
real division algebra, 1462
real projective space, 104
reduced homology, 761
reduced intersection pairing, 1735
reflection in a hyperplane, 304
reflexivity, 96
regular hexahedron, 989
regular neighborhood, 1489
regular octahedron, 989
regular tetrahedron, 988
Reidemeister moves, 533
Reidemeister-Schreier process, 544
relation, 96
relative homology group, 775
relative homotopy group, 1883
relative Hurewicz homomorphism, 1902
relators of a presentation, 408
rendezvous value, 142
reparametrization, 231
retract, 247
Riemannian manifolds
  isometric, 589
Riemannian structure, 586

hyperbolic, 602
ring, 486
Rokhlin homomorphism, 1778

section of a vector bundle, 1786
Seifert surface, 1629
self-linking number of a fattened knot, 1626
semi-group, 1759
semidirect product of groups, 476
Serre fibration, 1911
set
convex, 618
countable, 254
uncountable, 254
short exact sequence, 769
shuffle, 1323
sign of an intersection point, 1592
signature of a form, 1671
signature of a topological manifold, 1674
simplex, 734
simplicial complex, 936
simplicial precomplex, 936
simplicial structure, 938
singular chain, 736
singular coboundary, 1164
singular cochain, 1164
singular cochain complex of a topological space, 1164
singular cocycle, 1164
singular cohomology group of a topological space, 1164
singular homology group, 740
singular simplex, 736
smooth, 1295
skeleton, 643
smash product, 328
smooth $\overline{B}^m$-bundle, 1492
smooth cohomology theory, 1289
smooth homotopy, 334
smooth isotopy, 334
smooth map on $M \times [a, b]$, 333
smooth singular cohomology group, 1295
smooth structure, 183
solid torus, 91
space-filling curve, 124
spanning tree, 320, 321, 677
spatial graph, 134
sphere, 45
sphere packing, 1669
spin group, 1993
splitting of a 3-dimensional manifold, 1695
splitting of a short exact sequence, 836
standard R-orientation of S^n, 1102
standard generator of $H_n(S^n)$, 814
standard generator of $H_n(\overline{B}^n, S^{n-1})$, 816
standard simplex, 734
standard torus, 92
starting point of a path, 226
Steenrod operations, 1808
subbasis of a topology, 63
subcomplex of a CW-complex, 648, 657
subgraph, 320
subgroup
cocyclic, 541
normal, 406
subgroup generated by a subset, 407
subgroup normally generated by a subset, 407
submanifold, 179
non-separating, 977
proper, 180
separating, 977
submanifold charts, 180
submanifold with corner, 1488
submanifolds
complementary, 1562
smoothly isotopic, 337
subset
bounded, 57
closed, 44
convex, 78

dense, 49
full measure, 213
good, 763
measure zero, 213
open, 42
simply connected, 223
star-shaped, 235
substitution isomorphism, 413
superalgebra, 1305, 1406
support of a function, 1276
surface of genus g, 119
suspension functor, 454
suspension homomorphism, 727
suspension of a map, 453, 727
suspension of a topological space, 452, 727, 818
suspension operator, 865
symmetric form, 586
symmetry, 96
symplectic group, 1707

tangent bundle, 1783, 1785
tangent space, 195
tautological line bundle, 1783
tautological vector bundle, 1784
Teichmüller space, 607
telescope of a CW-complex, 684
tensor product, 1001
tensor product of chain complexes, 1041, 1308
Thom-Pontryagin map, 1618, 1620, 2008
Tietze transformations, 412
topological embedding, 1511
topological group, 139, 1982
topological manifold, 171
amphichiral, 1454
chiral, 1454
closed, 171
flexible, 1350
topological realization, 654
topological realization of a CW-complex, 643
topological realization of an abstract graph, 135
topological space, 42
k-connected, 728, 1899
acyclic, 1309
arc-connected, 147
aspherical, 1867
compact, 54
connected, 120
contractible, 307, 759
Hausdorff, 53
metrizable, 145, 179
normal, 75
paracompact, 1791
path-connected, 120
reasonable, 557
second-countable, 170
simply connected, 238
totally disconnected, 96
topological spaces
homotopy equivalent, 307
topologist's sine curve, 123
topology, 42
disjoint union topology, 83
generated by a basis, 60
leonine, 49
product topology, 94
product topology of finitely many topological spaces, 84
quotient topology, 97
subspace topology, 46
Torelli group, 1709
torsion group $\mathrm{Tor}(H, G)$, 1023
torsion group $\mathrm{Tor}_n(H, G)$, 1017
torsion subgroup, 372
torus, 91
total Pontryagin class, 1795
total space, 1782, 1913, 1962
totally real vectors, 580
transfer map, 1064
transition map, 182
transitivity, 96

transverse intersection of map and submanifold, 1556
transverse intersection point, 207
tree, 318, 676
triad of topological spaces, 1203
triangulation, 938
triple of topological spaces, 777
trivial knot, 361
trivial link, 1634
trivial preorder, 481
trivial tubular neighborhood, 347
  orientation-preserving, 347
trivial vector bundle, 1783
