Bibliography .................................................................................................................. 33
Introduction .................................................................................................................... 69

Part I. General Topology ......................................................................................... 71
1. Preliminaries ........................................................................................................... 72
   1.1. Basic set theory ................................................................................................. 72
   1.2. Relations and orders on sets ............................................................................. 73
   1.3. The cardinality of sets ....................................................................................... 78
   1.4. Conventions for (linear) algebra ...................................................................... 81
   Exercises for Chapter 1 ............................................................................................ 82

2. Topological spaces: basic definitions and properties ........................................ 83
   2.1. The definition of a topological space ................................................................. 83
   2.2. The Hausdorff property and convergence of sequences .................................. 94
   2.3. Compact topological spaces ............................................................................ 97
   2.4. Bases of a topology ......................................................................................... 102
   2.5. Continuous maps ............................................................................................ 107
   2.6. Homeomorphisms .......................................................................................... 115
   2.7. Normal topological spaces (*) ...................................................................... 120
   2.8. Convex subsets ............................................................................................... 123
   2.9. The two notions of connected topological spaces .......................................... 129
   2.10. The (path-) components of a topological space ............................................ 135
   2.11. Local properties .......................................................................................... 138
   2.12. The Lebesgue Lemma and uniformly continuous maps (*) ......................... 141
   2.13. Paracompact topological spaces (*) ............................................................... 144
   Exercises for Chapter 2 ........................................................................................... 147

3. Constructions of topological spaces ..................................................................... 159
   3.1. The disjoint union of topological spaces ......................................................... 159
   3.2. The product of finitely many topological spaces I .......................................... 161
   3.3. The product of finitely many topological spaces II ......................................... 167
   3.4. The product of arbitrarily many topological spaces (*) .................................... 171
3.5. Distance in metric spaces .......................................................... 175
3.6. Quotients of topological spaces ................................................. 177
3.7. Group actions on topological spaces ........................................... 185
3.8. Continuity of zeros (*) ............................................................... 191
3.9. Projective spaces ................................................................. 194
3.10. The pushout construction ......................................................... 197
3.11. Surfaces .............................................................................. 203
3.12. The join of two topological spaces (*) ....................................... 207
3.13. Topological groups ................................................................. 210
Exercises for Chapter 3 ................................................................. 211

4. Graphs ....................................................................................... 221
4.1. Abstract graphs and topological graphs ...................................... 221
4.2. Undirected abstract graphs and their topological realizations (*) ............................................................... 225
4.3. Trees ....................................................................................... 227
Exercises for Chapter 4 ................................................................. 230

5. General topology: some delicate bits (*) ........................................ 233
5.1. The compact-open topology (*) .................................................. 233
5.2. Mixing product and quotient topologies (*) .............................. 243
5.3. Proof of Theorem 5.16 (*) .......................................................... 251
5.4. Mixing product and quotient topologies II (*) ......................... 255
Exercises for Chapter 5 ................................................................. 257

Part II. Differential Topology .......................................................... 259
6. Topological manifolds and smooth manifolds .................................. 260
6.1. Second-countable topological spaces ........................................ 260
6.2. Topological manifolds: definition and examples .......................... 261
6.3. Surfaces are topological manifolds ............................................. 266
6.4. Properties of topological manifolds ............................................ 269
6.5. Smooth functions on subsets of \( \mathbb{R}^n \) ..................................... 272
6.6. Smooth manifolds ................................................................. 276
6.7. Topological properties of smooth manifolds ............................... 281
6.8. Manifolds and group actions ..................................................... 286
6.9. Tangent spaces of smooth manifolds ......................................... 290
6.10. Orientations of real vector spaces ............................................ 296
6.11. Orientations of smooth manifolds ............................................. 297
6.12. Intersections of submanifolds (*) ............................................. 305
6.13. The Regular Value Theorem I .................................................. 307
18.4. The fundamental groups of homotopy equivalent topological spaces ........................................ 551
18.5. The boundary of 2-dimensional topological manifolds (*) ....................................................... 553
18.6. Homotopies on quotients and pushouts (*) ............................................................................ 556
18.7. The wedge of topological spaces ............................................................................................. 559
18.8. Topological graphs .................................................................................................................. 563
18.9. Homotopy classes of loops (*) ................................................................................................. 569
18.10. Homotopies for pairs of topological spaces ........................................................................... 570
Exercises for Chapter 18 .................................................................................................................. 572

19.1. Free abelian groups and finitely generated abelian groups ......................................................... 580
19.2. The free product of groups ........................................................................................................ 587
19.3. An alternative definition of the free product of groups .............................................................. 594
19.4. The Grushko-Neumann Theorem ............................................................................................. 596
Exercises for Chapter 19 .................................................................................................................. 597

20. The basic Seifert-van Kampen Theorem ....................................................................................... 601
20.1. The formulation of the basic Seifert-van Kampen Theorem ....................................................... 601
20.2. Proof of the Seifert-van Kampen Theorem 20.2 ....................................................................... 611
20.3. More examples: surfaces and the connected sum of smooth manifolds ................................. 616
Exercises for Chapter 20 .................................................................................................................. 622

21. Presentations of groups and amalgamated products ...................................................................... 626
21.1. Basic definitions in group theory ............................................................................................... 626
21.2. Presentations of groups ............................................................................................................. 627
21.3. Tietze transformations .............................................................................................................. 631
21.4. The Andrews-Curtis Conjecture (*) .......................................................................................... 637
21.5. The abelianization of a group ................................................................................................... 638
21.6. The amalgamated product of groups I ...................................................................................... 643
21.7. The amalgamated product of groups II (*) ............................................................................... 648
Exercises for Chapter 21 .................................................................................................................. 649

22. The general Seifert-van Kampen Theorem .................................................................................. 652
22.1. The formulation of the general Seifert-van Kampen Theorem .................................................. 652
22.2. The fundamental groups of surfaces ......................................................................................... 655
22.3. Non-orientable surfaces ............................................................................................................ 660
22.4. Fundamental groups of high-dimensional smooth manifolds .................................................. 662
Exercises for Chapter 22 .................................................................................................................. 665

23. The classification of compact 2-dimensional manifolds I ............................................................... 668
23.1. The Surface Classification Theorem ........................................................................................ 668
23.2. The classification theorem for surfaces .................................................................................... 671

**Part IV. The universal covering** 815

**29. The existence of universal coverings** 816

**29.1. Local properties of topological spaces** 816
29.2. Lifting maps to coverings ........................................ 817
29.3. Semi-locally simply connected topological spaces ............... 822
29.4. Existence of covering spaces .................................... 823
29.5. Uniqueness of covering spaces .................................. 832
29.6. The universal covering .......................................... 834
Exercises for Chapter 29 ............................................. 840

30. Topics in covering theory (*) ..................................... 845
30.1. Self-diffeomorphisms of $S^1$ .................................. 845
30.2. Complex logarithms .............................................. 847
30.3. Preimages of subsets under coverings ............................ 848
30.4. Covering spaces of surfaces .................................... 850
Exercise for Chapter 30 ................................................ 852

31. Coverings of topological graphs and applications to group theory . 855
31.1. Coverings of topological graphs ................................ 855
31.2. Fundamental group of countable topological graphs .......... 856
31.3. Subgroups of free groups ....................................... 857
31.4. Subgroups of surface groups ................................... 859
31.5. Residually finite groups and Hopfian groups .................... 861
Exercises for Chapter 31 ............................................. 869

32. Hyperbolic geometry ............................................... 872
32.1. Hyperbolic space ............................................... 872
32.2. Angles in Riemannian manifolds ................................ 879
32.3. The distance metric of a Riemannian manifold ................. 880
32.4. The hyperbolic distance function ............................... 883
32.5. Complete metric spaces ........................................ 885
Exercises for Chapter 32 ............................................. 886

33. The universal covering of surfaces ................................ 887
33.1. Hyperbolic surfaces ............................................ 887
33.2. More hyperbolic structures on the surfaces of genus $g \geq 2$ (*) 891
33.3. More examples of hyperbolic surfaces .......................... 892
33.4. The universal covering of surfaces ............................. 897
33.5. Proof of Theorem 33.9 I ....................................... 898
33.6. Proof of Theorem 33.9 II ...................................... 902
33.7. Picard’s Theorem (*) ............................................ 905
33.8. Triangle groups (*) ............................................. 907
Exercises for Chapter 33 ............................................. 910

34. The deck transformation group ..................................... 911
### CONTENTS (DETAILED)

34.1. The deck transformation group and its relation to fundamental groups  . . . . 911
34.2. Fundamental groups of surfaces ................................................. 915
Exercises for Chapter 34 ........................................................................ 921
35. Related constructions in algebraic geometry and Galois theory (*) ......... 924
35.1. The fundamental group of an algebraic variety (*) .......................... 924
35.2. Galois theory (*) ........................................................................ 926

**Part V. CW-complexes and Cofibrations** ........................................... 929
36. CW-complexes I: Definitions, basic properties and constructions .......... 930
36.1. Definition of finite-dimensional CW-complexes and examples ........... 930
36.2. Two topologies on $\mathbb{R}^\infty$ ...................................................... 936
36.3. Infinite-dimensional CW-complexes .............................................. 940
36.4. Homotopies on infinite CW-complexes (*) .................................... 945
36.5. Properties of CW-complexes ........................................................ 947
36.6. The Finiteness Theorem for CW-complexes ................................... 953
36.7. Cellular maps ............................................................................. 955
36.8. Subcomplexes ............................................................................ 956
36.9. Products of CW-complexes I ....................................................... 960
36.10. Products of CW-complexes II (*) ............................................... 963
36.11. A convenient category of topological spaces (*) ............................ 964
36.12. Constructions of more CW-complexes ......................................... 969
36.13. Coverings of CW-complexes ....................................................... 973
Exercises for Chapter 36 ...................................................................... 975
37. CW-complexes II: Fundamental groups ........................................... 979
37.1. Fundamental groups of CW-complexes ....................................... 979
37.2. The Euler characteristic of a CW-complex .................................... 983
37.3. The fundamental group of 1-dimensional CW-complexes ............... 985
37.4. Fundamental groups of CW-complexes ....................................... 991
Exercises for Chapter 37 ..................................................................... 998
38. CW-complexes III: Advanced properties ........................................ 999
38.1. The Homotopy Extension Theorem .............................................. 999
38.2. Dropping base points ................................................................ 1004
38.3. Combining infinitely many homotopies and the telescope construction (*) 1008
38.4. The Cellular Approximation Theorem ......................................... 1011
38.5. Proof of Proposition 38.15 (*) ...................................................... 1016
Exercises for Chapter 38 ..................................................................... 1020
39. Cofibrations (*) ............................................................................. 1022
CONTENTS (DETAILED)

39.1. Cobrations: definition and examples .................................................. 1022
39.2. Properties of cobrations ................................................................. 1029
39.3. Products and cobrations (*) ............................................................. 1033
39.4. Push-outs and cobrations (*) ............................................................. 1038
39.5. Proof of Theorem 39.18 (*) ............................................................... 1041
Exercises for Chapter 39 ........................................................................ 1051

Part VI. Singular Homology .................................................................. 1053
40. Higher homotopy groups: a primer ..................................................... 1054
   40.1. Definition of the higher homotopy groups .................................... 1054
   40.2. Alternative descriptions of homotopy groups ................................ 1059
   40.3. Properties and basic calculations of higher homotopy groups .... 1062
   40.4. Covering spaces and higher homotopy groups ............................ 1068
   40.5. Are there any higher homotopy groups that are non-trivial? .... 1071
Exercises for Chapter 40 ....................................................................... 1074
41. The homology groups of a topological space ....................................... 1074
   41.1. Singular chains .............................................................................. 1075
   41.2. Definition of the homology groups of a topological space .......... 1078
   41.3. First calculations of homology groups ......................................... 1084
   41.4. Algebraic chain complexes ........................................................... 1085
   41.5. The functoriality of homology groups ......................................... 1087
   41.6. Direct products and direct sums (*) .............................................. 1089
   41.7. The homology groups of a direct sum ........................................... 1091
Exercises for Chapter 41 ....................................................................... 1092
42. Homology and homotopies .................................................................. 1096
   42.1. Chain homotopies ......................................................................... 1096
   42.2. Homology and homotopic maps .................................................. 1097
Exercises for Chapter 42 ....................................................................... 1104
43. The Excision Theorem ..................................................................... 1105
   43.1. Reduced homology groups ........................................................... 1105
   43.2. Long exact sequences ................................................................... 1107
   43.3. The homology groups of spheres .................................................. 1110
   43.4. Basic homological algebra ............................................................ 1114
   43.5. Relative homology groups ............................................................ 1119
   43.6. The Excision Theorem ................................................................. 1127
   43.7. The proof of the Excision Theorem 43.19: the idea .................... 1132
   43.8. The proof of the Excision Theorem 43.19: the full details .......... 1133
Exercises for Chapter 43 ................................................................. 1145
44. Applications and variations of the Excision Theorem 43.19 (*) .......... 1151
   44.1. The local homology groups of a topological space .................... 1151
   44.2. The topology of topological manifolds .................................. 1152
   44.3. The Topological Collar Neighborhood Theorem ....................... 1155
   44.4. Variations on the Excision Theorem 43.19 .............................. 1160
   44.5. The double of topological and smooth manifolds ....................... 1162
Exercises for Chapter 44 ................................................................. 1167
45. Homology and self-maps of spheres ........................................... 1170
   45.1. Explicit generators of relative homology groups ....................... 1170
   45.2. The standard generator of $\mathbb{H}_n(S^n)$ ............................... 1173
   45.3. Suspensions and homology groups ........................................... 1178
   45.4. The degree of a self-map of a sphere ..................................... 1180
   45.5. The local degree I .............................................................. 1187
   45.6. The local degree II .............................................................. 1190
   45.7. Proof of Proposition 45.5 (*) ................................................. 1197
Exercises for Chapter 45 ................................................................. 1201
46. The Mayer–Vietoris sequence and its applications ......................... 1205
   46.1. Split exact sequences .............................................................. 1205
   46.2. The Mayer–Vietoris sequence ................................................. 1208
   46.3. Applications of the Mayer–Vietoris sequence ......................... 1213
   46.4. The Mayer–Vietoris Theorem for manifolds and CW-complexes ...... 1216
   46.5. The homology groups of the torus and the Klein bottle ............... 1218
   46.6. The first homology group of a knot complement ....................... 1223
   46.7. The homology groups of a mapping cone (*) .......................... 1225
   46.8. The homology groups of a mapping torus (*) ......................... 1232
Exercises for Chapter 46 ................................................................. 1237
47. Homology groups and direct limits ............................................. 1243
   47.1. Direct limits and induced maps .............................................. 1243
   47.2. The homology groups of a nested sequence of topological spaces .. 1244
   47.3. The homology groups of the wedge of topological spaces .......... 1247
   47.4. Moore spaces (*) ................................................................. 1251
Exercises for Chapter 47 ................................................................. 1255
48. Cellular homology ................................................................. 1257
   48.1. The definition of cellular homology ....................................... 1257

INTRODUCTION

These are the lecture notes for a sequence of courses on algebraic and geometric topology at the University of Regensburg that started in the winter term of 2016/17 and which is still going on.

There are some issues with the lecture notes which are known to me:

1. Some references point to future, so far unwritten material.
2. The part on differential topology needs to be reorganized and cleaned up.
3. The definition of CW-complexes is suboptimal and will be revised.

If you have any comments, especially if you find mistakes or typos, please let me know.

sfriedl@gmail.com
Part I

General Topology
1. Preliminaries

In this preliminary chapter we introduce some concepts and results from set theory which we will use throughout these notes, but which otherwise have little to do with topology itself. The reader might want to skip this chapter and directly move to the next chapter.

1.1. Basic set theory. Throughout these notes we work with “naive set theory”. Like most working mathematicians this author does not want to get drawn into a discussion about what a set really is. Furthermore, when we describe sets we sometimes use creative notation and language. The hope is that the language is chosen in such a way that any good-willed reader will understand what is mean.

In this short section we recall a few basic definitions and results from set theory which will frequently use throughout these notes. Usually we will not refer to the statements explicitly, unless it helps to clarify an argument.

First we recall the following standard notation.

Notation. We denote by $\emptyset$ the empty set.

We continue with two of the most important definitions of set theory.

Definition. Let $\{U_i\}_{i \in I}$ be a family of subsets of a given set $X$. We write
\[
\bigcup_{i \in I} U_i = \{ x \in X \mid \text{there exists an } i \in I \text{ with } x \in X_i \}
\]
\[
\bigcap_{i \in I} U_i = \{ x \in X \mid \text{for every } i \in I \text{ we have } x \in X_i \}.
\]

In particular, if $I = \emptyset$, then $\bigcup_{i \in I} U_i = \emptyset$ and $\bigcap_{i \in I} U_i = X$.

Next we state, without proof, three elementary lemmas from set theory. Even though they are elementary it is helpful to have them on record.

Without further apologies, let us state the first lemma.

Lemma 1.1. Let $X$ be a set and let $\{A_i\}_{i \in I}$ and $\{B_j\}_{j \in J}$ be two families of subsets of $X$. Then
\[
\left( \bigcup_{i \in I} A_i \right) \cap \left( \bigcup_{j \in J} B_j \right) = \bigcup_{i \in I, j \in J} (A_i \cap B_j).
\]

We continue with de Morgan’s laws.

Lemma 1.2. (De Morgan’s laws) Let $X$ be a set and let $\{A_i\}_{i \in I}$ be a family of subsets of $X$. If given a subset $Y \subset X$ we denote its complement by $Y^c$, then
\[
\left( \bigcap_{i \in I} A_i \right)^c = \bigcup_{i \in I} A_i^c \quad \text{and} \quad \left( \bigcup_{i \in I} A_i \right)^c = \bigcap_{i \in I} A_i^c.
\]

Or equivalently, in a more cumbersome notation, we have
\[
X \setminus \left( \bigcap_{i \in I} A_i \right) = \bigcup_{i \in I} (X \setminus A_i) \quad \text{and} \quad X \setminus \left( \bigcup_{i \in I} A_i \right) = \bigcap_{i \in I} (X \setminus A_i).
\]

This simple observation will be useful at times.
The following lemma concerns the interaction between operations on sets and maps between sets.

**Lemma 1.3.** Let \( f : X \to Y \) be a map between two sets \( X \) and \( Y \). Then

1. For every \( U \subseteq X \) we have
   \[ f^{-1}(f(U)) \subseteq U \]
   furthermore, if \( f \) is injective\(^2\), then we have
   \[ U = f^{-1}(f(U)) \]
2. For every \( V \subseteq Y \) we have
   \[ f(f^{-1}(V)) \supseteq V \]
   furthermore, if \( f \) is surjective, then we have
   \[ V = f(f^{-1}(V)) \]
3. For every family \( \{U_i\}_{i \in I} \) of subsets of \( X \) we have
   \[ f\left( \bigcup_{i \in I} U_i \right) = \bigcup_{i \in I} f(U_i) \]
4. For every family \( \{U_i\}_{i \in I} \) of subsets of \( X \) we have
   \[ f\left( \bigcap_{i \in I} U_i \right) \subseteq \bigcap_{i \in I} f(U_i) \]
5. For every family \( \{V_i\}_{i \in I} \) of subsets of \( Y \) we have
   \[ f^{-1}\left( \bigcup_{i \in I} V_i \right) = \bigcup_{i \in I} f^{-1}(V_i) \]
6. For every family \( \{V_i\}_{i \in I} \) of subsets of \( Y \) we have
   \[ f^{-1}\left( \bigcap_{i \in I} V_i \right) = \bigcap_{i \in I} f^{-1}(V_i) \]
7. For every \( V \subseteq Y \) we have
   \[ f^{-1}(Y \setminus V) = X \setminus f^{-1}(V) \]

We conclude this short section with the following notation.

**Notation.** Given a set \( X \) we denote by \( \mathcal{P}(X) \) its **power set**, i.e. \( \mathcal{P}(X) \) is the set of all subsets of \( X \).

### 1.2. Relations and orders on sets.

We start out with recalling the notion of a relation.

**Definition.** A relation on a set \( S \) is a subset of \( S \times S \).

The definition of a relation in its full generality is pretty useless. It becomes more interesting once we introduce several adjectives.

**Definition.** Let \( S \) be a set and let \( R \subseteq S \times S \) be a relation on \( S \).

1. The relation is called **reflexive**, if for every \( s \in S \) we have \( (s, s) \in R \).
2. The relation is called **transitive**, if for every \( (s, t) \) and \( (t, u) \) in \( R \) we also have that \( (s, u) \in R \).
3. The relation is called **symmetric**, if for every \( (s, t) \) in \( R \) we also have that \( (t, s) \in R \).

We adopt the following notation.

**Notation.** Let \( S \) be a set and let \( R \subseteq S \times S \) be a relation on \( S \). Given \( x, y \in S \) we write \( x \mathrel{R} y \) if and only if \( (x, y) \in R \).

**Example.** We consider the set \( \mathbb{R} \) together with the relation
\[
\leq := \{ (x, y) \in \mathbb{R}^2 \mid y - x \text{ is not negative} \}.
\]

One can easily verify that this relation \( \leq \) is reflexive and transitive, but that it is not symmetric. Note that given \( x, y \in \mathbb{R} \) the above expression \( x \leq y \) has the usual meaning that we are all used to.

\(^2\)As a totally irrelevant side remark we would like to point out that the fundamental terms “surjective”, “injective” and “bijective” are actually fairly recent additions to the mathematical language. They were first introduced on page 80 of Nicolas Bourbaki’s “Théorie des ensembles” first published in 1954, see [Bou54]. The reader who has need read the biography of the great mathematician Nicolas Bourbaki is strongly encouraged to do so.
Most of the relations that we will consider are going to be reflexive and transitive. There
is a big difference though in the roles of symmetric and non-symmetric relations. Let us
calculate the symmetric ones first.

**Definition.** An equivalence relation on a set $S$ is a relation that is reflexive, transitive and
symmetric.

**Convention.** Equivalence relations on a set $S$ are almost invariably denoted by “$\sim$” or
some variation thereof.

To practice our conventions and notations, the three properties of an equivalence rela-
tion “$\sim$” on a set $S$ are precisely the following three statements:

(1) for any $s \in S$ we have $s \sim s$ (reflexivity),
(2) for any $s, t, u \in S$ with $s \sim t$ and $t \sim u$ we have $s \sim u$ (transitivity),
(3) for any $s, t \in S$ with $s \sim t$ we also have $t \sim s$ (symmetry).

We continue with the following definition.

**Definition.** Let $S$ be a set together with an equivalence relation “$\sim$”. An equivalence class
of $(S, \sim)$ is a subset $C$ of $S$ with the following three properties:

(1) the subset is non-empty,
(2) given any two $s, t \in C$ we have $s \sim t$, and
(3) given $s \in C$ and $t \in S$ with $s \sim t$ we have $t \in C$.

We refer to [Halm60, Section 7] for a confirmation of the above definitions.

The following lemma summarizes the key properties of equivalence classes.

**Lemma 1.4.** Let $S$ be a set together with an equivalence relation “$\sim$”.

(1) Every element of $S$ is contained in a unique equivalence class, namely

$$[s] := \{ t \in S \mid t \sim s \}.$$  

(2) Two equivalence classes are either disjoint or the same.

**Proof.** Surely the reader will have seen the proof of the lemma before. Nonetheless we
give the proof, in particular to highlight the fact that we do indeed need the symmetry
condition.

(1) Let $s \in S$. Since $\sim$ is reflexive we see that $s \in [s]$. Thus it remains to show

$$[s] := \{ t \in S \mid t \sim s \}$$

is indeed an equivalence class.

(a) We already showed that $s \in [s]$, in particular we see that $[s]$ is non-empty.

(b) Let $t, t' \in [s]$. By definition this means that $t \sim s$ and $t' \sim s$. By symmetry we

$s \sim t'$. By transitivity we deduce from $t \sim s$ and $s \sim t'$ that $t \sim t'$.

(c) Let $t \in [s]$ and suppose that $t \sim u$. Since by definition we have $s \sim t$ we obtain

from transitivity that $s \sim u$, i.e. we see that $u \in [s]$.

(2) Let $C$ and $D$ be two equivalence classes. We suppose that $C \cap D \neq \emptyset$. Thus there
exists an $x \in C \cap D$. We need to show that $C = D$. Thus let $d \in D$. By Condition
(2) of an equivalence class applied to $D$ we know that $x \sim d$. By condition (1) of an
 equivalence class, applied to $C$, we see that $d \in C$. Thus we have shown that $D \subseteq C$.
Evidently the same argument shows that $C \subseteq D$. ■
Throughout these notes we adopt the following standard notation.

**Notation.** Let $S$ be a set together with an equivalence relation “$\sim$”.

1. We denote by $S/\sim$ the set of equivalence classes.
2. Given $s \in S$ we denote by $[s]$ the unique equivalence class that contains $[s]$.

**Example.** Let $n \in \mathbb{N}$. We consider the set $\mathbb{Z}$ together with the equivalence relation that is given by

$$x \sim y \iff (x - y) \text{ is divisible by } n.$$

There are exactly $n$ equivalence classes, namely

$[0] = \{ \ldots, -2n, -n, 0, n, 2n, 3n, \ldots \}$

$[1] = \{ \ldots, 1 - 2n, 1 - n, 1, 1 + n, 1 + 2n, 1 + 3n, \ldots \}$

$\vdots$

$[n - 1] = \{ \ldots, -2n - 1, -n, -1, n - 1, 2n - 1, 3n - 1, \ldots \}.$

To the despair of many of my cultured friends we write $\mathbb{Z}_n := \mathbb{Z}/\sim$.

Next we turn our gaze towards relations which are not required to be symmetric. We have the following harmless definition.

**Definition.**

1. A relation “$\leq$” on a set $S$ is called **antisymmetric** if $a \leq b$ and $b \leq a$ implies $a = b$.
2. A relation that is reflexive, transitive and antisymmetric is called a **partial order**.
3. A set together with a partial order is called a **partially ordered set**.
4. Let “$\leq$” be a partial order on a set $A$. Given $a, b \in A$ we write $a < b$ if $a \leq b$ and if $a \neq b$.
5. Let $(A, \leq)$ and $(B, \leq)$ be two partially ordered sets. A map $f: A \to B$ is called **order-preserving**, if for every two elements $a_1, a_2 \in A$ with $a_1 \leq a_2$ we also have $f(a_1) \leq f(a_2)$.
6. We say that two partially ordered sets $(A, \leq)$ and $(B, \leq)$ have the same **order type** if there exists a bijection $f: A \to B$ which is order-preserving and such that the inverse $f^{-1}: B \to A$ is also order-preserving.

Now we give a few examples of partial orders.

**Examples.**

1. Let $X$ be a subset of $\mathbb{R}$ and denote by $\leq$ the usual “less or equal” relation on the real numbers. Then $(X, \leq)$ is a partially ordered set.
2. Let $M$ be a set. We denote by $\mathcal{P}(M)$ the power set of $M$, i.e. the set of all subsets of $M$. Then “being a subset”, i.e. the relation given by “$\subset$”, is a partial order on $\mathcal{P}(M)$.
3. We consider the three reflexive transitive relations that are illustrated in Figure 1.

Here it is understood that $P \leq Q$ if there exists a “directed path” from $Q$ to $P$.

(a) The example on the left has a loop. Given any two points $P, Q$ on the loop we have $P \leq Q$ and $Q \leq P$, hence this example is not a partial order.

\footnote{Note that “order-preserving” does not mean that $a_1 < a_2$ implies $f(a_1) < f(a_2)$.}
(b) This example is a partial order.
(c) This example is also a partial order.

\begin{figure}
\centering
\includegraphics[width=\textwidth]{example.png}
\caption{Example (a) Example (b) Example (c)}
\end{figure}

The following construction lets us build new examples of partially ordered sets out of given ones.

\textbf{Definition.} Let \((A, \leq)\) and \((B, \leq)\) be two partially ordered sets. Given \((a, b)\) and \((a', b')\) in \(A \times B\) we define\footnote{Note that if \(a < a'\), then we do not demand that \(b \leq b'\).}

\[(a, b) < (a', b') \iff \text{ either } a < a' \text{ or } a = a' \text{ and } b < b'.\]

and we define \((a, b) \leq (a', b')\) if either \((a, b) = (a', b')\) or \((a, b) < (a', b')\). One can easily verify that “\(\leq\)” is a partial order on \(A \times B\). We refer to this partial order on \(A \times B\) as the \textit{lexicographic order on }\(A \times B\).

We need a few more definitions before we can state the first non-trivial result.

\textbf{Definition.} Let \((P, \leq)\) be a partially ordered set.

1. A \textit{chain} in \(P\) is a subset \(Q\) such that for any two elements \(q, q' \in Q\) we have \(q \leq q'\) or \(q' \leq q\).
2. An \textit{upper bound} of a subset \(Q\) is an element \(p \in P\) such that \(q \leq p\) for all \(q \in Q\).
3. A \textit{maximal element} of a subset \(Q\) is an element \(q \in Q\) such that there is no \(r \in Q\) with \(q < r\).

\textbf{Examples.}

1. In Figure 2 we once again consider the partially ordered set in the middle of Figure 1.
   We show a chain, we show upper bounds for the chain and we show maximal elements for \(P\).

\begin{figure}
\centering
\includegraphics[width=\textwidth]{example2.png}
\caption{partially ordered set \(P\) chain \(Q\) upper bounds for the chain \(Q\) maximal elements of the set \(P\)}
\end{figure}

2. We consider \(P = [0, \infty)\) with the usual partial ordering. Every subset is a chain, but not every subset has an upper bound. For example \(P\) does not have an upper bound.
(3) We consider $P = (-\infty, 0]$ with the usual partial ordering. Every subset is a chain and 0 is an upper bound for every subset furthermore it is a maximal element of $P$.

Next we formulate Zorn’s Lemma. Its modest name conceals its true importance in mathematics.

**Lemma 1.5. (Zorn’s Lemma)** Suppose a partially ordered set $(P, \leq)$ has the property that every chain has an upper bound in $P$. Then the set $P$ contains at least one maximal element.

**Remark.**

(1) Zorn’s Lemma even made it into “The Simpsons”, see

http://www.simonsingh.net/Simpsons_Mathematics/zorns-lemma/

(2) The lemma is named after Max Zorn [Zo35] who published a proof in 1935. In fact the same statement was already proved by Casimir Kuratowski [Kura22] in 1922.

**Proof.** A nice discussion of the proof and its historical context is given in [Sti13, Section 7.2]. Alternatively see also [Cie97, Theorem 4.3.4] and [Je73, p. 9] for a proof. In fact, as is shown in [Sti13, p. 154] or alternatively [Je73, Theorem 2.1], Zorn’s Lemma is equivalent to the Axiom of Choice.

We continue with the next adjective that we can associate to a relation.

**Definition.**

(1) A relation “$\leq$” on a set $S$ is called *connex* if for every $a, b \in S$ we have $a \leq b$ or $b \leq a$.

(2) A partial order that is connex is called a *total order*.

(3) A set together with a total order is called a *totally ordered set*.

**Examples.**

(1) Evidently the usual “$\leq$”-relation on $\mathbb{R}$ is connex.

(2) None of the partial orders considered in Figure 1 is connex.

(3) Given two totally ordered sets $(A, \leq)$ and $(B, \leq)$ one can show easily that the lexicographic order on $A \times B$ is again a total order.

Finally we introduce one last type of partial orders.

**Definition.**

(1) A total order $\leq$ on a set $S$ is called a *well-order* if every non-empty subset has a minimal for all $u \in T$.

(2) A set together with a well-order is called a *well-ordered set*.

**Examples.**

(1) The usual order on $\mathbb{Q}$ is a total order but it is not a well-order, for example the subset $T := \{ x \in \mathbb{Q} \mid x^2 > 2 \}$ does not have a minimal element. But since $\mathbb{Q}$ is in bijection to $\mathbb{N}$ we see that $\mathbb{Q}$ admits a well-order.

(2) The usual order on $\mathbb{R}$ is a total order but it is not a well-order. It is a priori not so clear how one can define a well-order on $\mathbb{R}$.
(3) Given two well-ordered sets \((A, \leq)\) and \((B, \leq)\) one can again show easily that the lexicographic order on \(A \times B\) is a well-order.

Perhaps somewhat shockingly the following theorem, due to Ernst Zermelo, says that every set admits a well-ordering.

**Theorem 1.6. Well-ordering Theorem** Every set admits a well-order.

**Proof.** We refer to [Cie97, Theorem 4.3.3] or alternatively to [Je73, p. 9] for a proof. In fact, as for Zorn’s Lemma it is shown in [Je73, Theorem 2.1] that the Well-ordering Theorem is equivalent to the Axiom of Choice. ■

1.3. The cardinality of sets. In this section we introduce the notion of the cardinality of a set.

**Definition.**

(1) We say that two given sets \(S\) and \(T\) are *equinumerous* if there exists a bijection \(\varphi : S \to T\).

(2) Given a set \(S\) we define the *cardinality* \(\#S\) of \(S\) as the equinumerosity equivalence class of \(S\) in the class of all sets. Put differently we have

\[
\#S := \text{class of all sets } T \text{ that are equinumerous with } S.
\]

(3) If \(S\) is a finite set, then we write \(\#S = n\) for the unique \(n \in \mathbb{N}_0\) which satisfies \(\#S = \#\{1, \ldots, n\}\). If \(S\) infinite, then sometimes we write \(\#S = \infty\). At times we also write \(|S| \in \mathbb{N}_0 \cup \{\infty\}\) instead of \(\#S \in \mathbb{N}_0 \cup \{\infty\}\).

(4) Let \(S\) be a set. If \(\#S = n\) for some \(n \in \mathbb{N}_0\) or \(\#S = \#\mathbb{N}\), then we say that \(S\) is *countable*, otherwise we say that \(S\) is *uncountable*.

**Example.** We have \(\#(\mathbb{R} \setminus \{0\}) = \#\mathbb{R}\). Indeed a bijection is given by

\[
\mathbb{R} \setminus \{0\} \to \mathbb{R},
\]

\[
x \mapsto \begin{cases} 
  x, & \text{if } x \in \mathbb{R} \setminus \mathbb{N}_0, \\
  x - 1, & \text{if } x \in \mathbb{N}.
\end{cases}
\]

**Remark.**

(1) Another way of putting the definition of cardinality is that given two sets \(S\) and \(T\) we have \(\#S = \#T\) if and only if there exists a bijection from \(S\) to \(T\).

(2) In almost any proper course on real analysis it is shown that \(\mathbb{Q}\) is countable and that \(\mathbb{R}\) is not countable. Thus we \(\#\mathbb{Q} \neq \#\mathbb{R}\). This example also shows that the above notation \(\#S = \infty\) for an infinite set \(S\) is rather dangerous, since we have \(\#\mathbb{Q} = \infty\) and \(\#\mathbb{R} = \infty\) even though \(\#\mathbb{Q} \neq \#\mathbb{R}\).

On several occasions we will use the following lemma.

**Lemma 1.7.**

(1) *Every subset of a countable set is again countable.*
(2) Let \( S \) be a countable set and let \( f : S \to T \) be a map. The image \( f(S) \) is again countable.

(3) The union of countably many countable sets is again countable.

(4) Let \( T \) be a set and let \( S \) be a subset such that \( T \setminus S \) is countable. Then \( S \) is countable if and only if \( T \) is countable.

(5) The product of finitely many countable sets is again countable.

(6) If \( S \) is a finite set and if \( T \) is a countable set, then the set of maps from \( S \) to \( T \) is also countable.

**Sketch of proof.**

(1) After excluding the case that \( S \) is finite and the case that \( T \) is finite one sees that one has to prove the following: given any infinite subset \( T \) of \( \mathbb{N} \) there exists a bijection \( \varphi : \mathbb{N} \to T \). Such a bijection is given by defining \( \varphi(i) \) as the \( i \)-th smallest element of \( T \).

(2) Let \( S \) be a countable set and let \( f : S \to T \) be a map. We only need to consider the case that \( S = \mathbb{N} \) and that \( f(S) \) is infinite. In this case the bijection \( \varphi : \mathbb{N} \to f(S) \) is given by defining \( \varphi(1) = f(1) \) and by defining iteratively

\[
\varphi(i + 1) := \left\{ f(k) \mid k \in \mathbb{N} \text{ is the smallest number such that } f(k) \notin \{\varphi(1), \ldots, \varphi(i)\} \right\}.
\]

(3) It is fairly straightforward, albeit notationally slightly messy to give a direct proof. For completeness we refer to [Cie97, Corollary 5.2.6] for a proof.

(4) This statement follows immediately from (2) and (3).

(5) By induction and by ignoring the rather dull case of finite sets it remains to show that \( \mathbb{N}_0 \times \mathbb{N}_0 \) is countable. This can be shown by the well-known argument sketched in Figure 3.

(6) Let \( S = \{v_1, \ldots, v_n\} \) be a finite set and let \( T \) be a countable set. We have an obvious bijection between \( T^n \) and the set of maps from \( S \) to \( T \). Thus it follows from (4) that the set of maps from \( S \) to \( T \) is countable.

\[
\begin{align*}
\mathbb{N} \times \mathbb{N} & \quad \text{defines bijection } \mathbb{N} \to \mathbb{N} \times \mathbb{N} \\
\end{align*}
\]

**Figure 3. Illustration for the proof of Lemma 1.7**

We move on to the next definition.

**Definition.** Let \( S \) and \( T \) be two sets.

(1) We write \( \#S \leq \#T \) if there exists a monomorphism \( \varphi : S \to T \).

(2) We write \( S < T \) if \( \#S \leq \#T \) but \( \#S \neq \#T \).

**Examples.**

(1) We have \( \#\mathbb{Q} \leq \#\mathbb{R} \) but we had just pointed out that \( \#\mathbb{Q} \neq \#\mathbb{R} \) since \( \#\mathbb{Q} = \#\mathbb{N} \) but \( \#\mathbb{R} \neq \#\mathbb{N} \). Therefore \( \#\mathbb{Q} < \#\mathbb{R} \).

(2) It follows from the previous remark that a set \( S \) is countable if and only if \( \#S \leq \#\mathbb{N} \).
(3) Given a set $X$ we denote by $P(X)$ its power set, i.e. the set of all subsets of $X$. For every $X$ we have $\#X < \#P(X)$. Indeed, the map

$$
X \rightarrow P(X) \\
x \mapsto \{x\}
$$

is an injection, hence $\#X \leq \#P(X)$. Now let $f : X \rightarrow P(X)$ be a map. We have to show that it cannot be surjective. Indeed, the set

$$Y := \{x \in X \mid x \not\in f(x)\}$$

is not in the range of $f$: if there did exist a $z \in X$ with $f(z) = Y$, then $z \in Y$ if and only if $z \not\in Y$, which is a contradiction.

Now we can formulate the final result of this chapter.

**Theorem 1.8. (Bernstein-Schröder)** Let $S$ and $T$ be two sets. Then

$$\#S \leq \#T \text{ and } \#T \leq \#S \implies \#S = \#T.$$  

**Example.** Let $U$ be a non-empty subset of $\mathbb{R}$ which contains an open interval $(a, b)$ with $a < b$. Then $\#U = \#\mathbb{R}$. Indeed, the inclusion $U \rightarrow \mathbb{R}$ is of course injective, thus we see that $\#U \leq \#\mathbb{R}$. Furthermore the map $\varphi : (a, b) \rightarrow \mathbb{R}$ given by $x \mapsto \frac{x-a}{b-x}$ defines a bijection between $(a, b)$ and $\mathbb{R}$. Thus $\mathbb{R} \xrightarrow{\varphi^{-1}} (a, b) \rightarrow U$ is also an injection. This means that $\#\mathbb{R} \leq \#U$. Therefore it follows from the Bernstein-Schröder-Theorem that there exists a bijection from $U$ to $\mathbb{R}$.

**Sketch of proof (⋆).** Let $f : A \rightarrow B$ and $g : B \rightarrow A$ be two injective maps between two sets $A$ and $B$. Without loss of generality we can assume that $A$ and $B$ are disjoint. We denote by $\sim$ the equivalence relation on $A \sqcup B$ that is generated by $a \sim f(a)$ for $a \in A$ and by $g(b) \sim b$ for $b \in B$. Note that if $a \in A$ lies in the image of $g$, then by the injectivity of $f$ there exists a unique element $g^{-1}(a) \in B$ and we have $a \sim g^{-1}(a)$. The same remark works with the roles of $f$ and $g$ reversed.

Since $A \sqcup B$ is the disjoint union of all equivalence classes it suffices to prove the following claim.  

**Claim.** For each equivalence class $I$ there exists a bijection $A \cap I \rightarrow B \cap I$.

---

6This statement is known as Cantor’s Theorem.

7The theorem was initially stated by Cantor without a proof and it was first proved by Felix Bernstein (1878-1956) and Ernst Schröder (1841-1902) in 1896. Sometimes it is also called the Cantor-Bernstein-Schröder theorem.

8If $A$ and $B$ are not disjoint, then we replace $A$ by $A' = A \times \{0\}$ and $B$ by $B' = B \times \{1\}$, then $A'$ and $B'$ are disjoint, since any two elements in $A'$ and $B'$ now have different second coordinate.

9Indeed, recall that equivalence classes always give a disjoint decomposition of a set. In our case, if $I_j$, $j \in J$ denote the set of equivalence classes of $\sim$ on $A \sqcup B$, then we have

$$A \sqcup B = \bigsqcup_{j \in J} I_j$$

and therefore also

$$A = \bigsqcup_{j \in J} (A \cap I_j) \text{ and } B = \bigsqcup_{j \in J} (B \cap I_j).$$

Therefore it suffices to give a bijection $A \cap I_j \rightarrow B \cap I_j$ for every $j \in J$. 

So let \( I \) be an equivalence class and let \( a \in A \cap I \). The subset \( I \subseteq A \cup B \) consists of all elements equivalent to \( a \). The equivalence class \( I \) is then of one of the following three types:\(^{10}\)

\[
A \quad B \quad A \quad B \quad A \quad B
\]

1. \( a' \ldots f^{-1}(g^{-1}(a)), g^{-1}(a), a, f(a), g(f(a)), f(g(f(a))), \ldots \) with \( a' \in A \setminus g(B) \)
2. \( b' \ldots f^{-1}(g^{-1}(a)), g^{-1}(a), a, f(a), g(f(a)), f(g(f(a))), \ldots \) with \( b' \in B \setminus f(A) \)
3. \( \ldots f^{-1}(g^{-1}(a)), g^{-1}(a), a, f(a), g(f(a)), f(g(f(a))), \ldots \)

In case (1) the map \( f \) defines a bijection \( A \cap I \to B \cap I \), in case (2) the map \( g^{-1} \) defines a bijection \( A \cap I \to B \cap I \) and in case (3) both \( f \) and \( g^{-1} \) define a bijection \( A \cap I \to B \cap I \). ■

**Remark.** The continuum hypothesis, first formulated by Cantor in 1878, states that there exists no set \( S \) with \( \#\mathbb{Q} < \#S < \#\mathbb{R} \). Any attempt at proving this statement relies on first of all making precise what “sets” are supposed to be or what axioms they are supposed to satisfy. As wikipedia writes “the answer to this problem is independent of ZFC set theory (that is, Zermelo-Fraenkel set theory with the axiom of choice included), so that either the continuum hypothesis or its negation can be added as an axiom to ZFC set theory, with the resulting theory being consistent if and only if ZFC is consistent.” This independence was proved in 1963 by Paul Cohen for which he obtained a Fields medal in 1966. More useful information can as always be found on wikipedia:

### 1.4. Conventions for (linear) algebra.

Next we want to introduce the category of rings. Since the definition of a “ring” in the literature can differ considerably let us state precisely what we mean by a ring in these notes.

**Definition.**

1. A **ring** is a triple \( (R, + : R \times R \to R, \cdot : R \times R \to R) \) where \((R, +)\) is an abelian group and such that the following conditions are satisfied:
   
   a. the multiplication “\( \cdot \)” is associative,
   
   b. the multiplication “\( \cdot \)” is distributive,
   
   c. there exists a multiplicatively neutral element \( 1 = 1_R \).

2. A **ring homomorphism** between two rings \((R, +, \cdot)\) and \((S, +, \cdot)\) is a map \( R \to S \) that preserves the additive and multiplicative structures and that sends \( 1_R \) to \( 1_S \).

3. A **field** is a commutative ring such that every non-zero element has a multiplicative inverse.

**Remark.** Recall that “associative” means that for any \( a, b, c \in R \) we have \((a \cdot b) \cdot c = a \cdot (b \cdot c)\). It is well-known that this means that we can unambiguously define the product of finitely many elements using any choice of parentheses. Even though this statement is completely

\(^{10}\)There always exists an \( a \in A \cap I \). Indeed, \( I \) is by definition non-empty. If it contains an element in \( A \) we are done. Otherwise it contains an element in \( b \in B \), but then it also contains \( g(b) \in A \), since \( b \sim g(b) \).

\(^{11}\)Note that we do not claim that the elements in the given sequences are distinct, for example \( f : A \to B \) could be a bijection and \( g = f^{-1} \) its inverse, then the equivalence class consists only of the two elements \( a \) and \( g(a) \).
familiar, if one thinks about it, one realizes that this requires a proof. Such a proof is for example provided in [DF04] p. 19.

We move on to the next definition.

**Definition.** Let \( R \) be a commutative ring, let \( V \) and \( W \) be two free \( R \)-modules with finite bases \( \mathcal{B} = \{b_1, \ldots, b_m\} \) and \( \mathcal{C} = \{c_1, \ldots, c_n\} \) and let \( \varphi : V \to W \) be an \( R \)-homomorphism.

We refer to the unique \( (n \times m) \)-matrix \( P = (p_{ij}) \) with \( \varphi(v_i) = \sum_{j=1}^{n} p_{ji} \cdot w_j \) as the matrix representing \( \varphi \) with respect to the bases \( \mathcal{B} \) and \( \mathcal{C} \).

The previous definition is the standard definition well-known from earlier courses in linear algebra. Towards the end of the notes we will work with module homomorphisms over non-commutative rings. At that point we will see that at times it is convenient to switch to a different convention.

We conclude this chapter with the following definition.

**Definition.** Let \( R \) be a commutative domain. Given an \( R \)-module \( M \) we define

\[
\text{rank}(M) := \dim_{K(R)}(M \otimes_R K(R))
\]

where \( K(R) \) denotes the quotient field of \( R \).

---

**Exercises for Chapter 1.**

**Exercise 1.1.** Let \((V, \leq)\) be a totally ordered set of cardinality \( n \in \mathbb{N} \). We equip the set \( \{1, \ldots, n\} \) with the usual total order \( \leq \). Show that there exists a unique order-preserving bijection \( \{1, \ldots, n\} \to V \).

**Exercise 1.2.** Let \( f : X \to Y \) be a map between two sets. Show that there exist total orders “\( \leq_X \)” on \( X \) and “\( \leq_Y \)” on \( Y \) such that the map \( f \) is order-preserving.

**Exercise 1.3.** Show that there exists an uncountable well-ordered set \((X, \leq)\) such that for every \( y \in X \) the set \( \{x \in X \mid x \leq y\} \) is countable.

**Exercise 1.4.** We consider \( \mathbb{N} \) and \( \mathbb{Z} \) with the usual partial order \( \leq \).

(a) Does the lexicographically ordered set \( \mathbb{N} \times \mathbb{N} \) have the same order type as \( \mathbb{N} \)?

(b) Does the lexicographically ordered set \( \mathbb{Z} \times \mathbb{Z} \) have the same order type as \( \mathbb{Z} \)?

**Exercise 1.5.** We consider the half-open interval \([0, 1)\), the set \( \mathbb{R}_{\geq 0} \) and the set \( \mathbb{N}_0 \), each equipped with the usual partial order \( \leq \).

(a) Show that the lexicographically ordered set \([0, 1) \times \mathbb{N}_0 \) has the same order type as \( \mathbb{R}_{\geq 0} \).

(b) Show that the lexicographically ordered set \( \mathbb{N}_0 \times [0, 1) \) does not have the same order type as \( \mathbb{R}_{\geq 0} \).

**Exercise 1.6.**

(a) Let \( n \in \mathbb{N} \). Show that \( \mathbb{R} \) and \( \mathbb{R}^n \) have the same cardinality.

(b) Show that \( \mathbb{R} \) and \( \mathbb{R}^\mathbb{N} \) have the same cardinality.
In this chapter we give the definition of topological spaces, we provide many examples and we discuss a long list of basic properties. Many of these results might well be familiar to the reader. Nonetheless we attempt to give a fairly complete list of basic statements so that later on we have a firm common foundation to work with.

2.1. The definition of a topological space. In this section we give the definition of a topological space and we discuss some very basic definitions and statements. Presumably most readers will have seen this material. Throughout these lecture notes, in the proofs, we strive for giving precise references to earlier results. The main exceptions are the lemmas from this Section [2.1]. Usually we use them without referring to them explicitly.

The following definition will keep us occupied for the rest of these notes.

**Definition.**

(1) Let $X$ be a set. A **topology on $X$** is a subset $\mathcal{T}$ of $\mathcal{P}(X)$ with the following properties:

   a) the empty set and the entire set $X$ lie in $\mathcal{T}$,
   b) the intersection of finitely many sets in $\mathcal{T}$ is again a set in $\mathcal{T}$,
   c) the union of arbitrarily many sets in $\mathcal{T}$ is again a set in $\mathcal{T}$.

   The sets in $\mathcal{T}$ are called *open with respect to* $\mathcal{T}$. If $\mathcal{T}$ is understood from the context, then we just say *open*.

(2) A **topological space** is a pair $(X, \mathcal{T})$, where $X$ is a set and $\mathcal{T}$ is a topology on $X$.

**Remark.**

(1) Usually we suppress the topology from the notation, e.g. usually we just write “let $X$ be a topological space”.

(2) If $X$ is a topological space, then the properties of a topology imply immediately the following three statements:

   a) the empty set and the entire set $X$ are open,
   b) the intersection of finitely many open sets is again open,
   c) the union of arbitrarily many open sets is again open.

(3) It took mathematicians several decades to settle on the above definition, the long and tortuous history of the definition of a topological space is presented in [Moo08].

We start out with some very basic examples of topological spaces.

**Examples.**

(1) Let $X$ be a set, then $\mathcal{T} = \{\emptyset, X\}$ is a topology on $X$. This topology is sometimes called the **trivial topology on $X$**. Other names that are used are the **indiscrete topology** and the **chaotic topology**.

(2) Let $X$ be a set. Then $\mathcal{T} = \mathcal{P}(X)$ is also a topology on $X$. In other words, $\mathcal{T}$ is the topology such that every subset of $X$ is open. This topology is usually referred to as the **discrete topology on $X$**. Sometimes we say that a topological space is discrete, if the topology is indeed the discrete topology.

---

12In more humble words, $\mathcal{T}$ is a set of subsets of $X$. 
(3) Let $X$ be a set.
   (a) We define $T \subseteq \mathcal{P}(X)$ as follows:
   
   $U \in T :\iff$ either $U = \emptyset$ or $U$ is the complement of a finite subset of $X$.

   It follows easily from de Morgan’s laws, stated in Lemma 1.2, that $T$ is a topology on $X$. We refer to it as the cofinite topology. Sometimes this topology is also called the finite-complement topology.

   (b) Similarly we can define the co-countable topology $T \subseteq \mathcal{P}(X)$ as follows:
   
   $U \in T :\iff$ either $U = \emptyset$ or $U$ is the complement of a countable subset of $X$.

   It follows from de Morgan’s laws together with Lemma 1.7 that this is a topology on $X$.

(4) Let $X$ be the empty set. Together with $T = \{\emptyset\}$ this is a topological space, called the empty topological space. It is a never ending source of counterexamples to carelessly formulated statements.

(5) (a) Let $X = \{\ast\}$ be a set with a single element $\ast$. It follows immediately from the definition of a topology there is a unique topology on $X = \{\ast\}$, namely the topology given by $T = \{\emptyset, \{\ast\}\}$. Together with the empty set this is the only case where the topology is already determined by the set.

   (b) Given a set $X$ with 2 elements it is straightforward to see that there exist four distinct topologies on $X$.

   Not surprisingly the number of topologies on a finite set grows rapidly with the cardinality of the set, we refer to [KR70, BMc02] for details.

Surely some of the most interesting examples of topological spaces arise from metric spaces. For completeness’ sake we recall the definition of metric spaces. For completeness’ sake we recall the definition of metric spaces.

**Definition.** A metric space is a pair $(X, d)$ consisting of a set $X$ and a metric $d$ on $X$, i.e. a map

$$X \times X \to \mathbb{R}_{\geq 0} := \{x \in \mathbb{R} \mid x \geq 0\},$$

with the following properties:

1. $d(x, y) = 0$ if and only if $x = y$,
2. for all $x, y \in X$ we have $d(x, y) = d(y, x)$ (symmetry)
3. for all $x, y, z \in X$ we have $d(x, z) \leq d(x, y) + d(y, z)$ (triangle inequality).

Sometimes we refer to $d(x, y)$ as the distance between $x$ and $y$.

**Example.** In the following we consider $\mathbb{R}^n$ as a metric space with the Euclidean metric given by

$$d(x, y) := \|x - y\| \quad \text{where} \quad \|z\| = \|(z_1, \ldots, z_n)\| := \sqrt{z_1^2 + \cdots + z_n^2}.$$
In Exercise 2.4 we will equip \( \mathbb{R}^n \) with two other natural metrics, namely the Manhattan metric and the SNCF metric.

The following lemma shows that metric spaces give rise to topological spaces.

**Lemma 2.1.** Let \( (X, d) \) be a metric space. A subset \( U \) of \( X \) is called open if for every \( x \in U \) there exists an \( \epsilon > 0 \) such that \( B_\epsilon(x) := \{ y \in X \mid d(x, y) < \epsilon \} \) is contained in \( U \). These open sets define a topology on \( X \).

**Proof.**

(1) It is clear that the empty set and \( X \) itself are open.

(2) Suppose \( U_1, \ldots, U_k \) are open subsets of \( X \). We need to show that the intersection \( U_1 \cap U_2 \cap \cdots \cap U_k \) is also open. Thus let \( x \in U_1 \cap U_2 \cap \cdots \cap U_k \). For each \( i \in \{1, \ldots, k\} \) there exists an \( \epsilon_i > 0 \) with \( B_{\epsilon_i}(x) \subseteq U_i \). We set \( \epsilon := \min\{\epsilon_1, \ldots, \epsilon_k\} \). Then

\[
B_\epsilon(x) \subseteq B_{\epsilon_1}(x) \cap \cdots \cap B_{\epsilon_k}(x) \subseteq U_1 \cap U_2 \cap \cdots \cap U_k.
\]

Since \( \epsilon \leq \epsilon_i \) and \( B_{\epsilon_i}(x) \subseteq U_i \).

(3) Let \( \{U_i\}_{i \in I} \) be a family of open sets. We want to show that \( \bigcup_{i \in I} U_i \) is also open. Thus let \( x \in \bigcup_{i \in I} U_i \). This means that there exists an \( i \in I \) with \( x \in U_i \). Since \( U_i \) is open there exists an \( \epsilon > 0 \) with \( B_\epsilon(x) \subseteq U_i \). Thus we have

\[
B_\epsilon(x) \subseteq U_i \subseteq \bigcup_{i \in I} U_i.
\]

**Convention.** Given a metric space \( (X, d) \) we always view \( X \) as a topological space with the topology defined in Lemma 2.1. In particular, unless we say explicitly otherwise, we view \( \mathbb{R}^n \) with the topology arising from the Euclidean metric.

We proceed with the next definition.

**Definition.** Let \( X \) be a topological space. We say a subset \( A \) of \( X \) is closed if the complement \( X \setminus A \) is open.

The following lemma is an immediate consequence of the definition of a topology and de Morgan’s laws, see Lemma 1.2. The lemma mirrors the remark on page 83.

**Lemma 2.2.** Let \( X \) be a topological space.

(1) the empty set and the entire set \( X \) are closed,

(2) the intersection of arbitrarily many closed sets is again closed,

(3) the union of finitely many closed sets is again closed.
**Remark.** Let $X$ be a set. If we specify what we mean by closed sets such that the three properties of Lemma 2.2 are satisfied, then it follows once again from de Morgan’s laws that the complements of the closed sets define a topology.

The following proposition gives us important examples of closed and open subsets.

**Proposition 2.3.** Let $(X, d)$ be a metric space, let $y \in X$ and let $r \in \mathbb{R}$.

1. the set $B_r(y) = \{ x \in X \mid d(x,y) < r \}$ is open in $X$, 

2. the set $\overline{B}_r(y) = \{ x \in X \mid d(x,y) \leq r \}$ is closed in $X$, 

3. the set $S_r(y) = \{ x \in X \mid d(x,y) = r \}$ is closed in $X$.

**Proof.** Let $(X, d)$ be a metric space, let $y \in X$ and let $r \in \mathbb{R}$.

1. Let $x \in B_r(y)$. We set $s := d(x,y)$. By definition of $B_r(y)$ we have $s < r$. We set $t := r - s$. Since $t > 0$ it suffices to show that $B_t(x) \subseteq B_r(y)$. Thus let $z \in B_t(x)$. We see that

\[
    d(y, z) \leq d(x, y) + d(x, z) < s + t = r.
\]

Thus we see that $z \in B_r(y)$, which is what we needed to show. We refer to Figure 5 for an illustration.

2. Almost the same argument as in (1) shows that $X \setminus \overline{B}_r(y)$ is open, which implies that $\overline{B}_r(y)$ is closed.

3. We have $X \setminus S_r(y) = B_r(y) \cup (X \setminus \overline{B}_r(y))$. By (1) and (2) we see that $X \setminus S_r(y)$ is the union of two open sets, thus by the third property of a topological space we see that $X \setminus S_r(y)$ is open, thus $S_r(y)$ is indeed closed. \[\square\]

**Figure 5**

The most frequent application of Proposition 2.3 is to the metric space $\mathbb{R}^n$. Thus we introduce the following notation.

**Notation.** Let $n \in \mathbb{N}_0$. Given $y \in \mathbb{R}^n$ and $r \in \mathbb{R}$ we write

\[
    B^r_n(y) := \{ x \in \mathbb{R}^n \mid \| x - y \| < r \} \quad \text{called open } n\text{-ball}
\]
\[
    \overline{B}^r_n(y) := \{ x \in \mathbb{R}^n \mid \| x - y \| \leq r \} \quad \text{called closed } n\text{-ball}
\]
\[
    S^{n-1}_r(y) := \{ x \in \mathbb{R}^n \mid \| x - y \| = r \} \quad \text{called } (n - 1)\text{-sphere}.
\]
We adopt the following conventions:

1. Not surprisingly a 2-ball is often called a disk and a 1-sphere is usually referred to as a circle.
2. If the parameter $n$ is clear from the context we sometimes drop it from the notation.
3. If $y = 0$, then we drop $y$ from the notation and if $r = 1$, then we drop $r$ from the notation.
4. Sometimes we write $rB^n$ instead of $B^n_r(0)$ and sometimes we write $rB^n$ instead of $B^n_r(0)$.
5. We refer to the point $(0, \ldots, 0, 1) \in S^n = \{x \in \mathbb{R}^{n+1} \mid \|x\| = 1\}$ as the North Pole of $S^n$ and we refer to the point $(0, \ldots, 0, -1) \in S^n = \{x \in \mathbb{R}^{n+1} \mid \|x\| = 1\}$ as the South Pole of $S^n$.

We sketch $B^1, B^2, S^1$ and $S^2$ in Figure 6. Of course one cannot easily sketch the 3-sphere $S^3$. But it is worth pointing out that in some form it has been around for a while. In [Lip14] Chapter 2 and [Petn79] the argument is made that the universe in Dante’s Divina Commedia is precisely the 3-sphere.

**Definition.** Let $(X, \mathcal{T})$ be a topological space and let $Y \subset X$ be a subset. It follows almost immediately from Lemma 1.1 that

$$S := \{Y \cap U \mid U \in \mathcal{T}\}$$

is a topology on $Y$. We refer to $S$ as the **subspace topology** on $Y$.

**Convention.**

1. Unless we say something else, we consider each subset $Y$ of $\mathbb{R}^n$ always as a topological space with respect to the subspace topology.
2. Let $(X, \mathcal{T})$ be a topological space and let $Y \subset X$ be a subset. If $Y$ is indeed equipped with the subspace topology, then sometimes we refer to $Y$ as a **subspace** of $X$.

We continue with the following useful lemma.

**Lemma 2.4.** Let $X$ be a topological space and let $Y \subset X$ be a subset. We equip $Y$ with the subspace topology.

1. A set $V \subset Y$ is open in $Y$ if and only if there exists an open subset $U \subset X$ with $V = U \cap Y$.

---

These definitions also make sense for $r < 0$, in that case all of the sets are the empty set. Also note that for $n = 0$ we obtain that $S_r^{n-1}(y) = S_r^{-1}(y) = \emptyset$. 

A set \( B \subset Y \) is closed in \( Y \) if and only if there exists a closed subset \( A \subset X \) with \( B = A \cap Y \).

**Proof (\( \ast \)).** The first statement is just a reformulation of the definition of the subspace topology. We turn to the proof of the second statement. Now let \( B \subset Y \). Elementary set theory shows that for any subset \( U \) of \( X \) we have
\[
(*) \quad U \cap Y = Y \setminus B \iff (X \setminus U) \cap Y = B.
\]
We refer to Figure 7 for an illustration. Now the second statement is basically obvious. Indeed, we have
\[
B \text{ is closed in } Y \iff Y \setminus B \text{ is open in } Y \iff \text{there exists } U \subset Y \text{ open with } U \cap Y = Y \setminus B \iff \text{there exists } U \subset Y \text{ open with } (X \setminus U) \cap Y = B \text{ by } (*) \iff \text{there exists } A \subset Y \text{ closed with } A \cap Y = B.
\]
We have thus proved the desired statement.

![Figure 7](image)

**Figure 7.** Illustration for the proof of Lemma 2.4.

**Example.** We consider \( Y = (-1,2] \) equipped with the subspace topology coming from \( \mathbb{R} \).

1. It follows from Lemma 2.4 that \( V = (0,2] \) is an open subset of \( Y \), since we can write \( V = (0,4) \cap Y \) and \( (0,4) \) is an open subset of \( \mathbb{R} \).
2. It follows from Lemma 2.4 that \( B = (-1,0] \) is a closed subset of \( Y \), since we can write \( B = [-3,0] \cap Y \) and \( [-3,0] \) is a closed subset of \( \mathbb{R} \).

These two examples are illustrated in Figure 8.

![Figure 8](image)

**Figure 8**

We continue with the next basic definition.

---

14We indicate proofs and statements that can safely be skipped at a first reading of these notes by the symbol (\( \ast \)).
**Definition.** Let $X$ be a topological space.

1. Let $A \subseteq X$ be a subset. We say $U \subseteq X$ is a *neighborhood of $A$* if there exists an open set $V$ such that $A \subseteq V \subseteq U$. We say $U$ is an *open neighborhood of $A$*, if $U$ is furthermore open. This definition is illustrated in Figure \ref{fig:neighborhood}.

2. An (open) neighborhood of a point $x \in X$ is an (open) neighborhood of $\{x\}$.

![Figure 9](image_url)

**Remark.** Some books, see e.g. [Mun75, p. 96], demand that a neighborhood is open. Our definition of a neighborhood agrees with the definition in most books, e.g. [Bre93, Hat02, Jä05].

**Example.** If $X = \mathbb{R}$ and $A = [0, 2)$, then $U = (-1, 3]$ and $V = (-2, \infty)$ are neighborhoods of $A$ in $X$.

The following lemma gives a useful criterion for showing that a given subset is open.

**Lemma 2.5.** Let $X$ be a topological space and let $U \subseteq X$ be a subset. If given any $x \in U$ there exists a neighborhood $V$ of $x$ that is contained in $U$, then $U$ is open.

**Proof:** Let $X$ be a topological space and let $U \subseteq X$ be a subset. Suppose that given any $x \in U$ there exists a neighborhood $V_x$ of $x$ that is contained in $U$. By definition of a neighborhood there exists for each $x \in U$ an open subset $W_x$ with $x \in W_x \subseteq V_x$. We see that

$$ U = \bigcup_{x \in U} \{x\} \subseteq \bigcup_{x \in U} W_x \subseteq U. $$

since each $W_x$ is contained in $U$

It follows that $U = \bigcup_{x \in U} W_x$, i.e. $U$ is the union of open subsets of $X$, thus by the third property of a topology, $U$ itself is open. \hfill \blacksquare

On many occasions it will be useful to “break” a topological space into smaller pieces. This leads us to the following definition.

**Definition.** Let $X$ be a topological space.

1. A *cover* of a subset $A \subseteq X$ is a family $\{U_i\}_{i \in I}$ of subsets of $X$ with $A \subseteq \bigcup_{i \in I} U_i$.

2. We say a cover $\{U_i\}_{i \in I}$ is *open* if each $U_i$ is open. Similarly we define a *closed cover*.

3. We say a cover $\{U_i\}_{i \in I}$ is *finite* if $I$ is finite. Otherwise we say that the cover is *infinite*.

4. We say a cover $\{U_i\}_{i \in I}$ is *locally finite* if each $x \in X$ admits an open neighborhood $W$ such that $\{i \in I \mid U_i \cap W \neq \emptyset\}$ is finite.

**Remark.** What we call a “cover” is often also called a “covering”. We will reserve the name “covering” for a completely different concept.
Example. In Figure 10 to the right we sketch a closed cover \( \{U_i\}_{i \in I} \) of \( X = \mathbb{R}^2 \) which has the property that each \( x \in X \) is contained in only finitely many \( U_i \), but which nonetheless fails to be locally finite.

\[
\text{locally finite closed cover of } X = \mathbb{R}^2
\]

\[
\text{not locally finite}
\]

Figure 10

The following lemma is crucial for many arguments.

**Lemma 2.6.** Let \( X \) be a topological space and let \( M \) be a subset of \( X \).

1. Let \( \{U_i\}_{i \in I} \) be an open cover of \( X \). The following two statements hold:
   - (a) \( M \) is open if and only if each intersection \( M \cap U_i \) is open in \( U_i \),
   - (b) \( M \) is closed if and only if each intersection \( M \cap U_i \) is closed in \( U_i \).

2. Let \( \{A_i\}_{i \in I} \) be a locally finite closed cover of \( X \). (In most applications we will deal with a finite closed cover.) The following two statements hold:
   - (a) \( M \) is open if and only if each intersection \( M \cap A_i \) is open in \( A_i \),
   - (b) \( M \) is closed if and only if each intersection \( M \cap A_i \) is closed in \( A_i \).

**Remark.** Note that in Lemma 2.6 we allow an arbitrary family of open subsets but we only allow a finite family of closed subsets. One can easily see that this restriction is necessary. For example, consider \( X = \mathbb{R} \) and the infinite family \( \{A_i\}_{i \in I} \) of closed subsets of \( X = \mathbb{R} \) given by all subsets consisting of a single point. Let \( M \subset \mathbb{R} \) be a subset. For each \( i \in I \) the intersection \( M \cap A_i \) is either the empty set or all of \( A_i \), in particular the intersection \( M \cap A_i \) is closed in \( A_i \). But of course there is no reason why \( M \) should be a closed subset of \( \mathbb{R} \).

**Proof.** Let \( X \) be a topological space and let \( M \) be a subset of \( X \).

1. Let \( \{U_i\}_{i \in I} \) be an open cover of \( X \). The “only if”-directions of (a) and (b) are an immediate consequence of Lemma 2.4. It remains to prove the “if”-directions.
   - (a) Suppose that for every \( i \in I \) the intersection \( M \cap U_i \) is an open subset of \( U_i \). By definition of the subspace topology this means that for each \( i \in I \) there exists an open subset \( Z_i \) of \( X \) with \( Z_i \cap U_i = M \cap U_i \). We have
     \[
     M = \bigcup_{i \in I} (M \cap U_i) = \bigcup_{i \in I} (Z_i \cap U_i) = \text{open subset of } X.
     \]
     since \( \bigcup_{i \in I} U_i = X \)
     union of open subsets, hence open

   - (b) Now suppose that each intersection \( M \cap U_i \) is closed in \( U_i \). In other words, each set \( U_i \setminus (M \cap U_i) \) is open in \( U_i \). Since \( (X \setminus M) \cap U_i = U_i \setminus (M \cap U_i) \) we obtain from (a) that \( X \setminus M \) is open in \( X \). In other words, \( M \) is closed in \( X \).
(2) First note that, as in (1) it remains to prove the “if”-directions.

(b) First we deal with the case that we are given a finite closed cover \( \{A_i\}_{i=1,...,m} \) of \( X \) such that for each \( i \) the intersection \( M \cap A_i \) is a closed subset of \( A_i \). It follows from Lemma 2.4 that for each \( i \in \{1,...,m\} \) there exists a closed subset \( Z_i \) of \( X \) with \( Z_i \cap A_i = M \cap A_i \). We have

\[
M = \bigcup_{i=1}^{m} (M \cap A_i) = \bigcup_{i=1}^{m} (Z_i \cap A_i) = \text{closed subset of } X
\]

Now suppose that we are given a locally finite closed cover \( \{B_i\}_{i \in I} \) of \( X \) such that for each \( i \in I \) the intersection \( M \cap B_i \) is a closed subset of \( B_i \). Since the cover is locally finite there exists for each \( x \in X \) an open neighborhood \( W_x \) such that \( I_x := \{i \in I \mid W_x \cap B_i \neq \emptyset\} \) is finite. Since \( \{W_x \cap B_i\}_{i \in I_x} \) is a finite closed cover of \( W_x \) we obtain from the above that \( M \cap W_x \) is closed. But since \( \{W_x\}_{x \in X} \) is an open cover of \( X \) we obtain from (1b) that \( M \) is a closed subset of \( X \).

(a) As in (1) we can reduce the proof of (a) to the proof of (b).

We continue with the following definition which will show up every now and then.

**Definition.** Let \( X \) be a topological space. We say a subset \( A \) of \( X \) is dense if every non-empty open subset of \( X \) has a non-empty intersection with \( A \).

**Examples.**

1. Let \( n \in \mathbb{N} \). It follows from basic facts in real analysis that \( A = \mathbb{Q}^n \) is a dense subset of \( X = \mathbb{R}^n \).

2. It is very tempting to think that dense open subsets of \( X = [0, 1] \) must be “almost the whole set”. But the following example might dent one’s optimism. First we pick a bijection \( f: \mathbb{N} \to \mathbb{Q} \cap [0, 1] \). For \( i \in \mathbb{N} \) we write \( x_i := f(i) \). We consider the set

\[
U := \bigcup_{i \in \mathbb{N}} (x_i - \frac{1}{3^i}, x_i + \frac{1}{3^i}) \cap [0, 1] \subset [0, 1].
\]

The same argument as in (1) shows that \( U \) is a dense subset of \( [0, 1] \). Since \( U \) is the union of open subsets we see that \( U \) is also an open subset of \( [0, 1] \). On the other hand its Lebesgue measure satisfies

\[
\text{vol}(U) = (\nu)\left( \bigcup_{i \in \mathbb{N}} (x_i - \frac{1}{3^i}, x_i + \frac{1}{3^i}) \cap [0, 1] \right) \leq \sum_{i \in \mathbb{N}} (\nu)((x_i - \frac{1}{3^i}, x_i + \frac{1}{3^i})) \leq \sum_{i \in \mathbb{N}} \frac{2}{3^i} = 2.
\]

Thus we have shown that the Lebesgue measure of \( U \) is less than the Lebesgue measure of \( [0, 1] \). So by no means can one reasonably claim that \( U \) is “almost all of \([0, 1]\)”.

3. Here is an immediate, perhaps not entirely serious application of topology to the eternal problem for how to capture a lion in the desert [Barr81]: We give the desert the **leonic topology**, in which a subset is closed if it is the whole desert or if it contains...
no lions. The set of lions is now a dense subset. Now put an open cage in the desert. By density it contains a lion. Once we shut the cage we have caught the lion!

After this joke of dubious taste we return to serious mathematics.

**Lemma 2.7.**

1. Every open subset of \( \mathbb{R}^n \) is the union of open balls of the form \( B_\epsilon(x) \) where \( \epsilon \) is rational and \( x \in \mathbb{Q}^n \).
2. Every open subset of \( \mathbb{R}^n \) is the union of countably many open balls.

**Proof (\#).**

1. Let \( U \) be an open subset of \( \mathbb{R}^n \). For \( x \in U \) we set \( \mu_x := \sup \{ \mu \in [0, 1] \mid B_\mu(x) \subset U \} \). The hypothesis that \( U \) is open implies that \( \mu_x > 0 \). We pick a rational number \( \epsilon_x \in (\frac{1}{2\mu_x}, \mu_x) \). Note that \( B_{\epsilon_x}(x) \subset U \). It remains to prove the following claim.

   **Claim.** The subset \( U \) is the union of all \( B_{\epsilon_x}(x) \) with \( x \in U \cap \mathbb{Q}^n \).

   Let \( y \in U \). Since \( \mathbb{Q}^n \) is dense in \( \mathbb{R}^n \) we can pick \( x \in U \cap \mathbb{Q}^n \) with \( \|x - y\| < \frac{1}{4} \epsilon_y \). Note that this is equivalent to saying that \( y \in B_{\frac{1}{4} \epsilon_y}(x) \). Thus it remains to prove that \( B_{\frac{1}{2} \epsilon_y}(x) \subset B_{\epsilon_x}(x) \). Recall that we pointed out above that \( B_{\epsilon_y}(y) \subset U \). Since \( \|x - y\| < \frac{1}{4} \epsilon_y \) we have by the triangle inequality that \( B_{\frac{3}{4} \epsilon_y}(x) \subset B_{\epsilon_y}(y) \). Thus \( B_{\frac{3}{4} \epsilon_y}(x) \subset U \). By definition of \( \mu_x \) this implies that \( \frac{3}{4} \epsilon_y \leq \mu_x \). Hence we have \( \frac{1}{4} \epsilon_y \leq \frac{3}{8} \epsilon_y \leq \frac{1}{2} \mu_x \leq \epsilon_x \). But then we also have \( B_{\frac{3}{4} \epsilon_y}(x) \subset B_{\epsilon_x}(x) \), as desired. \( \square \)

![Figure 11. Illustration for the proof of Lemma 2.7.](image)

(2) This statement follows immediately from (1).

We move on to the next definition.

**Definition.** Let \( X \) be a topological space and let \( A \) be a subset of \( X \). We make the following two definitions:

- **interior** \( \overset{\circ}{A} := \) union of all open sets of \( X \) that are contained in \( A \)
- **closure** \( \overline{A} := \) intersection of all closed sets of \( X \) that contain \( A \)

Furthermore we define the **boundary of \( A \) in \( X \)** as \( \partial A := \overline{A} \setminus \overset{\circ}{A} \).

We will give examples in a second, but first we record a few observations that follow almost immediately from the definitions.

---

15Why is this a topology?
16Why is that?
17This and many other mathematical approaches to hunting lions can be found in [Boas95].
Lemma 2.8. Let $X$ be a topological space and let $A$ be a subset of $X$.

1. The interior $\hat{A}$ is an open subset of $X$.
2. The closure $\overline{A}$ of $A$ is a closed subset of $X$.
3. We have $\hat{A} \subset A \subset \overline{A}$.
4. If $A$ is open, then $\hat{A} = A$.
5. If $A$ is closed, then $\overline{A} = A$.
6. We have $\hat{A} = A \setminus \partial A$.

Proof.

1. The union of arbitrarily many open sets is, by definition of a topology, again an open set. Thus the interior $\hat{A}$ is an open subset of $X$.
2. In Lemma 2.2 we saw that the intersection of arbitrarily many closed sets is again a closed set. It follows immediately that the closure $\overline{A}$ is a closed subset of $X$.

The remaining four statements follow almost immediately from the definitions.

Lemma 2.9. Let $X$ be a topological space and let $A$ be a subset of $X$. We have the following three equalities:

1. $\hat{A} = \{ x \in A \mid \text{there exists a neighborhood } U \text{ of } x \text{ that is contained in } A \}$
2. $\overline{A} = \{ x \in X \mid \text{every neighborhood of } x \text{ contains at least one point in } A \}$
3. $\partial A = \{ x \in X \mid \text{every neighborhood of } x \text{ contains at least one point in } A \text{ and one point that does not lie in } A \}$

Proof. The proof of the lemma is Exercise 2.3.

Using Lemma 2.9 we can give examples of interiors, closures and boundaries.

Examples.

1. We consider the topological space $X = \mathbb{R}$ and the subset $A = [-1, 2)$. Using Lemma 2.9 one can easily see that the interior of $A$ is the open interval $(-1, 2)$ and that the closure of $A$ is the closed interval $[-1, 2]$. Furthermore $\partial A = \{-1, 2\}$.

2. Let $x \in \mathbb{R}^n$ and $r \in \mathbb{R}$. We view $B^n_r(x)$, $B^n_r(x)$ and $S^n_{r-1}(x)$ as subsets of $\mathbb{R}^n$. Using Lemma 2.9 one can show fairly easily that $B^n_r(x) = B^n_r(x)$ and $\partial B^n_r(x) = \partial B^n_r(x) = \partial S^n_{r-1}(x) = S^n_{r-1}(x)$.

3. In Figure 12 we show a subset of $\mathbb{R}^2$, and we also show its interior $\hat{A}$, its closure $\overline{A}$ and its boundary $\partial A$.

4. It is rather unfortunate that the notations $\hat{A}$, $\overline{A}$ and $\partial A$ hide the role of $X$. For example let us consider $A = [0, 2]$. If we view it as a subset of $X = \mathbb{R}$, then $\partial A = \partial [0, 2] = \{0, 2\}$. On the other hand, if we view $A = [0, 2]$ as a subset of $X = \mathbb{R}_{\geq 0}$, then $\partial A = \partial [0, 2] = \{2\}$. This ambiguity in the notation can sometimes...
be a source of confusion. Thus it would be more appropriate to specify the role of $X$ in the above notation. But mathematicians, as all humans, tend to be lazy and thus tend to simplify the notation.

We conclude this section with the following technical lemma.

**Lemma 2.10.** (*) Let $X$ be a topological space and let $\{U_i\}_{i \in I}$ be a family of subsets. The following inclusions hold:

1. interior of $\bigcup_{i \in I} U_i \supseteq \bigcup_{i \in I} \overset{o}{U}_i$ and
2. closure of $\bigcap_{i \in I} U_i \subseteq \bigcap_{i \in I} \overline{U}_i$.

Furthermore, if we are given finitely many subsets $U_1, \ldots, U_n$ of $X$, then the following equalities hold:

3. interior of $\bigcap_{i=1}^n U_i = \bigcap_{i=1}^n \overset{o}{U}_i$ and
4. closure of $\bigcup_{i=1}^n U_i = \bigcup_{i=1}^n \overline{U}_i$.

**Example.** It is easy to come up with examples of two subsets $U_1, U_2$ in $\mathbb{R}^n$ such that inclusions in Lemma 2.10 (1) and (2) are actually proper inclusions. Some examples are illustrated in Figure 13.

![Figure 13](image)

**Proof.** The statements follow fairly easily from the definitions. We leave it to the reader to verify the statements.

---

2.2. **The Hausdorff property and convergence of sequences.** Before we introduce the Hausdorff property we introduce two more examples of topological spaces. Both are of the type “$\mathbb{R}^n$ together with an extra point”.

**Examples.**

1. Let $n \in \mathbb{N}$. We consider the set

$$X := \mathbb{R}^n \cup \{\infty\},$$

i.e. $X$ consists of $\mathbb{R}^n$ and an extra point $\infty$. We say $U \subset X$ is open, if both of the following two conditions are satisfied:

- (a) for each point $x \in U \cap \mathbb{R}^n$ there exists an $\epsilon > 0$ such that $B_\epsilon(x) \subset U$,
- (b) if $\infty \in U$, then there exists a $C > 0$ such that \( \{x \in \mathbb{R}^n : \|x\| > C\} \subset U \).
It is straightforward to see that this defines indeed a topology on $X$. We refer to $\mathbb{R}^n \cup \{\infty\}$ as “$\mathbb{R}^n$ with a point at infinity”. For $n = 1$ we refer to $\mathbb{R} \cup \{\infty\}$ also as the “line with a point at infinity”.

(2) We consider the set

$$X := \mathbb{R} \cup \{\ast\},$$

i.e. $X$ consists of $\mathbb{R}$ and an extra point $\ast$. We say $U \subset X$ is open, if the following two conditions are satisfied:

(a) for each point $x \in U \cap \mathbb{R}$ there exists an $\epsilon > 0$ such that $(x - \epsilon, x + \epsilon) \subset U$,

(b) if $\ast \in U$, then there exists an $\epsilon > 0$ such that $(-\epsilon, 0) \cup (0, \epsilon) \subset U$.

One can easily verify that this is indeed a topology on $X$. We refer to this topological space as the “line with two zeros”.

Even though the “line with two zeros” looks at first glance similar to the “line with a point at infinity” we will soon see that they are strikingly different topological spaces.

---

**Definition.**

(1) We say a topological space $X$ is Hausdorff, if given any two distinct points $x \neq y$ there exist disjoint open neighborhoods $U$ of $x$ and $V$ of $y$.

(2) A Hausdorff space is a topological space that is Hausdorff.

The following proposition, which very likely is well-known to most readers, says that topological spaces arising from metric spaces are Hausdorff.

**Proposition 2.11.** Let $(X, d)$ be a metric space. The corresponding topological space is Hausdorff.

**Proof.** Let $x, y \in X$ be two different points. We set $\epsilon := \frac{1}{2}d(x, y)$. It follows from Proposition 2.3 that $U := B_\epsilon(x)$ and $V := B_\epsilon(y)$ are neighborhoods of $x$ respectively $y$. An elementary argument using the triangle inequality shows that $U$ and $V$ are disjoint.

**Example.** In Exercise 2.20 we will see that “$\mathbb{R}^n$ with a point at infinity” is Hausdorff and that on the other hand “the line with two zeros” is not Hausdorff.

The following lemma is basically trivial, but since it gets used on many occasions it is still worth spelling it out.
Lemma 2.12. Let $X$ be a topological space and let $A$ be a subset of $X$. If $X$ is Hausdorff, then $A$ is also Hausdorff.

The following gives us a modest but still somewhat useful consequence of being Hausdorff.

Lemma 2.13. Let $X$ be a topological space. If $X$ is Hausdorff, then for every $x \in X$ the corresponding subset $\{x\}$ is closed.

Proof. Let $x \in X$. Since $X$ is Hausdorff we know that for every $y \neq x$ there exist open disjoint neighborhoods $U_y$ of $x$ and $V_y$ of $y$. We have

$$X \setminus \{x\} = \bigcup_{y \in X \setminus \{x\}} \{y\} \subseteq \bigcup_{y \in X \setminus \{x\}} V_y \subseteq X \setminus \{x\}.$$  

Thus we see that the inclusions are equalities. Since each $V_y$ is open we see that $X \setminus \{x\}$ is the union of open sets, in particular $X \setminus \{x\}$ is open. In other words, $\{x\}$ is a closed subset of $X$.

Next we introduce the notion of a convergent sequence.

Definition. Let $X$ be a topological space. We say that a sequence $\{a_n\}_{n \in \mathbb{N}}$ converges if there exists an $a \in X$ such that for any neighborhood $U$ of $a$ there exists an $N \in \mathbb{N}$ such that for all $n \geq N$ we have $a_n \in U$. We refer to $a$ as a limit of the sequence.

Example. We consider the line with two zeros, i.e. the topological space $X = \mathbb{R} \cup \{\ast\}$ defined above. The sequence $a_n = \frac{1}{n}$ converges, more or less evidently with limit 0. But strikingly enough, it follows easily from the definitions that the sequence also converges to $\ast$. Thus we see that the limit is not unique.

The following lemma is most likely already familiar to the reader from real analysis.

Lemma 2.14. Let $X$ be a topological space. If $X$ is Hausdorff, then every convergent sequence in $X$ has a unique limit.

Proof. Assume there exists a sequence $\{a_n\}_{n \in \mathbb{N}}$ in $X$ that converges to two different points $x$ and $y$. Since $X$ is Hausdorff there exist two disjoint neighborhoods $U$ and $V$ of $x$ and $y$. But by our hypothesis, for large enough $n$ the $a_n$ have to lie in $U$ and $V$ at the same time. But that is not possible and we have thus obtained a contradiction.
2.3. **Compact topological spaces.** In this section we introduce the notion of compactness. Usually it takes a while till one appreciates the brilliance of the definition.

**Definition.** We say a topological space $X$ is **compact** if for each open cover $\{U_i\}_{i \in I}$ of $X$ there exist finitely many indices $i_1, \ldots, i_k \in I$ such that

$$X = U_{i_1} \cup \cdots \cup U_{i_k}.$$ 

**Remark.** The introduction of the notion of compact topological space by Pavel Alexandrov and Pavel Urysohn \[A\,U\,29\] in 1929 shows that often in mathematics the really clever thing is not necessarily the proofs, but coming up with just the right definition. It is difficult to exaggerate the role of compactness in topology.

**Example.** Every finite topological space (regardless of the topology) is compact, since there exist only finitely many distinct open subsets. This simple example can sometimes be quite useful.

In the following we will often use the following convention.

**Convention.** Let $P$ be a property of a topological space (e.g. being discrete, Hausdorff, compact). We say that a subset $Y$ of a topological space $X$ has the property $P$ if $Y$, equipped with the subspace topology, has the property $P$.

**Examples.**

1. The set $\mathbb{Z} \subset \mathbb{R}$ is easily seen to be a discrete subset.
2. Any finite set of a topological space is, by the above, a compact subset.

Frequently and often subconsciously the following elementary lemma is employed.

**Lemma 2.15.** Let $X$ be a topological space, let $A \subset X$ be a subset and let $\{U_i\}_{i \in I}$ be an open cover of $A$. If $A$ is compact, then there exist finitely many indices $i_1, \ldots, i_k \in I$ such that

$$A \subset U_{i_1} \cup \cdots \cup U_{i_k}.$$ 

**Proof.** Given $i \in I$ we set $V_i := U_i \cap A$. By definition of the subspace topology each $V_i$ is an open subset of $A$. Thus $\{V_i\}_{i \in I}$ is an open cover of $A$. Since $A$ is compact there exist $i_1, \ldots, i_k \in I$ with $A = V_{i_1} \cup \cdots \cup V_{i_k}$. This implies that $A \subset U_{i_1} \cup \cdots \cup U_{i_k}$. \[

\text{We continue with the following frequently employed lemma.}

**Lemma 2.16.** Let $X$ be a topological space.

1. The union of finitely many compact subsets of $X$ is again a compact subset.
2. The intersection of arbitrarily many compact subsets of $X$ is again a compact subset.

**Proof.** The statement follows easily from the definitions, we leave it to the reader to fill in the details.
Before we give some more interesting examples of compact topological spaces we want to
discuss a few properties of compact topological spaces and compact subsets. The following
lemma is frequently used, often subconsciously, in topology.

Lemma 2.17.

(1) Let \( X \) be a topological space. If \( X \) is compact, then any closed subset of \( X \) is also compact.

(2) Let \( X \) be a topological space and let \( A \subset X \) be a compact subset. If \( X \) is Hausdorff, then \( A \) is a closed subset of \( X \).

Examples.

(1) Let \( X \) be a topological space. As we pointed out on page 97, any finite subset of \( X \) is compact. Thus if \( X \) is Hausdorff, then it follows fromLemma 2.17 (2) that any finite subset of \( X \), in particular any point in \( X \), is a closed subset of \( X \). Thus we have found a new proof for Lemma 2.13.

(2) Let \( X \) be a topological space, let \( A \) be a closed subset and let \( K \) be a compact subset of \( X \). It follows fromLemma 2.17 (1) that \( A \cap K \) is also compact.

Proof.

(1) Let \( X \) be a compact topological space and let \( A \) be a closed subset. Let \( \{U_i\}_{i \in I} \) be an open cover of \( A \). By definition of the subset topology there exists for every \( i \in I \) an open subset \( V_i \) of \( X \) such that \( U_i = V_i \cap A \). Since \( A \) is closed the complement \( X \setminus A \) is open. The open subsets \( \{V_i\}_{i \in I} \) together with \( X \setminus A \) are an open cover of \( X \). Since \( X \) is compact we can cover \( X \) by finitely many of these open sets. But then we can also cover \( A \) by finitely many of the \( U_i \).

(2) Let \( X \) be a Hausdorff space and let \( A \) be a compact subset of \( X \). We want to show that \( X \setminus A \) is open. By Lemma 2.17 it suffices to prove the following claim.

Claim. Let \( x \in X \setminus A \). Then there exists an open neighborhood \( V \) of \( x \) that is contained in \( X \setminus A \).

We apply the Hausdorff property to \( x \) and every \( y \in A \). For every \( y \in A \) we obtain disjoint open neighborhoods \( U_y \) of \( y \) and \( V_y \) of \( x \). Evidently we have

\[
A = \bigcup_{y \in A} \{y\} \subset \bigcup_{y \in A} (U_y \cap A) \subset A.
\]

Thus we see that \( \{U_y \cap A\}_{y \in A} \) is an open cover of \( A \). Since \( A \) is compact there exist \( y_1, \ldots, y_k \in A \) such that

\[
A = \bigcup_{i=1}^{k} (U_{y_i} \cap A).
\]

Now we consider

\[
V := \bigcap_{i=1}^{k} V_{y_i}.
\]

Since \( V \) is the intersection of finitely many open sets, it is open itself. Furthermore \( V \) does not intersect any of the \( U_{y_i} \), \( i = 1, \ldots, k \). This implies that \( V \) is disjoint from \( A \subset U_{y_1} \cup \cdots \cup U_{y_k} \).

\[\blacksquare\]
Example. Let \( x \in \mathbb{R}^n \) and \( r \geq 0 \). It follows easily from the triangle inequality that the balls \( B^n_r(y) \), \( \overline{B}^n_r(y) \) and the sphere \( S^{n-1}_r(y) \) are bounded.

Lemma 2.19. Let \( A \subset \mathbb{R}^n \) be a subset. If \( A \) is compact, then \( A \) is closed and it is bounded.

Proof. Let \( A \subset \mathbb{R}^n \) be a compact subset.

(1) We want to show that \( \mathbb{R}^n \setminus A \) is open. Let \( x \in \mathbb{R}^n \setminus A \). We need to show that there exists an \( \epsilon > 0 \) with \( B^n_\epsilon(x) \subset \mathbb{R}^n \setminus A \). Given \( j \in \mathbb{N} \) we consider the open subset \( U_j = \mathbb{R}^n \setminus \overline{B}^n_1(x) \). Evidently these sets cover \( A \). Since \( A \) is compact we obtain from Lemma 2.15 that there exist \( j_1, \ldots, j_k \) with \( A \subset U_{j_1} \cup \cdots \cup U_{j_k} \). We set \( \epsilon = \min\{\frac{1}{j_1}, \ldots, \frac{1}{j_k}\} \). We obtain that \( A \subset \mathbb{R}^n \setminus B^n_\epsilon(x) \). Thus we have found the desired \( \epsilon \).

(2) We need to show that \( A \) is bounded, i.e. we need to show that there exists a \( C \geq 0 \) with \( A \subset \overline{B}^n_C(0) \). We consider the open subsets \( U_j = B^n_1(0) \) with \( j \in \mathbb{N} \). Evidently these sets cover \( A \). Since \( A \) is compact we obtain again from Lemma 2.15 that there
exist \( j_1, \ldots, j_k \) such that \( A \subset U_{j_1} \cup \cdots \cup U_{j_k} \). We set \( C = \max \{ j_1, \ldots, j_k \} \). We obtain that \( A \subset B_C^n(0) \subset \overline{B}_C^n(0) \). We have thus found the desired \( C \).

---

**Figure 18.** Illustration for the proof of Lemma 2.19

The ever-popular Heine-Borel Theorem says that mercifully the converse to Lemma 2.19 holds.

**Theorem 2.20. (Heine-Borel)** A subset of \( \mathbb{R}^n \) is compact if and only if it is bounded and closed.

**Examples.**

1. Let \( y \in \mathbb{R}^n \) and \( r \geq 0 \). It follows from the Heine-Borel Theorem 2.20 and Proposition 2.3 that the closed ball \( \overline{B}_r^n(y) \) and the sphere \( S_{r-1}^n(y) \) are compact.

2. It is an amusing exercise, see Exercise 2.20, to show, using the Heine-Borel Theorem 2.20, that \( \mathbb{R}^n \) with a point at infinity is compact.

3. It is an equally entertaining exercise, see Exercise 2.20, to show that the “line with two zeros” is not compact.

4. We set \( C_0 = [0, 1] \). We define sets \( C_i, i \in \mathbb{N} \) iteratively by setting

\[
C_i := \frac{1}{3}C_{i-1} \cup \left( \frac{2}{3} + \frac{1}{3}C_{i-1} \right)
\]

i.e. we obtain \( C_i \) from \( C_{i-1} \) by removing the “open middle third” of each interval. See Figure 19. The Cantor set is defined as

\[
\text{Cantor set } C := \bigcap_{i \in \mathbb{N}_0} C_i.
\]

Each \( C_i \) is closed, hence it follows from Lemma 2.2 that \( C \) itself is a closed subset of \( \mathbb{R} \). It is evidently bounded, hence the Heine-Borel Theorem 2.20 implies that the Cantor set is compact.

---

**Figure 19**

(5) Since the concepts of being bounded and closed are initially much more intuitive than being compact it is not uncommon that people like to replace “compact” by
“bounded and closed”. But this equality only holds for subsets of $\mathbb{R}^n$, it does not hold for other metric spaces. For example, the set $[0, 1] \cap \mathbb{Q}$ is a bounded and closed subset of the metric space $(\mathbb{Q}, d(x, y) = |x - y|)$, but as we will see in Exercise 2.44, it is not compact. Furthermore in Exercise 2.45 we will see that in general the conclusion of the Heine-Borel Theorem 2.20 does not hold for infinite-dimensional real vector spaces.

The following proposition is the key ingredient in the proof of the Heine-Borel Theorem 2.20.

**Proposition 2.21.** Let $n \in \mathbb{N}$ and let $a_i < b_i$, $i = 1, \ldots, n$ be real numbers. The hyperrectangle

$$[a_1, b_1] \times \cdots \times [a_n, b_n] \subseteq \mathbb{R}^n$$

is compact.

**Proof.** To simplify the notation we only treat the case $n = 1$. The general case is treated in a very similar fashion.\footnote{The full details are for example provided in [RudiW76, Theorem 2.4.1].} To simplify the notation we assume that $a = 0$ and $b = 1$. Thus we will now show that $I := [0, 1]$ is compact. In an attempt at a proof by contradiction we suppose that $I$ is not compact. This means that there exists an open covering $\{U_j\}_{j \in J}$ such that $I$ cannot be covered by finitely many of the $U_j$.

**Claim.** There exists a sequence of closed intervals

$$I = I_0 \supset I_1 \supset I_2 \supset \ldots$$

such that for any $m \in \mathbb{N}_0$ the following two conditions hold:

1. $I_m$ cannot be covered by finitely many of the $U_j$,
2. the length of $I_m$ equals $2^{-m}$.

We prove the claim by induction. We set $I_0 := I$. Suppose we have already found $I_0, I_1, \ldots, I_m$. We divide the interval $I_m$ into two closed intervals $I'$ and $I''$ of half the length. Since $I_m$ cannot be covered by finitely many $U_j$ it follows that at least one of the intervals $I'$ and $I''$ cannot be covered by finitely many $U_j$ either. We declare this interval to be $I_{m+1}$.\]

**Claim.** There exists an $x \in I$ with $x \in \bigcap_{m \in \mathbb{N}} I_m$.

For every $m \in \mathbb{N}$ we pick an $a_m \in I_m$. For any $m \geq n$ we know that $a_m$ and $a_n$ both lie in $I_n$. In particular

$$|a_m - a_n| \leq \text{length of } I_n = \frac{1}{2^n}.$$ 

It follows that $(a_m)_{m \in \mathbb{N}}$ is a Cauchy sequence. We denote by $x$ the limit of this Cauchy sequence. We want to show that $x \in \bigcap_{m \in \mathbb{N}} I_m$. Put differently, we want to show that for every $m \in \mathbb{N}$ we have $x \in I_m$. Thus let $m \in \mathbb{N}$. For all $n \geq m$ we have $a_n \in I_n \subseteq I_m$.\]
In particular, \((a_n)_{n \geq m}\) is a sequence that converges in \(I_m\). Since \(I_m\) is closed we see\(^{19}\) that \(\lim_{n \to \infty} a_n \in I_m\).

\[\begin{array}{c}
I_0 & I_2 & I_3 & I_1 \\
\uparrow & \uparrow & \uparrow & \uparrow \\
x \in \cap I_m
\end{array}\]

the open set \(U_j\) contains \(x\), and it also contains all \(I_m\) for sufficiently large \(m\)

**Figure 20.** Illustration for the proof of Proposition 2.21

Since \(\{U_j\}_{j \in J}\) is an open cover of \(I\) there exists a \(j \in J\) with \(x \in U_j\). Since \(U_j\) is open there exists an \(\epsilon > 0\) with \((x - \epsilon, x + \epsilon) \cap I \subset U_j\). We pick \(m \in \mathbb{N}\) with \(2^{-m} < \epsilon\). Now note that

\[
I_m \subset [x - 2^{-m}, x + 2^{-m}] \cap I \subset (x - \epsilon, x + \epsilon) \cap I \subset U_j
\]

since \(x \in I_m\) and since

choice of \(m\) choice of \(U_j\)

the length of \(I_m\) equals \(2^{-m}\)

i.e. \(I_m\) is contained in a unique \(U_j\). But this contradicts property (1) of the intervals \(I_m, m \in \mathbb{N}\).

Now we can finally give the proof of the Heine-Borel Theorem 2.20.

**Proof of the Heine-Borel Theorem 2.20** In light of Lemma 2.19 we only need to show that if \(A\) is a bounded and closed subset of \(\mathbb{R}^n\), then it is compact. Since \(A\) is bounded there exists a \(C \geq 0\) such that \(A \subset [-C, C]^n\). By Proposition 2.21 we know that \(A \subset [-C, C]^n\) is compact. Since \(A\) is closed in \(\mathbb{R}^n\) it follows from Lemma 2.4 that is also a closed subset of \([-C, C]^n\). It follows from Lemma 2.17 that \(A\) itself is compact.

2.4. **Bases of a topology.** We start out with the following definition.

**Definition.** Let \(X\) be a set and let \(\mathcal{B} \subset \mathcal{P}(X)\) be a subset of the power set of \(X\). We say \(\mathcal{B}\) has the **basis property** if the following two conditions are satisfied:

(B1) For any \(x \in X\) there exists a \(B \in \mathcal{B}\) with \(x \in B\).

(B2) Given any \(B_1, B_2 \in \mathcal{B}\) and given any \(x \in B_1 \cap B_2\) there exists a \(B_3 \in \mathcal{B}\) such that \(x \in B_3\) and \(B_3 \subset B_1 \cap B_2\). (See Figure 21 for an illustration.)

**Figure 21**

The following lemma justifies our sudden interest in this new definition.

---

\(^{19}\)Why do we see this?
Lemma 2.22. Let $X$ be a set and let $\mathcal{B} \subseteq \mathcal{P}(X)$. We define
\[
\mathcal{T}(\mathcal{B}) := \{V \subseteq X \mid \text{for every } x \in V \text{ there exists a } B \in \mathcal{B} \text{ with } x \in B \subseteq V\}.
\]
If $\mathcal{B}$ has the basis property, then $\mathcal{T}(\mathcal{B})$ is a topology on $X$.

Definition. Let $X$ be a set.

1. If $\mathcal{B} \subseteq \mathcal{P}(X)$ has the basis property, then we refer to $\mathcal{T}(\mathcal{B})$ as the topology on $X$ generated by $\mathcal{B}$. 

2. Conversely, if $\mathcal{T}$ is a given topology on $X$ and if $\mathcal{B} \subseteq \mathcal{P}(X)$ has the basis property and if $\mathcal{T} = \mathcal{T}(\mathcal{B})$, then we say that $\mathcal{B}$ is a basis of the topology $\mathcal{T}$ of $X$.

Examples.

1. If $(X,d)$ is a metric space, then
\[
\mathcal{B} = \{\text{all balls } B_r(x) \mid r > 0 \text{ and } x \in X\} \subset \mathcal{P}(X)
\]
satisfies (B1) and (B2). The topology generated by this family of subsets is, by definition, precisely the topology we already introduced on page 85.

2. Let $X$ be a set and let $\mathcal{T}$ be a topology on $X$. It follows easily from the definitions that $\mathcal{T}$ has the basis property. Furthermore it follows from Lemma 2.5 that the topology generated by $\mathcal{T}$ is in fact $\mathcal{T}$.

3. Let $n \in \mathbb{N}$ and let $\mathbb{R}^n \cup \{\infty\}$ be the topological space defined on page 95. It follows immediately from the definition of the topology that a basis for the topological space $\mathbb{R}^n \cup \{\infty\}$ is given by
\[
\mathcal{B} = \{B^n_r(x) \mid r > 0 \text{ and } x \in \mathbb{R}^n\} \cup \{\infty\} \cup (\mathbb{R}^n \setminus \overline{B}^n_C) \mid C \in \mathbb{R}\}.
\]

For completeness we provide the elementary proof of Lemma 2.22.

Proof (*). Let $X$ be a set and let $\mathcal{B} \subseteq \mathcal{P}(X)$. We write $\mathcal{T} := \mathcal{T}(\mathcal{B})$. We need to show that $\mathcal{T}$ satisfies the three properties (1), (2) and (3) in the definition of a topological space, see page 83. Given any $x \in X$ there exists by (B1) a $B \in \mathcal{B}$ with $x \in B$. By definition we see that $x \in \mathcal{T}$. Furthermore it is clear that the empty set $\emptyset$ lies in $\mathcal{T}$.

We need to show that the intersection of finitely many sets in $\mathcal{T}$ is again a set in $\mathcal{T}$.

First we consider the case of two sets in $\mathcal{T}$. Thus let $U,V \in \mathcal{T}$. We need to show that $U \cap V \in \mathcal{T}$. Let $x \in U \cap V$. Since $U$ and $V$ lie in $\mathcal{T}$ there exist $B,C \in \mathcal{B}$ with $x \in B \subseteq U$ and $x \in C \subseteq V$. By (B2) there exists a $D \in \mathcal{B}$ with $x \in D$ and $D \subseteq B \cap C$. In particular we have $x \in D \subseteq U \cap V$. This shows that $U \cap V \in \mathcal{T}$.

Now let $U_1,\ldots,U_k$ be sets in $\mathcal{T}$. Using the above statement and an elementary induction argument we see that $U_1 \cap \cdots \cap U_k$ lies in $\mathcal{T}$ as well.

Let $U_j, j \in J$ be a family of sets in $\mathcal{T}$. We need to show that the union $\bigcup_{j \in J} U_j$ lies in $\mathcal{T}$.

Thus let $x \in \bigcup_{j \in J} U_j$. This means that there exists a $k \in J$ with $x \in U_k$. Since $U_k \in \mathcal{T}$ there exists a $B_x \in \mathcal{B}$ with $x \in B_x \subseteq U_k$. But then we also have
\[
x \in B_x \subseteq U_k \subseteq \bigcup_{j \in J} U_j.
\]

20 Why is (B2) satisfied?
The following lemma can be used to show that two topologies on a given set agree.

**Lemma 2.23.** Let $X$ be a set and let $\mathcal{S}$ and $\mathcal{T}$ be topologies for $X$. Suppose that $\mathcal{C}$ is a basis for $\mathcal{T}$. (As discussed above we could take $\mathcal{C} = \mathcal{T}$.) If given any $x \in X$ and given any $V \in \mathcal{C}$ there exists a $U \in \mathcal{S}$ with $x \in U \subset V$, then $\mathcal{T} \subset \mathcal{S}$.

**Example.** Let $n \in \mathbb{N}$. We consider the two metrics
\[
\mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}_{\geq 0} \quad \text{and} \quad \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}_{\geq 0} \quad (v, w) \mapsto \|v - w\| \quad \text{and} \quad (v, w) \mapsto \max\{|v_i - w_i| \mid i \in \{1, \ldots, n\}\}.
\]
The former is the Euclidean metric that we introduced on page 84. We refer to the second metric as the maximum’s metric. We leave it as a task to the dedicated reader to show, using Lemma 2.23, that the two topologies on $\mathbb{R}^n$ agree.

**Proof.** It follows immediately from Lemma 2.23 that any set in $\mathcal{C}$ is open in $\mathcal{S}$. But then, once again using Lemma 2.23 we see that any set in $\mathcal{T}$ is open in $\mathcal{S}$, i.e. $\mathcal{T} \subset \mathcal{S}$. ■

Sometimes the following two lemmas can be useful.

**Lemma 2.24.** Let $X$ be a set and let $\mathcal{B} \subset \mathcal{P}(X)$. If $\mathcal{B}$ has the basis property, then $V \subset X$ is open with respect to $\mathcal{T}(\mathcal{B})$ if and only if $V$ is the union of sets in $\mathcal{B}$.

**Proof of Lemma 2.24.** We first prove the “$\Leftarrow$”-direction. Thus let $V$ be the union of sets in $\mathcal{B}$. Since sets in $\mathcal{B}$ are open with respect to $\mathcal{T}(\mathcal{B})$ and since $\mathcal{T}(\mathcal{B})$ is a topology we see that $V \in \mathcal{T}(\mathcal{B})$.

Now we prove the “$\Rightarrow$”-direction. Thus we suppose that $V \subset X$ is open with respect to $\mathcal{T}(\mathcal{B})$. For each $x \in V$ there exists, by definition of $\mathcal{T}(\mathcal{B})$, a set $B_x \in \mathcal{B}$ with $x \in B_x \subset V$. We obtain that
\[
V = \bigcup_{x \in V} \{x\} \subset \bigcup_{x \in V} B_x \subset V, \quad \text{thus it follows that $V = \bigcup_{x \in V} B_x$.}
\]

**Lemma 2.25.** Let $\mathcal{B}$ be a basis for the topology of a topological space $X$. Furthermore let $\{U_j\}_{j \in J}$ be an open cover of $X$, i.e. $\{U_j\}_{j \in J}$ is a family of open sets with $\bigcup_{j \in J} U_j = X$. Then $\{B \in \mathcal{B} \mid \text{there exists some } j \in J \text{ with } B \subset U_j\}$ is also a basis for the topology of $X$.

**Proof (⋆).** We write
\[
\mathcal{C} := \{B \in \mathcal{B} \mid \text{there exists some } j \in J \text{ with } B \subset U_j\}.
\]
Since $\mathcal{C} \subset \mathcal{B}$ we have $\mathcal{T}(\mathcal{C}) \subset \mathcal{T}(\mathcal{B})$. It remains to show the reverse inclusion $\mathcal{T}(\mathcal{B}) \subset \mathcal{T}(\mathcal{C})$. It follows easily from Lemma 2.23 that it suffices to show that $\mathcal{B} \subset \mathcal{T}(\mathcal{C})$. In other words, it suffices to prove the following claim.

**Claim.** Given any $x \in X$ and any $B \in \mathcal{B}$ with $x \in B$ there exists a $C \in \mathcal{C}$ such that $x \in C \subset B$. 
So let \( x \in X \) and let \( B \in \mathcal{B} \) with \( x \in B \). By hypothesis there exists a \( j \) such that \( x \in U_j \). Since \( U_j \) is open and since \( \mathcal{B} \) is a basis for the topology of \( X \) there exists a \( B' \in \mathcal{B} \) with \( x \in B' \subseteq U_j \). By (B2) there exists a \( B'' \subseteq B \) with \( x \in B'' \) and \( B'' \subseteq B \cap B' \subseteq U_j \). By definition we have \( B'' \in \mathcal{C} \). This concludes the proof of the claim and thus of the lemma. (We refer to Figure 22 for an illustration of the argument.)

![Figure 22. Illustration for the proof of Lemma 2.25](image)

**Example.** As we pointed out above, \( \mathcal{B} = \{ B^n_r(x) \mid r > 0 \text{ and } x \in \mathbb{R}^n \} \) is a basis for the usual topology of \( \mathbb{R}^n \). We denote by \( \mathcal{U} \) the family of all open sets that are contained in an open ball of radius 1. Then the open sets in \( \mathcal{U} \) cover \( \mathbb{R}^n \). It follows from Lemma 2.25 that
\[
\{ B^n_r(x) \mid r \in (0, 1) \text{ and } x \in \mathbb{R}^n \}
\]
is also a basis for \( \mathbb{R}^n \).

The following lemma gives us in particular another source of topologies.

**Lemma 2.26.** Let \( X \) be a set. For any \( \mathcal{C} \subseteq \mathcal{P}(X) \) the set
\[
\mathcal{B}(\mathcal{C}) := \text{all subsets of } X \text{ that can be written as intersections of a finite family of sets in } \mathcal{C}
\]
has the basis property.

**Proof (\(*\)).**

1. On page 72 we pointed out that if we take the empty family of subsets of \( X \), then the intersection is all of \( X \). In other words, we see that \( X \in \mathcal{B}(\mathcal{C}) \). It follows that \( \mathcal{B}(\mathcal{C}) \) satisfies (B1).
2. It is easy to verify that \( \mathcal{B}(\mathcal{C}) \) satisfies (B2).

The previous lemma leads us to the following definition.

**Definition.** Let \( X \) be a set and let \( \mathcal{C} \subseteq \mathcal{P}(X) \).

1. We define \( \mathcal{B} = \mathcal{B}(\mathcal{C}) \) as in Lemma 2.26 and we refer to \( \mathcal{T}(\mathcal{B}) \) as the **topology generated by** \( \mathcal{C} \).
2. Conversely, if \( \mathcal{T} \) is a topology on \( X \) and if the topology generated by \( \mathcal{C} \) agrees with \( \mathcal{T} \), then we say that \( \mathcal{C} \) is a **subbasis for** \( \mathcal{T} \).

**Example.**

1. Let \( \mathcal{C} \) be the set of all intervals in \( \mathbb{R} \) of length one. One can easily verify that \( \mathcal{C} \) generates the usual topology on \( \mathbb{R} \).
2. It follows easily from the definitions that a basis of a given topology is also a subbasis of the topology.
The following lemma gives us a convenient criterion for showing that a set of open subsets is in fact a (sub-) basis for a given topology.

**Lemma 2.27.** Let \( X \) be a topological space and let \( C \) be a family of open sets.

1. Suppose \( C \) has the following property:
   
   (\*) Given any open set \( U \) and given any \( x \in U \) there exists a \( C \in C \) with \( x \in C \subset U \). Then \( C \) is a basis for the topology of \( X \).

2. Suppose \( B \) is a basis for the topology of \( X \). If given any \( x \in X \) and given any \( B \in B \) there exist finitely many \( C_1, \ldots, C_m \in C \) with \( x \in C_1 \cap \cdots \cap C_m \subset B \), then \( C \) is a subbasis for the topology of \( X \).

**Example.** Using Lemma 2.27 (1) and using the density of \( \mathbb{Q} \subset \mathbb{R} \) one can easily show that the set of rational intervals forms a basis for the usual topology on \( \mathbb{R} \). In particular \( \mathbb{R} \) has a countable basis for its topology.

**Proof (\*).**

1. We denote by \( T \) the topology of \( X \). First we show that \( C \) has the basis property:
   
   (B1) If we apply the property of \( C \) to \( U = X \) then we obtain immediately that given any \( x \in X \) there exists a \( C \in C \) with \( x \in C \).

   (B2) Let \( x \in C_1 \cap C_2 \) with \( C_1, C_2 \in C \). Since \( C_1 \) and \( C_2 \) are open the intersection \( U = C_1 \cap C_2 \) is also open. It follows from the hypothesis on \( C \), applied to \( U \), that there exists a \( C \in C \) with \( x \in C \subset C_1 \cap C_2 \).

   We denote by \( S \) the topology on \( X \) that is generated by \( C \). We need to show that \( S = T \).

   First we show the inclusion \( S \subset T \). Since all sets in \( C \) are open with respect to \( T \) it follows from Lemma 2.24 that \( S \subset T \).

   Finally we show the reverse inclusion \( T \subset S \). Thus let \( U \in T \). We need to show that \( U \in S \). Thus let \( x \in U \). By our hypothesis there exists a \( C \in C \) with \( x \in C \subset U \).

   Therefore by definition we have \( U \in S \). We have thus shown that \( T \subset S \).

2. We leave the verification of this statement as a rather uninspiring exercise to the reader.

We conclude this section with the following not terribly inspiring lemma.

**Lemma 2.28.** (\*) Let \( X \) be a topological space and let \( A \subset X \) be a subset. If \( B \) is a basis for the topology of \( X \), then \( \{ B \cap A \mid B \in B \} \) is a basis for the topology of \( A \), equipped with the subspace topology.

**Proof (\*).** We prove the lemma using Lemma 2.27 (1). Thus let \( U \subset A \) be an open subset in \( A \) and let \( x \in U \). By definition of the subspace topology there exists an open subset \( V \subset X \) with \( U = V \cap A \). Since \( B \) is a basis for the topology of \( X \) there exists a \( B \in B \) with \( x \in B \subset V \). This implies that \( x \in B \cap A \subset V \cap A = U \). It follows from Lemma 2.27 (1) that \( \{ B \cap A \mid B \in B \} \) is indeed a basis for the topology of \( A \).

**Example.** We consider

\[
S^1 = \{(x, y) \in \mathbb{R}^2 \mid x^2 + y^2 = 1\} \subset \mathbb{R}^2.
\]
As we saw on page 103, a basis for the topology on $\mathbb{R}^2$ is given by

$$\mathcal{B} = \{ B_r(x, y) \mid (x, y) \in \mathbb{R}^2 \text{ and } r > 0 \}.$$ 

The intersection of such an open ball with $S^1$ is an “open interval on $S^1$”, i.e. it is a subset of the form \( \{ e^{i\varphi} \mid \varphi \in (a, b) \} \). It follows from Lemma 2.28 that these “open intervals” form a basis for the topology on $S^1$. We refer to Figure 24 for an illustration.

2.5. **Continuous maps.** The following is the key definition in the context of topological spaces.

**Definition.** We say a map $f : X \to Y$ between two topological spaces $X$ and $Y$ is **continuous**, if for each open set $U$ in $Y$ the preimage $f^{-1}(U)$ is open in $X$.

**Examples.**

1. Let $X$ and $Y$ be two topological spaces. If $Y$ is equipped with the trivial topology or if $X$ is equipped with the discrete topology, then any map $f : X \to Y$ is continuous.
2. We consider the set $X = \{ A, B, C, D \}$ where the topology is given by the set

$$\mathcal{T} := \{ \emptyset, \{ A \}, \{ C \}, \{ A, C \}, \{ A, B, C \}, \{ A, C, D \}, X \}.$$ 

We refer to this to topological spaces as the **pseudocircle**. It follows easily from the definitions that the map

$$f : S^1 \to X \quad e^{it} \mapsto \begin{cases} A, & \text{if } t \in (-\frac{\pi}{4}, \frac{\pi}{4}), \\ B, & \text{if } t = \frac{\pi}{4}, \\ C, & \text{if } t \in (\frac{\pi}{4}, \frac{3\pi}{4}), \\ D, & \text{if } t = \frac{3\pi}{4}. \end{cases}$$

is continuous. This map is illustrated in Figure 25.
3. Let $X$ and $Y$ be topological spaces and let $y \in Y$. The constant map

$$c_y : X \to Y \quad x \mapsto y$$
is continuous since the preimage of any set in $Y$ is either the $\emptyset$ or all of $X$. This simple example will come in handy on many occasions.

The following lemma gives a few more examples of continuous maps.

**Lemma 2.29.** Let $n \in \mathbb{N}$.

1. For each $i \in \{1, \ldots, n\}$ the projection map
   \[
   \mathbb{R}^n \to \mathbb{R} \\
   (x_1, \ldots, x_n) \mapsto x_i
   \]
   is continuous.

2. Let $f = (f_1, \ldots, f_n): X \to \mathbb{R}^n$ be a map from a topological space $X$ to $\mathbb{R}^n$. Then $f$ is continuous if and only if each $f_i: X \to \mathbb{R}$ is continuous.

**Proof.** We leave the slightly messy proof of the lemma to the reader. ■

**Lemma 2.30.**

1. If $f: X \to Y$ and $g: Y \to Z$ are two continuous maps between topological spaces, then the composition $g \circ f: X \to Z$ is also continuous.

2. Let $X$ be a topological space and let $A$ be a subset. If we equip $A$ with the subspace topology, then the inclusion map $i: A \to X$ is continuous.

3. Let $f: X \to Y$ be a continuous map between topological spaces and let $A$ be a subset. If we equip $A$ with the subspace topology, then the restriction of $f$ to the map $f|_A: A \to Y$ is also continuous.

4. Let $f: X \to Y$ be a continuous map. If $Z \subset Y$ is a subset with $f(X) \subset Z$, then the map $f: X \to Z$ is also continuous.

**Proof.**

1. Let $f: X \to Y$ and $g: Y \to Z$ be two continuous maps between topological spaces. We need to show that the composition $g \circ f: X \to Z$ is also continuous. Let $U \subset Z$ be an open subset. Then
   \[
   (g \circ f)^{-1}(U) = f^{-1}(g^{-1}(U)) = f^{-1}(\text{the open set } g^{-1}(U)) = \text{open.}
   \]
   since $g$ is continuous and $U$ is open
   since $f$ is continuous

2. This statement follows immediately from the definitions.

3. This statement is an immediate consequence of (1) and (2) since the restriction of $f$ to $A$ is precisely the same as $f \circ i$ where $i: A \to X$ denotes the inclusion.
(4) For clarity we denote by \( g: X \to Z \) the map given by \( x \mapsto f(x) \). Let \( U \subseteq Z \) be an open subset. We need to show that \( g^{-1}(U) \) is an open subset of \( X \). By definition of the subspace topology there exists an open subset \( V \subseteq X \) with \( U = Z \cap V \). Thus we see that

\[
g^{-1}(U) = g^{-1}(Z \cap V) = f^{-1}(Z \cap V) = f^{-1}(V) = \text{open subset of } X.
\]

\( \uparrow \) \( \uparrow \) \( \uparrow \)

definition of \( g \) since \( f(X) \subseteq Z \) since \( f \) is continuous

Now we can give many more examples of continuous maps.

**Lemma 2.31.** Let \( X \) be a topological space. If \( f: X \to \mathbb{R} \) and \( g: X \to \mathbb{R} \) are continuous maps, then the maps

\[
\begin{align*}
X \to \mathbb{R} & \quad x \mapsto f(x) + g(x) \\
X \to \mathbb{R} & \quad x \mapsto f(x) \cdot g(x) \\
X \to \mathbb{R} & \quad x \mapsto \max\{f(x), g(x)\} \\
X \to \mathbb{R} & \quad x \mapsto \min\{f(x), g(x)\}
\end{align*}
\]

are also continuous.

**Example.** Let \( A \) be a real \((m \times n)\)-matrix. It follows easily from **Lemma 2.29** (1), **Lemma 2.30** (1) and **Lemma 2.31** that the map

\[
f: \mathbb{R}^n \to \mathbb{R}^m \\
v \mapsto Av
\]

is continuous.

**Proof.** In Exercise 2.27 we will show that the maps

\[
\begin{align*}
\alpha: \mathbb{R}^2 & \to \mathbb{R} \\
(x, y) & \mapsto x + y
\end{align*} \quad \text{and} \quad
\begin{align*}
\beta: \mathbb{R}^2 & \to \mathbb{R} \\
(x, y) & \mapsto x \cdot y
\end{align*}
\]

are continuous. The map \( x \mapsto f(x) + g(x) \) equals the map

\[
X \quad \xrightarrow{x \mapsto f(x) + g(x)} \quad \mathbb{R}^2 \quad \xrightarrow{\alpha} \quad \mathbb{R}.
\]

By **Lemma 2.29** (2) the first map is continuous. By the above we know that \( \alpha \) is continuous. From **Lemma 2.30** (1) we deduce that the map \( f + g \) is continuous. The same argument also takes care of the map \( x \mapsto f(x) \cdot g(x) \). Finally note that for any \( a, b \in \mathbb{R} \) we have

\[
\max\{a, b\} = \frac{1}{2}(a + b + |a - b|) \quad \text{and} \quad \min\{a, b\} = \frac{1}{2}(a + b - |a - b|).
\]

Using this observation one can now easily show, by a slight modification of the previous arguments, that the maps \( x \mapsto \max\{f(x), g(x)\} \) and \( x \mapsto \min\{f(x), g(x)\} \) are continuous.

At times it is also useful to have a characterization of continuous maps in terms of closed sets.

**Lemma 2.32.** A map \( f: X \to Y \) between two topological spaces \( X \) and \( Y \) is continuous if and only if for each closed set \( A \) in \( Y \) the preimage \( f^{-1}(A) \) is closed in \( X \).

**Proof.** This lemma is a straightforward consequence of **Lemma 1.3** (7) and the definitions. We leave it to the reader to fill in the details.
For completeness’ sake we also state the following lemma which we will prove in Exercise 2.11.

**Lemma 2.33.** (⋆) Let \( f: X \to Y \) be a map between topological spaces. For any subset \( B \subset Y \) we have \( f^{-1}(\overline{B}) \subseteq \overline{f^{-1}(B)} \) and the analogous statement holds with the closures replaced by the interiors.

By Lemma 2.30 (3) we know that the restriction of a continuous map to any subset is still continuous. The following lemma can be viewed as a converse: if “enough” restrictions of a given map are continuous, then the original map is also continuous.

**Lemma 2.34.** Let \( X \) be a topological space and let \( \{X_i\}_{i \in I} \) be a family of subsets. The following two statements are equivalent:

1. A subset \( U \subset X \) is open if each \( U \cap X_i \) is open in \( X_i \).
2. A subset \( U \subset X \) is closed if each \( U \cap X_i \) is closed in \( X_i \).

Furthermore, if (1) or equivalently (2) holds, then also the following statement holds:

3. A map \( f: X \to Y \) to some topological space \( Y \) is continuous if each restriction \( f|_{X_i}: X_i \to Y \) is continuous.

**Proof.**

(1) \( \Rightarrow \) (2) We assume that (1) holds. Now let \( U \subset X \) be a subset. We have

\[
(X \setminus U) \cap X_i = X_i \setminus (X_i \cap U)
\]

for every \( i \in I \) the set \( X_i \cap U \) is closed in \( X_i \), \( \Rightarrow \) for every \( i \in I \) the set \( (X \setminus U) \cap X_i \) is open in \( X_i \), \( \Rightarrow \) \( X \setminus U \) is open in \( X \), \( \Rightarrow \) \( U \) is closed in \( X \).

(2) \( \Rightarrow \) (1) This proof is basically the same as the above argument.

(1) \( \Rightarrow \) (3) Let \( f: X \to Y \) be a map to some topological space \( Y \). We suppose that each \( f|_{X_i} \) is continuous. Let \( U \subset Y \) be an open subset. We need to show that \( f^{-1}(U) \) is an open subset of \( X \). By (1) it suffices to show that each intersection \( f^{-1}(U) \cap X_i \) is an open subset of \( X_i \). But this follows from the observation that \( f^{-1}(U) \cap X_i = (f|_{X_i})^{-1}(U) \) and the hypothesis that \( f|_{X_i} \) is continuous.

Initially the main application of Lemma 2.34 is the following lemma which we will use abundantly.

**Lemma 2.35. (Pasting Lemma)** Let \( f: X \to Y \) be a map between topological spaces.

1. If there exists an open subsets \( \{W_i\}_{i \in I} \) of \( X \) such that each restriction \( f|_{W_i} \) is continuous, then \( f \) itself is continuous.
2. If there exists a locally finite closed cover \( \{A_i\}_{i \in I} \) of \( X \) such that each restriction \( f|_{A_i} \) is continuous, then \( f \) itself is continuous.
In practice often the following variation on (2) gets used:

(2') If $X$ is Hausdorff and if there exists a locally finite cover $\{A_i\}_{i \in I}$ of $X$ such that each $A_i$ is compact and such that each restriction $f|_{A_i}$ is continuous, then $f$ itself is continuous.

Remark.

(1) In practice Lemma 2.35 (2) often gets used in the following way: Suppose we are given two topological spaces $X$ and $Y$ and closed subsets $A_1, \ldots, A_m$ of $X$ such that $X = A_1 \cup \cdots \cup A_m$. Furthermore we are given continuous maps $f_i : A_i \to Y$, $i = 1, \ldots, m$. If the $f_i$ agree on the overlaps, then the map

$$X \to Y$$

$$P \mapsto f_i(P) \text{ if } P \in A_i$$

is well-defined and it follows from Lemma 2.35 (2) that it is continuous.

(2) Note that in Lemma 2.35 (1) we are allowed to deal with arbitrarily many open subsets whereas in Lemma 2.35 (2) we are restricted to finitely many closed subsets. It is clear that Lemma 2.35 (2) cannot be generalized to arbitrarily many closed subsets, after all, the restriction of a map $f : \mathbb{R} \to \mathbb{R}$ to any one-point subset $\{x\}$ is continuous, but clearly not every map $f : \mathbb{R} \to \mathbb{R}$ is continuous.

Proof. Let $f : X \to Y$ be a map between topological spaces.

(1) This statement follows immediately from the combination of Lemma 2.6 (1a) and Lemma 2.34.

(2) Similar to (1) this statement follows immediately from the combination of Lemma 2.6 (2a) and Lemma 2.34.

(2') This statement follows immediately from (2) and Lemma 2.17 (2).

The notion of continuity is of course already familiar from earlier analysis courses. The following proposition shows that for maps between metric spaces the earlier “$\epsilon$–$\delta$”-definition of continuity agrees with the above definition of continuity.

Proposition 2.36. Let $f : X \to Y$ be a map between metric spaces. Then the following holds:

$$f \text{ is continuous } \iff \forall x \in X \forall \epsilon > 0 \exists \delta > 0 \forall x' \in B_\delta(x) \ d(f(x), f(x')) < \epsilon.$$  

Remark. We use Proposition 2.36 to import from real analysis the various continuous functions on $\mathbb{R}$ and $\mathbb{C}$, e.g. polynomials, trigonometric functions and the exponential function. The replacement of the classic “$\epsilon$–$\delta$”-definition of continuity by the definition in terms of open sets can even be helpful in the context of real analysis. For example, let us consider the function

$$f : \mathbb{R} \to \mathbb{R}$$

$$x \mapsto \begin{cases} \frac{1}{2}x^2, & \text{if } x \geq 0, \\ -x, & \text{if } x \leq 0. \end{cases}$$

With the “$\epsilon$–$\delta$”-definition it is slightly annoying to prove continuity at $0$. But applying Lemma 2.35 (2) to the closed subsets $A_1 = (-\infty, 0]$ and $A_2 = [0, \infty)$ it is totally evident that this function is continuous. We refer to Figure 26 for an illustration.
Remark. The purist will correctly complain that the definition of the map in the previous remark is irregular, since the two cases treated in the definition of the map $f$ are not disjoint. Nonetheless, on numerous occasions we will use such irregular definitions, usually to highlight the fact that we can use Lemma 2.35 to show that the map is continuous.

The proof of Proposition 2.36 requires some preparations. In particular it builds on the following proposition that frequently makes it much easier to show that a given map is continuous.

**Proposition 2.37.** Let $f: X \to Y$ be a map between topological spaces. Let $C$ be a subbasis for the topology of $Y$ (e.g. $C$ could be a basis for the topology). Then the following holds:

\[ f \text{ is continuous} \iff \text{for each } C \in C \text{ the preimage } f^{-1}(C) \text{ is open in } X. \]

**Proof (⋆).** Let $f: X \to Y$ be a map between topological spaces and let $C$ be a subbasis for the topology of $Y$. As in Lemma 2.25 we denote by $B := B(C)$ all subsets of $Y$ that can be obtained by intersecting finitely many sets of $C$.

The “$\Rightarrow$”-direction of the proposition follows from the observation that elements of a subbasis are in fact open. Thus let us turn to the “$\Leftarrow$”-direction. Now we assume that for each $C \in C$ the preimage $f^{-1}(C)$ is open in $X$. We start out with a little observation. Suppose we are given $C_1, \ldots, C_k \in C$, then

\[ f^{-1}(C_1 \cap \cdots \cap C_k) \supseteq f^{-1}(C_1) \cap \cdots \cap f^{-1}(C_k) \]

is also open in $X$. This shows, by definition, that for each $B \in B = B(C)$ the preimage $f^{-1}(B)$ is open in $X$.

Now we turn to the actual proof that $f$ is continuous. Thus let $U \subseteq Y$ be an open subset. By Lemma 2.24 there exists a family $\{B_j\}_{j \in J}$ of sets in $B$ with

\[ U = \bigcup_{j \in J} B_j. \]

Then we see that

\[ f^{-1}(U) = f^{-1}\left( \bigcup_{j \in J} B_j \right) = \bigcup_{j \in J} f^{-1}(B_j), \]

union of open sets, thus open in $X$.

■
Now that we have Proposition 2.37 under the belt we can easily provide a proof of Proposition 2.36.

**Proof of Proposition 2.36.** Let \( f : X \to Y \) be a map between metric spaces. We need to show that

\[
 f \text{ is continuous } \iff \forall x \in X \exists \delta > 0 \forall y \in B_\delta(x) \quad d(f(x), f(y)) < \varepsilon.
\]

We prove the two directions separately:

- “\( \Rightarrow \)” Let \( x \in X \) and let \( \varepsilon > 0 \). We consider \( V := f^{-1}(B_{\varepsilon}(f(x))) \subset X \). Since \( f \) is continuous we know that \( V \) is open. By the definition of the topology on a metric space there exists a \( \delta > 0 \) such that \( B_\delta(x) \subset V \). This delta has the desired property.

- “\( \Leftarrow \)” On page 103 we saw that the open balls form a basis for the topology of metric spaces. Thus by Proposition 2.37 it suffices to show that if \( y \in Y \) and \( \mu > 0 \), then \( f^{-1}(B_\mu(y)) \) is an open subset of \( X \). By the definition of the topology on \( X \) it suffices to prove the following claim.

**Claim.** Given any \( x \in f^{-1}(B_\mu(y)) \) there exists an \( \varepsilon > 0 \) with \( B_\varepsilon(x) \subset f^{-1}(B_\mu(y)) \).

We set \( \delta = \mu - d(f(x), y) \). Note that \( \delta > 0 \). By the triangle inequality we have \( B_\delta(f(x)) \subset B_\mu(y) \). Furthermore by our hypothesis on \( f \) there exists an \( \varepsilon > 0 \) such that \( f(B_\varepsilon(x)) \subset B_\delta(f(x)) \). Thus we see that \( B_\varepsilon(x) \subset f^{-1}(B_\mu(y)) \). We refer to Figure 27 for an illustration of this argument.

![Figure 27. Illustration of the proof of Proposition 2.36](image)

We continue with the following straightforward definition.

**Definition.** Let \( f : X \to Y \) be a map between topological spaces.

1. We say \( f \) is **open** if the image of every open subset of \( X \) is open in \( Y \).
2. We say \( f \) is **closed** if the image of every closed subset of \( X \) is closed in \( Y \).

**Examples.**

1. The projection \( \mathbb{R}^2 \to \mathbb{R} \) given by \( (x, y) \mapsto x \) is easily seen to be an open map but it is not a closed map.
2. On the other hand the inclusion \( i : \mathbb{R} \to \mathbb{R}^2, i(x) = (x, 0) \) is evidently not an open map but it is a closed map.

**Lemma 2.38.** Let \( X \) be a topological space.

1. If \( U \subset X \) is an open subset, then the inclusion map \( i : U \to X \) is open.
2. If \( A \subset X \) is a closed subset, then the inclusion map \( i : A \to X \) is closed.

---

21 Why is not a closed map?
Proof.

(1) Suppose that $V$ is an open subset of $U$. By definition of the subspace topology there exists an open subset $W \subset X$ with $V = U \cap W$. But then $i(V) = V = U \cap W$ is the intersection of two open subsets of $X$, thus it is an open subset of $X$.

(2) The proof of this statement is analogous to the proof of Statement (1), we just not to appeal to Lemma 2.4 (2) to make the necessary adjustments. ■

We have the following analogue to Proposition 2.37.

**Lemma 2.39.** Let $f : X \to Y$ be a map between topological spaces. Let $C$ be a subbasis for the topology of $X$ (e.g. $C$ could be a basis for the topology). Then the following holds

\[
\text{f is open } \iff \text{for each } C \in C \text{ the image } f(C) \text{ is open in } Y.
\]

Proof. The logic of the proof is very similar to the proof of Proposition 2.37. Eventually the proof boils down to Lemmas 2.24 and 1.3. ■

The first statement of the following lemma is perhaps the most important feature of compact sets.

**Lemma 2.40.**

1. Let $f : X \to Y$ be a continuous map. If $X$ is compact, then $f(X)$ is also compact.
2. Let $f : X \to \mathbb{R}$ be a continuous map. If $X$ is compact and non-empty, then $f$ assumes its maximum and its minimum, i.e. there exist $x_0, x_1 \in X$ such that

\[
f(x_0) \leq f(x) \leq f(x_1) \quad \text{for all } x \in X.
\]
3. Let $f : X \to Y$ be a continuous map. If $X$ is compact and if $Y$ is Hausdorff, then $f(X)$ is a closed subset of $Y$.

**Example.** Let $X$ be a topological space, let $Y$ be a subset and let $K \subset Y$ be another subset. If $K$ is a compact subset of $Y$, i.e. then $K$ is also a compact subset of $X$. This elementary observation follows immediately from Lemma 2.40 and the fact, observed above, that inclusion maps are continuous.

**Remark.** The statement of Lemma 2.40 (1) is really quite astounding. More precisely, we already saw that the image of an open set under a continuous map is not necessarily open. Similarly, the image of a closed set under a continuous map is not necessarily closed. For example consider the inclusion map $i : X = (0, 1) \to Y = \mathbb{R}$. Evidently $X$ is a closed subset of itself, but $i(X)$ is not a closed subset of $\mathbb{R}$. We will discuss such examples in more detail in Exercise 2.26.

Proof.

(1) Let $\{U_i\}_{i \in I}$ be an open cover of $f(X)$. We need to show that $f(X)$ is contained in the union of finitely many $U_i$’s. We have

\[
X = f^{-1}(f(X)) \subset f^{-1}\left(\bigcup_{i \in I} U_i\right) = \bigcup_{i \in I} f^{-1}(U_i).
\]

Lemma 1.3 (1) Lemma 1.3 (5)
By the continuity of $f$ we obtain that $\{f^{-1}(U_i)\}_{i \in I}$ is an open cover of $X$. Since $X$ is compact there exist $i_1, \ldots, i_k \in I$ such that

$$X = f^{-1}(U_{i_1}) \cup \cdots \cup f^{-1}(U_{i_k}).$$

We see that

$$f(X) = f(f^{-1}(U_{i_1}) \cup \cdots \cup f^{-1}(U_{i_k}))$$

$$\uparrow$$

Lemma 1.3 (3) \hspace{1cm} \uparrow$$

Lemma 1.3 (2)

(2) It follows from (1) and the Heine-Borel Theorem 2.20 that $f(X) \subset \mathbb{R}$ is bounded and closed. Thus $y_0 := \inf(f(X))$ and $y_1 := \sup(f(X))$ exist and they lie in $f(X)$. Any choice of points $x_0 \in f^{-1}(\{y_0\})$ and $x_1 \in f^{-1}(\{y_1\})$ have the desired properties.

(3) This statement is an immediate consequence of Lemma 2.17 (1) and the first statement. ■

On many occasions we will use the following elementary lemma.

Lemma 2.41. (*) Let $f : K \to X$ be a continuous map from a compact topological space $K$ to a topological space $X$. Suppose there exists a sequence $U_1, U_2, \ldots$ of subsets of $X$ with the following properties:

1. Each $U_i$ is open,
2. The sequence is nested, i.e. for each $i \in \mathbb{N}$ we have $U_i \subset U_{i+1}$,
3. We have $X = \bigcup_{i \in \mathbb{N}} U_i$.

Then there exists a $k \in \mathbb{N}$ with $f(K) \subset U_k$.

Proof (*). For $i \in \mathbb{N}$ we write $V_i = f^{-1}(U_i)$. Since $f$ is continuous it follows from (1) that each $V_i$ is an open subset of $K$. By (3) the $V_i$ cover all of $K$. Since $K$ is compact there exist $i_1, \ldots, i_n$ such that $K = V_{i_1} \cup \cdots \cup V_{i_n}$. We set $k := \max\{i_1, \ldots, i_n\}$. Since the $U_i$ are nested the $V_i$ are also nested. It follows that $K$ is already contained in $V_k$, put differently, $f(K)$ is contained in $U_k$. ■

In most instances we are dealing with continuous maps. Since constantly writing and reading “continuous maps” is tiresome for the author and the reader we adopt throughout the remainder of these lecture notes the following convention:

**Convention.** Henceforth any map between two topological spaces is assumed to be continuous, unless we say explicitly otherwise.

2.6. **Homeomorphisms.** We introduce the main objects of interest of this section.

**Definition.**

\[^{22}\text{A common application is that } K \text{ is a compact subset of } X \text{ and } f \text{ is the inclusion map.}\]
We say a map \( f : X \to Y \) between two topological spaces \( X \) and \( Y \) is a homeomorphism if the following three properties are satisfied:

\begin{enumerate}
\item \( f \) is continuous,
\item \( f \) is bijective,
\item the inverse map \( f^{-1} : Y \to X \) is also continuous.
\end{enumerate}
If there exists a homeomorphism between \( X \) and \( Y \) we say that \( X \) and \( Y \) are homeomorphic and sometimes we write \( X \cong Y \).

We say a map \( f : X \to Y \) between two topological spaces \( X \) and \( Y \) is an embedding if \( f \) is an embedding, i.e. if \( f : X \to f(X) \), where \( f(X) \) is equipped with the subspace topology, is a homeomorphism. We say the embedding is closed if \( f(X) \) is a closed subset of \( Y \) and we say the embedding is open if \( f(X) \) is an open subset of \( Y \).

**Remark.**

(1) If two topological spaces are homeomorphic, then they have the same topological properties, i.e. they share all properties that are defined purely in terms of the topology. For example, if \( X \) and \( Y \) are homeomorphic, then \( X \) is Hausdorff if and only if \( Y \) is Hausdorff, \( X \) is compact if and only if \( Y \) is compact and so on.

(2) It follows from Lemma 2.38 that an open (respectively closed) embedding is also an open (respectively closed) map.

**Convention.** At times we refer to a topological space that is homeomorphic to a ball or to a sphere also as a ball or a sphere.

**Examples.**

(1) Given \( n \in \mathbb{N} \) we denote by

\[
S^n_{\geq 0} := \left\{ (x_1, \ldots, x_{n+1}) \in S^n \mid x_{n+1} \geq 0 \right\}
\]

the upper hemisphere and we define similarly the lower hemisphere \( S^n_{\leq 0} \) to be

\[
S^n_{\leq 0} := \left\{ (x_1, \ldots, x_{n+1}) \in S^n \mid x_{n+1} \leq 0 \right\}.
\]

The maps

\[
\varphi : B^n \ni x \mapsto \left( x, \sqrt{1-\|x\|^2} \right) \quad \text{and} \quad p : S^n_{\geq 0} \to B^n \ni (x_1, \ldots, x_n, x_{n+1}) \mapsto (x_1, \ldots, x_n)
\]

are easily seen to be continuous and inverses to one another. Thus both maps are homeomorphisms. The same way we see that the lower hemisphere is also homeomorphic to the closed ball \( \overline{B^n} \).

(2) Let \( A \in \text{GL}(n, \mathbb{R}) \) be an invertible real matrix. It follows from the discussion on page 109 that the map \( \mathbb{R}^n \to \mathbb{R}^n \) given by multiplication by \( A \) is a homeomorphism. This simple observation has a useful consequence: Let \( V \) be an \( n \)-dimensional real vector space. We pick an isomorphism \( \varphi : \mathbb{R}^n \to V \) and we equip \( V \) with the unique topology that turns \( \varphi \) into a homeomorphism. By the above discussion this definition of a topology does not depend on the choice of \( \varphi \). Unless we say something else any finite-dimensional real vector space will be equipped with this topology. Note that with these topologies any isomorphism between real vector spaces of the same finite dimension is also a homeomorphism.
We consider the map
\[ f : [0, 1) \rightarrow S^1, \quad t \mapsto e^{2\pi it}. \]

The map \( f \) is a continuous bijection but it is not a homeomorphism. One can see
this by either directly showing that \( f^{-1} \) is not continuous or by noting that \([0, 1)\) is
not compact whereas \( S^1 \) is compact. We illustrate this example in Figure 28. The
importance of this example cannot be overestimated. It is an unfortunate fact of life
that all too often one writes down a continuous map \( f : X \rightarrow Y \) between topological
spaces, checks that it is a bijection, and walks away under the warm, but mistaken,
impression that one now has found a homeomorphism.

(4) To drive home the point we made in (3) we show in Figure 29 an injective continuous
map \( f : [-1, 1) \rightarrow \mathbb{R}^2 \) which is not an embedding. Especially once we move to more
abstract topological spaces it is easy to lose track of the fact that an injective
homeomorphism is not necessarily an embedding.

In many situations one is given an explicit continuous bijection \( f : X \rightarrow Y \) between
two topological spaces and one would like to show that \( f \) is in fact a homeomorphism.
Unfortunately usually it is very painful to write down the explicit inverse map \( f^{-1} : Y \rightarrow X \),
let alone to verify that it is continuous. Fortunately we have several results which often
help us in circumventing this difficulty.

**Lemma 2.42.** (*) Let \( f : X \rightarrow Y \) be a map between topological spaces that is continuous.
We assume that \( f \) is open or that \( f \) is closed.

1. If \( f \) is an injection, then \( f \) is an open (respectively closed) embedding.
2. If \( f \) is a bijection, then \( f \) is a homeomorphism.

**Proof.** (*). Let \( f : X \rightarrow Y \) be a map between topological spaces that is continuous.

1. We assume that \( f \) is a bijection. Furthermore we now assume that \( f \) is open. We
want to show that \( f \) is a homeomorphism. It remains to show that \( g := f^{-1} : Y \rightarrow X \)
is continuous. Thus let \( U \subset X \) be an open set. We need to show that \( g^{-1}(U) \) is an
open subset of \( Y \). But this is obvious, since \( g^{-1}(U) = f(U) \) is an open subset since
we assume that \( f \) is an open map.
Now suppose that the map $f$ is closed. The proof is almost identical to the above argument, except that now we have to use the continuity criterion provided by Lemma 2.32.

1. We assume that $f$ is an injection and we assume that $f$ is open. We write $Z := f(X)$. Since $f : X \to Y$ is open it follows basically immediately from the definition of the subspace topology that $f : X \to Z$ is also open. Thus we obtain from (2) that $f$ is an embedding. Furthermore, since $f$ is open we see that $f$ is an open embedding. The proof in the case that $f$ is closed is basically identical. ■

Example. Let $U$ be an open subset of $\mathbb{R}$ and let $f : U \to \mathbb{R}$ be a strictly monotonously increasing map, i.e. for any $x < y$ in $U$ we have $f(x) < f(y)$. Note that open intervals form a basis for the topology of $U$. By the Intermediate Value Theorem the image of an open interval under $f$ is again an open interval. Thus it follows from Lemma 2.39 that $f : U \to \mathbb{R}$ is an open map. Lemma 2.42 implies that $f : U \to f(U)$ is a homeomorphism.

The next proposition is certainly one of the most frequently used results in topology.

Proposition 2.43. Let $f : X \to Y$ be a continuous map between topological spaces. If $X$ is compact and if $Y$ is Hausdorff, then the following statements hold:

1. The map $f : X \to Y$ is closed.
2. If $f$ is an injection, then $f$ is a closed embedding.
3. If $f$ is a bijection, then $f$ is a homeomorphism.

Remark. In the above example we saw that certainly we cannot drop the condition that $X$ is compact from the proposition. But what about the “Hausdorff condition”? In Exercise 2.41 we will come up with an example of a bijective continuous map $f : X \to Y$ between two topological spaces where $X$ is compact but such that $f$ is nonetheless not a homeomorphism.

Proof. Let $f : X \to Y$ be a continuous map between topological spaces. We assume that $X$ is compact and that $Y$ is Hausdorff.

1. Let $A$ be a closed subset of $X$. We need to show that $f(A)$ is a closed subset of $Y$.
   In fact we see that
   $$A \subseteq X \text{ closed} \implies A \text{ is compact} \implies f(A) \text{ is compact} \implies f(A) \text{ is closed}.$$
   by Lemma 2.17 since $X$ is compact \hspace{1cm} by Lemma 2.17 \hspace{1cm} by Lemma 2.17 (1) \hspace{1cm} since $Y$ is Hausdorff

2. If $f$ is an injection, then it follows immediately from (1) together with Lemma 2.42 (1) that $f$ is a closed embedding.
3. This follows immediately from (2). ■

We formulate our first application of Proposition 2.43 (3) as a lemma.
Lemma 2.44. Let \( n \in \mathbb{N} \). We consider the map
\[
\Phi: S^n \rightarrow \mathbb{R}^n \cup \{\infty\}
\]
\[
(x_1, \ldots, x_{n+1}) \mapsto \begin{cases} 
\left( \frac{x_1}{1-x_{n+1}}, \ldots, \frac{x_n}{1-x_{n+1}} \right), & \text{if } x_{n+1} < 1, \\
\infty, & \text{if } x_{n+1} = 1.
\end{cases}
\]
where we equip \( \mathbb{R}^n \cup \{\infty\} \) with the topology that we introduced on page 95. We refer to \( \Phi \) as the stereographic projection. This map has the following properties:

1. The map \( \Phi \) sends the North Pole \( N = (0, \ldots, 0, 1) \in S^n \) to \( \infty \).
2. For any \( P \in S^n \) that does not equal the North Pole \( N \) the point \( \Phi(P) \in \mathbb{R}^n \) is the unique point such that the ray emanating from \( N \) and that goes through \( P \) intersects the plane \( \mathbb{R}^n \times \{0\} \) in \( (\Phi(P), 0) \). We refer to Figure 30 for an illustration.
3. For any \( (v_1, \ldots, v_n, 0) \in S^n \cap (\mathbb{R}^n \times \{0\}) \) we have \( \Phi(v_1, \ldots, v_n, 0) = (v_1, \ldots, v_n) \).
4. The map \( \Phi \) is continuous.
5. The map \( \Phi \) is a homeomorphism.
6. The restriction of \( \Phi \) to a map \( S^n \setminus \{N\} \rightarrow \mathbb{R}^n \) is also a homeomorphism.

![Figure 30. Stereographic projection from \( S^2 \setminus \{(0,0,1)\} \) onto \( \mathbb{R}^2 \).](image)

Con**vention.** Let \( n \in \mathbb{N} \). On many occasions we will use the homeomorphism from Lemma 2.44 to make the identification \( S^n = \mathbb{R}^n \cup \{\infty\} \). In particular we have \( S^2 = \mathbb{C} \cup \{\infty\} \).

**Proof.**

1. This statement follows immediately from the definition of \( \Phi \).
2. This statement follows from an elementary calculation which we leave to the reader.
3. This statement follows immediately from the definition of \( \Phi \).
4. We will prove this statement in Exercise 2.51.
5. We leave it to the reader to verify that \( \Phi \) is a bijection. Note that \( S^n \) is compact by the Heine-Borel Theorem 2.20. Furthermore note that on page 95 we pointed out that \( \mathbb{R}^n \cup \{\infty\} \) is Hausdorff. Hence it follows from Proposition 2.43 (3) that \( \Phi \) is a homeomorphism.
6. This statement follows immediately from (5). \( \blacksquare \)

If we are not in the setting of Proposition 2.43 (3), then it is often a major nuisance to try to show that a given map \( f: X \rightarrow Y \) is in fact a homeomorphism. The following proposition relaxes the condition on \( X \) being compact.
Proposition 2.45. Let $X$ be a topological space, let $n \in \mathbb{N}$ and let $f : X \to \mathbb{R}^n$ be an injective continuous map. Furthermore suppose that $X$ is the union of compact subsets $\{K_i\}_{i \in I}$ such that the following condition is satisfied:

(*) Given any $r > 0$ there exist only finitely many $i \in I$ with $f(K_i) \cap B^n_r \neq \emptyset$. Then $f$ is an embedding.

Remark. The statement and the proof of Proposition 2.45 also holds if we replace $\mathbb{R}^n$ by an arbitrary metric space $(Y, d)$ and if we replace the open balls $B^n_r$ by open balls in $(Y, d)$ centered around a fixed point.

Example. Let $X = \mathbb{R}_{\geq 0}$. We consider the “outward spiraling” map $f : X \to \mathbb{R}^2$ that is sketched in Figure 31. Given $i \in \mathbb{N}_0$ we set $K_i := [i, i + 1]$. These compact subsets cover all of $X = \mathbb{R}_{\geq 0}$ and they satisfy the condition (*) of the proposition. Thus we obtain from Proposition 2.45 that the map $f$ is an embedding.

![Figure 31](image_url)

Proof. By Lemma 2.42 (1) it remains to show that the map $f : X \to f(X)$ is closed. In fact, by definition of the subspace topology we only need to show that the map $f : X \to \mathbb{R}^n$ is closed.

Thus let $A$ be a closed subset of $X$. We need to show that $f(A)$ is a closed subset of $\mathbb{R}^n$. Given $s \in \mathbb{N}_0$ we consider $C_s := \overline{B^n_{s+1}} \setminus B^n_s$. Clearly $\{C_s\}_{s \in \mathbb{N}_0}$ is a locally finite closed cover of $\mathbb{R}^n$. By Lemma 2.6 (2b) it suffices to show that each $C_s \cap f(A)$ is closed. Thus let $s \in \mathbb{N}_0$. By hypothesis we know that $J := \{i \in I \mid f(K_i) \cap \overline{B^n_s} \neq \emptyset\}$ is a finite set. Now we see that

\[
\begin{align*}
C_s \cap f(A) &= C_s \cap f\left( \bigcup_{i \in I} K_i \right) \\
&= C_s \cap f\left( \bigcup_{j \in J} K_j \right) \\
&= C_s \cap f(\text{compact subset}) \\
&= C_s \cap \text{closed subset of } \mathbb{R}^n \\
&= \text{closed subset of } C_s.
\end{align*}
\]

by Lemma 2.16 (1), since each $K_i$ is compact and $J$ is finite

\[
\begin{align*}
\uparrow \text{definition of } J \\
\downarrow \text{Lemma 2.40} \\
\downarrow \text{Lemma 2.17} \\
\uparrow \text{definition of subspace topology}
\end{align*}
\]

2.7. Normal topological spaces (*). There are many other “separation axioms” that are similar to the Hausdorff condition. We refer to [Mun75] Chapter 4.2 for more details. The only property we will need at some point is the following.

Definition. A topological space $X$ is called normal if any two disjoint closed subsets $A$ and $B$ of $X$ are separated by open neighborhoods, i.e. if there exist disjoint open neighborhoods $U$ of $A$ and $V$ of $B$. 

The following lemma nicely combines two key notions that we have introduced so far.

**Lemma 2.46.** (*) Let $X$ be a Hausdorff space.

1. Let $A$ be a subset of $X$ and let $B$ be a compact subset of $X$. There exists an open subset $U$ of $X$ with $A \subseteq U$ and $U \cap B = \emptyset$.
2. If $X$ is compact, then it is also normal.

**Proof.** Let $X$ be a Hausdorff space. We start out with the following claim.

**Claim.** Let $A$ be a subset of $X$ and let $B$ be a compact subset of $X$. Given any $a \in A$ there exists an open neighborhood $U_a$ of $a$ and an open neighborhood $V_a$ of $B$ that are disjoint.

Let $a \in A$. Since $X$ is Hausdorff we can find for any $b \in B$ disjoint open neighborhoods $R_b$, $S_b$ of $a$ and $b$. Furthermore, since $B$ is compact there exist $b_1, \ldots, b_n \in B$ such that $B \subseteq S_{b_1} \cup \cdots \cup S_{b_n}$. The open sets

$$U_a := R_{b_1} \cap \cdots \cap R_{b_n} \quad \text{and} \quad V_a := S_{b_1} \cup \cdots \cup S_{b_n}$$

have the desired properties.

Now we turn to the proofs of the two statements.

1. Let $A$ be a subset of $X$ and let $B$ be a compact subset of $X$. Given any $a \in A$ we pick $U_a$ and $V_a$ as in the claim. The set $U := \bigcup_{a \in A} U_a$ is evidently an open neighborhood of $A$. Furthermore, since for each $a \in A$ we have $U_a \cap B = \emptyset$ we see also that $U \cap B = \emptyset$. In other words, $U$ has all the desired properties.

2. Now assume that $X$ is also compact. We need to show that $X$ is normal. Thus let $A$ and $B$ be two disjoint closed subsets of $X$. Note that Lemma 2.17(1) implies that $A$ and $B$ are also compact.

Since $B$ is compact we can make use of the above claim. In the following we use the notation of the above claim. Since $A$ is compact we can find $a_1, \ldots, a_m \in A$ such that $A \subseteq U_{a_1} \cup \cdots \cup U_{a_m}$. The open sets

$$U := U_{a_1} \cup \cdots \cup U_{a_m} \quad \text{and} \quad V := V_{a_1} \cap \cdots \cap V_{a_m}$$

have the desired properties.

**Remark.** Mathematical psychology tells us that Hausdorff does not imply normal. Indeed, an example of a topological space that is Hausdorff but not normal is given in [Mun75 Chapter 4.2].

The following proposition gives us an often convenient approach to showing that a topological space is normal.

**Proposition 2.47.** Let $(X, d)$ be a metric space. If we equip $X$ with the corresponding topology, then $X$ is normal.
Proof. We leave the proof of this proposition as a challenging exercise to the reader. Alternatively, we refer to [Wl70] Theorems 20.9 and 20.10 for a proof.

The following lemma is basically just a convenient reformulation of being normal.

**Lemma 2.48.** Let $X$ be a topological space and let $A \subset X$ be a closed subset and $U \subset X$ be an open subset with $A \subset U$. If $X$ is normal, then there exists an open subset $V$ with $A \subset V \subset \overline{V} \subset U$.

**Proof.** Let $X$ be a topological space and let $A \subset X$ be a closed subset and $U \subset X$ be an open subset with $A \subset U$. We set $B := X \setminus U$. This is a closed subset with $A \cap B = \emptyset$. Since $X$ is normal there exist disjoint neighborhoods $V$ of $A$ and $W$ of $B$. It remains to show that $\overline{V} \subset U$. In fact we have $V \subset X \setminus W \subset U$. But since $W$ is open we know that $X \setminus W$ is closed. By definition of $\overline{V}$ we have $\overline{V} \subset X \setminus W$.

**Lemma 2.49.** Let $X$ be a topological space and let $U_1, \ldots, U_m$ be open subsets such that $X = \bigcup_{i=1}^m U_i$. If $X$ is normal, then there exist open subsets $V_i \subset U_i$ such that $\overline{V_i} \subset U_i$ and such that $X = \bigcup_{i=1}^m V_i$.

**Remark.** A much stronger version of this lemma can be found in [Dug66] Theorem 6.1 or alternatively in [Grote69] Satz 43.

**Proof (#).** To simplify the notation we only discuss the case $m = 2$. We leave it to the reader to prove the general case.

Thus let $X$ be a topological space that is normal. Furthermore, let $U_1$ and $U_2$ be two open subsets with $U_1 \cup U_2 = X$. This data is equivalent to the statement that $X \setminus U_1$ and $X \setminus U_2$ are disjoint closed subsets of $X$. Since $X$ is normal there exists, by Lemma 2.48, a subset $W_1 \subset X$ with $X \setminus U_1 \subset W_1 \subset \overline{W_1} \subset U_2$. In particular we have $\overline{W_1} \cap (X \setminus U_2) = \emptyset$. Again, because of Lemma 2.48, there exists a subset $W_2 \subset X$ with $X \setminus U_2 \subset W_2 \subset \overline{W_2} \subset X \setminus W_1$. In particular we have $\overline{W_2} \cap \overline{W_1} = \emptyset$. We claim that $V_1 = X \setminus \overline{W_1}$ and $V_2 = X \setminus \overline{W_2}$ have the desired properties.

First note that for $i = 1, 2$ we have

$$V_i = X \setminus \overline{W_i} \subset X \setminus W_i \subset U_i.$$

Finally note

$$V_1 \cup V_2 = (X \setminus \overline{W_1}) \cup (X \setminus \overline{W_2}) = X \setminus (\overline{W_1} \cap \overline{W_2}) = X.$$

We refer to Figure 34 for an illustration.
We conclude this discussion of normal topological spaces with two significantly deeper results, namely Urysohn’s Lemma and the Tietze Extension Theorem. We will not really make use of these results, thus we will not provide the (non-trivial!) proofs.

We start out with what is known as Urysohn’s Lemma. Despite its modest name it is actually highly non-trivial.

**Lemma 2.50. (Urysohn’s Lemma)** Let $X$ be a topological space. If $X$ is normal, then for any two disjoint closed subsets $A$ and $B$ there exists a continuous function $f: X \to [0, 1]$ with $f|_A \equiv 0$ and $f|_B \equiv 1$.

**Proof.** Proofs of Urysohn’s Lemma are provided in many textbooks on general topology, see e.g. [Kel75, Lemma 4.4], [Mun75, Theorem 4.3.1] or [Jä05, p. 109].

**Theorem 2.51. (Tietze Extension Theorem)** Let $X$ be a topological space, let $A \subset X$ be a closed subset and let $f: A \to \mathbb{R}$ be a continuous map. If $X$ is normal, then there exists a continuous map $g: X \to \mathbb{R}$ with $g|_A = f$.

**Remark.** Let $X$ be a topological space and let $A$ and $B$ be two disjoint closed subsets. We consider the map on $A \cup B$ that is given by $f|_A \equiv 0$ and $f|_B \equiv 1$. If $X$ is normal, then we can extend $f$ by the Tietze Extension Theorem [2.51] to a continuous map on all of $X$. This shows that Urysohn’s Lemma is an immediate consequence of the Tietze Extension Theorem [2.51].

**Proof.** We refer to [Kel75 p. 242], [Mun75, Theorem 4.3.2] or [Jä05 p. 114] for proofs.

2.8. **Convex subsets.** We start out with the definition of a convex subset.

**Definition.**

1. We say that a subset $A \subset \mathbb{R}^n$ is convex, if for every two points $P$ and $Q$ in $A$ the segment $PQ := \{t \cdot P + (1 - t) \cdot Q \mid t \in [0, 1]\}$ also lies in $A$.

2. Given a subset $S$ of $\mathbb{R}^k$ the convex hull of $S$ is defined as the intersection of all convex subsets of $\mathbb{R}^k$ that contain $S$. Since the intersection of convex sets is again convex we see that the convex hull of $S$ is a convex subset of $\mathbb{R}^n$.

**Examples.**
(1) For any point \( x \in \mathbb{R}^n \) and any \( \epsilon > 0 \) the open ball \( B^o_\epsilon(x) \) is convex. Indeed, let 
\( P, Q \in B^o_\epsilon(x) \). Then for any \( t \in [0, 1] \) we have
\[
\| t \cdot P + (1-t) \cdot Q - x \| = \| t \cdot (P - x) + (1-t) \cdot (Q - x) \|
\]
\[
\leq t \cdot \| P - x \| + (1-t) \cdot \| Q - x \| < t \cdot \epsilon + (1-t) \cdot \epsilon = \epsilon.
\]
triangle inequality and homogeneity of \( \| - \| \)
since \( P, Q \in B^o_\epsilon(x) \)

We have thus shown that \( t \cdot P + (1-t) \cdot Q \in B^o_\epsilon(x) \). Basically the same way one shows that the closed ball \( \overline{B}_\epsilon(x) \) is also convex.

(2) It is straightforward to verify that any hyperrectangle \( [a_1, b_1] \times \cdots \times [a_n, b_n] \) is convex.

(3) In Exercise 2.36 we will show that the convex hull of points \( P_1, \ldots, P_n \in \mathbb{R}^k \) is given by the set
\[
\left\{ \sum_{i=1}^n t_i P_i \mid t_1, \ldots, t_n \in \mathbb{R}_{\geq 0} \text{ and } \sum_{i=1}^n t_i = 1 \right\}.
\]

(4) One of the most useful properties of convex subsets is that the intersection of arbitrarily many convex subsets is, basically by definition, again convex.

The following proposition gives a useful criterion for showing that subsets of \( \mathbb{R}^n \) are homeomorphic to an open or to a closed ball.

**Proposition 2.52.**

1. If \( A \) is a bounded open convex subset of \( \mathbb{R}^n \), then given any \( Q \in A \) there exists a canonical homeomorphism
\[
f_Q : A \rightarrow B^n := \{ x \in \mathbb{R}^n \mid \| x \| < 1 \}
\]
with \( f_Q(Q) = 0 \).

2. If \( A \) is a bounded closed convex subset of \( \mathbb{R}^n \), then given any point \( Q \) in the interior of \( A^n \) there exists a canonical homeomorphism
\[
f_Q : A \rightarrow \overline{B}^n = \{ x \in \mathbb{R}^n \mid \| x \| \leq 1 \}
\]
with the following properties:
   a. the homeomorphism \( f_Q \) sends \( Q \) to the origin,
   b. the homeomorphism \( f_Q \) restricts to a homeomorphism \( \partial A \rightarrow S^{n-1} \),
Examples.

(1) The open square \((0,1) \times (0,1)\) is clearly bounded and convex, thus it follows from Proposition 2.52 (1) that it is homeomorphic to the open disk \(B^2\).

(2) It follows from Proposition 2.52 (2) that any triangle, i.e., any subset of \(\mathbb{R}^2\) of the form \(A = \{ P + sv + tw \mid s, t \in [0,1] \text{ and } s + t \leq 1 \}\) where \(P \in \mathbb{R}^2\) and \(v, w\) are two linearly independent vectors, is homeomorphic to \(\overline{B}^2\).

\[
\begin{align*}
(0,1)^2 & \quad \text{is homeomorphic to} \quad \overline{B}^2
\end{align*}
\]

\[\text{Figure 36}\]

For readers who like gory details we present the more technical sibling of Proposition 2.52

**Proposition 2.53.**

1. Let \(A\) is a bounded open convex subset of \(\mathbb{R}^n\) and let \(Q \in A\). We consider the map
   \[
   \rho_A : A \setminus \{Q\} \to \mathbb{R}_{\geq 0}
   \]
   \[
   x \mapsto \sup \{ \| r x \| : r \in \mathbb{R}_{>0} \text{ and } r(x - Q) + Q \in A \}.
   \]
   This map is well-defined in the sense that the supremum exists for each \(x \in A \setminus \{Q\}\).
   Furthermore the map \(\rho_A\) is continuous and the map
   \[
   f_Q : A \to B^n
   \]
   \[
   x \mapsto \begin{cases}
   (x - Q) \cdot \frac{1}{\rho_A(x)}, & \text{if } x \neq Q, \\
   0, & \text{if } x = Q.
   \end{cases}
   \]
   is a homeomorphism with \(f_Q(Q) = 0\).

2. Let \(A\) be a bounded closed convex subset of \(\mathbb{R}^n\). If \(Q\) is a point in the interior of \(A\), then the same expression as in (1) defines a homeomorphism \(f_Q : A \to \overline{B}^n\) with \(f_Q(Q) = 0\). Furthermore \(f_Q\) restricts to a homeomorphism \(\partial A \to S^{n-1}\).

Examples.

\[\text{\footnotesize \text{\(^{23}\)Throughout the lecture notes we will on occasions write that “some objects exists canonically”. This means that in the proof we show the existence of the object by giving an explicit construction that does not rely on any choices.}}\]

\[\text{\footnotesize \text{\(^{24}\)Of course “bounded and closed” is in this instance, by the Heine-Borel Theorem \([\text{\footnotesize 220}]\) equivalent to “compact”. In this instance we prefer to talk of “bounded closed” to stress the analogy to statement (1) of the lemma.}}\]

\[\text{\footnotesize \text{\(^{25}\)Note that the interior might well be empty, i.e. such a point \(Q\) might not exist.}}\]

\[\text{\footnotesize \text{\(^{26}\)This says in particular that if \(A\) is a bounded closed convex subset of \(\mathbb{R}^n\) with non-empty interior, then \(A\) is homeomorphic to \(\overline{B}^n\).}}\]

\[\text{\footnotesize \text{\(^{27}\)The statement becomes slightly more readable if one sets \(Q = 0\).}}\]
(1) For \( i = 1, \ldots, n \) let \( a_i < b_i \) be real numbers. We consider the “hyperrectangle” \([a_1, b_1] \times \cdots \times [a_n, b_n]\). It follows from the discussion on page 124 and from Proposition 2.21 that the hyperrectangle is convex and compact. Proposition 2.53 (2) gives us an explicit homeomorphism
\[
f_{Q}: [a_1, b_1] \times \cdots \times [a_n, b_n] \to B^n
\]
that sends the boundary of the hyperrectangle to the sphere \( S^{n-1} \) and that sends the “midpoint” \( Q := \left( \frac{a_1+b_1}{2}, \ldots, \frac{a_n+b_n}{2} \right) \) to the origin. Throughout this course we will use this homeomorphism to identify the left-hand side with the right-hand side. It follows easily from the explicit description of \( f_Q \) that the restriction of \( f_Q \) to each open cone on a side is smooth.\(^{28}\) The homeomorphism from Proposition 2.53 (2) is illustrated in Figure 37.

\[
\text{the restriction of } f_{Q} \text{ to each of the four open triangles is smooth}
\]

\[\text{Figure 37}\]

(2) Let \( A \) be a bounded convex subset of \( \mathbb{R}^n \) such that the origin 0 lies in the interior of \( A \). Proposition 2.53 applied to \( Q = 0 \), implies in particular that the map
\[
f: \partial A \to S^{n-1} \quad x \mapsto \frac{x}{\|x\|}
\]
is a homeomorphism. This statement is illustrated in Figure 38.

\[\text{Figure 38}\]

The proof of Proposition 2.53 relies on the following lemma.

**Lemma 2.54.** (\( ^{*} \)) Let \( A \) be a bounded closed convex subset of \( \mathbb{R}^n \) such that the origin 0 lies in the interior of \( A \).

1. The map \( \rho_A: A \setminus \{0\} \to \mathbb{R}_{\geq 0} \) defined in Proposition 2.53 is continuous.

\(^{28}\) We leave it to the reader to make it precise what “open cone on a side” means. We will make use of this observation only once, and then it should be clear what we mean.
(2) The map

\[ f_0 : A \rightarrow \mathbb{B}^n \]

\[ x \mapsto \begin{cases} 
    x \cdot \frac{1}{\rho_A(x)}, & \text{if } x \neq 0, \\
    0, & \text{if } x = 0
\end{cases} \]

is continuous and it satisfies \( f_0^{-1}(S^{n-1}) = \partial A \).

**Proof of Lemma 2.54** (*). We start out with the following claim.

**Claim.** The map \( \rho_A : A \setminus \{0\} \rightarrow \mathbb{R} \) is defined, it is continuous, it is bounded from above and it is bounded from below by 1.

Since \( A \) is bounded it follows that \( \rho_A \) is defined and that it is bounded from above. It follows from the definition of \( \rho_A \) that \( \rho_A \) is bounded from below by 1. Therefore it remains to show that \( \rho_A \) is continuous. Now let \( x \in A \setminus \{0\} \) and let \( \epsilon > 0 \). It suffices to show the following two statements:

1. there exists an open neighborhood \( U \) of \( x \) in \( A \setminus \{0\} \) such that \( \rho_A(y) > \rho_A(x) - \epsilon \) for all \( y \in U \),
2. there exists an open neighborhood \( V \) of \( x \) in \( A \setminus \{0\} \) such that \( \rho_A(y) < \rho_A(x) + \epsilon \) for all \( y \in V \).

We first show the existence of \( U \). After possibly replacing \( \epsilon \) by \( \min\{ \frac{1}{2} \rho_A(x), \epsilon \} \) we can suppose that \( \epsilon \in (0, \rho_A(x)) \).

Since \( A \) is closed we have \( f_0(x) \in A \). Since 0 lies in the interior of \( A \) there exists an \( \eta > 0 \) such that \( B_\eta^0(0) \subset A \). Since \( A \) is convex, the convex hull \( C \) of \( B_\eta^0(0) \cup \{ f_0(x) \} \) is still contained in \( A \). Furthermore, since \( B_\eta^0(0) \) is open it is straightforward to see that \( C' := C \setminus \{ f_0(x) \} \) is an open subset of \( \mathbb{R}^n \). We denote by \( S_{\rho_A(x)-\epsilon}^{n-1} \) the sphere of radius \( \rho_A(x) - \epsilon \) around 0. The point \( x \cdot \frac{\rho_A(x)-\epsilon}{\|x\|} \) lies on \( S_{\rho_A(x)-\epsilon}^{n-1} \) and it lies in \( C' \). Since \( C' \) is open there exists an open neighborhood \( U' \) on \( S_{\rho_A(x)-\epsilon}^{n-1} \) that is contained in \( C' \). We set

\[ U := \{ rz \mid z \in U' \text{ and } r \in (0, 1) \}. \]

This is an open neighborhood of \( x \) and for any \( y \in U \) we have \( (\rho_A(x) - \epsilon) \cdot y \in A \), i.e. for any \( y \in A \) we have \( \rho_A(y) \geq \rho_A(x) - \epsilon \). Thus we have shown that the desired neighborhood \( U \) exists. The existence of \( V \) is proved in a very similar way. We refer to Chapter 11.3 [Berger09] for full details.

From the continuity of \( \rho_A \) it follows that \( f \) is continuous on \( A \setminus \{0\} \). From the fact that \( \rho_A \) is bounded it follows easily that \( f_Q \) is continuous in 0. Finally one can easily verify, using the convexity of \( A \), that \( f_0^{-1}(S^{n-1}) = \partial A \). We leave it to the reader to fill in the details.

**Proof of Proposition 2.53** (*).

(2) Let \( A \) be a bounded closed convex subset of \( \mathbb{R}^n \) and let \( Q \) be a point in the interior of \( A \). After a translation we can assume that \( Q = 0 \) is the origin, in particular we

\[ \square \]

Why is that the case?
can assume that the origin \( 0 \) lies in the interior of \( A \). By Lemma 2.54 we know that the map \( \rho_A: A \setminus \{0\} \to \mathbb{R}_{\geq 0} \) is defined and continuous. Next we consider the map

\[
    f_0: A \to \mathbb{B}^n,
    x \mapsto \begin{cases} 
        x \cdot \frac{1}{\rho_A(x)}, & \text{if } x \neq 0, \\
        0, & \text{if } x = 0.
    \end{cases}
\]

It is straightforward to verify that this map is bijective\(^{30}\) and by Lemma 2.54 we know that \( f_0 \) is continuous and that \( f_0^{-1}(S^{n-1}) = \partial A \). Note that our hypothesis on \( A \) and Heine-Borel Theorem 2.20 imply that \( A \) is compact. Thus we obtain from Proposition 2.43 (3) that \( f_0 \) is in fact a homeomorphism. Finally note that it follows from \( f_0^{-1}(S^{n-1}) = \partial A \) that \( f_0 \) restricts to a homeomorphism \( \partial A \to S^{n-1} \).

1. We denote by \( C = \overline{A} \) the closure of \( A \). Since \( A \) is open and convex we know by Exercise 2.9 that \( A = \hat{C} \). One verifies fairly easily that \( C \) is convex. It is clear that \( C \) is bounded and it follows from Lemma 2.8 that \( C \) is closed. One verifies easily that the map \( f_0 \) defined for \( C = \overline{A} \) restricts to the map \( f_0 \) defined for \( A \). Thus it follows from (2) that the map \( f_0: C = \overline{A} \to \mathbb{B}^n \) is a homeomorphism and it restricts to a homeomorphism \( f_0: \hat{C} \to B^n \). Since \( \hat{C} = A \) we get the desired homeomorphism. ■

Remark. One again let \( A \) be a bounded closed convex subset \( A \) of \( \mathbb{R}^n \) and let \( Q \) be a point in the interior of \( A \). Proposition 2.53 provides us with a homeomorphism \( f: A \to \overline{B}^n \). Since \( \partial A \) is not necessarily "smooth" (here we use smooth in a naive sense) one cannot hope to get such a map \( f \) that is smooth. But it does make sense to ask whether one can find such a map \( f \) such that the restriction to the interior \( \hat{A} \) of \( A \) is smooth, or even better, a diffeomorphism. In general the homeomorphism that we provide in Proposition 2.53 will not have this property. But we can modify the above construction to obtain a homeomorphism \( f: A \to \overline{B}^n \) such that the restriction to \( \hat{A} \to B^n \) is a diffeomorphism. This can be achieved by replacing the linear stretching on the rays by an appropriately chosen different map,

\(^{30}\)It follows easily from the convexity of \( A \), the hypothesis that \( \hat{A} \neq \emptyset \) and the definition of \( f_0 \) that for each \( v \in S^{n-1} \) the map \( f_0 \) restricts to a bijection on the "ray defined by \( v \)". i.e. it restricts to a bijection

\[
    A \cap \{rv \mid r \in \mathbb{R}_{>0}\} \to \mathbb{B}^n \cap \{rv \mid r \in \mathbb{R}_{>0}\}.
\]
e.g. we should stretch by 1 close to the origin to obtain differentiability at 0. It takes some effort to carry out this program rigorously, details can be found in [Fern07], Satz 237.\footnote{It is worth noting that this diffeomorphism is orientation-preserving. (See page \pageref{orientation-preserving} for the definition of “orientation-preserving”.)}

Other approaches to finding homeomorphisms \( f : A \to \overline{B^n} \) that restrict to a diffeomorphism \( \hat{A} \to \hat{B^n} \) are sketched in [BJ82] p. 86 and [GT98] p. 60.

2.9. The two notions of connected topological spaces. In this section we will see that there are two notions of connectedness of a topological space. As we will see, for most “reasonable” topological spaces the two notions mercifully coincide.

Definition.

1. We say that a topological space \( X \) is path-connected if given any two points \( x \) and \( y \), there exists a path from \( x \) to \( y \), i.e. there exists a map \( \gamma : [0, 1] \to X \) with \( \gamma(0) = x \) and \( \gamma(1) = y \).

2. We say that a topological space \( X \) is connected if the following holds\footnote{Recall that we write \( X = U \sqcup V \) if \( X \) is the disjoint union of \( U \) and \( V \), i.e. if \( X = U \cup V \) and if \( U \cap V = \emptyset \).}

\[ \text{if } X = U \sqcup V \text{ is the disjoint union of open sets } U, V \implies X = U \text{ or } X = V. \]

Examples.

1. It follows basically from the definitions that any convex subset of some \( \mathbb{R}^n \) is path-connected. But it is much less clear whether say \( \mathbb{R}^n \) is connected in the above sense.

2. Next let \( G \subset \mathbb{R}^2 \) be the graph of the function \( f : \mathbb{R} \to \mathbb{R} \) given by \( x \mapsto x^2 \). As in Figure 40 we consider the complement \( X = \mathbb{R}^2 \setminus G \). It is pretty clear that \( X \) is not path-connected, surely there is no path from a point \( P \) below \( G \) to a point above \( G \). But how can one show the non-existence of such a path?\footnote{The fact that such a path does not exist can be shown, with some dexterity, using real analysis. How?}

So we see that both notions of connectedness have their advantages and disadvantages. It is often easy to show that a given topological space is path-connected but it can be a pain to show that a given topological space is not path-connected. With connectedness it is precisely the other way round.

\[ G \]
\[ X \]
\[ Q \]
\[ P \]
\[ V \]
\[ U \]

Figure 40
It is basically obvious that any interval is path-connected. But as we will see, it takes some effort to show that the interval \([0, 1]\) is connected.

**Proposition 2.55.** The interval \([0, 1]\) is connected.

**Proof.** Let \(U\) and \(V\) be two disjoint open subsets of \([0, 1]\) with \(U \cup V = [0, 1]\). Without loss of generality we can assume that \(0 \in U\). We want to show that \(U = [0, 1]\). We consider

\[
A := \{ t \in [0, 1] \mid [0, t] \subset U \}.
\]

The set \(A\) contains 0, hence it is non-empty. Evidently the set is bounded thus we can consider \(T := \sup A\). We need to show that \(T = 1\) and that \(T \in U\).

First let us suppose that \(T \notin U\). This implies that \(T \in V\). Since \(V\) is open it follows that there exists an \(\epsilon > 0\) such that \((T - \epsilon, T + \epsilon) \cap [0, 1]\) is also contained in \(V\). In particular we have \((T - \epsilon, T + \epsilon) \cap A = \emptyset\) which implies that \(\sup A \leq T - \epsilon\). Thus we have obtained a contradiction.

Now we know that \(T \in U\). We still need to show that \(T = 1\). Since \(U\) is open it follows that there exists an \(\epsilon > 0\) such that \((T - \epsilon, T + \epsilon) \cap [0, 1] \subset U\). Thus \([0, T + \epsilon) \cap [0, 1] \subset U\). In light of the definition of \(T\) that is only possible if \(T = 1\).

---

**Corollary 2.56.** Every path-connected topological space is also connected.

**Proof.** Let \(X\) be a topological space that is path-connected. Suppose that \(X\) is not connected. This means that there exist disjoint open non-empty subsets \(U\) and \(V\) with \(X = U \cup V\). Since \(U\) and \(V\) are non-empty we can find points \(x \in U\) and \(y \in V\). Since \(X\) is path-connected there exists a path \(\gamma: [0, 1] \to X\) with \(\gamma(0) = x\) and \(\gamma(1) = y\). Then \(\gamma^{-1}(U) \cup \gamma^{-1}(V)\) is a decomposition of \([0, 1]\) into two disjoint non-empty open subsets. But that is a contradiction to Proposition 2.55.

---

The following lemma comes in handy on several occasions.

**Lemma 2.57.** Let \(f: X \to Y\) be a map between topological spaces.

1. If \(X\) is path-connected, then \(f(X)\) is also path-connected.
2. If \(X\) is connected, then \(f(X)\) is also connected.

**Proof.** We leave the elementary proof to the reader.

---

\(A = \) the set of all \(t \in [0, 1]\) such that the interval \([0, t]\) is contained in \(U\).
In the following lemma we show that most of the topological spaces that we had encountered so far are path-connected and connected. We will use this lemma on numerous occasions without explicitly referring to it.

**Lemma 2.58.**

1. Let \( n \geq 1 \). Every open ball \( B^n_r(y) \), every closed ball \( \overline{B}^n_r(y) \) and all of \( \mathbb{R}^n \) are path-connected and connected.
2. Every sphere \( S^n_r(y) \) with \( n \geq 1 \) is path-connected and connected.

**Proof.** By Corollary 2.56 it suffices to show that all these topological spaces are path-connected. It is clear that convex subsets of \( \mathbb{R}^n \) are path-connected.

1. It follows from the example on page 124 that all balls (open or closed) are path-connected.
2. We will show in Exercise 2.58 that spheres of dimension \( \geq 1 \) are path-connected. □

For better or worse, the converse to Corollary 2.56 is unfortunately not always correct.

**Example.** Consider the topological space

\[
X := \{(0,y) \mid y \in [-1,1]\} \cup \{(x,\sin(\frac{1}{x})) \mid x \in (0,\pi]\} \subset \mathbb{R}^2.
\]

The topological space \( X \) is the union of the graph of \( x \mapsto \sin(\frac{1}{x}) \) for \( x \in (0,\pi] \) and an interval on the \( y \)-axis. We sketch the topological space \( X \) in Figure 43. It is a very instructive exercise, see Exercise 2.52 to show that \( X \) is connected and it is an equally instructive exercise to show that \( X \) is not path-connected.

---

\[35\] This topological space is sometimes referred to as the *topologist’s sine curve.*
Remark. The fact that an example of a topological space that is connected but not path-connected is so “wild” indicates that perhaps for most “reasonable” spaces the two notions of connectedness and path-connectedness agree. In fact in basically all examples of topological spaces that we encounter throughout these notes the two notions of connectedness will agree.

By a clever use of the notion of connectedness one can sometimes prove statements which at first glance have nothing to do with connectedness. For example we can now prove the following lemma.

Lemma 2.59. Let $n \in \mathbb{N}_{\geq 2}$.

1. The topological spaces $\mathbb{R}$ and $\mathbb{R}^n$ are not homeomorphic.
2. The topological spaces $[0, 1]$ and $[0, 1]^n$ are not homeomorphic.

Remark. Later on, in Proposition 43.6, we will study the question whether for $k \neq l$ the topological spaces $\mathbb{R}^k$ and $\mathbb{R}^l$ can be homeomorphic.

Proof.

(1) Let us suppose that there exists a homeomorphism $f : \mathbb{R} \to \mathbb{R}^n$. Let $P \in \mathbb{R}$ be a point. Then $f$ restricts to a homeomorphism from $\mathbb{R} \setminus \{P\}$ to $\mathbb{R}^2 \setminus \{f(P)\}$. The topological space $\mathbb{R} \setminus \{P\} = (-\infty, P) \cup (P, \infty)$ is not path-connected while one can easily verify that $\mathbb{R}^n \setminus \{f(P)\}$ is path-connected. But as we remarked on page 116 homeomorphic spaces have the same topological properties. In particular two homeomorphic spaces are either both path-connected or they are both not path-connected. Thus we have obtained a contradiction.

(2) The proof of this statement is basically identical to the proof of (1). □

By Lemma 2.59 (2) we know that for $n \geq 2$ the interval $[0, 1]$ is not homeomorphic to the cube $[0, 1]^n$. One might think that this should surely be obvious since $[0, 1]^n$ is “clearly bigger” than $[0, 1]$. But the following proposition will disabuse the reader of this idea.

Proposition 2.60. Let $n \in \mathbb{N}$.

1. There exists a map $f : [0, 1] \to [0, 1]^n$ that is surjective.
2. There exists an injective map $f : S^1 \to [0, 1]^2$ such that $f(S^1)$ has non-zero 2-dimensional Lebesgue measure.

first six stages in the construction of the Hilbert space-filling curve

Figure 44. Illustration of Proposition 2.60.

\footnote{Why is this topological space not path-connected? How can one show this?}

\footnote{Just to make things clear, here we demand of course that $f$ is continuous.}
Remark.

(1) A surjective map from $[0, 1]$ to $[0, 1]^n$, or more generally from a one-dimensional smooth manifold to some smooth manifold of dimension $\geq 2$, is often called a space-filling curve.

(2) An injective map $f: S^1 \to [0, 1]^2$ such that $f([0, 1])$ has non-zero 2-dimensional Lebesgue measure is called an Osgood curve.

(3) By Proposition 2.43 (3) and Lemma 2.59 (2) we know that for $n \geq 2$ an injective map $f: [0, 1] \to [0, 1]^n$ cannot be possible be surjective. In other words, the maps promised by Proposition 2.60 (1) are necessarily non-injective.

Proof.

(1) Many examples of such maps are given in [Sag94], see e.g. [Sag94] Theorem 2.1.

(2) In 1903 William Osgood [Osg03] and Henri Lebesgue [Leb1903] independently showed that there exist injective maps $f: [0, 1] \to [0, 1]^2$ such that $f([0, 1])$ has non-zero 2-dimensional Lebesgue measure. Many more examples of such maps are given in [Sag94] Chapter 8.2. In Exercise 2.57 we will see how this fact can be used to find injective maps $g: S^1 \to [0, 1]^2$ such that $g(S^1)$ has non-zero 2-dimensional Lebesgue measure.

We continue with the following elementary but useful lemma.

Lemma 2.61. Every map $f: X \to Y$ from a connected topological space $X$ to a discrete topological space is constant.

Remark. One could argue that Lemma 2.61 is the lemma in topology that is most relevant to real life. More precisely, an immediate consequence of Lemma 2.61 is that any non-constant map $(a, b) \to A$ from an interval to a finite set is not continuous. This is of huge significance since humanity likes to squeeze a real-parameter (e.g. time, intelligence, performance) into a finite set of values (e.g. historical stages, grades in school and exams, hired-or-fired). Any such function is non-continuous and hence very problematic.

Proof. We need to show that for any $x \in X$ we have $f(x) = f(X)$. Since $Y$ is a discrete topological space we know that $\{f(x)\}$ and $Y \setminus \{f(x)\}$ are open subsets of $Y$. The preimages $U := f^{-1}(f(x))$ and $V := f^{-1}(Y \setminus \{f(x)\})$ are also open and they are evidently disjoint. Since $U$ is non-empty and since $X$ is connected we see that $V = \emptyset$. But this means that $f$ is constant.

In the remainder of this section we will discuss a few lemmas which will be useful for showing that certain topological spaces are (path-) connected. For example the next lemma gives a criterion for the union of (path-) connected subsets to be (path-) connected.

Lemma 2.62. (*) Let $X$ be a topological space and let $\{B_i\}_{i \in I}$ be a family of subsets such that the intersection $\bigcap_{i \in I} B_i$ is non-empty.

(1) If each $B_i$, $i \in I$ is path-connected, then $\bigcup_{i \in I} B_i$ is path-connected.

(2) If each $B_i$, $i \in I$ is connected, then $\bigcup_{i \in I} B_i$ is connected.
Remark. In Exercise 2.55 we will provide a partial converse to Lemma 2.62.

Proof (*). Let $X$ be a topological space and let $\{B_i\}_{i \in I}$ be a family of subsets such that the intersection $\bigcap_{i \in I} B_i$ contains a point $z$. We write $Z := \bigcup_{i \in I} B_i$.

1. We suppose that each $B_i, i \in I$ is path-connected. So let $x, y \in Z$. There exists an $i \in I$ with $x \in B_i$ and there exists a $j \in I$ with $y \in B_j$. Since $B_i$ and $B_j$ are path-connected we can pick a path $\gamma: [0, 1] \rightarrow B_i$ from $x$ to $z$ and we can pick a path $\delta: [0, 1] \rightarrow B_j$ from $z$ to $y$. It is clear that

$$
\begin{align*}
[0, 1] &\rightarrow Z \\
t &\mapsto \begin{cases} 
\gamma(2t), &\text{if } t \in [0, \frac{1}{2}] \\
\delta(2t-1), &\text{if } t \in \left[\frac{1}{2}, 1\right]
\end{cases}
\end{align*}
$$

is a path from $x$ to $y$.

2. We suppose that each $B_i, i \in I$ is connected. We write $Z = U \cup V$ where $U$ and $V$ are open subsets. Without loss of generality we can assume that $z \in U$. For each $i \in I$ we have a decomposition $B_i = (U \cap B_i) \cup (V \cap B_i)$ into disjoint open subsets (here we use the definition of the subspace topology). Since $B_i$ is connected and since $U \cap B_i \neq \emptyset$ we see that $B_i = U \cap B_i$. Thus we have shown that

$$U = \bigcup_{i \in I} (B_i \cap U) = \bigcup_{i \in I} B_i = Z.$$

Sometimes it is also useful to have criteria which show that removing a subset does not change connectedness.

Lemma 2.63. (*). Let $X$ be a topological space and let $A \subset X$ be a subset.

1. If $X$ is path-connected and if $\partial A$ is path-connected, then $X \setminus \hat{A}$ is also path-connected.
2. If $X$ is connected and if $\partial A$ is connected, then $X \setminus \hat{A}$ is also connected.

We will prove Lemma 2.63 in Exercise 2.54.

\[\text{Figure 46. Illustration of Lemma 2.63}\]

\[\text{Figure 45. Illustration for the proof of Lemma 2.62 (1)}\]

\[38\text{It follows from Lemma 2.35 (2) that this map is indeed continuous.}\]
2.10. **The (path-) components of a topological space.** Let us start with the following simple-minded definition.

**Definition.** Let $x$ and $y$ be two points in a topological space $X$. We say that the points $x$ and $y$ are path-equivalent, if there exists a map $\gamma: [0, 1] \to X$ with $\gamma(0) = x$ and $\gamma(1) = y$.

**Lemma 2.64.** For every topological space $X$ the notion of path-equivalence is indeed an equivalence relation.

**Proof.** All properties of an equivalence relation are trivial except possibly for transitivity. The fact that path-equivalence is transitive follows immediately from the argument in Lemma 2.62 (1).

**Definition.** Let $X$ be a topological space.

1. We call the path-equivalence classes of points the **path-components** of $X$.
2. We denote by $\pi_0(X)$ the set of path-components of $X$. Furthermore we write $\pi_0(X) = 0$ if $X$ is non-empty and if it consists of a single path-component.

**Example.** It is a straightforward consequence of the Intermediate Value Theorem that each point in $\mathbb{Q}$ is in fact already a path-component of $\mathbb{Q}$.

Later on it will at times be useful to know the path-components of certain matrix groups. The relevant results are summarized in the following lemma.

**Lemma 2.65.** Let $n \in \mathbb{N}$.

1. The real general linear group
   \[ \text{GL}(n, \mathbb{R}) = \{ A \in M(n \times n, \mathbb{R}) \mid \det(A) \neq 0 \} \subset M(n \times n, \mathbb{R}) = \mathbb{R}^{n^2} \]
   has precisely two path-components, namely
   \[ \text{GL}_+(n, \mathbb{R}) := \{ A \in \text{GL}(n, \mathbb{R}) \mid \det(A) > 0 \} \quad \text{and} \quad \{ A \in \text{GL}(n, \mathbb{R}) \mid \det(A) < 0 \}. \]
   Put differently, two invertible matrices lie in the same path-component if and only if the signs of their determinants agree. The same statement also holds for $\text{O}(n)$, more precisely $\text{O}(n)$ has precisely two path-components, namely
   \[ \text{SO}(n, \mathbb{R}) = \{ A \in \text{O}(n, \mathbb{R}) \mid \det(A) > 0 \} \quad \text{and} \quad \{ A \in \text{O}(n, \mathbb{R}) \mid \det(A) < 0 \}. \]
2. The group $\text{SL}(n, \mathbb{R}) = \{ A \in M(n \times n, \mathbb{R}) \mid \det(A) = 1 \}$ is path-connected.
3. The unitary group $\text{U}(n)$ and the special unitary group
   \[ \text{SU}(n) = \{ A \in \text{U}(n) \mid \det(A) = 1 \} \]
   are both path-connected, thus they consist of a single path-component.
4. The complex general linear group
   \[ \text{GL}(n, \mathbb{C}) = \{ A \in M(n \times n, \mathbb{C}) \mid \det(A) \neq 0 \} \subset M(n \times n, \mathbb{C}) = \mathbb{C}^{n^2} \]
   is path-connected.

---

39The notation “$\pi_0(X)$” might look rather odd at the moment, but it will become clearer later on, when we introduce the fundamental groups and the higher homotopy groups, why this is a perfectly sensible notation.
Remark. In Lemma 8.8 we collect more information on the relationships between the topological spaces that are given by the various matrix groups.

Proof. It is an instructive exercise in linear algebra to prove this lemma, see Exercise 2.60. Alternatively, the proof for these statements is given in [Bak02, Chapter 9.2]. ■

The following lemma follows immediately from the definitions and basic properties of equivalence relations.

**Lemma 2.66.** Let $X$ be a topological space.

1. As a set, $X$ is the disjoint union of its path-components.
2. Each path-component of $X$ is path-connected.
3. Each path-component $C$ of $X$ is a maximal path-connected subset, i.e. if $C \subseteq D$, then $D$ is not path-connected.

Our goal now is to define the “components” of a topological space that should play the same role as the path-components, i.e. we want to introduce the notion of “components” such that the statements of Lemma 2.66 hold, but with “path-connected” replaced by “connected” and “path-component” replaced by “component”.

We start out with the following definition.

**Definition.** Let $x$ and $y$ be two points in a topological space $X$. We say that the points $x$ and $y$ are equivalent, if there exists a connected subset of $X$ that contains both $x$ and $y$.

**Lemma 2.67.** For every topological space $X$ the above notion of equivalence is indeed an equivalence relation.

Proof. All properties of an equivalence relation are trivial except for transitivity. So suppose that $x$ and $y$ are equivalent and that $y$ and $z$ are equivalent. By definition there exists a connected subset $A$ that contains $x$ and $y$ and there exists a connected subset $B$ that contains $y$ and $z$. By Lemma 2.62(2) the union $A \cup B$ is connected and it thus follows that $x$ and $z$ are equivalent. ■

**Definition.** Let $X$ be a topological space. We call the equivalence classes of points on $X$ the components of $X$.

**Examples.**

1. The topologist’s sine curve that we illustrated in Figure 43 has two path-components but only a single component.
2. We consider $X = \mathbb{Q}$ with the subspace topology coming from $\mathbb{R}$. In Exercise 2.17 we show that the only connected subsets of $\mathbb{Q}$ are the subsets consisting of at most a point. It follows that the components of $\mathbb{Q}$ are precisely the one-point subsets.

The following is in particular the promised analogue of Lemma 2.66.

**Lemma 2.68.** Let $X$ be a topological space.

1. As a set $X$ is the disjoint union of its components.
2. Each component of $X$ is connected.
(3) Each component $C$ of $X$ is a maximal connected subset of $X$, i.e. if $C \subseteq D$, then $D$ is not connected.

(4) If $A$ is a subset of $X$ that is closed and open, then $A$ is the union of components of $X$.

(5) Each component of $X$ is the union of path-components of $X$.

Proof (*). Let $X$ be a topological space.

(1) This statement is clear.

(2) Now let $C$ be a component of $X$. We pick $c \in C$. For each $d \in C$ there exists by definition a connected subset $Y_d$ of $X$ that contains $c$ and $d$. We have

$$C = \bigcup_{c \in C} \{c\} \cup \bigcup_{c \in C} Y_c \subseteq C$$

which implies that $C = \bigcup_{c \in C} Y_c$.

by definition all points in $Y_d$ are equivalent to $c$, thus we have $Y_d \subseteq C$.

It follows from Lemma 2.62 (2) that $C$ is connected.

(3) This statement follows immediately from the definitions.

(4) Let $A$ be a subset of $X$ that is closed and open. Let $C$ be a component of $X$. Note that $A \cap C$ is a subset of $C$ that is closed and open. By (2) we know that $C$ is connected, hence we see that either $A \cap C = \emptyset$ or $A \cap C = C$. This shows that $A$ is precisely the union of all the components of $X$ that $A$ intersects.

(5) Let $C$ be a component of $X$. It follows from Lemma 2.66 that it suffices to show that if $P$ is a path-component of $X$, then either $P \subseteq C$ or $P \cap C = \emptyset$. Thus let $P$ be a path-component of $X$. Note that $P \cap C$ is Corollary 2.56.

We wrap up the discussion of the components of a topological space with the following lemma.

Lemma 2.69. Let $X$ be a topological space.

(1) Every component of $X$ is a closed subset of $X$.

(2) If $X$ has only finitely many components, then each component is also an open subset of $X$.

Example. We consider $X = \mathbb{Q}$. In this case every point is already a component. We see that every component is closed, but in this case no component is an open subset. Therefore we cannot drop the condition on the number of components in the second statement of the lemma.

Proof (*). Let $X$ be a topological space.

(1) Let $C$ be a component of $X$. We need to show that $X \setminus C$ is open. By Lemma 2.5 it suffices to show that any $P \in X \setminus C$ admits a neighborhood that does not intersect $C$. Thus let $P \in X \setminus C$. By Lemma 2.68 we know that $C \cup \{P\}$ is not connected. Therefore there exists a decomposition $C \cup \{P\} = U \sqcup V$ with $U$ and $V$ open subsets such that both $U$ and $V$ are non-empty. Without loss of generality $C \cap U \neq \emptyset$. Since $C$ is connected and since $C = (U \cap C) \sqcup (V \cap C)$ we see that $C = U \cap C$. Since $V$ is also non-empty we see that $V = \{P\}$. By the definition of the subspace topology that means that there exists an open subset $W$ of $X$ such that $W \cap (C \cup \{P\}) = V = \{P\}$.
But this shows that \( W \) is an open neighborhood of \( P \) that does not intersect \( C \). We have thus shown that the complement of \( C \) is open. We refer to Figure 47 for an illustration of the above argument.

(2) Now suppose that \( X \) has only finitely many components. Let \( C \) be a component of \( X \). We already know from (1) that \( C \) is closed. By definition the complement of \( C \) is the union of all other components. Since there are only finitely many and since they are closed by (1) it follows that the complement of \( C \) is closed, i.e. \( C \) is open.

\[ \text{Figure 47. Illustration for the proof of Lemma 2.69 (1).} \]

**Remark.** Let \( X \) be a topological space. We say that the points \( x \) and \( y \) are *quasi-equivalent*, if the following holds

if \( X = U \sqcup V \) is the disjoint union with \( U, V \) open \( \implies \) either \( x, y \in U \) or \( x, y \in V \).

It is straightforward to see that this indeed an equivalence relation on \( X \). The equivalence classes of this equivalence relation are called *quasi-components*. It follows immediately from the definitions that components are contained in quasi-components. But the notions are different, for example it is shown in [SS78, p. 137] that there exist topological spaces such that quasi-components are not connected. We will not make use of the concept of quasi-equivalence and quasi-components.

We conclude this section with the following lemma that can be viewed as a generalization of Lemma 2.57 and Lemmas 2.61.

**Lemma 2.70.** (*\) Let \( X \) and \( Y \) be topological space. If \( X \) is (path-) connected and if \( Y \) consists of (path-) components \( Y_i, i \in I \), then given any map \( f: X \to Y \) there exists an \( i \in I \) with \( f(X) \subset Y_i \).

**Proof (\*)**. Again we leave the proof as a straightforward exercise to the reader.

\[ \text{Figure 48.} \]

**2.11. Local properties.** As so often, let us start out with a definition.

**Definition.** Let \( P \) be a property of topological spaces and let \( X \) be a topological space.

1. We say \( X \) is *regionally* \( P \) if given any \( Q \in X \) and any neighborhood \( U \) of \( Q \) there exists a neighborhood \( V \) of \( Q \) that is contained in \( U \) that has the property \( P \).
2. We say \( X \) is *locally* \( P \) if given any \( Q \in X \) and any neighborhood \( U \) of \( Q \) there exists an *open* neighborhood \( V \) of \( Q \) that is contained in \( U \) that has the property \( P \).
Warning. Our usage of the expression “locally $P$” is non-standard. In fact most textbooks, see e.g. [Hat02, Bre93, Rot88], define “locally $P$” as what we call “regionally $P$”. (Note though that, as is apparent from [Mun75] p. 161, in [Mun75] our notion of “locally $P$” is being used.) The property that we now call “locally $P$” does not seem to have an established name. For our purpose it is useful to give names to both concepts since both have their uses and justifications. Later on we will also introduce notion of a local property of a map, in this context most books implicitly or explicitly seem to work with open neighborhoods. Thus it seems reasonable to us to use the word “local” whenever we deal with open neighborhoods and to rename the concept when any neighborhood is allowed.

Examples.

(1) Every open subset of $\mathbb{R}^n$ is locally path-connected. Indeed, suppose $A$ is an open subset of $\mathbb{R}^n$. Let $Q \in A$ and let $U$ be a neighborhood of $Q$ in $A$. Then there exists an $\epsilon > 0$ such that $B^n_\epsilon(x) \subset U$. The $\epsilon$-ball $B^n_\epsilon(x)$ is of course path-connected.

(2) The space $X = (-2, 1) \cup [3, 6] \subset \mathbb{R}$ with the usual topology is not path-connected but it is locally path-connected\footnote{Why is that?}. On the other hand $X = \mathbb{Q}$ is not even locally path-connected.

(3) The line with two zeros, i.e. the topological space $\mathbb{R} \cup \{\ast\}$ with the topology from page 95 is not Hausdorff, but one can easily show that $\mathbb{R} \cup \{\ast\}$ is locally Hausdorff.

The following lemma can at times be useful.

**Lemma 2.71.** Let $P$ be a property of topological spaces and let $X$ be a topological space. If $X$ is locally $P$, then the open subsets of $X$ that have $P$ form a basis for the topology of $X$.

**Proof.** This lemma follows immediately from Lemma 2.27 (1). □

The following lemma is the key to showing that for “reasonable” topological spaces the notions of being connected and being path-connected are actually the same.

**Lemma 2.72.** Let $X$ be a topological space that is locally path-connected. Then

$X$ is connected $\iff$ $X$ is path-connected.

**Proof.** The “$\Rightarrow$”-direction is an immediate consequence of Corollary 2.56. In Exercise 2.63 we will show that if $X$ is locally path-connected, then the converse also holds. □

In the following we discuss the notion of being regionally compact.

**Examples.**

(1) Every open subset of $\mathbb{R}^n$ is regionally compact. Indeed, suppose $A$ is an open subset of $\mathbb{R}^n$. Let $Q \in A$ and let $U$ be a neighborhood of $Q$ in $A$. Then there exists an $\epsilon > 0$ such that $B^n_\epsilon(x) \subset U$. The closed $\epsilon$-ball $\overline{B^n_\epsilon(x)}$ is a neighborhood of $x$ and it is compact by the Heine-Borel Theorem 2.20.

(2) Similar to (1) one can easily show that every interval is regionally compact. In fact later on we will mostly need the fact that the interval $[0, 1]$ is regionally compact.
In Exercise 2.65 we will see that there exists a topological space that is compact but not regionally compact. The following lemma shows that this slightly unintuitive phenomenon cannot occur if we restrict ourselves to topological spaces that are Hausdorff.

**Lemma 2.73.** (*) Let $X$ be a Hausdorff space.

1. If $X$ is compact, then $X$ is also regionally compact.
2. If given any point $P \in X$ there exists a compact neighborhood of $P$, then $X$ is regionally compact.

**Proof.**

(1) We will use Lemma 2.73 only once, in a rather inessential way. Therefore we leave the proof of this lemma as a not entirely trivial exercise to the reader. Alternatively we refer to [Wil70, Theorem 18.2] for a proof.

(2) This statement follows almost immediately from (1). [closed]

We conclude the discussion of regionally compact topological spaces with another health warning.

**Warning.** Recall that what we call “regionally compact” is often called “locally compact”. Even more confusing, in the literature frequently “locally compact” is used with different definitions. For example in [HY88, p. 71] and [Dug66, p. 237] a topological space is called “locally compact” if every point admits an open neighborhood such that its closure is compact. Furthermore in [SS78, p. 20], [Bre93, p. 31] and [Jos83, p. 266] a topological space is called “locally compact” if every point is contained in a compact neighborhood. The latter two notions of “locally compact” are in general different, see e.g. [SS78, Example 52]. Furthermore note that for the above two concepts of “locally compact” every compact topological space is already locally compact. But as we mentioned above, in Exercise 2.65 we will see that there exists a compact topological space that is not regionally compact topological. Nonetheless, it is a “metatheorem” that all concepts of “locally compact” in the literature agree for Hausdorff spaces.

In the following definition we turn from properties of topological spaces to properties of maps.

**Definition.** Let $P$ be a property of maps between topological spaces and let $f : X \rightarrow Y$ be a map between topological spaces.

1. We say that $f : X \rightarrow Y$ is locally $P$ at $x \in X$ if there exists an open neighborhood $U$ of $x$ and an open neighborhood $V$ of $f(x)$ such that $f : U \rightarrow V$ has the property $P$.
2. We say that $f$ is locally $P$ if it is locally $P$ at any $x \in X$.

**Examples.**

1. One easily verifies that the map $f : \mathbb{R} \rightarrow \mathbb{R}$ given by $f(x) = x^2$ is a local homeomorphism at all points $x \neq 0$.
2. The map

$$p : \mathbb{R} \rightarrow S^1$$

$$t \mapsto e^{2\pi it}$$
is a local homeomorphism. Indeed, let \( t \in \mathbb{R} \). We set \( U = (t - \frac{1}{2}, t + \frac{1}{2}) \) and \( V = p(U) \). The restriction of \( p \) to \( p: U \to V \) is continuous and a bijection. Furthermore it is not difficult to show that \( p \) is an open map, see also Exercise 2.34. It follows from Lemma 2.42 (2) that \( p: U \to V \) is a homeomorphism.

We will often use the statement of the following lemma without making reference to the lemma.

**Lemma 2.74.** Let \( f: X \to Y \) be a map between two topological spaces (for once we do not assume that \( f \) is continuous). If \( f \) is locally continuous, then \( f \) itself is continuous.

**Proof.** Let \( f: X \to Y \) be a locally continuous map between two topological spaces. It follows from Lemma 2.30 (2) that given any \( x \in X \) that there exists an open neighborhood \( U_x \) of \( x \) such that the restriction of \( f \) to \( U_x \) is continuous. It is an immediate consequence of Lemma 2.35 (1) that \( f \) itself is continuous. \( \blacksquare \)

### 2.12. The Lebesgue Lemma and uniformly continuous maps (*)

In this section we want to prove two statements that concern specifically maps whose domain is actually a metric space. It is perhaps initially difficult to get excited about these results, but they will come in handy later on.

First we intend to formulate and prove the Lebesgue Lemma. Despite its humble name it does actually play an important role in topology. The formulation of the Lebesgue Lemma requires the following definition.

**Definition.** Let \( X \) be a metric space. The diameter of a non-empty subset \( A \) of \( X \) is defined as

\[
\text{diam}(A) := \sup\{d(a, b) \mid a, b \in A\} \in \mathbb{R}_{\geq 0} \cup \{\infty\}.
\]

**Figure 49**

**Example.** One can easily show that

\[
\text{diameter of the hyperrectangle } [a_1, b_1] \times \cdots \times [a_n, b_n] = \sqrt{(b_1 - a_1)^2 + \cdots + (b_n - a_n)^2}.
\]

Now we can state the Lebesgue Lemma.

**Lemma 2.75. (Lebesgue Lemma)** Let \( K \) be a compact metric space and let \( \{U_i\}_{i \in I} \) be an open cover of \( K \). Then there exists a \( \delta > 0 \) such that for every subset \( A \) with \( \text{diam}(A) < \delta \) there exists an \( i \in I \) with \( A \subset U_i \).

**Remark.** Any \( \delta > 0 \) that has the property stated in the Lebesgue Lemma is usually called a Lebesgue number.

**Proof.** Since \( K \) is compact we can cover \( K \) with finitely many of the \( U_i \)'s. Put differently, without loss of generality we can assume that \( I = \{1, \ldots, n\} \) is a finite set.
If there exists an \( i \in \{1, \ldots, n\} \) with \( K = U_i \), then any \( \delta > 0 \) has the desired property. Now suppose that this is not the case, i.e. we suppose that for every \( i \) we have \( U_i \not\subset K \). \footnote{Where do we use in the subsequent argument that \( U_i \not\subset K \)?}

We first prove the following claim.

**Claim.** The function

\[
f : K \to \mathbb{R}
\]

\[
x \mapsto f(x) := \frac{1}{n} \sum_{i=1}^{n} d(x, K \setminus U_i)
\]

is continuous and positive.

It follows easily from the definitions and the triangle inequality that \( f \) is continuous. Now let \( x \in K \). We want to show that \( f(x) > 0 \). Since \( K = U_1 \cup \cdots \cup U_n \) there exists an \( i \) with \( x \in U_i \). Since \( U_i \) is open there exists an \( r > 0 \) with \( B_r(x) \subset U_i \). It follows that \( d(x, K \setminus U_i) \geq r \), hence \( f(x) \geq \frac{r}{n} \).

Since \( f \) is continuous and since \( K \) is compact it follows from Lemma \( \ref{lem:continuous_on_compact_is_uniformly_continuous} \) that the function \( f \) has a global minimum \( \delta \) on \( K \). It follows from the claim that this minimum \( \delta \) is greater than 0. Now we want to show that this \( \delta \) has the desired property. More precisely, we want to prove the following claim.

**Claim.** Let \( A \) be a subset of \( K \) with \( \text{diam}(A) < \delta \). Then there exists an \( i \in \{1, \ldots, n\} \) with \( A \subset U_i \).

Let \( x \in A \). We choose an \( m \in \{1, \ldots, n\} \) such that \( d(x, K \setminus U_m) \) is maximal. We want to show that \( A \subset U_m \). Since the diameter of \( A \) is less than \( \delta \) we have \( A \subset B_\delta(x) \). Thus it suffices to show that \( B_\delta(x) \subset U_m \). Put differently, we need to show that \( d(x, K \setminus U_m) \geq \delta \). Indeed we have

\[
d(x, K \setminus U_m) \geq \frac{1}{n} \sum_{i=1}^{n} d(x, K \setminus U_i) = f(x) \geq \delta.
\]

since \( d(x, K \setminus U_m) \geq d(x, K \setminus U_i) \) by the choice of \( \delta \)

**Figure 50.** Illustration of the proof of the Lebesgue Lemma.

In many cases the following corollary is even more useful.

**Corollary 2.76.** Let \( f : [0,1]^n \to X \) be a map from the cube \([0,1]^n\) to a topological space \( X \) and let \( \{V_i\}_{i \in I} \) be an open cover of \( X \). Then there exists an \( N > 0 \) such that for any \( a_1, \ldots, a_n \in \{0, \ldots, N-1\} \) there exists an \( i \in I \) such that

\[
f\left(\left[\frac{a_1}{N}, \frac{a_1+1}{N}\right] \times \cdots \times \left[\frac{a_n}{N}, \frac{a_n+1}{N}\right]\right) \subset V_i.
\]
More pictorially speaking the corollary says that if \( f : [0,1]^n \to X \) is a map, and if we are given an open cover of \( X \), then we can always find a small grid on the cube, such that each cube of the grid gets mapped into one of the open sets cover \( X \).

![Figure 51. Illustration of Corollary 2.76](image)

**Figure 51. Illustration of Corollary 2.76**

**Proof.** Let \( f : [0,1]^n \to X \) be a map from the cube \([0,1]^n\) to a topological space and let \( \{V_i\}_{i \in I} \) be an open cover of \( X \). By Proposition 2.21 we know that \([0,1]^n\) is compact. Thus we can apply Lemma 2.75 to the open cover \( U_i := f^{-1}(V_i), i \in I \) of \([0,1]^n\) and we obtain a \( \delta > 0 \) such that for each subset \( A \) with \( \text{diam}(A) < \delta \) there exists an \( i \in I \) with \( A \subseteq U_i = f^{-1}(V_i) \), which means that \( f(A) \subseteq V_i \). It follows from the example on page 141 that the diameter of the cube of side length \( \frac{1}{m} \) equals \( \frac{1}{\sqrt{m}} \). Thus for sufficiently large \( N \) any cube of side length \( \frac{1}{N} \) has diameter less than \( \delta \).

**Definition.** Let \( f : X \to Y \) be a map between two metric spaces \( X \) and \( Y \). By Proposition 2.36 we know that

\[
\text{\( f \) is continuous} \iff \forall x \in X \quad \forall \epsilon > 0 \quad \exists \delta > 0 \quad \forall y \in B_\delta(x) \quad d(f(x), f(y)) < \epsilon.
\]

Now we define

\[
\text{\( f \) is uniformly continuous} \iff \forall \epsilon > 0 \quad \exists \delta > 0 \quad \forall x \in X \quad \forall \ y \in B_\delta(x) \quad d(f(x), f(y)) < \epsilon.
\]

The following proposition is the second main result of this section.

**Proposition 2.77.** Let \( f : X \to Y \) be a continuous map between two metric spaces. If \( X \) is compact, then \( f \) is uniformly continuous.

**Proof (\( \ast \)).** Let \( f : X \to Y \) be a continuous map between two metric spaces and let \( \epsilon > 0 \). The “\( \leftarrow \)”-direction of Proposition 2.36 tells us in particular that given any \( x \in X \) there exists a \( \delta(x) > 0 \) such that for all \( y \in B_\delta(x)(x) \) we have \( d(f(x), f(y)) < \frac{\epsilon}{2} \). Since the open balls \( B_\delta(x)(x) \) form an open cover of \( X \) and since \( X \) is compact there exist \( x_1, \ldots, x_k \) such that \( B_\delta(x_1)/2(x_1) \cup \cdots \cup B_\delta(x_k)/2(x_1) = X \). We claim that

\[
\delta := \min \left\{ \frac{\delta(x_1)}{2}, \ldots, \frac{\delta(x_k)}{2} \right\}
\]

has the desired properties. Thus let \( x, y \in X \) with \( d(x, y) < \delta \). There exists a \( j \in \{1, \ldots, k\} \) with \( x \in B_\delta(x_j)(x_j) \). From the triangle inequality and from \( \delta \leq \frac{\delta(x_j)}{2} \) we obtain that \( y \in B_\delta(x_j)(x_j) \). It follows that

\[
d(f(x), f(y)) \leq d(f(x_j), f(x)) + d(f(x_j), f(y)) < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon.
\]

triangle inequality since \( x \in B_\delta(x_j)(x_j) \) and \( y \in B_\delta(x_j)(x_j) \).
We have thus shown that $\delta$ does indeed have the desired properties.

2.13. **Paracompact topological spaces** (*). In this short section we introduce the notion of a “partition of unity” and the notion of a paracompact topological space. Paracompactness is often useful for building interesting maps “out of” a given topological manifolds. Even though this material is important, it is best to skip this section and to return to it, once the actual need for the material arises.

**Definition.** Let $X$ be a topological space.

1. The **support** of a function $f : X \to \mathbb{R}$ is defined as
   \[
   \text{supp}(f) := \{x \in X \mid f(x) \neq 0\}.
   \]

2. A **partition of unity** on $X$ is a family of maps $\{f_i : X \to [0, 1]\}_{i \in I}$ with the following properties:
   a. For each $x \in X$ there exists an open neighborhood $U$ of $x$ such that $f_i$ vanishes on $U$ for all but finitely many $i$. In particular for each $x \in X$ there exist only finitely many $i \in I$ such that $x \in \text{supp}(f_i)$.
   b. For every $x \in X$ we have
   \[
   \sum_{i \in I} f_i(x) = 1.
   \]

3. Let $\{U_i\}_{i \in I}$ be an open cover. A **partition of unity subordinate to the open cover** is a partition of unity $\{f_j : X \to [0, 1]\}_{j \in J}$ such that for each $j \in J$ there exists an $i \in I$ with $\text{supp}(f_j) \subset U_i$.

**Example.** In Figure 52 we consider the topological space $X = \mathbb{R}$ with the open cover given by the intervals $U_i = (i-1, i+1)$, $i \in \mathbb{Z}$. Also we illustrate a smooth partition of unity subordinate to this open cover.

![Diagram of a smooth partition of unity](image)

**Figure 52**

**Definition.** A topological space $X$ is called **paracompact** if it is Hausdorff and if given any open cover $\{U_i\}_{i \in I}$ there exists a partition of unity subordinate to the open cover $\{U_i\}_{i \in I}$.

**Example.** As we will see, most topological spaces that are of interest to us, are in fact paracompact. For example in Theorems 2.82 and 6.57 and in Proposition 36.13 we will see that

\[\text{Note that by (a) there are only finitely many non-zero summands, hence the expression on the left-hand side makes sense even if } I \text{ is infinite.}\]
\[\text{As always, all maps are assumed to be continuous.}\]
metric spaces, “topological manifolds” and “CW-complexes” are paracompact. Nonetheless, elementary topological psychology tells us that surely not every topological space is paracompact. Indeed in Proposition 7.11 we will see that the “long line”, that we will define on page 334, is not paracompact.

The following lemma is sometimes useful for simplifying the notation.

**Lemma 2.78.** Let \( X \) be a paracompact topological space and let \( \{ U_i \}_{i \in I} \) be an open cover of \( X \). There exists a partition of unity \( \{ f_i : X \to [0,1] \}_{i \in I} \) such that for every \( i \in I \) we have \( \text{supp}(f_i) \subseteq U_i \).

**Proof.** Since \( X \) is paracompact we know, by definition, that there exists a partition of unity \( \{ g_j : X \to [0,1] \}_{j \in J} \) such that for each \( j \in J \) there exists an \( i(j) \in I \) with \( \text{supp}(g_j) \subseteq U_{i(j)} \). Now given \( i \in I \) we define

\[
   f_i : X \to [0,1] \quad x \mapsto \sum_{j \in J \text{ with } i(j) = i} g_j(x).
\]

Note that \( f_i \) is locally a finite sum of maps, hence the map \( f_i \) is locally continuous, which implies that \( f_i \) is continuous. Furthermore note that

\[
   \text{supp}(f_i) = \bigcup_{j \in J \text{ with } i(j) = i} \text{supp}(g_j) \subseteq U_i.
\]

It follows easily from Condition (a) of a partition of unity.

It is now clear that the functions \( \{ f_i : X \to [0,1] \}_{i \in I} \) have all the desired properties. \( \blacksquare \)

In our next theorem we will give a convenient characterization of paracompact topological spaces. To formulate the theorem we need the following straightforward definition.

**Definition.** Let \( X \) be a topological space and let \( \{ U_i \}_{i \in I} \) and \( \{ V_j \}_{j \in J} \) be two covers of \( X \). We say that \( \{ V_j \}_{j \in J} \) is a refinement of \( \{ U_i \}_{i \in I} \) if each \( V_j \) is contained in some \( U_i \).

**Theorem 2.79.** Let \( X \) be a topological space that is Hausdorff. The following two statements are equivalent:

1. The topological space \( X \) is paracompact.
2. Every open cover \( \{ U_i \}_{i \in I} \) admits a locally finite open cover \( \{ V_j \}_{j \in J} \) that is a refinement of \( \{ U_i \}_{i \in I} \).

**Remark.**

1. In many textbooks, e.g. [Mun75, Chapter 41], [Bre93, Definition I.12.3], [Kel75, p. 156] or [Dug66, Chapter VIII.2], the condition stated in Theorem 2.79 is used as the definition of a paracompact topological space. Fortunately by Theorem 2.79 our definition agrees with the alternative definition.

2. In some books, see e.g. [Jos83, p. 373], the Hausdorff condition is dropped from the definition of paracompactness.
Proof. The “$(1)\Rightarrow(2)$”-direction is basically trivial. Indeed let $\{U_i\}_{i\in I}$ be an open cover. Since $X$ is paracompact there exists a partition of unity $\{f_j: X \to [0, 1]\}_{j\in J}$ subordinate to the open cover $\{U_i\}_{i\in I}$. It follows immediately from the definitions that $\{f^{-1}((0, \infty))\}_{j\in J}$ is a locally finite open cover that is a refinement of $\{U_i\}_{i\in I}$.

The “$(2)\Rightarrow(1)$” is much more interesting. With some effort this direction can be proved using Urysohn’s Lemma 2.50. Since we will not make use of this direction we will not provide the details. Instead we refer to [Bre93, Chapter I.12.8], or alternatively [LW69, Appendix I Proposition 6] and [Dug66, Chapter VIII.4] for details.

The following, slightly technical proposition, sometimes makes it possible find a suitable countable open cover.

Proposition 2.80. (*) Let $X$ be a topological space and let $\{U_i\}_{i\in I}$ be an open cover of $X$. If $X$ is paracompact, then there exists a countable locally finite open cover $\{V_j\}_{j\in J}$ such that each component of any $V_j$ is contained in some $U_i$.

Proof (*). Since $X$ is paracompact there exists a partition of unity $\{f_j: X \to [0, 1]\}_{j\in J}$ subordinate to the given open cover $\{U_i\}_{i\in I}$. Given a finite subset $S \subset J$ we define

$$V_S := \{x \in X \mid f_s(x) > f_j(x) \text{ for all } s \in S \text{ and } j \notin S\}.$$

Since a partition of unity is locally finite one sees almost immediately that $V_S$ is an open subset of $X$. Furthermore note that given any $s \in S$ we have $V_S \subset \text{supp}(f_s)$. In particular there exists an $i \in I$ with $V_S \subset U_i$. Next note that for finite subsets $S$ and $T$ of $J$ we have $V_S \subset V_T$ if and only if $S \subset T$. Finally note that each $x \in X$ is contained in $V_S$ where $S$ is the finite set $S = \{j \in J \mid f_j(x) > 0\}$.

Now given $n \in \mathbb{N}_0$ we define $V_n$ to be the union of all $V_S$ with $\#S = n$. It follows from the above that the $V_S$ with $\#S = n$ are disjoint and open. Thus each component of $V_n$ is contained in some $V_S$, which in turn, as we saw above, is contained in some $U_i$. It is now clear that the family $\{V_n\}_{n\in\mathbb{N}_0}$ has all the desired properties.

The following proposition shows that a large and popular class of topological spaces is paracompact. The proposition perhaps also justifies somewhat the name “paracompact”.

Proposition 2.81. Let $X$ be a topological space. If $X$ is compact and Hausdorff, then it is also paracompact.

Proof. Let $X$ be a topological space that is compact and Hausdorff. Furthermore let $\{U_i\}_{i\in I}$ be an open cover of $X$. We perform the following steps:

1. Since $X$ is Hausdorff we know by Lemma 2.13 that any subset of $X$ consisting of a single point is closed.
2. Since $X$ is compact and Hausdorff we know by Lemma 2.46 that $X$ is normal.
3. Let $x \in X$. We pick an $i_x \in I$ with $x \in U_{i_x}$. It follows almost immediately from (1) and (2) that there exists an open neighborhood $V_x$ of $x$ with $V_x \subset U_{i_x}$.
4. Let $x \in X$. By Urysohn’s Lemma 2.50 applied to $A = \{x\}$ and $B = X \setminus V_x$, there exists a continuous function $\varphi_x: X \to [0, 1]$ with $\varphi_x(x) = 1$ and $\varphi_x|_{X \setminus V_x} \equiv 0$. Note that by construction we have $\text{supp}(\varphi_x) \subset U_{i_x}$.
(5) Evidently the open sets \( \{ \varphi_x^{-1}((0,1]) \} \) \( x \in X \) form an open cover of \( X \). Since \( X \) is compact we know that there exist \( y_1, \ldots, y_s \in X \) such that the corresponding sets cover \( X \).

(6) By construction for each \( x \in X \) there exists a \( j \in \{1, \ldots, s\} \) with \( \varphi_{y_j}(x) > 0 \). In particular \( \varphi_{y_1} + \cdots + \varphi_{y_s} \) is non-zero everywhere.

It follows easily from the construction and (4), (5) and (6) that the maps \( g_j := \frac{\varphi_{y_j}}{\varphi_{y_1} + \cdots + \varphi_{y_s}} \), \( j = 1, \ldots, s \) form a partition of unity subordinate to the open cover \( \{ U_i \}_{i \in I} \).

\[
\text{Figure 53. Illustration of the proof of Proposition 2.81}
\]

For completeness’ sake we also mention the following difficult theorem. We will not make use of it.

**Theorem 2.82. (Stone’s Theorem)** Every metric space is paracompact.

**Proof.** The theorem was first proved by Arthur Stone [Stone48] in 1948. A much shorter proof can be found in [RudiM69].

This concludes our discussion of paracompactness. We refer to [Mun75, Chapter 6.4] for many other interesting results on paracompact topological spaces.

---

**Exercises for Chapter 2.**

**Exercise 2.1.** Show that for statements (1), (2) and (4) of Lemma 1.3 there are indeed examples such that the stated inclusion is indeed a strict inclusion.

**Exercise 2.2.** Let \( f : X \to Y \) be a map between two sets. Let \( A \subset X \) and let \( B \subset Y \) be two subsets. Prove the following equivalence of statements:

\[
f(A) \subset B \iff A \subset f^{-1}(B).
\]

**Exercise 2.3.** Let \( X \) be a topological space and let \( A \) be a subset of \( X \). Show that the following three equalities hold:

1. \( \hat{A} = \{ x \in A \mid \text{there exists a neighborhood } U \text{ of } x \text{ that is contained in } A \} \)
2. \( \overline{A} = \{ x \in X \mid \text{every neighborhood of } x \text{ contains at least one point in } A \} \)
3. \( \partial A = \{ x \in X \mid \text{every neighborhood of } x \text{ contains at least one point in } A \) and one point that does not lie in \( A \} \)

**Exercise 2.4.** Let \( n \in \mathbb{N} \). We fix a point \( P \in \mathbb{R}^n \) and we consider the maps

\[
d_M : \mathbb{R}^n \to \mathbb{R}_{\geq 0} \\
(x_1, \ldots, x_n), (y_1, \ldots, y_n) \mapsto \sum_{i=1}^n |x_i - y_i|
\]

and

\[
d_S : \mathbb{R}^n \to \mathbb{R}_{\geq 0} \\
(x, y) \mapsto \|x - P\| + \|y - P\|.
\]
(a) Show that both maps define metrics on \( \mathbb{R}^n \).

Remark. The metric \( d_M \) is called the Manhattan-metric since it measures the distance between two points if one can go only vertically (avenues) and horizontally (streets). The Manhattan metric is sometimes also called the taxicab metric. The metric \( d_S \) is called the SNCF-metric since it models the distance in France where every train between two points necessarily has to go through Paris.

(b) Let \( n = 2 \). Sketch open balls in \( \mathbb{R}^n \) with respect to the two metrics.

![Manhattan metric](image1.png) \hspace{2cm} ![SNCF-metric](image2.png)

**Figure 54.** Illustration for Exercise 2.4.

**Exercise 2.5.** A norm on a real vector space \( V \) is a map \( f: V \to \mathbb{R}_{\geq 0} \) that satisfies the following three properties:

1. For every \( v \in V \) we have \( f(v) = 0 \iff v = 0 \).
2. For every \( v \in V \) and \( \lambda \in \mathbb{R} \) we have \( f(\lambda \cdot v) = |\lambda| \cdot f(v) \).
3. For every \( v, w \in V \) we have \( f(v + w) \leq f(v) + f(w) \).

A norm \( f \) induces a metric on \( d_f \) by setting \( d_f(v, w) := f(v - w) \), in particular it induces a topology on \( V \). Show that any two norms on a finite-dimensional vector space give rise to the same topology.

Remark. In Exercise 2.5 we will see that the analogous statement for infinite-dimensional vector spaces does not necessarily hold.

**Exercise 2.6.** Let \( C([0, 1]) \) be the real vector space of continuous maps from the interval \([0, 1]\) to \( \mathbb{R} \). We consider the supremum norm \( s(f) := \sup \{ f(x) | x \in [0, 1] \} \) and the integral norm \( i(f) := \int_0^1 f(x) \, dx \).

We denote the topologies corresponding to these norms by \( S \) and \( I \). Show that one topology is contained in the other and show that the two topologies are not the same.

Remark. This shows in particular that the identity map \( \text{id}: (C([0, 1], S) \to (C([0, 1], I) \) is not a homeomorphism.

**Exercise 2.7.** Let \( C([0, 1]) \) be the real vector space of continuous maps from the interval \([0, 1]\) to \( \mathbb{R} \) and let \( C^1([0, 1]) \) be the real vector space of continuously differentiable maps from the interval \([0, 1]\) to \( \mathbb{R} \). In this exercise we equip both vector spaces with the supremum norm \( s(f) := \sup \{ f(x) | x \in [0, 1] \} \). We consider the two maps

\[
D: C^1([0, 1]) \to C([0, 1]) \quad \text{and} \quad I: C^1([0, 1]) \to C([0, 1])
\]

\[
f \mapsto f' \quad \text{and} \quad f \mapsto \left( x \mapsto \int_0^x f(t) \, dt \right).
\]

Note that \( D \) and \( I \) are inverses of one another, in particular both are isomorphisms of real vector spaces.
(a) Show that $I$ is continuous.
(b) Show that $D$ is not continuous.

Remark. This exercise shows that integration is usually a well-behaved operation whereas differentiation can be problematic.

Remark. This exercise is a variation on Exercise 2.6.

Exercise 2.8. Let $U$ be an open subset of $\mathbb{R}^2$. Is it true that the interior of $U$ equals $U$?

Exercise 2.9. Let $U$ be an open subset of $\mathbb{R}^n$. We denote by $C = \overline{U}$ the closure of $U$.

(a) Suppose that $U$ is convex. Show that $U = \overset{\circ}{C}$.
(b) Given an example of an open subset $U$ of $\mathbb{R}^n$ where $U \neq \overset{\circ}{C}$.

Exercise 2.10. Let $n \in \mathbb{N}$. Show that there are precisely $n + 2$ homeomorphism types of compact convex subsets of $\mathbb{R}^n$.

Remark. Use Proposition 2.52 (2).

Exercise 2.11. Let $f : X \to Y$ be a map between topological spaces and let $B \subset Y$ be a subset.

(a) Show that $f^{-1}(\overline{B}) \subset \overline{f^{-1}(B)}$.
(b) Given an example that shows that in general we do not have an equality in (a).
(c) Show that $f(f^{-1}(\overline{B})) = \overline{B}$.

Now, since was so much fun we also do it with the interiors instead of the closures:

(d) Show that $f^{-1}(\overset{\circ}{B})$ is contained in the interior of $f^{-1}(B)$.
(e) Given an example that shows that in general we do not have an equality in (e).
(f) Show that $f(f^{-1}(\overset{\circ}{B})) = \overset{\circ}{B}$.

Exercise 2.12. Does there exist a map $f : S^2 \to S^2$ with a single fixed point, i.e. with a unique point $x$ such that $f(x) = x$?

Exercise 2.13. Let $\{U_i\}_{i \in I}$ be a family of subsets. If $I$ is finite, then we know by Lemma 2.10 that the following two equalities hold:

(a) interior of $\bigcap_{i \in I} U_i = \bigcap_{i \in I} \overset{\circ}{U_i}$ and (b) closure of $\bigcup_{i \in I} U_i = \bigcup_{i \in I} \overline{U_i}$.

Do these equalities also hold if $I$ is infinite?

Exercise 2.14. Let $(X, d)$ and $(Y, e)$ be two metric spaces and let $\varphi : X \to Y$ be a map.

(a) Suppose that there exists some $C > 0$ such that for every choice of $x, x' \in X$ we have $e(\varphi(x), \varphi(x')) < C \cdot d(x, x')$. Show that $d$ is continuous.
(b) Suppose that there exists some $c > 0$ such that for every choice of $x, x' \in X$ we have $e(\varphi(x), \varphi(x')) > c \cdot d(x, x')$. Furthermore suppose that $\varphi$ is surjective. Does it follow that $d$ is open?

Exercise 2.15. Show that every connected non-empty subset of $\mathbb{R}$ is an interval.

Exercise 2.16. Is every open subset of $\mathbb{R}$ the disjoint union of countably many open intervals?
Exercise 2.17. We consider $X = \mathbb{Q}$ with the subspace topology coming from $\mathbb{R}$. Show that the only connected subsets of $\mathbb{Q}$ are the subsets consisting of at most a point.

Exercise 2.18. Let $f: X \to Y$ be a map between topological spaces, let $U \subset X$ be a subset and let $A \subset Y$ be a subset.

(a) Suppose that $A$ is closed and suppose that $f(U) \subset A$. Show that $f(U) = A$.
(b) Suppose that $A$ is open and that $A \subset f(U)$, Show that $A \subset f(U)$.

Exercise 2.19. Let $(X, d)$ be a compact metric space. A rather surprising theorem, see \cite{Gros64} or alternatively \cite{Ris06}, says that there exists a unique $r \in [0, 1]$ such that for any finite sequence of points $x_1, \ldots, x_n \in X$ there exists an $x' \in X$ with $\frac{1}{n} \sum_{i=1}^{n} d(x_i, x') = r$.

This number is called the rendezvous value of $(X, d)$.

(a) Determine the rendezvous value of the interval $X = [0, 1]$ equipped with the metric $d(x, y) = |x - y|$.
(b) Determine the rendezvous value of the circle $X = S^1$ equipped with the Euclidean metric of $\mathbb{R}^2$.

Exercise 2.20.

(a) Show that “$\mathbb{R}^n$ with a point at infinity” is Hausdorff and compact.
(b) Show that “the line with two zeros” is neither Hausdorff nor compact.

Exercise 2.21. Let $X$ be a topological space. We say a subset $A \subset X$ is a retract of $X$ if there exists a retraction $r: X \to A$, i.e. a map with $r(a) = a$ for all $a \in A$. (Evidently we demand that $r$ is continuous).

(a) Suppose that $X$ is Hausdorff. Show that $A$ is a closed subset of $X$.
(b) Show that the conclusion of (a) does not necessarily hold if we do not assume that $X$ is Hausdorff.

Exercise 2.22. Let $X$ be a topological space. Given a compact subset $K \subset X$ we define $m(K)$ to be the number of non-compact path-components of $X \setminus K$ that are not contained in a compact subset of $X$. We refer to

$$\text{End}(X) := \max\{m(K) \mid K \text{ is a compact subset of } X\} \in \mathbb{N}_0 \cup \{\infty\}$$

as the number of ends of $X$.

(a) Given $n \in \mathbb{N}$ determine $m(\mathbb{R}^n)$.

Remark. This exercise shows that $\mathbb{R}$ is not homeomorphic to $\mathbb{R}^2$.

(b) Can you find connected topological spaces with arbitrarily large number of ends?

Remark. We will introduce the “ends” of a topological space in Exercise 25.13. We will see that what we now call the “number of ends” equals the cardinality of the set of ends.

Exercise 2.23. Given $a, b \in \mathbb{N}$ we define

$$U_a(b) := \{b + n \cdot a \mid n \in \mathbb{Z}\} \subset \mathbb{N}.$$ 

Furthermore we set

$$\mathcal{C} := \{U_p(b) \mid p, b \in \mathbb{N} \text{ and } p \text{ prime}\} \subset \mathcal{P}(\mathbb{N}).$$
Exercise 2.27. Given Exercise 2.24. We know that the image of a compact subset of $X$ under $f$ is compact.

(a) Show that $(\mathbb{N}, \mathcal{T})$ is Hausdorff.
(b) A topological space $X$ is called regular if given any $P \in X$ and given any closed subset $A \subset X$ there exist disjoint open subsets $U$ and $V$ with $P \in U$ and $A \subset V$. Show that $(\mathbb{N}, \mathcal{T})$ is not regular.

Exercise 2.24. Given $a \in \mathbb{Z} \setminus \{0\}$ and $b \in \mathbb{Z}$ we define
\[ S(a,b) := \{a \cdot n + b \mid n \in \mathbb{Z}\} = a \cdot \mathbb{Z} + b. \]

Let $\mathcal{T}$ be all subsets of $\mathbb{Z}$ that are the union of sets of the form $S(a,b)$.

(a) Show that $\mathcal{T}$ is a topology on $\mathbb{Z}$. (This topology is called the evenly spaced integer topology on $\mathbb{Z}$).
(b) Show that each set of the form $S(a,b)$ is also closed.
(c) Let $P$ be the set of prime numbers. Show that $\mathbb{Z} \setminus \{-1,1\} = \bigcup_{p \in P} S(0,p)$.
(d) Show that there exist infinitely many primes.

Remark. This proof that there exist infinitely many primes was found by Harry Furstenberg \cite{Furs55} in 1955.

Exercise 2.25. Let $f : X \to Y$ be a map between topological spaces. Show that $f$ is continuous if and only if for every $A \subset X$ we have $f(A) \subset \overline{f(A)}$.

Exercise 2.26. Let $f : X \to Y$ be a continuous map between topological spaces. By Lemma 2.40 we know that the image of a compact subset of $X$ under $f$ is a compact subset of $Y$.

(a) Give an example of a continuous map $f : \mathbb{R} \to \mathbb{R}$ and an open subset $U \subset \mathbb{R}$ such that $f(U)$ is not an open subset of $\mathbb{R}$.
(b) Give an example of a continuous map $f : \mathbb{R} \to \mathbb{R}$ and a closed subset $U \subset \mathbb{R}$ such that $f(U)$ is not a closed subset of $\mathbb{R}$.

Exercise 2.27. Show that the maps
\[ \alpha : \mathbb{R}^2 \to \mathbb{R} \quad \text{and} \quad \beta : \mathbb{R}^2 \to \mathbb{R} \]
\[ (x,y) \mapsto x + y \quad \text{and} \quad (x,y) \mapsto x \cdot y \]
are continuous.
Exercise 2.28. Let $X$ be a topological space, let $A \subset X$ be a closed subset and let $K \subset X$ be a compact subset. Show that $A \cap K$ is also a compact subset of $X$.

Exercise 2.29. Let $f : X \to Y$ be a continuous map from a topological space $X$ to some metric space $Y$, e.g. $Y = \mathbb{R}^n$. Let $P \in Y$ be a point that is not contained in $f(X)$. We suppose that $X$ is compact. Show that there exists an $r > 0$ such that $B_r(P) \cap f(X) = \emptyset$.

Exercise 2.30. Let $f, g : X \to Y$ be two maps between topological spaces.

(a) Suppose that $Y$ is Hausdorff. Show that $\{x \in X \mid f(x) = g(x)\}$ is a closed subset of $X$.

(b) Show that the conclusion of (a) does not necessarily hold if we do not assume that $Y$ is Hausdorff.

Exercise 2.31. Let $\mathbb{R}^n \cup \{\infty\}$ be “$\mathbb{R}^n$ with a point at infinity”. Let $v \in \mathbb{R}^n$. Show that the map

$$\mathbb{R}^n \cup \{\infty\} \to \mathbb{R}^n \cup \{\infty\}$$

$$Q \mapsto \begin{cases} Q + v, & \text{if } Q \in \mathbb{R}^n, \\ \infty, & \text{if } Q = \infty \end{cases}$$

is continuous.

Exercise 2.32. Let $X$ be a topological space and let $A \subset X$ be a subset.

(a) We suppose that $X$ is Hausdorff. Show that $\partial A = \partial \overline{A}$.

(b) Does the conclusion in (a) also hold if $X$ is not Hausdorff?

Exercise 2.33. Let $f$ be a complex polynomial of degree $\geq 1$. Show that the map

$$\Theta(f) : \mathbb{C} \cup \{\infty\} \to \mathbb{C} \cup \{\infty\}$$

$$t \mapsto \begin{cases} f(t), & \text{if } t \in \mathbb{C}, \\ \infty, & \text{if } t = \infty \end{cases}$$

is continuous.

Remark. By Lemma 2.44 we can make the identification $S^2 = \mathbb{C} \cup \{\infty\}$. Thus we see that complex polynomials of degree $\geq 1$ give rise to interesting self-maps of $S^2$.

Remark. The analogous statement also holds for a polynomial $f$ with real coefficients, it gives rise to a self-map $\Theta(f)$ of $\mathbb{R} \cup \{\infty\} = S^1$. We illustrate this situation in Figure 5.7.

Exercise 2.34. We consider the map

$$f : \mathbb{R} \to S^1$$

$$t \mapsto e^{2\pi it}$$

(a) Show that $f$ is an open map.

(b) Is $f$ also a closed map?
Exercise 2.35. Let $X$ be a set and let \( \{A_i\}_{i \in I} \) be a family of subsets. Suppose that each $A_i$ is equipped with a topology.

(a) We say $U \subset X$ is open if for each $i \in I$ the intersection $U \cap A_i$ is an open subset of $A_i$. Show that this defines a topology on $X$.

(b) We consider the set $X = [-2, 2]$.

(i) We consider the subsets $A_1 = [-2, 0]$ and $A_2 = [0, 2]$.

(ii) We consider the subsets $B_1 = [-2, 0]$ and $B_2 = (0, 2]$.

(iii) We consider the subsets $C_1 = [-2, 0]$, $C_2 = (0, 2]$ and $C_3 = (-1, 1)$.

(iv) We consider the subsets $D_1 = [-1, 1]$ and $D_2 = (0, 2]$.

For each of these four settings we equip the subsets with the obvious topology and we equip $X = [-2, 2]$ with the corresponding topology. Describe the resulting four topological spaces. Are these topological spaces that we are familiar with?

We refer to Figure 58 for an illustration.

Exercise 2.36. Let $P_1, \ldots, P_n \in \mathbb{R}^k$.

(a) Show that the convex hull of the set \( \{P_1, \ldots, P_n\} \) is given by the set

\[
\left\{ \sum_{i=1}^n t_i P_i \mid t_1, \ldots, t_n \in \mathbb{R}_{\geq 0} \text{ and } \sum_{i=1}^n t_i = 1 \right\}.
\]

Note: We make no hypothesis on the points $P_1, \ldots, P_n$, in particular some of them could be identical and we do not assume say that the vectors $P_2 - P_1, \ldots, P_n - 1$ are linearly independent.

(b) Show that the set in (a) is compact.

(c) Is the convex hull of a compact subset of $\mathbb{R}^k$ necessarily compact?

(d) Is the convex hull of an open subset of $\mathbb{R}^k$ necessarily an open subset?

Exercise 2.37. Let $f, g: X \to Y$ be two maps between topological spaces. Show that if $f$ and $g$ agree on a dense subset of $X$, then $f = g$.

Remark. Evidently by a “map” we mean as always a continuous map.
Exercise 2.38. Let $X$ be a topological space. We say a subset $U \subset X$ is large if $U$ is open and dense.

(a) Show that the intersection of finitely many large subsets of $X$ is again large.

(b) Is it true that the intersection of countably many large subsets of $X$ is necessarily large?

Exercise 2.39. Let $f, g : X \to Y$ be two maps between two topological spaces. Let $A \subset X$ be a subset such that $f$ and $g$ agree on $A$. Show that if $A$ is dense, if $Y$ is Hausdorff and if $f$ and $g$ are continuous, then $f$ and $g$ agree on all of $X$.

Exercise 2.40.

(a) Show that the half-open interval $[0, 1)$ and the open interval $(0, 1)$ are not homeomorphic.

(b) Is the half-open rational interval $[0, 1) \cap \mathbb{Q}$ homeomorphic to the open rational interval $(0, 1) \cap \mathbb{Q}$?

Exercise 2.41. Give an example of a bijective continuous map $f : X \to Y$ between two topological spaces where $X$ is compact but such that $f$ is nonetheless not a homeomorphism.

Exercise 2.42. Let $X$ and $Y$ be topological spaces and let $i : X \to Y$ be a map. We suppose that there exists a map $r : Y \to X$ with $r \circ i = \text{id}_X$. Show that $i$ is an embedding.

Exercise 2.43. Let $f : [0, 1] \to \mathbb{R}$ be a continuous function. Let $0 \leq a < b \leq 1$. Show that $f$ can only go finitely many times from $a$ to $b$. More precisely, show that it is not possible to find numbers $x_1 < y_1 < x_2 < y_2 < x_3 < y_3 < \ldots$ in $[0, 1]$ such that for each $i \in \mathbb{N}$ we have $f(x_i) = a$ and we have $f(y_i) = b$.

Exercise 2.44. Show that the topological space $[0, 1) \cap \mathbb{Q}$, equipped with the subspace topology coming from $\mathbb{R}$, is not compact.

Exercise 2.45. We consider

$$
\mathbb{R}^\infty := \{(x_1, x_2, \ldots) \in \mathbb{R}^\mathbb{N} \mid \text{there exists an } i \in \mathbb{N} \text{ such that } x_j = 0 \text{ for } j \geq i\}.
$$

We equip $\mathbb{R}^\infty$ with the Euclidean metric

$$
d : \mathbb{R}^\infty \times \mathbb{R}^\infty \to \mathbb{R}^\infty
$$

$$
((x_1, x_2, \ldots), (y_1, y_2, \ldots)) \mapsto \sqrt{\sum_{i \in \mathbb{N}} |x_i - y_i|^2}.
$$

Show that $(\mathbb{R}^\infty, d)$ is not compact.

Exercise 2.46.

(a) Let $A$ be a real $m \times n$-matrix. Show that there exists a $C \in \mathbb{R}$ such that for all $v \in \mathbb{R}^n$ we have $\|Av\| \leq C \cdot \|v\|$.

(b) Let $A \in \text{GL}(n, \mathbb{R})$ be an invertible matrix. Show that there exists a $\lambda > 0$ such that $\|Av\| \geq \lambda \|v\|$ for all $v \in \mathbb{R}^n$.

Hint. In both cases use that $S^{n-1}$ is compact.
Exercise 2.47. Let $X$ be a topological space. A subset $A \subseteq X$ is called \textit{precompact} if the closure $\overline{A}$ is compact. Let $X$ be a subset of some topological space $Y$ and let $A \subseteq X$ be a precompact subspace.

(a) Show that $A$ is not necessarily precompact in $Y$.
(b) Show that if $Y$ is Hausdorff, then $A$ is in fact precompact in $Y$.

\textit{Remark.} Dealing with closures can be quite subtle. For example, it seems to me that for (b) you want to use Lemma 2.43 (2) at some point.

Exercise 2.48. Let $X$ be a topological space. We say that a family $\{A_i\}_{i \in I}$ of subsets has the \textit{finite intersection property} if given any finite collection of indices $i_1, \ldots, i_r \in I$ the corresponding intersection $A_{i_1} \cap \cdots \cap A_{i_r}$ is non-empty.

(a) We assume that $X$ is a compact topological space and that all the $A_i$ are closed subsets. Show that $\bigcap_{i \in I} A_i \neq \emptyset$.

(b) Show that in (a) we cannot drop the hypothesis that $X$ is compact.

Exercise 2.49. Let $A$ be an invertible real $(m \times m)$-matrix. Show that the map

$$
\mathbb{R}^m \cup \{\infty\} \to \mathbb{R}^m \cup \{\infty\}
$$

$$
x \mapsto \begin{cases} 
A \cdot x, & \text{if } x \in \mathbb{R}^m, \\
\infty, & \text{if } x = \infty
\end{cases}
$$

is continuous.

\textit{Hint.} Use Exercise 2.46.

Exercise 2.50. Is every open map necessarily continuous? More precisely, if $f : X \to Y$ is a map between topological spaces with the property that for any open $U \subseteq X$ the image $f(U)$ is an open subset of $Y$, does it follow that $f$ is continuous?

Exercise 2.51. Let $n \in \mathbb{N}$. We consider the stereographic projection

$$
\Phi : S^n \to \mathbb{R}^n \cup \{\infty\}
$$

$$
(x_1, \ldots, x_{n+1}) \mapsto \begin{cases} 
\left( \frac{x_1}{1-x_{n+1}}, \ldots, \frac{x_n}{1-x_{n+1}} \right), & \text{if } x_{n+1} < 1, \\
\infty, & \text{if } x_{n+1} = 1
\end{cases}
$$

that we introduced in Lemma 2.44. Show that $\Phi$ is continuous.

Exercise 2.52. Show that the topologist’s sine curve, that we defined on page 131 is connected and show that it is not path-connected.

Exercise 2.53. Let $X$ be a topological space and let $\mathcal{U} \subseteq \mathcal{P}(X)$ be an open cover of $X$. Show that the following two statements are equivalent:

1. The topological space $X$ is connected.
2. Given any $P, Q \in X$ there exist $U_0, \ldots, U_k \in \mathcal{U}$ with $P \in U_0, Q \in U_k$ and such that $U_i \cap U_j = \emptyset$ if $|i - j| \geq 2$.

\textit{Remark.} Some people refer to this statement as the \textit{Sausage Lemma}.

Exercise 2.54. Let $X$ be a topological space and let $A \subseteq X$ be a subset.
Exercise 2.55. Let $X$ be a topological space and let $\{B_i\}_{i \in I}$ be a family of open subsets such that the intersection $Y := \bigcap_{i \in I} B_i$ is non-empty.

(a) We suppose that $X$ and $Y$ are path-connected. Show that each $B_i$ is path-connected. 

Hint. Use the Lebesgue Lemma 2.73.

(b) We suppose that $X$ and $Y$ are connected. Show that each $B_i$ is connected.

(c) Show that statements (a) and (b) are wrong if we drop the hypothesis that the $B_i$ are open.

(d) Do statements (a) and (b) hold if each $B_i$ is a closed subset?

Remark. This statement can be viewed as a partial converse to Lemma 2.62.

Exercise 2.56. Let $X$ be a topological space and let $A \subset X$ be a subset. Show that if $A$ is connected, then its closure $\overline{A}$ is also connected.

Exercise 2.57. Let $f: [0, 1] \to [0, 1]^2$ be an injective map such that $f([0, 1])$ has non-zero 2-dimensional Lebesgue measure. Show that there exists an injective map $g: S^1 \to [0, 1]^2$ such that $g(S^1)$ has non-zero 2-dimensional Lebesgue measure.

Remark. Note that this exercise provides the details for an easy step in the proof of Proposition 2.60 (2).

Exercise 2.58. A topological space $X$ is called arc-connected if given any two points $P, Q \in X$ there exists a map $f: [0, 1] \to X$ with $f(0) = P, f(1) = Q$ and which has the property that $f$ is an embedding.$^{45}$

(a) Show that the line with two zeros is not arc-connected.

(b) Let $n \geq 2$ and let $X$ be the “$\mathbb{R}^n$ with two origins”, which is defined in the hopefully obvious way. Is $X$ arc-connected?

Remark. A rather amazing (non-trivial!) theorem says that any topological space that is path-connected and which is Hausdorff is in fact arc-connected. We refer to [Wil70] Corollary 31.6, [Enge89] p. 381 and [HY88] p. 118 and p. 129 for a proof of this statement.

$^{45}$Sometimes, see e.g. [Wil70, Enge89], such topological spaces are also called arcwise connected. Rather confusingly some other books, e.g. [Bre93], use the term arcwise connected for what we call path-connected. The lesson is, that in any given book one always should look up the definitions.
Exercise 2.59.
(a) Let $n \in \mathbb{N}_{\geq 3}$. We consider $X_n := \{ r \cdot e^{2\pi i k/n} | r \in [0, 1) \text{ and } k \in \{0, \ldots, n - 1\}\}$. We write $P := 0$. Show that every self-homeomorphism $f : X_n \to X_n$ preserves $P$. We refer to Figure 60 for an illustration.
(b) Does the statement in (a) also hold for $n = 1$ and/or $n = 2$?

![Figure 60](image)

Exercise 2.60. Let $n \in \mathbb{N}$. We consider the general linear group $\text{GL}(n, \mathbb{R}) = \{ A \in M(n \times n, \mathbb{R}) | \det(A) \neq 0 \} \subset M(n \times n, \mathbb{R}) = \mathbb{R}^{n^2}$. Show that two matrices lie in the same path-component of $\text{GL}(n, \mathbb{R})$ if and only if the signs of their determinants agree. (Put differently, the goal is to prove the first part of Lemma 2.65.)

Exercise 2.61.
(a) Let $n \geq 1$. Show that the sphere $S^n$ is path-connected.
(b) Is the line with two zeros connected?

Exercise 2.62. A subset of a topological space is sometimes called clopen if it is open and closed. Let $n \in \mathbb{N}$. Determine all clopen subsets of $\mathbb{R}^n$.

Exercise 2.63. Let $X$ be a topological space that is locally path-connected. Show that if $X$ is connected, then it is also path-connected.

Exercise 2.64. Let $X$ be a path-connected subset of $\mathbb{R}^2$. Is it also necessarily regionally path-connected?

Exercise 2.65. We consider the set $X = (0, 1)$ with the topology where the open sets are precisely the sets $\emptyset, X$ and the intervals $(0, 1 - \frac{1}{n})$. Show that $X$ is compact and show that $X$ is not regionally compact.

Exercise 2.66. Let $X$ be a topological space. We consider the set $X^* := X \cup \{\infty\}$. We say $U \subset X^*$ is open if one of the following conditions is satisfied:

(1) $U$ is an open subset of $X$, or
(2) $\infty \in U$ and there exists a compact subset $K$ of $X$ such that $U = X^* \setminus K$.

The inclusion $c : X \to X^*$ is called the Alexandroff extension. Show that the following statements hold:

(a) The open sets do indeed define a topology on $X$.
(b) The map $c$ is continuous and open.
(c) Show that the topological space $X^*$ is compact.
(d) Show that if $X$ is non-compact, then $c(X) \subset X^*$ is dense.

(e) Show that $X^*$ is Hausdorff if and only if $X$ is Hausdorff and regionally compact.

Remark. The topological space $X^*$ is called the one-point compactification of $X$ or Alexandroff compactification of $X$.\footnote{Some authors use the expression “one-point compactification” only if $X$ is non-compact, Hausdorff and regionally compact.}

Remark. One can show easily that the one-point compactification of $\mathbb{R}^n$ equals the “$\mathbb{R}^n$ with a point at infinity” that we introduced on page 95.

Exercise 2.67. Let $X = \mathbb{N}$ with the discrete topology. Show that the one-point compactification of $X$, as defined in Exercise 2.66, is homeomorphic to a subset of $\mathbb{R}$.

Exercise 2.68.

(a) Show that every paracompact topological space is regular.

(b) Show that every paracompact topological space is normal.

Remark. These two statements can be viewed as a generalization of Lemma 2.46.

Exercise 2.69. Let $X$ be a paracompact topological space and let $A \subset X$ be a closed subset. Show that $A$ is also paracompact.
3. CONSTRUCTIONS OF TOPOLOGICAL SPACES

In this chapter we will get to know many techniques for constructing new examples of topological spaces out of given ones.

3.1. The disjoint union of topological spaces. We start out this section with a short set-theoretic discussion. Sometimes, given two sets $A$ and $B$ one would like to consider a new set that is the “disjoint union of $A$ and $B$”. This leads us to the following, arguably slightly awkward definition.

**Definition.**

(1) Let $A$ and $B$ be two sets. We define the disjoint union of $A$ and $B$ as

$$A \sqcup B := (A \times \{1\}) \cup (B \times \{2\}).$$

(2) If $\{A_i\}_{i \in I}$ is a family of sets, then we define the disjoint union as

$$\bigcup_{i \in I} A_i := \bigcup_{i \in I} (A_i \times \{i\}).$$

**Convention.** Let $A$ and $B$ be two sets. In most situations, when there is no danger of confusion, we use the obvious bijections $A = A \times \{1\}$ and $B = B \times \{2\}$ to identify $A$ and $B$ with the corresponding subsets of $A \sqcup B$. In particular, if $A$ and $B$ are already disjoint, then we make the identification $A \sqcup B = A \cup B$. The same convention applies to the disjoint union $\bigcup_{i \in I} A_i$. At times the author of these notes will rely on the good will of the reader to correctly interpret a given statement.

**Definition.** Given a family $\{X_i\}_{i \in I}$ of topological spaces we equip the disjoint union $\bigcup_{i \in I} X_i$ with the disjoint union topology that is defined by the condition that $U \subset \bigcup_{i \in I} X_i$ is open if and only if for each $i \in I$ the intersection $U \cap X_i$ is an open subset of $X_i$.

For completeness we state the following lemma which follows immediately from the definition of the disjoint union topology together with Lemma 2.34.

**Lemma 3.1.** Let $\{X_i\}_{i \in I}$ be a family of topological spaces. A subset $A \subset \bigcup_{i \in I} X_i$ is closed if and only if for each $i \in I$ the intersection $A \cap X_i$ is a closed subset of $X_i$.

The following lemma gives a criterion for showing that a union of subsets is actually the disjoint union of subsets.

**Lemma 3.2.** Let $X$ be a topological space and let $A$ and $B$ be two subsets of $X$. The following two statements are equivalent:

1. There exist open neighborhoods $U$ of $A$ and $V$ of $B$ with $U \cap B = \emptyset$ and $V \cap A = \emptyset$.
(2) The map
\[ A \cup B \rightarrow A \sqcup B \]
\[ x \mapsto \begin{cases} (x, 1), & \text{if } x \in A, \\ (x, 2), & \text{if } x \in B \end{cases} \]

is a homeomorphism.

The obvious generalization to an arbitrarily collection of subsets also holds.

**Proof.** We (i.e., you) will provide the proof in Exercise 3.1.

**Examples.**

1. Using Lemma 3.2, one can easily verify that the topological space \( S^1 \sqcup S^1 \) is homeomorphic to the topological space \( S^1(-2, 0) \sqcup S^1(2, 0) \subset \mathbb{R}^2 \). We also refer to Figure 61 for an illustration.

![Figure 61](image)

2. Using Lemma 3.2, one can also easily show that the topological space \([-1, 0) \sqcup (0, 1] \) is homeomorphic to \([-2, -1) \sqcup (0, 1] \subset \mathbb{R} \) and that it is not homeomorphic to \([-1, 1] \).

3. Let \( X \) be a topological space and let \( \{U_i\}_{i \in I} \) be family of pairwise disjoint open subsets. It follows immediately from Lemma 3.2 that the map
\[ \bigcup_{i \in I} U_i \rightarrow \bigcup_{i \in I} U_i \]
\[ x \mapsto (x, i) \quad \text{if } x \in U_i \]

is a homeomorphism.

The following lemma summarizes a few very basic properties of the disjoint union of two topological spaces. We leave it to the reader to write down the dreadfully dull proof.

**Lemma 3.3.** (*) Let \( \{X_i\}_{i \in I} \) be a family of topological spaces.

1. For each \( i \in I \) the inclusion map \( X_i \rightarrow \bigsqcup_{i \in I} X_i \) is an embedding which is open and closed.

2. A map \( f : \bigsqcup_{i \in I} X_i \rightarrow Y \) to some topological space \( Y \) is continuous if and only if each restriction \( f|_{X_i} \) is continuous. In particular the map
\[ \{\text{set of continuous maps } \bigsqcup_{i \in I} X_i \rightarrow Y\} \rightarrow \prod_{i \in I} \{\text{set of continuous maps } X_i \rightarrow Y\} \]
\[ f \mapsto (f|_{X_i})_{i \in I} \]

is a bijection.
(3) Let \( \{ f_i : X_i \to Y_i \}_{i \in I} \) be a family of maps between topological spaces. The map

\[
\bigcup_{i \in I} f_i : \bigcup_{i \in I} X_i \to \bigcup_{i \in I} Y_i
\]

\((x, i) \mapsto (f_i(x), i)\)

is continuous if and only if each \( f_i \) is continuous.

(4) The topological space \( \bigcup_{i \in I} X_i \) is compact if and only if each \( X_i \) is compact and if there are only finitely many \( i \in I \) such that \( X_i \neq \emptyset \).

The above statements hold the same way for the disjoint union of two topological spaces. Furthermore, given topological spaces \( X, Y \) and \( Z \) the following statements hold:

(5) The obvious bijection \( X \sqcup Y \to Y \sqcup X \) is a homeomorphism.

(6) The obvious bijection \( (X \sqcup Y) \sqcup Z \to X \sqcup (Y \sqcup Z) \) is a homeomorphism.

Remark.

(1) The diligent reader could extend Lemma 3.3 ad infinitum with statements regarding the interaction of disjoint union with the subspace topology, product topologies (which we will introduce shortly) and quotient topologies.

(2) Let \( X \) be a topological space and let \( \{ X_i \}_{i \in I} \) be its set of components. Note that Lemma 2.68 says that as a set we have \( X = \bigcup_{i \in I} X_i \). But, if we equip the right-hand side with the disjoint union topology that we introduced on page 159, then this is in general not an equality (or homeomorphism) of topological spaces. For example, an easy counterexample is given by \( X = Q \).

3.2. The product of finitely many topological spaces I. In the following two sections we introduce and discuss a suitable topology on the product of topological spaces. In this section and the following we deal with the product of finitely many topological spaces which is what we are mostly interested in. Afterwards we will quickly discuss a suitable topology on the product of arbitrarily many topological spaces.

Lemma 3.4. Let \( X_1, \ldots, X_k \) be topological spaces. The set

\[
\mathcal{B} = \{ U_1 \times \cdots \times U_k \mid \text{each } U_i \text{ is open in } X_i \}
\]

has the basis property from page 102.

Proof (*). We need to verify that \( \mathcal{B} \) satisfies the conditions (B1) and (B2) formulated on page 102.

(B1) We have \( X_1 \times \cdots \times X_k \in \mathcal{B} \). Thus given any \((x_1, \ldots, x_k) \in X_1 \times \cdots \times X_k\) there exists a set in \( \mathcal{B} \), namely \( X_1 \times \cdots \times X_k \), which contains \((x_1, \ldots, x_k)\). Thus \( \mathcal{B} \) satisfies (B1).

(B2) Let \( U_1 \times \cdots \times U_k \) and \( V_1 \times \cdots \times V_k \) be two sets in \( \mathcal{B} \). Then

\[
(U_1 \times \cdots \times U_k) \cap (V_1 \times \cdots \times V_k) = (U_1 \cap V_1) \times \cdots \times (U_k \cap V_k)
\]

is again a set in \( \mathcal{B} \). Thus \( \mathcal{B} \) also satisfies (B2).
**Definition.** Let $X_1, \ldots, X_k$ be topological spaces. The product topology on $X_1 \times \cdots \times X_k$ is the topology on $X_1 \times \cdots \times X_k$ that is generated by
\[ B = \{ U_1 \times \cdots \times U_k \mid \text{each } U_i \text{ is open in } X_i \}. \]
We refer to Figure 62 for an illustration.

\[ X_1 \xrightarrow{\longrightarrow} \]

\[ \text{products } U_1 \times U_2 \text{ of open sets} \]

\[ W \text{ is open in the product topology on } X_1 \times X_2 \]

**Convention.** Given topological spaces $X_1, \ldots, X_k$ we always equip $X_1 \times \cdots \times X_k$ with the product topology, unless we explicitly say something else.

The following lemma seems obvious, but as so many statements in general topology, the actual proof requires a little bit of thought.

**Lemma 3.5.** Let $k_1, \ldots, k_m \in \mathbb{N}_0$. The map
\[ \mathbb{R}^{k_1} \times \cdots \times \mathbb{R}^{k_m} \rightarrow \mathbb{R}^{k_1 + \cdots + k_m} \]
\[ ((x_1, \ldots, x_{k_1}), \ldots, (x_1, \ldots, x_{k_m})) \mapsto (x_1, \ldots, x_{k_1}, \ldots, x_1, \ldots, x_{k_m}) \]
is a homeomorphism. More generally, if we are given given $X_i \subset \mathbb{R}^{k_i}, i = 1, \ldots, m$, then the restriction of the above map to
\[ \frac{X^{k_1} \times \cdots \times X^{k_m}}{\text{product of subspace topologies}} \rightarrow \frac{X^{k_1} \times \cdots \times X^{k_m}}{\text{subspace topology from } \mathbb{R}^{k_1 + \cdots + k_m}} \]
is a homeomorphism.

**Proof (•).** It is clear that the map is a bijection. So it remains to show that the map and its inverse are continuous. The continuity of both maps can be shown using Proposition 2.37 and Lemma 2.3. We leave it to the reader to fill in the details.

**Convention.** Henceforth, given $k_1, \ldots, k_m \in \mathbb{N}_0$ we will always identify the product topological space $\mathbb{R}^{k_1} \times \cdots \times \mathbb{R}^{k_m}$ with $\mathbb{R}^{k_1 + \cdots + k_m}$. In particular, given $X_i \subset \mathbb{R}^{k_i}, i = 1, \ldots, m$, we view $X_1 \times \cdots \times X_m$ as a subset of $\mathbb{R}^{k_1 + \cdots + k_m}$.

**Example.** Let $s_1, \ldots, s_n \in \mathbb{N}_0$. We set $s = s_1 + \cdots + s_n$. By the above convention we can view $B^{s_1} \times \cdots \times B^{s_m}$ as a subset of $\mathbb{R}^s$. By definition this is an open subset of $\mathbb{R}^s$ and one verifies easily that it is convex and bounded. Thus it follows from Proposition 2.52 that
there exists a canonical homeomorphism \( B^s \times \cdots \times B^s \) to the ball \( B^s \) that sends \((0, \ldots, 0)\) to the origin. The same statement holds for the corresponding closed balls.

Before we can discuss more examples we introduce the following convention:

**Convention.**

(1) Given \( m \in \mathbb{N}_0 \) we make the identification
\[
\mathbb{C}^m \cong \mathbb{R}^{2m}
\]
\[
(x_1 + iy_1, \ldots, x_m + iy_m) \mapsto (x_1, y_1, x_2, y_2, \ldots, x_m, y_m).
\]

(2) Given \( m, n \in \mathbb{N}_0 \) we make the identification
\[
M(m \times n, \mathbb{R}) \cong \mathbb{R}^{mn}
\]
\[
(a_{ij})_{i=1, \ldots, m, j=1, \ldots, n} \mapsto (a_{11}, \ldots, a_{1n}, \ldots, a_{n1}, \ldots, a_{nm})
\]

Similarly we identify \( M(m \times n, \mathbb{C}) \) with \( \mathbb{R}^{2mn} \).

(3) We use these maps to view \((\text{every subset of } \mathbb{C}^m, M(m \times n, \mathbb{R}) \text{ and } M(m \times n, \mathbb{C})\) as topological spaces.

**Examples.**

(1) It follows almost immediately from our conventions and the examples on page 107 that for any \( k, l, m \in \mathbb{N}_0 \) the map
\[
M(k \times l, \mathbb{R}) \times M(l \times m, \mathbb{R}) \to M(k \times m, \mathbb{R})
\]
\[
(A, B) \mapsto A \cdot B
\]
is continuous. The same also applies to matrices over \( \mathbb{C} \).

(2) It follows from (1) and Lemma 2.32 that
\[
O(n) = \{A \in M(n \times n, \mathbb{R}) | A^T A = \text{id}\} = f^{-1}(\text{id}_n) \text{ with } M(n \times n; \mathbb{R}) \xrightarrow{f} M(n \times n; \mathbb{R})
\]
\[
A \mapsto A \cdot A^T
\]
is a closed subset of \( \mathbb{R}^{n^2} \). Since each column of an orthogonal matrix has norm one we see that \( O(n) \subset \mathbb{R}^{n^2} \) is a bounded subset. Thus it follows from the Heine-Borel Theorem 2.20 that \( O(n) \) is compact. Basically the same argument shows that the set \( U(n) \) of unitary \( n \times n \)-matrices is a compact topological space.

After these examples let us turn to the study of the more formal properties of the product topology. The following lemma states two properties of the product topology and it shows that the product topology is actually completely determined by these two properties.

**Lemma 3.6.** Let \( X_1, \ldots, X_k \) be topological spaces.

(1) For each \( i \in \{1, \ldots, k\} \) the projection map
\[
p_i: X_1 \times \cdots \times X_k \to X_i
\]
\[
(x_1, \ldots, x_k) \mapsto x_i
\]
is continuous.
Let \( W \) be a topological space. If \( f_i: W \to X_i, i = 1, \ldots, k \) are continuous maps, then the map
\[
W \to X_1 \times \cdots \times X_k \\
w \mapsto (f_1(w), \ldots, f_k(w))
\]
is continuous.

3. The product topology on the set \( X_1 \times \cdots \times X_k \) is the unique topology on \( X_1 \times \cdots \times X_k \) that satisfies properties (1) and (2).

**Example.** Let \( X \) be a topological space and let \( \{P\} \) be the topological space consisting of a single point \( P \) (note that \( \{P\} \) has a unique topological structure!). It follows from Lemma 3.6 that that the obvious bijection \( X \to X \times \{P\} \) a homeomorphism. On many occasions we will use this homeomorphism to make the identification \( X = X \times \{P\} \).

**Proof.**

(1),(2) These two statements follow easily from the definition.

(3) Let \( \mathcal{P} \) be the product topology on \( X_1 \times \cdots \times X_k \) and let \( \mathcal{T} \) be some other topology on \( X_1 \times \cdots \times X_k \) that satisfies (1) and (2). It follows easily from the fact that \( \mathcal{T} \) satisfies (1) that \( \mathcal{P} \subset \mathcal{T} \). Furthermore it follows from the fact that \( \mathcal{T} \) satisfies (2) that the map
\[
(X_1 \times \cdots \times X_k, \mathcal{P}) \to (X_1 \times \cdots \times X_k, \mathcal{T}) \\
(x_1, \ldots, x_k) \mapsto (p_1(x_1, \ldots, x_k), \ldots, p_k(x_1, \ldots, x_k)) = (x_1, \ldots, x_k)
\]
is continuous. Since this map is actually the identity we see that \( \mathcal{T} \subset \mathcal{P} \). Thus we have shown that \( \mathcal{T} = \mathcal{P} \).

The following remark can be viewed as a sibling of the future Remark 3.23.

**Remark 3.7.** We consider maps in and out of a product space \( X_1 \times X_2 \):

1. Lemma 3.6 gives us an easy to show that a given map \( X \to X_1 \times X_2 \) to a product space is continuous. More precisely, by Lemma 3.6 (1) we “just” need to show that the two coordinate maps \( X \to X_1 \) and \( X \to X_2 \) are continuous.
2. There is usually no easy way to show that a map \( X_1 \times X_2 \to X \) out of a product space is continuous.

We move on to a longish list of further properties of the product topology.

**Lemma 3.8.**

1. (a) The product topology is “commutative” in the sense that given two topological spaces \( A \) and \( B \) the obvious map \( A \times B \to B \times A \) is a homeomorphism.
   (b) The product topology is “associative” in the sense that given three topological spaces \( A, B \) and \( C \) the identity map is a homeomorphism between \((A \times B) \times C, A \times B \times C \) and \( A \times (B \times C) \).
   (c) The product topology commutes with subspace topology. More precisely, let \( X \) and \( Y \) be two topological spaces and let \( A \subset X \) and \( B \subset Y \) be subsets. Then the subspace topology of \( A \times B \subset X \times Y \) agrees with product topology of \( A \) and \( B \).
3. CONSTRUCTIONS OF TOPOLOGICAL SPACES

(d) The product topology is “distributive” with respect to the disjoint union topology. More precisely, let $X$ and $Y$ be two topological spaces and let $A$ be another topological space. The obvious map $(X \sqcup Y) \times A \to (X \times A) \sqcup (Y \times A)$ is a homeomorphism.

(2) Let $Y_1, \ldots, Y_k$ be topological spaces.
(a) Let $i \in \{1, \ldots, k\}$ and for $j \neq i$ let $y_j \in Y_j$. The inclusion map

$$Y_i \to Y_1 \times \cdots \times Y_i \times \cdots \times Y_k$$

$$y \mapsto (y_1, \ldots, y, \ldots, y_k)$$

is continuous and it is an embedding.\(^{48}\)

(b) If $f_i: Y_i \to Z_i$, $i = 1, \ldots, k$ are continuous maps between topological spaces, then the map

$$Y_1 \times \cdots \times Y_k \to Z_1 \times \cdots \times Z_k$$

$$(y_1, \ldots, y_k) \mapsto (f_1(y_1), \ldots, f_k(y_k))$$

is continuous.

Example. It follows from Lemma 3.6 (1) that given any topological space $X$ the diagonal map

$$X \to X \times X$$

$$x \mapsto (x, x)$$

is continuous. This fact will come in handy on many occasions.

Proof (*).

(1) All these statements are easily verified by hand. Note that Statements (b) and (c) can also deduced from the defining property of the product topology that we stated in Lemma 3.6 (3).

(2) (a) It follows from Lemma 3.6 (2) and the observation that the identity map and the constant map are both continuous that the given map is continuous. Clearly the map is a bijection. Finally the inverse is given by the projection onto the $i$-th factor, which is continuous by Lemma 3.6 (1).

(b) It follows from Lemma 2.30 and Lemma 3.6 that the maps $Y_1 \times \cdots \times Y_k \to Z_i$ given by $(y_1, \ldots, y_k) \to f_i(y_i)$ are continuous. It now follows from Lemma 3.6 (2) that the given map $Y_1 \times \cdots Y_k \to Z_1 \times \cdots \times Z_k$ is continuous. \(\blacksquare\)

In the remainder of this section we will state several technical lemmas which will be used consciously and unconsciously on numerous occasions. Despite their usefulness they do not make for pleasurable reading, so the reader is encouraged to move on to the next section.

Here is the first technical lemma.

\(^{48}\)Recall that “embedding” means that the map is a homeomorphism onto its image, in our setting this means that the inclusion map defines a homeomorphism $Y_i \to \{y_1\} \times \cdots \times \{y_{i-1}\} \times Y_i \times \{y_{i+1}\} \times \cdots \times \{y_k\}$.
Lemma 3.9. (*) Let $X_1, \ldots, X_k$ be topological spaces.

(1) If $A_i \subseteq X_i$, $i = 1, \ldots, k$ are closed subsets, then $A_1 \times \cdots \times A_k$ is a closed subset of $X_1 \times \cdots \times X_k$.

(2) Let $B_i \subseteq X_i$, $i = 1, \ldots, k$ be subsets. The following equalities hold:

- closure of $B_1 \times \cdots \times B_k$ in $X_1 \times \cdots \times X_k$ = $\overline{B_1 \times \cdots \times B_k}$
- interior of $B_1 \times \cdots \times B_k$ in $X_1 \times \cdots \times X_k$ = $\overline{B_1 \times \cdots \times B_k}$
- boundary of $B_1 \times \cdots \times B_k$ in $X_1 \times \cdots \times X_k$ = $\bigcup_{i=1}^{k} \partial B_i \times \cdots \times B_k$.

Proof (*).

(1) We have

$$(X_1 \times \cdots \times X_k) \setminus (A_1 \times \cdots \times A_k) = \bigcap_{i=1}^{k} (X_1 \times \cdots \times (X_i \setminus A_i) \times \cdots \times X_k).$$

Thus we see that $(X_1 \times \cdots \times X_k) \setminus (A_1 \times \cdots \times A_k)$ is the intersection of finitely many open sets, i.e. the set itself is open, which implies by definition that $A_1 \times \cdots \times A_k$ is closed.

(2) We will verify this statement in Exercise 3.5. □

We move on to the following lemma which also gets used surprisingly often throughout these notes.

Lemma 3.10. (*) Let $X$, $Y$ and $Z$ be topological spaces and let $f : X \times Y \to Z$ be a map. Suppose we are given finitely many closed subsets $A_1, \ldots, A_m$ of $X$ with $\bigcup_{i=1}^{m} A_i = X$. If each map $A_i \times Y \to X \times Y \to Z$ is continuous, then $f$ itself is continuous.

Proof (*). By Lemma 3.8 the identity

$$A_i \text{ equipped with the subspace topology from } X \times Y \to A_i \times Y \text{ equipped with the subspace topology from } X \times Y$$

is actually a homeomorphism. Together with our hypothesis this shows that for each $i \in \{1, \ldots, m\}$ the map

$$f|_{A_i \times Y} : A_i \times Y \to Z$$

equipped with subspace topology from $X \times Y$. 
is continuous. By Lemma 3.9 we know that $A_i \times Y$ is a closed subset of $X \times Y$. Now it follows from Lemma 2.35 (2) that $f$ is indeed continuous.

We conclude this section with the following technical lemma.

**Lemma 3.11.** (*) Let $X_1, \ldots, X_k$ be topological spaces and let $B_1, \ldots, B_k$ be bases for these topological spaces. Then
\[ C := \{ B_1 \times \cdots \times B_k \mid \text{for each } i \in \{1, \ldots, k\} \text{ we have } B_i \in B_i \} \]
is a basis for $X_1 \times \cdots \times X_k$.

**Example.** On page 106 we saw that the rational intervals form a basis for the usual topology on $\mathbb{R}$. Together with Lemma 3.11 and Lemma 1.7 (5) it follows that the set $B$ of rational hyperrectangles, i.e. that the set
\[ B = \{ \text{all hyperrectangles } [a_1, b_1] \times \cdots \times [a_k, b_k] \text{ with } a_1, \ldots, a_k, b_1, \ldots, b_k \in \mathbb{Q} \} \subset \mathcal{P}(\mathbb{R}^k) \]
forms a basis for the standard topology on $\mathbb{R}^k$. In particular we see that $\mathbb{R}^k$ admits a basis for the topology that consists of only countably many sets.

**Proof (∗).** The main idea is to prove the lemma using Lemma 2.27 (1). Therefore let $W \subset X_1 \times \cdots \times X_k$ be an open set and let $(x_1, \ldots, x_k) \in W$. By definition of the product topology there exist open sets $U_i \subset X_i$, $i = 1, \ldots, k$ with $(x_1, \ldots, x_k) \in U_1 \times \cdots \times U_k$ and $U_1 \times \cdots \times U_k \subset W$.

Let $i \in \{1, \ldots, k\}$. Since $B_i$ is a basis for $X_i$ we see that there exists a $B_i \in B_i$ with $x \in B_i \subset U_i$. It follows that
\[ (x_1, \ldots, x_k) \in B_1 \times \cdots \times B_k \subset U_1 \times \cdots \times U_k \subset W. \]
We deduce from Lemma 2.27 (1) that the given set $C$ is indeed a basis for $X_1 \times \cdots \times X_k$.

**Remark.** After this discussion the reader might be convinced that the product topology on $X \times Y$ is obviously the correct topology to use. As we will see in Section 36.11, one could make a good case that a subtly different topology is more suitable. But throughout most of these lecture notes we will stick it out with the product topology we just introduced.

### 3.3. The product of finitely many topological spaces II

The only real goal of this section is to prove the following essential proposition.

**Proposition 3.12.** Let $X_1, \ldots, X_k$ be non-empty topological spaces.

1. The product $X_1 \times \cdots \times X_k$ is Hausdorff if and only if each $X_i$ is Hausdorff.
2. The product $X_1 \times \cdots \times X_k$ is compact if and only if each $X_i$ is compact.
3. The product $X_1 \times \cdots \times X_k$ is (path)-connected if and only if each $X_i$ is (path)-connected.

**Remark.** Proposition 3.12 (2) also shows how the case $n = 1$ in Proposition 2.21 implies the general case of Proposition 2.21.

Before we head to the proof of Proposition 3.12 let us first discuss some examples in detail.
**Definition.**

1. We refer to $(S^1)^n$ as the $n$-dimensional torus. For $n = 2$ we just say the torus.
2. We refer to $S^1 \times \overline{B}^2$ as the solid torus and we refer to $S^1 \times B^2$ as the open solid torus.

We deduce from Proposition 3.12 that the $n$-dimensional torus $(S^1)^n$ and the solid torus $S^1 \times \overline{B}^2$ are compact.

The following lemma allows us to view (solid) tori as subsets of $\mathbb{R}^3$.

**Lemma 3.13.** We consider the map\(^{49}\)

$$\Theta: \mathbb{R}^2 \times S^1 \rightarrow \mathbb{R}^3$$

$$(x, y, e^{i\varphi}) \mapsto \begin{pmatrix} \cos \varphi & -\sin \varphi & 0 \\ \sin \varphi & \cos \varphi & 0 \\ 0 & 0 & 1 \end{pmatrix} \cdot \begin{pmatrix} 1 + \frac{1}{2}x \\ 0 \\ -\frac{1}{2}y \end{pmatrix}$$

(rotation around $z$-axis) describes circle in $z$-plane

The restrictions of $\Theta$ to $S^1 \times S^1$, $\overline{B}^2 \times S^1$ and $B^2 \times S^1$ are embeddings. (The restriction of $\Theta$ to $S^1 \times S^1$ is illustrated in Figure 65).

\[^{49}\]The map is chosen in such a way that it is orientation-preserving (we will introduce the notions of orientation and orientation-preserving later on page 299) and such that $\Theta((0,0) \times S^1) = S^1 \times \{0\}$.

---

**Proof (⋆).** It follows easily from the example on page 163 that the map $\Theta: S^1 \times \mathbb{R}^2 \rightarrow \mathbb{R}^3$ is continuous. An elementary argument shows that the restriction of $\Theta$ to $\overline{B}^2 \times S^1$ is injective. Since the solid torus $\overline{B}^2 \times S^1$ is compact we obtain from Proposition 2.43 (3) that the restriction of $\Theta$ to $\Theta: \overline{B}^2 \times S^1 \rightarrow \Theta(S^1 \times \overline{B}^2)$ is a homeomorphism. But then it follows also that the restrictions of $\Theta$ to $S^1 \times S^1$ and $B^2 \times S^1$ are embeddings.

Lemma 3.13 allows us to view (solid) tori as subsets of $\mathbb{R}^3$. The typical picture is shown in Figure 66. We refer to the images under these maps as the standard (solid) (open) torus in $\mathbb{R}^3$. Unfortunately, in a picture, it is hard to distinguish between tori, solid tori and open solid tori.

Now the time of procrastination is over, we need to provide the proof of Proposition 3.12.
3. CONSTRUCTIONS OF TOPOLOGICAL SPACES

$S^1 \times S^1$ is homeomorphic to

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure66}
\caption{Function $f$ and its graph.}
\end{figure}

**Proof of Proposition 3.12 (1)**. By induction we only have to deal with the case $k = 2$. Thus let $X$ and $Y$ be two topological spaces.

First we deal with the “$\Rightarrow$”-direction of statement (1). Thus we assume that $X$ and $Y$ are Hausdorff. Let $(x, y)$ and $(x', y')$ be two distinct points in $X \times Y$. Without loss of generality we can assume that $x \neq x'$. By our hypothesis there exist open neighborhoods $U$ of $x$ and $U'$ of $x'$ with $U \cap U' = \emptyset$. Note that

$$(U \times Y) \cap (U' \times Y) = (U \cap U') \times Y = \emptyset \times Y = \emptyset.$$ 

By definition of the product topology the sets $U \times Y$ and $U' \times Y$ are open in $X \times Y$. We have thus found disjoint open neighborhoods of $(x, y)$ and $(x', y')$. Therefore $X \times Y$ is Hausdorff. (This argument is sketched in Figure 67 to the left.)

Now we deal with the “$\Leftarrow$”-direction of statement (1). Therefore we suppose that $X \times Y$ is Hausdorff. We want to show that $X$ is Hausdorff. Thus let $x$ and $x'$ be two different points in $X$. Since $Y$ is non-empty there exists a $y \in Y$. Furthermore, since $X \times Y$ is Hausdorff there exist disjoint open neighborhoods $W$ and $W'$ of $(x, y)$ and $(x', y)$. By definition of the product topology there exist open neighborhoods $U$ of $x$ and $U'$ of $x'$ and open neighborhoods $V$ of $y$ and $V'$ of $y$ such that $(U \times V) \cap (U' \times V') = \emptyset$. In particular we see that $(U \times \{y\}) \cap (U' \times \{y\}) = \emptyset$. But this implies that $U \cap U' = \emptyset$. In particular $U$ and $U'$ are disjoint open neighborhoods of $x$ and $x'$. Thus we have shown that $X$ is Hausdorff. (This argument is sketched in Figure 67 to the right.) The proof that $Y$ is also Hausdorff is evidently basically the same. 

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure67}
\caption{Illustration of the proof of Proposition 3.12 (1).}
\end{figure}

**Proof of Proposition 3.12 (2)**. As in the proof of Statement (1) we only need to deal with the case $k = 2$. Thus let $X$ and $Y$ be two topological spaces. The “$\Rightarrow$”-direction of statement (2) is fortunately elementary, it follows immediately from Lemmas 3.8 and Lemma 2.40 (1).

Next we deal with “$\Leftarrow$”-direction of statement (2). This is by far the hardest part of the lemma. We start out with the following claim.
Claim. Let \( x_0 \in X \). If \( N \) is an open set of \( X \times Y \) that contains \( \{ x_0 \} \times Y \), then there exists a neighborhood \( W \) of \( x_0 \in X \) such that \( W \times Y \subset N \).

By definition of the product topology there exist sets of the form \( U_i \times V_i \), \( i \in I \) with the following properties:

1. each \( U_i \) is open in \( X \) and each \( V_i \) is open in \( Y \),
2. each \( U_i \) contains \( x_0 \), i.e. for each \( i \) we have \( \{ x_0 \} \times V_i \subset U_i \times V_i \),
3. each \( U_i \times V_i \) is contained in \( N \),
4. \( \{ x_0 \} \times Y \) is contained in the union of the \( U_i \times V_i \).

Since \( \{ x_0 \} \times Y \) is compact we can arrange that \( I \) is a finite set, i.e. we can assume that \( I = \{ 1, \ldots, n \} \). We set \( W = U_1 \cap \cdots \cap U_n \). This is an open subset of \( X \) that contains \( x_0 \).

It follows immediately from (3) and the definition of \( W \) that \( W \times Y \subset N \).

\[ \text{Figure 68. Illustration of the proof of Proposition 3.12 (2).} \]

Now we turn to the actual proof that \( X \times Y \) is compact. Thus suppose we are given an open cover \( \{ A_i \}_{i \in I} \) of \( X \times Y \). Let \( x \in X \). Since \( Y \) is compact there exists a finite set \( I(x) \subset I \) such that \( \{ x \} \times Y \subset \bigcup_{i \in I(x)} A_i \). By the above claim there exists an open neighborhood \( W(x) \) of \( x \) such that \( W(x) \times Y \subset \bigcup_{i \in I(x)} A_i \).

All these open sets \( \{ W(x) \}_{x \in X} \) are an open cover of \( X \). Since \( X \) is compact there exist \( x_1, \ldots, x_k \in X \) such that \( X = W(x_1) \cup \cdots \cup W(x_k) \). But then we see that

\[
X \times Y = (W(x_1) \cup \cdots \cup W(x_k)) \times Y = \bigcup_{j=1}^{k} W(x_j) \times Y \subset \bigcup_{j=1}^{k} \bigcup_{i \in I(x_j)} A_i \subset X \times Y.
\]

Thus we have successfully covered \( X \times Y \) by finitely many sets in the given open cover.

\[ \text{Proof of Proposition 3.12 (3) (⋆).} \]

As in the proof of Statement (1) we only need to deal with the case \( k = 2 \). Thus let \( X \) and \( Y \) be two topological spaces.

The ‘⇒’-direction of Statement (2) is once again basically elementary, Indeed, if \( X \times Y \) is (path)-connected, then it follows immediately from Lemma 2.57 applied to the projection maps \( X \times Y \to X \) and \( X \times Y \to Y \), that \( X \) and \( Y \) are (path)-connected.

Finally we deal with ‘⇐’-direction of statement (2). Now suppose that \( X \) and \( Y \) are path-connected. We need to show that \( X \times Y \) is also path-connected. Thus let \( (x, y) \) and \( (x', y') \) be two points in \( X \times Y \). Since \( X \) is path-connected we can find a path \( p : [0, 1] \to X \)

\[ \text{[Note that the projection maps are surjective since we assume that \( X \) and \( Y \) are non-empty.]} \]
from $x$ to $x'$ and similarly we can find a path $q$: $[0, 1] \rightarrow Y$ from $y$ to $y'$. Then

$$[0, 1] \rightarrow X \times Y$$

$$t \mapsto \begin{cases} (p(2t), y), & \text{if } t \in [0, \frac{1}{2}], \\ (x', q(2t - 1)), & \text{if } t \in (\frac{1}{2}, 1] \end{cases}$$

is a path from $(x, y)$ to $(x', y')$.

Finally suppose that $X$ and $Y$ are connected. We want to show that $X \times Y$ is also connected. We pick $a \in X$ and $b \in Y$. Let $x \in X$. Note that the subsets $\{x\} \times Y$ and $X \times \{b\}$ are connected by our hypothesis. Since these have the point $(x, b)$ in common we deduce from Lemma 2.62 (2) that $\{(x) \times Y\} \cup (X \times \{b\})$ is also connected. Finally note that

$$X \times Y = \bigcup_{x \in X} \{(x) \times Y\} \cup (X \times \{b\}).$$

All the sets on the right are connected and they have the point $(a, b)$ in common. Thus it follows again from Lemma 2.62 (2) that the union on the right-hand side is connected. We refer to Figure 69 for an illustration.

![Figure 69. Illustration for the proof of Lemma 3.12 (3).]

3.4. The product of arbitrarily many topological spaces (*). In this section we discuss the product of arbitrarily many topological spaces. In these notes we will only rarely deal with the case of the product of infinitely many topological spaces. Therefore we decided to deal with this case separately.

Let $\{X_i\}_{i \in I}$ a family of sets. The product of these sets is defined as the set

$$\prod_{i \in I} X_i := \left\{ f: I \rightarrow \bigcup_{i \in I} X_i \bigg| \text{for every } i \in I \text{ we have } f(i) \in X_i \right\}.$$ 

If the $X_i$ are topological spaces, then we intend to equip the product with a suitable topology. Before we specify the topology we should decide what statements we want to hold. It seems reasonable to demand that the obvious analogue of Lemma 3.6 holds. This leads us to the following lemma.

**Lemma 3.14.** Let $\{X_i\}_{i \in I}$ be a family of topological spaces. We set

$$\mathcal{B} := \left\{ \prod_{i \in I} U_i \subset \prod_{i \in I} X_i \bigg| \begin{array}{ll} (1) & \text{each } U_i \text{ is open in } X_i \text{ and } \\
 & \text{there exist only finitely many } i \text{'s with } U_i \neq X_i \end{array} \right\}.$$ 

---

51It follows from Lemma 3.6 (1) and Lemma 2.35 (2) that this map is indeed continuous.
The following statements hold:

(0) The set $B$ has the basis property that we introduced on page 102.
(1) Given any $i \in I$ the projection map

$$p_i : \prod_{i \in I} X_i \to X_i$$

$$f \mapsto f(i)$$

is continuous with respect to the topology from (0).
(2) Given a topological space $W$ and given a family $\{f_i : Y \to X_i\}_{i \in I}$ of continuous maps the resulting map

$$F : W \to \prod_{i \in I} X_i$$

$$w \mapsto \left( I \to \bigcup_{i \in I} X_i \right)$$

$$i \mapsto f_i(w)$$

is continuous with respect to the topology from (0).
(3) The topology introduced in (0) is the unique topology on the set $\prod_{i \in I} X_i$ that satisfies properties (1) and (2).

Proof. Let $\{X_i\}_{i \in I}$ be a family of topological spaces.

(0) The proof that $B$ has the basis property is basically identical to the proof of Lemma 3.4.
(1) It follows immediately from the definitions that the projection maps $p_i$ are continuous with respect to the given topology.
(2) Suppose we are given $W$ and maps $f_i : W \to X_i$. We denote by $F$ the map defined in (2). We claim that $F$ is continuous. By Proposition 2.37 it suffices to verify that the preimage of any set in $B$ is open. So let $\prod_{i \in I} U_i$ be a set in $B$. By definition there exists a finite set $J \subseteq I$ such that $U_i = X_i$ for any $i \notin J$. Then

$$F^{-1}\left( \prod_{i \in I} U_i \right) = \bigcap_{i \in I} f_i^{-1}(U_i) = \bigcap_{j \in J} f_j^{-1}(U_j)$$

intersection of finitely many open subsets of $Y$.

This concludes the proof that $F$ is continuous.
(3) Finally the proof of the uniqueness statement is basically the same as the proof of Lemma 3.6 (3).

The lemma leads us to the following definition.

Definition. Let $\{X_i\}_{i \in I}$ a family of topological spaces. We refer to the topology on $\prod_{i \in I} X_i$ that we defined in Lemma 3.14 as the product topology on $\prod_{i \in I} X_i$.

On several occasions we will use, consciously or unconsciously, the following lemma. Some of the statements are the obvious generalizations of Lemma 3.8.

Lemma 3.15.
3. CONSTRUCTIONS OF TOPOLOGICAL SPACES 173

(1) (a) If \(\{X_i\}_{i \in I}\) is a finite family of topological spaces, i.e. if \(I\) is finite, then the above product topology agrees with the product topology introduced on page 162.
(b) If we are families of topological spaces \(\{\{X_{ij}\}_{j \in J}\}_{i \in I}\), then the obvious map
\[
\prod_{j \in J} \left( \prod_{i \in I} X_i \right) \rightarrow \prod_{i \in I} X_i
\]
is a homeomorphism.
(c) The product topology commutes with subspace topology. More precisely, let \(\{X_i\}_{i \in I}\) be a family of topological spaces and for each \(i \in I\) let \(A_i\) be a subset. Then the subspace topology of \(\prod_{i \in I} A_i \subset \prod_{i \in I} X_i\) agrees with product topology on \(\prod_{i \in I} A_i\).
(d) Let \(X\) be a topological space and let \(I\) be a set. If we equip \(I\) with the discrete topology, then the map
\[
(X \times I) \rightarrow \bigcup_{i \in I} X \\
(x, i) \mapsto (x, i)
\]
is a homeomorphism.

(2) The obvious generalizations of Lemma 3.8 (2) hold.

Proof. All statements follow easily from the definitions and/or from Lemma 3.14. We leave it to the reader to provide the details.

Finally we have the following generalization of Proposition 3.16.

**Proposition 3.16.** Let \(\{X_i\}_{i \in I}\) be a family of non-empty topological spaces.

1. The product \(\prod_{i \in I} X_i\) is Hausdorff if and only if each \(X_i\) is Hausdorff.
2. The product \(\prod_{i \in I} X_i\) is compact if and only if each \(X_i\) is compact.
3. The product \(\prod_{i \in I} X_i\) is (path)-connected if and only if each \(X_i\) is (path)-connected.

The proof of all statements of Proposition 3.16 is basically the same as the proof of Proposition 3.12 except, for the “if”-direction of Proposition 3.16. This proof is now considerably harder and thus the proposition gets upgraded to a theorem:

**Theorem 3.17. (Tychonoff’s Theorem)** The product of arbitrarily many compact topological spaces is again a compact topological space.

**Sketch of proof.** We will not really make use of Tychonoff’s Theorem thus we limit ourselves to a sketch of the proof for \(I = \mathbb{N}\). Thus let \(\{X_i\}_{i \in \mathbb{N}}\) be a family of compact topological spaces. Furthermore let \(\{U_j\}_{j \in J}\) be a family of open sets of \(\prod_{i \in I} X_i\) such that we...
cannot cover $\prod_{i \in I} X_i$ by finitely many sets in the given open cover $\{U_j\}_{j \in J}$. We need to show that $\bigcup_{j \in J} U_j$ is a proper subset of $\prod_{i \in I} X_i$.

**Claim.** There exist $x_i \in X_i$, $i \in \mathbb{N}$ with the following property: Given any $k \in \mathbb{N}$ and given any open neighborhoods $V_i$ of $x_i$, $i = 1, \ldots, k$ the product

$$V_1 \times \cdots \times V_k \times X_{k+1} \times X_{k+2} \times \ldots$$

cannot be covered by finitely many sets in the given open cover.

The sequence $\{x_i\}_{i \in \mathbb{N}}$ is defined iteratively. The key to the proof is that we already know by Proposition 3.12 (2) that any finite product $X_1 \times \cdots \times X_k$ is compact. We leave it to the reader to fill in the details. \[\square\]

The following claim concludes the proof of the theorem for $I = \mathbb{N}$.

**Claim.** The point $(x_1, x_2, \ldots) \in \prod_{i \in I} X_i$ does not lie in any of the $U_j$.

Suppose there exists a $j \in J$ with $(x_1, x_2, \ldots) \in U_j$. By definition of the topology on $\prod_{i \in I} X_i$ (see Lemma 2.22) there exists a $k \in \mathbb{N}$ and open neighborhoods $V_i$ of $x_i$, $i = 1, \ldots, k$ such that

$$V_1 \times \cdots \times V_k \times X_{k+1} \times X_{k+2} \times \ldots \subseteq U_j.$$ 

But by construction of $(x_1, x_2, \ldots)$ this is impossible. \[\square\]

The proof of the general case of the Tychonoff Theorem can be done in a very similar way by equipping the index set $I$ with a total order. We refer to [Wri94] for details. Alternatively proofs of Tychonoff’s Theorem are provided in most textbooks on general topology, see e.g. [Mun75] Chapter 5.1 or [Jä05], Chapter X. A particularly concise proof is also given in [Chf92]. \[\square\]

We continue with a very instructive example.

**Example.** We equip $\{0, 2\}$ with the discrete topology. We consider the map

$$\varphi: \prod_{i \in \mathbb{N}} \{0, 2\} \to C = \text{Cantor set from page 100}$$

$$(f: \mathbb{N} \to \{0, 2\}) \mapsto \sum_{i=1}^{\infty} f(i) \cdot 3^{-i}.$$ 

It is elementary to see that $\varphi$ takes values in $C$. It is a refreshing exercise, left to the enthusiastic reader, to show that $\varphi$ is a bijection. The left-hand side is compact by Tychonoff’s Theorem 3.17 and the right-hand is evidently Hausdorff. In Exercise 3.19 we verify that $\varphi$ is continuous. It thus follows from Proposition 2.43 (3) that $\varphi$ is a homeomorphism.

Initially the definition of the Cantor set is nicely explicit, but the definition looks rather arbitrary. The previous example gives a much more natural definition of the Cantor set. Amazingly there exists a characterization of the Cantor set, up to homeomorphism, in terms of basic topological properties. To state the proposition we need two easy definitions.

**Definition.** Let $X$ be a topological space. A point $x_0 \in X$ is called isolated if $\{x_0\}$ itself is an open subset.
3. CONSTRUCTIONS OF TOPOLOGICAL SPACES

Examples.

(1) We consider \( X = \{ \frac{1}{n} \mid n \in \mathbb{N} \} \cup \{0\} \). The only point in \( X \) that is not isolated is 0.
(2) No point in the Cantor set is isolated.
(3) No point in \( \prod_{i \in \mathbb{N}} \{0, 2\} \) is isolated.
(4) The topological spaces \( \mathbb{Q} \) and \( \mathbb{Q} \setminus \{0\} \) equipped with the subspace topology coming from \( \mathbb{R} \) do not contain any isolated points.
(5) Let \( X \) be a topological space. If every point is isolated, then by definition \( X \) has the discrete topology. If \( X \) is furthermore finite, then it follows from Lemma 2.18 (1) that \( X \) is finite.

Definition. A topological space \( X \) is called totally disconnected if the only connected subsets are the empty set and the subsets consisting of a single point.

Example. The following topological spaces are totally disconnected:

(1) discrete topological spaces,
(2) the Cantor set,
(3) the infinite product \( \prod_{i \in \mathbb{N}} \{0, 2\} \),
(4) the topological spaces \( \mathbb{Q} \) and \( \mathbb{Q} \setminus \{0\} \) equipped with the subspace topology coming from \( \mathbb{R} \).

Here (1) is obvious and (4) was is dealt with in Exercise 2.17. We will deal with the remaining two examples in Exercise 3.20.

We conclude this section with the following amusing proposition.

Proposition 3.18. Let \( X \) be a topological space that is compact and totally disconnected. If \( X \) contains no isolated points, then \( X \) is homeomorphic to the Cantor set.

Proof. We will not make use of the proposition, hence we will not prove it. A proof is for example given in [Val13, Theorem 7.8] or [Wil70, Theorem 30.3]. \( \blacksquare \)

Example. By the above examples Proposition 3.18 implies not only that the Cantor set is homeomorphic to \( \prod_{i \in \mathbb{N}} \{0, 2\} \) but also to \( \mathbb{Q} \) and \( \mathbb{Q} \setminus \{0\} \). In particular we obtain the weird result that \( \mathbb{Q} \) and \( \mathbb{Q} \setminus \{0\} \) are homeomorphic.\footnote{\textsuperscript{53}Can you prove directly that \( \mathbb{Q} \) and \( \mathbb{Q} \setminus \{0\} \) are homeomorphic?}

3.5. Distance in metric spaces. Before we can state our next lemma we need to introduce the following definition.

Definition. Let \( X \) be a metric space. Given two non-empty subsets \( A \) and \( B \) we refer to 
\[
d(A, B) = \inf \{d(a, b) \mid a \in A \text{ and } b \in B \}
\]
as the distance between \( A \) and \( B \). If \( A = \{a\} \) consists of a single point, then we write 
\[
d(a, B) := d(\{a\}, B).
\]
Example. If two subsets $A$ and $B$ intersect, then we evidently have $d(A, B) = 0$. But in general the converse does not hold. For example if we consider $X = \mathbb{R}$, then

$$d\left(\text{open interval } (0, 1), \text{closed interval } [1, 2]\right) = 0,$$

but evidently the intervals do not intersect.

The reader might justly suspect that the phenomenon of the last example is due to the fact that one of the sets is not compact. In several arguments the following corollary will play a crucial role.

**Corollary 3.19.** Let $X$ be a metric space and let $K$ and $L$ be two non-empty subsets. We assume that one of the following holds:

(i) Both $K$ and $L$ are compact, or

(ii) $X = \mathbb{R}^n$, $K$ is compact and $L$ is a closed subset of $X = \mathbb{R}^n$.

The following statements hold:

1. There exist $x \in K$ and $y \in L$ with $d(x, y) = d(K, L)$.
2. If $K$ and $L$ are disjoint, then $d(K, L) > 0$.

**Proof.**

1. First we suppose that we are in the setting (i). It follows immediately from our hypothesis and Proposition 3.12 that $K \times L$ is compact. As we pointed out above, the metric $d: K \times L \to \mathbb{R}_{\geq 0}$ is continuous. The desired statement is now an immediate consequence of Lemma 2.40 (2).

Now suppose that we are in the setting (ii). We will reduce this case to setting (i). To do so we set $s := \max\{|x| | x \in K\} + 1 + d(K, L)$. We set $L' := L \cap \overline{B}_s(0)$. Note that it follows from the Heine-Borel Theorem 2.20 together with Lemma 2.17 (2) that $L'$ is compact. We leave it to the reader to verify that it follows easily from the choice of $s$ and the triangle inequality that $L' \neq \emptyset$ and that $d(K, L') = d(K, L)$.

We apply (i) to $X = \mathbb{R}^n$ together with the compact subsets $K$ and $L'$. We obtain $x \in K$ and $y \in L'$ with $d(x, y) = d(K, L') = d(K, L)$.
(2) If $d(K, L) = 0$, then it follows from (1) that there exists $x \in K$ and $y \in L$ with $d(x, y) = d(K, L) = 0$. This implies that $x = y$, i.e. the intersection of $K$ and $L$ is non-empty.

In Exercise 3.12 we will prove the following lemma.

**Lemma 3.20.** Let $X$ be a metric space. If $B \subseteq X$ is a non-empty subset, then the map

$$
X \to \mathbb{R}_{\geq 0},
$$

$$
x \mapsto d(x, B) := \inf\{d(x, b) \mid b \in B\}
$$

is continuous.

### 3.6. Quotients of topological spaces.

On page 74 we recalled the notion of an equivalence relation. Now we introduce a notation that we will use throughout these notes.

**Notation.** Given an equivalence relation $\sim$ on a set $X$ and given $x \in X$ we denote by $[x]$ the unique equivalence class that contains $x$. We refer to the map

$$
X \to X/\sim
$$

$$
x \mapsto [x]
$$

as the *canonical projection*. Sometimes $X/\sim$ is called a *quotient* of $X$.

After these preliminaries we return to topological spaces.

**Lemma 3.21.** Let $\sim$ be an equivalence relation on a topological space $X$. If we denote by $p: X \to X/\sim$ the canonical projection map from $X$ onto the set of equivalence classes $X/\sim$, then the following statements hold:

1. The set

$$
\mathcal{T} := \{U \subseteq X/\sim \mid p^{-1}(U) \text{ is open in } X\}
$$

is a topology on $X/\sim$.

2. Let $A \subseteq X/\sim$ be a subset. The set $A$ is closed in $X/\sim$ if and only if the preimage $p^{-1}(A)$ is closed in $X$.

3. The projection map $p: X \to X/\sim$ is continuous.

4. If $X$ is compact, then $X/\sim$ is also compact.

5. If $X$ is (path)-connected, then $X/\sim$ is also (path)-connected.

**Proof.**

1. This statement follows immediately from Lemma 1.3 (5) and (6).

2. This statement follows easily from Lemma 1.3 (7).

3. This statement is an immediate consequence of the definitions.

4. This statement follows immediately from (3) and from Lemma 2.40.

5. This statement follows immediately from (3) together with Lemma 2.57.

The following definition will not come as a surprise.

---

54 In other words, $U \subseteq X/\sim$ is open if and only if $p^{-1}(U) \subseteq X$ is open.
Definition. Let \( \sim \) be an equivalence relation on a topological space \( X \). We refer to the topology on \( X/\sim \) from Lemma 3.21 (1) as the quotient topology and we refer to \( X/\sim \) as a quotient space of \( X \).

The following lemma is also so basic that later on we will no longer cite it explicitly.

**Lemma 3.22.** Let \( \sim \) be an equivalence relation on a topological space \( X \) and let \( f: X \to Y \) be a map with the property that \( f(x) = f(y) \) whenever \( x \sim y \). Then the map

\[
g: X/\sim \to Y
\]

\[
[x] \mapsto f(x)
\]

is well-defined and it is the unique map \( g: X/\sim \to Y \), such that \( f = g \circ p \), i.e. such that the following diagram of maps commutes:

\[
\begin{array}{ccc}
X & \xrightarrow{p} & X/\sim \\
\downarrow{f} & & \downarrow{g} \\
& & Y
\end{array}
\]

If \( f \) is continuous, then \( g \) is also continuous.

**Definition.** Let \( f: X \to Y \) be a map as in Lemma 3.22.

1. We refer to the map \( g: X/\sim \to Y \) as the induced map.
2. At times we denote the induced map by \( \overline{f} \). Sometimes, when there is no danger of confusion we denote the induced map just by \( f \) itself.
3. Sometimes we also say that the map \( f: X \to Y \) descends to a map \( X/\sim \to Y \).

**Proof (\( \ast \)).** Let \( \sim \) be an equivalence relation on a set \( X \) and let \( f: X \to Y \) be a map with the property that \( f(x) = f(y) \) whenever \( x \sim y \). Let \( a \) be an element of \( X/\sim \). By definition there exists an \( x \in X \) with \( a = [x] \). We set

\[
g(a) := f(x).
\]

Evidently this definition does not depend on the choice of \( x \). The map \( g \) satisfies \( f = g \circ p \). Since the projection \( X \to X/\sim \) is surjective we see that \( g \) is uniquely determined by this property.

Now suppose that \( f \) is continuous. We need to show that \( g \) is continuous as well. Let \( U \subset Y \) be open. We need to show that \( g^{-1}(U) \subset X/\sim \) is open. By definition of the quotient topology we need to show that \( p^{-1}(g^{-1}(U)) \) is open in \( X \). We observe that

\[
p^{-1}(g^{-1}(U)) = (g \circ p)^{-1}(U) = f^{-1}(U) = \text{open subset}.
\]

by the commutative diagram since \( f \) continuous

We have thus shown that \( g \) is continuous. \( \blacksquare \)

The following remark can be viewed as a sibling of Remark 3.7.

**Remark 3.23.** We consider maps in and out of a quotient space \( X/\sim \):

1. In practice it is usually easy to show that a given map \( X/\sim \to Y \) out of the quotient space is continuous. More precisely, in practice it is often fairly clear that the map
We continue with a particularly important source of quotient spaces.

**Definition.** Let $X$ be a topological space and let $A \subset X$ be a subset.

1. (a) First we suppose that $A$ is a non-empty subset. For $P, Q \in X$ we define

$$P \sim Q \iff P = Q \text{ or } P, Q \text{ both lie in } A.$$ 

This is easily seen to be an equivalence relation on $X$. We write $X/A := X/\sim$ and we always equip $X/A$ with the quotient topology. We refer to $X/A$ as the quotient of $X$ by $A$. Note that $A \subset X$ is an equivalence class, thus it defines a point in $X/A$. In an attempt to avoid confusion we write $[A]$ for the point in $X/A$ that is given by the equivalence class $A$.

(b) If $A = \emptyset$ is the empty set, then we define $X/\emptyset := X \sqcup \{\emptyset\}$, i.e. $X/\emptyset$ equals the disjoint union of the topological space $X$ with the topological space consisting of a single point $\emptyset$. For consistency we denote this point by $[\emptyset]$ as well.

Note that $\emptyset/\emptyset$ is the topological space consisting of the single point $\{\emptyset\}$.

2. We refer to the obvious map $p: X \rightarrow X/A$ as the projection map.

**Remark.** Let us attempt to digest the definition of $X/A$. As a set $X/A$ corresponds precisely to the points in $X \setminus A$ together with the point $[A]$. Furthermore, by definition of the quotient topology a set $U \subset X/A$ is open if and only if $p^{-1}(U)$ is an open subset of $X$. Note that given any subset $Z \subset X/A = (X \setminus A) \cup \{[A]\}$ we have

$$p^{-1}(Z) = \begin{cases} Z, & \text{if } [A] \notin Z, \\ Z \cup A, & \text{if } [A] \in Z. \end{cases}$$

This shows that the open sets in $X/A$ correspond precisely to the open sets of $X$ that lie in $X \setminus A$ and the open sets of $X$ that contain $A$.

**Examples.**

1. We consider the quotient of $X = \mathbb{R}$ by the compact interval $A = [-1, 1]$. This example has two interesting features:

   (a) The quotient $X/A = \mathbb{R}/[-1, 1]$ is actually homeomorphic to an old favorite, namely one can easily verify that the maps

$$f: \mathbb{R} \rightarrow \mathbb{R}/[-1, 1], \quad g: \mathbb{R}/[-1, 1] \rightarrow \mathbb{R}$$

$$x \mapsto \begin{cases} [x+1], & \text{if } x \geq 0 \\ [x-1], & \text{if } x < 0 \end{cases} \quad \text{and} \quad P \mapsto \begin{cases} x-1, & \text{if } P = [x] \text{ with } x \geq 1 \\ x+1, & \text{if } P = [x] \text{ with } x < -1 \end{cases}$$

are continuous and inverses of one another.

---

55The reader will have spotted that the case $A = \emptyset$ is a major nuisance. It is conceivable that later on in proofs we will subconsciously suppress this special case. Whenever this occurs we leave it to the reader to deal with the case $A = \emptyset$ separately.

56In an attempt to lighten the notation, given $x \in X \setminus A$ we do not distinguish between the point $x \in X \setminus A$ and the equivalence class $\{x\} \subset X$. 

---
(b) Above we saw that projections $X \to X/\sim$ are basically by definition, continuous. One might think that projections should also be open. But in this example the projection $p: X = \mathbb{R} \to X/A = \mathbb{R}/[-1,1]$ is not an open map, for example it follows immediately from the previous remark that the image of the open set $(-1,1) \subset \mathbb{R}$ is not an open subset of $\mathbb{R}/[-1,1]$. We refer to Figure 72 for an illustration.

![Figure 72](image)

(2) We consider the quotient of $X = \mathbb{R}$ by the open interval $B = (-1,1)$. We denote by $p: \mathbb{R} \to \mathbb{R}/(-1,1)$ the projection map. Even though this example looks very similar to the previous one, it shows very different behavior. For example it turns out that the quotient $X/B = \mathbb{R}/(-1,1)$ is not Hausdorff. More precisely we consider the two points $[-1]$ and $[0]$ in $\mathbb{R}/(-1,1)$. The previous remark shows that any open neighborhood $U$ of $[-1]$ in $\mathbb{R}/(-1,1)$ has the property that $p^{-1}(U)$ is an open subset of $\mathbb{R}$ that contains $-1$. In particular $p^{-1}(U)$ has non-empty intersection with $B$. But this implies that $U = p(p^{-1}(U))$ contains the point $[0]$. Thus $[-1]$ and $[0]$ cannot be separated by open neighborhoods. We refer to Figure 73 for an illustration.

![Figure 73](image)

The following lemma is elementary but useful. On numerous occasions it will allow us to slightly shift our point of view.

**Lemma 3.24.** (*) Let $X$ be a topological space and let $A \subset X$ be a subset. Furthermore let $Y$ be another topological space and let $y_0 \in Y$. The map

$$\Phi: \left\{ \begin{array}{c} \text{set of continuous maps } f: X \to Y \\ \text{such that } f(A) = \{y_0\} \end{array} \right\} \to \left\{ \begin{array}{c} \text{set of continuous maps } f: X/A \to Y \\ \text{such that } f([A]) = y_0 \end{array} \right\}

(f: X \to Y) \mapsto (f: X/A \to Y)$$

is well-defined and it is a bijection.

**Proof.** (*) It follows from Lemma 3.22 that given a continuous map $f: X \to Y$ with $f(A) = \{y_0\}$ the corresponding map $f: X/A \to Y$ is continuous. This shows that the

Note that in Lemma 3.26 we will give a criterion that ensures that the quotient of a topological space is Hausdorff.
map $\Phi$ is well-defined. It is clear that $\Phi$ is injective. Finally suppose we are given a map $g : X/A \to Y$ with $g([A]) = y_0$. We denote by $f : X \to X/A \to Y$ the map that is given by precomposing $g$ with the obvious projection $X \to X/A$. It follows from Lemma 3.21 (3) that $f$ is continuous. Clearly we have $\Phi(f) = g$. This shows that $\Phi$ is also a surjection. ■

Example. Let $a < b$ be two real numbers. It follows easily from Lemma 3.21 (4), Lemma 3.22 and Proposition 2.43 (3) that the map

$$\Omega : [a, b]/\{a, b\} \to S^1$$

$$[t] \mapsto \exp \left( i \cdot \frac{2\pi(t-a)}{b-a} \right)$$

is a homeomorphism.

We continue with the following innocuous lemma.

**Lemma 3.25.**

(1) The map

$$([0, 1] \times S^n)/\{(0) \times S^n\} \to \mathcal{B}^{n+1}$$

$$[(r, v)] \mapsto r \cdot v$$

is a homeomorphism.

(2) Let $X$ be a topological space and let $f : [0, 1] \times S^n \to X$ be a continuous map. If $f(0, v) = f(0, w)$ for all $v, w \in S^n$, then the map

$$\mathcal{B}^{n+1} \to X$$

$$r \cdot v \mapsto f(r, v)$$

with $r \in [0, 1]$ and $v \in S^n$

is well-defined and continuous.

**Proof.**

(1) It follows from Lemma 3.22 that the given map is continuous. It is basically clear that the map is a bijection. The left-hand side is compact by Lemma 3.22 (4). It follows from Proposition 2.43 (3) that the map is a homeomorphism.

(2) It follows from the hypothesis that the map is well-defined. It follows from (1) and Lemma 3.22 that the map is continuous. ■

Example. It follows from Lemma 3.25, Lemma 3.22 and Proposition 2.43 (3) that the map

$$\Omega : \mathcal{B}^n/S^{n-1} \to S^n$$

$$[r \cdot v] \mapsto \begin{pmatrix} 0 & (-1)^{n-1} & \ldots & 0 \\ 0 & 0 & \text{id}_{n-1} & \ldots \\ -1 & \ldots & 0 \end{pmatrix}_{\in \text{SO}(n+1)} \cdot \begin{pmatrix} \cos(\pi r) \\ \sin(\pi r)v \end{pmatrix}_{\in \mathbb{R} \times \mathbb{R}^n = \mathbb{R}^{n+1}}$$

with $r \in [0, 1]$ and $v \in S^{n-1}$
is a homeomorphism. Note that for \( n = 1 \) and \( n = 2 \) this homeomorphism is illustrated in Figure 74. This homeomorphism has the following properties which we will care about in the future:

1. The map \( \Omega \) sends the point \([S^{n-1}] \in \overline{B^n}/S^{n-1}\) to the North Pole \((0, \ldots, 0, 1)\).
2. The map sends the origin to the South Pole \((0, \ldots, 0, -1)\).
3. The map \( B^n \to \overline{B^n}/S^{n-1} \overset{\Omega}{\to} S^n \) is smooth and, if we equip \( B^n \) and \( S^n \) with the usual orientations, the map is orientation-preserving. We hope that the reader is not too fazed by the fact that we use some expressions that strictly speaking we will only introduce later on page 299.

Throughout this course we will use this homeomorphism to identify \( \overline{B^n}/S^{n-1} \) with \( S^n \).

\[
\begin{array}{c}
\text{Figure 74}
\end{array}
\]

We conclude this section with a rather technical discussion. Namely, on page 180 we saw that the quotient of a topological space that is Hausdorff is not necessarily again Hausdorff. It is pretty clear that if one puts enough conditions on the equivalence relation, then one can avoid such misdemeanor. This leads us to the following definition.

**Definition.** Let \( X \) be a set and let \( \sim \) be an equivalence relation on \( X \).

1. We refer to \( \{(x, y) \in X \times X \mid x \sim y\} \) as the graph of the equivalence relation.
2. Now suppose \( X \) is equipped with a topology. We say that the equivalence relation is closed if the graph is a closed subset of \( X \times X \).

Now we can formulate the next lemma.

**Lemma 3.26.** (*) Let \( X \) be a topological space that is Hausdorff and compact. If \( \sim \) is a closed relation, then \( X/\sim \) is Hausdorff.

**Proof (\( \ast \)).** We denote by \( p: X \to X/\sim \) the projection. We start out with the following claim.

**Claim.** Given any closed subset \( C \) of \( X \) the projection \( p(C) \) is a closed subset of \( X/\sim \).

Let \( C \) be a closed subset of \( X \). We need to show that \( p^{-1}(p(C)) \) is closed in \( X \). We denote by \( G \) the graph of the equivalence relation and we denote by \( p_1, p_2: X \times X \to X \) the projection onto the first respectively the second factor. Then one easily sees that

\[
p^{-1}(p(C)) = \{y \in X \mid \text{there exists an } x \in C \text{ with } y \sim x\} = p_2(p_1^{-1}(C) \cap G).
\]
Note that \( p_1^{-1}(C) = C \times X \) is a closed subset of \( X \times X \).
Furthermore by our hypothesis, \( G \) is a closed subset of \( X \times X \). Thus we see that \( p_1^{-1}(C) \cap G \) is closed. By Proposition 3.12 and our hypothesis on \( X \) we know that \( X \times X \) is compact. It follows from Lemma 2.17 (1) that \( p_1^{-1}(C) \cap G \) is a compact subset of \( X \times X \). But then it follows from Lemma 2.40 (1) that \( p_2(p_1^{-1}(C) \cap G) \) is a compact subset of \( X \). But since \( X \) is Hausdorff we obtain that from Lemma 2.17 (2) that is also a closed subset of \( X \).

Now let \([x], [y] \in X/ \sim\) be two disjoint points in \( X/ \sim\). Since \( X \) is Hausdorff we know from Lemma 2.17 (2) that \([x]\) and \([y]\) are closed subsets of \( X \). By the claim we see that \([x]\) and \([y]\) are closed subsets of \( X/ \sim\). Since the projection map \( p : X \to X/ \sim\) is continuous we see that \( p^{-1}([x]) \) and \( p^{-1}([y]) \) are two disjoint closed subsets of \( X \). Since \( X \) is compact and Hausdorff we know that \( X \) is normal. Thus there exist open disjoint neighborhoods \( U \) and \( V \) of \( p^{-1}([x]) \) and \( p^{-1}([y]) \). We write \( U' = X \setminus U \) and \( V' = X \setminus V \). These are now closed subsets of \( X \). By the claim their images are closed subsets of \( X/ \sim\). Now we see that \((X/ \sim) \setminus p(U')\) and \((X/ \sim) \setminus p(V')\) are the desired open disjoint sets containing \([x]\) respectively \([y]\).

We conclude this section on quotient spaces with three technical lemmas.

**Lemma 3.27.** (*) Let \( X \) be a topological space and let \( \sim \) be an equivalence relation on \( X \). Furthermore let \( B \) be a basis of the topology of \( X \). If the projection \( p : X \to X/ \sim \) is an open map, then
\[
p(B) = \{ p(B) \mid B \in B \}
\]
is a basis for the topology of \( X/ \sim \).

**Proof** (*). First note that the sets in \( p(B) \) are indeed open subsets of \( X/ \sim \) since we assume that the projection is open. We use the criterion provided by Lemma 2.27 (1) to show that \( p(B) \) is a basis for the topology of \( X/ \sim \). Thus let \( U \subseteq X/ \sim \) be an open set and let \( y \in U \). We need to show that there exists a \( B \in B \) with \( y \in p(B) \subset U \).

We choose an \( x \in X \) with \( p(x) = y \). Since \( B \) is a basis for the topology of \( X \) and since \( p^{-1}(U) \) is open in \( X \) there exists by Lemma 2.27 (1) a \( B \in B \) with \( x \in B \subset p^{-1}(U) \). But then we also have that \( y = p(x) \in p(B) \subset p(p^{-1}(U)) = U \).

A careful reading of these notes shows that the following lemma gets used on many occasions without giving its due credit.

**Lemma 3.28.** (*)

(1) Let \( X \) be a topological space and let \( \sim_1 \) be an equivalence relation on \( X \). Furthermore let \( \sim_2 \) be an equivalence relation on \( X/ \sim_1 \). Given \( x, y \in X \) we define
\[
x \sim y \iff [x]_{\sim_1} \sim_2 [y]_{\sim_1}.
\]
Then the following two statements hold:
(a) \( \sim \) is an equivalence relation.
Proof.

(1) We leave the proof of this lemma as a gift to our dear reader.

(2) It follows from Lemma 3.21 (3) that the map \[X/ \sim_X \rightarrow Y/ \sim_Y\] is continuous.

It follows from \((f \times f)(\sim_X) \subseteq \sim_Y\) and Lemma 3.22 that this map descends to a continuous map \(X/ \sim_X \rightarrow Y/ \sim_Y\). \(\square\)

Finally we have the following lemma, which might not sound particularly interesting at first sight, but which will used on many occasions.

**Lemma 3.29.** Let \(X\) be a topological space and let \(A\) be a closed subset.

1. For every open subset \(U \subset X \setminus A\) the obvious map \(U \rightarrow X/A\) is an open embedding.
2. For every open neighborhood \(W\) of \(A\) the obvious map \(W \setminus A \rightarrow W/A \setminus A/A\) is a homeomorphism.

**Proof (\(*)**. Let \(X\) be a topological space and let \(A\) be a closed subset. In the following we denote by \(p : X \rightarrow X/A\) the projection.

1. Let \(U \subset X \setminus A\) be an open subset. We want to show that \(q : U \rightarrow X/A\) is an open embedding. It follows from \(U \subset X \setminus A\) that \(q\) is an injection. Furthermore note that by Lemma 3.21 (3) we know that \(q\) is continuous. By Lemma 2.42 (2) it remains to show that \(q : U \rightarrow X/A\) is an open map. Now let \(V \subset U\) be an open subset. We need to show that \(q(V) \subset X/A\) is open. We break the argument into three easy steps:
   a. It follows from Lemma 2.38 (1) and the fact that \(A\) is by hypothesis closed, that \(V\) is also an open subset of \(X\).
   b. Since \(A \cap V = \emptyset\) we see that \(p^{-1}(p(V)) = V\), which by (a) is in fact an open subset of \(X\).
   c. It follows from (b) and the definition of the quotient topology that \(p(V)\) is an open subset of \(X/A\).

---

\(^{59}\)Recall that an equivalence relation on \(X\) is by definition a subset of \(X \times X\), so it makes sense to ask whether \((f \times f)(\sim_X) \subseteq \sim_Y\).
3. CONSTRUCTIONS OF TOPOLOGICAL SPACES

(2) Let \( W \) be an open neighborhood of \( A \). We set \( U := W \setminus A \). Since \( A \) is closed we see that \( U \) is an open subset of \( W \setminus A \). We want to show that the obvious map \( q: W \setminus A \to W/A \setminus A/A \) is a homeomorphism. It is clear that \( q \) is a bijection and it follows from Lemma 3.28 (2) that \( q \) is continuous. By Lemma 2.42 (2) it remains to show that \( q: W \setminus A \to W/A \setminus A/A \) is an open map. Thus let \( V \) be an open subset of \( W \setminus A \). We have \( q(V) = p(V) \cap (W/A \setminus A/A) \). It follows from (1c) and the definition of the subspace topology that \( q(V) \) is an open subset of \( W/A \setminus A/A \). ■

3.7. Group actions on topological spaces. We continue with the following definition that eventually will provide a rich source of examples of topological spaces.

**Definition.** Let \( X \) be a set and let \( G \) be a group with trivial element \( e \).

(1) An action of \( G \) on \( X \) is a map

\[
G \times X \to X \quad (g, x) \mapsto g \cdot x
\]

with the following properties

\[
e \cdot x = x, \quad \text{for all } x \in X,
\]

\[
g \cdot (h \cdot x) = (g \cdot h) \cdot x, \quad \text{for all } x \in X \text{ and } g, h \in G.
\]

(2) The action is called free, if \( g \cdot x = x \) for some \( x \in X \) implies that \( g = e \).

(3) We say \( G \) acts transitively, if for every \( x \) and \( y \) in \( X \) there exists a \( g \in G \) with \( g \cdot x = y \).

(4) If \( X \) is a topological space, then we say that the action is continuous, if for every \( g \in G \) the map

\[
X \to X \quad x \mapsto g \cdot x
\]

is continuous.\(^6\)

**Remark.** Sometimes what we call an “action” is referred to as a “left-action”. A “right-action” is exactly the same as a left-action except that the second property gets replaced by \( g \cdot (h \cdot x) = (h \cdot G) \cdot x \). Or, more intuitively, a right-action is a map \( X \times G \to X \) such that we have \( (x \cdot h) \cdot g = x(h \cdot G) \). Basically all the statements and definitions that we give for left-actions carry over, with minuscule modifications, to the setting of right-actions.

**Examples.**

(1) Given any group \( G \) the map

\[
G \times G \to G \quad (g, h) \mapsto ghg^{-1}
\]

\(^6\)If the action is continuous, then the map \( x \mapsto g \cdot x \) is in fact a homeomorphism with inverse map given by \( x \mapsto g^{-1} \cdot x \).
defines an action of $G$ on itself. Let $G$ be a non-trivial group. Considering $h = e$ we see that this action is not free and it is also straightforward to see that the action is not transitive.

(2) Let $\mathbb{F}$ be a field and let $V$ be a $k$-dimensional vector space over $\mathbb{F}$. We denote by $B$ the set of all ordered bases of $V$. The map

$$
\begin{align*}
\text{GL}(k, \mathbb{F}) \times B & \to B \\
((a_{ij})_{i,j=1,\ldots,k}, (v_1, \ldots, v_k)) & \mapsto \left( \sum_{i=1}^{k} a_{i1} v_i, \ldots, \sum_{i=1}^{k} a_{ik} v_i \right)
\end{align*}
$$

is a transitive action. It is an amusing linear algebra exercise to figure out under what circumstances this action is free.

(3) The group $G = \mathbb{Z}^n$ acts on $X = \mathbb{R}^n$ by addition. This action is evidently free and continuous but it is not transitive.

(4) Basic linear algebra shows that the action of $O(n)$ on $S^{n-1}$ given by multiplication is transitive. Note thought that for $n \geq 3$ the action is not free.

We continue with the following definition.

**Definition.** Let $X$ be a set and let $G$ be a group that acts on $X$. It is straightforward to verify that

$$x \sim y :\iff \text{there exists a } g \in G \text{ such that } g \cdot x = y$$

is an equivalence relation on $X$. We write $X/G := X/\sim$.

If $X$ is a topological space, then we view $X/G$ as a topological space equipped with the quotient topology.

**Lemma 3.30.** Let $X$ be a topological space and let $G$ be a group that acts on $X$.

1. The projection map $X \to X/G$ is continuous.
2. If $G$ acts continuously on $X$, then the projection map is also open.

**Proof.** The first statement follows immediately from Lemma 3.21 (3). We turn to the proof of the second statement. Thus let $U \subset X$ be an open subset. We need to show that $p(U)$ is open in $X/G$. Thus we need to show that $p^{-1}(p(U))$ is an open subset of $X$. It follows easily from the definitions that

$$p^{-1}(p(U)) = \bigcup_{g \in G} gU.$$

Since $G$ acts continuously the map $x \mapsto gx$ is a homeomorphism. Thus we see that $p^{-1}(p(U))$ is the union of open sets, thus it is open itself.

The following lemma discusses one example in greater detail.

---

61 It is arguably more logical to write $G \setminus X$ since we are dealing with a left-action and to reserve the notation $X/G$ for right-actions. We stick to $X/G$ since it is closer to our language “$X$ mod $G$” and since we will not deal with right-actions at all.
Lemma 3.31. The map

\[ \mathbb{R}^n / \mathbb{Z}^n \to (S^1)^n \]

\[ [(t_1, \ldots, t_n)] \mapsto (e^{2\pi i t_1}, \ldots, e^{2\pi i t_n}) \]

is a homeomorphism.

Convention. Often we use the homeomorphism of Lemma \red{3.31} to make the identification \( \mathbb{R}^n / \mathbb{Z}^n = (S^1)^n \).

Proof. We start out with the following observations:

1. The map is continuous by Lemma \red{3.22} and it is easy to see that it is a bijection.
2. The obvious map \([0,1]^n \to \mathbb{R}^n \to \mathbb{R}^n / \mathbb{Z}^n\) is continuous and it is easily seen to be surjective. By Proposition \red{2.21} we know that \([0,1]^n\) is compact. It follows from Lemma \red{2.40} that \(\mathbb{R}^n / \mathbb{Z}^n\) is compact.
3. From Proposition \red{3.12} we obtain that \((S^1)^n\) is Hausdorff.

Now it follows easily from Proposition \red{2.43} (3) that the given map is indeed a homeomorphism.

We continue with more examples of group actions and the resulting quotient topological spaces.

Examples.

1. Let \(X = S^n\) and \(G = \{\pm 1\}\). The map

\[ \{\pm 1\} \times S^n \to S^n \]

\[ (\epsilon, P) \mapsto \epsilon \cdot P \]

defines an action that is free and continuous. We refer to the quotient space \(S^n / \{\pm 1\}\) as the \emph{n-dimensional real projective space} \(\mathbb{RP}^n\).\footnote{For \(n = 2\) we sometimes refer to \(\mathbb{RP}^2\) as the real projective plane.} In Exercise \red{3.22} we will show that \(\mathbb{RP}^1\) is homeomorphic to \(S^1\).

2. Let \(X = \mathbb{R}\) and \(G = \{\pm 1\}\). The map

\[ \{\pm 1\} \times \mathbb{R} \to \mathbb{R} \]

\[ (\epsilon, x) \mapsto \epsilon \cdot x \]

defines an action that is continuous. But this action is not free, since \((-1) \cdot 0 = 0\), but \(-1\) is not the trivial element in the group \(G = \{\pm 1\}\). In Exercise \red{3.24} we will show that \(\mathbb{R} / \{\pm 1\}\) is homeomorphic to the half-open interval \([0, \infty)\).

We formulate the next example as a lemma.

Lemma 3.32. Let \(n \in \mathbb{N}\).

1. The maps

\[ O(n+1) \times S^n \to S^n \]

\[ (A, v) \mapsto A \cdot v \]

and

\[ O(n+1) \times \overline{B}^{n+1} \to \overline{B}^{n+1} \]

\[ (A, v) \mapsto A \cdot v \]

define continuous actions of \(O(n+1)\) on \(S^n\) and on \(\overline{B}^{n+1}\).
(2) The action of $\text{SO}(n+1)$ on $S^n$ is free if and only if $n = 1$.
(3) The action of $\text{O}(n+1)$ on $S^n$ is transitive.
(4) If $n \geq 1$, then the action of $\text{SO}(n+1)$ on $S^n$ is also transitive.
(5) The obvious action of $\text{SO}(n)$ on the set of hyperplanes in $\mathbb{R}^n$ is transitive.

We can use the above to draw the following two consequences:
(6) For every $P \in S^n$ the complement $S^n \setminus \{P\}$ is homeomorphic to $\mathbb{R}^n$.
(7) Given any $x, y \in S^n$ there exists a homeomorphism $\varphi : B^{n+1} \to B^{n+1}$ with $\varphi(x) = y$.

**Proof.** Statements (1) and (2) can be verified easily. Statements (3) and (4) fall in the realm of linear algebra. We leave it to the reader to undust their favorite linear algebra book and prove the statements. For $n \geq 2$ Statement (5) follows from Statement (4) and the observation that the map

$$
S^n \to \text{set of hyperplanes in } \mathbb{R}^{n+1}
$$

$$
v \mapsto v^+ := \{w \in \mathbb{R}^{n+1} \mid \langle v, w \rangle = 0\}
$$

is a surjection. For $n = 1$ Statement (5) is trivial. Next note that Statement (6) follows from Statement (3) together with Lemma 2.44. Finally Statement (7) follows from Statements (1) and (3). \[\blacksquare\]

We consider our next example in greater detail.

**Examples.**
(1) Let $X = \mathbb{R} \times [-1, 1]$ and $G = \mathbb{Z}$. The map

$$
\mathbb{Z} \times (\mathbb{R} \times [-1, 1]) \to \mathbb{R} \times [-1, 1]
$$

$$(n, (x, y)) \mapsto (x + n, (-1)^n \cdot y)
$$

defines an action that is free and continuous. This action is illustrated in Figure 76. We refer to the quotient $X/\mathbb{Z}$ as the Möbius band. The same argument as in the proof of Lemma 3.31 shows that the Möbius band is compact.

![Figure 76](image)

The name "Möbius band" conjures up a certain picture. We will now see that our name is justified. Given $\varphi, \psi \in \mathbb{R}$ and $r \in [-1, 1]$ we set

$$
A(\varphi) := \begin{pmatrix}
\cos \varphi & -\sin \varphi & 0 \\
\sin \varphi & \cos \varphi & 0 \\
0 & 0 & 1
\end{pmatrix}
$$

and

$$
v(r, \psi) := \begin{pmatrix}
2 + r \sin \psi \\
0 \\
r \cos \psi
\end{pmatrix}.
$$

We consider the map

$$
\Psi : (\mathbb{R} \times [-1, 1])/\mathbb{Z} \to \mathbb{R}^3
$$

$$
[(\varphi, r)] \mapsto A(2\pi \cdot \varphi) \cdot v(r, \pi \varphi).
$$
The image of $\Psi$ is shown in Figure 77. The argument of Lemma 3.31 shows that $\Psi$ is an embedding. Thus the Möbius band, defined abstractly as above, is indeed homeomorphic to a subset of $\mathbb{R}^3$ that looks like what we had in mind.

\[ z \quad y \quad x \]
Möbius band viewed as a subset of $\mathbb{R}^3$

\textbf{Figure 77}

(2) On occasion we will also be interested in the \textit{open Möbius band} which is basically defined as above, except that we define it as the quotient of $\mathbb{R} \times (-1, 1)$ instead of the quotient of $\mathbb{R} \times [-1, 1]$.

If $X$ is a Hausdorff space and if $G$ acts continuously on $X$, then it is unfortunately not necessarily true that $X/G$ itself is Hausdorff. For example, consider the obvious action of $G = (\mathbb{Q}, +)$ on $X = \mathbb{R}$. It is a moderately insightful exercise, see Exercise 3.25, to verify that the quotient space $\mathbb{R}/\mathbb{Q}$ is not Hausdorff.

This example leads us to the following definition.

\textbf{Definition.} Let $X$ be a topological space and let $G$ be a group that acts on $X$. We say that $G$ acts \textit{properly} if for every two points $x$ and $y$ in $X$ there exist open neighborhoods $U$ of $x$ and $V$ of $y$ such that the set $\{ g \in G \mid gU \cap V \neq \emptyset \}$ is finite.

\textbf{Examples.}

(1) The action of any finite group is proper by definition.

(2) One can show easily that the action of $\mathbb{Z}$ on $\mathbb{R} \times [-1, 1]$ that we had considered on page 188 to define the Möbius band, is proper.

(3) It is straightforward to show that the action of $O(n+1)$ on $S^n$ from Lemma 3.32 is not proper.

We conclude this section with the following proposition.

\textbf{Proposition 3.33.} Let $G$ be a group that acts on a topological space $X$. If $X$ is Hausdorff and if the action is proper and continuous, then the quotient space $X/G$ is also Hausdorff.

Unless one has an insatiable appetite for technical proofs it is best to move on to the next section.

The proof of Proposition 3.33 relies on the following two lemmas.

\textbf{Lemma 3.34.} \textit{(\textasteriskcentered)} Let $G$ be a group that acts continuously and properly on a topological space. If $X$ is Hausdorff, then given any two points $a$ and $b$ in $X$ there exist open neighborhoods $A$ of $a$ and $B$ of $b$ with the following property: for every $g \in G$ with $ga \neq b$ we also have $gA \cap B = \emptyset$.

\textbf{Proof of Lemma 3.34} \textit{(\textasteriskcentered)} Let $G$ be a group that acts continuously and properly on a topological space $X$ that is Hausdorff. Let $a$ and $b$ be two points in $X$. Since $G$ acts properly
on $X$ there exist open neighborhoods $U$ of $a$ and $V$ of $b$ such that \{ $g \in G \mid gU \cap V \neq \emptyset$ \} is a finite set. We denote the elements of this finite set by $g_1, \ldots, g_r$. We set

$$I := \{ i = 1, \ldots, r \mid g_i a \neq b \}.$$ 

Since $X$ is Hausdorff we can find for every $i \in I$ an open neighborhood $U_i$ of $g_i a$ and an open neighborhood $V_i$ of $b$ such that $U_i \cap V_i = \emptyset$. We set

$$A := U \cap \bigcap_{i \in I} g_i^{-1} U_i \quad \text{and} \quad B := V \cap \bigcap_{i \in I} V_i.$$ 

The sets $A$ and $B$ are the intersection of finitely many open subsets,\(^{62}\) thus they are open. In particular $A$ is an open neighborhood of $a$ and $B$ is an open neighborhood of $b$.

Now one can easily verify that $A$ and $B$ have the desired properties. Indeed, let $g \in G$ with $ga \neq b$. If $g \notin \{ g_1, \ldots, g_r \}$, then $gU \cap V = \emptyset$, therefore $gA \cap B = \emptyset$. On the other hand, if $g \in \{ g_1, \ldots, g_r \}$, then there exists an $i \in I$ with $g = g_i$. It follows that $g_i (g_i^{-1} U_i) \cap V_i = U_i \cap V_i = \emptyset$, hence $g_i A \cap B = \emptyset$. ■

**Lemma 3.35.** (*) Let $G$ be a group that acts on a set $X$. We denote by $p: X \to X/G$ the projection. Let $A$ and $B$ be subsets of $X$. Then

$$p(A) \cap p(B) = \emptyset \iff \text{for every } g \in G \text{ we have } gA \cap B = \emptyset,$$

or equivalently,

$$p(A) \cap p(B) \neq \emptyset \iff \exists g \in G \text{ with } gA \cap B \neq \emptyset.$$

**Proof of Lemma 3.35**. We prove the second statement. The first statement is easily seen to be equivalent to the second statement. We have

$$p(A) \cap p(B) \neq \emptyset \iff \exists a \in A, b \in B \text{ with } p(a) = p(b) \in X/G \iff \exists a \in A, b \in B \text{ and } g \in G \text{ with } ga = b \iff \exists a \in G \text{ with } gA \cap B \neq \emptyset. \quad \blacksquare$$

Now we turn to the actual proof of Proposition 3.33.

**Proof of Proposition 3.33**. Let $G$ be a group that acts on a topological space $X$. We assume that $X$ is Hausdorff and that the action is proper and continuous. We want to show that the quotient space $X/G$ is also Hausdorff. We denote by $p: X \to X/G$ the projection map.

\(^{62}\)Here we use that $G$ acts continuously, since this implies that the sets $h^{-1} U_i$ are also open.
Let $x$ and $y$ be two distinct points in $X/G$. We pick $a$ and $b$ in $X$ with $p(a) = x$ and $p(b) = y$. Since $p(a) = x \neq y = p(b)$ we see that for every $g \in G$ we have $ga \neq b$. By Lemma 3.34 there exist open neighborhoods $A$ of $a$ and $B$ of $b$ such that $gA \cap B = \emptyset$ for every $g \in G$. It follows from Lemma 3.35 that $p(A)$ and $p(B)$ are disjoint.

Since $A$ and $B$ are open it follows from Lemma 3.30 that $p(A)$ and $p(B)$ are open subsets of $X/G$, in particular they are open neighborhoods of $x = p(a)$ and $y = p(b)$. We have thus found the desired disjoint open neighborhoods of $x$ and $y$ in $X/G$.

3.8. Continuity of zeros (*). Group actions can also appear in unexpected situations. For example let us consider the following question.

**Question 3.36.** Let $n \in \mathbb{N}$. Do the zeros of a polynomial of degree $n$ vary continuously with the coefficients of the polynomial?

The first question is, what does it mean that the “zeros of a polynomial” vary “continuously”? What are the topological spaces involved so that we can talk about continuity? The following proposition kills two birds at once: it makes the question precise and it gives a complete answer.

**Proposition 3.37.** Let $n \in \mathbb{N}$. We consider the action by the permutation group $S_n$ on $\mathbb{C}^n$ that is given by permuting the coefficients. The map

$$f : \mathbb{C}^n \to \mathbb{C}^n/S_n$$

$$(v_0, \ldots, v_{n-1}) \mapsto \left[ \begin{array}{c} \text{set of zeros of the polynomial} \\
\text{counted with multiplicities} \\
\end{array} \right]$$

is continuous, in fact it is a homeomorphism.

**Remark.** For $n = 1, 2, 3, 4$ one can hope to prove Proposition 3.37 by the formulas for determining zeros of polynomials of degree $n$. But since no such formula exists for general polynomials of higher degree this approach is doomed for $n \geq 5$.

The proof of Proposition 3.37 makes use Rouché’s Theorem from complex analysis.

**Theorem 3.38.** (Rouché’s Theorem) Let $U \subset \mathbb{C}$ be an open set, let $f, g : U \to \mathbb{C}$ be two holomorphic functions and let $z \in U$ and $r \in \mathbb{R}^+$ be such that $\overline{B}_r(z) = \{w \in \mathbb{C} \mid |w-z| \leq r\}$ is contained in $U$. If for all $w \in \partial B_r(z)$ we have $|g(w)| < |f(w)|$, then $f$ and $f + g$ have the same number of zeros (counted with multiplicities) within the open disk $B_r(z)$.

**Proof.** This theorem is proved in every self-respecting book on complex analysis, see e.g. [Lan99, Theorem VI.1.6].

**Example.** We consider $f(z) = z^5$ and the disk $\overline{B}_1(0)$. The polynomial $f(z)$ has one zero of multiplicity five in $\overline{B}_1(0)$. For any $a \in \mathbb{C}$ with $|a| < 1$ we have $|az| < |z|^5$ for all points $z \in \partial \overline{B}_1(0) = S^1$. Thus by Rouché’s Theorem 3.38 we see that for such $a$ the polynomial

\[64\text{Slightly more rigorously the map } f \text{ is defined as follows: given } (v_0, \ldots, v_{n-1}) \in \mathbb{C}^n \text{ we define } f(v_0, \ldots, v_{n-1}) := [(\alpha_1, \ldots, \alpha_n)] \text{ where } \alpha_1, \ldots, \alpha_n \in \mathbb{C} \text{ are determined uniquely (up to reordering) by the condition that } v_0 + v_1z + \cdots + v_{n-1}z^{n-1} + z^n = (z - \alpha_1) \cdots (z - \alpha_n) \in \mathbb{C}[z].\]
$z^5 + az$ also has five zeros (counted with multiplicities) in $B_1(0)$. In fact for most values of $a$ the polynomial will have five distinct zeros, each with multiplicity one.

We will also need the following definition:

**Definition.** Given $w = [(w_1, \ldots, w_n)]$ and $z = [(z_1, \ldots, z_n)]$ in $\mathbb{C}^n/S_n$ we define

$$d(w, z) = \min_{\sigma \in S_n} \max_{1 \leq j \leq n} |w_j - z_{\sigma(j)}|.$$

The following lemma summarizes two key statements regarding the above definition.

**Lemma 3.39.**

1. The map

$$d: \mathbb{C}^n/S_n \times \mathbb{C}^n/S_n \to \mathbb{R}_{\geq 0},$$

$$(w, z) \mapsto d(w, z)$$

is a metric on $\mathbb{C}^n/S_n$.

2. The topology defined by the metric $d$ on $\mathbb{C}^n/S_n$ agrees with the quotient topology on $\mathbb{C}^n/S_n$.

**Proof.** We hand over the task providing the proof of the lemma to the surely very meticulous reader. ■

Now we are in a position to prove Proposition 3.37.

**Proof of Proposition 3.37.** We consider the map

$$g: \mathbb{C}^n/S_n \to \mathbb{C}^n,$$

$$[(\alpha_1, \ldots, \alpha_n)] \mapsto \text{coefficients of the polynomial } (z - \alpha_1) \cdots (z - \alpha_n).$$

It is straightforward to check that $g$ is continuous and that $f$ and $g$ are inverses of one another.

It remains to show that $f$ is continuous. We introduce the following definitions: We denote by $d$ the above metric on $\mathbb{C}^n/S_n$. It follows from Lemma 3.39 that we can view $f$ as a map between the two metric spaces $(\mathbb{C}^n, \| - \|)$ and $(\mathbb{C}^n/S_n, d)$. Therefore it follows from Proposition 2.36 that it suffices to prove the following claim.

**Claim.**

$$\forall v \in \mathbb{C}^n \forall \epsilon > 0 \exists \delta > 0 \forall w \in \mathbb{C}^n \text{ with } \|w\| < \delta \quad d(f(v), f(v + w)) < \epsilon.$$

Before we start with the proof of the claim we introduce the following definition: Given $v = (v_0, \ldots, v_{n-1}) \in \mathbb{C}^n$ we denote by $p_v(z) := v_0 + v_1 z + \cdots + v_{n-1} z^{n-1} + z^n$ the corresponding polynomial. Now we turn to the proof of the claim. Thus let $v = (v_0, \ldots, v_{n-1}) \in \mathbb{C}^n$ and let $\epsilon > 0$. We denote by $\xi_1, \ldots, \xi_k$ the distinct zeros of the corresponding polynomial $p_v(z)$. (Note that if $p_v(z)$ has zeros of higher multiplicity, then $k < n$.) After possibly

---

65Slightly more precisely the map $g$ is defined as follows: given $[(\alpha_1, \ldots, \alpha_n)] \in \mathbb{C}^n/S_n$ we have $f([(\alpha_1, \ldots, \alpha_n)]) = (v_0, \ldots, v_{n-1})$ where $v_0, \ldots, v_{n-1} \in \mathbb{C}$ are uniquely determined by the condition that $v_0 + v_1 z + \cdots + v_{n-1} z^{n-1} + z^n = (z - \alpha_1) \cdots (z - \alpha_n) \in \mathbb{C}[z]$. 

replacing \( \epsilon \) by a smaller non-negative number we can assume, without loss of generality, that \( \epsilon < \frac{1}{2} \cdot |\xi_i - \xi_j| \) for all \( i \neq j \).

We denote by \( \Gamma \) the union of the circles of the radius \( \epsilon \) around \( \xi_1, \ldots, \xi_h \). Furthermore we set
\[
\eta := \inf_{z \in \Gamma} |p_v(z)| \in \mathbb{R}_{>0}.
\]
It is elementary to show that there exists a \( \delta > 0 \) such that for all \( w = (w_0, \ldots, w_{n-1}) \in \mathbb{C}^n \) such that \( \|w\| < \delta \) we have
\[
|w_0 + w_1 + \cdots + w_{n-1}z^{n-1}| < \eta \quad \text{for all } z \in \Gamma.
\]
We claim that this \( \delta \) has the desired property. Thus let \( w \in \mathbb{C}^n \) with \( |w| < \delta \). It follows from the definition of \( \delta \) and Rouché’s Theorem 3.38 that the polynomials \( p_v(z) \) and \( p_{v+w}(z) \) have the same number of zeros (counted with multiplicities) in the disks \( B_\epsilon(\xi_1), \ldots, B_\epsilon(\xi_h) \).

This means that the zeros of \( p_v(z) \) and can be matched up with the zeros of \( p_{v+w}(z) \) such that each zero is less then \( \epsilon \) removed from its match. This statement implies immediately that \( d(f(v), f(v + w)) < \epsilon \).

\[\square\]

**Remark.** With some effort one can also prove Proposition 3.37 without using Rouché’s Theorem 3.38. We outline the key steps, using the notation that we introduced in the above proof of Proposition 3.37.

1. By Lemma 2.42 it suffices to show that the map \( g: \mathbb{C}^n/S_n \rightarrow \mathbb{C}^n \) is open.
2. By Lemma 2.39 it suffices to show that for each \( \epsilon > 0 \) and each \( z \in \mathbb{C}^n/S_n \) the image of the open ball \( B_\epsilon(z) \subset (\mathbb{C}^n/S_n, d) \) under \( g \) is open.
3. Thus let \( \epsilon > 0 \) and \( z \in \mathbb{C}^n/S_n \).
4. We pick \( C \in \mathbb{R}_{\geq 0} \) such that \( g(B_\epsilon(z)) \subset B_C(0) \subset \mathbb{C}^n \).
5. There exists a \( D \in \mathbb{R}_{\geq 0} \) such that for any \( v \in \mathbb{C}^n \) which satisfies \( \|v\| \leq C \) we have \( f(v) \in B_D(0) \subset \mathbb{C}^n/S_n \). (This statement requires some unraveling and a little bit of thought. It can be proved using Rouché’s Theorem 3.38 but with a worse bound it can also be proved by hand.)
6. By Proposition 2.43 we know that \( g \) restricted to \( B_D(0) \rightarrow g(B_D(0)) \) is a homeomorphism. Thus \( g(B_\epsilon(z)) \) is an open subset of \( g(B_D(0)) \).
7. By (5) and (6), and since \( f \) and \( g \) are inverses of one another, we know that \( g(B_\epsilon(z)) \) is also open in \( B_D(0) \). But \( B_D(0) \) is an open subset of \( \mathbb{C}^n \), hence \( g(B_\epsilon(z)) \) is also open in \( \mathbb{C}^n \).

![Figure 79. Illustration for the proof of Proposition 3.37](image-url)
3.9. **Projective spaces.** Let \( n \in \mathbb{N} \). On page \([187]\) we introduced the real projective space \( \mathbb{R}P^n = S^n/\{\pm 1\} \). In this section we will give an alternative definition and we will introduce the complex projective spaces. Even though these projective spaces appear initially rather arbitrary they will on several occasions play an essential role in these notes.

Let \( X = \mathbb{R}^{n+1} \setminus \{0\} \) and let \( G = \mathbb{R} \setminus \{0\} \), where we view \( G \) as a group via multiplication. The map \( (\mathbb{R} \setminus \{0\}) \times (\mathbb{R}^{n+1} \setminus \{0\}) \to \mathbb{R}^{n+1} \setminus \{0\} \)
\[
(r, P) \mapsto r \cdot P
\]
defines an action that is free and continuous. It is straightforward to see that the map \( \mathbb{R}P^n = S^n/\{\pm 1\} \to (\mathbb{R}^{n+1} \setminus \{0\})/(\mathbb{R} \setminus \{0\}) \)
\[
[P] \mapsto [P]
\]
defines a homeomorphism. In fact we will use this homeomorphism to make the identification \( \mathbb{R}P^n = (\mathbb{R}^{n+1} \setminus \{0\})/(\mathbb{R} \setminus \{0\}) \). Our new point of view on real projective spaces has the advantage that we can create a different class of examples of topological spaces by replacing \( \mathbb{R} \) by \( \mathbb{C} \). More precisely, this discussion leads us to the following definition:

**Definition.** Let \( X = \mathbb{C}^{n+1} \setminus \{0\} \) and let \( G = \mathbb{C} \setminus \{0\} \). The map \( (\mathbb{C} \setminus \{0\}) \times (\mathbb{C}^{n+1} \setminus \{0\}) \to \mathbb{C}^{n+1} \setminus \{0\} \)
\[
(z, P) \mapsto z \cdot P
\]
defines an action that is free and continuous. The quotient space \( (\mathbb{C}^{n+1} \setminus \{0\})/(\mathbb{C} \setminus \{0\}) \) is called the \( n \)-dimensional complex projective space \( \mathbb{C}P^n \).

**Notation.** Let \( n \in \mathbb{N}_0 \).

(1) For \( (x_0, \ldots, x_n) \in \mathbb{R}^{n+1} \setminus \{0\} \) we denote by \([x_0: \ldots : x_n]\) the corresponding point in \( \mathbb{R}P^n \). We also use the same notation for points in complex projective spaces.

(2) Let \( m \leq n \). We consider the maps
\[
i: \mathbb{R}P^m \to \mathbb{R}P^n \\
[x_0: \ldots : x_m] \mapsto [x_0: \ldots : x_m : 0: \ldots : 0]
\]
and
\[
\jmath: \mathbb{C}P^m \to \mathbb{C}P^n \\
[z_0: \ldots : z_m] \mapsto [z_0: \ldots : z_m : 0: \ldots : 0].
\]

It follows almost immediately from Proposition \( 2.43(2) \) and Proposition \( 3.40 \) that both maps are embeddings. Thus we can and will view \( \mathbb{R}P^m \) as a subset of \( \mathbb{R}P^n \) and similarly we will view \( \mathbb{C}P^m \) as a subset of \( \mathbb{C}P^n \).

The following lemma shows that real and complex projective spaces have some of our favorite properties.

**Proposition 3.40.** The real projective and the complex projective spaces are compact and Hausdorff.

In the proof of Proposition \( 3.40 \) it is convenient to have the following description of complex projective spaces.

\[\text{For example an inverse is given by the map } (\mathbb{R}^{n+1} \setminus \{0\})/(\mathbb{R} \setminus \{0\}) \to S^n/\{\pm 1\} \text{ that is defined by } [x] \mapsto [\frac{x}{|x|}]. \text{ More precisely, it follows from Lemma } 3.22 \text{ and Lemma } 3.21(3) \text{ that both maps are continuous. Clearly they are inverses of one another.} \]
Lemma 3.41. Let \( n \in \mathbb{N}_0 \). We make the identification
\[
S^{2n+1} = \left\{ (z_1, \ldots, z_{n+1}) \in \mathbb{C}^{n+1} \mid |z_1|^2 + \cdots + |z_{n+1}|^2 = 1 \right\}.
\]
We consider the action
\[
S^1 \times S^{2n+1} \rightarrow S^{2n+1} \quad (w, (z_1, \ldots, z_{n+1})) \mapsto (w \cdot z_1, \ldots, w \cdot z_{n+1}).
\]
The maps
\[
f : S^{2n+1}/S^1 \rightarrow \mathbb{C}P^n \quad [z_1, \ldots, z_{n+1}] \mapsto [z_1 : \ldots : z_{n+1}]
\]
and
\[
p : \mathbb{C}P^n \rightarrow S^{2n+1}/S^1 \quad [z_1 : \ldots : z_{n+1}] \mapsto \frac{1}{\sqrt{|z_1|^2 + \cdots + |z_{n+1}|^2}}(z_1, \ldots, z_{n+1})
\]
are continuous and inverses of one another, in particular both maps are homeomorphisms. We will use these maps to make the identification \( \mathbb{C}P^n = S^{2n+1}/S^1 \).

**Proof of Proposition 3.40 (†).** Let \( n \in \mathbb{N} \). It follows easily from the definition of the quotient topology on the complex projective space \( \mathbb{C}P^n = (\mathbb{C}^{n+1} \setminus \{0\})/(\mathbb{C} \setminus \{0\}) \) and from Lemma 3.21 (3) together with Lemma 3.22 that both maps are continuous. It is easy to verify that the maps are inverses of one another.

**Proof of Proposition 3.40 (‡).** Let \( n \in \mathbb{N} \). It follows from Lemma 2.40 and Proposition 3.33 that the real projective space \( \mathbb{R}P^n = S^n/\{\pm 1\} \) is compact and Hausdorff.

For the complex projective space \( \mathbb{C}P^n \) we need to work just a little harder. Throughout the remainder of this proof we will use the identification \( \mathbb{C}P^n = S^{2n+1}/S^1 \) from Lemma 3.41. Note that since \( S^{2n+1} \) is compact it follows again from Lemma 2.40 that \( \mathbb{C}P^n = S^{2n+1}/S^1 \) is compact.

It remains to show that \( \mathbb{C}P^n = S^{2n+1}/S^1 \) is Hausdorff. A direct argument is sketched in Exercise 3.39. In the following we will provide a less direct but more general argument. Namely, we note that it follows from Lemma 3.26 that \( S^{2n+1}/S^1 \) is Hausdorff once we have shown that the graph of the equivalence relation, which is given by
\[
G = \left\{ (v_1, v_2) \in S^{2n+1} \times S^{2n+1} \mid \text{there exists } w \in S^1 \text{ with } w \cdot v_1 = v_2 \right\},
\]
is a closed subset of \( S^{2n+1} \times S^{2n+1} \). The graph \( G \) is the image of the map
\[
\Phi : S^{2n+1} \times S^1 \rightarrow S^{2n+1} \times S^{2n+1} \quad (v, w) \mapsto (v, w \cdot v).
\]
This map is continuous and the left-hand side is compact by Proposition 3.12 (2). Thus the image of \( \Phi \) is compact by Lemma 2.40. By Proposition 3.12 (1) we know that \( S^{2n+1} \times S^{2n+1} \) is Hausdorff. Thus we obtain from Lemma 2.17 that the image of \( \Phi \) is a closed subset of \( S^{2n+1} \times S^{2n+1} \).

In the following lemma we give alternative descriptions of \( \mathbb{R}P^n \) and \( \mathbb{C}P^1 \) that will be used on many occasions.

Lemma 3.42.
(1) Let \( n \in \mathbb{N} \). If we denote by \( \sim \) the equivalence relation on \( \mathbb{B}^n \) that is generated by \( P \sim -P \) for \( P \in S^{n-1} = \partial \mathbb{B}^n \), then the map

\[
\mathbb{R}P^n = S^n / \{ \pm 1 \} \xrightarrow{\sim} \overline{B}^n / \sim
\]

is a homeomorphism.

(2) The map

\[
\mathbb{C}P^1 \to \mathbb{C} \cup \{ \infty \} = \mathbb{R}^2 \cup \{ \infty \}
\]

for \( \{ [z_0 : z_1] \} \mapsto \{ z_0 \cdot z_1^{-1}, \text{ if } z_1 \neq 0, \infty, \text{ if } [z_0 : z_1] = [1 : 0] \}

is a homeomorphism.

**Figure 80. Illustration for Lemma 3.42 (1).**

**Proof.** First note that one can easily verify that both maps are actually well-defined and that they are bijections. Next we explain why the two maps are continuous:

1. By Lemma 3.22 it suffices to show that the corresponding map \( S^n \to \overline{B}^n / \sim \) is continuous. One can easily verify that the restriction to the closed subsets \( S^n_{\geq 0} \) and \( S^n_{\leq 0} \) are continuous. Thus it follows from Lemma 2.35 (2) that the map \( S^n \to \overline{B}^n \) is continuous.
2. It follows again from Lemma 3.22 that it suffices to show that the corresponding map \( \Theta: \mathbb{C}^2 \setminus \{ (0, 0) \} \to \mathbb{C} \cup \{ \infty \} \) is continuous. Note that for any \( C \in \mathbb{R} \) we have

\[
\Theta^{-1}(\text{complement of } \overline{B}^n_C) = \{ (z_0, z_1) \in \mathbb{C}^2 \setminus \{ (0, 0) \} : |z_0| > |z_1| \}
\]

which is an open subset of \( \mathbb{C}^2 \setminus \{ (0, 0) \} \). It follows quite easily from this discussion together with Proposition 2.37 and together with the discussion of the basis of \( \mathbb{R}^2 \cup \{ \infty \} \) on page 103 that the map \( \Theta \) is continuous.

By Proposition 3.40 we know that each \( \mathbb{R}P^n \) and \( \mathbb{C}P^n \) is compact. Using Lemma 3.26 one can show that \( \overline{B}^n / \sim \) is Hausdorff. Furthermore we know from Exercise 2.20 that \( \mathbb{R}^2 \cup \{ \infty \} \) is Hausdorff. Thus it follows from Proposition 2.43 (3) that both maps are homeomorphisms.

**Convention.**

(1) On many occasions we will use the homeomorphism from Lemma 3.42 to make the identification \( \mathbb{R}P^n = \overline{B}^n / \sim \).
(2) In Lemma 2.44 we gave an explicit homeomorphism $S^2 \to \mathbb{R}^2 \cup \{\infty\}$. Combining this homeomorphism with the homeomorphism from Lemma 3.42 we obtain a homeomorphism $S^2 \to \mathbb{C}P^1$ which we will often use to make the identification $S^2 = \mathbb{C}P^1$. Note that under this identification the North Pole $(0,0,1) \in S^2$ corresponds to the point $[1:0] \in \mathbb{C}P^1$.

We conclude this short section on projective spaces with two somewhat tangential remarks.

**Remark.**

(1) Here is a fun fact: if we consider $\mathbb{C}P^2/\sim$, where $\sim$ denotes the equivalence relation defined by complex conjugation, i.e. where $[z:w] \sim [\overline{z}:\overline{w}]$, then the quotient space is homeomorphic (in fact diffeomorphic in a suitable sense) to $S^4$. This statement is known as the Arnold-Kuiper-Massey Theorem, see e.g. [Hill17, Mass73, Sea06].

(2) The definition of projective spaces makes sense for any field, even for fields of non-zero characteristic. For example, if $F$ is a field of characteristic $p$ we can still define the set $\mathbb{F}P^n = (\mathbb{F}^{n+1} \setminus \{0\})/(\mathbb{F} \setminus \{0\})$. A priori this is just a set, but together with the Zariski topology, see [Har92 Lecture 2] or [SKKT00 Chapter 1], it actually becomes an unusual, but interesting topological space. For any field the map $\mathbb{F}P^n = (\mathbb{F}^{n+1} \setminus \{0\})/(\mathbb{F} \setminus \{0\}) \to \{\text{all one-dimensional subspaces of } \mathbb{F}^{n+1}\}$ $[v] \mapsto \mathbb{F} \cdot v$ is a bijection. Thus we can view $\mathbb{F}P^n$ as the set of all lines through the origin.

3.10. **The pushout construction.** In this section we consider a particularly important special case of a quotient topology which deserves its own section. Before we delve into topology we recall the following definition.

**Definition.** Suppose we are given a relation $\sim$ on a set $X$. We say $x,y \in X$ are equivalent if there exists a sequence $x = x_1, \ldots, x_k = y$ of elements in $X$ such that for all $i = 1, \ldots, k-1$ the following holds: either $x_i \sim x_{i+1}$ or $x_{i+1} \sim x_i$. We write again $x \sim y$ if $x$ and $y$ are equivalent. It is straightforward to see that this is now indeed an equivalence relation. We say it is generated by the initial relation.

**Example.** The relations $x \sim (x+1)$ with $x \in \mathbb{R}$ on $\mathbb{R}$ generate the familiar equivalence relation $x \sim y \iff x - y \in \mathbb{Z}$.

**Definition.** Let $f : X \to Y$ and $g : X \to Z$ be two maps between topological spaces. We define $Y \sqcup_X Z := (Y \sqcup Z)/\sim$ where $f(x) \sim g(x)$ for all $x \in X$. We refer to $Y \sqcup_X Z$ as the pushout of $f$ and $g$. Furthermore we refer to the maps $i : Y \to Y \sqcup_X Z$ $y \mapsto [y]$ and $j : Z \to Y \sqcup_X Z$ $z \mapsto [z]$ as the two natural maps.
The notion of a pushout will play an important role throughout the lecture notes. We first summarize some key properties of pushouts, afterwards we will discuss an important special case.

**Lemma 3.43.** (*) Let \( f: X \to Y \) and \( g: X \to Z \) be two maps between topological spaces. We obtain the following commutative diagram:

\[
\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow{g} & & \downarrow{i} \\
Z & \xrightarrow{j} & Y \cup_X Z = (Y \sqcup Z)/\sim
\end{array}
\]

The following statements hold:

1. The natural maps \( i: Y \to Y \cup_X Z \) and \( j: Z \to Y \cup_X Z \) are continuous.
2. (a) If \( Y \) and \( Z \) are compact, then \( Y \cup_X Z \) is also compact.
   (b) If \( f \) is injective, then the “opposite map” \( j \) is injective. The same statement holds for “surjective” and “bijective”.
   (c) If \( f \) is an embedding, then the “opposite map” \( j \) is an embedding.
   (d) If \( f \) is a homeomorphism, then the “opposite map” \( j \) is a homeomorphism.
   (e) Suppose that at least one of the two maps \( f \) or \( g \) is injective.
      (\( \alpha \)) If the image of \( f \) is a closed subset of \( Y \), then the image of the “opposite map” \( j \) is a closed subset of \( Y \cup_X Z \).
      (\( \beta \)) If the image of \( g \) is a closed subset of \( Z \), then the image of the “opposite map” \( i \) is a closed subset of \( Y \cup_X Z \).

Both statements also hold with “closed” replaced by “open”.

By symmetry the statements in (b), (c) and (d) hold also for \( g \) and its “opposite map” \( i \).

3. Suppose we are given two maps \( \alpha: Y \to W \) and \( \beta: Z \to W \) to some topological space \( W \) such that \( \alpha \circ f = \beta \circ g: X \to W \). The map

\[
\Theta: Y \cup_X Z \to W \\
[P] \mapsto \begin{cases} 
\alpha(x) & \text{if } P = [y] \text{ for some } y \in Y, \\
\beta(y) & \text{if } P = [z] \text{ for some } z \in Z
\end{cases}
\]

is well-defined and it is the unique map \( h: Y \sqcup_X Z \to W \) with \( \Theta \circ i = \alpha \) and \( \Theta \circ j = \beta \). Furthermore, if \( \alpha \) and \( \beta \) are continuous, then \( \Theta \) is also continuous. In particular, we obtain the following commutative diagram:
(4) Suppose we are given a map \( h : Z \to W \). Then the maps
\[
Y \cup_X W \to (Y \cup_X Z) \cup_Z W \quad \text{and} \quad (Y \cup_X Z) \cup_Z W \to Y \cup_X W
\]
\[
[P] \mapsto \begin{cases}
[[P]], & \text{if } P \in Y, \\
[P], & \text{if } P \in W
\end{cases}
\]
\[
[P] \mapsto \begin{cases}
[P], & \text{if } P \in Y, \\
h(P), & \text{if } P \in Z, \\
[P], & \text{if } P \in W
\end{cases}
\]
are continuous and inverses of one another, in particular they are homeomorphisms.

**Convention.** We refer to a commutative diagram as in Lemma 3.43 as a *pushout diagram* or a *pushout square*.\(^\text{67}\)

**Example.** Let \( n \in \mathbb{N}_0 \). We consider the maps \(^\text{68}\)
\[
g_\pm : \overline{B}^n_\pm = \overline{B}^n_\pm \to S^n
\]
\[
(x_1, \ldots, x_n) \mapsto ((-1)^n \cdot x_1, \ldots, x_n, \pm \sqrt{1 - x_1^2 - \cdots - x_n^2}).
\]
It follows from Lemma 3.43 (4) that the map
\[
\overline{B}^n_+ \cup_{S^{n-1}} \overline{B}^n_- \to S^n
\]
\[
[P] \mapsto \begin{cases}
g_+(P), & \text{if } P \in \overline{B}^n_+; \\
g_-(P), & \text{if } P \in \overline{B}^n_-;
\end{cases}
\]
is continuous. One can easily verify that it is a bijection. It follows from Lemma 3.43 (1) combined with Proposition 2.43 (3) that the map is a homeomorphism. We use this homeomorphism to make the identification \( \overline{B}^n_+ \cup_{S^{n-1}} \overline{B}^n_- = S^n \).

**Proof (\textasteriskcentered).** Throughout the proof we denote by \( p : Y \sqcup Z \to Y \cup_X Z \) the obvious projection.

1. This statement follows from Lemma 3.3 (4) together with Lemma 3.21 (4).
2. This statement follows immediately from Lemma 3.3 (1) and Lemma 3.21 (3).
3. (a) If \( Y \) and \( Z \) are compact, then it follows from Lemma 3.3 (4) and Lemma 3.21 (4) that \( Y \cup_X Z \) is compact.
   (b) Let \( z \in Z \). It follows basically from the definitions that the set of elements in \( Z \) that are equivalent to \( z \) with respect to the equivalence relation “\( \sim \)” on \( Y \sqcup Z \) equals precisely
   \[
   \bigcup_{k \in \mathbb{N}_0} g(f(f^{-1}(f^{-1}(f^{-1}(f^{-1}(f^{-1}(\ldots g(f^{-1}(\{z\}))))\ldots))))).
   \]
   If \( f \) is injective, then it follows immediately from Lemma 1.3 (1) and (2) that this set consists precisely of the element \( z \). In other words, the map \( j \) is injective.
   (c) We suppose that \( f : X \to Y \) is an embedding. By (1) we know that \( j \) is continuous and by (3b) we know that \( j : Z \to Y \cup_X Z \) is an injection. By Lemma 2.42 (2) and

\(^{67}\) There are various other names in the literature for this concept, e.g. “cocartesian square”, “fibered coproduct” or “amalgamated sum”.

\(^{68}\) We put in the superfluous looking sign \((−1)^n\) for the following reason: once we have introduced orientations of smooth manifolds and once we have introduced the standard orientations of \( \overline{B}^n_+ \) and \( S^n \) this sign assures us that the map \( g_+ : \overline{B}^n_+ \to S^n \) is orientation-preserving and it means that \( g_- : \overline{B}^n_- \to S^n \) is orientation-reversing.
by definition of the subspace topology on \( j(U) \) it remains to prove the following claim.

**Claim.** If \( U \) is an open subset of \( Z \), then there exists an open subset \( W \) of \( Y \cup_X Z \) such that \( j(U) = W \cap j(Z) \).

Let \( U \) be an open subset of \( Z \). Since \( g \) is continuous we know that \( g^{-1}(U) \) is an open subset of \( X \). Since \( f \) is an embedding we know that there exists an open subset \( V \subseteq Y \) with \( f(g^{-1}(U)) = f(X) \cap V \). We set \( W := p(U \cup V) \). A short argument shows that \( p^{-1}(W) = U \cup V \). Thus it follows from the definition of the quotient topology and the disjoint union topology that \( W \) is indeed an open subset of \( Y \cup_X Z \). Basically by construction we have \( j(U) = W \cap j(Z) \). \( \qed \)

(d) Suppose \( f: X \to Y \) is a homeomorphism. It follows immediately from (3b) and (3c) that \( j: Z \to Y \cup_X Z \) is a homeomorphism.

(e) Without loss of generality we can assume that \( f \) is injective. The statements for “closed” follow almost immediately from the following observations:

(i) By Lemma [3.21] a subset \( W \) of \( Y \cup_X Z \) is closed if and only if \( p^{-1}(W) \) is closed.

(ii) Since \( f \) is injective it follows from the argument in (2a) that
\[
p^{-1}(i(Y)) = Y \cup g(X) \quad \text{and} \quad p^{-1}(j(Z)) = f(g^{-1}(Z)) \cup Z = f(X) \cup Z.
\]

(iii) By Lemma [3.1] a subset \( U \cup V \) of \( Y \cup Z \) is closed if and only if \( U \) and \( V \) are closed.

The proof for “open” is basically the same.

(4) This statement is an immediate consequence of the definitions and Lemma [3.22].

(5) It follows immediately from applying (3) altogether three times that the maps are continuous. It is basically clear that they are inverses of one another. Thus both are homeomorphisms. \( \blacksquare \)

Now, as promised we will discuss an important class of pushouts, namely where the map \( f: X \to Y \) is just the inclusion of a subset. This leads us to the following definition.

**Definition.** Let \( Y \) and \( Z \) be topological spaces, let \( A \subseteq Y \) be a subset and let \( \varphi: A \to Z \) be a continuous map. (Note that \( \varphi \) does not need to be injective.) We write
\[
Y \cup_\varphi Z := Y \cup_{\varphi: A \to Z} Z := (Y \cup Z) / \sim
\]
where \( \sim \) is the equivalence relation generated by \( a \sim \varphi(a) \) for \( a \in A \). We call \( Y \cup_\varphi Z \) the topological space obtained by *gluing* \( Y \) to \( Z \) via the map \( f \). The definition is illustrated in Figure 81.

![Figure 81](image-url)
**Example.** Let \( Y \) be a topological space and let \( A \) be a subset of \( Y \). If \( Z \) is the topological space that consists of a single point, then there exists evidently precisely one map \( \varphi: A \to Z \) and it follows basically immediately from the definitions that \( Y \cup_Z Z \) is homeomorphic to \( Y/A \).

Out of a sense of duty we summarize the main properties of \( Y \cup_Z Z \).

**Lemma 3.44.** (\( \ast \)) Let \( Y \) and \( Z \) be two topological spaces, let \( A \subset Y \) be a subset and let \( \varphi: A \to Z \) be a map. We denote by \( i: Y \to Y \cup_Z Z \) and \( j: Z \to Y \cup_Z Z \) the obvious maps. For clarity we consider the following diagram:

\[
\begin{array}{ccc}
A & \xrightarrow{i} & Y \\
\varphi \downarrow & & \downarrow y \mapsto [y] \downarrow i \\
Z & \xrightarrow{j} & Y \cup_Z Z = (Y \cup Z)/\sim \\
\end{array}
\]

The following statements hold:

1. The maps \( i: Y \to Y \cup_Z Z \) and \( j: Z \to Y \cup_Z Z \) are continuous.
2. (a) If \( A \) is a closed subset of \( Y \), then \( j(Z) \) is a closed subset of \( Y \cup_Z Z \).
   (b) If \( \varphi(A) \) is a closed subset of \( Z \), then \( i(Y) \) is a closed subset of \( Y \cup_Z Z \).
   The same statements hold with “closed” replaced by “open”.
3. (a) If \( B \subset Y \setminus A \) is a closed set, then \( i(B) \) is a closed subset of \( Y \cup_Z Z \).
   (b) If \( C \subset Z \setminus \varphi(A) \) is a closed set, then \( j(C) \) is a closed subset of \( Y \cup_Z Z \).
   The same statements hold with “closed” replaced by “open”.
4. The map \( j: Z \to Y \cup_Z Z \) is an embedding.\(^{69}\)
5. Let \( f: Y \to W \) and \( g: Z \to W \) be two maps to a topological space \( W \). If we have \( g(\varphi(a)) = f(a) \) for all \( a \in A \), then

\[
h: Y \cup_Z Z \to W \\
p \mapsto \begin{cases} f(x) & \text{if } p = [x] \text{ for some } x \in Y, \\ g(y) & \text{if } p = [y] \text{ for some } y \in Z \end{cases}
\]

is well-defined and it is the unique map \( h: Y \cup_Z Z \to W \) with \( h \circ i = f \) and \( h \circ j = g \). Furthermore, if \( f \) and \( g \) are continuous, then \( h \) is also continuous.

**Proof (\( \ast \)).** Throughout the proof we will apply Lemma 3.43 to the embedding \( i: A \to Y \) and the map \( \varphi: A \to Z \).

1. This statement is a special case of Lemma 3.43 (2).
2. This statement is a special case of Lemma 3.43 (3d).
3. As on earlier occasions we denote by \( p: Y \sqcup Z \to Y \cup_Z Z \) the obvious projection.
   The proof of this statement is very similar to the proof of (2), we just need to notice that for \( B \subset Y \setminus A \) we have \( p^{-1}(i(B)) = B \sqcup \emptyset \) and that for \( C \subset Z \setminus \varphi(A) \) we have \( p^{-1}(j(C)) = \emptyset \sqcup C \).
4. This statement is a special case of Lemma 3.43 (3b).
5. This statement is a special case of Lemma 3.43 (4). \( \blacksquare \)

\(^{69}\)Note that if \( \varphi \) is not an embedding, then the setting is not symmetric in \( Y \) and \( Z \). For example, as we saw above, in general the map \( i: Y \to Y \cup_Z Z \) is not even injective.
The following lemma is quite subtle and gets used, often inadvertently, on many occasions.

**Lemma 3.45.** Let $X$ be a topological space and let $A$ and $B$ be two subsets of $X$ with $X = A \cup B$. We denote by $\varphi : A \cap B \to A \cap B$ the identity map. We suppose that one of the following two conditions hold:

1. Both subsets $A$ and $B$ are closed.
2. Both subsets $A$ and $B$ are open.

Then the map $A \cup \varphi : A \cap B \to A \cap B$ is a homeomorphism.

**Remark.** In general the conclusion of the lemma does not hold without some assumptions on $A$ and $B$. For example, consider $X = [-1, 1]$ together with the subsets $A = [-1, 0]$ and $B = (0, 1]$. In this case $A \cap B = \emptyset$, thus $A \cup \varphi B$ is the disjoint union of $A$ and $B$. It follows from Lemma 3.3 (4) and the Heine-Borel Theorem that $A \cup B$ is not compact. On the other hand $X = [-1, 1]$ is compact by the Heine-Borel Theorem. Thus the two topological spaces $A \cup \varphi B$ and $X$ are not homeomorphic. We refer to Figure 82 for an illustration.

**Proof.** Let $X$ be a topological space and let $A$ and $B$ be two subsets of $X$ with $X = A \cup B$. We denote by $\varphi : A \cap B \to A \cap B$ the identity map. In the following we consider the case that $A$ and $B$ are both closed subsets of $X$. The case that both $A$ and $B$ are open subsets is dealt with in almost entirely the same way.

It follows from Lemma 3.44 (5) that the given map $h : A \cup \varphi : A \cap B \to A \cap B$ is continuous. Furthermore, basically by definition the map $h$ is a bijection. By Lemma 2.42 (2) it remains to show that the map $h$ is closed. Thus let $W \subset A \cup \varphi B$ be a closed subset. Note that $h(W) = (W \cap A) \cup (W \cap B)$. It follows from Lemma 3.21 (2), applied to the projection map

$$A \cup B \to A \cup \varphi B = (A \cup B) / \sim,$$

that $A \cap W$ is closed in $A$ and that $B \cap W$ is closed in $B$. Since $A$ and $B$ are by hypothesis closed in $X$ we obtain from Lemma 2.38 (2) that $A \cap W$ and $B \cap W$ are closed in $X$. It follows that $h(W) = (W \cap A) \cup (W \cap B)$ is a closed subset of $X$. 

We conclude this section with an amusing description of spheres. We introduce the following notation:

(1) We write $I = [-1, 1]$. 
(2) Given $k \in \mathbb{N}_0$ we write \(^{70}\)
\[
\partial I^k = \{(x_1, \ldots, x_k) \in I^k \mid \text{at least one } x_i \text{ lies in } \{\pm 1\}\}.
\]

(3) We recall that given $k \in \mathbb{N}_0$ there exists by Proposition 2.52 a canonical homeomorphism
\[
\varphi_k: (\mathcal{B}^k, S^{k-1}) \xrightarrow{\cong} (I^k, \partial I^k)
\]
with $\varphi_k(0) = 0$.

Now let $m, n \in \mathbb{N}_0$. An elementary set-theoretic argument shows that
\[
((\partial I^m) \times I^n) \cup (I^m \times \partial I^n) = \partial I^{m+n}
\]
and the two subsets to the left coincide in $(\partial I^m) \times (\partial I^n)$. (We refer to Figure 83 for an illustration.) It follows from Lemma 3.45 that the inclusions induce a homeomorphism
\[
((\partial I^m) \times I^n) \cup_{id_{\partial I^m} \times id_{I^n}} (I^m \times \partial I^n) \xrightarrow{\cong} \partial I^{m+n}.
\]
Together with the above homeomorphisms we obtain a canonical homeomorphism
\[
(S^{m-1} \times \mathcal{B}^n) \cup_{id_{S^{m-1} \times S^{n-1}}} (\mathcal{B}^m \times S^{n-1}) \xrightarrow{\cong} S^{m+n-1}.
\]
For example, if we take $m = n = 2$, then we see that we can write $S^3$ as the union of two solid tori. We will discuss this particular case in greater detail later in Section 27.1.

![Figure 83](image)

**3.11. Surfaces.** In this section we introduce some of my favorite topological spaces, namely surfaces.

(1) We consider $X = [0, 1] \times [0, 1] \subset \mathbb{R}^2$ and the equivalence relation which is generated by
\[
(x, 0) \sim (x, 1) \text{ for all } x \in [0, 1].
\]
The quotient topological space $X/\sim$ is obtained from the square $X = [0, 1] \times [0, 1]$ by identifying each point on the upper edge with the corresponding point on the lower edge. Put differently, “we glue the upper edge to the lower edge”. Using Proposition 2.43 (3) one can easily show that the map
\[
X/\sim \to S^1 \times [0, 1]
\]
\[
[(s, t)] \mapsto (e^{2\pi it}, s)
\]
is a homeomorphism. We refer to $X/\sim$ and also to $S^1 \times [0, 1]$ as the **cylinder** or the **annulus**. Sometimes we refer to $S^1 \times (0, 1)$, which is homeomorphic to $(0, 1) \times [0, 1]/\sim$, as the **open cylinder** or **open annulus**.

---

\(^{70}\)It is not difficult to see that $\partial I^k$ is the boundary of $I^k$ viewed as a subset of $\mathbb{R}^k$. 
the points \((x, 1)\) and \((x, 0)\) are equivalent in \(X/\sim\) the points \([(x, 1)] = [(x, 0)]\) agree

\[
\begin{array}{c}
[0, 1] \times 1 \\
\downarrow \\
X = [0, 1] \times [0, 1] \\
\downarrow \\
[0, 1] \times 0 \\
\end{array}
\]

\[\xrightarrow{\sim} \]

\[\xrightarrow{\sim} \quad \text{cylinder} \]

**Figure 84.** Construction of a cylinder by gluing two edges.

(2) Now we consider \(X = [0, 1] \times [0, 1] \subset \mathbb{R}^2\), this time with the equivalence relation which is generated by

\[(0, y) \sim (1, 1 - y) \quad \text{for all } y \in [0, 1].\]

The quotient space \(X/\sim\) is obtained from the square \(X\) by gluing the edge on the left to the edge on the right, but this time “we glue the edges with a twist”. We will now see that this topological space is homeomorphic to the Möbius band as defined on page 188. We consider the map

\[
\begin{align*}
([0, 1] \times [0, 1])/\sim & \quad \to \quad (\mathbb{R} \times [-1, 1])/\mathbb{Z} \\
[(x, y)] & \quad \mapsto \quad [(x, 2y - 1)]
\end{align*}
\]

The left-hand side is compact by Lemma 3.21 (4) and the right-hand side is Hausdorff by Proposition 3.33 and the discussion on page 189. The map is clearly continuous and a bijection. Thus it follows from the ever-popular Proposition 2.43 (3) that the map is a homeomorphism. We will use this homeomorphism to identify \([0, 1] \times [0, 1])/\sim\) with the Möbius band. It is straightforward to see that this homeomorphism restricts

\[
\begin{array}{c}
(0, y) \\
\downarrow \\
(1, 1 - y) \\
\end{array}
\]

\[\xrightarrow{\sim} \]

\[\xrightarrow{\sim} \quad \text{Möbius band} \]

**Figure 85.** The Möbius band.

to a homeomorphism from \([0, 1] \times (0, 1))\,(0, y) \sim (1, 1 - y)\) to the open Möbius band \((\mathbb{R} \times (-1, 1))/\sim\).

(3) Now we consider again \(X = [0, 1] \times [0, 1] \subset \mathbb{R}^2\), but this time with the equivalence relation which is generated by

\[(x, 0) \sim (x, 1) \quad \text{for all } x \in [0, 1] \]

and by

\[(0, y) \sim (1, y) \quad \text{for all } y \in [0, 1].\]

Put differently, we obtain the quotient topological space \(X/\sim\) by gluing the top edge to the bottom edge and the left-hand edge to the right-hand edge, each time without
adding a twist. Figure 86 illustrates that the quotient space \( X/ \sim \) is indeed a torus. As in the previous example one can show that the inclusion \( X \to \mathbb{R}^2 \) descends to a homeomorphism \( X/ \sim \to \mathbb{R}^2/\mathbb{Z}^2 \). In other words, we can make the identification \( \mathbb{R}^2/\mathbb{Z}^2 = ([0, 1] \times [0, 1])/\sim \).

(4) Now we consider \( X = [0, 1] \times [0, 1] \subset \mathbb{R}^2 \), this time with the equivalence relation which is generated by

\[
(x, 0) \sim (x, 1) \quad \text{for all } x \in [0, 1]
\]

and by

\[
(0, y) \sim (1, 1 - y) \quad \text{for all } y \in [0, 1].
\]

Thus we obtain the quotient space \( X/ \sim \) by gluing the upper edge to the lower edge and by gluing the edge on the left to the edge on the right with a twist. The resulting topological space is called the Klein bottle. In Figure 87 we show the Klein bottle to the left. Furthermore we indicate a map from the Klein bottle to \( \mathbb{R}^3 \). This particular map is not injective.

the given map from the Klein bottle to \( \mathbb{R}^3 \) has a self-intersection

the images of these two circles are the same

(5) We denote by \( E_8 \) the regular octagon in \( \mathbb{C} \) with the vertices \( Q_k = e^{2\pi ik/16} \) where \( k = 1, 3, \ldots, 15 \), i.e. \( E_8 \) is the convex hull of these eight points in \( \mathbb{R}^2 \). Given two points \( A, B \in \mathbb{R}^2 = \mathbb{C} \) we denote by \( AB \) the Euclidean segment from \( A \) to \( B \). Furthermore, given \( \varphi \in \mathbb{R} \) we denote by \( r_\varphi : \mathbb{C} \to \mathbb{C} \) the reflection in the Euclidean line \( \{te^{i\varphi} | t \in \mathbb{R} \} \). We denote by \( \sim \) the equivalence relation on \( E_8 \) which is generated by

\[
P \in Q_{2k-1}Q_{2k+1} \sim r_{2\pi(2k+2)/16}(P) \in Q_{2k+3}Q_{2k+5}
\]

for \( k = 0, 1, 4, 5 \). These four relations are sketched in Figure 88. We refer to the topological space \( E_8/ \sim \) as the surface of genus 2. The equivalence relation is sketched in Figure 88. Furthermore, in Figure 89 we indicate how \( E_8/ \sim \) is related to the actual "physical" surface of genus 2 in \( \mathbb{R}^3 \). The same way we can define the surface \( \Sigma_g \) of
We have now introduced many examples of topological spaces, some of them, for example the Möbius band, the torus and the surface of genus 2, can easily be pictured as genus $g$ for any $g \geq 3$. More precisely, we take a regular $4g$-gon in $\mathbb{C}$ and for $j = 1, \ldots, g$ we identify the $(4j + 1)$-st edge with the $(4j + 3)$-rd edge and the $(4j + 2)$-nd edge with the $(4j + 4)$-th edge. Here each identification is given by a reflection. For $g = 3$ this construction is sketched in Figure 90.

Finally we refer to the sphere $S^2$ as the surface of genus 0 and we refer to the torus $S^1 \times S^1$ as the surface of genus 1.

(6) Given $g \in \mathbb{N}_{\geq 2}$ we consider the regular $2g$-gon $E_{2g}$ with the identification of the boundary segments shown in Figure 91. We refer to this topological space as the non-orientable surface $N_g$ of genus $g$. (Later on in Lemma 6.48 we will see why $N_g$ deserves its epithet.) Furthermore, we refer to the real projection place $\mathbb{RP}^2$ as the non-orientable surface of genus 1. In Exercise 3.43 we will see that the Klein bottle is homeomorphic to the non-orientable surface of genus 2. Furthermore, as a sneak preview, let us point out that later in Lemma 8.33 we will see that $N_g$ is diffeomorphic to the connected sum of $g$ copies of $\mathbb{RP}^2$.
subsets of “our universe”, i.e. they can be viewed as subsets of $\mathbb{R}^3$. This raises the following question.

**Question 3.46.** Can the real projective space $\mathbb{R}P^2$ and the Klein bottle, or more generally the non-orientable surfaces of some genus $\geq 3$, be viewed as subsets of $\mathbb{R}^3$?

3.12. **The join of two topological spaces** (*). In this section we introduce the join of two topological spaces. This construction will be useful on a few occasions, but it is difficult to argue that at this stage this is an essential topic in these notes.

Loosely speaking the join $X \ast Y$ is obtained by connecting each point in $X$ to each point in $Y$ via an interval. The following definition makes this idea precise.

**Definition.** Let $X$ and $Y$ be two non-empty topological spaces. We define the join $X \ast Y$ to be the topological space obtained from $X \times [0,1] \times Y$, equipped with the product topology, by performing the following two types of identifications:

1. For every $x \in X$ we identify all points in $\{x\} \times \{0\} \times Y$ to a single point and
2. For every $y \in Y$ we identify all points in $X \times \{1\} \times \{y\}$ to a single point.

Furthermore, if one of $X$ or $Y$ is the empty topological space, then we define the join $X \ast Y$ to be the other topological space.

For completeness we state the following lemma.

**Lemma 3.47.** (*). Let $X_1, Y_1, X_2, Y_2$ be four topological spaces and let $f: X_1 \rightarrow X_2$ and $g: Y_1 \rightarrow Y_2$ be maps. The corresponding map

$$f \ast g: X_1 \ast Y_1 \rightarrow X_2 \ast Y_2$$

$$[(x,t,y)] \mapsto [(f(x),t,g(y))]$$

is well-defined and continuous.

**Proof** (*). It is straightforward to verify that the map $f \ast g$ is well-defined. It follows easily from Lemma 3.22, Lemma 3.21 (3) and Lemma 3.8 (3c) that the map $f \ast g$ is continuous.

Before we deal with a few examples we give a criterion for showing that a map of the form $f: X \ast Y \rightarrow Z$ is a homeomorphism.

**Lemma 3.48.** If $X$ and $Y$ are compact topological spaces, then the following two statements hold:

1. The join $X \ast Y$ is compact.
(2) Let \( f: X \times [0, 1] \times Y \rightarrow Z \) be a map to a topological space \( Z \) such that for any \( x, x_1, x_2 \in X \) and \( y, y_1, y_2 \in Y \) we have the equalities \( f(x, 0, y_1) = f(x, 0, y_2) \) and \( f(x_1, 1, y) = f(x_2, 1, y) \). If \( Z \) is Hausdorff and if the induced map\(^72\)
\[
\Psi: X \ast Y \rightarrow Z
\]
\[
[(x, t, y)] \mapsto f(x, y, t)
\]
is a bijection, then the map \( \Psi \) is a homeomorphism.

**Proof.**

(1) It follows immediately from our hypothesis and Proposition 3.12 together with Lemma 3.21 that the join \( X \ast Y = (X \times [0, 1] \times Y) / \sim \) is compact.

(2) The map \( \Psi: X \ast Y \rightarrow Z \) is continuous by Lemma 3.22. Thus we obtain from our hypotheses on \( \Psi \) and \( Z \) together with Proposition 2.43 (3) that \( \Psi \) is indeed a homeomorphism. ■

The following, otherwise broadly irrelevant lemma, justifies somewhat the idea that the join \( X \ast Y \) is obtained by connecting each point in \( X \) to each point in \( Y \) via an interval.

**Lemma 3.49.** Given \( P, Q \in \mathbb{R}^n \) we denote by \( PQ = \{ x \cdot (1 - t) + y \cdot t \mid t \in [0, 1] \} \) the Euclidean segment determined by \( P \) and \( Q \). Let \( X \) and \( Y \) be two compact subsets of \( \mathbb{R}^n \) which have the property that for any \( x, x' \) and \( y, y' \) the segments \( \overline{xy} \) and \( \overline{x'y'} \) intersect at most in the end points. Then the map

\[
\Theta: X \ast Y = (X \times [0, 1] \times Y) / \sim \rightarrow \bigcup_{x \in X, y \in Y} \overline{xy}
\]
\[
[(x, t, y)] \mapsto x \cdot (1 - t) + y \cdot t
\]
is a homeomorphism.

**Proof.** It follows almost immediately from Lemma 3.48 and our hypothesis that the map \( \Theta \) is a homeomorphism. ■

We continue with another example of joins.

**Example.** We consider the join of the two intervals \( X = [0, 1] \) and \( Y = [0, 1] \). First let us consider Figure 92. The figure suggests that the join \( X \ast Y = [0, 1] \ast [0, 1] \) should be homeomorphic to a 3-dimensional pyramid. In fact let us consider the map

\[
([0, 1] \times [0, 1] \times [0, 1]) / \sim \rightarrow \Delta = \{(t_1, t_2, t_3) \in [0, 1]^3 \mid t_1 + t_2 + t_3 \leq 1 \}
\]
\[
[(x, t, y)] \mapsto \frac{1}{2} \cdot (x \cdot t, y \cdot (1 - t), t).
\]

It follows easily from Lemma 3.48 (2) that this map is a homeomorphism.

We record the next example of joins as a lemma.

\(^72\)It follows from our hypothesis on \( f \) that the map \( f \) descends to a map on \( X \ast Y = (X \times [0, 1] \times Y) / \sim \).
Lemma 3.50. Given any \( m, n \in \mathbb{N}_0 \) the map

\[
S^m \ast S^n \rightarrow S^{m+n+1} \\
[(x, t, y)] \mapsto \left( x \cdot \cos \left( \frac{\pi t}{2} \right), y \cdot \sin \left( \frac{\pi t}{2} \right) \right)
\]

is a homeomorphism.

Proof. Using Lemma 3.48 (2) one can fairly easily verify that the given map is a homeomorphism. □

Convention. Let \( m, n \in \mathbb{N}_0 \). We use the homeomorphism from Lemma 3.50 to add the identification \( S^m \ast S^n = S^{m+n+1} \) to our long list of avatars of the spheres.

For completeness we state the following fairly straightforward lemma which we will prove in Exercise 3.48.

Lemma 3.51. Let \( X \) and \( Y \) be topological spaces. If \( X \) and \( Y \) are both Hausdorff, then the join \( X \ast Y \) is also Hausdorff.

Finally we consider the delicate question whether the join is associative.

Proposition 3.52. Let \( X, Y \) and \( Z \) be non-empty topological spaces that are compact and Hausdorff. Then there exists a homeomorphism

\[
(X \ast Y) \ast Z \sim X \ast (Y \ast Z).
\]

Remark. As on page 82 we see that for finitely many topological spaces spaces \( X_1, \ldots, X_k \) that are non-empty compact and Hausdorff we can unambiguously define the join \( X_1 \ast \cdots \ast X_k \).

It turns out that the proof of Proposition 3.52 is surprisingly difficult, remarkably we will only be able to give it later on on page 250.

Remark. The join \( X \ast Y \), viewed as a set, can be equipped with another reasonable topology, namely the “initial topology”, see [BrownR06, Chapter 5.7]. By [BrownR06, Corollary 5.7.2] these two topologies agree if \( X \) and \( Y \) are compact and Hausdorff. When dealing with joins it seems that it is safest to stick to the case that \( X \) and \( Y \) are compact
and Hausdorff. For example Proposition 3.52 says that in this context the join is associative. But this statement is not true for all topological spaces. We refer to [Cohe57], [BrownR06], Chapter 5.7 and [FF16], Chapter 2.4 for details. 3.13. Topological groups. In this section we consider the notion of a topological group which will crop up every now and then in these notes.

**Definition.** A **topological group** is a topological space $X$ together with a group structure, such that the two maps:

$$X \times X \rightarrow X \quad \text{and} \quad X \rightarrow X$$

are continuous.

The most basic example of a topological group is given by taking any group and equipping it with the discrete topology. As we will see, somewhat surprisingly even this banal example can turn out to be interesting.

The following lemma gives us much more interesting examples of topological groups.

**Lemma 3.53.** For any $n \in \mathbb{N}$ the matrix groups $\text{GL}(n, \mathbb{R})$ and $\text{GL}(n, \mathbb{C})$ are topological groups.

**Proof.** As we pointed out on page 163 matrix multiplication is continuous. Furthermore, basic linear algebra, see e.g. [HJ13], Chapter 0.8.2, says that taking the inverse is given by the map:

$$\text{GL}(n, \mathbb{R}) \rightarrow \text{GL}(n, \mathbb{R})$$

$$A \mapsto \frac{1}{\det(A)} \cdot \text{matrix whose (i, j)-entry is given by taking the determinant of the matrix that is obtained from A by removing the i-th column and the j-th row of A.}$$

But this map is clearly continuous. This shows that $\text{GL}(n, \mathbb{R})$ is a topological group. Basically the same argument also shows that $\text{GL}(n, \mathbb{C})$ is a topological group.  

We obtain more examples of topological groups by taking subgroups and products:

**Lemma 3.54.**

1. Let $X$ be a topological group and let $Y$ be a subgroup. If we equip $Y$ with the subspace topology, then $Y$ is also a topological group.
2. Let $\{X_i\}_{i \in I}$ be a family of topological groups. If we equip \( \prod_{i \in I} X_i \) with the product topology and the obvious group structure, then it is again a topological group.

**Proof.**

1. This statement follows immediately from Lemma 2.30 together with Lemma 3.8 (1b).
2. This statement follows easily from Lemma 3.14 and Lemma 3.15 (2).
Example. It follows from Lemmas 3.53 and 3.54 (1) that $\text{SL}(n, \mathbb{R})$, $\text{O}(n)$, $\text{SO}(n)$, $\text{GL}(n, \mathbb{C})$, $\text{U}(n)$ and $\text{SU}(n)$ are topological groups.

Lemma 3.55. Let $G$ be a topological group.

(1) Given any $g \in G$ the two maps
\[ l_g : G \to G \quad \text{and} \quad r_g : G \to G \]
\[ h \mapsto g \cdot h \quad \text{and} \quad h \mapsto h \cdot g \]
are continuous.

(2) If $G$ is a topological group, then any two path-components of $G$ are homeomorphic.

Proof (*).

(1) The map $l_g$ is the composition of the two maps
\[ G \to G \times G \quad \text{and} \quad G \times G \to G \]
\[ h \mapsto (g, h) \quad \text{and} \quad (x, y) \mapsto x \cdot y. \]
The first map is continuous by Lemma 3.8 (2a) and the second map is continuous since $G$ is a topological group. Thus $l_g$ itself is continuous. The same argument shows that $r_g$ is continuous.

(2) Let $X, Y$ be two path-components of $G$. We pick $x \in X$ and $y \in Y$. We consider the map $\varphi : G \to G$ given by $g \mapsto yx^{-1}g$. By (1) we know that $\varphi$ is continuous. Furthermore it follows from Lemma 2.70 that $\varphi(X) \subset Y$.

We also consider the map $\psi : G \to G$ given by $g \mapsto xy^{-1}g$. The same argument as above shows that $\psi$ is continuous and that $\psi(Y) \subset X$. Clearly $\varphi$ and $\psi$ are inverses of one another. But this implies that $\varphi$ and $\psi$ are homeomorphisms between $X$ and $Y$.

Exercises for Chapter 3.

Exercise 3.1. Let $X$ be a topological space and let $A$ and $B$ be two subsets of $X$. Show that the following two statements are equivalent:

(1) There exist open neighborhoods $U$ of $A$ and $V$ of $B$ with $U \cap B = \emptyset$ and $V \cap A = \emptyset$.
(2) The map
\[ A \cup B \to A \sqcup B \]
\[ x \mapsto \begin{cases} (x, 1), & \text{if } x \in A, \\ (x, 2), & \text{if } x \in B \end{cases} \]
is a homeomorphism.

Remark. This is the content of Lemma 3.2.

Exercise 3.2. Let $C \subset \mathbb{R}$ be the Cantor set, as defined on page 100. Is the disjoint union $C \sqcup C$ homeomorphic to $C$ itself?
Exercise 3.3. Show that there are non-homeomorphic topological spaces $A$ and $B$ and a non-empty topological space $X$ such that $A \times X$ is homeomorphic to $B \times X$.

Hint. you could take $A = \{0\}$ and $B = \{0, 1\}$.

Exercise 3.4. Let $X$ be a topological space. We consider the “diagonal”
\[ \Delta := \{(x, x) \in X \times X \mid x \in X\}. \]
We equip $X \times X$ with the product topology and we equip $\Delta$ with the subspace topology. Show that the map $X \to \Delta$ given by $x \mapsto (x, x)$ is a homeomorphism.

Exercise 3.5. Let $X_1, \ldots, X_k$ be topological spaces and let $B_i \subset X_i$, $i = 1, \ldots, k$ be subsets. Show that the following equalities hold:

(a) closure of $B_1 \times \cdots \times B_k$ in $X_1 \times \cdots \times X_k = \overline{B_1 \times \cdots \times B_k}$
(b) interior of $B_1 \times \cdots \times B_k$ in $X_1 \times \cdots \times X_k = \mathring{B_1 \times \cdots \times B_k}$
(c) boundary of $B_1 \times \cdots \times B_k$ in $X_1 \times \cdots \times X_k = \bigcup_{i=1}^{k} \overline{B_1 \times \cdots \times \partial B_i \times \cdots \times B_k}$.

Exercise 3.6. Let $X$ be a compact topological space. Let $Y$ be a topological space, let $y_0 \in Y$ and let $U$ be an open subset of $X \times Y$ that contains $X \times \{y_0\}$. Show that there exists an open neighborhood $V$ of $y_0$ such that $X \times V \subset U$.

Remark. This statement is sometimes called the Tube Lemma.

![Figure 93. Illustration for Exercise 3.6](image)

Exercise 3.7. Let $X$ and $Y$ be topological spaces.

(a) Show that if $X$ is compact, then the projection map $p: X \times Y \to Y$ is a closed map.

Remark. This exercise is related to Exercise 3.6.

(b) Give an example that shows that in general in (a) we cannot drop the hypothesis that $X$ is compact.

Somewhat surprisingly, the converse to (a) holds. More precisely, if a topological space $X$ has the property, that for any other topological space $Y$ the projection map $p: X \times Y \to Y$ is a closed map, then $X$ is actually compact. This non-trivial statement is sometimes known as the Kuratowski-Mrówka Theorem, it was first proved by Stanisław Mrówka [Mró59] p. 21 in 1959. See also [Her96] p. 3 and see also [Enge89] Theorem 3.1.16 under the extra hypothesis that $X$ is Hausdorff.

Exercise 3.8. Let $X \subset \mathbb{R}^n$ be a compact convex non-empty subset. Show that there exists a $k \in \mathbb{N}_0$ such that $X$ is homeomorphic to $\overline{B}^k$.

Exercise 3.9. Let $\{X_i\}_{i \in I}$ be a family of topological spaces.
(a) Suppose that for each \( i \in I \) we are given a closed subset \( A_i \subset X_i \). If \( I \) is finite, then it follows from Lemma 3.9 that \( \prod_{i \in I} A_i \) is a closed subset of \( \prod_{i \in I} X_i \). Does this conclusion also hold if \( I \) is infinite?

(b) Let \( \{X_i\}_{i \in I} \) be a family of topological spaces. Suppose that for each \( i \in I \) we are given a subset \( A_i \subset X_i \). Show that

\[
\prod_{i \in I} A_i = \prod_{i \in I} A_i \subset \prod_{i \in I} X_i.
\]

Exercise 3.10. Let \( X \) and \( Y \) be topological spaces, let \( W \subset X \times Y \) be an open subset and let \( K \) be a compact subset of \( Y \). Show that \( U := \{x \in X \mid \{x\} \times K \subset W\} \) is an open subset of \( X \).

Exercise 3.11. Let \((X,d)\) be a metric space.

(a) Show that the map

\[
X \times X \rightarrow \mathbb{R}_{\geq 0}
\]

\((x,y) \mapsto d(x,y)\)

is continuous.

(b) Suppose that \( X \) is compact and that \( f : X \rightarrow X \) is a map with \( f(x) \neq x \) for all \( x \in X \). Show that there exists an \( \epsilon > 0 \) such that \( d(f(x),x) \geq \epsilon \) for all \( x \in X \).

Exercise 3.12. Let \((X,d)\) be a metric space and let \( B \subset X \) be a non-empty subset. Show that the map

\[
X \rightarrow \mathbb{R}_{\geq 0}
\]

\(x \mapsto d(x,B) := \inf\{d(x,b) \mid b \in B\}\)

is continuous.

![Figure 94. Illustration for Exercise 3.12.](image)

Exercise 3.13. Let \( X \) be a metric space and let \( A, B \) be two non-empty subsets of \( X \). Suppose that \( \text{diam}(A) + \text{diam}(B) < d(A, B) \). Show that \( A \cap B = \emptyset \).

Exercise 3.14. Let \( X \) and \( Y \) be topological spaces and let \( M \subset X \times Y \) be a compact subset. Show that there exist compact subsets \( K \subset X \) and \( L \subset Y \) such that \( M \subset K \times L \).

Exercise 3.15. Let \( X \) and \( Y \) be two topological spaces. Show that the product topology on \( X \times Y \) is the smallest topology that has the property that the two natural projection maps \( X \times Y \rightarrow X \) and \( X \times Y \rightarrow Y \) are continuous.

Exercise 3.16. Let \( A \) be the annulus and let \( M \) be the Möbius band. Are the product topological spaces \( A \times [0,1] \) and \( M \times [0,1] \) homeomorphic?

Exercise 3.17. Let \( X \) be a topological space that is compact and Hausdorff. Let \( f : X \rightarrow X \) be a map. We denote by \( F := \{x \in X \mid f(x) = x\} \) the fixed point set of \( f \). Show that \( F \) is a discrete subset of \( X \) if and only if \( F \) is finite.
Exercise 3.18. A topological space $X$ is called metrizable if there exists a metric $d$ on $X$ such that the given topology agrees with the topology coming from $d$. Now suppose that $X$ is a metrizable topological space. Show that given any closed set $A \subset X$ there exists a map $f : X \to \mathbb{R}$ such that $f^{-1}(\{0\}) = A$.

*Hint.* Use Exercise 3.12.

Exercise 3.19. Show that the map from $\prod_{i \in \mathbb{N}} \{0, 2\}$ to the Cantor set, that we defined on page 174 is continuous.

Exercise 3.20.

(a) Show that the Cantor set is totally disconnected.
(b) Show that $\prod_{i \in \mathbb{N}} \{0, 2\}$ is totally disconnected.

Exercise 3.21. Let $X$ be a topological space. Show that $X$ is Hausdorff $\iff$ the diagonal $\Delta = \{(x, x) \mid x \in X\}$ is a closed subset of $X \times X$.

Exercise 3.22.

(a) Show that the real projective space $\mathbb{R}P^1$ is homeomorphic to $S^1$.
(b) Do you think that the real projective space $\mathbb{R}P^2 = (\mathbb{R}^3 \setminus \{0\})/(\mathbb{R} \setminus \{0\})$ is homeomorphic to $S^2$? As of now we lack the tools to answer this question. Nonetheless, what do you think the answer will be?

Exercise 3.23. Let $\sim$ be an equivalence relation on a topological space $X$ and let $f : X \to Y$ be a map with the property that $f(x) = f(y)$ whenever $x \sim y$. Show that if $f : X \to Y$ is an open map, then the induced map $X/\sim \to Y$ is also an open map.

Exercise 3.24. Show that the topological space $\mathbb{R}/\{\pm 1\} = \mathbb{R}/x \sim -x$ is homeomorphic to the half-open interval $[0, \infty)$.

Exercise 3.25. Let the group $(\mathbb{Q}, +)$ act on the topological space $\mathbb{R}$ by addition. Show that $\mathbb{R}/\mathbb{Q}$ is not Hausdorff.

Exercise 3.26. Let $\sim$ be the equivalence relation on $\mathbb{R}_{\geq 0} \times \mathbb{R}$ that is generated by

(1) $(0, \varphi) \sim (0, \varphi')$ for all $\varphi, \varphi' \in \mathbb{R}$ and by
(2) $(r, \varphi) \sim (r, \varphi + k \cdot 2\pi)$ for all $r \in \mathbb{R}_{\geq 0}, \varphi \in \mathbb{R}$ and $k \in \mathbb{Z}$.

We equip $(\mathbb{R}_{\geq 0} \times \mathbb{R})/\sim$ with the quotient topology.

(a) Show that the map

$$\Theta : (\mathbb{R}_{\geq 0} \times \mathbb{R})/\sim \to \mathbb{C}$$

$$(r, \varphi) \mapsto r \cdot e^{i\varphi}$$

is a homeomorphism.

*Hint.* To show that the map is a homeomorphism you might want to use Proposition 2.45.
3. CONSTRUCTIONS OF TOPOLOGICAL SPACES

(b) Let \( f: \mathbb{R}_{\geq 0} \times \mathbb{R} \to X \) be a continuous map to some topological space \( X \) such that \( f(P) = f(Q) \) whenever \( P \sim Q \). Show that the map

\[
\mathbb{C} \to X \\
re^{i\varphi} \mapsto f(r, \varphi)
\]

is continuous.

Remark. This exercise is a variation on Lemma 3.25.

Exercise 3.27. Let \( \gamma \in \mathbb{R} \) and let \( s \in \mathbb{R} \). We consider the map

\[
f_s: \mathbb{C} \setminus \mathbb{R}_{>0} \cdot e^{i\gamma} \to \mathbb{C} \\
r \cdot e^{i\varphi} \mapsto r \cdot e^{i\varphi - s}.
\]

(a) Show that \( f_s \) is well-defined and continuous.
(b) Suppose that \( s \neq 0 \). Show that \( f_s \) is a local homeomorphism.

Exercise 3.28.

(a) Show that any matrix \( A \in \text{O}(2n) \) with \( \det(A) = -1 \) has 1 as an eigenvalue.
   
   Hint. Show that if \( \lambda \in \mathbb{C} \) is an eigenvalue of \( A \), then so is \( \overline{\lambda} \).

(b) Let \( G \subset \text{O}(2n) \) be a subgroup that acts freely on \( S^{2n-1} \). Show that \( G \) is contained in \( \text{SO}(2n) \).

(c) Show that the analogue of (b) does not hold for subgroups of \( G \subset \text{O}(2n - 1) \).

Exercise 3.29. Let \( n \in \mathbb{N} \) and let \( \varphi: S^n \to S^n \) be a homeomorphism. We consider the map

\[
\Phi: \overline{B}^{n+1} \to \overline{B}^{n+1} \\
x \mapsto \begin{cases} 
\|x\| \cdot \varphi(\frac{x}{\|x\|}), & \text{if } x \neq 0, \\
0, & \text{otherwise.}
\end{cases}
\]

(a) Show that \( \Phi \) is continuous.
(b) Show that \( \Phi \) is a homeomorphism.
(c) Give any example of a diffeomorphism \( \varphi: S^n \to S^n \) such that the map \( \Phi: \overline{B}^{n+1} \to \overline{B}^{n+1} \) is not a diffeomorphism.

Hint. You might want to use Lemma 3.25.

Remark. The fact that we can extend \( \varphi \) to a homeomorphism of \( \overline{B}^{n+1} \) is sometimes referred to as the Alexander trick. We will get to know a more fancy Alexander trick later on page 540.

**Exercise 3.30.** Given \( v, w \in \mathbb{R}^2 \setminus \{(0,0)\} \) we define

\[
\angle(v, w) := \text{unique } \varphi \in (-\pi, \pi] \text{ such that } w = r \cdot \begin{pmatrix} \cos(\varphi) & -\sin(\varphi) \\ \sin(\varphi) & \cos(\varphi) \end{pmatrix} \cdot w \text{ for some } r \in \mathbb{R}_{>0}.
\]

(a) Show that the map

\[
\Phi: (\mathbb{R}^2 \setminus \{(0,0)\}) \times (\mathbb{R}^2 \setminus \{(0,0)\}) \to (-\pi, \pi] \\
(v, w) \mapsto \angle(v, w)
\]

is not continuous.

(b) Show that the map

\[
\Phi: (\mathbb{R}^2 \setminus \{(0,0)\}) \times (\mathbb{R}^2 \setminus \{(0,0)\}) \to \mathbb{R}/2\pi\mathbb{Z} \\
(v, w) \mapsto [\angle(v, w)]
\]

is continuous. (Here \( \mathbb{R}/2\pi\mathbb{Z} \) denotes the quotient of the topological space \( \mathbb{R} \) by the group \( (2\pi\mathbb{Z}, +) \).

**Exercise 3.31.** We consider the following subsets of \([0, 1]\):

\[
A = \{0, \frac{1}{3}, \frac{2}{3}, 1\}, \quad B = \{\frac{1}{n} \mid n \in \mathbb{N}\} \quad \text{and} \quad C = \{0\} \cup B.
\]

(a) Show that the quotient \([0, 1]/A\) is homeomorphic to a subset of \(\mathbb{R}^2\). See e.g. Figure 97 for an idea.

(b) Is the quotient \([0, 1]/B\) homeomorphic to a subset of \(\mathbb{R}^2\)?

(c) Is the quotient \([0, 1]/C\) homeomorphic to a subset of \(\mathbb{R}^2\)?

**Exercise 3.32.** Let \( X \) be topological space and let \( A \) and \( B \) be two subsets with \( A \cup B = X \). We write \( C := A \cap B \). We consider the disjoint union \( A \sqcup B = (A \times \{1\}) \cup (B \times \{2\}) \) and we consider \( Y = (A \sqcup B)/\sim \) where for each \( c \in C \) we identify the point \((c, 1) \in A \times \{1\}\) with the corresponding point \((c, 2) \in B \times \{2\}\). We consider the map

\[
p: Y = (A \sqcup B)/\sim \to X
\]

that is given by

\[
[(a, 1)] \mapsto a \quad \text{for } a \in A, \\
[(b, 2)] \mapsto b \quad \text{for } b \in B.
\]
(a) Is the map \( p \) necessarily continuous?
(b) Is the map \( p \) necessarily open?
(c) Suppose that \( A \) and \( B \) are open subsets of \( X \). Show that \( p \) is a homeomorphism.

Remark. The failure of \( p \) to be a homeomorphism can lead to nasty surprises.

Exercise 3.33. Let \( \Sigma \) be the surface of genus 4.

(a) Show that \( \Sigma \) admits a free and continuous action by \( \mathbb{Z}_2 \).
(b) Show that \( \Sigma \) admits a free and continuous action by \( \mathbb{Z}_3 \).
(c) Show that \( \Sigma \) admits a free and continuous action by \( \mathbb{Z}_6 \).

Remark. In Proposition 55.11 we will see that if a finite group \( G \) admits a free and continuous action on \( \Sigma \), then the order of \( G \) divides 6.

Exercise 3.34. Give an example of maps \( f : X \to Y \) and \( X \to Z \) between infinite topological spaces such that the pushout \( Y \cup_X Z \) consists of a single point.

Exercise 3.35. Let \( X \) be a topological space and let \( A \subset X \) be a subset. We denote by \( \{\ast\} \) the topological space with a single point. Let \( i : A \to X \) be the inclusion map and let \( p : A \to \{\ast\} \) be the unique map there is. Show that the corresponding pushout \( X \cup_A \{\ast\} \) is homeomorphic to the quotient \( X/A \).

Remark. Note that we also allow the case \( A = \emptyset \).

Exercise 3.36. Let \( X \) be a topological space and let \( A \) and \( B \) be two disjoint subsets. We equip \( A \) with the subspace topology and we equip \( X/B \) with the quotient topology. We denote by \( i : A \to X \) the inclusion map and we denote by \( p : X \to X/B \) the projection.

(a) Show that the map \( p \circ i : A \to X/B \) is continuous and injective.
(b) Show that the map \( p \circ i : A \to X/B \) is not necessarily an embedding.
(c) Suppose that there exists an open subset \( U \subset X \) with \( A \subset U \) and \( U \cap B = \emptyset \). Show that the map \( p \circ i : A \to X/B \) is an embedding.

![Figure 98. Illustration for Exercise 3.36](image)

Exercise 3.37. Similar to the definition of the Möbius band on page 188 we consider the action of the group \( G = \mathbb{Z} \) on \( X = \mathbb{R} \times \{-1, 1\} \) that is given by

\[
Z \times (\mathbb{R} \times \{-1, 1\}) \to \mathbb{R} \times \{-1, 1\} \quad (n, (x, y)) \mapsto (x + n, (-1)^n \cdot y).
\]

Show that \( X/G = X/\mathbb{Z} \) is homeomorphic to \( S^1 \).

Exercise 3.38. Let

\[
\langle -, - \rangle : \mathbb{C}^n \times \mathbb{C}^n \to \mathbb{C} \quad ((v_1, \ldots, v_n), (w_1, \ldots, w_n)) \mapsto \sum_{i=1}^n v_i \cdot \overline{w_i}
\]
be the standard complex hermitian inner product on \( \mathbb{C}^n \). Show that for any \( v, w \in \mathbb{C}^n \) the following two statements hold:

(a) \(|\langle v, w \rangle| \leq |v| \cdot |w|\).

(b) \(|\langle v, w \rangle| = |v| \cdot |w|\) if and only if there exist \( \lambda, \mu \in \mathbb{C} \) with \( \lambda \cdot v = \nu \cdot w \) and such that \((\lambda, \mu) \neq (0, 0)\).

The first statement is known as the *Cauchy-Schwarz inequality*.

**Remark.** For any commutative ring \( R \) and any \((a_1, \ldots, a_n) \in R^n \) and \((b_1, \ldots, b_n) \in R^n\) we have the equality

\[
\left( \sum_{i=1}^n a_i b_i \right)^2 + \sum_{\{i,j\} \mid 1 \leq i < j \leq n} (a_i b_j - a_j b_i)^2 = \left( \sum_{i=1}^n a_i^2 \right) \cdot \left( \sum_{i=1}^n b_i^2 \right).
\]

**Exercise 3.39.** We consider the map

\[
(C \setminus \{0\}) \times (\mathbb{C}^{n+1} \setminus \{0\}) \rightarrow \mathbb{C}^{n+1} \setminus \{0\}
\]

\[(z, P) \mapsto z \cdot P.
\]

By definition we have \( \mathbb{C}P^n := (\mathbb{C}^{n+1} \setminus \{0\})/(C \setminus \{0\}) \).

1. Show that the obvious map \( p: \mathbb{C}^{n+1} \setminus \{0\} \rightarrow \mathbb{C}P^n \) is open.
2. In Proposition 3.40 we showed that \( \mathbb{C}P^n \) is Hausdorff. In this exercise we want to give a more direct, down-to-earth proof that \( \mathbb{C}P^n \) is Hausdorff. Thus let \([x], [y] \in \mathbb{C}P^n \) be two disjoint points. Let \( \langle -,- \rangle \) be the usual hermitian inner product on \( \mathbb{C}^{n+1} \) that we introduced in Exercise 3.38. We consider

\[
U_x = \{ z \in \mathbb{C}^{n+1} \setminus \{0\} \mid |\langle z, y \rangle| < |\langle z, x \rangle| \} \quad \& \quad U_y = \{ z \in \mathbb{C}^{n+1} \setminus \{0\} \mid |\langle z, x \rangle| < |\langle z, y \rangle| \}.
\]

(a) Show that \( U_x \) and \( U_y \) are open subsets of \( \mathbb{C}^{n+1} \setminus \{0\} \).

(b) Show that \( p(U_x) \) and \( p(U_y) \) are disjoint. (Note that they are open by (1) and (2a).)

(c) Show that \([x] \in p(U_x)\) and \([y] \in p(U_y)\). (*Hint.* Use Exercise 3.38(b).)

**Exercise 3.40.** Let \( \sim \) be the equivalence relation on \( \overline{B}^3 \) that is given by \( x \sim -x \) for \( x \in S^2 \). We consider the map

\[
F: \overline{B}^3 / \sim \rightarrow SO(3)
\]

matrix in \( SO(3) \) which represents rotation by the angle \( \pi \cdot r \) around the axis \( \mathbb{R}_{\geq 0} \cdot v \) where the rotation direction is given by the right-hand rule

We refer to Figure 99 for an illustration.

(a) Give a rigorous description of \( F \) and show that \( F \) is continuous.

(b) Use your linear algebra skills to show that \( F \) is a bijection.

(c) Show that \( F \) is a homeomorphism.

**Remark.** On page 196 we showed that \( \overline{B}^3 / \sim \) is homeomorphic to \( \mathbb{R}P^3 \). Thus in combination we have just shown the amusing and surprising fact that \( \mathbb{R}P^3 \) is homeomorphic to \( SO(3) \). We will give a different proof of this fact later on in Theorem 51.2.
Exercise 3.41. We say a group $G$ acts discretely on a topological space $X$, if it acts continuously and if for each $x \in X$ there exists an open neighborhood $U$ such that we have $U \cap gU$ for all $g \neq e$. Can the group $\mathbb{Z}$ act discretely on $S^2$?

Exercise 3.42. Let $X$ be a Hausdorff space and let $G$ be a group that acts discretely on $X$. (See Exercise 3.41 for the notion of a discrete action.) Furthermore let $K$ be a compact subset of $X$.

(a) We assume that $X$ is locally compact. Show that $\{g \in G \mid gK \cap K \neq \emptyset\}$ is finite.

(b) Does the conclusion of (a) also hold if we drop the hypothesis that $X$ is locally compact? This statement is [Scot78 Lemma 1.2].

Exercise 3.43. Show that the Klein bottle, as defined on page 205, is homeomorphic to the non-orientable surface $N_2$ of genus 2, as defined on page 206. We refer to Figure 100 for a reminder of the definitions.

Exercise 3.44. Show that for any choice of $m, n \in \mathbb{N}_0$ there exists a homeomorphism $\mathbb{B}^m \ast \mathbb{B}^n \cong \mathbb{B}^{m+n+1}$.

Exercise 3.45. We let $X = S^1$ be the standard circle in the $xy$-plane of $\mathbb{R}^3$ and we let $Y$ be the circle in $S^3 = \mathbb{R}^3 \cup \{\infty\}$ that is given by the $z$-axis together with the point $\{\infty\}$. (See Figure 101 for a simple illustration.) Show that we can “continuously” connect every point on $X$ to every point $Y$ such that the paths fill out $S^3$. In other words, try to visualize the fact that $S^1 \ast S^1 \cong X \ast Y$ is homeomorphic to $S^3$.

Exercise 3.46. Build a Möbius band out of a strip of paper and cut it along the central curve. What topological space do you obtain that way?
Exercise 3.47. Let $X$ and $Y$ be topological spaces. Show that the join $X \ast Y$ is homeomorphic to the pushout of the maps

$$
\begin{array}{ccc}
X \times \{0, 1\} \times Y & \longrightarrow & X \times [0, 1] \times Y \\
\downarrow & & \downarrow \\
X \sqcup Y & & 
\end{array}
$$

where the horizontal map is the inclusion and the vertical map is defined by the two projections $X \times \{0\} \times Y \to X$ and $X \times \{1\} \times Y \to Y$.

Remark. This exercise explains in particular the initially slightly odd convention in the definition of the join for the special case that at least one of $X$ or $Y$ is the empty topological space.

Exercise 3.48. Let $X$ and $Y$ be topological spaces. Show that if $X$ and $Y$ are Hausdorff, then the join $X \ast Y$ is also Hausdorff.
4. Graphs

In this short chapter we will first introduce the purely combinatorial concept of an (undirected) abstract graph. Afterwards we introduce the corresponding topological realizations. These notions are of interest for various reasons. Abstract graphs are ubiquitous in mathematics and at times they will also play a useful role in our discussions. The corresponding topological realizations form fairly simple, but nonetheless interesting examples of topological spaces.

4.1. Abstract graphs and topological graphs. We start out with the following rather abstract definition.

**Definition.** An abstract graph $G$ is a quadruple $(V, E, i, t)$ where $V$ is a set, $E$ is a set and $i, t : E \to V$ are maps from $E$ to $V$.

1. The elements of $V$ are called the vertices of $G$ and the elements of $E$ are called the edges of $G$.
2. Given $e \in E$ the point $i(e)$ is called the initial point of $e$ and $t(e)$ is called the terminal point of $e$. We refer to $i(e)$ and $t(e)$ as the endpoints of $e$.
3. We say an edge $e \in E$ is a loop if $i(e) = t(e)$. Otherwise we call $e$ a non-loop.
4. We say $G$ is finite (countable) if both $V$ and $E$ are finite (countable).

**Remark.** The origins of graph theory go back to Leonhard Euler [Eul1736] and his work in 1736 on the problem on the seven bridges of Königsberg, see Exercise 4.1.

**Examples.**

(A) We take $V = \{A, B, C\}$ and $E = \{e, f, g, h\}$. Furthermore let $i : E \to V$ be the map that is defined by $i(e) = A$, $i(f) = B$, $i(g) = B$ and $i(h) = A$ and let $t : E \to V$ be the map that is defined by $t(e) = B$, $t(f) = C$, $t(g) = C$ and $t(h) = A$. The quadruple $(V, E, i, t)$ is an abstract graph.

(B) Let $a, b \in \mathbb{Z}$. We denote by $G_{a,b} = (V, E, i, t)$ the abstract graph with vertex set $V = \mathbb{Z}$, edge set $E = \mathbb{Z} \times \{0, 1\}$ and where $i(n, 0) = i(n, 1) = n$ and $t(n, 0) = n + a$ and $t(n, 1) = b$.

At this stage it is difficult to visualize the above definitions. Soon we will get to know a tool which rectifies this problem.

The following definition is somewhat topology-like.

**Definition.** We say that an abstract graph $(V, E, i, t)$ is connected if for every two vertices $v \neq w \in V$ there exist vertices $v = v_0, v_1, \ldots, v_n = w$ and edges $e_0, \ldots, e_{n-1}$ such that for each $i \in \{0, \ldots, n-1\}$ the endpoints of $e_i$ are $v_i$ and $v_{i+1}$.

**Examples.** We want to determine whether or not the above examples (A) and (B) of abstract graphs are connected.

(A) This abstract graph is connected, for example if we take $v = A$ and $w = C$, then $v_0 = A$, $v_1 = B$ and $v_2 = C$ and $e_0 = e$ and $e_1 = f$ have the desired property.

(B) Let $a, b \in \mathbb{Z}$. Basically by definition the abstract graph $G_{a,b}$ is connected if and only if for every two integers $x, y \in \mathbb{Z}$ there exist $n, m \in \mathbb{Z}$ such that $x - y = ma + nb$. Elementary number theory says that this is the case if and only if $a$ and $b$ are coprime.
So far this definition has little to do with topology. We will change this sorry state of affairs by introducing the topological realization of a graph. The idea is, basically, that the topological realization of an abstract graph \( G = (V, E, i, t) \) is given by one point for each vertex \( v \in V \) and one interval for each edge \( e \in E \) with endpoints given by \( \varphi(e) \). The definition below is the formalization of that idea.

**Definition.** Let \( G = (V, E, i, t) \) be an abstract graph.

1. We define the topological realization of \( G \) as the topological space \(|G| := (V \sqcup (E \times [0, 1]))/\sim \) where for any \( e \in E \) we have \((e, 0) \sim i(e) \) and \((e, 1) \sim t(e)\).

   Here \( E \) is equipped with the discrete topology.

2. Given \( e \in E \) we refer to the map \( \Phi_e: [0, 1] \xrightarrow{x \mapsto (e, x)} \{e\} \times [0, 1] \to |G| \) as the characteristic map of the edge \( e \).

3. Let \( e \in E \). By a slight abuse of language we refer to \(|e| = \Phi_e([0, 1])\) also as an edge of \(|G|\). Furthermore we refer to \( \langle e \rangle := \Phi_e((0, 1)) \) as an open edge of \(|G|\).

Before we attempt to give a better intuition for the definition of the topological realization we need to get the following lemma out of the way.

**Lemma 4.1.** Let \( G = (V, E, i, t) \) be an abstract graph.

1. The obvious map \( V \to |G| \) is an inclusion and the image is a discrete subset of \(|G|\).
2. \(|G|\) is Hausdorff.
3. Let \( e \in E \).
   a. The map \( \Phi_e: [0, 1] \to |G| \) is continuous and closed.
   b. The map \( \Phi_e: (0, 1) \to |G| \) is an open embedding.
   c. If \( i(e) = t(e) \), then \( \Phi_e \) induces a homeomorphism \([0, 1]/\sim \to |e|\).
   d. If \( i(e) \neq t(e) \), then \( \Phi_e \) restricts to a homeomorphism \([0, 1] \to |e|\).

   The same statements (a), (b), (c) and (d) also hold for the map \( \tilde{\Phi}_e: [0, 1] \to |G| \) given by \( t \mapsto \Phi_e(1 - t) \). This map satisfies \( \tilde{\Phi}_e(0) = t(e) \) and \( \tilde{\Phi}_e(1) = i(e) \). For convenience we sometimes refer to \( \tilde{\Phi}_e \) also as a characteristic map of the edge \( e \).

4. \( G \) is finite if and only if \(|G|\) is compact.
5. The following statements are equivalent:
   a. \( G \) is connected,
   b. given any two distinct vertices \( v, v' \) there exists an embedding \( \gamma: [0, 1] \to |G| \) with \( \gamma(0) = v, \gamma(1) = v' \) and such that \( \gamma([0, 1]) \subset |G| \) is the union of edges,
   c. the topological realization \(|G|\) is path-connected,
   d. the topological realization \(|G|\) is connected.

**Proof (\(\ast\)).**
(1) This statement follows fairly easily from the definitions of the quotient topology and the disjoint union topology. We leave it to the reader to fill in the details.

(2) Ditto.

(3) Let \( e \in E \).

(a) It follows immediately from Lemma 3.3 (1) and Lemma 3.21 (3) that \( \Phi_e \) is continuous. Furthermore it follows easily from the definitions together with Lemma 3.1 and Lemma 3.21 (3) that \( \Phi_e \) is closed.

(b) One can easily verify that \( \Phi_e : (0, 1) \to |G| \) is injective and that it is an open map. Thus it follows from Lemma 2.42 that it is an embedding.

(c) We suppose that \( i(e) = t(e) \). It follows easily from Lemma 3.28 that \( \Phi_e \) induces a continuous map \([0, 1]/0 \sim 1 \to |e|\) and that this map is a bijection. It follows from (2) and Proposition 2.43 (3) that the map \( \Phi_e : [0, 1]/0 \sim 1 \to |e| \) is in fact a homeomorphism.

(d) Now we suppose that \( i(e) \neq t(e) \). In this case the map is clearly injective. Thus it follows from (2) together with Proposition 2.43 (3) that \( \Phi_e : [0, 1] \to |e| \) is a homeomorphism.

The statements regarding \( \tilde\Phi_e \) follow from the fact that the map \( t \mapsto 1 - t \) is a homeomorphism of \([0, 1]\).

(4) First assume that \( G \) is finite. It follows almost immediately from Lemma 3.3 (4) together with Lemma 2.40 that \(|G|\) is compact. In Exercise 4.6 we will show that any compact subset of the topological realization of a graph is contained in the topological realization of a “subgraph”. This statement immediately implies that if \(|G|\) is finite, then \( G \) is finite.

(5) We will prove this statement in Exercise 4.3.

Even though the above definition of the topological realization of an abstract graph is a perfectly fine, rigorous and precise definition, it is perhaps not the most intuitive definition. It would be much more fun to work with topological spaces that we can “see”. This leads us to the following definition.

**Definition.** A topological graph is a triple \((X, G = (V, E, i, t), \Theta : |G| \to X)\) where the following holds:

1. \( X \) is a topological space,
2. \( G = (V, E, i, t) \) is an abstract graph,
3. \( \Theta : |G| \to X \) is a homeomorphism between the topological realization \(|G|\) of \( G \) and the topological space \( X \).

Given a topological graph \((X, G = (V, E, i, t), \Theta : |G| \to X)\) we introduce the following extra definitions:

1. Given \( v \in V \) we refer to \( \Theta(v) \) as a vertex of the topological graph.
2. Given \( e \in E \) we refer to \( \Theta(|e|) \) as an edge of the topological graph. Given a loop \( e \) we refer to \( |e| \) as a loop of the topological graph.
3. We refer to the abstract graph \( G = (V, E, i, t) \) as the underlying abstract graph.
4. Sometimes we refer, somewhat incorrectly, to \( X \) as a topological realization of \( G \).
Sometimes we will just say that $X$ is a topological graph. Furthermore on occasions we will suppress $G = (V, E, i, t), \Theta : |G| \to X$ from the notation.

The following lemma gives us a way to construct topological graphs with a given underlying abstract graph.

**Lemma 4.2.** Let $G = (V, E, i, t)$ be an abstract graph and let $n \in \mathbb{N}_0$. Suppose we are given the following data:

1. An injective map $\alpha : V \to \mathbb{R}^n$.
2. For each $e \in E$ we are given a map $\beta_e : [0, 1] \to \mathbb{R}^n$ which is injective on $(0, 1)$ and which satisfies $\beta_e(0) = \alpha(i(e))$ and $\beta_e(1) = \alpha(t(e))$.
3. For $e \neq f \in E$ we have $\beta_e((0, 1)) \cap \beta_f((0, 1)) = \emptyset$.

If $G$ is infinite, then we also demand that the following condition is satisfied:

4. For every $r \in \mathbb{R}_{>0}$ there exist only finitely many $v \in V$ with $\alpha(v) \cap B_r^n(0) \neq \emptyset$ and there exist only finitely many $e \in E$ with $\beta_e([0, 1]) \cap B_r^n(0) \neq \emptyset$.

Then the following map is an embedding:

$$|G| = (V \cup (E \times [0, 1])) / \sim \xrightarrow{\downarrow} \mathbb{R}^n \quad [x] \mapsto \begin{cases} \alpha(x), & \text{if } x \in V, \\ \beta_e(t), & \text{if } x = (e, t) \in E \times [0, 1]. \end{cases}$$

**Proof.** It follows easily from our hypotheses that the map is well-defined and that it is an injection. Furthermore we obtain from Lemma 3.22 [4.2] that the map is continuous. If $G$ is finite, then it follows from Lemma 4.1 [4.1] together with Proposition 2.43 (3) that the given map $|G| \to \mathbb{R}^n$ is an embedding. In the general case the same conclusion follows from Proposition 2.45 [4.5].

**Examples.** We return to the two examples of abstract graphs that we gave on page 221.

(A) As on page 221 we consider $V = \{A, B, C\}$ and $E = \{e, f, g, h\}$ together with the maps $i, t : E \to V$ given by $i(e) = A$, $i(f) = B$, $i(g) = B$ and $i(h) = A$ and given by $t(e) = B$, $t(f) = C$, $t(g) = C$ and $t(h) = A$. In Figure 102 [4.2] we show two topological realizations [4.2] of this abstract graph.

(B) Let $a, b \in \mathbb{Z}$. As on page 221 we consider the abstract graph with vertex set $V = \mathbb{Z}$, edge set $\mathbb{Z} \times \{0, 1\}$ and where $i(n, 0) = i(n, 1) = n$ and $t(n, 0) = n + a$ and $t(n, 1) = b$.

In Figure 103 [4.3] we show topological realizations of the graphs $G_{2,3}$ and $G_{0,2}$.

It is elementary [4.9] to show that given any finite abstract graph $G$ there exists an embedding of $|G|$ into $\mathbb{R}^n$. We conclude this section with the following question.

---

[4.2] Here evidently we use the slightly sloppy language from above. More precisely, we do not show the actual topological realization $|G|$ but we show a topological graph $X$ such that the underlying abstract graph equals $G$.

[4.9] When we say that it is “elementary to show something” this usually means that one can show the statement using basic methods without the need to use advanced results. This does not mean that this is necessarily easy. In this particular case a rigorous proof is given in [CELR94] p. 2.
4. GRAPHS

**Question 4.3.** Let $G$ be a finite abstract graph. Does there necessarily exist an embedding of $|G|$ into $\mathbb{R}^2$?

**Example.** We consider the finite abstract graphs $G$, $H$ and $I$ that are (implicitly) illustrated in Figure 104. Do their topological realizations admit embeddings into $\mathbb{R}^2$?

Surely the answer to Question 4.3 must be no, but it is not clear how one can prove this statement rigorously. We will return to this question in Section 56.3.

### 4.2. Undirected abstract graphs and their topological realizations

In this section we will introduce the notion of an undirected abstract graph and the corresponding topological realizations. In many settings undirected abstract graphs are more suitable than the abstract graphs from the previous section. But as we will see, the topological realization of an undirected abstract graph is more unwieldy. Thus in these notes we will mostly work with abstract graphs and we will leave it to the reader to generalize some of the later results to the setting of undirected abstract graphs.

Without further ado, here is the definition.

**Definition.** An undirected abstract graph $G$ is a triple $(V, E, \varphi)$ where $V$ is a set, $E$ is a set and $\varphi$ is a map

$$\varphi : E \rightarrow \{ \text{subsets of } V \text{ with one or two elements} \}.$$
Examples. We take $V$ to be the set of all subway stations in München and we take $E$ to be the set of all segments of the subway system. The map $\varphi$ then assigns to each $e \in E$ the two stations that are connected by the segment $e$. The triple $(V, E, \varphi)$ is an undirected abstract graph.

Now comes the slightly intimidating definition of the topological realization of an undirected abstract graph.

**Definition.** Let $G = (V, E, \varphi)$ be an undirected abstract graph. We define the *topological realization* of $G$ as the topological space\(^7\)

$$|G| := \left( V \sqcup \bigsqcup_{e \in E} [0, 1] \sqcup \bigsqcup_{e \in E} [0, 1] \times \text{Bij}([0, 1], \varphi(e)) \right) / \sim$$

where $\sim$ is generated by the following two relations:

1. For each $e \in E$ with $\# \varphi(e) = 1$ we identify $0$ and $1$ in the corresponding copy of $[0, 1]$ with the unique point $\varphi(e) \in V$.
2. For each $e \in E$ with $\# \varphi(e) = 2$ we make the following identifications:
   - (a) For each $\gamma \in \text{Bij}([0, 1], \varphi(e))$ we set $(0, \gamma) \sim (0)$ and $(1, \gamma) \sim (1)$.
   - (b) For $\alpha \neq \beta \in \text{Bij}([0, 1], \varphi(e))$ and each $t \in [0, 1]$ we set $(t, \alpha) \sim (1 - t, \beta)$.

**Example.** Using a variation on Lemma 4.2\(^4\) or alternatively using Lemma 4.4\(^5\) below one can see that the subset of $\mathbb{R}^2$ shown in Figure 105 is a topological realization of the subway system of München.

**Lemma 4.4.** Let $G = (V, E, i, t)$ be an abstract graph.

1. We define $\varphi : E \to \mathcal{P}(V)$ by $\varphi(e) = \{i(e), t(e)\}$. The triple $\tilde{G} = (V, E, \varphi)$ is an undirected abstract graph.
2. The map

$$\Theta_G : |G| \to |\tilde{G}|$$

$$[x] \mapsto \begin{cases} [x], & \text{if } x \in V, \\ [t \in [0, 1], \gamma], & \text{if } x = (e, t) \in E \times [0, 1] \text{ with } i(e) = t(e), \\ [(t, \gamma)], & \text{if } x = (e, t) \in E \times [0, 1] \text{ with } i(e) \neq t(e), \\ \text{here } \gamma(0) = i(e), \gamma(1) = t(e) \\ \end{cases}$$

is a homeomorphism.

\(^7\)Let $e \in E$ be a vertex with $\# \varphi(e) = 2$. Note that in this case $\text{Bij}([0, 1], \varphi(e))$ has precisely two elements. The problem is that there is no "preferred" bijection, so we need to consider both in our definition.
Proof.

(1) This statement follows immediately from the definitions.
(2) It follows fairly easily from the definitions that the map is well-defined and a bijection.
Furthermore one can deduce easily from Lemma 3.28 that the map is continuous.
Working directly with the definitions one sees that the map is open. In summary it follows from Lemma 2.42 that the map is indeed a homeomorphism.

Remark. Perhaps by now it has become clear why the definition of the topological realization of an undirected abstract graph is more painful than the definition of the topological realization of an abstract graph. In both cases we want to attach one interval for each edge. If we are given a map $i, t: E \to V$, then we have a preferred way of doing so. If we are only given a map $\varphi: E \to \mathcal{P}(V)$ none of the two ways is preferred, thus we need to attach an interval in both ways and then we need to “anti-identify” the two intervals.

The following definition is almost verbatim the same as the definition of a connected abstract graph that we provided on page 221.

Definition. We say that an undirected abstract graph $(V, E, \varphi)$ is connected if for every two vertices $v \neq w \in V$ there exist vertices $v = v_0, v_1, \ldots, v_n = w$ and edges $e_0, \ldots, e_{n-1}$ such that for each $i \in \{0, \ldots, n-1\}$ the endpoints of $e_i$ are $v_i$ and $v_{i+1}$.

The following totally elementary lemma can be viewed as an analogue of Lemma 2.61.

Lemma 4.5. Let $G = (V, E, i, t)$ be an abstract graph or let $G = (V, E, \varphi)$ be an undirected abstract graph. Let $f: V \to X$ be a map to some set $X$ such that for any $e \in E$ the values of $f$ on the endpoints of $e$ agree. If $G$ is connected, then $f$ is constant.

Proof. This lemma follows almost immediately from the definitions.

4.3. Trees. In this last section we study a basic but surprisingly useful class of abstract graphs.
**Definition.** Let $G = (V, E, i, t)$ be an abstract graph.

1. If $G$ is finite, then we refer to $\chi(G) = \#V - \#E = \text{number of vertices} - \text{number of edges}$ as the **Euler characteristic of $G$.**

2. A **tree** is a finite connected abstract graph with Euler characteristic $1$.

3. The **valence of a vertex $v$** is defined as

   $$\text{valence}(v) := \#\{e \in E | i(e) = v\} + \#\{e \in E | t(e) = v\}.$$ 

For undirected abstract graphs we introduce the obvious analogues of the above notions.

In a slightly less formal way, the valence of a vertex $v$ is the number of edges at $v$, but hereby we have to count any loop at $v$ twice, since it “goes twice into $v$”.

---

**Lemma 4.6.** Let $G = (V, E, i, t)$ be an abstract graph or let $G = (V, E, \varphi)$ be an undirected abstract graph. If $G$ is a tree and if $G$ has at least one edge, then $G$ admits at least two vertices of valence one.

**Proof.** We prove Lemma 4.6 for abstract graphs, the proof for undirected abstract graphs is verbatim the same. Thus let $G = (V, E, i, t)$ be a tree that has at least one edge. Since $G$ has at least one edge and since it is by definition connected, we see that the tree $G$ does not have a vertex of valence 0. We calculate that

$$\sum_{v \text{ vertex valence } \geq 1} \text{valence}(v) = \sum_{v \text{ vertex valence } = v} (\#\{e \in E | i(e) = v\} + \#\{e \in E | t(e) = v\})$$

$$= 2 \cdot \#\text{edges} = 2 \cdot \#\text{vertices} - 2.$$ 

This equality can only hold if there are at least two vertices with valence less than 2. By the above the valence has to be at least one, so there exist at least two vertices with valence one.

On one occasion the following corollary will come in handy.
Corollary 4.7. Let $G = (V, E, i, t)$ be an abstract graph and let $\bar{v} \in V$ be a vertex. If $G$ is a tree, then there exist distinct edges $e_1, \ldots, e_k$ and distinct vertices $v_1, \ldots, v_k$ with the following properties:

1. We have $V = \{\bar{v}, v_1, \ldots, v_k\}$ and $E = \{e_1, \ldots, e_k\}$.
2. For each $i \in \{1, \ldots, k\}$ the vertex $v_i$ is an endpoint of the edge $e_i$.
3. If some vertex $v_i$ is an endpoint of some $e_j$, then $j \leq i$.

The same statement also holds for undirected abstract graphs. We refer to Figure 107 for an illustration.

Proof. For abstract graphs we will provide the proof of the corollary in Exercise 4.5. For undirected abstract graphs the proof is verbatim the same.

Now we provide a few more definitions on graphs.

Definition. Let $G = (V, E, i, t)$ be an abstract graph.

1. A subgraph of $G = (V, E, i, t)$ is an abstract graph $G' = (V', E', i', t')$ such that $V' \subseteq V$ and $E' \subseteq E$ are subsets such that $i' = i|_{E'}$ and $t' = t|_{E'}$. If $G'$ is a tree, then we refer to $G'$ as a subtree. Since $i'$ and $t'$ are determined by $V'$ and $E'$ we often suppress both of them from the notation.
2. We say an edge $e$ is adjacent to a subgraph $G'$ if $e$ has two endpoints where one of the endpoints lies on $G'$ and the other does not.
3. A spanning tree for $G$ is a subgraph that is a tree and which does not admit an adjacent edge.

For undirected abstract graphs we introduce the obvious analogues of the above notions.

Remark. Let $G = (V, E, i, t)$ be an abstract graph.

1. Every $v \in V$ gives rise to the rather trivial subgraph with a single vertex $v$ and no edge.
(2) If an edge \( e \) of \( E \) is adjacent to some subgraph \( G' \), then it is not part of the subgraph. Indeed, by definition of a subgraph, for any edge that is part of the subgraph also its endpoints have to lie in the subgraph.

(3) The example of Figure 108 shows that an abstract graph usually has many different spanning trees.

(4) A spanning tree is often also called a \textit{maximal tree}.

We conclude this chapter with the following proposition.

\textbf{Proposition 4.8.} Let \( G = (V, E, i, t) \) be a finite connected non-empty abstract graph.

\begin{enumerate}
  \item The graph \( G \) admits a spanning tree.
  \item Every spanning tree of \( G \) contains all vertices of \( G \).
\end{enumerate}

The same statement also holds for undirected abstract graphs.

\textbf{Proof.} In the following we provide the proof for abstract graphs. The proof for undirected abstract graphs is verbatim the same. Thus let \( G = (V, E, i, t) \) be a finite connected abstract graph.

(1) We pick a vertex \( v \in V \). We define \( T_0 = \{v\} \) and view \( T_0 \) as a subtree of \( G \). Now we construct iteratively a sequence of subtrees \( T_0 \subset T_1 \subset \ldots \) as follows: Suppose we have a subtree \( T_i = (V_i, E_i) \). If there exists an edge \( e \in E \) that is adjacent to \( T_i \), then we “add \( e \) to \( T_i \),” more precisely, we define \( T_{i+1} = (V_i \cup \varphi(e), E_i \cup e) \). Note that by definition of an adjacent edge we just added precisely one edge and precisely one vertex to \( T_i \). Thus we see that \( \chi(T_{i+1}) = \chi(T_i) = \cdots = \chi(T_0) = 1 \), i.e. \( T_{i+1} \) is indeed a subtree. Since \( G \) is finite this process stops after finitely many steps. Let \( T \) be the final subtree of our sequence. Note that by definition \( T \) is in fact a spanning tree. This argument is illustrated in Figure 109 on the left.

(2) Let \( T \) be a subgraph of \( G \) that is a tree. Suppose that there exists a vertex \( w \) that does not lie in \( T \). We will show that \( T \) is not maximal. Let \( v \) be a vertex in \( T \). Since \( G \) is connected there exists a sequence of edges \( e_0, \ldots, e_n \) with the following properties:

(a) \( v \) is a vertex of \( e_0 \),
(b) for each \( i \in \{0, \ldots, n-1\} \) a vertex of \( e_i \) is also a vertex of \( e_{i+1} \), and
(c) \( w \) is a vertex of \( e_n \).

Then there exists an \( i \in \{0, \ldots, n-1\} \) such that a vertex of \( e_i \) lies in \( T \) and the other one does not. But then \( e_i \) is an edge adjacent to \( T \). This shows that \( T \) was not maximal. This argument is illustrated in Figure 109 on the right.

\hspace{\stretch{1}}

\textbf{Exercises for Chapter 4.}

\textbf{Exercise 4.1.} In Figure 110 we see the seven bridges of Königsberg. Is it possible to cross all seven bridges in a walk without crossing a single bridge twice?

\textbf{Exercise 4.2.} Let \( G = (V, E, \varphi) \) and \( G' = (V', E', \varphi') \) be two undirected abstract graphs. If the topological realizations \( |G| \) and \( |G'| \) are homeomorphic, does it follow that the undirected abstract graphs \( G \) and \( G' \) are isomorphic?
Exercise 4.3. Let $G$ be an abstract graph. Show that the following are equivalent:

(a) $G$ is connected,
(b) given any two distinct vertices $v, v'$ there exists an embedding $\gamma: [0, 1] \to |G|$ with $\gamma(0) = v, \gamma(1) = v'$ and such that $\gamma([0, 1]) \subset |G|$ is the union of edges,
(c) the topological realization $|G|$ is path-connected,
(d) the topological realization $|G|$ is connected.

Exercise 4.4. Are the two topological graphs $G$ and $H$ shown in Figure 111 homeomorphic?

Exercise 4.5. Let $G = (V, E, i, t)$ be an abstract graph and let $\bar{v} \in V$ be a vertex. We suppose that $G$ is a tree. Show that there exist distinct edges $e_1, \ldots, e_k$ and distinct vertices $v_1, \ldots, v_k$ with the following properties:

(1) We have $V = \{\bar{v}, v_1, \ldots, v_k\}$ and $E = \{e_1, \ldots, e_k\}$.
(2) For each $i \in \{1, \ldots, k\}$ the vertex $v_i$ is an endpoint of the edge $e_i$.
(3) If some vertex $v_i$ is an endpoint of some $e_j$, then $j \leq i$.

We refer to Figure 107 for an illustration.
Exercise 4.6. Let $G$ be an abstract graph and let $K \subseteq |G|$ be compact subset. Show that there exists a finite subgraph $H$ of $G$ with $K \subseteq |H|$.

Exercise 4.7. Let $G = (V, E, i, t)$ be a countable connected non-empty abstract graph. We pick a vertex $v \in V$. Show that there exists a sequence \( \{G_j = (V_j, E_j, i, t)\}_{j \in N} \) of subgraphs with the following properties:

1. Each $G_j$ is finite and connected.
2. Each $G_j$ contains $v$.
3. We have $G = \bigcup_{j \in N} G_j$ in the sense that $V = \bigcup_{j \in N} V_j$ and $E = \bigcup_{j \in N} E_j$. 
5. General topology: some delicate bits

In this chapter we will introduce the compact-open topology and we will discuss the very delicate interplay between product and quotient topologies. In all likelihood the reader is better off with consulting the chapter only when the results of this chapter are actually used.

5.1. The compact-open topology. So far we had mostly studied topological spaces that arose more or less directly from geometry. In this section we will see that topological spaces also arise naturally from more abstract set ups.

First, recall that we saw on page 96 that a topology on a given set $X$ makes it possible to talk of the convergence of a sequence in $X$. From real analysis we know that it is not only interesting to think about convergence of sequences of points but also to talk of convergence of functions. In fact, in real analysis one often encounters two different types of convergence that we now recall.

**Definition.** Let $U \subset \mathbb{R}^n$ be a subset, let $\{f_n: U \to \mathbb{R}\}_{n \in \mathbb{N}}$ be a sequence of functions and let $f: U \to \mathbb{R}$ be a function. We define

$(f_n)_{n \in \mathbb{N}}$ converges pointwise to $f$ :\[\iff \forall x \in U \quad \forall \epsilon > 0 \exists N \in \mathbb{N} \quad \forall n \geq N \quad |f_n(x) - f(x)| < \epsilon\]

and

$(f_n)_{n \in \mathbb{N}}$ converges uniformly to $f$ :\[\iff \forall \epsilon > 0 \exists N \in \mathbb{N} \forall x \in U \forall n \geq N \quad |f_n(x) - f(x)| < \epsilon.\]

**Example.** We consider the sequence of functions

$f_n: \mathbb{R} \to \mathbb{R}$

\[t \mapsto \begin{cases} 0, & \text{if } t < 0 \text{ or } t > \frac{2}{n}, \\ n \cdot t, & \text{if } t \in [0, \frac{1}{n}], \\ 2 - n \cdot t, & \text{if } t \in (\frac{1}{n}, \frac{2}{n}). \end{cases}\]

We refer to Figure 112 for an illustration. One easily verifies that this sequence converges pointwise to the zero function but it does not converge uniformly to the zero function.

![Figure 112](image)

At times one also wants to study convergence of sequences of continuous maps between general topological spaces. This leads us to the following definition.

**Definition.** Let $X$ and $Y$ be topological spaces.

1. We denote by $X^Y = C(Y, X)$ the set of all continuous maps from $Y$ to $X$.

---

78Here and in the following we sometimes talk explicitly about “continuous” maps, even though it is usually understood in these notes that all maps are continuous.
(2) The *compact-open topology* on $X^Y$ is the topology generated, in the sense of the definition on page 105, by all the sets of the form

$$M(K, U) := \{ f \in X^Y \mid f(K) \subseteq U \}$$

where $K \subseteq Y$ is compact and where $U \subseteq X$ is open. This definition is illustrated in Figure 113.

![Figure 113](image)

**Examples.**

(1) Let $Y \subseteq \mathbb{R}$ be an interval. We want to consider the compact-open topology on $C(Y, \mathbb{R}) = \mathbb{R}^Y$. As usual we picture elements of $C(Y, \mathbb{R})$ by their graphs. In Figure 114 we show on the left an open set $M(K, U)$ as above and on the right we show the graph of some function $f \in C(Y, \mathbb{R})$ and an open neighborhood thereof.

Now let $f_n \in C(Y, \mathbb{R})$, $n \in \mathbb{N}$ be a sequence of functions and let $f \in C(Y, \mathbb{R})$. We leave it as an amusing, albeit somewhat lengthy, exercise to show that the following holds:

$$\text{(f_n)_{n \in \mathbb{N}} converges to } f \text{ with respect to the compact-open topology} \iff \text{for each compact subset } K \subseteq Y \text{ the sequence (f_n|_K)_{n \in \mathbb{N}} converges uniformly to } f|_K$$

Alternatively a proof for this statement is given in [Wil70, Theorem 43.7] or in [Jos83, Theorem 15.1.2].

$M(K, U)$ are the continuous functions whose graph is contained in this set

$\text{open neighborhood of } f \in C(Y, \mathbb{R}) \text{ with respect to the compact-open topology}$

![Figure 114](image)

(2) We consider $Y = \{1, \ldots, n\}$ which we equip with the discrete topology. In Exercise 5.7 we will see that for any topological space $X$ we have a homeomorphism $X^Y \cong X^n$.

The final example deserves its own lemma.

---

\[^79\text{We refer to page 96 for the definition of convergence of a sequence in a topological space.}\]
Lemma 5.1. Let $m, n \in \mathbb{N}$. We have the obvious inclusion

$$
M(m \times n, \mathbb{R}) \to C(\mathbb{R}^n, \mathbb{R}^m) = (\mathbb{R}^m)^{\mathbb{R}^n}
$$

$$
A \mapsto \left(\begin{array}{c}
\mathbb{R}^n \\
v
\end{array}\right) \mapsto Av
\right).
$$

The compact-open topology on $C(\mathbb{R}^n, \mathbb{R}^m)$ induces the usual topology on $M(m \times n, \mathbb{R})$ that we introduced on page 163.

Sketch of proof. This statement can be proved, with some effort, using Lemma 2.23. Alternatively the statement can also be deduced from [Hat02, Proposition A.13] or [Mun75, Theorem 5.1].

To get some practice with the compact-open topology we will prove the following two lemmas in Exercises 5.1 and 5.2.

Lemma 5.2. Let $X$ and $Y$ be topological spaces. If $Y$ is Hausdorff, then $X^Y$ is also Hausdorff.

Lemma 5.3. If $X$ and $Y$ are non-empty topological spaces, then the map

$$
X \to X^Y
$$

$$
x \mapsto \text{constant map} y \mapsto x
$$

is continuous and it is an embedding.

We continue with a few technical statements on the compact-open topology. In most applications later on we will consider the case that $Y = [0, 1]$. In particular the extra hypothesis in the subsequent propositions on the topological space $Y$ will not be an issue in our future applications.

Proposition 5.4. Let $X$ and $Y$ be topological spaces. If $Y$ is regionally compact, then the following two statements hold:

1. The evaluation map $e : X^Y \times Y \to X$

$$
((f : Y \to X), y) \mapsto f(y)
$$

is continuous.

2. For any $y \in Y$ the evaluation map $e_y : X^Y \to X$

$$
(f : Y \to X) \mapsto f(y)
$$

is continuous.

Proof (§). 

1. Let $U$ be an open subset of $X$. We need to show that $e^{-1}(U)$ is open. By Lemma 2.5 it suffices to show that given $(f, y) \in e^{-1}(U)$ there exists a neighborhood $W$ of $(f, y)$ with $W \subset e^{-1}(U)$. Thus let $f \in X^Y$ and $y \in Y$ with $e(f, y) = f(y) \in U$. Since $f$ is continuous and since $Y$ is regionally compact there exists a compact neighborhood

80Here we equip $X^Y \times Y$ with the product topology from page 162
$K$ of $y$ which is contained in the open neighborhood $f^{-1}(U)$ of $y$. In other words, we have found a compact neighborhood $K$ of $y$ with $f(K) \subset U$. Therefore we have $f \in M(K, U)$ and the map $e$ sends $W := M(K, U) \times K$ into $U$. By the definition of the product topology the set $W = M(K, U) \times K$ is in fact a neighborhood of $(f, y)$ in $X^Y \times Y$.

(2) This statement follows from (1) and Lemma 3.8 (2a).

We continue with the following elementary but essential lemma.

**Lemma 5.5.** $(\ast)$ Let $X$ and $Y$ be topological spaces.

1. If $\varphi : X \to \tilde{X}$ is a continuous map, then the induced map

$$\varphi^* : X^Y \to \tilde{X}^Y$$

$$\quad (f : Y \to X) \mapsto (\varphi \circ f : Y \to \tilde{X})$$

is continuous.

2. If $\varphi : X \to \tilde{X}$ is an embedding, then so is $\varphi^* : X^Y \to \tilde{X}^Y$.

3. Let $\varphi, \psi : X \to \tilde{X}$ be continuous maps. If $\varphi$ and $\psi$ are homotopic, then so are $\varphi^*, \psi^* : X^Y \to \tilde{X}^Y$.

4. If $\tilde{X}$ is a topological space that is homotopy equivalent to $X$, then $\tilde{X}^Y$ is also homotopy equivalent to $X^Y$.

5. If $\psi : Y \to \tilde{Y}$ is a continuous map, then the induced map

$$\psi_* : X^Y \to X^Y$$

$$\quad (f : Y \to X) \mapsto (f \circ \psi : Y \to X)$$

is continuous.

**Remark.** Lemma 5.5 (2) says in particular, that given topological spaces $X$ and $Y$ and a subset $A$ of $X$, we can view $A^Y$ as a subset of $X^Y$.

**Proof $(\ast)$,** To clarify the statements we replace the notation $M(K, U)$ by the notation $M_{XY}(K, U)$, with the obvious interpretation thereof.

1. We check continuity using the continuity criterion of Proposition 2.37. Thus let $K \subset Y$ be a compact subset and let $U \subset \tilde{X}$ be an open subset. We have

$$(\varphi^*)^{-1}(M_{\tilde{X}Y}(K, U)) = \{f \in X^Y \mid \varphi^*(f) \in M_{\tilde{X}Y}(K, U)\} = \{f : Y \to X \mid ((\varphi \circ f)(K) \subset U\}

= \{f : Y \to X \mid f(K) \subset \varphi^{-1}(U)\} = M_{XY}(K, \varphi^{-1}(U)).$$

by Exercise 2.2

Since $\varphi$ is continuous we see that $\varphi^{-1}(U)$ is an open subset of $X$. Since the sets $M(K, U)$ form by definition a basis for the topology of $\tilde{X}^Y$ we deduce from Proposition 2.37 that $\varphi^*$ is indeed continuous.

81 We apologize to the reader for using the notion of being homotopic, even though it is only introduced on page 337. The reader who made it that far into this chapter will surely not be frightened by this inconvenience.
(2) Since \( \varphi \) is an embedding we can identify \( X \) with its image in \( \tilde{X} \). Put differently, it suffices to consider the case of an inclusion \( i: X \to \tilde{X} \). By Lemma 2.42 (1) together with Lemma 2.39 it suffices to show that for any compact subset \( K \subset Y \) and any open subset \( U \subset X \) the image \( i_* (M_{XY}(K,U)) \) is an open subset of \( i_* (X^Y) \). Since \( U \subset X \) is open there exists, by definition of the subspace topology, an open subset \( V \subset \tilde{X} \) such that \( U = V \cap X \). We have
\[
i_* (M_{XY}(K,U)) = \{ i \circ f: Y \to \tilde{X} \mid f: Y \to X \text{ and } f(K) \subset U \} \]
\[
\uparrow
\]
Since \( f(Y) \subset X \) implies for any \( x \in X \) that \( f(x) \in U \) if and only if \( f(x) \in V \)

By the definition of the subspace topology this is an open subset of \( i_* (X^Y) \subset \tilde{X}^Y \).

(3) Let \( F: X \times [0,1] \to Y \) be a homotopy between \( F_0 = \varphi \) and \( F_1 = \psi \). Using Proposition 2.37 and Lemma 2.35 it is not particularly challenging to show that the map
\[
(Y \times [0,1] \to \tilde{X}^Y)
\]
\[
(g: Y \to X, t) \mapsto \begin{pmatrix} Y \to \tilde{X} \\ y \mapsto F(g(x), t) \end{pmatrix}
\]
is continuous. This is the desired homotopy between \( \varphi^* \) and \( \psi^* \).

(4) This statement follows almost immediately from (3).

(5) Let \( K \subset Y \) be a compact subset and let \( U \subset X \) be an open subset. We have
\[
(\psi_*)^{-1} (M_{XY}(K,U)) = \{ f \in X^{\tilde{Y}} \mid \psi_* (f) \in M_{XY}(K,U) \}
\]
\[
= \{ f: \tilde{Y} \to X \mid (f \circ \psi)(K) \subset U \} = M_{XY}(\psi(K), U).
\]

Since \( \psi \) is continuous we obtain from Lemma 2.40 that \( \psi(K) \) is a compact subset of \( \tilde{Y} \). Thus we obtain again from Proposition 2.37 that \( \psi_* \) is indeed continuous. \( \blacksquare \)

On many occasions we will also need the following rather technical proposition.

**Proposition 5.6.** Let \( Y \) be a topological space that is regionally compact. Furthermore let \( X \) and \( T \) be two topological spaces. Let \( H: Y \times T \to X \) be a map. Given \( t \in T \) we denote by \( H_t: Y \to X \) the map defined by \( H_t(y) := H(y,t) \). Then
\[
H: Y \times T \to X \text{ is continuous } \iff \begin{cases} (1) \text{ each } H_t: Y \to X \text{ is continuous, and} \\ (2) \text{ the map } T \to X^Y \text{ given by } t \mapsto H_t \text{ is continuous.} \end{cases}
\]

In other words, the map
\[
(X^Y \times T) \to (X^Y)^T
\]
\[
(H: Y \times T \to X) \mapsto \begin{pmatrix} T \to X^Y \\ t \mapsto (y \mapsto H(y,t)) \end{pmatrix}
\]
is well-defined\(^{82}\) and it is a bijection.

\(^{82}\)Note that by (1) we know that \( H_t \in X^Y \).

\(^{83}\)Here “well-defined” means that the map \( T \to X^Y \) actually defines an element in \( (X^Y)^T \). More precisely, the map \( T \to X^Y \) given by \( z \mapsto (y \mapsto H(y,z)) \) actually lies in \( (X^Y)^T \).
Proof (*). Note that the “in other words” part of the proposition is indeed just a reformulation of the first part of the proposition. Thus it remains to prove the equivalence of the two statements in the beginning.

First we prove the “$\Leftarrow$”-direction. We point out that $H : Y \times T \to X$ is the composition of the two maps

$$Y \times T \to X^Y \times Y \quad \text{and the evaluation map} \quad X^Y \times Y \to X$$

The first map is continuous by (2) and Lemma 3.8. Furthermore, since $Y$ is regionally compact we obtain from Proposition 5.4 that the second map is continuous. Thus $H$ itself is continuous.

Now we turn to the “$\Rightarrow$”-direction. Thus we suppose that $H : Y \times T \to X$ is continuous.

1. Let $t \in T$. The map $H_t$ is the composition of the inclusion $Y \to Y \times T$, $y \mapsto (y,t)$ with the map $H$. The first map is continuous by Lemma 3.8 (2a) and the second map is continuous by our hypothesis. Hence $H_t$ is also continuous. In particular we now know that $H_t$ defines an element in $X^Y$.

2. We need to show that the map $T \to X^Y$ given by $t \mapsto H_t$ is continuous. By Proposition 2.37 and Lemma 2.5 it suffices to show that for any set of the form $M(K,U) \subset X^Y$ and any $t \in T$ with $H_t \in M(K,U)$ there exists a neighborhood $W$ of $t \in T$ such that for all $t' \in W$ we have $H_{t'} \in M(K,U)$.

Thus let $K$ be a compact subset of $Y$, let $U$ be an open subset of $X$ and let $t \in T$ with $H_t \in M(K,U)$. We start out with the following claim.

Claim. Given any $y \in K$ there exist open neighborhoods $V_y \subset Y$ of $y$ and $W_y \subset T$ of $t$ such that $H(V_y \times W_y) \subset U$.

By the continuity of $H : Y \times T \to X$ we know that $H^{-1}(U)$ is an open subset of $Y \times K$. Note that $H(y,t) = H_t(y) \in U$ since $H_t \in M(K,U)$ and $y \in K$. Thus $H^{-1}(U)$ is an open neighborhood of $(y,t) \in Y \times K$. The existence of $V_y$ and $W_y$ is now a consequence of the definition of the product topology of $Y \times T$. \[\square\]

It follows from the compactness of $K$ and Lemma 2.15 that there exist points $y_1, \ldots, y_n \in K$ with $K \subset V_{y_1} \cup \cdots \cup V_{y_n}$. We set $W := \bigcap_{i=1}^n W_{y_i} \subset T$. Note that this is an open neighborhood of $t$. Then

$$H(K \times W) \subset H\left(\bigcup_{i=1}^n V_{y_i} \times W\right) \subset H\left(\bigcup_{i=1}^n V_{y_i} \times W_{y_i}\right) = \bigcup_{i=1}^n H(V_{y_i} \times W_{y_i}) \subset U.$$  

since $K \subset \bigcup_{i=1}^n V_{y_i}$ since $W \subset W_{y_i}$

It follows from this observation and the definition of $H_{t'}$ and $M(K,U)$ that for any $t' \in W$ we have $H_{t'} \in M(K,U)$. \[\square\]

On one later occasion we will also need the following equally technical proposition.
Proposition 5.7. Let $X, Y$ and $Z$ be topological spaces. If $Y$ and $Z$ are both regionally compact and Hausdorff, then the map\footnote{By Proposition 5.6 we know that the map is well-defined and that it is a bijection.}
\[
X^Y \times Z \to (X^Y)^Z \\
(f: Y \times Z \to X) \mapsto (Z \to X^Y \mapsto (y \mapsto f(y,z)))
\]
is a homeomorphism.

Remark. In fact a slightly stronger version of Proposition 5.7 holds. By \cite[Dug66, Theorem XII.5.3]{Dug66} one only needs to assume that $Y$ is regionally compact, with no further restrictions on $X$, $Y$ or $Z$. We will not need this stronger statement.

Once again no sane person will ever voluntarily read the proof. For those readers who are still around we first provide the proof of the following lemma.

Lemma 5.8. Let $X$ and $Y$ be topological spaces. Furthermore let $\mathcal{V}$ be a subbasis for $X$. We consider
\[
\mathcal{C} = \{M(K, V) \in \mathcal{P}(X^Y) \mid K \text{ a compact subset of } Y \text{ and } V \in \mathcal{V}\}.
\]
If $Y$ is Hausdorff, then $\mathcal{C}$ is subbasis\footnote{We refer to page \pageref{subbasis} for the definition of a subbasis of a topological space.} for the topology of $X^Y$.

Proof. Let $K$ be a compact subset of $Y$, let $U$ be an open subset of $X$ and let $f$ be a point in $M(K, U)$, i.e. $f: Y \to X$ is a map with $K \subset f^{-1}(U)$. By Lemma 2.27 (2) we need to show that there exist finitely many $C_1, \ldots, C_m \in \mathcal{C}$ with $f \in \bigcap_{i=1}^m C_i \subset M(K, U)$.

Since $\mathcal{V}$ is a subbasis for the topology of $X$ we can write $U = \bigcup_{i \in I} U_i$ where each $U_i$ is of the form $U_i = \bigcap_{V \in P_i} V$ where $P_i$ is a finite subset of $\mathcal{V}$. Since $K$ is compact and since $f$ is continuous it follows from Lemma 2.15 that there exists a finite subset $J \subset I$ such that $K \subset \bigcup_{j \in J} f^{-1}(U_j)$.

Since $K$ is compact and Hausdorff we obtain from Lemma 2.46 that $K$ is normal. It follows from Lemma 2.49 together with Lemma 2.17 (1) and the hypothesis that $Y$ is Hausdorff, that there exist compact subsets $K_j \subset f^{-1}(U_j)$, $j \in J$, with $K \subset \bigcup_{j \in J} K_j$.

Thus we see that
\[
f \in \bigcap_{j \in J} M(K_j, U_j) = \bigcap_{j \in J} M(K_j, \bigcap_{V \in P_j} V) = \bigcap_{j \in J} \bigcap_{V \in P_j} M(K_j, V) \subset M(K, U).
\]

The finitely many sets $\{M(K_j, V)\}_{j \in J, V \in P_j}$ in $\mathcal{C}$ thus do the trick.\hfill $\blacksquare$
Proof of Proposition 5.7 Let $X, Y$ and $Z$ be topological spaces. We assume that $Y$ and $Z$ are both regionally compact and Hausdorff. We need to show that the map

$$
\Phi: X^{Y \times Z} \to (X^Y)^Z
$$

$$(f: Y \times Z \to X) \mapsto \left( Z \mapsto X^Y, z \mapsto (y \mapsto f(y, z)) \right)$$

is a homeomorphism. We start out with the following claim.

Claim. The set

$$
\mathcal{C} = \left\{ M(A \times B, U) \in \mathcal{P}(X^{Y \times Z}) \mid A \text{ a compact subset of } Y, B \text{ a compact subset of } Z \text{ and } U \text{ an open subset of } X \right\}
$$

is a subbasis for the topological space $X^{Y \times Z}$.

Let $K \subset Y \times Z$ be a compact subset, let $U$ be an open subset of $X$ and let $f$ be a point in $M(K, U)$, i.e. $f: Y \times Z \to X$ is a map with $K \subset f^{-1}(U)$. By Lemma 2.27 (2) we need to show that there exist finitely many $C_1, \ldots, C_m \in \mathcal{C}$ with $f \in \bigcap_{i=1}^m C_i \subset M(K, U)$.

Let $k \in K \subset Y \times Z$. We write $k = (y, z)$. Since $f^{-1}(U)$ is an open subset of $Y \times Z$ it follows from the definition of the product topology on $Y \times Z$ that there exist open neighborhoods $V_y \subset Y$ of $y$ and $W_z \subset Z$ of $z$ such that $k = (y, z) \in V_y \times W_z \subset f^{-1}(U)$. Since $Y$ and $Z$ are regionally compact we can find a compact neighborhood $A_k \subset Y$ of $y$ and a compact neighborhood $B_k \subset Z$ of $z$ such that $k = A_k \times B_k \subset V_y \times W_z \subset f^{-1}(U)$. Since $K$ is compact it follows from Lemma 2.15 that there exist finitely many points $k_1, \ldots, k_m \in K$ such that $K \subset \bigcup_{i=1}^m A_{k_i} \times B_{k_i}$. Now we see that

$$
f \in \bigcap_{i=1}^m M(A_{k_i} \times B_{k_i}, U) = M\left( \bigcup_{i=1}^m A_{k_i} \times B_{k_i}, U \right) \subset M(K, U).
$$

As we already remarked in Proposition 5.6 the given map $\Phi: X^{Y \times Z} \to (X^Y)^Z$ is clearly a bijection. Furthermore under this bijection the sets $M(A \times B, U)$ are precisely the sets $M(B, M(A, U))$. By the claim the former sets form a subbasis for $X^{Y \times Z}$. Thus it suffices to show that the latter sets form a subbasis for $(X^Y)^Z$. But that is an immediate consequence of Lemma 5.8 applied twice, and our hypothesis that $Y$ and $Z$ are Hausdorff.
The following proposition is also somewhat technical.

**Proposition 5.9.** Let $X, Y$ and $Z$ be topological spaces. If $Y$ is regionally compact, then the map

$$\Phi: X^Y \times Y^Z \to X^Z$$

$$(f, g) \mapsto f \circ g$$

is continuous.

The proof of Proposition 5.9 rests on the following little lemma.

**Lemma 5.10.** Let $Y$ be a topological space that is regionally compact. If $K$ is a compact subset that is contained in an open subset $U$ of $Y$, then there exists a compact subset $L$ with $K \subset \overset{\circ}{L} \subset L \subset U$.

**Proof.** Let $x \in K$. Since $Y$ is regionally compact there exists a compact neighborhood $L_x \subset U$ of $x$. Since $K$ is compact there exist $x_1, \ldots, x_m \in K$ with $K \subset \overset{\circ}{L}_{x_1} \cup \cdots \cup \overset{\circ}{L}_{x_m}$. We set $L := L_{x_1} \cup \cdots \cup L_{x_m}$. By Lemma 2.16 (1) we know that $L$ is compact. We have

$$K \subset \bigcup_{i=1}^m \overset{\circ}{L}_{x_i} \subset \text{interior of } \bigcup_{i=1}^m L_x = \overset{\circ}{L}_{x_i} \subset L \subset U.$$  

Lemma 2.10 (1)

**Proof of Proposition 5.9.** By Proposition 2.37 and Lemma 2.5 and the definition of the product topology on $X^Y \times Y^Z$ it suffices to prove the following claim.

**Claim.** Let $K$ be a compact subset of $Z$ and let $V$ be an open subset of $X$. If $f \in X^Y$ and $g \in Y^Z$ satisfy $f \circ g \in M(K, V)$, then there exists an open subset $U \subset Y$ and a compact subset $L \subset Y$ with

$$\Phi\left( M(L, V) \times M(K, U) \right) \subset M(K, V).$$

First note that $g(K) \subset Y$ is compact by Lemma 2.40 and that $f^{-1}(V) \subset Y$ is open since $f$ is evidently continuous. Since $Y$ is regionally compact we obtain from Lemma 5.10 that there exists a compact subset $L$ with $g(K) \subset \overset{\circ}{L} \subset L \subset f^{-1}(U)$. It is clear that $U = L$ and $L$ have the desired properties. ■

The following corollary gives us a very long list of new examples of topological groups.
Corollary 5.11. Let $X$ be a topological space. If $X$ is compact and Hausdorff, then the group 
\[ \text{Homeo}(X) := \text{the set of all self-homeomorphisms of } X, \]

equipped with the subspace topology coming from $X^X$, is a topological group.

Remark. Let $X$ be a topological space that is regionally compact and Hausdorff. In light of Proposition 5.9 one might expect that in this case Homeo($X$) forms a group. In [Dij05] it is shown that this is in general not the case. On the other hand it is shown in [Are46] Theorem 4] that if $X$ is furthermore regionally connected, then Homeo($X$) is in fact a topological group.

Proof (*). Let $X$ be a topological space that is compact and Hausdorff. First note that by Lemma 2.73 we know that $X$ is regionally compact. Thus it follows from Proposition 5.9 that the multiplication map Homeo($X$) × Homeo($X$) → Homeo($X$) is continuous. Therefore it suffices to show that the map 
\[ \Phi: \text{Homeo}(X) \to \text{Homeo}(X) \]

\[ f \mapsto f^{-1} \]

is continuous. The proof of continuity rests on the following simple claim.

Claim. If $K \subseteq X$ and $U \subseteq X$ are subsets, then $\Phi^{-1}(M(K, U)) = M(X \setminus U, X \setminus K)$.

Let $h \in \text{Homeo}(X)$. We have

\[ h \in \Phi^{-1}(M(K, U)) \iff h^{-1} \in M(K, U) \iff h^{-1}(K) \subseteq U \iff K \subseteq h(U) \iff X \setminus h(U) \subseteq X \setminus K \iff h \in M(X \setminus U, X \setminus K). \]

By Proposition 2.37 it suffices to prove the following claim.

Claim. If $K \subseteq X$ is a compact subset and if $U \subseteq X$ is an open subset, then $\Phi^{-1}(M(K, U))$ is an open subset of $X$.

By the previous claim we know that $\Phi^{-1}(M(K, U)) = M(X \setminus U, X \setminus K)$. Since $U$ is open we know that $X \setminus U$ is closed. Since $X$ is compact we obtain from Lemma 2.17 (1) that $X \setminus U$ is compact. Furthermore, since $K$ is compact and since $X$ is Hausdorff we obtain from Lemma 2.17 (2) that $X \setminus K$ is open. Thus we see that $M(X \setminus U, X \setminus K)$ is an open subset of $X^X$.

We conclude this section with a different source of topological groups.
Lemma 5.12. Let $X$ be a topological space.

1. Let $\tilde{X}$ and $Y$ be topological spaces. If $Y$ is regionally compact, then the map
   
   $$\Psi: X^Y \times \tilde{X}^Y \rightarrow (X \times \tilde{X})^Y$$
   
   $$(f, \tilde{f}) \mapsto \left( f \times \tilde{f}: Y \rightarrow X \times \tilde{X}, 
   y \mapsto (f(y), \tilde{f}(y)) \right)$$

   is continuous.

2. Let $G$ be a topological group. If $G$ is regionally compact, then the topological space $G^X$ together with the multiplication
   
   $$G^X \times G^X \rightarrow G^X$$
   
   $$(f, g) \mapsto \left( X \rightarrow G, 
   x \mapsto f(x) \cdot g(x) \right)$$

   is a topological group.

Proof.

1. By Proposition 2.37 it suffices to show that for any compact subset $K \subset Y$ and any open subset $W \subset X \times \tilde{X}$ the preimage $\Psi^{-1}(M_{(X \times \tilde{X})^Y}(K, W))$ is an open subset of $X^Y \times \tilde{X}^Y$. We will do so by appealing to Lemma 2.5.

   Thus let $(f, \tilde{f}) \in \Psi^{-1}(M_{(X \times \tilde{X})^Y}(K, W))$. Note that this means that we are given $f: Y \rightarrow X$ and $\tilde{f}: Y \rightarrow \tilde{X}$ with $(f \times \tilde{f})(K) \subset W$. For each $y \in K$ we can and will pick open subsets $U_y$ of $X$ and $\tilde{U}_y$ of $\tilde{X}$ such that $(f \times \tilde{f})(y) \in U_y \times \tilde{U}_y \subset W$.

   By Lemma 3.6 (1) we know that $(f \times \tilde{f})^{-1}(U_y \times \tilde{U}_y)$ is an open subset of $Y$. Since $Y$ is regionally compact there exists a compact neighborhood $K_y$ of $y$ such that $y \in K_y \subset (f \times \tilde{f})^{-1}(U_y \times \tilde{U}_y)$.

   Since $K$ is compact we obtain from Lemma 2.15 that there exist $y_1, \ldots, y_m \in Y$ such that $K \subset K_{y_1} \cup \cdots \cup K_{y_m}$. Now we see that

   $$\left( f, \tilde{f} \right) \in \bigcap_{i=1}^m M_{X^Y}(K_{y_i}, U_{y_i}) \times M_{\tilde{X}^Y}(K_{y_i}, \tilde{U}_{y_i}) \subset \Psi^{-1}(M_{(X \times \tilde{X})^Y}(K, W)) \subset X^Y \times \tilde{X}^Y.$$  

   since $(f \times \tilde{f})(K_{y_i}) \subset U_{y_i} \times \tilde{U}_{y_i}$ since $U_{y_i} \times \tilde{U}_{y_i} \subset W$ and since $K \subset \bigcup K_{y_i}$

   It follows from Lemma 2.5 that $\Psi^{-1}(M_{(X \times \tilde{X})^Y}(K, U))$ is indeed an open subset of $X^Y \times \tilde{X}^Y$. We refer to Figure 118 for an illustration.

2. At this stage there is not much left that needs to be done, we outsource the argument to Exercise 5.3.

5.2. Mixing product and quotient topologies (*). In this, rather technical section, we will see that mixing product and quotient topologies can be quite delicate. We start out with the following elementary lemma.
Lemma 5.13. Let $X$ and $Y$ be two topological spaces. Suppose we are given an equivalence relation $\sim_x$ on $X$. We denote by $\sim_x$ the equivalence relation on $X \times Y$ that is generated by $(x,y) \sim_x (x',y')$ whenever $x \sim x'$. The following map is a bijection and it is continuous:

$$
\varphi: (X \times Y)/\sim_x \to (X/\sim) \times Y
\quad ((x,y)] \mapsto ([x],y).
$$

Proof (⋆). It follows basically immediately from the definition of $\sim_x$ that the map $\varphi$ is a bijection. We will walk cautiously through the continuity argument.

We denote by $p: X \times Y \to (X \times Y)/\sim_x$ and $q: X \to X/\sim$ the two obvious projection maps. We have the following commutative diagram

$$
\begin{array}{ccc}
X \times Y & \xrightarrow{q \times \text{id}_Y} & (X/\sim) \times Y \\
\downarrow{p} & & \downarrow{\varphi} \\
(X \times Y)/\sim_x & \xrightarrow{\varphi} & (X/\sim) \times Y.
\end{array}
$$

Let $W \subset (X/\sim) \times Y$ be an open subset. We need to show that $\varphi^{-1}(W)$ is an open subset of $(X \times Y)/\sim_x$. By definition of the quotient topology we need to show that $p^{-1}(\varphi^{-1}(W))$ is an open subset of $X \times Y$.

By Lemma 2.3 and the definition of the product topology it suffices to prove the following claim.

Claim. For each $(x,y) \in p^{-1}(\varphi^{-1}(W)) \subset X \times Y$ there exists an open neighborhood $U_x$ of $x \in X$ and an open neighborhood $V_y$ of $y \in Y$ such that $U_x \times V_y \subset p^{-1}(\varphi^{-1}(W))$.

Since $([x],y) \in W$ and since $W$ is an open subset of $(X/\sim) \times Y$ we obtain, by definition of the product topology, an open neighborhood $\widetilde{U}_{[x]}$ of $[x] \in X/\sim$ and an open neighborhood $\widetilde{V}_y$ of $y \in Y$ with $\widetilde{U}_{[x]} \times \widetilde{V}_y \subset W$. We set $U_x := q^{-1}(\widetilde{U}_{[x]})$. By definition of the quotient topology this is an open subset of $X$. It remains to show that $U_x \times V_y \subset p^{-1}(\varphi^{-1}(W))$. In other words, we need to show that $\varphi(p(U_x \times V_y)) \subset W$. This inclusion follows from the following short argument:

$$
\varphi(p(U_x \times V_y)) = (\varphi \circ p)(U_x \times V_y) = (q \times \text{id}_Y)(U_x \times V_y) = q(q^{-1}(\widetilde{U}_{[x]})) \times V_y = \widetilde{U}_{[x]} \times V_y \subset W.
$$

by the above commutative triangle since $U_x = q^{-1}(\widetilde{U}_{[x]})$

This concludes the proof of the claim and thus also of the lemma. 

One would expect that the map from Lemma 5.13 surely must be a homeomorphism. But perhaps rather shockingly, the next lemma shows that in general this is not the case:
Lemma 5.14. There exist topological spaces $X$ and $Y$ and an equivalence relation $\sim$ on $X$ with the following property: If we denote by $\sim_x$ the equivalence relation on $X \times Y$ generated by $(x, y) \sim_x (x', y)$ whenever $x \sim x'$, then the map

$$
\varphi: (X \times Y)/\sim_x \to (X/\sim) \times Y
$$

$\quad [(x, y)] \mapsto ([x], y)$

is a bijection and it is continuous, but it is not a homeomorphism.

Remark. We refer to [Fab05 Theorem 1], [BrownR06 p. 111] and [Bou98 p. 128] for other examples which also show that mixing product and quotient topologies is in general a very dangerous idea.

Proof. We consider $X = \mathbb{R} \times \mathbb{N} = \{(x, n) \mid x \in \mathbb{R}, n \in \mathbb{N}\}$, equipped with the product topology. Let $\sim$ be the equivalence relation on $X$ that is generated by $(0, m) \sim (0, n)$ for all $m, n \in \mathbb{N}$. We set $Y := \prod_{i \in \mathbb{N}} \mathbb{R}$, equipped with the product topology introduced on page 172.

By Lemma 5.13 we know that the map

$$
\varphi: (X \times Y)/\sim_x \to (X/\sim) \times Y
$$

$\quad [(x, y)] \mapsto ([x], y)$

is a bijection and that it is continuous. It remains to show that $\varphi$ is not a homeomorphism. We will do so by exhibiting an open subset $V$ of $(X \times Y)/\sim_x$ such that the image $\varphi(V)$ is not an open subset of $(X/\sim) \times Y$.

Before we can proceed we need to introduce the following notation:

1. We denote by $q: X \to X/\sim$ the obvious projection.
2. We write $f = q \times \text{id}_Y: X \times Y \to (X/\sim) \times Y$.
3. Given $n \in \mathbb{N}$ we set

$U_n := \{(t, n), (y_1, y_2, y_3, \ldots) \mid (t, n) \in X \times Y, |t \cdot y_n| < 1\}$.

and we set $U := \bigcup_{n \in \mathbb{N}} U_n$.

The key to proving the lemma is the following claim.

Claim. The set $U$ has the following properties:

1. $U$ is an open subset of $X \times Y$,
2. $f^{-1}(f(U)) = U$,
3. $f(U)$ is not open in $(X/\sim) \times Y$.

We set out to prove that $U$ does indeed have the three promised properties.

1. We want to show that $U$ is an open subset of $X \times Y$. It suffices to show that each $U_n$ is open. First note that the map

$$
\gamma: X \times Y = \mathbb{R} \times \mathbb{N} \times \prod_{i \in \mathbb{N}} \mathbb{R} \to \mathbb{R}
$$

$\quad (t, n, y_1, y_2, \ldots) \mapsto t \cdot y_n$
is continuous by Lemma 3.14. Furthermore note that \( \{n\} \) is an open subset of \( \mathbb{N} \). Now we see that

\[
U_n = \gamma^{-1}((-1, 1)) \cap \mathbb{R} \times \{n\} \times \prod_{i \in \mathbb{N}} \mathbb{R}
\]

is the intersection of two open sets, thus it is open itself.

(2) We need to show \( f^{-1}(f(U)) = U \). By Lemma 1.3 (1) it remains to show that \( f^{-1}(f(U)) \subseteq U \). In other words, we need to show that if \( v \) is an element of \( X \times Y \) with \( f(v) \in f(U) \), then \( v \in U \). But this statement follows from the following claim.

**Claim.** Let \( v = ((s, m), (y_1, y_2, \ldots)) \) and \( w = ((t, n), (z_1, z_2, \ldots)) \) be two elements in \( X \times Y \). If \( f(v) = f(w) \) and if \( w \in U \), then we also have \( v \in U \).

If \( v = w \), then there is nothing to show. On the other hand, if \( v \neq w \), then it follows from the definition of the map \( f \) and the equivalence relation \( \sim \) that \( s = t = 0 \). But this implies that \( v \) and \( w \) lie in every \( U_n \), in particular they both lie in \( U \). \( \Box \)

(3) We prove this statement by contradiction. Thus suppose that \( f(U) \) is, contrary to our hopes, an open subset of \( (X/\sim) \times Y \). Note that \( ((0,0),(0,0,\ldots)) \in U \). This implies that \( f(((0,0),(0,0,\ldots))) = ([0,0],[0,0,\ldots]) \) is contained in \( f(U) \). By definition of the product topology of \( (X/\sim) \times Y \) and of the product topology of \( Y = \prod_{i \in \mathbb{N}} \mathbb{R} \) there exists an open subset \( V \subset X/\sim \) and open subsets \( W_i \subset \mathbb{R} \) with \( ([0,0],[0,0,\ldots]) \in V \times \prod_{i \in \mathbb{N}} W_i \subset f(U) \) and such that all but finitely \( W_i \) are equal to \( \mathbb{R} \). We pick an \( N \in \mathbb{N} \) with \( W_N = \mathbb{R} \). Since \( [(0,0)] \in V \) we see that \( q^{-1}(V) \) is an open subset of \( X = \mathbb{R} \times \mathbb{N} \) that contains the subset \( q^{-1}([(0,0)]) = \{0\} \times \mathbb{N} \). In particular \( q^{-1}(V) \) contains some point \( (s, N) \) with \( s \neq 0 \). We pick a real number \( y_N > 1/|s| \) and we consider the point

\[
P := ((s,N),(0,\ldots,0,y_N,0,\ldots)) \in X \times Y.
\]

Note that

\[
P \in q^{-1}(V) \times \prod_{i \in \mathbb{N}} W_i = f^{-1}\left(V \times \prod_{i \in \mathbb{N}} W_i\right) \subseteq f^{-1}(f(U)) \subseteq U = \bigcup_{n \in \mathbb{N}} U_n.
\]

by (2)

since \((s,N)\in q^{-1}(V)\)

and \( W_N = \mathbb{R} \)

since \( f = q \times \text{id}_Y \)

see above

By definition of the \( U_n \)'s we see that the only possibility is that \( P \in U_N \). But we have

\[|s \cdot y_N| > 1, \text{ i.e. } P \text{ cannot possibly lie in } U_N.\]

We have thus obtained a contradiction. \( \Box \)

It remains to prove the following claim.

**Claim.** We set \( V := p(U) \).

(1) \( V \) is an open subset of \( (X \times Y)/\sim_X \),

(2) \( \varphi(V) \) is not an open subset of \( (X/\sim) \times Y \).
We denote by $p: X \times Y \to (X \times Y)/\sim$ the obvious projection map. We have the following commutative diagram

$$
\begin{array}{ccc}
X \times Y & \xrightarrow{f=q \times \text{id}_Y} & (X/\sim) \times Y \\
\downarrow{p} & & \downarrow{\varphi} \\
(X \times Y)/\sim & & (X/\sim) \times Y
\end{array}
$$

Note that

$$p^{-1}(V) = p^{-1}(p(U)) = f^{-1}(f(U)) = U = \text{an open subset of } X \times Y.$$

since $p = \varphi^{-1} \circ f$ and since $\varphi$ is a bijection by the previous claim.

By the definition of the quotient topology on $(X \times Y)/\sim$ this means that $V$ is indeed an open subset of $(X \times Y)/\sim$. Furthermore we have $\varphi(V) = \varphi(p(U)) = f(U)$. But by the previous claim we know that $f(U)$ is not an open subset of $(X/\sim) \times Y$. This concludes the proof of the claim and thus of the lemma.

The previous lemma leads us to the following cautionary remark:

**Remark.**

In general products and quotients of topological spaces do not mix well.

**Definition.** We say that a map $f: X \to Y$ between topological spaces is a quotient map if $f$ is surjective and if a subset $U \subset Y$ is open in $Y$ if and only if the preimage $f^{-1}(U)$ is open in $X$.

**Examples.**

(1) We consider the map $f: \mathbb{R} \to \mathbb{R}$ whose graph is shown in Figure 119. This map is continuous, it is *not* an open map, but the reader is invited to verify that the map is in fact a quotient map.

(2) Let $X = \{0, 1\}$ be a set of two elements 0, 1. Let $\mathcal{S} = \{\emptyset, X\}$ be the trivial topology and let $\mathcal{T} = \{\emptyset, X, \{0\}, \{1\}\}$ be the discrete topology. Evidently the identity map $(X, \mathcal{T}) \to (X, \mathcal{S})$ is a continuous bijection. But clearly it is not a quotient map.

The following lemma summarizes a few elementary properties of quotient maps.

**Lemma 5.15.**

(1) Let $X$ be a topological space and let $\sim$ be an equivalence relation on $X$. The projection map $X \to X/\sim$ is a quotient map.

(2) If $f: X \to Y$ is a quotient map, then it is also continuous.
(3) If \( f : X \rightarrow Y \) is a bijection between topological spaces and if it is a quotient map, then \( f \) is a homeomorphism.

**Proof.**

1. This statement follows immediately from the definition of the quotient topology on the quotient \( X/\sim \).
2. Let \( f : X \rightarrow Y \) be a quotient map. If follows immediately from the “only if” bit of the definition of a quotient map that \( f \) is continuous.
3. This statement follows immediately from (2) and Lemma 2.42 (2). ■

The following is the key technical theorem which in most reasonable situations will help us to navigate the choppy waters involving product and quotient maps.

**Theorem 5.16.** Let \( f : X \rightarrow Z \) be a map between topological spaces that is a quotient map. Furthermore let \( Y \) be a topological space. If \( Y \) is regionally compact (e.g. if \( Y = [0,1] \)), then the map

\[
 f \times \text{id}_Y : X \times Y \rightarrow Z \times Y
\]

is also a quotient map.

**Remark.** This theorem is sometimes called the “Whitehead Theorem” since it was first proved by John Whitehead [WhitJ48, Lemma 4] in 1948. We reserve the name “Whitehead Theorem” for Theorem 1.19.9.

We will provide the proof of Theorem 5.16 in the next section. In the following we first state and prove some useful consequences of Theorem 5.16. In fairness to the reader one should perhaps say that it is arguably best to move on to the next chapter. It is only advisable to read the remainder of this section once one really faces acute technical problems involving the mix of product and quotient maps.

The following little lemma is the key to many applications of Theorem 5.16.

**Lemma 5.17.** Suppose we are given a commutative diagram of maps between topological spaces:

\[
\begin{array}{ccc}
 X & \xrightarrow{f} & Z \\
 \downarrow{p} & & \downarrow{\varphi} \\
 Y & \xrightarrow{\varphi} & Z.
\end{array}
\]

The following two statements hold:

1. If \( p \) and \( f \) are quotient maps, then \( \varphi \) is also a quotient map.
2. If \( p \) is a quotient map and if \( f \) is continuous, then \( \varphi \) is continuous.

**Proof.**

1. Suppose that \( p \) and \( f \) are quotient maps. Let \( V \subset Z \) be an open subset. We have the following implications:

\[
\begin{align*}
 V & \text{ is open} \iff f^{-1}(V) \text{ is open} \iff p^{-1}(\varphi^{-1}(V)) \text{ is open} \iff \varphi^{-1}(V) \text{ is open.} \\
 \text{since } f \text{ is a quotient map} & \quad \text{since } f = \varphi \circ p \text{ we have} \\
 f^{-1}(V) &= p^{-1}(\varphi^{-1}(V)) & \text{since } p \text{ is a quotient map and} \\
 p(p^{-1}(\varphi^{-1}(V))) &= \varphi^{-1}(V).
\end{align*}
\]
Furthermore, it follows from the fact that the diagram commutes and the fact that \( f \) is surjective, that \( \varphi \) is surjective. We have thus verified that \( \varphi \) is a quotient map.

(2) Now we suppose that \( p \) is a quotient map and that \( f \) is continuous. We need to show that given an open subset \( V \subseteq Z \) the preimage \( \varphi^{-1}(V) \) is open. The argument is basically exactly the same as in (1), except that the first arrow is only a right arrow, since we only assume that \( f \) is continuous.

We have the following addendum to Lemma 5.13.

**Lemma 5.18.** Let \( X \) and \( Y \) be two topological spaces. Suppose we are given an equivalence relation \( \sim \) on \( X \). We denote by \( \sim \) the equivalence relation on \( X \times Y \) that is generated by \((x,y) \sim (x',y)\) whenever \( x \sim x' \). If \( Y \) is regionally compact, then the following map is a homeomorphism:

\[
\varphi : (X \times Y) / \sim \rightarrow (X / \sim) \times Y \\
[(x,y)] \mapsto ([x],y).
\]

**Proof.** As we pointed out in the proof of Lemma 5.13 it is basically clear that \( \varphi \) is a bijection. By Lemma 5.13 it remains to show that \( \varphi \) is a quotient map. We denote by \( p : X \times Y \rightarrow (X \times Y) / \sim \) and \( q : X \rightarrow X / \sim \) the two obvious projection maps. We have the following commutative diagram

\[
\begin{array}{ccc}
X \times Y & \xrightarrow{\varphi} & (X / \sim) \times Y \\
\downarrow p & & \downarrow (X / \sim) \times Y \\
(X \times Y) / \sim & \xrightarrow{\sim} & (X / \sim) \times Y.
\end{array}
\]

By Lemma 5.13(1) we know that \( p \) and \( q \) are quotient maps. Since \( Y \) is regionally compact we obtain from Theorem 5.16 that \( q \times \text{id}_Y \) is a quotient map. It follows from Lemma 5.17(1) that \( \varphi \) is also a quotient map.

Later on we will use the following special case of Lemma 5.18.

**Lemma 5.19.** Let \( X \) and \( Y \) be two topological spaces, let \( A \subseteq X \) be a subset and let \( f : A \rightarrow Y \) be a map. Using the notation from page 200, we see that the map

\[
(X \times [0,1]) \cup_{f \times \text{id}_{[0,1]}} (Y \times [0,1]) \rightarrow (X \cup_f Y) \times [0,1] \\
[(P,t)] \mapsto ([P],t)
\]

is a homeomorphism.

**Proof.** Once one unravels the definitions it is clear that this statement follows immediately from Lemma 5.18 together with the observation that \([0,1]\) is regionally compact.

Now we can also finally prove the following proposition which says that the join of topological spaces is associative, at least for reasonable topological spaces.

**Proposition 3.52.** Let \( X \), \( Y \) and \( Z \) be non-empty topological spaces that are compact and Hausdorff. Then there exists a homeomorphism

\[
(X \ast Y) \ast Z \xrightarrow{\cong} X \ast (Y \ast Z).
\]
Remark. Recall that we pointed out on page 210 that in general the join is not associative. In light of Lemma 5.14 this is perhaps no longer that shocking.

Proof. We define the join $X * Y * Z$ as follows: we consider

$$\{(r, x, s, y, t, z) \in [0, 1] \times X \times [0, 1] \times Y \times [0, 1] \times Z \mid r + s + t = 1\} / \sim$$

where “$\sim$” is generated by the following relations:

1. $(0, x, s, y, t, z) \sim (0, x', s, y, t, z)$,
2. $(r, x, 0, y, t, z) \sim (r, x, 0, y', t, z)$,
3. $(r, x, s, y, 0, z) \sim (r, x, s, y, 0, z')$.

In the following we will use “$\sim$” with several means, we leave it to the reader to figure out any given moment what is meant by this symbol.

Claim. The map

$$\Theta: (((X \times [0, 1] \times Y) / \sim) \times [0, 1] \times Z) / \sim \rightarrow (X \times [0, 1] \times Y \times [0, 1] \times Z) / \sim$$

is a homeomorphism.

We consider the following diagram

We make the following clarifications and observations:

1. All the maps are the obvious (projection) maps, except for $\varphi$ which is the map given by Lemma 5.14. The diagram commutes basically by definition.
2. It follows from Lemma 3.28 that $\Phi$ is continuous.
3. Our hypothesis that $Z$ is Hausdorff and compact implies by Proposition 3.12 together with Lemma 2.73 that $[0, 1] \times Z$ is regionally compact. Thus we obtain from Lemma 5.18 that $\varphi$ is actually a homeomorphism.
4. It follows from (2) and (3) that $\Psi$ is continuous.
5. It follows from (4) together with Lemma 3.22 that $\Theta$ is continuous.
6. It follows easily from the definitions that $\Theta$ is a bijection.
7. By our hypotheses on $X$, $Y$ and $Z$ we obtain from Proposition 3.12 and Lemma 2.40 that the domain $(X * Y) * Z$ of the map $\Theta$ is compact. Furthermore, by an argument as in Exercise 3.48 one sees that the target $X * Y * Z$ of the map $\Theta$ is Hausdorff.
(8) It follows from (5), (6) and (7) together with Proposition 2.43 (3) that \( \Theta \) is a homeomorphism. \( \blacklozenge \)

Basically the same argument as in the above claim also shows that there exists a homeomorphism \( X \ast (Y \ast Z) \to X \ast Y \ast Z \). In summary we see that there exists a homeomorphism \( X \ast (Y \ast Z) \to (X \ast Y) \ast Z \). \( \blacksquare \)

We conclude this list of applications of Theorem 5.16 with the following proposition that gives a fairly explicit illustration of how Theorem 5.16 can be used.

**Proposition 5.20.** (\( \ast \)) Let \( X \) be a topological space, let \( A \) be a subset of \( X \) and let \( Y \) be a topological space that is regionally compact. Then the map

\[
\varphi : \left( \frac{X}{A} \right) \times Y \to \left( \frac{X \times Y}{A \times Y} \right)
\]

\[
([x], y) \mapsto [(x, y)]
\]

is a quotient map, in particular it is continuous.

**Example.** In Figure 120 we illustrate the map studied in Proposition 5.20 in the case that \( X = \mathbb{R}, A = [a, b] \) and \( Y = [0, 1] \).

\[
\begin{array}{c}
X = \mathbb{R} \quad A = [a, b] \\
\end{array}
\]

\[
\begin{array}{c}
(X/A) \times [0, 1] \\
\end{array}
\]

\[
\begin{array}{c}
\varphi \\
\end{array}
\]

\[
\begin{array}{c}
\left( \frac{X \times [0, 1]}{(A \times [0, 1])} \right) \\
\end{array}
\]

**Figure 120**

**Proof (\( \ast \)).** We denote by \( p : X \times Y \to \left( \frac{X \times Y}{A \times Y} \right) \) and \( q : X \to \frac{X}{A} \) the two obvious projection maps. We have the following commutative diagram

\[
\begin{array}{ccc}
X \times Y & \xrightarrow{\varphi} & \left( \frac{X \times Y}{A \times Y} \right) \\
\xleftarrow{q \times \text{id}_Y} & & \xrightarrow{p} \\
(X/A) \times Y & & \\
\end{array}
\]

By Lemma 5.15 the maps \( p \) and \( q \) are quotient maps. Since \( Y \) is regionally compact we obtain from Theorem 5.16 that \( q \times \text{id}_Y \) is a quotient map. It follows from Lemma 5.17 that \( \varphi \) is also a quotient map. By Lemma 5.15 (2) this implies that \( \varphi \) is indeed continuous. \( \blacksquare \)

5.3. **Proof of Theorem 5.16 (\( \ast \)).** Now that we procrastinated for as long as possible, we will finally run out of reasons not to turn to the proof of Theorem 5.16. In fact we provide two proofs.

The first proof of Theorem 5.16 cleverly reduces the proof to Proposition 5.6. This approach pushes all the set-theoretic nastiness into the proof of Proposition 5.6. The second proof of Theorem 5.16 is a bare-hands argument which can be read independently of the previous section on the compact-open topology.
First proof of Theorem 5.16 using Proposition 5.6. We write \( W = Z \times Y \) and equip \( W \) with the topology that turns
\[
g : X \times Y \to W \quad (x, y) \mapsto (f(x), y)
\]
into a quotient map. In other words, as a set we have \( W = Z \times Y \), but this time equipped with the topology that is defined by the condition that \( U \subset W \) is open if and only if \( g^{-1}(U) \) is open. Note that with this topology on \( W \) the map \( g \) is in particular continuous. Next we consider the following diagram
\[
\begin{array}{ccc}
X \times Y & \xrightarrow{f \times \text{id}_Y} & Z \times Y \\
\downarrow{g(x,y) = (f(x),y)} & & \downarrow{h(z,y) = (z,y)} \\
W & \xleftarrow{\hat{g}} & W
\end{array}
\]
where \( h : Z \times Y \to W \) is the identity. Since \( g \) is by definition a quotient map it remains to show that \( h \) is a homeomorphism. Evidently \( h \) is a bijection. Furthermore note that every open set in \( Z \times Y \) is open in \( W \) since \( f \times \text{id}_Y \) is continuous. Thus it remains to show that \( h \) is continuous.

We consider the maps
\[
\hat{g} : X \to W^Y \quad \hat{h} : Z \to W^Y
\]
\[
x \mapsto \left( \begin{array}{c}
Y \\
y \mapsto g(x,y)
\end{array} \right) \text{ and } z \mapsto \left( \begin{array}{c}
Y \\
y \mapsto h(z,y)
\end{array} \right)
\]
These maps fit into the following commutative diagram:
\[
\begin{array}{ccc}
X & \xrightarrow{\hat{g}} & W^Y \\
\downarrow{f} & & \downarrow{\hat{h}} \\
Z & \xrightarrow{\hat{h}} & W^Y
\end{array}
\]
We make the following observations:

1. Since \( g : X \times Y \to W \) is continuous and since \( Y \) is by hypothesis regionally compact we obtain from Proposition 5.6 that \( \hat{g} : X \to W^Y \) is continuous.
2. By our hypothesis the map \( f \) is a quotient map.
3. It follows from (1) and (2), together with Lemma 5.17 (2), that the map \( \hat{h} : Z \to W^Y \) is continuous.
4. It follows from Proposition 5.6 and (3) that \( h \) is indeed continuous. ■

Our second proof of Theorem 5.16 is independent of earlier results. But it does mean that we will have to get our hands somewhat dirty.

**Definition.** Let \( f : X \to Y \) be a map between two sets. We say \( U \subset X \) is **saturated with respect to** \( f \) if \( U = f^{-1}(f(U)) \). If \( f \) is understood, then we just say \( U \) is **saturated**.

**Remark.** Let \( f : X \to Y \) be a map between two sets.

1. Let \( U \subset Y \) be a subset. By Lemma 1.3 (1) we know that \( U \subset f^{-1}(f(U)) \). Thus \( U \) is saturated if and only if \( f^{-1}(f(U)) \subset U \).
(2) If \( f \) is an injection, then it follows from Lemma 5.3 (1) that every subset of \( X \) is saturated.

The following is, besides Lemma 5.3, the only purely set-theoretic lemma of these notes.

**Lemma 5.21.** Let \( f : X \to Z \) be a map between two sets and let \( Y \) be another set. Let \( \tilde{W} \) be a subset of \( X \times Y \) that is saturated with respect to the map \( f \times \text{id}_Y : X \times Y \to Z \times Y \). Let \( K \subset Y \). We consider the set

\[
U := \{ x' \in X \mid \{ x' \} \times K \subset \tilde{W} \}.
\]

The set \( U \) is saturated with respect to \( f \).

**Proof.** We write \( h = f \times \text{id}_Y \). By the above we need to show that \( f^{-1}(f(U)) \subset U \). Thus let \( x \in f^{-1}(f(U)) \subset X \). We have

\[
h(\{ x \} \times K) = (f \times \text{id}_Y)(\{ x \} \times K) = \{ f(x) \} \times K = \{ f(x') \} \times K = h(\{ x' \} \times K) \subset h(\tilde{W}).
\]

\[
\begin{align*}
\uparrow & \quad \text{definition of } h \\
\uparrow & \quad \text{since } f(x) \in f(U) \text{ we know that } f(x) = f(x') \text{ for some } x' \in U \\
\uparrow & \quad \text{definition of } h = f \times \text{id}_Y \\
\uparrow & \quad \text{since } x' \in U
\end{align*}
\]

It follows that

\[
\{ x \} \times K \subset h^{-1}(h(\{ x \} \times K)) \subset h^{-1}(h(\tilde{W})) = \tilde{W}.
\]

Lemma 5.3 (1) \quad by the above argument \quad since \( \tilde{W} \) is saturated

We have thus shown that \( x \in U \). \( \square \)

We will also need the following lemma which is again in the realm of topological spaces. It can be viewed as a minuscule generalization of the Tube Lemma from Exercise 5.6.

**Lemma 5.22.** (*) Let \( X \) and \( Y \) be topological spaces, let \( x \in X \) and let \( K \subset Y \) be a compact subset. Let \( \tilde{W} \subset X \times Y \) be an open subset that contains \( \{ x \} \times K \). There exist open neighborhoods \( U \subset X \) of \( x \) and \( V \subset Y \) of \( K \) such that \( \{ x \} \times K \subset U \times V \subset \tilde{W} \).
Proof of Lemma 5.22 (*). Since \( \widetilde{W} \subseteq X \times Y \) is open and since \( \{x\} \times K \subseteq \widetilde{W} \) we can find for any \( k \in K \) open neighborhoods \( A_k \) of \( x \in X \) and \( B_k \) of \( y \in Y \) such that \( A_k \times B_k \subseteq \widetilde{W} \). Since \( K \) is compact there exist \( k_1, \ldots, k_m \in K \) such that \( K \subseteq B_{k_1} \cup \cdots \cup B_{k_m} \). We define \( U := B_{k_1} \cap \cdots \cap B_{k_m} \). Since \( U \) is the intersection of finitely many open sets each of which contain \( x \) we see that \( U \) is an open neighborhood of \( x \). Clearly we have the inclusions \( \{x\} \times K \subseteq U \times X \subseteq \widetilde{W} \).

For convenience we remind the reader of the following lemma.

**Lemma 2.5** Let \( X \) be a topological space and let \( U \subseteq X \) be a subset. If given any \( x \in U \) there exists a neighborhood \( V \) of \( x \) that is contained in \( U \), then \( U \) is open.

Now we can provide our alternative proof of Theorem 5.16.

**Second proof of Theorem 5.16** Let \( f : X \to Z \) be a map between topological spaces that is a quotient map. Furthermore let \( Y \) be a topological space that is regionally compact. We need to show that the map

\[
f \times \text{id}_Y : X \times Y \to Z \times Y
\]

is also a quotient map.

Since \( f \) is a quotient map we know by Lemma 5.15 (2) that \( f \) is continuous. Therefore it follows from Lemma 3.8 (2b) that the map \( f \times \text{id}_Y \) is continuous. Thus it remains to show that if \( W \subseteq Z \times Y \) is a subset such that the preimage \( \widetilde{W} := (f \times \text{id}_Y)^{-1}(W) \) is an open subset of \( X \times Y \), then \( W \) itself is open.

We intend to use Lemma 2.5 to show that \( W \) is open. Thus let \( (z, y) \in W \). We pick \( x_0 \in f^{-1}(\{z\}) \). We equip \( \{x_0\} \times Y \subseteq X \times Y \) with the subspace topology. By Lemma 3.8 (2a) the map

\[
i : Y \to \{x_0\} \times Y
\]

\[
y \mapsto (x_0, y)
\]

is an embedding. In particular \( Y_{x_0} := i^{-1}(\widetilde{W} \cap (\{x_0\} \times Y)) \) is an open subset of \( Y \). Note that \( \{x_0\} \times Y_{x_0} \subseteq \widetilde{W} \). Since \( Y \) is regionally compact we can find a compact neighborhood \( K_{x_0} \) of \( x_0 \) that is contained in \( Y_{x_0} \). By definition of a neighborhood there exists an open subset \( Y'_{x_0} \) of \( Y \) with \( x_0 \in Y'_{x_0} \subseteq K_{x_0} \). We define

\[
U_{x_0} := \{x \in X \mid \{x\} \times K_{x_0} \subseteq \widetilde{W}\}.
\]

**Claim.** The set \( f(U_{x_0}) \) is an open subset of \( Z \).

First we intend to use Lemma 2.5 to show that \( U_{x_0} \) is indeed an open subset of \( Y_{x_0} \). Thus let \( x \in U_{x_0} \). Since \( \widetilde{W} \) is an open subset of \( X \times Y \) and since \( K_{x_0} \) is compact it follows from Lemma 5.22 that there exist open subsets \( A \subseteq X \) and \( B \subseteq Y \) with \( x \in A \) and \( K_{x_0} \subseteq B \) such that \( A \times B \subseteq \widetilde{W} \). Evidently this implies that \( A \subseteq U_{x_0} \). Since \( x \in A \) we have verified that the openness criterion of Lemma 2.5 is satisfied. We have thus shown that \( U_{x_0} \) is an open subset of \( Y_{x_0} \).

Now we want to show that \( V := f(U_{x_0}) \) is an open subset of \( Z \). By Lemma 5.21 we know that \( U_{x_0} \) is saturated with respect to \( f \). In other words, we know that \( U_{x_0} = f^{-1}(V) \).
Now we use that by hypothesis \( f : X \to Z \) is a quotient map. Since \( f^{-1}(V) = U_{x_0} \) is open by (1) we obtain that \( V \) itself is open. But that is what we had wanted to show.

By definition of the product topology we obtain that \( f(U_{x_0}) \times Y'_{x_0} \) is an open subset of \( X \times Y \). Evidently we have \( (x, y) \in f(U_{x_0}) \times Y'_{x_0} \). It remains to prove the following claim.

**Claim.** We have \( f(U_{x_0}) \times Y'_{x_0} \subseteq W \).

The claim follows from the following equalities and inclusions:

\[
\begin{align*}
   f(U_{x_0}) \times Y'_{x_0} &= (f \times \text{id}_Y)(U_{x_0} \times Y'_{x_0}) \\
   &\subseteq (f \times \text{id}_Y)(U_{x_0} \times K_{x_0}) \\
   &= (f \times \text{id}_Y)(\text{W}) \\
   &= W.
\end{align*}
\]

since \( Y'_{x_0} \subseteq K_{x_0} \) \( \quad \text{definition of } U_{x_0} \) \( \quad \text{by Lemma 1.3 (2)} \) \( \quad \text{by definition} \)

\( W = (f \times \text{id}_Y)^{-1}(W) \)

**Remark.** A different proof of Theorem [5.16] based on Propositions [5.4] and [5.6] is given in [Hat02, Lemma A.17].

### 5.4. Mixing product and quotient topologies II (*).

In this section we prove a second statement regarding the interplay between product and quotient topologies. More precisely, we will prove the following proposition.

**Proposition 5.23.** (*Let \( X \) and \( Y \) be topological spaces. Let \( B \) be a subset of \( Y \). We denote by \( q : Y \to Y/B \) the projection. If \( B \) is a compact subset of \( Y \) and if \( Y \) is Hausdorff, then the map

\[
\text{id}_X \times q : X \times Y \to X \times (Y/B) \\
   (x, y) \mapsto (x, [y])
\]

is a quotient map.

**Remark.**

1. At first glance the statement of Proposition 5.23 might sound quite similar to the statement of Theorem 5.16. But in a way it is quite different, this time there are no conditions at all on the “unaffected” factor \( X \), but we do put a condition on the projection \( Y \to Y/B \).
2. According to [D08, Chapter 2.2, Exercise 16] one does not need to assume that \( Y \) is Hausdorff.
3. Finally we refer to [BrownR06, Chapter 4.3] for more information on the interplay between product and quotient topologies.

In the proof of Proposition 5.23 we need the following fairly elementary lemma.

**Lemma 5.24.** (*Let \( X \) and \( Y \) be topological spaces and let \( B \) be a compact subset of \( Y \). Let \( x \in X \). If \( W \) is an open subset of \( X \times Y \) that contains \( \{x\} \times B \), then there exists an open subset \( U \) of \( X \) and an open subset \( \tilde{V} \subseteq Y \) with \( \{x\} \times B \subseteq U \times \tilde{V} \subseteq W \).

**Proof.** (*). Let \( W \) be an open subset of \( X \times Y \) that contains \( \{x\} \times B \). By definition of the product topology we can find for each \( b \in B \) an open neighborhood \( U_b \) of \( x \) in \( X \) and an open neighborhood \( V_b \) of \( b \) in \( Y \) such that \( U_b \times V_b \subseteq W \). Since \( B \) is compact there exist
\(b_1, \ldots, b_m\) such that \(B \subset V_{b_1} \cup \cdots \cup V_{b_m}\). One can easily verify that \(U := U_{b_1} \cap \cdots \cap U_{b_m}\) and \(\tilde{V} := V_{b_1} \cup \cdots \cup V_{b_m}\) have the desired properties.

**Proof of Proposition 5.23 (\(*\).** Let \(X\) and \(Y\) be topological spaces and let \(B\) be a compact subset of \(Y\). We assume that \(Y\) is Hausdorff. We denote by \(q : Y \to Y/B\) the obvious projection. Note that \(p = \text{id}_X \times q\). First note that it follows from Lemma 3.22 and Lemma 3.8 (2b) that \(p\) is continuous. This implies the “only if”-direction. It remains to show that “if”-direction. Thus let \(W \subset X \times (Y/B)\) be a subset that has the property that \(p^{-1}(W)\) is an open subset of \(X \times Y\). We need to show that \(W\) is an open subset of \(X \times (Y/B)\). By Lemma 2.5 and the definition of the product topology it suffices to prove the following claim.

**Claim.** For each \((x, [y]) \in W \subset X \times (Y/B)\) there exists an open neighborhood \(U_x\) of \(x \in X\) and an open neighborhood \(V_{[y]}\) of \([y] \in Y/B\) such that \(U_x \times V_{[y]} \subset W\).

As in the proof of Proposition 5.20 we consider two cases separately. First we consider the case that \([y] = [B] \in Y/B\). It follows that \(p^{-1}((x, [y])) = \{x\} \times B\). By hypothesis \(p^{-1}(W)\) is an open subset of \(X \times Y\) that contains \(p^{-1}((x, [y])) = \{x\} \times B\). Therefore it follows from Lemma 5.24 there exists an open subset \(U_x\) of \(X\) and an open subset \(\tilde{V}_y \subset Y\) with \(\{x\} \times B \subset U_x \times \tilde{V}_y \subset p^{-1}(W)\). We denote by \(V_{[y]}\) the image of \(\tilde{V}_y\) under the projection \(q : Y \to Y/B\). Note that \(V_{[y]}\) is an open neighborhood of \([y] \in Y/B\). Finally note that

\[
U_x \times V_{[y]} = (\text{id}_X \times q)(U_x \times \tilde{V}_y) = p(U_x \times \tilde{V}_y) \subset p(p^{-1}(W)) = W.
\]

It remains to consider the case that \([y] \neq [B] \in Y/B\). We see that \((x, y) \in W\). Since \(B\) is compact and since \(Y\) is Hausdorff we know by Lemma 2.17 that \(B\) is a closed subset of \(Y\), i.e. \(Y \setminus B\) is open. It follows immediately from the definition of the product topology on \(X \times B\), the fact that \(Y \setminus B\) is open, the fact that \(p^{-1}(W)\) is an open neighborhood of \((x, y)\) and the fact that \(y \notin B\) that there exists an open neighborhood \(U_x\) of \(x\) and an open neighborhood \(\tilde{V}_y\) of \(y\) with \(\tilde{V}_y \subset X \setminus B\) and with \(U_x \times \tilde{V}_y \subset p^{-1}(W)\). One easily verifies that \(U_x\) and \(V_y = q(\tilde{V}_y)\) have the desired properties.

\[\footnote{Indeed, since \(B \subset \tilde{V}_y\) we see that \(q^{-1}(V_{[y]}) = q^{-1}(q(\tilde{V}_y)) = \tilde{V}_y \cup B = \tilde{V}_y\), which is an open set. By the definition of the quotient topology on \(Y/B\) we see that \(q^{-1}(V_{[y]})\) is indeed open.} \]
Exercises for Chapter 5.

Exercise 5.1. Let $X$ and $Y$ be topological spaces. Suppose that $Y$ is Hausdorff. Show that $X^Y$ is also Hausdorff.

Exercise 5.2. Let $X$ and $Y$ be non-empty topological spaces. We consider the following map

$$
\varphi: X \to X^Y
\quad
x \mapsto \text{constant map } y \mapsto x
$$

(a) Show that $\varphi$ is continuous.
(b) Show that $\varphi$ is an embedding.

Exercise 5.3. Let $X$ be a topological space that is compact and Hausdorff. Show that the group $\text{Homeo}(X)$ of self-homeomorphisms of $X$, equipped with the compact-open topology, is a topological group.

Exercise 5.4. Let $X, \tilde{X}$ and $Y$ be topological spaces. We suppose that $Y$ is regionally compact and Hausdorff. Show that the map

$$
X^Y \times \tilde{X}^Y \to (X \times \tilde{X})^Y
\quad
(f, g) \mapsto \left( Y \to X \times \tilde{X} \right)
\quad
y \mapsto (f(y), \tilde{f}(y))
$$

is a homeomorphism.

Remark. We refer to [Enge89] Exercise 3.4B, p. 165 for a similar, and for the most part, much more general statement.

Exercise 5.5. Let $X$ be a topological space and let $G$ be a topological group. We suppose that $G$ is regionally compact. Show that $G^X$ with the multiplication

$$
G^X \times G^X \to G^X
\quad
(f, g) \mapsto \left( X \to G \right)
\quad
x \mapsto f(x) \cdot g(x)
$$

is a topological group.

Exercise 5.6. Let $n \in \mathbb{N}$. We consider the following map

$$
\Theta: SO(n) \to \text{Homeo}(S^{n-1}) := \text{self-homeomorphisms of } S^{n-1}
\quad
A \mapsto (P \mapsto A \cdot P).
$$

(a) Show that the map $\Theta$ is continuous.
(b) Show that the map $\Theta$ is an embedding.

Hint. Use Lemma 2.30 (4) and Lemma 5.1.

Exercise 5.7. Let $Y = \{1, \ldots, n\}$ be a finite discrete topological space with $n$ elements and let $X$ be a topological space. Show there exists a homeomorphism $X^Y \cong X^n$. 
Part II

Differential Topology
6. Topological manifolds and smooth manifolds

In this chapter we introduce topological manifolds and study some basic properties. We also introduce smooth structures on topological manifolds. A topological manifold equipped with a smooth structure will just be called a smooth manifold. In the literature the term “smooth manifold” can be used with quite different conventions and meanings. So we try to state clearly the various definitions used throughout these notes. At the end, just for fun, we give the classification of 1-dimensional (topological) smooth manifolds.

6.1. Second-countable topological spaces. Our goal is to give as soon as possible the definition of a topological manifold. Unfortunately we first have to get the following technical and slightly annoying definition out of the way.

Definition. A topological space is called second-countable if there exists a countable basis for the topology.

Remark.

(1) Some books say instead that such a topological space “satisfies the second axiom of countability”.

(2) In case you were wondering, a topological space $X$ is called first-countable if given any $P \in X$ there exists a countable family of open neighborhoods $\{U_i\}_{i \in I}$ of $P$ such that each open neighborhood of $P$ contains at least one $U_i$. We will not make use of this notion.

Of course not every topological space is second-countable. For example consider $X = \mathbb{R}$, but for once equipped with the discrete topology. Since $\mathbb{R}$ is uncountable one sees almost immediately that $X = \mathbb{R}$ is not second-countable. There are almost more subtle examples, for example we will see in Exercise 6.3 that there exist compact topological spaces that are not second-countable.

Nonetheless, we will use the next lemma to see that most topological spaces that we are interested in are actually second-countable.

Lemma 6.1.

(1) Every subset of some $\mathbb{R}^n$ is second-countable. (Recall that, unless we say something else, we equip $\mathbb{R}^n$ with the standard topology introduced on page 85).

(2) If $X$ is a topological space that is second-countable, then every subset is also second-countable.

(3) If $X_1, \ldots, X_k$ are topological spaces that are second-countable, then $X_1 \times \cdots \times X_k$ is second-countable.

(4) Let $X$ be a topological space. If there exists a countable family of open subsets $\{U_i\}_{i \in I}$ such that $\bigcup_{i \in I} U_i = X$ and if each $U_i$ is second-countable, then $X$ itself is second-countable.

(5) Let $X$ be a topological space and let $\sim$ be an equivalence relation on $X$. If $X$ is second-countable and if the projection $X \to X/\sim$ is an open map, then $X/\sim$ is also second-countable.

Proof (*).
6. TOPOLOGICAL MANIFOLDS AND SMOOTH MANIFOLDS

(1) This follows from the discussion on page 167.
(2) This statement follows from Lemma 2.28 together with Lemma 1.7 (3).
(3) This statement follows from Lemma 3.11 together with Lemma 1.7 (5).
(4) For each $U_i$ we pick a countable basis $B_i$ of the topology of $U_i$. It is straightforward to verify that $\bigcup_{i \in I} B_i$ is a basis for the topology of $X$. By Lemma 1.7 (2) this is a countable set.
(5) This statement follows from Lemma 3.27 together with Lemma 1.7 (3). ■

The following lemma gives us a convenient property of second-countable topological spaces.

**Lemma 6.2.** (*) Let $X$ be a topological space and let $\{U_i\}_{i \in I}$ be an open cover of $X$. If $X$ is second-countable, then there exists a countable subset $J \subset I$ with $X = \bigcup_{j \in J} U_j$.

**Proof.** (*)&

Let $\mathcal{B}$ be a countable basis for the topology of $X$. We write $\mathcal{B}' := \{ V \in \mathcal{B} \mid V \subset U_i \text{ for some } i \in I \}$.

Given $V \in \mathcal{B}'$ we pick $j \in I$ with $V \subset U_j$. It follows from Lemma 1.7 that the set $J \subset I$ of all such $j$ is countable. It remains to show that $X = \bigcup_{j \in J} U_j$.

Thus let $x \in X$. By hypothesis there exists an $i \in I$ with $x \in U_i$. Since $\mathcal{B}$ is a basis for the topology of $X$ there exists a $V \in \mathcal{B}$ with $x \in V \subset U_i$. Note that $V \in \mathcal{B}'$. But this implies that $x \in U_j$ for some $j \in J$. ■

6.2. **Topological manifolds: definition and examples.** In this section we give the definition of a topological manifold. In these notes the study of topological manifolds will be one of our main objectives. First we need to introduce the following notation.

**Notation.** Given $n \in \mathbb{N}_0$ we write

\[
\begin{align*}
H_n &= \{(x_1, \ldots, x_n) \in \mathbb{R}^n \mid x_n \geq 0\} \\
\partial H_n &= \{(x_1, \ldots, x_n) \in \mathbb{R}^n \mid x_n = 0\}.
\end{align*}
\]

We refer to $H_n$ as the *upper half-space in* $\mathbb{R}^n$. We equip both sets with the subspace topology coming from $\mathbb{R}^n$. One can easily verify that $\partial H_n$ is indeed the boundary of $H_n$ viewed as a subset of $\mathbb{R}^n$. Evidently the map $\mathbb{R}^{n-1} \to \partial H_n$ given by $x \mapsto (x, 0)$ is a homeomorphism.

Now we can move on to the definition of a topological manifold.

**Definition.** Let $X$ be a topological space.

(1) An *$n$-dimensional chart for $X$ at a point* $x \in X$ is a homeomorphism $\Phi: U \to V$ where $U$ is an open neighborhood of $x$ and

(i) $V$ is an open subset of $\mathbb{R}^n$ or

(ii) $V$ is an open subset of the upper half-space $H_n$ and $\Phi(x)$ lies in $\partial H_n$.

In the former case we say that $\Phi$ is a chart of type (i), in the latter case we say that $\Phi$ is a chart of type (ii). We refer to Figure 124 for an illustration.
We say $X$ is an $n$-dimensional topological manifold, if $X$ is second-countable and Hausdorff, and if for every $x \in X$ there exists an $n$-dimensional chart $\Phi: U \to V$ at $x$.

We say that a point $x$ on a topological manifold is a boundary point if $x$ does not admit a chart of type (i). We denote by $\partial X$ the set of all boundary points of $X$.

An $n$-dimensional manifold $X$ is closed if $X$ is compact with $\partial X = \emptyset$.

Furthermore, it follows from Proposition 2.11 and Lemma 2.12 that a topological space that admits an atlas also admits a finite atlas.

Let $A$ be a subset of $\mathbb{R}^n$. By Lemma 6.1 we know that $A$ is second-countable. Furthermore, it follows from Proposition 2.11 and Lemma 2.12 that $A$ is also Hausdorff.

The first statement is an immediate consequence of Lemma 6.1(4). The second statement in turn is an immediate consequence of the first statement since every compact topological space that admits an atlas also admits a finite atlas.

Now we turn to giving examples of topological manifolds.

Examples. Let $n \in \mathbb{N}$.

1. We consider the sphere $S^n$. As usual we refer to $N := (0, \ldots, 0, 1) \in S^n$ as the North Pole and similarly we refer to $S := (0, \ldots, 0, -1) \in S^n$ as the South Pole.

2. It might sound more natural to define a boundary point to be a point that admits a chart of type (ii). In fact we will see in Lemma 4.1 that a point on a topological manifold admits either a chart of type (i) or a chart of type (ii). But the proof of this statement is not trivial and as of now we can not prove this statement.

3. The latter condition just means that all points in $X$ admit a chart of type (i).
It follows quite easily from slight modifications of the arguments in the proof of Lemma 2.44 that the stereographic projection $S^n \setminus \{N\} \to \mathbb{R}^n$ from the North Pole together with the stereographic projection $S^n \setminus \{S\} \to \mathbb{R}^n$ from the South Pole are two $n$-dimensional charts of type (i) that cover all of $S^n$. By Lemma 6.3 this shows that $S^n$ is an $n$-dimensional topological manifold.

Note that both charts are of type (i), thus we see that the boundary of the topological manifold $S^n$ is the empty set. Finally note that $S^n$ is compact, thus $S^n$ is a closed $n$-dimensional topological manifold.

Figure 125

(2) Every open subset $U$ of $\mathbb{R}^n$ is an $n$-dimensional topological manifold. This follows again from Lemma 6.3 and the observation that the identity map is a chart of type (i) for all points. In particular we see that the boundary of $U$ is empty.

(3) Let $M$ be an open subset of the upper half-space $H_n = \{(x_1, \ldots, x_n) \in \mathbb{R}^n \mid x_n \geq 0\}$. Again, using Lemma 6.3 it is straightforward to see that $M$ is an $n$-dimensional topological manifold:

(a) Given any point $X = (x_1, \ldots, x_n) \in M$ with $x_n > 0$ the identity map on the open subset $U := \{(y_1, \ldots, y_n) \in M \mid y_n > 0\}$ is a chart of type (i) around $x$.

(b) Given any point $(x_1, \ldots, x_n) \in M$ with $x_n = 0$ the identity map $M \to M$ is a chart of type (ii) around $x$.

In this example we run into a major, and rather painful, subtlety. Namely one would think that the boundary of $M$ as a topological manifold should be precisely the points in $M$ with $x_n = 0$. But at the moment we cannot draw this conclusion. After all, in principle, such points also might admit charts of type (i). Only after having introduced and studied homology groups we will see that no such charts of type (i) exist.

(4) Next we want to show that the closed $n$-ball $\overline{B}^n$ is an $n$-dimensional topological manifold. We provide the following charts:

(a) We consider the chart of type (i) that is given by the identity on $B^n$.

\[90\] The vigilant reader will have noticed that we have committed a major sin: we introduced an object called “boundary” twice, with quite different meanings:

(a) On page 92 we introduced the boundary $\partial A$ of a subset $A$ of a topological space $X$.

(b) On page 262 we introduced the boundary $\partial M$ of a topological manifold $M$.

Usually it is clear from the context what we mean when we write $\partial$. 
(b) We set \( U := \{(x_1, \ldots, x_n) \in \overline{B^n} | x_n > 0\} \) and we consider the map
\[
U \to H_n
(x_1, \ldots, x_n) \mapsto (x_1, \ldots, x_n-1, \sqrt{x_1^2 + \cdots + x_{n-1}^2 - x_n}).
\]
This is a chart of type (ii) for all points in \( \{(x_1, \ldots, x_n) \in S^{n-1} | x_n > 0\} \). We refer to Figure 127 for an illustration of this chart.

(c) We consider the obvious variations of the previous chart for \( x_n < 0 \) and for other coordinates.

These charts form an atlas for \( \overline{B^n} \), together with Lemma 6.3 this shows that \( \overline{B^n} \) is an \( n \)-dimensional topological manifold. We have found a chart of type (i) for each point in \( B^n \) and for the points on \( S^{n-1} \) we had found points of type (ii). This shows that \( \partial B^n \subset S^{n-1} \). Furthermore we have the strong suspicion that \( \partial B^n = S^{n-1} \) but as of right now we cannot confirm this. We will only be able to confirm our hunch by the time we have proved Proposition 44.2.

(5) Given \( a < b \) in \( \mathbb{R} \) the interval \( [a, b] \) is easily seen to be a 1-dimensional topological manifold. Every point in \( (a, b) \) admits a chart of type (i). Using Exercise 2.40 one can show fairly easily that the two points \( a, b \in [a, b] \) do not admit charts of type (i). Thus the boundary of \( [a, b] \) consists, as expected, of the two points \( a \) and \( b \).

(6) In Exercise 6.2 we will verify that the line with two zeros admits a chart of type (i) for every point. It is also easy to see that the line with two zeros is second-countable. But since the line with two zeros is not Hausdorff we see that it is not a topological manifold.

(7) We consider the topological space \( X \) that is given by the set \( X = \mathbb{R} \) but for once we equip \( X = \mathbb{R} \) with the discrete topology. Every point of \( X \) admits a 0-dimensional chart and \( X \) is obviously Hausdorff. But \( X \) is not second-countable, thus \( X \) is not a topological manifold.

(8) We conclude this list of examples with the simplest of all examples: the empty set is a topological manifold of any dimension.

The following proposition gives a useful method for constructing more topological manifolds.
Proposition 6.5. Let $M$ be an $m$-dimensional topological manifold with possibly non-empty boundary and let $N$ be an $n$-dimensional topological manifold with empty boundary. Then the following hold:

1. The product $M \times N$ is an $(m + n)$-dimensional topological manifold.
2. We have $\partial (M \times N) \subset \partial M \times N$.
3. If $M$ and $N$ are closed, then $M \times N$ is also closed.

The above statements also hold with the roles of $M$ and $N$ reversed.

Examples.

1. It follows from Proposition 6.5 and the above examples that for any $n \in \mathbb{N}$ the $n$-dimensional torus $(S^1)^n$ is a closed $n$-dimensional topological manifold.
2. It follows from Proposition 6.5 and the above examples that the annulus $S^1 \times [0, 1]$ is a 2-dimensional topological manifold and that $S^1 \times \overline{B^2}$ is a 3-dimensional topological manifold.

Proof. (\star)

(1) First note that it follows from Proposition 6.12 (1) that $M \times N$ is Hausdorff and it follows from Lemma 6.1 that $M \times N$ is second-countable. One can now easily use products of charts to show that $M \times N$ is an $(m + n)$-dimensional topological manifold.

(2) The product of charts of type (i) is again a chart of type (i). This immediately implies the second statement.

(3) This statement follows from (2) and Proposition 3.12 (2).

We conclude this chapter with the following two lemmas.

Lemma 6.6. (\star) Let $M$ and $N$ be two topological manifolds.

1. Any union of components of $\partial M$ is a closed subset of $M$. In particular $\partial M$ itself is a closed subset of $M$.
2. If $M$ is compact, then $\partial M$ is also compact.

Proof. (\star). The lemma follows from the elementary observation that the restriction of a chart for a point on a topological manifold has the same type as the original chart. We leave it to the reader to fill in the minuscule details.

The following lemma is slightly more interesting than the previous lemma.

Lemma 6.7. (\star) Let $M$ be a topological manifold.

1. Any union of components of $\partial M$ is a closed subset of $M$. In particular $\partial M$ itself is a closed subset of $M$.
2. If $M$ is compact, then $\partial M$ is also compact.

\footnote{Note that right now we can only prove the inclusion “$\subset$”. Later on in Proposition 44.2 we will see that in fact we have an equality.}
Proof (*). Let $M$ be a topological manifold.

(1) First note that, basically by definition, the set of points in $M$ admitting a chart of type (i) is an open subset of $M$. It follows from the definition of $\partial M$ that $M \setminus \partial M$ is an open subset. Thus the boundary $\partial M$ is a closed subset of $M$. We denote by \{Y_i\}_{i \in I}$ the components of $\partial M$. By Lemma 2.69 each $Y_i$ is an open subset of $\partial M$. Thus for any $i \in I$ there exists, by definition of the subspace topology, an open set $Z_i \subset M$ with $Z_i \cap \partial M = Y_i$. For any $J \subset I$ we have

$$M \setminus \bigcup_{j \in J} Y_j = (M \setminus \partial M) \cup \bigcup_{j \notin J} Z_j.$$  

We have thus shown that the union of components of $\partial M$ corresponding to $J$ is indeed a closed subset of $M$.

(2) Now suppose that $M$ is compact. Thus $\partial M$ is a closed subset of the compact topological space $M$. We obtain from Lemma 2.17 (1) that $\partial M$ itself is compact. ■

6.3. Surfaces are topological manifolds. On pages 205 and 206 we introduced the (non-) orientable surfaces of some genus. The name already suggests that these should be 2-dimensional topological manifolds, and the following proposition confirms our impression.

Proposition 6.8.

(1) For every $g \in \mathbb{N}_0$ the surface $\Sigma_g$ of genus $g$ is a closed 2-dimensional topological manifold.

(2) For every $g \in \mathbb{N}$ the non-orientable surface $N_g$ of genus $g$ is a closed 2-dimensional topological manifold.

Proof (*). To simplify the discussion we will only prove Statement (1) of the proposition. We leave it to the reader to modify the argument to deal with the non-orientable case.

We start out this proof with the discussion of the two cases $g = 0$ and $g = 1$ that we had basically dealt with already. First recall that on page 263 we saw that any $S^n$ is a closed $n$-dimensional topological manifold. The surface of genus 0 is by definition the sphere $S^2$, thus we are done by the above. Furthermore, the surface of genus 1 is by definition the torus $S^1 \times S^1$. The desired statement thus follows from the above and Proposition 6.5.

It remains to deal with the case $g \geq 2$. To simplify the notation we prove the proposition for $g = 2$. The proof of the general case is totally analogous. We consider the octagon $E_8$ with the vertices $Q_k = e^{2\pi ik/16}$, $k = 1, 3, \ldots, 15$ and the equivalence relation $\sim$ that we introduced on page 205. We illustrate the octagon together with the equivalence relation in Figure 128.

Note that $E_8$ is compact by the Heine-Borel Theorem 2.20. Thus we obtain from Lemma 3.21 (4) that $E_8/\sim$ is also compact. In the following we will see that $E_8/\sim$ admits a finite atlas, by Lemma 6.4 this implies in particular that $E_8/\sim$ is second-countable.\footnote{It would also not be difficult to prove second-countability "by hand".}
that $E_8$ is compact by the Heine-Borel Theorem \[2.20\] Thus we obtain from Lemma \[2.40\] that $E_8/\sim$ is also compact. We leave it to the reader to verify that $E_8/\sim$ is Hausdorff.

Thus, to show that $E_8/\sim$ is a closed 2-dimensional topological manifold it remains to give a finite atlas for $E_8/\sim$ that consists only of charts of type (i).

First we consider the map

$$
\Phi: U := p(\hat{E}_8) \to V = \hat{E}_8 \subset \mathbb{R}^2,
p(X) \mapsto X.
$$

This is a chart of type (i) for each point in the interior of $E_8$.

Next we introduce charts that cover the interiors of the edges. First we consider the edge given by $Q_{-1}$ and $Q_1$. We denote by $U$ and $U'$ the half-disks that are illustrated in Figure \[130\] (Note that it is understood that the line segment is included but that the circle is not included in $U$ and $U'$.) Let $f: \mathbb{R}^2 \to \mathbb{R}^2$ be the reflection in the line that goes through $Q_{-1}$ and $Q_1$. It is straightforward to verify that the map

$$
\Psi_1: p(U \cup U') \to \text{the open disk } U \cup f(r_{\pi}(U)) \subset \mathbb{R}^2,
p(X) \mapsto \begin{cases} X, & \text{if } X \in U \\ f(r_{\pi}(X)), & \text{if } X \in U' \end{cases}
$$

is well-defined. Furthermore, using Lemma \[2.35\] (2) one can show that $\Psi_1$ and its inverse are both continuous. Finally, it follows easily from the definitions that $p(U \cup U')$ is an open subset of $E_8/\sim$. Thus $\Psi_1$ is a chart of type (i) for all points in the interior of the edge from $Q_{-1}$ to $Q_1$. Similarly we define charts $\Psi_2, \Psi_3, \Psi_4$ that take care of the other pairs of edges.

\[93\] This can either be done “by hand”, or more elegantly but possibly with more work, by using Lemma \[3.26\]
It remains to find a chart of type (i) that takes care of the point $P$ in $E_8/\sim$ that is represented by the vertices. (It is a fun exercise to verify that all vertices get identified.) We pick an $\eta > 0$ such that the $\eta$-disks centered at $Q_1, \ldots, Q_{15}$ are disjoint. For $k = 1, 3, \ldots, 15$ we set $U_k := B_\eta(Q_k) \cap E_8$. The sets $U_1, U_3, \ldots, U_{15}$ are disjoint and one can easily verify that

$$p(U_1) \cup p(U_3) \cup \cdots \cup p(U_{15})$$

is an open neighborhood of $p(Q_1) = p(Q_3) = \cdots = p(Q_{15})$.

Before we write down the chart rigorously it might help to visualize the situation. To

we repositioned the pieces of pie, now in a counterclockwise fashion

consecutive pieces of pie get identified along the edges of the same color

the union of the

pieces of pie forms an

open neighborhood of $P$

we compress and rotate

the pieces of pie

we glue the pieces of pie

together to obtain a disk

Figure 131

the left of Figure 131 we see the sets $U_1, \ldots, U_{15}$. Next we arrange these “pieces of pie” as in the second second part of Figure 131 Thus we see the “pieces of pie” with an angle of $\frac{2\pi}{11}$ where we show the various identifications of the edges. The map from the second to the third part is given by compressing the angle of the “pieces of pie” to a third and by rotating the “pieces of pie”. These eight “pieces of pie”, each with an angle of $\frac{\pi}{4}$, can be combined
to give a disk in \( \mathbb{R}^2 \).

Now we want to turn the above idea into formal mathematics. We consider the map
\[
\Omega : p(U_1) \cup \cdots \cup p(U_{15}) \to B^2_\eta(0)
\]
that is defined on each \( p(U_k), k \in \{1, 3, \ldots, 15\} \) to be the map
\[
p(Q_k + re^{i\alpha}) \mapsto re^{i\left(\frac{1}{2}(\alpha - \beta(k)) + \gamma(k)\right)}.
\]
where \( r \in [0, \eta) \) and \( \alpha \in [\beta(k), \beta(k) + \frac{2\pi}{3}] \).

Here \( \beta(k) \) and \( \gamma(k) \) are given by the following table:

<table>
<thead>
<tr>
<th>( k )</th>
<th>1</th>
<th>3</th>
<th>5</th>
<th>7</th>
<th>9</th>
<th>11</th>
<th>13</th>
<th>15</th>
</tr>
</thead>
<tbody>

It is straightforward, albeit slightly cumbersome, to verify that \( \Omega \) is a bijection. Furthermore, using Exercise 3.27 together with Lemma 2.35 (2) one can show fairly easily that \( \Omega \) is continuous and that its inverse is also continuous. In other words, the map \( \Omega \) is a homeomorphism. As pointed out above, it is straightforward to verify that \( p(U_1) \cup \cdots \cup p(U_{15}) \) is an open subset of \( E_8/\sim \). In summary, we have shown that \( \Omega \) is a chart of type (i) for \( P \).

The eight charts \( \Phi, \Psi_1, \Psi_2, \Psi_3, \Psi_4 \) and \( \Omega \) are now charts of type (i) that cover all of \( E_8/\sim \). We have thus found the desired atlas. 

6.4. Properties of topological manifolds. Topological manifolds are particularly important and also particularly nice topological spaces. For example the next lemma shows in particular that when it comes to topological manifolds we do not have to worry about the two different definitions of connectedness.

**Lemma 6.9.**

1. Every \( n \)-dimensional topological manifold is locally homeomorphic to an open convex subset of \( \mathbb{R}^n \) or \( H_n \).
2. Every topological manifold is locally path-connected.
3. A topological manifold is connected if and only if it is path-connected.
4. Every topological manifold is regionally compact.

Throughout the lecture notes we will on many occasions make use of Lemma 6.9 (3) without referring to it explicitly.

**Proof (\( \ast \)).** Let \( X \) be an \( n \)-dimensional topological manifold.

1. Let \( M \) be an \( n \)-dimensional topological manifold and let \( P \in M \). First assume that \( P \notin \partial M \). This means that there exists a chart \( \Phi : U \to V \) to some open subset \( V \) of \( \mathbb{R}^n \). We set \( Q = \Phi(P) \). Since \( V \) is open there exists an \( r > 0 \) such that \( B^n_r(Q) \subset V \). Evidently \( B^n_r(Q) \) is convex and we see that \( \Phi^{-1}(B^n_r(Q)) \) is an open neighborhood of \( P \) that is homeomorphic to a convex subset of \( \mathbb{R}^n \). Basically the same argument also works if \( P \in \partial M \).
2. Since convex sets are path-connected we obtain from (1) that topological manifolds are locally path-connected.
(3) This statement is an immediate consequence of (3) and of Lemma 2.72.

(4) On page 139 we saw that open subsets of $\mathbb{R}^n$ are regionally compact. The same argument shows that open subsets of $H_n$ are regionally compact. Using Lemma 2.40 it is now easy to see that topological manifolds are regionally compact. □

On several occasions we will need the following, slightly technical lemma.

**Lemma 6.10.** Let $M$ be a topological manifold and let $\Phi: U \to V$ be a chart. Let $A \subset V$ be a subset that is compact. Then the corresponding subset $\Phi^{-1}(A)$ is a closed subset of $M$. $\square$

**Proof.** Let $M$ be a topological manifold and let $\Phi: U \to V$ be a chart. We denote by $\Psi = \Phi^{-1}: V \to U$ be the inverse map. Let $A \subset V$ be a subset that is compact. It follows from Lemma 2.40 that $\Psi(A)$ is a compact subset of $M$. But $M$ is Hausdorff by definition of a topological manifold. Hence it follows from Lemma 2.17 (2) that $\Psi(A) = \Phi^{-1}(A)$ is closed in $M$. □

Next we specify what we mean by a submanifold.

**Definition.** Let $M$ be an $n$-dimensional topological manifold.

(1) We say a subset $N \subset M$ is a $k$-dimensional submanifold if given any $P \in N$ one of the following holds:

(a) there exists a chart $\Phi: U \to V$ of type (i) for $M$ and $P$ such that

$\Phi(U \cap N) = V \cap \{(0, \ldots, 0, x_1, \ldots, x_k) | x_i \in \mathbb{R}\},$

(b) or there exists a chart $\Phi: U \to V$ of type (ii) for $M$ and $P$ such that $\Phi(P)$ lies in $E_{n-1}$ and

$\Phi(U \cap N) = V \cap \{(0, \ldots, 0, x_1, \ldots, x_k) \in \mathbb{R}^n | x_k \geq 0\},$

(c) or there exists a chart $\Phi: U \to V$ of type (i) for $M$ and $P$ such that $\Phi(P)$ lies in $E_{n-1}$ and

$\Phi(U \cap N) = V \cap \{(0, \ldots, 0, x_1, \ldots, x_k) \in \mathbb{R}^n | x_k \geq 0\}.$

We refer to such charts as submanifold charts of $N$.

(2) We say a submanifold $N$ is proper if $N$ is a closed subset of $M$ and if for each $P \in N$ we can find submanifold charts of type (a) and (b).

We illustrate the three types of submanifold charts in Figure 133.

---

94 It does not suffice that $A$ is a closed subset of the topological space $V$. Indeed, $A = V$ is a closed subset of $V$, but $U = \Phi^{-1}(V)$ is in general not a closed subset of $M$.

95 Why are the zeros to the left and not to the right?
6. TOPOLOGICAL MANIFOLDS AND SMOOTH MANIFOLDS

Examples.

(1) In Figure 134 we give typical examples of submanifolds, some of which are proper, some are not. We also show some subsets that are not submanifolds. In particular it is worth pointing out that a non-empty submanifold is never a submanifold.\footnote{Indeed, suppose that $N$ is a non-empty submanifold of a topological manifold $M$. It follows immediately from the definitions of a submanifold that $N$ contains a point $P$ that is contained in a chart of type (i) for $M$. But by the definition of $\partial M$ on page 262 this means that $P \notin \partial M$.}

(2) Let $f : V \to W$ be a map between two topological manifolds with $f(V) \subset W \setminus \partial W$. In Exercise 6.10 we will see that the graph $\text{Gr}(f) := \{(x, f(x)) \mid x \in V\}$ is a proper submanifold of the topological manifold $V \times W$.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{example_submanifolds.png}
\caption{Examples of submanifolds.}
\end{figure}

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{graph_map.png}
\caption{Graph of a map $f : V \to W$.}
\end{figure}
(3) Let $M$ be a topological manifold. It follows easily from the definitions that a subset $X \subset M$ is a 0-dimensional submanifold of $M$ if and only if $X$ is a discrete subset of $M$.

**Remark.** The notion of a “submanifold” is used differently by different authors. Therefore, reading the literature it is a good idea to check what definition of a submanifold the authors use. In particular our definition of a “proper submanifold” is often used as the definition of a submanifold.

We conclude this section with the following lemma that is almost obvious.

**Lemma 6.11.** Let $M$ be a topological manifold. If $N \subset M$ is a $k$-dimensional submanifold, then it is also a $k$-dimensional topological manifold.

**Proof.** It follows from Lemmas 2.12 and 6.1 that $N$ is Hausdorff and second-countable. It is clear from the definitions that $N$ admits a $k$-dimensional atlas. Thus $N$ is indeed a $k$-dimensional topological manifold. ■

**Remark.** Let $M$ be a topological manifold and let $U \subset M$ be an open subset. It follows almost immediately from the definitions that $U$ is a codimension-zero submanifold of $M$. Furthermore, if we view $U$ as a topological manifold in its own right, then it follows again basically immediately from the definitions that $\partial U = U \cap \partial M$.

### 6.5. Smooth functions on subsets of $\mathbb{R}^n$

In the next section we want to define the notion of a “smooth structure” on a topological manifold. In this section we want to recall some basic definitions and facts regarding “classical” smooth functions.

Before we discuss smooth functions we have to agree on what we mean by smooth maps on a subset of $\mathbb{R}^n$.

**Definition.**

1. Let $U$ be an open subset of $\mathbb{R}^n$. We say a map $f = (f_1, \ldots, f_m): U \to \mathbb{R}^m$ is smooth, if all iterated partial derivatives $\frac{\partial^{d} f_i}{\partial x_{k_1} \cdots \partial x_{k_d}}$, of arbitrarily large degree, of each coordinate function $f_i$ exist.

2. Let $A$ be any subset of $\mathbb{R}^n$. We say a map $f: A \to \mathbb{R}^m$ is smooth, if given any $a \in A$ there exists an open neighborhood $U$ (in $\mathbb{R}^n$) of $a$ and a smooth map $\tilde{f}: U \to \mathbb{R}^m$ which coincides with $f$ on $A \cap U$.

**Example.**

1. The function $f: [0, \infty) \to \mathbb{R}$ given by $f(x) = \sqrt{x}$ is not smooth, since it cannot be extended to a smooth function on any open interval $(a, b)$ that contains 0.

2. One can easily show that any function $f: \mathbb{Z} \to \mathbb{R}$ is smooth.

3. In the following our main interest will lie in maps defined on open subsets of the upper half-space $H_n = \{(x_1, \ldots, x_n) \in \mathbb{R}^n | x_n \geq 0\}$. Thus let $U$ be an open subset of $H_n$ and let $f: U \to \mathbb{R}^m$ be a function. By a more advanced version of Borel’s Theorem, see [Hör90a, Theorem I.1.2.6], the map $f$ is smooth in the above sense if and only if $f$ is continuous, if $f|_{\tilde{H}_n \cap U}$ is smooth and if all the partial derivatives of $f|_{\tilde{H}_n \cap U}$ have continuous extensions to all of $U$. We will not make use of this fact.
For $n = 1$ the following proposition sometimes gives a useful criterion for showing that a given map on an interval is smooth in the above sense.

**Proposition 6.12.** Let $a < b$ be two real numbers and let $f: [a, b] \to \mathbb{R}$ be a function. The following two statements are equivalent:

1. The function $f: [a, b] \to \mathbb{R}$ is smooth in the above sense.
2. All derivatives of $f: (a, b) \to \mathbb{R}$ are defined on the open interval $(a, b)$ and they extend to continuous maps on the closed interval $[a, b]$.

**Proof.** The “(1)⇒(2)”-implication is basically clear. The “(2)⇒(1)”-implication is a consequence of Borel’s Theorem, see [Strg81 Theorem 4.32].

The following lemma is one of the key tools for constructing interesting smooth functions.

**Lemma 6.13.**

1. Suppose that we are given real numbers $a \leq b < c \leq d$ and $\varepsilon > 0$. There exists a smooth function $f: [a, d] \to [0, 1]$ with the following properties:
   (a) $f|_{[a, b]} \equiv 0$ and $f|_{[c, d]} \equiv 1$.
   (b) $f$ is strictly monotonously increasing on $[b, c]$.
   (c) Given any $t \in (a, d)$ we have $f'(t) < (1 + \varepsilon) \cdot \frac{1}{c-b}$.

2. Let $a < b$ be two positive real numbers and let $n \in \mathbb{N}$. There exists a smooth function $f: \mathbb{R}^n \to [0, 1]$ such that $f(x) = 1$ whenever $\|x\| \leq a$ and such that $f(x) = 0$ whenever $\|x\| > b$.

**Diagram:**

![Graph of f](image)

**Figure 136.** Illustration of Lemma 6.13

**Proof.**

1. This statement is proved in any self-respecting analysis course, we refer to [Kön04 Chapter 9] for details.
2. By (1) there exists a smooth function $\varphi: [0, \infty) \to [0, 1]$ such that $\varphi(x) = 0$ for $x \in [0, a]$ and such that $\varphi(x) = 1$ for $x \in [b, \infty)$. Now consider the map
   $$f: \mathbb{R}^n \to [0, 1], \quad x \mapsto 1 - f(\|x\|).$$

   Since $x \mapsto \|x\|$ is smooth on $\mathbb{R}^n \setminus \{0\}$ we see that $f$ is smooth on $\mathbb{R}^n \setminus \{0\}$. Furthermore, since $f$ is constant on a neighborhood of the origin we see that $f$ is in fact smooth on all of $\mathbb{R}^n$.

Next we recall the definition of the differential.
**Definition.** Let $U \subset \mathbb{R}^n$ be an open subset, let $f = (f_1, \ldots, f_m): U \to \mathbb{R}^m$ be a smooth map and let $P \in U$. We refer to the $(m \times n)$-matrix $Df_P := \{ \frac{\partial f_i}{\partial x_j} \big|_{P} \}_{i=1,\ldots,m,j=1,\ldots,n}$ as the differential of $f$ at $P$.

If $f: U \to \mathbb{R}^m$ is a smooth function on an open subset of $\mathbb{R}^n$, then given any $P \in U$ the map $f$ is “close” to the affine linear map $w \mapsto Df_P(P-w)+f(P)$. The following proposition, which is contained in every book on multivariable real analysis (see e.g. [Fors08, p. 70]), makes this notion precise.

**Proposition 6.14.** Let $U \subset \mathbb{R}^n$ be an open subset and let $f: U \to \mathbb{R}^m$ be a smooth map. Given any $P \in U$ we have

$$\lim_{v \to 0} \frac{\|f(P+v)-f(P)-Df_P(v)\|}{\|v\|} = 0.$$ 

We also recall the chain rule for differentials.

**Proposition 6.15.** Let $U \subset \mathbb{R}^k$ and $V \subset \mathbb{R}^l$ be open subsets and let $f: U \to \mathbb{R}^l$ and $g: V \to \mathbb{R}^m$ be smooth maps with $f(U) \subset V$. Given any $P \in U$ we have

$$D(g \circ f)_P = Df_{f(P)} \cdot Df_P$$

“chain rule”.

The next proposition says that locally, up to translation, one describe any smooth map as matrix multiplication where the coefficients of the matrix are allowed to vary.

**Proposition 6.16.** Let $U \subset \mathbb{R}^n$ be an open convex subset that contains the origin. Furthermore let $f: U \to \mathbb{R}^m$ be a smooth map with $f(0) = 0$. There exists a smooth map $A: U \to M(m \times n, \mathbb{R})$ such that $A(0) = Df_0$ and such that

$$f(x) = A(x) \cdot x \quad \text{for all } x \in U.$$

**Proof.** By considering the coordinate functions of a given map $f = (f_1, \ldots, f_m): U \to \mathbb{R}^m$ separately we see that it suffices to deal with the case $m = 1$. Thus let $f: U \to \mathbb{R}$ be a smooth map with $f(0) = 0$. Note that in this case we need to show that there exist smooth maps $a_1, \ldots, a_n: U \to \mathbb{R}$ such that $a_i(0) = \frac{\partial f}{\partial x_i}(0)$ and with

$$f(x) = \sum_{i=1}^n a_i(x_i) \cdot x_i \quad \text{for all } x = (x_1, \ldots, x_n) \in U.$$ 

We observe that given any $x = (x_1, \ldots, x_n) \in U$ we have

$$f(x) = f(x) - f(0) = \int_{t=0}^{t=1} \frac{d}{dt} f(tx) \, dt = \int_{t=0}^{t=1} \sum_{i=1}^n \frac{\partial f(tx)}{\partial x_i} \cdot x_i \, dt = \sum_{i=1}^n \int_{t=0}^{t=1} \frac{\partial f(tx)}{\partial x_i} \, dx_i \cdot x_i = a_i(x).$$

It follows from the above equality and the product rule that we have indeed the equality $a_i(0) = \frac{\partial f}{\partial x_i}(0)$.

We move on to the following definition.

**Definition.** Let $U \subset \mathbb{R}^m$ and $V \subset \mathbb{R}^n$ be open sets. We say that a map $f: U \to V$ is a **diffeomorphism** if $f$ is smooth, if $f$ is a bijection and if $f^{-1}: V \to U$ is also smooth. If such a diffeomorphism exists, then we say that $U$ and $V$ are **diffeomorphic**.
Next we recall the following proposition from the analysis courses. Since it is one of the reasons why later on dealing with smooth manifolds is easier than dealing with topological manifolds we also give the proof.

**Proposition 6.17.** Let $U \subset \mathbb{R}^m$ and $V \subset \mathbb{R}^n$ be open sets.

1. If $f: U \to V$ is a diffeomorphism, then for any $P \in U$ the differential $D_f P$ is an invertible matrix.
2. If $U$ and $V$ are diffeomorphic and non-empty, then $m = n$.

**Example.** Suppose $U$ is an open subset, let’s say connected, of $\mathbb{R}^n$ and that $f: U \to \mathbb{R}^n$ is a smooth map such that $D_f P$ is invertible for every $P \in U$. One might be tempted to think that $f: U \to f(U)$ is already a diffeomorphism itself. But this is not necessarily the case, a counterexample is for example given by

$$f: \mathbb{C} \setminus \{0\} \to \mathbb{C} \setminus \{0\} \quad z \mapsto z^2.$$ 

One can easily verify that $D_f z$ is invertible for every $z \in \mathbb{C} \setminus \{0\}$. But $f$ is evidently not injective.

**Proof.**

1. Let $f: U \to V$ be a diffeomorphism between open sets $U \subset \mathbb{R}^m$ and $V \subset \mathbb{R}^n$. We denote by $g: V \to U$ the inverse of $f$. Let $P \in U$. It follows from the chain rule, i.e. from Proposition 6.15, that the matrices $D_f P$ and $D_{f(P)} g$ are inverses of one another, in particular $D_f P$ is invertible.

2. Since $U$ is non-empty we can find a $P \in U$. By (1) the $(m \times n)$-matrix $D_f P$ is invertible, this means that the matrix is a square matrix, i.e. $m = n$. ■

Before we state the next theorem let us introduce the following harmless definition.

**Definition.** Let $f: U \to V$ be a smooth map between two open subsets of $\mathbb{R}^n$ and let $P \in U$. We say $f$ is a local diffeomorphism at $P$ if there exist open neighborhoods $U'$ of $P$ in $U$ and $V'$ of $f(P)$ in $V$ such that $f|_{U'}: U' \to V'$ is a diffeomorphism.

![Figure 137](image)

Now we can formulate the following theorem which can be viewed as a partial inverse to Proposition 6.26 (1a).

**Theorem 6.18. (Inverse Function Theorem)** Let $f: U \to V$ be a smooth map between two open subsets of $\mathbb{R}^n$ and let $P \in U$ be a point. If $D_f P$ is invertible, then $f$ is a local diffeomorphism at $P$. 

Proof. This theorem is proved in most courses on multivariable real analysis. A proof is for example given in [Lee02, Corollary C.34].

The Inverse Function Theorem \textbf{6.18} is one of the main results in real analysis. For example the proof of the following proposition rests heavily on the Inverse Function Theorem \textbf{6.18}.

\textbf{Theorem 6.19. (Smooth Invariance of Domain Theorem)} Let $U \subset \mathbb{R}^n$ be an open set and let $f: U \to \mathbb{R}^n$ be a smooth map such that the differential $Df_P$ is invertible at every point $P$ in the open set $U$. Then the following two statements hold:

1. The map $f$ is open, i.e. given any open subset $V \subset U$ the image $f(V)$ is an open subset of $\mathbb{R}^n$.
2. If $f$ is injective, then $f: U \to f(U)$ is a diffeomorphism.

Remark. In the Topological Invariance of Domain Theorem \textbf{50.6} we will see that the statement of the Smooth Invariance of Domain Theorem \textbf{6.19} (1) also holds if we only assume that $f$ is continuous and injective.

Proof. This proposition is a straightforward consequence of the Inverse Function Theorem \textbf{6.18}. We leave it to the reader to fill in the few remaining details or alternatively we refer to [Lee02, Corollary C.36] for a proof.

On a few occasions we will need the following proposition that is proved in [Pol01, Theorem 2.1].

\textbf{Proposition 6.20.} Let $U \subset \mathbb{R}^n$ be an open subset, let $f: U \to \mathbb{R}^n$ be a smooth map and let $P \in U$. If $Df_P$ is invertible, then there exists an $\epsilon > 0$ such that $f(B^n_\epsilon(P))$ is convex.

6.6. Smooth manifolds. In this section we will define the notion of a smooth structure on a topological manifold. We will refer to a topological manifold that is equipped with a “smooth structure” as a smooth manifold. One can easily fill many books just with the theory of smooth manifolds. Since it is not our goal to write a book on smooth manifolds we will only give a fairly quick introduction to smooth manifolds. We refer to the many books on smooth manifolds, e.g. [Lee02, Jä93] for details.

Now we can continue with the definition of a smooth manifold.

\textit{Definition.}

\begin{enumerate}
\item An atlas $\{\Phi_i: U_i \to V_i\}_{i \in I}$ for an $n$-dimensional topological manifold $X$ is called smooth if for all $i, j \in I$ the transition map
\[
\Phi_j \circ \Phi_i^{-1}: \Phi_i(U_i \cap U_j) \to \Phi_j(U_i \cap U_j)
\]
is smooth.

\item An $n$-dimensional smooth manifold is a pair $(X, \mathcal{A})$ consisting of an $n$-dimensional topological manifold $X$ together with a smooth atlas $\mathcal{A}$ for $X$. (As with many other definitions we usually suppress the choice of a smooth atlas from the notation.) We refer to $X$ as the underlying topological manifold.
\end{enumerate}
(3) We define the boundary of a smooth manifold \((X, \mathcal{A})\) as the set of all points that do not admit a chart of type (i) from the given atlas \(\mathcal{A}\).\(^{97}\)

**Remark.**

(1) In the literature the term “manifold” gets used with wildly different meanings, in particular often it gets to mean “topological manifold” or “smooth manifold”. To prevent any misunderstanding we only rarely write “manifold” without any decorations, in we mostly do so in informal discussions where the precise meaning is irrelevant.

(2) Rather surprisingly in 1960 Michel Kervaire [Kerv60] showed that there exists a 10-dimensional topological manifold that does not admit a smooth atlas.

The following proposition gives us interesting examples of smooth manifolds.

**Proposition 6.21.** The following topological spaces admit a smooth atlas:

1. open subsets of \(\mathbb{R}^n\),
2. all closed balls \(\overline{B}^n\),
3. all spheres \(S^n \subset \mathbb{R}^{n+1}\),
4. the \(n\)-dimensional torus \((S^1)^n\),
5. the surfaces of genus \(g \in \mathbb{N}_0\), as defined on page 205,
6. the non-orientable surfaces of genus \(g \in \mathbb{N}\), as defined on page 206.

More precisely, the atlases that we provided in Section 6.2 and in the proof of Proposition 6.8 are smooth.

**Proof (⋆).** It is straightforward to verify that the atlases for examples (1) to (4) that we provided in Section 6.2 are smooth. It remains to consider the (non-orientable) surfaces of genus \(g \geq 2\). The atlas that we provided in the proof of Proposition 6.8 looks more dubious. In fact all transition maps are compositions of (some of) the following types of maps:

1. reflections in lines,
2. translations,
3. and for some \(\eta > 0\) the map
   \[
   \{ re^{ia} | r \in (0, \eta), a \in (0, \frac{\pi}{4}) \} \rightarrow \{ re^{ia} | r \in (0, \eta), a \in (0, \frac{3\pi}{4}) \}
   
   \frac{r e^{i\alpha}}{\mid z \mid} \mapsto \frac{r e^{3i\alpha}}{\mid z \mid^3},
   \]
4. the inverse of (3).

It is clear that the first three types of maps are smooth. It follows from Theorem 6.19 (2) that the fourth map is also smooth. Thus the transition maps in the atlas are smooth. \(\blacksquare\)

For completeness we state the following lemma which follows easily from the definitions.

---

\(^{97}\)In fact in Proposition 44.2 (2) we will see that the boundary of a smooth manifold in the above sense agrees with the boundary of a topological manifold. But since so far we do not have the tools to prove this statement we prefer to use this definition.
**Lemma 6.22.** Let $M$ be a smooth manifold and let $X$ be an open subset of $M$.

1. The restrictions of the charts of the smooth atlas of $M$ to $X$ define a smooth atlas for $X$.
2. The boundary $\partial X$ of $X$ viewed as a smooth manifold is given by $\partial X = X \cap \partial M$.

**Remark.**

1. There exist smooth manifolds that are homeomorphic but not diffeomorphic. In fact, John Milnor [Miln56a] showed in 1956 that there exist smooth manifolds that are homeomorphic to $S^7$ but that are not diffeomorphic to $S^7$. In other words, Milnor showed that $S^7$ admits at least two different smooth structures.

---

98 If $M$ is an $m$-dimensional smooth manifold and if $N$ is an $n$-dimensional smooth manifold, then the map $\Psi \circ f \circ \Phi^{-1}$ is a map from an open subset of $\mathbb{R}^m$ or from an open subset of $H_m = \{(x_1, \ldots, x_m) | x_m \geq 0\}$ to $\mathbb{R}^n$, hence the notion of smooth makes sense for such a map.

99 This is of course just a generalization of the definition on page 272.
(2) It follows from [KSi77, p. 251] together with [KeM63, Theorem 1.2] that in dimension \( n \neq 4 \) every topological manifold admits at most a finite number of smooth structures. (We also refer to [AMB07, Chapter 7] and especially to [Scor05, p. 207-224] for more details.) Amazingly, this statement is wrong in dimension 4. More precisely there is a plethora of closed 4-dimensional smooth manifolds that admit an infinite number of smooth structures, see e.g. Theorem 102.13 for details.

The following harmless lemma contains three basic statements about smooth maps between smooth manifolds.

**Lemma 6.23.** Let \( f : M \to N \) be a map between two smooth manifolds.

1. If there exists an open cover \( \{U_i\}_{i \in I} \) of \( M \) such that each restriction \( f|_{U_i} : U_i \to N \) is smooth, then \( f \) itself is smooth.
2. If \( f : M \to N \) is smooth it is also continuous.
3. If \( f : M \to N \) is a bijection (e.g. if it is a homeomorphism) and if it is a local diffeomorphism, then it is in fact a diffeomorphism.

**Proof.**

(1) This statement follows from the observation that smoothness is an open condition.

(2) This statement is a straightforward consequence of Lemma 2.35 and the well-known fact that given an open set \( U \subset \mathbb{R}^n \), any smooth map \( U \to \mathbb{R}^m \) is also continuous. We refer to [Lee02, Proposition 2.4] for more details.

(3) Let \( f : M \to N \) be a local diffeomorphism that is a bijection. We need to show that \( f^{-1} : N \to M \) is also smooth. But that follows immediately from (1) and our hypothesis that \( f \) is a local diffeomorphism. \( \blacksquare \)

We continue with the following definition.

**Definition.** Given a smooth atlas \( \mathcal{A} \) for a topological manifold \( M \) we define the **maximal smooth atlas** of \((M, \mathcal{A})\) to be the set of all charts of type (i) and (ii) from page 261 that are smooth maps with respect to the given smooth structure.\(^{100}\)

The verification of the following lemma is left to the reader.

**Lemma 6.24.** Let \((M, \mathcal{A})\) be a smooth manifold.

1. The maximal atlas of \((M, \mathcal{A})\) is a smooth atlas for \( M \) that contains \( \mathcal{A} \).
2. The maximal atlas of \((M, \mathcal{A})\) equals the union of all smooth atlases of \( M \) that are equivalent to the atlas \( \mathcal{A} \).

In the previous section we introduced the notion of a submanifold of a topological manifold. We add the following convention.

**Convention.** If \( M \) is a smooth manifold, then we demand that in the definition of a “submanifold” on page 270 the charts come from the maximal smooth atlas.

\(^{100}\)Let \( \Phi : U \to V \) be a chart for \( M \). By the convention from Lemma 6.22 we view \( U \) as a smooth manifold. Furthermore recall that we view any open subset of \( \mathbb{R}^n \) and \( H_n \) as a smooth manifold with the obvious smooth atlas given by the identity. Thus it makes sense to ask whether or not \( \Phi : U \to V \) is smooth.
Remark. Sometimes the above convention can be ambiguous. For example, if we consider $M = \mathbb{R}^2$ it is not clear whether we view $M$ as a topological manifold or as a smooth manifold. If from the context it is not clear what we mean, then we distinguish in our language between a topological submanifold and a smooth submanifold. This distinction is illustrated in Figure 139.

![Figure 139](image.png)

**Figure 139**

topological submanifold of $\mathbb{R}^2$, but not a smooth submanifold of $\mathbb{R}^2$

smooth submanifold of $\mathbb{R}^2$

Examples.

1. We consider the topological manifold $M = \mathbb{R}^2$ with the smooth atlas $\mathcal{A}$ given by the identity $\Phi = \text{id}_M$. Let $f: \mathbb{R} \to \mathbb{R}$ be a smooth function. We consider the subset $\mathcal{N} = \{(x, f(x)) \mid x \in \mathbb{R}\}$. We cannot use the unique chart $\Phi$ in our atlas $\mathcal{A} = \{\Phi\}$ to show that $\mathcal{N}$ is indeed a submanifold of the smooth manifold $(\mathbb{R}^2, \mathcal{A})$. But the chart $\Psi: \mathbb{R}^2 \to \mathbb{R}^2$ given by $\Psi(x, y) = (x, y - f(x))$ lies in the maximal atlas of $(\mathbb{R}^2, \mathcal{A})$ and we can use it to verify that $\mathcal{N}$ is indeed a submanifold of the smooth manifold $(\mathbb{R}^2, \mathcal{A})$.

2. In Figure 140 we show a smooth manifold $M$ with boundary together with two subsets $K$ and $L$. In Exercise 6.11 we will see that both $K$ and $L$ are submanifolds of the topological manifold $M$ but that they are not submanifolds if we view $M$ as a smooth manifold.

![Figure 140](image.png)

Remark. As we remarked on page 272 there are various subtly different definitions of a “submanifold” out in the literature. This is even more pronounced when it comes to submanifolds of smooth manifolds, especially if $M$ and $N$ are allowed to have boundary.

1. Surely there is no textbook that would consider $L$ in Figure 140 as a submanifold of the smooth manifold $M$. As we remarked above, if we follow our convention or the convention of [Wall16, p. 31], then $K$ is not a submanifold of $M$. On the other
hand the definition used in [Lee02, p. 98] or [Hirs76, p. 30] views \( K \) as a smooth submanifold of the smooth manifold \( M \).

(2) Also note that what we call a proper submanifold is called a neat submanifold in [Hirs76, p. 30].

The following lemma follows almost immediately from Lemma 6.11 and the definitions. We leave it to the reader to fill in the details.

**Lemma 6.25.** Let \( M \) be a smooth manifold and let \( N \) be a submanifold of \( M \). Then \( N \) admits a natural structure of a smooth manifold which has the property that the inclusion map \( N \to M \) is a smooth map.

**Example.** Let \( M \) be a smooth manifold and let \( U \subset M \) be an open subset. As on page 272 one sees easily that \( U \) is a codimension-zero submanifold of \( M \). Furthermore, if we use Lemma 6.25 to view \( U \) as a smooth manifold in its own right, then it follows again basically immediately from the definitions that \( \partial U = U \cap \partial M \).

On many occasions we will develop the theory of topological and of smooth manifolds in parallel. In colloquial terms we sometimes use just the term “manifolds”, without adjectives, to indicate that we are interested on both types or that the type is irrelevant. In actual definitions and statements we will never use the term “manifold” and we will specify explicitly use the cumbersome expressions “smooth manifold” and “topological manifold”. Since the underlying topological space of a smooth manifold is a topological manifold, many results on topological manifolds hold by fiat also for smooth manifolds.

6.7. **Topological properties of smooth manifolds.** In this section we will employ several results from Section 6.5 to draw conclusions on smooth manifolds. The fact that real analysis provides us with such powerful tools is one of the reasons why dealing with smooth manifolds is much easier than dealing with topological manifolds.

**Proposition 6.26.** Let \( M \) be a non-empty \( m \)-dimensional smooth manifold and let \( N \) be an \( n \)-dimensional smooth manifold. If \( M \) and \( N \) are diffeomorphic, then \( m = n \).

**Proof.** The proposition follows easily from Proposition 6.17 by considering charts.

Proposition 6.26 thus says, in particular, that the dimension of a non-empty smooth manifold is well-defined. Eventually, using homology groups, we will show that the analogous statements also holds for topological manifolds.

As mentioned earlier, the Inverse Function Theorem 6.18 and the resulting Theorem 6.19 are some of the main tools coming from real analysis. In particular one can use them to prove the following, slightly subtle proposition.

**Proposition 6.27.** Let \( X \) be an \( n \)-dimensional smooth manifold, i.e. \( X \) is an \( n \)-dimensional topological manifold equipped with a smooth atlas. The following statements hold:

1. Every point on \( X \) admits either a chart of type (i) from the given smooth atlas or it admits a chart of type (ii) from the given smooth atlas.
2. The boundary \( \partial X \) has a canonical structure of an \( (n-1) \)-dimensional smooth manifold with \( \partial(\partial X) = \emptyset \). Furthermore the inclusion map \( \partial X \to X \) is a smooth map.
Any union of components of \( \partial X \) is a closed subset of \( X \). In particular \( \partial X \) itself is a closed subset of \( X \).

(b) If \( X \) is compact, then \( \partial X \) is also compact.

(4) If \( \partial X \) is non-empty, then \( X \setminus \partial X \) is non-compact.

(5) If \( N \subset X \) is a proper \( k \)-dimensional submanifold, then we have \( N \cap \partial X = \partial N \) and \( N \cap \partial X = \partial \) is a proper \((k - 1)\)-dimensional submanifold of \( \partial X \).

\[ \text{Figure 141. Illustration of Proposition 6.27(5).} \]

**Remark.** Here again we would expect that a similar statement should hold for topological manifolds. But since for topological manifolds we have fewer tools, e.g. right now we are missing an analogue of Theorem \([6.19\) we have to postpone a proof for topological manifolds to Proposition 44.2.

**Proof (\( \star \)).** Let \( X \) be an \( n \)-dimensional topological manifold that is equipped with a smooth atlas \( \{ \Phi_i : U_i \to V_i \}_{i \in I} \).

(1) With a little bit of effort this statement can be deduced from Theorem \([6.19\). We refer to [Lee02 Theorem 1.46] for the full details.

(2) First note that it follows from Lemma \([2.12\) and from Lemma \([6.1\) (2) that \( \partial X \) is Hausdorff and second-countable. Now it remains to show that \( \partial X \) has a canonical smooth structure. We start out with the following observation. Let \( \Phi : U \to V \) be a chart of type (ii) for \( X \). Note that it is a chart of type (i) precisely for the points in \( \Phi^{-1}(\partial H_n) \). It follows from (1) and the definition of \( \partial X \) that \( \Phi^{-1}(\partial H_n) = \partial X \cap U \).

Given \( i \in I \) we now set \( \tilde{V}_i = V_i \cap \partial H_n \), we set \( \tilde{U}_i := \Phi_i^{-1}(\partial H_n) \) and we set \( \tilde{\Phi}_i := \Phi_i |_{\tilde{U}_i} \).

It follows fairly easily from the above discussion that that \( \{ \tilde{\Phi}_i : \tilde{U}_i \to \tilde{V}_i \}_{i \in I} \) is a smooth atlas for \( \partial M \) and that with respect to this atlas every point in \( \partial X \) admits a chart of type (i). In other words, \( \partial(\partial X) = \emptyset \).

Finally note that it follows easily from the fact that the inclusion \( \mathbb{R}^{n-1} \xrightarrow{x \mapsto (x,0)} \mathbb{R}^n \)

is smooth that the inclusion \( \partial X \to X \) is a smooth map.

(3) The proof of the third statement is identical to the proof of Lemma \([6.7\)\(^{102}\).

(4) So suppose that the boundary \( \partial X \) is non-empty. Let \( P \in \partial X \). Let \( P \in \partial X \). Given \( r \in \mathbb{R} \geq 0 \) we write \( V_r := \{(x_1, \ldots , x_n) \in B^n_r \mid x_n \geq 0 \} \) and we denote by \( V_r \) the closure of \( V_r \) in \( \mathbb{R}^n \). We write \( V = V_1 \). We can and will pick a chart \( \Phi : U \to V \) of type (ii) with \( \Phi_1 \) has a canonical smooth structure.

\(^{101}\)Here \( \partial N \) denotes the boundary of \( N \), viewed as a smooth manifold in its own right.

\(^{102}\)Note that this statement does not follow directly from Lemma \([6.7\) since our definition of the boundary of a smooth manifold, given on page \([277\) is a priori different from the definition of the boundary of a topological manifold. Only later in Proposition \([44.2\) (2) will we see that there is no difference.
Ph(P) = 0. We write \( \Psi := \Phi^{-1} \colon V \to U \). Given \( n \in \mathbb{N} \) we consider

\[
U_n = \left( X \setminus \Psi\left( \frac{1}{n} \right) \right) \cap \left( X \setminus \partial X \right)
\]

(open by [3a] and (3))

We make the following observations:

(a) As discussed, the sets \( U_n \) are open and it is clear that they cover \( X \setminus \partial X \).

(b) It follows from (1) that \( U \cap \partial X = \Psi(\partial V) \). This implies that no finite collection of these sets covers \( X \setminus \partial X \).

(c) The combination of (a) and (b) shows \( X \setminus \partial X \) is not compact.

(5) This statement follows now easily from the definition of a proper submanifold. We leave it to the reader to fill in the details.

Next we introduce the following notation.

**Notation.** Let \( M \) be an \( n \)-dimensional smooth manifold and let \( X \) be an \( n \)-dimensional submanifold. We write \(^{103}\)

\[ \partial_0 X := \partial X \setminus M \quad \text{and} \quad \partial_1 X := \partial X \cap \partial M. \]

We refer to Figure 143 for an illustration.

The following lemma is used frequently, often without noticing it.

**Lemma 6.28.** Let \( M \) be an \( n \)-dimensional smooth manifold and let \( X \) be an \( n \)-dimensional submanifold. If \( X \) is a closed subset of \( M \) (e.g. if \( X \) is a compact subset), then the following statements hold:

1. \( \partial_0 X \) and \( \partial_1 X \) are unions of components of \( \partial X \).
2. The boundary of \( X \) as a subset of \( M \) agrees with \( \partial_0 X \).
3. The interior \( \hat{X} \) of \( X \) as a subset of \( M \) agrees with \( X \setminus \partial_0 X \).

\(^{103}\)Here \( \partial X \) denotes the boundary of \( X \) viewed as a smooth manifold in its own right.
Proof (*). Let $X$ be an $n$-dimensional submanifold of $M$ that is a closed subset of $M$.

(1) It follows easily from Proposition 6.27 (1) that $\partial_1 X = \partial X \cap \partial M$ is an open subset of $\partial X$. Since $X$ is a closed subset of $M$, it also follows from Proposition 6.27 (3) that $\partial_1 X = \partial X \cap \partial M$ is a closed subset of $\partial X$. Thus it follows from Lemma 2.68 (4) that $\partial_1 X$ is a union of components of $\partial X$. Evidently $\partial_0 X$ is the union of the remaining components of $\partial X$.

(2) Let $P \in M$. The desired statement follows from the following observations:

\[ P \text{ lies in the boundary of } X \text{ as a subset of } M \iff P \text{ lies on } X \text{ and every open neighborhood of } P \text{ contains a point in } M \setminus X \iff P \text{ admits a submanifold chart of type (\(\gamma\))} \]

since $X$ is a submanifold of codimension zero

\[ P \text{ lies on the boundary of } X \text{ viewed as a smooth manifold but it does not lie on } \partial M. \]

Proposition 6.27 (1)

(3) This statement follows immediately from (2) together with Lemma 2.8 (6).

We continue with the following definition.

Definition. Let $M$ be an $n$-dimensional smooth manifold. We say $M$ is decomposed into submanifolds \{\(A_i\)\}_{i \in I} if the following conditions hold:

1. We have $M = \bigcup_{i \in I} A_i$.
2. Each $A_i$ is an $n$-dimensional submanifold of $M$.
3. Each $A_i$ is a closed subset of $M$.
4. For any $i, j \in I$ with $i \neq j$ the intersection $A_i \cap A_j$ is a union of boundary components of $A_i$ and it is a union of boundary components of $A_j$.

This definition is illustrated in Figure 144.

![Figure 144](image)

The following lemma shows that the Klein bottle and the real projective plane admit some interesting decompositions into submanifolds.

Lemma 6.29.

1. We can decompose the Klein bottle into two submanifolds $M$ and $N$ where $M$ and $N$ are both diffeomorphic to the Möbius band.
6. TOPOLOGICAL MANIFOLDS AND SMOOTH MANIFOLDS

Proposition 6.30. (*) Let \( M \) be an \( n \)-dimensional smooth manifold and let \( W \) be an \( n \)-dimensional submanifold of \( M \) with \( W \cap \partial M = \emptyset \). If \( W \) is compact, then the following two statements hold:

1. The smooth manifold \( M \) is decomposed into the submanifolds \( M \) and \( X := M \setminus \hat{W} \).

(Recall that by Lemma 6.28 we know that the interior \( \hat{W} \) of \( W \) as a subset of \( M \) agrees with \( W \setminus \partial W \) where \( \partial W \) denotes the boundary of \( W \) viewed as a smooth manifold in its own right.)

2. If \( M \) is connected and if \( \partial W \) is connected, then \( M \setminus \hat{W} \) is also connected.
(3) If $M$ is compact, then $M \setminus \mathring{W}$ is also compact.

\[\begin{tikzpicture}
  \node (M) at (0,0) {$M$};
  \node (W) at (0,-2) {$W$};
  \node (Wd) at (0,-4) {$W \setminus \partial W$};
  \node (Mbd) at (0,-6) {$M \setminus \partial M$};
  \draw [->] (M) -- (W);
  \draw [->] (M) -- (Wd);
  \draw [->] (W) -- (Wd);
\end{tikzpicture}\]

Figure 148. Illustration of Proposition 6.30.

Proof (*).

(1) First note that it is a consequence of Lemma 2.17 and the fact that smooth manifolds are Hausdorff that $W$ is a closed subset of $M$. The statement is now a fairly immediate consequence of Lemma 6.28. We leave it to the reader to fill in the details.

(2) This statement follows immediately from Lemma 6.28 together with Lemma 2.63.

(3) Since $\mathring{W}$ is an open subset of $M$ we see that $M \setminus \mathring{W}$ is a closed subset of $M$. If $M$ is compact, then it follows from Lemma 2.17 that $M \setminus \mathring{W}$ is indeed compact.

We conclude this section with one more technical statement. To formulate this statement we need the following definition which we had already introduced in Exercise 2.47.

Definition. Let $X$ be a topological space. A subset $A \subset X$ is called precompact if the closure $\overline{A}$ is compact.

Now we can formulate the last result of this section.

Proposition 6.31. (*) Given any $n$-dimensional topological manifold $M$ there exists a countable basis $\{U_i\}_{i \in \mathbb{N}}$ of the topology with the following properties:

(1) Each $U_i$ is open and each $U_i$ is precompact.

(2) Given any $i \in \mathbb{N}$ there exists either a homeomorphism $\varphi_i : B^n \to M$ or a homeomorphism $\varphi_i : B^n \cap H_n \to M$.

Furthermore, if $M$ is in fact a smooth manifold, then the following condition is satisfied:

(2') In (2) above, the maps $\varphi_i$ can be chosen to be diffeomorphisms.

Sketch of proof (*).

(1) If $M$ is an open subset of $\mathbb{R}^n$, then the statement follows immediately from Lemma 2.7.

If $M$ is an open subset of the upper half-space $H_n$, then the statement follows from a modest variation on the argument of Lemma 2.7.

(2) By Lemma 6.2 we know that $M$ admits a countable atlas.

(3) The general statement is now a consequence of (1), (2) and Exercise 2.47.

We leave it to the reader to fill in the details. Alternatively, a somewhat more detailed account of the proof is given in [Lee02, Lemma 1.10].

6.8. Manifolds and group actions. Now we return to group actions since these are one of the best ways to construct new topological spaces and manifolds.
**Definition.** Let $M$ be a smooth manifold with an action by a group $G$. We say that the action is *smooth* if for every $g \in G$ the map

$$
M \to M \\
x \mapsto g \cdot x
$$

is smooth.

**Example.** Basically all the actions on smooth manifolds that we had written down so far are smooth. We will study some examples in greater detail after the next proposition.

The following proposition is the main result of this section.

**Proposition 6.32.** If $G$ is a group that acts freely, properly and continuously on an $n$-dimensional topological manifold $M$, then the following hold:

1. The quotient space $M/G$ is also an $n$-dimensional topological manifold and the projection map $p : M \to M/G$ is a local homeomorphism.
2. If $M$ is a smooth manifold and if $G$ acts smoothly, then there exists a unique smooth structure on $M/G$ such that the projection map $p : M \to M/G$ is a local diffeomorphism.

Furthermore, in both cases the following three statements hold:

(a) The $G$-action restricts to an action on $\partial M$ and we have $\partial(M/G) = (\partial M)/G$.
(b) If $M$ is compact, then $M/G$ is compact.
(c) If $M$ is closed, then $M/G$ is closed.

**Examples.**

1. The action

$$
\mathbb{Z}^n \times \mathbb{R}^n \to \mathbb{R}^n \\
(z,v) \mapsto z + v
$$

from page 186 is free, proper and smooth. It follows from Proposition 6.32 that $\mathbb{R}^n/\mathbb{Z}^n$ is an $n$-dimensional smooth manifold.

2. Using the action of $G = \mathbb{Z}$ on $M = \mathbb{R} \times [-1,1]$ from page 188 we obtain that the Möbius band $([\mathbb{R} \times [-1,1]])/\mathbb{Z}$ is a 2-dimensional smooth manifold. Furthermore, we have

$$
\partial(\text{Möbius band}) = ([\mathbb{R} \times \{-1,1\}])/\mathbb{Z} \cong S^1.
$$

[Proposition 6.32 (a)](3) see Exercise 3.37

3. Finally, using the action from page 187 of $G = \{\pm 1\}$ on $M = S^n$ we obtain that the real projective space $\mathbb{R}P^n = S^n/\{\pm 1\}$ is a closed $n$-dimensional smooth manifold. Now let $m \leq n$. On page 194 we introduced the convention that we view $\mathbb{R}P^m$ as a subset of $\mathbb{R}P^n$. We leave it as a voluntary exercise to verify that $\mathbb{R}P^m$ is in fact a submanifold of $\mathbb{R}P^n$.

The proof of Proposition 6.32 relies on the following two somewhat technical lemmas.

---

104 We will give an explicit smooth atlas for $\mathbb{R}P^n$ in Exercise 6.22.
Lemma 6.33. (*) Let $X$ be a topological space and let $G$ be a group that acts freely, properly and continuously on $X$. If $X$ is Hausdorff, then for every $x \in X$ there exists an open neighborhood $U$ such that $gU \cap U = \emptyset$ for all $g \neq e$.

Proof of Lemma 6.33. (*) Let $X$ be a topological space that is Hausdorff. Furthermore let $G$ be a group that acts freely, properly and continuously on $X$. Finally let $x \in X$. Since $G$ acts freely we know that for every non-trivial $g \in G$ we have $gx \neq x$.

Since the action is proper and continuous we can apply Lemma 3.34 to $a = b = x$ and we obtain open neighborhoods $A$ and $B$ of $x$ such that $gA \cap B = \emptyset$ for every non-trivial $g \in G$. Thus $U := A \cap B$ has the desired property.

Lemma 6.34. (*) Let $X$ be a topological space that is Hausdorff. Furthermore let $G$ be a group that acts continuously on $X$. We denote by $p: X \to X/G$ the projection. If $U \subseteq X$ is an open subset such that the map $p: U \to X/G$ is injective, then the map $p: U \to p(U)$ is a homeomorphism.

Proof of Lemma 6.34. (*) By Lemma 3.30 the projection $p: X \to X/G$ is continuous. Thus the restriction of $p$ to $U$ is also continuous. By our hypothesis the map $p: U \to p(U)$ is injective and evidently it is surjective. Thus the map is a bijection. By Lemma 3.30 (2) the map is furthermore open. It follows from Lemma 2.42 (2) that the map $f: U \to p(U)$ is in fact a homeomorphism.

Now we are in a position to prove Proposition 6.32. For clarity we deal with topological manifolds and smooth manifolds separately.

Proof of Proposition 6.32 for topological manifolds. Let $M$ be an $n$-dimensional topological manifold and let $G$ be a group that acts on $M$. We suppose that the action is continuous, free and proper. We want to show that $M/G$ is an $n$-dimensional topological manifold. Thus we need to prove the following claim.

Claim.

(1) $M/G$ is second-countable,
(2) $M/G$ is Hausdorff, and
(3) every point $y \in M/G$ admits an $n$-dimensional chart.

The first statement of the claim follows immediately from Lemma 3.30 and 6.1 (5). The second statement follows from Proposition 3.33. Thus it remains to deal with the third statement. As usual we denote by $p: M \to M/G$ the projection. Let $y \in M/G$. We pick an $x \in M$ with $p(x) = y$. We make the following two observations:

(a) Since $M$ is an $n$-dimensional topological manifold there exists an $n$-dimensional chart $\Phi: V \to W$ with $x \in V$.
(b) By Lemma 6.33 there exists an open neighborhood $U$ of $x$ such that $gU \cap U \neq \emptyset$ for every $g \neq e$. Note that this implies that the restriction of $p: M \to M/G$ to $U$ is injective.
After possibly replacing $U$ and $V$ by $U \cap V$ we can assume that $U = V$. Note that by Lemma 3.30 (2) the projection $p(U)$ is an open neighborhood of $x$. Now we consider the maps

$$p(U) \xrightarrow{p^{-1}} U \xrightarrow{\Phi} W.$$

The map $\Phi$ is by definition a homeomorphism. Furthermore it follows from Lemma 6.34 that the map $p: U \to p(U) \subset M/G$ is a homeomorphism as well. Thus the above map $\Phi \circ p^{-1}: p(U) \to W$ is a homeomorphism, in particular it is an $n$-dimensional chart for $M/G$ that contains $y$. This completes the proof of the claim and thus completes the proof that $M/G$ is an $n$-dimensional topological manifold.

$M = \mathbb{R}$ and the group $G = \mathbb{Z}$ acts by addition

![Diagram](image)

**Figure 149.** Illustration for the proof of Proposition 6.32.

It remains to prove the following claim.

**Claim.**

1. The projection $p: M \to M/G$ is a local homeomorphism.
2. The $G$-action on $M$ restricts to an action on $\partial M$ and we have $\partial(M/G) = (\partial M)/G$.
3. If $M$ is compact, then $M/G$ is compact.
4. If $M$ is closed, then $M/G$ is closed.

We turn to the proofs of these four statements.

1. Implicitly we had already proved the first statement, indeed, given $x \in M$ we run through the above argument and we see, with the same notation, that $p(U)$ is an open subset of $M/G$ and that $p: U \to p(U)$ is a homeomorphism.
2. It follows from Lemma 6.6 (1) that the $G$-action on $M$ restricts to an action on $\partial M$. Furthermore it follows easily from Lemma 6.6 (2) and the above statement (1) that $\partial(M/G) = (\partial M)/G$. We leave it to the reader to fill in the details.
3. The third statement is of course just an immediate consequence of Lemma 2.40.
4. This statement is an immediate consequence of statements (2) and (3).

This completes the proof of the second claim. ■

**Proof of Proposition 6.32 for smooth manifolds (⋆).** Let $(M, \mathcal{A})$ be an $n$-dimensional smooth manifold. Let $G$ be a group that acts freely, properly and smoothly
on $M$. We need to show that $M/G$ admits a smooth atlas such that the projection map $p: M \to M/G$ is a local diffeomorphism.

(1) We run through the proof of Proposition 6.32 (1), but this time only using charts for $M$ that lie in $\mathcal{A}$, and we obtain an atlas $\{\Phi_i: U_i \to V_i\}_{i \in I}$ for $M/G$. It is straightforward to see that any transition map $\Phi_j \circ \Phi_i^{-1}: \Phi_i(U_i \cap U_j) \to \Phi_j(U_i \cap U_j)$ can be written as the composition of (some) the following maps:
(a) charts$^{105}$ and their inverses,
(b) restrictions to open subsets,
(c) the restriction of the action of $g \in G$ on $M$ to some open subset.
All these maps are smooth maps between smooth manifolds.$^{106}$ Thus the transition maps are smooth.

(2) Note that in the above proof of Proposition 6.32 (1) we already saw that the projection $p: M \to M/G$ is a local homeomorphism. It is straightforward to verify that, with our choice of a smooth atlas for $M/G$, the projection is in fact a local diffeomorphism.

The proof of the remaining statements (a), (b) and (c) is basically identical to the above proof for topological manifolds.

Finally, the statement that the smooth structure on $M/G$ is uniquely determined by the smooth structure on $M$ and the property that the projection $M \to M/G$ is a local diffeomorphism is a consequence of Lemma 6.23 (1) and the fact that the action is proper. We leave it to the reader to fill in the details.

We conclude this section with the following amusing lemma. It gives an example of a diffeomorphism that will pop up on several occasions.

**Lemma 6.35.** Let $n \in \mathbb{N}$. If $A \in \text{GL}(n, \mathbb{Z})$ is a matrix, then the map

$$ f(A): \mathbb{R}^n/\mathbb{Z}^n \to \mathbb{R}^n/\mathbb{Z}^n $$

$$ v \mapsto Av $$

is a diffeomorphism. It is orientation-preserving if and only if $A \in \text{SL}(n, \mathbb{Z})$.

**Proof.** We will provide the proof in Exercise 6.18.

**Example.** We consider the map $A = \begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix} \in \text{GL}(2, \mathbb{Z})$. The corresponding self-diffeomorphism $f(A)$ of $\mathbb{R}^2/\mathbb{Z}^2 = ([0, 1] \times [0, 1])/\sim$ is illustrated in Figure 150.

6.9. **Tangent spaces of smooth manifolds.** In this and the following section we introduce tangent spaces and orientations on smooth manifolds. A more detailed account is given in most textbooks on smooth manifolds. The following discussion is based on [Lee02, Chapter 15], [Jä93, Chapter 4] and [Frie16a].

---

$^{105}$Recall that we view open subsets of $\mathbb{R}^n$ as smooth manifolds. With this convention charts are in fact diffeomorphisms between smooth manifolds.

$^{106}$Here the smooth manifolds are open subsets of $\mathbb{R}^n$ or of $M$. 
Definition. Let $M$ be a smooth manifold and let $P \in M$.\footnote{We should stress that we allow $P$ to be in the boundary of $M$.}

1. A derivation at $P$ is a linear map $v : C^\infty(M, \mathbb{R}) \to \mathbb{R}$ such that for every choice of $f, g \in C^\infty(M, \mathbb{R})$ we have
   \[ v(fg) = f(P) \cdot v(g) + v(f) \cdot g(P). \]

2. The set of all derivations at $P$ is called the tangent space $T_PM$ at $P$. We refer to elements of $T_PM$, i.e. we refer to derivations at $P$, also as tangent vectors.

3. Let $P \in \partial M$. We say a tangent vector $v \in T_PM$ points outward, if the following two conditions are satisfied:
   (a) For every smooth map $f : M \to \mathbb{R}_{\geq 0}$ with $f|_{\partial M} \equiv 0$ we have $v(f) \geq 0$.
   (b) There exists a smooth map $f : M \to \mathbb{R}_{\geq 0}$ with $f|_{\partial M} \equiv 0$ such that $v(f) > 0$.

By replacing “$\geq$” and “$>$” by “$\leq$” and “$<$” we obtain the notion of an inward pointing tangent vector.

This definition of a tangent space might sound rather odd, but the following proposition should help in getting some intuition for the definition.

**Proposition 6.36.** Let $M$ be an open subset of $\mathbb{R}^n$ or of $H_n$. For any $P \in M$ the map

\[
\mathbb{R}^n \to T_PM
\]

\[
v \mapsto \left( C^\infty(M, \mathbb{R}) \to \mathbb{R} \quad f \mapsto \frac{d}{dt}|_{t=0}f(P + tv) \right)
\]

is an isomorphism of vector spaces.

**Proof.** The proof of this proposition is an amusing exercise in real analysis. A detailed proof for the case that $M$ is an open subset of $\mathbb{R}^n$ is given in [Lee02, Proposition 3.2]. The case that $M$ is an open subset of $H_n$ follows fairly easily from the definition of a smooth map on $H_n$, see page 272.\qed

Convention. Given an open subset $M$ of $\mathbb{R}^n$ or of $H_n$ and given $P \in M$ we will use the isomorphism $\mathbb{R}^n \cong T_PM$ from Proposition 6.36 to make the identification $T_PM = \mathbb{R}^n$.

The following proposition summarizes some basic properties of the tangent space.
Proposition 6.37. Let $M$ and $N$ be two smooth manifolds.

1. If $f: M \to N$ is a smooth map, then for any $P \in M$ the map
   \[
   Df_P = f_* : T_PM \to T_{f(P)}N
   \]
   \[v \mapsto \left( C^\infty(N, \mathbb{R}) \to \mathbb{R} \right) \]
   \[g \mapsto v(g \circ f) \]
   is linear.

2. The maps from (1) have the following two properties:
   (a) If $\text{id}: M \to M$ is the identity map, then for any $P \in M$ the corresponding map
       $D\text{id}_P: T_PM \to T_PM$ is also the identity.
   (b) For any two smooth maps $f: L \to M$ and $g: M \to N$ between smooth manifolds and any $P \in L$ we have
       \[
       D(g \circ f)_P = Dg_{f(P)} \circ Df_P : T_PL \to T_{g(f(P))}N.
       \]

3. (a) If $f: M \to N$ is a local diffeomorphism, then for any $P \in M$ the corresponding map $Df_P: T_PM \to T_{f(P)}N$ is an isomorphism.
   (b) If $M$ is a codimension-zero submanifold of $N$, then for any $P \in M$ the corresponding map $Df_P: T_PM \to T_{f(P)}N$ is an isomorphism.

4. If $M$ is an $n$-dimensional smooth manifold, then for any $P \in M$ the tangent space is an $n$-dimensional vector subspace of the vector space $\text{Hom}(C^\infty(M, \mathbb{R}), \mathbb{R})$.

Definition. Given a smooth map $f: M \to N$ between two smooth manifold and given $P \in M$ we refer to the map $Df_P: T_PM \to T_{f(P)}N$ from Proposition 6.37 (1) as the differential of $f$ at $P$.

Sketch of proof. The first three statements follow fairly easily from the definitions. Using charts one can reduce the proof of Statement (4) to the case that $M$ is an open subset of $\mathbb{R}^n$ or $H_n$. But we had dealt with this case in Proposition 6.36. We refer to [Lee02, Proposition 3.10] and [Lee02, Proposition 3.6] for more details.

There are several alternative interpretations of the tangent space of a smooth manifold. In the following we will discuss a commonly used definition for submanifolds of $\mathbb{R}^k$.

Definition.

1. Let $M$ be an $n$-dimensional submanifold of $\mathbb{R}^k$. Given any $P \in M$ we define the visual tangent space
   \[V_PM := \text{all derivatives } \gamma'(0) \text{ of smooth maps } \gamma: (-\epsilon, 0] \to M \text{ with } \gamma(0) = P\]
   and all derivatives $\gamma'(0)$ of smooth maps $\gamma: [0, \epsilon) \to M$ with $\gamma(0) = P$.

   This definition is illustrated in Figure 151.

---

\[\text{\textsuperscript{108}}\] The reader who is already familiar with categories will notice that this statement just says that the tangent space at a point is a functor from the category of pointed smooth manifolds to the category of real vector spaces.
Lemma 6.38. (\footnote{Using charts and the chain rule one can show fairly easily that this map is well-defined.}) \footnote{The slightly unfortunate fact we use the same symbol, namely $D f_P$, for two a priori different objects will be dealt with shortly.} \textit{If $W \subset \mathbb{R}^n$ is a $k$-dimensional vector space, then $W$ is a $k$-dimensional submanifold of $\mathbb{R}^n$ and for any $P \in W$ we have $V_P W = W$.}
Proof (*). It follows from elementary linear algebra that \( W \) is a \( k \)-dimensional submanifold of \( \mathbb{R}^n \). We leave it as an elementary exercise to the reader to verify that for any \( P \in W \) we have \( V_P W = W \).

The next proposition elucidates in particular the relationship between the tangent space \( T_P M \) and the visual tangent space \( V_P M \) of a submanifold \( M \) of \( \mathbb{R}^k \).

**Proposition 6.39.**

1. The obvious analogues of the statements of Proposition 6.37 hold for the visual tangent spaces.
2. Let \( M \) be an \( n \)-dimensional submanifold of \( \mathbb{R}^k \) and let \( P \in M \). The map

\[
\Phi_M: V_P M \to T_P M
\]

\[
\gamma'(0) \mapsto \left( C^\infty(M, \mathbb{R}) \to \mathbb{R}, f \mapsto \frac{df}{dt}\bigg|_{t=0} f(\gamma(t)) \right)
\]

is an isomorphism of vector spaces.

(a) The isomorphism restricts to a bijection between outward tangent vectors in \( V_P M \) and outward tangent vectors in \( T_P M \). The same statement also holds with “outward” replaced by “inward”.

(b) If \( f: M \to N \) is a smooth map between submanifolds of \( \mathbb{R}^k \) respectively \( \mathbb{R}^l \), then the following diagram commutes

\[
\begin{array}{ccc}
V_P M & \xrightarrow{\Phi_M} & T_P M \\
\downarrow \Phi & & \downarrow \Phi \\
V_{f(P)} N & \xrightarrow{\Phi_N} & T_{f(P)} N
\end{array}
\]

**Proof.**

1. The proof that the obvious analogues of the statements for Proposition 6.37 hold for the visual tangent spaces is fairly elementary and is left to the reader.

2. First note that it follows almost immediately from the definitions that the given diagram does indeed commute. It remains to show that the horizontal maps are isomorphisms. Using charts it suffices to show this for open subsets of \( \mathbb{R}^n \) and of \( \mathbb{H}^n \). But in this special case that is an immediate consequence of Proposition 6.36.

**Convention.** Given a submanifold \( M \) of some \( \mathbb{R}^k \) and \( P \in M \) we will use the isomorphism from Proposition 6.39 to make the identification \( T_P M = V_P M \).

**Remark.** The above reinterpretation of the tangent space \( T_P M \) can be generalized to any smooth manifold. More precisely, if \( M \) is a smooth manifold and \( P \in M \setminus \partial M \) one can interpret \( T_P M \) as equivalence classes of smooth paths, i.e. of equivalence classes of smooth maps \( \gamma: (-\epsilon, \epsilon) \to M \) with \( \gamma(0) = P \). We refer to [Lee02, p. 72] or [Jä93, Chapter 3.3] for details. The interpretation (or very often the definition) of the tangent space in terms of equivalence classes of smooth paths is very intuitive, but it has the disadvantage that it gets awkward to write down the definition of the tangent space at a point on the boundary.
The following definition is the obvious generalization of the concept introduced on page 275.

**Definition.** Let \( f : M \to N \) be a smooth map between two smooth manifolds and let \( P \in M \setminus \partial M \). We say \( f \) is a local diffeomorphism at \( P \) if there exist open neighborhoods \( U \) of \( P \) in \( M \) and \( V \) of \( f(P) \) in \( N \) such that \( f|_U : U \to V \) is a diffeomorphism.

By Proposition [6.37] we know that for a local diffeomorphism the differential at any point is an isomorphism. The following theorem gives the much more interesting converse. The theorem gives in particular a convenient criterion for showing that a map between smooth manifolds is a (local) diffeomorphism.

**Theorem 6.40. (Inverse Mapping Theorem)\( (*) \)** Let \( f : M \to N \) be a smooth map between two smooth manifolds.

1. Let \( P \in M \) such that \( Df_P \) is invertible.
   - (a) If \( P \notin \partial M \), then \( f \) is a local diffeomorphism at \( P \).
   - (b) If \( P \in \partial M \) and if there exists an open neighborhood \( U \) of \( P \) with \( f(\partial M \cap U) \subset \partial N \), then \( f \) is a local diffeomorphism at \( P \).
2. If \( Df_P \) is invertible for every \( P \in M \), if \( f \) is a bijection and if \( f(\partial M) = \partial N \), then \( f \) is a diffeomorphism.

**Examples.**

1. We consider the inclusion \( i : H = \{(x,y) \in \mathbb{R}^2 | y \geq 0 \} \to \mathbb{R}^2 \) together with the point \( P = (0,0) \in \partial H \). We see that the differential \( Di_P \) is an isomorphism, but the inclusion is not a local diffeomorphism at \( P \). This shows that in general in the formulation of the Inverse Mapping Theorem [6.40] we have to put an extra condition on \( f \) if \( P \in \partial M \).

2. We consider the map
   \[
   f : \mathbb{R}^n \to B^n \\
   (x_1, \ldots, x_n) \mapsto \frac{x_1^2 + \cdots + x_n^2}{1 + x_1^2 + \cdots + x_n^2} \cdot (x_1, \ldots, x_n).
   \]
   One can easily verify that \( f \) satisfies the conditions of the Inverse Mapping Theorem [6.40] (2), thus we see that \( f \) is a diffeomorphism. This is actually quite interesting since at first glance it is not totally apparent why \( f^{-1} : B^n \to \mathbb{R}^n \) is smooth at the origin.

3. We consider the smooth map \( f : M \to N \) that is illustrated in Figure 152. It is a bijection and for every \( x \in M \) the differential \( Df_x : T_x M \to T_{f(x)} N \) is an isomorphism. But evidently \( f \) is not a diffeomorphism. This shows that we cannot drop the condition \( f(\partial M) = \partial N \) in the statement of Inverse Mapping Theorem [6.40] (2).

![Figure 152](image-url)
Sketch of proof.

(1) (a) This can be reduced fairly easily to the Inverse Function Theorem\textsuperscript{6.18} that deals with maps between open subsets of some $\mathbb{R}^n$. We refer to \textsuperscript{Lee02}, Theorem 4.5

for more details.

(b) This statement can also be deduced from the Inverse Function Theorem\textsuperscript{6.18} and the definition of a smooth map on the half-plane $H_n$.

In both cases we leave it to the reader to fill in the details.

(2) The second statement follows immediately from (1) and Lemma\textsuperscript{6.23}(3).

6.10. Orientations of real vector spaces. In the following section we will introduce and study orientations of smooth manifolds. To prepare for that section we will introduce in this section the notion of an orientation of a finite-dimensional real vector space and we will study a few basic properties.

**Definition.** Let $V$ be a finite-dimensional non-trivial real vector space.

1. We say that two bases\textsuperscript{111} of $V$ are equivalent if the determinant of the base change matrix is positive.

2. An equivalence class of bases is called an orientation for $V$. An oriented vector space is a vector space together with an orientation.

3. Let $O$ be an orientation for $V$. We say a basis $\{v_1, \ldots, v_k\}$ of $V$ is a positive basis, if $\{v_1, \ldots, v_k\}$ lies in $O$, otherwise we say that it is a negative basis.

**Remark.**

1. It is straightforward to see that any finite-dimensional non-zero real vector space admits precisely two orientations. Given an orientation $O$ for some vector space $V$ we denote by $-O$ the other orientation. Sometimes we refer to it as the opposite orientation.

2. We always view $\mathbb{R}^n$ as equipped with the orientation such that the canonical basis $\{e_1, \ldots, e_n\}$ is a positive basis.

**Definition.** Let $V$ and $W$ be oriented vector spaces. We say an isomorphism $\Phi: V \to W$ is orientation-preserving if the image of a positive basis of $V$ is a positive basis of $W$. Otherwise we say that $\Phi$ is orientation-reversing.

The following lemma often gets used subconsciously:

**Lemma 6.41.** Let $V_0, \ldots, V_k$ be oriented vector spaces and let $f_i: V_i \to V_{i+1}$, $i = 0, \ldots, k-1$ be isomorphisms. Then

the map $f_{k-1} \circ \cdots \circ f_0: V_0 \to V_k$

is orientation-preserving $\iff$ the number of $f_i$ which are orientation-reversing is even.

**Proof.** The lemma is an elementary exercise in linear algebra that is left to the reader. ■

\textsuperscript{111}Here and throughout the notes a basis of a finite-dimensional vector space is always understood to be an ordered basis.
Lemma 6.42. Let $U, V$ and $W$ be a finite-dimensional real vector spaces and suppose we are given maps

$$U \xrightarrow{\varphi} V \xrightarrow{\psi} W$$

such that $\varphi$ is injective, $\psi$ is surjective and $\text{im}(\varphi) = \ker(\psi)$.\footnote{\text{The experienced reader will notice that this just means that that $0 \rightarrow U \xrightarrow{\varphi} V \xrightarrow{\psi} W \rightarrow 0$ is a short exact sequence.}} We suppose that $U$ and $W$ are oriented. We pick a positive basis $\{u_1, \ldots, u_k\}$ for $U$ and we pick a positive basis $\{w_1, \ldots, w_m\}$ for $W$. Furthermore we pick a right-inverse $s: W \rightarrow V$ of $\varphi$, i.e. we have $\psi \circ s = \text{id}_W$. Then $\{u_1, \ldots, u_k, s(w_1), \ldots, s(w_l)\}$ is an oriented basis for $V$ and the orientation it defines only depends on the orientations of $U$ and $W$.

Definition. In the setting of the above lemma we say that orientations of $U$, $V$ and $W$ are compatible if the orientations of $U$ and $W$ define, in the sense of Lemma 6.42, the orientation of $V$.

Sketch of proof. It is clear that the given vectors define a basis for $V$. Furthermore note that any other choice of a positive basis for $U$, choice of positive basis for $W$ and right-inverse $W \rightarrow V$ leads to a base change matrix of the form

$$\begin{pmatrix} A & X \\ 0 & B \end{pmatrix}$$

with $\det(A) > 0$ and $\det(B) > 0$. Thus the two sets of choices lead to equivalent bases for $W$. \hfill $\blacksquare$

Remark. In Lemma 12.6 we will see that every finite-dimensional complex vector space comes with a canonical orientation. The algebraically inclined reader might want to figure out what this means and how this works.

6.11. Orientations of smooth manifolds. After the preparations from the last section we can now introduce the notion of an orientation on a smooth manifold.

Definition. Let $M$ be a $k$-dimensional smooth manifold with $k \geq 1$.

(1) An orientation for $M$ is a map which assigns to every tangent space $T_P M$, $P \in M$, an orientation such that the following condition is satisfied:\footnote{Convention on page 291}

(*) For every chart $\Phi: U \rightarrow V$ of the smooth structure of $M$ and any component $U'$ of $U$ the map

$$\Phi_*: T_P M \xrightarrow{\cong} T_{\Phi(P)} V = \mathbb{R}^k$$

is either orientation-preserving for all $P \in U'$ or it is orientation-reversing for all $P \in U'$.

(2) A smooth manifold together with an orientation is called an oriented smooth manifold.
A smooth manifold that admits an orientation is called *orientable*, otherwise we say that the smooth manifold is *non-orientable.*

We refer to figure 153 for an illustration.

**Convention.**

1. Given a picture of a 1-dimensional submanifold $M$ of $\mathbb{R}^2$ or $\mathbb{R}^3$ we indicate an orientation by drawing a positive vector in $T_P M = V_P M \subset \mathbb{R}^3$. (Note in this case a non-zero vector is already a basis for the tangent space).

2. Given a picture of a 2-dimensional submanifold of $\mathbb{R}^3$ we often adopt one of the usual two conventions for indicating an orientation:
   
   (a) We draw part of a little circle together with a directional arrow. This indicates that a positive basis is given by $v, w$ where $w$ is obtained by rotating $v$ into the indicated direction by an angle in $(0, \pi)$.

   (b) Alternatively we draw a normal vector $n$, in this case a basis $v, w$ of the tangent space is positive if $n, v, w$ is a positive basis for $\mathbb{R}^3$.

   Both conventions indicate the same orientation of $M$.

**Figure 153**

In practice the following lemma can be quite useful for verifying that orientations of tangent spaces actually define an orientation of a smooth manifold.

**Lemma 6.43.** Let $M$ be a $k$-dimensional smooth manifold with $k \geq 1$. Suppose that for each $P \in M$ we are given an orientation of $T_P M$. The following statements are equivalent:

1. The orientations of the tangent spaces define an orientation $M$.

2. Given any $P \in M$ there exists a chart $\Phi: U \to V$ in the given smooth structure of $M$ such that for any component $U'$ of $U$ the map

$$
\Phi_*: T_P M \xleftarrow{\cong} T_P U \xrightarrow{\Phi_\ast} T_{\Phi(P)} V = \mathbb{R}^k
$$

is either orientation-preserving for all $P \in U'$ or it is orientation-reversing for all $P \in U'$.

**Proof (⋆).** The implication (1) $\Rightarrow$ (2) is a tautology. The reverse implication (2) $\Rightarrow$ (1) follows from the fact that a map that is locally constant, is actually constant. We leave it to the reader to fill in the details.

**Examples.**

Later, on page 1718 we will introduce the notion of an orientation on a 0-dimensional smooth manifold.

One can show fairly easily that it suffices to show that this condition holds for some family of charts that cover $M$. We do not need to verify it for all charts in the given atlas.
(1) Let $U$ be an open subset of $\mathbb{R}^n$ with $n \in \mathbb{N}$. We equip $U$ with the orientation where a positive basis for any tangent space $T_P U = \mathbb{R}^n$ is given by the standard basis for $\mathbb{R}^n$. Since an atlas is given by the identity map we see that this defines an orientation on $U$.

(2) Let $n \in \mathbb{N}$. Given $P \in S^n$ we say that a basis $v_1, \ldots, v_n \in T_P S^n = V_P S^n \subset \mathbb{R}^{n+1}$ is positive if $\det(P, v_1, \ldots, v_n) > 0$.\footnote{How would you formulate this orientation convention purely in terms of derivations?} Using Lemma 6.43 one can easily verify that these orientations define an orientation of the smooth manifold $S^n$. Unless we explicitly say something else we will always view $S^n$ as an oriented smooth manifold with the above orientation.

(3) Let $M$ be an oriented smooth manifold. If for each tangent space we pick the opposite orientation then evidently we obtain again an orientation, which we refer to as the \textit{opposite orientation}. We denote the resulting oriented smooth manifold by $-M$.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{orientation.png}
\caption{Figure 154 Orientations of $S^1$ and $S^2$}
\end{figure}

\textbf{Definition.} Let $f : M \to N$ be a local diffeomorphism between two oriented smooth manifolds.

(1) We say the map $f$ is \textit{orientation-preserving} if for every $P \in M$ the induced isomorphism $f_* : T_P M \to T_{f(P)} N$ is orientation-preserving.

(2) We say the map $f$ is \textit{orientation-reversing} if for every $P \in M$ the induced isomorphism $f_* : T_P M \to T_{f(P)} N$ is orientation-reversing.

\textbf{Examples.}

(1) Let $A \in O(n)$. In Exercise 6.28 we will see that the map $S^n \to S^n$ given by $x \mapsto A \cdot x$ is orientation-preserving if and only if $\det(A) = 1$.

(2) Let $U \subset \mathbb{R}^n$ be an open subset. Let $A \in GL(n)$ with $\det(A) > 0$ and let $v \in \mathbb{R}^n$.

It follows easily from the definitions that the map $f$ given by $f(x) = x \mapsto A \cdot x + v$ defines an orientation-preserving diffeomorphism $U \to f(U)$.

(3) Let $f : M \to N$ be a local diffeomorphism between two oriented smooth manifolds. If $M$ is non-empty and \textit{connected}, then it follows from Lemma 6.46 below that $f$ is either orientation-preserving or orientation-reversing. On the other hand for disconnected $M$ one can easily come up with maps that are neither orientation-preserving nor orientation-reversing.

The following lemma gives an easy criterion for showing that a diffeomorphism between two open subsets of $\mathbb{R}^n$ is orientation-preserving.
Lemma 6.44. Let $f: X \to Y$ be a diffeomorphism between two open subsets of $\mathbb{R}^n$. Given $P \in X$ we have

$$f_\ast = Df_P: T_P X \to T_{f(P)} Y$$

is orientation-preserving if and only if

$$\det(Df_P) > 0.$$ 

Proof. By Proposition 6.39 we have the following commutative diagram

$$\begin{array}{ccc}
\mathbb{R}^n & \xrightarrow{\Phi_X} & T_P X \\
\downarrow f_\ast = Df_P & & \downarrow f_\ast = Df_P \\
\mathbb{R}^n & \xrightarrow{\Phi_Y} & T_{f(P)} Y
\end{array}$$

where the horizontal maps are isomorphisms and where the horizontal maps are orientation-preserving by definition of the orientations of the oriented smooth manifolds $U$ and $V$. Thus it follows from Lemma 6.41 that the left-hand vertical map is orientation-preserving if and only if the right-hand vertical map is orientation-preserving. But by definition the left-hand vertical map is orientation-preserving if and only if $\det(Df_P) > 0$. □

The following lemma gives another approach to defining an orientation on a given smooth manifold.

Lemma 6.45. (⋆) Let $(M, \mathcal{A})$ be a smooth manifold. Suppose that all transition maps between charts in $\mathcal{A}$ are orientation-preserving. Given $P \in M$ we define

$$\text{orientation of } T_P M := (D\Phi_P)^{-1}(\text{orientation of } T_{\Phi(P)} V = \mathbb{R}^n)$$

where $\Phi: U \to V$ is a chart around $P$ from the given atlas. The following statements hold:

1. The definition of the orientation of $T_P M$ does not depend on the choice of the chart.
2. The orientations of the tangent space $T_P M$ define an orientation for $M$.

Sketch of proof (⋆). The first statement follows easily from the hypothesis that the transition maps are orientation-preserving. The second statement is a consequence of the observation in Footnote 114. □

Example. We consider the surface $\Sigma$ of genus 2. In Proposition 6.8 we gave an explicit atlas for $\Sigma$. In Proposition 6.21 we saw that the transition maps are smooth. We leave it to the reader to verify that all the transition maps are in fact orientation-preserving. Thus it follows from Lemma 6.45 that $\Sigma$ is orientable. Basically the same argument shows that all surfaces of genus $g \geq 3$ are also orientable. Note that, as the name suggests, the same approach does not work for the non-orientable surfaces of some genus $g \in \mathbb{N}$.

The following lemma summarizes a few elementary properties of orientations.

Lemma 6.46. Let $n \in \mathbb{N}$ and let $M$ be an $n$-dimensional smooth manifold.

1. If two orientations on $M$ agree at a point and if $M$ is path-connected, then the two orientations agree everywhere.

116Unfortunately the symbol $Df_P$ has several, subtly different meanings. To the left it stands for the induced map on tangent spaces. To the right it stands for the $n \times n$-matrix given by the partial derivatives of $f$. 
(2) If $M$ is path-connected and non-empty, then $M$ is either non-orientable or it admits precisely two orientations, which are opposites of one another.

(3) Let $f: M \to N$ be a diffeomorphism. If $M$ is path-connected, then for any $P \in M$ we have

$$f \text{ is orientation-preserving } \iff D_P f: T_P M \to T_{f(P)} N \text{ is orientation-preserving}.$$ 

(4) Suppose $M$ is equipped with an orientation $O$. Let $f: M \to M$ be a self-diffeomorphism. Then

$$f \text{ is orientation-preserving with respect to } O \iff f \text{ is orientation-preserving with respect to } -O.$$ 

(5) Let $N$ be a submanifold of codimension zero. (In many applications $N$ is just an open subset of $M$.) Then $N$ admits a unique orientation such that the inclusion map $N \to M$ is orientation-preserving.

(6) If $M \setminus \partial M$ admits an orientation, then $M$ admits a unique orientation such that the inclusion $M \setminus \partial M \to M$ is orientation-preserving.

Proof ($\ast$).

(1) Suppose we are given two orientations on $M$. We denote by $U$ the set of all points where the orientations agree and we denote by $V$ the set of all points where the orientations disagree. It follows easily from the definitions that $U$ and $V$ are open. If the orientations agree at a point we see that $U \neq \emptyset$. It follows from Lemma 6.9 (3) that $U = M$.

(2) This statement follows easily from (1).

(3) The proof of this statement is very similar to the proof of the first statement. We leave it to the reader to fill in the details.

(4) This statement follows immediately from the definitions and Lemma 6.41.

(5) This statement follows easily from Proposition 6.37.

(6) Using charts it suffices to prove this statement for smooth manifolds that are open subsets of $H^n$, but in this case the statement is clear. □

We move on to constructing orientations via group actions. The first part of the following proposition can be viewed as a refinement of Proposition 6.32.

**Proposition 6.47.** Let $G$ be a group that acts freely, properly and smoothly on an $n$-dimensional smooth manifold $M$.

(1) If $M$ is oriented and if for each $g \in G$ the map

$$M \to M$$

$$P \mapsto g \cdot P$$

is orientation-preserving, then $M/G$ admits an orientation such that the projection map $p: M \to M/G$ is orientation-preserving.
Conversely, if $M/G$ admits an orientation, then there exists a unique orientation on $M$ such that the projection map $p: M \to M/G$ is orientation-preserving. Furthermore this orientation has the property that the $G$-action on $M$ is orientation-preserving.

Remark. In Exercise 6.20 we will prove a partial converse to Proposition 6.47 (2).

Proof. We leave it to the reader to write down the fairly straightforward proof of the proposition.

Example. Note that the differential of any translation map on $\mathbb{R}^n$ is the identity. Thus it follows from Lemma 6.46 (3) that the action of $\mathbb{Z}^n$ on $\mathbb{R}^n$ that is given by addition is orientation-preserving. It follows from Proposition 6.47 that $\mathbb{R}^n/\mathbb{Z}^n$ is orientable.

We formulate the next examples as a lemma.

Lemma 6.48. The following smooth manifolds are non-orientable:

(1) the Möbius band,
(2) the projective plane $\mathbb{R}P^2$,
(3) the Klein bottle, and
(4) any non-orientable surface of genus $\geq 1$.

Proof. Let $X = \mathbb{R} \times (-1, 1)$ and $G = \mathbb{Z}$. Very similar to the definition on page 188 we consider the action

$$\mathbb{Z} \times (\mathbb{R} \times (-1, 1)) \to \mathbb{R} \times (-1, 1)
(n, (x, y)) \mapsto (x + n, (-1)^n \cdot y).$$

This action is again free, proper and smooth. As on page 189 we refer to the quotient as the open Möbius band.

Claim. The open Möbius band is non-orientable.

Suppose that the open Möbius band $X/\mathbb{Z}$ admits an orientation. It follows from Proposition 6.47 that $X = \mathbb{R} \times (-1, 1)$ admits an orientation such that the $\mathbb{Z}$-action is orientation-preserving. It follows from Lemma 6.46 (3) and (4) that this $\mathbb{Z}$-action preserves the usual orientation on $X = \mathbb{R} \times (-1, 1)$. Given $n \in \mathbb{Z}$ we consider the diffeomorphism of $X = \mathbb{R} \times (-1, 1)$ that is given by the action by $n$, i.e. we consider the diffeomorphism

$$\Phi_n: \mathbb{R} \times (-1, 1) \to \mathbb{R} \times (-1, 1)
(x, y) \mapsto (x + n, (-1)^n \cdot y).$$

Given any $(x, y) \in X$ the differential of $\Phi_n$ is given by the matrix $\begin{pmatrix} 1 & 0 \\ 0 & (-1)^n \end{pmatrix}$. It follows from Lemma 6.44 that for $n$ odd the diffeomorphism $\Phi_n$ is not orientation-preserving. We have thus obtained a contradiction.

We turn to the actual proof that the three given smooth manifolds are non-orientable. By Lemma 6.46 (5) it suffices to prove the following claim.

Claim. The open Möbius band is diffeomorphic to open subsets of the Möbius band, of the projective plane $\mathbb{R}P^2$, of the Klein bottle and for any non-orientable surface of genus $g \geq 3$.
It is clear that the open Möbius band is an open subset of the Möbius band. The statements regarding the projective plane $\mathbb{R}P^2$ and the Klein bottle follow immediately from Lemma 6.29. Finally in Figure 155 we show that for any $g \geq 3$ the non-orientable surface of genus $g$ admits an open subset that is diffeomorphic to the open Möbius band. ■

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{non-orientable_surface_of_genus_3}
\caption{Figure 155}
\end{figure}

**Remark.** For most people starting out with mathematics the definition of a submanifold $M$ of some $\mathbb{R}^n$ and the definition of a tangent space to $M$ as a vector subspace of $\mathbb{R}^n$ are quite natural and reasonable. But initially it is perhaps not clear why one should introduce "abstract" smooth manifolds. Furthermore the definition on page 291 of the tangent space $T_P M$ to such a smooth manifold traditionally leads to a lot of head scratching.

The above proof of Lemma 6.48 is a good example why it is useful to introduce these abstract notions. In principle it is possible to show that Möbius band is non-orientable purely by working in the explicit 3-dimensional setting, see e.g. [Frie16a, Lemma 9.16]. But this proof is rather messy and not very illuminating. In contrast, the fact that we can work with abstract smooth manifolds, in this case with $(\mathbb{R} \times [-1, 1])/\mathbb{Z}$, and their tangent spaces liberates us from the constraints of the 3-dimensional setting and we obtain a much clearer and much more elegant proof that the Möbius band is non-orientable.

The following lemma, which we will prove in Exercise 6.12, generalizes Lemma 6.48 (3).

**Lemma 6.49.** Let $n \in \mathbb{N}_0$. The real projective space $\mathbb{R}P^n$ is orientable if and only if $n$ is odd.

In the next lemma we will see that the boundary of an oriented smooth manifold inherits an orientation.

**Lemma 6.50.** Let $n \geq 2$ and let $M$ be an oriented $n$-dimensional smooth manifold. Let $P \in \partial M$. We denote by $w \in T_P M$ a tangent vector which points outward in the sense of the definition on page 291. We say that a basis $v_1, \ldots, v_{n-1}$ for $T_P(\partial M)$ is a positive basis of $T_P(\partial M)$ if $w, v_1, \ldots, v_{n-1}$ is a positive basis of $T_P M$. The following two statements hold:

1. The definition of a positive basis for $P$ does not depend on the choice of $w$.
2. These orientations of the tangent spaces of $\partial M$ define an orientation on $\partial M$.

**Proof.** We leave the fairly elementary verification of the lemma to the reader. Alternatively full details are given in [Lee02, Proposition 15.24]. ■

**Convention.** Let $n \geq 2$ and let $M$ be an oriented $n$-dimensional smooth manifold. Unless we say something else we always equip $\partial M$ with the orientation given by Lemma 6.50. We refer to this orientation of $\partial M$ as the boundary orientation.
Examples.

(1) If we equip the smooth manifold $\overline{B}^{n+1}$ with the usual orientation coming from $\mathbb{R}^{n+1}$, then the orientation of $\partial \overline{B}^{n+1} = S^n$ agrees with the above orientation of $S^n$.

(2) Given an oriented smooth manifold $N$ we denote by $-N$ the smooth manifold equipped with the opposite orientation. It follows almost immediately from the definitions that $\partial(-N) = -\partial N$.

We conclude this section with the following proposition.

**Proposition 6.51.** (*) Let $M$ be a smooth manifold with possibly non-empty boundary and let $N$ be a smooth manifold with empty boundary. Given $Q \in N$ and $P \in M$ we consider the inclusion maps

$$i_Q : M \to M \times N \quad \text{and} \quad j_P : N \to M \times N$$

$$x \mapsto (x, Q) \quad \text{and} \quad y \mapsto (P, y).$$

The following statements hold:

1. The product $M \times N$ admits a unique smooth manifold structure such that products of smooth charts for $M$ and $N$ lie in the smooth atlas for $M \times N$.
2. With the smooth manifold structure as in (1) the following statements hold:
   a. The projections from $M \times N$ onto $M$ and onto $N$ are smooth.
   b. All the inclusion maps $i_P$ and $j_Q$ are smooth.
3. a. Let $P \in M$ and $Q \in N$. The map

$$i_Q^* + (i_P^* : T_P M \oplus T_Q N \to T_{(P,Q)}(M \times N)$$

is an isomorphism. Sometimes we use this isomorphism to identify the vector spaces to the left and right.

   b. If $M$ and $N$ are oriented and of dimension $\geq 1$, then we obtain an orientation on $M \times N$ by defining

   \[ \text{positive basis of } T_{(P,Q)}(M \times N) := (i_Q^* \text{(positive basis of } T_P M), \text{ followed by } (j_P^* \text{(positive basis of } T_Q N)). \]

   We refer to this orientation as the product orientation on $M \times N$.
4. We have $\partial(M \times N) = (\partial M) \times N$.
5. We suppose that $M$ and $N$ are oriented and that both are of dimension $\geq 1$.
   a. If the dimension of $M$ is at least two, then the equality $\partial(M \times N) = (\partial M) \times N$ from (4) is in fact an equality of oriented smooth manifolds.
(b) In one-dimensional setting we have the following equality of oriented smooth manifolds:
\[ \partial([a, b] \times N) = -(\{a\} \times N) \sqcup (\{b\} \times N) \]
with the obvious variations if we work with half-open intervals instead.

All of the above statements, except for (5), hold also with the roles of \(M\) and \(N\) reversed.

Remark.

1. In Proposition 80.9 we will deal with the product of two smooth manifolds where both manifolds are allowed to have non-empty boundary.
2. On page 1718 we will introduce orientations of 0-dimensional manifolds and we will extend the definition of the product orientation to this setting.

Proof (*)

1, 2. By Proposition 6.5, we already know that \(M \times N\) is a topological manifold. Furthermore it is very easy to see that the products of charts from the smooth atlases for \(M\) and for \(N\) define a smooth atlas for \(M \times N\) which has the properties specified in (2).
3. The elementary proof of this statement is left to the reader.
4. First we want to argue that we have the equality \(\partial(M \times N) = \partial M \times N\). In Proposition 6.5 we could only show the inclusion “\(\subseteq\)”. The situation is much better in the present setting of smooth manifolds since now we have Proposition 6.27 (1) at our disposal. Using this proposition one can show fairly easily that we have \(\partial(M \times N) = M \times \partial N\). We refer to [Lee02, Proposition 1.45 and 2.12] for more details.
5. It is elementary (albeit potentially slightly confusing) to deduce this statement regarding the orientations from the definitions.

This concludes our introduction to the notion of an orientation of a smooth manifold. Perhaps somewhat intuitively there does also exist a perfectly fine notion of the orientation of a topological manifold. We will introduce this notion in Chapter 86.

6.12. Intersections of submanifolds (*). In this section we want to study the following question: given a smooth manifold \(M\) and two submanifolds \(X\) and \(Y\), is the intersection \(X \cap Y\) again a submanifold of \(M\)? It is not difficult to show that in general the answer is negative. For example consider \(M = \mathbb{R}^2\) with the two submanifolds \(X\) and \(Y\) that are shown in Figure 157. The intersection \(X \cap Y\) has three components, one of which is a submanifold of dimension one, and the other two components consist of a single point.

---

Note that here, when we are dealing with smooth manifolds, we can determine the boundary. This is in contrast to the slightly unfortunate situation in Proposition 6.5.

This statement has a rather ad hoc flair. In fact in Section 68.3 we will give a more elegant treatment. But for the time being this formulation will satisfy all our needs.

In Exercise 6.26 we will determine the relationship between the orientations of \(\partial(M \times N)\) and \(M \times \partial N\) if \(N\) is allowed to have non-empty boundary.

Here we use our super subtle definition of the boundary of a smooth manifold, see page 277.
see that $X \cap Y$ is not a smooth manifold (after all, what would its dimension be?), in particular it is not a submanifold of $M$.

If one spends some time pondering the question why in the previous example the intersection $X \cap Y$ is not a submanifolds, then one is inexorably led towards the following definition.

**Definition.** Let $M$ be an $m$-dimensional smooth manifold. Let $X$ and $Y$ be proper submanifolds of $M$.

1. Let $P \in X \cap Y$. We say $P$ is a transverse intersection point if $P \notin \partial M$ and if $X$ and $Y$ intersect transversally in $P$, i.e. if the equality
   \[ T_P X + T_P Y = T_P M \]
   holds.
2. We say that $X$ and $Y$ intersect transversally if each intersection point is a transverse intersection point.

The following lemma is basically an amusing real analysis exercise.

**Lemma 6.52.** Let $M$ be an $m$-dimensional smooth manifold, let $X \subset M$ a proper submanifold of codimension $k$ and let $Y$ be a proper submanifold of $M$ of codimension $l$.

1. If $P \in M$ is a transverse intersection point of $X$ and $Y$, then there exists a chart $\Phi: U \to V$ around $P$ with
   \[ \Phi(U \cap X) = V \cap (\mathbb{R}^{m-k} \times \{0\}) \quad \text{and} \quad \Phi(U \cap Y) = V \cap (\{0\} \times \mathbb{R}^{m-l}). \]

\[ \text{Figure 157} \]

\[ M = \mathbb{R}^2 \]

\[ X \cap Y \]

\[ \text{Figure 158} \]

\[ \text{intersection point is transverse} \]

\[ \text{intersection point is not transverse} \]

\[ \text{intersection point is not transverse} \]

\[ \text{Figure 158} \]

Note that in the following we work with smooth manifolds, we will need the smooth atlas in the definition of a transverse intersection point.

Since $X$ is a submanifold of $M$ we can view the tangent space $T_P X$ as a subspace of $T_P M$.

Note that if $X$ and $Y$ intersect transversally, then $X \cap Y \cap \partial M = \emptyset$. 

---

121 Note that in the following we work with smooth manifolds, we will need the smooth atlas in the definition of a transverse intersection point.

122 Since $X$ is a submanifold of $M$ we can view the tangent space $T_P X$ as a subspace of $T_P M$.

123 Note that if $X$ and $Y$ intersect transversally, then $X \cap Y \cap \partial M = \emptyset$. 

(2) If the submanifolds $X$ and $Y$ intersect transversally, then $X \cap Y$ is a submanifold of codimension $k+1$.

(3) If $W$ is compact codimension-zero submanifold of $M$ and if $Y$ intersects $\partial W$ transversally, then $Y \cap W$ is a proper submanifold of $W$.

**Figure 159.** Illustration of Lemma 6.52

**Proof.**

(1) The first statement is proved in [Kos93 Theorem IV.1.6] or implicitly also in [Lee02 Theorem 6.30 (b)].

(2) The second statement is an immediate consequence of the first statement.

(3) The last statement can also be deduced without too much effort from the first statement.

**Example.** In Figure 160 we see two infinite cylinders $X$ and $Y$ in the smooth manifold $\mathbb{R}^3$. The cylinders are submanifolds of codimension one. They intersect transversally and the intersection consists of two circles, i.e. $X \cap Y$ is a one-dimensional submanifold of $\mathbb{R}^3$. Put differently, $X \cap Y$ is a submanifold of codimension two.

**Figure 160**

6.13. **The Regular Value Theorem I.** In general it can be quite painful to show directly that a given object is a smooth manifold. For example, we will shortly see that the set of orthogonal matrices $O(n)$ form a smooth manifold. But only the most enterprising atlas reader will feel like writing down an explicit atlas.

In this section we will state the Regular Value Theorem which is a convenient way for showing that certain objects are indeed smooth manifolds. Not surprisingly the formulation of the Regular Value Theorem is preceded by the definition of a regular value. This notion might be familiar to the reader from an earlier course on real analysis.
**Definition.** Let $M$ and $N$ be smooth manifolds (possibly with boundary). Let $f: M \to N$ be a smooth map.

1. Let $P \in M \setminus \partial M$. We say $P$ is a **regular point** if the corresponding differential $Df_P: T_PM \to T_{f(P)}N$ is an epimorphism. Otherwise we say that $P$ is a **critical point**.

2. Let $P \in \partial M$. We say $P$ is a **regular point** if the differential $Df_P: T_P(\partial M) \to T_{f(P)}N$ is an epimorphism. Otherwise we say that $P$ is a **critical point**.

3. We say $Q \in N$ is a **regular value** if all points in the preimage $f^{-1}(Q)$ are regular. Otherwise we call $Q$ a **critical value**.

The following elementary observation will be used several times without explicitly mentioning it.

**Observation.** Let $f: M \to N$ be a smooth map between smooth manifolds.

1. If $Q \in N$ is a point with $f^{-1}(Q) = \emptyset$, then $Q$ is a regular value.

2. If $\dim(M) < \dim(N)$, then the converse to (1) holds, thus a point $P \in N$ is a regular value if and only if $f^{-1}(P) = \emptyset$.

The following theorem is often a convenient way for showing that a given subset of a smooth manifold, e.g. a given subset of some $\mathbb{R}^n$, is in fact a smooth manifold.

**Theorem 6.53. (Regular Value Theorem)** Let $M$ be an $m$-dimensional smooth manifold, let $N$ be an $n$-dimensional smooth manifold without boundary, let $f: M \to N$ be a smooth map and let $s \in N$ be a regular value of $f$.

1. The preimage $X := f^{-1}(\{s\})$ is a proper $(m-n)$-dimensional submanifold of $M$.

2. If $M$ is orientable, then $X$ is also orientable.

3. The intersection of $X$ with any compact set of $M$ is compact. In particular, if $M$ is compact, then $X$ is also compact.

**Remark.** In Section 11.1 we will formulate many generalizations, extensions and variations on the Regular Value Theorem 6.53.

**Sketch of proof.** The first statement is proved in basically every book on smooth manifolds, see e.g. [Miln65a, p. 11] or [Lee02, Corollary 5.14]. The second statement is unfortunately not written down explicitly in the literature, but it can be proved without too much effort by modifying the proof of (1). The third statement follows from the observation that $f^{-1}(\{s\})$ is a closed subset of the compact topological space $M$, hence it itself is compact.

**Examples.**

1. In Figure [161] we show the torus $M$ as a submanifold of $\mathbb{R}^3$ and we consider the “height function” $f: M \to \mathbb{R}$ given by $f(x, y, z) = z$. This function has precisely four critical points which are indicated in Figure [161] on the left. On the right we show a regular value $s$ and its preimage and we show a critical value $t$ and its preimage $f^{-1}(\{t\})$ which in this case is not a submanifold.

---

**Note.** The restriction of a map on a smooth manifold to its boundary is also a smooth map.
(2) Similarly to (1) we again consider a smooth manifold \( M \subset \mathbb{R}^3 \) together with the "height function". This time \( M \) has boundary and \( f^{-1}\{s\} \) is a proper submanifold of \( M \) with non-empty boundary.

\[
f(x, y, z) = z = 0
\]

the map \( Df_P: T_PM \to \mathbb{R} \) is an epimorphism but

the map \( Df_P: T_P \partial M \to \mathbb{R} \) is not an epimorphism, hence \( P \) is a critical point

![Diagram](image)

Figure 162. Illustration of the Regular Value Theorem 6.53

(3) Let \( g \in \mathbb{N}_0 \). According to [Hirs76, p. 28] there exists a polynomial function \( f: \mathbb{R}^3 \to \mathbb{R} \) such that 0 is a regular value and such that \( f^{-1}\{0\} \) is a surface of genus \( g \). For example, if we take

\[
f(x, y, z) = (4x^2(1 - x^2) - y^2)^2 + z^2 - \frac{1}{4},
\]

then [Hirs76, p. 28] states that \( f^{-1}\{0\} \) is a surface of genus 2.

Lemma 6.54. Let \( f: M \to N \) be a smooth map between two smooth manifolds of the same dimension.

1. For any regular point \( x \in M \setminus \partial M \) the map \( f \) is a local diffeomorphism around \( x \).
2. If \( y \in N \) is a regular value and if \( M \) is compact, then \( f^{-1}\{y\} \) is finite subset of \( M \).

Proof (\(*\)).

1. Let \( x \in M \setminus \partial M \) be a regular value of \( f \). This means that \( Df_x: T_{f(x)}M \to T_yN \) is an epimorphism. Since \( M \) and \( N \) have the same dimension this implies that \( Df_x \) is an isomorphism. It follows from the hypothesis that \( x \in M \setminus \partial M \) together with the Inverse Mapping Theorem 6.40 that \( f \) is a local diffeomorphism around \( x \).
2. Let \( y \) be a regular value of \( f \). It follows from the Regular Value Theorem 6.53 (1) and (3) that \( f^{-1}\{y\} \) is a compact 0-dimensional submanifold of \( M \). It follows from the discussion on page 272 together with Lemma 2.18 and our hypothesis that \( M \) is compact that \( f^{-1}\{x\} \) is a finite subset of \( M \).
The following lemma can be viewed as a particularly interesting application of the Regular Value Theorem \[6.53\].

**Lemma 6.55.** Let \( n \in \mathbb{N} \). The set 
\[
O(n) = \{ A \in M(n \times n, \mathbb{R}) \mid A^T A = \text{id} \}
\]
of orthogonal matrices (and thus also its component \( \text{SO}(n) \)) is a \( \frac{1}{2}n(n-1) \)-dimensional submanifold of \( M(n \times n, \mathbb{R}) = \mathbb{R}^{n^2} \). Furthermore the set of unitary matrices 
\[
U(n) = \{ A \in M(n \times n, \mathbb{C}) \mid A^T A = \text{id} \}
\]
is an \( n^2 \)-dimensional submanifold of \( M(n \times n, \mathbb{C}) = \mathbb{C}^{n^2} = \mathbb{R}^{2n^2} \) and the set of special unitary matrices 
\[
\text{SU}(n) = \{ A \in M(n \times n, \mathbb{C}) \mid A^T A = \text{id} \text{ and } \det(A) = 1 \}
\]
is an \( (n^2 - 1) \)-dimensional submanifold of \( M(n \times n, \mathbb{C}) = \mathbb{C}^{n^2} = (\mathbb{R}^2)^{n^2} = \mathbb{R}^{2n^2} \). All of the above examples, viewed as smooth manifolds in their own right, are closed.

**Proof.** We start with a preamble: Throughout the proof we use Proposition \[6.39\] to identify the abstract tangent spaces \( T_P M \) with the visual tangent spaces \( V_P M \).

Now we proceed to the actual proof of the lemma. First we prove the desired statements for \( O(n) \).

**Claim.**

1. The set 
\[
\text{Sym}(n, \mathbb{R}) = \{ B \in M(n \times n, \mathbb{R}) \mid B^T = B \} = \{ (b_{ij}) \in M(n \times n, \mathbb{R}) \mid b_{ij} = b_{ji} \}
\]
is a submanifold of \( M(n \times n, \mathbb{R}) = \mathbb{R}^{n^2} \) of dimension \( \frac{1}{2}n(n+1) \).

2. The map 
\[
f : M(n \times n, \mathbb{R}) \to \text{Sym}(n, \mathbb{R}) \quad A \mapsto A^T A
\]
is smooth and \( \text{id} \) is a regular value.

The first statement follows immediately from Lemma \[6.38\]. We turn to the proof of the second statement. It should be clear that \( f \) is smooth and that \( f \) does indeed take values in \( \text{Sym}(n, \mathbb{R}) \). So it remains to show that \( \text{id} \) is a regular value.

In the following we again use Lemma \[6.38\] which implies that the tangent spaces of the submanifolds \( \text{Sym}(n, \mathbb{R}) \) and \( M(n \times n, \mathbb{R}) \) are just given by these subvector spaces. So let 
\( A \in M(n \times n, \mathbb{R}) \) with \( A^T A = \text{id} \) and let 
\( C \in T_{\text{id}} \text{Sym}(n, \mathbb{R}) = \text{Sym}(n, \mathbb{R}) \). We need to show that there exists a \( B \) in \( T_A M(n \times n, \mathbb{R}) = M(n \times n, \mathbb{R}) \) with \( D f_A B = C \).

We start out with the following little calculation: Given \( B \in M(n \times n, \mathbb{R}) \) we have 
\[
\frac{d}{dt} \bigg|_{t=0} f(A + tB) = \frac{d}{dt} \bigg|_{t=0} (A^T + tB^T) \cdot (A + tB) = \frac{d}{dt} \bigg|_{t=0} (A^T A + tA^T B + tB^T A + t^2 B^T B) = A^T B + B^T A.
\]
Using that \( A^T \cdot A = \text{id} \) and \( C = C^T \) it is now easy to see that \( B := \frac{1}{2} A \cdot C \) satisfies \( D f_A B = C \).
It follows from the claim, together with the Regular Value Theorem\ref{thm:regular_value} that $O(n)$ is a proper submanifold of $M(n \times n, \mathbb{R}) = \mathbb{R}^{n^2}$ of dimension $n^2 - \frac{1}{2} n(n + 1) = \frac{1}{2} n(n - 1)$. Since $\mathbb{R}^{n^2}$ has no boundary and since $O(n)$ is a proper submanifold we see that the boundary of $O(n)$ is also empty. Finally note that we already saw on page \pageref{page:163} that $O(n)$ is compact. These last two observations imply that $O(n)$ is in fact a closed smooth manifold.

The proof for $U(n)$ is almost verbatim the same as the proof for $O(n)$. The proof for $SU(n)$ requires just a little bit of extra thought. We will deal with it in Exercise \ref{ex:SU(n)}.

For later usage we introduce the notion of a submersion:

*Definition.* A map $f : M \to N$ between smooth manifolds is called a *submersion* if $f$ is smooth and if given any $P \in M$ the map $Df_P : T_P M \to T_{f(P)} N$ is an epimorphism.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{submersion}
\caption{Illustration of the Submersion Theorem\ref{thm:submersion}.}
\end{figure}

Any projection of the form $f : M \times N \to N$ is evidently a submersion. The following theorem says that if $C$ is a convex subset of $\mathbb{R}^n$, then given any compact smooth manifold $M$ any submersion $f : M \to N$ is basically precisely of that form.

*Theorem 6.56. (Submersion Theorem)* Let $M$ be a compact $m$-dimensional smooth manifold, let $C$ be an $n$-dimensional submanifold of $\mathbb{R}^n$ and let $f : M \to C$ be a surjective map. If $C$ is a convex subset of $\mathbb{R}^n$ and if $f$ is a submersion, then there exists a closed smooth manifold $Y$ and a diffeomorphism $\varphi : M \to C \times Y$ such that the following diagram commutes:

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{submersion_diagram}
\caption{Illustration of the Submersion Theorem\ref{thm:submersion}.}
\end{figure}

*Proof.* This theorem follows from the proof of [Dun18, Theorem 8.5.10] or alternatively the proof of [Ebe07, Theorem 4.1].

\hfill \blacksquare
6.14. **Partitions of unity on manifolds.** In this short section we show in particular that manifolds are paracompact. This fact will be a key technical tool for constructing interesting functions on smooth manifolds.

First we recall the following definitions from page 144.

**Definition.** Let $X$ be a topological space.

1. The *support* of a function $f: X \to \mathbb{R}$ is defined as $\text{supp}(f) := \{x \in X \mid f(x) \neq 0\}$.
2. A *partition of unity* on $X$ is a family of maps $\{f_i: X \to [0, 1]\}_{i \in I}$ with the following properties:
   a. For each $x \in X$ there exists an open neighborhood $U$ of $x$ such that $f_i$ vanishes on $U$ for all but finitely many $i$.
   b. For every $x \in X$ we have $\sum_{i \in I} f_i(x) = 1$.
3. Let $\{U_i\}_{i \in I}$ be an open cover. A *partition of unity subordinate to the open cover* $\{U_i\}_{i \in I}$ is a partition of unity $\{f_j\}_{j \in J}$ such that for each $j \in J$ there exists an $i \in I$ with $\text{supp}(f_j) \subset U_i$.
4. We say $X$ is *paracompact* if $X$ is Hausdorff and if given any open cover $\{U_i\}_{i \in I}$ there exists a partition of unity subordinate to the open cover.

The following theorem guarantees the existence of many interesting (smooth) partitions of unity.

**Theorem 6.57.**

1. Every topological manifold is paracompact.
2. Let $M$ be a smooth manifold. For every open cover of $M$ there exists a smooth partition of unity subordinate to the given open cover.

Before we provide the proof of Theorem 6.57, we first show how one can use the existence of partitions of unity to construct two types of useful functions on manifolds.

**Definition.** Let $X$ be a topological space. An *exhaustion function* is a map $f: X \to \mathbb{R}_{\geq 0}$ such that for every $c \in \mathbb{R}_{\geq 0}$ the preimage $f^{-1}([0, c])$ is a compact subset of $X$.

**Examples.**

1. Let $M = [0, 1)$ the half-open interval viewed as a 1-dimensional smooth manifold. In this case the function defined by $f(x) = \frac{1}{1-x}$ has the desired properties.
2. We consider the surface of infinite genus illustrated in Figure 165. In this case the function $f(x, y, z) = x$ has the desired properties of Lemma 6.58.

\[ M \text{ is the surface of "infinite genus" \ldots} \]

\[ f(x, y, z) = x \]

\[ 0 \]

---

125 See page 144 for the definition of a partition of unity subordinate to a given open cover.
Lemma 6.58.

(1) Every topological manifold admits an exhaustion function.
(2) Every smooth manifold admits a smooth exhaustion function.

Proof. We prove the statement for smooth manifolds. The proof for topological manifolds is almost identical. Thus let $M$ be a smooth manifold. By Proposition 6.31 there exists a countable cover $\{U_i\}_{i \in \mathbb{N}}$ of $M$ by precompact sets. Furthermore, by Theorem 6.57 there exists a smooth partition of unity $\{\psi_i\}_{i \in \mathbb{N}}$ subordinate to this open cover. We define

$$f : M \to \mathbb{R}_{\geq 0}, \\
x \mapsto \sum_{i \in \mathbb{N}} i \cdot \psi_i(x).$$

Since locally this is a finite sum of smooth functions we see that $f$ is smooth. It remains to prove the following claim.

Claim. For any $c \in \mathbb{R}$ the preimage $f^{-1}([0, c])$ is compact.

Let $c \in \mathbb{R}$. We pick $N \in \mathbb{N}$ with $N \geq c$. We start out with the following observation: Given any point $x \not\in U_1 \cup \cdots \cup U_N$ we have

$$f(x) = \sum_{i=1}^{\infty} i \cdot \psi_i(x) = \sum_{i=N+1}^{\infty} i \cdot \psi_i(x) \geq \sum_{i=N+1}^{\infty} N \cdot \psi_i(x) = N \cdot \sum_{i=1}^{\infty} \psi_i(x) = N > c,$$

since $x \not\in U_1 \cup \cdots \cup U_N$ and since $\text{supp} \psi_i \subset U_i \subset U_i$.

It follows from this observation that

$$f^{-1}([0, c]) = f^{-1}([0, c]) \cap (U_1 \cup \cdots \cup U_N).$$

It follows from Exercise 2.28 that $f^{-1}([0, c])$ is indeed compact. ■

We conclude this section with the following lemma that will be proved in Exercise 6.34.

Lemma 6.59. Let $M$ be a smooth manifold. For any continuous function $f : M \to \mathbb{R}_{>0}$ there exists a smooth function $g : M \to \mathbb{R}_{>0}$ such that $g(x) \in (0, f(x)]$ for all $x \in M$.

Now we turn to the proof of Theorem 6.57. As we will see shortly, the proof is a consequence of the following proposition which sounds technical, but which is interesting in its own right.
**Proposition 6.60.** Given any $n$-dimensional topological manifold $M$ and given any open cover $\{U_i\}_{i \in I}$ there exists an atlas $\{\Phi_j : V_j \to W_j\}_{j \in J}$ with the following properties:

1. The index set $J$ is countable. If $M$ is compact, then $J$ can be chosen to be finite.
2. Given any $j \in J$ there exists an $i$ with $V_j \subset U_i$.
3. Each $W_j$ is either the open $n$-ball $B^n$ or the open half-ball $B^n \cap H^n$.
4. Given any point $x \in M$ there exists an open neighborhood $W$ of $x$ which has the property that $W \cap W_j = \emptyset$ for all but finitely many $j \in J$.
5. We have $M = \bigcup_{j \in J} \Phi_j^{-1}(W_j \cap \overline{B^n_{\frac{3}{4}}})$.

If $M$ is in fact a smooth manifold, then we can also arrange that the following extra condition is satisfied:

6. The charts are smooth, i.e. they lie in the maximal atlas of $M$.

**Remark.**

1. An atlas with Property (4) is sometimes called *locally finite*.
2. With more effort, see e.g. [Mun75, Exercise 7.9 on p. 315] one can arrange for any topological manifold (not necessarily compact) that $\# J \leq n + 1$.

Let us first show how we can deduce Theorem 6.57 from Proposition 6.60.

**Proof of Theorem 6.57 assuming Proposition 6.60.** Let $M$ be a topological or a smooth manifold with a given open cover $\{U_i\}_{i \in I}$ of $M$. We apply Proposition 6.60 and we use the notation of Proposition 6.60. Note that according to Lemma 6.13 there exists a smooth function $\gamma : B^n \to [0, 1]$ such that $\gamma(x)$ whenever $\|x\| \leq \frac{1}{2}$ and such that $\gamma(x) = 0$ whenever $\|x\| > \frac{3}{4}$. For each $j \in J$ we consider the function

$$g_j : M \to [0, 1], \quad x \mapsto \begin{cases} \gamma(\Phi_j(x)), & \text{if } x \in V_j, \\ 0, & \text{otherwise.} \end{cases}$$

We make the following observations:

a) Let $j \in J$. Note that the restriction of $g_j$ to the open sets $V_j$ and $M \setminus \Phi_j^{-1}(\overline{B^n_{\frac{3}{4}}})$ is continuous, hence $g_j$ is continuous by Lemma 2.35 (2). Using (6) and Lemma 6.23 (1) we also see that the $g_j$ are smooth, if we start out with a smooth manifold.

b) It follows from (4) that given any $x \in M$ there exists an open neighborhood $W$ of $x$ such that $g_j(x) = 0$ for all but finitely many $j \in J$.

c) It follows from (2) that for each $j \in J$ there exists an $i \in I$ with $\text{supp}(g_j) \subset U_i$.

d) It follows from (5) that for each $x \in M$ there exists a $j \in J$ with $g_j(x) \neq 0$.

It follows from (b) that it makes sense to consider the function $G : M \to \mathbb{R}_{\geq 0}$ that is given by $G(x) := \sum_{j \in J} g_j(x)$ and that this function is smooth. It is now clear that the functions $x \mapsto \frac{g_j(x)}{G(x)}$ are a (smooth) partition of unity subordinate to the given open cover. ■
Lemma 6.61. Let $M$ be a topological manifold. There exists a family of compact subsets \( \{C_n\}_{n \in \mathbb{N}} \) of $M$ and a family of open subsets \( \{D_{n+\frac{1}{2}}\}_{n \in \mathbb{N}} \) of $M$ such that the following two conditions are satisfied:

1. for every $n \in \mathbb{N}$ we have $C_n \subset D_{n+\frac{1}{2}} \subset C_{n+1}$,
2. we have $M = \bigcup_{n \in \mathbb{N}} C_n$.

Proof. Let $M$ be a topological manifold. It follows easily from Lemma 6.2 that there exists a family \( \{A_n\}_{n \in \mathbb{N}} \) of compact subsets such that $M = \bigcup_{n \in \mathbb{N}} A_n$. It suffices to prove the following claim.

Claim. There exists a sequence of compact subsets $C_1, C_2, \ldots$ of $M$ and a sequence of open subsets $D_{1+\frac{1}{2}} \subset D_{2+\frac{1}{2}} \subset \ldots$ such that for each $n \in \mathbb{N}$ we have $A_n \subset C_n \subset D_{n+\frac{1}{2}} \subset C_{n+1}$.

We set $C_1 := A_1$. Suppose that we already defined $C_1, \ldots, C_n$ and $D_{1+\frac{1}{2}}, \ldots, D_{n-1+\frac{1}{2}}$. Since $M$ is regionally compact we know that for each $x \in C_n \cup A_{n+1}$ there exists a compact neighborhood $K_x$. By definition of a neighborhood there exists an open neighborhood $U_x$ of $x$ with $U_x \subset K_x$. These open sets $U_x$ cover the subset $C_n \cup A_{n+1}$ which is compact by Lemma 2.16 (1). Thus there exist $x_1, \ldots, x_m$ such that $C_n \cup A_{n+1} \subset U_{x_1} \cup \cdots \cup U_{x_m}$. We set $D_{n+\frac{1}{2}} := U_{x_1} \cup \cdots \cup U_{x_m}$ and we set $C_{n+1} = K_{x_1} \cup \cdots \cup K_{x_m}$. Note that $C_{n+1}$ is compact by Lemma 2.16 (1). We have thus extended our sequences by one. Iterating this procedure gives us the desired sequences.

Now we are finally ready to provide the proof of Proposition 6.60.

Proof of Proposition 6.60. To simplify the discussion we only treat the case that $M$ is a topological manifold with empty boundary. The proof of all other cases can be basically the same and is left to the reader.

Thus let $M$ be an $n$-dimensional topological manifold with empty boundary and let $\{U_i\}_{i \in I}$ be an open cover of $M$. We pick a family of compact subsets $\{C_n\}_{n \in \mathbb{N}}$ and a family of open subsets $\{D_{n+\frac{1}{2}}\}_{n \in \mathbb{N}}$ with the properties stated in Lemma 6.61.

Note that it follows from Lemma 2.17 (2) that each $D_{n+\frac{1}{2}} \setminus C_{n-1}$ is an open of $M$. Furthermore, by design these open subsets cover all of $M$. Using this observation it is elementary to see that given any $x \in M$ there exists a chart $\Phi_x : V_x \to W_x$ with the following property:

1. $V_x$ is an open neighborhood of $x$ which is contained in some $U_i$ and for which there exists an $n \in \mathbb{N}$ with $V_x \subset D_{n+\frac{1}{2}} \setminus C_{n-1}$,
(2) \( W_x \) is the open \( n \)-ball \( B^n \) of radius 1.

For each \( x \in M \) we set \( \tilde{U}_x := \Phi_x^{-1}(B^n) \). Evidently these are open sets which cover all of \( M \). It follows from Lemma 2.13 that for each \( n \in \mathbb{N} \) there exists a finite set \( J_n \subset M \) such that \( C_n \subset \bigcup_{x \in J_n} \tilde{U}_x \). We set \( J := \bigcup_{n \in \mathbb{N}} J_n \). One can now easily verify that the atlas \( \{ \Phi_j : V_j \to W_j \}_{j \in J} \) has all the desired properties. We leave this straightforward task to the reader. \( \blacksquare \)

6.15. **Sets of measure zero and Sard’s Theorem.** One can ask, whether a smooth map between smooth manifolds always admits regular values. In this section we will formulate Sard’s Theorem which gives an affirmative answer to this question.

To formulate the theorem we need the notion of a “subset of measure zero” that we will now introduce. The precise definition is not all that important, what matters in practice are the properties stated in the subsequent proposition.

**Definition.**

1. A **cuboid** is any subset of \( \mathbb{R}^m \) of the form \([c_1, d_1] \times \cdots \times [c_m, d_m]\). We define the volume of such a cuboid as

\[
\text{vol}([c_1, d_1] \times \cdots \times [c_m, d_m]) = \prod_{i=1}^{m} (d_i - c_i).
\]

2. Let \( X \subset \mathbb{R}^m \) be a subset. We say that \( X \) **has measure zero** if given any \( \epsilon > 0 \) there exists a countable family \( \{A_i\}_{i \in I} \) of cuboids such that \( X \subset \bigcup_{i \in I} A_i \) and such that

\[
\sum_{i \in I} (\nu(A_i)) < \epsilon.
\]

This definition is illustrated in Figure 169.

3. Let \( M \) be an \( m \)-dimensional smooth manifold.

   a. We say that a subset \( X \subset M \) is a **subset of measure zero** if for every chart \( \Phi : U \to V \) from the smooth atlas the set \( \Phi(X \cap U) \) is a subset of measure zero of \( \mathbb{R}^m \).

   b. We say that a subset \( X \subset M \) is a **subset of full measure** if \( M \setminus X \) is a subset of measure zero.

![Figure 169](image)

The following proposition summarizes key properties of subsets of measure zero.

**Proposition 6.62.** Let \( M \) be an \( m \)-dimensional smooth manifold.

1. a. The union of countably many subsets of measure zero is again a subset of measure zero.

   b. The intersection of countably many subsets of full measure is again a subset of full measure.
(2) (a) Given any subset $X$ of measure zero of $M$ the complement $M \setminus X$ is dense in $M$.
(b) Every subset of $M$ of full measure is dense in $M$.
(3) Let $X$ be a subset of $M$. If there exist charts $\{\Phi_i : U_i \to V_i\}_{i \in I}$ from the smooth atlas such that $\bigcup_{i \in I} U_i = M$ and such that each $\Phi_i(U_i \cap X)$ is a subset of measure zero of $\mathbb{R}^m$, then $X$ is a subset of measure zero.
(4) If $f : M \to N$ is a smooth map between smooth manifolds and if $\dim(M) < \dim(N)$, then $f(M)$ is a subset of measure zero in $N$. In other words, $N \setminus f(M)$ is a subset of full measure.
(5) (a) Let $f : M \to N$ be a smooth map between smooth manifolds of the same dimension. If $X$ is a subset of measure zero in $M$, then $f(X)$ has measure zero in $N$.
(b) If $f : M \to N$ is a diffeomorphism, then $X \subset M$ has full measure if and only if $f(X)$ does.

Figure 170. Illustration of Proposition 6.62 (2) and (4).

Sketch of proof.

(1) Let $\{X_i\}_{i \in I}$ be a countable family of subsets of measure zero of $\mathbb{R}^n$. Using the fact that $\sum_{i \in \mathbb{N}} \frac{1}{2^i} = 1$ it is straightforward to show that $\bigcup_{i \in I} X_i$ is also a subset of measure zero. Statement (1a) is an easy consequence of this observation. Statement (1b) is just a convenient reformulation of Statement (1a).
(2) Statement (2a) follows easily from the observation that a subset of $\mathbb{R}^m$ that contains an open ball $B^m_r(z)$ of radius $r > 0$ does not have measure zero. We refer to [Lee02 Proposition 6.8] for more details. Once again Statement (2b) is just a reformulation of Statement (2a).
(3) This statement is proved in [Lee02 Lemma 6.6].
(4) We write $m = \dim(M)$ and we write $n = \dim(N)$. We pick a countable family $\{\Phi_i : U_i \to V_i\}_{i \in I}$ of charts for $M$ from the maximal smooth atlas for $M$ such that $M = \bigcup_{i \in I} U_i$. It follows easily from [Lee02 Proposition 6.5] and the hypothesis that $m < n$ that every $f(\Phi_i(U_i))$ is a subset of measure zero of $N$. It follows from (1) that $f(M)$ is subset of measure zero of $N$.
(5) Statement (5a) is [Lee02 Theorem 6.9]. Finally note that Statement (5b) follows easily from Statement (5a).

In Exercise 6.19 (2) we will show that such a countable atlas exists.
Now we can formulate Sard’s Theorem which shows that a smooth map between smooth manifolds always admits a plethora of regular values. The theorem is named after Arthur Sard [Sar42] who first proved a similar statement in 1942.

**Theorem 6.63. (Sard’s Theorem)** If $f: M \to N$ is a smooth map between smooth manifolds (possibly with boundary)\(^{127}\) then the set of critical values of $f$ is of measure zero in $N$.

![Figure 171. Illustration of Sard’s Theorem 6.63.](image)

**Remark.**

1. As we pointed out on page 308, if $f: M \to N$ is a smooth map between smooth manifolds with $\dim(M) < \dim(N)$, then a point $P \in N$ is a regular value if and only if $f^{-1}(P) = \emptyset$. It follows from this observation that Sard’s Theorem 6.63 together with Proposition 6.62 (2) implies Proposition 6.62 (4).

2. Sard’s Theorem 6.63 can also be used to give one more proof of the fundamental theorem of algebra, we refer to [Bre93, Corollary II.6.4] or [Miln65a, p. 8] for details.

3. Sometimes Sard’s Theorem is also called Morse-Sard Theorem, since the case that $N = \mathbb{R}$ was first proved by Anthony Morse [MorsA39] in 1939.

**Proof.** The theorem is a straightforward consequence of [Lee02, Theorem 6.10].

We conclude this section with the following proposition which often allows us to reduce a statement about non-compact smooth manifolds to a statement about compact smooth manifolds.

**Proposition 6.64.** Let $W$ be an $n$-dimensional smooth manifold with compact boundary. There exists a sequence $X_1, X_2, \ldots$ of $n$-dimensional smooth submanifolds of $W$ with the following four properties:

1. The sequence is nested, i.e. for each $i \in \mathbb{N}$ we have $X_i \subset X_{i+1}$.
2. Each $X_i$ is compact and connected.
3. The $X_i$ are submanifolds in the sense of the definition on page 270.
4. We have $\bigcup_{i \in \mathbb{N}} \hat{X}_i = W$.

**Remark.** There is an analogue of Proposition 6.64 if $\partial W$ is non-compact. Since that statement is more technical to formulate we postpone it to Proposition 11.4.

**Proof.** Let $W$ be an $n$-dimensional smooth manifold. If $W$ is empty, then there is nothing to show, so we might as well assume that $W$ is non-empty. We pick a point $w_0 \in W$. By

---

\(^{127}\) We stress that $M$ and $N$ are allowed to have boundary, since (a) we need these cases, and (b) since many proofs in the literature assume that $M$ and $N$ do not have boundary.
Lemma 6.58 there exists a smooth exhaustion function on $\partial W$, i.e., there exists a smooth function $f: W \to \mathbb{R}_{\geq 0}$ with the property that for any $c \in \mathbb{R}_{\geq 0}$ the preimage $f^{-1}([0,c])$ is a compact subset of $W$. Since $\partial W$ is compact it follows from Lemma 2.40 that there exists a $C \in \mathbb{R}_{\geq 0}$ such that $f(\partial W) \subset (-\infty, C]$ and such that $C \geq f(w_0)$.

It follows from Sard’s Theorem 6.63 and Proposition 6.62 (2) that there exists an increasing sequence $C < C_1 \leq C_2 \leq C_3 \leq \ldots$ of regular values of $f$ such that $\lim_{i \to \infty} C_i = \infty$. For each $i \in \mathbb{N}$ we denote by $X_i$ the path-component of $f^{-1}((-\infty, C_i])$ that contains $w_0$. By Exercise 6.31 which is a reasonably straightforward consequence of the Regular Value Theorem 6.53, and by our choice of $f$ we know that each $X_i$ is a compact $n$-dimensional submanifold. We have now shown that the $X_i$ satisfy Properties (1), (2) and (3).

Now let $P \in W$. Since $W$ is path-connected there exists a path $\gamma: [0, 1] \to W$ from $w_0$ to $P$. Since $[0, 1]$ is compact it follows again from Lemma 2.40 and from $\lim_{i \to \infty} C_i = \infty$ that there exists an $i$ with $\gamma([0, 1]) \subset f^{-1}((-\infty, C_i])$. This implies almost immediately that $P \in \hat{X}_i$. We have thus shown that (4) is also satisfied. ■

**Figure 172. Illustration of the proof of Proposition 6.64**

---

**Exercises for Chapter 6.**

**Exercise 6.1.** Given $I \subset \mathbb{R}$ we denote by $C^b(I, \mathbb{R})$ the set of all bounded maps $I \to \mathbb{R}$ and given $f \in C^b(I, \mathbb{R})$ we set

$$
\|f\| := \sup\{f(x) \mid x \in I\}.
$$

Note that $(C^b(I, \mathbb{R}), \|\|)$ is a metric space. We will equip $C^b(I, \mathbb{R})$ with the corresponding topology.

(a) Show that if $I$ is a compact interval, then $C^b(I, \mathbb{R})$ is second-countable.

(b) Show that if $I$ is a non-compact interval, then $C^b(I, \mathbb{R})$ is not second-countable.

**Exercise 6.2.** Show that the line with two zeros admits a chart of type (i) for every point.

**Exercise 6.3.** Let $I$ be an uncountable set. By the Tychonoff Theorem 3.17 we know that $[0, 1]^I$ is compact. Show that $[0, 1]^I$ is not second-countable.

**Exercise 6.4.** A topological space is called *separable* if it admits a subset that is countable and dense.

(a) Show that every second-countable topological space is separable.
(b) Let X be a set. We equip X with the cofinite topology that we defined on page 84.

(i) Show that X is separable.

(ii) Suppose that X is uncountable. Show that X is not second-countable.

Remark. This example is taken from [SS78, Example 19].

(c) Let X be a topological space that is separable and Hausdorff. Show that X is second-countable.

Exercise 6.5. Does there exist a compact topological space that satisfies all axioms of a closed 1-dimensional topological manifold except for the Hausdorff axiom?

Exercise 6.6. Let f: M → N be a map between two topological manifolds. Show that given any x ∈ M there exist neighborhoods U of x and V of f(x) with f(U) ⊂ V such that both U and V are homeomorphic to closed balls.

Exercise 6.7. We consider the topological space X = {(x, y) ∈ R^2 | xy = 0} shown in Figure 173. Show that X is not a topological manifold.

Remark. It is clear that things go awry at the origin P. But it is somewhat tricky to nail down why there is no chart around that point.

Exercise 6.8. Let M be a smooth manifold and let W be a submanifold of M. Show that for every component C of ∂W we have either C ⊂ ∂M or C ⊂ M \ ∂M.

Exercise 6.9. Show that there exists a smooth map f = (f_1, f_2): [0, 1] → [0, 1] × [0, 1] with the following properties:

(a) For t ∈ [0, 1/4] we have f(t) = (0, 1 - t).
(b) For t ∈ [3/4, 1] we have f(t) = (1, t).
(c) The map f_1: [0, 1] → [0, 1] is monotonously increasing.
(d) For each t ∈ [0, 1] we have f'(t) ≠ 0 ∈ R^2.
(e) For t ≠ {0, 1} we have f_2(t) ∈ (0, 1).

Hint. use Lemma 6.13

Exercise 6.10. Let f: V → W be a map between two topological manifolds such that f(V) ⊂ W \ ∂W. Show that the corresponding graph Gr(f) := {(x, f(x)) | x ∈ V} is a proper submanifold of the topological manifold V × W.
Exercise 6.11. In Figure 175 we show \( M = \{(x,y) \mid y \geq 0\} \) together with two subsets \( K := \{(x,x^2) \mid x \geq 0\} \) and \( L := \{(x,|x|+1) \mid x \in \mathbb{R}\} \). Show that both \( K \) and \( L \) are submanifolds of the topological manifold \( M \) but that they are not submanifolds if we view \( M \) as a smooth manifold.

![Figure 175](image)

Exercise 6.12. Let \( n \in \mathbb{N}_0 \).

(a) Show that the action of \( G = \{\pm 1\} \) on \( S^n \) is orientation-preserving if and only if \( n \) is odd.

Hint. Use Proposition 6.39 (2) and Lemma 6.46 (3).

(b) Show that the real projective space \( \mathbb{RP}^n \) is orientable if and only if \( n \) is odd.

Hint. Use (a) together with Lemma 6.46 and Proposition 6.47.

Exercise 6.13. Let \( n \in \mathbb{N} \). We consider \( M = \mathbb{R}^n \cup \{\infty\} \). We denote by 0 the origin of \( \mathbb{R}^n \).

(a) We consider the maps \( \Phi = \text{id} : \mathbb{R}^n \to \mathbb{R}^n \) and

\[
\Psi : M \setminus \{0\} \to \mathbb{R}^n
\]

\[
x \mapsto \begin{cases} \frac{1}{\|x\|^2} \cdot x, & \text{if } x \neq \infty, \\ 0, & \text{if } x = \infty. \end{cases}
\]

Show that \( \Phi \) and \( \Psi \) form a smooth atlas for \( M \).

(b) We consider the map

\[
f : M \to M
\]

\[
x \mapsto \begin{cases} 3x, & \text{if } x \neq \infty, \\ \infty, & \text{if } x = \infty. \end{cases}
\]

Show that \( f \) smooth and show that \( Df_0 = 3 \cdot \text{id} \) and \( Df_\infty = \frac{1}{3} \cdot \text{id} \).

Exercise 6.14. Let \( U \) be an open convex neighborhood of \( 0 \in \mathbb{R}^n \) and let \( f : U \to \mathbb{R} \) be a smooth map with \( f(0) = 0 \). We assume that 0 is a critical point, i.e. we assume that the differential \( Df_0 \) is zero. Show that there exist smooth functions \( h_{ij} : U \to \mathbb{R} \), \( i,j = 1,\ldots,n \) such that \( h_{ij} = h_{ji} \) and such that

\[
f(x) = \sum_{i=1}^{n} \sum_{j=1}^{n} h_{ij}(x) \cdot x_i \cdot x_j \quad \text{for all } x = (x_1,\ldots,x_n) \in U.
\]

Hint. Make use of Proposition 6.16.

Exercise 6.15. Let \( M \subset \mathbb{R}^n \) be a \( k \)-dimensional smooth submanifold and let \( P \in M \setminus \partial M \).

(a) Show that there exists an \( A \in O(n) \) with \( A \cdot V_P M = \{(x,0) \in \mathbb{R}^n \mid x \in \mathbb{R}^k \} \).
(b) Show that there exists a neighborhood $U$ of $P \subset M$ such that the map

$$
U \to V_P M \xrightarrow{x \mapsto Ax} \{(x, 0) \mid x \in \mathbb{R}^k\} \xrightarrow{(x, 0) \mapsto x} \mathbb{R}^k
$$

is a chart.

**Exercise 6.16.** Let $M$ and $N$ be two smooth manifolds of dimension $\geq 1$. Show that $M \times N$ is orientable if and only if $M$ and $N$ are both orientable.

**Exercise 6.17.**

(a) Let $p : S^n \to \mathbb{R}^n \cup \{\infty\}$ be the stereographic projection from Lemma 2.44. It restricts to a diffeomorphism $\varphi : S^n \setminus \{(0, \ldots, 0, 1)\} \to \mathbb{R}^n$. We equip both sides with the usual orientation. Show that $\varphi$ is orientation-preserving if and only if $n$ is odd.

(b) We consider the projection

$$
\psi : S^n_{>0} = \{(x_1, \ldots, x_{n+1}) \in S^n \mid x_{n+1} > 0\} \to B^n
$$

$$(x_1, \ldots, x_{n+1}) \mapsto (x_1, \ldots, x_n).$$

We equip both sides with the usual orientation. Show that $\psi$ is orientation-preserving if and only if $n$ is even.

**Exercise 6.18.** Let $n \in \mathbb{N}$ and let $A \in \text{GL}(n, \mathbb{Z})$ be a matrix. Show that the map

$$
f(A) : \mathbb{R}^n / \mathbb{Z}^n \to \mathbb{R}^n / \mathbb{Z}^n \quad v \mapsto Av
$$

is a diffeomorphism.

**Exercise 6.19.**

(a) Let $M$ be a topological manifold. Show that $M$ admits a countable atlas.

*Hint.* Use that topological manifolds are second-countable and use Lemma 2.25.

(b) Let $M$ be a smooth manifold. Show that $M$ admits a countable atlas such that each chart lies in the maximal smooth atlas of $M$.

**Exercise 6.20.** Let $G$ be a group that acts freely, properly and smoothly on an $n$-dimensional oriented smooth manifold $M$. Suppose that $M/G$ is orientable.

(a) Suppose that $M$ is path-connected. Show that every $g \in G$ acts on $M$ in an orientation-preserving way.

*Hint.* Use Proposition 6.47 (2).

(b) Show that the conclusion of (a) does not hold if $M$ is not path-connected.

*Remark.* This exercise can be viewed as a converse to Proposition 6.47 (1).

**Exercise 6.21.** Let $M$ be a smooth manifold and let $N \subset M$ be a smooth submanifold with $\dim(N) < \dim(M)$.

(a) Show that the interior of $N$ in $M$ is the empty set.

(b) Show that the closure of $M \setminus N$ in $M$ equals $M$. 

Exercise 6.22. Let \( n \in \mathbb{N}_0 \). As on page \([194]\) we identify the real projective space \( \mathbb{R}P^n \) with \( \mathbb{R}^{n+1} \setminus \{0\} / (\mathbb{R} \setminus \{0\}) \).

(a) Let \( i \in \{0, \ldots, n\} \). Show that \( V_i := \{ [x_0 : \cdots : x_n] \in \mathbb{R}P^n | x_i \neq 0 \} \) is an open subset of \( \mathbb{R}P^n \).

(b) Show that the maps

\[
\Phi_i: \{ [x_0 : \cdots : x_n] \in \mathbb{R}P^n | x_i \neq 0 \} \rightarrow \mathbb{R}^n
\]

\[
[x_0 : \cdots : x_n] \mapsto (\frac{x_0}{x_i}, \frac{x_1}{x_i}, \ldots, \frac{x_{i-1}}{x_i}, \frac{x_{i+1}}{x_i}, \ldots, \frac{x_n}{x_i}).
\]

form a smooth atlas for \( \mathbb{R}P^n \).

Exercise 6.23. Let \( M := \{(x_1, \ldots, x_n) \in \mathbb{R}^n | x_1 \leq 0\} \), \( N := \{(x_1, \ldots, x_n) \in \mathbb{R}^n | x_1 \geq 0\} \) and \( H := \{(x_1, \ldots, x_n) \in \mathbb{R}^n | x_1 = 0\} \). Let \( X \subset M \) be a \( k \)-dimensional topological submanifold with \( \partial X = X \cap H \) and let \( Y \subset N \) be a \( k \)-dimensional topological submanifold with \( \partial Y = Y \cap H \). We suppose that \( X \cap H = Y \cap H \). Show that \( X \cup Y \) is a \( k \)-dimensional topological submanifold of \( \mathbb{R}^n \).

![Figure 176. Illustration for Exercise 6.23](image.png)

Exercise 6.24. Let \( M \) be a compact smooth manifold and let \( N \) be a proper codimension-zero submanifold of \( M \). Show that if \( M \) is connected and if \( N \neq \emptyset \), then \( M = N \).

Exercise 6.25. Let \( M \) be a topological manifold, let \( P \in M \) and let \( f: K \rightarrow M \) be a map from a compact topological space \( K \) to \( M \). Show that if \( P \notin f(K) \), then there exists an open neighborhood \( U \) of \( P \) with \( f(K) \cap U = \emptyset \).

Exercise 6.26. Let \( M \) be an \( m \)-dimensional smooth manifold with possibly non-empty boundary and let \( N \) be an \( n \)-dimensional smooth manifold with empty boundary. We equip the product smooth manifolds \( M \times N \) and \( N \times M \) with the product orientations as defined in Proposition 6.3.

(a) Show that the diffeomorphism

\[
M \times N \rightarrow N \times M
(x, y) \mapsto (y, x)
\]

is orientation-preserving if and only if \( m \cdot n \) is even.

(b) We equip \( \partial M \) and \( N \times M \) with the boundary orientation and we equip \( N \times \partial M \) with the product orientation. Show that we have the following equality of oriented smooth manifolds:

\[
\partial(N \times M) = \begin{cases} 
N \times \partial M, & \text{if } n \text{ is even,} \\
-(N \times \partial M), & \text{if } n \text{ is odd.}
\end{cases}
\]
Exercise 6.27. We consider the smooth manifold $M = \mathbb{R} \times [-1, 1]$ together with the submanifolds

$$W_t := \{(t + \frac{1}{y^2 - 1}, y) | y \in (-1, 1)\} \quad \text{where} \ t \in \mathbb{R}.$$ 

Show that there is no smooth path $\gamma: [-1, 1] \to M$ that connects the bottom $\mathbb{R} \times \{1\}$ with the top $\mathbb{R} \times \{-1\}$ such that $\gamma$ is transverse to every $W_t$, i.e. such that for any $s \in (-1, 1)$ with $\gamma(s) \in W_t$ we have $\gamma'(s) \not\in V_{\gamma(s)}W_t$.

Remark. This decomposition of the interior of $M = \mathbb{R} \times [-1, 1]$ into submanifolds is sometimes called a Reeb foliation.

![Illustration of Exercise 6.27](image-url)

Exercise 6.28. Let $A \in O(n)$. Show that the map $S^n \to S^n$ given by $x \mapsto A \cdot x$ is orientation-preserving if and only if $\det(A) = 1$.

Exercise 6.29. Let $f: M \to N$ be a smooth map between two smooth manifolds. We assume that $\partial M = \emptyset$.

(a) Show that the set of regular points of $f$ is an open subset of $M$.

Hint. You can use the fact that a real $(m \times n)$-matrix $A$ has rang $m$ if and only if $\det(A \cdot A^T) \neq 0$.

(b) Let $v \in N$ be a regular value such that $f^{-1}(v)$ is finite. We assume that $M$ is compact. Show that there exists an open neighborhood $U$ of $v$ such that each point in $U$ is a regular value.

(c) Show that in general the set of regular values of $f$ is not an open subset of $N$.

Exercise 6.30. Let $f: M \to N$ be a map between two closed $n$-dimensional smooth manifolds which is injective and which has the property that for $P \in M$ the differential $Df_P$ is an isomorphism. Show that $f$ is a diffeomorphism.

Exercise 6.31. Let $M$ be an $m$-dimensional smooth manifold and let $f: M \to \mathbb{R}$ be a smooth function.

(a) Let $s \in \mathbb{R}$ be a regular value of $f$ such that for each component $C$ of $\partial M$ we have either $f^{-1}\{s\} \cap C = C$ or $f^{-1}\{s\} \cap C = \emptyset$. Show that $X := f^{-1}((-\infty, s])$ is a smooth codimension-zero submanifold of $M$ with $\partial_0 X = f^{-1}\{s\} \setminus \partial M$ and $\partial_1 X = X \cap \partial M$.

(b) Let $s < t \in \mathbb{R}$ be regular values such that for each component $C$ of $\partial M$ we have either $f^{-1}\{s\} \cap C = C$ or $f^{-1}\{s\} \cap C = \emptyset$ and such that for each component $C$ of $\partial M$ we have either $f^{-1}\{t\} \cap C = C$ or $f^{-1}\{t\} \cap C = \emptyset$. Show that $X := f^{-1}([s, t])$ is a smooth codimension-zero submanifold of $M$ with $\partial_0 X = (f^{-1}\{s\} \cup f^{-1}\{t\}) \setminus \partial M$ and $\partial_1 X = X \cap \partial M$. 

Figure 177. Illustration of Exercise 6.27
Hint. Use the Regular Value Theorem 6.33.

Remark. Later in the Regular Value Theorem 11.2 for \( \mathbb{R} \) we will prove a refinement of the above statement.

Exercise 6.32. Let \( n \in \mathbb{N} \).

(a) Show that

\[
\text{GL}(n, \mathbb{R}) = \{ A \in M(n \times n, \mathbb{R}) \mid \det(A) \neq 0 \}
\]

is a smooth manifold of dimension \( n^2 \).

(b) Show that

\[
\text{SL}(n, \mathbb{R}) = \{ A \in M(n \times n, \mathbb{R}) \mid \det(A) = 1 \}
\]

is a smooth manifold of dimension \( n^2 - 1 \).

Exercise 6.33. Show that

\[
\text{SU}(n, \mathbb{R}) = \{ A \in M(n \times n, \mathbb{C}) \mid \overline{A}^T A = \text{id} \text{ and } \det(A) = 1 \}
\]

is a smooth manifold of dimension \( n^2 - 1 \).

Exercise 6.34. Let \( M \) be a smooth manifold and let \( f : M \to \mathbb{R}_{>0} \) be a continuous function. Show that there exists a smooth function \( g : M \to \mathbb{R}_{>0} \) such that \( g(x) \in (0, f(x)] \) for all \( x \in M \).

Hint. Use a suitable partition of unity.

Exercise 6.35. Let \( M \) be a compact \( n \)-dimensional smooth manifold and let \( K \) and \( L \) be two compact subsets of \( M \). Show that there exists a smooth map \( f : M \to \mathbb{R} \) such that \( \sup \{ f : A \to \mathbb{R} \} < \inf \{ f : B \to \mathbb{R} \} \).

Hint. Use Theorem 6.57 (2).

Exercise 6.36. Let \( M \) be a closed \( n \)-dimensional smooth manifold.

(a) Let \( \{U, V\} \) be an open cover of \( M \). Show that there exist compact \( n \)-dimensional submanifolds \( A \) and \( B \) of \( M \) such that \( A \subseteq U, V \subseteq B, A \cup B = M \) and such that \( A \cap B = \partial A = \partial B \).

Hint. Use Exercises 6.31 and 6.35.

(b) Let \( K \) and \( L \) be compact subsets of \( M \). Show that there exist compact \( n \)-dimensional submanifolds \( A \) and \( B \) of \( M \) such that \( K \subseteq A, L \subseteq B, A \cup B = M \) and such that \( A \cap B = \partial A = \partial B \).

\[\begin{align*}
\text{Figure 178. Illustration of Exercise 6.36}
\end{align*}\]
7. 1-DIMENSIONAL MANIFOLDS AND THE LONG LINE

In this section we will consider “1-dimensional objects”. More precisely, we will do the following:

(1) We will give the classification of 1-dimensional (topological) smooth manifolds.
(2) We will construct the long line, this is a path-connected topological space that satisfies all properties of a 1-dimensional topological manifold, except that it is not second-countable.

7.1. The classification of 1-dimensional (topological) smooth manifolds (∗). One of the goals of topology is to completely classify suitable classes of topological spaces. For example one could try to classify all connected topological and smooth manifolds of a given dimension. In this short section we give a complete classification in the 1-dimensional setting.

In the following we first deal with 1-dimensional topological manifolds.

**Theorem 7.1.** Let $M$ be a non-empty connected 1-dimensional topological manifold. Then the homeomorphism type of $M$ is given by the following table.

<table>
<thead>
<tr>
<th>Compact</th>
<th>without boundary</th>
<th>with non-empty boundary</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>the circle $S^1$</td>
<td>the closed interval $[0,1]$</td>
</tr>
<tr>
<td>Non-compact</td>
<td>the open interval $(0,1)$</td>
<td>the half-open interval $[0,1)$</td>
</tr>
</tbody>
</table>

Note that the adjectives “Hausdorff” and “second-countable” in the definition of a topological manifold are both necessary:

(1) The line with two zeros satisfies all axioms of a smooth manifold except for the Hausdorff axiom.
(2) If one drops the condition that a topological manifold has to be second-countable, then there are two more examples of connected 1-dimensional topological manifolds, namely the “open long ray $L^+$ and the “long line $L” which we will introduce on page 334.

In the following proposition we first deal with the case that $M$ is closed. Afterwards we will outline how one can obtain the general statement.

**Proposition 7.2.** Let $M$ be a closed connected non-empty 1-dimensional topological manifold. Then $M$ is homeomorphic to $S^1$.

In the proof of Proposition 7.2 we will need the following lemma.

**Lemma 7.3.** Let $M$ be a 1-dimensional topological manifold and let $\Phi: U \to (-2,2)$ be a chart. Let $[a,b] \subset (-2,-2)$ be a compact interval. Then $\Phi^{-1}([a,b])$ is a closed subset of $M$.

**Proof.** Since $\Phi$ is a homeomorphism the map $\Phi^{-1}: (-2,2) \to U$ is also continuous. Since $[a,b]$ is compact it follows from Lemma 2.40 that $\Phi^{-1}([a,b])$ is also compact. But by

---

128 By Exercise 2.40 we know that the half-open interval $[0,1)$ is not homeomorphic to the open interval $(0,1)$.
Lemma 2.17 (2) any compact subspace of a Hausdorff space is closed. But $M$ is a topological manifold, in particular $M$ is Hausdorff. Therefore $\Phi^{-1}([a,b])$ is a closed subset of $M$. ■

*Definition.* Let $M$ be a 1-dimensional topological manifold.

1. A *c-parametrization* for $M$ is a homeomorphism $\Psi : [-1, 1] \to C$ from the compact interval $[-1, 1]$ to a closed subset $C$ of $M$. We say the c-parametrization is *open* if $\Psi((-1, 1))$ is an open subset of $M$.
2. We say that two c-parametrizations $\Psi$ and $\Psi'$ are *almost disjoint* if $\Psi((-1, 1)) \cap \Psi'((-1, 1)) = \emptyset$.
3. A *c-atlas* is a family of c-parametrizations $\{\Psi_i : [-1, 1] \to C_i\}_{i \in I}$ of $M$ such that the union of the $C_i$’s equals $M$. We call the c-atlas *open* if all c-parametrizations in the c-atlas are open. We say the c-atlas *almost disjoint* if any two different c-parametrizations in the c-atlas are almost-disjoint.

Using Lemma 7.3 one can prove the following lemma that is illustrated in Figure 179.

**Lemma 7.4.** Let $M$ be a 1-dimensional topological manifold and let $\Psi_1 : [-1, 1] \to C_1$ and $\Psi_2 : [-1, 1] \to C_2$ be two open c-parametrizations such that $C_1 \cap C_2$ is non-empty but such that $C_2$ is not contained in $C_1$. Then

$$[-1, 1] \setminus \Psi_1^{-1}(\Psi_2(((-1, 1) \cap C_1))) = [a, b]$$

for some $-1 \leq a < b \leq 1$.

![Illustration of Lemma 7.4](image)

**Figure 179. Illustration of Lemma 7.4.**

Now we can provide the proof of Proposition 7.2.

**Proof of Proposition 7.2.** Let $M$ be a closed connected 1-dimensional topological manifold. We start out with the following claim.

**Claim.** There exists a finite open almost-disjoint c-atlas $\Psi_i : [-1, 1] \to C_i$ with $i = 1, \ldots, k$.

Since $M$ is assumed to be closed there exists for each $P \in M$ a chart $\Phi_P : U_P \to (-2, 2)$ of type (i) such that $\Phi_P(P) = 0$. The open sets $\Phi_P^{-1}((-1, 1))$ are an open cover of $M$.

Since $M$ is compact there exist $P_1, \ldots, P_k$ such that the open sets $\Phi_{P_i}^{-1}((-1, 1))$, $i = 1, \ldots, k$ are an open cover of $M$. It follows that the union of the sets $C_i := \Phi_{P_i}^{-1}([-1, 1])$, $i = 1, \ldots, k$ is also all of $M$. It follows from Lemma 7.3 that each $C_i$ is a closed subset of $M$.

---

129 Here we use implicitly the following fact, which is for example an immediate consequence of Lemma 2.38: if $U$ is open in $M$, and if $V$ is open in $U$, then $V$ is also open in $M$. Why is that?
For \( i = 1, \ldots, k \) we now consider the homeomorphism \( \Psi_i \) that is given by
\[
\Psi_i := (\Phi_P|_{C_i})^{-1} : [-1, 1] \xrightarrow{\sim} C_i.
\]
By the above discussion these are open \( c \)-parametrizations. After possibly removing some \( c \)-parametrizations we can assume that no \( C_i \) is contained in any other \( C_j \).

Now we make the following modifications to our \( c \)-atlas. If for some \( i < j \) we have
\[
\Psi_i((-1, 1)) \cap \Psi_j((-1, 1)) \neq \emptyset,
\]
then it follows from Lemma\[7.4\] that
\[
[-1, 1] \setminus \Psi_i^{-1}(\Psi_j((-1, 1)) \cap C_i) = [a, b]
\]
for some \(-1 \leq a < b \leq 1\). Now we replace \( \Psi_i \) by the map
\[
[-1, 1] \xrightarrow{\text{linear homeomorphism}} [a, b] \xrightarrow{\psi_i} M.
\]
Repeating this process we obtain finitely many open \( c \)-parametrizations that are furthermore almost-disjoint. These \( c \)-parametrizations form the desired \( c \)-atlas.

In the following we say that a \( c \)-atlas is \textit{simple} if given any \( P \in M \) there exist at most two \( c \)-parametrizations that contain \( P \).

**Claim.** Every almost-disjoint open \( c \)-atlas is simple.

This follows from the fact that any point \( P \) on a 1-dimensional topological manifold has the property, that given any open neighborhood \( U \) there exists an open neighborhood \( V \) of \( x \), contained in \( U \), such that \( V \setminus \{P\} \) contains precisely two components. If a point \( P \in M \) is contained in \( k \) \( c \)-parametrizations of an open almost-disjoint \( c \)-atlas, then one can easily show that \( P \) admits an open neighborhood \( U \) such that for any open neighborhood \( V \) of \( P \) contained in \( U \) the set \( V \setminus \{P\} \) has at least \( k \) components.

Now let \( \Psi_i : [-1, 1] \to C_i \) and \( \Psi_j : [-1, 1] \to C_j \) be two \( c \)-parametrizations of our \( c \)-atlas such that \( C_i \cap C_j \) consists of a single point. Since the \( c \)-parametrizations are almost disjoint we have \( C_i \cap C_j \subset \Psi_i(\pm 1) \) and \( C_i \cap C_j \subset \Psi_j(\pm 1) \). After possibly replacing \( \Psi_i(t) \) by \( \Psi_i(-t) \) and/or \( \Psi_j(t) \) by \( \Psi_j(-t) \) we can assume that \( \Psi_i(1) = \Psi_j(-1) \). We consider the map
\[
\Psi : [-1, 1] \to C_1 \cup C_2
\]
\[
\begin{align*}
x &\mapsto \begin{cases}
\Psi_i(2x + 1), &\text{if } x \in [-1, 0], \\
\Psi_j(2x - 1), &\text{if } x \in [0, 1].
\end{cases}
\end{align*}
\]
It is straightforward to verify that \( \Psi \) is a bijection and continuous. It follows from Proposition\[2.43\](3) that \( \Psi \) is in fact a homeomorphism\[30\].

By iteratively applying the procedure from the previous claim to our \( c \)-atlas we obtain a finite almost-disjoint simple \( c \)-atlas\[31\] \( \Psi_i : C_i \to [-1, 1], i = 1, \ldots, k \) such that for any \( i \neq j \) either \( C_i \cap C_j \) is empty or it consists of two points.

Now pick a \( c \)-parametrization \( \Psi_i : [-1, 1] \to C_i \) from the \( c \)-atlas. Since \( M \) is closed and since \([-1, 1]\) is not closed we see that \( \Psi_i \) is not a homeomorphism\[32\] in particular \( C_i \neq M \).

\[30\] Here we use that \( M \) is Hausdorff, hence the subset \( C_i \cup C_j \) is also Hausdorff.

\[31\] Note that we no longer claim that the resulting \( c \)-atlas is open.

\[32\] Careful reading shows that here we make use of the fact that a half-open interval is not homeomorphic to an open interval.
Since $M$ is connected and since each $C_j$ is a closed of $M$ we see that there exists another $c$-parametrization $\Psi_j : [-1,1] \to C_j$ such that $C_i \cap C_j \neq \emptyset$. By our choice of $c$-atlas the set $C_i \cap C_j$ consists of two points.

After possibly replacing $\Psi_i(t)$ by $\Psi_i(-t)$ we can assume that $\Psi_i(1) = \Psi_j(-1)$ and $\Psi_i(-1) = \Psi_j(1)$. We consider the map

$$\Psi : [-1,1]/-1 \sim 1 \to C_i \cup C_j$$

$$x \mapsto \begin{cases} 
\Psi_i(2x+1), & \text{if } x \in [-1,0], \\
\Psi_j(2x-1), & \text{if } x \in [0,1].
\end{cases}$$

It is straightforward to verify that $\psi$ is a bijection. Furthermore note that it follows from $\Psi_i(-1) = \Psi_j(1)$ and Lemma 3.22 that $\Psi$ is continuous. Thus it follows from Proposition 2.43 (3) that $\Psi$ is in fact a homeomorphism.

Thus we have found a homeomorphism from $[-1,1]/-1 \sim 1 = S^1$ to $C_i \cup C_j$. It remains to prove the following claim.

**Claim.** We have $C_i \cup C_j = M$.

The $c$-atlas we work with is simple and almost-disjoint. Since $\Psi_i(\pm 1) = \Psi_j(\mp 1)$ it follows that $C_i$ and $C_j$ did not intersect any other $C_k$. This shows that $C_i \cup C_j$ and $\bigcup_{k \neq i,j} C_k$ are disjoint. Since both are closed and since $M$ is connected and since $C_i \cup C_j$ is non-empty it follows that $M = C_i \cup C_j$. $\blacksquare$

Now we outline the proof of Theorem 7.1.

**Proof.** Let $M$ be a non-empty connected 1-dimensional topological manifold. Recall that we need to show that the homeomorphism type of $M$ is given by the following table:

<table>
<thead>
<tr>
<th>compact</th>
<th>without boundary</th>
<th>with non-empty boundary</th>
</tr>
</thead>
<tbody>
<tr>
<td>non-compact</td>
<td>the circle $S^1$</td>
<td>the closed interval $[0,1]$</td>
</tr>
<tr>
<td></td>
<td>the open interval $(0,1)$</td>
<td>the half-open interval $[0,1)$.</td>
</tr>
</tbody>
</table>

So let us deal with these cases separately:

1. If $M$ is closed, then we know by Proposition 7.2 that $M$ is homeomorphic to $S^1$.

2. If $M$ is compact and with non-empty boundary, then we can consider the “double” $D M := M \cup_{\partial M = \partial M'} M'$ where $M'$ is a second copy of $M$. One can easily verify that $D M$ is a compact 1-dimensional topological manifold without boundary. Furthermore one sees that it follows from $\partial M \neq \emptyset$ that $D M$ is connected. Thus by (1) we

---

[^33]: Here we use that we identify $-1$ and $1$ on the left-hand side.
know that $D M$ is homeomorphic to $S^1$. Using Exercise 2.15 one can easily show that any compact proper submanifold of $S^1$ is homeomorphic to $[0, 1]$.

(3) Suppose that $M$ is non-compact with empty boundary. It follows from Lemma 6.58 (1) that $M$ admits an exhaustion function $f: M \to \mathbb{R}_{\geq 0}$. (Note that this is the point where we use that according to our definition topological manifolds are second-countable.) In Exercise 7.1 we will use this exhaustion function, together with (2), to show that $M$ is homeomorphic to $(0, 1)$.

(4) Finally assume that $M$ is non-compact with non-empty boundary. As in (2) we consider the double $D M$. This time it is straightforward to see that $D M$ is a non-compact connected 1-dimensional topological manifold with empty boundary. By (3) we know that $D M$ is homeomorphic to $(0, 1)$. It follows easily from Exercise 2.15 that $M$ is homeomorphic to a half-open interval.

If we consider smooth manifolds instead of topological manifolds and diffeomorphisms instead of homeomorphisms we get the same answer. More precisely the following proposition holds.

**Theorem 7.5.** Let $M$ be a non-empty connected 1-dimensional smooth manifold. Then the diffeomorphism type of $M$ is given by the following table

<table>
<thead>
<tr>
<th></th>
<th>without boundary</th>
<th>with non-empty boundary</th>
</tr>
</thead>
<tbody>
<tr>
<td>compact</td>
<td>the circle $S^1$</td>
<td>the closed interval $[0, 1]$</td>
</tr>
<tr>
<td>non-compact</td>
<td>the open interval $(0, 1)$</td>
<td>the half-open interval $[0, 1)$</td>
</tr>
</tbody>
</table>

**Proof.** It is not that difficult to modify the proof of Theorem 7.5 to prove the desired result. One just needs to be a little more cautious with the various constructions of maps.

For compact smooth manifolds we will also provide a different proof, using “Morse theory”, in Proposition 108.1. As in the setting of topological manifolds the non-compact case can again be reduced to the compact case by using the smooth analogue of Exercise 7.1. We leave it to the reader to fill in the details.

Finally we also refer to the appendix of [Miln65a] for a different proof of Theorem 7.5.

7.2. **Interlude: The order topology.** In the next section we will introduce the “long line”, which is a topological space, that has all the properties of a connected 1-dimensional topological manifold, except that it is not second-countable. The construction of the “long line” makes use of the order topology which we will introduce in this section.

First we recall some definitions. At least this particular author invariably forgets the precise meanings of the different type of orders that exist.

**Definition.** A partial order on a set $X$ is a relation $\leq$ that has the following properties:

1. For every $x \in X$ we have $x \leq x$.
2. Whenever $x \leq y$ and $y \leq x$, then we have $x = y$.
3. Whenever $x \leq y$ and $y \leq z$, then we also have $x \leq z$. 

For compact smooth manifolds we will also provide a different proof, using “Morse theory”, in Proposition 108.1. As in the setting of topological manifolds the non-compact case can again be reduced to the compact case by using the smooth analogue of Exercise 7.1. We leave it to the reader to fill in the details.

Finally we also refer to the appendix of [Miln65a] for a different proof of Theorem 7.5.

7.2. **Interlude: The order topology.** In the next section we will introduce the “long line”, which is a topological space, that has all the properties of a connected 1-dimensional topological manifold, except that it is not second-countable. The construction of the “long line” makes use of the order topology which we will introduce in this section.

First we recall some definitions. At least this particular author invariably forgets the precise meanings of the different type of orders that exist.

**Definition.** A partial order on a set $X$ is a relation $\leq$ that has the following properties:

1. For every $x \in X$ we have $x \leq x$.
2. Whenever $x \leq y$ and $y \leq x$, then we have $x = y$.
3. Whenever $x \leq y$ and $y \leq z$, then we also have $x \leq z$. 

For compact smooth manifolds we will also provide a different proof, using “Morse theory”, in Proposition 108.1. As in the setting of topological manifolds the non-compact case can again be reduced to the compact case by using the smooth analogue of Exercise 7.1. We leave it to the reader to fill in the details.

Finally we also refer to the appendix of [Miln65a] for a different proof of Theorem 7.5.

A *total order* is a partial order that also satisfies the following condition:

(4) For every \( x, y \in X \) we have \( x \leq y \) or \( y \leq x \).

Finally a *well-order* is a total order that satisfies the following condition:

(5) Every non-empty subset has a minimal element.

Such a pair \((X, \leq)\) is called a *partially ordered set, totally ordered set* respectively *well-ordered set*.

Next we introduce some self-explanatory notation.

**Notation.** Let \((X, \leq)\) be a totally ordered set. As usual, given \( x, y \in X \) we write \( x < y \) if \( x \leq y \) and \( x \neq y \). Given \( x, y \in X \) we write

\[
\begin{align*}
(x, y) &:= \{ a \in X \mid x < a < y \}, \\
[x, y) &:= \{ a \in X \mid x \leq a < y \} \\
[x, y] &:= \{ a \in X \mid x \leq a \leq y \}.
\end{align*}
\]

We refer to these subsets in the obvious way as open intervals, half-open intervals and closed intervals.

**Definition.** Let \((X, \leq)\) be a totally ordered set on \( X \). Let \( \mathcal{B} \) be the subset of the power set \( \mathcal{P}(X) \) given by the subsets of \( X \) of the following four types:

(1) All intervals \((a, b)\) in \( X \).
(2) If \( x_0 \) is a smallest element of \((X, \leq)\), then we also consider the intervals \([x_0, b)\).
(3) If \( x_1 \) is a largest element of \((X, \leq)\), then we also consider the intervals \((a, x_1]\).
(4) The total set \( X \).

We leave it to the reader to verify that \( \mathcal{B} \) has the basis property, as defined on page 102. By Lemma 2.22 the basis \( \mathcal{B} \) defines a topology on \( X \). We refer to this topology as the *order topology on \( X \).*

**Examples.**

(1) If we equip \( X = \mathbb{R} \) with the usual total order \( \leq \), then the resulting order topology equals, basically by definition, the usual topology on \( X \).

(2) We equip \( X = \mathbb{R} \times \mathbb{R} \) with the lexicographic order induced from the usual well-order on the two \( \mathbb{R} \)-factors. Now we equip \( X \) with the corresponding order topology. In Figure 181 we show some open intervals in \( \mathbb{R} \times \mathbb{R} \). We will discuss this fun example in greater detail in Exercise 7.3.

---

Figure 181

---

\[^{134}\text{At first glance it might look unnecessary to explicitly throw in \( X \) into the set \( \mathcal{B} \). But if \( X \) should happen to consist of a single element, then the sets of type (1), (2) and (3) actually do not satisfy property B1.}]

Convention. In this chapter, given a totally ordered set \((X, \leq)\) we equip \(X\) with the corresponding order topology. On numerous occasions we will use the obvious statement that if two totally ordered sets \((X_1, \leq_1)\) and \((X_2, \leq_2)\) are of the same order type, then the corresponding topological spaces are homeomorphic.

On several occasions we will use the following lemma, which we will prove in Exercise 7.2 without explicitly referring to it.

**Lemma 7.6.** Let \((X, \leq)\) be a totally ordered set. Given any interval \(I = (a, b), [a, b), (a, b] \) and \([a, b)\) in \(X\) the order topology on \((I, \leq)\) agrees with the subspace topology coming from \(X\).

**Example.** Later in this section the half-open interval \([0, 1) \subset \mathbb{R}\), equipped with the usual total order \(\leq\), will play an important role. It follows from Lemma 7.6 that the resulting order topology equals the usual topology on \(X \subset \mathbb{R}\).

We conclude this section with the following fairly straightforward lemma.

**Lemma 7.7.** Let \((X, \leq)\) be a totally ordered set. The topological space \(X\) that is given by the order topology is Hausdorff.

**Proof.** Let \((X, \leq)\) be a totally ordered set. We start out with the following claim.

**Claim.** Given any \(x \in X\) the sets
\[
(−\infty, x) := \{a \in X \mid a < x\} \quad \text{and} \quad (x, \infty) := \{b \in X \mid x < b\}
\]
are open subsets in the order topology.

If \(X\) has a minimal element \(x_0\), then evidently we have \((−\infty, x) = [x_0, x)\). By definition this set is open. If \(X\) does not have a minimal element, then we have \((−\infty, x) = \bigcup_{a < x} (a, x)\) which is of course an open subset of \(X\). Basically the same argument also shows that \((x, \infty)\) is open.

Now let \(x \neq y\) be two distinct points in \(X\). Since \((X, \leq)\) is totally ordered we know that \(x < y\) or \(y < x\). Without loss of generality we can assume that \(x < y\). If there exists an \(s \in (x, y)\), then we set \(U := (−\infty, s)\) and \(V := (s, \infty)\). Otherwise we set \(U := (−\infty, y)\) and \(V := (x, \infty)\). By the claim \(U\) and \(V\) are open. It is now clear that these are disjoint open neighborhoods of \(x\) and \(y\).

\[\begin{array}{cc}
\begin{array}{c}
\xrightarrow{U := (−\infty, s)} \quad & \xrightarrow{V := (s, \infty)}
\end{array}\\
\end{array}\]

**Figure 182.** Illustration for the proof of Lemma 7.7.

### 7.3. The long line

**Definition.** Let \((X, \leq)\) be an ordered set. Given \(x \in X\) we refer to \(S_x := \{y \in X \mid y < x\}\) as the \(x\)-section of \((X, \leq)\).
We consider the well-ordered set \((\mathbb{N}, \leq)\). Evidently the set is countable, but every section is actually finite. The following, quite remarkably, theorem says that the same type of mismatch between the cardinalities of all sections and the cardinality of the actual well-ordered set can also happen for other cardinalities.

**Theorem 7.8.**

1. There exists an uncountable well-ordered set such that every section is countable.
2. If \(X\) and \(Y\) are two well-ordered sets as in (1), then \(X\) and \(Y\) have the same order type.

We denote by \(\omega_1\) any well-ordered set as in (1).

**Remark.**

1. The alert reader will have noticed that statement (1) of Theorem 7.8 is precisely the content of Exercise 1.3.
2. The order type of such a well-ordered set as in Theorem 7.8 is often called the first uncountable ordinal. We refer to [Je03] and [Dev93] Chapter 3 for an introduction into the concept of “ordinals”.
3. The construction of the well-ordered set \(\omega_1\) is a product of the ever-fertile mind of our friends the set-theorists. To the best of my knowledge there is no “down to earth” construction of \(\omega_1\).
4. The set well-ordered set \(\omega_1\) is studied, in “everyday language”, in [Mun75] p. 67 and [Gaul14] Chapter B.2.

**Proof.**

1. By the Well-ordering Theorem 1.6 there exists a well-order on any set. In particular there exists a well-order \(\leq\) on the uncountable set \(X = \mathbb{R}\). If every section of \((X, \leq)\) is countable, then we are done since \(\mathbb{R}\) is uncountable. If not, then we consider the following non-empty subset

\[ S := \{ x \in X \mid \text{the } x\text{-section is uncountable} \}. \]

Recall that by definition of a well-order we know that the non-empty subset \(S\) of \(X\) has a minimal element \(z\). Finally we consider the corresponding \(z\)-section \(Y := S_z := \{ x \in X \mid x < z \}\). Note that it follows from the construction of \(z\) that \(Y = S_z\) is uncountable. Furthermore note that it follows immediately from the definition of \(z\) that every section of \(Y = S_z\) is actually countable.

2. We will not make use of this statement, thus we will not provide a proof. Instead we refer to [Mun75] p. 73] or alternatively to [Je03] Theorem I.2.12] for a proof. ■

Later on we will need the following simple lemma.

**Lemma 7.9.** The well-ordered set \(\omega_1\) does not have a maximal element.

**Proof.** Let \(x \in \omega_1\). We need to show that \(x\) is not a maximal element. By one of the two defining properties of \(\omega_1\) we know that the section \(S_x = \{ y \in X \mid y < x \}\) is countable. It follows from Lemma 1.7 (4) that \(\{ y \in X \mid y \leq x \} = S_x \cup \{ x \}\) is also countable. Since \(\omega_1\) is uncountable we see that \(x\) cannot be a maximal element. ■
Now we are finally ready to give the definition of the mythical long line.

**Definition.**

1. We equip $[0, 1)$ with the usual well-order. Next we equip $\mathbb{L}_{\geq 0} := \omega_1 \times [0, 1)$ with the lexicographic order that we introduced on page 76 and we equip $\mathbb{L}_{\geq 0}$ with the corresponding order topology. We refer to this topological space $\mathbb{L}_{\geq 0}$ as the closed long ray.
2. We denote by $\ast \in \omega_1$ the minimal element. We refer to $\mathbb{L}^+ := \mathbb{L}_{\geq 0} \setminus \{\ast, 0\}$, equipped with the subspace topology coming from $\mathbb{L}_{\geq 0}$, as the open long ray.
3. We write $\mathbb{L}_{\leq 0} := \mathbb{L}_{\geq 0}$. We refer to the topological space $\mathbb{L} := \mathbb{L}_{\leq 0} \cup (\ast, 0)$ as the long line. (In the literature the long line is sometimes also called the Alexandroff line.)

**Remark.** In many references, see e.g. [Mun66a, p. 158], [SS78, p. 71] and [Kra09, p. 66], the open long ray is called the long line.

The following proposition shows in particular that the open long ray $\mathbb{L}^+$ and the long line $\mathbb{L}$ both satisfy all properties of a 1-dimensional topological manifold, except that neither is second-countable.

**Theorem 7.10.** The open long ray $\mathbb{L}^+$ and the long line $\mathbb{L}$ both have the following properties:

1. they are Hausdorff,
2. they are locally homeomorphic to $\mathbb{R}$,
3. they are path-connected and
4. they are not second-countable.

**Remark.**

1. The proof we give below is based on the sketch given in [Mun66a, p. 158]. An alternative account of the proof is given in [Gaul14, Chapter 1.2].
2. The discovery of the long line $\mathbb{L}$ goes back to work of Georg Cantor [Cant1883] from 1885.
3. A slightly less otherworldly example of a topological space that satisfies all properties of a path-connected topological manifold, except that it is not second-countable, is given in [Bre93, Corollary 17.5] and [Spr57, p. 56].

We will prove Theorem 7.10 in the next section. In the remainder of this section we will discuss the open long ray and long line in greater detail. First of all the following proposition lists several weird and surprising properties of the open long ray and the long line.

**Proposition 7.11.**

1. Every map $f : \mathbb{L}^+ \to \mathbb{R}$ is eventually constant, i.e. there exists an $(x, s) \in \mathbb{L}^+$ such that $f((y, t)) = f(x, s)$ for every $(y, t) \geq (x, s)$.
2. The topological space $\mathbb{L}^+$ is not paracompact.
For the remaining statements we need the notion of maps being homotopic, which we only introduce on page 337. Furthermore we need the notion of a topological space to be contractible, this notion will be introduced on page 347.

(3) Every bounded map \( f : \mathbb{L}^+ \to \mathbb{L}^+ \) is homotopic to a constant map.
(4) Every unbounded map \( f : \mathbb{L}^+ \to \mathbb{L}^+ \) is homotopic to the identity map.
(5) An unbounded map \( f : \mathbb{L}^+ \to \mathbb{L}^+ \) is never homotopic to bounded map.
(6) The open long line \( \mathbb{L}^+ \) is not contractible.

Proof.

(1) It is a great exercise to try to prove this statement. If, inexplicably, the reader is not inclined to provide the arguments, then we refer to [Gaul14, Proposition 1.17] for a proof.

(2) By Theorem 2.79 it suffices to show that \( \mathbb{L}^+ \) admits an open cover that does not admit a locally finite open refinement. In fact one can show that the open subsets \( U(x,s) := ((s,0),(x,s)) \) of \( \mathbb{L}^+ \) is such an open cover. Since we will not make use of this statement we will not show that this cover does not admit a locally finite open refinement. The statement can be proved using a slight variation on the argument given on [Jos83, Theorem 15.3.2(vi)].

(3)-(5) These statements are proved in [Gaul14, Proposition 1.12].

(6) This statement follows immediately from (5) and Lemma 18.12.

At this stage one might fear that now, when we no longer restrict ourselves to second-countable topological spaces, the genie is out of the bottle, and that thus any type of classification result is completely out of reach. Rather stunningly this is not the case.

The following theorem can now be viewed as a generalization of Theorem 7.1.

**Theorem 7.12.** Let \( X \) be a topological space that is Hausdorff and path-connected.

(1) If \( X \) is locally homeomorphic to an open subset of \( \mathbb{R} \), then \( X \) is homeomorphic to one of the following: \( S^1 \), \( \mathbb{R} \), \( \mathbb{L}^+ \) and \( \mathbb{L} \).

(2) If \( X \) is locally homeomorphic to an open subset of \( \mathbb{R}_{\geq 0} \), then either \( X \) is homeomorphic to one of the above, or one of the following: \([0,1)\), \([0,1]\) and \( \mathbb{L}_{\geq 0} \).

Proof.

(1) This statement is proved in [Knes58].

(2) This statement can be deduced easily from (1) by first removing the “boundary points”. We leave it to the reader to provide the details.

By Theorem 7.10 we now know in particular that the long line \( \mathbb{L} \) admits an atlas. In fact, as is shown in [Gaul14, Proposition 7.9], there exists an atlas on \( \mathbb{L} \) that is smooth, i.e. such that all transition maps are smooth. Much more impressively, it turns out that there are uncountable many mutually non-diffeomorphic smooth structures on \( \mathbb{L} \). We refer to [Gaul14, Theorem 7.14] and [Ny92] for a precise formulation and a proof of this assertion.

7.4. **Proof of Theorem 7.10** In this section we finally provide the proof of Theorem 7.10.

We start out with some general definitions and statements regarding well-ordered sets.
**Definition.** Let \((X, \leq)\) be a well-ordered set. A subset \(A\) of \(X\) is called **inductive** if for every \(a \in X\) with \(S_a \subset A\) we also have \(a \in A\).

**Examples.**

1. Let \(X = \mathbb{R}_{\geq 0}\). The interval \(A = [0, 2)\) is not inductive whereas \(A = [0, 2]\) is inductive.
2. One can easily show that the only inductive subset of \(\mathbb{N}_0\) is \(\mathbb{N}_0\).

The grandiose name of the following theorem is designed to impress friends and family.

**Theorem 7.13. (Principle of Transfinite Induction)** Let \((X, \leq)\) be a well-ordered set. If \(A \subset X\) is an inductive subset of \(X\), then \(A = X\).

**Proof.** Let \(A \subset X\) be an inductive subset. We suppose that \(A \neq X\). Since \(X\) is well-ordered the set \(X \setminus A\) has a minimal element \(y\). Since \(y\) is the minimal element of \(X \setminus A\) we see that for every \(x < y\) we have \(x \in A\). But this means that the \(y\)-section \(S_y\) is contained in \(A\). But since \(A\) is inductive this implies that \(y \in A\). We have thus obtained a contradiction. ■

In the proof of Theorem 7.10 we will need the following fairly straightforward lemma.

**Definition.** Let \((X, \leq)\) be a partially ordered set.

1. Let \(x \in X\). We say that \(a \in X\) is an **immediate predecessor** of \(x\) if \(a < x\) and if there is no \(b \in X\) with \(a < b < x\).
2. Let \(x \in X\). We say that \(a \in X\) is an **immediate successor** of \(x\) if \(x < a\) and if there is no \(b \in X\) with \(x < b < a\).
3. Let \(A \subset X\) be a subset. We say that \(x \in X\) is an **upper bound** of \(A\) if for every \(a \in A\) we have \(a \leq x\).
4. Let \(A \subset X\) be a subset. We say that \(x \in X\) is a **supremum** of \(A\) if \(x\) is an upper bound of \(A\) and if there is no upper bound of \(A\) that is less than \(x\).
5. Let \(x_1 < x_2 < \ldots\) be an increasing sequence of elements in \(X\). If \(b = \sup\{x_1, x_2, \ldots\}\) then we say that \(b\) is a **limit** of the sequence.

**Examples.**

1. Every element in \(\mathbb{Z}\) has an immediate predecessor and an immediate successor.
2. No element in \(\mathbb{R}\) has an immediate predecessor and no element in \(\mathbb{R}\) has an immediate successor.
3. If \((X, \leq)\) is a well-ordered set, then it follows easily from the definitions that every proper subset \(A \subset X\) admits a unique supremum.

**Lemma 7.14.** Let \((X, \leq)\) be a well-ordered set and let \(x \in X\) such that the corresponding section \(S_x\) is countable. Precisely one of the following three statements holds:

1. \(x\) is the minimal element of \(X\).
2. There exists an immediate predecessor of \(x\).
3. \(x\) is the limit of an increasing sequence \(x_0 < x_1 < x_2 < \ldots\) of elements of \(X\).

**Proof.** Let \((X, \leq)\) be a well-ordered set and let \(x \in X\) such that the corresponding section \(S_x = \{w \in X \mid w < x\}\) is countable. We only need to consider the case that \(x \in X\) is not
the minimal element. This means that the section $S_x$ is non-empty. If the section $S_x$ is finite, then it admits a maximal element, which is clearly an immediate predecessor of $x$. Next we suppose that the section $S_x$ is infinite. By hypothesis on $x$ we know that $S_x$ is also countable. Thus there exists a bijection $\varphi : \mathbb{N}_0 \to S_x$. Now given any $n \in \mathbb{N}_0$ we set $y_n := \max\{\varphi(0), \ldots, \varphi(n)\}$. By construction we have $y_1 \leq y_2 \leq y_3 \leq \ldots$. If the sequence $y_1, y_2, \ldots$ is eventually constant, i.e. if there exists an $N$ such that $y_n = Y_N$ for every $n \geq N$, then $Y_N$ is easily seen to be an immediate predecessor of $x$. Otherwise there exists a subsequence $y_{s_1} < y_{s_2} < y_{s_3} < \ldots$ which is strictly increasing. By construction $x$ is the limit of this sequence.

Finally we leave it to the reader to verify that three possibilities are mutually exclusive.

\textbf{Example.} We consider the subset $X := \mathbb{N}_0 \cup \{n - \frac{1}{k} \mid n \in \mathbb{N}_0 \text{ and } k \in \mathbb{N}_{\geq 2}\}$ of $\mathbb{R}$, equipped with the usual partial order. One can easily verify that $(X, \leq)$ is actually well-ordered. The number $0$ is evidently the minimal element. Every $x$ of the form $n - \frac{1}{k}$ with $n \in \mathbb{N}$ and $k \in \mathbb{N}_{\geq 2}$ has an immediate successor, namely $n - \frac{1}{k-1}$. Finally every $n \in \mathbb{N}$ is the limit of the increasing sequence $x_i = n - \frac{1}{i+1}$.

\begin{figure}[h]
\centering
\includegraphics[width=0.8\textwidth]{figure183.png}
\caption{The interval $[0, 1]$ is partitioned into three intervals: the minimal element, each element has an immediate predecessor, and the limit of an increasing sequence.}
\end{figure}

\textbf{Lemma 7.15.} Let $(X, \leq)$ be a totally ordered set. If $a < b < c$ are three elements of $X$, The interval $[a, c)$ has the order type of $[0, 1]$ if and only if each of the two intervals $[a, b)$ and $[b, c)$ has the order type of $[0, 1]$.

(2) Let $b \in X$ be the limit of an increasing sequence $x_0 < x_1 < \ldots$ of elements of $X$. If each $[x_n, x_{n+1})$ has the order type of $[0, 1)$, then so does $[x_0, b)$.

\textbf{Proof.} Throughout the proof we will make use of the following simple observation: if $(A, \leq)$ and $(B, \leq)$ are two totally ordered sets, then they have the same order type if and only if there exists an order-preserving bijection $f : A \to B$. In other words, the fact that $A$ and $B$ are totally ordered implies that the inverse $f^{-1} : B \to A$ is automatically order-preserving. Now we turn to the proofs of the two statements.

(1) Let $a < b < c$ be three elements of $X$. First suppose that there exist order-preserving bijections $f : [a, b) \to [0, 1)$ and $g : [b, c) \to [0, 1)$. It is clear that the map $[a, c) \to [0, 1)\begin{align*}
t \mapsto \begin{cases} 
\frac{1}{2} \cdot f(t), & \text{if } t \in [a, b), \\
\frac{1}{2} + \frac{1}{2} \cdot g(t), & \text{if } t \in [b, c)
\end{cases}
\end{align*}$
is an order-preserving bijection. Conversely suppose that there exists an order-preserving bijection $h : [a, b) \to [0, 1)$. We point out that $h([a, b)) = [0, h(b))$ and
We will now treat these three cases separately.

(2) Now let $b \in X$ be the limit of an increasing sequence $x_0 < x_1 < \ldots$ of elements of $X$. We suppose that for each $n \in \mathbb{N}_0$ there exists an order-preserving bijection $\varphi_n : [x_n, x_{n+1}) \to [0, 1)$. One can now easily verify that the map

$$[x_0, b) = \bigcup_{n \in \mathbb{N}_0} [x_n, x_{n+1}) \to [0, 1)$$

$$t \mapsto \frac{1}{2^{n+1}} \cdot \varphi_n(t) + \sum_{i=0}^{n-1} \frac{1}{2^i}$$

for $t \in [x_n, x_{n+1})$

since $b$ is the limit of the increasing sequence $x_0 < x_1 < \ldots$ is an order-preserving bijection.

The next lemma contains the heart of the proof of Theorem 7.10.

**Lemma 7.16.** As above we denote by $\ast$ the minimal element of $\omega_1$ and let $x \in \omega_1 \setminus \{\ast\}$.

1. The half-open interval $((\ast, 0), (x, 0)) \subset \mathbb{L}_{\geq 0}$ has the order type of $[0, 1)$.
2. The open interval $((\ast, 0), (x, 0)) \subset \mathbb{L}_{\geq 0}$ has the order type of $(0, 1)$.

**Proof.** We consider the set

$$B := \{ b \in \omega_1 \setminus \{\ast\} \mid \text{the set } ((\ast, 0), (b, 0)) \text{ has order type of } [0, 1) \}.$$

We want to show that $B = \omega_1 \setminus \{\ast\}$. Note that it follows from the fact that $\omega_1$ is well-ordered that the complement of the minimal element $\ast$, i.e. the set $\omega_1 \setminus \{\ast\}$, is again well-ordered. Thus it follows from Theorem 7.13 i.e. it follows from the Principle of Transfinite Induction, that it suffices to show that $B$ is inductive.

Now let $b \in B$ such that $S_b \subset B$. By Lemma 7.14 we know that one of the following holds:

1. $b$ is the minimal element of $B$.
2. $b$ has an immediate predecessor $a$.
3. $b$ is the limit of an increasing sequence $x_0 < x_1 < \ldots$ of elements of $X$.

We will now treat these three cases separately.

1. Suppose that $b$ is the minimal element of $\omega_1 \setminus \{\ast\}$. In this case we see easily that

$$\{ (\ast, 0), (b, 0) \} = \{ (\ast, t) \mid t \in [0, 1) \},$$

which evidently has the order type of $[0, 1)$.

2. Suppose that $b$ has an immediate predecessor $a$. Since $S_b \subset B$ and $a < b$ we see that

$a \in B$, i.e. we see that $((\ast, 0), (a, 0))$ has order type $[0, 1)$. Next note that the fact that $a$ is an immediate predecessor of $b$ implies that $\{ (a, 0), (b, 0) \} = \{ (a, x) \mid x \in [0, 1) \}$. Thus we see that this interval also has order type $[0, 1)$. It follows from Lemma 7.15 (1) that $((\ast, 0), (b, 0))$ has order type $[0, 1)$.

3. Now suppose that $b$ is the limit of an increasing sequence $x_0 < x_1 < \ldots$ of elements of $X$. Since $S_b \subset B$ and since for each $x_n$ we have $x_n < b$ we see as in (2) that each $((\ast, 0), (x_n, 0))$ has order type $[0, 1)$. It follows from Lemma 7.15 (1) that each interval $((x_n, 0), (x_{n+1}, 0))$ has order type $[0, 1)$. Finally it follows from Lemma 7.15 (2) that the interval $((\ast, 0), (b, 0))$ has order type $[0, 1)$.

Now we can finally provide the proof of Theorem 7.10.
7. 1-DIMENSIONAL MANIFOLDS AND THE LONG LINE

7.1 - DIMENSIONAL MANIFOLDS AND THE LONG LINE

\[ \{(x, 0) \} \times [0, 1) \quad \{a\} \times [0, 1) \quad \{b\} \times [0, 1) \quad \{x_n\} \times [0, 1) \quad \{b\} \times [0, 1) \]

Figure 184. Illustration for the proof of Lemma 7.16

Proof of Theorem 7.10

We will prove the desired statements only for the open long ray \( \mathbb{L}^+ \). We leave it to the reader to make the minor modifications needed to show that the analogous statements also hold for the long line \( \mathbb{L} \). Now recall that we need to show the following four statements regarding the open long ray \( \mathbb{L}^+ \).

1. \( \mathbb{L}^+ \) is Hausdorff,
2. \( \mathbb{L}^+ \) is locally homeomorphic to an open subset of \( \mathbb{R} \),
3. \( \mathbb{L}^+ \) is path-connected,
4. \( \mathbb{L}^+ \) is not second-countable.

We turn to the proofs of these four statements.

1. This statement conveniently enough follows immediately from Lemma 7.7.
2. Let \((x, t) \in \mathbb{L}^+\). By Lemma 7.9 we can pick some \( y > x \). Since \( y > x \) we see that the open interval \( U := ((*, 0), (y, 0)) \) is an open neighborhood of \((x, t)\). Note that by Lemma 7.16 we know that the interval \([(*, 0), (y, 0)]\) has the order type of \([0, 1)\). It follows that the open interval \( U := ((*, 0), (y, 0)) \) is homeomorphic to \((0, 1)\).
3. Let \((x, s)\) and \((y, t)\) be two points in \( \mathbb{L}^+ \). By Lemma 7.9 we can pick \( z \in \mathbb{X} \) with \( z > x \) and \( z > y \). As in (2) we obtain from Lemma 7.16 that the open interval \( U := ((*, 0), (z, 0)) \) is homeomorphic to \((0, 1)\). Since the open interval contains the points \((x, s)\) and \((y, t)\) and since \((0, 1)\) is path-connected we see that there exists a path \( \gamma : [0, 1] \rightarrow \mathbb{L}^+ \) that connects \((x, s)\) and \((y, t)\).
4. Let \( \mathcal{B} \) be a basis for the topological space \( \mathbb{L}^+ \). We need to show that \( \mathcal{B} \) is uncountable. For each \( x \in \omega_1 \) we consider the open interval \( U_x := ((x, \frac{1}{2}), (x, \frac{3}{4})) \). It follows from the definition of a basis that given any \( x \in \mathbb{X} \) there exists a set \( B_x \in \mathcal{B} \) with \((x, \frac{1}{2}) \in B_x \subset U_x \). Since the \( U_x \) are disjoint we see that the \( B_x \) are distinct. Since \( \mathbb{X} \) is uncountable we obtain from Lemma 1.7 (1) that \( \mathcal{B} \) is uncountable.

Exercises for Chapter 7.

Exercise 7.1. Let \( M \) be a non-compact connected non-empty 1-dimensional topological manifold with empty boundary.

(a) Show that there exists a sequence \( X_0 \subset X_1 \subset \ldots \) of compact connected 1-dimensional submanifolds of \( M \) such that for each \( i \in \mathbb{N}_0 \) we have \( X_i \subset \tilde{X}_{i+1} \) and such that...
\[ M = \bigcup_{i \in \mathbb{N}_0} X_i. \]

*Hint.* Use Lemma 6.58.

(b) Show that \( M \) is homeomorphic to \( \mathbb{R} \).

*Remark.* You can use that on page 330 we proved that every compact connected non-empty 1-dimensional topological manifold is homeomorphic to \([0, 1]\).

**Exercise 7.2.**

(a) Let \((X, \leq)\) be a totally ordered set. Show that given any interval \( I = (a, b), [a, b), (a, b] \) and \([a, b)\) in \( X \) the order topology on \((I, \leq)\) agrees with the subspace topology coming from \( X \).

(b) Let \((X, \leq)\) be a totally ordered set and let \( A \subset X \) be a subset. Show that the order topology on \((A, \leq)\) does not necessarily agree with the subspace topology coming from \( X \).

**Exercise 7.3.** We consider \( X := \mathbb{R} \times \mathbb{R} \), for once equipped with the order topology \( \mathcal{O} \).

(a) Let \( \mathcal{T} \) be the usual topology on \( X = \mathbb{R} \times \mathbb{R} = \mathbb{R}^2 \). Do we have an inclusion \( \mathcal{O} \subset \mathcal{T} \)? Do we have an inclusion \( \mathcal{T} \subset \mathcal{O} \)?

(b) Show that the topological space \((X, \mathcal{O})\) is Hausdorff.

(c) Is the topological space \((X, \mathcal{O})\) second-countable?

(d) Is \((X, \mathcal{O})\) locally homeomorphic to open subsets of \( \mathbb{R} \)?

(e) Is \((X, \mathcal{O})\) homeomorphic to the long line?

**Exercise 7.4.** Let \( \omega_1 \) be the well-ordered set introduced in Theorem 7.8.

(a) Show that for every \( x \in \omega_1 \) the subset \( \{ y \in \omega_1 \mid x < y \} \) is uncountable.

(b) Let \( X = \{ x \in \omega_1 \mid x \) has no immediate successor\} \). Show that \( X \) is uncountable.

**Exercise 7.5.**

(a) We consider the well-ordered set \( \mathbb{L}^+ := \omega_1 \times [0, 1) \). Show that every increasing sequence in \( \mathbb{L}_{\geq 0} \) converges.

(b) A topological space that has the property that every sequence admits a convergent subsequence is called sequentially compact. Show that the closed long ray \( \mathbb{L}^+ \) is sequentially compact.

**Exercise 7.6.** Show that the open long ray \( \mathbb{L}^+ \) and the long line \( \mathbb{L} \) are not homeomorphic. *Hint.* What happens if you remove a point?

**Exercise 7.7.**

(a) Let \((X, \leq)\) be a well-ordered set. Let \( x \in X \). Show that either \( x \) is the largest element of \( X \) or that \( X \) has an immediate successor.

(b) Give an example of a partially ordered set \((X, \leq)\) that is not well-ordered but that nonetheless has the property that every \( x \in X \) has an immediate successor.

**Exercise 7.8.** Let \((X, \leq)\) be a partially ordered set and let \( x \in X \).

(1) We say \( x \) has depth \(-1\) if \( x \) is a minimal element of \( X \).

(2) We say \( x \) has depth \( 0 \) if \( x \) has an immediate predecessor.
Now we iteratively define what it means for \( x \in X \) to have depth \( k \in \mathbb{N}_{\geq 2} \).

(3) We say \( x \) has depth \( k \) if \( x \) is not of depth \( k - 1 \) but if there exists an increasing sequence \( x_1 < x_2 < \ldots \) in \( X \), such that each \( x_i \) has depth \( < k \), and such that \( x \) is a limit of this sequence.

Show that there exists a countable well-ordered subset of \( \mathbb{R} \) that admits elements of depth two.

**Exercise 7.9.** Does the long line \( L \) admit an embedding into \( \mathbb{R}^2 \)?
8. Differential topology

Differential topology is the study of smooth manifolds and their submanifolds viewed as topological spaces. In this section we will first give several basic definitions in differential topology. Afterwards we will state, without proof but with precise references, some technical results which later on will make our life much easier.

8.1. Immersions and smooth embeddings. We start out with some definitions that will crop up frequently throughout these lecture notes.

Definition. Let \( N \) be a compact topological manifold and let \( M \) be any topological manifold. A map \( \varphi: N \to M \) is called proper if \( \varphi^{-1}(\partial M) = \partial N \).

We illustrate the definition of a proper map in Figure 185.

\[
\begin{array}{c}
\text{Figure 185} \\
\text{proper map}
\end{array}
\]

The following definition is related in spirit to the notion of a submersion that we had introduced on page 311.

Definition. A map \( \varphi: N \to M \) between two smooth manifolds is called an immersion if the following conditions are satisfied:

1. The map \( \varphi \) is smooth.
2. For each \( P \in N \) the induced map \( \varphi_*: T_P N \to T_{\varphi(P)} M \) is a monomorphism.
3. For each \( P \in N \setminus \partial N \) we have \( \varphi(P) \in M \setminus \partial M \).
4. For each \( P \in \partial N \) with \( \varphi(P) \in \partial M \) the image \( \varphi_*(T_P N) \) is not contained in \( T_{\varphi(P)}(\partial M) \).

An immersion that also satisfies the following extra condition

5. \( \varphi: N \to M \) is an embedding

is called a smooth embedding.

The following proposition relates the notion of smooth embeddings to the notion of submanifolds.

\[^{135}\text{Another way of expressing this condition is that the map } T_P N \to T_{\varphi(P)} M / T_{\varphi(P)} \partial M \text{ is an epimorphism.}\]

\[^{136}\text{Recall that “embedding” means that the map } \varphi: N \to \varphi(N) \text{ is a homeomorphism where } \varphi(N) \subset M \text{ is endowed with the subspace topology.}\]

\[^{137}\text{If } N \text{ is compact, then it follows from Proposition 2.43(2) that it suffices to verify that } \varphi \text{ is injective and continuous.}\]
**Proposition 8.1.** Let \( N \) be an \( n \)-dimensional smooth manifold and let \( M \) be a smooth manifold.

1. Let \( \varphi : N \to M \) be a smooth embedding such that \( \varphi(N \setminus \partial N) \subset M \setminus \partial M \) and such that the following condition is satisfied:

   (*) For every component \( C \) of \( \partial N \) we have either \( \varphi(C) \subset \partial M \) or \( \varphi(C) \subset M \setminus \partial M \). Then \( \varphi(N) \) is an \( n \)-dimensional submanifold of \( M \) and the map \( \varphi : N \to \varphi(N) \) is a diffeomorphism.

2. Suppose \( N \) is compact. If \( \varphi : N \to M \) is a proper smooth embedding, then \( \varphi(N) \) is a proper \( n \)-dimensional submanifold of \( M \) and the map \( \varphi : N \to \varphi(N) \) is a diffeomorphism.

**Remark.**

1. Let \( M \) be a smooth manifold and let \( W \) be a submanifold. It follows fairly easily from the definitions and Exercise 6.8 that the inclusion map \( \iota : W \to M \) is a smooth embedding and that it satisfies Condition (*) from Proposition 8.1 (1).

2. In Figure 188 we show a smooth embedding \( \varphi : N \to M \) that does not satisfy Condition (*) from Proposition 8.1 (1). This author has to admit that he had initially overlooked that (*) was a necessary condition. This shows once again that statements, for which detailed proofs are not given, tend to be incorrectly phrased.
Proof. For the proof of (2) we need to make the following observation: If \( \varphi : N \to M \) is a map and \( N \) is compact, then it follows from Lemma 2.40 and Lemma 2.17 that \( \varphi(N) \) is a closed subset of \( M \).

For the actual proof of (1) and (2) we have to refer to the literature. For smooth manifolds without boundary the proposition is proved in [Lee02, Proposition 5.2] and [BG88, Corollary 2.6.11]. The proof for smooth manifolds with boundary is quite similar. We leave it to the reader to fill in the details. Note that [Lee02, Proposition 5.2] actually deals with smooth manifolds with boundary. But as we pointed out on page 281, the definition of a submanifold with boundary in [Lee02] differs from our definition and also the notion of a smooth embedding differs from our definition. ■

Examples.

(1) It is straightforward to verify that the map \( \Psi : \mathbb{R}^2 \times S^1 \to \mathbb{R}^3 \) given in Lemma 3.13 restricts to a smooth embedding \( \Psi : S^1 \times S^1 \to \mathbb{R}^3 \) and that it also restricts to a smooth embedding \( \Psi : B^2 \times S^1 \to \mathbb{R}^3 \). By Proposition 8.1 this allows us to view \( S^1 \times S^1 \) and \( B^2 \times S^1 \) as submanifolds of \( \mathbb{R}^3 \).

(2) Let \( n \in \mathbb{N}_0 \). In Lemma 2.44 we used the stereographic projection to give an explicit homeomorphism \( \Phi : S^n \to \mathbb{R}^n \cup \{\infty\} \). We leave it to the reader to verify that the map \( \mathbb{R}^n \to \mathbb{R}^n \cup \{\infty\} \xrightarrow{\Phi^{-1}} S^n \) is a smooth embedding. We will use this embedding to view \( \mathbb{R}^n \) as a submanifold of the smooth manifold \( S^n \).

In the following proposition we consider immersions and smooth embeddings between smooth manifolds of the same dimension.

Proposition 8.2. Let \( M \) and \( N \) be smooth manifolds of the same dimension and furthermore let \( \varphi : N \to M \setminus \partial M \) be a map.

(1) If \( \varphi : N \to M \setminus \partial M \) is an immersion, then \( \varphi(N \setminus \partial N) \) is an open subset of \( M \).

(2) If \( \varphi : N \to M \setminus \partial M \) is a smooth embedding and if \( N \) is compact, then the following three statements hold:

(a) \( M \) is decomposed, in the sense of the definition on page 284, into the submanifolds \( \varphi(N) \) and \( X := M \setminus \varphi(N \setminus \partial N) \).

(b) The boundary of \( M \setminus \varphi(N \setminus \partial N) \) as a smooth manifold in its own right is given by \( \partial M \cup \varphi(\partial N) \).

(c) If \( \partial N \) is connected and if \( M \) is connected, then \( X \) is also connected.

(d) If \( M \) is compact, then \( M \setminus \varphi(N \setminus \partial N) \) is also compact.

(We refer to Figure 189 for an illustration.)

(3) If \( M \) and \( N \) are closed and connected and if \( \varphi : N \to M \) is a smooth embedding, then \( \varphi \) is a diffeomorphism.

Sketch of proof.

(1) Let \( \varphi : N \to M \setminus \partial M \) be an immersion. It is not difficult to deduce from Theorem 6.19 that \( \varphi(N \setminus \partial N) \) is an open subset of \( M \). We leave it to the reader to fill in the details.

(2) This statement follows immediately from Propositions 8.1 and 6.30.
(3) We already know by Proposition 8.1 that $\varphi : N \to \varphi(N)$ is a diffeomorphism. Thus it suffices to show that $\varphi(N) = M$. First note that it follows from Lemma 2.40 and Lemma 2.17 (2) that $\varphi(N)$ is a closed subset of $M$. Furthermore, it follows easily from Theorem 6.19 that $\varphi(N)$ is an open subset of $M$. Since $M$ is connected we see that $M = \varphi(N)$. \[\square\]

We conclude this discussion of immersions and smooth embeddings with the following instructive example which is dressed up as a lemma.

**Lemma 8.3.** Given $\lambda \in \mathbb{R}$ we consider the following map

$$
\varphi_\lambda : \mathbb{R} \to \mathbb{R}^2/\mathbb{Z}^2
$$

$$
t \mapsto [(t, \lambda \cdot t)].
$$

The following statements hold:

1. The map $\varphi_\lambda$ is an immersion if and only if $\lambda \neq 0$.
2. The map $\varphi_\lambda$ is injective if and only if $\lambda$ is irrational.
3. If $\lambda$ is irrational, then $\varphi_\lambda : \mathbb{R} \to \mathbb{R}^2/\mathbb{Z}^2$ is not an embedding, i.e. $\varphi_\lambda$ is not a smooth embedding.
4. Suppose $\lambda$ is rational. We write $\lambda = \frac{p}{q}$ with $p \in \mathbb{Z}$ and $q \in \mathbb{N}$ such that $p$ and $q$ are coprime. Then the map

$$
\varphi_\lambda : S^1 = e^{2\pi it} \to \mathbb{R}^2/\mathbb{Z}^2
$$

$$
t \mapsto [(qt, \lambda \cdot qt)]
$$

is a smooth embedding.

**Figure 189.** Illustration of Proposition 8.2 (2).
Proof. Statements (1), (2) and (4) are amusing exercises. Statement (3) requires the simple number theoretic fact that given any \( \alpha \in \mathbb{R} \) and any \( N \in \mathbb{N} \) there exist \( n, m \in \mathbb{Z} \) with \( 1 \leq n \leq N \) and with \(|n\alpha - m| < \frac{1}{N} \)\footnote{This statement is known as Dirichlet’s Approximation Theorem, but it is actually elementary to prove, see e.g. \cite{Lee2002} Lemma 4.21.} We leave the details to the reader. \( \blacksquare \)

Examples.

(1) It is straightforward to verify that the map
\[
S^1 \times S^1 \to \mathbb{R}^3
\]
\[
(e^{i\theta}, e^{i\varphi}) \mapsto ((2 + \sin(\theta)) \cdot \cos(\varphi), (2 + \sin(\theta)) \cdot \sin(\varphi), \cos(\theta))
\]
is a smooth embedding of the 2-dimensional torus into \( \mathbb{R}^3 \).

(2) Let \( M \) be a closed non-empty \( n \)-dimensional topological manifold. In Corollary \footnote{Theorem 50.8} we showed that there is no embedding of \( M \) into \( \mathbb{R}^n \).

8.2. Smooth homotopies. Now suppose we are given two smooth maps \( f_0, f_1: M \to N \) between smooth manifolds. On page \footnote{Page 540} we defined a homotopy between \( f_0 \) and \( f_1 \) to be a map \( F: M \times [0,1] \to N \) with \( F_0 = f_0 \) and \( F_1 = f_1 \). As we will see shortly, on many occasions this definition is not very useful. It is much more reasonable to consider “smooth” homotopies, namely we want \( F \) itself to be a smooth map.

But this leads to a slightly annoying question: What does it mean for \( F: M \times [0,1] \to N \) to be smooth? If \( M \) is closed, then by Proposition \footnote{Proposition 6.51} (1) we can view \( M \times [0,1] \) as a smooth manifold and we know what it means for a map \( F: M \times [0,1] \to N \) to be smooth. But what should we do if \( M \) has non-empty boundary?

This leads us to the following definition.

**Definition.** Let \( M \) and \( N \) be smooth manifolds and let \( a < b \) be two real numbers. We say a map \( \varphi: M \times [a, b] \to N \) is smooth if the following conditions are satisfied:

1. The map \((M \setminus \partial M) \times [a, b] \to N \) is smooth.
2. Given any \( x \in \partial M \) there exists an open neighborhood \( U \) of \( x \) in \( M \), an \( \epsilon \in (0, b - a) \) and a smooth map \( \psi: U \times (a - \epsilon, a + \epsilon) \to N \) that agrees with \( \varphi \) on \( U \times [a, a + \epsilon] \).
3. Given any \( x \in \partial M \) there exists an open neighborhood \( U \) of \( x \) in \( M \), an \( \epsilon \in (0, b - a) \) and a smooth map \( \psi: U \times (b - \epsilon, b + \epsilon) \to N \) that agrees with \( \varphi \) on \( U \times (b - \epsilon, b) \).

Note that in all three cases it makes sense to talk of a map being smooth since by Proposition \footnote{Proposition 6.51} (4) we know that \((M \setminus \partial M) \times [a, b] \) is a smooth manifold with boundary \((M \setminus \partial M) \times \{a, b\} \), that \( U \times (a - \epsilon, a + \epsilon) \) is a smooth manifold with boundary \( \partial U \times (a - \epsilon, a + \epsilon) \) and finally \( U \times (b - \epsilon, b + \epsilon) \) is a smooth manifold with boundary \( \partial U \times (b - \epsilon, b + \epsilon) \).

**Remark.**

1. If \( M \) is a smooth manifold without boundary, then the cases (2) and (3) do not occur and the above definition of a smooth map \( \varphi: M \times [a, b] \to N \) is precisely the one we had always used.

2. Let \( M \) be a smooth manifold. We could view \( M \times [0,1] \) as a smooth manifold with “corners”, see e.g. \cite{Wall1916} p. 30 or \cite{Lee2002} Chapter 16] for a definition. The definition of a smooth map on a smooth manifold with corners is very similar to the...
If there exists an $\epsilon > 0$, we can define the notion of a smooth homotopy. Let $M$ and $N$ be smooth manifolds and let $F: M \times [0, 1] \to N$ be a homotopy. If there exists an $\epsilon > 0$ and a smooth map $M \times (-\epsilon, 1 + \epsilon) \to N$ that restricts to $F$ on $M \times [0, 1]$, then $F$ is by definition smooth. For example, it follows easily from this observation that the map
\[
S^1 \times [0, 1] \to \mathbb{R}^2 \\
(z, t) \mapsto z \cdot (1 - t)
\]
is a smooth homotopy from the inclusion map $S^1 \to \mathbb{R}^2$ to a constant map.

The following elementary lemma is sometimes useful when one tries to combine smooth homotopies.

**Lemma 8.4.** (*Let $M$ and $N$ be smooth manifolds and let $F: M \times [0, 1] \to N$ be a smooth homotopy. There exists an $\epsilon \in (0, \frac{1}{2})$ and a smooth homotopy $G: M \times [0, 1] \to N$ with $G_0 = F_0$ and $G_1 = F_1$ and such that $G_t = G_0$ for all $t \in [0, \epsilon]$ and $G_t = G_1$ for all $t \in [1 - \epsilon, 1]$.**

**Proof.** Using Lemma 6.13 one can easily find a smooth map $\varphi: [0, 1] \to [0, 1]$ such that $\varphi(0) = 0$, $\varphi(1) = 1$, $\varphi(t) = 0$ for all $t \in [0, \epsilon]$ and $\varphi(t) = 1$ for all $t \in [1 - \epsilon, 1]$. The map $(x, t) \mapsto F(x, \varphi(t))$ has the desired properties.

We continue with our next definition.
Definition. Let $M$ and $N$ be smooth manifolds.

1. A (proper) smooth isotopy of $M$ in $N$ is a smooth\footnote{Note that we defined on page 346 what it means for the map $F: M \times [0, 1] \to N$ to be smooth. Also note that the notion of a smooth isotopy is stronger than of an isotopy $M \times [0, 1] \to N$ which happens to be a smooth map. We also require each $F_t$ to be a (proper) smooth embedding. We will discuss this in Exercise 8.4.} map
$$F: M \times [0, 1] \to N \quad (z, t) \mapsto F(z, t)$$

such that for each $t \in [0, 1]$ the map $F_t: M \to N$ is a (proper) smooth embedding.

2. We say that two (proper) smooth embeddings $f_0, f_1: M \to N$ are (properly) smoothly isotopic if there exists a (proper) smooth isotopy $F: M \times [0, 1] \to N$ with $F_0 = f_0$ and $F_1 = f_1$.

If $M = N$ and if each $F_t$ is a diffeomorphism, then we refer to a smooth isotopy as a diffeotopy and we say diffeotopic instead of smoothly isotopic.

The following lemma gives in particular an example of a diffeotopy.

**Lemma 8.5.** Let $n \in \mathbb{N}$.

1. If $\gamma: [0, 1] \to O(n)$ is a smooth path, then the map
$$F: B^n \times [0, 1] \to B^n \quad (x, t) \mapsto \gamma(t) \cdot x$$

is a diffeotopy rel the origin.

2. Let $A \in SO(n)$. If $n \geq 2$, then there exists a diffeotopy of $B^n$ from id$_{B^n}$ to the diffeomorphism of $B^n$ that is given by multiplication by $A$.

The same statement holds with $B^n$ replaced by $\mathbb{R}^n$ and $S^{n-1}$.

**Proof.**

1. The first statement is basically obvious.

2. Suppose that $n \geq 2$ and let $A \in SO(n)$. By Lemma 2.65 the smooth manifold $SO(n)$ is path-connected. Therefore, by Exercise 18.7 there exists a smooth path in $SO(n)$ from id to $A$. The statement now follows from (1). \hfill \blacksquare

**Remark.** The term “diffeotopic” is (alas!) used differently by different authors. Our definition agrees with the definition given in most textbooks, see e.g. [Wall16, p. 49] and [BJ82, Definition 9.3]. But it differs from the definition provided in [Hirs76, Chapter 8], there the map on $M \times [0, 1]$ only needs to be continuous, but each $F_t$ needs to be a diffeomorphism. At least a priori this is a weaker condition.

We leave the proof of the following lemma as a voluntary exercise to the eager reader.

**Lemma 8.6.** Let $M$ be an oriented connected smooth manifold and let $F: M \times [0, 1] \to M$ be a diffeotopy. Then either all maps $F_t: M \to M$ are orientation-preserving or all $F_t$ are orientation-reversing.

For later purposes we state the following lemma.
Lemma 8.7. (*) Let $N$ be a smooth manifold, let $M$ be another smooth manifold and let $f, g, h : M \to N$ be proper smooth embeddings.

(1) If $f$ is smoothly isotopic to $g$ and $g$ is smoothly isotopic to $h$, then $f$ is also smoothly isotopic to $h$. The same statement also holds for “diffeotopic” instead of “smoothly isotopic”.

(2) Being “smoothly isotopic” and being “diffeotopic” is an equivalence relation.

Proof (*). The only non-trivial aspect of Statement (2) is contained in Statement (1). So let us prove Statement (1). Let $\Phi : M \times [0, 1] \to N$ be a smooth isotopy from $f$ to $g$. Furthermore let $\Psi : M \times [0, 1] \to N$ be a smooth isotopy from $g$ to $h$. The first idea is of course to “stack” the two smooth isotopies together, i.e. to consider the map

$$M \times [0, 1] \to N$$

$$(P, t) \mapsto \begin{cases} 
\Phi(P, 2 \cdot t), & \text{if } t \in [0, \frac{1}{2}], \\
\Psi(P, 2 \cdot t - 1), & \text{if } t \in [\frac{1}{2}, 1].
\end{cases}$$

By Lemma 14.3 we know that this map is continuous. The problem with this approach is that this map is not necessarily smooth at $M \times \{\frac{1}{2}\}$. Thus we have to modify the above approach slightly. It follows from Lemma 6.13 that there exist a smooth function $f : [0, 1] \to [0, 1]$ with $f(0) = 0$ such that $f(t) = 1$ for all $t \in [\frac{1}{2}, 1]$ and a smooth function $g : [0, 1] \to [0, 1]$ with $g(1) = 1$ such that $g(t) = 0$ for all $t \in [0, \frac{1}{2}]$. It is now straightforward to verify that the map

$$M \times [0, 1] \to N$$

$$(P, t) \mapsto \begin{cases} 
\Phi(P, f(2 \cdot t)), & \text{if } t \in [0, \frac{1}{2}], \\
\Psi(P, g(2 \cdot t - 1)), & \text{if } t \in [\frac{1}{2}, 1].
\end{cases}$$

is a smooth isotopy from $f$ to $h$. The proof for “diffeotopic” instead of “smoothly isotopic” is verbatim the same.

The following lemma gives an interesting example of a smooth deformation retraction.

Lemma 8.8. (*) Let $n \in \mathbb{N}_0$ and let $k \in \{1, \ldots, n\}$. We write

$$\text{GL}(n, k) = \text{set of } k\text{-tuples of linearly independent vectors of } \mathbb{R}^n$$

$$\text{O}(n, k) = \text{set of } k\text{-tuples of orthonormal vectors of } \mathbb{R}^n.$$ 

(Note that for $k = n$ we have $\text{GL}(n, k) = \text{GL}(n)$ and $\text{O}(n, k) = \text{O}(n)$.) We denote by $r : \text{GL}(n, k) \to \text{O}(n, k)$ the map given by the Gram-Schmidt orthonormalization process.\[
\text{The following statements hold:}\]

(1) The above map $r : \text{GL}(n, k) \to \text{O}(n, k)$ is realized by a smooth deformation retraction $R : \text{GL}(n, k) \times [0, 1] \to \text{O}(n, k)$ which has the following extra property:

(*) For any $k$-dimensional vector subspace $V$ of $\mathbb{R}^n$ and any $t \in [0, 1]$ we have

$$R(\text{basis of } V, t) \subset \text{basis of } V.$$ In particular $r$ is smooth and it is a retraction.

(2) The inclusion $\text{O}(n, k) \to \text{GL}(n, k)$ is a homotopy equivalence.
The analogous statement hold if we replace the pair $O(n, k)$ and $GL(n, k)$ by one of the following four pairs:

(a) $SO(n)$ and $GL_+(n, \mathbb{R})$,
(b) $U(n)$ and $GL(n, \mathbb{C})$,
(c) $SO(n)$ and $SL(n, \mathbb{R})$.
(d) $SU(n)$ and $SGL(n, \mathbb{C})$.

**Sketch of proof** Proof (**).

(1) One easily verifies that each of the $2k$ steps of the Gram-Schmidt process is realized by a smooth deformation retraction that satisfies (**). The proof of Lemma 8.7 shows that we can combine these smooth deformation retractions to obtain the desired smooth deformation retraction that satisfies (**).

(2) This statement follows immediately from (1) and Lemma 18.14.

We consider the four extra pairs:

(a) The given smooth deformation retraction restricts to a deformation retraction from $GL_+(n, \mathbb{R})$ to $SO(n)$.

(b) The proof in this case is basically identical to the proof concerning the pair $O(n)$ and $GL(n, \mathbb{R})$.

(c) The given smooth deformation retraction does not restrict to a deformation retraction from $SL(n, \mathbb{R})$ to $SO(n)$. The problem is that in the Gram-Schmidt process we have to successively normalize the column vectors to length one. This process does not preserve the determinant. The solution is that when we normalize the $i$-th column vector by a factor $r$, then we compensate by simultaneously rescaling the $(i+1)$-st column vector by $r^{-1}$. This issue does not arise when we have arrived at the last column vector, since starting out with a matrix of determinant one there is no need to rescale the last column vector.

(d) The proof in this case is basically identical to the proof of (c). ■

For general culture we cite the following difficult theorem due to Jean Cerf [Cer70]. We could not find results in the literature that deal with the lower dimensional cases.

**Theorem 8.9. (Cerf Theorem)** (**) Let $n \geq 6$. Every orientation-preserving diffeomorphism of $B^n$ is diffeotopic to the identity.

We conclude this dense section with a short discussion of submanifolds.

**Definition.** Let $M_0, M_1$ be two (proper) submanifolds of a smooth manifold $N$.

(1) A (proper) smooth isotopy is a (proper) smooth isotopy $F: M_0 \times [0, 1] \to N$ with $F_0 = \text{id}_{M_0}$ and with $F_1(M_0) = M_1$.

(2) We say that the two submanifolds are (properly) smoothly isotopic if there exists a (proper) smooth isotopy between $M_0$ and $M_1$.

---

140 This map is defined in any course on linear algebra, see e.g. [Cu74, Theorem 15.9].

141 In Exercise 8.18 we will see that $GL(n, k)$ is an open subset of $\mathbb{R}^{n^2}$. Therefore the word “smooth” makes sense in the most naive sense.
If $M_0$ and $M_1$ are oriented smooth manifolds, then we demand that the map $F_1: M_0 \to M_1$ is orientation-preserving.

**Example.** In Figure 192 we consider some oriented 1-dimensional submanifolds of a surface $\Sigma$. In some cases it is clear that submanifolds are smoothly isotopic, in other cases this looks dubious.

![Smoothly isotopic submanifolds](image)

**Figure 192**

For completeness’ sake we state the following lemma.

**Lemma 8.10.** Let $N$ be a smooth manifold. The property of being (properly) smoothly isotopic is an equivalence relation on the set of (proper) submanifolds of (oriented) submanifolds of $M$.

**Proof.** It follows from Proposition 8.1 (1) that being (properly) smoothly isotopic is a symmetric relation. It now follows as before from Lemma 8.7 that being (properly) smoothly isotopic is an equivalence relation.

8.3. The Collar Neighborhood Theorem. After the preparations from the last two sections we now have the language to state many useful results from differential topology.

**Definition.** Let $M$ be a smooth manifold. A collar of $\partial M$ is defined as a smooth embedding $f: [0, 1] \times \partial M \to M$ that has the following two properties:

(a) the restriction of $f$ to $\{0\} \times \partial M = \partial M$ is the identity,

(b) the image $f([0, 1] \times \partial M)$ is a closed subset of $M$.

We refer to the image of $f$ as a collar neighborhood.

**Example.** Let $m \in \mathbb{N}$ and let $W$ be a closed smooth manifold. The map

$$f: [0, 1] \times (S^{m-1} \times W) \to \overline{B}^m \times W$$

$$(t, P, w) \mapsto ((1 - \frac{1}{2}t) \cdot P, w)$$

is evidently a collar for the smooth manifold $\overline{B}^m \times W$. We refer to this map as the standard collar of $\overline{B}^m \times W$ and we refer to the image of $f$ as the standard collar neighborhood of $\overline{B}^m \times W$.

**Convention.**

(1) We continue with the notation from the definition. By abuse of notation we usually denote the image of $f$ by $[0, 1] \times \partial M$ as well. In particular we make the identification $\{0\} \times \partial M = \partial M$. Sometimes we refer to $[0, 1) \times \partial M$ as an open collar neighborhood of $\partial M$. 
(2) Let \( m, n \in \mathbb{N} \) and let \( W \) be a closed smooth manifold. Unless we say something else we will equip \( B^m \times W \) with the above standard collar.

Remark.

(1) It follows from the consideration of orientations on product smooth manifolds, see Proposition 6.51 (4), that it is better to consider products \([0, 1] \times \partial M\) instead of products \(\partial M \times [0, 1]\). For example, if \(\partial M\) is oriented, then it follows from our conventions that \(\partial([0, 1] \times \partial M) = \{0\} \times \partial M\) as oriented smooth manifolds.

(2) Let \([0, 1] \times \partial M\) be a collar neighborhood. It follows from Lemmas 2.6 and 3.9 that any product \([a, b] \times \partial M\) is also a closed subset of \(M\).

(3) Our condition (b), namely that a collar neighborhood needs to be closed, is non-standard. If \(\partial M\) is compact, which is anyway the case in most situations, the image of any smooth embedding \([0, 1] \times \partial M \to M\) is a closed subset by Lemma 2.17. Thus the condition only has content if \(\partial M\) is non-compact. It seems to me that in the case of non-compact boundary it is often implicitly assumed that any subset that satisfies (a) is actually closed. But in general this is not the case. For example, in Figure 194 we consider \(M = \{(x, y) \in \mathbb{R}^2 \mid y \geq 0\}\) and the image of a smooth embedding \([0, 1] \times \partial M\) that does not contain a certain point \(P\), but such that \(P\) lies in the closure of the smooth embedding. In other words, the image of \([0, 1] \times \partial M\) is not a closed subset of \(M\).

![Diagram](image194.png)

Figure 194

The following lemma justifies the names “collar neighborhood” and “open collar neighborhood”.

**Lemma 8.11.** Let \(M\) be a smooth manifold and let \(f : [0, 1] \times \partial M \to M\) be a collar. For any \(t \in (0, 1)\) the set \([0, t] \times \partial M\) is an open subset of \(M\), in particular it is in fact a neighborhood of \(\partial M\) in the sense of the definition on page 89.
The proof of this lemma is quite similar to the proof of Proposition 8.2, i.e., the proof is a reasonably straightforward consequence of Theorem 6.19. Once again we leave it to the reader to fill in the details.

Now we can state the Collar Neighborhood Theorem.

**Theorem 8.12. (Collar Neighborhood Theorem)** Every smooth manifold admits a collar neighborhood.

**Remark.**

1. In Theorem 8.20 we will state a refinement of the Collar Neighborhood Theorem 8.12 which can also take into account submanifolds.
2. In the Topological Collar Neighborhood Theorem 44.5 we will generalize the above theorem to the setting of topological manifolds.

**Proof (⋆).** Let $M$ be a smooth manifold. Basically any book on differential topology shows that there exists a smooth embedding $f : [0, 1] \times \partial M \to M$ such that $f$ is the identity map on the subset $\{0\} \times \partial M = \partial M$. For instance this statement is proved in [Wall16, Theorem 1.5.5] or alternatively [Lee02, Theorem 9.25], [BJ82, Theorem 13.6], [Muk15, Theorem 7.2.13]. It is also not that difficult to rewrite our proof of the Topological Collar Neighborhood Theorem 44.5 for the setting of smooth manifolds. Furthermore, if $\partial M$ is compact one can also prove the existence of such a smooth embedding using the Smooth Manifold Product Theorem 104.8.

In the following we will outline, following [Lee02b], how one can modify the smooth embedding $f$ to obtain a smooth embedding $g : [0, 1] \times \partial M \to M$ such that the image is in fact a closed subset of $M$. By Lemma 6.58 there exists a map $\mu : M \to [0, \infty)$ with the property that given any $C \in \mathbb{R}$ the preimage $f^{-1}([0, C])$ is a compact subset of $M$. We consider the map

$$
\varphi : \partial M \to [0, 1] \\
x \mapsto \sup \{ t \in [0, 1] \mid \mu(f(x, s)) > \mu(f(x, 0)) - 1 \text{ for all } s \in [0, t] \}.
$$

Using charts one can show fairly easily that the map $\varphi$ is continuous and that $\varphi(x) > 0$ for every $x \in \partial M$. By Lemma 6.59 there exists a smooth map $\psi : \partial M \to [0, 1]$ such that $\psi(x) \in (0, \varphi(x)]$ for all $x \in \partial M$. It suffices to prove the following claim:

**Claim.** The map

$$
g : [0, 1] \times \partial M \to M \\
(t, x) \mapsto f(\psi(x) \cdot t, x)
$$

is a smooth embedding with $g|_{\{0\} \times M} = \text{id}$ and such that $g([0, 1] \times \partial M)$ is a closed subset of $M$. 

The only statement which requires some thought is to show that \( g([0, 1] \times \partial M) \) is a closed subset of \( M \). We have
\[
M \setminus g([0, 1] \times \partial M) = \left( \bigcup_{C \in \mathbb{R}} \mu^{-1}([0, C]) \right) \setminus g([0, 1] \times \partial M) = \bigcup_{C \in \mathbb{R}} \mu^{-1}([0, C]) \setminus g([0, 1] \times \partial M)
\]
compact by Prop. 2.27(3a) and Exercise 2.28
\[
= \bigcup_{C \in \mathbb{R}} \mu^{-1}([0, C]) \setminus g([0, 1] \times (\partial M \setminus \mu^{-1}([0, C + 1])))
\]
closed by Lemma 2.40 and Lemma 2.17

Thus we have shown that \( M \setminus g([0, 1] \times \partial M) \) is the union of open subsets of \( M \), thus \( M \setminus g([0, 1] \times \partial M) \) itself is open, i.e. \( g([0, 1] \times \partial M) \) is closed.

The following proposition says, that under a fairly mild hypothesis, collar neighborhoods are essentially unique.

**Proposition 8.13.** (⋆) Let \( M \) be a smooth manifold and let \( f_0, f_1 : [0, 1] \times \partial M \to M \) be two smooth embeddings that are the identity map on \( \partial M \times \{0\} = \partial M \). If \( \partial M \) is compact\(^{142}\), then there exists a diffeotopy
\[
H : M \times [0, 1] \to M
\]
rel \( \partial M \)\(^{143}\) from \( H_0 = \text{id}_M \) to a diffeomorphism \( \Phi = H_1 : M \to M \) with \( \Phi \circ f_0 = f_1 \). In particular \( \Phi \) restricts to a diffeomorphism
\[
\Phi : f_0([0, 1] \times \partial M)) \to f_1([0, 1] \times \partial M).
\]

**Figure 195**

**Proof.** The proposition is proved in [Wall16, Proposition 2.5.7]. A very similar statement is also proved in [BJ82, Theorem 13.7].

For later we record the following corollary to the Collar Neighborhood Theorem 8.12.

---

\(^{142}\)To get a uniqueness statement for non-compact boundary one needs to consider smooth embeddings such that the image is closed. Unfortunately it seems like nobody every proved a uniqueness statement in this more general context. Both references prefer to assume that the boundary is compact. For most purposes it is irrelevant whether a more general version of Proposition 8.13 holds, but it is nonetheless somewhat unsatisfactory that the general case has not been treated yet.

\(^{143}\)Recall that this means that \( H(P, t) = P \) for all \( P \in \partial M \) and \( t \in [0, 1] \).
Corollary 8.14. (*) Let $M$ be an $n$-dimensional smooth manifold. Let $[0, 1] \times \partial M$ be a collar neighborhood.

1. The subset $W := M \setminus ([0, 1] \times \partial M)$ is an $n$-dimensional smooth manifold with boundary given by $\{1\} \times \partial M$.
2. The subset $W = M \setminus ([0, 1] \times \partial M)$ is a deformation retract of $M$ and it is a deformation retract of $M \setminus \partial M$.
3. If $M$ is non-empty, then $M$ is homotopy equivalent to a non-compact $n$-dimensional smooth manifold without boundary.

Proof.

1. This statement follows fairly easily from Proposition 6.27. We leave it to the reader to fill in the details.

2. We write $W := M \setminus ([0, 1] \times \partial M)$ and we set $M' := M \setminus \partial M$. We consider the map

$$F: M \times [0, 1] \to M$$

$$(Q, t) \mapsto \begin{cases} (t \cdot s + (1 - t), R), & \text{if } Q = (s, R) \in [0, 1] \times \partial M, \\ Q, & \text{if } Q \not\in M \setminus [0, 2] \times \partial M. \end{cases}$$

Note that by definition the collar neighborhood $[0, 1] \times \partial M$ is a closed subset of $M$ and that we know by Lemma 8.11 that $M \setminus ([0, 1] \times \partial M)$ is also a closed subset of $M$. Since the restriction of $F$ to each of these two closed subsets is continuous we obtain from Lemma 2.35 (2) that the map $F: M \times [0, 1] \to M$ is indeed continuous. This map defines a deformation retraction from $M$ to $W$ and also from $M' = M \setminus \partial M$ to $W$.

3. It follows from (2) and Lemmas 18.14 and 18.11 that $M$ and $M'$ are homotopy equivalent. Finally note that it follows from Proposition 6.27 that $M'$ is non-compact, that it is an open subset of $M$ (in particular it is an $n$-dimensional smooth manifold) and that the smooth manifold $M'$ does not have any boundary. $\blacksquare$

Remark. We proved Corollary 8.14 (3) by considering an “internal” collar $[0, 1] \times \partial M$. An alternative approach would be to consider $M$ together with an “external” collar, namely $W := M \cup_{\partial M = \partial M \times \{0\}} ([0, 1] \times \partial M)$. In this approach one needs to show that $W$ is indeed an $n$-dimensional smooth manifold, that it is non-compact and that $M$ is a deformation retract of $W$. Even though this sounds very reasonable, it also comes with its share of
technical difficulties, for example, what is the quickest argument for showing that \( W \) is second-countable?

8.4. Gluing smooth manifolds. The following proposition says that if, given a (possibly) disconnected smooth manifold, we glue boundary components via a diffeomorphism, then the quotient is canonically a smooth manifold. For future reference we write down the full gory details, even though this makes the proposition somewhat unreadable.

**Proposition 8.15.** Let \( M \) be an \( n \)-dimensional smooth manifold (we do not assume that \( M \) is connected). Let \( A \) and \( B \) be disjoint unions of boundary components of \( M \). Furthermore let \( f: A \to B \) be a diffeomorphism. Then given any neighborhood \( U \) of the image of \( A \) in \( M/a \sim f(a) \) there exists a homeotopy \( H: (M/a \sim f(a)) \times [0, 1] \to M/a \sim f(a) \) with the following three properties:

1. (a) The topological space \( M/a \sim f(a) \) for \( a \in A \) is an \( n \)-dimensional topological manifold.
2. (b) Any choice of a collar \( \varphi: [0, 1] \times \partial M \to M \) for \( \partial M \) equips the topological manifold \( M/a \sim f(a) \) canonically with the structure of an \( n \)-dimensional smooth manifold such that \( M \setminus (A \cup B) \) is a submanifold and such that the image of \( A \) under the map \( A \to M \to M/a \sim f(a) \) is a codimension one submanifold.
3. (c) Let \( \varphi \) and \( \psi \) be two collars. By (1b) these two collars give rise to two smooth structures \( A_\varphi \) and \( A_\psi \) on the topological manifold \( M/a \sim f(a) \). If \( \partial M \) is compact then given any neighborhood \( U \) of the image of \( A \) in \( M/a \sim f(a) \) there exists a homeotopy \( H: (M/a \sim f(a)) \times [0, 1] \to M/a \sim f(a) \) with the following three properties:
   1. (i) \( H_0 = \text{id} \).
   2. (ii) \( H_1: (M/a \sim f(a), A_\varphi) \to (M/a \sim f(a), A_\psi) \) is a diffeomorphism.
   3. (iii) \( H(x, t) = x \) for all \( x \notin U \).
4. (d) If \( \partial M \) is compact, then the diffeomorphism type of \( M/a \sim f(a) \) does not depend on the choice of the collar.

(2) If \( M \) consists of two components \( X \) and \( Y \) with \( A \subset X \) and \( B \subset Y \), then the following statements hold:

(a) The obvious maps \( i: X \to M/a \sim f(a) \) and \( j: Y \to M/a \sim f(a) \) are smooth embeddings.
(b) The images \( i(X) \) and \( j(Y) \) are closed subsets of \( M/a \sim f(a) \) and they are codimension-zero submanifolds of \( M/a \sim f(a) \).

(3) If \( M \) is compact, then \( M/a \sim f(a) \) is also compact.

(4) The boundary of \( M/a \sim f(a) \) is given by \( \partial M \setminus (A \cup B) \).

(5) If each component of \( M \) contains at least one component of \( A \) or \( B \), then \( M/a \sim f(a) \) is connected.

(6) Assume that \( M \) is oriented. We equip \( A \) and \( B \) with the boundary orientations.

(a) If \( f \) is orientation-reversing, then \( M/a \sim f(a) \) admits an orientation such that the inclusion \( M \setminus (A \cup B) \to M/a \sim f(a) \) is orientation-preserving.
(b) If \( M \) is connected and if \( f \) is not orientation-reversing, then \( M/a \sim f(a) \) is non-orientable.
(7) Let $\tilde{M}$ be a compact $n$-dimensional smooth manifold, let $\tilde{A}$ and $\tilde{B}$ be disjoint unions of boundary components of $\tilde{M}$ and let $f: \tilde{A} \to \tilde{B}$ be a diffeomorphism. Furthermore let $\varphi: M \to \tilde{M}$ be a diffeomorphism such that $\varphi(A) = \tilde{A}$, $\varphi(B) = \tilde{B}$ and such that for any $a \in A$ we have $\varphi(f(a)) = \tilde{f}(\varphi(a))$. The induced map

$$\varphi: M/a \sim f(a) \to \tilde{M}/a \sim \tilde{f}(a)$$

$$[x] \mapsto [\varphi(x)]$$

is a homeomorphism\(^{146}\) and this homeomorphism is homeotopic to a diffeomorphism.

**Remark.**

(1) We will prove the analogue of Proposition 8.15 for topological manifolds later on in Proposition 44.8.

(2) The fact that the differential structure on $M/a \sim f(a)$ depends on the choice of a collar, and that only the diffeomorphism type is well-defined, is an awkward nuisance. Like many other sources we usually gloss over this issue.

(3) In Exercise 8.25 we will prove more statements about the tricky question under which circumstances $M/a \sim f(a)$ is orientable.

For better readability we first provide the proof of Statement (1) of Proposition 8.15 before we prove the remaining statements.

**Proof of Proposition 8.15 (1).** In the following we write $W := M/a \sim f(a)$ and $M' := M \setminus (A \cup B)$. It follows from Proposition 6.27 (3a) that $A$ and $B$ are closed subsets of $M$. Thus we see that $M'$ is an open subset of $M$ and of $W$. We denote by $p: M \to W$

---

\(^{144}\)Recall that by Proposition 6.27 the boundary components $A$ and $B$ are canonically $(n-1)$-dimensional smooth manifolds.

\(^{145}\)By the Collar Neighborhood Theorem 8.12 we know that a collar always exists.

\(^{146}\)This statement is slightly vague, the totally precise statement can be found in the proof.

\(^{147}\)The slightly annoying restriction to the case that the boundary $\partial M$ is compact is due to the fact that we need to apply Proposition 8.13. It might well be that the statement holds without any restrictions on $A$ and $B$. Also note that in practice one deals almost always with the case of compact boundary components.

\(^{148}\)It is basically clear that $\varphi$ is a homeomorphism. But note that $\varphi$ is in general not a diffeomorphism since in general is not smooth along the image of $A$ in $M/a \sim f(a)$. So the real statement is that this flaw can be rectified by a homeotopy.
the projection map. Let \( \alpha: [0, 1] \times \partial M \to M \) be a collar. First we intend to provide a smooth atlas for \( W \). We do so as follows:

(\( \alpha \)) We restrict all the charts in the given atlas of \( M \) to the open subset \( M' \).

(\( \beta \)) We equip \( A \) with the smooth \((n - 1)\)-dimensional atlas \( \{ \phi_i: U_i \to V_i \}_{i \in I} \) that is provided by Proposition 6.27. Given \( i \in I \) we define

\[
\begin{align*}
\text{open subset of } M/a \sim f(a) & \quad p([0, 1) \times U_i) \cup p([0, 1) \times f(U_i)) \\
\beta_i & \quad (\beta_i)(x) = (t, \Phi_i(y)), \\
& \quad \text{if } x = p(\alpha(t, y)) \text{ with } t \in [0, 1) \text{ and } y \in U_i, \\
& \quad (-t, \Phi_i(f^{-1}(\{y\}))), \quad \text{if } x = p(\alpha(t, y)) \text{ with } t \in [0, 1) \text{ and } y \in f(U_i).
\end{align*}
\]

Using (\( \alpha \)) and (\( \beta \)) one easily verifies that the charts from (\( \alpha \)) and (\( \beta \)) define an \( n \)-dimensional smooth atlas, let’s call it \( \mathcal{A}_\beta \), for \( W \). (We refer to Figure 198 for an illustration.) As usual we still have to deal with the slightly annoying task of showing that \( W \) is Hausdorff and second-countable:

(i) We leave it to the reader to show, using (\( \alpha \)) and (\( \beta \)) above, that \( W \) is Hausdorff.

(ii) Let \( B = \{ B_i \}_{i \in I} \) be a countable basis for the topology of \( M \). Once again we leave it to the reader to verify, using (\( \alpha \)) and (\( \beta \)) above, that

\[
\{ B_i \cap M' \}_{i \in I} \cup \left\{ p([0, 1) \times ((B_i \cap A) \cup (f(B_i \cap A))]) \right\}_{i \in I}
\]

is a basis for the topology of \( W \). Since this is a countable family of sets we see that \( W \) is second-countable.

We have now shown that \( M/a \sim f(a) \) is a topological manifold and that the choice of the collar \( \alpha \) provides \( M/a \sim f(a) \) canonically with a smooth structure \( \mathcal{A}_\alpha \). This concludes the proof of (1a) and (1b).

![Figure 198](image-url)

We move on to (1c). Now we assume that \( \partial M \) is compact. Suppose we are given two collars \( \alpha: [0, 1] \times \partial M \to M \) and \( \beta: [0, 1] \times \partial M \to M \). By Proposition 8.13 there exists a diffeotopy \( H: M \times [0, 1] \to M \) rel \( \partial M \) from \( H_0 = \text{id}_M \) to a diffeomorphism \( \Phi = H_1: M \to M \) with \( \Phi \circ \alpha = \beta: [0, 1] \times \partial M \to M \). We consider the map

\[
F: (M/a \sim f(a)) \times [0, 1] \to M/a \sim f(a), \quad (p(Q), t) \mapsto [p(Q, t)].
\]
Note that it follows from Proposition 18.20 that this map is actually continuous. It is basically clear that each \( F_i \) is a homeomorphism. Finally note that \( F_1 \) defines a diffeomorphism from \((M/a \sim f(a), \mathcal{A}_a)\) to \((M/a \sim f(a), \mathcal{A}_b)\). We leave it to the reader to refine the argument to ensure that the map \( F \) is a constant homotopy outside of a given open neighborhood \( U \) of the image of \( A \) in \( M/a \sim f(a) \).

Finally not that (1d) is an immediate consequence of (1c).

**Proof of Proposition 8.15 (2)-(7) (**) .

(2) It follows from Lemma 3.44 (4) that the obvious maps \( i: X \to M/a \sim f(a) \) and \( j: Y \to M/a \sim f(a) \) are embeddings. Furthermore it follows almost immediately from inspecting the atlas we had just constructed that the images \( i(X) \) and \( j(Y) \) are codimension-zero submanifolds of \( M/a \sim f(a) \). Finally it follows easily from the aforementioned fact that \( A \) and \( B \) are closed subsets, that \( i(X) \) and \( j(Y) \) are closed subsets of \( M/a \sim f(a) \). We leave the details to the reader.

(3) This statement follows immediately from Lemma 3.21 (4).

(4) The atlas that we gave above for \( W = M/a \sim f(a) \) has a chart of type (i) for every point in \( M \setminus (\partial M \setminus (A \cup B)) \) and a chart of type (ii) for every point in \( \partial M \setminus (A \cup B) \). Therefore it follows from Proposition 6.27 (1) that the boundary of \( W = M/a \sim f(a) \) is given by \( \partial M \setminus (A \cup B) \).

(5) This statement follows, without too much effort, from Lemma 2.62.

(6) This statement can be proved once again using the Collar Neighborhood Theorem 8.12. We leave the verification of this statement as a slightly annoying exercise to the dedicated reader.

(7) It is clear that the induced map \( \varphi: M/a \sim f(a) \to \tilde{M}/a \sim \tilde{f}(a) \) is a homeomorphism. It remains to prove that \( \varphi \) is homeotopic to a diffeomorphism. We pick disjoint collar neighborhoods \([0, 1] \times A\) and \([0, 1] \times B\). We equip \( \tilde{A} \) and \( \tilde{B} \) with the collar neighborhoods \( \varphi([0, 1] \times A) \) and \( \varphi([0, 1] \times B) \). Using Lemma 6.13 (1) one can easily find a diffeotopy from \( \varphi \) to a diffeomorphism \( \psi: M \to M \) that is “constant” along \([0, \frac{1}{2}] \times A\) and \([0, \frac{1}{2}] \times B\), i.e. which satisfies \( \psi(x, t) = (\psi(x, 0), t) \) for all \( x \in A \cup B \) and all \( t \in [0, \frac{1}{2}] \). This map again descends to a map \( \tilde{\psi}: M/a \sim f(a) \to \tilde{M}/a \sim \tilde{f}(a) \). It is straightforward to verify that \( \tilde{\psi} \) is actually a diffeomorphism and that the diffeotopy from \( \varphi \) to \( \psi \) descends to a homeotopy from \( \varphi \) to \( \tilde{\psi} \).

For many purposes and constructions it does not make a difference if we modify a map by a diffeotopy. For example we have the following lemma which often gets used implicitly.

**Lemma 8.16.** Let \( M \) be an \( n \)-dimensional smooth manifold (we do not assume that \( M \) is connected) with compact boundary. Let \( A \) and \( B \) be two distinct compact boundary components of \( M \). Furthermore let \( f_0 \) and \( f_1 \) be two diffeomorphisms from \( A \) to \( B \). If \( f_0 \) and \( f_1 \) are diffeotopic, then the results of gluing via \( f_0 \) respectively via \( f_1 \) are diffeomorphic, i.e. we have a diffeomorphism

\[
M/x \sim f_0(x) \xrightarrow{\cong} M/x \sim f_1(x).
\]
Furthermore, given a neighborhood of $A$ and given a neighborhood of $B$ one can find a diffeomorphism that is the identity outside of the chosen neighborhoods. Finally, if $M$ is oriented and if $f_0$ and $f_1$ are orientation-reversing, then the above diffeomorphism is in fact orientation-preserving.

**Sketch of proof.** Since $f_0$ and $f_1$ are diffeotopic and since they are diffeomorphisms there exists a diffeotopy $F: A \times [0, 1] \to A$ from $f_1 \circ f_0^{-1}$ to $\text{id}_A$. With the same approach as in the proof of Lemma 8.7 we can arrange that $F_t = \text{id}_A$ for $t \in [\frac{1}{2}, 1]$.

Next note that by the Collar Neighborhood Theorem 8.12 we can pick a collar neighborhood $[0, 1] \times \partial M$. (Since $A$ is compact we can, after possibly rescaling, arrange that $[0, 1] \times \partial A$ is contained in a given neighborhood of $A$.) One can now easily verify that

$$M/x \sim f_0(x) \to M/x \sim f_1(x)$$

$$y \mapsto \begin{cases} y, & \text{if } y \in M \setminus ([0, 1] \times A), \\ F(a,t) & \text{if } y = (t,a) \in [0, 1] \times A \end{cases}$$

is a diffeomorphism. Furthermore it is clear that this diffeomorphism has all the required properties. □

### 8.5. Cutting along submanifolds.

In this section we will introduce the operation of cutting along a codimension-one submanifold. This construction can be seen as the inverse of the gluing operation from the last section.

**Definition.** Let $M$ be an oriented smooth manifold and let $F \subset M$ be a compact oriented proper submanifold of codimension one. By the General Tubular Neighborhood Theorem 10.5 together with Proposition 10.6 we know that there exists an orientation-preserving tubular map $\Phi: [-1, 1] \times F \to M$. We define

$$M \setminus F := (M \setminus F) \sqcup (F \times \{\pm 0\})$$

with the topology that is generated by the following sets:

1. the usual open subsets of $M \setminus F$,
2. the sets of the form $\Phi(U \times (0, \epsilon)) \cup (U \times \{+0\})$ where $U$ is an open subset of $F$ and where $\epsilon \in (0, 1)$,
3. the sets of the form $\Phi(U \times (-\epsilon, 0)) \cup (U \times \{-0\})$ where $U$ is an open subset of $F$ and where $\epsilon \in (0, 1)$.

We refer to $M \setminus F$ as $M$ cut along $F$. This definition is illustrated in Figure 199. We also introduce the following extra notation:

1. We denote by $F_\pm$ the images of $F \times \{\pm 0\}$ in $M \setminus F$. Furthermore we denote by $i_\pm: F_\pm \to M \setminus F$ the obvious inclusion maps.

The following proposition summarizes some of the key properties of this construction.\[149\]

---

\[149\]Here $\pm 0$ are just understood to be the two symbols $+0$ and $-0$ with no further meaning.
Proposition 8.17. Let $M$ be an orientable $n$-dimensional smooth manifold and let $F \subset M$ be a compact orientable proper submanifold of codimension one.

1. The definition of the topological space $M \setminus F$ does not depend on the choice of the tubular map.\(^\text{150}\)

2. The topological space $M \setminus F$ admits a canonical structure of an $n$-dimensional smooth manifold such that $F_-$ and $F_+$ are boundary components.

3. If $\Phi: [-1,1] \times F \to M$ is an orientation-preserving tubular map, then the complement $M \setminus \Phi((-1,1) \times F)$ is diffeomorphic to $M \setminus F$ and $M \setminus \Phi([-1,1) \times F)$ is a deformation retract of $M \setminus F$.

4. The map

\[
\chi_F: M \setminus F \to M
\]

\[
P \mapsto \begin{cases} 
P, & \text{if } P \in M \setminus F, \\
Q, & \text{if } P = [(Q, \pm0)] \text{ for some } Q \in F.
\end{cases}
\]

is smooth and it descends to a diffeomorphism\(^\text{152}\)

\[
\overline{\chi_F}: (M \setminus F)/i_-(x) = i_+(x) \to M.
\]

with $x \in F$

\textbf{Remark.}

1. In the figures, see e.g. Figure 200, we will use Proposition 8.17 (3) as an excuse to draw $M \setminus F$ the same way that we would draw $M \setminus \Phi((-1,1) \times F)$.

2. In the literature the smooth manifold $M \setminus \Phi((-1,1) \times F)$ sometimes is also called “$M$ cut along $F$”. This name is partly justified by Proposition 8.17 (3). But one should note that our notion of “$M$ cut along $F$” is much more elegant since the definition does not depend on the choice of a tubular neighborhood.

3. A slightly different approach to defining the operation of “cutting along a codimension one manifold” is given in [Wall16] p. 64.

\textbf{Sketch of proof.}

\(^\text{150}\) Note that here “does not depend” is meant in the strong sense, that different choices of the trivial tubular neighborhood give precisely the same topological space.

\(^\text{151}\) Note that we know by Proposition 8.2 that the left-hand side is a smooth manifold.

\(^\text{152}\) Note that the left-hand side is a smooth manifold by Proposition 8.15.
(1) This statement follows easily from the uniqueness result on tubular maps, see Proposition \[10.7\].

(2) Using an explicit tubular map it should be pretty clear to the reader how to show that \( M \setminus F \) is actually an \( n \)-dimensional topological manifold and how to write down a smooth atlas. It follows again from the uniqueness of tubular neighborhoods, see Proposition \[10.7\] that the smooth structure on \( M \setminus F \) does not depend on the choice of the tubular map.

(3) We pick a tubular map \( \Psi : [-1, 1] \times F \to M \). Evidently \( \Phi(t, P) := \Psi(\frac{1}{2} t, P) \) also defines a tubular neighborhood. By the above it suffices to prove the statement for \( \Phi \). We consider the map

\[
\Theta : M \setminus F \to M \setminus \Phi((-1, 1) \times F)
\]

\[
P \mapsto \begin{cases} 
P, & \text{if } P \in M \setminus \Psi((-1, 1) \times F), \\
\Psi\left(\frac{1}{2} t + \frac{1}{2}, Q\right), & \text{if } P = \Psi(t, Q) \text{ with } t \in (0, 1), \\
\Psi\left(\frac{1}{2} t - \frac{1}{2}, Q\right), & \text{if } P = \Psi(t, Q) \text{ with } t \in (-1, 0), \\
\Psi(\pm \frac{1}{2}, Q), & \text{if } P = (\pm 0, Q) \text{ for some } Q \in F.
\end{cases}
\]

Using Lemma \[2.35\] (2) one can easily show that \( \Theta \) is continuous. We leave it to the reader to write down an explicit inverse to \( \Theta \) which then shows that \( \Theta \) is a homeomorphism. As always it is not difficult to slightly adjust the map \( \Theta \) to turn it into a diffeomorphism.

It is an elementary, but admittedly rather messy, task to write down an explicit deformation retraction from \( M \setminus F \) to \( M \setminus \Phi((-1, 1) \times F) \). Since we will not make use of this statement we cannot be bothered with providing all the details.

(4) We pick a tubular map \( \Phi : [-1, 1] \times F \to M \). It is straightforward to verify that the map \( \chi_F \) is continuous on the open subsets \( M \setminus F \) and \( \Phi((-1, 1) \times F) \cup F_- \cup F_+ \). It follows from Lemma \[2.35\] (1) that \( \chi_F \) is continuous. Furthermore it follows from Lemma \[3.22\] that the induced map \( \overline{\chi}_F : (M \setminus F)/ \sim \to M \) is also continuous. It is clear that the map \( \overline{\chi}_F \) is a bijection. Furthermore using Lemma \[2.39\] one can easily show that the map \( \overline{\chi}_F \) is open. Thus it follows from Lemma \[2.42\] that the map \( \overline{\chi}_F \) is in fact a homeomorphism. Finally it is not hard to see that the map is actually a diffeomorphism.

We leave it to the insatiable appetite of the reader for technical proofs to fill in the details.
Proposition 8.17 together with the following proposition shows that cutting and gluing are indeed inverse operations.

**Proposition 8.18.** Let $M$ be an orientable $n$-dimensional smooth manifold and let $A$ and $B$ be disjoint unions of boundary components of $M$. Furthermore let $f: A \rightarrow B$ be an orientation-preserving diffeomorphism. Let $W = M/a \sim f(a)$ be the smooth manifold that is obtained from gluing $A$ to $B$. We denote by $F$ the image of $A$ under the map $A \rightarrow M \rightarrow W = M/a \sim f(a)$. By Proposition 8.15 we know that $F$ is a codimension one submanifold of $W$. The result of cutting $W$ along $F$ is diffeomorphic to $M$.

**Proof.** We leave it to the reader to verify that the obvious maps are indeed diffeomorphisms.

---

8.6. **Gluing submanifolds** (*). In the previous section we introduced the notion of a collar neighborhood of the boundary of a given smooth manifold $M$. In many situations one is also given a proper submanifold $N$ and one would like the collar neighborhood and the submanifold to live in harmony. In this section we will deal with this situation and show that harmony can indeed be achieved. The results in this section are even more technical than in the previous section. Thus it is best to skip this section at first reading and only to look at it when we actually use it later on.

In Proposition 8.13 we saw that if we are given a smooth manifold $M$ (which in many examples will be disconnected) and a diffeomorphism $f: \partial M \rightarrow \partial M$, then any choice of a collar neighborhood of $\partial M$ lets us view $M/x \sim f(x)$ again as a smooth manifold. Now suppose that we are given a proper submanifold $N$ of $M$ with $f(\partial N) = \partial N$. We would like to view $N/x \sim f(x)$ as a submanifold of $M/x \sim f(x)$. But it is easy to find examples where this is not the case, since in all likelihood $N/x \sim f(x)$ will not be smooth at the gluing points. We refer to Figure 202 for an illustration where we consider $M = ((-\infty, 0] \times \mathbb{R}) \sqcup ([1, \infty) \times \mathbb{R})$ with the obvious gluing and the obvious collar neighborhoods.

If one thinks about this issue for a few minutes then one is almost inexorably lead to the following definition.

**Definition.** Let $M$ be a smooth manifold with a collar neighborhood $[0, 1] \times \partial M$, let $N$ be a proper submanifold of $M$. Furthermore let $\epsilon \in [0, 1]$. We say that $N$ is a product with respect to $[0, \epsilon] \times \partial M$ if the map $[0, \epsilon] \times \partial N \rightarrow [0, \epsilon] \times M$ defines a diffeomorphism $[0, \epsilon] \times \partial N \rightarrow ([0, \epsilon] \times M) \cap N$. 
Example. We consider $M = [0, \infty) \times \mathbb{R}$ with the obvious collar neighborhood $[0, 1] \times \mathbb{R}$. Furthermore we consider the proper submanifold $N$ that is illustrated in Figure 203. Note that $N$ is a product with respect to $[0, \frac{1}{2}] \times \mathbb{R}$ but that it is not a product with respect to $[0, 1] \times \mathbb{R}$.

![Figure 202]

The following proposition gives an approach to circumventing this issue. For better readability it is formatted as if it was statement (7) of Proposition 8.15.

**Proposition 8.19.** Let $M$ be an $n$-dimensional smooth manifold (we do not assume that $M$ is connected). Let $A$ and $B$ be two distinct boundary components of $M$. Furthermore let $f: A \to B$ be a diffeomorphism.

(7) Let $N$ be a proper submanifold of $M$ such that the map $f$ restricts to a diffeomorphism $A \cap N \to B \cap N$. If there exists a collar neighborhood of $M$ such that $N$ is a product with respect to $[0, \epsilon] \times \partial N$ for some $\epsilon > 0$ and if we use this collar neighborhood to define the smooth manifold structure on $M/a \sim f(a)$, then $N/a \sim f(a)$ is a submanifold of $M/a \sim f(a)$.

**Proof.** The proof follows easily from the definition of the smooth structure on $M/a \sim f(a)$ as provided in the proof of Proposition 8.15 (1). We will not bore the reader with unnecessary details. □

The question arises whether we can always find such a nice collar neighborhood. The following theorem, which is a refined version of the above Collar Neighborhood Theorem 8.12 gives an affirmative answer.

![Figure 203]
Theorem 8.20. (Collar Neighborhood Theorem) Let \( M \) be a smooth manifold. If \( N \) is a proper submanifold of \( M \), then \( M \) admits a collar neighborhood \( [0, 1] \times \partial M \) such that \( N \) is a product with respect to \( [0, 1] \times \partial M \).

![Illustration of the Collar Neighborhood Theorem](image)

**Figure 204. Illustration of the Collar Neighborhood Theorem 8.20**

**Proof.** This statement is precisely [Wall16] Proposition 1.5.6 (ii). \( \blacksquare \)

At times one is given a collar neighborhood for the smooth manifold \( M \) that one is quite happy with. The following proposition says that we can modify the given submanifold to still obtain the desired statement.

**Proposition 8.21.** (*) Let \( M \) be a smooth manifold, let \( N \) be a compact proper submanifold of \( M \) and let \( [0, 1] \times \partial M \) be a collar neighborhood for \( M \). There exists a diffeomorphism \( F \) of \( M \) rel \( \partial M \) and an \( \epsilon > 0 \) such that \( F_0 = \text{id} \) and such that \( F_1(N) \) is a product with respect to \( [0, \epsilon] \times \partial M \).

**Sketch of proof (***). If \( \partial M \) is compact, then we can take \( \epsilon = 1 \) and the statement follows immediately from the above Collar Neighborhood Theorem 8.20 and the uniqueness statement given by Proposition 8.13.

It \( \partial M \) is non-compact (and later in Proposition 8.22 we will be interested in such cases), then we can not use the above “of the shelf argument” and we need to work a little harder. Note that it follows from the hypothesis that \( N \) is a proper submanifold that the map

\[
p: N \cap ([0, 1] \times \partial M) \xrightarrow{\text{inclusion}} [0, 1] \times \partial M \xrightarrow{(t,x) \mapsto t} [0, 1]
\]

is a submersion in a neighborhood of \( \partial N \). Since \( N \) is compact we see that there exists an \( \eta > 0 \) such that \( p \) is in fact a submersion on \( p^{-1}([0, \eta]) \). It follows from the Submersion Theorem 6.56 there exists a smooth embedding \( \varphi: [0, \eta] \times \partial N \to [0, \eta] \times \partial M \) with the following properties:

1. \( \varphi([0, \eta] \times \partial N) = V \cap ([0, \eta] \times \partial M) \),
2. for each \( t \in [0, \eta] \) we have \( \varphi(\{t\} \times \partial N) \subset \{t\} \times \partial M \).

Similar to Lemma 6.13 there exists a smooth function \( f: [0, \eta] \to [0, \eta] \) such that \( f(t) = 0 \) for \( t \in [0, \frac{\eta}{3}] \) and such that \( f(t) = t \) for \( t \in [\frac{3\eta}{4}, \eta] \). One can now easily verify that

\[
N' := \{(\varphi(P, f(t)), t) \mid P \in \partial N \text{ and } t \in [0, \eta]\} \cup (N \setminus (N \cap ([0, \eta] \times \partial M)))
\]

is a submanifold that is product with respect to \( [0, \frac{\eta}{3}] \times \partial M \). We refer to Figure 205 for an illustration of the argument.

It is not difficult to write down an explicit proper isotopy \( E: [0, 1] \times N \to M \) rel \( \partial N \) with \( E_0 = \text{id} \) and \( E_1(N) = N' \). The existence of the desired isotopy \( F \) of \( M \) is now a consequence of the Isotopy Extension Theorem 8.27 (2) below. \( \blacksquare \)
The above results now allow us to prove the following proposition which will be used on several occasions.

**Proposition 8.22.** Let $M$ and $N$ be two $n$-dimensional smooth manifolds with boundary components $A \subset M$ and $B \subset N$ and let $f: A \to B$ be a diffeomorphism. Suppose we have chosen collar neighborhoods for $\partial M$ and $\partial N$ such that $M \cup_f N$ comes with a smooth manifold structure. Furthermore let $X \subset M$ and $Y \subset N$ be two proper $m$-dimensional submanifolds such that $f(X \cap A) = Y \cap B$. Then there exists a proper submanifold $Z \subset M \cup_f N$ with the following three properties:

1. $Z \cap A = X \cap A$ (and thus also $Z \cap B = Y \cap B$),
2. outside of any previously chosen neighborhood of $A = B \subset M \cup_f N$ we have the equality $Z = X \cup_f Y$, and
3. the submanifold $Z$ is homeomorphic to $X \cup_f Y$.

We refer to Figure 206 for an illustration.

**Proof.** The proposition can be deduced quite easily from Propositions 8.19 and 8.21. We leave it to the reader to fill in the details.

---

8.7. **The push-in of a submanifold** (*). In this short section we introduce the following quite natural definition.

**Definition.** Let $W$ be a smooth manifold with compact boundary and let $X$ be a compact submanifold of the boundary $\partial W$. Note that by the Collar Neighborhood Theorem 8.12 we
can pick a collar neighborhood \( \mu: [0, 1] \times \partial W \to W \) and we can pick a collar neighborhood \( \nu: [0, 1] \times \partial X \to X \). Furthermore by Lemma 6.13 we can pick a smooth monotonously increasing function \( \varphi: [0, 1] \to [0, 1] \) with \( \varphi(0) = 0, \varphi(t) > 0 \) for \( t > 0 \) and \( \varphi(t) = 1 \) for \( t \in [\frac{1}{2}, 1] \). We consider the map

\[
\begin{align*}
  f: X & \to W \\
  P & \mapsto \begin{cases} 
    \mu(\varphi(t), P), & \text{if } P = \nu(t, Q) \text{ for some } t \in [0, 1] \text{ and some } Q \in \partial X, \\
    \mu(1, P), & \text{otherwise}.
  \end{cases}
\end{align*}
\]

We call \( f(X) \) the push-in of \( X \). We refer to Figure 207 for an illustration.

![Figure 207](image)

The following lemma summarizes the key properties of push-ins.

**Lemma 8.23.** Let \( W \) be a smooth manifold with compact boundary and let \( X \) be a compact submanifold of \( \partial W \). The push-in \( Y \) of \( X \) is a compact proper submanifold of \( W \) whose boundary equals \( \partial Y = \partial X \).

**Proof.** We continue with the notation from the definition of the push-in. First we claim that \( f \) is smooth. This can be seen as follows: It follows easily from the choice of \( \varphi \) that the map \( f \) is evidently smooth on \( [0, 1] \times \partial X \) and \( X \setminus ([0, \frac{3}{4}] \times \partial X) \). Since these sets are open and since they cover all of \( X \) we see that \( f \) is indeed smooth.

Note that one can easily verify that \( f \) is a proper smooth embedding. It follows from Proposition 8.1 (2) that \( f(X) \) is a proper submanifold. It is now straightforward to verify that \( Y := f(X) \) has the desired properties.

### 8.8. The Tubular Neighborhood Theorem I

The following definition resembles the definition of the collar of the boundary of a smooth manifold.

**Definition.** Let \( M \) be an \( m \)-dimensional smooth manifold and let \( N \) be a closed \( [154] \) \( n \)-dimensional submanifold.

1. A **tubular map for \( N \)** is a smooth embedding \( F: \overline{B}^{m-n} \times N \to M \setminus \partial M \) such that for any \( P \in N \) we have \( F(0, P) = P \). The image of a tubular map is called a **tubular neighborhood for \( N \)**. (Note that it follows immediately from Proposition 8.2 that a tubular neighborhood of \( N \) is in fact a neighborhood of \( N \) in the sense of the definition on page 89.)
2. If \( M \) and \( N \) are oriented, then we say that a tubular map for \( N \) is **orientation-preserving** if the smooth embedding \( F: \overline{B}^{m-n} \times N \to M \) is orientation-preserving where we equip \( \overline{B}^{m-n} \times N \) with the product orientation introduced on page 304.

\[153\] It follows from Proposition 8.13 that the push-in of \( X \) is unique in a suitable sense.
Examples.

(1) We consider $M = S^1 \times S^1$ together with the submanifold $N = S^1 \times \{1\}$. The map

$$=\overline{B}^1 \times S^1 \to \overline{S}^1 \times S^1
(t, z) \mapsto (e^{it}, z)$$

is a tubular map for $N$. We refer to Figure 208 for an illustration.

![Figure 208](image)

(2) We consider the $m$-dimensional smooth manifold $\mathbb{R}^m$ and the $n$-dimensional submanifold $K := \{(x, 0) \in \mathbb{R}^m | x \in \mathbb{R}^{n+1}\}$. In this case the following is an example of a tubular map:

$$\Theta: \overline{B}^{m-n} \times K \to \mathbb{R}^m
((x, y), P) \mapsto (1 + \frac{x}{2} \cdot P, y).$$

with $x \in \mathbb{R}$ and $y \in \mathbb{R}^{m-n-1}$

Theorem 8.24. (Tubular Neighborhood Theorem) Let $M$ be an $m$-dimensional smooth manifold and let $N$ be a closed $n$-dimensional submanifold. Suppose we are in one of the following four situations:

1. $N$ is zero-dimensional,
2. $N$ is one-dimensional and $M$ is orientable,
3. $N$ is of codimension one and $M$ and $N$ are both orientable,
4. we have $M = \mathbb{R}^m$ or $M = S^m$ and $N$ is a closed orientable submanifold of codimension two,

5. we have $M = \mathbb{R}^m$ or $M = S^m$ and $N$ is diffeomorphic to a sphere of dimension less than $\frac{m}{2}$,

then $N$ admits a tubular map $F: \overline{B}^{m-n} \times N \to M$. Furthermore, if $M$ and $N$ are oriented, then we can find an orientation-preserving tubular map $F: \overline{B}^{m-n} \times N \to M$.155

---

154 Here by “closed” we mean that $N$ is closed as a smooth manifold, i.e. $N$ is compact and $\partial N = \emptyset$.

155 If $N$ is 0-dimensional, then $\overline{B}^{m-n} \times N$ is just a finite union of copies of $\overline{B}^m$ and we give it the obvious orientation.
**Example.** In Figure 209 we illustrate the first three of the above cases. Note that in the third example we consider the case that \( M \) is a 3-dimensional ball and \( N \) is a 2-dimensional disk. In particular in this case \( N \) actually has a boundary. This artistic freedom is due to the fact that it is rather challenging to draw a 3-dimensional smooth manifold together with a tubular neighborhood of a closed 2-dimensional submanifold.

\[
\begin{array}{c}
M^2 \\
N^0 \\
\text{trivial tubular neighborhood}
\end{array} \quad \begin{array}{c}
M^2 \\
N^1 \\
\text{trivial tubular neighborhood}
\end{array} \quad \begin{array}{c}
M^3 \\
N^2 \\
\text{trivial tubular neighborhood}
\end{array}
\]

**Figure 209**

**Remark.** It is not entirely clear in what range of dimensions the conclusion of Theorem 8.24 holds. For example it follows from [Kerv59 Theorem 8.2] that if \( N \) is diffeomorphic to \( S^k \) with \( k \leq 6 \), then \( N \) admits a tubular map, regardless of the dimension \( m \). On the other hand it is shown by André Haefliger [HSL65 p. 174] and Jerry Levine [Lev65b Table 7.2] that there exist smooth embeddings \( \varphi: S^{11} \to \mathbb{R}^7 \) such that \( \varphi(S^{11}) \) has a “non-trivial normal bundle”, which implies that \( \varphi(S^{11}) \) does not admit a tubular map.

Our sketch of a proof of the Tubular Neighborhood Theorem 8.24 relies very much on the following proposition, which will come in handy at a few other occasions.

**Proposition 8.25.** Let \( N \) be a closed \( k \)-dimensional smooth submanifold of \( \mathbb{R}^n \). Given \( P \in N \) we write

\[
(V_P N)^\perp = \{ w \in \mathbb{R}^n \mid \langle v, w \rangle = 0 \text{ for all } v \in V_P N \}.
\]

There exists an \( \epsilon > 0 \) such that the following conditions are satisfied:

1. The subset

\[
Z(N, \epsilon) := \{ P + w \mid P \in N \text{ and } w \in (V_P N)^\perp \text{ with } \| w \| \leq \epsilon \}
\]

is a compact \( n \)-dimensional submanifold of \( \mathbb{R}^n \).

2. \( Z(N, \epsilon) \) is a neighborhood of \( N \).

3. The map

\[
Z(N, \epsilon) \to N, \quad P + w \mapsto P \text{ where } P \in N \text{ and } w \in (V_P N)^\perp
\]

is well-defined and smooth.

**Sketch of a proof of Proposition 8.25.** Let \( N \) be a closed \( k \)-dimensional submanifold of \( \mathbb{R}^n \). We consider

\[
\{ (w, P) \in \mathbb{R}^n \times \mathbb{R}^n \mid P \in N \text{ and } w \in (V_P N)^\perp \}.
\]
Without too much effort one can equip $WN$ with an “obvious” structure of an $n$-dimensional submanifold of $\mathbb{R}^n \times \mathbb{R}^n$. We consider the map

$$f: WN \rightarrow \mathbb{R}^n$$

$$(w, P) \mapsto P + w.$$  

One can easily verify that this map is smooth and that for each $P \in N$ the differential of $f$ at $(0, P)$ is an isomorphism. It follows from the Inverse Mapping Theorem 6.40 that for each $P \in N$ there exists an open neighborhood $U_P$ of $P$ and an $\epsilon_P > 0$ such that $f$ restricted to $\{(Q, w) \mid Q \in U_P, \text{ and } w \in (V_Q N)^\perp \text{ with } \|w\| < \epsilon_P\}$ is a smooth embedding. But since $N$ is compact this implies that there exists an $\epsilon > 0$ such that the restriction of $f$ to

$$Z := \{(w, P) \mid P \in N \text{ and } w \in (V_P N)^\perp \text{ with } \|w\| \leq \epsilon\}$$

is a smooth embedding. Note that $f(Z) = Z(N, \epsilon)$. It is now straightforward to verify that $Z(N, \epsilon)$ has all the desired properties. We leave it to the reader to fill in the details. We refer to Figure 211 for an illustration.

\[\text{Figure 210. Illustration of Proposition 8.25}\]

the submanifold $WN$ of $\mathbb{R}^n \times \mathbb{R}^n$

\[\text{Figure 211. Illustration for the proof of Proposition 8.25}\]

We move on to provide an even more sketchy proof of the Tubular Neighborhood Theorem 8.24.

**Sketch of a proof of Tubular Neighborhood Theorem 8.24** (1)-(4). In the following we provide a sketch of the argument if $M = \mathbb{R}^n$ and if $N$ is a closed $k$-dimensional submanifold of $\mathbb{R}^n$. In this special situation we apply Proposition 8.25 and we obtain an $\epsilon > 0$ together with the submanifold $Z(N, \epsilon)$. We claim that there exists a tubular map $F: \overline{B}^{n-k} \times N \rightarrow M$ such that $F(\overline{B}^{n-k} \times N)$ equals precisely $Z(N, \epsilon)$.

As in the proof of Proposition 8.25 we consider

$$WN = \{(w, P) \in \mathbb{R}^n \times \mathbb{R}^n \mid P \in N \text{ and } w \in (V_P N)^\perp\}$$

together with the map

$$f: WN \rightarrow \mathbb{R}^n$$

$$(w, P) \mapsto P + w.$$
Claim. In our four situations there exists a diffeomorphism
\[ \Phi: \mathbb{R}^{n-k} \times N \to WN \]
such that for each \( P \) the map restricts to an isometry \( \mathbb{R}^{n-k} \times \{P\} \to (V_P N)^\perp \times \{P\} \) of vector spaces.

We consider the cases (1)-(4) separately:

1. This case is trivial.
2. This case follows from [Hau14] Proposition 9.2.3.
3. This case follows from [MiS74] Axiom 3 together with [Hau14] Proposition 9.2.3.
4. This case is dealt with in [Bre93] Corollary VII.14.6, alternatively see [Er69] p. 100 and [Rosm00] Corollary 6.2.

Sketch of a proof of Tubular Neighborhood Theorem 8.24 (5). We deal with the last case of the Tubular Neighborhood Theorem 8.24 by hand. In the following we consider the case \( M = \mathbb{R}^m \) and the case that \( N \) is diffeomorphic to the sphere \( S^r \), with \( r < \frac{m}{2} \). The case \( M = S^m \) is treated the same way.

First note that the case \( r = 1 \) is dealt with in (2). Thus we now assume that \( r \geq 2 \). Let \( \varphi: S^r \rightarrow N \subset \mathbb{R}^m \) be a diffeomorphism. We denote by \( \theta: S^r \rightarrow \mathbb{R}^m \) the standard smooth embedding that is given by \( x \mapsto (x, 0) \). We set \( K := \theta(S^r) \). On page 368 we saw that \( K \) admits a tubular map \( \Theta: \overline{B}^{m-r} \times K \rightarrow \mathbb{R}^m \).

Next note, since \( r > 2m \) and \( r \geq 2 \) we obtain from Haefliger’s Unknotting Theorem 27.35 that there exists a smooth isotopy \( F: S^r \times [0, 1] \rightarrow \mathbb{R}^m \) with \( F_0 = \theta \) and \( F_1 = \varphi \). By the Isotopy Extension Theorem 8.27 there exists a diffeotopy \( G: \mathbb{R}^m \times [0, 1] \rightarrow \mathbb{R}^m \) with \( G_1 \circ \theta = \varphi \). The map \( \Phi := G_1 \circ \Theta \circ (id \times \varphi^{-1}): \overline{B}^{m-r} \times N \rightarrow \mathbb{R}^m \) is a tubular map for \( N \).

Finally note that the Statement (5) is also proved in [Kerv59] Theorem 8.2
c

Remark. As many readers might already know, there exists a generalization of the Tubular Neighborhood Theorem 8.24 that deals with any compact proper submanifold \( N \). The precise definition of a tubular neighborhood is in general somewhat lengthy and technical (and frankly often done imprecisely in the literature). Thus we postpone the formulation to Section 10.2 when we really need the more general case.

The following proposition tells us to what degree tubular maps are unique.

Proposition 8.26. (Uniqueness of tubular maps and tubular neighborhoods) Let \( M \) be an \( m \)-dimensional smooth manifold and let \( N \) be a closed \( n \)-dimensional submanifold. Furthermore let \( F, G: \overline{B}^{m-n} \times N \rightarrow M \) be two tubular maps for \( N \). Then there exists a diffeotopy
\[ H: M \times [0, 1] \rightarrow M \]
rel $N$ from $H_0 = \text{id}_M$ to a diffeomorphism $\Phi = H_1$ such that the following two statements hold:

1. The diffeomorphism $\Phi = H_1$ restricts to diffeomorphisms

$$
\Phi: F(\overline{B}^{m-n} \times N) \rightarrow G(\overline{B}^{m-n} \times N)
$$

$$
\Phi: M \setminus F(\overline{B}^{m-n} \times N) \rightarrow M \setminus G(\overline{B}^{m-n} \times N).
$$

2. For all $P \in N$ the diffeomorphism $\Phi = H_1$ restricts to a boundary preserving diffeomorphism

$$
\Phi: F(\overline{B}^{m-n} \times \{P\}) \rightarrow G(\overline{B}^{m-n} \times \{P\})
$$

and the self-diffeomorphism $G^{-1} \circ \Phi \circ F$ of $\overline{B}^{m-n} \times \{P\} = \overline{B}^{m-n}$ is given by multiplication by a matrix $A \in O(m-n)$.

If $M$ and $N$ are oriented and if $F$ and $G$ are orientation-preserving, then all the above diffeomorphisms are orientation-preserving, in particular the matrix $A$ mentioned in (2) lies in $\text{SO}(m-n)$.

![Illustration of Proposition 8.26](image)

**Proof.** A proof for the proposition is given in [Wall16 Theorem 2.5.5 and Theorem 2.5.8]. We refer to [BJ82 Theorem 12.13], [Kos93 Corollary III.3.2] and [Lan01 Theorem IV.6.2] for alternative approaches, which, with a little bit of mental gymnastics, can also be used to prove the proposition.

The last statement that, under the given hypotheses, the diffeomorphisms are orientation-preserving is a consequence of Lemma 8.6 and the fact that $\text{id}_M$ is orientation-preserving.

Before we can state the next theorem we need to introduce one more innocuous definition.

**Definition.** Let $M$ be a smooth manifold. We say that a diffeotopy $F: M \times [0, 1] \rightarrow M$ has **compact support** if there exists a compact subset $K \subset M$ such that $F(x, t) = x$ for all $x \not\in K$ and all $t \in [0, 1]$.

**Examples.**

1. Evidently every diffeotopy of a compact smooth manifold has compact support.
2. The diffeotopy $F: \mathbb{R} \times [0, 1] \rightarrow \mathbb{R}$ given by $F(x, t) = x + t$ does **not** have compact support.
3. In Figure 213 we sketch a non-trivial diffeotopy of $\mathbb{R}$ with compact support.

---

15. Recall that this means that $H(P, t) = P$ for all $P \in N$ and $t \in [0, 1]$.  

The following theorem is one of the key technical tools for dealing with smooth manifolds.

**Theorem 8.27. (Isotopy Extension Theorem)** Let $M$ be a smooth manifold and let $N$ be a compact smooth manifold.

1. Let $f: N \to M \setminus \partial M$ be a smooth embedding. If $F: N \times [0, 1] \to M \setminus \partial M$ is a smooth isotopy from $f$ to some smooth embedding $f'$, then there exists a diffeotopy $G: M \times [0, 1] \to M$ rel some neighborhood of $\partial M$ with $G_0 = \text{id}$ such that
   \[ G(f(x), t) = F(x, t) \quad \text{for all } x \in N \text{ and } t \in [0, 1]. \]

2. (*) Let $f: N \to M$ be a proper smooth embedding. If $F: N \times [0, 1] \to M$ is a proper smooth isotopy from $f$ to some proper smooth embedding $f'$, then there exists a diffeotopy $G: M \times [0, 1] \to M$ with $G_0 = \text{id}$ such that
   \[ G(f(x), t) = F(x, t) \quad \text{for all } x \in N \text{ and } t \in [0, 1]. \]

   Furthermore, if $F$ is an isotopy rel $\partial N$, then we can choose $G$ to be a diffeotopy rel $\partial M$.

In both cases we can furthermore arrange that the diffeotopy $G$ has compact support.

**Examples.**

1. Let $M$ be a smooth manifold. The Isotopy Extension Theorem [8.27] often gets applied as follows: $N$ is a submanifold in $M \setminus \partial M$ and we start out with the inclusion map $i: N \to M$. The Isotopy Extension Theorem [8.27] thus loosely says, that if we deform $N$ in $M$, then we can do so by “dragging $M$” along.

2. In fact often we apply (1) to the special case that $N = \{P\}$ consists of a single point $P \in M \setminus \partial M$. In this case a smooth isotopy of $P$ is just a smooth path $F: [0, 1] \to M \setminus \partial M$ with $F(0) = P$. The Isotopy Extension Theorem [8.27] says that there exists a diffeotopy $G: M \times [0, 1] \to M$ rel a neighborhood of $\partial M$ from the identity to a diffeomorphism $G_1$ with $G(P, t) = F(t)$ for all $t \in [0, 1]$. We refer to Figure 214 for an illustration.

![Figure 213](image1)

**Figure 213**

graphs of $F(\{x\} \times [0, 1])$ for different values of $x \in \mathbb{R}$

![Figure 214](image2)

**Figure 214.** Illustration of the Isotopy Extension Theorem [8.27]
**Remark.** Just for reference we point out that there is a version of the Isotopy Extension Theorem 8.27 for topological manifolds. We refer to [EKi71, Corollary 1.4] and [FNOP19, Theorem 2.10] for details. We have no intention to make use of it.

**Proof of the Isotopy Extension Theorem 8.27.** The theorem follows almost immediately from the statements and the proofs of Theorem 2.4.2 and Theorem 2.4.6 of Wall16. Note that the results of Wall16 do not explicitly say that we can assume that $G_0 = \text{id}$, but a quick look at the proof of Wall16 Theorem 2.4.2 shows that this is the case. Similarly in (2) the fact that in the given situation we can choose $G$ to be a diffeotopy rel $\partial M$ is not mentioned in Wall16, but it does follow from the proof. We also refer to [Kos93, Theorem II.5.2], [Hirs61, Theorem 8.1.3] and [Pal60b, Chapter 6] for related results.

The following corollary to the Isotopy Extension Theorem 8.27 is quite useful.

**Corollary 8.28.** Let $M$ be a smooth manifold without boundary and let $N$ be a compact smooth manifold. Let $f: N \to M$ and $g: N \to M$ be two smooth embeddings. If there exists a smooth isotopy $F: N \times [0, 1] \to M$ from $f$ to $g$, then there exists a diffeomorphism from $M \setminus f(N)$ to $M \setminus g(N)$.

**Proof.** First note that by the Isotopy Extension Theorem 8.27 there exists a diffeotopy $G: M \times [0, 1] \to M$ with $G_0 = \text{id}$ such that $G_1(f(N)) = g(N)$. But this implies that $G_1: M \to M$ is a diffeomorphism with $G_1(f(N)) = g(N)$. It follows that $G_1$ restricts to a diffeomorphism $M \setminus f(N) \to M \setminus g(N)$.

**Example.** The statement of Corollary 8.28 and the statement of the Isotopy Extension Theorem 8.27 are quite subtle. In Figure 215 we illustrate two smooth embeddings $f, g: S^1 \to \mathbb{R}^3$ and we illustrate a map $F: S^1 \times [0, 1] \to \mathbb{R}^3$ with $F_0 = f$, $F_1 = g$ and with the property that every single $F_t: S^1 \to \mathbb{R}^3$ is a smooth embedding. But as should be pretty clear (and we will give a rigorous proof in Section 27.2) the complements $\mathbb{R}^3 \setminus f(S^1)$ and $\mathbb{R}^3 \setminus g(S^1)$ are not diffeomorphic. This shows that in the formulations of Corollary 8.28 and the Isotopy Extension Theorem 8.27 it is essential that the map $F$ is smooth on all of $N \times [0, 1]$.

![Figure 215](image)

We also have the following proposition which is at times quite useful.

---

Since $N$ is compact we know by Lemmas 2.40 and 2.17 that $M \setminus f(N)$ and $M \setminus g(N)$ are open subsets of $M$, in particular they are smooth manifolds in their own right.
**Proposition 8.29.** Let \( M \) be a connected \( n \)-dimensional smooth manifold.

1. Given any two points \( P \) and \( Q \) in \( M \setminus \partial M \) there exists a diffeotopy rel a neighborhood of \( \partial M \) from the identity to a diffeomorphism \( \Phi : M \to M \) with \( \Phi(P) = Q \).
2. If \( n \geq 2 \), then given distinct points \( P_1, \ldots, P_m \) and distinct points \( Q_1, \ldots, Q_m \) in \( M \setminus \partial M \) there exists a diffeotopy rel a neighborhood of \( \partial M \) from the identity to a diffeomorphism \( \Phi : M \to M \) with \( \Phi(P_i) = Q_i \) for \( i = 1, \ldots, m \).

In both cases we can furthermore arrange that the diffeotopy has compact support. (Note that if \( M \) is oriented, then it follows from Lemma 8.6 that in both cases \( \Phi \) is in fact orientation-preserving.)

![Figure 216. Illustration of Proposition 8.29](image)

In the proof of Proposition 8.29 we will make use of the following lemma which will be useful in its own right.

**Lemma 8.30.** Let \( M \) be a smooth manifold.

1. Any path \( \gamma : [0,1] \to M \setminus \partial M \) is path-homotopic in \( M \setminus \partial M \) to a smooth path. (Here recall “path-homotopic” means that we keep the endpoints fixed).
2. If \( M \) is connected, then any two points \( P, Q \) in \( M \setminus \partial M \) can be connected by a smooth path in \( M \setminus \partial M \).

**Proof of Lemma 8.30**

1. The first statement follows from Exercise 8.7 applied to \( W := M \setminus \partial M \).
2. Now suppose that \( M \) is connected. From Lemma 6.9 (3) and Exercise 8.12 we obtain that \( M \setminus \partial M \) is path-connected. Thus the second statement follows from the first statement.

Now we can move on to the actual proof of Proposition 8.29.

**Proof of Proposition 8.29.** Let \( M \) be a connected \( n \)-dimensional smooth manifold.

1. Let \( P, Q \) be two points in \( M \setminus \partial M \). By Lemma 8.30 there exists a smooth path \( F : [0,1] \to M \setminus \partial M \) from \( P \) to \( Q \). The desired statement follows now from the Isotopy Extension Theorem 8.27 using the above example.
2. (*) We prove this statement by induction on \( m \). We dealt with the case \( m = 1 \) in (1).

Now suppose that we know the statement for some \( m \in \mathbb{N}_{\geq 2} \). Thus let \( P_1, \ldots, P_m, P_{m+1} \) and \( Q_1, \ldots, Q_{m+1} \) be two sets of distinct points in \( M \setminus \partial M \). By induction we can without loss of generality already assume that \( P_i = Q_i \) for \( i = 1, \ldots, m \). Now pick disjoint closed \( n \)-balls around \( P_1, \ldots, P_m \) that are disjoint from \( P := P_{m+1} \) and

\[^{159}\text{The super vigilant reader will have noticed that implicitly we are using Lemma 8.7.}\]
$Q := Q_{m+1}$. We denote by $W$ the smooth manifold obtained from $M$ by removing the corresponding open balls.\footnote{Here we implicitly use Lemma 6.28} Since $n \geq 2$ we obtain from Proposition 6.30 that $W$ is still connected. Thus we can apply (1) to $P$ and $Q$ in $W$ to obtain a diffeotopy of $W$ with all the desired properties. Since the diffeotopy is the identity near the boundary of $W$ we can extend it via the identity to a diffeotopy of all of $M$. \hfill \blacksquare

On one occasion later on we will need the following proposition.

**Proposition 8.31.** (\*) Let $M$ be a connected non-orientable $n$-dimensional smooth manifold, let $P_1, \ldots, P_m$ be points in $M \setminus \partial M$ and let $I \subset \{1, \ldots, m\}$ be a subset. There exists a diffeotopy rel a neighborhood of $\partial M$ from the identity to a diffeomorphism $\Phi: M \to M$ with the following properties:

1. for all $i \in \{1, \ldots, m\}$ we have $\Phi(P_i) = P_i$,  
2. the diffeotopy fixes all $P_i$ with $i \notin I$,  
3. the map $D \Phi_{P_i}: T_{P_i}M \to T_{P_i}M$ is orientation-preserving if and only if $i \in I$.

Furthermore can assume that the diffeotopy has compact support.

**Proof.** We leave it to the reader to use the paths from Lemma 17.5 to modify the proof of Proposition 8.29 to obtain a proof of the proposition. \hfill \blacksquare

We conclude with the following theorem which follows easily from [Wall16, Proposition 2.4.7].

**Theorem 8.32.** (Extension Theorem) (\*) Let $f: N \to M$ be a smooth embedding of a smooth manifold with boundary into a smooth manifold $M$ such that $f(N) \subset M \setminus \partial M$. Then there exists a smooth embedding\footnote{Here the topological space $(N \sqcup (\partial N \times [0, 1]))/\partial N = \partial N \times 0$ is understood to be the topological space $(N \sqcup (\partial N \times [0, 1]))/\sim$ where $P \in \partial N$ is equivalent to $P \times \{0\}$ on $\partial N \times [0, 1]$.}$f: (N \sqcup (\partial N \times [0, 1]))/\partial N = \partial N \times 0 \to M$ which restricts to the original $f$ on $N$ and such that the image lies in $M \setminus \partial M$.

![Figure 217. Illustration of the Extension Theorem 8.32](image)

8.9. The connected sum operation for smooth manifolds. In this section we introduce the connected sum of two smooth manifolds. As we will see this construction combines features from the last two sections.
Definition. Let \( n \in \mathbb{N} \). Let \( M \) and \( M' \) be two connected non-empty \( n \)-dimensional smooth manifolds.

1. Suppose that at least one of \( M \) or \( M' \) is non-orientable. We pick two smooth embeddings \( \varphi: B^n \to M \setminus \partial M \) and \( \varphi': B^n \to M' \setminus \partial M' \) and we define the connected sum of \( M \) and \( M' \) as
   \[
   M \# M' := (M \setminus \varphi(B^n)) \sqcup (M' \setminus \varphi'(B^n))/\sim \text{ where } \varphi(P) \sim \varphi'(P) \text{ for all } P \in S^{n-1}.
   \]
2. If both \( M \) and \( M' \) are orientable, then we pick orientations for \( M \) and \( M' \). Let \( \varphi: B^n \to M \setminus \partial M \) and \( \varphi': B^n \to M' \setminus \partial M' \) be smooth embeddings such that \( \varphi \) is orientation-preserving and such that \( \varphi' \) is orientation-reversing. As before we define the connected sum of the oriented smooth manifolds \( M \) and \( M' \) as
   \[
   M \# M' := (M \setminus \varphi(B^n)) \sqcup (M' \setminus \varphi'(B^n))/\sim \text{ where } \varphi(P) \sim \varphi'(P) \text{ for all } P \in S^{n-1}.
   \]

For completeness we define the connected sum of an empty smooth manifold with another connected smooth manifold \( M \) to be \( M \), i.e. \( \emptyset \# M := M \# \emptyset := M \).

![Figure 218](image)

Remark. In Section 100.5 we will introduce the connected sum of topological manifolds.

In Proposition 8.35 we will discuss the properties of the connected sum. In particular we will see that in a suitable sense the connected sum \( M \# N \) is well-defined, i.e. independent of any of the choices. So we will talk of “the connected sum” instead of “a connected sum”.

Before we go to the technicalities let us consider the connected sum in the 2-dimensional setting.

Lemma 8.33.

1. Let \( k \in \mathbb{N} \). The iterated connected sum of \( g \) tori is diffeomorphic to the surface of genus \( g \), as defined on page 206.
2. Let \( k \in \mathbb{N} \). The iterated connected sum of \( k \) copies of \( \mathbb{R}P^2 \) is diffeomorphic to the non-orientable surface of genus \( k \), as defined on page 206.

Remark. On page 2569 we will provide an alternative proof of Lemma 8.33 (2).

Examples.

1. In Figure 220 we give a pictorial argument why the connected sum of two tori is diffeomorphic to the surface of genus two. We will provide a somewhat more formal argument in the proof of Lemma 8.33 (1).

\[162\] The reader will surely benignly overlook the fact that in some of the proofs down the line we do not deal with this special case separately.
(2) By Exercise 3.43 we know that the Klein bottle is diffeomorphic to the non-orientable surface of genus 2. Thus Lemma 8.33 (2) implies that the connected sum $\mathbb{R}P^2 \# \mathbb{R}P^2$ is diffeomorphic to the Klein bottle. It is instructive to do this example separately. First in Figure 221 on the top we recall the argument why $\mathbb{R}P^2$ minus an open disk is diffeomorphic to the Möbius band. This shows that $\mathbb{R}P^2 \# \mathbb{R}P^2$ is given by gluing two Möbius bands along their common boundary. In Figure 221 on the bottom we see a closed curve in the Klein bottle that decomposes the Klein bottle into two Möbius bands. Put differently, we see that both $\mathbb{R}P^2 \# \mathbb{R}P^2$ and the Klein bottle are the result of gluing two Möbius bands along their boundary. It is now straightforward to see that the Klein bottle is diffeomorphic to $\mathbb{R}P^2 \# \mathbb{R}P^2$.

**Figure 221**

**Sketch of proof.**

(1) We prove the statement for $g = 2$. More precisely, in Figure 222 to the left we show two copies of the torus and two embeddings of $B^2$, one is orientation-preserving
and the other one is orientation-reversing. Furthermore we indicate a map from the corresponding connected sum to the surface of genus 2. With some good will one can see that this gives rise to the desired diffeomorphism. We leave it to the reader to deal with the case \( g \geq 3 \).

\[ \text{torus } \# \text{ torus} \quad \rightarrow \quad \text{surface of genus 2} \]

**Figure 222.** Illustration for the proof of Lemma 8.33.

(2) We outsource the proof of this statement to Exercise 8.21.

Our final example of a connected sum works in all dimensions.

**Lemma 8.34.** The connected sum of an \( n \)-dimensional smooth manifold \( M \) with \( S^n \) is diffeomorphic to \( M \).

**Proof.** Indeed, this can be seen as follows: in the construction of the connected sum \( M \# S^n \) we consider the ball \( S^n_\geq 0 \) in \( S^n \). Since \( S^n \setminus S^n_\geq 0 = S^n_\leq 0 \) is again a closed ball it is very believable that \( M \# S^n \) is again diffeomorphic to \( M \). Later on, in Lemma 8.37 we will turn this cartoon of an argument into a proper proof.

Now we turn to the technical proposition that contains all the statements anybody ever wanted to know about the topology of the connected sum of two smooth manifolds.

**Proposition 8.35.** Let \( n \in \mathbb{N} \). Let \( M \) and \( M' \) be two connected \( n \)-dimensional smooth manifolds. (If both \( M \) and \( M' \) are orientable, then we demand that \( M \) and \( M' \) are oriented.) Let \( \varphi: \overline{B^n} \to M \setminus \partial M \) and \( \varphi': \overline{B^n} \to M' \setminus \partial M' \) be smooth embeddings. If \( M \) and \( M' \) are orientable, then we demand that \( \varphi \) is orientation-preserving and that \( \varphi' \) is orientation-reversing. The following seven statements hold:

1. The resulting connected sum \( M \# M' \) is a \( n \)-dimensional topological manifold that admits a canonical smooth structure which has the property that \( M \setminus \varphi(B^n) \) and \( M' \setminus \varphi'(B^n) \) are submanifolds.
2. (a) The boundary of \( M \# M' \) is given by \( \partial M \sqcup \partial M' \).
   
   (b) If \( M \) and \( M' \) are compact, then \( M \# M' \) is also compact.
   
   (c) If \( M \) and \( M' \) are closed, then \( M \# M' \) is also closed.
3. If \( n \geq 2 \) or if at least one of \( M \) or \( M' \) is closed, then \( M \# M' \) is also connected.
4. The diffeomorphism type of \( M \# M' \) does not depend on the choice of \( \varphi \) and \( \varphi' \).
5. If \( M \) and \( M' \) are oriented, then the smooth manifold \( M \# M' \) admits a unique orientation that coincides with the orientations of \( M \setminus \varphi(B^n) \) and \( M' \setminus \varphi'(B^n) \).
(6) The connected sum operation is symmetric in the sense that the smooth manifolds $M \# M'$ and $M' \# M$ are diffeomorphic. If $M$ and $M'$ are oriented, then there exists in fact an orientation-preserving diffeomorphism $M \# M' \to M' \# M$.

(7) If $n \geq 2$, then the connected sum operation is associative, in the sense that if we are furthermore given a connected (oriented) $n$-dimensional smooth manifold $M''$, then there exists an (orientation-preserving) diffeomorphism from $(M \# M') \# M''$ to $M \# (M' \# M'')$.

**Remark.**

1. Note that the connected sum $\mathbb{R} \# \mathbb{R}$ of $\mathbb{R}$ with itself is the disjoint union of two copies of $\mathbb{R}$, thus it is disconnected. This shows that in Proposition 8.35 (3) we cannot drop the hypothesis that $n \geq 2$.

2. In Exercise 8.17 we will show that if the connected sum of two smooth manifolds is orientable, then each summand is orientable. This can be viewed as a converse to Proposition 8.35 (5).

3. Proposition 8.35 (7), together with the discussion on page 82, allows us to unambiguously define the connected sum of any finite non-empty set of smooth manifolds of dimension $n \geq 2$. For safety we define the connected sum of the empty set of $n$-dimensional smooth manifolds as $S^n$.

4. As discussed in Proposition 8.15 (1), the precise smooth atlas on $M \# M'$ will depend on the choice of certain collar neighborhoods, but the diffeomorphism type of $M \# M'$ is well-defined.

5. A slightly different approach to defining the connected sum of two smooth manifolds is presented in [KeM63, p. 505] and [Kos93, p. 90]. In that reference the gluing is performed along open subsets which reduces some of the issues that arise while gluing along boundary components, i.e. while gluing along subsets that are not open.

In the proof of Proposition 8.35 (4) we will need the following theorem which was originally proved by Richard Palais [Pal60a] in 1960.

**Theorem 8.36.** Let $M$ be an $n$-dimensional smooth manifold. (If $M$ is orientable, then we pick an orientation for $M$.) In the following let $\varphi_1, \ldots, \varphi_m : \overline{B^n} \to M \setminus \partial M$ and $\psi_1, \ldots, \psi_m : \overline{B^n} \to M \setminus \partial M$ be two sets of $m$ smooth embeddings of $\overline{B^n}$ with disjoint images. (If $M$ is orientable, then we demand that all $\varphi_i$ and $\psi_i$ are orientation-preserving or that all are orientation-reversing.) If $n \geq 2$ or if $m = 1$, then there exists a diffeotopy $F : M \times [0, 1] \to M$.

---

164 It is a fun exercise to figure out why the hypothesis $n \geq 2$ is actually necessary.
rel some neighborhood of \( \partial M \) from the identity \( F_0 = \text{id}_M \) to a diffeomorphism \( F_1: M \to M \) such that for each \( i \in \{1, \ldots, m\} \) the following diagram commutes:

\[
\begin{array}{ccc}
\varphi_i & \rightarrow & \psi_i \\
\downarrow F_1 & & \downarrow \cong \\
M & \cong & M.
\end{array}
\]

Furthermore we can assume that \( F \) has compact support. (Note that if \( M \) is orientable, then the diffeomorphism \( F_1 \) is in fact orientation-preserving by Lemma 8.6).

**Remark.**

1. In Exercise 8.8 we will give an alternative proof of Theorem 8.36.
2. In Theorem 100.10 we will state an analogue of Theorem 8.36 in the setting of topological manifolds.

**Proof of Theorem 8.36.** Before we start with the actual proof we want to point out that on several occasions we implicitly use Lemma 8.6 which allows us to “compose” smooth isotopies and diffeotopies. We also introduce the notation that given \( A \in O(n) \) we denote by \( \rho(A) \) the diffeomorphism of \( \overline{B}^n \) that is given by multiplication by \( A \).

For \( i = 1, \ldots, m \) we write \( P_i := \varphi_i(0) \) and \( Q_i := \psi_i(0) \). If \( n \geq 2 \) or if \( m = 1 \), then we can apply Proposition 8.29 so that we can arrange that \( P_i = Q_i \) for \( i = 1, \ldots, m \).

For a short period we consider the cases that \( M \) is orientable and non-orientable separately.

1. Suppose that \( M \) is orientable. Recall that in this case we assume that \( M \) is in fact oriented. Furthermore we assume that all the \( \varphi_i \) and \( \psi_i \) are either orientation-preserving or orientation-reversing. In particular for each \( i \in \{1, \ldots, m\} \) the map \( D(\psi_i^{-1} \circ \varphi_i): T_0 \overline{B}^n \to T_0 \overline{B}^n \) is orientation-preserving.

2. Suppose that \( M \) is non-orientable. We denote by \( I \subset \{1, \ldots, m\} \) the set of \( i \)'s for which the map \( D(\psi_i^{-1} \circ \varphi_i): T_0 \overline{B}^n \to T_0 \overline{B}^n \) is orientation-reversing. We apply Proposition 8.31 to \( I \). Using the resulting diffeotopy we can henceforth assume that each map \( D(\psi_i^{-1} \circ \varphi_i): T_0 \overline{B}^n \to T_0 \overline{B}^n \) is in fact orientation-preserving.

We continue with the common discussion.

We observe that \( \varphi_1, \ldots, \varphi_m \) and \( \psi_1, \ldots, \psi_m \) are tubular maps for the closed 0-dimensional submanifold \( N = \{P_1, \ldots, P_m\} \). Thus it follows from Proposition 8.26 that there exist matrices \( A_1, \ldots, A_m \in O(n) \) and a smooth isotopy rel \( N = \{P_1, \ldots, P_m\} \) from \( \varphi_1 \sqcup \cdots \sqcup \varphi_m \) to \( \psi_1 \circ \rho(A_1) \sqcup \cdots \sqcup \psi_m \circ \rho(A_m) \). Since each \( D(\psi_i^{-1} \circ \varphi_i): T_0 \overline{B}^n \to T_0 \overline{B}^n \) is orientation-preserving we see that each \( A_i \) lies in fact in \( SO(n) \).

Therefore it follows from Lemma 8.5 that there exists a smooth isotopy from the map \( \psi_1 \circ \rho(A_1) \sqcup \cdots \sqcup \psi_m \circ \rho(A_m) \) to the map \( \psi_1 \sqcup \cdots \sqcup \psi_m \). Thus we have found a smooth isotopy from \( \varphi_1 \sqcup \cdots \sqcup \varphi_m \) to \( \psi_1 \sqcup \cdots \sqcup \psi_m \). The existence of the desired diffeotopy follows from the Isotopy Extension Theorem 8.27.

Now we can provide the proof of Proposition 8.35

**Proof of Proposition 8.35.**
(1) We write \( W := M \setminus \varphi(B^n) \) and \( W' := M \setminus \varphi'(B^n) \). By Proposition 8.2 (2) these are both \( n \)-dimensional smooth manifolds with boundary components \( \varphi(S^{n-1}) \) and \( \varphi'(S^{n-1}) \). Note that by definition we have
\[
M \# M' = (W \sqcup W')/a \sim \varphi'(\varphi^{-1}(a)) \quad \text{where } a \in \varphi(S^{n-1}).
\]
It follows from Proposition 8.15 that \( M \# M' \) admits a canonical structure of an \( n \)-dimensional smooth manifold such that \( W \) and \( W' \) are submanifolds.

(2) (a) It follows from Proposition 8.15 (4) that \( \partial(M \# M') = \partial M \cup \partial M' \).

(b) Suppose that \( M \) and \( M' \) are compact. It follows from Proposition 8.15 (5) together with Proposition 8.2 that \( M \# M' \) is compact.

(c) This statement is an immediate consequence of (a) and (b).

(3) (a) Let \( n \in \mathbb{N}_{\geq 2} \). In this case \( S^{n-1} \) is connected. It follows from Proposition 8.1 that \( W \) and \( W' \) are connected. We obtain from Proposition 8.15 (5) that \( M \# M' \) is indeed connected.

(b) Now suppose that \( n = 1 \) and that at least one of \( M \) or \( M' \) is closed. Let us say that \( M \) is closed. It follows from the classification of compact 1-dimensional smooth manifolds, see Theorem 7.5, that \( M \) is diffeomorphic to \( S^1 \) and that \( M' \) is diffeomorphic either to \( S^1 \) or to \( B^1 \). One can now show “by hand” that \( M \# M' \) is connected.

(5) Now we suppose that \( M \) and \( M' \) are oriented. Recall that in this case we suppose that the map \( \varphi : \overline{B^n} \to M \setminus \partial M \) is orientation-preserving and furthermore that the map \( \varphi' : \overline{B^n} \to M' \setminus \partial M' \) is orientation-reversing. We continue with the notation from (1). It follows from Lemma 6.46 that \( W \) and \( W' \) inherit an orientation from \( M \) and \( M' \). The gluing map \( \varphi' \circ \varphi^{-1} : \varphi(S^{n-1}) \to \varphi'(S^{n-1}) \) is orientation-reversing. Thus the desired statement follows from Proposition 8.15.

(4) We need to show that the definition of \( M \# M' \) is independent of the choices of the smooth embeddings \( \varphi \) and \( \varphi' \). Given smooth embeddings \( \varphi : \overline{B^n} \to M \setminus \partial M \) and \( \varphi' : \overline{B^n} \to M' \setminus \partial M' \) we now introduce the following cumbersome notation:
\[
(M \# M')(\varphi', \varphi') := (M \setminus \varphi(B^n)) \sqcup (M' \setminus \varphi'(B^n)) / \varphi(P) \sim \varphi'(P) \quad \text{for all } P \in S^{n-1}.
\]
Below we show independence of \( \varphi \) and \( \varphi' \).

(a) First we consider the case that both \( M \) and \( M' \) are orientable. Therefore let \( \varphi, \psi : \overline{B^n} \to M \setminus \partial M \) be two orientation-preserving smooth embeddings and furthermore let \( \varphi', \psi' : \overline{B^n} \to M' \setminus \partial M' \) be two orientation-reversing smooth embeddings. By Theorem 8.36 there exist in particular diffeomorphisms \( F : M \to M \) with \( F \circ \varphi = \psi \) and \( F' : M' \to M' \) with \( F' \circ \varphi' = \psi' \). One can now easily verify that the map
\[
(M \# M')(\varphi, \varphi') \to (M \# M')(\psi, \psi')
x \mapsto \begin{cases}
F(x) & \text{if } x \in M \setminus \varphi(B^n), \\
F'(x) & \text{if } x \in M' \setminus \varphi'(B^n)
\end{cases}
\]
is a diffeomorphism.

(b) Next we consider the case that \( M \) and \( M' \) are both non-orientable. Then basically the same argument as in (a) applies. The only difference is that we now apply
Remark. The fact that the diffeomorphism type of the connected sum is well-defined is rather subtle.

(1) If $M$ and $M'$ are two orientable smooth manifolds, then the diffeomorphism type of the connected sum is defined only if both smooth manifolds are in fact oriented, i.e. they are equipped with an orientation. In general the definition does depend on the choice of orientation. More precisely, there exist oriented smooth manifolds $M$ and $M'$ such that $M \# M'$ is not diffeomorphic (in fact not even homeomorphic) to $M \# (-M')$, where $-M'$ denotes as usual the smooth manifold $M'$ with the opposite orientation. We will see such examples later, namely in Corollary 101.12 once we have introduced the cup product on cohomology groups.

(2) Often the connected sum operation gets abbreviated as follows: Given two smooth manifolds we remove an open ball from each smooth manifold and then glue $M$ and

\[ B^n \to M \setminus \partial M \]

and $\psi': B^n \to M' \setminus \partial M'$ be two smooth embeddings. Furthermore let $\varphi', \psi': B^n \to M' \setminus \partial M'$ be two smooth embeddings. If $\varphi$ and $\psi$ are both orientation-preserving or if both are orientation-reversing, then the same argument as in (a) and (b) applies. Now suppose that this is not the case. We denote by $\tau: B^n \to B^n$ any orientation-reversing diffeomorphism (e.g. $\tau$ could be the reflection in one of the coordinate axes.) Then as before we see that $(M \# M')(\varphi, \varphi')$ is diffeomorphic to $(M \# M')(\psi \circ \tau, \psi' \circ \tau)$. But $(M \# M')(\psi \circ \tau, \psi' \circ \tau)$ is, basically by definition, the same as $(M \# M'(\psi, \psi')$.

(d) The case that $M$ is non-orientable and that $M'$ is orientable is of course dealt with the same way as in (c).

(6) We need to show that the connected sum operation is symmetric. The only slight asymmetry that occurs in the definition is if both $M$ and $M'$ are oriented. Thus we only need to deal with this case. Now let $\varphi: B^n \to M \setminus \partial M$ be an orientation-preserving embedding and let $\varphi': B^n \to M' \setminus \partial M'$ be an orientation-reversing embedding. Let $\rho: B^n \to B^n$ be a reflection in some hyperplane. Note that the map $\varphi' \circ \rho: B^n \to M' \setminus \partial M'$ is now an orientation-preserving embedding and that the map $\varphi \circ \rho: B^n \to M \setminus \partial M$ is now an orientation-reversing embedding. If we use these two maps to define $M' \# M$ we see almost immediately that the “obvious” map $M \# M' \to M' \# M$ is an orientation-preserving diffeomorphism.

(7) Finally we still need to show that the connected sum operation is actually associative. To do so we pick smooth embeddings (with appropriate orientation conditions)

$\varphi: B^n \to M \setminus \partial M$, $\varphi': B^n \to M' \setminus \partial M'$, $\psi: B^n \to M' \setminus \partial M'$ and $\psi': B^n \to M'' \setminus \partial M''$

such that $\varphi'$ and $\psi'$ have disjoint images. Note that $\varphi'$ also defines a smooth embedding $B^n \to M \# M'$ and that $\psi'$ also defines a smooth embedding $B^n \to M' \# M''$. If we use all these smooth embeddings it is clear that there exists an (orientation-preserving) diffeomorphism from $(M \# M') \# M''$ to $M \# (M' \# M'')$. 

Theorem 8.36 to the case of non-orientable smooth manifolds, so we no longer have to make any assumptions on whether or not $\varphi, \psi$ and $\varphi', \psi'$ are orientation-preserving.
M' together, along the boundary spheres that we had just created, in such a way that the orientations of the boundaries are opposite. This description is rather dangerous since the diffeomorphism type of the connected sum is only well-defined if we glue the boundary components via the diffeomorphism given by the smooth embeddings of the closed balls. In Proposition ?? we will see that the above shortened description of the connected sum operation is incorrect.

The following lemma now gives the promised proof of the statement that performing the connected sum with $S^n$ does not alter the diffeomorphism type.

**Lemma 8.37.** Let $M$ be a non-empty $n$-dimensional smooth manifold $M$. The connected sum $M \# S^n$ is diffeomorphic to $M$.  

**Proof.** First we pick an orientation-preserving embedding $\varphi: \overline{B^n} \to M \setminus \partial M$. Next let $g_-: \overline{B^n} \to S^n_{\leq 0} \subset S^n$ and $g_+: \overline{B^n} \to S^n_{\geq 0} \subset S^n$ be the two embeddings from page 199. The map
\[ M \# M' = (M \setminus \varphi(B^n)) \sqcup (S^n \setminus g_-(B^n))/\sim \to M, \]
\[ P \mapsto \begin{cases} P, & \text{if } P \in M \setminus \varphi(B^n), \\ \varphi(g_+^{-1}(Q)), & \text{if } P \in S^n \setminus g_-(B^n) \end{cases} \]
is now a diffeomorphism.\(^{165}\) It follows from Proposition 8.35 (4) that we also have $M \# S^n$ for any choice of orientation-reversing embedding $\overline{B^n} \to S^n$. ■

In Exercise 8.27 we will use Theorem 8.36 to prove the following corollary which can be viewed as a strengthening of the result obtain in Exercise 18.7.

**Corollary 8.38.** Let $M$ be a connected smooth manifold and let $P, Q$ be two distinct points in $M$. Then there exists a smooth embedding $\gamma: [0, 1] \to M$ with $\gamma(0) = P$ and $\gamma(1) = Q$.

We conclude this section with the following lemma.

**Lemma 8.39.** Let $n \geq 1$.

1. Given two connected non-empty $n$-dimensional smooth manifolds $X$ and $Y$ the connected sums $X \# Y$ and $Y \# X$ are diffeomorphic.

2. Given three connected non-empty $n$-dimensional smooth manifolds $X$, $Y$ and $Z$ the connected sums $(X \# Y) \# Z$ and $X \# (Y \# Z)$ are diffeomorphic.

**Remark.** Let $n \geq 1$. It follows from Lemma 8.39 and the remark on page 82 that given connected $n$-dimensional smooth manifolds $M_1, \ldots, M_k$ we can unambiguously define the diffeomorphism type of the connected sum $M_1 \# \ldots \# M_k$ without having to worry in what order we perform the connected sum of two smooth manifolds.

**Proof.** The first statement is just an immediate consequence of the definitions, whereas the second statement is a fairly straightforward consequence of Theorem 8.36. We leave it to the reader to fill in the details. ■

\(^{165}\) The reader who is equipped with a logical magnifying glass will spot that it requires a little bit of thought why this map is really a diffeomorphism, in particular one needs to spend a little bit of time thinking about the question why the map is smooth in the first place.
8.10. Knots and their complements. Before we introduce knots we recall several different ways how we can describe the 3-sphere \( S^3 \). More precisely, by definition and Lemma 2.44 we have

\[
S^3 = \{ (z, w) \in \mathbb{C}^2 | |w|^2 + |z|^2 = 1 \} = \{ (w, x, y, z) \in \mathbb{R}^4 | w^2 + x^2 + y^2 + z^2 = 1 \} \cong \mathbb{R}^3 \cup \{ \infty \}.
\]

via the stereographic projection from Lemma 2.44

We will go back and forth between these models without mentioning these maps. In particular, as discussed on page 344, we will always view \( \mathbb{R}^3 \) as a submanifold of the smooth manifold \( S^3 = \mathbb{R}^3 \cup \{ \infty \} \).

**Definition.** A knot is a submanifold of \( S^3 = \mathbb{R}^3 \cup \{ \infty \} \) that is diffeomorphic to \( S^1 \).\(^{166}\) We say that the knot is *oriented* if it is oriented as a 1-dimensional smooth manifold.

**Remark.**

(1) It follows from Proposition 8.1 that a subset of \( S^3 \) is a knot if and only if it is the image of a smooth embedding \( S^1 \to S^3 \).\(^{167}\)

(2) The definition of a knot is supposed to model the “physical objects” that we have in mind and that are sketched in Figure 223. It is therefore perhaps at first not clear why we consider knots in \( S^3 = \mathbb{R}^3 \cup \{ \infty \} \) instead of knots in \( \mathbb{R}^3 \). The reason is that topologists prefer, if possible, to work with compact spaces. In particular the compact space \( S^3 = \mathbb{R}^3 \cup \{ \infty \} \) is often strongly preferable to the non-compact space \( \mathbb{R}^3 \).

We start out with the most boring but also the most important knot.

**Definition.** The *trivial knot* is defined as \( \{(x, y, 0) \in \mathbb{R}^3 | x^2 + y^2 = 1 \} \subset \mathbb{R}^3 \cup \{ \infty \} = S^3 \).\(^{168}\)

In Figure 223 we show the trivial knot together with two other examples of knots. More precisely, we show 1-dimensional submanifolds of \( \mathbb{R}^3 \) that we view as 1-dimensional submanifolds of \( \mathbb{R}^3 \cup \{ \infty \} = S^3 \).

Now we want to say that two knots are “the same” if one can be “deformed” into the other. Fortunately we already have the language to make this picture precise: The notion of a smooth isotopy between (oriented) submanifolds that we introduced on page 350 makes this notion precise. For the reader’s convenience we repeat the definition of “smoothly isotopic” in our context.

\(^{166}\) Sometimes, to distinguish this knot from the higher dimensional siblings that we will introduce on pages 303 and \(?\) we also refer to such a knot as a *classical knot*.

\(^{167}\) To be more precise, the “if”-direction is a consequence of Proposition 8.1. On the other hand, if \( K \subset S^3 \) is a knot, then by definition there exists a diffeomorphism \( \varphi : S^1 \to K \subset S^3 \) and it follows easily from the definitions that the map \( \varphi \) viewed as a map from \( S^1 \to S^3 \) is a smooth embedding whose image is precisely \( K \).

\(^{168}\) In principle it is possible to give a precise description of all these three knots. For example we just gave a definition of the trivial knot as \( \{(x, y, 0) | x^2 + y^2 = 1 \} \subset S^3 = \mathbb{R}^3 \cup \{ \infty \} \). Later, on page 777, we will give a precise definition of the trefoil. It is also clear that one can give a precise description of the figure-8 knot, but this description would be painful to write down and it would not add to our understanding. We therefore stick with the picture, with the understanding, that if somebody was challenging us, we could write down a precise description in coordinates. But it is considered very impolite to challenge a topologist to give a rigorous description.
Definition. We say that two knots \( K \) and \( J \) are smoothly isotopic if there exists a smooth isotopy from \( K \) to \( J \), i.e. a smooth map

\[
F: S^1 \times [0,1] \to S^3
\]

such that the following hold:

1. we have \( F(S^1 \times \{0\}) = K \) and \( F(S^1 \times \{1\}) = J \), and
2. for each \( t \in [0,1] \) the map \( S^1 \to S^3 \) given by \( z \mapsto F(z,t) \) is a smooth embedding.

If \( K \) and \( J \) are oriented, then we demand that the map \( K \to J \) given by \( x \mapsto F_1(F_0^{-1}(x)) \) is orientation-preserving.

Remark. It follows from Lemma 8.7 that the property of being smoothly isotopic defines an equivalence relation on the set of knots.

For example the three knots shown in Figure 224 are smoothly isotopic. Usually we do not distinguish two knots if they are smoothly isotopic. For example, any knot that is smoothly isotopic to a trivial knot is called trivial knot. Sometimes we also say that a knot that is smoothly isotopic to a trivial knot is trivial.

Playing around with pictures for some time shows that it might be quite difficult to show that the trefoil is smoothly isotopic to the trivial knot. This arouses the suspicion, that the trefoil is in fact not smoothly isotopic to the trivial knot. This raises the following question.

**Question 8.40.** How can we show that the trefoil is not smoothly isotopic to the trivial knot?

It is also fun to consider orientations. This leads us to the following definition.

Definition. A knot \( K \) is called reversible if the two orientations on \( K \) give smoothly isotopic oriented knots.\(^{169}\)

\(^{169}\)In the literature what we call a reversible knot is often called an invertible knot. We reserve the adjective invertible for a related, but different notion, see page 2388.
Example. As we see in Figure 225, it is basically clear that the trivial knot is reversible. In Exercise 8.29 we will see that the trefoil and the figure-8 knot are also reversible.

This leads us to the following question which we will answer on page 2390.

Question 8.41. Is every knot reversible?

In the remainder of this section we will ignore orientations and instead we will discuss the following generalization of Question 8.40.

Question 8.42. Given a knot \( K \), how can we determine whether or not \( K \) is smoothly isotopic to the trivial knot?

The following proposition allows us to turn these two questions into the question, whether two topological spaces are diffeomorphic.

Proposition 8.43. Let \( K \) and \( J \) be two knots. If they are smoothly isotopic, then the following two statements hold:

1. There exists an orientation-preserving diffeomorphism \( \Phi : S^3 \to S^3 \) with \( \Phi(K) = J \). If \( K \) and \( J \) are oriented, then \( \Phi \) restricts to an orientation-preserving diffeomorphism \( K \to J \).
2. There exists an orientation-preserving diffeomorphism between the knot complements \( S^3 \setminus K \) and \( S^3 \setminus J \).

Proof. Let

\[
F : S^1 \times [0, 1] \to S^3 \\
(z, t) \mapsto F(z, t)
\]

be a smooth isotopy from a knot \( K \) to a knot \( J \). By the Isotopy Extension Theorem 8.27 we can extend the smooth isotopy \( F \) to a diffeotopy of \( S^3 \). This means in particular that there exists a diffeotopy

\[
G : S^3 \times [0, 1] \to S^3 \\
(z, t) \mapsto G(z, t)
\]

from the identity to a diffeomorphism \( \Phi = G_1 : S^3 \to S^3 \) with \( \Phi|_K = F_1 \), in particular with \( \Phi(K) = J \). By Lemma 8.6 the diffeomorphism \( \Phi \) is orientation-preserving. The map \( \Phi \) restricts to an orientation-preserving diffeomorphism \( \Phi : S^3 \setminus K \to S^3 \setminus J \). ■

It is natural to ask to what degree the converse of Proposition 8.43 holds. It turns out that in both cases the converse holds, but in both cases these are difficult theorems. First we have the following theorem that was proved in 1969 by Jean Cerf [Cer68].

---

\[ \text{The phrase “given a knot } K \text{” is consciously slightly vague.} \]
Theorem 8.44. (Cerf Theorem) Every orientation-preserving diffeomorphism of $S^3$ is dieotopic to the identity.

Now we obtain the promised converse to Proposition 8.43 (1).

Corollary 8.45. Let $K$ and $J$ be two knots. If there exists an orientation-preserving diffeomorphism $\Phi: S^3 \to S^3$ with $\Phi(K) = J$, then $K$ and $J$ are smoothly isotopic.

**Proof.** Let $\Phi: S^3 \to S^3$ be an orientation-preserving diffeomorphism with $\Phi(K) = J$. By the Cerf Theorem 8.44 there exists a diffeotopy $F: S^3 \times [0, 1] \to S^3$ with $F_0 = \text{id}$ and $F_1 = \Phi$. The restriction of $F$ to $[0, 1] \times K$ is the desired smooth isotopy from $K$ to $J$. ■

The following theorem also gives us the converse to Proposition 8.43 (2).

Theorem 8.46. (Gordon-Luecke) Let $K$ and $J$ be two knots in $S^3$. If there exists an orientation-preserving diffeomorphism between the knot complements $S^3 \setminus K$ and $S^3 \setminus J$, then $K$ and $J$ are smoothly isotopic.

**Proof.** This theorem is significantly more difficult to prove than Proposition 8.43. In fact a proof was given only in the 1980s by Cameron Gordon and John Luecke [GL89] Theorem 1. The proof builds on the work of William Thurston [Thu82] for which he got the fields medal in 1982. ■

The following proposition gives a neat characterization of trivial knots.

**Proposition 8.47.** Let $K$ be a knot. The following two statements are equivalent:

1. The knot $K$ bounds a disk, i.e. there exists a smooth embedding $\varphi: \overline{B}^2 \to S^3$ with $\varphi(S^1) = K$.
2. The knot $K$ is smoothly isotopic to the trivial knot.

**Figure 226. Illustration of Proposition 8.47.**

In the proof of Proposition 8.47 we will need the following lemma which is interesting in its own right.

**Lemma 8.48.** Let $n \in \mathbb{N}$ and let $\varphi: \overline{B}^n \to \mathbb{R}^n$ be an embedding with $\varphi(0) = 0$.

1. If $\varphi$ is orientation-preserving, then $\varphi$ is smoothly isotopic, rel 0, to the identity.
2. If $\varphi$ is orientation-reversing, then $\varphi$ is smoothly isotopic, rel 0, to the reflection $\rho: \overline{B}^n \to \mathbb{R}^n$ that is given by $(x_1, x_2, \ldots, x_n) \mapsto (-x_1, x_2, \ldots, x_n)$.

**Proof of Lemma 8.48** This lemma is a special case of Proposition 8.26. But it is more fun to prove the lemma “by hand”. We will do so in Exercise 8.6. ■

**Sketch of a proof of Proposition 8.47** Let $K$ be a knot. We need to prove the equivalence of (1) and (2).
First we prove the almost trivial “(2)⇒(1)”-direction. It is clear that the trivial knot \( \{(x, y, 0) \in \mathbb{R}^3 \mid x^2 + y^2 = 1\} \subset \mathbb{R}^3 \cup \{\infty\} = S^3 \) bounds a disk. It follows immediately from the Isotopy Extension Theorem \([8.27]\) that any knot that is smoothly isotopic to the trivial knot also bounds a disk.

Now we turn to the proof of the much more interesting “(2)⇒(1)”-direction. Thus let \( \varphi: \overline{B}^2 \to S^3 = \mathbb{R}^3 \cup \{\infty\} \) be a smooth embedding with \( \varphi(S^1) = K \). We write \( \mathbb{R}^3 = \mathbb{C} \times \mathbb{R} \) and we make the identification \( \mathbb{C} = \mathbb{C} \times \{0\} \subset \mathbb{R}^3 \). It suffices to show that there exists a smooth isotopy from \( \varphi \) to a smooth embedding \( \psi: \overline{B}^2 \to \mathbb{R}^3 \) such that \( \psi(S^1) = S^1 \subset \mathbb{C} \).

We perform the following steps:

0. By Lemma \([2.65](1)\) we know that \( \text{SO}(4) \) is path-connected. Together with Exercise \([18.7]\) we see that we can find a smooth isotopy such that afterwards we have \( \infty \notin \varphi(\overline{B}^2) \).

1. Using that \( \text{SL}(3, \mathbb{R}) \) is path-connected, see again Lemma \([2.65](2)\), and using again Exercise \([18.7]\) we can find a smooth isotopy such that afterwards we have \( \varphi(0) = 0 \) and \( (D \varphi_0)(0, \overline{B}^2) = \mathbb{C} \times \{0\} \).

2. We can shrink the disk, i.e., we can precompose the map \( \varphi: \overline{B}^2 \to \mathbb{C} \times \mathbb{R} \) with the smooth isotopy \( \overline{B}^2 \times [0, 1] \to \overline{B}^2 \) that is given by \( (p, t) \mapsto p \cdot t \) for some \( \epsilon \in (0, 1] \), such that composition \( p \circ \varphi \) of \( \varphi \) with the projection \( p: \mathbb{R}^3 = \mathbb{C} \times \mathbb{R} \to \mathbb{C} \) is an embedding.

3. We write \( \varphi = \varphi_\mathbb{C} \times \varphi_\mathbb{R}: \overline{B}^2 \to \mathbb{C} \times \mathbb{R} \). It follows from (2) that the map

\[
\overline{B}^2 \times [0, 1] \to \mathbb{C} \times \mathbb{R} \\
(x, t) \mapsto (\varphi_\mathbb{C}(x), \varphi_\mathbb{R}(x) \cdot t)
\]

is a smooth isotopy. This shows that we only need to deal with a smooth embedding \( \varphi: \overline{B}^2 \to \mathbb{C} \) with \( \varphi(0) = 0 \).

4. Now we can apply Lemma \([8.48]\).

We illustrate the steps (2) to (4) in Figure \([227]\). We leave it to the reader to fill in all the technical details and to make all steps rigorous.

![Figure 227](image)

We continue our discussion of knots with a definition.

**Definition.** Let \( K \) be an oriented knot in \( S^3 \). By the Tubular Neighborhood Theorem \([8.24]\) there exists an orientation-preserving smooth embedding

\[
F: \overline{B}^2 \times K \to S^3
\]
such that \( F(0, P) = P \) for all \( P \in K \). For any \( P \in K \) we refer to the oriented submanifold \( F(S^1 \times \{P\}) \) as a meridian of \( K \).

A priori the definition of the meridian depends on the choice of the tubular neighborhood. The following lemma, which is an immediate consequence of Proposition 8.50, says that the meridian is well-defined up to smooth isotopy.

**Lemma 8.49.** The meridian of an oriented knot in \( S^3 \) is well-defined up to smooth isotopy in \( S^3 \setminus K \).

The following proposition gives a convenient criterion for showing that a given closed oriented curve is indeed a meridian.

**Proposition 8.50.** Let \( K \) be an oriented knot in \( S^3 \). Let \( \mu \subset S^3 \setminus K \) be a closed oriented curve. Suppose there exists a smooth embedding \( \varphi : \overline{B}^2 \subset S^3 \) with the following two properties:

1. the \( \varphi|_{S^1} \) defines an orientation-preserving diffeomorphism \( S^1 \to \mu \),
2. the image \( \varphi(\overline{B}^2) \) intersects \( K \) transversally in a single point \( P \),
3. a positive basis for \( \mathcal{T}_P(\varphi(\overline{B}^2)) \) together with a positive basis for \( \mathcal{T}_P K \) gives a positive basis for \( \mathcal{T}_P S^3 \)\(^{172}\),

then \( \mu \) is a meridian of \( K \).

**Remark.** More casually speaking, Proposition 8.50 says that a meridian is any closed curve which circles once around a knot where the orientation is given by the right-hand-rule, i.e. if the thumb points into the direction of the knot, then the fingers point into the direction of the meridian. This rule is illustrated in Figure 229.

**Sketch of proof.** By the Tubular Neighborhood Theorem \(^{8.24}\) there exists an orientation-preserving smooth embedding \( F : \overline{B}^2 \times K \to S^3 \) such that \( F(0, P) = P \) for all \( P \in K \). For

\(^{171}\)It follows immediately from Proposition 8.1 that \( F(S^1 \times \{P\}) \) is indeed a submanifold of \( S^3 \setminus K \).

\(^{172}\)Later, on page \( 2271 \) we will say that \( P \) is a positive intersection point of \( \varphi(\overline{B}^2) \) and \( K \).
convenience we denote the image of $F$ by $B^2 \times K$. We perform the following steps which are quite similar to the steps in the proof of Proposition 8.47.

(a) We pick a point $Q \neq P$ on $K$. We can shrink the disk such that $\varphi(B^2)$ is contained in $B^2 \times (K \setminus \{Q\})$.

(b) It follows from our hypothesis (1) and the definition of differentiability that we can shrink the disk even further, such that the map

$$\varphi: B^2 \rightarrow B^2 \times (K \setminus \{Q\}) \xrightarrow{(v,z) \mapsto (v,P)} B^2 \times \{P\}$$

is an embedding. It follows from the hypothesis (2) that this map is actually orientation-preserving.

(c) Similar to Step (3) of the proof of Proposition 8.47 we see that $\varphi$ is smoothly isotopic, rel $(0,P)$, to an orientation-preserving embedding into $B^2 \times \{P\}$.

(d) The statement now follows from Lemma 8.48.

As in the proof of Proposition 8.47 we leave it to the reader to fill in the details. ■

As in the proof of Proposition 8.47, we leave it to the reader to fill in the details.

![Diagram](image.png)

**Figure 230.** Illustration of the proof of Proposition 8.50.

Later on, in Chapter 27, we will study the fundamental group of a knot complement. Implicitly we will make use of the following lemma.

**Lemma 8.51.** Given any knot $K \subset S^3$ the complement $S^3 \setminus K$ is path-connected.

**Proof.** We will provide the proof in Exercise 8.28. ■

### Exercises for Chapter 8.

**Exercise 8.1.** Let $f: M \rightarrow N$ be a smooth map between two smooth manifolds. Let $P \in M \setminus \partial M$. We suppose that $D f_P: T_P M \rightarrow T_{f(P)} N$ is a monomorphism. Show that there exists an open neighborhood $U$ of $p$ such that the restriction of $f$ to a map $U \rightarrow N$ is a smooth embedding.

*Hint.* Use the Inverse Function Theorem 6.18

**Exercise 8.2.** Let $X$ and $Y$ be closed topological manifolds and let $f: X \rightarrow Y$ an embedding in the sense of the definition on page 116 in other words, we assume that $f: X \rightarrow Y$ is a homeomorphism onto its image. Is $f(X)$ necessarily a submanifold of $Y$?

*Remark.* In other words, we are wondering whether the obvious analogue of Proposition 8.1 also holds in the context of topological manifolds.
**Exercise 8.3.** Let $M$ and $N$ be smooth manifolds and let $f: M \to N$ be an immersion. We denote by $\Delta = \{(x, x) \in M \times M | x \in M\}$ the “diagonal” of $M \times M$.

(a) Show that there exists an open neighborhood $U$ of the diagonal $\Delta$ such that for any $(x, y) \in U \setminus \Delta$ we have $f(x) \neq f(y)$.

(b) We suppose that $M$ is compact. Show that $f$ admits only finitely many double points, i.e. that there exist only finitely many distinct pairs $(x_1, y_1), \ldots, (x_n, y_n)$ in $M \times M \setminus \Delta$ such that $f(x_i) = f(y_i)$ for $i = 1, \ldots, n$.

**Exercise 8.4.** Give an example of smooth manifolds $M$ and $N$ together with an isotopy $F: M \times [0, 1] \to N$ which is smooth, but which is not a smooth isotopy in the sense of the definition on page 348.

![Illustration for Exercise 8.3](image)

**Figure 231.** Illustration for Exercise 8.3

**Exercise 8.5.** Let $f: M \to N$ be an immersion between two smooth manifolds without boundary.

(a) Show that given any $P \in M$ there exists an open neighborhood $U$ of $P$ such that the restriction $f|_U: U \to M$ is a smooth embedding.

*Hint.* Use the Inverse Mapping Theorem 6.40.

(b) We suppose that $M$ and $N$ are compact, non-empty and connected. Show that $f$ is a covering map.

(c) Does the conclusion of (b) still hold if instead we only assume that $M$ and $N$ are connected and that $f$ is surjective?

![Illustration of Exercise 8.5](image)

**Figure 232.** Illustration of Exercise 8.5

**Exercise 8.6.** Let $n \in \mathbb{N}$ and let $\varphi: \mathbb{B}^n \to \mathbb{R}^n$ be an embedding with $\varphi(0) = 0$. The goal of this exercise is to show the following two statements:

1. If $\varphi$ is orientation-preserving, then $\varphi$ is smoothly isotopic, rel 0, to the identity.
2. If $\varphi$ is orientation-reversing, then $\varphi$ is smoothly isotopic, rel 0, to the reflection $\rho: \mathbb{B}^n \to \mathbb{R}^n$ that is given by $(x_1, x_2, \ldots, x_n) \mapsto (-x_1, x_2, \ldots, x_n)$.

We will prove the two statements in a few easy steps:

(a) (i) Show that if $\varphi$ is orientation-preserving, then $\varphi$ is smoothly isotopic rel 0 to a map $\psi$ such that $D \psi_0 = \text{id}$.

(ii) Show that if $\varphi$ is orientation-reversing, then $\varphi$ is smoothly isotopic rel 0 to a map $\psi$ such that $D \psi_0 = D \rho_0$.

*Hint.* Use Lemma 2.65 together with Exercise 18.7.
(b) Let $\psi: \mathbb{B}^n \to \mathbb{R}^n$ be a map with $D\psi_0 = \text{id}$. Show that there exists an $\epsilon > 0$ such that the map

$$F: \mathbb{B}^n_\epsilon \times [0, 1] \to \mathbb{R}^n \quad (z, t) \mapsto \psi(z) \cdot (1 - t) + z \cdot t$$

is a smooth isotopy.

*Hint.* Consider the function $\mathbb{B}^n_\epsilon \times \mathbb{R} \to \mathbb{R}^{n+1} \times \mathbb{R}$ given by $(z, t) \mapsto (F(z, t), t)$ and apply the Inverse Function Theorem 6.18 to the points $(0, t)$ and use that $[0, 1]$ is compact. Alternatively use Proposition 6.16.

(c) Prove the original statements (1) and (2).

*Remark.* At some point you surely want to use Lemma 8.7.

---

**Exercise 8.7.** Let $M$ be a connected $n$-dimensional smooth manifold.

(a) Suppose that $M$ is oriented. Let $\varphi, \psi: \mathbb{B}^n \to M$ be two orientation-preserving smooth embeddings. Show that there exists a smooth isotopy $F: \mathbb{B}^n \times [0, 1] \to M$ with $F_0 = \varphi$ and $F_1 = \psi$.

*Hint.* First use Exercise 8.6 to deal with the case that there exists a chart $\Theta: U \to \mathbb{B}^n$ for $M$ with $\varphi(\mathbb{B}^n) \subset U$ and $\psi(\mathbb{B}^n) \subset U$. Use the Sausage Lemma, stated and proved in Exercise 2.53, to deal with the general case.

(b) Prove (a) for the case that $M$ is non-orientable.

*Hint.* Let $p: \tilde{M} \to M$ be the orientation covering that we introduced in Proposition 17.3. By (a) we know that the conclusion holds for $\tilde{M}$. Now Exercise 17.6 comes in handy.

---

**Exercise 8.8.** Let $M$ be a connected $n$-dimensional smooth manifold.

(a) Suppose that $M$ is oriented. Let $\varphi: \mathbb{B}^n \to M \setminus \partial M$ and $\psi: \mathbb{B}^n \to M \setminus \partial M$ be two orientation-preserving smooth embeddings of $\mathbb{B}^n$. Show that there exists a diffeotopy $F: M \times [0, 1] \to M$ rel some neighborhood of $\partial M$ with $F_0 = \text{id}_M$ and with $F_1 \circ \varphi = \psi$.

(b) Suppose that $M$ is non-orientable. Let $\varphi: \mathbb{B}^n \to M \setminus \partial M$ and $\psi: \mathbb{B}^n \to M \setminus \partial M$ be two smooth embeddings of $\mathbb{B}^n$. Show that there exists a diffeotopy $F: M \times [0, 1] \to M$ rel some neighborhood of $\partial M$ with $F_0 = \text{id}_M$ and with $F_1 \circ \varphi = \psi$.

*Hint.* Use Exercises 8.6 and 8.7 together with the Isotopy Extension Theorem 8.27.

*Remark.* Applying this theorem iteratively one can now easily provide an alternative proof of Theorem 8.36.

---

**Exercise 8.9.** Let $M$ and $N$ be two smooth manifolds with empty boundary. We suppose that $\dim(M) < \dim(N)$. Furthermore let $W$ be a submanifold of $N$ without boundary.
Finally we suppose that for every point \( P \in M \) with \( f(P) \in W \) we have the equality \( Df_P(T_P M) + T_{f(P)} W = T_{f(P)} N \). Show that \( W \setminus f(M) \) has full measure in \( W \).

**Hint.** Use Exercise 8.5 Lemma 6.52 (2) and Proposition 6.62.

**Exercise 8.11.** Give an example of a map \( f: M \to N \) between smooth manifolds with \( \dim(N) \geq \dim(M) \) which is not homotopic to an immersion.

**Exercise 8.12.** Let \( M \) be a smooth manifold. Show that \( M \) is path-connected if and only if \( M \setminus \partial M \) is path-connected.

**Hint.** Use the Collar Neighborhood Theorem 8.12.

**Exercise 8.13.** Let \( M \) be a compact smooth manifold and let \( C \) be a union of components of \( \partial M \). Let \( \varphi: C \to C \) be a diffeomorphism.

(a) Show that the smooth manifold

\[(M \sqcup ([0,1] \times C))/\sim \text{ where } x \sim \varphi(x,0) \text{ for } x \in C\]

is diffeomorphic to \( M \).

**Remark.** Recall that the definition of the smooth structure depend on the choice of a collar \([0,1] \times C\).

(b) In fact show that given any neighborhood \( U \) of \( C \subset M \) there exists a diffeomorphism that is the identity on the common subset \( M \setminus U \).

**Remark.** \([0,1] \times C\) is sometimes called an *external collar*.

**Exercise 8.14.** For \( i = 1, 2 \) let \( M_i \) be an \( n \)-dimensional smooth manifold, let \( A_i \) and \( B_i \) be two distinct boundary components of \( M_i \) and let \( f_i: A_i \to B_i \) be a diffeomorphism.
Furthermore suppose we are given a diffeomorphism $\Phi: M_1 \to M_2$ such that the following diagram commutes:

\[
\begin{array}{ccc}
A_1 & \xrightarrow{\Phi|_{A_1}} & A_2 \\
\downarrow{g_1} & & \downarrow{g_2} \\
B_1 & \xrightarrow{\Phi|_{B_1}} & B_2.
\end{array}
\]

We define the manifolds $N_i := M_i/\sim$ as in Proposition 8.15.

(a) Show that the “obvious” map $N_1 \to N_2$ given by $[P] \mapsto [\Phi(P)]$ is a homeomorphism.

(b) Give an example where the map from (a) is not a diffeomorphism.

(c) Show that $N_1$ and $N_2$ are diffeomorphic.

*Hint.* Use the Collar Neighborhood Theorem 8.12.

**Exercise 8.15.** Let $M$ be a compact smooth manifold and let $f: M \to M$ be a diffeomorphism such that $f|_{\partial M}: \partial M \to \partial M$ is diffeotopic to $\id_{\partial M}$. Show that $f$ is diffeotopic to a map $g: M \to M$ such that $g|_{\partial M} = \id$.

**Exercise 8.16.** Let $n \in \mathbb{N}_0$. On page 199 we showed that $\mathbb{B}^n_+ \cup_{S^{n-1}} \mathbb{B}^n_-$ is homeomorphic to $S^n$. By Proposition 8.15 we should now view $\mathbb{B}^n_+ \cup_{S^{n-1}} \mathbb{B}^n_-$ as a smooth manifold. Show that this smooth manifold is diffeomorphic to $S^n$.

**Exercise 8.17.** Let $M$ and $N$ be connected non-empty $n$-dimensional smooth manifolds. Suppose that a connected sum $M \# N$ is orientable. Show that $M$ and $N$ are also orientable.

**Exercise 8.18.** Let $n \in \mathbb{N}_0$ and let $k \in \{1, \ldots, n\}$. We write

\[
\text{GL}(n, k) = \text{set of } k\text{-tuples of linearly independent vectors of } \mathbb{R}^n.\]

Show that $\text{GL}(n, k)$ is an open subset of $\mathbb{R}^{nk}$.

**Exercise 8.19.** Let $M$ be a connected $n$-dimensional smooth manifold. Let $P \in M$. Show that if $n \geq 2$, then $M \setminus \{P\}$ is also connected.

**Exercise 8.20.** We consider the Möbius band $M$ in $S^3 = \mathbb{R}^3 \cup \{\infty\}$ as shown in Figure 8.20.

It should be pretty clear that there exists an isotopy $F$ which turns $\partial M$ into the unknot $K$. By the Isotopy Extension Theorem 8.27 this isotopy $F$ can be extended to a diffeotopy $G$ of $S^3$. In particular we obtain a map $G_1: S^3 \to S^3$ with $G_1(\partial M) = K$. What does $G_1(M)$ look like? Put differently, we just saw that there exists an embedded Möbius band in $S^3$ with boundary given by $K$. What does it look like?

![Figure 236. Illustration of Exercise 8.20](image-url)
**Exercise 8.21.** Let \( g \in \mathbb{N}_{\geq 2} \). Show that the connected sum of \( g \) copies of \( \mathbb{R}P^2 \) is diffeomorphic to the non-orientable surface of genus \( g \) that we introduced on page \([206]\). 

*Remark.* We refer to Figure \([219]\) for an illustration.

**Exercise 8.22.** Does the statement of the Tubular Neighborhood Theorem \([8.24]\) (2) also hold if the smooth manifold \( M \) is non-orientable? More precisely, let \( M \) be a non-orientable \( m \)-dimensional smooth manifold and let \( N \) be a 1-dimensional submanifold. Does there exist a smooth embedding 

\[
F: \overline{B}^{m-1} \times N \to M
\]

such that \( F(0, P) = P \) for all \( P \in N \)?

**Exercise 8.23.** Let \( K = \{(x, y, 0) \in \mathbb{R}^3 \mid x^2 + y^2 = 1\} \) be the trivial knot in \( \mathbb{R}^3 \cup \{\infty\} = S^3 \). Let \( X = S^3 \setminus K \) and let \( Y = \mathbb{R}^3 \setminus K \). One of the two topological spaces \( X \) or \( Y \) is homotopy equivalent to \( S^1 \). Which one?

**Exercise 8.24.** We consider the disk \( \overline{B}^2 \) with two distinct points \( P \) and \( Q \). By Proposition \([8.29]\) there exists an orientation-preserving diffeomorphism \( f \) of \( \overline{B}^2 \) that swaps \( P \) and \( Q \) and that is the identity on \( S^1 \). Try to visualize such a map. (See also Figure \([237]\) for a mental aid.)

**Figure 237**

**Exercise 8.25.** Let \( M \) and \( N \) be two connected oriented \( n \)-dimensional smooth manifolds, let \( A \) be a union of boundary components of \( M \) and let \( B \) be a union of boundary components of \( N \) and let \( \varphi: A \to B \) be a diffeomorphism.

(a) Show that if \( \varphi \) is orientation-preserving or orientation-reversing, then \( M \sqcup \varphi \ N \) admits an orientation such that the map \( M \to M \sqcup \varphi \ N \) is an orientation-preserving smooth embedding.

(b) Show that if \( M \sqcup \varphi \ N \) admits an orientation, then the map \( A \to B \) is orientation-preserving or orientation-reversing.

**Exercise 8.26.** Show that there exists a smooth deformation retraction from \( \text{GL}_+(n, \mathbb{R}) \) to \( \text{SL}(n, \mathbb{R}) \).

**Exercise 8.27.** Let \( M \) be a connected \( n \)-dimensional smooth manifold.

(a) Let \( P, Q \) be two distinct points in \( M \setminus \partial M \). Show that there exists a smooth embedding \( \gamma: [0, 1] \to M \setminus \partial M \) with \( \gamma(0) = P \) and \( \gamma(1) = Q \).

*Hint.* If \( P \) and \( Q \) lie in an open \( n \)-ball, then it is clear how to prove the statement. Use Theorem \([8.36]\) to show that \( P \) and \( Q \) do indeed lie in an open \( n \)-ball.
8. DIFFERENTIAL TOPOLOGY

(b) Let $P, Q$ be two distinct points in $M$. Show that there exists a smooth embedding $\gamma: [0, 1] \to M$ with $\gamma(0) = P$ and $\gamma(1) = Q$.

Hint. Use (a) and the Collar Neighborhood Theorem 8.12.

Exercise 8.28. Let $K \subset S^3$ be a knot. Show that the knot complement $S^3 \setminus K$ is path-connected.

Remark. It is not that easy to give a rigorous proof for this statement. You should use a tubular neighborhood of $K$ to get some control over the situation. Furthermore you might want to have a look at Exercise 2.55.

Exercise 8.29. Show that the trefoil and the figure-8 knot are reversible. In other words, show that the two oriented knots shown in Figure 238 to the left, respectively to the right, are smoothly isotopic.

![Tangle Diagram](trefoil.png)

trefoil with the two orientations

![Tangle Diagram](fig8.png)

figure-8 knot with the two orientations

Figure 238. Illustration for Exercise 8.29

Exercise 8.30. Let $M$ be a closed $k$-dimensional smooth manifold.

(a) Let $n \in \mathbb{N}_{\geq k+1}$ and let $f: M \to S^n = \mathbb{R}^n \cup \{\infty\}$ be an embedding. Show that there exists a smooth isotopy $F: M \times [0, 1] \to S^n = \mathbb{R}^n \cup \{\infty\}$ with $F_0 = f$ and such that $F_1(M) \subset \mathbb{R}^n$.

Hint. Use Proposition 6.62 (4), Lemma 3.32 (4) and Lemma 8.5 (2).

(b) Let $n \in \mathbb{N}_{\geq k+2}$ and let $f_0, f_1: M \to \mathbb{R}^n$ be two embeddings. Suppose there exists a smooth isotopy $F: M \times [0, 1] \to S^n = \mathbb{R}^n \cup \{\infty\}$ with $F_0 = f_1$ and $F_1 = f_1$. Show that there exists also a smooth isotopy $G: M \times [0, 1] \to \mathbb{R}^n$ with $G_0 = f_1$ and $G_1 = f_1$.

Remark. The basic idea of the proof is the same as in (a). But this time the argument requires a little more ingenuity.

(c) Show that the dimension restrictions on $n$ in (a) and (b) are necessary.

Remark. The exercise, applied to $M = S^1$ and $n = 3$, shows in particular that the “theory of knots in $\mathbb{R}^3$” is the same as the “theory of knots in $S^3$".
9. Maps between smooth manifolds

9.1. Embeddings of smooth (topological) manifolds into \( \mathbb{R}^n \). In this section we will show that every topological respectively smooth manifold can be embedded into some \( \mathbb{R}^n \). Later, in Chapter 11 we will discuss smooth embeddings of manifolds into \( \mathbb{R}^n \) in much greater detail, for example we will study how small \( n \) can be chosen. But in the intermediate future the following proposition will be good enough for us.

**Proposition 9.1.**

1. For any smooth manifold \( M \) there exists some \( n \in \mathbb{N} \) and a smooth embedding \( \varphi : M \to \mathbb{R}^n \) such that \( \varphi(M) \) is a closed subset of \( \mathbb{R}^n \).
2. Given any topological manifold \( M \) there exists an \( n \in \mathbb{N} \) and an embedding \( M \to \mathbb{R}^n \) such that \( \varphi(M) \) is a closed subset of \( \mathbb{R}^n \).

**Proof.** We will only provide a proof for the proposition if \( M \) is compact. The case of non-compact smooth manifolds is dealt with in [Wall16, Corollary 4.7.8]. Furthermore, non-compact topological manifolds are dealt with in [Mun75, p. 315]. Note that in both settings the non-compact is significantly harder than the argument we provide below.

1. First let \( M \) be a compact \( m \)-dimensional smooth manifold. Since \( M \) is compact we can pick a finite smooth atlas \( \{ \Phi_i : U_i \to V_i \}_{i=1}^{s} \). By Theorem 6.57 we can find a smooth partition of unity subordinate to the open cover \( \{ U_i \}_{i=1}^{s} \) of \( M \). Put differently, we can find smooth functions \( \nu_i : M \to [0,1], \, i = 1, \ldots, s \) such that for every \( i \in \{1, \ldots, s\} \) we have \( \nu_i(x) + \cdots + \nu_s(x) = 1 \). For \( i = 1, \ldots, s \) we define

\[
\tilde{\Phi}_i : M \to \mathbb{R}^m \ni x \mapsto \begin{cases} 
\Phi_i(x) \cdot \nu_i(x), & \text{if } x \in U_i, \\
0, & \text{otherwise.}
\end{cases}
\]

It follows easily from Lemma 6.23 (1) that each of these maps \( \tilde{\Phi}_i \) is smooth. Finally it remains to prove the following claim.

**Claim.** The map

\[
\varphi : M \to \mathbb{R}^{s-m+s} \ni x \mapsto (\tilde{\Phi}_1(x), \ldots, \tilde{\Phi}_s(x), \nu_1(x), \ldots, \nu_s(x))
\]

is a smooth embedding.

For completeness’ sake we provide the proof of the claim, even though the interest in the full details might be quite muted.

(i) First we show that \( \varphi \) is injective. Let \( x, x' \in M \). We pick \( i \) with \( \nu_i(x) \neq 0 \). If \( \nu_i(x') = 0 \), then evidently \( \varphi(x) \neq \varphi(x') \). If \( \nu_i(x) \neq 0 \), then \( x, x' \in U_i \). Note that \( \Phi_i(x) \neq \Phi_i(x') \), which is equivalent to \( \nu_i(x)^{-1} \cdot \tilde{\Phi}_i(x) \neq \nu_i(x')^{-1} \cdot \tilde{\Phi}_i(x') \). But this means that \( (\tilde{\Phi}_i(x), \nu_i(x)) \neq (\tilde{\Phi}_i(x'), \nu_i(x')) \), which implies that \( \varphi(x) \neq \varphi(x') \).

\[\text{Hmm, how does the smoothness of } \tilde{\Phi}_i \text{ follow from Lemma 6.23 (1)?}\]
(ii) It follows from (i), the hypothesis that $M$ is compact and Proposition 2.43 (2) that the map $\varphi$ is an embedding.

(iii) We need to show that for each $x \in M$ the differential $D\varphi_x : T_x M \to \mathbb{R}^{s \cdot m + s}$ is a monomorphism. We pick $i$ with $\nu_i(x) \neq 0$. We consider the map

$$U_i \to \{(v,t) \in \mathbb{R}^m \times \mathbb{R} \mid t \neq 0\} \to \mathbb{R}^m$$

$$y \mapsto (\tilde{\Phi}_i(y), \nu_i(y))$$

$$(v,t) \mapsto \frac{1}{t} \cdot v.$$  

Note that the composition is just the diffeomorphism $\Phi_i$, thus the differential at $x$ is a monomorphism. But this implies that the differential of the first map at $x$ is a monomorphism. Finally this note that this implies that the differential of $\varphi$ at $x$ is a monomorphism. 

(2) The proof for compact topological manifolds is basically the same as in (a). The only difference is that from Theorem 6.57 we only obtain a continuous partition of unity subordinate to the open cover $\{U_i\}_{i=1,...,s}$ of $M$. In particular now the map $\varphi : M \to \mathbb{R}^{s \cdot m + s}$ that we constructed in (a) is only an embedding.  

We conclude this short section with an amusing corollary.

**Definition.** A topological space $X$ is called **metrizable** if there exists a metric $d$ on $X$ such that the given topology agrees with the topology coming from $d$.

Now we can state the promised corollary.

**Corollary 9.2.** *Every topological manifold $M$ is metrizable.*

**Proof.** Let $M$ be a topological manifold. By Proposition 9.1 (2) there exists an $n \in \mathbb{N}$ and a map $\varphi : M \to \mathbb{R}^n$ which is an embedding. In other words, $M$ is homeomorphic to a subset of $\mathbb{R}^n$. This means that the usual Euclidean metric $d$ defines a metric on $\varphi(M)$ such that the topology coming from $d$ agrees with the topology given by $\varphi(M)$. 

9.2. **The Whitney Approximation Theorem.** As we will see later on, there are many ways to construct interesting continuous maps between two smooth manifolds. The following theorem allows us to “replace” such a continuous map by a smooth map.

**Theorem 9.3. (Whitney Approximation Theorem)** Let $M$ be a smooth manifold (with or without boundary) and let $N$ be a smooth manifold (with or without boundary).

(1) Let $f : M \to N$ be a map that is smooth on a (possibly empty) closed subset $A$. There exists a homotopy $F : M \times [0, 1] \to N$ with the following properties:

(a) The homotopy is a homotopy rel $A$.
(b) We have $F_0 = f$.
(c) The map $F_1 : M \to N$ is smooth.

Suppose that we are given a continuous function $\rho : M \to \mathbb{R}_{>0}$ and suppose that we are given a metric $d$ on $N$. Then we can find a homotopy $F$ as above that also satisfies the following extra condition:

(d) For every $(x,t) \in M \times [0, 1]$ we have $d(F(x,t), f(x)) \leq \rho(x)$. 

(2) Let \( f, g : M \to N \) be two smooth maps that agree on a (possibly empty) closed subset \( A \). If \( f \) and \( g \) are homotopic rel \( A \), then there exists also a smooth homotopy between \( f \) and \( g \) that is constant on \( A \).

**Remark.** Suppose we are in the setting of the Whitney Approximation Theorem 9.3. Let \( f : M \to N \) be a map that is injective (respectively surjective, bijective). Now we know that we can find a homotopy from \( f \) to some smooth map \( F_1 = g : M \to N \), but the theorem does not give us any control over whether the smooth map \( F_1 = g \) is also injective (respectively surjective, bijective).

![Figure 239. Illustration of Theorem 9.3 (1).](image)

**Proof.**

(1) The first statement, without Condition (d), is the content of [Lee02, Theorem 6.26] and [Lee02, Theorem 9.27]. The full statement including Condition (d) follows by almost the same argument as in the proof of [Lee02, Theorem 6.26] and [Lee02, Theorem 9.27], one just needs to make full use of [Lee02, Theorem 6.21]. We refer to [MTo97, Lemma A.9] for a closely related argument. A weaker version of (1) is also proved in [Hirs76, Lemma 5.1.5] and in [DFN85, Theorem 10.1.2].

(2) The proof of Statement (2) can reduced to Statement (1) without too many problems. We refer to [Lee02, Theorem 6.29] or alternatively to [DFN85, Theorem 12.1.4] for details.

We continue with the following pleasant corollary to the Whitney Approximation Theorem 9.3.

**Corollary 9.4.** Let \( n \in \mathbb{N} \). We pick a base point \( * \) on \( S^n \). Furthermore let \( M \) be a smooth manifold without boundary. We pick a base point \( x_0 \). The obvious map

\[
\{ \text{all smooth maps } f : (S^n, *) \to (M, x_0) \text{ up to smooth homotopies} \} \to \pi_n(M, x_0)
\]

is an isomorphism.

**Remark.** In Exercise 9.1 we will use this isomorphism, together with Proposition 6.62 to give a quick proof of Proposition 14.14, i.e. we will reprove that for \( n \geq 2 \) we have \( \pi_1(S^n) = 0 \).

**Proof.** Note that it follows immediately from the definition on page 278 that the restriction of any map \( S^n \to M \) to any one-point subset \( \{ * \} \) is smooth. Thus the corollary follows immediately from the Whitney Approximation Theorem 9.3 applied to \( A = \{ * \} \).

\(^{174}\) Let \( M \) and \( N \) be smooth manifolds and let \( A \subset M \) be an arbitrary subset. On page 278 we defined what it means for a map \( f : A \to N \) to be smooth.
We conclude this section with two and a half more technical consequences of the Whitney Approximation Theorem [9.3]. These results are interesting in their own right, but the reader might want to skip them initially.

**Proposition 9.5.** (*Let* \( M \) *be smooth manifold (with or without boundary) and let* \( N \) *be a smooth manifold without boundary. Furthermore let* \( f: M \to N \) *be a map. Finally let* \( A \) *and* \( X \) *be disjoint closed subsets such that the restriction of* \( f \) *to* \( A \) *is smooth and let* \( U \subseteq N \) *be an open subset that contains* \( f(M \setminus X) \). *If* \( X \neq \emptyset \), *then there exists a homotopy* \( F: M \times [0, 1] \to N \) *with the following properties:

1. The homotopy is a homotopy rel* \( X \cup A \).
2. We have \( F_0 = f \).
3. The restriction of \( F_1 \) to the open subset \( M \setminus X \) is smooth.\(^{175}\)
4. For each \( t \in [0, 1] \) we have \( F_t(M \setminus X) \subseteq U \).

\( \rho: W \to \mathbb{R}_{\geq 0} \)
\( w \mapsto \rho(w) := c(w, X) = \inf\{c(w, x) : x \in X\} \)

Since \( X \) is closed and since the topology defined by \( c \) agrees with the topology on \( M \) we see that \( \rho(w) > 0 \) for every \( w \in W \). By Lemma 3.20 we know that \( \rho: M \to \mathbb{R}_{\geq 0} \) is continuous. Since \( N \) is a smooth manifold without boundary we can apply the Whitney Approximation Theorem [9.3] to the map \( f: W \to N \) and we obtain that there exists a homotopy \( G: W \times [0, 1] \to N \) with the following properties:

(a) The homotopy is a homotopy rel* \( A \).
(b) We have \( G_0 = f|_W \).
(c) The map \( G_1: W \to N \) is smooth.
(d) For every \( (w, t) \in W \times [0, 1] \) we have \( d(G(w, t), f(w)) \leq \rho(w) \).

\(^{175}\)Since \( X \) is closed we see that \( M \setminus X \) is an open subset of \( M \), thus we can view \( M \setminus X \) as a smooth manifold in its own right.
It follows easily from (d) and the definition of $\rho$ that the map

$$F: M \times [0, 1] \to N$$

$$(x, t) \mapsto \begin{cases} G(x, t), & \text{if } x \in W, \\ f(x), & \text{if } x \in X \end{cases}$$

is continuous. Now it is straightforward to verify that this map has all the desired properties.

Finally we consider the case that $U \neq N$. In this case we consider the map

$$\rho: W \to \mathbb{R}_{\geq 0}$$

$$w \mapsto \rho(w) := \min\{c(w, X), d(f(w), N \setminus U)\}.$$ 

Since $U$ is open and since $f(W) \subset U$ we see that $\rho$ is again non-zero every. The rest of the argument is basically the same and it follows from (d) that for each $t \in [0, 1]$ we have $F_t(M \setminus X) \subset U$.  

Loosely speaking the following proposition says that a map $M \to X$ from a smooth manifold to a topological space $X$ can be made smooth with respect to open balls $B^n$ contained in $X$.

**Proposition 9.6.** Let $M$ be a smooth manifold and let $f: M \to X$ be a map to a Hausdorff space $X$. Let $\varphi: \overline{B}^n \to X$ be an injective map such that $\varphi(B^n)$ is an open subset of $X$. Given any $r \in (0, 1)$ there exists a map $g: M \to X$ with the following properties:

1. $g$ is homotopic to $f$ rel the complement of $f^{-1}(\varphi(B^n))$ in $M$,
2. the map $$f^{-1}(\varphi(B^n)) \to B^n$$ $$x \mapsto \varphi^{-1}(g(x))$$

is smooth.  

**Figure 241**

**Proof.** Since $\overline{B}^n$ is compact, since $X$ is Hausdorff and since $\varphi: \overline{B}^n \to X$ is injective we know by Proposition 2.43 (2) that $\varphi$ is a closed embedding. Thus we might as well identify $\overline{B}^n$ with its image under the map $\varphi: \overline{B}^n \to X$. Now let $r \in \mathbb{R}_{>0}$. By Lemma 2.38 we know that $B^r_n$ is also an open subset of $X$. Furthermore, note that it follows from the fact that $X$ is Hausdorff, together with Lemma 2.17 (1), that $B^r_n$ and $\overline{B}^n$ are a closed subsets of $X$. We consider the map

$$\alpha: M \to \overline{B}^n/S^{n-1}$$

$$x \mapsto \begin{cases} f(x), & \text{if } x \in f^{-1}(B^n), \\ [S^{n-1}], & \text{if } x \in M \setminus f^{-1}(B^n). \end{cases}$$
Note that \( \alpha \) is continuous.\(^1\)\(^6\) As discussed on page \(^1\)\(^8\) we can view \( \overline{B^n}/S^{n-1} \) as a smooth manifold such that \( B^n \) is a submanifold. Therefore we can apply Proposition 9.5 to the map \( \alpha: M \to \overline{B^n}/S^{n-1} \) with \( A = \emptyset \), with the closed subset \( X = M \setminus f^{-1}(B^n) \)\(^1\)\(^7\) and with the open subset \( U = B^n_r \subset N \). We obtain a homotopy \( F: M \times [0, 1] \to \overline{B^n}/S^{n-1} \) with the following properties:

1. The homotopy is a homotopy rel \( X = M \setminus f^{-1}(B^n) \).
2. We have \( F_0 = \alpha \).
3. The restriction of \( F_1 \) to \( X = f^{-1}(B^n) \) is smooth.
4. For each \( t \in [0, 1] \) we have \( F_t(f^{-1}(B^n)) \subset B^n \).

Finally we consider the map

\[
G: M \times [0, 1] \to X \quad (x, t) \mapsto \begin{cases} F(x, t), & \text{if } x \in f^{-1}(B^n) \\ f(x), & \text{if } x \in M \setminus f^{-1}(B^n). \end{cases}
\]

Note that the restrictions of \( G \) to the closed subsets \((M \setminus f^{-1}(B^n)) \times [0, 1]\) and \( f^{-1}(B^n) \times [0, 1]\) are continuous.\(^1\)\(^7\) Thus we obtain from Lemma 3.10 that \( G \) is continuous. It is now straightforward to verify that \( g := G_1 \) has all the desired properties.\(^*\)

The following proposition is a slight variation on Proposition 9.6.

**Proposition 9.7.** Let \( M \) be a smooth manifold and let \( f: M \to X \) be a map to a Hausdorff space \( X \). Let \( n \in \mathbb{N} \) and let \( * \in S^n \) be a point. Finally let \( \varphi: S^n \to X \) be an injective map such that \( \varphi(S^n \setminus \{ * \}) \) is an open subset of \( X \). There exists a map \( g: M \to X \) with the following properties:

1. \( g \) is homotopic to \( f \) rel the complement of \( f^{-1}(\varphi(S^n \setminus \{ * \})) \) in \( M \),
2. the map

\[
f^{-1}(\varphi(S^n \setminus \{ * \})) \to S^n \setminus \{ * \} \quad x \mapsto \varphi^{-1}(g(x))
\]

is smooth.

**Proof.** We leave it to the reader to modify the proof of Proposition 9.6 to obtain the desired result. As the reader will notice, in this case there is no need to work with some \( r \in (0, 1) \). In particular the conclusion we get is slightly more satisfactory. \(\blacksquare\)

\(^*\)Indeed, the restrictions of \( \alpha \) to the closed subset \( M \setminus f^{-1}(B^n) \) is a constant map and the restriction of \( \alpha \) to the closed subset \( f^{-1}(B^n) \) is given by the composition of the map \( f \) with the projection map \( \overline{B^n} \to \overline{B^n}/S^{n-1} \). Therefore we obtain from Lemma 2.35 (2) that \( \alpha \) is indeed continuous.

\(^1\)\(^7\)Note the discrete subscript “\( r \)”.\(^1\)\(^7\)For nervous people, like the author, let us verify in slightly greater detail that the restriction of \( G \) to \( f^{-1}(B^n_r) \times [0, 1] \) is indeed continuous. First note that by (4) the restriction of the map \( F \) to \( f^{-1}(B^n_r) \times [0, 1] \) takes values in \( B^n_r \). It follows from Exercise 2.11 (3) and Exercise 3.9 that the restriction of the map \( F \) to \( f^{-1}(B^n_r) \times [0, 1] \) takes values in the closure of \( B^n_r \) in \( \overline{B^n}/S^{n-1} \). Since \( r \in (0, 1) \) we see that the closure equals \( \overline{B^n_r} \subset B^n \). Now we see that the restriction of the map \( G \) to \( f^{-1}(B^n_r) \times [0, 1] \) equals the composition of the map \( F: f^{-1}(B^n_r) \times [0, 1] \to \overline{B^n_r} \) with the inclusion \( \overline{B^n_r} \to X \).
Example. Let $\bigvee_{i=1}^{k} S^{n_i}$ be a wedge of spheres. We denote by $*$ the wedge point. Let $M$ be a smooth manifold and let $f : M \to \bigvee_{i=1}^{k} S^{n_i}$ be a map. By iteratively applying Proposition 9.7 altogether $k$ times we see that $f$ is homotopic rel $f^{-1}(\{*\})$ to a map that is smooth on the open sets $f^{-1}(S^{n_i} \setminus \{*\})$, $i = 1, \ldots, k$.

![Figure 242](image)

**Lemma 9.8.** Let $M$ be an orientable $n$-dimensional smooth manifold, let $f : M \to X$ be a map to some Hausdorff space $X$, let $\varphi : B^k \to X$ be a map and let $x \in \varphi(B^k)$ be a point such that the following conditions are satisfied:

1. the image $\varphi(B^k)$ is an open subset of $X$,
2. the restriction of $f$ to $f^{-1}(\varphi(B^k))$ is a smooth map,
3. the point $x$ defines a closed subset of $X$\footnote{Wait, does this perhaps follow from our other hypotheses?}

Then $f^{-1}\{x\}$ is a proper $(n - k)$-dimensional submanifold of $M$.

![Figure 243](image)

**Proof (\textasteriskcentered).** Note that $U := f^{-1}(\varphi(B^k))$ is an open subset of $M$, in particular, as discussed in Lemma 6.22 it is a smooth manifold in its own right. It follows from this observation and (3) that we can apply the Regular Value Theorem 6.53. We obtain that $f^{-1}\{x\}$ is a proper orientable $(n - k)$-dimensional submanifold of $U$. In particular $f^{-1}\{x\}$ admits submanifold charts of type $(\alpha)$ and $(\beta)$, as defined on page 270 with respect to the smooth manifold $U$. Since $U$ is an open subset of $M$ we see that these submanifold charts are also submanifold charts of the same type for the set $f^{-1}\{x\}$, viewed as a subset of $M$.

Since $X$ is by hypothesis Hausdorff we know, by Lemma 2.13 that $\{x\}$ is a closed subset of $X$. Finally, since $f$ is of course understood to be continuous on all of $M$ we obtain that $f^{-1}\{x\}$ is a closed subset of $M$. In other words, we have shown that $f^{-1}\{x\}$ satisfies all the conditions, as set out on page 270 of being a proper submanifold of $M$. \qed

9.3. The Transversality Theorem. The following definition is a harmless generalization of the definition from page 306.
Definition. Let $M$ be a smooth manifold and let $Y$ be a proper submanifold of $M$. Let $X$ be some other smooth manifold and let $f: X \to M$ be a smooth map. We say $f$ intersects $Y$ transversally if for every $P \in X$ with $f(P) \in Y$ the following two conditions are satisfied:

1. We have $P \not\in \partial X$ and $f(P) \not\in \partial Y$.
2. We have the following equality:\[ f_*(T_P X) + T_{f(P)} Y = T_{f(P)} M. \]

$$\text{Figure 244}$$

Examples.

1. Let $M$ be a smooth manifold and let $X$ and $Y$ be two proper submanifolds of $M$. We denote by $i: X \to M$ the inclusion map. It follows immediately from the definitions that $i$ intersects $Y$ transversally if and only if $X$ intersects $Y$ transversally in the sense of the definition on page 306.

2. Let $X$ be a smooth manifold and let $f: X \to \mathbb{R}^n$ be a smooth map. Furthermore let $y \in \mathbb{R}^n$. By definition the map $f$ is transverse to the 0-dimensional submanifold $\{y\}$ if and only if $y$ is a regular value of $f$.

The following lemma might ring a bell. Considering the above examples we see that it is quite close to the statement of Lemma 9.9 and to the statement of the Regular Value Theorem 6.53.

Lemma 9.9. Let $M$ be a smooth manifold and let $Y$ be a proper submanifold of $M$ of codimension $l$. Let $X$ be some other smooth manifold and let $f: X \to M$ be a smooth map. If $f$ intersects $Y$ transversely, then the following statements hold:

1. The preimage $f^{-1}(Y)$ is a proper submanifold of $X$ of codimension $l$.
2. If $M$, $X$ and $Y$ are orientable, then $f^{-1}(Y)$ is orientable.
3. If $X$ is compact, then so is $f^{-1}(Y)$.

Proof. The proof of this lemma is not overly hard. For space reasons we skip the proof and instead we refer to [Lee02, Theorem 6.30] for a proof of (1). We leave the task of verifying the remaining statements to the reader. □

The following definition is a variation on the definition that we gave on page 348.

Definition. Let $M$ be a smooth manifold.

1. Let $W, W'$ be two proper submanifolds and let $Z$ be (possibly empty) subset of $W$. We say that $W$ and $W'$ are (smoothly) isotopic rel $Z$, if there exists a (smooth)
isotopy from $W$ to $W'$ rel $Z$, i.e. a map
\[ H : W \times [0,1] \rightarrow M \]
\[ (z,t) \mapsto H(z,t) \]
such that the following hold:
(a) for each $P \in W$ we have $H(P,0) = P$,
(b) for each $P \in Z$ and any $t \in [0,1]$ we have $H(P,t) = P$,
(c) the map
\[ W \rightarrow M \]
\[ z \mapsto H(z,1) \]
defines a homeomorphism (diffeomorphism) from $W$ to $W'$,
(d) for each $t \in [0,1]$ the map $W \rightarrow M$ given by $P \mapsto H(P,t)$ is a proper embedding (is a proper smooth embedding).

If $W$ and $W'$ are two oriented proper submanifolds, then we also want the following condition to be satisfied:
(e) the diffeomorphism $W \rightarrow W'$ in (c) is orientation-preserving.

(2) Let $X$ and $Y$ be two submanifolds of $M$. We say $X$ and $Y$ can be made transverse (respectively disjoint) if there exist transverse (respectively disjoint) submanifolds $X'$ and $Y'$ of $M$ such that $X'$ is smoothly isotopic to $X$ and $Y'$ is smoothly isotopic to $Y$.

The next theorem says in particular that we can make any two proper submanifolds of a given smooth manifold transverse.

**Theorem 9.10. (Transversality Theorem)** Let $M$ be a smooth manifold and let $Y$ be a proper submanifold of $M$.

1. If $X$ is a smooth manifold and if $f : X \rightarrow M$ is a smooth map, then there exists a smooth homotopy from $f$ to a smooth map that is transverse to $Y$.
2. Let $X$ be a proper submanifold of $M$. Given any neighborhood $U$ of $X$ there exists a smooth isotopy $F : X \times [0,1] \rightarrow U$, such that $F(P,t) \in \partial M$ for all $P \in \partial X$ and $t \in [0,1]$, from $X$ to a proper submanifold $X'$ that is transverse to $Y$.

![Figure 245. Illustration of Theorem 9.10 (2).](image)

**Proof.**

(1) The first part of this statement is proved in [Lee02] Theorem 6.36. A slightly less general statement is proved in [GP74, p. 70].

\[\text{Note that the two statements are similar, but at least a priori they are independent in the sense that neither implies the other statement.}\]
(2) The theorem follows from Proposition 4.4.4, Theorem 4.5.6 and Proposition 4.5.7 of [Wall16].

**Example.** Let $M$ be a smooth manifold. Furthermore let $X$ and $Y$ be two proper submanifolds. If $\dim(X) + \dim(Y) < \dim(M)$, then one deduces easily from the definitions that $X$ and $Y$ intersect transversally if and only if $X$ and $Y$ are disjoint. With this observation the Transversality Theorem [9.10] (2) says in particular that any two proper 1-dimensional submanifolds $X$ and $Y$ of the 3-dimensional ball $B^3$ can be made disjoint after an isotopy rel boundary. This statement is illustrated in Figure 246.

9.4. **The Self-Transversality Theorem.** We conclude this section with a short discussion of self-transverse maps.

**Definition.** Let $M$ and $X$ be smooth manifolds and let $\varphi: (X, \partial X) \to (M, \partial M)$ be a proper smooth map. We say $\varphi$ is self-transverse if for every two points $P, Q \in X$ with $\varphi(P) = \varphi(Q)$ we have

$$\varphi_*(T_P X) + \varphi_*(T_Q Y) = T_{\varphi(P)} M$$

and if for every two points $P, Q \in \partial X$ with $\varphi(P) = \varphi(Q)$ we have

$$\varphi_*(T_P X) + \varphi_*(T_Q Y) = T_{\varphi(P)}(\partial M).$$

The proof of the following lemma is similar to the proof of Lemma 6.52. We leave it to the reader to make the necessary adjustments of the argument.

**Lemma 9.11.** Let $M$ be an $n$-dimensional smooth manifold and let $X$ be an $m$-dimensional smooth manifold. Furthermore let $\varphi: (X, \partial X) \to (M, \partial M)$ be a proper smooth map. If $\varphi$ is a self-transverse immersion, then the set

$$\{ P \in X \mid \text{there exists a } Q \neq P \text{ with } \varphi(P) = \varphi(Q) \}$$

is a proper submanifold of $M$ of dimension $2m - n$.\(^{183}\)

\(^{182}\)A first look at [Wall16, Theorem 4.5.6] might be slightly confusing since it demands that $Y$ is a “submanifold of $J^r(M, N)$” for some $r \in \mathbb{N}_0$. But as is explained on page 101 of [Wall16], we have $J^0(M, X) = M \times X$, and $Y \times \{+\}$ is clearly a submanifold.
In the following we will discuss to what degree we can “upgrade” a map between smooth manifolds. First we see that if the codimension is large enough, then we can turn a given map into an immersion via a homotopy.

**Theorem 9.12.** Let $M$ be a compact smooth manifold and let $N$ be a smooth manifold. If $\dim(M) \geq 2 \cdot \dim(N)$, then any map $f : M \to N$ is homotopic to an immersion.

**Proof.** This theorem follows from [GG73, Theorem II.5.6] and the argument in [Wall16, Proof of Proposition 4.4.4]. ■

**Remark.** Note that the conclusion of Theorem 9.12 does not hold without a condition on the dimensions. For example the map $S^1 \to \mathbb{R}$ that is given by $(x,y) \mapsto x$ is not homotopic to an immersion. A more subtle example of such a phenomenon is given in Figure 254.

To formulate the last theorem we need to introduce a self-explanatory definition.

**Definition.** Let $f : X \to Y$ be a map between two sets. We say $f$ is a map without triple points, if there are no pairwise distinct points $P, Q, R \in X$ with $f(P) = f(Q) = f(R)$.

The following is a variation on the Transversality Theorem 9.10 (2). It says, that if we are already given an immersion, then we can actually make it self-transverse.

**Theorem 9.13.** (Self-Transversality Theorem) Let $M$ be a smooth manifold, let $X$ be a smooth manifold, let $\varphi : (X, \partial X) \to (M, \partial M)$ be an immersion and let $U$ be a neighborhood of $\varphi(X)$.

1. There exists a smooth isotopy $F : X \times [0, 1] \to U$ from $\varphi$ to a self-transverse immersion.\footnote{In other words, the codimensions add up, i.e. the codimension of $X$ is $n - m$, the codimension of the set of double points if $2(n - m)$, i.e. the dimension is $n - 2(n - m) = 2m - n$.}

2. If $M$ is compact and if $\dim(M) = 2 \cdot \dim(X)$, then there exists a smooth isotopy $F : X \times [0, 1] \to U$ from $\varphi$ to a self-transverse immersion without triple points.

**Proof.**

1. This statement is a straightforward consequence of [Wall16, Proposition 4.6.6].

2. With a little bit of an effort one can show that this statement follows from (1) together with [Adac93, Theorem II.6.2.8]. ■

**Remark.** Let $M$ and $X$ be closed smooth manifolds and let $\varphi : X \to M$ be a continuous map. The combination of Theorem 9.12 together with the Self-Transversality Theorem 9.13 gives us the following two statements:

1. If $\dim(M) > 2 \cdot \dim(X)$, then $\varphi$ is homotopic to a smooth embedding.

2. If $\dim(M) = 2 \cdot \dim(X)$, then $\varphi$ is homotopic to a self-transverse immersion without triple points. We refer to Figure 248 for an illustration.

We discuss these statements in greater detail in Theorem 9.15.

The following is an often used consequence of the above transversality theorems.\footnote{To avoid confusion, note that we start out with the hypothesis that we are given an immersion. If we have do not know that $\varphi$ is an immersion, then we first need to apply Theorem 9.12, which requires that $\dim(M) \geq 2 \cdot \dim(X)$.}
**Corollary 9.14.** Let $M$ be a connected $n$-dimensional smooth manifold and let $Y$ be a proper $k$-dimensional smooth submanifold of $M$. If $k \leq n - 2$, then $M \setminus Y$ is path-connected.

**Proof.** We leave the basically trivial case $n = 2$ to the reader. Furthermore, to simplify the discussion we assume that $\partial M = \emptyset$. We leave it to the reader to modify the argument below to deal with the case that $\partial M \neq \emptyset$.

Thus in the following we assume that $n \geq 3$ and that $\partial M = \emptyset$. Let $P, Q \in M \setminus Y$. Since $Y$ is proper we know that $Y$ is in particular a closed subset of $M$. This implies that we can find smooth embeddings $\Phi: \overline{B}^n \to M \setminus Y$ and $\Psi: \overline{B}^n \to M \setminus Y$ with $\Phi(0) = P$, $\Psi(0) = Q$ and such that the images are disjoint. Now we consider $N := M \setminus (\Phi(B^n) \cup \Psi(B^n))$. Note that it follows from Proposition 8.2 that $N$ is a connected $n$-dimensional smooth manifold.

We pick points $P' \in \Phi(S^{n-1}) \subset \partial N$ and $Q' \in \Psi(S^{n-1}) \subset \partial N$. Since $N$ is connected we know by Lemma 6.9 that $N$ is also path-connected. This means that there exists a path $\gamma: [0, 1] \to N$ with $\gamma(0) = P'$ and $\gamma(1) = Q'$. By Exercise 18.7 we can arrange that $\gamma$ is actually an immersion.\footnote{It would be tempting to use the Whitney Approximation Theorem 9.3 together with Theorem 9.12 to obtain this statement, but unfortunately for the latter statement we do not have a relative statement which allows us to keep endpoints fixed.} Furthermore, since $n \geq 3$ we obtain from the Self-Transversality Theorem 9.13 that we can arrange that $\gamma$ is actually an embedding. By the Transversality Theorem 9.10 (2) we know that $\gamma$ is homotopic to a map $\widetilde{\gamma}: [0, 1] \to N$ which is transverse to $Y$. Since $k \leq n - 2$ this means that $\widetilde{\gamma}([0, 1])$ is actually disjoint from $Y$. Now pick a path in $\Phi(\overline{B}^n)$ from $P$ to $\widetilde{\gamma}(0)$, concatenate it with $\widetilde{\gamma}$ and then concatenate it with a path in $\Psi(\overline{B}^n)$ from $\widetilde{\gamma}(1)$ to $Q$. This construction gives us the desired path in $M \setminus Y$ from $P$ to $Q$.\hfill \qed
9.5. **Homotopies to proper immersions and embeddings.** We start out with the following definition that is a slight generalization of the concept introduced on page 410.

**Definition.** Let $M$ be a compact topological manifold, let $A$ be a submanifold of $M$ and let $X$ be any topological manifold. A map $\varphi: X \to M$ is called proper rel $A$ if $\varphi^{-1}(\partial M \cup A) = \partial X$.

On many occasions the following theorem allows us to “upgrade” a map between smooth manifolds to a map with nicer properties.

**Theorem 9.15.** Let $M$ be a smooth manifold, let $A \subset M \setminus \partial M$ be a (possibly empty) submanifold of $M$ and let $X$ be a compact smooth manifold. Furthermore let $f: X \to M$ be a map with $f(\partial X) \subseteq \partial M \cup A$.

1. The map $f: (X, \partial X) \to (M, \partial M \cup A)$ is homotopic\(^{186}\) to a smooth map $\tilde{f}: X \to M$ that is proper rel $A$.\(^{187}\)

2. If $\dim(M) \geq 2 \cdot \dim(X)$, then the map $f: (X, \partial X) \to (M, \partial M \cup A)$ is homotopic to an immersion $\tilde{f}: X \to M$ that is proper rel $A$ and which has furthermore the property that there exist points $P_1, \ldots, P_k$ in $M \setminus \partial M$ with the following properties:
   (a) for each $i$ the preimage $\tilde{f}^{-1}(P_i)$ consists of precisely two points $Q^+_i$ which furthermore satisfy that $f_*(T_{Q^+_i} X) + f_*(T_{Q^-_i} X) = T_{P_i}(M)$,
   (b) the restriction of $\tilde{f}$ to $X \setminus \{Q^+_1, \ldots, Q^+_k\}$ is injective.

3. If $\dim(M) \geq 2 \cdot \dim(X) + 1$, then the map $f: (X, \partial X) \to (M, \partial M \cup A)$ is homotopic to a smooth embedding $\tilde{f}: X \to M$ that is proper rel $A$.

Furthermore, if $f$ is already smooth on $\partial X$ or if $f$ is already a smooth embedding on $\partial X$, then in (1) and (3) we can find a homotopy rel $\partial X$.

**Examples.**

1. In Figure 250 we consider a 2-dimensional smooth manifold $M$ together with a map $f: [-1, 1] \to M$. We first see that $f$ is homotopic to a smooth map and then we see that it is homotopic to a smooth map without triple points and such that all double points are “transverse”.

   **2-dimensional manifold $M$**

   ![Diagram of a 2-dimensional manifold $M$ with a submanifold $A$, a proper map $[-1, 1] \to M$, a proper smooth map, and no triple points and double points are transverse.]

   **Figure 250. Illustration of Theorem 9.15 (2).**

---

\(^{186}\)Here and in the following it is always understood that these are homotopies of maps between pairs of topological spaces. We refer to page 571 for the definition of this notion.

\(^{187}\)This statement is very close to the statement of the Whitney Approximation Theorem 9.3.
9. MAPS BETWEEN SMOOTH MANIFOLDS

(2) In Figure 251 we consider $M = [-1, 1] \times \mathbb{R}^2$ and a map $f: [-1, 1] \to M$. We first see that $f$ is homotopic to a smooth map and then we see that it is homotopic to a smooth embedding.

$M = [-1, 1] \times \mathbb{R}^2$

\begin{figure}[h]
\centering
\includegraphics[width=0.8\textwidth]{figure251.png}
\caption{Illustration of Theorem 9.15 (3).}
\end{figure}

(3) Note that every smooth map $S^1 \to \mathbb{R}$ necessarily has a maximum and minimum, which implies that such a map cannot be an immersion. This shows that in general we cannot drop the hypothesis that $\dim(M) \geq 2 \cdot \dim(X)$ in Theorem 9.15.

(4) In Figure 252 we show a map $f$ from $S^1$ to some 2-dimensional smooth manifold $M$ which is “clearly” not homotopic to an embedding. This shows that in general we cannot drop the hypothesis that $\dim(M) \geq 2 \cdot \dim(X) + 1$ in Theorem 9.15.

\begin{figure}[h]
\centering
\includegraphics[width=0.8\textwidth]{figure252.png}
\caption{Figure 252}
\end{figure}

Proof. The statements are modest generalizations of [Hir76, Chapter 2, Theorem 2.6] and [Hir76, Chapter 2, Theorem 2.13], except that the reference does not talk explicitly about homotopies, instead it says that given a map $f$ one can find a smooth map $\tilde{f}$ with the desired properties which is “close to $f$” in a suitable sense.

In the following we will sketch an argument why two maps that are “close” are actually homotopic. To simplify the discussion we assume that $M$ is closed. By Proposition 9.1 we can view $M$ as a submanifold of some $\mathbb{R}^n$. Careful reading of the above references shows that it remains to prove the following claim.

Claim. There exists some $\epsilon > 0$ with the following property: any two maps $f, \tilde{f}: X \to M$ with $\sup\{\|f(x) - \tilde{f}(x)\|_{\mathbb{R}^n} \mid x \in X\} < \epsilon$ are homotopic.

On page 369 in our sketch of the proof of Proposition 8.25 we showed that there exists a closed neighborhood $N$ of $M \subset \mathbb{R}^n$ together with a deformation retraction $p: N \to M$. Since $N$ is a neighborhood and since $M$ is compact we obtain easily that there exists an $\epsilon > 0$ such that for every $y \in M$ we have $q(B_\epsilon(y)) \subset N$. 
Now let \( f,g : X \to M \) be two maps with \( \sup \{ \| f(x) - \tilde{f}(x) \| : x \in X \} < \epsilon \). We consider the following map:

\[
F : X \times [0,1] \to M
\]

\[
(x,t) \mapsto (p \circ q)((1-t) \cdot f(x) + t \cdot \tilde{f}(x)) \\
\in B_{\epsilon}(f(x))
\]

By choice of \( \epsilon \) we see that \( F \) is actually defined. It is now straightforward to verify that \( F \) is a proper homotopy between \( f \) and \( \tilde{f} \).

**Remark.** We conclude this chapter with a word of caution. Let \( M \) and \( N \) be two smooth manifolds with \( \dim(M) < 2 \cdot \dim(N) \). It is quite difficult to see what type of self-intersections can appear in a proper map \( f : M \to N \). A good example of an overlooked type of self-intersection is provided by the proper map \( f : \overline{B}^2 \to M \) from the disk \( \overline{B}^2 \) to a 3-dimensional ellipsoid \( M \) that is shown in Figure 254. The topic of singularities that can arise by mapping a surface into a 3-dimensional smooth manifold are studied in greater detail in [Carte95, Chapter 1.3].

**Exercises for Chapter 9.**

**Exercise 9.1.** Let \( n \in \mathbb{N}_{\geq 2} \). Use the Whitney Approximation Theorem [9.3] and Proposition [6.62] to give a quick proof that \( \pi_1(S^n) = 0 \).

**Exercise 9.2.** Provide a proof for Proposition [9.7].

**Exercise 9.3.** Let \( M \) be a compact topological manifold and let \( A \subset M \) be a non-empty closed subset with \( A \neq M \). Show that \( M \setminus A \) is not compact.

**Hint.** Use Corollary [9.2] and Exercise [3.18].
Exercise 9.4. Let $M$ be a closed $n$-dimensional smooth manifold and let $x_1, \ldots, x_k \in M$ be disjoint points. Show that there exists a smooth embedding $\varphi: M \to \mathbb{R}^m$ such that $\varphi(M)$ is “flat” near $\varphi(x_1), \ldots, \varphi(x_k)$, in the sense that there exist disjoint neighborhoods $U_1, \ldots, U_k$ of $x_1, \ldots, x_k$ and points $y_1, \ldots, y_k \in \mathbb{R}^{m-n}$ such that for each $i \in \{1, \ldots, k\}$ we have $\varphi(U_i) \subset \mathbb{R}^n \times \{y_i\}$.

Exercise 9.5. Let $M$ be a compact smooth manifold and let $\alpha: S^k \to M$ be a map. Show that there exists an $r \in \mathbb{N}_0$ and a smooth embedding $\varphi: S^k \to \partial(M \times \overline{B}^r)$ such that the maps $S^k \ni x \mapsto (x, 0) \mapsto M \times \overline{B}^r$ and $\varphi: S^k \to M \times \overline{B}^r$ are homotopic.
10. Regular and Tubular Neighborhoods

In this chapter we will introduce the notion of a regular neighborhood of a subset of a smooth manifold and we will show that submanifolds admit tubular neighborhoods and we will show that tubular neighborhoods are regular. The results of this chapter can be viewed as a generalization of the Tubular Neighborhood Theorem 8.24. For the most part it might be OK to just skip this chapter and work with a naive understanding of regular and tubular neighborhoods. Nonetheless, the reader should be aware that these notions can be defined properly, that the definitions are not entirely self-evident, and that existence of such neighborhoods is non-trivial.

10.1. Regular neighborhoods. In this section we will introduce the notion of a regular neighborhood of a compact subset of a topological manifold. This notion is a variation on the eponymous concept that we defined on page 1603 and it is a variation on the notion of a tubular neighborhood that we encountered on page 367.

Definition. Let \( M \) be an \( m \)-dimensional topological manifold and let \( K \) be a compact subset. A regular neighborhood of \( K \) is an \( m \)-dimensional compact submanifold \( N \) with corner of \( M \) with the following properties:

1. \( K \) is contained in the interior \( \hat{N} \) of \( N \),
2. \( K \) is a deformation retract of \( N \),
3. \( \partial_0 N \) is a deformation retract of \( N \setminus K \).

We refer to \( \hat{N} \) as an open regular neighborhood of \( K \).

\[ M \] \quad \text{regular neighborhood} \quad N \]

\[ K \]

\[ \partial_0 N \]

Figure 256

Example. Let \( M \) be a PL-manifold and let \( K \subset M \setminus \partial M \) be a subcomplex. In Section 64.3 we defined the regular neighborhood \( N_K(M) \) of \( K \) in \( M \). By Proposition 64.12 we know that \( N_K(M) \) does indeed have the properties demanded in the above definition of a regular neighborhood. In other words, by Proposition 64.12 we know that \( K \) has a regular neighborhood in the above sense.

We continue this section with the following lemma which can be viewed as a generalization of Lemma 68.16 (3).

Lemma 10.1. Let \( K \) be a compact subset of a topological manifold \( M \). If \( N \) is a regular neighborhood of \( K \), then the following statements hold:

1. \( M \setminus \hat{N} \) is a deformation retract of \( M \setminus K \).
2. The inclusion \( M \setminus \hat{N} \to M \setminus K \) is a homotopy equivalence, in particular it induces an isomorphism of homotopy groups (for suitable base points) and homology groups.
3. \( M \setminus \hat{N} \) is path-connected if and only if \( M \setminus K \) is path-connected.
(4) The inclusion map $M \setminus \hat{N} \to M \setminus K$ induces isomorphisms of fundamental groups and (co-) homology groups.

**Proof.**

(1) By definition of a regular neighborhood there exists a deformation retraction $r$ from $N \setminus K$ to $\partial_0 N$. We extend this deformation retraction to all of $M \setminus K$ in the obvious way. More precisely, we consider the map

$$f : (M \setminus K) \times [0, 1] \to M \setminus K$$

$$(P, t) \mapsto \begin{cases} P, & \text{if } P \notin N, \\ r(P, t), & \text{if } P \in N \setminus K. \end{cases}$$

Using Lemma 3.10 and Proposition 8.2 one can easily show that this map is indeed continuous. Once continuity is verified it is straightforward to show that $f$ is indeed a deformation retraction from $M \setminus K$ to $M \setminus \hat{N}$.

(2) It follows from (1) and Lemma 18.14 that the inclusion is a homotopy equivalence.

The statement regarding homotopy groups and homology groups follow from Proposition 40.7 (2) and Corollary 42.8.

(3) This statement follows from (2) and Lemma 18.13.

(4) This last statement follows from (2) together with Proposition 18.16 (2), Corollary 42.8 and Lemma 73.13 (3).

Figure 257. Illustration of Lemma 10.1

The following corollary, which in the literature is often used implicitly or explicitly, gives one application of the theory of regular neighborhoods.

**Lemma 10.2.** Let $M$ be a compact topological manifold and let $K \subset M$ be a compact subset. If $K$ admits a regular neighborhood, then the following two statements hold:

1. the fundamental group $\pi_1(M \setminus K)$ is finitely presented, and
2. for each $k \in \mathbb{N}_0$ the homology group $H_k(M \setminus K; \mathbb{Z})$ is finitely generated.

**Proof.** Note that by Lemma 10.1 the topological space $M \setminus K$ is homotopy equivalent to $M \setminus \hat{N}$. Since $M$ is compact it follows from Lemma 89.1 (3) that $M \setminus \hat{N}$ is also compact. Furthermore, by Lemma 89.1 (4) we know that $M \setminus \hat{N}$ is an $n$-dimensional smooth manifold. Summarizing we have seen that $M \setminus \hat{N}$ is a compact $n$-dimensional smooth manifold. The lemma now follows from Proposition 85.13 and Lemma 10.1 (4).

In the Tubular Neighborhood Theorem 8.24 we showed that if $M$ is an orientable smooth manifold, then every closed 1-dimensional submanifold admits a trivial tubular
neighborhood, which is easily seen to be a regular neighborhood. It is thus natural to guess that something similar should also hold for higher-dimensional submanifolds. In fact we have the following theorem.

**Theorem 10.3. (Regular Neighborhood Theorem)** Let $M$ be a smooth manifold. Every compact proper submanifold of $M$ admits a regular neighborhood.

An outline of the proof will be sketched in the next section.

![Figure 258. Illustration of the Regular Neighborhood Theorem](image)

10.2. **The Tubular Neighborhood Theorem II.** In Section 8.8 we introduced the notion of a “trivial tubular neighborhood” of a submanifold and we saw in Theorem 8.24 that some types of submanifolds admit trivial tubular neighborhoods.

In this section we will first introduce the general notion of a tubular neighborhood of a submanifold. We will then discuss existence and uniqueness, before we then show that tubular neighborhoods give rise to regular neighborhoods.

**Definition.** Let $m \in \mathbb{N}_0$.

1. Let $K$ be a smooth manifold. A smooth $\mathcal{B}^m$-bundle over $K$ is a smooth manifold $N$ together with a smooth map $p: N \to K$ with the following property: given any $x \in K$ there exists a trivialization of $p$ around $x$, i.e., there exists an open neighborhood $U$ of $x$ and a diffeomorphism $\Phi: p^{-1}(U) \to \mathcal{B}^m \times U$ such that the following diagram commutes:

$$
\begin{array}{ccc}
p^{-1}(U) & \xrightarrow{\Phi} & \mathcal{B}^m \times U \\
p \downarrow & & \downarrow \Phi \\
U & & U.
\end{array}
$$

A smooth $\mathcal{B}^1$-bundle is often called a smooth interval bundle and a smooth $\mathcal{B}^2$-bundle is often called a smooth disk bundle.

2. An isomorphism between two smooth $\mathcal{B}^m$-bundles $p: M \to K$ and $q: N \to K$ is defined to be a diffeomorphism $\Phi: M \to N$ such that the following diagram commutes

$$
\begin{array}{ccc}
M & \xrightarrow{\Phi} & N \\
\downarrow p & & \downarrow q \\
K & & K.
\end{array}
$$

If such an isomorphism exists we say that the two smooth $\mathcal{B}^m$-bundles are isomorphic.

The following gives two trivial but nonetheless extremely important examples of constructions of smooth $\mathcal{B}^m$-bundles.
Example.

(1) Let $K$ be a smooth manifold and let $m \in \mathbb{N}_0$. We denote by $p: \mathbb{B}^m \times K \to K$ the obvious projection map. This map is evidently a smooth $\mathbb{B}^m$-bundle over $K$ and we refer to it as the \textit{trivial smooth $\mathbb{B}^m$-bundle over $K$}.

(2) Let $p: N \to K$ be a smooth $\mathbb{B}^m$-bundle. If $Y \subset K$ is a submanifold, then the restriction $p: p^{-1}(Y) \to Y$ is also a smooth $\mathbb{B}^m$-bundle.

\underline{Definition.}

(1) Let $W$ be a smooth manifold and let $p: \mathbb{B}^m \times W \to W$ and $q: \mathbb{B}^m \times W \to W$ be two smooth $\mathbb{B}^m$-bundles. We say an isomorphism $\Phi: \mathbb{B}^m \times W \to \mathbb{B}^m \times W$ of smooth $\mathbb{B}^m$-bundles is \textit{linear} if there exists a map $g: W \to \text{O}(m)$ such that for any $(v, w) \in \mathbb{B}^m \times W$ we have

$$\Phi(v, w) = (g(w) \cdot v, w).$$

(2) A \textit{linear $\mathbb{B}^m$-bundle} is a smooth $\mathbb{B}^m$-bundle $p: N \to K$ together with a family of trivializations $\{(U_i, \Phi_i: p^{-1}(U_i) \to \mathbb{B}^m \times U_i)\}_{i \in I}$ such that for any $i, j \in I$ the isomorphism $\Phi_j \circ \Phi_i^{-1}: \mathbb{B}^m \times (U_i \cap U_j) \to \mathbb{B}^m \times (U_i \cap U_j)$ of smooth $\mathbb{B}^m$-bundles over $U_i \cap U_j$ is linear. Henceforth, by a trivialization of a linear $\mathbb{B}^m$-bundle we always mean a trivialization from the above family.

(3) An \textit{isomorphism of two linear $\mathbb{B}^m$-bundles} $p: M \to K$ and $q: N \to K$ is defined as an isomorphism $\Theta: M \to N$ of smooth $\mathbb{B}^m$-bundles such that for any trivializations $(U, \Phi: p^{-1}(U) \to \mathbb{B}^m \times U)$ of $p$ and $(V, \Psi: q^{-1}(V) \to \mathbb{B}^m \times V)$ of $q$ the isomorphism $\Phi \circ \Theta \circ \Psi^{-1}: \mathbb{B}^m \times (U \cap V) \to \mathbb{B}^m \times (U \cap V)$ of smooth $\mathbb{B}^m$-bundles over $U \cap V$ is linear.

The trivializations of a linear $\mathbb{B}^m$-bundle play a role similar to the smooth atlas of a smooth manifold. In the case of a smooth manifold we usually suppress the specific atlas from the notation. This leads us to the following convention.

\underline{Convention.} In the following we will usually suppress the family of trivializations in the notation of a linear $\mathbb{B}^m$-bundle.

\underline{Examples.}

(1) Any trivial $\mathbb{B}^m$-bundle is a linear $\mathbb{B}^m$-bundle in the obvious way.

(2) We consider the Möbius band $M = ([0, 1] \times [-1, 1])/(0, x) \sim (1, -x)$ together with the projection map

$$p: M = ([0, 1] \times [-1, 1])/(0, x) \sim (1, -x) \to [0, 1] \sim [0, 1] / 0 \sim 1$$

$$[(x, y)] \mapsto [x].$$

In Exercise [11.7] we will verify that this map defines a linear interval bundle. We refer to Figure [259] for an illustration.

For future reference we formulate the following lemma that classifies isomorphisms of some linear $\mathbb{B}^m$-bundles.

\underline{Lemma 10.4.}
Figure 259

(1) Let $N$ be an oriented $n$-dimensional smooth manifold and let $k \in \mathbb{N}$. The map

$$\{\text{maps } N \to \text{SO}(k)\}/\text{homotopy} \to \{\text{orientation-preserving isomorphisms of } \mathbb{B}^k \times N\}/\text{isotopy}$$

$$[f: N \to \text{SO}(k)] \to \left( \mathbb{B}^k \times N \to \mathbb{B}^k \times N, (v, P) \mapsto (f(P) \cdot v, P) \right)$$

is a bijection.

(2) Let $N$ be an oriented $n$-dimensional smooth manifold. The identity is the only orientation-preserving linear $\mathbb{B}^1$-isomorphism of the trivial bundle $\mathbb{B}^1 \times N$.

(3) Up to isotopy every isomorphism of the linear bundle $\mathbb{B}^2 \times S^1$ is of the form

$$\mathbb{B}^2 \times S^1 \to \mathbb{B}^2 \times S^1, (w, z) \mapsto (w \cdot z^k, w)$$

for some $k \in \mathbb{Z}$.

Sketch of proof.

(1) This statement follows fairly easily from the definitions. We leave the details to the reader.

(2) This follows from (1) and the trivial observation that $\text{SO}(1) = \{1\}$, thus there exists precisely one map from $N$ to $\text{SO}(1)$.

(3) This statement follows from (1) and the observation that any map $S^1 \to \text{SO}(2) = S^1$ is homotopic to a map of the form $z \mapsto z^k$ for some $k \in \mathbb{Z}$. This in turn is a fairly straightforward consequence of the fact that $\pi_1(S^1, 1) \cong \mathbb{Z}$, see Proposition 16.17.

Now we can formulate the definition that we had been aiming for.

Definition. Let $M$ be an $n$-dimensional smooth manifold and let $K$ be a compact proper $k$-dimensional submanifold. A tubular neighborhood for $K$ is a pair $(N, p: N \to K)$ with the following properties:

1. $N$ is a compact codimension-zero submanifold with corner.
2. $N$ is a neighborhood of $K$.
3. The map $p: N \to K$ is a linear $\mathbb{B}^{n-k}$-bundle such that $p(x) = x$ for all $x \in K$.

188 So why don’t we have to worry about base points?
(4) We have \( \partial_1 N = p^{-1}(\partial K) \).\(^{189}\)

**Remark.** There are many books that introduce the notion of a tubular neighborhood, see e.g. \([\text{Kos}93, \text{BJ}82, \text{Bre}93, \text{Lan}02]\) \& \([\text{Wall}16]\). The definitions and results tend to be subtly different and it requires some effort to go back and forth between these books. Our treatment is, by accident, very similar to the one given in \([\text{Wall}16]\) Chapter 2.5.

**Example.**

1. Let \( M \) be an \( n \)-dimensional smooth manifold and let \( K \) be a closed \( k \)-dimensional submanifold. On page \( 367 \) we defined a tubular map to be a smooth embedding \( F: \overline{B}^{m-k} \times K \to M \) such that for any \( P \in K \) we have \( F(0, P) = P \). Furthermore we referred to the image \( \Phi(\overline{B}^{m-k} \times K) \) as tubular neighborhood for \( K \). One can easily verify that \( N := \Phi(\overline{B}^{n-k} \times K) \) with the obvious map to \( K \) defines a tubular neighborhood in the above sense.

2. As above we consider the Möbius band \( M = ([0, 1] \times [-1, 1]) / \sim \). Furthermore let \( K = [0, 1] \times \{0\} \subset M \) be the submanifold that is given by the central circle.\(^{190}\) In Figure 260 we illustrate a tubular neighborhood for \( K \).

![Figure 260](image)

The following theorem is a generalization of the earlier Tubular Neighborhood Theorem 8.24.

**Theorem 10.5. (General Tubular Neighborhood Theorem)** Let \( M \) be a smooth manifold and let \( K \) be a proper submanifold. If \( K \) is compact, then \( K \) admits a tubular neighborhood.

**Proof.** The sketch for the existence of a tubular neighborhood that we provided for the previous Tubular Neighborhood Theorem 8.24 is also valid in this more general context. As before a full proof is provided in \([\text{Wall}16]\) Theorem 2.3.3. Closely related and similar results are also proved in \([\text{Kos}93]\) Section III.2, \([\text{Bre}93]\) Theorem II.11.14, \([\text{Lee}02]\) Theorem 6.24, \([\text{BJ}82]\) Theorem 12.11 and \([\text{Lan}02]\) Chapter IV. \( \square \)

In Theorem 8.24 we already saw that certain types of submanifolds admit a trivial tubular neighborhood. To this list we add a few more examples.

---

\(^{189}\)Note that in Proposition 44.2 we showed that for the proper submanifold \( K \) we have \( \partial K = \partial M \cap K \).

\(^{190}\)Could we not just take all of \( M \) to be a tubular neighborhood?
Proposition 10.6. (⋆) Let M be an orientable smooth manifold and let N be an orientable proper submanifold. Suppose one of the following holds:

1. N is one-dimensional,
2. N is of codimension one,
3. N is 2-dimensional and every component of N has non-empty boundary.

Then K admits a trivial tubular neighborhood.

Proof. By the General Tubular Neighborhood Theorem \[10.5\] it remains to show that a tubular neighborhood is already trivial. For (1) and (2) this gets taken care of by the same references as in the Tubular Neighborhood Theorem \[8.24\]. It remains to deal with (3). Note that with our hypothesis the topological space N admits a retraction onto a 1-dimensional CW-complex.\[191\] Now it follows fairly easily from Propositions 9.1.1 and Proposition 9.2.3 of \[Hau14\] that the tubular neighborhood is indeed trivial.

Example. Let \( M = \mathbb{B}^2 \times S^1 \) be the solid torus. We can view the Möbius band as a proper submanifold N of M. Note that \( M \setminus N \) is actually connected. From this observation it follows fairly easily that N does not admit a trivial tubular neighborhood. This shows that in Proposition \[10.6\] (2) we cannot drop the hypothesis that N is orientable.

![solid-torus-moebius-band](image)

\( \text{Figure 261} \)

The following proposition gives an appropriate uniqueness of tubular neighborhoods. The proposition can be viewed as a generalization of Proposition \[8.26\].

Proposition 10.7. (Uniqueness of tubular neighborhoods) Let M be an n-dimensional smooth manifold and let K be a compact proper k-dimensional submanifold. Furthermore let \( p: U \to K \) and \( q: V \to K \) be two tubular neighborhoods of K. Then there exists a diffeotopy \( F: M \times [0,1] \to M \) with the following properties:

1. \( F(P,0) = P \) for all \( P \in M \),
2. \( F(P,t) = P \) for all \( P \in K \) and \( t \in [0,1] \),
3. the diffeomorphism \( \Phi = F_1: M \to M \) restricts to diffeomorphisms \( \Phi: M \setminus \hat{U} \to M \setminus \hat{V} \) and \( \Phi: U \to V \), and the latter map is an isomorphism of linear \( \mathbb{B}^{n-k} \)-bundles,
4. the diffeotopy \( F \) has compact support.

Proof. As in the case of Proposition \[8.26\] a proof is provided in \[Wall16\] Chapter 2.5.

Convention. By the uniqueness of tubular neighborhoods that we had just proved in Proposition \[10.7\] we usually do not have to worry about the precise choice of a tubular neighborhood.

\[191\]To be super-precise, this follows from the classification of 2-dimensional smooth manifolds with boundary, see the Surface Classification Theorem \[23.4\] and Lemma \[23.12\].
neighborhood. Given a compact proper submanifold of a smooth manifold $M$ we usually denote by $N(K)$ some choice of a tubular neighborhood.

**Remark.** The General Tubular Neighborhood Theorem [10.5] is stated for smooth manifolds instead of the more general context of topological manifolds. With slight modifications the definition of a tubular neighborhood also makes sense for a $k$-dimensional proper submanifold $K$ of an $n$-dimensional topological manifold $M$.

1. By [FNOP19] Theorem 4.6] tubular neighborhoods exist for any compact proper submanifold of a 4-dimensional topological manifold. If the submanifold is one-dimensional and the topological manifold is orientable, then there exists a trivial tubular neighborhood. Furthermore, by [FNOP19] Theorem 4.7] such a tubular neighborhood is unique in an appropriate sense.

2. If $k = n - 2$, i.e. if $K$ is a codimension 2 submanifold, then some type of tubular neighborhood seems to exist, see e.g. [DV09] Theorem 6.8.1] and [FQ90] p. 137] for details. We also refer to [Ped77] and [Joha72] for some positive results. Note though that when it comes to topological manifolds one should be very cautious with references. It is advisable to very carefully check the definitions used in papers on topological manifolds.

3. If $k = n - 3$, i.e. if $K$ is a codimension 3 submanifold, then, according to [DV09] p. 347] and [Edw09] p. 9], a tubular neighborhood does not exist in general.

Fortunately for the most part we will not deal with topological manifolds and the General Tubular Neighborhood Theorem [10.5] will be good enough for our purposes.

**Definition.**

1. A linear $\overline{B}^m$-bundle $p: N \to K$ is called **trivial** if it is isomorphic, as a linear $\overline{B}^m$-bundle, to the trivial $\overline{B}^m$-bundle $\overline{B}^m \times K \to K$.

2. Let $M$ be an $m$-dimensional smooth manifold and let $K$ be a $k$-dimensional submanifold.
   
   a. A tubular neighborhood $(N, p: N \to K)$ of $K$ is called **trivial** if the linear $\overline{B}^m$-bundle $p: N \to K$ is trivial.

   b. A **tubular map** is a map $F: \overline{B}^{m-k} \times K \to N$ with the following properties:
      
      (i) for every $P \in K$ we have $F(P, 0) = P$,
      
      (ii) we have $F(\overline{B}^{m-k} \times K) \cap \partial N = F(\overline{B}^{m-k} \times \partial K)$,
      
      (iii) the image $F(\overline{B}^{m-k} \times K)$ is a submanifold with corner of $N$.

   It is clear that if $F$ is tubular map, then $N := F(\overline{B}^{m-k} \times K)$ with the obvious map to $K$ is a trivial tubular neighborhood.

**Example.** As on page [419] we consider again the Möbius band $M = ([0, 1] \times [-1, 1])/\sim$ and the submanifold $K = [0, 1] \times \{0\} \subset M$. At least from the picture it is pretty clear that $K$ does not admit a trivial tubular neighborhood.\footnote{What would be a rigorous proof for the statement that $K$ does not admit a trivial tubular neighborhood?}
The following lemma gives some other instances where the tubular neighborhood is non-trivial.\footnote{Is the hypothesis that $K$ is orientable, necessary? Put differently, is there an example of an orientable smooth manifold and a compact proper codimension-one submanifold such that the tubular neighborhood is non-trivial?}

**Lemma 10.8.** Let $M$ be an orientable smooth manifold and let $K$ be a proper submanifold. If $K$ is non-orientable, then the tubular neighborhood is non-trivial.

**Sketch of Proof.** We prove the converse, if the $K$ admits a trivial tubular neighborhood, then $K$ is orientable. So suppose that $K$ is a proper $k$-dimensional submanifold of an orientable $m$-dimensional smooth manifold $M$ and suppose that $K$ admits a trivial neighborhood $\overline{B}^{m-k} \times K$. Let $P \in K \subset M$. We identify $T_P K$ and $T_0 \overline{B}^{m-k}$ with its images in $T_{(0, P)} M$ under the obvious inclusion maps $K \to \{0\} \times K \to M$ and $\overline{B}^{m-k} \to \overline{B}^{m-k} \times \{P\} \to P$. We define

$$B \subset T_P K \text{ is a positive basis } \iff \text{ a positive basis of } T_0 \overline{B}^{m-k} \text{ followed by } B \text{ is a positive basis of } T_{(0, P)} M.$$  

One easily verifies that this defines an orientation for $K$.

If we get away from the pesky non-orientable (sub-) smooth manifolds we get some more positive results.

**Proposition 10.9.** Let $M$ be an oriented\footnote{To be more precise, we still need examples of say closed non-orientable smooth manifolds that are embedded in orientable smooth manifolds. We will shortly see that we can embed any real projective space $\mathbb{R}P^n$ into $\mathbb{R}^{2n}$.} $m$-dimensional smooth manifold and let $K$ be a compact oriented proper submanifold.

(1) If $K$ is of dimension one and $m \geq 2$, then there exists a trivial tubular neighborhood $N(K) = \overline{B}^{m-1} \times K$ such that the product orientation of $\overline{B}^{m-1} \times K$ matches the orientation of $N(K) \subset M$.

(2) If $K$ is of codimension one, then there exists a trivial tubular neighborhood of the form $N(K) = [-1, 1] \times K$ such that the product orientation of $[-1, 1] \times K$ matches the orientation of $M$.
We refer to Figure 263 for an illustration of the definition of $\Phi$. Finally recall that by definition of a regular neighborhood we have to prove the following claim.

---

We had mentioned the case $\dim(K) = 1$ explicitly in the original Tubular Neighborhood Theorem \[8.24\]

At this point it is essential that we work with a linear $\mathbb{B}^{n-k}$-bundle.

Evidently we only have to show continuity locally. So let $v \in N$. We can pick a trivialization that contains $x$ and then it follows immediately from the definitions that the maps $\Phi$ and $\Psi$ are continuous in the neighborhood of $x$ corresponding to the trivialization.
Claim.

(1) \( K \) is contained in the interior of \( N \),
(2) \( K \) is a deformation retract of \( N \),
(3) \( \partial_0N \) is a deformation retract of \( N \setminus K \).

We turn to the proof of the claim.

(1) By definition of a neighborhood we know that \( K \) is contained in the interior of \( N \).
(2) The above map \( \Phi: N \times [0,1] \to N \) is easily seen to be a deformation retraction from \( N \) to \( K \).
(3) The above map \( \Psi: (N \setminus K) \times [0,1] \to N \setminus K \) is easily seen to be a deformation retraction from \( N \setminus K \) to \( \partial_0N \).

This concludes the proof of the claim and thus also of the proposition.

Remark. One of the frustrating aspects about tubular neighborhoods is that every book seems to work with a different definition. IMHO a tubular neighborhood should have the following two features:

(1) it should be a regular neighborhood, and
(2) it should satisfy a uniqueness statement.

By Propositions 10.7 and 10.11 our definition has these two properties. It is not always apparent that the definitions in the literature have these two features.

We conclude this chapter with a lemma which says that for transverse submanifolds one can find “transverse” tubular neighborhoods. We will not really make use of the lemma in these notes, but it seems to me that this lemma often gets used implicitly in the literature.

**Lemma 10.12.** (*) Let \( M \) be a smooth manifold and let \( X \) and \( Y \) be proper submanifolds of \( M \). If the submanifolds \( X \) and \( Y \) are compact and if they intersect transversally, then there exist tubular neighborhoods \( p: U \to X \) and \( q: V \to Y \) such that\footnote{From Figure 263 it should be pretty clear what we want to say. But does the statement of the lemma capture this idea? It is at times difficult to turn a picture into a precise mathematical statement.}

\[ U \cap V = p^{-1}(V \cap X) = q^{-1}(U \cap Y). \]

**Proof.** I could not find a reference for the third statement in any of the standard books on differential topology \cite{Lee02, Wall16, Kos93, GP74}. But the standard proof for the
existence of tubular neighborhoods can easily be adapted to prove the statement. The restriction to compact $X$ and $Y$ is almost certainly not necessary.

10.3. Spatial graphs ($\ast$). Note that in the definition of a regular neighborhood we did not demand that $K$ is a submanifold, in particular $K$ could a priori be any subset. As we will see in Exercise [10.4] it is not difficult to come up with compact subsets of even just $\mathbb{R}$ which do not regular neighborhoods. On the other hand one might hope that reasonable subsets of some $\mathbb{R}^n$ admit regular neighborhoods. For example consider the “spatial graphs” shown in Figure [265]. It seems reasonable to expect that these actually admit regular neighborhoods.

To make sense of this hunch we first need a definition of a “spatial graph” which captures the above examples. A first attempt might be to attempt to define a “a spatial” as the image of an embedding of a (say finite) topological into $\mathbb{R}^3$. But ever since on page [2065] and in Exercise [85.14] we learned of wild knots and its strange behaviors we know that we need some control over such embeddings to end up with reasonable objects.

Some leisurely thinking leads us to the following definition is modelled on the notion of a topological graph that we introduced on page [223].

**Definition.** A **spatial graph** is a triple $(G = (V, E, i, t), \Theta : |G| \to \mathbb{R}^3)$ where the following holds:

1. The quadruple $G = (V, E, i, t)$ is a finite abstract graph.
2. The map $\Theta : |G| \to \mathbb{R}^3$ is an embedding of the topological realization $|G|$ into $\mathbb{R}^3$.
3. For every edge $e$ with characteristic map $\Phi_e : [0, 1] \to |G|$ the following statements hold:
   a. The map $f := \Theta \circ \Phi_e : [0, 1] \to \mathbb{R}^3$ is smooth. Note that by Proposition [6.12] this means that the derivative $f'$ is defined on all of $(0, 1)$ and that it extends continuously to a map $f' : [0, 1] \to \mathbb{R}^3$.
   b. The first derivative $f'(t)$ is non-zero for all $t \in [0, 1]$.

Sometimes we just refer to $\Theta(|G|)$ as a “spatial graph” and we just ignore the extra data involved in the proper definition of a spatial graph.
Example. It should hopefully be clear that the examples sketched in Figure 265 are spatial graphs.

Now we can formulate the following proposition.

**Proposition 10.13.** Every finite spatial graph $G$ in $\mathbb{R}^3$ admits a regular neighborhood.

**Proof.** This proposition is proved in [FH18, FH19]. Note that in [FH18, FH19] it is also shown that there is a type of regular neighborhood which is unique in an appropriate sense. □

---

**Exercises for Chapter 10.**

**Exercise 10.1.** Let $K$ be the Klein bottle. Show that there exists a closed orientable 3-dimensional smooth manifold $M$ which contains $K$ as a submanifold.

*Hint.* You could first try to find a compact 3-dimensional smooth manifold with toroidal boundary that contains $M$ as a submanifold.

**Exercise 10.2.** Let $M$ be a 2-dimensional smooth manifold. Furthermore let $f : [0, 1] \to M$ be a smooth embedding such that $f(0) \in \partial M$ and such that $f([0, 1]) \subset M \setminus \partial M$. Show that the inclusion $M \setminus f([0, 1]) \to M$ is a homotopy equivalence.

*Hint.* Use the Extension Theorem [8.32] and the General Tubular Neighborhood Theorem [10.5].

**Exercise 10.3.** Let $M$ be an orientable $n$-dimensional smooth manifold and let $K$ be a compact proper $k$-dimensional submanifold.

1. Suppose $K$ admits a trivial tubular neighborhood $B^{n-k} \times K$.
   a. Show that the tubular neighborhood can be extended to a trivial tubular neighborhood $2B^{n-k} \times K$.
   *Hint.* Apply the General Tubular Neighborhood Theorem [10.5] and Proposition [10.6] to the proper $(n-1)$-dimensional submanifold $S^{n-k-1} \times K$. 

---

**Figure 266. Illustration of Proposition 10.13.**

**Figure 267.**
(b) Show that there exists a smooth isotopy $F: (M \setminus K) \times [0,1] \rightarrow M \setminus K$ with $F_0 = \text{id}$ and $F_1(M \setminus K) = M \setminus (B^{n-k} \times K)$.

Note that by Proposition 8.1 this implies in particular that $M \setminus B^{n-k} \times K$ is diffeomorphic to $M \setminus K$.

(2) Now suppose that $K$ does not admit a trivial tubular neighborhood. Formulate the appropriate generalization of (1) and prove it.

Exercise 10.4. Show that the subset $K := \{0\} \cup \{\frac{1}{n} \mid n \in \mathbb{N}\}$ of $\mathbb{R}$ does not admit a regular neighborhood.

Exercise 10.5. Let $G$ and $G'$ be two spatial graphs in $\mathbb{R}^3$ with regular neighborhoods $N(G)$ and $N(G')$. Which of the following two implications is correct?

$G$ and $G'$ are isotopic $\iff N(G)$ and $N(G')$ are isotopic?

Exercise 10.6. We consider the spatial graph $G$ shown in Figure 269.

(a) Determine a presentation for $\pi_1(\mathbb{R}^3 \setminus G)$.

(b) What is the abelianization of $\pi_1(\mathbb{R}^3 \setminus G)$?
11. The Whitney Embedding Theorem

We continue with our attempt to expand our toolkit for dealing with smooth manifolds.

11.1. The Regular Value Theorem II (\(*\)). In this section we formulate several refinements of the Regular Value Theorem 6.53. The refinements will play an important role later on, but perhaps it is best to skip the section at first reading.

**Theorem 11.1. (Regular Value Theorem)** Let \( M \) be an \( m \)-dimensional smooth manifold, let \( N \) be an \( n \)-dimensional smooth manifold without boundary, let \( f: M \to N \) be a smooth map and let \( s \in N \) be a regular value of \( f \).

1. The preimage \( X := f^{-1}(\{s\}) \) is a proper \((m - n)\)-dimensional submanifold of \( M \).
2. If \( M \) is orientable, then \( X \) is also orientable.
3. If \( M \) is compact, then \( X \) is also compact.

For the last statement we assume that \( M \) is compact and orientable.

4. There exists an open neighborhood \( U \) of \( s \in N \) such that for any smooth embedding \( \varphi: \overline{B}^n \to U \) with \( \varphi(0) = s \) there exists a tubular map \( \Phi: \overline{B}^n \times X \to M \) such that the following two statements hold:
   (a) we have \( f^{-1}(\varphi(\overline{B}^n)) = \Phi(\overline{B}^n \times X) \),
   (b) the following diagram commutes:
   \[
   \begin{array}{ccc}
   \overline{B}^n \times X & \xrightarrow{\Phi} & M \\
   \downarrow{(p,x)\mapsto p} & \quad & \downarrow{f} \\
   \overline{B}^n & \xrightarrow{\varphi} & N.
   \end{array}
   \]

   If \( M \) is oriented, then the orientation on \( X \) can be chosen such that \( \Phi \) is orientation-preserving.

The first three statements of the above theorem are precisely the content of the original Regular Value Theorem 6.53.

**Example.** In Figure 161 we show the torus \( M \) as a submanifold of \( \mathbb{R}^3 \) and we consider the “height function” \( f: M \to \mathbb{R} \) given by \( f(x,y,z) = z \). This function has precisely four critical points which are indicated in Figure 161 on the left. On the right we show a regular value \( s \) and its preimage and we show a critical value \( t \) and its preimage \( f^{-1}(\{t\}) \) which in this case is not a submanifold.

\[\text{Figure 270. Illustration of the Regular Value Theorem 11.2}\]
Sketch of proof. As mentioned above, the first three statements of the theorem form precisely the content of the original Regular Value Theorem 6.53. So it remains to deal with the final statement. This can be deduced quite easily from the Submersion Theorem 6.56. We leave it to the reader to fill in the details. ■

For the reader's convenience we discuss the cases that \( N = \mathbb{R} \) and \( N = S^1 \) separately. These two special cases also allow us to elucidate the somewhat confusing fourth statement of the Regular Value Theorem 11.1.

**Theorem 11.2. (Regular Value Theorem for \( N = \mathbb{R} \))** Let \( M \) be an \( n \)-dimensional smooth manifold, let \( f: M \to \mathbb{R} \) be a smooth map and let \( s \in \mathbb{R} \) be regular value of \( f \). Then beyond statements (1), (2), (3) of the Regular Value Theorem 11.1 the following two statements hold:

1. If \( M \) is compact and orientable, then there exists an \( \epsilon > 0 \) and a tubular neighborhood \( [-\epsilon, \epsilon] \times X \) of \( X \) such that \( f^{-1}([s - \epsilon, s + \epsilon]) = [-\epsilon, \epsilon] \times X \) and such that the following diagram commutes

\[
\begin{array}{ccc}
[-\epsilon, \epsilon] \times X & \to & M \\
\downarrow (t, x) \mapsto t & & \downarrow f \\
[-\epsilon, \epsilon] & \to & \mathbb{R},
\end{array}
\]

If \( M \) is oriented, then the orientation on \( X \) can be chosen such that the smooth embedding \( [-\epsilon, \epsilon] \times X \to M \) is orientation-preserving.

2. The preimage \( W := f^{-1}((-\infty, s]) \) is an \( n \)-dimensional submanifold of \( M \) with corner where

\[
\partial_0 W = f^{-1}\{s\}, \quad \partial_1 W = W \cap \partial M \quad \text{and} \quad \partial_c W = f^{-1}\{s\} \cap \partial M.
\]

**Remark.** The Regular Value Theorem 11.2 can be viewed as a refinement of Exercise 6.31.

Sketch of proof.

(4) Note that given any neighborhood \( U \) of \( s \in \mathbb{R} \) there exists an \( \epsilon > 0 \) such that \( [s - \epsilon, s + \epsilon] \subseteq U \). The statement now follows immediately from the Regular Value Theorem 11.1 (4) applied to the map \( \varphi: [-\epsilon, \epsilon] \to \mathbb{R} \) given by \( t \mapsto t + s \).
(5) If one takes a look at the proof of the Regular Value Theorem \[11.1\] (1) one sees that it actually provides submanifold charts of type \((\beta)\) and \((\delta)\) for \(W := f^{-1}((-\infty, s])\) and it provides submanifold charts of type \((\beta)\) for any point on \(f^{-1}(\{s\})\). Also note that \(f^{-1}((-\infty, s))\) is an open subset of \(M\). We leave it to the reader to assemble from these observations the full proof of the statement.

We also mention the following variation on the Regular Value Theorem \[11.1\]

**Theorem 11.3. (Regular Value Theorem for \(N = S^1\))** Let \(M\) be an \(n\)-dimensional smooth manifold, let \(f: M \to S^1\) be a smooth map and let \(z = e^{2\pi i t} \in S^1\) be a regular value. Then beyond statements (1), (2), (3) of the Regular Value Theorem \[11.1\] the following statement holds:

(4) If \(M\) is compact and orientable, then there exists an \(\epsilon > 0\) and a tubular neighborhood \([-\epsilon, \epsilon] \times X\) of \(X\) such that \(f^{-1}(\{e^{2\pi i(t+s)} \mid t \in [-\epsilon, \epsilon]\}) = [-\epsilon, \epsilon] \times X\) and such that the following diagram commutes:

\[
\begin{array}{ccc}
[-\epsilon, \epsilon] \times X & \xrightarrow{(t,x) \mapsto t} & M \\
\downarrow & & \downarrow f \\
[-\epsilon, \epsilon] & \xrightarrow{s \mapsto e^{2\pi i(t+s)}} & S^1.
\end{array}
\]

If \(M\) is oriented, then the orientation on \(X\) can be chosen such that the smooth embedding \([-\epsilon, \epsilon] \times \to M\) is orientation-preserving.

**Example.** Let \(N\) be a smooth manifold and let \(\varphi: N \to N\) be a diffeomorphism. We consider the mapping torus \(M := \text{Tor}(N, \varphi) = (N \times [0, 1])/(x, 0) \sim (\varphi(x), 1)\) together with the canonical projection \(f: M \to S^1\) given by \(f([p, x]) = e^{2\pi i x}\). Then every \(z = e^{2\pi i x} \in S^1\) is a regular value and the preimage \(f^{-1}(z) = N \times \{x\}\) is just a “parallel” copy of \(N\).

**Proof.** As in the case of Theorem \[11.2\] (4) this statement can be deduced easily from the Regular Value Theorem \[11.1\] (4).

The following proposition is a generalization of Proposition \[6.64\] to the case of smooth manifolds with non-compact boundary.
**Proposition 11.4.** Let $W$ be an $n$-dimensional smooth manifold. There exists a sequence $X_1, X_2, \ldots$ of $n$-dimensional submanifolds with corner of $W$ with the following three properties:

1. The sequence is nested, i.e. for each $i \in \mathbb{N}$ we have $X_i \subset X_{i+1}$.
2. Each $X_i$ is compact and connected.
3. We have $\bigcup_{i \in \mathbb{N}} \hat{X}_i = W$.

If $\partial W$ is compact, then we can furthermore arrange that the following holds:

4. The corner set of the submanifolds with corner $X_i$ is the empty set, in other words, the $X_i$ are submanifolds in the sense of the definition on page 270.

![3-dimensional manifold with non-compact boundary](image)

**Figure 273.** Illustration of the proof of Proposition 11.4

**Proof.** The proof of Proposition 11.4 is almost identical to the proof of Proposition 6.64 for the most part we just need to replace the Exercise 6.31 by Regular Value Theorem 11.2. In particular we again pick a suitable smooth function $f: W \to \mathbb{R}$, an increasing sequence of regular values $C_i$ with $\lim_{i \to \infty} C_i = \infty$ and given $i \in \mathbb{N}$ we define $X_i$ to be a suitable path-component of $f^{-1}((-\infty, C_i])$. We leave it to the reader to fill in the details.

We conclude this section with the following corollary which basically says that one can “wrap” any compact subset of a compact subset of a smooth manifold in a suitable codimension-zero compact submanifold.

**Lemma 11.5. (⋆)** Let $M$ be a smooth manifold.

1. Let $K$ be a compact subset of $M \setminus \partial M$ and let $U$ be a neighborhood of $K$ in $M$. There exists a submanifold $X$ such that $K \subset \hat{X} \subset X \subset U$.
2. Let $K$ be any compact subset of $M$, let $U$ be a neighborhood of $K$ in $M$ and let $V$ be some neighborhood of $K \cap \partial M$ (evidently one could take $V = \partial M$). Then there exists a submanifold $X$ with corner such that $K \subset \hat{X} \subset X \subset U$ and such that $K \cap \partial M \subset \hat{X} \cap \partial M \subset X \cap \partial M \subset V$.

**Proof (⋆).** Let $M$ be a smooth manifold. Recall that by Proposition 6.27 we know that $\partial M$ is a closed subset of $M$.

1. Let $K$ be a compact subset of $M \setminus \partial M$. Basically by definition of a neighborhood we might as well assume that $U$ is an open subset of $M$. Since $\partial M$ is closed we can furthermore assume that $U$ is an open subset of $M \setminus \partial M$. Since $U$ is an open subset of $M \setminus \partial M$ it follows from Lemma 6.22 that we can view it as a smooth manifold in...
its own right and that \( \partial U = \emptyset \). Thus we can apply Proposition 11.4 to the smooth manifold \( U \). It follows from the fact that \( K \) is compact, from Lemma 2.13 and from the fact that the submanifolds provided by Proposition 11.4 are nested that there exists a submanifold \( X \) of \( U \) with \( K \subset X \subset X \subset U \). Since \( U \) is an open subset of \( M \) one obtains basically immediately that \( X \) is also a submanifold of \( M \).

(2) We consider \( W := U \setminus (\partial M \setminus V) \). It follows from the fact that \( \partial M \) is a closed subset of \( M \), the fact that \( V \) is an open subset of \( \partial M \) and Lemma 2.38 that \( W \) is an open subset of \( M \). By Lemma 6.22 we can view \( X \) as a smooth manifold in its own right with \( \partial W = W \cap \partial M = \partial M \setminus (U \cup V) \). The proof of (2) is now almost identical to the proof of (1). We leave it to the reader to make the minute modifications. ■

![Figure 274. Illustration for Lemma 11.5 (1).](image)

11.2. Embeddings of (topological) smooth manifolds into \( \mathbb{R}^n \) II. In this and the coming section we study the existence of smooth embeddings of (topological) smooth manifolds into some sufficiently high-dimensional \( \mathbb{R}^n \). For the reader’s convenience we recall the following definitions from page 312.

**Definition.**

(1) A map \( \varphi: N \to M \) between two topological manifolds is called a *embedding* if \( \varphi: N \to \varphi(N) \) is a homeomorphism and if \( \varphi(N) \) is a submanifold of \( M \). (Here we view \( \varphi(N) \) as a topological space equipped with the subspace topology coming from \( M \).)

(2) A map \( \varphi: N \to M \) between two smooth manifolds is called an *immersion* if the following conditions are satisfied:
   
   (a) \( \varphi \) is smooth,
   
   (b) for each \( P \in N \) the induced map \( \varphi_*: T_P N \to T_{\varphi(P)} M \) is a monomorphism,
   
   (c) for each \( P \in N \setminus \partial N \) we have \( \varphi(P) \in M \setminus \partial M \),
   
   (d) for each \( P \in \partial N \) with \( \varphi(P) \in \partial M \) the image \( \varphi_* (T_P N) \) is not contained in \( T_{\varphi(P)} (\partial M) \).

An immersion that also satisfies the following extra condition

(e) \( \varphi: N \to \varphi(N) \) is an embedding,

is called an *smooth embedding*.

**Remark.**

(1) Let \( \varphi: N \to M \) be an injective map between topological manifolds. As is shown in Figure 276 such a map is not necessarily a smooth embedding. But it follows from Lemma 2.40 that such a map is an embedding under the added hypothesis that

Another way of expressing this condition is that the map \( T_P N \to T_{\varphi(P)} M/T_{\varphi(P)} \partial M \) is an epimorphism.
11. THE WHITNEY EMBEDDING THEOREM

N is compact. On several occasions we will use this observation without saying it explicitly.

(2) The super-meticulous reader will have noticed that the above definition of a smooth embedding between smooth manifolds differs slightly from the definition we gave on page 342. In the original definition we had not demanded that the image of a smooth embedding is (a topological) submanifold, but instead we saw in Proposition 8.1 that this property follows already from the a priori slightly weaker notion of a smooth embedding that we had introduced on page 342. So any fears of incoherence in these notes just mercifully dissipated.

Examples.

(1) It is straightforward to verify that the map

\[ S^1 \times S^1 \to \mathbb{R}^3 \]
\[ (e^{i\theta}, e^{i\varphi}) \mapsto ((2 + \sin(\theta)) \cdot \cos(\varphi), (2 + \sin(\theta)) \cdot \sin(\varphi), \cos(\theta)) \]

is a smooth embedding of the 2-dimensional torus into \( \mathbb{R}^3 \).

(2) Let \( M \) be a closed non-empty \( n \)-dimensional topological manifold. In Corollary 50.8 we showed that there is no embedding of \( M \) into \( \mathbb{R}^n \).

For the reader’s convenience we recall the following proposition.

**Proposition 9.1.**

(1) Given any smooth manifold \( M \) there exists some \( n \in \mathbb{N} \) and a smooth embedding \( M \to \mathbb{R}^n \).

(2) Given any topological manifold \( M \) there exists an \( n \in \mathbb{N} \) and a map \( \varphi: M \to \mathbb{R}^n \) which is an embedding.

The question arises, how small \( n \) can be chosen with respect to the dimension of the manifold? For smooth manifolds we have the following result.

**Proposition 11.6.** If \( M \) is an \( m \)-dimensional smooth manifold, then there exists a smooth embedding \( M \to \mathbb{R}^{2n+1} \).

The proof of Proposition 11.6 requires the following lemma, which is of interest in its own right.
**Lemma 11.7.** Let $M$ be an $m$-dimensional submanifold of $\mathbb{R}^n$. If $n > 2m + 1$, then there exists a non-zero vector $v \in \mathbb{R}^n$ which does not lie in any tangent space $T_PM$ and that is not secant to $M$, in other words, for any two distinct points $x, y \in M$ the difference $x - y$ is not parallel to $v$.

![Illustration for Lemma 11.7](image)

**Proof of Lemma 11.7** Let $M$ be an $m$-dimensional submanifold of $\mathbb{R}^n$. We suppose that $n > 2m + 1$. We consider the maps

$$f: \{(P, w) \mid P \in M, w \in T_PM \setminus \{0\}\} \rightarrow \mathbb{R}P^{n-1}$$

$$(P, w) \mapsto [w]$$

and

$$g: \{(x, y) \in M \times M \mid x \neq y\} \rightarrow \mathbb{R}P^{n-1}$$

$$(x, y) \mapsto [x - y].$$

By the discussion on page 287 we can view $\mathbb{R}P^{n-1}$ as an $(n - 1)$-dimensional smooth manifold. One can easily verify that the left-hand sides of both $f$ and $g$ are smooth manifolds of dimension $2m$ and that the two maps are smooth. Since $2m < n - 1$ we obtain from Proposition 6.62 that the complement of the images of $f$ and $g$ is dense, in particular non-empty. This means that there exists a $v \in \mathbb{R}P^{n-1}$ such that the preimages of $v$ under $f$ and $g$ are both the empty set. But that means that $v$ has the desired properties. \[\blacksquare\]

Now we turn to the proof of Proposition 11.6.

**Proof of Proposition 11.6** Let $M$ be a compact $m$-dimensional smooth manifold. We claim that we can embed $M$ into $\mathbb{R}^{2m+1}$. By Proposition 9.1 we can assume that $M$ is already a submanifold of some $\mathbb{R}^n$. If $n \leq 2m + 1$ there is nothing to prove, so we may assume that $n > 2m + 1$. By Lemma 11.7 there exists a non-zero vector $v \in \mathbb{R}^n$ which does not lie in any tangent space $T_PM$ and that is not secant to $M$, in other words, for any two distinct points $x, y \in M$ the difference $x - y$ is not parallel to $v$.

We consider the projection of $\mathbb{R}^n$ onto the orthogonal complement of $v$, i.e., we consider the map

$$\mathbb{R}^n \rightarrow \{w \in \mathbb{R}^n \mid \langle w, v \rangle = 0\}$$

$$u \mapsto u - \langle u, v \rangle \cdot \frac{v}{\|v\|^2}.$$

It follows easily from the claim that the restriction of the projection to $M$ is a smooth embedding. Thus we have embedded $M$ into a real vector space of dimension $n - 1$. Iterating this process we get a smooth embedding of $M$ into $\mathbb{R}^{2m+1}$. \[\blacksquare\]

In the remainder of this section and in the subsequent section we will discuss refinements of Proposition 11.6 for smooth manifolds. Many of the results also have more or less obvious

---

201 Here we use Proposition 6.39 to interpret the tangent space $T_PM$ as a vector subspace of $\mathbb{R}^n$. 

analogues for topological manifolds, but to simplify the discussion we will not spell out the statements for topological manifolds.

Our first goal is to consider smooth manifolds with boundary in greater detail. We recall the following definition and notation.

**Definition.**

1. Let $N$ be a compact smooth manifold and let $M$ be any smooth manifold. A map $\varphi: N \to M$ is called proper if $\varphi^{-1}(\partial M) = \partial N$.

2. Given $n \in \mathbb{N}$ we write $H_n := \{(x_1, \ldots, x_n) \in \mathbb{R}^n \mid x_n \geq 0\}$.

For smooth manifolds with boundary the following proposition refines the statement of Proposition 9.1.

**Proposition 11.8.** Let $M$ be a compact $m$-dimensional smooth manifold.

1. Given any $n \geq 2m + 1$ there exists a proper smooth embedding $M \to H_n$.

2. Suppose we are given a smooth embedding $f: \partial M \to \mathbb{R}^k$ of the boundary of $M$. Given any $n \geq 2m + k + 1$ there exists a proper smooth embedding $F: M \to H_n$ such that the following diagram commutes:

$$
\begin{array}{ccc}
\partial M & \xrightarrow{f} & M \\
\downarrow & & \downarrow F \\
\mathbb{R}^k & \xrightarrow{x \to (x,0)} & H_n.
\end{array}
$$

**Proof.** Both statements of the proposition follow from the following claim.

**Claim.** Let $M$ be a compact $m$-dimensional smooth manifold and let $Y$ be a (possibly empty) union of components of $\partial M$. Suppose we are given a smooth embedding $f: Y \to \mathbb{R}^k$ of the boundary of $M$. Let $n \geq 2m + k + 1$. Then there exists a proper smooth embedding $F: M \to H_n$ such that the following diagram commutes:

$$
\begin{array}{ccc}
Y & \xrightarrow{f} & M \\
\downarrow & & \downarrow F \\
\mathbb{R}^k & \xrightarrow{x \to (x,0)} & H_n.
\end{array}
$$

\footnote{Indeed, the first statement of the proposition follows from $Y = \emptyset$ and $k = 0$. The second statement follows from setting $Y = \partial M$.}
Evidently the proof of the claim is quite similar to the proofs of Proposition 9.1 and Proposition 11.6. Therefore we will only indicate in what ways the proof needs to be modified.

(a) By the Collar Neighborhood Theorem \[8.12\] we can pick a collar \([0, 1] \times \partial M\). Note that using Lemma 6.13 one can easily construct a smooth non-decreasing function \(\eta: [0, 1] \to [0, 1]\) with \(\eta(t) = t\) for all \(t \in [0, \frac{1}{4}]\) and with \(\eta(t) = 1\) for all \(t \in [\frac{1}{2}, 1]\). We define

\[
\mu: M \to [0, 1] \\
P \mapsto \begin{cases} 
\eta(t), & \text{if } P = (t, Q) \text{ with } t \in [0, 1] \text{ and } Q \in \partial M, \\
1, & \text{otherwise}
\end{cases}
\]

and we define

\[
\tilde{f}: M \to \mathbb{R}^k \\
P \mapsto \begin{cases} 
f(Q) \cdot (1 - \eta(t)), & \text{if } P = (t, Q) \text{ with } t \in [0, 1] \text{ and } Q \in \partial M, \\
0, & \text{otherwise.}
\end{cases}
\]

In the following we use the same notation and definitions as in the proof of Proposition 9.1. In particular we pick a finite atlas \(\{\Phi_i: U_i \to V_i\}_{i=1,...,s}\), we pick a corresponding smooth partition of unity \(\nu_i: M \to [0, 1], i = 1, \ldots, s\) and we define \(\tilde{\Phi}_i: M \to \mathbb{R}^m, i = 1, \ldots, s\) the same way as before. Similar to the proof of Proposition 9.1 one can verify that the map

\[
F: M \to \mathbb{R}^k \times \mathbb{R}^{s-m+s} \times \mathbb{R}_{\geq 0} = H_{k+s-m+s+1} \\
x \mapsto \begin{pmatrix} 
\tilde{f}(x), \\
\mu(x) \\
\Phi_1(x), \ldots, \Phi_s(x), \\
\nu_1(x), \ldots, \nu_s(x)
\end{pmatrix} \\
\in \mathbb{R}^k \\
\in \mathbb{R}^{s-m+s} \\
\in \mathbb{R}_{\geq 0}
\]

is a proper smooth embedding. It is clear that the map \(F\) makes the diagram in the claim commute.

(b) To prove the claim it now remains to show that given such a proper smooth embedding \(F: M \to H_n\) with \(n > 2m+k+1\) we can find a lower-dimensional proper smooth embedding with the same properties. Without loss of generality we can assume that \(M\) is already a submanifold of \(H_n\).

Similar to the proof of Proposition 11.6 we can find a non-zero vector \(v \in \mathbb{R}^n\) with the following three properties:

(a) the vector does not lie in any tangent space \(T_x M\),
(b) for any two distinct points \(x, y \in M\) the difference \(x - y\) is not parallel to \(v\),
(c) the vector is orthogonal to \(\mathbb{R}^k \times \{0\}\).\[204\]

Note that projection onto the hyperplane that is orthogonal to \(v\) is the identity on \(\mathbb{R}^k \times \{0\}\). Thus as in the proof of Proposition 11.6 we can lower the dimension by one without losing any of the desired properties. \[\square\]

\[203\] It follows from Lemma 6.23 (2) that these two maps are smooth.
\[204\] Here we need that we have “extra \(k\) dimensions”, i.e. we need that \(n > 2m + 1 + k\).
As happens so often in mathematics, the proof of a result immediately invites new questions. For example, in light of Propositions 9.1, 11.6 and 11.8 the following question arises.

**Question 11.9.** For a given (topological) smooth manifold $M$, e.g. $M = \mathbb{R}P^n$, what is the minimal $k \in \mathbb{N}$ such that $M$ admits a (topological) smooth embedding into $\mathbb{R}^k$?

We will address this question in the following chapter.

We conclude this section with a discussion of the uniqueness of smooth embeddings of a given smooth manifold $M$ into some $\mathbb{R}^n$. Let us consider the three smooth embeddings $f_0, f_1, f_2: S^1 \to \mathbb{R}^3$ that are shown in Figure 279. The smooth embeddings $f_0, f_1$ are “essentially the same”, in the sense that they are smoothly isotopic. On the other hand it follows from Proposition 27.6, Exercise 20.9 and the Isotopy Extension Theorem 8.27 that the two smooth embeddings $f_0$ and $f_2$ are not smoothly isotopic.

![Figure 279](image-url)

Now we identify $\mathbb{R}^3$ with $\mathbb{R}^3 \times \{0\} \subset \mathbb{R}^4$. Therefore we can view the above smooth embeddings $f_0, f_1, f_2$ as smooth embeddings $f_0, f_2: S^1 \to \mathbb{R}^4$. In Figure 280 we do our best to illustrate an isotopy $F: S^1 \times [0,1] \to \mathbb{R}^3 \times \mathbb{R}_{\geq 0} \subset \mathbb{R}^4$ from $f_2$ to $f_1$. The key to the understanding of the figure is that we use “pinkness” as the fourth coordinate, i.e. two points in $\mathbb{R}^3$ with different levels of “pinkness” differ in the fourth coordinate. With this convention the map $F \times S^1 \times [0,1] \to \mathbb{R}^3 \times \mathbb{R}_{\geq 0}$ shown in Figure 280 has the property that each $F_t$ is a smooth embedding. We have thus shown that $f_2, f_1$, viewed as smooth embeddings into $\mathbb{R}^4$, are smoothly isotopic.

In the above longish example we have seen that smooth embeddings which are not smoothly isotopic can become smoothly isotopic once we add extra dimensions. The following proposition shows that this phenomenon holds in general. More precisely, the proposition says that any two smooth embeddings of a given closed smooth manifold into some $\mathbb{R}^k$ become smoothly isotopic if we are allowed to increase the dimensions.

**Proposition 11.10.** Let $M$ be a closed smooth manifold. Suppose we are given two smooth embeddings $f_0, f_1: M \to \mathbb{R}^k$. There exists a smooth isotopy $F: M \times [0,1] \to \mathbb{R}^{2k}$ such that...

---

\(^{207}\)In fact in Proposition 11.11 we will give a much more formal proof that in fact any two knots in $\mathbb{R}^3$ become smoothly isotopic once we view them as knots in $\mathbb{R}^4$. 
for \( i = 0, 1 \) the following diagram commutes

\[
\begin{array}{ccc}
\mathbb{R}^k \quad f_i \quad M \\
\downarrow \quad \downarrow \quad \downarrow \\
\mathbb{R}^{2k} \quad F_i \quad \mathbb{R}^{2k}
\end{array}
\]

\( x \mapsto (x,0) \)

**Proof.** By Lemma 6.13 there exists a smooth function \( \nu: [0, 1] \to [0, 1] \) with \( \nu(t) = 1 \) for \( t \in [0, \frac{1}{2}] \) and \( \nu(t) = 0 \) for \( t \in [\frac{3}{4}, 1] \). We consider the map

\[
F: M \times [0, 1] \to \mathbb{R}^{2k}
\]

\[
(x, t) \mapsto (f_0(x) \cdot \nu(t) + f_1(x) \cdot (1 - \nu(t)), f_0(x) \cdot (1 - \nu(t)) \cdot \nu(t)).
\]

It is straightforward to verify that \( F \) is a smooth isotopy and that \( F \) makes the given diagram commute for \( i = 0, 1 \).

**Proposition 11.11.** Let \( M \) be a closed \( n \)-dimensional smooth manifold.

1. Given any two smooth embeddings \( f_0, f_1: M \to \mathbb{R}^{2n+2} \) there exists a smooth isotopy \( F: M \times [0, 1] \to \mathbb{R}^{2n+2} \) from \( f_0 \) to \( f_1 \).
2. Given any two smooth embeddings \( f_0, f_1: M \to S^{2n+2} \) there exists a smooth isotopy \( F: M \times [0, 1] \to S^{2n+2} \) from \( f_0 \) to \( f_1 \).

**Remark.**

1. In Proposition 27.6 we will see that there exist “non-trivial knots”, more precisely, we will see that there exist two smooth embeddings \( S^1 \to S^3 \) which are not smoothly isotopic. This shows that the conclusion of the dimension range in Proposition 11.11 is optimal, at least for \( n = 1 \).
2. Proposition 11.11 implies in particular that any two smooth embeddings \( S^1 \to \mathbb{R}^4 \) are smoothly isotopic. Thus we have now obtained a formal proof that any two knots in \( \mathbb{R}^3 = \mathbb{R}^3 \times \{0\} \) become smoothly isotopic once we view them as knots in \( \mathbb{R}^4 \).
3. As usual, under extra hypotheses one can obtain better results. One such instance is given by Haefliger’s Unknotting Theorem 27.35. More examples of such uniqueness statements are given in Wall16 Chapter 6.4.
Proof of Proposition 11.11 (1). Let \( M \) be a closed \( n \)-dimensional smooth manifold. Suppose we are given two smooth embeddings \( f_0, f_1: M \to \mathbb{R}^{2n+2} \). By Proposition 11.10 there exists an \( N \geq 2n+2 \) and a smooth isotopy \( F: M \times [0,1] \to \mathbb{R}^N \) such that for \( i = 0, 1 \) the following diagram commutes

\[
\begin{array}{ccc}
\mathbb{R}^{2n+2} & \xrightarrow{f_i} & \mathbb{R}^N \\
\downarrow{x \mapsto (x,0)} & & \downarrow{f_i} \\
\end{array}
\]

If \( N = 2n+2 \), then we are done. Now suppose that \( N > 2n+2 \). To deal with this case we need to introduce some notation. We consider the map \( G: M \times [0,1] \to \mathbb{R}^N \times [0,1] \) that is given by \((P, t) \mapsto (F(P, t), t)\). Since \( F \) is a smooth isotopy one can show easily that \( G \) is in fact a proper smooth embedding. Therefore \( X := G(M \times [0,1]) \) is a proper submanifold of \( \mathbb{R}^N \times [0,1] \).

Claim. There exists a non-zero vector \( v \in \mathbb{R}^N \) with

(1) \( v \) does not lie in \( \mathbb{R}^{2n+2} \times \{0\} \),

and furthermore, such that for every \( t \in [0,1] \) the following conditions are also satisfied by \( v \):

(2) Given any \( P \in M \) we have \( v \notin T_P(F_i(M)) \).

(3) Given any two distinct points \( x, y \in F_i(M) \) the difference \( x - y \) is not parallel to \( v \).

Evidently the idea for the proof of the claim is to tweak the argument in the proof of Lemma 11.7. First of all, we denote by \( p: X \to [0,1] \) the projection map \((P, t) \mapsto t\). Next we consider the maps

\[
f: \{(P, w) \mid P \in X, w \in T_P X \setminus \{0\} \text{ and } p_*(w) = 0\} \to \mathbb{R}P^{N-1}
(P, w) \mapsto [w]
\]

and

\[
g: \{(x, y) \in X \times X \mid x \neq y \text{ and } p(x) = p(y)\} \to \mathbb{R}P^{N-1}
((x, t), (y, t)) \mapsto [x - y].
\]

By the discussion on page 287 we can view \( \mathbb{R}P^{N-1} \) as an \((N-1)\)-dimensional smooth manifold. It is fairly elementary to verify that the left-hand sides of both \( f \) and \( g \) are smooth manifolds of dimension \( 2 \cdot \dim(X) - 1 = 2n+1 \) and that the two maps \( f \) and \( g \) are smooth. Our hypothesis that \( N > 2n+2 \) implies that \( 2n+1 < N-1 \). Thus we obtain from Proposition 6.62 that the complement of the images of \( f \) and \( g \) is dense. This implies that there exists a \([v] \in \mathbb{R}P^{N-1}\) such that \( v \notin \mathbb{R}^{2n+2} \times \{0\} \) and such that the preimages of \([v]\) under \( f \) and \( g \) are both the empty set. One can easily verify that this means that \( v \) has the desired properties.

Now we proceed with the following steps:

(i) Since \( v \) does not lie in \( \mathbb{R}^{2n+2} \times \{0\} \) we can pick a codimension one subvector space \( W \subset \mathbb{R}^N \) which contains \( \mathbb{R}^{2n+2} \times \{0\} \) and which has the property that \( W \oplus \mathbb{R} \cdot v = \mathbb{R}^N \).

(ii) We denote by \( q: W \oplus \mathbb{R} \cdot v = \mathbb{R}^N \to W \) the projection.
(iii) Since $W$ contains $\mathbb{R}^{2n+2} \times \{0\}$ we can pick an isomorphism $\Phi: W \to \mathbb{R}^{N-1}$ such that $\Phi(P,0) = (P,0)$ for all $P \in \mathbb{R}^{2n+2}$.

Next we consider the map

$$\tilde{F}: M \times [0,1] \to \mathbb{R}^{N-1}
\quad (P,t) \mapsto (\Phi \circ q)(F(P,t)).$$

We make the following observations:

(a) It follows immediately from (iii) that for any $P \in M$ we have $\tilde{F}_0(P) = (f_0(P),0)$ and $\tilde{F}_1(P) = (f_1(P),0)$.

(b) It follows from Properties (2) and (3) of $v$ that $\tilde{F}$ is a smooth isotopy.

Thus we have shown that $f_0$ and $f_1$ are isotopic in $\mathbb{R}^{N-1}$. By iterating this process we see that there exists a smooth isotopy between $f_0$ and $f_1$ in $\mathbb{R}^{2n+2}$. $lacksquare$

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure281.png}
\caption{Illustration for the proof of Proposition 11.11 (1).}
\end{figure}

**Proof of Proposition 11.11 (2).** The case of two smooth embeddings $M \to S^{2n+2}$ can be reduced easily to the case of smooth embeddings $M \to \mathbb{R}^{2n+2}$. We will work out the details in Exercise 11.9. $lacksquare$

The final proposition of this section is the “boundary version” of Proposition 11.10. This proposition will play an important role later in Section 117.1. But till then it is best to ignore it.

**Proposition 11.12.** (\*) Let $M$ be a compact smooth manifold and let $Y$ be a (possibly empty) union of boundary components of $M$. Suppose we are given two proper smooth embeddings $f_0, f_1: M \to H_k$.

1. If $f_0|_Y = f_1|_Y$, then there exists a proper smooth isotopy $F: M \times [0,1] \to H_{2k} \text{ rel } Y$ such that for $i = 0, 1$ the following diagram commutes

\[
\begin{array}{ccc}
M & \xrightarrow{F_t} & M \\
\downarrow f_i & & \downarrow f_i \\
H_k & \xrightarrow{x \mapsto (0,x)} & H_{2k}.
\end{array}
\]

2. If $f_0(Y) = f_1(Y)$, then there exists a proper smooth isotopy $F: M \times [0,1] \to H_{2k} \text{ rel } Y$ such that for $i = 0, 1$ the image of $f_i(M)$ under the obvious inclusion $H_k \to H_{2k}$ agrees with $F_i(M)$. 
The analogous statements also hold if we replace $H_k$ by $[0, 1] \times \mathbb{R}^{k-1}$ and if we replace $H_{2k}$ by $[0, 1] \times \mathbb{R}^{2k-1}$.

**Proof (\(\ast\)).**

(1) We suppose that $f_0|_Y = f_1|_Y$. As in the proof of Proposition 11.10 we pick a smooth function $\nu: [0, 1] \to [0, 1]$ with $\nu(t) = 1$ for $t \in [0, \frac{1}{4}]$ and $\nu(t) = 0$ for $t \in [\frac{3}{4}, 1]$. Furthermore, as in the proof of Proposition 11.8 we pick a collar $[0, 1] \times \partial M$, we pick a non-decreasing smooth function $\eta: [0, 1] \to [0, 1]$ with $\eta(t) = 1$ for all $t \in [0, \frac{1}{4}]$ and $\eta(t) = 0$ for all $t \in [\frac{3}{4}, 1]$ and we consider the smooth functions

$$
\mu: M \to [0, 1],
\eta(t), \text{ if } P = (t, Q) \text{ with } t \in [0, 1] \text{ and } Q \in Y,
1, \text{ otherwise}
$$

and

$$
\epsilon: M \to [0, 1],
\eta(t), \text{ if } P = (t, Q) \text{ with } t \in [0, 1] \text{ and } Q \in \partial M,
1, \text{ otherwise}.
$$

Finally we consider the map

$$
M \times [0, 1] \xrightarrow{F} \mathbb{R}^k \times H_k = H_{2k}
$$

$$(x, t) \mapsto \left(\mu(x) \cdot (f_0(x) \cdot (1 - \eta(t)) \cdot \eta(t)) + f_0(x) \cdot \eta(t) + f_1(x) \cdot (1 - \eta(t)) + \epsilon(x) \cdot e_k\right) \in \mathbb{R}^k \in H_k.
$$

It is straightforward to verify that $F$ is a proper smooth isotopy rel $Y$ and that $F$ makes the given diagram commute for $i = 0, 1$.

(2) Now we only suppose that $f_0(Y) = f_1(Y)$. We consider the map $\varphi := f_1^{-1} \circ f_0: M \to M$. By Proposition 8.1 (2) we know that $\varphi$ is a diffeomorphism of $M$. Note that the smooth embeddings $f_0: M \to H_k$ and $f_1 \circ \varphi: M \to H_k$ agree on $Y$. Thus we can apply (1). The proper smooth isotopy that we obtain this way evidently has the desired property.

The above proofs also apply, with minuscule modifications, if we replace $H_k$ by $[0, 1] \times \mathbb{R}^{k-1}$ and if we replace $H_{2k}$ by $[0, 1] \times \mathbb{R}^{2k-1}$.

**Example.** We consider the two smooth embeddings $f_0, f_1: M = [0, 1] \to H_3$ shown in Figure 282. They agree on $Y = \{0\}$. By Proposition 11.12 these two smooth embeddings become smoothly isotopic rel $Y$ if we view $f_0$ and $f_1$ as smooth embeddings into $H_6$.

---

**Figure 282**

---
11.3. The Whitney Embedding Theorem (*). In this section we state several propositions and theorems that generalize the results from the previous section to larger classes of smooth manifolds and that give slightly improved bounds on the dimensions required to obtain (unique) smooth embeddings. We will not make use of the results, therefore we will not provide any proofs.

The following proposition can be viewed as a moderately difficult generalization of Proposition 11.6.

**Proposition 11.13.**

1. Every $n$-dimensional smooth manifold $M$ without boundary admits a proper smooth embedding $f: M \rightarrow \mathbb{R}^{2n+1}$ such that $f(M)$ is a closed subset of $\mathbb{R}^{2n+1}$.
2. Every $n$-dimensional smooth manifold $M$ with non-empty boundary admits a proper smooth embedding $f: M \rightarrow H_{2n+1}$ such that $f(M)$ is a closed subset of $H_{2n+1}$.

**Proof.** As indicated above, it is an entertaining and slightly challenging exercise to modify the proofs of Proposition 11.6 and 11.8 to obtain the results. The argument is carried out in [Why36, Theorem 1], [Bre93, Theorem II.10.8], [Hirs76, Theorems 1.3.5 and 1.4.3] and [Lee02, Theorem 6.15].

**Remark.** Note that in Proposition 11.13 it is essential that smooth manifolds are, by definition, second-countable. If we did not make this assumption, then any set with the discrete topology would be a 0-dimensional smooth manifold, but there are sets whose cardinality is bigger than the cardinality of any $\mathbb{R}^n$. More precisely, by Cantor’s Theorem, see page 80, the power set of $\mathbb{R}$ does not admit an injection into any $\mathbb{R}^n$.

In Propositions 11.6, 11.8 and 11.13 we had in particular seen that every $n$-dimensional smooth manifold admits a smooth embedding into $\mathbb{R}^{2n+1}$. The following theorem decreases the dimension by one. Even though this looks like a minor achievement, the proof of the Whitney Embedding Theorem is quite intricate.

**Theorem 11.14. (Whitney Embedding Theorem)** Every $n$-dimensional smooth manifold admits a smooth embedding into $\mathbb{R}^{2n}$.

**Proof.** This result was first proved by Hassler Whitney [Why44a, p. 236] in 1944. For closed smooth manifolds more recent accounts of the proof can be found in [Adac93, Theorem II.2.11] or [Pra07, Chapter 6.3].

**Remark.**

1. Under some extra conditions one can obtain better results. For example we saw on page 309 that every closed orientable 2-dimensional smooth manifold embeds into $\mathbb{R}^3$. Furthermore Hirsch [Hirs61] and Wall [Wall65b] showed that every 3-dimensional smooth manifold embeds into $\mathbb{R}^5$. Finally for $n > 4$ Haefliger-Hirsch [HH63, Theorem 1.2] showed that every closed orientable $n$-dimensional smooth manifold embeds into $\mathbb{R}^{2n-1}$.

2. In [Mun75, p. 313] it is shown that every $n$-dimensional topological manifold admits an embedding into $\mathbb{R}^{2n+1}$. At least for compact topological manifolds one can actually
find an embedding into $\mathbb{R}^{2n}$. We refer to [MeS06, Corollary 4.14] and [BrM99] for details.

(3) If $M$ and $N$ are two smooth manifolds that can be embedded (respectively immersed) into $\mathbb{R}^n$, then the construction in [Hae61a, Chapter 1] [Hae67, Chapter 3] shows that the connected sum $M \# N$ can also be embedded in $\mathbb{R}^n$.

(4) Let $M$ be a compact connected smooth manifold and let $N$ be a simply connected smooth manifold. If $\dim(N) = 2 \cdot \dim(M)$ and $\dim(M) \geq 3$, then [Wall16, Theorem 6.3.4] says that any map $M \to N$ is homotopic to a smooth embedding. As is explained on [Wall16, p. 182] the various hypothesis on $M$, $N$ and the dimensions are necessary.

The following theorem is a refinement of Propositions 11.10, 11.11 and 11.12.

**Theorem 11.15.**

1. Let $M$ be a closed $n$-dimensional smooth manifold. If $m \geq 2n + 1$ and $m \geq n + 3$, then any two smooth embeddings $f_0, f_1 : M \to \mathbb{R}^m$ are smoothly isotopic.
2. Let $M$ be a compact $n$-dimensional smooth manifold. If $m \geq 2n + 1$ and $m \geq n + 3$, then any two proper smooth embeddings $f_0, f_1 : M \to H_m$ are related by a proper smooth isotopy.

**Proof.** Both statements follow from [Hud72, Theorem 4]. For connected smooth manifolds the first statement also follows from [Hae61a, p. 47] or alternatively from [Wall16, Theorem 6.4.11].

**Remark.**

1. We consider again the two smooth embeddings $f_0, f_2 : S^1 \to \mathbb{R}^3$ from Figure 279. As we pointed out on page 437 these two smooth embeddings are not smoothly isotopic. This shows that in Theorem 11.15 we not only need the condition that $m \geq 2n + 1$ (which is satisfied in this example) but also the condition that $m \geq n + 3$.
2. The statements of Theorem 11.15 can be generalized considerably, in particular the target smooth manifolds do not necessarily need to be $\mathbb{R}^m$ and $H_m$. We refer to [Hae61a, p. 47], [Hud72], [Sko] and [Adac93, Theorem II.2.3] for many generalizations.

Sometimes it is also interesting to look at immersions instead of embeddings. In most cases one gets analogues of the above statements, except that one can lower the dimension of the target by one. For example the following variation on Proposition 11.6 holds.

**Proposition 11.16.** Every $n$-dimensional smooth manifold admits an immersion into $\mathbb{R}^{2n}$.

**Proof.** We will prove Proposition 11.16 in Exercise 11.8.

Furthermore, with significantly more work one can prove the following theorem which is the analogue of the Whitney Embedding Theorem 11.14.

**Theorem 11.17. (Whitney Immersion Theorem)** Every smooth manifold of dimension $n \geq 2$ admits an immersion into $\mathbb{R}^{2n-1}$.
Proof. This theorem is proved in [Why44b, p. 247] and [Wall16, Theorem 6.3.6]. ■

For the record we also state the following theorem which is the analogue of Theorem 11.13 (1).

**Theorem 11.18.** Let $M$ be a closed connected $n$-dimensional smooth manifold and let $N = \mathbb{R}^k$ or $N = S^k$. Furthermore let $f_0, f_1 : M \to N$ be two smooth embeddings. If $k \geq 2n$, then there exists a smooth homotopy $F : M \times [0,1] \to N$ from $f_0$ to $f_1$ and a finite subset $T \subset [0,1]$ with the following properties:

1. For each $t \in [0,1] \setminus T$ the map $F_t : M \to N$ is an embedding.
2. For each $t \in T$ the map $F_t : M \to N$ is a self-transverse immersion without triple points. (We refer to pages 407 and 408 for the definition of “self-transverse” and “without triple points”.)

**Remark.** It does not take much effort to use Theorem 11.18 (1) to give an alternative proof that the Gordian distance between knots, as defined on page 809, is actually finite.

**Exercises for Chapter 11.**

**Exercise 11.1.** Let $M$ be a compact smooth manifold. We want to show that there is no retraction from $M$ to $\partial M$. Thus suppose that there exists a retraction from $M$ to $\partial M$.

(a) Use the Whitney Approximation Theorem 9.3 to show that there exists a smooth retraction $g$ from $M$ to $\partial M$.

(b) By Sard’s Theorem 6.63 we know that $g$ admits a regular value $y$. What does Theorem 11.1 say about $g^{-1}\{y\}$? Show that this contradicts the classification of 1-dimensional smooth manifolds that we gave in Theorem 7.5.

**Remark.** In Corollary 87.28 we will give an alternative proof of the fact that there is no retraction from $M$ to $\partial M$.

**Exercise 11.2.** Let $M$ be a compact $n$-dimensional smooth manifold and let $K$ and $L$ be compact subsets of $M$. Show that there exist compact $n$-dimensional submanifolds with corner $A$ and $B$ of $M$ such that $K \subset \hat{A}$, $L \subset \hat{B}$, $A \cup B = M$ and such that $A \cap B = \partial A = \partial B$.

**Remark.** This exercise is a generalization of Exercise 6.36 (2). In particular you should make use of Exercise 6.35.
11. THE WHITNEY EMBEDDING THEOREM

Exercise 11.3. Let $M$ be a smooth manifold and let $V$ and $W$ be two disjoint closed subsets. Show that for any $\epsilon > 0$ there exists a smooth function $f: M \to \mathbb{R}$ such that
\[ f(V) \subset (-\epsilon, \epsilon) \quad \text{and} \quad f(W) \subset (1 - \epsilon, 1 + \epsilon). \]

*Hint.* Use Urysohn’s Lemma 2.50.

Exercise 11.4. Let $M$ be a smooth manifold, let $U$ be an open subset of $M$ and let $K$ be a compact subset of $M$ that is contained in $U$. Show that there exists a compact codimension-zero submanifold $N$ of $M$ with $K \subset N \subset U$.

Exercise 11.5. Let $f_0, f_1: S^1 \to \mathbb{R}^3$ be two smooth embeddings. As usual we identify $\mathbb{R}^3$ with $\mathbb{R}^3 \times \{0\} \subset \mathbb{R}^4$. By Proposition 11.11, we know that $f_0, f_1: S^1 \to \mathbb{R}^4$ are isotopic. Show that $f_0$ and $f_1$ are also isotopic as maps $S^1 \to \mathbb{R}^3 \times [0, \infty)$.

Exercise 11.6. Let $M$ be a compact $m$-dimensional smooth manifold. Show by hand that there exists an immersion $f: M \to \mathbb{R}^{2m}$.

*Hint.* Modify the proof of Proposition 11.6.

Exercise 11.7. We consider the Möbius band $M = ([0, 1] \times [-1, 1])/\sim (1, -x)$ together with the projection map
\[
p: M = ([0, 1] \times [-1, 1])/\sim \to [0, 1]/0 \sim 1 \quad [(x, y)] \mapsto [x].
\]

Show that this map defines a linear interval bundle.

Exercise 11.8. Let $M$ be an $m$-dimensional smooth manifold. Show that there exists an immersion $M \to \mathbb{R}^{2m}$.

*Hint.* Modify the proof of Proposition 11.6.

Exercise 11.9.
(a) Let $M$ be a closed $m$-dimensional smooth manifold and let $f: M \to S^l = \mathbb{R}^l \cup \{\infty\}$ be a smooth embedding. Show that if $m < l$, then $f$ is smoothly isotopic to a smooth embedding $gf: M \to \mathbb{R}^l$.

(b) Let $M$ be a closed $n$-dimensional smooth manifold. Show that given any two smooth embeddings $f_0, f_1: M \to S^{2n+2}$ there exists a smooth isotopy $F: M \times [0, 1] \to S^{2n+2}$ from $f_0$ to $f_1$.

*Hint.* Use Proposition 11.11 (1).
12. COMPLEX MANIFOLDS

In this chapter we start out with a very short introduction to complex manifolds.

12.1. Holomorphic functions. First we recall the definition of a holomorphic function.

Definition. Let \( U \subset \mathbb{C} \) be an open subset. A function \( f : U \to \mathbb{C} \) is holomorphic if for every \( z_0 \in U \) the limit

\[
\frac{d}{dz} f(z_0) := f'(z_0) := \lim_{z \to z_0} \frac{f(z) - f(z_0)}{z - z_0} \in \mathbb{C}
\]

exists.

Example. In any textbook on complex analysis it is shown that polynomials, the exponential function, and more generally functions defined by power series are holomorphic. Moreover products, fractions, sums and compositions of holomorphic functions are again holomorphic.

The definition of a complex function being holomorphic is almost verbatim the same as the definition of a real function being differentiable. But rather surprisingly being holomorphic is significantly more restrictive, as is shown in the following two standard results in complex analysis, see e.g. [Jä11] or [Lan99].

Theorem 12.1. (Liouville’s Theorem) Every bounded holomorphic map \( f : \mathbb{C} \to \mathbb{C} \) is constant.

Theorem 12.2. (Maximum Principle) Let \( U \) be an open connected subset of \( \mathbb{C} \) and let \( f : U \to \mathbb{C} \) be a holomorphic function. If the function \( |f| : U \to \mathbb{R}_{\geq 0} \) has a local maximum, then \( f \) is constant.

The following proposition also belongs to the usual repertoire of a course on complex analysis, see e.g. [Lan99], Chapter IX.1.

Proposition 12.3. (Schwarz Reflection Principle) Let \( U \) be an open subset of the upper half-plane \( \{z \in \mathbb{C} \mid \text{Im}(z) \geq 0\} \) and let \( f : U \to \mathbb{C} \) be a continuous function with the following properties:

1. \( f \) is holomorphic on \( \hat{U} = \{z \in U \mid \text{Im}(z) > 0\} \),
2. \( f \) only assumes real values on \( U \cap \mathbb{R} \).

We set \( U' := \{z \mid z \in U\} \), i.e. \( U' \) is the reflection of \( U \) in the x-axis. Then the function

\[
\tilde{f} : U \cup U' \to \mathbb{C}, \quad z \mapsto \begin{cases} f(z), & \text{if } z \in U, \\ \overline{f(z)}, & \text{if } z \in U', \end{cases}
\]

is holomorphic.

12.2. Complex manifolds. Given a topological manifold we now introduce the notion of a holomorphic atlas and a complex manifold. The definition is almost the same as for a smooth atlas and a smooth manifold, except that we have to replace “smooth” by “holomorphic”.
Definition.

1. Let $U \subset \mathbb{C}^n$ be open. We say that a map $f = (f_1, \ldots, f_n) : U \to \mathbb{C}^n$ is holomorphic if for every $i \in \{1, \ldots, m\}$, $j \in \{1, \ldots, n\}$ and any $(w_1, \ldots, w_{i-1}, w_i, w_{i+1}, \ldots, w_m) \in \mathbb{C}^{m-1}$ the map

$$
\left\{ z \in \mathbb{C} \mid (w_1, \ldots, w_{i-1}, z, w_{i+1}, \ldots, w_m) \in U \right\} \to \mathbb{C} \\
z \mapsto f_j(w_1, \ldots, w_{i-1}, z, w_{i+1}, \ldots, w_m)
$$

is holomorphic.

2. Let $M$ be a $2n$-dimensional topological manifold $M$ without boundary. An atlas $\{\Phi_i : U_i \to V_i\}_{i \in I}$ for $M$ is called holomorphic if for all $i, j \in I$ the transition map

$$
\Phi_j \circ \Phi_i^{-1} : \Phi_i(U_i \cap U_j) \to \Phi_j(U_i \cap U_j)
$$

is holomorphic.

3. An $n$-dimensional complex manifold is a pair $(M, \mathcal{A})$ consisting of a $2n$-dimensional topological manifold $M$ without boundary, together with a holomorphic atlas for $M$.

4. We define the maximal holomorphic atlas of a complex manifold the same way as we defined the maximal smooth atlas of a smooth manifold, see page 279.

Remark. Since holomorphic maps are in particular smooth we see that every $n$-dimensional complex manifold is in particular a $2n$-dimensional smooth manifold.

Examples.

1. Let $U$ be an open subset of $\mathbb{C}^n$. The identity map is an atlas for $U$ and it is evidently a holomorphic atlas. Thus $U$ is an $n$-dimensional complex manifold.

2. We consider the action

$$(\mathbb{Z} \oplus \mathbb{Z}i) \times \mathbb{C} \to \mathbb{C} \\
((a+bi), z) \mapsto z + a + bi.$$

The same argument as in the proof of Proposition 6.32 shows that $\mathbb{C}/(\mathbb{Z} \oplus \mathbb{Z}i)$ is a 1-dimensional complex manifold. The topological space $\mathbb{C}/(\mathbb{Z} \oplus \mathbb{Z}i)$ is evidently diffeomorphic to the torus $\mathbb{R}^2/\mathbb{Z}^2 = S^1 \times S^1$. Thus we can view the torus $S^1 \times S^1$ as a complex manifold.
Definition. We say that a map \( f : M \to N \) between two complex manifolds is **holomorphic** if \( f \) is continuous and if for every chart \( \Phi : U \to V \) in the holomorphic atlas of \( M \) and every chart \( \Psi : W \to Y \) in the holomorphic atlas of \( N \) the map

\[
\Phi(f^{-1}(W) \cap U) \xrightarrow{\Psi \circ f \circ \Phi^{-1}} Y
\]

is holomorphic.

**Example.** It follows easily from the definitions that the projection map \( \mathbb{C} \to \mathbb{C}/(\mathbb{Z} \oplus \mathbb{Z}i) \) is holomorphic.

The following proposition will be proved in Exercise 12.1.

**Proposition 12.4.** Let \( M \) be a compact 1-dimensional complex manifold. Then any holomorphic function \( f : M \to \mathbb{C} \) is constant.

**Remark.** If \( M = \mathbb{C}/(\mathbb{Z} \oplus \mathbb{Z}i) \), then we can also give another, arguably easier proof. More precisely, let \( f : \mathbb{C}/(\mathbb{Z} \oplus \mathbb{Z}i) \to \mathbb{C} \) be a holomorphic function. Since \( \mathbb{C}/(\mathbb{Z} \oplus \mathbb{Z}i) \) is compact the function \( f \) is bounded. We denote by \( p : \mathbb{C} \to \mathbb{C}/(\mathbb{Z} \oplus \mathbb{Z}i) \) the projection map. Then the composition \( f \circ p : \mathbb{C} \to \mathbb{C} \) is a bounded holomorphic function, thus constant by the Liouville Theorem 12.1. Since \( p \) is surjective it follows that \( f \) is also constant.

In the next definition we generalize the notion of (local) diffeomorphism in the obvious way to the complex setting.

**Definition.**

1. We say that a map \( f : M \to N \) between two complex manifolds is a **biholomorphism** if \( f \) is a bijection and if both \( f \) and \( f^{-1} \) are holomorphic.
2. We say that a map \( f : M \to N \) between two complex manifolds is a **local biholomorphism** if given any \( P \in M \) there exists an open neighborhood \( U \) of \( P \) and an open neighborhood \( V \) of \( f(P) \) such that \( f : U \to V \) is a biholomorphism.
3. We say that two holomorphic atlases for a given topological manifold are **equivalent** if the identity map is a biholomorphism between the two complex manifolds corresponding to the complex atlases. A **complex structure** on a topological manifold is a choice of an equivalence class.

**Examples.**

1. In some cases one can explicitly write down a biholomorphism. For example, for the upper half-plane \( \mathbb{H} = \{ x + iy \mid y > 0 \} \) and the open disk \( \mathbb{D} = \{ z \in \mathbb{C} \mid |z| < 1 \} \) it is straightforward to verify that the maps

\[
\Phi : \mathbb{H} \to \mathbb{D} \quad \text{and} \quad \Psi : \mathbb{D} \to \mathbb{H}
\]

\[
z \mapsto \frac{z-i}{z+i} \quad \text{and} \quad w \mapsto \frac{i+iw}{1-w}
\]

are biholomorphisms that are inverse to one another.

2. The proof of Proposition 6.32 shows that \( \mathbb{C}/(\mathbb{Z} + \mathbb{Z}i) \) has the structure of a 1-dimensional complex manifold in such a way that the projection map \( \mathbb{C} \to \mathbb{C}/(\mathbb{Z} + i\mathbb{Z}) \) is a local biholomorphism.
(3) Let \( a, b \in \mathbb{C} \) be two complex numbers that are linearly independent over \( \mathbb{R} \). We write \( T(a, b) = \mathbb{C}/(\mathbb{Z}a + \mathbb{Z}b) \). The same argument as in (2) shows that this is a 1-dimensional complex manifold such that the projection map \( p: \mathbb{C} \to T(a, b) \) is a local biholomorphism. Now suppose that \( v, w \in \mathbb{C} \) are also two complex numbers that are linearly independent over \( \mathbb{R} \). We can form the torus \( T(v, w) = \mathbb{C}/(\mathbb{Z}v + \mathbb{Z}w) \). The tori \( T(a, b) \) and \( T(v, w) \) are diffeomorphic. But the argument of [Bal06, p. 15] shows that the 1-dimensional complex manifolds \( T(a, b) \) and \( T(v, w) \) are biholomorphic only if \( ab^{-1} = vw^{-1} \in \mathbb{C} \) or if \( ab^{-1} = vw^{-1} \in \mathbb{C} \).

The next lemma gives us an example of a complex manifold that will play a major role later on.

**Lemma 12.5.** Let \( n \in \mathbb{N} \). On page 194 we introduced the complex projective space

\[
\mathbb{C}P^n = (\mathbb{C}^{n+1} \setminus \{0\})/(\mathbb{C} \setminus \{0\}).
\]

For \( i = 0, \ldots, n \) we consider the map

\[
\Phi_i: \{(z_0 : \ldots : z_n) \in \mathbb{C}P^n \mid z_i \neq 0\} \to \mathbb{C}^n
\]

\[
[z_0 : \ldots : z_n] \mapsto \left(\frac{z_0}{z_i}, \ldots, \frac{z_{i-1}}{z_i}, \frac{z_{i+1}}{z_i}, \ldots, \frac{z_n}{z_i}\right).
\]

These maps form a holomorphic atlas for \( \mathbb{C}P^n \) that turn the complex projective space \( \mathbb{C}P^n \) into a closed \( n \)-dimensional complex manifold, in particular we can view \( \mathbb{C}P^n \) as a closed \( 2n \)-dimensional oriented real smooth manifold.

**Proof.** In Proposition 3.40 (see also Exercise 3.39) we saw that each \( \mathbb{C}P^n \) is compact and Hausdorff. As we will show below, \( \mathbb{C}P^n \) admits a finite atlas, thus it follows from Lemma 6.4 that \( \mathbb{C}P^n \) is second-countable. For the remaining statements it is easy to overlook that first one needs to prove the following claim.

**Claim.** If \( i \in \{0, \ldots, n\} \), then

\[
V_i := \{(z_0 : \ldots : z_n) \in \mathbb{C}P^n \mid z_i \neq 0\}
\]

is an open subset of \( \mathbb{C}P^n \).

The claim is equivalent to showing that the complement \( \mathbb{C}P^n \setminus V_i \) is a closed subset of \( \mathbb{C}P^n \). We note that

\[
\mathbb{C}P^n \setminus V_i = \text{the image of the map } f: \mathbb{C}P^{n-1} \to \mathbb{C}P^n
\]

\[
[w_0 : \ldots : w_{n-1}] \mapsto [w_0 : \ldots : w_{i-1} : 0 : w_i : \ldots : w_{n-1}].
\]

The map \( f \) is easily seen to be continuous. Since \( \mathbb{C}P^{n-1} \) is compact we obtain from Lemma 2.40 that \( f(\mathbb{C}P^{n-1}) \) is compact. But since \( \mathbb{C}P^n \) is Hausdorff we obtain from Lemma 2.17(2) that \( f(\mathbb{C}P^{n-1}) = \mathbb{C}P^n \setminus V_i \) is in fact a closed subset of \( \mathbb{C}P^n \).

Using this claim it is now straightforward to verify that the given maps \( \Phi_0, \ldots, \Phi_n \) form a holomorphic atlas for \( \mathbb{C}P^n \). This shows that \( \mathbb{C}P^n \) is a complex \( n \)-dimensional smooth manifold. Note that the charts are of type (i). This shows that \( \mathbb{C}P^n \) has no boundary points, in particular since it is compact, it is closed. Finally the last statement is an immediate consequence of Proposition 12.7.
Remark. The notion of a submanifold also extends in the obvious way to the setting of complex manifolds. Let \( m \leq n \). On page \[194\] we introduced the convention that we view \( \mathbb{CP}^m \) as a subset of \( \mathbb{CP}^n \). Using the above atlas one can easily that \( \mathbb{CP}^m \) is in fact a complex submanifold of \( \mathbb{CP}^n \).

12.3. The canonical orientation of a complex manifold.

Definition. Let \( V \) be an \( n \)-dimensional complex vector space. We say that a set of vectors \( \{v_1, \ldots, v_n\} \) in \( V \) is totally real if the vectors \( v_1, iv_1, \ldots, v_n, iv_n \) form a basis of \( V \), viewed as a \( 2n \)-dimensional real vector space.

Lemma 12.6.

1. Let \( V \) be an \( n \)-dimensional complex vector space.
   
   (a) \( V \) admits a set of totally real vectors.
   
   (b) If \( \{v_1, \ldots, v_n\} \) and \( \{w_1, \ldots, w_n\} \) are two sets of totally real vectors for a complex vector space \( V \), then the bases \( \{v_1, iv_1, \ldots, v_n, iv_n\} \) and \( \{w_1, iw_1, \ldots, w_n, iw_n\} \) are equivalent in the sense of page \[296\].

2. Let \( f: V \to W \) be an isomorphism of \( n \)-dimensional complex vector spaces. If we equip \( V \) and \( W \), viewed as real vector spaces, with the orientation from (1), then \( f: V \to W \) is an orientation-preserving isomorphism.

Definition. Given a finite-dimensional complex vector space we refer to the orientation introduced in Lemma 12.6 (1) as the canonical orientation.

Example. Let \( n \in \mathbb{N}_0 \). If we make the usual identification \( \mathbb{C}^n = (\mathbb{R}^2)^n = \mathbb{R}^{2n} \), then the corresponding canonical orientation on \( \mathbb{C}^n = \mathbb{R}^{2n} \) agrees with the standard orientation.

Proof.

1. (a) This statement follows immediately from the observation that \( V \) is isomorphic, as a complex vector space, to \( \mathbb{C}^n \), and for \( \mathbb{C}^n \) a totally real basis is given by vectors \( e_i = (0, \ldots, 1, \ldots, 0) \), \( i = 1, \ldots, n \).

   (b) First we consider the case \( n = 1 \). In this case we are given two non-zero vectors \( v \) and \( w \). Then \( v = (a + bi)w \) for some \( a + bi \neq 0 \). The base change matrix from the real basis \( \{v, iv\} \) to the real basis \( \{w, iw\} \) is given by the real \( 2 \times 2 \)-matrix

   \[
   \begin{pmatrix}
   a & -b \\
   b & a
   \end{pmatrix}
   \]

   Evidently the determinant of this matrix is positive. This concludes the proof of the claim for \( n = 1 \). The general statement is basically just an exercise in linear algebra. This exercise though turns out to be slightly harder than one might expect\[206\]. A proof is for example given in [CCL99, Theorem 7.2.1].

\[206\] Basically the problem is as follows: Let \( A \) and \( B \) be two real \( n \times n \)-matrices such that \( \det(A + iB) \in \mathbb{C} \) is non-zero. Why does it follow that the determinant of the real matrix

\[
\begin{pmatrix}
A & -B \\
B & A
\end{pmatrix}
\]

is positive?
The following proposition says that complex manifolds admit a canonical orientation, in particular they are orientable.

**Proposition 12.7.**

1. Let $M$ be an $n$-dimensional complex manifold.
   a. Given any $P \in M$ we can use charts from the holomorphic atlas to equip $T_P M$ with the structure of an $n$-dimensional vector space.
   b. If we equip each complex vector space $T_P M$ with the corresponding canonical orientation, then these orientations define an orientation on $M$, viewed as a $2n$-dimensional real smooth manifold. We refer to this orientation as the canonical orientation of the complex manifold $M$.

2. If $f: M \to N$ is a local biholomorphism between two complex manifolds, then $f$ is an orientation-preserving diffeomorphism between $M$ and $N$, viewed as oriented smooth manifolds.

**Sketch of a proof.**

1. (a) Let $M$ be an $n$-dimensional complex manifold and let $P \in M$. We pick a chart $\Phi: U \to V$ from the holomorphic atlas around $P$. We get an induced isomorphism $D\Phi_P: T_P M \to T_P V = \mathbb{C}^n$. We use this isomorphism to equip $T_P M$ with the structure of a complex vector space. Since $\Phi$ comes from a holomorphic atlas one obtains from Exercise 12.2 that this complex vector space structure does not depend on the choice of the chart $\Phi$.
   
   (b) This statement follows easily from the definitions. We leave it to the reader to fill in the details.

2. The proof is identical to the proof of (1b).

**Corollary 12.8.** The Klein bottle and the real projective plane $\mathbb{R}P^2$ do not admit the structure of a complex manifold.

**Proof.** In Lemma 6.48 we showed that neither the Klein bottle nor the real projective plane $\mathbb{R}P^2$ are orientable. This is in contrast to the fact, shown in Proposition 12.7, that complex manifolds are orientable.

**12.4. Properties of complex manifold.** The following theorem is the complex analogue of the Regular Value Theorem 6.53. As in the real case is again a machine for providing examples of complex manifolds.

**Theorem 12.9.** (Regular Value Theorem for Complex Manifolds) Let $M$ be an $m$-dimensional complex manifold and let $N$ be an $n$-dimensional complex manifold. Furthermore $f: M \to N$ be a holomorphic map and let $s \in N$ be a regular value of $f$.

1. The preimage $X := f^{-1}\{s\}$ is an $(m-n)$-dimensional complex submanifold of $M$.
2. The intersection of $X$ with any compact set of $M$ is compact. In particular, if $M$ is compact, then $X$ is also compact.
Example. Let \( n \in \mathbb{Z} \). In Exercise 12.3 we will use the Regular Value Theorem 12.9 for Complex Manifolds to show that \( \{ [x : y : z] \in \mathbb{C}P^2 \mid x^n + y^n + z^n = 0 \} \) is a closed 1-dimensional complex manifold.

**Proof.** The proof is almost identical to the proof of the “real” Regular Value Theorem 6.53. We refer to [Huy05, p. 11 and p. 58] for some more details.

As we had already pointed out on page 197 the one-dimensional projective space \( \mathbb{C}P^1 \) is homeomorphic to \( \mathbb{S}^2 \). This shows that \( \mathbb{S}^2 \) can be viewed as a 1-dimensional complex manifold. We had just seen that the 2-sphere and the torus are complex manifolds and we saw that non-orientable smooth manifolds cannot be complex manifolds. The following question now arises:

**Question 12.10.** Let \( g \geq 2 \). Does the surface of genus \( g \) have the structure of a complex manifold?

We will discuss this question in Proposition 33.2.

**Remark.** It is often very hard to determine whether or not a given orientable even-dimensional smooth manifold can also be a complex manifold. For example, Armand Borel and Jean-Pierre Serre [BoS53] showed in 1953 that for \( n \neq 2, 6 \) the \( n \)-dimensional sphere \( \mathbb{S}^n \) cannot be a complex manifold. On the other hand it is still an open question whether \( \mathbb{S}^6 \) is a complex manifold.

In general it is hard to write down an explicit biholomorphism between two complex manifolds. One of the main sources of biholomorphisms is the Riemann Mapping Theorem.

**Theorem 12.11.** (Riemann Mapping Theorem) Let \( U \subset \mathbb{C} \) be a simply connected open subset \( U \) of \( \mathbb{C} \). If \( U \neq \mathbb{C} \), then \( U \) is biholomorphic to \( \mathbb{D} \).

The Riemann Mapping Theorem was first stated by Bernhard Riemann in 1851 his thesis. The first rigorous proof was given by William Osgood in 1900, see [Wals73]. The Riemann mapping theorem is proved in most textbooks on complex analysis, see e.g. [Jä11] or alternatively [Lan99, Chapter X].

In many applications it is also useful to know that the biholomorphism from the Riemann Mapping Theorem extends to the boundary of \( U \) and \( \mathbb{D} \). To state the corresponding theorem we need one more definition.

**Definition.**

1. We write \( \overline{\mathbb{C}} = \mathbb{C} \cup \{ \infty \} \) which we equip with the topology that we defined on page 95.
2. Given \( U \subset \overline{\mathbb{C}} \) we denote by \( \overline{U} \) the closure of \( U \) in \( \overline{\mathbb{C}} \).
3. A Jordan curve is the image of an injective map \( S^1 \to \overline{\mathbb{C}} \).

The following theorem was proved in 1913 by Constantin Carathéodory.\(^{208}\) A proof is for example provided in [GM05, Chapter I.3].

---

\(^{207}\)Armand Borel (1923–2003) was a Swiss mathematician, Jean-Pierre Serre (*1926) is a French mathematician who was awarded a Fields medal in 1954.

\(^{208}\)Constantin Carathéodory (1873–1950) was a Greek mathematician who was in particular a professor at the LMU in Munich.
Theorem 12.12. (Carathéodory Theorem) Let $U \subseteq \mathbb{C}$ be a simply connected open subset $U$ of $\mathbb{C}$ and let $\phi: U \to \mathbb{D}$ be a biholomorphism. If $\partial U$ is a Jordan curve, then $\phi$ extends to a homeomorphism $\overline{U} \to \mathbb{C}$.

**Example.** We consider the open subset $U$ of $\mathbb{C}$ that is shown in Figure 287. It is a simply connected open proper subset of $\mathbb{C}$ and the boundary is clearly a Jordan curve. Thus it follows from the Riemann Mapping Theorem and from Carathéodory’s Theorem that there exists a homeomorphism $\phi: \overline{U} \to \mathbb{D}$ which restricts to a biholomorphism $\phi: U \to \mathbb{D}$.

![Figure 287](image)

Exercise for Chapter 12

**Exercise 12.1.** Let $M$ be a compact connected 1-dimensional complex manifold. Show that any holomorphic function $f: M \to \mathbb{C}$ is constant.

*Hint.* Use the Maximum Principle, i.e. use Theorem 12.2.

**Exercise 12.2.** Let $U \subset \mathbb{C}^n$ be an open set and let $f: U \to \mathbb{C}^m$ be a holomorphic map. Show that given any $P \in U$ the differential $Df_P$ lies in $M(m \times n, \mathbb{C}) \subset M(2m \times 2n, \mathbb{R})$.

**Exercise 12.3.** Let $n \in \mathbb{Z}$. Show that $\{[x : y : z] \in \mathbb{C}P^2 | x^n + y^n + z^n = 0\}$ is a closed 1-dimensional complex submanifold of $\mathbb{C}P^2$. 
Part III

Fundamental Groups
13. **How can we show that two topological spaces are (not) homeomorphic?**

In the previous two sections we collected many examples of topological spaces. In many cases it was relatively straightforward to see that two topological spaces are homeomorphic. For example we wrote down an explicit homeomorphism from $\mathbb{R}^n/\mathbb{Z}^n$ to $(S^1)^n$. Sometimes it is rather painful to explicitly write down a homeomorphism, for example it was not particularly easy to find a homeomorphism from the open cube $(0,1)^n$ to the open ball $B^n = \{x \in \mathbb{R}^n | \|x\| < 1\}$. Nonetheless, if two topological spaces are homeomorphic, then usually one can write down an explicit homeomorphism.

On the other hand, how can we tell that two topological spaces are not homeomorphic? There are a couple of trivial criteria: being compact, connected, Hausdorff are properties of topological spaces that are shared by homeomorphic topological spaces. This implies for example that the closed cube $[0,1]^n$ is not homeomorphic to the open cube $(0,1)^n$, since the former topological space is compact and the latter is not.

But these criteria are of no use when it comes to studying more subtle examples. For example they do not suffice to address the following questions:

(1) Can surfaces with different genera be homeomorphic?
(2) Given $k \in \mathbb{Z}_{\geq 0}$ we denote by $U$ the complement of $k$ points in $\mathbb{R}^2$. If $k \neq l$, is it possible that $U_k$ and $U_l$ are homeomorphic?
(3) Is the complement of the trefoil homeomorphic to the complement of the trivial knot?

In each case we suspect that the answer is no. Certainly we do not succeed in finding a homeomorphism, but how can we show that this is not due to lack of imagination, but that there is indeed no homeomorphism?

![trefoil](trefoil.png) ![trivial knot](trivial_knot.png)

**Figure 288**

The reader might have encountered some ideas for tackling these questions in one or both of the following topics:

(a) Differential forms on smooth manifolds, in particular de Rham cohomology, as developed say in [BoT82, Lee02].
(b) Complex analysis, see e.g. [Lan99, Jä11].

For the reader who has seen differential forms and de Rham cohomology we recall that each smooth manifold $M$ and each $k \in \mathbb{Z}_{\geq 0}$ we can assign the de Rham cohomology group $H^k_{\text{dR}}(M)$. It follows more or less from the definition that diffeomorphic smooth manifolds have isomorphic de Rham cohomology groups. This approach has several disadvantages:

(1) the de Rham cohomology groups are only defined for smooth manifolds,
13. HOW TO SHOW THAT TOPOLOGICAL SPACES ARE (NOT) HOMEOMORPHIC

(2) the de Rham cohomology groups can only be used to show that two smooth manifolds are not diffeomorphic, a priori they cannot be used to show that two smooth manifolds are not homeomorphic.

(3) at least just starting from the definition it is not clear how one can calculate the de Rham cohomology groups of a given smooth manifold.

Later on, in Chapter 73, we will introduce “singular cohomology” which will take care of all of these three issues.

Next we give some definitions that are familiar to the reader who has taken a course on complex analysis.

(1) Given a subset $U$ of $\mathbb{C}$, we defined a path in $U$ to be a map $\gamma: [a, b] \to U$. If $\gamma(a) = \gamma(b)$, then we say that $\gamma$ is a loop.

(2) Two paths $\gamma_0, \gamma_1: [a, b] \to U$ with the same starting point $P := \gamma_0(a) = \gamma_1(a)$ and the same endpoint $Q := \gamma_0(b) = \gamma_1(b)$ are called path-homotopic in $U$, if there exists a map

$$\Gamma: [a, b] \times [0, 1] \to U$$

with the following properties

(a) for every $t \in [a, b]$ we have

$$\Gamma(t, 0) = \gamma_0(t) \text{ and } \Gamma(t, 1) = \gamma_1(t),$$

(b) for every $s \in [0, 1]$ we have

$$\Gamma(a, s) = P \quad \text{and} \quad \Gamma(b, s) = Q.$$

Put differently, a path-homotopy between two paths consists of a “continuous” family of paths $\{\Gamma(-, s)\}_{s \in [0, 1]}$ from $P$ to $Q$ which interpolates between the paths $\gamma_0$ and $\gamma_1$. In Figure 289 we illustrate a path-homotopy between two paths.

(3) A loop $\gamma: [a, b] \to U$ is called null-homotopic if it is path-homotopic to the constant path given by $\delta(t) := \gamma(a)$ for all $t \in [a, b]$.

(4) We say $U$ is simply connected if $U$ is non-empty and if each loop is null-homotopic.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{path_homotopy.png}
\caption{Schematic image of a path-homotopy $\Gamma$ between two paths $\gamma_0$ and $\gamma_1$ from $P$ to $Q$.}
\end{figure}
**Example.** Every loop in $\mathbb{R}^2 = \mathbb{C}$ is null-homotopic. Indeed, we let $\gamma: [0, 1] \to \mathbb{C}$ be a loop with starting and endpoint $P$. Then

$$\Gamma: [a, b] \times [0, 1] \to \mathbb{R}^n \quad (t, s) \mapsto \gamma(t) \cdot (1 - s) + P \cdot s$$

is a path-homotopy between the loop $\gamma$ and the constant path at $P$. The fact that every loop in $\mathbb{C}$ is null-homotopic is illustrated in Figure ??

Now we recall the following definition from complex analysis.

**Definition.** Let $U \subset \mathbb{C}$ be an open subset, let $f: U \to \mathbb{C}$ be a holomorphic function and let $\gamma: [a, b] \to U$ be a smooth path. We define the path integral of $f$ along $\gamma$ as follows:

$$\int_{\gamma} f(z) \, dz := \int_{t=a}^{t=b} f(\gamma(t)) \cdot \gamma'(t) \, dt \in \mathbb{C}.$$  

**Examples.**

1. Let $U = \mathbb{C} \setminus \{0\}$, let $f(z) = \frac{1}{z}$ and let $\gamma: [0, 1] \to \mathbb{C} \setminus \{0\}$ be the loop given by $\gamma(t) = e^{2\pi i t}$, i.e. $\gamma$ is a loop that “goes once around the origin”. Then

$$\int_{\gamma} f(z) \, dz = \int_{t=0}^{t=1} f(\gamma(t)) \cdot \gamma'(t) \, dt = \int_{t=0}^{t=1} \frac{1}{e^{2\pi i t}} \cdot e^{2\pi i t} \cdot 2\pi i \, dt = 2\pi i.$$

2. If $\gamma$ is a constant path, then $\gamma'(t) \equiv 0$. This shows that the path-integral along a constant path is zero.

The following proposition is one of the main results in complex analysis, see e.g. [Lan99, Theorem III.5.1].

**Proposition 13.1.** Let $U \subset \mathbb{C}$ be an open subset, let $f: U \to \mathbb{C}$ be a holomorphic function and let $\gamma, \delta: [a, b] \to U$ be two smooth paths. If $\gamma$ and $\delta$ are path-homotopic, then

$$\int_{\gamma} f(z) \, dz = \int_{\delta} f(z) \, dz.$$

The following corollary is a consequence of Proposition [13.1] and of the above calculations.

**Corollary 13.2.** The loop $\gamma: [0, 1] \to \mathbb{C} \setminus \{0\}$ given by $\gamma(t) = e^{2\pi i t}$ is not path-homotopic to a constant path, i.e. $\gamma$ is not null-homotopic.

**Remark.** In the following Chapter [13.2] we will use Corollary [13.2] so that we have at least one non-trivial topological statement in our toolbox. Somewhat later, after somewhat
lengthy preparations, we will proof a general result, namely Corollary 16.18 which in particular will provide us with a new proof of Corollary 13.2.

**Example.** If two subsets of $\mathbb{C}$ are homeomorphic, then evidently either both are simply connected or none is. From Corollary 13.2 it now follows immediately that $\mathbb{R}^2 = \mathbb{C}$ and $\mathbb{R}^2 \setminus \{(0,0)\} = \mathbb{C} \setminus \{0\}$ are not homeomorphic.

This second approach to showing that two topological spaces are different also has several disadvantages over the first approach:

1. A priori these notions are defined only for subsets of $\mathbb{C}$,
2. this approach does not allow us to show that the two subsets $U = \mathbb{C} \setminus \{0\}$ and $V = \mathbb{C} \setminus \{0, 1\}$ are not homeomorphic, since neither is simply connected.

The first objection is of course easy to rectify, since the definitions make sense for any topological space. But if we work with more general situations a new problem arises: how can we show, without using complex analysis, that a topological space is not simply connected? In the following chapters we will address all these issues.

In particular, when it comes to distinguishing $U = \mathbb{C} \setminus \{0\}$ and $V = \mathbb{C} \setminus \{0, 1\}$, then naively we would say that $V$ has “more” loops that are not null-homotopic than $U$. In the Chapter 14 we will in particular make precise what “more” means.
14. The fundamental group

14.1. Path-homotopy classes of paths. In this section we extend some of the ideas and notions about paths that we introduced in the previous section to the more general setting of paths in topological spaces.

**Definition.** Let $X$ be a topological space.

1. A path in $X$ is a map $\gamma : [a, b] \to X$. We call $\gamma(a)$ the starting point of $\gamma$ and we call $\gamma(b)$ the endpoint of $\gamma$. Often we say that $\gamma$ is a path from $\gamma(a)$ to $\gamma(b)$.
2. A loop is a path for which the starting point and the endpoint coincide.

**Convention.** In the following, if we do not specify the domain of a path or a loop, then it is understood to be $[0, 1]$.

**Definition.** Given a path $\gamma : [0, 1] \to X$ we refer to the path $\gamma^{-1} : [0, 1] \to X$ that is given by $\gamma^{-1}(t) = \gamma(1-t)$ as the inverse path of $\gamma$.

![Figure 292](image)

**Definition.** Let $X$ be a topological space.

1. Let $\gamma_0, \gamma_1 : [a, b] \to X$ be two paths with the same starting point $P$ and the same endpoint $Q$. A path-homotopy between the paths $\gamma_0$ and $\gamma_1$ is a map

$$
\Gamma : [a, b] \times [0, 1] \to X
\quad (t, s) \mapsto \Gamma(t, s),
$$

with the following properties

(a) for every $t \in [a, b]$ we have

$$
\Gamma(t, 0) = \gamma_0(t) \text{ and } \Gamma(t, 1) = \gamma_1(t),
$$

(b) for every $s \in [0, 1]$ we have

$$
\Gamma(a, s) = P \quad \text{and } \Gamma(b, s) = Q.
$$

2. If there exists a path-homotopy between two paths $\gamma_0$ and $\gamma_1$, then we say that $\gamma_0$ and $\gamma_1$ are path-homotopic, and we write $\gamma_0 \simeq \gamma_1$.

3. We say a loop $\gamma : [a, b] \to X$ is null-homotopic, if it is path-homotopic to the constant path $\delta$ given by $\delta(t) = \gamma(a)$ for all $t \in [a, b]$.

**Examples.**

(A) Let $\gamma_0, \gamma_1 : [a, b] \to \mathbb{R}^n$ be two paths in $\mathbb{R}^n$ with same starting point and the same endpoint. Then

$$
\Gamma : [a, b] \times [0, 1] \to \mathbb{R}^n
\quad (t, s) \mapsto \gamma_0(t) \cdot (1-s) + \gamma_1(t) \cdot s
$$

---

*Recall that all maps are understood to be continuous, unless we say something else.*
is a path-homotopy between $\gamma_0$ and $\gamma_1$. We had already illustrated this fact in Figure 290.

(B) Let $X = \mathbb{C} \setminus \{0\} = \mathbb{R}^2 \setminus \{(0,0)\}$. As we had just seen in Corollary 13.2 the path

$$\gamma: [0, 1] \to X$$

$$t \mapsto e^{2\pi it} = (\cos(2\pi t), \sin(2\pi t))$$

is not null-homotopic in $X$.

(C) Let $Y = S^1 \times (0,2)$ and consider the loop

$$\tilde{\gamma}: [0, 1] \to Y = S^1 \times (0,2)$$

$$t \mapsto (e^{2\pi it}, 1).$$

This loop is not null-homotopic. This can be seen as follows: we consider the map

$$\Phi: Y = S^1 \times (0,2) \to X = \mathbb{C} \setminus \{0\}$$

$$(z,t) \mapsto z \cdot t.$$  

If $\tilde{\gamma}$ was null-homotopic in $Y$, then there would exist a path-homotopy

$$\tilde{F}: [0, 1] \times [0,1] \to Y$$

from $\tilde{\gamma}$ to the constant path $\delta(t) := (1,1)$, $t \in [0,1]$. But then

$$F := \Phi \circ \tilde{F}: [0, 1] \times [0,1] \to X$$

would be a path-homotopy in $X = \mathbb{C} \setminus \{0\}$ from the path $\gamma := \Phi \circ \tilde{\gamma}$ to the constant path $\delta := \Phi \circ \tilde{\delta}$. But $\gamma = \Phi \circ \tilde{\gamma}$ is precisely the path $\gamma$ from example (B) which we showed not to be null-homotopic in $X = \mathbb{C} \setminus \{0\}$.

(D) We consider the two loops in Figure 293. In both cases it is hard to see how these loops could possibly be path-homotopic to a constant path, but it is also difficult to find an argument why that should not be possible.\(^{210}\)

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure293.png}
\caption{Loop in $\mathbb{C} \setminus \{0,1\}$ and loop in the complement of a knot}
\end{figure}

(E) We consider the real projective space $\mathbb{RP}^2$. Recall that in Lemma 3.42 we gave an identification $\mathbb{RP}^2 = \overline{B^2}/\sim$ where $\sim$ is the equivalence relation on $\overline{B^2}$ generated by $P \sim -P$ for $P \in S^1 = \partial \overline{B^2}$. Then

$$\gamma: [0, 1] \to \overline{B^2}/\sim$$

$$t \mapsto [(\cos(\pi t), \sin(\pi t))]$$

is a loop in $\mathbb{RP}^2 = \overline{B^2}/\sim$, see Figure 294.\(^{211}\) But is it null-homotopic?

\(^{210}\) For example the given loop in $\mathbb{C} \setminus \{0,1\}$ is actually null-homotopic in $\mathbb{C} \setminus \{0\}$ and it is null-homotopic in $\mathbb{C} \setminus \{1\}$. In particular our trick of using Corollary 13.2 does not work in this case.

\(^{211}\) Why is it a loop?
(F) On page 107 we considered the pseudocircle, namely the set $X = \{A, B, C, D\}$ with a slightly unusual topology. Furthermore we gave an example of a continuous non-constant loop $f: S^1 \to X$. The question arises, is this loop null-homotopic?

**Remark.** Let $X$ be a topological space and let $x_0 \in X$. It follows from Lemma 3.24 that the maps

$$\{\text{loops } \gamma: [0, 1] \to X \text{ with } \gamma(0) = \gamma(1) = x_0\} \leftrightarrow \{\text{maps } f: S^1 \to X \text{ with } f(1) = x_0\}$$

$$\left(\gamma: [0, 1] \to X \mapsto (t \mapsto f(e^{2\pi it})) \leftrightarrow (f: S^1 \to X) \mapsto (z = e^{2\pi it} \mapsto \gamma(t))\right)$$

are evidently bijections. Thus we can think of loops in $X$ where the starting and endpoint is $x_0$ as maps from $S^1$ to $X$ that send 1 to $x_0$. We will use this bijection to go back and forth between these two points of view.

The following lemma gives a useful criterion for a loop to be null-homotopic.

**Lemma 14.1.** Let $X$ be a topological space and let $x_0 \in X$. Let $\gamma: [0, 1] \to X$ be a loop with $\gamma(0) = \gamma(1) = x_0$. We denote by

$$\varphi: S^1 \to X$$

$$z = e^{2\pi it} \mapsto \gamma(t)$$

the corresponding map from $S^1$ to $X$. Then $\gamma$ is null-homotopic if and only if there exists a map $\Phi:\overline{B^2} \to X$ so that $\Phi|_{S^1} = \varphi$.

**Proof.** We start out this proof with a few elementary preparations. We write $A := ([0, 1] \times \{0\}) \cup (\{0, 1\} \times [0, 1])$ and we consider the map

$$g: [0, 1] \times [0, 1] \to \overline{B^2}$$

$$(t, s) \mapsto se^{2\pi it} + 1 - s.$$
is a homeomorphism.

Now we turn to the actual proof of the lemma. Thus let $X$ be a topological space, let $x_0 \in X$ and let $\gamma: [0, 1] \to X$ be a loop with $\gamma(0) = \gamma(1) = x_0$. We define $\varphi: S^1 \to X$ via $\varphi(e^{2\pi im}) = \gamma(t)$.

First we suppose that $\gamma$ is null-homotopic. This means that there exists a path-homotopy $F: [0, 1] \times [0, 1] \to X$ such that $F(t, 0) = x_0$ and $F(t, 1) = \gamma(t)$ for all $t \in [0, 1]$ and such that $F(0, s) = F(1, s) = x_0$ for all $s \in [0, 1]$. In other words, $F$ is constant on $A$.

We consider the map

$$\Phi: B^2 \xleftarrow{\cong} ([0, 1] \times [0, 1])/A \to X$$

$$[P] \mapsto F(P).$$

One can easily verify that we have $\Phi|_{S^1} = \varphi$.

Conversely, if there exists a map $\Phi: B^2 \to X$ so that $\Phi|_{S^1} = \varphi$, then one can easily verify that $\Phi \circ g: [0, 1] \times [0, 1] \to X$ is a path-homotopy from the loop $\gamma$ to the constant loop $c_{x_0}$.

Before we continue with the examples we need to gather a few more elementary facts about path-homotopies of paths.

**Proposition 14.2.** Let $X$ be a topological space and let $x, y \in X$. Then “path-homotopy” is an equivalence relation on the set of paths $\gamma: [a, b] \to X$ from $x$ to $y$.

The proof of Proposition 14.2 makes use of the following lemma which we will use, implicitly or explicitly, surprisingly often.

**Lemma 14.3.** (*) Let $X$ be a topological space and let $a < b < c$ be real numbers. Let $f: X \times [a, c] \to Y$ be a map to some topological space $Y$. If the restrictions of $f$ to $X \times [a, b]$ and to $X \times [b, c]$ are continuous, then $f$ itself is continuous.

**Proof of Lemma 14.3** This statement is an immediate consequence of Lemma 2.35 (2) and the observation, see Lemma 3.9, that $X \times [a, b]$ and $X \times [b, c]$ are in fact closed subsets of $X \times [a, c]$.

---

Note that we implicitly use Lemma 3.22 to argue that the map $([0, 1] \times [0, 1])/A \to X$ is well-defined and continuous.

Why did we not just define $g$ to be the map that sends the horizontal lines to concentric circles where each of them is centered around the origin?
Proof of Proposition 14.2. In order to simplify the notation we only work with paths defined on the interval $[0, 1]$. We have to show that “path-homotopy” satisfies the three properties of an equivalence relation. Let $\alpha, \beta, \gamma : [0, 1] \to X$ be three paths from $x$ to $y$.

(1) The “constant path-homotopy” given by $\Gamma(t, s) := \gamma(t)$ defines a path-homotopy between $\gamma$ and $\gamma$.

(2) Let $\Gamma$ be a path-homotopy from $\alpha$ to $\beta$. Then the map $\Gamma'$ defined by

$$\Gamma'(t, s) := \Gamma(t, 1 - s)$$

is a path-homotopy from $\beta$ to $\alpha$.

(3) Let $\Gamma$ be a path-homotopy from $\alpha$ to $\beta$ and let $\Delta$ be a path-homotopy from $\beta$ to $\gamma$. We consider the map

$$[0, 1] \times [0, 1] \to X$$

$$(t, s) \mapsto \begin{cases} 
\Gamma(t, 2s), & \text{if } s \in [0, \frac{1}{2}], \\
\Delta(t, 2s - 1), & \text{if } s \in \left(\frac{1}{2}, 1\right]
\end{cases}$$

It follows from Lemma 14.3 that this map is continuous. It is now clear that this map is a path-homotopy from $\alpha$ to $\gamma$. This part of the proof is illustrated in Figure 297. ■

Definition. Given a path $f : [0, 1] \to X$ in a topological space $X$ we denote by $[f]$ the equivalence class of $f$ with respect to the equivalence relation which is given by path-homotopies. We call $[f]$ the path-homotopy class of $f$.

Definition. Let $\gamma : [a, b] \to X$ be a path in a topological space and let $\varphi : [a, b] \to [a, b]$ be a map with $\varphi(a) = a$ and $\varphi(b) = b$. We refer to $\gamma \circ \varphi : [a, b] \to X$ as a reparametrization of $\gamma$.

The following lemma says that reparametrizing does not change the path-homotopy class of a path.

Lemma 14.4. Let $\gamma : [a, b] \to X$ be a path in a topological space. If a path $\delta : [a, b] \to X$ is obtained from $\gamma$ by a reparametrization, then $\gamma$ and $\delta$ are path-homotopic.

Proof. Let $\gamma : [a, b] \to X$ be a path in a topological space and let $\varphi : [a, b] \to [a, b]$ be a map with $\varphi(a) = a$, $\varphi(b) = b$. Then a path-homotopy between $\gamma$ and $\gamma \circ \varphi$ is given by

$$P : [a, b] \times [0, 1] \to X$$

$$(t, s) \mapsto \gamma(t \cdot s + \varphi(t) \cdot (1 - s)).$$

Note that $\varphi$ is not required to be a homeomorphism.

Where do we actually use the hypothesis that $\varphi(a) = a$ and $\varphi(b) = b$?
It is pictorially clear that we can concatenate two paths if the endpoint of the first path agrees with the starting point of the second path. We use this observation to define the product of two paths.

**Definition.** Let $X$ be a topological space and let $\alpha: [a, b] \to X$ and $\beta: [c, d] \to X$ be two paths with $\alpha(b) = \beta(c)$. We define the **product of $\alpha$ and $\beta$** as the path $\alpha \ast \beta$ which is given by

$$
\alpha \ast \beta: [0, 1] \to X \\
t \mapsto \begin{cases} 
\alpha(a + 2t(b - a)), & \text{if } t \in [0, \frac{1}{2}] \\
\beta(c + (2t - 1)(d - c)), & \text{if } t \in \left(\frac{1}{2}, 1\right].
\end{cases}
$$

The product of two paths is thus given by “first running along $\alpha$” and then “running along $\beta$”. Here we reparametrized the path so that the domain of $\alpha \ast \beta$ is $[0, 1]$. This convention might look slightly odd, but later on we will mostly work with paths that are defined on the interval $[0, 1]$.

![Figure 298. Definition of the product of two paths.](image)

We continue with the following lemma, the statement of which is illustrated in Figure 299.

**Lemma 14.5.** Let $\alpha, \alpha': [a, b] \to X$ and $\beta, \beta': [c, d] \to X$ be two pairs of paths in a topological space $X$ such that $\alpha(b) = \alpha'(b) = \beta(c) = \beta'(c)$. Then

\[ \alpha \simeq \alpha' \text{ and } \beta \simeq \beta' \implies \alpha \ast \beta \simeq \alpha' \ast \beta'. \]

Put differently, if $[\alpha] = [\alpha']$ and $[\beta] = [\beta']$, then $[\alpha \ast \beta] = [\alpha' \ast \beta']$.

**Proof.** We leave it to the reader to provide the fairly elementary proof. 

![Figure 299. Illustration of Lemma 14.5](image)
Definition. Let $[\alpha]$ and $[\beta]$ be two equivalence classes of paths in a topological space $X$ with $\alpha(1) = \beta(0)$. We define the product of the equivalence classes $[\alpha]$ and $[\beta]$ as 

$$[\alpha] \cdot [\beta] = [\alpha * \beta].$$

The following proposition says that the product of equivalence classes of paths shares many properties of the product structure of a group.

**Proposition 14.6.** Let $\alpha, \beta, \gamma: [0,1] \to X$ be three paths in a topological space $X$. Then the following hold:

1. If $\alpha(1) = \beta(0)$ and $\beta(1) = \gamma(0)$, then

$$[\alpha] \cdot ([\beta] \cdot [\gamma]) = ([\alpha] \cdot [\beta]) \cdot [\gamma].$$

2. For $x \in X$ we denote by $e_x$ the constant path that is given by $e_x(t) := x$, $t \in [0,1]$. Then the following equality holds

$$[e_{\alpha(0)}] \cdot [\alpha] = [\alpha] = [\alpha] \cdot [e_{\alpha(1)}].$$

3. We denote by $\overline{\alpha}$ the inverse path. Then the following equalities hold

$$[\alpha] \cdot [\overline{\alpha}] = [e_{\alpha(0)}] \quad \text{and} \quad [\overline{\alpha}] \cdot [\alpha] = [e_{\alpha(1)}].$$

**Proof (⋆).** Let $\alpha, \beta, \gamma: [0,1] \to X$ be three paths in a topological space $X$.

1. Suppose that $\alpha(1) = \beta(0)$ and $\beta(1) = \gamma(0)$. We need to show that

$$\alpha * (\beta * \gamma) \simeq (\alpha * \beta) * \gamma.$$  

We consider the map

$$\Phi: [0,1] \to X \quad \text{by definition} \quad \Phi \circ p \simeq \Phi \circ q = (\alpha * \beta) * \gamma \quad \text{by Lemma [4.4] by definition}$$

According to Lemma 14.5 this definition does not depend on the choice of the representatives $\alpha$ and $\beta$ of the equivalence classes.

Put differently, the paths $\alpha * (\beta * \gamma)$ and $(\alpha * \beta) * \gamma$ are path-homotopic. Note that these paths are similar in the sense that both paths “run through” the points on $\alpha$, $\beta$, and $\gamma$, but at different speeds. In general the paths are not equal, for example we have $(\alpha * (\beta * \gamma))(\frac{1}{2}) = \alpha(1)$ and $((\alpha * \beta) * \gamma)(\frac{1}{2}) = \beta(1)$. 
We consider the map
\[ q : [0, 1] \to [0, 1] \]
\[ t \mapsto \begin{cases} 
0, & \text{if } t \in [0, \frac{1}{2}], \\
2t - 1, & \text{if } t \in [\frac{1}{2}, 1]. 
\end{cases} \]

Then
\[ e_{\alpha(0)} * \alpha = \alpha \circ q \simeq \alpha. \]
by definition by Lemma 14.4

This shows that \([e_{\alpha(0)}] \cdot [\alpha] = [e_{\alpha(0)} * \alpha] = [\alpha]. \)
Almost the same argument also implies that \([\alpha] = [\alpha] \cdot [e_{\alpha(1)}]. \)

(2) We consider the map
\[ q : [0, 1] \to [0, 1] \]
\[ t \mapsto \begin{cases} 
0, & \text{if } t \in [0, \frac{1}{2}], \\
2t - 1, & \text{if } t \in [\frac{1}{2}, 1]. 
\end{cases} \]

Then
\[ e_{\alpha(0)} * \alpha = \alpha \circ q \simeq \alpha. \]
by definition by Lemma 14.4

This shows that \([e_{\alpha(0)}] \cdot [\alpha] = [e_{\alpha(0)} * \alpha] = [\alpha]. \)
Almost the same argument also implies that \([\alpha] = [\alpha] \cdot [e_{\alpha(1)}]. \)

(3) We write \(P = \alpha(0). \)
Note that \(\alpha * \overline{\alpha}\) is a loop in \(P. \)
We consider the map
\[ F : [0, 1] \times [0, 1] \to X \]
\[ (t, s) \mapsto \begin{cases} 
\alpha(2t \cdot s), & \text{if } t \in [0, \frac{1}{2}], \\
\alpha(2s - 2t \cdot s), & \text{if } t \in [\frac{1}{2}, 1]. 
\end{cases} \]

It follows from Lemma 14.3 that this map is indeed continuous. For \(s = 0\) we obtain the constant path at \(P\) and for \(s = 1\) we obtain the path \(\alpha * \overline{\alpha}. \) For any \(s \in [0, 1]\) we furthermore have \(F(0, s) = F(1, s) = P. \) Thus \(F\) is a path-homotopy from the constant path to \(\alpha * \overline{\alpha}\) which implies that \([e_{\alpha(0)}] = [\alpha * \overline{\alpha}] = [\alpha] \cdot [\overline{\alpha}]. \) Almost the same argument shows that \([\overline{\alpha} * \alpha] = [e_{\alpha(1)}]. \)

Figure 300. Illustration of the proof of Proposition 14.6 (3).

14.2. The fundamental group of a pointed topological space. In Proposition 14.6 we saw that the product of path-homotopy classes of paths shares many properties of the multiplication in a group. Nonetheless the path-homotopy classes of paths do not form a group, since the product of two paths is not defined, unless the endpoint of the first path agrees with the starting point of the second path.

We will resolve this problem by restricting our attention to loops.

**Definition.** Let \(X\) be a topological space and let \(x_0 \in X\) be a point. A loop in \((X, x_0)\) is a path \(f : [0, 1] \to X\) with \(f(0) = f(1) = x_0, \) i.e. \(x_0\) is the starting as well as the endpoint of \(f. \)

**Proposition 14.7.** Let \(X\) be a topological space and \(x_0 \in X. \) The set
\[ \pi_1(X, x_0) := \{ \text{path-homotopy classes of loops in } (X, x_0) \} \]

together with the product map \([\alpha] \cdot [\beta] := [\alpha * \beta]\) forms a group where the neutral element is represented by the constant path at \(x_0\) and where the inverse of \([\gamma]\) is given by \([\overline{\gamma}]. \)

\(^{219}\)Note that part of the definition of “loop in \((X, x_0)\)” is that the domain is the interval \([0, 1]. \)
Proposition. It is clear that the product of any two loops in \((X,x_0)\) is defined. According to Lemma 14.5 the product of paths descends to a well-defined map
\[
\pi_1(X,x_0) \times \pi_1(X,x_0) \to \pi_1(X,x_0)
\]
\[
([\alpha],[\beta]) \mapsto [\alpha] \cdot [\beta] := [\alpha * \beta].
\]
According to Proposition 14.6 (1) this product map satisfies the associativity axiom. The trivial element is according to Proposition 14.6 (2) given by the path-homotopy class of the constant loop \([e_{x_0}]\). Furthermore according to Proposition 14.6 (3) the inverse of the path-homotopy class of a loop \(\gamma: [0,1] \to X\) in \(x_0\) is given by the path-homotopy class of the loop defined by \(\tau(t) := \gamma(1-t), t \in [0,1]\).

**Definition.** We call \(\pi_1(X,x_0)\) the fundamental group of \(X\) with respect to the base point \(x_0\).

One of our main goals in the intermediate future will be to determine the fundamental group of the topological spaces that we introduced in the earlier sections.

**Examples.**

1. We consider \(X = \mathbb{R}^n\) and let \(x_0 \in \mathbb{R}^n\) be an arbitrary point. As we pointed out on page 460 all loops in \((X,x_0)\) are null-homotopic. More precisely, if \(\gamma: [0,1] \to \mathbb{R}^n\) is a loop in \((\mathbb{R}^n,x_0)\), then
\[
F: [0,1] \times [0,1] \to \mathbb{R}^n
\]
\[
(t,s) \mapsto \gamma(t) \cdot (1 - s) + x_0 \cdot s
\]
is a path-homotopy between the loop \(\gamma\) and the constant loop \(e_{x_0}\). Thus it follows that \(\pi_1(X,x_0) = 0\).

2. We say that a subset \(X \subset \mathbb{R}^n\) is star-shaped if there exists an \(x \in X\) such that for all \(y \in X\) the segment \(\{xt + y(1-t) \mid t \in [0,1]\}\) lies in \(X\). For example open and closed balls and open and closed rectangles are star-shaped. Furthermore all convex subsets are star-shaped. Precisely the same proof as in (1) shows that the \(\pi_1(X,x) = 0\).

---

\[^{220}\text{If } \pi_1(X,x_0) \text{ is the trivial group, then we usually write } \pi_1(X,x_0) = 0. \text{ This notation is commonly used, even though it is not entirely logical: we use the multiplicative notation for the product structure on the group } \pi_1(X,x_0), \text{ and it would therefore make more sense to write } \pi_1(X,x_0) = 1 \text{ if the group } \pi_1(X,x_0) \text{ is trivial.}\]
**Theorem 14.8.** Let $X$ be a proper subset \(^{221}\) of $\mathbb{C}$, let $x_0 \in X$ be a point and let $w \in \mathbb{C} \setminus X$ be a point in the complement of $X$. The map

$$
\pi_1(X, x_0) \to \mathbb{Z}
$$

$$
[\gamma] \mapsto \frac{1}{2\pi i} \int_\gamma \frac{1}{z-w} \, dz
$$

is a well-defined homomorphism.

**Remark.** As in the case of Corollary [13.2] we do not really need Theorem [14.8] and its subsequent Corollary [14.9]. If one has seen complex analysis, or if one is willing to take Theorem [14.8] on face value, it allows us to show that some fundamental groups are non-trivial, before we have developed the full machinery for calculating fundamental groups. But eventually we will supplant Corollary [14.9] by a much stronger statement proved using purely topological methods.

**Proof.** A vigilant reader might first have noticed that the statement of Theorem [14.8] contains a slight cheat. We use the path integral over a continuous path $\gamma$, whereas so far on page 458 we gave only the definition for the integral over a smooth path. The more general definition of a path integral is given in [Lan99] Chapter III.4. The fact that the given integral takes values in $\mathbb{Z}$ is proved in [Lan99] Lemma IV.4.1. Furthermore the fact that this integral defines a well-defined map on the fundamental group is a consequence of [Lan99] Theorem III.5.1. Finally it follows almost immediately from the definitions that the given map is a homomorphism. ■

![Figure 302](image)

The previous example together with Theorem [14.8] give us the following neat corollary.

**Corollary 14.9.** There exists an epimorphism $\pi_1(S^1, 1) \to \mathbb{Z}$.

**Proof.** The corollary follows from Theorem [14.8] and the calculation on page 458. ■

This raises the following question.

**Question 14.10.** Is the above epimorphism $\pi_1(S^1, 1) \to \mathbb{Z}$ in fact an isomorphism?

The definition of the fundamental group of a topological space $X$ relies on the choice of a base point $x_0$. The following proposition shows that, at least for path-connected topological spaces, the choice of the base point does not affect the isomorphism type of the fundamental group.

---

\(^{221}\)We say $A$ is a proper subset of $B$ if $A \subset B$ and if $A \neq B$. 
Proposition 14.11. Let $X$ be a topological space, let $x_0$ and $x_1$ be two points in $X$ and let $p: [0, 1] \to X$ be a path from $x_0$ to $x_1$. Then the following five statements hold:

1. The map
   \[ p_*: \pi_1(X, x_1) \to \pi_1(X, x_0) \]
   \[ [\gamma] \mapsto [p \cdot \gamma \cdot \bar{p}] \]
   is well-defined and it is a group isomorphism.

2. If $x_0 = x_1$, then the map $p_*$ is just conjugation by $[p] \in \pi_1(X, x_0)$, i.e. for any $g \in \pi_1(X, x_0) = \pi_1(X, x_1)$ we have
   \[ p_*(g) = [p] \cdot g \cdot [p]^{-1} \in \pi_1(X, x_0). \]

3. If $q: [0, 1] \to X$ is a path from $x_1$ to another point $x_2$, then
   \[ (p \cdot q)_* = p_* \circ q_*: \pi_1(X, x_2) \to \pi_1(X, x_0). \]

4. If $\pi_1(X, x_0)$ is abelian, then for any two paths $p, q: [0, 1] \to X$ from $x_0$ to $x_1$ we have
   \[ p_* = q_*: \pi_1(X, x_1) \to \pi_1(X, x_0). \]

5. If $f: X \to Y$ is a map to another topological space, then the following diagram commutes:
   \[
   \begin{CD}
   \pi_1(X, x_0) @> p_* >> \pi_1(X, x_1) \\
   @V f_* VV @V f_* VV \\
   \pi_1(Y, f(x_0)) @> (f \circ p)_* >> \pi_1(Y, f(x_1)).
   \end{CD}
   \]

Figure 303. Schematic sketch of Proposition 14.11 (1).

Proof (\(*\)). Let $X$ be a topological space and let $x_0$ and $x_1$ be two points in $X$ that are connected via a path $p: [0, 1] \to X$ from $x_0$ to $x_1$.

1. Let $\gamma$ be a loop in $(X, x_1)$. Then $p \cdot \gamma \cdot \bar{p}$ is evidently a loop in $(X, x_0)$. From Lemma 14.3 and Proposition 14.6 it follows that the path-homotopy class of $p \cdot \gamma \cdot \bar{p}$ depends only on the choice of the path-homotopy class of $\gamma$, i.e. the map
   \[ \Phi: \pi_1(X, x_1) \to \pi_1(X, x_0) \]
   \[ [\gamma] \mapsto [p \cdot \gamma \cdot \bar{p}] \]
   is well-defined. Furthermore for two loops $\gamma, \delta$ in $(X, x_1)$ we have
   \[ \Phi([\gamma]) \cdot \Phi([\delta]) = [p \cdot \gamma \cdot \bar{p}] \cdot [p \cdot \delta \cdot \bar{p}] = [p \cdot \gamma \cdot \bar{p} \cdot p \cdot \delta \cdot \bar{p}] = [p \cdot \gamma \cdot \bar{p} \cdot p \cdot \delta \cdot \bar{p}] = [p \cdot \gamma \cdot \bar{p} \cdot p \cdot \delta \cdot \bar{p}] = \Phi([\gamma \cdot \delta]). \]

   Proposition 14.6(3) and Lemma 14.3, Proposition 14.6(2) and Lemma 14.5.
Thus we have shown that Φ is a group homomorphism. Furthermore Φ is even a
group isomorphism, since an inverse map is given by

\[ \Psi : \pi_1(X, x_0) \to \pi_1(X, x_1) \]

\[ \delta \mapsto [\bar{p} \ast \delta \ast p] \].

(2),(3) These two statements follow basically immediately from the definitions.

(4) This statement is a straightforward consequence of (1), (2) and (3). We will provide
the proof in Exercise 14.3.

(5) This statement again follows immediately from the definitions.

We obtain the following corollary:

**Corollary 14.12.** Let X be a path-connected topological space and let \( x_0, x_1 \in X \). Then
the groups \( \pi_1(X, x_0) \) and \( \pi_1(X, x_1) \) are isomorphic.

**Example.** Let X be a star-shaped subset of \( \mathbb{R}^n \). Above we saw that there exists an \( x \in X \)
such that \( \pi_1(X, x) = 0 \). It now follows from Corollary 14.12 that \( \pi_1(X, y) = 0 \) for any
point \( y \in X \). Put differently, the fundamental group of every star-shaped subset of \( \mathbb{R}^n \)
with respect to any base point is trivial.

If X is a path-connected topological space, then Corollary 14.12 states that the iso-
morphism type of the fundamental group does not depend on the choice of the base
point. Sometimes we suppress the base point from the notation and we denote by \( \pi_1(X) \) the
isomorphism type of the fundamental group.

**Definition.** Let X be a non-empty path-connected topological space. If \( \pi_1(X) = 0 \) then
we say that X is *simply connected*.

The following lemma will be proved in Exercise 14.2.

**Lemma 14.13.** Let X be a topological space and let \( P, Q \) be two points in X. If X is
simply connected, then any two paths from \( P \) to \( Q \) are path-homotopic.

We already saw on page 1468 that \( \mathbb{R}^n \) and more generally, all star-shaped subsets of \( \mathbb{R}^n \)
are simply connected. The following statement is much more interesting:

**Proposition 14.14.** For any \( n \geq 2 \) the sphere \( S^n \) is simply connected.

In the proof of Proposition 14.14 we will need the following lemma.

**Lemma 14.15.** For any \( P \in S^n \) the topological space \( S^n \setminus \{P\} \) is simply connected.

**Proof.** In Lemma 2.44 we showed that there exists a homeomorphism \( f : S^n \to \mathbb{R}^n \cup \{\infty\} \).
We set \( Q := f^{-1}(\infty) \). Thus \( f \) restricts to homeomorphism \( f : S^n \setminus \{Q\} \to \mathbb{R}^n \).
Now let P be any other point on \( S^n \). There exists a homeomorphism \( g : S^n \to S^n \) with \( g(P) = Q \).

---

222 Why is \( \Phi \circ \Psi \) the identity on \( \pi_1(X, x_0) \) and why is \( \Psi \circ \Phi \) the identity on \( \pi_1(X, x_1) \)?

223 Since X is a path-connected topological space it is irrelevant which base point we consider.

224 It is straightforward to see that for subsets of \( \mathbb{C} \) we obtain the same notion of “simply connectedness”
as on page 1457.

225 The existence of the homeomorphism follows from Proposition 8.29. But one can also easily give an
elementary proof of that fact. More precisely, using basic facts from linear algebra one can show that there
Then \( f \circ g : S^n \to \mathbb{R}^n \cup \{\infty\} \) restricts to a homeomorphism \( S^n \setminus \{P\} \to \mathbb{R}^n \). But \( \mathbb{R}^n \) is simply connected, hence \( S^n \setminus \{P\} \) is also simply connected. 

Now we can turn to the proof of Proposition \[14.14\].

**Proof of Proposition \[14.14\].**

Here is a very short “proof”: Let \( x_0 \in S^n \) and let \( \gamma : [0, 1] \to S^n \) be a loop in \( x_0 \). We have to show that \( \gamma \) is null-homotopic. We pick a point \( P \) that does not lie in the image of \( \gamma \). By Lemma \[14.15\] the topological space \( S^n \setminus \{P\} \) is simply connected, hence \( \gamma \) is null-homotopic in \( S^n \setminus \{P\} \), in particular it is null-homotopic in \( S^n \).

This sounds convincing, except for one crucial gap: we did not justify why there exists a point \( P \) that does not lie in the image of \( \gamma \). In fact, as we saw in Proposition \[2.60\] such a point does not need to exist since there are surjective maps from an interval to any \( S^n \).

We write
\[
N := (0, \ldots, 0, 1) \quad \text{“North Pole” and } U := S^n \setminus \{N\},
\]
and also
\[
S := (0, \ldots, 0, -1) \quad \text{South Pole and } V := S^n \setminus \{S\}.
\]

We fix a base point \( x_0 \) on \( S^n \) that is neither \( N \) nor \( S \). By Lemma \[14.15\] it suffices to show that any loop in \((S^n, x_0)\) is path-homotopic to a loop in \( U = S^n \setminus \{N\} \).

So let \( \gamma \) be a loop in \((S^n, x_0)\).

**Claim.** There exists a subdivision
\[
0 = t_0 < t_1 < \ldots < t_{k-1} < t_k = 1,
\]
such that the following hold:

1. For each \( i \in \{0, \ldots, k-1\} \) we have \( \gamma([t_i, t_{i+1}]) \subset U \) or \( \gamma([t_i, t_{i+1}]) \subset V \), and
2. For each \( i \in \{1, \ldots, k-1\} \) we have \( \gamma(t_i) \neq N \) and \( \gamma(t_i) \neq S \).

By Corollary \[2.76\] applied to \( \gamma : [0, 1] \to S^n \) and \( S^n = U \cup V \) there exists a \( k \) such that for any \( i \in \{0, \ldots, k-1\} \) the image \( \gamma([\frac{i}{k}, \frac{i+1}{k}]) \) lies in \( U \) or in \( V \). In particular the subdivision \( t_i = \frac{i}{k} \), \( i = 0, \ldots, k \) satisfies condition (1).

Now suppose that there exists an \( i \in \{1, \ldots, k-1\} \) with \( \gamma(t_i) = N \). Then neither \( \gamma([t_{i-1}, t_i]) \) nor \( \gamma([t_i, t_{i+1}]) \) can be contained in \( U = S^n \setminus \{N\} \). So by (1) both have to be contained in \( V \), in particular we have \( \gamma([t_{i-1}, t_{i+1}]) \subset V \). But then we can remove \( t_i \) from the subdivision. Iterating this process we can assume that for each every \( i \) we have \( \gamma(t_i) \neq N \). Similarly we can arrange for every \( i \) we have \( \gamma(t_i) \neq S \). 

As mentioned before, by Lemma \[14.15\] it now suffices to prove the following claim.

**Claim.** The loop \( \gamma : [0, 1] \to S^n \) in \((S^n, x_0)\) is path-homotopic to a path that does not hit the North Pole \( N \).

exists an orthogonal matrix \( A \) with \( A \cdot P = Q \). Then the map \( g : S^n \to S^n \) that is given by multiplication by \( A \) has the desired property.
We pick a subdivision as in the previous claim. Suppose there exists an \( i \in \{0, \ldots, k-1\} \) such that \( \gamma([t_i, t_{i+1}]) \) hits \( N \). By the choice of our subdivision we know that \( \gamma([t_i, t_{i+1}]) \) lies entirely in \( V = S^n \setminus \{S\} \). Since \( S^n \setminus \{N, S\} \) is path-connected and since \( \gamma(t_i) \neq N, S, \gamma(t_{i+1}) \neq N, S \) we can pick a path \( \delta: [t_i, t_{i+1}] \to U \cap V = S^n \setminus \{N, S\} \) that connects \( \gamma(t_i) \) and \( \gamma(t_{i+1}) \). Since the paths \( \gamma|[t_i, t_{i+1}] \) and \( \delta \) both lie in the simply connected set \( V = S^n \setminus \{S\} \) they are path-homotopic by Lemma \[14.13\]. In the loop \( \gamma \) we now replace \( \gamma([t_i, t_{i+1}]) \) by \( \delta \). We obtain a new loop that is path-homotopic to the original loop and that does not hit \( N \) on the interval \([t_i, t_{i+1}]\). Iterating this procedure gives us the desired path-homotopy to a loop that does not hit \( N \).

\[\square\]

**Exercises for Chapter 14**

**Exercise 14.1.** Consider the torus \( T = S^1 \times S^1 \) and consider the loop
\[
[0, 1]/0 \sim 1 \to T = S^1 \times S^1 \\
t \mapsto (e^{2\pi it}, 1).
\]
Is the loop null-homotopic? If yes, provide a path-homotopy to a constant path. If not, show that the path is not null-homotopic.

**Exercise 14.2.** Let \( X \) be a topological space and let \( P, Q \) be two points in \( X \). We suppose that \( X \) is simply connected. Show that any two paths from \( P \) to \( Q \) are path-homotopic.

**Exercise 14.3.** Let \( X \) be a topological space and let \( x_0 \) and \( x_1 \) be two points in \( X \). Furthermore let \( p, q: [0, 1] \to X \) be two paths from \( x_0 \) to \( x_1 \). We suppose that \( \pi_1(X, x_0) \) is abelian. Show that \( p_* = q_*: \pi_1(X, x_1) \to \pi_1(X, x_0) \).

**Exercise 14.4.**

(a) Let \( f: X \to Y \) be a surjective map of topological spaces and let \( x \in X \). Is the induced map \( f_*: \pi_1(X, x) \to \pi_1(Y, f(x)) \) necessarily an epimorphism?

(b) Let \( f: X \to Y \) be an injective map of topological spaces and let \( x \in X \). Is the induced map \( f_*: \pi_1(X, x) \to \pi_1(Y, f(x)) \) necessarily a monomorphism?

\[\text{We know it lies in } U \text{ or } V, \text{ but since it hits } N \text{ it cannot lie in } U.\]

\[\text{Where did we use in the proof that } n \geq 2?\]
Exercise 14.5. Given a group \( \pi \) we define its \textit{automorphism group} \( \text{Aut}(\pi) \) as the group of all self-isomorphisms of \( \pi \). We define the \textit{inner automorphism group} as

\[
\text{Inn}(\pi) := \{ \varphi \in \text{Aut}(\pi) \mid \text{there exists an } h \in \pi \text{ such that } \varphi(g) = hgh^{-1} \text{ for all } g \in G \}.
\]

One can easily verify that \( \text{Inn}(\pi) \) is a normal subgroup of \( \text{Aut}(\pi) \). Thus we can define the \textit{outer automorphism group} to be the group

\[
\text{Out}(\pi) := \text{Aut}(\pi)/\text{Inn}(\pi).
\]

Now let \( X \) be a path-connected topological space, let \( x_0 \in X \) and let \( n \in \mathbb{N} \).

(a) Show that the map

\[
\Theta: \text{Homeo}(X) \rightarrow \text{Out}(\pi_1(X, x_0))
\]

\[
(f: X \rightarrow X) \mapsto (\pi_1(X, x_0) \xrightarrow{\gamma} \pi_1(X, f(x_0)) \xrightarrow{\gamma} \pi_1(X, x_0))
\]

pick any path \( \gamma \) from \( x_0 \) to \( f(x_0) \) and consider the corresponding isomorphism given by Proposition 14.11 is well-defined, i.e. independent of the choice of the paths.

(b) Show that \( \Theta: \text{Homeo}(X) \rightarrow \text{Out}(\pi_1(X, x_0)) \) is a group homomorphism.
15. Categories, functors and natural transformations

In this section we introduce the notion of a category, of a functor and of a natural transformation that many readers will already have encountered in different courses. These notions might initially appear to be rather abstract, but they play an essential role in algebraic topology and they are regularly used in all branches of pure mathematics.

15.1. Definition and examples of categories.

**Definition.** A category $\mathcal{C}$ consists of the following data:

1. A class $\text{Ob}(\mathcal{C})$ of mathematical objects which are called the objects of the category,
2. for each pair $(X,Y)$ of objects there exists a set $\text{Mor}_\mathcal{C}(X,Y)$ of morphisms $\text{Mor}_\mathcal{C}(X,Y)$,
3. for any three objects $X,Y$ and $Z$ there exists a map

$$\text{Mor}_\mathcal{C}(X,Y) \times \text{Mor}_\mathcal{C}(Y,Z) \to \text{Mor}_\mathcal{C}(X,Z), \quad (f,g) \mapsto g \circ f,$$

that satisfies the following axioms:

(A) (associativity): For every $f \in \text{Mor}_\mathcal{C}(W,X), g \in \text{Mor}_\mathcal{C}(X,Y)$ and $h \in \text{Mor}_\mathcal{C}(Y,Z)$ we have

$$(h \circ g) \circ f = h \circ (g \circ f) \in \text{Mor}_\mathcal{C}(W,Z).$$

(B) (identity): For every object $X$ there exists a morphism $\text{id}_X \in \text{Mor}_\mathcal{C}(X,X)$ with the property that

$$\text{id}_X \circ f = f \quad \text{for all } f \in \text{Mor}_\mathcal{C}(Z,X), \quad \text{and} \quad f \circ \text{id}_X = f \quad \text{for all } f \in \text{Mor}_\mathcal{C}(X,Y).$$

We adopt the following (naming) conventions:

(a) If the category is clear from the context, then we just write $\text{Mor}(X,Y)$ instead of $\text{Mor}_\mathcal{C}(X,Y)$.

(b) We say a morphism $\varphi \in \text{Mor}_\mathcal{C}(X,Y)$ is a morphism from $X$ to $Y$.

In the following we introduce all kinds of categories. Many of those will be faithful companions throughout these notes.

**Definition.**

228 As many “working mathematicians” the author has a slightly guilty conscience for not knowing what a “set” and what a “class” is. Therefore the reader is referred to \textbf{[Cie97, FPr85]} for details. Truth be told, most mathematicians learn from logicians at some point when to say “class” instead of “set”, but many mathematicians do not know exactly what they are doing at that point.

229 One could ask why $\text{Mor}_\mathcal{C}(X,Y)$ has to be a set, why not just a class? To the best of my knowledge the axioms on morphisms that we write down also make sense if $\text{Mor}_\mathcal{C}(X,Y)$ is only required to be a class. Here’s a long discussion which gives a satisfactory answer to people in category theory:

\texttt{http://mathoverflow.net/questions/48810/why-need-the-morphisms-to-form-a-set}

I myself do not understand the answer.
(a) We refer to the category $\text{Set}$ with
\[
\text{Ob}(\text{Set}) := \text{all sets}, \\
\text{Mor}(X,Y) := \text{all maps from } X \text{ to } Y,
\]

together with the usual composition of maps the category of sets.

(b) Let $\mathbb{K}$ be a field. We refer to the category $\text{Vec}_{\mathbb{K}}$ with
\[
\text{Ob}(\text{Vec}_{\mathbb{K}}) := \text{all } \mathbb{K}\text{-vector spaces}, \\
\text{Mor}(X,Y) := \text{Hom}_{\mathbb{K}}(X,Y) = \text{all } \mathbb{K}\text{-homomorphisms from } X \text{ to } Y,
\]

with the usual composition of homomorphisms as the category of $\mathbb{K}$-vector spaces.

(c) We refer to the category $\text{Gr}$ with
\[
\text{Ob}(\text{Gr}) := \text{all groups}, \\
\text{Mor}(X,Y) := \text{Hom}(X,Y) = \text{all group homomorphisms from } X \text{ to } Y,
\]

with the usual composition of group homomorphisms as the category of groups.

(d) We refer to the category $\text{AbGr}$ with
\[
\text{Ob}(\text{AbGr}) := \text{all abelian groups}, \\
\text{Mor}(X,Y) := \text{Hom}(X,Y) = \text{all group homomorphisms from } X \text{ to } Y,
\]

with the usual composition of group homomorphisms as the category of abelian groups.

(e) We refer to the category $\text{Ring}$ with
\[
\text{Ob}(\text{Ring}) := \text{all rings}, \\
\text{Mor}(R,S) := \text{Hom}(R,S) = \text{all ring homomorphisms from } R \text{ to } S,
\]

with the usual composition of ring homomorphisms as the category of rings. Similarly we define the category $\text{CRing}$ of commutative rings.

(f) We refer to the category $\text{Top}$ with
\[
\text{Ob}(\text{Top}) := \text{all topological spaces}, \\
\text{Mor}(X,Y) := C(X,Y) := \text{all continuous maps from } X \text{ to } Y,
\]

with the usual composition of maps as the category of topological spaces. A pointed topological space is a pair $(X,x_0)$, where $X$ is a topological space and $x_0$ is a point in $X$. We refer to the category $\text{PTop}$ with
\[
\text{Ob}(\text{PTop}) := \text{all pointed topological spaces}, \\
\text{Mor}((X,x_0),(Y,y_0)) := \text{all continuous maps } f \text{ from } X \text{ to } Y \text{ with } f(x_0) = y_0
\]

with the usual composition of maps as the category of pointed topological spaces.

(g) We refer to the category $\text{TopGr}$ with
\[
\text{Ob}(\text{TopGr}) := \text{all topological groups}, \\
\text{Mor}(X,Y) := \text{all homomorphisms from } X \text{ to } Y \text{ that are continuous},
\]

with the usual composition of maps as the category of topological groups.
(h) We refer to the category $\text{SmMfd}$ with

$$\text{Ob}(\text{SmMfd}) := \text{all smooth manifolds},$$

$$\text{Mor}(X,Y) := \text{all smooth maps from } X \text{ to } Y,$$

with the usual composition of maps as the category of smooth manifolds. We define the category $\text{pSmMfd}$ of pointed smooth manifolds the same way as we defined the category of pointed topological spaces. Finally we refer to the category $\text{OrSmMfd}$ with

$$\text{Ob}(\text{OrSmMfd}) := \text{all oriented smooth manifolds},$$

$$\text{Mor}(X,Y) := \text{all orientation-preserving diffeomorphisms from } X \text{ to } Y,$$

with the usual composition of maps as the category of oriented smooth manifolds.

(i) A pair of topological spaces is a pair $(X,A)$, where $X$ is a topological space and $A$ is a subset of $X$. We refer to the category $\text{PairTop}$ with

$$\text{Ob}(\text{PairTop}) := \text{all pairs of topological spaces},$$

$$\text{Mor}((X,A),(Y,B)) := \text{all continuous maps } f \text{ from } X \text{ to } Y \text{ with } f(A) \subset B$$

with the usual composition of maps as the category of pairs of topological spaces.

(j) Let $G = (V,E,i: E \rightarrow V,t: E \rightarrow V)$ and $G' = (V',E',i': E' \rightarrow V',t': E' \rightarrow V')$ be two abstract graphs in the sense of the definition on page 221. We define a map $G \rightarrow G'$ of abstract graphs to be a pair $(\alpha: V \rightarrow V', \beta: E \rightarrow E')$ of maps such that for each $e \in E$ we have $i'(\beta(e)) = \alpha(i(e))$ and $t'(\beta(e)) = \alpha(t(e))$. We refer to the category $\text{AbsGraph}$ with

$$\text{Ob}(\text{AbsGraph}) := \text{all abstract graphs},$$

$$\text{Mor}(G,G') := \text{all maps from } G \text{ to } G' \text{ in the above sense}$$

with the usual composition of maps as the category of abstract graphs. Similarly, we consider the closely related setup of undirected abstract graphs which we introduced on page 226. We define a map $G \rightarrow G'$ between two undirected abstract graphs $G = (V,E,\varphi: E \rightarrow \mathcal{P}(V))$ and $G' = (V',E',\varphi': E' \rightarrow \mathcal{P}(V'))$ to be a pair $(\alpha: V \rightarrow V', \beta: E \rightarrow E')$ of maps such that for every $e \in E$ we have the equality $\varphi'(\beta(e)) = \alpha(\varphi(e))$. We refer to the category $\text{UndirAbsGraph}$ with

$$\text{Ob}(\text{UndirAbsGraph}) := \text{all undirected abstract graphs},$$

$$\text{Mor}(G,G') := \text{all maps from } G \text{ to } G' \text{ in the above sense}$$

with the usual composition of maps as the category of undirected abstract graphs.

The name “morphisms” suggests that morphisms are necessarily maps. But as we will see in the following two examples, this is not necessarily always the case.

Example.

(k) We consider the category $\mathcal{C}$ with

$$\text{Ob}(\mathcal{C}) := \text{all sets},$$

$$\text{Mor}(X,Y) := \begin{cases} \{\text{id}_X\}, & \text{if } X = Y \\ \emptyset, & \text{if } X \neq Y. \end{cases}$$

\footnote{We refer to page 81 for our definition of a ring.}
The composition map only needs to be defined if \( X = Y = Z \)\(^{231}\), and in this case we define \( \text{id}_X \circ \text{id}_X := \text{id}_X \). One can easily convince oneself that this defines a category.

1. Let \( G \) be an arbitrary group. We consider

\[
\begin{align*}
\text{Ob}(C) & := \{ \text{a set with a unique element } * \}, \\
\text{Mor}(*,*) & := G.
\end{align*}
\]

We define

\[
\begin{align*}
\text{Mor}(*,*) \times \text{Mor}(*,*) & \rightarrow \text{Mor}(*,*) \\
(f,g) & \mapsto g \circ f := gf
\end{align*}
\]

via the group structure on \( \text{Mor}(*,*) = G \). The axioms of a category can be easily deduced from the group axioms of \( G \).

**Convention.** If the category we are working with at a given moment is understood, then we just write “map” instead of “morphisms”. For example we might write “let \( f : X \rightarrow Y \) be a map”, if \( X \) and \( Y \) are groups, then it is understood that the map is in fact a homomorphism, whereas if \( X \) and \( Y \) are topological spaces, then it is understood that \( f \) is continuous. This convention thus generalizes the convention that we introduced on page 115.

The following definition is almost self-explanatory.

**Definition.** Let \( C \) be a category. A **subcategory** is a category \( D \) such that \( \text{Ob}(D) \subset \text{Ob}(C) \) and such that for each \( X,Y \in \text{Ob}(D) \) we have \( \text{Mor}_D(X,Y) \subset \text{Mor}_C(X,Y) \). We say \( D \) is a **full subcategory** if for each \( X,Y \in \text{Ob}(D) \) we have \( \text{Mor}_D(X,Y) = \text{Mor}_C(X,Y) \).

**Examples.**

1. The category \( \mathcal{A}b\mathcal{G}r \) of abelian groups is a full subcategory of the category of groups \( \mathcal{G}r \).
2. The category \( \mathcal{V}ec_\mathbb{R} \) of \( \mathbb{R} \)-vector spaces is a subcategory of the category \( \mathcal{A}b\mathcal{G}r \) of abelian groups, but it is not a full subcategory.

We conclude this introduction with the following definition and a short discussion thereof.

**Definition.** Let \( C \) be a category.

1. In the following we call a morphism \( F \in \text{Mor}_C(X,Y) \) **invertible** if there exists a morphism \( G \in \text{Mor}_C(Y,X) \) such that \( F \circ G = \text{id}_Y \) and \( G \circ F = \text{id}_X \). Sometimes we refer to invertible morphisms also as **isomorphisms**.
2. We denote by \( \text{Mor}_C(X,Y)_{\text{inv}} \) the set of all invertible morphisms.

**Examples.**

1. In the category of topological spaces the invertible morphisms are precisely the homeomorphisms.
2. In the category of smooth manifolds the invertible morphisms are precisely the diffeomorphisms.
3. In the category considered in (k) every morphism is an isomorphism.

We leave it to the reader to prove the following elementary lemma.

\(^{231}\)If \( X \neq Y \) then \( \text{Mor}(X,Y) = \emptyset \), but then \( \text{Mor}(X,Y) \times \text{Mor}(Y,Z) \) is also the empty set for any \( Z \).
Lemma 15.1. Let $C$ be a category. If $f \in \text{Mor}_C(X,Y)$ is an invertible morphism, then for any $Z \in \text{Ob}(C)$ the maps

$$
\begin{align*}
\text{Mor}_C(Y,Z) & \to \text{Mor}_C(X,Z) \\
g & \mapsto g \circ f
\end{align*}
$$

and

$$
\begin{align*}
\text{Mor}_C(Z,X) & \to \text{Mor}_C(Z,Y) \\
g & \mapsto f \circ g
\end{align*}
$$

are bijections.

15.2. Functors. In this section we introduce the notions of covariant and contravariant functors.

Definition. Let $C$ and $D$ be two categories. A covariant functor $F : C \to D$ consists of a map

$$
F : \text{Ob}(C) \to \text{Ob}(D)
$$

and for all $X,Y \in C$ there exists furthermore a map

$$
F : \text{Mor}_C(X,Y) \to \text{Mor}_D(F(X),F(Y)),
$$

such that the following axioms are satisfied

(F1) $F(\text{id}_X) = \text{id}_{F(X)}$ for all $X \in \text{Ob}(C)$,

(F2) for $\phi \in \text{Mor}_C(X,Y)$ and $\psi \in \text{Mor}_C(Y,Z)$ the following equality holds

$$
F(\psi \circ \phi) = F(\psi) \circ F(\phi) \in \text{Mor}_D(F(X),F(Z)).
$$

Convention. For a covariant functor $F$ and $\phi \in \text{Mor}_C(X,Y)$ we often write $\phi_*$ instead of $F(\phi)$. The second axiom then becomes $(\psi \circ \phi)_* = \psi_* \circ \phi_*$. Now we give some examples of functors.

Examples.

1. As above let $\mathcal{V}_\mathbb{R}$ be the category of real vector spaces and let $W$ be a real vector space. Then the map

$$
F : \text{Ob}(\mathcal{V}_\mathbb{R}) \to \text{Ob}(\mathcal{V}_\mathbb{R}) \\
V \mapsto \text{Hom}_\mathbb{R}(W,V),
$$

together with the maps

$$
\begin{align*}
\text{Mor}_{\mathcal{V}_\mathbb{R}}(U,V) & \to \text{Mor}_{\mathcal{V}_\mathbb{R}}(F(U),F(V)) \\
(\phi : U \to V) & \mapsto \left( \begin{array}{ll}
\text{Hom}_\mathbb{R}(W,U) & \to \text{Hom}_\mathbb{R}(W,V) \\
f & \mapsto \phi \circ f
\end{array} \right)
\end{align*}
$$

defines a covariant functor.

2. Let $\mathcal{P}smMfd$ be the category of pointed smooth manifolds and let $\mathcal{V}_\mathbb{R}$ be the category of real vector spaces. By Proposition 6.37 (2) we know that the map

$$
F : \text{Ob}(\mathcal{P}smMfd) \to \text{Ob}(\mathcal{V}_\mathbb{R}) \\
(M,P) \mapsto T_PM,
$$

together with the maps

$$
\begin{align*}
\text{Mor}_P((M,P),(N,Q)) & \to \text{Mor}_{\mathcal{V}_\mathbb{R}}(T_PM,T_QN) \\
f & \mapsto f_* = Df_P
\end{align*}
$$

is a covariant functor from the category of pointed smooth manifolds to the category of real vector spaces.
(3) Let $\mathsf{Top}$ be the category of topological spaces and let $X \in \text{Ob}(\mathsf{Top})$. It follows easily from Lemma 3.8 (2b) that the map

$$F: \text{Ob}(\mathsf{Top}) \rightarrow \text{Ob}(\mathsf{Top})$$

$$Y \mapsto X \times Y,$$

together with the maps

$$\text{Mor}_{\mathsf{Top}}(Y, Z) \rightarrow \text{Mor}_{\mathsf{Top}}(X \times Y, X \times Z)$$

$$f \mapsto \text{id}_X \times f$$

is a covariant functor from the category $\mathsf{Top}$ of topological spaces to itself.

(4) Let $\mathsf{Top}$ be the category of topological spaces and let $\mathsf{Set}$ be the category of sets. It follows easily from Lemma 2.70 that the map

$$F: \text{Ob}(\mathsf{Top}) \rightarrow \text{Ob}(\mathsf{Set})$$

$$X \mapsto \pi_0(X),$$

together with the maps

$$\text{Mor}_{\mathsf{Top}}(X, Y) \rightarrow \text{Mor}_{\mathsf{Set}}(\pi_0(X), \pi_0(Y))$$

$$f \mapsto \left( \begin{array}{cc} \pi_0(X) & \pi_0(Y) \\ C & f(C) \end{array} \right)$$

is a covariant functor from the category of topological spaces to the category of sets.

(5) Let $\mathsf{AbsGraph}$ be the category of abstract graphs and let $\mathsf{UndirAbsGraph}$ be the category of undirected abstract graphs. It follows easily from the definitions that the map

$$F: \text{Ob}(\mathsf{AbsGraph}) \rightarrow \text{Ob}(\mathsf{UndirAbsGraph})$$

$$(V, E, i: E \rightarrow V, t: E \rightarrow V) \mapsto \left( \begin{array}{ccc} V, E & \rightarrow & \mathcal{P}(V) \\ e & \mapsto & \{i(e), t(e)\} \end{array} \right)$$

together with the hopefully maps from the morphisms in $\mathsf{AbsGraph}$ to the morphisms in $\mathsf{UndirAbsGraph}$ is a covariant functor from the category $\mathsf{AbsGraph}$ of abstract graphs to the category $\mathsf{UndirAbsGraph}$ of undirected abstract graphs. We make the following two comments:

(a) The reader will surely remember that implicitly we studied this functor in Lemma 4.4. There, given an abstract graph $G$ we gave an explicit homeomorphism $|G| \rightarrow |F(G)|$ between the topological realization of the abstract graph $G$ and the topological realization of the undirected abstract graph $F(G)$.

(b) It follows from the Axiom of Choice that given any undirected abstract graph $G$ there exists an $G'$ with $F(G') = G$.

(6) Let $\mathsf{OrSmMfd}$ be the category of oriented smooth manifolds. The map

$$\text{Ob}(\mathsf{OrSmMfd}) \rightarrow \text{Ob}(\mathsf{OrSmMfd})$$

$$M \mapsto \partial M \text{ equipped with the orientation from Lemma 6.50}$$

together with the maps

$$\text{Mor}_{\mathsf{OrSmMfd}}(M, N) \mapsto \text{Mor}_{\mathsf{OrSmMfd}}(\partial M, \partial N)$$

$$(f: M \rightarrow N) \mapsto (f|_{\partial M}: \partial M \rightarrow \partial N)$$

is a covariant functor.
We state our next example as a lemma.

**Lemma 15.2.** The following two statements hold:

1. Let $G = (V, E, i, t)$ and $G' = (V', E', i', t')$ be two abstract graphs. Furthermore let $f := (\alpha: V \to V', \beta: E \to E')$ be a map between the two abstract graphs. Recall that, by the definition on page 477, this means that for each $e \in E$ we have the equalities $i'(\beta(e)) = \alpha(i(e))$ and $t'(\beta(e)) = \alpha(t(e))$. Now we consider the following map between the topological realizations of $G$ and $G'$:

$$ |f|: |G| = (V \sqcup (E \times [0, 1])) / \sim \to |G'| = (V' \sqcup (E' \times [0, 1])) / \sim $$

$$ [x] \mapsto \begin{cases} 
\alpha(x), & \text{if } x \in V, \\
(\beta(e), t), & \text{if } x = (e, t) \in E \times [0, 1]. 
\end{cases} $$

This map $|f|: |G| \to |G'|$ is well-defined and continuous.

2. The map

$$ F: \text{Ob}(\text{AbsGraph}) \to \text{Ob}(\text{Top}) $$

$$ G \mapsto |G|, $$

**Proof.**

1. It follows almost immediately from the definitions that the map is well-defined. We leave it to the reader to verify, e.g. using Lemma 3.28, that the map is continuous.

2. This statement follows easily from the definitions. 

We formulate our last example also as a lemma.

**Lemma 15.3.** Let $\mathcal{D}$ be a category and let Set be the category of sets. Furthermore let $W \in \text{Ob}(\mathcal{D})$. The map

$$ F: \text{Ob}(\mathcal{D}) \to \text{Ob}(\text{Set}) $$

$$ X \mapsto \text{Mor}_\mathcal{D}(W, X) $$

**Proof.** The statement follows easily from the axioms of a category.
Definition. Let $C$ and $D$ be two categories. A contravariant functor $F : C \to D$ consists of a map

$$F : \text{Ob}(C) \to \text{Ob}(D)$$

and for all $X, Y \in C$ there exists furthermore a map

$$\text{Mor}_C(X, Y) \to \text{Mor}_D(F(Y), F(X))$$

such that following axioms are satisfied:

(F1) $F(\text{id}_X) = \text{id}_{F(X)}$ for all $X \in \text{Ob}(C)$,

(F2) for any $\phi \in \text{Mor}_C(X, Y)$ and $\psi \in \text{Mor}_C(Y, Z)$ we have

$$F(\psi \circ \phi) = F(\phi) \circ F(\psi) \in \text{Mor}_D(F(Z), F(X)).$$

The definition of a contravariant functor looks very much the same as the definition of a covariant functor. The difference is that a contravariant functor “reverses the direction of maps” and the orders of $F(\psi)$ and $F(\phi)$ in the second axiom are swapped.

Convention. For a contravariant functor $F$ and $\phi \in \text{Mor}_C(X, Y)$ we often write $\phi^*$ instead of $F(\phi)$. The second axiom then becomes $(\psi \circ \phi)^* = \phi^* \circ \psi^*$.

Examples.

(1) Let $\mathcal{V}_{\mathbb{R}}$ be the category of real vector spaces. Then the map

$$F : \text{Ob}(\mathcal{V}_{\mathbb{R}}) \to \text{Ob}(\mathcal{V}_{\mathbb{R}})$$

$$V \mapsto V^* := \text{Hom}_\mathbb{R}(V, \mathbb{R}) =: \text{dual vector space of } V,$$

together with the maps

$$\text{Mor}_{\mathcal{V}_{\mathbb{R}}}(U, V) \to \text{Mor}_{\mathcal{V}_{\mathbb{R}}}(V^*, U^*)$$

$$(\phi : U \to V) \mapsto \left( \text{Hom}_\mathbb{R}(V, \mathbb{R}) \to \text{Hom}_\mathbb{R}(U, \mathbb{R}) \right) f \mapsto f \circ \phi$$

is a contravariant functor.

(2) Let $\text{Top}$ be the category of topological spaces and let $\mathcal{V}_{\mathbb{R}}$ be the category of real vector spaces. Then the map

$$F : \text{Ob}(\text{Top}) \to \text{Ob}(\mathcal{V}_{\mathbb{R}})$$

$$X \mapsto C(X, \mathbb{R}) := \text{set of continuous functions } X \to \mathbb{R},$$

together with the maps

$$\text{Mor}_{\text{Top}}(X, Y) \to \text{Mor}_{\mathcal{V}_{\mathbb{R}}}(C(Y, \mathbb{R}), C(X, \mathbb{R}))$$

$$(\phi : X \to Y) \mapsto \left( C(Y, \mathbb{R}) \to C(X, \mathbb{R}) \right) f \mapsto f \circ \phi$$

is a contravariant functor.

(3) Let $\text{SmMfd}$ be the category of smooth manifolds, let $\mathcal{V}_{\mathbb{R}}$ be the category of real vector spaces and let $k \in \mathbb{Z}_{\geq 0}$. In [BoT82, Chapter 2] or [Lee02, Corollary 17.3] it
is shown that the map

\[ F : \text{Ob}(\text{SmMfd}) \to \text{Ob}(\text{Vec}_R) \]

\[ M \mapsto H^k_{\text{dr}}(M) := k\text{-th de Rham cohomology group of } M, \]

together with the maps

\[ \text{Mor}_{\text{SmMfd}}(M, N) \to \text{Mor}_{\text{Vec}_R}(H^k_{\text{dr}}(N), H^k_{\text{dr}}(M)) \]

\[ (f : M \to N) \mapsto \left( f^* : H^k_{\text{dr}}(N) \to H^k_{\text{dr}}(M) \right) [\omega] \mapsto [f^*\omega] \]

is a contravariant functor.

Again we formulate our last example as a lemma.

**Lemma 15.4.** Let \( \mathcal{D} \) be a category and let \( \text{Set} \) be the category of sets. Furthermore let \( W \in \text{Ob}(\mathcal{D}) \). The map

\[ F : \text{Ob}(\mathcal{D}) \to \text{Ob}(\text{Set}) \]

\[ X \mapsto \text{Mor}_{\mathcal{D}}(X, W) \]

together with the maps

\[ \text{Mor}_{\mathcal{D}}(Y, Z) \to \text{Mor}_{\text{Set}}(\text{Mor}_{\mathcal{D}}(Z, W), \text{Mor}_{\mathcal{D}}(Y, W)) \]

\[ f \mapsto \left( \text{Mor}_{\mathcal{D}}(Z, W) \to \text{Mor}_{\mathcal{D}}(Y, W) \right) g \mapsto g \circ f \]

is a contravariant functor.

**Proof.** Again the statement follows easily from the axioms of a category. \( \blacksquare \)

We will not see any other examples of contravariant functors in the near future. We will come back to them when we will study cohomology groups.

We conclude this section with the following basically obvious lemma.

**Lemma 15.5.** Every functor (regardless of whether it is covariant or contravariant) sends invertible morphisms to invertible morphisms.

15.3. The fundamental group as functor. Now, after recalling the definition of categories and functors, we turn back to the study of fundamental groups.

Let \( f : X \to Y \) be a map between topological spaces and let \( x_0 \in X \) be a base point. If \( \gamma : [0, 1] \to X \) is a loop in the point \( x_0 \), then \( f \circ \gamma : [0, 1] \to Y \) is a loop in the point \( f(x_0) \). It is straightforward to see that

\[ f_* : \pi_1(X, x_0) \to \pi_1(Y, f(x_0)) \]

\[ [\gamma] \mapsto [f \circ \gamma] \]

is a well-defined map, i.e. \( f_*([\gamma]) \) is independent of the choice of the representative of the path-homotopy class.\(^{232}\) Furthermore it follows easily from the definitions\(^{233}\) that \( f_* \) is a

---

\(^{232}\) Indeed, suppose that \( \gamma \) and \( \delta \) are two loops in \((X, x_0)\) that are path-homotopic. Let \( F \) be a path-homotopy between \( \gamma \) and \( \delta \). Then \( f \circ F \) is a path-homotopy between \( f \circ \gamma \) and \( f \circ \delta \). We had used almost the same argument on page \( 461 \).

\(^{233}\) If \( \gamma \) and \( \delta \) are loops in \( x_0 \), then it follows immediately from the definitions that \( (f \circ \gamma) \ast (f \circ \delta) = f \circ (\gamma \ast \delta) \).
group homomorphism. We call $f_*$ the induced map. It also follows easily from the definitions that
\[(id_X)_* = \text{id}_{\pi_1(X,x_0)}, \quad \text{for all pointed pairs } (X,x_0),\]
\[(g \circ f)_* = g_* \circ f_* \quad \text{for all maps } f: (X,x_0) \to (Y,y_0) \text{ and } g: (Y,y_0) \to (Z,z_0).\]

Summarizing we just convinced ourselves of the validity of the following proposition.

**Proposition 15.6.** Let $\mathcal{PTop}$ be the category of pointed topological spaces and let $\mathcal{Gr}$ be the category of groups. Then the map
\[
\text{Ob}(\mathcal{PTop}) \to \text{Ob}(\mathcal{Gr})
\]
\[(X,x_0) \mapsto \pi_1(X,x_0)\]

together with the maps
\[
\text{Mor}((X,x_0),(Y,y_0)) \to \text{Mor}(\pi_1(X,x_0),\pi_1(Y,y_0))
\]
\[(f: (X,x_0) \to (Y,y_0)) \mapsto \left( f_*: \pi_1(X,x_0) \to \pi_1(Y,y_0) \right)\]
is a covariant functor.

Next we will see that the functoriality of the fundamental groups can be helpful for studying certain questions.

**Definition.** Let $X$ be a topological space and let $A \subset X$ be a subspace. We say $A$ is a retract of $X$ if there exists a retraction $r: X \to A$, i.e. a map with $r(a) = a$ for all $a \in A$.

**Examples.**

1. Let $X$ be a topological space. Then any point $x_0 \in X$ is a retract of $X$, indeed, the map $r(x) = x_0$ for $x \in X$ is a retraction.
2. The circle $S^1 \times \{1\}$ is a retract of the torus $S^1 \times S^1$, in fact a retraction is given by $r(z,w) = (z,1)$.
3. The circle $S^1$ is a retract of $B^2 \setminus \{(0,0)\}$, indeed, the map
\[
B^2 \setminus \{(0,0)\} \to S^1
\]
\[z \mapsto \frac{z}{|z|}\]
is a retraction. (Here we consider $B^2$ as subset of $\mathbb{C}$.)
4. The set $S^0 = \{-1, 1\}$ is not a retract of $B^1 = [-1,1]$. Indeed, since $[-1,1]$ is connected and since $S^0$ is discrete it follows from Lemma 2.61 that any map from $[-1,1]$ to $S^0$ has to be constant. Thus there does not exist a map $f: [-1,1] \to S^0$ with $f(-1) = -1$ and $f(1) = 1$.
5. Finally we consider the knotted curve $C$ in the solid torus $\overline{B}^2 \times S^1$ that is shown in Figure 305. We invite the reader to think about the question whether or not $C$ is a retract of $\overline{B}^2 \times S^1$. We will answer the question in Section 119.3.

Now we can push the second-to-last example up by one dimension.

**Lemma 15.7.** The circle $S^1$ is not a retract of $\overline{B}^2$. 
Proof. We denote by \( i: S^1 \rightarrow \overline{B}^2 \) the inclusion map. Suppose there exists a retraction \( r: \overline{B}^2 \rightarrow S^1 \). By definition this means that \( r \circ i = \text{id}_{S^1} \). We obtain the following commutative diagram of maps between topological spaces

\[
\begin{array}{ccc}
B^2 & \xrightarrow{i} & S^1 \\
r \downarrow & & \downarrow r_{\text{oi}=\text{id}_{S^1}} \\
S^1 & \xrightarrow{(1)} & S^1
\end{array}
\]

which induces

\[
\begin{array}{ccc}
\pi_1(B^2,1) & \xrightarrow{i_*} & \pi_1(S^1,1) \\
r_* \downarrow & & \downarrow (r_{\text{oi}})_* = (1)_{S^1} \\
\pi_1(S^1,1) & \xrightarrow{(1)} & \pi_1(S^1,1)
\end{array}
\]

It follows from the functoriality of fundamental groups that \( r_* \circ i_* = (r_{\text{oi}})_* \), i.e. the diagram on the right-hand side commutes. By the functoriality we know that \((1)_{S^1}\)_* is the identity of \( \pi_1(S^1,1) \).

We saw on page 471 that \( \pi_1(B^2,1) \) is the trivial group whereas we saw in Corollary 14.9 that \( \pi_1(S^1,1) \) is not the trivial group. The lower horizontal map in the second diagram is thus an isomorphism of a non-trivial group, but the upper map factors through the trivial group, i.e. the composition of \( i_* \) and \( r_* \) cannot be an isomorphism of a non-trivial group. Thus we have obtained a contradiction.

The last example and the last lemma now raise the following question.

**Question 15.8.** Let \( n \geq 2 \). Is \( S^n \) a retract of \( \overline{B}^{n+1} \)?

At the moment we cannot answer this question. We will first need to develop new invariants before we can return to this question. We will not be able to answer this question for many months.

Almost exactly the same argument as in the proof of Lemma 15.7 gives a proof of the following lemma which we will prove in Exercise 15.3.

**Lemma 15.9.** Let \( X \) be a topological space and let \( A \subset X \) be a retract of \( X \). Let \( a \in A \). We denote by \( i: A \rightarrow X \) the inclusion map.

1. There exists an epimorphism \( \varphi: \pi_1(X,a) \rightarrow \pi_1(A,a) \) such that \( \varphi \circ i_* = \text{id} \) on \( \pi_1(A,a) \).
2. The inclusion induced map \( \pi_1(A,a) \rightarrow \pi_1(X,a) \) is a monomorphism.

**Example.** We had just seen on page 484 that the circle \( S^1 \times \{1\} \) is a retract of the torus \( S^1 \times S^1 \). Furthermore we saw in Corollary 14.9 that \( \pi_1(S^1,1) \) is not the trivial group. It follows from Lemma 15.9 that the fundamental group of the torus is also non-trivial. In

---

234 Why not?
Proposition \ref{14.14} we saw that $\pi_1(S^2) = 0$. Thus we see that the torus $S^1 \times S^1$ and the sphere $S^2$ are not homeomorphic.

**Lemma 15.10.\(^\star\)** Let $E_8$ be the regular octagon from the definition of the surface of genus 2, see page \pageref{205} for details, and let $\Sigma = E_8/\sim$ be the surface of genus 2. Let $P$ and $Q$ be two adjacent vertices of $E_8$. Then the following hold:

1. The map
   \[
   \gamma: S^1 \rightarrow E_8/\sim \\
   e^{2\pi it} \mapsto [t \cdot P + (1 - t) \cdot Q]
   \]
   is an embedding.

2. There exists a map $\Phi: E_8/\sim \rightarrow S^1 \times S^1$ such that the following diagram commutes
   \[
   \begin{array}{ccc}
   S^1 & \xrightarrow{\gamma} & E_8/\sim \\
   \downarrow{\Phi} & & \downarrow{\sim} \\
   S^1 \times S^1 & \xrightarrow{\sim} & E_8/\sim
   \end{array}
   \]

3. The subset $\gamma(S^1)$ is a retract of $\Sigma = E_8/\sim$.

4. There exists an epimorphism $\pi_1(\Sigma, P) \rightarrow \mathbb{Z}$ that sends $[\gamma]$ onto 1.\(^\ddagger\)

---

**Figure 306. Illustration of Lemma 15.10**

**Remark.** The lemma shows in particular that the four loops that we drew in Figure \ref{89} on the surface of genus 2 represent non-trivial elements in the fundamental group. Almost the same way one can show that in the surface of genus $g$, $g \geq 2$, defined as a quotient of a regular $4g$-gon, each edge gives rise to a non-trivial element of the fundamental group.

**Proof (\(^\star\)).**

1. It is clear that $\gamma$ is continuous and injective. By Proposition \ref{6.8} we know that $\Sigma = E_8/\sim$ is Hausdorff. It follows from Proposition \ref{2.43} (2) that $\gamma$ is a closed embedding.
2. The map $\Phi$ is sketched in Figure \ref{307} on the top. It is given by sending all points in the lower pentagon to a single point, such a map can be extended continuously to the upper pentagon in such a way that the remaining four sides of the upper pentagon

\(^\ddagger\)Recall that by the bijection on page \pageref{462} we view maps $f: S^1 \rightarrow \Sigma$ with $f(1) = P$ as elements in $\pi_1(\Sigma, P)$. 

get sent homeomorphically to the four sides of the square. This map $\Phi$ has the desired property.

(3) The retraction is now given by the concatenation of the maps

$$
\Sigma \xrightarrow{\Phi} S^1 \times S^1 \xrightarrow{(z,w)\mapsto z} S^1.
$$

(4) This statement is a consequence of (3), Lemma 15.9 and Corollary 14.9.

---

**Figure 307**

In many applications we will want to know whether a given map between topological spaces induces an isomorphism of fundamental groups. The following lemma says that in many settings the property of being an isomorphism is independent of the choice of base point.

**Proposition 15.11.** Let $\varphi: X \to Y$ be a map between topological spaces and let $x_0 \in X$.

1. If $\gamma: [0,1] \to X$ is a path from $x_0$ to some point $x_1$, then the following diagram commutes:

$$
\begin{array}{ccc}
\pi_1(X,x_1) & \xrightarrow{\gamma_*} & \pi_1(X,x_0) \\
\varphi_* & \cong & \varphi_* \\
\pi_1(Y,\varphi(x_1)) & \xrightarrow{(\varphi\circ\gamma)_*} & \pi_1(Y,\varphi(x_0)).
\end{array}
$$

---

\(^{236}\)It is clearly slightly painful to write down this map explicitly. It is easier to write down a similar map, which maps a square $X$ onto a triangle $Y$ in such a way that one side of the square gets sent to a vertex of the triangle and such that the remaining three sides of the square get sent to the three sides of the triangle. For example the map

$$
X := [0,1] \times [0,1] \to Y := \{(x,y) \in \mathbb{R}^2 \mid x \in [0,1], y \in [0,x]\}
$$

is of that form.

\(^{237}\)In the lower part of Figure 307 we illustrate the map for the surfaces viewed as subsets of $\mathbb{R}^3$. There the map $\Phi$ is given by crushing the right-hand half of the surface of genus 2 to a single point.
(2) If \( \varphi \colon \pi_1(X, x_0) \to \pi_1(Y, \varphi(x_0)) \) is an isomorphism (epimorphism, monomorphism) for some base point \( x_0 \in X \), then for any other base point \( x_1 \) in the same path component of \( X \) the map \( \varphi_\ast \colon \pi_1(X, x_1) \to \pi_1(Y, \varphi(x_1)) \) is also an isomorphism (epimorphism, monomorphism).

**Proof.**

(1) This statement follows immediately from the definitions.

(2) This statement follows from (1) and the fact that the horizontal maps are isomorphisms. ■

15.4. **Natural transformations.** In this last section we introduce the notion of a natural transformation between two functors. This notion will initially not play a major role, but once we introduce homology groups this notion will become increasingly important to state results precisely. As of right now we do not have enough functors at our hand to perhaps truly appreciate the value of the notion of a natural transformation.

After this long preambles, let us give the definition of natural transformations.

**Definition.** Let \( \mathcal{C} \) and \( \mathcal{D} \) be two categories and let \( F, G : \mathcal{C} \to \mathcal{D} \) be two covariant functors. A **natural transformation** between the functors \( F \) and \( G \) assigns to each \( X \in \text{Ob}(\mathcal{C}) \) a morphism \( \Phi_X : F(X) \to G(X) \) in \( \mathcal{D} \) such that for each morphism \( f : X \to Y \) in \( \mathcal{C} \) the following diagram commutes:

\[
\begin{array}{ccc}
F(X) & \xrightarrow{F(f)} & F(Y) \\
\Phi_X \downarrow & & \downarrow \Phi_Y \\
G(X) & \xrightarrow{G(f)} & G(Y).
\end{array}
\]

If for every \( X \in \text{Ob}(\mathcal{C}) \) the morphism \( \Phi_X : F(X) \to G(X) \) is an isomorphism, then we refer to the natural transformation as a **natural isomorphism**. Given \( X \in \text{Ob}(\mathcal{C}) \) we often say that \( F(X) \) and \( G(X) \) are **naturally isomorphic.**

The same way we can of course also define the notion of a natural transformation between two contravariant functors.

**Remark.** The notion of a natural transformation can also be summarized in the following diagram:

\[
\begin{array}{ccc}
F(X) & \xrightarrow{F_\ast(f)} & F(Y) \\
\Phi_X \downarrow & & \downarrow \Phi_Y \\
G(X) & \xrightarrow{G_\ast(f)} & G(Y).
\end{array}
\]

\[\text{239}\text{Here the horizontal maps are the isomorphisms that we introduced in Proposition }14.11(1).\]

\[\text{240}\text{In the literature the words “natural isomorphism” and “canonical isomorphism” are often used indiscriminately, but whereas the expression “natural isomorphism” has a precise meaning, the expression “canonical isomorphism” is not a well-defined mathematical concept.}\]
Here the wiggly arrows are not maps but they are just meant to remind us which objects a functor associates to the objects \(X\) and \(Y\).

Now we will see that we have encountered natural transformations and natural isomorphisms much more often than one might have initially thought.

**Examples.**

1. Let \(\mathcal{CRing}\) be the category of commutative rings and let \(\mathcal{Gr}\) be the category of groups. Let \(n \in \mathbb{N}\). We consider the functors
   \[
   F: \mathcal{CRing} \to \mathcal{Gr} \quad \text{and} \quad G: \mathcal{CRing} \to \mathcal{Gr}
   \]
   \[
   R \mapsto GL(n, R) \quad \text{and} \quad R \mapsto R^* := \text{units in } R.
   \]
   For each commutative ring \(R\) we consider the group homomorphism
   \[
   \Phi_R: GL(n, R) \to R^*
   \]
   \[
   A \mapsto \det(A).
   \]
   We claim that these group homomorphisms define a natural transformation from \(F\) to \(G\). Thus let \(f: R \to S\) be a homomorphism between commutative rings and let \(A \in F(R)\), i.e. \(A = (a_{ij})\) is a matrix in \(GL(n, R)\). We have
   \[
   \Phi_S(F_s(f)(A)) = \det((f(a_{ij}))_{i,j=1,...,n}) = \sum_{\sigma \in S_n} \text{sign}(\sigma) \cdot \prod_{i=1}^{n} f(a_{i,\sigma(i)})
   \]
   \[
   = f\left(\sum_{\sigma \in S_n} \text{sign}(\sigma) \cdot \prod_{i=1}^{n} a_{i,\sigma(i)}\right) = f(\det(A)) = G_s(f)(\Phi_R(A)).
   \]
   But that means, by definition, that the \(\Phi_R\) define a natural transformation from \(F\) to \(G\).

2. Let \(\mathcal{Vec}_\mathbb{R}\) be the category of real vector spaces and consider the functor \(F\) given by
   \[
   V \mapsto (V^*)^*
   \]
   and
   \[
   (f: V \to W) \mapsto ((f^*)^*: (V^*)^* \to (W^*)^*).
   \]
   For each real vector \(V\) we denote by \(\Phi_V\) the homomorphism
   \[
   V \to (V^*)^*
   \]
   \[
   v \mapsto \left(\varphi: V \to \mathbb{R} \mapsto \varphi(v)\right).
   \]
   It is straightforward to verify that these maps define a natural transformation from the identity functor to the functor \(F\).\(^{241}\)

---

\(^{241}\)As usual, given a real vector space \(V\) we denote by \(V^* = \text{Hom}_\mathbb{R}(V, \mathbb{R})\) the dual space. Therefore \((V^*)^*\) is the dual space of the dual space of \(V\). The functor given by \(V \mapsto V^*\) is contravariant, but the "double functor" \(V \mapsto (V^*)^*\) is again covariant.

\(^{242}\)Is this in fact a natural isomorphism, i.e. is \(V\) always isomorphic to \((V^*)^*\)?
Let \( \text{Ring} \) be the category of rings. We consider the functors \( F: \text{Ring} \rightarrow \text{Ring} \) and \( G: \text{Ring} \rightarrow \text{Ring} \)

\[
R \mapsto \mathbb{Z} \quad \text{and} \quad R \mapsto R.
\]

For each commutative ring \( R \) we consider the ring homomorphism

\[
\Phi_R: \mathbb{Z} \rightarrow R \quad n \mapsto n \cdot 1_R.
\]

This is a natural transformation from \( F \) to \( G \). Thus, given a commutative ring, we refer to this ring homomorphism \( \mathbb{Z} \rightarrow R \) as the natural ring homomorphism.

Perhaps in this instance it is also important to give a “non-example”.

**Example.** Let \( \mathcal{C} \) be the category of finitely generated abelian groups. Given an abelian group \( A \) we denote by \( \text{Tor}(A) \) its torsion subgroup and we denote by \( FA := A/\text{Tor}(A) \) the maximal torsion-free quotient. We consider the following two covariant functors:

\[
F: \mathcal{C} \mapsto A \quad \text{and} \quad G: \mathcal{C} \rightarrow \mathcal{C} \quad A \mapsto \text{Tor}(A) \oplus FA.
\]

It follows from the classification of finitely generated abelian groups, see Theorem 19.4, that for any finitely generated abelian group \( A \) the groups \( F(A) = A \) and \( G(A) = \text{Tor}(A) \oplus FA \) are isomorphic. Now we claim that nonetheless there is no natural isomorphism between \( F \) and \( G \). Indeed, suppose there was such a natural isomorphism \( \Phi \). Let us consider the group \( A = \mathbb{Z}_2 \oplus \mathbb{Z} \) and the homomorphism \( f: A = \mathbb{Z}_2 \oplus \mathbb{Z} \rightarrow \mathbb{Z}_2 \oplus \mathbb{Z} = A \)

\[
([a], b) \mapsto ([b], 0).
\]

Since we assume that \( \Phi \) is a natural isomorphism we obtain the following commutative diagram

\[
\begin{array}{ccc}
F(A) & \overset{\Phi_A}{\rightarrow} & G(A) \\
\downarrow F(f) & & \downarrow G(f) \\
F(A) & \overset{\Phi_A}{\rightarrow} & G(A)
\end{array}
\]

which specializes in our setting to the following commutative diagram

\[
\begin{array}{ccc}
\mathbb{Z}_2 \oplus \mathbb{Z} & \overset{\Phi_A}{\rightarrow} & \mathbb{Z}_2 \oplus \mathbb{Z} \\
\downarrow \quad F(f) & & \downarrow \quad G(f) \\
\mathbb{Z}_2 \oplus \mathbb{Z} & \overset{\Phi_A}{\rightarrow} & \mathbb{Z}_2 \oplus \mathbb{Z}
\end{array}
\]

Note that the vertical map to the left is non-trivial whereas a close inspection shows that the vertical map to the right is trivial. But this collides with the statement that the horizontal maps are isomorphisms.

On many occasions we, and many authors, say that a certain map is “natural”. This means that the map is in fact a natural transformation between two suitable functors between two suitable categories. Sometimes it takes some thought to figure out what the right context is.

---

243Let us explain why \( G \) is in fact a covariant functor. Let \( f: A \rightarrow B \) be a homomorphism between two abelian groups. Since a homomorphism sends torsion elements to torsion elements we see that \( f \) restricts to a homomorphism \( \text{Tor}(A) \rightarrow \text{Tor}(B) \). This also implies that \( f \) descends to a homomorphism \( FA = A/\text{Tor}(A) \rightarrow FB = B/\text{Tor}(B) \). Summarizing we see that \( f: A \rightarrow B \) induces a homomorphism \( G(f): G(A) = \text{Tor}(A) \oplus FA \rightarrow G(B) = \text{Tor}(B) \oplus FB \).
Example. On page 292, given a submanifold $M$ of some $\mathbb{R}^n$ and a point $P \in M \setminus \partial M$, we introduced the visual tangent space $V_P M$ which is a vector subspace $V_P M$ of $\mathbb{R}^n$. In Proposition 6.39 (2) we showed that the map

$$\Phi_M: V_P M \rightarrow T_P M$$

$$\gamma'(0) \mapsto \left( C^\infty(M, \mathbb{R}) \rightarrow \mathbb{R} \quad f \mapsto \left. \frac{d}{dt} \right|_{t=0} f(\gamma(t)) \right)$$

is an isomorphism of vector spaces. Now we want to say that this is a “natural isomorphism”. What does this mean? Let $\mathcal{P}$ be the category of pointed submanifolds of some $\mathbb{R}^n$. More precisely, let $\mathcal{P}$ be the category with

$$\text{Ob}(\mathcal{P}) = \{(M, P) \mid M \text{ is a submanifold of some } \mathbb{R}^n \text{ and } P \in M \setminus \partial M\}$$

$$\text{Mor}((M, P), (N, Q)) = \{\text{all smooth maps } f: M \rightarrow N \text{ with } f(P) = Q\}.$$ 

It follows easily from the definitions that the maps $\Phi_M$ define a natural transformation from the functor

$$\mathcal{P} \rightarrow \text{Vec}_\mathbb{R}, \quad (M, P) \mapsto V_P M$$

to the functor

$$\mathcal{P} \rightarrow \text{Vec}_\mathbb{R}, \quad (M, P) \mapsto T_P M.$$ 

All of the above examples of natural transformations are perhaps not particularly impressive. But as we will see, the concept of a natural transformation will eventually become one of the key notions in this course.

Exercises for Chapter 15

Exercise 15.1. Show that $\pi_1(S^1 \times S^1)$ admits an epimorphism onto $\mathbb{Z}^2$.

Exercise 15.2. Show that there exists a homeomorphism of the torus $S^1 \times S^1$ that does not extend to a diffeomorphism of the solid torus $S^1 \times B^2$.

Exercise 15.3. Let $a \in A$. We denote by $i: A \rightarrow X$ the inclusion map.

(a) Show that there exists an epimorphism $\varphi: \pi_1(X, a) \rightarrow \pi_1(A, a)$ such that $\varphi \circ i_*$ is the identity on $\pi_1(A, a)$.

(b) Show that the inclusion induced map $\pi_1(A, a) \rightarrow \pi_1(X, a)$ is a monomorphism.

Exercise 15.4. As above let $\text{Top}$ be the category of topological spaces, let $\text{AbsGraph}$ be the category of abstract graphs and let $\text{UndirAbsGraph}$ be the category of undirected abstract graphs. In Lemma 15.2 we defined a functor $| - |$ from $\text{AbsGraph}$ to $\text{Top}$. Furthermore on page 480 we defined a functor $F$ from $\text{AbsGraph}$ to $\text{UndirAbsGraph}$ such that for any abstract graph the homeomorphism $\Theta_G: |G| \rightarrow |F(G)|$ between the topological realizations is a homeomorphism.

Is it possible to define a functor $\Psi$ from $\text{UndirAbsGraph}$ to $\text{Top}$ such that the homeomorphisms $\Theta_G$ are natural?

Remark. Beware of loops.
Exercise 15.5. Let $C$ be a category.

(1) A morphism $g \in \text{Mor}_C(X,Y)$ is called a monomorphism if for every two morphisms $f_1, f_2 \in \text{Mor}_C(W,X)$ with $g \circ f_1 = g \circ f_2$ we also have $f_1 = f_2$.

(2) A morphism $g \in \text{Mor}_C(X,Y)$ is called an epimorphism if for every two morphisms $h_1, h_2 \in \text{Mor}_C(Y,Z)$ with $h_1 \circ g = h_2 \circ g$ we also have $h_1 = h_2$.

We consider these notions in two different categories.

(a) Show that in the category $\text{AbGr}$ of abelian groups the monomorphisms are precisely the injective homomorphisms and that the epimorphisms are precisely the surjective homomorphisms.

Remark. The same statements also hold in the category $\text{Gr}$ of all groups. The proof for monomorphisms is straightforward, but the proof for epimorphisms is non-trivial, we refer to [Lin70] and [Pare70], p. 16 for details.

(b) Show that in the category $\text{Top}$ of topological spaces a monomorphism is not necessarily injective and show that an epimorphism is not necessarily surjective.

(c) Show that in the category $\text{Ring}$ of rings the inclusion $\mathbb{Z} \to \mathbb{Q}$ is an epimorphism.

(d) An abelian group $G$ is called divisible if for every $g \in G$ and $n \in \mathbb{N}$ there exists an $h \in G$ with $n \cdot h = g$. We define the category of divisible abelian groups in the obvious way. Show that in this category the obvious homomorphism $\mathbb{Q} \to \mathbb{Q}/\mathbb{Z}$ is a monomorphism.

Exercise 15.6. Let $C$ be a category. An object $X \in \text{Ob}(C)$ is called initial if for each object $Y \in \text{Ob}(C)$ there exists a unique morphism from $X$ to $Y$. Similarly an object $X \in \text{Ob}(C)$ is called terminal if for each object $Y \in \text{Ob}(C)$ there exists a unique morphism from $Y$ to $X$.

(a) Show that if an initial object exists, then it is unique up to isomorphism. The same statement of course holds for terminal objects.

(b) Show that the category $\text{Top}$ of topological spaces admits an initial and a terminal object.

(c) Give an example of a category that contains an initial object but not a terminal object.

(d) Give an example of a category that contains a terminal object but that does not contain an initial object.
16. Fundamental groups and coverings

We have now introduced the fundamental group of a (pointed) topological space and we have proved several basic facts. But the only proof that fundamental groups are non-trivial relied on a fact from complex analysis. In particular, so far we have not yet managed to compute a single fundamental group that is not the trivial group. For example, we know that \( \pi_1(S^1) \) is non-trivial, but we do not know what group it is.

In this chapter we will compute many non-trivial fundamental groups using the theory of covering spaces.

**Definition.** Let \( p: X \to B \) be a map between topological spaces.

1. We say an open subset \( U \subset B \) is uniformly covered, if \( p^{-1}(U) \) is the union of disjoint open subsets \( \{V_i\}_{i \in I} \) with the property, that the restriction of \( p \) to each subset \( V_i \) is a homeomorphism.
2. We say the map \( p: X \to B \) is a covering, if it is surjective and if for every \( b \in B \) there exists an open neighborhood \( U \) of \( b \) which is uniformly covered.

**Remark.** If \( U \) is a uniformly covered subset of \( B \), then clearly any open subset of \( U \) is also uniformly covered. For example it follows that if \( p: X \to B \) is a covering and if \( B \) is a smooth manifold, then any point \( b \in B \) admits also a connected uniformly covered neighborhood.\(^{215}\)

**Examples.**

(a) The map

\[
p: \mathbb{R} \to S^1 \quad \varphi \mapsto e^{i\varphi}
\]

is a covering. Indeed, let \( P = e^{i\alpha} \) be a point in \( S^1 \). We pick the open neighborhood

\[
U := \{ e^{i\varphi} \mid \varphi \in (\alpha - \frac{\pi}{4}, \alpha + \frac{\pi}{4}) \}.
\]

Then

\[
p^{-1}(U) := \bigsqcup_{j \in \mathbb{Z}} (\alpha - \frac{\pi}{4} + 2\pi j, \alpha + \frac{\pi}{4} + 2\pi j),
\]

and for each \( j \in \mathbb{Z} \) the restriction of \( p \) to \( V_j \to U \) is a homeomorphism. This example is illustrated in Figure 308.

\(^{214}\)On page 89 we introduced the notion of a “cover”. As we mentioned on page 89 such a “cover” is sometimes also called a “covering”. Now we introduce the notion of a “covering”. Rather maddeningly, in the literature this notion often also gets called a “cover”. Fortunately, from the context, it is usually clear what is meant by “cover” and “covering”. These issues do not arise in other languages, e.g. in German and French what we call “cover” is referred to as “Überdeckung” and “recouvrement” and what we call “covering” is referred to as “Überlagerung” and “revêtement”.

\(^{215}\)Why does this follow for smooth manifolds? Why does this not hold for all topological spaces \( B \)?
(b) We consider the “infinite helix”

\[ H := \{ (re^{it}, t) \mid r \in (1, 2) \text{ and } t \in \mathbb{R} \} \]

together with the “annulus”

\[ A := \{ re^{it} \mid r \in (1, 2) \text{ and } t \in \mathbb{R} \}. \]

The map

\[ p: H \rightarrow A \]

\[ (re^{it}, t) \mapsto re^{it} \]

is a covering. This statement is illustrated in Figure 309. The proof of the statement is similar to the proof in the previous example.

(c) The map

\[ p: \mathbb{R}^n \rightarrow \mathbb{R}^n / \mathbb{Z}^n \]

\[ x \mapsto [x] = x + \mathbb{Z}^n \]

is a covering. Indeed, let \([x] = [(x_1, \ldots, x_n)]\) be a point in \(\mathbb{R}^n / \mathbb{Z}^n\). We consider

\[ W := \{ (y_1, \ldots, y_n) \mid |y_i - x_i| < \frac{1}{2} \} \subset \mathbb{R}^n \]

and we put \(U := p(W)\). Then \(U\) is an open \(^{216}\) neighborhood of \([x]\). Furthermore

\[ p^{-1}(U) = \bigcup_{i \in \mathbb{Z}^n} (W + i), \]

\(^{216}\)The set \(U\) is open since the projection map \(p: \mathbb{R}^n \rightarrow \mathbb{R}^n / \mathbb{Z}^n\) is open by Lemma 3.30 (2).
and for each $i$ the restriction of $p$ to $W + i \subset \mathbb{R}^n$ is a homeomorphism.\(^\text{247}\)

(d) For every $n \in \mathbb{N}$ the map

$$p : S^n \to \mathbb{RP}^n = \mathbb{R}P^n \cong S^n / x \sim -x$$

is a covering. Indeed, for $[x] \in \mathbb{RP}^n$ we set

$$W = \{y \in S^n \mid x \cdot y > 0\}.$$ scalar product

Then $p(W)$ is an open neighborhood of $[x]$ and it is uniformly covered by the two open sets $W$ and $-W$.

(e) The projection map

$$p : S^1 \to [-1, 1]$$

$$ (x, y) \mapsto x$$

is not a covering. Indeed, the point $b = 1 \in [-1, 1]$ has no open neighborhood that is uniformly covered. This example is illustrated in Figure 310.

\[\text{Figure 310}\]

Now we can formulate the following lemma that will be proved in Exercise 16.1.

**Lemma 16.1.** Let $p : X \to B$ be a covering of topological spaces. If $B$ is a path-connected topological space, then for any two points $P$ and $Q$ in $B$ we have

$$\#p^{-1}(P) = \#p^{-1}(Q).$$

**Example.** For a general map $p : X \to B$ between topological spaces the number of preimages of a point depends of course on the point chosen in $B$. For instance in the above example (e) we have $\#p^{-1}(0) = 2$ but $\#p^{-1}(1) = 1$.

**Definition.** Let $p : X \to B$ be a covering of a path-connected topological space.

1. We define the degree $[X : B]$ of $p$ as the cardinality of $\#p^{-1}(b)$ for some $b \in B$.\(^\text{248}\)

2. If the degree is a finite number $n$, then we say that $p$ is an $n$-fold covering of $B$. Otherwise we say that $p$ is an infinite covering. If the cardinality is countable, then sometimes we call it a countable covering.

**Examples.**

\(^{247}\)It is straightforward to verify that the map $p : V_i := W + i \to U$ is a bijection. It follows from Lemma 3.30 (1) that the projection map $p$ is continuous and as we had just mentioned in the previous footnote, the projection map is also open. It follows that the map $p : V_i = W + i \to U$ is a homeomorphism.

\(^{248}\)It follows from Lemma 16.1 that this definition does not depend on the choice of $b$. 

(1) We had just seen that the map \( p: S^n \to S^n/ \sim = \mathbb{RP}^n \).
(2) Let \( n \in \mathbb{N} \). As usual we consider \( S^1 = \{ z \in \mathbb{C} \mid \vert z \vert = 1 \} \) as a subset of \( \mathbb{C} \). Then the map \( p: S^1 \to S^1 \) given by \( p(z) := z^n \) is a covering. Indeed, let \( z = e^{2\pi i \varphi} \) be a point in \( S^1 \). Then
\[
U := \left\{ e^{2\pi i \psi} \mid \psi \in (\varphi - \frac{1}{4}, \varphi + \frac{1}{4}) \right\}
\]
has the desired property. Indeed, we have
\[
p^{-1}(U) = \bigcup_{j=1}^{n} \left\{ e^{2\pi i \psi} \mid \psi \in \left( \frac{1}{n}(\varphi - \frac{1}{4}) + \frac{j}{n}, \frac{1}{n}(\varphi + \frac{1}{4}) + \frac{j}{n} \right) \right\},
\]
and the restriction of \( p \) to each set \( V_j \) is easily seen to be a homeomorphism. This shows that \( p \) is a covering and it is clear that \( p \) is an \( n \)-fold covering.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure311.png}
\caption{Figure 311}
\end{figure}

(3) Let \( n \in \mathbb{N} \). Note that basically the same argument as before shows that the map \( p: \mathbb{C} \setminus \{0\} \to \mathbb{C} \setminus \{0\} \) given by \( p(z) = z^n \) is an \( n \)-fold covering.
(4) We consider the map
\[
p: \mathbb{R} \times [-1,1]/(x,y) \sim (x + 1, y) \quad \text{annulus}
\]
\[
\quad \to \quad \mathbb{R} \times [-1,1]/(x,y) \sim (x + \frac{1}{2}, y) \quad \text{Möbius band}
\]
It is straightforward to show that \( p \) is a 2-fold covering. Thus we can view the annulus as a 2-fold covering of the Möbius band. This covering is illustrated in Figure 312.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure312.png}
\caption{Figure 312}
\end{figure}
If in the previous example we replace the interval $[-1, 1]$ by the circle $[-1, 1]/-1 \sim 1$, then on the left-hand side we obtain the torus and on the right-hand side we obtain the Klein bottle. This shows that there exists a degree 2 covering map from the torus to the Klein bottle.

In Figure 313 we sketch three coverings of topological graphs. The coverings are hereby given by sending edges of a certain color, with the indicated direction, to the edge of the same color with the indicated direction.

Figure 313

**Question 16.2.** We had just seen that there exists a covering map $S^2 \to \mathbb{R}P^2$ of degree two and that there exists a covering map from the torus to the Klein bottle of degree two. This raises the question: between which surfaces do there exist covering maps? More precisely we can ask the following:

1. Does there exist a covering map from the torus $S^1 \times S^1$ to the sphere $S^2$?
2. Does there exist a covering map from the sphere $S^2$ to the torus $S^1 \times S^1$?

The following lemma summarizes some basic facts about coverings.

**Lemma 16.3.** Let $p: X \to B$ be a covering of topological spaces. Then the following hold:

1. The map $p: X \to B$ is open.
2. For any $b \in B$ the preimage $p^{-1}(b)$ is a discrete subset of $X$.
3. If $B$ is Hausdorff, then $X$ is also Hausdorff.
4. If $p$ is a finite covering and if $B$ is compact, then $X$ is also compact.
5. If $p$ is an infinite covering, then $X$ is non-compact.

**Proof (⋆).** Let $p: X \to B$ be a covering of topological spaces.

(1) Let $U$ be an open subset of $X$. We need to show that $p(U)$ is open. It suffices to show that for each $P \in p(U)$ there exists an open neighborhood $V$ such that $P \in V \subset U$. Since $p$ is a covering there exists an open neighborhood $W$ of $P$ such that $p^{-1}(W)$ is the union of disjoint open subsets $\{W_i\}_{i \in I}$ with the property that the restriction of $p$ to each subset $W_i$ is a homeomorphism.

Since $P \in p(U)$ there exists a $Q \in U$ with $p(Q) = U$. There exists an $i \in I$ with $Q \in W_i$. Since $W_i$ is open and since $U$ is open the set $U \cap W_i$ is also open in $X$. Since

---

249 It is a good exercise to convince oneself, that the indicated maps are in fact coverings.

250 Recall that this means that the image of each open set in $X$ is open in $B$. 
$p: W_i \to W$ is a homeomorphism and since $U \cap W_i$ is open in $W_i$ the set $p(U \cap W_i)$ is also open in $p(W_i) = W$. But since $W$ is open the set $V := p(U \cap W_i)$ is also an open subset of $B$. It is the desired open neighborhood of $P$ with $P \in V \subset U$.

Figure 314. Illustration for the proof of Lemma 16.3 (1).

(2) Let $b \in B$. Since $p: X \to B$ is a covering there exists an open neighborhood $U$ of $b$ such that $p^{-1}(U)$ is the union of disjoint open subsets $\{V_i\}_{i \in I}$ with the property that the restriction of $p$ to each subset $V_i$ is a homeomorphism. For each $i \in I$ there exists a unique point $x_i \in V_i$ with $p(x_i) = b$ and the preimage $p^{-1}(b)$ consists of precisely the $x_i$, $i \in I$. Since each $V_i$ is open in $X$ it follows from the definition of the subspace topology that each $x_i \in p^{-1}(b)$ is an open subset of $p^{-1}(b)$. Put differently, the subspace topology on $p^{-1}(b)$ is the discrete topology. But this is equivalent to saying that $p^{-1}(b)$ is a discrete subset of $X$.

(3) This statement is relatively easy to prove and it in Exercise 16.5.

(4) Let $p: X \to B$ be an $n$-fold covering of a compact space $B$. Let $\{U_i\}_{i \in I}$ be an open cover of $X$. Let $b \in B$. We pick an open connected neighborhood $M$ of $b$ that is uniformly covered. For each $x \in p^{-1}(b)$ we denote by $N_x$ the component of $p^{-1}(M)$ that contains $x$. For each point in $x \in p^{-1}(b)$ we pick an $i_x \in I$ with $x \in U_{i_x}$. We write

$$W_b := \bigcap_{x \in p^{-1}(b)} p(U_{i_x} \cap N_x).$$

Claim. The preimage $p^{-1}(W_b)$ is contained in the union of $n = \#p^{-1}(b)$ subsets of our open cover $\{U_i\}_{i \in I}$.

Since $M$ is uniformly covered the map $p: N_x \to M$ is a homeomorphism for any $x \in p^{-1}(y)$. We denote by $p_x: N_x \to M$ this homeomorphism. We write $F := p^{-1}(b)$. We then have

$$p^{-1}(W_b) = \bigcup_{y \in F} \bigcup_{x \in F} p_y^{-1}\left(\bigcap_{x \in F} p_x(U_{i_x} \cap N_x)\right) = \bigcup_{y \in F} \bigcap_{x \in F} p_y^{-1}(p_x(U_{i_x})) \cap p_y^{-1}(p_x(N_x)) \subseteq \bigcup_{y \in F} U_{i_y}.$$
By (1) each \( p(U_{i_0} \cap N_x) \) is an open subset of \( B \) and since \( p^{-1}(b) \) is a finite set we see that \( W_b \) is an open subset of \( B \). Furthermore \( b \) is contained in each \( p(U_{i_0} \cap N_x) \), so \( W_b \) is in fact an open neighborhood of \( b \in B \). Since \( B \) is compact we can cover \( B \) by finitely many of these open sets, i.e. there exist \( b_1, \ldots, b_k \in B \) with \( B = W_{b_1} \cup \cdots \cup W_{b_k} \). The preimages \( p^{-1}(W_{b_1}), \ldots, p^{-1}(W_{b_k}) \) cover \( X \). By the above claim each preimage \( p^{-1}(W_{b_i}) \) is contained in the union of \( n = \#p^{-1}(b_i) \) subsets of our open cover \( \{U_i\}_{i \in I} \).

Summarizing we have shown that we can cover \( X \) by \( n \cdot k \) sets out of the collection \( \{U_i\}_{i \in I} \).

(5) Let \( p: X \to B \) be an infinite covering. If \( B \) is non-compact, then it follows from Lemma 2.40 that \( X \) is also non-compact. So now suppose that \( B \) is compact. By definition we can cover \( B \) by open sets that are uniformly covered. Since \( B \) is compact we can cover \( B \) by finitely many open sets \( U_1, \ldots, U_k \) that are uniformly covered. Without loss of generality we can assume that \( U_k \) is not contained in \( U_1 \cup \cdots \cup U_{k-1} \).

Now let \( P \) be a point in \( U_k \setminus (U_1 \cup \cdots \cup U_{k-1}) \). Furthermore let \( V_i, \ i \in I \) be the disjoint open subsets of \( X \) such that \( p^{-1}(U_k) \) is the union of the \( V_i \)'s and such that the restriction of \( p \) to each \( V_i \) is a homeomorphism. For \( i \in I \) we denote by \( Q_i \in V_i \) the unique point with \( p(Q_i) = P \). Now we consider the open cover

\[
X = p^{-1}(U_1) \cup \cdots \cup p^{-1}(U_{k-1}) \cup \bigcup_{i \in I} V_i.
\]

Note that for \( i \in I \) the point \( Q_i \) is contained only in \( V_i \). This means that we cannot remove any of the open sets \( V_i, \ i \in I \) from the open cover. Since \( I \) is infinite it follows that \( X \) does not satisfy the definition of a compact set, i.e. \( X \) is not compact. ■

We conclude this section with the following lemma that we will prove in Exercise 16.4.

**Lemma 16.4.** Let \( p: \tilde{X} \to X \) be a 2-fold covering. We define

\[
f: \tilde{X} \to \tilde{X}
\]

\[
Q \mapsto \text{the unique other point in } p^{-1}(p(Q)).
\]

(The definition of \( f \) is illustrated in Figure 316). This map is continuous and it has the property that the following diagram commutes:

\[
\begin{array}{ccc}
\tilde{X} & \xrightarrow{f} & \tilde{X} \\
p \downarrow & & \downarrow p \\
X. & & X.
\end{array}
\]

16.2. **Group actions and covering spaces.** We recall two definitions about actions from pages 185 and 189 and we introduce one new definition.

**Definition.** Let \( G \) be a group which acts continuously on a topological space \( X \).

(1) We say \( G \) acts freely if \( g \cdot x = x \) for \( g \in G \) and \( x \in X \) implies that \( g = e \).

\(^{253}\)Indeed, if \( U_k \) was contained in \( U_1 \cup \cdots \cup U_{k-1} \), then we could remove \( U_k \) from the collection of open sets and we continue with the collection \( U_1, \ldots, U_{k-1} \).
We say $G$ acts \textit{properly} if for every two points $x$ and $y$ in $X$ there exist open neighborhoods $U$ of $x$ and $V$ of $y$ such that the set $\{g \in G \mid gU \cap V \neq \emptyset\}$ is finite.

We say $G$ acts \textit{discretely}, if for each $x \in X$ there exists an open neighborhood $U$ so that

$$U \cap gU = \emptyset \text{ for all } g \neq e.$$ 

The following lemma summarizes the relationship between these different definitions.

\textbf{Lemma 16.5.} Let $G$ be a group which acts continuously on a topological space $X$.

1. If $G$ is finite, then the action is proper.
2. If $G$ acts discretely, then it also acts freely.
3. If $X$ is a Hausdorff space and if the action by $G$ is free and proper, then the action is also discrete.

\textbf{Proof.} The first two statements follow immediately from the definitions. The third statement is the content of Lemma 6.33.

\textbf{Examples.}

(A) The group $G = \mathbb{Z}^n$ acts on $X = \mathbb{R}^n$ by addition. This action is discrete. Indeed, for each $x = (x_1, \ldots, x_n) \in \mathbb{R}^n$ the open neighborhood

$$U = \{y = (y_1, \ldots, y_n) \in \mathbb{R}^n \mid \max\{|x_1 - y_1|, \ldots, |x_n - y_n|\} < \frac{1}{2}\}$$

has the desired property.

(B) Let $X = \mathbb{R} \times [-1,1]$ and $G = \mathbb{Z}$. The action

$$\mathbb{Z} \times (\mathbb{R} \times [-1,1]) \to \mathbb{R} \times [-1,1]$$

$$(n, (x,y)) \mapsto (x + n, (-1)^n y)$$

is discrete. Indeed, for any $(x,y) \in X$ the open neighborhood

$$U = \{(a,b) \mid |a - x| < \frac{1}{2} \text{ and } b \in [-1,1]\}$$

has the desired property.

(C) Let $X = S^n$ and $G = \{\pm 1\}$. The map

$$\{\pm 1\} \times S^n \to S^n$$

$$(\epsilon, P) \mapsto \epsilon \cdot P$$

defines an action that is discrete. Indeed, for any $P \in S^n$ the open hemisphere

$$U = \{Q \in S^n \mid P \cdot Q > 0\}$$

\textit{scalar product}
has the desired property.\footnote{Alternatively one can argue, that the action is obviously free and $S^n$ is Hausdorff, hence the action is discrete by Lemma \ref{lemma:discrete-action}(1) and (3).}

(D) Every discrete action is free, but as we will see in this example, the converse does not hold. Let $X = \mathbb{R}^{n+1} \setminus \{0\}$ and $G = \mathbb{R} \setminus \{0\}$. The map
\[
(\mathbb{R} \setminus \{0\}) \times (\mathbb{R}^{n+1} \setminus \{0\}) \to \mathbb{R}^{n+1} \setminus \{0\}
\]
\[
(r, P) \mapsto r \cdot P
\]
defines an action. It is straightforward to see that the action is free. But the action is not discrete. Indeed, it is easy to see that for each open non-empty set $U$ there exist uncountably many real numbers $r \neq 1$ with $U \cap rU \neq \emptyset$.

(E) We consider the following two self-homeomorphisms of $\mathbb{R}^2$:
\[
A: \mathbb{R}^2 \to \mathbb{R}^2 \\
(x, y) \mapsto (x + 1, 1 - y)
\]
\[
B: \mathbb{R}^2 \to \mathbb{R}^2 \\
(x, y) \mapsto (x, y + 1).
\]

We denote by $G$ the subgroup of all homeomorphisms of $\mathbb{R}^2$ that is generated by $A$ and $B$. This means \footnote{For example the map $B \circ A \circ A \circ B^{-1} \circ A$ lies in $G.$}
\[
G = \text{all self-homeomorphisms of } \mathbb{R}^2 \text{ that can be written as a finite concatenation of the maps } A, B, A^{-1} \text{ and } B^{-1}.
\]

The group $G$ acts by definition on $\mathbb{R}^2$. In Exercise \ref{exercise:discrete-action} we will see that this action of $G$ on $\mathbb{R}^2$ is discrete.

We consider again the square $X = [0, 1] \times [0, 1]$ with the equivalence relation that is generated by $(0, y) \sim (1, 1 - y)$ and $(x, 0) \sim (x, 1)$. It is straightforward to see that the map
\[
X / \sim \to \mathbb{R}^2 / G \\
[(x, y)] \mapsto [(x, y)]
\]
is a homeomorphism. Put differently, $\mathbb{R}^2 / G$ is homeomorphic to the Klein bottle.

(F) Let
\[
X = S^3 = \{(z_1, z_2) \in \mathbb{C}^2 \mid |z_1|^2 + |z_2|^2 = 1\}
\]
and let $G = \mathbb{Z}_p$ for some $p \in \mathbb{Z} \setminus \{0\}$. Furthermore let $q \in \mathbb{Z}$ with $\gcd(p, q) = 1$. Then the map
\[
\mathbb{Z}_p \times S^3 \to S^3 \\
(k + p\mathbb{Z}, (z_1, z_2)) \mapsto (e^{2\pi i k/p}z_1, e^{2\pi i q/p}z_2)
\]
defines a smooth, orientation-preserving and discrete action of $\mathbb{Z}_p$ on $S^3$.\footnote{It is straightforward to verify that the map does indeed define an action. It is clear that the action is smooth and a direct calculation shows that the action is orientation-preserving. One can also easily verify that the action is free. It follows from Lemma \ref{lemma:discrete-action}(1) and (3) that the action is discrete.} We denote by $L(p, q) = S^3 / \mathbb{Z}_p$ the quotient space. It follows from Propositions \ref{proposition:orientable} and that $L(p, q)$ is again a closed 3-dimensional smooth manifold. Furthermore it follows from Proposition \ref{proposition:orientable} that $L(p, q)$ is orientable, in fact it has an orientation such that the projection map $p: S^3 \to L(p, q)$ is orientation-preserving. We will always
view $L(p, q)$ as a smooth manifold equipped with this orientation. We refer to the smooth manifolds $L(p, q)$ as lens spaces.\footnote{The name "lens space" comes from an alternative description of these smooth manifolds.} We consider two special cases:

(a) For $p = 1$ we only have the action of the trivial group on $S^3$ and the quotient space $L(1, q)$ is therefore just the original sphere $S^3$. 

(b) For $p = 2$ we have $q$ is odd, so for $k = 0$ we have $e^{2\pi i k/2} = e^{2\pi i k/2} = 1$ and for $k = 1$ we have $e^{2\pi i k/2} = e^{2\pi i k/2} = -1$. Put differently, the action of $Z_2$ on $S^3$ is the same as the action of $Z_2 = \{\pm 1\}$ that we had used in the definition of the real projective space $\mathbb{R}P^n$. This shows that $L(2, q) = \mathbb{R}P^n$.

We discuss the last type of examples in slightly more detail. For $p \in \mathbb{N}$ and $q \in \mathbb{N}$ with $\gcd(p, q) = 1$ we just introduced a new topological space, namely the lens space $L(p, q)$. It is natural to ask, for which parameters $(p, q)$ are these topological spaces homeomorphic?

**Lemma 16.6.** Let $p \in \mathbb{N}$ and furthermore let $q, r \in \mathbb{Z}$ with $\gcd(p, q) = \gcd(p, r) = 1$. If $q \equiv \pm r \pm 1 \bmod p$\footnote{By our hypothesis we have $\gcd(p, r) = 1$. This implies that there exists a multiplicative inverse of $r$ modulo $p$, i.e. there exists an $s$ with $r \cdot s \bmod p$. We write $r^{-1} := s$.} then $L(p, q)$ and $L(p, r)$ are diffeomorphic.\footnote{In particular any lens space is of the form $L(p, q)$ with $q \in \{0, \ldots, p - 1\}$.}

**Proof.** Let $p \in \mathbb{N}$ and let $q, r \in \mathbb{Z}$ with $\gcd(p, q) = \gcd(p, r) = 1$. We suppose that $q \equiv \pm r \pm 1 \bmod p$. We define a map

$$L(p, q) \to L(p, r)$$

as follows:

- **Case 1:** $q \equiv r \bmod p$. $([z_1, z_2]) \mapsto ([z_1, z_2])$
- **Case 2:** $q \equiv -r \bmod p$. $([z_1, z_2]) \mapsto ([z_1, \bar{z}_2])$
- **Case 3:** $q \equiv r^{-1} \bmod p$. $([z_1, z_2]) \mapsto ([z_2, z_1])$
- **Case 4:** $q \equiv -r^{-1} \bmod p$. $([z_1, z_2]) \mapsto ([z_2, \bar{z}_1])$

In all four cases it is straightforward to verify that the given map is well-defined and that it is in fact a diffeomorphism. ■

In the proof of Lemma 16.6 it was quite straightforward to write down the homeomorphism. This raises the question whether there are homeomorphisms between more lens spaces that are harder to find, or whether all other pairs of lens spaces are non-homeomorphic. More precisely, we have the following question.

**Question 16.7.** Let $p, \tilde{p} \in \mathbb{N}$ and let $q, \tilde{q} \in \mathbb{Z}$ with $\gcd(p, q) = \gcd(\tilde{p}, \tilde{q}) = 1$. If $L(p, q)$ and $L(\tilde{p}, \tilde{q})$ are homeomorphic, does it follow that $p = \tilde{p}$ and $q \equiv \pm \tilde{q}^{-1} \bmod p$?

This question will keep us busy for a very long time.

We had just seen on page 500 that the group $\{\pm 1\}$ acts freely and continuously on any sphere. We had also seen that any finite cyclic group $\mathbb{Z}_p$ acts freely and continuously on the $3$-sphere. This raises the question, whether such an action by $\mathbb{Z}_p$ also exists on the $2$-sphere. More generally we can ask the following question.

**Question 16.8.** Given $n \in \mathbb{N}$, which finite cyclic groups can act freely and continuously on the $n$-dimensional sphere $S^n$?\footnote{In particular any lens space is of the form $L(p, q)$ with $q \in \{0, \ldots, p - 1\}$.}
We will give a complete answer to this question in Exercise 45.21 and Proposition 55.10.

The following proposition connects the notion of discrete actions to the theory of covering spaces.

**Proposition 16.9.** Let $X$ be a topological space together with a discrete and continuous action by a group $G$. Then the canonical projection $p: X \to X/G$ is a covering.

**Example.** This proposition, combined with examples (A) and (C), gives in particular new proofs that the maps $\mathbb{R}^n \to \mathbb{R}^n/\mathbb{Z}^n$ and $S^n \to S^n/\sim = \mathbb{R}P^n$ are covering maps.

**Proof.** Let $G$ be a group which acts discretely and continuously on a topological space $X$. We want to show that the projection map $p: X \to X/G$ is a covering. Let $[x] \in X/G$. Since the group acts discretely there exists an open neighborhood $V$ of $x \in X$ such that $V \cap gV = \emptyset$ for all $g \neq e$.

We put $U := p(V)$. It follows from Lemma 3.30 that the set $U$ is an open neighborhood of $[x] = p(x)$.

The preimage $p^{-1}(U)$ is the disjoint union of the open subsets $gV$, $g \in G$. The restriction of the map $p$ to any $gV$ is a continuous, bijective map $gV \to U$ and according to Lemma 3.30 this map is furthermore open. It follows that the restriction of $p$ to any $gV$ is in fact a homeomorphism. Thus we see that $U$ is uniformly covered. Since this holds for any point in $X/G$ we have shown that the projection map $p: X \to X/G$ is a covering. □

The following proposition is a slight generalization of the previous proposition.

**Proposition 16.10.** Let $X$ be a topological space together with a discrete and continuous action by a group $G$. Furthermore let $H$ be a subgroup of $G$. Then the canonical projection

$$p: X/H \to X/G$$

$$[x] \mapsto [x]$$

is a covering.

For $H$ the trivial group we recover the statement of Proposition 16.9. In fact the proof of Proposition 16.10 is almost identical to the proof of Proposition 16.9. We leave the details to the reader.

**Examples.**

1. Let $X = \mathbb{R} \times [-1, 1]$ and $G = \mathbb{Z}$. Once again we consider the discrete action

$$\mathbb{Z} \times (\mathbb{R} \times [-1, 1]) \to \mathbb{R} \times [-1, 1]$$

$$(n, (x, y)) \mapsto (x \pm \frac{1}{2} n, (-1)^n y).$$

Any cyclic group $\mathbb{Z}_k$, $k \neq 0$ admits a non-trivial action on $S^n$ where $j \in \mathbb{Z}_k$ acts by rotation around the $x$-axis by the angle $2\pi j$. But this action is not free, since the points $(-1, 0, \ldots, 0)$ and $(1, 0, \ldots, 0)$ are fixed.

2. Why is $p^{-1}(U) = \bigcup_{g \in G} gV$ and why are the sets $gV$ disjoint?

2. Why is the map bijective?
Let \( H = 2\mathbb{Z} \). According to Proposition 16.10, the projection map \( p: X/H \to X/G \) is a covering. Put differently, all the horizontal maps in the following commutative diagram are coverings:

\[
\begin{array}{ccc}
(\mathbb{R} \times [-1, 1])/2\mathbb{Z} & \to & (\mathbb{R} \times [-1, 1])/\mathbb{Z} \\
\downarrow & & \downarrow \\
(\mathbb{R} \times [-1, 1])/(x, y) \sim (x + \frac{1}{2} 2k, (1 - 1)^2k y) & \to & (\mathbb{R} \times [-1, 1])/(x, y) \sim (x + \frac{1}{2} k, (1)^k y) \\
\downarrow & & \downarrow \\
= \text{the annulus} & & = \text{Möbius band} \\
\end{array}
\]

Each point on \( X/G \) has precisely two preimages, so the covering is in fact a 2-fold covering. Thus we recover the result from page 496 that the annulus is a 2-fold covering of the Möbius band.

(2) We consider again the group \( G \) of self-homeomorphisms of \( \mathbb{R}^2 \) that is generated by

\[
A: \mathbb{R}^2 \to \mathbb{R}^2 \quad \text{and} \quad B: \mathbb{R}^2 \to \mathbb{R}^2,
\]

\[
(x, y) \mapsto (x + 1, 1 - y) \quad \text{and} \quad (x, y) \mapsto (x, y + 1).
\]

We let \( H \) be the subgroup of \( G \) generated by \( A^2 \) and \( B \). Note that \( A^2 \) is the map given by

\[
A^2: \mathbb{R}^2 \to \mathbb{R}^2 \quad : \quad (x, y) \mapsto (x + 1, 1 - y) \quad \text{and} \quad (x, y) \mapsto (x + 1, 1 - (1 - y)).
\]

Note that \( A^2 \) and \( B \) are two homeomorphisms that commute, so any element in \( H \) is in fact of the form

\[
A^{2k} \circ B^{l}: \mathbb{R}^2 \to \mathbb{R}^2 \quad (x, y) \mapsto (x + 2k, y + l)
\]

for some \( k, l \in \mathbb{Z} \). By Proposition 16.10, the projection map \( p: \mathbb{R}^2/H \to \mathbb{R}^2/G \) is a covering map. We already know that \( \mathbb{R}^2/G \) is the Klein bottle. It follows immediately from the above description of \( H, \mathbb{R}^2/H = \mathbb{R}^2/(2\mathbb{Z} \oplus \mathbb{Z}) \), so \( \mathbb{R}^2/H \) is just the 2-dimensional torus. As on page 497 we see that we can view the 2-dimensional torus as a 2-fold covering of the Klein bottle.

16.3. Lifting of paths.

**Definition.** Let \( p: X \to B \) be a map between topological spaces and let \( f: [a, b] \to B \) be a path. Let \( x \in X \) be a point with \( p(x) = f(a) \). A path \( g: [a, b] \to X \) is called a lift of \( f \) to the starting point \( x \), if \( g(a) = x \) and if \( p \circ g = f \), i.e. if the following diagram of maps
commutes:

\[
\begin{array}{c}
\overset{g}{\longrightarrow} X \\
\downarrow_{p} \ \\
\overset{f}{[a, b] \longrightarrow B.}
\end{array}
\]

Examples.

(1) We consider the map

\[
p: \mathbb{R} \rightarrow S^1 \\
t \mapsto e^{it}
\]

and the path

\[
f: [0, b] \rightarrow S^1 \\
t \mapsto e^{2it}
\]

with starting point \( f(0) = 1 \). Let \( x = 4\pi \). Then \( p(x) = p(4\pi) = 1 \) and

\[
g: [0, b] \rightarrow \mathbb{R} \\
t \mapsto 4\pi + 2t
\]

is a lift of \( f \) to the starting point \( 4\pi \). Note that if \( b = \pi \), then \( f \) is a loop in \( (S^1, 1) \), but the lift is not a loop in \( (\mathbb{R}, 4\pi) \). Put differently, the lift of a loop is not necessarily again a loop. This example is illustrated in Figure 317.

\[\text{Figure 317}\]

(2) In Figure 318 we illustrate the lifting of a path in the covering \( p: H \rightarrow A \) of an infinite helix over an annulus that we had considered on page 194.

\[\text{Figure 318}\]
**Proposition 16.11.** Let $p: X \to B$ be a covering and let $f: [0,1] \to B$ be a path. Then given any $x \in X$ with $p(x) = f(0)$ there exists a unique lift $g: [0, 1] \to X$ of $f$ to the starting point $x$.

**Proof.** Let $p: X \to B$ be a covering, let $f: [0,1] \to B$ be a path and let $x$ be a point in $X$ with $p(x) = f(0)$. We first show the existence of a lift and then we prove the uniqueness of the lift.

(a) We consider

$$S := \{ s \in [0,1] \mid \text{there exists a lift of } f|_{[0,s]} \text{ to the starting point } x \}.$$ 

Note that $S$ is non-empty since $0$ has the desired property. We put $t := \sup(S)$. We want to show that $t = 1$ and that $t \in S$. It suffices to show that there exists an $\epsilon > 0$ such that $[t, t + \epsilon) \cap [0,1]$ still lies in $S$. We set $b := f(t)$. Since $p$ is a covering there exists an open neighborhood $U$ of $b \in B$, which is uniformly covered. As a reminder, this means that $p^{-1}(U)$ is the union of disjoint open subsets $\{V_i\}_{i \in I}$ with the property that the restriction of $p$ to each subset $V_i$ is a homeomorphism. Since $U$ is open and since $f$ is continuous there exists an $\epsilon > 0$ such that $f((t - \epsilon, t + \epsilon) \cap [0,1]) \subset U$.

By the definition of $t$ there exists an $s \in (t - \epsilon, t) \cap S$. We denote by $g$ the lift of $f|_{[0,s]}$ to the starting point $x$. There exists a unique $i \in I$ such that $g(s) \in V_i$. We denote by $p_i: V_i \to U$ the homeomorphism which is given by the restriction of $p$ to $V_i$.

We consider the map

$$h: [0, t + \epsilon) \cap [0,1] \to X$$

$$z \mapsto \begin{cases} g(z), & \text{if } z \in [0, s], \\ p_i^{-1}(f(z)), & \text{if } z \in (s, t + \epsilon) \cap [0,1]. \end{cases}$$

Since $g(s) = p_i^{-1}(f(s))$ we see that this map is indeed continuous. It is clear that this defines a lift of $f$ to the starting point $x$.

(b) Now we show the uniqueness of the lift. The proof of that statement is similar to the proof of the existence of a lift. So suppose that $g, h: [0, 1] \to X$ are two lifts of $f$ to the starting point $x$. We want to show that $g = h$. We consider

$$S := \{ s \in [0,1] \mid g(t) = h(t) \text{ for all } t \in [0, s] \}.$$
Note that \(0 \in S\), i.e. \(S\) is non-empty. We put \(t := \sup(S)\). We want to show that \(t = 1\) and that \(t \in S\). Again it suffices to show that there exists an \(\epsilon > 0\) such that \([t, t + \epsilon) \cap [0, 1]\) still lies in \(S\).

We put \(b := f(t)\). Since \(p\) is a covering there exists an open neighborhood \(U\) of \(b \in B\) which is uniformly covered. Since \(U\) is open and since \(f\) is continuous there exists an \(\epsilon > 0\) such that \(f((t - \epsilon, t + \epsilon) \cap [0, 1]) = U\). We pick an \(s \in (t - \epsilon, t] \cap [0, 1]\). There exists a unique \(i \in I\) such that \(g(s) \in V_i\). We denote by \(p_i: V_i \rightarrow U\) the homeomorphism which is given by the restriction of \(p\) to \(V_i\).

Since \(g(s) = h(s)\) it follows that \(h(s) \in V_i\). Then it follows that \(g(z) \in V_i\) and \(h(z) \in V_i\) for all \(z \in (t - \epsilon, t + \epsilon) \cap [0, 1]\). It follows from the definitions that

\[ g(z) = p_i^{-1}(f(z)) \quad \text{and} \quad h(z) = p_i^{-1}(f(z)) \]

for all \(z \in (t - \epsilon, t + \epsilon) \cap [0, 1]\). In particular \([t, t + \epsilon) \cap [0, 1]\) lies in \(S\). \(\blacksquare\)

16.4. Lifting of path-homotopies. In the last chapter we saw that given a covering map \(p: X \rightarrow B\) any path \(f: [0, 1] \rightarrow B\) can be lifted to a path \(g: [0, 1] \rightarrow X\). In this chapter we want to study the question whether the lifts of path-homotopic paths are still path-homotopic.

Before we start this discussion we first generalize the notion of a lift.

**Definition.** Let \(p: X \rightarrow B\) be a covering and let \(f: Y \rightarrow B\) be a map between topological spaces. A **lift of \(f\) to \(X\)** is a map \(\tilde{f}: Y \rightarrow X\) such that \(p \circ \tilde{f} = f\), i.e. such that the following diagram of maps commutes:

\[
\begin{array}{ccc}
Y & \xrightarrow{\tilde{f}} & X \\
\downarrow{f} & & \downarrow{p} \\
B & \xrightarrow{f} & B.
\end{array}
\]

**Proposition 16.12.** Let \(p: X \rightarrow B\) be a covering, let \(B\) be a topological space, let \(Y\) be a topological manifold\(^{262}\) and let \(f: Y \times [0, 1] \rightarrow B\) be a map. Furthermore let \(\tilde{f}: Y \times 0 \rightarrow X\) be a lift of \(f|_{Y \times 0}\). Let \(\tilde{f}: Y \times [0, 1] \rightarrow X\) be the map that is uniquely determined\(^{263}\) by the property that for each \(y \in Y\) the path \(t \mapsto \tilde{f}(y, t)\) is the lift of the path \(t \mapsto f(y, t)\) to the starting point \(\tilde{f}(y, 0)\). Then the map \(\tilde{f}: Y \times [0, 1] \rightarrow X\) is continuous.

The statement of Proposition\(^{16.12}\) is sketched in Figure\(^{320}\). One way of formulating Proposition\(^{16.12}\) is that a “continuous” family of paths in \(B\) lifts again to a “continuous” family of paths in \(X\).

\(^{261}\)Once again, all maps are understood to be continuous.

\(^{262}\)Later on we will apply the proposition to the case that \(Y = [0, 1]\) and that \(Y = B^n\) for some \(n \in \mathbb{N}_0\).

\(^{263}\)The existence and the uniqueness of this map is an immediate consequence of Proposition\(^{16.11}\).
PROOF (*). Let \( p : X \to B \) be a covering, let \( f : Y \times [0, 1] \to B \) be a continuous map and let \( \tilde{f} : Y \times 0 \to X \) be a continuous lift of \( f|_{Y \times 0} \). (Here and throughout this proof we do not suppose that all maps are continuous.) We begin with the following definitions:

1. A good set \( U \times I \) consists of a connected subset \( U \subset Y \) and an open interval \( I \subset [0, 1] \) such that \( f(U \times I) \) lies in a uniformly covered subset of \( B \).
2. We say a good set \( U \times I \) is very good, if there exists a \( t \in I \) such that the restriction of \( \tilde{f} \) to \( U \times \{t\} \) is continuous.
3. Let \( y \in Y \) and \( t \in [0, 1] \). A (very) good neighborhood of \((y, t)\) is a (very) good set \( U \times I \) with \( y \in U \) and \( t \in I \).

It follows easily from the continuity of \( f \), the hypothesis that \( Y \) is a topological manifold and the fact that \( p : X \to B \) is a covering that each point \((y, t)\) admits a good neighborhood.

\[ \text{Claim. Let } U \subset Y \text{ open and let } I \subset [0, 1] \text{ be an open interval such that } U \times I \text{ is very good. Then } \tilde{f} \text{ is continuous on } U \times I. \]

\[ \text{We say } A \subset [0, 1] \text{ is an open interval, if } A \text{ is an interval and if } A \text{ is open with respect to the subspace topology of } [0, 1]. \text{ Put differently, } A = (a, b), \text{ or } A = [0, a) \text{ or } A = (b, 1] \text{ or } A = [0, 1] \text{ for } 0 \leq a \leq b \leq 1. \]

\[ \text{Why does this follow?} \]

\[ \text{Here we use the fact, established in Corollary 2.56 and Lemma 6.9(2), that the topological manifold } Y \text{ is locally connected.} \]
Let $U \subset Y$ be an open connected subset and let $I \subset [0, 1]$ be an interval such that $U \times I$ is very good. This means in particular that there exists a $t \in I$ such that

\[
U \rightarrow X \\
y \mapsto \tilde{f}(y, t)
\]

is continuous.

According to our hypothesis there exists a uniformly covered subset $W \subset B$ such that $f(U \times I) \subset W$. Since $U \times I$ is connected we can without loss of generality suppose that $W$ is connected. Since $W$ is uniformly covered the preimage $p^{-1}(W)$ is the union of disjoint open subsets $\{V_j\}_{j \in J}$, with the property, that the restriction of $p$ to each subset $V_j$ is a homeomorphism.

Now we want to show that there exists a $j \in J$ with $\tilde{f}(U \times I) \subset V_j$. We choose a $y \in U$. Then there exists a unique $j \in J$ such that $\tilde{f}(y, t) \in V_j$. Since $\tilde{f}$ is continuous $U \times \{t\}$ and since $U$ is connected it follows from Lemma 2.70\footnote{We apply Lemma 2.70 to the continuous map $U \times \{t\} \rightarrow p^{-1}(W)$ from the connected set $U$ to the set $p^{-1}(W)$ with components $V_j$, $j \in J$.} that $\tilde{f}(U \times \{t\}) \subset V_j$. Now let $z \in U$. We just showed that $\tilde{f}(z, t) \in V_j$. By the construction of $\tilde{f}$ the map $\tilde{f}$ is continuous on $\{z\} \times I$. Since $I$ is connected it follows again from Lemma 2.70 that $\tilde{f}(\{z\} \times I) \subset V_j$. We have thus shown that $\tilde{f}(U \times I) \subset V_j$. This part of the argument is sketched in Figure 322.

We denote by $p_j : V_j \rightarrow W$ the homeomorphism which is given by the restriction of $p$ to $V_j$. Since $\tilde{f}(U \times I) \subset V_j$ it follows that on $U \times I$ the map $\tilde{f}$ is given by $\tilde{f} = p_j^{-1} \circ f$. In particular the map $\tilde{f}$ is a composition of continuous maps, so it is continuous on $U \times I$.

\begin{claim}
Let $y \in Y$. We consider

\[T := \{t \in [0, 1] \mid \text{there exists a very good neighborhood of } (y, t)\}.
\]

We claim that $T = [0, 1]$.

Thus let $y \in Y$. Since $[0, 1]$ is connected it suffices to show the following three statements:

(1) $T \neq \emptyset$,

(2) $T$ is open, and

(3) $T$ is closed.
Now we will prove these three statements:

1. As we pointed out above, every point in \( Y \times I \), in particular the point \((y, 0)\), admits a good neighborhood. By our hypothesis \( \tilde{f} \) is continuous on \( Y \times \{0\} \). It follows that the good neighborhood is in fact very good.

2. It is easy to see that \( T \) is open. Indeed, suppose that we are given a very good neighborhood \( U \times I \) of \((y, t)\). Then \( U \times I \) is also a very good neighborhood for any \((y, s) \in U \times I \). Therefore the open neighborhood \( I \) of \( t \) also lies in \( T \).

3. It remains to show that \( T \) is closed. Put differently, we need to show that \( T \) equals its closure \( \overline{T} \). Thus let \( t \in \overline{T} \). As we already pointed out, there exists a good neighborhood \( U \times I \) of \((y, t)\). Since \( t \in \overline{T} \) there exists an \( s \in T \cap I \). Since \( s \in T \) it follows from the above claim that there exists a very good open neighborhood \( V \times J \) of \((y, s)\). By the previous claim the restriction of \( \tilde{f} \) to \( V \times J \) is continuous, in particular it is continuous on \((U \cap V) \times \{s\}\). We denote by \( W \) the component of \( U \cap V \) that contains \( y \). Then \( W \times I \) is a very good neighborhood of \((y, t)\). This step is illustrated in Figure 323.

![Figure 323](image)

We have just shown that given any \( y \in Y \) and any \( t \in [0, 1] \) there exists a very good neighborhood \( U_{y,t} \) of \((y, t)\). By the first claim the map \( \tilde{f} \) is continuous on each \( U_{y,t} \). But the open subsets \( U_{y,t} \) cover all of \( Y \times [0, 1] \). It follows from Lemma 2.74 that \( \tilde{f} \) is continuous on \( Y \times [0, 1] \).

**Corollary 16.13.** Let \( p : X \to B \) be a covering and let \( f, g : [0, 1] \to B \) be two paths. Let \( \tilde{f}, \tilde{g} : [0, 1] \to X \) be two lifts with the same starting point. If \( f \) and \( g \) are path-homotopic, then the endpoints of \( \tilde{f} \) and \( \tilde{g} \) agree and the paths \( \tilde{f} \) and \( \tilde{g} \) are path-homotopic.

![Figure 324](image)
Proof (\#). We write $P := f(0) = g(0)$ and $Q := f(1) = g(1)$. We denote by $\tilde{P} := \tilde{f}(0) = \tilde{g}(0)$ the common starting point of the lifts and we write $\tilde{Q} := \tilde{f}(1)$. Let
\[
H : [0, 1] \times [0, 1] \to B \\
(t, s) \mapsto H(t, s)
\]
be a path-homotopy between the paths $f$ and $g$. As a reminder, $H$ is a map such that
\[
H(t, 0) = f(t) \quad \text{and} \quad H(t, 1) = g(t) \quad \text{for all} \ t \in [0, 1],
\]
and such that
\[
H(0, s) = P \quad \text{and} \quad H(1, s) = Q \quad \text{for all} \ s \in [0, 1].
\]
On $\{0\} \times [0, 1]$ we consider the lift $\tilde{H}$ of $H$ which is given by $\tilde{H}(0, s) = \tilde{P}$. Furthermore we denote by $\tilde{H} : [0, 1] \times [0, 1] \to X$ the map which is defined as follows: for each $s \in [0, 1]$ the path $t \mapsto \tilde{H}(t, s)$ is the unique lift of the path $t \mapsto H(t, s)$ to the starting point $\tilde{P}$ lift.

According to Proposition 16.12 the map $\tilde{H}$ is in fact continuous. By definition of $\tilde{H}$ we have
\[
\tilde{H}(t, 0) = \tilde{f}(t) \quad \text{and} \quad \tilde{H}(t, 1) = \tilde{g}(t) \quad \text{for all} \ t \in [0, 1],
\]
For each $s \in [0, 1]$ we have $p(\tilde{H}(1, s)) = Q$. Since $\tilde{H}$ is continuous we obtain a map
\[
[0, 1] \to p^{-1}(Q) \subset X \\
s \mapsto \tilde{H}(1, s).
\]
Since $[0, 1]$ is connected it follows from Lemma 2.61 and Lemma 16.3 that $\tilde{H}(1, s) = \tilde{Q}$ for all $s \in [0, 1]$. In particular we obtain that
\[
\tilde{f}(1) = \tilde{H}(1, 0) = \tilde{Q} = \tilde{H}(1, 1) = \tilde{g}(1).
\]
Thus it follows that $\tilde{H}$ is indeed a path-homotopy between the paths $\tilde{f}$ and $\tilde{g}$. \hfill \Box

Definition. Let $p : X \to B$ be a map between topological spaces and let $x_0 \in X$ and $b_0 \in B$. We say a map $p : X \to B$ is a covering of pointed topological spaces, if $p : X \to B$ is a covering and if $p(x_0) = b_0$.

Corollary 16.14. For any covering $p : (X, x_0) \to (B, b_0)$ of pointed topological spaces the induced map $p_* : \pi_1(X, x_0) \to \pi_1(B, b_0)$ is a monomorphism.

Proof. We have\footnote{We use the notation from page 466 for $y \in Y$ we denote by $e_y$ the constant path $e_y(t) := x$, $t \in [0, 1]$.}
\[
[f] \in \ker (\pi_1(X, x_0) \xrightarrow{p_*} \pi_1(B, b_0)) \implies [p \circ f] = e \in \pi_1(B, b_0) \implies p \circ f \simeq e_{x_0} \\
\implies f \simeq e_{x_0} \implies [f] = e \in \pi_1(X, x_0).
\]
by Corollary 16.13 since $f$ is the lift of $p \circ f$ and $e_{x_0}$ is the lift of $e_{b_0}$ to the starting point $x_0$. \hfill \Box

Example. In Question 16.2 (1) we had asked whether there exists a covering map from the torus $S^1 \times S^1$ to the sphere $S^2$. By Proposition 14.14 we know that $\pi_1(S^2) = 0$ whereas we saw on page 486 that $\pi_1(S^1 \times S^1)$ is non-trivial. Using Corollary 16.14 we can now answer Question 16.2 (1) in the negative: there is no covering map from $S^1 \times S^1$ to $S^2$.\footnote{We use the notation from page 466 for $y \in Y$ we denote by $e_y$ the constant path $e_y(t) := x$, $t \in [0, 1]$.}
We conclude the section with the following lemma.

**Lemma 16.15.** Let \( p: (X, x_0) \rightarrow (B, b_0) \) be a covering of pointed topological spaces.

1. Let \( f \) be a loop in \((B, b_0)\). We denote by \( \tilde{f} \) the lift of \( f \) to the starting point \( x_0 \). Then the following holds:
   \[
   \tilde{f} \text{ is a loop in } (X, x_0) \iff [f] \text{ lies in } p_* (\pi_1 (X, x_0)) \subset \pi_1 (B, b_0).
   \]
   In particular, if \( \tilde{f} \) is not a loop in \((X, x_0)\), then \([f]\) is a non-trivial element of \( \pi_1 (B, b_0) \).

2. Now we suppose that \( X \) is simply connected. Let \( f \) and \( g \) loops in \((B, b_0)\) and let \( \tilde{f} \) and \( \tilde{g} \) be the lifts of \( f \) and \( g \) to the starting point \( x_0 \). Then the following holds:
   \[
   f \text{ and } g \text{ are path-homotopic loops } \iff \text{ the endpoints of } \tilde{f} \text{ and } \tilde{g} \text{ agree.}
   \]

3. If \( X \) is path-connected, then \([X : B] = [\pi_1 (B, b_0) : p_* (\pi_1 (X, x_0))]\).

**Remark.** In Exercise 16.9 we will use Lemma 16.15 (3) to answer Question 16.2 (2) in the negative.

**Proof (\(*\)).**

1. We prove the "⇒"-direction. So let \( f \) be a loop in \((B, b_0)\). We denote by \( \tilde{f} \) the lift of \( f \) to the starting point \( x_0 \). If \( \tilde{f} \) is a loop in \((X, x_0)\), then it defines an element in \( \pi_1 (X, x_0) \) and we have \([f] = [p \circ \tilde{f}] = p_* ([\tilde{f}]) \in p_* (\pi_1 (X, x_0))\). The proof of the "⇐"-direction is Exercise 16.8.

2. The "⇒"-direction is an immediate consequence of Corollary 16.13. The proof of the "⇐"-direction is done once again in Exercise 16.8. For that direction we need that \( X \) is simply connected.

3. This statement is proved in Exercise 16.8. \( \square \)

**Example.** The last sentence of Lemma 16.15 (1) can at times be surprisingly useful for showing that a given element in a fundamental group. As proof of concept, we consider the pointed topological space \((B, b_0)\) and we show a loop \( f: [0, 1] \rightarrow B \) shown in Figure 325. We also show a covering \( p: (X, x_0) \rightarrow (B, b_0) \) of pointed topological spaces together with the lift \( \tilde{f} \) of \( f \) to the starting point \( x_0 \). Since \( \tilde{f} \) is not a loop we see that \([f] \in \pi_1 (B, b_0)\) is non-trivial. In Exercise 16.10 we will use the same approach to show that \( \pi_1 (B, b_0) \) is actually non-abelian.

![Figure 325](image.png)

Note that \([f]\) lies in \( p_* (\pi_1 (X, x_0)) \subset \pi_1 (B, b_0)\) means that there exists a loop \( g \) in \((X, x_0)\) such that \( p \circ g \) is *path-homotopic* to \( f \). A priori it does not mean that there exists a loop \( g \) with \( p \circ g = f \).
16.5. **Group actions and fundamental groups.** The following proposition finally allows us to determine many fundamental groups. This proposition is the reward for the many rather theoretical results of the previous sections.

**Theorem 16.16.** Let $X$ be a topological space and let $G$ be a group which acts continuously and discretely on $X$. We choose an $x \in X$. We denote by $p : X \to X/G$ the canonical projection map.

1. If $X$ is simply connected, then the map
   \[ G \to \pi_1(X/G, [x]) \]
   \[ g \mapsto [p \circ \text{(path in } X \text{ from } x \text{ to } g \cdot x)] \]
   is a well-defined isomorphism of groups. In particular we have $\pi_1(X/G) \cong G$.

2. (*) Regardless of whether or not $X$ is simply connected, the subgroup $p_*(\pi_1(X,x))$
   is normal in $\pi_1(X/G, [x])$ and the map
   \[ G \to \pi_1(X/G, [x])/p_*(\pi_1(X,x)) \]
   \[ g \mapsto [p \circ \text{(path in } X \text{ from } x \text{ to } g \cdot x)] \]
   is a well-defined isomorphism of groups.

---

![Diagram](image.png)

**Figure 326.** Illustration of Theorem 16.16(1).

Before we provide the proof of Theorem 16.16, let us impatiently use it to finally confirm our suspicion that the fundamental group of $S^1$ is isomorphic to $\mathbb{Z}$.

**Proposition 16.17.**

1. The maps
   \[ \Phi : \mathbb{Z} \to \pi_1(\mathbb{R}/\mathbb{Z}, [0]) \]
   \[ n \mapsto \begin{cases} [0, 1] \to \mathbb{R}/\mathbb{Z} \\ t \mapsto p(nt) = [nt] \end{cases} \]
   the map $t \mapsto nt$ is a path from 0 to $0 + n$

   \[ \Psi : \mathbb{Z} \to \pi_1(S^1, 1) \]
   \[ n \mapsto \begin{cases} [0, 1] \to S^1 \\ t \mapsto e^{2\pi int} \end{cases} \]
   are isomorphisms of groups.

2. Let $n \in \mathbb{N}$. We consider the map $f : S^1 \to S^1$ that is given by $z \mapsto z^n$. The induced map on $\pi_1(S^1, 1)$ is given by multiplication by $n$. 

---

![Diagram](image.png)
(3) The map
\[ \Theta : \pi_1(S^1, 1) \to \mathbb{Z} \]
\[ [\gamma] \mapsto \frac{1}{2\pi i} \int_{\gamma} \frac{1}{z} \, dz \]
is an isomorphism.

**Proof.**

(1) We consider the action of \( G = \mathbb{Z} \) on the simply connected topological space \( X = \mathbb{R} \).

We denote by \( p : \mathbb{R} \to \mathbb{R}/\mathbb{Z} \) the canonical projection map. It follows immediately from Theorem 16.16 that the given map \( \Phi : \mathbb{Z} \to \pi_1(\mathbb{R}/\mathbb{Z}, [0]) \) is an isomorphism. We denote by \( \phi : \mathbb{R}/\mathbb{Z} \to S^1 \) the homeomorphism given by \( \phi([t]) = e^{2\pi it} \). If we compose the above isomorphism with the isomorphism \( \phi_* : \pi_1(\mathbb{R}/\mathbb{Z}, [0]) \to \pi_1(S^1, 1) \), then we see that the second map \( \Psi : \mathbb{Z} \to \pi_1(S^1, 1) \) is also an isomorphism.

(2) This statement follows easily from the definitions. To practice the definitions we will prove this statement in Exercise 16.14.

(3) It is straightforward to see that \( \Theta \circ \Psi : \mathbb{Z} \to \pi_1(S^1, 1) \to \mathbb{Z} \) is the identity. By (1) the first map \( \Psi \) is an isomorphism. Thus \( \Theta = \Phi^{-1} \) is also an isomorphism. \( \square \)

We will provide many more examples for Theorem 16.16 immediately after the proof of Theorem 16.16.

**Proof of Theorem 16.16 (\(*\)).** To simplify the discussion we only provide the proof of Theorem 16.16 (1). The proof of Theorem 16.16 (2) is almost the same. We leave it to the reader to make the necessary modifications.

Let \( X \) be a simply connected topological space and let \( G \) be a group which acts continuously and discretely on \( X \).\(^{270}\) We choose an \( x \in X \). We denote by \( p : X \to X/G \) the canonical projection map. We consider the map
\[ \Phi : G \to \pi_1(X/G, [x]) \]
\[ g \mapsto [p \circ (\text{path in } X \text{ from } x \text{ to } gx)] \].

We need to prove the following four statements:

1. \( \Phi \) is well-defined,
2. \( \Phi \) is a group homomorphism,
3. \( \Phi \) is surjective,
4. \( \Phi \) is injective.

Now we provide the proofs for these four claims.

(1) We first show that the map \( \Phi \) is well-defined. Let \( g \in G \). Since \( X \) is in particular path-connected there exists a path from \( x \) to \( gx \). Now let \( f \) be an arbitrary path in \( X \) from \( x \) to \( gx \). From \( p(x) = [x] = [gx] = p(gx) \) it follows that \( p \circ f \) is a loop in \( (X/G, [x]) \). In particular \( p \circ f \) does indeed define an element in \( \pi_1(X/G, [x]) \).

Now we need to show that this element does not depend on the choice of \( f \). So let \( f' \) be another path in \( X \) from \( x \) to \( gx \). Since \( X \) is simply connected it follows from Lemma 14.13 that the paths \( f \) and \( f' \) are path-homotopic in \( X \), i.e., there exists

\(^{270}\) It is perhaps helpful to read the proof with the example of the action of \( \mathbb{Z}^n \) on \( \mathbb{R}^n \) in mind.
a path-homotopy $H: [0, 1] \times [0, 1] \to X$ from $f$ to $f'$. But then $p \circ H: [0, 1] \times [0, 1] \to X/G$ is a path-homotopy from the loop $p \circ f$ to the loop $p \circ f'$. This shows that the map $\Phi$ is well-defined.

(2) Now we show that $\Phi$ is a group homomorphism. Let $g, h \in G$ and pick be a path $k$ from $x$ to $gx$ and pick a path $l$ from $x$ to $hx$. Then $g^k x^l$ is a path from $gx$ to $ghx$ and $k^* g^l$ is a path from $x$ to $ghx$. It follows that since $p(gx) = p(x) \in X/G$ for all $x \in X$

$$\Phi(gh) = [p \circ (k^* g^l)] = [(p \circ k) * (p \circ gl)] \uparrow = [(p \circ k) * (p \circ l)] \downarrow = [p \circ k] \cdot [p \circ l] = \Phi(g) \cdot \Phi(h).$$

(3) Now we prove that $\Phi$ is surjective. We choose an arbitrary element $c \in \pi_1(X/G, [x])$ and represent it by a loop $\tilde{f}$ in $(X/G, [x])$. According to Proposition 16.11 there exists a lift $\tilde{f} : [0, 1] \to X$ of the path $f$ to the starting point $x$. By definition we have $p \circ \tilde{f} = f$. In particular we obtain for the endpoint of $\tilde{f}$ that $p(\tilde{f}(1)) = [x]$, therefore it follows that $\tilde{f}(1) = gx$ for some $g \in G$. Thus we have proved that

$$\Phi(g) = [p \circ (\text{path from } x \to gx)] = [p \circ \tilde{f}] = [f] = c.$$

(4) We conclude the proof of the proposition by showing that $\Phi$ is injective. Let $g \in G$. Then the following holds:

$$\Phi(g) = e \quad \Rightarrow \quad [p \circ (\text{path } f \text{ from } x \to gx)] = e \in \pi_1(X/G, [x]) \quad \Rightarrow \quad p \circ f \simeq e_{[x]} \text{ in } X/G \quad \Rightarrow \quad f(1) = e_{x}(1) \quad \Rightarrow \quad gx = x \quad \Rightarrow \quad g = e.$$

by Corollary 16.13 since $f$ is a lift of $p \circ f$ and $e_{x}$ is a lift of $e_{[x]}$ to the starting point $x$, hence free

This shows that $\Phi$ is indeed injective.

We have thus shown that $\Phi$ is a well-defined isomorphism.

Now we can determine the fundamental groups of many of the topological spaces that we have encountered so far.

27. Here $g^l$ denotes the path $[0, 1] \to X$ that is given by $t \mapsto g \cdot l(t)$. 
Corollary 16.18. We have the following isomorphisms of fundamental groups

(A) \( \pi_1(n\text{-dimensional torus}) = \pi_1(\mathbb{R}^n/\mathbb{Z}^n) \cong \mathbb{Z}^n \)

in particular
\[ \pi_1(S^1) = \pi_1(\mathbb{R}/\mathbb{Z}) \cong \mathbb{Z}, \]

(B) for any \( n \neq 0, 1 \)
\[ \pi_1(\text{real projective space } \mathbb{R}P^n) = \pi_1(S^n/\{\pm 1\}) \cong \mathbb{Z}_2, \]

(C) \[ \pi_1(\text{Möbius band}) = \pi_1((\mathbb{R} \times [-1,1])/\mathbb{Z}) \cong \mathbb{Z}, \]

(D) \[ \pi_1(\text{lens space } L(p,q)) = \pi_1(S^3/\mathbb{Z}_p) \cong \mathbb{Z}_p. \]

Proof (*). By Proposition 14.14 we know that for any \( n \geq 2 \) the sphere \( S^n \) is simply connected. Furthermore we know by the discussion on page 468 that \( \mathbb{R}^n, n \geq 1 \), and that the strip \( \mathbb{R} \times [-1,1] \) are simply connected. We saw on page 500 that all the actions are discrete. The actions are of course also continuous. The corollary is now an immediate consequence of Theorem 16.16. ■

Thus we have now finally determined the fundamental groups of many spaces. In Proposition 14.14 we saw that \( \pi_1(S^2) = 0 \) whereas we have now seen that \( \pi_1(S^1 \times S^1) \cong \mathbb{Z}^2 \). The fundamental groups are not isomorphic, hence the sphere \( S^2 \) and the torus \( S^1 \times S^1 \) are not homeomorphic.

We also obtained a partial answer to Question 16.7 if two lens spaces \( L(p,q) \) and \( L(\tilde{p},\tilde{q}) \) are homeomorphic, then \( p = \tilde{p} \). But as of right now we cannot say anything about the parameters \( q \) and \( \tilde{q} \).

Examples. Theorem 16.16 not only gives us the fact that \( \pi_1(X/G) \) is isomorphic to the group \( G \), but it also gives us an explicit isomorphism. Now we will study this isomorphism in two examples to explicitly determine non-trivial elements in the fundamental group of the torus and the real projective space.

(1) As a reminder, the torus is defined as
\[
T = \mathbb{R}^2/\mathbb{Z}^2 = [0,1] \times [0,1]/(x,0) \sim (x,1) \text{ and } (0,y) \sim (1,y).
\]

The explicit isomorphism of Theorem 16.16
\[
\Phi: \mathbb{Z}^2 \to \pi_1(T, (0,0))
\]

assumes in particular the following values
\[
\Phi((1,0)) = x : \begin{cases} [0,1] \to ([0,1] \times [0,1])/ \sim \\ t \mapsto [(t,0)] \\
\end{cases}
\]

\( t \mapsto (t,0) \) is a path from \((0,0)\) to \((1,0)\)

and
\[
\Phi((0,1)) = y : \begin{cases} [0,1] \to ([0,1] \times [0,1])/ \sim \\ t \mapsto [(0,t)] \\
\end{cases}
\]

\( t \mapsto (0,t) \) is a path from \((0,0)\) to \((0,1)\).

---

[272] Here we are slightly generous in our usage of the equality sign. More precisely, strictly speaking \( \mathbb{R}^2/\mathbb{Z}^2 \) is not the same as \( ([0,1] \times [0,1])/ \sim \). But there exists a canonical homeomorphism between these two spaces that we use to identify these spaces.
In the description of the torus as a subset of $\mathbb{R}^3$, see Figure 328, these two loops correspond to the “longitude” and the “meridian”.

![Figure 328](image)

The loop $g$ in $(S^2, Q)$ is clearly null-homotopic. But then the loop $p \circ g$ is also null-homotopic. This example is illustrated in Figure 329.

**Example.** We consider the Klein bottle. Recall that on page 501 we introduced the group $G$ that is given by all self-homeomorphisms of $\mathbb{R}^2$ that can be written as concatenations of the two self-homeomorphisms

$$A: \mathbb{R}^2 \rightarrow \mathbb{R}^2 \quad \text{and} \quad B: \mathbb{R}^2 \rightarrow \mathbb{R}^2$$

$$(x, y) \mapsto (x + 1, 1 - y) \quad \text{and} \quad (x, y) \mapsto (x, y + 1)$$

and their inverses. In Exercise 16.7 we will see $G$ acts discretely on $\mathbb{R}^2$ and we saw on page 501 that $\mathbb{R}^2/G$ is homeomorphic to the Klein bottle. It follows from Theorem 16.16 that

$$\pi_1(\text{Klein bottle}) \cong G = \text{group that is generated by the homeomorphisms} \ A \ and \ B.$$
the closed loop \( f \ast (-f) \) is path-homotopic to the constant loop \( e_Q \)

\[
\begin{align*}
\text{Figure 329}
\end{align*}
\]

The maps \( A \) and \( B \) do not commute. Indeed, the map \( A \circ B : \mathbb{R}^2 \to \mathbb{R}^2 \) is given by

\[
(x, y) \mapsto (x + 1, (1 - (y + 1))) = (x + 1, -y)
\]

whereas the map \( B \circ A : \mathbb{R}^2 \to \mathbb{R}^2 \) is given by

\[
(x, y) \mapsto (x + 1, (1 - y) + 1) = (x + 1, 2 - y).
\]

Thus we see that the fundamental group of the Klein bottle is a non-abelian group.

In Figure 330 we show the two elements \( b \) and \( c \) of the fundamental group of the Klein bottle \( K = ([0, 1] \times [0, 1])/\sim \) which correspond to \( B \) and \( C = B^{-1} \circ A \) under the isomorphism of Theorem 16.16 and the homeomorphism from page 501. Since the two homeomorphisms \( B(x, y) = (x, y + 1) \) and \( C(x, y) = (x + 1, -y) \) do not commute, the corresponding elements \([b]\) and \([c]\) of \( \pi_1(K) \) do not commute either.

\[
\begin{align*}
\text{Figure 330}
\end{align*}
\]

The previous example showed that fundamental groups can be non-abelian groups. In fact, as we will see later in Chapter 20 many, actually arguably “most” fundamental groups are non-abelian. This will pose several major problems. For example, what is a good way to describe a non-abelian group? How can we decide whether or not two non-abelian groups are isomorphic?

We conclude this section with a more unusual topological space. Namely we remark in Exercise 16.13 we will use Theorem 16.16 to show that the fundamental group of the pseudocircle, i.e. of the topological space \( X = \{A, B, C, D\} \) from page 107 is isomorphic to \( \mathbb{Z} \). In particular we show that the loop given on page 107 is not null-homotopic. This answers the question we had posed on page 462.
16.6. **The fundamental group of the product of two topological spaces.** The next proposition says that the fundamental groups of the product $A \times B$ of two topological spaces $A$ and $B$ is the direct product of the fundamental groups of $A$ and $B$. Before we state the proposition explicitly we recall the definition of the direct product of two groups.

**Definition.** Let $G$ and $H$ two groups. We can form the cartesian product

$G \times H := \{(g, h) \mid g \in G \text{ and } h \in H\}.$

This is again a group with the group structure given by

$$(g_1, h_1) \cdot (g_2, h_2) := (g_1g_2, h_1h_2)$$

for $g_1, g_2 \in G$ and $h_1, h_2 \in H$. We call the group $G \times H$ the direct product of the groups $G$ and $H$.

We start out with the following lemma, which strictly speaking we will not need, but which is worth knowing.

**Lemma 16.19.** (*) Let $\varphi_1 : G_1 \rightarrow \pi$ and $\varphi_2 : G_2 \rightarrow \pi$ be two group homomorphisms. If for every $g_1 \in G_1$ and $g_2 \in G_2$ the images $\varphi_1(g_1) \in \pi$ and $\varphi_2(g_2) \in \pi$ commute, i.e. if we have $\varphi_1(g_1) \cdot \varphi_2(g_2) = \varphi_2(g_2) \cdot \varphi_1(g_1)$, then the map

$$\varphi_1 \times \varphi_2 : G_1 \times G_2 \rightarrow \pi, \quad (g_1, g_2) \mapsto \varphi_1(g_1) \cdot \varphi_2(g_2)$$

is a homomorphism.\(^275\)

**Proof.** (*)& We write $\Phi = \varphi_1 \times \varphi_2$. Let $g_1, g'_1 \in G_1$ and let $g_2, g'_2 \in G_2$. We have

$$\Phi(g_1, g_2) \cdot \Phi(g'_1, g'_2) = \varphi_1(g_1) \cdot \varphi_2(g_2) \cdot \varphi_1(g'_1) \cdot \varphi_2(g'_2)$$

$$= \varphi_1(g_1) \cdot \varphi_1(g'_1) \cdot \varphi_2(g_2) \cdot \varphi_2(g'_2)$$

$$= \varphi_1(g_1g'_1) \cdot \varphi_2(g_2g'_2)$$

$$= \Phi(g_1g'_1, g_2g'_2).$$

By our hypothesis.

Now we can formulate the promised proposition.

**Proposition 16.20.** Let $A$ and $B$ be two topological spaces and let $a_0 \in A$ and $b_0 \in B$. We consider the inclusion maps

$$i : A \rightarrow A \times B, \quad a \mapsto (a, b_0)$$

and $j : B \rightarrow A \times B, \quad b \mapsto (a_0, b)$

and we consider the projection maps

$$p : A \times B \rightarrow A, \quad (a, b) \mapsto a$$

and $q : A \times B \rightarrow B, \quad (a, b) \mapsto b$.

Then the maps

$$\Phi : \pi_1(A, a_0) \times \pi_1(B, b_0) \rightarrow \pi_1(A \times B, (a_0, b_0))$$

$$(x, y) \mapsto i_*(x) \cdot j_*(y)$$

\(^275\)In fact the converse also holds, if $\varphi_1 \times \varphi_2$ is a homomorphism, then the for every $g_1 \in G_1$ and $g_2 \in G_2$ the images $\varphi_1(g_1) \in \pi$ and $\varphi_2(g_2) \in \pi$ commute. Why is that?
Finally it follows from Proposition 14.14 and Corollary 16.20 that for any $k,l \geq 2$ we have

$$\pi_1(S^1 \times L(p,q)) \cong \pi_1(S^1) \times \pi_1(L(p,q)) \cong \mathbb{Z} \times \mathbb{Z}_p.$$

Similarly, we see, using Proposition 14.14 that for any $k \geq 2$ we have

$$\pi_1(S^1 \times S^k) \cong \pi_1(S^1) \times \pi_1(S^k) \cong \mathbb{Z} \times 0 \cong \mathbb{Z}.$$

Of course we can also apply Proposition 16.20 several times and we see once again that

$$\pi_1(S^1 \times \cdots \times S^1) \cong \pi_1(S^1) \times \cdots \times \pi_1(S^1) \cong \mathbb{Z} \times \cdots \times \mathbb{Z} \cong \mathbb{Z}^n.$$

Finally it follows from Propositions 14.14 and 16.20 that for any $k,l \geq 2$ we have

$$\pi_1(S^k \times S^l) \cong \pi_1(S^k) \times \pi_1(S^l) \cong 0 \times 0 = 0.$$

In particular we see that the fundamental group cannot distinguish the products of spheres of dimension $\geq 2$. For example at the moment we cannot show that the two 6-dimensional smooth manifolds $S^3 \times S^3$ and $S^2 \times S^2 \times S^2$ are not homeomorphic.

In the proof of Proposition 16.20 we will need the following purely group-theoretic lemma.

**Proof of Proposition 16.20 (\*).** It is clear that

$$\Psi = (p_*, q_*) : \pi_1(A \times B, (a_0, b_0)) \rightarrow \pi_1(A, a_0) \times \pi_1(B, b_0)$$

is a homomorphism. Thus it suffices to show that $\Phi$ and $\Psi$ are inverses of one another. Once we have shown that, it follows for free that $\Phi$ is also a homomorphism.

To show that $\Phi$ and $\Psi$ are inverses of one another we introduce another map, namely we consider

$$\Theta : \pi_1(A, a_0) \times \pi_1(B, b_0) \rightarrow \pi_1(A \times B, (a_0, b_0))$$

$$(\{f : (S^1, 1) \rightarrow (A, a_0), g : (S^1, 1) \rightarrow (B, b_0)\}) \mapsto \left[ \begin{array}{c} (f^1, 1) \rightarrow (A \times B, (a_0, b_0)) \\ z \mapsto (f(z), g(z)) \end{array} \right].$$

It is almost a tautology that $\Theta$ and $\Psi$ are inverses of one another. Thus it remains to prove the following claim.

**Claim.** The two maps $\Phi, \Theta : \pi_1(A, a_0) \times \pi_1(B, b_0) \rightarrow \pi_1(A \times B, (a_0, b_0))$ agree.

We use the convention from page 462 to change our view of fundamental groups. Thus let $f : [0, 1] \rightarrow A$ be a loop in $(A, a_0)$ and $g : [0, 1] \rightarrow B$ be a loop in $(B, b_0)$. We need to show that

$$i_*([f]) \cdot j_*([g]) = [(t \mapsto (f(t), g(t)))] \in \pi_1(A \times B, (a_0, b_0)).$$

---

276 Note that a priori it is not clear that $\Phi$ is a homomorphism since it is not clear whether the hypothesis of Lemma 16.19 is satisfied.

277 One can easily verify that $\Theta$ is well-defined.
In other words, we need to show that the two loops
\[
[0, 1] \to A \times B \\
t \mapsto \begin{cases} 
(f(2t), b_0), & \text{if } t \in [0, \frac{1}{2}] \\
(a_0, g(2t - 1)), & \text{if } t \in [\frac{1}{2}, 1]
\end{cases}
\]
and
\[
[0, 1] \to A \times B \\
t \mapsto (f(t), g(t))
\]
are path-homotopic. In fact an explicit path-homotopy is given by the map
\[
F : [0, 1] \times [0, 1] \to A \times B \\
(t, s) \mapsto \begin{cases} 
(f(\frac{2t}{1+s}), g(st)), & \text{if } t \in [0, \frac{1}{2}] \\
(f(st), g(\frac{2t-1+s}{1+s})), & \text{if } t \in [\frac{1}{2}, 1].
\end{cases}
\]

Summarizing we have now finally managed to calculate many non-trivial fundamental groups. Nonetheless, the list of topological spaces for which we cannot yet calculate the fundamental group is still pretty long, it includes

1. topological graphs,
2. knot complements,
3. the complement of more than one point in \( \mathbb{C} \), e.g. \( \mathbb{C} \setminus \{0, 1\} \),
4. surfaces of genus \( \geq 2 \).

In the following chapters we will introduce more methods for determining the fundamental group of a given topological space. But first we give in the next section two applications of our results.

### 16.7. The Fundamental Theorem of Algebra and the Borsuk-Ulam Theorem

As a first application of our methods we give a proof of the Fundamental Theorem of Algebra. Somewhat surprisingly, contrary to the standard proof \cite{Lan99}, Corollary III.7.6, this proof does not make any use of complex analysis.

**Theorem 16.21. (Fundamental Theorem of Algebra)** Every nonconstant polynomial with coefficients in \( \mathbb{C} \) has a zero in \( \mathbb{C} \).

**Proof.** Let \( q(z) \) be a polynomial with complex coefficients with \( q(z) \neq 0 \) for all \( z \in \mathbb{C} \) with \( |z| = r \). We consider the path
\[
f_q^r : [0, 1] \to S^1 \\
 s \mapsto \frac{q(re^{2\pi is})/q(r)}{|q(re^{2\pi is})/q(r)|}
\]
Note that \( f_q^r(s = 0) = f_q^r(s = 1) = 1 \), i.e. \( f_q^r \) is a loop in \( (S^1, 1) \). Now let
\[
p(z) = a_n z^n + a_{n-1} z^{n-1} + \cdots + a_1 z + a_0
\]
be a polynomial of degree \( n \geq 1 \). We assume that \( p(z) \) has no zeros in \( \mathbb{C} \). For \( t \in [0, 1] \) we also consider the polynomial
\[
p_t(z) := a_n z^n + t(a_{n-1} z^{n-1} + \cdots + a_1 z + a_0).
\]

\footnote{Note that this is indeed a path-homotopy of loops.}
Note that $p_1(z) = p(z)$ and $p_0(z) = a_n z^n$. Since $a_n \neq 0$ there exists an $s > 0$ such that
\[ |a_n z^n| > |a_{n-1} z^{n-1} + \cdots + a_1 z + a_0| \]
for any $z$ with $|z| = s$. This inequality implies that for any $t \in [0, 1]$ and any $z$ with $|z| = s$ we have $p_t(z) \neq 0$, i.e. $p_t(z)$ has no zeros on the circle $|z| = s$.

We obtain the following sequence of path-homotopic loops:

\[
\begin{align*}
\text{constant loop at } 1 & \quad \downarrow \quad f_0^{p(z)} \\ & \sim \quad f_s^{p(z)} \\ & \sim \quad f_s^{p_1(z)} \\ & \sim \quad f_s^{p_0(z)} \\ \text{the loop } & \quad \downarrow \quad [0, 1] \to S^1 \quad t \mapsto e^{2\pi i t}.
\end{align*}
\]

By Proposition 16.17 we had known that the loop on the right defines a non-trivial element in the fundamental group $\pi_1(S^1, 1)$, but we had just shown that it is path-homotopic to the constant path. Thus we have obtained a contradiction.

The following theorem goes back to the Polish mathematicians Karol Borsuk (1905-1982) and Stanislaw Ulam (1909-1984).\footnote{Ulam became much more famous through his work on the hydrogen bomb.} It was first proved in 1932.

**Theorem 16.22. (Borsuk-Ulam Theorem)** For every map $f : S^2 \to \mathbb{R}^2$ there exists a pair of antipodal points $x$ and $-x$ in $S^2$ with $f(x) = f(-x)$.

**Examples.**

(1) It follows from the Borsuk-Ulam Theorem that there exist two antipodal points on earth with the same temperature and the same barometric pressure.

(2) The Borsuk-Ulam Theorem implies in particular that there is no injective map from $S^2 \to \mathbb{R}^2$.

(3) The statement of the Borsuk-Ulam Theorem also makes sense for $2$ replaced by any $n \in \mathbb{N}$. For $n = 1$ one can prove the statement using elementary methods.\footnote{How would you prove the statement?} We will address the problem for $n \geq 3$ once we have introduced homology groups.

**Proof.** We prove the theorem by contradiction. So suppose there exists a map $f : S^2 \to \mathbb{R}^2$ such that $f(x) \neq f(-x)$ for all $x \in S^2$. This allows to define the map
\[ g : S^2 \to S^1, \quad x \mapsto \frac{f(x) - f(-x)}{\|f(x) - f(-x)\|}. \]

Note that $g(-x) = -g(x)$ for all $x \in S^2$. Now let $\eta$ be the loop that is defined by
\[ \eta : [0, 1] \to S^2, \quad s \mapsto \eta(s) = (\cos(2\pi s), \sin(2\pi s), 0) \]

\footnote{In fact we can write it down explicitly: it follows easily from the triangle inequality that any $s \in \mathbb{R}$ such that $s \cdot |a_n| > |a_{n-1}| + \cdots + |a_0|$ will work.}
and let \( h = g \circ \eta: [0, 1] \to S^1 \) be the composition of \( \eta \) with \( g \). We pick a \( c \in \mathbb{R} \) such that \( h(0) = e^{2\pi i c} \). We denote by \( p: \mathbb{R} \to S^1, t \mapsto e^{2\pi i t} \), the usual covering map. We note that for \( z, w \in \mathbb{R} \) we have
\[
p(z) = p(w) \iff z - w \in \mathbb{Z} \quad \text{and} \quad p(z) = -p(w) \iff z - w \in \frac{1}{2} + \mathbb{Z}.
\]
By Proposition 16.11 we can lift the path \( h: [0, 1] \to S^1 \) to a path \( \tilde{h}: [0, 1] \to \mathbb{R} \) with \( \tilde{h}(0) = c \). We refer to Figure 331 for an illustration of all the definitions.

\[
\begin{array}{cccc}
0 & 1 & \eta & \tilde{h} \\
\end{array}
\]

**Figure 331.** Illustration of the proof of the Borsuk-Ulam Theorem 16.22

Given any \( s \in [0, \frac{1}{2}] \) we have
\[
p(\tilde{h}(s + \frac{1}{2})) = h(s + \frac{1}{2}) = g(\eta(s + \frac{1}{2})) = g(-\eta(s)) = -g(\eta(s)) = -h(s) = -p(\tilde{h}(s)).
\]
by the definition of \( \eta \) since \( g(-x) = -g(x) \) for all \( x \in S^2 \)

By the above discussion of \( p \) this implies that
\[
\tilde{h}(s + \frac{1}{2}) - \tilde{h}(s) = \frac{q(s)}{2}
\]
with \( q(s) \) an odd integer. The map \( q: [0, \frac{1}{2}] \to \mathbb{Z} \) is the difference of two continuous maps, hence continuous. It follows from Lemma 2.61 that it is constant. We denote this constant value by \( q \). Since \( q \) is odd it is in particular non-zero.

It follows from the above that
\[
\tilde{h}(1) = \tilde{h}(\frac{1}{2}) + \frac{q}{2} = \tilde{h}(0) + \frac{q}{2} + \frac{q}{2} = \tilde{h}(0) + q.
\]
Since \( q \) is non-zero we obtain from Lemma 16.15 that \( h = g \circ \eta \) is not null-homotopic. But \( h \) was the composition \( h = g \circ \eta: [0, 1] \to S^2 \to S^1 \). By Proposition 14.14 the loop \( \eta \) is null-homotopic in \( S^2 \) which implies by Proposition 15.6 that \( h = g \circ \eta \) is null-homotopic in \( S^1 \). Thus we have obtained a contradiction. \( \blacksquare \)

**Exercises for Chapter 16**

**Exercise 16.1.** Let \( p: X \to B \) be a covering of topological spaces. We suppose that \( B \) is a path-connected topological space. Show that for any two points \( P \) and \( Q \) in \( B \) we have
\[
\#p^{-1}(P) = \#p^{-1}(Q).
\]
Exercise 16.2.
(a) Let \( p : X \to B \) be a map between topological spaces that is two-to-one, i.e. such that for any \( b \in B \) the preimage \( p^{-1}(b) \) consists of precisely two points. Is \( p \) necessarily a covering map?
(b) Is the map
\[
\mathbb{C} \to \mathbb{C} \setminus \{0\} \quad z \mapsto \exp(z)
\]
a covering map? \( \text{Hint.} \ z = x + iy \) with \( x, y \in \mathbb{R} \).
(c) Let \( p : X \to B \) be a surjective map between topological spaces. Let \( f : [0, 1] \to B \) be a map. Does there always exist a lift from \( f \) to \( X \), i.e. does there exist a map \( g : [0, 1] \to X \) such that \( p \circ g = f \)? Give a short justification for your answer.

Exercise 16.3.
(a) Show that there exists a map \( p : X \to B \) be a map between topological spaces that is a local homeomorphism and that is surjective but which is not a covering map.
(b) Let \( p : X \to B \) be a map between topological spaces that is a local homeomorphism and that is surjective. Furthermore we suppose that \( p \) is proper, i.e. we assume that the preimage of each compact set is compact. Is \( p \) necessarily a covering map?

Exercise 16.4. Let \( p : \tilde{X} \to X \) be a 2-fold covering. We define
\[
f : \tilde{X} \to \tilde{X} \quad Q \mapsto \text{the unique other point in } p^{-1}(p(Q)).
\]
Show that this map is continuous.

Exercise 16.5. Let \( p : X \to B \) be a covering of topological spaces. Show that if \( B \) is Hausdorff, then \( X \) is also Hausdorff.

Exercise 16.6. Consider the 5-fold covering map
\[
p : X = S^1 \to B = S^1 \quad z \mapsto z^5.
\]
Let \( f : [0, 1] \to B = S^1 \) be the loop given by \( t \mapsto e^{2\pi it} \). By Proposition 6.11 this loop lifts to a path \( g : [0, 1] \to X = S^1 \). For which \( k \) is the lift \( g \) again a loop?

Exercise 16.7. We consider the following two self-homeomorphisms of \( \mathbb{R}^2 \):
\[
A : \mathbb{R}^2 \to \mathbb{R}^2 \quad (x, y) \mapsto (x + 1, 1 - y) \quad \text{and} \quad B : \mathbb{R}^2 \to \mathbb{R}^2 \quad (x, y) \mapsto (x, y + 1).
\]
We denote by \( G \) the subgroup of all homeomorphisms of \( \mathbb{R}^2 \) that is generated by \( A \) and \( B \). This means
\[
G = \text{all self-homeomorphisms of } \mathbb{R}^2 \text{ that can be written as a finite concatenation of the maps } A, B, A^{-1} \text{ and } B^{-1}.
\]
(a) For \( n \in \mathbb{Z} \), what is \( A^{-n}BA^n \)? (Perhaps start out with \( n = 1 \).)
(b) We write $C = A^2$. We denote by $H$ the subgroup of all homeomorphisms of $\mathbb{R}^2$ that is generated by $C$ and $B$. This means

$$H = \text{all self-homeomorphisms of } \mathbb{R}^2 \text{ that can be written as a finite concatenation of the maps } C, B, C^{-1} \text{ and } B^{-1}.$$ 

Does $A$ lie in $H$?

*Hint.* Consider which self-diffeomorphisms of $\mathbb{R}^2$ are orientation-preserving.

(c) Show that any element $X$ of $G$ lies in $H$ or it is of the form $G = AY$ with $Y \in H$.

(d) Show that the group $G$ acts discretely on $\mathbb{R}^2$.

**Exercise 16.8.** Let $p: (X, x_0) \to (B, b_0)$ be a covering of pointed topological spaces.

(a) Let $f$ be a loop in $(B, b_0)$. We denote by $\tilde{f}$ the lift of $f$ to the starting point $x_0$. Show that if $[f]$ lies in $p_*(\pi_1(X, x_0)) \subset \pi_1(B, b_0)$, then $\tilde{f}$ is a loop in $(X, x_0)$.

(b) Now we suppose that $X$ is simply connected. Let $f$ and $g$ loops in $(B, b_0)$ and let $\tilde{f}$ and $\tilde{g}$ be the lifts of $f$ and $g$ to the starting point $x_0$. Show that if the endpoints of $\tilde{f}$ and $\tilde{g}$ agree, then $f$ and $g$ are path-homotopic loops.

(c) Show that if $X$ is path-connected, then $[X : B] = [\pi_1(B, b_0) : p_*(\pi_1(X, x_0))]$.

**Exercise 16.9.** Show that there is no covering map from the sphere $S^2$ to the torus $S^1 \times S^1$.

*Hint.* Use Lemma 16.15

**Exercise 16.10.** We consider the pointed topological space $(B, b_0)$ and we consider the loops $\alpha, \beta: [0, 1] \to B$ shown in Figure 325

(a) Show that there exists a covering $p: (X, x_0) \to (B, b_0)$ of pointed topological spaces such that the loop $\alpha * \beta * \overline{\alpha} * \overline{\beta}$ does not lift to a loop in $(X, x_0)$.

(b) Use Lemma 16.15 (1) to show that $\pi_1(B, b_0)$ is non-abelian.

**Exercise 16.11.**

(a) Does there exist a covering map $p: K \to T$ from the Klein bottle to the 2-dimensional torus?

(b) Let $X$ be a topological space and let $b \in \pi_1(X, x_0)$. Does there necessarily exist a map $f: (S^1, 1) \to (X, x_0)$ with $b \in f_*(\pi_1(S^1, 1))$?

(c) Let $X$ be a topological space and let $b, c \in \pi_1(X, x_0)$. Does there necessarily exist a map $f: (S^1 \times S^1, (1, 1)) \to (X, x_0)$ with $b, c \in f_*(\pi_1(S^1 \times S^1, (1, 1)))$?

**Exercise 16.12.** Which of the maps between topological graphs that are shown in Figure 333 are covering maps?
Exercise 16.13.

(a) Use Theorem 16.16 to show that the fundamental group of the pseudocircle, i.e. of the topological space $X = \{A, B, C, D\}$ from page 107, is isomorphic to $\mathbb{Z}$.

(b) Let $f : S^1 \to X$ be the map that we introduced on page 107. Show that the induced map $f_* : \pi_1(S^1, 1) \to \pi_1(X, A)$ is an isomorphism.

Exercise 16.14. Let $n \in \mathbb{N}$. We consider the map $f : S^1 \to S^1$ that is given by $z \mapsto z^n$. Show that the induced map on $\pi_1(S^1, 1)$ is given by multiplication by $n$.

Exercise 16.15. Let $A$ and $B$ be topological spaces and let $a_0 \in A$ and $b_0 \in B$. We consider the maps

$$f : A \to A \times B \quad \text{and} \quad g : B \to A \times B$$

$$a \mapsto (a, b_0) \quad \text{and} \quad b \mapsto (a_0, b)$$

and the map

$$\Phi : \pi_1(A, a_0) \times \pi_1(B, b_0) \to \pi_1(A \times B, (a_0, b_0))$$

$$(x, y) \mapsto f_*(x) \cdot g_*(y)$$

(a) Show that $\Phi$ is a monomorphism, i.e. that it is injective.

*Hint.* Consider the maps

$$p : A \times B \to A \quad \text{and} \quad q : A \times B \to B$$

$$(a, b) \mapsto a \quad \text{and} \quad (a, b) \mapsto b.$$

(b) Show that $\Phi$ is an epimorphism, i.e. that it is surjective.

*Hint.* Let $h(t) = (\alpha(t), \beta(t))$ be a loop in $(A \times B, (a_0, b_0))$. Consider the map

$$\Psi : [0, 1] \times [0, 1] \to A \times B$$

$$(s, t) \mapsto (\alpha(s), \beta(t)).$$

*Hint.* You might want to use ideas similar to the proof that the map $\Phi$ is a homomorphism.

Exercise 16.16. Let $A \in \text{GL}(n, \mathbb{Z})$ be a matrix. In Lemma 6.35 we saw that the map

$$f(A) : \mathbb{R}^n/\mathbb{Z}^n \to \mathbb{R}^n/\mathbb{Z}^n$$

$$v \mapsto Av.$$
is a homeomorphism. We identify $\pi_1(\mathbb{R}^n/\mathbb{Z}^n, 0)$ with $\mathbb{Z}^n$ as in Theorem [16.16]. Show that the following diagram

$$
\begin{array}{c}
\pi_1(\mathbb{R}^n/\mathbb{Z}^n, 0) \\
\downarrow \quad \quad \downarrow \\
\mathbb{Z}^n \\
\end{array}
\xrightarrow{f(A)_{*}}
\begin{array}{c}
\pi_1(\mathbb{R}^n/\mathbb{Z}^n, 0) \\
\downarrow \quad \quad \downarrow \\
\mathbb{Z}^n \\
\end{array}
$$

commutes.

**Exercise 16.17.** Let $(X,d)$ be a metric space and let $p: \widetilde{X} \to X$ be a covering. Given $x, y \in \widetilde{X}$ we define

$$
\tilde{d}(x, y) := \inf \left\{ \sum_{i=0}^{n-1} d(w_i, w_{i+1}) \left| \begin{array}{l}
\text{with } w_0, \ldots, w_n \in X, \ p(w_0) = x, \ p(w_n) = y \text{ and such} \\
\text{that for each } i \in \{0, \ldots, n-1\} \text{ there exists a uniformly} \\
\text{covered open subset that contains } w_i \text{ and } w_{i+1} \\
\end{array} \right. \right\}.
$$

(a) Show that $\tilde{d}$ defines on $\widetilde{X}$ and that the corresponding topology equals the topology of $\widetilde{X}$.

(b) Show that $p: \widetilde{X} \to X$ is a local isometry.

**Remark** Recall that a topological space $X$ is called *metrizable* if there exists a metric $d$ on $X$ such that the given topology agrees with the topology coming from $d$. The exercise shows in particular that every covering of a metrizable topological space is again metrizable.
17. Coverings of smooth and topological manifolds

17.1. Coverings of manifolds are manifolds. In this section we show that covering spaces of (topological) smooth manifolds are themselves (topological) smooth manifolds.

**Proposition 17.1.** Let \( p: \tilde{X} \to X \) be a countable covering\(^{282}\) of a connected \( n \)-dimensional topological manifold.

1. The covering space \( \tilde{X} \) is also an \( n \)-dimensional topological manifold. Furthermore, \( \partial \tilde{X} = p^{-1}(\partial X) \).
2. (a) If \( X \) admits a smooth atlas, then \( \tilde{X} \) also admits a smooth atlas such that \( p \) is a local diffeomorphism\(^{283}\) in particular such that \( p \) is a smooth map.
   (b) If \( X \) is equipped with a smooth structure\(^{284}\) then \( \tilde{X} \) admits a unique smooth structure such that \( p: \tilde{X} \to X \) is a local diffeomorphism.
3. If \( X \) is an oriented smooth manifold, then \( \tilde{X} \) also admits an orientation such that \( p: \tilde{X} \to X \) is orientation-preserving.
4. If \( X \) is equipped with a complex structure, then \( \tilde{X} \) admits a unique complex structure such that \( p: \tilde{X} \to X \) is a local biholomorphism.

**Convention.** If \( X \) is a smooth manifold, i.e. if \( X \) is a topological manifold equipped with a smooth structure, and if we have constructed a finite covering \( p: \tilde{M} \to M \), then we always equip \( \tilde{M} \) with the unique smooth structure given by Proposition 17.1 (2b). The same convention also applies to coverings of complex manifolds.

In the proof of Proposition 17.1 we will need the following technical lemma.

**Lemma 17.2. (\( \ast \))** Let \( p: \tilde{X} \to X \) be a countable covering of a topological space \( X \). If \( X \) is second-countable, then \( \tilde{X} \) is also second-countable.

**Proof (\( \ast \)).** Let \( p: \tilde{X} \to X \) be a countable covering of a topological space \( X \). Recall that we say \( U \subset X \) is uniformly covered, if \( p^{-1}(U) \) is the union of disjoint open subsets \( \{ \tilde{U}_i \}_{i \in I} \) with the property that the restriction of \( p \) to each subset \( \tilde{U}_i \) is a homeomorphism. If \( U \) is uniformly covered, then every open subset of \( U \) is also uniformly covered.

Let \( \mathcal{B} \) be a countable basis for the topology of \( X \). We denote by \( \mathcal{U} = \{ U_j \}_{j \in J} \) the family of all open subsets of \( X \) that are uniformly covered. Since \( p \) is a covering we have \( \bigcup_{j \in J} U_j = X \). It follows from Lemma 2.25 that

\[ \mathcal{B}' := \{ B \in \mathcal{B} \mid \text{there exists a } j \in J \text{ with } B \subset U_j \} \]

is also a basis for the topology of \( X \).

---

\(^{282}\)Recall that a covering \( p: \tilde{X} \to X \) of a connected topological space is called countable if the degree, i.e. the cardinality of the preimage of a point in \( X \), is countable.

\(^{283}\)Recall that a map \( f: M \to N \) between two smooth manifolds is called a local diffeomorphism if given any \( P \in M \) there exists an open neighborhood \( U \) of \( P \) and open neighborhood \( V \) of \( f(P) \) such that \( f: U \to V \) is a diffeomorphism.

\(^{284}\)We refer to page 278 for the definition of a smooth structure on a smooth manifold.
Now let $B \in \mathcal{B}'$. Since open subsets of uniformly covered subsets are uniformly covered we know that $p^{-1}(B)$ is the union of disjoint open sets $B_i$, $i \in I_B$ such that the restriction of $p$ to each $B_i$ is a homeomorphism. Since $p$ is a countable covering the index set $I_B$ is countable.

**Claim.**

\[ \tilde{B} := \{ B_i \mid B \in \mathcal{B}' \text{ and } i \in I_B \} \]

is a basis for the topology of $\tilde{X}$.

It is straightforward to see that $\tilde{B}$ has the basis property. Every set in $\tilde{B}$ is of course open in $\tilde{X}$. By Lemma 2.24 it suffices to show that given any open set $W$ of $\tilde{X}$ and any point $x \in W$ there exists a set $B_i$ in $\tilde{B}$ with $x \in B \subset W$. So let $x \in W$. Since $\mathcal{B}'$ is a basis for the topology of $X$ there exists a $B \in \mathcal{B}'$ with $p(x) \in B \subset p(W)$. But then there exists an $i \in I_B$ with $x \in B_i \subset W$. This completes the proof of the claim.

Since $\mathcal{B}'$ is countable and since each $I_B$ is countable we see that $\tilde{B}$ consists of countably many open sets. This shows that $\tilde{X}$ is second-countable. \[ \blacksquare \]

Now we can provide the proof of Proposition 17.1

**Proof of Proposition 17.1 (**) Let $p: \tilde{X} \to X$ be a countable covering of a connected $n$-dimensional topological manifold $X$.

1. First we note that it follows from the hypothesis that $X$ is a topological manifold that $X$ is Hausdorff. It follows from Lemma 16.3 (3) that $\tilde{X}$ is also Hausdorff. Similarly it follows from our hypothesis that $X$ is a topological manifold and that $p$ is a countable covering together with Lemma 17.2 that $\tilde{X}$ is second-countable.

Since $p: \tilde{X} \to X$ is a covering there exists a family of open subsets $\{ U_i \}_{i \in I}$ of $X$ such that each $U_i$ is uniformly covered. Furthermore, since $X$ is an $n$-dimensional smooth manifold there exists an atlas $\{ \Phi_j: V_j \to W_j \}_{j \in J}$ for $X$. After possibly replacing each $V_j$ by the family $\{ V_j \cap U_i \}_{i \in I}$ we can without loss of generality assume that each $V_j$ is uniformly covered. Thus for each $j$ the preimage $p^{-1}(V_j)$ is the union of disjoint open subsets $\{ \tilde{V}_{ji} \}_{i \in I_j}$ with the property, that the restriction of $p$ to each subset $\tilde{V}_{ji}$ is a homeomorphism. It is clear that $\{ \Phi_j \circ p: \tilde{V}_{ji} \to W_j \mid j \in J \text{ and } i \in I_j \}$ is an atlas for $\tilde{X}$.

Finally we intend to determine the boundary of $\tilde{X}$. Let $y \in \tilde{X}$. Using the fact that $p: \tilde{X} \to X$ is a local homeomorphism one can easily show that the point $y \in \tilde{X}$ does not admit a chart of type (i) in the sense of page 261 if and only if $p(y) \in X$ does not admit such a chart. This implies that $\partial \tilde{X} = p^{-1}(\partial X)$.

2. (a) The transition maps of the atlas from (1) are precisely given by restrictions to open subsets of the transition maps of the atlas $\{ \Phi_j: V_j \to W_j \}_{j \in J}$ for $X$. Thus if we start out with a smooth atlas for $X$, then the atlas we just constructed for $\tilde{X}$ is also smooth.
We also know that a covering map is a local homeomorphism. It follows immediately from the definitions that with this smooth atlas for $\tilde{X}$ these homeomorphisms are in fact diffeomorphisms.

(b) This statement follows easily from (a), together with Lemma 6.23. We leave it to the reader to fill in the details.

(3) This statement follows easily from the fact that $p$ is a local diffeomorphism.

(4) The proof of this statement is almost identical to the proof of (2).

17.2. The orientation covering of a non-orientable smooth manifold. We saw that many of our examples of non-orientable smooth manifolds admit a 2-fold covering such that the covering space is an orientable smooth manifold.

(1) For example the projection map $p: S^2 \to \mathbb{R}P^2 = S^2/\{\pm 1\}$ shows that the real projective plane is covered by the sphere.

(2) On page 496 we had considered the map

\[
p: \mathbb{R} \times [-1, 1]/(x, y) \sim (x + 1, y) \rightarrow \mathbb{R} \times [-1, 1]/(x, y) \sim (x + \frac{1}{2}, 1 - y)
\]

and we remarked this is a 2-fold covering. Thus the non-orientable Möbius band admits a 2-fold covering such that the covering space is orientable.

(3) Almost the same map as in (2) also shows that the torus is a 2-fold covering of the Klein bottle.

Now we will see that any non-orientable smooth manifold admits a unique 2-fold covering such that the covering space is orientable.

**Proposition 17.3.**

(1) To each smooth manifold $M$ we can canonically associate an oriented smooth manifold $\tilde{M}$ together with a 2-fold covering $p: \tilde{M} \to M$ and to each local diffeomorphism $f: M \to N$ we can associate an orientation-preserving local diffeomorphism $\tilde{f}: \tilde{M} \to \tilde{N}$ such that the following diagram commutes.

\[
\begin{array}{ccc}
\tilde{M} & \xrightarrow{\tilde{f}} & \tilde{N} \\
\downarrow p & & \downarrow p \\
M & \xrightarrow{f} & N.
\end{array}
\]
(2) Let $M$ be a connected smooth manifold and let $p: \widetilde{M} \to M$ be the 2-fold covering constructed in (1).

(a) If $M$ is orientable, then there exists an orientation-preserving diffeomorphism to

\[ \Theta: \widetilde{M} \to M \sqcup -M \]

such that the following diagram commutes:

\[
\begin{array}{ccc}
\widetilde{M} & \xrightarrow{\Theta} & M \sqcup -M \\
\downarrow{p} & & \downarrow{q} \\
M & \xleftarrow{q} & \\
\end{array}
\]

where $q$ is the obvious map given by the identity on each component of $M \sqcup -M$.

(b) If $M$ is non-orientable, then $\widetilde{M}$ is connected.

(c) In either case, the oriented smooth manifold $\widetilde{M}$ admits an orientation-reversing self-diffeomorphism $\Xi_M: \widetilde{M} \to \widetilde{M}$ such that the following diagram commutes:

\[
\begin{array}{ccc}
\widetilde{M} & \xrightarrow{\Xi_M} & \widetilde{M} \\
\downarrow{p} & & \downarrow{p} \\
M & \xleftarrow{q} & \\
\end{array}
\]

Furthermore, given an orientation-preserving local diffeomorphism $f: M \to N$ we have $\widetilde{f} \circ \Xi_M = \Xi_N \circ \widetilde{f}$.

(3) Let $M$ be a connected non-orientable smooth manifold. Suppose that $p: \widetilde{M} \to M$ and $q: \hat{M} \to M$ are two connected 2-fold coverings such that $\widetilde{M}$ and $\hat{M}$ are orientable. Then there exists a diffeomorphism $\Phi: \widetilde{M} \to \hat{M}$ such that the following diagram commutes:

\[
\begin{array}{ccc}
\widetilde{M} & \xrightarrow{\Phi} & \hat{M} \\
\downarrow{p} & & \downarrow{q} \\
M & \xleftarrow{q} & \\
\end{array}
\]

If $\widetilde{M}$ and $\hat{M}$ are oriented, then we can arrange that $\Phi$ is orientation-preserving.

Remark. In Proposition [86.15] we will prove an analogue of Proposition [17.3] for topological manifolds.

Definition. Let $M$ be a connected non-orientable smooth manifold. We refer to the covering $p: \widetilde{M} \to M$ from Proposition [17.3] (1) as the orientation covering of $M$. By Proposition [17.3] (2) this covering is unique in an appropriate sense, which justifies speaking of the orientation covering.

Proof. We start out with a general construction. Let $W$ be an $n$-dimensional smooth manifold. We consider the set

\[ \widetilde{W} = \{(Q, O) \mid Q \in W \text{ and } O \text{ is an orientation of } T_Q W \} \]

\[ ^{285} \text{Here canonically means that we give an explicit construction in the proof, but we do not to burden the reader with the explicit construction at this very moment.} \]

\[ ^{286} \text{We leave it to the reader to express this statement in categorical language.} \]
together with the map
\[ p = p_W : \tilde{W} \to W \]
\[ (Q, O) \mapsto Q. \]

Now we have to put a topology on \( \tilde{W} \). We use the following notation:

(i) We denote by \( O_{\mathbb{R}^n} \) the standard orientation of \( \mathbb{R}^n \).

(ii) Given an orientation \( O \) for an \( n \)-dimensional vector space we denote by \( -O \) the
unique other orientation.

(iii) Given an isomorphism \( \varphi : V \to W \) between vector spaces and given an orientation \( O \)
on \( W \) we denote by \( \varphi^*O \) the corresponding orientation on \( V \).

Given a chart \( \Phi : U \to V \) of \( W \) and \( \epsilon \in \{-, +\} \) we define
\[ B_\epsilon(\Phi) := \{(Q, \epsilon \cdot \Phi^*O_{\mathbb{R}^n}) \mid Q \in U\} \subset \tilde{W}. \]

It is straightforward to show that the collection of these sets \( B_\pm(\Phi) \) satisfies the basis
properties (B1) and (B2) from page 102. Now we endow \( \tilde{W} \) with the topology generated
by the sets \( B_\pm(\Phi) \). We leave it to the reader to show that \( p : \tilde{W} \to W \) is continuous. Next
we show that \( p \) is a 2-fold covering. So let \( Q \in W \). We pick a connected chart \( \Phi : U \to V \)
around \( Q \). Then \( p^{-1}(U) = B_-(\Phi) \cup B_+(\Phi) \). It follows from Lemma 6.46 (1) applied to
the connected smooth manifold \( U \) that \( B_-(\Phi) \) and \( B_+(\Phi) \) are disjoint. Furthermore it is
straightforward to see that the two projections maps \( p : B_\pm(\Phi) \to U \) are homeomorphisms.

This shows that \( U \) is uniformly covered by two sets, i.e. \( p \) is a 2-fold covering.

In the proof of Proposition 17.1 we saw that a smooth atlas for \( \tilde{W} \) is given by all maps
\( B_\pm(\Phi) \xrightarrow{p} U \xrightarrow{\Phi} V \) for all connected charts \( \Phi : U \to V \) of \( W \). In particular \( \tilde{W} \) is again an
\( n \)-dimensional smooth manifold and with this atlas the projection map \( p : \tilde{W} \to W \) is a
local diffeomorphism.

Now we show that \( \tilde{W} \) is orientable, in fact we will equip \( \tilde{W} \) with a canonical orientation.
So let \( (Q, O) \in \tilde{W} \). The map \( p : \tilde{W} \to W \) is a local diffeomorphism. Now we equip \( T_{(Q,O)}\tilde{W} \)
with the orientation \( p^*O \). By Footnote 114 it suffices to consider the continuity of the
orientation with respect to the above atlas. So let \( \Phi : U \to V \) be a connected chart of \( W \).
Let \( \epsilon \in \{-, +\} \) and denote by \( \Phi_\epsilon : B_\pm(\Phi) \to V \) the corresponding chart of \( \tilde{W} \). But then
by construction we know that \( \Phi_\epsilon \) is orientation-preserving for all points if \( \epsilon = + \) and it is
orientation-reversing for all points if \( \epsilon = - \).

Finally we turn to the actual proof of the proposition.

(1) Let \( M \) be a smooth manifold. We define \( \tilde{M} \) as above. It follows from the above
discussion that the smooth manifold \( \tilde{M} \) is an oriented smooth manifold and that
\( p_M : \tilde{M} \to M \) is a 2-fold covering. Furthermore, to a local diffeomorphism \( f : M \to N \)

---

287 Strictly speaking we should write \((D\Phi_p)^*O_{\mathbb{R}^n}\) instead of just \(\Phi^*O_{\mathbb{R}^n}\).
288 OK, so why does it satisfy (B2)?
289 Here we say a chart \( \Phi : U \to V \) is connected if \( U \) is connected.
290 Put differently, using \( p \) we can identify \( T_{(Q,O)}\tilde{W} \) with \( T_QW \) and we equip it with the orientation
at hand, namely \( O \).
between smooth manifolds we assign the following commutative diagram

\[
\begin{array}{ccc}
\tilde{M} & \xrightarrow{(Q,O) \mapsto (f(Q), f_*(O))} & \tilde{N} \\
\downarrow^p & \equiv & \downarrow^p \\
M & \xrightarrow{f} & N.
\end{array}
\]

It follows easily from the definitions that the top map \( \tilde{f} : \tilde{M} \to \tilde{N} \) is an orientation-preserving local diffeomorphism.

(2) Let \( M \) be a connected smooth manifold.

(a) If \( M \) is orientable, then there exists an obvious orientation-preserving diffeomorphism \( \Theta : \tilde{M} \to M \sqcup -M \) that has the desired properties.

(b) Now suppose that \( M \) is non-orientable. We need to show that \( \tilde{M} \) is connected. If it was not connected, then it would consist of at least two components \( \{ \tilde{M}_i \}_{i \in I} \).

Since \( M \) is connected the restriction of each \( p : \tilde{M} \to M \) to \( \tilde{p}_i : \tilde{M}_i \to M \) would also be a covering. Clearly \( 2 = [\tilde{M} : M] = \sum_{i \in I} [\tilde{M}_i : M] \). It follows that \( \# I = 2 \) and that each \( \tilde{p}_i : \tilde{M}_i \to M \) is a covering of degree one, i.e. each \( \tilde{p}_i \) is a homeomorphism. Since \( \tilde{p}_i \) is a local diffeomorphism it follows that \( \tilde{p}_i : \tilde{M}_i \to M \) is in fact a diffeomorphism. But that is not possible since \( M \) was assumed to be non-orientable whereas \( \tilde{M}_i \) is orientable.

(c) It is pretty straightforward to verify that the map \( \Xi : \tilde{M} \to \tilde{M} \) that is given by \( (Q, O) \mapsto (Q, -O) \) has all the desired properties.

(3) Let \( M \) be a connected non-orientable smooth manifold. Suppose we are given two connected 2-fold coverings of \( M \) by oriented smooth manifolds. We can assume that one of the two coverings is the covering constructed in (1). Let \( q : N \to M \) be some other connected 2-fold covering such that \( N \) is orientable. It follows easily from the fact that \( q \) is a local diffeomorphism and the discussion in (1) that there exists a 2-fold covering \( \tilde{q} : \tilde{N} \to \tilde{M} \) which makes the following diagram commute

\[
\begin{array}{ccc}
\tilde{N} & \xrightarrow{\tilde{q}} & \tilde{M} \\
\downarrow^p_N & & \downarrow^p_M \\
N & \xrightarrow{q} & M.
\end{array}
\]

From (2) and the fact that \( N \) is connected and orientable we obtain that \( \tilde{N} \) consists of two components \( \tilde{N}_1 \) and \( \tilde{N}_2 \). The restriction of \( p_N \) to \( \tilde{N}_1 \) and the restriction of \( \tilde{q} \) to \( \tilde{N}_1 \) are 1-fold coverings, hence diffeomorphisms. It is clear that \( \tilde{q} \circ (p_N|_{\tilde{N}_1})^{-1} : N \to \tilde{M} \) has the desired properties. If \( N \) is oriented, then one can easily arrange that the map \( N \to \tilde{M} \) is orientation-preserving.

**Remark.** A similar proof of Proposition [17.3](1) with slightly more detail is also given in [Lee09, Chapter 8.7].
Corollary 17.4.

(1) If \( M \) is a connected non-orientable smooth manifold, then there exists an epimorphism \( \pi_1(M) \to \mathbb{Z}_2 \).

(2) Every simply connected smooth manifold is orientable.

Proof. The second statement of the corollary is an immediate consequence of the first statement. Thus it suffices to prove the first statement.

Let \( M \) be a connected non-orientable smooth manifold. By Proposition 17.3 there exists a connected 2-fold covering \( p: \tilde{M} \to M \) such that \( \tilde{M} \) is orientable. It follows from Lemma 16.15 that \( p_*(\pi_1(\tilde{M})) \) is an index 2 subgroup of \( \pi_1(M) \). In Exercise 17.1 we will show that every index 2 subgroup of a group \( \pi \) is normal. In particular \( p_*(\pi_1(M)) \) is a normal index 2 subgroup of \( \pi_1(M) \). Note that this implies that we obtain an epimorphism \( \pi_1(M) \to \Gamma := \pi_1(M)/p_*(\pi_1(\tilde{M})) \). The group \( \Gamma \) has two elements, but any group with two elements is isomorphic to \( \mathbb{Z}_2 \). Thus we found the desired epimorphism \( \pi_1(M) \to \mathbb{Z}_2 \). 

We conclude this section with a discussion of orientation-preserving and reversing loops.

Definition. Let \( M \) be a connected non-orientable smooth manifold, let \( x_0 \in M \) be a point and let \( \gamma: [0,1] \to M \) be a loop in \( x_0 \). We denote by \( p: \tilde{M} \to M \) the orientation covering provided by Proposition 17.3. We pick \( \tilde{x}_0 \in p^{-1}(x_0) \) and we denote by \( \tilde{\gamma}: [0,1] \to \tilde{M} \) the unique lift of \( \gamma \), provided by Proposition 16.11, to the starting point \( \tilde{x}_0 \). We say \( \gamma \) is orientation-preserving if \( \tilde{\gamma}(1) = \tilde{\gamma}(0) \), otherwise we say that \( \gamma \) is orientation-reversing.\(^{201}\)

Example. Let \( M \) be the Möbius band and let \( \tilde{M} \) be the annulus. As on page 496 we consider the 2-fold covering \( p: \tilde{M} \to M \) which is just an incarnation of the orientation covering. We pick a point in \( \tilde{M} \) and we denote by \( \gamma \) a loop that goes “once around \( M \)” The lift of \( \gamma \) is not a loop, hence \( \gamma \) is orientation-reversing. We refer to Figure 334 for an illustration.

\[\text{Figure 334}\]

We conclude this chapter with the following lemma which gives an alternative proof to Corollary 17.4 (1).

\(^{201}\) It follows easily from Lemma 16.4 that this definition does not depend on the choice of \( \tilde{x}_0 \).
Lemma 17.5. Let $M$ be a connected non-orientable smooth manifold and let $x_0 \in M$ be a point. The map

$$\Phi: \pi_1(M, x_0) \to \{\pm 1\}$$

$$[\gamma: [0, 1] \to M] \mapsto \begin{cases} 1, & \text{if } \gamma \text{ is orientation-preserving}, \\ -1, & \text{if } \gamma \text{ is orientation-reversing} \end{cases}$$

is well-defined and it is an epimorphism.

**Proof.** We denote by $p: \tilde{M} \to M$ the orientation covering. The following three easy observations imply the lemma.

1. It follows immediately from Corollary 16.13 that $\Phi$ is well-defined.
2. Using Lemma 16.4 one easily verifies that $\Phi$ is a homomorphism.
3. We denote by $\tilde{x}_0'$ the other point in $p^{-1}(x_0)$. By Proposition 17.3 there exists a path $\delta: [0, 1] \to \tilde{M}$ from $\tilde{x}_0$ to $\tilde{x}_0'$. It follows basically immediately from the definitions that $\Phi([p \circ \delta]) = -1$. This shows that $\Phi$ is an epimorphism. 

Exercises for Chapter 17

**Exercise 17.1.** Let $\pi$ be a group. Show that every index 2 subgroup of $\pi$ is normal.

**Exercise 17.2.** Let $M$ be a connected non-orientable smooth manifold and let $p: \tilde{M} \to M$ be the orientable 2-fold covering from Proposition 17.3. Show that

$$\# \text{boundary components of } \tilde{M} = \# \text{non-orientable boundary components of } M + 2 \cdot \# \text{orientable boundary components of } M.$$

**Exercise 17.3.** Let $f: S^1 \to S^1$ be a map with $f(1) = 1$. Let $p: \mathbb{R} \to S^1$ be the covering that is given by $t \mapsto e^{it}$.

(a) Show that there exists a unique map $\tilde{f}: \mathbb{R} \to \mathbb{R}$ with $f(0) = 0$ such that the following diagram commutes:

$$\begin{array}{ccc}
\mathbb{R} & \xrightarrow{\tilde{f}} & \mathbb{R} \\
p \downarrow & & \downarrow p \\
S^1 & \xrightarrow{f} & S^1.
\end{array}$$

(b) Suppose that $f$ is a diffeomorphism. Show that the map $\tilde{f}$ from (a) is also a diffeomorphism.

**Exercise 17.4.**

(a) We consider the following commutative diagram:

$$\begin{array}{ccc}
\tilde{M} & \xrightarrow{\tilde{f}} & \tilde{N} \\
p \downarrow & & \downarrow q \\
M & \xrightarrow{f} & N
\end{array}$$
where \( \tilde{M}, M, \tilde{N} \) and \( N \) are smooth manifolds and where \( p \) and \( q \) are covering maps of the same finite degree. Show that \( f \) is a diffeomorphism if and only if \( \tilde{f} \) is a diffeomorphism.

(b) Let \( M \) and \( N \) be smooth manifolds and let \( f: M \to N \) be a diffeomorphism. We denote by \( p: \tilde{M} \to M \) and \( q: \tilde{M} \to M \) the orientation coverings of \( M \) and \( N \). Show that there exists an orientation-preserving diffeomorphism \( \tilde{f}: \tilde{M} \to \tilde{N} \) such that the following diagram commutes:

\[
\begin{array}{ccc}
\tilde{M} & \xrightarrow{\tilde{f}} & \tilde{N} \\
p & & \downarrow q \\
M & \xrightarrow{f} & N.
\end{array}
\]

**Exercise 17.5.** Let \( p: T \to K \) be the 2-fold covering of the Klein bottle by the torus that we discussed on page 197. Give an example of a smooth map \( f: K \to K \) such that there is no map \( \tilde{f}: T \to T \) which makes the following diagram commute:

\[
\begin{array}{ccc}
T & \xrightarrow{\tilde{f}} & T \\
p & & \downarrow p \\
K & \xrightarrow{f} & K.
\end{array}
\]

**Exercise 17.6.** Let \( M \) be an oriented \( n \)-dimensional smooth manifold, let \( N \) be a non-orientable connected \( n \)-dimensional smooth manifold and let \( f: M \to N \) be a smooth embedding. We denote by \( p: \tilde{N} \to N \) the orientation-covering from Proposition 17.3. Show that there exists an orientation-preserving smooth embedding \( g: M \to \tilde{N} \) with \( p \circ g = f \).
18. Homotopies and homotopy equivalent topological spaces

In this chapter we will see that “homotopy equivalent” topological spaces have isomorphic fundamental groups. In some instances this fact will allow us to reduce the calculation of fundamental groups to some of our earlier calculations.

The definition of being “homotopy equivalent” is slightly subtle and rests on the notion of two maps being homotopic.

18.1. Homotopic maps. In its most basic form a homotopy is a continuous deformation of maps between two topological spaces. To make this notion precise it is convenient to introduce the following notation.

**Notation.** Let $X$ and $Y$ be two topological spaces and let $a < b$ be two real numbers. Given a map $F: X \times [a, b] \to Y$ and given $t \in [a, b]$ we sometimes denote by $F_t$ the map

$$F_t: X \to Y, \quad x \mapsto F(x, t).$$

Now we move on to the actual definition we are interested in.

**Definition.** Let $X$ and $Y$ be two topological spaces.

1. A homotopy from $X$ to $Y$ is a map $F: X \times [0, 1] \to Y$.
2. Let $f_0, f_1: X \to Y$ be two maps. A homotopy between the maps $f_0$ and $f_1$ is a homotopy $F: X \times [0, 1] \to Y$ with $F_0 = f_0$ and $F_1 = f_1$. If there exists a homotopy between the maps $f_0$ and $f_1$, then we say that $f_0$ and $f_1$ are homotopic and sometimes we write $f_0 \simeq f_1$.

**Examples.**

1. In Figure 335 we show four maps $\alpha, \beta, \gamma$ and $\delta$ from the circle $S^1$ to the annulus $Y = B_2(0) \setminus B_1(0)$. The maps $\alpha$ and $\beta$ are homotopic whereas the maps $\gamma$ and $\delta$ look as if they are not homotopic. We will develop methods for showing that these maps are indeed not homotopic.

2. Recall that all maps between topological spaces are understood to be continuous.

3. Note that the map $F_t$ is indeed continuous.
(2) Given an orthogonal matrix $A \in O(n)$ we denote by $\rho(A)$ the map $f : S^{n-1} \to S^{n-1}$ that is given $x \mapsto A \cdot x$.
(a) If $\gamma : [0, 1] \to SO(n)$ is a path from some matrix $A$ to some matrix $B$, then the map
$$S^{n-1} \times [0, 1] \to S^{n-1} \quad (x, t) \mapsto \gamma(t) \cdot x$$
is a homotopy from $\rho(A)$ to $\rho(B)$.
(b) Let $A \in O(n)$. If $\det(A) = 1$, i.e. if $A \in SO(n)$, then it follows from Lemma 2.65 (2) that there exists a path $\gamma : [0, 1] \to SO(n)$ with $\gamma(0) = A$ and $\gamma(1) = \text{id}$. It follows from (a) that $\rho(A)$ is homotopic to the identity. Much later, on page 1182 we will see that if $\det(A) = -1$, then $f$ is actually not homotopic to the identity.

The next example is written down as a lemma.

**Lemma 18.1.** Let $X$ be a topological space and let $Y \subset \mathbb{R}^n$ be a subset. Furthermore let $f_0, f_1 : X \to Y$ be two maps. If $Y$ is convex, then
$$F : X \times [0, 1] \to Y \quad (x, t) \mapsto f_0(x) \cdot (1 - t) + f_1(x) \cdot t$$
is a homotopy between $f_0$ and $f_1$.

**Proof** $(*)$. Basically by definition we have $F_0 = f_0$ and $F_1 = f_1$. But we are not done yet, the conscientious reader will not have failed to notice that we need to show that the map $F$ is actually continuous. The map $F$ can be written as the composition of the following two maps:
$$X \times [0, 1] \to \mathbb{R}^n \times \mathbb{R}^n \times [0, 1] \to \mathbb{R}^n.$$
The first map is continuous by Lemma 3.8 (3) and the second map is continuous by basic results of real analysis. □

**Remark.** Let $\gamma_0, \gamma_1 : [a, b] \to Y$ be two maps from an interval to a topological space $Y$. We just said that the two maps are homotopic if there exists a map $\Gamma : [a, b] \times [0, 1] \to Y$ such that
(i) $\Gamma(t, 0) = \gamma_0(t)$ and $\Gamma(t, 1) = \gamma_1(t)$ for all $t \in [a, b]$.
We can also view these two maps as paths. If they have the same same starting point $\gamma_0(a) = \gamma_1(a) =: P$ and the same endpoint $\gamma_0(b) = \gamma_1(b) =: Q$, then we said on page 457 that the paths are path-homotopic if there exists a map $\Gamma : [a, b] \times [0, 1] \to Y$ that satisfies (i) and that satisfies also
(ii) $\Gamma(a, s) = P$ and $\Gamma(b, s) = Q$ for all $s \in [0, 1]$.

In the literature sometimes “path-homotopic” is also called “homotopic”. To distinguish the two notions of homotopies what we call “homotopic” is sometimes called “freely homotopic”. Clearly two path-homotopic paths are also homotopic. But in general the converse does
not hold. For example, consider the two paths
\[ \alpha: [0, 1] \to Y = \mathbb{C} \setminus \{0\} \quad \text{and} \quad \beta: [0, 1] \to Y = \mathbb{C} \setminus \{0\} \]
\[ x \mapsto e^{2\pi ix} \quad \text{and} \quad x \mapsto 1. \]
Here \( \alpha \) goes counterclockwise once around the origin and \( \beta \) is the constant path. We saw in Corollary 13.2 that \( \alpha \) and \( \beta \) are not path-homotopic. On the other hand they are homotopic. Indeed a homotopy is given by
\[ F: [0, 1] \times [0, 1] \to Y = \mathbb{C} \setminus \{0\} \]
\[ (x, t) \mapsto e^{2\pi ix(1-t)}. \]
This free is illustrated in Figure 336.

\[ \begin{array}{c}
\text{the path } \alpha \text{ is not path-homotopic} \\
\text{to a constant path}
\end{array} \]
\[ \begin{array}{c}
\text{the path } \alpha \text{ is homotopic} \\
\text{to a constant path}
\end{array} \]

if we do not have to fix the “second” endpoint, then we can continuously turn \( \alpha \) into a constant path

\textbf{Figure 336}

The difference between a path-homotopy and a homotopy of paths is that in the former context we want to “keep the endpoints fixed”. Sometimes when we study other maps between topological spaces we also might want to keep a suitable subset fixed under a homotopy. This leads us to the following definition.

\textit{Definition.} Let \( X \) and \( Y \) be topological spaces and let \( A \subset X \) be a subset.

1. We say a map \( F: X \times [0, 1] \to Y \) is a \textit{homotopy rel} \( A \) if for all \( x \in A \) and \( s, t \in [0, 1] \) we have \( F(x, s) = F(x, t) \). Sometimes we also say that such a homotopy is \textit{stationary on} \( A \).

2. We say that two maps \( f, g: X \to Y \) with \( f|_A = g|_A \) are \textit{homotopic rel} \( A \) if there exists a homotopy \( F \text{ rel } A \) with \( F_0 = f \) and \( F_1 = g \).

\textbf{Examples.}

1. By definition two paths \( \alpha, \beta: [0, 1] \to X \) in a topological space \( X \) are path-homotopic if and only if the two maps are homotopic rel \( \{0, 1\} \).

2. We consider the two maps \( f, g: \overline{B}^2 \to S^2 \) that are shown in Figure 337. These maps agree on \( S^1 \). It is fairly easy to see that the two maps are homotopic but it seems rather unlikely that they are homotopic rel \( S^1 \). Unfortunately right now we lack the tools for showing the latter statement.

We continue with the next variation on the notion of homotopy.
Definition. Let $X$ and $Y$ be two topological spaces.

1. An isotopy is a homotopy $F: X \times [0, 1] \to Y$ such that for each $t \in [0, 1]$ the map $F_t: X \to Y$ is an embedding. A homeotopy is a homotopy $F: X \times [0, 1] \to Y$ such that for each $t \in [0, 1]$ the map $F_t: X \to Y$ is a homeomorphism.

2. Let $f_0, f_1: X \to Y$ be two maps that are embeddings. We say $f_0$ and $f_1$ are isotopic if there exists an isotopy $F: X \times [0, 1] \to Y$ with $F_0 = f_0$ and $F_1 = f_1$.

Examples.

1. In Figure 338 we show two maps $f_0, f_1: [0, 1] \to \mathbb{R}^2$ that are embeddings. We also indicate two homotopies $F$ and $G$ between $f_0$ and $f_1$. The map $F$ is an isotopy, the map $G$ is not.

2. Let $n \in \mathbb{N}$. Let $f: \overline{B}^n \to \overline{B}^n$ be a homeomorphism. If $f|_{S^{n-1}} = \text{id}_{S^{n-1}}$, then $f$ is isotopic to $\text{id}_{\overline{B}^n}$. Indeed, in Exercise 18.3 we will see that the map

$$H: \overline{B}^n \times [0, 1] \to \overline{B}^n$$

$$(x, t) \mapsto \begin{cases} t \cdot f(x), & \text{if } 0 \leq \|x\| < t, \\ x, & \text{otherwise} \end{cases}$$

is continuous and that each $H_t$ is a homeomorphism. It is clear that $H_0 = \text{id}$ and $H_1 = f$. Thus we see that $H$ is the desired isotopy. The fact that $f$ is isotopic to $\text{id}_{\overline{B}^n}$ is often referred to as the Alexander trick.\(^{294}\) The definition of the homotopy $H$ is illustrated in Figure 339.

Now we can formulate the following lemma that is a refined version of Proposition 2.52 (2).

\(^{294}\)The existence of such a homotopy was first observed by a James Alexander in 1923, see [A124].
Lemma 18.2. (*) Let $A$ be a bounded closed convex subset of $\mathbb{R}^n$ with non-empty interior. Let $Q$ be a point in the interior of $A$. There exists a canonical isotopy $F: A \times [0,1] \to \mathbb{R}^n$ with the following three properties:

1. We have $F_0 = \text{id}_A$.
2. The map $F_1$ is a homeomorphism from $A$ to $\overline{B}^n$ and this map restricts to a homeomorphism $\partial A \to S^{n-1}$.
3. For any $t \in [0,1]$ we have $F(Q,t) = (1-t) \cdot Q$.

Proof (*). First consider the case that $Q$ is the origin. In the following we use the notation that we introduced in the proof of Proposition 2.53 (2). Similar to the discussion on page 128 we consider the map

$$F: A \times [0,1] \to \overline{B}^n$$

$$(x,t) \mapsto \begin{cases} x \cdot \frac{1}{(1-t)+t \cdot \rho(x)}, & \text{if } x \neq 0, \\ 0, & \text{if } x = 0. \end{cases}$$

It is straightforward to verify that this map has all the desired properties.

We leave it to the reader to modify the above proof to deal with the case that $Q$ is not the origin. $\blacksquare$

Sometimes it is useful to combine two homotopies or isotopies. This leads us to the following definition.

Lemma 18.3. (*) Let $X$ and $Y$ be topological spaces and let $A \subset X$ be a (possibly empty) subset of $X$. Let $G, H: X \times [0,1] \to Y$ be two homotopies rel $A$. If $G_1 = H_0$, then the map

$$G * H: X \times [0,1] \to Y$$

$$(P,t) \mapsto \begin{cases} G(P,2t), & \text{if } t \in [0, \frac{1}{2}], \\ H(P,2t - 1), & \text{if } t \in [\frac{1}{2}, 1]. \end{cases}$$

is a homotopy rel $A$ from $G_0$ to $H_1$. Furthermore, if $G$ and $H$ are isotopies, then $G * H$ is also an isotopy. We refer to $G * H$ as the combination of $G$ and $H$.

Proof (*). We only need to verify that $G * H$ is indeed continuous, but that is a consequence of Lemma 14.3 together with our hypothesis that $G_1 = H_0$. $\blacksquare$
In Proposition 14.2 we showed that being path-homotopic is an equivalence relation on the set of paths between two points. The first part of the following lemma is the obvious generalization to "homotopy of maps".

**Lemma 18.4.**

1. Let $X$ be and $Y$ topological spaces and let $A$ be a (possibly empty) subset of $X$. Then "homotopy rel $A$ of maps" forms an equivalence relation on the set of maps from $X$ to $Y$.

2. Let $f, g: X \to Y$, let $\alpha: W \to X$ and $\beta: Y \to Z$ be maps between topological spaces. The following conclusion holds:

   \[ f \simeq g \implies f \circ \alpha \sim g \circ \alpha \quad \text{and} \quad \beta \circ f \sim \beta \circ g.\]

**Proof.**

1. Not surprisingly the proof of Lemma 18.4 is basically identical to the earlier proof of Proposition 14.2. The only change is that we need to use Lemma 18.3 to show that the combination of two homotopies is indeed a homotopy, i.e. continuous.

2. This statement is basically obvious, we just need to precompose and postcompose a homotopy $H$ between $f$ and $g$ by $\alpha$ respectively $\beta$.

We continue with a rather classical type of an example.

**Definition.** Let $n \in \mathbb{N}$ and let $V \subset \mathbb{R}^n$ be a hyperplane, i.e. $V$ is a vector subspace of codimension one. We pick a vector $v$ of unit length orthogonal to $V$. We refer to the map

\[ \rho_V: \mathbb{R}^n \to \mathbb{R}^n, \quad w \mapsto w - 2 \cdot \langle v, w \rangle \cdot v \]

as the reflection in the hyperplane $V$. We refer to Figure 340 for an illustration.

**Figure 340**

**Lemma 18.5.** Let $n \in \mathbb{N}$.

1. Any reflection in a hyperplane of $\mathbb{R}^n$ has the following properties:
   
   (a) it is a diffeomorphism,
   
   (b) it is an isometry (i.e. it preserves the Euclidean distance) and preserves the origin,
   
   (c) it restricts to diffeomorphisms of $\overline{B}^n$ and $S^{n-1}$.

2. Any two reflections in hyperplanes of $\mathbb{R}^n$ are in fact related by a smooth isotopy $F: \mathbb{R}^n \times [0,1] \to \mathbb{R}^n$ such that each $F_t$ is also a reflection. In particular the isotopies are isotopies rel the origin.
18. HOMOTOPIES AND HOMOTOPY EQUIVALENT TOPOLOGICAL SPACES

**Proof.** Let \( n \in \mathbb{N} \).

(1) Let \( \rho \) be a reflection in a hyperplane of \( \mathbb{R}^n \). Clearly \( \rho \) is smooth and it satisfies \( \rho \circ \rho = \text{id}_{\mathbb{R}^n} \). This implies immediately that \( \rho \) is a diffeomorphism. A short amusing calculation shows that \( \rho \) preserves the scalar product, hence length. Since \( \rho(0) = 0 \) we see that \( \rho \) restricts to diffeomorphisms of \( \mathbb{B}^n \) and \( S^{n-1} \).

(2) Suppose we are given two hyperplanes \( V \) and \( W \) of \( \mathbb{R}^n \). By Lemma 3.32 there exists an orthogonal matrix \( A \in \text{SO}(n) \) with \( A \cdot V = W \). By Lemma 2.65 (2) together with Exercise 18.7 we know that there exists a smooth path \( \gamma: [0, 1] \to \text{O}(n) \) with \( \gamma(0) = \text{id} \) and \( \gamma(1) = A \). One can now easily verify that the map \( \mathbb{R}^n \times [0, 1] \to \mathbb{R}^n \) \( (P, t) \mapsto \rho_{\gamma(t)} \cdot V(P) \) is the desired smooth isotopy. \( \blacksquare \)

We return to more theoretical material.

**Lemma 18.6.** Let \( X, Y \) and \( Z \) be topological spaces. Let \( f, f': X \to Y \) and \( g, g': Y \to Z \) be maps.

(1) If \( f \) and \( f' \) are homotopic and if \( g \) and \( g' \) are homotopic, then the map \( g \circ f \) is homotopic to \( g' \circ f' \).

(2) If there exists a subset \( A \) of \( X \) such that \( f \) and \( f' \) are homotopic rel \( A \) and if there exists a subset \( B \) of \( Y \) such that \( f(A) = f'(A) \subset B \) and such that \( g \) and \( g' \) are homotopic rel \( B \), then \( g \circ f \) is homotopic to \( g' \circ f' \) rel \( A \).

**Proof.**

(1) Let \( F: X \times [0, 1] \to Y \) be a homotopy between \( f \) and \( f' \) and let \( G: Y \times [0, 1] \to Z \) be a homotopy between \( g \) and \( g' \). We consider the map \( H: X \times [0, 1] \to Z \) \( (x, t) \mapsto G(F(x, t), t) \).

This map is a homotopy between \( g \circ f \) and \( g' \circ f' \).

(2) One can easily verify that the homotopy in (1) also does the trick for (2). \( \blacksquare \)

**Definition.** Given two topological spaces \( X \) and \( Y \) we define \( [X, Y] := \{ \text{maps } X \to Y \}/\sim \) where \( f \sim g \) if there exists a homotopy between \( f \) and \( g \).

Sometimes, given a map \( f: X \to Y \) we denote by \( [f] \) the equivalence class it represents in \( [X, Y] \).

**Example.** We write \( I = [0, 1] \). In Exercise 18.9 we will see that for any path-connected topological space \( X \) the set \( [I, X] \) consists of a single element, i.e. all maps \( I = [0, 1] \to X \) are homotopic.

---

\(^{295}\)Technically speaking we did not introduce the notion of a smooth isotopy yet, we will do so on page 348, but presumably that does not pose a problem to the reader.
The following lemma is an immediate consequence of Lemmas 18.11 and 18.6.

**Lemma 18.7.** Let $X, Y$ and $Z$ be topological spaces. The map

$$([X,Y] \times [Y,Z] \to [X,Z] \quad (f, g) \mapsto [g \circ f])$$

is well-defined.

Lemma 18.7 leads us to the following definition.

**Definition.** We define the homotopy category $\text{HomTop}$ of topological spaces by

$$\text{Ob}(\text{HomTop}) := \text{all topological spaces},$$

$$\text{Mor}(X, Y) := [X, Y]$$

with the composition

$$\text{Mor}(X, Y) \times \text{Mor}(Y, Z) \to \text{Mor}(X, Z) \quad ([f], [g]) \mapsto [g \circ f].$$

Note that in this category the morphisms are not maps but they are equivalence classes of maps.

We conclude this section with the following elementary but useful lemma.

**Lemma 18.8.**

1. Let $f : X \to Y$ be a map between topological spaces. The element $[f] \in \text{Mor}(X, Y)$ is an isomorphism in the category $\text{HomTop}$ if and only if $f$ is a homotopy equivalence.
2. Let $f : X_1 \to X_2$ be a map between topological spaces and let $A$ be a topological space.

   If $f$ is a homotopy equivalence, then the induced maps

   $$[X_2, A] \to [X_1, A] \quad \text{and} \quad [A, X_1] \to [A, X_2]$$

   are bijections.

**Proof.**

1. This statement is a tautology, it follows immediately from the definitions.
2. This statement follows immediately from (1) together with Lemma 15.1. ■

18.2. **Closed oriented curves and fundamental groups.** (*) The following definition gets used frequently throughout the notes.

**Definition.** Let $M$ be a smooth manifold. A closed (oriented) curve in $M$ is a closed (oriented) connected 1-dimensional submanifold either of $\partial M$ or of $M$.

**Convention.** Often we just write “curve” instead of “closed curve”.

**Remark.**

1. Note that the boundary $\partial M$ a smooth manifold $M$ is not a submanifold of $M$. In particular, if $M$ is a 2-dimensional smooth manifold and $C$ is a closed boundary

---

297 We refer to page 478 for the definition of an isomorphism in a category.
component, then $C$ is not a submanifold of $M$, but it is a closed curve in $M$ in the above sense.

(2) On occasions, when we deal with explicit examples, we will use gentle generalizations of the above notion of a closed oriented curve, which in practice should not cause any confusion.

\[
\text{manifold } M
\]
\[
\text{closed oriented curves in } M
\]

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure341.png}
\caption{Closed (oriented) curves in a given smooth manifold $M$ have the nice feature that they are easy to draw. But strictly speaking they do not represent elements in $\pi_1(M)$ since elements in $\pi_1(M)$ are represented by maps $S^1 \to M$ and not just the images of such maps. Thus we need to clarify the connection between curves and homotopy classes of maps.}
\end{figure}

The key to this issue is the following lemma, which is also of independent interest.

**Lemma 18.9.**

1. Let $f : [0, 1] \to [0, 1]$ be a self-homeomorphism.
   
   (a) If $f$ is monotonously increasing, then $f$ is isotopic to the map $f(x) = x$.
   
   (b) If $f$ is monotonously decreasing, then $f$ is isotopic to the map $f(x) = -x$.

2. Every self-homeomorphism of $S^1$ is isotopic to the map $f(z) = z$ or to the map $g(z) = \overline{z}$.

3. Let $f : S^1 \to S^1$ be a diffeomorphism. If $f$ is orientation-preserving, then $f$ is diffeotopic to the identity, otherwise $f$ is diffeotopic to the reflection $r : S^1 \to S^1$ given by $(x, y) \mapsto (x, -y)$.

**Proof.** We will provide the proof of Statements (1) and (2) in Exercise 18.4. The proof of Statement (3) is quite similar to the proof of Statement (2). One just needs to work a little harder since one needs to make sure that a map is actually smooth. Alternatively we refer to the proof that we will give in Proposition 30.1 which cleverly sidesteps these technical issues by working with covering spaces.

**Corollary 18.10.** Let $M$ be a smooth manifold and let $C \subset M$ be a closed oriented curve in $M$. Furthermore let $x_0 \in C$. For any two orientation-preserving diffeomorphisms $\alpha, \beta : S^1 \to C$ with $\alpha(1) = \beta(1) = x_0$ we have $[\alpha] = [\beta] \in \pi_1(M, x_0)$.

**Proof.** It is fairly straightforward to prove the corollary using Lemmas 18.9 (1) and 14.4. We leave the task of filling in the details to the reader.

298 It is an elementary real analysis exercise to show that every self-homeomorphism $f : [0, 1] \to [0, 1]$ is either monotonously increasing or monotonously decreasing.
Convention. Let $M$ be a smooth manifold and let $C \subset M$ be a closed oriented curve in $M$. Throughout these notes we use that Corollary 18.10 allows us to view $C$ unambiguously as an element in $\pi_1(M, x_0)$ for any base point $x_0 \in C$.

18.3. Homotopy equivalent topological spaces. The following definition is one of the key definitions in topology. Unfortunately it usually takes some time to fully digest it.

Definition. Let $X$ be and $Y$ topological spaces.

1. A map $f : X \to Y$ is a homotopy equivalence between $X$ and $Y$, if $f$ admits a homotopy inverse, i.e. a map $g : Y \to X$ with $g \circ f \simeq \text{id}_X$ and $f \circ g \simeq \text{id}_Y$.

2. If there exists a homotopy equivalence between $X$ and $Y$, then we say that $X$ and $Y$ are homotopy equivalent.

3. Given a topological space $X$ we refer to the class of all topological spaces that are homotopy equivalent to $X$ as the homotopy type of $X$.

The name “homotopy equivalence” already suggests that this is an equivalence relation on the class of topological spaces. This is indeed the case.

Lemma 18.11.

1. Let $f : X \to Y$ and $g : Y \to Z$ be maps between topological spaces. If two out of the three maps $f$, $g$ and $g \circ f$ are homotopy equivalences, then so is the third.

2. The relation “homotopy equivalence” is an equivalence relation on the class of all topological spaces.

3. Let $f, g : X \to Y$ be two maps between topological spaces. If $f$ is a homotopy equivalence and if $g$ is homotopic to $f$, then $g$ is also a homotopy equivalence.

4. Let $X, Y$ and $Z$ be topological spaces.

   a. Let $f : X \to Y$ and let $g_0, g_1 : Y \to Z$ be maps such that $g_0 \circ f \simeq g_1 \circ f$. If $f$ is a homotopy equivalence, then $g_0 \simeq g_1$.

   b. Let $f_0, f_1 : X \to Y$ and let $g : Y \to Z$ be maps such that $g \circ f_0 \simeq g \circ f_1$. If $g$ is a homotopy equivalence, then $f_0 \simeq f_1$.

Proof (*).

1. Let $f : X \to Y$ and $g : Y \to Z$ be maps between topological spaces. There are three slightly different statements that need to be proved.

a. First suppose that the maps $f : X \to Y$ and $g : Y \to Z$ admit homotopy inverses $f' : Y \to X$ and $g' : Z \to Y$. Then we see that

\[
(f' \circ g') \circ (g \circ f) = f' \circ (g' \circ g) \circ f \simeq f' \circ \text{id}_Y \circ f = f' \circ f \simeq \text{id}_X.
\]

   by Lemma [18.4] (2) since $g' \circ g \simeq \text{id}_Y$

---

The perspicacious reader might notice that here things get logically a little dicey. More precisely, on page \[we had recalled the notion of an equivalence relation. But we had only defined the notion of an “equivalence relation” on a set and “all topological spaces” do not form a set they “only” form a class. One can also define the notion of an “equivalence relation” on a class, see e.g. [FPr85 Kapitel 2]. But we do not want to get into the discussion “what is a class?”. As a cheap way out we interpret the second statement of the lemma as saying that reflexivity, symmetry and transitivity hold for “homotopy equivalence” with the obvious interpretation.
Similarly one shows that \((g \circ f) \circ (f' \circ g') \simeq \text{id}_Z\). Thus we have shown that \(g \circ f\) is a homotopy equivalence.

(b) Next suppose that \(f: X \to Y\) and \(g \circ f: X \to Z\) admit homotopy inverses \(f': Y \to X\) and \(h': Z \to X\). Then we see that

\[
(f \circ h') \circ g \simeq f \circ h' \circ (g \circ f) \circ f' \simeq f \circ \text{id}_X \circ f' \simeq \text{id}_Y.
\]

by Lemma 18.4 (2) since \(f \circ f' \simeq \text{id}_Y\) since \(h'\) is a homotopy inverse of \(g \circ f\).

Similarly one shows that \(g \circ (f \circ h') \simeq \text{id}_Z\). Thus we have shown that \(g\) is a homotopy equivalence.

(c) A slight variation on the argument of (1b) shows that if \(g\) and \(g \circ f\) are homotopy equivalence, then so is \(f\).

(2) It is clear that the only property of an equivalence relation that requires any thought is transitivity. But this follows from (1).

(3) We leave the elementary verification of the last statement to the reader.

(4) The proof is very similar to the proof of (1). Again we leave the details to the reader. \(\blacksquare\)

Before we give examples of homotopy equivalent topological spaces we introduce the following definition.

**Definition.** Let \(X\) be a topological space. We say \(X\) is *contractible*, if \(X\) is homotopy equivalent to a topological space which consists of precisely one point.

The following elementary lemma gives a handy criterion for showing that a topological space is contractible.

**Lemma 18.12.** Let \(X\) be a topological space.

\[
(1) \text{X is contractible} \iff (2) \text{there exists an } x_0 \in X \text{ such that the inclusion } \{x_0\} \to X \text{ is a homotopy equivalence} \iff (3) \text{there exists an } x_0 \in X \text{ such that the identity map } \text{id}_X \text{ is homotopic to the constant map } c_{x_0}.
\]

**Remark.** In Exercise 18.20 we will see that if statement (2) or (3) of Lemma 18.12 holds for a single point, then it holds for all points in \(X\).

![Figure 342](image.png)

**Figure 342**

**Proof (•).**

(1)\(\Rightarrow\) (2) First suppose that \(X\) is contractible. Let \(Y = \{\ast\}\) be the topological space consisting of a single element. Since \(X\) is contractible we know that there exists a map \(g: \{\ast\} \to X\) that is a homotopy equivalence. We set \(x_0 := g(\ast)\). Basically by definition the inclusion map \(\{x_0\} \to X\) is also a homotopy equivalence.
(2)⇒(3) Let \( x_0 \in X \) be a point such that the inclusion map \( f: \{x_0\} \to X \) is a homotopy equivalence. Let \( g: X \to \{x_0\} \) be the unique map. Since \( f \) is a homotopy equivalence we know that \( f \circ g \) is homotopic to \( \text{id}_X \). But \( f \circ g = c_{x_0} \). Thus we have shown that \( \text{id}_X \) is homotopic to \( c_{x_0} \).

(3)⇒(1) Finally we suppose that the identity map of \( X \) is homotopic to a constant map \( f: X \to \{x_0\} \). Let \( \star \) be the unique point in the image of \( \star \). We set \( Y := \{\star\} \). Let \( g: \{\star\} \to X \) be the inclusion map. By hypothesis we have \( g \circ f \simeq \text{id}_X \). Furthermore we evidently have \( f \circ g = \text{id}_Y \). This shows that \( X \) is homotopic equivalent to \( Y = \{\star\} \). □

We give two basic examples of homotopy equivalent topological spaces.

Examples.

(1) Let \( X \) be a star-shaped subset of \( \mathbb{R}^n \) and let \( x_0 \in X \) be a point such that for any \( x \in X \) the segment from \( x_0 \) to \( x \) lies in \( X \). Basically by the same argument as in Lemma 18.1 we see that the map

\[
f: X \times [0, 1] \to X \\
(x, t) \mapsto x_0 \cdot (1 - t) + x \cdot t
\]

is a homotopy from \( \text{id}_X \) to a constant map. By Lemma 18.12 this shows that \( X \) is contractible.

(2) It follows from the previous example together with Lemma 18.11 that for any \( n \in \mathbb{N} \) and any \( k \in \mathbb{N} \) the topological spaces \( \mathbb{R}^n \) and \( \mathbb{R}^k \) are homotopy equivalent.

We leave the proof of the following lemma as an edifying exercise to the reader, see Exercise 18.23.

Lemma 18.13. Let \( f: X \to Y \) be a map between topological spaces. If \( f \) is a homotopy equivalence, then \( f \) induces a bijection \( \pi_0(X) \to \pi_0(Y) \). In particular, \( X \) is path-connected if and only if \( Y \) is path-connected.

Definition. Let \( X \) be a topological space and let \( A \) be a subset.

(1) A homotopy \( F: X \times [0, 1] \to X \) is called stationary on \( A \), if \( F(a, t) = a \) for all \( a \in A \) and all \( t \in [0, 1] \).

(2) A deformation retraction from \( X \) to \( A \) is a homotopy \( F: X \times [0, 1] \to X \) which has the following three properties:

(a) \( F_0 = \text{id}_X \),
(b) the homotopy is stationary on \( A \),
(c) \( F_1(X) \subseteq A \).

(3) We say that \( A \) is a deformation retract of \( X \) if there exists a deformation retraction from \( X \) to \( A \).

(4) We say a retraction \( r: X \to A \) is realized by a deformation retraction if there exists a deformation retraction \( F \) from \( X \) to \( A \) with \( F_1 = r \).

We say a point \( a \in X \) is a deformation retract of \( X \) if the subset \( \{a\} \) if a deformation retract of \( X \).
18. HOMOTOPIES AND HOMOTOPY EQUIVALENT TOPOLOGICAL SPACES

Examples.

(1) For any topological space $X$ and any interval $I \subset \mathbb{R}$ containing 0 the subspace $X \times \{0\}$ is a deformation retract of $X \times I$. In fact the deformation retraction is given by

$$ (X \times I) \times [0,1] \rightarrow X \times I \quad ((x,s),t) \mapsto (x,s \cdot (1-t)). $$

(2) Let $n \in \mathbb{N}$. In Exercise 18.24 we will prove the following two statements:
   (a) The sphere $S^{n-1}$ is a deformation retract of $\mathbb{R}^n \setminus \{0\}$.
   (b) The hemispheres $S_{\leq 0}^{n-1}$ is a deformation retract of $\bar{B}^n$.
   (c) Given any three non-collinear points $A, B, C \in \mathbb{R}^n$ the triangle $\Delta_{ABC}$ admits a deformation retraction to the union of any two sides of the triangle.

These three examples are illustrated in Figure 344.

\begin{figure}[h]
\centering
\includegraphics[width=0.8\textwidth]{deformation_retract.png}
\caption{Schematic picture of a deformation retraction.}
\end{figure}

Remark. Let $X$ be a topological space and let $A \subset B \subset X$ be subspaces. It follows almost immediately from Lemma 18.3 that if $A$ is a deformation retract of $B$ and $B$ is a deformation retract of $X$, then $A$ is a deformation retract of $X$.

In Exercise 18.25 we will prove the following elementary lemma.

---

\footnote{Note that $F_1 : X \rightarrow A$ is retraction from $X$ to $A$.}

\footnote{Unfortunately in the literature the term “deformation retract” is used differently by different authors. Our notion of a “deformation retract” agrees with the definition in [Hat02] p. 2 and [Mun84] p. 208. What we call a “deformation retract” is called a “strong deformation retract” in [Bre93] p. 45 and [Rot88] p. 209]. In these books this notion is used to distinguish it from the notion of a “weak deformation retract”, which means that there exists a map $F : X \times [0,1] \rightarrow X$ such that
   (1) for every $x \in X$ we have $F(x,0) = x$ and $F(x,1) \in A$,
   (2) for every $a \in A$ we have $F(a,1) = a$.

It turns out that the two concepts are indeed different. For example, let $Z$ be the infinite zigzag comb from Exercise 18.11. Every point is a weak deformation retract but no point is a strong deformation retract of $X$.

\footnote{It follows from the discussion on page 109 and Lemma 3.8(2b) that this map is actually continuous.}
Lemma 18.14. Let $A$ be a subset of a topological space $X$ which admits a deformation retraction $F$ from $X$ to $A$. Then the inclusion map

$$A \to X \quad \text{and the map} \quad X \to A$$

$$a \mapsto a \quad \text{and} \quad x \mapsto F(x, 1)$$

are both homotopy equivalences. In particular the deformation retract $A$ is homotopy equivalent to the total space $X$.

The lemma often gives a convenient way for showing that two spaces are homotopy equivalent. For example the lemma, together with the previous example implies that the sphere $S^{n-1}$ and $\mathbb{R}^n \setminus \{0\}$ are homotopy equivalent.

The notions of a topological space being contractible and admitting a deformation retraction to a point sound quite similar. The following lemma gives the precise relationship between these two notions.

Lemma 18.15.

1. If a topological space $X$ admits a deformation retraction to a point $x_0 \in X$, then $X$ is homotopy equivalent to $\{x_0\}$, in particular $X$ is contractible.
2. If a topological space $X$ is contractible, then given any point $x_0 \in X$ there exists a homotopy $H: X \times [0, 1] \to X$ such that $H_0 = \text{id}_X$ and $H_1(x) = x_0$ for all $x_0 \in X$.
3. The “infinite zigzag comb” shown in Figure 345 is contractible, but it does not admit a deformation retraction to a point.

![Figure 345](attachment:image.png)

**Proof.**

1. This statement follows immediately from Lemma 18.14.
2. Suppose $X$ is a topological space that is contractible. By Lemma 18.12 we know that there exists a homotopy $G: X \times [0, 1] \to X$ from $\text{id}_X$ to a constant map. Let $x_1$ be the image of this constant map. Recall that we know from Lemma 18.13 that $X$ is path-connected. Thus there exists a path $\gamma: [0, 1] \to X$ from $x_1$ to $x_0$. The desired homotopy is now given by the map

$$H: X \times [0, 1] \to X$$

$$(x, t) \mapsto \begin{cases} G(x, 2 \cdot t), & \text{if } t \in [0, \frac{1}{2}], \\ \gamma(2 \cdot t - 1), & \text{if } t \in [\frac{1}{2}, 1]. \end{cases}$$

3. This statement will be proved in Exercise 18.11.

---

303 This map is continuous by Lemma 2.35 (2).
18.4. The fundamental groups of homotopy equivalent topological spaces. Now we will see that homotopy equivalent topological spaces have isomorphic fundamental groups. On numerous occasions this fact will often greatly simplify the calculation of fundamental groups.

**Proposition 18.16.**

1. Let \( f, g : X \to Y \) be two maps between topological spaces and let \( x_0 \in X \). If \( f \) and \( g \) are homotopic, then there exists a path \( \alpha : [0,1] \to Y \) from \( f(x_0) \) to \( g(x_0) \) such that the following diagram commutes:

\[
\begin{array}{ccc}
\pi_1(X, x_0) & \xrightarrow{f_*} & \pi_1(Y, f(x_0)) \\
\alpha_* & \downarrow & \alpha_* \\
\pi_1(Y, g(x_0)) & \xrightarrow{g_*} & \pi_1(Y, g(x_0))
\end{array}
\]

Here the vertical map is the isomorphism given by Proposition 14.11. In particular \( f_* : \pi_1(X, x_0) \to \pi_1(Y, f(x_0)) \) is an isomorphism \( \iff \) \( g_* : \pi_1(X, x_0) \to \pi_1(Y, g(x_0)) \) is an isomorphism.

The analogous statement holds if we replace “isomorphism” by “epimorphism” or “monomorphism”. Furthermore, the following two refinements hold:

(a) If \( f \) and \( g \) are homotopic rel \( x_0 \), then \( f_* = g_* \).

(b) If \( f(x_0) = g(x_0) \) and if the maps \( f \) and \( g \) are homotopic, then there exists an \( \alpha \in \pi_1(Y, f(x_0)) \) such that \( f_*(z) = \alpha \cdot g_*(z) \cdot \alpha^{-1} \) for every \( z \in \pi_1(X, x_0) \).

2. Let \( f : X \to Y \) be a map between topological spaces and let \( x_0 \in X \). If \( f \) is a homotopy equivalence, then the induced map

\( f_* : \pi_1(X, x_0) \to \pi_1(Y, f(x_0)) \)

is an isomorphism.

3. If \( X \) is contractible topological space, then for any \( x_0 \in X \) we have \( \pi_1(X, x_0) = 0 \).

**Example.** For any \( n \geq 2 \) and any \( Q \in \mathbb{R}^n \) we have

\[
\pi_1(\mathbb{R}^n \setminus \{Q\}) \cong \pi_1(\mathbb{R}^n \setminus \{0\}) \cong \pi_1(S^{n-1}) \cong \begin{cases} \mathbb{Z}, & \text{if } n = 2, \\ 0, & \text{if } n \geq 3. \end{cases}
\]

**Proof (continued).**

(1) Let \( f, g : X \to Y \) be two maps between topological spaces and let \( x_0 \in X \). Let \( H : X \times [0,1] \to Y \) be a homotopy between \( f \) and \( g \). We denote by

\[
\alpha : [0,1] \to Y \\
t \mapsto H(x_0, t)
\]

the path with which the homotopy \( H \) connects the points \( H(x_0, 0) = f(x_0) \) and \( H(x_0, 1) = g(x_0) \).
Claim. The maps
\[ f_\ast : \pi_1(X, x_0) \to \pi_1(Y, f(x_0)) \quad \text{and} \quad \pi_1(X, x_0) \to \pi_1(Y, f(x_0)) \]
are identical.

Let \( s : [0, 1] \to X \) be a loop in \((X, x_0)\). We need to show that the loops \( f \circ s \) and \( \bar{\alpha} * (g \circ s) * \alpha \) are path-homotopic. We consider the map
\[ G : [0, 1] \times [0, 1] \to X \]
\[(r, t) \mapsto \begin{cases} \alpha(4r), & \text{if } r \in [0, \frac{1}{4t}], \\ H \left( s \left( \frac{r - \frac{1}{4}t}{1 - \frac{1}{4}t}, 1 - t \right) \right), & \text{if } r \in (\frac{1}{4t}, 1 - \frac{1}{4}t), \\ \alpha(4r - 3), & \text{if } r \in [1 - \frac{1}{4}t, 1]. \end{cases} \]
Using Lemma 14.3, it is straightforward to verify that \( G \) is indeed a continuous map. Furthermore it follows easily from the definition that the map \( G \) satisfies
\[ G(0, t) = G(1, t) = f(x_0) \quad \text{for all } t \in [0, 1] \]
and that it satisfies
\[ G(r, 0) = (f \circ s)(r) \quad \text{and} \quad G(r, 1) = (\bar{\alpha} * (g \circ s) * \alpha)(r) \quad \text{for all } r \in [0, 1]. \]
This observation shows that \( G \) is in fact a path-homotopy between the loops \( f \circ s \)

![Diagram](image)

**Figure 346.** Schematic image of \( H \) and \( G \).

and \( \alpha * (g \circ s) * \bar{\alpha} \) in \((Y, f(x_0))\).

As in the statement of the proposition we consider the following diagram:

\[ \pi_1(X, x_0) \xrightarrow{f_\ast} \pi_1(Y, f(x_0)) \]

We make the following observations:

(a) It follows from the claim that the diagram commutes.

(b) By Proposition 14.11, we know that the vertical map is an isomorphism.

(c) It follows from (a) and (b) that \( f_\ast \) is an isomorphism if and only if \( g_\ast \) is an isomorphism.

\[ ^{304} \text{To be precise, } G \text{ is a homotopy between } f \circ s \text{ and a suitable parametrization of } \alpha * (g \circ s) * \bar{\alpha}. \]
(d) Now suppose that $f$ and $g$ are homotopic rel $x_0$. By definition this means that there exists a homotopy $H$ with $H(x_0, t) = f(x_0)$ for all $t \in [0, 1]$. In other words, $\alpha(t) := H(x_0, t)$ is a constant path. It follows from the above that $f_* = g_*$. 

(e) If $f(x_0) = g(x_0)$, then $\alpha$ is a loop in $(Y, f(x_0))$, i.e. it defines an element in $\pi_1(Y, y_0)$. Thus we have $[\alpha * (g \circ s) * \overline{\alpha}] = [\alpha] \cdot g_*(s) \circ [\alpha]^{-1}$. By the above commutative diagram we obtain the desired equality.

The analogous statement holds if we replace “isomorphism” by “epimorphism” or “monomorphism”.

(2) Let $f: X \to Y$ be a map between topological spaces which is a homotopy equivalence. Let $x_0 \in X$ be a point. We pick a homotopy inverse $g: Y \to X$ of $f$. According to our hypothesis we have $g \circ f \simeq \text{id}_X$ and $f \circ g \simeq \text{id}_Y$. It follows from (1) and the functoriality of fundamental groups that $g_* \circ f_*$ is an isomorphism of $\pi_1(X, x_0)$ and that $f_* \circ g_*$ is an isomorphism of $\pi_1(Y, f(x_0))$. Thus it remains to prove the following purely group theoretic claim.

**Claim.** Let $\alpha: A \to B$ and $\beta: B \to A$ be group homomorphisms. If $\alpha \circ \beta$ and $\beta \circ \alpha$ are isomorphisms, then $\alpha$ is an isomorphism.

First note that the fact that $\beta \circ \alpha: A \to A$ is an isomorphism implies that $\alpha$ is a monomorphism. Furthermore, the fact that $\alpha \circ \beta: B \to B$ is an isomorphism implies that $\alpha$ is an epimorphism. Thus we have shown that $\alpha$ is a monomorphism and an epimorphism, therefore it is an isomorphism. □

(3) This statement is just a frequently used special case of the second statement. ■

In Lemma 2.59 we already saw that the topological spaces $\mathbb{R}$ and $\mathbb{R}^2$ are not homeomorphic. Now we can prove a similar statement in one dimension higher.

**Lemma 18.17.** The topological spaces $\mathbb{R}^2$ and $\mathbb{R}^3$ are not homeomorphic.

Unfortunately we are still not able to settle the question whether for $k \neq l \geq 3$ the topological spaces $\mathbb{R}^k$ and $\mathbb{R}^l$ can be homeomorphic. Before we can settle this question we will have to develop a completely new set of tools.

**Proof.** Let us suppose that there exists a homeomorphism $f: \mathbb{R}^2 \to \mathbb{R}^3$. Let $P \in \mathbb{R}^2$ be a point. We put $Q := f(P)$. Then $f$ restricts to a homeomorphism from $\mathbb{R}^2 \setminus \{P\}$ to $\mathbb{R}^3 \setminus \{Q\}$. But then we obtain that

$$\mathbb{Z} \cong \pi_1(\mathbb{R}^2 \setminus \{P\}) \cong \pi_1(\mathbb{R}^3 \setminus \{Q\}) = 0.$$ 

Thus we obtained a contradiction. ■

18.5. **The boundary of 2-dimensional topological manifolds ( ).** The goal of this section is to prove the a subtle statement that the boundary of a 2-dimensional topological manifold is what you think it should be. To make sense of this it is perhaps worth reminding us of the definitions from page 261.
**Definition.** Let $F$ be a $n$-dimensional topological manifold.

(a) An $n$-dimensional chart for $F$ at a point $x \in X$ is a homeomorphism $\Phi: U \to V$ where $U$ is an open neighborhood of $x$ and $V$ is one of the following:

(i) $V$ is an open subset of $\mathbb{R}^n$ or

(ii) $V$ is an open subset of the upper half-space $H := \{(x_1, \ldots, x_n) \in \mathbb{R}^n \mid x_n \geq 0\}$ and $\Phi(x)$ lies on $\partial H = \{(x_1, \ldots, x_n) \in \mathbb{R}^n \mid x_n = 0\}$.

In the former case we say that $\Phi$ is a chart of type (i) in the latter case we say that $\Phi$ is a chart of type (ii).

(b) We say that a point $x$ on a topological manifold is a boundary point if $x$ does not admit a chart of type (i). We denote by $\partial X$ the set of all boundary points of $X$.

**Proposition 18.18.** Let $F$ be an 2-dimensional topological manifold. The following statements hold:

1. Every point on $F$ admits either a chart of type (i) or it admits a chart of type (ii).
2. If $F$ is equipped with a smooth atlas, i.e. if we view $F$ as a smooth manifold, then the boundary of $F$ as a topological manifold agrees with the boundary of $F$ viewed as a topological manifold.
3. The boundary $\partial F$ is an 1-dimensional topological manifold with empty boundary, i.e. we have $\partial(\partial F) = \emptyset$.

**Remark.** It might come as a surprise that we do not yet know the statement of the proposition. In fact in Proposition 6.27 we saw that the boundary of any $n$-dimensional smooth manifold is an $(n-1)$-dimensional smooth manifold. But we did not show the corresponding statement for topological manifolds. In fact at the moment we can prove the statement only for topological manifolds of dimension two. We will deal with the case of higher-dimensional topological manifolds in Proposition 44.2 once we introduced and studied homology groups.

**Example.** In Figure 347 we show once again the Möbius band $M$ and the annulus $A$. Proposition 18.18 together with Proposition 6.27 says that the boundary of the Möbius band $M$ and the annulus $A$, as a topological manifold, is exactly what we think it should be. In particular we see that $\partial M$ consists of one component whereas $\partial A$ consists of two components. Since homeomorphisms of topological manifolds induced homeomorphisms of their boundaries and since $\partial M$ is not homeomorphic to $\partial A$ we see that the Möbius band $M$ is not homeomorphic to the annulus $A$.

![Figure 347](image-url)

The key ingredient in the proof of Proposition 18.18 is the following lemma.
Lemma 18.19. Let $H = \{(x, y) \in \mathbb{R}^2 \mid y \geq 0\}$ be the upper half-space in $\mathbb{R}^2$. If $V$ is an open subset of $H$ with $V \cap \partial H \neq \emptyset$, then $V$ is not homeomorphic to an open subset of $\mathbb{R}^2$.

Figure 348. Illustration of Lemma 18.19

Proof. Let $V$ be an open subset of the upper half-space $H$ which contains at least one point $Q \in \partial H = \{(x, 0) \mid x \in \mathbb{R}\}$. Furthermore let $U$ be an open subset of $\mathbb{R}^2$. Suppose there exists a homeomorphism $\Phi: U \to V$. We write $\Psi := \Phi^{-1}$ and we write $P = \Psi(Q)$.

Since $U$ is open in $\mathbb{R}^2$ we can pick a $\sigma > 0$ with $B_\sigma(P) \subset U$. Furthermore, since $V$ is open in $H$ and since $\Psi$ is continuous there exists an $\epsilon > 0$ with $B_\epsilon(Q) \cap H \subset V$ and with $\Psi(B_\epsilon(Q)) \subset B_\sigma(P)$. Finally, by the continuity of $\Phi$ there exists an $\eta > 0$ with $\Phi(B_\eta(P)) \subset B_\epsilon(Q)$. We refer to Figure 349 for an illustration. We consider the following commutative diagram of maps

\[
\begin{array}{ccc}
(B_\epsilon(Q) \setminus \{Q\}) \cap H & \xrightarrow{\Phi} & B_\eta(P) \setminus \{P\} \\
& \xrightarrow{\Psi = \Phi^{-1}} & \xrightarrow{i} B_\sigma(P) \setminus \{P\},
\end{array}
\]

where $i: B_\eta(P) \setminus \{P\} \to B_\sigma(P) \setminus \{P\}$ denotes the inclusion map. Now we pick a base point $x \in B_\eta(P) \setminus \{P\}$. By the functoriality of fundamental groups, the above commutative diagram gives rise to the following commutative diagram

\[
\begin{array}{ccc}
\pi_1((B_\epsilon(Q) \setminus \{Q\}) \cap H, \Phi(x)) & \xrightarrow{\Phi_*} & \pi_1(B_\eta(P) \setminus \{P\}, x) \\
& \xrightarrow{\Psi_* = \Phi_*^{-1}} & \xrightarrow{i_*} \pi_1(B_\sigma(P) \setminus \{P\}, x).
\end{array}
\]

We make the following observations:

Figure 349. Illustration for the proof of Lemma 18.19
(1) the topological spaces on the left and on the right are homotopy equivalent to $S^1$, in particular the fundamental groups are non-trivial,

(2) by Exercise \[18.22\] the inclusion map $B_{\eta}(P) \setminus \{P\} \to B_{\sigma}(P) \setminus \{P\}$ is a homotopy equivalence, therefore it follows from Proposition \[18.16\] (2) that the inclusion induced map $i_*: \pi_1(B_{\eta}(P) \setminus \{P\}, x) \to \pi_1(B_{\sigma}(P) \setminus \{P\}, x)$ is an isomorphism,

(3) the topological space $(B_{\epsilon}(Q) \setminus \{Q\}) \cap H$ is star-shaped\footnote{Why is that?}, which implies by the discussion on page 471 that $\pi_1((B_{\epsilon}(Q) \setminus \{Q\}) \cap H, \Phi(x)) = 0$.

Summarizing we just showed that an isomorphism of non-trivial groups factors through the trivial group. This is not possible and hence we have obtained the desired contradiction. ■

Now we can turn to the proof of Proposition \[18.18\].

**Proof of Proposition \[18.18\]** Let $F$ be an 2-dimensional topological manifold.

(1) Let $x$ be a point on $F$. We need to show that $x$ admits either a chart of type (i) or it admits a chart of type (ii). Suppose that $x$ admits a chart $\Phi: U \to V$ of type (i) and also a chart $\Psi: X \to Y$ of type (ii). Then $\Phi \circ \Psi^{-1}: \Phi(U \cap X) \to \Phi(U \cap X)$ would give rise to a homeomorphism from an open set of $H$ containing a point on $\partial H = \{(x, 0) \mid x \in \mathbb{R}\}$ to an open set in $\mathbb{R}^2$. But by Lemma \[18.19\] such a homeomorphism cannot exist.

(2) Now suppose that $F$ is equipped with a smooth atlas. For the purpose of this proof we write $\partial^{\text{top}}F$ and $\partial^{\text{sm}}F$. By the definitions on pages 262 and 3 we have

$$\partial^{\text{top}}F = \text{all points that do not admit a chart of type (i)}$$

$$\partial^{\text{sm}}F = \text{all points that do not admit a chart of type (i) from the smooth atlas}.$$

By definition we have $\partial^{\text{top}}F \subset \partial^{\text{sm}}F$. Now let $P \in \partial^{\text{sm}}F$. This means that $P$ does not admit a chart of type (i) from the smooth atlas. By definition of a smooth manifold it admits a chart of type (ii). But by (1) this means that it cannot admit any chart of type (i). Thus we see that $P \in \partial^{\text{sm}}F$.

(3) We need to show that the boundary $\partial F$ is a 1-dimensional topological manifold which has no boundary, i.e. such that $\partial Y = \emptyset$. First let $P \in F$ be a point on the boundary. Let $\Phi: U \to V$ be a chart of type (ii) for $P$. It follows from the (1) and the definitions that $\partial F \cap U = \Phi^{-1}(\partial H \cap V)$. Thus we see that $\Phi$ restricts to a chart $\Phi: \partial F \cap U \to \partial H \cap V$ of type (i), here we view $\partial H \cap V$ as an open subset of $\partial H = \mathbb{R}$. This shows that $\partial F$ admits a 1-dimensional atlas where all charts are charts of type (i). Since $F$ is second-countable and Hausdorff we obtain from Lemma \[6.1\] (2) and Lemma \[2.12\] that $\partial F$ is also second-countable and Hausdorff. ■

**18.6. Homotopies on quotients and pushouts** (*). In this section we collect several subtle lemmas which show that, under the right circumstances, homotopies descend to quotient spaces and that given a “gluing $X \cup_f Y$” we can also glue homotopies. This section is much less pleasant to read than the previous section and it is arguably best if the reader only takes a peek once the results are actually used.
Before we state the two technical lemmas, we point out that the proof of the lemmas eventually boils down to the rather subtle and delicate Theorem 5.16. One might view both lemmas “obvious”, but they are not.

After this preamble, let us move to the key result of this section which shows that homotopies descend to quotients.

**Proposition 18.20.** Let $X$ and $Y$ be topological spaces. Furthermore let $\sim_X$ be an equivalence relation on $X$ and let $\sim_Y$ be an equivalence relation on $Y$. If $F : X \times [0, 1] \to Y$ is a homotopy such that $F(x, t) \sim_Y F(x', t)$ whenever $x \sim_X x'$, then the map $\varphi : (X/\sim_X) \times [0, 1] \to Y/\sim_Y$

$$([x], t) \mapsto [F(x, t)]$$

is continuous.

**Proof.** We denote by $p : X \to X/\sim_X$ and $q : Y \to Y/\sim_Y$ the obvious projection maps.

We have the following commutative diagram

$$
\begin{array}{ccc}
X \times [0, 1] & \xrightarrow{p \times \text{id}_{[0, 1]}} & (X/\sim_X) \times [0, 1] \\
& \searrow \varphi & \swarrow q \circ F \\
& Y/\sim_Y &
\end{array}
$$

By Lemma 5.15 (1) the map $p$ is a quotient map. Since $[0, 1]$ is regionally compact we obtain from Theorem 5.16 that $p \times \text{id}_{[0, 1]}$ is also a quotient map. Note that by Lemma 3.21 (3) and by hypothesis the map $q \circ F$ is continuous. Thus we obtain from Lemma 5.17 (1) that $\varphi$ is continuous.

**Examples.**

1. We consider $X = Y = [0, 1] \times [-1, 1]$ and the equivalence relation $\sim = \sim_X = \sim_Y$ that is given by

$$(0, y) \sim (1, -y) \quad \text{for all } y \in [-1, 1].$$

Basically the same argument as on page 204 shows that we can view $X/\sim$ as the Möbius band. We consider the map

$$H : (X/\sim) \times [0, 1] \to X/\sim$$

$$(((x, y)], t) \mapsto [(x, y \cdot (1 - t))].$$

It follows from Proposition 18.20 that this map $H$ is in fact continuous. One sees easily that $H$ is deformation retraction from the Möbius band $([0, 1] \times [-1, 1])/\sim$ to the central circle $[0, 1] \times \{0\}$ of the Möbius band. It follows from this discussion together with Lemma 18.14 that the Möbius band is homotopy equivalent to $S^1$. We refer to Figure 350 for an illustration.

2. Let $n \in \mathbb{N}$ and let $\varphi : [0, 1] \to \text{GL}(n, \mathbb{R})$ be a map. It follows from Proposition 18.20 that the map

$$\mathbb{R}P^{n-1} \times [0, 1] \to \mathbb{R}P^{n-1}$$

$$([P], t) \mapsto [\varphi(t) \cdot P]$$

It follows from our hypothesis on $F$ that the map $\varphi$ is well-defined.
is continuous. The same conclusion also holds if we replace “\( \mathbb{R} \)” by “\( \mathbb{C} \).

The following lemma is a hands-on special case of Proposition \[18.20\].

**Lemma 18.21.** Let \( X \) be a topological space. Furthermore let \( A \subset B \) be two subsets of \( X \). If \( F: B \times [0, 1] \to X \) is a homotopy with \( F(A \times [0, 1]) \subset A \), then the induced map

\[
\varphi: (B/A) \times [0, 1] \to X/A
\]

\[
([x], t) \mapsto [F(x, t)]
\]

is continuous.

**Proof.** This statement follows immediately from Proposition \[18.20\] and the fact that quotients of topological spaces are defined via equivalence relations.

It is perhaps easier to appreciate the following useful corollary.

**Corollary 18.22.** Let \( X \) be a topological space and let \( A \) be a subset of \( X \). If \( A \) is a deformation retract of \( X \), then the point \( A/A \) is a deformation retract of \( X/A \). In particular \( X/A \) is contractible.

**Proof.** Let \( r: X \times [0, 1] \to X \) be a deformation retraction from \( X \) to \( A \). Since \( r \) is deformation retraction we obtain from Lemma \[18.21\] that the map

\[
(X/A) \times [0, 1] \to X/A
\]

\[
([x], t) \mapsto [r(x, t)].
\]

is well-defined and continuous. Now it is clear that this map is a deformation retraction from \( X/A \) to \( A/A \).

We conclude this section with the following lemma which shows how to define homotopies on pushouts.

**Lemma 18.23.** Let \( f: X \to Y \) and \( g: X \to Z \) be maps between topological space. As on page \[197\] we define the pushout

\[
Y \cup_X Z := (Y \sqcup Z)/ \sim \quad \text{where } f(x) \sim g(x) \text{ for all } x \in X.
\]

\[307\]Since \( F \) is a homotopy rel \( A \) we see that the map is well-defined.
Furthermore let $W$ be another topological space. Suppose that we are given two homotopies $G: Y \times [0, 1] \to W$ and $H: Z \times [0, 1] \to W$ such that for any $x \in X$ and any $t \in [0, 1]$ we have $G(f(x), t) = H(g(x), t)$. Then the map

$$F: (Y \cup X) \times [0, 1] \to W$$

$$([P], t) \mapsto \begin{cases} G(P, t), & \text{if } P \in Y, \\ H(P, t), & \text{if } P \in Z \end{cases}$$

is well-defined and it is continuous.

**Proof.** It follows from Lemma 3.8 that the map

$$(Y \sqcup Z) \times [0, 1] \to W$$

$$(P, t) \mapsto \begin{cases} G(P, t), & \text{if } P \in Y, \\ H(P, t), & \text{if } P \in Z \end{cases}$$

is continuous. The statement now follows from Proposition 18.20 and the definition of the pushout as a quotient of $Y \sqcup Z$. ■

### 18.7. The wedge of topological spaces.

**Definition.** Let \{$(X_i, x_i)$\}$_{i \in I}$ be a family of pointed topological spaces.

1. We refer to

$$\bigvee_{i \in I} X_i := \bigvee_{i \in I} (X_i, x_i) := \left( \bigsqcup_{i \in I} X_i \right)/\sim$$

where $x_i \sim x_j$ for all $i, j \in I$

as the **wedge of the pointed topological spaces** $(X_i, x_i)$. We refer to the point given by the identifications as the **wedge point**. If we do not say anything else it will be denoted by $\ast$.

2. Let $Y$ be a topological space and suppose that we are given a family of maps \{f$_i$: $X_i \to Z$\}$_{i \in I}$ such that for every $i, j \in I$ we have $f_i(x_i) = f_j(x_j)$. We define the map

$$\bigvee_{i \in I} f_i : \bigvee_{i \in I} (X_i, x_i) \to Z$$

$$[y] \mapsto f_i([y]) \text{ if } y \in X_i.$$

It follows from Lemma 3.22 that this map is indeed continuous.

3. If $i = \{i_1, \ldots, i_k\}$ is a finite family, then often we just write $(X_{i_1}, x_{i_1}) \vee \cdots \vee (X_{i_k}, x_{i_k})$ and similarly we just write $f_{i_1} \vee \cdots \vee f_{i_k}$.

**Examples.**

1. The wedge $(A, a) \vee (B, b)$ of two pointed topological spaces $(A, a)$ and $(B, b)$ should be viewed as the result of gluing $A$ and $B$ along the points $a$ and $b$. The wedge of two pointed circles is shown in Figure 352.

2. Let $n \in \mathbb{N}_0$ and let $G = (V = \{v\}, E, i, t)$ be an abstract graph with a **single** vertex. It follows quite easily from Lemma 3.28 (1) together with the fact that $[0, 1]/0 \sim 1$.
is homeomorphic to $S^1$ that the map

$$|G| = (V \sqcup (E \times [0, 1]))/\sim \to \bigvee_{e \in E} S^1_e$$

$$[x] \mapsto \begin{cases} * , & \text{if } x = v, \\ e^{2\pi it} \in S^1_e, & \text{if } x = (e, t) \in E \times [0, 1] \end{cases}$$

is a homeomorphism. Evidently this also shows that every topological graph with one vertex and $n$ edges is homeomorphic to the wedge of $n$ circles.

(3) In general the homeomorphism type of the wedge depends on the choice of base points. This becomes particularly clear if we consider disconnected topological spaces. For example it is pretty clear that the wedges $(A, a) \vee (B, b)$ and $(A, a) \vee (B, \tilde{b})$ considered in Figure 353 are not homeomorphic.

Even though we just saw that in general the homeomorphism type of the wedge of two topological spaces depends on the choice of the base points, there are also many other situations where the choice is basically irrelevant. For example we have the following lemma.

**Lemma 18.24.** Let $\{X_i\}_{i \in I}$ be a family of smooth manifolds. We suppose that for each $i \in I$ we are given points $x_i, y_i \in X_i \setminus \partial X_i$. If each $X_i$ is connected, then there exists a homeomorphism

$$\bigvee_{i \in I} (X_i, x_i) \xrightarrow{\cong} \bigvee_{i \in I} (X_i, y_i).$$

**Proof.** The lemma is an almost immediate consequence of Proposition 8.29. We leave it to the reader to fill in the details.

This leads us to the following convention which is often safe, but which can also be ambiguous.
Convention. Let \( \{X_i\}_{i \in I} \) be a family of non-empty topological spaces. For each \( i \in I \) we pick a point \( x_i \in X_i \) and we write
\[
\bigvee_{i \in I} X_i := \bigvee_{i \in I} (X_i, x_i).
\]

Examples.

(1) On numerous occasions we will talk about the wedge \( S^1 \lor S^1 \) of two circles. By Lemma 18.24 there is usually no need to specify which points in the two copies of \( S^1 \) get identified.

(2) In Exercise 18.26 we will see that the wedge of two circles is homotopy equivalent to \( \mathbb{C} \setminus \{\pm 1\} \). More precisely, we will show that
\[
S^1 \lor S^1 = \left\{ z \in \mathbb{C} \mid |z + 1| = 1 \right\} \cup \left\{ z \in \mathbb{C} \mid |z - 1| = 1 \right\}
\]

is a deformation retract of \( \mathbb{C} \setminus \{\pm 1\} \).

Definition. Let \( \{(X_j, x_j)\}_{j \in J} \) be a family of pointed topological spaces. Given \( k \in J \) we refer to the maps
\[
i_k : X_k \to \bigvee_{j \in J} X_j \quad \text{and} \quad p_k : \bigvee_{j \in J} X_j \to X_k
\]
\[
x \mapsto [x] \quad \text{and} \quad [x] \mapsto \begin{cases} x, & \text{if } x \in X_k, \\ x_k, & \text{otherwise} \end{cases}
\]
as the natural inclusion respectively the natural projection.

Lemma 18.25. (*) Let \( \{X_j\}_{j \in J} \) be a family of topological spaces and suppose that for each \( j \in J \) we are given a point \( x_j \in X_j \). Let \( k \in J \).

(1) The natural inclusion \( i_k \) is an embedding.

(2) A map \( f : \bigvee_{j \in J} X_j \to Y \) to a topological space is continuous if and only if for each \( k \in J \) the map \( f \circ i_k : X_k \to Y \) is continuous.

(3) The natural projection \( p_k \) is continuous.

Remark. In most cases Lemma 18.25 allows us to safely view each \( X_k \) as a subset of the wedge \( \bigvee_{j \in J} X_j \).

Proof (*).

(2) This statement follows easily from Lemma 3.3 and Lemma 3.22.

(3) This is an immediate consequence of (2).
(1) It follows easily from Lemma 3.3 and Lemma 3.21 (3) that the natural inclusion \( i_k \) is continuous. It is clear that the natural inclusion \( i_k \) is an injection. Evidently we have \( p_k \circ i_k = \text{id}_{X_k} \). Since the natural projection \( p_k \) is continuous we see that the natural inclusion \( i_k \) is indeed an embedding. 

The following lemma collects a few basic properties of the wedge of topological spaces. It is entirely possible that later on we use the lemma without giving it credit.

**Lemma 18.26.** Let \( \{ (X_i, x_i) \}_{i \in I} \) be a family of pointed topological spaces.

1. If \( I \) is finite and if each \( X_i \) is compact, then \( \bigvee_{i \in I} X_i \) is compact.
2. If each \( X_i \) is Hausdorff, then \( \bigvee_{i \in I} X_i \) is Hausdorff.
3. If each \( X_i \) is (path)-connected, then \( \bigvee_{i \in I} X_i \) is (path)-connected.

**Proof (\( \ast \)).**

1. It follows immediately from Lemma 18.25 (3) and Lemma 3.3 (2) that the map
   \( \bigsqcup_{i \in I} p_i : \bigsqcup_{i \in I} X_i \to \bigvee_{i \in I} X_i \) is continuous. Thus the desired statement follows from Lemma 3.3 (4) together with Lemma 2.40.
2. We will prove this statement in Exercise 18.27.
3. We will prove this statement in Exercise 18.28.

We conclude this section with two technical lemmas which can safely be skipped at a first reading.

**Lemma 18.27.** \( \ast \) Let \( \{ (X_i, x_i) \}_{i \in I} \) be a family of pointed topological spaces and let \( (Z, z_0) \) be a pointed topological space. Let \( \{ f_i : (X_i, x_i) \to (Z, z_0) \}_{i \in I} \) and \( \{ g_i : (X_i, x_i) \to (Z, z_0) \}_{i \in I} \) be two families of maps. The following statement holds:

\[
\text{for every } i \in I \text{ there exists a homotopy rel } x_i \text{ from } f_i \text{ to } g_i \iff \text{the maps } \bigvee_{i \in I} f_i \text{ and } \bigvee_{i \in I} g_i \text{ from } \bigvee_{i \in I} X_i \text{ to } Z \text{ are homotopic rel the wedge point.}
\]

**Proof.** The “\( \Leftarrow \)”-direction of the lemma follows immediately from Lemma 18.25 (1). If the index set \( I \) has two elements, then the “\( \Rightarrow \)”-direction lemma is a straightforward consequence of Lemma 18.23 which eventually reduces the problem to Lemma 5.18. For a general family the “\( \Rightarrow \)”-direction lemma can also be reduced easily to Lemma 5.18.

It is worth pointing out that the proof of the “\( \Rightarrow \)”-direction is not obvious. As we just pointed out, it all boils down to Lemma 5.18 This lemma in turn relies on the delicate, frequently overlooked, underappreciated Theorem 5.16.

The following lemma gives in particular a nice little application of Lemma 18.27.

**Lemma 18.28.** \( \ast \) Let \( (A, a_0) \) and \( (B, b_0) \) be two pointed topological spaces. We consider the wedge \( A \vee B = (A, a_0) \vee (B, b_0) \). If \( \{a_0\} \) is a deformation retract of \( A \), then \( B = \{a_0\} \vee B \) is a deformation retract of \( A \vee B \).
Proof (*) Let \( F : A \times [0, 1] \rightarrow A \) be a deformation retraction from \( A \) to \( \{a_0\} \). Let \( G \) be the trivial homotopy on \( B \). It follows again from Lemma 18.23 that we can combine the two homotopies to get the desired deformation retraction.

18.8. **Topological graphs.** In this section we have another look at abstract graphs and their topological incarnations. First we recall the following definitions from page 228.

**Definition.** Let \( G = (V, E, i, t) \) be an abstract graph.

1. If \( G \) is finite, i.e. if \( V \) and \( E \) are finite, then we refer to
   \[
   \chi(G) = |V| - |E| = \text{number of vertices} - \text{number of edges}
   \]
   as the **Euler characteristic of \( G \).**
2. A **tree** is a finite connected abstract graph with Euler characteristic 1.
3. The **valence of a vertex** \( v \) is defined as
   \[
   \text{valence}(v) := \#\{e \in E \mid i(e) = v\} + \#\{e \in E \mid t(e) = v\}.
   \]

Given a topological graph \( (X, G = (V, E, i, t), \Theta : |G| \rightarrow X) \) we define the properties of \( X \) to be the properties of \( G \), e.g. we define \( \chi(X) := \chi(G) \) and we say that \( X \) is a tree if \( G \) is a tree.

![Illustration of Lemma 18.28](image)

**Figure 355.** Illustration of Lemma 18.28

**Proposition 18.29.** Let \( T \) be a topological graph that is a tree. Then the following hold:

1. If \( T \) has at least one edge, then it admits at least two vertices of valence one.
2. The tree \( T \) admits a deformation retraction to a vertex, in particular it is contractible.
3. The fundamental group \( \pi_1(T) \) is trivial.

**Proof (**). Basically by definition of a topological graph it suffices to deal throughout with the topological realizations of a tree. Thus let \( T = (V, E, i, t) \) be a tree.

1. This statement is precisely the content of Lemma 4.6

\[308\] On many occasions we will use the fact, established in Lemma 4.1(5), that a topological graph is connected if and only if the underlying abstract graph is connected.
(2) We will prove that any tree admits a deformation retraction to a vertex. We will prove this statement by induction on the number of edges. If a tree has zero edges, then it follows from the connectedness of \( T \) that \( T \) consists of precisely one vertex. So we are done.

Now suppose that all trees with \( n \) edges admit a deformation retraction to a vertex. Let \( T = (V,E,i,t) \) be a tree with \( n+1 \) edges. By (1) we know that \( T \) admits a vertex \( v \) of valence one. We denote by \( e \) the unique edge with \( v \) as an endpoint. We set \( T' = (V \setminus \{v\}, E \setminus \{e\}, i|_{E \setminus \{e\}}, t|_{E \setminus \{e\}}) \). Note that \( T' \) is again an abstract graph. Furthermore note that we reduced the number of vertices and of edges by one, so the Euler characteristic is unchanged, i.e. \( \chi(T') = \chi(T) = 1 \), so \( T' \) is again a tree.

We will now show that \( |T'| \) is a deformation retract of \( |T| \). We denote by \( u \) the other endpoint of \( e \). We consider the maps
\[
f: |T| \to |T'| \\
x \mapsto \begin{cases} u, & \text{if } x \in |e|, \\ x, & \text{otherwise} \end{cases}
\]
\[
g: |T'| \to |T| \\
x \mapsto x.
\]
It follows quite easily from Lemma 3.28 (2) together with Lemma 3.3 that both maps are continuous.

We claim that \( g \) is a homotopy inverse to \( f \). Evidently \( f \circ g = \text{id}_{|T'|} \). We need to show that \( g \circ f \simeq \text{id}_{|T|} \). By definition and by Lemma 4.1 (3) we can pick a characteristic map \( \Phi_e: [0,1] \to |e| \) with \( \Phi_e(0) = u \) and \( \Phi_e(1) = v \). Next we consider the map
\[
H: |T| \times [0,1] \to |T| \\
(x,t) \mapsto \begin{cases} \Phi_e(\Phi_e^{-1}(x) \cdot t), & \text{if } x \in |e|, \\ x, & \text{otherwise}. \end{cases}
\]
We leave it to the reader to verify, say using Proposition 18.20 and Lemmas 3.28 (2) and 3.3 that \( H \) is continuous. Now it is clear that \( H \) is a homotopy from \( g \circ f \) to \( \text{id}_T \).

We have thus shown that \( |T'| \) is a deformation retract of \( |T'| \). By our induction hypothesis \( |T'| \) admits a deformation retraction to a vertex \( v \in T' \). So it follows from Lemma 18.3 that \( |T| \) also admits a deformation retraction to the vertex \( v \). Finally it follows from this fact together with Lemma 18.15 (1) that \( T \) is contractible.

![Diagram](image)

**Figure 357.** Illustration for the proof that every tree is contractible.

(3) It follows from (2) and Proposition 18.16 (3) that the fundamental group of \( T \) is trivial.

\( \blacksquare \)
Next we recall a few more definitions from page 229.

**Definition.** Let $G = (V, E, i, t)$ be an abstract graph.

1. A **subgraph** of $G = (V, E, i, t)$ is an abstract graph $G' = (V', E', i', t')$ such that $V' \subseteq V$ and $E' \subseteq E$ are subsets such that $i' = i|_{E'}$ and $t' = t|_{E'}$.
2. A **spanning tree** for $G$ is a subgraph that is a tree and which does not admit an adjacent edge.

We extend the above definitions in an obvious way to topological graphs.

**Figure 358**

The following lemma summarizes a few basic properties of subgraphs.

**Lemma 18.30.** Let $G = (V, E, i, t)$ be an abstract graph and let $G' = (V', E', i', t')$ be a subgraph.

1. The inclusions $V' \to V$ and $E' \to E$ define a map $i: G' \to G$ of abstract graphs in the sense of the definition on page 477.
2. The induced map $|i|: |G'| \to |G|$ between the topological realization is a closed embedding.

In the following we will use (2) to view $|G'|$ as a closed subset of $|G|$.

**Proof.**

1. This statement follows immediately from the definitions.
2. By the discussion on page 481 we know that the map $|i|$ is continuous. By Lemma 2.42 it remains to show that $|i|$ is a closed map. We leave it to the reader to show, using Lemma 3.1 and Lemma 3.21 (3), that $|i|$ is closed.

We conclude this discussion of abstract and topological graphs with the following proposition.

**Proposition 18.31.** Let $(X, G = (V, E, i, t), \Theta: |G| \to X)$ be a finite topological graph.

1. For every spanning tree $T$ of $X$ the projection $X \to X/T$ is a homotopy equivalence.
2. If $X$ is connected and non-empty, then the topological graph $X$ is homotopy equivalent to the wedge of $1 - \chi(X)$ circles.
3. Two finite connected topological graphs with the same Euler characteristic are homotopy equivalent.

**Remark.**

1. In Proposition 37.8 and Corollary 39.10 we will provide generalizations of Proposition 18.31.
(2) Later, in Proposition \[20.5\] we will study the question, whether the converse to statement (3) holds: if two finite connected topological graphs are homotopy equivalent, does it follow that the Euler characteristics are the same?

\[
\text{maximal tree } T \\
\text{quotient out } T \\
\text{G/T}
\]

**Figure 359. Illustration of Proposition \[18.31\] (1).**

\[
\text{topological graph of Euler characteristic } 8 - 10 = -2 \\
\text{is homotopy equivalent to } \\
\text{wedge of three circles}
\]

**Figure 360. Illustration of Proposition \[18.31\] (2).**

For the proof of Proposition \[18.31\] it is convenient to introduce the following definition.

**Definition.** Let \( G = (V, E, i, t) \) be an abstract graph and let \( H = (W, F) \) be a non-empty subgraph.

1. We define \( \sim \) to be the equivalence relation generated by \( v \sim v' \) if \( v \) and \( v' \) are both vertices in \( H \). We denote by \( \ast \) the equivalence class defined by the vertices in \( H \).
2. We denote by \( \rho : V \to V/\sim \) the map given by \( v \mapsto [v] \).
3. Finally we define the abstract graph

\[
G/H := (V/\sim, E \setminus F, \rho \circ i : E \setminus F \to V/\sim, \rho \circ t : E \setminus F \to V/\sim)
\]

The following lemma summarizes a few properties of the abstract graph \( G/H \).

**Lemma 18.32.** Let \( G = (V, E, i, t) \) be an abstract graph and let \( H = (W, F) \) be a non-empty subgraph. We continue with the above notation.

1. We have \( \chi(G/H) = \chi(G) - \chi(H) + 1 \).
2. We consider the map

\[
p: |G| = (V \sqcup (E \times [0, 1]))/\sim \to |G/H| = (V/\sim \sqcup ((E \setminus F) \times [0, 1]))/\sim
\]

\[
[x] \mapsto \begin{cases} 
\ast, & \text{if } x \in |H|, \\
[\rho(x)], & \text{if } x \in V, \\
[(e, t)], & \text{if } x = (e, t) \text{ with } e \in E \setminus F \text{ and } t \in [0, 1].
\end{cases}
\]

This map has the following two properties:

(a) The map \( p: |G| \to |G/H| \) is well-defined and continuous.
(b) If the abstract graph \( G \) is finite, then the map \( p: |G| \to |G/H| \) descends to a homeomorphism \( |G|/|H| \to |G/H| \).
HOMOTopies AND HOMotopy Equivalent Topological Spaces

Proof.

(1) We calculate that
\[ \chi(G/H) = \#(V/\sim) - \#(E\setminus F) = (\#V - \#W + 1) - (\#E - \#F) = \chi(G) - \chi(H) + 1. \]

(2) (a) Once one has entangled all the definitions one sees that the map is indeed well-defined and one sees, using Lemma 3.28, that the map is indeed continuous.
(b) Since \( G \) is finite we know by Lemma 4.1 (4) and Lemma 2.40 that \( |G|/|H| \) is compact. Furthermore, by Lemma 4.1 (2) and we know that \( |G/H| \) is Hausdorff. It is elementary to see that the induced map \( p: |G|/|H| \to |G/H| \) is a bijection. Thus we obtain from Proposition 2.43 (3) that \( p: |G|/|H| \to |G/H| \) is a homeomorphism.

Proof of Proposition 18.31. Basically by definition we only need to deal with the topological realization of an abstract graph. Thus let \( G = (V, E, i, t) \) be a finite connected abstract graph.

(1) Let \( T = (W, F) \) be a spanning tree of \( G \). We consider the following little commutative diagram

\[
\begin{array}{ccc}
|G| & \xrightarrow{p} & |G/T| \\
\downarrow{x \mapsto [x]} & & \downarrow{} \\
|G|/|T| & & \\
\end{array}
\]

where \( p \) is the map introduced in Lemma 18.32 (2). We need to show that the projection map \( |G| \to |G|/|T| \) to the left is a homotopy equivalence. By Lemma 18.32 (2b) we know that the diagonal map to the right is a homeomorphism. Thus it suffices to show that the horizontal map \( p: |G| \to |G/T| \) is a homotopy equivalence.

Note that by Proposition 18.29 (2) we know that \( |T| \) admits a deformation retraction \( R: |T| \times [0, 1] \to |T| \) to some vertex \( t_0 \in T \). Put differently, there exists a homotopy \( R: |T| \times [0, 1] \to |T| \) such that \( R_1 = \text{id}_{|T|} \) and such that \( R_0 = c_{t_0} \) is the constant map.

Let \( f \) be an edge of \( G \) that is not contained in \( T \). If \( i(f) = t(f) \), then it follows from Lemma 4.1 that there exists a map \( \Phi_f: [-2, 2] \to |G| \) which induces a homeomorphism \([-2, 2]/-2 \sim 2 \to |f|\]. Furthermore, if \( i(f) \neq t(f) \), then it follows from Lemma 4.1 that there exists a map \( \Phi_f: [-2, 2] \to |G| \) which restricts to a homeomorphism \([-2, 2] \to |f|\].

We write \( a_f = \Phi_f(-2) \) and \( b_f = \Phi_f(2) \). Note that it

---

309 Note that it follows from Lemma 18.30 (2) that it is legitimate to view \( |H| \) as a subset of \( |G| \).

310 In other words, the map \( \Phi_f \) is just a rescaling of characteristic maps of \( f \).
Note that by Proposition 4.8, we know that the spanning tree $T$ together with Proposition 4.8.

Next we consider the quotient graph $G/T$. Let $p : |G| \to |G/T|$ be the projection. For every edge $f$ of $G/T$, i.e., for every $f \in E \setminus F$, we denote by $\Psi_f : [-2, 2] \to |G/T|$ the map $p \circ \Phi_f$. We consider the map

$$q : |G/T| \to |G|, \quad x \mapsto \begin{cases} R(a_f, -s - 1), & \text{if } x = \Psi_f(s) \text{ for some } s \in [-2, -1], \\ \Psi_f(2 \cdot s), & \text{if } x = \Psi_f(s) \text{ for some } s \in [-1, 1], \\ R(b_f, s - 1), & \text{if } x = \Psi_f(s) \text{ for some } s \in [1, 2]. \end{cases}$$

It follows fairly easily from Lemma 3.28 that $q$ is continuous. (The maps $p$ and $q$ are illustrated, to the best of the author’s abilities, in Figure 362.) It remains to prove the following claim.

**Claim.** The maps $p$ and $q$ are homotopy inverses of one another.

The proof of the claim is fairly elementary, just notationally a little messy. First we consider the following map

$$H : |G/T| \times [0, 1] \to |G/T|, \quad (x, t) \mapsto \begin{cases} \ast, & \text{if } x = \Psi_f(s) \text{ for some } s \in [-2, -1 - t], \\ \Psi_f(\frac{2s}{1+t}), & \text{if } x = \Psi_f(s) \text{ for some } s \in [-1 - t, 1 + t], \\ \ast, & \text{if } x = \Psi_f(s) \text{ for some } s \in [1 + t, 2]. \end{cases}$$

It follows, reasonably easily, from the combination of Lemma 3.28 and Proposition 18.20, that $H$ is continuous. It follows immediately from the definitions that $H_0 = p \circ q$ and $H_1 = \text{id}_{|G/T|}$. Next we consider the following map

$$\tilde{H} : |G| \times [0, 1] \to |G|, \quad (x, t) \mapsto \begin{cases} R(x, t), & \text{if } x \in T, \\ R(a_f, s + 2 + t), & \text{if } x = \Phi_f(s) \text{ for some } s \in [-2, -1 - t], \\ \Phi_f(\frac{2s}{1+t}), & \text{if } x = \Phi_f(s) \text{ for some } s \in [-1 - t, 1 + t], \\ R(b_f, -s + 2 + t), & \text{if } x = \Phi_f(s) \text{ for some } s \in [1 + t, 2]. \end{cases}$$

Again, using Lemma 3.28 and Proposition 18.20, one can show that $\tilde{H}$ is continuous. Furthermore it follows again immediately from the definitions that $\tilde{H}_0 = q \circ p$ and $\tilde{H}_1 = \text{id}_{|G|}$.

Note that by Proposition 4.8 (1) we know that $G$ admits a spanning tree $T$. Furthermore note that in (1) we showed that the map $p : |G| \to |G/T|$ is a homotopy equivalence. Thus it remains to show that $|G/T|$ is homeomorphic to the wedge of $1 - \chi(G)$ circles. We make the following observation:

(a) By Proposition 4.8 the spanning tree $T$ contains all vertices of $G$. In other words, the abstract graph $G/T$ contains only a single vertex.

(b) It follows from Lemma 18.32 (2) and the definition of a tree in terms of the Euler characteristic that $\chi(G/T) = \chi(G) - \chi(T) + 1 = \chi(G)$.

(c) By (1) and (2) we know that $G/T$ has $1 - \chi(G)$ edges.
18. Homotopies and Homotopy Equivalent Topological Spaces

18.9. Homotopy classes of loops (\ast). In the last section of this chapter we want to study the question, when are two maps $S^1 \to X$ to a topological space homotopic? In fact the following proposition gives in some sense a complete answer to the above question.

**Proposition 18.33.** Let $X$ be a topological space and let $f_0, f_1 : S^1 \to X$ be two maps. We write $x_0 = f_0(1)$ and $x_1 = f_1(1)$.

1. The following statement holds:\[ f_0 \text{ and } f_1 \text{ are homotopic } \iff \text{ there exists a path } \gamma \text{ from } x_0 \text{ to } x_1 \text{ such that } [\gamma * f_1 * \gamma] = [f_0] \in \pi_1(X, x_0). \]
2. If $x_0 = x_1$, then the following statement holds: \[ f_0 \text{ and } f_1 \text{ are homotopic } \iff [f_0] \text{ and } [f_1] \text{ are conjugate in } \pi_1(X, x_0). \]

**Proof.** Note that the second statement is an immediate consequence of the first statement and the observation that if $x_0 = x_1$ any path from $x_0$ to $x_1$ is in fact a loop and thus defines an element in $\pi_1(X, x_0)$. Therefore it suffices to prove the first statement.

Now let $X$ be a topological space. We take the view that maps $S^1 \to X$ are the same as loops, i.e. maps $[0, 1] \to X$ such that 0 and 1 get sent to the same point. Thus let $f_0, f_1 : [0, 1] \to X$ be two loops. We write $x_0 = f_0(1)$ and $x_1 = f_1(1)$.

$\Rightarrow$ Suppose there exists a homotopy $F : [0, 1] \times [0, 1] \to X$ with $F(0, t) = F(1, t)$ for all $t \in [0, 1]$ and such that $F_0 = f_0$ and $F_1 = f_1$. We denote by $\gamma : [0, 1] \to X$ the

\[ \gamma = \lambda \mapsto f_0(\lambda) \]

$\Rightarrow$ Conversely, let $\gamma : [0, 1] \to X$ be such a loop. Define a homotopy $F : [0, 1] \times [0, 1] \to X$ by $F(t, s) = \gamma(s)$ for all $t \in [0, 1]$. It is clear that $F$ is a homotopy from $f_0$ to $f_1$. Therefore $f_0$ and $f_1$ are homotopic.
path that is given by $\gamma(t) = F(0, t)$ for $t \in [0, 1]$. We consider the surjective map $\Phi: [0, 1] \times [0, 1] \to [0, 1] \times [0, 1]$ that is shown in Figure 364. The map $\Phi \circ F$ is easily seen to be a homotopy between the loops $f_0$ and $\gamma \ast f_1 \ast \gamma$. But that is exactly what we needed to show.

\[ \xrightarrow{\Phi} \]

**Figure 364.** First illustration for the proof of Proposition 18.33

"\leq" In the following we now suppose that there exists a path $\gamma$ from $x_0$ to $x_1$ such that $[\gamma \ast f_1 \ast \gamma] = [f_0] \in \pi_1(X, x_0)$. By definition this means that there exists a homotopy $F: [0, 1] \times [0, 1] \to X$ with $F(0, t) = F(1, t) = x_0$ for all $t \in [0, 1]$ and such that $F_0 = f_0$ and $F_1 = \gamma \ast f_1 \ast \gamma$. We consider the homeomorphism $\Psi: [0, 1] \times [0, 1] \to [0, 1] \times [0, 1]$ that is shown in Figure 365. The map $\Psi \circ F$ is easily seen to be a homotopy between $c_{x_0} \ast f_0 \ast c_{x_0}$ and $f_1$, viewed as maps $S^1 \to X$. But the map $c_{x_0} \ast f_0 \ast c_{x_0}$ is easily seen to be homotopic to the map $f_0$. Since being homotopic is transitive we have indeed shown that $f_0$ and $f_1$ are homotopic.

\[ \xrightarrow{\Psi} \]

**Figure 365.** Second illustration for the proof of Proposition 18.33

18.10. **Homotopies for pairs of topological spaces.** On page 537 we defined what it means for two maps $f, g: X \to Y$ between topological spaces to be homotopic. On many occasions one would like to restrict the freedom of a homotopy by fixing some subset pointwise or setwise. This idea leads us to two relative versions of "homotopy". The first version we already saw on page 539. For the reader’s convenience we recall the definition.

**Definition.** Let $f, g: X \to Y$ be two maps between topological spaces and let $A \subset X$ be a subset such that $f|_A = g|_A$.

1. A homotopy between $f$ and $g$ rel $A$ is a homotopy $H: X \times [0, 1] \to Y$ between $f$ and $g$ such that $H(a, t) = f(a) = g(a)$ for all $t \in [0, 1]$ and all $a \in A$.
2. We say $f$ and $g$ are homotopic rel $A$, if such a homotopy rel $A$ exists.

\[ \xrightarrow{f} \]

\[ \xrightarrow{g} \]

**Figure 366.** The maps $f$ and $g$ are homotopic, but they are not homotopic rel $A$.

We continue with another notion of a “relative homotopy”.

\[ \xrightarrow{\text{relative homotopy}} \]
Definition. Let $X$ and $Y$ be topological spaces and let $A \subset X$ and $B \subset Y$ be subsets.

1. A map $f: (X, A) \to (Y, B)$ is defined as a map defined as a map $f: X \to Y$ such that $f(A) \subset B$.

Now let $f, g: (X, A) \to (Y, B)$ be two maps.

2. A homotopy between $f$ and $g$ is a map defined as a map $H: X \times [0, 1] \to Y$, such that the following two conditions are satisfied:

   - $(a) \ H(x, 0) = f(x)$ and $H(x, 1) = g(x)$ for all $x \in X$, and
   - $(b) \ H(a, t) \in B$ for all $a \in A$ and all $t \in [0, 1]$.

3. If there exists a homotopy between $f$ and $g$, then we say that $f$ and $g$ are homotopic and we write $f \simeq g$.

\[
\begin{array}{c}
X \\
\downarrow
\end{array}
\xrightarrow{A}
\begin{array}{c}
Y \\
\downarrow
\end{array}
\]

$\alpha, \beta: (X, A) \to (Y, B)$ are homotopic but $\alpha, \gamma: (X, A) \to (Y, B)$ are not homotopic

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure367}
\caption{Figure 367}
\end{figure}

For completeness we also mention the following definition which is the obvious relative analogue of the concepts that we introduced on page 546.

Definition. Let $(X, A)$ and $(Y, B)$ be two pairs of topological spaces.

1. A map $f: (X, A) \to (Y, B)$ is a homotopy equivalence between $(X, A)$ and $(Y, B)$, if there exists a map $g: (Y, B) \to (X, A)$ such that the following hold:

   - $(a) \ g \circ f$ and $\text{id}_X$ are homotopic as maps of $(X, A)$ to itself,
   - $(b) \ f \circ g$ and $\text{id}_Y$ are homotopic as maps of $(Y, B)$ to itself.

2. If there exists a homotopy equivalence between $(X, A)$ and $(Y, B)$, then we say that $(X, A)$ and $(Y, B)$ are homotopy equivalent.

Examples.

1. The two pairs of topological spaces $(X, A)$ and $(Y, B)$ shown in Figure 368 are homotopy equivalent.

2. Let $X$ be a topological space and let $A \subset B$ be subsets of $X$. If $A$ is a deformation retract of $B$, then the inclusion map $(X, A) \to (X, B)$ is easily seen to be a homotopy equivalence of pairs of topological spaces.

3. Let $A \subset Y$ be subsets of $X$. If $Y$ is a deformation retract of $X$, then the inclusion map $(Y, A) \to (X, A)$ is again easily seen to be a homotopy equivalence of pairs of topological spaces.

---

\[312\] As usual all maps between topological spaces are understood to be continuous.

\[313\] For $A = B = \emptyset$ we get the usual notion of a homotopy between maps $f, g: X \to Y$. 
The above notions can be generalized even further. For example, one could define triples of topological spaces and there is an obvious definition of what it means for maps $f, g: (X, A, B) \to (Y, C, D)$ between triples of topological spaces to be homotopic. Similarly, given pairs of topological spaces $(X, A)$ and $(Y, B)$ and a subset $Z$ of $A$ there is an obvious definition for what it means for two maps $f, g: (X, A) \to (Y, B)$ to be homotopic rel. $Z$. We will not spell out all the definitions. From the context it should always be clear what we mean.

Exercises for Chapter 18

Exercise 18.1. Let $X$ be a topological space and let $f, g: X \to S^1$ be maps. We assume that for any $x \in X$ we have $f(x) \neq -g(x) \in S^1$. Show that $f$ and $g$ are homotopic.

Hint. Consider the map $S^1 \to S^1$ that is given by $z \mapsto f(z) \cdot g(z)^{-1}$.

Exercise 18.2. Let $X$ be a topological space and let $f: X \to \mathbb{R}^n \setminus \{0\}$ be a map. Show that $f$ is homotopic to the map $X \to \mathbb{R}^n \setminus \{0\}$ given by $x \mapsto \frac{f(x)}{||f(x)||}$.

Exercise 18.3. Let $n \in \mathbb{N}$ and let $f: \overline{B}^n \to \overline{B}^n$ be a homeomorphism with $f|_{S^{n-1}} = \text{id}_{S^{n-1}}$. We consider the map

$$H: \overline{B}^n \times [0, 1] \to \overline{B}^n$$

$$(x, t) \mapsto \begin{cases} t \cdot f(x), & \text{if } 0 \leq ||x|| < t, \\ x, & \text{otherwise.} \end{cases}$$

(a) Show that $H$ is continuous.

(b) Show that for each $t \in [0, 1]$ the map $H_t: \overline{B}^n \to \overline{B}^n$ is a homeomorphism.

Remark. We have thus shown that every homeomorphism of $S^n$ extends to a homeomorphism of $\overline{B}^{n+1}$. In Proposition ?? we will see that exists a diffeomorphism $\varphi: S^6 \to S^6$ that does not extend to a diffeomorphism of $\overline{B}^7$.

Exercise 18.4.

(a) Let $f: [0, 1] \to [0, 1]$ be a self-homeomorphism.

(i) Show that $f$ is monotonously increasing or monotonously decreasing.

(ii) Suppose $f$ is monotonously increasing. Show that $f$ is isotopic to the map $f(x) = x$.

(iii) Suppose $f$ is monotonously decreasing. Show that $f$ is isotopic to the map $f(x) = -x$. 

Figure 368
(b) Show that any self-homeomorphism of $S^1$ is isotopic to the map $f(z) = z$ or to the map $g(z) = z$.

Hint. Let $f: S^1 \to S^1$ be a self-homeomorphism. First consider the case that $f(1) = 1$.

Exercise 18.5. Let $h$ be a complex polynomial of degree $\geq 1$. In Exercise 2.33 we showed that the map

$$\Theta(h): \mathbb{C} \cup \{\infty\} \to \mathbb{C} \cup \{\infty\}$$

$$z \mapsto \begin{cases} h(z), & \text{if } z \in \mathbb{C}, \\ \infty, & \text{if } z = \infty \end{cases}$$

is continuous. Now let $f$ and $g$ be two polynomials with complex coefficients of degree $\geq 1$. Suppose that $\deg(f) = \deg(g)$. Show that the maps $\Theta(f)$ and $\Theta(g)$ are homotopic.

Remark. It is quite easy to write down a candidate for a homotopy. But why is the map you wrote down actually continuous?

Exercise 18.6. Let $n \in \mathbb{N}$.

(a) Show that $\text{SL}(n, \mathbb{R})$ is a retract of $\text{GL}(n, \mathbb{R})$ and show that it is not a deformation retract of $\text{GL}(n, \mathbb{R})$.

(b) Solve (a) with $\mathbb{C}$ instead of $\mathbb{R}$.

Exercise 18.7. Let $M$ be a smooth manifold without boundary. We say that a path $\gamma: [a, b] \to M$ is piecewise smooth if there exists a subdivision $a = s_0 < s_1 < \ldots < s_m = b$ such that for $i = 0, \ldots, m - 1$ the map $\gamma|_{[s_i, s_{i+1}]}$ is smooth.

(a) Show that any path $\alpha: [0, 1] \to M$ is path-homotopic to a piecewise smooth path $\beta$.

(b) Show that any piecewise smooth path $\beta: [0, 1] \to M$ is path-homotopic to a smooth path $\gamma: [0, 1] \to M$.

Hint. Use Lemmas 6.13 and 14.4

(c) Suppose that $\dim(M) \geq 2$. Show that any path $\alpha: [0, 1] \to M$ is path-homotopic to a smooth path $\delta$ such that $\delta'(t) \neq 0$ for every $t \in [0, 1]$. (Later on we will say that $\delta$ is an immersion.)

Exercise 18.8. Using Lemma 2.44 we can make the identification $S^1 = \mathbb{R} \cup \{\infty\}$. Now let $f$ be a polynomial with real coefficients of degree $n \geq 1$. In Exercise 2.33 we showed that the map

$$F: S^1 = \mathbb{R} \cup \{\infty\} \to \mathbb{R} \cup \{\infty\} = S^1$$

$$t \mapsto \begin{cases} f(t), & \text{if } t \in \mathbb{R}, \\ \infty, & \text{if } t = \infty \end{cases}$$

is continuous. (See Figure 57 for an illustration.) Show that $F$ is homotopic to one of the following three types of self-maps of $S^1$:

(1) $a(z) = z$  (2) $b(z) = \overline{z}$  (3) $c(z) = 1$.

Exercise 18.9. Let $X$ be a topological space and let $Y$ be a contractible topological space.

(a) Show that all maps $X \to Y$ are homotopic.

(b) We suppose that $X$ is path-connected. Show that all maps $Y \to X$ are homotopic.
Exercise 18.10. Let $U \subset \mathbb{R}^n$ be a neighborhood of 0 and let $f: U \to \mathbb{R}^n$ be a map with $f^{-1}({0}) = \{0\}$. Furthermore let $g: U \to \mathbb{R}^n$ be a map with $f(x) - g(x) = O(||x||^2)$, i.e. we assume that there exists a $C \geq 0$ and a $\delta > 0$ such that $||f(x) - g(x)|| < M \cdot ||x||^2$ for all $x \in \mathbb{B}_\delta^n$. Show that there exists an $s > 0$ such that the maps $f$ and $g$ are homotopic as maps of pairs $(\mathbb{B}_s^n, \mathbb{B}_s^n \setminus \{0\}) \to (\mathbb{R}^n, \mathbb{R}^n \setminus \{0\})$.

Exercise 18.11.
(a) We consider the topological space $X = \{(x,y) \mid x \in [0,1] \cap \mathbb{Q}, y \in [0,1-x]\} \cup ([0,1] \times \{0\})$ that is shown in Figure 369 to the left.
(i) Show that given any point $P$ in $[0,1] \times \{0\}$ there exists a deformation retraction from $X$ to $P$.
(ii) Show that for any point $Q$ in $X$ that does not lie on $[0,1] \times \{0\}$ there is no deformation retraction from $X$ to $Q$.
(b) We consider the infinite zigzag comb $Z$ that is shown in Figure 369 to the right.
(i) Show that $Z$ is contractible.
(ii) Show that $Z$ does not admit a deformation retraction to any point in $Z$.

Exercise 18.12. Let $X = \{a, b\}$ be the topological space with two elements $a$ and $b$ and where the open sets are precisely $\emptyset, \{a\}, X$.
(a) Is $\{a\}$ a deformation retract of $X$?
(b) Is $\{b\}$ a deformation retract of $X$?

Exercise 18.13.
(a) Let $r > 0$. Show that $\mathbb{R}^n \setminus \mathbb{B}_r^n(0)$ is a deformation retract of $\mathbb{R}^n \setminus \{0\}$.
(b) Let $A$ be a convex subset of $\mathbb{R}^n$ which contains the origin $0$. Show that $\mathbb{R}^n \setminus \mathbb{B}_r^n(0)$ is a deformation retract of $\mathbb{R}^n \setminus A$.
Remark. This sounds like one should use Proposition 2.53 but it turns out that this proposition is a not necessary.

Exercise 18.14. Let $X$ be a topological space and let $H: X \times [0,1] \to X$ be a deformation to a subset $A$. We consider
$$\phi: X \to [0,1], \quad x \mapsto \inf\{t \in [0,1] \mid H(x,t) \in A\}.$$ Is the map $\phi$ necessarily continuous?
Exercise 18.15. Let $X$ be a topological space and let $Y$ be a topological space that is regionally compact. Let $f_0, f_1 : Y \to X$ be two maps. Then the following holds:

\[ f_0 \text{ and } f_1 \text{ are homotopic } \iff f_0 \text{ and } f_1 \text{ lie in the same path component of } Y^X. \]

Remark. Use Proposition 5.6.

Exercise 18.16. Show that the topological spaces

\[ X = \{ \frac{1}{n} \mid n \in \mathbb{N} \} \cup \{0\} \quad \text{and} \quad Y = \{ \frac{1}{n} \mid n \in \mathbb{N} \} \cup \{-1\} \]

are not homotopy equivalent.

Exercise 18.17. We consider the two maps $f, g : [0, 1] \to \mathbb{R}^3$ shown in Figure 371. Note that $f(0) = g(0)$ and $f(1) = g(1)$.

(a) Show that the maps $f$ and $g$ are homotopic rel $\{0\}$.
(b) Are the two maps $f$ and $g$ homotopic rel $\{0, 1\}$?

Exercise 18.18. Let $f : X \to Y$ be a map between topological spaces. A map $g : Y \to X$ is called a homotopy left inverse of $f$ if $g \circ f$ is homotopic to $\text{id}_X$. Furthermore, a map $h : Y \to X$ is called a homotopy right inverse of $f$ if $f \circ h$ is homotopic to $\text{id}_Y$. Show that if $f$ admits a homotopy left inverse $g$ and a homotopy right inverse $h$, then $f$ is in fact a homotopy equivalence and both $g$ and $h$ are homotopy inverses.

Exercise 18.19. Let $f : X \to Y$ and $g : A \to B$ be maps between topological spaces. We say $f$ is a retract of $g$ if there exists a commutative diagram of maps

\[
\begin{array}{ccc}
X & \xrightarrow{p} & A \\
\downarrow{f} & \cong & \downarrow{g} \\
Y & \xrightarrow{r} & B \\
\downarrow{s} & \cong & \downarrow{f} \\
\end{array}
\]

such that $q \circ p = \text{id}_X$ and $s \circ r = \text{id}_Y$. Show that if $g$ is a homotopy equivalence, then $f$ is also a homotopy equivalence.

Hint. Use Exercise 18.18.
Exercise 18.20. Let $X$ be a path-connected topological space. Suppose that there exists an $x_0 \in X$ such that the inclusion $\{x_0\} \to X$ is a homotopy equivalence. Show that for any $x_1 \in X$ the inclusion $\{x_1\} \to X$ is a homotopy equivalence.

Exercise 18.21. Does there exist a topological space with three elements that is homotopy equivalent to the topology space $X = \{\ast\}$ given by a single point?

Exercise 18.22. Let $0 < r < s$ be two real numbers. Show that the obvious inclusion map $B^n(r) \setminus \{0\} \to B^n(s) \setminus \{0\}$ is a homotopy equivalence,

Exercise 18.23. Let $f : X \to Y$ be a map between topological spaces. Show that if $f$ is a homotopy equivalence, then $f$ induces a bijection $\pi_0(X) \to \pi_0(Y)$.

Exercise 18.24. Let $n \in \mathbb{N}$. Prove the following three statements:

(a) The sphere $S^{n-1}$ is a deformation retract of $\mathbb{R}^n \setminus \{0\}$.

(b) The hemispheres $S^{n-1}_{\geq 0}$ is a deformation retract of $B^n$.

(c) Given any three non-collinear points $A, B, C \in \mathbb{R}^n$ the triangle $\Delta_{ABC}$ admits a deformation retraction to the union of any two sides of the triangle.

*Hint.* You could first consider the case that $A = (0, 0), B = (0, 1)$ and $C = (1, 0)$.

These three examples are illustrated in Figure 344.

Exercise 18.25. Let $A$ be a subset of a topological space $X$ which admits a deformation retraction $F$ from $X$ to $A$. Show that the inclusion map

$$
A \to X \quad \text{and the map} \quad X \to A
$$

$$
a \mapsto a \quad \text{and} \quad x \mapsto F(x, 1)
$$

are both homotopy equivalences.

Exercise 18.26. Show that

$$
S^1 \vee S^1 = \left\{ z \in \mathbb{C} \left| |z + 1| = 1 \right. \right\} \cup \left\{ z \in \mathbb{C} \left| |z - 1| = 1 \right. \right\}
$$

is a deformation retract of $\mathbb{C} \setminus \{\pm 1\}$.

Exercise 18.27. Let $\{(X_i, x_i)\}_{i \in I}$ be a family of pointed topological spaces. We suppose that each $X_i$ is Hausdorff. Show that $\bigvee_{i \in I} X_i$ is also Hausdorff.

Exercise 18.28. Let $\{(X_i, x_i)\}_{i \in I}$ be a family of pointed topological spaces.

(a) We suppose that each $X_i$ is path-connected. Show that $\bigvee_{i \in I} X_i$ is path-connected.

(b) We suppose that each $X_i$ is connected. Show that $\bigvee_{i \in I} X_i$ is connected.

Exercise 18.29. Let $X := \{(x, y) \in \mathbb{R}^2 \mid x^2 + y^2 \leq 1\}$. We denote by $\| - \|$ the usual Euclidean norm on $X$. We denote by $P = (0, 0)$ the center of $X$. The *Paris metric* on $X$ is given by

$$
X \times X \to \mathbb{R}_{\geq 0}
$$

$$(A, B) \mapsto \|A - P\| + \|B - P\|.$$
This metric takes its name from the fact that all (OK, many) train lines in France go towards Paris. So if you want to go from $A$ to $B$ you invariably (OK, often) have to go through Paris.

(a) Show that the map

$$
\varphi: \bigvee_{z \in S^1} [0,1]_z \rightarrow X
$$

$$
[r] \mapsto r \cdot z \quad \text{if } r \in [0,1]_z.
$$

is not a homeomorphism.

(b) Does there exist a homeomorphism between $\bigvee_{z \in S^1} [0,1]_z$ and $X$?

![Figure 372. Illustration of Exercise 18.29.](image)

**Exercise 18.30.** Let $(X,x_0)$ and $(Y,y_0)$ be two pointed topological spaces. We use the base points to define the wedge $X \vee Y$.

(a) Show that the map

$$
f: X \vee Y \rightarrow X \times Y
$$

$$
[P] \mapsto \begin{cases} (P,y_0), & \text{if } P \in X, \\
(x_0,P), & \text{if } P \in Y
\end{cases}
$$

is an embedding.

*Remark.* We do not assume that $X$ and $Y$ have any nice properties.

(b) Using (a) we can view $X \vee Y$ as a subspace of $X \times Y$. We refer to the quotient

$$X \wedge Y := (X,x_0) \wedge (Y,y_0) := (X \times Y)/(X \vee Y)
$$

as the smash product of $(X,x_0)$ and $(Y,y_0)$. Show that for any $m,n \in \mathbb{N}_0$ the smash product $S^m \wedge S^n$ is homeomorphic to $S^{m+n}$.

We refer to Figure 373 for an illustration.

![Figure 373. Illustration for Exercise 18.30.](image)

**Exercise 18.31.** We consider the following two subsets of $\mathbb{C}$:

$$X := \{z \in \mathbb{C} \mid |z-2|=1\} \cup [-1,1] \cup \{z \in \mathbb{C} \mid |z+2|=1\}$$

and

$$Y := \{z \in \mathbb{C} \mid |z-1|=1\} \cup \{z \in \mathbb{C} \mid |z+1|=1\}. $$
Show that $X$ and $Y$ are homotopy equivalent.

Remark. It follows basically from Proposition [18.31] that $X$ and $Y$ are homotopy equivalent. The exercise thus consists of showing “by hand” that $X$ and $Y$ are homotopy equivalent.

Exercise 18.32. Let $\{X_i\}_{i \in I}$ be a family of topological spaces. Suppose that for each $i \in I$ we are given a point $x_i \in X_i$ with the property that $\{x_i\}$ is a closed subset of $X_i$. We use these points to form the wedge $\cup_{i \in I} X_i$. We denote by $\ast$ the wedge point. Suppose that for each $i \in I$ we are given an open neighborhood $U_i$ of $x_i$ in $X_i$ such that $x_i$ is a deformation retract of $U_i$. We set $U := \bigcup_{i \in I} U_i$.

(a) Show that $U$ is an open neighborhood of $\ast$.

(b) Let $J \subset I$ be a subset. Show that $\bigcup_{i \in J} X_i$ is a deformation retract of $U \cup \bigcup_{i \in J} X_i$. (In particular, with $J = \emptyset$ this implies that $\ast$ is a deformation retract of $U$.)

Remark. You need to show that the wannabe deformation retraction which you wrote down is continuous. You might want to use a result along the lines of Lemma [5.18].

Exercise 18.33. Let $\{X_i\}_{i \in I}$ be a family of topological spaces. Suppose that for each $i \in I$ we are given a point $x_i \in X_i$. We use these points to form the wedge $\bigcup_{i \in I} X_i$. Let $K \subset \bigcup_{i \in I} X_i$ be a compact subset.

(a) We suppose that each $X_i$ is Hausdorff. Show that there exists a finite subset $J \subset I$ such that $K \subset \bigcup_{i \in J} X_i$.

Hint. For any $i \in I$ with $K \cap (X_i \setminus \{x_i\}) \neq \emptyset$ pick some point $a_i \in K \cap (X_i \setminus \{x_i\})$. We denote by $A$ the union of these points. Show that $A$ is a discrete subset of $K$.

(b) Show that in general the conclusion of (a) does not hold if we do not assume that the $X_i$ are Hausdorff.

Exercise 18.34. We consider the subset $X$ of $\mathbb{R}^2$ that is shown in Figure [375]. It is the union of infinitely many circles $A_i \subset \mathbb{R}^2$, $i \in \mathbb{N}$ that meet in the origin. Furthermore let $Y = \bigcup_{i \in \mathbb{N}} S^1$. There exists a fairly obvious bijection $f : X \to Y$ which sends each $A_i$ to the $i$-th factor of $Y$.

(a) Is the map $f$ continuous?

(b) Is the map $f^{-1}$ continuous?
Exercise 18.35. In the following we consider the wedge $X := \bigvee_{i \in \mathbb{N}_0} [0, 1]$ given by “wedging” the points $0 \in [0, 1], i \in \mathbb{N}_0$.

(a) Show that the sequences of points $x_i := \frac{i}{2i} \in [0, 1], i \in \mathbb{N}_0$ does not converge to the wedge point.

(b) Show that $X$ is not metrizable, i.e. show that it does not admit a metric such that the topology given by the metric agrees with the topology of $X$.

Exercise 18.36. Let $f, g: (X, x_0) \to (Y, y_0)$ be two maps between pointed topological spaces.

(a) Show that if $f$ and $g$ are homotopic rel $\{x_0\}$, then $f_* = g_*: \pi_1(X, x_0) \to \pi_1(Y, y_0)$.

(b) Does the conclusion of (a) hold if we only demand that $f$ and $g$ are homotopic, but we no longer demand that they are homotopic rel the base point?

Exercise 18.37. Let $f: X \to Y$ be a map between two topological spaces. Let $x_0 \in X$ be a base point. We write $y_0 = f(x_0)$ and we denote by $i: f(X) \to Y$ the inclusion map. Suppose that $f_*: \pi_1(X, x_0) \to \pi_1(Y, y_0)$ is an isomorphism. Does it follow that $i_*: \pi_1(f(X), y_0) \to \pi_1(Y, y_0)$ is also an isomorphism?

Exercise 18.38.

(a) Show that every topological graph is locally contractible.

(b) Let $\{(X_i, x_i)\}_{i \in I}$ be a family of pointed topological spaces. We suppose that each $X_i$ is locally contractible. Show that the wedge $\bigvee_{i \in I} X_i$ is also locally contractible.

Remark. If you get away without using Proposition 18.20 then you should go carefully over your continuity arguments.

Exercise 18.39. Let $T$ be a tree and let $v \in T$ be any vertex. Show that $T$ admits a deformation retraction to $v$.

Remark. This is a slight refinement of the statement of Proposition 18.29 (2).

Before we continue with developing the theory of fundamental groups of topological spaces we want to introduce several basic constructions in group theory and we want state several facts which we will use throughout the remainder of this course.

19.1. Free abelian groups and finitely generated abelian groups. The following definition will stay with us throughout these notes.

**Definition.**

1. Let $S$ be a non-empty set. We write \( \mathbb{Z}^S := \) all maps from $S$ to $\mathbb{Z}$. Furthermore, for $S$ the empty set we write \( \mathbb{Z}^\emptyset := \{0\} \). We consider \( \mathbb{Z}^S \) with the obvious group structure, i.e. the group structure that is given by \( \mathbb{Z}^S \times \mathbb{Z}^S \to \mathbb{Z}^S \)
\[
(f, g) \mapsto \left( \begin{array}{c} S \\ s \mapsto f(s) + g(s) \end{array} \right).
\]

2. Given any set $S$, we are mostly interested in the subgroup \( \mathbb{Z}^{(S)} := \) all maps from $S$ to $\mathbb{Z}$ which are non-zero for only finitely many $s \in S$.

   We refer to \( \mathbb{Z}^{(S)} \) as the free abelian group generated by $S$ or as the free abelian group on the generating set $S$.

3. We refer to the cardinality of $S$ as the rank of \( \mathbb{Z}^{(S)} \).

When working with free abelian groups it is usually helpful to use the following notation.

**Notation.** Let $S$ be a set.

1. Given $s \in S$ we denote by $s$ also the map

\[
S \to \mathbb{Z} \\
t \mapsto \begin{cases} 1, & \text{if } t = s, \\ 0, & \text{otherwise}. \end{cases}
\]

This map lies of course in \( \mathbb{Z}^{(S)} \). Thus we can view $S$ as a subset of \( \mathbb{Z}^{(S)} \).

2. Given elements $s_1, \ldots, s_k \in S$ and $n_1, \ldots, n_k \in \mathbb{Z}$ we obtain the corresponding element $n_1 s_1 + \cdots + n_k s_k$ of \( \mathbb{Z}^{(S)} \). We refer to $n_1 s_1 + \cdots + n_k s_k$ as a formal linear combination of elements in $S$. Every element of \( \mathbb{Z}^{(S)} \) can be written as such a formal linear combination of finitely many elements of $S$. Indeed, for $f \in \mathbb{Z}^{(S)}$ we can write
\[
f = \sum_{s \in S \text{ with } f(s) \neq 0} f(s) \cdot s.
\]

The following lemma says that the free abelian group generated by a set $S$ has a "universal property". The lemma also says that possessing such a universal property classifies free abelian groups up to isomorphism.

---

\[^{314}\] It is straightforward to see that both sides define the same map $S \to \mathbb{Z}$, so they are the same element of $\mathbb{Z}^{(S)}$.\]
Lemma 19.1.

(1) Let $S$ be a set and let $\phi: S \to G$ be a map to an abelian group $G$. Then there exists a unique homomorphism $\psi: \mathbb{Z}^S \to G$ that makes the following diagram commute

\[
\begin{array}{ccc}
S & \xleftarrow{\phi} & \mathbb{Z}^S \\
\downarrow & & \downarrow \\
\downarrow & & \downarrow \\
G & \xrightarrow{\psi} & G.
\end{array}
\]

(2) Conversely let $\pi$ be a group that admits a subset $S$ with the following universal property: given any map $\phi: S \to G$ to an abelian group $G$ there exists a unique homomorphism $\psi: \pi \to G$ that makes the following diagram commute

\[
\begin{array}{ccc}
S & \xrightarrow{\phi} & \pi \\
\downarrow & & \downarrow \\
\downarrow & & \downarrow \\
G & \xrightarrow{\psi} & G.
\end{array}
\]

Then $\pi$ is isomorphic to $\mathbb{Z}^S$.

Lemma 19.1 suggests the following definition.

Definition.

(1) We say that a group $\pi$ is a free abelian group on a generating set $S$, if $\pi$ has the universal property with respect to $S$. In other words, by Lemma 19.1 $G$ needs to be isomorphic to $\mathbb{Z}^S$.

(2) We say that a group $\pi$ is free abelian if it is a free abelian group on some generating set $S$.

Proof.

(1) We consider the map $^\text{315}$

\[
\psi: \mathbb{Z}^S \to G \\
f = \sum_{i=1}^{n} n_i s_i \mapsto \psi(f) := \sum_{i=1}^{n} n_i \cdot \phi(s_i).
\]

It is straightforward to verify that $\psi$ has the desired property and that it is the unique such homomorphism.

(2) Let $\pi$ be a group that has the universal property with respect to $S$. We need to show that $\pi$ is isomorphic to $\mathbb{Z}^S$. It is more elegant to show that it is isomorphic to any other group $\pi'$ that has the universal property with respect to $S$.

This argument is similar to many other “universal property” proofs in algebra. We consider the inclusion maps $\varphi: S \to \pi$ and $\varphi': S \to \pi'$. By the universal property of $\varphi$ and $\varphi'$ there exist homomorphisms $\psi: \pi \to \pi'$ and $\psi': \pi' \to \pi$ that make the

---

$^\text{315}$ Here we assume that $G$ is written as an additive group. If $G$ is a multiplicative group we would need to replace $n_i \cdot \phi(s_i)$ by $\phi(s_i)^{n_i}$ and we would need to replace the sum by a product.
following diagrams commute:

\[
\begin{array}{ccc}
S & \xrightarrow{\phi} & \pi \\
& \phi' \searrow & \downarrow \psi' \\
& \phi \nearrow & \pi' \\
\end{array}
\quad \text{and} \quad
\begin{array}{ccc}
S & \xrightarrow{\phi'} & \pi' \\
& \phi' \searrow & \downarrow \psi' \\
& \phi \nearrow & \pi \\
\end{array}
\]

In particular we get the commutative diagrams

\[
\begin{array}{ccc}
S & \xrightarrow{\phi} & \pi \\
& \phi' \searrow & \downarrow \psi \\
& \phi \nearrow & \pi' \\
\end{array}
\quad \text{which simplifies to} \quad
\begin{array}{ccc}
S & \xrightarrow{\phi} & \pi \\
& \phi' \searrow & \downarrow \psi' \circ \psi \\
& \phi \nearrow & \pi \\
\end{array}
\quad \text{and of course we also have the commutative diagram}
\]

\[
\begin{array}{ccc}
S & \xrightarrow{\phi} & \pi \\
& \phi' \searrow & \downarrow \psi' \circ \pi \\
& \phi \nearrow & \pi \\
\end{array}
\]

It follows from the uniqueness part of the universal property applied to the two diagrams on the right that \(\psi' \circ \psi = \text{id}_\pi\). The same way one shows that \(\psi \circ \psi' = \text{id}_{\pi'}\). In particular \(\psi\) and \(\psi'\) are isomorphisms.

\[\blacksquare\]

\textbf{Lemma 19.2.}

(1) Any subgroup \(G\) of a free abelian group \(F\) is again a free abelian group.

(2) If \(\varphi: \mathbb{Z}^{(S)} \to \mathbb{Z}^{(T)}\) is a monomorphism, then \(\#S \leq \#T\).

(3) If \(\varphi: \mathbb{Z}^{(S)} \to \mathbb{Z}^{(T)}\) is an epimorphism, then \(\#S \geq \#T\).

\textbf{Proof.} The first two statements are proved in [Rot88, Theorem 9.3]. It remains to prove the third statement. Now let \(\varphi: \mathbb{Z}^{(S)} \to \mathbb{Z}^{(T)}\) be an epimorphism. For each \(t \in T\) there exists therefore some \(\phi(t) \in S\) with \(\varphi(\phi(t)) = t\). By Lemma [19.1] there exists a unique homomorphism \(\psi: \mathbb{Z}^{(T)} \to \mathbb{Z}^{(S)}\) with \(\psi(t) = \phi(t)\) for all \(t \in T\). Therefore we have \(\varphi(\psi(t)) = \varphi(\phi(t)) = t\) for all \(t\), so \(\varphi \circ \psi = \text{id}\), in particular \(\psi\) is a monomorphism. It follows from (2) that \(\#T \leq \#S\).

\[\blacksquare\]

\textbf{Definition.}

(1) If \(F\) is a free abelian group, then we define the \textit{rank of} \(F\) as the cardinality of any set \(S\) with \(F \cong \mathbb{Z}^{(S)}\).

(2) Given an abelian group \(G\) we say that \(S \subset G\) is a \textit{generating set} if the canonical homomorphism \(\mathbb{Z}^{(S)} \to G\) is an epimorphism.

(3) Given an abelian group \(G\) we say that \(S \subset G\) is a \textit{basis} if the canonical homomorphism \(\mathbb{Z}^{(S)} \to G\) is an isomorphism.

(4) We say that an abelian group \(G\) is \textit{finitely generated} if it admits a finite generating set.

\[316\] Here we denote by \(\#S\) and \(\#T\) the cardinalities of the sets \(S\) and \(T\), as defined on page 78.
**Example.** Let $S$ be a finite set with $m$ elements $s_1, \ldots, s_m$. Let $\phi: S \to \mathbb{Z}^m$ be the map given by $\phi(s_i) = e_i$. Then the resulting homomorphism $\Psi: \mathbb{Z}^S \to \mathbb{Z}^m$ is an isomorphism. Put differently, $\mathbb{Z}^m$ is a free abelian group of rank $m$.

We leave it to the reader to provide the proof of the following useful characterizations of generating sets.

**Lemma 19.3.** Let $G$ be an abelian group and let $S \subset G$ be a subset. Then the following two statements are equivalent:

1. $S$ is a generating set of $G$.
2. Any subgroup $H$ of $G$ that contains $S$ is already equal to $G$.

We use this opportunity to recall the classification of finitely generated abelian groups which had been proved in the algebra course. A proof is for example also provided in [Hun80, Chapter II.2].

**Theorem 19.4.** (Classification of Finitely Generated Abelian Groups) Let $A$ be a finitely generated abelian group. There exist non-zero natural numbers $a_1, \ldots, a_k$ with $a_i|a_{i+1}$ for $i = 1, \ldots, k-1$ and an $r \in \mathbb{N}_0$ such that

$$A \cong \mathbb{Z}^r \oplus \bigoplus_{i=1}^k \mathbb{Z}_{a_i}.$$  

Furthermore the numbers $a_1, \ldots, a_k$ and $r$ are uniquely determined by $A$.

**Definition.** Given a finitely generated abelian group $A$ we denote the direct sum of the cyclic groups on the right-hand side of Theorem 19.4 as the canonical form of $A$.

**Example.** The Chinese Remainder Theorem says that for any coprime $m$ and $n$ we have an isomorphism

$$\mathbb{Z}_{mn} \cong \mathbb{Z}_m \times \mathbb{Z}_n = \mathbb{Z}_m \oplus \mathbb{Z}_n$$

$$k + mn\mathbb{Z} \mapsto (k + m\mathbb{Z}, k + n\mathbb{Z}).$$

For example consider $A = \mathbb{Z}_3 \oplus \mathbb{Z}_5$. It is not in the form of Theorem 19.4 but we have the isomorphism $\mathbb{Z}_3 \oplus \mathbb{Z}_5 \cong \mathbb{Z}_{15}$, which is of the desired form. Thus $\mathbb{Z}_{15}$ is the canonical form of $\mathbb{Z}_3 \oplus \mathbb{Z}_5$.

We will not provide a proof for Theorem 19.4, but we will sketch a proof for the following lemma. The third statement of the lemma is a somewhat weaker version of Theorem 19.4.

**Lemma 19.5.**
(1) Let $V$ be an $m \times n$-matrix over $\mathbb{Z}$. For matrices $A \in \text{GL}(m, \mathbb{Z})$ and $B \in \text{GL}(n, \mathbb{Z})$ we have an isomorphism

$$Z^m/AVBZ^n \cong Z^m/VZ^n.$$ 

(2) Let $V$ be an $m \times n$-matrix over $\mathbb{Z}$. There exist two matrices $A \in \text{GL}(m, \mathbb{Z})$ and $B \in \text{GL}(n, \mathbb{Z})$ such that

$$A \cdot V \cdot B = \begin{pmatrix} p_1 & 0 & 0 & 0 \\ 0 & \ddots & 0 & 0 \\ 0 & 0 & p_t & 0 \\ 0 & 0 & 0 & 0_{(m-t)\times(n-t)} \end{pmatrix} \in M(m \times n, \mathbb{Z})$$

for some $p_1, \ldots, p_t \in \mathbb{N}$.

(3) Let $A$ be a finitely generated abelian group. Then there exists an $r \geq 0$ and there exist $p_1, \ldots, p_t \in \mathbb{N}$ such that

$$A \cong \mathbb{Z}^r \oplus \bigoplus_{i=1}^{t} \mathbb{Z}_{p_i}.$$ 

As mentioned before, we will only provide sketch for the proof of the lemma.

**Sketch of proof.**

(1) The proof of the first statement is elementary. We leave it to the reader to fill in the details.

(2) First note that if an $m \times n$-matrix $P$ is obtained from an $m \times n$-matrix $Q$ by swapping two rows, then $P$ is obtained by left-multiplying $Q$ by an $m \times m$-matrix of the form

$$\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$ 

Similarly if $P$ is obtained from an $m \times n$-matrix $Q$ by adding the $k$-th row to the $l$-th row, then $P$ is obtained by left-multiplying $Q$ by an $m \times m$-matrix of the form

$$\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}.$$ 

$^{319}$ The matrices $A$ and $B$ are invertible over $\mathbb{Z}$, i.e. their determinants are $\pm 1$.

$^{320}$ Here the last row and column of zeros can be arbitrarily large.

$^{321}$ Here is the reality check whether that is really correct: we have

$$\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{pmatrix} c & d \\ a & b \end{pmatrix}.$$
where the extra 1 sits in the $(1, k)$-entry. Both these $m \times m$-matrices lie in $\text{GL}(m, \mathbb{Z})$. If we do the same operations for columns, then this corresponds to right multiplication by the same type of matrices in $\text{GL}(n, \mathbb{Z})$ as above.

Now let $V$ be an $m \times n$-matrix over $\mathbb{Z}$. If $V$ is the zero matrix, then there is nothing to show. So suppose that $V$ is not the zero matrix. We perform the following steps:

(a) After swapping rows and columns we can arrange that the absolute value of the $(1, 1)$-entry is less or equal than the absolute value of all other entries. After possibly multiplying the first column by $-1$ we can assume that the $(1, 1)$-entry $v_{11}$ is positive.

(b) By adding and subtracting the first column from the other columns we can arrange that all entries in the first row, except for the $(1, 1)$-entry, lie between 0 and $v_{11} - 1$.

(c) The same way as in (2) we can arrange that all entries in the first column, except for the $(1, 1)$-entry, lie between 0 and $v_{11} - 1$.

Now we have to distinguish two cases:

(a) If there exists outside of the $(1, 1)$-entry another entry in the first row or column that is non-zero, then we start again with (1). Note that the new entry $(1, 1)$-entry will be less than before. So this process will come to a halt after finitely many steps.

(b) If all entries in the first row and column, except for the $(1, 1)$-entry are zero, then

$$V = \begin{pmatrix} v_{11} & 0 \\ 0 & V' \end{pmatrix}$$

for some $(m - 1) \times (n - 1)$-matrix $V'$ and we perform the same operations on the smaller matrix $V'$.

(3) Let $A$ be a finitely generated abelian group. By the definition of a finitely generated abelian group there exists an epimorphism $\psi: \mathbb{Z}^m \to A$. Since $\mathbb{Z}$ is a Noetherian ring we know that $\ker(\psi)$ is again a finitely generated free abelian group of rank $n \leq m$. In particular there exists an isomorphism $v: \mathbb{Z}^n \to \ker(\psi)$. We denote by $V$ the $m \times n$-matrix that represents the resulting map $\mathbb{Z}^n \to \ker(\psi) \subset \mathbb{Z}^m$ with respect to the standard bases. Then $A \cong \mathbb{Z}^m/V\mathbb{Z}^n$. We pick matrices $A$ and $B$ as in (2). From (1) it follows that $\mathbb{Z}^m/V\mathbb{Z}^n$ is isomorphic to $\mathbb{Z}^m/AVB\mathbb{Z}^n$. But the latter is isomorphic to $\mathbb{Z}_{p_1} \oplus \cdots \oplus \mathbb{Z}_{p_t} \oplus \mathbb{Z}^{m-n}$.

**Definition.** Let $A$ be an abelian group.

1. If $A$ is finitely generated, then we refer to the $r$ in the statement of Theorem 19.4 as the **rank** of the finitely generated abelian group $A$. We denote it by $\text{rank}(A)$.

2. We refer to

$$\text{Tor}(A) = \{ a \in A \mid \text{there exists an } n \in \mathbb{N} \text{ with } na = 0 \}$$

as the **torsion subgroup** of $A$. If $\text{Tor}(A)$ is the trivial subgroup, then we say that $A$ is **torsion-free**.
In the following three lemmas we collect several basic facts about finitely generated abelian groups. Most of the statements follow more or less directly from Theorem 19.4. We will not prove the lemmas. We leave it to the reader to deduce the statements from Theorem 19.4 and the algebra course the reader took.

**Lemma 19.6.** Let

$$0 \to A \to B \to C \to 0$$

be a short exact sequence of abelian groups such that at least two of these groups are finitely generated. Then the following holds:

1. all three groups are finitely generated abelian groups,
2. \(\text{rank}(B) = \text{rank}(A) + \text{rank}(C)\),
3. if \(A\) and \(C\) are torsion-free, then \(B\) is also torsion-free.

**Remark.** Let \(B\) be a finitely generated group and let \(\varphi: B \to C\) be an epimorphism. Note that \(C\) is evidently also finitely generated. If \(B\) is abelian it thus follows from Lemma 19.6 (1) that the kernel \(\ker(\varphi)\) is also finitely generated. Note that if \(B\) is not abelian, then this conclusion does not necessarily hold. For example in Exercise 19.16 we will give an example of a group epimorphism \(\varphi: B \to C\) from a non-commutative group \(B\) on two generators onto an abelian group \(C\), such that the kernel is infinitely generated.

**Lemma 19.7.** Let \(A \in M(n \times n, \mathbb{Z})\) be a matrix. Then

\[\mathbb{Z}^n / A\mathbb{Z}^n\] is finite \(\iff\) \(\det(A) \neq 0\).

Furthermore, if \(\det(A) \neq 0\), then

$$0 \to \mathbb{Z}^n \xrightarrow{A} \mathbb{Z}^n \to \mathbb{Z}^n / A\mathbb{Z}^n \to 0$$

is a short exact sequence and \(\mathbb{Z}^n / A\mathbb{Z}^n\) is a finite group with \(|\det(A)|\) elements.

We also have the following lemma.

**Lemma 19.8.**

1. If \(A, B\) and \(C\) are finitely generated abelian groups, then
   \[A \oplus C \cong B \oplus C \implies A \cong B.\]

2. Let \(A\) be a subgroup of an abelian group \(B\).
   (a) \(\text{Tor}(A)\) is a subgroup of \(\text{Tor}(B)\).
   (b) If \(B\) is finitely generated, then \(A\) is also finitely generated, and we have the inequality \(\text{rank}(A) \leq \text{rank}(B)\).

3. If \(A\) is a subgroup of a free abelian group of rank \(r\), then \(A\) is a free abelian group with rank less or equal than \(r\).\hspace{1em}³²⁵

³²²If \(A\) is a finitely generated free abelian group, then this definition of rank agrees with the definition given for free abelian groups on page 580.

³²³In Exercise 19.15 we will see that \(A\) is indeed a subgroup.

³²⁴Recall that this means that the map \(A \to B\) is injective, that \(B \to C\) is surjective and that the image of \(A \to B\) agrees with the kernel of \(B \to C\).
(4) If $A$ is a subgroup of a free abelian group $B$ and if $\text{rank}(A) < \text{rank}(B)$, then $A$ is a proper subgroup, i.e. $A \neq B$.

(5) Let $\varphi : A \to B$ be a homomorphism between two finitely generated abelian groups that are abstractly isomorphic.\footnote{In fact this statement is already contained in Lemma 19.2.} If $\varphi$ is an epimorphism, then $\varphi$ is already an isomorphism.

(6) If $A$ is a finitely generated abelian group and $\varphi : A \to B$ is an epimorphism, then $B$ is also finitely generated and $\text{rank}(A) \geq \text{rank}(B)$.

Abelian groups that are not finitely generated are not classified and they tend to be significantly harder to deal with. For example the following lemma shows that not every torsion-free abelian group is a free abelian group.

**Lemma 19.9.** The abelian group $(\mathbb{Q}, +)$ is torsion-free but not free abelian.

**Proof.** Clearly $(\mathbb{Q}, +)$ is torsion-free. If it was free abelian, then there would exist an epimorphism to $\mathbb{Z}$. In Exercise 19.1 we will show that such an epimorphism cannot exist. \hfill ■

In Exercise 19.3 (1) we will see that the conclusion of Lemma 19.8 (1) does not hold for general abelian groups. But the following statement actually does hold.

**Proposition 19.10.** Let $A$ and $B$ be any two abelian groups. If $C$ is a finitely generated abelian group, then

$$A \oplus C \cong B \oplus C \implies A \cong B.$$ 

**Proof.** We will consider a special case in Exercise 19.3 (b). The general case is proved in [Cohn56, Walka56]. \hfill ■

19.2. The free product of groups. We first recall the definition of the direct product of two groups $G$ and $H$ that we already gave on page 519. The direct product of two groups $G$ and $H$ is defined as

$$G \times H := \{(g, h) \mid g \in G \text{ and } h \in H\}$$

together with the group structure that is given by

$$(g_1, h_1) \cdot (g_2, h_2) := (g_1 g_2, h_1 h_2)$$

for $g_1, g_2 \in G$ and $h_1, h_2 \in H$. We call the group $G \times H$ the direct product of the groups $G$ and $H$. Via the monomorphisms

$$g \mapsto (g, e) \quad \text{and} \quad h \mapsto (e, h)$$

we can view $G$ and $H$ as subgroups of $G \times H$. Note that these subgroups commute, i.e. for every $g \in G$ and $h \in H$ we have the equality $(g, e) \cdot (e, h) = (g, h) = (e, h) \cdot (g, e)$.

Now we will introduce the “free product” $G \ast H$ of two groups $G$ and $H$. The definition is perhaps initially harder than the definition of the “direct product” $G \times H$. But for many, perhaps even most applications, the free product is more useful.
Definition. Let \( G \) be and \( H \) be two groups. We consider the set \( G \ast H \) of all finite sequences \((x_1, \ldots, x_m)\) such that the following conditions are satisfied:
(a) each \( x_i \) lies in one of the groups \( G \) or \( H \),
(b) no \( x_j \) is the neutral element of \( G \) or of \( H \),
(c) any two consecutive \( x_j \)’s lie in two different groups.

Here we also allow the “empty sequence” \( () \). Such sequences are sometimes called reduced words in \( G \) and \( H \).

Let \((x_1, \ldots, x_m)\) and \((y_1, \ldots, y_n)\) be two elements in \( G \ast H \). We define the product of these two elements as follows:
(1) First suppose that \( x_m \) and \( y_1 \) lie in different groups. Then we define
\[
(x_1, \ldots, x_m) \cdot (y_1, \ldots, y_n) := (x_1, \ldots, x_m, y_1, \ldots, y_n).
\]
(2) Now suppose that \( x_m \) and \( y_1 \) lie in the same group. Let \( j \in \{1, \ldots, \min\{m, n\}\} \) be the maximal element such that \( x_{m+1-i} = y_i^{-1} \) for \( i = 1, \ldots, j \). If \( j < \min\{m, n\} \), then we define\(^{327}\)
\[
(x_1, \ldots, x_m) \cdot (y_1, \ldots, y_n) := (x_1, \ldots, x_{m-j} \cdot y_{j+1}, \ldots, y_n) \neq e.
\]
If \( j = m \), then we define
\[
(x_1, \ldots, x_m) \cdot (y_1, \ldots, y_n) := (y_{m+1}, \ldots, y_n).
\]

We proceed similarly if \( j = n \).

Another way of stating the product formula is as follows: given two sequences \((x_1, \ldots, x_m)\) and \((y_1, \ldots, y_n)\) we stack them together \((x_1, \ldots, x_m, y_1, \ldots, y_n)\) and then we delete any occurrence of a subsequence of the form \( a, a^{-1} \) for \( a \in G \) or \( a \in H \) and if a subsequence is of the form \( a, b \) with \( a, b \in G \) or \( a, b \in H \), then we replace it by \( ab \).

We henceforth refer to \( G \ast H \) together with this product structure as the free product of \( G \) and \( H \).

We have the following important lemma.

**Lemma 19.11.** The free product of two groups \( G \) and \( H \) is again a group. The neutral element of \( G \ast H \) is hereby given by the empty sequence \( () \) and the inverse of an element \((x_1, \ldots, x_m)\) in \( G \ast H \) is given by
\[
(x_1, \ldots, x_m)^{-1} = (x_m^{-1}, \ldots, x_1^{-1}) \in G \ast H.
\]

**Proof.** It is clear that the empty sequence is a neutral element. It follows immediately from the definition of the product that the inverse of an element \((x_1, \ldots, x_m)\) in \( G \ast H \) is given by \((x_m^{-1}, \ldots, x_1^{-1})\). It remains to show that the multiplication satisfies associativity.

In principle one can show associativity naively “by hand”, but there are surprisingly many cases one needs to distinguish, so that the proof becomes rather painful.

\(^{327}\)Since \( x_m \) and \( y_1 \) lie in the same group, the elements \( x_{m-j} \) and \( y_{j+1} \) also lie in the same group, so it makes sense to consider \( x_{m-j} \cdot y_{j+1} \).
We will therefore follow a different approach. We write $W = G \ast H$ and we denote by $(P(W), \circ)$ the group of all permutations of $W$, i.e. $P(W)$ is the set of all bijections from $W$ to $W$ and the group structure is given by composition of maps. For $g \in G$ we consider the map

$$
\lambda_g : W \rightarrow W
$$

$$(x_1, \ldots, x_m) \mapsto \begin{cases} (g, x_1, x_2, \ldots, x_m), & \text{if } x_1 \in H, \\ (gx_1, x_2, \ldots, x_m), & \text{if } x_1 \in G \text{ and } g \neq x_1^{-1}, \\ (x_2, \ldots, x_m), & \text{if } g = x_1^{-1}. \end{cases}
$$

It is now straightforward to see that for any $g, g' \in G$ and any $(x_1, \ldots, x_m) \in W$ we have $g(g' \cdot (x_1, \ldots, x_m)) = (gg') \cdot (x_1, \ldots, x_m)$. This means that $\lambda_g \circ \lambda_{g'} = \lambda_{gg'}$. It is now straightforward to see that the map

$$
\lambda : G \rightarrow P(W)
$$

$g \mapsto \lambda_g$

is a group homomorphism. Similarly we define $\lambda : H \rightarrow P(W)$. Now we consider the map

$$
\lambda : W \rightarrow P(W)
$$

$$(x_1, \ldots, x_n) \mapsto \lambda_{x_1} \circ \cdots \circ \lambda_{x_n}.
$$

This map is injective since $\lambda(x_1, \ldots, x_n)$ applied to the empty word () gives the word $(x_1, \ldots, x_n)$. Hence $\lambda(x_1, \ldots, x_n)$ is not the identity map from $W \rightarrow W$, i.e. $\lambda(x_1, \ldots, x_n)$ is non-trivial in $P(W)$.

Furthermore the map $\lambda : W \rightarrow P(W)$ satisfies $\lambda(x \cdot y) = \lambda_x \circ \lambda_y$. Put differently, $\lambda$ defines an injective map $\lambda : (W, \cdot) \rightarrow (P(W), \circ)$ that preserves the product structure. But since $(P(W), \circ)$ satisfies the associativity law we now see that $(W, \cdot)$ also satisfies the associativity law. 

The following lemma summarizes two main properties of the free product of two groups.

**Lemma 19.12.** Let $G$ and $H$ be two groups. The following two statements hold:

1. The maps

$$
i : G \rightarrow G \ast H \quad \text{and} \quad j : H \rightarrow G \ast H \quad \text{are monomorphisms.}
$$

2. For any two group homomorphisms $\alpha : G \rightarrow A$ and $\beta : H \rightarrow A$ there exists a unique group homomorphism $\gamma : G \ast H \rightarrow A$ such that the following diagram commutes

$$
\begin{array}{ccc}
G \ast H & \xrightarrow{i} & G \\
\downarrow{j} & & \downarrow{\alpha} \\
H & \xrightarrow{\beta} & A.
\end{array}
$$

---

328It is straightforward to see that the sequences on the right do indeed lie in $G \ast H$. 

Example. Let $G$ and $H$ be groups. We denote by $α: G → G × H$ and $β: H → G × H$ the obvious inclusion maps. It follows from Lemma 19.12 there exists a unique homomorphism $γ: G * H → G × H$ which makes the following diagram commute:

\[
\begin{array}{ccc}
G * H & \xrightarrow{i} & G \\
\downarrow{j} & \nearrow{γ} & \downarrow{α} \\
H & \xrightarrow{β} & G × H.
\end{array}
\]

Remark. In the literature the direct product of two groups often gets introduced in a slightly different way, namely by a “universal property”. More precisely, let $G$ be and $H$ be two groups. The direct product of $G$ and $H$ is then defined as a group $K$ together with two homomorphisms $i: G → K$ and $j: G → K$ which satisfy the following universal property: for every two group homomorphisms $α: G → A$ and $β: H → A$ there exists a unique group homomorphism $γ: K → A$ such that the following diagram commutes:

\[
\begin{array}{ccc}
K & \xrightarrow{i} & G \\
\downarrow{j} & \nearrow{γ} & \downarrow{α} \\
H & \xrightarrow{β} & A.
\end{array}
\]

Lemma 19.12 can now be reinterpreted as saying that the direct product of two groups always exists. An argument that is very similar to the one we gave on page 582 shows that the direct product is unique in the following sense: If $(K, i: G → K, j: H → K)$ and $(K', i': G → K', j': H → K')$ both satisfy the above universal property, then there exists a unique isomorphism $Φ: K → K'$ such that $i' = Φ ∘ i$ and $j' = Φ ∘ j$. \[\text{[329]}\]

Proof. It is clear that the maps $i$ and $j$ are injective, furthermore it follows immediately from the definition of the group structure on $G * H$ that the maps are group homomorphisms.

Now let $α: G → A$ and $β: H → A$ be two group homomorphisms. For an element $(g_1, h_1, \ldots, g_k, h_k) ∈ G * H$ with $g_i ∈ G, h_i ∈ H, i = 1, \ldots, n$ we define

\[γ(g_1, h_1, \ldots, g_k, h_k) := α(g_1) · β(h_1) \cdots · α(g_k) · β(h_k).\]

The same way we define $γ$ for all other elements in $G * H$. Now one can show easily that $γ$ is a group homomorphism.

It remains to show the uniqueness of $γ$. Any element in $G * H$ is a product of elements of the form $i(g), g ∈ G$ and $j(h), h ∈ H$. It follows that any homomorphism $δ: G * H → A$ is already uniquely determined by the values of $δ$ on all elements of the form $i(g), g ∈ G$ and $j(h), h ∈ H$. Put differently, there is at most one homomorphism $δ: G * H → A$ with $δ(i(g)) = α(g)$ for all $g ∈ G$ and $δ(i(h)) = β(h)$ for all $h ∈ H$. \[\blacksquare\]

Remark.

(1) We will use the monomorphisms from Lemma 19.12 to view $G$ and $H$ as subgroups of $G * H$.

---

\[\text{[329]}\] Why does $K = G × H$ with the obvious maps $i: G → K$ and $j: H → K$ not satisfy this universal property? Or does it?
(2) If there is no danger of confusion, then we often shorten \((x_1, \ldots, x_m) \in G \ast H\) to the notation \(x_1 \ldots x_m\). This notation is coherent with the convention (1). Note that if \(g \in G\) and \(h \in H\) are non-trivial elements, then the sequences \((g, h)\) and \((h, g)\) both lie in \(G \ast H\) and they are different. With the convention that we just introduced that means that \(g \cdot h \neq h \cdot g\). Put differently, a non-trivial element of \(G\) never commutes with a non-trivial element of \(H\).

(3) The construction of the free product of two groups generalizes in an obvious way to the free product of finitely many, in fact even to infinitely many groups.

Let \(t\) be a symbol. We define
\[
\langle t \rangle := \{\ldots, t^{-2}, t^{-1}, e, t, t^2, \ldots \}.
\]
The set \(\langle t \rangle\) admits an obvious group structure that is given by \(t^i \cdot t^j := t^{i+j}\). This group is called the infinite cyclic group generated by \(t\). The map \(\mathbb{Z} \to \langle t \rangle\), \(n \mapsto t^n\) is evidently an isomorphism. Now we come to one of the main definitions in group theory.

**Definition.** For a set \(S\) we refer to \(\langle S \rangle := \text{free product of the groups } \langle s \rangle, s \in S\) as the free group on the (generating) set \(S\). Via the map \(s \mapsto \langle s \rangle\) we can and will view \(S\) as a subset of \(\langle S \rangle\).

**Example.** If \(S = \{t_1, \ldots, t_k\}\), then we obtain the group
\[
\langle t_1, \ldots, t_k \rangle := \langle t_1 \rangle \ast \cdots \ast \langle t_k \rangle
\]
which we also refer to as the free group on the generators \(t_1, \ldots, t_k\). Each element of the free group \(\langle t_1, \ldots, t_k \rangle\) is thus of the form
\[
t_{r_1}^{s_1} t_{r_2}^{s_2} \cdots t_{r_l}^{s_l}
\]
with \(r_i \neq r_{i+1}\) for \(i = 1, \ldots, l-1\) and \(s_i \neq 0\) for \(i = 1, \ldots, l\).

**Convention.** Sometimes we denote the free group on \(k\) generators just by \(F_k\).

**Example.** We consider the free group \(\langle x, y \rangle\) on the two generators \(x\) and \(y\). Elements in this group are of the form \(xy^3x^{-2}y\) or \(y^{-2}xy\). The multiplication is the “obvious one”, for example
\[
(xy^3x^{-1}y^2) \cdot (y^{-2}x^3xy^{-1}) = xy^3x^2yxy^{-1}.
\]
The group is not abelian since \(xy \neq yx\).\(^{330}\)

We continue with the following lemma that we will prove in Exercise [19.4]

**Lemma 19.13.** Let \(S\) be a set. The free group \(\langle S \rangle\) is torsion-free. In other words, every non-trivial element in the free group \(\langle S \rangle\) has infinite order.

The following innocent looking lemma summarizes the key property of free groups.

**Lemma 19.14.** Let \(S\) be a set, let \(G\) be an arbitrary group and let \(g: S \to G\) be a map. Then there exists a unique homomorphism \(\varphi: \langle S \rangle \to G\) with \(\varphi(s) = g(s)\) for every \(s \in S\).

\(^{330}\)Why is \(xy \neq yx\)?
Proof. For \( s \in S \) the map
\[
\langle s \rangle \to G \\
\langle s^n \rangle \to g(s)^n
\]
is evidently the unique homomorphism \( \varphi_s : \langle s \rangle \to G \) with \( \varphi_s(s) = g(s) \). It now follows from the obvious generalization of Lemma 19.12 to the case of the free product of arbitrarily many groups that there exists a unique homomorphism \( \varphi : \langle S \rangle \to G \) with \( \varphi(s) = \varphi_s(s) = g(s) \) for \( s \in S \).

\[ \blacksquare \]

Remark. Sometimes in the literature free groups are defined via a universal property. More precisely, let \( S \) be a set. A free group on \( S \) is sometimes defined as a group \( K \) together with a map \( f : S \to K \) which satisfies the following universal property: for any map \( g : S \to G \) from the set \( S \) to a group \( G \), there exists a unique group homomorphism \( \varphi : K \to G \) such that the following diagram commutes
\[
\begin{array}{c}
S \\
\downarrow g \\
K \\
\downarrow \varphi \\
G
\end{array}
\]
In this language our above Lemma 19.14 says that the obvious map \( S \to \langle S \rangle \) is a free group on \( S \) in the above sense. As before, a slight variation on the argument on page 582 shows that the free group on \( S \) is unique in an appropriate sense.

Definition.

(1) A group \( G \) is called free, if it is isomorphic to the free group \( \langle S \rangle \) on some set \( S \). We say a subset \( S \subset G \) is a basis, if the natural map \( \langle S \rangle \to G \) is an isomorphism.

(2) Given group \( G \) we say that \( S \subset G \) is a generating set if the natural homomorphism \( \langle S \rangle \to G \) is an epimorphism. Sometimes we also say that the elements in \( S \) are generators of \( G \).

(3) We say that a group \( G \) is finitely generated if it admits a finite generating set.

Examples.

(1) As on page 501 we consider the following two self-homeomorphisms of \( \mathbb{R}^2 \):
\[
A : \mathbb{R}^2 \to \mathbb{R}^2 \\
(x, y) \mapsto (x + 1, 1 - y)
\]
and
\[
B : \mathbb{R}^2 \to \mathbb{R}^2 \\
(x, y) \mapsto (x, y + 1)
\]

\[ ^{331} \text{Note that in contrast to Lemma 19.1, the group } G \text{ is now not necessarily abelian.} \]

\[ ^{332} \text{Here we mean by “canonical map } \langle S \rangle \to G \text{” the unique homomorphism } \psi : \langle S \rangle \to G \text{ from Lemma 19.14 that makes the following diagram commute} \]
\[
\begin{array}{c}
S \\
\downarrow \varphi \\
\langle S \rangle \\
\downarrow \psi \\
G
\end{array}
\]
where \( S \to G \) is the inclusion map.
and we denote by $G$ the subgroup of all homeomorphisms of $\mathbb{R}^2$ that is generated by $A$ and $B$. This means that

$$G = \text{all self-homeomorphisms of } \mathbb{R}^2 \text{ that can be written as a finite concatenation of the maps } A, B, A^{-1} \text{ and } B^{-1}.$$  

We saw on page 501 that $\mathbb{R}^2/G$ equals the Klein bottle $K$ and using Theorem 16.16 we saw on page 518 that $\pi_1(\text{Klein bottle}) \cong G$. The group $G$ is finitely generated in the above sense. More precisely, it follows immediately from the definition of $G$ that $S = \{A, B\} \subset G$ is a generating set for $G$.

(2) For any set $S$ there exists by Lemma 19.14 a unique homomorphism $\langle S \rangle \to \mathbb{Z}^{(S)}$ that sends $s \in S$ to $s$ viewed as an element in $\mathbb{Z}^{(S)}$. Since the set $S \subset \mathbb{Z}^{(S)}$ generates $\mathbb{Z}^{(S)}$ we see that this homomorphism is an epimorphism. It follows that any finitely generated abelian group in the sense of page 582 is also a finitely generated group in the above sense.

The subgroup of a free abelian group is again a free abelian group. Does the same hold for free groups? We record this as a question for future reference.

**Question 19.15.** Is every subgroup of a free group again a free group?

The next lemma says in particular that free groups on two sets are isomorphic if and only if the cardinalities of the sets are the same.

**Lemma 19.16.** Let $S$ and $T$ be two sets.

1. If there exists an epimorphism $\langle S \rangle \to \langle T \rangle$, then $\#S \geq \#T$.
2. If $\langle S \rangle$ is isomorphic to $\langle T \rangle$, then $\#S = \#T$.
3. If given $n \in \mathbb{N}$ we denote by $F_n$ the free group on $n$ generators, then for $k \neq l$ the groups $F_k$ and $F_l$ are not isomorphic.

**Proof.**

(1) We first recall that we had just seen in the previous example that for any set $U$ there exists a unique epimorphism $\psi_U : \langle U \rangle \to \mathbb{Z}^{(U)}$ that sends $u \in U$ to $u$ viewed as an element in $\mathbb{Z}^{(U)}$.

Now let $S$ and $T$ be two sets and let $\varphi : \langle S \rangle \to \langle T \rangle$ be an epimorphism. By Lemma 19.1 there exists a unique homomorphism $\bar{\varphi} : \mathbb{Z}^{(S)} \to \mathbb{Z}^{(T)}$ that sends $s \in S$ to $\psi_T(\varphi(s)) \in \mathbb{Z}^{(T)}$. We obtain the following diagram of homomorphisms

$$\begin{array}{ccc}
\langle S \rangle & \xrightarrow{\varphi} & \langle T \rangle \\
\downarrow{\psi_S} & & \downarrow{\psi_T} \\
\mathbb{Z}^{(S)} & \xrightarrow{\bar{\varphi}} & \mathbb{Z}^{(T)}
\end{array}$$

It follows immediately from the definition of $\bar{\varphi}$ that this diagram commutes.\textsuperscript{333} Since the top horizontal is an epimorphism and since the vertical maps are epimorphisms

\textsuperscript{333}Here we use that a homomorphism $\gamma : \langle S \rangle \to G$ is uniquely determined by the values of $\gamma$ on $S$. Put differently, if $\alpha : \langle S \rangle \to G$ and $\beta : \langle S \rangle \to G$ are two homomorphisms with $\alpha(s) = \beta(s)$ for all $s \in S$, then it follows immediately from the uniqueness statement of Lemma 19.14 that $\alpha = \beta$. 
we see that the bottom horizontal map is also an epimorphism. It follows from Lemma 19.2 that \( \# S \geq \# T \).

(2) Let \( f: \langle S \rangle \to \langle T \rangle \) be an isomorphism. We apply (1) to \( f \) and to \( f^{-1} \) and we obtain that \( \# S \geq \# T \) and \( \# T \geq \# S \). It follows from the Bernstein-Schröder Theorem 1.8 that \( \# S = \# T \).

(3) This statement is an immediate consequence of (2). \( \square \)

19.3. An alternative definition of the free product of groups. For some purposes it is sometimes useful to work with a different model for the free product of two groups.

Let \( A \) and \( B \) be two groups. We set

\[ S(A, B) := \{ \text{all finite sequences } (g_1, \ldots, g_k) \text{ with each } g_i \text{ in } A \text{ or } B \} \]

and we denote by \( \sim \) the equivalence relation on \( S(A, B) \) that is generated by the relations

\[ (g_1, \ldots, g_i, e, g_{i+2}, \ldots, g_k) \sim (g_1, \ldots, g_i, g_{i+2}, \ldots, g_k) \]

and by the relations

\[ (g_1, \ldots, g_i, g_{i+1}, \ldots, g_k) \sim (g_1, \ldots, g_i g_{i+1}, \ldots, g_k) \]

if both \( g_i \) and \( g_{i+1} \) lie in \( A \) or both lie in \( B \). It is now straightforward to verify that the map

\[ S(A, B)/\sim \times S(A, B)/\sim \to S(A, B)/\sim \]

\[ \left( [(g_1, \ldots, g_k)], [h_1, \ldots, h_l] \right) \mapsto [(g_1, \ldots, g_k, h_1, \ldots, h_l)] \]

is well-defined and that it defines a group structure on \( S(A, B)/\sim \).

**Proposition 19.17.** Let \( A \) and \( B \) be two groups. Then the map

\[ \Phi: S(A, B)/\sim \to A * B \]

\[ [(g_1, \ldots, g_k)] \mapsto g_1 \cdots g_k \]

is well-defined and it is an isomorphism. The inverse map is given by

\[ \Psi: A * B \to S(A, B)/\sim \]

\[ (g_1, \ldots, g_k) \mapsto [(g_1, \ldots, g_k)] \].

In the proof of Proposition 19.17 we will need the following little lemma.

**Lemma 19.18.** Let \( \Phi: G \to H \) and \( \Psi: H \to G \) be two group homomorphisms such that \( \Phi \circ \Psi = \text{id}_H \) and such that \( \Psi \) is an epimorphism. Then \( \Phi \) is an isomorphism.
The lemma can be summarized as follows, if we are given a commutative diagram of the form

\[
\begin{array}{ccc}
H & \xrightarrow{\Psi} & G \\
\downarrow{\Phi} & & \downarrow{\Phi} \\
\id & & H,
\end{array}
\]

then \(\Phi\) is an isomorphism.\(^{338}\)

**Proof.** It follows from \(\Phi \circ \Psi = \id_H\) that \(\Phi\) is an epimorphism. It remains to show that \(\Phi\) is a monomorphism. So let \(g \in \ker(\Phi)\). Since \(\Psi\) is an epimorphism there exists an \(h \in H\) with \(\Psi(h) = g\). Since \(\Phi \circ \Psi = \id_H\) we see that \(h = \Phi(\Psi(h)) = \Phi(g) = e\). Thus \(h = e\) and thus \(g = \Psi(h) = \Psi(e) = e\). \(\blacksquare\)

**Proof.** It is straightforward to verify that the map

\[
\Phi: S(A, B)/\sim \rightarrow A \ast B \\
[(g_1, \ldots, g_k)] \mapsto g_1 \cdots g_k
\]

is well-defined and that it is a homomorphism. This homomorphism is surjective since \(A \ast B\) is a subset of \(S(A, B)\). Next we consider the map

\[
\Psi: A \ast B \rightarrow S(A, B)/\sim \\
(g_1, \ldots, g_k) \mapsto [(g_1, \ldots, g_k)].
\]

It is straightforward to see that \(\Psi\) is a homomorphism. It is clear that \(\Phi \circ \Psi = \id_{A \ast B}\). It is not so obvious that \(\Psi \circ \Phi = \id_{S(A, B)/\sim}\). In fact we will proceed in a slightly different fashion: to show that \(\Phi\) is an isomorphism it suffices, according to Lemma 19.18 to show that \(\Psi\) is surjective. This in turn follows from the following claim.

**Claim.** Any element in \(S(A, B)\) is equivalent to an element in \(A \ast B\).

We prove the claim by induction on the length of a sequence in \(S(A, B)\). Clearly the claim holds for all sequences of length 0. Suppose we already know the claim for all sequences of length \(\leq k-1\). Let \((g_1, \ldots, g_k)\) be a sequence of length \(k\). If \((g_1, \ldots, g_k) \in A \ast B\), then we are done. Now suppose that this is not the case. Then one of the following occurs:

1. either there exists an \(i \in \{1, \ldots, k\}\) with \(g_i = e\), or
2. there exists an \(i \in \{1, \ldots, k-1\}\) with \(g_i, g_{i+1} \in A\), or
3. there exists an \(i \in \{1, \ldots, k-1\}\) with \(g_i, g_{i+1} \in B\).

In the first case the sequence is equivalent to \((g_1, \ldots, g_{i-1}, g_{i+1}, \ldots, g_k)\). In the second and third case the sequence is equivalent to \((g_1, \ldots, g_{i-1}, g_{i+1}, \ldots, g_k)\). In all three cases we have thus shown that our original sequence is equivalent to a sequence of length \(k-1\). So we are done by our induction hypothesis. \(\blacksquare\)

---

\(^{338}\)Is \(\Psi\) also necessarily an isomorphism?

\(^{339}\)Put differently, \(A \ast B \rightarrow S(A, B)/\sim\) is the homomorphism that is given by the universal property of \(A \ast B\).
Let $A$ and $B$ be two groups. In the following we will use the isomorphism of Proposition 19.17 to identify the group $S(A, B)/\sim$ with the free product $A * B$. Both groups have their advantages:

1. In the group $S(A, B)/\sim$ it is easier to write down the product of two elements, we just need to juxtapose sequences of elements in $A$ and $B$.
2. On the other hand in the group $A * B$ it is trivial to check whether two elements are the same. For example for two non-trivial elements $a \in A$ and $b \in B$ the elements $(a, b)$ and $(b, a)$ of $A * B$ are by definition different. But from the definition of $S(A, B)/\sim$ it is not immediately clear that $[(a, b)]$ and $[(b, a)]$ are indeed different.

19.4. **The Grushko-Neumann Theorem.** We start out with the following natural definition.

**Definition.** Let $G$ be a finitely generated group. We denote by $d(G) \in \mathbb{N}_0$ the minimal number of elements in a generating set for $G$.

**Remark.** It is an unfortunate fact of life that in the literature the number $d(G)$ is usually referred to as the rank of the group $G$. But for abelian groups the invariants $\text{rank}(G)$ and $d(G)$ can differ quite dramatically. For example for $G = (\mathbb{Z}_2)^n$ we have $\text{rank}(G) = 0$ but $d(G) = n$.

The following theorem was proved by Igor Grushko [Gru40] in 1940 and independently by Bernhard Neumann [Neum43] in 1940.

**Theorem 19.19. (Grushko-Neumann Theorem)** Given any two finitely generated groups $A$ and $B$ we have

$$d(A * B) = d(A) + d(B).$$

**Proof.** The proof is evidently given in the above two references, but it can also be found in any self-respecting book on combinatorial group theory, see e.g. [LS77, Corollary IV.1.9] and [MKS76, p. 192].

We already saw that some groups can be written as a direct product of two groups in different ways. For example it follows from the Chinese Remainder Theorem that the groups $\mathbb{Z}_3 \times \mathbb{Z}_{35}$ and $\mathbb{Z}_5 \times \mathbb{Z}_{21}$ are isomorphic. The following theorem says that the situation is much more rigid for free products. Before we can state the theorem we have to introduce the following definition.

**Definition.** A group $G$ is *indecomposable* if it is not isomorphic to the free product of two non-trivial groups.

The following lemma will be proved in Exercise 19.6.

**Lemma 19.20.** Abelian groups and finite groups are indecomposable.

Now we can state the Grushko Decomposition Theorem.

---

Igor Grushko was a Russian mathematician. The theorem was proved in 1940.
Theorem 19.21. Let $G$ be a finitely generated group.

1. The group $G$ is isomorphic to the free product $G = A_1 \ast \cdots \ast A_k$ of non-trivial indecomposable groups.

2. The isomorphism types of $A_1, \ldots, A_k$ are unique up to permutation. More precisely, if $A_1, \ldots, A_k$ and $B_1, \ldots, B_l$ are indecomposable finitely generated groups such that

$$A_1 \ast \cdots \ast A_k \cong B_1 \ast \cdots \ast B_l,$$

then $k = l$ and furthermore there exists a permutation $\sigma \in S_k$ such that $A_i \cong B_{\sigma(i)}$ for $i = 1, \ldots, k$.

Proof.

(1) This statement follows easily from induction on $d(G)$ and the Grushko-Neumann Theorem [19.19]. Indeed, if $d(G) = 0$ then there is nothing to prove. Next suppose that the statement is known for all groups $G$ with $d(G) < k$. Let $G$ be a group with $d(G) = k$. If $G$ is indecomposable, we are done. If $G$ is not indecomposable, then we can write $G$ as the free product of two non-trivial groups $A$ and $B$. By the Grushko-Neumann Theorem [19.19] we have $d(G) = d(A) + d(B)$. Since $A$ and $B$ are non-trivial we have $d(A) \geq 1$ and $d(B) \geq 1$. Thus we have $d(A) < k$ and $d(B) < k$ and by induction we can find decompositions for $A$ and $B$. These two decompositions put together give the desired decomposition for $G = A \ast B$.

(2) The uniqueness statement was proved by Aleksandr Kurosh in 1934, see [Kuro34, Isomorphismsatz] and [Kuro60, p. 27]. Alternative proofs are given in [Stal75, p. 168f] and [Nel, Theorem 4.5]. Also see [CM82, Chapter II.4] for more context.

Example. It follows from Lemma [19.20] and from the Grushko Decomposition Theorem [19.21] that the free product $\mathbb{Z}_3 \ast \mathbb{Z}_{35}$ is not isomorphic to the free product $\mathbb{Z}_5 \ast \mathbb{Z}_{21}$.

Exercises for Chapter 19

Exercise 19.1. Show that $\mathbb{Q}$ does not admit an epimorphism onto $\mathbb{Z}$.

Exercise 19.2. Given $n \in \mathbb{Z}$ we consider the matrix $B(n) = \begin{pmatrix} 0 & 3 \\ 3 & n \end{pmatrix}$ and we consider the abelian group $A_n := \mathbb{Z}^2/B(n)\mathbb{Z}^2$. Complete the following sentence: given $m, n \in \mathbb{Z}$ the abelian groups $A_m$ and $A_n$ are isomorphic if and only if \ldots.

Exercise 19.3.

(a) Show that there exists an abelian group $G$ with $G \oplus G \cong G$.

(b) Let $A$ be a finitely generated abelian group. Show that if $B$ is an abelian group with $B \oplus A \cong A$, then $B \cong 0$.

*Hint.* Arguably it is easiest to start out with the special case that $A = \mathbb{Z}$.

Exercise 19.4. Let $S$ be a set. Show that every non-trivial element in the free group $\langle S \rangle$ has infinite order.

34] If $G$ is trivial then $k = 0$ and the free product of zero groups is by convention the trivial group.
Exercise 19.5. Let $M$ be a connected smooth manifold, let $P_1, \ldots, P_n$ and $Q_1, \ldots, Q_n$ be points on $M$. Does there exist an action by a free group $F$ on $M$ such that for any $i \in \{1, \ldots, n\}$ there exists a $g \in F$ with $g \cdot P_i = Q_i$?

Exercise 19.6. Show that abelian groups and finite groups are indecomposable.

Exercise 19.7. Let $G$ be an additive abelian group. We say that an element $g \in G$ is primitive if there does not exist an $h \in G$ and an $n \geq 2$ with $n \cdot h = g$.

1) Suppose $G$ is finitely generated. Let $g \in G$. Show that the following statements are equivalent:
   (a) $g$ is a primitive element.
   (b) We can write $G = \mathbb{Z} \cdot g \oplus H$ for some abelian group $H$.
   (c) There exists a homomorphism $\varphi: G \to \mathbb{Z}$ with $\varphi(g) = 1$.

2) Which of the implications in (1) also hold for infinitely generated abelian groups?

Exercise 19.8. Let $p, q, r \in \mathbb{N}_{\geq 2}$ be coprime. By the Chinese Remainder Theorem we know that $\mathbb{Z}_{pq} \times \mathbb{Z}_r \cong \mathbb{Z}_p \times \mathbb{Z}_{qr}$. Show, without making use of the Grushko Decomposition Theorem, that $\mathbb{Z}_{pq} \ast \mathbb{Z}_r$ is not isomorphic to $\mathbb{Z}_p \ast \mathbb{Z}_{qr}$.

Exercise 19.9. Let $S$ and $T$ be sets. If there exists a monomorphism $\varphi: \langle S \rangle \to \langle T \rangle$, does it follow that $\#S \leq \#T$?

Exercise 19.10. A group $G$ is called locally free if every finitely generated subgroup is free. Is every locally free group also a free group?

Exercise 19.11. Let $G$ be a group and let $g \in G$. The centralizer of $g \in G$ is defined as

$$C_G(g) := \{h \in G \mid gh = hg\}.$$ 

(a) Let $A$ and $B$ be groups and let $g \in A \ast B$. We view $A$ and $B$ as subgroups of $A \ast B$ in the obvious way. Let $g \in A \ast B$. Show that

$$C_G(g) = \begin{cases} C_A(g), & \text{if } g \in A, \\ C_B(g), & \text{if } g \in B, \\ \langle h \rangle, & h \in A \ast B \text{ of infinite order otherwise.} \end{cases}$$

(b) Let $S$ be a set. Show that every abelian subgroup of the free group $\langle S \rangle$ is isomorphic to $\mathbb{Z}$.

Remark. Note that $S$ is not necessarily finite.

Exercise 19.12. Let $G$ be a group and let $x, y \in G$. Suppose there exists an action of $G$ on some set $X$ and two disjoint subsets $A$ and $B$ of $X$ such that the following two conditions are satisfied:

1) for every $n \in \mathbb{Z} \setminus \{0\}$ we have $x^n \cdot A \subseteq B$, and
2) for every $n \in \mathbb{Z} \setminus \{0\}$ we have $y^n \cdot B \subseteq A$. 

Show that \(x\) and \(y\) generate a free subgroup of \(G\), i.e. show that the map \(\langle x \rangle \ast \langle y \rangle \to G\) is a monomorphism.

*Hint.* Show that any non-trivial element \((g_1, \ldots, g_k) \in \langle x \rangle \ast \langle y \rangle\) acts non-trivially on \(X\).

*Remark.* This statement is known as the Ping-Pong Lemma.

Exercise 19.13. We consider the group \(G = \text{SL}(2, \mathbb{Z})\) and we consider the two matrices 
\[ x = \begin{pmatrix} 1 & 2 \\ 0 & 1 \end{pmatrix}, \quad y = \begin{pmatrix} 1 & 0 \\ 2 & 1 \end{pmatrix}. \]
Use the Ping-Pong Lemma from Exercise 19.12 to show that \(x\) and \(y\) generate a free subgroup of \(G\).

*Hint.* Consider \(X = \mathbb{R}^2\) together with the subsets \(A = \{(x, y) \in \mathbb{R}^2 \mid |y| > |x|\}\) and 
\(B = \{(x, y) \in \mathbb{R}^2 \mid |x| > |y|\}\).

Exercise 19.14. A group \(\pi\) is called *residually finite* if given any non-trivial element \(g \in \pi\) there exists a homomorphism \(\alpha : \pi \to G\) to a finite group \(G\) such that \(\alpha(g)\) is non-trivial.

(a) Show that for any \(n \in \mathbb{N}\) the group \(\text{GL}(n, \mathbb{Z})\) is residually finite.

(b) Show that the free group on two generators is residually finite.

Exercise 19.15. Let \(G\) be a group. We consider the subset 
\[ \text{Tor}(G) := \{ g \in G \mid \text{there exists an } n \in \mathbb{N} \text{ with } g^n = e \}. \]

(a) Suppose that \(G\) is abelian. Show that \(\text{Tor}(G)\) is a subgroup of \(G\). We refer to it as the *torsion subgroup* of \(G\).

(b) Give an example of a group \(G\) such that \(\text{Tor}(G)\) is not a subgroup of \(G\).

Exercise 19.16.

(a) Let \(\phi : \langle x, y \rangle \to \mathbb{Z}\) be the homomorphism given by \(\phi(x) = 1\) and \(\phi(y) = 0\). Show that \(\ker(\phi)\) is infinitely generated.

*Remark.* In Proposition 21.14 we will see that any non-trivial normal subgroup of infinite index of a free group is infinitely generated.

(b) Let \(\psi : \langle s, t \rangle \times \langle x, y \rangle \to \mathbb{Z}\) be the homomorphism given by \(\psi(s) = 1, \psi(t) = 0, \psi(x) = 1\) and \(\psi(y) = 0\). Show that \(\ker(\psi)\) is finitely generated.

Exercise 19.17. We consider the free group \(F = \langle x, y \rangle\). Let \(a = (a_1, a_2, \ldots, a_m)\) be a reduced word in \(\langle x \rangle\) and \(\langle y \rangle\). We denote by \(\overline{a} = (a_m, \ldots, a_1)\) the reverse word. Given any reduced word \(z = (z_1, \ldots, z_n)\) we write 
\[ |z|_a = \text{number of non-overlapping subsequences of } z_1, \ldots, z_n \text{ that agree with } a_1, \ldots, a_m. \]
Now we consider the following map

\[ \varphi_a : \langle x, y \rangle \to \mathbb{Z}_{\geq 0}, \quad z \mapsto |z|^a - |z|^a. \]

(a) Show that in general \( \varphi_a \) is not a homomorphism.
(b) Show that there exists a \( D > 0 \) such that for every \( g, h \in \langle x, y \rangle \) we have

\[ |\varphi_a(g \cdot h) - \varphi_a(g) - \varphi_a(h)| \leq D. \]

Remark. Any map \( \varphi : G \to \mathbb{R} \) from a group \( G \) to \( \mathbb{R} \) that admits a \( D \) as above is called a quasi-morphism. The above quasi-morphism is called the Brooks quasi-morphism \([Brooks81]\).

Exercise 19.18. Let \( A \in M(m \times n; \mathbb{Z}) \).
(a) Show that there exist matrices \( P \in \text{GL}(m, \mathbb{Z}) \) and \( Q \in \text{GL}(n, \mathbb{Z}) \) such that \( PAQ \) is of the form

\[ PAQ = \begin{pmatrix} D_{k \times k} & 0_{k \times (n-k)} \\ 0_{k \times (m-k)} & 0_{(n-k) \times (m-k)} \end{pmatrix} \]

where \( D = \text{diag}(d_1, \ldots, d_k) \) is a diagonal \((k \times k)\)-matrix with diagonal entries \( d_1, \ldots, d_k \in \mathbb{N} \).
(b) Show that in (a) we can find \( P \) and \( Q \) such that for each \( i \in \{1, \ldots, k-1\} \) we have \( d_i | d_{i+1} \).

Remark. The corresponding matrix \( PAQ \) is called the Smith normal form of \( A \). The above result is sometimes called the Smith Normal Form Theorem. We refer to \([NewM72\text{, Chapter 15}]\) and \([Nor12\text{, Chapter 1}]\) for more information.

Exercise 19.19. Let \( G \) and \( H \) be two groups.
(a) Suppose there exist monomorphisms \( \varphi : G \to H \) and \( \psi : H \to G \). Does it follow that \( G \) and \( H \) are isomorphic?
(b) Suppose there exist epimorphisms \( \varphi : G \to H \) and \( \psi : H \to G \). Does it follow that \( G \) and \( H \) are isomorphic?
20. The basic Seifert–van Kampen Theorem

We are still lacking the computation of fundamental groups of even fairly simple topological spaces. Now we will take a new approach to calculating fundamental groups. Namely in the following two chapters we will formulate and prove results which allow us to calculate the fundamental group of a given topological space from the fundamental groups of suitable subspaces.

20.1. The formulation of the basic Seifert–van Kampen Theorem. The idea of the Seifert–van Kampen theorem is to reduce the calculation of the fundamental group of a topological space \( X \) to the determination of fundamental groups of “simpler subsets” of \( X \).

Let \( X \) be a topological space and let \( U, V \subset X \) be two subsets with \( X = U \cup V \) and with \( U \cap V \neq \emptyset \). We choose a base point \( x_0 \in U \cap V \) and we consider the following inclusion maps and the corresponding induced homomorphisms of the fundamental groups:

\[
\begin{array}{ccc}
U \cap V & \rightarrow & U \\
\downarrow & & \downarrow i \\
V & \rightarrow & X = U \cup V \\
\downarrow j & & \downarrow j_* \\
\pi_1(U \cap V, x_0) & \rightarrow & \pi_1(U, x_0) \\
\downarrow & & \downarrow j_* \\
\pi_1(V, x_0) & \rightarrow & \pi_1(X, x_0) = \pi_1(U \cup V, x_0).
\end{array}
\]

Our goal is to determine the fundamental group of the total space \( X = U \cup V \) in terms of the fundamental groups of \( U, V, U \cap V \) and the induced maps \( \pi_1(U \cap V, x_0) \rightarrow \pi_1(U, x_0) \) and \( \pi_1(U \cap V, x_0) \rightarrow \pi_1(V, x_0) \).

We start out with the following lemma:

**Lemma 20.1.** Let \( X \) be a topological space and let \( U, V \subset X \) be two open subsets with \( X = U \cup V \) and such that \( U \cap V \neq \emptyset \). We choose a base point \( x_0 \in U \cap V \). If \( U \cap V \) is path-connected, then the homomorphism

\[
\pi_1(U, x_0) * \pi_1(V, x_0) \rightarrow \pi_1(X, x_0),
\]

which is induced by the homomorphisms \( \pi_1(U, x_0) \rightarrow \pi_1(X, x_0) \) and \( \pi_1(V, x_0) \rightarrow \pi_1(X, x_0) \) and by Lemma 19.12 (2), is surjective.

**Examples.**

(1) We consider the sphere

\[
X = S^2 = \{(x, y, z) \mid x^2 + y^2 + z^2 = 1\},
\]

with the covering \( X = U \cup V \) given by the two open subsets

\[
U = \{(x, y, z) \mid x^2 + y^2 + z^2 = 1 \text{ and } z > -\frac{1}{2}\},
\]

\[
V = \{(x, y, z) \mid x^2 + y^2 + z^2 = 1 \text{ and } z < \frac{1}{2}\}.
\]

We pick the base point \( x_0 = (1, 0, 0) \in U \cap V \). Here the intersection \( U \cap V \) is path-connected, therefore we can apply Lemma 20.1. It says that we have an epimorphism

\[
\pi_1(U, x_0) * \pi_1(V, x_0) \rightarrow \pi_1(S^2, x_0).
\]
The subspaces $U$ and $V$ are homeomorphic to an open disk\footnote{A homeomorphism is for example given by stereographic projection.} thus the fundamental groups are trivial. It follows that the trivial group\footnote{Here we use the obvious fact that the free product of two copies of the trivial group is again the trivial group.} surjects onto $\pi_1(S^2, x_0)$, thus $\pi_1(S^2, x_0)$ itself is trivial. Precisely the same argument shows that $\pi_1(S^n) = 0$ for $n \geq 3$.

We had already obtained this result in Proposition\footnote{Why does it suffice to prove this claim?}. In fact, as we will see shortly, the proof of Lemma\footnote{Indeed, if $s(t_i)$ lies in $U \setminus V$, then $s([t_i, t_i])$ and $s([t_i, t_{i+1}])$ cannot lie in $V$, hence they both lie in $U$. This implies that $s([t_{i-1}, t_{i+1}])$ lies in $U$, and therefore we can remove $t_i$ from the subdivision.}.\footnote{Proof of Lemma 20.1} In fact, as we will see shortly, the proof of Lemma\footnote{We consider the sphere}.\footnote{We pick the base point $x_0 = 1$. The subsets $U$ and $V$ are both homeomorphic to an open interval, hence $\pi_1(U, x_0) = \pi_1(V, x_0) = 0$, but of course we know from Corollary\footnote{No} that $\pi_1(X, x_0) \cong \mathbb{Z}$. Thus we see that $\pi_1(U, x_0) * \pi_1(V, x_0) \to \pi_1(X, x_0)$ is not an epimorphism. This is not a contradiction to Lemma 20.1, since in this example the intersection $U \cap V$ is not path-connected.} since in this example the intersection $U \cap V$ is not path-connected.

Now we turn to the proof of Lemma\footnote{Proof of Lemma 20.1}.\footnote{Let $X$ be a topological space and let $U, V \subset X$ be two open subsets with $X = U \cup V$ and such that $U \cap V \neq \emptyset$. We choose a base point $x_0 \in U \cap V$. It suffices to prove the following claim.\footnote{Claim. Every loop $s:[0,1] \to X = U \cup V$ in $x_0$ is path-homotopic to a loop which is the product of finitely many loops in $(U, x_0)$ or in $(V, x_0)$.}}.

**Proof of Lemma 20.1** Let $X$ be a topological space and let $U, V \subset X$ be two open subsets with $X = U \cup V$ and such that $U \cap V \neq \emptyset$. We choose a base point $x_0 \in U \cap V$. It suffices to prove the following claim\footnote{Claim. Every loop $s:[0,1] \to X = U \cup V$ in $x_0$ is path-homotopic to a loop which is the product of finitely many loops in $(U, x_0)$ or in $(V, x_0)$.}.

**Claim.** Every loop $s:[0,1] \to X = U \cup V$ in $x_0$ is path-homotopic to a loop which is the product of finitely many loops in $(U, x_0)$ or in $(V, x_0)$.

So let $s:[0,1] \to X = U \cup V$ be a loop in $x_0$. Since $U$ and $V$ are open we can use Corollary\footnote{No} to find a subdivision

$$0 = t_0 < t_1 < t_2 < \ldots < t_k < t_{k+1} = 1$$

of the interval $[0,1]$ such that the image of each $s_i := s|_{[t_i, t_{i+1}]}$ lies in $U$ or in $V$. The same argument as in the proof of Proposition\footnote{Proof of Lemma 20.1} shows that we can assume that each $s(t_i)$ lies in $U \cap V$.\footnote{The problem is that even though the paths $s_i$ lie in $U$ respectively in $V$, they are not necessarily loops in $x_0$. But since $U \cap V$ is path-connected we can find for each $i \in \{1, \ldots, k\}$ a path $p_i$ in $U \cap V$ which connects $s(t_i) \in U \cap V$ to the base point $x_0 \in U \cap V$.}
Now we have the following path-homotopies:

by Lemma 14.4, since \( s \) is a reparametrization of \( s_0 \ast \cdots \ast s_k \)

\[
s \simeq s_0 \ast \cdots \ast s_k \simeq s_0 \ast p_1 \ast \overline{p}_1 \ast s_1 \ast p_2 \ast \overline{p}_2 \ast s_2 \ast p_3 \ast \overline{p}_3 \ast \cdots \ast \overline{p}_k \ast s_k
\]

\[
\simeq (s_0 \ast p_1) \ast (\overline{p}_1 \ast s_1 \ast p_2) \ast (\overline{p}_2 \ast s_2 \ast p_3) \ast \cdots \ast (\overline{p}_k \ast s_k).
\]

Thus we have shown that \( s \) is path-homotopic to a product of loops in \((U, x_0)\) and \((V, x_0)\). \(\square\)

**Theorem 20.2. (Seifert–van Kampen)**\(^{316}\) Let \( X \) be a topological space and let \( U, V \subset X \) be two open subsets with \( X = U \cup V \) and with \( U \cap V \neq \emptyset \). We choose a base point \( x_0 \in U \cap V \). If \( U \cap V \) is simply connected, then the map

\[
\pi_1(U, x_0) \ast \pi_1(V, x_0) \to \pi_1(X, x_0)
\]

that is induced by \( \pi_1(U, x_0) \to \pi_1(X, x_0) \) and \( \pi_1(V, x_0) \to \pi_1(X, x_0) \) and Lemma 19.12 (2), is an isomorphism.

**Remark.** One might wonder whether the hypothesis that \( U \cap V \) is simply connected is really necessary. But this is indeed the case. For example we could take \( X = S^1 \times [-1, 1] \) with \( U = S^1 \times [-1, \frac{1}{2}] \) and \( V = S^1 \times (-\frac{1}{2}, 1] \). In this case we have \( \pi_1(X) \cong \mathbb{Z} \) which is not isomorphic to the non-abelian group \( \pi_1(U) \ast \pi_1(V) \cong \mathbb{Z} \ast \mathbb{Z} \).

We postpone the proof of the Seifert–van Kampen Theorem 20.2 to the next section and we first discuss several examples and applications of the theorem.

\(^{316}\)The proof of Lemma 20.1 is arguably easier to follow than the proof of Proposition 14.14. The reason is that in the special case Proposition 14.14 we introduced more notation, e.g. North Pole and South Pole, than was perhaps strictly necessary. All we really needed was that we could cover \( S^2 \) by two open simply connected subsets \( U \) and \( V \) such that \( U \cap V \) is path-connected. The precise choice of \( U \) and \( V \) is irrelevant.

\(^{317}\)The theorem was proved independently by Herbert Seifert (1907–1996) and Egbert van Kampen (1908–1942).
Let $A$ and $B$ be two topological spaces and let $a \in A$ and $b \in B$ be two points. Recall that on page 559 we defined the wedge $A \lor B$ of $A$ and $B$ as

$$A \lor B := A \sqcup B / a = b.$$  

We illustrate this definition in Figure 378. In the following we will often identify $A$ and $B$ with their respective images in $A \lor B$. Another way of thinking about the wedge of $A$ and $B$ is to say that the wedge $X = A \lor B$ can be decomposed into two subsets $A$ and $B$ such that $A \cap B$ is a point. Since $A \cap B$ is a point it is in particular simply connected. Thus it sounds like one should be able to apply the Seifert–van Kampen Theorem 20.2. This is almost correct, except that in the Seifert–van Kampen Theorem we have to deal with decompositions of a topological space $X$ into open subsets. We therefore need to introduce a somewhat technical definition.

![Figure 378. The wedge of a circle with a torus.](image)

**Definition.** We say a point $x$ in a topological space $X$ is *good*, if the following two conditions are satisfied:

1. $\{x\}$ is a closed subset of $X$ and
2. there exists an open neighborhood $U$ of $x$ such that $x$ is a deformation retract of $U$.

**Remark.**

1. If $X$ is Hausdorff, then it we know by Lemma 2.13 that any subset consisting of a single point is closed. Thus the first condition in the definition of a good point is satisfied “for free”.
2. What we call a “good point” is sometimes called a “nondegenerate point”, see e.g. [Lee00, p. 212]. On the other hand, the term “nondegenerate point” is defined in a subtly different way, see e.g. [Spa95, p. 380] or [Bre93, p. 435]. Also note that a point $x \in X$ is good if the pair $(X, \{x\})$ is good in the sense of [Hat02, p. 114].

**Examples.**

1. Let $X$ be an $n$-dimensional topological manifold (e.g. a sphere). We claim that every point is good. Since $X$ is by definition Hausdorff we only need to show that Condition (2) is always satisfied. Thus let $x \in X$. Using a chart around $x$ one easily sees that $x$ admits an open neighborhood that is homeomorphic to the open ball $B^n$ or to the “open half-ball” $\{(x_1, \ldots, x_n) \in B^n \mid x_n \geq 0\}$. In both cases $x$ is evidently a deformation retract of that open neighborhood.
2. We consider $X = \mathbb{C} \setminus \{\frac{1}{n} \mid n \in \mathbb{N}\}$. Morally speaking the point $x = 0$ is not good, “since any open neighborhood of 0 has non-trivial fundamental group”. In Exercise 20.1 we will provide a proper proof that $x = 0$ is not a good point of $X$.  

Proposition 20.3. Let $A$ and $B$ be two path-connected topological spaces and let $a \in A$ and $b \in B$ be good points. Then the inclusion maps induce an isomorphism \[ \pi_1(A, a) \ast \pi_1(B, b) \xrightarrow{\cong} \pi_1(A \vee B, a = b). \]

Remark. In the definition of a “good point” we demanded that the one-point subset given by the point is closed. Strictly speaking we do not need this fact in the proof of Proposition 20.3.

Proof. Let $A$ and $B$ be two path-connected topological spaces and let $a \in A$ and $b \in B$ be good points. We write $X = A \vee B$ and $x_0 = \{a, b\} \in A \vee B$. By Lemma 18.25 we can view $A$ and $B$ as subsets of $X = A \vee B$ in the obvious way.

We pick an open neighborhood $C$ in $A$ of $a$ that deformation retracts to $a$. Furthermore we pick an open neighborhood $D$ of $b$ in $B$ that deformation retracts to $b$. We consider $U := A \vee D$ and $V := B \vee C$, each viewed as subsets of $X = A \vee B$.

Figure 380. Schematic image for the proof of Proposition 20.3.

Now we consider the following diagram

\[
\begin{array}{ccc}
\pi_1(A, a) \ast \pi_1(B, b) & \xrightarrow{\cong} & \pi_1(X, x_0) \\
\downarrow & & \downarrow \\
\pi_1(U, x_0) \ast \pi_1(V, x_0) & \xrightarrow{\cong} & \pi_1(X, x_0).
\end{array}
\]

\[\text{More precisely, the two natural inclusions } A \to A \vee B \text{ and } B \to A \vee B \text{ induce homomorphisms } \pi_1(A, a) \to \pi_1(A \vee B, a = b) \text{ and } \pi_1(B, b) \to \pi_1(A \vee B, a = b). \text{ Combined with Lemma 19.12 (2) we obtain the homomorphism } \pi_1(A, a) \ast \pi_1(B, b) \to \pi_1(A \vee B, a = b).\]
We make the following observations:

1. The vertical and horizontal maps are all induced by the various inclusions of topological spaces. In particular the diagram commutes.
2. It follows from the definition of the quotient topology on \( A \vee B = (A \cup B)/ \sim \) that \( U \) and \( V \) are open subsets of \( X \).
3. It follows from Lemma \[18.28\] that \( A \) is a deformation retract of \( U = A \vee C \).
4. As in (3) we see that \( B \) is a deformation retract of \( V = B \vee D \).
5. Furthermore, very similar to the argument in (3), we see that \( A \cap B \) is a deformation retract of \( U \cap V = C \vee D \). It follows from Lemma \[18.14\] and Proposition \[18.16\] (2) that \( U \cap V \) is simply connected.
6. By (2) and (5) we can apply the Seifert-van Kampen Theorem \[20.2\] to the decomposition \( A \vee B = U \cup V \) and we obtain that the bottom horizontal map of the above diagram is an isomorphism.
7. It follows from (3), (4) and Lemma \[18.14\] that the inclusions \( A \to U = A \cup D \) and \( B \to V = B \cup C \) are homotopy equivalences.
8. It follows from (6) together with Proposition \[18.16\] (2) that the two inclusion induced maps \( \pi_1(A, a) \to \pi_1(U, a) \) and \( \pi_1(B, b) \to \pi_1(V, b) \) are isomorphisms, which implies that the left vertical map in the above commutative diagram is an isomorphism.
9. We deduce that the top horizontal map is, as desired, also an isomorphism.

Examples.

1. We consider again the wedge \( S^1 \vee S^1 \) with \( a = (1, 0) \) and \( b = (-1, 0) \). These points are simple.\[349\] By Proposition \[16.17\] we know that \( \pi_1(S^1, a) = \langle x \rangle \) and \( \pi_1(S^1, b) = \langle y \rangle \)

\[\begin{array}{ccc}
A & \longrightarrow & B \\
a = (1, 0) & b = (-1, 0)
\end{array}\]

\[\begin{array}{c}
\pi_1(S^1 \vee S^1) = \langle x, y \rangle \\
y^{-1}x^{-1}yx \text{ is a non-trivial element in } \pi_1(S^1 \vee S^1) = \langle x, y \rangle
\end{array}\]

Figure 381. The wedge of two circles.

where \( x \) and \( y \) are represented by loops that go “once around the circle”, as illustrated in Figure 381. Proposition \[20.3\] says that the inclusion maps induce an isomorphism

\[\langle x, y \rangle = \langle x \rangle * \langle y \rangle = \pi_1(S^1, a) * \pi_1(S^1, b) \xrightarrow{\cong} \pi_1(S^1 \vee S^1, a = b)\]

(2) We consider the loop \( \gamma \) from page \[461\] in \( \mathbb{C} \setminus \{\pm 1\} \) that is also illustrated in Figure 382 on the left. We had already pointed out on page \[561\] that there exists a deformation

\[\begin{array}{c}
349\text{This follows either from the general statement that any point on a topological manifold is simple, or more simply, by taking } A \text{ and } B \text{ to be small “intervals” around } a \text{ and } b.
350\text{Recall that } \langle x \rangle \text{ denotes the free group generated by } x, \text{ i.e. } \langle x \rangle = \{\ldots, x^{-1}, e = x^0, x, x^2, \ldots \}.
\end{array}\]
retraction $f$ from $\mathbb{C} \setminus \{ \pm 1 \}$ to the wedge of two circles that is given by

$$S^1 \lor S^1 = \{ z \in \mathbb{C} \mid |z + 1| = 1 \} \cup \{ z \in \mathbb{C} \mid |z - 1| = 1 \}. \tag{20.1}$$

We then have $f_*([\gamma]) = [f \circ \gamma] = \langle y^{-1}x^{-1}yx \rangle \in \langle x, y \rangle = \pi_1(S^1 \lor S^1)$, which is non-trivial. Thus we see that $f \circ \gamma$ is not null-homotopic in $S^1 \lor S^1$ which implies that $\gamma$ is not null-homotopic in $\mathbb{C} \setminus \{ \pm 1 \}$.

![ret retraction f from C \{±1} to S^1 \lor S^1](image)

**Figure 382**

Before we continue we condense the above example into a lemma.

**Lemma 20.4.** Let $k \in \mathbb{N}_0$. The map

$$\langle x_1, \ldots, x_k \rangle \to \pi_1^{\left(\bigsqcup_{i=1}^k S^1, \ast\right)}$$

that is given by

$$x_i \mapsto \left[ [0, 1] \to S^1, t \mapsto e^{2\pi it} \right]$$

is an isomorphism.

**Convention.** We refer to the images of $x_1, \ldots, x_k$ under the isomorphism of Lemma 20.4 as the standard generating set of $\pi_1^{\left(\bigsqcup_{i=1}^k S^1, \ast\right)}$.

**Proof.** Similar to the above example the lemma follows from applying Proposition 20.3 altogether $k - 1$ times.

**Proposition 20.5.**

1. Let $G = (V, E, i, t)$ be a finite connected non-empty abstract graph and let $T$ be a maximal tree of $G$. Let $e_1, \ldots, e_n$ be the edges not contained in $T$. We pick some $v \in V$. For $j = 1, \ldots, n$ we pick a path $\alpha_j : [0, 1] \to |T|$ from $v$ to $i(e_j)$, we denote by $\beta_j : [0, 1] \to [(e_j, t)] \in |G|$ the obvious path from $i(e_j)$ to $t(e_j)$, and we pick a path $\gamma$...
\[ \gamma_j : [0, 1] \to |T| \text{ from } t(e_j) \text{ to } v. \] Then the map

\[ \Theta_G : \langle x_1, \ldots, x_n \rangle \to \pi_1(|G|, v) \]

that is given by

\[ x_j \mapsto [\alpha_j * \beta_j * \gamma_j] \]

is an isomorphism.

(2) Let \( X \) be a finite connected non-empty topological graph with \( v \) vertices and \( e \) edges. Then

\[ \pi_1(X) \cong \text{free group on } 1 - \chi(X) = 1 + e - v \text{ generators}. \]

(3) Two finite connected topological graphs are homotopy equivalent if and only if they have the same Euler characteristic. \[ \square \]

---

**Proof.**

(1) We consider the maps

\[ \langle x_1, \ldots, x_n \rangle \xrightarrow{\Theta_G} \pi_1(|G|, v) \to \pi_1(|G|/|T|, v) \overset{\cong}{\leftarrow} \pi_1 \left( \bigvee_{j=1}^n S^1 \right) \overset{\cong}{\leftarrow} \langle y_1, \ldots, y_n \rangle. \]

isomorphism by Propositions 18.31 and 18.16 (2) isomorphism given by Lemma 20.4

It follows fairly easily from the explicit descriptions of the various maps that for each \( j \in \{1, \ldots, n\} \) the images of \( x_j \) and \( y_j \) in \( \pi_1(|G|/|T|, v) \) are represented by homotopic loops, in particular the images of \( x_j \) and \( y_j \) in \( \pi_1(|G|/|T|, v) \) are the same. But now it follows from the above and the fact that all other maps are isomorphisms that \( \Theta_G \) itself is indeed an isomorphism.

(2) Basically by definition we only need to prove the statement if \( X = |G| \) is the topological realization of a finite connected non-empty abstract graph \( G = (V, E, i, t) \). By Proposition 4.8 (1) we know that \( G \) admits a spanning tree \( T = (W, F) \). By Proposition 4.8 we know that \( T \) contains all vertices of \( V \). Furthermore, since \( T \) is a tree we know by definition of a tree that \( \#W = \#F = 1 \). Thus it follows that there are precisely \( \#E - \#F = e - (\#W - 1) = e - v + 1 \) edges of \( G \) that are not contained in \( T \). The desired statement now follows from (1).

(3) Let \( X \) and \( X' \) be two finite connected topological graphs. If \( \chi(X) = \chi(X') \), then we already saw in Proposition 18.31 (3) that \( X \) and \( X' \) are homotopy equivalent. On the other hand, if \( \chi(X) \neq \chi(X') \), then it follows from (1) together with Lemma 19.16 that \( X \) and \( X' \) are not homotopy equivalent. \[ \square \]
As a last example in this section we would like to determine the fundamental group of\[ X = \left( \mathbb{R} \sqcup (\mathbb{Z} \times S^2) \right) / n \sim (n, (0, 0, -1)). \]

The space $X$ consists of an infinite line where to each $n \in \mathbb{Z}$ we attach a 2-dimensional sphere. The space $X$ is illustrated in Figure 384. Given $k \in \mathbb{N}$ we denote by $X_k$ the topological space that is obtained by $X$ by restricting oneself to the interval $(-k - \frac{1}{2}, k + \frac{1}{2})$, i.e.

\[ X_k = \left( \left( -k - \frac{1}{2}, k + \frac{1}{2} \right) \sqcup \{ -k, \ldots, k-1, k \} \times S^2 \right) / n \sim (n, (0, 0, -1)). \]

Note that $X_k$ can be viewed as the wedge of an open interval with $2k+1$ spheres. It follows immediately from Proposition 14.14 Proposition 20.3 and a straightforward induction argument that $\pi_1(X_k) = 0$ for all $k$. Furthermore one can easily convince oneself that the sets $X_k$ are open. It now follows from the following lemma that $\pi_1(X)$ is also trivial.

**Lemma 20.6.** Let $X$ be a path-connected topological space and let $x_0 \in X$. Furthermore let $X_k, k \in \mathbb{N}$ be a sequence of subsets of $X$ such that the following hold:

1. each $X_k$ is open,
2. each $X_k$ is simply connected,
3. the sequence $X_k$ is nested, i.e. for each $k$ we have $X_k \subset X_{k+1},$
4. we have $\bigcup_{k \in \mathbb{N}} X_k = X.$

Then $\pi_1(X, x_0) = 0$.

The proof of the lemma, which will make essential use of Lemma 2.41 is the content of Exercise 20.2.

We conclude this section with the following generalization of Proposition 20.3:

**Proposition 20.7.** (* Let $\{A_k\}_{k \in K}$ be a family of topological spaces. For each $k \in K$ suppose that we are given a good point $a_k \in A_k$. Given $j \in K$ we denote by

\[ i_j : A_j \rightarrow \bigvee_{k \in K} A_k \quad \text{respectively} \quad p_j : \bigvee_{k \in K} A_k \rightarrow A_j \]

the natural inclusion map respectively the natural projection map. We denote by $\ast$ the wedge point of $\bigvee_{i \in I} X_i$. For every $n \in \mathbb{N}_0$ the projections $p_k$ induces an isomorphism

$$\ast p_k: \pi_1 \left( \bigvee_{k \in K} A_k, \ast \right) \to \text{free product of the groups } \{ \pi_1(A_k, a_k) \}_{k \in K}.$$  

The inverse is induced by the inclusions $i_k$.

**Proof (\ast).** Let $\{A_k\}_{k \in K}$ be a family of topological spaces. For each $k \in K$ suppose that we are given a good point $a_k \in A_k$. We use these points to form the wedge $\bigvee_{k \in K} A_k$. Recall that the fact that $a_k$ is good means that

1. $\{a_k\}$ is a closed subset of $A_k$ and
2. there exists an open neighborhood $U_k$ of $a_k$ in $A_k$ such that $a_k$ is a deformation retract of $U_k$.

The trick in the proof of Proposition 20.7 is to reduce the statement to the case of Proposition 20.7.

We will show that the map

$$\ast k \in K i_k: \ast \pi_1(A_k) \to \pi_1 \left( \bigvee_{k \in K} A_k \right)$$

is an isomorphism. (Here and throughout we work with the obvious base points, which we suppress from the notation.) Once we will have established this fact it is straightforward to show that the inverse is given by $\ast k \in K p_k \ast$.

The idea of the proof is to show that the map is a monomorphism and an epimorphism.

**Claim.** The map

$$\ast k \in K i_k: \ast \pi_1(A_k) \to \pi_1 \left( \bigvee_{k \in K} A_k \right)$$

is an epimorphism.

We introduce the following notation:

1. We write $B := \bigvee_{k \in K} A_k$ and we set $U := \bigcup_{k \in K} U_k \subset B$.
2. Given a subset $J \subset K$ we write $B_J := \bigvee_{j \in J} A_j$ and we write $\hat{B}_J := U \cup B_J$.

Given a finite subset $J \subset K$ we have the following commutative diagram

$$
\begin{array}{ccc}
\ast j \in J \pi_1(A_j) & \cong & \pi_1(B_J) \\
\downarrow & & \downarrow \\
\ast k \in K \pi_1(A_k) & \to & \pi_1(B).
\end{array}
$$
20. THE BASIC SEIFERT–VAN KAMPEN THEOREM

We make the following observations and comments:

(1) The maps are either the obvious algebraic inclusion maps or they are the obvious maps induced by inclusions of topological spaces. It follows almost immediately from the definitions that the diagram commutes.

(2) Since $J$ is finite we obtain, from applying Proposition 20.3 finitely many times, that the top horizontal map is an isomorphism.

(3) By Exercise 18.32 we know that $B_J$ is a deformation retract of $\hat{B}_J$. It follows from Proposition 18.16 (2) that the top diagonal map is an isomorphism.

(4) By Exercise 18.33 we know that given any compact subset $L \subset B$ there exists a finite subset $J \subset K$ with $L \subset \hat{B}_J$.

Now we show that the above map $\star_{k \in K} i_k \ast$ is an epimorphism. So suppose we are given some $[\sigma : S^1 \to B] \in \pi_1(B)$. It follows from (4) there exists a finite subset $J \subset K$ such that $\sigma \in C_n(\hat{B}_J)$. But considering the above diagram, and using the fact that the top horizontal map is an isomorphism we see that $[\sigma]$ actually lies in the image of $\star_{k \in K} i_k \ast$. ■

Claim. The map

$$\star_{k \in K} i_k : \star_{k \in K} \pi_1(A_k) \to \pi_1\left( \bigvee_{k \in K} A_k \right)$$

is a monomorphism.

We continue with the notation that we introduced in the proof of the previous claim. Given any two finite subsets $J \subset \tilde{J} \subset K$ we have the following commutative diagram

$$\star_{j \in J} \pi_1(A_j) \xrightarrow{\cong} \pi_1(B_J) \xrightarrow{\cong} \pi_1(B_{\tilde{J}}) \xrightarrow{\cong} \pi_1(\hat{B}_{\tilde{J}}).$$

In Exercise 20.7 we will use this diagram to show that the map $\star_{k \in K} i_k \ast$ is also a monomorphism. ■

20.2. Proof of the Seifert–van Kampen Theorem 20.2. After this long list of applications we finally provide the proof of the Seifert–van Kampen Theorem 20.2.

Proof. Let $X$ be a topological space and let $U, V \subset X$ be two open subsets with $X = U \cup V$ and with $U \cap V \neq \emptyset$ such that $U \cap V$ is simply connected. We choose a base point $x_0 \in U \cap V$. We write $A := \pi_1(U, x_0)$ and $B := \pi_1(V, x_0)$. We need to show that the map

$$\Phi : A \ast B = \pi_1(U, x_0) \ast \pi_1(V, x_0) \to \pi_1(X, x_0)$$

that is induced by the inclusions $U \to X$ and $V \to X$ is an isomorphism. Taking into account Lemma 20.1 it suffices to show that the map is injective. To prove injectivity it is...
enough to show that there exists a map \( \Psi: \pi_1(X, x_0) \to A \ast B \) such that \( \Psi \circ \Phi = \text{id}_{A \ast B} \).

We will prove the existence of such a map \( \Psi \) in three steps:

1. we first construct a map \( \Psi: \{\text{loops in } (X, x_0)\} \to A \ast B \);
2. then we show that \( \Psi \) descends to a well-defined map

\[
\Psi: \pi_1(X, x_0) \to A \ast B \\
[g] \mapsto \Psi(g)
\]

3. and finally we show that \( \Psi \circ \Phi = \text{id}_{A \ast B} \).

For the remainder of the proof we will identify \( A \ast B \) with \( S(A, B) / \sim \) using the isomorphism given by Proposition [19.17].

We start out with step (1). Let \( g: [0, 1] \to X \) be a loop in \( (X, x_0) \). We apply Corollary 2.76 to the map \( g: [0, 1] \to X \) and the open cover \( X = U \cup V \). We obtain an \( N \) such that for every \( i \in \{0, \ldots, N - 1\} \) the image of the interval \( [\frac{i}{N}, \frac{i+1}{N}] \) under the map \( g \) lies in \( U \) or in \( V \). We introduce a few definitions.

(a) We say a subinterval of \([0, 1]\) can be colored green if the image of the subinterval under the map \( g \) lies in \( U \) and we say an interval can be colored blue if the image of the subinterval lies in \( V \). Note that the image of a subinterval lies in \( U \cap V \) if and only if the subinterval can be colored green as well as blue.

(b) A coloring is a map \( \alpha: \{0, \frac{1}{N}, \ldots, 1 - \frac{1}{N}\} \to \{\text{blue, green}\} \) such that each subinterval \([i, i + \frac{1}{N}]\) can be colored by \( \alpha(i) \). This definition is illustrated in Figure 385.

![Figure 385](image)

(c) Given a coloring \( \alpha \) we denote by \( 0 < a_1 < \cdots < a_{k-1} < 1 \) the numbers where the coloring of the subintervals changes from one color to another. This definition is also illustrated in Figure 385. Note that for each \( a_i \) the intervals \([a_i - \frac{1}{N}, a_i]\) and \([a_i, a_i + \frac{1}{N}]\) can be colored in two different colors, which implies that \( g(a_i) \in U \cap V \).

(d) A basing for a coloring \( \alpha \) is a collection of paths \( p_1, \ldots, p_{k-1} \) in \( U \cap V \) such that each path \( p_i \) goes from \( x_0 \) to \( g(a_i) \)\(^{352}\).

\(^{352}\)Such basing exists since each \( g(a_i) \) lies in \( U \cap V \) and since \( U \cap V \) is path-connected.
Now given a coloring $\alpha$ and a basing $p_1, \ldots, p_{k-1}$ we define

$$\overline{\Psi}(g) := [g|_{[0,a_1]} * \overline{p_1}] , [p_1 * g|_{[a_1,a_2]} * \overline{p_2}], \ldots, [p_{k-1} * g|_{[a_{k-1},1]}] \in S(A,B)/ \sim = A*B.$$

Our next goal is to prove the following claim.

Claim. The definition of $\overline{\Psi}(g)$ does not depend on any of the choices made.

We need to prove the following three statements:

(a) given $N$ and a coloring the definition does not depend on the choice of the basing,
(b) given $N$ the definition does not depend on the choice of the coloring,
(c) the definition does not depend on the choice of $N$.

We first fix a coloring $\alpha$ and we show that the definition of $\overline{\Psi}(g)$ does not depend on the choice of the basing. First we pick a different path $q_1$ from $x_0$ to $g(a_1)$ instead of the original path $p_1$. (See Figure 386 for an illustration.) In this case we have

$$\overline{\Psi}(g) \text{ using the basing } p_1, p_2, \ldots, p_{k-1} =$$

$$= [g|_{[0,a_1]} * \overline{p_1}] , [p_1 * g|_{[a_1,a_2]} * \overline{p_2}], \ldots, [p_{k-1} * g|_{[a_{k-1},1]}]$$

$$= [g|_{[0,a_1]} * \overline{q_1}] , [q_1 * \overline{q_1} * p_1 * g|_{[a_1,a_2]} * \overline{p_2}], \ldots, [p_{k-1} * g|_{[a_{k-1},1]}]$$

since $q_1 * \overline{q_1}$ is null-homotopic

$$= [g|_{[0,a_1]} * \overline{q_1}] , [q_1 * g|_{[a_1,a_2]} * \overline{p_2}], \ldots, [p_{k-1} * g|_{[a_{k-1},1]}]$$

$\overline{p_1} * q_1$ and $\overline{q_1} * p_1$ are null-homotopic since $U \cap V$ is simply connected.

Precisely the same argument shows that the choices of the other paths $p_i$ are also irrelevant. This concludes the proof of (a).

---

383 Each path $p_m * g|_{[a_m,a_{m+1}]} * \overline{p}_{m+1}$ is a loop in $(U,x_0)$ or $(V,x_0)$, so each path represents an element in $\pi_1(U,x_0)$ or $\pi_1(V,x_0)$. Thus we obtain a sequence of elements in $\pi_1(U,x_0)$ and $\pi_1(V,x_0)$. The equivalence class of this sequence defines an element in $S(A,B)/ \sim = A*B$.

384 This definition is almost the same as in the proof of Lemma 20.1.

385 This is the only time that in the proof we use the hypothesis that $U \cap V$ is simply connected. In fact if one studies the argument carefully one sees that we only used that the maps $\pi_1(U \cap V,x_0) \to \pi_1(U,x_0)$ and $\pi_1(U \cap V,x_0) \to \pi_1(V,x_0)$ are trivial.
Now we show that the definition does not depend on the choice of the coloring. So suppose we have two colorings \( \alpha \) and \( \beta \). We can turn one coloring into the other by a finite sequence of color swaps of a single subinterval. Therefore it suffices to consider the case that there exists a single \( i \) where the values for \( \alpha(i) \) and \( \beta(i) \) differ.

We consider the case, sketched in Figure 387, with \( \alpha(i) = \text{blue} \) and \( \beta(i) = \text{green} \) such that the common coloring to the left is green and the common coloring to the right is blue. All other cases are dealt with in a similar way.

Let \( 0 = a_0 < a_1 < \cdots < a_k = 1 \) be the decomposition for \( \alpha \). We pick a basing \( p_1, \ldots, p_{k-1} \) for \( \alpha \). There exists a unique \( m \) with \( a_m = i \). The corresponding decomposition for the coloring \( \beta \) is given by \( 0 = a_0 < a_1 < \cdots < a_m + \frac{1}{N} < a_{m+1} < a_k = 1 \). We write \( q = g_{[a_m, a_m + \frac{1}{N}]} \). Since \( [a_m, a_m + \frac{1}{N}] \) can be colored green and blue we see that \( q \) lies actually in \( U \cap V \). We have

\[
\text{definition of } \overline{\Psi}(g) \text{ using the coloring } \alpha \text{ and the basing } p_1, \ldots, p_{k-1} = \nonumber
\]
\[
= [g|_{[0,a_1]} \cdot p_1, \ldots, [p_{m-1} \cdot g|_{[a_{m-1},a_m]} \cdot p_m, [p_m \cdot g|_{[a_m,a_{m+1}]} \cdot p_{m+1}, \ldots] \nonumber
\]
\[
= [g|_{[0,a_1]} \cdot p_1, \ldots, [p_{m-1} \cdot g|_{[a_{m-1},a_m + \frac{1}{N}]} \cdot p_m \cdot q \cdot g|_{[a_m,a_{m+1}]} \cdot p_{m+1}, \ldots] \nonumber
\]
\[
\text{since } g|_{[a_m, a_{m+\frac{1}{N}}]} = g|_{[a_m, a_{m+\frac{1}{N}}]} \cdot q \text{ and } g|_{[a_m, a_{m+\frac{1}{N}}]} \approx q \cdot g|_{[a_m, a_{m+\frac{1}{N}}]} \nonumber
\]
\[
= \text{definition of } \overline{\Psi}(g) \text{ using the coloring } \beta \text{ and basing } p_1, \ldots, p_m, p_{m+1} \cdot q \cdot p_{m+1}, \ldots, p_{k-1}. \nonumber
\]

(We refer to Figure 387 for an illustration of the proof.) This concludes the proof of (b).

\[
\text{Figure 387}
\]

It remains to prove (c). First suppose that instead of dividing \([0, 1]\) into \( N \) intervals we divide it into \( m \cdot N \) intervals for some \( m \in \mathbb{N} \). A coloring for the subdivision into \( N \) subintervals then also gives rise to a coloring into \( m \cdot N \) subintervals, and it follows immediately from the definitions that we end up with the same element of \( A \ast B \). Now if had chosen a different \( N' \) instead, then we can replace \( N \) and \( N' \) by \( N \cdot N' \) and by the argument we just made we obtain the same element of \( A \ast B \). This concludes the proof of (c). Summarizing, we are now done with the proof of the claim.

We turn to step (2) of the above program. We need to prove the following claim.

**Claim.** If \( g, g': [0, 1] \rightarrow X \) are two path-homotopic loops in \((X, x_0)\), then \( \overline{\Psi}(g) = \overline{\Psi}(g') \).

\[\text{In fact the only case which requires a slightly modified argument is that the coloring to the left and right are the same, i.e. either both are blue or both are green. We leave it to the reader to perform that argument.}\]
Let \( g, g' : [0, 1] \to X \) be two path-homotopic loops in \((X, x_0)\). We pick a path-homotopy

\[
H : [0, 1] \times [0, 1] \to X \\
\quad (t, s) \mapsto H^s(t).
\]

from the loop \( g \) to the loop \( g' \). We apply Corollary 2.76 to the map \( H : [0, 1] \times [0, 1] \to X \) and the open cover \( X = U \cup V \). We obtain an \( N \in \mathbb{N} \) such that for every choice of \( i, j \in \{0, \frac{1}{N}, \ldots, 1 - \frac{1}{N}\} \) the image of the square \([i, i + \frac{1}{N}] \times [j, j + \frac{1}{N}]\) under the map \( H \) lies in \( U \) or in \( V \). Given \( j \in \{0, \frac{1}{N}, \ldots, 1\} \) we now define

\[
g(j) : [0, 1] \to X \\
\quad t \mapsto H^j(t)
\]

Note that each \( g(j) \) is a loop in \( x_0 \) and that \( g(0) = g \) and \( g(1) = g' \). Therefore it suffices to show that for any \( j \in \{0, \frac{1}{N}, \ldots, 1 - \frac{1}{N}\} \) we have \( \overline{\Psi}(g(j)) = \overline{\Psi}(g(j + \frac{1}{N})) \). So let \( j \in \{0, \frac{1}{N}, \ldots, 1 - \frac{1}{N}\} \).

As above we say that a subset of \([0, 1] \times [0, 1]\) can be colored green if the image of the subset under the map \( H \) lies in \( U \) and we say the subset can be colored blue if the image lies in \( V \). We pick a map \( \alpha : \{0, \frac{1}{N}, \ldots, 1 - \frac{1}{N}\} \to \{\text{blue, green}\} \) such that for each \( i \) the value \( \alpha(i) \) is a color with which the square \([i, i + \frac{1}{N}] \times [\frac{j}{N}, \frac{j+1}{N}]\) can be colored. Note that \( \alpha \) also defines a coloring for the loops \( g(j) \) and \( g(j + \frac{1}{N}) \).

We define \( 0 = a_0 < a_1 \ldots < a_k = 1 \) as above for the coloring \( \alpha \). Furthermore we pick a basing \( p_i, i = 1, \ldots, k - 1 \) for the loop \( g(j) \). For \( i = 0, \ldots, k \) we write \( q_i = H^{[j, j + \frac{1}{N}]}|_{a_i} \). Put differently, \( q_j \) connects a point on the loop \( g(j) \) to the corresponding point on the loop \( g(j + \frac{1}{N}) \).

Now we have

\[
\overline{\Psi}(g(j)) = \overline{\Psi}(g(j)) \text{ defined using the coloring } \alpha \text{ and the basing } p_1, \ldots, p_{k-1} \\
= \left[ \cdots \left[ p_m \ast H^j|_{[a_m, a_{m+1}]} \ast \overline{p}_{m+1} \ast \cdots \right] = g(j)|_{[a_m, a_{m+1}]} \right] \\
= \left[ \cdots \left[ p_m \ast q_m \ast H^j|_{[a_m, a_{m+1}]} \ast \overline{q}_{m+1} \ast \overline{p}_{m+1} \ast \cdots \right] \\
\quad \uparrow \text{ since each } q_m \ast \overline{q}_m \text{ is null-homotopic} \\
= \left[ \cdots \left[ p_m \ast q_m \ast H^{j + \frac{1}{N}}|_{[a_m, a_{m+1}]} \ast \overline{q}_{m+1} \ast \overline{p}_{m+1} \ast \cdots \right] = g(j + \frac{1}{N})|_{[a_m, a_{m+1}]} \right] \\
\quad \downarrow \text{ since } H \text{ restricts to path-homotopies from } \overline{q}_m \ast H^j|_{[a_m, a_{m+1}]} \ast q_{m+1} \\
\text{ to } H^{j + \frac{1}{N}}|_{[a_m, a_{m+1}]} \text{ for } m = 0, \ldots, k - 1 \\
= \overline{\Psi}(g(j + \frac{1}{N})) \text{ defined using } \alpha \text{ and the basing } p_1 \ast q_1, \ldots, p_{k-1} \ast q_{k-1}.
\]

This last part of the proof is illustrated in Figure 388. This concludes the proof of the claim and thus of part (2) of our three step program.

Summarizing we now showed that the map \( \overline{\Psi} \) descends to a well-defined map

\[
\Psi : \pi_1(X, x_0) \to A \ast B \\
\quad [g] \mapsto \left[ \overline{\Psi}(g) \right].
\]

It remains to prove the following claim.
Claim. We have $\Psi \circ \Phi = \text{id}_{A \ast B}$.

So let $[y_1] \cdots [y_k] \in A \ast B$ where $y_1, \ldots, y_k$ are loops in $(U, x_0)$ and $(V, x_0)$. Then

\[
\begin{align*}
(\Psi \circ \Phi)([y_1] \cdots [y_k]) &= \Psi([y_1 \ast \cdots \ast y_k]) = [\Psi(y_1 \ast \cdots \ast y_k)] = [y_1 \ast \cdots \ast y_k] \\
&= [y_1] \cdots [y_k].
\end{align*}
\]

by definition of $\Psi$.

This concludes the proof of the claim and thus also the proof of the Seifert–van Kampen Theorem \textbf{20.2}.

\section*{20.3. More examples: surfaces and the connected sum of smooth manifolds.}

Given $g \in \mathbb{N}_0$ we denote by $\Sigma_g$ the surface of genus $g$. In this section we first want to prove the following proposition.

\textbf{Proposition 20.8}. For $g \neq h$ the surface $\Sigma_g$ of genus $g$ is not homeomorphic to the surface $\Sigma_h$ of genus $h$.

As on several earlier occasions we want to prove this result by considering what happens if we remove a point from the topological spaces.

\textbf{Lemma 20.9}. Let $g \in \mathbb{N}_0$. We denote by $\Sigma_g$ the surface of genus $g$.

1. For any point $P$ the complement $\Sigma_g \setminus \{P\}$ is homotopy equivalent to the wedge of $2g$ circles. In particular

\[
\pi_1(\Sigma_g \setminus \{P\}) \cong \langle x_1, y_1, \ldots, x_g, y_g \rangle.
\]

2. Let $f : B^2 \to \Sigma_g$ be a smooth embedding. The complement $\Sigma_g \setminus f(B^2)$ is homotopy equivalent to the wedge of $2g$ circles. Furthermore, if $Q \in f(S^1)$ is a point, then there exists an isomorphism

\[
\pi_1(\Sigma_g \setminus f(B^2), Q) \cong \langle x_1, y_1, \ldots, x_g, y_g \rangle
given by

\[
[f : S^1 \to \Sigma_g \setminus f(B^2)] \mapsto [x_1, y_1] \cdots [x_g, y_g].
\]
Proof of Lemma 20.9. We prove the lemma for the surface $\Sigma$ of genus 2. The proof for $g \geq 3$ is almost identical. So let $\Sigma = E_8/\sim$ as sketched in Figure 390.

(1) We denote by $O$ the origin in $E_8 \subset \mathbb{C}$. We first show that $\Sigma \setminus \{O\}$ is homotopy equivalent to the wedge of 4 circles.

Claim. There exists a deformation retraction from $\Sigma \setminus \{O\} = (E_8 \setminus \{O\})/\sim$ to the subset $\partial E_8/\sim$.

First we consider the map

$$r: E_8 \setminus \{O\} \to \partial E_8$$

$$re^{i\varphi} \mapsto \text{unique point } se^{i\varphi} \text{ on } \partial E_8.$$

This map “projects points radially outward towards the boundary”. The deformation retraction is now given by “pushing outward radially”, i.e. it is given by the map

$$((E_8 \setminus \{O\})/\sim) \times [0, 1] \mapsto (E_8 \setminus \{O\})/\sim$$

$$([P], t) \mapsto [P \cdot (1 - t) + r(P) \cdot t].$$

Claim. The space $\partial E_8/\sim$ is homeomorphic to the wedge of 4 circles.

A homeomorphism is given by sending the point on $\partial E_8/\sim$ that corresponds to the vertices to the common point of the four circles, and by sending the edges that get identified to the same circle. We refer to Figure 391 for an illustration. We leave it to the reader to write down the proof in detail.

\[\text{Note that this map cannot be extended continuously to } O.\]

\[\text{Here we use polar coordinates, i.e. } r, s \text{ are positive real numbers.}\]
The two claims put together show that $\Sigma \setminus \{O\}$ is homotopy equivalent to the wedge of 4 circles. Now we obtain that
\[
\pi_1(\Sigma_2 \setminus \{P\}) \cong \pi_1(\text{wedge of 4 circles}) \cong \langle x_1, y_1, x_2, y_2 \rangle.
\]

Now let $P$ be some other point on $\Sigma$. By Proposition 8.29 there exists a homeomorphism $\Phi: \Sigma \to \Sigma$ with $\Phi(P) = O$. This shows that $\Sigma \setminus \{P\}$ is homeomorphic to $\Sigma \setminus \{O\}$. We can thus appeal to the above calculation to get the desired result.

(2) The proof of this statement is very similar to the proof of the first statement. First remove an open disk centered at $O$ and we perform almost the same calculation as above. One easily sees that the boundary curve corresponds to the product of commutators. It follows from Theorem 8.36 that the same calculation also works for any other disk. We leave the details to the reader. $\blacksquare$

Now we can turn to the proof of Proposition 20.8.

Proof of Proposition 20.8 Let $S$ and $T$ be two surfaces of genus $g$ and $h$. Suppose that there exists a homeomorphism $f: S \to T$. Pick a point $P \in S$. We write $Q = f(P)$. The homeomorphism $f$ restricts to a homeomorphism $f: S \setminus \{P\} \to T \setminus \{Q\}$. It now follows that
\[
\langle x_1, \ldots, x_{2g} \rangle \cong \pi_1(S \setminus \{P\}) \xrightarrow{\cong f_*} \pi_1(T \setminus \{Q\}) \cong \langle y_1, \ldots, y_{2h} \rangle.
\]

We obtain from Lemma 19.16 that $g = h$. $\blacksquare$

For many applications the following theorem, which is a variation on the Seifert–van Kampen Theorem 20.2 is very useful.

Theorem 20.10. (Seifert–van Kampen Theorem for topological manifolds) Let $M$ be an $m$-dimensional topological manifold and let $R, S \subset M$ be two $m$-dimensional submanifolds such that the following hold:

1. $M = R \cup S$,
2. $R \cap S$ is a component of $\partial R$ and it is a component of $\partial S$,
3. $R \cap S$ is non-empty and simply connected,

Note that here we use Proposition 6.21 which says that $\Sigma$ is a smooth manifold with empty boundary.
(4) \( R \) and \( S \) are closed subsets of \( M \). (Note that by Lemma 2.17 (2) this condition is satisfied if \( R \) and \( S \) are compact.)

Then for any base point \( x_0 \in R \cap S \) the inclusion induced map

\[
\pi_1(R, x_0) \ast \pi_1(S, x_0) \to \pi_1(M, x_0)
\]

is an isomorphism.

We will of course prove Theorem 20.10 by reducing it to Theorem 20.2. As we will see, the proof is very similar to the proof of Proposition 20.3 where we determined the fundamental group of a wedge of two spaces.

The proof of Theorem 20.10 relies on the following lemma which we will use on several occasions.

**Lemma 20.11.** \((*)\) Let \( X \) be a topological space. Furthermore let \( A \) and \( B \) be two subsets with \( X = A \cup B \). If \( A \cap B \) is a deformation retract of \( B \) and if \( A \) and \( B \) are closed subsets of \( X \), then \( A \) is a deformation retract of \( X \).

![Figure 392](https://example.com/figure392.png)

**Figure 392.** Illustration of Lemma 20.11

**Proof \((*)\).** Lemma 20.11 can also be viewed as a consequence of Lemma 3.45 and the slightly scary Lemma 18.23. Since our situation is fairly straightforward we also give a direct, fairly elementary proof.

We pick a deformation retraction \( F : B \times [0, 1] \to B \) from \( B \) to \( A \cap B \). We consider the map

\[
G : X \times [0, 1] \to X
\]

\[(x, t) \mapsto \begin{cases} x, & \text{if } x \in A, \\ F(x, t), & \text{if } x \in B. \end{cases}\]

Since \( A \) and \( B \) are closed subsets of \( X \) we obtain from Lemma 3.10 that \( G \) is continuous. It is now clear that \( G \) is the desired deformation retraction from \( X \) to \( A \).

**Remark.** On two occasions we are going to struggle a lit bit to verify the hypothesis of Lemma 20.11 that \( A \) and \( B \) need to be closed. Thus it is good to remind ourselves of the fact that hypothesis are usually added not to vex the reader but since they are necessary. For example, let us consider the situation shown in Figure 393. Here \( A \cap B \) is a deformation retract of \( B \), but it should be pretty clear that \( A \) is not a deformation retract of \( A \cup B = S^1 \).

![Figure 393](https://example.com/figure393.png)

**Figure 393**
Proof of Theorem 20.10 (\textit{*}). Let \( M \) be an \( m \)-dimensional topological manifold and let \( R, S \subset M \) be two \( m \)-dimensional submanifolds such that the following hold:

1. \( M = R \cup S \),
2. \( R \cap S \) is a union of components of \( \partial R \) and it is a union of components of \( \partial S \),
3. \( R \cap S \) is simply connected,
4. \( R \) and \( S \) are closed subsets of \( M \).

We pick a base point \( x_0 \in R \cap S \). Furthermore we pick maps \( f: [0, 1] \times \partial R \to R \) and \( g: [0, 1] \times \partial S \to S \) that are provided by the Collar Neighborhood Theorem 8.12.\textsuperscript{360} It follows from (2) that we can set

\[
U := R \cup \left[0, 1\right) \times g\left([R \cap S]\right) \quad \text{and} \quad V := S \cup \left[0, 1\right) \times f\left([R \cap S]\right).
\]

\[
U = R \cup g\left([0, 1) \times \partial S\right) \quad \text{and} \quad V = S \cup f\left([0, 1) \times \partial R\right).
\]

\textbf{Figure 394. Illustration of the proof of Theorem 20.10.}

We consider the following diagram

\[
\begin{array}{ccc}
\pi_1(R, x_0) \times \pi_1(S, x_0) & \rightarrow & \pi_1(M, x_0) \\
\downarrow & & \downarrow \\
\pi_1(U, x_0) \times \pi_1(V, x_0) & \rightarrow & \pi_1(M, x_0).
\end{array}
\]

The following steps are similar to the ones we performed in the proof of Proposition 20.3.

1. Since the vertical maps are induced by inclusions we see that the diagram commutes.
2. We claim that \( U \) is an open subset of \( M = R \cup S \). Since \( R \) and \( S \) are by our hypothesis (4) closed subsets of \( M \) we obtain from Lemma 2.6 (2a) it suffices to show that \( U \cap R \) is open in \( R \) and that \( U \cap S \) is open in \( S \). Evidently \( U \cap R = R \) is open in \( R \). Furthermore, \( U \cap S = g\left([0, 1] \times (R \cap S)\right) \) is an open subset of \( S \) by (2) and Lemma 8.11.
3. We want to use Lemma 20.11 to show that \( R \) is a deformation retract of \( U \). We need to verify that the hypotheses of Lemma 20.11 are satisfied, i.e. we need to show that \( R \) and \( g([0, 1) \times (R \cap S)) \) are closed subsets of \( U \). By our hypothesis \( R \) and \( S \) are closed subsets of \( M \). It follows from Lemma 2.4 (2) that \( R = R \cap U \) and \( g([0, 1) \times (R \cap S)) = S \cap U \) are closed subsets of \( U \).
4. The obvious analogues of (2) and (3) hold for \( V \) and \( S \).

\textsuperscript{360}Recall that being simply connected entails being non-empty, hence such a point exists.

\textsuperscript{361}If we are dealing with a smooth manifold we can also use the Collar Neighborhood Theorem 8.12.
(5) We obtain from (2), (3), (4) and Proposition 18.16 (2) that the vertical map on the left is an isomorphism.

(6) Similar to (3) one can show that $R \cap S$ is a deformation retract of $U \cap V$. It follows from (3), Lemma 18.14 and Proposition 18.16 (2) that $U \cap V$ is simply connected.

(7) It follows from the Seifert–van Kampen Theorem 20.2 that the bottom horizontal map of the above commutative diagram is an isomorphism.

(8) Since the vertical maps are isomorphisms we see that the top horizontal map is also an isomorphism. ■

We conclude this section by considering the connected sum of two smooth manifolds of dimension $\geq 3$. More precisely, we have the following proposition:

**Proposition 20.12.** Let $n \geq 3$ and let $M$ and $M'$ be two oriented connected non-empty $n$-dimensional smooth manifolds. Then

$$\pi_1(M \# M') \cong \pi_1(M) \ast \pi_1(M').$$

**Examples.**

(1) Let $p, q$ be two coprime integers and let $r, s$ be another two coprime integers. We can then consider the lens spaces $L(p, q)$ and $L(r, s)$. It follows from Proposition 20.12 and Corollary 16.18 that

$$\pi_1(L(p, q) \# L(r, s)) \cong \mathbb{Z}_p \ast \mathbb{Z}_r.$$  

It follows for example from this calculation of fundamental groups, from Lemma 19.20 and from the Grushko Decomposition Theorem 19.21 that the two topological spaces $L(3, 1) \# L(35, 1)$ and $L(5, 1) \# L(21, 1)$ are not homeomorphic.

(2) Let $n \geq 3$ and let $M$ and $N$ be two oriented connected $n$-dimensional smooth manifolds. We denote by $-N$ the same smooth manifold as $N$ but with the opposite orientation. It follows from Proposition 20.12 that $\pi_1(M \# N) \cong \pi_1(M \# (-N))$.

**Proof of Proposition 20.12.** Let $M$ and $M'$ be two oriented connected non-empty $n$-dimensional smooth manifolds and let $\varphi : \overline{B}^n \to M$ and $\varphi' : \overline{B}^n \to M'$ be two smooth embeddings where $\varphi$ is orientation-preserving and $\varphi'$ is orientation-reversing. Recall that the connected sum of $M$ and $M'$ is defined as

$$M \# M' := \left( (M \setminus \varphi(B^n)) \sqcup (M' \setminus \varphi'(B^n)) \right) / \varphi(P) = \varphi'(P) \text{ for } P \in S^{n-1}.$$ 

We pick a base point $x_0$ that lies in the intersection of the images of $X$ and $X'$ in $M \# M'$.

**Claim.** The inclusion induced maps $\pi_1(X, x_0) \to \pi_1(M, x_0)$ and $\pi_1(X', x_0) \to \pi_1(M', x_0)$ are isomorphisms.

We show that the inclusion induced map $\pi_1(X, x_0) \to \pi_1(M, x_0)$ is an isomorphism. We write $Y = \varphi(\overline{B}^n)$. It follows from Proposition 8.1 that $X$ and $Y$ are $n$-dimensional

---

Note that by Proposition 8.35 (3) we know that $M \# M'$ is also connected, thus we do not need to worry about base points.
submanifolds of $M$. Note that $X \cup Y = M$ and that $X \cap Y = \partial Y \cong S^{n-1}$. Since $n \geq 3$ we obtain from Proposition [14.14] that $X \cap Y$ is simply connected. We obtain that

$$
\pi_1(X, x_0) \xrightarrow{\cong} \pi_1(X, x_0) \ast \pi_1(B^n, x_0) \xrightarrow{\cong} \pi_1(M, x_0).
$$

Since $\pi_1(B^n, x_0) = \{e\}$ we obtain from Proposition 14.14 that $X \cap Y$ is simply connected. We obtain that

$$
\pi_1(X, x_0) \ast \pi_1(X', x_0) \xrightarrow{\cong} \pi_1(M, x_0) \ast \pi_1(M', x_0).
$$

Since the horizontal maps are induced by the inclusion maps we see that the inclusion induced map

$$
\pi_1(X, x_0) \to \pi_1(M, x_0)
$$

is an isomorphism. The same way we can show that the inclusion induced map

$$
\pi_1(X', x_0) \to \pi_1(M', x_0)
$$

is an isomorphism.

Now we see that

$$
\pi_1(M \# M, x_0) \xrightarrow{\cong} \pi_1(X, x_0) \ast \pi_1(X', x_0) \xrightarrow{\cong} \pi_1(M, x_0) \ast \pi_1(M', x_0).
$$

by Theorem 20.10 since above claim $X \cap X' \cong S^{n-1}$ is simply connected 363.

Remark. We cannot apply the Seifert–van Kampen Theorem 20.2 to the connected sum of two surfaces, since in this case the fundamental group of the overlap $R \cap R'$ in the proof of Proposition 20.12 is not simply connected. In particular we cannot use this approach to determine the fundamental group of the surface of genus 2, which by Figure 220 is the connected sum of two tori. Our next goal is to formulate and prove a generalization of the Seifert–van Kampen Theorem 20.2 which will allow us to determine the fundamental group of the surface of genus $g$ for $g \geq 2$.

Exercises for Chapter 20

Exercise 20.1. We consider $X = \mathbb{C} \setminus \{1/n \mid n \in \mathbb{N}\}$. Show that the point $x = 0$ is not good, i.e. show that there does not exist an open neighborhood $U$ of $x = 0$ such that $x = 0$ is a deformation retract of $U$.

Exercise 20.2.

(1) Let $X$ be a path-connected topological space and let $x_0 \in X$. Furthermore let $X_k, k \in \mathbb{N}$ be a sequence of subsets of $X$ such that the following hold:

(a) each $X_k$ is open,

(b) each $X_k$ is simply connected,

(c) the sequence $X_k$ is nested, i.e. for each $k$ we have $X_k \subset X_{k+1}$,

(d) we have $\bigcup_{k \in \mathbb{N}} X_k = X$.

Show that $\pi_1(X, x_0) = 0$.

Hint. Use Lemma 2.41

(2) Does the conclusion of (1) also hold if the sets $X_k$ are not open?

Exercise 20.3. Let $M$ be a topological manifold of dimension $n \geq 3$. Let $P$ be a point and let $x_0 \in M \setminus \{P\}$ be a base point. Show that the inclusion induced map

$$
\pi_1(M \setminus \{P\}, x_0) \to \pi_1(M, x_0)
$$

363 Here the directions of the arrow indicate in which direction the obvious inclusion induced maps point.
Exercise 20.4.

(a) How can one hang a painting with two nails provided, such that if one removes either of the two nails, the painting falls down?
(b) What is a solution to (a) if we use three nails instead of two nails?

*Hint.* What does this have to do with free groups?

![Illustration of Exercise 20.4](image)

**Figure 395.** Illustration of Exercise 20.4

Exercise 20.5. Show that condition (4) in the statement of the Seifert–van Kampen Theorem 20.10 for smooth manifolds cannot be dropped. More precisely, give an example of an $m$-dimensional smooth manifold and $m$-dimensional submanifolds $R$ and $S$ such that conditions (1), (2) and (3) are satisfied, but such that $\pi_1(R, x_0) \ast \pi_1(S, x_0)$ is not isomorphic to $\pi_1(M, x_0)$.

*Hint.* The dimension $m$ does not have to be taken particularly large.

Exercise 20.6. We consider the two topological manifolds $X$ and $Y$ that are shown in Figure 396. Show that $X$ and $Y$ are not homeomorphic.

*Remark.* As a smooth manifold $X$ is orientable and $Y$ is non-orientable. But as of right now we do not know whether orientability is preserved under homeomorphisms.

*Hint.* You could use Proposition 18.18 and consider the interaction between the topological manifolds and their boundaries.

![Illustration of Exercise 20.6](image)

**Figure 396.** Illustration of Exercise 20.6

Exercise 20.7. In the proof of Proposition 20.7, given on page 610 show that the map

$$\ast i_k : \ast \pi_1(A_k) \rightarrow \pi_1 \left( \bigvee_{k \in K} A_k \right)$$

is a monomorphism.

*Hint.* Consider the commutative diagram shown on page 611.

Exercise 20.8. Let $\Sigma$ be the 2-dimensional smooth manifold that is shown in Figure 397. We denote by $C$ the boundary of $\Sigma$. 
(a) What is the homeomorphism type of the topological space that we obtain from gluing a disk \( \overline{B}^2 \) to \( \Sigma \) along the boundary \( C \)?
(b) Is \( C \) a retract of \( \Sigma \)?

Exercise 20.9.
(a) Let \( n \geq 3 \) and furthermore let \( K \subset \mathbb{R}^n \) be a compact subset. We view \( K \) also as a subset of \( S^n = \mathbb{R}^n \cup \{ \infty \} \). Let \( x_0 \in \mathbb{R}^n \setminus K \). Show that the inclusion induced map \( \pi_1(\mathbb{R}^n \setminus K, x_0) \to \pi_1(S^n \setminus K, x_0) \) is an isomorphism.
(b) Does the conclusion of (a) also hold for \( n = 2 \)?
(c) Does the conclusion of (c) also hold for non-compact subsets of \( \mathbb{R}^n \)?

Exercise 20.10. We consider the two topological spaces
\[
X = \mathbb{R}^2 \setminus \{ (\frac{1}{n}, 0) \mid n \in \mathbb{N} \} \quad \text{and} \quad Y = \mathbb{R}^2 \setminus \{ (\frac{1}{n}, y) \mid n \in \mathbb{N}, y \in [-1, 1] \}.
\]
We write \( x_0 = (0, 0) \). We refer to Figure 398 for an illustration.
(a) Show that \( \pi_1(X, x_0) \) is uncountable.

\textit{Hint.} For \( n \in \mathbb{N} \) we write \( Z_n := \mathbb{R}^2 \setminus \{ \frac{1}{n}, 0 \} \) and we denote by \( f_n : X \to Z_n \) the inclusion map. Use the induced maps \( f_n \circ \pi_1(X, x_0) \to \pi_1(Z, x_0) \cong \mathbb{Z} \) to find a homomorphism from \( \pi_1(X, x_0) \) to a group such that the image is uncountable.
(b) Show that \( \pi_1(Y, x_0) \) is countable.

\textit{Hint.} Use Exercise 2.43 to find a monomorphism from \( \pi_1(Y, x_0) \) into a countable group.

Exercise 20.11. Show that given any \( k \in \mathbb{N} \) and given any \( n \geq 3 \) there exists a closed orientable connected \( n \)-dimensional smooth manifold \( M \) such that \( \pi_1(M) \cong \langle x_1, \ldots, x_k \rangle \).

Exercise 20.12. We consider the wedge \( S^1 \vee S^1 \) of two circles and we denote by \( * \) the wedge point. We consider the map \( f : S^1 \vee S^1 \to S^1 \vee S^1 \) that is shown in Figure 399.
(a) Show that \( f \) is a homotopy equivalence.
(b) Show that every homeomorphism of \( S^1 \vee S^1 \) preserves the wedge point \( * \).
(c) Determine
\[ \{ \varphi \in \text{Aut}(\pi_1(S^1 \vee S^1, *)) \mid \text{there exists a homeomorphism } g \text{ with } \varphi = g_* \}. \]

(d) Show that \( f \) is not homotopic to a self-homeomorphism of \( S^1 \vee S^1 \).

Remark. In Proposition ?? we will show that there exist self-homotopy equivalences of smooth manifolds that are not homotopic to homeomorphisms.

\[ S^1 \vee S^1 \xrightarrow{f} \]

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure399.png}
\caption{Illustration for Exercise 20.12}
\end{figure}
21. Presentations of groups and amalgamated products

We have now made some progress, for example we have shown that surfaces of different genus are not homeomorphic. But this proof is perhaps slightly unsatisfactory in so far as we used the trick of removing a point, instead of dealing directly with the fundamental groups of surfaces.

In the next section we will cover the generalized Seifert–van Kampen Theorem. It will allow us to compute many more fundamental groups. In particular we will determine the fundamental groups of surfaces and knot complements.

Before we can state the generalized Seifert–van Kampen Theorem we need to introduce more concepts from group theory. We will do so in this chapter.

21.1. Basic definitions in group theory. We recall a few basic definitions from group theory.

**Definition.** Let $G$ be a group.

(1) A subgroup $H$ is called normal if for every $g \in G$ we have $g^{-1}Hg = H$. If $H \subseteq G$ is normal, then we often write $H \triangleleft G$. If $\{H_i\}_{i \in I}$ is a family of normal subgroups of $G$, then it is straightforward to see that the intersection $\bigcap_{i \in I} H_i$ is again a normal subgroup of $G$.

(2) Let $H$ be a subgroup of $G$. The subgroup $H$ defines an equivalence relation on $G$ by defining $g \sim \tilde{g}$ if there exists an $h \in H$ with $gh = \tilde{g}$. Put differently, we have $g \sim \tilde{g}$ if $\tilde{g}^{-1}g \in H$. (Note that the equivalence classes are precisely the sets of the form $gH = \{gh \mid h \in H\}$ for some $g \in G$.) We denote the set of equivalence classes by $G/H$.

**Remark.** Let $H$ be a normal subgroup of $G$.

(1) For any $h \in H$ and $a, b \in G$ we have

$$abhH = ab \cdot b^{-1}h H = abH.$$  \hspace{1cm} \text{in $H$ since $H$ is normal}

(2) If $aH = bH$, then for any $c, d \in G$ we have

$$cdH = cb(b^{-1}a)dH = cbdH.$$  \hspace{1cm} \text{above remark (1)}

Now we will see that the group structure on $G$ descends to a group structure on $G/H$. More precisely, given $aH$ and $bH$ we set

$$aH \cdot bH := abH.$$  

It follows immediately from the above remark (1) that this definition does not depend on the representatives $a$ and $b$. It is now straightforward to see that this defines indeed a group structure on $G/H$. The following lemma plays the same role as Lemma 3.22 does for topological spaces.
Lemma 21.1. Let $G$ be a group and let $H$ be a normal subgroup. Let $\varphi : G \to \Gamma$ be a group homomorphism with the property that $H \subseteq \ker(\varphi)$. Then there exists a unique homomorphism $\psi : G/H \to \Gamma$ such that the following diagram commutes

$$
\begin{array}{ccc}
G & \longrightarrow & G/H \\
\varphi \downarrow & & \downarrow \psi \\
\Gamma & & 
\end{array}
$$

Proof. For $gH \in G/H$ we put $\psi(gH) := \varphi(g)$. Since $H \subseteq \ker(\varphi)$ this definition is independent of the choice of the representatives $g$. It is straightforward to verify that $\psi$ is a homomorphism and that it is uniquely determined by the desired property. ■

21.2. Presentations of groups.

Definition. Let $G$ be a group and let $A \subseteq G$ be a subset. We define

$$
\text{subgroup of } G \text{ generated by } A := \langle A \rangle := \bigcap_{A \subseteq H \subseteq G} H,
$$

i.e. $\langle A \rangle$ is the intersection of all subgroups $H$ of $G$ which contain $A$. This is again a subgroup of $G$, namely the smallest subgroup of $G$ which contains $A$. Similarly we define

$$
\text{subgroup of } G \text{ normally generated by } A := \langle\langle A \rangle \rangle := \bigcap_{A \subseteq H \triangleleft G} H,
$$

i.e. $\langle\langle A \rangle \rangle$ is the intersection of all normal subgroups $H$ of $G$ which contain $A$. This is again a normal subgroup of $G$, namely the smallest normal subgroup of $G$ which contains $A$.

The following lemma follows immediately from the definitions and from the fact that in an abelian group every subgroup is normal.

Lemma 21.2. Let $G$ be a group and let $A \subseteq G$ be a subset.

(1) If $A$ is a subgroup, then $\langle A \rangle = A$.
(2) If $A$ is a normal subgroup, then $\langle\langle A \rangle \rangle = A$.
(3) If $G$ is abelian, then $\langle\langle A \rangle \rangle = \langle A \rangle$.
(4) For any $B \subseteq G$ with $A \subseteq B \subseteq \langle A \rangle$ we have $\langle B \rangle = \langle A \rangle$.
(5) Suppose that for each $a \in A$ we are given $g_a \in A$. Then $\langle\{g_aoa^{-1} \mid a \in A\} \rangle = \langle A \rangle$.

The following lemma gives a more explicit description of $\langle A \rangle$ and $\langle\langle A \rangle \rangle$.

Lemma 21.3. Let $G$ be a group and let $A \subseteq G$ be a subset.

(1) Then $\langle A \rangle$ equals the set of all elements of $G$ which can be written as products of elements in $A$ and their inverses, i.e.

$$
\langle A \rangle = \{a_1^{\epsilon_1} \cdots a_k^{\epsilon_k} \mid a_1, \ldots, a_k \in A \text{ and } \epsilon_1, \ldots, \epsilon_k \in \{-1, 1\}\}.
$$
The subset \( \langle A \rangle \) equals the set of all elements of \( G \) which can be written as products of conjugates of elements in \( A \) and their inverses, i.e.
\[
\langle A \rangle = \{ g_1 a_1^{\epsilon_1} g_1^{-1} \ldots g_k a_k^{\epsilon_k} g_k^{-1} | a_1, \ldots, a_k \in A, g_1, \ldots, g_k \in G \text{ and } \epsilon_1, \ldots, \epsilon_k \in \{-1, 1\} \}.
\]

Example. On page 501 we introduced a subgroup of the group \( H \) of all self-homeomorphisms of \( \mathbb{R}^2 \) that was generated by two given self-homeomorphisms \( A \) and \( B \). The lemma shows that the definition of “being generated” by a subset used on page 501 agrees with the above more formal definition.

Proof. We only prove the second statement. The proof of the first statement is very similar. So let \( G \) be a group and let \( A \subset G \) be a subset. The subgroup \( \langle A \rangle \) contains all elements of \( A \) and their inverses. The normal subgroup \( \langle A \rangle \) then contains also all elements of the form \( g a^\pm g^{-1}, g \in G, a \in A \). Since \( \langle A \rangle \) is a subgroup it is also closed under multiplication, i.e., it contains products of such elements. It follows that \( \langle A \rangle \) contains the right-hand side of (2). Conversely it is straightforward to see that the right-hand side is indeed a normal subgroup of \( G \) that contains \( A \), hence it is contained in the left-hand side of (2).

\[\text{Lemma 21.4. Let } G \text{ be a group and let } A \subset G \text{ be a subset. Let } \alpha: G \to \Gamma \text{ be a group homomorphism such that } \alpha(a) = e \in \Gamma \text{ for all } a \in A. \text{ Then there exists a unique group homomorphism } \beta: G/\langle A \rangle \to \Gamma \text{ such that the following diagram commutes:}
\]

\[
\begin{array}{ccc}
G & \longrightarrow & G/\langle A \rangle \\
\alpha \downarrow & & \downarrow \beta \\
& \Gamma. & \\
\end{array}
\]

Proof. Let \( G \) be a group and let \( A \subset G \) be a subset. Furthermore let \( \alpha: G \to \Gamma \) be a group homomorphism such that \( \alpha(a) = e \in \Gamma \) for all \( a \in A \). This means that \( A \subset \ker(\alpha) \). Since \( \ker(\alpha) \) is a normal subgroup it follows from the definition of \( \langle A \rangle \) that \( \langle A \rangle \subset \ker(\alpha) \). The proposition now follows immediately from Lemma 21.1.

The following definition will subsequently play an important role:

Definition. Let \( X \) be a set and let \( R \) be a subset of the free group \( \langle X \rangle \) generated by the set \( X \). We define
\[
\langle X \mid R \rangle := \langle X \rangle / \langle \langle R \rangle \rangle.
\]

If \( X = \{x_1, \ldots, x_k\} \) and \( R = \{r_1, \ldots, r_l\} \), then we use the convenient shorthand
\[
\langle x_1, \ldots, x_k \mid r_1, \ldots, r_l \rangle := \langle \{x_1, \ldots, x_k\} \mid \{r_1, \ldots, r_l\} \rangle.
\]

Examples.

\[\text{Why is the right-hand side normal?}\]
(1) For any \( k \in \mathbb{N}_0 \) we have
\[
\langle g \mid g^k \rangle = \langle g \rangle / \langle g^k \rangle = \langle g \rangle / \langle g^k \rangle \cong \mathbb{Z}_k.
\]
since \( \langle g \rangle \) is abelian it follows from Lemma 21.2 that \( \langle g^k \rangle = \langle g \rangle \).

(2) The group \( \langle x_1, \ldots, x_k \mid \rangle \) with \( R = \emptyset \) is just the free group on \( x_1, \ldots, x_k \).

Before we continue we formulate an elementary but useful lemma.

**Lemma 21.5.** Let \( \langle x_1, \ldots, x_k \mid r_1, \ldots, r_l \rangle \) be a presentation.

1. Given any \( a, b \in \langle x_1, \ldots, x_k \rangle \), given any \( i \in \{1, \ldots, l\} \) and given any \( c \in \{-1, 1\} \) we have
\[
a \cdot r_i^c \cdot b = a \cdot b \in \langle x_1, \ldots, x_k \mid r_1, \ldots, r_l \rangle.
\]

2. Let \( a, b \in \langle x_1, \ldots, x_k \rangle \) and \( c, d \in \langle x_1, \ldots, x_k \rangle \). If \( a = b \in \langle x_1, \ldots, x_k \mid r_1, \ldots, r_l \rangle \), then
\[
c \cdot a \cdot d = c \cdot b \cdot d \in \langle x_1, \ldots, x_k \mid r_1, \ldots, r_l \rangle.
\]

**Proof.** The first statement is just a special case of Remark (1) on page 626 and the second statement is just a special case of Remark (2) on page 626.

This lemma allows us to prove the following lemma.

**Lemma 21.6.**

1. There exists a unique homomorphism
\[
\beta : \pi = \langle x, y \rangle / \langle \langle x, y \rangle \rangle = \langle x, y \mid [x, y] \rangle \rightarrow \mathbb{Z}^2
\]
with \( \beta(x) = (1, 0) \) and \( \beta(y) = (0, 1) \). Furthermore this homomorphism is an isomorphism.

2. Let \( m \in \mathbb{N} \). There exists a unique isomorphism
\[
\beta : \langle x_1, \ldots, x_m \mid [x_i, x_j] = e \text{ for all } i, j \in \{1, \ldots, m\} \rangle \cong \mathbb{Z}^m
\]
which sends each \( x_i \) to the \( i \)-th standard basis vector \( e_i \) of \( \mathbb{Z}^m \).

**Proof.** By Lemma 19.14 there exists a unique homomorphism \( \alpha : \langle x, y \rangle \rightarrow \mathbb{Z}^2 \) which satisfies \( \alpha(x) = (1, 0) \) and \( \alpha(y) = (0, 1) \). Note that
\[
\alpha([x, y]) = \alpha(xy^{-1}y^{-1}) = \alpha(x) + \alpha(y) - \alpha(x) - \alpha(y) = 0.
\]
Thus by Lemma 21.4 there exists a unique group homomorphism
\[
\beta : \pi = \langle x, y \rangle / \langle \langle x, y \rangle \rangle = \langle x, y \mid [x, y] \rangle \rightarrow \mathbb{Z}^2
\]
with \( \beta(x) = (1, 0) \) and \( \beta(y) = (0, 1) \). It is clear that \( \beta \) is an epimorphism. Thus it remains to show that \( \alpha \) is a monomorphism. This follows immediately from the following claim.

**Claim.** Given any \( w \in \langle x, y \rangle \) there exist \( m, n \in \mathbb{Z} \) with \( w = x^my^n \in \langle x, y \mid [x, y] \rangle \).

First we note that we have the following equalities in \( \langle x, y \mid [x, y] \rangle \)
\[
yx = xyx^{-1}y^{-1} \cdot yx = xy \quad \text{and} \quad xy^{-1} = y^{-1} \cdot xy \cdot y^{-1} = y^{-1} \cdot xy \cdot y^{-1} = y^{-1}x.
\]

\[
\uparrow \text{Lemma 21.5(1)} \quad \text{and} \quad \uparrow \text{calculation on the left and Lemma 21.5(2)}
\]
Lemma 19.14 there exists a unique homomorphism \( \alpha \) since \( R \). This shows that \( \alpha \) is the identity map of powers of \( x \) and \( y \) can be reordered to equal a product of the \( x^n y^m \). For example in \( \pi \) we have the equality
\[
\begin{align*}
x^3 y^2 x^{-1} y &= x^3 y \cdot y x^{-1} y = x^3 y x^{-1} y \cdot y = x^3 \cdot x^{-1} y \cdot y^2 = x^2 y^2. \\
&\uparrow \quad \text{since } y x^{-1} = x^{-1} y \\
&\uparrow \quad \text{since } y x^{-1} = x^{-1} y
\end{align*}
\]
□

We consider one more example.

Example. We consider the following three self-homeomorphisms of \( \mathbb{R}^2 \):
\[
A: \mathbb{R}^2 \to \mathbb{R}^2 \quad \text{and} \quad B: \mathbb{R}^2 \to \mathbb{R}^2 \quad \text{and} \quad \tilde{A}: \mathbb{R}^2 \to \mathbb{R}^2
\]
\[
(s, t) \mapsto (s + 1, 1 - t) \quad \text{and} \quad (s, t) \mapsto (s, t + 1) \quad \text{and} \quad (s, t) \mapsto (s + 1, -t).
\]

We already know the first two maps from page 501. We denote by \( G \) the subgroup of all homeomorphisms of \( \mathbb{R}^2 \) that is generated by \( A \) and \( B \). We are interested in the group \( G \) since \( \mathbb{R}^2/G \) is the Klein bottle \( K \) and by Theorem 16.16 we have \( \pi_1(K) \cong G \).

Note that \( \tilde{A} = B^{-1} A \). Let \( X = \{x, y\} \) be the set that consists of two elements. By Lemma 19.14 there exists a unique homomorphism \( \alpha: \langle x, y \rangle \to G \) with \( \alpha(x) = \tilde{A} \) and \( \alpha(y) = B \). Now let \( R \) be the subset of \( \langle X \rangle = \langle x, y \rangle \) that consists of the single element \( y x y x^{-1} \). We want to consider \( \alpha(y x y x^{-1}) \in G \), which is by definition a map from \( \mathbb{R}^2 \) to \( \mathbb{R}^2 \).

For any point \( (s, t) \in \mathbb{R}^2 \) this map is given by
\[
\alpha(y x y x^{-1})(s, t) = B \tilde{A} B \tilde{A}^{-1}(s, t) = B \tilde{A} (s - 1, -t) = B \tilde{A} (s - 1, -t + 1) = B (s, t - 1) = (s, t).
\]
This shows that \( \alpha(y x y x^{-1}) \) is the identity map of \( \mathbb{R}^2 \), i.e. it is the trivial element in \( G \). It follows from Lemma 21.4 that \( \alpha \) descends to a homomorphism
\[
\beta: \langle x, y \rangle / \langle y x y x^{-1} \rangle = \langle x, y \mid y x y x^{-1} \rangle \to G.
\]
This homomorphism is an epimorphism, since the image of \( \beta \) is the group generated by \( \tilde{A} = B^{-1} A \) and \( B \), but this group is the same as the group generated by \( A \) and \( B \), i.e. the image of \( \beta \) is \( G \). Is the homomorphism \( \beta \) also a monomorphism? We will come back to this question later on page 657.

We continue with the following definitions.

Definition. (1) A presentation is a set \( X \) together with a subset \( R \subset \langle X \rangle \). We call the elements of \( X \) the generators and we call the elements of \( R \) the relations of the presentation.
(2) Let \( \pi \) be a group. A presentation for \( \pi \) is a presentation \( (X, R) \) together with an isomorphism
\[
\langle X \mid R \rangle \xrightarrow{\cong} \pi.
\]
Very often one just says \( \langle X \mid R \rangle \) is a presentation for \( \pi \) and the explicit isomorphism is suppressed from the notation.
(3) We say that a group \( \pi \) is finitely generated, if \( \pi \) admits a presentation with finitely many generators.
(4) We say a group $\pi$ is *finitely presented*, if $\pi$ admits a presentation with finitely many generators and finitely many relators.

Now we give some examples of finitely generated and finitely presented groups.

**Examples.**

(1) Every group admits a presentation. Indeed, let $\pi$ be a group. Then we set $X := \pi$, i.e. $X$ is the set of elements of $\pi$. By Lemma 19.14 there exists a unique homomorphism $\alpha: \langle X \rangle \to \pi$ with $\alpha(g) = g$ for all $g \in X = \pi$. We set $R := \ker(\alpha)$. Then $\langle X \mid R \rangle \cong \langle X \rangle / \langle \langle R \rangle \rangle$ by Lemma 21.2 since $R = \ker(\alpha)$ is a normal subgroup.

(2) We saw on page 592 that $\pi$ is a finitely generated group. But is it also finitely presented? (This statement is pretty obvious. The idea is that in a free group $\langle x_1, \ldots, x_k \rangle$ there are uncountably many infinite sequences of elements $\{r_1, r_2, \ldots\}$. The difficulty is to show that there exist uncountably many sequences that give raise to non-isomorphic groups.)

21.3. **Tietze transformations.**

**Definition.** Let $\pi$ be a group and let

$$\phi: \langle x_1, \ldots, x_k \mid r_1, \ldots, r_l \rangle \cong \pi$$

be a presentation. We obtain new presentations as follows:

(1) For any element $s$ of $\langle r_1, \ldots, r_l \rangle \subset \langle X \rangle$ we obtain the presentation

$$\langle x_1, \ldots, x_k \mid r_1, \ldots, r_l, s \rangle \cong \langle x_1, \ldots, x_k \mid r_1, \ldots, r_l \rangle \cong \pi$$

---

367 The relators are often also called relations.
368 This definition of a finitely generated group is equivalent to the one we gave on page 502. Why is that?
369 That statement is pretty obvious.
370 This statement is much less obvious. The idea is that in a free group $\langle x_1, \ldots, x_k \rangle$ there are uncountably many infinite sequences of elements $\{r_1, r_2, \ldots\}$. The difficulty is to show that there exist uncountably many sequences that give raise to non-isomorphic groups.
(2) For any \( x \neq x_1, \ldots, x_k \) and any two words \( s, t \) in \( x_1, \ldots, x_k \) we obtain the presentation:

\[
\langle x_1, \ldots, x_k, x \mid r_1, \ldots, r_l, s \cdot x \cdot t \rangle \rightarrow \langle x_1, \ldots, x_k \mid r_1, \ldots, r_l \rangle \overset{\phi}{\rightarrow} \pi.
\]

\[
x_i \mapsto x_i \quad x \mapsto s^{-1} \cdot t
\]

The above two methods, and their inverses, of obtaining new presentations out of a given one are called Tietze transformations.\(^{372}\)

The above Tietze transformations show that from a given finite presentation we can obtain infinitely many new finite presentations. This fact is not that surprising. What is much more interesting is the following theorem which was first proved by Heinrich Tietze [Tie1908] in 1908.

**Theorem 21.7. (Tietze Theorem)** Any two finite presentations for a given group are related by a finite sequence of Tietze transformations.

In the proof of the Tietze Theorem 21.7 we will need the following four pretty elementary preparatory lemmas.

**Lemma 21.8.** Let \( \theta : G \rightarrow H \) be a group homomorphism and let \( X \) be a generating set for \( G \). The subgroup of \( G \ast H \) that is generated by \( \{ g \cdot \theta(g^{-1}) \mid g \in G \} \) equals the subgroup of \( G \ast H \) that is normally generated by \( \{ x \cdot \theta(x^{-1}) \mid x \in X \} \).

**Proof of Lemma 21.8** We set \( N := \{ x \cdot \theta(x^{-1}) \mid x \in X \} \). We only need to show that given any \( g \in G \) we have \( g \cdot \theta(g^{-1}) \in \langle N \rangle \). This statement follows easily by induction on the length of \( g \) as a word in the generating set \( X \) and the observation that for \( x, y \in X \) we have the following equality:

\[
xy \cdot \theta((xy)^{-1}) = xy \cdot \theta(y^{-1}) \cdot \theta(x^{-1}) = \underbrace{x \cdot y \cdot \theta(y^{-1}) \cdot x^{-1}}_{\in N} \cdot \underbrace{x \cdot \theta(x^{-1})}_{\in N}.
\]

**Lemma 21.9.** Let \( G \) and \( H \) be two groups, let \( \theta : G \rightarrow H \) be an isomorphism and let \( \alpha : G \rightarrow \pi \) be an isomorphism. We consider the homomorphism

\[
\Psi : G \ast H \rightarrow \pi
\]

defined by \( \alpha \) on \( G \) and by \( \alpha \circ \theta^{-1} \) on \( H \). The kernel of the homomorphism \( \Psi \) is generated by \( \{ g \cdot \theta(g^{-1}) \mid g \in G \} \).

**Proof of Lemma 21.9** We set \( M := \{ g \cdot \theta(g^{-1}) \mid g \in G \} \). We need to show that the kernel of the homomorphism \( \Psi \) is generated by \( M \). Let \( g_1 \cdot h_1 \cdot \ldots \cdot g_k \cdot h_k \in \ker(\Psi) \subset G \ast H \), where we use self-explanatory notation.

If \( k = 1 \), then it follows from \( e = \Psi(g_1 \cdot h_1) = \alpha(g_1) \cdot \alpha(\theta^{-1}(g_1)) = \alpha(g_1 \cdot \theta^{-1}(g_1)) \) and the fact that \( \alpha \) and \( \theta \) are isomorphisms that \( g_1 \cdot h_1 = g_1 \cdot \theta(g_1^{-1}) \).

Now suppose that \( k > 1 \). If \( g_1 \neq e \), then we can write

\[
g_1 \cdot h_1 \cdot g_2 \cdot h_2 \cdot \ldots \cdot g_k \cdot h_k = \underbrace{g_1 \cdot \theta(g_1^{-1}) \cdot \theta(g_1)}_{\in M} \cdot \underbrace{h_1 \cdot g_2 \cdot h_2 \cdot \ldots \cdot g_k \cdot h_k}_{\in H}.
\]

372 The map to the left is an isomorphism, in fact an inverse is given by \( x_i \mapsto x_i \).
If $g_1 = e$, then we write

$$h_1 \cdot g_2 \cdot h_2 \cdot \cdots \cdot g_k \cdot h_k = \left( \theta^{-1}(h_1) \cdot \phi(\theta^{-1}(h_1))^{-1} \right) \cdot \left( \theta^{-1}(h_1) \cdot g_2 \cdot h_2 \cdot \cdots \cdot g_k \cdot h_k \right).$$

Iterating this procedure we obtain the desired statement.

**Lemma 21.10.** Let

$$\phi: \langle x_1, \ldots, x_k \mid r_1(x_1, \ldots, x_k), \ldots, r_l(x_1, \ldots, x_k) \rangle \to \pi$$

be a presentation. For pairwise different $y_1, \ldots, y_k$ the presentation

$$\langle y_1, \ldots, y_k \mid r_1(y_1, \ldots, y_k), \ldots, r_l(y_1, \ldots, y_k) \rangle \to \pi$$

$$y_i \mapsto \phi(x_i)$$

can be obtained from the original one by Tietze transformations.

**Proof of Lemma 21.10.** We consider the Tietze transformations

$$\langle x_1, \ldots, x_k \mid r_1(x_1, \ldots, x_k), \ldots, r_l(x_1, \ldots, x_k) \rangle \overset{(2)}{\longrightarrow} \langle x_1, \ldots, x_k, y_1 \mid r_1(x_1, \ldots, x_k), \ldots, y_1 \cdot x_1^{-1} \rangle$$

$$\langle x_1, \ldots, x_k, y_1 \mid r_1(x_1, \ldots, x_k), \ldots, y_1 \cdot x_1^{-1}, r_1(y_1, \ldots, x_k), \ldots \rangle$$

Iterating this process leads to the desired sequence of Tietze transformations.

**Lemma 21.11.** Let $\alpha: A \to B$ and $\beta: B \to C$ be group epimorphisms. Let $X \subset A$ be a subset such that $\ker(\alpha) = \langle \langle X \rangle \rangle$ and let $Y \subset B$ be a subset such that $\ker(\beta) = \langle \langle \alpha(Y) \rangle \rangle$. Then $\ker(\beta \circ \alpha: A \to C) = \langle \langle X \cup Y \rangle \rangle$.

**Proof of Lemma 21.11** It is clear that $X \cup Y \subset \ker(\beta \circ \alpha: A \to C)$. To prove the reverse inclusion let $g \in \ker(\beta \circ \alpha: A \to C)$. We have $\alpha(g) \in \ker(\beta) = \langle \langle \alpha(Y) \rangle \rangle$. Since $\alpha$ is an epimorphism the map $\alpha: \langle \langle Y \rangle \rangle \to \langle \langle \alpha(Y) \rangle \rangle$ is an epimorphism. Thus there exists an $h \in \langle \langle Y \rangle \rangle$ with $\alpha(g) = \alpha(h)$. But this implies that $g \cdot h^{-1} \in \ker(\alpha) = \langle \langle X \rangle \rangle$. It follows that $g \in \langle \langle X \cup Y \rangle \rangle$.

**Proof of the Tietze Theorem 21.7** Let $\pi$ be a group and let $\phi_1: \langle X_1 \mid R_1 \rangle \overset{\sim}{\longrightarrow} \pi$ and $\phi_2: \langle X_2 \mid R_2 \rangle \overset{\sim}{\longrightarrow} \pi$ be two finite presentations for $\pi$. We need to show that they are related by Tietze transformations. First note that it follows from Lemma 21.10 that by applying a sequence of Tietze transformations we can arrange that $X_1 \cap X_2 = \varnothing$.

We denote by $p_1: \langle X_1 \rangle \to \langle X_1 \mid R_1 \rangle$ and $p_2: \langle X_2 \rangle \to \langle X_2 \mid R_2 \rangle$ the obvious epimorphisms. We set $X := X_1 \cup X_2$. We consider the homomorphism

$$\Psi: \langle X_1 \rangle \ast \langle X_2 \rangle = \langle X \rangle \to \pi$$

that is induced by $\phi_1 \circ p_1$ on $\langle X_1 \rangle$ and $\phi_2 \circ p_2$ on $\langle X_2 \rangle$. 
Note that the restriction of $\Psi$ to $\langle X_2 \rangle$ is an epimorphism. Therefore we can pick for each $x \in X_1$ a $w_x \in \langle X_2 \rangle$ with $\Psi(x) = \Psi(w_x)$. We write $S_1 := \{x \cdot w_x^{-1} \mid x \in X_1\} \subset \langle X \rangle$. The same way we define $S_2 \subset \langle X \rangle$.

**Claim.** We have ker$(\Psi) = \langle\langle R_2 \cup S_1 \rangle\rangle$.

First note that it follows almost immediately from Lemmas 21.8, 21.9 and 21.11 that ker$(\Psi) = \langle\langle R_1 \cup R_2 \cup S_1 \rangle\rangle$. Thus it remains to show that $\langle\langle R_1 \cup R_2 \cup S_1 \rangle\rangle = \langle\langle R_2 \cup S_1 \rangle\rangle$. Put differently, given $r_1 \in R_1$ we need to show that $r_1 \in \langle\langle R_2 \cup S_1 \rangle\rangle$. Let $\theta: \langle\langle X_1 \rangle\rangle \to \langle\langle X_2 \rangle\rangle$ be the homomorphism that is given by $x \mapsto w_x$ for $x \in X_1$. Note that we have the following commutative diagram:

$$
\begin{array}{ccc}
\langle X_1 \rangle & \xrightarrow{\theta} & \langle X_2 \rangle \\
\downarrow{p_1} & & \downarrow{p_2} \\
\langle X_1 \mid R_1 \rangle & \cong & \langle X_2 \mid R_2 \rangle.
\end{array}
$$

In particular we have $(\phi_2 \circ p_2)(\theta(r_1)) = (\phi_1 \circ p_1)(r_1) = 1$. This implies that $\theta(r_1) \in \langle\langle R_2 \rangle\rangle$. On the other hand it follows from Lemma 21.8 that $r_1 \cdot \theta(r_1)^{-1} \in \langle\langle S_1 \rangle\rangle$. Thus we see that $r_1 = r_1 \cdot \theta(r_1)^{-1} \cdot \theta(r_1) \in \langle\langle S_1 \cup R_2 \rangle\rangle$.

After these preparations we turn to the actual proof of the theorem.

(a) First note that we can turn the presentation $\langle X_2 \mid R_2 \rangle$ into $\langle X \mid R_2 \cup S_1 \rangle$ by a sequence of Tietze transformations (2), where we add one by one the elements of $X_1$ and for each element of $X_1$ we add the corresponding relation in $S_1$.

(b) Note that $R_1 \cup S_2 \subset \ker(\Psi)$. By the claim this implies that $R_1 \cup S_2 \subset \langle\langle R_2 \cup S_1 \rangle\rangle$. In particular, using Tietze transformations (1) we can turn the presentation $\langle X \mid R_2 \cup S_1 \rangle$ into the presentation $\langle X \mid R_1 \cup S_2 \cup R_2 \cup S_1 \rangle$.

(c) By exactly the same reasoning as in (a) and (b) we can also turn the presentation $\langle X_1 \mid R_1 \rangle$ into the presentation $\langle X \mid R_1 \cup S_2 \cup R_2 \cup S_1 \rangle$ via a sequence of Tietze transformations.

Since $\langle X_1 \mid R_1 \rangle$ and $\langle X_2 \mid R_2 \rangle$ can be turned into precisely the same presentation using Tietze transformations, the two presentations are in fact related by Tietze transformations.

**Remark.** Alternative proofs of the Tietze Theorem 21.7 can be found in [Tie1908] and also [LS77] Proposition II.2.2 and [MKS76] Theorem 1.5.

The following lemma often works well in practice to show that two presentations correspond to isomorphic groups.

**Lemma 21.12.** Let $X = \{x_1, \ldots, x_k\}$ be a finite set and furthermore let $r = \{r_1, \ldots, r_l\}$ be a finite subset of $\langle X \rangle = \langle x_1, \ldots, x_k \rangle$. Suppose that we can write each $r_i(x_1, \ldots, x_k)$ as a word $s_i(x_1, \ldots, x_{k-1}, x_k \cdot w)$ where $w$ is a word in $x_1, \ldots, x_{k-1}$, then the homomorphism

$$
\langle x_1, \ldots, x_k \mid r_1, \ldots, r_l \rangle \to \langle x_1, \ldots, x_{k-1}, t \mid s_1, \ldots, s_l \rangle
$$

that is induced by $x_i \mapsto x_i$, $i = 1, \ldots, k - 1$, and $x_k \mapsto tw^{-1}$ is an isomorphism.
Definition. We refer to the isomorphism of Lemma 21.12 as the isomorphism given by the substitution $t = x_k \cdot w$.

Example. A picky reader might decide that the formulation of Lemma 21.12 is not completely precise. But the following example should make the meaning clear:

$$
\langle a, b \mid a^{-1}ba^{-1}bab^{-1} \rangle = \langle a, b \mid a^{-1}b \cdot a^{-1}b \cdot a \cdot (a^{-1}b)^{-1} \cdot a^{-1} \rangle.
$$

Proof. It follows from Lemma 21.13 that there exists in fact a unique homomorphism

$$
\langle x_1, \ldots, x_k \mid r_1, \ldots, r_l \rangle \rightarrow \langle x_1, \ldots, x_{k-1}, t \mid s_1, \ldots, s_t \rangle
$$

that has the property that $x_i \mapsto x_i$, $i = 1, \ldots, k - 1$ and that $x_k \mapsto tw^{-1}$. Furthermore, we have a map from the right to left by the reverse substitution $t \mapsto x_k \cdot w$. It is straightforward to verify that these homomorphisms are inverses of one another, hence both are isomorphisms.

As we will now see, finite presentations of groups are useful for finding group homomorphisms. To formulate the corresponding lemma we need the following definition.

Definition. Let $X = \{x_1, \ldots, x_k\}$ be a set and let $r \in \langle X \rangle$. Furthermore let $G$ be a group and let $g_1, \ldots, g_k$ be elements of $G$. We say that $g_1, \ldots, g_k$ satisfy the relation $r$ if the homomorphism $\langle x_1, \ldots, x_k \rangle \rightarrow G$ that is given by $x_i \mapsto g_i$, $i = 1, \ldots, k$ sends $r$ to the trivial element.

Examples.

(1) We consider $\{x_1, x_2\}$ and the word $r = x_1x_2x_1^{-1}x_2^{-1}$. If a group is abelian, then any two elements $g_1, g_2$ satisfy the relation $x_1x_2x_1^{-1}x_2^{-1}$.

(2) Let $G$ be a finite group with $d$ elements. We consider the set $\{x\}$. It follows from Lagrange’s Theorem, see e.g. [KuS04, p. 8], that every element in $G$ satisfies the relation $x^d$.

Lemma 21.13. Let $\pi$ be a group with a finite presentation $\pi = \langle x_1, \ldots, x_k \mid r_1, \ldots, r_l \rangle$. For any group $G$ the map

$$
\text{Hom}(\pi, G) \rightarrow \{\text{all } (g_1, \ldots, g_k) \in G^k \text{ that satisfy } r_1, \ldots, r_l\}
$$

$$
\text{f} \mapsto (f(x_1), \ldots, f(x_k))
$$

is a bijection.

Remark. Note that if $G$ is a finite group, then the right-hand side of Lemma 21.13 is a finite set. In practice it is usually straightforward, albeit tedious, to determine the right-hand side.

Proof. This lemma follows immediately from Lemma 21.4 and Lemma 19.14.

Next, recall that in Exercise 19.16 we gave an explicit example of a group epimorphism $\phi: \langle x, y \rangle \rightarrow \mathbb{Z}$ such that the kernel $\ker(\phi)$ is infinitely generated. The next proposition shows that this was not a fluke.

---

The fact that there exists a unique such homomorphism is a consequence of Lemma 19.14.
**Proposition 21.14.** Every non-trivial normal subgroup of a free group is infinitely generated.

**Proof.** A purely group theoretic proof is given in [LS77] Proposition I.3.12. Alternatively a proof using topological methods is provided in [dlH00] p. 45. \[\Box\]

Fortunately the following proposition, which we obtain from [DrK18] Lemma 7.29, gives us at least some control over the “size” of a kernel.

**Proposition 21.15.** Let \( \varphi: \pi \to G \) be a group epimorphism. If \( \pi \) is finitely generated and if \( G \) is finitely presented, then \( \ker(\varphi) \) is finitely normally generated. In other words, there exists a finite subset \( S \subset \ker(\varphi) \) such that \( \langle \langle S \rangle \rangle = \ker(\varphi) \).

**Example.** Let \( \varphi: \langle x, y \rangle \to \mathbb{Z}^2 \) be the epimorphism that is given by \( \varphi(x) = (1, 0) \) and \( \varphi(y) = (0, 1) \). In Exercise 21.8 we will see that \( \ker(\varphi) \) is normally generated by a single element, namely the commutator \( xyx^{-1}y^{-1} \).

We conclude this section with an interesting little lemma. For the formulation we need the following harmless definition.

**Definition.** Let \( G \) and \( H \) be groups. We say \( H \) is a retract of \( G \) if there exist a group homomorphisms \( \varphi: H \to G \) and \( \rho: G \to H \) such that \( \rho \circ \varphi = \text{id}_H \).

**Lemma 21.16.** \((*)\) Every retract of a finitely presented group is also finitely presented.

**Proof \((*)\).** Let \( H \) be a group, let \( G \) be a finitely presented group and let \( \varphi: H \to G \) and \( \rho: G \to H \) be group homomorphisms such that \( \rho \circ \varphi = \text{id}_H \). We need to show that \( H \) is also finitely presented.

To do so we pick a finite presentation \( G = \langle g_1, \ldots, g_k \mid r_1, \ldots, r_l \rangle \) for the group \( G \). We write \( F = \langle g_1, \ldots, g_k \rangle \). In the following we denote by \( p: F \to G \) the obvious epimorphism. For each \( i \in \{1, \ldots, k\} \) we pick \( w_i \in F \) with \( p(w_i) = (\varphi \circ \rho \circ p)(g_i) \in G \). It suffices to prove the following claim.

**Claim.** A finite presentation for \( H \) is given by \( \langle g_1, \ldots, g_k \mid r_1, \ldots, r_l, g_i^{-1}w_1, \ldots, g_i^{-1}w_k \rangle \).

Let \( L \) be the group that is defined by the finite presentation of the claim. We denote by \( u: G \to L \) and \( q: F \to L \) the obvious projections. Note that for each \( j \in \{1, \ldots, l\} \) we have \( \rho(p(r_i)) = \rho(e) = e \) and for each \( i \in \{1, \ldots, k\} \) we have

\[
\rho(p(g_i^{-1}w_i)) = \rho(p(g_i^{-1})) \cdot \rho(p(w_i)) = \rho(p(g_i^{-1})) \cdot \rho(p(g_i)) = e.
\]

since \( p(w_i) = (\varphi \circ \rho \circ p)(g_i) \) and since \( \rho \circ \varphi = \text{id}_H \)

It follows from Lemma 21.4 that the homomorphism \( p \circ \varphi: F \to H \) factors through a homomorphism \( v: L \to H \).

We want to show that \( u \circ \varphi \) is an isomorphism. First note that

\[
v \circ (u \circ \varphi) = (v \circ u) \circ \varphi = \rho \circ \varphi = \text{id}_H.
\]

since \( \rho = v \circ u \).
By Lemma 19.18 it remains to show that \( u \circ \varphi \) is an epimorphism. Note that for \( i = 1, \ldots, k \) we have
\[
(u \circ \varphi)(\rho \circ p)(w_i) = u(p(w_i)) = q(w_i) = g_i \in L.
\]
Since \( g_1, \ldots, g_k \) is a generating set for \( L \) we see that \( u \circ \varphi \) is indeed an epimorphism.

For convenience we summarize all objects in the following diagram
\[
\begin{array}{ccc}
H & \overset{\varphi}{\longrightarrow} & G = \langle g_1, \ldots, g_k \mid r_1, \ldots, r_l \rangle \\
\downarrow{\rho} & & \downarrow{p} \\
L := \langle g_1, \ldots, g_k \mid r_1, \ldots, r_l, g_1^{-1}w_1, \ldots, g_k^{-1}w_k \rangle.
\end{array}
\]

21.4. The Andrews-Curtis Conjecture (*). In this section we want to introduce Nielsen transformations and we want to present the Andrews-Curtis Conjecture. Both are mostly peripheral to the content of these notes. But for general culture it is perhaps interesting to know that in this supposedly fairly elementary context of finite presentations there are difficult conjectures lurking in the background.

First we introduce the following notation.

**Notation.** Given a set \( S \) and \( n \in \mathbb{N}_0 \) we refer to an element \((g_1, \ldots, g_n) \in S^n\) as an ordered set of elements in \( S \).

Now we can introduce the definition we are really interested in.

**Definition.** Let \( \pi \) be a group and let \((g_1, \ldots, g_n)\) be an ordered set of elements in \( \pi \). A *Nielsen operation* is one of the following three ways of obtaining a new ordered set of elements in \( \pi \):

1. \((g_1, g_2, g_3, \ldots, g_n) \sim (g_1^{-1}, g_2, g_3, \ldots, g_n)\)
2. \((g_1, g_2, g_3, \ldots, g_n) \sim (g_2, g_1, g_3, \ldots, g_n)\)
3. \((g_1, g_2, g_3, \ldots, g_n) \sim (g_1 \cdot g_2, g_2, g_3, \ldots, g_n)\).

The following theorem that was proved by Jakob Nielsen [Nie24] (see also [LS77, Proposition I.4.1] and [MKS76, Theorem 3.2]) in 1924.

**Theorem 21.17. (Nielsen 1924)** Let \( F = \langle x_1, \ldots, x_n \rangle \) be a free group. If \( y_1, \ldots, y_n \in F \) form a basis\(^{375}\) for the free group \( F \), then \((y_1, \ldots, y_n)\) can be obtained from \((x_1, \ldots, x_n)\) through a finite sequence of Nielsen operations (1), (2) and (3).

**Remark.**

1. Let \( F = \langle g_1, \ldots, g_n \rangle \) be a finitely generated free group. It follows from Lemma 19.14 that any Nielsen operation, applied to \((g_1, \ldots, g_n)\), gives rise to an endomorphism of

---

\(^{374}\) Note that we do not assume that \( g_1, \ldots, g_n \) are pairwise different.

\(^{375}\) Recall that by the definition on page 392 the elements \( y_1, \ldots, y_n \) form a basis if the natural map \( \langle y_1, \ldots, y_n \rangle \to F \) is an isomorphism.
the free group \( F \). One can easily show that these endomorphisms are in fact automorphisms of the free group. We refer to any such automorphism as a \emph{Nielsen automorphism}. Nielsen’s Theorem \[21.17\] implies almost immediately that any automorphism of the free group is in fact a composition of finitely many Nielsen automorphisms. In other words, the group \( \text{Aut}(F) \) is generated by the Nielsen transformations.

(2) The fact that the group \( \text{Aut}(F) \) is generated by the Nielsen operations is similar in spirit to the fact, established in any self-respecting linear algebra course, that the group \( \text{Aut}(\mathbb{Z}^n) = \text{GL}(n, \mathbb{Z}) \) is generated by elementary matrices.

The following conjecture was formulated by James Andrews and Morton Curtis \[AC65\] in 1965.

\begin{conjecture} \textbf{(Andrews-Curtis Conjecture)} \end{conjecture}

Let \( \langle g_1, \ldots, g_n | r_1, \ldots, r_n \rangle \) be a finite presentation. If the corresponding group is the trivial group, then \( (r_1, \ldots, r_n) \) can be obtained from \( (g_1, \ldots, g_n) \) through a finite sequence of operations where we allow the Nielsen operations (1), (2), (3) and the following fourth operation:

(4) \( (g_1, g_2, g_3, \ldots, g_n) \rightsquigarrow (hg_1h^{-1}, g_2, g_3, \ldots, g_n) \) for some \( h \in \pi \).

The Andrews-Curtis Conjecture is notoriously difficult. It seems like most experts believe the conjecture to be false, but not much progress has been made over the last decades. Finally note that the Andrews-Curtis Conjecture will raise its head once more in Section \[107.2\].

21.5. \textbf{The abelianization of a group}. The following definition should already be familiar from the algebra course.

\begin{definition} \end{definition}

Let \( \pi \) be a group. We refer to

\[
[\pi, \pi] := \langle \{ [x, y] \mid x, y \in \pi \} \rangle
\]

as the \emph{commutator subgroup} of \( \pi \).

We start out with the following elementary lemma.

\begin{lemma} \end{lemma}

Let \( \pi \) be a group. Then the following hold:

(1) The group \( \pi/[\pi, \pi] \) is abelian.

(2) We have

\[
[\pi, \pi] := \left\{ \prod_{i=1}^{n} [x_i, y_i] \mid x_1, y_1, \ldots, x_n, y_n \in \pi \right\}.
\]

\begin{remark} \end{remark}

Note that in general not every element of the commutator subgroup is a commutator. For example, if \( \pi = \langle a, b, c, d \rangle \) is the free group on four generators \( a, b, c, d \), then we have \([a, b] \cdot [c, d] \in [\pi, \pi]\), but it is not a commutator.\[376\]

---

\[376\] Why not?
Proof. Let $\pi$ be a group.

(1) For any two elements $x, y \in \pi$ we have
$$xy[\pi, \pi] = yx \cdot x^{-1}y^{-1}xy[\pi, \pi] = yx \cdot [x^{-1}, y^{-1}] \underbrace{[\pi, \pi]}_{\in [\pi, \pi]} = yx [\pi, \pi].$$

This shows that $\pi/[\pi, \pi]$ is indeed abelian.

(2) Note that the inverse of a commutator is again a commutator, i.e. given $x, y \in \pi$ we have
$$[x, y]^{-1} = (xy^{-1}x^{-1})^{-1} = yxy^{-1}x^{-1} = [y, x].$$
Furthermore a conjugate of a commutator is again a commutator. Indeed, given $x, y, g \in \pi$ we have
$$g[x, y]g^{-1} = gxy^{-1}y^{-1}g^{-1} = gx^{-1}gy^{-1}gx^{-1}gy^{-1}g^{-1} = (gx^{-1})(gy^{-1})(gx^{-1})^{-1}(gy^{-1})^{-1} = [gx^{-1}, gy^{-1}].$$

It follows from this discussion and from Lemma 21.3 that each element of the commutator subgroup can be written as a product of commutators, i.e.
$$[\pi, \pi] := \left\{ \prod_{i=1}^{n} [x_i, y_i] \mid x_1, y_1, \ldots, x_n, y_n \in \pi \right\}. \quad \square$$

Definition. Let $\pi$ be a group. We call
$$\pi_{ab} := \pi/[\pi, \pi]$$
the abelianization of $\pi$.\footnote{The abelianization of a group $\pi$ is sometimes also written as $H_1(\pi)$. The reason for that somewhat strange looking notation will become clear later on when we formulate the Hurewicz Theorem\footnote{52.5} and when we consider the homology groups, see Chapter ??..}

The following proposition summarizes some of the key properties of the abelianization of groups.

Proposition 21.20.

1. If $\pi$ is abelian, then $\pi_{ab} = \pi$.
2. Let $\pi$ be a group and let $\alpha: \pi \to H$ be a homomorphism to an abelian group. Then there exists a unique homomorphism $\beta: \pi_{ab} = \pi/[\pi, \pi] \to H$ such that the following diagram commutes:

$$\begin{array}{ccc}
\pi & \longrightarrow & \pi_{ab} = \pi/[\pi, \pi] \\
\alpha \downarrow & & \downarrow \beta \\
& & H.
\end{array}$$

In particular for any group $\pi$ and any abelian group $G$ the map
$$\alpha: \pi_{ab} \to G \quad \text{and} \quad \alpha: \pi \to \pi_{ab} \to G$$
$$\text{Hom}(\pi_{ab}, G) \to \text{Hom}(\pi, G)$$
$$\text{Hom}(\pi_{ab}, G) \to \text{Hom}(\pi, G)$$

is a bijection.
(3) Let \( G \) and \( H \) be two groups. There exists a unique isomorphism
\[
(G \ast H)_{ab} \cong G_{ab} \times H_{ab}
\]
which makes the following diagram commute:
\[
\begin{array}{ccc}
G \ast H & \xrightarrow{\cong} & G \times H \\
\downarrow & & \downarrow \\
(G \ast H)_{ab} & \xrightarrow{\cong} & G_{ab} \times H_{ab},
\end{array}
\]
where the other three maps are the obvious projection maps.

(4) Let \( F = \langle x_1, \ldots, x_m \rangle \) be the free group on \( m \) generators \( x_1, \ldots, x_m \). Then the map
\[
\Phi: F_{ab} = F/[F,F] \rightarrow \mathbb{Z}^m \\
[x_i] \mapsto e_i := \text{the } i\text{-th standard basis vector}
\]
is an isomorphism.

(5) Let \( \pi = \langle x_1, \ldots, x_m \mid r_1, \ldots, r_n \rangle \) be a finitely presented group. We denote by
\[
\Phi: \langle x_1, \ldots, x_m \rangle \rightarrow \mathbb{Z}^m
\]
the homomorphism that is given by \( \Phi(x_i) = e_i \). There exists a unique isomorphism
\[
\Psi: \pi/[\pi,\pi] \xrightarrow{\cong} \mathbb{Z}^m/\langle \Phi(r_1), \ldots, \Phi(r_n) \rangle
\]
such that the following diagram commutes
\[
\begin{array}{ccc}
\langle x_1, \ldots, x_m \rangle & \xrightarrow{x_i \mapsto e_i} & \mathbb{Z}^m \\
\downarrow & \Phi & \downarrow \\
\pi = \langle x_1, \ldots, x_m \rangle/\langle r_1, \ldots, r_n \rangle & \xrightarrow{\Psi} & \mathbb{Z}^m/\langle \Phi(r_1), \ldots, \Phi(r_n) \rangle.
\end{array}
\]

(6) The maps
\[
G \mapsto G_{ab} = G/[G,G]
\]
and
\[
(\varphi: G \rightarrow H) \mapsto \left( \varphi_*: G_{ab} = G/[G,G] \mapsto H_{ab} = H/[H,H] \right)
\]
define a covariant functor from the category \( \mathcal{G}r \) of groups to the category \( \mathcal{A}b\mathcal{G}r \) of abelian groups.

(7) Given a group \( G \) we denote by
\[
\Phi_G: G \rightarrow G_{ab} = G/[G,G] \\
g \mapsto [g]
\]
the projection map. These maps \( \Phi_G \) define a natural transformation from the identity functor \( \mathcal{G}r \rightarrow \mathcal{G}r \) to the abelianization functor \( \mathcal{G}r \rightarrow \mathcal{G}r \) that we had introduced in (6).

(8) Isomorphic groups have isomorphic abelianizations.
If $\varphi: A \to B$ is an epimorphism, then the induced map $A_{ab} \to B_{ab}$ is also an epimorphism.

**Examples.**

(1) By Proposition 21.20 (1) and (3) we have

$$\left( \mathbb{Z}_3 * \mathbb{Z}_{35} \right)_{ab} \cong \mathbb{Z}_3 \times \mathbb{Z}_{35} \quad \text{and} \quad \left( \mathbb{Z}_5 * \mathbb{Z}_{21} \right)_{ab} \cong \mathbb{Z}_5 \times \mathbb{Z}_{21}.$$

It follows from the Chinese Remainder Theorem that the abelianizations are isomorphic. On the other hand on page 597 we had already observed that the Grushko Decomposition Theorem 19.21 implies that the groups $\mathbb{Z}_3 * \mathbb{Z}_{35}$ and $\mathbb{Z}_5 * \mathbb{Z}_{21}$ are not isomorphic. Thus we have seen that non-isomorphic groups can have isomorphic abelianizations.

(2) We give an explicit example for statement (5). Let

$$\pi = \langle x, y \mid x^2y^{-2}x, y^{-1}x^3yx \rangle.$$

Let $\Phi: \langle x, y \rangle \to \mathbb{Z}^2$ be the epimorphism given by $\Phi(x) = (1, 0)$ and $\Phi(y) = (0, 1)$. Then the abelianization of $\pi$ is given by

$$\pi_{ab} = \mathbb{Z}^2 / \langle \Phi(x^3y^{-2}), \Phi(y^{-1}x^3yx) \rangle = \mathbb{Z}^2 / \begin{pmatrix} 3 & 4 \\ -2 & 0 \end{pmatrix} \mathbb{Z}^2 \cong \mathbb{Z}_8.$$

(3) Let $S$ be a set. It is straightforward to show that the abelianization of the free group $\langle S \rangle$ generated by $S$ is isomorphic to the free abelian group $\mathbb{Z}^{\langle S \rangle}$ generated by $S$.

(4) Given $k \in \mathbb{N}$ we denote by $S_k$ the permutation group on $k$ elements and we denote by $A_k \subseteq S_k$ the alternating group, i.e. the group of all permutations with positive sign. In the algebra course it was shown that for $k \geq 5$ the group $A_k$ is simple, i.e. the only normal subgroups of $A_k$ are the trivial group and the group $A_k$ itself. The commutator subgroup $[A_k, A_k]$ is normal. Since $A_k$ is not abelian we cannot have $[A_k, A_k] = \{e\}$. Thus we see that $[A_k, A_k] = A_k$, which implies that the abelianization of $A_k$ is the trivial group.

Now we provide the proof of Proposition 21.20.

**Proof of Proposition 21.20.**

(1) The first statement is obvious.\(^{382}\)

---

\(^{378}\)By Lemma 19.14 there exists a unique homomorphism $F \to \mathbb{Z}^m$ with $x_i \mapsto e_i$. By (1) this map descends to a homomorphism $F/[F,F] \to \mathbb{Z}^m$. The way we write down the map is a little bit sloppy, since we only specify the map on the generators of $F/[F,F]$.

\(^{379}\)Super-picky readers might argue that in (6) we introduced a functor from $\mathcal{G}r$ to $\mathcal{AbGr}$, but of course we can also view it as a functor from $\mathcal{G}$ to $\mathcal{G}$.

\(^{380}\)Why? Is the group isomorphic to $\mathbb{Z}_6$?

\(^{381}\)A proof of this statement is also given in any self-respecting algebra book, see e.g. [Rob95, p. 69].

\(^{382}\)Why?
(2) Let $\pi$ be a group and let $\alpha : \pi \to H$ be a homomorphism to an abelian group. Then $[\pi, \pi]$ lies in the kernel of $\alpha$. The desired statement now follows immediately from Lemma 21.1.

(3) The maps

$$\Phi : (G \ast H)_{ab} \to G_{ab} \times H_{ab} \quad \text{and} \quad \Psi : G_{ab} \times H_{ab} \to (G \ast H)_{ab}$$

$$(x_1, \ldots, x_k) \mapsto \left(\prod_{x_i \in G} x_i, \prod_{x_i \in H} x_i\right)$$

are easily seen to be well-defined, to be homomorphisms and to be inverses of one another.

(4) This statement follows immediately from the statements (1) and (3) together with the observation that $\langle x_1, \ldots, x_m \rangle = \langle x_1 \rangle \ast \cdots \ast \langle x_m \rangle$, that $\langle x_i \rangle_{ab} \cong \mathbb{Z}$ and that $\mathbb{Z}^m = \mathbb{Z} \times \cdots \times \mathbb{Z}$.

(5) It is straightforward to see that there exists a unique homomorphism

$$\Psi : \pi/[\pi, \pi] \to \mathbb{Z}^m/\langle \Phi(r_1), \ldots, \Phi(r_n) \rangle$$

that makes the diagram of statement (5) commute. It remains to show that $\Psi$ is an isomorphism. We write $F = \langle x_1, \ldots, x_m \rangle$ and we write $G = \langle y_1, \ldots, y_n \rangle$. We consider the following diagram

$$
\begin{array}{ccc}
G_{ab} = G/[G, G] & \xrightarrow{[y_i] \mapsto e_i} & \mathbb{Z}^n \\
\downarrow \quad [y_i] \mapsto [r_i] & \Downarrow \quad \Phi([x_i]) = e_i & \downarrow \\
F_{ab} = F/[F, F] & \xrightarrow{\Phi([x_i]) = e_i} & \mathbb{Z}^m \\
\downarrow \quad \psi & \Downarrow & \downarrow \\
\pi_{ab} = \pi/[\pi, \pi] & \xrightarrow{\psi} & \mathbb{Z}^m \\
\end{array}
$$

Note that the diagram commutes. By (4) the top two horizontal maps are isomorphisms. The bottom vertical maps are clearly epimorphisms and it is clear that the images of the top vertical maps lie in the kernel of the bottom vertical maps. It now follows from an elementary “diagram chase” that the bottom horizontal map is also an isomorphism.\footnote{More precisely, we use the following fact: suppose we are given a commutative diagram}

$$
\begin{array}{ccc}
A & \xrightarrow{\cong} & A' \\
\downarrow & \Downarrow & \downarrow \\
B & \xrightarrow{\cong} & B' \\
\downarrow & \Downarrow & \downarrow \\
C & \xrightarrow{\cong} & C',
\end{array}
$$

of group homomorphisms where the bottom vertical maps are epimorphisms, where the top two horizontal maps are isomorphisms and where the kernels of the bottom vertical maps are the images of the top vertical maps. Then the bottom horizontal map is also an isomorphism. This general statement can be proved by a “diagram chase”. This statement can also be viewed as a special case of the “five lemma”.

We leave the details to the reader.
21. PRESENTATIONS OF GROUPS AND AMALGAMATED PRODUCTS

(6) This statement follows easily from the definitions and the observation that the image of a commutator under a group homomorphism is once again a commutator.

(7) This statement is basically obvious once one has internalized the definition of a natural transformation.

(8) This statement is an immediate consequence of (6).

(9) We will prove this statement in Exercise 21.6. ■

21.6. The amalgamated product of groups I. In the formulation of the generalized version of the Seifert–van Kampen theorem we will need to replace the free product of two groups by the “amalgamated product” of two groups.

In Section 19.2 we had first defined the free product via an explicit construction. We had then explained that one can also characterize the free product via a universal property. In this section we will proceed the other way round, we will first state the desired universal property and then we will explicitly construct a group which satisfies the universal property.

Proposition 21.21. Let \( \alpha : G \rightarrow A \) and \( \beta : G \rightarrow B \) be two group homomorphisms. Then there exists a triple

\[
(A \ast_G B, \varphi : A \rightarrow A \ast_G B, \psi : B \rightarrow A \ast_G B)
\]

where \( A \ast_G B \) is a group and \( \varphi \) and \( \psi \) are homomorphisms with the following properties:

(a) the following diagram commutes:

\[
\begin{array}{ccc}
G & \xrightarrow{\alpha} & A \\
\downarrow{\beta} & & \downarrow{\varphi} \\
B & \xrightarrow{\psi} & A \ast_G B,
\end{array}
\]

(b) if \( (H', \varphi' : A \rightarrow H', \psi' : B \rightarrow H') \) is another triple which satisfies property (a), then there exists a unique homomorphism \( \Theta : A \ast_G B \rightarrow H' \) such that \( \varphi' = \Theta \circ \varphi \) and \( \psi' = \Theta \circ \psi \), i.e. such that the following diagram commutes

\[
\begin{array}{ccc}
G & \xrightarrow{\alpha} & A \\
\downarrow{\beta} & & \downarrow{\varphi} \\
B & \xrightarrow{\psi} & A \ast_G B \\
& & \downarrow{\Theta} \\
& & H'.
\end{array}
\]

Proof. Let \( \alpha : G \rightarrow A \) and \( \beta : G \rightarrow B \) be two group homomorphisms. As usual we view \( A \) and \( B \) as subgroups of \( A \ast B \). We put

\[
A \ast_G B := A \ast B/\langle\langle \{\alpha(g)\beta(g)^{-1}\}_{g \in G} \rangle\rangle
\]

and we define \( \varphi : A \rightarrow A \ast_G B \) as the composition of the obvious homomorphisms

\[
A \hookrightarrow A \ast B \rightarrow A \ast B/\langle\langle \{\alpha(g)\beta(g)^{-1}\}_{g \in G} \rangle\rangle,
\]
and precisely the same way we define the homomorphism $\psi: B \to A *_G B$. It follows from the construction of $A *_G B$ that $\phi(\alpha(g)) = \psi(\beta(g))$ for all $g \in G$. Therefore the triple $(A *_G B, \phi: A \to A *_G B, \psi: B \to A *_G B)$ satisfies property (a).

Now let $(H', \phi': A \to H', \psi': B \to H')$ be another triple which satisfies property (a). We consider the following diagram

where $\Phi: A * B \to H'$ is the unique homomorphism determined by $\psi'$ and $\phi'$. Since $\phi' \circ \alpha = \phi' \circ \beta$ it follows that for any $g \in G$ we have

$$\Phi(\alpha(g) \cdot \beta(g)^{-1}) = \Phi(\alpha(g)) \cdot \Phi(\beta(g))^{-1} = \phi'(\alpha(g)) \cdot \psi'(\beta(g))^{-1} = e.$$ 

Put differently, all elements of the form $\alpha(g) \beta(g)^{-1}$ in $A * B$ lie in the kernel of $\Phi$. By Lemma 21.4 there exists a unique homomorphism $\Theta: A * B / \langle \langle \{ \alpha(g) \beta(g)^{-1} \}_{g \in G} \rangle \rangle \to H'$ which makes the following diagram commute

$$A * B \xrightarrow{\phi} A * G B = A * B / \langle \langle \{ \alpha(g) \beta(g)^{-1} \}_{g \in G} \rangle \rangle \xrightarrow{\Theta} H'.$$

This proves the existence of $\Theta$. The uniqueness follows from the observation that another choice of $\Theta'$ would give another choice for $\Phi$, but this homomorphism is unique. □

**Definition.** Let $\alpha: G \to A$ and $\beta: G \to B$ be two group homomorphisms. We write

$$A *_G B := A * B / \langle \langle \{ \alpha(g) \beta(g)^{-1} \}_{g \in G} \rangle \rangle$$

and we refer to $A *_G B$ as the *amalgamated product of $A$ and $B$ with amalgam $G*G*.384*385*

We refer to the obvious homomorphisms $A \to A *_G B$ and $B \to A *_G B$ as the *natural homomorphisms*.

**Remark.** A variation on the argument on page 582 shows that if

$$(H, \phi: A \to H, \psi: B \to H)$$

384. The notation is a little misleading since the homomorphisms $\alpha$ and $\beta$ do not get mentioned in the notation, even though they play of course an important role. In particular different choices of $\alpha$ and $\beta$ can lead to non-isomorphic amalgamated products.

385. We leave it again to the reader to figure out in what sense these homomorphisms are “natural”.
is a triple that has both the properties (a) and (b) of Proposition 21.21, then there exists a unique isomorphism \( \Theta : A \ast_G B \rightarrow H \) such that \( \varphi(a) = \Theta(a) \) for all \( a \in A \) and \( \psi(b) = \Theta(b) \) for all \( b \in B \). Often we will use this uniquely defined isomorphism to identify \( H \) with the amalgamated product \( A \ast_G B \).

**Example.** Let \( G = \mathbb{Z}_2, A = \mathbb{Z}_4 \) and \( B = \mathbb{Z}_6 \) and consider the homomorphisms

\[
\alpha : G \rightarrow A \quad \text{and} \quad \beta : G \rightarrow B,
\]

\[
[k] \mapsto [2k] \quad \text{and} \quad [k] \mapsto [3k].
\]

Furthermore we consider the homomorphisms

\[
\varphi : A = \mathbb{Z}_4 \rightarrow \text{SL}(2, \mathbb{Z}) \quad \text{and} \quad \varphi : B = \mathbb{Z}_6 \rightarrow \text{SL}(2, \mathbb{Z}),
\]

\[
k \mapsto \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}^k \quad \text{and} \quad k \mapsto \begin{pmatrix} 1 & 1 \\ -1 & 0 \end{pmatrix}^k.
\]

It is straightforward to verify that \( \varphi \circ \alpha = \psi \circ \beta \), therefore there exists by Proposition 21.21 a homomorphism

\[ A \ast_G B = \mathbb{Z}_4 \ast_{\mathbb{Z}_2} \mathbb{Z}_6 \rightarrow \text{SL}(2, \mathbb{Z}). \]

More surprisingly, this homomorphism is in fact an isomorphism. We refer to [Rosb94, p. 218] and [Ser80, p. 35] for a proof.

The following lemma summarizes some important special cases of the amalgamated product of groups.

**Lemma 21.22.**

1. For two groups \( A \) and \( B \) and \( G = \{ e \} \) the trivial group, the corresponding amalgamated product is the usual free product, i.e.

\[ A \ast_{\{ e \}} B = A \ast B. \]

2. If \( \alpha : G \rightarrow A \) is a group homomorphism and if \( \beta : G \rightarrow \{ e \} \) is the trivial homomorphism, then

\[ A \ast_G \{ e \} = A/\langle \langle \alpha(G) \rangle \rangle. \]

3. Let \( \alpha : G \rightarrow A \) and \( \beta : G \rightarrow B \) be group homomorphisms. We consider the diagram

\[
\begin{array}{ccc}
G & \xrightarrow{\alpha} & A \\
\downarrow{\beta} & & \downarrow \\
B & \rightarrow & A \ast_G B.
\end{array}
\]

The following two statements hold:

(a) If the left vertical map \( \beta \) is an isomorphism, then the right vertical map is also an isomorphism and the inverse \( A \ast_G B \rightarrow A \) is given by the identity on \( A \) and \( \beta^{-1} : B \rightarrow G \).

(b) If the left vertical map \( \beta \) is an epimorphism, then the right vertical map is also an epimorphism.

---

386 Are these really homomorphisms?

387 Indeed, the one non-trivial element of \( G = \mathbb{Z}_2 \) gets sent under both maps to \(-\text{id}\).
(4) Let $A, B, C$ and $G, H$ be groups and let $\alpha : G \to A$, $\beta : G \to B$, $\tilde{\beta} : H \to B$ and $\gamma : H \to C$ be group homomorphisms. Then the universal properties of the amalgamated products define an isomorphism

$$(A *_G B) *_H C \cong A *_G (B *_H C).$$

(5) Let $\alpha : G \to A$ and $\beta : G \to B$ be group homomorphisms and let $\varphi : H \to G$ be an epimorphism. The natural map $A *_G B \to A *^H B$ is an isomorphism.

(6) Let $\alpha : G * H \to A$ and $\beta : G * H$ to be group homomorphisms. If the restriction of $\beta$ to $H$ is trivial, then the natural map $A *^G * H B \to A / \langle \langle H \rangle \rangle *^G B$ is an isomorphism.

**Remark.** Lemma 21.22 (4) is actually quite useful since it allows us to form iterated amalgamated products without having to worry about parentheses.

**Sketch of proof.** The first two statements follow immediately from the definition

$$A *_G B := A * B / \langle \langle \{ \alpha(g)\beta(g)^{-1} \} \rangle \rangle.$$

The remaining statement follow either directly from the universal property of the amalgamated product or from the actual description. For some statements we will fill in the details in Exercise 21.12.

The following lemma gives us a convenient description of the amalgamated product of two finitely presented groups.

**Lemma 21.23.** Let

$$A = \langle x_1, \ldots, x_k \mid r_1, \ldots, r_p \rangle$$

and

$$B = \langle y_1, \ldots, y_l \mid s_1, \ldots, s_q \rangle$$

be two finitely presented groups. Furthermore let $\alpha : G \to A$ and $\beta : G \to B$ be two group homomorphisms and let $g_1, \ldots, g_m$ be generators of $G$. Then

$$A *^G B = \langle x_1, \ldots, x_k, y_1, \ldots, y_l \mid r_1, \ldots, r_p, s_1, \ldots, s_q \text{ and } \alpha(g_i) = \beta(g_i), i = 1, \ldots, m \rangle.$$

**Examples.**

1. Let $A_1 = \langle x_1, y_1 \rangle$ and $A_2 = \langle x_2, y_2 \rangle$ be two free groups. Furthermore for $i = 1, 2$ let $\varphi_i : \langle t \rangle \to A_i$ be the homomorphism that is given by $\varphi_i(t^n) := [x_i, y_i]^n$. Then we obtain from Lemma 21.23 that

$$A_1 *_{\langle t \rangle} A_2 = \langle x_1, y_1, x_2, y_2 \mid [x_1, y_1] = [x_2, y_2] \rangle.$$

2. Let $A = \langle a \rangle$ and let $B = \langle b \rangle$ be two infinite cyclic groups and let $G = \langle x, y \mid [x, y] \rangle$ be a group that is isomorphic to $\mathbb{Z}^2$. We consider the homomorphism $\alpha : G \to A$ that is given by $\alpha(x) = a$ and $\alpha(y) = e$ and we consider the homomorphism $\beta : G \to B$.

---

388 The statements are similar in spirit to the statement of Lemma 3.43 for the pushout of topological spaces.

389 In an attempt to lessen the burden on the reader we refrained from writing down the super-precise statement.
that is given by $\beta(x) = e$ and $\beta(y) = b$. Then

$$A *_G B = \langle a, b \mid \alpha(x) = \beta(x), \alpha(y) = \beta(y) \rangle = \langle a, b \mid a = e, e = b \rangle = \langle \rangle = \{e\}.$$  

Lemma 21.23  

Tietze transformation (2), see page 632

This shows in particular that the amalgamated product of two non-trivial groups can in fact be trivial.

**Proof of Lemma 21.23** We need to show that

$$\langle\langle \{g \mid \alpha(g) \beta(g)^{-1}\} \rangle\rangle_{g \in G} = \langle\langle \{g_i \mid \alpha(g_i) \beta(g_i)^{-1}\} \rangle\rangle_{i=1, \ldots, m}.$$  

Put differently, we need to prove the following claim.

**Claim.** In the free product $A * B$ we have

$$\langle\langle \{g \mid \alpha(g) \beta(g)^{-1}\} \rangle\rangle = \langle\langle \{g_i \mid \alpha(g_i) \beta(g_i)^{-1}\} \rangle\rangle_{i=1, \ldots, m}.$$  

It is clear that the right-hand side is contained in the left-hand side. To show the reverse inclusion we need to show that for each $g \in G$ we have $\alpha(g) \beta(g)^{-1} \in \langle\langle \{g_i \mid \alpha(g_i) \beta(g_i)^{-1}\} \rangle\rangle_{i=1, \ldots, m}$. We start out with two observations:

1. We first consider the case $g = g_i^{-1}$ for some $i$. Then

$$\alpha(g) \beta(g)^{-1} = \alpha(g_i^{-1}) \beta(g_i^{-1})^{-1} = \alpha(g_i)^{-1} \alpha(g_i) \beta(g_i)^{-1} \alpha(g_i)^{-1} \alpha(g_i),$$

thus $\alpha(g) \beta(g)^{-1}$ is a conjugate of the inverse of $\alpha(g_i) \beta(g_i^{-1})$, in particular it lies in $\langle\langle \{g_i \mid \alpha(g_i) \beta(g_i)^{-1}\} \rangle\rangle_{i=1, \ldots, m}$.

2. Note that if $a, b$ and $c$ are elements in a group $\pi$ such that $ac$ and $b$ lie in a normal subgroup $\Gamma$, then $abc = ac \cdot c^{-1}bc$ also lies in $\Gamma$.

Now we turn to the proof of the claim. We define the length of $g \in G$ as

$$\ell(g) = \min\{n \mid \text{we can write } g = g_{i_1}^{\epsilon_1} \cdots g_{i_n}^{\epsilon_n} \text{ for } \epsilon_j \in \{-1, 1\} \text{ and } i_j \in \{1, \ldots, m\}\}.$$  

Since $g_1, \ldots, g_m$ are generators of $G$ any $g \in G$ has a length.

We prove the claim by induction on the length of $g \in G$. For $\ell(g) = 0$ there is nothing to prove. Now suppose we have shown the claim for all elements of length $n - 1$. Now let $g \in G$ be an element of length $n$. Thus we can write $g = g_{i_1}^{\epsilon_1} \cdots g_{i_n}^{\epsilon_n}$ for $\epsilon_1, \ldots, \epsilon_n \in \{-1, 1\}$ and $i_1, \ldots, i_n \in \{1, \ldots, m\}$. We then have

$$\alpha(g) \beta(g)^{-1} = \alpha(g_i) \beta(g_i)^{-1} = \alpha(g_{i_1}^{\epsilon_1} \cdots g_{i_n}^{\epsilon_n}) \cdot \beta(g_{i_1}^{e_{i_1}} \cdots g_{i_n}^{e_{i_n}})$$

$$= \alpha(g_{i_1}^{\epsilon_1}) \cdots \alpha(g_{i_{n-1}}^{\epsilon_{n-1}}) \cdot \alpha(g_{i_n}^{\epsilon_n}) \cdot \beta(g_{i_1}^{e_{i_1}}) \cdots \beta(g_{i_{n-1}}^{e_{n-1}}) \cdot \beta(g_{i_n}^{e_{i_n}}) =: a \cdot :b \cdot :c.$$  

Note that $b$ lies in the normal subgroup $\langle\langle \{\alpha(g_i) \beta(g_i)^{-1}\} \rangle\rangle_{i=1, \ldots, m}$ by (1) and $ac$ lies in the normal subgroup $\langle\langle \{\alpha(g_i) \beta(g_i)^{-1}\} \rangle\rangle_{i=1, \ldots, m}$ by induction. Thus $abc = \alpha(g) \beta(g)^{-1} \in \langle\langle \{g_i \mid \alpha(g_i) \beta(g_i)^{-1}\} \rangle\rangle_{i=1, \ldots, m}$ by (2).
21.7. The amalgamated product of groups II (\(*\)). In this last section we will state
and outline proofs of a few more advanced properties of amalgamated products.

Recall that on page 647 we saw that the amalgamated product of two non-trivial groups
can be trivial. The following proposition gives a criterion for the amalgamated product to
be non-trivial.

**Proposition 21.24.** Let \(\alpha: G \to A\) and \(\beta: G \to B\) be two group homomorphisms. If
\(\alpha\) and \(\beta\) are both monomorphisms, then the natural homomorphisms \(A \to A \ast_G B\) and
\(B \to A \ast_G B\) are also both monomorphisms.

**Convention.** If we are in the setting of Proposition 21.24, then we will use the natural
monomorphisms \(A \to A \ast_G B\) and \(B \to A \ast_G B\) to identify \(A\), \(B\) and \(G\) with the images in
\(A \ast_G B\) under these monomorphisms.

**Remark.** In Exercise 21.10 we will see that there exists an injective group homomorphism
\(\alpha: G \to A\) and a non-injective group homomorphism \(\beta: G \to B\) such that the amalgamated
product \(A \ast_G B\) is trivial. This shows that there is no obvious way how one can weaken
the hypothesis in Proposition 21.24 that both maps are monomorphisms.

The proof of Proposition 21.24 relies on the following proposition which is proved in
[Ser80, p. 3], or alternatively [vdW48, LS77, Theorem IV.2.6] and [CgRR08, Satz 5.2].

**Theorem 21.25. (Normal Form Theorem)** Let \(\alpha: G \to A\) and \(\beta: G \to B\) be two
group monomorphisms. We identify \(G\) with its image in \(A\) and \(B\). Let \(S \subset A\) be a set
of coset representatives for \(G \setminus A\) and let \(T \subset B\) be a set of coset representatives for \(G \setminus B\).
Then any element \(h\) in \(A \ast_G B\) we can be written uniquely as a product
\(h = g \cdot c_1 \cdots c_k\) where \(g \in G\) and \(c_1, \ldots, c_k \in S \cup T\).

**Proof of Proposition 21.24.** Let \(\alpha: G \to A\) and \(\beta: G \to B\) be two group monomor-
phisms. Let \(S\) be a set of coset representatives for \(G \setminus A\) and let \(T\) be a set of coset
representatives for \(G \setminus B\). We have the following modest commutative diagram

\[
\begin{array}{ccc}
G \times S & \xrightarrow{(g,s) \mapsto g \cdot s} & A \\
\downarrow{(g,s) \mapsto g \cdot s} & & \downarrow{\text{natural homomorphism}} \\
A \ast_G B \\
\end{array}
\]

The top map is a bijection by definition of \(S\). Furthermore the diagonal map is an injection
by the Normal Form Theorem 21.25. Thus the vertical map is a monomorphism.

We conclude this chapter with another consequence of the Normal Form Theorem 21.25.

**Proposition 21.26.** Let \(\alpha: G \to A\) and \(\beta: G \to B\) be two group monomorphisms. Fur-
thermore let \(\varphi: \pi \to A \ast_G B\) be a group epimorphism. We write \(\tilde{A} := \varphi^{-1}(A)\), \(\tilde{B} := \varphi^{-1}(B)\)
and \(\tilde{G} := \varphi^{-1}(G)\). Then there exists a unique isomorphism \(\psi: \tilde{A} \ast_{\tilde{G}} \tilde{B} \to \pi\) which makes
the following diagram commute:

\[
\begin{array}{ccc}
\tilde{A} \ast \tilde{G} \tilde{B} & \xrightarrow{\psi} & \pi \\
\downarrow & \searrow & \downarrow \\
\pi & \rightarrow & A \ast_G B.
\end{array}
\]

**Proof.** Let \( \alpha : G \to A \) and \( \beta : G \to B \) be two group monomorphisms. It follows from the universal property of the amalgamated product that there exists a unique homomorphism \( \psi : \tilde{A} \ast \tilde{G} \tilde{B} \to \pi \) which makes the above diagram commute. It remains to show that \( \psi \) is an isomorphism.

Let \( S \) be a set of coset representatives for \( G \setminus A \) and let \( T \) be a set of coset representatives for \( G \setminus B \). By the Normal Form Theorem \[21.25\] we know that any element \( h \) in \( A \ast_G B \) can be written uniquely as a product \( h = g \cdot c_1 \cdots c_k \) where \( g \in G \) and \( c_1, \ldots, c_k \in S \cup T \). We write \( \ell(h) := k \).

Now we turn to the proof that \( \psi \) is an epimorphism. We need to show that every \( g \in \pi \) lies in the image of \( \psi \). We prove this statement by induction on \( \ell(\varphi(g)) \). If \( \ell(\varphi(g)) \leq 1 \), then \( \varphi(g) \in A \) or \( \varphi(g) \in B \). But this means that \( g \in \psi(\tilde{A}) \) or \( g \in \psi(\tilde{B}) \). Suppose we know that we have an \( n \in \mathbb{N} \) such that the desired statement holds whenever \( \ell(\varphi(g)) \leq n \). Let \( g \in \pi \) with \( \ell(\varphi(g)) = n + 1 \). Since \( \varphi \) is an epimorphism we see that there exist \( x, y \in \pi \) with \( g = x \cdot y \) such that \( \ell(\varphi(x)) = n \) and \( \ell(\varphi(y)) = 1 \). By induction we know that \( x \) and \( y \) lie in the image of \( \psi \). But then so does \( g = x \cdot y \).

It remains to show that \( \psi \) is also a monomorphism. Thus let \( h \in \ker(\psi) \). Since \( \varphi \) restricts to a surjective map \( \tilde{G} \setminus \tilde{A} \to G \setminus A \) we see that there exists a set \( S \) of coset representatives for \( \tilde{G} \setminus \tilde{A} \) with \( \varphi(S) \subset S \). Similarly there exists a set \( T \) of coset representatives for \( \tilde{G} \setminus \tilde{B} \) with \( \varphi(T) \subset T \). By the Normal Form Theorem \[21.25\] we can write \( h = \tilde{g} \cdot \tilde{c}_1 \cdots \tilde{c}_k \) with \( \tilde{g} \in \tilde{G} \) and \( \tilde{c}_1, \ldots, \tilde{c}_k \in \tilde{S} \cup \tilde{T} \). Note that

\[
e = \varphi(e) = \varphi(\psi(h)) = \varphi(\tilde{g}) \cdot \varphi(\tilde{c}_1) \cdots \varphi(\tilde{c}_k) \in A \ast_G B.
\]

It follows immediately from the uniqueness statement of the Normal Form Theorem \[21.25\] that \( k = 0 \), i.e. we see that \( h = \tilde{g} \in \tilde{G} \). But the restriction of \( \psi : \tilde{A} \ast \tilde{G} \tilde{B} \to \pi \) to \( \tilde{G} \) is of course just the inclusion \( \tilde{G} \to \pi \), in particular the restriction is a monomorphism. Thus we see that \( h = e \).

\[
\square
\]

**Exercises for Chapter \[21\]**

**Exercise 21.1.** Let \( \pi \) be a group and let \( A, B \subset \pi \) be two subsets of \( \pi \). Show that there exists a natural isomorphism between \( (\pi/\langle A \rangle)/\langle B \rangle \) and \( \pi/\langle A \cup B \rangle \).

**Exercise 21.2.** Let \( \pi \) be a finitely generated group. Show that every finite-index subgroup is also finitely generated.
Remark. In Proposition 37.15 we will prove the more subtle result that every finite-index subgroup of a finitely presented group is finitely presented.

Exercise 21.3. Let $\pi$ be a finitely generated group and let $G$ be a finite group. Show that the set $\text{Hom}(\pi, G)$ of homomorphisms from $\pi$ to $G$ is a finite set.

Exercise 21.4.
(a) Show that $\langle x_1, \ldots, x_k \mid x_k \rangle \cong \langle x_1, \ldots, x_{k-1} \rangle$.
(b) Show that in the group $\langle x, y \mid xyx^{-1}y^{-1} \rangle$ we have the equalities $yx^{-1} = x^{-1}y$ and $x^{-1}y^{-1} = y^{-1}x^{-1}$.

Exercise 21.5.
(a) Let $k \geq 5$. Determine the abelianization of the permutation group $S_k$.
(b) Let $G$ be an abelian group, let $\alpha: G \to A$ and $\beta: G \to B$ be epimorphisms. Show that $A \ast_G B$ is also abelian.

Exercise 21.6. Given a group $G$ we denote by $G_{ab}$ its abelianization.
(a) Let $\varphi: A \to B$ be an epimorphism. Show that the induced map $A_{ab} \to B_{ab}$ is also an epimorphism.
(b) Let $\varphi: A \to B$ be a monomorphism. Is the induced map $A_{ab} \to B_{ab}$ also a monomorphism?

Exercise 21.7. Given any $l, m, n \in \mathbb{N}$. We consider the von Dyck group
$$T(l, m, n) := \langle a, b \mid a^l, b^m, (ab)^n \rangle.$$
Show that $T(l, m, n)_{ab} \cong \mathbb{Z}_{\gcd(l,m,n)}$.

Remark. It follows in particular that if $l, m, n$ are coprime, then the abelianization is trivial. If $\frac{1}{l} + \frac{1}{m} + \frac{1}{n} < 1$, then it follows from Corollary 33.22 together with Lemma 33.21 that the von Dyck group $T(l, m, n)$ is nonetheless infinite.

Exercise 21.8. Let $\varphi: \langle x, y \rangle \to \mathbb{Z}^2$ be the epimorphism that is given by $\varphi(x) = (1, 0)$ and $\varphi(y) = (0, 1)$. Show that the kernel $\ker(\varphi)$ is normally generated by the commutator $[x, y] = xyx^{-1}y^{-1}$.

Exercise 21.9. Let $\varphi: G \to A$ and $\psi: G \to B$ group monomorphisms which we use to define the amalgamated product $A \ast_G B$. Suppose that the map $A \to A \ast_G B$ is an isomorphism. Show that $\psi$ is an isomorphism.

Exercise 21.10. Let $G$ be a group. Let $\alpha: G \to A$ be a monomorphism to a simple group $A$ and let $\beta: G \to B$ be an epimorphism that is not an isomorphism. Show that the amalgamated product $A \ast_G B$ is trivial.

Exercise 21.11. Let $A$ and $G$ be groups and let $\varphi: A \to G$ be an epimorphism. Furthermore let $G'$ be a copy of $G$. We consider the amalgamated product $G \ast_A G'$ given by using twice the epimorphism $\varphi': A \to G$ and $\varphi: A \to G' = G$. Show that the natural homomorphism $G \to G \ast_A G'$ is an isomorphism.
Exercise 21.12.
(a) Let \( \alpha : G \to A \) and \( \beta : G \to B \) be group homomorphisms and let \( \varphi : H \to G \) be an epimorphism. Show that the natural map \( A \ast_G B \to A \ast_H B \) is an isomorphism.
(b) Let \( \alpha : G \ast H \to A \) and \( \beta : G \ast H \to B \) be group homomorphisms. We assume that the restriction of \( \beta \) to \( H \) is trivial. Show that the natural map \( A \ast_{G \ast H} B \to A/\langle \langle H \rangle \rangle \ast_G B \) is an isomorphism.

Exercise 21.13. Let \( X \) be a path-connected topological space and let \( x_0 \in X \). Furthermore let \( C \subset X \) be a subset that is homeomorphic to \( S^1 \). We pick a homeomorphism \( \varphi : S^1 \to C \) and a path \( \gamma : [0, 1] \to X \) from \( x_0 \) to \( \varphi(1) \). We denote by \( \widetilde{\gamma} : [0, 1] \to X \) the map that is given by \( t \mapsto \varphi(e^{2\pi i t}) \). Show that the subgroup
\[
\langle \langle C \rangle \rangle := \langle \langle \gamma \ast \varphi \ast \widetilde{\gamma} \rangle \rangle \subset \pi_1(X, x_0)
\]
neither depends on the choice of \( \varphi \) nor on the choice of \( \gamma \).

![Figure 400. Illustration for Exercise 21.13.](image)

Exercise 21.14. Let \( \pi \) be a group and let \( S \) be a generating set for \( \pi \). We set \( V := \pi \), we set \( E := V \times S \) and we define the initial map \( i : E = V \times S \to V \) by \( i((v, s)) = v \) and we define the terminal map \( t : E = V \times S \to V \) by \( t((v, s)) = v \cdot s \). Note that \( (V, E, i, t) \) is an abstract graph. It is called the Cayley graph \( \Gamma(\pi, S) \) of the group \( \pi \) with respect to the generating set \( S \).

(a) We consider \( \pi = \langle x, y \mid x y x^{-1} y^{-1} \rangle \) with the generating set \( S = \{x, y\} \). Sketch \(|\Gamma(\pi, S)|\) as a subset of \( \mathbb{R}^2 \).
(b) We consider \( \pi = \langle x, y \mid \varnothing \rangle \) with the generating set \( S = \{x, y\} \). Sketch \(|\Gamma(\pi, S)|\) as a subset of \( \mathbb{R}^2 \).
(c) We consider \( \pi = \langle x, y \mid x^2, x y x^{-1} y^{-1} \rangle \) with the generating set \( S = \{x, y\} \). Sketch \(|\Gamma(\pi, S)|\) as a subset of \( \mathbb{R}^3 \).

Exercise 21.15. Let \( K = \mathbb{R} \) or \( K = \mathbb{C} \). Let \( n \in \mathbb{N} \).
(a) Show that the abelianization of \( \text{SL}(n, K) \) is the trivial group.
   \( \text{Hint.} \) Try to write the elementary matrices as commutators.
(b) Determine the abelianization of \( \text{GL}(n, K) \).

\( \text{Remark.} \) A group with trivial abelianization is sometimes called \textit{perfect}. We have thus shown that the groups \( \text{SL}(n, K) \) are perfect.
22. The General Seifert–van Kampen Theorem

In this chapter we will generalize the “basic” Seifert–van Kampen Theorem \(^{20.2}\) to the setting where we no longer need to assume that the intersection \(U \cap V\) is simply connected. We will use the resulting Seifert–van Kampen Theorem \(^{22.1}\) to determine the fundamental groups of the (non-) orientable surfaces \(\Sigma_g\) and \(N_g\). In Chapter \(^{23}\) we will use these calculations to give the classification of compact 2-dimensional smooth and topological manifolds.

Towards the end of this chapter we will use the Seifert–van Kampen Theorem \(^{22.1}\) to prove Proposition \(^{22.10}\) which says, in a nutshell, that every finitely presented group occurs as the fundamental group of a closed smooth manifold of dimension \(\geq 4\).

22.1. The formulation of the general Seifert–van Kampen Theorem. With the group theoretic preparations from Chapter \(^{21}\) we can now formulate and prove the general Seifert–van Kampen Theorem.

**Theorem 22.1. (Seifert–van Kampen)** Let \(X\) be a topological space and let \(X = U \cup V\) be a decomposition of \(X\) in two open subsets \(U\) and \(V\) such that \(U \cap V\) is non-empty and path-connected. Let \(x_0 \in U \cap V\). Then there exists an isomorphism

\[
\Phi: \pi_1(U, x_0) \ast_{\pi_1(U \cap V, x_0)} \pi_1(V, x_0) \xrightarrow{\cong} \pi_1(X, x_0)
\]

such that the following diagram commutes:

\[
\begin{array}{ccc}
\pi_1(U \cap V, x_0) & \xrightarrow{} & \pi_1(U, x_0) \\
\downarrow & & \downarrow \\
\pi_1(V, x_0) & \xrightarrow{} & \pi_1(U, x_0) \ast_{\pi_1(U \cap V, x_0)} \pi_1(V, x_0) \\
\Phi & \cong & \pi_1(X, x_0).
\end{array}
\]

Here all the “undecorated” maps are the obvious inclusion induced homomorphisms.

![Figure 401. Illustration of Theorem 22.1](image)

\[\pi_1(X, x_0) \cong \pi_1(U, x_0) \ast_{\pi_1(U \cap V, x_0)} \pi_1(V, x_0)\]

The proof of the general Seifert–van Kampen Theorem is a modification of the proof of the more “basic” Seifert–van Kampen Theorem \(^{20.2}\) where we had assumed that \(U \cap V\) is in fact simply connected. We only sketch the proof of the general Seifert–van Kampen Theorem \(^{22.1}\) The full details are for example given in Section 1.2 of [Hat02].
Sketch of the proof. The various inclusions of topological spaces give rise to the following commutative diagram:

\[
\begin{array}{ccc}
\pi_1(U \cap V, x_0) & \xrightarrow{i} & \pi_1(U, x_0) \\
\downarrow j & & \downarrow k \\
\pi_1(V, x_0) & \xrightarrow{l} & \pi_1(V, x_0) \\
\downarrow & & \downarrow \Phi \\
\pi_1(X, x_0) & & \pi_1(X, x_0).
\end{array}
\]

By Proposition 21.21 there exists a unique homomorphism

\[\Phi : \pi_1(U, x_0) * \pi_1(U \cap V, x_0) \pi_1(V, x_0) \to \pi_1(X, x_0)\]

such that the following diagram commutes:

\[
\begin{array}{ccc}
\pi_1(U \cap V, x_0) & \xrightarrow{i} & \pi_1(U, x_0) \\
\downarrow j & & \downarrow k \\
\pi_1(V, x_0) & \xrightarrow{l} & \pi_1(U, x_0) * \pi_1(U \cap V, x_0) \pi_1(V, x_0) \\
\downarrow & & \downarrow \Phi \\
\pi_1(X, x_0) & & \pi_1(X, x_0).
\end{array}
\]

It remains to show that \(\Phi\) is surjective and that \(\Phi\) is injective.

We first show surjectivity. We consider the following commutative diagram of homomorphisms

\[
\begin{array}{ccc}
\pi_1(U, x_0) * \pi_1(U \cap V, x_0) \pi_1(V, x_0) & & \\
\downarrow \Phi & & \\
\pi_1(U, x_0) * \pi_1(V, x_0) & & \pi_1(X, x_0).
\end{array}
\]

By Lemma 20.1 the horizontal map is surjective. It follows that the diagonal map \(\Phi\) on the right is also surjective.

Now we turn to the proof of the injectivity of \(\Phi\). We write \(A = \pi_1(U, x_0), B = \pi_1(V, x_0)\) and \(G = \pi_1(U \cap V, x_0)\). As on page 594 we consider the set

\[S(A, B) := \{\text{all finite sequences } (x_1, \ldots, x_k) \text{ with each } x_i \text{ in } A \text{ or } B\}.
\]

Furthermore we denote by \(\sim_G\) the equivalence relation on \(S(A, B)\) generated by the relation

\[(x_1, \ldots, x_l, e, x_{l+2}, \ldots, x_k) \sim (x_1, \ldots, x_l, x_{l+2}, \ldots, x_k)\]

where \(e\) is trivial in \(A\) or \(B\), by the relation

\[(x_1, \ldots, x_l, x_{l+1}, \ldots, x_k) \sim (x_1, \ldots, x_l, x_{l+1}, \ldots, x_k)\]

if both \(x_l\) and \(x_{l+1}\) lie in \(A\) or both lie in \(B\), and also by the relation

\[(x_1, \ldots, x_l, i(g), x_{l+2}, \ldots, x_k) \sim (x_1, \ldots, x_l, j(g), x_{l+2}, \ldots, x_k)\]

What are the maps, and why does the diagram commute?
for \( g \in G \). Similar to Proposition 19.17, one can now show that the map

\[
S(A, B) / \sim_G \rightarrow A * G B
\]

\[
[(x_1, \ldots, x_k)] \mapsto x_1 \cdots x_k
\]

is a well-defined bijection. We will use this isomorphism to identify \( S(A, B) / \sim_G \) with \( A * G B \).

The proof of the present theorem is now almost identical to the proof of Theorem 20.2, one just needs to replace the discussion involving \( S(A, B) / \sim \) by the corresponding objects in \( S(A, B) / \sim_G \). More precisely, in Footnote 355 we pointed out where in the proof of Theorem 20.2 we used the hypothesis that \( U \cap V \) is simply connected. At that point in the proof of Theorem 20.2 we need to replace \( A * B = S(A, B) / \sim \) with \( A * G B = S(A, B) / \sim_G \).

Full details for the proof can be found for example in Section 1.2 of [Hat02].

The same way that we deduced Theorem 20.10 from Theorem 20.2, we can now obtain the following theorem from Theorem 22.1.

**Theorem 22.2. (Seifert–van Kampen Theorem for Topological Manifolds)** Let \( M \) be an \( m \)-dimensional topological manifold and let \( R, S \subset M \) be two \( m \)-dimensional submanifolds such that the following hold:

1. \( M = R \cup S \),
2. \( R \cap S \) is a component of \( \partial R \) and it is a component of \( \partial S \),
3. \( R \) and \( S \) are closed subsets of \( M \).

We pick a base point \( x_0 \in R \cap S \). Then the inclusion induced map

\[
\pi_1(R, x_0) * \pi_1(R \cap S, x_0) \pi_1(S, x_0) \rightarrow \pi_1(M, x_0)
\]

is an isomorphism.

**Example.** Given \( n \in \mathbb{N}_0 \) we denote as usual by \( S^n_{\leq 0} \) the upper hemisphere of \( S^n \) and we denote by \( S^n_{\geq 0} \) the lower hemisphere of \( S^n \). We denote by \( S^n_{=0} = S^n_{\geq 0} \cap S^n_{\leq 0} \) the “equator” of \( S^n \), which is of course homeomorphic to \( S^{n-1} \). Given any \( n \in \mathbb{N}_{\geq 2} \) and any \( P \in S^n_{=0} \) we can perform the following calculation:

by page 116 the hemispheres are homeomorphic to \( \mathbb{B}^n \), hence the fundamental groups are trivial

\[
\pi_1(S^n, P) \cong \pi_1(S^n_{\leq 0}, P) * \pi_1(S^n_{\geq 0}, P) \cong \{ e \} * \pi_1(S^{n-1}, P) \{ e \} \cong \{ e \}.
\]

by the Seifert–van Kampen Theorem 22.2, note that we use by definition or by Lemma 21.22 that our hypothesis \( n \in \mathbb{N}_{\geq 2} \) implies that \( S^{n-1} \) is path-connected

This calculation gives a new, and arguably more conceptual proof of Proposition 14.14.
22.2. The fundamental groups of surfaces. Now we want to use the Seifert–van Kampen Theorem \[22.1\] to determine the fundamental groups of surfaces of genus \( g \geq 2 \). Before we do so we consider the torus, the Klein bottle and the real projective plane to gain some confidence in our newly acquired methods.  

(1) We first consider the torus \( T = \left( [0, 1] \times [0, 1] \right) / \sim \). In the following we will use the following notation, see also Figure \[403\] for an illustration: 

(a) We denote by \( Q \) the point on \( T \) corresponding to the four vertices of the square. 
(b) We write \( T = U \cup V \) where 

\[
U = T \setminus B_{\frac{1}{2}}(\frac{1}{2}, \frac{1}{2}) \subset T \quad \text{and} \quad V = B_{\frac{1}{4}}(\frac{1}{2}, \frac{1}{2}) \subset T,
\]

i.e. \( U \) is the complement of a closed disk and \( V \) is an open disk and \( U \cap V \) is an open annulus.
(c) We let \( P = (r, r) \in U \cap V \) and we denote by \( p \) the direct path from \( Q \) to \( P \).
(d) We pick a loop \( \gamma \) in \((U \cap V, P)\) that “goes counterclockwise around the annulus” and that represents a generator of the infinite cyclic group \( \pi_1(U \cap V, P) \cong \mathbb{Z} \).
(e) We denote by \( x \) and \( y \) the two loops in \((T, Q)\) corresponding to the horizontal and the vertical edge of the square. By a slight abuse of notation we denote the corresponding elements in \( \pi_1(T, Q) \) by \( x \) and \( y \) as well.

\[
\begin{align*}
\pi_1(T, P) &\cong \pi_1(U, P) *_{\pi_1(U \cap V, P)} \pi_1(V, P) \quad = \pi_1(U, P) *_{\pi_1(U \cap V, P)} \{e\} \\
& = \pi_1(U, P) / \langle \langle i_*(\pi_1(U \cap V, P)) \rangle \rangle \quad = \pi_1(U, P) / \langle \langle [\gamma] \rangle \rangle \\
& \quad \overset{\text{by Lemma } \[21.22\]}{= A / \langle \langle \alpha(G) \rangle \rangle} \quad \text{since } \pi_1(U \cap V, P) = \langle [\gamma] \rangle \\
& \quad \overset{\text{by Proposition } \[14.11\]}{= \pi_1(U, Q) / \langle \langle [p * \gamma * \overline{p}] \rangle \rangle} \quad \text{since } p * \gamma * \overline{p} \text{ is path-homotopic to } xyx^{-1}y^{-1} \\
& \quad \overset{\text{rise to an isomorphism } p_*}{\cong \pi_1(U, Q) / \langle \langle xyx^{-1}y^{-1} \rangle \rangle} \quad = \langle \gamma \rangle.
\end{align*}
\]

The following examples can also be handled using Theorem \[22.2\] instead of Theorem \[22.1\]. The advantage of using Theorem \[22.1\] at this point is that in the illustrations one can draw \( U \cap V \) better if \( U \) and \( V \) are open subsets.

Since \( U \cap V \) is an open annulus its fundamental group is isomorphic to \( \mathbb{Z} \).
As in the proof of Lemma 20.9 we can show that \( W := \partial([0,1] \times [0,1]) \) is a deformation retract of \( U \) and that \( W \) is homeomorphic to the wedge of two circles. By Lemma 20.4 we can therefore make the identification \( \pi_1(W, P) = \langle x, y \rangle \), see also Figure 404. Now we continue with the above calculation of \( \pi_1(T, P) \). We have

\[
(*) \quad = \pi_1(U, Q)/\langle \langle xyx^{-1}y^{-1} \rangle \rangle \xrightarrow{\sim} \pi_1(W, P)/\langle \langle xyx^{-1}y^{-1} \rangle \rangle \xrightarrow{\sim} \pi_1(T, P)
\]

by Lemma 18.14 and Proposition 18.16 (2)

\[
= \langle x, y \rangle/\langle \langle xyx^{-1}y^{-1} \rangle \rangle = \langle x, y \mid [x, y] \rangle \xrightarrow{\sim} \mathbb{Z}^2.
\]

Thus we have reproved that the fundamental group of the torus is isomorphic to the free abelian group \( \mathbb{Z}^2 \).

\[\text{Figure 404}\]

(2) We turn to the Klein bottle \( K \). The approach to calculating the fundamental group of the Klein bottle is almost identical to the above approach to calculating the fundamental group of the torus. We just replace the situation illustrated in Figure 404 by the situation illustrated in Figure 405. The same argument as above shows that

\[\pi_1(K) \cong \langle x, y \mid yxyx^{-1} \rangle.\]

Using this presentation and using Proposition 21.20 (5) we obtain in particular that the abelianization of \( \pi_1(K) \) is given by

\[\pi_1(K)_{ab} \cong \langle x, y \mid yxyx^{-1} \rangle_{ab} \cong \mathbb{Z}^2/\left(\mathbb{Z}/2\right) \cong \mathbb{Z} \oplus \mathbb{Z}._2.\]

On page 518 we already gave a very different calculation of \( \pi_1(K) \). More precisely, we introduced the group \( G \) that is given by all self-homeomorphisms of \( \mathbb{R}^2 \) that can be written as concatenations of the two self-homeomorphisms

\[
A: \mathbb{R}^2 \to \mathbb{R}^2 \quad (s, t) \mapsto (s + 1, 1 - t) \quad \text{and} \quad B: \mathbb{R}^2 \to \mathbb{R}^2 \quad (s, t) \mapsto (s, t + 1)
\]

and their inverses and we showed that \( \pi_1(K) \cong G \). On page 630 we already showed that there exists a homomorphism \( \Phi: \langle x, y \mid yxyx^{-1} \rangle \to G \) with \( \Phi(x) = B^{-1}A \) and \( \Phi(y) = B \). This homomorphism is in fact an isomorphism. This can be seen as

\[\text{In particular this shows that } \pi_1(K) \text{ is finitely presented. This answers the question we had raised on page 631}\]
follows. Denote by $H$ the group of all self-homeomorphisms of $\mathbb{R}^2$. We consider the diagram

$$\langle x, y \mid yxyx^{-1} \rangle \xrightarrow{\cong} \pi_1(K) \xleftarrow{\cong} \Phi \cong \text{subgroup of } H \text{ generated by } A, B.$$ 

Here the isomorphisms to $\pi_1(K)$ are the ones given by the two calculations of the fundamental group. If one goes carefully through the definitions of the two horizontal maps, then one can see that the diagram commutes. Since two of the three maps are isomorphisms and since the diagram commutes it follows that $\Phi$ is also an isomorphism.

![Diagram of the Klein bottle](image)

**Figure 405**

(3) Next we consider again the real projective space $\mathbb{R}P^2$. Here we use the description of $\mathbb{R}P^2$ from Lemma 3.42 as

$$\mathbb{R}P^2 = \mathbb{B}^2 / \sim \quad \text{where for } z \in S^1 \text{ we have } z \sim -z.$$ 

As in the previous two examples we decompose $\mathbb{R}P^2$ into an open disk $V$ and the complement of a closed disk $U$ such that $U \cap V$ is an annulus. We consider the base point $Q = [1] = [-1] \in \mathbb{R}P^2$ and we denote by $\alpha$ the loop

$$\alpha : [0, 1] \to \mathbb{R}P^2 \quad t \mapsto [e^{i\pi t}].$$ 

By a slight abuse of notation we now denote by $\alpha$ also the corresponding element in $\pi_1(\mathbb{R}P^2, Q)$. Furthermore we denote by $W$ the image of $\alpha$ in $\mathbb{R}P^2$. Evidently $\alpha$ is a generator of $\pi_1(W, Q)$. Then, with similar arguments as in the torus case, we see that

$$\pi_1(\mathbb{R}P^2) \cong \pi_1(U, Q) / \langle p \ast \gamma \ast \overline{p} \rangle \cong \pi_1(W, Q) / \langle p \ast \gamma \ast \overline{p} \rangle \cong \langle \alpha \rangle / \langle \alpha^2 \rangle \cong \mathbb{Z}_2.$$ 

Seifert–van Kampen Theorem 22.1 and Lemma 21.22 (2) since $W$ is a deformation retract of $U$ and $\pi_1(W, Q) = \langle \alpha \rangle$ and $[p \ast \gamma \ast \overline{p}] = \alpha^2$

In particular we obtain the same result, as we should, as in Corollary 16.18

(4) Now that we have gained some confidence that the approach of determining fundamental groups using Seifert–van Kampen Theorem 22.1 does indeed give the right fundamental groups we turn to the surfaces of higher genus that we could not handle with our previous methods.

So let us consider the surface $F = E_8 / \sim$ of genus 2. As in the torus case we write $F = U \cup V$ where $V$ is an open disk and where $U$ is the complement of a closed disk.
such that $U \cap V$ is an annulus. Similar to the torus case we write $W = \partial E_8/\sim$. By the proof of Proposition 20.8 we know that $W$ is a deformation retraction of $U$ and that $W$ is homeomorphic to the wedge of four circles corresponding to $x_1, y_1, x_2, y_2$. See also Figures 407 and 408 for an illustration. Basically exactly the same argument

as in the torus case shows that

$$\pi_1(E_8/\sim, P) \cong \pi_1(U, Q)/\langle [x_1y_1, x_1^{-1}y_1^{-1}, x_2y_2, x_2^{-1}y_2^{-1}]_{= [x_1y_1][x_2y_2]} \rangle$$

$$\cong \pi_1(W, Q)/\langle [x_1, y_1][x_2, y_2] \rangle$$

$$\cong \langle x_1, y_1, x_2, y_2 \rangle/\langle [x_1, y_1][x_2, y_2] \rangle = \langle x_1, y_1, x_2, y_2 \mid [x_1, y_1][x_2, y_2] \rangle.$$

Thus we have finally succeeded in calculating the fundamental group of the surface of genus 2.

The following gives in particular a new proof for Proposition 20.8.
Proposition 22.3.

(1) For any \( g \in \mathbb{N}_0 \) we have
\[
\pi_1(\text{surface } \Sigma_g \text{ of genus } g) \cong \langle x_1, y_1, \ldots, x_g, y_g \mid [x_1, y_1] \cdots [x_g, y_g] \rangle
\]
and we have
\[
\pi_1(\text{surface of genus } g)_{ab} \cong \mathbb{Z}^{2g}.
\]

(2) For \( g \neq h \) the surfaces of genus \( g \) and \( h \) are not homeomorphic.

**Proof.**

(1) Let \( g \in \mathbb{N}_0 \). For \( g = 0 \) we obtain the fundamental group from Proposition 14.14 and for \( g = 1 \) we obtain the presentation from the discussion on page 656. For \( g \geq 2 \) the presentation follows from a straightforward generalization of the calculation preceding the proposition. Finally the stated abelianization of the fundamental group is an immediate consequence of Proposition 21.20 (5).

(2) For \( g \neq h \) we obtain from the above calculation and from the classification of finitely generated abelian groups that we gave in Theorem 19.4 that the abelianizations of the fundamental groups of the surfaces of genus \( g \) and \( h \) are not isomorphic. Hence the surfaces are not homeomorphic. \( \blacksquare \)

**Remark.**

(1) In Figure 409 we show loops that represent the generators \( x_1, y_1, x_2, y_2 \) of the fundamental group for the surface of genus 2.

![Figure 409](image)

**Figure 409**

(2) As explained in Figure 220 we can view the surface \( \Sigma \) of genus 2 as the connected sum of two copies of the torus \( T \). We can also use this point of view to determine the fundamental group of the surface \( \Sigma \) of genus 2. More precisely, we have \( \Sigma = F_1 \cup F_2 \) with \( F_1 = T \setminus B^2 \) and \( F_2 = T \setminus B^2 \) where \( F_1 \cap F_2 = \partial F_1 = \partial F_2 \cong S^1 \) and we obtain that\(^{304}\)

\[
\pi_1(\Sigma) \cong \pi_1(F_1) \ast_{\pi_1(F_1 \cap F_2)} \pi_1(F_2) \cong \langle x_1, y_1 \rangle \ast \langle x_2, y_2 \rangle
\]

\[
\cong \langle x_1, x_2, y_1, y_2 \mid [x_1, y_1] = [x_2, y_2] \rangle.
\]

\(^{304}\)Why is this group isomorphic to the above group \( \langle x_1, y_1, x_2, y_2 \mid [x_1, y_1][x_2, y_2] \rangle \)?
Let \( g \geq 2 \) and let \( \pi \) be the fundamental group of the surface of genus \( g \). We have just shown that \( \pi_{\text{ab}} \cong \mathbb{Z}^{2g} \). This raises the question, whether perhaps \( \pi \) is isomorphic to \( \mathbb{Z}^{2g} \) or to the free group \( F_{2g} \) on \( 2g \) generators. The proof of the following lemma is Exercise 22.1

**Lemma 22.4.** The group \( \pi = \langle x_1, y_1, \ldots, x_g, y_g \mid [x_1, y_1] \cdots [x_g, y_g] \rangle \) is non-abelian.

The lemma says in particular that \( \pi \) is not isomorphic to \( \mathbb{Z}^{2g} \). It is much harder to determine whether or not \( \pi \) is a free group. We record this as a question for later.

**Question 22.5.** Let \( \pi \) be the fundamental group of the surface of genus \( g \). Is \( \pi \) isomorphic to the free group \( F_{2g} \) on \( 2g \) generators?

We will give an answer to the question in Proposition 31.17 and also on page 1371.

Let \( \pi \) be the fundamental group of the surface of genus \( g \). In Exercise 22.3 we will see that if \( g \geq 2 \), then \( \pi \) contains a free group on two generators as a subgroup. This raises the question, what other groups can occur as subgroups of \( \pi \)? Let us record this as a question.

**Question 22.6.** Let \( \pi \) be the fundamental group of the surface of genus \( g \). What isomorphism types of subgroups can appear? Is every subgroup again a free group or the fundamental group of a surface?

We will provide the answer to Question 22.6 in Proposition 31.6.

### 22.3. Non-orientable surfaces

In this section we will discuss the fundamental groups of the non-orientable surfaces \( N_g \) of some genus \( g \in \mathbb{N} \). It is also worth recalling that in Exercise 8.21 we showed that the connected sum of \( g \) copies of \( \mathbb{R}P^2 \) is diffeomorphic to the non-orientable surface of genus \( g \) that we introduced on page 206.

\[
\begin{array}{ccc}
\mathbb{R}P^2 & \# & \mathbb{R}P^2 \\
\text{non-orientable surface } N_3 \text{ of genus } 3 & \text{is diffeomorphic to} & \text{Figure 410}
\end{array}
\]

The following proposition is the analogue of Proposition 22.3.

**Proposition 22.7.**

1. For any \( g \in \mathbb{N} \) we have
   \[
   \pi_1(\text{non-orientable surface } N_g \text{ of genus } g) \cong \langle x_1, \ldots, x_g \mid x_1^2 \cdots x_g^2 \rangle
   \]
   and we have
   \[
   \pi_1(\text{non-orientable surface } N_g \text{ of genus } g)_{\text{ab}} \cong \mathbb{Z}^{g-1} \oplus \mathbb{Z}_2.
   \]
2. For \( g \neq h \) the non-orientable surfaces of genus \( g \) and \( h \) are not homeomorphic.

**Proof.**

1. Let \( g \in \mathbb{N} \). Recall that the non-orientable surface of genus one is by definition the real projective plane. In Corollary 16.18 we saw that \( \pi_1(\mathbb{R}P^2) \cong \mathbb{Z}_2 \cong \langle x \mid x^2 \rangle \). The case \( g \geq 2 \) follows from a straightforward modification of the calculation of
the fundamental group of the surface of genus 2 that we gave on page 658. Using Figure 411 the reader should have no troubles with assembling a full argument. Finally note that the stated abelianization of the fundamental group is an immediate consequence of Proposition 21.20 (5).

(2) For \( g \neq h \) we obtain from the above calculation and from the classification of finitely generated abelian groups that we gave in Theorem 19.4 that the abelianizations of the fundamental groups of the non-orientable surfaces of genus \( g \) and \( h \) are not isomorphic. Hence the non-orientable surfaces of genus \( g \) and \( h \) are not homeomorphic. ■

![Figure 411. Illustration for the proof of Proposition 22.7](image)

As mentioned above, in Exercise 8.21 we showed that for any \( g \in \mathbb{N} \) the non-orientable surface of genus \( g \) is diffeomorphic to the connected sum of \( g \) copies of \( \mathbb{R}P^2 \). In particular the Klein bottle is diffeomorphic to \( \mathbb{R}P^2 \# \mathbb{R}P^2 \). Just for fun and for practice we provide the direct calculation of the fundamental group of \( \mathbb{R}P^2 \# \mathbb{R}P^2 \) using the Seifert–van Kampen Theorem 22.2 for Smooth Manifolds. The calculation is somewhat interesting since it involves some interesting maps between fundamental groups.

Lemma 22.8. We have

\[
\pi_1(\mathbb{R}P^2 \# \mathbb{R}P^2) \cong \langle x, y \mid x^2 = y^2 \rangle.
\]

Proof. In order to distinguish the two copies of \( \mathbb{R}P^2 = B^2/\sim \) we write \( P = \mathbb{R}P^2 \) and \( Q = \mathbb{R}P^2 \). The proof is of course a variation on the proof of Proposition 20.12. We have

\[
\pi_1(\mathbb{R}P^2 \# \mathbb{R}P^2) = \pi_1(P \# Q) \cong \pi_1(P \setminus \frac{1}{2}B^2) \ast_{\pi_1(\frac{1}{2}S^1)} \pi_1(Q \setminus \frac{1}{2}B^2).
\]

by the definition of \( P \# Q \) and the Seifert–van Kampen Theorem 22.2.

We pick a generator \( g \) for \( \pi_1(\frac{1}{2}S^1) \). In the calculation of the fundamental group of the real projective plane on page 657 we saw that \( \pi_1(P \setminus \frac{1}{2}B^2) \cong \langle x \rangle \) and that the inclusion induced map \( \pi_1(\frac{1}{2}S^1) \to \pi_1(P \setminus \frac{1}{2}B^2) \) is given by \( g \mapsto x^2 \). Evidently the same holds for \( Q \) with \( \pi_1(Q \setminus \frac{1}{2}B^2) \cong \langle y \rangle \). Summarizing we see that

\[
\pi_1(\mathbb{R}P^2 \# \mathbb{R}P^2) \cong \pi_1(P \setminus \frac{1}{2}B^2) \ast_{\pi_1(\frac{1}{2}S^1)} \pi_1(Q \setminus \frac{1}{2}B^2)
\]

\[
\cong \text{amalgamated product of } \left( \langle g \rangle \to \langle x \rangle \text{ and } \langle g \rangle \to \langle y \rangle \right).
\]

\[
\cong \langle x, y \mid x^2 = y^2 \rangle = \langle x, y \mid x^2y^{-2} \rangle.
\]

Lemma 21.23.
We have thus shown that $\pi_1(\mathbb{RP}^2 \# \mathbb{RP}^2) \cong \langle x, y \mid x^2 = y^2 \rangle$.

We conclude this section with a short discussion of the properties of fundamental groups of compact 2-dimensional smooth manifolds. We recall that the fundamental group of the real projective space $\mathbb{RP}^2$ is isomorphic to $\mathbb{Z}_2$, therefore it is torsion and in particular it is not torsion-free. It is less clear whether or not the fundamental groups of the other 2-dimensional smooth manifolds are torsion-free. More precisely, we have the following question.

**Question 22.9.**

1. Let $g \in \mathbb{N}$. Is the fundamental group $\pi_1(\text{surface of genus } g) \cong \langle x_1, y_1, \ldots, x_g, y_g \mid [x_1, y_1] \cdots [x_g, y_g] \rangle$ torsion-free?
2. Let $k \geq 2$. Is the fundamental group $\pi_1(k \cdot \mathbb{RP}^2) \cong \langle x_1, \ldots, x_k \mid x_1^2, \ldots, x_k^2 \rangle$ torsion-free?

We will come back to this question in Exercise 25.10, Corollary 31.7 and Proposition ??.

### 22.4. Fundamental groups of high-dimensional smooth manifolds.

Later on, in Proposition 64.6, we will see that the fundamental group of a compact connected smooth manifold is necessarily finitely presented. In this section we want to study the converse: which finitely presented groups can occur as fundamental groups of smooth manifolds?

First note that it follows from Theorem 7.5 that only the trivial group and $\mathbb{Z}$ occur as the fundamental group of a compact connected 1-dimensional topological manifold. Similarly, we will see shortly in Theorem 23.4 that only “few” finitely presented groups occur as the fundamental group of compact connected 2-dimensional topological manifold. In contrast we will now see that once we go to dimension $\geq 4$ any finitely presented group occurs as the fundamental group of a closed orientable smooth manifold.

**Proposition 22.10.** Let $\pi$ be a finitely presented group. Given any $n \geq 4$ there exists a closed orientable connected non-empty $n$-dimensional smooth manifold $M$ with $\pi_1(M) \cong \pi$.

**Remark.**

1. We will give an alternative proof of Proposition 22.10 on page 2550.
2. Proposition 22.10 is a key ingredient of the proof of the fact, stated in Theorem 28.4, that closed smooth manifolds of a fixed dimension $\geq 4$ cannot be classified.

The proof of Proposition 22.10 relies on two lemmas and one theorem. The first lemma is actually quite interesting in its own right.

**Lemma 22.11.** Let $W$ be a connected $n$-dimensional smooth manifold. Suppose we are given $k \in \mathbb{N}_0$ and a submanifold of the form $\overline{B}^{n-k} \times K$ where $K$ is diffeomorphic to $S^k$.

1. If $n \geq k + 3$, then for every base point $w_0 \in W \setminus (B^{n-1} \times K)$ the inclusion induced map $\pi_1(W \setminus (B^{n-1} \times K), w_0) \rightarrow \pi_1(W, w_0)$ is an isomorphism.
(2) If \( n = k + 2 \), then for every base point \( w_0 \in W \setminus (B^{n-1} \times K) \) the inclusion induced map \( \pi_1(W \setminus (B^{n-1} \times K), w_0) \to \pi_1(W, w_0) \) is an epimorphism.

**Proof of Lemma 22.11.** We write \( X = W \setminus (B^{n-k} \times K) \). Note that it follows from Proposition 15.11 that it suffices to prove the statement for some base point \( w_0 \in S^{n-k-1} \times K \).

First we consider the case that \( n \geq k + 3 \). Next note that we have the following two isomorphisms:

\[
\pi_1(X, w_0) \xrightarrow{\cong} \pi_1(X, w_0) \ast \pi_1(S^{n-k-1} \times K, w_0) \xrightarrow{\cong} \pi_1(B^{n-k} \times K, w_0) \xrightarrow{\cong} \pi_1(W, w_0).
\]

The map is an isomorphism by Lemma 21.22 (3a) and since the map \( \pi_1(S^{n-k-1} \times K, w_0) \to \pi_1(B^{n-k} \times K, w_0) \) is an isomorphism, note that for the latter statement we used that \( n \geq k + 3 \). Hence the inclusion induced map \( \pi_1(X, w_0) \to \pi_1(W, w_0) \) is indeed an isomorphism.

If \( n = k + 2 \), then the inclusion induced map \( \pi_1(S^{n-k-1} \times K) \to \pi_1(B^{n-k} \times K) \) is an epimorphism but no longer an isomorphism. If we now use Lemma 21.22 (3b) instead of Lemma 21.22 (3a) we see that \( \pi_1(X, w_0) \to \pi_1(W, w_0) \) is at the very least an epimorphism.

\[\blacklozenge\]

**Lemma 22.12.** Let \( W \) be an \( n \)-dimensional smooth manifold and suppose we are given a boundary component of the form \( S^{n-2} \times C \) where \( C \) admits a diffeomorphism \( \varphi : S^1 \to C \). We set

\[X := (W \cup (S^{n-2} \times B^2))/\sim\text{ where } (x, \varphi(y)) \sim (x, y) \text{ for } (x, y) \in S^{n-2} \times S^1.\]

If \( n \geq 4 \), then for any \( w_0 \in W \) the inclusion induced map \( \pi_1(W, w_0) \to \pi_1(X, w_0) \) induces an isomorphism \( \pi_1(W, w_0)/\langle\langle C \rangle\rangle \xrightarrow{\cong} \pi_1(X, w_0). \)

**Proof.** Note that it follows from Proposition 15.11 that it suffices to prove the statement for some base point \( w_0 \in S^{n-2} \times C \). Next note that we have the following two isomorphisms:

\[
\pi_1(W, w_0)/\langle\langle C \rangle\rangle \xrightarrow{\cong} \pi_1(W, w_0) \ast \pi_1(S^{n-2} \times C, w_0) \xrightarrow{\cong} \pi_1(S^{n-2} \times B^2, w_0) \xrightarrow{\cong} \pi_1(X, w_0).
\]

The map is an isomorphism by Lemma 21.22 (2), here we use that \( \pi_1(S^{n-2} \times B^2, w_0) = 0 \) and that \( \pi_1(S^{n-2} \times C, w_0) = \langle C \rangle \), Theorem 22.2 which we can apply by Proposition 8.15 note that for the latter statement we used that \( n \geq 4 \).

Since the horizontal maps are induced by the inclusions we see that the inclusion induced map \( \pi_1(W, w_0)/\langle\langle C \rangle\rangle \to \pi_1(X, w_0) \) is indeed an isomorphism.

\[\blacklozenge\]

\[\text{Here we use that Exercise 21.13 tells us that } C = \{0\} \times C \text{ gives us a well-defined normal subgroup } \langle\langle C \rangle\rangle.\]

The proof of Proposition 22.10 also requires the following theorem, which is a special case of Theorem 9.15.
**Theorem 22.13.** Let $M$ be a smooth manifold and let $\varphi : S^1 \sqcup \cdots \sqcup S^1 \to M$ be a map. If $\dim(M) \geq 3$, then $\varphi$ is homotopic to a smooth embedding $\psi : S^1 \sqcup \cdots \sqcup S^1 \to M$.

![Illustration of Theorem 22.13](image)

**Proof of Proposition 22.10.** Throughout the proof we will mostly ignore base points. But at the end of the proof we will argue, why being a little sloppy with base points in between does not affect the outcome.

Let $\pi = \langle g_1, \ldots, g_k \mid r_1, \ldots, r_l \rangle$ be a finitely presented group. Furthermore let $n \geq 4$.

We consider

$$X := \bigl( S^1 \times S^{n-1} \bigr)^k \cong \bigl( S^1 \times S^{n-1} \bigr) \ast \cdots \ast \bigl( S^1 \times S^{n-1} \bigr).$$

It follows basically from Proposition 8.33 that $X$ is a closed orientable connected $n$-dimensional smooth manifold.

We see that

$$\pi_1 \bigl( S^1 \times S^{n-1} \bigr) \ast \cdots \ast \bigl( S^1 \times S^{n-1} \bigr) \cong \pi_1(S^1) \ast \cdots \ast \pi_1(S^1)$$

by Proposition 20.12 since $n \geq 3$.

By the discussion on page 520 we know that $\pi_1(S^1) \cong \mathbb{Z}$.

We use this isomorphism to make the identification $\pi_1(X, x_0) = \langle g_1, \ldots, g_k \rangle$. Next we pick loops $b_1, \ldots, b_l : (S^1, \ast) \to (X, x_0)$ that represent $r_1, \ldots, r_l \in \pi_1(X, x_0) = \langle g_1, \ldots, g_k \rangle$.

By hypothesis we have $\dim(X) = n \geq 4$. Thus we can apply Theorem 22.13 and we obtain that the map $b_1 \sqcup \cdots \sqcup b_l : S^1 \sqcup \cdots \sqcup S^1 \to X$ is in fact homotopic to a smooth embedding $c_1 \sqcup \cdots \sqcup c_l : S^1 \sqcup \cdots \sqcup S^1 \to X$. For $i = 1, \ldots, l$ we write $C_i := c_i(S^1)$. It follows from Proposition 8.1 and the Tubular Neighborhood Theorem 8.24 that we can thicken up the $C_i$ to disjoint submanifolds $\overline{B}^{n-1} \times C_i, \ldots, \overline{B}^{n-1} \times C_l$. We consider

$$Y := X \setminus \bigcup_{i=1}^l (B^{n-1} \times C_i)$$

and

$$Z := \left( Y \setminus \bigcup_{i=1}^l \bigl( S^{n-2} \times \overline{B}_i^2 \bigr) \right) / \sim \quad \text{where } (x, c_i(y)) \sim (x, y) \text{ for } x \in S^{n-2} \text{ and } y \in S_i = S^1.$$  

\[396\] The smooth manifold $Y$ is effectively obtained from $(S^1 \times S^{n-1}) \ast \cdots \ast (S^2 \times S^{n-2})$ by removing copies of $\overline{B}^{n-1} \times S^1$ and gluing in copies of $S^{n-2} \times \overline{B}^2$. This operation is frequently called a surgery. We will discuss surgeries in greater detail in Chapter ??.
It follows from Proposition 8.2 and Proposition 8.15 that $Z$ is indeed a closed oriented connected $n$-dimensional smooth manifold. Finally we see that

$$\pi_1(Z) \cong \pi_1(Y)/\langle C_1, \ldots, C_l \rangle \cong \langle g_1, \ldots, g_k \rangle / \langle x_1 x_1^{-1}, \ldots, x_l x_l^{-1} \rangle$$

by the above, the $x_i$ are necessary since we lost track of the base points

We have thus found the promised smooth manifold.

It follo ws from Proposition 8.2 and Proposition 8.15 that $Z$ is indeed a closed oriented connected $n$-dimensional smooth manifold. Finally we see that

$\pi_1(Z) \cong \pi_1(Y)/\langle C_1, \ldots, C_l \rangle \cong \langle g_1, \ldots, g_k \rangle / \langle x_1 x_1^{-1}, \ldots, x_l x_l^{-1} \rangle$

by the above, the $x_i$ are necessary since we lost track of the base points

We have thus found the promised smooth manifold.

In the proof of Proposition 22.10 we used on several occasions that we are dealing with dimensions $\geq 4$. The following question arises naturally.

**Question 22.14.** Is every finitely presented group the fundamental group of a closed (or at least compact) orientable connected 3-dimensional smooth manifold?

We will answer Question 22.14 in Theorem ???.

---

**Exercises for Chapter 22**

**Exercise 22.1.** Let $g \in \mathbb{N}_{\geq 2}$. We consider the group

$$\pi := \pi_1(\text{surface of genus } g) \cong \langle x_1, y_1, \ldots, x_g, y_g \mid [x_1, y_1] \cdots [x_g, y_g] \rangle.$$

(a) Show that $\pi$ admits an epimorphism onto a free group of rank $\geq 2$.

(b) What is the largest $k \in \mathbb{N}$ for which you manage to find an epimorphism onto a free group of rank $k$?

**Exercise 22.2.** We consider the curve $C$ on the surface $\Sigma_3$ of genus three that is shown in Figure 413.

(a) Show that $C$ represents the trivial element in $\pi_1(\Sigma_3, P)_{ab}$.

(b) Show that $C$ represents a non-trivial element in $\pi_1(\Sigma_3, P)$.

**Exercise 22.3.** Let $\pi$ be the fundamental group of the surface $\Sigma$ of genus $g$. Show that $\pi$ contains a free subgroup of rank 2.
Hint. You could make use of your solution to Exercise 22.1 or you could show that there exists an embedding \( \varphi : S^1 \vee S^1 \to \Sigma \) such that \( \varphi(S^1 \vee S^1) \) is a retract of \( \Sigma \). We refer to Figure 415 for an illustration.

**Exercise 22.4.** Let \( K \) be the Klein bottle. Recall that on page 656 we showed that \( \pi_1(K) \cong \langle x, y \mid yxyx^{-1} \rangle \) and in Proposition 22.3 we showed that \( \pi_1(K) \cong \langle x, y \mid x^2y^2 \rangle \). Give a purely algebraic proof that the groups \( \langle x, y \mid yxyx^{-1} \rangle \) and \( \langle x, y \mid x^2y^2 \rangle \) are isomorphic.

**Exercise 22.5.**

(a) Let \( M \) be an oriented connected \( m \)-dimensional smooth manifold and let \( N \) be a 1-dimensional submanifold that is diffeomorphic to \( S^1 \). Let \( x_0 \in M \setminus N \). Suppose that \( m \geq 4 \). Show that the inclusion induced map \( \pi_1(M \setminus N, x_0) \to \pi_1(M, x_0) \) is an isomorphism.

*Hint.* Use the Tubular Neighborhood Theorem 8.24.

(b) Show that the conclusion (a) does not hold for \( m = 3 \), i.e. give an example of a connected 3-dimensional smooth manifold \( M \) and a connected 1-dimensional submanifold \( N \) such that the inclusion induced map \( \pi_1(M \setminus N, x_0) \to \pi_1(M, x_0) \) is not an isomorphism.

*Remark.* The smooth manifold \( M \) in the example does not have to be closed.

**Exercise 22.6.** Let \( X \) be the result of removing the interior of a smoothly embedded disk from a torus. Furthermore let \( Y \) be the result of removing the interiors of three disjointly smoothly embedded disks from the sphere \( S^2 \).

(a) Show that \( X \) and \( Y \) are homotopy equivalent.

(b) Show that \( X \) and \( Y \) are not homeomorphic.

**Exercise 22.7.** Let \( g \in \mathbb{N} \) and let \( \Sigma \) be the surface of genus \( g \) minus one open disk. We pick a diffeomorphism \( \varphi : S^1 \to \partial \Sigma \). Let \( \psi : S^1 \times \partial \Sigma \to \partial \Sigma \times S^1 \) be the diffeomorphism
given by \((z, w) \mapsto (\varphi(z), \varphi^{-1}(w))\). We consider the inclusion map

\[
f: (S^1 \times \partial \Sigma) \cup_{\psi} (\partial \Sigma \times S^1) \to \Sigma \times \Sigma
\]

\[
[(z, w)] \mapsto \begin{cases} (z, \varphi(w)), & \text{if } (z, w) \in S^1 \times \partial \Sigma, \\ (\varphi(z), w), & \text{if } (z, w) \in \partial \Sigma \times S^1. \end{cases}
\]

Show that the induced map

\[
f_*: \pi_1((S^1 \times \partial \Sigma) \cup_{\varphi} (\partial \Sigma \times S^1)) \to \pi_1(\Sigma \times \Sigma)
\]

has non-trivial kernel.

Remark. You might want to use the Normal Form Theorem 21.25.
23. THE CLASSIFICATION OF COMPACT 2-DIMENSIONAL MANIFOLDS I

One of the goals of mathematicians is to classify certain objects. For example one goal would be, given a dimension \( n \in \mathbb{N} \), to “classify” all compact connected non-empty \( n \)-dimensional topological manifolds. But what does “classify” mean? One interpretation would be the following:

I) Provide a collection \( \{X_i\}_{i \in I} \) of compact connected non-empty \( n \)-dimensional topological manifolds with the following two properties:

(a) Any compact connected non-empty \( n \)-dimensional topological manifold is homeomorphic to some \( X_i \).

(b) If \( i \neq j \), then \( X_i \) and \( X_j \) are not homeomorphic.

II) Furthermore provide an algorithm which determines, given a compact connected \( n \)-dimensional topological manifold \( M \), to which \( X_i \) it is homeomorphic to.

With obvious modifications the same goal can also be formulated in the smooth setting.

For \( n = 1 \) we have achieved this goal with Theorems 7.1 and 7.3. In this setting a complete list is given by \( \{S^1, [0, 1]\} \) and given a compact connected non-empty 1-dimensional topological or smooth manifold it is trivial to determine to which of the two it corresponds.

In this chapter we turn our gaze to the 2-dimensional setting. We will state the classification theorem for topological and smooth manifolds and we will prove (Ib) and (II) in the above setting. For the proof of (Ia) we will need some patience though, we will only provide it in Chapter 108.

23.1. The Surface Classification Theorem. As mentioned above, one goal of any classification theorem is to provide a “complete” list of objects. We already have a good list of closed surfaces. Now we need to add surfaces with non-empty boundary to our arsenal. We start out with reminding the reader of the following subtle fact.

Proposition 18.18

(2) Let \( M \) be a 2-dimensional smooth manifold. The boundary of \( M \), viewed as a smooth manifold agrees with the boundary of \( M \) viewed as a topological manifold.

Now let us move on to the first definition of this chapter,

Definition. Let \( \Sigma \) be a closed connected non-empty 2-dimensional smooth manifold and let \( n \in \mathbb{N}_0 \). We pick smooth embeddings \( \varphi_1, \ldots, \varphi_n \colon \overline{B^2} \to \Sigma \) with disjoint images. We refer to \( \Sigma \setminus (\varphi_1(B^2) \cup \cdots \cup \varphi_n(B^2)) \) as \( \Sigma \) minus \( n \) open disks.

The following lemma captures some of the main features of the above definition.

\[\Sigma \quad \text{min} \quad \text{three open disks}\]

\(\Sigma\) minus three open disks

\[\Sigma \quad \text{min} \quad \text{three open disks}\]

\[\Sigma \quad \text{min} \quad \text{three open disks}\]

\(\Sigma\) minus three open disks

---

\[\text{Footnote: The statement is indeed subtle, for example we will only be able to prove the higher-dimensional analogue in Proposition 44.2 after a thorough study of homology groups.}\]
Lemma 23.1. Let \( \Sigma \) be a closed connected non-empty 2-dimensional smooth manifold and let \( n \in \mathbb{N}_0 \).

1. The topological space \( \Sigma \) minus \( n \) open disks is a compact connected topological submanifold of \( \Sigma \) with \( n \) boundary components, which are given by the boundaries of the closed disks whose interiors were removed.
2. \( \Sigma \) minus \( n \) open disks is a submanifold of the smooth manifold \( \Sigma \), in particular it is a smooth manifold in its own right.
3. The diffeomorphism type of the smooth manifold \( \Sigma \) minus \( n \) open disks does not depend on the choice of the disks.

Sketch of proof.

(1),(2) Let \( \varphi_1, \ldots, \varphi_n: \overline{B^2} \to \Sigma \) be smooth embeddings with disjoint images. Note that we obtain from applying Proposition 8.2 (2) iteratively altogether \( n \) times that \( \Sigma \setminus (\varphi_1(B^2) \cup \cdots \cup \varphi_n(B^2)) \) is a compact connected submanifold of \( \Sigma \). In particular we see that it is a smooth and topological manifold in its own right. The fact that the boundary, as a topological manifold, is precisely given by \( \varphi_1(S^1), \ldots, \varphi_n(S^1) \) follows from Propositions 6.27 and 18.18.

(3) This statement follows easily from Theorem 8.36.

This leads us to the following notation:

**Notation.** Given \( g, n \in \mathbb{N}_0 \) we write

\[ \Sigma_{g,n} := \text{the surface of genus } g \text{ minus } n \text{ open disks.} \]

Furthermore for \( g \in \mathbb{N} \) and \( n \in \mathbb{N}_0 \) we write

\[ N_{g,n} := \text{the non-orientable surface of genus } g \text{ minus } n \text{ open disks.} \]

Sometimes we refer to \( g \) as the *genus* of \( \Sigma_{g,n} \) and also of \( N_{g,n} \).

**Examples.**

1. The surface \( \Sigma_{0,2} \) is the result of removing two open disjoint disks from the 2-sphere. It is pretty elementary to show that the resulting smooth manifold is diffeomorphic to the “cylinder” \( [0, 1] \times S^1 \). We refer to Figure 418 for an illustration of this statement.

   ![Figure 418](image)

2. A smooth manifold that is diffeomorphic to \( S^2 \) minus three open disks is often called a *pair of pants*. We refer to Figure 419 for an illustration which hopefully justifies the name. As we will see in Exercise 23.8, pairs of pants can be viewed as a “building block” for almost all compact connected 2-dimensional smooth manifolds.

3. We saw in Figure 147 that the result of removing an open disk from \( \mathbb{R}P^2 \) is the Möbius band, i.e. \( N_{1,1} \) is the Möbius band.
The following lemma shows that the fundamental groups of our new friends are rather dull and uninformative.

**Lemma 23.2.**

1. Given \( g \in \mathbb{N}_0 \) and \( n \in \mathbb{N} \) the surface \( \Sigma_{g,n} \) admits a deformation retract to a topological graph of Euler characteristic \( 2 - 2g - n \). In particular \( \pi_1(\Sigma_{g,n}) \) is a free group on \( 2g + n - 1 \) generators.

2. Given \( k \in \mathbb{N} \) and \( n \in \mathbb{N} \) the surface \( N_{k,n} \) admits a deformation retract to a topological graph of Euler characteristic \( 2 - k - n \). In particular \( \pi_1(N_{k,n}) \) is a free group on \( k + n - 1 \) generators.

**Remark.** Lemma 23.2 can be viewed as a generalization of the fact, essentially shown in Lemma 20.9, that \( \Sigma_{g,1} \) admits a deformation retraction to a wedge \( \Gamma \) of \( 2g \) circles, which is of course a topological graph of Euler characteristic \( 1 - 2g \).

**Sketch of proof.**

1. We denote by \( C_1, \ldots, C_n \) the boundary components of \( \Sigma_{g,n} \). Let \( \Gamma \) be the topological space that is given by the wedge of \( 2g \)-circles (which is obtained from identifying as usual the edges of the \( 4g \)-gon pairwise), together with the boundary components \( C_1, \ldots, C_{n-1} \) and together with edges \( e_1, \ldots, e_{n-1} \) that connect the wedge point to \( C_1, \ldots, C_{n-1} \). The deformation retraction from \( \Sigma_{g,n} \) to \( \Gamma \) is given by pushing the remaining boundary component \( C_n \) “inward”. We illustrate this in Figure 420 (This is one of the rare occasions where we provide a “proof by picture”. It is of course possible to give a completely rigorous proof, but one does not gain anything from doing so.) We equip \( \Gamma \) with the obvious structure of a topological graph which has \( n = 1 + (n-1) \) vertices and \( 2g + 2(n-1) \) edges. Note that \( \chi(\Gamma) = 2 - 2g - n \). Finally we see that

\[
\pi_1(\Sigma_{g,n}) \cong \pi_1(\Gamma) \cong \pi_1\left( \text{connected topological graph } \Gamma \text{ with } \chi(\Gamma) = 2 - 2g - n \right) \cong \text{free group on } 2g + n - 1 \text{ generators}
\]

by the above together with Lemma 18.14 and Proposition 18.16 by Proposition 20.3

2. The proof of this statement is almost identical to the proof of the first statement. ■

In the following we will see that we can “recover” the closed surfaces \( \Sigma_g \) and \( N_g \) from any \( \Sigma_{g,n} \) respectively any \( N_{g,n} \). The key to doing so is the following definition.

**Definition.** Let \( M \) be a topological manifold. Let “\( \sim \)” be the equivalence relation on \( M \) that is generated by \( x \sim y \) whenever \( x \) and \( y \) lie on the same component of \( \partial M \). We write \( \hat{M} := M/\sim \).
The following lemma shows in particular that $\widetilde{\Sigma_{g,n}}$ is homeomorphic to $\Sigma_g$ and that $\widetilde{N_{g,n}}$ is homeomorphic to $N_g$.

**Lemma 23.3.** Let $F$ be a closed connected non-empty 2-dimensional smooth manifold and let $n \in \mathbb{N}_0$. If we set $M$ to be $F$ minus $n$ open disks, then $\widetilde{M}$ is homeomorphic to $F$.

**Proof.** Let $\varphi_1, \ldots, \varphi_n : B^2 \to F$ be smooth embeddings with disjoint images. We need to show that for $M := F \setminus (\varphi_1(B^2) \cup \cdots \cup \varphi_n(B^2))$ there exists a homeomorphism $\widetilde{M} \to F$. By Theorem 8.32 we can extend the smooth embeddings $\varphi_1, \ldots, \varphi_n$ to smooth embeddings $\widetilde{B}^2_2(0) \to F$ with disjoint images. We consider the following map $\Theta : \widetilde{M} \to F$

$$\Theta : \widetilde{M} \to F \quad P \mapsto \begin{cases} \varphi_i(Q \cdot 2 \cdot (\|Q\| - 1)), & \text{if } P = [\varphi_i(Q)] \text{ for some } i \in \{1, \ldots, n\} \text{ and } Q \in \widetilde{B}^2_2(0) \setminus B^2, \\
\emptyset, & \text{otherwise.} \end{cases}$$

It follows from Lemmas 3.22 and 2.33 (2) that $\Theta$ is continuous. Note that by Lemma 2.40 we know that $\widetilde{M}$ is compact. Now it follows almost immediately from Proposition 2.43 (3) that the given map $\Theta : \widetilde{M} \to F$ is indeed a homeomorphism.

**Figure 420.** Illustration for the proof of Lemma 23.2

23.2. The classification theorem for surfaces. The following theorem achieves Goal (1) that we set out on page 668.

**Theorem 23.4.** (Surface Classification Theorem) Every compact connected non-
empty 2-dimensional topological manifold is homeomorphic to either
(1) the surface $\Sigma_{g,n}$ for unique $g, n \in \mathbb{N}_0$ or
(2) to the surface $N_{k,n}$ for unique $k \in \mathbb{N}$ and $n \in \mathbb{N}_0$.

Furthermore, if we are given a smooth manifold, then we can upgrade “homeomorphic” to
diffeomorphic.

**Remark.** The surfaces $\Sigma_{g,n}$, and thus also the surfaces $\Sigma_{g,n}$, come with a canonical orientation and each of these surfaces admits an orientation-reversing self-diffeomorphism given by a reflection. Thus, if we are given a compact oriented connected 2-dimensional smooth manifold, then we can in fact find an orientation-preserving 2-dimensional smooth manifold to the corresponding $\Sigma_{g,n}$.

Theorem [23.4](#) leads us to the following definition.

**Definition.** Let $M$ be a compact connected non-empty 2-dimensional topological manifold. By the Surface Classification Theorem [23.4](#) there exists a unique $g \in \mathbb{N}_0$ such that $M$ is homeomorphic to some $\Sigma_{g,n}$ or to some $N_{g,n}$. We refer to $g$ as the genus $\text{genus}(M)$ of $M$.

At the end of the section we will state a slightly more precise version of the Surface Classification Theorem [23.4](#) that gives us Goal (II) from page [668](#). Before we talk about the proof of the Surface Classification Theorem [23.4](#) let us discuss a few examples.

**Examples.**

(1) At least for closed orientable connected 2-dimensional manifolds it is perhaps tempting to dismiss the Surface Classification Theorem [23.4](#) (1) as “obvious”. After all, what other closed orientable connected 2-dimensional smooth manifold could there possibly be? It is thus instructive to consider Figure 422. It shows a hexagon and a decagon where opposite sides are identified. The quotient spaces are closed orientable 2-dimensional smooth manifolds.

To which of the standard surfaces are they diffeomorphic to? We will come back to this question on page [1364](#).

![Hexagon and Decagon with Opposite Sides Identified](#)

**Figure 422**

---

Indeed, basically the same proof that showed that the $4g$-gon, with appropriate sides identified, is a closed orientable 2-dimensional smooth manifold also shows that the topological spaces shown in Figure 422 are closed orientable 2-dimensional smooth manifolds.
(2) Let $g \in \mathbb{N}$. We consider the surface $\Sigma_g$ of genus $g$. The connected sum $\Sigma_g \# \mathbb{R}P^2$ contains a Möbius band as a submanifold of codimension 0, hence $\Sigma_g \# \mathbb{R}P^2$ is non-orientable. It follows from the Surface Classification Theorem 23.4 that $\Sigma_g \# \mathbb{R}P^2$ is diffeomorphic to $k \cdot \mathbb{R}P^2$ for some unique $k \in \mathbb{N}$. In Exercise 23.2 we will determine $k$ as a function of $g$.

The Surface Classification Theorem 23.4 is an immediate consequence of the following three theorems.

**Theorem 108.7.** Let $\Sigma$ be a compact connected non-empty 2-dimensional smooth manifold.

1. If $\Sigma$ is orientable, then $\Sigma$ is diffeomorphic to the surface $\Sigma_{g,n}$ for some $g,n \in \mathbb{N}_0$.
2. If $\Sigma$ is non-orientable, then $\Sigma$ is diffeomorphic to the surface $\mathbb{N}_{k,n}$ for some $k \in \mathbb{N}$ and $n \in \mathbb{N}_0$.

**Theorem 23.5.** Every compact 2-dimensional topological manifold admits a smooth structure.

**Theorem 23.6.** The topological spaces $\Sigma_{g,m}$ and $\mathbb{N}_{h,n}$ are pairwise non-homeomorphic.

We now turn to the discussion of the proofs of the three theorems.

**Proof of Theorem 108.7.** We provide the proof of Theorem 108.7 in Chapter 108. Actually the proof is not as advanced as it may sound. The only ingredient one needs is the notion and existence of a handle decomposition which are given in Chapter 104. We will also sketch an alternative approach to proving Theorem 108.7 in Exercise ??. Also note that there are several other approaches to proving Theorem 108.7. For example [Mata02, Chapter 5.2] and [Hirs76, Chapter 9.3] give a proof using “Morse theory”.

**Proof of Theorem 23.5.** Let $M$ be a compact 2-dimensional topological manifold. There are two approaches to showing that $M$ admits a smooth structure.

1. In 1922 Tibor Radó [Rad26] showed that $M$ is homeomorphic to a finite 2-dimensional simplicial complex. Alternative proofs are given in [Mo77, p. 60], [DM68, Corollary 1], [Th92, Theorem 4.1], [MTh01, Theorem 3.1.1], [AS60, p. 107] and [GX13, Appendix E]. A sketch of the proof is provided in [Lee00, Theorem 5.12].

We will give the definition of a simplicial complex on page 1497. For the purpose of this proof it suffices to know that this means that $M$ is homeomorphic to a topological space that is obtained from gluing finitely many triangles linearly along their sides.

Recall that in Proposition 6.21 we showed that the surface $E_{2g}/\sim$ of genus $g$ admits a smooth structure. The proof can be modified without too many problems...
to show that any compact 2-dimensional topological manifold that admits a simplicial structure, also admits a smooth structure.

(2) In [Hat13, Theorem A] a direct proof is given for the fact that $M$ admits a smooth structure. Note that this approach does not rely on the Schönflies Theorem 50.3.

Since we did not really prove the first two theorems we should at least provide full details for the third theorem. The idea is to find a complete set of invariants to distinguish the $\Sigma_{g,m}$ and $N_{h,n}$ pairwise. The first invariant we want to use is of course the (abelianization) of the fundamental group. But since this invariant is is not enough we have to look for further invariants. One idea would be to use the number of boundary components. But as we saw in Figure 396 even this extra information is not enough. To resolve this conundrum let us recall the following notation from page 670.

**Notation.** Let $M$ be a topological manifold. Let $\sim$ be the equivalence relation on $M$ that is generated by $x \sim y$ whenever $x$ and $y$ lie on the same component of $\partial M$. We write $\hat{M} := M/\sim$.

The following proposition contains all invariants that we will need.

**Proposition 23.7.** For $g \in \mathbb{N}_0$ and $k \in \mathbb{N}$ we have the following table of invariants:

<table>
<thead>
<tr>
<th>$X$</th>
<th>$\Sigma_g$</th>
<th>$\Sigma_{g,m}$ with $n \geq 1$</th>
<th>$N_k$</th>
<th>$N_{k,n}$ with $n \geq 1$</th>
</tr>
</thead>
<tbody>
<tr>
<td>isomorphism type of $\pi_1(X)_{ab}$</td>
<td>$\mathbb{Z}^g$</td>
<td>$\mathbb{Z}^{2g+m-1}$</td>
<td>$\mathbb{Z}^{k-1} \oplus \mathbb{Z}_2$</td>
<td>$\mathbb{Z}^{k+n-1}$</td>
</tr>
<tr>
<td>number of boundary components</td>
<td>0</td>
<td>$n$</td>
<td>0</td>
<td>$n$</td>
</tr>
<tr>
<td>isomorphism type of $\pi_1(\hat{X})_{ab}$</td>
<td>$\mathbb{Z}^g$</td>
<td>$\mathbb{Z}^g$</td>
<td>$\mathbb{Z}^{k-1} \oplus \mathbb{Z}_2$</td>
<td>$\mathbb{Z}^{k-1} \oplus \mathbb{Z}_2$</td>
</tr>
</tbody>
</table>

**Proof.** The proposition is an immediate consequence of Propositions 22.3 and 22.7 together with Lemmas 23.1, 23.2, and 23.3. ■

Now we can prove Theorem 23.6.

**Proof of Theorem 23.6.** It follows immediately from Proposition 23.7 that the $\Sigma_{g,m}$ and $N_{h,n}$ are pairwise non-homeomorphic. For completeness we point out that in Exercise 48.15 we will use (relative) homology groups to give an alternative proof of Theorem 23.6. ■

Proposition 23.7 also gives us a practical way to determine whether two surfaces are homeomorphic respectively diffeomorphic. This proposition also gives a hopefully satisfying answer to Goal (II) from page 668.

**Proposition 23.8.** Let $M$ and $N$ be two compact connected non-empty 2-dimensional topological (respectively smooth) manifolds. The following are equivalent:

1. $M$ and $N$ are homeomorphic (respectively diffeomorphic),
2. (a) $\pi_1(M)_{ab} \cong \pi_1(N)_{ab}$,
   (b) $M$ and $N$ have the same number of boundary components,
   (c) $\pi_1(\hat{M})_{ab} \cong \pi_1(\hat{N})_{ab}$.

In the smooth setting we can replace (c) by
(c') $M$ and $N$ have the same orientability.
Remark.

(1) Only much later, in Proposition 8.11, will we see that homeomorphisms between smooth manifolds preserve orientability. If we factor this proposition in, then we can replace (c) by (c') also in the topological setting.

(2) In Proposition 31.17 we will see that the fundamental group of the surface $\Sigma_g$ is not isomorphic to the free group on $2g$ generators. Once we know this fact, one can replace (a) and (b) by $\pi_1(M) \cong \pi_1(N)$.

Proof. In the topological setting this proposition follows immediately from Proposition 23.7 and the Surface Classification Theorem 23.4. In the smooth setting the proposition follows from the above, together with the fact that on page 300 we showed that the $\Sigma_{g,m}$ are orientable and that in Lemma 6.48 we showed that the $N_{k,n}$ are non-orientable.

We conclude this discussion of the classification theorem with a long remark on various other approaches to giving the topological classification of 2-dimensional topological manifolds.

Remark. The Surface Classification Theorem 23.4 says in particular that every compact non-empty 2-dimensional topological (respectively smooth) manifold is homeomorphic (respectively diffeomorphic) to one of the $\Sigma_{g,n}$ or one of the $N_{k,n}$. Basically all proofs in the literature that deal with the purely topological setting use the fact, mentioned on page 673, that a 2-dimensional topological manifold admits a simplicial structure. The idea then is to modify the simplicial structure to turn it into a simplicial structure of one of $\Sigma_{g,n}$ or $N_{k,m}$. The traditional account of this proof is given in [ST34, ST80] or alternatively in [Mass91] Theorem 5.1. A variation on this proof, which is usually referred to as Conway’s Zip Proof, is outlined in [FW99, Wild10], with full details given in [Gle] and [SchubJ17]. Another proof is given in [Tn92] and [Meie]. There is also a proof due to Eric Zeeman, see [Ze66, Put2]. The proof given in [Arm88] Chapter 7 is somewhat different, its basic idea is related to the approach taken in Exercise ???. Finally we point to [GX13] for a book that is completely dedicated to the proof of the Surface Classification Theorem 23.4 in the topological setting.

By now we might have the impression that we have a solid understanding of surfaces. The following question provides a good test for our true understanding.

**Question 23.9.** Let $M$ be the surface of genus $g \in \mathbb{N}_0$ and let $p: \widetilde{M} \to M$ be a covering of finite degree $d$ such that $\widetilde{M}$ itself is connected. By Proposition 17.1 and Lemma 16.3 we know that $\widetilde{M}$ is a closed orientable connected 2-dimensional smooth manifold. Can we determine the genus of $\widetilde{M}$ in terms of $g$ and $d$?

We will answer this question later on in Proposition 31.6. It is worth trying to come up with an answer with our current knowledge.
23.3. **Non-compact 2-dimensional manifolds.** Just for kicks we also want to consider non-compact 2-dimensional manifolds. A short moment’s thought there is a plethora of examples:

1. Given any connected 2-dimensional smooth manifold $\Sigma$ and given any non-empty closed discrete subset $A \subset \Sigma$ one can easily show that the complement $\Sigma \setminus A$ is in fact a non-compact connected 2-dimensional smooth manifold. For example, this shows that $W = \mathbb{R}^2 \setminus \{(n, 0) \mid n \in \mathbb{Z}\}$ is a non-compact connected 2-dimensional smooth manifold.

2. In Figure 423 we show two non-compact 2-dimensional smooth manifolds $X$ and $Y$ for which the name “infinite genus” seems appropriate.

In Exercises [23.14] and Exercise [23.15] we will show, with some effort, that the non-compact 2-dimensional smooth manifolds $W$, $X$ and $Y$ are pairwise not diffeomorphic. This already shows that the classification of non-compact connected 2-dimensional smooth manifolds can get a little tricky. In fact the classification of non-compact orientable connected 2-dimensional smooth manifolds without boundary was first given by Ian Richards [Ric63] in 1963, building on earlier work of Béla Kerékjártó [Kere23] from 1923. In [PM07] this result was extended to the case of 2-dimensional smooth manifolds with non-empty boundary.

**Figure 423**

**Remark.** As an aside we point out that the surface $Y$ of infinite genus shown in Figure [423] is sometimes called the **Loch Ness monster**. The reason is shown in Figure [424]: the visible part of an infinite Loch Ness monster, together with the surface of the infinite Loch Ness form a 2-dimensional smooth manifold that is diffeomorphic to $Y$. More information on the mathematical Loch Ness monster and an explicit rigorous construction are given in [ARM17].

**Figure 424**

23.4. **Retractions onto boundary components of 2-dimensional manifolds.** (⋆) In this section we will deal with the following question: for which 2-dimensional smooth
manifolds is a given boundary component a retract? This discussion is useful but not essential and one can safely skip this section.

Without further apologies let us recall the following definition from page 484.

**Definition.** Let $X$ be a topological space. We say that a subset $A$ of $X$ is a retract of $X$ if there exists a retraction $r: X \to A$, i.e. a map with $r(a) = a$ for all $a \in A$.

For the reader’s convenience we also recall the statement of Lemma 15.7.

**Lemma 15.7.** The circle $S^1$ is not a retract of $B^2$.

We quickly recall the proof of Lemma 15.7.

**Proof.** We denote by $i: S^1 \to B^2$ the inclusion map. Suppose there exists a retraction $r: B^2 \to S^1$, i.e. a map with $r \circ i = \text{id}_{S^1}$. We obtain the commutative diagram

But a commutative diagram as given on the right-hand side cannot exist since an isomorphism of a non-trivial group cannot factor through the trivial group.

In light of Lemma 15.7 the following question arises:

**Question 23.10.** Let $\Sigma$ be a 2-dimensional smooth manifold and let $C$ be a boundary component of $\Sigma$. Is $C$ a retract of $\Sigma$?

By the Surface Classification Theorem 23.4 it suffices to address Question 23.10 for the smooth manifolds $\Sigma_{g,m}$ and $N_{h,n}$. For notational convenience we will work throughout with $\Sigma = \Sigma_{g,m}$. We will deal with $\Sigma = N_{h,n}$ in Exercise 23.13.

So let us consider $\Sigma = \Sigma_{g,n}$. Lemma 15.7 says that the answer to Question 23.10 is no if $g = 0$ and $n = 1$. The proof of Lemma 15.7 suggests that if we want to answer Question 23.10 then given a boundary component $C$ of $\Sigma_{g,n}$ we should try to understand the inclusion induced map $\pi_1(C) \to \pi_1(\Sigma_{g,n})$. Of course by Lemma 23.2 we know that $\pi_1(\Sigma_{g,n})$ is a free group on $2g + n - 1$ generators. But back then we mostly cared about the isomorphism type of $\pi_1(\Sigma_{g,n})$ and we did not worry about the relationship of $\Sigma_{g,n}$ and its boundary components.

The following lemma gives a new description of $\pi_1(\Sigma_{g,n})$. This description is more complicated in the sense that it is not totally immediate that $\pi_1(\Sigma_{g,n})$ is a free group. On the other hand it makes it clearer how the boundary components of $\Sigma_{g,n}$ interact with $\Sigma_{g,n}$.

**Lemma 23.11.** Let $g \in \mathbb{N}_0$ and let $n \in \mathbb{N}$. We denote the boundary components of $\Sigma_{g,n}$ by $C_1, \ldots, C_n$. The following statements hold:

1. Let $\ast \in \Sigma_{g,n}$ be the standard base point given by the “vertex” of $E_{2g}/\sim$. We pick an orientation for $\Sigma_{g,n}$. There exists a presentation $\pi_1(\Sigma_{g,n}, \ast) = \langle x_1, y_1, \ldots, x_g, y_g, z_1, \ldots, z_n \mid [x_1, y_1] \cdots [x_g, y_g] \cdot z_1 \cdots z_n \rangle$
with the following properties:

(a) The elements \(x_1, y_1, \ldots, x_g, y_g\) are represented by the edges of the 2g-gon in the "usual way".

(b) For any \(i \in \{1, \ldots, n\}\) the element \(z_i\) is represented by a curve of the form \(\alpha \ast \gamma \ast \overline{\alpha}\) where \(\alpha\) is a path from \(*\) to a point on \(C_i\) and \(\gamma\) is a path that goes once around \(C_i\) in an orientation-preserving way.

We refer to Figure 429 for an illustration.

(2) For every \(i \in \{1, \ldots, n\}\) the obvious map

\[
\langle x_1, y_1, \ldots, x_g, y_g, z_1, \ldots, z_n \rangle \to \langle x_1, y_1, \ldots, x_g, y_g, z_1, \ldots, z_n \mid [x_1, y_1] \cdots [x_g, y_g] \cdot z_1 \cdots z_n \rangle
\]

is an isomorphism. The inverse is induced by the obvious assignments together with

\[
z_i \mapsto z_{i-1}^{-1} \cdots z_1^{-1} \cdot [y_g, x_g] \cdots [y_1, x_g] \cdot z_n^{-1} \cdots z_{i+1}^{-1}.
\]

In particular \(\pi_1(\Sigma_{g,n})\) is a free group on \(2g + n - 1\) generators.

(3) If \(g \geq 1\) or if \(n \geq 2\), then for every \(i \in \{1, \ldots, n\}\) the inclusion induced map \(\pi_1(C_i) \to \pi_1(\Sigma_{g,n})\) is a monomorphism.

Sketch of the Proof. Let \(g \in \mathbb{N}_0\) and let \(n \in \mathbb{N}\).

(1) First note that by Proposition 8.29 we can without loss of generality assume that the base point corresponds to any of the vertices of the \(4g\)-gon as shown in Figure 426. The following argument is very similar to the argument on the pages 656 and 658 and it relies heavily on the notation from Figure 426. We have

Seifert-van Kampen Theorem 22.1

\[
\pi_1(\Sigma_{g,n}) \xrightarrow{\phi} \pi_1(U) \ast \pi_1(V) \cong \pi_1(U) / \langle \pi_1(U \cap V) \rangle \cong \langle x_1, y_1, \ldots, x_g, y_g, z_1, \ldots, z_n \rangle / \langle [x_1, y_1] \cdots [x_g, y_g] \cdot z_1 \cdots z_n \rangle.
\]

followings from the deformation retraction shown in Figure 428 together with Lemma 18.14 and Proposition 18.16 (2)

\footnote{Since we picked an orientation for \(\Sigma_{g,n}\) each boundary component also inherits an orientation.}
(2) It follows immediately from Lemma ?? (2) that for any \( i \in \{1, \ldots, n\} \) the obvious map

\[
\langle x_1, y_1, \ldots, x_g, y_g, z_1, \ldots, \hat{z}_i, \ldots, z_n \rangle \to \langle x_1, y_1, \ldots, x_g, y_g, z_1, \ldots, z_n | [x_1, y_1] \cdots [x_g, y_g] z_1 \cdots z_n \rangle
\]

is an isomorphism. The map that we give in the inverse direction is evidently a converse.

(3) Now suppose that \( g \geq 1 \) or that \( n \geq 2 \). Let \( i \in \{1, \ldots, n\} \). The image of \( \pi_1(C_i) \) in \( \pi_1(\Sigma_{g,n}) \) is the subgroup generated by \( z_i \). It suffices to show that \( z_i \) is an element of infinite order in \( \pi_1(\Sigma_{g,n}) \). We apply (2) to \( i \). We obtain an isomorphism

\[
\pi_1(\Sigma_{g,n}) \to \langle x_1, y_1, \ldots, x_g, y_g, z_1, \ldots, \hat{z}_i, \ldots, z_n \rangle
\]

\[
z_i \mapsto z_{i-1}^{-1} \cdots z_i^{-1} \cdots [y_g, x_g] \cdots [y_1, x_1] \cdots z_n^{-1} \cdots z_{i+1}^{-1}.
\]

Since \( g \geq 1 \) or \( n \geq 2 \) we see that the element on the right-hand side is represented by a non-empty reduced word. Thus by definition it represents a non-trivial element in a free group. By Lemma 19.13 we know that every non-trivial element of a free group has infinite order. Thus we have shown that \( z_i \) is indeed an element of infinite order of \( \pi_1(\Sigma_{g,n}) \).

Finally the following technical lemma can be viewed as a refinement of Lemma 23.2 (1).

**Lemma 23.12.** Let \( g \in \mathbb{N}_0 \) and let \( n \in \mathbb{N} \).

1. We denote the boundary components of \( \Sigma_{g,n} \) by \( C_1, \ldots, C_n \). Given any \( i \in \{1, \ldots, n\} \) there exists a topological graph \( G \subset \Sigma_{g,n} \) which contains all \( C_j \) with \( i \neq j \) and which contains a point on \( C_j \), a deformation retraction \( r: \Sigma_{g,n} \to G \), a spanning tree \( T \subset G \) and a homeomorphism

\[
\Theta: G/T \to C_1 \lor \cdots \lor \hat{C}_i \lor \cdots \lor C_n \lor S^1 \lor \cdots \lor S^1
\]

2. such that the following diagram commutes:

\[
\begin{array}{ccc}
\Sigma_{g,n} & \xrightarrow{r} & G \\
\downarrow & & \downarrow \Theta \\
C_j & \xrightarrow{\Theta} & C_1 \lor \cdots \lor \hat{C}_i \lor \cdots \lor C_n \lor S^1 \lor \cdots \lor S^1
\end{array}
\]

\[
p \circ \Theta \cong 1
\]
Note that \((p \circ r)_* : \pi_1(\Sigma_{g,n}) \to \pi_1(G/T)\) is an isomorphism by Propositions \[18.16\] and \[18.34\] (1).

(2) The fundamental group \(\pi_1(\Sigma_{g,n})\) is a free group on \(2g + n - 1\) generators.

Given \(k \in \mathbb{N}\) and \(n \in \mathbb{N}\) completely analogous statements also hold for \(N_{k,n}\).

Figure 427. Illustration of Lemma \[23.12\]

Sketch of proof.

(1) In Figure 427 we show that, starting from any boundary component \(C_i\) of \(\Sigma_{g,n}\), we can push “inward” to obtain a deformation retraction \(r\) to a subset that is a topological graph \(G\) that can be described as

\[
G = \left( C_1 \sqcup \cdots \sqcup \tilde{C}_i \sqcup \cdots \sqcup C_n \sqcup S^1 \lor \cdots \lor S^1 \right) \text{ together with a spanning tree } T.
\]

The vertical map to the right is the homeomorphism given by the discussion on page 560. It follows immediately from the construction that the diagram commutes.

(2) This statement follows from (1) together with Lemma \[20.4\].

The proof for \(N_{k,n}\) is almost identical to the above proof for \(\Sigma_{g,n}\). We leave it to the reader to figure out the precise statements and to write down the proof.

The following lemma gives an answer to Question \[23.10\].

**Lemma 23.13.** Let \(g \in \mathbb{N}_0\).

(1) The unique boundary component of \(\Sigma_{g,1}\) is not a retract of \(\Sigma_{g,1}\).

(2) For \(k \geq 2\) every boundary component of \(\Sigma_{g,k}\) is a retract of \(\Sigma_{g,k}\).

**Proof.** Let \(g \in \mathbb{N}_0\).

(1) The case \(g = 0\) was dealt with in Lemma \[15.7\]. Now we assume that \(g \geq 1\). We denote by \(C\) the unique boundary component of \(\Sigma := \Sigma_{g,1}\). We had just seen in Lemma \[23.11\] that \(\pi_1(C) \to \pi_1(\Sigma)\) is a monomorphism if \(g \geq 1\). So we cannot apply the same argument as in Lemma \[15.7\] where we studied the induced map on the level.

\[\text{Here } \tilde{C}_i \text{ means that we leave out } C_i.\]

\[\text{We leave it to others with more time and energy to write down a rigorous argument. One possibility would be to apply several times the deformation retractions that we found in Exercise } \[18.24\].\]

\[\text{This argument is evidently closely related to the proof of Lemma } \[20.9\].\]
of fundamental groups. The idea now is to study instead the induced map on the abelianizations of the fundamental groups.

We denote by \( i: C \rightarrow \Sigma \) the inclusion map and we suppose that there exists a retraction \( r: \Sigma \rightarrow C \), i.e., a map with \( r \circ i = \text{id}_C \). We write \( \pi_1(C) = \langle t \rangle \) and we use the isomorphism from Lemma 23.11 to make the identification

\[
\pi_1(\Sigma) = \langle x_1, y_1, \ldots, x_g, y_g, z \mid [x_1, y_1] \cdots [x_g, y_g] \cdot z \rangle
\]

where \( z \) corresponds to \( t \) under the inclusion \( C = \partial \Sigma \rightarrow \Sigma \). We obtain the commutative diagram

\[
\begin{array}{ccc}
\Sigma & \xrightarrow{i} & C \\
\downarrow{r} & & \downarrow{r \circ i = \text{id}_C} \\
C & & C
\end{array}
\]

which induces by Proposition 21.20 the commutative diagram

\[
\begin{array}{ccc}
\pi_1(C) & \xrightarrow{i_*} & \pi_1(\Sigma) \\
\downarrow{(r \circ i)_* = \text{id}} & & \downarrow{= (t)} \\
\pi_1(C)_{ab} & = & \pi_1(\Sigma)_{ab}
\end{array}
\]

In \( \pi_1(\Sigma) \) we have

\[
z = ([x_1, y_1] \cdots [x_g, y_g])^{-1} \in \pi_1(\Sigma).
\]

This shows that \( z \) lies in the commutator subgroup of \( \pi_1(\Sigma) \), i.e., \( z \) represents the trivial element in \( \pi_1(\Sigma)_{ab} \). Thus we have shown that the left diagonal map is the zero map. But the bottom horizontal map is an isomorphism of a non-trivial group and the diagram commutes. We have thus obtained a contradiction.

(2) This statement follows immediately from Lemma 23.12 since we can project the wedge of circles onto any circle. Alternatively, a retraction from \( \Sigma_{2,n} \) to a boundary component is sketched in Figure 428. The general case is treated the same way.\footnote{The proof is somewhat similar to the proof of Lemma 15.10}

retraction to the green boundary component

\[
\begin{array}{ccc}
\Sigma_{2,n} & \xrightarrow{\sim} & \text{cylinder minus} \\
& & \text{\( n - 2 \) open disks}
\end{array}
\]

Figure 428

23.5. Curves on surfaces. In this section we will use the Surface Classification Theorem 23.4 to draw several hopefully interesting consequences on curves on surfaces. We start out with the following lemma.

**Lemma 23.14.** Let \( \Sigma \) be a compact connected 2-dimensional smooth manifold. We denote the boundary components of \( \Sigma \) by \( C_1, \ldots, C_n \). Given any permutation \( \sigma \in S_n \) there exists
a diffeomorphism \( f \) of \( \Sigma \) with \( f(C_i) = C_{\sigma(i)}, \ i = 1, \ldots, n \). Furthermore, if \( \Sigma \) is oriented, then we can choose \( f \) to be orientation-preserving.

**Figure 429.** Illustration of Lemma 23.14

**Proof.** In the proof we deal with the setting that \( \Sigma \) is orientable. The case that \( \Sigma \) is non-orientable is dealt with in almost the same way. We pick an orientation for \( \Sigma \) and we equip the boundary components \( C_1, \ldots, C_n \) with the corresponding orientations. Furthermore we pick orientation-reversing diffeomorphisms \( \varphi_1, \ldots, \varphi_n: S^1 \to C_i \) and we consider

\[
M := (\Sigma \sqcup (B_1^2 \sqcup \cdots \sqcup B_n^2))/\varphi_i(x) \sim x \quad \text{with} \quad x \in S^1 \quad \text{and} \quad i \in \{1, \ldots, n\}.
\]

It follows from Proposition 6.30 that \( M \) is a closed oriented connected 2-dimensional smooth manifold with obvious orientation-preserving smooth embeddings \( \psi_i: B^2 \to M \). Now let \( \sigma \in S_n \) be a permutation. Note that \( \sigma \) follows from Theorem 8.36 that there exists a diffeotopy \( F: M \times [0, 1] \to M \) with \( F_0 = \text{id} \) such that for each \( i \in \{1, \ldots, n\} \) we have

\[
F_1 \circ \varphi_i = \varphi_{\sigma(i)}: B^2 \to M.
\]

Note that \( F_1 \) is orientation-preserving by Lemma 8.6. The desired diffeomorphism is now given by the restriction of \( F_1 \) to \( \Sigma \).

We move on to the following general definition.

**Definition.** Let \( M \) be a smooth manifold and furthermore let \( N \subset M \) be a closed submanifold of codimension one. We say \( N \) is non-separating if \( M \setminus N \) is connected, otherwise we see that \( N \) is separating.

**Figure 430**

Next we recall that on page 360 we introduced the notion of cutting an orientable smooth manifold along a proper codimension-one submanifold. In Proposition 8.17(4) and Proposition 8.18 we saw that this is operation is the inverse of the operation of gluing two boundary components that we introduced in Proposition 8.15. We will not recall the precise definitions but we hope that Figure 431 will bring back fond memories.

The following lemma explains how gluing and cutting affects surfaces.
Lemma 23.15. Let $\Sigma$ be a compact oriented connected 2-dimensional smooth manifold.

1. Let $C$ and $D$ be two distinct boundary components of $\Sigma$. Gluing $C$ to $D$ via an orientation-reversing diffeomorphism increases the genus by one and it decreases the number of boundary components by two.

2. Let $F$ be a closed non-separating curve on $\Sigma$. Cutting along $F$ decreases the genus by one and it increases the number of boundary components by two. (In particular this implies that the genus of $\Sigma$ is $\geq 1$.)

**Sketch of proof.**

1. By the Surface Classification Theorem 23.4 we can assume that $\Sigma = \Sigma_{g,n}$ for some $g \in \mathbb{N}_0$ and some $n \in \mathbb{N}_{\geq 2}$. We denote by $M$ the result of gluing the boundary components $C$ and $D$ via an orientation-reversing diffeomorphism. Note that it follows from Proposition 8.15 that $M$ is a compact oriented connected 2-dimensional smooth manifold. In particular it has some genus $h$. Also note that it follows from Lemma 23.14 that the diffeomorphism type of $M$ does not depend on the choice of the two boundary components $C$ and $D$.

   It is now elementary, albeit painful, to show clearly that gluing $C$ to $D$ via an orientation-reversing diffeomorphism increases the genus by one. We will deal with a special case in Exercise 23.12. The general case is not much harder. Finally note that evidently the number of boundary components goes down by two.

   For readers who are slightly unhappy about the above proof of the statement that the genus goes up by one we also give an alternative approach. Namely, the genus of $M$ can be read off directly from suitable invariants. For example later on we will use the HNN-Seifert–van Kampen Theorem 26.3 to calculate $\pi_1(M)$ which, together with Proposition 23.7 implies that $h = g + 1$. Alternatively one can use the Euler characteristic, which we will introduce in Chapter 55 together with Lemmas 55.5 and 55.6 to see once again that $h = g + 1$.

2. Note that if we cut along a non-separating curve, then the resulting 2-dimensional smooth manifold is again connected. Thus we see that Statement (2) is an immediate consequence of Statement (1) together with Proposition 8.18.

We move on to the following definition.
**Definition.** Let $\Sigma$ be an oriented 2-dimensional smooth manifold and let $C$ and $D$ be two closed oriented curves in $\Sigma$. We say $C$ and $D$ are equivalent if there exists an orientation-preserving self-diffeomorphism $f$ of $\Sigma$ that restricts to an orientation-preserving diffeomorphism $f: C \to D$.

It is clear that if two curves are equivalent, then either both are separating or both are non-separating. Furthermore if they are both separating, then the results of cutting the 2-dimensional smooth manifold along the curves are diffeomorphic. The following proposition gives us the converse to this observation.

**Proposition 23.16.** Let $\Sigma$ be a compact oriented connected 2-dimensional smooth manifold and let $C$ and $D$ be two closed oriented curves in $\Sigma \setminus \partial \Sigma$.

1. If $C$ and $D$ are non-separating, then $C$ and $D$ are equivalent.
2. Suppose $C$ and $D$ are separating. If $\Sigma$ cut along $C$ is diffeomorphic to $\Sigma$ cut along $D$, then $C$ and $D$ are equivalent.

**Example.** It follows from Proposition 23.16 (1) that the two non-separating curves shown in Figure 432 are actually equivalent. Furthermore it follows easily from Proposition 23.16 (2) and the future Exercise 55.5 that any separating curve on the surface of genus four is equivalent to one of the separating curves shown in Figure 432.

![Figure 432](image)

**Remark.** In Exercise 23.17 we will generalize Proposition 23.16 to certain pairs of curves.

**Sketch of proof.** Let $\Sigma$ be a compact oriented connected 2-dimensional smooth manifold.

1. Let $C$ and $D$ be two closed oriented non-separating curves on $\Sigma$. We denote by $M$ respectively $N$ the smooth manifold obtained from $\Sigma$ by cutting along $C$ respectively $D$. We denote by $C_\pm$ and $D_\pm$ the boundary components arising from $C$ and $D$. Since $C$ and $D$ are non-separating it follows from Lemma 23.15 (2) and Lemma 23.14 that there exists an orientation-preserving diffeomorphism $\varphi: M \to N$ that restricts to orientation-preserving diffeomorphisms $\varphi: C_\pm \to D_\pm$. Using Lemma 18.9 and using a collar neighborhood one can arrange that under the obvious identifications $C_- = C_+$ and $D_- = D_+$ the maps $\varphi: C_- \to D_-$ and $\varphi: C_+ \to D_+$ agree. As in Proposition 8.15 (7) we see that $\varphi: M \to N$ descends to an orientation-preserving diffeomorphism $\tilde{\varphi}: M/C_- = C_+ \to N/D_- = D_+$. If we combine this diffeomorphism
with the diffeomorphisms $\Sigma \to M/C_- = C_+$ and $\Sigma \to N/D_- = D_+$ from Proposition 23.18 we obtain the desired diffeomorphism. 

(2) The argument is similar to the proof of Statement (1), except that we do not need to appeal to Lemma 23.15 (2), instead we can use our hypothesis directly. We leave it to the reader to fill in the details.

Figure 433. Illustration for the proof of Proposition 23.16

In the remainder of this section we will state a few consequences of Proposition 23.16.

**Proposition 23.17.** Let $\Sigma$ be a compact orientable connected 2-dimensional smooth manifold and let $C$ be a closed oriented curve on $\Sigma$.

1. If $C$ is non-separating, then $C$ is not null-homotopic.
2. If $C$ is separating, and if the two components of $\Sigma$ cut along $C$ are not disks, then $C$ is not null-homotopic.

Figure 434. Illustration for (the proof of) Proposition 23.17

**Proof.** Let $\Sigma$ be a compact 2-dimensional smooth manifold and let $C$ be a closed oriented curve on $\Sigma$.

1. First assume that $C$ is non-separating. By the Surface Classification Theorem 23.4 we can assume that $\Sigma = \Sigma_{g,n}$ for some $g \in \mathbb{N}_0$ and some $n \in \mathbb{N}_0$. Since $C$ is non-separating we know by Lemma 23.15 (2) that $g \geq 1$. Next note that by Proposition 23.16 we only need to show that there exists a single non-separating curve on $\Sigma_{g,n}$ that is not null-homotopic. By Lemma 23.11 we have a presentation

$$\pi_1(\Sigma_{g,n}, *) = \langle x_1, y_1, \ldots, x_g, y_g, z_1, \ldots, z_n | [x_1, y_1] \cdot \ldots \cdot [x_g, y_g] \cdot z_1 \cdot \ldots \cdot z_n \rangle$$

where each $x_i$ is represented by a non-separating curve. But the $x_i$ represent non-trivial elements in the abelianization of $\pi_1(\Sigma_{g,n})$, in particular the corresponding curves are not null-homotopic.

2. Now we suppose that $C$ is separating. We cut $\Sigma$ along $C$ and we obtain two connected surfaces. By the Surface Classification Theorem 23.4 we can assume that the two
surfaces are of the form $\Sigma_{g,m}$ and $\Sigma_{h,n}$. By hypothesis neither surface is a disk, so we have $g > 0$ or $m > 1$ and we have $h > 0$ or $n > 1$. To simplify the notation we now assume that $g = 1$ and $h = 1$ and $m = 2$ and $n = 2$. We perform the following calculation:

Seifert–van Kampen Theorem \([22.2]\) by Lemma \([23.11]\) here $C$ corresponds to $c_1$ and to $z_1^{-1}$

\[
\pi_1(\Sigma) \cong \pi_1(\Sigma_{1,2}) *_{\pi_1(C)} \pi_1(\Sigma_{1,2}) = \langle a, b, c_1, c_2 | [a, b] \cdot c_1 \cdot c_2 \rangle *_{\pi_1(C)} \langle x, y, z_1, z_2 | [x, y] \cdot z_1 \cdot z_2 \rangle
\]

by Lemma \([21.23]\)

where the curve $C$ corresponds to $c_1 = z_1^{-1}$. We need to show that $c_1$ represents a non-trivial element in $\pi_1(\Sigma)$. In our present setting we see that $c_1$ represents a non-trivial element in the abelianization, but this is not the case if $m = 1$. So we need to come up with an alternative argument to show that $c_1$ is non-trivial. Note that it follows from Lemma \([21.13]\) that there exists a homomorphism

\[
\varphi : \langle a, b, c_1, c_2, x, y, z_1, z_2 | [a, b] \cdot c_1 \cdot c_2, [x, y] \cdot z_1 \cdot z_2, c_1 = z_1^{-1} \rangle \to \langle u, v \rangle
\]

with\(^{408}\)

\[
a \mapsto u, \quad b \mapsto v, \quad c_1 \mapsto [v, u], \quad c_2 \mapsto e, \quad x \mapsto v, \quad y \mapsto u, \quad z_1 \mapsto [u, v], \quad z_2 \mapsto e.
\]

Finally note that $\varphi(c) = [u, v]$ is a non-trivial element of the free group $\langle u, v \rangle$. It follows that $C$ is not null-homotopic. \(\blacksquare\)

**Remark.** What is the “right” proof for a statement is often a matter of taste. For example an alternative, arguably more conceptual, proof for Proposition \([23.17](1)\) can be obtained by the combination of the Surface Classification Theorem \([23.4]\) together with the future HNN-Seifert–van Kampen Theorem \([26.3]\), Lemma \([23.11](3)\) and Proposition \([26.2]\). Similarly an alternative proof for Proposition \([23.17](2)\) can be obtained by the combination of the Surface Classification Theorem \([23.4]\) with Seifert–van Kampen Theorem \([22.2]\) Lemma \([23.11]\) \((3)\) and Proposition \([21.24]\).

We conclude this section with the following consequence of Proposition \([23.17]\).

**Proposition 23.18.** Let $\Sigma$ be a compact orientable 2-dimensional smooth manifold. Furthermore let $f : S^1 \to \Sigma$ be a smooth embedding. If $f$ is null-homotopic, then there exists a smooth embedding $F : \overline{B}^2 \to \Sigma$ with $F|_{S^1} = f$.

**Proof.** Let $f : S^1 \to \Sigma$ be a smooth embedding that is null-homotopic. By Proposition \([23.17](1)\) we know that $f(S^1)$ is separating. Let $A$ and $B$ be the two components of $\Sigma$ cut along $f(S^1)$. By Proposition \([23.17](2)\) we know that at least one of $A$ and $B$ is diffeomorphic to a disk. Let us assume that $A$ is diffeomorphic to $\overline{B}^2$. It follows easily from Lemma \([18.9](3)\), see also Proposition \([30.1](2)\), that there exists such a diffeomorphism $F : \overline{B}^2 \to A$ with $F|_{S^1} = f$. \(\blacksquare\)

\(^{408}\)Recall that $[s, t]$ denotes the commutator of $s$ and $t$, i.e. we have $[s, t] = s t s^{-1} t^{-1}$. The verification that the relations are indeed satisfied relies on the trivial but useful observation that $[s, t]^{-1} = [t, s]$. 
Exercises for Chapter 23

Exercise 23.1. Determine the genus of the surface $M$ shown in Figure 435.

![Figure 435. Illustration for Exercise 23.1](image)

Exercise 23.2. Let $g \in \mathbb{N}$. By the Surface Classification Theorem 23.4 we know that $\Sigma_g \# \mathbb{R}P^2$ is diffeomorphic to $k \cdot \mathbb{R}P^2$ for some unique $k \in \mathbb{N}$. Determine $k$ as a function of $g$.

Exercise 23.3. Let $X$ be the Möbius band minus two disks. We denote by $A, B, C$ the three boundary components of $X$. We glue a torus minus one open disk and a Möbius band to the boundary components of $X$. By Proposition 8.13 we obtain a compact 2-dimensional smooth manifold.

(a) Do the resulting diffeomorphism types depend on the gluing?
(b) How do the resulting smooth manifolds fit into the classification scheme of the Surface Classification Theorem 23.4?

We refer to Figure 436 for an illustration.

![Figure 436. Illustration of Exercise 23.3](image)

Exercise 23.4. Recall that in Figure 147 we saw that $N_{1,1}$ is a Möbius band. In particular we can view $N_{0,1}$ as a submanifold of $\mathbb{R}^3$.

(a) Is $N_{2,1}$ diffeomorphic to a submanifold of $\mathbb{R}^3$?
(b) Show that $N_{3,1}$ is diffeomorphic to a submanifold of $\mathbb{R}^3$.
(c) For which $k \in \mathbb{N}$ is $N_{k,1}$ diffeomorphic to a submanifold of $\mathbb{R}^3$?

Exercise 23.5. Let $F$ be the sphere minus $k$ open disks. (Alternatively, let $F$ be the disk $\mathbb{D}^2$ minus $k-1$ open disks.) We denote by $C_1, \ldots, C_k$ the boundary components of $F$. We pick a base point $x_0 \in F$. Furthermore for each $i \in \{1, \ldots, k\}$ we pick a path $\gamma_i$ from a point on $C_i$ to $x_0$. Finally let $\Gamma \subseteq \pi_1(F, x_0)$ be a proper normal subgroup. Show that there exists an $i \in \{1, \ldots, k\}$ such that $C_i$, viewed as an element in $\pi_1(F, x_0)$ via the path $\gamma_i$, does not lie in $\Gamma$.

Hint. You might want to start out with your preferred base point $x_0$ and your preferred paths $\gamma_1, \ldots, \gamma_k$, e.g. as shown in Figure 137.
Exercise 23.6. Let $\Sigma$ be the torus minus one disk. We denote by $P \in \partial \Sigma$ a base point. Furthermore let $x, y, z$ be the curves shown in Figure 438. We denote by $x, y, z$ also the elements in $\pi_1(\Sigma, P)$ represented by these curves.

(a) Convince yourself of the fact that $\pi_1(\Sigma, P) = \langle x, y, z \mid [x, y] = z \rangle$.

Remark. This statement is closely related to the statement of Lemma 23.11 but it takes some effort to get the orientations of the curves right.

(b) Show that $z \in \pi_1(\Sigma, P)$ is not a proper power, i.e. show that there is no $w \in \pi_1(\Sigma, P)$ such that $z = w^d$ for some $d \in \mathbb{N}_{\geq 2}$.

Exercise 23.7. What is the genus of the surface shown in Figure 439?

Exercise 23.8. We say a 2-dimensional smooth manifold $M$ admits a pair of pants decomposition if there exist submanifolds $P_1, \ldots, P_k$ such that each $P_i$ is a pair of pants and such that for each $i \neq j$ the intersection $P_i \cap P_j$ is a (possibly empty) union of boundary components of $P_i$ and also of $P_j$.

(a) Determine all $g, n \in \mathbb{N}_0$ such that $\Sigma_{g,n}$ admits a pair of pants decomposition.

(b) Determine all $g \in \mathbb{N}$ and $n \in \mathbb{N}_0$ for which $N_{k,n}$ admits a pair of pants decomposition.

Exercise 23.9. Let $\Sigma$ be a compact connected 2-dimensional smooth manifold and let $C$ and $D$ be two closed oriented non-separating curves in $\Sigma \setminus \partial \Sigma$. In Proposition 23.16 we showed that if $\Sigma$ is orientable, then there exists a self-diffeomorphism $\varphi$ of $\Sigma$ with $\varphi(C) = D$.

(a) Show that this conclusion does not necessarily hold if we drop the hypothesis that $\Sigma$ is orientable.
(b) Where in the proof of Proposition 23.16 did we really make use of the hypothesis that $\Sigma$ is orientable?

Exercise 23.10. We consider the 2-dimensional smooth manifold $M$ together with the map $\varphi: S^1 \to M$ that is shown in Figure 441. Show that $\varphi$ is not homotopic to a smooth embedding.

Remark. At this stage it is a challenging, but by now means impossible, task to provide a completely rigorous proof.

Exercise 23.11.

(a) Let $k \in \mathbb{N}$. By Proposition 17.3 we know that the non-orientable surface $N_k$ admits an essentially unique 2-fold covering $\Sigma \to N_k$ that is orientable. What is the genus of $\Sigma$?

Hint. First deal with the cases $N_1 \cong \mathbb{R}P^2$ and $N_2 \cong \mathbb{R}P^2 \# \mathbb{R}P^2$. Given $k \in \mathbb{N}_{\geq 2}$ you can write $N_k$ as the connected sum of an orientable smooth manifold with $\mathbb{R}P^2$ or with $\mathbb{R}P^2 \# \mathbb{R}P^2$.

(b) Let $k \in \mathbb{N}$ and $m \in \mathbb{N}_0$. By Proposition 17.3 we now know that the non-orientable surface $N_{k,m}$ admits an essentially unique 2-fold covering $\Sigma \to N_{k,m}$ that is orientable. What is the genus of $\Sigma$ and what is the number of boundary components of $\Sigma$?

Hint. In Exercise 55.2 we will give a different, perhaps less ad hoc approach to dealing with these two questions.

Exercise 23.12. Let $F$ be the torus minus two open disks. We pick an orientation-reversing diffeomorphism $\varphi: C \to D$ between the two boundary components. Show that $F/c \sim \varphi(c)$ is diffeomorphic to the surface of genus $w_0$.

Figure 442. Illustration of Exercise 23.12
Exercise 23.13. For which values of $g \in \mathbb{N}$ and $n \in \mathbb{N}$ is every boundary component of $N_{g,n}$ a retract of $N_{g,n}$?

![Figure 443. Illustration for Exercise 443](image)

Exercise 23.14. Let $W = \mathbb{R}^2 \setminus \{(n,0) \mid n \in \mathbb{Z}\}$ and let $X$ be the surface of infinite genus that is shown in Figure 444. Show that $W$ and $X$ are not diffeomorphic.

Hint. What compact submanifolds can occur?

Remark. The same argument also shows that $W$ is not diffeomorphic to the other surfaces of “infinite genus” that are shown in Figure 445.

Remark. Later in Exercise 82.5 we will see that $W$ and $X$ are not homeomorphic. With the present knowledge it is at best quite challenging to give a watertight proof that $W$ and $X$ are not homeomorphic.

![Figure 444. Illustration of Exercise 23.14](image)

Exercise 23.15. Let $X$ be a topological space. Given a compact subset $K \subset X$ we define $m(K)$ to be the number of non-compact path-components of $X \setminus K$ that are not contained in a compact subset of $X$. As in Exercise 2.22 we refer to

$$\text{End}(X) := \max\{m(K) \mid K \text{ is a compact subset of } X\} \in \mathbb{N}_0 \cup \{\infty\}$$

as the number of ends of $X$.

(a) Determine the number of ends for each of the three non-compact surfaces shown in Figure 445.

(b) Which (if any) of the three “surfaces of infinite genus” shown in Figure 445 are homeomorphic?

(c) For each $n \in \mathbb{N}$ give an example of a non-compact connected 2-dimensional smooth manifolds such that the number of ends equals $n$.

![Figure 445. Illustration of Exercise 23.15](image)

Exercise 23.16. Let $n \in \mathbb{N}$, let $M_n$ be $S^2$ minus $n$ open disks and let $C$ be a closed curve in $M_n \setminus \partial M_n$. 
Exercise 23.17. Let $\Sigma$ be a closed orientable connected 2-dimensional smooth manifold and let $\{A, B\}$ and $\{A', B'\}$ be pairs of closed curves on $\Sigma$ such that $A$ intersects $B$ transversally in a single point and such that $A'$ intersects $B'$ transversally in a single point.

(a) Show that there exists a diffeomorphism $f: \Sigma \to \Sigma$ with $f(A) = A'$ and $f(B) = B'$. 

Remark. The statement of this exercise, and of the closely related Proposition 23.16 are proved and extended, in [FaM11] Chapter 1.3. They refer to statements of this type as the change of coordinates principle.

(b) Suppose that all the curves are oriented. Can we find $f$ such that the maps $f: A \to A'$ and $f: B \to B'$ are both orientation-preserving?
24. Mapping cones, cylinders and tori

In this section we first introduce two systematic ways to construct new topological spaces out of a given topological space and we present three systematic ways to construct new topological spaces out of a map \( f: X \rightarrow Y \) between given topological spaces. Initially it might not be entirely apparent why we should be interested, but all five examples will play an important role at various points. The main excuse for presenting these constructions at this very moment is that they allow us to play a little bit with our newly acquired abilities for computing fundamental groups.

24.1. The cone and suspension of a topological space. In this section we define the cone and suspension of a topological space. The cone of a topological space is a particularly easy construction.

**Definition.** Given a non-empty topological space \( X \) the cone on \( X \) is defined to be the topological space

\[
\text{Cone}(X) := (X \times [0,1])/(X \times \{0\}) = (X \times [0,1])/\sim \quad \text{where} \quad (x,0) \sim (x',0) \quad \text{for all} \quad x,x' \in X.
\]

Similarly we define the open cone on \( X \) to be

\[
\text{Cone}^o(X) := (X \times [0,1])/(X \times \{0\}) = (X \times [0,1])/\sim \quad \text{where} \quad (x,0) \sim (x',0) \quad \text{for all} \quad x,x' \in X.
\]

We refer to the point \( X \times \{0\} \) as the tip of the cone \( \text{Cone}(X) \) and of the open cone \( \text{Cone}^o(X) \) or alternatively as the cone point. For completeness we define the cone and the open cone of the empty topological space to be the one point topological space \( \{\ast\} \). In this setting we refer to \( \ast \) as the tip of the cone.

![Figure 4.47](image.png)

**Examples.**

1. Let \( n \in \mathbb{N}_0 \). It follows from Lemma 3.22 that the map

\[
\text{Cone}(S^n) \rightarrow \overline{B}^{n+1}
\]

\[
[(v,t)] \mapsto v \cdot t
\]

is continuous. One can easily verify that the map is a bijection. It follows immediately from Lemma 3.21 (4) and Proposition 3.12 that \( \text{Cone}(S^n) \) is compact. Since \( \overline{B}^{n+1} \) is Hausdorff we obtain from Proposition 2.43 (3) that the given map is a homeomorphism. On a few occasions we will use this specific homeomorphism to make the identification \( \text{Cone}(S^n) = \overline{B}^{n+1} \).
(2) Let \( X \) be a subset of \( \mathbb{R}^n \). We define its physical cone as
\[
\widetilde{\text{Cone}}(X) := \text{union of all line segments from } (x, 0) \text{ to } (0, 1) \in \mathbb{R}^{n+1}.
\]

(a) In Exercise 24.1 we will see that if \( X \) is a compact subset of \( \mathbb{R}^n \), then the map
\[
f_X : \text{Cone}(X) \rightarrow \widetilde{\text{Cone}}(X)
\]
\[
[(x,t)] \mapsto t \cdot (x,0) + (1-t) \cdot (0,1)
\]
is a homeomorphism.

(b) After looking at Figure 447 and considering Examples (1) and (2a) one might walk away with the feeling that one has a pretty good understanding of the cone construction. But this optimism is potentially ill-founded. For example in Exercise 24.1 we see will see that for \( X = (0,1) \subset \mathbb{R} \) the above map \( f_X : \text{Cone}(X) \rightarrow \text{Cone}(X) \) from (2a) is not a homeomorphism.

This definition does not seem to be particularly interesting, but we have one lemma whose proof is perhaps slightly more subtle than one might initially think.

**Lemma 24.1.** Let \( X \) be a topological space. The tip of the cone \( \text{Cone}(X) \) is a deformation retract of \( \text{Cone}(X) \).

**Proof.** If \( X = \emptyset \), then it follows from the definition of \( \text{Cone}(\emptyset) = \{\ast\} \) that the cone equals the tip. Thus it remains to consider the case of a non-empty topological space. We consider the “obvious” map
\[
\varphi : (X \times [0,1])/(X \times \{0\}) \times [0,1] \rightarrow (X \times [0,1])/(X \times \{0\})
\]
\[
([[x,s]], t) \mapsto [(x,s \cdot (1-t))]
\]

One might think that this map “obviously” does the trick. The wary reader will not have failed to notice that here we are mixing the product and the quotient topologies, which, as we have learned the painful way in Section 5.2, can be quite dangerous and can lead to non-continuous maps.

So let us show that the map \( \varphi \) is indeed continuous. Since there is an abundance of intervals we now write \( S = [0,1] \) and \( T = [0,1] \). We consider the following two maps
\[
H : (X \times S) \times T \rightarrow X \times S
\]
\[
((x,s), t) \mapsto (x,s \cdot (1-t))
\]
and
\[
p : X \times S \rightarrow \text{Cone}(X)
\]
\[
(x,s) \mapsto [(x,s)].
\]

\footnote{The fact that one actually needs to prove that the map \( \varphi \) is continuous seems to get swept under the carpet in every single book on (algebraic) topology that I have consulted.}
Note that $H$ and $p$ are continuous. We have the following commutative diagram

\[
\begin{array}{ccc}
(X \times S) \times T & \xrightarrow{p \times \text{id}_T} & \text{Cone}(X) \times T \\
\downarrow & & \downarrow \varphi \\
\text{Cone}(X) \times T & \xrightarrow{p \circ H} & \text{Cone}(X).
\end{array}
\]

By Lemma 5.15 the map $p$ is continuous. Since $T$ is regionally compact we obtain from Theorem 5.16 that $p \times \text{id}_T$ is a quotient map. By the discussion above we know that $p \circ H$ is continuous. Thus it follows from Lemma 5.17 (2) that $\varphi$ is continuous. \hfill \blacksquare

We move on to the next definition.

**Definition.** Let $X$ be a non-empty topological space. We define the *suspension of $X$* to be the topological space

\[
\Sigma(X) := (X \times [-1, 1]) / \sim
\]

where we identify all points in $X \times \{-1\}$ to a single point and we identify all points in $X \times \{1\}$ to a single point. Furthermore, we define the suspension of the empty topological space to be the topological space $S^0 = \{\pm1\}$, equipped with the discrete topology.

![Figure 448](image)

Before we give an example we state a basic lemma regarding suspensions.

**Lemma 24.2.** Let $X$ be a topological space.

1. If $X$ is compact, then $\text{Cone}(X)$ and the suspension $\Sigma(X)$ are also compact.
2. If $X$ is Hausdorff, then $\text{Cone}(X)$ and the suspension $\Sigma(X)$ are also Hausdorff.
3. (*) The maps
   \[
   X \to \text{Cone}(X) \quad \text{and} \quad \Sigma(X) \to \text{Cone}(X)
   \]
   \[
   x \mapsto [(x, 1)] \quad \text{and} \quad [(x, t)] \mapsto [(x, 1-t)]
   \]
   are closed embeddings.
4. (*) The maps
   \[
   X \times (0, 1) \to \text{Cone}^0(X) \quad \text{and} \quad X \times (-1, 1) \to \Sigma(X)
   \]
   \[
   (x, t) \mapsto [(x, t)] \quad \text{and} \quad (x, t) \mapsto [(x, t)]
   \]
   are open embeddings.

\[\text{Figure 448}\]

---

410 The map $p$ is continuous by definition of the topology on $\text{Cone}(X)$. But what is a super-formal argument for showing that $H$ is continuous?
Sometimes we will use the embeddings in (3) and (4) to identify the domains with their images. For example we will use these maps to view $X$ as a closed subset of $\text{Cone}(X)$ and to view $\text{Cone}(X)$ as a closed subset of $\Sigma(X)$. In particular we can and will at times view $X$ as a closed subset of $\Sigma(X)$.

**Example.** It is pretty clear from Figure 448 that the suspension of $S^n$ is homeomorphic to $S^{n+1}$. In fact throughout the course we will use the following homeomorphism to identify $\Sigma(S^n)$ with $S^{n+1}$:

\[ \Sigma(S^n) \xrightarrow{\cong} S^{n+1} \subset \mathbb{R}^{n+1} \times \mathbb{R} \\
([P,t]) \mapsto (P \cos \left( \frac{\pi}{2} t \right), \sin \left( \frac{\pi}{2} t \right)) \in \mathbb{R}^{n+1}, \in \mathbb{R} \]

Note that this homeomorphism sends the “North Pole” of $\Sigma(S^n)$ to the “North Pole” of $S^{n+1}$.

For future reference we record the following lemma.

**Lemma 24.3.** If $X$ is a path-connected non-empty topological space, then its suspension $\Sigma(X)$ is simply connected.
We have thus shown that $\Sigma(X)$ is indeed simply connected.

We conclude this discussion of suspensions with the fairly obvious notion of the suspension of a map.

**Definition.** Given a map $f : X \to Y$ between topological spaces we denote by

$$
\Sigma(f) : \Sigma(X) \to \Sigma(Y)
$$

$$
[(x,t)] \mapsto [(f(x),t)]
$$

the suspension of $f$.

Most of the statements of the following lemma will not come as a surprise.

**Lemma 24.4. (*)&

(1) If $f : X \to Y$ is a map between topological spaces, then $\Sigma(f) : \Sigma(X) \to \Sigma(Y)$ is also continuous.

(2) If $f : X \to Y$ and $g : Y \to Z$ are maps between topological spaces, then the maps $\Sigma(g \circ f)$ and $\Sigma(g) \circ \Sigma(f)$ from $\Sigma(X)$ to $\Sigma(Z)$ agree.

(3) The maps

$$
\begin{align*}
X & \mapsto \Sigma(X) \\
(f : X \to Y) & \mapsto (\Sigma(f) : \Sigma(X) \to \Sigma(Y))
\end{align*}
$$

define a covariant functor from the category of topological spaces to the category of topological spaces. We refer to this functor as the suspension functor.

(4) Let $f, g : X \to Y$ be two maps between topological spaces. If $f$ and $g$ are homotopic rel a (possibly empty) subset $A$, then $\Sigma(f)$ and $\Sigma(g)$ are homotopic rel $\Sigma(A)$.

(5) If $f : X \to Y$ is a homotopy equivalence of topological spaces, then the suspension $\Sigma(f) : \Sigma(X) \to \Sigma(Y)$ is also a homotopy equivalence.

**Proof (*)&.

(1) We consider the following commutative diagram

$$
\begin{array}{ccc}
X \times [-1,1] & \xrightarrow{f \times \text{id}_{[-1,1]}} & Y \times [-1,1] \\
\downarrow & & \downarrow \\
\Sigma(X) & \xrightarrow{\Sigma(f)} & \Sigma(Y).
\end{array}
$$

By Lemma 3.8 (2b) we know that the top horizontal map is continuous. By Lemma 3.21 (3) the left and right vertical maps are continuous. It follows that the diagonal map is continuous. Finally we obtain from Lemma 3.22 that the bottom horizontal map is continuous.

(2) This statement follows immediately from the definitions.

(3) This statement follows immediately from (1) and (2) and the definitions.

(4) Clearly it suffices to prove the following claim.
Claim. If $F : X \times [0, 1] \to Y$ is a map, then the map

$$G : (\Sigma(X)) \times [0, 1] \to (\Sigma(Y))$$

is continuous.

Verifying this claim is more subtle than one might have thought initially.\[^{112}\] We denote by $\sim_x$ the equivalence relation on $(X \times [-1,1]) \times [0, 1]$ that is generated by $(x,t,s) \sim ((x',t'),s)$ whenever $(x,t) \sim (x',t')$. We consider the following diagram:

$$((X \times [-1,1]) / \sim) \times [0, 1] \xrightarrow{G} ((Y \times [-1,1]) / \sim)$$

The top map is a homeomorphism by Lemma 3.18 and the fact that $[0,1]$ is regionally compact. The top vertical map is continuous by Lemma 3.22 and the bottom vertical map is continuous by Lemma 3.21 (3). It is clear that the diagram commutes. It now follows that $G$ is continuous. \(\blacksquare\)

(5) The last statement is an immediate consequence of the proof of (4). \(\blacksquare\)

More interesting than the totally predictable Lemma 24.4 is perhaps the following scary example, which is dressed up as a lemma to make it more visible.

**Lemma 24.5.** We consider the topological space $X = [-1,1]$, the subset $A = (-1,1)$ and the inclusion map $i : A \to X$. The induced map $\Sigma(i) : \Sigma(A) \to \Sigma(X)$ is not an embedding.

**Proof.** We will provide the proof in Exercise 24.10. \(\blacksquare\)

24.2. **Mapping cylinder and mapping cone.** In this section we associate to a map $f : X \to Y$ between two topological spaces two different topological spaces. The main interest in these topological spaces is that these topological spaces encode some of the information contained in the actual map. On numerous occasions this will allow us to translate questions about maps between topological spaces into questions about topological spaces.

We start out with the definition of a mapping cylinder.

**Definition.** Let $f : X \to Y$ be a map between topological spaces. We define the corresponding **mapping cylinder** to be the topological space

$$\text{Cyl}(f) := \text{Cyl}(f : X \to Y) := ((X \times [0,1]) \sqcup Y) / \sim$$

where $(x,1) \sim f(x)$ for all $x \in X$.

We illustrate the definition in Figure 450.
Remark. In many, arguably most, textbooks on algebraic topology the mapping cylinder is
defined by identifying \((x, 0)\) with \(f(x)\) instead of identifying \((x, 1)\) with \(f(x)\). The definitions
are evidently equivalent, but as the author knows from experience, the usage of two different
definitions can cause some confusion. The totally non-mathematical advantage of our
definition is that it leads to “horizontal” pictures which take up less space.

Example. If \(X\) is a topological space and if \(f: X \to \{y\}\) is the constant map to the
topological space consisting of a single element \(y\), then the mapping cylinder \(\text{Cyl}(f)\) is
homeomorphic to \(\text{Cone}(X)\). This statement is almost, but not completely\(^\text{[413]}\) evident. We
invite the general-topology-aficionado to fill in the details.

Definition. Let \(f: X \to Y\) be a map between topological spaces. We refer to the maps
\[
X \to \text{Cyl}(f: X \to Y) \quad \text{and} \quad Y \to \text{Cyl}(f: X \to Y)
\]
\[
x \mapsto [(x, 0)] \quad \text{and} \quad y \mapsto [y]
\]
as the natural inclusions. Sometimes we use these inclusions to identify \(X\) and \(Y\) with the
respective subsets of the mapping cylinder.

The following lemma says that the natural inclusions are embeddings. This means
that we can legitimately identify \(X\) and \(Y\) with their images in the mapping cylinder
\(\text{Cyl}(f: X \to Y)\). On many occasions we will implicitly use the lemma without actually
referring to it.

Lemma 24.6. \(^(*)\) Let \(f: X \to Y\) be a map between topological spaces.

\begin{enumerate}
\item If \(X\) and \(Y\) are compact, then \(\text{Cyl}(f)\) is also compact.
\item If \(X\) and \(Y\) are Hausdorff, then \(\text{Cyl}(f)\) is also Hausdorff.
\item The natural inclusions \(X \to \text{Cyl}(f)\) and \(Y \to \text{Cyl}(f)\) are embeddings, in particular
they are continuous.
\item The images of the natural inclusions \(X \to \text{Cyl}(f)\) and \(Y \to \text{Cyl}(f)\) are closed
subsets.
\end{enumerate}

Proof. We leave the proofs of the first two and of the last statement as voluntary exercises
to the reader. Finally we will provide the proof of the third statement in Exercise 24.6. \(\blacksquare\)

We continue with a (non-) example. We will not really make use of this lemma, but
Lemma 24.7 should warn the reader that the topology on a mapping cylinder is not necessarily
what one might think it is.

\[^{413}\text{Note that the statement is not true for the empty topological space. This observation shows that}
the statement requires at least a little bit of thought.\]
Lemma 24.7. (*) Let $X$ be a topological space and let $A \subset X$ be a subset. We denote by $i: A \to X$ the inclusion map and we consider the map

$$\Theta: \text{Cyl}(i) = ((A \times [0, 1]) \sqcup X)/(a, 1) \sim i(a) \to (A \times [0, 1]) \sqcup (X \times \{0\}) \quad \text{equipped with the subspace topology}
$$

coming from the product $X \times [0, 1]$.

$$[P] \mapsto \begin{cases} P, & \text{if } P \in A \times [0, 1], \\ (P, 1), & \text{if } P \in X. \end{cases}$$

The following two statements hold:

1. The map $\Theta$ is continuous and it is a bijection.
2. If $A$ is a closed subset of $X$, then $\Theta$ is a homeomorphism.
3. There exist situations, e.g. $X = [0, \infty)$ and $A = [0, 1)$, in which $\Theta$ is not a homeomorphism.

Proof.

(1) It follows easily from Lemma 3.22 that the given map $\Theta$ is continuous. Furthermore it is basically clear that $\Theta$ is a bijection.

(2) Suppose that $A$ is a closed subset of $X$. Note that $A \times \{1\}$ is a closed subset of $A \times [0, 1]$. It follows basically from Lemma 3.45 that $\Theta$ is a homeomorphism.

(3) We consider the case $X = [0, \infty)$ and $A = [0, 1)$. We denote by

$$p: (A \times [0, 1]) \sqcup X \to \text{Cyl}(i) = ((A \times [0, 1]) \sqcup X)/\sim$$

the projection map. We consider the open set $U := \{(x, t) \in [0, 1) \times [0, 1] \mid x > t\}$ of $A \times [0, 1)$. Furthermore we consider the open subset $V := [0, 2)$ of $X = [0, \infty)$. Note that $p^{-1}(p(U \sqcup V)) = U \sqcup V$. Thus it follows immediately from the definition of the quotient topology on $\text{Cyl}(i) = ((A \times [0, 1]) \sqcup X)/\sim$ that $p(U \sqcup V)$ is an open subset of $\text{Cyl}(i)$. On the other hand we have

$$\Theta(p(U \sqcup V)) = U \cup \{(x, 1) \mid x \in V\},$$

but considering the point $(1, 1)$ one can easily verify that this is not an open subset of $(A \times [0, 1]) \sqcup (X \times \{0\})$.  

\[\text{Figure 451. Illustration of the proof of Lemma 24.7 (3).}\]

The following lemma summarizes some basic properties of the mapping cylinder.
Lemma 24.8. Let \( f: X \to Y \) be a map between topological spaces.

(1) The subspace \( Y \) is a deformation retract of \( \text{Cyl}(f: X \to Y) \), in fact an explicit deformation retraction is given by the following map
\[
H: \text{Cyl}(f: X \to Y) \times [0, 1] \to \text{Cyl}(f: X \to Y)
\]
\[
(P, t) \mapsto \begin{cases} 
  P, & \text{if } P \in Y, \\
  [(Q, s \cdot (1-t) + t)], & \text{if } P = [(Q, s)], \text{ where } Q \in X \text{ and } s \in [0, 1].
\end{cases}
\]

(2) We denote by \( r = H_1 \) the retraction \( \text{Cyl}(f: X \to Y) \to Y \) given by (1). If we denote by \( i: X \to \text{Cyl}(f) \) and \( j: Y \to \text{Cyl}(f) \) the natural inclusions, then the following statements hold:

(a) The map \( j: Y \to \text{Cyl}(f: X \to Y) \) and \( r: \text{Cyl}(f: X \to Y) \to Y \) are homotopy equivalences.

(b) The map \( i: X \to \text{Cyl}(f: X \to Y) \) is a homotopy equivalence if and only if the map \( f: X \to Y \) is a homotopy equivalence.

Remark. On page 698 we saw that the mapping cylinder of a constant map \( f: X \to \{y\} \) is homeomorphic to the cone on \( X \). Thus we see that Lemma 24.8 (1) can be viewed as a generalization of Lemma 24.1.

![Illustration of Lemma 24.8 (1)](image)

Figure 452. Illustration of Lemma 24.8 (1).

Proof.

(1) We need to show that the map \( H \) is continuous. First note that the two maps
\[
(X \times [0, 1]) \times [0, 1] \to \text{Cyl}(f)
\]
\[
(Q, t) \mapsto [(Q, s \cdot (1-t) + t)]
\]

are continuous. But this implies, by the somewhat delicate Lemma 18.23, that
\[
H: ((X \times [0, 1]) \cup_{(x,1)} f(x) Y) \times [0, 1] \to \text{Cyl}(f)
\]

is itself continuous. Once continuity is out of the way it is basically clear that \( H \) is a deformation retraction. Therefore it follows from Lemma 18.14 that the inclusion \( Y \to \text{Cyl}(f: X \to Y) \) is a homotopy equivalence.

(2) (a) It follows from Lemma 18.14 that \( j \) and \( r \) are homotopy equivalences.

\[^{414}\text{For once this is basically obvious.}\]
(b) We consider the map
\[ G : X \times [0, 1] \to \text{Cyl}(f : X \to Y) \]
\[ (x, t) \mapsto [(x, t)]. \]

This map is continuous by Lemma 3.22. We make the following observations:

\[ i = G_0 : X \to \text{Cyl}(f) \text{ is a homotopy equivalence} \iff i = G_1 : X \to \text{Cyl}(f) \text{ is a homotopy equivalence} \]
\[ = f \circ r \circ G_1 : X \to Y \text{ is a homotopy equivalence} \]
by Lemma 18.11(3), since by Lemma 18.11(1), since by (2a) we know that \( r \) is a homotopy equivalence.

We have thus shown that \( i \) is a homotopy equivalence if and only if \( f = r \circ G_1 \) is a homotopy equivalence. ■

In the above discussion we associated to a map \( f : X \to Y \) between topological spaces a new topological space, namely the mapping cylinder \( \text{Cyl}(f : X \to Y) \). But we see in Lemma 24.8(1) that the mapping cylinder, as a topological space, is in many ways the same as \( Y \). Therefore we move on to the definition of the mapping cone which is a much more interesting construction.

**Definition.** Given a map \( f : A \to X \) between topological spaces the corresponding mapping cone is defined as
\[
\text{Cone}(f : A \to X) := (\text{Cone}(A) \sqcup X)/\sim \text{ where } [(a, 1)] \sim f(a) \text{ for all } a \in A.
\]

We refer to the point \([A \times \{0\}]\) as the *cone point* of the mapping cone. We illustrate the definition in Figure 453.

![Figure 453](image)

**Remark.** Let \( f : A \to X \) be a map between topological spaces. If \( A \) is non-empty, then it follows almost immediately from the definitions that
\[
\text{Cone}(f : A \to X) = \text{Cyl}(f : A \to X)/(A \times \{0\}).
\]

The following lemma summarizes some properties of mapping cones.

**Lemma 24.9.** (*) Let \( f : A \to X \) be a map between topological spaces.

1. We denote by \( i : A \to \text{Cone}(A) \) the map that is given by \( a \mapsto [(a, 1)] \). The mapping cone \( \text{Cone}(f : A \to X) \) is the same as the pushout of the maps \( i : A \to \text{Cone}(A) \)
and \( f: A \to X \), i.e. we have the pushout diagram

\[
\begin{array}{ccc}
A & \xrightarrow{i} & \text{Cone}(A) \\
\downarrow{f} & & \downarrow \\
X & \xrightarrow{} & \text{Cone}(f: A \to X).
\end{array}
\]

(2) The natural inclusion

\[
X \to \text{Cone}(f: A \to X) \quad \text{respectively} \quad \text{Cone}^0(A) \to \text{Cone}(f: A \to X)
\]

\( x \mapsto [x] \text{ respectively } x \mapsto [x] \)

is a closed respectively an open embedding. Often we will use these natural inclusions to identify \( X \) with its image in \( \text{Cone}(f: A \to X) \) and to identify the open cone \( \text{Cone}^0(A) \) with its image in \( \text{Cone}(f: A \to X) \).

(3) If the map \( f: A \to X \) is a (closed or open) embedding, then the natural map \( \text{Cone}(A) \to \text{Cone}(f: A \to X) \) is a (closed or open) embedding.

(4) If \( A \) is non-empty, then the map

\[
\text{Cone}(f: A \to X)/X \to \Sigma(A)
\]

\( [(a,t)] \mapsto [(a,1-2t)] \)

is a natural homeomorphism.

(5) The cone point \( * \) defines a closed subset of \( \text{Cone}(f: A \to X) \).

(6) There exists a natural deformation retraction from \( \text{Cone}(f: A \to X) \setminus \{ * \} \) to \( X \). In particular the subset \( X \) is a deformation retract of the complement of the cone point.

\[\text{Figure 454. Illustration of Lemma 24.9 (4).}\]

Sketch of proof.

(1) This statement follows basically immediately from the definitions.

(2) This statement follows immediately from (1) together with Lemma 3.43.

(3) This statement also follows immediately from (1) together with Lemma 3.43.

(4) It is clear that the given map is a bijection. One can easily verify, without any extra wizardry, that the given map is indeed a homeomorphism.

(5) This statement follows quite easily from the definition of the topologies involved.

(6) The proof of this statement is basically identical to the proof of Lemma 24.8 (1). ■

So what have we done so far? We have associated to a map \( f: X \to Y \) between topological spaces the topological space \( \text{Cone}(f: X \to Y) \). This construction will allow us...
to turn questions about maps between topological spaces into questions about topological spaces. As always in algebraic topology, not only do we want a map

set of maps between topological spaces $\rightarrow$ set of topological spaces,

but we really want a functor. It is clear what the category should be on the right. It is a little less clear what the category should be on the left. Here it is.

**Definition.** We refer to the category $\text{MapTop}$ with

$$\begin{align*}
\text{Ob}(\text{MapTop}) & := \text{all maps between topological spaces}, \\
\text{Mor}(f: X \rightarrow Y, \tilde{f}: \tilde{X} \rightarrow \tilde{Y}) & := (\varphi: X \rightarrow \tilde{X}, \psi: Y \rightarrow \tilde{Y}) \quad \text{such that the diagram} \\
& \begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\varphi \downarrow & & \downarrow \psi \\
\tilde{X} & \xrightarrow{\tilde{f}} & \tilde{Y}
\end{array}
\end{align*}$$

with the (hopefully) obvious composition of morphisms as the category of maps between topological spaces.

The following lemma says that we can view “taking the mapping cone” and “taking the mapping cylinder” as covariant functors.

**Lemma 24.10.** (*)

(1) The maps

$$f: X \rightarrow Y \mapsto \text{Cyl}(f: X \rightarrow Y)$$

and

$$\varphi: X \rightarrow \tilde{X}, \psi: Y \rightarrow \tilde{Y} \mapsto \begin{pmatrix} \text{Cyl}(f: X \rightarrow Y) & \text{Cyl}(\tilde{f}: \tilde{X} \rightarrow \tilde{Y}) \\ [P] & \begin{cases} [\varphi(x), t], & \text{if } P = (x, t) \text{ with,} \\
[\psi(y)], & \text{if } P = y \text{ with } y \in Y \end{cases} \end{pmatrix}$$

define a covariant functor from the category $\text{MapTop}$ of maps between topological spaces to the category $\text{Top}$ of topological spaces.

(2) If, in the setting of (1), the maps $\varphi$ and $\psi$ are embeddings, then the corresponding map $\text{Cyl}(f: X \rightarrow Y) \rightarrow \text{Cyl}(\tilde{f}: \tilde{X} \rightarrow \tilde{Y})$ is also an embedding.

(3) The analogues of (1) and (2), with obvious modifications, hold if we replace mapping cylinders by mapping cones.

(4) Given a morphism

$$\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\varphi \downarrow & & \downarrow \psi \\
\tilde{X} & \xrightarrow{\tilde{f}} & \tilde{Y}
\end{array}$$

the map from (3) for mapping cones fits into the following commutative diagram:

$$\begin{array}{cccc}
Y & \xrightarrow{\psi} & \text{Cone}(f: X \rightarrow Y) & \xrightarrow{\Sigma(\varphi)} \Sigma(X) \\
\varphi \downarrow & & \downarrow & \\
\tilde{Y} & \xrightarrow{\tilde{\psi}} & \text{Cone}(\tilde{f}: \tilde{X} \rightarrow \tilde{Y}) & \xrightarrow{\Sigma(\tilde{\varphi})} \Sigma(\tilde{X})
\end{array}$$
Lemma follows basically from the definitions.

From Lemma 3.44 (5). The continuity of the map between the mapping cones now follows again from Lemma 3.44 (5).

The second statement will be proved in Exercise 24.9 (3). Finally statement (4) of the lemma follows basically from the definitions.

\[ \text{Cone}(X) \to \text{Cone}(\tilde{X}) \]
\[ [(x, t)] \mapsto [(\varphi(x), t)] \]

is continuous. The continuity of the map between the mapping cones now follows again from Lemma 3.44 (5).

The following lemma shows in particular that homotopic maps give rise to homotopy equivalent mapping cones. In particular at times this lemma allows us to translate the question whether two maps are homotopic to the question whether two topological spaces are homotopy equivalent.

**Proposition 24.11.** Let \( f_0, f_1 : A \to X \) be maps between topological spaces. If \( f_0, f_1 \) are homotopic, then there exists a homotopy equivalence \( \text{Cone}(f_0) \to \text{Cone}(f_1) \) rel the union of \( X \) and the cone point.

\[ \text{image of a homotopy } H \]

\[ \text{Cone}(f) \]

\[ \text{Cone}(g) \]

It is not that difficult to write down explicit maps between the cones and to write down explicit homotopies. But we prefer to go take a more conceptual approach. Namely, instead of proving Proposition 24.11 directly we will prove the following more technical lemma.

\[ \text{\footnote{In fancy speak this commutative diagram says that the inclusion maps into the mapping cone and the projection from the mapping cone to the suspension are natural transformations between suitable functors.}} \]
Lemma 24.12. (*) Let $f_0, f_1 : A \to X$ be maps between topological spaces. Furthermore let $H : A \times [0, 1] \to X$ be a homotopy between $f_0$ and $f_1$. Let $j \in \{0, 1\}$. We denote by $i_j : A \to A \times \{j\}$ the obvious inclusion map.

1. The inclusion map $i_j$ induces by Lemma 24.10 (3) a map $\text{Cone}(f_j) \to \text{Cone}(H)$. This map is an embedding.

2. If we use the map from (1) to view $\text{Cone}(f_j)$ as a subset of $\text{Cone}(H)$, then it is a deformation retract of $\text{Cone}(H)$.

Proof of Proposition 24.11 assuming Lemma 24.12 (*). Let $H$ be a homotopy between $f_0$ and $f_1$. By Lemma 24.12 we can view $\text{Cone}(f_0)$ and $\text{Cone}(f_1)$ as deformation retracts of $\text{Cone}(H)$. It follows from Lemma 18.14 and Lemma 18.11 that $\text{Cone}(f_0)$ and $\text{Cone}(f_1)$ are homotopy equivalent. A quick inspection of the maps involved shows that the two cones are homotopy equivalent rel the union of $X$ and the cone point.

Proof of Lemma 24.12 (*). Let $f_0, f_1 : A \to X$ be maps between topological spaces. Furthermore let $H : A \times [0, 1] \to X$ be a homotopy between $f_0$ and $f_1$. For notational convenience we only deal with the case $j = 0$. We denote by $i : A \to A \times \{0\}$ the obvious inclusion map. We get a commutative diagram

$$
\begin{array}{ccc}
A & \xrightarrow{f_0} & X \\
i & \downarrow & \downarrow H \\
A \times [0, 1] & \xrightarrow{H} & X.
\end{array}
$$

Thus we get from Lemma 24.10 (3) a map $\text{Cone}(f_0) \to \text{Cone}(H)$. It follows almost immediately from Lemma 24.10 (3) that this map is an embedding.

Since this proof suffers from an abundance of intervals playing different roles we rescale two of the intervals:

1. We use the interval $[0, 1]$ for the homotopy $H$.
2. We use the interval $[0, 2]$ for the definition of the mapping cone.
3. We use the interval $[0, 3]$ for the definition of the desired deformation retraction.

With this convention out of the way we pick a deformation retraction

$$
\varphi : ([0, 1] \times [0, 2]) \times [0, 3] \to [0, 1] \times [0, 2]
$$

rel $([0, 2] \times \{0\}) \cup (\{2\} \times [0, 1])$ such that $\varphi(r, s, t) = (r, \frac{1}{3}st)$ whenever $r \in [0, \frac{1}{3}]$. It is straightforward to see that such a deformation retraction exists. We refer to Figure 458 for an illustration.
It is straightforward to verify that this map has the desired properties.

Using Lemma 3.21 (3) and Lemma 18.23 one can easily show that this map $G$ is continuous. It is straightforward to verify that this map has the desired properties.

For completeness’ sake we also state the following corollary.

**Corollary 24.13.** (\(\ast\)) Let $f : A \to X$ be a map between topological spaces and let $g : X \to Y$ be a homotopy equivalence. The map

\[ Cyl(f : A \to X) \to Cyl(g \circ f : A \to Y) \]

\[ [P] \mapsto \begin{cases} [(a, t)], & \text{if } P = (a, t) \in A \times [0, 1], \\ [g(P)], & \text{if } P \in X \end{cases} \]

is a homotopy equivalence rel $A \times \{0\}$. The same way one sees that the mapping cones of $f$ and $g \circ f$ are homotopy equivalent.

**Example.** Let $f : S^1 \to \mathbb{R}^2$ be the inclusion and let $g : \mathbb{R}^2 \to \{\ast\}$ be the retraction to the origin. In Figure 459 we show the corresponding mapping cones, which we now know are homotopy equivalent by Corollary 24.13

\[ \text{Cone}(f : S^1 \to X) \quad \text{Cone}(g \circ f : S^1 \to Y) \]

**Proof.** The corollary is a straightforward consequence of Proposition 24.11. We leave it to the reader to fill in the details.

The following lemma calculates the fundamental groups of mapping cones.
24. MAPPING CONES, CYLINDERS AND TORI

**Lemma 24.14.** (*) Let $f : A \to X$ be a map between topological spaces and let $a_0 \in A$. We write $x_0 := f(a_0)$. If $A$ is path-connected, then the inclusion induces an isomorphism

$$\pi_1(X, x_0)/f_* (\pi_1(A, a_0)) \to \pi_1(\text{Cone}(f : A \to X), [x_0]).$$

**Example.** Let $n \in \mathbb{N}$ and let $A = X = S^1$. We consider the map $f : A = S^1 \to X = S^1$ that is given by $f(z) = z^n$. It follows from Lemma 24.14 and Proposition 16.17, perhaps counter-intuitively, that $\pi_1(\text{Cone}(f : A \to X)) \cong \mathbb{Z}_n$. We refer to Figure 460 for an attempt at an illustration of this example.

![Figure 460](image_url)

**Proof.** We will provide the proof in Exercise 24.12.

We conclude our discussion of mapping cones with the following proposition.

**Proposition 24.15.** (*) Let $X$ be a topological space and let $A$ be a subset of $X$. We denote by $i : A \to X$ the inclusion map. We use Lemma 24.9(2) to view $X$ as a subset of $\text{Cone}(i : A \to X)$.

1. If $A$ is contractible, then given any $a_0 \in A$ there exists a deformation retraction $G$ from $\text{Cone}(i : A \to X)$ to $X$ such that $G_1(\text{cone point } [A \times \{0\}]) = a_0$.
2. If $a_0 \in A$ is a deformation retract of $A$, then there exists a deformation retraction $G$ from $\text{Cone}(i : A \to X)$ to $X$ such that for any $t \in [0, 1]$ we have $G_1([\{a_0, t\}]) = a_0$.

![Figure 461](image_url)

**Proof.** We first prove Statement (1). Thus let $a_0 \in A$. Since $A$ is contractible it follows from Lemma 18.15 (2) that there exists a map $r : A \times [0, 1] \to A$ such that $r_0 = \text{id}$ and such that $r_1(a) = a_0$ for all $a \in A$. We pick continuous functions $x, y : [0, 1] \times [0, 1] \to [0, 1]$ with the following properties:

(a) For any $t \in [0, 1]$ we have $x(0, t) = 1$ or $y(0, t) = 0$.
(b) We have $x(s, 0) = 0$ and $y(s, 0) = s$ for all $s \in [0, 1]$.
(c) We have $y(s, 1) = 1$ for all $s \in [0, 1]$.
(d) We have $x(1, t) = 0$ and $y(1, t) = 1$ for all $t \in [0, 1]$.

We sketch graphs of such functions $x$ and $y$ in Figure 462. Now we consider the map

$$F : ((A \times [0, 1])/(A \times \{0\})) \times [0, 1] \to ((A \times [0, 1])/(A \times \{0\})) \quad \text{such that} \quad ((a, s), t) \mapsto ((r(a, x(s, t)), y(s, t))).$$
We make the following observations:

(0) Since $x$ and $y$ are continuous and since $[0,1]$ is regionally compact we obtain from Lemmas 3.22 and Lemma 5.18 that $F$ is continuous.

(1) It follows from (a) that $F$ is actually well-defined.

(2) It follows from (b) that $F_0 = \text{id}$.

(3) It follows from (c) that $F_1$ takes values in $A \times \{1\}$.

(4) It follows from (d) that $F$ is a homotopy rel $A \times \{1\}$.

In summary this shows that $F$ is a deformation retraction from $\text{Cone}(A)$ to $A \times \{1\}$. Now we consider the map

$$G: (\text{Cone}(A) \cup_{(a,1)=0} X) \times [0,1] \to \text{Cone}(i: A \to X)$$

$$([P], t) \mapsto \begin{cases} [F(P, t)] & \text{if } P \in \text{Cone}(A), \\ [P] & \text{if } P \in X. \end{cases}$$

It follows from Lemma 18.23 that this map is continuous. Clearly $G$ is a deformation retract from $\text{Cone}(i: A \to X)$ to $X$. By construction it sends the cone point to $a_0$.

It remains to prove Statement (2). If we start out with a deformation retraction $r$ from $A$ to $a_0$, then the above homotopy $F$ has the desired property. 

24.3. The mapping cone of a suspension (*). In this section we show that under favorable circumstances the operation of taking a mapping cone (or mapping cylinder) commutes with the operation of taking the suspension of a map. This technical proposition will play a useful role later on. The proposition is also a good way to test whether we really understand the various topologies involved in the definition of mapping cones, mapping cylinders and suspensions.

**Proposition 24.16.** If $f: X \to Y$ is a map between topological spaces, then the map

$$\Phi: \Sigma(\text{Cone}(f: X \to Y)) \to \text{Cone}(\Sigma(f): \Sigma(X) \to \Sigma(Y))$$

$$P \mapsto \begin{cases} ([((x,t), s)], & \text{if } P = [((x,s), t)] \text{ with } x \in X, t \in [-1,1] \\
& \text{and with } s \in [0,1], \\
[([y], t)], & \text{if } P = [([y], t)] \text{ with } y \in Y \text{ and } t \in [-1,1]. \end{cases}$$

is a homeomorphism.
Lemma 24.17. Let $X$ be a topological space. If $Y$ is a regionally compact topological space (e.g. if $Y = [0, 1]$), then the map

$$\varphi: \Sigma(X) \times Y \to \Sigma(X \times Y)$$

$$([x, t], y) \mapsto [(x, y), t]$$

is continuous.

In Figure 464 we illustrate Lemma 24.17. This cute picture is not meant to hide the grim reality that for arbitrary topological spaces $X$ it actually requires a non-trivial input to prove Lemma 24.17.

Proof. We denote by $p: (X \times Y) \times [-1, 1] \to \Sigma(X \times Y)$ and $q: X \times [-1, 1] \to \Sigma(X)$ the two obvious projection maps. We have the following commutative diagram

$$
\begin{array}{ccc}
(X \times [-1, 1]) \times Y & \xrightarrow{(x, t, y) \mapsto (x, y, t)} & (X \times Y) \times [-1, 1] \\
\downarrow q \times \text{id}_Y & & \downarrow p \\
\Sigma(X) \times Y & \xrightarrow{\varphi} & \Sigma(X \times Y).
\end{array}
$$

By Lemma 3.8 the top horizontal map is a homeomorphism. By Lemma 5.15 the maps $p$ and $q$ are quotient maps. Since $Y$ is regionally compact we obtain from Theorem 5.16 that $q \times \text{id}_Y$ is a quotient map. It follows from Lemma 5.17 that $\varphi$ is also a quotient map. By Lemma 5.15 (2) this implies that $\varphi$ is indeed continuous.
Proof of Proposition 24.16. Let \( f : X \to Y \) be a map between topological spaces. One can easily verify that the given map \( \Phi \) is a bijection. It remains to show that \( \Phi \) and \( \Phi^{-1} \) are continuous. We will do so in the following two claims. The domain and the target of \( \Phi \) are both a scary mix of product and quotient topologies. Thus we need to tread super carefully.

Claim. The map \( \Phi \) is continuous.

To prove the claim we introduce the following notation:

(a) We consider the map \( \varphi : X \times \{1\} \to Y \) that is given by \( \varphi(x, 1) = f(x) \).

(b) We denote by \( p : \text{Cone}(f : X \to Y) \times [-1, 1] \to \Sigma(\text{Cone}(f : X \to Y)) \) the projection map.

We consider the following diagram:

\[
\begin{array}{ccc}
(X \times [0, 1]) \times [-1, 1] & Y \times [-1, 1] \\
\downarrow i & \downarrow j \\
((X \times [0, 1]) \times [-1, 1]) \cup_{\varphi \times \text{id}_{[-1, 1]}} (Y \times [-1, 1]) & \text{Cone}(f : X \to Y) \times [-1, 1] \\
\downarrow ((P,t) \mapsto [(P,t)]) & \downarrow q ([(P,t)] \mapsto [(P,t)]) \\
\Sigma(\text{Cone}(f : X \to Y)) & \Phi & \text{Cone}(\Sigma(f) : \Sigma(X) \to \Sigma(Y)).
\end{array}
\]

We make the following observations:

1. By Lemma 5.19 we know that the vertical map between the second and the third row is a homeomorphism.
2. It follows from (1) together with Lemma 3.22 applied to the projection map \( q \), that \( \Phi \) is continuous if \( \Psi \) is continuous.
3. It follows from Lemma 3.44 (5) that \( \Psi \) is continuous if \( \Psi \circ i \) and \( \Psi \circ j \) are continuous.
4. We have the following commutative diagram:

\[
\begin{array}{ccc}
Y \times [-1, 1] & \xrightarrow{\Psi \circ i} & \text{Cone}(\Sigma(f) : \Sigma(X) \to \Sigma(Y)). \\
(P,t) \mapsto [(P,t)] & \downarrow & Q \mapsto [Q] \\
& \Sigma(Y) & \\
\end{array}
\]

The diagonal maps are continuous by Lemma 3.21 (3) and Lemma 3.44 (5). Thus we see that \( \Psi \circ i \) is continuous. The same argument shows that \( \Psi \circ j \) is continuous.

The combination of (2), (3) and (4) shows that \( \Phi \) is indeed continuous. \( \square \)
Claim. The map
\[ \Phi^{-1}(\Sigma(\text{Cone}(f : X \to Y))) \]
\[ P \mapsto \begin{cases} [(x, s), t], & \text{if } P = [(x, t)] \text{ with } s \in [0, 1] \\
[(y), t], & \text{if } P = [(y), t] \text{ with } t \in [-1, 1]. \end{cases} \]
is continuous.

By Lemma 3.44 it suffices to show that the maps
\[ \Sigma(X) \times [0, 1] \to \Sigma(\text{Cone}(f : X \to Y)), \quad [(x, t)], s \mapsto [(x, s), t] \]
\[ \Sigma(Y) \to \Sigma(\text{Cone}(f : X \to Y)), \quad [(y), t] \mapsto [(y), t] \]
are continuous. The second map is continuous by Lemma 24.4 (1). Furthermore it follows from the combination of Lemma 24.17 with Lemma 24.4 (1) that the first map is continuous.

24.4. The mapping torus. In this last section we discuss the mapping torus. This construction gives rise to many interesting topological spaces. We will also see that determining the fundamental group of a mapping torus is somewhat challenging, but not impossible.

**Definition.** Let \( X \) be a topological space and let \( f : X \to X \) be a map. We refer to
\[ \text{Tor}(X, f) := (X \times [0, 1]) / \sim \]
where \((x, 0) \sim (f(x), 1)\) for all \( x \in X \),
as the **mapping torus** of \((X, f)\). We refer to the map
\[ \text{Tor}(X, f) = (X \times [0, 1])/(x, 0) \sim (f(x), 1) \to S^1, \]
\[ [(x, t)] \mapsto e^{2\pi i t} \]
as the **natural projection onto** \( S^1 \). Sometimes \( X \) is called the **fiber** of the mapping torus and \( f \) is called the **monodromy** of the mapping torus.

It follows from Lemma 3.22 that the natural projection is indeed continuous.

The following lemma shows that the mapping torus is a pushout. This is very useful since it allows us to use all the results from Lemma 3.43.

**Lemma 24.18.** Let \( X \) be a topological space and let \( f : X \to X \) be a map. The natural maps
\[ \alpha : X \times [0, 1] \to \text{Tor}(X, f), \quad (x, t) \mapsto [(x, t)] \] \[ \beta : X \to \text{Tor}(X, f), \quad x \mapsto [(x, 0)] \]
induce the following natural homeomorphism:
\[ X \times \{0, 1\} \to X \]
\[ X \times [0, 1] \to (X \times [0, 1]) \cup_{X \times \{0, 1\}} X \]
\[ \cong \]
\[ \text{Tor}(X, f). \]
Proof. First note that it follows from Lemma 3.43 (3) that $\Psi$ is continuous. Next we consider the natural map
\[
\Phi: (X \times [0, 1]) / \sim \rightarrow (X \times [0, 1]) \cup X \times \{0, 1\}
\]
\[
[(x, t)] \mapsto [(x, t)].
\]
It follows from Lemma 3.43 (1) and Lemma 3.22 that $\Phi$ is continuous. One can easily verify that $\Phi$ and $\Psi$ are inverses of one another. Thus we have shown that both maps are homeomorphisms.

For completeness’ sake we state the following almost self-evident lemma which gets used, often subconsciously, on numerous occasions.

**Lemma 24.19.** Let $X$ be a topological space and let $f: X \rightarrow X$ be a map.

1. The map
\[
\Theta: (X \times \mathbb{R})/(x, r) \sim (f(x), r + 1) \rightarrow \text{Tor}(X, f) = (X \times [0, 1])/(x, 0) \sim (f(x), 1)
\]
\[
[(x, t)] \mapsto [(x, t)]
\]

is a homeomorphism.
2. For every interval $I \subset \mathbb{R}$ of length less than one, the map
\[
\varphi: X \times I \rightarrow (X \times \mathbb{R})/ \sim \Theta \rightarrow \text{Tor}(X, f)
\]
\[
(x, t) \mapsto [(x, t)]
\]

is an embedding. Furthermore, if $I$ is closed respectively open, then $\varphi$ is a closed respectively open embedding.

Proof. First note that it is straightforward to write down an inverse to $\Theta$. The second statement follows from elementary arguments. We leave it to the reader to fill in the details.

The following lemma takes care of our two favorite properties of topological spaces, namely compactness and being Hausdorff.

**Lemma 24.20.** Let $X$ be a topological space and let $f: X \rightarrow X$ be a homeomorphism.

1. If $X$ is Hausdorff, then the mapping torus $\text{Tor}(X, f)$ is Hausdorff.
2. If $X$ is compact, then the mapping torus $\text{Tor}(X, f)$ is compact.

Proof.

1. This statement will be proved in Exercise 24.13.
2. This statement follows immediately from Proposition 3.12 (2) and Lemma 3.21 (4).

Next we will see that several well-established topological spaces are actually mapping tori.

**Examples.**
(1) We consider the topological space $[0, 1]$ and let $f: [0, 1] \to [0, 1]$ be the self-homeomorphism of $[0, 1]$ that is given by $f(w) = 1 - w$. It follows immediately from the definitions that the corresponding mapping torus Tor$([0, 1], f)$ is precisely the Möbius band as defined on page \ref{204}. We refer to Figure \ref{465} for an illustration.

![Diagram of a mapping torus](image)

**Figure 465.** The Möbius band as a mapping torus.

(2) Let $X = S^1$ and let $f: X \to X$ be the homeomorphism that is given by $f(z) = \bar{z}$. It follows easily from Proposition \ref{2.43} (3) and Lemma \ref{24.20} (1) that the map

$$
\left( [0, 1] \times [0, 1] \right) / (x, 0) \sim (x, 1), (0, y) \sim (1, 1 - y), \; \left[ (x, y) \right] \mapsto \left[ (e^{2\pi i y}, x) \right]
$$

is a homeomorphism from the Klein bottle to the mapping torus Tor$([0, 1], f)$. This homeomorphism is also illustrated in Figure \ref{466}.

![Diagram of a Klein bottle and mapping torus](image)

**Figure 466**

(3) As a final example we consider $X = \mathbb{Z}_3 = \{0, 1, 2\}$, equipped with the discrete topology. Let $f: X \to X$ be the homeomorphism that is given by $f(x) = x + 1 \mod 3$. As we illustrate in Figure \ref{467}, the mapping torus Tor$([0, 1], f)$ is homeomorphic to the Klein bottle $[0, 1] \times [0, 1]/ \sim$

![Diagram of a mapping torus](image)

**Figure 467**

We slow down a little to consider the case $\varphi = \text{id}$ in more detail. On page \ref{203} we already saw that Tor$([0, 1], \text{id})$ is homeomorphic to the torus $S^1 \times S^1$. Thus the following lemma does not come as a surprise.

---

\textsuperscript{418}What does the mapping torus Tor$([0, 1], f(z) = \bar{z})$ look like?
Lemma 24.21. Given any topological space $X$ the map

$$
\Phi: \text{Tor}(X, \text{id}) \to X \times S^1
\]

$$(x, t) \mapsto (x, e^{2\pi it})$$

is a homeomorphism.

**Convention.** Let $X$ be a topological space. We use the homeomorphism from Lemma 24.21 to make the identification $\text{Tor}(X, \text{id}) = X \times S^1$.

**Proof (\ast).** It is easy to verify that $\Phi$ is a bijection. Using Remark 3.23 (1) one can easily show that $\Phi$ is continuous. It still remains to show that $\Phi$ is actually a homeomorphism.

First we provide an argument based on Proposition 5.23. First note that it follows from Proposition 2.43 (3) that the map $[0, 1]/\{0, 1\} \to S^1$ induced by $[t] \mapsto e^{2\pi i}$ is a homeomorphism. We use this homeomorphism to replace $S^1$ by $[0, 1]/\{0, 1\}$. Next we consider the following diagram:

$$
\begin{array}{ccc}
X \times [0, 1] & \xrightarrow{(x,t)\mapsto(x,\{t\})} & X \times ([0,1]/\{0,1\}) \\
\downarrow \Phi^{-1} & & \downarrow \Phi \\
(X \times [0,1])/(x,0) & \sim & (x,1).
\end{array}
$$

By Proposition 5.23 applied to $Y = [0, 1]$ and the compact subset $B = \{0, 1\}$ we know that $p$ is a quotient map. By Lemma 3.21 (3) we know that $q$ is continuous. Since the diagram commutes we obtain from Lemma 5.17 that $\Phi^{-1}$ is continuous. We have thus shown that $\Phi$ is a homeomorphism.

In the rather unlikely event that the reader skipped Proposition 5.23 we also give a more direct argument. By Lemma 2.42 (2) it remains to show that $\Phi$ is an open map. So let $U$ be an open subset of $\text{Tor}(X, \text{id}) = (X \times [0, 1]) / \sim$. Let $P := [(x, t)] \in U$ be a point. We can assume that $t \in [0, 1)$. We need to show that $Q := \Phi([(x, t)])$ admits an open neighborhood $Y$ that is contained in $V := \Phi(U)$. In the following we denote by $p: X \times [0, 1] \to \text{Tor}(X, \text{id})$ the projection map.

If $t \in (0, 1)$, then by the definition of the topology on $\text{Tor}(X, \text{id})$ there exists an open subset $W \subset X$ and an open interval $(a, b) \subset (0, 1)$ with $P \in W \times (a, b) \subset U$. We set $Y := \Phi(W \times (a, b)) = W \times \{e^{2\pi it} | t \in (a, b)\}$. Note that $p^{-1}(Y) = Y$ is an open subset of $X \times [0, 1]$. Thus $Y$ has the desired property.

Now suppose that $t = 0$. In $X \times [0, 1]$ we pick an open neighborhood $W_1 \times [0, \epsilon_1]$ of the point $(x, 0)$ that is contained in $p^{-1}(U)$. Similarly we pick an open neighborhood $W_2 \times (1-\epsilon_2, 1]$ of the point $(x, 1)$ that is also contained in $p^{-1}(U)$. It is now straightforward to see that $Y := (W_1 \cap W_2) \times \{e^{2\pi is} | s \in (-\epsilon_2, \epsilon_1)\}$ has the desired property.

Now we continue the discussion of mapping tori with a few more examples.

**Examples.**

1. In [Rolf90 Chapter 10.I.10] and [BZH14 Section 5.C] it is shown that the complement of the trefoil and the complement of the figure-8 knot are homeomorphic to a mapping torus, where the fiber is given by removing a point from the torus.
(2) If one wants to construct new interesting topological spaces out of a given topological space we need to find “non-trivial” self-homeomorphisms. For example let $\Sigma$ be an oriented surface and let $C \subset \Sigma$ be a closed oriented curve on $\Sigma$, i.e. $C$ is an oriented submanifold diffeomorphic to $S^1$. By the Tubular Neighborhood Theorem [8,24] there exists an orientation-preserving smooth embedding $\Phi: [-1, 1] \times S^1 \to \Sigma$ such that $\Phi: \{0\} \times S^1 \to C$ is an orientation-preserving diffeomorphism. By Lemma [6,13] we can pick a smooth map $\gamma: [-1, 1] \to [0, 2\pi]$ with $\gamma(-1) = 0$ and $\gamma(1) = 2\pi$ which is constant close to $-1$ and $1$. We refer to the orientation-preserving diffeomorphism\^{419} as a Dehn\^{420} twist along the curve $C$. The definition of a Dehn twist is illustrated in Figure 469.

\footnote{One can easily verify that this map is a diffeomorphism. An inverse is given by a Dehn twist in the “opposite direction”.

Max Dehn (1878-1952) was a German-Jewish mathematician. In 1939 he fled to Norway. After the German occupation of Norway he fled to America via Siberia and Japan. He died in 1952 in Black Mountain, North Carolina.}

For completeness we also state the following lemma.

**Lemma 24.22.** Let $M$ be an $n$-dimensional smooth manifold and let $f: M \to M$ be a diffeomorphism. The following statements hold:

1. The mapping torus $\text{Tor}(M, f)$ is naturally an $(n + 1)$-dimensional smooth manifold such that the obvious inclusion map $M \times (0, 1) \to \text{Tor}(M, f)$ is a smooth map.

2. The boundary $\partial \text{Tor}(M, f)$ is given by the mapping torus $\text{Tor}(\partial M, f|_{\partial M})$, in particular, if $M$ is closed, then $\text{Tor}(M, f)$ is also closed.
If $M$ is orientable and if $f$ is orientation-preserving, then $\text{Tor}(M,f)$ is also an orientable smooth manifold.

**Proof ($\ast$).** First consider the case that $M$ has no boundary. By Proposition 6.51 (4) we know that $M \times [0,1]$ is an $(n+1)$-dimensional smooth manifold with boundary given by $M \times \{0,1\}$. Note that we obtain the mapping torus $\text{Tor}(M,f)$ from the smooth manifold $M \times [0,1]$ by identifying the boundary component $M \times \{0\}$ with $M \times \{1\}$. Thus the statements are an immediate consequence of Proposition 8.15.

We will not make use of Lemma 24.22 when $M$ has non-empty boundary. Thus we leave it to the curious reader to modify the above argument to the general case. □

The lemma says in particular that self-diffeomorphisms of surfaces give rise to 3-dimensional smooth manifolds. This construction is an important source of examples of 3-dimensional smooth manifolds.

**Definition.** Let $X$ and $Y$ be topological spaces. Two homeomorphisms $f,g: X \to Y$ are called isotopic, if there exists an isotopy from $f$ to $g$, i.e. a map

$$H: X \times [0,1] \to Y$$

$$(x,t) \mapsto H(x,t)$$

such that the following hold:

1. We have $H(x,0) = f(x)$ and $H(x,1) = g(x)$ for all $x \in X$,
2. for each $t \in [0,1]$ the map $X \to Y$ given by $x \mapsto H(x,t)$ is a homeomorphism.

**Examples.**

1. We consider $X = [0,2]$ and the two self-homeomorphisms given by $f(x) = x$ and by $g(x) = \frac{1}{2} \cdot x^2$. Then

$$H: X \times [0,1] \to X$$

$$(x,t) \mapsto f(x) \cdot (1-t) + g(x) \cdot t$$

is an isotopy from $f$ to $g$.

2. Lickorish [Lic62] showed that any self-homeomorphism of a compact orientable 2-dimensional smooth manifold is isotopic to the concatenation of finitely many Dehn twists.

The following lemma will be proved in Exercise 24.14.

**Lemma 24.23.** Let $X$ be a topological space. If $f,g: X \to X$ are two homeomorphisms that are isotopic, then the mapping tori $\text{Tor}(X,f)$ and $\text{Tor}(X,g)$ are homeomorphic.

**Example.** We consider $X = S^1$ and the self-homeomorphism that is given by $g(z) = -z$. Note that the map $H(z,t) = e^{\pi i t} \cdot z$ defines an isotopy from $f = \text{id}$ to $g$. It follows from Lemma 24.23 that the mapping torus $\text{Tor}(S^1,g(z) = -z)$ is homeomorphic to the torus $\text{Tor}(S^1,\text{id}) = S^1 \times S^1$.

Now we can determine which surfaces are mapping tori.

42\ Let $t \in [0,1]$. Why is the map $[0,2] \to [0,2]$ given by $x \mapsto H(x,t)$ a homeomorphism?
Proposition 24.24. The annulus, the Möbius band, the torus and the Klein bottle are, up to homeomorphism, the only connected, compact 2-dimensional topological manifolds that can be written as a mapping torus $\text{Tor}(X, f)$ of a connected 1-dimensional topological manifold $X$.

Proof. By the examples (1), (2) on page 713 and by Lemma 24.21 we know that there exist the following types of homeomorphisms:

- annulus $S^1 \times [0, 1] \cong \text{Tor}([0, 1], \text{id})$
- Möbius band $\cong \text{Tor}([0, 1], x \mapsto 1 - x)$
- torus $S^1 \times S^1 \cong \text{Tor}(S^1, \text{id})$
- Klein bottle $\cong \text{Tor}(S^1, z \mapsto \bar{z})$.

In particular all these four smooth manifolds are homeomorphic to mapping tori. It remains to show that these are the only connected, compact 2-dimensional topological manifolds that can be written as a mapping torus.

It follows from Theorem 7.1 that any compact connected 1-dimensional topological manifold is homeomorphic to $[0, 1]$ or to $S^1$. We know from Lemma 18.9 that any self-homeomorphism is isotopic to one of the self-homeomorphisms that we had written down above. But then it follows from Lemma 24.23 that any mapping torus is homeomorphic to one from the above list. 

For proving statements about mapping tori the following lemma gives a useful alternative point of view. We leave the task of providing the elementary proof to the reader.

Lemma 24.25. Let $X$ be a topological space and let $f : X \to X$ be a homeomorphism. Then the following hold:

1. The map $\mathbb{Z} \times (X \times \mathbb{R}) \to X \times \mathbb{R}$
\[(n, (x, t)) \mapsto (f^n(x), t + n)\]
defines a continuous, proper and discrete action $\mathbb{Z}$ of the group $\mathbb{Z}$ on $X \times \mathbb{R}$.

2. The map $\text{Tor}(X, f) = (X \times [0, 1]) / \sim \to (X \times \mathbb{R}) / \mathbb{Z}$
\[[(x, t)] \mapsto [(x, t)]\]
is a homeomorphism.

In the following, given a topological space $X$ and a homeomorphism $f : X \to X$ we denote the corresponding quotient space by $(X \times \mathbb{R}) / \mathbb{Z}_f$ and we will identify the mapping torus $\text{Tor}(X, f)$ with $(X \times \mathbb{R}) / \mathbb{Z}_f$ using the homeomorphism of Lemma 24.25.

Remark. It follows from Lemma 24.25 together with Proposition 6.32 that if $X$ is a $n$-dimensional topological (respectively smooth) manifold and $f$ is a homeomorphism, then the corresponding mapping torus $\text{Tor}(X, f) = (X \times \mathbb{R}) / \mathbb{Z}_f$ is a $(n + 1)$-dimensional topological (respectively smooth) manifold. Furthermore, if $X$ is in fact an $n$-dimensional smooth

---

422 Here for $n \geq 1$ we write $f^n(x) = (f \circ \cdots \circ f)(x)$, for $n = 0$ we write $f^0(x) = x$ and for $n \leq -1$ we write $f^n(x) = (f^{-1} \circ \cdots \circ f^{-1})^{|n|}$.

423 Why is it an action?
manifold and \( f : X \to X \) is a diffeomorphism, then almost the same argument shows that the mapping torus \( \text{Tor}(X, f) = (X \times \mathbb{R})/\mathbb{Z}_f \) is an \((n + 1)\)-dimensional smooth manifold.

**Lemma 24.26.** Let \( X \) be a topological space and let \( f : X \to X \) be a homeomorphism. Then the map

\[
X \times \mathbb{R} \to (X \times \mathbb{R})/\mathbb{Z}_f = \text{Tor}(X, f)
\]

\[
(x, t) \mapsto [(x, t)]
\]

is a covering of infinite degree. Furthermore for \( k \in \mathbb{N} \) the map

\[
\text{Tor}(X, f^k) = (X \times \mathbb{R})/\mathbb{Z}_{f^k} \to (X \times \mathbb{R})/\mathbb{Z}_f = \text{Tor}(X, f)
\]

\[
[(x, t)] \mapsto [(x, k \cdot t)]
\]

is a \( k \)-fold covering.

**Proof.** Let \( X \) be a topological space and let \( f : X \to X \) be a homeomorphism. The first statement is an immediate consequence of Lemma 24.25 and Proposition 16.10.

Now let \( k \in \mathbb{N} \). We consider the following commutative diagram of maps:

\[
\begin{array}{ccc}
(X \times \mathbb{R})/\mathbb{Z}_{f^k} & \xrightarrow{[(x, t)] \mapsto [(x, k \cdot t)]]} & (X \times \mathbb{R})/\mathbb{Z}_f \\
[(x, t)] \mapsto [(x, k \cdot t)] & & [(x, t)] \mapsto [(x, t)] \\
(X \times \mathbb{R})/(k \cdot \mathbb{Z}_f) & \xrightarrow{[(x, t)] \mapsto [(x, k \cdot t)]} & (X \times \mathbb{R})/\mathbb{Z}_f.
\end{array}
\]

The left diagonal map is easily seen to be well-defined and to be a homeomorphism. By Proposition 16.10, the right diagonal map is a \( k \)-fold covering. It follows that the top horizontal map is also a \( k \)-fold covering. \( \blacksquare \)

**Examples.**

1. We apply Lemma 24.26 to \( X = [0, 1] \) and the homeomorphism that is given by \( f(x) := 1 - x \). Note that \( f^2(x) = f(f(x)) = f(1 - x) = 1 - (1 - x) = x \) for all \( x \), i.e. \( f^2 = \text{id} \). Thus we recover the statement from page 496 that the annulus \( \text{Tor}([0, 1], \text{id}) \) is a 2-fold covering of the Möbius band \( \text{Tor}([0, 1], f(x) = 1 - x) \).

2. We apply Lemma 24.26 to \( X = S^1 \) and the self-homeomorphism of \( X = S^1 \) that is given by \( f(z) := \bar{z} \). As in the previous example we see that \( f^2 = \text{id} \). Thus we get, after the discussion on page 504, a new proof that the torus \( \text{Tor}(S^1, \text{id}) \) is a 2-fold covering of the Klein bottle \( \text{Tor}(S^1, f(z) = \bar{z}) \).

Our next goal is to determine the fundamental groups of mapping tori. Before we can do so we need to introduce a new concept from group theory.

**Definition.** Let \( N \) be a group, let \( k \in \mathbb{N}_0 \) and let \( \varphi : N \to N \) be an isomorphism such that \( \varphi^k = \text{id} \). We define the semidirect product of \( N \) and \( \mathbb{Z}_k \) with respect to \( \varphi \) as the group \( N \rtimes \varphi \mathbb{Z}_k \) where the underlying set is given by the direct product \( N \times \mathbb{Z}_k \) but where the group multiplication is given by

\[
(h, m) \cdot (h', m') := (h \cdot \varphi^m(h'), m + m').
\]

If \( \varphi \) is understood from the context, then we drop it from the notation, i.e. we write \( N \rtimes \mathbb{Z}_k \) instead of \( N \rtimes \varphi \mathbb{Z}_k \). If \( \varphi \neq \text{id} \), then we say that the semidirect product as non-trivial.
Examples.

(1) Let $N$ be a group and $\varphi = \text{id}_N$, then $N \rtimes \mathbb{Z} = N \times \mathbb{Z}$ is the direct product of $N$ and $\mathbb{Z}$.

(2) Let $G = \mathbb{Z}_2$ and let $N = \mathbb{Z}_n$ for some $n \in \mathbb{N}_0$. We denote by $\varphi : \mathbb{Z}_n \to \mathbb{Z}_n$ the isomorphism that is given by multiplication by $-1$. Clearly this isomorphism satisfies $\varphi^2 = \text{id}$, thus we can form the semidirect product $\mathbb{Z}_n \rtimes_\varphi \mathbb{Z}_2$, which is called the $n$-th dihedral group $D_n$. It has $2n$ elements. As an example, the third dihedral group $D_3$ is isomorphic to the permutation group $S_3$ via the isomorphism

$$\Psi : \mathbb{Z}_3 \rtimes \mathbb{Z}_2 \to S_3, \quad (h,m) \mapsto (1\ 2\ 3)^h \cdot (1\ 2)^m.$$  

(3) Let $k \in \mathbb{N}_{\geq 2}$. In Exercise 31.17 we will see that we can write the direct product $\langle x_1, \ldots, x_k \rangle \times \mathbb{Z}$ in many “inequivalent” ways as a semidirect product of a finitely generated free group with $\mathbb{Z}$.

Remark. In Exercise 24.16 we will see that $N = \{(h,0) \mid h \in N\} \subset N \rtimes \mathbb{Z}_k$ is a normal subgroup of $N \rtimes \mathbb{Z}_k$. Put differently, we have $N \triangleleft N \rtimes \mathbb{Z}_k$. This is the reason for the symbol “$\triangleleft$” in the notation of the semidirect product.

We have the following elementary lemma.

**Lemma 24.27.** Let $G$ be a group and let $\gamma : G \to \mathbb{Z}$ be an epimorphism. We pick an element $t \in G$ with $\gamma(t) = 1$ and we write $N := \ker(\gamma)$. We denote by $\varphi$ the isomorphism

$$\varphi : N \to N, \quad h \mapsto \text{ht}^{-1}.$$  

Then the map

$$\Psi : G \to N \rtimes_\varphi \mathbb{Z}, \quad g \mapsto (\text{gt}^{-\gamma(g)}, \gamma(g))$$

is an isomorphism of groups.

**Proof.** It is straightforward to verify that $\Psi$ is injective and surjective. It remains to show that $\Psi$ is a homomorphism: given $g, h \in G$ we have indeed

$$\Psi(g \cdot h) = (\text{ght}^{-\gamma(gh)}, \gamma(gh)) = (\text{gt}^{-\gamma(g)} \cdot t^{\gamma(g)} \cdot \text{ht}^{-\gamma(h)} \cdot t^{-\gamma(g)}, \gamma(g) + \gamma(h)) = (\text{gt}^{-\gamma(g)} \cdot \gamma(g)) \cdot (\text{ht}^{-\gamma(h)} \cdot \gamma(h)) = \Psi(g) \cdot \Psi(h).$$

424 Note that this condition is automatically satisfied if $k = 0$, i.e. for any isomorphism $\varphi$ of any group we always have $\varphi^0 = \text{id}$.

425 In particular, if $N$ is finite and $k \in \mathbb{N}$, then the cardinality of $N \rtimes \mathbb{Z}_k$ is given by $|N| \cdot k$.

426 It is an elementary argument to show that $N \rtimes \mathbb{Z}_k$ with the given multiplication is indeed a group.

427 First note that a straightforward calculation shows that $(1\ 2)^{-1} \cdot (1\ 2\ 3)^{-1} = (1\ 3\ 2) = (1\ 2\ 3)^{-1}$. This implies that also for any $m \in \mathbb{Z}_2$ and $s \in \mathbb{Z}$ we have $(12)^{-m} \cdot (123)^{s} \cdot (12)^m = (123)^{s-1}$. Now for any $(h,m), (h',m') \in \mathbb{Z}_n \rtimes \mathbb{Z}_2$ we have

$$\Psi(h,m) \cdot \Psi(h',m') = (123)^h \cdot (12)^m \cdot (123)^{h'} \cdot (12)^{m'} = (123)^{h + m'} \cdot (12)^{m + m'} = \Psi(h + m, h' + m').$$

428 Note that $\gamma(\text{gt}^{-\gamma(g)}) = \gamma(g) + \gamma(t)(-\gamma(g)) = 0$, i.e. $\text{gt}^{-\gamma(g)}$ does indeed lie in $N = \ker(\gamma)$.
The following proposition shows that the fundamental group of a mapping torus $\text{Tor}(X, f)$ is isomorphic to a semidirect product of $\pi_1(X)$ with $\mathbb{Z}$.

**Proposition 24.28.** Let $X$ be some non-empty path-connected topological space and furthermore let $f : X \to X$ be some homeomorphism. Then there exists an isomorphism $\psi : \pi_1(\text{Tor}(X, f)) \cong \pi_1(X) \rtimes \mathbb{Z}$ such that the following diagram commutes

$$
\begin{array}{ccc}
\pi_1(X) & \to & \pi_1(\text{Tor}(X, f)) \\
\downarrow & \cong & \downarrow \psi \\
\pi_1(X) & \to & \pi_1(X) \rtimes \mathbb{Z}
\end{array}
$$

Here the top-left horizontal map is induced by the inclusion $X = X \times \{0\} \to \text{Tor}(X, f)$ and the top-right horizontal map is induced by the canonical projection map $\text{Tor}(X, f) \to S^1$. The bottom-left horizontal map is given by the natural inclusion into the first term of the semidirect product and the bottom-right horizontal map is given by the projection onto the second term of the semidirect product.

**Proof.** We have

$$\pi_1(\text{Tor}(X, f)) = \pi_1((X \times \mathbb{R})/\mathbb{Z}_f) \cong \pi_1(X \times \mathbb{R}) \rtimes \mathbb{Z} \cong \pi_1(X) \rtimes \mathbb{Z}.$$ 

Thus we have obtained an isomorphism $\psi : \pi_1(\text{Tor}(X, f)) \cong \pi_1(X) \rtimes \mathbb{Z}$. We leave the verification that the given diagram commutes to the reader.

**Remark.** A careful reading of the proof of the proposition shows that we can identify the automorphism in the semidirect product. More precisely, let $X$ be a path-connected topological space and let $f : X \to X$ be a homeomorphism. Let $x$ be a base point and let $\gamma$ be path from $f(x)$ to $x$. We denote by $\varphi$ the automorphism of $\pi_1(X, x)$ that is given by

$$\pi_1(X, x) \xrightarrow{f_*} \pi_1(X, f(x)) \xrightarrow{\cong \text{Prop. 14.11}} \pi_1(X, x).$$

Then $\pi_1(\text{Tor}(X, f)) \cong \pi_1(X, x) \rtimes \varphi \mathbb{Z}$.

We conclude this section with a discussion of several examples.

**Examples.**

1. Let $K = \text{Tor}(S^1, f(z) := z)$ be the Klein bottle. Then the automorphism $f_* =: \varphi$ of $\pi_1(S^1) = \mathbb{Z}$ is multiplication by $-1$. It follows from the previous remark that $\pi_1(\text{Klein bottle}) \cong \mathbb{Z} \rtimes \varphi \mathbb{Z}$.

---

429 Note that both maps on the bottom are group homomorphisms.

430 On page 656 we saw that $\pi_1(K) \cong \langle x, y | yxyx^{-1} \rangle$. What is an explicit isomorphism between the groups $\langle x, y | yxyx^{-1} \rangle$ and $\mathbb{Z} \rtimes \varphi \mathbb{Z}$?
(2) Let \( A \in \text{GL}(n, \mathbb{Z}) \) be a matrix. Recall that in Exercise 16.16 we showed that the map 
\( f(A) : \mathbb{R}^n / \mathbb{Z}^n \to \mathbb{R}^n / \mathbb{Z}^n \) given by \( [v] \mapsto [Av] \) is a homeomorphism. Furthermore we know that, under the usual identification \( \pi_1(\mathbb{R}^n / \mathbb{Z}^n, 0) = \mathbb{Z}^n \) as in Theorem 16.16
the induced map \( f(A)_* \) on \( \pi_1(\mathbb{R}^n / \mathbb{Z}^n, 0) = \mathbb{Z}^n \) is given by multiplication by \( A \). It follows from the above remark that \( \pi_1(\text{Tor}(\mathbb{R}^n / \mathbb{Z}^n, f(A))) \cong \mathbb{Z}^n \rtimes_A \mathbb{Z} \). Note that this implies that \( \pi_1(\text{Tor}(\mathbb{R}^n / \mathbb{Z}^n, f(A))) \) is solvable.\(^{431}\)

(3) Let \( X \) be a connected topological space. We calculate that

\[
\pi_1(X \times S^1) = \pi_1(\text{Tor}(X, \text{id}_X)) \cong \pi_1(X) \rtimes \text{id} \mathbb{Z} = \pi_1(X) \times \mathbb{Z} = \pi_1(X) \times \pi_1(S^1).
\]

\( \uparrow \)

Lemma 24.21 by the above remark

So in this special case we obtain the same result as in Proposition 16.20.

Exercises for Chapter 24

Exercise 24.1. Given a subset \( X \) of \( \mathbb{R}^n \) we define its physical cone as

\[
\text{Cone}(X) := \text{union of all line segments from } (x, 1) \text{ to } (0, 0) \subset \mathbb{R}^{n+1}
\]

and we consider the map

\[
f_X : \text{Cone}(X) \to \text{Cone}(X)
\]

\[
[(x, t)] \mapsto t \cdot (x, 1) + (1 - t) \cdot (0, 1).
\]

(a) Let \( X \) be a compact subset of \( \mathbb{R}^n \). Show that the map \( f_X \) is a homeomorphism.

(b) Let \( X = (0, 1) \subset \mathbb{R} \). Show that the map \( f_X \) is not a homeomorphism.

Remark. It is actually true that \( f_X \) is continuous and a bijection. To show that \( f_X \) is not a homeomorphism we need to show that there exists an open subset \( U \) of \( \text{Cone}(X) \) such that the image under \( f_X \) is not open. You could try your hand at

\[
U := \text{Cone}(X) \setminus \{(\frac{1}{n}, 1) \mid n \in \mathbb{N}_{\geq 2}\}.
\]

We refer to Figure 470 for an illustration.

**Figure 470**

\(^{431}\)Recall that a group \( G \) is solvable if there exist subgroups \( G_0 = \{1\} \subset G_1 \subset G_2 \subset \cdots \subset G_k = G \) such that for \( i = 0, \ldots, k - 1 \) the group \( G_i \) is normal in \( G_{i+1} \) and such that \( G_{i+1} / G_i \) is abelian. In our case the filtration is given by \( \{0\} \subset \mathbb{Z}^n \subset \mathbb{Z}^n \rtimes_A \mathbb{Z} \).
**Exercise 24.2.** Let $X$ be a topological space. Show that $\text{Cone}(X)$ respectively the suspension $\Sigma(X)$ are homeomorphic to the pushout of the diagram

$$
\begin{array}{c}
X \xrightarrow{x \mapsto (x,1)} X \times [0,1] \\
\downarrow \{\ast\} \\
\text{Cone}(X)
\end{array}
\quad \text{respectively} \quad
\begin{array}{c}
X \xrightarrow{x \mapsto [(x,0)]} \text{Cone}(X) \\
\downarrow \text{Cone}(X)
\end{array}
$$

**Remark.** These descriptions of the cone and the suspension explain our definitions for the case that $X$ is the empty topological space.

**Exercise 24.3.** Let $X$ be a topological space.

(a) Show that the cone $\text{Cone}(X)$ is naturally homeomorphic to the join $X * \{\ast\}$.

(b) Show that the suspension $\Sigma(X)$ is naturally homeomorphic to the join $X * S^0$.

**Exercise 24.4.** Let $X$ be a topological space. Show that if $X$ is Hausdorff, then the suspension $\Sigma(X)$ is also Hausdorff.

**Exercise 24.5.** Let $X$ be a topological space. Show that the injections

$$
\begin{align*}
X & \to \text{Cone}(X) \\
x & \mapsto [(x,1)]
\end{align*}
\quad \text{and} \quad
\begin{align*}
\text{Cone}(X) & \to \Sigma(X) \\
[(x,t)] & \mapsto [(x,1-t)]
\end{align*}
$$

are embeddings.

**Exercise 24.6.** Let $f: X \to Y$ be a map between topological spaces. Show that the natural inclusions

$$
\begin{align*}
X & \to \text{Cyl}(f: X \to Y) \\
x & \mapsto (x,0)
\end{align*}
\quad \text{and} \quad
\begin{align*}
Y & \to \text{Cyl}(f: X \to Y) \\
y & \mapsto [y]
\end{align*}
$$

are embeddings.

**Exercise 24.7.** Let $f: X \to Y$ be a map between topological spaces and let $Z$ be a topological space.

(a) Show that the map

$$
\Theta: \text{Cyl}(f \times \text{id}: X \times Z \to Y \times Z) \to \text{Cyl}(f: X \to Y) \times Z
$$

$$
P \mapsto \begin{cases} 
([Q,t], s), & \text{if } P = [(Q,t, s)] \text{ with } Q \in X, t, s \in [0,1], \\
([Q], s), & \text{if } P = [(Q, s)] \text{ with } Q \in Y, s \in [0,1]. 
\end{cases}
$$

is continuous.

(b) Suppose that $Z$ is regionally compact. Show that the map $\Theta$ from (a) is a homeomorphism.

*Hint.* Use Lemma 5.18.

**Exercise 24.8.** Let $X$ be a topological space and let $A$ be a subset of $X$.

(a) We denote by $i: A \to X$ the inclusion. Show that the map

$$
\begin{align*}
A \times [0,1] & \to \text{Cyl}(i) = ((A \times [0,1]) \sqcup X)/\sim \\
(a, t) & \mapsto [(a, t)]
\end{align*}
$$

is an embedding.
(b) Let \( f: A \rightarrow X \) be an embedding. Is the map \( A \times [0,1] \rightarrow \text{Cyl}(f) \) necessarily an embedding?

**Exercise 24.9.** Give a proof of Lemma 24.10 (3).

**Exercise 24.10.** We consider the topological space \( X = [-1,1] \), the subset \( A = (-1,1) \) and the inclusion map \( i: A \rightarrow X \). Show that the induced map \( \Sigma(i): \Sigma(A) \rightarrow \Sigma(X) \) is not an embedding.

*Remark.* It might help to have a look at the equally scary Exercise 24.1.

**Exercise 24.11.** Let \( X \) and \( Y \) be topological spaces. We consider the corresponding join \( X \ast Y = (X \times [0,1] \times Y) / \sim \) as defined on page 207. Show that the map
\[
X \ast Y = (X \times [0,1] \times Y) / \sim \cong (\text{Cone}(X) \times Y) \cup_{(Y \times \{1\}) \times Y = X \times (Y \times \{1\})} (X \times \text{Cone}(Y))
\]
\[
[(x, t, y)] \mapsto \begin{cases} (x, [(y, 2t)]), & \text{if } t \in [0, \frac{1}{2}], \\ ([x, 2(t - 1)]), y, & \text{if } t \in [\frac{1}{2}, 1]. \end{cases}
\]
is a homeomorphism.

*Remark.* Evidently you need to verify that all the maps are actually continuous.

**Exercise 24.12.** Let \( f: A \rightarrow X \) be a map between topological spaces and let \( a_0 \in A \). We write \( x_0 := f(a_0) \). We suppose that \( A \) is path-connected. Show that the natural inclusion map \( X \rightarrow \text{Cone}(f: A \rightarrow X) \) induces an isomorphism
\[
\pi_1(X, x_0)/\pi_1(A, a_0) \rightarrow \pi_1(\text{Cone}(f: A \rightarrow X)).
\]

**Exercise 24.13.** Let \( X \) be a topological space and let \( f: X \rightarrow X \) be a homeomorphism. We assume that \( X \) is Hausdorff. Show that the mapping torus \( \text{Tor}(X, f) \) is also Hausdorff.

**Exercise 24.14.** Let \( X \) be a topological space. Show that if \( f, g: X \rightarrow X \) are two homeomorphisms that are isotopic, then the mapping tori \( \text{Tor}(X, f) \) and \( \text{Tor}(X, g) \) are homeomorphic.

**Exercise 24.15.** Let
\[
\begin{array}{ccccccccc}
1 & \rightarrow & K & \xrightarrow{\varphi} & \pi & \xrightarrow{\psi} & G & \xrightarrow{\gamma} & 1 \\
\downarrow{\alpha} & & \downarrow{\varphi} & & \downarrow{\beta} & & \downarrow{\gamma} & & \downarrow{1} \\
1 & \rightarrow & \tilde{K} & \xrightarrow{\tilde{\varphi}} & \tilde{\pi} & \xrightarrow{\tilde{\psi}} & \tilde{G} & \rightarrow & 1
\end{array}
\]
be a commutative diagram of group homomorphisms with the following properties:

1. \( \varphi \) and \( \tilde{\varphi} \) are monomorphisms.
2. \( \psi \) and \( \tilde{\psi} \) are epimorphisms.
3. \( \text{im} (\varphi) = \ker (\psi) \) and \( \text{im} (\tilde{\varphi}) = \ker (\tilde{\psi}) \).

Show that if two out of the three vertical maps \( \alpha \), \( \beta \) and \( \gamma \) are isomorphisms, then so is the third one.

*Remark.* We will generalize this statement later on in the Five Lemma 43.12.

**Exercise 24.16.** Let \( N \) be a group, let \( k \in \mathbb{N}_0 \) and let \( \varphi: N \rightarrow N \) be an isomorphism such that \( \varphi^k = \text{id} \). As on page 718 we define the *semidirect product* of \( N \) and \( \mathbb{Z}_k \) with respect to
Let $\varphi$ be the group $N \rtimes_\varphi \mathbb{Z}_k$ where the underlying set is given by the direct product $N \times \mathbb{Z}_k$, and where the multiplication is given by

$$(h, m) \cdot (h', m') := (h \cdot \varphi^m(h'), m + m').$$

(a) Show that $N \rtimes_\varphi \mathbb{Z}_k$ is indeed a group.
(b) Show that $N = \{(h, 0) \in N \rtimes_\varphi \mathbb{Z}_k \mid h \in N\}$ is a normal subgroup of $N \rtimes \mathbb{Z}_k$.
(c) Is $\mathbb{Z}_k = \{(0, n) \in N \rtimes_\varphi \mathbb{Z}_k \mid n \in \mathbb{Z}_k\} \subset N \rtimes_\varphi \mathbb{Z}_k$ necessarily a normal subgroup?
(d) Suppose that $k = 0$. Let $n \in \mathbb{N}$ and let $K$ be a subgroup of $N$ of some finite index $m$.

Show that if $K$ is preserved by $\varphi$, then $K \rtimes n\mathbb{Z}$ is a subgroup of $N \rtimes \mathbb{Z}$ of index $m \cdot n$.

**Exercise 24.17.** Let $\pi$ be a group and let $\phi: \pi \times \langle t \rangle \rightarrow \mathbb{Z}$ be an epimorphism. We suppose that $k := \phi(t) \neq 0$. We set $\Gamma := \ker(\pi \rightarrow \mathbb{Z})$. Since $\phi$ is an epimorphism there exists an $x \in \pi$ such that $\gcd(\phi(x), k) = 1$. Let $\mu: \Gamma \rightarrow \Gamma$ be the automorphism that is given by $g \mapsto xgx^{-1}$. Show that the map

$$\Gamma \rtimes_\mu \mathbb{Z} \rightarrow \pi \times \mathbb{Z}$$

$$(g, n) \mapsto (gx^n, n + \phi(g))$$

is an isomorphism.

**Hint.** You could use Exercise 24.15 together with Exercise 24.16(d).

**Remark.**

(1) By Exercise 21.2 and Proposition 37.15 we know that if $\pi$ is finitely generated (presented), then so is $\Gamma$. The exercise thus says that if a finitely presented group $\pi$ admits an epimorphism onto $\mathbb{Z}$, then we can write a product $\pi \times \mathbb{Z}$ in many interesting and perhaps surprising ways as a semidirect product.

(2) We will prove a manifold analogue in Proposition 79.12.

**Exercise 24.18.** Let $(X, x_0)$ be a path-connected topological space and let $f: X \rightarrow X$ be a homeomorphism with $f(x_0) = x_0$. Show that there exists an isomorphism of the following form:

$$\pi_1(\text{Tor}(X, f))_{ab} \cong \mathbb{Z} \oplus \text{coker} \left( \pi_1(X, x_0)_{ab} \xrightarrow{f_* - \text{id}} \pi_1(X, x_0)_{ab} \right).$$

**Exercise 24.19.** Let $\varphi: \overline{B}^2 \rightarrow \overline{B}^2$ be the map that is given by $(x, y) \mapsto (x, -y)$. Is the corresponding mapping torus $\text{Tor}(\overline{B}^2, \varphi)$ homeomorphic to the solid torus?

**Exercise 24.20.** Let $G$ and $\pi$ be groups and let $\varphi: \pi \rightarrow \text{Aut}(G)$ be a homomorphism. We consider the set $G \times \pi$ with the multiplication

$$(g, a) \cdot (h, b) := (g \cdot \varphi(a)(h), a \cdot b).$$

(a) Show that $G \times \pi$ with the above multiplication is a group. This group is denoted by $G \rtimes_\varphi \pi$ and it is called the semidirect product of $G$ and $\pi$ with respect to $\varphi$.
(b) In what sense does this definition of the semidirect product of two groups generalize the concept introduced on page 718?
(c) Let $K$ be a group and let $\alpha: K \rightarrow \pi$ be an epimorphism onto a group $\pi$. We suppose that $\alpha$ admits a right-inverse, i.e. we suppose that there exists a homomorphism $\varphi: \pi \rightarrow K$ with $\alpha \circ \varphi = \text{id}_{\pi}$. Show that $K$ is isomorphic to a semidirect product of the form $\ker(\alpha) \rtimes \pi$. 

(d) (i) Let $n \in \mathbb{N}$. Show that $\text{GL}(n, \mathbb{R})$ is isomorphic to a semidirect product of the form $\text{SL}(n, \mathbb{R}) \rtimes (\mathbb{R} \setminus \{0\})$.

(ii) For which $n \in \mathbb{N}$ is $\text{GL}(n, \mathbb{R})$ isomorphic to a direct product $\text{SL}(n, \mathbb{R}) \times (\mathbb{R} \setminus \{0\})$?

(iii) Repeat (i) and (ii) with $\mathbb{C}$ instead of $\mathbb{R}$.
25. Limits

The goal of this section is to determine the fundamental group of “unbounded spaces”, e.g. we would like to determine the fundamental group of the surface of “infinite genus” illustrated in Figure 471. One idea might be to view the surface of “infinite genus” as the limit of a sequence given by compact surfaces. But then we need to make precise what we mean by a “limit of topological spaces” and “limit of the corresponding fundamental groups”. We will do so in the following sections.

![Surface of “infinite genus”](image)

**Figure 471**

25.1. **Preordered and directed sets.** The following definition partly recalls some notions that we introduced on page 73.

**Definition.** Let $X$ be a set and let $\leq$ be a relation on $X$.

1. The relation is called reflexive if for every $x \in X$ we have $x \leq x$.

2. The relation is called transitive if for every $x, y, z \in X$ we have
   \[
   x \leq y \quad \text{and} \quad y \leq z \quad \implies \quad x \leq z.
   \]

3. A reflexive and transitive relation is called a preorder.

4. A set together with a preorder is called a preordered set.

5. A directed set is a preordered set such that for any $x, y \in X$ there exists a $z \in X$ with $x \leq z$ and $y \leq z$.

**Examples.**

1. Let $X$ be a subset of $\mathbb{R}$ and denote by $\leq$ the usual “less or equal” relation on the real numbers. Then $(X, \leq)$ is a directed set. In particular $(\mathbb{N}, \leq)$ is a directed set.

2. Given any set $X$ the relation “$\leq$” where $x \leq y$ only if $x = y$ is a preorder, which we call the trivial preorder on $X$.

3. Let $M$ be a set. We denote by $\mathcal{P}(M)$ the power set of $M$, i.e. the set of all subsets of $M$. Then “being a subset”, i.e. the relation given by “$\subseteq$”, defines a preorder on $\mathcal{P}(M)$. Thus $(\mathcal{P}(M), \subseteq)$ is a preordered set, in fact it is straightforward to see that it is even a directed set.

4. The set $X = \{0, x, y\}$ with the trivial relations $0 \leq 0, x \leq x, y \leq y$ and the non-trivial relations $0 \leq x$ and $0 \leq y$ is a preordered set. We refer to $(\{0, x, y\}, \leq)$ as the push-pull set. Note that this is not a directed set, since there is no $z \in X$ with $x \leq z$ and $y \leq z$.

---

\(^{432}\)Actually we also need to make precise what we mean by the surface of “infinite genus”.
(5) We consider the set \( \mathbb{N} \). The divisibility relation \( k \mid l \) for \( k, l \in \mathbb{N} \) is a preorder on \( \mathbb{N} \) and with this preorder \( \mathbb{N} \) is in fact a directed set. \[^{433}\]

**Exercise 25.1.** We consider the following subset of \( \mathbb{R}^2 \):

\[
X := \bigcup_{n \in \mathbb{N}} \text{circle of radius } \frac{1}{n} \text{ around } \left( \frac{1}{n}, 0 \right) = \bigcup_{n \in \mathbb{N}} \left\{ (x, y) \in \mathbb{R}^2 \mid (x - \frac{1}{n})^2 + y^2 = \frac{1}{n^2} \right\}.
\]

This subset, equipped with the subspace topology is colloquially referred to as the **Hawaiian earrings**, see Figure 472 for an illustration.

(a) Let \( A = \{0\} \cup \{ \frac{1}{n} \mid n \in \mathbb{N} \} \). Show that \( X \) is homeomorphic to \([0, 1]/A\).

*Remark.* We encountered the topological space \([0, 1]/A\) in Exercise 3.31

(b) Show that \( X \) is compact.

(c) Is \( X \) homeomorphic to the wedge of countably infinitely many circles?

(d) Show that \( \pi_1(X) \) is infinitely generated.

(e) Even better than (d): Show that \( \pi_1(X) \) is uncountably generated, i.e. show that there is no countable generating set for \( \pi_1(X) \).

The combination of (b) and (d) implies, perhaps somewhat surprisingly, that there exist compact topological spaces whose fundamental groups are infinitely generated.

*Remark.* The precise determination of \( \pi_1(X) \) is actually rather delicate, we refer to [MoM86] and [Smi92] for details. In particular, despite appearances, it is shown in [Smi92] that \( \pi_1(X) \) is not a free group.

**Figure 472.** Illustration for Exercise 25.1

**Exercise 25.2.** For \( n \in \mathbb{N} \) let \( C_n \) be the circle in \( \mathbb{R}^2 \times \{0\} \) of radius \( \frac{1}{2n} \) with center \( \left( \frac{1}{n}, 0 \right) \). The **harmonic archipelago** \( H \) is the topological space that obtained from \( \mathbb{R}^2 \) as follows: For each \( n \in \mathbb{N} \) we delete an open disk between \( C_n \) and \( C_{n+1} \) and we glue on a cone such that the \( z \)-coordinate of the cone equals 1. We refer to Figure 473 for an illustration.

(a) Give a precise description of the harmonic archipelago \( H \).

*Remark.* You might want to skip this exercise, unless you are inclined to super-rigorous mathematics.

(b) Show that the harmonic archipelago \( H \) is non-compact.

(c) Let \( x_0 = (0, 0) \) be the origin. Show that for each \( n \) the inclusion induced map \( \pi_1(C_n, x_0) \to \pi_1(H, x_0) \) is a monomorphism.

(d) As in Exercise 25.1 we refer to \( X := \bigcup C_n \) as the Hawaiian earrings. Show that the inclusion induced map \( \pi_1(X, x_0) \to \pi_1(H, x_0) \) is not a monomorphism.

(e) Is \( \pi_1(H, x_0) \) countable or uncountable?

\[^{433}\]Indeed, given \( k, l \in \mathbb{N} \) we have \( k \mid kl \) and \( l \mid kl \).
25.2. The direct limit of a direct system.

**Definition.** Let \((I, \leq)\) be a preordered set and let \(C\) be a category. A **direct system in the category** \(C\) **over** \(I\) is a family of objects \(\{X_i\}_{i \in I}\) in \(C\), together with a family of morphisms \(\{f_{ij} : X_i \to X_j\}\) for all \(i, j \in I\) with \(i \leq j\) such that the following two conditions are satisfied:

1. \[f_{ii} = \text{id}_{X_i}\] for all \(i \in I\),
2. \[f_{ik} = f_{jk} \circ f_{ij}\] for all \(i, j, k \in I\) with \(i \leq j \leq k\).

**Examples.**

(A) We consider the directed set \(I = (\mathbb{N}, \leq)\) and the category of groups. For \(i \in \mathbb{N}\) we consider the group \(\mathbb{Z}^i\) and for \(i \leq j\) we denote by

\[f_{ij} : \mathbb{Z}^i \to \mathbb{Z}^j\]

\[(x_1, \ldots, x_i) \mapsto (x_1, \ldots, x_i, 0, \ldots, 0)\]

the inclusion map. Then \(\{(\mathbb{Z}^i)_{i \in \mathbb{N}}, \{f_{ij}\}_{i \leq j}\}\) forms clearly a direct system.

(B) Again we consider \(I = (\mathbb{N}, \leq)\) and the category of groups. Given \(i \in \mathbb{N}\) we define

\[F_i := \langle x_1, \ldots, x_i \rangle = \text{the free group on } i \text{ generators}\]

and given \(i \leq j\) we set

\[f_{ij} : F_i \to F_j\]

\[x_k \mapsto x_k, \text{ for } k = 1, \ldots, i.\]

This is clearly a direct system of groups.

(C) Given \(r \in \mathbb{N} \cup \{\infty\}\) we set

\[X_r := (0, r + \frac{1}{2}) \cup \bigcup_{j=1}^{r} \left\{ z \in \mathbb{C} \mid |z - (j + \frac{1}{4}i)| = \frac{1}{4} \right\} \subset \mathbb{C}.\]

\[\text{circle of radius } \frac{1}{4} \text{ around } j + \frac{1}{4}i \in \mathbb{C}\]

For example, for \(r \in \mathbb{N}\) the set \(X_r\) is the subset of \(\mathbb{C} = \mathbb{R}^2\) that is given by the interval \((0, r + \frac{1}{2})\) with \(r\) circles attached. We refer to Figure 474 for an illustration.

Now we consider the directed set \((\mathbb{N}, \leq)\) and for \(r \leq s\) we denote by \(f_{rs} : X_r \to X_s\) the obvious inclusion map. This is clearly a direct system of topological spaces.

---

434In the literature one often demands that \(I\) is a directed set, see e.g. [Hat02, p. 243], but this is not necessary.
(D) We can generalize example (C) as follows. Let \((I, \leq)\) be a preordered set and let \(\{X_i\}_{i \in I}\) be a family of topological spaces such that for any \(i \leq j\) we have \(X_i \subset X_j\). Given \(i \leq j\) we denote by \(\iota_{ij}: X_i \to X_j\) the inclusion map. Then \((\{X_i\}_{i \in I}, \{\iota_{ij}\}_{i \leq j})\) is a direct system in the category of topological spaces.

(E) Let \(\{(0, x, y), \leq\}\) be the push-pull set and let \(\mathcal{C}\) be a category. A direct system in the category \(\mathcal{C}\) over the preordered set \((\{0, x, y\}, \leq)\) consists of three objects \(A_0, A_x, A_y\), the identity morphisms \(\text{id}_{A_0}, \text{id}_{A_x}, \text{id}_{A_y}\) and morphisms \(f_x: A_0 \to A_x\) and \(f_y: A_0 \to A_y\). We refer to such a system as a pushout system and often we arrange the morphisms in a diagram as follows

\[
\begin{array}{ccc}
A_0 & \xrightarrow{f_x} & A_x \\
\downarrow{f_y} & & \downarrow \\
A_y
\end{array}
\]

**Definition.** Let \((I, \leq)\) be a preordered set and let \(\mathcal{C}\) be a category. Suppose we are given a direct system \((\{X_i\}_{i \in I}, \{f_{ij}\}_{i \leq j})\) in the category \(\mathcal{C}\). A direct limit of the direct system is an object \(Y\) in \(\mathcal{C}\) together with morphisms \(g_i: X_i \to Y, i \in I\) in the category \(\mathcal{C}\) such that the following two conditions are satisfied:

1. For all \(i \leq j\) we have \(g_j \circ f_{ij} = g_i: X_i \to Y\), i.e. for all \(i \leq j\) the following diagram commutes

\[
\begin{array}{ccc}
X_j & \xrightarrow{g_j} & Y \\
\downarrow{f_{ij}} & & \downarrow \\
X_i & \xrightarrow{g_i}
\end{array}
\]

2. If we are given another object \(Y'\) and morphisms \(g'_i: X_i \to Y', i \in I\) that satisfy (1), then there exists a unique morphism \(F: Y \to Y'\) such that for all \(i \leq j\) the following diagram commutes

\[
\begin{array}{ccc}
X_j & \xrightarrow{g'_j} & Y' \\
\downarrow{f_{ij}} & \overset{?}{\xrightarrow{F}} & \downarrow \\
X_i & \xrightarrow{g'_i}
\end{array}
\]
The “usual argument” for objects that satisfy a universal property\(^\text{437}\) shows that if the direct limit exists, then it is unique in an appropriate sense. We denote the direct limit by \(\lim_\rightarrow X_i\) or sometimes by \(\lim_{I} X_i\).\(^\text{438}\)

**Examples.** Now we discuss the direct limits of the direct systems we had discussed above.

(A) We consider the above direct system in the category of groups that is given by the free abelian groups \(\mathbb{Z}^i, i \in \mathbb{N}\), with the obvious inclusion homomorphisms \(\mathbb{Z}^i \rightarrow \mathbb{Z}^j\) for \(i \leq j\). We claim that \(\lim_\rightarrow \mathbb{Z}^i = \mathbb{Z}(\mathbb{N}) = \{(x_1, x_2, \ldots) \mid x_i \in \mathbb{Z} \text{ but only finitely many } x_i\text{'s are non-zero}\}\), where the maps \(\mathbb{Z}^j \rightarrow \lim_\rightarrow \mathbb{Z}^i = \mathbb{Z}(\mathbb{N}), j \in \mathbb{N}\) are the obvious inclusion maps. Indeed, given a group \(Y'\) and homomorphisms \(g'_j : \mathbb{Z}^j \rightarrow Y'\) that satisfy condition (1) we define

\[
F : \lim_\rightarrow \mathbb{Z}^i = \mathbb{Z}(\mathbb{N}) \rightarrow Y' \\
(x_1, \ldots, x_j, 0, \ldots) \mapsto g'_j(x_1, \ldots, x_j).
\]

It is straightforward to see that this definition is well-defined, i.e. independent of the choice of \(x_j\).\(^\text{440}\) It is clear that the diagram (2) commutes. Furthermore, since \((x_1, \ldots, x_j, 0, \ldots) = g_j(x_1, \ldots, x_j)\) it is clear that \(F\) is the unique homomorphism that makes the diagram (2) commute.

Thus we have now shown that the direct limit is the free abelian group on an infinite countable generating set.

(B) We consider the above direct system in the category of groups that is given by the free groups \(F_i := \langle x_1, \ldots, x_i \rangle, i \in \mathbb{N}\), with the obvious inclusion homomorphisms \(F_i \rightarrow F_j\) for \(i \leq j\). Similar to the proof of (A) one can show that

\[
\lim_\rightarrow F_i = \langle x_1, x_2, x_3, \ldots \rangle = \text{free group on the generators } x_1, x_2, x_3, \ldots.
\]

where the maps \(F_j \rightarrow \lim_\rightarrow F_i = \langle x_1, x_2, \ldots \rangle, j \in \mathbb{N}\) are the obvious maps. Put differently, the direct limit is the free group on an infinite countable generating set.

(C) We continue with the direct system \((X_r, r \in \mathbb{N})\) in the category of topological spaces from above. Perhaps not surprisingly the direct limit is the interval \((0, \infty)\) with infinitely many circles attached, i.e.

\[
\lim_\rightarrow X_r = X_\infty = (0, \infty) \cup \bigcup_{j=1}^{\infty} \{ z \in \mathbb{C} \mid |z - (j + \frac{1}{4}i)| = \frac{1}{4} \} \subset \mathbb{C},
\]

\(^{435}\)Somewhat confusingly a “direct limit” is often also called a “projective limit” or “colimit of a direct system”.

\(^{436}\)The notation \(\exists!\) means that there exists a uniquely defined morphism that makes the diagram commute.

\(^{437}\)See for instance the discussion on page 582 for an example of such an argument.

\(^{438}\)Here we ignore the maps \(f_{ij}\) and \(g_i\) in the notation. Usually these maps are clear from the context.

\(^{439}\)Why is the direct limit not given by \(\mathbb{Z}^\mathbb{N}\), i.e. the group of all infinite sequences?

\(^{440}\)Here we did not demand that \(x_j \neq 0\).
where the maps $X_s \to \lim X_r = X_\infty$, $s \in \mathbb{N}$ are the obvious inclusion maps. We leave the verification of this statement to the reader.

(Figure 475)

(D) Let $(I, \leq)$ be a preordered set and let $\{X_i\}_{i \in I}$ be a family of topological spaces such that for any $i \leq j$ we have $X_i \subset X_j$. In the category of topological spaces we have

$$\lim X_i = X := \bigcup_{i \in I} X_i,$$

where the topology on $X = \bigcup_{i \in I} X_i$ is given by the rule that $U \subset X$ is open if and only if $U \cap X_i$ is open for all $i \in I$. Furthermore the maps $g_j: X_j \to X = \bigcup_{i \in I} X_i, j \in \mathbb{N}$ are the obvious inclusion maps.\[^{441}\] The verification of this statement is Exercise 25.3.

**Definition.** If the direct limit of a pushout system

$$A_0 \xrightarrow{f_x} A_x \xleftarrow{f_y} A_y$$

exists, then we refer to it as the **pushout** of the pushout system. The defining property of the pushout $Z$ can be summarized in the following commutative diagram:\[^{442}\]

---

**Examples.**

1. We first consider the pushout in the category of groups. By Proposition 21.21 the pushout of a pushout system in the category of groups

$$\begin{array}{ccc}
G & \xrightarrow{\alpha} & A \\
\beta \downarrow & & \downarrow \beta \\
B & \xrightarrow{A \ast G B = \langle \{\alpha(g) \cdot \beta(g^{-1}) \}_{g \in G} \rangle} & A
\end{array}$$

is given by

$$\begin{array}{ccc}
G & \xrightarrow{\alpha} & A \\
\beta \downarrow & & \downarrow \beta \\
B & \xrightarrow{A \ast G B} & A
\end{array}$$

\[^{441}\] Why are the maps $g_j$ continuous, i.e. why are they morphisms in the category of topological spaces.

\[^{442}\] Here we suppress the morphism $g_0: A_0 \to Z$ from the diagram since it is given by $g_x \circ f_x = g_y \circ f_y$. 
(2) Now we consider the pushout in the category of topological spaces. In Lemma 3.43 we already showed, in ever so slightly different words, that the pushout of the pushout system of topological spaces

\[
\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow{g} & & \downarrow{g} \\
Z & \rightarrow & Y \cup_X Z
\end{array}
\]

is given by

\[
\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow{g} & & \downarrow{g} \\
Z & \rightarrow & Y \cup_X Z := (Y \sqcup Z)/f(x) \sim g(x).
\end{array}
\]

Here we equip \(Y \cup_X Z\) with the quotient topology induced from the obvious topology on \(Y \sqcup Z\).

(3) The direct limit of a direct system does not always exist. For example, denote by \(C\) the category with two objects, namely the trivial group and the group \(\mathbb{Z}_2\), and where the morphisms are the usual group homomorphisms. Then the pushout system

\[
\begin{array}{ccc}
0 & \rightarrow & \mathbb{Z}_2 \\
\downarrow & & \downarrow \beta \\
\mathbb{Z}_2 & \rightarrow & C
\end{array}
\]

does not have a direct limit since there is no commutative diagram of the form

\[
\begin{array}{ccc}
0 & \rightarrow & \mathbb{Z}_2 \\
\downarrow & & \downarrow \beta \\
\mathbb{Z}_2 & \rightarrow & C
\end{array}
\]

with \(C = 0\) or \(C = \mathbb{Z}_2\) such that in the following two diagrams there exists the desired diagonal maps from \(C\) to \(Y' = \mathbb{Z}_2\):

\[
\begin{array}{ccc}
0 & \rightarrow & \mathbb{Z}_2 \\
\downarrow & \xrightarrow{\alpha} & C \\
\mathbb{Z}_2 & \rightarrow & Y' = \mathbb{Z}_2
\end{array}
\]

and

\[
\begin{array}{ccc}
0 & \rightarrow & \mathbb{Z}_2 \\
\downarrow & \xrightarrow{\alpha} & C \\
\mathbb{Z}_2 & \rightarrow & Y' = \mathbb{Z}_2
\end{array}
\]

Proposition 25.1. The direct limit of any direct system exists in the following categories:

(0) the category of sets,
(1) the category \(\text{Top}\) of topological spaces,
(2) the category \(\text{Gr}\) of groups,
(3) the category \(\text{AbGr}\) of abelian groups,
(4) the category \(\text{Ring}\) of rings,
(5) the category \(\text{R-Mod}\) of \(R\)-modules, where \(R\) is a commutative ring.

Sketch of proof. Let \((I, \leq)\) be a preordered set and let \(C\) be one of the six given categories. Furthermore let \((\{X_i\}_{i \in I}, \{f_{ij} : X_i \rightarrow X_j\}_{i \leq j})\) be a direct system in \(C\).

(0),(1) If we work in the category of sets, then we define the direct limit as the set

\[
\lim_{\longrightarrow} X_i := \left( \bigsqcup_{i \in I} X_i \right)/\sim \text{ where } x \sim f_{ij}(x) \text{ for all } i \leq j, x \in X_i.
\]

443 Why is there no such diagram with \(C = 0\) or \(C = \mathbb{Z}_2\) and homomorphisms \(\alpha\) and \(\beta\)?
If we work in the category of topological spaces, then \( \bigsqcup_{i \in I} X_i \) is equipped with the topology where a subset \( U \) is open if and only if \( U \cap X_i \) is open for all \( i \).

2. If we work in the category of groups, then we cannot use the definition of (0) and (1), since the union of groups is not a group. Therefore we define the direct limit via the “smallest group that contains all \( X_i \),” i.e. we define it as the group

\[
\lim \longrightarrow X_i := \left( \bigoplus_{i \in I} X_i \right) / \langle\langle \{ f_{ij}(x) \cdot x^{-1} \mid i \leq j \text{ and } x \in X_i \} \rangle\rangle.
\]

3), 4), 5) If we work in the category of abelian groups, or in the category of rings or in the category of \( R \)-modules, then we define

\[
\lim \longrightarrow X_i := \left( \bigoplus_{i \in I} X_i \right) / \{ f_{ij}(x) - x \mid i \leq j \text{ and } x \in X_i \}.
\]

Furthermore in all six cases we denote by \( g_j : X_j \to \lim \longrightarrow X_i, \ j \in I \) the obvious maps. It is now straightforward to verify that in all five categories we provided a direct limit. We leave the details to the reader.

\[\blacksquare\]

Remark.

(1) Suppose we are given a direct system \( \{X_i\}_{i \in I}, \{f_{ij} : X_i \to X_j\}_{i \leq j} \) in any of the four algebraic categories mentioned in the previous proposition. Now we assume that \( (I, \leq) \) is not only a preordered set, but that it is in fact a directed set. Then, as for direct limits of sets and topological spaces, we can also define

\[
\lim \longrightarrow X_i := \left( \bigsqcup_{i \in I} X_i \right) / \sim \text{ where } x \sim f_{ij}(x) \text{ for all } i \leq j, x \in X_i
\]

and we denote by \( g_j : X_j \to \lim \longrightarrow X_i, \ j \in I \), the obvious maps. If we work in the category of groups, then \( \lim \longrightarrow X_i \) is naturally a group as follows: if we are given \( a \in X_i \) and \( b \in X_j \), by definition of a directed set there exists \( k \in I \) with \( i \leq k \) and \( j \leq k \), and we define

\[
[a] \cdot [b] := \left( \underbrace{f_{ik}(a)}_{\in X_k} \cdot \underbrace{f_{jk}(b)}_{\in X_k} \right) \in \lim \longrightarrow X_i.
\]

It follows easily from the definition of a direct system that this definition of the product structure is independent of the choice of \( k \) and that this defines indeed a group structure on \( \lim \longrightarrow X_i \). Similarly we deal with the case that we work in the other three algebraic categories.

(2) An important special case is given by \( I = \mathbb{N}_0 \) and where the maps \( f_{ij} : X_i \to X_j \) are inclusion maps. In this case one can in fact take

\[
\lim \longrightarrow X_i := \bigcup_{i \in \mathbb{N}_0} X_i.
\]

\[\text{444 Not that for the above example of the pushout we do not get the same topological space (why not?) but we get a topological space that is homeomorphic (why?) to the above pushout. Since we only care about the direct limit up to homeomorphism this makes no difference.}\]

\[\text{445 Here we really mod out by the subgroup generated by the differences } f_{ij}(x) - x.\]
The algebraic structure is defined as in the previous remark.

We continue our discussion with the following lemma that gives a particularly simple but commonly used calculation of a direct limit.

**Lemma 25.2.** Let \( f_n : X_n \rightarrow X_{n+1} \) be a sequence of morphisms in any category. Suppose there exists an \( N \in \mathbb{N} \) such that all \( f_n \) for \( n \geq N \) are isomorphisms. Then \( \lim \rightarrow X_n \) exists and it is naturally isomorphic to \( X_N \), more precisely, a direct limit is given by \( \lim \rightarrow X_n := X_N \) and the maps

\[
(f_{N-1} \circ \cdots \circ f_{n+1} \circ f_n) : X_n \rightarrow X_N \quad \text{if} \quad n \leq N,
\]

\[
(f_n \circ \cdots \circ f_{N+1} \circ f_N)^{-1} : X_n \rightarrow X_n \quad \text{if} \quad n > N
\]

define a direct limit.

**Proof.** We will provide the proof in Exercise 25.2.

---

**25.3. The direct limit in the topological category.** In this short section we discuss a few results about direct limits that are specific to the category of topological spaces. We start out with the discussion of an important example of direct limits in the topological category.

**Lemma 25.3.** Let \( \{X_i\}_{i \in \mathbb{N}_0}, \{f_{ij}: X_i \rightarrow X_j\}_{i \leq j} \) be a direct system in the category of topological spaces. We assume that all the maps \( f_{ij}: X_i \rightarrow X_j \) are inclusion maps.

1. In this case one can in fact take

\[
\lim \rightarrow X_i := \bigcup_{i \in \mathbb{N}_0} X_i
\]

where the topology is given, as in the proof of Proposition 25.1, by the condition that \( U \subset X \) is open if and only if each \( U \cap X_i \) is an open subset of \( X_i \).

2. For each \( i \in \mathbb{N} \) the obvious map \( X_i \rightarrow \lim \rightarrow X_i \) is an embedding.

**Proof (\#).**

1. The argument is the same as in the proof of Proposition 25.1 (1).

2. Let \( i \in \mathbb{N} \). The map \( X_i \rightarrow \lim \rightarrow X_i \) is evidently injective and continuous. By Lemma 2.42 (1) it remains to show that the map is an open map. Thus let \( U_i \subset X_i \) be an open subset. By definition of the subspace topology there exists an open subset \( U_{i+1} \subset X_{i+1} \) such that \( U_{i+1} \cap X_i = U_i \). We iterate this procedure to obtain subsets \( U_i, U_{i+1}, U_{i+2}, \ldots \) We set \( U := \bigcup_{j \geq n} U_j \). Evidently \( U \cap X_i = U_i \).

Finally we conclude this section with two lemmas which show that in the category of topological spaces direct limits commute, under favorable circumstances, with direct products and quotients.

**Lemma 25.4.** (\#) Let \( (I, \leq) \) be a preordered set and let \( \{X_i\}_{i \in I}, \{f_{ij} : X_i \rightarrow X_j\}_{i \leq j} \) be a direct system in the category of topological spaces. We denote by \( g_i : X_i \rightarrow \lim \rightarrow X_i \) the canonical maps. Furthermore let \( Y \) be a topological space. By definition of the direct limit
the maps
\[ g_i \times \text{id}_Y : X_i \times Y \rightarrow \overline{\lim X_i} \times Y \]
induce a map
\[ \overline{\lim (X_i \times Y)} \rightarrow \overline{\lim X_i} \times Y. \]
If \( Y \) is regionally compact, then this map is a homeomorphism.

**Example.** Let \( f : X \rightarrow Y \) and \( g : X \rightarrow Z \) be maps between topological spaces. These maps define a pushout system, and taking the product with \([0, 1]\) also defines a pushout system. We get the following two diagrams:

\[
\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow{g} & & \downarrow{\text{id}} \\
Z & \xrightarrow{j} & X \cup_Y Z
\end{array}
\quad \text{and} \quad
\begin{array}{ccc}
X \times [0, 1] & \xrightarrow{f \times \text{id}} & Y \times [0, 1] \\
\downarrow{g \times \text{id}} & & \downarrow{\text{id}} \\
Z \times [0, 1] & \xrightarrow{j} & X \times [0, 1] \cup_Y Z \times [0, 1]
\end{array}
\]

By the property of the pushout we have the diagonal map. Since \([0, 1]\) is regionally compact we obtain from Lemma 25.4 or more directly from Lemma 5.18 that the diagonal map is a homeomorphism.

**Sketch of proof.** This lemma follows easily from the explicit description of the direct limit in the category of topological spaces that we gave in Proposition 25.1 together with Lemma 5.18.

---

**Lemma 25.5. (**)** Let \((I, \leq)\) be a preordered set and let \(\{X_i\}_{i \in I}, \{f_{ij} : X_i \rightarrow X_j\}_{i \leq j}\) be a direct system in the category of topological spaces. Let \(G\) be a group. Suppose that for each \(i \in I\) we are given an action of \(G\) on \(X_i\) such that given any \(i \leq j\) the following diagram commutes:

\[
\begin{array}{ccc}
G \times X_i & \xrightarrow{id_G \times f_{ij}} & X_i \\
\downarrow{id_G} & & \downarrow{f_{ij}} \\
G \times X_j & \xrightarrow{f_{ij}} & X_j
\end{array}
\]

It follows almost immediately from this data that \(G\) also acts on \(\overline{\lim X_i}\). We denote by \(g_i : X_i \rightarrow \overline{\lim X_i}\) the canonical maps. By definition of the direct limit the corresponding maps

\[ X_i/G \rightarrow (\overline{\lim X_i})/G \]
induce a map

\[ \overline{\lim (X_i/G)} \rightarrow (\overline{\lim X_i})/G. \]

This map is a homeomorphism.

**Sketch of proof.** This lemma follows easily from the explicit description of the direct limit in the category of topological spaces that we gave in Proposition 25.1.
25.4. **Fundamental groups and direct limits.** In this section we want to address the following question:

**Question 25.6.** Let \( \{X_i\}_{i \in I}, \{f_{ij}\}_{i \leq j} \) be a direct system of topological spaces. Now we can form the direct limit \( \varinjlim X_i \) of the topological spaces. The maps \( f_{ij} \) also induce homomorphisms on fundamental groups. The question is, when does “taking limits commute with taking fundamental groups”, i.e. under what circumstances do we have

\[
\pi_1(\varinjlim X_i) = \varinjlim \pi_1(X_i) ?
\]

**Example.** We have already seen two instances where the equality of the question holds.

(1) Suppose \( X \) is a topological space that is the union of two open subsets \( U \) and \( V \) such that \( U, V \) and \( U \cap V \) are path-connected. We fix a base point in \( U \cap V \). Then

\[
\pi_1(\varinjlim_{U \cap V \to U} X) = \pi_1(X) = \pi_1(U) \ast_{\pi_1(U \cap V)} \pi_1(V) = \varinjlim_{\pi_1(U \cap V) \to \pi_1(U)} \pi_1(V)
\]

see page [732] Seifert-van Kampen see page [731] Theorem [22.1]

(2) Let \( X \) be a path-connected topological space and let \( X_k, k \in \mathbb{N} \) be a sequence of subsets of \( X \) such that the following hold:

- (a) each \( X_k \) is open,
- (b) each \( X_k \) is simply connected,
- (c) the sequence \( X_k \) is nested, i.e. for each \( k \) we have \( X_k \subset X_{k+1} \),
- (d) we have \( \bigcup_{k \in \mathbb{N}} X_k = X \).

Then for any \( w \in X_1 \) we have

\[
\pi_1(\varinjlim_{i \in \mathbb{N}} X_i, w) = \pi_1(\bigcup_{i \in \mathbb{N}} X_i, x_0) = \{e\} = \varinjlim \{e\} = \varinjlim \pi_1(X_i, w).
\]

see Lemma [25.3] Lemma [20.6]

The following proposition generalizes the second example.

**Proposition 25.7.** Let \( X_i, i \in \mathbb{N} \) be a sequence of topological spaces such that the following holds:

1. the sequence is nested, i.e. for each \( i \in \mathbb{N} \) we have \( X_i \subset X_{i+1} \), and such that one of the following two conditions holds:
   1. every compact subset of \( \varinjlim X_i \) is already contained in one of the \( X_i \), or
   2. each \( X_i \) is open in \( X_{i+1} \).

---

\footnote{As it is this question is not well-phrased, since fundamental groups depend on base points and we ignored them in the above discussion.}

\footnote{Recall that by the discussion on page [729] the topological spaces \( \{X_i\}_{i \in \mathbb{N}} \) together with the inclusion maps form a direct system in the category of topological spaces. The direct limit is given by the union of all \( X_i \)'s, where the union is given a suitable topology. Furthermore note that the inclusion induced maps \( \pi_1(X_i, w) \to \pi_1(X_j, w) \) turn the groups \( \{\pi_1(X_i, w)\}_{i \in \mathbb{N}} \) into a direct system in the category of groups.}
Then for any \( w \in X_1 \) we have
\[
\pi_1(\lim X_i, w) = \lim \pi_1(X_i, w).
\]

**Remark.** We will see that the proof of Proposition 25.7 is a generalization of the ideas behind the proof of Lemma 20.6. The following lemma shows that the hypothesis (3) in Proposition 25.7 implies in fact hypothesis (2).

**Lemma 25.8.** Let \( X_i, i \in \mathbb{N} \) be a sequence of topological spaces such that each \( X_i \) is open in \( X_{i+1} \). Then every compact subset of \( \lim X_i \) is already contained in one of the \( X_i \).

**Proof of Lemma 25.8.** Let \( X_i, i \in \mathbb{N} \) be a nested sequence of topological spaces such that each \( X_i \) is open in \( X_{i+1} \).

**Claim.** For every \( i \in \mathbb{N} \) the subset \( X_i \) is open in \( X \).

By the definition of the topology on \( X \) we have to show that for each \( j \in \mathbb{N} \) the intersection \( X_i \cap X_j \) is open in \( X_j \). Since the sequence is nested it follows that for \( j \leq i \) we have \( X_i \cap X_j = X_j \), in particular \( X_i \cap X_j \) is open in \( X_j \). Now we need to show that \( X_i \) is open in any \( X_{i+k} \) with \( k \in \mathbb{N}_0 \). We do so by induction on \( k \). For \( k = 0 \) the statement is clear. Suppose we already know that \( X_i \) is open in \( X_{i+k} \). Then \( X_i \) is an open subset in \( X_{i+k} \) and \( X_{i+k} \) is in turn an open subset of \( X_{i+k+1} \) by our hypothesis. It follows that \( X_i \) is open in \( X_{i+k+1} \) and \( X_{i+k+1} \) is in turn an open subset of \( X_{i+k+2} \) by our hypothesis. It follows that \( X_i \) is open in \( X_{i+k+2} \).

Now let \( K \subset \lim X_i \) be a compact subset. From the claim we know that each \( X_i \) is open in \( X = \lim X_i \) we obtain immediately from Lemma 2.41 and the hypothesis that the \( X_i \)'s are nested that there exists a \( k \in \mathbb{N} \) such that \( K \subset X_k \).

The proof of Proposition 25.7 also relies on the following lemma that we will use implicitly and explicitly on numerous occasions.

**Lemma 25.9.** Let \((X, x_0)\) be a pointed topological space.

1. Given any \( g \in \pi_1(X, x_0) \) there exists a compact subset \( K \) of \( X \) with \( x_0 \in K \) such that \( g \) lies in the image of the inclusion induced map \( \pi_1(K, x_0) \to \pi_1(X, x_0) \).
2. Let \( Y \) be a subset of \( X \) with \( x_0 \). If \( g \in \pi_1(Y, x_0) \) lies in the kernel of the inclusion induced map \( \pi_1(Y, x_0) \to \pi_1(X, x_0) \), then there exists a compact subset \( K \) of \( X \) such that \( g \) lies in the kernel of the inclusion induced map \( \pi_1(Y, x_0) \to \pi_1(Y \cup K, x_0) \).

**Proof.**

1. Let \( g \in \pi_1(X, x_0) \). We represent \( g \) by a loop \( \gamma : [0, 1] \to X \). By Lemma 2.40 the image \( \gamma([0, 1]) \) is compact. Thus \( K := \gamma([0, 1]) \) has the desired property.
2. Now suppose that we are given \( g = [\gamma] \in \pi_1(Y, x_0) \) that lies in the kernel of the inclusion induced map \( \pi_1(Y, x_0) \to \pi_1(X, x_0) \). By definition this means that there exists a path-homotopy \( H : [0, 1] \times [0, 1] \to X \) from the path \( \gamma \) to the constant path.\[448\]

\[448\] Here we use the following general fact: if \( U \) is an open subset in \( V \) and \( V \) is an open subset of \( W \), then \( U \) is an open subset of \( W \). Why is that true?
We appeal again to Lemma 2.40 to deduce that $K := H([0,1] \times [0,1])$ is a compact subset of $X$. Evidently $K$ has the desired property. 

![Diagram](image)

**Figure 476. Illustration for Lemma 25.9**

Now we can provide the proof Proposition 25.7.

**Proof of Proposition 25.7.** By Lemma 23.8 we only have to prove the proposition under the hypothesis (2). Thus let $X_i, i \in \mathbb{N}$ be a nested sequence of topological spaces such that every compact subset of $\lim \rightarrow X_i$ is already contained in one of the $X_i$. Let $w \in X_1$.

We write $X = \bigcup_{i \in I} X_i = \lim \rightarrow X_i$.

Given $k \leq l$ we denote by $\varphi_{i,l}^{kl}$ the inclusion induced map $\pi_1(X_k, w) \to \pi_1(X_l, w)$. We denote by $\Phi: \lim \rightarrow \pi_1(X_i, w) \to \pi_1(X, w)$ the unique homomorphism that makes the following diagram commute for any $k \leq l$:

$\begin{tikzcd}
\pi_1(X_l, w) \ar[r] \ar[dr, \psi_k] & \lim \rightarrow \pi_1(X_i, w) \ar[r, \Phi] \ar[d, \psi_i] & \pi_1(X, w) \ar[dl, \varphi_{i,l}^{kl}]
\end{tikzcd}$

We need to show that $\Phi$ is an isomorphism. First we show that the map $\Phi$ is surjective. Let $g \in \pi_1(X,w)$. By Lemma 25.9 (1) and our hypothesis (2) there exists a $k \in \mathbb{N}$ such that $g$ lies in the image of the inclusion induced map $\pi_1(X_k, w) \to \pi_1(X, w)$. We consider the following commutative diagram

$\begin{tikzcd}
\lim \rightarrow \pi_1(X_i, w) \ar[r, \Phi] \ar[d, \psi_i] & \pi_1(X, w) \ar[d, \varphi_{i,l}^{kl}]
\end{tikzcd}$

By our choice of $k$ we see that $g$ lies in the image of the curved map, hence it also lies in the image of $\Phi$. This proves the proof that $\Phi$ is surjective.

Now we show that the map $\Phi$ is injective. So let $g \in \lim \rightarrow \pi_1(X_i, w)$. Since $(\mathbb{N}, \leq)$ is a directed set we can use the description of the direct limit from page 733 i.e. we can write

$\lim \rightarrow \pi_1(X_i, w) = \left( \bigcup_{i \in \mathbb{N}} \pi_1(X_i, w) \right) / \sim$ where $g \sim \varphi_{i,l}^{kl}(g)$ for all $k \leq l$, $g \in \pi_1(X_k, w)$.

In particular we see that there exists a $k$ such that $g$ lies in the image of the map $\psi_k: \pi_1(X_k, w) \to \lim \rightarrow \pi_1(X_k, w)$. It follows from Lemma 25.9 (1) and our hypothesis (2)
that there exists an \( l \geq k \) such that \( \varphi_{kl}(\gamma) \) is trivial in \( \pi_1(X_l, w) \). We obtain the following diagram

\[
\begin{array}{ccc}
\pi_1(X_1, w) & \xrightarrow{[\gamma] \mapsto e} & \lim \pi_1(X_i, w) \\
\downarrow & & \downarrow \lim_{g \to e} \\
\pi_1(X_k, w) & \xrightarrow{[\gamma] \mapsto g} & \pi_1(X, w).
\end{array}
\]

It follows immediately that \( g \) itself is trivial. This concludes the proof that \( \Phi \) is injective.  

**Examples.**

(1) As on page 728 we denote by \( X_\infty \) the interval \((0, \infty)\) with infinitely many circles attached. We pick the base point \( w = \frac{1}{4} \). We then have

\[
\pi_1(X_\infty, w) = \pi_1\left(\lim_{s \to \infty} X_s, w\right) = \lim \pi_1(X_s, w) = \lim \langle x_1, \ldots, x_r \rangle = \langle x_1, x_2, \ldots \rangle.
\]

Furthermore the proof of Proposition 20.5 and the above argument show that the generators \( x_1, x_2, \ldots \) of \( \pi_1(X_\infty) \) can be chosen such that \( x_n, n \in \mathbb{N} \), corresponds to a loop which goes “once around the \( n \)-th circle”.

(2) Now we consider

\[
\tilde{X} := \mathbb{R} \cup \bigcup_{j \in \mathbb{Z}} \left\{ z \in \mathbb{C} \mid z - (j + \frac{1}{4} i) = \frac{1}{4} \right\} \subset \mathbb{C}.
\]

Put differently, \( \tilde{X} \) is the real axis with infinitely many circles attached. The same argument as in (1) shows that \( \pi_1(\tilde{X}) \) is the free group on infinitely many generators \( x_n, n \in \mathbb{Z} \). In Figure 477 we illustrate a covering map \( p: \tilde{X} \to X = S^1 \cup S^1 \). By Corollary 16.14 the map \( \pi_1(\tilde{X}) \to \pi_1(X) \) is a monomorphism. We had just seen that \( \pi_1(\tilde{X}) \) is a free group on infinitely generators and by the discussion on page 606 we know that \( \pi_1(X) \) is a free group on two generators. In fact, with appropriate orientations and conventions this shows that the homomorphism

\[
\pi_1(\tilde{X}) = \langle \ldots, x_{-2}, x_{-1}, x_0, x_1, x_2, \ldots \rangle \to \langle s, t \rangle = \pi_1(X)
\]

\[
x_n \mapsto s^n t s^{-n}
\]

The third equality follows from Proposition 20.5 to be more precise, it follows from the fact that for any \( r \leq s \) the inclusion map \( \iota_{rs}: X_r \to X_s \) and the isomorphisms of Proposition 20.5 give rise to a commutative diagram

\[
\begin{array}{ccc}
\pi_1(X_r, w) & \xrightarrow{\sim} & \langle x_1, \ldots, x_r \rangle \\
\downarrow (\iota_{rs})_* & & \downarrow \iota_{rs} \mid x_i \mapsto x_i \\
\pi_1(X_s, w) & \xrightarrow{\sim} & \langle x_1, \ldots, x_s \rangle.
\end{array}
\]

The fact that this diagram commutes follows easily from the proof of Proposition 20.5. We leave the details to the reader.
is a monomorphism. In particular we see that the free group \( \langle s, t \rangle \) contains a subgroup that is “much larger” than the original free group itself.

\[
\begin{array}{c}
\x_0 \quad \x_1 \quad \x_2
\end{array}
\xrightarrow{p}
\begin{array}{c}
\tilde{X}
\end{array}
\xrightarrow{t}
\begin{array}{c}
\x = S^1 \cup S^2
\end{array}
\]

**Figure 477**

(3) An argument similar to (1) shows that \( \pi_1(C \setminus \mathbb{Z}) \) is a free group generated by \( \x_n, n \in \mathbb{Z} \) where \( \x_n \) is a loop which goes “once around the \( n \)-th hole”. We leave the task of providing the details to the reader. We refer to Figure 478 for an illustration.

**Figure 478**

25.5. **The surface of “infinite genus”** (*). In this section we return to the initial goal of this chapter, namely we want to determine the fundamental group of the surface of “infinite genus” that we illustrate in Figure 479. Before we can calculate its fundamental group we have to give a precise description of the surface of infinite genus.

**Figure 479**

**Definition.** We write

\[
F := \text{the torus minus two open disks.}
\]

We label the two boundary components by \( C_- \) and \( C_+ \). We pick orientation-preserving diffeomorphisms \( \varphi_{\pm} : S^1 \rightarrow C_{\pm} \). We define

\[
\Sigma_\infty := \left( \bigcup_{i \in \mathbb{Z}} (F \times \{i\}) \right) / \sim \quad \text{where} \quad (\varphi_+(x), i) \sim (\varphi_-(x), i + 1) \quad \text{for} \quad x \in S^1 \quad \text{and} \quad i \in \mathbb{Z}.
\]

We refer to \( \Sigma_\infty \) as the **surface of infinite genus**. It should be clear that this definition gives a rigorous description of the surface that we sketched in Figure 479.

**Lemma 25.10.**

---

450 One might be tempted to say that the surface of infinite genus is the connected sum of infinitely many tori. But it is not clear that “connected sum of infinitely many tori” is actually a well-defined concept.
By Lemma 23.11 we have
\[ \pi_1(F) = \langle a, b, c, c' \mid c = [a, b] \cdot c' = \langle x, y, z, z' \mid z = [x, y] \cdot z' \rangle \]

This is indeed a consequence of Lemma 23.11, the only change is that we reversed the orientation of one of the boundary curves.
where the generators $z, z'$ and $c, c'$ correspond to the two boundary components. We refer to Figure 482 for an illustration. An induction argument, using the Seifert–van Kampen

\[
\pi_1(X_k) \xrightarrow{\cong} \langle x_1, y_1, \ldots, x_k, y_k, z_k, c_k \mid \prod_{j=1}^{k} [a_j, b_j]c_k = \prod_{j=1}^{k} [x_j, y_j]z_k \rangle
\]

\[
\pi_1(X_l) \xrightarrow{\cong} \langle x_1, y_1, \ldots, x_l, y_l, z_l, c_l \mid \prod_{j=1}^{l} [a_j, b_j]c_l = \prod_{j=1}^{l} [x_j, y_j]z_l \rangle
\]

where the left vertical map is induced by the inclusion $X_k \rightarrow X_l$. We leave the details to the energetic reader. For any $l \geq k$ we also have the following commutative diagram of

\[
\xymatrix{
X_k \ar[r] \ar[d]_{\cong} & X_l \\
X_l \ar[r] & X_l \ar[d]_{\cong}
}
\]
homomorphisms:

\[
\langle x_1, y_1, \ldots, x_k, y_k \rangle \xrightarrow{\approx}_{p \mapsto \prod_{j=1}^{k} [a_j, b_j] c_k} \langle x_1, y_1, \ldots, x_k, y_k z_k, c_k \rangle \xrightarrow{\approx}_{p \mapsto \prod_{j=1}^{k} [a_j, b_j] c_k} \langle x_1, y_1, \ldots, x_k, b_k z_k, c_k, \prod_{j=1}^{k} [a_j, b_j] c_k = \prod_{j=1}^{k} [x_j, y_j] z_k \rangle
\]

The horizontal homomorphisms are in fact isomorphisms, this is for example a consequence of the Tietze transformations from page \[632\]

We denote by \( \Sigma_\infty \) the surface of infinite genus. Furthermore given any \( i \in \mathbb{N}_0 \) we write \( U_i = X_i \setminus \partial X_i \). Note that each \( U_i \) is in fact an open subset of \( \Sigma_\infty \). We have

\[
\begin{align*}
\pi_1(\Sigma_\infty) &= \pi_1 \left( \lim_{i \to \infty} U_i \right) \\
&\xrightarrow{\text{since } \Sigma_\infty = \bigcup_{i \in \mathbb{N}_0} U_i} \lim_{i \to \infty} \pi_1(U_i) = \lim_{i \to \infty} \pi_1(X_i) \\
&\xrightarrow{\text{since } \pi_1(U_i) \xrightarrow{\approx} \pi_1(X_i)} \lim_{i \to \infty} \langle x_1, y_1, \ldots, x_i, y_i \rangle = \langle x_1, y_1, \ldots, x_i, y_i, z_i, c_i \rangle \\
&\xrightarrow{\text{see example on page } 730} \lim_{i \to \infty} \langle x_1, y_1, \ldots, x_i, y_i, z_i, c_i, \prod_{j=1}^{i} [a_j, b_j] c_i = \prod_{j=1}^{i} [x_j, y_j] z_i \rangle
\end{align*}
\]

This concludes the proof of the lemma.

In the final part of this section we will see that we can actually use Lemma \[25.11\] to draw an interesting conclusion on fundamental groups of surfaces of finite genus. First we have the following lemma.

**Lemma 25.12.** Let \( g \geq 2 \). We denote by \( \Sigma_\infty \) the surface of infinite genus and we denote by \( \Sigma_g \) the surface of genus \( g \).

1. There exists an action of \( \mathbb{Z} \) on \( \Sigma_\infty \) that is discrete and continuous and such that the quotient \( \Sigma_\infty / \mathbb{Z} \) is homeomorphic to \( \Sigma_g \).
2. There exists a covering \( p: \Sigma_\infty \to \Sigma_g \) of infinite degree.

**Sketch of proof.**

Indeed, we write \( X = \{ x_1, y_1, \ldots, x_m, y_m, a_1, b_1, \ldots, a_m, b_m \} , u = \prod_{j=1}^{m} [a_j, b_j] , v = \prod_{j=1}^{m} [x_j, y_j] , c = c_m \) and \( z = z_m \), then

\[
\langle X, z, c \mid uc = vz \rangle = \langle X, z, c \mid z = v^{-1}uc \rangle \xrightarrow{2} \langle X, c \rangle \xrightarrow{2} \langle X, c, p \mid p = uc \rangle = \langle X, c, p \mid X, c = u^{-1}p \rangle \xrightarrow{2} \langle X, p \rangle
\]

where all three isomorphisms are the isomorphisms of the Tietze transformation (2). It is straightforward to see that the concatenation equals for \( m = k, l \) precisely the horizontal maps in the diagram.
Figure 484. Illustration of Lemma \ref{lem:infinite_genus} 

(1) We continue with the notation from page \pageref{page:740} and Lemma \ref{lem:topological_sphere}. Let $g \in \mathbb{N}_{\geq 2}$. As before we consider

$$
\Sigma_{\infty} := \left( \bigcup_{i \in \mathbb{Z}} (F \times \{i\}) \right) / \sim \quad \text{where} \quad (\varphi_{+}(x), i) \sim (\varphi_{-}(x), i + 1) \quad \text{for} \quad x \in S^1 \quad \text{and} \quad i \in \mathbb{Z}.
$$

Given $n \in \mathbb{Z}$ and $[(x,k)] \in \Sigma_{\infty}$ we define $n \cdot [(x,k)] := [(x,k + (g - 1) \cdot n)]$. It follows from Exercise \ref{ex:quotient_continuous} that this action is continuous and proper. Furthermore we obtain from Exercise \ref{ex:topological_space} that the quotient $\Sigma_{\infty}/\mathbb{Z}$ is homeomorphic to the topological space that is given by identifying the two boundary components of

$$
\left( \bigcup_{i=0}^{g-1} (F \times \{i\}) \right) / \sim \quad \text{where} \quad (\varphi_{+}(x), i) \sim (\varphi_{-}(x), i + 1) \quad \text{for} \quad x \in S^1 \quad \text{and} \quad i \in \{0, \ldots, g - 1\}.
$$

The experienced reader will surely be convinced that this topological space is homeomorphic to the surface of genus $g$. We leave it to the scrupulous reader to fill in the details.

(2) This statement follows immediately from (1) together with Proposition \ref{prop:covering}. 

Using the results of this section we can prove the following proposition.

**Proposition 25.13.** Let $g \geq 2$. We consider the automorphism

$$
\varphi: \langle \{x_{1,i}, y_{1,i}, \ldots, x_{g-1,i}, y_{g-1,i}\}_{i \in \mathbb{Z}} \rangle \rightarrow \langle \{x_{1,i}, y_{1,i}, \ldots, x_{g-1,i}, y_{g-1,i}\}_{i \in \mathbb{Z}} \rangle
$$

that is induced by

- $x_{j,i} \mapsto x_{j,i+1}$
- $y_{j,i} \mapsto y_{j,i+1}$.

There exists an isomorphism

$$
\pi_1(\Sigma_g) \cong \langle \{x_{1,i}, y_{1,i}, \ldots, x_{g-1,i}, y_{g-1,i}\}_{i \in \mathbb{Z}} \rangle \times_{\varphi} \mathbb{Z}.
$$

**Sketch of proof.** We consider the surface $\Sigma_{\infty}$ of infinite genus together with the $\mathbb{Z}$-action that is provided by Lemma \ref{lem:infinite_genus} (1). By Proposition \ref{prop:covering} (2) we know that the projection $p: \Sigma_{\infty} \rightarrow \Sigma_{\infty}/\mathbb{Z} = \Sigma_g$ is a covering.

We pick a base point $a_0 \in \Sigma_g$. Next let $\tilde{a}_0 \in \Sigma_{\infty}$ be a point with $p(\tilde{a}_0) = a_0$. It follows from Corollary \ref{cor:covering} that $p_*: \pi_1(\Sigma_{\infty}, \tilde{a}_0) \rightarrow \pi_1(\Sigma_g, a_0)$ is a monomorphism. We will use

\footnote{It follows from the Collar Neighborhood Theorem \ref{thm:collar} together with Lemma \ref{lem:neighborhood} that there exist open disjoint neighborhoods of the two boundary components of $F$, thus the extra hypothesis for Exercise \ref{ex:topological_space} (c) is in fact satisfied.}
this monomorphism to view \( \pi_1(\Sigma_\infty, \tilde{a}_0) \) as a subgroup of \( \pi_1(\Sigma_g, a_0) \). We pick a path \( \tilde{\mu} \in \Sigma_\infty \) from \( a_0 = 0 \cdot a_0 \) to \( 1 \cdot a_0 \). We write \( \mu := p \circ \tilde{\mu} \) and we consider the isomorphism

\[
\psi: \pi_1(\Sigma_\infty, \tilde{a}_0) \rightarrow \pi_1(\Sigma_\infty, a_0)
\]

we write \( g \mapsto [\mu] \cdot g \cdot [\mu]^{-1} \).

Now we have the following isomorphisms:

by Lemma \( \text{25.11} \) we have an explicit isomorphism \( \pi_1(\Sigma_\infty, \tilde{a}_0) \cong \langle \{x_{1,i}, y_{1,i}, \ldots, x_{g-1,i}, y_{g-1,i}\}_{i \in \mathbb{Z}} \rangle \).

we leave it to the reader to verify that \( \psi \) and \( \varphi \) match up

\[
\pi_1(\Sigma_g, a_0) \xrightarrow{\sim} \pi_1(\Sigma_\infty, \tilde{a}_0) \times \psi \mathbb{Z} \overset{k}{\cong} \langle \{x_{1,i}, y_{1,i}, \ldots, x_{g-1,i}, y_{g-1,i}\}_{i \in \mathbb{Z}} \rangle \times \varphi \mathbb{Z}.
\]

by Theorem \( \text{16.16} \) (2) we have an epimorphism \( \gamma: \pi_1(\Sigma_g, a_0) \rightarrow \mathbb{Z} \) with \( \gamma([\mu]) = 1 \) and with kernel \( \pi_1(\Sigma_\infty, a_0) \).

thus we obtain the isomorphism from Lemma \( \text{24.27} \).

We have thus found the promised isomorphism.

We have thus found the promised isomorphism.

Figure 485. Illustration for the proof of Proposition \( \text{25.13} \).

Using Proposition \( \text{25.13} \) we can prove the following proposition.

**Proposition 25.14.** Let \( g \geq 2 \). Every abelian subgroup of \( \pi_1(\Sigma_g) \) is isomorphic to \( \mathbb{Z} \).

**Proof.** This proposition is a pleasant application of Proposition \( \text{25.13} \) and Exercise \( \text{19.11} \). We will provide the details in Exercise \( \text{25.9} \). \boxed{}

25.6. The inverse limit of an inverse system. For completeness’ sake also introduce the inverse limit of an inverse system, even though it will not play a role in the intermediate future.

**Definition.** Let \((I, \leq)\) be a preordered set and let \( \mathcal{C} \) be a category. An **inverse system in the category** \( \mathcal{C} \) over \( I \) is a family of objects \( \{X_i\}_{i \in I} \) in \( \mathcal{C} \), together with a family of morphisms \( \{f_{ji}: X_j \rightarrow X_i\} \) for all \( i, j \in I \) with \( i \leq j \), such that the following two conditions are satisfied:

1. \( f_{ii} = \text{id}_{X_i} \) for all \( i \in I \),
2. \( f_{ki} = f_{ji} \circ f_{kj} \) for all \( i, j, k \in I \) with \( i \leq j \leq k \).

**Examples.**

(A) For each \( i \in \mathbb{N} \) we define \( X_i := \mathbb{Z}^i \) and for \( i \leq j \) we denote by \( f_{ji}: \mathbb{Z}^j \rightarrow \mathbb{Z}^i \)

\[
(x_1, \ldots, x_j) \mapsto (x_1, \ldots, x_i).
\]

\text{454}So here for \( i \leq j \) we have a morphism \( X_j \rightarrow X_i \) instead of \( X_i \rightarrow X_j \) in a direct system.
the projection onto the first $i$ coordinates. Then $\left(\{Z^i\}_{i\in\mathbb{N}}, \{f_{ji}\}_{i\leq j}\right)$ forms an inverse system in the category of groups.

(B) Let $p$ be a prime. For each $i \in \mathbb{N}$ we define $X_i := \mathbb{Z}_{p^i}$ and for $i \leq j$ we denote by

$$f_{ji}: \mathbb{Z}_{p^j} \to \mathbb{Z}_{p^i}$$

$$n + p^j\mathbb{Z} \mapsto n + p^i\mathbb{Z}$$

the obvious projection map. Then $\left(\{\mathbb{Z}_{p^i}\}_{i\in\mathbb{N}}, \{f_{ji}\}_{i\leq j}\right)$ forms an inverse system in the category of rings.

(C) We let $I = \mathbb{N}$, but this time we use the preorder given by divisibility, i.e. we write $k \leq l$ if and only if $k|l$. For each $k \in \mathbb{N}$ we define $X_k := \mathbb{Z}_k$ and for $k|l$ we denote by

$$f_{lk}: \mathbb{Z}_l \to \mathbb{Z}_k$$

$$n + l\mathbb{Z} \mapsto n + k\mathbb{Z}$$

the obvious projection map. Then $\left(\{\mathbb{Z}_k\}_{k\in\mathbb{N}}, \{f_{lk}\}_{k|l}\right)$ forms an inverse system in the category of rings.

The following definition is the “mirror” image of the definition of the direct limit of a direct system.

**Definition.** Let $(I, \leq)$ be a preordered set and let $C$ be a category. Furthermore suppose we are given an inverse system $\left(\{X_i\}_{i\in I}, \{f_{ji}\}_{i\leq j}\right)$ in the category $C$. An inverse limit of the inverse system is an object $Y$ in $C$ together with morphisms $g_i: Y \to X_i$, $i \in I$, in the category $C$ such that the following two conditions are satisfied:

1. For all $i \leq j$ we have $f_{ji} \circ g_j = g_i: Y \to X_i$, i.e. for all $i \leq j$ the following diagram commutes

\[
\begin{array}{ccc}
Y & \xrightarrow{g_j} & X_j \\
\downarrow{g_i} & \searrow{f_{ji}} & \searrow{g_i} \\
X_i & \rightarrow & X_i.
\end{array}
\]

2. If we are given another object $Y'$ and morphisms $g'_i: Y' \to X_i$, $i \in I$, that satisfy (1), then there exists a unique morphism $F: Y' \to Y$ such that for all $i \leq j$ the following diagram commutes

\[
\begin{array}{ccc}
Y' & \xrightarrow{F} & Y \\
\downarrow{g'_j} & \searrow{g'_j} & \searrow{g_i} \\
X_j & \rightarrow & X_i.
\end{array}
\]

\[\text{Somewhat confusingly an “inverse limit” is often also called an “inductive limit” or “limit of an inverse system”}\].
The “usual argument” for objects that satisfy a universal property shows that if the inverse limit exists, then it is unique in an appropriate sense. We denote the inverse limit by \( \lim_{\leftarrow} X_i \) or sometimes by \( \lim_{\leftarrow} I X_i \).

In the following diagram we compare schematically the definition of the direct limit of a direct system to the inverse limit of an inverse system:

![Diagram](image)

**Examples.** In order to get an idea of how to construct inverse limits we first consider the special case that the preorder on \( I \) is trivial, in the sense that we have \( i \leq j \) if and only if \( i = j \).

(D) Let \( I \) be a set with the trivial preorder. Suppose that for every \( i \in I \) we are given a set \( X_i \). Together with the identity maps of the \( X_i \) this defines an inverse system over \( I \) in the category of sets. We claim that the inverse limit is given by

\[
\lim_{\leftarrow} X_i = \prod_{i \in I} X_i
\]

together with the maps \( g_i \) that are given by the projection onto the \( i \)-component. Now we verify this statement. Since we only have \( i \leq j \) if \( i = j \) there is nothing to verify in part (1) of the definition of the inverse limit. Now suppose we are given a

\[456\] The difference between a direct limit and an inverse limit is not the direction of the arrows between the \( X_i \). In fact given a preorder “\( \leq \)” one could define a preorder “\( \leq^* \)” via \( a \leq^* b \) if and only if \( b \leq a \), hence a direct system over \((I, \leq)\) is an inverse system over \((I, \leq^*)\). The real difference is whether the \( X_i \) map to the limit, or whether the limit maps to the \( X_i \).

\[457\] Recall that the product \( \prod_{i \in I} X_i \) is defined as the set of all maps \( f : I \to \bigcup_{i \in I} X_i \) with the property that \( f(i) \in X_i \) for all \( i \in I \). Such a map \( f \) is often written as \((f(i))_{i \in I}\) and often we refer to \( f(i) \) as the \( i \)-component of \( f \). Furthermore we refer to the map

\[
\prod_{i \in I} X_i \to X_i \\
f \mapsto f(i)
\]

as the projection onto the \( i \)-component. Note that if the \( X_i \)'s are groups, rings or modules, then the product inherits this algebraic structure by component-wise multiplication and addition.
set \( Y' \) and maps \( g'_i: Y' \to X_i \). Then we define

\[
F: Y' \to \lim_{\leftarrow} X_i
y \mapsto \left( \begin{array}{c}
i \mapsto \prod_{i \in I} X_i \\
i \mapsto g'_i(y)
\end{array} \right).
\]

It is straightforward to verify that \( F \) is uniquely determined and that it has the desired property. We have thus determined the inverse limit \( \lim_{\leftarrow} X_i \).

(E) Let \( I \) be a set with the trivial preorder and suppose that for any \( i \in I \) we are given a topological space \( X_i \). Together with the identity maps of the \( X_i \) this defines an inverse system over \( I \) in the category of topological spaces. As in (D) we define

\[
\lim_{\leftarrow} X_i = \prod_{i \in I} X_i
\]

and each map \( g_i \) is again given by the projection onto the \( i \)-component.

To conclude that we have found an inverse limit in the category of topological spaces we still have to equip \( \prod_{i \in I} X_i \) with a topology which has the following two properties:

(i) the maps \( g_i: \prod_{i \in I} X_i \to X_i \) are continuous,

(ii) given a topological space \( Y' \) and continuous maps \( g'_i: Y' \to X_i \) the map \( F \), defined as in (D), is continuous.\(^{458}\)

We set

\[
\mathcal{B} := \left\{ \prod_{i \in I} U_i \subset \prod_{i \in I} X_i \right\} \quad \text{such that}
\begin{align*}
&\text{(1) each } U_i \text{ is open in } X_i \text{ and} \\
&\text{(2) there exist only finitely many } i \text{'s with } U_i \neq X_i
\end{align*}
\]

It is straightforward to verify that \( \mathcal{B} \) has the basis property that we introduced on page \(^{459}\). We equip \( \prod_{i \in I} X_i \) with the topology generated by this basis and we refer to this topology as the product topology.\(^{459}\)

Now we need to verify that we found the correct topology on the direct limit.

(i) It follows immediately from the definitions that the maps \( g_i \) are continuous with respect to the product topology.

(ii) Suppose we are given \( Y \) and \( g'_i \) as above. We denote by \( F \) the map defined as above. We claim that \( F \) is continuous. By Proposition \(^{457}\) it suffices to verify

\(^{458}\)On the product \( \prod_{i \in I} X_i \) we could also consider the topology \( T \) that is generated by all sets of the form \( \prod_{i \in I} U_i \) with \( U_i \) open in \( X_i \). This might be a more “natural” topology on \( \prod_{i \in I} X_i \). But with this topology \( T \) the map \( F \) does not necessarily have to be continuous. The problem is that \( T \) has “too many” open sets.

\(^{459}\)If the index set \( I \) is finite, i.e. if we consider the product of finitely many topological spaces, then this definition of the product topology agrees with the definition given on page \(^{462}\).
that the preimage of any set in $B$ is open. So let $\prod_{i \in I} U_i$ be a set in $B$. Then

$$F^{-1}\left(\prod_{i \in I} U_i\right) = \bigcap_{i \in I} (g'_i)^{-1}(U_i) = \bigcap_{U_i \neq X_i \text{ open in } Y'} (g'_i)^{-1}(U_i) = \text{intersection of finitely many open subsets of } Y'.$$

This concludes the proof that $F$ is continuous.

Now we can prove fairly easily that inverse limits exist in many categories that are of interest to us.

**Proposition 25.15.** The inverse limit of any inverse system exists in the following categories:

1. the category $\text{Set}$ of sets,
2. the category $\text{Top}$ of topological spaces,
3. the category $\text{Gr}$ of groups,
4. the category $\text{TopGr}$ of topological groups,
5. the category $\text{AbGr}$ of abelian groups,
6. the category $\text{Ring}$ of rings,
7. the category of $R$-modules, where $R$ is a commutative ring.

Furthermore, the direct limits of (0), . . . , (6) are “coherent”. For example if $\{X_i\}_{i \in I}$ is a direct system of topological groups, then the direct limit is the direct system of the corresponding topological spaces together together with an appropriate group structure.

We will see that the proof of Proposition 25.15 is a relatively straightforward generalization of the examples (D) and (E) above.

**Proof.** Let $(I, \leq)$ be a preordered set and let $C$ be one of the seven given categories. Furthermore let $(\{X_i\}_{i \in I}, \{f_{ji}: X_j \to X_i\}_{i \leq j})$ be an inverse system in the category $C$. We define

$$\lim_{\leftarrow} X_i := \{(x_i)_{i \in I} \in \prod_{i \in I} X_i \mid f_{ji}(x_j) = x_i \text{ for all } i \leq j\}.$$

Furthermore we denote by $g_i: \lim_{\leftarrow} X_i \to X_i$ the obvious projection maps. It follows immediately from the definitions that for any $i \leq j$ we have $f_{ji} \circ g_j = g_i$. Furthermore, given an object $Y'$ and morphisms $g'_i: Y' \to X_i, i \in I$ which satisfy the condition $f_{ji} \circ g'_j = g'_i$ for all $i \in I$ we define

$$F: Y' \to \lim_{\leftarrow} X_i \quad y \mapsto \left( I \to \prod_{i \in I} X_i \quad i \mapsto g'_i(y) \right).$$

It is straightforward to verify that $F(Y')$ lies in $\lim_{\leftarrow} X_i$ and that $F$ is the unique map with the desired property. This shows that the inverse limit exists in the category of sets.

\footnote{We will now see that we can use the “same” inverse limit for all the categories, this is very different from the construction of the direct limit for the same categories. There, in the proof of Proposition 25.1 we had to use several different construction.}
For the remaining six categories we will use the same definition of the direct limit as a set and the same maps, but we now have to verify that we have objects and morphisms in the given category.

(1) Suppose that we work in the category of topological spaces. We equip $\prod_{i \in I} X_i$ with the product topology that we defined in Example (E) above. We equip $\lim_{\leftarrow} X_i$ with the subspace topology. The same argument as in Example (E) shows that the maps $g_i$ and $F$ are continuous.

(2) In the category of groups we view $\prod_{i \in I} X_i$ as a group via component-wise multiplication. Since the $f_{ij}$ are group homomorphisms we see that $\lim_{\leftarrow} X_i$ is a subgroup of $\prod_{i \in I} X_i$. It is straightforward to verify that the above maps are all morphisms in the category of groups.

(3) We equip the set $\lim_{\leftarrow} X_i$ with the topological structure and the group structure as in the above statements (1) and (2). It follows from Lemma 3.54 that this turns $\lim_{\leftarrow} X_i$ into a topological group, which turns out to be the inverse limit of the inverse system of topological groups.

(4),(5),(6) These categories are dealt with the same way as (2).

For all seven categories we have now provided an inverse limit. Since we always equipped the same set with different structures we see that the direct limits are coherent.

Remark. We consider the important special case that the preordered set $(I, \leq) = (\mathbb{N}, \leq)$. Furthermore let

$$(\{X_n\}_{n \in \mathbb{N}}, \{f_{nm} : X_n \rightarrow X_m\}_{m \leq n})$$

be an inverse system over $(\mathbb{N}, \leq)$ in any of the above seven categories. Given $n \in \mathbb{N}_{\geq 2}$ we write $g_n := f_{n,n-1} : X_n \rightarrow X_{n-1}$. We have

$$\lim_{\leftarrow} X_i = \{(x_1, x_2, x_3, \ldots) \mid x_n \in X_n \text{ for all } n \in \mathbb{N} \text{ and } f_{nm}(x_n) = x_m \text{ for all } m \leq n\}$$

$$= \{(x_1, x_2, x_3, \ldots) \mid x_n \in X_n \text{ for all } n \in \mathbb{N} \text{ and } g_n(x_n) = x_{n-1} \text{ for all } n \in \mathbb{N}_{\geq 2}\}$$

follows from $f_{nm} = f_{n,n-1} \circ \cdots \circ f_{m+1,m} = g_n \circ \cdots \circ g_{m+1}$

$$\vdots \quad \vdots \quad \downarrow \quad \downarrow$$

$$x_3 \in X_3$$

$$\downarrow \quad \downarrow g_3$$

$$x_2 \in X_2$$

$$\downarrow \quad \downarrow g_2$$

$$x_1 \in X_1$$

This discussion shows that we can view of elements in the inverse limit as “upward going sequences”.

Now we return to our initial examples of inverse systems and their inverse limits.
Examples.
(A) It follows quite easily from the previous remark that
\[ \lim_{\to} Z^n = \{(x_1, x_2, x_3, \ldots) | x_n \in \mathbb{Z}\} \cong \mathbb{Z}^n. \]
Note that this is an uncountable group. Recall that on page 730 we had determined that
\[ \lim_{\to} Z^i = \mathbb{Z}^{(\mathbb{N})} = \{(x_1, x_2, \ldots) | \text{only finitely many } x_i \text{ are non-zero}\} \]
which is a countable group. Thus we see that in this particular case the inverse limit is “much larger” than the direct limit.

(B) Let \( p \) be a prime. The inverse limit \( \hat{\mathbb{Z}}_p := \lim_{\to} \mathbb{Z}_{p^i} \) of the rings \( \mathbb{Z}_{p^i} = \mathbb{Z}/p^i\mathbb{Z} \) is called the ring of the \( p \)-adic numbers. The \( p \)-adic numbers play a very prominent role in many branches of pure mathematics.

(C) The inverse limit \( \hat{\mathbb{Z}} := \lim_{\to} \mathbb{Z}_n \) of the rings \( \mathbb{Z}_n \), \( n \in \mathbb{N} \), with the preorder on \( \mathbb{N} \) defined by the divisibility relation \( k | l \), is called the ring of the profinite integers. Using the Chinese Remainder Theorem one can show that
\[ \hat{\mathbb{Z}} \cong \prod_{\text{prime } p} \hat{\mathbb{Z}}_p. \]

Now we continue with three examples that we had not considered yet.

(D) We let \((I, \le) = (\mathbb{N}, \le)\). Given \( i \in \mathbb{N} \) we set \( X_i := \mathbb{N} \) and for \( i \le j \) we define
\[ f_{ji} : X_j = \mathbb{N} \to X_i = \mathbb{N}, \quad n \mapsto n + (j - i). \]
Then \( \{(X_i = \mathbb{N})_{i \in \mathbb{N}}, \{f_{ji}\}_{i \le j}\} \) forms an inverse system in the category of sets. In Exercise 25.8 we will see that in this case the inverse limit is the empty set.

(E) Let \( X \) be a topological space. We denote by \( K \) the set of all compact subsets of \( X \). We consider \( K \) with the preorder given by inclusion, i.e. we have \( A \le B \) if \( A \subseteq B \). Given \( A \in K \) we define \( X_A := X \setminus A \). Furthermore given \( A \le B \) we denote by \( f_{AB} : \pi_0(X_B) \to \pi_0(X_A) \) the map induced by the inclusion \( X_B \to X_A \). It is straightforward to verify that the sets \( \{\pi_0(X_A)\}_{A \in K} \) together with the inclusion induced maps \( f_{AB} \) for \( A \le B \) define an inverse system in the category of sets. The elements of \( \text{ends}(X) := \lim_{\to} \pi_0(X_A) \) are called the ends of \( X \). In Exercise 25.13 we will determine the number of ends of \( X = \mathbb{R}^n \).

---

461 Why is \( \mathbb{Z}^{(\mathbb{N})} \) countable?

462 Note though that we are comparing limits of different system, first of a direct system and then of an inverse system.

463 In number theory one often uses a different convention, namely one writes explicitly \( \mathbb{Z}/p\mathbb{Z} \) for the quotient ring and one denotes the \( p \)-adic numbers by \( \mathbb{Z}_p \). If the expression “\( \mathbb{Z}_p \)” appears in a paper or a book it is a good idea to check the convention used by the author.

464 Recall that on page 135 given a topological space \( Y \) we defined \( \pi_0(Y) \) as the set of path-components of \( Y \). A map \( f : Y \to Z \) between two topological spaces induces a map \( f_* : \pi_0(Y) \to \pi_0(Z) \) in an obvious way.
Given a topological space \( Y \) we denote by \( C(Y, \mathbb{R}) \) the abelian group of all continuous functions on \( Y \). Note that for each subset \( W \subset Y \) we have a homomorphism \( C(Y, \mathbb{R}) \to C(W, \mathbb{R}) \) given by \( f \mapsto f|_W \), i.e. given by restricting a function on \( Y \) to a function on \( W \).

Let \( X \) be a topological space and let \( \{U_i\}_{i \in \mathbb{N}} \) be a sequence of open subsets such that for each \( i \in \mathbb{N} \) we have \( U_i \subset U_{i+1} \) and such that \( \bigcup_{i \in \mathbb{N}} U_i = X \). Then the groups \( \{C(U_i, \mathbb{R})\}_{i \in \mathbb{N}} \) together with the restriction maps form an inverse system. We leave it to the reader to verify that the restriction maps from \( X \) to the \( U_i \) gives rise to an isomorphism

\[
C(X, \mathbb{R}) \to \lim_{\leftarrow} C(U_i, \mathbb{R}).
\]

**Definition.** Let \( \{(0, x, y), \leq\} \) be the push-pull set as defined on page \( 726 \) i.e. the preorder set with the non-trivial relations \( 0 \leq x \) and \( 0 \leq y \), and let \( C \) be a category. An inverse system in the category \( C \) over \( \{(0, x, y), \leq\} \) consists of three objects \( A_0, A_x, A_y \), the identity morphisms \( \text{id}_{A_0}, \text{id}_{A_x}, \text{id}_{A_y} \) and morphisms \( f_x : A_x \to A_0 \) and \( f_y : A_y \to A_0 \). We refer to such a system as a *pullback system* and often we arrange the morphisms in a diagram as follows

\[
\begin{array}{ccc}
A_y & & \to A_0 \\
\downarrow{g_y} & & \\
A_x & \xrightarrow{f_x} & A_0. \\
\end{array}
\]

If the inverse limit of such a pullback system exists, then we refer to it as the *pullback* of the pullback system. The defining property of the pullback \( Z \) can be summarized in the following diagram

\[
\begin{array}{ccc}
Z' & \xrightarrow{g'_y} & A_y \\
\downarrow{g'_x} & & \downarrow{g_y} \\
pullback Z & \xrightarrow{g_x} & A_y \\
\downarrow{g'_x} & & \downarrow{g_y} \\
A_x & \xrightarrow{f_x} & A_0 \\
\end{array}
\]

The following lemma deals with the pullback in the category of topological spaces.

**Lemma 25.16.** Let \( p : X \to B \) be a map of topological spaces, let \( C \) be a topological space and let \( f : C \to B \) be a map.

1. In the category of topological spaces the pullback of the pullback system

\[
\begin{array}{ccc}
X & \xrightarrow{\text{is given by}} & \{(c, x) \in C \times X \mid f(c) = p(x)\} \\
\downarrow{p} & & \downarrow{(c, x) \to c} \\
C & \xrightarrow{f} & B \\
\end{array}
\]

\[
\xrightarrow{(c, x) \to x} X
\]

Often the pullback is denoted by \( f^*X \).
(2) If \( X \) and \( C \) are connected, then \( f^*X \) is also connected.

(3) Let \( p: X \to B \) be a covering.
   
   (a) The pullback \( q: f^*X \to C \) is also a covering.
   
   (b) If \( B \) is connected, then
       \[
       \deg(q: f^*X \to C) = \deg(p: X \to B).
       \]

   (c) Let \( c \in C \). We write \( b = f(c) \) and we pick \( x \in X \) such that \( p(x) = b \). The following equality holds:
       \[
       q_*(\pi_1(f^*X,(c,x))) = f_*(-(p_*(\pi_1(X,x)))) \subset \pi_1(C,c).
       \]

Proof (\(*\)).

(1) This statement follows quite easily from the definitions or alternatively from the proof of Proposition 25.15.

(2) We will prove this statement in Exercise 25.17.

(3) Let \( p: X \to B \) be a covering. We write \( Z := f^*X \) and \( z := (c,x) \). Finally we denote by \( q: f^*X \to C \) the map given by \( (c,x) \mapsto c \).

(a) Suppose \( V \subset B \) is uniformly covered. In Exercise 25.16 we will verify that \( f^{-1}(V) \) is uniformly covered. Since \( f^{-1}(V) \) is open we see that \( q: Z \to C \) is a covering.

(b) Since \( B \) is connected it makes sense to speak of the degree of \( p \). For any \( c \in C \) we have a bijection
       \[
       q^{-1}(c) = \{(c,x) \in C \times X | f(c) = p(x)\} \xrightarrow{\text{bijection}} p^{-1}(f(c)) = \deg(p).
       \]

This shows that the degree of \( q \) equals the degree of \( p \).

(c) We need to show that \( q_*(\pi_1(Z,z)) = f_*(\pi_1(X,x)) \). We show the two inclusions “\( \subset \)” and “\( \supset \)” separately.

“\( \subset \)” Let \( \tilde{f}: Z \to X \) be the map given by \( (c,x) \to x \). By construction we have \( f \circ q = \tilde{f} \circ p \). But this implies immediately that \( f_*(q_*\pi_1(Z,z)) \) is contained in \( p_*(\pi_1(X,x)) \).

“\( \supset \)” Let \( \gamma: [0,1] \to C \) be a loop in \( (C,c) \) with \( [f \circ \gamma] = f_*([\gamma]) \in p_*(\pi_1(X,x)) \). We write \( g := f \circ \gamma \). Let \( \tilde{g}: [0,1] \to X \) be the lift with \( \tilde{g}(0) = x \). Since \( [g] \in p_*(\pi_1(X,x)) \) we obtain from Lemma 16.15(1) that \( \tilde{g} \) is actually a loop. Thus the map \( \alpha: [0,1] \to C \times X \) that is given by \( t \mapsto (\gamma(t),\tilde{g}(t)) \) is a loop. By construction the loop takes values in \( Z \) and evidently we have \( q_*([\alpha]) = [\gamma] \).

This shows that \( [\gamma] \in q_*(\pi_1(Z,z)) \).

We conclude this section on inverse limits with the following lemma.

**Lemma 25.17.** Let \((I, \leq)\) be a preordered set and let \( (\{X_i\}_{i \in I}, \{f_{ji}: X_j \to X_i\}_{i \leq j}) \) be an inverse system of topological spaces.

(1) If all the \( X_i \)'s are Hausdorff, then the inverse limit \( \lim_{\leftarrow} \) \( X_i \) is a closed subset of \( \prod_{i \in I} X_i \).

(2) If all the \( X_i \)'s are compact and Hausdorff, then the inverse limit \( \lim_{\leftarrow} \) \( X_i \) is also compact.

\[465\]Recall that covering maps are in particular surjective, in particular such \( x \) exists.
Example. Let $p$ be a prime. The abelian group $\hat{\mathbb{Z}}_p$ is the inverse limit of finite, hence compact groups. It follows from Proposition 25.18 that $\hat{\mathbb{Z}}_p$ is also a compact topological group. On the other hand $\hat{\mathbb{Z}}_p$ is infinite, which shows that the topology on $\hat{\mathbb{Z}}_p$ is not the discrete topology.

Proof. Let $(I, \leq)$ be a preordered set and let $(\{X_i\}_{i \in I}, \{f_{ji} : X_j \to X_i\}_{i \leq j})$ be an inverse system of topological spaces.

(1) We suppose that all the $X_i$ are Hausdorff. Given $i \in I$ we denote by $p_i : \prod_{j \in I} X_j \to X_i$ the projection map and we denote by $D_i = \{(x, x) \mid x \in X_i\} \subset X_i \times X_i$ the diagonal. By Exercise 3.21 the hypothesis that $X_i$ is Hausdorff implies that the diagonal $D_i$ is a closed subset of $X_i \times X_i$. By the proof of Proposition 25.15 we have

$$\lim_{\leftarrow} X_i := \{ (x_i)_{i \in I} \in \prod_{i \in I} X_i \mid f_{ik}(x_i) = x_k \text{ for all } k \leq l \}$$

$$= \bigcap_{k \leq l} \{ x \in \prod_{i \in I} X_i \mid ((f_{lk} \circ p_l) \times p_k)(x) \in D_k \} = \bigcap_{k \leq l} ((f_{lk} \circ p_l) \times p_k)^{-1}(D_k) \text{ closed since } D_k \text{ closed}$$

Thus we see that $\lim_{\leftarrow} X_i$ is the intersection of closed subsets of $\prod_{i \in I} X_i$, hence $\lim_{\leftarrow} X_i$ itself is a closed subset.

(2) Now we suppose that all the $X_i$ are Hausdorff and compact. We obtain from Tychonoff’s Theorem 3.17 that $\prod_{i \in I} X_i$ is compact. Together with (1) we see that $\lim_{\leftarrow} X_i$ is a closed subset of a compact topological space. Thus it follows from Lemma 2.17 (1) that $\lim_{\leftarrow} X_i$ is also compact. 

25.7. The profinite completion of a group (*). Note that we can view any group as a topological group by equipping it with the discrete topology. With this topology a group is compact if and only if it is finite. Furthermore any homomorphism of groups equipped with the discrete topology is also a morphism in the category TopGr of topological groups.

Proposition 25.18. Let $(I, \leq)$ be a preordered set and let $(\{G_i\}_{i \in I}, \{f_{ji} : G_j \to G_i\}_{i \leq j})$ be an inverse system of finite groups. Then the inverse limit $\lim_{\leftarrow} G_i$ exists in the category of topological groups and it is a compact topological group.

Proof. It follows from Proposition 25.15 that the inverse limit $\lim_{\leftarrow} G_i$ exists in the category of topological groups. Since all the $G_i$’s are finite, in particular compact, it follows from Lemma 25.17 (2) that the inverse limit $\lim_{\leftarrow} G_i$ is also compact. 

\footnote{Note that this is very different from the situation of the direct limit. The direct limit of topological spaces is not necessarily compact, for example the direct limit of the direct system $[0, n], n \in \mathbb{N}$ is given by the non-compact space $\bigcup_{n \in \mathbb{N}} [0, n] = [0, \infty)$.}

\footnote{In fact $\hat{\mathbb{Z}}_n$ is uncountable (why?).}
Now let $\pi$ be a group. We consider the set of all finite index normal subgroups $\{\pi_i\}_{i \in I}$. We equip the index set $I$ with the preorder defined by the convention that $i \leq j$ if and only if $\pi_j \subset \pi_i$.\footnote{Note that we wrote $\pi_j \subset \pi_i$ instead of $\pi_i \subset \pi_j$.} Given $i \leq j$ we denote by $\varphi_{ji} : \pi / \pi_j \to \pi / \pi_i$ the obvious projection map. Then $\left(\{\pi_i\}_{i \in I}, \{\varphi_{ji} : \pi / \pi_j \to \pi / \pi_i\}_{i \leq j}\right)$ forms an inverse system. We refer to

$$\hat{\pi} := \lim_{\leftarrow} \pi / \pi_i$$

as the \textit{profinite completion} of $\pi$. By Proposition \ref{prop:profinitecompletion} the profinite completion $\hat{\pi}$ is a compact topological group. It follows immediately from the definition of an inverse limit that there exists a unique homomorphism $\pi \to \hat{\pi}$ such that for any $i$ the following diagram commutes:

\begin{align*}
\pi & \xrightarrow{\varphi} \hat{\pi} \\
& \downarrow \quad \downarrow \\
\pi / \pi_i & \to \pi / \pi_i.
\end{align*}

\textbf{Examples.}

(1) The profinite completion $\hat{\mathbb{Z}}$ of the group $\mathbb{Z}$ equals precisely the profinite integers that we had encountered on page \pageref{page:profiniteintegers}.

(2) The profinite completion of a finite group $G$ is the group itself, i.e. $\hat{G} = G$.\footnote{\textbf{Why is that?}}

(3) Let $G = \mathbb{Q}$. This group has no proper subgroups of finite index.\footnote{\textbf{Why not?}} It follows immediately from the definitions that $\hat{\mathbb{Q}} = \{0\}$.

Now let $\varphi : A \to B$ be a group homomorphism. We denote by $\{B_i\}_{i \in I}$ the finite index normal subgroups of $B$. For $B_j \subset B_i$ we denote again by $p_{ji} : B / B_j \to B / B_i$ the projection map. For every $i \in I$ the preimage $\varphi^{-1}(B_i)$ is a finite index normal subgroup of $A$.\footnote{\textbf{Why is it a finite index subgroup?}} Now we define $\psi_i : A \to A / \varphi^{-1}(B_i) \xrightarrow{\varphi} B / B_i$. Note that $\psi_i$ is continuous since the first map is continuous by definition and the second map is a map between two topological spaces that are equipped with the discrete topology. It follows immediately from the definitions that for $B_j \subset B_i$ we have $p_{ji} \circ \psi_j = \psi_i$. It now follows from the definition of the inverse limit in the category of topological groups that there exists a unique continuous homomorphism $\hat{\varphi} : \hat{A} \to \hat{B}$ such that for any $i$ the following diagram commutes

\begin{align*}
\hat{A} & \xrightarrow{\hat{\varphi}} \hat{B} \\
& \downarrow \quad \downarrow \\
\psi_i & \quad B / B_i.
\end{align*}
It follows easily from the definitions and Proposition 25.18 that the maps

\[ A \mapsto \hat{A} \]

together with the maps

\[ \text{Mor}(A, B) \to \text{Mor}(\hat{A}, \hat{B}) \]

\[ (\varphi: A \to B) \mapsto (\hat{\varphi}: \hat{A} \to \hat{B}) \]

define a functor from the category of groups to the category of compact topological groups.

---

**Exercises for Chapter 25**

**Exercise 25.3.** Let \((I, \leq)\) be a preordered set and let \(\{X_i\}_{i \in I}\) be a family of topological spaces such that for any \(i \leq j\) we have \(X_i \subset X_j\). We define

\[ \lim_{\longrightarrow} X_i = X := \bigcup_{i \in I} X_i, \]

where the topology on \(X = \bigcup_{i \in I} X_i\) is given by the rule that \(U \subset X\) is open if and only if \(U \cap X_i\) is open for all \(i \in I\). Furthermore we denote by \(g_j: X_j \to X = \bigcup_{i \in I} X_i, j \in \mathbb{N}\) the obvious inclusion maps. Show that \(\lim_{\longrightarrow} X_i\) together with the maps \(g_j\) is the direct limit of the direct system in the category of topological spaces.

**Exercise 25.4.** Let \(\{X_i\}_{i \in \mathbb{N}}\) be a family of topological spaces. Suppose that for each \(i \in \mathbb{N}\) we are given an injective map \(f_i: X_i \to X_{i+1}\).

(a) Show the map \(X_i \to \lim_{\longrightarrow} X_i\) is not necessarily an embedding.

(b) Suppose that each \(f_i: X_i \to X_{i+1}\) is an embedding. Show that in this case each map \(X_i \to \lim_{\longrightarrow} X_i\) is in fact an embedding.

**Exercise 25.5.**

(a) For \(i \in \mathbb{N}\) we define \(F_i = \langle x_i, x_{i+1} \rangle\). For \(i \in \mathbb{N}\) we denote by \(g_i: F_i \to F_{i+1}\) the homomorphism that is given by \(g_i(x_i) = e, g_i(x_{i+1}) = x_{i+1}\). Furthermore for \(i < j\) we define \(f_i: F_i \to F_j\) to be the homomorphism \(g_{j-1} \circ \cdots \circ g_{i+1} \circ g_i\). What is the direct limit \(\lim_{\longrightarrow} F_i\) in the category of groups?

(b) Given \(k \in \mathbb{N}\) we define \(X_k = \mathbb{N}\) to be the topological space where the open sets are \(\{1, \ldots, k\}, \{k + 1\}, \{k + 2\}, \ldots\). For \(k \leq l\) we denote by \(f_{kl}: X_k \to X_l\) the identity map. (Note that with the choice of our topologies on \(X_k\) and \(X_l\) this map is in fact continuous). What is the direct limit \(\lim_{\longrightarrow} X_i\) in the category of topological spaces?

**Remark.** as a set the direct limit is again \(\mathbb{N}\), but what is the topology?

**Exercise 25.6.** Suppose we are given two pushouts
Furthermore suppose we are given a commutative diagram

An example for such a situation is sketched in Figure 486.

(a) Show that there exists a unique map \( P \to \tilde{P} \) which makes the cube commute.
(b) Suppose that the maps \( X \to \tilde{X}, Y \to \tilde{Y} \) and \( Z \to \tilde{Z} \) are homotopy equivalences. Does it follow that the map \( P \to \tilde{P} \) is a homotopy equivalence?

Exercise 25.7. Proof Lemma 25.2. It is best to prove it using the definition of direct limits instead of using any of the above explicit descriptions of direct limits.

Exercise 25.8. We let \((I, \leq) = (\mathbb{N}, \leq)\). Given \(i \in \mathbb{N}\) we set \(X_i := N\) and for \(i \leq j\) we define

\[
f_{ji} : X_j = \mathbb{N} \to X_i = \mathbb{N}, \quad n \mapsto n + (j - i).
\]

Then \(\{X_i = \mathbb{N}\}_{i \in \mathbb{N}}, \{f_{ji}\}_{i < j}\) forms an inverse system in the category of sets. Show that the inverse limit is the empty set.

Exercise 25.9. Let \(g \geq 2\). We denote by \(\Sigma_g\) the surface of genus \(g\). Show that every abelian subgroup of \(\pi_1(\Sigma_g)\) is isomorphic to \(\mathbb{Z}\).

Hint. Make use of Proposition 25.13 and Exercise 19.11.

Exercise 25.10. Let \(g \in \mathbb{N}_{\geq 2}\). Use Proposition 25.13 to show that the fundamental group of the surface of genus \(g\) is torsion-free.

Exercise 25.11. Let

\[
\begin{array}{c}
A \xrightarrow{g} B \\
\downarrow f \\
C
\end{array}
\]

be a pushout system in some category which admits pushouts. (E.g. we could consider the category of groups, \(R\)-modules or topological spaces). We consider the direct limit, i.e. the pushout

\[
\begin{array}{c}
A \xrightarrow{f} B \\
g \downarrow \\
C \xrightarrow{s} X.
\end{array}
\]
Show that if \( f: A \to B \) is an isomorphism in the given category, then the opposite map \( s: C \to X \) is also an isomorphism in the category.

**Remark.** This statement generalizes the statement of Lemma 3.43 (3c).

**Exercise 25.12.** Let \( C \) be some category. We consider the following commutative diagram of morphisms in \( C \):

\[
\begin{array}{ccc}
A & \xrightarrow{\varphi} & B \\
\downarrow{\alpha} & & \downarrow{\beta} \\
A' & \xrightarrow{\varphi'} & B'.
\end{array}
\]

\[
\begin{array}{ccc}
& & C \\
\downarrow{\gamma} & & \\
& & C'.
\end{array}
\]

We suppose that the big rectangle forms a pushout square.

(a) We suppose that the square to the left is a pushout square. Show that the square to the right is also a pushout square.

(b) We suppose that the square to the right is a pushout square. Is the square to the left also a pushout square?

**Exercise 25.13.** Let \( X \) be a topological space. We denote by \( K \) the set of all compact subsets of \( X \). We consider \( K \) with the preorder given by inclusion, i.e., given \( A, B \in K \) we have \( A \leq B \) if \( A \subseteq B \). Given \( A \in K \) we define \( X_A := \pi_0(X \setminus A) \). Furthermore given \( A \leq B \) we denote by \( f_{AB}: \pi_0(X_B) \to \pi_0(X_A) \) the map induced by the inclusion \( X_B \to X_A \). It follows immediately from the discussion on page 480 that the sets \( \{\pi_0(X_A)\}_{A \in K} \), together with the inclusion induced maps \( f_{AB} \) for \( A \leq B \) define an inverse system in the category of sets. The elements of \( \lim \leftarrow \pi_0(X_A) \) are called the *ends of \( X \).

(a) Let \( \text{Top} \) be the category of topological spaces and let \( \text{Set} \) be the category of sets. Show that

\[
X \mapsto \lim \pi_0(X_A)
\]

gives rise to a covariant functor from \( \text{Top} \) to \( \text{Set} \).

(b) Show that for a topological space \( X \) the cardinality of \( \lim \pi_0(X_A) \), viewed as an element in \( \mathbb{N}_0 \cup \{\infty\} \), equals the number of ends of \( M \) as defined in Exercise 2.22.

(c) Let \( n \in \mathbb{N}_0 \). Determine the number of ends of \( X = \mathbb{R}^n \).

(d) For each \( k \in \mathbb{N}_0 \) give an example of a connected 1-dimensional CW-complex \( X \) with precisely \( k \) ends.

**Exercise 25.14.** Let \( X \) be a topological space, let \( A \) and \( B \) be two subsets of \( X \) and let \( f: A \to B \) be a homeomorphism. We define

\[
\tilde{X} := \left( \bigcup_{i \in \mathbb{Z}} X \times \{i\} \right) / (a, i) \sim (f(a), i - 1) \quad \text{for } a \in A \text{ and } i \in \mathbb{Z}.
\]

We consider the action of \( \mathbb{Z} \) on \( \tilde{X} \) that is given by \( n \cdot [(x, i)] := [(x, i+n)] \) for \( (x, i) \in X \times \{i\} \).

(a) Show that this action is continuous.

\(^{472}\)Recall that by the definition on page 135 given a topological space \( Y \) we had denoted \( \pi_0(Y) \) by the set of path-components of \( X \).
(b) We write \( X(f) = X/ \sim \) where \( a \sim f(a) \) for \( a \in A \). Show that the maps

\[
\Phi: X(f) \rightarrow \tilde{X}/\mathbb{Z} \quad \text{and} \quad \Psi: \tilde{X}/\mathbb{Z} \rightarrow X(f)
\]

\([x] \mapsto [(x,0)] \quad \text{and} \quad [(x,i)] \mapsto [x]

are continuous and inverses of one another. (This implies of course that both maps are homeomorphisms.)

(c) Suppose that there exist disjoint open neighborhoods \( U \) of \( A \) and \( V \) of \( B \). Show that the action is discrete.

Exercise 25.15. We consider the profinite integers, i.e. the inverse limit \( \hat{\mathbb{Z}} := \varprojlim \mathbb{Z}_n \) of the rings \( \mathbb{Z}_n, n \in \mathbb{N} \), with the preorder on \( \mathbb{N} \) defined by the divisibility relation \( k \mid l \). Does there exist an epimorphism \( \hat{\mathbb{Z}} \rightarrow \mathbb{Z} \) of groups?

Exercise 25.16. Show that the pullback \( f^* X \rightarrow C \) of a covering \( p: X \rightarrow B \) under a map \( f: C \rightarrow B \) is again a covering.

Exercise 25.17. Let \( f^* X \rightarrow C \) be the pullback of a map \( p: X \rightarrow B \) and a map \( f: C \rightarrow B \). Show that if \( X \) and \( C \) are connected, then \( f^* X \) is also connected.

Exercise 25.18. Let \( 1 \rightarrow A \xrightarrow{\alpha} B \xrightarrow{\beta} C \rightarrow 1 \) be a short exact sequence of groups. Furthermore let \( g: Z \rightarrow C \) be a group homomorphism. Show that there exists a commutative diagram of group homomorphisms of the form below such that the top horizontal sequence is also exact:

\[
1 \longrightarrow A \xrightarrow{\tilde{\alpha}} Y \xrightarrow{\tilde{\beta}} Z \longrightarrow 1
\]

\[
1 \longrightarrow A \xrightarrow{\alpha} B \xrightarrow{\beta} C \longrightarrow 1.
\]

Exercise 25.19.

(a) We consider the inverse system \((X_i)_{i \in \mathbb{N}}\) where \( X_i = \mathbb{Z} \) and where for each \( i \geq j \) the map \( X_i \rightarrow X_j \) is given by multiplication by \( 2^{i+j} \). Determine \( \varprojlim X_i \) in the category of abelian groups.

(b) Now we work in the category of sets. Show that there exists an inverse system \((\{X_i\}_{i \in \mathbb{N}}, \{f_{ji}: X_j \rightarrow X_i\}_{i \leq j})\) of non-empty sets such that \( \varprojlim X_i = \emptyset \).

Remark. In Exercise 25.20 we will see that the inverse limit of an inverse system of finite non-empty sets is in fact non-empty.

Exercise 25.20. In this exercise we consider the category of topological space. Let \((\{X_i\}_{i \in \mathbb{N}}, \{f_{ji}: X_j \rightarrow X_i\}_{i \leq j})\) be an inverse system of topological spaces that are non-empty, Hausdorff and compact.

(a) For each \( j \in \mathbb{N} \) we set

\[
Z_j := \{(x_i)_{i \in \mathbb{N}} \mid \text{for all } i \leq j \text{ we have } x_i = f_{ji}(x_j)\} \subset \prod_{i \in \mathbb{N}} X_i.
\]

Show that \( Z_j \) is closed and non-empty.

Hint. You might want to consider Lemma 25.17 (1).
(b) Show that for any \( i, j \in \mathbb{N} \) we have \( Z_i \cap Z_j \neq \emptyset \).

(c) Apply Tychonoff’s Theorem \[3.17\] together with Exercise \[2.48\] to conclude that \( \lim X_i \neq \emptyset \).

**Remark.** We can apply this statement in particular to an inverse system of finite non-empty sets, viewed as topological spaces by equipping each of the finite sets with the discrete topology. Evidently a finite discrete topological space is Hausdorff and compact.

**Exercise 25.21.** Let \( I \) be preordered set, let \( \{f_i: A_i \to A_j\}_{i \leq j} \) be a direct system in the category of abelian groups and let \( \{g_i: B_i \to B_j\}_{j \leq i} \) be an inverse system in the category of abelian groups. Suppose that for each \( i \in I \) we are given a bilinear map \( \varphi_i: A_i \times B_i \to \mathbb{Z} \) such that for any \( i \leq j \), and \( a \in A_i \) and \( b \in B_j \) we have \( \varphi_i(a_i, g_j(b_j)) = \varphi_j(f_i(a_i), b_j) \). Define an “interesting” bilinear map

\[
\lim_{\to} A_i \times \lim_{\leftarrow} B_i \to \mathbb{Z}.
\]
26. The HNN-Seifert–van Kampen Theorem

One of our main goals at the moment is to calculate fundamental groups of interesting topological spaces. As we have discovered, one of the most powerful tools is the Seifert–van Kampen Theorem \[22.1\]  

In light of Exercise 3.32 (c) we can say, modulo technical details, that the Seifert–van Kampen Theorem \[22.1\] allows us to calculate the fundamental group of a topological space \( X = Y \cup_f Z \) that is obtained from gluing two path-connected topological spaces \( Y \) and \( Z \) along path-connected open subsets \( A \subset Y \) and \( B \subset Z \). This situation is illustrated in Figure 487 to the left.

Sometimes one is given the situation that is shown in Figure 487 to the right. Namely we are given a path-connected topological space \( X \) and we glue two disjoint path-connected open subsets \( A \) and \( B \) together. In this chapter we will prove the HNN-Seifert–van Kampen Theorem which will allow us to calculate the fundamental group in the latter situation.

\[
\pi_1(Y \cup_f Z) = \pi_1(Y) \ast_\pi_1(A) \pi_1(Z)
\]

**Figure 487**

We start out with the following notation.

**Notation.** Let \( X \) be a topological space, let \( A \) and \( B \) be two subsets of \( X \) and let \( f: A \to B \) be a homeomorphism. We write

\[
X(f) := X(f; A \to B) := X/\sim \quad \text{where } f(a) \sim a \text{ for } a \in A.
\]

**Examples.**

1. Let \( X \) be the torus with two open disks removed. We denote by \( A \) and \( B \) the two boundary components and we endow them with the orientation coming from a fixed orientation of the torus. Let \( f: A \to B \) be an orientation-reversing diffeomorphism. Then one sees that \( X(f; A \to B) \) is diffeomorphic \[473\] to the surface of genus 2. This statement is illustrated in Figure 488 \[474\].

2. Let \( Y \) be a topological space and let \( f: Y \to Y \) be a homeomorphism. We consider \( X = Y \times [0, 1] \). Furthermore, by an abuse of notation, we denote by \( f: Y \times \{0\} \to Y \times \{1\} \) also the map defined by \( f(y, 0) = (f(y), 1) \). It follows immediately from the

\[473\] Note that by Lemma 8.16 we know that \( X(f; A \to B) \) is indeed a smooth manifold.

\[474\] What topological space do we obtain if \( f \) is chosen to be orientation-preserving?
$X$ is the torus with two open disks removed

Figure 488

\[
X(f) = (Y \times [0, 1])(f) = (Y \times [0, 1]) / \sim = \text{Tor}(X, f),
\]

where \text{Tor}(X, f) denotes the mapping torus that we introduced on page \[711\].

Our goal now is to determine $\pi_1(X(f))$ in terms of the fundamental groups of $X$, $A$ and the induced map $f_*: \pi_1(A) \to \pi_1(B)$. To formulate the Seifert–van Kampen Theorem \[22.1\] we needed to introduce the notion of an amalgamated product of groups. So it does perhaps now come as a surprise that we need a new construction from group theory to formulate the desired result.

**Definition.** Let $\pi$ and $\Gamma$ be two groups and let $\alpha, \beta: \Gamma \to \pi$ be two homomorphisms. We refer to
\[
\langle \pi, t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle := (\pi * \langle t \rangle) / \langle \langle \{ \alpha(g)t\beta(g)^{-1}t^{-1} \}_{g \in \Gamma} \rangle
\]

as the HNN-extension corresponding to $(\pi, \alpha, \beta)$.\footnote{The concept of such a group was introduced by Graham Higman, Bernhard Neumann and Hannah Neumann [HNN50] in 1950, whence the name.}

**Example.** Let $\pi$ be a group and let $\Gamma$ be the trivial group. It follows immediately from the definitions that the corresponding HNN-extension is the free product $\pi * \langle t \rangle$.

The following lemma summarizes some basic properties of HNN-extensions. It says in particular that a semidirect product is a special case of an HNN-extension.

**Lemma 26.1.**

(1) Let $\pi = \Gamma$. Furthermore let $\alpha: \pi \to \pi$ and $\beta: \pi \to \pi$ be isomorphisms. We write $\varphi = \beta \circ \alpha^{-1}: \pi \to \pi$. In this setting the map
\[
\Phi: \pi \times_{\varphi} \mathbb{Z} \to \langle \pi, t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle
\]
\[
(g, n) \mapsto g \cdot t^n
\]
is an isomorphism.

(2) Let $\pi = \langle x_1, \ldots, x_k \mid r_1, \ldots, r_l \rangle$ be a finitely presented group and let $g_1, \ldots, g_m$ is a generating set for $\Gamma$. A presentation for the HNN-extension of $(\pi, \alpha, \beta)$ is given by
\[
\langle x_1, \ldots, x_k, t \mid r_1, \ldots, r_l, \alpha(g_i) = t\beta(g_i)t^{-1} \text{ for } i = 1, \ldots, m \rangle.
\]
26. THE HNN-SEIFERT–VAN KAMPEN THEOREM

(3) Let \( \pi \) and \( \Gamma \) be two groups and let \( \alpha, \beta : \Gamma \to \pi \) be two homomorphisms. Then there exists an epimorphism

\[
\langle \pi, t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle \to \mathbb{Z}
\]

that is uniquely determined by \( g \mapsto 0 \) if \( g \in \pi \) and \( t^n \mapsto n \).

Sketch of proof.

(1) We first verify that the given map is indeed a homomorphism. Let \((g, m)\) and \((h, n)\) be two elements in \( \pi \times \varphi \mathbb{Z} \). First we assume that \( m \geq 0 \). Then the following equalities hold in \( \langle \pi, t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle \):

\[
\Phi(g, m) \cdot \Phi(h, n) = gt^{-m} \cdot ht^{-n} = g t^{-m} \cdot t^m \varphi^m(h) t^{-m} \cdot t^n = g \varphi^m(h) t^{-m-n} = \Phi(g \varphi^m(h), m+n) = \Phi((g, m)(h, n)).
\]

Definition of product structure on \( \pi \times \varphi \mathbb{Z} \).

If \( m < 0 \) then a very similar calculation, using that \( \beta \) is an isomorphism, shows again that \( \Phi(g, m) \cdot \Phi(h, n) = \Phi((g, m)(h, n)) \). This shows that \( \Phi \) is indeed a homomorphism. By Lemma 19.12 there exists a unique homomorphism \( \Psi : \pi \ast \langle t \rangle \to \pi \times \mathbb{Z} \) with \( \Psi(g) = (g,0) \) for every \( g \in \pi \) and with \( \Psi(t) = (0,1) \). Using Lemma 21.4 and using an elementary calculation one can easily show that \( \Psi \) descends to a map \( \langle \pi, t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle \to \pi \times \mathbb{Z} \). Since \( \Phi \circ \Psi \) and \( \Psi \circ \Phi \) are the identity on the generating sets \( \pi \) and \( t \) we see that both homomorphisms are the identity. In particular \( \Phi \) is an isomorphism.

(2) This time we apply Lemma 21.4 twice to obtain the desired isomorphism and its inverse.

(3) This statement is once again an immediate consequence of Lemma 21.4.

The following proposition is an analogue of Proposition 21.4.

Proposition 26.2. (*) Let \( \pi \) and \( \Gamma \) be two groups and let \( \alpha, \beta : \Gamma \to \pi \) be two homomorphisms. If \( \alpha \) and \( \beta \) are monomorphisms, then the obvious inclusion map

\[
\pi \to \langle \pi, t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle := \langle \pi \ast \langle t \rangle \rangle / \langle \{ \alpha(g)t\beta(g)^{-1}t^{-1} \}_{g \in \Gamma} \rangle
\]

\[
h \mapsto h
\]

is also a monomorphism.

Proof. The proposition is proved in [Ser80, p. 45]. Alternatively the proposition follows from the Normal Form Theorem for HNN-extensions which is formulated and proved in [LS77, Theorem IV.2.1] or alternatively in [CgRR08, Satz 6.3] and [Sti93, Chapter 9.2].

Now we return to topological spaces. The following theorem can be considered a sibling of the Seifert–van Kampen Theorem 22.1.
**Theorem 26.3. (HNN-Seifert–van Kampen Theorem)** Suppose we are in one of the following two settings:

1. We are given a path-connected topological space $X$, two open disjoint subsets $A$ and $B$ of $X$ and a homeomorphism $f: A \to B$.
2. We are given a path-connected smooth manifold $X$, two distinct components $A$ and $B$ of $\partial X$ and a homeomorphism $f: A \to B$.

We pick a base point $x_0 \in A$ and we pick a path $\gamma$ in $X$ from $x_0$ to $f(x_0)$. Furthermore we write $\Gamma = \pi_1(A, x_0)$. Finally we denote by

$$\alpha: \Gamma = \pi_1(A, x_0) \to \pi_1(X, x_0)$$

the inclusion induced map and we denote by

$$\beta: \Gamma = \pi_1(A, x_0) \xrightarrow{L} \pi_1(B, f(x_0)) \to \pi_1(X, f(x_0)) \xrightarrow{\gamma} \pi_1(X, x_0)$$

the concatenation of the maps induced by $f$, the inclusion and the base point change isomorphism from Proposition 14.11 using the path $\gamma$. Then there exists an isomorphism

$$\Phi: \pi_1(X(f), x_0) \cong \langle \pi_1(X, x_0), t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle$$

which has the following two properties:

1. The diagram

$$\begin{array}{ccc}
\pi_1(X, x_0) & \xrightarrow{\Phi} & \langle \pi_1(X, x_0), t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle \\
\pi_1(X(f), x_0) & \xrightarrow{\Phi} & \langle \pi_1(X, x_0), t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle \\
\end{array}$$

with the obvious diagonal maps commutes.

2. The closed loop in $X(f)$ defined by $\gamma$ corresponds under the isomorphism $\Phi$ to $t$.

![Figure 489](image.png)

**Figure 489.** Illustration for the HNN-Seifert–van Kampen Theorem 26.3 (1).

**Remark.** The HNN-Seifert–van Kampen Theorem 26.3 is a frequently used tool in the calculation of fundamental groups of topological spaces. The popularity of the result is in contrast to the sparsity of proofs in the literature. A sketch of an outline of a proof is given in [SW79]. A much more general statement is proved in [Bou07], Proposition IV.5.5 on p. 431.

**Example.** As on page 761 we consider the surface $X$ that is given by removing two open disks from a torus. We refer to the two boundary components as $A$ and $B$. We equip $A$ and $B$ with the orientations given in Figure 490. We pick a diffeomorphism $f: A \to B$ that
preserves the orientation. As discussed on page 761, the resulting topological space $X(f)$ is homeomorphic to the surface of genus two.

We pick a base point $x_0 \in A$. We pick a loop $a$ in $(A, x_0)$, we pick loops $c, d$ in $(X, x_0)$, a path $\gamma$ in $X$ from $x$ to $f(x)$ and a loop $b$ in $(B, f(x))$ as indicated in Figure 490. Finally we write $\tilde{b} = \gamma * b * \overline{\gamma}$. By Lemma 23.11 and as in the proof of Lemma 25.11 we have an isomorphism

$$\pi_1(X, x_0) \xrightarrow{\cong} \langle c, d, a, \tilde{b} \mid a = [c, d] \cdot \tilde{b} \rangle.$$  

We write $\Gamma = \pi_1(A, x_0)$. Note that $\Gamma = \langle a \rangle$ and $\alpha(a) = a$ and $\beta(a) = \tilde{b}$. We see that

$$\pi_1(X(f), x_0) \cong \langle \pi_1(X), t \mid \alpha(\Gamma) = t \beta(\Gamma) t^{-1} \rangle \uparrow \langle c, d, a, \tilde{b}, t \mid a = [c, d] \cdot \tilde{b}, a = \overline{\tilde{b}} t^{-1} \rangle$$

by Tietze transformations

Thus we have now obtained the same presentation that we had already obtained in Proposition 22.3.

![Figure 490](image)

In the proof of Theorem 26.3 (1) we will need one extra piece of notation and one more lemma.

**Notation.** Let $\pi$ and $\Gamma$ be groups and let $\alpha, \beta: \Gamma \to \pi$ be homomorphisms. Given $i \in \mathbb{Z}$ we write $\pi_i := \pi$ and $\Gamma_i := \Gamma$. We write

$$\ldots \pi_{-2} \ast_{\Gamma_{-1}} \pi_{-1} \ast_{\pi_0} \pi_0 \ast_{\Gamma_1} \pi_1 \ast_{\Gamma_2} \pi_2 \ldots = \lim \left( \pi_{-i} \ast_{\Gamma_{-i+1}} \ldots \pi_{-1} \ast_{\pi_0} \pi_0 \ast_{\Gamma_1} \pi_1 \ldots \ast_{\pi_i} \Gamma_i \right).$$

By a slight abuse of language we refer to this group as an infinite amalgamated product.

By the universal property of the direct limit there exists an automorphism $\Xi$ of this infinite amalgamated product that shifts all indices by one to the right.

---

\[476\] By Lemma 21.22 (4) we can form the iterated amalgamated product without having to worry about parentheses.
Lemma 26.4. With the above notation there exists a well-defined map
\[
\left( \ldots \pi_{-2} \ast_{\Gamma_{-1}} \pi_{-1} \ast_{\Gamma_0} \pi_0 \ast_{\Gamma_1} \pi_1 \ast_{\Gamma_2} \pi_2 \ldots \right) \times \Xi \mathbb{Z} \xrightarrow{\cong} \langle \pi, t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle
\]
\[(g_i, n) \mapsto gt^i \cdot t^n, \text{ where } g_i \in \pi_i\]
which is an isomorphism.

Example. If \(\alpha\) and \(\beta\) are isomorphisms, then it follows easily from Lemma \([21.22](3)\) that the “infinite amalgamated product” is isomorphic to \(\pi\). We see that in this special case the statement of Lemma \([26.4]\) is basically the same as the statement of Lemma \([26.1](1)\).

Sketch of proof of Lemma \([26.4]\) It follows easily from the universal property of the direct limit and of the amalgamated product that there exists a well-defined map
\[
\left( \ldots \pi_{-2} \ast_{\Gamma_{-1}} \pi_{-1} \ast_{\Gamma_0} \pi_0 \ast_{\Gamma_1} \pi_1 \ast_{\Gamma_2} \pi_2 \ldots \right) \rightarrow \langle \pi, t \mid \alpha(\Gamma) = t\beta(\Gamma)t^{-1} \rangle
\]
\[g_i \mapsto gt^i, \text{ where } g_i = g \in \pi_i = \pi.\]
A straightforward calculation as in the proof of Lemma \([26.1](1)\) shows that we get an induced map on the semidirect product. This shows that the map given in the lemma actually makes sense. It remains to show that the map is an isomorphism. Note that using Lemma \([21.4]\) one can easily show that there exists a well-defined homomorphism from right to left which is an inverse to our given map. We leave it to the reader to fill in the details. ■

Proof of Theorem \([26.3](1)\). \(^{477}\) Let \(X\) be a path-connected topological space, let \(A\) and \(B\) be two open disjoint path-connected subsets of \(X\) and let \(f: A \rightarrow B\) be a homeomorphism. We pick a base point \(x \in A\) and we pick a path \(\gamma\) in \(X\) from \(x\) to \(f(x)\). Furthermore we define
\[
\widehat{X(f)} := \left( \bigcup_{i \in \mathbb{Z}} X \times \{i\} \right) / (a, i) \sim (f(a), i - 1) \quad \text{for } a \in A \text{ and } i \in \mathbb{Z}.
\]
We equip \(\widehat{X(f)}\) with the base point \(\hat{x}\) which is represented by \((x, 0)\). There is an obvious action of \(\mathbb{Z}\) on \(\widehat{X(f)}\) given by \(n \cdot [(P, i)] := [(P, i + n)]\) for \((P, i) \in X \times \{i\}\). Since \(A\) and \(B\) are open and disjoint we can apply Exercise \([25.14]\). We obtain that this action is discrete and continuous and that the map
\[
\Phi: X(f) \rightarrow \widehat{X(f)}/\mathbb{Z}
\]
\[\left[ x \right] \mapsto [(x, 0)]\]
is a homeomorphism.

For \(i \in \mathbb{Z}\) we now write \(X_i := X \times \{i\}\), \(A_i := A \times \{i\}\), \(B_i := B \times \{i\}\) and \(x_i := \{x\} \times \{i\}\). Furthermore we write \(\pi_i := \pi_1(X_i, x_i)\) and \(\Gamma_i = \pi_1(A_i, x_i)\). We refer to Figure \([491]\) for an illustration.

\(^{477}\) As we saw on pages \([762]\) and in Lemma \([26.1](1)\), we can view Theorem \([26.3]\) as a generalization of Proposition \([24.28]\). In fact the subsequent proof is partly modelled on the proof of Proposition \([24.28]\).
Claim. Given any \( i \in \mathbb{Z} \) we consider the homomorphism

\[
\pi_i = \pi_1(X_i, x_i) \rightarrow \pi_1(\widetilde{X}(f), x_i) \rightarrow \pi_1(\widetilde{X}(f), \bar{x}).
\]

induced by the inclusion \( X_i \rightarrow \widetilde{X}(f) \) and \( i \) translates of the path \( \gamma \) to connect \( x_i \) to \( \bar{x} = x_0 \)

These homomorphisms induce an isomorphism

\[
\ldots \pi_{-2} \ast \pi_{-1} \ast \pi_0 \ast \pi_1 \ast \pi_2 \ast \ldots \xrightarrow{\cong} \pi_1(\widetilde{X}(f), \bar{x}).
\]

Here given \( i \in \mathbb{Z} \) the maps in the amalgamated product are defined as follows:

\[
\pi_1(X_{i-1}, x_{i-1}) \xleftarrow{\cong} \pi_1(X_{i-1}, f(x_{i-1})) \xleftarrow{\cong} \pi_1(B_{i-1}, f(x_i)) \xrightarrow{\cong} \pi_1(A_i, x_i) \xrightarrow{\cong} \pi_1(X_i, x_i).
\]

To prove the claim we need to introduce one more gadget. Namely, given \( n \in \mathbb{N} \) we write

\[\widetilde{Y}_n := \left( \bigcup_{i = -n}^{n} X_i \right) / (a, i) \sim (f(a), i - 1) \quad \text{for} \quad a \in A, i \in \{ -n + 1, \ldots, n \}.\]

It follows from the Seifert–van Kampen Theorem \[22.1\] applied iteratively \( 2n \) times, that

\[\pi_1(\widetilde{Y}_n, \widetilde{x}) \xleftarrow{\cong} \pi_{-n} \ast \pi_{-n+1} \ast \ldots \ast \pi_{n-1} \ast \pi_n.\]

Now we see that

\[\pi_1(\widetilde{X}(f), \bar{x}) = \pi_1(\lim_{\rightarrow} \widetilde{Y}_n, \bar{x}) \xleftarrow{\cong} \lim_{\rightarrow} \pi_1(\widetilde{Y}_n, \bar{x}) \xleftarrow{\cong} \ldots \pi_{-2} \ast \pi_{-1} \ast \pi_0 \ast \pi_1 \ast \pi_2 \ast \ldots\]

since \( A, B \) are open in \( X \) we can apply Proposition \[25.7\] (3) of the right hand side
In summary we obtain isomorphisms

\[
\pi_1(X(f), x) \cong \pi_1\left(\frac{X(f)}{Z}, [\widehat{x}]\right) \cong p_*\left(\pi_1\left(\frac{\widehat{X}(f)}{\widehat{Z}}, \widehat{x}\right)\right) \rtimes \Theta Z
\]

by Theorem [16.16 (2)] and Lemma [24.27], here the automorphism above homeomorphism \(\Theta\) is given by conjugation by \([\gamma] \in \pi_1(X(f), x)\)

\[
\cong \pi_1(X(f), \widehat{x}) \rtimes Z \cong \left(\ldots \pi_{-2} \ast \pi_{-1} \ast \pi_0 \ast \pi_1 \ast \pi_2 \ldots\right) \rtimes \Xi Z
\]

Corollary [16.14] here, as on page [765] we denote by \(\Xi\) the automorphism of the infinite amalgamated product that “shifts every term by one to the right”, the isomorphism is then given by the above claim and the verification that under this isomorphism the automorphisms \(\Theta\) and \(\Xi\) match up

\[
\cong \langle \pi_1(X(f), x), t | \alpha(\Gamma) = t\beta(\Gamma)t^{-1}\rangle.
\]

We leave it to the reader to verify that the given isomorphism has all the properties that were promised.

Sketch of the proof of Theorem 26.3 (2) (*). The proof of Theorem 26.3 (2) is basically the same as the proof of Theorem 26.3 (1), we just need to replace the Seifert–van Kampen Theorem 22.1 by the Seifert–van Kampen Theorem 22.2 for smooth manifolds. We leave it to the reader to fill in the details and to make the necessary changes to the proof.

In many situations the following corollary to the HNN-Seifert–van Kampen Theorem 26.3 is quite useful.

**Corollary 26.5.** (* Let \(X\) be a topological space. We suppose that it can be written as a union \(X = Y \cup Z\) such that the following conditions are satisfied:

1. \(Y\) and \(Z\) are open subsets,
2. \(Y\) is path-connected,
3. \(Z\) is simply connected,
4. \(Y \cap Z\) consists of two simply connected path components \(A\) and \(B\), each of which is open in \(X\).

Let \(y\) be a point in \(Y\) and let \(\gamma\) be the concatenation of a path in \(Y\) from \(y\) to a point \(a \in A\), a path in \(Z\) from \(a\) to a point \(b \in B\) and a path in \(Y\) from \(b\) to \(y\). Then the map

\[
\pi_1(Y, y) \ast \langle t \rangle \to \pi_1(X, y)
\]

that is given by the inclusion induced map \(\pi_1(Y, y) \to \pi_1(X, y)\) and given by \(t \mapsto [\gamma]\) is an isomorphism.

**Example.** We consider the topological space \(X\) that is obtained from “gluing an interval” to the torus. Using the notation from Figure 493 one can show quite easily, using Corollary 26.3 that \(\pi_1(X, x_0) \cong \langle x, y, t | [x, y] \rangle \cong \mathbb{Z}^2 \ast \langle t \rangle\). We refer to Figure 493 for an illustration. We will work out the details of this example in Exercise 26.1.
Figure 492. Illustration of Corollary 26.5.

Figure 493

Figure 494. Illustration for the proof of Corollary 26.5.

Proof. Let $Z'$ be a disjoint copy of $Z$ (e.g. we could set $Z' = Z \times \{0\}$). We consider $W = (Y \sqcup Z')/a \sim a'$ where we identify each point $a \in A$ with the corresponding point in $Z'$. We denote by $B'$ the copy of $B$ in $Z'$ and thus also the copy in $W$. Thus we see that $B$ and its doppelgänger $B'$ are contained in $W$. We denote by $f : B' \to B$ the obvious homeomorphism. We obtain the following isomorphisms:

\[
\pi_1(X, y) \cong \pi_1(W(f), y) \cong \pi_1(W, y) \ast \langle t \rangle \cong (\pi_1(Y, y) \ast \pi_1(Z', y)) \ast \langle t \rangle = \pi_1(Y, y) \ast \langle t \rangle.
\]

by the HNN-Seifert–van Kampen Theorem 26.3 and since $B$ is simply connected

by Lemma 3.45 the obvious map \( X \to W(f) \) is a homeomorphism

Seifert–van Kampen Theorem 20.2 since $A$ and $Z'$ are simply connected

One can easily verify that this is precisely the map in the statement of the corollary.

We conclude this chapter with the following technical lemma which we will need once

at a later occasion.

Lemma 26.6. (*) Let $n \in \mathbb{N}$ and let $M$ be the 2-sphere with $n$ open disks removed. We enumerate the boundary components by $C_1, \ldots, C_n$. For $i = 1, \ldots, n$ we pick a path

\footnote{It follows from our hypothesis that $A, Y, Z$ are open in $X$ that in the settings of the HNN-Seifert–van Kampen Theorem 26.3 and the Seifert–van Kampen Theorem 20.2 we do in fact deal with open subsets.}
\( \beta_i : [0, 1] \to C_i \) that goes once around \( C_i \). We pick a base point \( * \in M \setminus \partial M \). We pick paths \( \alpha_1, \ldots, \alpha_n : [0, 1] \to M \) with the following properties:

1. each \( \alpha_i \) is a smooth embedding,
2. each \( \alpha_i \) is a path from \( * \) to the point \( \beta_i(0) \),
3. for each \( i \) we have \( \alpha_i([0, 1]) \subset M \setminus \partial M \),
4. the images of the paths only intersect at \( * \).

For any \( j \in \{1, \ldots, n\} \) the homomorphism

\[
\langle y_1, \ldots, y_j-1, y_{j+1}, \ldots, y_n \rangle \to \pi_1(M, *)
\]

that is uniquely determined by

\[
y_i \mapsto [\alpha_i * \beta_i * \overline{\alpha_j}]
\]

is an isomorphism.

**Remark.**

1. This proposition should ring a bell, it sounds quite like Lemma 23.11. The difference is that in Lemma 23.11 we only said that there exist certain paths \( \beta_i \) such that the given map is an isomorphism. The above lemma gives a more precise statement what type of paths work.
2. One might think that perhaps one can use any old paths \( \alpha_i \) to obtain a basis for the free group \( \pi_1(M, *) \). But as we will see in Exercise 26.6 this is not the case.

We conclude this chapter with a sketch of a proof of Lemma 26.6. Perhaps the most friendly words that can be uttered regarding the proof are that the proof shows that it can be quite hard to write down rigorous arguments once one leaves the friendly word of submanifolds and instead tries to deal with more general subsets.

**Sketch of a proof.** Without loss of generality we can assume that \( j = n \). We consider \( N := M \setminus \alpha_n([0, 1]) \). This is an open subset of the smooth manifold \( M \), thus \( N \) itself is a smooth manifold. Furthermore by Exercise 10.2 we know that the inclusion \( M \setminus \alpha_n([0, 1]) \to M \) is a homotopy equivalence.\footnote{The alert reader will not have failed to notice that we are referring to an exercise that is dealt with later in the notes. Fortunately we do not need to be afraid of circular logic. The exercise builds on an extension of the Tubular Neighborhood Theorem 8.24 to submanifolds with boundary. This formulation, see Theorem 10.5 is just a little awkward and was thus postponed to later on. But if one uses a naive extension of the Tubular Neighborhood Theorem 8.24 to the case of submanifolds with boundary, then one can easily prove Exercise 10.2 with our present knowledge.} For \( i = 1, \ldots, n-1 \) we write \( X_i := \alpha_i([0, 1]) \subset N \). It follows from (1) and Proposition 8.1 (1) that \( X = X_1 \cup \cdots \cup X_{n-1} \) is a submanifold of \( N \). By the Tubular Neighborhood Theorem 8.24 we can pick a tubular map \([-1, 1] \times X \). We...
write \( W := N \setminus (-1, 1) \times X \), we pick a base point \( \star \in W \) and we pick path \( p \) in \( M \) from \( \star \) to \( \star \).

Using Corollary 26.5 one can prove\(^{480}\) the following:

1. there exist loops \( \eta_1, \ldots, \eta_{n-1} \) in \((N, \star)\) such that the obvious map
   \[
   \pi_1(W, \star) \star \langle [\eta_1], \ldots, [\eta_{n-1}] \rangle \to \pi_1(N, \star)
   \]
   is an isomorphism,
2. for each \( i \in \{1, \ldots, n-1\} \) the loop \( p \star \eta_i \star \bar{p} \) is path-homotopic to \( \alpha_i \star \beta_i \star \bar{\alpha}_i \).

Putting everything together we see that we have an isomorphism
\[
\pi_1(W) \star \langle [\alpha_1 \star \beta_1 \star \bar{\alpha}_1], \ldots, [\alpha_{n-1} \star \beta_{n-1} \star \bar{\alpha}_{n-1}] \rangle \xrightarrow{\cong} \pi_1(M).
\]

By Lemma 23.11 we know that the right-hand side is a free group of rank \( n - 1 \). It follows from the Grushko-Neumann Theorem 19.19 that \( \pi_1(W) \) is trivial. We have thus obtained the desired isomorphism.\(^{481}\)

---

**Exercises for Chapter 26**

**Exercise 26.1.** Give full details for the calculation of the fundamental group of the topological space shown in Figure 493.

**Exercise 26.2.** Let \( \pi = \langle a \rangle \), let \( \Gamma = \langle t \rangle \) and let \( \alpha, \beta : \Gamma \to \pi \) be the homomorphisms given by \( \alpha(t) = a \) and \( \beta(t) = a^2 \). Show that the corresponding HNN-extension is isomorphic to the semidirect product \( \mathbb{Z}[\frac{1}{2}] \rtimes \mathbb{Z} \) where \( \varphi : \mathbb{Z}[\frac{1}{2}] \to \mathbb{Z}[\frac{1}{2}] \) is the group homomorphism given by multiplication by 2.

**Exercise 26.3.** Let \( X \) be a path-connected topological space. Furthermore let \( f : X \to X \) be a homeomorphism. In Proposition 24.28 we saw that there exists an isomorphism \( \psi : \pi_1(\text{Tor}(X, f)) \cong \pi_1(X) \rtimes \mathbb{Z} \). Give an alternative proof of this statement using the HNN-Seifert-van Kampen Theorem 26.3.

**Exercise 26.4.** Let \( X \) be the result of removing two open disks from the surface of genus \( g \). We denote by \( C \) and \( D \) the resulting boundary components. We pick orientation-preserving diffeomorphisms \( \varphi : S^1 \to C \) and \( \psi : S^1 \to D \).

(a) We consider the homeomorphism
\[
f : C \times S^1 \to D \times S^1 \quad \text{with} \quad (c, z) \mapsto (\psi(z), \varphi^{-1}(c)).
\]
What is the abelianization of the fundamental group of \((X \times S^1)(f)\)?

(b) Does the answer to (a) change if we pick \( \varphi \) to be orientation-preserving and \( \psi \) to be orientation-reversing?

\(^{480}\)Here is the point where the demanding reader might feel that not enough details are provided. \(^{481}\)The esthetically-inclined reader might object to the use of the Grushko-Neumann Theorem. But any other approach also opens up a can of worms. For example one might be tempted to show that \( W \) is contractible.
Exercise 26.5. Let $X$ be a topological space. In Lemma 24.3 we showed that if $X$ is non-empty and path-connected, then the fundamental group of the suspension $\Sigma(X)$ is trivial.

(a) Suppose that $X$ has two path-components. Show that $\pi_1(\Sigma(X)) \cong \mathbb{Z}$.
(b) Suppose that $X$ has $k$ path-components with $k \geq 1$. Show that $\pi_1(\Sigma(X))$ is isomorphic to a free group on $k - 1$ generators.

Exercise 26.6. We consider the permutation group $S_4$ where given $\alpha, \beta \in S_4$ we write $\alpha \cdot \beta = \alpha \circ \beta$. We consider the cycles $\sigma = (1 \ 2 \ 3 \ 4) = (1 \ 2 \ 3 \ 4)$, $\mu = (1 \ 2) = (1 \ 2 \ 3 \ 4)$ and $\nu = (1 \ 3) = (1 \ 2 \ 3 \ 4)$.

(a) Show that $\sigma$ and $\mu$ form a generating set for $S_4$.
(b) Show that $\sigma$ and $\nu$ do not form a generating set for $S_4$.
(c) Show that $(\mu \cdot \sigma) \cdot \mu \cdot (\mu \cdot \sigma)^{-1} = \nu$.
(d) Show that the endomorphism $\langle x, y \rangle \to \langle x, y \rangle$ that is given by $x \mapsto (yx)^{-1}x(yx)$ and $y \mapsto y$ is not an isomorphism.
(e) We consider $M$ which is defined as the disk $\overline{B^2}$ minus two open disks. We consider the base point $\ast$ and the curves $\beta_1$ and $\beta_2$ as shown in Figure 496. Show that for $i = 1, 2$ there exist paths $\alpha_i$ from $\ast$ to the starting point of $\beta_i$ such that $[\alpha_1 \ast \beta_1 \ast \overline{\alpha_1}]$ and $[\alpha_2 \ast \beta_2 \ast \overline{\alpha_2}]$ do not form a generating set for $\pi_1(M, \ast)$.

\[482\text{Recall that for pairwise disjoint } a_1, \ldots, a_k \in \{1, \ldots, n\} \text{ we denote by } (a_1 a_2 \ldots a_k) \in S_n \text{ the permutation that is given by }\]
\[\{1, \ldots, n\} \to \{1, \ldots, n\}, \quad m \mapsto \begin{cases} a_{i+1}, & \text{if } m = a_i \text{ for some } i \in \{1, \ldots, k-1\}, \\ a_1, & \text{if } m = a_k, \\ m, & \text{otherwise.} \end{cases}\]

Put differently, the numbers $(a_1, \ldots, a_k)$ get cyclically permuted and all other numbers stay the same.

\[483\text{It follows easily from stereographic projection that } M \text{ is diffeomorphic to } S^2 \text{ minus three open disks.}\]
27. AN EXCURSION INTO KNOT THEORY

In this chapter we will study the fundamental groups of the complements of knots. In particular we will use these calculations to show that the trivial knot, the trefoil and the figure-8 knot are pairwise different, i.e. we will show that they are pairwise not smoothly isotopic.

27.1. One more avatar of spheres. The spheres $S^n = \{ x \in \mathbb{R}^{n+1} \mid \|x\| = 1 \}$ are some of the most important topological spaces. We already saw that there are different ways to think about spheres, in particular on pages 119, 182 and 199 we made the following identifications

$$S^n = \mathbb{R}^n \cup \{ \infty \}, \quad S^n = \overline{B}^n / S^{n-1}, \quad \text{and} \quad S^n = \overline{B}_+^n \cup_{S^{n-1}} \overline{B}_-^n.$$ 

Furthermore, on page 203 we had given a canonical homeomorphism

$$\left( S^{m-1} \times \overline{B}^n \right) \cup_{S^{m-1} \times S^{n-1}} \left( \overline{B}^m \times S^{n-1} \right) \xrightarrow{\cong} S^{m+n-1}.$$ 

Even though the homeomorphism is canonical, it is not particularly explicit. Furthermore it has the disadvantage that, if one looks up the definition, one sees that the restriction to the two solid tori $S^{m-1} \times \overline{B}^n$ and $\overline{B}^m \times S^{n-1}$ is not smooth. The following lemma rectifies these two problems.

**Lemma 27.1.** Let $m, n \in \mathbb{N}_0$. We consider the following two maps:

$$\Phi : S^{m-1} \times \overline{B}^n \to A := \left\{ (z, w) \in \mathbb{R}^m \times \mathbb{R}^n = \mathbb{R}^{m+n} \mid \|w\|^2 + \|z\|^2 = 1 \text{ and } \|z\|^2 \geq \frac{1}{2} \right\}$$

$$(a, b) \mapsto \left( \frac{a}{\sqrt{\|a\|^2 + \|b\|^2}}, \frac{b}{\sqrt{\|a\|^2 + \|b\|^2}} \right)$$

and

$$\Psi : \overline{B}^m \times S^{n-1} \to B := \left\{ (z, w) \in \mathbb{R}^m \times \mathbb{R}^n = \mathbb{R}^{m+n} \mid \|w\|^2 + \|z\|^2 = 1 \text{ and } \|w\|^2 \geq \frac{1}{2} \right\}$$

$$(a, b) \mapsto \left( \frac{a}{\sqrt{\|a\|^2 + \|b\|^2}}, \frac{b}{\sqrt{\|a\|^2 + \|b\|^2}} \right).$$

These maps have the following properties:

1. The map $\Phi : S^{m-1} \times \overline{B}^n \to A$ is an orientation-preserving diffeomorphism.
2. The map $\Psi : \overline{B}^m \times S^{n-1} \to B$ is a diffeomorphism, it is orientation-preserving if and only if $m$ is even.
3. The map $\Theta : \left( S^{m-1} \times \overline{B}^n \right) \cup_{S^{m-1} \times S^{n-1}} \left( \overline{B}^m \times S^{n-1} \right) \to S^{m+n-1}$

$$[P] \mapsto \begin{cases} \Phi(P), & \text{if } P \in S^{m-1} \times \overline{B}^n; \\ \Psi(P), & \text{if } P \in \overline{B}^m \times S^{n-1}. \end{cases}$$

is well-defined, it is a diffeomorphism, and it is orientation-preserving if and only if $m$ is even.
**Convention.** We use the diffeomorphism \( \Theta \) from Lemma 27.1 (2) to add the smooth manifold \((S^{m-1} \times \overline{B}^{n}) \cup_{S^{m-1} \times S^{n-1}} (\overline{B}^{m} \times S^{n-1})\) to our list of avatars of \(S^{m+n-1}\).

\[
\tilde{\Psi} : B = \{(z, w) \in \mathbb{R}^{m} \times \mathbb{R}^{n} = \mathbb{R}^{m+n} \mid \|w\|^{2} + \|z\|^{2} = 1 & \|w\|^{2} \geq \frac{1}{2}\} \to \overline{B}^{m} \times S^{n-1} \quad (z, w) \mapsto \left(\frac{z}{\|w\|}, \frac{w}{\|w\|}\right).
\]

One can easily verify that \(\tilde{\Psi}\) and \(\Psi\) are inverses of one another and that \(\Psi\) and \(\tilde{\Psi}\) are smooth. This observation implies that \(\Psi : \overline{B}^{m} \times S^{n-1} \to B\) is a diffeomorphism. It remains to show that \(\Psi\) is orientation-preserving. By Lemma 6.46 it suffices to prove the following claim.

**Claim.** For \(e_{m+1} = ((0, \ldots, 0), (1, 0, \ldots, 0)) \in \overline{B}^{m} \times S^{n-1}\) the corresponding differential \(D\Psi_{e_{m+1}} : V_{e_{m+1}}(\overline{B}^{m} \times S^{n-1}) \to V_{\Psi(e_{m+1})} B\) is orientation-preserving if and only if \(m\) is even.

By the orientation conventions from page 299 and Proposition 6.51 we know that \(\{e_{1}, \ldots, e_{m}, e_{m+2}, \ldots, e_{m+n}\}\) is a positive basis for \(V_{e_{m+1}}(\overline{B}^{m} \times S^{n-1})\). First note that a straightforward calculation shows that the differential of \(\Psi\) at the point \(e_{m+1}\) is actually the identity. Next note that \(\Psi(e_{m+1}) = e_{m+1}\). Finally note that by definition \(\{v_{1}, \ldots, v_{m+n-1}\}\) is a positive basis for \(V_{\Psi(e_{m+1})} B = V_{e_{m+1}} S^{m+n-1}\) if and only if \(\det(e_{m+1}, v_{1}, \ldots, v_{m+n-1}) > 0\). The claim follows almost immediately from these observations.

(1) The proof of this statement is almost identical to the above proof of (2).
(3) It is clear that \(\Phi\) and \(\Psi\) agree on \(S^{m-1} \times S^{n-1}\). Therefore it follows from Lemma 3.22 that the given map \(\Theta : (S^{m-1} \times \overline{B}^{n}) \cup_{S^{m-1} \times S^{n-1}} (\overline{B}^{m} \times S^{n-1}) \to S^{m+n-1}\) is well-defined and continuous. Using (1) one easily verifies that the map is a bijection. It follows from Proposition 2.43 (3) that the map \(\Theta\) is a homeomorphism. Going through the definition of the smooth structure of the smooth manifold on the left, as defined in Proposition 8.15 (1b), shows that the map is actually a diffeomorphism. Finally it follows from (1) and (2) that the diffeomorphism is actually orientation-preserving.
Throughout this chapter we are mostly interested in the case \( m = n = 2 \). In this setting we have the following identifications which are given by definition and by Lemma 2.44:
\[ S^3 = \{(w, x, y, z) \mid w^2 + x^2 + y^2 + z^2 = 1\} = \{(z, w) \in \mathbb{C}^2 \mid |w|^2 + |z|^2 = 1\} = \mathbb{R}^3 \cup \{\infty\}. \]

via the stereographic projection as defined in Lemma 2.44.

We will go back and forth between these models without mentioning these maps. In particular, as discussed on page 344, we will view \( \mathbb{R}^3 \) as a submanifold of the smooth manifold \( S^3 = \mathbb{R}^3 \cup \{\infty\} \). Furthermore we now view \( A \) and \( B \) as subsets of \( S^3 = \mathbb{R}^3 \cup \{\infty\} \).

In this setting we have

"central curve of \( A \)" = \( \Phi(S^1 \times \{0\}) = S^1 \times \{0\} \) = the trivial knot

and we have

"central curve of \( B \)" = \( \Psi(\{0\} \times S^1) \) = the \( z \)-axis \( \cup \{\infty\} \).

We visualize the solid torus \( A \) and the central curve of the solid torus \( B \) in Figure 498. The solid torus \( B \) is more difficult to illustrate. It consists of a closed disk attached to each point on the central curve. For example the closed disk attached to the origin is just the "obvious" closed disk in the \( xy \)-plane that touches the torus \( \Phi(S^1 \times S^1) \).

**Figure 498**

![Diagram](image)

Lemma 3.13 and Lemma 27.1 give us two smooth embeddings of the 2-dimensional torus \( S^1 \times S^1 \) into \( \mathbb{R}^3 \). The following lemma says that these two smooth embeddings are essentially the same.

**Lemma 27.2.** (⋆) We denote by \( \Omega : S^3 \setminus \{(0, 1)\} \to \mathbb{R}^3 \) the stereographic projection as defined in Lemma 2.44. We consider the two smooth embeddings

\[ \mathbb{B}^2 \times S^1 \xrightarrow{\Omega} \mathbb{R}^3 \]

\[ (x, y, e^{i\varphi}) \mapsto \begin{pmatrix} \cos \varphi & -\sin \varphi & 0 \\ \sin \varphi & \cos \varphi & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} 1 + \frac{z}{w} \\ \frac{w}{\sqrt{|z|^2 + |w|^2}} \end{pmatrix} \]

and

\[ \mathbb{B}^2 \times S^1 \xrightarrow{\Xi} S^3 \setminus \{(0, 1)\} \xrightarrow{\Omega} \mathbb{R}^3 \]

\[ (z, w) \mapsto \begin{pmatrix} w \\ \sqrt{|z|^2 + |w|^2} \end{pmatrix} \]

provided by Lemma 3.13 and provided by Lemma 27.1. There exists a smooth diffeomorphism \( G \) of \( S^3 \) rel \( \{(0, 0)\} \times S^1 \) with \( G_0 = \text{id} \) and \( G_1 \circ \Theta = \Omega \circ \Xi \).

What is the disk attached to the point \( \infty \)?
Convention. In all the future examples we will not distinguish between the two smooth embeddings of the solid torus $B^2 \times S^1 \to \mathbb{R}^3$ that are given in Lemma 27.2.

Sketch of proof (*). By the Isotopy Extension Theorem 8.27 it suffices to show that there exists a smooth isotopy rel $\{(0,0)\} \times S^1$ from $\Theta$ to $\Omega \circ \Xi$.

We write $H = \{(x,0,z) \in \mathbb{R}^3 \mid x > 0\}$. Let us first consider the restrictions of $\Theta$ and $\Omega \circ \Xi$ to the disk $B^2 \times \{1\}$. In both cases the image lies in $H$. These maps are illustrated in Figure 499. We leave it to the dear reader to show that there exists a smooth isotopy $F: B^2 \times \{1\} \times [0,1] \to H$ rel $\{(0,0,1)\}$ from $\Theta$ to $\Omega \circ \Xi$.

The desired isotopy is given by “rotating $F$” around the $z$-axis. Slightly more precisely it is given by the map

\[
\begin{align*}
B^2 \times S^1 \times [0,1] & \to \mathbb{R}^3 \\
((x,y),e^{i\varphi},t) & \mapsto \text{rotation of } F((x,y),t) \in \mathbb{R}^3 \text{ by } \varphi \text{ around the } z\text{-axis}. \end{align*}
\]

Figure 499. Illustration for the proof of Lemma 27.2.

27.2. The fundamental group of the complement of the trefoil. Now we want to finally turn to the study of knots. In particular we would like to study the knots that are illustrated in Figure 500. In Question 8.40 we had raised the question, how can one show that the trefoil is not trivial?

Figure 500. The trivial knot, the trefoil and the figure-8 knot.

Now we have some tools to attack this question. We saw in Proposition 8.43 that if $K$ and $J$ are smoothly isotopic knots, then the knot complements $S^3 \setminus K$ and $S^3 \setminus J$ are diffeomorphic. In particular if $\pi_1(S^3 \setminus K)$ and $\pi_1(S^3 \setminus J)$ are not isomorphic, then $K$ and $J$ are not smoothly isotopic. Thus we arrive at the following variation on Question 8.40.

**Question 27.3.** Can the fundamental group be used to distinguish the trefoil from the trivial knot?

\[\text{Note that } \Xi: B^2 \times S^1 \to S^3 \text{ is just the composition of the swap } B^2 \times S^1 \to S^1 \times B^2 \text{ and the smooth embedding } \Phi: S^1 \times B^2 \to S^3.\]

\[\text{As a reality check note that it follows from Lemma 2.44 that } \Theta \text{ and } \Omega \circ \Xi \text{ agree on } \{(0,0)\} \times S^1.\]
Before we continue we want to give a precise description of the trivial knot and the trefoil. In fact, we will use the occasion to introduce an interesting family of knots which contains the trefoil knot.

**Definition.**

1. As on page 385 we define the *trivial knot* as the knot
\[ U := \{ (e^{it}, 0) \mid t \in \mathbb{R} \} = \{ (z, w) \in \mathbb{C}^2 \mid |w|^2 + |z|^2 = 1 \} \]
or equivalently
\[ U := \{ (\cos t, \sin t, 0) \mid t \in \mathbb{R} \} \subset \mathbb{R}^3 \cup \{ \infty \}. \]

2. Let \( p, q \in \mathbb{N} \) be coprime. We consider the curve \( C = \{ (p \cdot t, q \cdot t) \mid t \in \mathbb{R} \} \) on the torus \( T = [0, 2\pi] \times [0, 2\pi] / \sim \). We define the \((p, q)\)-torus knot \( T(p, q) \) as the image of \( C \) under the map
\[ \Phi: T = [0, 2\pi] \times [0, 2\pi] / \sim \to S^3 \]
\[ (s, t) \mapsto \left( \frac{1}{\sqrt{2}} e^{is}, \frac{1}{\sqrt{2}} e^{it} \right). \]

3. We define the *trefoil* to be the \((2, 3)\)-torus. This definition of the trefoil is illustrated in Figure 501.

![Figure 501](image)

Now we turn to the calculation of the fundamental groups of the complements of the trivial knot and of the trefoil.

**Proposition 27.4.** If \( U \) is the trivial knot, then \( S^3 \setminus U \) is diffeomorphic to \( S^1 \times \mathbb{C} \), in particular \( \pi_1(S^3 \setminus U) \cong \mathbb{Z} \).

**Proof.** Note that
\[
S^3 \setminus U = \{ (z, w) \in \mathbb{C}^2 \mid |z|^2 + |w|^2 = 1 \} \setminus \{ (z, 0) \mid |z| = 1 \} \\
= \{ (z, w) \in \mathbb{C}^2 \mid |z|^2 + |w|^2 = 1 \text{ and } |w|^2 > 0 \}.
\]

Now basically the same argument as in the proof of Lemma 27.1 shows that the map
\[ \Phi: S^1 \times \mathbb{C} \to S^3 \setminus U = \{ (z, w) \in \mathbb{C}^2 \mid |w|^2 + |z|^2 = 1 \text{ and } |w|^2 > 0 \} \]
\[ (a, b) \mapsto \left( \frac{b}{\sqrt{|a|^2 + |b|^2}}, \frac{a}{\sqrt{|a|^2 + |b|^2}} \right) \]

The name \( U \) comes from the fact that the trivial knot is often also called the *unknot*. 
is a diffeomorphism. Since $S^1 \times \mathbb{C}$ is homotopy equivalent to $S^1$ we obtain from the above and from Proposition 18.16(2) that $\pi_1(S^3 \setminus U) = \pi_1(S^1 \times \mathbb{C}) = \pi_1(S^1) \cong \mathbb{Z}$. 

**Remark.** Let $U$ be the trivial knot. A careful reading of the proof of Proposition 27.4 shows that a generator of $\pi_1(S^3 \setminus U)$ is given by a meridian that we defined on page 390. We refer to Figure 502 for an illustration of the trivial knot and a meridian.

![Figure 502: Trivial Knot and Meridian](image)

**Proposition 27.5.**

1. Let $p,q \in \mathbb{N}$ be coprime. Then $\pi_1(S^3 \setminus T(p,q)) \cong \langle x, y \mid x^p = y^q \rangle$.
2. If $K$ is the trefoil, then $\pi_1(S^3 \setminus K) \cong \langle x, y \mid x^2 = y^3 \rangle$.

**Proof.** By definition of the trefoil Statement (2) is just a special case of Statement (1). Thus we only need to prove Statement (1). Let $p,q \in \mathbb{N}$ be coprime. By Lemma 27.1 there exists a diffeomorphism

$$\Phi: S^3 \cong \left( S^1 \times \mathbb{B}^2 \right) \cup_{S^1 \times S^1} \left( \mathbb{B}^2 \times S^1 \right)$$

which is, up to scaling by a factor of $\sqrt{2}$, the identity on $T := S^1 \times S^1$. We identify the $(p,q)$-torus knot with its image under $\Phi$, i.e. we have

$$K = \{ (e^{psi}, e^{qsi}) \mid s \in \mathbb{R} \} \subset T.$$  

We write $A_K = A \setminus K, B_K = B \setminus K$ and $T_K = T \setminus K$. Note that $A_K$ and $B_K$ are submanifolds of $X_K := S^3 \setminus K$ and with $^{489}$ $A_K \cap B_K = \partial A_K = \partial B_K = T_K$ and with $A_K \cup B_K = X_K$. Note that $x := S^1 \times \{0\}$ is a deformation retract of $A_K$ and that $y := \{0\} \times S^1$ is a deformation retract of $B_K$. Finally note that $T_K$ retracts onto a parallel copy of $K$. More precisely, for $\epsilon > 0$ sufficiently small, the subset $T_K$ retracts onto the loop

$$z = \{ (e^{psi+\epsilon}, e^{qsi}) \mid s \in \mathbb{R} \} \subset T_K.$$  

By an abuse of notation we denote by $x, y$ and $z$ also the loops corresponding to the circles $x, y$ and $z$ with the obvious orientation. Then the inclusion induced maps

$$\pi_1(A_K) \leftarrow \pi_1(T_K) \rightarrow \pi_1(B_K)$$

become

$$\langle x \rangle \leftarrow \langle z \rangle \rightarrow \langle y \rangle$$

Thus we see that

$$\pi_1(X_K) = \pi_1(A_K) \ast \pi_1(T_K) \ast \pi_1(B_K) \cong \langle x \rangle \ast_{x^p = y^q} \langle y \rangle = \langle x, y \mid x^p = y^q \rangle.$$

Seifert–van Kampen Theorem 22.2 above discussion Lemma 21.23

\[ \text{Here we mean by } \partial A_K \text{ and } \partial B_K \text{ the boundary of } A_K \text{ and } B_K \text{ viewed as submanifolds of } S^3. \]
Now the question is whether or not $\pi_1(S^3 \setminus K) = \langle x, y \mid x^2 = y^3 \rangle$ is isomorphic to $\pi_1(S^3 \setminus U) = \mathbb{Z}$. As usual we first consider the abelianization of $\pi_1(S^3 \setminus K)$, but it is straightforward to see, using Proposition 21.20 that the abelianization is isomorphic to $\mathbb{Z}$. Despite this slight setback the following lemma does fortunately show that the group $\pi_1(S^3 \setminus K) = \langle x, y \mid x^2 = y^3 \rangle$ is not isomorphic to $\pi_1(S^3 \setminus U) = \mathbb{Z}$.

**Proposition 27.6.**

(1) The group $\langle x, y \mid x^2 = y^3 \rangle$ admits an epimorphism onto the permutation group $S_3$, in particular the group $\langle x, y \mid x^2 = y^3 \rangle$ is not isomorphic to $\mathbb{Z}$.

(2) The trefoil is not smoothly isotopic to the trivial knot.

**Proof.**

(1) It follows from Lemma 21.4 and a straightforward calculation that there exists a unique homomorphism

$$\Phi: \langle x, y \mid x^2 = y^3 \rangle \to S_3 = \text{permutation group on three elements}$$

with

$$\Phi(x) = \sigma := (1 2) = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 1 & 3 \end{pmatrix}$$

and

$$\Phi(y) = \tau := (1 2 3) = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 3 & 1 \end{pmatrix}.$$

The permutations $\sigma$ and $\tau$ do not commute, hence the image of $\Phi$ is a non-abelian subgroup of $S_3$. On the other hand the abelian group $\mathbb{Z}$ cannot admit an epimorphism onto a non-abelian group.\[493\]

(2) It follows from (1) and above discussion that the trefoil is non-trivial. ■

The following question arises naturally.

**Question 27.7.** Are the $(p, q)$-torus knots pairwise different, i.e. if $(p, q)$ and $(r, s)$ for coprime pairs of natural numbers, does it follow that $T(p, q)$ and $T(r, s)$ are not smoothly isotopic?

The approach of the proof of Proposition 27.6 is most likely too pedestrian to deal with Question 27.7. We will return to Question 27.7 at a much later stage.

**Remark.** Let $p, q \in \mathbb{N}$ be coprime. We consider the map

$$f: S^3 = \{(z, w) \in \mathbb{C}^2 \mid |z|^2 + |w|^2 = 1\} \to \mathbb{C} \quad (z, w) \mapsto z^q - w^p.$$
Note that by definition the \((p, q)\)-torus knot \(T(p, q)\) equals \(f^{-1}(\{0\})\). It follows from work of Milnor, see \[\text{Miln68, Theorem 4.8}\] and \[\text{Sav12, Chapter 8}\] (see also \[\text{EN85, p. 125}\] and \[\text{Rolf90, Chapter 10.I}\]), that there exists a surface and a self-diffeomorphism of order \(pq\) together with a diffeomorphism \(\Theta: S^3 \setminus T(p, q) \to \text{Tor}(\Sigma, \varphi)\) such that the following diagram commutes

\[
\begin{array}{ccc}
S^3 \setminus T(p, q) & \xrightarrow{\Theta} & \text{Tor}(\Sigma, \varphi) \\
\downarrow_{P \mapsto f(P)} & \simeq & \\
S^1 & \xrightarrow{[(z, t)] \mapsto e^{2\pi i t}} & \end{array}
\]

This generalizes the observation from \[\text{714}\] that the complement of the trefoil is diffeomorphic to a mapping torus.

The question arises, whether the fundamental group is strong enough to detect the smooth isotopy class of a knot. In the section we will see that this is perhaps a trifle to optimistic.

27.3. **The mirror image of a knot.** We continue with the following nicely geometric definition.

**Definition.** Given a knot \(K \subset S^3\) the reflection of \(K\) in any hyperplane of \(R^4\) is called *mirror* of \(K\) and denoted by \(K^{\text{mir}}\).

**Lemma 27.8.**

1. Let \(K \subset S^3\) be a knot. The reflections in any two hyperplanes of \(R^4\) give rise to smoothly isotopic knots.
2. Let \(K \subset R^3\) be a knot. We use the diffeomorphism \(R^3 \cup \{\infty\} \to S^3\) from Lemma 2.44 to view \(K\) as a knot in \(S^3\). The image of \(K\) under a reflection of an affine hyperplane in \(R^3\) corresponds under this embedding to a mirror of \(K\).

**Sketch of proof.**

1. We will prove this statement in Exercise 27.1, making use of Lemma 2.65 and Exercise 18.7.
2. Let \(K \subset R^3\) be a knot. First note that the same argument as in (1) shows that reflection in any two affine hyperplanes of \(R^3\) lead to smoothly isotopic knots in \(R^3\). Thus it remains to show that there exists a single hyperplane \(H\) of \(R^3\) such that the reflection of \(K\) in \(H\) corresponds to the mirror image of \(K \subset R^3 \subset S^3\) as defined above. Next note that the stereographic projection, that we used in Lemma 2.44 commutes with the reflection in the \((x_1 = 0)\)-hyperplane of \(R^4\) respectively \(R^3\). Thus we see that the hyperplane \((x_1 = 0)\) has the desired property.

**Convention.** Let \(K \subset S^3\). Since usually we only care about knots up to smooth isotopy we use Lemma 27.8 to talk of “the mirror image” of \(K\) instead of the slightly more correct “a mirror image of \(K\)”.

**Example.** Let \(K \subset R^3 \subset R^3 \cup \{\infty\} = S^3\) be a knot. Keeping Lemma 27.8 (2) we see in Figure 503 the trefoil and its mirror and we also see the figure-8 knot and its mirror.
The question arises, whether the mirror image of a knot is “truly different” from the original knot. We are now naturally led to the following definition.

**Definition.** We say that a knot $K$ in $\mathbb{R}^3$ is *amphichiral* if it is smoothly isotopic to its mirror image, otherwise we call the knot $K$ *chiral*.

**Examples.**

1. The trivial knot equals of course its mirror, in particular the trivial knot is amphichiral.
2. In Figure 504 we show that the figure-8 knot $J$ is smoothly isotopic to its mirror image $J^*$, i.e. the figure-8 knot is also amphichiral.

It is now natural to ask whether the trefoil is amphichiral. But endless hours of playing around with the trefoil do not lead to any success. So the suspicion arises that the following question should be answered in the negative.

**Question 27.9. Is the trefoil chiral?**

Much later, in Proposition 99.5 and ?? we will use two different approaches to give negative answer to this question. In the first approach we use the fundamental group together with the “longitude”, in the latter approach we use linking pairings of the 2-fold branched covering of $K$.

We return to the study of fundamental groups. Let $K \subset S^3$ be a knot and let $K^{\text{mir}}$ be its mirror image. Evidently $S^3 \setminus K$ is diffeomorphic to $S^3 \setminus K^{\text{mir}}$, so we cannot hope to distinguish $K$ and $K^{\text{mir}}$ using the fundamental groups of their complements. This leads us to the following question:
**Question 27.10.** Let $K$ and $J$ be two knots such that the fundamental groups of $S^3 \setminus K$ and $S^3 \setminus J$ are isomorphic. Does this imply that $K$ is smoothly isotopic to $J$ or to its mirror $J^*$?

27.4. **The connected sum of oriented submanifolds and knots (\*)**. In this section, given two submanifolds $K \subset M$ and $L \subset N$ we introduce the corresponding connected sum $K \# L \subset M \# N$. Eventually our main interest will be in the connected sum of knots $K, L \subset S^3$.

To introduce the connected sum of submanifolds and knots we need to make a few preparations.

**Notation.** Let $n \in \mathbb{N}$ and let $k \in \{1, \ldots, n-1\}$.

1. We denote by $B^n_2$ and $B^k_2$ the closed balls of radius 2 in $\mathbb{R}^n$ and $\mathbb{R}^k$.
2. We set $J^k := \{(x, 0) \in B^n_2 \mid x \in B^k_2\}$ and we view equip $J^k$ with the obvious orientation.
3. Let $M$ be a closed oriented $n$-dimensional smooth manifold and let $K \subset M$ be a closed oriented $k$-dimensional submanifold. Furthermore let $\varphi : B^n_2 \to M$ be a smooth embedding.
   a. We say $\varphi$ is $K$-admissible if $\varphi(J^k) = \varphi(B^n_2) \cap K$, if $\varphi : B^n_2 \to M$ is orientation-preserving and if $\varphi|_{J^k} : J^k \to \varphi(B^n_2) \cap K$ is orientation-preserving.
   b. We say $\varphi$ is $K$-anti-admissible if the same conditions as in (a) hold, except that we now demand that both maps are orientation-reversing.

In Figure 505 we illustrate the definition of a $K$-admissible map in the special case that $M = S^3$ and that $K$ is in fact a knot.

![Figure 505](image)

The following proposition says that $K$-admissible maps always exist and that in a sense they are unique.

**Proposition 27.11.** Let $M$ be a closed oriented $n$-dimensional smooth manifold. Furthermore let $K \subset M$ be a closed oriented $k$-dimensional submanifold.

1. There exists a $K$-admissible map.
2. If $M$ is connected, then for any $K$-admissible maps $\varphi : B^n_2 \to M$ and $\psi : B^n_2 \to M$ there exists a diffeotopy $F : M \times [0, 1] \to M$ such that $F_0 = \text{id}$, such that $F_1 \circ \varphi = \psi$ and such that each $F_t \circ \varphi$ is $K$-admissible.

The obvious analogues of (1) and (2) also hold for “$K$-anti-admissible”.

**Sketch of proof.** The first statement follows easily from the definition of a submanifold. The second statement is an analogue of Theorem 8.36. Unfortunately it seems like nobody ever bothered to write down a proof for Statement (2). Thus we must all the authority we have and we claim that this statement can be proven in an analogous fashion. ■
Let us quickly move on to the key definition of this section which can be viewed as a variation on the definition on page 377.

Definition. Let $M$ be a closed oriented $n$-dimensional smooth manifold and let $K \subset M$ be a closed oriented $k$-dimensional submanifold. Furthermore let $N$ be a closed oriented $n$-dimensional smooth manifold and let $L \subset N$ be a closed oriented $k$-dimensional submanifold. We pick a $K$-admissible map $\varphi: \overline{B}_2^n \to M$ and we pick an $L$-anti-admissible map $\psi: \overline{B}_2^k \to N$. We use $\varphi: \overline{B}_2^n \to M$ and $\psi: \overline{B}_2^k \to N$ to define $M \# N$. Furthermore we use $J_k^n \psi: \overline{B}_1^k \xrightarrow{(x,0)} J_k^n \to K$ and $J_k^n \varphi: \overline{B}_1^k \xrightarrow{(x,0)} J_k^n \to L$ to define the connected sum $K \# L$ as we did on page 377. We refer to the resulting pair $(M \# N, K \# L)$ as the connected sum of $(M, K)$ and $(N, L)$.

![Diagram](image_url)

**Figure 506**

The following proposition can be viewed as an analogue of Proposition 8.35.

**Proposition 27.12.** Let $M$ be a closed oriented $n$-dimensional smooth manifold and let $K$ be a closed oriented $k$-dimensional submanifold of $M$. Furthermore let $N$ be a closed oriented $n$-dimensional smooth manifold and let $L$ be a closed oriented $k$-dimensional submanifold of $N$.

1. The subset $K \# L$ is a closed $k$-dimensional smooth submanifold of $M \# N$.
2. If $M$ and $N$ are both connected, then the oriented diffeomorphism type of the pair $(M \# N, K \# L)$ does not depend on the choice of the $K$-admissible map and the $L$-anti-admissible map.

**Sketch of proof.**

1. We leave it to the reader to verify this statement. Note that here one needs to make use of the fact that the (anti-)admissible maps give us control on $\overline{B}_2^n$ and not just on $\overline{B}^k$.
2. This statement follows fairly easily from Proposition 27.11.

Now we can finally specialize to our beloved setting of knots in $S^3$. Following most books in knot theory, see e.g. [Rol90], p. 40 and [Kaw96], p. 30] we introduce the connected sum of two oriented knots as follows:

**Definition.**

1. Let $K$ and $L$ be two oriented knots in $S^3$. We pick a $K$-admissible map $\varphi: \overline{B}_2^3 \to S^3$ and we pick an $L$-anti-admissible map $\psi: \overline{B}_2^3 \to S^3$. We perform the connected sum

---

494: Note that here we deliberately restrict ourselves from balls of radius 2 to balls of radius 1.
sum \( (S^3 \# S^3, K \# L) \) and we use the explicit orientation-preserving diffeomorphism 
\( S^3 \# S^3 \to S^3 \) from Lemma 8.37 to view \( K \# L \) as an oriented knot in \( S^3 \).

(2) We say a knot \( K \) is prime if it is not smoothly isotopic to the connected sum of two 
non-trivial knots.

Examples.

(1) In Figure 507 we show the connected sum of the trefoil \( K \) and the figure-8 knot \( L \). 
Admittedly it can take a minute to connect the picture to the actual definition. Just 
for fun we also show meridians of \( K \), \( L \) and \( K \# L \).

(2) In Figure 508 we show the trefoil and its “mirror image” \( K^{\text{mir}} \), i.e. the reflection of 
\( K \) in the \( xy \)-hyperplane. The connected sum \( K \# K \) is called the square knot and 
the connected sum \( K \# K^{\text{mir}} \) is called the granny knot. It is notoriously tricky to 
distinguish the square knot and the granny knot, even up to taking “mirror images”.

Proposition 27.13. On the set of smooth isotopy classes of oriented knots the connected 
sum operation is well-defined and commutative.

Sketch of proof. First note that it follows almost immediately from the Isotopy Ex-
tension Theorem 8.27 together with Proposition 27.12 that the connected sum operation 
is indeed well-defined.\(^{495}\) A slight variation on the proof of Proposition 8.35 (5) shows that 
the connected sum of knots is commutative.

But now let us return to our main hobby these days, namely the calculation of funda-
mental groups. We have the following proposition.

\(^{495}\)Note though that the statement does not follow just from Proposition 27.12 since we claim that 
\( K \# L \) is well-defined up to isotopy in \( S^3 \). This is a priori not the same statement as saying that the oriented 
diffeomorphism type of \( (S^3 \# S^3, K \# L) \) is well-defined.
**Proposition 27.14.** Let \( K \) and \( L \) be two oriented knots in \( S^3 \). We pick meridians \( \mu_K \) and \( \mu_L \) and base points \( x_0 \in \mu_K \) and \( y_0 \in \mu_L \). There exists an isomorphism

\[
\pi_1(S^3 \setminus (K \# L)) \cong \pi_1(S^3 \setminus K, x_0) \ast_{\langle \mu_K \rangle = \langle \mu_L \rangle} \pi_1(S^3 \setminus L, y_0).
\]

given by making the identification \( \mu_K = \mu_L \).

**Sketch of proof.** To preserve our sanity we only provide a sketch of the proof. We pick a \( K \)-admissible map \( \varphi: B^3_2 \to S^3 \) and we pick an \( L \)-anti-admissible map \( \psi: B^3_2 \to S^3 \). We write \( D^3_+ := S^3 \setminus \varphi(B^3), \ D^3_- := \varphi(B^3) \) and \( K_+ := D^3_+ \cap K \). Similarly we write \( E^3_+ := S^3 \setminus \psi(B^3), \ E^3_- := \psi(B^3) \) and \( L_+ := E^3_+ \cap K \). Since all meridians are equivalent we can arrange that \( \mu_K \subset \varphi(S^2) \) and that \( \mu_L \subset \psi(S^2) \).

Now we consider the following diagram

\[
\pi_1(S^3 \setminus K \# L) \cong \pi_1(S^3 \# S^3 \setminus K \# L) \cong \pi_1(S^3 \setminus K) \ast_{\langle \mu_K \rangle = \langle \mu_L \rangle} \pi_1(S^3 \setminus L).
\]

Here the vertical maps are isomorphisms by another two applications of the Seifert–van Kampen Theorem 22.2, applied this time to \( S^3 \setminus K = (D^3_+ \setminus K_+) \cup (D^3_- \setminus K_-) \) and to \( S^3 \setminus L = (E^3_+ \setminus L_+) \cup (E^3_- \setminus L_-) \). Note that here we secretly use Lemma 21.22 (3) twice. ■

![Figure 509. Illustration for the proof of Proposition 27.14](image)

**Remark.** In Section 70.7 we will introduce the “internal connected sum” of two oriented submanifolds. In particular we will introduce the “internal connected sum” of two oriented knots which, for most intents and purposes agrees with the connected sum of two oriented knots.

In Exercise 27.6 we will prove the following corollary to Proposition 27.14.

**Corollary 27.15.** Let \( K \) and \( L \) be oriented knots. The fundamental groups of \( S^3 \setminus (K \# L) \) and \( S^3 \setminus (K \# L^* \) are isomorphic.

In particular we see that the square knot and the granny knot cannot be distinguished by the fundamental group of their complements. On the other hand we will see in Exercise ?? that the granny knot is neither smoothly isotopic to the square knot nor to its mirror image. In particular we see that in general the answer to Question 27.10 is negative.

---

496 Readers who go through the proof with a fine logical comb will notice that the last sentence requires some extra thought.
Fortunately the following deep theorem shows that the situation is much better once we restrict to prime knots. Namely, under this extra hypothesis we actually do get a positive answer to Question 27.10.

**Theorem 27.16. (Whitten Theorem)** Let $K$ and $L$ be two prime knots in $\mathbb{R}^3 \subset \mathbb{R}^3 \cup \{\infty\} = S^3$. If $\pi_1(S^3 \setminus K)$ is isomorphic to $\pi_1(S^3 \setminus L)$, then $K$ is smoothly isotopic to $L$ or to its mirror image $L^*$. 

**Proof.** Let $K$ and $L$ be two prime knots such that the fundamental groups $\pi_1(S^3 \setminus K)$ and $\pi_1(S^3 \setminus L)$ are isomorphic. Wilbur Whitten [Whi87, Corollary 2.1], building on the Gordon-Luecke Theorem [8.46], showed that there exists a diffeomorphism $F: S^3 \to S^3$ with $F(K) = L$. By possibly composing $F$ with the reflection in a hyperplane we see that there exists an orientation-preserving diffeomorphism $F: S^3 \to S^3$ with $F(K) = L$ or with $F(K) = L^*$. The claimed statement now follows from Corollary [8.45].

### 27.5. Knot diagrams.

In the previous section we gave a completely rigorous calculation of the isomorphism type of the fundamental group of the complement of a trefoil and we used this to show that the trefoil is not smoothly isotopic to the trivial knot. In the next section we will give a practical algorithm for determining the isomorphism type of the fundamental group of the complement of a given knot. The key to formulating the algorithm is the notion of a knot diagram that we will study in this section.

Before we start with knot theory we introduce one bit of notation.

**Notation.** Given a smooth map $f: S^1 \to \mathbb{R}^n$ and $z = e^{is} \in S^1$ we write

$$f'(z) := \text{derivative at the point } s \text{ of the function } \mathbb{R} \to \mathbb{R}^n \text{ given by } t \mapsto f(e^{it})$$

**Definition.** A map $\gamma: S^1 \to \mathbb{R}^2$ is called diagrammatic if the following conditions are satisfied:

(a) the map is an immersion,

(b) if $z \neq w \in S^1$ satisfy $\gamma(z) = \gamma(w)$, then $\gamma'(z)$ and $\gamma'(w)$ are linearly independent,

(c) given any $P \in \gamma(S^1)$ the preimage $\gamma^{-1}(P)$ consists of either one or two points.

Furthermore any $z \in S^1$ for which there exists a $w \neq z \in S^1$ with $\gamma(z) = \gamma(w)$ is called a double point of $\gamma$. The definitions are illustrated in Figure 510.

![diagram](diagram.png)

**Lemma 27.17.** Every diagrammatic map has only finitely many double points.

**Exercise 27.4.** The following lemma will be proved in Exercise 27.4.
Definition.
(1) A knot diagram is a diagrammatic map $\gamma: S^1 \to \mathbb{R}^2$ together with a map
$$c: \{\text{double points of } \gamma\} \to \{\pm 1\}$$
which has the property that for $z \neq w \in S^1$ with $\gamma(z) = \gamma(w)$ we have $c(z) \neq c(w)$.
(2) Let $(\gamma, c)$ be a knot diagram. Let $z$ be a double point. If $c(z) = +1$, then we say
that the double point is an overcrossing, otherwise we call it an undercrossing.

The next lemma shows that knot diagrams give rise to knots.

Lemma 27.18. Let $(\gamma: S^1 \to \mathbb{R}^2, c)$ be a knot diagram. We can pick disjoint compact segments $I_1, \ldots, I_k$ of $S^1$ and a smooth function $\eta: S^1 \to [-1, 0]$ with the following properties:

(a) Each segment contains a unique undercrossing and each undercrossing is contained
in some segment.
(b) No segment contains an overcrossing.
(c) The value of $\eta$ outside the segments is equal to 0.
(d) On each segment the function has a unique local minimum, namely at the corre-
    sponding undercrossing where the value of $\eta$ is equal to $-1$.

The following two statements hold:
(1) The image of $S^1$ under the map $S^1 \to \mathbb{R}^3$ given by $z \mapsto (\gamma(z), \eta(z))$ is a knot.
(2) Any two choices of segments and $\eta$ as above give rise to smoothly isotopic knots.

If we equip $S^1$ with the standard orientation, then in the above statements we can also
replace “knot” by “oriented knot”.

Lemma 27.18 shows that a knot diagram gives rise to an essentially unique (oriented)
knot. We refer to this knot as the knot associated to the knot diagram. At times we will
rather blur the difference between a knot diagram and the associated knot.

Example. In Figure 511 we show to the left a knot diagram. To the right we show the
associated knot. It is pretty clear that the resulting knot is smoothly isotopic to the trefoil.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{knot_diagram_figure.png}
\caption{Knot diagram and associated knot}
\end{figure}

Proof. It follows quite easily from Lemma 6.13 that such segments $I_1, \ldots, I_k$ and that
such a function $\eta$ exist. Given such a function it is clear that the map $z \mapsto (\gamma(z), \eta(z))$
is injective. Since $\gamma$ is an immersion it follows that the map $z \mapsto (\gamma(z), \eta(z))$ is in fact
a smooth embedding. Thus it follows from Proposition 8.1 (1) that the image is a one-dimensional submanifold of $\mathbb{R}^3 \cup \{\infty\} = S^3$ that is diffeomorphic to $S^1$. In other words, the image is a knot.

Finally suppose we are given functions $\eta$ and $\eta'$ with the properties stated as above. We consider the map

$$H : S^1 \times [0,1] \to \mathbb{R}^3 \cup \{\infty\} = S^3$$

$$(z,t) \mapsto (\gamma(z), \eta(z) \cdot (1-t) + \eta'(z) \cdot t).$$

This map is smooth. By construction we know that for any two distinct points $z, w \in S^1$ with $\gamma(z) = \gamma(w)$ we have $\eta(z) < \eta(w)$ if and only if $c(z) = -1$ if and only if $\eta'(z) < \eta'(w)$. Using this observation one can easily verify that each $H_t$ is a smooth embedding. In other words, the map $H_t$ is a smooth isotopy between the two (oriented) knots corresponding to $\eta$ and $\eta'$.

In practice, i.e. in future examples, we do what every other sane topologist does, namely we draw a suggestive picture and we interpret it as a knot diagram and a corresponding knot in the obvious way. For example in Figure 512 we show the first knots in the standard table of knots. We refer to the standard textbooks on knot theory [Rolff90, BZH14] for a continuation of the table. But it should already be pretty clear from this table that knots form a straightforward way to produce an almost endless list of interesting topological problems.

![Figure 512](image_url)

In Lemma 27.18 we saw that any knot diagram gives rise to a knot. The following proposition gives us the converse:

**Proposition 27.19.** Given any knot $K \subset S^3$ there exists a knot diagram such that $K$ is smoothly isotopic to the knot associated to the knot diagram.

The proof of Proposition 27.19 mostly rests on the next lemma. The formulation of this lemma requires the following notation.
Notation. Given $v \in S^2$ we denote by

$$
\pi_v \colon \mathbb{R}^3 \rightarrow v^\perp := \{ w \in \mathbb{R}^3 \mid \langle v, w \rangle = 0 \}
$$

the projection onto the orthogonal complement of $v$.

Now we can formulate the lemma.

**Lemma 27.20.** Let $K \subset \mathbb{R}^3$ be a knot. We pick a diffeomorphism $f \colon S^1 \rightarrow K$. We consider the following three properties of a vector $v \in S^2$:

(a) the map $\pi_v \circ f \colon S^1 \rightarrow v^\perp = \{ w \in \mathbb{R}^3 \mid \langle v, w \rangle = 0 \}$ is an immersion,

(b) whenever $z \neq w \in S^1$ satisfy $(\pi_v \circ f)(z) = (\pi_v \circ f)(w)$, then $(\pi_v \circ f)'(z)$ and $(\pi_v \circ f)'(w)$ are linearly independent,

(c) for every $P \in (\pi_v \circ f)(S^1)$ the preimage $(\pi_v \circ f)^{-1}(P)$ consists of either one or two points.

The set

$$
\{ v \in S^2 \mid v \text{ satisfies (a), (b) and (c)} \}
$$

has full measure in $S^2$.

**Remark.** In Proposition 6.62 (2) we showed that a subset of full measure is dense. The chronically bored reader can try to show that the set $\{ v \in S^2 \mid v \text{ satisfies (a), (b) and (c)} \}$ considered in Lemma 27.20 is open.

**Proof.** Let $K \subset \mathbb{R}^3$ be a knot. We pick a diffeomorphism $f \colon S^1 \rightarrow K$. We say that a subset of a smooth manifold $W$ is *large* if it is open and if it has full measure in $W$. It follows from Proposition 6.62 (5b) that the intersection of two large subsets is again large. Furthermore, it follows from Proposition 6.62 (1) that any self-diffeomorphism of $S^2$ sends large sets to large sets.

It is convenient to consider an extra property of vectors in $S^2$ which is somewhat weaker than the above property (c):

(c’) given any $P \in (\pi_v \circ f)(S^1)$ the preimage $(\pi_v \circ f)^{-1}(P)$ consists of finitely many points.

We write

$$
V(a) := \{ v \in S^2 \mid v \text{ satisfies (a)} \}.
$$

Similarly we define $V(b), V(c), V(a, b), V(a, b, c')$ and so on. Note that with this language we need to show that $V(a, b, c)$ has full measure.

Let $v \in S^2$. We start out with three elementary observations regarding the projection maps $\pi_v$.

(1) Given $u \in \mathbb{R}^3 \setminus \{0\}$ we have

$$
\pi_v(u) = 0 \iff u \in \mathbb{R} \cdot v \iff \frac{u}{\|u\|} \in \{ v, -v \}.
$$

(2) The projection map $\pi_v$ is linear, hence for any $P \in \mathbb{R}^3$ we have $(D \pi_v)_P = \pi_v$.

(3) It follows from (2) and the chain rule that given any $z \in S^1$ we have the equality

$$(\pi_v \circ f)'(z) = \pi_v(f'(z)).$$

\[^{497}\text{We refer to page 316 for the definition of a subset of full measure.}\]
Next we consider the three maps
\[ \varphi: S^1 \to S^2 \quad \psi: \{(z, w) \in S^1 \times S^1 \mid z \neq w\} \to S^2 \quad \rho: S^2 \to S^2 \]
\[ z \mapsto \frac{f'(z)}{\|f'(z)\|} \quad (z, w) \mapsto \frac{f(z) - f(w)}{\|f(z) - f(w)\|} \quad v \mapsto -v. \]

We make the following observations:

(4) If \( X \) is a subset of full measure (respectively large subset) of \( S^2 \), then it follows from the above discussion that \( X \cap \rho(X) \) is also a subset of full measure (respectively large).

(5) Since \( f \) is smooth we see that the map \( \varphi \) is also smooth.

(6) Given \( v \in S^2 \) it follows easily from (1) and (3) that \( \pi_v \circ f: S^1 \to \mathbb{R}^2 \) is an immersion if and only if neither \( v \) nor \(-v\) lies in \( \varphi(S^1) \). In other words, we have the equality \( V(a) = (S^2 \setminus \varphi(S^1)) \cap \rho(S^2 \setminus \varphi(S^1)) \).

(7) Note that \( M = \{(z, w) \in S^1 \times S^1 \mid z \neq w\} \) is an open subset of the smooth manifold \( S^1 \times S^1 \), thus it is a smooth manifold in an obvious way. With this smooth manifold structure the map \( \psi: M \to S^2 \) is easily seen to be smooth.

(8) For each \((x, y) \in S^1\) we make the identification \( T_{(x, y)} S^1 = \mathbb{R} \) via the basis vector \((-y, x)\). Given \((z, w) \in M\) we use the above identification to make the identification \( T_{(z, w)} M = T_{(z, w)} (S^1 \times S^1) = \mathbb{R}^2 \). Furthermore given \( v \in S^2 \) we already saw on page 293 that we have the equality \( T_v S^2 = v^\perp = \{w \in \mathbb{R}^3 \mid \langle v, w \rangle = 0\} \subset \mathbb{R}^3 \).

(9) Using the identifications from (8) an elementary calculation shows that for a point \((z, w) \in M\) we can write the differential \( D\psi_{(z, w)} \), viewed as a homomorphism \( T_{(z, w)} M = \mathbb{R}^2 \to T_{\psi_{(z, w)}} S^2 \subset \mathbb{R}^3 \), in the following way as a \((3 \times 2)\)-matrix:
\[ D\psi_{(z, w)} = \frac{1}{\|f(z) - f(w)\|} \begin{pmatrix} \pi_{\psi_{(z, w)}}(f'(z)) & -\pi_{\psi_{(z, w)}}(f'(w)) \end{pmatrix}. \]

(10) It follows from (9) that \((z, w) \in M\) is a regular point of \( \psi \) if and only if the vectors \( \pi_{\psi_{(z, w)}}(f'(z)) \) and \( \pi_{\psi_{(z, w)}}(f'(w)) \) are linearly independent.

(11) Let \( v \in S^2 \). It follows immediately from (1) and the linearity of \( \pi_v \) that we have \( \pi_v(f(z)) = \pi_v(f(w)) \) if and only if \( \psi(z, w) = v \) or \( \psi(z, w) = -v \).

---

498 Since \( f \) is an immersion we see that the map \( \varphi \) is well-defined, i.e. we do not divide by zero. Similarly, since \( f \) is in particular injective we see that the map \( \psi \) is well-defined, i.e. once again we do not divide by zero.

499 The astute reader will notice that throughout the argument it might be more reasonable to work with maps \( \varphi \) and \( \psi \) that take values in \( \mathbb{RP}^2 = S^2 / \sim \sim - \sim \) instead of taking values in \( S^2 \). We stick with the maps to \( S^2 \) since \( S^2 \) has the advantage that its tangent spaces can be described easily as vector subspaces of \( \mathbb{R}^3 \), which makes it easy to write down differentials. Also, the approach of working with maps to \( \mathbb{RP}^2 \) instead creates an extra layer of notation which is as annoying as our notation which requires the extra map \( \rho \).

500 As on many other occasions we use Proposition 6.39 to view the tangent space of a submanifold of some \( \mathbb{R}^n \) as a vector subspace of \( \mathbb{R}^n \).

501 This calculation can be performed easily using the chain rule and by writing \( \psi \) as the composition of the map \((z, w) \mapsto f(z) - f(w)\) followed by the map \( P \mapsto \frac{P}{\|P\|} \).
We denote by $\sigma: S^1 \times S^1$ the diffeomorphism given by $(z, w) \mapsto (w, z)$. It follows immediately from the definitions that $\psi \circ \sigma = \rho \circ \psi$.

(13) It follows easily from (3), (10), (11) and (12) that

$$V(b) = \{\text{regular values of } \psi\}.$$

After these initial remarks we turn to our first claim.

Claim.

(a) The sets $V(a)$ and $V(a, b)$ are large.

(\beta) We have $V(a) = V(a, c')$ and $V(a, b) = V(a, b, c')$.

We prove the two statements of the claim in several steps.

(i) Since $S^1$ is compact we obtain from Lemma 2.40 and Lemma 2.17 that $S^2 \setminus \varphi(S^1)$ is an open subset of $S^2$. Furthermore, since $\varphi$ is smooth and since $\dim(S^1) < \dim(S^2)$ we obtain from Proposition 6.62 (5) that $S^2 \setminus \varphi(S^1)$ is a subset of full measure. In summary, we have shown that $S^2 \setminus \varphi(S^1)$ is large. It follows from (5) and (6) that $V(a) = (S^2 \setminus \varphi(S^1)) \cap \rho(S^2 \setminus (\varphi(S^1)))$ is large.

(ii) It follows from Sard’s Theorem 6.63 that the set of regular values of $\psi$ is a subset of full measure. It follows from (i) and (13), together with Proposition 6.62 (1) that $V(a, b) = V(a) \cap V(b)$ has full measure.

(iii) Let $v \in V(a)$. It follows from (11), from the fact that $S^1$ is compact and from Exercise 8.3 that $\psi^{-1}(v)$ is finite. In particular we see that $V(a, c') = V(a)$ and thus also $V(a, b, c') = V(a, b)$.

(iv) It remains to show that $V(a, b)$ is open. Let $v \in V(a, b) = V(a) \cap V(b)$. From (13) and (iii), together with Exercise 6.29 (2), we obtain an open neighborhood $U$ of $v \in S^2$ that is still contained in $V(b)$. Since $V(a)$ is open we see that $U \cap V(a)$ is an open neighborhood of $v \in S^2$ that is still contained in $V(a, b)$. It follows from Lemma 2.5 that $V(a, b)$ is indeed open.

Before we continue it is perhaps helpful to summarize what we have shown so far: In the claim we have seen that $V(a, b, c') = V(a, b)$ is large, in particular that it has full measure. But our actual goal is to show that $V(a, b, c)$ has full measure.

To do so we consider the map

$$\Xi: \{(x, y, z) \in S^1 \times S^1 \times S^1 \mid x \neq y \text{ and } x \neq z\} \rightarrow S^2 \times S^2,$$

$$(x, y, z) \mapsto (\psi(x, y), \psi(x, z)).$$

We make the following simple observations:

(14) We view $N$ as a smooth manifold in an obvious way. Evidently the map $\Xi$ is smooth.

(15) It follows easily from (1) that we have $v \in V(c)$ if and only if none of the four vectors $(\pm v, \pm v)$ lies in $\Xi(N)$.

(16) If one of the four vectors $(\pm v, \pm v)$ lies in $\Xi(N)$, then so does $(v, v)$. This can be seen as follows: If $\Xi(x, y, z) \in \{(\pm v, \pm v)\}$, then $f(x), f(y), f(z)$ lie on the line $\mathbb{R} \cdot v$. After possibly permuting $x, y, z$ we can assume that $f(x) = f(y) + r \cdot v$ and that $f(x) = f(z) + s \cdot v$ with $r, s > 0$. But with this permutation we have $\Xi(x, y, z) = (v, v)$.
Claim. We consider the “partial diagonal”
\[ \Delta := \{(v, v) \in S^2 \times S^2 \mid v \in V(a, b)\}. \]

The complement of \( \Xi(N) \cap \Delta \) has full measure in \( \Delta \).

In the previous claim we saw that \( V(a, b) \) is an open subset of \( S^2 \). Using this fact it is straightforward to see that \( \Delta \) is a 2-dimensional submanifold of \( S^2 \times S^2 \). Thus, by Exercise 8.9 (b) it suffices to prove that if \( (x, y, z) \in N \) satisfies \( \Xi(x, y, z) = (v, v) \) for some \( v \in V(a, b) \), then \( \Xi \) intersects \( \Delta \) transversally, i.e. we have the equality
\[
(D \Xi(x,y,z))(T_{(x,y,z)} N) + T_{(v,v)} \Delta = T_{(v,v)}(S^2 \times S^2) \subset \mathbb{R}^3 \times \mathbb{R}^3 = \mathbb{R}^6.
\]

We write \( p = \pi_v(f'(x)) \), \( q = \pi_v(f'(y)) \) and \( r = \pi_v(f'(z)) \) and write \( \mu = \frac{1}{\|f(x) - f(y)\|} \) and \( \nu = \frac{1}{\|f(x) - f(z)\|} \). By (10) and (13), and by the fact that \( v \in V(b) \), we know that \( p, q \) and \( r \) are pairwise linearly independent. In particular \( q \) and \( r \) form a basis for \( T_v S^2 \). Note that this implies that \( \begin{pmatrix} q \\ q \end{pmatrix} \) and \( \begin{pmatrix} r \\ r \end{pmatrix} \) form a basis for \( T_{(v,v)}(S^2 \times S^2) \). Thus, using (9) we see that
\[
(D \Xi(x,y,z))(T_{(x,y,z)} N) + T_{(v,v)} \Delta = \text{span of the columns of } \begin{pmatrix} \mu \cdot p & -\nu \cdot q & 0 & q & r \\ \nu \cdot p & 0 & -\nu \cdot r & q & r \end{pmatrix}.
\]

Using that \( p, q \) and \( r \) are pairwise linearly independent it is not hard to see that the five columns of the matrix on the right span a 4-dimensional subspace of \( \mathbb{R}^6 \). Since this subspace is contained in the 4-dimensional subspace \( T_{(v,v)}(S^2 \times S^2) \) we see that it equals \( T_{(v,v)}(S^2 \times S^2) \).

We consider the “diagonal map” \( d: V(a, b) \to \Delta \subset S^2 \times S^2 \) that is given by \( d(v) = (v, v) \). One can easily show that \( d: V(a, b) \to \Delta \) is a diffeomorphism. It follows from (16) that \( V(a, b, c) = d^{-1}(\Delta \setminus \Xi(N)) \). By the claim \( \Delta \setminus \Xi(N) \) is a subset of full measure of \( \Delta \). Since \( d \) is a diffeomorphism we obtain from Proposition 6.62 (5b) that \( V(a, b, c) = d^{-1}(\Delta \setminus \Xi(N)) \) has full measure in \( V(a, b) \). We saw above that \( V(a, b) \) has full measure in \( S^2 \). It follows easily from Proposition 6.62 (5a) that \( \Delta \setminus \Xi(N) \) has full measure in \( S^2 \).

Now we can provide the proof of Proposition 27.19.

Proof of Proposition 27.19. Let \( K \subset S^3 = \mathbb{R}^3 \cup \{\infty\} \) be a knot. As we saw in Exercise 8.30 (a), it follows easily from Lemma 3.32 (4) and Lemma 8.5 (2) that, possibly after applying a smooth isotopy, we can assume that \( K \subset \mathbb{R}^3 \).

Next we pick \( v \in S^2 \) as in Lemma 27.20. It follows from Lemma 3.32 (4) and Lemma 8.5 (2) that, possibly after applying a smooth isotopy, we can assume that \( v = e_3 \). We define \( \gamma := \pi_{e_3} \circ f: S^1 \to \mathbb{R}^2 \times \{0\} = \mathbb{R}^2 \). It follows immediately from the fact that \( v = e_3 \) has the three properties (a), (b) and (c) stated in Lemma 27.20 that \( \gamma \) is diagrammatic. Next we consider the function
\[
\epsilon: S^1 \to \mathbb{R} \\
w \mapsto z\text{-coordinate of } f(w).
\]
Furthermore, given \( z_1 \neq z_2 \in S^1 \) with \( \gamma(z_1) = \gamma(z_2) \) we define
\[
c(z_i) := \begin{cases} 
+1, & \text{if } \epsilon(z_i) > \epsilon(z_{3-i}), \\
-1, & \text{if } \epsilon(z_i) < \epsilon(z_{3-i}).
\end{cases}
\]

It is clear that \((\gamma, c)\) is a knot diagram. We pick a function \( \eta: S^1 \to [-1, 0] \) as in Lemma 27.18. We consider the map
\[
H: S^1 \times [0, 1] \to \mathbb{R}^3, \quad (z, t) \mapsto (\gamma(z), (1-t) \cdot \epsilon(t) + t \cdot \eta(t)).
\]
Clearly this map is smooth. Given any \( z, w \in S^1 \) with \( \gamma(z) = \gamma(w) \) we have \( \eta(z) < \eta(w) \) if and only if \( c(z) = -1 \) if and only if \( \eta(z) < \eta(w) \). From this observation we deduce that each \( H_t \) is actually a smooth embedding. Thus we see that \( H \) is a smooth isotopy from \( K \) to the knot associated to the knot diagram \((\gamma, \eta)\).

We have now seen that every knot, up to smooth isotopy, arises from a knot diagram. The question arises, when do two knot diagrams give rise to smoothly isotopic knots. The following theorem gives a complete answer. We formulate the theorem in a slightly informal way since we will not make use of it.

**Theorem 27.21.** Two knot diagrams give rise to smoothly isotopic knots if and only if the two diagrams are related by a finite sequence of smooth isotopies of \( \mathbb{R}^2 \) and Reidemeister moves. The three Reidemeister moves are illustrated in Figure 513.

**Proof.** The theorem, not surprisingly, goes back to work of Kurt Reidemeister [Rei32] Chapter 3 in 1932. The formulation and proof in [Rei32] is in terms of “polygonal knots”. The statement of the theorem is well known in our setting, where knots are defined as submanifolds of \( S^3 \) and it appears in any textbook on knot theory. A satisfactory proof can be found in [OSS15, Theorem B.1.1].

![Figure 513](image)

**Remark.** Throughout these lecture notes we will see on several occasions that the tools of algebraic topology, e.g. fundamental groups, linking pairings and Reidemeister torsion can be used fruitfully to study knots. Proposition 27.19 and Theorem 27.21 open up an alternative route to studying knots. More precisely, these two results show that there exists a bijection

\[
\text{knot diagrams up to smooth isotopy } \xrightarrow{\sim} \text{knots up to smooth isotopy}
\]

This bijection lies at the heart of the definition of several knot invariants, like the Jones polynomial [Jon85] that was introduced in 1984 and the HOMFLY-PT polynomial [FYHLMO85].
that was discovered in 1985. These polynomial invariants are quite different from any of the invariants that are obtained through algebraic-topological methods. We refer to [Lic97a, Chapters 3 and 15] and [BZH14, Chapter 17] for more information on these invariants.

27.6. The Wirtinger presentation. In the previous section we saw that we can associate a knot diagram to any given knot. In this section we will see that we give an explicit algorithm that, given a knot diagram, produces a presentation for the fundamental group of the complement $S^3 \setminus K$ of a knot $K$.

In this section we will take several liberties and we will not attempt to give full details in the proofs. The issue is that any attempt to make the proofs completely rigorous renders them totally unreadable.

Before we can state the promised algorithm we need to introduce a few more definitions.

Definition. Let $K \subset \mathbb{R}^3$ be an oriented knot that is associated to some knot diagram $(f: S^1 \to \mathbb{R}^2, c)$.

1. We refer to the images of the double points as the crossings of $K$.
2. Let $x \in f(S^1)$ be a crossing. Let $z, w \in S^1$ with $f(z) = f(w) = x$ and such that $z$ is an undercrossing and $w$ is an overcrossing. We say $x$ is a positive crossing if the ordered basis $\{f'(w), f'(z)\}$ is a positive basis for $\mathbb{R}^2$. Otherwise we say that $x$ is a negative crossing.
3. We refer to the components of $K \cap (\mathbb{R}^2 \times \{0\})$ as the strands of $K$.

These definitions are illustrated in Figures 514 and 515.

Remark. In a picture of a diagram the strands are understood to correspond precisely to the segments drawn.

The following lemma will be proved in Exercise 27.8.

Lemma 27.22. If a knot diagram has at least one crossing, then the number of crossings equals the number of strands.
The following proposition shows how to determine the fundamental group of a knot that is associated to a knot diagram. We will sacrifice some rigor in the formulation in an attempt to make it more readable. We leave it to the reader to make the proposition totally rigorous.

**Proposition 27.23.** Let $K$ be a knot that is associated to a given knot diagram that has at least one crossing. We enumerate the strands cyclically by $x_1, \ldots, x_n$ where we make the identifications $x_0 = x_n$ and $x_{n+1} = x_1$. For the crossing between the strands $x_j$ and $x_{j+1}$ we define a relation $r_j$ as shown in Figure 516. Then we have an isomorphism

$$
\pi_1(S^3 \setminus K) \cong \langle x_1, \ldots, x_n \mid r_1, \ldots, r_n \rangle.
$$

Furthermore we can drop any one of the relations and we still obtain an isomorphism.

**Remark.** Given a knot $K$, any presentation with $n$ generators and $n - 1$ relators as obtained from Proposition 27.23 is called a Wirtinger presentation of $\pi_1(S^3 \setminus K)$.

In the following we first explain why Proposition 27.23 is plausible. Afterwards we will provide the technical proof of Proposition 27.23.

"Plausibility argument for Proposition 27.23". Suppose we are given a knot diagram that has $n$ crossings. We denote by $K$ the corresponding knot. We work with the base point $* = (0, 0, 2) \in \mathbb{R}^3$ which lies "above" the knot $K$. We enumerate the strands cyclically. For the $j$-th strand we denote by $x_j$ the oriented triangle that starts at $*$ and "circles once around the $j$-th strand" according to the "right-hand rule". We illustrate the definition in Figure 517.

Next we consider the situation at a positive crossing. By "sliding" various $x_j$ along the strands and by some further path-homotopies we can assume that we are in the situation in Figure 518 on the left. If one follows the loop $x_k \cdot x_{j+1} \cdot x_k^{-1} \cdot x_j^{-1}$ on its journey one...
realizes that on three occasions one goes back and forth to the base point. Thus the loop is actually path-homotopic to the loop shown in Figure 518 on the right. But that loop is clearly null-homotopic. Almost the same logic applies to negative crossings.

\[ x_k \ast x_{j+1} \ast \overline{x_k} \ast \overline{x_j} \]

is path-homotopic to this loop

but this loop is clearly null-homotopic

**Figure 518**

This discussion, together with Lemmas 19.14 and 21.4 shows that there exists a unique group homomorphism

\[ \langle x_1, \ldots, x_n \mid \text{relations corresponding to crossings} \rangle \to \pi_1(S^3 \setminus K, \ast) \]

with

\[ x_i \mapsto [x_i]. \]

It remains to show that this group homomorphism is in fact an isomorphism. We will do so next in the proper proof of Proposition 27.23.

**Sketch of a proof for Proposition 27.23.** Suppose once again that we are given a knot diagram \((\gamma: S^1 \to \mathbb{R}^2, c)\) that has \(n \geq 1\) crossings. We denote by \(P_1, \ldots, P_n\) the double points of \(\gamma\). We pick a smooth function \(\eta: S^1 \to [-1, 0]\) as in the statement of Lemma 27.18. We denote by \(K\) the image of the map \(S^1 \to \mathbb{R}^3\) given by \(z \mapsto (\gamma(z), \eta(z))\). It follows from property (d) of Lemma 27.18 that

\[ K \cap (\mathbb{R}^2 \times \mathbb{R}_{\leq -1}) = K \cap (\mathbb{R}^2 \times \{-1\}) = \{(P_1, -1), \ldots, (P_n, -1)\}. \]

In contrast to the above plausibility argument we now actually work with the base point \(\infty \in S^3 = \mathbb{R}^3 \cup \{\infty\}\). We set

\[ A := \{(x, y, z) \in \mathbb{R}^3 \mid z \geq -1\} \cup \{\infty\} \setminus K, \]

and

\[ B := \{(x, y, z) \in \mathbb{R}^3 \mid z \leq -1\} \cup \{\infty\} \setminus K. \]

We start out with the following claim.

**Claim 1.** The inclusion maps induce an isomorphism

\[ \pi_1(A, \infty) \ast_{\pi_1(A \cap B, \infty)} \pi_1(B, \infty) \cong \pi_1(S^3 \setminus K). \]

Evidently the statement of the claim smells like it should be a consequence of the Seifert–van Kampen 22.1. The problem is that \(A\) and \(B\) are not open subsets of \(S^3 \setminus K\).
We rectify this problem by replacing \( A \) and \( B \) by suitable open subsets. We define
\[
U := A \cup (\mathbb{R}^2 \setminus \{P_1, \ldots, P_n\}) \times (-2, -1)
\]
and
\[
V := B \cup (\mathbb{R}^2 \setminus \gamma(S^1)) \times [-1, 0)
\]
\[
\cup \{(z, t) \mid \text{there exists } w \in S^1 \text{ with } z = \gamma(w) \text{ and } t \in [-1, \eta(z)]\}.
\]
One can easily verify that \( U \) and \( V \) are open subsets of \( S^3 \setminus K \). Furthermore the “obvious retractions” of the blue sets to the corresponding subsets of \( \mathbb{R}^2 \times \{-1\} \) show that \( A \) is a deformation retract of \( U \), that \( B \) is a deformation retract of \( V \) and that \( A \cap B \) is a deformation retract of \( U \cap V \). Now we see that the inclusion maps induce isomorphisms
\[
\pi_1(S^3 \setminus K) \xrightarrow{\cong} \pi_1(U, \infty) *_{\pi_1(U \cap V, \infty)} \pi_1(V, \infty) \xrightarrow{\cong} \pi_1(A, \infty) *_{\pi_1(A \cap B, \infty)} \pi_1(B, \infty).
\]
by the Seifert–van Kampen Theorem \( \PageIndex{22} \) and Proposition \( \PageIndex{18} \) (2).

Our next goal is to understand the groups \( \pi_1(A, \infty) \), \( \pi_1(B, \infty) \) and \( \pi_1(A \cap B, \infty) \). We handle these three groups consecutively. To better understand \( \pi_1(A, \infty) \) we introduce the following objects.

1. As in the plausibility argument we set \( * = (0, 0, 2) \). We fix once and for all a path-connecting \( * \) to \( \infty \).
2. We write \( D := \{(\gamma(z), w) \mid z \in S^1 \text{ and } w \in [-1, \eta(z)]\} \).
3. We cyclically enumerate the strands of the knot.
4. For \( j \in \{1, \ldots, n\} \) we denote by \( D_j \) the unique component of \( D \) that contains the \( j \)-th strand in its closure.
5. For \( j = 1, \ldots, n \) we denote by \( x_j \) a loop in \( * \) that is the boundary of a triangle that intersects \( D_j \) precisely once in a positive direction. We use the path from (1) to view each \( x_j \) as a loop in \( \infty \).

Some of the above objects are illustrated on the left of Figure \( \PageIndex{519} \).

**Claim 2.** The obvious map \( \langle x_1, \ldots, x_n \rangle \to \pi_1(A, \infty) \) is an isomorphism.

Note that each \( D_j \) is contractible and hence simply connected. Furthermore one can easily show that \( A \setminus \hat{D} \) is contractible. We use Corollary \( \PageIndex{26.5} \) iteratively \( n \) times to prove the claim. We leave it to the assiduous reader to fill in the details.

Fortunately the next group \( \pi_1(B, \infty) \) on our list is easy to handle.

**Claim 3.** The group \( \pi_1(B, \infty) \) is trivial.

Using the stereographic projection from Lemma \( \PageIndex{2.44} \) and using the map defined on page \( \PageIndex{116} \) it is not hard to see that there exists a homeomorphism
\[
f: \{(x, y, z) \in \mathbb{R}^3 \mid z \leq -1\} \cup \{\infty\} \to \overline{B}^3
\]
which sends the points in \( \mathbb{R}^2 \times \{-1\} \) to \( S^2 \). Since \( K \cap (\mathbb{R}^2 \times \mathbb{R}_{\leq -1}) = \{(P_1, -1), \ldots, (P_n, -1)\} \) we see that \( B \) is homeomorphic to \( \overline{B}^3 \) with \( n \) points on its boundary removed. But this...
does not change the fact that the origin is a deformation retract. We have thus shown that 
\( f(B) \), and hence also \( B \), is contractible. But this implies by Proposition 18.16 (3) that 
\( \pi_1(B, \infty) \) is indeed trivial.

Finally we turn to the group \( \pi_1(A \cap B, \infty) \). We pick orientation-preserving smooth 
eMBEDDINGS \( \varphi_i : B^2 \to \mathbb{R}^2 \times \{-1\} \), \( i = 1, \ldots, n \) with disjoint images and such that for each 
i \( \varphi_i(0) = (P_i, -1) \). It follows almost immediately\(^{501}\) from Lemma 26.6 that we have an equality
\[
\langle z_1, \ldots, z_n | z_1 \cdots z_n \rangle = \pi_1(A \cap B, \infty)
\]
where for any \( i \in \{1, \ldots, n\} \) the element \( z_i \) is represented by a curve of the form \( \alpha_i \ast \gamma_i \ast \overline{\alpha}_i \)
where \( \alpha_i \) is a suitable path from \( \infty \) to a point on \( \varphi_i(S^1) \) and \( \gamma_i \) is a path that goes once
around \( \varphi_i(S^1) \) in an orientation-preserving way.

Now we can finally prove the desired statement. Indeed, we have
\[
\pi_1(S^3 \setminus K) \cong \pi_1(A, \infty) \ast_{\pi_1(A \cap B, \infty)} \pi_1(B, \infty) \cong \pi_1(A, \infty) / \langle \langle \pi_1(A \cap B, \infty) \rangle \rangle
\]
by Claim 1
\[
\cong \langle x_1, \ldots, x_n \rangle / \langle \langle z_1, \ldots, z_n \rangle \rangle \cong \langle x_1, \ldots, x_n \rangle / \langle \langle r_1, \ldots, r_n \rangle \rangle.
\]
by Claim 2, Lemma 21.2 (4) and the above fact that \( \{z_1, \ldots, z_n\} \) is a generating set for \( \pi_1(A \cap B, \infty) \)
the “plausibility argument shows that each \( z_i \) is conjugate to \( r_i \), thus it follows from
Lemma 21.2 (5) that \( \langle \langle z_1, \ldots, z_n \rangle \rangle = \langle \langle r_1, \ldots, r_n \rangle \rangle \).

It remains to show that we can drop any one of the relations. Thus let \( j \in \{1, \ldots, n\} \). It
follows easily from \( z_1 \cdots z_n = e \) that \( z_j \in \langle z_1, \ldots, z_{j-1}, z_{j+1}, \ldots, z_n \rangle \). Now note that by
Lemma 21.2 (4) this implies that \( \langle \langle z_1, \ldots, z_n \rangle \rangle = \langle \langle z_1, \ldots, z_{j-1}, z_{j+1}, \ldots, z_n \rangle \rangle \). Therefore we
see that in the above equality we can drop the relation \( r_j \).

As mentioned above, we continue with two examples, namely the trefoil and the figure-8
knot. First we consider the knot diagram for the trefoil \( K \) that is shown in Figure 520 to
the left. We number the strands as shown. To the right we show how the three crossings
give rise to three relations. As pointed out in Proposition 27.23 we can drop any one of the
relations.

\(^{501}\)The slightly cautious “almost” refers to the fact that we also make use of the fairly obvious fact that 
\( ((\mathbb{R}^2 \times \{-1\}) \cup \{\infty\}) \setminus \bigcup_{i=1}^n \varphi_i(B^2) \) is a deformation retract of \( A \cap B = ((\mathbb{R}^2 \times \{-1\}) \cup \{\infty\}) \setminus \{P_1, \ldots, P_n\} \).
This discussion shows that we have proved the following lemma.

**Lemma 27.24.** Let $K$ be the trefoil. There exists an isomorphism
\[ \pi_1(S^3 \setminus K) \cong \langle x_1, x_2, x_3 \mid x_3^{-1}x_2x_3x_1^{-1}, x_2^{-1}x_1x_2x_3^{-1} \rangle. \]

**Remark.** Let $K$ be the trefoil. In Proposition 27.5 we had also shown that there exists an isomorphism $\pi_1(S^3 \setminus K) \cong \langle x, y \mid x^2 = y^3 \rangle$. In particular we have now shown that the two groups $\langle x_1, x_2, x_3 \mid x_3^{-1}x_2x_3x_1^{-1}, x_2^{-1}x_1x_2x_3^{-1} \rangle$ and $\langle x, y \mid x^2 = y^3 \rangle$ are isomorphisms. In Exercise 27.9 we will give a purely algebraic proof of this statement.

The following corollary to Proposition 27.23 gives us the disappointing news that our old trick of using abelianizations of fundamental groups cannot be used to distinguish knots.

**Corollary 27.25.** Given any knot $K$ the abelianization of the group $\pi_1(S^3 \setminus K)$ is isomorphic to $\mathbb{Z}$.

**Proof.** We will prove the corollary in Exercise 27.5. Later, on page 1318 once we have introduced homology groups we will give a different, arguably more conceptual proof of the lemma.

After this sobering corollary we move on to the next example.

**Lemma 27.26.** Let $J$ be the figure-8 knot. There exists an isomorphism
\[ \pi_1(S^3 \setminus J) \cong \langle x_1, x_2, x_3, x_4 \mid x_3x_2x_3^{-1}x_1^{-1}, x_4^{-1}x_3x_4x_2^{-1}, x_1x_4x_1^{-1}x_3^{-1} \rangle. \]

**Proof.** We leave it to the reader to use the knot diagram shown in Figure 521 to prove the lemma.

---

![Knot diagram for the trefoil with three negative crossings](image1)

![Knot diagram for the figure-8 knot](image2)
On its own Lemma 27.26 is not particularly enlightening. It is initially not clear whether this group is isomorphic to $\mathbb{Z}$ or to the fundamental group of the complement of the trefoil. By Corollary 27.25 we know that there is no hope that the abelianization will tell us something interesting.

So we need a different approach. Recall that in Proposition 27.6 we used the (non-)existence of an epimorphism onto the symmetric group $S_3$ to distinguish the trefoil from the trivial knot. The idea now is to repeat this trick with a different finite group. Recall that on page 719 we introduced the dihedral groups $D_n$ which have $2n$ elements. It is encouraging that $D_3 \cong S_3$; thus we try our luck with $D_5$.

Using Lemma 21.13 and enough time on our hands we obtain the following table:

<table>
<thead>
<tr>
<th></th>
<th>trivial knot</th>
<th>trefoil</th>
<th>figure-8 knot</th>
</tr>

This table shows that we have proved the following corollary.

**Corollary 27.27.** The trivial knot, the trefoil and the figure-8 knot are pairwise not smoothly isotopic.

This approach of trying to distinguish knots by the (non-)existence of epimorphisms onto finite groups is rather ad hoc, but not without its merits. For example the following proposition is proved in [BFT15, BR20].

**Proposition 27.28.** Let $K$ be either the trivial knot, the trefoil or the figure-8 knot. Furthermore let $J$ be another knot. If for all finite groups $G$ the group $\pi_1(S^3 \setminus K)$ admits an epimorphism onto $G$ if and only if $\pi_1(S^3 \setminus J)$ does, then $J$ is smoothly isotopic to $K$ or to the mirror image of $K$, i.e. the reflection of $K$ in the xy-plane.

We conclude this section with the following question which is still open.

**Question 27.29.** Let $K$ and $J$ be two knots in $\mathbb{R}^3 \subset \mathbb{R}^3 \cup \{\infty\} = S^3$. Suppose that the finite groups onto which $\pi_1(S^3 \setminus K)$ and $\pi_1(S^3 \setminus J)$ admit epimorphisms are the same. Does this imply that $K$ and $J$ are smoothly isotopic, up to possibly taking a reflection in the xy-plane?

27.7. The Reidemeister-Schreier process. Even though Corollary 27.25 was quite disappointing, using a clever jiu-jitsu move we will see in this section that we can actually turn Corollary 27.25 to our advantage. The key to doing so is contained in the following definition and the subsequent lemma.

**Definition.** Let $\pi$ be a group and let $n \in \mathbb{N}$. We say that a subgroup $\Gamma \subset \pi$ is cocyclic of order $n$ if $\Gamma$ is a normal subgroup such that $\pi/\Gamma$ is isomorphic to $\mathbb{Z}_n$.

**Lemma 27.30.** If $\pi$ is a group whose abelianization is isomorphic to $\mathbb{Z}$, then given any $n \in \mathbb{N}$ there exists a unique subgroup that is cocyclic of order $n$. It is given by the kernel of any epimorphism $\pi \to \mathbb{Z}_n$.

The reader might ask, why we do not try our luck with $D_4$. But for reasons we cannot get into right now, given a knot $K$ and an even number $2n$ there cannot be an epimorphism $\pi_1(S^3 \setminus K) \to D_{2n}$.
Proof. Let \( \pi \) be a group whose abelianization is isomorphic to \( \mathbb{Z} \) and let \( n \in \mathbb{N} \). We denote by \( \psi: \pi \to \pi_{ab} \) the obvious projection and we pick an isomorphism \( \varphi: \pi_{ab} \cong \mathbb{Z} \). It is clear that \( (\varphi \circ \psi)^{-1}(n\mathbb{Z}) \) is a subgroup of \( \pi \) that is cyclic of order \( n \). On the other hand, suppose that \( \Gamma \) is a subgroup of \( \pi \) that is cyclic of order \( n \). We pick an isomorphism \( \theta: \pi/\Gamma \cong \mathbb{Z}_n \). It follows from Proposition 21.20 that there exists a unique epimorphism \( \alpha: \mathbb{Z} \to \mathbb{Z}_n \) such that the following diagram commutes:

\[
\begin{array}{ccc}
\pi & \xrightarrow{\psi} & \pi_{ab} \\
g \mapsto g\Gamma & \xrightarrow{\varphi} & \mathbb{Z} \\
\pi/\Gamma & \xrightarrow{\theta} & \mathbb{Z}_n.
\end{array}
\]

It follows immediately that \( \Gamma = (\varphi \circ \psi)^{-1}(n\mathbb{Z}) \).

Corollary 27.25 and Lemma 27.30 allow us to make the following definition.

**Definition.** Given a knot \( K \) and \( n \in \mathbb{N} \) we denote by \( \pi(K, n) \) the unique subgroup of \( \pi_1(S^3 \setminus K) \) that is cyclic of order \( n \).

**Example.** If \( K \) is the trivial knot, then we saw in Proposition 27.4 that we can make an identification \( \pi_1(S^3 \setminus K) = \mathbb{Z} \). It follows easily that for any \( n \in \mathbb{N} \) we have \( \pi(K, n) = n \cdot \mathbb{Z} \), in particular \( \pi(K, n) \) is isomorphic to \( \mathbb{Z} \).

We have now a new tool for trying to distinguish knots:

**Lemma 27.31.** Let \( K \) and \( J \) be two knots. If \( K \) and \( J \) are smoothly isotopic, then given any \( n \in \mathbb{N} \) the groups \( \pi(K, n) \) and \( \pi(J, n) \) are isomorphic. In particular the abelianizations of these groups are isomorphic.

The question arises, given a knot \( K \) and \( n \in \mathbb{N} \), how can we determine \( \pi(K, n) \) from a given presentation for \( \pi_1(S^3 \setminus K) \)? Fortunately the following proposition gives us an explicit algorithm. To facilitate the uptake we formulate the following proposition in a slightly informal way.

**Proposition 27.32.** Let \( \pi = \langle x_1, \ldots, x_m, t \mid r_1, \ldots, r_l \rangle \) be a group and let \( \phi: \pi \to \mathbb{Z}_n \) be an epimorphism such that \( \phi(x_1) = \cdots = \phi(x_m) = 0 \) and \( \phi(t) = 1 \). Then a presentation for the subgroup \( \ker(\phi: \pi \to \mathbb{Z}_n) \) is given by

\[
\langle y_{1,0}, \ldots, y_{1,n-1}, \ldots, y_{m,0}, \ldots, y_{m,n-1}, u \mid s_1^0, \ldots, s_1^{n-1}, \ldots, s_l^0, \ldots, s_l^{n-1} \rangle
\]

where each \( s_i^j \) is obtained as follows:

1. For \( i = 1, \ldots, l \) and \( j = 0, \ldots, n - 1 \) we write \( t^j r_i t^{-j} \) as an expression in

\[
x_1, t x_1 t^{-1}, \ldots, t^{n-1} x_1 t^{-n+1}, \ldots, x_m, t x_m t^{-1}, \ldots, t^{n-1} x_m t^{-n+1} \text{ and } t^n.
\]

2. Then we replace each term \( t^j x_i t^{-j} \) by \( y_{i,j} \) and we replace \( t^n \) by \( u \). We obtain a word in the new generators and denote it by \( s_i^j \).

The inclusion map \( \ker(\phi: \pi \to \mathbb{Z}_n) \to \pi \) is then given by sending each \( y_{i,j} \) to \( t^j x_i t^{-j} \) and by sending \( u \) to \( t^n \).
We set \( \phi \) where

Thus we see that there exists a unique epimorphism under two explicit examples.

Example. Let \( K \subset S^3 \) be the trefoil. We write \( \pi = \pi_1(S^3 \setminus K) \). In Proposition 27.5 we showed that we can make the identification \( \pi = \langle x, t \mid x^3 \cdot t^{-2} \rangle \). By Lemma 21.13

\[ \pi(K, 2) = \ker(\phi: \pi \to \mathbb{Z}_2) \]

Evidently \( \pi(K, 2) = \ker(\phi: \pi \to \mathbb{Z}_2) \). Now we will use Proposition 27.32 to find a presentation \( \langle y_0, y_1, u \mid s_0, s_1 \rangle \) for \( \ker(\phi: \pi \to \mathbb{Z}_2) \). We write

\[ t^0 r t^{-2} = x^3 \cdot t^{-2} \text{ and more interestingly } t^1 r t^{-1} = t x^3 t^{-3} = (t x t^{-1})^3 t^{-2} = (\underbrace{t x t^{-1}}_{y_i})^3 t^{-2}. \]

Thus we see that

\[ \pi(K, 2) = \ker(\phi: \pi \to \mathbb{Z}_2) = \langle y_0, y_1, u \mid y_0^3 u^{-1}, y_0^3 u^{-1} \rangle = \langle y_0, y_1 \mid y_0^3 = y_1^3 \rangle. \]

Using Proposition 21.20 we can now easily compute that the abelianization of the above group \( \pi(K, 2) = \ker(\phi: \pi \to \mathbb{Z}_2) \) is isomorphic to \( \mathbb{Z} \oplus \mathbb{Z}_3 \).

This calculation, together with Lemma 27.31 and the above discussion of the trivial knot, gives a new proof of Proposition 27.6.

The previous example was fairly straightforward since we had started out with a presentation where one generator got sent to one, and the other ones got sent to zero. Unfortunately this is not the case for Wirtinger presentations, so we will need to work somewhat harder. In the following example we consider the figure-8 knot \( K \) and we carry out the first steps needed to calculate the isomorphism type of \( \pi(K, 2) \).

Example. Let \( J \) be the figure-8 knot. In Lemma 27.26 we saw that we can make the identification

\[ \pi_1(S^3 \setminus J) = \langle y_1, y_2, y_3, y_4 \mid y_1^{-1} y_4 y_1 y_3^{-1}, y_3^{-1} y_2 y_3 y_1^{-1}, y_2^{-1} y_1 y_2 y_4^{-1} \rangle. \]

We denote by \( \phi: \pi_1(S^3 \setminus J) \to \mathbb{Z}_2 \) the epimorphism that is given by sending each \( y_i \) to 1. We set \( t := y_1 \). The goal is to replace the generators \( y_1, y_2, y_3 \) by generators \( x_1, x_2, x_3 \) which satisfy \( \phi(x_i) = 0 \). In fact we have

\[ \pi_1(S^3 \setminus J) = \langle t, y_2, y_3, y_4 \mid t^{-1} y_4 y_3^{-1}, y_3^{-1} y_2 y_3 t^{-1}, y_2^{-1} t y_2 y_4^{-1} \rangle = \langle t, y_2, y_3, y_4 \mid t^{-1} y_4 y_3^{-1}, y_3^{-1} t y_3 t^{-1} y_2 t^{-1} t y_4^{-1} \rangle \]

\[ = \langle t, x_2, x_3, x_4 \mid t^{-1} x_4 t x_3^{-1}, t^{-1} x_3^{-1} x_2 t x_3, t^{-1} x_2 t x_2 x_4^{-1} \rangle. \]

By substitution \( x_i = y_i t^{-1}, x_i^{-1} = t y_i^{-1} \), see Lemma 21.12
At this point we have a presentation to which we can apply Proposition 27.32. A heroic calculation shows that $\pi(J,2)_{ab} \cong \mathbb{Z} \oplus \mathbb{Z}_5$. Thus we obtain a new proof that the figure-8 knot and the trefoil are not smoothly isotopic.

The above procedure for distinguishing knots works fairly well in practice. For example, with enough time at one’s hand, or alternatively a convenient computer implementation, one can use the above methods to show that all the knots shown in Figure 512 are in fact pairwise different.

Nonetheless, the above approach is not overly satisfying. It would be much better to have invariants of knots that are much quicker to calculate. We will come back to this challenge at a much later point.

The above discussion, in particular Proposition 27.32 raises the following purely algebraic question.

**Question 27.33.** Let $\pi$ be a group with a given finite presentation and let $\phi: \pi \to G$ be an epimorphism onto a finite group.

1. Is the kernel $\ker(\phi: \pi \to G)$ a finitely presented group?
2. If the answer to (1) is yes, how can we determine a finite presentation for the kernel in terms of the given data?

It turns out that the answer to the first question is yes.

**Proposition 27.34.** If $\pi$ is a finitely presented group and $\phi: \pi \to G$ is an epimorphism onto a finite group, then $\ker(\phi: \pi \to G)$ is also finitely presented.

The proof of the proposition is given in most books on combinatorial group theory, see e.g. [LS77, Chapter II.4], [MKS76, Chapter 2.3] or [Bog08, Chapter 2.9]. In fact the proof is algorithmic, in particular it also gives an affirmative answer to the second question. The algorithm is called the Reidemeister-Schreier process. The general Reidemeister-Schreier process is somewhat messy to formulate. Thus we refer to the above literature for details.

**Remark.** In the proof of Proposition 27.6 we showed that the group $\langle x, t \mid x^3 \cdot t^{-2} \rangle$ admits an epimorphism $\alpha$ onto the permutation group $S_3$. In [Bog08, Example 2.9.3] the general Reidemeister-Schreier process is used to determine a presentation for the kernel of $\alpha: \langle x, t \mid x^3 \cdot t^{-2} \rangle \to S_3$.

27.8. **High-dimensional knots.** Since the study of knots in $S^3$ was so much fun, it would be a shame not to consider high-dimensional knots.

**Definition.** An $n$-dimensional knot in $S^k$ is a smooth submanifold of $S^k$ that is diffeomorphic to $S^n$. For $n = 1$ and $k = 3$ we say that such a knot is classical, when we allow any dimension then sometimes we say the knot is high-dimensional.

We start out with a boring example.

**Example.** Let $n, k \in \mathbb{N}$ with $k \geq n$. We refer to $U := \{(x,0) \in S^{n+2} \subset \mathbb{R}^{k+1} \mid x \in S^n\}$ as the trivial $n$-dimensional knot in $S^k$. 

**Definition.** We say an $n$-dimensional knot in $S^k$ is trivial if it is smoothly isotopic to the trivial $n$-dimensional knot in $S^k$. 

In Exercise 11.9 we showed, building on Proposition 11.11, that every \( n \)-dimensional knot in a sphere of dimension \( \geq 2n + 3 \) is trivial. The following theorem is a refinement of this result.

**Theorem 27.35. (Haefliger’s (Un-)knotting Theorem)**

1. Let \( n, k \in \mathbb{N} \). If \( 2k > 3(n + 1) \), then every \( n \)-dimensional knot in \( S^k \) is trivial.
2. Given any \( n \in \mathbb{N} \) there exists a \((4m-1)\)-dimensional knot in \( S^{6m} \) that is non-trivial.

**Example.** It follows immediately from Haefliger’s Unknotting Theorem 27.35 and an elementary calculation, that for any \( n \geq 2 \) every \( n \)-dimensional knot in \( S^{2n+1} \) is trivial. As we saw in Proposition 27.6, this conclusion does not hold for \( n = 1 \).

**Proof.** The first statement was proved by André Haefliger [Hae61a, p. 47] in 1961. (An alternative proof is given in [Wall16, p. 192].) Shortly afterwards André Haefliger [Hae62b] also proved the second statement.

**Remark.** In the remainder of this section we will only consider knots of codimension two, i.e. \( n \)-dimensional knots in \( S^{n+2} \). In principle one could also study embedded spheres of other codimensions. But first note that the Generalized Smooth Schönflies Theorem 50.4 implies that, at least for \( n \neq 4 \), codimension one knots in \( S^n \) are trivial. Also note that André Haefliger [Hae67, Hae62a, Hae61b, Hae62b] showed that in codimensions \( \geq 3 \) there can be knots that are non-trivial. But Eric Zeeman [Ze63c, p. 505] and John Stallings [Stal63, Corollary 9.3] showed that knots of codimension \( \geq 3 \) are “unknotted” in the “PL-category” and in the “topological category”. Thus usually topologists tend to stick to knots of codimension two. Nonetheless, we will make use of knots of larger codimension in page ??.

We continue with the following very unsurprising lemma.

**Lemma 27.36.** Let \( n \in \mathbb{N} \).

1. Let \( K \) and \( L \) be two \( n \)-dimensional knots in \( S^{n+2} \). If \( K \) and \( L \) are smoothly isotopic, then \( \pi_1(S^{n+2} \setminus K) \cong \pi_1(S^{n+2} \setminus L) \).
2. If \( K \) is a trivial \( n \)-dimensional knot in \( S^{n+2} \), then \( \pi_1(S^{n+2} \setminus K) \cong \mathbb{Z} \).

**Proof.**

1. The proof of this statement is verbatim the same as the proof of Proposition 8.43.
2. Let \( K \) be a trivial \( n \)-dimensional knot in \( S^{n+2} \). We see that

\[
\pi_1(S^{n+2} \setminus K) \cong \pi_1(S^{n+2} \setminus U) \cong \pi_1(S^1) \cong \mathbb{Z},
\]

by (1)

by Corollary 16.18

Evidently the question now is whether there exist non-trivial high-dimensional knots. Or perhaps better, the question is whether we will manage to explicitly construct such examples. The good news is, we can indeed do so.
In the following we will present a construction, which has its origins in the work of Emil Artin [Art25] and Eric Zeeman [Ze65] that turns an $n$-dimensional knot into a family of $(n + 1)$-dimensional knots. We make the following preparations:

(1) As on page 199 we make the identification $S^{n+2} = \overline{B}_+^{n+2} \cup_{S^{n+1}} \overline{B}_-^{n+2}$.
(2) By Lemma 27.1 we can make the identification $S^{n+3} = (S^1 \times \overline{B}^{n+2}) \cup_{S^1 \times S^{n+1}} (\overline{B}^2 \times S^{n+1})$.
(3) We make the identification $\mathbb{R}^{n+2} = \mathbb{C} \times \mathbb{R}^n$. In particular we view $\overline{B}^{n+2}$ as a subset of $\mathbb{C} \times \mathbb{R}^n$.
(4) Given $z \in S^1$ we denote by

$$\rho_z : \overline{B}^{n+2} \to \overline{B}^{n+2} \quad (w, x) \mapsto (z \cdot w, x)$$

the rotation of $\overline{B}^{n+2}$ by the “angle” $z \in S^1$ around “the $0 \times \overline{B}^n$-axis”.

Now let $K \subset S^{n+2}$ be a knot. It follows fairly easily from Theorem 8.36 and the fact that $K$ is a smooth submanifold that, after possibly applying a diffeotopy of $S^{n+2}$, we can assume that $J_- := K \cap \overline{B}_-^{n+2} = \{(0, w) \mid w \in \overline{B}^n\}$ is the “trivial disk knot” in $\overline{B}^{n+2}$. We denote by $J_+ := K \cap \overline{B}_+^{n+2}$ the “other disk knot”. Next, given $m \in \mathbb{Z}$ we denote by $\Phi_m$ the diffeomorphism

$$\Phi_m : S^1 \times \overline{B}^{n+2} \to S^1 \times \overline{B}^{n+2} \quad (z, x) \mapsto (z, \rho_z^m(x)).$$

Informally speaking $\Phi_m$ spins $\overline{B}^{n+2}$ altogether $m$ times as we go around the $S^1$-direction. Note that $\Phi_0$ is the identity and also note that each $\Phi_m$ leaves the subset $S^1 \times S^{n-1}$ invariant as a subset. Now we define the $m$-twist spin $S_m(K)$ as follows:

$$S_m(K) := \Phi_m(S^1 \times J_+) \cup_{S^1 \times S^{n-1}} (\overline{B}^2 \times S^{n-1}) \subset (S^1 \times \overline{B}^{n+2}) \cup_{S^1 \times S^{n+1}} (\overline{B}^n \times S^{n+1}).$$

We leave it to the reader to verify that $S_m(K)$ is indeed an $(n + 1)$-dimensional knot.

In Figure 522 we do our best to illustrate this construction for $n = 1$. Again informally speaking, $S_m(K)$ is given by spinning the disk knot $J_+$ around the $S^1$-direction, performing $m$ spins around $J_+$ as you go around $S^1$, and then capping off the result by $\overline{B}^2 \times S^{n-1}$.

![Figure 522](image-url)

The following proposition will show shortly, perhaps unsurprisingly, that some twist spins are non-trivial. Perhaps more surprisingly the proposition also shows that $(\pm 1)$-twist spins are always trivial.
Proposition 27.37. Let $K \subset S^{n+2}$ be an $n$-dimensional knot.

1. For the 0-twist spin there exists an isomorphism $\pi_1(S^{n+3} \setminus S_0(K)) \cong \pi_1(S^{n+2} \setminus K)$.

2. For every $\epsilon \in \{-1, 1\}$ the $\epsilon$-twist spin knot $S_\epsilon(K)$ is trivial.

Sketch of proof.

(1) We have the following isomorphisms:

\[
\begin{array}{c}
\pi_1(S^{n+3} \setminus S_0(K)) \\ \cong \\ \pi_1(S^1 \times (\mathbb{B}^{n+2} \setminus J_+)) * \pi_1(S^1 \times (S^{n+1} \setminus S^{n-1})) \\ \cong \\ \text{isomorphisms given by Proposition 16.20} \\
((t) \times \pi_1(\mathbb{B}^{n+2} \setminus J_+)) * (s) * (t) \langle s \rangle \\ \cong \\ \text{isomorphism by the group theoretic} \\
\pi_1(\mathbb{B}^{n+2} \setminus J_+) \\ \cong \\ \pi_1(S^{n+2} \setminus K).
\end{array}
\]

By now the reader will be fully aware of the fact that it is supremely painful to completely keep track of all identifications, base points, induced maps and so on. Thus we also took some liberties to improve readability.

(2) This statement is proved implicitly in [Ze65, p. 486] and explicitly in [FO15, Corollary 2.1]. The reason for writing [FO15] was that it felt easier to prove the statement, than to try to read the proofs written down by others. So we warmly recommend to try to prove the statement on your own.

Corollary 27.38. Given any $n \in \mathbb{N}$ there exists an $n$-dimensional knot in $S^{n+2}$ that is non-trivial.

Proof. Let $K \subset S^3$ be the trefoil and let $n \in \mathbb{N}$. We see that

\[
\pi_1(S^{n+2} \setminus (n-1)\text{-st iterated 0-twist spin of } K) \cong \pi_1(S^3 \setminus K) \not\cong \mathbb{Z}.
\]

Proposition 27.37  Proposition 27.37 and Proposition 27.6

It now follows from Lemma 27.36 (2) that the $(n - 1)$-st iterated 0-twist spin of the trefoil is a non-trivial knot.

Exercises for Chapter 27

Exercise 27.1. Let $K \subset S^3$ be a knot and let $H_1$ and $H_2$ be two hyperplanes of $\mathbb{R}^4$. For $i = 1, 2$ we denote by $K_i^*$ the reflection of $K$ in the hyperplane $H_i$. Show that $K_1^*$ and $K_2^*$...
are smoothly isotopic.  
*Hint.* Use Lemma 2.63 and Exercise 18.7.

**Exercise 27.2.** Given $k \in \mathbb{Z}$ we consider the map
\[
S^1 \times S^1 \to S^1 \times S^1 \quad (w, z) \mapsto (wz^k, z).
\]
Show that $(S^1 \times B^2) \cup_{\phi_k} (S^1 \times B^2)$ is homeomorphic to $S^3$ if and only if $k \in \{-1, 1\}$.  
*Hint.* It might be helpful to compute the fundamental group or the first homology group of this topological space.

**Exercise 27.3.** We consider the two knot diagrams shown in Figure 523. Use Reidemeister moves to show that the associated knots are smoothly isotopic.

![Figure 523](image)

**Exercise 27.4.** Show that every diagrammatic map has only finitely many double points.

**Exercise 27.5.** Let $K$ be a knot. Use Proposition 27.23 to show that the abelianization of the group $\pi_1(S^3 \setminus K)$ is isomorphic to $\mathbb{Z}$.

**Exercise 27.6.** Let $K$ and $L$ be oriented knots. We denote by $L^*$ the mirror image of $L$. Show that the fundamental groups of $S^3 \setminus (K \# L)$ and $S^3 \setminus (K \# L^*)$ are isomorphic.

**Exercise 27.7.** We defined the sign of a crossing of a diagram of an oriented knot. How does the sign change if we reverse the orientation of the knot?

**Exercise 27.8.** Show that if a knot diagram has at least one crossing, then the number of crossings equals the number of strands.

**Exercise 27.9.** Give a purely algebraic proof that the two groups $\langle x, y \mid x^2 = y^3 \rangle$ and $\langle a, b, c \mid c^{-1}bca^{-1}, b^{-1}abc^{-1} \rangle$ are isomorphic.  
*Remark.* You could use the Tietze transformations introduced in Lemma 21.12 and you could use Lemma 21.12.

**Exercise 27.10.** Let $K \subset S^3$ be a knot. We consider the “cone”
\[
C := \{r \cdot P \mid P \in K \text{ and } r \in [0, 1]\} \subset \overline{B^4}.
\]
(a) Show that $C$ is homeomorphic to the disk $\overline{B^2}$.
(b) We suppose that $K$ is smoothly isotopic to the unknot. Show that $C$ is a topological submanifold of the topological manifold $\overline{B^4}$.

**Exercise 27.11.** Let $K \subset S^3$ be the trefoil. As in Exercise 27.10 we consider the “cone”
\[
C := \{r \cdot P \mid P \in K \text{ and } r \in [0, 1]\} \subset \overline{B^4}.
\]
In Exercise 27.10 we shewed that $C$ is homeomorphic to the disk $\overline{B^2}$. In the following we will show that $C$ is not a submanifold of the topological manifold $\overline{B^4}$.  

(a) Let $\alpha: \pi_1(S^3 \setminus K) \to \mathbb{Z}$ and $\beta: \mathbb{Z} \to \pi_1(S^3 \setminus K)$ be two maps. Show that the composition $\beta \circ \alpha: \pi_1(S^3 \setminus K) \to \pi_1(S^3 \setminus K)$ is not an isomorphism.

(b) Suppose that $F$ is a proper 2-dimensional topological submanifold of $\overline{B}^4$. Show that given any point $P \in F \cap B^4$ there exists a map $\Phi: \overline{B}^4 \to \overline{B}^4$ that is an embedding such that $\Phi(0) = P$ and such that $\Phi(\overline{B}^2 \times \{0\}) = \Phi(\overline{B}^4) \cap C$.

(c) Show that $C$ is not a topological submanifold of $\overline{B}^4$.

_Hint._ Evidently the idea is to apply (c) to the point $P = 0 \in C$. The difficulty is that the map $\Phi$ from (c) is not just a rescaling of the identity but it is potentially a completely different chart. To deal with the problem we introduce some notation.

(i) Given $I \subset [0, 1]$ we write $D_I := \{v \in \overline{B}^3 \mid \|v\| \in I\}$.
(ii) Given $I \subset [0, 1]$ we write $N_I := \Phi(D_I)$.
(iii) Given $t \in (0, 1]$ we write $D_t := D_{(t)}$ and $N_t := N_{(t)}$.

Show that the following statements hold:

1. Given any $t \in (0, 1]$ there exists an $s \in (0, 1)$ with $D_{[0,s]} \subset N_{[0,t]}$.
2. Given any $s \in (0, 1]$ there exists a $t \in (0, 1)$ with $N_{[0,t]} \subset D_{[s,1]}$.
3. Given any choice of $r < s$ in $(0, 1]$ the two inclusion maps $D_r \cup C \to D_{[r,s]} \cup C$ and $D_s \setminus C \to D_{[r,s]} \setminus C$ are homotopy equivalences, in particular they induce isomorphism of fundamental groups. Each of the fundamental groups is isomorphic to $\pi_1(S^3 \setminus K)$.
4. Given any choice of $r < s$ in $(0, 1]$ the two inclusion maps $N_r \setminus C \to N_{[r,s]} \setminus C$ and $N_s \setminus C \to N_{[r,s]} \setminus C$ are homotopy equivalences, in particular they induce isomorphism of fundamental groups. Each of the fundamental groups is isomorphic to $\mathbb{Z}$.
5. Use the above discussion together with (b) to show that such $\Phi$ cannot exist.

---

**Exercise 27.12.** Let $K$ be the trefoil. Compute the abelianization of the group $\pi(K, 3)$.

**Exercise 27.13.** Let $\pi$ be a group. We say that a subset $S \subset \pi$ normally generates $\pi$ if $\langle S \rangle = \pi$. We define the weight of $\pi$ as

$$w(\pi) := \min\{\#S \mid S \text{ is a subset of } \pi \text{ that normally generates } \pi\} \in \mathbb{N}_0 \cup \{\infty\}.$$ 

(a) Determine the weight of $\mathbb{Z}^m$. 

---
(b) Determine the weight of the free group on \(m\) generators.
(c) Let \(K \subset S^3\) be a knot. Show that \(w(\pi_1(S^3 \setminus K)) = 1\).

**Exercise 27.14.** We say two knots \(K\) and \(J\) in \(\mathbb{R}^3\) are related by a *crossing change* if there exists a smooth map \(F: S^1 \times [0, 1] \to \mathbb{R}^3\) and some \(s \in (0, 1)\) with the following properties:

1. We have \(F_0(S^1) = K\) and \(F_1(S^1) = J\).
2. For every \(t \neq s\) the map \(F_t: S^1 \to S^3\) is an embedding.
3. The map \(F_s: S^1 \to S^3\) is an immersion and there exist \(w, z \in S^1\) with the following properties:
   - (i) the restriction of \(F_s\) to \(S^1 \setminus \{w, z\}\) is an injection,
   - (ii) \(F_s(w) = F_s(z)\) and the vectors \(F'_s(w)\) and \(F'_s(z)\) are linearly independent.

In Figure 526 we illustrate the definition of a crossing change. Given two knots \(K\) and \(J\) the minimal number of crossing changes needed to turn \(K\) into \(J\) is called the *Gordian distance between \(K\) and \(J\).* The Gordian distance of a knot \(K\) to the trivial knot is called the *unknotting number of \(K\).* Given explicit knots these numbers are notoriously difficult to calculate.

(a) Show that any two knots in \(\mathbb{R}^3\) are related by a sequence of finitely many crossing changes. In other words, show that the Gordian distance between two knots is finite.

*Hint.* You could use the fact that every knot admits a knot diagram.

(b) What are the best lower and upper bounds you can find on the Gordian distance between the trefoil and the figure-8 knot?

*Remark.* For readers who prefer completely formal proofs it can be a fun challenge to tweak the argument of the proof of Proposition 11.11 to obtain a proof of (a).

**Exercise 27.15.** Let \(n \in \mathbb{N}\) and let \(k \in \{1, \ldots, n-1\}\). We consider the submanifold \(K := \{(x, 0) \in \mathbb{R}^{n+1} | x \in S^k\}\). Show that \(S^n \setminus K\) is homotopy equivalent to \(S^{n-k-1}\).

**Exercise 27.16.** Let \(K \subset S^3\) be an oriented knot and let \(m \in \mathbb{Z}\). As on page 805 we consider the \(m\)-twist spin \(S_m(K) \subset S^4\). We view \(S^3\) as a subset of \(S^4\) via the embedding \(z \mapsto (z, 0)\). The intersection \(S_m(K) \cap S^3\) is a knot. What is the smooth isotopy type of this knot? A possible answer is that this knot is a connected sum of \(K\) with some suitable other knot.
28. Decision problems

In the last chapters we had developed several techniques for determining the fundamental groups of topological spaces. In particular we managed to find finite presentations for the fundamental groups of large classes of topological spaces, e.g. topological graphs, surfaces, knot complements and mapping tori. In fact we now have enough tools to determine, with enough effort and perseverance, a presentation for the fundamental groups of most “nice” spaces. Furthermore we will see later in Propositions 64.6 and 85.13 on that the fundamental group of every compact topological manifold admits a finite presentation.

The question that now arises is, what information can we extract from a finite presentation of a group? Here are a couple of natural questions.

**Question 28.1.**

(1) Does there exist an algorithm that can decide whether or not a given finite presentation \( \pi = \langle g_1, \ldots, g_k \mid r_1, \ldots, r_l \rangle \) represents the trivial group?

(2) Does there exist an algorithm that can decide whether or not two given finite presentations \( \pi = \langle g_1, \ldots, g_k \mid r_1, \ldots, r_l \rangle \) and \( \Gamma = \langle h_1, \ldots, h_m \mid s_1, \ldots, s_n \rangle \) represent isomorphic groups?

(3) Does there exist an algorithm that can determine, given
   (a) a finite presentation \( \pi = \langle g_1, \ldots, g_k \mid r_1, \ldots, r_l \rangle \) and
   (b) a word \( w \) in \( g_1, \ldots, g_k \), i.e. an element \( w \in \langle g_1, \ldots, g_k \rangle \), whether or not \( w \) represents the trivial element in the group \( \pi \)?

(4) Does there exist an algorithm that can determine, given
   (a) a finite presentation \( \pi = \langle g_1, \ldots, g_k \mid r_1, \ldots, r_l \rangle \) and
   (b) and two words \( v \) and \( w \) in \( g_1, \ldots, g_k \), whether or not \( v \) and \( w \) represent conjugate elements in the group \( \pi \)?

**Remark.**

(1) This question was first posed by Max Dehn [Deh1911] in 1911. In fact shortly afterwards, in 1912 Max Dehn [Deh1912] gave positive answers to the word problem and the conjugacy problem for the fundamental groups of compact 2-dimensional smooth manifolds.

(2) The above question is formulated in a slightly informal way. After all, what is an “algorithm” supposed to be? The questions are made more precise in [CZ93 Chapter 7], [Sti82] and [MillC92].

On page [632] we introduced the Tietze transformations on presentations. We pointed out that two finite presentations for a given group are in fact related by a finite sequence of Tietze transformations. In particular, if \( \pi = \langle g_1, \ldots, g_k \mid r_1, \ldots, r_l \rangle \) is a presentation for the trivial group, then we can turn the presentation after finitely many Tietze transformations into the trivial presentation \( \langle \rangle \). The problem is that we do not know how many Tietze transformations are required to turn a presentation of a trivial group into a

\(^{506}\)The question whether such an algorithm exists is often called the **isomorphism problem**.

\(^{507}\)The question whether such an algorithm exists is often called the **word problem**.

\(^{508}\)The question whether such an algorithm exists is often called the **conjugacy problem**.
trivial presentation. In particular at times it can be very hard to find the correct Tietze transformations.

**Example.** We consider the presentation

\[ \pi = \langle a, b, c \mid a^3, b^3, c^4, ac = ca^{-1}, aba^{-1} = bcb^{-1} \rangle. \]

This is a presentation of the trivial group as can be seen as follows:

1. from \( aba^{-1} \sim bcb^{-1} \) we get \( (aba^{-1})^3 \sim (bcb^{-1})^3 \),
2. since \( a^{-1}a \sim 1 \) and \( b^{-1}b \sim 1 \) it follows that \( (aba^{-1})^3 \sim ab^3a^{-1} \) and \( (bcb^{-1})^3 \sim bc^3b^{-1} \),
3. we have \( b^3 \sim 1 \), hence \( ab^3a^{-1} \sim 1 \), therefore we get from (1) and (2) that \( bc^3b^{-1} \sim 1 \) hence \( c^3 \sim 1 \),
4. we have \( c^3 \sim 1 \) but we also have the relation \( c^4 \sim 1 \), so \( c \sim 1 \),
5. since \( aba^{-1} \sim bcb^{-1} \) it follows that \( aba^{-1} \sim 1 \) and so \( b \sim 1 \),
6. from \( ac \sim ca^{-1} \) and \( c \sim 1 \) it follows that \( a \sim a^{-1} \), hence \( a^2 \sim 1 \),
7. together with \( a^3 \sim 1 \) we obtain \( a \sim 1 \).
8. we now showed that \( a, b, c \) are all equivalent to 1, thus we see that the group defined by the presentation is the trivial group.

This example shows that if a presentation corresponds to the trivial group, then it can be surprisingly complicated to verify this statement.

Now suppose we are given a finite presentation and we have to decide whether or not it is a presentation of the trivial group. We can modify the presentation using Tietze transformations. If at some point we end up with the trivial presentation we know that the given presentation corresponds to the trivial group. But what happens if after many attempts at modifying the presentation using Tietze transformations we still do not have the trivial presentation. Does that mean that the presentation corresponds to a non-trivial group? Or does it just mean that we did not try long enough?

So the real question is, does there exist an algorithm, that given a presentation which defines a non-trivial group, actually verifies that the group is non-trivial?

Unfortunately the answer is quite sobering.

**Theorem 28.2.** The answer to all four questions raised in Question 28.1 is no.

**Remark.** Here “no” means that one can show that no such algorithm exists. This is a much stronger statement than saying that we do not know of an example of such an algorithm.

**Proof.**

1. Adyan [Ady55] and Michael Rabin [Rab58] showed in 1955 that the answer to the first question is no. Alternatively see [MillC92, Theorem 3.3] for a proof.
2. An algorithm that performs (2) would also give an algorithm for determining whether or not a given presentation is isomorphic to the trivial group with the empty presentation \( \langle \rangle \). But since the answer to (1) is no, it follows that the answer to (2) is also no. Historically, it was first proved by Sergey Novikov [Nov65] and William Boone [Boo58] that (2) has a negative answer before a negative answer to (1) was given.\(^509\)

\(^{509}\)For elements \( g, h \) of \( \langle a, b, c \rangle \) we write \( g \sim h \) if they represent the same element in \( \pi \).
(3) If there did exist an algorithm that dealt with the third problem, then we could apply it in particular to the generators. Since a presentation presents the trivial group if and only if all generators are trivial, it follows that an algorithm for (3) would also give an algorithm for (1). Since the latter cannot exist, the former cannot exist either.

(4) An element in a group is trivial if and only if it is conjugate to the trivial element. Hence the fact that (3) has a negative answer leads to a negative answer to (4).

**Remark.**

(1) There are many other non-existence results in the vein of Theorem 28.2. For example, [MillC92, Corollary 3.4], see also Exercise 28.2 says the following:
(a) it is undecidable whether a finitely presented group is free,
(b) it is undecidable whether a finitely presented group is abelian,
(c) it is undecidable whether a finitely presented group is nilpotent,
(d) it is undecidable whether a finitely presented group is solvable,
(e) it is undecidable whether a finitely presented group is simple,
(f) it is undecidable whether a finitely presented group is torsion-free.

(2) The statement of Theorem 28.2 that the answer to all four questions of Question 28.1 is no, is of course somewhat disappointing. But this raises the question whether there are interesting classes of groups for which the answer is actually yes. For example Mikhail Gromov [Grom87] introduced the notion of a “word hyperbolic group” for which the answer to all four questions turns out to be yes. Examples of word hyperbolic groups are given by
(a) finite groups,
(b) free groups, fundamental groups of surfaces of genus $\geq 2$,
(c) fundamental groups of hyperbolic smooth manifolds of any dimension,
(d) fundamental groups of “Riemannian manifolds with negative sectional curvature”.

In fact in a precise sense a “random” finitely presented group is word hyperbolic, see e.g. [Ol05] for more details.

The topic of word hyperbolic groups is a very important topic of mathematics in its own right. See e.g. [Lö15] for an introduction to word hyperbolic groups.

Of course our main goal is not to classify groups, but our goal is to understand “nice” topological spaces. For example ideally we would like to classify compact topological and smooth manifolds. The following theorem gives us some hope that this task is not completely hopeless.

**Theorem 28.3.** Let $n \in \mathbb{N}_0$.

(1) There exist only countably many homeomorphism classes of compact $n$-dimensional topological manifolds.

---

Mikhail Gromov (1943-) is a French-Russian mathematician famous for his many contributions to geometry and group theory. He was the first person to view groups as “geometric objects”, giving rise to the subject of “geometric group theory”.
(2) There exist only countably many diffeomorphism classes of compact $n$-dimensional smooth manifolds.

**Proof.** The first statement is proved in [CK70]. The second statement follows from [Pets84, p. 77] and the fact that every smooth manifold admits a Riemannian structure, see e.g. [Wall16, Theorem 1.3.1]. For $n \geq 6$ the second statement can also be deduced from the fact that every compact $n$-dimensional smooth manifold admits a finite simplicial structure, see Theorem 64.2, the fact that there are only countably many isomorphism classes of finite simplicial complexes, see Exercise 61.4, and the (very difficult) Theorem ?? which says that for $n \geq 6$ every compact topological manifold admits at most finitely many smooth structures. ■

Given $n \in \mathbb{N}$ we would like to classify closed orientable connected $n$-dimensional smooth manifolds up to diffeomorphism. For $n = 1$ we did so in Theorem 7.5 and for $n = 2$ we saw the classification in the Surface Classification Theorem 23.4. In particular we saw that in these dimensions only “few groups” appear as fundamental groups.

We also proved the following result which shows that in dimension $\geq 4$ the situation is dramatically different.

**Proposition 22.10.** Given any finitely presented group $\pi$ and any $n \geq 4$ there exists a closed orientable connected $n$-dimensional smooth manifold with fundamental group $\pi$.

Theorem 28.2 and Proposition 22.10 are at the heart of the proof of the following theorem.

**Theorem 28.4.** Let $n \geq 4$.

1. Then there is no algorithm that can decide whether or not two closed orientable $n$-dimensional smooth manifolds are homeomorphic.
2. Then there is no algorithm that can decide whether or not two closed orientable $n$-dimensional smooth manifolds are diffeomorphic.

**Proof.** The first statement was first proved by Markov [Mark58]. We refer to [BHP68, Theorem 1] and [Hak73] for a detailed discussion of the proofs of both statements. ■

This leaves us with the case of $3$-dimensional smooth manifolds. It turns out that in this dimension there does in fact exist such an algorithm.

**Theorem 28.5.** There exists an algorithm that can decide whether or not two closed orientable connected $3$-manifolds are diffeomorphic.

In this case the algorithm is considerably more complicated than in the $1$-dimensional and the $2$-dimensional case. The proof that such an algorithm exists is due to the work of many mathematicians, first and foremost William Thurston [Thu82] and Grigori Perelman. The proof of the theorem was completed about 2003. It is impossible to mention here all the work that goes into proving Theorem 28.5. We refer to the survey paper [AFW15, Theorem 4.27] for details and precise references.
Exercises for Chapter 28

Exercise 28.1.
(a) Show that every finite group is isomorphic to some permutation group $S_n$.
(b) Let $\pi = \langle x_1, \ldots, x_k \mid r_1, \ldots, r_l \rangle$ be a finitely presented group. Suppose that we know that $\pi$ is finite. Show that there exists an algorithm which determines an injective homomorphism $\varphi : \pi \to S_n$ for some $n \in \mathbb{N}$.
(c) Let $\pi = \langle g_1, \ldots, g_k \mid r_1, \ldots, r_l \rangle$ and $\Gamma = \langle h_1, \ldots, h_m \mid s_1, \ldots, s_n \rangle$ be two finitely presented groups. Suppose we know that $\pi$ and $\Gamma$ are finite. Show that there exists an algorithm that can determine whether or not $\pi$ and $\Gamma$ are isomorphic.

Exercise 28.2.
(a) Show that it is undecidable whether a finitely presented group is free.
(b) Show that it is undecidable whether a finitely presented group is abelian.
(c) Show that it is undecidable whether a finitely presented group is nilpotent.
(d) Show that it is undecidable whether a finitely presented group is solvable.

Somewhat more precisely, for each group property show that there is no algorithm that can decide whether or not a given finite presentation $\pi = \langle g_1, \ldots, g_k \mid r_1, \ldots, r_l \rangle$ represents a group that has said property.

Exercise 28.3. A group $\pi$ is called residually finite if given any non-trivial element $g \in \pi$ there exists a homomorphism $\alpha : \pi \to G$ to a finite group $G$ such that $\alpha(g)$ is non-trivial. Show that the word problem is solvable in a finitely generated group that is residually finite.

Remark. A solution to this exercise can be found in [MILC92, Theorem 5.2].
Part IV

The universal covering
29. The existence of universal coverings

After spending a lot of time on determining the fundamental groups of topological spaces we now want to return to the study of covering maps. One key goal of this section is to address the following question.

**Question 29.1.** Does every path-connected topological space $B$ admit a path-connected covering map $p: X \to B$ such that $X$ is simply connected?

We know of course that the answer is yes for the torus, the Klein bottle and the Möbius band. But does such a covering exist for the surface of genus 2? Or does it exist for the complement $S^3 \setminus K$ of a knot $K \subset S^3$? How about the wedge $S^1 \vee S^1$ of two circles?

29.1. **Local properties of topological spaces.** Before we can address Question 29.1 we need to recall the definition of a local property of topological spaces that we already gave in Section 2.11.

**Definition.** Let $P$ be a property of topological spaces. We say a topological space $X$ is *locally $P$* if given any $Q \in X$ and any neighborhood $U$ of $Q$ there exists an open neighborhood $V$ of $Q$ that is contained in $U$ that has the property $P$.

**Examples.**

1. By Proposition 18.16 we know that every contractible topological space is simply connected. Thus every locally contractible topological space is also locally simply connected. Furthermore every simply connected topological space is by definition path-connected, thus every locally simply connected topological space is also locally path-connected.
2. On page 139 we saw that every open subset of $\mathbb{R}^n$ is locally simply connected.
3. By Lemma 6.9 (1) every topological manifold is locally homeomorphic to some non-empty convex subset of $\mathbb{R}^n$. Since non-empty convex subsets are contractible we see that every topological manifold is locally contractible.
4. In Exercise 29.1 we will show that every topological graph is locally contractible and we will show that the wedge of locally contractible topological spaces is again locally contractible.
5. We consider

   $$X := \mathbb{R}^2 \setminus \bigcup_{n=1}^{\infty} \frac{1}{n} \times [-1,1],$$

   with the usual subspace topology coming from $\mathbb{R}^2$. Then $X$ is path-connected but not locally path-connected. Indeed, we consider the point $(0,0) \in X$ and the neighborhood $U = (-\frac{1}{2},\frac{1}{2}) \times (-\frac{1}{2},\frac{1}{2}) \cap X$. It is straightforward to show that there does not exist a path-connected neighborhood $V$ of $(0,0)$ which is contained in $U$. We refer to Figure 527 for an illustration.
6. We consider

   $$X := \mathbb{R}^2 \setminus \bigcup_{n=1}^{\infty} \left( \frac{1}{n},0 \right),$$

   with the subspace topology coming from $\mathbb{R}^2$. Then $X$ is path-connected, locally path-connected but it is not locally simply connected. Indeed the origin admits no
neighborhood of the desired form, since any neighborhood of the origin contains “infinitely many holes”. We made this statement precise in Exercise 20.1.

29.2. Lifting maps to coverings. Let \( p : (X, x_0) \to (B, b_0) \) be a covering of pointed topological spaces. Furthermore let \( f : (Z, z_0) \to (B, b_0) \) be a map. Recall that on page 507 we said that \( f \) lifts, if there exists a lift \( \tilde{f} : (Z, z_0) \to (X, x_0) \), i.e. a map \( \tilde{f} : Z \to X \) with \( \tilde{f}(z_0) = x_0 \) and which makes the following diagram commute

\[
\begin{array}{ccc}
(Z, z_0) & \xrightarrow{f} & (B, b_0) \\
\downarrow & & \downarrow \\
(X, x_0) & \xrightarrow{\tilde{f}} & \pi_1(X, x_0)
\end{array}
\]

For example, if \( f : ([0, 1], 0) \to (B, b_0) \) is a map from the interval \([0, 1]\) to \( B \), i.e. if \( f \) is a path with starting point \( b_0 \), then we saw in Proposition 16.11 that there exists a unique lift of \( f \) to a map \( \tilde{f} : ([0, 1], 0) \to (X, x_0) \).

Example. Consider the following maps:

\[
\begin{array}{ccc}
(S^1, 1) & \xrightarrow{\tilde{f}} & (S^1, 1) \\
\downarrow & & \downarrow \\
(S^1, 1) & \xrightarrow{f} & (S^1, 1)
\end{array}
\]

Here the map \( p \) is a 3-fold covering. Does the map \( f \) lift to a map \( \tilde{f} \)?

To answer the question we need to study lifts of maps a little more carefully. Let \( p : (X, x_0) \to (B, b_0) \) be a covering of pointed topological spaces and let \( f : (Z, z_0) \to (B, b_0) \) be a map. Suppose that there exists a lift \( \tilde{f} : (Z, z_0) \to (X, x_0) \). We then obtain the commutative diagram

\[
\begin{array}{ccc}
(Z, z_0) & \xrightarrow{\tilde{f}} & (X, x_0) \\
\downarrow & & \downarrow \\
(B, b_0) & \xrightarrow{p} & \pi_1(X, x_0)
\end{array}
\]

from the functoriality of the fundamental group it follows that \( f_* = (p \circ \tilde{f})_* = p_* \circ f_* \), i.e. we get the commutative diagram

\[
\begin{array}{ccc}
\pi_1(Z, z_0) & \xrightarrow{\tilde{f}_*} & \pi_1(X, x_0) \\
\downarrow & & \downarrow \\
\pi_1(B, b_0) & \xrightarrow{p_*} & \pi_1(B, b_0)
\end{array}
\]
Thus it follows that if \( f \) lifts, then
\[
\text{im}(f_*) = \text{im}((p \circ \tilde{f})_*) = \text{im}(p_* \circ \tilde{f}_*) \subseteq \text{im}(p_*).
\]
So summarizing, if there exists a lift of \( f \), then
\[
\text{im}(f_* : \pi_1(Z, z_0) \to \pi_1(B, b_0)) \subseteq \text{im}(p_* : \pi_1(X, x_0) \to \pi_1(B, b_0)).
\]

**Example.** In the above example we have \( \pi_1(S^1, 1) = \mathbb{Z} \) and \( \text{im}(f_*) = 2\mathbb{Z} \) whereas we have \( \text{im}(p_*) = 3\mathbb{Z} \). So we see that \( f \) does not lift.

The following proposition says, that the above conclusion has a converse, for “reasonably” topological spaces. More precisely, we have the following proposition which, under a modest technical hypothesis, gives a complete criterion for when a map lifts.

**Proposition 29.2.** Let \( p : (X, x_0) \to (B, b_0) \) be a covering of pointed topological spaces. Furthermore let \( Z \) be a path-connected topological space and let \( f : (Z, z_0) \to (B, b_0) \) be a map.

\[
\begin{align*}
(1) \quad & \text{If \( Z \) is locally path-connected, then we have the following equivalence of statements:} \\
& \quad \text{there exists a lift} \quad \tilde{f} : (Z, z_0) \to (X, x_0) \quad \overset{\tilde{f}_*}{\longrightarrow} \quad \pi_1(Z, z_0) \to \pi_1(B, b_0) \\
& \quad \overline{\text{im}(f_*)} \quad \iff \quad \text{im}(f_*) \subseteq \text{im}(p_*). \\
(2) \quad & \text{There exist at most one such lift, in other words, any two such lifts agree.}
\end{align*}
\]

**Examples.** Let \( p : (X, x_0) \to (B, b_0) \) be a covering of pointed topological spaces.

(1) The condition on the fundamental groups in Proposition 29.2 is automatically satisfied if \( Z \) is simply connected.

(2) Now let \( f : (S^n, s_0) \to (B, b_0) \) be a map. The topological manifold \( S^n \) is path-connected and locally path-connected. By Proposition 14.14 the sphere \( S^n \) is simply connected if \( n \geq 2 \). Thus it follows from (1) that there exists a uniquely determined lift \( \tilde{f} : (S^n, s_0) \to (X, x_0) \) of the map \( f : (S^n, s_0) \to (B, b_0) \).

In the proof of Proposition 29.2 we will need the following lemma.

**Lemma 29.3.** Let \( p : (X, x_0) \to (B, b_0) \) be a covering of pointed spaces, let \( \gamma \) be a path in \( B \) with starting point \( b_0 \) and let \( \delta \) be another path in \( B \) with \( \delta(0) = \gamma(1) \). We denote by \( \tilde{\gamma} \) the lift of \( \gamma \) with starting point \( x_0 \). Then
\[
\text{endpoint of the lift of} \quad \gamma * \delta \quad \text{to the starting point} \quad x_0 = \text{endpoint of the lift of} \quad \delta \quad \text{to the starting point} \quad \tilde{\gamma}(1).
\]

**Proof.** Let \( p : (X, x_0) \to (B, b_0) \) be a covering of pointed spaces, let \( \gamma \) be a path in \( B \) with starting point \( b_0 \) and let \( \delta \) be another path in \( B \) with \( \delta(0) = \gamma(1) \). We denote by \( \tilde{\gamma} \) the lift of \( \gamma \) with starting point \( x_0 \) and we denote by \( \tilde{\delta} \) the lift of \( \delta \) to the starting point \( \tilde{\gamma}(1) \). Finally we denote by \( \tilde{\gamma} * \tilde{\delta} \) the lift of \( \gamma * \delta \) to the starting point \( x_0 \). For \( t \in [0,1] \) we write \( \beta(t) = (\gamma * \delta)(\frac{1}{2}(t + 1)) \) and \( \tilde{\beta}(t) = (\tilde{\gamma} * \tilde{\delta})(\frac{1}{2}(t + 1)) \). Note that by definition we

\[ \text{endpoint of the lift of} \quad \gamma * \delta \quad \text{to the starting point} \quad x_0 = \text{endpoint of the lift of} \quad \delta \quad \text{to the starting point} \quad \tilde{\gamma}(1). \]
have $\beta(t) = \delta(t)$ for $t \in [0, 1]$ and that $\tilde{\beta}$ and $\tilde{\delta}$ are both lifts of $\beta = \delta$ to the starting point $\beta(0) = \gamma(1) = \delta(0)$. Thus it follows that

$$\text{endpoint of } \tilde{\gamma} \ast \tilde{\delta} = (\tilde{\gamma} \ast \tilde{\delta})(1) = \tilde{\beta}(1) = \tilde{\delta}(1) = \text{endpoint of } \tilde{\delta}. \uparrow$$

by Proposition 16.11

Now we can give the proof of Proposition 29.2. To make the proof slightly more readable we prove the two statements (1) and (2) separately.

**Proof of Proposition 29.2 (1).** Let $p: (X, x_0) \to (B, b_0)$ be a covering of pointed topological spaces. Furthermore let $Z$ be a path-connected and locally path-connected topological space and let $f: (Z, z_0) \to (B, b_0)$ be a map.

By the discussion on page 818 we only have to prove the "$\Leftarrow$"-direction of the proposition. So suppose that we have

$$\text{im}(f_* : \pi_1(Z, z_0) \to \pi_1(B, b_0)) \subset \text{im}(p_* : \pi_1(X, x_0) \to \pi_1(B, b_0)).$$

We have to construct a lift $\tilde{f}: (Z, z_0) \to (X, x_0)$. We will do so as follows. Let $z \in Z$ be a point. Since $Z$ is path-connected we can find a path $\alpha: [0, 1] \to Z$ with $\alpha(0) = z_0$ and $\alpha(1) = z$. According to Proposition 16.11 we can lift the path $f \circ \alpha: [0, 1] \to B$ to a path $(f \circ \alpha): [0, 1] \to X$ with starting point $x_0$. We define

$$\tilde{f}(z) := (f \circ \alpha)(1).$$

This definition is illustrated in Figure 529.

We have to verify the following statements:

1. The map $\tilde{f}: Z \to X$ is well-defined,
2. The map $\tilde{f}$ is continuous,
3. The map $\tilde{f}$ is a lift,
4. and the map $\tilde{f}$ is the unique lift.

We will do so in the following:

1. We have to show that for $z \in Z$ the point $\tilde{f}(z) \in X$ is well-defined, i.e. independent of the choice of the path $\alpha$. Thus let $\beta: [0, 1] \to Z$ be another path with $\beta(0) = z_0$.
and \( \beta(1) = z \). (This situation is illustrated in Figure 530.) It follows that
\[
(f \circ \alpha)(t = 1) = (\text{lift of } f \circ \alpha \text{ to the starting point } x_0)(t = 1)
\]
\[= (\text{lift of } (f \circ \alpha) * (f \circ \beta) * (f \circ \beta) \text{ to the starting point } x_0)(t = 1)\]
\[\uparrow\]
by Corollary 16.13 since \( f \circ \alpha \) and \( (f \circ \alpha) * (f \circ \beta) * (f \circ \beta) \) are path-homotopic
\[= (\text{lift of } (f \circ (\alpha * \beta)) \text{ to the starting point } x_0)(t = 1)\]
\[\uparrow\]
Lemma 29.3 where \( \overline{f \circ \gamma} \) denotes the lift of \( f \circ \gamma \) to the starting point \( x_0 \)
\[= (\text{lift of } f \circ \beta \text{ to starting point } x_0)(t = 1) = (f \circ \beta)(t = 1).\]
\[\uparrow\]
by our hypothesis we have \( [f \circ \gamma] = f_*(\gamma) \in \text{im} (f_*) \subset p_*(\pi_1(X, x_0)) \),

hence \( \overline{f \circ \gamma} \) is a loop in \( x_0 \) by Lemma 16.13.

Thus we have shown that the map \( \tilde{f} \) is well-defined.

---

512Lemma 16.15 (1) says the following: if \( \delta \) is a loop in \( (B, b_0) \) and if \( \tilde{\delta} \) denotes the lift of \( \delta \) to the starting point \( x_0 \), then the following holds:

\[ \tilde{\delta} \text{ is a loop in } (X, x_0) \iff [\delta] \text{ lies in } p_*(\pi_1(X, x_0)) \subset \pi_1(B, b_0). \]

We apply the lemma to \( \delta = f \circ \gamma \).
(2) Now we want to show that \( \tilde{f} \) is continuous. So let \( z \in Z \). We pick a path \( \alpha \) from \( z_0 \) to \( z \). Since \( p \) is a covering there exists an open neighborhood \( V \) of \( \tilde{f}(z) \) such that the restriction of \( p \) to \( V \) is an embedding. We denote by \( q: p(V) \to V \) the inverse map. Since \( Z \) is locally path-connected there exists an open neighborhood \( U \) of \( z \) that is contained in \( f^{-1}(p(V)) \) and that is path-connected. Since \( f \) and \( q \) are continuous it suffices to prove the following claim.

**Claim.** On the open neighborhood \( U \) of \( z \) the map \( \tilde{f} \) agrees with \( q \circ f \).

So let \( w \in U \). Since \( U \) is path-connected there exists a path \( \delta \) from \( z \) to \( w \) that lies in \( U \). Then

\[
\tilde{f}(w) = \text{endpoint of the lift of } f \circ (\alpha \circ \delta) = (f \circ \alpha) \circ (f \circ \delta) \text{ to the starting point } x_0
\]

= endpoint of the lift of \( f \circ \delta \) to the starting point \( \tilde{f}(z) \)

\[\uparrow\]

by Lemma 29.3 and the definition of \( \tilde{f}(z) \) as the endpoint of \( \tilde{f} \circ \alpha \)

= endpoint of \( q \circ (f \circ \delta) = (q \circ f)(\delta(1)) = (q \circ f)(w) \).

Since \( q = p^{-1} \) we know that \( q \circ (f \circ \delta) \) is the lift of \( f \circ \delta \) to the starting point \( f(z) \).

(3) We need to show that \( \tilde{f} \) is a lift, i.e. we need to show that \( p \circ \tilde{f} = f \). So let \( z \in Z \). Then

\[
p(\tilde{f}(z)) = p((\tilde{f} \circ \alpha)(1)) = (f \circ \alpha)(1) = f(\alpha(1)) = z.
\]

Pick path \( \alpha \) from \( z_0 \) to \( z \) and denote by \( \tilde{f} \circ \alpha \) the lift of \( f \circ \alpha \).

**Figure 531.** Illustration for the proof of Proposition 29.2 (1).

**Proof of Proposition 29.2** (2). Let \( p: (X, x_0) \to (B, b_0) \) be a covering of pointed topological spaces. Furthermore let \( Z \) be a path-connected topological space. Finally suppose we are given a map \( f: (Z, z_0) \to (B, b_0) \).

We will now see, using the uniqueness of the lift of paths established in Proposition 16.11 that any two lifts \( \tilde{f}, \tilde{f}': (Z, z_0) \to (X, x_0) \) agree. Thus let \( z \in Z \). Since \( Z \) is path-connected there exists a path \( \alpha: [0, 1] \to Z \) from \( z_0 \) to \( z \). Then \( f \circ \alpha: [0, 1] \to B \)
is a path and \( \tilde{f} \circ \alpha \) and \( \tilde{f}' \circ \alpha \) are both lifts of \( f \circ \alpha \) to the starting point \( x_0 \). By Proposition 16.11 we have \( \tilde{f} \circ \alpha = \tilde{f}' \circ \alpha \). In particular the endpoints agree. But this implies the desired statement that
\[
\tilde{f}(z) = (\tilde{f} \circ \alpha)(1) = (\tilde{f}' \circ \alpha)(1) = \tilde{f}'(z). 
\]

In Exercise 29.3 we will prove the following corollary.

**Corollary 29.4.** Let \( \pi : X \to B \) be a covering of topological spaces. Then every open simply connected and locally path-connected subset \( U \subset B \) is uniformly covered.

### 29.3. Semi-locally simply connected topological spaces.

Our next goal will be to show that every “reasonable” path-connected non-empty topological spaces admits a covering that is simply connected. To make precise what we mean by “reasonable” we need to introduce the following definition.

**Definition.** A topological space \( X \) is called **semi-locally simply connected** if for every point \( x \in X \) there exists an open neighborhood \( U \) of \( x \) such that the inclusion induced map \( \pi_1(U, x) \to \pi_1(X, x) \) is the trivial map.

**Examples.**

1. Every simply connected topological space is semi-locally simply connected.
2. Let \( H \) be the Hawaiian earring that we introduced on page 727. In Exercise 29.2 we will see that \( H \) is not semi-locally simply connected.
3. Evidently every topological space that is locally simply connected is also semi-locally simply connected. But the converse does not hold. For example let us consider the cone \( \text{Cone}(H) \) on the Hawaiian earring.
   a. By Lemma 24.1 we know that the tip of \( \text{Cone}(H) \) is a deformation retract. This implies that \( \text{Cone}(H) \) is simply connected, in particular it is semi-locally simply connected.
   b. On the other hand we will see in Exercise 29.2 that \( \text{Cone}(H) \) is not locally simply connected.

![Hawaiian earrings](Hawaiian_earrings.png)

**Figure 532**

\[513\text{Note that in contrast to “locally simply connected” there is no general notion of what “semi-locally” means. In other words, we define “semi-locally simply connected” as a single object.}\]

\[514\text{If there exists a neighborhood \( W \) of \( x \) such that the inclusion induced map \( \pi_1(W, x) \to \pi_1(X, x) \) is the trivial map, then the interior \( U \) of \( W \) is an open neighborhood of \( x \) and the inclusion induced map \( \pi_1(U, x) \to \pi_1(X, x) \) is trivial, since it factors through the trivial map \( \pi_1(W, x) \to \pi_1(X, x) \). Thus in the definition it makes no real difference whether we demand a “neighborhood” or an “open neighborhood”.}\]
29.4. **Existence of covering spaces.** Let \( p: (X, x_0) \to (B, b_0) \) be a covering of pointed topological spaces. In Corollary [16.14](#) we saw that

\[
p_*: \pi_1(X, x_0) \to \pi_1(B, b_0)
\]

is an injective map. Thus we can view \( \pi_1(X, x_0) \) as a subgroup of \( \pi_1(B, b_0) \).

Generalizing Question 29.1 one can now ask, whether to each subgroup \( \Gamma \) of \( \pi_1(B, b_0) \) there exists a corresponding covering with \( p_*(\pi_1(X, x_0)) = \Gamma \). We will see that this is indeed the case, at least under the rather technical assumption that the topological space \( B \) is locally path-connected and semi-locally simply connected.

The following proposition gives in particular an affirmative answer to Question 29.1 under rather modest hypotheses.

**Proposition 29.5.** Let \( Y \) be a topological space that is path-connected, locally path-connected and semi-locally simply connected, let \( y_0 \in Y \) and let \( \Gamma \subset \pi = \pi_1(Y, y_0) \) be a subgroup.

1. There exists a path-connected covering \( p: (X, x_0) \to (Y, y_0) \) of pointed topological spaces such that \( p_*(\pi_1(X, x_0)) = \Gamma \).
2. For the covering \( p \) from (1) we have

\[
[X : Y] = [\pi_1(Y, y_0) : \Gamma].
\]

**Examples.**

1. We consider \( (Y, y_0) = (S^1, 1) \). We pick an identification \( \pi_1(S^1, 1) = \mathbb{Z} \). Given \( n \in \mathbb{N} \) we consider \( \Gamma = n\mathbb{Z} \subset \mathbb{Z} = \pi_1(S^1, 1) \). Then the covering

\[
p: S^1 \to S^1
\]

\[
z \mapsto z^n
\]

has the property that \( p_*(\pi_1(S^1, 1)) = n\mathbb{Z} \). Another example is given by the covering

\[
q: \mathbb{R}/n\mathbb{Z} \to S^1
\]

\[
t + n\mathbb{Z} \mapsto e^{2\pi it}.
\]

Here we also have \( \text{im}(q_*) = n\mathbb{Z} \).

2. Let \( Z \) be a simply connected topological space and let \( z_0 \in Z \). Furthermore let \( \pi \) be a group that acts on \( Z \) continuously and discretely. We consider \( Y = Z/\pi \), we denote by \( q: Z \to Y = Z/\pi \) the projection map and we write \( y_0 = q(z_0) \). Using the isomorphism of Theorem [16.16](#) we can identify \( \pi \) with \( \pi_1(Y, y_0) \).

Now let \( \Gamma \subset \pi = \pi_1(Y, y_0) \) be a subgroup. Then the group \( \Gamma \) also acts on \( Z \) and we can consider the projection map

\[
p: X := Z/\Gamma \to Y := Z/\pi
\]

We denote by \( x_0 \) the image of \( z_0 \) under the projection map \( Z \to X = Z/\Gamma \). One can show easily that \( p: X = Z/\Gamma \to Y = Z/\pi \) is a covering map with \( p_*(\pi_1(X, x_0)) = \Gamma \).

---

515 Here we say that a covering \( p: X \to Y \) is path-connected if \( X \) is path-connected.

516 This means that we pick an isomorphism \( \pi_1(S^1, 1) \xrightarrow{\sim} \mathbb{Z} \) and then ignore it in the notation.
We summarize the situation in the following diagram

\[
\begin{array}{ccc}
Z & \xrightarrow{q} & X = Z/\Gamma \\
\downarrow & & \downarrow \\
Y = Z/\pi & \xleftarrow{p} & \pi_1(X, x_0) = \Gamma \\
\end{array}
\]

\[
\pi_1(Z, z_0) = \{e\} \quad \pi_1(Y, y_0) = \pi.
\]

Now we turn to the proof of Proposition 29.5. Note that we only need show the existence of such a covering, the statement about the degree of the covering is an immediate consequence of Lemma 16.15 (3).

We start out with a general discussion of the construction of the covering. Only afterwards will we turn to the nitty-gritty of the proof. In particular for the time being let \( Y \) be any path-connected topological space, without any other adjectives. Furthermore let \( y_0 \in Y \) and let \( \Gamma \subset \pi_1(Y, y_0) \) be a subgroup.

To get an idea for the construction, let us first consider the case that \( \Gamma \) is the trivial group. In this case we want to construct a covering \( p : X \to Y \) such that \( X \) is simply connected. Let us assume for a second, that we have such an \( X \). We pick \( x_0 \in X \) with \( p(x_0) = y_0 \). Then, somewhat similar to the statement of Theorem 16.16, we have a map

\[
\Phi : X \to \{\text{path-homotopy classes of paths starting in } y_0\} \\
x \mapsto p \circ (\text{any path from } x_0 \text{ to } x).
\]

In fact the proof of Theorem 16.16 comes close to showing that the map \( \Phi \) is a bijection. Hence \( \Phi \) is in fact a homeomorphism, provided we equip the right-hand side with an appropriate topology.

Now that we are not given \( X \), the idea is, that given \( (Y, y_0) \) we can define the right-hand side of the above bijection, and with a suitable topology we will have found our \( X \).

As on page 233 we denote by \( Y^{[0,1]} \) the set of all maps \([0,1] \to Y\). Next we consider the path space\(^{17}\)

\[
P_{y_0} := \{\gamma \in Y^{[0,1]} | \gamma(0) = y_0\} = \{\text{all paths in } Y \text{ with starting point } y_0\}.
\]

For \( u, v \in P_{y_0} \) we write

\[
u \sim v :\iff u \text{ and } v \text{ have the same endpoint and } [u * v] \in \Gamma.
\]

Using the fact that \( \Gamma \subset \pi_1(Y, y_0) \) is a subgroup one can show easily that \( \sim \) is indeed an equivalence relation on \( P_{y_0} \). The definitions of \( P_{y_0} \) and \( \sim \) are illustrated in Figure 533. We write \( X_{y_0, \Gamma} := P_{y_0} / \sim \) and \( x_0 := [e_{y_0}] \), i.e. \( x_0 \) is the equivalence class of the constant path.

Now we consider the evaluation map

\[
p : X_{y_0, \Gamma} = P_{y_0} / \sim \to Y \\
[v] \mapsto v(1).
\]

\(^{17}\)On page 2660 the path space will be called \( P(Y, y_0) \). Later on it will play an important role, but for the purpose of this discussion it is easier to work with a shorter notation.
It remains to equip $X_{y_0, \Gamma} = P_{y_0}/ \sim$ with a sensible topology and to show that the map $p: X_{y_0, \Gamma} = P_{y_0}/ \sim \to Y$ has all the desired properties.

In fact in the following we provide two approaches to defining such a topology:

1. The first one is “by hand”, namely we construct a topology on $X_{y_0, \Gamma} = P_{y_0}/ \sim$ from scratch.
2. The second approach is “off-the-shelves”, meaning we make use of the compact-open topology that we introduced on page 234.

Put differently, both Lemma 29.6 and Lemma 29.7 can be used to complete the proof of Proposition 29.5.

We start out with the “by hand” approach.

**Lemma 29.6.** Let $Y$ be a path-connected topological space, let $y_0 \in Y$ and let $\Gamma \subset \pi_1(Y, y_0)$ be a subgroup. We write $P := P_{y_0}$ and we write $X := X_{y_0, \Gamma}$. Given $x = [f] \in X = P/ \sim$ and given an open neighborhood $V$ of $p(x) = f(1) \in Y$ we consider

$$U(x, V) := \{[f * u] \mid u \text{ is a path in } V \text{ with starting point } f(1) \} \subset X = P/ \sim.$$  

With this notation the following statement holds:

1. The family of all such subsets $U(x, V)$ of $X$ satisfy the “basis property” that we introduced on page 102.

The topology that is generated on $X = X_{Y_0, \Gamma}$ via the sets $U(x, V)$ is called the whisker topology. If $Y$ is locally path-connected and semi-locally simply connected, and if we equip $X = X_{Y_0, \Gamma}$ with the whisker topology, then the following statements hold:

1. The above evaluation map $p: X \to Y$ is continuous and open.
2. The map $p: X \to Y$ is a covering.
3. The topological space $X$ is path-connected,
4. We have $p_* (\pi_1(X, x_0)) = \Gamma$.

**Proof.** Let $Y$ be a path-connected, let $y_0 \in Y$ and let $\Gamma \subset \pi_1(Y, y_0)$ be a subgroup. We write $P := P_{y_0}$ and we write $X := X_{y_0, \Gamma}$. Given $x = [f] \in X = P/ \sim$ and given an open path-connected neighborhood $V$ of $p(x) = f(1) \in Y$ we consider

$$U(x, V) := \{[f * u] \mid u \text{ is a path in } V \text{ with starting point } f(1) \} \subset X = P/ \sim.$$  

We denote by $B$ the family of all such subsets of $X$.

1. We need to show that $B$ has the basis property.
   1. (B1) For each $x \in X$ we have $x \in U(x, X)$. This shows that $B$ satisfies (B1).
(B2) Now let \( x = [f] \) be a point in the intersection of \( U(a, A) \) and \( U(b, B) \). Let \( V \) be any open neighborhood \( V \) of \( f(1) \) with \( V \subset A \cap B \), e.g. we could take \( V = A \cap B \). It is straightforward to see that \( U(x, V) \subset U(a, A) \cap U(b, B) \). We refer to Figure 534 for an illustration.

![Figure 534](image)

In the following we assume that \( Y \) is locally path-connected and that \( Y \) is semi-locally simply connected. We equip \( X = X_{Y_0, \Gamma} \) with the whisker topology, i.e. we equip it with the topology generated by \( B \). Since \( Y \) is locally path-connected it follows easily that the whisker topology is also generated by

\[
\mathcal{C} := \{ U(x, V) \in B \mid x \in X \text{ and } V \text{ is a path-connected open neighborhood of } p(x) \}.
\]

(1) We need to show that the map \( p: X = P/ \sim \rightarrow Y \) is continuous and open. We start with the following observation: for every \( x \in X \) and every open path-connected neighborhood \( V \) of \( p(x) \) we have \( p(U(x, V)) = V \).

Now we turn to the actual proof of continuity. So let \( A \subset Y \) be an open subset and let \( x = [f] \in p^{-1}(A) \). It suffices to show that there exists an open subset \( B \) of \( Y \) such that \( U(x, B) \subset p^{-1}(A) \). Since \( Y \) is locally path-connected, there exists an open neighborhood \( B \) of \( x \) that is contained in \( A \) and that is path-connected. By the above observation we have \( p(U(x, B)) = B \subset A \), i.e. \( U(x, B) \subset p^{-1}(A) \).

Finally we show that \( p \) is also open. By Lemma 2.39 it suffices to verify that images of the basis \( \mathcal{C} \) of the topology of \( X \) are open. But this statement we had just verified in the above observation.

(2) Now we want to prove that \( p: X = P/ \sim \rightarrow Y \) is a covering map. So let \( y \in Y \) be a point. We need to show that there exists a connected open neighborhood \( V \) of \( y \) such that the restriction of \( p \) to each component of \( p^{-1}(V) \) is a homeomorphism.

Since \( Y \) is semi-locally simply connected, there exists an open neighborhood \( U \) of \( y \) such that the inclusion induced map \( \pi_1(U, x) \rightarrow \pi_1(Y, y) \) is the trivial map. We claim that \( V \) already has the desired property.

**Claim.**

\[
p^{-1}(V) = \bigsqcup_{\tilde{y} \in p^{-1}(y)} U(\tilde{y}, V).
\]

It is clear that the right-hand side is contained in the left-hand side. Next we want to show that the left-hand side is contained in the right-hand side. So let \( [g] \in p^{-1}(V) \). Here \( g \) is a path in \( Y \) from \( y_0 \) to a point \( v \in V \). Since \( V \) is in particular path-connected

\[518\text{By definition we have } p(U(x, V)) \subset V. \text{ But since } V \text{ is path-connected we also have } V \subset p(U(x, V)).\]
there exists a path $h$ in $V$ from $v$ to $y$. We then have
\[
[g] = [g * h * \tilde{h} \in U((g * h), V).
\]

We refer to Figure 535 for an illustration.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure535}
\caption{Figure 535}
\end{figure}

It remains to show that the sets on the right-hand side of the claim are disjoint. So let $[v'], [v''] \in p^{-1}(y)$ and let $[g] \in U([v'], V) \cap U([v''], V)$. Then there exist paths $u'$ and $u''$ in $V$ with $[v' * u'] = [v'' * u'']$. It follows that
\[
[v'] = [v' * u' * \overline{u'}] = [v'' * u'' * \overline{u'']} = [v'']
\]

$u'' * \overline{u'}$ is null-homotopic since the map $\pi_1(V, y) \to \pi_1(Y, y)$ is the trivial map.

Thus $U([v'], V) \cap U([v''], V)$ intersect only if $[v'] = [v'']$. We refer to Figure 536 for an illustration.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure536}
\caption{Figure 536}
\end{figure}

The sets $U(\tilde{y}, V)$ are by definition open. By the above claim the sets are also disjoint. Thus it suffices to prove the following claim.

\textbf{Claim.} For each $\tilde{y} \in p^{-1}(y)$ the restriction of the projection map $p: X = P/ \sim \to Y$ to the map $p: U(\tilde{y}, V) \to V$ is a homeomorphism.

So let $\tilde{y} \in p^{-1}(y)$. As we had just pointed out in (1), the map $p: U(\tilde{y}, V) \to V$ is surjective. From the fact that the inclusion induced map $\pi_1(V, y) \to \pi_1(Y, y)$ is trivial it also follows immediately that $p$ is injective. Furthermore we had just verified in (1) that $p$ is continuous and open. Therefore $p: U(\tilde{y}, V) \to V$ is a homeomorphism.

\textbf{(3)} Now we want to show that $X = P/ \sim$ is path-connected. We start out with the following claim.

\textbf{Claim.} Let $\alpha: [0, 1] \to Y$ be a path. Then
\[
\tilde{\alpha}: [0, 1] \to X = P/ \sim \\
\begin{array}{c}
t \mapsto [0, 1] \to Y \\
s \mapsto \alpha(ts)
\end{array}
\]
is a continuous map.

By Proposition 2.37 it suffices to show that for each $U(x, V)$ in the basis $C$ of the topology on $X$ the preimage $\tilde{\alpha}^{-1}(U(x, V))$ is open in $[0, 1]$. So suppose we are given $U(x, V)$. We denote by $\{I_j\}_{j \in J}$ the path-components of $\alpha^{-1}(V)$. Since $\alpha$ is continuous each $I_j$ is an open subset of $[0, 1]$. Note that for each $j \in J$ we either have $\tilde{\alpha}(I_j) \subset U(x, V)$ or $\tilde{\alpha}(I_j) \cap U(x, V) = \emptyset$. It follows that

$$\tilde{\alpha}^{-1}(U(x, V)) = \text{union of all the } I_j \text{ with the property that } \tilde{\alpha}(I_j) \subset U(x, V).$$

Thus we see that $\tilde{\alpha}^{-1}(U(x, V))$ is a union of open subsets of $[0, 1]$, hence the preimage itself is open.

To show that $X$ is path-connected it suffices to show that for every point $x \in X$ there exists a path in $X$ from $x_0 = [e_{y_0}]$ to $x$. So let $x = [\alpha] \in X$. Then such a path is given by $\tilde{\alpha} : [0, 1] \to X$, where $\tilde{\alpha}$ is defined as in the claim. By the claim $\tilde{\alpha}$ is indeed continuous.

(4) It remains to show that $p_*(\pi_1(X, x_0)) = \Gamma$. Let $g \in \pi_1(Y, y_0)$. We choose a representatives $\alpha : [0, 1] \to Y$ of $g$. We consider the following path $\tilde{\alpha}$ in $X = P/\sim$

$$\tilde{\alpha} : [0, 1] \to X = P/\sim$$

$$t \mapsto \left[ [0, 1] \to Y, \quad s \mapsto \alpha(ts) \right].$$

Note that $\tilde{\alpha}$ is evidently the lift of $\alpha$ to the starting point $x_0$. Then we have $g \in p_*(\pi_1(X, x_0)) \iff \tilde{\alpha}$ is a loop $\iff$ in $X = P/\sim$ we have $\tilde{\alpha}(1) = x_0 = [e_{y_0}] \iff \alpha \in \Gamma$.

Next we use the “off-the-shelves”-topology, namely we will make use of the compact-open topology. For the reader’s convenience we recall the definition from page 233.

**Definition.** Let $Y$ and $A$ be topological spaces. The **compact-open topology** on the set $Y^A$, i.e. on the set of all maps from $A$ to $Y$, is the topology generated, in the sense of the definition on page 103, by all the sets of the form

$$M(K, U) := \{ f \in Y^A \mid f(K) \subset U \}$$

where $K \subset A$ is compact and where $U \subset Y$ is open.

**Lemma 29.7.** Let $Y$ be a path-connected topological space and let $y_0 \in Y$. Furthermore, let $\Gamma \subset \pi_1(Y, y_0)$ be a subgroup.

(i) We equip $Y^{[0, 1]} = \text{set of all maps } [0, 1] \to Y \text{ with the compact-open topology}.$

(ii) We equip $P_{y_0} = \{ \gamma \in Y^{[0, 1]} \mid \gamma(0) = y_0 \}$ with the subspace topology.

(iii) We equip $X_{y_0, \Gamma} = P_{y_0}/\sim$ with the quotient topology.

---

519 This might require a few minutes of thought.

520 Note that this map is continuous by the claim in (3).
29. THE EXISTENCE OF UNIVERSAL COVERINGS

We refer to this topology on \(X_{y_0,\Gamma} = P_{y_0} / \sim\) as the CO-topology on \(X_{y_0,\Gamma}\). We write \(X := X_{y_0,\Gamma}\). If \(Y\) is locally path-connected and semi-locally simply connected, then the following statements hold:

1. The above evaluation map \(p : X \to Y\) is continuous and open.
2. The map \(p : X \to Y\) is a covering.
3. The topological space \(X\) is path-connected.
4. We have \(p_* (\pi_1(X, x_0)) = \Gamma\).

Proof. Let \(Y\) be a topological space that is path-connected, locally path-connected and semi-locally simply connected, let \(y_0 \in Y\) and let \(\Gamma \subset \pi_1(Y, y_0)\) be a subgroup. We write \(X := X_{y_0,\Gamma}\) and we equip \(X := P/\sim\) with the CO-topology. We make a few preparations:

(i) We consider the maps

\[
\begin{align*}
P & \xrightarrow{\sim} Y^{[0,1]} \\
q & \downarrow \\
X = P/\sim & \xrightarrow{\sim} Y
\end{align*}
\]

where \(q\) is the projection map and \(ev : Y^{[0,1]} \to Y\) is given by the evaluation at 1. By Lemma 3.21 (3) we know that \(q\) is continuous. Furthermore by Proposition 5.4 we know that the map \(ev : Y^{[0,1]} \to Y\) is continuous. Thus it follows from Lemma 2.30 (3) and Lemma 3.22 (2) that the induced map \(p : X = P/\sim \to Y\) is continuous.

(ii) Since \(Y\) is locally path-connected it follows from Lemma 2.71 that the open path-connected subsets of \(Y\) form a basis for the topology of \(Y\). Since \([0, 1]\) is Hausdorff we obtain from Lemma 5.8 that the sets \(M(K, U)\), with \(K \subset [0, 1]\) compact and \(U\) open and path-connected form a basis for the topology of the compact-open topology on \(Y^{[0,1]}\).

(iii) Let \(x = [f] \in X = P/\sim\) and let \(V\) be an open path-connected neighborhood of \(p(x) = f(1) \in Y\). As in Lemma 29.6 we consider

\[
U(x, V) := \{[f \ast u] \mid u\text{ is a path in } V\text{ with starting point } f(1)\} \subset X = P/\sim.
\]

We want to show that \(U(x, V)\) is an open subset of \(X\). By definition of the quotient topology we need to show that \(q^{-1}(U(x, V))\) is an open subset of \(P\). This statement is easily seen to be a consequence of the following claim.

Claim. Let \(g : [0, 1] \to Y\) be a path with \(g(0) = y_0\) and \(g(1) \in V\). The set

\[
\left\{ h \in P \mid \text{there exists a path } u : [0, 1] \to V\text{ with } u(0) = g(1) \text{ such that } h \text{ is path-homotopic to } g \ast u \right\}
\]

is an open subset of \(P\).

Let \(h \in P\) be a path that is path-homotopic to \(g \ast u\) for some path \(u : [0, 1] \to V\). Note that it follows from the fact that \(Y\) is semi-locally simply connected, together with Corollary 2.76 that there exists an \(n \in \mathbb{N}\) and open subsets \(D_1, \ldots, D_n\) of \(Y\) with the following properties:

(a) For each \(i \in \{0, \ldots, n-1\}\) we have \(h([\frac{i}{n}, \frac{i+1}{n}]) \subset D_i\).
(b) For each $i \in \{0, \ldots, n-1\}$ the inclusion induced map $\pi_1(D_i, h(\frac{i}{n})) \to \pi_1(Y, h(\frac{i}{n}))$ is the trivial map.

Since $Y$ is locally path-connected we can furthermore find open path-connected neighborhood $E_1, \ldots, E_{n-1}$ of $h(\frac{1}{n}), \ldots, h(\frac{n-1}{n})$. Now let

$$Z := \bigcap_{i=0}^{n-1} M(\{\frac{i}{n}, \frac{i+1}{n}\}, D_i) \cap \bigcap_{i=1}^{n-1} M(\{\frac{i}{n}\}, E_i) \cap M(\{1\}, V).$$

We make the following observations:

(a) By definition of the compact-open topology we know that $Z$ is an open subset of $Y^{[0,1]}$. Furthermore it follows from (a) and the choice of $E_1, \ldots, E_{n-1}$ that $h \in Z$.

(b) By Lemma 2.5 it remains to show that $Z \cap P$ is contained in the set that we described in the statement of the claim.

Now let $k \in Z \cap P$.

(γ) Since $k(1) \in V$ and since $V$ is path-connected there exists a path $v: [0,1] \to V$ from $h(1)$ to $k(1)$.

(δ) Since the $E_1, \ldots, E_{n-1}$ are path-connected we can arrange, after a path-homotopy, that $k(\frac{i}{n}) = (h \ast v)(\frac{i}{n})$ for $i = 0, \ldots, n-1$.

(η) It follows from (b) together with a slight variation on Lemma 14.13 that we can show that $k$ is path-homotopic to $h \ast v$.

Since $k$ is path-homotopic to $h \ast v$ and since $h$ is path-homotopic to $g \ast u$ we have now shown that $k$ is path-homotopic to $g \ast (u \ast v)$. But this means that $k$ lies again in the set defined in the statement of the claim. \qed

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure.png}
\caption{Illustration for the proof of Lemma 29.7}
\end{figure}

(iv) Let $\alpha: [0,1] \to Y$ be a path with $\alpha(0) = y_0$. It follows easily from Proposition 5.6 and Lemma 2.30 (4) that the map

$$[0,1] \to P \subset Y^{[0,1]} \quad t \mapsto \left( \begin{array}{c}
[0,1] \to Y \\
0 \to \alpha(t) \end{array} \right).$$

is continuous.

Now we turn to the actual proofs of the four statements.

(1) In (i) we already showed that $p: X = P/ \sim \to Y$ is continuous. We still need to show that $p$ is open. It follows from an elementary argument, see Exercise 3.23, that it suffices to show that the evaluation map $ev = p \circ q: P \to Y$ is open. In fact it follows from (ii), together with Lemmas 2.28 and Lemma 2.39 that it suffices to prove the following claim.
Claim. For each compact subset $K \subset [0, 1]$ and each path-connected open subset $V \subset Y$ we have $\text{ev}(M(K, V) \cap P) = V$.

A straightforward argument, that uses that $Y$ and $V$ are path-connected, shows that

$$
\text{ev}(M(K, V) \cap P) = \begin{cases} 
\emptyset, & \text{if } M(K, V) = \emptyset, \\
Y, & \text{if } 1 \notin K \text{ and } M(K, V) \neq \emptyset, \\
V, & \text{if } 1 \in K.
\end{cases}
$$

Thus we see that in any case the image $\text{ev}(M(K, V))$ is an open subset of $Y$. \(\Box\)

(2) Now we want to prove that $p: X = P/ \sim \to Y$ is a covering map. So let $y \in Y$ be a point. We need to show that there exists a connected open neighborhood $V$ of $y$ such that the restriction of $p$ to each component of $p^{-1}(V)$ is a homeomorphism.

Since $Y$ is semi-locally simply connected, there exists an open neighborhood $V$ of $y$ such that the inclusion induced map $\pi_1(V, y) \to \pi_1(Y, y)$ is the trivial map. We claim that $V$ already has the desired property.

Claim.

$$p^{-1}(V) = \bigsqcup_{\bar{y} \in p^{-1}(y)} U(\bar{y}, V).$$

For the reader’s convenience we repeat word-by-word the proof from page 827. First note that it is clear that the right-hand side is contained in the left-hand side. Next we want to show that the left-hand side is contained in the right-hand side. So let $[g] \in p^{-1}(V)$. Here $g$ is a path in $Y$ from $y_0$ to a point $v \in V$. Since $V$ is in particular path-connected there exists a path $h$ in $V$ from $v$ to $y$. We then have

$$[g] = [g * h * \bar{h}] \in U(g * h, V).$$

It remains to show that the sets on the right-hand side of the claim are disjoint. So let $[v'], [v''] \in p^{-1}(y)$ and let $[g] \in U([v'], V) \cap U([v''], V)$. Then there exist paths $u'$ and $u''$ in $V$ with $[v' * u'] = [v'' * u'']$. It follows that

$$[v'] = [v' * u' * \bar{u}'] = [v'' * u'' * \bar{u}'] \uparrow [v''],$$

$u'' * \bar{u}'$ is null-homotopic since the map $\pi_1(V, y) \to \pi_1(Y, y)$ is the trivial map.

Thus $U([v'], V) \cap U([v''], V)$ intersect only if $[v'] = [v'']$. \(\Box\)

By (iii) we know that the sets $U(\bar{y}, V)$ are open. By the above claim the sets are also disjoint. Thus it suffices to prove the following claim.

Claim. For each $\bar{y} \in p^{-1}(y)$ the restriction of the projection map $p: X = P/ \sim \to Y$ to the map $p: U(\bar{y}, V) \to V$ is a homeomorphism.

The proof of this claim is again almost verbatim the same as on page 827. So let $\bar{y} \in p^{-1}(y)$. It follows easily from the fact that $V$ that the map $p: U(\bar{y}, V) \to V$ is surjective. From the fact that the inclusion induced map $\pi_1(V, y) \to \pi_1(Y, y)$ is trivial it also follows immediately that $p$ is injective. Furthermore we had just verified in
(1) that $p$ is continuous and open. Therefore $p: U(\bar{y}, V) \to V$ is a homeomorphism.

(3) It follows from the fact that $Y$ is path-connected together with (iv) that $P$ is path-connected. By Lemma 3.21 (5) this implies that $X = P/\sim$ is path-connected.

(4) It remains to show that $p_*(\pi_1(X,x_0)) = \Gamma$. The proof we now give is basically identical to the proof on page 828. Thus let $g \in \pi_1(Y,y_0)$. We choose a representatives \( \alpha: [0,1] \to Y \) of $g$. We consider the following map:

\[ \tilde{\alpha}: [0,1] \to X = P/\sim \]
\[ t \mapsto \left[ [0,1] \to Y, \quad s \mapsto \alpha(ts) \right]. \]

By (iv) we know that $\tilde{\alpha}$ is in fact continuous. It is now clear that $\tilde{\alpha}$ is the lift of $\alpha$ to the starting point $x_0$. Then we have

$g \in p_*(\pi_1(X,x_0)) \Leftrightarrow \tilde{\alpha}$ is a loop \( \Leftrightarrow \) in $X = P/\sim$ we have $\tilde{\alpha}(1) = x_0 = [e_{y_0}] \Leftrightarrow \alpha \in \Gamma$.

\[ \uparrow \]
Lemma 16.13 (1)

\[ \uparrow \]
Remark.

(1) The construction of the universal covering of a topological space has its origin in the work of Hermann Weyl from 1913, see [Wey1913] [Wey64], p. 58.

(2) Let $Y$ be a path-connected topological space, let $y_0 \in Y$ and let $\Gamma \subset \pi = \pi_1(Y,y_0)$ be a subgroup. Recall that in Lemma 29.6 we introduced the whisker topology and that in Lemma 29.7 we introduced the CO-topology on $X_{y_0,\Gamma} := P_{y_0}/\sim$.

(a) In [FZ07], Lemma 2.1 it is shown that the CO-topology is contained in the whisker topology.

(b) In [FZ07], Example 2.2 it is shown that the two topologies are in general not equal, for example they disagree for the Hawaiian earrings that we introduced on page 727.

(c) It follows from Proposition 29.8 (see also [FZ07], Lemma 2.1) that the two topologies agree for every topological space that is locally path-connected and semi-locally simply connected.

(3) The various choices of topologies on $X_{y_0,\Gamma} = P_{y_0}/\sim$ are discussed in greater detail in [FZ07], [VZ14], and [Pav20]. The history of the construction of covering spaces is also outlined [Pav20].

29.5. **Uniqueness of covering spaces.** Now the question arises, to what degree is the covering corresponding to the subgroup $\Gamma$ unique. To answer that question we need an appropriate notion of two coverings being equivalent.

**Definition.** Let $p: X \to B$ and $q: Y \to B$ be two coverings of a topological space $B$. We say $p$ and $q$ are *equivalent*, if there exists a homeomorphism $\Phi: X \to Y$ such that the
following diagram commutes:

\[
\begin{array}{ccc}
X & \xrightarrow{\Phi} & Y \\
\downarrow{p} & \cong & \downarrow{q} \\
B. & & 
\end{array}
\]

Similarly we define the equivalence of coverings of pointed topological spaces.

**Example.** Given \( n \in \mathbb{N} \) the two coverings

\[
p: S^1 \to S^1 \quad \text{and} \quad q: \mathbb{R}/n\mathbb{Z} \to S^1
\]

\( z \mapsto z^n \quad \text{and} \quad t + n\mathbb{Z} \mapsto e^{it} \)

are equivalent. In fact the desired map \( \Phi: S^1 \to \mathbb{R}/n\mathbb{Z} \) is given by \( e^{2\pi it} \mapsto [nt] \).

Now we can formulate the following proposition:

**Proposition 29.8.** Let \( B \) be a topological space, let \( b_0 \in B \) and let \( \Gamma \subset \pi_1(B,b_0) \) be a subgroup.

(1) Let \( p: (X,x_0) \to (B,b_0) \) be a path-connected and locally path-connected covering such that \( p_* (\pi_1(X,x_0)) = \Gamma \). This covering has the following universal property: for any other path-connected covering \( q: (Y,y_0) \to (B,b_0) \) with \( \Gamma \subset q_* (\pi_1(Y,y_0)) \) there exists a unique covering \( r: (X,x_0) \to (Y,y_0) \) such that the following diagram commutes:

\[
\begin{array}{ccc}
(X,x_0) & \xrightarrow{r} & (Y,y_0) \\
\downarrow{p} & & \downarrow{q} \\
(B,b_0) & & 
\end{array}
\]

(2) If \( B \) is path-connected, locally path-connected and semi-locally simply connected, then there exists, up to equivalence, a unique path-connected covering \( p: (X,x_0) \to (B,b_0) \) of pointed topological spaces such that \( p_* (\pi_1(X,x_0)) = \Gamma \).

**Remark.** Let \( B \) be a topological space that is path-connected, locally path-connected and semi-locally simply connected. Furthermore let \( b_0 \in B \) and let \( \Gamma \subset \pi_1(B,b_0) \) be a subgroup. It follows from Proposition 29.8 that the whisker topology and the CO-topology a on the set \( X = \{ \gamma \in B^{[0,1]} \mid \gamma(0) = b_0 \} / \sim \), which we introduced in Lemmas 29.6 and 29.7, are actually the same.

**Proof.** Let \( B \) be a topological space and let \( b_0 \in B \).

(1) Let \( p: (X,x_0) \to (B,b_0) \) and \( q: (Y,y_0) \to (B,b_0) \) be two path-connected coverings such that \( p_* (\pi_1(X,x_0)) \subset q_* (\pi_1(Y,y_0)) \). We assume furthermore that \( X \) is locally path-connected. It follows from Proposition 29.7 that there exists a unique map \( r: (X,x_0) \to (Y,y_0) \) which makes the following diagram commute

\[
\begin{array}{ccc}
(X,x_0) & \xrightarrow{r} & (Y,y_0) \\
\downarrow{p} & & \downarrow{q} \\
(B,b_0) & & 
\end{array}
\]
It remains to show that \( r \) is a covering. This will be done in Exercise 29.4.

(2) The existence of such a covering is just the statement of Proposition 29.5. The uniqueness statement is an immediate consequence of (1)\(^\text{521}\) and the usual proof of uniqueness for an object satisfying a universal property. We leave the details to the reader. \( \blacksquare \)

Propositions 29.5 and 29.8 (2) lead us to the following definition.

**Definition.** Let \( B \) be a topological space that is path-connected, locally path-connected and semi-locally simply connected, let \( b_0 \in B \) and let \( \Gamma \subset \pi_1(B, b_0) \) be a subgroup.

1. As in the proof of Proposition 29.5 we consider the set

\[
\tilde{B}^\Gamma_{b_0} := \{ \text{all paths in } B \text{ with starting point } b_0 \}/\sim
\]

where \( u \sim v \) if and only \( u \) and \( v \) have the same endpoint and if \( [u * v] \in \Gamma \). We equip the set \( \tilde{B}^\Gamma_{b_0} \) with the topology introduced in the proof of Proposition 29.5. We refer to \( \tilde{B}^\Gamma_{b_0} \) together with map \( p: \tilde{B}^\Gamma_{b_0} \to B \) given by \( [u] \mapsto u(1) \) as the canonical covering corresponding to \( (B, b_0, \Gamma) \). Furthermore we refer to the point in \( \tilde{B}^\Gamma_{b_0} \) that is represented by the constant path as the canonical base point of \( \tilde{B}^\Gamma_{b_0} \).

2. We refer to any path-connected covering \( p: (X, x_0) \to (B, b_0) \) of pointed topological spaces with \( p_* (\pi_1(X, x_0)) = \Gamma \) as the covering of \( B \) corresponding to \( \Gamma \). By Proposition 29.8 (2) any two such coverings are equivalent, in particular any such covering is equivalent to the above canonical covering. In practice usually we do not care about this indeterminacy.

Proposition 29.8 can be viewed as a “machine” that constructs covering spaces of a given topological space \( X \). In the next section we discuss the case that \( X \) is a surface in somewhat greater detail to get a better feeling for what is happening.

### 29.6. The universal covering

In Proposition 29.8 we saw that subgroups of fundamental groups give rise to covering spaces. An obvious choice of a subgroup is the trivial group and we immediately obtain the following corollary to Proposition 29.8.

**Corollary 29.9.** Let \( X \) be a topological space that is path-connected, locally path-connected and semi-locally simply connected. Furthermore let \( x_0 \in X \). Then the following holds:

1. There exists, up to equivalence, a unique path-connected covering

\[
p: (\tilde{X}, \tilde{x}_0) \to (X, x_0)
\]

such that \( \tilde{X} \) is simply connected.

\(^{521}\)If one does the argument carefully, then one sees, that here we use the following fact: if \( B \) is locally path-connected, then also every covering space of \( B \) is locally locally path-connected.
Let \( q: (Y, y_0) \to (X, x_0) \) be another path-connected covering. Then there exists a unique covering \( r: (\tilde{X}, \tilde{x}_0) \to (Y, y_0) \) such that the following diagram commutes:

\[
\begin{array}{c}
(\tilde{X}, \tilde{x}_0) \\
p \downarrow \quad \downarrow r \\
(X, x_0) \\
q \leftarrow \leftarrow (Y, y_0)
\end{array}
\]

Proof. Let \( X \) be a topological space that is path-connected, locally path-connected and semi-locally simply connected and let \( x_0 \in X \).

1. We apply Proposition \(29.8\) to the trivial subgroup of \( \pi_1(X, x_0) \) and we obtain, up to equivalence, a unique path-connected covering \( p: (\tilde{X}, \tilde{x}_0) \to (X, x_0) \) such that \( p_*(\pi_1(\tilde{X}, \tilde{x}_0)) \) is the trivial group. But then it follows from Corollary \(16.14\) that \( \tilde{X} \) is simply connected.

2. The second statement is also an immediate consequence of Proposition \(29.8\). \(\square\)

Definition. Let \( X \) be a topological space that is path-connected, locally path-connected and semi-locally simply connected and let \( x_0 \in X \).

1. We refer to the canonical covering \( p: \tilde{X}_{x_0} := \tilde{X}^{\{e\}} \to X \), as defined on page \(834\), as the canonical universal covering of \((X, x_0)\).

2. We refer to any covering \( p: (\tilde{X}, \tilde{x}_0) \to (X, x_0) \) such that \( \tilde{X} \) is simply connected as a universal covering of \((X, x_0)\). As we remarked in the definition on page \(834\), very often we suppress the fact that the universal covering is well-defined only up to equivalence.

3. Sometimes we ignore base points and we say that a covering \( p: \tilde{X} \to X \) is the universal covering if \( \tilde{X} \) is simply connected.

Remark. Note that most “reasonable” topological spaces are locally path-connected and semi-locally simply connected. For example we saw on page \(816\) that every topological manifold is locally simply connected, which implies in particular that it is locally path-connected and semi-locally simply connected. Thus, given a path-connected topological manifold we can talk of its universal covering.

Examples.

1. The map

\[
p: \mathbb{R} \to \mathbb{R}/\mathbb{Z} = S^1 \\
t \mapsto e^{2\pi it}
\]

is the universal covering of \( S^1 \).

\(^{522}\)In the literature the universal covering of a topological space is usually indicated by the same symbol but decorated with a tilde, e.g. the universal covering of \( X \) is usually denoted by \( \tilde{X} \).
(2) More generally, the map
\[ p: \mathbb{R}^n \rightarrow (S^1)^n \]
\[ (t_1, \ldots, t_n) \mapsto (e^{2\pi i t_1}, \ldots, e^{2\pi i t_n}) \]
is the universal covering of the \( n \)-dimensional torus \((S^1)^n\).

(3) The projection map \( p: S^3 \rightarrow S^3/\mathbb{Z}_p = L(p, q) \) is the universal covering of the lens space \( L(p, q) \).

**Remark.** The universal covering is often also just called the *universal cover*. Also very often one suppresses the actual map \( p \) from the notation. For example, often one says that \( \mathbb{R}^n \) is the universal covering of \((S^1)^n\). The name “universal cover(ing)” stems from the fact, proved in Corollary 29.9, that the universal cover(ing) of a topological space \( X \) “covers” every other covering of \( X \).

We have now shown that for every topological space \( X \) that is locally path-connected and semi-locally simply connected there exists a universal covering \( p: \tilde{X} \rightarrow X \). So far we have given an abstract construction, but if possible we would like to visualize it. We have just given an explicit description of the universal covering of the \( n \)-dimensional torus \((S^1)^n\) and the lens spaces. Now we will describe the universal covers of \( X = S^1 \vee S^2 \) and \( X = S^1 \vee S^1 \).

First we consider \( X = S^1 \vee S^2 \) where we identify \( i \in S^1 \) with \((0, 0, -1) \in S^2\). As on page 609 we consider the topological space
\[ \tilde{X} = (\mathbb{R} \cup (\mathbb{Z} \times S^2)) / n \sim (n, (0, 0, -1)), \quad n \in \mathbb{Z}. \]

It is straightforward to see that the map
\[ p: (\mathbb{R} \cup (\mathbb{Z} \times S^2)) / n \sim (n, (0, 0, -1)) \rightarrow S^1 \vee S^2 \]
\[ P \mapsto \begin{cases} e^{i(2\pi P + \frac{\pi}{4})}, & \text{if } P \in \mathbb{R} \\ Q, & \text{if } P = (n, Q) \text{with } n \in \mathbb{Z}, Q \in S^2 \end{cases} \]
is well-defined and in fact a covering. We saw on page 609 that \( \tilde{X} \) is simply connected. Thus \( p: \tilde{X} \rightarrow X \) is the universal covering of \( X \).

**Figure 538**

Now we turn to \( X = S^1 \vee S^1 \). In the following we give a semi-rigorous description of the universal covering of \( S^1 \vee S^1 \) as a subset of \( \mathbb{R}^2 \). Iteratively we build a sequence of topological spaces \( Y_k, k \in \mathbb{N}_0 \) as follows:

(1) The space \( Y_0 \) is the cross centered at the origin where each segment has length 1.
(2) Given $Y_k$ we attach to each endpoint of $Y_k$ three segments of length $\frac{1}{4k}$ such that each endpoint of $Y_k$ now has a neighborhood that is a cross. We denote the resulting space by $Y_{k+1}$.

Finally we put $Y = \bigcup_{k \in \mathbb{N}_0} Y_k$. This construction is illustrated in Figure 539. We summarize

![Figure 539](image)

some of the key properties of the construction in the following claim.

**Claim.**

1. Each $Y_k$ is a tree.\footnote{In Figure 539 and 540 the lengths of the segments is $\frac{1}{4k}$ since these are easier to draw.}
2. $Y$ is simply connected.

**Sketch of proof.** First note that $\chi(Y_0) = 5 - 4 = 1$. For $k \geq 1$ we obtain $Y_k$ from $Y_{k-1}$ by adding three vertices and three edges, hence $\chi(Y_k) = \chi(Y_{k-1}) = \cdots = \chi(Y_0) = 1$.\footnote{Recall that by definition a tree is a topological graph with finitely many vertices $V$ and edges $E$, such that the Euler characteristic $\chi(G) = |V| - |E| = 1$.} This shows that each $Y_k$ is a tree. It follows from Proposition 18.29 that each $Y_k$ is simply connected.

Given $k \in \mathbb{N}$ we denote by $U_k$ the result of removing the $4^{k+1}$ endpoints of $Y_k$. Note that each $U_k$ is open in $Y_k$, hence each $U_k$ is open in $Y$. Furthermore each $U_k$ deformation retracts to $Y_{k-1}$. Hence it follows from the fact that each $Y_k$ is simply connected that also each $U_k$ is simply connected.

It follows as in Lemma 20.6 that $Y = \bigcup_{k \in \mathbb{N}} Y_k = \bigcup_{k \in \mathbb{N}} U_k$ itself is simply connected. $\blacksquare$

Now we construct a covering $p: Y \rightarrow S^1 \vee S^1$. To distinguish the two copies of $S^1$ we name them $A$ and $B$, which are wedged together along $a \in A$ and $b \in B$. We give both $A$ and $B$ the usual counterclockwise orientation. Furthermore we orient each edge of the infinite topological graph $Y$ as indicated in Figure 540. We consider the map $p: Y \rightarrow A \vee B$ that is given as follows:

1. each vertex of the infinite topological graph $Y$ gets sent to the point $a = b \in A \vee B$,
2. each horizontal edge of $Y$ gets sent in an orientation-preserving way to $A \setminus \{a\}$,
3. each vertical edge of $Y$ gets sent in an orientation-preserving way to $B \setminus \{b\}$.
This map is illustrated in Figure 540. It is relatively straightforward to convince oneself that \( p: Y \to X \) is in fact a covering. Since \( Y \) is simply connected, this is the universal covering of \( X = A \vee B = S^1 \vee S^1 \).

We have now determined explicitly the universal covers of several topological spaces. The surfaces of genus \( g \geq 2 \) are arguably one of the most interesting types of topological manifolds. Therefore it is natural to ask the following question.

**Question 29.10.** What does the universal covering of the surface of genus \( g \geq 2 \) look like?

We continue with the following lemma which will prove helpful at times.

**Lemma 29.11.** Let \( X \) be a topological space that is path-connected, locally path-connected and semi-locally simply connected with universal covering \( p: \tilde{X} \to X \). Given any map \( f: X \to X \), given any \( x_0 \in X \), given any \( \tilde{x}_0 \in \tilde{X} \) and given any \( \tilde{y}_0 \in \tilde{X} \) with \( p(\tilde{y}_0) = f(x_0) \) there exists a unique map \( \tilde{f}: \tilde{X} \to \tilde{X} \) with \( \tilde{f}(\tilde{x}_0) = \tilde{y}_0 \) such that the following diagram commutes:

\[
\begin{array}{ccc}
\tilde{X} & \xrightarrow{\tilde{f}} & \tilde{X} \\
p \downarrow & & \downarrow p \\
X & \xrightarrow{f} & X
\end{array}
\]

Furthermore, if \( f \) is a homeomorphism, then \( \tilde{f} \) is also a homeomorphism.

**Remark.** Lemma 29.11 is a generalization of Exercise 17.3 (a).

**Proof.** We consider the map \( f \circ g := p: \tilde{X} \to X \). Since \( \tilde{X}_0 \) is the universal covering, since \( \pi_1(\tilde{X}, \tilde{x}_0) \) and since \( X \) is locally path-connected and semi-locally simply connected we obtain from Proposition 29.2 that there exists a unique lift \( \tilde{g}: \tilde{X} \to \tilde{X} \) of \( g \) with \( \tilde{g}(\tilde{x}_0) = \tilde{y}_0 \). This map is precisely the map we were trying to find. We will show in Exercise 29.10 that \( \tilde{f} \) is a homeomorphism.

---

Note: We have to check that each point in \( X = A \vee B \) admits an open neighborhood that is uniformly covered. It is clear that such a point exists for all points that are not the wedge point. For the wedge point itself the desired open neighborhood is given by small open intervals on \( A \) and \( B \). Then each component of the preimage consists of a little cross with center \( P \), with one horizontal edge going into \( P \), one horizontal edge going out of \( P \), one vertical edge going into \( P \) and one vertical edge going out of \( P \).
We conclude this section with a more general statement. Recall that in Theorem \ref{Proposition 29.5} we saw that if $X$ is a simply connected topological space and if $G$ is a group that acts continuously and discretely on $X$, then the fundamental group of the quotient space $X/G$ is isomorphic to $G$. Now we will show that, under modest extra hypotheses, the converse holds. More precisely, we have the following proposition.

**Proposition 29.12.** (\*) Let $Y$ be a topological space that is path-connected, locally path-connected and semi-locally simply connected and let $y_0 \in Y$. We write $\pi = \pi_1(Y, y_0)$. Then there exists a simply connected topological space $X$, namely the universal covering of $Y$, and a continuous and discrete action of $\pi$ on $X$ such that $Y$ is homeomorphic to $X/\pi$.

**Proof (\*).** Let $Y$ be a topological space that is path-connected, locally path-connected and semi-locally simply connected and let $y_0 \in Y$ be a base point. In Proposition 29.5 we already showed that $Y$ admits a simply connected covering. We recall the explicit construction given in the proof of Proposition 29.5. Thus we consider

$$P := \{ f \in Y^{[0,1]} \mid f(0) = y_0 \} = \{ \text{all paths in } Y \text{ with starting point } y_0 \}.$$  

For $u, v \in P$ we write

$$u \sim v \iff \text{u and v have the same endpoint and } [u * \overline{v}] = e \in \pi_1(Y, y_0)$$

and we put $X = P/ \sim$. As in Lemma 29.6 given $x = [f] \in X = P/ \sim$ and an open path-connected neighborhood $V$ of $f(1)$ we define

$$U(x, V) := \{ [f * u] \mid u \text{ is a path in } V \text{ with starting point } f(1) \} \subset X = P/ \sim.$$  

Furthermore, as in Lemma 29.6 we endow $X$ with the whisker topology, i.e. with the topology generated by these sets $U(x, V)$.

**Claim.** The map

$$\pi_1(Y, y_0) \times X \to X \quad ([g], [u]) \mapsto [g * u]$$

is a well-defined action.

We first show that the map is independent of the choice of $u$. So suppose that $u, v \in P$ are equivalent. Then $g * u$ and $g * v$ still have the same endpoint. Now we need to consider the second condition in the definition of $\sim$. We have

$$[(g * u) * (\overline{g * v})] = [g * u * \overline{v} * \overline{g}] = [g] * [u * \overline{v}] * [g]^{-1} = e \in \pi_1(Y, y_0).$$

It is straightforward to see that the map does not depend on the choice of representative $g$. Finally we want to show that it is indeed an action. So let $[g], [h] \in \pi_1(Y, y_0)$. Then

$$[g] \cdot ([h] \cdot [u]) = [g] \cdot [h * u] = [g * (h * u)] = [(g * h) * u] = [g * h] \cdot [u] = ([g] \cdot [h]) \cdot [u].$$

Now we need to show the following:

1. the group $\pi_1(Y, y_0)$ acts continuously and discretely on $X = P/ \sim$,
2. there exists a homeomorphism $f : X/\pi_1(Y, y_0) \to Y$.  

\[\square\]
We do this in the following two steps:

(1) It follows immediately from the definition of the whisker topology on $X = P/\sim$ and from Proposition 2.37 that the action is continuous.

Now we need to show that the action is discrete. So let $x = [\gamma] \in P/\sim$. We set $z := \gamma(1) \in Y$. Since $Y$ is semi-locally simply connected there exists an open neighborhood $V$ of $z = \gamma(1)$ such that the inclusion induced map $\pi_1(V, z) \to \pi_1(Y, z)$ is trivial. It suffices to show that for $[g] \in \pi_1(Y, y_0)$ we have

$$[g] \cdot U(x, V) \cap U(x, V) \neq \emptyset \implies [g] = e \in \pi_1(Y, y_0).$$

So suppose that $[g] \cdot U(x, V) \cap U(x, V) \neq \emptyset$. This means that there exist paths $a$ and $b$ in $U$, starting from $P$ such that $g \cdot \gamma \cdot a$ and $\gamma \cdot b$ have the same endpoint and they are path-homotopic in $Y$. But then

$$[g] = [g] \cdot [\gamma] \cdot [a \cdot b] \cdot [\gamma]^{-1} = [(g \cdot \gamma \cdot a) \cdot (\gamma \cdot b)] = e \in \pi_1(Y, y_0).$$

We refer to Figure 541 for an illustration.

(2) We consider the map

$$f: X/\pi_1(Y, y_0) \to Y \quad [\gamma] \mapsto \gamma(1).$$

It is straightforward to see that this map is a bijection. It follows immediately from Lemma 3.22 that the map is continuous and it follows from Lemma 2.39 that the map is open. Thus it is a homeomorphism.

---

**Exercises for Chapter 29**

**Exercise 29.1.**

(a) Show that every topological graph is locally contractible.

(b) Let $\{X_i\}_{i \in I}$ be a family of locally contractible topological spaces. Show that any wedge $\bigvee_{i \in I} X_i$ is also locally contractible.

**Remark.** For a rigorous argument you will want to use Proposition 18.20.

**Exercise 29.2.** Let $H$ be the Hawaiian earring that we introduced on page 727 and that we show in Figure 542 to the left.

(a) Show that $H$ is not semi-locally simply connected.

(b) Show that cone($H$) is not locally simply connected.
Exercise 29.3. Let $\pi: X \to B$ be a covering of topological spaces. Show that every simply connected and locally path-connected subset $U \subset B$ is uniformly covered.

Exercise 29.4. Let $p: (X, x_0) \to (B, b_0)$ and $q: (Y, y_0) \to (B, b_0)$ be two path-connected coverings of topological spaces such that $p_*(\pi_1(X, x_0)) \subset q_*(\pi_1(Y, y_0))$. It follows from Proposition 29.2 that there exists a unique map $r: (X, x_0) \to (Y, y_0)$ which makes the following diagram commute

$$
\begin{array}{ccc}
(X, x_0) & \xrightarrow{p} & (B, b_0) \\
\downarrow{r} & & \downarrow{q} \\
(Y, y_0) & \xrightarrow{q} & (B, b_0)
\end{array}
$$

Show that $r$ is a covering.

Exercise 29.5. We consider Figure 543.

(a) Let $X$ be the wedge of two circles and let $p: Y \to X$ be the universal covering that is illustrated in the figure. Denote the usual generators of $\pi_1(X)$ by $a$ and $b$. By an abuse of notation we denote by $a$ and $b$ also representing loops. What does the lift of the loop $a * b * a * b$ to $Y$ to the starting point $y_0$ look like?

(b) We continue with the notation from (1). Now consider the loop

$$
\gamma := a * a * b * a * b * a * b * a * b * a * b * a * b * a * b.
$$

We denote by $\widetilde{\gamma}$ the lift of $\gamma$ to the starting point $y_0$. Is $y_0$ the endpoint of $\widetilde{\gamma}?$

(c) Does there exist a homeomorphism $f: Y \to \widetilde{Y}$ with $f(y_0) = z_0$?

Exercise 29.6. Let $X = S^1 \cup \{\ast\}$ be $S^1 = \{z \in \mathbb{C} | |z| = 1\}$ with two “1”, where the topology is defined as for the line with two zeros, see page 95. Does $X$ admit a universal cover? If yes, can you describe it explicitly?

Exercise 29.7.

(a) Let $M$ be the Möbius band. We pick an identification $\pi_1(M) = \mathbb{Z}$. Given $k \in \mathbb{N}$ we denote by $\Gamma_k$ the kernel of the epimorphism $\pi_1(M) = \mathbb{Z} \to \mathbb{Z}_k$. Let $M_k \to M$ be the covering corresponding to $\Gamma_k$. What well-known topological space is $M_k$? You do not have to justify your answer.

(b) Draw the universal covering of $\mathbb{R}P^2 \vee S^1$ as a subset of $\mathbb{R}^3$. 

---

**Figure 542**

Hawaiian earrings $H$

not semi-locally simply connected

not locally simply connected

\[
\text{Cone}(H)
\]
Exercise 29.8. Let $X$ be a topological space and let $f: X \to X$ be a homeomorphism. We denote by $M := \text{Tor}(X, f) := (X \times [0, 1])/(x, 0) \sim (f(x), 1)$ the corresponding mapping torus (see page 711). Let $p: \tilde{M} \to M$ be a finite covering. Show that $\tilde{M}$ is homeomorphic to a mapping torus.

Exercise 29.9. We say two smooth manifolds $M$ and $N$ are commensurable if $M$ and $N$ admit finite covers $\tilde{M}$ and $\tilde{N}$ that are diffeomorphic.

(a) Show that the torus and the surface of genus two are not commensurable.
(b) Let $g, h \in \mathbb{N}_{n>2}$. Let $M$ be the surface of genus $g$ and let $N$ be the surface of genus $h$. Show that $M$ and $N$ are commensurable.
(c) Determine which compact connected 2-dimensional smooth manifolds are commensurable.

Exercise 29.10. Let $X$ be a topological space and let $p: \tilde{X} \to X$ be a covering. Let $f: X \to X$ be a homeomorphism and let $\tilde{f}: \tilde{X} \to \tilde{X}$ be a map such that the following diagram commutes:

$$
\begin{array}{ccc}
\tilde{X} & \xrightarrow{\tilde{f}} & \tilde{X} \\
p & & p \\
\downarrow & & \downarrow \\
X & \xrightarrow{f} & X
\end{array}
$$

Show that $\tilde{f}$ is also a homeomorphism.

Remark. This is a generalization of Exercise 17.3(b).
Exercise 29.11. Give an example of a topological space $X$, a finite covering $p: \tilde{X} \to X$ and a homeomorphism $f: X \to X$ which does not lift to a map $\tilde{f}: \tilde{X} \to \tilde{X}$, i.e. such there is no map $\tilde{f}: \tilde{X} \to \tilde{X}$ such that the following diagram commutes:

$$
\begin{array}{ccc}
\tilde{X} & \xrightarrow{\tilde{f}} & \tilde{X} \\
p | & & |p \\
X & \xrightarrow{f} & X
\end{array}
$$

Exercise 29.12. Let $X$ be a path-connected topological space that is locally path-connected and let $p: \tilde{X} \to X$ be a finite covering of degree $d$.

(a) Let $f: X \to X$ be a homeomorphism. Show that there exists a map $\tilde{f}: \tilde{X} \to \tilde{X}$ such that $p \circ \tilde{f} = f^d \circ p$.

(b) Does the conclusion of (a) also hold, if we do not assume that $f$ is a homeomorphism?

Exercise 29.13. Let $X$ be a path-connected topological space that is locally path-connected and semi-locally simply connected. Furthermore let $x_0 \in X$. By Proposition 29.8 there exists an, essentially unique, covering $p: (\tilde{X}, \tilde{x}_0) \to (X, x_0)$. We refer this covering as the universal abelian covering of $(X, x_0)$.

(a) Let $X$ be torus minus one open disk. Give an explicit description of the universal abelian cover of $X$.

(b) Let $X$ be the sphere minus three open disks. Give an explicit description of the universal abelian cover of $X$.

Evidently the expression “explicit” is a little vague, you could interpret it as an explicit description as a submanifold of say $\mathbb{R}^3$.

Exercise 29.14. Let $f: (X,x_0) \to (Y,y_0)$ be a map between pointed topological spaces such that $f_*: \pi_1(X,x_0) \to \pi_1(Y,y_0)$ is a monomorphism. We assume that both $X$ and $Y$ are locally path-connected and semi-locally simply connected. Let $\Gamma$ be a subgroup of $\pi_1(Y,y_0)$. Let $\tilde{Y} \to Y$ be the covering corresponding to $\Gamma$. Show that the pullback $p: f^*\tilde{Y} \to X$, as defined in Lemma 25.16 is the covering corresponding to the subgroup $f_*^{-1}(\Gamma)$ of $\pi_1(X,x_0)$.

Exercise 29.15. Let $X$ be a path-connected topological space that is locally path-connected and that is semi-locally simply connected. Furthermore let $p: \tilde{X} \to X$ be the universal covering. Let $x_0 \in X$ be a base point and let $\varphi: \pi_1(X,x_0) \to \Gamma$ be a group homomorphism. We consider

$$
q: \tilde{X}_\varphi := (\tilde{X} \times \Gamma)/(\langle x, g \rangle \sim \langle h \cdot x, \varphi(h) \cdot g \rangle) \to X
$$

where we equip $\Gamma$ with the discrete topology, $\tilde{X} \times \Gamma$ with the product topology and $\tilde{X}_\varphi$ with the quotient topology.

(a) Suppose that $\varphi$ is an epimorphism. Show that $q: \tilde{X}_\varphi \to X$ is the covering corresponding to $\ker(\varphi)$. 

(b) In general, show that the number of components of $\tilde{X}_\phi$ has the same cardinality as $\text{coker}(\phi)$ and show that the restriction of $q: \tilde{X}_\phi \to X$ to each component of $\tilde{X}_\phi$ is the covering corresponding to $\text{ker}(\phi)$. 
30. Topics in covering theory

In this chapter we will discuss several applications and examples of the existence of (universal) coverings of suitable topological spaces.

30.1. Self-diffeomorphisms of $S^1$. Using covering theorem we can now prove the following proposition on self-diffeomorphisms of $S^1$.

**Proposition 30.1.** Let $f: S^1 \to S^1$ be a diffeomorphism.

1. If $f$ is orientation-preserving, then $f$ is diffeotopic to the identity, otherwise $f$ is diffeotopic to the reflection $r: S^1 \to S^1$ given by $(x, y) \mapsto (x, -y)$.

2. The diffeomorphism $f$ extends to a diffeomorphism of $B^2$.

**Remark.** In Section ??, given an orientable smooth manifold $M$, we will introduce the "mapping class group" $\text{MCG}^+(M)$ which basically measures "how many interesting" orientation-preserving self-diffeomorphisms a smooth manifold has. In this language Proposition 30.1 says that $\text{MCG}^+(S^1)$ is trivial. In Section ?? we will also discuss mapping class groups of higher dimensional spheres. In particular we will see that in general the naive analogues in higher dimensions do not hold.

**Proof.**

1. As usual we identify $S^1$ with $\mathbb{R}/\mathbb{Z}$. Thus let $f: \mathbb{R}/\mathbb{Z} \to \mathbb{R}/\mathbb{Z}$ be a diffeomorphism.

First we consider the case that $f$ is orientation-preserving. We denote by $p: \mathbb{R} \to \mathbb{R}/\mathbb{Z}$ the usual covering map. By Proposition 29.2 applied to the map $f \circ p: \mathbb{R} \to \mathbb{R}/\mathbb{Z}$ there exists a map $\tilde{f}: \mathbb{R} \to \mathbb{R}$ such that the following diagram commutes:

\[
\begin{array}{ccc}
\mathbb{R} & \xrightarrow{\tilde{f}} & \mathbb{R} \\
p \downarrow & & \downarrow p \\
\mathbb{R}/\mathbb{Z} & \xrightarrow{f} & \mathbb{R}/\mathbb{Z}.
\end{array}
\]

We make the following observations regarding $\tilde{f}$:

(a) Since $p$ is a local diffeomorphism and since $f$ is a smooth map we see that $\tilde{f}$ is also smooth.

(b) Since $f$ is orientation-preserving and since $p$ is a local diffeomorphism we see that $\tilde{f}$ is also orientation-preserving. This implies that $\tilde{f}$ is a strictly monotonously increasing function.

(c) Since $f$ is a diffeomorphism and since the above diagram commutes we see that for any $x \in \mathbb{R}$ the restriction of $\tilde{f}$ to the interval $[x, x+1)$ defines a bijection with $[f(x), f(x+1))$.

Note that in Lemma 18.9 we proved an analogous statement for self-homeomorphisms of $S^1$. The case of self-homeomorphisms is technically easier since it is often easier to write down a continuous map than to write down a smooth map.

Why?
(d) For any $x \in \mathbb{R}$ we have, by the commutativity of the diagram, the equality $f(x + 1) - f(x) \in \mathbb{Z}$.

(e) It follows from (b), (c) and (d) that for any $x \in \mathbb{R}$ we have $f(x + 1) = f(x) + 1$. Now we consider the map

$$F: \mathbb{R} \times [0, 1] \rightarrow \mathbb{R}$$

$$(x, t) \mapsto f(x) \cdot (1 - t) + x \cdot t.$$  

This map is evidently smooth. Since $x \mapsto x$ is a strictly monotonously increasing dieomorphism of $\mathbb{R}$ one can see easily that for any $t \in [0, 1]$ the map $F_t: \mathbb{R} \rightarrow \mathbb{R}$ has the above Properties (a) to (e). This implies in particular that the map $F$ descends to a map

$$F: (\mathbb{R}/\mathbb{Z}) \times [0, 1] \rightarrow \mathbb{R}/\mathbb{Z}$$

$$(x, t) \mapsto \tilde{f}(x) \cdot (1 - t) + x \cdot t$$

where each $F_t: \mathbb{R}/\mathbb{Z} \rightarrow \mathbb{R}/\mathbb{Z}$ is a homeomorphism. Since each $\tilde{F}_t$ is a local diffeomorphism and since $p$ is a local diffeomorphism we obtain from Lemma 6.23(3) that each $F_t$ is in fact a diffeomorphism. We have thus shown that $F$ is indeed a dieotopy from $f$ to the identity.

Finally we consider the case that $f$ is orientation-reversing. In this case $r \circ g$ is orientation-preserving. We apply the above result to $r \circ g$ and we easily obtain the desired dieotopy from $f$ to $r$.

(2) Let $f: S^1 \rightarrow S^1$ be a dieomorphism. By (1) we know that there exists a dieotopy $F: S^1 \times [0, 1] \rightarrow S^1$ from $f$ to $g = \text{id}$ or to $g = r$. By Lemma 6.13 there exists a smooth map $f: [\frac{1}{2}, 1] \rightarrow [0, 1]$ with $f(t) = 0$ for $t \in [\frac{1}{2}, \frac{5}{8}]$ and $f(t) = 1$ for $t \in [\frac{7}{8}, 1]$. The promised extension is now given by

$$B^2 \rightarrow B^2$$

$$P = (x, y) \mapsto \begin{cases} P = (x, y), & \text{if } \|P\| \leq \frac{1}{2} \text{ and } f \text{ is orientation-preserving,} \\ (x, -y), & \text{if } \|P\| \leq \frac{1}{2} \text{ and } f \text{ is orientation-reversing,} \\ F(\frac{P}{\|P\|}, 2 - 2 \cdot \|x\|), & \text{if } \|P\| \in [\frac{1}{2}, 1]. \end{cases}$$

The following corollary is an immediate consequence of Proposition 30.1.

**Corollary 30.2.** If $C$ and $D$ are two oriented smooth manifolds that are diffeomorphic to $S^1$, then any two orientation-preserving dieomorphisms $C \rightarrow D$ are dieotopic.

We conclude this section with the following corollary.

**Corollary 30.3.** Let $M$ be a 2-dimensional smooth manifold (possibly disconnected) and let $A$ and $B$ be two distinct boundary components of $M$. Suppose $A$ and $B$ are equipped with orientations. Given any two orientation-preserving dieomorphisms $f, g: A \rightarrow B$ the resulting smooth manifolds

$$M/f(a) \sim a \quad \text{and} \quad M/g(a) \sim a \quad (\text{in both cases with } a \in A)$$

are diffeomorphic.
Loosely speaking, the corollary says that if we glue two oriented boundary components of a surface together in an orientation-preserving way, then the diffeomorphism type of the resulting smooth manifold does not depend on the specific choice of the orientation-preserving diffeomorphism.

**Proof.** It follows from Proposition 6.27 and Theorem 7.5 that $A$ and $B$ are both diffeomorphic to $S^1$. The corollary is now an immediate consequence of Lemma 8.16 and Corollary 30.2.

### 30.2. Complex logarithms

In this short section we will discuss complex logarithms. This discussion does not play a role in the remainder of these notes, but it is a fun application of covering theory.

**Definition.** Let $U \subset \mathbb{C} \setminus \{0\}$ be a subset. We say the complex logarithm exists on $U$ if there exists a map $\ln: U \to \mathbb{C}$ such that $\exp(\ln(z)) = z$ for all $z \in U$.

The following proposition gives a very pleasing sufficient and necessary criterion for complex logarithms to exist.

**Proposition 30.4.** $\ast$ Let $U \subset \mathbb{C} \setminus \{0\}$ be an open path-connected subset. The following statement holds:

| the complex logarithm exists on $U$ | $\iff$ for some $x_0 \in U$ the inclusion induced map $\pi_1(U, x_0) \to \pi_1(\mathbb{C} \setminus \{0\}, x_0)$ is the trivial map. |

![Diagram](image)

**Figure 5.44. Illustration of Proposition 30.4**

**Proof ($\ast$).** Let $U \subset \mathbb{C} \setminus \{0\}$ be an open path-connected subset and let $x_0 \in U$. We consider the following rather simple minded diagram

\[
\begin{array}{c}
\text{U} \\
\mapright{\text{i}} \\
\mathbb{C} \setminus \{0\} \\
\mapup{\exp(z)} \\
\mathbb{C}
\end{array}
\]

We make the following observations:

1. As on page 493 one can show that the vertical map $\exp$ is actually a covering map.
2. The question whether the complex logarithm exists on $U$ is equivalent to the question whether the inclusion map $i: U \to \mathbb{C} \setminus \{0\}$ lifts to a map $U \to \mathbb{C}$.

---

528 As always, all maps are understood to be continuous.
529 It follows from Proposition 15.11 that the condition on the right-hand side does not depend on the choice of the base point.
(3) Since \( \exp : \mathbb{C} \to \mathbb{C} \setminus \{0\} \) is surjective we can pick a \( y_0 \in \mathbb{C} \) with \( \exp(y_0) = x_0 \).

(4) Note that \( \mathbb{C} \) is simply connected. The image \( \text{im}(\exp, \pi_1(\mathbb{C}, y_0) \to \pi_1(\mathbb{C} \setminus \{0\}, x_0)) \) is therefore the trivial group.

(5) Since \( U \) is an open subset of \( \mathbb{C} \setminus \{0\} \) it is in particular locally path-connected. Thus we can apply Proposition 29.2. Together with (4) we obtain from Proposition 29.2 the statement

there exists a lift of \( i : U \to \mathbb{C} \setminus \{0\} \) \( \iff \) the map \( \pi_1(U, x_0) \to \pi_1(\mathbb{C} \setminus \{0\}, x_0) \) is the trivial map.

(6) The combination of (2) and (5) is precisely the statement we had set out to prove. ■

30.3. Preimages of subsets under coverings. Let \((B, b_0)\) be a pointed topological space that is path-connected, locally path-connected and semi-locally simply connected. In Proposition 29.3 (2) we saw that subgroups of \( \pi_1(B, b_0) \) give rise to coverings of \( B \). Arguably the most common source of subgroups is given by considering kernels of group homomorphisms \( \pi_1(B, b_0) \to G \).

Example. Let \( B \) be the 2-dimensional sphere \( S^2 \) minus three open disks. We pick a base point \( b_0 \) for \( B \) and we pick loops \( u, v, w \) as shown in Figure 545. From Lemma 23.11 we know that \( \pi_1(B, b_0) = \langle u, v, w \mid uwv \rangle \). By Lemma 21.14 there exists a unique homomorphism \( \varphi : \pi_1(B, b_0) \to \mathbb{Z}_6 \) with \( \varphi(u) = 2, \varphi(v) = 3 \) and \( \varphi(w) = -5 \). Let \( p : X \to B \) be the covering corresponding to \( \text{ker}(\varphi) \). By Proposition 17.1 we know that \( X \) is again a compact orientable 2-dimensional smooth manifold, where the boundary is given by \( \partial X = p^{-1}(\partial B) \). Thus we know from the Surface Classification Theorem 23.4 that there exist unique \( g \in \mathbb{N}_0 \) and \( n \in \mathbb{N} \) such that \( X \) is homeomorphic to \( \Sigma_{g,n} \), i.e. such that \( X \) is homeomorphic to the surface of genus \( g \) minus \( n \) open disks.

Therefore the following question arises:

**Question 30.5.** In the previous example, what are \( g \) and \( n \)?

The final proposition of this chapter will allow us to answer one half of Question 30.5, namely we can determine \( n \). We will determine \( g \) in Exercise 31.3.

**Proposition 30.6.** Let \((B, b_0)\) be a pointed topological space that is path-connected, locally path-connected and semi-locally simply connected. Let \( \varphi : \pi_1(B, b_0) \to G \) be a group epimorphism and let \( p : (X, x_0) \to (B, b_0) \) be the covering with \( p_\ast(\pi_1(X, x_0)) = \text{ker}(\varphi) \). Finally let \( A \) be a path-connected subset of \( B \) and let \( a_0 \in A \). We denote by \( i : A \to B \) the
inclusion map and we pick a path $\gamma$ from $b_0$ to $a_0$. We consider the homomorphism

$$\psi := \varphi \circ \gamma_* \circ i_* : \pi_1(A, a_0) \xrightarrow{i_*} \pi_1(B, a_0) \xrightarrow{\gamma_*} \pi_1(B, b_0) \xrightarrow{\varphi} G.$$ 

With these preparations the following two statements hold:

1. Each path-component of $p^{-1}(A)$ is the covering of $A$ corresponding to the subgroup $\ker(\psi : \pi_1(A, a_0) \to G)$.
2. If $G$ is a finite group, then

\[ \text{number of path-components of } p^{-1}(A) = [G : \text{im}(\psi : \pi_1(A, a_0) \to G)] \]

Example. As promised we can now determine the number $n$ of boundary components of the covering $X$ in the previous example. More precisely, denote by $U, V, W$ the three boundary components of $B$. We make the following three observations:

1. The image of $\pi_1(V)$ in $\mathbb{Z}_6$ is the subgroup generated by $\varphi(u) = 2$, thus the subgroup has index two, which by Proposition 30.6 implies that $p^{-1}(U)$ consists of two components.
2. The image of $\pi_1(W)$ in $\mathbb{Z}_6$ is the subgroup generated by $\varphi(v) = 3$, thus $p^{-1}(V)$ consists of three components.
3. The image of $\pi_1(U)$ in $\mathbb{Z}_6$ is the subgroup generated by $\varphi(w) = -5$. Since $-5$ is coprime to 6 we see that this subgroup is all of $\mathbb{Z}_6$, thus $p^{-1}(W)$ consists of precisely one component.

Altogether we see that $X$ has $2 + 3 + 1 = 6$ boundary components.

Remark. The reader who is in need of a brain teaser might want to come up with an appropriate generalization of Proposition 30.6 to the case where we consider coverings of $B$ coming from a non-normal subgroup.

Proof. To simplify the notation a little bit we assume that $a_0 = b_0$, in particular we ignore the role of $\gamma$. Throughout the proof we refer to Figure 546 for an illustration.

1. Let $W$ be a path-component of $p^{-1}(A)$. We pick a point $w_0 \in W$ with $p(w_0) = a_0$. We start out with the following slightly subtle claim.

Claim. We have the following equality:

$$p_*(\pi_1(X, w_0)) = \ker(\varphi : \pi_1(B, a_0) \to G).$$

We pick a path $\gamma$ in $X$ from $x_0$ to $w_0$. Since $p \circ \gamma$ is a loop in $a_0$ we can write $h := [p \circ \gamma] \in \pi_1(B, a_0)$. We consider the following diagram

$$\begin{array}{ccc}
\pi_1(X, w_0) & \xrightarrow{\gamma_*} & \pi_1(X, x_0) \\
\downarrow{p_*} & \cong & \downarrow{p_*} \\
\pi_1(B, a_0) & \xrightarrow{g \mapsto gh^{-1}} & \pi_1(B, a_0) \\
\downarrow{\varphi} & \cong & \downarrow{\varphi} \\
G & \xrightarrow{g \mapsto \varphi(h)g\varphi(h)^{-1}} & G.
\end{array}$$
The top square commutes by Proposition 14.11 (2) and (5). Evidently the bottom square also commutes. By definition of \((X, x_0)\) we have
\[
p_*(\pi_1(X, x_0)) = \ker(\varphi: \pi_1(B, a_0) \to G).
\]
The claim now follows from the fact that the diagram commutes and that the horizontal maps are isomorphisms.

In the following we denote by \(j: W \to X\) the inclusion map. We consider the following diagram

\[
\begin{array}{ccc}
\pi_1(W, w_0) & \xrightarrow{j_*} & \pi_1(X, w_0) \\
\downarrow^{p_*} & & \downarrow^{p_*} \\
\pi_1(A, a_0) & \xrightarrow{i_*} & \pi_1(B, a_0) \\
& \xrightarrow{\psi} & \pi_1(B, a_0) \\
& \downarrow^{\varphi} & \downarrow^{\varphi} \\
& & G.
\end{array}
\]

Recall that we need to show the equality \(p_*(\pi_1(W, w_0)) = \ker(\psi)\). We show the two inclusions separately.

“\(\leq\)” This inclusion follows immediately from the definitions, from the commutativity of the above diagram and from the claim.

“\(\geq\)” Thus let \(g \in \ker(\psi)\). We represent it by a loop \(\gamma\) in \((A, a_0)\). By the above claim and Lemma 16.15 the loop \(i \circ \gamma\) in \((B, a_0)\) lifts to a loop \(\widetilde{\gamma}\) in \((X, w_0)\). By definition the image of \(\widetilde{\gamma}\) lies in \(p^{-1}(A)\) and it contains \(w_0\). In particular the image of \(\widetilde{\gamma}\) lies in the path-component of \(p^{-1}(A)\) that contains \(w_0\), in other words, \(\widetilde{\gamma}\) is actually a loop in \((W, w_0)\). Since \(g = p_*(\widetilde{\gamma})\) we obtain that \(g \in p_*(\pi_1(W, w_0))\).

(2) We write \(n = |G|\) and \(k = |\text{im}(\psi): \pi_1(A, a_0) \to G|\). It follows from Lemma 16.15 and (1) that each path-component of \(p^{-1}(A)\) is a \(k\)-fold covering of \(A\). By Lemma 16.15 the map \(p: X \to B\) is an \(n\)-fold covering. Evidently \(p: p^{-1}(A) \to A\) is also an \(n\)-fold covering. It follows almost immediately that \(p^{-1}(A)\) has necessarily \(n/k\) path-components. But \(n/k = |G|/|\text{im}(\psi)|\) is by definition the degree of \(\text{im}(\psi)\) in \(G\). ■

![Figure 546: Illustration for the proof of Proposition 30.6](image)

30.4. Covering spaces of surfaces. Suppose we start out with a surface \(F\) of genus \(g\) and a finite index subgroup \(\Gamma\) of \(\pi_1(F)\), then by Proposition 29.3 we obtain a corresponding finite covering \(p: \widetilde{F} \to F\). By Proposition 17.1 and Lemma 16.3 (4) the topological space
\( \tilde{F} \) is again a closed orientable connected 2-dimensional smooth manifold. From the Surface Classification Theorem \[23.4\] we know that \( \tilde{F} \) is again a surface of some genus \( h \). How can we determine \( h \) from \( g \) and \( \Gamma \)?

For future reference we record the question.

**Question 30.7.** Given a surface \( F \) of genus \( g \) and a finite index subgroup \( \Gamma \) of \( \pi_1(F) \), what is the genus of the corresponding finite cover?

It will take a while till we can give a satisfactory answer. In fact we will obtain a complete answer only once we have introduced the Euler characteristic.

But we want to discuss one example in detail. We consider the surface \( F \) of genus two that we view as the connected sum of two tori \( S = S^1 \times S^1 \) and \( T = S^1 \times S^1 \). We denote by \( u, v \) the standard generators for \( \pi_1(S) \) given by the two copies of \( S^1 \) in each torus. Similarly we denote by \( x, y \) the standard generators for \( \pi_1(T) \). We pick an embedded closed disk in \( S \) and an embedded closed disk in \( T \) which both lie in the complement of the standard generators. We denote the corresponding open disks by \( D \) and \( E \) and we write \( S^* = S \setminus D \) and \( T^* \setminus E \). We build the connected sum \( \tilde{S} \# T \) by gluing \( S^* \) to \( T^* \) along the boundary. Furthermore, by a slight abuse of notation, we denote by \( u, v \) and \( x, y \) also the generators of \( \pi_1(S^*) = \langle u, v \rangle \) and \( \pi_1(T^*) = \langle x, y \rangle \).

By the discussion on page 659 the abelianization of \( \pi_1(S \# T) = \pi_1(\langle S^* \cup_{\partial S^* \cup \partial T^*} T^* \rangle) \) is the free abelian group on \( u, v, x, y \). Now we consider the epimorphism

\[
\varphi : \pi_1(S \# T) \to \pi_1(S \# T)/[\pi_1(S \# T), \pi_1(S \# T)] \to \mathbb{Z}_3
\]

given by \( u \mapsto 1, v \mapsto 0, x \mapsto 0 \) and \( y \mapsto 0 \). Our goal in the following discussion is to visualize the covering \( p : \tilde{F} \to F = S \# T \) corresponding to \( \ker(\varphi) \). Since \( \varphi \) is an epimorphism onto a group of order 3 we see that \( \ker(\varphi) \) is a subgroup of index 3. By Lemma 16.15 this implies that \( p \) is a 3-fold covering.

---

\[\text{Figure 547}\]

---

Footnote: It follows from Corollary 30.3 that we can be a bit casual in our language, i.e. we can talk about “gluing surfaces” without specifying explicit diffeomorphisms of boundary components, as long as we take into account orientations.
We first consider the torus $S = S^1 \times S^1$ and furthermore we consider the epimorphism
\[ \psi: \pi_1(S) = \langle u, v \mid [u, v] \rangle \to \mathbb{Z}_3 \] given by $\psi(u) = 1$ and $\psi(v) = 0$. The covering corresponding to $\ker(\psi) \subset \pi_1(S)$ is equivalent to the covering
\[ \widetilde{S} = S^1 \times S^1 \to S = S^1 \times S^1 \]
\[ (a, b) \mapsto (a^3, b). \]

Now we consider the epimorphism $\psi^* : \pi_1(S^*) \to \mathbb{Z}_3$ given by $\psi^*(u) = 1$ and $\psi^*(v) = 0$. By the argument of Footnote 531 the covering corresponding to $\ker(\psi^*)$ is then given by
\[ p : \widetilde{S}^* := \widetilde{S} \setminus p^{-1}(D) \to S^* = S \setminus D. \]
Recall that we perform the connected sum operation $S \# T$ by gluing $T^* := T \setminus E$ to $S^* = S \setminus D$ to obtain $F = S \# T$. The same way we can also glue three copies of $T^*$, i.e. $T^* \times \{1, 2, 3\}$, to the three boundary components of $\widetilde{S}^*$ to obtain a closed smooth manifold $\widetilde{F}$. It follows from Lemma 2.35 (2’) that the map
\[ q : \widetilde{F} \to F \]
\[ P \mapsto \begin{cases} p(P), & \text{if } P \in \widetilde{S}^*, \\ Q, & \text{if } P = Q \times \{n\} \text{ with } Q \in T^* \text{ and } n \in \{1, 2, 3\} \end{cases} \]
is continuous. Similar to Footnote 531 one can now see that $q : \widetilde{F} \to F$ is indeed the covering of $F$ corresponding to $\ker(\varphi)$. This construction is illustrated in Figure 549 which also shows that $\widetilde{F}$ is a surface of genus 4.

Exercise for Chapter 30.

Exercise 30.1. We write $\mathbb{C}^* := \mathbb{C} \setminus \{0\}$.

\[ ^{53}\text{Indeed, since } \widetilde{S} \to S \text{ is a connected 3-fold covering we know from Lemma 16.15 that } p_*(\pi_1(\widetilde{S})) \text{ is a subgroup of } \pi_1(S) \text{ of index three. Furthermore it is contained in the subgroup } \ker(\pi_1(S) \xrightarrow{\psi} \mathbb{Z}_3) \text{ which also has index three, thus } p_*(\pi_1(\widetilde{S})) = \ker(\psi: \pi_1(S) \to \mathbb{Z}_3). \text{ But by Proposition 29.8 all path-connected coverings that correspond to the same subgroup are equivalent.}\]
(a) Let $m \in \mathbb{N}$. Show that the map

$$C^* \to C^*$$

$$z \mapsto z^m$$

is a holomorphic map between complex manifolds and show that this map is a covering map with degree $= m$.

(b) Show that the exponential map

$$\exp: \mathbb{C} \to \mathbb{C}^* := \mathbb{C} \setminus \{0\}$$

$$z \mapsto \exp(z)$$

is a holomorphic map between complex manifolds and show that this map is a covering map of infinite degree.

(c) A complex logarithm on an open subset $U \subset \mathbb{C}^*$ is a map $f: U \to \mathbb{C}$ such that for all $z \in U$ we have $f(\exp(z)) = z$.

(i) Show that every complex logarithm is holomorphic.

(ii) Show that on any simply connected open subset $U \subset \mathbb{C}^*$ one can define a complex logarithm.

(iii) Show that it is not possible to define a complex logarithm on all of $\mathbb{C}^*$.

**Exercise 30.2.** Let $\Sigma$ be a compact oriented connected 2-dimensional smooth manifold and let $f: \partial \Sigma \to \partial \Sigma$ be a diffeomorphism. Show that there exists a diffeomorphism $\Sigma \to \Sigma$ with $F|_{\partial \Sigma} = f$ if and only if $f$ is either orientation-preserving or orientation-reversing.

**Exercise 30.3.** Let $n \in \mathbb{N}_{\geq 3}$. 
We consider the connected sum \( M = \mathbb{RP}^n \# \mathbb{RP}^n \). We consider the following homomorphism
\[
\varphi : \pi_1(\mathbb{RP}^n \# \mathbb{RP}^n) \xrightarrow{\cong} \pi_1(\mathbb{RP}^n) \ast \pi_1(\mathbb{RP}^n) \xrightarrow{\cong} \mathbb{Z}_2 \ast \mathbb{Z}_2 = \langle a, b \mid a^2, b^2, ab = ba \rangle \rightarrow \mathbb{Z}_2.
\]
\[a \mapsto 1\]
\[b \mapsto 1\]

We denote by \( \tilde{M} \) the cover corresponding to \( \ker(\varphi : \pi_1(M) \rightarrow \mathbb{Z}_2) \). Show that \( \tilde{M} \) is diffeomorphic to \( S^1 \times S^{n-1} \).

\[\text{Hint. Use Proposition 30.6.}\]

Let \( k \in \mathbb{N} \). We consider the connected sum \( M \) of \( k \) copies of \( \mathbb{RP}^n \). As in (a) we have an obvious epimorphism \( \pi_1(M) \rightarrow \mathbb{Z}_2 \). It turns out that the corresponding covering space \( \tilde{M} \) is diffeomorphic to the connected sum of \( m \) copies of \( S^1 \times S^{n-1} \). Determine \( m \) in terms of \( k \).
31. COVERINGS OF TOPOLOGICAL GRAPHS AND APPLICATIONS TO GROUP THEORY

In this chapter we will apply the results obtained in Chapter 29 to prove several results in group theory.

31.1. Coverings of topological graphs. In our proofs of the promised group-theoretic results we will need the following proposition which is also of interest in its own right.

**Proposition 31.1.** Let \( G = (V, E, i, t) \) be a connected abstract graph and let \( p: \tilde{X} \to |G| \) be a covering of the topological realization \( X := |G| \) of \( G \). Then there exists a natural\(^{532}\) abstract graph \( \tilde{G} = (\tilde{V}, \tilde{E}, i, t) \), a natural homeomorphism \( f: |\tilde{G}| \to \tilde{X} \) and a natural map \( q: \tilde{G} \to G \) of abstract graphs with the following properties:

1. We have \( \#\tilde{V} = [\tilde{X} : X] \cdot \#V \) and \( \#\tilde{E} = [\tilde{X} : X] \cdot \#E \).
2. The following diagram commutes:

\[
\begin{array}{ccc}
|G| & \xrightarrow{|q|} & |\tilde{G}| \\
\downarrow & & \downarrow \quad f \\
|G| & \xrightarrow{=} & \tilde{X}
\end{array}
\]

Here \(|q|\) denotes the topological realization of the map \( q \), as defined in Lemma 15.2.

**Remark.** In Proposition 36.37 we will generalize the above proposition to the setting of “CW-complexes”.

**Proof.** Let \( G = (V, E, i, t) \) be a connected abstract graph. Recall that on page 222 we defined the topological realization of \( G \) as follows:

\[ |G| := (V \sqcup (E \times [0, 1]))/\sim \quad \text{where for } e \in E \text{ we have } (e, 0) \sim i(\ell(e)) \text{ and } (e, 1) \sim t(\ell(e)). \]

Note that by Lemma 4.1 we know that \(|G|\) is connected. Given \( e \in E \) we set \( \mu(e) := [(e, \frac{1}{2})] \), i.e. \( \mu(e) \) is the “midpoint” of \( e \). Furthermore, given \( e \in E \) we denote by \( \gamma_e: [0, 1] \to X \) the path given by \( t \mapsto [(e, t)] \).

Note that in Exercise 18.38 we showed that \( X = |G| \) is locally contractible, in particular it is locally path-connected. Thus in the following discussion we will have no troubles with applying the results from Chapter 29.

Now let \( p: \tilde{X} \to |G| \) be a covering of the topological realization \( X = |G| \) of \( G \). We set \( \tilde{V} := p^{-1}(V) \subset \tilde{X} \) and we set \( \tilde{E} := p^{-1}(\{\mu(e) : e \in E\}) \subset \tilde{X} \). Since \( X = |G| \) is connected we know that the degree \([\tilde{X} : X]\) is defined. By definition, or if you want, by Lemma 16.1 we have \( \#\tilde{V} = [\tilde{X} : X] \cdot \#V \) and \( \#\tilde{E} = [\tilde{X} : X] \cdot \#E. \)

Now let \( \bar{e} \in \tilde{E} \). We denote by \( \varphi(\bar{e}) \) the unique edge in \( E \) with \( p(\bar{e}) = \mu(\varphi(\bar{e})) \). By Proposition 29.2 there exists a unique lift \( \tilde{\gamma}_\varphi: [0, 1] \to \tilde{X} \) of \( \gamma_{\varphi(\bar{e})}: [0, 1] \to X \) with \( \tilde{\gamma}(\frac{1}{2}) = \bar{e} \).

We set \( i(\bar{e}) = \tilde{\gamma}(0) \) and \( t(\bar{e}) = \tilde{\gamma}(1) \). Since \( \tilde{\gamma}_\varphi \) is a lift of \( \gamma_\varphi \) we see that \( i(\bar{e}) \) and \( t(\bar{e}) \) actually lie in \( \tilde{V} \). In other words, \((\tilde{V}, \tilde{E}, i, t)\) is actually an abstract graph. Furthermore

\[^{532}\text{We leave the pleasure of figuring out what “natural” means to the reader.}\]
note that the two maps \( p: \tilde{V} \to V \) and \( \varphi: \tilde{E} \to E \) define by, basically by construction, a map \( q: \tilde{G} = (\tilde{V}, \tilde{E}, i, t) \to (V, E, i, t) = G \) of abstract graphs.

Next we define \( f: |\tilde{G}| \to \tilde{X} \) via the inclusion \( \tilde{V} \to \tilde{X} \) and by sending \((\tilde{e}, t)\) to \( \tilde{\gamma}_e(t) \). It follows immediately from Lemma 3.22 that \( f \) is continuous. Furthermore, using the existence and uniqueness statement of Proposition 29.2 it is not difficult to see that the map \( f \) is actually a bijection. Next note that, with a little bit of an effort, one can also show that \( f \) is an open map. Thus we obtain from Lemma 2.42 that \( f \) is actually a homeomorphism.

Finally note that it is straightforward to see that the given diagram in the proposition does indeed commute.

\[ \begin{array}{c}
\tilde{X} \\
\downarrow \\
X = |\tilde{G}| \\
\end{array} \quad \begin{array}{c}
\begin{array}{c}
\tilde{\gamma}_e \\
p \\
\end{array} \end{array} \quad \begin{array}{c}
\begin{array}{c}
p^{-1}(\mu(e)) \\
0 \\
1 \\
\gamma_e \\
\mu(e) \\
\end{array} \end{array} \]

**Figure 5.50. Illustration for the proof of Proposition 31.1**

31.2. **Fundamental group of countable topological graphs.** In Proposition 20.5 we showed that the fundamental group of any finite topological graph is a free group. We generalize this result to countable topological graphs.

**Proposition 31.2.** If \( X \) is a countable connected non-empty topological graph, then \( \pi_1(X) \) is a free group.

**Remark.** In Theorem 37.9 we will show that the fundamental of any (not necessarily countable) connected topological graph is a free group. Since the proof of this more general statement is technically rather demanding we feel that it is worth to prove this intermediate statement.

The proof of Proposition 31.2 builds on the following reasonably straightforward lemma.

**Lemma 31.3.** Let \( H \) be a finite connected graph and let \( G \) be a connected non-empty subgraph of \( H \). Let \( v \) be a vertex of \( G \). We denote by \( i: |G| \to |H| \) the inclusion. We set \( s := \chi(H) - \chi(G) \). Then there exists a homomorphism \( \varphi: \langle x_1, \ldots, x_s \rangle \to \pi_1(|H|, v) \) such that the map

\[ i_* \ast \varphi: \pi_1(|G|, v) \ast \langle x_1, \ldots, x_s \rangle \to \pi_1(|H|, v) \]

is an isomorphism.

**Proof of Lemma 31.3** Let \( H = (W, F, i, t) \) be a finite connected graph. Furthermore let \( G = (V, E, i, t) \) be a connected non-empty subgraph of \( H \). By Proposition 4.8 (1) there exists a spanning tree \( S \) for \( G \). By a rather elementary argument, which we outsourced to Exercise 31.1 there exists a spanning tree \( T \) of \( H \) such that \( T \cap G = S \). Let \( e_1, \ldots, e_m \) be the edges of \( G \) not contained in \( S \) and let \( e_{m+1}, \ldots, e_n \) be the edges of \( H \) not contained in \( T \).
For }j = 1, \ldots, m\text{ we pick a path }\alpha_j\text{ in }|S|\text{ from }v\text{ to }i(e_j),\text{ we denote by }\beta_j\text{ the obvious path form }i(e_j)\text{ to }t(e_j)\text{ and we pick a path }\gamma_j\text{ in }|S|\text{ from }t(e_j)\text{ to }v.\text{ We proceed analogously for }j = m + 1, \ldots, n,\text{ except that now can no longer demand that the paths }\alpha_j\text{ and }\gamma_j\text{ lie in }|S|,\text{ but we will demand that they lie in }|T|.\text{ Finally we consider the following diagram:}

\[
\begin{array}{ccc}
\pi_1(|G|, v) * \langle y_{m+1}, \ldots, y_{m+n} \rangle & \xrightarrow{\Theta_G \circ \text{id}} & \pi_1(|H|, v).
\end{array}
\]

Here the homomorphisms }\Theta_G\text{ and }\Theta_H\text{ are the maps induced by }y_j \mapsto [\alpha_j * \beta_j * \gamma_j].\text{ By Proposition }20.5\text{ we know that both }\Theta_G\text{ and }\Theta_H\text{ are isomorphisms. This shows that the homomorphism }\langle x_1, \ldots, x_{n-m} \rangle \rightarrow \pi_1(|H|, v)\text{ given by }x_j \mapsto \Theta_H(y_{m_j})\text{ has the desired properties. Finally one can easily verify that }\chi(G) = 1 + m\text{ and }\chi(H) = 1 + n.\text{ Thus we see that }n - m = \chi(H) - \chi(G).\]

Figure 551. Illustration for the proof of Lemma 31.3.

Now we can provide the proof of Proposition 31.2

**Proof of Proposition 31.2** Let }G = (V, E, i, t)\text{ be a countable connected non-empty abstract graph. We pick a vertex }v \in V.\text{ We need to show that }\pi_1(G, v)\text{ is a free group. By Exercise 4.7 we know that there exists a sequence }\{G_j\}_{j \in \mathbb{N}}\text{ of subgraphs with the following properties:}

1. Each }G_j\text{ is finite connected.
2. Each }G_j\text{ contains }v.
3. We have }G = \bigcup_{j \in \mathbb{N}} G_j\text{ in the sense that }V = \bigcup_{j \in \mathbb{N}} V_j\text{ and }E = \bigcup_{j \in \mathbb{N}} E_j.

We see that

\[
\pi_1(|G|, v) = \pi_1\left(\bigcup_{j \in \mathbb{N}} |G_j|, v\right) = \lim_{\uparrow} \pi_1(|G_j|, v) = \text{ free group.}
\]

by Exercise 4.6 and Proposition 25.7 follows from Lemma 31.3 and the discussion on page 730.

31.3. Subgroups of free groups. In this section we will apply our topological results to the study of free groups. First we introduce the following definition.

**Definition.** Given a free group }F, i.e. given a group }F\text{ that is isomorphic to the free group }\langle S \rangle\text{ generated by some set }S,\text{ we refer to the cardinality of }S\text{ as the rank of }F.\]

\footnote{533It follows from the discussions on the pages 641 and 582 that the rank of }F\text{ is well-defined.}
The following proposition is arguably the most interesting result of this chapter. The statement is purely group-theoretical, but as we will see, a topological point of view leads to a very neat proof.

**Proposition 31.4.** Let $F$ be a free group of countable rank:

1. Every subgroup of $F$ is again a free group.
2. If $F$ is finitely generated and if $G$ is a finite-index subgroup of $F$, then

$$\text{rank}(G) - 1 = [F : G] \cdot (\text{rank}(F) - 1).$$

**Examples.**

1. If $F = \mathbb{Z}$ then the formula from Proposition 31.4 does indeed show that every finite-index subgroup of $\mathbb{Z}$ is again a free group of rank one, i.e. every finite-index subgroup of $\mathbb{Z}$ is isomorphic to $\mathbb{Z}$.

2. Let $\alpha: F := \langle a, b \rangle \to \mathbb{Z}_3$ be the epimorphism defined given by $\alpha(a) = 1$ and $\alpha(b) = 0$. It follows from Proposition 31.4 that the kernel $G := \ker(\alpha)$ is a free group of rank $[F : G] \cdot (\text{rank}(F) - 1) + 1 = 3 \cdot 1 + 1 = 4$. In Exercise 31.2 we will determine four elements of $G = \ker(\alpha)$ that are generators for this free group.

**Remark.**

1. In Corollary 37.10 we will extend the statement to all free groups, i.e. we will drop the condition that the rank should be countable. The idea of the proof is fairly similar to the one used below, but the proof of the more general statement is overall “technologically” somewhat more fancy.

2. There are purely group theoretic proofs of Proposition 31.4 and of Corollary 37.10, see e.g. [Schre27, HallM76, Theorem 7.2.1] or [Bau93, Chapter III.3], but the topological proof that we had just provided is arguably conceptually the clearest proof.

3. Corollary 37.10 and Proposition 31.4 are a special case of the Kurosh Subgroup Theorem. This theorem says that if $G$ is the product of groups $A_i, i \in I$ and if $H$ is a subgroup of $G$, then $H$ is a free product of a free group and groups $B_i, i \in I$ where each $B_i$ is a (potentially trivial) group that is conjugate to a subgroup of $A_i$. We refer to [LS77, Theorem IV.1.10] for details and a proof.

**Proof.** Let $F = \langle E \rangle$ be a free group on a countable generating set $E$ and let $G$ be a subgroup of $F$. Note that it follows easily from Lemma 1.7 that $G$ is a countable set. Let $\Gamma = (\{x_0\}, E, i, t)$ be the abstract graph with one vertex and one edge for each element of $E$. By the discussion on page 360 we know that the topological realization $X := \lvert G \rvert$ is homeomorphic to the wedge $\bigvee_{e \in E} S^1_e$. It follows from Lemma 20.4 that there exists an isomorphism $\varphi: F = \langle E \rangle \to \pi_1(X, x_0)$. By Proposition 36.10 (6) and Proposition 29.5 there exists a path-connected covering $p: (Y, y_0) \to (X, x_0)$ of degree $[F : G]$ such that $p_*(\pi_1(Y, y_0)) = G$. By Corollary 16.14 the map $p_*$ is injective. Thus we see that $\pi_1(Y, y_0)$ itself is isomorphic to $G$. By Proposition 31.1 we can equip $Y$ with the structure of a

---

\[534\] Does the equality hold if $G$ is infinite-index and if we interpret $[F : G] \cdot (\text{rank}(F) - 1)$, as usual, as $\infty \cdot (\text{rank}(F) - 1) = \infty$ for $F \not\simeq \mathbb{Z}$?
topological graph. Since $E$ and $G$ are countable we see that $Y$ is a countable topological graph. We deduce from Proposition \[31.2\] that $G \cong \pi_1(Y, y_0)$ is a free group. This completes the proof of (1).

Now suppose that $F$ is finitely generated and that $G$ is a finite-index subgroup of $F$. We see that we have the following equalities:

$$\text{rank}(\pi_1(Y, y_0)) - 1 = \chi(Y) = [Y : X] \cdot \chi(X) = [F : G] \cdot (\text{rank}(\pi_1(X, x_0)) - 1).$$

This completes the proof of (2).

\[31.4. \textbf{Subgroups of surface groups.}\] We start out with the following proposition that is similar in spirit to Proposition \[31.2\] but potentially it is more surprising.

\[\textbf{Proposition 31.5.}\] If $M$ is a connected 2-dimensional smooth manifold that is non-compact, then $\pi_1(M)$ is a free group.

\[\textbf{Remark.}\] A somewhat different proof of Proposition \[31.5\] is given in [Sti93, p. 142].

\[\textbf{Example.}\] The 2-dimensional smooth manifolds shown in Figure 552 are non-compact and thus their fundamental groups are free. For the example on the left we saw this already in Lemma \[25.11\].

\[\textbf{Figure 552}\]

\[\textbf{Proof.}\] Let $M$ be a connected 2-dimensional smooth manifold that is non-compact. In Corollary \[14.7\] we will show, using the Collar Neighborhood Theorem \[8.12\], that $M$ is homotopy equivalent to a smooth manifold with empty boundary. So we might as well assume that $M$ has no boundary.

By Proposition \[6.64\] we know that there exists a sequence $X_1, X_2, \ldots$ of $n$-dimensional smooth submanifolds of $M$ with the following four properties:

1. The sequence is nested, i.e. for each $i \in \mathbb{N}$ we have $X_i \subset X_{i+1}$.
2. Each $X_i$ is compact and connected.
3. The $X_i$ are submanifolds in the sense of the definition on page 270.
4. We have $\bigcup_{i \in \mathbb{N}} X_i = M$.

We pick an embedding $\varphi : B^2 \rightarrow X_1 \setminus \partial X_1$ and given any $i \in \mathbb{N}$ we set $X'_i := X_i \setminus \varphi(B^2)$. With a moderate effort we see, by iteratively applying the Surface Classification Theorem \[23.4\] and Lemma \[23.12\], that there exists a sequence of finite topological graphs $\{G_i\}_{i \in I}$ with the following properties:

1. $G_1$ contains a point $v \in \varphi(S^1)$.
2. For each $i \in \mathbb{N}$ we have $G_i \subset G_{i+1}$. 
(7) Each $G_i$ is a deformation retract of $X'_i$.

We see that

$$
\pi_1(M \setminus \varphi(B^2), v) = \pi_1\left( \bigcup_{j \in \mathbb{N}} X'_j, v \right) = \lim_{\to} \pi_1(X'_j, v) = \lim_{\to} \pi_1(|G_j|, v) = \pi_1(G_1, v) \ast \text{free group}.
$$

follows from (4) and Proposition 25.7

by (7) and Proposition 15.16 follows from Lemma 31.3 and the discussion on page 730

Now we can perform the following calculation:

Seifert–van Kampen Theorem 22.2

$$
\pi_1(M, v) = \pi_1((M \setminus \varphi(B^2)) \cup_C \varphi(B^2), v) \cong \pi_1(M \setminus \varphi(B^2), v) *_{\pi_1(C, v)} \pi_1(\varphi(B^2), v)
$$

by the above calculation of $\pi_1(M \setminus \varphi(B^2), v)$

by Lemma 23.12 we know that we can

write $\pi_1(G_1, v) = \pi_1(C, v) * \text{free group}$

Next we address the following question.

**Question 22.6.** Let $\pi$ be the fundamental group of the surface of genus $g \geq 2$. What isomorphism types of subgroups can appear? Is every subgroup again a free group or the fundamental group of a surface?

The following proposition gives an affirmative answer.

**Proposition 31.6.** Let $M$ be the surface of genus $g$ and let $\Gamma \subset \pi_1(M)$ be a subgroup.

1. If the index $[\pi : \Gamma]$ is finite, then $\Gamma$ is the fundamental group of the surface of genus $[\pi : \Gamma] \cdot (g - 1) + 1$.
2. If the index $[\pi : \Gamma]$ is infinite, then $\Gamma$ is a free group.

**Remark.** In Exercise 31.6 we will consider the case of subgroups of the fundamental group of a non-orientable surface of some genus $g \in \mathbb{N}$.

**Proof.** Let $g \in \mathbb{N}_{\geq 2}$ and let $\Sigma$ be the surface of genus $g$. We pick a base point $x_0 \in \Sigma$. Let $\Gamma \subset \pi_1(\Sigma, x_0)$ be a subgroup. We obtain from Proposition 36.10 (6) and Proposition 29.5 that there exists a path-connected covering $p: (\tilde{\Sigma}, \tilde{x}_0) \to (\Sigma, x_0)$ of index $[\pi_1(M, x_0) : \Gamma]$
with \( p_\ast(\pi_1(\Sigma, \tilde{x}_0)) = \Gamma \). By Proposition 17.1 we know that \( \tilde{\Sigma} \) is an orientable 2-dimensional smooth manifold with empty boundary.

(1) If the index \([\pi : \Gamma]\) is finite, then we know by Lemma 16.3 (4) that \( \tilde{\Sigma} \) is again compact. This implies that we now know that \( \tilde{\Sigma} \) is a closed 2-dimensional smooth manifold.

In Exercise 31.6 we will show that the genus is given by the slightly weird formula

(2) By Lemma 16.3 (5) we know that \( \tilde{\Sigma} \) is non-compact. Thus it follows from Proposition 31.5 that \( \Gamma \cong \pi_1(\Sigma) \) is a free group.

We will prove the following corollary to Proposition 31.6 in Exercise 31.4. Note that it gives an affirmative answer to Question 22.9 (1).

**Corollary 31.7.** For every \( g \in \mathbb{N} \) the fundamental group of the surface of genus \( g \) is torsion-free.

We conclude this section with the following proposition which is closely related to Proposition 21.14. We will not prove the proposition, but we will use it at one occasion later on.

**Proposition 31.8.** Let \( M \) be a surface of genus \( \geq 2 \). If \( \Gamma \subset \pi_1(M) \) is a normal non-trivial subgroup of infinite-index, then \( \pi_1(M) \) is a free group of infinite rank.

**Proof.** Let \( M \) be a surface of genus \( \geq 2 \) and let \( \Gamma \subset \pi_1(M) \) be a normal non-trivial subgroup of infinite-index. By Proposition 31.6 it remains to show that \( \Gamma \) is infinitely generated. A proof for this statement is given in [Cat03, Lemma 3.4], alternatively one can prove the second statement using [Lü97, Theorem 0.7]. A significantly stronger statement is proved in [BrH07, Theorem 1].

31.5. **Residually finite groups and Hopfian groups.** Let \((X, x_0)\) be a pointed topological space that is path-connected, locally path-connected and semi-locally simply connected. In Proposition 29.8 we saw that there exists a bijection between the set of subgroups of \( \pi_1(X, x_0) \) and the set of equivalence classes of path-connected coverings of \((X, x_0)\).

Let \((X, x_0)\) be a pointed topological space that is path-connected, locally path-connected and semi-locally simply connected that is compact. It follows from the above, that given a (finite-index) subgroup of \( \pi_1(X, x_0) \) we can associate to \((X, x_0)\) a (finite) covering \( p: \tilde{X} \to X \). For the most part we like to stick to the world of compact topological spaces \( X \). By Lemma 16.3 this means that we are interested in finite-index subgroups of \( \pi_1(X, x_0) \). This leads us to the following, purposefully vague question.

**Question 31.9.** Which (finitely generated) groups have lots of finite-index subgroups?

In this section we will try to address Question 31.9. The following definition, which we already stated in Exercise 19.14 gives one popular way to turn Question 31.9 into a proper mathematical question.

**Definition.** A group \( \pi \) is called residually finite if given any non-trivial element \( g \in \pi \) there exists a homomorphism \( \alpha: \pi \to G \) to a finite group \( G \) such that \( \alpha(g) \) is non-trivial.

**Examples.**
(1) The group $\mathbb{Z}$ is residually finite, indeed given $g \in \mathbb{Z}$ we can consider the epimorphism $\alpha : \mathbb{Z} \to \mathbb{Z} / \langle |g| + 1 \rangle \cdot \mathbb{Z}$ onto a finite group, which evidently satisfies $\alpha(g) \neq 0$.

(2) It follows easily from the classification of finitely generated abelian groups, see 19.4, a slight generalization of (1), that every finitely generated abelian group is residually finite.

(3) In Exercise 31.12 we will see that the group $(\mathbb{Q}, +)$ is not residually finite.

The following is now a meaningful interpretation of Question 31.9.

**Question 31.10.** Which (finitely generated) groups are residually finite?

Before we address Question 31.10 let us heighten the interest in Question 31.10 by stating a surprising property of residually finite groups.

**Definition.** A group $\pi$ is called Hopfian if every epimorphism $\varphi : \pi \to \pi$ is in fact a monomorphism.

**Example.**

(1) It follows immediately from Lemma 19.8 (5) that every finitely generated abelian group is Hopfian.

(2) Note that in contrast to (1), the infinitely generated free abelian group $\mathbb{Z}^{(\mathbb{N})}$ is actually not Hopfian. Indeed, the homomorphism $\varphi : \mathbb{Z}^{(\mathbb{N})} \to \mathbb{Z}^{(\mathbb{N})}$ which is given by $\varphi(x_1, x_2, x_3, \ldots) = (x_2, x_3, \ldots)$ is an epimorphism, but evidently it is not a monomorphism.

It is self-evident that being Hopfian is a convenient property. As we will see later in the Hopf Conjecture 69.14, the notion of a Hopfian group also naturally arises in topology. The following proposition relates the two concepts that we just introduced.

**Proposition 31.11.** Let $\pi$ be a finitely generated group. If $\pi$ is residually finite, then it is Hopfian.

**Remark.** Shortly we will see that the converse to Proposition 31.11 does not hold.

**Proof.** Let $\pi$ be a finitely generated group that is residually finite. Let $\varphi : \pi \to \pi$ be an epimorphism. Now we assume that $\varphi$ is not a monomorphism. We pick a non-trivial element $g \neq e \in \ker(\varphi)$. Since $\pi$ is residually finite there exists a homomorphism $\alpha : \pi \to G$ onto a finite group $G$ such that $\alpha(g) \neq e$.
