102.1. The K3-surface and Rokhlin’s Theorem. In the following we will give a mostly chronological account of the developments regarding the two (or possibly four?) questions posed in Question 102.1.

In Theorem 101.5 we introduced the initially rather unexpected form \( E_8 \). One might wonder whether a form as strange as \( E_8 \) can ever appear “in nature”. As we will now see, somewhat surprisingly this is indeed the case.

Definition. We refer to

\[
\text{K3} := \left\{ [z_0 : z_1 : z_2 : z_3] \in \mathbb{CP}^3 \mid z_0^4 + z_1^4 + z_2^4 + z_3^4 = 0 \right\}
\]

as the K3-surface. Sometimes the K3-surface is also called the Kummer surface.

Remark. The odd name “K3-surface” comes about as follows.

1. First of all, as we will see in Proposition 102.2, K3 is a 2-dimensional complex manifold, i.e. it is a complex surface.

2. According to [OTL16] the definition of the K3-surface is already implicit in the work of Srinivasa Ramanujan in the 1910s. The K3-surface was (re-) discovered by André Weil [Weil58] who named it in honor of three algebraic geometers, Kummer, Kähler and Kodaira, and also the mountain K2 in Pakistan which is the second highest mountain on earth. More precisely, André Weil wrote: “Dans la seconde partie de mon rapport, il s’agit des variétés kählériennes dites K3, ainsi nommées en l’honneur de Kummer, Kähler, Kodaira et de la belle montagne K2 au Cachemire”.

The following proposition summarizes some of the key aspects of the K3-surface.
Proposition 102.2. The K3-surface is a closed simply connected complex manifold of complex dimension 2 or equivalently of real dimension 4. Furthermore we have

\[\text{intersection form of the K3-surface } \cong 2 \cdot E_8 \oplus 3 \cdot H.\]

Proof. All the statements are proved in [GoS99, Theorem 1.3.8] or alternatively [McS16, p. 176]. The intersection form is also calculated in [Huy16, Proposition 3.5]. The calculation of the intersection form, perhaps somewhat disappointingly, makes use of Corollary 101.19.

Remark. The K3-surface, albeit with a somewhat different definition as ours, plays a big role in (algebraic) geometry, as is indicated by the fact that a whole book [Huy16] is dedicated to the study of the K3-surface(s). Note that it follows from [Huy16, Theorem 2.4.2 and 7.1.1] that the K3-surface as defined above, viewed as a smooth manifold, admits many non-biholomorphic complex structures.

In the following we want to discuss one particular aspect of the K3-surface. Namely, the calculation of the intersection form of the K3-surface, of the intersection form of \(S^2 \times S^2\) and Proposition 100.12 raises the question whether one can split off copies of \(S^2 \times S^2\) from the K3-surface. More precisely the following question arose almost immediately after the introduction of the K3-surface.

Question 102.3.

1. Does there exist a closed oriented 4-dimensional topological manifold \(M\) such that the K3-surface is homeomorphic to \(M \# S^2 \times S^2\)?
2. Does there exist a closed oriented 4-dimensional smooth manifold \(M\) such that the K3-surface is diffeomorphic to \(M \# S^2 \times S^2\)?

We will return to the question shortly. But before we do so, we continue with our chronological discussion. Next in line is a result proved by Vladimir Rokhlin in 1952. To formulate Rokhlin’s Theorem we need the notion of a “spin structure”. The definition of a “spin structure” is for example given in [GoS99, Chapter 1.4.2], but the precise definition is of no concern to us and we will use this notion as a black box. We just note that in the following we say that a smooth manifold is spin, if it admits a spin structure. We now state the key result on the existence of spin structures in our context.

---

1426 We had seen already on page 449 that there exist complex manifolds that are diffeomorphic but not biholomorphic.
Proposition 102.4. Let \( X \) be a closed oriented 4-dimensional smooth manifold.

(1) If \( X \) is spin, then the intersection form \( Q_X \) is even.

(2) If the intersection form \( Q_X \) is even and if \( H_1(X; \mathbb{Z}) \) has no 2-torsion, then the smooth manifold \( X \) is spin.

Proof. The proposition is the content of [GoS99, Corollary 5.7.6], which in turn is proved using the "Wu formula". The proposition is also discussed in [Scor05, p. 163].

Now let us state Rokhlin’s celebrated theorem.

Theorem 102.5. (Rokhlin 1952) Let \( X \) be a closed oriented 4-dimensional smooth manifold. If \( X \) is spin, then \( \text{sign}(X) \) is divisible by 16.

Proof. This theorem was proved by Vladimir Rokhlin [Rok52, Rok86a, p. 21] in 1952. More modern proofs of Rokhlin’s Theorem are given in [FK78, LaM89, Theorem II.2.13 and Corollary IV.1.2] and [Sav02, Theorem 2.1].

Remark. We will now see that the converse to neither of the two statements in Proposition 102.4 holds.

(1) We consider the Enriques surfaces

\[
X := \left\{ [z_0:z_1:z_2:z_3] \in \mathbb{C}P^3 \mid z_0^4+z_1^4+z_2^4+z_3^4=0 \right\} / (z_0, z_1, z_2, z_3) \sim (z_1, -z_0, z_3, -z_2).
\]

We make the following observations:

(a) It is elementary to show that the equivalence relation \( \sim \) on K3 defines a smooth free orientation-preserving action by the group \( \mathbb{Z}_2 \).

(b) It follows from (a) and Propositions 6.32 and 6.47 that the Enriques surface is a closed oriented connected 4-dimensional smooth manifold.

(c) Since the K3-surface is simply connected it follows from (a), together with Lemma 16.3, Proposition 16.9 and Theorem 16.16 that \( \pi_1(X) \cong \mathbb{Z}_2 \). In particular we obtain from the Hurewicz Theorem 52.5 that \( H_1(X; \mathbb{Z}) \) has 2-torsion.

(d) As is shown in [Hab82], the intersection form \( Q_X \) is isometric to \( E_8 \oplus H \), in particular \( Q_X \) is even and \( \text{sign}(X) = 8 \).

Note that it follows from (d) together with Rokhlin’s Theorem 102.5 that \( X \) cannot be spin. In particular we see that the converse to Proposition 102.4 (1) does not hold. We refer to [Hab82, FS84, GoS99, p. 93] and [LaM89, p. 90] for more details on the Enriques surface.

(2) We consider the smooth manifold \( S^1 \times \mathbb{R}P^3 \). It follows from the discussion on page ?? that \( S^1 \times \mathbb{R}P^3 \) is parallelizable, i.e. its tangent bundle is a trivial bundle. This implies that \( S^1 \times \mathbb{R}P^3 \) admits a spin structure. Since \( H_2(S^1 \times \mathbb{R}P^3; \mathbb{Z}) = 0 \) we see that its intersection form is even. But \( H_1(S^1 \times \mathbb{R}P^3) \cong \mathbb{Z} \oplus \mathbb{Z}_2 \) has 2-torsion. Thus we see that the converse to Proposition 102.4 (2) does not hold.

The combination of Proposition 102.4 and Rokhlin’s Theorem 102.5 gives us the following variation on Rokhlin’s Theorem. This was historically the first result to address Question 102.1 (2).
Theorem 102.6. (Rokhlin 1952) Let \( X \) be a closed oriented 4-dimensional smooth manifold. If the intersection form \( Q_X \) is even and if \( H_1(X;\mathbb{Z}) \) has no 2-torsion (e.g. if \( X \) is simply connected), then \( \text{sign}(X) \) is divisible by 16.

In a different direction the following theorem was the first noteworthy result towards an affirmative answer to Question 102.1 (1).

Theorem 102.7. (Milnor 1958) Let \( X \) and \( Y \) be two closed oriented simply connected 4-dimensional topological manifolds. Then
\[
X \text{ and } Y \text{ are homotopy equivalent } \iff Q_X \text{ is isometric to } \pm Q_Y.
\]

Proof. This theorem was proved for smooth manifolds by John Milnor [Miln58b, Theorem 3] in 1958, building on work of John Whitehead [WhdJ49a, Theorem 1.2.25] and [Kir89, Theorem 2.1] sketch a proof that also works for topological manifolds.

102.2. The work of Michael Freedman and Simon Donaldson. After the somewhat preliminary results by Vladimir Rokhlin and John Milnor the early 1980s saw two major breakthroughs by Michael Freedman and Simon Donaldson.

First, in 1981 Michael Freedman [Fre82] gave a complete answer to Question 102.1 in the category of topological manifolds. More precisely, Michael Freedman [Fre82] proved the following theorem.

Theorem 102.8. (Freedman 1981) Let \( Q \) be a nonsingular symmetric form over the integers.

1. If \( Q \) is even, then up to an orientation-preserving homeomorphism, there exists a unique closed oriented simply connected topological manifold whose intersection form is isometric to \( Q \).

2. If \( Q \) is odd, then up to orientation-preserving homeomorphisms, there exist precisely two closed oriented simply connected topological manifolds whose intersection forms are isometric to \( Q \). These two topological manifolds are distinguished by the Kirby-Siebenmann invariant which is discussed in the subsequent remark.

Remark.

1. Let \( X \) be a simply connected closed topological manifold. By the Hurewicz Theorem 53.5 we know that the Hurewicz homomorphism \( \pi_2(X) \to H_2(X;\mathbb{Z}) \) is an isomorphism. In particular, if \( \pi_2(X) \) vanishes, then \( H_2(X;\mathbb{Z}) = 0 \). This fact shows that Theorem 102.8 applied to the form on the trivial group \( \{0\} \), implies that every homotopy 4-sphere is homeomorphic to \( S^4 \). We will discuss this in greater detail in Chapter ??.

\[\text{Recall that from Proposition 101.18 we know, for purely algebraic reasons, that the signature of a non-singular even symmetric form is divisible by 8.}\]

\[\text{Michael Freedman (*1951) is an American mathematician, in 1986 he was awarded the Fields medal for the proof of Theorem 102.8.}\]
(2) The two homeomorphism types of Theorem 102.8 are distinguished by the Kirby-Siebenmann invariant \( k_S(M) \in \text{H}^4(M; \mathbb{Z}_2) = \mathbb{Z}_2 \) of a closed connected non-empty 4-dimensional topological manifold \( M \). This invariant is defined in \( [KSi77] \) p. 318 or alternatively in \( [FQ90] \) Section 10.2B and \( [Rudy16] \) Chapter 3.4. The Kirby-Siebenmann invariant has the following properties:

(a) By \( [Rudy16] \) Theorem 3.4.3 this invariant vanishes if \( X \) admits a PL-structure. Recall that in Theorem 64.14 we saw that every smooth manifold admits a PL-structure. In particular we see that the Kirby-Siebenmann invariant vanishes for smooth manifolds. We refer to \( [Cer68] \) p. IX and \( [Scor05] \) p. 220 for more details.

(b) By \( [FNOP19] \) Theorem 7.3 the Kirby-Siebenmann invariant is additive under the connected sum operation.

(3) Freedman’s Theorem also answers Question 102.3 (1) in the affirmative. More precisely, by the existence statement of Theorem 102.8 (1) there exists a closed oriented simply connected 4-dimensional topological manifold \( X \) with \( Q_X \cong E_8 \). It follows from Propositions 100.11 and 100.12 together with the uniqueness statement of Theorem 102.8 (1), there exists an orientation-preserving homeomorphism of the K3-surface to \( X \# X \# 3 \cdot (S^2 \times S^2) \).

(4) We conclude this remark with a quick foray into the high-dimensional world. For \( n \geq 3 \) Wall \( [Wall62] \) (see also \( [Ran02] \) p. 269) classified diffeomorphism classes of pairs \( (M, \partial M) \) where \( M \) is an orientable \( (n-1) \)-connected 2n-dimensional smooth manifold and where the boundary \( \partial M \) is a homotopy sphere. The classification goes via the intersection form and one extra invariant which lies in the homotopy group \( \pi_{n-1}(\text{SO}(n)) \).

Example. On page 2415 we saw that the intersection form of \( \mathbb{C}P^2 \) is represented by the \((1 \times 1)\)-matrix (1). By (2b) we know that the Kirby-Siebenmann invariant of \( \mathbb{C}P^2 \) vanishes. Theorem 102.8 (2) together with Remark (2) says that there exists a closed oriented simply connected 4-dimensional topological manifold, which usually is denoted by \( *\mathbb{C}P^2 \), with the same intersection form as \( \mathbb{C}P^2 \) but with non-zero Kirby-Siebenmann invariant. Theorem 102.8 (2) also says that \( *\mathbb{C}P^2 \) is unique up to an orientation-preserving homeomorphism. The topological manifolds \( \mathbb{C}P^2 \) and \( *\mathbb{C}P^2 \) are not homeomorphic since the Kirby-Siebenmann invariants differ. But note that by Theorem 102.7 the topological manifolds \( \mathbb{C}P^2 \) and \( *\mathbb{C}P^2 \) are homotopy equivalent.

Among many other consequences we obtain the following rather surprising result.

**Theorem 102.9.** There exist closed orientable 4-dimensional topological manifolds that do not admit a smooth structure.

---

1429 Here it is worth recalling that Proposition 75.15 (3) says that for a closed connected non-empty 4-dimensional topological manifold we have \( \text{H}^4(X; \mathbb{Z}_2) = \mathbb{Z}_2 \).  
1430 We refer to page 1599 for the definition of a PL-structure.  
1431 See page 2161 for the definition of a homotopy sphere.
Proof. At this point we can combine the above results to give two types of examples of such smooth manifolds:

1. It follows from Theorem $102.8(2)$ and the above Remark (3) that given any non-singular odd symmetric form $Q$ there exists a closed oriented 4-dimensional topological manifold $X$ with $Q_X \cong Q$ and non-trivial Kirby-Siebenmann invariant. As we pointed out above in Remark (2a), this topological manifold does not admit a smooth structure.

2. If we apply Freedman’s Theorem $102.8(1)$ to the non-singular positive-definite even form $E_8$ we obtain a certain closed oriented simply connected 4-dimensional topological manifold which, by Rokhlin’s Theorem $102.6$, cannot admit a smooth structure.

In a remarkable twist, shortly after Freedman proved his results on the intersection forms of 4-dimensional topological manifolds, Simon Donaldson$^{1432}$, see [Don83, Theorem A] and [Don87, Theorem 1], proved the following result regarding intersection forms of 4-dimensional smooth manifolds$^{1433}$.

**Theorem 102.10. (Donaldson 1982)** Let $X$ be a closed oriented connected 4-dimensional smooth manifold. If $Q_X$ is positive-definite, then $Q_X$ is represented by the identity matrix.

**Example.** We consider the positive definite symmetric form $E_8 \oplus E_8$. It has signature 16, hence Rokhlin’s Theorem $102.6$ has no objections. But Donaldson’s Theorem $102.10$ implies that this form cannot be the intersection form of a closed oriented connected 4-dimensional smooth manifold.

To understand the significance of Donaldson’s Theorem, often referred to as Donaldson’s Theorem A, recall that on page 2455 we saw that there are more than $10^{51}$ isometry classes of non-singular positive-definite symmetric forms of rank 40. By Freedman’s Theorem $102.8$ all of them arise as intersection forms of closed oriented connected 4-dimensional topological manifolds. By Donaldson’s Theorem $102.10$ the only one which appears as the intersection form of a closed oriented connected 4-dimensional smooth manifold is the one represented by the identity matrix$^{1434}$.

**Remark.** It is difficult to exaggerate the importance of Donaldson’s Theorem in mathematics. For example it is at the heart of the proof of Theorem ?? which says that $\mathbb{R}^4$ is not diffeomorphic to $S^4$.

---

$^{1432}$ Simon Donaldson (*1957) is an English mathematician. He proved Theorem $102.10$ when he was a second year PhD student. The Fields medalist Michael Atiyah described in [At87] the work of Simon Donaldson as follows: “In 1982, when he was a second-year graduate student, Simon Donaldson proved a result that stunned the mathematical world.” Simon Donaldson was awarded the Fields medal in 1986.

$^{1433}$ An exposition of the proof is also given in [Law85] and a different proof, using Seiberg-Witten invariants is given in [Nic00, Theorem 2.4.18] and a proof using Heegaard Floer homology is given in [OS03, Theorem 9.1].

$^{1434}$ The identity matrix represents, by Proposition $100.12$ and the discussion on page 2415 the intersection form of the connected sum of 40 copies of $\mathbb{C}P^2$.

$^{1435}$ Admittedly it is also hard to underestimate the role of Donaldson’s Theorem outside of mathematics.
admits uncountably many smooth structures. But Donaldson’s Theorem can also appear in
totally unexpected situations. For example in 2017 Duncan McCoy [McCoy17] used Don-
aldson’s Theorem, and many other ingredients, to show that if $K$ is an alternating knot
with unknotting number one\footnote{\textsuperscript{1436}} then such a crossing change can already be performed
in an alternating diagram. For example, according to [LiM] the three alternating knots
shown in Figure 1447 have unknotting number one. By the aforementioned result we now
know that we can turn these three knots into the trivial knot by changing a crossing in the
alternating diagrams shown. Which crossings do you need to change?

Now that we have digested Donaldson’s Theorem [102.10] the question arises, what
can we say about \textit{indefinite} intersection forms of closed oriented 4-dimensional smooth
manifolds? First recall that in Corollary [101.17] we saw that every non-singular indefinite
odd symmetric form is isometric to $m \cdot (1) \oplus n \cdot (-1)$ for some $m, n \in \mathbb{N}$. Next note that
according to Proposition [100.12] and the discussion on page 2413 every such form is realized
by the smooth manifold $m \cdot \mathbb{C}P^2 \# n \cdot \mathbb{C}P^2$.

Therefore, in the following we only need to discuss the realizability of non-singular
indefinite \textit{even} symmetric forms. Recall that in Corollary [101.19] we showed that every
non-singular even indefinite symmetric form is isometric to $m \cdot H \oplus n \cdot E_8$ for some $m \in \mathbb{N}_0$ and
$n \in \mathbb{Z} \\setminus \{0\}$. The following theorem, proved by Mikio Furuta [Furu01] in 2001 gives
some restrictions on the possible values of $m$ and $n$.

\footnote{\textsuperscript{1436}We refer to page 809 for the definition of the unknotting number of a knot. A knot is called
\textit{alternating} if it admits a diagram that is alternating, i.e. which has the property that each undercrossing
is followed by an overcrossing and vice versa.}
**Theorem 102.11. (Furuta’s 10/8-Theorem)** If $M$ is a closed oriented connected 4-dimensional smooth manifold with indefinite even intersection form, then

$$b_2(M) \geq \frac{10}{8} \cdot \sign(M) + 2.$$ 

In particular, $Q_M \cong m \cdot H \oplus n \cdot E_8$ with $m \geq |n| + 1$.

**Remark.** Furuta’s 10/8-Theorem allows us to answer Question 102.3 (2) in the negative. More precisely, suppose that we have a decomposition of the K3-surface as a connected sum $M \# N$. We make the following four observations:

1. Without loss of generality we have $\sign(M) \geq \sign(N)$.
2. It follows from Proposition 102.2, Lemma 101.14 (3) and Proposition 100.12 that $Q_M$ and $Q_N$ are even.
3. From Lemma 101.11 (2) and Proposition 102.2 we obtain that $\sign(M) + \sign(N) = 16$.
4. By Proposition 102.2 and Proposition 100.11 we know that $b_2(M) + b_2(N) = 22$.

If we combine these facts with Rokhlin’s Theorem 102.6 we obtain easily that we have $\sign(M) = 16$. Furthermore, it follows from Donaldson’s Theorem 102.10 that $Q_M$ is indefinite. Now Furuta’s 10/8-Theorem implies that $b_2(M) \geq \frac{10}{8} \cdot 16 + 2 = 22$, but by Proposition 102.2 this equals $b_2(K3)$. Thus we obtain from Proposition 100.11 that $b_2(N) = 0$. We can conclude that we cannot split off a copy of $S^2 \times S^2$ from K3. This answers Question 102.3 (2) in the negative.

Furuta’s 10/8 Theorem is not yet optimal since it does not quite close the gap between the forms which we can realize by smooth manifolds and the forms which we can exclude. More precisely it follows from Proposition 100.12, the calculation of the intersection forms of the K3-surface, see Proposition 102.2, and of the intersection form of $S^2 \times S^2$ that for any $m \in \mathbb{Z} \setminus \{0\}$ and any $n \geq 3|m|$ there exists a closed oriented simply connected 4-dimensional smooth manifold with intersection form isometric to $m \cdot E_8 \oplus n \cdot H$. More precisely, we have

$$\text{intersection form of } m \cdot K3 \# (n - 3|m|) \cdot (S^2 \times S^2) \cong m \cdot E_8 \oplus n \cdot H.$$ 

The following conjecture predicts that this result is optimal.

**Conjecture 102.12. (11/8-Conjecture)** If $M$ is a closed oriented 4-dimensional smooth manifold with indefinite even intersection form, then

$$b_2(M) \geq \frac{11}{8} \cdot \sign(M).$$

Equivalently, if $Q_M \cong m \cdot H \oplus n \cdot E_8$ with $n \neq 0$, then $m \geq \frac{3}{2}|n|$.

---

1437 This second statement follows from the first statement together with Corollary 101.19 and the calculation of the rank and signature of $H$ and $E_8$.

1438 By Proposition 100.11 and Proposition 102.2 we also know that $\pi_1(N) = 0$. Recall that by the Hurewicz Theorem 53.3 we know that if $\pi_1(N) = 0$ and $H_2(N; \mathbb{Z}) = 0$, then $\pi_2(N) = 0$. Thus it follows from Theorem ?? that $N$ is homeomorphic to $S^4$. Since Question ?? is still open, we do not know whether $N$ is diffeomorphic to $S^4$.

1439 As before, the fact that these two statements are equivalent follows from Corollary 101.19 and the calculation of the rank and signature of $H$ and $E_8$. 
Remark.
(1) A proof of the 11/8-Conjecture would imply, by Freedman’s Theorem [102.8], that any closed oriented simply connected 4-dimensional smooth manifold is homeomorphic to either a connected sum of the form \( m \cdot \mathbb{CP}^2 \# n \cdot \mathbb{CP}^2 \) or alternatively to a connected sum of the form \( m \cdot \mathbb{K}^3 \# n \cdot (S^2 \times S^2) \).

(2) For simply connected smooth manifolds currently the best result is [HLSX18, Corollary 1.13] which says that if \( M \) is a closed oriented simply connected 4-dimensional smooth manifold that is not homeomorphic to \( S^4 \), \( S^2 \times S^2 \) or the K3-surface and whose intersection form is indefinite and even, then \( b_2(M) \geq \frac{10}{8} \cdot |\text{sign}(M)| + 4 \).

The other question which arises in this context is whether closed orientable 4-dimensional smooth manifolds that are homeomorphic are also necessarily diffeomorphic. It turns out that in many cases the answer is very much no. For example the following theorem was proved in 1998 by Ron Fintushel and Ron Stern [FS98].

**Theorem 102.13.** There exist closed orientable 4-dimensional smooth manifolds \( X_i, i \in \mathbb{N} \) such that each \( X_i \) is homeomorphic to the K3-surface, but such that the \( X_i \) are pairwise non-diffeomorphic.

Similar results have been obtained for many other 4-dimensional smooth manifolds, e.g. for \( \mathbb{CP}^2 \# k \mathbb{CP}^2 \) with \( k = 9 \) by Simon Donaldson [Don87] in 1987, \( k = 8 \) by Dieter Kotschick [Kot89] in 1989 and \( k = 7 \) by Jongil Park [Park05] in 2005, and since then also for \( k = 6, 5, 4, 3, 2 \), see e.g. [AP08, AP10] for more details on the history of this problem.

The following question is surely one of the most interesting problem in the theory of 4-dimensional smooth manifolds.

**Question 102.14.** Does every closed oriented connected 4-dimensional smooth manifold \( M \) admit infinitely many pairwise non-diffeomorphic smooth structures? Put differently, given any such \( M \), do there always exist infinitely many smooth manifolds \( M_i, i \in \mathbb{N} \) which are homeomorphic to \( M \) but which are pairwise non-diffeomorphic?

Note that an affirmative answer to Question 102.14 would also give a positive answer to Question 102.14.

The following theorem, proved by C. T. C. Wall [Wall64, Theorem 3] in 1964 (see also [Scor05, p. 149] and [Qu83, Theorem 1.1]) shows that in some sense homeomorphic simply connected smooth manifolds are not that far from being diffeomorphic.

**Theorem 102.15.** Let \( M \) and \( N \) be two closed oriented simply connected 4-dimensional topological manifolds. If \( M \) and \( N \) are homeomorphic, then there exists a \( k \in \mathbb{N} \) such that \( M \# k \cdot (S^2 \times S^2) \) and \( N \# k \cdot (S^2 \times S^2) \) are diffeomorphic.

This raises the question, whether in the above theorem \( k = 1 \) suffices. More precisely the following question is still open.

**Question 102.16.** Let \( M \) and \( N \) be two closed oriented simply connected 4-dimensional topological manifolds that homeomorphic. Is \( M \# (S^2 \times S^2) \) diffeomorphic to \( N \# (S^2 \times S^2) \)?

There are some indications, see [JZ18], that the answer to the above question should be no.
Exercises for Chapter 102.

Exercise 102.1. As we discussed on page 2464, it follows from Theorem 102.8 that there exists a closed orientable simply connected 4-dimensional topological manifold $\ast\mathbb{C}P^2$ whose intersection form is represented by the $(1 \times 1)$-matrix $(1)$ and with $k_s(\ast\mathbb{C}P^2) = 1$.

Let $M$ and $N$ be two closed oriented simply connected 4-dimensional topological manifolds. Show that there exist $m, m', n, n' \in \mathbb{N}_0$ and $\epsilon \in \{0, 1\}$ such that the topological manifolds $M \# m \cdot \mathbb{C}P^2 \# m' \cdot \overline{\mathbb{C}P^2} \# \epsilon \cdot \ast\mathbb{C}P^2$ and $N \# n \cdot \mathbb{C}P^2 \# n' \cdot \overline{\mathbb{C}P^2}$ are homeomorphic. Hint. Make use of the properties of the Kirby-Siebenmann invariant discussed on page 2464. Furthermore it is strongly advisable to use Theorem 101.16.

Exercise 102.2. Let $M$ and $N$ be two closed oriented simply connected 4-dimensional smooth manifolds. Show that there exist $m, m', n, n' \in \mathbb{N}_0$ such that $M \# m \cdot \mathbb{C}P^2 \# m' \cdot \overline{\mathbb{C}P^2}$ is diffeomorphic to $N \# n \cdot \mathbb{C}P^2 \# n' \cdot \overline{\mathbb{C}P^2}$.

Remark. Make use of Exercise 102.1 and use the fact from page 2453 that the two smooth manifolds $(S^2 \times S^2)\#\mathbb{C}P^2$ and $\mathbb{C}P^2\#\overline{\mathbb{C}P^2} \# \mathbb{C}P^2$ are diffeomorphic.
Part XI

Handle Structures and Morse Theory
103. Handle decompositions of smooth manifolds

As we have seen, CW-complexes and simplicial complexes have turned out to be useful tools in topology since often they make it possible to break a given topological space into smaller, more manageable pieces. In Theorems 64.2 and 64.5 we saw that every smooth manifold admits a simplicial structure, in particular it admits a CW-structure. Thus in principle we can study a smooth manifold by starting with a 0-dimensional CW-complex and attaching cells of dimensions 1, 2, . . . . The catch is that the inbetween objects are usually not smooth manifolds.

In this section we will introduce handle decompositions of smooth manifolds. These are in many ways quite similar to CW-structures, except that now all intermediate objects are smooth manifolds. In Chapter 104 we will use Morse theory to show that every compact smooth manifold admits a handle decomposition.

103.1. Handle attachments. The following definition is inspired by the definition of a thickened knot that we gave on page 2384.

**Definition.** Let \( W \) be an \( m \)-dimensional smooth manifold. A thickened \( l \)-sphere is a smooth embedding \( B^{m-l} \times S^l \to W \).

Our first proposition introduces the notion of a handle attachment and it summarizes some of the key properties.

**Proposition 103.1.** Let \( M \) be a compact \( n \)-dimensional smooth manifold. Furthermore suppose that we are given a thickened \((k-1)\)-sphere in the boundary \( \partial M \), i.e. suppose we are given a smooth embedding \( \varphi: B^{n-k} \times S^{k-1} \to \partial M \). We refer to

\[
M \cup \varphi h^k := M \cup_{\partial M} \varphi(B^{n-k} \times S^{k-1})
\]

as the result of a \( k \)-handle attachment to \( M \). The following statements hold:

1. (a) The topological space \( M \cup \varphi h^k \) is an \( n \)-dimensional topological manifold.
   (b) Every choice of a collar \( \Theta: [0, 1] \times \partial M \to M \) equips \( M \cup \varphi h^k \) canonically with the structure of an \( n \)-dimensional smooth manifold. This smooth structure has the property that \( M \) and \( B^{n-k} \times S^{k-1} \) are both submanifolds with corner, where the corner set in both cases is given by \( \varphi(S^{n-k-1} \times S^{k-1}) \).
   (c) Let \( \Theta \) and \( \Xi \) be two collars. By (1b) these two collars give rise to two smooth structures \( A_\Theta \) and \( A_\Xi \) on the topological manifold \( M \cup \varphi h^k \). Given any neighborhood \( U \) of the image of \( \varphi(B^{n-k} \times S^{k-1}) \) in \( M \cup \varphi h^k \) there exists a homeotopy \( H: (M \cup \varphi h^k) \times [0, 1] \to M \cup \varphi h^k \) with the following four properties:
      (i) \( H_0 = \text{id} \).
      (ii) \( H_1: (M \cup \varphi h^k, A_\Theta) \to (M \cup \varphi h^k, A_\Xi) \) is a diffeomorphism.
      (iii) For each \( t \in [0, 1] \) the map \( h_t \) restricts to a diffeomorphism of \( M \) and it restricts to a diffeomorphism of \( B^{n-k} \times S^k \).
      (iv) \( H(x, t) = x \) for all \( x \not\in U \) and all \( t \in [0, 1] \).
(d) Any two choices of collar neighborhoods give rise to diffeomorphic smooth structures on $M$.
(2) $M \cup \varphi h^k$ is compact.
(3) The boundary of the smooth manifold $M \cup \varphi h^k$ is given by
$$\partial(M \cup \varphi h^k) = (\partial M \setminus \varphi(B^{n-k} \times S^{k-1})) \cup \varphi|_{\partial M \times S^{n-k-1}, S^{k-1}} (S^{n-k-1} \times \overline{B}^k)$$.
(4) If $\varphi, \psi : \overline{B}^{n-k} \times S^{k-1} \to \partial M$ are two smooth embeddings that are smoothly isotopic, then $M \cup \varphi h^k$ and $M \cup \psi h^k$ are diffeomorphic. Furthermore, given any neighborhood $U$ of $\partial M$ one can find a diffeomorphism that is the identity on the common subset $M \setminus U$.

Remark.

(1) The fact that the precise smooth structure on $M \cup \varphi h^k$ depends on a choice of a collar is a nuisance. Usually we use (1c) as an excuse to ignore this issue, albeit with a slightly bad conscience.
(2) The modification of the boundary that we saw in Proposition 103.1 (5) is called a surgery along $\varphi(\{0\} \times S^{k-1}) \subset \partial M$. We will study surgeries in greater detail in Chapter ??.
(3) We deal with the question of whether $M \cup \varphi h^k$ is orientable respectively connected in Lemma 103.8 and Proposition 103.9

Sketch of proof.

---

1440 Recall that by the definition on page 200 this means that
$$M \cup \varphi h^k := (M \cup (\overline{B}^{n-k} \times \overline{B}^k)) / \sim \quad \text{where } \varphi(P) \sim P \text{ for } P \in \overline{B}^{n-k} \times S^{k-1}.$$  
1441 The fact that in the notation the map $\varphi$ now goes from right to left is a little awkward, but all other conventions lead sooner or later also to slightly unnatural results.
1442 Recall that by the Collar Neighborhood Theorem 8.12 a collar $[0, 1] \times \partial M \to M$ always exists.
(1) The proof of Statement (1) is quite similar to the proof of Proposition 8.15 (1).
(a) Let \( \Theta : [0, 1] \times \partial M \to M \) be a collar. We use this collar and the standard product neighborhood \([0, 1] \times \overline{B}^{n-k} \times S^{k-1} \subset \overline{B}^{n-k} \times \overline{B}^k\) together with the argument from the proof of Proposition 8.15 (1) to find suitable canonical charts for all points that do not lie on \( \varphi(S_n^{n-k-1} \times S^{k-1}) \). Furthermore, for points on \( \varphi(S_n^{n-k-1} \times S^{k-1}) \) one can easily find “charts” such that the image equals \( \{(x_1, \ldots, x_n) \in \mathbb{R}^n \mid x_{n-1} \leq 0 \text{ or } x_n \geq 0 \} \). Similar to the proof of Proposition 8.9, we compose those charts with the map

\[
\Psi : \mathbb{R}^{n-2} \times \{(x, y) \in \mathbb{R}^2 \mid x \leq 0 \text{ or } y \geq 0\} \to \mathbb{R}^{n-2} \times \mathbb{R} \times \mathbb{R}_{\geq 0}
\]

\[
(x_1, \ldots, x_{n-2}, r \cos(\varphi), r \sin(\varphi)) \mapsto (x_1, \ldots, x_{n-2}, r \cos(\frac{2}{3}\varphi), r \sin(\frac{2}{3}\varphi)).
\]

If one interprets the above discussion with good will, then one can see that this defines a smooth atlas on \( M \cup \varphi \mathcal{H}^k \) which has all the desired properties.
(b) We proved this statement already in (a).
(c) As in the proof of Proposition 8.15 (1c) this statement follows without too much effort from the uniqueness statement for collars, see Proposition 8.13.
(d) This statement is an immediate consequence of (c).

\[\text{Figure 1449. Illustration for the proof of Proposition 103.1 (1).}\]

(2) It follows from the compactness of \( M \) and \( \overline{B}^{n-k} \times \overline{B}^k \) together with Lemma 3.21 (4) that \( M \cup \varphi \mathcal{H}^k \) is compact.

(3) Similar to the proof of Proposition 8.15 (4) one can prove the statement about the description of \( \partial(M \cup \varphi \mathcal{H}^k) \) quite easily using Proposition 6.27.

(4) It follows from (1c) that throughout the proof of (4) we can work with the same collar neighborhood \([0, 1] \times \partial M\). Now let \( \varphi, \psi : \overline{B}^{n-k} \times S^{k-1} \to \partial M \) be two smooth embeddings. We suppose that they are smoothly isotopic. Let \( F : \overline{B}^{n-k} \times S^{k-1} \times [0, 1] \to \partial M \) be a smooth isotopy with \( F_0 = \varphi \) and \( F_1 = \psi \). By the Isotopy Extension Theorem 8.27 together with Lemma 8.4, there exists a diffeotopy \( G : \partial M \times [0, 1] \to \partial M \) with \( G_t = \text{id} \) for \( t \in [0, \frac{1}{4}] \) and with \( G_t \circ \varphi = \psi \) for all \( t \in [\frac{3}{4}, 1] \). One can now easily
verify that the map
\[ \Xi: M \cup_k h^k \to M \cup_k h^k \]

\[ [x] \mapsto \begin{cases} 
[x], & \text{if } x \in M \setminus ([0, 1] \times \partial M), \\
(t, G(1 - t, y)), & \text{if } x = (t, y) \in [0, 1] \times \partial M, \\
[x], & \text{if } x \in \overline{B}^{n-k} \times \overline{B}^k
\end{cases} \]

is a diffeomorphism. Finally suppose that we are given a neighborhood \( U \) of \( \partial M \). Evidently we can pick a collar neighborhood \([0, 1] \times \partial M\) that is contained in \( M \setminus U \). The diffeomorphism that we just constructed is now the identity on the common subset \( M \setminus U \).

As on so many other occasions we leave it to the reader to fill in the annoying details. ■

**Remark.** The approach in the proof of Proposition 103.1 for defining charts for \( M \cup_k h^k \) at the points in \( \phi(S^{n-k-1} \times S^{k-1}) \) is sometimes called *rounding corners* or *smoothing corners*.

Proposition 103.1 motivates the following definition.

**Definition.** Let \( M \) be a compact \( n \)-dimensional smooth manifold. Suppose we are given a thickened \((k - 1)\)-sphere \( \phi: \overline{B}^{n-k} \times S^{k-1} \to \partial M \).

(1) We say
\[ M \cup_h h^k := M \cup_{\partial M \times \overline{B}^{n-k} \times S^{k-1}} \left( \overline{B}^{n-k} \times \overline{B}^k \right) \]
is obtained from \( M \) by attaching the \( k \)-handle \( \overline{B}^{n-k} \times \overline{B}^k \) along \( \phi \). In particular we refer to the image of \( \overline{B}^{n-k} \times \overline{B}^k \) in \( M \cup_{\phi} h^k \) as a \( k \)-handle or as a handle of index \( k \).

(2) (a) We refer to the image of \( \{0\} \times S^{k-1} \) in \( \partial M \) as the *attaching sphere of the handle*.
(b) We refer to the image of \( \{0\} \times \overline{B}^k \) in \( M \cup_{\phi} h^k \) as the *core of the handle*.
(c) We refer to the image of \( S^{n-k} \times \{0\} \) in \( \partial(M \cup_{\phi} h^k) \) as the *belt sphere of the handle*.

We refer to Figure 1451 for an illustration of these definitions.

**Example.** Let \( M \) be a compact \( n \)-dimensional smooth manifold.

(1) Let us consider the extreme cases of attaching a 0-handle and attaching an \( n \)-handle.
(a) It follows basically from the definitions that attaching a 0-handle is the same as taking the disjoint union with \( \overline{B}^n \).
We illustrate these two examples in Figure 1452.

(b) It follows immediately from Proposition 8.2 (3) that any smooth embedding \( \varphi: \overline{B^n} \times S^{n-1} \to \partial M \) is a diffeomorphism onto a component of \( \partial M \). Thus an \( n \)-handle attachment is the same as gluing an \( n \)-ball to a boundary component that is diffeomorphic to \( S^{n-1} \) via the diffeomorphism \( \varphi \). Note that in Proposition ?? we will see that in general the result depends on the choice of \( \varphi \).

Figure 1452

(2) Next we turn to attachments of 1-handles. As is shown in Figure 1453, the effect of attaching a 1-handle depends on the choice of the attaching map \( \varphi: \overline{B^{n-1}} \times S^0 \to \partial M \). In Lemma 103.10 we will see that the four examples of 1-handle attachments that we see in Figure 1453 exhaust in a suitable sense all possibilities for 1-handle attachments.

Figure 1453

(3) For handle attachments that are not of index 0, 1 and \( \dim(M) \) there is no straightforward classification of all possibilities. For example we consider the smooth manifold
Let $\gamma: S^1 \to S^3$ be a smooth embedding. Note that $K = \gamma(S^1)$ is a knot. In Lemma 99.1 we saw that for each $d \in \mathbb{Z}$ there exists an essentially unique tubular map $B^2 \times K \to S^3$ of self-linking number $d$. Any such tubular map describes a 2-handle attachment to $B^4$. There is no reason to believe that all these 2-handle attachments can be classified easily.

103.2. **Handle decompositions.** The following is a good example of a self-explanatory definition.

**Definition.** Let $M$ be a compact $n$-dimensional smooth manifold. A handle decomposition for $M$ is a diffeomorphism

$$\Theta: M \xrightarrow{\cong} \emptyset \cup \varphi_1 h^{k_1} \cup \cdots \cup \varphi_m h^{k_m}$$

where for every $i = 1, \ldots, m$ the map $\varphi_i$ is a thickened $(k_i - 1)$-sphere in the boundary of the smooth manifold $\emptyset \cup \varphi_1 h^{k_1} \cup \cdots \cup \varphi_{i-1} h^{k_{i-1}}$. Usually we suppress the name of the diffeomorphism, in this case $\Theta$, from the notation.

**Examples.**

1. In Figure 1454 we show a handle decomposition for the surface of genus $g = 2$. This handle decomposition consists of one 0-handle, $2g$ 1-handles and one 2-handle.

   ![Figure 1454](image)

   We formulate the next two types of examples as a lemma.
Lemma 103.2.

(1) Let $n \in \mathbb{N}$. We consider the thickened $(n-1)$-sphere that is given by the identity

$$\text{id}: \mathbb{B}^n \to S^{n-1} \to \partial(\mathbb{B}^n).$$

If we attach an $n$-handle to $\mathbb{B}^n$ along $\text{id}$ we obtain a smooth manifold that is diffeomorphic to $S^n$. In particular we see that $S^n$ admits a handle decomposition with a single 0-handle and a single $n$-handle.

(2) Let $m, k \in \mathbb{N}$. We consider the thickened $(k-1)$-sphere

$$\varphi: \mathbb{B}^m \times S^{k-1} \to S^{m+k-1} = \partial(\mathbb{B}^{m+k})$$

$$(x, y) \mapsto \frac{\frac{1}{2} \cdot (x, y)}{\|\frac{1}{2} \cdot (x, y)\|}$$

with $(x, y) \in \mathbb{B}^m \times S^{k-1} \subset \mathbb{R}^m \times \mathbb{R}^k = \mathbb{R}^{m+k}$.

If we attach a $k$-handle to the 0-handle $\mathbb{B}^{m+k}$ along the thickened $(k-1)$-sphere $\varphi$, then we obtain a smooth manifold that is diffeomorphic to $\mathbb{B}^m \times S^k$. In particular we see that $\mathbb{B}^m \times S^k$ admits a handle decomposition with a single 0-handle and a single $k$-handle.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure.png}
\caption{Illustration of Lemma 103.2 (2).}
\end{figure}

Proof.

(1) Let $n \in \mathbb{N}$. As on page 199 we consider the maps

$$g_{\pm}: \mathbb{B}^n = \mathbb{B}^n_{\pm} \to S^n$$

$$(x_1, \ldots, x_n) \mapsto ((-1)^n \cdot x_1, \ldots, x_n, \pm \sqrt{1 - x_1^2 - \cdots - x_n^2}).$$

We leave it to the reader to verify that the map\footnote{As we mentioned in the formulation of Proposition 103.1, the precise smooth structure on $\mathbb{B}^n_+ \cup_{S^{n-1}} \mathbb{B}^n_-$ depends on the choice of a collar. We follow the convention from page 352, namely we consider $\mathbb{B}^n_+$ with the standard collar that we introduced on page 351. With this convention the given map is indeed an honest-to-God diffeomorphism.}

$$\mathbb{B}^n_+ \cup_{S^{n-1}} \mathbb{B}^n_- \to S^n$$

is an orientation-preserving diffeomorphism.

$$[P] \mapsto \begin{cases}
g_+(P), & \text{if } P \in \mathbb{B}^n_+; \\
g_-(P), & \text{if } P \in \mathbb{B}^n_-.
\end{cases}$$
(2) We will prove this statement in Exercise 103.2.

In the above we have now seen that some of our favorite smooth manifolds admit a handle decomposition. In Chapter 104 we will prove the Handle Decomposition Theorem 104.11 which states that in fact every compact smooth manifold admits a handle decomposition. In the remainder of this chapter we perform the less exciting task of proving several basic facts about handle attachments and handle decompositions.

103.3. Handle rearrangements. The following proposition shows that when we attach several handles, then we can rearrange the handle attachments so that they are done with increasing indices.

**Proposition 103.3.** Let $M$ be a compact $n$-dimensional smooth manifold. Suppose that for $i = 1, \ldots, m$ we are given smooth embeddings

$$\varphi_i : \overline{B}^{n-k_i} \times S^{k_i-1} \to \partial(M \cup \varphi_1 h^{k_1} \cdots \cup \varphi_{i-1} h^{k_{i-1}} h^i).$$

Furthermore let

$$\psi : \overline{B}^{n-l} \times S^{l-1} \to \partial(M \cup \varphi_1 h^{k_1} \cdots \cup \varphi_m h_{m}^{k_m})$$

be a smooth embedding. If for $i = 1, \ldots, m$ we have $l \leq k_i$, then there exists a smooth embedding

$$\tilde{\psi} : \overline{B}^{n-l} \times S^{l-1} \to \text{interior of } (\partial M \cap \partial(M \cup \varphi_1 h^{k_1} \cdots \cup \varphi_{m} h_{m}^{k_{m}})) \text{ in } \partial M$$

such that $M \cup \varphi_1 h^{k_1} \cdots \cup \varphi_{m} h_{m}^{k_{m}} \cup \psi h^{l}$ is diffeomorphic to $M \cup \tilde{\psi} h^{l} \cup \varphi_1 h^{k_1} \cdots \cup \varphi_{m} h_{m}^{k_{m}}$. Furthermore, given any neighborhood $U$ of $\partial M$ one can find a diffeomorphism that is the identity on the common subset $M \setminus U$.

**Remark.** Colloquially replacing the $\psi$-handle by the $\tilde{\psi}$-handle in (the proof of) Proposition 103.3 is called a handle slide.

**Proof.** To simplify the notation we prove the proposition for the special case $m = 1$. The proof of the general case is not much harder and we leave it to the reader to fill in the details.

Thus suppose that we are given a smooth embedding $\varphi : \overline{B}^{n-k} \times S^{k-1} \to \partial M$ and suppose that we are given a smooth embedding $\psi : \overline{B}^{n-l} \times S^{l-1} \to \partial(M \cup \varphi h^k)$ with $l \leq k$.

Note that it follows from the fact that $\psi$ takes values in the interior of $\partial M \cap \partial(M \cup \varphi_1 h^{k_1} \cdots \cup \varphi_{m} h_{m}^{k_{m}}))$ in $\partial M$ that the maps $\varphi_1, \ldots, \varphi_m$ can also be used to attach successively handles to $M \cup \tilde{\psi} h^l$.
To simplify the notation we make the obvious identification \( S^{l-1} = \{0\} \times S^{l-1} \subset \B^{n-l} \times S^{l-1} \).

We write \( f := \psi|_{S^{l-1}} \). Note that \( f(S^{l-1}) \) is precisely the attaching sphere of the \( \psi \)-handle.

We denote by \( K = S^{n-k-1} \times \{0\} \subset \partial(M \cup_\varphi h^k) \) the belt sphere of the \( \varphi \)-handle.

**Claim.** There exists a smooth isotopy \( F: S^{l-1} \times [0, 1] \to \partial(M \cup_\varphi h^k) \) such that \( F_0 = f \) and \( F_1(S^{l-1}) \subset \partial(M \cup_\varphi h^k) \setminus K \).

Note that we know by Proposition \ref{prop:isotopy} and Proposition \ref{prop:isotopy2} (1) that \( f(S^{l-1}) \) and \( K \) are both submanifolds of \( \partial(M \cup_\varphi h^k) \).

By the Transversality Theorem \ref{thm:transversality} there exists a smooth isotopy \( F: S^{l-1} \times [0, 1] \to \partial(M \cup_\varphi h^k) \) with \( F_0 = f \) such that \( F_1(S^{l-1}) \) is transverse to the belt sphere \( K \). Note that

\[
\dim(F_1(S^{l-1})) + \dim(K) = l - 1 + n - k - 1 \leq n - 2 < n - 1 = \dim(\partial(M \cup_\varphi h^k)).
\]

It follows immediately from the definition of transverse intersection and this inequality of dimensions that \( F_1(S^{l-1}) \) is actually disjoint from the belt sphere \( K \). \( \square \)

We continue with the following technical enhancement of the previous claim.

**Claim.** There exists a smooth isotopy \( \Psi: (\B^{n-l} \times S^{l-1}) \times [0, 1] \to \partial(M \cup_\varphi h^k) \) with \( \Psi_0 = \psi \) and such that \( \Psi_1(\B^{n-l} \times S^{l-1}) \subset \partial M \setminus \varphi(\B^{n-k} \times S^{k-1}) \).

It follows from Proposition \ref{prop:isotopy2} (1) that \( \varphi(S^{n-k-1} \times \B^k) \) is a tubular neighborhood for the belt sphere \( K = S^{n-k-1} \times \{0\} \subset \partial(M \cup_\varphi h^k) \). We obtain from the previous claim together with Exercise \ref{ex:isotopy} and Lemma \ref{lem:isotopy} a smooth isotopy \( G: f(S^{l-1}) \times [0, 1] \to \partial(M \cup_\varphi h^k) \) such that \( G_0 = \id \) and such that \( G_1(f(S^{l-1})) \subset \partial(M \cup_\varphi h^k) \setminus \varphi(\B^{n-k} \times S^{k-1}) \).

Next note that using the Isotopy Extension Theorem \ref{thm:isotopyextension} we can extend \( G \) to a smooth isotopy \( G: (\psi(\B^{n-l} \times S^{l-1})) \times [0, 1] \to \partial(M \cup_\varphi h^k) \). Unfortunately a priori we do not know that \( G_1(\psi(\B^{n-l} \times S^{l-1})) \subset \partial M \setminus \varphi(\B^{n-k} \times S^{k-1}) \). But it follows immediately from the “Tube Lemma”, see Exercise \ref{ex:isotopy2}, that there exists an \( \epsilon > 0 \) such that the map

\[
\Psi: (\B^{n-l} \times S^{l-1}) \times [0, 1] \to \partial(M \cup_\varphi h^k)
\]

\[
((v, P), t) \mapsto G(\psi((1 - t) + \epsilon \cdot t) \cdot v, P), t)
\]

has all the desired properties. \( \square \)

It follows easily from Proposition \ref{prop:isotopy2} (5) that \( \tilde{\psi} := \Psi_1 \) has all the desired properties. \( \blacksquare \)

Proposition \ref{prop:isotopy2} leads us to the following definition.

**Definition.** Let \( M \) be a compact \( n \)-dimensional smooth manifold. Suppose we are given a handle decomposition where the handles are attached with non-decreasing indices, i.e. we
have a handle decomposition of the following form:

\[ M = \emptyset \cup \bigcup_{\varphi_{0,1}} h^0 \cup \bigcup_{\varphi_{2,0}} h^1 \cup \ldots \cup \bigcup_{\varphi_{n,1}} h^n. \]

We introduce the following two concepts:

1. Given \( i \in \{0, \ldots, n\} \) we refer to \( M_i := \emptyset \cup \bigcup_{\varphi_{0,1}} h^0 \cup \bigcup_{\varphi_{2,0}} h^1 \cup \ldots \cup \bigcup_{\varphi_{i,1}} h^i \) as the \( i \)-skeleton of the handle decomposition.

2. We say that a handle decomposition is standard if it is of the above form and if for each \( i \in \{0, \ldots, n\} \) the attaching maps \( \varphi_{i,1}, \ldots, \varphi_{i,r_i} \) take values in \( \partial M_{i-1} \).

**Corollary 103.4.** Let \( M \) be a compact \( n \)-dimensional smooth manifold. If \( M \) admits a handle decomposition, then it also admits a handle decomposition with the same number of handles of each index, but which is now standard.

**Proof.** This follows immediately from iteratively applying Proposition 103.3 to reorder the handles.

**Remark.** In Chapter ?? we will see several other ways for modifying a given handle decomposition. But for the time being the above rearranging of handle attachments is good enough.
103.4. **Dual handle decomposition.** In this section we will see that we can associate to each handle decomposition a “dual” handle decomposition. More precisely, we have the following proposition.

**Proposition 103.5.** Let $M$ be a closed $n$-dimensional smooth manifold together with a handle decomposition

$$M = \emptyset \cup_{\varphi_0} h_{k_0}^0 \cup \cdots \cup_{\varphi_m} h_{k_m}^m.$$ 

There exists canonical handle decomposition

$$M = \emptyset \cup_{\psi_m} \overline{h}_{n-k_m}^m \cup \cdots \cup_{\psi_0} \overline{h}_{n-k_0}^0,$$

called dual handle decomposition, with the following properties:

1. For each $i \in \{0, \ldots, m\}$ the following statements hold:
   
   (a) The $i$-th handle of the dual handle decomposition equals, as a subset of $M$, the $(m-i)$-th handle of the original handle decomposition.
   
   (b) The indices of the handles are reversed, in the sense that
      
      \[
      \text{index of the } i\text{-th handle of the dual handle decomposition} = n - \text{index of the } (m-i)\text{-th handle of the original handle decomposition}.
      \]

   In particular the number $i$-handles in the dual handle decomposition equals the number of $(n-i)$-handles in the original decomposition.

   (c) The roles of attaching spheres and belt spheres is reversed in the sense that
      
      \[
      \text{belt sphere of the } i\text{-th handle of the dual handle decomposition} = \text{attaching sphere of the } (m-i)\text{-th handle of the original handle decomposition}.
      \]

      Furthermore the same statement, with the roles of attaching and belt spheres reversed, also holds.

2. If the original handle decomposition is standard, then so is the dual handle decomposition.

3. The dual of the dual handle decomposition is the original handle decomposition.

**Example.** In Figure [1460] we show to the left the a handle decomposition of $S^2$. But as we see, the decomposition of the sphere into subsets can also be read the other way and we obtain the dual handle decomposition.

![Figure 1460](image.png)

**Remark.**
(1) It follows immediately from the Proposition 103.5 that every handle decomposition of a closed connected non-empty $n$-dimensional smooth manifold admits at least one $n$-handle. This gives in particular a solution to Exercise 103.3 (a).

(2) The handle decomposition that we construct in the proof of Proposition 103.5 is sometimes called the dual handle decomposition.

The following lemma is the key ingredient in the proof of Proposition 103.5.

**Lemma 103.6.** Let $X$ be an $n$-dimensional smooth manifold and let $\varphi: \overline{B}^{n-k} \times S^{k-1} \to \partial X$ be a smooth embedding. Let $X \cup_{\varphi} h^k := X \cup_{\partial X} \overline{\mathbb{B}}^{n-k} \times S^{k-1} (B^{n-k} \times \mathbb{B}^k)$ be the result of attaching the corresponding $k$-handle to $X$. Furthermore let $Y$ be an $n$-dimensional smooth manifold and let $\gamma: \partial Y \to \partial (X \cup_{\varphi} h^k)$ be a diffeomorphism. We consider the maps

$$\psi: \overline{B}^{n-k} \times S^{k-1} \to \partial Y$$

$$(x, y) \mapsto \gamma^{-1}(y, x)$$

and

$$\delta: \partial X \to \partial (Y \cup_{\psi} h^k)$$

$$(x, y) \mapsto \begin{cases} \gamma^{-1}(P), & \text{if } P \in \partial X \setminus \varphi(B^{n-k} \times S^{k-1}), \\ \varphi^{-1}(P), & \text{if } P \in \varphi(B^{n-k} \times S^{k-1}) \end{cases}$$

The obvious map from

$$\left( X \cup_{\partial X} \overline{\mathbb{B}}^{n-k} \times S^{k-1} \right) \cup_{\partial (X \cup_{\varphi} h^k)} Y$$

to

$$\left( Y \cup_{\partial Y} \overline{\mathbb{B}}^{n-k} \times S^{k-1} \right) \cup_{\partial (Y \cup_{\psi} h^k)} X$$

is a diffeomorphism.

Lemma 103.6 can be summarized as follows: If a smooth manifold $W$ is obtained from $X$ by attaching a $k$-handle and then gluing on $Y$, then we can also obtain $W$ from $Y$ by attaching an $(n-k)$-handle and gluing on $X$. 

**Figure 1461.** Illustration of Lemma 103.6
Sketch of proof of Lemma 103.6. Once one has digested the statement of the lemma, one realizes that the lemma comes close to being a tautology. One can easily verify that the "obvious" maps in both directions are well-defined and inverses of one another. Furthermore using Lemma 3.44 (4) it is straightforward to verify that these maps are continuous, thus both maps are homeomorphisms. One still needs to show that both maps are in fact smooth. This joyless task is best left to the reader’s odimate.

Proof of Proposition 103.5. Let \( M = \emptyset \cup \phi_0 h^{k_0} \cup \ldots \cup \phi_m h^{k_m} \) be a handle decomposition. Given \( i = 0, \ldots, m \) we write \( X_i := \emptyset \cup \phi_0 h^{k_0} \cup \ldots \cup \phi_{i-1} h^{k_{i-1}} \), \( M_i := X_i \cup \phi_i h^{k_i} \), and \( Y_i := M \setminus M_i \). Note that \( Y_i \) is an \( n \)-dimensional smooth manifold by Proposition 6.30. Also note that \( Y_m = M \setminus M = \emptyset \). Since \( M \) is closed we can apply Lemma 103.6 iteratively altogether \( (m + 1) \) times. We see that \( M = \emptyset \cup \psi_m h^{n-k_m} \cup \ldots \cup \psi_0 h^{n-k_0} \) where for \( i = 0, \ldots, m \) the map \( \psi_i \) is given by

\[
\psi_i: B^{k_i} \times S^{n-k_i-1} \to \partial(\emptyset \cup \psi_m h^{n-k_m} \cup \ldots \cup \psi_{i+1} h^{n-k_{i+1}})
\]

It is straightforward to verify that this dual handle decomposition has all the properties stated in the proposition.

We conclude this section with the following perhaps slightly surprising corollary.

**Corollary 103.7.** Let \( M \) be a closed connected non-empty \( n \)-dimensional smooth manifold. For every handle decomposition of \( M \) we have the inequality:

\[
1 + \#(n - 1)\text{-handles} - \#n\text{-handles} \geq \text{minimal size of a generating set of } \pi_1(M).
\]

**Proof.** Let \( M \) be a closed connected non-empty \( n \)-dimensional smooth manifold that is equipped with a handle decomposition of \( M \). We have the following (in-)equalities:

\[
\begin{align*}
1 + \#(n - 1)\text{-handles} - \#n\text{-handles} &= 1 + \#1\text{-handles} - \#0\text{-handles} \\
&\geq \text{minimal size of a generating set of } \pi_1(M).
\end{align*}
\]

\[\uparrow \quad \text{Proposition 103.5} \quad \text{Corollary 103.12} \]

103.5. **Handle attachments: Connectedness and orientability.** In this section we will see how handle attachments affect connectedness and orientability. In the subsequent section we will see how handle attachments affect various algebraic invariants. First let us deal with the basic concept of connectedness.

**Lemma 103.8.** Let \( M \) be a compact \( n \)-dimensional smooth manifold. Suppose that we are given a thickened \( (k-1) \)-sphere in the boundary \( \partial M \), i.e. suppose we are given a smooth embedding \( \varphi: B^{n-k} \times S^{k-1} \to \partial M \). The following statements hold:

- \((k > 1)\) The inclusion induced map \( \pi_0(M) \to \pi_0(M \cup \varphi h^k) \) is a bijection.
- \((k = 1)\) (a) If the attaching map \( \varphi: B^{l-1} \times S^0 \to \partial M \) takes values in a single component of \( \partial M \), then the inclusion induced map \( \pi_0(M) \to \pi_0(M \cup \varphi h^k) \) is a bijection.
(b) If the attaching map \( \varphi : \overline{B}^{n-1} \times S^0 \to \partial M \) takes values in two components of \( \partial M \), then the number of components goes down by one.

\((k=0)\) \( M \cup \varphi h^0 \) has one extra component, namely the 0-handle.

2-handle does not change connectedness
0-handle adds an extra component

this 1-handle does not change connectedness
this 1-handle reduces the number of components by one

Figure 1462. Illustration of Lemma [103.8]

**Proof.** The statements for \( k > 1 \) and \( k = 1 \) follow easily from Lemma 2.62. The statement for \( k = 0 \) follows from the fact that adding a 0-handle is just taking the disjoint union with the 0-handle.

Next we study the slightly subtle question how attaching a handle affects orientability.

**Proposition 103.9.** Let \( M \) be a compact oriented \( n \)-dimensional smooth manifold. Suppose that we are given a thickened \((k-1)\)-sphere in the boundary \( \partial M \), i.e. suppose we are given a smooth embedding \( \varphi : \overline{B}^{n-k} \times S^{k-1} \to \partial M \). The following statements hold:

(i) Let \( \tau : S^{k-1} \to S^{k-1} \) be a reflection in some hyperplane of \( \mathbb{R}^k \). The corresponding map \( \varphi \circ (\text{id}_{\overline{B}^{n-k}} \times \tau) : \overline{B}^{n-k} \times S^{k-1} \to \partial M \) is also a thickened \((k-1)\)-sphere and the smooth manifold \( M \cup_{\varphi} (\text{id} \times \tau) h^k \) is diffeomorphic to \( M \cup_{\varphi} h^k \).

(ii) If \( \varphi : \overline{B}^{n-k} \times S^{k-1} \to \partial M \) is orientation-reversing, then there exists an orientation-reversing smooth embedding \( \psi : \overline{B}^{n-k} \times S^{k-1} \to \partial M \) such that \( M \cup_{\psi} h^k \) is diffeomorphic to \( M \cup_{\varphi} h^k \).

Now we consider the various dimensions separately:

\((k \geq 2)\) \( M \cup_{\varphi} h^k \) admits an orientation which agrees with the given orientation on \( M \setminus \partial M \).

\((k = 1)\) (a) \( \left[1445\right] \) \( \varphi : \overline{B}^{n-1} \times S^0 \to \partial M \) is orientation-preserving or orientation-reversing, then \( M \cup_{\varphi} h^k \) admits an orientation that agrees with the given orientation on \( M \setminus \partial M \).

(b) We suppose that the image of \( \varphi \) lies in a single component of \( M \). If (a) is not satisfied, then \( M \cup_{\varphi} h^k \) is non-orientable.

\((k = 0)\) \( M \cup_{\varphi} h^0 = M \sqcup \overline{B}^n \) is again orientable.

**Proof.**

(i) The reflection \( \tau : S^{k-1} \to S^{k-1} \) extends in an obvious way to a diffeomorphism \( \tau : \overline{B}^k \to \overline{B}^k \). The diffeomorphism from \( M \cup_{\varphi} (\text{id} \times \tau) h^k \) to \( M \cup_{\varphi} h^k \) is given by the identity on \( M \) and by \( \text{id}_{\overline{B}^{n-k}} \times \tau \) on \( \overline{B}^{n-k} \times \overline{B}^k \).

\[^{1445}\] Recall that according to the orientation convention on page 1719 we have an orientation-preserving diffeomorphism \( \overline{B}^{n-1} \times S^0 \to -\overline{B}^{n-1} \sqcup \overline{B}^{n-1} \).
(ii) This statement follows immediately from (1).

After these preparations we turn to the proofs of the main statements of the proposition.

\((k \geq 2)\) This statement follows immediately from (ii) together with Proposition 8.15 (6).

\((k = 1)\) (a) This statement follows immediately from (ii) together with Proposition 8.15 (6).

(b) This statement is basically a special case of Exercise 8.25.

\((k = 0)\) This case is trivial.

Proposition 103.9 (3) motivates the following definition.

**Definition.** Let \(M\) be a compact oriented \(n\)-dimensional smooth manifold. We say a thickened 0-sphere \(\varphi: \overline{B}^n \times S^0 \to \partial M\) is orientable if \(\varphi\) is orientation-preserving or if it is orientation-reversing. Otherwise we say that the thickened 0-sphere is non-orientable.

The following lemma basically shows that there are not that many different possibilities for attaching 1-handles.

**Lemma 103.10.** Let \(M\) be a compact oriented \(n\)-dimensional smooth manifold, let \(F\) be a component of \(\partial M\) and let \(\varphi, \psi: \overline{B}^{n-1} \times S^0 \to F\) be two thickened 0-spheres. If \(\varphi\) and \(\psi\) are both orientable or if they are both non-orientable, then \(M \cup_{\varphi} h^1\) and \(M \cup_{\psi} h^1\) are diffeomorphic.

**Proof.** Let \(\varphi, \psi: \overline{B}^{n-1} \times S^0 \to F\) be two thickened 0-spheres. First assume that \(n \geq 3\). As in Proposition 103.9 (1) let \(\tau: S^0 \to S^0\) be the map that swaps the two points \(\pm 1\). By Proposition 103.9 we can, if convenient, replace \(\varphi\) by \(\varphi \circ (\text{id} \times \tau)\) and we can replace \(\psi\) by \(\psi \circ (\text{id} \times \tau)\). It follows from this observation that we can arrange that the maps \(\varphi: \overline{B}^{n-1} \times \{1\} \to \partial M\) and \(\psi: \overline{B}^{n-1} \times \{1\} \to \partial M\) are both orientation-preserving. It follows from our orientation hypothesis on \(\varphi\) and \(\psi\) that \(\varphi: \overline{B}^{n-1} \times \{-1\} \to \partial M\) and \(\psi: \overline{B}^{n-1} \times \{-1\} \to \partial M\) are both orientation-preserving or they are both orientation-reversing.
Since $n = \dim(M) \geq 3$ we have $\dim(\partial M) \geq 2$. Thus we can apply Theorem 8.36 which implies that the two maps $\varphi$ and $\psi$ are smoothly isotopic. Thus it follows from Proposition 103.1 that $M \cup_\varphi h^1$ and $M \cup_\psi h^1$ are diffeomorphic.

It remains to deal with the cases $n = 1$ and $n = 2$. The case $n = 1$ is basically trivial. Finally we will deal with the case $n = 2$ in Exercise 103.1.

103.6. Handle attachments: Algebraic invariants. In this section we will discuss how a handle attachment alters some of our favorite algebraic invariants of topological spaces, namely the fundamental group and the homology groups. The statements below are basically the same as for cell attachments that we gave in Propositions 37.11 and Lemma 46.19. First we have the following analogue of Proposition 37.11.

**Proposition 103.11.** Let $M$ be a compact $n$-dimensional smooth manifold, let $k \in \mathbb{N}$ and let $\varphi: \overline{B}^{n-k} \times S^{k-1} \to \partial M$ be a thickened $(k-1)$-sphere. We pick $(x_0, y_0) \in S^{n-k-1} \times S^{k-1}$ and we set $P := \varphi(x_0, y_0) \in \partial M$. The following statements hold:

1. The inclusion induced map $\pi_1(M, P) \to \pi_1(M \cup_\varphi h^k, P)$ is an isomorphism.
2. Let $\beta: S^1 \to M$ be the loop that is given by $z \mapsto \varphi(x_0, z)$. The inclusion induced map $\pi_1(M, P) \to \pi_1(M \cup_\varphi h^2, P)$ descends to an isomorphism $\pi_1(M, P)/\langle [\beta] \rangle \cong \pi_1(M \cup_\varphi h^2, P)$.

3. We set $P' := \varphi(x_0, -y_0) \in \partial M$.
   
   (a) Suppose that $P$ and $P'$ lie in the same component of $M$. Let $\gamma$ be a loop in $M \cup_\varphi h^1$ that is given by the concatenation of the obvious path in the 1-handle from $P$ to $P'$ and some path in $M$ from $P'$ to $P$. With this notation the map $\pi_1(M, P) * \langle t \rangle \to \pi_1(M \cup_\varphi h^1, P)$ that is given by $t \mapsto [\gamma]$ is an isomorphism.
   
   (b) Suppose that $P$ and $P'$ lie in two different components of $M$. Then we get an isomorphism $\pi_1(M, P) * \pi_1(M, P') \to \pi_1(M \cup_\varphi h^1, P)$.

**Proof.** The statements follow fairly easily from a slight generalization of the Seifert–van Kampen Theorem 22.2 and the HNN-Seifert–van Kampen Theorem 26.3 (b). Overall the
proof is very similar to the proof of Proposition 37.11 and we leave it to the reader to make the obvious alterations to obtain a proof for the present proposition.

**Corollary 103.12.** Let $M$ be a compact connected non-empty smooth manifold. For every handle decomposition of $M$ we have the inequality:

$$1 + \#1\text{-handles} - \#0\text{-handles} \geq \text{minimal size of a generating set of } \pi_1(M).$$

**Proof.** Let $M$ be a compact connected non-empty smooth manifold that is equipped with a handle decomposition. We denote by $r$ the number of 0-handles and we denote by $s$ the number of 1-handles. First note, that by Corollary 103.4 we can assume that the handle decomposition is standard. We pick a base point $P$ in one of the 0-handles. By the definition of a generating set, see page 592, it suffices to prove the following claim.

**Claim.** There exists an epimorphism from a group of rank $1 + s - r$ onto $\pi_1(M,P)$.

Given $k \in \mathbb{N}_0$ we denote by $M^k$ the $k$-skeleton of $M$. It follows fairly easily from our hypothesis that $M$ is connected, together with Lemma 103.8 and Proposition 103.11 that $\pi_1(M^1, P)$ is a free group on $1 + s - r$ generators. Next note that it follows from Proposition 103.11 that the inclusion induced map $\pi_1(M^1, P) \to \pi_1(M, P)$ is an epimorphism. Thus we have shown, as desired, that there exists an epimorphism from a group of rank $1 + s - r$ onto $\pi_1(M, P)$. ■

Next we study the effect of a handle attachment to homology groups. The following lemma is an analogue of Lemma 46.19.

**Lemma 103.13.** Let $M$ be a compact $n$-dimensional smooth manifold, let $k \in \mathbb{N}_0$, let $\varphi: \overline{B}^{n-k} \times S^{k-1} \to \partial M$ be a thickened $(k-1)$-sphere and let $x \in \overline{B}^{n-k}$. We denote by $\iota: M \to M \cup \varphi h^k$ the inclusion map. There exists a natural exact sequence of the form induced by the map $y \mapsto \varphi(x,y)$.

$$0 \to H_k(M) \xrightarrow{\iota}\ H_k(M \cup \varphi h^k) \to \tilde{H}_{k-1}(S^{k-1}) \xrightarrow{\approx \mathbb{Z}} \to H_{k-1}(M) \xrightarrow{\iota}\ H_{k-1}(M \cup \varphi h^k) \to 0.$$ 

Furthermore, for any $l \neq k - 1, n$ the inclusion induced map $i_*: H_l(M) \to H_l(M \cup \varphi h^k)$ is an isomorphism.

**Remark.** By considering the 0-th homology groups one can deduced Lemma 103.8 from Lemma 103.13.

\[\text{Note this statement also holds for } k = 0, \text{ we just need to remember that by Lemma 43.1 we have } \tilde{H}_{-1}(\emptyset) = \mathbb{Z}.\]
Proof. We consider the following diagram:

\[
\begin{array}{c}
H_j(M \cup h^k) \xrightarrow{\partial} \tilde{H}_{j-1}(\varphi(B^{n-k} \times S^{k-1})) \to H_{j-1}(M) \oplus \tilde{H}_{j-1}(\varphi(B^{n-k} \times \overline{B}^k)) \to H_{j-1}(M \cup h^k) \to \tilde{H}_{j-1}(S^{k-1})
\end{array}
\]

Here the upper sequence is the long exact sequence coming from a slight generalization of the Mayer-Vietoris Theorem 46.10 for Smooth Manifolds. The maps emanating from below are the obvious maps. The statements of the lemma follow from staring at this diagram for a few short minutes.

this 2-handle leaves \(H_1\) unchanged, but it increases the rank of \(H_2\) by one

this 1-handle adds a generator to \(H_1\)

this 2-handle “kills” a generator of \(H_1\) and it leaves \(H_2\) unchanged

Figure 1466. Illustration of Lemma 103.13.

103.7. Handle attachments: Invariants of the boundary \((\ast)\). In this section, given a handle attachment \(M \cup h^k\) we will study the interaction between algebraic invariants of \(M \cup h^k\) and its boundary \(\partial(M \cup h^k)\). Again we first consider fundamental groups.

Lemma 103.14. Let \(M\) be a connected \(n\)-dimensional smooth manifold such that \(\partial M\) is also connected. Let \(\varphi: B^{n-k} \times S^{k-1} \to \partial M\) be a thickened \((k-1)\)-sphere. The following statements hold:

1. If \(1 \leq k < n - 1\), then the boundary \(\partial(M \cup h^k)\) is connected and non-empty.
2. (a) If \(1 \leq k \leq n - 3\) and if \(\pi_1(\partial M) \to \pi_1(M)\) is an isomorphism, then the induced map \(\pi_1(\partial(M \cup h^k)) \to \pi_1(M \cup h^k)\) is also an isomorphism.
   (b) If \(1 \leq k \leq n - 2\) and if \(\pi_1(\partial M) \to \pi_1(M)\) is an epimorphism, then the induced map \(\pi_1(\partial(M \cup h^k)) \to \pi_1(M \cup h^k)\) is also an epimorphism.

Proof. First we prove Statement (1). By Proposition 103.1 we have

\[
\partial(M \cup h^k) = (\partial M \setminus \varphi(B^{n-k} \times S^{k-1})) \cup_{\varphi|} S^m \times_{k-1} (S^{n-k-1} \times \overline{B}^k).
\]

It follows from Lemma 2.63 that \(\partial(M \cup h^k)\) is indeed connected. Since \(n - k - 1 \geq 0\) we see that the boundary is furthermore non-empty.
We turn to the proof of Statement (2). We pick and immediately ignore a base point in $\varphi(S^{n-k-1} \times S^{k-1})$. We consider the following diagram:

$$
\pi_1((\partial M \setminus \varphi(B^{n-k} \times S^{k-1})) \cup \left. S^{n-k-1} \times S^{k-1} \right| \to \pi_1(M \cup (B^{n-k} \times B^k)) \uparrow \\
\pi_1((\partial M \setminus \varphi(B^{n-k} \times S^{k-1})) \cup \left. S^{n-k-1} \times S^{k-1} \right| \to \pi_1(M \cup (B^{n-k} \times B^k)).
$$

All the maps are induced by inclusions, hence the diagram commutes. First we consider the case that $1 \leq k \leq n - 3$. In this setting we need to show that the top map is an isomorphism. This statement is a consequence of the following two observations:

(i) Note that it follows from Lemma 22.11 (1) and our hypothesis that $k \leq n - 3$ that the map $\pi_1((\partial M \setminus \varphi(B^{n-k} \times S^{k-1})) \to \pi_1(\partial M)$ is an isomorphism. Next note that it follows from this observation together with the Seifert–van Kampen Theorem 22.2 and Lemma 21.22 (1) that the diagonal map is an isomorphism.

(ii) By hypothesis we know that $\pi_1(\partial M) \to \pi_1(M)$ is an isomorphism. It follows from this observation together with the Seifert–van Kampen Theorem 22.2 and Lemma 21.22 (1) that the vertical map is an isomorphism.

Finally we consider the case that $k \leq n - 2$. In this setting we perform the same argument as above, except that need to replace Lemma 22.11 (1) by Lemma 22.11 (2) and that we need to replace Lemma 21.22 (1) by Lemma 21.22 (2).

\textbf{Corollary 103.15.} Let $n \in \mathbb{N}$ with $n \geq 4$. Let $M$ be a compact connected non-empty $n$-dimensional smooth manifold that is equipped with a handle decomposition. Then

(1) If all handles have index $\leq n - 3$, then the boundary $\partial M$ is connected and the inclusion induced map $\pi_1(\partial M) \to \pi_1(M)$ is an isomorphism.

(2) If all handles have index $\leq n - 2$, then the boundary $\partial M$ is connected and the inclusion induced map $\pi_1(\partial M) \to \pi_1(M)$ is an epimorphism.

\textbf{Proof.} Let $M$ be a compact connected non-empty $n$-dimensional smooth manifold that is equipped with a handle decomposition. If $M$ has a single 0-handle, then the statement follows immediately from Lemma 103.14.

Now suppose that $M$ has in fact more than one 0-handle. In Corollary ?? we will see that we can arrange that the handle decomposition has a single 0-handle. Alternatively we can argue directly as follows. Let $A_1, \ldots, A_k$ be the 0-handles. It follows easily from the hypothesis that $M$ is connected that there exist 1-handles $B_1, \ldots, B_{k-1}$ such that $W := (A_1 \cup \cdots \cup A_k) \cup (B_1 \cup \cdots \cup B_{k-1})$ is connected. It is straightforward to verify that $\pi_1(W)$ is trivial and that $\partial W$ is connected. We obtain $M$ from $W$ by attaching handles of index $\geq 1$. Thus the desired statement again follows from Lemma 103.14.

We continue with the “homological analogue” of Lemma 103.14.
Lemma 103.16. Let $M$ be an $n$-dimensional smooth manifold. Suppose we are given a thickened $(k-1)$-sphere $\varphi: \overline{B}^{n-k} \times S^{k-1} \rightarrow \partial M$. Let $j \in \mathbb{N}_0$. The following statements hold:

1. If $j \leq n-k-2$ and if $H_i(\partial M) \rightarrow H_i(M)$ is an isomorphism for $i = 0, \ldots, j$, then $H_j(\partial(M \cup \varphi h^k)) \rightarrow H_j(M \cup \varphi h^k)$ is also an isomorphism for $i = 0, \ldots, j$.
2. If $j \leq n-k-1$ and if $H_i(\partial M) \rightarrow H_i(M)$ is an isomorphism for $i = 0, \ldots, j-1$ and if it is an an epimorphism for $i = j$, then the analogous statements hold for the maps $H_j(\partial(M \cup \varphi h^k)) \rightarrow H_j(M \cup \varphi h^k)$.

Proof. The lemma follows from applying the Mayer-Vietoris Theorem [46.10] to the decomposition $\partial M = (\partial M \setminus \varphi(B^{n-k} \times S^{k-1})) \cup (\overline{B}^{n-k} \times S^{k-1})$, to $M \cup \varphi h^k$ and finally to $\partial(M \cup \varphi h^k) = (\partial M \setminus \varphi(B^{n-k} \times S^{k-1})) \cup (S^{n-k-1} \times \overline{B}^k)$. Since we will not make use of this result, but it is good to know it exists, and in principle it can be used to deduce some results on handle decompositions from our long experience with CW-structures.

The following is an immediate corollary to Lemma 103.16.

Corollary 103.17. Let $M$ be a compact non-empty $n$-dimensional smooth manifold that is equipped with a handle decomposition and let $j \in \mathbb{N}_0$.

1. If all handles have index $\leq n-j-2$, then for $i = 0, \ldots, j$ the inclusion induced map $H_i(\partial M) \rightarrow H_i(M)$ is an isomorphism.
2. If all handles have index $\leq n-j-1$, then for $i = 0, \ldots, j-1$ the inclusion induced map $H_i(\partial M) \rightarrow H_i(M)$ is an isomorphism and the inclusion induced map $H_j(\partial M) \rightarrow H_j(M)$ is an epimorphism.

103.8. Handle decompositions and CW-structures (*). We conclude this chapter with a proposition that shows that a handle decomposition of a smooth manifold $M$ gives rise to a CW-complex that is homotopy equivalent to the smooth manifold $M$. We will not really make use of this result, but it is good to know it exists, and in principle it can be used to deduce some results on handle decompositions from our long experience with CW-structures.

Proposition 103.18. Every compact smooth manifold $M$ that is equipped with a handle decomposition is homotopy equivalent to a CW-complex $X$ such that for each $k \in \mathbb{N}_0$ the number of $k$-handles of $M$ equals the number of $k$-cells of $X$.

Remark. We will prove Proposition 103.18 using the Homotopy Pushout Theorem 39.18 which comes with a rather intimidating proof. A slightly more direct proof for Proposition 103.18 is given in [Mil63a, Theorem 3.4].
As we mentioned in the remark, the key to proving Proposition 103.18 is the following theorem whose easy formulation belies the difficulty of the proof.

**Theorem 39.18. (Homotopy Pushout Theorem)** Suppose we are given the following commutative diagram of maps between topological spaces:

\[
\begin{array}{ccc}
Y & \xleftarrow{f} & A \\
\varphi_Y & \downarrow & \varphi_A \\
Y' & \xleftarrow{f'} & A' \\
\end{array}
\quad \begin{array}{ccc}
& X & \\
& \varphi_X & \\
& \downarrow & \\
& X' & \\
\end{array}
\]

If the vertical maps are homotopy equivalences and if the maps \(i\) and \(i'\) to the right are closed cofibrations, then the induced map

\[Y \cup_A X \to Y' \cup_{A'} X'\]

between the pushouts is a homotopy equivalence.

**Proof of Proposition 103.18.** Let \(M\) be a compact smooth manifold with a given handle decomposition. By Corollary 103.4 we can arrange, without changing the number of handles of any index, that the handle decomposition is standard.

Given \(k \in \mathbb{N}_0\) we denote, as on page 2481, by \(M^k\) the \(k\)-skeleton of the handle decomposition. In other words, \(M^k\) is the union of all handles of dimension \(\leq k\). Furthermore, given any CW-complex \(X\) we denote by \(X^k\) its \(k\)-skeleton, i.e. \(X^k\) is the union of cells of dimension \(\leq k\). We will prove the following slight refinement of the original statement of Proposition 103.18.

**Statement.** There exists a CW-complex \(X\) and a homotopy equivalence \(g\): \(M \to X\) with the following two properties:

1. for each \(k \in \mathbb{N}_0\) we have \(g(M^k) \subset X^k\),
2. for each \(k \in \mathbb{N}_0\) the number of \(k\)-cells of \(X\) equals the number of \(k\)-handles of \(M\).

By an elementary induction argument it suffices to prove the following claim.

**Claim.** Let \(N\) be a compact \(n\)-dimensional smooth manifold that is equipped with a standard handle decomposition. We suppose that there exists a homotopy equivalence \(f\): \(N \to X\) to some CW-complex \(X\) such that for every \(k \in \mathbb{N}_0\) we have \(f(N^k) \subset X^k\). Let \(\varphi: B^{n-k} \times S^{k-1} \to \partial N\) be a smooth embedding. There exists a cellular map \(\psi: S^{k-1} \to X\) and a homotopy equivalence \(g\):

\[
g: \left(\frac{N \sqcup (B^{n-k} \times B^k)}{=N \cup_{\varphi} h^k} \right)/ \sim \to \left(\frac{X \sqcup \overline{B^k}}{\psi(x) \sim x \text{ for all } x \in S^{k-1}}\right)/ \sim.
\]

---

\(^{1447}\) We refer to page 1023 for the definition of a closed cofibration. To get the hang of the argument it is not that important though to recall the definition of a closed cofibration.

\(^{1448}\) We equip \(S^{k-1}\) with the canonical CW-structure that we introduced on page 935.

\(^{1449}\) Note that it follows from Lemma 36.32 and the fact that \(\psi\) is cellular that \((X \cup \overline{B^k})/ \sim\) is a CW-complex with one extra \(k\)-cell.
We consider the map \( \eta: S^{k-1} \to X \) that is given by \( \eta(x) := (g \circ \varphi)(0, x) \). By the Cellular Approximation Theorem \([38.13]\) there exists a homotopy \( F: S^{k-1} \times [0, 1] \to X \) from \( F_0 = \eta: S^{k-1} \to X \) to a cellular map \( F_1 = \psi: S^{k-1} \to X \). We obtain the following commutative diagram:

\[
\begin{array}{cccc}
N & \xleftarrow{\partial N} & \varphi B^{n-k} \times S^{k-1} & \xrightarrow{\eta} & B^{n-k} \times B^k \\
\downarrow \text{id} & & \downarrow x \mapsto (0, x) & & \downarrow x \mapsto (0, x) \\
N & \xleftarrow{\varphi(0, x)} & S^{k-1} & \xrightarrow{x \mapsto (0, x)} & B^k \\
\downarrow f & & \downarrow \eta & & \downarrow \\
X & \xleftarrow{\eta} & S^{k-1} & \xrightarrow{x \mapsto (x, 0)} & B^k \\
\downarrow \text{id} & & \downarrow & & \downarrow x \mapsto (x, 0) \\
X & \xleftarrow{\psi} & S^{k-1} & \xrightarrow{x \mapsto (x, 1)} & B^k \\
\downarrow \text{id} & & \downarrow & & \downarrow x \mapsto (x, 1) \\
X & & S^{k-1} & & B^k.
\end{array}
\]

It is clear that all of the vertical maps are homotopy equivalences. Furthermore note that it follows immediately from Proposition \([39.14]\) and \([39.12]\) that all of the right horizontal maps are closed cofibrations. Thus it follows from the Homotopy Pushout Theorem \([39.18]\) applied altogether four times, that the induced maps between the various pushouts have homotopy inverses. Combining these four homotopy equivalences, respectively their homotopy inverses, we obtain the promised homotopy equivalence

\[
N \cup \varphi B^{n-k} \times S^{k-1} (B^{n-k} \times B^k) \xrightarrow{(N \cup (B^{n-k} \times B^k))/\sim} X \cup_{S^{k-1}} B^k. = (X \cup B^k)/\sim
\]

\[\blacksquare\]

**Exercises for Chapter 103.**

**Exercise 103.1.** Let \( M \) be a compact oriented 2-dimensional smooth manifold and let \( F \) be a component of \( \partial M \). Show that any two orientation-preserving 1-handle attachments to \( F \) lead to diffeomorphic smooth manifolds.
Exercise 103.2. Let $m, k \in \mathbb{N}$. We consider the thickened $(k - 1)$-sphere

$$\varphi: \mathbb{B}^m \times S^{k-1} \to S^{m+k-1} = \partial(\mathbb{B}^{m+k})$$

$$(x, y) \mapsto \frac{1}{\|x\|} (\frac{1}{2} \cdot x, y).$$

(a) Show that $\mathbb{B}^{m+k} \cup_{\varphi} h^k$ is homeomorphic to $\mathbb{B}^m \times S^k$.

(b) Show that $\mathbb{B}^{m+k} \cup_{\varphi} h^k$ is diffeomorphic to $\mathbb{B}^m \times S^k$.

Exercise 103.3. Let $M$ be a closed connected non-empty $n$-dimensional smooth manifold.

(a) Show that every handle decomposition of $M$ admits at least one $n$-handle.

(b) Suppose we are given a handle decomposition of $M$ with a unique $n$-handle. Show that this $n$-handle has non-empty intersection with every other handle.

Exercise 103.4. On page 2477 we saw that the surface of genus 2 admits a handle decomposition with four 1-handles. Does it also admit a handle decomposition with less than four 1-handles?

Exercise 103.5. Let $M$ be a compact oriented $n$-dimensional smooth manifold and let $\varphi: \mathbb{B}^{n-k} \times S^{k-1} \to \partial M$ be a thickened $(k - 1)$-sphere. Show that if $k \geq 2$ and $n \geq k + 3$, then there exists an epimorphism $\pi_1(\partial M) \to \pi_1(\partial(M \cup_{\varphi} h^k))$.

Exercise 103.6. Let $K \subset S^3$ be a knot. We pick a tubular neighborhood $\mathbb{B}^2 \times K$ and as on page 1728 we consider the knot exterior $X_K := S^3 \setminus (B^2 \times K)$. Can we add handles to $X_K$ to obtain a smooth manifold that is diffeomorphic to $S^3$?

Exercise 103.7. We consider the 3-dimensional smooth manifold $M$ shown in Figure 1469. Furthermore we consider the thickened 1-sphere $\varphi: \mathbb{B}^3 \times S^1 \to \partial M$ shown in Figure 1469. Can you recognize the diffeomorphism type of $M \cup_{\varphi} h^2$? Can you prove that it is what you think it is?

![Figure 1469. Illustration for Exercise 103.7](image)

Exercise 103.8. Let $M$ be a connected $n$-dimensional smooth manifold. Furthermore let $\varphi: \mathbb{B}^{n-1} \times S^0 \to \partial M$ be a thickened 0-sphere in $\partial M$. Let $\tau: \mathbb{B}^{n-1} \to \mathbb{B}^{n-1}$ be the reflection in a hyperplane. We consider the thickened 0-sphere

$$\mathbb{B}^n \times S^0 \to \partial M$$

$$(P, \epsilon) \mapsto \begin{cases} \varphi(\tau(P), -1), & \text{if } \epsilon = -1, \\
\varphi(P, 1), & \text{if } \epsilon = 1. \end{cases}$$

Is it possible that $M \cup_{\varphi} h^1$ and $M \cup_{\varphi} h^1$ are diffeomorphic?

---

\(^{1450}\)This exercise is meant only for the heroically inclined reader.
Exercise 103.9. Let $M$ be a compact $n$-dimensional smooth manifold such that $\partial M$ is connected. Let $k \in \mathbb{N}_0$ and let $\varphi : B^{n-k} \times S^{k-1} \to \partial M$ be a thickened $(k-1)$-sphere. Show that if $\in \{1, \ldots, n-1\}$, then $\partial(M \cup \varphi h^k)$ is also connected.

Illustration of Exercise 103.9.

Exercise 103.10. Let $M$ be a compact $n$-dimensional smooth manifold.

(a) Let $k \in \mathbb{N}_0$ and let $\varphi : B^{n-k} \times S^{k-1} \to \partial M$ be a thickened $(k-1)$-sphere. Prove that

$$\chi(M \cup \varphi h^k) = \chi(M) + (-1)^k.$$

(b) Show that given any handle decomposition for $M$ the following equality holds:

$$\sum_{k \in \mathbb{N}_0} (-1)^k \cdot \text{number of } k\text{-handles} = \chi(M).$$

Exercise 103.11. Let $k \in \mathbb{N}$ and let $M$ be a compact orientable $2k$-dimensional smooth manifold which admits a handle decomposition such that all handles have index $\leq k$. Is the inclusion induced map $H_k(\partial M) \to H_k(M)$ necessarily an epimorphism?

Exercise 103.12. Let $M$ be a compact smooth that is equipped with a standard handle decomposition. Given $k \in \mathbb{N}_0$ we denote by $M^k$ the $k$-skeleton of the handle decomposition, i.e. $M^k$ is the union of all handles up to dimension $\leq k$. Let $P$ be a point in the 0-skeleton and let $i \in \mathbb{N}$.

(a) Show that for any $k > i$ the inclusion induced map $\pi_i(M^k, P) \to \pi_i(M, P)$ is an isomorphism.

(b) Show that the inclusion induced map $\pi_k(M^k, P) \to \pi_k(M, P)$ is an epimorphism.

Remark. This exercise can be viewed as a handle analogue of the corresponding statement for CW-complexes that we proved in Proposition [40.9]
104. Morse theory I: Closed smooth manifolds

In the last chapter we introduced handle decompositions and showed explicitly that some of our favorite compact smooth manifolds admit handle decompositions. In this chapter we will show, using Morse theory, that every compact smooth manifold admits a handle decomposition.

104.1. Non-degenerate critical points. The following definition is just a special case of the definition on page 308.

**Definition.** Let \( M \) be a smooth manifold and let \( f: M \to \mathbb{R} \) be a smooth function. We say \( P \in M \) is a *regular point* if \( Df_P: T_P M \to \mathbb{R} \) is non-zero, otherwise we say \( P \) is a *critical point*.

In our previous discussions we were trying hard to avoid critical points. In the following we will see that the study of critical points can actually be quite fruitful. In particular, as we will see shortly, critical points come in different flavors which have a great influence on the topology of the smooth manifold.

**Lemma 104.1.** Let \( M \) be an \( n \)-dimensional smooth manifold and let \( f: M \to \mathbb{R} \) be a smooth function. Let \( P \in M \setminus \partial M \) be a critical point. We pick a chart \( \Phi: U \to V \) for \( P \). We write \( Q := \Phi(P) \). The congruence\footnote{Here recall that two real \( n \times n \)-matrices \( G \) and \( H \) are called *congruent* if there exists a matrix \( Z \in \text{GL}(n, \mathbb{R}) \) such that \( Z^T G Z = H \).} class of the Hessian matrix\footnote{Implicitly we use throughout that the Hessian matrix is symmetric. The fact that given a smooth function the partial derivatives commute is variously known (depending on the geographic location of the author) as the Schwarz Theorem, the Young Theorem or the Clairaut Theorem.}

\[
\text{Hess}(f \circ \Phi^{-1})_Q := \left( \frac{\partial^2}{\partial x_i \partial x_j} f \circ \Phi^{-1} \right)_{i,j=1,...,n} \in M(n \times n, \mathbb{R})
\]

is independent of the choice of the chart.

![Figure 1471. Illustration for Lemma 104.1](image_url)

**Proof.** There are two approaches to proving the lemma:

1. Let \( \Psi: X \to Y \) be some other chart around \( P \). We set \( R := \Psi(Q) \) and we set \( Z := D(\Psi \circ \Phi^{-1})_P \). A slightly heroic calculation, see\footnote{\cite{Gaul82} p. 51}, shows that \( Z^T \cdot \text{Hess}(f \circ \Phi^{-1})_R \cdot Z = \text{Hess}(f \circ \Phi^{-1})_P \).

2. The statement can also be proved more elegantly by defining intrinsically a symmetric form \( H_P f: T_P M \times T_P M \to \mathbb{R} \) which now happens to be represented by the matrix \( \text{Hess}(f \circ \Phi^{-1})_P \). At this point the lemma is a consequence of the purely algebraic Lemma 101.1. This approach is taken in\footnote{\cite{Miln63a} p. 4} and\footnote{\cite{Nic11} p. 6}.

\[ \square \]
It follows from Lemma 104.1, common sense and the combination of Lemma 101.1 (1c) and Proposition 101.8 that the following definition is independent of any choices.

**Definition.** Let $M$ be an $n$-dimensional smooth manifold and let $f: M \to \mathbb{R}$ be a smooth function. Let $P \in M \setminus \partial M$ be a critical point. We pick a chart $\Phi: U \to V$ for $P$ and we write $Q := \Phi(P)$.

1. We say the critical point $P$ is *nondegenerate* if $\det(\text{Hess}(f \circ \Phi^{-1})_Q) \neq 0$. Otherwise we call the critical point *degenerate*.

2. We refer to

$$\text{index}(f, P) := \text{number of negative eigenvalues of } \text{Hess}(f \circ \Phi^{-1})_Q$$

as the *index of the critical point $P$*.

**Examples.**

1. The “mother of all examples” are the functions

$$\mathbb{R}^n \to \mathbb{R}$$

$$(x_1, \ldots, x_n) \mapsto c + \sum_{i=1}^{n} a_i x_i^2$$

with $c, a_1, \ldots, a_n \in \mathbb{R}$. Evidently the origin 0 is a critical point. With respect to the identity chart the Hessian $\text{Hess}(f)_0$ is the diagonal matrix with diagonal entries $a_1, \ldots, a_n$. Thus the origin is a nondegenerate critical point if and only if all $a_i$ are non-zero. Finally, we have the following equality:

$$\text{index}(f, 0) = \text{number of negative } a_i.$$

2. We consider the smooth manifold $M \subset \mathbb{R}^3$ that is shown in Figure 1473 together with the “height function” $f: M \to \mathbb{R}$ that is defined by $f(x, y, z) = z$. In Figure 1473 we indicate all critical points of $f$ and we show their indices.

---

1453 Alternatively one could use Proposition 101.8 to define

$$\text{index}(f, P) := b^- (\text{Hess}_P f : T_P M \times T_P M \to \mathbb{R})$$

where $\text{Hess}_P f$ is the intrinsic Hessian mentioned above and where $b^- (\varphi)$ of a symmetric form $\varphi: V \times V \to \mathbb{R}$ is defined, see page 2447, as the maximal dimension of a vector subspace $W$ of $V$ for which the symmetric form $\varphi|_W$ is negative definite.
The following result says that, up to taking an appropriate chart, the above mother of all examples is the only example of a non-degenerate critical point. The result was first proved by Marston Morse [MorsM34] in 1934.

**Theorem 104.2. (Morse Lemma)** Let $M$ be an $n$-dimensional smooth manifold. Furthermore let $f: M \to \mathbb{R}$ be a smooth function and let $P \in M \setminus \partial M$ be a critical point. If $P$ is non-degenerate, then there exists a chart $\Phi: U \to V$ around $P$ with $U \subset M \setminus \partial M$ and with $\Phi(P) = 0$ such that for every $(x_1, \ldots, x_n) \in V$ we have

$$(f \circ \Phi^{-1})(x_1, \ldots, x_n) = f(P) - x_1^2 - \cdots - x_k^2 + x_{k+1}^2 + \cdots + x_n^2$$

where $k = \text{index}(f, P)$.

**Remark.**

(1) Recall that the Inverse Mapping Theorem [6.40] says that if the differential $Df_P$ of a given map $f: M \to N$ between two smooth manifolds at a point $P \in M \setminus \partial M$ is invertible, then the map is locally a diffeomorphism. The Morse Lemma is a similar statement: at a non-degenerate critical point the local behavior of a smooth map $f: M \to \mathbb{R}$ is determined by the second partial derivatives.

(2) Our proof of the Morse Lemma [104.2] is basically the same proof as in [Miln63a Lemma 2.2]. Somewhat different proofs are given in [Nic11] Theorem 1.12 and [Lau11] Section 3.3.2.

(3) Let $M$ be an $n$-dimensional smooth manifold and let $f: M \to \mathbb{R}$ be a smooth function. Furthermore let $P \in M \setminus \partial M$ be a non-degenerate critical point. It follows easily from the Morse Lemma [104.2] that

(a) $P$ is a local maximum if and only if $\text{index}(f, P) = n$.
(b) $P$ is a local minimum if and only if $\text{index}(f, P) = 0$. 

**Figure 1473. Illustration of the Morse Lemma 104.2**

**Figure 1474. Illustration of the Morse Lemma 104.2**
One of the key ingredients to the proof of the Morse Lemma [104.2] is the following proposition.

**Proposition 6.16.** Let $U \subset \mathbb{R}^n$ be an open convex subset that contains the origin and let $f: U \rightarrow \mathbb{R}$ be a smooth function with $f(0) = 0$. There exist smooth maps $a_1, \ldots, a_n: U \rightarrow \mathbb{R}$ such that for $i = 1, \ldots, n$ we have $a_i(0) = \frac{\partial f}{\partial x_i}(0)$ and such that

$$f(x_1, \ldots, x_n) = \sum_{i=1}^{n} a_i(x_1, \ldots, x_n) \cdot x_i \quad \text{for all } x = (x_1, \ldots, x_n) \in U.$$

This proposition gives us the following corollary, which is actually the content of Exercise 6.14.

**Corollary 104.3.** Let $U \subset \mathbb{R}^n$ be an open convex subset that contains the origin and let $f: U \rightarrow \mathbb{R}$ be a smooth function with $f(0) = 0$. If $0$ is a critical point of $f$, then there exist smooth functions $h_{ij}: U \rightarrow \mathbb{R}$, $i, j = 1, \ldots, n$ such that $h_{ij} = h_{ji}$ and such that

$$f(x) = \sum_{i,j=1}^{n} h_{ij}(x) \cdot x_i \cdot x_j \quad \text{for all } x \in U.$$

**Proof of Corollary 104.3.** First note that by Proposition 6.16 there exist smooth maps $a_1, \ldots, a_n: U \rightarrow \mathbb{R}$ such that for $i = 1, \ldots, n$ we have $a_i(0) = \frac{\partial f}{\partial x_i}(0) = 0$ and such that

$$f(x) = \sum_{i=1}^{n} a_i(x) \cdot x_i \quad \text{for all } x = (x_1, \ldots, x_n) \in U.$$

Since $0$ is a critical point we know that $a_1(0) = \cdots = a_n(0) = 0$. Thus, given $i \in \{1, \ldots, n\}$ we can once again apply the ever-useful Proposition 6.16 to the smooth map $a_i$ and we obtain smooth maps $b_1, \ldots, b_n: U \rightarrow \mathbb{R}$ with $b_i(0) = (\frac{\partial}{\partial x_j} a_i)(0) = (\frac{\partial}{\partial x_j} a_i)(f(0))$ and such that

$$a_i(x) = \sum_{j=1}^{n} b_j(x) \cdot x_j \quad \text{for all } x \in U.$$

It now clear that the maps $h_{ij} := \frac{1}{2}(b_{ij} + b_{ji})$ have the desired properties.

Now we can provide the proof of the Morse Lemma [104.2].

**Proof of the Morse Lemma [104.2]** We make a few preparations.

1. We can assume that $M$ is an open convex neighborhood $U$ of $0 \in \mathbb{R}^n$, that $P = 0$ is the non-degenerate critical point of $f: U = M \rightarrow \mathbb{R}$ and that $f(0) = 0$.

2. Throughout the proof we use the usual notation that given $x \in \mathbb{R}^n$ we denote its coordinates by $x_1, \ldots, x_n$.

3. Let $V$ and $W$ be open neighborhoods of $0 \in \mathbb{R}^n$. We say two smooth maps $g: V \rightarrow \mathbb{R}$ and $h: W \rightarrow \mathbb{R}$ are equivalent, if there exist open sets $0 \in V' \subset V$ and $0 \in W' \subset W$ and a diffeomorphism $\Psi: V' \rightarrow W'$ with $\Psi(0) = 0$ such that $(g \circ \Psi^{-1})(y) = h(y)$ for all $y \in W'$. Note that this is indeed an equivalence relation.

With these preparations we can reformulate our goal as follows.

**Goal.** We want to show that $f: U \rightarrow \mathbb{R}$ is equivalent to a map that is of the form

$$(x_1, \ldots, x_n) \mapsto \epsilon_1 \cdot x_1^2 + \cdots + \epsilon_n \cdot x_n^2.$$
for some $\epsilon_1, \ldots, \epsilon_n \in \{-1, 1\}$.

Note that once we have proved this goal we are done, since it follows from Lemma 104.1 that that the number of negative $\epsilon_i$’s in a map as above equals precisely $\text{index}(f,P)$.

Now let us turn to the task of achieving this goal. First note that by Corollary 104.3 we know that there exist smooth functions $h_{ij} : U \rightarrow \mathbb{R}$, $i, j = 1, \ldots, n$ such that $h_{ij} = h_{ji}$ and such that $f$ is given by

$$(x_1, \ldots, x_n) \mapsto \sum_{i=1}^{n} \sum_{j=1}^{n} h_{ij}(x) \cdot x_i \cdot x_j.$$ 

The idea now is to “diagonalize” the matrices $(h_{ij}(x))_{i,j=1,\ldots,n}$. At this point it is worth recalling that in Proposition 101.6 we gave a constructive proof of the fact that given any real symmetric $(n \times n)$-matrix $A = (a_{ij})$ with $\det(A) \neq 0$ there exists a matrix $P \in \text{GL}(n, \mathbb{R})$ and $\epsilon_1, \ldots, \epsilon_n \in \{-1, 1\}$ such that $P^T A P$ is the diagonal matrix with entries $\epsilon_1, \ldots, \epsilon_n$. The idea now is to imitate the proof of Proposition 101.6. As in the proof of Proposition 101.6 we proceed iteratively. This leads us to the following claim.

**Claim.** Given any $s \in \{0, \ldots, n\}$ the map $f : U \rightarrow \mathbb{R}$ is equivalent to a map of the form

$$(x_1, \ldots, x_n) \mapsto \sum_{i=1}^{s} \sum_{j=1}^{s} \mu_{ij}(x) \cdot x_i \cdot x_j + \sum_{i=s+1}^{n} \epsilon_i \cdot x_i^2,$$

where the $\mu_{ij}$ are smooth functions with $\mu_{ij} = \mu_{ji}$ and with $\epsilon_i \in \{\pm 1\}$.

Recall that our goal was precisely to prove the claim for $s = 0$. As we remarked above, for $s = n$ there is nothing left to show, since we already saw that it follows from Corollary 104.3 that $f$ is of the required form. Next suppose that the statement holds for some $s \in \{1, \ldots, n\}$. We need to show that the statement also holds for $s - 1$. We might as well assume that $f$ itself is already of the form

$$(x_1, \ldots, x_n) \mapsto \sum_{i=1}^{s} \sum_{j=1}^{s} \mu_{ij}(x) \cdot x_i \cdot x_j + \sum_{i=s+1}^{n} \epsilon_i \cdot x_i^2 \quad \text{with } \mu_{ij} = \mu_{ji}.$$ 

Since 0 is a non-degenerate critical point we know that the matrix $(\mu_{ij}(0))_{i,j=1,\ldots,s}$ is invertible. As we saw in the proof of Proposition 101.6 it is an elementary linear algebra fact that there exists a matrix $A \in \text{GL}(s, \mathbb{R})$ such that the $ss$-entry of $A^T (\mu_{ij}(0))_{i,j=1,\ldots,s} \cdot A$ is non-zero. By applying the diffeomorphism $\Phi$ that is given by the invertible matrix

$$
\begin{pmatrix}
A & 0 \\
0 & \text{id}_{n-s}
\end{pmatrix}
$$

we see that we might as well assume that $y_{ss}(0) \neq 0$. After possibly shrinking $U$ we can assume that $y_{ss}(x) \neq 0$ for all $x \in U$. Now we consider the map

$$\Phi : U \rightarrow \mathbb{R}^n$$

$$x = (x_1, \ldots, x_n) \mapsto (x_1, \ldots, x_{s-1}, \sqrt{|y_{ss}(x)|} \cdot (x_s + \sum_{i=1}^{s-1} \frac{y_{is}(x)}{|y_{ss}(x)|} \cdot x_i), x_{s+1}, \ldots, x_n).$$

Evidently $\Phi(0) = 0$. A straightforward calculation shows that $\det(D\Phi_0) = \sqrt{|y_{ss}(0)|} \neq 0$. It follows from the Inverse Function Theorem 6.18 that, possibly after shrinking $U$ even further, the map $\Phi : U \rightarrow \mathbb{R}^n$ is a diffeomorphism onto its image. It remains to show that
$f \circ \Phi^{-1}$ is of the form

$$y = (y_1, \ldots, y_n) \mapsto \sum_{i=1}^{s-1} \sum_{j=1}^{s-1} \nu_{ij}(y) \cdot y_i \cdot y_j + \sum_{i=s}^{n} \epsilon_i \cdot y_i^2$$

with $\nu_{ij} = \nu_{ji}$.

Thus let $y = (y_1, \ldots, y_n) \in \Phi(U)$. We write $(x_1, \ldots, x_n) = x := \Phi^{-1}(y)$. Note that by definition of $\Phi$ we have

$$(y_1, \ldots, y_n) = (x_1, \ldots, x_{s-1}, \sqrt{|\mu_{ss}(x)|} \cdot (x_s + \sum_{i=1}^{s-1} \frac{\mu_{is}(x)}{|\mu_{ss}(x)|} \cdot x_i), x_{s+1}, \ldots, x_n).$$

We perform the following little calculation:

$$y_s^2 = |\mu_{ss}(x)| \cdot (x_s + \sum_{i=1}^{s-1} \frac{\mu_{is}(x)}{|\mu_{ss}(x)|} \cdot x_i) \cdot (x_s + \sum_{j=1}^{s-1} \frac{\mu_{js}(x)}{|\mu_{ss}(x)|} \cdot x_j)$$

$$= |\mu_{ss}(x)| \cdot (x_s^2 + \sum_{i=1}^{s-1} \sum_{j=1}^{s-1} \frac{\mu_{is}(x)}{|\mu_{ss}(x)|^2} \cdot x_i \cdot x_j + 2 \sum_{i=1}^{s-1} \frac{\mu_{is}(x)}{|\mu_{ss}(x)|} \cdot x_i \cdot x_s).$$

Finally note that

follows from the above description of $f$ follows immediately from the above calculation of $y_s^2$

$$(f \circ \Phi^{-1})(y) = f(x) = \sum_{i=1}^{s-1} \sum_{j=1}^{s-1} \mu_{ij}(x) \cdot x_i \cdot x_j + 2 \cdot \sum_{i=1}^{s} \mu_{is} \cdot x_i \cdot s_s + \sum_{i=s+1}^{n} \epsilon_i \cdot x_i^2$$

$$= \sum_{i=1}^{s-1} \sum_{j=1}^{s-1} \left( \mu_{ij}(x) - \frac{\mu_{is}(x) \cdot \mu_{js}(x)}{|\mu_{ss}(x)|} \right) \cdot x_i \cdot x_j + \frac{\mu_{ss}(x)}{|\mu_{ss}(x)|} \cdot y_s^2 + \sum_{i=s+1}^{n} \epsilon_i \cdot x_i^2$$

follows from $x_i = y_i$ for $i \neq s$, from $x = \Phi^{-1}(y)$ and from the fact that the sign of $\mu_{ss}(x)$ is constant on $U$

This concludes the induction step.

**Corollary 104.4.** Let $M$ be a smooth manifold and let $f : M \to \mathbb{R}$ be a smooth function such that no critical point is contained in $\partial M$.

1. The set of non-degenerate critical points of $f$ is a discrete subset of $M$.
2. If $M$ is compact and if all critical points are non-degenerate, then there exist only finitely many non-degenerate critical points of $f$.

**Remark.** As shown in Figure 1475 the set of non-degenerate critical points of a smooth function is not necessarily a closed subset. This shows in particular that in Corollary 104.4(2) we really need to assume that all critical points are non-degenerate.
Proof.

(1) It follows immediately from the Morse Lemma \[104.2\] that every non-degenerate critical point admits an open neighborhood which contains no other critical point. But this means, by definition, that the non-degenerate critical points of \(f\) form a discrete subset of \(M\).

(2) In Exercise \[6.29\] we showed that the set of critical points of \(f\) is a closed subset of \(M\).

Before we discuss the general existence of Morse functions on smooth manifolds let us consider some explicit examples of Morse functions.

Examples.

(1) In Figure \[1476\] we show three surfaces \(S^2, F\) and \(T\) in \(\mathbb{R}^3\). In each case the “height function”

\[
h : \mathbb{R}^3 \to \mathbb{R} \\
(x, y, z) \mapsto z
\]

is a Morse function. Evidently \(S^2\) and \(F\) are diffeomorphic, but the numbers of critical points differ. Just for fun we point out that August Möbius \([\text{Möb1863}]\) in 1863 drew basically the same pictures, see Figure \[1477\].

(2) Let \(n \in \mathbb{N}_0\). We pick real numbers \(c_0 < c_1 < \cdots < c_n\). We consider the following functions on \(\mathbb{R}P^n\) and \(\mathbb{C}P^n\):

\[
f : \mathbb{R}P^n \to \mathbb{R} \\
[x_0 : \cdots : x_n] \mapsto \sum_{j=0}^n c_j \cdot x_j^2 \\
g : \mathbb{C}P^n \to \mathbb{R} \\
[z_0 : \cdots : z_n] \mapsto \sum_{j=0}^n c_j \cdot |z_j|^2.
\]
Using the explicit charts given in Exercise 6.22 and Lemma 12.5 we will verify in Exercise 104.3 that both maps are Morse functions, that both maps have precisely $n + 1$ critical points and that these are of index $0, 1, \ldots, n$ respectively $0, 2, \ldots, 2n$.

(3) Let $n \in \mathbb{N}$. In Lemma 6.55 we showed that $SO(n)$ is a closed smooth manifold of dimension $\frac{1}{2}n(n - 1)$. Let $1 < c_1 < \cdots < c_n$ be real numbers. In [Mata02 Lemma 3.12] it is shown that the map

$$SO(n) \rightarrow \mathbb{R}$$

$$A = (a_{ij}) \mapsto \sum_{j=1}^{n} c_j \cdot a_{jj}$$

is a Morse function. Furthermore it is shown that the critical points are precisely the diagonal matrices in $SO(n)$. With very similar ideas one can also obtain explicit Morse functions on the smooth manifolds $U(n)$ and $SU(n)$. We refer to [Mata02 Examples 3.13 and 3.14] for details.

The following proposition provides a rich source of Morse functions.

**Proposition 104.5.** Let $M$ be a closed smooth submanifold of some $\mathbb{R}^n$.

1. The set of $Q \in \mathbb{R}^n$ for which the map $M \rightarrow \mathbb{R}$ given by $x \mapsto ||x - Q||^2$ is a Morse function is a set of full measure.\footnote{We refer to page 316 for the definition of a subset of full measure.}

2. The set of $v \in \mathbb{R}^n$ for which the map $M \rightarrow \mathbb{R}$ given by $x \mapsto \langle x, v \rangle$ is a Morse function is a set of full measure.
Sketch of proof. Let $M$ be a closed smooth submanifold of some $\mathbb{R}^n$.

(1) Given $Q \in \mathbb{R}^n$ we consider the map
\[
f_Q : M \to \mathbb{R} \\
x \mapsto \|x - Q\|^2.
\]
Furthermore we consider
\[
N := \{(p, w) \in \mathbb{R}^n \times \mathbb{R}^n \mid p \in M \text{ and } w \in (V_p M)^\perp\}.
\]
It is not particularly difficult to show that $N$ is an $n$-dimensional submanifold of $\mathbb{R}^{2n}$. Next we consider the “endpoint map”
\[
E : N \to \mathbb{R}^n \\
(p, w) \mapsto p + w
\]
which is evidently smooth. We say $Q \in \mathbb{R}^n$ is a focal point if $Q$ is a critical value of $E$. A slightly heroic calculation, see [Miln63a, Lemma 6.5], shows that $Q$ is a focal point if and only if the map $f_Q : M \to \mathbb{R}$ has nondegenerate critical points. The desired statement now follows from the above discussion together with Sard’s Theorem 6.63 which tells us that the set of critical values of $E$ is of measure zero in $\mathbb{R}^n$.

(2) This statement is proved in [Nic11, Corollary 1.25].

\[\text{Figure 1479. Illustration for the proof of Proposition 104.6 (1).}\]

**Proposition 104.6.** Every closed smooth manifold admits a Morse function.

**Remark.**

(1) There are many refinements of Proposition 104.6 in the literature. For example, by [Mata02, Theorem 2.20] every smooth function on a closed smooth manifold can be approximated by Morse functions.

(2) Using a doubling argument and collar neighborhoods it is a routine exercise to show, using Proposition 104.6, that also every compact smooth manifold admits a Morse function. But as we will see in Chapter 105 for compact smooth manifolds it is much more convenient to work with Morse functions that “respect the boundary”. In Proposition 105.4 we will provide such a refinement of Proposition 104.6 for smooth manifolds with boundary.

(3) In Proposition 105.10 we will see that one can always find “self-indexing” Morse functions.

**Proof.** Let $M$ be a closed smooth manifold. It follows from Proposition 9.1 together with Proposition 8.1 that we can assume that $M$ is a submanifold of some $\mathbb{R}^n$. It now follows from Proposition 104.5 that $M$ admits a Morse function. ■
104.3. **The Smooth Manifold Product Theorem.** In this section and the following section we will see that there is a close relationship between the topology of a smooth manifold and the non-degenerate critical points of a Morse function.

**Notation.** Let \( M \) be a smooth manifold and let \( f : M \to \mathbb{R} \) be a smooth function. Given \( a \in \mathbb{R} \) we write
\[
M_a := f^{-1}((-\infty, a]) = \{ x \in M \mid f(x) \leq a \}.
\]
Note that if \( a \) is a regular value and if \( \partial M \cap f^{-1}(\{a\}) = \emptyset \), then it follows from the Regular Value Theorem 6.53 that \( f^{-1}(\{a\}) \) is a closed submanifold of \( M \) and it follows from Exercise 6.31 that \( M_a \) is a submanifold of \( M \) with boundary \( f^{-1}(\{a\}) \cup (\partial M \cap f^{-1}((-\infty, a])) \).

**Example.** In Figure 1480 we show a smooth manifold \( M \) together with the “length” function \( f : M \to \mathbb{R} \) given by \((x, y, z) \mapsto x\). For various \( a_i \in \mathbb{R} \) we show the corresponding preimage \( f^{-1}(\{a_i\}) \). The submanifold \( M_{a_i} \) is of course everything to the \( \leq \)-left of \( f^{-1}(\{a_i\}) \).

\[\begin{array}{c}
\text{critical points} \\
M \\
\end{array}\]

**Theorem 104.7.** Let \( M \) be a compact smooth manifold and let \( f : M \to \mathbb{R} \) be a smooth function. Let \( a < b \in \mathbb{R} \) such that \( f^{-1}([a, b]) \) does not contain a critical point of \( f \). If \( f^{-1}([a, b]) \cap \partial M = \emptyset \), then there exists a diffeomorphism \( M_a \to M_b \). Furthermore, given any \( \varepsilon > 0 \) one can find diffeomorphism \( M_a \to M_b \) that is the identity on the common subset \( M_{a-\varepsilon} \).

**Example.** In Figure 1480 there is no critical point in \( f^{-1}([a_5, a_6]) \). Thus we obtain from Theorem 104.7 that the manifolds \( M_{a_5} \) and \( M_{a_6} \) are diffeomorphic. Furthermore, we can find a diffeomorphism that is the identity on “most of \( M_{a_5} \”).

Our proof of Theorem 104.7 rests on the following result, that will turn out to be of independent interest later on.

**Theorem 104.8. (Smooth Manifold Product Theorem)** Let \( M \) be a compact smooth manifold, let \( f : M \to \mathbb{R} \) be a smooth function and let \( a < b \in \mathbb{R} \). We suppose that for every \( P \in f^{-1}([a, b]) \) the differential \( Df_P : T_PM \to \mathbb{R} \) is non-zero. Furthermore we suppose that the following conditions are satisfied:

1. \( f^{-1}(\{a\}) \) is a closed submanifold of \( M \) or it is a union of components of \( \partial M \).
2. \( f^{-1}(\{b\}) \) is a closed submanifold of \( M \) or it is a union of components of \( \partial M \).

Then \( f^{-1}([a, b]) \) is diffeomorphic to \([a, b] \times f^{-1}(\{a\})\).
Sketch of a proof of Theorem 104.8. Note that using Proposition 9.1 and Proposition 8.1 we can assume that $M$ is a submanifold of some $\mathbb{R}^n$. Given $P \in M$ we denote by $\nabla f_P \in V_P M$ the gradient of $f$ at $P$.

1457 Let $P \in M$. We recall the following definition from page 308:

(1) If $P \not\in M \setminus \partial M$, then $P$ is a regular point if $D f_P : T_P M \to \mathbb{R}$ is non-zero.

(2) If $P \in \partial M$, then $P$ is a regular point if the map $D f_P : T_P \partial M \to \mathbb{R}$ is non-zero.

Thus we see that for points in $M \setminus \partial M$ our condition just says that we demand that $P$ is a regular point. For points on the boundary our condition is more relaxed.

1460 To make sense of the proposition we need to make the following two observations:

(i) Our hypotheses (1) and (2), together with Exercise 6.31 imply that Lemma 6.25 that $f^{-1}([a, b])$ is naturally a smooth manifold.

(ii) Our hypothesis (1), together with the combination of Lemma 6.25 and Proposition 6.27 shows that $f^{-1}(\{a\})$ is a closed smooth manifold in its own right. It follows from Proposition 6.51 that the product $[a, b] \times f^{-1}(\{a\})$ is naturally a smooth manifold.

Thus it actually does make sense to say that $f^{-1}([a, b])$ is diffeomorphic to $[a, b] \times f^{-1}(\{a\})$.

1457 Recall that on page 292 we introduced the visual tangent space $V_P M$ which, by the discussion on page 491, is naturally isomorphic to $T_P M$.

1458 The gradient $\nabla f_P \in V_P M$ of $f$ at $P \in M$ is defined as the unique vector in $V_P M$ which satisfies $(w, \nabla f_P) = D f_P(w) \in \mathbb{R}$ for all $w \in V_P M$. It is fairly elementary to show that $P \mapsto \nabla f_P$ is a smooth map $M \to \mathbb{R}^n$. 

Claim. If $\gamma : [0, \epsilon] \to f^{-1}([a, b])$ is a solution to the differential equation $\gamma'(t) = v(\gamma(t))$, then $(f \circ \gamma)'(t) \equiv 1$.

We perform the following calculation:

\[
(f \circ \gamma)'(t) = D(f \circ \gamma)_t \overset{\text{chain rule}}{=} D f_{\gamma(t)}(\gamma'(t)) \overset{\text{definition of gradient, here we set } P := \gamma(t)}{=} \langle \gamma'(t), \nabla f_P \rangle = \langle \frac{1}{\|\nabla f_P\|^2}, \nabla f_P, \nabla f_P \rangle = 1.
\]

by hypothesis we have $\gamma'(t) = v(\gamma(t))$, since $P = \gamma(t)$ and by definition of $v$.

We set $W := f^{-1}(\{a\})$. It remains to prove the following claim.

Claim.

(1) Given any $P \in W$ there exists a unique smooth map $\gamma_P : [a, b] \to f^{-1}([a, b])$ such that $\gamma_P(a) = P$ and such that for each $t \in [a, b]$ we have $\gamma'_P(t) = v(\gamma_P(t))$.

(2) The map

\[\Theta : [a, b] \times W \to M, \quad (t, P) \mapsto \gamma_P(t)\]

is a smooth embedding with image $f^{-1}([a, b])$. 

We now provide the proofs of the two statements of the claim.

(1) This statement follows from the previous claim and standard theory of differential equations.

(2) It follows from (1) that the map \( \Theta: [a, b] \times W \to M \) is well-defined. Furthermore it follows again from standard theory of differential equations that the map is smooth and that for each \( t \in [a, b] \) the map \( W \to M \) given by \( P \mapsto \gamma_P(t) \) is a smooth embedding with image \( f^{-1}(\{t\}) \). It follows easily from this observation and the previous claim that the map \( \Theta: [a, b] \times W \to M \) is actually a smooth embedding with image \( f^{-1}([a, b]) \).

We leave it to the reader to dig out their favorite books on differential equations to fill in the details. Very similar statements are also proved in [MiIn63a p. 10] and [Lee02 Theorem 9.12, Corollary 9.17].

![Diagram](image)

**Figure 1481.** Illustration for the proof of Theorem 104.7

Now we have no troubles with providing the desired proof of Theorem 104.7

**Proof of Theorem 104.7** Let \( M \) be a compact smooth manifold and let \( f: M \to \mathbb{R} \) be a smooth function. Let \( a < b \in \mathbb{R} \) such that \( f^{-1}([a, b]) \) does not contain a critical point of \( f \). We suppose that \( f^{-1}([a, b]) \cap \partial M = \emptyset \). By the Regular Value Theorem 6.53 we know that \( W := f^{-1}\{a\} \) is a closed smooth submanifold of \( M \). By Theorem 104.8 we know that \( f^{-1}([a, b]) \) is diffeomorphic to \( [a, b] \times W = [a, b] \times f^{-1}\{a\} \). It now follows from Exercise 8.13 (or alternatively from Lemma 105.2) that \( M_b = M_a \cup f^{-1}([a, b]) \) is diffeomorphic to \( M_a \). Furthermore, if we are given some \( \epsilon > 0 \), then it follows from Exercise 8.13 that we can find a diffeomorphism that is the identity on \( M_{a-\epsilon} \).

**104.4. The Handle Addition Theorem.** Let \( M \) be a compact smooth manifold and let \( f: M \to \mathbb{R} \) be a smooth function. Furthermore let \( a < b \in \mathbb{R} \) such that \( a \) and \( b \) are regular values and such that \( f^{-1}([a, b]) \cap \partial M = \emptyset \). Note that the Regular Value Theorem 6.53 implies that \( f^{-1}\{a\} \) and \( f^{-1}\{b\} \) are closed submanifolds of \( M \). Note that if the stronger condition holds that \( f^{-1}([a, b]) \) does not contain a critical point of \( f \), then the Smooth Manifold Product Theorem 104.8 says that \( M_b \) is diffeomorphic to \( M_a \). But what happens if \( f^{-1}((a, b)) \) contains a critical point?

On the left of Figure 1482 we show a 2-dimensional smooth manifold \( M \) together with a smooth function \( f: M \to \mathbb{R} \) such that there exists a unique critical point of index \( k = 1 \) in \( f^{-1}((a, b)) \). On the left of Figure 1482 we show the result of attaching a handle of index \( k = 1 \) to \( M_a \). Some goodwill shows that \( M_b \) is diffeomorphic to the result of attaching this
handle of index \( k = 1 \) to \( M_a \). In fact given any \( \epsilon > 0 \) one can find a diffeomorphism that is the identity on the common subset \( M_{a-\epsilon} \).

![Diagram](image1)

**Figure 1482**

The following all-important theorem shows that a suitable generalization of the above observation holds in all reasonable settings.

**Theorem 104.9. (Handle Addition Theorem)** Let \( M \) be a compact smooth manifold and let \( f: M \to \mathbb{R} \) be a smooth function. Furthermore let \( a < b \in \mathbb{R} \) such that \( a \) and \( b \) are regular values and such that \( f^{-1}([a, b]) \cap \partial M = \emptyset \).

1. Suppose there exists a single critical point \( P \in f^{-1}([a, b]) \). We set \( k := \text{index}(f, P) \). If \( P \) is non-degenerate, then \( M_b \) is diffeomorphic to the result of attaching a \( k \)-handle to \( M_a \).

2. Suppose there exists a single critical value \( c \in [a, b] \). Let \( P_1, \ldots, P_m \) be the preimages of \( c \). We suppose that \( P_1, \ldots, P_m \) are non-degenerate critical points. Let \( k_1, \ldots, k_m \) be the indices of the critical points. Then \( M_b \) is diffeomorphic to the result of attaching \( m \) handles of index \( k_i \), \( i = 1, \ldots, m \) to \( M_a \) along thickened spheres with disjoint images.

Furthermore, in both settings, given any \( \epsilon > 0 \) there exists an diffeomorphism as above which is the identity on the common subset \( M_{a-\epsilon} \).

![Diagram](image2)

**Figure 1483.** Illustration for Theorem 104.9 (1).

**Example.** In Figure 1484 we return to the setting of Figure 1480. We show all the critical points and we indicate the indices. Furthermore, reading from left to right we show how \( M \) gets built out of the empty manifold by various handle attachments. To simplify our pictures we do not distinguish between a smooth manifold that is the result of attaching a
k-handle and a smooth manifold that is diffeomorphic to the result of attaching a k-handle.

\[ \varnothing \]

\[ 0 \]

\[ 0 \]

\[ 0 \]

\[ \text{handle attachments from left to right} \]

\[ \text{Figure 1484} \]

**Remark.** We provide an almost complete proof of Theorem 104.9. Only at the very end of the proof, on page 2512 when we need to prove that a certain map is a diffeomorphism, we not feel like dealing with the technical challenge of verifying that a given homeomorphism is in fact a diffeomorphism. We refer to our usual sources, namely [Nic11, Theorem 2.7 and Remark 2.9], [Miln63a, Theorem 3.2, Remark on p. 17, Remark 3.3] and [Kos93, Chapter VII.2] for more details.

**Proof.** Let \( M \) be a compact smooth manifold, let \( f: M \to \mathbb{R} \) be a smooth function and let \( a < b \in \mathbb{R} \) be regular values such that \( f^{-1}([a, b]) \cap \partial M = \varnothing \). In the following we will only prove Statement (1). Statement (2) can be proved either by generalizing the proof of Statement (1) or by using Exercise 104.7. We leave it to the reader to fill in the details for the proof of Statement (2).

Thus we suppose there exists a single critical point \( P \in f^{-1}([a, b]) \) and we suppose that \( P \) is non-degenerate. We set \( c := f(P) \) and we set \( k := \text{index}(f, P) \). We need to show that \( M_b \) is diffeomorphic to the result of attaching a k-handle to \( M_a \).

We make the following preparations:

1. We set \( l := n - k \).
2. We make the identification \( \mathbb{R}^n = \mathbb{R}^k \times \mathbb{R}^l \). Given \( x = (x_1, \ldots, x_k) \in \mathbb{R}^k \) we write \( x^2 = x_1^2 + \cdots + x_k^2 \) and similarly given \( y = (y_1, \ldots, y_l) \in \mathbb{R}^l \) we write \( y^2 = y_1^2 + \cdots + y_l^2 \).
3. By the Morse Lemma 104.2 we can identify a neighborhood of \( P \) in \( M \setminus \partial M \) with a neighborhood \( V \) of \( (0, 0) \in \mathbb{R}^k \times \mathbb{R}^l \) such that \( P = (0, 0) \) and such that for every \( (x, y) \in V \) we have \( f(x, y) = c - x^2 + y^2 \).
4. Since \( a \) and \( b \) are regular values we know that \( c \in (a, b) \). Thus we can pick an \( \eta > 0 \) such that \( a \leq c - \eta < c + \eta \leq b \) and such that \( B_{\sqrt{2\eta}}(0) \subset V \). Note that by our hypothesis there are no critical points in \( f^{-1}([a, c - \eta]) \) and there are no critical points in \( f^{-1}([c + \eta, b]) \). Thus it follows from Theorem 104.7 that it suffices to show that \( M_{c+\eta} \) is diffeomorphic to the result of attaching a k-handle to \( M_{c-\eta} \).

Note that only in the neighborhood \( V \) do we have completely control over \( f \). Unfortunately a priori the difference \( M_b \setminus M_a \) is not contained in the neighborhood \( V \). To deal with this issue we introduce an auxiliary function. First note that by Lemma 6.13 there exists a smooth map \( \phi: [0, \infty) \to \mathbb{R}_{\geq 0} \) with \( \phi(0) > \eta \), \( \phi(t) = 0 \) for \( t \geq 2\eta \) and such that \( \phi'(t) \in (-1, 0) \) for all \( t \in [0, \infty) \). We refer to Figure 1485 for an illustration.
Next we consider the map

\[
F : M \rightarrow \mathbb{R} \\
P \mapsto \begin{cases} 
  f(x, y) - \phi(x^2 + 2y^2) = c - x^2 + y^2 - \phi(x^2 + 2y^2), & \text{if } P = (x, y) \in \overline{B}_{\sqrt{2}\eta}(0), \\
  f(P), & \text{otherwise}.
\end{cases}
\]

The following claim summarizes some of the key properties of \(F\).

\textbf{Claim 1.}

1. The map \(F\) is smooth.
2. The critical points of \(F\) are precisely the critical points of \(f\).
3. Given any \(r \in \mathbb{R}\) we have \(F^{-1}((-\infty, r]) \subset F^{-1}((-\infty, r])\).
4. We consider the ellipsoid \(E := \{(x, y) \in \mathbb{R}^2 \mid x^2 + 2y^2 \leq 2\eta\}\). Given any \(r \in \mathbb{R}\) we have \(F^{-1}((-\infty, r]) \setminus f^{-1}((-\infty, r]) \subset E \subset \overline{B}_{\sqrt{2}\eta}(0)\).
5. The smooth manifold \(F^{-1}((-\infty, c - \eta])\) is diffeomorphic to \(F^{-1}((-\infty, c + \eta])\).
6. We have \(F^{-1}((-\infty, c + \eta]) = f^{-1}((-\infty, c + \eta])\).

In particular we have

\[
M_{c-\eta} = f^{-1}((-\infty, c - \eta]) \overset{(3)}{\subset} F^{-1}((-\infty, c - \eta]) \overset{\uparrow}{\cong} F^{-1}((-\infty, c + \eta]) \overset{(6)}{=} f^{-1}((-\infty, c + \eta]) = M_{c+\eta}.
\]

by (4) the difference is contained in \(E \subset \overline{B}_{\sqrt{2}\eta}(0)\) diffeomorphic by (5)

The various level sets of \(f\) and \(F\) are illustrated in Figure 1486

\[\text{Figure 1486. Second illustration for the proof of Theorem 104.9}\]
We turn to the proof of the claim. We prove the statements in a somewhat different order.

(1) Note that \( \phi \) is zero outside of \( \overline{B}_{\sqrt{2}\eta}(0) \). It follows from this observation together with the fact \( \overline{B}_{\sqrt{2}\eta}(0) \) is contained in \( V \) that \( F \) is smooth.

(2) It is clear that we only need to consider the points \((x, y)\) with \( x^2 + 2y^2 \leq 2\eta \). For those points we compute, using the chain rule from Proposition 6.15 that

\[
\begin{aligned}
D f(x, y) &= (2x, 2y) \\
D F(x, y) &= (2x \cdot \left(-1 - \phi'(x^2 + 2y^2)\right), 2y \cdot (1 - 2\phi'(x^2 + 2y^2))).
\end{aligned}
\]

We see that \( D f(x, y) = (0, 0) \) if and only if \( D F(x, y) = (0, 0) \).

(3) Since \( \phi(x, y) \geq 0 \) for all \((x, y)\) in \( \overline{B}_{\sqrt{2}\eta}(0) \) we see that \( F(P) \leq f(P) \) for all \( P \in M \). But this implies that for any \( r \in \mathbb{R} \) we have \( f^{-1}((\infty, r]) \subset F^{-1}((\infty, r]) \).

(4) Note that the two maps \( f : M \to \mathbb{R} \) and \( F : M \to \mathbb{R} \) agree outside of \( E \subset \overline{B}_{\sqrt{2}\eta}(0) \). The desired statement is an immediate consequence of this observation.

(5) Note that given any \((x, y)\) in \( E \) we have

\[
\begin{aligned}
F(x, y) &\leq f(x, y) = c - x^2 + y^2 \\
&\leq c + \frac{1}{2}x^2 + y^2 \\
&\leq c + \eta.
\end{aligned}
\]

The desired equality follows from this observation together with (4).

(6) We need to show that the smooth manifold \( F^{-1}((\infty, c - \eta]) \) is diffeomorphic to \( F^{-1}((\infty, c - \eta]) \). By Theorem 104.7 together with (2) it suffices to prove that the preimage \( F^{-1}([c - \eta, c + \eta]) \) does not contain a critical point of \( f \). This statement follows from the following inclusions and statements:

by construction we have \( \phi(0) > \eta \) 
thus \( F(0, 0) = c - \phi(0) < c - \eta \)
thus this set does not contain \((0, 0)\)

\[
\begin{aligned}
F^{-1}([c - \eta, c + \eta]) &= F^{-1}((\infty, c + \eta]) \setminus F^{-1}((\infty, c - \eta]) \\
&\subset f^{-1}((\infty, c + \eta]) \setminus f^{-1}((\infty, c - \eta]) = F^{-1}([c - \eta, c + \eta]),
\end{aligned}
\]

by hypothesis this contains a single critical point of \( f \), namely \((0, 0)\)

By Claim 1 it suffices to prove that the smooth manifold \( F^{-1}((\infty, c - \eta]) \) is diffeomorphic to the result of attaching a \( k \)-handle to \( M_{c-\eta} = f^{-1}((\infty, c - \eta]) \). This step is performed in the following claim.

Claim 2. We consider the thickened \((k - 1)\)-sphere

\[
\varphi : \overline{B}^{n-k} \times S^{k-1} \to f^{-1}([c - \eta]) \subset \partial M_{c-\eta}
\]

\[
(x, y) \mapsto \left(2 \eta \cdot x^2 + \eta \cdot y, \sqrt{2\eta} \cdot x\right).
\]

The smooth manifold \( M_{c-\eta} \cup_{\varphi} h^k = f^{-1}((\infty, c - \eta]) \cup_{\varphi} h^k \) is diffeomorphic to the smooth manifold \( F^{-1}((\infty, c - \eta]) \).
The Handle Decomposition Theorem. The furthermore statement of Theorem 104.7.

We only provide a sketch of the proof of Claim 2. As so often trying to show that a given map is really a diffeomorphism quickly leads to unreadable arguments. The full details for the proof are provided in [Kos93, p. 129]. First note that a fairly straightforward argument shows that for any $x \in \overline{B}^k_{\sqrt{\eta}}(0)$ there exists an $r(x) \in \mathbb{R}_{>0}$ such that

$$\{y \in \overline{B}^l \mid F(x, y) \leq c + \eta\} = \overline{B}^{|n-k|}(r(x)) \setminus \overline{B}^k_{\sqrt{\eta}}(0).$$

Now the desired diffeomorphism is given by

$$f^{-1}((\infty, c - \eta]) \cup \varphi(B^l \times \overline{B}^k) \rightarrow F^{-1}((\infty, c - \eta])$$

$$P \mapsto \left\{ \begin{array}{ll} P, & \text{if } P \in f^{-1}((\infty, c - \eta]), \\
(\sqrt{2\eta x^2 + \eta \cdot y}, x \cdot r(\sqrt{2\eta x^2 + \eta})), & \text{if } P = (x, y) \in \overline{B}^l \times \overline{B}^k. \end{array} \right.$$

This completes the sketch of the proof of the claim. 

Finally suppose we are given an $\epsilon > 0$. We need to show that there exists an diffeomorphism as above which is the identity on the common subset $M_{a-\epsilon}$. As the reader will surely have noticed, this is an immediate consequence of our construction together with the “furthermore” statement of Theorem 104.7.

104.5. The Handle Decomposition Theorem. With the results from the previous section it is now pretty straightforward to prove the following result.

**Proposition 104.10.** Let $M$ be a closed smooth manifold. If $f : M \rightarrow \mathbb{R}$ is a Morse function, then there exists a standard handle decomposition of $M$ such that for each $k \in \mathbb{N}_0$ the number of $k$-handles equals the number of critical points of $f$ of index $k$.

**Proof.** Let $M$ be a closed smooth manifold and furthermore let $f : M \rightarrow \mathbb{R}$ be a Morse function. Recall that by Corollary 104.4 (2) we know that $f$ has only finitely many critical points. We order the corresponding critical values by $\lambda_1 < \cdots < \lambda_s$. Next we pick real numbers $\mu_0 < \lambda_1 < \mu_1 < \lambda_2 < \mu_2 < \cdots < \mu_{s-1} < \lambda_s$ and furthermore we pick some $\mu_s \geq \max(f : M \rightarrow \mathbb{R})$. Note that $M_{\mu_0} = \emptyset$ and $M_{\mu_s} = M$. It follows from Theorem 104.9 that each $M_{\mu_i}$ is diffeomorphic to the result of attaching finitely many
handles to $M_{\mu_{i-1}}$. In fact Theorem 104.9 says that we can arrange that the handles are in one-to-one correspondence to the critical points with critical value $\lambda_i$ and that the indices of the handles correspond precisely to the indices of the critical points. This shows that $M = M_{\mu_i}$ admits a handle decomposition with the predicted number of handles. Finally we apply Corollary 103.4 to conclude that $M$ actually admits a standard handle decomposition with the same number of handles with the same indices.

Remark.

(1) In Proposition 105.9 we will prove a converse to Proposition 104.10, namely we will see that handle decompositions give rise to Morse functions.

(2) Let $M$ be a closed smooth manifold and let $f: M \to \mathbb{R}$ is a Morse function. In the proof of Proposition 104.10 we just saw that $f$ gives rise to a handle decomposition of $M$. Evidently $-f: M \to \mathbb{R}$ is also a Morse function. The corresponding handle decomposition is for all intents and purposes the same as the dual handle decomposition that we introduced in Proposition 104.10. Since we will not make use of this statement we will also not bother with providing a proof.

Now we can easily prove the main theorem of this chapter.

**Theorem 104.11. (Handle Decomposition Theorem)** Every closed smooth manifold admits a standard handle decomposition.

Remark.

(1) In the literature the Handle Decomposition Theorem is often called the Handle Presentation Theorem.

(2) We will deal with compact smooth manifolds with non-empty boundary in the following chapter. In particular we will prove the Relative Handle Decomposition Theorem 105.6 that says that every compact smooth manifold admits a handle structure rel a given union of boundary components. As we point out in Theorem 105.7 this implies in particular that every compact smooth manifold admits a standard handle decomposition.

---

Note that implicitly we use our hypothesis that $M$ is closed, since to apply Theorem 104.9 we need to ensure that $f^{-1}([\mu_{i-1}, \mu_i]) \cap \partial M = \emptyset$. 

---

**Figure 1488.** Illustration for the proof of Proposition 104.10.
Proof. Let $M$ be a closed smooth manifold. By Proposition 104.6 we know that there exists a Morse function $f: M \to \mathbb{R}$. It follows from Proposition 104.10 that $M$ admits a standard handle decomposition. ■

We can now give a new proof for some of the statements of Proposition 64.6.

**Proposition 64.6.** Let $M$ be a closed $n$-dimensional smooth manifold.

1. For every $k > n$ we have $H_k(M; \mathbb{Z}) = 0$.
2. Given any $P \in M$ the fundamental group $\pi_1(M, P)$ is finitely presented.
3. All homology groups of $M$ are finitely generated abelian groups.

**Remark.**

1. Morse theory can also be used to prove the above formulation of Proposition 64.6 for compact smooth manifolds with non-empty boundary. In fact there are at least two approaches to achieving this goal:
   (a) Either one applies the above result to the double $D M$ of a compact smooth manifold with boundary and one applies a little bit of algebra, e.g. Lemma 21.16.
   (b) Alternatively one can wait for Theorem 105.7 where we prove the generalization of the Handle Decomposition Theorem 104.11 to compact smooth manifolds with non-empty boundary.
2. In Theorem 106.11 and Proposition 106.10 we will give explicit upper bounds on the “size” of the homology groups of a closed smooth manifold in terms of the number of critical points of a Morse function respectively the number of handles in a handle decomposition.

**Sketch of proof.** Let $M$ be a closed $n$-dimensional smooth manifold. By the Handle Decomposition Theorem 104.11 we know that $M$ admits a handle decomposition. It follows easily from a straightforward induction argument using Proposition 103.11 that for any $P \in M$ the fundamental group $\pi_1(M, P)$ is finitely presented. Similarly it follows from a straightforward induction argument using Lemma 103.13 that for every $k > n$ we have $H_k(M; \mathbb{Z}) = 0$ and, using the elementary group-theoretic Lemma 19.6 (1), we see that all homology groups of $M$ are finitely generated abelian groups. ■

The next proposition is also a straightforward consequence of our results.

**Proposition 104.12.** Let $M$ be a closed smooth manifold.

1. If $f$ is a Morse function for $M$, then $M$ is homotopy equivalent to a CW-complex where the number of $k$-cells equals precisely the number of critical points of index $k$.
2. The smooth manifold is homotopy equivalent to a finite CW-complex.

**Example.** Let $n \in \mathbb{N}_0$. Recall that on page 2502 we showed that there exists a Morse function $f: \mathbb{R}P^n \to \mathbb{R}$ with precisely one critical point for each index $0, \ldots, n$. It follows from Proposition 104.12 that $\mathbb{R}P^n$ is homotopy equivalent to a CW-complex with precisely one cell of dimension $0, \ldots, 2n$ and no other cells. In the same vein the above results show that $\mathbb{C}P^n$ is homotopy equivalent to a CW-structure with precisely one cell of degree $0, 2, \ldots, 2n$ and no other cells. This discussion almost recovers the result of Lemma 36.1.
Proof.

(1) This statement follows immediately from Corollary 104.4 (2), Theorem 104.9 and Proposition 103.18.
(2) This statement is a consequence of (1) and Proposition 104.6. Put differently, it is a consequence of the Handle Decomposition Theorem 104.11 and Proposition 103.18.

Remark.

(1) There are various other proofs that Morse functions give rise to CW-complexes that are homotopy equivalent to $M$, see e.g. [BaH04, Theorem 3.28], [Miln65b, Chapter 3] and [Mata02, Theorem 4.18]. Terse argument are also given in [Nic11, Theorem 2.10] and [Wall16, Proposition 5.3.1]. Furthermore an even terser argument is given in [Hirs76, Theorem 6.4.1].

(2) Given a closed smooth manifold there is a notion of a more refined version of a Morse function, namely of a Morse-Smale function. We will not provide the definition, instead we refer to [BaH04, p. 7] for the definition. But we try to pique the reader’s interest with the following two statements:

(a) The Kupka-Smale Theorem, proved independently by Ivan Kupka [Kupk63] and Steven Smale [Sma63], says that every closed smooth manifold admits a Morse-Smale function. Alternatively see [BaH04, Theorem 6.6] for a proof.

(b) In [Lau92, p. 222] (see also [BaH04, p. 179]) it is shown that a Morse-Smale function gives rise to a CW-complex that is actually homeomorphic to $M$ and such that for each $k \in \mathbb{N}_0$ the critical points of index $k$ are in one-to-one correspondence to the $k$-cells.

(3) Proposition 104.12 (2) is related to several earlier results:

(a) In Theorems 64.2 we showed that every compact smooth manifold $M$ admits a finite simplicial structure. By Theorem 64.5 this implies in particular that $M$ admits a finite CW-structure.

(b) In Corollary 63.37 we used the Nerve Theorem 63.32 to show that every compact smooth manifold is weakly homotopy equivalent to a finite CW-complex.

(c) Finally in Corollary 85.18 we used Borsuk’s Theorem 85.3 to show that every topological manifold is homotopy equivalent to a CW-complex.

104.6. Reeb’s Theorem. Theorem 104.9 also allows us to prove the following theorem which was first proved by Georges Reeb [Reeb46] in 1946.

Theorem 104.13. (Reeb’s Theorem) Let $M$ be a closed $n$-dimensional smooth manifold. If $M$ admits a smooth function $f: M \to \mathbb{R}$ with precisely two critical points which are both non-degenerate, then $M$ is homeomorphic to $S^n$.

Remark. For the record we mention that by [Miln64b, Theorem 1] the conclusion of Theorem 104.13 also holds if the critical points are degenerate.

Reeb’s Theorem 104.13 is an immediate consequence of Theorem 104.9 together with the following proposition.
**Proposition 104.14.** Let $n \in \mathbb{N}$.

1. If $\varphi: S^{n-1} \to S^{n-1}$ is a homeomorphism, then $\overline{B}^n \cup_{\varphi} \overline{B}^n$ is homeomorphic to $S^n$.
2. Let $M$ be a closed $n$-dimensional smooth manifold. If $M$ admits a handle decomposition consisting of a single 0-handle and a single $n$-handle, then $M$ is homeomorphic to $S^n$.

**Proof.**

1. Let $\varphi: S^{n-1} \to S^{n-1}$ be a homeomorphism. We apply the Alexander trick to get an extension of $\varphi: S^{n-1} \to S^{n-1}$ to the ball $\overline{B}^n$. More precisely we consider the following map:

$$\Phi: \overline{B}^n \to \overline{B}^n, \quad x \mapsto \begin{cases} \|x\| \cdot \varphi\left(\frac{x}{\|x\|}\right), & \text{if } x \neq 0, \\ 0, & \text{otherwise.} \end{cases}$$

By Exercise 3.29 we know that this map $\Phi$ is a homeomorphism. Finally we consider the following sequence of homeomorphisms:

$$\overline{B}^n_+ \cup_{\varphi: S^{n-1} \to S^{n-1}} \overline{B}^n_- \xrightarrow{\varphi} \overline{B}^n_+ \cup_{\text{id}: S^{n-1} \to S^{n-1}} \overline{B}^n_- \xrightarrow{\text{homeomorphism from page 109}} S^n.$$  

(2) Let $M$ be a closed $n$-dimensional smooth manifold that $M$ admits a handle decomposition consisting of a single 0-handle and a single $n$-handle. This means that there exists a diffeomorphism $\varphi: S^{n-1} \to S^{n-1}$ such that $M$ is diffeomorphic to $\overline{B}^n \cup_{\varphi} \overline{B}^n$. It now follows from (1) that $M$ is homeomorphic to $S^n$. 

---

**Figure 1489.** Illustration for the proof of Theorem 104.13

Reeb’s Theorem 104.13 and Proposition 104.14 raise several fantastic questions. First of all, it is natural to ask whether the analogue of Proposition 104.14 (1) holds if we replace “homeomorphism” by “diffeomorphism”. Put differently, we have the following question.

**Question 104.15.** Let $\varphi: S^{n-1} \to S^{n-1}$ be a diffeomorphism. Is the smooth manifold $\overline{B}^n \cup_{\varphi} \overline{B}^n$ diffeomorphic to $S^n$?

\[\text{Note that by Proposition 8.15 we can equip } \overline{B}^n \cup_{\varphi} \overline{B}^n \text{ with a canonical smooth structure.}\]
Next let us reflect whether we can upgrade the composition of maps towards the end of the proof Proposition 104.14 into a diffeomorphism. The good news is that, by Exercise 8.16, we can replace the map on the right-hand side by a diffeomorphism. The bad news is that, as we saw in Exercise 3.29, the map \( \Phi: B^n \to B^n \) given by the Alexander trick is not smooth at the origin, in particular \( \Phi \) is not diffeomorphism. But perhaps we can pick \( \Phi \) more cleverly? This leads us to our second question.

**Question 104.16.** Let \( n \in \mathbb{N} \). Does every diffeomorphism \( \varphi: S^n \to S^n \) extend to a diffeomorphism of \( B^{n+1} \)?

In Propositions ?? and ?? we will provide answers to Questions 104.16 and 104.15.

---

**Exercises for Chapter 104.**

**Exercise 104.1.** Show that every Morse function is a height function. More precisely, let \( M \) be a smooth manifold and let \( f: M \to \mathbb{R} \) be a Morse function. Show that there exists a smooth embedding \( \varphi: M \to \mathbb{R}^n \) such that \( f = h \circ \varphi \) where \( h: \mathbb{R}^n \to \mathbb{R} \) is the map given by \( (x_1, \ldots, x_n) \mapsto x_n \).

**Exercise 104.2.** Sketch Morse functions on the torus \( T = [0, 1]^2 / \sim \), the real projection plane \( \mathbb{R}P^2 = B^2 / x \sim -x \) and the surface of genus two \( E_2 / \sim \) such that each Morse function has a single local maximum and a single local minimum.

![Illustration for Exercise 104.2](image)

**Exercise 104.3.** Let \( n \in \mathbb{N}_0 \). We pick real numbers \( c_0 < c_1 < \cdots < c_n \). We consider the following functions on \( \mathbb{R}P^n = S^n / \{ \pm \text{id} \} \) and \( \mathbb{C}P^n = S^{2n+1} / S^1 \):

\[
\begin{align*}
f: \mathbb{R}P^n &\to \mathbb{R} \\
[x_0: \cdots : x_n] &\mapsto \sum_{j=0}^{n} c_j \cdot x_j^2 \quad \text{and} \quad g: \mathbb{C}P^n &\to \mathbb{R} \\
[z_0: \cdots : z_n] &\mapsto \sum_{j=0}^{n} c_j \cdot |z_j|^2.
\end{align*}
\]

(a) Show that \( f \) is a Morse function, that \( f \) has precisely \( n + 1 \) critical points and that these are of index \( 0, 1, \ldots, n \).

(b) Show that \( g \) is a Morse function, that \( g \) has precisely \( n + 1 \) critical points and that these are of index \( 0, 2, \ldots, 2n \).

**Remark.** You might want to use the explicit charts given in Exercise 6.22 and Lemma 12.5.

**Exercise 104.4.** Let \( M \) be a smooth manifold and let \( f: M \to \mathbb{R} \) be a Morse function. Furthermore let \( \lambda: M \to \mathbb{R} \) be a smooth function such that \( D\lambda_P \neq 0 \) for every \( P \in M \). Show that \( \lambda \cdot f: M \to \mathbb{R} \) is also a Morse function and that the critical points, and the
corresponding indices, of $\lambda f$ agree with the critical points, and the corresponding indices, of $\lambda$.

**Exercise 104.5.** Let $M$ and $N$ be two closed smooth manifolds and let $f: M \to \mathbb{R}$ and $g: N \to \mathbb{R}$ be Morse functions.

(a) Let $a, b \in \mathbb{R}$ with $a > \max(|f|)$ and $b > \max(|g|)$. Show that the map

$$f \cdot g: M \times N \to \mathbb{R}, \quad (x, y) \mapsto (a + f(x)) \cdot (b + g(y))$$

is a Morse function.

(b) Determine the critical points, and their indices, of the Morse function of $f \cdot g$ in terms of the critical points, and their indices, of $f$ and $g$.

**Exercise 104.6.** Let $M$ and $N$ be two closed $n$-dimensional smooth manifolds and let $f: M \to \mathbb{R}$ and $g: N \to \mathbb{R}$ be Morse functions with unique critical points of index 0 and $n$. Show that the connected sum $M \# N$ admits a Morse function $\varphi$ with unique critical points of index 0 and $n$ and such that for $k \in \{1, \ldots, n - 1\}$ we have

$$\text{number of critical points of } \varphi: M \# N \to \mathbb{R} = \text{number of critical points of } f: M \to \mathbb{R} + \text{number of critical points of } g: N \to \mathbb{R}.$$

**Exercise 104.7.** Let $M$ be a smooth manifold, let $f: M \to \mathbb{R}$ be a smooth function and let $P \in M \setminus \partial M$ be a non-degenerate critical point of $f$. Let $U$ be a compact neighborhood of $P \in M \setminus \partial M$ which contains no other critical point. Show that there exists an $\epsilon > 0$ such that for every $\mu \in [0, \epsilon]$ there exists a smooth function $g: M \to \mathbb{R}$ with the following four properties:

1. The function $g$ agrees with $f$ outside of $U$.
2. $P$ is a critical point of $g$ with $\text{index}(g, P) = \text{index}(f, P)$.
3. $g(P) = f(P) + \mu$.
4. $P$ is the only critical point of $g$ in $U$.

\[\text{Figure 1491. Illustration of Exercise 104.7}\]
105. Morse theory II: The Relative Handle Decomposition Theorem

In Proposition 104.6 we showed that every closed smooth manifold admits a Morse function. Using Theorem 104.9 this allowed us to prove the Handle Decomposition Theorem 104.11 which says that every closed smooth manifold admits a handle decomposition.

As we remarked on page 2504, it is not difficult to prove, using Proposition 104.6 that in fact every compact smooth manifold $M$ admits a Morse function $f: M \to \mathbb{R}$. But this is not enough to prove the Handle Decomposition Theorem 104.11 for compact smooth manifolds with non-empty boundary since Theorem 104.9 has the hypothesis that $f^{-1}([a,b]) \cap \partial M = \emptyset$.

In this chapter we will see that compact smooth manifolds have in fact a handle decomposition. In fact we will do more, namely we will develop the theory of relative handle decompositions and we will study more refined versions of Morse functions. As we will see on several occasions, this extra effort for smooth manifolds with boundary will also come in handy in the study of closed smooth manifolds.

105.1. Relative Handle Decompositions. For smooth manifolds with non-empty boundary it will be convenient to study relative handle decompositions. This concept generalizes the notion of a handle decomposition that we introduced on page 2477.

**Definition.** Let $M$ be a compact $n$-dimensional smooth manifold and let $A$ be a (possibly empty) union of components of $\partial M$.

1. A handle decomposition for $M$ rel $A$ is a diffeomorphism

$$\Theta: M \xrightarrow{\approx} ([0,1] \times A) \cup_{\varphi_0} h^{k_0} \cup \cdots \cup_{\varphi_m} h^{k_m}$$

where for $i = 0, \ldots, m$ the map $\varphi_i$ is a thickened $(k_i - 1)$-sphere in the boundary of the smooth manifold $([0,1] \times A) \cup_{\varphi_0} h^{k_0} \cup \cdots \cup_{\varphi_{i-1}} h^{k_{i-1}}$ and where $\Theta^{-1}: [0,1] \times A \to M$ is a collar of $A$.

2. The notion of a standard handle decomposition rel $A$ is defined the same way as we did for the case $A = \emptyset$ on page 2481.

![Figure 1492](image)

The following proposition is basically a generalization of Proposition 103.3.

**Proposition 105.1.** Let $M$ be a compact $n$-dimensional smooth manifold. Furthermore let $\partial M = A \sqcup B$ be a decomposition of $\partial M$ into two disjoint unions of components $A$.
and $B$. Finally let

$$M = ([0,1] \times A) \cup_{\varphi_0} h_0 \cup \cdots \cup_{\varphi_m} h_m$$

be a handle decomposition of $M$ rel $A$. We consider

$$M' := (M \setminus ([0,1] \times A)) \cup_{B = B \times \{0\}} ([0,1] \times B)$$

and we set $A' := \{1\} \times A \subset M'$ and $B' := \{1\} \times B \subset M'$.

(0) There exists a diffeomorphism from $M$ to $M'$ that restricts to the obvious diffeomorphism $A \to A'$ and $B \to B'$.

There exists canonical handle decomposition

$$M' = ([0,1] \times B') \cup_{\psi_m} h_{n-k_m} \cup \cdots \cup_{\psi_0} h_{n-k_0}$$

of $M'$ rel $B'$ called dual handle decomposition, with the following properties:

1. For each $i \in \{0, \ldots, m\}$ the following statements hold:
   a. The $i$-th handle of the dual handle decomposition equals, as a subset of $M \cap M'$, the $(m-i)$-th handle of the original handle decomposition.
   b. The indices of the handles are reversed, in the sense that
      $$\text{index of the } i\text{-th handle of the dual handle decomposition} = n - \text{index of the } (m-i)\text{-th handle of the original handle decomposition}.$$  
      In particular the number of $i$-handles in the dual handle decomposition equals the number of $(n-i)$-handles in the original decomposition.
   c. The roles of attaching spheres and belt spheres is reversed in the sense that
      $$\text{belt sphere of the } i\text{-th handle of the dual handle decomposition} = \text{attaching sphere of the } (m-i)\text{-th handle of the original handle decomposition}.$$  
      Furthermore the same statement, with the roles of attaching and belt spheres reversed, also holds.

2. If the original handle decomposition is standard, then so is the dual handle decomposition.

3. The dual of the dual handle decomposition is the original handle decomposition.

Example. In Figure 1493 we show again $M$, the torus minus two open disks, with two boundary components $A$ and $B$. To the left we show the above handle decomposition of $M$ rel $A$. To the right we see the corresponding dual handle decomposition of $M'$ rel $B'$.

In the proof of Proposition 105.1 we will make use of the following lemma, which also doubles as Exercise 8.13.

Lemma 105.2. Let $M$ be a compact smooth manifold and let $C$ be a union of components of $\partial M$. Let $\varphi: C \to C$ be a diffeomorphism. Given any neighborhood $U$ of $C \subset M$ there
exists a diffeomorphism

\[ M \to \left( M \cup ([0,1] \times C) \right) / \sim \]

where \( x \sim \varphi(x,0) \) for \( x \in C \)

that is the identity on the common subset \( M \setminus U \) and that restricts to the obvious diffeomorphism from \( C \) to \([1] \times C\).

**Remark.** In the setting of Lemma 105.2 we sometimes refer to \([0,1] \times C\) as an external collar.

**Proof of Lemma 105.2.** As is explained in Proposition 8.15 (1), to say that the topological space \( (M \cup ([0,1] \times C)) / \sim \) is a smooth manifold we actually need to pick a collar \([-1,0] \times C\) with \( C = \{0\} \times C\) to define the actual smooth atlas. Since \( U \) is a neighborhood of \( C \) and since \( C \) is compact there exists an \( \epsilon > 0 \) such that \([-\epsilon,0] \times C \subset U\). Using Lemma 6.13 one can easily show that there exists a smooth function \( \eta: [-\epsilon,0] \to [-\epsilon,1] \) with \( \eta(t) = t \) for \( t \in [-\epsilon,-\frac{\epsilon}{2}] \), \( \eta(0) = 1 \) and such that \( \eta'(t) > 0 \) for all \( t \). The desired diffeomorphism is now given by the identity on \( M \setminus ([\epsilon,0] \times C) \) and by stretching \([-\epsilon,0] \times C\) to \([-\epsilon,1] \times C\) via the map \((t,P) \mapsto (\eta(t),P)\).

**Proof of Proposition 105.1.**

(0) It follows from Proposition 8.2 that \( W := M \setminus ([0,1] \times A)\) is a smooth manifold. It follows from Lemma 105.2 that both \( M = ([0,1] \times A) \cup W \) and \( M' = W \cup ([0,1] \times B)\) are diffeomorphic to \( W\).

(1)-(3) The proof of the remaining statements is basically identical to the proof of Proposition 103.5. We only need a minuscule generalization of Lemma 103.6, namely instead of considering diffeomorphisms \( \gamma: \partial Y \to \partial (X \cup h^k) \) we also need to allow diffeomorphisms \( \gamma: C \to D \) where \( C \) is a component of \( \partial Y \) and \( D \) is a component
of \( \partial(X \cup \varphi h^k) \) that contains \( h^k \cap \partial(X \cup \varphi h^k) \). We leave it to the reader to fill in the details.

The following proposition says that we can “stack” relative handle decompositions.

**Proposition 105.3.** Let \( M \) be a compact \( n \)-dimensional smooth manifold and let \( N \) be a compact \( n \)-dimensional smooth manifold. Furthermore let \( A \) be a union of boundary components of \( M \) and let \( B \) be a union of boundary components of \( N \). Next let

\[
M = ([0,1] \times A) \cup_{\varphi_0} h^{k_0} \cup \cdots \cup_{\varphi_r} h^{k_r}
\]

and

\[
N = ([0,1] \times B) \cup_{\psi_0} h^{l_0} \cup \cdots \cup_{\psi_s} h^{l_s}
\]

be handle decompositions rel \( A \) respectively rel \( B \). Finally let \( \Theta : B \to \partial M \setminus A \) be a diffeomorphism. We consider the smooth manifold \( M \cup_{\Theta} N \). There exists a handle decomposition of the form

\[
M \cup_{\Theta} N \cong ([0,1] \times A) \cup_{\varphi_0} h^{k_0} \cup \cdots \cup_{\varphi_r} h^{k_r} \cup_{\psi_0} h^{l_0} \cup \cdots \cup_{\psi_s} h^{l_s}
\]

rel \( A \), where the attaching maps \( \tilde{\psi}_0, \ldots, \tilde{\psi}_s \) are obtained in a hopefully obvious way from the attaching maps \( \psi_0, \ldots, \psi_s \).

**Proof.** We have the following diffeomorphisms:

\[
M \cup_{\Theta} N = M \cup_{\Theta} (([0,1] \times B) \cup_{\psi_0} h^{l_0} \cup \cdots \cup_{\psi_s} h^{l_s}) = (M \cup_{\Theta} ([0,1] \times B)) \cup_{\varphi_0} h^{k_0} \cup \cdots \cup_{\varphi_r} h^{k_r} \cup_{\psi_0} h^{l_0} \cup \cdots \cup_{\psi_s} h^{l_s}
\]

\[
\cong M \cup_{\tilde{\psi}_0} h^{l_0} \cup \cdots \cup_{\tilde{\psi}_s} h^{l_s} = (([0,1] \times A) \cup_{\varphi_0} h^{k_0} \cup \cdots \cup_{\varphi_r} h^{k_r} \cup_{\tilde{\psi}_0} h^{l_0} \cup \cdots \cup_{\tilde{\psi}_s} h^{l_s}.
\]

**Examples.**

1. Let \( M \) be a compact smooth manifold with a handle decomposition

\[
M = \emptyset \cup_{\varphi_0} h^{k_0} \cup \cdots \cup_{\varphi_r} h^{k_r}.
\]

We can view this as a handle decomposition rel \( \emptyset \). By Proposition 105.1, we can equip \( M \) with the dual handle decomposition, which is de facto a handle decomposition rel \( \partial M \). If we glue two copies of \( M \) along the common boundary, i.e., if we consider the double \( D M \), then it follows from Proposition 105.3 that we can stack the original handle decomposition and the dual decompositions. In summary we obtain a handle
decomposition for the double $D_M$ of the form

$$D_M = \emptyset \cup \varphi_0^{k_0} \cup \ldots \cup \varphi_r^{k_r} \cup \varphi_z^{n-k_r} \cup \ldots \cup \varphi_0^{n-k_0}.$$ 

(2) First let $k, l \in \mathbb{N}$.

(a) In Exercise 103.2 we showed that $B^k \times S^l$ admits a handle decomposition rel $\emptyset$ consisting of one 0-handle and one $l$-handle.

(b) By (a) together with Proposition 105.1 we see that $B^k \times S^l$ admits a handle decomposition rel $\partial(B^k \times S^l)$ consisting of one $(k+l)$-handle and one $k$-handle. Now let $m, n \in \mathbb{N}$. In Lemma 27.1 we showed that $S^{m+n-1}$ is diffeomorphic to $(S^{m-1} \times B^1) \cup_{S^{m-1} \times S^{n-1}} (B^m \times S^{n-1})$. Note that by Proposition 105.3 we can stack the handle decomposition of $S^{m-1} \times B^1$ rel $\emptyset$ with the handle decomposition of $B^m \times S^{n-1}$ rel $\partial(B^m \times S^{n-1})$. Thus we see that $S^{m+n-1}$ admits a handle decomposition consisting of four handles of index $0, m-1, m$ and $m+n-1$.

105.2. Morse functions for smooth manifolds with boundary. Our goal will be to show the existence of suitable relative handle decompositions. The key tool to doing so is the following generalization of Proposition 104.6

**Proposition 105.4.** Let $M$ be a compact smooth manifold and let $A$ and $B$ be two disjoint unions of components of $\partial M$. There exists a Morse function $f: M \to [0,1]$ such that $A = f^{-1}(\{0\})$ and such that $B = f^{-1}(\{1\})$.

**Example.** In Figure 1496 we show a surface $M$ with $A$ and $B$ as in Proposition 105.4. We also show a different embedding of $M$ into $\mathbb{R}^3$ such that the height function $(x, y, z) \mapsto z$ has the desired properties.

![Figure 1496](image)

The proof of Proposition 105.4 requires some technical preparations. First let us introduce the following definition.

**Definition.** Let $M$ be a smooth manifold, let $f: M \to \mathbb{R}$ be a smooth function and let $A$ be a union of components of $\partial M$. We say $f$ is pointing inwards on $A$ if for every $P \in A$ and every inward pointing tangent vector $\mathbf{v}$, $P \in T_PM$ we have $Df_P(v) > 0$. Similarly we are defining that $f$ is pointing outwards on $A$.

\[^{1462}\text{We refer to page 291 for the definition of an inward pointing tangent vector.}\]
Lemma 105.5. Let $N$ be a closed smooth manifold and let $f: [0, 1] \times N \to \mathbb{R}$ be a smooth function that is pointing inwards on $\{0\} \times N$ and that has no critical points. There exists a smooth function $g: [0, 1] \times N \to \mathbb{R}$ with the following properties:

1. The map $g$ agrees with $f$ on $[\frac{1}{2}, 1] \times N$.
2. The map $g$ has no critical points and it is pointing inwards on $\{0\} \times N$.
3. The map $g$ is constant on $\{0\} \times N$ and the value on $\{0\} \times N$ equals the minimum of $g$ on $[0, 1] \times N$.

Sketch of a proof of Lemma [105.5]. We pick some $s \in \mathbb{R}$ that is less than the minimum of $f$ on $[0, 1] \times N$. Using Lemma 6.13 it is pretty straightforward to see that there exist smooth maps $\alpha, \beta: [0, 1] \to \mathbb{R}$ with $\alpha + \beta \equiv 1$, $\alpha(t) = 1$ for sufficiently small $t$ and $\beta(t) = 1$ for $t \in [\frac{1}{2}, 1]$ such that the map

$$g: [0, 1] \times N \to \mathbb{R}$$

$$(t, P) \mapsto \alpha(t) \cdot (s + t) + \beta(t) \cdot f(P, t)$$

has all the desired properties. We leave it to the reader to fill in the dull technical details.

Sketch of a proof of Proposition [105.4]. Let $M$ be a compact smooth manifold and let $A$ and $B$ be two disjoint unions of components of $\partial M$. A slight refinement of Proposition 11.8 shows that we can view $M$ as a submanifold of $\{x \in \mathbb{R}^n \mid \|x\| \in [1, 2]\}$ such that $\varphi(A) \subset S_1^{n-1}$ and such that $\varphi(B) \subset S_2^{n-1}$. Using the Collar Neighborhood Theorem 8.12 we obtain collar neighborhoods $[0, 1] \times A$ and $[0, 1] \times B$.

As in the proof of Proposition 104.5 one can show that given any $\epsilon > 0$ there exists a $Q \in \overline{B}_\epsilon$ such that

$$f_Q: M \to \mathbb{R}$$

$$x \mapsto \|x - Q\|^2$$

is a Morse function. It is straightforward to see that by picking a sufficiently small $\epsilon > 0$ we can arrange that $f_Q: M \to \mathbb{R}$ is pointing inwards on $A$ and that it is pointing outwards on $B$. Thus, Using Lemma 105.5 applied to $[0, 1] \times A$ and $[0, 1] \times B$ we can modify $f_Q$ to obtain a Morse function on $M$ that is constant on $A$ and that is constant on $B$ and such that all other values lie between the values on $A$ and $B$. After rescaling we have obtained the desired Morse function.

A more detailed and authoritative proof of Proposition 105.4 is given in [Miln65b, Theorem 2.3].
105.3. The Relative Handle Decomposition Theorem. Our goal in this section is to prove the following refinement of the Handle Decomposition Theorem 104.11.

Theorem 105.6. (Relative Handle Decomposition Theorem) Let \( M \) be a compact \( n \)-dimensional smooth manifold. Given any union \( A \) of components of \( \partial M \) there exists a handle decomposition of \( M \) rel \( A \).

Proof of the Relative Handle Decomposition Theorem 105.6. Let \( M \) be a compact smooth manifold and let \( A \) be a union of components of \( \partial M \). We denote by \( B \) the union of the remaining components of \( \partial M \). By Proposition 105.4 there exists a Morse function \( f: M \to [0, 1] \) such that \( A = f^{-1}(\{0\}) \) and \( B = f^{-1}(\{1\}) \). We make the following two observations:

(a) Since \( \partial M = A \cup B \) we have \( f^{-1}((0, 1)) \cap \partial M = \emptyset \).

(b) Note that \( A \cup B = \partial M \). Thus, by definition of a Morse function, \( A \) and \( B \) do not contain critical points, in other words, 0 is not a critical value and 1 is not a critical value.

By Corollary 104.4 (2) the Morse function has only finitely many critical points. We order the critical values by \( 0 < \lambda_1 < \cdots < \lambda_s < 1 \). (Note that by (b) we know that \( 0 < \lambda_1 \) and \( \lambda_s < 1 \).) We pick real numbers \( 0 < \epsilon < \mu_0 < \lambda_1 < \mu_1 < \lambda_2 < \mu_2 < \cdots < \mu_{s-1} < \lambda_s < 1 = \mu_s \).

Note that it follows from (a) and the Regular Value Theorem 6.53 that \( f^{-1}(\{\epsilon\}) \) is a closed submanifold of \( M \). Thus it follows from the Smooth Manifold Product Theorem 104.8 that \( M_{\epsilon} = f^{-1}([0, \epsilon]) \) is diffeomorphic to \( [0, 1] \times A \).

Next note that it follows from Theorem 104.9 and (a) that for each \( i \in \{1, \ldots, s\} \) there exists a diffeomorphism from \( M_{\mu_i} \) to the result of attaching finitely many handles to \( M_{\mu_{i-1}} \). Furthermore, Theorem 104.9 says that we can find such a diffeomorphism that is the identity on the common subset \( M_{\epsilon} \). This shows that \( M = M_{\mu_s} \) admits a handle decomposition rel \( A \).
Finally note that it follows immediately from iteratively applying Proposition 103.3 that we can rearrange our handle attachments to obtain a standard handle decomposition of $M \text{ rel } A$.

![Diagram of handle decomposition]

**Figure 1499.** Illustration for the proof of Theorem 105.6.

We conclude this section with the following generalization of Proposition 104.12.

**Proposition 105.8.** Every compact smooth manifold is homotopy equivalent to a finite CW-complex.

**Proof.** This statement follows immediately from the Handle Decomposition Theorem 105.7 together with Proposition 103.18.

### 105.4. Constructing Morse functions from handle decompositions.

By the Handle Addition Theorem 104.9, we know that Morse functions give rise to handle decompositions. In this section we will see that we can also go backwards. For example we have the following converse to Theorem 104.9.

**Proposition 105.9.** Let $M$ be a compact smooth manifold and suppose we are given a decomposition $\partial M = A \sqcup B$ where $A$ and $B$ are unions of components of $\partial M$.

1. Let $\varphi : B^{n-k} \times S^{k-1} \to B$ be a thickened $(k-1)$-sphere and let $f : M \to \mathbb{R}$ be a map that points inwards on $A$ and that points outwards on $B$. Then there exists a smooth map $g : M \cup_\varphi h^k \to \mathbb{R}$ with the following properties:
   a. The restriction of $g$ to $M$ equals $f$.
   b. $g$ points outwards on $\partial(M \cup_\varphi h^k) \setminus A$.
   c. In the handle $B^{n-k} \times B^k$ the map $g$ has precisely one critical point, and this critical point has index $k$.

2. If $M$ is equipped with a handle decomposition $M \cong ([0, 1] \times A) \cup_{\varphi_1} h^1 \cup \ldots \cup_{\varphi_m} h^m$ rel $A$, then there exists a smooth map $g : M \to \mathbb{R}$ with the following properties:
   a. On $[0, 1] \times A$ the map $g$ equals the projection onto $[0, 1]$.
   b. The map $g$ has precisely $m$ critical points $P_1, \ldots, P_m$, each of which is non-degenerate and such that for $i = 1, \ldots, m$ the index of the critical point $P_i$ equals the index of the handle $\varphi_i$.

**Proof.**

1. This statement is proved by running the proof of Theorem 104.9 “backwards”. In particular the idea is, to define $g$ on the $k$-handle to be a suitable modification of the
function
\[
\bar{B}^k \times \bar{B}^{n-k} \to \mathbb{R} \\
(x_1, \ldots, x_k, y_1, \ldots, y_{n-k}) \mapsto -x_1^2 - \cdots - x_k^2 + y_1^2 + \cdots + y_{n-k}^2.
\]

We refer to [Kos93, p. 130] for the details.

(2) This statement follows immediately from applying (1) altogether \(m\) times.

We conclude this section with a neat refinement of Proposition 104.6. To formulate the result we introduce the following definition.

**Definition.** Let \(M\) be a compact \(n\)-dimensional smooth manifold and suppose we are given a decomposition \(\partial M = A \sqcup B\) where \(A\) and \(B\) are unions of components of \(\partial M\). A Morse function \(f: M \to \mathbb{R}\) is called *self-indexing with respect to \(A\) and \(B\)*, if the following conditions are satisfied.

1. We have \(f|_A \equiv -\frac{1}{2}\) and \(f|_B \equiv n + \frac{1}{2}\).
2. If \(P\) is a critical point of \(f\), then \(f(P) = \text{index}(f, P)\).

**Proposition 105.10.** Let \(M\) be a compact \(n\)-dimensional smooth manifold and suppose we are given a decomposition \(\partial M = A \sqcup B\) where \(A\) and \(B\) are unions of components of \(\partial M\). There exists a self-indexing Morse function \(f: M \to \mathbb{R}\) with respect to \(A\) and \(B\).

**Sketch of proof.** Let \(M\) be a compact \(n\)-dimensional smooth manifold and suppose we are given a decomposition \(\partial M = A \sqcup B\) where \(A\) and \(B\) are unions of components of \(\partial M\). By the Handle Decomposition Theorem 104.11 there exists a standard handle decomposition
\[
M = ([0, 1] \times A) \cup_{\varphi_{0,1}^0} h_0 \cdots \cup_{\varphi_{0,r_0}^0} h_0 \cup \cdots \cup_{\varphi_{n,1}^n} h^n \cdots \cup_{\varphi_{n,r_n}^n} h^n
\]

with \(0\)-handles and \(n\)-handles.
rel $A$. Given $i \in \{-1, \ldots, n\}$ we denote by $M_i$ the $i$-skeleton of the relative handle decomposition and we set $B_i := \partial M_i \setminus A$. It suffices to prove the following claim.

**Claim.** For $i = -1, \ldots, n$ there exists a Morse function $f_i$ on $M_i$ with the following properties:

1. We have $f|_A \equiv -\frac{1}{2}$ and $f|_{B_i} \equiv i + \frac{1}{2}$.
2. If $P$ is a critical point of $f_i$, then $f_i(P) = \text{index}(f_i, P)$.

For $i = -1$ we have $M_i = [0, 1] \times A$ and we choose the map that is given by $(t, a) \mapsto t - \frac{1}{2}$. Now suppose the claim holds for some $i \in \{-1, \ldots, n-1\}$. By Proposition 105.9 we can extend the map $f_i : M_i \to \mathbb{R}$ to a Morse function on $g : M_{i+1} \to \mathbb{R}$ such that $g$ has precisely $r_{i+1}$ extra critical points, and each of these critical points has index $i + 1$. Note that the value of $g$ on these critical points is necessarily greater than $i + \frac{1}{2}$ and that the value of $g$ on each $S^{n-k-1} \times B^k$ is greater than $i + 1$. By rescaling, see Exercise 104.4, we can arrange that the value of $g$ at each of these critical points is precisely $i + 1$ and we can arrange that the value of $g$ on each $S^{n-k-1} \times B^k$ is greater than $i + \frac{1}{2}$. The values of $g$ on $B_i$ now lie in $[i + \frac{1}{2}, i + \frac{3}{2})$ and $g$ points outwards on $B_i$. Using a collar neighborhood for $B_i$ together with Lemma 105.5 it is now fairly straightforward to arrange that the map $g$ actually equals $i + \frac{3}{2}$ on $B_i$. As always, the adventurous reader is warmly invited to fill in the details. ■

For full details we refer to the original proof by Stephen Smale [Sma61b, Theorem C]. Alternatively the statement is also proved in [Miln65b, p. 45] and [Nic11, Chapter 2.4].

105.5. **Handle decompositions of topological manifolds.** The notion of a handle decomposition also makes sense, with a few suitable modifications in the definition, for compact topological manifolds. So the question arises, does every compact topological manifold admit a handle decomposition? It turns out that this is a subtle question.

1. By Theorem ?? every compact topological manifold of dimension $\leq 3$ admits a smooth structure. Thus it follows from Theorem 105.7 that every such topological manifold admits a handle decomposition.

2. Rob Kirby and Larry Siebenmann [KSi77, Essay III.2, Theorem 2.1] (see also [Kupe17b, Theorem 1.22]) showed that every compact topological manifold of dimension $\geq 6$ admits a topological handle decomposition. Later Frank Quinn [Qu82, Theorem 2.3.1] extended this result to the 5-dimensional setting.

3. It follows from Proposition ?? that every closed 4-dimensional topological manifold that admits a topological handle decomposition also admits a smooth structure. But in Theorem 102.9 we saw that there exist closed 4-dimensional topological manifolds that do not admit a smooth structure. In particular there exist closed 4-dimensional topological manifolds that do not admit a handle decomposition.

---

**Exercises for Chapter 105.**

**Exercise 105.1.** In Figure 1502 we show once again $M$, the torus with two disks removed. Let $A$ be one of the two boundary components. In Figure 1492 we showed that $M$ admits
a handle decomposition rel $A$ with one 0-handle, three 1-handles and one 2-handle. Does there exist a handle decomposition of $M$ rel $A$ with fewer handles?

![Diagram](image)

**Figure 1502. Illustration of Exercise 105.1**

**Exercise 105.2.** Let $M$ be a compact connected non-empty smooth manifold that is equipped with a handle decomposition. On page 2522 we saw that the double $D M$ comes with a canonical handle decomposition. For which dimensions of $M$ can you use this fact to argue that the inclusion induced map $\pi_1(M) \to \pi_1(D M)$ is an isomorphism?

**Exercise 105.3.** Give an explicit self-indexing Morse function for the torus $S^1 \times S^1$ and the Klein bottle.

![Diagram](image)

**Figure 1503. Illustration for Exercise 105.3**
106. HANDLE HOMOLOGY AND THE MORSE INEQUALITIES

In this chapter we will see that a handle decomposition of a compact smooth manifold gives rise to a chain complex, namely the handle chain complex. This chain complex can be viewed as an analogue of the cellular chain complex of a CW-complex. We will see that the corresponding homology groups, called handle homology groups, are naturally isomorphic to the usual singular homology groups. We will use this isomorphism to prove the Morse inequalities, which show that the “size” of singular homology groups gives a lower bound on the number of singularities of a Morse function on a given smooth manifold.

106.1. Handle homology. In Chapter 48 we introduced the cellular chain complex of a CW-complex $X$. Recall that this chain complex has the following two features:

1. The chain groups are defined to be $C^\text{CW}_k(X) := H_k(X^k, X^{k-1})$. By Lemma 48.1 this chain group can be viewed as the free abelian groups on the set of $k$-cells.
2. The corresponding cellular homology groups are naturally isomorphic to the singular homology groups.

In this section we will outline how one can perform something very similar in the setting of smooth manifolds with a given handle decomposition.

The following lemma is an analogue of Lemma 48.1.

**Lemma 106.1.** Let $M$ be a compact $n$-dimensional smooth manifold together with a standard handle decomposition

$$M \equiv \varnothing \cup \bigcup_{i=1}^{r_0} \varphi_{0,i}^0 \cup \ldots \cup \bigcup_{i=1}^{r_n} \varphi_{n,i}^n,$$

Let $k \in \mathbb{N}_0$. As on page 2481 we denote by $M^k$ the $k$-skeleton of the handle decomposition, i.e. $M^k$ is union of all handles of index $\leq k$.

(1) Let $k \in \{0, \ldots, n\}$. Given $i \in \{1, \ldots, r_i\}$ we denote by $\Phi_{k,i} : \overline{B}_i^k \to \{0\} \times \overline{B}_i^k \to M^k$ the map that is given by the inclusion map of the core of the $i$-th $k$-handle. For every $k, j \in \mathbb{N}_0$ the following map is an isomorphism:

$$\bigoplus_{i=1}^{r_i} \Phi_{k,i} : \bigoplus_{i=1}^{r_i} \mathbb{H}_j(\overline{B}_i^k, \partial \overline{B}_i^k) \to \mathbb{H}_j(M^k, M^{k-1}).$$

In particular the following holds:

(a) For $i \neq k$ we have $\mathbb{H}_i(M^k, M^{k-1}) = 0$.
(b) The group $\mathbb{H}_k(M^k, M^{k-1})$ is a free abelian group where the rank equals the number of $k$-handles.

(2) For $i > k$ we have $\mathbb{H}_i(M^k) = 0$.

(3) For $i < k$ the inclusion $j : M^k \to M$ induces an isomorphism $j_* : \mathbb{H}_i(M^k) \cong \mathbb{H}_i(M)$.

(4) The inclusion $j : M^k \to M$ induces an epimorphism $j_* : \mathbb{H}_k(M^k) \to \mathbb{H}_k(M)$.

---

Note that this definition makes sense since the handle decomposition is standard.
Note that by definition of a standard handle decomposition, see page 2481, the restriction of $\Phi_{k,i}$ to $\partial \overline{B}_i^k$ does indeed take values in $M^{k-1}$. 
**Remark.** The statement of Lemma 106.1 (3) and (4) is very similar in spirit to the content of Exercise 103.12.

**Proof.** Not surprisingly the proof of the lemma is very similar to the proof of Lemma 48.1. But completeness sake let us go through the motions.

1. We consider the following diagram

\[
\bigoplus_{i=1}^{r_i} H_k(B_i^k, \partial B_i^k) \xrightarrow{\bigoplus \Phi_{k,i}} H_k(M^k, M^{k-1}) \]

The left vertical map is induced by the inclusions \( x \mapsto (0, x) \). It is an isomorphism by Corollary 43.18. The bottom horizontal map is induced by homeomorphisms, thus it is also an isomorphism. Next note that the right vertical map is induced by the obvious inclusions. It follows almost immediately from the Excision Theorem 89.2 that the right vertical map is an isomorphism. Clearly he diagram clearly commutes. Hence we get that the top horizontal map is indeed an isomorphism. Finally the “in particular” statements now follow immediately from Lemma 45.1.

2. We fix \( i \in \mathbb{N} \). We want to show that \( H_i(M^k) = 0 \) for \( k = 0, \ldots, i-1 \). First of all we have \( H_i(M^0) = 0 \) since \( M^0 \) is diffeomorphic to a disjoint union of \( n \)-balls. Now assume that we already know that \( H_i(M^k) = 0 \) for some \( k < i-1 \). We want to show that \( H_i(M^{k+1}) = 0 \). We consider the long exact sequence of the pair \((M^{k+1}, M^k)\):

\[
\cdots \rightarrow H_{i+1}(M^{k+1}, M^k) \rightarrow H_i(M^k) \rightarrow H_i(M^{k+1}) \rightarrow H_i(M^{k+1}, M^k) \rightarrow \cdots
\]

Thus we obtain that indeed \( H_i(M^{k+1}) = 0 \).

3. We fix \( i \in \mathbb{N}_0 \). Let \( m > i \). This time we consider the following excerpt from the long exact sequence of the pair \((M^{m+1}, M^m)\):

\[
\cdots \rightarrow H_{i+1}(M^{m+1}, M^m) \rightarrow H_i(M^m) \rightarrow H_i(M^{m+1}) \rightarrow H_i(M^{m+1}, M^m) \rightarrow \cdots
\]

This discussion implies in particular that we have inclusion induced isomorphisms \( H_i(M^k) \cong H_i(M^{k+1}) \cong \cdots \cong H_i(M^n) = H_i(M) \).
(4) In (3) we showed that the inclusion induced map $H_k(M^{k+1}) \to H_k(M)$ is an isomorphism. Thus it suffices to show that the inclusion induced map $H_k(M^k) \to H_k(M^{k+1})$ is an epimorphism. To show this we consider the following excerpt from long exact sequence of the pair $(M^{k+1}, M^k)$:

$$
\ldots \to H_{k+1}(M^{k+1}, M^k) \to H_k(M^k) \to H_k(M^{k+1}) \to H_k(M^{k+1}, M^k) \to \ldots
$$

We see that the inclusion induced map $H_k(M^k) \to H_k(M^{k+1})$ is indeed an epimorphism.

**Lemma 106.2.** Let $M$ be compact smooth manifold together with a standard handle decomposition. Given $k \in \mathbb{N}_0$ we denote by $d = d_k$ the map

$$
H_k(M^k, M^{k-1}) \xrightarrow{\partial_k} H_{k-1}(M^{k-1}) \xrightarrow{j_{k-1}} H_{k-1}(M^{k-1}, M^{k-2})
$$

where $\partial_k$ is the connecting map in the long exact sequence of the pair $(M^k, M^{k-1})$ and where $j_{k-1}$ is the map induced by the projection $C_{k-1}(M^{k-1}) \to C_{k-1}(M^{k-1}, M^{k-2})$. These maps have the property that for every $k \in \mathbb{N}_0$ we have $d_k \circ d_{k+1} = 0$.

**Proof.** This proof is easy. We just need to copy-paste the proof of Lemma 48.2. Thus we consider the following commutative diagram of maps

$$
\begin{array}{ccc}
H_{k+1}(M^{k+1}, M^k) & \xrightarrow{d_{k+1}} & H_k(M^k) \\
\xrightarrow{\partial_{k+1}} & & \xrightarrow{j_k} \\
H_k(M^{k+1}, M^k) & \xrightarrow{d_k} & H_{k-1}(M^{k-1}, M^{k-2}) \\
& \xrightarrow{\partial_k} & \xrightarrow{j_{k-1}} \\
& & H_{k-1}(M^{k-1})
\end{array}
$$

The map $\partial_k \circ j_k : H_k(M^k) \to H_{k-1}(M^{k-1})$ is the composition of two successive maps in the long exact sequence of the pair $(M^k, M^{k-1})$, i.e. the map $\partial_k \circ j_k$ is the zero map. Since the diagram commutes we obtain that $d_k \circ d_{k+1} = 0$.

**Definition.** Let $M$ be compact smooth manifold together with a standard handle decomposition.

1. We refer to the map $d_k$ from Lemma 106.2 as the **handle boundary map**.
2. We write $C^\text{han}_k(M) := H_k(M^k, M^{k-1})$ and we refer to $(C^\text{han}_k(M), d_*)$ as the **handle chain complex**.
3. We denote the homology groups of the handle chain complex by $H^\text{han}_k(M)$ and we refer to these groups as the **handle homology groups of the smooth manifold $M$ with the given handle decomposition**.

\[\text{It follows from Lemma 106.2 that } (H_k(M^k, M^{k-1}), d_k)_{k \in \mathbb{N}_0} \text{ is indeed a chain complex.}\]
In Proposition 48.4 we showed that for a CW-complex the singular and cellular homology groups are naturally isomorphic. The following proposition proves the analogous statement in our present setting.

**Proposition 106.3.** Let $M$ be a compact smooth manifold together with a standard handle decomposition. Given any $k \in \mathbb{N}_0$ there exists a uniquely determined natural isomorphism

$$\Phi_M: H_k(M) \xrightarrow{\cong} H^\text{han}_k(M)$$

with the property that the following diagram commutes:

$$\xymatrix{ H_k(M) \ar[r]^{\Phi_M} & H^\text{han}_k(M) \ar[d]^{j_k} \ar[r] & \ker(d_k) \ar[d]^{j_k} \ar[r] & \ker(d_k) \ar[d]^{j_k} \ar[r] & 0}$$

In particular, in light of the above and Corollary 42.8, the isomorphism type of the handle homology groups depends only on the homotopy type of $M$.

**Proof of Proposition 106.3.** The proof of Proposition 106.3 is almost embarrassingly similar to the proof of Proposition 48.4 (1). For the reader’s convenience we nonetheless provide an abbreviated version of the argument. As in the proof of Proposition 48.4 (1) we add a couple of maps to the commutative diagram that we had already encountered in the proof of Lemma 106.2.

![Diagram](https://via.placeholder.com/150)

Recall that by Lemma 106.1 (1) and (2) we know that $H_k(M^{k+1}, M^k) = 0$, $H_k(M^{k-1}) = 0$ and $H_{k-1}(M^{k-2}) = 0$. It follows almost immediately from these facts that the diagonal

---

1466 We leave it to the reader to figure out what “natural” should mean in this context.

1467 Here we again denote by $j_k: H_k(M^k) \to H_k(M^k, M^{k-1})$ the obvious map. In the long exact sequence of the pair $(M^k, M^{k-1})$ we see that the image of $H_k(M^n)$ in $H_k(M^k, M^{k-1})$ lies in the kernel of the connecting homomorphism $\partial_k$. This implies that the map $j_k: H_k(M^k) \to H_k(M^k, M^{k-1})$ takes values in $\ker(d_k)$.
sequences in the above diagram are exact. Next we consider the diagram:

\[
\begin{align*}
H_k(M^k) / \text{im}(\partial_{k+1}) &\xrightarrow{\cong} H_k(M^{k+1}) \xrightarrow{} H_k(M), \\
\ker(d_k) / \text{im}(d_{k+1}) &\xrightarrow{\text{id}} H_k^{\text{han}}(M)
\end{align*}
\]

a diagram chase shows that \(j_k\) induces an isomorphism \(\Phi_M\) such that the following diagram commutes:

\[
\begin{array}{ccc}
H_k(M^k) & \xrightarrow{\Phi} & H_k^{\text{han}}(M) \\
\ker(d_k) & \xrightarrow{j_k} & \end{array}
\]

Next note that by construction the isomorphism \(\Phi_M\) has the property that the following diagram commutes:

\[
\begin{array}{ccc}
H_k(M) & \xrightarrow{\Phi} & H_k^{\text{han}}(M) \\
\ker(d_k) & \xrightarrow{j_k} & \end{array}
\]

Note that the top-left diagonal map is an epimorphism by Lemma 106.1 (4). This implies immediately that \(\Phi_M\) is uniquely determined.

Finally we leave it to the reader who figured out what it means for the isomorphism to be “natural” to actually show that it is natural.

In the next section we will discuss a practical approach to calculating the boundary maps in the handle chain complex. But even without this knowledge we can already obtain interesting consequences of Proposition 106.3. For example we can prove the following corollary.

**Corollary 106.4.** Let \(M\) be a compact smooth manifold. Given any handle decomposition for \(M\) the following equality holds:

\[
\sum_{k \in \mathbb{N}_0} (-1)^k \cdot \text{number of } k\text{-handles} = \chi(M).
\]

**Proof.** Let \(M\) be a compact smooth manifold together with a handle decomposition. Given \(k \in \mathbb{N}_0\) we denote by \(c_k\) the number of \(k\)-handles. By Corollary 103.4 we can find a standard handle structure on \(M\) such that for every \(k \in \mathbb{N}_0\) the number of \(k\)-handles also equals \(c_k\). Using this new handle decomposition we perform the following calculation:

\[
\begin{align*}
\chi(M) &= \sum_{k \in \mathbb{N}_0} (-1)^k \cdot \text{rk}(H_k(M)) \\
&= \sum_{k \in \mathbb{N}_0} (-1)^k \cdot \text{rk}(H_k^{\text{han}}(M)) \\
&= \sum_{k \in \mathbb{N}_0} (-1)^k \cdot \text{rk}(C_k^{\text{han}}(M)) \\
&= \sum_{k \in \mathbb{N}_0} (-1)^k \cdot c_k.
\end{align*}
\]

\[\text{by Lemma 55.3} \quad \text{by Lemma 106.1} \]

Admittedly we could already have proved that particular corollary earlier on, namely using Lemma 103.13. This was precisely the content of Exercise 103.10.
Next we obtain the following corollary.

**Corollary 106.5.** The Euler characteristic of every closed odd-dimensional smooth manifold is zero.

**Remark.** In Proposition 88.7 we used Poincaré Duality to prove a generalization of Corollary 106.5 to compact odd-dimensional topological manifolds.

**Proof.** Let \( M \) be a closed \( (2n+1) \)-dimensional smooth manifold. By the Handle Decomposition Theorem (104.11) we can equip \( M \) with a handle decomposition. By Proposition 103.5 we can also consider the corresponding dual handle decomposition. Now we see that

\[
\chi(M) = \sum_{k=0}^{2n+1} (-1)^k \cdot \text{number of } k\text{-handles in the handle decomposition} = \sum_{k=0}^{2n+1} (-1)^k \cdot \text{number of } (2n+1-k)\text{-handles in the dual handle decomposition}
\]

Thus we see that \( \chi(M) = 0 \).

We conclude this section with an even more pleasing corollary.

**Corollary 106.6.** Let \( M \) be a closed smooth manifold. For every Morse function \( f: M \to \mathbb{R} \) we have

\[
\sum_{k \in \mathbb{N}_0} (-1)^k \cdot \# \text{critical points of } f \text{ of index } k = \chi(M).
\]

**Remark.**

1. For \( M = S^2 \) the statement of Corollary 106.6 implicitly appears already in a paper written by Clerk Maxwell [Max1870] in 1870 with the beautiful title “on hills and dales”.

2. In Exercise 106.13 we will see that Corollary 106.6 can also be deduced from the Poincaré-Hopf Theorem 97.5.

**Proof.** Let \( f: M \to \mathbb{R} \) be a Morse function on a closed smooth manifold. It follows from Proposition 104.10 that \( M \) admits a handle decomposition such that for each \( k \in \mathbb{N}_0 \) the number of \( k \)-handles equals the number of critical points of index \( k \). The desired equality now follows immediately from Corollary 106.4.

106.2. **The boundary maps in the handle chain complex.** The following proposition is a useful tool for calculating the boundary maps in a given handle chain complex.

**Proposition 106.7.** Let \( M \) be an oriented \( n \)-dimensional smooth manifold together with a standard handle decomposition

\[
M \cong \emptyset \cup \varphi_{0,1} h^0 \cup \ldots \cup \varphi_{0,r_0} h^0 \cup \ldots \cup \varphi_{n,1} h^n \cup \ldots \cup \varphi_{n,r_n} h^n.
\]

The boundary maps in the handle chain complex are given by

\[
\partial h^k = \sum_{l=0}^k (-1)^l \varphi_{l,k} h^{k-l}.
\]
We assume that the inclusion maps of all the handles are orientation-preserving. Given \( k \in \mathbb{N}_0 \) and given \( i \in \{1, \ldots, r_i\} \) we denote by \( \Phi_{k,i} \colon \{0\} \times \overline{B}^k \rightarrow M^k \) the map that is given by the inclusion map of the core of the handle. By Lemma 106.1 we know that

\[
\mathcal{B}_k := \{ \Phi_{k,1*}([\{0\} \times \overline{B}^k]), \ldots, \Phi_{k,r_k*}([\{0\} \times \overline{B}^k]) \}
\]

is a basis of \( \mathcal{H}^\text{han}_k(M) := H_k(M^k, M^{k-1}) \). Given \( j \in \{1, \ldots, r_k\} \) and \( i \in \{1, \ldots, r_i\} \) we have the following equality.

\[
(i, j)\text{-entry of the matrix representing } d_{k+1} \colon H^\text{han}_{k+1}(M) \rightarrow H^\text{han}_k(M)
\]

with respect to the bases \( \mathcal{B}_{k+1} \) and \( \mathcal{B}_k \) is the algebraic intersection number in \( \partial M_k \) of the attaching sphere of the \((k+1, j)\)-handle with the belt sphere of the \((k, i)\)-handle.

**Example.** We consider the 3-dimensional smooth manifold \( M \) which is shown in Figure 1505. It has three 0-handles, three 1-handles and two 2-handles. Using Proposition 106.7 one sees that the corresponding handle chain complex is isomorphic to the following chain complex:

\[
0 \rightarrow \mathbb{Z} \left( \begin{array}{ccc} 0 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 1 & 0 \end{array} \right) \mathbb{Z} \rightarrow \mathbb{Z} \left( \begin{array}{ccc} 0 & 1 & 0 \\ -1 & 1 & 0 \\ 1 & -1 & 0 \end{array} \right) \mathbb{Z} \rightarrow 0.
\]

Thus we obtain that \( H^\text{han}_k(M) \cong \begin{cases} 0, & \text{if } k \geq 3, \\
\mathbb{Z}, & \text{if } k = 2, \\
\mathbb{Z}, & \text{if } k = 1, \\
\mathbb{Z}^2, & \text{if } k = 0. \end{cases} \)

By Lemma 103.2 (2) we know that the component of \( M \) that is given by gluing the first 2-handle to the first 0-handle is diffeomorphic to \( \mathbb{B}^3 \times S^2 \). But what we can say about the other component of \( M \)? We will answer this question on page ??.

**Remark.** Let \( M \) be an oriented smooth manifold that is equipped with a standard handle decomposition.

1. If the various attaching spheres and the belt spheres intersect transversally, then we know by Theorem 94.3 that the algebraic intersection number of the attaching spheres and the belt spheres can be determined in a pleasingly geometric way. If the right-hand side note that \( \partial M_k \) is a compact oriented \((n-1)\)-dimensional smooth manifold, the attaching sphere of the \((k+1, j)\)-handle is an oriented \( k \)-dimensional sphere in \( \partial M_k \) and the belt sphere of the \((k, i)\)-handle is an oriented \((n-k-1)\)-dimensional sphere in \( \partial M_k \). So, according to the definition on page 2280 it makes sense to consider in \( \partial M_k \) the algebraic intersection number of the two spheres.
they do not intersect transversally, do no despair, since we can iteratively apply the Transversality Theorem 106.10 to find an isotopy of the attaching spheres so that the resulting attaching spheres intersect the belt spheres transversally. By Proposition 106.7 (4) these isotopies do not change the diffeomorphism type of the smooth manifold. Put differently, after possibly fiddling a little bit with the handle decomposition we can compute the handle homology groups using intersection numbers of transverse spheres.

(2) In (1) we just argued that the boundary maps in the handle chain complex can be determined geometrically. In [DGK19] this approach is used to define handle homology without referring to singular homology. Furthermore in [DGK19] it is shown using the Cerf Theorem ??, but again without making use of singular homology groups, that the isomorphism types of these geometrically defined handle homology groups only depend on the diffeomorphism type of the underlying smooth manifold. An outline of the argument is also given in [GoS99, Chapter 4.2].

In fact this approach, together with Lemma 103.6, can be used to give an alternative proof of some of the statements of the Poincaré Duality Theorem 88.1. We refer to [Kos93, Theorem VII.5.1] and [DGK19] for details.

Proof. Let \( M \) be an oriented \( n \)-dimensional smooth manifold together with a standard handle decomposition

\[
M \cong \emptyset \cup \bigcup_{\varphi_{0,r_0}} h_0^0 \cup \cdots \cup \bigcup_{\varphi_{0,r_0}} h_n^0 \cup \cdots \cup \bigcup_{\varphi_{n,r_n}} h_n^0 \cup \bigcup_{\varphi_{n,r_n}} h_n
\]

which has the property that the inclusion maps of all the handles are orientation-preserving. Let \( k \in \mathbb{N}_0 \), let \( j \in \{1, \ldots, r_k+1\} \) and let \( i \in \{1, \ldots, r_k\} \). We introduce the following notation:

1. We denote by \( W \) the result of attaching to \( M^{k-1} \) all \( k \)-handles except for the \( i \)-th \( k \)-handle.
2. We denote by \( \alpha: \overline{B^{n-k}} \times \overline{B^k} \to M^k \) the embedding corresponding to the \((k, i)\)-handle. Since the handle decomposition is standard we see that \( \alpha(\overline{B^{n-k}} \times S^{k-1}) \subset M^{k-1} \subset W \).
3. Furthermore note that \( \alpha(S^{n-k-1} \times \{0\}) \) is the belt sphere of the \((k, i)\)-handle.

We refer to Figure 1506 for an illustration.
Next we consider the following diagram:

\[
\begin{array}{cccccc}
H_{k+1}(\{0\} \times B^{k+1}_n, \{0\} \times S^k) & \beta_* & H_{k+1}(M^{k+1}, M^k) & \partial_{k+1} & H_k(M^k) \\
& \beta_* & H_k(M^k, W) & \downarrow & H_k(M^k, M^{k-1}) \\
H_k(\{0\} \times S^k) & \downarrow & H_k(M^k, W) & \cong & H_k(M^k, M^{k-1}) \\
\alpha_* & \cong & \alpha_*^{-1} \\
H_k(\partial M_k, \partial M_k \setminus \alpha(S^{k-1} \times B^{n-k})) & \downarrow & H_k(\partial M_k, \partial M_k \setminus \alpha(S^{k-1} \times B^{n-k})) & \downarrow & H_k(\partial M_k, \partial M_k \setminus \alpha(S^{k-1} \times B^{n-k})) \\
\alpha_* & \cong & \alpha_*^{-1} \\
H_k(S^{n-k-1} \times B^k, S^{n-k-1} \times S^{k-1}) & \downarrow & H_k(\bar{B}^{n-k} \times B^k, \bar{B}^{n-k} \times S^{k-1}) & \downarrow & \mathbb{Z} \\
\sigma \to \tilde{Q}(|S^{n-k-1} \times \{0\}|, \sigma) & \downarrow & \mathbb{Z} & \downarrow & \mathbb{Z} \\
\mathbb{Z} & \cong & \mathbb{Z}.
\end{array}
\]

We make the following clarifications and observations:

1. By a slight abuse of notation we denote all of the following inclusion maps by \( h \):

\[
h: \alpha(\bar{B}^{n-k} \times B^k) \to M^k \\
h: (\alpha(\bar{B}^{n-k} \times B^k), \alpha(\bar{B}^{n-k} \times S^{k-1})) \to (M^k, W) \\
h: (\alpha(S^{n-k-1} \times B^k), \alpha(S^{n-k-1} \times S^{k-1})) \to (\partial M_k, \partial M_k \setminus \alpha(S^{k-1} \times B^{n-k})).
\]

2. It follows from the Excision Theorem 89.2 that the maps

\[
h_*: H_k(\alpha(\bar{B}^{n-k} \times B^k), \alpha(\bar{B}^{n-k} \times S^{k-1})) \to H_k(M^k, W) \quad \text{and}
\\
h_*: H_k(\alpha(S^{n-k-1} \times B^k), \alpha(S^{n-k-1} \times S^{k-1})) \to H_k(\partial M_k, \partial M_k \setminus \alpha(S^{k-1} \times B^{n-k}))
\]

are isomorphisms.
(3) We consider the two asymmetric intersection pairings

\[ Q : \text{FH}_{n-k-1}(S^{n-k-1} \times B_k) \times \text{FH}_k(S^{n-k-1} \times B_k, S^{n-k-1} \times S^{k-1}) \rightarrow \mathbb{Z} \]

\[ \tilde{Q} : \text{FH}_{n-k}(B^{n-k} \times B_k, S^{n-k-1} \times B_k) \times \text{FH}_k(B^{n-k} \times B_k, B^{n-k} \times S^{k-1}) \rightarrow \mathbb{Z} \]

as defined on page 2428.

(4) The undecorated maps are the obvious maps induced by inclusions.

(5) It follows from the naturality of the connecting homomorphism that the top rectangle in the diagram commutes.

(6) The regions between the second and the fifth row commute by the functoriality of relative homology groups.

(7) It follows from Proposition 100.17 that the bottom left square commutes.

(8) Finally note that it follows from Proposition 88.2 that

\[ Q\left([B^{n-k} \times \{0\}], [\{0\} \times B_k]\right) = 1 \]

It follows from this observation that the bottom right triangle commutes.

We denote by \[ \Xi : H_{k+1}(\{0\} \times B_k^{k+1}, \{0\} \times S^k) \rightarrow \mathbb{Z} \] the composition of the blue maps, i.e. the composition of the maps on right-hand path. We can now prove the desired equality:

\[
\begin{align*}
&\text{$(i,j)$-entry of the matrix representing $d_{k+1}$} \\
&\text{intersection form of $S^{n-k-1} \times B_k$} \\
&\downarrow \\
&\Xi([\{0\} \times B_k^{k+1}]) \\
&\text{intersection form of $\alpha(S^{n-k-1} \times B_k)$} \\
&\downarrow \\
&Q([S^{n-k-1} \times \{0\}], \alpha_s^{-1}(\beta([\{0\} \times S^k]))) \\
&\uparrow \text{by the commutative diagram and since $\alpha$ is an orientation-preserving embedding} \\
&Q(\partial([\{0\} \times B_k^{k+1}]) = [\{0\} \times S^k] \\
&Q_{\partial M_k}([\alpha(S^{n-k-1} \times \{0\})], [\beta([0] \times S^k)]). \\
&\uparrow \text{by Proposition 100.19}
\end{align*}
\]

This is precisely the equality that we had intended to show. ■

106.3. The Morse inequalities. Given a topological space $X$ or a smooth manifold $M$ we show in this section that the “size” of homology groups gives rise to lower bounds on the number of cells of a CW-structure for $X$ or number of handles in a handle decomposition of $M$. Furthermore we will see that the homology groups give lower bounds on the number of non-degenerate critical points of a Morse function on $M$.

The key to proving these results is some charming algebra. To formulate the main algebraic statement we need to introduce the following notation.

**Notation.** Given a chain complex $C_*$ and given $j \in \mathbb{N}_0$ we denote by $b_j(C) \in \mathbb{N}_0 \cup \{\infty\}$ the rank of $H_j(C)$ and we denote by $q_j(C) \in \mathbb{N}_0 \cup \{\infty\}$ the minimal number of generators of the torsion subgroup $\text{Tor} H_j(C)$.
Proposition 106.8. Let $C_*$ be a chain complex\cite{footnote1} of finitely generated free abelian groups.

(a) Given any $k \in \mathbb{N}_0$ we have the inequality
\[ \sum_{j=0}^{k} (-1)^j \cdot \text{rank}(C_{k-j}) \geq q_k(C) + \sum_{j=0}^{k} (-1)^j \cdot b_{k-j}(C). \]

(b) Given any $k \in \mathbb{N}_0$ we have the inequality
\[ \text{rank}(C_k) \geq q_k(C) + q_{k-1}(C) + b_k(C). \]

Remark.

(α) (a) Let $k \in \mathbb{N}_0$. If we add Inequality (a) for $k$ and $k-1$, then we obtain precisely Inequality (b). In other words, Proposition 106.8 (b) is a consequence of Proposition 106.8 (a). In Exercise 106.3 we will see that the converse is not true. Put differently, in general the inequalities one obtains from (a) are stronger than the inequalities from (b).

(b) By adding and subtracting equations one can also show easily that the following two statements are equivalent:
(i) For every $k \in \mathbb{N}_0$ the inequality in (a) is an equality.
(ii) For every $k \in \mathbb{N}_0$ the inequality in (b) is an equality.

(β) We refer to [Far04, Chapter 1] for an alternative proof of Proposition 106.8 and for a generalization to chain complexes over more general rings.

The proof of Proposition 106.8 relies on the following elementary lemma.

Lemma 106.9. If $F \xrightarrow{\varphi} G \rightarrow H \rightarrow 0$ is an exact sequence where $F$ and $G$ are finitely generated free abelian groups, then
\[ \text{rank}(F) \geq \text{minimal number of generators of the torsion subgroup of } H. \]

Proof of Lemma 106.9. We write $m = \text{rank}(F)$ and $n = \text{rank}(G)$. Furthermore we set $k := \min\{m, n\}$. Since $\mathbb{Z}$ is a principal ideal domain it follows from the Smith Normal Form Theorem, see Exercise 19.18, that we can find bases for $F$ and $G$ such that the only entries of the corresponding $(n \times m)$-matrix $A$ representing $\varphi$ are on the diagonal. We denote by $a_1, \ldots, a_k$ these diagonal entries. Then we see that
\[ \text{torsion subgroup of } H \cong \text{torsion subgroup of } \mathbb{Z}^n/\mathbb{Z}^m \cong \bigoplus_{a_i \neq 0} \mathbb{Z}_a_i. \]

Thus we see that the torsion subgroup of $H$ admits a generating set with at most $k$ elements. Since $k \leq m$ we see that the minimal number of generators of the torsion subgroup of $H$ is $\leq \text{rank}(F)$.

Proof of Proposition 106.8.

(a) Let $(C_*, \partial_*)$ be a chain complex of finitely generated free abelian groups. For each $k \in \mathbb{N}_0$ we write $Z_k := \ker(\partial_k : C_k \rightarrow C_{k-1})$, $B_k := \text{im}(\partial_{k+1} : C_{k+1} \rightarrow C_k)$ and

\footnote{Note that according to our convention on page 1086 a chain complex “starts” at degree 0.}
$H_k = Z_k/B_k = H_k(C_*)$. Basically by definition we have for each $k \in \mathbb{N}_0$ the short exact sequences

(a) $0 \to B_k \to Z_k \to H_k \to 0$ and  
(b) $0 \to Z_k \to C_k \to B_{k-1} \to 0$.

Given $k \in \mathbb{N}_0$ we perform the following calculation:

follows from Lemma \ref{lemma:19.6}(2) applied to the above two short exact sequences

$$
\sum_{j=0}^{k} (-1)^j \cdot \text{rank}(C_{k-j}) = \sum_{j=0}^{k} (-1)^j \cdot (\text{rank}(H_{k-j}) + \text{rank}(B_{k-j}) + \text{rank}(B_{k-j-1}))
$$

$$
= \text{rank}(B_k) + \sum_{j=0}^{k} (-1)^j \cdot \text{rank}(H_{k-j}) \geq q_k(C) + \sum_{j=0}^{k} (-1)^j \cdot \text{rank}(H_{k-j})
$$

all the other terms cancel by Lemma \ref{lemma:106.9} applied to the exact sequence (a)

(b) As mentioned above, this inequality follows immediately from adding the inequality (a) for $k$ and $k-1$. Indeed, one sees that almost all of the terms cancel and thus one obtains the promised inequality. \hfill \blacksquare

Evidently the idea now is to apply Proposition \ref{prop:106.8} to topology. To do so it is convenient to introduce the following definition.

**Notation.** Given a topological space $X$ and given $j \in \mathbb{N}_0$ we write

$$
b_j(X) := b_j(C_*(X)) = \text{rank}(H_j(X)) \quad \text{and} \quad q_j(X) := q_j(C_*(X)).
$$

In other words, $q_j(X)$ is the minimal number of generators of the torsion subgroup $\text{Tor} H_j(X)$.

**Proposition 106.10.**

(1) Let $M$ be a compact smooth manifold that is equipped with a handle decomposition. Given $k \in \mathbb{N}_0$ we denote by $d_k$ the number of $k$-handles in the handle decomposition.

(a) Given any $k \in \mathbb{N}_0$ we have the inequality

$$
\sum_{j=0}^{k} (-1)^j \cdot d_{k-j} \geq q_k(M) + \sum_{j=0}^{k} (-1)^j \cdot b_{k-j}(M).
$$

(b) Given any $k \in \mathbb{N}_0$ we have the inequality

$$
d_k \geq q_k(M) + q_{k-1}(M) + b_k(M).
$$

(2) Let $X$ be a CW-complex with finitely many cells in each dimension. Given $k \in \mathbb{N}_0$ we denote by $d_k$ the number of $k$-cells. The same inequalities as in (1) hold.

**Example.** Let $n \in \mathbb{N}_0$. By Proposition \ref{prop:48.10} we know that given any $j \in \mathbb{N}_0$ we have

$$
H_j(\mathbb{R}P^n) \cong \begin{cases} 
\mathbb{Z}, & \text{if } j = 0 \text{ or if } j = n \text{ and } n \text{ is odd}, 
\mathbb{Z}_2, & \text{if } j \text{ is odd and } j < n, 
0, & \text{if } j \text{ is even and } 0 < j \neq 0 \text{ or if } j > n.
\end{cases}
$$

\footnote{On page \pageref{page:1366} we called $b_j(X)$ the $j$-th Betti number of $X$.}
It follows almost immediately from this calculation that for any \( j \in \{0, \ldots, n\} \) we have
\[ q_j(\mathbb{R}P^n) + q_{j-1}(\mathbb{R}P^n) + q_{j-1}(\mathbb{R}P^n) = 1. \]
By Proposition 106.10 (1b) this implies that any handle decomposition of \( \mathbb{R}P^n \) has at least one handle of each index \( 0, \ldots, n \). Furthermore by Proposition 106.10 (2b) this calculation implies that any CW-decomposition of \( \mathbb{R}P^n \) has at least one cell of each index \( 0, \ldots, n \). In particular this shows that the CW-structure of \( \mathbb{R}P^n \) that we introduced in Lemma 36.1 is “minimal”. This observation also gives a solution to Exercise 48.9.

**Proof.**

(1) Let \( M \) be a compact smooth manifold that is equipped with a handle decomposition. Given \( k \in \mathbb{N}_0 \) we denote by \( d_k \) the number of \( k \)-handles in the handle decomposition. It follows from Corollary 103.4 that without loss of generality we can assume that the handle decomposition is standard. This allows us to consider the handle chain complex \( C_{\text{han}}^* (M) \). Now we can prove Inequality (a):

\[
\sum_{j=0}^{k} (-1)^j \cdot d_{k-j} = \sum_{j=0}^{k} (-1)^j \cdot \text{rank} (C_{\text{han}}^{k-j}(M)) \geq q_k(C_{\text{han}}^*(M)) + \sum_{j=0}^{k} (-1)^j \cdot b_{k-j}(C_{\text{han}}^{k-j}(M))
\]

by Lemma 106.1 we have \( d_i = \text{rank} (C_{\text{han}}^i(M)) \) Proposition 106.10

\[
=k \sum_{j=0}^{k} (-1)^j \cdot d_{k-j} = \sum_{j=0}^{k} (-1)^j \cdot \text{rank} (C_{\text{han}}^{k-j}(M)) \geq q_k(C_{\text{han}}^*(M)) + \sum_{j=0}^{k} (-1)^j \cdot b_{k-j}(C_{\text{han}}^{k-j}(M))
\]

by Proposition 106.3 we know that \( H_j(C_{\text{han}}^*(M)) \cong H_j(M) \)

Finally, as we pointed out above, Inequality (b) is an immediate consequence of Inequality (a).

(2) Let \( X \) be a CW-complex with finitely many cells in each dimension. The proof in this setting is almost identical to the proof in (1), we just need to work with the cellular chain complex \( C_{\text{CW}}^*(X) \) and we make use of the fact that by Lemma 48.1 we know that \( d_i = \text{rank} (C_{\text{CW}}^i(X)) \) and we use that by Proposition 48.4 we know that \( H_j(C_{\text{CW}}^*(X)) \cong H_j(X) \).

Now we can formulate what is arguably the most interesting result of this section, since it connects two initially rather disparate objects.

**Theorem 106.11. (Morse Inequalities)** Let \( M \) be a closed smooth manifold together with a Morse function \( f : M \to \mathbb{R} \). Given \( k \in \mathbb{N}_0 \) we write

\[
d_k := \text{number of critical points of index } k.
\]

The following two inequalities hold:

(a) Given any \( k \in \mathbb{N}_0 \) we have the inequality

\[
\sum_{j=0}^{k} (-1)^j \cdot d_{k-j} \geq q_k(M) + \sum_{j=0}^{k} (-1)^j \cdot b_{k-j}(M).
\]

(b) Given any \( k \in \mathbb{N}_0 \) we have the inequality

\[
d_k \geq q_k(M) + q_{k-1}(M) + b_k(M).
\]
Examples. Let \( n \in \mathbb{N}_0 \).

1. Recall that on page 2541 we just showed that for every \( j \in \{0, \ldots, n\} \) we have \( q_j(\mathbb{R}P^n) + q_{j-1}(\mathbb{R}P^n) + q_{j-1}(\mathbb{R}P^n) = 1 \). By Theorem 106.11 (b) this implies that any Morse function on \( \mathbb{R}P^n \) has at least one critical point of each index \( 0, \ldots, n \). In particular the Morse function on \( \mathbb{R}P^n \) that we gave on page 2502 has the minimal number of critical points.

2. On page 1262 we showed that given any \( j \in \mathbb{N}_0 \) we have

\[
H_j(\mathbb{C}P^n) \cong \begin{cases} 
\mathbb{Z}, & \text{if } j = 0, 2, 4, \ldots, 2n, \\
0, & \text{otherwise.}
\end{cases}
\]

As in (1) it follows that the Morse function on \( \mathbb{C}P^n \) that we gave on page 2502 has the minimal number of critical points.

3. Let \( M \) be a closed connected non-empty \( n \)-dimensional smooth manifold. By Theorem 66.6, or alternatively by Theorem 87.1 and Proposition 87.22 we know the following:

(a) If \( M \) is orientable, then \( H_n(M) \cong \mathbb{Z} \) and \( \text{Tor}(H_{n-1}(M)) = 0 \).

(b) If \( M \) is non-orientable, then \( H_n(M) \cong \mathbb{Z} \) and \( \text{Tor}(H_{n-1}(M)) \cong \mathbb{Z}_2 \).

Rather charmingly, in either case we see that \( q_n(M) + q_{n-1}(M) + b_n(M) = 1 \), which matches the fact that any Morse function has to have at least one global maximum, i.e. one critical point of index \( n \).

Proof of Theorem 106.11. Let \( M \) be a closed smooth manifold together with a Morse function \( f : M \to \mathbb{R} \). By Proposition 104.10 we know that \( M \) admits a standard handle decomposition of \( M \) such that for each \( k \in \mathbb{N}_0 \) the number of \( k \)-handles equals the number of critical points of \( f \) of index \( k \). The inequalities now follow from the inequalities of Proposition 106.10 (1). \( \blacksquare \)

Remark. Let \( M \) be a closed smooth manifold and let \( f : M \to \mathbb{R} \) be a Morse function. Given \( j \in \mathbb{N}_0 \) we denote by \( d_j \) the number of critical points of \( f \) of index \( j \). It follows from the Morse inequalities proved in Theorem 106.11 together with the de Rham Theorem 79.6 and Corollary 75.20 (2), that for every \( k \in \mathbb{N}_0 \) we have the inequality

\[
\sum_{j=0}^{k} (-1)^j \cdot d_{k-j} \geq \sum_{j=0}^{k} (-1)^j \cdot \dim_{\mathbb{R}}(H^{k-j}_{dR}(M)).
\]

This inequality can also proved directly using purely analytic methods, we refer to [Cha93 Appendix] and [Wit82] for details.

The question arises how “sharp” the Morse inequalities are. This leads us to the following definition.

Definition. Let \( M \) be a closed smooth manifold.

1. A Morse function \( f : M \to \mathbb{R} \) is called perfect if for every \( k \in \mathbb{N}_0 \) we have

\[
\text{number of critical points of index } k = q_k(M) + q_{k-1}(M) + b_k(M).
\]
A handle decomposition is called \textit{minimal} if for every $k \in \mathbb{N}_0$ we have
\begin{equation*}
\text{number of handles of index } k = q_k(M) + q_{k-1}(M) + b_k(M).
\end{equation*}

**Remark.** Let $M$ be a closed smooth manifold.

1. Recall that by Propositions 104.10 and 105.9 we can go back and forth between Morse functions and handle decompositions. In particular we see that $M$ admits a perfect Morse function if and only if $M$ admits a minimal handle decomposition.

2. Note that by the remark on page 2540 we know that if a Morse function is perfect, then the inequalities stated in Theorem 106.11(a) are also equalities. The same logic applies to the inequalities on the number of handles stated in Proposition 106.10(1a).

It is now natural to ask which closed smooth manifolds admit perfect Morse functions. It follows from Corollaries 103.12 and 103.7 that the fundamental group gives additional lower bounds on the number of critical points of a Morse function. Thus in the following discussion we restrict ourselves to the case of simply connected smooth manifolds. So now we have a reasonable question:

**Question 106.12.** Does every closed simply connected smooth manifold admit a perfect Morse function?

In fact in 1962 Steven Smale [Sma62, Theorem 6.1] proved the following theorem which gives an affirmative answer to Question 106.12 for high-dimensional smooth manifolds.

**Theorem 106.13.** Let $M$ be a closed smooth manifold. If $M$ is simply connected and if $\dim(M) \geq 6$, then $f$ admits a perfect Morse function.

**Remark.** In [Shark93, Chapter VII] Theorem 106.13 gets generalized, in a suitable sense, to certain closed non-simply connected smooth manifolds.

Thus let us turn our gaze towards the low-dimensional case. It follows from the classification of 2-dimensional smooth manifolds, see Theorem 23.4, and the resolution of the Poincaré Conjecture in dimension 3, see Theorem ??, that Question 106.12 has an affirmative answer in dimensions 2 and 3 for the silly reason that the spheres are the only closed simply connected smooth manifolds in those dimensions. Furthermore for 5-dimensional smooth manifolds it follows from the classification of closed simply connected 5-dimensional smooth manifolds given by Denis Barden in 1965, see [Bard65, Corollary 2.2.2], that Question 106.12 has an affirmative answer.

Finally we turn to the 4-dimensional setting. Since low-dimensional topologists usually prefer to think about handles we switch from Morse functions to handles.

**Lemma 106.14.** Let $M$ be a closed orientable simply connected 4-dimensional smooth manifold. A handle decomposition is minimal if and only if it has no 1-handles and no 3-handles.

**Proof.** Let $M$ be a closed orientable simply connected 4-dimensional smooth manifold. Note that in Exercise 88.19 we saw that it follows easily from the Hurewicz Theorem 32.3.

\footnote{We will sketch a proof in Exercise ??}
Corollary \ref{corollary:17.4}, the Poincaré Duality Theorem \ref{thm:poincare-duality} and the Universal Coefficient Theorem \ref{thm:universal-coefficient} for Cohomology Groups that $H_1(M) = 0$, $H_3(M) = 0$ and that $H_2(M)$ is torsion-free. In particular we see that $q_k(M) + q_{k-1}(M) + b_k(M) = 0$ for $k = 1$ and $k = 3$.

Now we turn to the actual proof of the lemma. First note that the above calculation shows that a minimal handle decomposition has no 1-handles and no 3-handles. Conversely, suppose that we have a handle decomposition with no 1-handles and no 3-handles. It follows easily from Lemma \ref{lemma:103.8} that the handle decomposition contains precisely one 0-handle and, say by considering the dual handle decomposition, we see that the handle decomposition contains precisely one 4-handle. Finally note that

\[
\#2\text{-}handles = \chi(M) - 2 = b_2(M) = q_2(M) + q_1(M) + b_2(M).
\]

by Corollary \ref{corollary:106.4} since $H_1(M) = H_3(M) = 0$ and since $H_0(M) = H_4(M) \cong \mathbb{Z}$.

We have thus shown that the handle decomposition is minimal.\hfill\qed

This leads us to following open problem, see \cite[Problem 4.18]{Kir97}.

**Question 106.15.**

1. Does every $M$ closed simply connected 4-dimensional smooth manifold admit a handle decomposition without 1-handles?
2. Does every $M$ closed simply connected 4-dimensional smooth manifold admit a handle decomposition without 1- and 3-handles?

Note that a positive answer to Question \ref{question:106.15} (2) would imply, by Reeb’s Theorem \ref{thm:reeb} that every closed simply connected 4-dimensional smooth manifold $M$ with $H_2(M) = 0$ is homeomorphic to $S^4$. By Freedman’s Theorem \ref{thm:freedman} this statement is correct. But this indicates that in all likelihood it will be very difficult to show that Question \ref{question:106.15} (2) has a positive answer.

**Remark.** Chapters \ref{chap:104}, \ref{chap:105} and \ref{chap:106} contain almost everything that we want to say about Morse theory. More detailed accounts of Morse theory are given in \cite{Miln63a, Nic11, Mata02, Lau11, Kos93, Knu15}. There are also many variations on standard Morse theory. We want to mention two of them:

1. Instead of smooth maps $M \to \mathbb{R}$ one can also consider smooth maps $M \to S^1$. The notion of a Morse function also makes sense, with basically the same definition, in this setting. The corresponding theory is developed in \cite{Nov81, Nov82, Paj06, Far04}. In particular one can use “twisted homology” groups to give lower bounds on the number of critical points of a Morse function $f: M \to S^1$. We refer to \cite[Corollary 3.3]{Far04} and \cite{Nov81, Nov82} for details.

2. Given a CW-complex or an (abstract) simplicial complex Robin Forman \cite{Form95, Form98} developed the, initially surely counterintuitive, notion of “discrete Morse theory”. We refer to \cite{Form02, Knu15, Scov19} and \cite{Koz08}, Chapter 11 for details.
Exercises for Chapter 106

Exercise 106.1. Consider the 3-dimensional smooth manifold that is sketched in Figure 1507.

(a) Determine $\pi_1(M)$.
(b) Make an educated guess what well-known smooth manifold $M$ is diffeomorphic to.

![Attaching sphere of the 2-handle](image)

Figure 1507. Illustration of Exercise 106.1

Exercise 106.2.

(a) Let $M$ be a compact orientable connected 2-dimensional topological manifold. Show that $\chi(M) \leq 2$.

Remark. Evidently this follows from the Surface Classification Theorem 23.4. But it would be more elegant to have a proof that does not rely on this result.

(b) Show that given any $k \in \mathbb{Z}_{\leq 2}$ there exists a compact orientable connected 2-dimensional smooth manifold $\tilde{M}$ with $\chi(\tilde{M}) = k$.

(c) Let $n \in \mathbb{N}_{\geq 3}$. Show that given any $k \in \mathbb{Z}$ there exists a compact orientable connected $n$-dimensional smooth manifold $M$ with $\chi(M) = k$.

Exercise 106.3. Give an example of a chain complex of finitely generated free abelian groups where the inequality of Proposition 106.8 (b) holds for all $k \in \mathbb{N}_0$, but such that the inequality of Proposition 106.8 (a) does not hold for all $k \in \mathbb{N}_0$.

Exercise 106.4. Given a closed connected non-empty smooth manifold $M$ and given a Morse function $f : M \to \mathbb{R}$ we denote by $d_k(M, f)$ the number of critical points of $f$ of index $k$. From the Morse Inequalities of Theorem 106.11 and from Corollaries 103.12 and 103.7 we obtain lower bounds on the number of critical points $d_k(M, f)$ of a Morse function $f$ in terms of the homology groups and the fundamental group of $M$. Show that these lower bounds are not optimal, i.e. show that there exists a closed connected non-empty smooth manifold $M$ that does not admit a Morse function $f : M \to \mathbb{R}$ such that these lower bounds are equalities.

Hint. Apply the Morse Inequalities of Theorem 106.11 to finite covers of a suitable $M$. For example you could take $M$ to be the mapping torus $\text{Tor}((S^1)^m, \phi)$ for a suitable diffeomorphism of a high-dimensional torus $(S^1)^m$.

Exercise 106.5. Let $M$ be a smooth homology 3-sphere, i.e. let $M$ be a 3-dimensional smooth manifold such that for every $k \in \mathbb{N}_0$ we have $H_k(M; \mathbb{Z}) \cong H_k(S^3; \mathbb{Z})$. Show that if $\pi_1(M)$ is non-trivial, then every Morse function on $M$ has at least six critical points.

Remark. In Proposition 66.12 we saw that the Poincaré Homology Sphere is an example of such $M$. 

Exercise 106.6. Let $M$ be a closed smooth homology 5-sphere, i.e., let $M$ be a 5-dimensional smooth manifold such that for every $k \in \mathbb{N}_0$ we have $H_k(M; \mathbb{Z}) \cong H_k(S^5; \mathbb{Z})$. Show that if $\pi_1(M)$ is non-trivial, then every Morse function on $M$ has at least ten critical points.

Remark. In Exercise 106.5 we dealt with the case of smooth homology 3-spheres. Furthermore note that in Exercise 66.13 and in Proposition 107.5 we give examples of such $M$.

Exercise 106.7. Let $p \in \mathbb{N}$ and let $q \in \mathbb{Z}$ be coprime to $p$. We pick $r, s \in \mathbb{Z}$ such that $qr - ps = -1$. We write

$$A = \begin{pmatrix} q & p \\ s & r \end{pmatrix}$$

and we consider the orientation-reversing diffeomorphism $\varphi: \mathbb{R}^2/\mathbb{Z}^2 \rightarrow \mathbb{R}^2/\mathbb{Z}^2$.

Let $\theta: \mathbb{R}^2/\mathbb{Z}^2 \rightarrow (S^1)^2$ be the usual diffeomorphism that is given by $[(x, y)] \mapsto (e^{2\pi i x}, e^{2\pi i y})$.

We set $M := ((B^2 \times S^1) \sqcup (B^2 \times S^1))/\sim$ where $(x, y) \sim (\theta \circ \varphi \circ \theta^{-1})(x, y)$ for $x, y \in S^1 \times S^1$.

By Proposition 8.15 we know that $M$ is a closed 3-dimensional smooth manifold.

(a) Show that $M$ admits a handle decomposition with a unique handle in dimensions 0, 1, 2 and 3.

(b) Show that for every $n \in \mathbb{N}_0$ we have

$$H_n^{\text{hand}}(M) \cong \begin{cases} \mathbb{Z}, & \text{if } n = 0, 3, \\ 0, & \text{if } n = 2 \text{ or } n > 3, \\ \mathbb{Z}_p, & \text{if } n = 1. \end{cases}$$

Remark. In Lemma ?? we will see that $M$ is diffeomorphic to the lens space $L(p, q)$. Thus this exercise together with Proposition 106.3 gives us a new calculation of the singular homology groups of lens spaces.

Exercise 106.8. Let $g, n \in \mathbb{N}_0$. As usual we denote by $\Sigma_{g,n}$ the surface of genus $g$ minus $n$ open disks. What is the minimal number of handles in a handle decomposition of $\Sigma_{g,n}$?

Exercise 106.9. Let $n \in \mathbb{N}$. What is the minimal number $k$ of critical points of a Morse function on the $n$-dimensional torus $(S^1)^n$? You need to show that there exists a Morse function such that the number of critical points equals $k$ and you need to show that every Morse function has at least $k$ critical points.

Exercise 106.10. Let $M$ be a compact smooth manifold and let $A$ be a union of components of $\partial M$. Suppose we are given a handle decomposition of $M$ rel $A$. Define a relative handle chain complex $C^\text{chan}_*(M, A)$ such that the corresponding homology groups $H^\text{han}_*(M, A)$ are isomorphic to the relative singular homology groups of $(M, A)$.

Exercise 106.11. Let $M$ be a compact smooth manifold and let $A$ be two a union of components of $\partial M$. Furthermore let $f: M \rightarrow [0, 1]$ be a Morse function such that $A = f^{-1}(\{0\})$ and such that $\partial M = f^{-1}(\{1\})$. Formulate a result that gives a lower bound on the number of critical points of such $f$ in terms of the relative homology groups $H_*(M, A)$.

Remark. In Proposition 105.4 we saw that such a Morse function always exists.

Hint. Make use of Exercise 106.10.
Exercise 106.12. Let $M$ be a closed smooth manifold and let $f : M \to \mathbb{R}$ be a Morse function. Given $k \in \mathbb{N}_0$ we denote by $d_k$ the number of critical points of index $k$. The Morse function is called lacunary if for every $k \in \mathbb{N}_0$ at least one of $d_k$ and $d_{k+1}$ is zero. Show that every lacunary Morse function is perfect.

Remark. This statement is sometimes called the Morse lacunary principle.

Exercise 106.13. Let $M$ be a closed smooth manifold and let $f : M \to \mathbb{R}$ be a smooth map. Furthermore let $g$ be a Riemannian structure on $M$, as defined on page 872. Given $P \in M$ we define the gradient of $f$ at $P$ to be the unique vector $\text{grad} f_P \in T_PM$ that satisfies

$$g_P(\text{grad} f_P, w) = Df_P(w) \in T_{f(P)}\mathbb{R} = \mathbb{R} \quad \text{for all } w \in T_PM.$$

One can easily show that $P \mapsto \text{grad} f_P$ defines a vector field on $M$ in the sense of the definition on page 1185.

(a) We suppose that $f$ is a Morse function. Show that every zero of the vector field $\text{grad} f$ is isolated.

(b) Let $P$ be a critical point of $f$. Show that

$$\text{index}(\text{grad} f, P) = (-1)^{\text{index}(f, P)}.$$

Remark. This exercise shows that Corollary 106.6 can also be deduced from the Poincaré-Hopf Theorem.
In this chapter we will do the following:

1. We will use handles to construct interesting compact and closed smooth manifolds out of finite presentations of groups.
2. We will show that every finite CW-complex is homotopy equivalent to a compact smooth manifold.

107.1. Finite presentations of groups and handle decompositions.

Proposition 107.1. Let \( \pi = \langle g_1, \ldots, g_k \mid r_1, \ldots, r_l \rangle \) be a finite presentation. Given any \( n \geq 4 \) there exists a compact orientable connected non-empty \( n \)-dimensional smooth manifold with the following properties:

1. \( \pi_1(M) \cong \pi \).
2. \( M \) admits a standard handle decomposition with precisely one 0-handle, \( k \) 1-handles, \( l \) 2-handles and no handles of index \( \geq 2 \).

Proof. Let \( \pi = \langle g_1, \ldots, g_k \mid r_1, \ldots, r_l \rangle \) be a finite presentation and let \( n \geq 4 \). We start with the 0-handle \( B^n \). Since \( n \geq 2 \) we can pick \( k \) orientation-preserving thickened 0-spheres \( \varphi_1, \ldots, \varphi_k : \overline{B}^{n-1} \times S^0 \to \partial B^n \) with disjoint images and we denote by \( W \) the result of attaching the corresponding \( k \) 1-handles to the 0-handle \( B^n \). Note that \( W \), and thus also \( \partial W \), is orientable by Proposition 103.9.

We pick a base point \( P \in \partial W \). It follows from Proposition 103.11 that we can make an identification \( \pi_1(W, P) = \langle g_1, \ldots, g_k \rangle \). Since \( n \geq 3 \) we know by Lemma 103.14 that the inclusion induced map \( \pi_1(\partial W, P) \to \pi_1(W, P) \) is an epimorphism. Therefore we can pick loops \( \alpha_1, \ldots, \alpha_l : (S^1, *) \to (\partial W, P) \) that represent \( r_1, \ldots, r_l \in \pi_1(W, P) = \langle g_1, \ldots, g_k \rangle \).

By hypothesis we have \( \dim(\partial W) = n - 1 \geq 3 \). Thus we can apply Theorem 9.15 and we obtain that the map \( \alpha_1 \sqcup \cdots \sqcup \alpha_l : S^1 \sqcup \cdots \sqcup S^1 \to \partial W \) is in fact homotopic to a smooth embedding \( \beta_1 \sqcup \cdots \sqcup \beta_l : S^1 \sqcup \cdots \sqcup S^1 \to \partial W \). It follows from Proposition 8.1 and the Tubular Neighborhood Theorem 8.24 that we can find smooth embeddings \( \psi_1, \ldots, \psi_l : \overline{B}^{n-2} \times S^1 \to \partial W \) with disjoint images such that for each \( i \in \{1, \ldots, l\} \) and each \( x \in S^1 \) we have \( \psi_i(0, x) = \beta_i(x) \).

Finally we consider

\[
M := W \cup_{\psi_1} h^2 \cdots \cup_{\psi_l} h^2 = \varnothing \cup \overline{B}^n \cup_{\varphi_1} h^1 \cup \cdots \cup_{\varphi_k} h^1 \cup_{\psi_1} h^2 \cup \cdots \cup_{\psi_l} h^2.
\]

The Proposition follows from the following calculation:

\[
\pi_1(M, P) \cong \langle g_1, \ldots, g_k \rangle / \langle \langle x_1r_1x_1^{-1}, \ldots, x_lr_lx_l^{-1} \rangle \rangle \cong \langle g_1, \ldots, g_k \rangle / \langle \langle r_1, \ldots, r_l \rangle \rangle = \langle g_1, \ldots, g_k \mid r_1, \ldots, r_l \rangle.
\]

by Lemma 21.2 (5) by definition

Now we can provide a new proof of the following proposition.

\[1473\]Note that we can apply the Tubular Neighborhood Theorem 8.24 since \( \partial W \) is orientable.
**Proposition 22.10.** Let \( \pi = \langle g_1, \ldots, g_k \mid r_1, \ldots, r_l \rangle \) be a finite presentation. Given any \( n \geq 4 \) there exists a closed orientable connected non-empty \( n \)-dimensional smooth manifold \( W \) with \( \pi_1(W) \cong \pi \).

**Remark.** Proposition 22.10 is a key ingredient of the proof of the fact, stated in Theorem 28.4, that closed smooth manifolds of a fixed dimension \( \geq 4 \) cannot be classified.

**Proof.** Let \( \pi = \langle g_1, \ldots, g_k \mid r_1, \ldots, r_l \rangle \) be a finite presentation and let \( n \geq 4 \). By Proposition 107.1 there exists a compact orientable connected non-empty \( n \)-dimensional smooth manifold with the following properties:

1. \( \pi_1(M) \cong \pi \).
2. \( M \) admits a handle decomposition \( M = \emptyset \cup h_0 \cup_{\varphi_1} h_1 \cup \cdots \cup_{\varphi_k} h_1 \cup_{\psi_1} h_2 \cup \cdots \cup_{\psi_l} h_2 \).

By Lemma 44.12 the double \( W := D_M \) is a closed orientable connected non-empty \( n \)-dimensional smooth manifold. Thus it suffices to prove the following claim.

**Claim.** There exists an isomorphism \( \pi_1(D_M) \cong \pi \).

For fun we provide two different proofs.

1. Note that by Corollary 103.15 we know that the boundary \( \partial M \) is connected. Therefore it follows from the Seifert-van Kampen Theorem 22.2 we have an isomorphism \( \pi_1(D_M) \cong \pi_1(M)*_{\pi_1(\partial M)} \pi_1(M) \). Since \( n \geq 4 \) and since \( M \) has only handles of index \( \leq 2 \) we obtain from Corollary 103.15 that the inclusion induced map \( \pi_1(\partial M) \to \pi_1(M) \) is an epimorphism. It follows from the group-theoretic Lemma 44.15 that the map \( \pi_1(M) \to \pi_1(D_M) \) is actually an isomorphism.
2. On page 2523 we pointed out that it is a consequence of Propositions 105.1 and 105.3 that the double admits a handlebody presentation of the following form:

\[
D_M = \emptyset \cup h_0 \cup_{\varphi_1} h_1 \cup_{\psi_1} h_2 \cup_{\psi_1} h_2 \cup_{\psi_1} h_2 \cup_{\psi_1} h_2 \cup_{\psi_1} h_2 \cup_{\psi_1} h_2 \cup_{\psi_1} h_2 \cup_{\psi_1} h_2 \cup_{\psi_1} h_2 \cup_{\psi_1} h_2 \cup_{\psi_1} h_2 \cup_{\psi_1} h_2 \cup_{\psi_1} h_2
\]

where the \((n - 2)\)-handles corresponding to \( \alpha_1, \ldots, \alpha_1 \) are dual to the 2-handles given by \( \psi_1, \ldots, \psi_1 \) and the \((n - 1)\)-handles corresponding to \( \beta_k, \ldots, \beta_1 \) are dual to the 1-handles given by \( \varphi_k, \ldots, \varphi_1 \).

(a) First let us deal with the case that \( n \geq 5 \). In this case \( D_M \) is obtained from \( M \) by attaching handles of index \( \geq 3 \). But by Proposition 103.11 we know that handle attachments of index \( \geq 3 \) do not affect the fundamental group. Thus we see that \( \pi_1(D_M) \cong \pi_1(M) \cong \pi \).
107. CONSTRUCTING SMOOTH MANIFOLDS USING HANDLES

(b) The case \( n = 4 \) is a little bit more interesting. We have

\[
\pi_1(DM) = \pi_1(M)/\langle\langle \text{attaching circles of the dual 2-handles } \alpha_1, \ldots, \alpha_1 \rangle\rangle
\]

\[
= \pi_1(M)/\langle\langle \text{belt circles of the 2-handles } \psi_1, \ldots, \psi_1 \rangle\rangle \cong \pi_1(M) \cong \pi.
\]

by Proposition \[103.11\]

This is a good moment to remind the reader of the following question.

**Question 22.14.** Is every finitely presented group the fundamental group of a closed (or at least compact) orientable connected 3-dimensional smooth manifold?

We will answer Question 22.14 in Theorem ??.

107.2. Integral homology spheres and homotopy spheres. We remind the reader of the following definitions from page 1670 and page 2161.

**Definition.** Let \( M \) be an \( n \)-dimensional smooth manifold \( M \).

1. If for every \( k \in \mathbb{N}_0 \) we have \( H_k(M) \cong H_k(S^n) \), then we refer to \( M \) as a smooth homology \( n \)-sphere.
2. If \( M \) is a homology sphere and if \( M \) is simply connected, then we refer to \( M \) as a smooth homotopy \( n \)-sphere.

Our goal in this section is to apply the construction used in Proposition 22.10 to construct smooth homology and potentially interesting smooth homotopy spheres.

We start out with the following proposition, which the reader might recognize as Exercise 88.21.

**Proposition 107.2.** Let \( M \) be a compact orientable \( n \)-dimensional topological manifold. For every \( j \in \mathbb{N}_0 \) there exists an isomorphism

\[
H_j(DM) \cong H_j(M) \oplus \text{Hom}(H_{n-j}(M), \mathbb{Z}) \oplus \text{Tor}(H_{n-j-1}(M)).
\]

**Proof.** Let \( i: M \to DM \) be the natural inclusion and let \( r: DM \to M \) be the folding map that we introduced on page 1164. Note that by definition we have \( r \circ i = \text{id}_M \). We consider the long exact sequence in homology of the pair \((DM, M)\):

\[
\ldots \rightarrow H_j(M) \xrightarrow{i_*} H_j(DM) \rightarrow H_j(DM, M) \rightarrow \ldots
\]

Now we see that we have the following isomorphisms:

Excision Theorem \[44.10\] here the blue \( M \) stands for the second copy of \( M \) in the double \( DM \)

\[
H_j(DM) \cong H_j(M) \oplus H_j(DM, M) \cong H_j(M) \oplus H_j(M, \partial M)
\]

since \( r \circ i = \text{id}_M \) we see that the above long exact sequence breaks up into short exact sequences, furthermore it follows from Lemma 46.2 that each short exact sequence splits and that the middle term is isomorphic to the direct sum of the two other terms

\[
\cong H_j(M) \oplus H^{n-j}(M) \cong H_j(M) \oplus \text{Hom}(H_{n-j}(M), \mathbb{Z}) \oplus \text{Tor}(H_{n-j-1}(M)).
\]

Poincaré Duality Theorem \[88.1\] Universal Coefficient Theorem \[75.13\] ■
Now we can prove the following refinement of Proposition 22.10.

**Corollary 107.3.** Let \( \pi = (g_1, \ldots, g_k \mid r_1, \ldots, r_l) \) be a finite presentation.

1. Given any \( n \geq 5 \) there exists a closed orientable connected non-empty \( n \)-dimensional smooth manifold \( W \) with \( \pi_1(W) \cong \pi \) and such that\(^{1474}\)

\[
\begin{align*}
H_i(W) & \cong \\
& \begin{cases}
\pi_{ab}, & \text{if } i = 1, \\
\mathbb{Z}^{l-k+\text{rk}(\pi_{ab})}, & \text{if } i = 2, \\
\mathbb{Z}^{l-k+\text{rk}(\pi_{ab})} \oplus \text{Tor}(\pi_{ab}), & \text{if } i = n-2, \\
\mathbb{Z}^{\text{rk}(\pi_{ab})}, & \text{if } i = n-1, \\
0, & \text{if } i = 0 \text{ or if } i = n, \\
\text{else.} &
\end{cases}
\end{align*}
\]

2. There exists a closed orientable connected non-empty smooth manifold \( W \) of dimension \( n = 4 \) with \( \pi_1(W) \cong \pi \) and such that the homology groups are as in (1), except that for \( i = 2 \) we take the direct sum of the terms that we wrote down for \( i = 2 \) and \( i = n-2 \).

**Proof.** As in the proof of Proposition 22.10 that we just gave on page 2550 we use Proposition 107.1 to obtain a compact orientable connected non-empty \( n \)-dimensional smooth manifold with the following properties:

1. \( \pi_1(M) \cong \pi \).

2. \( M \) admits a handle decomposition with precisely one 0-handle, \( k \) 1-handles, \( l \) 2-handles and no handles of index > 2.

In the above proof of Proposition 22.10 we saw that the fundamental group of \( W := D(M) \) is isomorphic to \( \pi \) and that \( W \) is a closed orientable connected non-empty \( n \)-dimensional smooth manifold. It remains to show that the homology groups of \( W = D(M) \) are as stated. In fact it follows from Proposition 107.2 that it suffices to prove the following claim.

**Claim.**

\[
H_0(M) \cong \mathbb{Z}, \quad H_1(M) \cong \pi_{ab}, \quad H_2(M) \cong \mathbb{Z}^{l-k+\text{rk}(\pi_{ab})} \quad \text{and} \quad H_i(M) = 0 \text{ for } i \geq 3.
\]

The statements for \( H_0(M) \) and \( H_1(M) \) follow immediately from Proposition 41.5 and the Hurewicz Theorem 52.3. Next note that that

\[
H_i(M) \cong H_i^{\text{han}}(M) = \begin{cases}
0, & \text{if } i > 2, \\
\ker(C_2^{\text{han}}(M) \to C_1^{\text{han}}(M)), & \text{if } i = 2.
\end{cases}
\]

Proposition 106.3 since \( M \) has no handles of index \( \geq 3 \).

\(^{1474}\) We denote by \( \pi_{ab} \) the abelianization of \( \pi \), as defined on page 639.
Note that this observation for \( i = 2 \), together with Lemma 19.8, shows that \( H_2(M) \) is a free abelian group. Finally note that

\[
\begin{align*}
\text{by definition of } \chi(M) & \quad \text{by Corollary 106.4 and the above calculations} \\
\end{align*}
\]

As we mentioned, our goal is to construct smooth homology spheres and smooth homotopy spheres. Corollary 107.3 leads us to the following group theoretic definitions.

**Definition.**

1. The *deficiency* of a finite presentation \( \langle x_1, \ldots, x_k \mid r_1, \ldots, r_l \rangle \) is defined to be \( k - l \).
2. A finite presentation is called *balanced*, if its deficiency equals zero.
3. A group \( \pi \) is called *perfect* if its abelianization \( \pi_{ab} \) is trivial.

The following proposition gives us some interesting examples of (presentations of) groups.

**Proposition 107.4.**

1. For every closed connected non-empty 3-dimensional smooth manifold \( M \) the fundamental group \( \pi_1(M) \) admits a balanced presentation.
2. The binary icosahedral group, that we introduced on page 1671 is a perfect group of order 120 that admits a balanced presentation.
3. For every odd prime \( p \) the group \( \text{SL}(2, \mathbb{F}_p) \) is perfect and it admits a balanced presentation.

**Proof.**

(1) We will prove this statement in Exercise 107.2. Alternatively the statement is proved in Theorem ??.

(2) Let \( \pi \) be the binary icosahedral group. In Proposition 66.12 we showed that \( \pi \) is a perfect group of order 120. It remains to show that \( \pi \) admits a balanced presentation. There are two possible approaches:
   (a) In [KSc79] Chapter II it is shown that the binary icosahedral group is isomorphic to \( \langle x, y \mid x^3 = y^5, x^3 = (xy)^2 \rangle \).
   (b) Recall that by definition \( \pi \subset SU(2) \). Thus it makes sense to consider the quotient \( M := S^3/\pi \), which we called the Poincaré Homology Sphere. In Proposition 66.12 we showed that \( M \) is a closed orientable 3-dimensional smooth manifold. Thus it follows from (1) that \( \pi \cong \pi_1(M) \) admits a balanced presentation.

(3) In Exercise 107.3 we will see that \( \text{SL}(2, \mathbb{F}_p) \) is perfect. The much more subtle fact that \( \text{SL}(2, \mathbb{F}_p) \) admits a balanced presentation is shown in [CR80].

In Proposition 66.11 we showed that there exist smooth homology 3-spheres. The combination of Corollary 107.3 and Proposition 107.4 gives us the high-dimensional analogue.

**Proposition 107.5.** Given any \( n \geq 4 \) there exists a smooth homology \( n \)-sphere with non-trivial fundamental group.
In Exercise 66.13 we used a different construction to obtain high-dimensional smooth homology spheres.

Michel Kervaire [Kerv69, Theorem 1] completely determined which finitely presented groups can occur as fundamental groups of smooth homology $n$-spheres for $n \geq 4$.

The construction that we used in the proof of Proposition 107.1 and that we used in the above proof of Propositions 22.10 is a never-ending source of joy, since even for presentations of the trivial group one obtains interesting examples of smooth manifolds:

**Example.** Let $k \in \mathbb{Z}$. We consider the presentation

$$\langle x, y \mid xyx = yxy, x^{k+1} = y^k \rangle.$$

We will now see that this is a presentation of the trivial group. Indeed, we have

(a) $y = x^{-1}y^{-1}xy = (yx)^{-1} yxy = (yx)^{-1} x(yx)$

(b) $y^{k+1} = (yx)^{-1} x^{k+1} (yx) = (yx)^{-1} y^{k+1} (yx) = x^{-1} y^{k+1} x = x^{-1} x^{k+1} x = x^{k+1} = y^k$.

Thus $y^{k+1} = y^k$ which implies that $y = 1$. From (1) it follows that also $x = 1$. We have thus shown that this is indeed a presentation of the trivial group.

Let $n \geq 4$. We apply the construction of the proof of Propositions 22.10 and 107.1 to the above balanced presentation of the trivial group. By Corollary 107.3 we obtain a smooth homotopy $n$-sphere.

The following question arises:

**Question 107.6.** Are the smooth homotopy $n$-spheres that we just constructed diffeomorphic to $S^n$?

For $n = 4$ and some special cases Question 107.6 was answered in the affirmative [Gom91]. In general though, at least for $n = 4$ Question 107.6 seems to be wide open. We refer to [GoS99, p. 149] and [Kir89, p. 18] for more information.

We have now seen that finite presentations of groups give rise to interesting smooth manifolds. The question arises, to what degree different presentations give rise to different smooth manifolds. It is worth recalling the following theorem.

**Theorem 21.7.** (Tietze Theorem) Any two finite presentations for some given group are related by a finite sequence of Tietze transformations, i.e. by a sequence of the following
two transformations:

(a) \( \langle x_1, \ldots, x_k \mid r_1, \ldots, r_i \rangle \mapsto \langle x_1, \ldots, x_k \mid r_1, \ldots, r_l, s \rangle \)

where \( s \) is a word in \( r_1, \ldots, r_l \), and

(b) \( \langle x_1, \ldots, x_k \mid r_1, \ldots, r_i \rangle \mapsto \langle x_1, \ldots, x_k, x \mid r_1, \ldots, r_l, s \cdot x \cdot t \rangle \)

where \( x \neq x_1, \ldots, x_k \) and where \( s, t \) are words in \( x_1, \ldots, x_k \).

In our context, where we study balanced presentations of the trivial group, we could like to go from one presentation to another while keeping the deficiency fixed. This leads us to the following definition.

**Definition.** Let \( \langle x_1, \ldots, x_k \mid r_1, \ldots, r_l \rangle \) be a presentation. An **Andrews-Curtis transformation** is one of the following ways to obtain a new presentation:

(a) \( \langle x_1, \ldots, x_k \mid r_1, \ldots, r_i, \ldots, r_l \rangle \mapsto \langle x_1, \ldots, x_k, x^{-\epsilon} \cdot r_i \cdot x^\epsilon, \ldots, r_l \rangle \)

where \( j \in \{1, \ldots, k\} \) and \( \epsilon \in \{\pm 1\} \)

(b) \( \langle x_1, \ldots, x_k \mid r_1, \ldots, r_i, \ldots, r_l \rangle \mapsto \langle x_1, \ldots, x_k, x, \mid r_1, \ldots, r_i \cdot r_j, \ldots, r_l \rangle \)

where \( i \neq j \in \{1, \ldots, l\} \)

(c) \( \langle x_1, \ldots, x_k \mid r_1, \ldots, r_l \rangle \mapsto \langle x_1, \ldots, x_k, x \mid r_1, \ldots, r_l, x \rangle \)

where \( x \neq x_1, \ldots, x_k \).

The following is now a slight reformulation of the Andrews-Curtis Conjecture which we first encountered in Section 21.4.

**Conjecture 21.18.** (Andrews-Curtis Conjecture) Any balanced presentation of the trivial group can be turned into the empty presentation by a finite sequence of Andrews-Curtis transformations.

In the Handle Cancellation Theorem ?? and the Handle Addition Theorem ?? we will see that the Andrews-Curtis transformations have analogues for handle decompositions. In particular, as is argued on [GoS99, p. 149], an affirmative answer to the Andrews-Curtis Conjecture 21.18 would imply that Question 107.6 has a positive answer.

For better or worse the evidence towards the Andrews-Curtis Conjecture 21.18 is rather shaky. For example, let \( k \in \mathbb{Z} \). As above we consider the following balanced presentation of the trivial group:

\( \langle x, y \mid xyx = yxy, x^{k+1} = y^k \rangle \).

For most \( k \) it is unknown whether the presentation can be turned into the empty presentation by a finite sequence of Andrews-Curtis transformations. In fact the consensus seems to be that the Andrews-Curtis Conjecture 21.18 is most likely false.

**Remark.**

(1) More information and some partial results regarding the Andrews-Curtis Conjecture 21.18 can be found in [Barm11, Chapter 11].

(2) Sergey Matveev [Matv87, p. 917] (see also [Kupe17a, Proposition 4.2] and [Barm11, Chapter 11]) showed that the Andrews-Curtis Conjecture 21.18 is equivalent to a special case of the Zeeman Conjecture 119.20.

107.3. **Handle decompositions and CW-structures.** In Proposition 103.18 we saw that every compact smooth manifold \( M \) that is equipped with a handle decomposition is
homotopy equivalent to a CW-complex $X$ such that for each $k \in \mathbb{N}_0$ the number of $k$-handles of $M$ equals the number of $k$-cells of $X$. In this section we will prove the following converse to this statement.

**Proposition 107.7.** Given any finite CW-complex $X$ there exists a compact orientable smooth manifold $M$ that is homotopy equivalent to $X$ and which admits a handle decomposition such that for each $k \in \mathbb{N}_0$ the number of $k$-cells of $X$ equals the number of $k$-handles of $M$.

![Diagram of CW-complex $X$ and thickening $M$ of $X$]

**Remark.**

(1) In Proposition 107.7 we do not make any claims about the dimension of $M$. We leave it to the reader to figure out what is the lowest dimension for $M$ that one can achieve with our proof.

(2) Let $X$ be a finite CW-complex. Any compact smooth manifold $M$ that is homotopy equivalent to $X$ is called a thickening of $X$. Proposition 107.7 thus says in particular that every finite CW-complex admits a thickening.

(3) The theory of thickenings of finite CW-complexes is developed in detail in Maz63 and Wall66b. In particular given a finite $k$-dimensional CW-complex it follows from Wall66b, p. 76 (see also BCFHLN19, Theorem 4.1) that the the following statements hold:

(a) Given any $n \geq 2k$ there exists an $n$-dimensional thickening of $X$.
(b) If $n \geq 2k + 1$ and if $n \geq 6$, then any two $n$-dimensional thickenings of $X$ are actually diffeomorphic.

We refer to BCFHLN19, Chapter 4 for more information on thickenings.

(4) The topic of finding smooth manifolds that “look” like a given topological space is also discussed in BuS10, Chapter 2.

The proof of Proposition 107.7 rests on the following lemma.

**Lemma 107.8.** If $N \geq 2r + 2$, then for every smooth embedding $\varphi : S^r \to \mathbb{R}^N$ there exists an orientation-preserving smooth embedding $\Phi : B^{N-r} \times S^r \to \mathbb{R}^N$ such that $\Phi(0, P) = \varphi(P)$ for all $P \in S^r$.

**Proof.** The statement of the lemma is basically the content of the Tubular Neighborhood Theorem 8.24 (5). For the reader’s convenience we recall the proof. First we consider the standard smooth embedding $\theta : S^r \to \mathbb{R}^{r+1} \times \mathbb{R}^{N-r-1} = \mathbb{R}^N$ which is given by $x \mapsto (x, 0)$. This smooth embedding can be “thickened” up. For example we could consider the smooth
embedding
\[ \Theta: \mathbb{B}^{N-r} \times S^r \to \mathbb{R}^{r+1} \times \mathbb{R}^{N-r-1} = \mathbb{R}^N \]
\[(x, y), P) \mapsto ((1 + \frac{x}{2}) \cdot P, y). \]

with \( x \in \mathbb{R} \) and \( y \in \mathbb{R}^{N-r-1} \)

After possibly composing \( \Theta \) with a reflection in the last coordinate we see that \( \Theta \) is orientation-preserving. By hypothesis we have \( N \geq 2r + 2 \). Thus we obtain from Proposition 11.11 that there exists a smooth isotopy \( F: S^r \times [0, 1] \to \mathbb{R}^N \) with \( F_0 = \theta \) and \( F_1 = \varphi \).

By the Isotopy Extension Theorem 8.27 there exists a diffeotopy \( G: \mathbb{R}^N \times [0, 1] \to \mathbb{R}^N \) with \( G_1 \circ \theta = \varphi \). The map \( \Phi := G_1 \circ \Theta: \mathbb{B}^{N-r} \times S^r \to \mathbb{R}^N \) has all the desired properties.

The heart of the proof of Proposition 107.7 is contained in the following lemma.

**Lemma 107.9.** Let \( X \) be a finite CW-complex and let \( \alpha: S^{k-1} \to X \) be a map. If \( X \) is homotopy equivalent to a compact orientable smooth manifold \( M \), then there exists a compact orientable smooth manifold \( N \) and an orientation-preserving thickened \((k - 1)\)-sphere \( \varphi: \mathbb{B}^{\dim(N) - k} \times S^{k-1} \to \partial N \) such that the following are satisfied:

1. \( N \) is also homotopy equivalent to \( X \).
2. \( N \cup_\varphi h^k \) is homotopy equivalent to \( X \cup_\alpha \mathcal{B}^k \).
3. If \( M \) is equipped with a handle decomposition, then we can equip \( N \) with a handle decomposition such that for each \( k \in \mathbb{N}_0 \) the number of \( k \)-handles of \( M \) equals the number of \( k \)-handles of \( N \).

**Proof of Proposition 107.7.** Note that in the setting of Lemma 107.9 we know by Propositions 103.1 and 103.9 that \( N \cup_\varphi h^k \) is again a compact orientable smooth manifold with one extra \( k \)-handle. Thus we see that Proposition 107.7 follows immediately from Lemma 107.9 and an elementary induction argument.

**Proof of Lemma 107.9.** Let \( f: X \to M \) be a homotopy equivalence between a finite CW-complex \( X \) and a compact orientable \( m \)-dimensional smooth manifold \( M \). Furthermore let \( \alpha: S^{k-1} \to X \) be a map.

We pick some \( r \geq \max\{k, 2k - \dim(M)\} \). We write \( \tilde{M} := M \times \mathbb{B}^r \) and we equip the product \( \tilde{M} \) with the smooth atlas provided by Proposition 80.9. Note that the map \( i: M \to \tilde{M} \) given by \( x \mapsto (x, 0) \) is a homotopy equivalence.

**Claim.** We write \( \tilde{f} := i \circ f: X \to \tilde{M} \). There exists a homotopy \( F: S^{k-1} \times [0, 1] \to \tilde{M} \) from the map \( \tilde{f} \circ \alpha: S^{k-1} \to \tilde{M} = M \times \mathbb{B}^r \) to a smooth embedding \( \theta: S^{k-1} \to \partial \tilde{M} \).

By the combination of the Whitney Approximation Theorem 9.3 and the Transversality Theorem 9.10 we know that the map \( \tilde{f} \circ \alpha: S^{k-1} \to \tilde{M} \) is homotopic to a smooth map that is transverse to the proper submanifold \( M \times \{0\} \) of \( \tilde{M} = M \times \mathbb{B}^r \). Note that

\[
\dim(S^{k-1}) + \dim(M \times \{0\}) = k - 1 + \dim(M) < r + \dim(M) = \dim(M \times \mathbb{B}^r).
\]

since \( r \geq k \)
Thus the image of a map $S^{k-1} \to \tilde{M}$, which is transverse to $M \times \{0\}$, actually misses $M \times \{0\}$. Therefore we now know that $\tilde{f} \circ \alpha: S^{k-1} \to \tilde{M}$ is homotopic to a map that misses $M \times \{0\}$. Next, using the deformation retraction from $B^\ell \setminus \{0\}$ to $S^{k-1}$ we see that $\tilde{f} \circ \alpha: S^{k-1} \to \tilde{M}$ is actually homotopic to a map $\varphi: S^{k-1} \to M \times S^{k-1} \subset \partial \tilde{M}$. Finally, since

$$2(k - 1) < \dim(M) + r - 1 = \dim(\partial \tilde{M})$$

we obtain from Theorem 9.15 that $\varphi: S^{k-1} \to \partial \tilde{M}$ is homotopic to a smooth embedding $\theta: S^{k-1} \to \partial \tilde{M}$.

Next we pick an $n \in \mathbb{N}$ with $n \geq \max\{2 \cdot \dim(\tilde{M}) + 1, 2k\}$. Since $n \geq 2 \cdot \dim(\tilde{M}) + 1$ we obtain immediately from Proposition 11.8 that there exists a proper smooth embedding $\tilde{M} \to H_n := \{(x_1, \ldots, x_n) \in \mathbb{R}^n | x_n \geq 0\}$. In other words, we can assume that $\tilde{M}$ is a proper smooth submanifold of $H_n$.

By the General Tubular Neighborhood Theorem 10.5 the proper submanifold $\tilde{M}$ of $H_n$ admits a tubular neighborhood $N \subset H_n$. By definition of a tubular neighborhood, see page 4118, we know that $N$ is a compact codimension-zero submanifold of $H_n$ with corner. Furthermore, by Proposition 10.11 we know that the inclusion $j: \tilde{M} \to N$ is a homotopy equivalence. As we mentioned in Lemma 89.1 by rounding corners as in the proof of Proposition 80.9, we can view $N$ as an $n$-dimensional smooth manifold.

The map $j \circ \theta: S^{k-1} \to \partial \tilde{M} \subset \partial N$ takes values in $\partial H_n$. Since $N \cap \partial H_n$ is a codimension-zero submanifold of $\partial H_n$ we see that there exists an open neighborhood $U$ of $\theta(S^{k-1})$ in $\partial H_n$ that is contained in $N$. Since $\partial H_n$ is diffeomorphic to $\mathbb{R}^{n-1}$ and since, by our choice of $n$, we have $n - 1 \geq 2(k - 1) + 2$, we obtain from Lemma 107.8 that there exists an orientation-preserving smooth embedding $\Theta: B^{n-k} \times S^{k-1} \to \partial H_n$ such that $\Theta(0, P) = \theta(P)$ for all $P \in S^{k-1}$. After possibly “shrinking” the balls we can arrange that the image of $\Theta$ actually lies in $U \subset N \cap \partial H_n$.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure1511.png}
\caption{Illustration for the proof of Proposition 107.7}
\end{figure}

Statement (2) of the lemma is a consequence of the following claim.

**Claim.** The topological space $X \cup_{\alpha} B^k$ is homotopy equivalent to the smooth manifold $N \cup_{\theta} h^k$. 

The experienced reader will doubtlessly spot that this is the right moment to roll out the Homotopy Pushout Theorem 39.18. To apply this great theorem let us consider the following commutative diagram:

\[
\begin{array}{cccccc}
X & \xrightarrow{\alpha} & S^{k-1} & \xrightarrow{id} & \emptyset \\
\downarrow f & & \downarrow id & & \\
M & \xrightarrow{f_\alpha} & S^{k-1} & \xrightarrow{id} & B^k \\
\downarrow \tilde{f} & & \downarrow x\mapsto(x,0) & & \\
\tilde{M} & \xrightarrow{F} & S^{k-1} \times [0,1] & \xrightarrow{id} & B^k \times [0,1] \\
\downarrow \tilde{f}_\alpha & & \downarrow x\mapsto(x,1) & & \\
\tilde{M} & \xrightarrow{\theta} & S^{k-1} & \xrightarrow{id} & B^k \\
\downarrow j & & \downarrow x\mapsto(0,x) & & \\
N & \xrightarrow{j_\theta} & S^{k-1} & \xrightarrow{id} & B^k \\
\downarrow \Theta & & \downarrow x\mapsto(0,x) & & \\
N & \xrightarrow{\Theta} & B^{n-k} \times S^{k-1} & \xrightarrow{id} & B^{n-k} \times B^k.
\end{array}
\]

All of the vertical maps are clearly homotopy equivalences. Furthermore note that it follows immediately from Proposition 39.4 and 39.12 that all of the right horizontal maps are closed cofibrations. Thus it follows from the Homotopy Pushout Theorem 39.18 applied altogether six times, that the induced maps between the various pushouts have homotopy inverses. Combining these six homotopy equivalences, respectively their homotopy inverses, we obtain the promised homotopy equivalence from \(X \cup_\alpha B^k\) to \(N \cup_\Theta h^k\).

Finally assume that \(M\) is equipped with a handle decomposition. We sketch the proof how we can find a handle decomposition for \(N\) with the same number of handles. First, except for a slight sense of uneasy about rounding corners, it is pretty clear that we can equip \(\tilde{M} = M \times \emptyset\) with a handle decomposition that is given by taking the product of each handle of \(M\) with \(\emptyset\). Now we consider the actual smooth manifold \(N\) which we are interested in. Note that \(N\) is by definition of a tubular neighborhood the total space of a linear \(\emptyset\)-bundle \(p: N \rightarrow \tilde{M}\). This bundle might well be non-trivial, thus there is no reason to assume that \(N\) is actually a product \(\tilde{M} \times \emptyset\). But, it follows from the same argument as in Proposition ?? and the fact that each handle is contractible that the restriction of \(p\) to each handle is actually a trivial linear \(\emptyset\)-bundle. Thus we see that the handle structure on \(\tilde{M}\) does give rise to a handle structure on \(N\) with exactly the same number of handles of each index.

The next proposition explains what type of closed smooth manifolds one can obtain by the ever-popular doubling procedure to the smooth manifolds constructed in the proof of Proposition 107.7.
Proposition 107.10. Let $X$ be a finite $k$-dimensional CW-complex. There exists an $N \geq 2k + 1$ such that for every $n \geq N$ there exists a closed orientable $n$-dimensional smooth manifold $M$ which admits a standard handle decomposition and which admits a homotopy equivalence

$$\varphi: X \to M^{n-k-1}$$

from $X$ to the $(n-k-1)$-skeleton of $M$.

**Remark.** Note that in the setting of Proposition 107.10 we obtain from Exercise 103.12 and Lemma 106.1 (3) and (4), together with Proposition 40.7 and Corollary 42.8, that the map $X \to M^{n-k-1} \to M$ induces an isomorphism of homotopy groups and homology groups up to dimension $n-k-2$.

**Proof.** Let $X$ be a finite $k$-dimensional CW-complex. By Proposition 107.7 there exists a homotopy equivalence $\psi: X \to V$ from $X$ to a compact smooth manifold $V$ which has the nice property that it admits a handle decomposition such that all handles are of index $\leq k$. By Corollary 103.4 we can arrange that this handle decomposition is standard. After possibly replacing $V$ by some $B^N \times V$ we can arrange that $\dim(V) \geq 2k + 1$. We set $N := \dim(V)$. Now let $n \geq N$. We set $W := B^{n-N} \times V$ and we set $M := DW$. We equip the double $M = DW$ with the handle decomposition that we described on page 2522, namely which is given by the handle decomposition on $M$ and the dual handle decomposition on the second copy of $M$. In particular we see that we can equip $M$ with a handle decomposition such that the $(n-k-1)$-skeleton equals $W$. The map $\varphi: X \to M^{n-k-1} = V \times B^{n-N}$ given by $P \mapsto (\psi(P), 0)$ is now the promised homotopy equivalence from $X$ to the $(n-k-1)$-skeleton of $M$. ■

In Proposition 107.7 we just showed that every finite CW-complex $X$ is homotopy equivalent to a compact smooth manifold $X$. The following question, which implicitly we had already asked on page 2178 arises.

**Question 107.11.** Given a finite CW-complex $X$, what extra conditions do we need to impose on $X$ to ensure that $X$ is homotopy equivalent to a closed smooth or topological manifold?

We make a couple of initial observations. Let $X$ be a CW-complex.

1. If $X$ is homotopy equivalent to a closed orientable $n$-dimensional topological manifold, then it follows from the Poincaré Duality Theorem 88.1 together with Proposition 42.5, Lemmas 73.13 and 83.8 that there exists a class $\sigma \in H_n(X; \mathbb{Z})$ such that for each $k \in \mathbb{N}_0$ the map

$$\cap \sigma: H^{n-k}(X; \mathbb{Z}) \to H_k(X; \mathbb{Z})$$

$$\psi \mapsto \psi \cap \sigma$$

is an isomorphism.

2. If $X$ is homotopy equivalent to a closed non-orientable topological manifold, then it follows from Proposition 86.15 that $X$ admits a 2-fold covering $\tilde{X}$ which is homotopy equivalent to a closed orientable topological manifold.
(3) If $X$ is homotopy equivalent to a closed (orientable) $n$-dimensional topological manifold, then every finite covering of $X$ is also homotopy equivalent to a closed (orientable) $n$-dimensional topological manifold. In particular given any finite covering the properties stated in (1) and (2) need to hold.

(4) These observations in (1), (2) and (3) already give lots of restrictions. We will generalize these conditions on page ??.

The extra conditions stated in (2), (3) and (4) vanish, if $X$ is a simply connected CW-complex. Thus we have arrived at the following subtle variation on Question 107.11

**Question 107.12.** Let $X$ be a finite simply connected CW-complex $X$ which admits a class $\sigma \in H_n(X; \mathbb{Z})$ as in (1). Is $X$ homotopy equivalent to a closed $n$-dimensional smooth or topological manifold?

It turns out that the answer to Question 107.12 is no. Namely, there are other, more subtle bundle-theoretic obstructions to being homotopy equivalent to a closed smooth or topological manifold. Slightly more precisely, the obstruction is given by showing that the “Spivak Normal Fibration” of a given finite CW-complex has the structure of a vector bundle. In fact in [DaP15, p. 21] (see also [MM79, p. 32]) it is shown that there exists a finite simply connected 5-dimensional CW-complex $X$ such that the cohomology ring is isomorphic to the cohomology ring of $S^2 \times S^3$ but such that $X$ is not homotopy equivalent to a closed topological manifold. Similar examples of such simply connected CW-complexes are given in [GiS65, Theorem 5.2]. We also refer to [CLM21, Chapter 5.5] and to [CW21, Chapter 1.1.2] for details.

---

**Exercises for Chapter 107.**

**Exercise 107.1.** In the proof of Proposition 22.10 that we gave on page 2550 we used the following statement. Let $M$ be a compact connected non-empty smooth manifold that admits a handle decomposition such that all handles have index $\leq 2$. If $\dim(M) \geq 4$, then the inclusion induced map $\pi_1(M) \to \pi_1(DM)$ is an isomorphism. Does this statement also hold if $\dim(M) = 3$?

**Exercise 107.2.** Let $M$ be a closed connected 3-dimensional smooth manifold. Show that $\pi_1(M)$ admits a balanced presentation.

*Hint.* By the Handle Decomposition Theorem 104.11 we know that $M$ admits a handle decomposition. By Corollaries 106.4 and 106.5 we know that

$$\sum_{k=0}^{3} (-1)^k \cdot \text{number of } k\text{-handles} = 0.$$ 

You could first consider the case that the handle decomposition contains precisely one 0-handle and one 3-handle. Afterwards try to tackle the general case.
Exercise 107.3. Let $k$ be a field with at least three elements. Show that $\text{SL}(2, k)$ is perfect, i.e. show that the abelianization is the trivial group.

*Hint.* Use that for any non-zero $d \in k$ and $a \in k$ we have
\[
\begin{pmatrix} d & 0 \\ 0 & d^{-1} \end{pmatrix} \begin{pmatrix} 1 & a \\ 0 & 1 \end{pmatrix} \begin{pmatrix} d^{-1} & 0 \\ 0 & d \end{pmatrix} = \begin{pmatrix} 1 & (d^2 - 1)a \\ 0 & 1 \end{pmatrix}.
\]

Exercise 107.4. Give an example of a finite CW-complex $X$ which is not homotopy equivalent to a closed topological manifold but which admits a class $\sigma \in H_n(X; \mathbb{Z})$ such that for each $k \in \mathbb{N}_0$ the map
\[
\cap \sigma : H^{n-k}(X; \mathbb{Z}) \to H_k(X; \mathbb{Z}) \quad \psi \mapsto \psi \cap \sigma
\]
is an isomorphism.

*Hint.* You could consider the wedge of a sphere with a suitable CW-complex with non-trivial fundamental group.
108. THE CLASSIFICATION OF COMPACT 2-DIMENSIONAL SMOOTH MANIFOLDS II

In this fairly short chapter we will finally complete the proof of the classification of compact 2-dimensional smooth manifolds. But first, as a warm-up, let us go one dimension lower, namely let us give a proof for half of the content of Theorem 7.5.

**Proposition 108.1.** Every compact connected non-empty 1-dimensional smooth manifold is diffeomorphic either to $S^1$ or to $[0,1]$.

**Remark.** As we explained on page 330 using the fact that topological manifolds are by definition second-countable it is not difficult to deduce from Proposition 108.1 that every non-compact connected 1-dimensional smooth manifold is diffeomorphic to either the open interval $(0,1)$ or the half-open interval $[0,1)$.

**Proof.** Let $M$ be a compact connected non-empty 1-dimensional smooth manifold. By the Handle Decomposition Theorem 104.11 we can equip $M$ with a standard handle decomposition.

**Claim.** There exists a standard handle decomposition for $M$ with a single 0-handle.

Since $M$ is non-empty we know that $M$ has at least one 0-handle. Now suppose that our handle decomposition has more than one 0-handle. Since $M$ is connected and since the handle decomposition is standard it follows from Lemma 103.8 that there exists a 1-handle $H$ that gets glued to two different 0-handles $D$ and $E$. It is elementary to see that $D \cup E \cup H$ is diffeomorphic to $[-1,1]$. Thus we can combine $D \cup E \cup H$ to a single 0-handle. Note that the resulting handle decomposition is still standard. We now proceed iteratively.

We now fix a handle decomposition for $M$ with a single 0-handle $D$. If the handle decomposition does not contain a 1-handle, then $M = D$, in particular $M$ is diffeomorphic to $[0,1]$.

Now suppose that the handle decomposition contains at least one 1-handle. Since the handle decomposition is standard we know that all attaching maps of the 1-handles take values in $\partial M^1 = \partial D$. Now let $\varphi: \{0\} \times S^0 \to \partial D$ be an attaching map of a 1-handle. Note that the map is injective. Since both sets consist of precisely two elements we see that the attaching map is a bijection. In particular we see that $D \cup \varphi (\{0\} \times B^1)$ is a closed 1-dimensional smooth manifold. It is elementary to see that this smooth manifold is diffeomorphic to $S^1$. Since this smooth manifold is closed we see that there are no other 1-handles. Thus we have shown that $M$ is diffeomorphic to $S^1$. ■

![Figure 1512. Illustration for the proof of Proposition 108.1](image)

108.1. **Handle decompositions of 2-dimensional smooth manifolds.** In this section we will study handle decompositions of some of our favorite 2-dimensional smooth manifolds. We will also learn how to modify handle decompositions of 2-dimensional smooth...
manifolds. In the next section we will use the results from this section to give a surprisingly short proof of the statement that any compact connected non-empty 2-dimensional smooth manifold is diffeomorphic to one of the standard examples.

We start out with the following lemma which is very specific to the 2-dimensional setting.

**Lemma 108.2.** Let $M$ be a 2-dimensional smooth manifold, let $C$ be a boundary component and let $\varphi: S^1 \to C$ be a diffeomorphism. The diffeomorphism type of $M \cup \varphi h^2$ does not depend on the choice of $\varphi$.

**Remark.** The proof of Lemma 108.2 rests on the fact, proved in Proposition 30.1 (2), that for $n = 2$ every diffeomorphism of $S^{n-1}$ extends to a diffeomorphism of $B^n$. Note that by Theorem ?? and the Cerf Theorem 8.44 the analogous statement also holds for $n = 3$ and $n = 4$. In particular the obvious analogue of Lemma 108.2 also holds in those dimensions. But we will see in Proposition ?? that the analogue of Lemma 108.2 does not hold for $n = 7$.

**Proof.** Let $M$ be a 2-dimensional smooth manifold, let $C$ be a boundary component of $M$ and let $\varphi, \psi: S^1 \to C$ be two diffeomorphisms. We consider the self-diffeomorphism $f := \varphi \circ \psi^{-1}: S^1 \to S^1$. By Proposition 30.1 (2) the self-diffeomorphism $f$ of $S^1$ extends to a self-diffeomorphism $F$ of the disk $B^2$. Now we obtain from Proposition 8.15 (7) that $M \cup \varphi h^2 = M \cup_{C \varphi} S^1 \overline{B^2}$ is diffeomorphic to $M \cup \psi h^2 = M \cup_{C \psi} S^1 \overline{B^2}$. ■

In the following we will state and prove a few results which are not germane to the 2-dimensional setting, but which also have analogues in the higher-dimensional setting, which we will eventually discuss in Chapter ???. In this and the following section we will use slightly informal language and we will partially work with figures. Nonetheless the mathematically mature reader should have no troubles with making the whole discussion completely and utterly rigorous.

First we formulate the following special case of Proposition 103.1 (4).

**Lemma 108.3.** Let $M$ be a 2-dimensional smooth manifold. Given any smooth isotopy $F: (\overline{B^1} \times S^0) \times [0, 1] \to \partial M$ there exists a diffeomorphism $M \cup_{F_0} h^1 \to M \cup_{F_1} h^1$. Any such replacement of the 1-handle given by $F_0$ by the 1-handle given by $F_1$ is called a handle slide.

**Example.** For what follows it will be very helpful to get a little experience with what handle slides can do.

**Lemma 108.4.** Every closed connected non-empty 2-dimensional smooth manifold admits a handle decomposition with the following properties:

1. There exists a single 0-handle.
2. The attaching maps of all of the 1-handles take values in the boundary of the 0-handle.
3. There exists a single 2-handle.
Remark. In Corollary ?? we will see that the conclusion of Lemma $108.4$ in fact holds in all dimensions.

Sketch of proof. By the Handle Decomposition Theorem $104.11$ we can equip $M$ with a standard handle decomposition. Since $M$ is non-empty we know that there exists at least one $0$-handle. Suppose that $M$ has more than one $0$-handle. Since $M$ is connected it follows from the fact that the handle decomposition is standard together with Lemma $103.8$ that there exists a $1$-handle $H$ that gets glued to two different $0$-handles $D$ and $E$. In Exercise $108.2$ we will see that $D \cup E \cup H$ is again diffeomorphic to a disk. Thus we can combine $D \cup E \cup H$ to a single $0$-handle. It is straightforward to verify that the new handle decomposition is again standard and that the number of $2$-handles is unaffected. We now proceed iteratively till we get down to a single $0$-handle.

Next we apply the above procedure to the dual handle decomposition and we can arrange that the dual handle decomposition has a single $0$-handle. Furthermore, as mentioned above, we can do this without changing the fact that the dual handle decomposition is standard and without changing the fact that the dual handle decomposition has a single $2$-handle.

In summary, we have found a standard handle decomposition with a single $0$-handle and a single $2$-handle.

\[
\begin{array}{c}
\text{0-handle } D & \text{1-handle } H & \text{0-handle } E \\
\ \ \ M & \ \ \ M & \ \ \ \\
\text{2-handle } K & \text{1-handle } H & \text{0-handle } L \\
\end{array}
\]

Figure 1514. Illustration of the proof of Lemma $108.4$ (1).

Definition.

(1) We say a handle decomposition of $2$-dimensional smooth manifold is completely standard, if it is of the form described in Lemma $108.4$.

\[1476\] In fact this statement is in this context equivalent to saying that the handle decomposition is standard in the sense of the definition on page $2481$. 

(2) Let \( M \) be a 2-dimensional smooth manifold that is equipped with a completely standard handle decomposition. We equip \( \overline{B}^1 \times \overline{B}^1 \) with the product orientation and we equip \( \overline{B}^1 \times S^0 = \overline{B}^1 \times \partial \overline{B}^1 \subset \overline{B}^1 \times \overline{B}^1 \) with the boundary orientation. As on page 2486 we say that a 1-handle with attaching map \( \varphi: \overline{B}^1 \times S^0 \to \partial \overline{B}^2 \) is **orientable** if the attaching map is either orientation-preserving on both components of \( \overline{B}^1 \times S^0 \) or if it is orientation-reversing on both components of \( \overline{B}^1 \times S^0 \). Otherwise we say that the 1-handle is **non-orientable**.

![Diagram showing orientation of \( \overline{B}^1 \times S^0 \), orientable 1-handle, and non-orientable 1-handle](image)

**Figure 1515**

**Lemma 108.5.** Let \( M \) be a 2-dimensional smooth manifold \( M \) with a completely standard handle decomposition. The following two statements are equivalent:

1. \( M \) is orientable.
2. All 1-handles are orientable.

**Proof.** In Proposition 8.15(6) we dealt with the orientability of smooth manifolds that are given by gluing oriented smooth manifolds along unions of boundary components. In our setting we only glue along codimension-zero submanifolds of the boundary. But the same statements hold and we see that our lemma is basically a special case of Proposition 8.15(6). □

**Convention.**

1. Let \( M \) be a 2-dimensional smooth manifold \( M \) with a single 0-handle \( \overline{B}^2 \). If \( M \) is orientable, then we equip \( M \) with the orientation such that the natural map \( \overline{B}^2 \to M \) given by the 0-handle is orientation-preserving.
2. Let \( M \) be a closed 2-dimensional smooth manifold. If we are given a handle decomposition for \( M \) with a single 2-handle, then in the figures we show the 0-handles and the 1-handle attachments and we indicate with a discrete \( \cup h^2 \) the 2-handle. Note that by Lemma 108.2 the 2-handle attachment is basically unambiguous.

**Examples.**

1. In Figure 1516 we show several completely standard handle decompositions for several of our favorite surfaces.
2. (a) In Figure 1517 we show a completely standard handle decomposition for the surface of genus 0. This handle decomposition has an obvious generalizations to higher genera.
   (b) In Figure 1518 we show a completely standard handle decomposition for the non-orientable surface of genus 3, as defined on page 206. Again this example has obvious generalizations to higher genera.
Lemma 108.6. Let $M$ and $N$ be two closed 2-dimensional smooth manifolds. We assume that both are equipped with a completely standard handle decomposition. Then $M \# N$ has a completely standard handle decomposition such that the 1-handles are given by “juxtaposing” the 1-handle attachments for $M$ and the 1-handle attachments for $N$. We will not give a formal definition of “juxtaposing”, instead we refer to Figure 1319 for a hopefully unambiguous “definition by illustration”.

Proof. We denote by $D = \overline{B}^2$ the unique 0-handle of $M$ and we denote by $K$ the unique 2-handle of $M$. Furthermore we denote by $E = \overline{B}^2$ the unique 0-handle of $N$ and we denote by $L$ the unique 2-handle of $N$. It follows almost immediately from Exercise 103.3 that we
can pick a smooth embedding $\varphi: \overline{B^2} \to M$ such that $\varphi(\overline{B^2}_{\leq 0})$ is contained in the 0-handle $D$, such that $\varphi: \overline{B^2}_{\leq 0} \to D = \overline{B^2}$ is orientation-preserving and such that $\varphi(\overline{B^2}_{\geq 0})$ is contained in the 2-handle $K$. Similarly we pick a smooth embedding $\varphi: \overline{B^2} \to N$, with the only real difference being, that we demand that the map $\psi: \overline{B^2}_{\leq 0} \to E$ is orientation-reversing. Now we have

by definition of the connected sum, note that if $M$ and $N$ are oriented, then the orientation conventions work out

$$M \# N = (M \setminus \varphi(B^2)) \sqcup (N \setminus \psi(B^2))/\varphi(x) \sim \psi(x) \text{ for } x \in S^1$$

Thus we have obtained a handle decomposition for $M \# N$ with a single 0-handle, a single 2-handle, and such that the handles of $M$ and $N$ get attached to disjoint semicircles in the boundary of the 0-handle. In other words, the 1-handle attachments are juxtaposed.

Examples.

(1) In Figure 1521 we use Lemma 108.6 to give a handle decomposition of the connected sum $\mathbb{R}P^2 \# \mathbb{R}P^2$ of two copies of the real projective plane $\mathbb{R}P^2$. Furthermore we show a handle slide that results in the handle decomposition of the Klein bottle that we
already saw in Figure 1516. This argument shows in particular that $\mathbb{R}P^2 \# \mathbb{R}P^2$ is diffeomorphic to Klein bottle. Thus we have obtained a new proof of Lemma 8.33.

\[ \mathbb{R}P^2 \stackrel{\cup h^2}{\#} \mathbb{R}P^2 \rightarrow \mathbb{R}P^2 \# \mathbb{R}P^2 \rightarrow \text{Klein bottle} \]

handle slide given by sliding the “left leg” of the green handle over the pink handle

**Figure 1521**

2. (a) In Figure 1522 we show, using altogether three handle slides, that the connected sum $\mathbb{R}P^2 \# \mathbb{R}P^2 \# \mathbb{R}P^2$ is diffeomorphic to the connected sum of $\mathbb{R}P^2$ with the torus.

(b) Now let $g \in \mathbb{N}_0$. We consider the connected sum of $2g + 1$ copies of $\mathbb{R}P^2$ as given by attaching $2g + 1$ non-orientable 1-handles to a single 0-handle. We iteratively apply the procedure in Figure 1522 to the three right-most non-orientable 1-handles. We turn the two right-most non-orientable 1-handles into a pair of interlocking orientable 1-handles. Eventually we see that the connected sum of $2g + 1$ copies of $\mathbb{R}P^2$ is diffeomorphic to the connected sum of $\mathbb{R}P^2$ with the surface of genus $g$.

\[ \mathbb{R}P^2 \# \mathbb{R}P^2 \# \mathbb{R}P^2 \rightarrow \mathbb{R}P^2 \# \mathbb{R}P^2 \rightarrow \mathbb{R}P^2 \# \text{torus} \]

**Figure 1522**

108.2. **The classification of compact 2-dimensional smooth manifolds.** We recall the following notation that we introduced on page 669.

**Notation.** Given $g, n \in \mathbb{N}_0$ we write $\Sigma_{g,n}$

- $\Sigma_{g,n}$ := the surface of genus $g$ minus $n$ open disks.

Furthermore for $g \in \mathbb{N}$ and $n \in \mathbb{N}_0$ we write

- $N_{g,n}$ := the non-orientable surface of genus $g$ minus $n$ open disks.
In Theorem 23.6 we showed that the above surfaces are pairwise non-homeomorphic, in particular we showed they are pairwise non-diffeomorphic. In this section we prove that any compact connected 2-dimensional smooth manifold is diffeomorphic to one of the above surfaces. This finally completes the classification of compact surfaces that we started in Chapter 23.

Here is the precise theorem we intend to prove.

**Theorem 108.7.** Let \( \Sigma \) be a compact connected non-empty 2-dimensional smooth manifold.

1. If \( \Sigma \) is orientable, then \( \Sigma \) is diffeomorphic to the surface \( \Sigma_{g,n} \) for some \( g, n \in \mathbb{N}_0 \).
2. If \( \Sigma \) is non-orientable, then \( \Sigma \) is diffeomorphic to the surface \( N_{k,n} \) for some \( k \in \mathbb{N} \) and \( n \in \mathbb{N}_0 \).

**Remark.**

1. Our proof of Theorem 108.7 is inspired by the ambitious [GoS99, Exercise 4.2.4]. The key idea was communicated to us by Robert Gompf. The proof we provide is also outlined in [Mart16, Chapter 6.1.6].
2. In Exercise ?? we will also sketch an alternative approach to proving Theorem 108.7.
3. One can prove Theorem 108.7 through Morse theory, without using handles. This approach is taken in [Mata02, Chapter 5.2] and [Hirs76, Chapter 3].
4. On page 675 we discuss several other approaches to proving the analogue of Theorem 108.7 in the setting of topological manifolds.

To increase readability we split the proof of Theorem 108.7 into two parts. First we treat closed manifolds, afterwards we will prove the general case.

**Proof of Theorem 108.7 for closed manifolds.** By the Handle Decomposition Theorem 104.11 together with Lemma 108.4 it suffices to prove the proposition for a closed 2-dimensional smooth manifold that is equipped with a completely standard handle decomposition, i.e. that is equipped with a handle decomposition with the following properties:

1. There exists a single 0-handle \( D \).
2. The attaching maps of all of the 1-handles take values in the boundary of the 0-handle.
3. There exists a single 2-handle.

We prove this statement by induction on the number of 1-handles. If we have zero 1-handles, then \( M \) is given by gluing a 2-handle to a 0-handle via some attaching map \( \varphi : S^1 \to S^1 \). Now we see that we have the following diffeomorphisms:

\[
M = B^2 \cup_\varphi h^2 = B^2 \cup_{S^1 \times S^1} B^2 \cong B^2 \cup_{S^1 \times S^1} \bar{B}^2 \cong \bar{S}^2.
\]

by Lemma 108.2 all attaching maps give the same diffeomorphism type

Next suppose that the claim holds whenever the number of 1-handles is \( \leq k \). Thus let \( M \) be a smooth manifold as above with \( k + 1 \) 1-handles.

\[^{1477}\text{We refer to page 668 for the definition of “minus n open disks”.}\]
Perhaps slightly surprisingly the case that the smooth manifold is non-orientable is slightly easier. So let us deal with this case initially. Since \( M \) is now assumed to be non-orientable we obtain from Lemma 108.5 that there exists a non-orientable 1-handle. We denote the corresponding attaching map by \( \alpha \). We denote by \( \psi_1, \ldots, \psi_k \) the attaching maps of the remaining 1-handles. Let \( I \subset \partial D \) be a compact interval that contains the image of the attaching map of the chosen 1-handle and let \( J \subset \partial D \) be the compact interval with \( \partial D = I \cup J \) and \( I \cap J = \partial I = \partial J \). Here comes the key observation: Since the 1-handle is non-orientable we see that \( \partial(\overline{B}^2_\alpha \cup h^1) \) is connected. Thus we can iteratively slide all handle attachments \( \psi_1, \ldots, \psi_k \) that end up on \( I \) across the chosen 1-handle so that they take values in the interval \( J \). (We refer to Figure 1523 for an illustration.) We denote the new handle attachment maps by \( \tilde{\psi}_1, \ldots, \tilde{\psi}_k \).

We now see that

\[
M \cong \overline{B}^2 \cup_\alpha \overline{h}^1 \cup_\psi_1 h^1 \cup_\psi_k h^1 \cup h^2 \quad \Rightarrow \quad \overline{B}^2 \cup_\alpha \overline{h}^1 \cup_{\tilde{\psi}_1} h^1 \cup_\tilde{\psi}_k h^1 \cup h^2
\]

follows from Lemmas 108.2 and 108.3

\[
\cong (\overline{B}^2_\alpha \cup h^1 \cup h^2) \# (\overline{B}^2 \cup_{\tilde{\psi}_1} h^1 \cup_\tilde{\psi}_k h^1 \cup h^2) \cong (k+1) \cdot \mathbb{R}P^2 \cong \text{non-orientable surface of genus } k+1.
\]

We have thus proved the induction step if \( M \) is non-orientable.

**Figure 1523.** First illustration for the proof of Theorem 108.7.

Now we turn to the case that \( M \) is orientable. We pick any 1-handle. Since \( M \) is orientable the chosen 1-handle is orientable. Note that this implies that the boundary of \( \overline{B}^2_\alpha \cup h^1 \) is disconnected. But since we work with a completely standard handle decomposition we know that, once we attached all 1-handles, the boundary is connected. This implies that there exists at least one other 1-handle that connects the two components of
the boundary of \( \overline{B^2 \cup_h h^1} \). We pick such a 1-handle and we call it the \textit{dual handle}. We denote its attaching map by \( \tilde{\beta} \). We denote by \( \psi_1, \ldots, \psi_{k-1} \) the attaching maps of the remaining 1-handles. Let \( I \subset \partial D \) be a compact interval that contains the image of the attaching maps \( \alpha \) and \( \beta \) and let \( J \subset \partial D \) be the compact interval with \( \partial D = I \cup J \) and \( I \cap J = \partial I = \partial J \). Here comes the key observation: \textit{It is straightforward to see that \( \partial(\overline{B^2 \cup_h h^1 \cup \tilde{\beta} h^1}) \) is connected. Thus we can iteratively slide all handle attachments \( \psi_1, \ldots, \psi_k \) that end up on \( I \) across the two 1-handles so that they take values in the interval \( J \).} (We refer to Figure 1524 for an illustration.) We denote the new handle attachment maps by \( \psi_1, \ldots, \tilde{\psi}_{k-1} \). We now see that

\[
M \cong \overline{B^2 \cup_{\alpha} h^1 \cup_{\beta} h^1 \cup \psi_1 h^1 \cup \tilde{\psi}_{k-1} h^1} \cup h^2 \cong \overline{B^2 \cup_{\alpha} h^1 \cup_{\beta} h^1 \cup \tilde{\psi}_{k-1} h^1} \cup h^2
\]

follows from Lemma 108.2 and 108.3.

\[
\cong \left( \overline{B^2 \cup_{\alpha} h^1 \cup_{\beta} h^1} \cup h^2 \right) \quad \# \quad \left( \overline{B^2 \cup_{\alpha} h^1 \cup_{\tilde{\psi}_{k-1}} h^1} \cup h^2 \right)
\]

follows from Lemma 8.33 (1) or alternatively the discussion on page 2569.

\[
\cong \text{surface of genus } \frac{k+1}{2}.
\]

by Lemma 108.6.

since all bands are orientable we know that this is an orientable surface, thus by induction we know that it is diffeomorphic to \( \Sigma_{\frac{k+1}{2}} \).

We have thus now proved the induction step also in the case that \( M \) is orientable.

standard handle decomposition for the orientable \( M \) with \( k + 1 \) 1-handles

\[
\begin{array}{c}
\text{we pick this 1-handle} \\
\cup h^2 \\
\end{array}
= 
\begin{array}{c}
\text{dual 1-handle} \\
\cup h^2 \\
\end{array}
\]

connected sum of torus with surface with \( k - 1 \) orientable 1-handles

\textbf{Figure 1524.} Second illustration for the proof of Theorem 108.7

In the following we will finally deal with 2-dimensional smooth manifolds with non-empty boundary.

\textbf{Proof of Theorem 108.7} for all manifolds. Let \( M \) be a compact connected non-empty 2-dimensional smooth manifold. By Proposition 6.27 the boundary \( \partial M \) is a closed 1-dimensional smooth manifold. Since \( \partial M \) is compact it has finitely many components that we denote by \( C_1, \ldots, C_n \). (Note that we allow the case that \( n = 0 \).) Each component
$C_i$ is compact and has no boundary. Thus it follows from Proposition 108.1 that for each $i = 1, \ldots, n$ there exists a diffeomorphism $f_i: S^1 \to C_i$.

We denote by $\widetilde{M}$ the result of gluing a disk to each boundary component. More precisely, we consider

$$\widetilde{M} := \left( M \sqcup \bigcup_{i=1}^n (\overline{B}^2 \times \{i\}) \right) / \sim \text{ where } f_i(P) \sim (P, i) \text{ for } P \in S^1 \text{ and } i \in \{1, \ldots, n\}.$$  

By Proposition 8.15 we know that $\widetilde{M}$ is a closed connected non-empty 2-dimensional smooth manifold that contains $M$ as a smooth submanifold and which has the property that the obvious maps $\overline{B}^2 \times \{i\} \to \widetilde{M}$ are all smooth embeddings. Furthermore it follows from Proposition 8.15 (6) and the observation that $\overline{B}^2$ admits an orientation-reversing diffeomorphism, that $M$ is orientable if and only if $\widetilde{M}$ is orientable.

Now suppose that $M$ is orientable. By the above $\widetilde{M}$ is also orientable. Since $\widetilde{M}$ is closed orientable connected and non-empty we know by the above that there exists a diffeomorphism $\Phi: \Sigma_g \to \widetilde{M}$ from the surface of some genus $g$ to $\widetilde{M}$. Then $\Phi$ restricts to a diffeomorphism

$$\Phi: \Sigma_g \setminus \bigcup_{i=1}^n \Phi^{-1}(B^2 \times \{i\}) \to M.$$  

If $M$ is non-orientable, then $\widetilde{M}$ is closed connected non-orientable and non-empty, thus we know that it is diffeomorphic to the non-orientable surface $N_g$ for some $g$. As above we see that $M$ is diffeomorphic to $N_{g,n}$.

---

**Exercises for Chapter 108**

**Exercise 108.1.** We denote by $p: \mathbb{R}^3 \to \mathbb{R}$ the projection onto the third coordinate. Let $\gamma: S^1 \to \mathbb{R}^3$ be a smooth embedding such that the map $p \circ \gamma: S^1 \to \mathbb{R}$ has precisely two critical points. Show that $\gamma(S^1)$, viewed as a submanifold of $\mathbb{R}^3 \cup \{\infty\} = \mathbb{S}^3$ is smoothly isotopic to the trivial knot.

**Exercise 108.2.** We consider the attaching map

$$\varphi: \overline{B}^1 \times S^0 \to \overline{B}^2 \times \{\pm 1\}$$  

$$(y, \epsilon) \mapsto \left((\epsilon \cdot \sqrt{1 - \frac{y^2}{4}}, \frac{y}{2}), \epsilon\right).$$
Show that \((B^1 \times B^1) \cup \varphi: B^1 \times S^0 \to B^2 \times \{\pm 1\} \) is diffeomorphic to \(B^2\).

**Remark.**

1. It follows easily from this exercise together with Theorem 8.36 that any attaching of a 1-handle to two disks is diffeomorphic to \(B^2\).
2. By “rotating around the x-axis” one sees that a similar statement also holds in the higher-dimensional setting.

Part XII

Steenrod operations
109. STREENROD OPERATIONS

In this chapter we introduce the Steenrod operations. These are cohomology operations which satisfy several axioms. In the first three sections we will state the axioms and draw several interesting conclusions. Afterwards we will sketch a proof for the existence of the Steenrod operations.

109.1. The axioms of Steenrod operations.

**Definition.**

1. Let $A$ and $B$ be abelian groups and let $m, n \in \mathbb{N}_0$. Any natural transformation from the contravariant functor
   \[
   H^m(-; A) : \text{category of topological spaces} \to \text{category of sets}
   \]
   to the contravariant functor
   \[
   H^n(-; B) : \text{category of topological spaces} \to \text{category of sets}
   \]
   is called a cohomology operation of degree $n - m$. In other words, a cohomology operation consists for any topological space $X$ of a map $\Phi_X : H^m(X; A) \to H^n(X; B)$ of sets such that for any map $f : X \to Y$ between topological spaces the following diagram commutes:
   \[
   \begin{array}{ccc}
   H^m(Y; A) & \xrightarrow{f^*} & H^m(X; A) \\
   \Phi_Y & & \Phi_X \\
   H^n(Y; B) & \xrightarrow{f^*} & H^n(X; B).
   \end{array}
   \]

2. A cohomology operation is called additive if each map $H^m(X; A) \to H^n(X; B)$ is a homomorphism.

3. A cohomology operation is called non-trivial if there exists a topological space $X$ such that the map $H^m(X; A) \to H^n(X; B)$ is non-trivial in the sense that the image is not just the trivial element.

With the obvious modifications the same definitions also apply to relative cohomology viewed as functors from the category of pairs of topological spaces to the category of sets.

Perhaps somewhat surprisingly we have already assembled a substantial list of non-trivial cohomology operations.

**Examples.**

1. Let $n \in \mathbb{N}_0$ and let $G$ be an abelian group. Given a pair of topological spaces $(X, A)$ we consider the connecting homomorphism $H^n(X, A; G) \to H^{n+1}(X; G)$. It follows from Lemma 73.15 (3) that these homomorphisms define an additive cohomology operation of degree one.

2. Let $\varphi : A \to B$ be a homomorphism between two abelian groups and let $n \in \mathbb{N}_0$. On page 1823 we saw that given any topological space $X$ we obtain an induced homomorphism $\varphi_* : H^n(X; A) \to H^n(X; B)$. By Lemma 73.9 we know that these maps define an additive cohomology operation of degree zero.

3. Let $0 \to A \xrightarrow{i} B \xrightarrow{p} C \to 0$ be a short exact sequence of abelian groups. On page ?? we introduced the $n$-th Bockstein homomorphism $\beta_n : H^n(X; C) \to H^{n+1}(X; A)$. In
Lemma ?? we saw that the $n$-th Bockstein homomorphisms define an additive cohomology operation of degree one.

(4) Let $k \in \mathbb{N}$. It follows from Proposition 82.4 (1) that for any $m \in \mathbb{N}_0$ and any commutative ring $R$ the maps

$$H^n(X, A; R) \rightarrow H^{km}(X, A; R)$$

$$\varphi \mapsto \varphi^k = \underbrace{\varphi \cup \cdots \cup \varphi}_{k \text{ times}}$$

define a cohomology operation of degree $km - m$. Note that this type of a cohomology operation is in general not additive. For example, if $k \geq 2$, then it follows easily from the calculation of the cup product of $\mathbb{C}P^k$, see Proposition 90.7, that the map $H^2(\mathbb{C}P^k; \mathbb{Z}) \rightarrow H^{2k}(\mathbb{C}P^k; \mathbb{Z})$ given by $\varphi \mapsto \varphi^k$ is not a homomorphism.

(5) If $R$ is a commutative ring with $1 + 1 = 0$, then the cohomology operation $\varphi \mapsto \varphi^2$ is in fact additive. Indeed for any $\varphi, \psi \in H^n(X, A; R)$ we have

$$(\varphi + \psi)^2 = \varphi \cup \varphi + \varphi \cup \psi + \psi \cup \varphi + \psi \cup \psi$$

$$= \varphi \cup \varphi + (1 + (-1)^{m^2}) \cdot \varphi \cup \psi + \psi \cup \psi = \varphi \cup \varphi + \psi \cup \psi = \varphi^2 + \psi^2.$$  

by Proposition 81.8 we have $\psi \cup \varphi = (-1)^{m^2} \cdot (\varphi \cup \psi)$ since $1 - 1 = 0 = 1 + 1$ in $R$.

Note that all of the cohomology operations that we have introduced above are of non-negative degree. This raises the following amusing question.

**Question 109.1.** Does there exist a non-trivial cohomology operation of negative degree?

We will come back to this question in Proposition ??.

The following theorem gives us new and interesting cohomology operations. The theorem was first proved by Norman Steenrod [Stee47] in 1947.

**Theorem 109.2.** There exists a family

$$Sq^i: H^n(X, A; \mathbb{Z}_2) \rightarrow H^{n+i}(X, A; \mathbb{Z}_2) \quad \text{with } i \in \mathbb{N}_0 \text{ and } n \in \mathbb{N}_0$$

of additive cohomology operations which satisfies the following axioms:

1. $Sq^0 = \text{id}$.
2. For any $\varphi \in H^i(X, A; \mathbb{Z}_2)$ we have $Sq^i(\varphi) = \varphi^2 = \varphi \cup \varphi \in H^{2i}(X, A; \mathbb{Z}_2)$.
3. For any $\varphi \in H^j(X, A; \mathbb{Z}_2)$ with $i > j$ we have $Sq^i(\varphi) = 0$.
4. Let $(X, A, B)$ be an excisive triad of topological spaces. For any $\varphi \in H^r(X, A; \mathbb{Z}_2)$ any $\psi \in H^s(X, B; \mathbb{Z}_2)$ and any $k \in \mathbb{N}_0$ we have

$$Sq^k(\varphi \cup \psi) = \sum_{i=0}^{k} \underbrace{Sq^i(\varphi)}_{\in H^{i+i}(X, A; \mathbb{Z}_2)} \cup \underbrace{Sq^{k-i}(\psi)}_{\in H^{s+k+i}(X, B; \mathbb{Z}_2)} \in H^{r+s+k}(X, A \cup B; \mathbb{Z}_2).$$

This equality is often called the Cartan formula.

---

1478 We refer to page 2005 for the definition of the relative cup product.

1479 This can be viewed as the cohomological “freshman’s dream”. Perhaps it should called the incoming PhD student’s dream.
In the next two sections we will discuss some properties and applications of these cohomology operations. Only after these two sections, once we are convinced that Steenrod operations are indeed useful and interesting, will we provide a proof for Theorem 109.2.

Remark.

(1) The first three axioms of Theorem 109.2 can be summarized as follows: Given any \( \varphi \in H^k(X, A; \mathbb{Z}_2) \) we obtain the following table

<table>
<thead>
<tr>
<th>( Sq^0(\varphi) )</th>
<th>( Sq^1(\varphi) )</th>
<th>( \ldots )</th>
<th>( Sq^{k-1}(\varphi) )</th>
<th>( Sq^k(\varphi) )</th>
<th>( Sq^{k+1}(\varphi) )</th>
<th>( \ldots )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \varphi )</td>
<td>?</td>
<td>( \ldots )</td>
<td>?</td>
<td>( \varphi^2 )</td>
<td>0</td>
<td>( \ldots )</td>
</tr>
</tbody>
</table>

(2) Throughout the remainder of this chapter we will almost invariably consider cohomology with \( \mathbb{Z}_2 \)-coefficients. We point out that by Proposition 81.8 the cup product on the \( \mathbb{Z}_2 \)-cohomology \( H^*(X, A; \mathbb{Z}_2) \) of a given pair of topological spaces \((X, A)\) is actually commutative.

The following theorem is [SE62, Theorem VIII.3.10].

**Theorem 109.3.** Any two families of additive cohomology operations that satisfy Axioms (1) to (4) are identical.

This theorem allows us to give a name to the above cohomology operations.

**Definition.** We refer to the cohomology operations from Theorem 109.2 as the Steenrod operations.

The following theorem shows that the first Steenrod operation \( Sq^1 \) is actually an old acquaintance of ours.

**Theorem 109.4.** The first Steenrod operation \( Sq^1 \) is the Bockstein homomorphism corresponding to the short exact sequence \( 0 \rightarrow \mathbb{Z}_2 \xrightarrow{[a]} \mathbb{Z}_4 \rightarrow \mathbb{Z}_2 \rightarrow 0 \).

**Proof.** We will not make use of this theorem, thus we decline to provide a proof. The theorem is proved in [Bre93, p. 418] or alternatively in [MTa68, p. 23] or [Hat02, Theorem 4.L.12].

Evidently our goal now is to compute Steenrod operations in specific examples. We start out with the following slightly disappointing lemma.

**Lemma 109.5.** For any wedge of finitely many spheres all Steenrod operations in degrees \( \geq 1 \) are zero.

**Proof.** We will prove the lemma in Exercise 109.2.

In remainder of this section we intend to compute the Steenrod operations for the real projective spaces \( \mathbb{R}P^n \) with \( n \in \mathbb{N}_0 \). Before we consider the real projective spaces in detail it is convenient to reformulate the Cartan formula.
For the reformulation we need the following notation:

**Notation.** Let \((X, A)\) be a pair of topological spaces. Given \(\varphi \in H^k(X, A; \mathbb{Z}_2)\) we write

\[
\text{Sq}(\varphi) := \text{Sq}^0(\varphi) + \text{Sq}^1(\varphi) + \cdots + \text{Sq}^k(\varphi) \in H^*(X, A; \mathbb{Z}_2) = \bigoplus_{n \in \mathbb{N}_0} H^n(X, A; \mathbb{Z}_2).
\]

Furthermore we extend the homomorphism \(\text{Sq}\) in the obvious way to a homomorphism \(\text{Sq}: H^*(X; \mathbb{Z}_2) \to H^*(X; \mathbb{Z}_2)\).

**Remark.** Let \((X, A)\) be a pair of topological spaces and let \(\varphi \in H^k(X, A; \mathbb{Z}_2)\). Recall that by Axiom (3) given \(\varphi \in H^k(X, A; \mathbb{Z}_2)\) we have \(\text{Sq}^i(\varphi) = 0\) for \(i > k\). Thus we can write

\[
\text{Sq}(\varphi) = \text{Sq}^0(\varphi) + \text{Sq}^1(\varphi) + \cdots + \text{Sq}^k(\varphi) = \sum_{i \in \mathbb{N}_0} \text{Sq}^i(\varphi).
\]

With this notation we can formulate the following lemma.

**Lemma 109.6.** Let \((X, A)\) be a pair of topological spaces.

1. Given any \(\varphi, \psi \in H^*(X, A; \mathbb{Z}_2)\) we have

\[
\text{Sq}(\varphi \cup \psi) = \text{Sq}(\varphi) \cup \text{Sq}(\psi).
\]

2. Given any \(\varphi \in H^*(X, A; \mathbb{Z}_2)\) and given any \(k \in \mathbb{N}_0\) we have \(\text{Sq}(\varphi^k) = \text{Sq}(\varphi)^k\).

**Proof.** The first statement follows easily from the Cartan formula. Indeed, we see that

\[
\text{Sq}(\varphi \cup \psi) = \sum_{k \in \mathbb{N}_0} \sum_{i=0}^k \text{Sq}^i(\varphi) \cup \text{Sq}^{k-i}(\psi)
\]

\[
= \sum_{r \in \mathbb{N}_0} \sum_{s \in \mathbb{N}_0} \text{Sq}^r(\varphi) \cup \text{Sq}^s(\psi) = \left( \sum_{r \in \mathbb{N}_0} \text{Sq}^r(\varphi) \right) \cup \left( \sum_{s \in \mathbb{N}_0} \text{Sq}^s(\psi) \right) = \text{Sq}(\varphi) \cup \text{Sq}(\psi).
\]

The second statement is an immediate consequence of the first statement.

Before we state a corollary we introduce the following semi-obvious definition.

**Definition.** Let \(r, s \in \mathbb{N}_0\). If \(0 \leq r \leq s\), then we set \(\binom{s}{r} = \frac{s!}{r!(s-r)!}\), otherwise we set \(\binom{s}{r} = 0\).

Now we can state the promised corollary.

**Corollary 109.7.** Let \(X\) be a topological space. For any cohomology class \(\varphi \in H^1(X; \mathbb{Z}_2)\) of degree one, any \(k \in \mathbb{N}\) and any \(i \in \mathbb{N}\) we have

\[
\text{Sq}^i(\varphi^k) = \binom{k}{i} \cdot \varphi^{k+i} \in H^{k+i}(X; \mathbb{Z}_2).
\]

**Examples.**

1. By Proposition 90.16 we know that given any \(n \in \mathbb{N}_0\) we have a ring isomorphism \((H^*(\mathbb{R}P^n; \mathbb{Z}_2), \cup) \cong \mathbb{Z}_2[\overline{x}]/(x^{n+1})\), where \(x \in H^1(\mathbb{R}P^n; \mathbb{Z}_2)\), and we have a ring isomorphism \((H^*(\mathbb{R}P^\infty; \mathbb{Z}_2), \cup) \cong \mathbb{Z}_2[\overline{x}]\), where \(x \in H^1(\mathbb{R}P^\infty; \mathbb{Z}_2)\). Since Steenrod operations are additive we see that the result of Corollary 109.7 gives us the promised calculations of all Steenrod operations for the real projective spaces.
(2) In Exercise 109.3 we will use a similar argument to calculate the Steenrod operations on $H^*(\mathbb{C}P^n; \mathbb{Z}_2)$.

**Proof.** We calculate that

$$\text{Sq}(\varphi^k) = \text{Sq}(\varphi) = (\text{Sq}^0(\varphi) + \text{Sq}^1(\varphi))^k = (\varphi + \varphi^2)^k = \varphi^k \cup (1 + \varphi)^k = \sum_{j=0}^k \binom{k}{j} \varphi^{k+j}.$$  

Lemma 109.6 (2) by Axiom (3) Axioms (1) and (2) since the ring $(H^*(X; \mathbb{Z}_2), \cup)$ is commutative.

The desired conclusion follows from comparing the terms in degree $k+i$ on both sides. ■

109.2. **Steenrod operations and connecting homomorphisms.** This section is completely dedicated to the proof of the following proposition. In the subsequent section we will see that the proposition has powerful applications.

**Proposition 109.8.** If $(X, A)$ is a pair of topological spaces, then the Steenrod operations commute with the connecting homomorphisms in cohomology. More precisely, given any $i, n \in \mathbb{N}_0$ the following diagram commutes:

$$
\begin{array}{ccc}
H^n(A; \mathbb{Z}_2) & \xrightarrow{\delta} & H^{n+1}(X, A; \mathbb{Z}_2) \\
\text{Sq}^i \downarrow & & \downarrow \text{Sq}^i \\
H^{n+i}(A; \mathbb{Z}_2) & \xrightarrow{\delta} & H^{n+i+1}(X, A; \mathbb{Z}_2).
\end{array}
$$

In the proof of Proposition 109.8 we will make use of the cross product on cohomology which we now introduce.

**Definition.** Let $R$ be a commutative ring, let $X$ be a topological space and let $(Y, B)$ be a pair of topological spaces. Furthermore let $\varphi \in H^m(X; R)$ and $\psi \in H^n(Y, B; R)$. We denote by $p: X \times Y \to X$ and $q: X \times Y \to Y$ the projections. We define the cross product

$$\varphi \times \psi := p^*(\varphi) \cup q^*(\psi) \in H^{n+m}(X \times Y, X \times B; R).$$

lies in $H^m(X \times Y; R)$ lies in $H^n(X \times Y, X \times B; R)$

The following proposition basically says that in Axiom (4), i.e. in the Cartan formula, we can replace the cup product by the cross product.

**Proposition 109.9.** Let $X$ be a topological space and let $(Y, B)$ be a pair of topological spaces. For any $\varphi \in H^r(X; \mathbb{Z}_2)$, $\psi \in H^s(Y, B; \mathbb{Z}_2)$ and $n \in \mathbb{N}_0$ the following equality holds:

$$\text{Sq}^n(\varphi \times \psi) = \sum_{i=0}^n \text{Sq}^i(\varphi) \times \text{Sq}^{n-i}(\psi) \in H^{r+s+n}(X \times Y, X \times B; \mathbb{Z}_2).$$

1482 Recall that on page 1964 given two homology classes $\mu \in H_m(X; \mathbb{Z})$ and $\nu \in H_n(Y; \mathbb{Z})$ we defined the cross product $\mu \times \nu \in H_{m+n}(X \times Y; \mathbb{Z})$. It should usually be clear from the context whether in a given situation we mean the cross product on homology or on cohomology.
Proof (\(\ast\)). Let \(X\) be a topological space and let \((Y, B)\) be a pair of topological spaces. Furthermore let \(\varphi \in H^r(X; \mathbb{Z}_2)\) and \(\psi \in H^s(Y, B; \mathbb{Z}_2)\). We denote by \(p: X \times Y \to X\) and \(q: X \times Y \to Y\) the projections. We start out with the following claim.

Claim. We have the following equalities:

\(\begin{align*}
(a) & \quad p^*(\varphi) = \varphi \times 1_Y \in H^r(X \times Y; \mathbb{Z}_2) \quad \text{and} \quad q^*(\psi) = 1_X \times \psi \in H^s(X \times Y; \mathbb{Z}_2). \\
(b) & \quad \varphi \times \psi = (\varphi \times 1_Y) \cup (1_X \times \psi) \in H^{r+s}(X \times Y; \mathbb{Z}_2).
\end{align*}\)

Let us provide the proof of the claim.

(a) We perform the following easy calculation:

\[
\varphi \times 1_Y = p^*(\varphi) \cup q^*(1_Y) = p^*(\varphi) \cup 1_{X \times Y} = p^*(\varphi). \\
\text{by definition we have} \\
p^*(1_X) = q^*(1_Y) = 1_{X \times Y} \quad \text{1}_{X \times Y} \text{ is multiplicatively neutral,} \\
\text{see Proposition 109.7}
\]

Evidently the same argument also shows that \(q^*(\psi) = 1_X \times \psi\).

(b) This statement follows from (a) and the definition of the cross product.

Now we turn to the proof of the actual statement of the proposition. We have the following equalities in \(H^{r+s+n}(X \times Y; \mathbb{Z}_2)\):

\[
\begin{align*}
\text{part (b) of the claim} & \quad \text{by the Cartan formula, i.e. by Axiom (4)}\\
\text{Sq}^n(\varphi \times \psi) & = \text{Sq}^n((\varphi \times 1_Y) \cup (1_X \times \psi)) = \sum_{i=0}^{n} \text{Sq}^i(\varphi \times 1_Y) \cup \text{Sq}^{n-i}(1_X \times \psi) \\
& = \sum_{i=0}^{n} \text{Sq}^i(p^*(\varphi)) \cup \text{Sq}^{n-i}(q^*(\psi)) = \sum_{i=0}^{n} p^*(\text{Sq}^i(\varphi)) \cup q^*(\text{Sq}^{n-i}(\psi)) \\
\text{part (a) of the claim} & \quad \text{since Sq}^i \text{ and } \text{Sq}^{n-i} \text{ are natural transformations}\\
& = \sum_{i=0}^{n} \text{Sq}^i(\varphi) \times \text{Sq}^{n-i}(\psi). \\
& \quad \text{by definition of the cross product}
\end{align*}
\]

We have thus obtained the desired equality. \(\blacksquare\)

The proof of Proposition 109.8 rests on the following lemma.

**Lemma 109.10.** Let \(X\) be a topological space, let \((Y, B)\) be a pair of topological spaces and let \(R\) be a commutative ring. If \(\varphi \in H^m(X; R)\) and \(\psi \in H^s(B; R)\), then

\[
\begin{align*}
\delta(\varphi \times \psi) & = (-1)^m \cdot \varphi \times \delta \psi \in H^{m+n+1}(X \times Y, X \times B; R).
\end{align*}
\]

Recall that given a topological space \(W\) we denote by \(1_Z \in H^0(W; \mathbb{Z}_2)\) the cohomology class that is represented by the cocycle that assigns to each singular 0-simplex the value 1 \(\in \mathbb{Z}_2\).
Proof of Lemma 109.10. This equality follows fairly easily from Lemma 81.2 the definition of the cross product via the cup product and the explicit description of the connecting homomorphism on page 1820. We leave it to the reader to fill in the details. □

Proof of Proposition 109.8. We start out with a warm-up case.

Claim. Let $Z$ be a topological space and let $a < b$ be two real numbers. The conclusion of the proposition holds for the pair $(Z \times [a, b], Z \times \partial([a, b]))$ of topological spaces.

Let $\theta \in H^n(Z \times \partial([a, b]); \mathbb{Z}_2) = H^n(Z \times \{a, b\}; \mathbb{Z}_2)$. Recall that we need to show that $Sq^i(\delta \theta) = \delta(Sq^i(\theta))$. First note that $\theta$ can be written as $\theta = \varphi \times \psi$ for some $\varphi \in H^n(Z; \mathbb{Z}_2)$ and some $\psi \in H^0(\partial([a, b]); \mathbb{Z}_2)$. Thus let

$\delta \psi \in H^1([a, b], \partial([a, b]); \mathbb{Z}_2)$ and $H^1([a, b], \partial([a, b]); \mathbb{Z}_2) = 0$ for every $i \geq 2$ we know that $Sq^i(\delta \psi) = 0$ for $j \geq 1$.

Proof by Lemma 109.10 we also use that $(-1)^n = 1 \in \mathbb{Z}_2$ and Proposition 109.9:

$\downarrow \quad \downarrow \quad \downarrow \quad \downarrow \quad \downarrow$

$i \quad Sq^i(\varphi \times \delta \psi) \quad Sq^i(\delta \varphi) \quad Sq^i(\varphi) \times Sq^j(\delta \psi) \quad Sq^i(\varphi \times \psi) \quad Sq^i(\delta \psi) \quad \delta(Sq^i(\varphi \times \psi)) \quad \delta(Sq^i(\theta))$

Axiom (1) says

Lemma 109.10 by Proposition 109.9 together with Axioms (1) and (3) and the fact that $\psi \in H^0(\partial([a, b]); \mathbb{Z}_2)$. □

The remainder of the proof of the proposition consists in cleverly reducing the general case to the above special case. Thus let $(X, A)$ be a pair of topological spaces. We denote by $i: A \to X$ the inclusion map. We set

$\text{Cyl}(i) = \text{mapping cylinder of the inclusion } i: A \to X := ((A \times [0, 1]) \cup X)/ \sim$ where $(a, 1) \sim a$ for all $a \in A$.

We point out that by Exercise 24.8 and Lemma 24.6 we know that the obvious inclusions $A \times [0, 1] \to \text{Cyl}(i)$ and $X \to \text{Cyl}(i)$ are embeddings. Thus we can view $A \times [0, 1]$ and $X$ as subsets of $\text{Cyl}(i)$. Now we consider the following subsets of the mapping cylinder $\text{Cyl}(i)$:

$B := (A \times [\frac{1}{2}, 1]) \cup X$ and $C := A \times \{0\}$.

We refer to Figure 1528 for an illustration. The five statements in the following claim break the proof of the proposition into five manageable steps.

\[\text{Figure 1528}\]
Claim.

(1) The conclusion of the proposition holds for \((A \times [0, \frac{1}{2}], A \times \partial([0, \frac{1}{2}]))\).
(2) The conclusion of the proposition holds for \((\text{Cyl}(i), B \cup C))\).
(3) The conclusion of the proposition holds for \((\text{Cyl}(i), C))\).
(4) The conclusion of the proposition holds for \((\text{Cyl}(i), A \times [0, 1]))\).
(5) The conclusion of the proposition holds for \((X, A))\).

The five statements of the claim are illustrated in Figure 1529.

Before we work our way through the five steps we need to make two related observations. Let \(f : (X, A) \to (Y, B)\) be a map of pairs of topological spaces. We obtain the following cubical diagram:

\[
\begin{array}{cccccc}
H^n(Y; \mathbb{Z}_2) & \xrightarrow{f^*} & H^n(X; \mathbb{Z}_2) & \xrightarrow{\delta} & H^{n+1}(Y, B; \mathbb{Z}_2) & \xrightarrow{f^*} \\
\downarrow & & & & & \\
H^{n+i}(B; \mathbb{Z}_2) & \xrightarrow{f^*} & H^{n+i}(X; \mathbb{Z}_2) & \xrightarrow{\delta} & H^{n+i+1}(Y, B; \mathbb{Z}_2) & \xrightarrow{f^*} \\
\downarrow & & & & & \\
H^{n+i}(A; \mathbb{Z}_2) & \xrightarrow{f^*} & H^{n+i+1}(X, A; \mathbb{Z}_2) & \xrightarrow{\delta} & H^{n+i+1}(X, A; \mathbb{Z}_2). & \\
\end{array}
\]

It follows from the naturality of the Steenrod operations that the parallelograms to the left and right commute. Furthermore, it follows from the naturality of the connecting homomorphism, see Lemma 73.15, that the top and bottom parallelograms commute. Using these facts we can make the following two observations:

- (i) If the square in the front commutes and if the map \(f^*\) to the bottom right is an isomorphism, then it follows from a stroll through the cube, as indicated in Figure 1530, that the square in the back also commutes.
- (ii) If the square in the back commutes and if the map \(f^*\) to the top left is an isomorphism, then it follows as in (i) that the square in the front also commutes.

Now we turn to the actual proof of the five steps in the claim.

(1) This statement follows immediately from the previous claim.
(2) We consider the inclusion map \(f : (A \times [0, \frac{1}{2}], A \times \partial([0, \frac{1}{2}])) \to (\text{Cyl}(i), B \cup C)\) and we consider the corresponding cube. By (1) we know that the square in the front commutes. We leave it to the reader to cleverly apply the Excision Theorem for
Cohomology Groups 74.1 to show that the map $f^*$ to the bottom right of the cube is an isomorphism. Thus we obtain from (i) that the square in the back commutes.

(3) We consider the inclusion map $f: (\text{Cyl}(i), C) \to (\text{Cyl}(i), B \cup C)$ and we consider the corresponding cube. By (2) we know that the square in the back commutes. Since on the first entry $f$ is the identity we see that the top left map $f^*$ is an isomorphism. Thus we obtain from (ii) that the square in the front also commutes.

(4) We consider the inclusion map $f: (\text{Cyl}(i), A \times \{0\}) \to (\text{Cyl}(i), A \times [0,1])$. By (3) we know that the square in the front commutes. Since $A \times \{0\}$ is a deformation retract of $A \times [0,1]$ we obtain from Lemma 73.13 (4) that the map $f^*$ to the bottom right of the cube is an isomorphism. Thus we obtain from (i) that the square in the back also commutes.

(5) We consider the obvious inclusion

$$f: X \to \text{Cyl}(i)$$

$$x \mapsto [(x,1)].$$

It also defines a map $f: (X, A) \to (\text{Cyl}(i), A \times [0,1])$ of pairs of topological spaces. We consider the corresponding cube. By (4) we know that the square in the back commutes. By Lemma 24.8 (1) the map $f: X \to \text{Cyl}(i)$ is in fact a homotopy equivalence. Thus it follows from Lemma 73.13 that the top left $f^*$ is an isomorphism. Therefore we obtain from (ii) that the square in the front commutes.

109.3. **Steenrod operations and suspensions.** In Proposition 109.8 we saw that Steenrod operations commute with connecting homomorphisms in cohomology. In this section we will use this fact to show that Steenrod operations behave well under taking suspensions. This fact will help us to obtain new information on homology groups of spheres.

First recall that in Proposition 45.7 we saw that taking the suspension $\Sigma(X)$ of a topological space shifts the reduced homology groups “upwards by one”. The following proposition says that the same phenomenon occurs when we consider cohomology groups.
Proposition 109.11. Let $X$ be a non-empty topological space, let $n \in \mathbb{N}$ and let $G$ be an abelian group. As on page 1178 we denote by $C_- X$ and $C_+ X$ the “lower and upper half” of the suspension $\Sigma(X)$. We refer to Figure 1531 for an illustration.

1. The following maps are isomorphisms

$$H^n(X; G) \xrightarrow{\delta} H^{n+1}(C_+ X, X; G) \leftarrow H^{n+1}(\Sigma(X), C_- X; G) \rightarrow H^{n+1}(\Sigma(X); G).$$

Here the map to the left is the connecting homomorphism of the pair $(C_+ X, X)$ from Lemma 73.15. The remaining two horizontal maps are induced by the obvious inclusion maps.

2. The isomorphism

$$\Sigma_X: H^n(X; G) \xrightarrow{\cong} H^{n+1}(\Sigma(X); G)$$

that is given by the maps in (1) is in fact a natural isomorphism.

\[\text{Figure 1531. Illustration for Proposition 109.11}\]

Proof. The proof is a slight variation on the proof of Proposition 45.7. We leave it to the reader to fill in the details.

The following proposition shows that Steenrod operations behave well under taking suspensions.

Proposition 109.12. Given any topological space $X$, any $n \in \mathbb{N}$ and any $i \in \mathbb{N}_0$ the following diagram commutes:

$$
\begin{array}{ccc}
H^n(X; \mathbb{Z}_2) & \xrightarrow{\Sigma_X} & H^{n+1}(\Sigma(X); \mathbb{Z}_2) \\
\downarrow \text{Sq}^i & & \downarrow \text{Sq}^i \\
H^{n+i}(X; \mathbb{Z}_2) & \xrightarrow{\Sigma_X} & H^{n+i+1}(\Sigma(X); \mathbb{Z}_2).
\end{array}
$$

Remark. The proposition says in particular that if there exists a non-trivial Steenrod operation on a topological space $X$, then its suspension inherits a non-trivial Steenrod operation. This is in so far interesting as we know by Lemma 82.7 that the cup product vanishes on suspensions. The fact that suspensions can have non-trivial Steenrod operations will allow us to prove several hitherto inaccessible results.

\[\text{1485} \text{ Basically the same statement works for } n = 0, \text{ the only nuisance is that in that case we need to work with reduced cohomology groups.}\]

\[\text{1486} \text{ Here we use Lemma 24.2 (3) to identify } X \text{ with the subset } C_- X \cap C_+ X \text{ of } \Sigma(X).\]
**Proof.** We consider the following diagram

\[
\begin{align*}
\Sigma X & \quad \xrightarrow{\delta} \quad \Sigma X \\
H^n(X; \mathbb{Z}_2) & \xrightarrow{\delta} H^{n+1}(C_+ X, X; \mathbb{Z}_2) & \cong & \quad H^{n+1}(\Sigma(X), C_- X; \mathbb{Z}_2) \\
& \quad \downarrow \text{Sq}^i & & \quad \downarrow \text{Sq}^i \\
H^{n+i}(X; \mathbb{Z}_2) & \xrightarrow{\delta} H^{n+i+1}(C_+ X, X; \mathbb{Z}_2) & \cong & \quad H^{n+i+1}(\Sigma(X), C_- X; \mathbb{Z}_2). \\
\end{align*}
\]

The first square commutes by Proposition 109.8. The two other squares commute by the naturality of the Steenrod operation \(\text{Sq}^i\). Thus we see that, as desired, the diagram commutes.

Next we recall that by the definitions on pages 1071 and 2212 we have three different types of Hopf maps:

**Definition.** We consider the following maps

\[
\begin{align*}
H : S^3 & \to S^2 = \mathbb{C}P^1 \\
(\bar{z}_1, \bar{z}_2) & \mapsto [\bar{z}_1 : \bar{z}_2] \\
H_H : S^7 & \to S^4 = \mathbb{H}P^1 \\
(\bar{z}_1, \bar{z}_2) & \mapsto [\bar{z}_1 : \bar{z}_2] \\
H_O : S^{15} & \to S^8 = \mathbb{O}P^1 \\
(\bar{z}_1, \bar{z}_2) & \mapsto [\bar{z}_1 : \bar{z}_2].
\end{align*}
\]

In Theorem 91.3 we showed that the Hopf map \(H : S^3 \to S^2\) is not null-homotopic. The key to doing so were the following two observations:

1. The mapping cone \(\text{Cone}(H : S^3 \to S^2)\) is homeomorphic to \(\mathbb{C}P^2\).
2. The cup product on \(\mathbb{C}P^2\) has the property that for a generator \(\varphi \in H^2(\mathbb{C}P^2; \mathbb{Z})\) the square \(\varphi^2\) is non-zero.

Since the Steenrod operations are a generalization of the mod 2 “cup product square” and since Steenrod operations behave well with respect to suspensions it seems reasonable that we can use Steenrod operations to show that the suspensions of the Hopf maps are not null-homotopic.

Indeed, we can prove the following theorem.

**Theorem 109.13.**

1. For any \(n \geq 2\) the \((n-2)\)-fold suspension

\[
\Sigma^{n-2}(H) : \Sigma^{n-2}(S^3) \to \Sigma^{n-2}(S^2) = S^n
\]

of the Hopf map defines a non-trivial element in \(\pi_{n+1}(S^n)\). In particular for any \(n \geq 2\) we have \(\pi_{n+1}(S^n) \neq 0\).
2. For any \(n \geq 4\) the \((n-4)\)-fold suspension

\[
\Sigma^{n-4}(H_H) : \Sigma^{n-4}(S^7) \to \Sigma^{n-4}(S^4) = S^n
\]
of the quaternionic Hopf map defines a non-trivial element in $\pi_{n+3}(S^n)$. In particular for any $n \geq 4$ we have $\pi_{n+3}(S^n) \neq 0$.

(3) For any $n \geq 8$ the $(n-8)$-fold suspension

$$\Sigma^{n-8}(H_\circ): \Sigma^{n-8}(S^{15}) \rightarrow \Sigma^{n-8}(S^8)$$

of the octonionic Hopf map defines a non-trivial element in $\pi_{n+7}(S^n)$. In particular for any $n \geq 8$ we have $\pi_{n+7}(S^n) \neq 0$.

Before we turn to the proof of Theorem 109.13 we recall, for the reader’s convenience, the following, frequently overlooked, proposition which says that taking suspensions and taking mapping cones commutes.

**Proposition 24.16.** If $f: X \rightarrow Y$ is a map between topological spaces, then there exists a homeomorphism

$$g: \text{Cone}(\Sigma(f)): \Sigma(X) \rightarrow \Sigma(Y) \xrightarrow{\sim} \Sigma(\text{Cone}(f): X \rightarrow Y)).$$

We also state the following lemma which we are already dimly aware of.

**Lemma 109.14.** If a map $\varphi: S^m \rightarrow S^n$ is homotopic to a constant map, then the corresponding mapping cone $\text{Cone}(\varphi): S^m \rightarrow S^n$ is homotopy equivalent to $S^{m+1} \vee S^n$.

**Proof.** We have

$$\text{Cone}(\varphi): S^m \rightarrow S^n \cong \text{Cone}(\text{constant map}: S^m \rightarrow S^n) \cong S^{m+1} \vee S^n.$$  

by Lemma 24.12 since $\varphi$ is homotopic to a constant map  

Lemma 91.1$\blacksquare$

![Figure 1532. Illustration of Lemma 109.14](image)

Now we turn to the proof of Theorem 109.13 For clarity’s sake we first provide a detailed proof of Theorem 109.13 (1). Afterwards we explain how to modify that proof to obtain statements (2) and (3) of Theorem 109.13.

**Proof of Theorem 109.13 (1).** In the following we will show that $\Sigma(H): S^4 \rightarrow S^3$ is not homotopic to a constant map. The general statement regarding the $(n-2)$-fold suspension $\Sigma^{n-2}(H)$ follows easily from iterating the argument below.

For once we do a proof by contradiction. So let us assume that the map $\Sigma(H): S^4 \rightarrow S^3$ is in fact homotopic to a constant map. We make the following preparations:

(1) To simplify the notation we denote the mapping cone of a map $f: X \rightarrow Y$ by $C(f)$ instead of $\text{Cone}(f)$. Furthermore we write $\mathbb{F} = \mathbb{Z}_2$.

(2) By Lemma 91.2 there exists a homeomorphism $f: \mathbb{C}(H): S^3 \rightarrow S^2 \xrightarrow{\cong} \mathbb{C}P^2$.

(3) We denote by $g: \Sigma(\mathbb{C}(H)) \xrightarrow{\cong} \mathbb{C}(\Sigma(H))$ the homeomorphism from Proposition 24.16.
(4) Since we assume that the map $H$ is homotopic to a constant map we obtain from Lemma 109.14 that there exists a homotopy equivalence $h: C(\Sigma(H)) \rightarrow S^3 \vee S^5$.

Now we consider the following diagram:

$$
\begin{array}{cccc}
H^2(\mathbb{C}P^2; \mathbb{F}) & \xrightarrow{f^*} & H^2(C(H); \mathbb{F}) & \xrightarrow{\Sigma} H^3(\Sigma(C(H)); \mathbb{F}) & \xrightarrow{\cong} H^3(C(\Sigma(H)); \mathbb{F}) & \xleftarrow{g^*} H^3(S^5 \vee S^3; \mathbb{F}) \\
\downarrow \text{Sq}^2 & & \downarrow \text{Sq}^2 & & \downarrow \text{Sq}^2 & & \downarrow \text{Sq}^2 \\
H^4(\mathbb{C}P^2; \mathbb{F}) & \xrightarrow{f^*} & H^4(C(H); \mathbb{F}) & \xrightarrow{\Sigma} H^5(\Sigma(C(H)); \mathbb{F}) & \xrightarrow{\cong} H^5(C(\Sigma(H)); \mathbb{F}) & \xleftarrow{g^*} H^5(S^5 \vee S^3; \mathbb{F}).
\end{array}
$$

We make the following observations:

1. The maps $\Sigma$ are the suspension isomorphisms given by Proposition 109.11.
2. It follows from Axiom (2) that the two vertical maps on the left are actually the same.
3. It follows from the naturality of $\text{Sq}^2$ that the first, third and the fourth square commute.
4. It follows from Proposition 109.12 that the second square commutes.
5. Since $f$ and $g$ are homeomorphisms we see that the induced maps $f^*$ and $g^*$ are isomorphisms. Furthermore, since $h$ is a homotopy equivalence we obtain from Lemma 73.13 (3) that the horizontal maps $h^*$ are isomorphisms.
6. By Proposition 90.13 we know that there exists a unique non-trivial $x \in H^2(\mathbb{C}P^2; \mathbb{F})$ and that this element satisfies $x \cup x \neq 0 \in H^4(\mathbb{C}P^2; \mathbb{F}) \cong \mathbb{F}$. In particular we see that the left vertical homomorphism is an isomorphism and that it is non-trivial.
7. By Lemma 109.5 we know that the vertical homomorphism to the right is trivial.

In summary we have shown that the above diagram commutes, we have shown that all horizontal maps are isomorphisms, we have seen that the left vertical map is non-trivial and have pointed out that the right vertical map is trivial. But this is absurd. In other words, we have obtained a contradiction to our hypothesis that the map $\Sigma(H): S^4 \rightarrow S^3$ is null-homotopic.

Proof of Theorem 109.13 (2) and (3). As we will see shortly, the proof for the quaternionic and octonionic Hopf maps is basically the same as the proof for the “classical” Hopf map.

Let us first consider the quaternionic Hopf. By Lemma 91.2 (2) there exists a homeomorphism $f: C(H_\mathbb{H}) \xrightarrow{\cong} \mathbb{H}P^2$. If $\Sigma(H_\mathbb{H}): S^8 \rightarrow S^5$ was null-homotopic we would, as in the proof of (1), obtain a commutative diagram of the following form:

$$
\begin{array}{cccc}
H^4(\mathbb{H}P^2; \mathbb{F}) & \xrightarrow{f^*} & H^4(C(H_\mathbb{H}); \mathbb{F}) & \xrightarrow{\Sigma} H^5(\Sigma(C(H_\mathbb{H})); \mathbb{F}) & \xrightarrow{\cong} H^5(C(\Sigma(H_\mathbb{H})); \mathbb{F}) & \xleftarrow{g^*} H^5(S^3 \vee S^5; \mathbb{F}) \\
\downarrow \text{Sq}^4 & & \downarrow \text{Sq}^4 & & \downarrow \text{Sq}^4 & & \downarrow \text{Sq}^4 \\
H^8(\mathbb{H}P^2; \mathbb{F}) & \xrightarrow{f^*} & H^8(C(H_\mathbb{H}); \mathbb{F}) & \xrightarrow{\Sigma} H^9(\Sigma(C(H_\mathbb{H})); \mathbb{F}) & \xrightarrow{\cong} H^9(C(\Sigma(H_\mathbb{H})); \mathbb{F}) & \xleftarrow{g^*} H^9(S^3 \vee S^5; \mathbb{F}).
\end{array}
$$
By Proposition 90.20 (1) the cup product on the left is non-trivial. Thus the same logic as in the proof of (1) leads to a contradiction.

The argument for the octonionic Hopf map is almost identical to the argument for the quaternionic Hopf map. We just need to redo the above argument with Lemma 91.2 (3) and with Proposition 90.20 (2).

For the record we jot down the following proposition that we proved in the proof of Theorem 109.13. We will make use of it later on.

**Proposition 109.15.** Given any \( n \in \mathbb{N}_0 \) the maps

\[
\begin{align*}
(1) & \quad \text{Sq}^2 : H^{2+n}(\text{Cone}(\Sigma^n(H)); \mathbb{Z}_2) \to H^{4+n}(\text{Cone}(\Sigma^n(H)); \mathbb{Z}_2) \\
(2) & \quad \text{Sq}^4 : H^{4+n}(\text{Cone}(\Sigma^n(H_3)); \mathbb{Z}_2) \to H^{8+n}(\text{Cone}(\Sigma^n(H_3)); \mathbb{Z}_2) \\
(3) & \quad \text{Sq}^8 : H^{8+n}(\text{Cone}(\Sigma^n(H_3)); \mathbb{Z}_2) \to H^{16+n}(\text{Cone}(\Sigma^n(H_3)); \mathbb{Z}_2)
\end{align*}
\]

are isomorphisms.

### 109.4. Proof of Theorem 109.2 I.

In the final two sections we will give a partial proof of Theorem 109.2. More precisely, we will construct the Steenrod operations and we will provide the proof of some of the properties. The proof is split into two parts:

1. The goal of this section is to construct a certain interesting sequence of natural maps

\( \Delta_n : C_*(X) \to C_*(X) \otimes C_*(X) \), \( n \in \mathbb{N}_0 \), where the zeroth map \( \Delta_0 \) is a diagonal approximation.

2. In the subsequent section we will show how this sequence of maps can be used to define the Steenrod operations.

In preparation for the construction of the sequence \( \Delta_n \) we recall some definitions and results from earlier on. First recall that on page 1433 we introduced the tensor product \( A_* \otimes B_* \) of two chain complexes \( A_* \) and \( B_* \). We will make use of the following harmless lemma.

**Lemma 84.7.** Let \( A_* \) and \( B_* \) be chain complexes. The unique map

\[
T : A_* \otimes B_* \to B_* \otimes A_*,
\]

that for \( a \in A_k \) and \( b \in B_l \) is given by

\[
a \otimes b \mapsto (-1)^{kl} \cdot b \otimes a
\]

is a chain map.

Since we will make use of this later on, we point out that \( T \) is natural in \( A_* \) and \( B_* \) and we point out that \( T^2 = \text{id} \). Next we recall the following definition from page 1984.

**Definition.** A diagonal approximation consists of a natural chain map

\[
\Phi : C_*(X) \to C_*(X) \otimes C_*(X)
\]

for each topological space \( X \), such that for each \( x \in X \), viewed as a singular 0-simplex, the following equality holds in \( (C_*(X) \otimes C_*(X))_0 = C_0(X) \otimes C_0(X) \):

\[
\Phi(x) = x \otimes x.
\]

**Example.** We will try to rise to the challenge of finding a suitable illustration for a diagonal approximation \( \Phi \). We start out with the following observation: if \( \sigma : \Delta^1 \to X \) is a singular
1-simplex from a point $P$ to a point $Q$, then $\Phi(\sigma) \in (C_*(X) \otimes C_*(X))_1$ needs to satisfy
\[ \partial \Phi(\sigma) = \Phi(\partial \sigma) = \Phi(Q - P) = \Phi(Q) - \Phi(P) = Q \otimes Q - P \otimes P. \]
since $\Phi$ is a chain map since $\Phi$ is determined on singular 0-simplices

For example $\Phi(\sigma) = (C_*(X) \otimes C_*(X))_1 = C_1(X) \otimes C_0(X) \oplus C_0(X) \otimes C_1(X)$ could be of the form $\alpha \otimes P + Q \otimes \beta$ where $\alpha: \Delta^1 \to X$ and $\beta: \Delta^1 \to X$ are singular simplices from $P$ to $Q$. This situation is illustrated, with artistic liberties, in Figure 1533.

![Diagonal approximation](image)

**Figure 1533**

The following proposition contains the two key results on diagonal approximations.

**Proposition 81.6.**

1. There exist diagonal approximations.
2. Given any two diagonal approximations $\Phi$ and $\Psi$ there exists a natural chain homotopy equivalence between $\Phi$ and $\Psi$.

**Proof.** We gave an explicit example of a diagonal approximation in Lemma 81.5. In Proposition 80.17 we gave a proof of (2) using the Acyclic Model Theorem 80.16 (2). ■

The following theorem shows that any diagonal approximation can be extended to a sequence of maps.

**Theorem 109.16.**

1. Given any topological space $X$ there exists a sequence of natural maps
   \[ \Delta_n: C_*(X) \to C_*(X) \otimes C_*(X), \quad n \in \mathbb{N}_0 \]
   of degree $n$ such that the following two conditions are satisfied:
   (a) The map $\Delta_0$ is a diagonal approximation.
   (b) For every $n \in \mathbb{N}_0$ the following equality holds
   \[ \partial \circ \Delta_{n+1} + (-1)^n \cdot \Delta_{n+1} \circ \partial = (T + (-1)^{n+1} \cdot \text{id}) \circ \Delta_n. \]
2. Given two sequences $\Delta_n, \Delta'_n$, $n \in \mathbb{N}_0$, as in (1) there exists a sequence of natural maps
   \[ H_n: C_*(X) \to C_*(X) \otimes C_*(X), \quad n \in \mathbb{N}_0 \]
   of degree $n$ such that the following two conditions are satisfied:
   (a) $H_0$ is the zero map.
   (b) For every $n \in \mathbb{N}_0$ the following equality holds
   \[ \partial \circ H_{n+1} + (-1)^n \cdot H_{n+1} \circ \partial = \Delta_n - \Delta'_n - (T + (-1)^n \cdot \text{id}) \circ H_n. \]
In the proof of Theorem 109.16 we will need the following innocuous variation on the definition of a chain map that we had given on page 1086.

**Definition.**

1. A **chain map** \( f : C_* \to D_* \) of degree \( d \) between two chain complexes consists of a family \( \{ f_n : C_n \to D_{n+d} \}_{n \in \mathbb{N}_0} \) of maps such that for each \( n \in \mathbb{N}_0 \) the following equality holds:
   \[
   f_{n-1} \circ \partial_n = \partial_{n+d} \circ f_n.
   \]
2. An **anti-chain map** \( f : C_* \to D_* \) of degree \( d \) is basically the same data as a chain map of degree \( d \), except that for each \( n \in \mathbb{N}_0 \) the following equality holds:
   \[
   f_{n-1} \circ \partial_n = -\partial_{n+d} \circ f_n.
   \]

**Remark.** Given an anti-chain map \( \{ f_n \}_{n \in \mathbb{N}_0} \) of degree \( d \) one can easily see that the maps \( \{ (-1)^n \cdot f_n \}_{n \in \mathbb{N}_0} \) form a chain map of degree \( d \). This little trick makes it possible to translate all kinds of statements about chain maps to anti-chain maps. For example, as in Lemma 41.7 we see that an anti-chain map induces a map on homology groups.

In the proof of Theorem 109.16 we will need the following consequence of the Acyclic Model Theorem 80.13.

**Theorem 109.17. (Acyclic Model Theorem)** Let \( \text{Top} \) be the category of topological spaces and let \( \mathcal{C} \) be the category of generalized chain complexes.

1. Let \( S : C_* (X) \to C_* (X) \otimes C_* (X) \) be a natural chain map of degree \( d \). If we have \( d \geq 1 \), then for any topological space \( X \) and any \( k \in \mathbb{N}_0 \) there exists a natural map \( P_X : C_k (X) \to (C_* (X) \otimes C_* (X))_{k+d+1} \) such that for any \( k \in \mathbb{N}_0 \) we have
   \[
   \partial \circ P_X + P_X \circ \partial = S_X : C_k (X) \to (C_* (X) \otimes C_* (X))_{k+d}.
   \]
2. For a natural anti-chain map \( S : C_* (X) \to C_* (X) \otimes C_* (X) \) of degree \( d \) the analogous data exists except that now we have
   \[
   \partial \circ P_X - P_X \circ \partial = S_X : C_k (X) \to (C_* (X) \otimes C_* (X))_{k+d}.
   \]

**Proof of the Acyclic Model Theorem 109.17**

1. Given any topological space \( X \) we consider \( G(X) := (C_* (X) \otimes C_* (X))[-d] \). Here we use the notation introduced on page 2039, namely given a chain complex \( D_* \) we denote by \( D_* [-d] \) the chain complex \( D_* \) “shifted by \( d \) to the right”. This shift turns \( G(X) \) into a generalized chain complex. Furthermore, this shift turns \( S : C_* (X) \to G(X) \) into a natural chain map of degree 0.

---

\(^{1487}\) By a map of degree \( n \) between chain complexes \( C_* \) and \( D_* \) we mean a collection of maps \( C_k \to D_{k+n}, k \in \mathbb{N}_0 \).

\(^{1488}\) Note that both sides are maps \( C_* (X) \to C_* (X) \otimes C_* (X) \) of degree \( n \).

\(^{1489}\) In other words, the map \( H_{n+1} \) is a chain homotopy between \( \Delta_n \) and \( \Delta'_n \) up to the “error term” \(-T \cdot (-1)^n \cdot \text{id} \circ H_n \).

\(^{1490}\) Recall that a generalized chain complex is like a chain complex except that we allow chain groups in negative degrees.
Next note that for any \( k \in \mathbb{N}_0 \) and any \( i \geq 0 \) we have
\[
H_i(\mathbb{G}(\Delta^k)) = H_i((C_*(\Delta^k) \otimes C_*(\Delta^k))[−d]) = H_{i+d}(C_*(\Delta^k) \otimes C_*(\Delta^k))
\]
\[
= \bigoplus_{p+q=i+d} H_p(\Delta^k) \otimes H_q(\Delta^k) = 0.
\]
by the Künneth Theorem \[58.7\] for chain complexes and since \( d \geq 1 \)

Thus we see that all the hypotheses of the Acyclic Model Theorem \[80.13\] are satisfied. Therefore we see that for any topological space \( X \) and any \( k \in \mathbb{N}_0 \) there exists a natural map \( P_X: C_k(X) \to G_{k+1}(X) \) such that for any \( k \in \mathbb{N}_0 \) we have
\[
\partial \circ P_X + P_X \circ \partial = S_X: C_k(X) \to G_k(X).
\]

(2) Suppose we are given a natural anti-chain map \( S \) of degree \( d \). As in the remark preceding the theorem we can turn \( S \) into a natural chain map \( T \) by setting \( T_k = (-1)^k \cdot S_k, \; k \in \mathbb{N}_0 \). We apply (1) and we obtain natural maps \( Q_X \). Now we define \( P_k := (-1)^k \cdot (Q_X)_k, \; k \in \mathbb{N}_0 \). One easily verifies that the desired equality holds. ■

Now, finally, we can turn to the actual proof of Theorem \[109.16\].

**Proof of Theorem \[109.16\]**

(1) We construct the maps \( \Delta_n: C_*(X) \to C_*(X) \otimes C_*(X), \; n \in \mathbb{N}_0 \) iteratively.

(i) First of all, we know by the Proposition \[81.6(1)\] above that there exists a diagonal approximation \( \Delta_0: C_*(X) \to C_*(X) \otimes C_*(X) \).

(ii) Note that \( T \circ \Delta_0: C_*(X) \to C_*(X) \otimes C_*(X) \) is another diagonal approximation. It follows from Proposition \[81.6(2)\] that there exists a natural chain homotopy \( \Delta_1: C_*(X) \to C_*(X) \otimes C_*(X) \) between \( \Delta_0 \) and \( T \circ \Delta_0 \). In other words, there exists a natural map \( \Delta_1: C_*(X) \to C_*(X) \otimes C_*(X) \) of degree one such that
\[
\partial \circ \Delta_1 + \Delta_1 \circ \partial = (T \circ \Delta_0) - \Delta_0 = (T - \text{id}) \circ \Delta_0.
\]

Thus we are done with the construction of the map \( \Delta_1 \). This step is illustrated in Figure \[1534\].

\[
\Delta_1(\sigma) \in (C_*(X) \otimes C_*(X))_2 \text{ is a “homotopy” between } \Delta_0(\sigma) \text{ and } (T \circ \Delta_0)(\sigma)
\]
(iii) The starting point for defining the next map $\Delta_2$ is the following amusing little calculation:

$$
\text{since } T^2 = \text{id} \quad \text{by (ii)} \\
0 = (T^2 - \text{id}) \circ \Delta_0 = (T + \text{id}) \circ (T - \text{id}) \circ \Delta_0 = (T + \text{id}) \circ (\partial \circ \Delta_1 + \Delta_1 \circ \partial) \\
= \partial \circ (T + \text{id}) \circ \Delta_1 + (T + \text{id}) \circ \Delta_1 \circ \partial. 
$$

since $T$ and $\text{id}$ are chain maps they commute with the boundary maps

This shows that the map $(T + \text{id}) \circ \Delta_1 : C_*(X) \to C_*(X) \otimes C_*(X)$ is a natural anti-chain map of degree one. By the Acyclic Model Theorem 109.17 (2) there exists a natural map $\Delta_2 : C_*(X) \to C_*(X) \otimes C_*(X)$ of degree two such that

$$
\partial \circ \Delta_2 - \Delta_2 \circ \partial = (T + \text{id}) \circ \Delta_1.
$$

This concludes the construction of the map $\Delta_2$.

(iv) Just for kicks we do the calculation for the next stage as well. We perform the following calculation:

$$
\text{since } T^2 = \text{id} \quad \text{by (iii)} \\
0 = (T^2 - \text{id}) \circ \Delta_1 = (T - \text{id}) \circ (T + \text{id}) \circ \Delta_1 = (T - \text{id}) \circ (\partial \circ \Delta_2 - \Delta_2 \circ \partial) \\
= \partial \circ (T - \text{id}) \circ \Delta_2 - (T - \text{id}) \circ \Delta_2 \circ \partial. 
$$

since $T$ and $\text{id}$ are chain maps they commute with the boundary maps

This shows that the map $(T - \text{id}) \circ \Delta_2 : C_*(X) \to C_*(X) \otimes C_*(X)$ is a natural chain map of degree two. By the Acyclic Model Theorem 109.17 (1) there exists a natural map $\Delta_3 : C_*(X) \to C_*(X) \otimes C_*(X)$ of degree three such that

$$
\partial \circ \Delta_3 + \Delta_3 \circ \partial = (T - \text{id}) \circ \Delta_2.
$$

This concludes the construction of the map $\Delta_3$.

(iv) Now we iterate this procedure and we obtain the desired sequence of natural maps $\Delta_n$.

(2) Given two sequences $\Delta_n, \Delta'_n$ as in (1) we define the desired maps $H_n, n \in \mathbb{N}_0$ in a fashion that is quite similar to the approach taken in (1).

(i) We set $H_0 = 0$.

(ii) Next we point out that by definition $\Delta_0$ and $\Delta'_0$ are diagonal approximations. Thus it follows from Proposition 81.6 (2) that there exist natural maps $H_1$ such that

$$
\partial \circ H_1 + H_1 \circ \partial = \Delta_0 - \Delta'_0.
$$

(iii) We calculate that

$$
\partial \circ (\Delta_1 - \Delta'_1 - (T - \text{id}) \circ H_1) + (\Delta_1 - \Delta'_1 - (T - \text{id}) \circ H_1) \circ \partial \\
= (\partial \circ \Delta_1 + \Delta_1 \circ \partial) - (\partial \circ \Delta'_1 + \Delta'_1 \circ \partial) - \partial \circ (T - \text{id}) \circ H_1 - (T - \text{id}) \circ H_1 \circ \partial \\
= (T - \text{id}) \circ (\partial \circ \Delta_1 + \Delta_1 \circ \partial) - (T - \text{id}) \circ (\partial \circ H_1 + H_1 \circ \partial) \\
= 0. 
$$

since $\partial \circ \Delta_1 + \Delta_1 \circ \partial = (T - \text{id}) \circ \Delta_0$ (same for $\Delta'_0, \Delta'_1$) and since $\partial \circ H_1 + H_1 \circ \partial = \Delta_0 - \Delta'_0$

\[\text{These are equalities of maps } C_*(X) \to C_*(X) \otimes C_*(X).\]
This shows that $\Delta_1 - \Delta'_1 - (T - \text{id}) \circ H_1$ is an anti-chain map of degree one. By the Acyclic Model Theorem \[109.17\] (2) there exists a natural map $H_2$ with

$$H_2 \circ \partial - \partial \circ H_2 = -(T - \text{id}) \circ H_1 + \Delta_1 - \Delta'_1.$$

(iv) Now we iterate this procedure to obtain the desired sequence of natural maps.

One easily sees that we get the correct pattern for the signs involved. ■

**Remark.** If there did exist a diagonal approximation $\Delta_0: C_*(X) \to C_*(X) \otimes C_*(X)$ that is symmetric in the sense that $T \circ \Delta_0 = \Delta_0$, then we could take $\Delta_1 = 0$ and we could also take all higher $\Delta_n$ to be zero. Later, in Chapter \[109\] we will see that this is in general not the case. So even though diagonal approximations are symmetric on the degree 0 level, they cannot be chosen to be symmetric in higher degrees.

109.5. **Proof of Theorem 109.2 II.** In this section we will use the sequence of natural maps $\Delta_n: C_*(X) \to C_*(X) \otimes C_*(X)$, $n \in \mathbb{N}_0$, from Theorem \[109.16\] to define the Steenrod operations.

To get an inspiration for how to define the Steenrod operations we first recall the definition of the cup product. To do so we need the following lemma which is inspired by the definitions on from page \[1979\].

**Lemma 109.18.** Let $C_*$ and $D_*$ be chain complexes and let $R$ be a commutative ring. Given $p, q \in \mathbb{N}_0$ we consider the map $\Xi: \text{Hom}(C_p, R) \otimes \text{Hom}(D_q, R) \to \text{Hom}((C \otimes D)_{p+q}, R)$

$$\varphi \otimes \psi \mapsto \left( (C \otimes D)_{p+q} \xrightarrow{\text{projection}} C_p \otimes D_q \xrightarrow{\varphi \otimes \psi} R \otimes R \to R \quad a \otimes b \mapsto a \cdot b \right).$$

The corresponding map

$$\Xi := \bigoplus_{p, q \in \mathbb{N}_0} \Xi_{p, q}: \text{Hom}(C_*, R) \otimes \text{Hom}(D_*, R) \to \text{Hom}(C_* \otimes D_*, R)$$

is a cochain map.

**Proof.** The statement follows basically immediately from the definitions. ■

The following lemma gives us a slight reformulation of the original definition of the cup product.

**Lemma 109.19.** Let $X$ be a topological space and let $R$ be a commutative ring. Furthermore let $\Delta_0: C_*(X) \to C_*(X) \otimes C_*(X)$ be a diagonal approximation. We consider the cochain map

$$\text{Hom}(C_*(X), R) \otimes \text{Hom}(C_*(X), R) \xrightarrow{\Xi} \text{Hom}(C_*(X) \otimes C_*(X), R) \xrightarrow{\Delta^*_0} \text{Hom}(C_*(X), R).$$

---

\[1432\] The tensor product of cochain complexes is defined basically the same way as we defined the tensor product of chain complexes, see page \[1433\].
The corresponding map
\[ H^p(X; R) \times H^q(X; R) \to H^{p+q}(X; R) \]
\[ ([\varphi], [\psi]) \mapsto [h_0(\varphi \otimes \psi)] \]
equals the cup product as defined on page 1980.

Proof (∗). We denote by \( d: X \to X \times X \) the diagonal map that is given by \( d(x) = (x, x) \).

Let \( \Theta: C_*(X \times X) \to C_*(X) \otimes C_*(X) \) denote an Eilenberg-Zilber map from Theorem 80.1.

For the purpose of this proof the only thing we need to know about the Eilenberg-Zilber map \( \Theta \) is that, basically by definition, the map \( \Theta \circ d: C_*(X) \to C_*(X \times X) \to C_*(X) \otimes C_*(X) \)
is a diagonal approximation. We consider the following diagram:
\[
\begin{array}{cccccccc}
\Hom(C_*(X), R) \otimes \Hom(C_*(X), R) & \xrightarrow{=} & \Hom(C_*(X) \otimes C_*(X), R) & \xrightarrow{\Delta} & \Hom(C_*(X), R) \\
& \downarrow{\Theta} & & \downarrow{d^*} & \\
& & \Hom(C_*(X \times X), R).
\end{array}
\]

The lower sequence of maps is at the heart of the definition of the cup product on page 1980. Since \( \Theta \circ d \) is a diagonal approximation we obtain from Proposition 81.6 that \( \Delta_0 \) and \( \Theta \circ d \) are chain homotopic. But by Lemma 73.8 (4) this means that the two maps induce the same map on cohomology. The lemma follows almost immediately from the above observations.

Now we turn to the actual construction of the Steenrod operations. To do so we pick a sequence of natural maps
\[ \Delta_n: C_*(X) \to C_*(X) \otimes C_*(X), \quad n \in \mathbb{N}_0 \]
which satisfies the conditions set out in Theorem 109.16 (1). In light of Lemma 109.19 it is clear what we want to do next. Namely we want to replace \( \Delta_0 \) by the “higher maps” \( \Delta_n \). This leads us straight to the following definition.

Definition. Let \( X \) be a topological space and let \( R \) be a commutative ring. Given \( i \in \mathbb{N}_0 \) we define
\[
\Hom(C_*(X), R) \otimes \Hom(C_*(X), R) \xrightarrow{=} \Hom(C_*(X) \otimes C_*(X), R) \xrightarrow{\Delta_i} \Hom(C_*(X), R).
\]
Recall that \( \Delta_i \) is a map of degree \( i \). Since we dualize we see that \( h_i \) is a map of degree \(-i\).
For convenience we define \( h_i := 0 \) for \( i \in \mathbb{Z}_{<0} \).

Now we can finally define the Steenrod operations.
**Theorem 109.20.** Let \( X \) be a topological space, let \( A \subset X \) be a subset and let \( R \) be a commutative ring. If \( 1 + 1 = 0 \) in \( R \), then for any \( q \in \mathbb{N}_0 \) and any \( i \in \mathbb{N}_0 \) the map

\[
\text{Sq}^i : H^q(X, A; R) \to H^{q+i}(X, A; R)
\]

\[
\varphi \otimes \psi \mapsto h_q(\varphi \otimes \psi)
\]

\[
e \in C^q \otimes C^r
\]
is a well-defined natural homomorphism.

**Remark.** The proof of Theorem 109.20 that we give below is a long and winding calculation, with few interesting viewpoints. Perhaps more interesting than the question, why the definition works, is the question, why does the map

\[
\text{C}^q(X, A; R) \otimes \text{C}^r(X, A; R) \to \text{C}^{q+r+j}(X, A; R)
\]

\[
\varphi \otimes \psi \mapsto h_j(\varphi \otimes \psi)
\]

not descend to a map on cohomology?

The proof of Theorem 109.20 requires some preparations. First of all, note that the equalities in Theorem 109.16 translate into the following lemma.

**Lemma 109.21.** Let \( X \) be a topological space. Furthermore let \( R \) be a commutative ring with \( 1 + 1 = 0_R \). For any \( \alpha, \beta \in \text{C}^*(X; R) \) we have the following equality:

\[
h_{n+1}(\delta(\alpha \otimes \beta)) + \delta(h_{n+1}(\alpha \otimes \beta)) = h_n(\alpha \otimes \beta + \beta \otimes \alpha) \in \text{C}^*(X; R).
\]

**Proof.** Recall, see Theorem 109.16, that one of the defining properties of the sequence \( \Delta_n \) is that for every \( n \in \mathbb{N}_0 \) the following equality holds:

\[
\partial \circ \Delta_{n+1} + (-1)^n \cdot \Delta_{n+1} \circ \partial = (T + (-1)^{n+1} \cdot \text{id}) \circ \Delta_n.
\]

We dualize this equality, we use the equality \( 1 + 1 = 0 \), we use the fact, shown in Lemma 109.18 and that \( \Xi \) is a cochain map. After performing all these steps one obtains the desired equality. We leave it to the reader to fill in the few remaining details. \( \blacksquare \)

For elements of the form \( \alpha \otimes \alpha \) the following lemma shows how the maps \( h_n \) relate to coboundaries.

**Lemma 109.22.** Let \( X \) be a topological space and let \( R \) be a commutative ring. If \( 1 + 1 = 0 \) in \( R \), then for any \( \alpha \in \text{C}^n(X; R) \) we have

\[
h_{n+1}(\delta \alpha \otimes \delta \alpha) = \delta h_{n+1}(\alpha \otimes \delta \alpha) + h_n(\alpha \otimes \alpha) \in \text{C}^{n+1}(X; R).
\]

**Proof.** Since we assume that \( 1 + 1 = 0 \) in \( R \) we can ignore conveniently enough ignore signs throughout the proof. Thus we compute

\[
h_{n+1}(\delta \alpha \otimes \delta \alpha) = h_{n+1}(\delta(\alpha \otimes \delta \alpha)) = h_{n+1}(\delta \alpha \otimes \delta \alpha) + h_n(\delta(\alpha \otimes \alpha)) = \delta h_{n+1}(\alpha \otimes \delta \alpha) + h_n(\alpha \otimes \alpha) + \delta h_n(\alpha \otimes \alpha).
\]

\( \uparrow \)

definition of \( \delta \) on tensor product \hspace{1cm} \text{by Lemma 109.21 and since } h_{n-1}(\alpha \otimes \alpha + \alpha \otimes \alpha) = 0 \]

\( \downarrow \)

Lemma 109.21 and since \( h_{n-1}(\alpha \otimes \alpha + \alpha \otimes \alpha) = 0 \) since \( 1 + 1 = 0 \) \( \blacksquare \)
In the proof of Theorem 109.20, we will need the following little lemma.

**Lemma 109.23.** Let $X$ be a topological space and let $R$ be a commutative ring with $1+1 = 0$. For any $\alpha, \beta \in C^q(X; R)$ the following equality holds:

$$h_n((\alpha + \beta) \otimes (\alpha + \beta)) = h_n(\alpha \otimes \alpha) + h_n(\beta \otimes \beta) + h_{n+1}(\delta(\alpha \otimes \beta)) + \delta(h_{n+1}(\alpha \otimes \beta)).$$

**Proof of Lemma 109.23.** This follows from “multiplying out”, the linearity of $h_n$ and the equality

$$h_n(\alpha \otimes \beta + \beta \otimes \alpha) = h_{n+1}(\delta(\alpha \otimes \beta)) + \delta(h_{n+1}(\alpha \otimes \beta)).$$

by Lemma 109.21. \qed

Now, after these lengthy preparations we can provide the proof of Theorem 109.20.

**Proof of Theorem 109.20.** Let $X$ be a topological space, let $A \subset X$ be a subset and let $R$ be a commutative ring. First we consider the case that $A = \emptyset$. Let $\varphi \in C^q(X; R)$ be a representative of some element in $H^q(X; R)$.

1. Note that $\varphi \otimes \varphi$ is of degree $2q$. Thus $h_{q-i}(\varphi \otimes \varphi)$ is of degree $2q - (q - i) = q + i$.
2. Let $\varphi \in C^q(X; R)$ be a cocycle. We calculate that

$$\delta h_{q-i}(\varphi \otimes \varphi) = h_{q-i}(\delta(\varphi \otimes \varphi)) + h_{q-i-1}(\varphi \otimes \delta \varphi + \varphi \otimes \delta \varphi) = h_{q-i}(\delta \varphi \otimes \varphi + \varphi \otimes \delta \varphi) = 0.$$  

by Lemma 109.21, definition of $\delta$ on tensor product, since $\varphi$ is a cocycle

Thus we have shown that $h_{q-i}(\varphi \otimes \varphi)$ is a cocycle. In other words, we have shown that it defines an element in cohomology.

3. Let $\psi \in C^{q-1}(X; R)$. We have the following equality in $H^{q+i}(X; R)$:

$$[h_{q-i}((\varphi + \delta \psi) \otimes (\varphi + \delta \psi))] = [h_{q-i}(\varphi \otimes \varphi) + h_{q-i}(\delta \psi \otimes \delta \psi)] = [h_{q-i}(\varphi \otimes \varphi)].$$

by Lemma 109.23, here we use that $\delta(\varphi \otimes \delta \psi) = \delta \varphi \otimes \delta \psi + \varphi \otimes \delta \delta \psi = 0$ Lemma 109.22

This shows that the map $Sq^i$ is well-defined, i.e. it does not depend on the choice of the representative of the cohomology class.

4. It follows quite easily from Lemma 109.23 that $Sq^i$ is in fact a homomorphism.

Finally we consider the case that $A \neq \emptyset$. Using the observation on page 1829, we make the identification

$$C^q(X, A; R) = \{ \varphi \in C^q(X; R) \mid \varphi \text{ vanishes on } C_q(A) \subset C_q(X) \}.$$

It follows from the naturality of $h_n$ that if $\varphi \in C^q(X)$ vanishes on $C_q(A)$, then $h_{q-i}(\varphi \otimes \varphi)$ vanishes on the subgroup $C_*(A) \otimes C_*(X) + C_*(X) \otimes C_*(A)$ of $C_*(X) \otimes C_*(X)$. Thus we see that the map

$$Sq^i: H^q(X, A; R) \to H^{q+i}(X, A; R), \quad [\varphi] \mapsto [h_{q-i}(\varphi \otimes \varphi)]$$

is well-defined. \qed
We continue with the following proposition.

**Proposition 109.24.** The definition of the maps $\text{Sq}^i$ does not depend on the choice of the natural maps $\Delta_n$.

**Proof.** Suppose we are given another sequence of maps $\tilde{\Delta}_n$ that have the properties described in Theorem 109.16 (1). We define the maps $\tilde{h}_i$ in the obvious way. By Theorem 109.16 (2) there exists a sequence of natural maps

$$H_n : C_k(X) \rightarrow C_k(X) \otimes C_k(X), \quad n \in \mathbb{N}_0$$

of degree $n$ such that $H_0 = 0$ and such that for every $n \in \mathbb{N}_0$ the following equality holds:

$$\partial \circ H_{n+1} + (-1)^n \cdot H_{n+1} \circ \partial = \Delta_n - \tilde{\Delta}_n - (T + (-1)^n \cdot \text{id}) \circ H_n.$$

Given a cocycle $\varphi \in C^q(X,A;\mathbb{Z}_2)$ and $i \in \mathbb{N}_0$ we see that we have the following equality in $H^{2q-i}(X,A;\mathbb{R})$:

$$\text{definition of } h_i, \tilde{h}_i$$

$$[h_i(\varphi \otimes \varphi)] - [\tilde{h}_i(\varphi \otimes \varphi)] = [\Delta_i^*(\Xi(\varphi \otimes \varphi)) - \Delta_i^*(\Xi(\varphi \otimes \varphi))]$$

$$\uparrow$$

$$= [H_{i+1}^*(\delta(\Xi(\varphi \otimes \varphi) + (H_{i+1}^*(\varphi \otimes \varphi) + H_i^*((T + \text{id})^*(\Xi(\varphi \otimes \varphi))))]$$

by \((*)\) and since $1 + 1 = 0$

$$= [H_{i+1}^*(\Xi(\varphi \otimes \varphi) + (\varphi \otimes \varphi))] = 0.$$

We have thus shown that the two definitions using $\Delta_n$ and $\tilde{\Delta}_n$ agree. \[\blacksquare\]

By Proposition 109.24, the maps $\text{Sq}^i$ are unambiguously defined. Thus we can make the following definition.

**Definition.** Given a pair of topological spaces $(X,A)$ and $i \in \mathbb{N}_0$ we refer to each map

$$\text{Sq}^i : H^q(X,A;\mathbb{Z}_2) \rightarrow H^{q+i}(X,A;\mathbb{Z}_2)$$

as the $i$-th Steenrod operation.

By Theorem 109.20, the Steenrod operations are additive cohomology operations. To complete the proof of Theorem 109.2 we need to verify that the maps $\text{Sq}^i$ have all the other desired properties. In other words we need to prove the following theorem.

**Theorem 109.25.** The Steenrod operations $\text{Sq}^i$ have the following properties:

1. $\text{Sq}^0 = \text{id}$.
2. For any $\varphi \in H^i(X,A;\mathbb{Z}_2)$ we have $\text{Sq}^i(\varphi) = \varphi^2$.
3. For any $\varphi \in H^j(X,A;\mathbb{Z}_2)$ with $j < i$ we have $\text{Sq}^i(\varphi) = 0$.
4. For any $\varphi \in H^r(X,A;\mathbb{Z}_2)$ and $\psi \in H^s(X,A;\mathbb{Z}_2)$ we have

$$\text{Sq}^k(\varphi \cup \psi) = \sum_{i=0}^{k} \text{Sq}^i(\varphi) \cup \text{Sq}^{k-i}(\psi).$$
Proof.

(1) The notation might suggest that this statement is surely trivial, but that is not the case. For time, space and mental energy reasons we will not give the proof, which at first glance does not seem terribly enlightening anyway. Instead we refer to [Spa95, p. 274] for details.

(2) First we deal with the absolute case. Thus let $\varphi \in C^i(X; R)$ be a cocycle. We calculate
\[
\Sq^i(\varphi) = [h_{i-i}(\varphi \otimes \varphi)] = [h_0(\varphi \otimes \varphi)] = [\varphi] \cup [\varphi].
\]
by definition Lemma 109.19

The case that we are dealing with a cocycle $\varphi \in C^i(X, A; R)$ is proved basically the same way.

(3) Let $\varphi \in C^j(X, A; Z_2)$ be a cocycle and suppose that $i > j$. We have
\[
\Sq^i([\varphi]) = [h_{j-i}(\varphi)] = [0].
\]
by definition since $j - i < 0$ we have $h_{j-i} = 0$

(4) This statement is proved in [Spa95, p. 274].

Exercises for Chapter 109.

Exercise 109.1.

(a) Show that for any $k \in \mathbb{N}_{\geq 3}$ and $m \in \mathbb{N}$ the map $H^m(X; Z_2) \to H^{mk}(X; Z_2)$ given by $\varphi \mapsto \varphi^k$ is not an additive cohomology operation.

(b) Is the map $H^4(X; Z_3) \to H^3(X; Z_3)$ given by $\varphi \mapsto \varphi^3$ an additive cohomology operation?

Exercise 109.2. Let $X = S^m \vee S^n$ be the wedge of two spheres. Show that for $i \geq 1$ all Steenrod operations $\Sq^i : H^k(X; Z_2) \to H^k(X; Z_2)$ are zero.

Hint. Reread the proof of Lemma 81.11.

Exercise 109.3. Find a closed formula for the $i$-th Steenrod operation on $H^*(\mathbb{C}P^\infty; Z_2)$.

Hint. Use Proposition 90.13 (2).
The following theorem was first proved by José Ádem [Ade52, Ade57] in 1952.

**Theorem 110.1. (Adem Relations)** For any \(0 < a < 2b\) we have the following equality of cohomology operations:\footnote{These are equalities of cohomology operations \(H^n(X,A;\mathbb{Z}_2) \to H^{n+a+b}(X,A;\mathbb{Z}_2)\). In particular, since we work over \(\mathbb{Z}_2\)-coefficients, we only care about the binomial coefficient modulo 2. We will discuss the mod 2 reductions of binomial coefficients in Lemma 110.3.}

\[
Sq^a \circ Sq^b = \left\lfloor \frac{a}{2} \right\rfloor \sum_{j=0}^{\left\lfloor \frac{a}{2} \right\rfloor} \binom{b-1-j}{a-2j} \cdot Sq^{a+b-j} \circ Sq^j.
\]

These equalities are called the Adem relations.

**Remark.** As is remarked on [SE62, p. 2], the Adem relations are a consequence of the properties of Steenrod operations that were stated in Theorem 109.2. This observation also follows from the uniqueness result stated in Theorem 109.3.

**Proof.** Since the proof would consume too much of our valuable time we will not provide it. Instead we refer to the original paper by Adem [Ade52, Ade57] or alternatively to [BuM82, SE62 Theorem VIII.1.5], [MTa68, p. 23], or [Hat02 Theorem 4.I.13] for a proof. □

Even though we will not prove the Adem relations, we will shamelessly exploit them in this chapter. Afterwards the conscientious reader will surely feel compelled to read the proof of the Adem relations.

Just to get a feeling for the Adem relations we determine for small values of \(a\) what the relations really look like.

**Example.** For \(a = 1\) and for any \(b \in \mathbb{N}\) we have

\[
Sq^1 \circ Sq^b = \left\lfloor \frac{1}{2} \right\rfloor \sum_{j=0}^{\left\lfloor \frac{1}{2} \right\rfloor} \binom{b-1-j}{a-2j} \cdot Sq^{a+b-j} \circ Sq^j = \left(\begin{array}{c} b-1 \\ 1 \end{array}\right) \cdot Sq^{1+b} \circ Sq^0 = (b-1) \cdot Sq^{1+b}.
\]

Furthermore, for \(a = 2\) and any \(b \in \mathbb{N}_{\geq 2}\) we have

\[
Sq^2 \circ Sq^b = \left(\begin{array}{c} b-1 \\ 2 \end{array}\right) \cdot Sq^{2+b} \circ Sq^0 + \left(\begin{array}{c} b-2 \\ 0 \end{array}\right) \cdot Sq^{1+b} \circ Sq^1 = \left(\begin{array}{c} b-1 \\ 2 \end{array}\right) \cdot Sq^{2+b} + Sq^{1+b} \circ Sq^1.
\]

In particular setting \(b = 2\) we see that

\[
Sq^2 \circ Sq^2 = Sq^3 \circ Sq^1.
\]
110.1. **Application of the Adem relations to homotopy groups of spheres.** Recall that in Theorem 109.13 we used Steenrod operations to show that the three Hopf maps $H: S^3 \to S^2$, $H_H: S^7 \to S^4$ and $H_O: S^{15} \to S^8$ and their suspensions define non-trivial elements in the corresponding homotopy groups of spheres.

In this section we will use the Adem relations to show that the 2-fold iteration of these Hopf maps also define non-trivial elements in the homotopy groups of spheres. More precisely, we have the following theorem.

**Theorem 110.2.**

1. For any $n \geq 2$ the map
   $$\Sigma^{n-2}(\begin{array}{c} S^3 \to S^2 \\ \text{map} \: S^3 \to S^2 \end{array} \circ \Sigma^2(H)) : S^{n+2} \to S^n$$
   defines a non-trivial element in $\pi_{n+2}(S^n)$. In particular for any $n \geq 2$ we have $\pi_{n+2}(S^n) \neq 0$.
2. For any $n \geq 4$ the map
   $$\Sigma^{n-4}(\begin{array}{c} S^7 \to S^4 \\ \text{map} \: S^7 \to S^4 \end{array} \circ \Sigma^3(H_H)) : S^{n+6} \to S^n$$
   defines a non-trivial element in $\pi_{n+6}(S^n)$. In particular for any $n \geq 4$ we have $\pi_{n+6}(S^n) \neq 0$.
3. For any $n \geq 8$ the map
   $$\Sigma^{n-8}(\begin{array}{c} S^{15} \to S^8 \\ \text{map} \: S^{15} \to S^8 \end{array} \circ \Sigma^7(H_O)) : S^{n+14} \to S^n$$
   defines a non-trivial element in $\pi_{n+14}(S^n)$. In particular for any $n \geq 8$ we have $\pi_{n+14}(S^n) \neq 0$.

For the reader’s convenience we recall the two lemmas which will play a key role in the proof of Theorem 110.2.

**Lemma 91.4.** Let $f: A \to X$ be a map between two topological spaces. We denote by $j: X \to \text{Cone}(f: A \to X)$ the obvious inclusion. Then there exists a natural long exact sequence of the form

$$\ldots \to H^{k-1}(A; \mathbb{Z}_2) \xrightarrow{\delta} \tilde{H}^k(\text{Cone}(f: A \to X); \mathbb{Z}_2) \xrightarrow{j^*} H^k(X; \mathbb{Z}_2) \xrightarrow{f^*} H^k(A; \mathbb{Z}_2) \xrightarrow{\delta} \ldots$$

As an example for Lemma 91.4 let us consider the mapping cone of the iterated suspension of the Hopf map.

**Example.** Let $k \in \mathbb{N}_0$. We consider $\Sigma^k(H): S^{k+3} \to S^{k+2}$, i.e. we consider the $k$-fold suspension of the Hopf map $H: S^3 \to S^2$. As we saw in Lemma 91.3, it follows almost immediately from the long exact sequence of Lemma 91.4 that the maps

$$\tilde{H}^{k+2}(\text{Cone}(\Sigma^k(H): S^{k+3} \to S^{k+2}); \mathbb{Z}_2) \xrightarrow{j^*} H^{k+2}(S^{k+2}; \mathbb{Z}_2)$$
and
\[ H^{k+3}(S^{k+3}; \mathbb{Z}_2) \xrightarrow{\delta} \widetilde{H}^{k+4}(\text{Cone}(\Sigma^k(H) : S^{k+3} \rightarrow S^{k+2}); \mathbb{Z}_2) \]
are isomorphisms, and that all the other reduced cohomology groups of the mapping cone vanish.

In the following we recall three statements of Lemma 24.9 which are at the moment relevant to us. It might be helpful to have a peek at Figure 1535.

**Lemma 24.9** Let \( f : A \rightarrow X \) be a map between topological spaces.

1. The inclusion \( X \rightarrow \text{Cone}(f : A \rightarrow X) \) is an embedding.
2. The map
   \[ h : \text{Cone}(f : A \rightarrow X)/X \rightarrow \Sigma(A) \]
   \[ [(a, t)] \mapsto [(a, 1 - 2t)] \]
   is a homeomorphism.
3. The subset \( X \) is a deformation retract of the open neighborhood that is given by the complement of the cone point.

![Figure 1535. Illustration of Lemma 24.9](image)

Now we turn to the proof of Theorem 110.2. As in the proof of Theorem 109.13 we first consider the case of the classical Hopf map, i.e. we first prove Statement (1).

**Proof of Theorem 110.2** (1). Let \( n \in \mathbb{N}_{\geq 2} \). We write

\[ \Sigma^{n-2}(H \circ \Sigma(H)) = \left( \begin{array}{c} \Sigma^{n-2}(H) \circ \Sigma^{n-1}(H) : S^{n+2} \rightarrow S^n \end{array} \right) \]

Lemma 24.4 (2)

We need to show that \( g \circ f : S^{n+2} \rightarrow S^n \) defines a non-trivial element in \( \pi_{n+2}(S^n) \). As in the proof of Theorem 109.13 we do a proof by contradiction. Thus suppose that there exists a homotopy from \( g \circ f : S^{n+2} \rightarrow S^n \) to a constant map. By Lemma 40.4 we can use this homotopy to construct a map \( \varphi : \text{Cone}(S^{n+2}) = \overline{B}^{n+3} \rightarrow S^n \) such that \( \varphi|_{S^{n+2}} = g \circ f \).

---

As we discussed on page 692, given any \( m \in \mathbb{N}_0 \) the map \( \text{Cone}(S^m) \rightarrow \overline{B}^{m+1} \) given by \( [(v, t)] \mapsto v \cdot t \) is a homeomorphism. We will use this map to make the identification \( \overline{B}^{m+1} = \text{Cone}(S^m) \).
We consider the map
\[ \phi: \frac{(\text{Cone}(S^{n+2}) \sqcup S^{n+1})}{\sim} \rightarrow S^n \]
\[ [P] \mapsto \begin{cases} 
  g(P), & \text{if } P \in S^{n+1}, \\
  \varphi(P), & \text{if } P \in \text{Cone}(S^{n+2}) = B^{n+3}.
\end{cases} \]

Our main object of interest is now, perhaps rather confusingly, the mapping cone of \( \phi \). This mapping cone comes with two interesting maps:

\[ \text{Cone}(S^{n+1}) \xrightarrow{f} S^{n+1} \xrightarrow{g} S^n \]
\[ \varphi: S^{n+2} \rightarrow B^{n+2} \]

\( \text{Cone}(f) \)

\[ \text{Cone}(g) \]

\[ \text{Cone}(\varphi) \]

\[ \phi \]

\[ \text{Cone}(\phi) \]

Figure 1536. Illustration for the proof of Theorem 110.2.

(1) Since we have an inclusion \( S^{n+1} \rightarrow \text{Cone}(f) \) and since \( \phi|_{S^{n+1}} = g \) we obtain, see Lemma 24.10 (3), also an inclusion map
\[ i: \text{Cone}(g: S^{n+1} \rightarrow S^n) \rightarrow \text{Cone}(\phi: \text{Cone}(f) \rightarrow S^n). \]

(2) We also consider the projection map
\[ p: \text{Cone}(\phi: \text{Cone}(f) \rightarrow S^n) \rightarrow \text{Cone}(\phi: \text{Cone}(f) \rightarrow S^n)/S^n. \]

In the following two claims we will study the maps on cohomology induced by the inclusion \( i \) and the projection \( p \).

**Claim 1.**

(a) The induced map
\[ i^*: H^k(\text{Cone}(\phi); \mathbb{Z}_2) \rightarrow H^k(\text{Cone}(g); \mathbb{Z}_2) \]

is an isomorphism for \( k \neq n + 1 \).

(b) We have \( H^{n+1}(\text{Cone}(\phi); \mathbb{Z}_2) = 0 \).

---

\[ \text{It follows from } \varphi|_{S^{n+2}} = g \circ f \text{ that this map is well-defined. Furthermore we obtain immediately from Lemma 3.44 (5) that this map is continuous.} \]
We consider the following diagram:

\[
\begin{array}{ccc}
H^{k-2}(S^{n+2}; \mathbb{Z}_2) & \rightarrow & H^{k-1}(S^{n+1}; \mathbb{Z}_2) \\
\downarrow & & \downarrow \\
\rightarrow H^{k-1}(\text{Cone}(f); \mathbb{Z}_2) & \rightarrow & H^k(\text{Cone}(\phi); \mathbb{Z}_2) \\
\downarrow & \downarrow \downarrow & \downarrow \downarrow \\
\rightarrow H^k(\text{Cone}(g); S^n; \mathbb{Z}_2) & \rightarrow & H^k(S^n; \mathbb{Z}_2) \\
\downarrow & \downarrow & \downarrow \\
H^k(\text{Cone}(\phi); \mathbb{Z}_2) & \rightarrow & H^k(S^n; \mathbb{Z}_2) \\
\end{array}
\]

Here the two horizontal and the two vertical sequences are obtained from Lemma 91.4. The diagram commutes by the naturality of the long exact sequence. The two statements of the claim follow easily from the above diagram (see also the discussion on page 2601) and the calculation of the cohomology groups of spheres with \( \mathbb{Z}_2 \)-coefficients.

**Claim 2.** The map

\[ p^* : H^k(\text{Cone}(\phi)/S^n; \mathbb{Z}_2) \rightarrow H^k(\text{Cone}(\phi); \mathbb{Z}_2) \]

is an isomorphism for \( k \neq n, n + 1 \).

We consider the following diagram:

\[
\begin{array}{ccc}
\cdots & \rightarrow & H^{k-1}(S^n; \mathbb{Z}_2) \\
\downarrow & \delta & \downarrow \\
H^{k-1}(\text{Cone}(\phi), S^n; \mathbb{Z}_2) & \rightarrow & H^k(\text{Cone}(\phi); \mathbb{Z}_2) \\
\downarrow & \downarrow & \downarrow \\
H^k(\text{Cone}(\phi)/S^n; \mathbb{Z}_2) & \rightarrow & \cdots \\
\end{array}
\]

Here on top we see the long exact sequence in cohomology of the pair \((\text{Cone}(\phi), S^n)\). Furthermore the vertical map is the natural map from Proposition 74.2 which has in particular the property that it makes the diagram commute. Furthermore, it follows from Proposition 74.2 (2) and Lemma 24.9 (6) that the vertical map is an isomorphism. The desired statement follows immediately from this discussion and the calculation of the cohomology groups of \( S^n \).
Next we consider the following diagram.

\[
\begin{array}{ccc}
H^n(\text{Cone}(\Sigma^{n-2}(H)); \mathbb{Z}_2) & \xrightarrow{\text{Sq}^2} & H^{n+2}(\text{Cone}(\Sigma^{n-2}(H)); \mathbb{Z}_2) \\
\downarrow & & \downarrow \\
H^n(\text{Cone}(g); \mathbb{Z}_2) & \xrightarrow{\text{Sq}^2} & H^{n+2}(\text{Cone}(g); \mathbb{Z}_2) \\
\uparrow \cong & & \uparrow \cong \\
H^n(\text{Cone}(\phi); \mathbb{Z}_2) & \xrightarrow{\text{Sq}^2} & H^{n+2}(\text{Cone}(\phi); \mathbb{Z}_2) \\
\xrightarrow{i^*} & & \xrightarrow{i^*} \\
& \xrightarrow{\text{Sq}^2} & H^{n+4}(\text{Cone}(\phi); \mathbb{Z}_2) \\
& \xrightarrow{\theta^*} & H^{n+4}(\text{Cone}(\phi)/S^n; \mathbb{Z}_2) \\
& \xrightarrow{h^*} & H^{n+4}(\Sigma(\text{Cone}(f)); \mathbb{Z}_2) \\
& \xrightarrow{\text{Sq}^2} & H^{n+4}(\Sigma(\text{Cone}(f)); \mathbb{Z}_2) \\
& \xrightarrow{\Phi^*} & H^{n+4}(\Sigma(\text{Cone}(f)); \mathbb{Z}_2) \\
& \xrightarrow{\text{Sq}^2} & H^{n+4}(\text{Cone}(\Sigma^n(H)); \mathbb{Z}_2) \\
\end{array}
\]

We make the following clarifications and observations:

1. At the top and bottom we use that by definition \( f = \Sigma^{n-1}(H) : S^{n+2} \to S^{n+1} \) and \( g = \Sigma^{n-2}(H) : S^{n+1} \to S^n \).
2. We obtain from Proposition 109.15(1) that the top and bottom horizontal maps \( \text{Sq}^2 \) are isomorphisms.
3. It follows from the above two claims that the vertical maps \( i^* \) and \( p^* \) are isomorphisms.
4. The map \( h : \text{Cone}(\phi) : \text{Cone}(f) \to S^n)/S^n \to \Sigma(\text{Cone}(f)) \) is the homeomorphism from Lemma 24.9(4).
5. The map \( \theta : \Sigma(S^{n+2}) \to \Sigma(S^{n+1}) \to \Sigma(\text{Cone}(f) : S^{n+2} \to S^{n+1}) \) is the homeomorphism from Proposition 24.16.
6. It follows from the naturality of the Steenrod operations that all the squares commute.
7. The combination of the above arguments implies that both of the maps \( \text{Sq}^2 \) in the third row are isomorphisms.

Finally we consider the following diagram.

\[
\begin{array}{ccc}
H^n(\text{Cone}(\phi); \mathbb{Z}_2) & \xrightarrow{\text{Sq}^2} & H^{n+2}(\text{Cone}(\phi); \mathbb{Z}_2) \\
\xrightarrow{\text{Sq}^1} & & \xrightarrow{\text{Sq}^3} \\
H^{n+1}(\text{Cone}(\phi); \mathbb{Z}_2) & =0 &
\end{array}
\]
We make the following observations:

(1) By the discussion preceding the diagram we know that the two maps on the top are isomorphisms.
(2) As we saw on page 2600, we have the Adem relation $\text{Sq}^2 \circ \text{Sq}^2 = \text{Sq}^3 \circ \text{Sq}^1$. This implies that the diagram commutes.
(3) We have

$$H^n(\text{Cone}(\phi); \mathbb{Z}_2) \cong H^n(\text{Cone}(\Sigma^{n-2}(H)); \mathbb{Z}_2) \cong H^n(\Sigma^n; \mathbb{Z}_2) \cong \mathbb{Z}_2.$$  

Claim 1 (a) see the example on page 2601

(4) In Claim 1 (b) we had shown that the group $H^{n+1}(\text{Cone}(\phi); \mathbb{Z}_2)$ is trivial. By (1) and (3) the two horizontal maps in the diagram give us an isomorphism of a non-trivial group. On the other hand, by (2) and (4) this isomorphism factors through a trivial group. This is absurd. We have thus obtained a contradiction.

Now we turn to the proof of the remaining two statements of Theorem 110.2.

Proof of Theorem 110.2 (2) and (3). The proof for the quaternionic Hopf map $H_H$ and the octonion Hopf map $H_O$ is almost the same as the above proof that deals with the classical Hopf map $H$. We just need to replace Proposition 109.15 (1) by Proposition 109.15 (2) and (3) and we need to use the following Adem relations:

$$\text{Sq}^4 \circ \text{Sq}^4 = \text{Sq}^6 \circ \text{Sq}^2 + \text{Sq}^7 \circ \text{Sq}^1$$
$$\text{Sq}^8 \circ \text{Sq}^8 = \text{Sq}^{12} \circ \text{Sq}^4 + \text{Sq}^{14} \circ \text{Sq}^2 + \text{Sq}^{15} \circ \text{Sq}^1.$$  

These relations can be obtained easily by hand from Theorem 110.1. Alternatively one can use the Adem relations calculator:

https://math.berkeley.edu/~kruckman/adem/

As in the proof for the Hopf maps one sees that the initial Steenrod operations on the right hand side all end up in a cohomology group which is zero. Thus one obtains again a contradiction to the hypothesis that the maps $\Sigma^{n-4}(H_H \circ \Sigma^3(H_H)): S^{n+6} \to S^n$ and $\Sigma^{n-8}(H_O \circ \Sigma^7(H_O)): S^{n+14} \to S^n$ are null-homotopic.

110.2. Decomposing Steenrod operations and the Hopf invariant revisited. The key to extracting extra mileage out of Steenrod operations is the following innocuous lemma from elementary number theory.

**Lemma 110.3.** Let $n, k \in \mathbb{N}_0$. If we write $n = \sum_{i \in \mathbb{N}_0} n_i \cdot 2^i$ and $k = \sum_{i \in \mathbb{N}_0} k_i \cdot 2^i$ with $n_i, k_i \in \{0, 1\}$, then

$$\binom{n}{k} = \prod_{i \in \mathbb{N}_0} \binom{n_i}{k_i} \mod 2.$$
Remark.

(1) Note that for \( r, s \in \{0, 1\} \) it follows easily from the definition on page 2579 that

\[
\binom{s}{r} = \begin{cases} 
1, & \text{if } r \leq s, \\
0, & \text{otherwise}.
\end{cases}
\]

(2) Let \( n \in \mathbb{N} \) and let \( k \in \{0, \ldots, d\} \). We define \( n_i, k_i \) as above. It follows from Lemma 110.3 and (1) that \( \binom{n}{k} \) is odd if and only if for each \( i \) we have \( k_i \leq n_i \).

If we draw the usual Pascal triangle, then by shading odd and even terms in different colors we obtain a Sierpinski triangle. We refer to Figure 1537 for an illustration.

![Sierpinski Triangle Diagram](https://upload.wikimedia.org/wikipedia/commons/8/87/Sierpinski_Pascal_triangle.svg)

Figure 1537

(3) In fact the obvious analogue of Lemma 110.3 holds with the prime 2 replaced by any prime \( p \). This more general statement is known as Lucas’ Theorem, a proof is for example provided in [Fi47].

**Proof.** Let \( n, k \in \mathbb{N}_0 \). We write \( n = \sum_{i \in \mathbb{N}_0} n_i \cdot 2^i \) and \( k = \sum_{i \in \mathbb{N}_0} k_i \cdot 2^i \) with \( n_i, k_i \in \{0, 1\} \) In the polynomial ring \( \mathbb{Z}_2[x] \) we have the following equalities

\[
\sum_{i=0}^{n} \binom{n}{i} x^i = (1 + x)^n = (1 + x)^{\sum_{i \in \mathbb{N}_0} n_i 2^i} = \prod_{i \in \mathbb{N}_0} (1 + x^{2^i})^{n_i} = \prod_{i \in \mathbb{N}_0} \sum_{j_i=0}^{n_i} \binom{n_i}{j_i} x^{j_i 2^i}.
\]

\[
\quad \text{binomial formula} \quad \text{since in } \mathbb{Z}_2[x] \text{ we have } (a + b)^2 = a^2 + b^2 \quad \text{binomial formula}
\]

A more elaborate version of this figure can be found here:

The argument has some similarities with the proof of the claim on page 2209.
Now we compare the $x^k$-coefficients, we see that

\[
\binom{n}{k} = x^k\text{-coefficient of } \sum_{i=0}^{\infty} \binom{n}{i} x^i = x^k\text{-coefficient of } \prod_{i \in \mathbb{N}_0} \sum_{j_i=0}^{n_i} \binom{n_i}{j_i} x^{j_i} 2^i = \prod_{i \in \mathbb{N}_0} \binom{n_i}{k_i}.
\]

by the above equality

\[
\binom{n}{k} = \binom{n}{k + \text{ord}_2(k)} \text{ by the uniqueness of the 2-adic description}
\]

of a natural number we only get $x^k$

if each variable $j_i$ equals $k_i$

We have thus proved the desired equality.

This lemma allows us to prove the following theorem.

**Theorem 110.4.** Let $i \in \mathbb{N}_0$. If $i$ is not a power of 2, then $\text{Sq}^i$ is decomposable, in the sense that it can be written as the sum of compositions of Steenrod operations of smaller degree.

**Example.** By the discussion on page 2600 we know that for any $k \in \mathbb{N}_0$ we have

\[
\text{Sq}^{2k+1} = \text{Sq}^1 \circ \text{Sq}^{2k} \quad \text{and} \quad \text{Sq}^{4k+2} = \text{Sq}^2 \circ \text{Sq}^{4k} + \text{Sq}^{4k+1} \circ \text{Sq}^1.
\]

In particular we see that

\[
\text{Sq}^3 = \text{Sq}^1 \circ \text{Sq}^2, \quad \text{Sq}^5 = \text{Sq}^1 \circ \text{Sq}^4, \quad \text{Sq}^6 = \text{Sq}^2 \circ \text{Sq}^4 + \text{Sq}^5 \circ \text{Sq}^1 \quad \text{and} \quad \text{Sq}^7 = \text{Sq}^1 \circ \text{Sq}^6.
\]

**Proof.** Suppose that we are given $i \in \mathbb{N}_0$ that is not a power of two. This means that we can write $i = a + b$ where $b = 2^k$ and $a \in \{1, \ldots, 2^k - 1\}$. Since $0 < a < 2b$ we obtain an Adem relation for $\text{Sq}^a \circ \text{Sq}^b$ from Theorem 110.1. This relation can be rewritten as follows:

\[
\left( \binom{b-1}{a} \right) \cdot \text{Sq}^{a+b} = \text{Sq}^a \circ \text{Sq}^b + \sum_{j=1}^{\lfloor \frac{b-1}{2} \rfloor} \binom{b-1-j}{a-2j} \cdot \text{Sq}^{a+b-j} \circ \text{Sq}^j.
\]

It remains to show that $\left( \binom{b-1}{a} \right) = 1 \mod 2$. We calculate

by Lemma 110.3 where $b-1 = \sum_{i \in \mathbb{N}_0} d_i \cdot 2^i$ and $a = \sum_{i \in \mathbb{N}_0} c_i \cdot 2^i$ with $c_i, d_i \in \{0, 1\}$

\[
\left( \binom{b-1}{a} \right) = \prod_{i \in \mathbb{N}_0} \left( \binom{d_i}{c_i} \right) = \prod_{i=0}^{k-1} \left( \binom{1}{c_i} \right) \cdot \prod_{i=k}^{\infty} \left( \begin{array}{c} 0 \\ 0 \end{array} \right) = 1 \mod 2.
\]

since $b-1 = 2^k - 1 = 1 + 2 + \cdots + 2^{k-1}$ we have $d_0 = \cdots = d_{k-1} = 1$ and $d_k = d_{k+1} = \cdots = 0$

furthermore, since $a < 2^k - 1$ we have $c_k = c_{k+1} = \cdots = 0$

**Corollary 110.5.** Let $X$ be a topological space and let $n \in \mathbb{N}_0$. We consider the Steenrod operation

\[
\text{Sq}^i : H^n(X; \mathbb{Z}_2) \to H^{n+i}(X; \mathbb{Z}_2).
\]

If the cohomology groups in between vanish, i.e. if $H^{n+1}(X; \mathbb{Z}_2) = \cdots = H^{n+i-1}(X; \mathbb{Z}_2) = 0$, and if $i$ is not a power of 2, then the Steenrod operation is the zero map.

\[\text{Note that the equalities also make sense for } k > n. \text{ In this setting one sees easily that all terms are in fact zero.}\]
Proof. Since \( i \) is not a power of 2 we know by Theorem 110.4 that \( \text{Sq}^i \) can be written as the sum of compositions of Steenrod operations of smaller degree. But by our hypothesis for any \( j \in \{1, \ldots, i-1\} \) we have \( H^{n+j}(X; \mathbb{Z}_2) = 0 \). But this implies in particular that for any such \( j \) we have \( \text{Sq}^j : H^n(X; \mathbb{Z}_2) \to H^{n+j}(X; \mathbb{Z}_2) = 0 \). ■

\[
\begin{array}{ccccccccc}
\text{Sq}^i & & & & & & \text{Sq}^i \\
H^n(X; \mathbb{Z}_2) & 0 & 0 & 0 & 0 & 0 & 0 & 0 & H^{n+i}(X; \mathbb{Z}_2)
\end{array}
\]

**Figure 1538.** Illustration for the proof of Corollary 110.5

In Question 84.19 we asked whether all (reasonable) superalgebras can be realized as cohomology rings. We will now see that this is not the case. Before we can state the corresponding proposition we need to introduce the following definition.

**Definition.** Let \( m \in \mathbb{N} \) be an even number and let \( s \in \mathbb{Z} \). We define \( R_m(s) \) to be the superalgebra which is given by the group:

\[
R_m(s) = \begin{cases} 
\mathbb{Z} \cdot 1, & \text{in degree 0}, \\
\mathbb{Z} \cdot x, & \text{in degree } m, \\
\mathbb{Z} \cdot y, & \text{in degree } 2m, \\
0, & \text{in all other degrees}
\end{cases}
\]

and where the multiplication is given by \( x \cdot x = s \cdot y \). In other words, the multiplication table is given as follows

<table>
<thead>
<tr>
<th></th>
<th>1</th>
<th>x</th>
<th>y</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>x</td>
<td>y</td>
</tr>
<tr>
<td>x</td>
<td>x</td>
<td>s \cdot y</td>
<td>0</td>
</tr>
<tr>
<td>y</td>
<td>y</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

**Example.**

1. For any \( m \) the superalgebra \( R_m(1) \) is evidently isomorphic to \( \mathbb{Z}[x]/(x^3) \) where \( x \) is of degree \( m \).
2. By (1) together with Proposition 90.7 and Proposition 90.20 we have isomorphisms

\[
(H^*(\mathbb{C}P^2; \mathbb{Z}), \cup) \cong R_2(1), \quad (H^*(\mathbb{H}P^2; \mathbb{Z}), \cup) \cong R_4(1) \quad \text{and} \quad (H^*(\mathbb{O}P^2; \mathbb{Z}), \cup) \cong R_8(1).
\]

Next we prove the following proposition which gives a negative answer to Questions 84.19 and 90.21.

**Proposition 110.6.** Let \( m \) be an even number and let \( s \) be an odd number. If \( m \) is not a power of 2, then there is no topological space \( X \) such that \( (H^*(X; \mathbb{Z}), \cup) \) is isomorphic to \( R_m(s) \).

In the proof of Proposition 110.6 we will need the following lemma.

\[\text{It follows from the fact that } m \text{ is even that this is indeed a superalgebra.}\]
Lemma 110.7. Let $m \in \mathbb{N}$. We denote by $\varphi : \mathbb{Z} \to \mathbb{Z}_m$ the canonical map. Given any topological space $X$ there exists a long exact sequence

$$\cdots \to H^k(X; \mathbb{Z}) \xrightarrow{\cdot m} H^k(X; \mathbb{Z}) \xrightarrow{\varphi} H^k(X; \mathbb{Z}_m) \xrightarrow{\delta} H^{k+1}(X; \mathbb{Z}) \to \cdots$$

Proof of Lemma 110.7. We denote by $\psi : \mathbb{Z} \to \mathbb{Z}$ the map that is given by multiplication by $m$. We have the short exact sequence

$$0 \to \mathbb{Z} \xrightarrow{\psi} \mathbb{Z} \xrightarrow{\varphi} \mathbb{Z}_m \to 0.$$ 

By the discussion on page ?? we have the corresponding Bockstein sequence in cohomology which looks as follows:

$$\cdots \xrightarrow{\delta} H^k(X; \mathbb{Z}) \xrightarrow{\psi} H^k(X; \mathbb{Z}) \xrightarrow{\varphi} H^k(X; \mathbb{Z}_2) \xrightarrow{\delta} H^{k+1}(X; \mathbb{Z}) \to \cdots$$

By the almost, but not entirely trivial Lemma ?? we know that $\psi_*$ is indeed multiplication by $m$. \hfill \blacksquare

Proof of Proposition 110.6. Let $m$ be an even number. Furthermore let $X$ be a topological space such that $(H^*(X; \mathbb{Z}), \cup) = R_m(s)$ for some odd number $s$. We need to show that $m$ is a power of 2. We denote by $\varphi : \mathbb{Z} \to \mathbb{Z}_2$ the canonical map. We consider the following diagram

$$
\begin{array}{ccc}
H^m(X; \mathbb{Z}) & \xrightarrow{x \mapsto x^2 = x \cup x = s \cdot y} & H^{2m}(X; \mathbb{Z}) \\
\downarrow \varphi_* & & \downarrow \varphi_* \\
H^m(X; \mathbb{Z}_2) & \xrightarrow{z \mapsto z^2 = z \cup z} & H^{2m}(X; \mathbb{Z}_2) \\
& \downarrow & \\
H^m(X; \mathbb{Z}_2) & \xrightarrow{z \mapsto Sq^m(z)} & H^{2m}(X; \mathbb{Z}_2).
\end{array}
$$

We make the following clarifications and observations:

1. It follows from Proposition 82.4 (2) that the upper square commutes.
2. It follows from Lemma 110.7 and our hypothesis on the topological space $X$ that the map $\varphi_* : H^{2m}(X; \mathbb{Z}) \to H^{2m}(X; \mathbb{Z}_2)$ is an epimorphism and that $H^{2m}(X; \mathbb{Z}_2) \cong \mathbb{Z}_2$. In particular we see that $\varphi_*(y) \in H^{2m}(X; \mathbb{Z}_2)$ is a non-trivial element of order 2.
3. Since $s$ is odd we obtain from (2) that $\varphi_*(s \cdot y) = s \cdot \varphi_*(y)$ is a non-trivial element of $H^{2m}(X; \mathbb{Z}_2)$.
4. The lower square commutes by Axiom (2) of Steenrod operations, see Theorem 109.2 (2).
5. By our hypothesis on $X$ we know that the intermediate cohomology groups vanish, i.e. we have $H^{m+1}(X; \mathbb{Z}_2) = \cdots = H^{2m-1}(X; \mathbb{Z}_2) = 0$.

It follows from (3) and (4) that the bottom horizontal map has non-trivial image. But by Corollary 110.5 together with (5) this is only possible if $m$ is indeed a power of 2. \hfill \blacksquare

As promised in the title of the section, we now return to the Hopf invariant. Let $f : S^{2n-1} \to S^n$ be a map where $n \geq 2$. Recall that on page ?? we introduced the Hopf invariant $\mathrm{Hopf}(f) \in \mathbb{Z}$. The following lemma translates the Hopf invariant into the
language of the above discussion. The lemma can also be viewed as an alternative definition of the Hopf invariant, at least up to sign.

**Lemma 110.8.** Let \( n \geq 2 \). If \( f : S^{2n-1} \to S^n \) is a map, then there exists an isomorphism

\[
(H^*(\text{Cone}(f); \mathbb{Z}), \cup) \cong R_n(\text{Hopf}(f))
\]

of superalgebras.

**Proof.** This statement follows immediately from Lemma 91.5 and the definition of the Hopf invariant, see page 2217.

The following proposition is the summary of our previous discussion of the Hopf invariant.

**Proposition 110.9.** Let \( n \geq 2 \).

1. The Hopf invariant \( \text{Hopf}: \pi_{2n-1}(S^n) \to \mathbb{Z} \) is a homomorphism.
2. The Hopf invariant \( \text{Hopf}: \pi_{2n-1}(S^n) \to \mathbb{Z} \) is zero for odd \( n \).
3. If \( \mathbb{R}^n \) can be equipped with the structure of a division algebra, then there exists a map \( f: S^{2n-1} \to S^n \) with \( \text{Hopf}(f) = 1 \).
4. For \( k = 1, 2, 4 \) the Hopf maps \( H, H_H \) and \( H_D \) give elements in \( \pi_{4k-1}(S^{2k}) \) with Hopf invariant 1.
5. Given any \( k \in \mathbb{N} \) there exists a map \( f: S^{4k-1} \to S^{2k} \) with \( \text{Hopf}(f) = 2 \).

**Proof.** The proof follows from Proposition 91.7, Corollary 91.8, Lemma 91.11 and Propositions 91.13 and 91.12.

We recall the following question that we asked a while ago.

**Question 91.17.** For which \( n \in \mathbb{N}_{\geq 2} \) does there exist a map \( f: S^{2n-1} \to S^n \) with \( \text{Hopf}(f) = 1 \)?

The following theorem is an immediate consequence of Proposition 110.6 and Lemma 110.8.

**Theorem 110.10.** Let \( n \geq 2 \). If there exists a map \( f: S^{2n-1} \to S^n \) with \( \text{Hopf}(f) = 1 \), then \( n \) is a power of 2.

The combination of Proposition 110.9 (3) and Theorem 110.10 gives us an alternative proof of the following theorem.

**Theorem 90.23.** (Hopf 1940) If \( \mathbb{R}^n \) admits the structure of a real division algebra, then \( n \) is a power of 2.

It is an amusing mental exercise, left to the reader, to compare the two proofs of Theorem 90.23. The first one relies on the calculation of the cup product of \( \mathbb{R}P^n \times \mathbb{R}P^n \) with \( \mathbb{Z}_2 \)-coefficients and a fact in elementary number theory that is proved on page 2209. The second proof uses Steenrod operations and a different input from elementary number theory, namely Lemma 110.3. Note that in some sense the former proof is more satisfactory since we could provide full details, whereas the latter proof relies on the Adem relations that we did not prove.
For completeness we remark that in 1960 Frank Adams [Adam60] (see also [AdA66], [May99a] Chapter 24.6 and [Hus93] Theorem 15.4.3) proved the following strengthening of Theorem 110.10. Note that this theorem finally gives a complete answer to Question 91.17.

**Theorem 110.11.** Let \( n \geq 2 \). If there exists a map \( f : S^{2n-1} \to S^n \) with \( \text{Hopf}(f) = 1 \), then \( n = 2, 4 \) or \( n = 8 \).

The combination of Proposition 110.9 (3) and Theorem 110.11 gives us an alternative proof of the following beautiful theorem.

**Theorem 90.25.** Every finite-dimensional division algebra over \( \mathbb{R} \) is of dimension 1, 2, 4 or 8.

### 110.3. The Steenrod cyclic reduced powers (*)

The Steenrod operations \( \text{Sq}^i \) are cohomology operations on cohomology groups with \( \mathbb{Z}_2 \)-coefficients. It turns out that there exist also analogous cohomology operations for cohomology with \( \mathbb{Z}_p \)-coefficients. More precisely, the following theorem holds:

**Theorem 110.12.** Let \( p \) be an odd prime. There exists a family

\[
P^i : H^n(X, A; \mathbb{Z}_p) \to H^{n+2i(p-1)}(X, A; \mathbb{Z}_p)
\]

of additive cohomology operations which satisfies the following axioms:

1. \( P^0 = \text{id} \).
2. For any \( \varphi \in H^2i(X, A; \mathbb{Z}_p) \) we have \( P^i(\varphi) = \varphi^p \in H^{2pi}(X, A; \mathbb{Z}_p) \).
3. For any \( \varphi \in H^j(X, A; \mathbb{Z}_p) \) with \( i > j \) we have \( P^i(\varphi) = 0 \).
4. Let \( (X, A, B) \) be an excisive triad of topological spaces. For any \( \varphi \in H^r(X, A; \mathbb{Z}_p) \) and any \( \psi \in H^s(X, B; \mathbb{Z}_p) \) and any \( k \in \mathbb{N}_0 \), we have

\[
P^k(\varphi \cup \psi) = \sum_{i=0}^{k} P^i(\varphi) \cup P^{k-i}(\psi) \in H^{r+s+2k(p-1)}(X, A \cup B; \mathbb{Z}_p).
\]

This equality is often called the Cartan formula.

**Proof.** This theorem is proved in [SE62] Chapter VI. A very different proof is given in [Hat02] Theorem 4.1.L.16.

The following theorem plays the role of Theorem 110.1.

---

\(^{1500}\)Note that if for argument’s sake one plugs \( p = 2 \) into the statements of Theorem 110.12 then one does not get the statements of Theorem 109.2 since the degree formulas are different. In other words there is no easy way to combine Theorems 109.2 and 110.12 into a single statement.

\(^{1501}\)We refer to page 1851 for the definition of an excisive triad. By Proposition 74.12 most “reasonable” triads are in fact excisive. In fact we will only use the special cases that \( A = B \), or that at least one of \( A \) or \( B \) is the empty set. We refer again to page 2005 for the definition of the relative cup product.
**Theorem 110.13. (Adem Relations)** Let $p$ be an odd prime.

1. For any $0 < a < pb$ we have the following equality of cohomology operations:

$$P_a \circ P_b = \sum_{j=0}^{\left\lfloor \frac{a}{p} \right\rfloor} (-1)^{a+j} \cdot \left( \frac{(p-1)(b-j) - 1}{a - pj} \right) \cdot P_a + b - j \circ P_j.$$ 

2. Given $i \in \mathbb{N}$ we denote by $\beta: H^i(X; \mathbb{Z}_p) \to H^{i+1}(X; \mathbb{Z}_p)$ the Bockstein homomorphism that corresponds to the short exact sequence $0 \to \mathbb{Z}_p \to \mathbb{Z}_{pq} \to \mathbb{Z}_p \to 0$. For any $0 < a \leq pb$ the following mystifying equality holds:

$$P_a \circ \beta \circ P_b = \sum_{j=0}^{\left\lfloor \frac{a}{p} \right\rfloor} (-1)^{a+j} \cdot \left( \frac{(p-1)(b-j) - 1}{a - pj} \right) \cdot \beta \circ P_a + b - j \circ P_j.$$ 

These equalities are called the Adem relations.

**Example.** Let us consider the case of the prime $p = 3$. In this case the corresponding reduced Steenrod operations are additive cohomology operations of the form

$$P_i: H^n(X, A; \mathbb{Z}_3) \to H^{n+4i}(X, A; \mathbb{Z}_3).$$

For $a = 1$ and $b = 3$ we obtain the Adem relation

$$P^1 \circ P^3 = \sum_{j=0}^{\left\lfloor \frac{1}{3} \right\rfloor} (-1)^{1+j} \left( \frac{2 \cdot (3-j) - 1}{1 - 3 \cdot j} \right) \cdot P^{4-j} \circ P^j = (-1) \cdot \left( \frac{5}{1} \right) \cdot P^4 = -5 \cdot P^4 = P^4.$$ 

Theorem 110.13(1) only one summand, namely for $j = 0$ we work in $\mathbb{Z}_3$.

The Steenrod cyclic reduced powers can, not surprisingly, be used to give more information on homotopy groups of spheres. We refer to [SE62, Chapter VI.5] and [Hat02, Example 4.L.6] for details.

Instead of providing more results on homotopy groups of spheres we want to give a different application of the Steenrod cyclic reduced powers, namely we want to prove the following proposition which gives a negative answer to Question 90.22.

**Proposition 110.14.** There is no topological space $X$ such that $H^*(X; \mathbb{Z}_3)$ is isomorphic to $\mathbb{Z}_3[\varphi]/(\varphi^4)$ with $\varphi \in H^8(X; \mathbb{Z}_3)$.

**Proof.** We provide a proof by contradiction. So suppose there exists a topological space $X$ such that $H^*(X; \mathbb{Z}_3)$ is isomorphic to $\mathbb{Z}_3[\varphi]/(\varphi^4)$ with $\varphi \in H^8(X; \mathbb{Z}_3)$. We see that

$$0 \not\cong \varphi^3 \downarrow \quad P^4(\varphi) = (P^1 \circ P^3)(\varphi) = P^1(\hat{P^3}(\varphi)) \downarrow = 0.$$ 

since we assume that $H^*(X; \mathbb{Z}_3) \cong \mathbb{Z}_3[\varphi]/(\varphi^4)$ since $P^4 = P^1 \circ P^3$ since $H^{20}(X; \mathbb{Z}_3) = 0$

We have thus obtained a contradiction. 

\[\Box\]
Remark. In Exercise 110.2 we will use Proposition 110.14 to give a negative answer to Question 60.11. So with most reasonable interpretations it is fair to say that there is no smooth manifold that deserves the name $\mathbb{O}P^n$ with $n \geq 3$.

Exercises for Chapter 110.

Exercise 110.1. Let $X$ be a topological space and let $x \in H^1(X; \mathbb{Z}_2)$ be a cohomology class of degree one. Show that for any $k \in \mathbb{N}$ and any $i \in \mathbb{N}$ we have

$$\text{Sq}^i(x^2^k) = \begin{cases} x^2^k, & \text{if } i = 0, \\ x^2^{k+1}, & \text{if } i = 2^k, \\ 0, & \text{otherwise.} \end{cases}$$

Exercise 110.2. Let $n \geq 3$. Show that there is no closed orientable $8n$-dimensional smooth manifold that admits a CW-structure with precisely one cell in dimensions $0, 8, 16, \ldots, 8n$. Remark. This exercise gives a negative answer to Question 60.11.
Part XIII

Homotopy Theory and Eilenberg-Maclane Spaces
111. Relative homotopy groups

111.1. The definition of relative homotopy groups. While studying homology groups we saw at some point that it was convenient to introduce the relative homotopy groups $H_k(X, A)$ corresponding to a pair of topological spaces $(X, A)$. In our latest attempt to understand homotopy groups we will now, perhaps not surprisingly, introduce relative homotopy groups. We start out with introducing the following notation.

Notation. Throughout this chapter we write $I = [0, 1]$ for the unit interval. Furthermore, given $n \in \mathbb{N}$ we use the following notation:

1. we denote by $I^n \subset \mathbb{R}^n$ the cube in $\mathbb{R}^n$,
2. we denote by $\partial I^n$ the boundary of $I^n$ viewed as a subset of $\mathbb{R}^n$,
3. by a slight abuse of notation we make the identification $I^{n-1} = I^{n-1} \times \{0\}$,
4. we write $J^{n-1} = \partial I^n / I^{n-1}$.

We refer to Figure 1540 for an illustration.

![Figure 1540](image)

The following definition is a variation on the notion of a pointed topological space that we introduced on page 476.

Definition. A pointed pair of topological spaces is a triple $(X, A, x_0)$, where $X$ is a topological space, $A$ is a subset of $X$ and $x_0$ is a point in $A$. A morphism between pointed pairs of topological spaces $(X, A, x_0)$ and $(Y, B, y_0)$ is a map $f : X \to Y$ with $f(A) \subset B$ and $f(x_0) = y_0$. We refer to the corresponding category as the category of pointed pairs of topological spaces.

Definition. Let $(X, A, x_0)$ be a pointed pair of topological spaces. Given $n \geq 1$ we define the $n$-th relative homotopy group of $(X, A, x_0)$ to be\footnote{On page 571 we defined the notion of maps between pairs of topological spaces and we defined the notion of a homotopy between such maps. These notions extend in an obvious way to triples of topological spaces.}

$$\pi_n(X, A, x_0) := \text{homotopy classes of maps } (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\}).$$

The definition is illustrated in Figure 1541.

![Figure 1541](image)
Examples.

(1) Let \((X, A, x_0)\) be a pointed pair of topological spaces. We want to get a better understanding of elements in \(\pi_1(X, A, x_0)\). For \(n = 1\) we have \(I^1 = [0, 1], \partial I^1 = \{0, 1\}\) and \(J^0 = \{1\}\). A map \((I^1, \partial I^1, J^0) \to (X, A, \{x_0\})\) is thus the same as a path in \(X\) that starts at a point in \(A\) and that ends in \(x_0\). We refer to Figure 1542 and 1543 for an illustration.

![Figure 1542](image)

the maps define the same element in \(\pi_1(X, A, x_0)\)

![Figure 1543](image)

the maps define (presumably) three different elements in \(\pi_1(X, A, x_0)\)

(2) Let \((X, x_0)\) be a pointed topological space. For any \(n \geq 1\) the map

\[
\pi_n(X, x_0) \to \pi_n(X, \{x_0\}, x_0)
\]

\[
[f : (I^n, \partial I^n) \to (X, \{x_0\})] \mapsto [f : (I^n, \partial I^n, J^{n-1}) \to (X, \{x_0\}, \{x_0\})]
\]

defines, basically by definition, a natural bijection. In the following we will use this natural bijection to make the identification \(\pi_n(X, x_0) = \pi_n(X, \{x_0\}, x_0)\).

(3) Let \(X\) be a topological space, let \(A\) be a subset of \(X\) and let \(x_0 \in A\) be a point. For any \(n \geq 1\) the map

\[
\pi_n(X, x_0) \to \pi_n(X, A, x_0)
\]

\[
[f : (I^n, \partial I^n) \to (X, \{x_0\})] \mapsto [f : (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})]
\]

is a natural map from absolute homotopy groups to relative homotopy groups.

In the previous discussion we already referred to \(\pi_n(X, A, x_0)\) as a "relative homotopy group". This was slightly premature, but now we will actually deliver the goods and provide a group structure.

Definition. Let \((X, A, x_0)\) be a pointed pair of topological spaces and let \(n \geq 2\). Given two maps \(f, g : (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})\) we define

\[
f \ast g : I^n \to X
\]

\[
(t_1, \ldots, t_n) \mapsto \begin{cases} f(2t_1, t_2, \ldots, t_n), & \text{if } t_1 \in [0, \frac{1}{2}], \\ g(2t_1 - 1, t_2, \ldots, t_n) & \text{if } t_1 \in [\frac{1}{2}, 1]. \end{cases}
\]
Note that $f * g$ is again a map $(I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})$ of triples. The definition of $f * g$ is illustrated in Figure 1544.

![Diagram](image)

**Figure 1544**

The following proposition finally gives the justification for the name *relative homotopy group*.

**Proposition 111.1.** Let $(X, A, x_0)$ be a pointed pair of topological spaces.

1. Let $n \geq 2$. The map
   
   $$
   \pi_n(X, A, x_0) \times \pi_n(X, A, x_0) \to \pi_n(X, A, x_0)
   ([f], [g]) \mapsto [f * g]
   $$

   is well-defined and it defines a group structure on $\pi_n(X, A, x_0)$. Furthermore the following two statements hold:
   
   (a) the trivial element in $\pi_n(X, A, x_0)$ is represented by the constant map $I^n \to X$ that sends every point in $I^n$ to $x_0$,
   
   (b) the inverse of the relative homotopy class $[f : (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})]$ is represented by the map
   
   $$(I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})
   (t_1, t_2, \ldots, t_n) \mapsto (1 - t_1, t_2, \ldots, t_n).$$

2. For $n \geq 2$ the above natural bijection $\pi_n(X, x_0) \cong \pi_n(X, \{x_0\}, x_0)$ is in fact a group isomorphism.

3. For $n \geq 2$ the above natural map $\pi_n(X, x_0) \to \pi_n(X, A, x_0)$ is a group homomorphism.

4. For $n \geq 3$ the group $\pi_n(X, A, x_0)$ is abelian.

5. Let $n \in \mathbb{N}$. Given a morphism $f : (X, A, x_0) \to (Y, B, y_0)$ of pointed pairs of topological spaces the map

   $$
   f_* : \pi_n(X, A, x_0) \to \pi_n(Y, B, y_0)
   [\varphi] \mapsto [f \circ \varphi]
   $$

   is well-defined. Furthermore the following four statements hold:

   (a) For $n \geq 2$ the induced map $f_*$ is a group homomorphism.
   
   (b) The maps $f_*$ define a functor from the category of pointed pairs of topological spaces to the category of sets (respectively groups for $n \geq 2$).
(c) Let \( n \geq 1 \) and let \( f, g : (X, A) \to (Y, B) \) be two maps between pairs of topological spaces. If \( f_* : \pi_n(X, A, x_0) \to \pi_n(Y, B, f(x_0)) \) is a bijection for all \( x_0 \in A \) and if \( g \) is homotopic\(^{1505}\) to \( f \), then \( g_* : \pi_n(X, A, x_0) \to \pi_n(Y, B, g(x_0)) \) is also a bijection for all \( x_0 \in A \).

(d) Let \( f : (X, A) \to (Y, B) \) be a map between pairs of topological spaces and let \( x_0 \in A \). If \( f \) is a homotopy equivalence, then the map

\[
    f_* : \pi_n(X, A, x_0) \to \pi_n(Y, B, f(x_0))
\]

is a bijection (in particular it is an isomorphism if \( n \geq 2 \)).

**Sketch of proof.**

1. The proof of the first statement is quite similar to the proof of Proposition \([40.1]\) We leave it to the reader to fill in the details.

2. This statement requires just slightly more thought than one might think. More precisely, given two maps \( f \) and \( g \) from \( (I^n, \partial I^n, J^n-1) \) to \( (X, \{x_0\}, \{x_0\}) \), the “product maps” \( f \ast g \) considered on page \( 1055 \) for \( \pi_n(X, \{x_0\}) \) (and illustrated in Figure \( 679 \)) and in the above proposition for \( \pi_n(X, A, x_0) \) are not identical. Nonetheless, using Lemma \([40.2]\) or Proposition \([53.11]\) it is straightforward to show that they are homotopic. This observation shows that the above identification of sets is in fact an identification of groups.

3. We already know that the map is a bijection. Thus it suffices to show that it is a group homomorphism. But this follows from (3) applied to \( A = \{x_0\} \).

4. The proof of this statement is an entertaining variation on the proof of Proposition \([40.3]\). The proof is the content of Exercise \([111.2]\).

5. Statements (a) and (b) follow basically immediately from the definitions. Statement (c) and (d) are proved in a similar fashion to Proposition \([40.7]\).

**Remark.**

1. We will see shortly that the relative homotopy group \( \pi_2(X, A, x_0) \) is in general not abelian.

2. For want of a better idea, given a pointed pair of topological spaces \( (X, A, x_0) \) we refer to \( \pi_1(X, A, x_0) \) also as a *relative homotopy group* even though strictly speaking we did not define a group structure on \( \pi_1(X, A, x_0) \).

In light of Proposition \([111.1]\) we adopt the following convention:

**Convention.** For \( n \geq 3 \) we usually use additive notation for the group structure on the relative homotopy groups \( \pi_n(X, A, x_0) \).

Let \( X \) be a topological space and let \( A \subset B \subset X \) be two subsets. In Proposition \([43.15]\) we saw that this data gives rise to a long exact sequence of homology groups. Shortly we will see that a similar statement holds for relative homotopy groups. We did not define a group structure on \( \pi_1(X, A, x_0) \) and we did not define a group structure on \( \pi_0(X, x_0) \). (In fact we will see in Exercise \([111.3]\) that there is no natural way to turn these sets into groups.) Nonetheless we would like to include these objects at the lower end of the long

\(^{1505}\)Here we mean of course, “homotopic as a map between pairs of topological spaces”.

exact sequence of (relative) homotopy groups. In fact, as it turns out, \( \pi_1(X,A,x_0) \) and \( \pi_0(X,x_0) \) have ever so slightly more structure than just the structure of a set.

**Definition.**

1. A **pointed set** is a pair \((S, s_0)\) where \(S\) is a set and \(s_0 \in S\) is a point. We call \(s_0\) the *trivial element* in \(S\).
2. A **morphism** from a pointed set \((S, s_0)\) to a pointed set \((T, t_0)\) is a map \(f: S \to T\) with \(f(s_0) = t_0\). Furthermore we adopt the following language:
   a. Given a morphism \(f: (S, s_0) \to (T, t_0)\) we refer to \(\ker(f) := f^{-1}(t_0)\) as the *kernel* of \(f\).
   b. We say a morphism \(f: (S, s_0) \to (T, t_0)\) is *trivial* if \(\ker(f) = S\), put differently, if all elements in \(S\) get sent to \(t_0\).
   c. We say a morphism \(f: (S, s_0) \to (T, t_0)\) is a *monomorphism* if \(\ker(f) = \{s_0\}\).
   d. We say a morphism \(f: (S, s_0) \to (T, t_0)\) is an *epimorphism* if \(f\) is surjective.
3. We say that a sequence
   \[
   \ldots \xrightarrow{f_{n+2}} (S_{n+1}, s_{n+1}) \xrightarrow{f_{n+1}} (S_n, s_n) \xrightarrow{f_n} (S_{n-1}, s_{n-1}) \xrightarrow{f_{n-1}} \ldots
   \]
   of morphisms of pointed sets is *exact* if for every \(n \in \mathbb{N}_0\) we have the usual equality \(\ker(f_n) = \text{im}(f_{n+1})\).

**Examples.**

1. Any group \(G\) gives rise to the pointed set \((G, \{e\})\) where \(e \in G\) evidently denotes the trivial element. We will thus always view a group as a pointed set. Any group homomorphism is also a morphism of the corresponding pointed sets. Furthermore an exact sequence of homomorphisms of groups is also an exact sequence of pointed sets.

2. If \(G\) is a group and \(H\) is a subgroup, then the set of right cosets \(G/H\) is a pointed set with trivial element given by \(H \in G/H\). The obvious projection map \(G \to G/H\) is a morphism of pointed sets.

The following little lemma will be proved in Exercise [111.4](#).

**Lemma 111.2.** Let \(\varphi: G \to H\) be a group homomorphism. Furthermore let \((S, s_0)\) be a pointed set which is equipped with an \(H\)-action. Suppose that we have an exact sequence
   \[
   \{e\} \to G \xrightarrow{\varphi} H \xrightarrow{\psi} (S, s_0) \to \{e\}
   \]
   where \(\psi\) is a morphism of pointed sets that preserves the \(H\)-action. Then \(\varphi(G)\) is a subgroup of \(H\) whose index equals the cardinality of the set \(S\).

**Example.** The previous lemma might sound rather artificial. But we have seen it before in group theory: suppose that \(H\) is a group and \(G\) is a subgroup. As above we view the set of right cosets \(G/H\) as a pointed set. Left-multiplication by \(G\) defines an action on \(G/H\). Evidently the projection \(G \to G/H\) preserves the right-action and we get a short exact sequence \(\{e\} \to G \to H \to G/H \to \{e\}\) as in Lemma [111.2](#).

We continue with pointed sets that arise in topology.
Examples.

(1) Let \((X, x_0)\) be a pointed topological space. Recall that on page 1054, we defined \(\pi_0(X, x_0)\) to be the set of homotopy classes of maps from the point \(I^0\) to \(X\). In other words, \(\pi_0(X, x_0)\) is the set of path-components of \(X\). We view \(\pi_0(X, x_0)\) as a pointed set where the trivial element is given by the map that sends the unique point in \(I^0\) to \(x_0\). A map \(f : X \to Y\) between topological spaces defines a morphism \(f_* : \pi_0(X, x_0) \to \pi_0(Y, f(x_0))\) of pointed sets in the obvious way. Sometimes, by an unfortunate abuse of language, we refer to \(\pi_0(X, x_0)\) as a homotopy group of \(X\).

(2) Similarly to the above, given a pointed pair of topological spaces \((X, A, x_0)\) we view \(\pi_1(X, A, x_0)\) as pointed set where the trivial element is once again represented by the constant path \(I \to X\) given by sending all points to \(x_0\).

We conclude this section with the following elementary lemma that will be proved in Exercise 111.6.

**Lemma 111.3.** Let \((X, A, x_0)\) be a pointed pair of topological spaces and let \(n \geq 1\). Let \(f : (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})\) be a map. If \(f(I^n) \subset A\), then \(f\) represents the trivial element in \(\pi_n(X, A, x_0)\).

Since it is much easier to convince oneself of a statement if one sees an explicit example, we show such a map with \(f(I^n) \subset A\) in Figure 1545.

![Figure 1545](image)

**111.2. The long exact homotopy sequence of a pair.** In Proposition 13.15, we saw that we can associate to a pair \((X, A)\) of topological spaces a long exact sequence of (relative) homology groups. The goal of this section is to do the same for homotopy groups. More precisely we will associate to a pointed pair \((X, A, x_0)\) of topological spaces a long exact sequence of (relative) homotopy groups.

**Proposition 111.4.** Let \((X, A, x_0)\) be a pointed pair of topological spaces.

1. For any \(n \geq 1\) the map

\[
\partial_n : \pi_n(X, A, x_0) \to \pi_{n-1}(A, x_0)
\]

\[
[f : (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})] \mapsto \begin{bmatrix}
(I^{n-1}, \partial I^{n-1}) & (A, \{x_0\}) \\
(x_1, \ldots, x_{n-1}) & f(x_1, \ldots, x_{n-1}, 0)
\end{bmatrix}
\]

---

1506 Put differently, as for relative homology groups, all objects that “land in \(A\)” are in fact trivial in the relative homotopy group.

1507 Note that by the above discussion of pointed sets, the statement of Lemma 111.3 is also meaningful for \(n = 1\).
is well-defined. (See Figure 1546 for an illustration.) We refer to it as the connecting morphism. It has the following two properties:

(a) The connecting morphism is a morphism of pointed sets and it is a group homomorphism for \( n \geq 2 \).

(b) The connecting morphism is a natural transformation from the covariant functor \( \pi_n(X, A, x_0) \) to the covariant functor \( \pi_{n-1}(A, x_0) \). In everyday language this just simply means that for a map \( f : (X, A, x_0) \to (Y, B, y_0) \) between pointed pairs of topological spaces the following diagram commutes:

\[
\begin{array}{ccc}
\pi_n(X, A, x_0) & \xrightarrow{\partial} & \pi_{n-1}(A, x_0) \\
\downarrow f_* & & \downarrow f_* \\
\pi_n(Y, B, y_0) & \xrightarrow{\partial} & \pi_{n-1}(B, y_0).
\end{array}
\]

(2) The following sequence is exact

\[
\cdots \to \pi_n(A, x_0) \xrightarrow{i_*} \pi_n(X, x_0) \to \pi_n(X, A, x_0) \xrightarrow{\partial i} \pi_{n-1}(A, x_0) \to \cdots \to \pi_0(X, x_0).
\]

Here \( i : A \to X \) is the inclusion map and the map \( \pi_n(X, x_0) \to \pi_n(X, A, x_0) \) is the natural map introduced on page 2617.

![Figure 1546](image)

**Examples.**

(1) We consider \( X = \mathbb{R}^2 \) and we consider \( A = A_0 \sqcup A_1 \) which is the union of disjoint closed disks \( A_0 \) and \( A_1 \) in \( X = \mathbb{R}^2 \). We denote by \( x_0 \in A_0 \) and \( x_1 \in A_1 \) the centers of the two disks. Furthermore we denote by \( f : I = [0, 1] \to X \) a map with \( f(0) = x_1 \) and \( f(1) = x_0 \). (We refer to Figure 1547 for an illustration.) Finally, for any \( n \in \mathbb{N}_0 \) and any \( i \in \{0, 1\} \) we denote by \( c_{x_i} : I^n \to A_i \) the constant map that sends all points to \( x_i \). It follows from Lemma 18.14 together with Lemma 18.13 and Propositions 18.16 (2) and 40.7 (2) that all the homotopy groups of \( A \) and \( X \) are generated by \( [c_{x_0}] \) except for \( \pi_0(A, x_0) \) that equals the set \( \{[c_{x_0}], [c_{x_1}]\} \).

As discussed on page 2617, \( f \) defines an element in \( \pi_1(X, A, x_0) \). Using the definitions one sees almost immediately that \( \partial [f] = [c_{x_1}] \in \pi_0(A, x_0) \). It follows easily from this data and Proposition 111.4 (2) that \( \pi_1(X, A, x_0) \) consists of precisely two elements, namely \( [c_{x_0}] \) and \( [f] \).

(2) Let \( X = \mathbb{R}^2 \). We denote by \( A \) the wedge of two circles, viewed as a subset of \( X = \mathbb{R}^2 \). Furthermore we denote by \( x_0 \) the wedge point. It follows from Proposition 111.4 (2)
The following sequence is exact that \( \pi_2(X, A, x_0) \cong \pi_1(A, x_0) \). In Lemma 22.4 we saw that \( \pi_1(A, x_0) \) is non-abelian, thus \( \pi_2(X, A, x_0) \) is also non-abelian.

In fact we can identify two elements in \( \pi_2(X, A, x_0) \) that do not commute. We consider the two maps \( f, g : (I^2, \partial I^2, J^1) \to (X, A, \{x_0\}) \) that are illustrated in Figure 1548. It follows easily from the definitions that \( \partial[f], \partial[g] \) are the standard generators of the free group \( \pi_1(S^1 \vee S^1, x_0) \). Since these do not commute we see that \( [f] \) and \( [g] \) do not commute either.

\[ X = \mathbb{R}^2 \]

\[ \begin{tikzpicture}
\node (A) at (0,0) [circle,fill,inner sep=1pt] {} ;
\node (B) at (1,0) [circle,fill,inner sep=1pt] {} ;
\node (C) at (0,2) [circle,fill,inner sep=1pt] {} ;
\node (D) at (1,2) [circle,fill,inner sep=1pt] {} ;
\draw (A) to (B) to (C) to (D) to (A);
\end{tikzpicture} \]

\\( A \mapsto f \mapsto B \mapsto C \mapsto D \mapsto A \)

\[ \begin{tikzpicture}
\node (A) at (0,0) [circle,fill,inner sep=1pt] {} ;
\node (B) at (1,0) [circle,fill,inner sep=1pt] {} ;
\node (C) at (0,2) [circle,fill,inner sep=1pt] {} ;
\node (D) at (1,2) [circle,fill,inner sep=1pt] {} ;
\draw (A) to (B) to (C) to (D) to (A);
\end{tikzpicture} \]

\\( B \mapsto g \mapsto C \mapsto D \mapsto A \)

\[ f \mapsto g \mapsto f \mapsto g \mapsto f \mapsto g \mapsto f \mapsto g \]

\[ \begin{array}{c}
\partial_n : \pi_n(X, A, x_0) & \to & \pi_{n-1}(A, B, x_0) \\
\left[ f : (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\}) \right] & \mapsto & \left[ (I^{n-1}, \partial I^{n-1}, J^{n-2}) \to (A, B, \{x_0\}) \\
(x_1, \ldots, x_{n-1}) & \mapsto & f(x_1, \ldots, x_{n-1}, 0) \\
\right]
\end{array} \]

is easily seen to be a well-defined morphism of pointed sets. Our goal is to prove the following claim.

Claim. The following sequence is exact:

\[ \ldots \to \pi_n(A, B, x_0) \overset{i_*}{\to} \pi_n(X, B, x_0) \overset{j_*}{\to} \pi_n(X, A, x_0) \overset{\partial_n}{\to} \pi_{n-1}(A, B, x_0) \to \ldots \to \pi_1(X, A, x_0). \]

where \( i : (A, B) \to (X, B) \) and \( j : (X, B) \to (X, A) \) are the obvious morphisms of pointed pairs of topological spaces.

---

\( \text{\footnote{1508}{We refer to page 606 for the calculation of the fundamental group of \( S^1 \vee S^1 \).}} \)

\( \text{\footnote{1509}{This sequence plays of course the role of the long exact sequence in homology groups of a triple of topological spaces, see Proposition 43.15}} \)
Note that this claim, applied to $B = \{x_0\}$ together with Proposition 111.3 (2) almost implies that the sequence of the proposition is exact. The only problem is that the sequence of the claim stops slightly earlier, more precisely it stops at the subindex one instead of subindex zero. Thus the only piece missing is the exactness of the sequence of the proposition at the last three pointed sets. We leave the verification of exactness at these three spots as an elementary exercise to the conscientious reader.

![Figure 1549. First illustration for the proof of Proposition 111.4](image)

Now we turn to the proof of the claim. Not surprisingly the proof of the claim breaks up into three separate proofs, namely we need to verify exactness at the three different groups.

**Exactness at** $\pi_n(X, B, x_0)$. It follows easily from Lemma 111.3 that $j_\ast \circ i_\ast = (j \circ i)_\ast$ is the trivial morphism. We leave it to the reader to verify that $\ker(j_\ast) \subset \text{im}(i_\ast)$.

**Exactness at** $\pi_n(X, A, x_0)$. It follows again easily from Lemma 111.3 and the definition of the connecting homomorphism $\partial$ that $\partial \circ j_\ast$ is the trivial morphism. Now suppose we are given $f: (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})$ such that the restriction of $f$ to $I^\ast \times \{0\}$ represents the trivial element in $\pi_{n-1}(A, B, x_0)$. This means that there exists a homotopy $H: I^{n-1} \times I \to A$ (with all the required restrictions) from $f|_{I^n \times \{0\}}$ to the constant map. The map

$$I^n \times [0, 1] \to X$$

$$(x_1, \ldots, x_n, t) \mapsto \begin{cases} f \left( x_1, \ldots, x_{n-1}, \frac{t}{2}, x_n + (1-x_n) \right), & \text{if } x_n \in \left[ \frac{t}{2}, 1 \right] \\ H \left( x_1, \ldots, x_{n-1}, 2x_n - t \right), & \text{if } x_n \in \left[ 0, \frac{t}{2} \right] \end{cases}$$

is continuous by Lemma 14.3 and it defines a homotopy (again with all the desired extra properties) from $f$ to a map that represents an element in $\pi_n(X, B, x_0)$. The definition of the homotopy is sketched, to the best of my abilities, in Figure 1550.

**Exactness at** $\pi_n(A, B, x_0)$. First note that $i_\ast \circ \partial$ is the trivial morphism. Indeed, if $f: (I^{n+1}, \partial I^{n+1}, J^n) \to (X, A, \{x_0\})$ is a map, then $f: (I^n \times [0, 1], \partial I^n \times [0, 1]) \to (X, x_0)$ defines a homotopy from $\partial f = f|_{I^n \times \{0\}}$ to the constant map $c_{x_0}$. Thus $(i_\ast \circ \partial)[f] = [i_\ast \circ \partial f]$ is the trivial element in $\pi_n(X, B, x_0)$.

Now suppose that we are given a map $f: (I^n, \partial I^n, J^{n-1}) \to (A, B)$ such that $j \circ f$ represents the trivial element in $\pi_n(X, B, x_0)$. This means that there exists a homotopy $H$ (with all the obvious conditions) from $j \circ f$ to the constant map $c_{x_0}$. We define

$$g: I^n \to B$$

$$(x_1, \ldots, x_n) \mapsto H(x_1, \ldots, x_{n-1}, 0, x_n).$$
We pick a homeomorphism $\Psi : I^2 \to I^2$ with the properties as illustrated in Figure 1551\(^{1510}\) (Here it is psychologically convenient to think of $I^2$ as the square in the plane with $x_n$ and $x_{n+1}$-coordinates.) It follows immediately from the definitions that the map

\[
I^{n+1} \to X
\]

\[
(x_1, \ldots, x_n, x_{n+1}) \to H(x_1, \ldots, x_{n-1}, \Psi(x_n, x_{n+1}))
\]
defines an element in $\pi_{n+1}(X, A, x_0)$ such that the connecting morphism sends it to the element in $\pi_n(A, B, x_0)$ represented by the map\(^{1511}\)

\[
f \ast g : I^n \to X
\]

\[
(t_1, \ldots, t_n) \mapsto \begin{cases} f(t_1, \ldots, t_{n-1}, 2t_n), & \text{if } t_n \in [0, \frac{1}{2}], \\ g(t_1, \ldots, t_{n-1}, 2t_n - 1), & \text{if } t_n \in [\frac{1}{2}, 1] \end{cases}
\]

It remains to show that $f \ast g$ and $f$ represent the same element in $\pi_n(A, B, x_0)$. This can be done in a fashion similar to the above proof of exactness. More precisely, a homotopy between $f$ and $f \ast g$, again with all the desired properties, is given by

\[
I^n \times [0, 1] \to X
\]

\[
(x_1, \ldots, x_n, t) \mapsto \begin{cases} \frac{1}{2} \left( 1 - \frac{t}{2} \right) \cdot x_n + (1 - x_n), & \text{if } x_n \in \left[ \frac{t}{2}, 1 \right] \\ H(x_1, \ldots, x_{n-1}, 2x_n - t), & \text{if } x_n \in \left[ 0, \frac{t}{2} \right] \end{cases}
\]

\(^{1510}\)The triangles in Figure 1551 indicate how one could write down an explicit homeomorphism.

\(^{1511}\)Strictly speaking this definition of $f \ast g$ differs from the definition on page 2617 since we use a different coordinate to perform the product. But it is convenient to use the same notation.
111.3. Paths acting on relative homotopy groups. Let \((X,x_0)\) be a pointed topological space. In Section 54.3 we saw that the fundamental group \(\pi_1(X,x_0)\) of \(X\) acts on any homotopy group \(\pi_n(X,x_0)\). In this section we will discuss an analogous construction for relative homotopy groups. In particular, given a pointed pair \((X,A,x_0)\) of topological spaces we will see that the fundamental group \(\pi_1(A,x_0)\) of \(A\) (let us stress that here we write \(A\) instead of \(X\)) acts on any relative homotopy group \(\pi_n(X,A,x_0)\).

The following definition is quite similar to the definition on page 1352.

**Definition.** Let \(X\) be a topological space, let \(A\) be a subset of \(X\) and let \(n \in \mathbb{N}_{\geq 2}\). Furthermore let \(\gamma: [0,1] \to A\) be a path in the subset \(A\) from a point \(x_0\) to a point \(x_1\). Finally let

\[ f: (I^n, \partial I^n, J^{n-1}) \to (X,A,\{x_1\}) \]

be a map. We define

\[ f^\gamma: (I^n, \partial I^n, J^{n-1}) \to (X,A,\{x_0\}) \]

to be the map that is illustrated in Figure 1552. For our particularly pedantic readers we now also give a super-rigorous definition of \(f^\gamma\): First of all, given \(t \in [0,1]\) we define

\[ C_t = \left[ \frac{t}{4}, \frac{4-t}{4} \right]^{n-1} \times [0,1-\frac{t}{2}], \]

Now we define

\[ f^\gamma: (I^n, \partial I^n, J^{n-1}) \to (X,A,x_0) \]

\[ (x_1, \ldots, x_n) \mapsto \begin{cases} f(2x_1 - \frac{1}{2}, \ldots, 2x_n), & \text{if } (x_1, \ldots, x_n) \in C_1 = \left[ \frac{1}{4}, \frac{3}{4} \right]^{n-1} \times [0,\frac{1}{2}], \\ \gamma(t), & \text{if } (x_1, \ldots, x_n) \in \partial C_t \text{ for } t \in [0,1]. \end{cases} \]

The following proposition can be viewed as the “relative analogue” of Proposition 40.5.

**Proposition 111.5.** Let \(X\) be a topological space, let \(A\) be a subset of \(X\) and let \(n \in \mathbb{N}_{\geq 2}\).

1. If \(\gamma: [0,1] \to A\) is a path from \(x_0\) to \(x_1\), then the map

\[ \gamma_*: \pi_n(X,A,x_1) \to \pi_n(X,A,x_0) \]

\[ [f] \mapsto [f^\gamma] \]

is a well-defined map that is a group homomorphism.

---

\(^{1512}\)What is wrong with \(n = 1\)?

\(^{1513}\)Note that in contrast to the definition on page 1352 we only consider paths in \(A\). At this point we do not allow paths in \(X\).
(2) If $x_0$ and $x_1$ are two points in $A$ which lie in the same path-component of $A$, then $\pi_n(X,A,x_0)$ is isomorphic to $\pi_n(X,A,x_1)$.

(3) Let $\varphi: (X,A) \to (Y,B)$ be a map between pairs of topological spaces.

(a) If $\gamma: [0,1] \to A$ is a path from $x_0$ to $x_1$, then the following diagram commutes:

$$
\begin{array}{ccc}
\pi_n(X,A,x_1) & \xrightarrow{\gamma_*} & \pi_n(X,A,x_0) \\
\downarrow{\varphi_*} & & \downarrow{\varphi_*} \\
\pi_n(Y,B,\varphi(x_1)) & \xrightarrow{(\varphi \circ \gamma)_*} & \pi_n(Y,B,\varphi(x_0)).
\end{array}
$$

(b) If $\varphi_*: \pi_n(X,A,x_0) \to \pi_n(Y,B,\varphi(x_0))$ is an isomorphism (epimorphism, monomorphism) for some base point $x_0 \in A$, then for any other point $x_1$ in the same path component of $A$ the map $\varphi_*: \pi_n(X,A,x_1) \to \pi_n(Y,B,\varphi(x_1))$ is also an isomorphism (epimorphism, monomorphism).

(4) Let $\gamma$ and $\delta$ be two paths in $A$ from $x_0$ to $x_1$. If $\gamma$ and $\delta$ are path-homotopic in $A$, then the corresponding maps $\gamma_*$ and $\delta_*$ from $\pi_n(X,A,x_1)$ to $\pi_n(X,A,x_0)$ agree.

(5) If $\gamma$ is a path in $A$ from $x_0$ to $x_1$ and if $\delta$ is a path in $A$ from $x_1$ to $x_2$, then

$$(\gamma \star \delta)_* = \gamma_* \circ \delta_*: \pi_n(X,A,x_2) \to \pi_n(X,A,x_0).$$

(6) The map

$$
\pi_1(A,x_0) \times \pi_n(X,A,x_0) \to \pi_n(X,A,x_0) \\
([\gamma],[f]) \mapsto [\gamma] \cdot [f] := [f^\gamma]
$$

defines an action (in the sense of the definition on page 185) on the group $\pi_1(A,x_0)$ on the group $\pi_n(X,A,x_0)$.

(7) We denote by $i: A \to X$ the inclusion map and by $\varphi: \pi_n(X,x_0) \to \pi_n(X,A,x_0)$ the natural map. Then, with the convention from page 207, the following diagram commutes

$$
\begin{array}{ccc}
\pi_1(X,x_0) \times \pi_n(X,x_0) & \xrightarrow{i_*} & \pi_n(X,A,x_0) \\
\downarrow{\varphi_*} & & \downarrow{\varphi_*} \\
\pi_1(A,x_0) \times \pi_n(A,x_0) & \xrightarrow{\varphi_*} & \pi_n(X,A,x_0).
\end{array}
$$

(8) If $\gamma: [0,1] \to A$ is a path from $x_0$ to $x_1$, then the following diagram commutes:

$$
\begin{array}{ccc}
\pi_n(X,A,x_1) & \xrightarrow{[f] \mapsto [f^\gamma]} & \pi_n(X,A,x_0) \\
\downarrow{\partial} & & \downarrow{\partial} \\
\pi_{n-1}(A,x_1) & \xrightarrow{[f] \mapsto [f^\gamma]} & \pi_{n-1}(A,x_0).
\end{array}
$$

\textbf{Proof.} The proof of the first six statements of the proposition is basically identical to the proof of Proposition 54.9. The last two statements follow easily from the definitions. To protect the trees we will not carry out the details.  \[1514\]

\[1514\] Here it is worth remembering that by definition, see page 465, the product path $\gamma \star \delta$ is given by first traversing $\gamma$ and then traversing $\delta$.\[1514\]
Remark. Let $X$ be a topological space, let $A$ be a non-empty subset and let $n \in \mathbb{N}_{\geq 2}$. If $A$ is path-connected, then it follows from Proposition 111.5 (2) that the isomorphism type of the relative higher homotopy groups $\pi_n(X, A, x_0)$ does not depend on the choice of a base point in $A$. Thus if we are only interested in the isomorphism type of the $n$-th relative homotopy group of $(X, A)$, then sometimes we just write $\pi_n(X, A)$, i.e. we suppress the base point from the notation.

Recall that for the relative homotopy groups $\pi_n(X, A, x_0)$ with $n \geq 3$ we use the additive notation for the group structure. Thus Lemma 54.13, Propositions 40.3, 111.1 (4) and 111.5 lead us to the following observation:

Observation. Let $(X, A, x_0)$ be a pointed pair of topological spaces. If $n \geq 3$, then the abelian group $\pi_n(X, A, x_0)$ admits a natural $\mathbb{Z}[\pi_1(A, x_0)]$-left module structure.

Example. We consider the wedge $X = S^1 \vee S^2$ where we identify $i \in S^1$ with $(0, 0, -1) \in S^2$. We denote by $x_0$ the wedge point. Furthermore let $A = S^1 \subset X$. We denote by $t \in \pi_1(S^1, i)$ the standard generator. (We refer to Figure 1553 for an illustration.) By Proposition 20.3 we know that the inclusion $A \rightarrow X$ induces an isomorphism $\pi_1(A, x_0) \rightarrow \pi_1(X, x_0)$. We use this isomorphism to make the identification $\pi_1(A, x_0) = \pi_1(X, x_0) = \langle t \rangle$. It follows from Proposition 111.4 and Proposition 111.5 (7) that the natural map $\pi_2(X, x_0) \rightarrow \pi_2(X, A, x_0)$ is an isomorphism of $\mathbb{Z}[t^\pm 1]$-modules. In particular, by Proposition 54.15 we have

$$\pi_2(X, A, x_0) \xrightarrow{\cong} \pi_2(S^1 \vee S^2) \xrightarrow{\cong} \mathbb{Z}[t^\pm 1].$$

![Figure 1553](image-url)

111.4. Alternative description of relative homotopy groups. Let $(X, x_0)$ be a pointed topological space. Recall that on page 1059 we had in particular introduced the following identifications:

$$\pi_n(X, x_0) = \text{set (of homotopy classes) of maps } (I^n, \partial I^n) \rightarrow (X, x_0) = \text{set (of homotopy classes) of maps } (S^n, *) \rightarrow (X, x_0).$$

These identifications allowed us to go back and forth between different view points regarding homotopy groups.

Before we continue with our discussion of relative homotopy groups we also want to introduce a second view point regarding relative homotopy groups. The key to doing so is the following elementary lemma.

Lemma 111.6. Let $n \in \mathbb{N}$. There exists an explicit map $\varphi: I^n \rightarrow \mathbb{B}^n$ with the following three properties:

1. we have $\varphi(J^{n-1}) = \ast := (0, \ldots, 0, 1)$ and $\varphi(I^{n-1}) = S^{n-1}$. 

(2) the map \( \varphi \) descends to a homeomorphism \((I^n/J^{n-1}, I^{n-1}/\partial I^{n-1}) \xrightarrow{\cong} (\mathcal{B}^n, S^{n-1})\),

(3) the restriction of \( \varphi \) to the map \( I^n \setminus \partial I^n \to B^n \) is an orientation-preserving diffeomorphism.

---

**Figure 1554. Illustration for Lemma [111.6]**

**Sketch of a proof for Lemma [111.6] (\*).** We write \( Q = (\frac{1}{2}, \ldots, \frac{1}{2}, 0) \in I^n \). Given any point \( x \in I^n \setminus \{Q\} \) we define

\[
\rho(x) := \sup \{ \|rx\| \mid r \in \mathbb{R}_{>0} \text{ and } r(x - Q) + Q \in I^n \}.
\]

We consider the map

\[
\alpha: I^n / J^{n-1} \to \left\{ (x_1, \ldots, x_n) \in \mathbb{R}^n \mid x_n \geq 0 \right\} \cup \{ \infty \}
\]

\[
[x] \mapsto \begin{cases} 
\frac{x-Q}{\|x-Q\|} \cdot \tan \left( \frac{\pi}{2} \cdot \frac{\|x-Q\|}{\rho(x)} \right), & \text{if } x \neq Q, \\
0, & \text{if } x = Q.
\end{cases}
\]

This map stretches each of the segments from \( Q \) to a point on \( J^{n-1} \) to an infinite ray emanating from the origin. In particular all points in \( J^{n-1} \) get sent to infinity, i.e. the map is well-defined. We refer to Figure 1555 for an illustration.

Similar to the proof of Proposition 2.53, we see that the map \( \alpha \) is a homeomorphism that restricts to a homeomorphism \( I^{n-1}/\partial I^{n-1} \to (\mathbb{R}^{n-1} \times \{0\}) \cup \{ \infty \} \). Let \( \beta: \mathbb{R}^n \cup \{\infty\} \to S^n \) be the inverse of the stereographic projection that we introduced in Lemma 2.44. Note that \( \beta(\infty) = (0, \ldots, 0, 1) \). Furthermore note that the homeomorphism \( \beta \) restricts to a homeomorphism

\[
\beta: H^n \cup \{\infty\} \to S^n_{\geq 0} := \{(x_1, \ldots, x_{n+1}) \in S^n \mid x_n \geq 0\}.
\]

Finally we consider the following map:

\[
I^n \to I^n / J^{n-1} \xrightarrow{\alpha} H_n \cup \{\infty\} \xrightarrow{\beta} S^n_{\geq 0} \to \mathcal{B}^n
\]

\[
(x_1, \ldots, x_n, x_{n+1}) \mapsto (x_1, \ldots, x_n, x_{n+1}).
\]

Using Exercise 6.17 one can easily verify that this map has all the desired properties.\(^{111.17}\)
Convention. Using the map
\[ \varphi: (I^n, \partial I^n, J^{n-1}) \to (B^n, S^{n-1}, *) \]
from Lemma \ref{lem:homotopy} we make the following identifications
\[ \pi_n(X, A, x_0) = \text{set (of homotopy classes) of maps} \ (I^n, \partial I^n, J^{n-1}) \to (X, A, x_0) = \text{set (of homotopy classes) of maps} \ (B^n, S^{n-1}, *) \to (X, A, x_0). \]
We refer to Figure \ref{fig:homotopy} for an illustration.

Remark. Let \((X, A, x_0)\) be a pointed pair of topological spaces and let \(n \in \mathbb{N}\). As above we make the identifications
\[ \pi_n(X, A, x_0) = \left\{ \text{homotopy classes of maps} \ (B^n, S^{n-1}, *) \to (X, A, x_0) \right\} \text{ and } \pi_{n-1}(A, x_0) = \left\{ \text{homotopy classes of maps} \ (S^{n-1}, *) \to (A, x_0) \right\}. \]
We leave it to the interested reader to verify that the connecting homomorphism \(\pi_n(X, A, x_0) \to \pi_{n-1}(A, x_0)\) from Proposition \ref{prop:connecting} is given by the map
\[ \partial_n: \pi_n(X, A, x_0) \to \pi_{n-1}(A, x_0) \quad [f: (B^n, S^{n-1}, *) \to (X, A, x_0)] \mapsto [f|_{S^{n-1}}: (S^{n-1}, *) \to (A, x_0)]. \]

111.5. Connected (pairs of) topological spaces. For convenience we recall the following definition from page \ref{page:connected}.

Definition. Let \(k \in \mathbb{N}_0\). We say a topological space \(X\) is \(k\)-connected, if \(\pi_i(X) = 0\) for \(i = 0, \ldots, k\).

This definition has the following obvious “relative” analogue.

Definition. Let \(X\) be a topological space, let \(A \subset X\) and let \(k \in \mathbb{N}\). We say \((X, A)\) is \(k\)-connected if every path-component of \(X\) contains a point of \(A\) and if for every \(i \in \{1, \ldots, k\}\) and every \(x_0 \in A\) we have \(\pi_i(X, A, x_0) = 0\).

The following lemma provides a convenient reformulation of the previous definition.
Lemma 111.7. Let $X$ be a topological space, let $A \subset X$ and let $k \in \mathbb{N}$. The following two statements are equivalent:

1. The pair $(X, A)$ is $k$-connected.
2. Every path-component of $X$ contains a point of $A$, furthermore for every $a \in A$ and every $j \in \{1, \ldots, k-1\}$ the inclusion induced map $\pi_j(A, a) \to \pi_j(X, a)$ is an isomorphism and the inclusion induced map $\pi_k(A, a) \to \pi_k(X, a)$ is an epimorphism.

Example. Let $X$ be a topological space and let $A \subset X$ be a deformation retract. It follows from Proposition 10.7(2) that for any $x_0 \in A$ and any $i \in \mathbb{N}_0$ the inclusion induced map $\pi_i(A, x_0) \to \pi_i(X, x_0)$ is an isomorphism. It follows from Lemma 111.7 that $(X, A)$ is $k$-connected for every $k \in \mathbb{N}$.

Proof. We denote by $i: A \to X$ the inclusion map. Let $a \in A$. By Proposition 111.4 we have the following long exact sequence of homotopy groups:

$$\ldots \to \pi_k(A, a) \xrightarrow{i_*} \pi_k(X, a) \to \pi_k(X, A, a) \xrightarrow{\partial} \pi_{k-1}(A, a) \xrightarrow{i_*} \pi_{k-1}(X, a) \to \ldots$$

The lemma is an immediate consequence of the existence of this long exact sequence. ■

The following proposition gives a convenient characterization of the vanishing relative homotopy groups.

Proposition 111.8. Let $X$ be a topological space and let $A \subset X$. For any $n \in \mathbb{N}$ the following two statements are equivalent:

1. Every map $(\overline{B}^n, S^{n-1}) \to (X, A)$ is homotopic rel $S^{n-1}$ to a map $\overline{B}^n \to A$,
2. for every $x_0 \in A$ we have $\pi_n(X, A, x_0) = 0$.

Furthermore, for $n = 0$ the above statement (1) is equivalent to

2' every path-component of $X$ contains a point of $A$.

Example. We consider the infinite cylinder $X = S^1 \times \mathbb{R}$ and the annulus $A = S^1 \times [-1, 1]$. Evidently $A$ is a deformation retract of $X$. Thus, by the previous example the pair $(X, A)$ is $k$-connected for every $k \in \mathbb{N}_0$. In Figure 1557 we show a map $f: (\overline{B}^2, S^1) \to (X, A)$. Furthermore we show a map $g: \overline{B}^2 \to A$ that is homotopic, rel $S^1$, to $f$.

![Figure 1557](image-url)

Proof of Proposition 111.8. First note that it is elementary to see that for $n = 0$ the statements (1) and (2') are equivalent. Now let $n \geq 1$. The implication (1) $\Rightarrow$ (2) is an immediate consequence of Lemma 111.3 and the by now well-known fact that there exists a homeomorphism $(I^n, \partial I^n) \xrightarrow{\cong} (\overline{B}^n, S^{n-1})$. 

The most interesting statement of the proposition is the implication (2) ⇒ (1). Thus we now assume that \( \pi_n(X, A, x_0) = 0 \) for every \( x_0 \in A \). Let \( f: (\overline{B}^n, S^{n-1}) \to (X, A) \) be a map. We need to show that \( f \) is homotopic rel \( S^{n-1} \) to a map that takes values only in \( A \). Let \( \varphi: I^n \to \overline{B}^n \) be the map from Lemma 11.6 with \( \varphi(J^{n-1}) = (0, \ldots, 0, 1) \). We set \( x_0 := f(0, \ldots, 0, 1) \). Note that the map \( f \circ \varphi: I^n \to X \) is actually a map

\[
I^n \times [0, 1] \to X
\]

\[
(x_1, \ldots, x_n, t) \mapsto \begin{cases} 
F(x_1, \ldots, x_{n-1}, \frac{1}{2} \cdot (x_n - \frac{t}{2}), t), & \text{if } x_n \in \left[\frac{t}{2}, 1\right] \\
F(x_1, \ldots, x_{n-1}, 0, \frac{1}{2} \cdot x_n), & \text{if } x_n \in \left[0, \frac{t}{2}\right].
\end{cases}
\]

The definition of the homotopy is sketched, with moderate success, in Figure 1558. This map has the following properties:

0. the map is continuous by Lemma 14.3,
1. the map is a homotopy rel \( I^{n-1} \times \{0\} \),
2. the map is a homotopy from \( f \circ \varphi \) to a map that takes values in \( A \),
3. the map sends \( J^{n-1} \times [0, 1] \) to \( x_0 \).

It follows from Property (3), and using the above map \( \varphi: (I^n, J^{n-1}) \to (\overline{B}^n, (0, \ldots, 0, 1)) \), that \( F \) defines a homotopy \( G: \overline{B}^n \times [0, 1] \to X \). Property (1) implies that \( G \) is a homotopy rel \( S^{n-1} \). Furthermore Property (2) says that \( G \) is a homotopy from \( f \) to a map that takes values in \( A \). Thus \( G \) is the desired a homotopy. ■

The following proposition gives us an important example of a \( k \)-connected pair of topological spaces.

**Proposition 111.9.** Let \( X \) be a CW-complex and let \( k \in \mathbb{N}_0 \).

1. If \( A \) is a subcomplex such that all cells in \( X \setminus A \) have dimension greater than \( k \), then the pair \( (X, A) \) is \( k \)-connected.
2. The pair \( (X, X^k) \) is \( k \)-connected.
111. Relative Homotopy Groups

Proof.

(1) Let $X$ be a CW-complex, let $A$ be a subcomplex and let $k \in \mathbb{N}_0$. Suppose that all cells in $X \setminus A$ have dimension greater than $k$. This implies in particular that every path-component of $X$ contains at least one point in $A$. The remainder of the proof is almost the same as the proof of Proposition 40.9. The key difference is that we need to replace the Cellular Approximation Theorem 38.13 by the Cellular Approximation Theorem 38.14 for Pairs of CW-complexes and that now we use the $(1) \Rightarrow (2)$ implication of Proposition 111.8. We leave it to the reader to carry out the modest modifications of the proof of Proposition 40.9.

(2) This statement is of course an immediate consequence of the first statement. ■

The following corollary is an extremely useful consequence of Lemma 111.7 and Proposition 111.9(2). We had proved it earlier in the guise of Proposition 40.9.

**Corollary 111.10.** Let $X$ be a CW-complex, let $k \in \mathbb{N}_0$ and let $x \in X^k$. The following two statements hold:

1. For $j = 1, \ldots, k - 1$ the inclusion induced map $\pi_j(X^k, x) \to \pi_j(X, x)$ is an isomorphism.
2. The inclusion induced map $\pi_k(X^k, x) \to \pi_k(X, x)$ is an epimorphism.

111.6. The relative Hurewicz Theorem. In this section we state the “Relative Hurewicz Theorem” that generalizes the original Hurewicz Theorem 53.5 to the relative setting.

**Definition.** Let $(X, A, x_0)$ be a pointed pair of topological spaces and let $n \in \mathbb{N}$. We denote by $[I^n] \in H_n(I^n, \partial I^n; \mathbb{Z})$ the fundamental class of $I^n$. We refer to the map

$$\Phi_{(X,A,x_0)}: \pi_n(X, A, x_0) \to H_n(X, A; \mathbb{Z})$$

$$[f: (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})] \mapsto f_*([I^n])$$

as the relative Hurewicz homomorphism.

The following lemma summarizes some elementary properties of the relative Hurewicz homomorphism.

**Lemma 111.11.**

1. Let $(X, A, x_0)$ be a pointed pair of topological spaces and let $n \in \mathbb{N}_{\geq 2}$. The map

$$\Phi_{(X,A,x_0)}: \pi_n(X, A, x_0) \to H_n(X, A; \mathbb{Z})$$

$$[f: (I^n, \partial I^n, J^{n-1}) \to (X, A, \{x_0\})] \mapsto f_*([I^n])$$

is well-defined and it is a homomorphism.
(2) Let \((X, x_0)\) be a pointed topological space and let \(n \geq 2\). The following diagram commutes

\[
\begin{array}{ccc}
\pi_n(X, x_0) & \xrightarrow{\Phi_{(X,x_0)}} & H_n(X; \mathbb{Z}) \\
\cong & & \cong \\
\pi_n(X, \{x_0\}, x_0) & \xrightarrow{\Phi_{(X,x_0),x_0}} & H_n(X, \{x_0\}; \mathbb{Z}).
\end{array}
\]

Here the left-hand vertical map is given by the identification from page 2617 and the right-hand vertical map is the obvious map from absolute to relative homology groups.

(3) Let \((X, A, x_0)\) be a pointed pair of topological spaces. The following diagram commutes

\[
\begin{array}{ccc}
\ldots & \xrightarrow{\pi_n(A, x_0)} & \pi_n(X, x_0) & \xrightarrow{\pi_n(X, A, x_0)} & \pi_{n-1}(A, x_0) & \xrightarrow{\partial} & \pi_1(X, x_0) \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
\ldots & \xrightarrow{H_n(A; \mathbb{Z})} & H_n(X; \mathbb{Z}) & \xrightarrow{H_n(X, A; \mathbb{Z})} & H_{n-1}(A; \mathbb{Z}) & \xrightarrow{\partial} & \ldots & H_1(X; \mathbb{Z}).
\end{array}
\]

Here the horizontal sequences are the long exact sequences given by Corollary 43.16 and by Proposition 111.4 and the vertical maps are the Hurewicz homomorphisms.

Sketch of proof.

(1) The proof of the first statement is evidently just a straightforward variation on the proof of Lemma 53.1. We refer to [Bre93, Lemma VII.10.2] or [Hat02, Proposition 4.36] for details.

(3) We have to show that each of the three squares commutes.

(a) The first square commutes basically by definition, see also Lemma 53.1 (3).

(b) The fact that the second square commutes is an immediate consequence of the definitions of the “absolute” and the “relative” Hurewicz homomorphisms, see above and page 1324.

(c) Finally it follows fairly easily from Lemma 87.24 and Proposition 87.27 that the third square commutes.

(2) This is just a special case of the second square considered in (3). 

Again the following question arises: to what degree is the relative Hurewicz homomorphism in fact an isomorphism? One might hope that if a pair \((X, A)\) is \((n - 1)\)-connected, then the Hurewicz homomorphism \(\Phi_{(X,A,x_0)}: \pi_n(X, A, x_0) \to H_n(X, A; \mathbb{Z})\) is an isomorphism. But the following example shows that this is not the case.

**Example.** We consider again \(X = S^1 \vee S^2\) and \(A = S^1 \subset X\). We denote by \(x_0\) the wedge point. It follows easily from the long exact sequence of homotopy groups provided
by Proposition 111.4 that \((X, A)\) is 1-connected. We see that in this case the map
\[
\Phi_{(X,A,x_0)}: \pi_2(X, A, x_0) \rightarrow H_2(X, A; \mathbb{Z})
\]
\[\cong \mathbb{Z}, \text{see page 2628}\]
is not an isomorphism.

The following lemma is the key to understanding why the relative Hurewicz homomorphism fails to be a monomorphism.

**Lemma 111.12.** Let \((X, A, x_0)\) be a pointed pair of topological spaces and let \(n \in \mathbb{N}_{\geq 2}\). Furthermore let \(\sigma \in \pi_n(X, A, x_0)\). For any \(g \in \pi_1(A, x_0)\) we have
\[
\Phi_{(X,A,x_0)}(g \cdot \sigma) = \Phi_{(X,A,x_0)}(\sigma).
\]

**Proof.** Let \((X, A, x_0)\) be a pointed pair of topological spaces and let \(n \in \mathbb{N}_{\geq 2}\). Furthermore let \([f]\) \(\in \pi_n(X, A, x_0)\) and let \([\gamma]\) \(\in \pi_1(A, x_0)\). As in Proposition 54.9 (7) we see that the maps \(f: (I^n, \partial I^{n-1}) \rightarrow (X, A)\) and \(f^\gamma: (I^n, \partial I^{n-1}) \rightarrow (X, A)\) are homotopic. We obtain that
\[
\Phi_{(X,A,x_0)}([\gamma] \cdot [f]) = \Phi_{(X,A,x_0)}([f^\gamma]) = (f^\gamma)_*(\pi_n(I^n)) = f_*(\pi_n(I^n)) = \Phi_{(X,A,x_0)}([f]).
\]
by Proposition 43.17 since \(f\) and \(f^\gamma\) are homotopic as maps \((I^n, \partial I^n) \rightarrow (X, A)\).

The above lemma leads us to the following definition.

**Definition.** Let \((X, A, x_0)\) be a pointed pair of topological spaces.

(1) For \(n \in \mathbb{N}_{\geq 3}\) we define \(\pi'_n(X, A, x_0)\) to be the quotient group
\[
\pi'_n(X, A, x_0) := \pi_n(X, A, x_0)/\{g \cdot \sigma - \sigma \mid g \in \pi_1(A, x_0)\text{ and }\sigma \in \pi_n(X, A, x_0)\}.\]

(2) We define
\[
\pi'_2(X, A, x_0) := \pi_2(X, A, x_0)/\langle \langle \{(g \cdot \sigma) \cdot \sigma^{-1} \mid g \in \pi_1(A, x_0), \sigma \in \pi_2(X, A, x_0)\} \rangle \rangle.
\]

(3) By Lemma 111.12 the Hurewicz homomorphism
\[
\Phi_{(X,A,x_0)}: \pi_n(X, A, x_0) \rightarrow H_n(X, A; \mathbb{Z})
\]
descends to a homomorphism
\[
\Phi_{(X,A,x_0)}: \pi'_n(X, A, x_0) \rightarrow H_n(X, A; \mathbb{Z}).
\]

We refer to this homomorphism again as the **Hurewicz homomorphism**.
**Remark.** Let \((X,A,x_0)\) be a pointed pair of topological spaces. It is a fun exercise to show “by hand” that \(\pi'_2(X,A,x_0)\) is an abelian group. We refer to [Hat02, Lemma 4.39] for details.

**Example.** Once again we consider \(X = S^1 \vee S^2\) and \(A = S^1 \subset X\). We denote by \(x_0\) the wedge point. As usual we write \(\pi_1(A,x_0) = \langle t \rangle\). On page 2628 we already saw that \(\pi_2(X,A,x_0) \cong \mathbb{Z}[t^{\pm 1}]\) as \(\mathbb{Z}[\pi_1(A,x_0)] = \mathbb{Z}[t^{\pm 1}]\)-modules. Thus we have an isomorphism

\[
\pi'_2(X, A, x_0) \cong \mathbb{Z}[t^{\pm 1}]/\{ (tk - 1) \cdot f \mid f \in \mathbb{Z}[t^{\pm 1}] \text{ and } k \in \mathbb{Z} \}.
\]

It is an amusing algebra exercise to show that the group on the right-hand side is isomorphic to \(\mathbb{Z}\).

The following theorem is a generalization of the Hurewicz Theorem [53.5] to the relative case.

**Theorem 111.13. (Relative Hurewicz Theorem)** Let \((X,A,x_0)\) be a pointed pair of topological spaces such that \(X\) and \(A\) are path-connected. Let \(n \geq 2\). If the pair \((X,A)\) is \((n-1)\)-connected, then the following two statements hold:

1. We have \(H_k(X,A;\mathbb{Z}) = 0\) for \(k = 1, \ldots, n-1\).
2. The Hurewicz homomorphism

\[
\Phi_{(X,A,x_0)} : \pi_n(X, A, x_0) \rightarrow H_n(X, A; \mathbb{Z})
\]

is an isomorphism. In particular, if \(\pi_1(A, x_0) = 0\), then the Hurewicz homomorphism

\[
\Phi_{(X,A,x_0)} : \pi_n(X, A, x_0) \rightarrow H_n(X, A; \mathbb{Z})
\]

is an isomorphism.

**Proof.** We will not provide a proof of the Relative Hurewicz Theorem. A full proof is given in [Bre93, Theorem VII.10.7] or alternatively in [Hat02, Theorem 4.37] and [Spa95, Proposition 7.5.1]. If \(A\) is simply connected, then it is a great exercise to figure out to what degree the proof of the Hurewicz Theorem [53.5] can be modified to deal with the relative case.

The following theorem, which can be viewed as a corollary to the Relative Hurewicz Theorem [111.13], is a nice illustration of the usefulness of relative homotopy groups.

**Theorem 111.14.** Let \(X\) and \(Y\) be two topological spaces and furthermore let \(f : X \rightarrow Y\) be a map. We pick a base point \(x_0 \in X\) and we write \(y_0 = f(x_0)\).

1. If for every \(i \in \mathbb{N}_{\geq 2}\) the induced map

\[
f_* : \pi_i(X, x_0) \rightarrow \pi_i(Y, y_0)
\]

is an isomorphism, then for every \(i \in \mathbb{N}_{\geq 2}\) the induced map

\[
f_* : H_i(X; \mathbb{Z}) \rightarrow H_i(Y; \mathbb{Z})
\]

is also an isomorphism.
(2) If $X$ and $Y$ are simply connected, then the converse to (1) holds. More precisely, in this case, if for every $i \in \mathbb{N}_{\geq 2}$ the induced map
\[ f_* : H_i(X; Z) \xrightarrow{\cong} H_i(Y; Z) \]
is an isomorphism, then for every $i \in \mathbb{N}_{\geq 2}$ the induced map
\[ f_* : \pi_i(X, x_0) \xrightarrow{\cong} \pi_i(Y, y_0) \]
is also an isomorphism.

**Remark.** In some textbooks, see e.g. [Bre93, p. 481], [DaK01, p. 162] and [Spa95, p. 399], this theorem is referred to as the Whitehead Theorem. We will reserve the name “Whitehead Theorem” for a much more interesting later result, namely Theorem 119.9.

**Proof.** The idea is to “replace” the map $f : X \to Y$ by an inclusion map so that we can apply the commutative diagram from Lemma 111.11. The key to doing so is the notion of the mapping cylinder that we introduced on page 697. Recall that the mapping cylinder corresponding to $f$ is defined as the topological space
\[ \text{Cyl}(f) := ((X \times [0, 1]) \sqcup Y)/ \sim \text{ where } (x, 1) \sim f(x) \text{ for all } x \in X. \]

![Diagram of mapping cylinder Cyl(f)](image)

We consider the maps
\[ i : X \to \text{Cyl}(f) \quad \text{respectively} \quad r : \text{Cyl}(f) \to Y \]
\[ x \mapsto (x, 0) \quad \text{and} \quad P \mapsto \begin{cases} P, & \text{if } P \in Y, \\ f(Q), & \text{if } P = [(Q, t)] \text{ with } Q \in X, t \in [0, 1]. \end{cases} \]

Note that we have $roi = f : X \to Y$. Also note that in Lemma 24.8 (2a) we showed that the retraction $r : \text{Cyl}(f) \to Y$ is a homotopy equivalence. We use the inclusion $i : X \to \text{Cyl}(f)$ to identify $X$ with $i(X)$, i.e. we view $X$ as a subset of $\text{Cyl}(f)$.

In the following we prove Statement (2) of the theorem. Thus we assume that $X$ and $Y$ are simply connected and we assume that for every $i \in \mathbb{N}_{\geq 2}$ the induced map
\[ f_* : H_i(X; Z) \xrightarrow{\cong} H_i(Y; Z) \]
is an isomorphism. We need to show that for every $i \in \mathbb{N}_{\geq 2}$ the induced map
\[ f_* : \pi_i(X, x_0) \xrightarrow{\cong} \pi_i(Y, y_0) \]
is also an isomorphism. We consider the following maps

\[ \ldots \to \pi_3(\text{Cyl}(f), X, x_0) \xrightarrow{\partial} \pi_2(X, x_0) \xrightarrow{i_*} \pi_2(\text{Cyl}(f), x_0) \to \pi_2(\text{Cyl}(f), X, x_0) \to 0 \]

\[ \ldots \to H_3(\text{Cyl}(f), X; \mathbb{Z}) \xrightarrow{\partial} H_2(X; \mathbb{Z}) \xrightarrow{i_*} H_2(\text{Cyl}(f); \mathbb{Z}) \to H_2(\text{Cyl}(f), X; \mathbb{Z}) \to 0 \]

where the vertical maps between the second and the third row are the Hurewicz homomorphisms. The desired statement follows from the following observations:

(a) The triangles commute since \( f = r \circ i \). Furthermore the squares commute by Lemma 111.11.

(b) By our hypothesis the maps \( f_*: H_*(X; \mathbb{Z}) \to H_*(Y; \mathbb{Z}) \) are isomorphisms. Furthermore, since \( r \) is a deformation retraction we obtain from Corollary 42.8 that the maps \( r_*: H_*(\text{Cyl}(f); \mathbb{Z}) \to H_*(Y; \mathbb{Z}) \) are isomorphisms.

(c) Since \( f_* = (r \circ i)_* = r_* \circ i_* \) we obtain immediately from our result in (b) that the maps \( i_*: H_*(X; \mathbb{Z}) \to H_*(\text{Cyl}(f); \mathbb{Z}) \) are also isomorphisms.

(d) It follows from (c) and the bottom long exact sequence that all the relative homology groups \( H_*(\text{Cyl}(f), X; \mathbb{Z}) \) vanishes.

(e) It follows easily from (d), the hypothesis that \( X \) is simply connected and the Relative Hurewicz Theorem 111.13 that all the relative homotopy groups \( \pi_*(\text{Cyl}(f), X, x_0) \) vanish.

(f) Using (e) we obtain immediately from the top long exact sequence that the maps \( i_*: \pi_*(X, x_0) \to \pi_*(\text{Cyl}(f), x_0) \) are isomorphisms.

(g) By Proposition 40.7 (2) we know that the maps \( r_*: \pi_*(\text{Cyl}(f), x_0) \to \pi_*(Y, y_0) \) are isomorphisms.

(h) Finally note that it follows from \( f_* = r_* \circ i_* \) together with (f) and (g) that the maps \( f_*: \pi_*(X, x_0) \to \pi_*(Y, y_0) \) are indeed isomorphisms.

The proof of Statement (1) is very similar to the above argument. We leave it to the reader to fill in the details. ■

We conclude this section with a discussion of homotopy spheres. Recall that by the definition on page 2161 a homotopy \( n \)-sphere \( \Sigma \) is a closed \( n \)-dimensional topological manifold that is \((n - 1)\)-connected, i.e. the homotopy groups of \( \Sigma \) agree with the homotopy groups of \( S^n \) up to degree \( n - 1 \).

The following pleasant corollary shows that in fact all homotopy groups of \( \Sigma \) are isomorphic to the corresponding homotopy groups of \( S^n \).

**Corollary 111.15.** Let \( n \in \mathbb{N}_{\geq 2} \). If \( \Sigma \) is a homotopy \( n \)-sphere, then for every \( i \in \mathbb{N}_0 \) we have \( \pi_i(\Sigma) \cong \pi_i(S^n) \).
Proof. Let \( \Sigma \) be a homotopy \( n \)-sphere. Note that by Theorem 111.14 (2) it suffices to find a map \( f : S^n \to \Sigma \) such that for every \( i \in \mathbb{N}_{\geq 2} \) the induced map \( f_* : H_i(S^n; \mathbb{Z}) \to H_i(\Sigma; \mathbb{Z}) \) is an isomorphism.

So let us try to find such a map \( f \). We pick a base point \( x_0 \in \Sigma \). By the definition and Proposition ?? we know that \( \Sigma \) is a closed connected non-empty \( n \)-dimensional topological manifold with \( H_i(\Sigma; \mathbb{Z}) \cong \pi_i(\Sigma, x_0) = 0 \) for \( i = 1, \ldots, n - 1 \). It follows from the Hurewicz Theorem 53.5 that the Hurewicz homomorphism \( \Phi : \pi_n(\Sigma, x_0) \to H_n(\Sigma; \mathbb{Z}) \) is an isomorphism. Note that the fact that \( \pi_1(\Sigma, x_0) = 0 \) together with Corollary 86.16 implies that \( \Sigma \) is orientable. Therefore by Theorem 87.1 we know that \( H_n(\Sigma; \mathbb{Z}) \cong \mathbb{Z} \). Since the Hurewicz homomorphism is an isomorphism we can pick a map \( f : S^n \to \Sigma \) such that \( f_*([S^n]) \in H_n(\Sigma; \mathbb{Z}) \cong \mathbb{Z} \) is a generator.

We claim that \( f \) has the desired properties. By choice of \( f \) we know that the map \( f_* : H_n(S^n; \mathbb{Z}) \to H_n(\Sigma; \mathbb{Z}) \) is an epimorphism. But since both groups are isomorphic to \( \mathbb{Z} \) we see that the map is in fact an isomorphism. Since \( S^n \) and \( \Sigma \) are path-connected we obtain from the discussion on page 1088 that \( f_* : H_0(S^n; \mathbb{Z}) \to H_0(\Sigma; \mathbb{Z}) \) is also an isomorphism. Furthermore for all other dimensions \( f_* \) induces an isomorphism of homology groups for the rather banal reasons that all other homology groups of \( S^n \) and \( \Sigma \) are zero. (Indeed, we saw above that the homology groups in dimension less than \( n \) vanish and it follows from Theorem 87.3 that the homology groups vanish in dimension greater than \( n \).)  

111.7. Excision for relative homotopy groups? We have now seen that the (relative) homotopy groups and (relative) homology groups have some properties in common:

1. both invariants are functorial,
2. in both cases homotopic maps induce the same maps on the invariants,
3. a (pointed) pair of topological spaces gives rise to a long exact sequence.

These formal similarities between (relative) homotopy and (relative) homology groups makes one wonder whether an analogue of the Excision Theorem 43.19 holds for relative homotopy groups.

For better or worse this is not the case. More precisely, the next lemma shows that a naive analogue of the Excision Theorem 43.19 fails even in very simple situations.

Lemma 111.16. We consider the 2-dimensional sphere \( X = S^2 \) together with the subset \( A := S^2_{z \leq 0} = \{(x, y, z) \in S^2 | z \leq 0\} \) given by the lower hemisphere and together with the subset \( Z = \{(0, 0, -1)\} \) that is given by the South Pole. Then \( \pi_3(X, A) \not\cong \pi_3(X \setminus Z, A \setminus Z) \).

Proof. We start out with the following observations:

1. On page 116 we saw that \( A = S^2_{z \leq 0} \) is homeomorphic to \( B^2 \). In particular \( A \) is contractible which implies by Proposition 40.7 (2) that \( \pi_2(A) = \pi_3(A) = 0 \).

Here evidently the closure of \( Z \) is contained in the interior of \( A \), i.e. the hypotheses for the Excision Theorem 43.19 for homology groups are satisfied.
(2) The above homeomorphism also shows that \( A \setminus Z \) is homeomorphic to \( \overline{B}^2 \setminus \{(0)\} \) which is homotopy equivalent to \( S^1 \). This implies that \( \pi_2(A \setminus Z) = \pi_3(A \setminus Z) = 0 \).

(3) Finally in Lemma \ref{lem:blakers-massey-1} we saw that \( X \setminus Z = S^2 \setminus \{(0, 0, -1)\} \) is homeomorphic to \( \mathbb{R}^2 \) which implies that \( \pi_2(X \setminus Z) = \pi_3(X \setminus Z) = 0 \).

It follows from these observations and the long exact sequence of homotopy groups, provided by Proposition \ref{prop:blakers-massey-1}, that \( \pi_3(X \setminus Z, A \setminus Z) \cong \pi_2(A \setminus Z) \cong \pi_2(S^1) = 0 \) and furthermore that \( \pi_3(X, A) \cong \pi_3(S^2) \). But in Theorem \ref{thm:blakers-massey-1} we saw that \( \pi_3(S^2) \) is non-trivial. We have thus shown that \( \pi_3(X, A) \) is not isomorphic to \( \pi_3(X \setminus Z, A \setminus Z) \).

\[ \text{Remark.} \] We just used the fact that \( \pi_3(S^2) \neq 0 \) to show that relative homotopy groups do not satisfy excision. It is a good moment to remind ourselves of Theorem \ref{thm:blakers-massey-2}. The theorem suggests that if relative homotopy groups did satisfy excision, then it would follow from Proposition \ref{prop:blakers-massey-1} that, at least morally, (abelianized) homotopy groups would agree with homology groups. But the calculations \( \pi_3(S^2) \neq 0 \) and \( H_3(S^2) = 0 \) show that this is not the case.

In much more restricted circumstances there is in fact an excision theorem. For the record we state the following theorem. We will not make use of it and therefore we will not provide the proof (which by all accounts seems to be somewhat messy.)

**Theorem 111.17. (Blakers-Massey Theorem)**

1. Let \( X \) be a topological space and let \( A \) and \( B \) be subsets such that \( X = \hat{A} \cup \hat{B} \).
   If \((A, A \cap B)\) is \( n \)-connected and if \((B, A \cap B)\) is \( m \)-connected, then the inclusion induced map
   \[ \pi_k(A, A \cap B) \to \pi_k(X, B) \]
   is an isomorphism for \( k \leq m + n \) and it is an epimorphism for \( k = m + n \).

2. The conclusion of (1) also holds if \( X \) is a CW-complex and \( A \) and \( B \) are two subcomplexes of \( X \) with \( X = A \cup B \) such that \( A \cap B \) is non-empty and connected.

**Proof.** The first statement was originally proved in 1952 by Albert Blakers and William Massey \cite{blakers-massey-1}. Proofs can also be found in \cite[Corollary 16.27]{graben}, \cite[Theorem 6.4.1]{toen}, \cite[p. 211]{toen-2} or \cite[Chapter VII.7]{whitney}. The second statement can presumably be deduced from the first statement. Alternatively see \cite[Theorem 4.23]{hatcher-2}. \[ \square \]

---

\[ ^{1525} \] To turn this logic into a proper argument might be a little tricky because of base point issues.
Exercises for Chapter 111.

Exercise 111.1. Show that the three paths to the right of Figure 1543 define three different elements in $\pi_1(X, A, x_0)$.

Exercise 111.2. Let $(X, A, x_0)$ be a pointed pair of topological spaces. Show that if $n \geq 3$, then the relative homotopy group $\pi_n(X, A, x_0)$ is abelian.

Exercise 111.3. Let $X$ be a topological space and $x_0 \in X$. We consider the set $\pi_0(X, x_0)$. We all know that $\pi_0(X, x_0)$ is “not a group”. But why not? After all, every non-empty set can be equipped with a group structure (why is that?). So why is not possible to equip $\pi_0(X, x_0)$ with a group structure in a “meaningful way”? More precisely, if we could equip it with a group structure in a reasonable sense, what properties would we demand? Why can these not be satisfied?

Exercise 111.4. Let $\varphi: G \to H$ be a group homomorphism. Furthermore let $(S, s_0)$ be a pointed set which is equipped with an $H$-action. Suppose that we have an exact sequence

$$\{e\} \to G \xrightarrow{\varphi} H \xrightarrow{\psi} (S, s_0) \to \{e\}$$

where $\psi$ is a morphism of pointed sets that preserves the $H$-action. Show that $\varphi(G)$ is a subgroup of $H$ whose index equals the cardinality of the set $S$.

Exercise 111.5. Is a monomorphism of pointed sets necessarily injective?

Exercise 111.6. Provide a proof for Lemma 111.3.

Exercise 111.7. Let $(X, A, x_0)$ be a pointed pair of topological spaces and let $n \in \mathbb{N}$. By the convention of page 2630 we can view elements in $\pi_n(X, A, x_0)$ as homotopy classes of maps $(\mathcal{B}^n, S^{n-1}, *) \to (X, A, \{x_0\})$. Using this point of view, how can we visualize the action of $\pi_1(A, x_0)$ on $\pi_n(X, A, x_0)$?

Exercise 111.8. Give an example of a connected CW-complex $X$, a connected subcomplex $A \subseteq X$ and an $n \in \mathbb{N}$ such that the homotopy group $\pi_n(X/A)$ is not isomorphic to the relative homotopy group $\pi_n(X, A)$. 

112. Fibrations

In this chapter we introduce fibrations and we show that fibrations give rise to a long exact sequence of homotopy groups. In the subsequent two chapters we will give many more examples of fibrations and we will see that fibrations allow us to compute various interesting higher homotopy groups.

112.1. Definition and examples of fibrations. The following is the key definition of this chapter.

**Definition.** Let \( p: Y \to B \) be a map between topological spaces.

1. Let \( X \) be a topological space. We say that the map \( p: Y \to B \) has the homotopy lifting property with respect to \( X \) if given any map \( F: X \times [0,1] \to B \) and given any map \( \tilde{f}: X \times \{0\} \to Y \) with \( p \circ \tilde{f} = F \circ i \) there exists a map \( \tilde{F}: X \times [0,1] \to Y \) such that the following diagram commutes:

\[
\begin{array}{ccc}
X \times \{0\} & \xrightarrow{\tilde{f}} & Y \\
\downarrow i & & \downarrow p \\
X \times [0,1] & \xrightarrow{\tilde{F}} & B.
\end{array}
\]

Sometimes we refer to \( \tilde{F}: X \times [0,1] \to Y \) as a lift of \( F: X \times [0,1] \to B \). (Note that we do not demand that the lift \( \tilde{F} \) is in any way unique.) We refer to Figure 1561 for an illustration of the definition.

2. We say that the map \( p: Y \to B \) is a fibration if \( p \) has the homotopy lifting property with respect to all topological spaces.

3. We say that the map \( p: Y \to B \) is a Serre fibration if \( p \) has the homotopy lifting property with respect to all closed balls \( \overline{B}^n \), \( n \in \mathbb{N}_0 \). So perhaps somewhat confusingly a Serre fibration is not necessarily a fibration.

![Figure 1561](image)

**Remark.**

1. Different textbooks mean different objects when they talk about “fibrations”. Our definition coincides with the language used in \[Hat02, Rot88, DaK01\]. In \[Bre93\], what we call a “fibration” is called a “Hurewicz fibration”.

\[ Y = \overline{B}^3 \]

\[ B = \overline{B}^2 \]
(2) If \( p: Y \to B \) is a Serre fibration and if \( Y \) and \( B \) are CW-complexes, then it follows from [StW84, Cau92] that \( p \) is in fact a fibration. We will not make use of this result.

**Examples.**

(1) In Proposition 16.12 we already showed that every covering \( p: Y \to B \) has the homotopy lifting property (in fact with a unique lift) with respect to every topological manifold, in particular with respect to any closed ball \( \overline{B}^n \). This implies in particular that every covering is a Serre fibration.

(2) Let \( B \) and \( G \) be topological spaces. We denote by \( p: B \times G \to B \) and \( q: B \times G \to G \) the two obvious projections. In the following we show that the projection map \( p: B \times G \to B \) is a fibration. Indeed, in the setting above the map

\[
\tilde{F}: X \times [0, 1] \to B \times G \\
(x, t) \mapsto (F(x, t), q(\tilde{f}(x, 0)))
\]

makes the diagram commute. As is shown in Figure 1562, in contrast to the first example, the lift \( \tilde{F} \) is in general not unique.

\[
\begin{array}{ccc}
\{\ast\} \times \{0\} & \bullet & \tilde{f} \\
\{\ast\} \times [0, 1] & \to & F \\
\end{array}
\]

\[
B \times G \quad \text{two different lifts}
\]

\[
P \quad B = [-1, 1]
\]

**Figure 1562**

(3) For any \( n \in \mathbb{N} \) the map

\[
\overline{B}^{n+1} \to \overline{B}^n \\
(x_1, \ldots, x_n, x_{n+1}) \mapsto (x_1, \ldots, x_n)
\]

is a Serre fibration. With some effort this statement can be proved “by hand”. The case \( n = 1 \) is precisely the content of Exercise 112.1.

We conclude the list of examples with a “non-example”. To make this example more readable we package it as a lemma.

**Lemma 112.1.** The map \( p: S^1 \to [-1, 1] \) that is given by the projection onto the \( x \)-coordinate is not a Serre fibration.

**Proof.** We consider the topological space \( X = \overline{B}^1 = [-1, 1] \) together with the maps \( \tilde{f}: X \times \{0\} \to S^1 \) and \( F: [-1, 1] \times [0, 1] \to [-1, 1] \) that are illustrated in Figure 1563. We claim that there is no lifting \( \tilde{F}: X \times [0, 1] \to S^1 \). More precisely, we prove the following claim.

**Claim.** If \( \tilde{F}: X \times [0, 1] \to S^1 \) is a map with \( p \circ \tilde{F} = F \), then \( \tilde{F}|_{X \times \{0\}} \) does not agree with \( \tilde{f} \).
Thus let \( \tilde{F} : X \times [0,1] \to S^1 \) be a map with \( p \circ \tilde{F} = F \). We make the following observations:

1. The preimage \( F^{-1}(0) \) is connected by the definition of \( F \).
2. We obtain from (1) and Lemma 2.57 that the image \( \tilde{F}(F^{-1}(0)) \) is also connected.
3. The fact that \( p \circ \tilde{F} = F \) implies that \( \tilde{F}(F^{-1}(0)) \subset p^{-1}(0) \).
4. By definition of the map \( p \) we have \( p^{-1}(0) = \{(0, \pm 1)\} \).
5. It follows from (2), (3) and (4) that \( \tilde{F} \) restricted to \( F^{-1}(0) \) is constant.
6. The combination of (5) and (6) proves our claim.

The combination of (5) and (6) proves our claim.

\[
\begin{align*}
X \times \{0\} & \xrightarrow{\tilde{F}} S^1 \\
X \times [0,1] & \xrightarrow{F} 0 \\
X \times \{0\} & \xrightarrow{\text{the preimage of 0 is disconnected}} \\
\end{align*}
\]

Figure 1563

We continue with introducing some language and notation.

Notation.

1. Given a fibration or a Serre fibration \( p : Y \to B \) we sometimes refer to \( B \) as the base space and to \( Y \) as the total space.\(^{[1527]}\) Furthermore, given a point \( * \in B \) we refer to \( F := p^{-1}(*) \) as a fiber. The last definition is somewhat dangerous since, as we see in the last of the above examples, the homeomorphism type \( p^{-1}(*) \) depends on the choice of \( * \). We will shortly discuss “uniqueness” of the fiber. Finally throughout this chapter we denote by \( i : F \to Y \) the inclusion map.

2. Given \( n \in \mathbb{N}_0 \) we define \( I, I^n \) and \( J^n \) as on page \text{2616}.

Before we can formulate the main theorem of this chapter we need to make some preparations.

Lemma 112.2.

1. For each \( n \in \mathbb{N} \) there exists an orientation-preserving homeomorphism

\[
(\overline{B^n} \times [0,1], \overline{B^n} \times \{0\} \cup S^{n-1} \times [0,1]) \xrightarrow{\cong} (\overline{B^n} \times [0,1], \overline{B^n} \times \{0\})
\]

\(^{[1526]}\)Since I always find these arguments confusing let me give the argument: Let \( y \in \tilde{F}(F^{-1}(0)) \). This means that there exists a \( P \in F^{-1}(0) \) with \( y = F(P) \). We have \( p(y) = p(F(P)) = F(P) \), but \( P \in F^{-1}(0) \), thus \( p(y) = 0 \). In other words, we have \( y \in p^{-1}(0) \).

\(^{[1527]}\)This mirrors the language that we introduced on page ?? for vector bundles.
of pairs of topological spaces. (This statement is illustrated in Figure 1564 on the left.)

(2) For each \( n \in \mathbb{N} \) there exists a homeomorphism

\[
(I^n, J^{n-1}) \cong (I^n, I^{n-1} \times \{0\})
\]

of pairs of topological spaces. (This statement is illustrated in Figure 1564 on the right.)

\(\text{Figure 1564. Illustration of Lemma 112.2}\)

**Sketch of proof (\(*\)).**

(1) For \( n = 1 \) such a homeomorphism is illustrated in Figure 1565. The general case is given by “rotating this homeomorphism around the \( x_1 = 0 \)-axis in \( \mathbb{R}^n \).”

(2) Using the homeomorphism \( \overline{B}^{n-1} \cong I^{n-1} \) from Proposition 2.53 (2) one can easily reduce the proof of (2) to the statement that we had just proved in (1).

\(\blacksquare\)

We will also soon need the following elementary lemma.

**Lemma 112.3.** Let \( p: Y \to B \) be a Serre fibration. Let \( y_0 \in Y \). We write \( b_0 = p(y_0) \). Furthermore let \( n \in \mathbb{N} \). Given any map \( \varphi: (I^n, \partial I^n) \to (B, \{b_0\}) \) there exists a map \( \widetilde{\varphi}: (I^n, J^{n-1}) \to (Y, \{y_0\}) \) such that the following diagram commutes:

\[
\begin{array}{ccc}
Y & \rightarrow & Y \\
\downarrow_{\widetilde{\varphi}} \nearrow_{\partial I^n} & & \searrow_{p} \\
I^n & \rightarrow & B.
\end{array}
\]

We refer to Figure 1566 for an illustration.
**Figure 1566. Illustration of Lemma 112.3**

**Proof.** Let \( \Psi: (I^n, J^{n-1}) \to (I^n, I^{n-1} \times \{0\}) \) be a homeomorphism as in Lemma 112.2. We consider the diagram

\[
\begin{array}{c}
\begin{array}{c}
I^{n-1} \times \{0\} \\
\downarrow \\
I^{n-1} \times [0, 1]
\end{array}
\end{array}
\xrightarrow{\Psi^{-1}}
\begin{array}{c}
J^{n-1} \\
\downarrow \\
I^n
\end{array}
\xrightarrow{G}
\begin{array}{c}
Y \\
\downarrow \\
B
\end{array}
\]

Note that the diagram without the red dashed arrow commutes. Since \( p \) is a Serre fibration and since \( I^{n-1} \) is homeomorphic to the \((n-1)\)-ball, see Proposition 2.52 (2), it follows that a map \( G: I^{n-1} \times I \to Y \) exists that makes the diagram commute. It is now straightforward to verify that \( G \circ \Psi: I^n \to B \) has the desired properties. \(\square\)

**112.2. The homotopy fiber of a fibration.** First we introduce the following, arguably long overdue notation.

**Notation.** Given two topological spaces \( X \) and \( Y \) we define \([X, Y]\) to be the set of homotopy equivalence classes of maps from \( X \) to \( Y \).\(^{1528}\)

The following lemma is a reformulation of Lemma 18.6.

**Lemma 112.4.** Let \( X, Y \) and \( Z \) be topological spaces. The map

\[
[Y, Z] \times [X, Y] \mapsto [X, Z]
\]

\( (\,[g], \,[f]\, ) \mapsto [g \circ f]\)

is well-defined.

Now we can formulate the key technical proposition of this section.

**Proposition 112.5.** Let \( p: Y \to B \) be a fibration. Given \( b \in B \) we write \( F_b := p^{-1}(b) \). Let \( \alpha: [0, 1] \to B \) be a path from a point \( b_0 \) to a point \( b_1 \). We consider the following diagram

\[
\begin{array}{c}
\begin{array}{c}
F_{b_0} \times \{0\} \\
\downarrow
\end{array}
\end{array}
\xrightarrow{(x,0)\to x}
\begin{array}{c}
Y \\
\downarrow \\
B
\end{array}
\]

\( F_{b_0} \times [0, 1] \xrightarrow{(x,t)\to\alpha(t)} B. \)

\(^{1528}\)Recall that in Lemma 18.4 we saw that “being homotopic” is an equivalence relation.
Since \( p: Y \to B \) is a fibration there exists a diagonal map \( H(\alpha): F_{b_0} \times [0, 1] \to Y \).

(We refer to Figure 1567 for an illustration.) We define \( \Theta(\alpha) := H(\alpha)_1 \). The following statements hold:

1. The map \( \Theta(\alpha) \) goes from \( F_{b_0} \) to \( F_{b_1} \).
2. The map \( \Theta(\alpha) \), viewed as an element in \([F_{b_0}, F_{b_1}]\), is well-defined.
3. The map \( \Theta(\alpha): F_{b_0} \to F_{b_1} \) is a homotopy equivalence.
4. If two paths \( \alpha, \beta: [0, 1] \to B \) from \( b_0 \) to \( b_1 \) are path-homotopic, then \([\Theta(\alpha)] = [\Theta(\beta)]\).
5. If \( c_0 \) is the constant path at \( b \in B \), then \([\Theta(c_0)] = [\text{id}_{F_b}] \in [F_b, F_b] \).
6. If \( \alpha \) is a path in \( B \) from \( b_0 \) to \( b_1 \) and \( \beta \) is a bath in \( B \) from \( b_1 \) to \( b_2 \), then

\[
[\Theta(\alpha \ast \beta)] = [\Theta(\beta)] \circ [\Theta(\alpha)].
\]

Remark. The picture behind the statement of Proposition 112.5 is that while walking along \( B \) we can drag the fiber along. Thus any path defines a map between the corresponding fibers.

Proof (*). Let \( p: Y \to B \) be a fibration over a topological space \( B \). Given \( b \in B \) we write \( F_b := p^{-1}(b) \). Let \( \alpha: [0, 1] \to B \) be a path from a point \( b_0 \) to a point \( b_1 \). We consider the following diagram

\[
\begin{array}{ccc}
F_{b_0} \times \{0\} & \xymatrix{ \ar[r]^-{(p,0)\to p} & Y } & F_{b_0} \\
\downarrow^-i & & \downarrow^-p \\
F_{b_0} \times [0, 1] & \xymatrix{ \ar[r]^-{(x,t)\to\alpha(t)} & B } & Y
\end{array}
\]

Since \( p: Y \to B \) is by hypothesis a fibration there exists in fact such a diagonal map \( H(\alpha): F_{b_0} \times [0, 1] \to Y \). Note that the map \( H(\alpha)_0: F_{b_0} \to B \) is just the obvious inclusion. We turn to the proofs of the statements, albeit perhaps in an unexpected order:

1. Since the above diagram commutes we see immediately that the map \( H(\alpha)_1 \) is a map from \( F_{b_0} \to F_{b_1} \).

\footnote{Recall that in general \( H(\alpha) \) is not uniquely determined by the data, i.e. there might be many such maps.}
(4) Let $\alpha, \beta : [0, 1] \to B$ be two paths from $b_0$ to $b_1$. We pick maps $H(\alpha)$ and $H(\beta)$ as above, keeping in mind that $H(\alpha)$ and $H(\beta)$ are not uniquely determined. Now we assume that $\alpha$ and $\beta$ are path-homotopic. We need to show the following claim.

**Claim.** The maps $H(\alpha)_1, H(\beta)_1 : F_{b_0} \to F_{b_1}$ are homotopic.

We start out the proof of the claim with the following observation. It follows immediately from Lemma 12.2 (2), applied to $n = 2$, that there exists a self-homeomorphism

$$\Psi : [0, 1] \times [0, 1] \to [0, 1] \times [0, 1]$$

that restricts to a homeomorphism

$$([0, 1] \times \{0, 1\}) \cup (\{0\} \times [0, 1]) \to [0, 1] \times \{0\}.$$

For reassurance the construction of such a map is also sketched in Figure 1568. Now we pick a homotopy $G : [0, 1] \times [0, 1] \to B$ rel $\{0, 1\}$ from $\alpha$ to $\beta$. We consider the following diagram

\[
\begin{array}{ccc}
F_{b_0} \times [0, 1] \times \{0\} & \xrightarrow{id_{F_{b_0}} \times \Psi^{-1}} & (F_{b_0} \times [0, 1] \times \{0\}) \cup (F_{b_0} \times \{0\}) \times [0, 1] \\
\downarrow & & \downarrow \\
F_{b_0} \times [0, 1] \times [0, 1] & \xrightarrow{id_{F_{b_0}} \times \Psi} & F_{b_0} \times [0, 1] \times [0, 1] \\
\downarrow & & \downarrow \\
\Xi & \xrightarrow{\Xi \circ (id_{F_{b_0}} \times \Psi)} & Y \\
\end{array}
\]

We make the following clarifications and observations:

(a) The map $\Omega$ is defined as follows:

(i) on $F_{b_0} \times [0, 1] \times \{0\} = F_{b_0} \times [0, 1]$ the map $\Omega$ is given by $H(\alpha)$,

(ii) on $F_{b_0} \times [0, 1] \times \{1\} = F_{b_0} \times [0, 1]$ the map $\Omega$ is given by $H(\beta)$,

(iii) on $F_{b_0} \times \{0\} \times [0, 1]$ the map $\Omega$ is given by the projection onto $F_{b_0}$ followed by the inclusion into $Y$.

(b) It follows immediately from the definitions that the diagram commutes.

(c) Since $p : Y \to B$ is a fibration we see that there exists a map $\Xi$ that makes the outer diagram commute.

\[\text{As on so many other occasions we can use Lemma 2.35 (2) to show that the map } \Omega \text{ is indeed continuous.}\]
(d) The map \( \Xi \circ (\id_{F_{b_0}} \times \Psi) : F_{b_0} \times [0, 1] \times [0, 1] \to Y \) is a homotopy between \( H(\alpha) \) and \( H(\beta) \). In particular the map \( (\Xi \circ (\id_{F_{b_0}} \times \Psi))_1 : F_{b_0} \times [0, 1] \to Y \) is the desired homotopy between \( H(\alpha)_1 \) and \( H(\beta)_1 \). \( \square \)

(5) This statement follows from the observation that for the constant path \( c_b \) at a point \( b \in B \) we can choose \( H(c_b) : F_0 \times [0, 1] \to F_b \) to be the projection. Evidently we obtain that \( \Theta(c_b) = H(c_b)_1 = \id_{F_b} \).

(6) Let \( \alpha \) be a path in \( B \) from \( b_0 \) to \( b_1 \) and let \( \beta \) be a path in \( B \) from \( b_1 \) to \( b_2 \). Almost the same way that we define the product \( \alpha \ast \beta \) we combine \( H(\alpha) \) and \( H(\beta) \). More precisely, we consider the map\footnote{It follows again from Lemma \ref{sec:prop} that this map is continuous.}

\[
H(\alpha \ast \beta) : F_{b_0} \times [0, 1] \to X
\]

\[
(P, t) \mapsto \begin{cases} 
H(\alpha)(P, 2t), & \text{if } t \in [0, \frac{1}{2}], \\
H(\beta)(\alpha(P), 2t - 1), & \text{if } t \in [\frac{1}{2}, 1].
\end{cases}
\]

One can easily verify that this map has all the properties that we expect from a map that is called \( H(\alpha \ast \beta) \). The desired statement is now an immediate consequence of the observation that \( H(\alpha \ast \beta)_1 = H(\beta)_1 \circ H(\alpha)_1 \).

(3) Let \( \alpha : [0, 1] \to B \) be a path from \( b_0 \) to \( b_1 \). We pick a map \( H(\alpha) : F_{b_0} \times [0, 1] \to X \) as above. We want to show that the corresponding map \( H(\alpha)_1 : F_{b_0} \to F_{b_1} \) is a homotopy equivalence. We denote by \( \overline{\alpha} : [0, 1] \to B \) the inverse path of \( \alpha \), i.e. the path from \( b_1 \) to \( b_0 \) that is given by \( \overline{\alpha}(t) = \alpha(1 - t) \). We pick a map \( H(\overline{\alpha}) : F_{b_1} \times [0, 1] \to X \) as above. It remains to prove the following claim.

Claim.

(a) The map \( H(\overline{\alpha})_1 \circ H(\alpha)_1 : F_{b_0} \to F_{b_1} \) is homotopic to the identity of \( F_{b_0} \).

(b) The map \( H(\alpha)_1 \circ H(\overline{\alpha})_1 : F_{b_1} \to F_{b_0} \) is homotopic to the identity of \( F_{b_1} \).

We prove the first statement. The proof of the second statement is verbatim the same. We have

\[
[H(\overline{\alpha})_1 \circ H(\alpha)_1] = [H(\alpha \ast \overline{\alpha})] = [H(c_{b_0})] = [\id_{F_{b_0}}].
\]

by (6) \( \uparrow \)

by (4) \( \uparrow \)

by \ref{sec:prop} \( \uparrow \)

by (5). \( \square \)

(2) We apply the argument from (4) to \( \beta = \alpha \) together with two maps \( H(\alpha) \) and \( H(\beta) \) that make the diagram commute. We obtain by (3) that \( H(\alpha) \) and \( H(\beta) \) are homotopic, i.e. we see that \( [H(\alpha)] \in [F_{b_0}, F_{b_1}] \) is well-defined.

Using Proposition \ref{sec:prop} and the proof thereof, we almost immediately obtain the following proposition.

**Proposition 112.6.** Let \( p : Y \to B \) be a map between topological spaces. We assume that \( B \) is path-connected.

(1) If \( p : Y \to B \) is a fibration, then for any two points \( b_0, b_1 \in B \) the fibers \( p^{-1}(b_0) \) and \( p^{-1}(b_1) \) are homotopy equivalent.
Remark. A more precise statement of Proposition $112.6(1)$ holds: any path $\gamma: [0, 1] \to B$ from $b_0$ to $b_1$ defines naturally a homotopy equivalence between the fibers $p^{-1}(b_0)$ and $p^{-1}(b_1)$. We refer to [DaK01, Theorem 6.12] for the precise formulation and proof of this statement.

Proof.

(1) This statement follows immediately from Proposition $112.5(3)$ and the hypothesis that $B$ is path-connected.

(2) Let $p: Y \to B$ be a Serre fibration with $B$ a path-connected topological space. Let $b_0, b_1 \in B$ such that the fibers $F_{b_0} := p^{-1}(b_0)$ and $F_{b_1} := p^{-1}(b_1)$ are discrete subsets. In the proof of Proposition $112.5(3)$ we used the homotopy lifting property for the topological spaces $X = F_{b_i} \times [0, 1]^n$ with $i \in \{0, 1\}$ and $n \in \{1, 2\}$. Since $F_{b_0}$ and $F_{b_1}$ are discrete we see that each component of $X = F_{b_i} \times [0, 1]^n$ is homeomorphic to $[0, 1]^n$, i.e. each component is homeomorphic to $B^n$. Since we can do the lifting component-wise it suffices in our context that we are given a Serre fibration. We leave it to the reader to fill in the details.

Proposition $112.6(1)$ allows us to make the following definition.

**Definition.** Let $p: Y \to B$ be a fibration over a path-connected topological space $B$. We refer to the homotopy type of the fibers as the *homotopy fiber* of the fibration.

Remark. A more precise statement of Proposition $112.6(1)$ holds: any path $\gamma: [0, 1] \to B$ from $b_0$ to $b_1$ defines naturally a homotopy equivalence between the fibers $p^{-1}(b_0)$ and $p^{-1}(b_1)$. We refer to [DaK01, Theorem 6.12] for the precise formulation and proof of this statement.

Examples.

(1) Let $p: \tilde{X} \to X$ be a covering map over a path-connected topological space. As discussed on page 2643 such a map is a Serre fibration. It follows immediately from the definition of a covering map that for each $x \in X$ the fiber $p^{-1}(x)$ is a discrete subset of $\tilde{X}$. Therefore it follows from Lemma 18.13 and Proposition $112.6(2)$ that given any two points $x_0, x_1 \in X$ there exists a bijection $p^{-1}(x_0) \to p^{-1}(x_1)$. In other words, we have found a new proof for Lemma 16.1.

(2) Let us consider again the “non-example” from Lemma 112.1, i.e. we consider the map

$$p: Y = S^1 = \{(x, y) \in \mathbb{R}^2 \mid x^2 + y^2 = 1 \} \to B = [-1, 1]$$

$$(x, y) \mapsto x.$$ 

In this case $p^{-1}(-1) = \{(−1, 0)\}$ and $p^{-1}(0) = \{(0, ±1)\}$ are discrete subsets, but the number of components is different. From Lemma 18.13 we deduce that $p^{-1}(-1)$ is not homotopy equivalent to $p^{-1}(0)$. Thus Proposition $112.6(2)$ gives a new proof (after the more hands-on proof provided by Lemma 112.1) that $p$ is not a Serre fibration.

(3) We consider the map $p: Y \to B$ given by the total space

$$Y := \{(x, y) \mid y = 1 - x \text{ and } x \in [0, 1]\} \cup \bigcup_{n \in \mathbb{N}} \{(x, y) \mid x \in [0, 1] \text{ and } y = 1 + \frac{1}{n}\}$$
the base space $B = [0, 1]$ and the obvious projection $p: Y \to X$. (This example is illustrated in Figure 1569.) It is an amusing exercise to show that $p: Y \to B$ is a Serre fibration. We saw in Exercise 18.16 that the fibers $p^{-1}(0)$ and $p^{-1}(1)$ are not homotopy equivalent. It follows from Proposition 112.6 (1) that $p: Y \to B$ is not a fibration.

We can also show more directly that $p$ is not a fibration: We consider $X = p^{-1}(1)$, the usual projection map $f: X \times [0, 1] \to B = [0, 1]$ together with the obvious inclusion $\tilde{f}: X \times \{0\} \to Y$. It is once again an amusing elementary exercise to show that there is no map $\tilde{F}: X \times [0, 1] \to B$ with all the desired properties. This shows that $p: Y \to B$ is not a fibration.

![Figure 1569](image-url)

**112.3. The long exact homotopy sequence of a Serre fibration.** For us the most interesting aspect of Serre fibrations is that they give rise to long exact sequences of homotopy groups. More precisely, we have the following theorem.

**Theorem 112.7.** Let $p: Y \to B$ be a Serre fibration. Let $y_0 \in Y$. We write $b_0 = p(y_0)$ and $F = p^{-1}(b_0)$.

1. Given any $n \in \mathbb{N}$ the following map is well-defined:

$$
\partial_n: \pi_n(B, b_0) \to \pi_{n-1}(F, y_0)
$$

$$
[\varphi: (I^n, \partial I^n) \to (B, b_0)] \mapsto \begin{cases}
\text{pick a map } \tilde{\varphi}: (I^n, J^{n-1}) \to (Y, \{y_0\}) \text{ with } p \circ \tilde{\varphi} = \varphi \\
(\text{we know from Lemma 112.3 that such a map exists})
\end{cases}
$$

and then restrict the map $\varphi$ to $I^{n-1} = I^{n-1} \times \{0\}$.

(The definition of $\partial_n$ is moderately successfully illustrated in Figure 1570.) Furthermore, these maps $\partial_n$ have the following properties:

(a) The maps are morphisms of groups (if $n \geq 2$) and of pointed sets (if $n = 1$).

---

The discussion of this example would be more intelligible if we followed the convention of [Bre93], p. 450] and if we referred to “fibrations” as “Hurewicz fibrations” to better distinguish them from “Serre fibrations”.
(b) The maps are natural in the following two senses: Suppose we are given another Serre fibration $p': Y' \to B'$ and suppose we are given a commutative diagram

$$
\begin{array}{ccc}
Y & \xrightarrow{p} & B \\
\Phi & \downarrow & \phi \\
Y' & \xrightarrow{p'} & B'.
\end{array}
$$

If we write $y'_0 = \Phi(y_0), b'_0 = \phi(b_0)$ and $F' = (p')^{-1}(b'_0)$, then for any $n \in \mathbb{N}$ the following diagram commutes

$$
\begin{array}{ccc}
\pi_n(B, b_0) & \xrightarrow{\partial_n} & \pi_{n-1}(F, y_0) \\
\phi_* & \downarrow & (\Phi|_F)_* \\
\pi_n(B', b'_0) & \xrightarrow{\partial_n} & \pi_{n-1}(F', y'_0).
\end{array}
$$

(c) Let $\alpha : [0, 1] \to B$ be a path from $b_0$ to some point $b_1$. We write $F_1 = p^{-1}(b_1)$. If $\Theta(\alpha) : F \to F_1$ is a map as in Proposition 112.5, then the following diagram commutes

$$
\begin{array}{ccc}
\pi_n(B, b_0) & \xrightarrow{\partial_n} & \pi_{n-1}(F, y_0) \\
\alpha_* & \downarrow & \Theta(\alpha)_* \\
\pi_n(B, b_1) & \xrightarrow{\partial_n} & \pi_{n-1}(F_1, y_1)
\end{array}
$$

where $y_1 = \Theta(\alpha)(y_0)$.

(2) The following sequence is exact.

$$
\begin{array}{ccccccccc}
& & \cdots & \xrightarrow{\partial_{n+1}} & \pi_n(F, y_0) & \xrightarrow{i_*} & \pi_n(Y, y_0) & \xrightarrow{p_*} & \pi_n(B, b_0) & \xrightarrow{\partial_n} \\
& & \downarrow & & \partial_n & & \downarrow & & \partial_n & \\
& & \pi_{n-1}(F, y_0) & \xrightarrow{i_*} & \pi_{n-1}(Y, y_0) & \xrightarrow{p_*} & \pi_{n-1}(B, b_0) & \xrightarrow{\partial_1} \\
& & \downarrow & & \partial_1 & & \downarrow & & \partial_1 \\
& & \pi_0(F, y_0) & \xrightarrow{i_*} & \pi_0(Y, y_0) & \xrightarrow{p_*} & \pi_0(B, b_0).
\end{array}
$$

(3) If the inclusion map $i : F \to Y$ is actually homotopic rel $y_0$ to the constant map $c_{y_0} : F \to \{y_0\}$, then for any $n \in \mathbb{N}_{\geq 2}$ the above long exact sequence breaks into a short exact sequence

$$
0 \to \pi_n(Y, y_0) \xrightarrow{p_*} \pi_n(B, b_0) \xrightarrow{\partial_n} \pi_{n-1}(F, y_0) \to 0.
$$

Furthermore the short exact sequence splits, which implies that for any $n \in \mathbb{N}_{\geq 2}$ we have an isomorphism

$$
\pi_n(B, b_0) \cong \pi_n(Y, y_0) \oplus \pi_{n-1}(F, y_0).
$$

Before we head towards the proof of Theorem 112.7 we want to see what the theorem tells us in two types of fibrations that we had considered above, namely for coverings and products.

---

\textsuperscript{1533} Here we allow of course that $b_1 = b_0$.

\textsuperscript{1534} Here, at the lower end, we mean “exact” in the sense of the definition on page 2620.
Example. Let \( p: Y \to B \) be a covering of path-connected topological spaces. As mentioned above, by Proposition \([16.12]\) we know that \( p \) is a Serre fibration. We pick \( y_0 \in Y \) and we write \( b_0 = p(y_0) \) and \( F = p^{-1}(b_0) \). It follows immediately from the definition of a covering map that \( F \), equipped with the subspace topology coming from \( Y \), is a discrete topological space, in particular \( \# \pi_0(F, y_0) = \# F \) and \( \pi_i(F, y_0) = 0 \) for \( i \geq 1 \). From the long exact sequence provided by Theorem \([112.7]\) we obtain the following two pieces of information:

(1) At the lower end the long exact sequence looks as follows:
\[
\pi_1(F, y_0) \to \pi_1(Y, y_0) \xrightarrow{\partial_1} \pi_0(F, y_0) \to \pi_0(Y, y_0) \to \pi_0(B, b_0).
\]

In other words we obtain the short exact sequence
\[
\{e\} \to \pi_1(Y, y_0) \xrightarrow{p_*} \pi_1(B, b_0) \xrightarrow{\partial} \pi_0(F, y_0) \to \{e\}.
\]

We draw the following two conclusions:

(a) The map \( p_*: \pi_1(Y, y_0) \to \pi_1(B, b_0) \) is a monomorphism.

(b) With a little bit of extra thought \([1535]\) we obtain from the short exact sequence, Proposition \([112.5]\), Theorem \([112.7]\) (1c) and Lemma \([111.3]\) that \( p_*(\pi_1(Y, y_0)) \) is a subgroup of \( \pi_1(B, b_0) \) of index \( \# \pi_0(F, y_0) = \# F = [Y : B] \).

These two statements are precisely the content of Lemma \([15.9]\) and Lemma \([16.15]\) (3).

(2) Since all other homotopy groups of \( F \) vanish we see that for any \( n \geq 2 \) the map \( p_*: \pi_n(Y, y_0) \to \pi_n(B, b_0) \) is an isomorphism. This result recovers Proposition \([40.13]\).

We move on to the next application. More precisely we want to apply Theorem \([112.7]\) to the case of a Serre fibration of the form \( X \times Y \to X \). This leads to a new proof of Propositions \([16.20]\) and \([40.8]\).

\[\text{Figure 1570}\]
Let $X$ and $Y$ be two topological spaces and let $x_0 \in X$ and $y_0 \in Y$. We consider the maps
\[ i: X \to X \times Y \quad \text{and} \quad j: Y \to X \times Y \]
\[ x \mapsto (x, y_0) \quad \text{and} \quad y \mapsto (x_0, y). \]
For any $n \in \mathbb{N}$ the map\[ \Phi: \pi_n(X, x_0) \times \pi_n(Y, y_0) \to \pi_n(X \times Y, (x_0, y_0)) \]
\[ (\varphi, \psi) \to i_*(\varphi) \cdot j_*(\psi) \]
is an isomorphism.

\textbf{Proof.} We denote by $p: X \times Y \to X$ and $q: X \times Y \to Y$ the two obvious projections. On page 2643 we saw that both projections are fibrations. We concentrate on the first projection map $p: X \times Y \to X$. It is a fibration with fiber $p^{-1}(x_0) = \{x_0\} \times Y$. Using the obvious homeomorphism $Y \to \{x_0\} \times Y$ we obtain from Theorem 112.7 the long exact sequence
\[ \ldots \to \pi_n(Y, y_0) \xrightarrow{j_*} \pi_n(X \times Y, (x_0, y_0)) \xrightarrow{p_*} \pi_n(X, x_0) \to \pi_{n-1}(Y, y_0) \xrightarrow{i_*} \ldots. \]
Evidently we have $q \circ j = \text{id}_Y$ which implies that $q_* \circ j_* = \text{id}_{\pi_1(Y, y_0)}$. It follows that for every $n \in \mathbb{N}_0$ the map $j_*: \pi_n(F, (x_0, y_0)) \to \pi_n(X \times Y, (x_0, y_0))$ is a monomorphism. Thus for each $n \in \mathbb{N}$ we see that
\[ 0 \to \pi_n(Y, y_0) \xrightarrow{j_*} \pi_n(X \times Y, (x_0, y_0)) \xrightarrow{p_*} \pi_n(X, x_0) \to 0 \]
is exact. Once again using that $q_* \circ j_* = \text{id}$ we obtain from Splitting Lemma 46.2 that the given map
\[ \Phi: \pi_n(X, x_0) \times \pi_n(Y, y_0) \to \pi_n(X \times Y, (x_0, y_0)) \]
\[ (\varphi, \psi) \to i_*(\varphi) \cdot j_*(\psi) \]
is indeed an isomorphism. ■

Even these modest applications should already convince the reader that it is worth proving Theorem 112.7. After the proof we will give many more examples of fibrations and we will find many more interesting applications.

11.2.4. **Proof of Theorem 112.7.** The proof of Theorem 112.7 requires some preparations, i.e. we first need to prove some propositions.

\textbf{Proposition 112.8.} Let $p: Y \to B$ be a Serre fibration and let $(K, L)$ be a pair of CW-complexes. We denote by $i: K \times \{0\} \cup L \times [0, 1] \to K \times [0, 1]$ the inclusion map. Given any map $F: K \times [0, 1] \to B$ and given any map $\tilde{f}: K \times \{0\} \cup L \times [0, 1] \to Y$ with $p \circ \tilde{f} = F \circ i$
there exists a map \( \tilde{F}: K \times [0, 1] \to Y \) such that the following diagram commutes:

\[
\begin{array}{ccc}
K \times \{0\} \cup L \times [0, 1] & \xrightarrow{\tilde{f}} & Y \\
\downarrow i & & \downarrow \phi \\
K \times [0, 1] & \xrightarrow{\phi} & B.
\end{array}
\]

Figure 1571. Illustration of Proposition 112.8.

**Proof.** We start out with a reformulation of our task: Given \( n = 0, 1, 2, 3, \ldots \) we need to define maps

\[
\tilde{F}^n: (K \times \{0\}) \cup (K^n \cup L) \times [0, 1] \to Y
\]

that make the above diagram commute and which have the property that for \( n < m \) the maps \( \tilde{F}^n \) and \( \tilde{F}^m \) agree on the common domain.

We set \( \tilde{F}^{-1} = \tilde{f} \). Suppose we have already defined maps \( \tilde{F}^{-1}, \ldots, \tilde{F}^{n-1} \) as above. Let \( \{\Phi_i: (\overline{B}^n, S^{n-1}) \to (K^n, L^{n-1})\}_{i \in I} \) be the characteristic maps of the \( n \)-cells of \( K \) that do not lie in \( L \). Recall that by Lemma 112.2 (1) there exists a homeomorphism

\[
\Psi: (\overline{B}^n \times [0, 1], (\overline{B}^n \times \{0\}) \cup (S^{n-1} \times [0, 1])) \cong (\overline{B}^n \times [0, 1], \overline{B}^n \times \{0\}).
\]

For each \( i \in I \) we consider the following diagram

\[
\begin{array}{cccc}
\overline{B}^n \times \{0\} & \xrightarrow{\Psi^{-1}} & \overline{B}^n \times \{0\} \cup S^{n-1} \times \{1\} & \xrightarrow{\tilde{F}^{n-1} \circ \Phi_i} & Y \\
\downarrow \Psi^{-1} & & \downarrow \xi_i & & \downarrow p \\
\overline{B}^n \times [0, 1] & \xrightarrow{\Psi^{-1}} & \overline{B}^n \times [0, 1] & \xrightarrow{F \circ \Phi_i} & B.
\end{array}
\]

One can easily verify that the two rectangles commute. Since \( p: Y \to B \) is a Serre fibration there exists a map \( \Xi_i: \overline{B}^n \times [0, 1] \to Y \) that makes the diagram commute. These maps \( \{\Xi_i\}_{i \in I} \) can now be used to extend \( \tilde{F}^{n-1} \) to the desired map \( \tilde{F}^n \).

**Proposition 112.9.** Let \( p: Y \to B \) be a Serre fibration and let \( (K, L) \) be a pair of CW-complexes such that \( L \) is a deformation retract of \( K \). We denote by \( i: L \to K \) the inclusion map. Given any map \( f: K \to B \) and given any map \( g: L \to Y \) with \( f \circ i = p \circ g: L \to B \)
there exists a map \( \tilde{f}: K \to Y \) such that the following diagram commutes:

\[
\begin{array}{ccc}
K & \xrightarrow{i} & L \\
\downarrow{f} & & \downarrow{g} \\
B & \xrightarrow{p} & Y
\end{array}
\]

Example. Later on we will apply Proposition 112.9 to the special case that \( K = \mathbb{B}^n \) and that \( L = \{(0, \ldots, 0, 1)\} \). We refer to Figure 1572 for an illustration.

![Diagram](image)

Figure 1572

Proof. We make the following preparations:

1. Since \( L \) is a deformation retract of \( K \) there exists by definition of a deformation retraction, see page 548, a homotopy \( H: K \times [0, 1] \to K \) rel \( L \) such that \( H_0 = \text{id}_K \) and \( H_1(K) \subset L \). We denote by \( r = H_1: K \to L \) the corresponding retraction.

2. We denote by \( \text{proj}: L \times [0, 1] \to L \) the obvious projection.

Now we consider the following commutative diagram

\[
\begin{array}{ccc}
L \times \{0\} & \xleftarrow{} & K \times \{1\} \cup L \times [0, 1] \\
\downarrow & & \downarrow \phi \cup \text{proj} \\
K \times \{0\} & \xrightarrow{} & K \times [0, 1]
\end{array}
\]

To be somewhat more precise, the map \( r \cup \text{proj}: K \times \{1\} \cup L \times [0, 1] \) is defined via the retraction \( r \) on \( K = K \times \{1\} \) and the projection \( L \times [0, 1] \to L \). The right-hand square commutes by our hypothesis. One easily verifies that the middle square commutes. It follows from Proposition 112.8 that there exists a map \( \Phi: K \times [0, 1] \to Y \) that makes the diagram commute. For any \( k \in K \) we have

\[ (p \circ \Phi)(k, 0) = f(H(k, 0)) = f(H_0(k)) = f(k) \]

and for any \( l \in L \) we have

\[ \Phi(l, 0) = (g \circ \text{proj})(l, 0) = g(\text{proj}(l, 0)) = g(l). \]

This shows that the restriction of \( \Phi \) to \( K = K \times \{0\} \) has the desired properties. \( \blacksquare \)
**Proposition 112.10.** Let \( p: Y \to B \) be a Serre fibration. Let \( y_0 \in Y \). We write \( b_0 = p(y_0) \). Let \( B' \subset B \) be any subset with \( b_0 \in B' \). We set \( Y' := p^{-1}(B') \). Then

\[
p_*: \pi_n(Y, Y', y_0) \to \pi_n(B, B', b_0)
\]
is an isomorphism for all \( n \in \mathbb{N} \). (We refer to Figure 1573 for an illustration.)

![Illustration of Proposition 112.10](image1)

In the proof of Proposition 112.10 we will need the following elementary lemma.

**Lemma 112.11.** Let \( n \in \mathbb{N} \). If \( x \in S^{n-1} \), then \((\overline{B}^n \times \partial[0, 1]) \cup (\{x\} \times [0, 1])\) is a deformation retract of \( \overline{B}^n \times [0, 1] \).

![Illustration of Lemma 112.11](image2)

**Proof of Lemma 112.11.** As usual we write \( I = [0, 1] \). Given \( k \in \{1, \ldots, n\} \) we consider

\[
X_k := (I^{n-1} \times \partial I) \cup \left( \{1, 1, \ldots, 1\} \times I^k \right).
\]

(We refer to Figure 1575 for an illustration.) Using Proposition 2.52 (2) and Lemma 3.32 (3) one can show easily that there exists a homeomorphism

\[
(\overline{B}^n \times [0, 1], (\overline{B}^n \times \{0, 1\}) \cup (\{x\} \times [0, 1])) \xrightarrow{\sim} (X_n, X_1).
\]

Thus it suffices to show that each \( X_i \) is a deformation retract of \( X_{i+1} \). But such deformation retractions one can actually write down by hand.

Now we can provide the proof of Proposition 112.10.

**Proof of Proposition 112.10.** Let \( p: Y \to B \) be a Serre fibration and let \( n \in \mathbb{N} \). Furthermore let \( y_0 \in Y \). We write \( b_0 = p(y_0) \). Finally let \( B' \subset B \) be any subset with \( b_0 \in B' \). We set \( Y' := p^{-1}(B') \). Throughout this proof we use the identification from page 1575, i.e. we view elements in a relative homotopy group \( \pi_n(X, A, x_0) \) as homotopy classes of maps \((\overline{B}^n, S^{n-1}, \ast) \to (X, A, x_0)\).
First we show that $p_* : \pi_n(Y, Y', y_0) \to \pi_n(B, B', b_0)$ is an epimorphism. Thus suppose we are given a map $f : (B^\alpha, S^{n-1}, *) \to (B, B', b_0)$. It follows from Proposition 112.9 applied to $(K, L) = (B^\beta, *)$, that there exists a map $g : B^\alpha \to Y$ such that the following diagram commutes:

$$
\begin{array}{ccc}
{\ast} & \to & Y \\
\downarrow & & \downarrow p \\
B^\alpha & \overset{g}{\dashrightarrow} & B.
\end{array}
$$

Basically by definition $g$ is a map $(B^\alpha, S^{n-1}, *) \to (Y, Y', y_0)$. Since $f = p \circ g$ we have $[f] = p_*([g])$.

Next we show that $p_* : \pi_n(Y, Y', y_0) \to \pi_n(B, B', b_0)$ is also a monomorphism. Therefore suppose that we are given two maps $g_0, g_1 : (B^\alpha, S^{n-1}, *) \to (Y, Y', y_0)$ such that the equality $p_*([g_0]) = p_*([g_1]) \in \pi_n(B, B', b_0)$ holds. This equality means that $p \circ g_0$ is homotopic to $p \circ g_1$ via a homotopy $F : (B^\alpha, S^{n-1}, *) \times [0, 1] \to (B, B', b_0)$. We consider the following commutative diagram (first without the dashed arrow):

$$
\begin{array}{ccc}
(\overline{B}^\alpha \times \{0, 1\}) \cup (\{\ast\} \times [0, 1]) & \overset{\text{via } g_0, g_1}{\to} & Y \\
\downarrow & & \downarrow p \\
\overline{B}^\alpha \times [0, 1] & \overset{F}{\dashrightarrow} & B.
\end{array}
$$

By Proposition 112.9 and Lemma 112.11 there exists a map $\tilde{F} : \overline{B}^\alpha \times [0, 1] \to Y$ such that the above diagram commutes. This map $\tilde{F} : \overline{B}^\alpha \times [0, 1] \to Y$ is easily seen to be a homotopy between $g_0$ and $g_1$ which shows that $[g_0] = [g_1] \in \pi_n(Y, Y', y_0)$.

With these preparations it is surprisingly easy to provide a proof of Theorem 112.7 (1) and (2).

**Proof of Theorem 112.7 (1) and (2).** Let $p : Y \to B$ be a Serre fibration. Furthermore let $y_0 \in Y$. We write $b_0 = p(y_0)$ and $F = p^{-1}(b_0)$. We denote by $i : F \to Y$ the
We make the following comments:

(a) The top horizontal sequence of maps is the long exact sequence of homotopy groups of the pointed pair of topological spaces \((Y, F, y_0)\), see Proposition \[111.4\] for details.

(b) The top vertical map is an isomorphism by Proposition \[112.10\].

(c) The bottom vertical map is the identification given on page \[2617\].

(d) It follows immediately from the definitions that the left-hand triangle commutes.

(e) The right-hand triangle commutes by definition of the diagonal map.

It follows immediately from the definition of \(p_*\) that given any \(n \in \mathbb{N}\) the map

\[
\partial_n \circ p_*^{-1} : \pi_n(B, b_0) \to \pi_{n-1}(F, y_0)
\]

is given by

\[
[\varphi : (I^n, \partial I^n) \to (B, b_0)] \mapsto \begin{cases}
\text{the restriction of } \tilde{\varphi} \text{ to } I^{n-1} = I^{n-1} \times \{0\} \\
\text{where } \tilde{\varphi} \text{ is a map } (I^n, J^{n-1}) \to (Y, \{y_0\}) \\
\text{with } p \circ \tilde{\varphi} = \varphi
\end{cases}
\]

This observation shows that the map given in statement (1) of the theorem is well-defined and that it is a homomorphism (respectively a morphism of pointed sets). We leave it to the few readers who made it that far to verify that the maps \(\partial_n\) have the two properties stated in (1b) and (1c).

Furthermore, since the top sequence is exact and since the vertical maps are isomorphisms we see that the sequence given in statement (2) of the theorem is indeed exact. □

**Proof of Theorem \[112.7\] (3).** Let \(p : Y \to B\) be a Serre fibration. Furthermore let \(y_0 \in Y\). We write \(b_0 = p(y_0)\) and \(F = p^{-1}(b_0)\). We denote by \(i : F \to Y\) the inclusion map. Now we suppose that the inclusion map \(i : F \to Y\) is homotopic rel \(y_0\) to the constant map \(c_{y_0} : F \to \{y_0\}\). Put differently, we suppose that there exists a homotopy \(G : F \times [0, 1] \to Y\) rel \(y_0\) such that \(G_0 = i\) and \(G_1(f) = y_0\) for every \(f \in F\).

It follows almost immediately from Lemmas \[46.2\] and \[46.4\] that it suffices to show that for any \(n \in \mathbb{N}_{\geq 2}\) there exists a homomorphism \(\lambda : \pi_{n-1}(F, y_0) \to \pi_n(B, b_0)\) such that \(\partial_n \circ \lambda = \text{id}_{\pi_{n-1}(F, y_0)}\). We consider the map \[1536\]

\[
\lambda : \pi_{n-1}(F, y_0) \to \pi_n(Y, F, y_0) \to \pi_n(B, \{y_0\}) = \pi_n(B, b_0)
\]

\[
[\varphi : (I^{n-1}, \partial I^{n-1}) \to (F, y_0)] \mapsto [(I^n, \partial I^n, J^{n-1}) \to (Y, F, \{y_0\})]
\]

\[
(x, t) \mapsto G(\varphi(x), t)
\]

\[1536\]It takes a second to actually verify that the map \((x, t) \mapsto G(\varphi(x), t)\) defines in fact a map \((I^n, \partial I^n, J^{n-1}) \to (Y, F, \{y_0\})\).
It is elementary to verify that $\lambda$ is in fact a homomorphism. It follows almost immediately from the definitions that $\partial_n \circ \lambda = \text{id}_{\pi_{n-1}(F;g_0)}$. 

11.2.5. **The path space fibration.** We recall the following, long dormant, definition from page 234.

**Definition.** Let $X$ and $Y$ be topological spaces.

1. We denote by $X^Y = C(Y, X)$ the set of all maps from $Y$ to $X$.
2. The *compact-open topology* on $X^Y$ is the topology generated, in the sense of the definition on page 105, by all the sets of the form

$$M(K, U) := \{ f \in X^Y | f(K) \subset U \}$$

where $K \subset Y$ is compact and where $U \subset X$ is open.

In the following we state slightly simplified versions of two technical results which we proved a long time ago.

**Proposition 5.4.** Let $X$ be a topological space.

1. The evaluation map

$$e: X^{[0,1]} \times [0,1] \rightarrow X$$
$$((f: [0,1] \rightarrow X), y) \mapsto f(y)$$

is continuous.
2. For each $y \in [0,1]$ the evaluation map

$$e: X^{[0,1]} \rightarrow X$$
$$(f: [0,1] \rightarrow X) \mapsto f(y)$$

is continuous.

**Proposition 5.6.** Let $X$ and $T$ be two topological spaces. Let $H: T \times [0,1] \rightarrow X$ be a map. Given $t \in T$ we denote by $H_t: [0,1] \rightarrow X$ the map defined by $H_t(y) = H(t, y)$. Then $H: T \times [0,1] \rightarrow X$ is continuous $\iff$

1. Each $H_t: [0,1] \rightarrow X$ is continuous, and
2. The map $T \rightarrow X^{[0,1]}$ given by $t \mapsto H_t$ is continuous.

This reminder allows us to introduce our latest best friends.

**Definition.** Let $X$ be a topological space.

1. We define

$$\text{free path space } X^{[0,1]} := \text{set of all maps } [0,1] \rightarrow X$$

where $X^{[0,1]}$ is as usual equipped with the compact-open topology. Furthermore we introduce the

$$\text{free loop space } \Omega(X) := \{ f \in X^{[0,1]} | f(0) = f(1) \}.$$ 

We equip the free loop space with the compact-open topology coming from $X^{[0,1]}$.

---

\footnote{Of course here we mean “all continuous maps”.
}
(2) Suppose we are also given a base point $x_0 \in X$. We introduce the 

\[
\text{path space } P(X, x_0) := \{ f \in X^{[0,1]} \mid f(0) = x_0 \}
\]

and the 

\[
\text{loop space } \Omega(X, x_0) := \{ f \in X^{[0,1]} \mid f(0) = f(1) = x_0 \}.
\]

We equip both sets with the compact-open topology coming from $X^{[0,1]}$.

(3) We denote by $c_{x_0} : [0,1] \rightarrow X$ the constant path given by sending all $t$'s to $x_0$. 

![Diagram showing elements in the free path space $X^{[0,1]}$, path space $P(X, x_0)$, and loop space $\Omega(X, x_0)$](image)

**Examples.**

(1) Let $(X, x_0)$ be a pointed topological space and let $\alpha, \beta \in \Omega(X, x_0)$. It follows from Proposition 5.6 that a path in $\Omega(X, x_0)$ from $\alpha$ to $\beta$ is basically the same as a homotopy between the maps $\alpha$ and $\beta$ viewed as loops in $(X, x_0)$. Thus we see that we have a natural identification 

\[
\pi_0(\Omega(X, x_0)) = \pi_1(X, x_0).
\]

(2) Let $(X, x_0)$ be a pointed topological space. It follows from Proposition 5.4 that the map 

\[
e : P(X, x_0) \rightarrow X \\
f \mapsto f(1)
\]

is continuous. We can ask whether this map has a left-inverse. More precisely, the question is whether there exists a continuous map $s : X \rightarrow P(X, x_0)$ such that $e(s(x)) = x$ for all $x \in X$. This sounds like a rather random question, so let us reformulate it. The question is, can we continuously assign to each $x \in X$ a path from $x_0$ to $x$? Clearly that is possible say for $(X, x_0) = (\mathbb{R}^2, 0)$, we just assign to each $x \in \mathbb{R}^2$ the direct path $e(x)$ that is given by $t \mapsto t \cdot x$. But can we do so say for $X = S^1$ or $X = S^2$? We will answer this question in Exercise [112.2](#).

For the record we state the following lemma.

**Lemma 112.12.** The maps 

\[
(X, x_0) \mapsto (\Omega(X, x_0), c_{x_0}) \\
(f : (X, x_0) \rightarrow (Y, y_0)) \mapsto \left( \begin{array}{c} \Omega(X, x_0) \rightarrow \Omega(Y, y_0) \\
(\gamma : [0,1] \rightarrow X) \mapsto (f \circ \gamma : [0,1] \rightarrow Y) \end{array} \right)
\]

define a covariant functor from the category $\mathcal{PTop}$ of pointed topological spaces to the category $\mathcal{PTop}$ of pointed topological spaces. We refer to this functor as the loop space functor.

---

1538 This question is somewhat similar to Question 51.7 and it also falls into the vaguely defined realm of “topological robotics”. 

---
Proof. Let \( f : (X, x_0) \to (Y, y_0) \) be a map between pointed topological spaces. It follows from Lemma 5.5 (1) that the map
\[
\Omega(X, x_0) \to \Omega(Y, y_0)
\]
\((\gamma : [0, 1] \to X) \mapsto (f \circ \gamma : [0, 1] \to Y)\)
is actually continuous. With this observation out of the way it is straightforward to prove the lemma. ■

The following lemma says that in some sense (free) path spaces, in isolation, are not particularly interesting examples of topological spaces.

**Lemma 112.13.**

1. Let \( X \) be a topological space. We view \( X \) as a subset of the free path space \( X^{[0,1]} \) via the inclusion \( x \mapsto c_x \). Then \( X \) is a deformation retract of the free path space \( X^{[0,1]} \).
2. If \( (X, x_0) \) is a pointed topological space, then \( \{c_{x_0}\} \) is a deformation retract of the path space \( P(X, x_0) \), in particular the path space \( P(X, x_0) \) is contractible.

![Figure 1577. Illustration of Lemma 112.13 (2).](image)

Proof. We prove statement (2). The proof of statement (1) is basically identical. Thus let \( (X, x_0) \) be a pointed topological space. We consider the “obvious” deformation retraction given by
\[
F : P(X, x_0) \times [0, 1] \to P(X, x_0) \quad ((f : [0, 1] \to X), t) \mapsto \left([0, 1] \to X \quad s \mapsto f(s \cdot (1 - t))\right)
\]
The only reason why we are not already done is that we still need to verify that \( F \) is in fact continuous. As we will see this is slightly delicate. We consider the map
\[
G : X^{[0,1]} \times [0, 1] \to X^{[0,1]}
\]
that is defined in exactly the same way as \( F \). Since \( F = G|_{P(X, x_0) \times [0, 1]} \) it suffices to show that \( G \) is continuous. By the “⇒”-direction of Proposition 5.6 applied to \( T = X^{[0,1]} \times [0, 1] \) it suffices to show that the map
\[
H : [0, 1] \times (X^{[0,1]} \times [0, 1]) \to X \quad (s, ((g : [0, 1] \to X), x)) \mapsto g(s \cdot x)
\]

\[\text{Note that this inclusion } X \to X^{[0,1]} \text{ is by Lemma 5.3 an embedding.}\]
is continuous. But the map $H$ can be written as the composition

$$H: [0, 1] \times X^{[0,1]} \times [0, 1] \to X^{[0,1]} \times [0, 1] \to X$$

$$(s, g, x) \mapsto (g, s \cdot (1 - x))$$

$$(g, t) \mapsto g(t).$$

The first map is continuous by Lemma 3.8 and the second map is continuous by Proposition 5.4 (1). Thus we see that $H$ itself is continuous. □

In contrast to the previous proposition the following theorem shows that (free) path spaces give rise to interesting maps.

**Theorem 112.14.**

1. Let $X$ be a topological space. The evaluation map

$$p: X^{[0,1]} \to X$$

$$(f: [0, 1] \to X) \mapsto f(1)$$

is a fibration. Furthermore, given any $x_0 \in X$ the fiber $p^{-1}(x_0)$ is the topological space of all paths $[0, 1] \to X$ that end in $x_0$.
2. Let $(X, x_0)$ be a pointed topological space. The evaluation map

$$p: P(X, x_0) \to X$$

$$(f: [0, 1] \to X) \mapsto f(1)$$

is a fibration with fiber $p^{-1}(x_0) = \Omega(X, x_0)$.

Theorem 112.14 leads us to the following definition.

**Definition.**

1. Let $X$ be a topological space. We refer to the above fibration $p: X^{[0,1]} \to X$ as the free path space fibration of $X$.
2. Let $(X, x_0)$ be a pointed topological space. In the following we refer to the above fibration $p: P(X, x_0) \to X$ as the path space fibration of $(X, x_0)$.

**Proof.** We prove statement (2). The proof of statement (1) is basically identical and is thus left to the reader. Thus let $(X, x_0)$ be a pointed topological space. First note that the map $p: P(X, x_0) \to X$ is continuous by Proposition 5.4 (2). Next recall that we need to solve the following type of extension problem for some topological space $W$ and $c > 0$:

$$\begin{array}{ccc}
W \times \{0\} & \xrightarrow{\bar{f}} & P(X, x_0) \subset X^{[0,1]} \\
\downarrow & & \downarrow \\
W \times [0, c] & \xrightarrow{\bar{F}} & X.
\end{array}$$

We refer to Figure 1578 for an illustration.

In the diagram we write $W \times [0, c]$ instead of the more customary $W \times [0, 1]$ for purely psychological reasons, it makes it easier to distinguish the two types of intervals which arise throughout the proof and which play very different roles.
The idea for the proof is quite simple: Given \((w, s) \in W \times [0, c]\) we have to “systematically” find an element \(\gamma \in P(X, x_0)\) with \(p(\gamma) = F(w, s)\), i.e. we have to find a path \(\gamma: [0, 1] \rightarrow X\) from \(x_0\) to \(F(w, s)\). But there is an obvious path, namely we first travel along \(\tilde{f}(w, 0)\) from \(x_0\) to \(F(w, 0)\) and then use the path \(t \mapsto F(w, t)\) to get from \(F(w, 0)\) to \(F(w, s)\). That is exactly what we will do, except that we need to be a little careful with our parametrizations.

Now we have to turn this idea into a proper proof. We consider the map

\[
\tilde{F}: W \times [0, c] \rightarrow P(X, x_0)
\]

\((w, s) \mapsto \begin{cases} [0, 1] \rightarrow X \\ \quad t \mapsto \begin{cases} \tilde{f}(w, 0)(\frac{t}{1 - s/c}), & \text{if } t \in [0, 1 - \frac{s}{c}], \\ F(w, 2 \cdot (t - 1 + \frac{s}{c})), & \text{if } t \in [1 - \frac{s}{c}, 1] \end{cases} \end{cases} \)

We claim that this map has all the desired properties:

1. Let \((w, s) \in W \times [0, c]\). We make the following observations:
   a. The given map \([0, 1] \rightarrow X\) starts at \(x_0\).
   b. It follows easily from Lemma 2.35 (2) that the given map \([0, 1] \rightarrow X\) is indeed continuous.

   In other words, the given map \([0, 1] \rightarrow X\) does indeed define an element in \(P(X, x_0)\).

2. For each \((w, s) \in W \times [0, c]\) we have by construction that \(\tilde{F}(w, s)(t = 1) = F(w, s)\).
   In other words, we have \(p \circ \tilde{F} = F\).

Thus it remains to prove the following claim:

Claim. The map \(\tilde{F}: W \times [0, c] \rightarrow P(X, x_0)\) is continuous.

We consider the map

\[
\tilde{G}: W \times [0, c] \times [0, 1] \rightarrow X
\]

\((w, s, t) \mapsto \tilde{F}(w, s)(t) = \begin{cases} \tilde{f}(w, 0)(\frac{t}{1 - s/c}), & \text{if } t \in [0, 1 - \frac{s}{c}], \\ F(w, 2 \cdot (t - 1 + \frac{s}{c})), & \text{if } t \in [1 - \frac{s}{c}, 1] \end{cases} \)
It follows easily from the fact that $F$ and $\tilde{f}$ are continuous that the restrictions of $\tilde{G}$ to the closed subsets

$$A_1 := W \times \{(s, t) \in [0, c] \times [0, 1] \mid t \in [0, 1 - \frac{s}{2c}]\},$$

and

$$A_2 := W \times \{(s, t) \in [0, c] \times [0, 1] \mid t \in [1 - \frac{s}{2c}, 1]\}$$

are continuous. Therefore it follows from Lemma 2.35 (2) that $\tilde{G}$ is continuous. Finally we deduce from the “$\Rightarrow$”-direction of Proposition 5.6 applied to $T = W \times [0, c]$, $Y = [0, 1]$ and $H = \tilde{G}$ that $\tilde{F}$ is also continuous. 

We obtain the following amusing corollary which later on will turn out to play an important role.

**Corollary 112.15.** Given any pointed topological space $(X, x_0)$ and any $n \geq 1$ the map

$$\partial_n: \pi_n(X, x_0) \xrightarrow{\cong} \pi_{n-1}(\Omega(X, x_0), c_{x_0})$$

$$[f: ([0, 1]^n, \partial([0, 1]^n)) \to (X, x_0)] \mapsto \left[([0, 1]^{n-1}, \partial([0, 1]^{n-1})) \to (\Omega(X, x_0), c_{x_0}) \quad x \mapsto \left(\begin{array}{c} [0, 1] \\ t \mapsto f(x, t) \end{array}\right)\right]$$

is a natural isomorphism.

**Figure 1579.** Illustration of Corollary 112.15

**Remark.** For $n = 1$ the statement of Corollary 112.15 recovers the result from page 2661 where we saw that there exists a natural identification

$$\pi_0(\Omega(X, x_0), c_{x_0}) = \pi_1(X, x_0).$$

**Proof.** There are two approaches to proving the corollary, namely one can prove it by “the machine” and one can prove it “by hand”.

1. Let $f: (X, x_0) \to (Y, y_0)$ be a map between pointed topological spaces. It is clear that we obtain a commutative diagram

$$\begin{array}{ccc}
P(X, x_0) & \xrightarrow{\gamma \mapsto f \circ \gamma} & P(Y, y_0) \\
p \downarrow & & \downarrow p \\
X & \xrightarrow{f} & Y.
\end{array}$$

\[\text{[1541]}\text{Using Proposition 5.6 one can show directly, with some slight effort, that the map } \partial_n \text{ is well-defined.}\]
It follows from Theorems 112.14 (1) and (2) and 112.7 that we have commutative diagram of long exact sequences

\[ \cdots \rightarrow \pi_n(P(X, x_0), c_{x_0}) \rightarrow \pi_n(X, x_0) \xrightarrow{\partial} \pi_{n-1}(\Omega(X, x_0), c_{x_0}) \rightarrow \pi_{n-1}(P(X, x_0), c_{x_0}) \rightarrow \cdots \]

\[ \cdots \rightarrow \pi_n(P(Y, y_0), c_{y_0}) \rightarrow \pi_n(Y, y_0) \xrightarrow{\partial} \pi_{n-1}(\Omega(Y, y_0), c_{y_0}) \rightarrow \pi_{n-1}(P(Y, y_0), c_{y_0}) \rightarrow \cdots \]

We obtain from Lemma 112.13 and Proposition 40.7 (2) that the homotopy groups of the path spaces \( P(X, x_0) \) and \( P(Y, y_0) \) are trivial. Thus the connecting homomorphisms are natural isomorphisms. We leave it to the reader to verify that in our situation the connecting homomorphisms from Theorem 112.7 are precisely the maps that we wrote down. Incidentally this then also shows that the maps, as written down, actually do make sense.

(2) In Exercise 112.4 we will prove the corollary “by hand”. □

**Example.** We consider the loop space of the 2-dimensional sphere with the base point given by the North Pole \( N = (0, 0, 1) \). We calculate that

\[ \pi_1(\Omega(S^2, N), c_N) \xrightarrow{\cong} \pi_2(S^2, N) \xrightarrow{\cong} \mathbb{Z}. \]

Corollary 112.15 Corollary 53.6 (1)

In Figure 1580 we see a loop \{\( \gamma_z \)\}_{z \in S^1} of loops in the pointed topological space \((S^2, N)\). Put differently, we see a loop in the pointed topological space \((\Omega(S^2, N), c_N)\). It is an amusing and instructive exercise to run through the above two isomorphisms to verify that our loop in the pointed topological space \((\Omega(S^2, N), c_N)\) is actually a generator of \( \pi_1(\Omega(S^2, N), c_N) \).

So what does this example actually really mean? It means that even though each individual loop \( \gamma_z \) is null-homotopic in \( S^2 \), we cannot continuously deform all the loops \( \gamma_z \) altogether into the constant loop. It is a good idea to think about what it would mean for \([z \mapsto \gamma_z] \in \pi_1(\Omega(S^2, N), c_N)\) to be null-homotopic and why, pictorially, this is not the case in our situation.

In Figure 1580 we see a loop \{\( \gamma_z \)\}_{z \in S^1} of loops in the pointed topological space \((S^2, N)\). **Figure 1580**

Note that the statement of Corollary 112.15 can be summarized as follows: The loop space functor

\[ \Omega: \text{category } P\text{Top of pointed topological spaces } \rightarrow \text{category } P\text{Top of pointed topological spaces } \]

\[ (X, x_0) \mapsto (\Omega(X, x_0), c_{x_0}) \]
shifts homotopy groups down by one degree, i.e. for every pointed topological space \((X, x_0)\) and every \(n \in \mathbb{N}\) we have a natural isomorphism
\[
\pi_n(X, x_0) \xrightarrow{\simeq} \pi_{n-1}(\Omega(X, x_0), c_{x_0}).
\]
This should be compared to the fact that in Proposition 15.7 we saw that the suspension functor
\[
\Sigma: \text{category} \ Top \ of \ topological \ spaces \to \text{category} \ Top \ of \ topological \ spaces \quad X \mapsto \Sigma(X)
\]
shifts reduced homology groups up by one degree, i.e. for every topological space \(X\) and any \(n \in \mathbb{N}\) we have a natural isomorphism
\[
\tilde{H}_n(X) \xrightarrow{\simeq} \tilde{H}_{n+1}(\Sigma(X)).
\]
In Exercise 112.8 we will discuss whether we can also shift homotopy groups upwards and whether we can shift reduced homology groups downwards in a functorial way.

112.6. **Every map can be replaced by a fibration.** In this section we will see that one can “replace” any map \(f: X \to Y\) between topological spaces by a fibration \(P_f \to Y\) that has very similar properties to the map \(f\).

We start out with the notion of the pullback of a fibration. Perhaps not surprisingly the definition is almost identical to the definition of the pullback of a vector bundle that we gave on page ??.

**Lemma 112.16.** Let \(f: A \to B\) be a map between topological spaces and let \(q: Z \to B\) be a fibration. As in Lemma 25.16 (1) we consider the pullback
\[
f^*Z := \{(a, z) \mid a \in A \text{ and } z \in q^{-1}(f(a))\} \subset A \times Z.
\]

The following statements hold:

1. **The pullback map**
   \[
   p: f^*Z := \{(a, z) \mid a \in A \text{ and } z \in q^{-1}(f(a))\} \to A \\
   (a, z) \mapsto a
   \]
   is also a fibration. Furthermore for any \(a \in A\) the fiber \(p^{-1}(a)\) is homeomorphic to the fiber \(q^{-1}(f(a))\).

diagram

2. **The following diagram commutes**
\[
\begin{array}{ccc}
    f^*Z & \xrightarrow{(a,z) \mapsto z} & Z \\
    \downarrow p & & \downarrow q \\
    A & \xrightarrow{f} & B
\end{array}
\]

**Proof.**

2. It is straightforward to verify that the diagram commutes.
Let $X$ be any topological space. We consider the following diagram where initially we ignore the diagonal arrows:

\[
\begin{array}{ccccccc}
X \times \{0\} & \xrightarrow{\tilde{g}} & f^*Z & \xrightarrow{(a,z) \mapsto z} & Z \\
\downarrow & \swarrow \tilde{G} & \downarrow p & \downarrow q & & \\
X \times [0,1] & \xrightarrow{G} & A & \xrightarrow{\tilde{f} \circ G} & B.
\end{array}
\]

Here the maps $G: X \times [0,1] \to A$ and $\tilde{g}: X \times \{0\} \to f^*Z$ are “the challenge” we have to deal with in the definition of a fibration. Since $q: Z \to B$ is a fibration there exists a map $\tilde{f} \circ G: X \times [0,1] \to Z$ that makes the diagram commute. It is now straightforward to verify that the map

\[
X \times [0,1] \to f^*Z = \{(a,z) | a \in A \text{ and } z \in q^{-1}(f(a))\}
\]

\[
(x,t) \mapsto (G(x,t), (\tilde{f} \circ G)(x,t))
\]

makes the above diagram commute. We have thus shown that $p: f^*Z \to A$ is also a fibration.

Finally we have to prove the statement regarding the fibers. Thus let $a \in A$. It follows immediately from the definitions that $p^{-1}(a) = \{a\} \times q^{-1}(f(a)) \subset A \times Z$. It follows from Lemma 3.8 (2a) that the fiber $p^{-1}(a)$ is homeomorphic to the fiber $q^{-1}(f(a))$.

**Definition.** Using the notation from Lemma 112.16 we refer to $f^*Z \to A$ as the pullback of the fibration $q: Z \to B$ under the map $f: A \to B$.

Now we turn to the actual problem that we had stated in the beginning of this section.

**Definition.** Let $f: X \to Y$ be a map between topological spaces. Similar to the free path space fibration we now consider the fibration

\[
q: Y^{[0,1]} \to Y \\
\gamma \mapsto \gamma(0).
\]

We refer to the map

\[
p: P_f := f^*(Y^{[0,1]}) = \{(x,\gamma): [0,1] \to Y \in X \times Y^{[0,1]} | \gamma(0) = f(x)\} \to Y \\
(x,\gamma) \mapsto \gamma(1)
\]

as the mapping path fibration.

In Proposition 39.7 we saw that any map $f: X \to Y$ between topological spaces can be “replaced” by a cofibration $X \to \text{Cyl}(f)$. The following proposition is the analogue of Proposition 39.7 for fibrations.

---

1542 This map is basically the same as the free path space fibration except that now we consider the evaluation $\gamma(0)$ instead of the evaluation $\gamma(1)$.

1543 Note that it follows from Proposition 5.4 (2) that this map is in fact continuous.
Proposition 112.17. Let \( f : X \to Y \) be a map between topological spaces. We denote by \( p : P_f \to Y \) the corresponding mapping path fibration.

1. The map
\[
h : X \to P_f \\
x \mapsto (x, \text{constant path } c_{f(x)})
\]
is a homotopy equivalence and it has the property that it makes the following diagram commute:
\[
\begin{array}{ccc}
X & \xrightarrow{h} & P_f \\
\downarrow{f} & & \downarrow{p} \\
Y & \nearrow{\gamma}
\end{array}
\]

2. The map \( p : P_f \to Y \) is a fibration.

Given any \( y \in Y \) the fiber is given by \( \{(x, \gamma) \mid x \in X \text{ and } \gamma : [0, 1] \to Y \text{ is a path from } f(x) \text{ to } y\} \).

Definition. Let \( f : X \to Y \) be a map between topological spaces. We suppose that \( Y \) is path-connected. We refer to the homotopy type of the fiber of the corresponding mapping path fibration \( P_f \to Y \) as the homotopy fiber of \( f \).

Remark. If \( f : X \to Y \) is a fibration, then it is shown in [DaK01, Theorem 6.18] that the map \( h : X \to P_f \) in Proposition 112.17 (1) is a “fiber homotopy equivalence”, thus, loosely speaking, the original fibration \( f : X \to Y \) and the new fibration \( p : P_f \to Y \) are essentially the same. We will not make use of this fact.

Example. Proposition 112.17 thus says that any map \( f : X \to Y \) between topological spaces can be “replaced” by a fibration. As a reality check let us consider again the “non-example” from Lemma 112.1, i.e. we consider the map \( f : S^1 \to [-1, 1] \) that is given by the projection onto the \( x \)-coordinate. Lemma 112.1 says that \( f \) is not a fibration. Let us see what the above construction does in this case.

As pointed out in Proposition 112.17 (2), given any \( y \in [-1, 1] \) the preimage of \( y \) under the map \( p : P_f \to Y = [-1, 1] \) is given by
\[
p^{-1}(y) = \{(x, \gamma) \mid x \in S^1 \text{ and } \gamma : [0, 1] \to [-1, 1] \text{ is a path from } f(x) \text{ to } y\}.
\]

In Figure 1581 we strive to illustrate three points in the preimage of a point \( y \in [-1, 1] \). In Exercise 112.3 we will see that for each \( y \in [-1, 1] \) the preimage \( p^{-1}(y) \) is homotopy equivalent to \( S^1 \). In particular this shows that the homotopy fiber of \( f : S^1 \to [-1, 1] \) is \( S^1 \). This exercise does not quite show yet that the map \( p : P_f \to [-1, 1] \) is a fibration, but at the very least it is consistent with Proposition 112.6 (1).

Proof of Proposition 112.17. Let \( f : X \to Y \) be a map between topological spaces. We consider the map
\[
p : P_f = f^*(Y^{[0,1]}) = \{(x, \gamma : [0, 1] \to Y) \mid (x, \gamma)(0) = f(x) \} \to Y \\
(x, \gamma) \mapsto \gamma(1).
\]
We turn to the proof of the two statements:

(1) Given $y \in Y$ we denote, as usual, by $c_y: [0,1] \to Y$ the constant path given by $c_y(t) = y$ for all $t \in [0,1]$. We consider the map $h: X \to P_f$ that is given by $x \mapsto (x, c_f(x)).$\footnote{It follows from Lemma 3.8 (2b) and Lemma 4.3 that this map is continuous.} We claim it has the desired properties. It is obvious that $p \circ h = f$, i.e. the diagram given in the proposition commutes. So it remains to show that $h$ is a homotopy equivalence. We consider the map $g: P_f \to X$ given by $g(x, \gamma) = x$. Evidently we have $g \circ h = \text{id}_X$. We are done once we have shown that $h \circ g$ is homotopic to $\text{id}_{P_f}$. In fact such a homotopy is given by\footnote{An argument as in the proof of Lemma 112.13 (2) shows that the map $H$ is indeed continuous.}

\[
H: P_f \times [0,1] \to P_f
\]
\[
((x, \gamma), t) \mapsto \left( x, \left( \begin{array}{c}
[0,1] \to Y \\
 s \mapsto \gamma(s \cdot t)
\end{array} \right) \right).
\]
\[
\gamma: [0,1] \to Y \text{ is a path with } \gamma(0) = f(x)
\]

One easily verifies that $H_0 = h \circ g$ and that $H_1 = \text{id}_{P_f}$.

(2) We want to show that the map $p: P_f \to Y$ is a fibration. Thus let $A$ be any topological space. Let $c > 0$. We consider the following “challenge diagram”\footnote{As in the proof of Theorem 112.14 we prefer to work, for purely psychological reasons, with $A \times [0,c]$ instead of $A \times [0,1]$.}

\[
\begin{array}{ccc}
A \times \{0\} & \xrightarrow{\tilde{g}} & P_f = \{(x, \gamma: [0,1] \to Y) \in X \times Y^{[0,1]} | \gamma(0) = f(x)\} \\
\downarrow \hspace{1cm} \downarrow \hspace{1cm} \downarrow p \hspace{1cm} \downarrow \hspace{1cm} \downarrow \\
A \times \{0, c\} & \xrightarrow{G} & Y.
\end{array}
\]

To define $\tilde{G}$ we first split up the map $\tilde{g}$ into its components. More precisely, we define maps $\tilde{g}_1: A \to X$ and $\tilde{g}_2: A \to Y^{[0,1]}$ via the equality

\[
\tilde{g}(a,0) = (\tilde{g}_1(a), \tilde{g}_2(a)) \in P_f \subset X \times Y^{[0,1]} \text{ for all } a \in A.
\]
112. FIBRATIONS

Note that by definition of $P_f$ the path $\tilde{g}_2(a) \in Y^{[0,1]}$ is a path from $f(\tilde{g}_1(a))$ to $G(a,0)$. We need to define a suitable map $\tilde{G}: A \times [0,c] \to P_f \subset X \times Y^{[0,1]}$. We consider the two factors separately:

(a) We already have the map $A \times [0,c] \to A \xrightarrow{\tilde{g}_1} X$.

(b) To each $(a,s) \in A \times [0,c]$ we need to assign “systematically” a path $[0,1] \to Y$ from $f(\tilde{g}_1(a))$ to $G(a,s)$. The idea is quite simple: Given $(a,s) \in A \times [0,c]$ we consider the path $[0,1] \to Y$ that is given by first traveling along the path $\tilde{g}_2(a)$ from $f(\tilde{g}_1(a))$ to $G(a,0)$ and then we travel along the path $t \mapsto G(a,t)$ from $G(a,0)$ to $G(a,s)$. More precisely, similar to the proof of Theorem 112.14 we consider the map $\tilde{G}_2: A \times [0,c] \to Y^{[0,1]}$:

$$
\tilde{G}_2: A \times [0,c] \to Y^{[0,1]} \\
(a,s) \mapsto \begin{cases} 
[0,1] \to Y \\
\quad t \mapsto \begin{cases} 
\tilde{g}_2(a)(\frac{t}{1-\frac{s}{c}}), & \text{if } t \in [0,1-\frac{s}{c}], \\
G(a,2 \cdot (t-1+\frac{s}{c})), & \text{if } t \in [1-\frac{s}{c},1] 
\end{cases} 
\end{cases}
$$

We refer to Figure 1582 for an illustration of the definition of $\tilde{G}_2$.

Finally we consider the following map:

$$
\tilde{G}: A \times [0,c] \to P_f \\
(a,s) \mapsto (\tilde{g}_1(a), \tilde{G}_2(a,s)).
$$

We make the following observations:

(a) It follows easily from the definitions that $\tilde{G}$ takes values in $P_f$.

(b) It follows from the above and Lemma 3.8 (2b) that $\tilde{G}$ is continuous.

(c) It is straightforward to verify that $\tilde{G}$ makes the diagram commute.

We have thus verified that $\tilde{G}$ has all the desired properties.

We refer to Figure 1582 for an illustration of the proof of Proposition 112.17.

The statement of Proposition 112.17 that any map $f: X \to Y$ between topological spaces can be “replaced” by a fibration is quite surprising and perhaps also somewhat puzzling. Therefore we want to consider one more example.

---

The argument in the proof of Theorem 112.14 also shows that the map $\tilde{G}_2$ does indeed take values in $Y^{[0,1]}$ and that the map $\tilde{G}_2: A \times [0,c] \to Y^{[0,1]}$ is continuous.
Example. We denote by $\Sigma$ the surface of genus 2 and we denote by $T$ the torus. We consider the map $f: \Sigma \to T$ that is illustrated in Figure 1583. We denote by $p: P_f \to T$ the mapping path fibration and we denote by $F$ the corresponding homotopy fiber. So what can we say about the mysterious homotopy fiber $F$?

We have the following diagram

$$
\begin{array}{cccccccccccc}
\ldots & \longrightarrow & \pi_2(F) & \longrightarrow & \pi_2(P_f) & \stackrel{p_*}{\longrightarrow} & \pi_2(T) & \stackrel{\partial}{\longrightarrow} & \pi_1(F) & \longrightarrow & \pi_1(P_f) & \stackrel{p_*}{\longrightarrow} & \pi_1(T) & \longrightarrow & \ldots \\
& & \uparrow h_* \cong & & \downarrow f_* & & \downarrow h_* \cong & & \downarrow f_* & & \downarrow h_* \cong & & \downarrow f_* & & \\
& & \pi_2(\Sigma) & & & & \pi_1(\Sigma). & & & & & & & & \\
\end{array}
$$

We make the following explanations and observations:

1. The top sequence is the long exact sequence coming from Theorem 112.7. The vertical maps are induced by the homotopy equivalence $h: \Sigma \to P_f$ from Proposition 31.8 (1). In particular the vertical maps are isomorphisms by Proposition 40.7 (2).

2. Since $p \circ h = f$ we see that the diagram commutes.

3. By the discussion on page 1070 we know that $\pi_n(T) = \pi_n(\Sigma) = 0$ for $n \geq 2$.

4. It is pretty clear that the map $f_*: \pi_1(\Sigma) \to \pi_1(T)$ is an epimorphism.

5. We obtain from the above discussion and from Proposition 31.8 that $F$ is path-connected, that $\pi_n(F) = 0$ for $n \geq 2$ and that $\pi_1(F)$ is an infinitely generated free group.

Thus we see that the homotopy groups of $F$ are isomorphic to the homotopy groups of an infinite wedge of circles.

![Figure 1583. A degree-one map from the surface of genus 2 to the torus.](image)

112.7. Adjoint functors (*). In Chapter 39 we introduced the notion of a “cofibration” and we just got acquainted with the notion of a “fibration”. In this section we will discuss the relationship between these two notions.

First we point out a formal similarity between fibrations and cofibrations, namely they both give rise to long exact sequences:

1. Let $p: Y \to B$ be a fibration. Let $y_0 \in Y$. We write $b_0 = p(y_0)$ and we denote by $F = p^{-1}(b_0)$ the homotopy fiber of $p$. Let $i: F \to Y$ be the inclusion map. By Theorem 112.7 we obtain the following long exact sequence of homotopy groups:

$$
\begin{array}{cccccccccccc}
\ldots & \longrightarrow & \pi_n(F,y_0) & \stackrel{i_*}{\longrightarrow} & \pi_n(Y,y_0) & \stackrel{p_*}{\longrightarrow} & \pi_n(B,b_0) & \stackrel{\partial}{\longrightarrow} & \pi_{n-1}(F,y_0) & \stackrel{i_*}{\longrightarrow} & \ldots \\
\end{array}
$$

2. Let $i: A \to X$ be a cofibration. We refer to the mapping cone $C := \text{Cone}(i)$ as the cofiber. If $i(A)$ is a closed non-empty subset of $X$, then it follows easily from
Corollary\ref{fib:43.16} and Corollary\ref{fib:46.17} that we obtain a long exact sequence of reduced homology groups of the following form:

\[
\ldots \xrightarrow{\partial} \tilde{H}_n(A) \xrightarrow{i} \tilde{H}_n(X) \xrightarrow{p_*} \tilde{H}_n(C) \xrightarrow{\partial} \tilde{H}_{n-1}(A) \xrightarrow{i} \ldots
\]

This basically recovers the statement of Lemma\ref{fib:46.18}.

Here is another similarity between fibrations and cofibrations:

1. Let \( p: Y \to B \) be a fibration and let \( f: A \to B \) be a map. As in Lemma\ref{fib:25.16} (1) we consider the pullback

\[
\begin{array}{ccc}
A & \xrightarrow{f} & B \\
\downarrow & & \downarrow \\
Y & \xrightarrow{p} & B
\end{array}
\]

where \( f^* Y = \{(a, y) \in A \times Y \mid f(a) = p(y)\} \). In Lemma\ref{fib:112.16} we saw that the pullback \( f^* Y \to A \) is also a fibration.

2. Now let \( i: A \to X \) be a cofibration and let \( f: A \to B \) be a map to another topological space. As on page 732 we consider the pushout

\[
\begin{array}{ccc}
A & \xrightarrow{f} & B \\
\downarrow & & \downarrow \\
X & \xrightarrow{f_*} & f_* X
\end{array}
\]

where \( f_* X = (X \sqcup B)/i(a) \sim f(a) \) for all \( a \in A \). By Proposition\ref{fib:39.17} (1) we will know that the pushout \( B \to f_* X \) is again a cofibration.

So, to summarize: the pullback of a fibration is again a fibration and the pushout of a cofibration is again a cofibration.

The main goal of this section though is to formulate an arguably more direct relationship between the notions of a fibration and a cofibration. The key to doing so is the following definition from category theory.

\textbf{Definition.} We say that two covariant functors \( F: \mathcal{C} \to \mathcal{D} \) and \( G: \mathcal{D} \to \mathcal{C} \) between categories \( \mathcal{C} \) and \( \mathcal{D} \) form an \textit{adjoint pair} if given any \( c \in \text{Ob}(\mathcal{C}) \) and \( d \in \text{Ob}(\mathcal{D}) \) there exists a bijection

\[
\text{Mor}_\mathcal{D}(F(c), d) \to \text{Mor}_\mathcal{C}(c, G(d))
\]

that is natural in \( c \) and \( d \). We also say that the functor \( F \) is the \textit{left adjoint} of \( G \) and that \( G \) is the \textit{right adjoint} of \( F \).

\textbf{Examples.}

1. Let \( S \) be the category of sets and let \( \mathcal{G} \) be the category of groups. We consider the two functors

\[
F: S \to \mathcal{G} \quad \text{and} \quad G: \mathcal{G} \to S
\]

\[
S \mapsto \langle S \rangle \quad \text{and} \quad (\pi, \cdot) \mapsto \pi.
\]

\footnote{We leave it to our reader to figure out what “natural in \( c \) and \( d \)” means.}
In other words, $F$ associates to a set $S$ the free group $\langle S \rangle$ generated by $S$ that we defined on page 591. Furthermore, $G$ assigns to a group $(\pi, \cdot)$ the underlying set $\pi$ defined on page 591. Using Lemma 19.14 one sees that for a set $S$ and a group $\pi$ the map

$$\text{Mor}_S(S, \pi) \to \text{Mor}_G(\langle S \rangle, (\pi, \cdot))$$

$(\text{map } h: S \to \pi \text{ of sets}) \mapsto \text{the unique homomorphism } \langle S \rangle \to (\pi, \cdot) \text{ that restricts to } h \text{ on the subset } S \subset \langle S \rangle$ is a natural bijection. Thus we see that the functors $F$ and $G$ are adjoint.

(2) Let $\mathbf{AbGr}$ be the category of abelian groups and let $A$ be an abelian group. We consider the two functors

$$F: \mathbf{AbGr} \to \mathbf{AbGr} \quad \text{and} \quad G: \mathbf{AbGr} \to \mathbf{AbGr},$$

$$B \mapsto A \otimes B \quad \text{and} \quad B \mapsto \text{Hom}(A, B).$$

Now let $B, C \in \mathbf{AbGr}$. We consider the map

$$\text{Mor}_{\mathbf{AbGr}}(A \otimes B, C) \to \text{Mor}_{\mathbf{AbGr}}(B, \text{Hom}(A, C))$$

$$(f: A \otimes B \to C) \mapsto \left( B \to \text{Hom}(A, C), \quad b \mapsto \left( A \to Y, \quad a \mapsto f(a \otimes b) \right) \right).$$

Using Lemma 57.2 (3) one can easily show that this map is a bijection. This shows that $F$ and $G$ form an adjoint pair.

(3) Let $\mathbf{Top}$ be the category of topological spaces. Rather similarly to the previous example we consider the two functors

$$F: \mathbf{Top} \to \mathbf{Top} \quad \text{and} \quad G: \mathbf{Top} \to \mathbf{Top},$$

$$X \mapsto X \times [0, 1] \quad \text{and} \quad X \mapsto X^{[0, 1]}.$$

Now let $X, Y \in \text{Ob}(\mathbf{Top})$, i.e. let $X$ and $Y$ be topological spaces. We consider the map

$$\text{Mor}_{\mathbf{Top}}(X \times [0, 1], Y) \to \text{Mor}_{\mathbf{Top}}(X, Y^{[0, 1]})$$

$$(f: X \times [0, 1] \to Y) \mapsto \left( X \to Y^{[0, 1]}, \quad x \mapsto \left( [0, 1] \to Y, \quad t \mapsto f(x, t) \right) \right).$$

---

1551. In what sense is this a functor?
1552. Such a functor, where we “forget” some of the given structure is often called a forgetful functor.
1553. For abelian groups $X$ and $Y$ we have by definition that $\text{Mor}_{\mathbf{AbGr}}(X, Y) = \text{Hom}(X, Y)$.
1554. Here we equip $X \times [0, 1]$ with the product topology and we equip $X^{[0, 1]}$ with the compact-open topology.
It follows from Proposition 5.6 that this map is well-defined and that it is a bijection. We have thus shown that \( F \) and \( G \) form an adjoint pair.

Now we can explain the formal relationship between fibrations and cofibrations. Let \( E \) and \( B \) be topological spaces and let \( p: E \to B \) be a map. Recall that by definition \( p: E \to B \) is a fibration if we can always complete the following diagram:

\[
\begin{array}{ccc}
Y & \xrightarrow{F} & E \\
\downarrow_{y \mapsto (y,0)} & & \downarrow_{p} \\
Y \times [0,1] & \xrightarrow{F} & B.
\end{array}
\]

Now we “dualize” this diagram as follows:

1. We reverse the orientation of each arrow,
2. We replace monomorphisms by epimorphisms,
3. We replace \( Y \times [0,1] \) by \( Y^{[0,1]} \),
4. For purely psychological reasons we replace \( p: E \to B \) by \( i: A \to X \).

We obtain the following diagram:

\[
\begin{array}{ccc}
Y & \xrightarrow{F} & X \\
\uparrow_{f \mapsto f(0)} & & \uparrow_{i} \\
Y^{[0,1]} & \xleftarrow{f} & A.
\end{array}
\]

Finally recall that we had just shown in Example (3) that given two topological spaces \( A \) and \( B \) we have a natural identification

\[
\text{Mor}(A \times [0,1], B) = \text{Mor}(A, B^{[0,1]}).
\]

Thus (with a few other more or less mysterious changes) the previous challenge diagram translates into the following challenge diagram:

\[
\begin{array}{ccc}
X & \xrightarrow{\times (x,0)} & X \times [0,1] \\
\downarrow_{f} & & \downarrow_{i} \\
Y & \xleftarrow{f} & A \times [0,1].
\end{array}
\]

But this challenge diagram looks familiar: it is precisely the diagram that appears in the definition of a cofibration.

More precisely, if we consider this map in the category of sets, then it is obviously a bijection. Proposition 5.6 shows that the map \( f \) on the left is continuous if and only if the corresponding map on the right is continuous. This shows that we also have a bijection between the sets of continuous maps, i.e. between the sets of morphisms in the category of topological spaces.
We conclude this chapter with three quotes:

(1) “In the mathematical disciplines of algebraic topology and homotopy theory, Eckmann–Hilton duality in its most basic form, consists of taking a given diagram for a particular concept and reversing the direction of all arrows [...]”

(2) “Eckmann–Hilton duality can be extremely helpful as an organizational principle, reducing significantly what one has to remember, and providing valuable hints on how to proceed in various situations.”

(3) “In mathematics [...] currying is the technique of translating the evaluation of a function that takes multiple arguments into evaluating a sequence of functions, each with a single argument. For example, a function that takes two arguments, one from X and one from Y, and produces outputs in Z, by currying is translated into a function that takes a single argument from X and produces as outputs functions from Y to Z.”

So we see that in the above discussion we performed Eckmann-Hilton duality combined with some currying.

Exercises for Chapter 112.

Exercise 112.1. Show that the projection map

\[ \overline{B}^2 \to \overline{B}^1 = [-1, 1] \]

\[(x, y) \mapsto x\]

is a Serre fibration.

Exercise 112.2. Let \( n \in \mathbb{N}_0 \) and let \( x_0 \) be a point on \( S^n \). It follows from Proposition 5.4 that the map

\[ e: P(S^n, x_0) \to S^n \]

\[ \{ f: [0, 1] \to S^n \mid f(0) = x_0 \} \mapsto f(1) \]

is continuous. For which \( n \in \mathbb{N}_0 \) does \( e \) admit a left-inverse?

Exercise 112.3. We consider the map \( f: S^1 \to [-1, 1] \) that is given by the projection onto the x-coordinate. We define the mapping path fibration \( q: P_f \to [-1, 1] \) as in Proposition 112.17. Show that for each \( y \in [-1, 1] \) the preimage \( q^{-1}(y) \) admits a deformation retraction to a circle.

Remark. See Figure 1581 for an illustration of the mapping path fibration.
Exercise 112.4. Let \((X, x_0)\) be a pointed topological space and let \(n \in \mathbb{N}\). Show “with your bare hands” that the map
\[
\partial_n \colon \pi_n(X, x_0) \xrightarrow{\cong} \pi_{n-1}(\Omega(X, x_0), c_{x_0})
\]
\[
[f : ([0, 1]^n, \partial([0, 1]^n)) \to (X, x_0)] \mapsto \begin{bmatrix}
([0, 1]^{n-1}, \partial([0, 1]^{n-1})) \to (\Omega(X, x_0), c_{x_0}) \\
x \mapsto \left(0 \to X, t \mapsto f(x, t)\right)
\end{bmatrix}
\]
is a natural isomorphism.

Remark. This is of course the statement of Corollary 112.15.

Exercise 112.5. Let \((X, x_0)\) be a pointed topological space. In Corollary 112.15 we give for any \(n \geq 1\) a natural isomorphism
\[
\pi_n(X, x_0) \xrightarrow{\cong} \pi_{n-1}(\Omega(X, x_0), c_{x_0}).
\]
What does this statement mean for \(n = 1\)? It seems to say that \(\pi_0(\Omega(X, x_0), c_{x_0})\) admits a natural group structure. Can you define such a natural group structure without using the above isomorphism?

Exercise 112.6. Convince yourself, without using Corollary 112.15, that the loop in the pointed topological space \((\Omega(S^2, N), c_N)\) that is shown in Figure 1580 is not null-homotopic.

Exercise 112.7. Let \(X\) be a topological space and let \(x_0 \in X\) be a base point. Recall that the loop space \(\Omega(X, x_0)\) is defined as the set \(\Omega(X, x_0) = \{f \in X^{[0,1]} | f(0) = f(1) = x_0\}\) together with the compact-open topology. We denote by \(\sim\) the equivalence relation on \(\Omega(X, x_0)\) given by homotopy of paths. By definition we have \(\pi_1(X, x_0) = \Omega(X, x_0)/\sim\). We equip \(\pi_1(X, x_0)\) with the quotient topology. We can thus view \(\pi_1(X, x_0)\) as a topological space. Show that \(\pi_1(S^1, 1)\) is a discrete topological space.

Hint. It is possibly easier to show that for any pointed topological space \((X, x_0)\) that admits a universal covering the fundamental group \(\pi_1(X, x_0)\) is a discrete topological space.

Remark. There are examples of pointed topological spaces for which \(\pi_1(X, x_0)\) is not a discrete topological space. For example the fundamental group of the Hawaiian Earrings, introduced in Exercise 25.1, is not a discrete topological space. We refer to Fab05, Fab11 for details.

Exercise 112.8.

(a) Show that there is no functor
\[
\Phi : \text{category of pointed topological spaces} \to \text{category of pointed topological spaces}
\]
which admits for every \(n \in \mathbb{N}\) a natural isomorphism
\[
\pi_n(X, x_0) \xrightarrow{\cong} \pi_{n+1}(\Phi(X, x_0)).
\]

(b) Show that there is no functor
\[
\Psi : \text{category of topological spaces} \to \text{category of topological spaces}
\]
which admits for every $n \in \mathbb{N}$ a natural isomorphism
\[ \tilde{H}_n(X) \cong H_{n-1}(\Psi(X)). \]

Hint. In Exercise [43.4] (b) we proved the following statement. If $X$ is a topological space with $\tilde{H}_0(X) \cong \mathbb{Z}$, then given any map $f: X \to X$ the induced map $f_*$ on $\tilde{H}_0(X)$ is given by multiplication by some $\epsilon \in \{-1, 0, 1\}$. 
113. FIBER BUNDLES

In this chapter we will introduce fiber bundles. For us they will be the most important source of fibrations. In this and the following chapter one of our favorite games will be to find more and more fiber bundles to obtain lots of non-trivial information on homotopy groups of various topological spaces.

113.1. The definition of fiber bundles. The following proposition says that being a Serre fibration is a “local property”.

**Proposition 113.1.** Let \( p: Y \to B \) be a map between topological spaces. If for every \( b \in B \) there exists an open neighborhood \( U \) of \( b \) such that \( p^{-1}(U) \to U \) is a Serre fibration, then \( p: Y \to B \) itself is a Serre fibration.

**Proof.** Let \( p: Y \to B \) be a map between topological spaces. In this proof we say \( U \subset B \) is small if \( p^{-1}(U) \to U \) is a Serre fibration.

Now assume that \( p: Y \to B \) has the property that \( B \) can be covered by small sets. We want to show that this hypothesis implies that the map \( p: Y \to B \) is a Serre fibration. Therefore let \( n \in \mathbb{N}_0 \), let \( F: \overline{B}^n \times [0, 1] \to B \) and let \( \tilde{f}: \overline{B}^n \times \{0\} \to Y \) be maps such that the rectangle in the following diagram commutes:

\[
\begin{array}{ccc}
\overline{B}^n \times \{0\} & \xrightarrow{\tilde{f}} & Y \\
\downarrow{\cong} & & \downarrow{p} \\
\overline{B}^n \times [0, 1] & \xrightarrow{F} & B.
\end{array}
\]

We need to show that there exists a diagonal map \( \tilde{F}: \overline{B}^n \times [0, 1] \to Y \) such that the above diagram commutes.

**Claim.** There exists a CW-structure \( X \) on \( \overline{B}^n \) and real numbers \( 0 = s_0 < s_1 < \cdots < s_k = 1 \) such that for each cell \( e \) of \( X \) and each \( i \in \{0, \ldots, k-1\} \) the image \( F(e \times [s_i, s_{i+1}]) \) is small.

By Lemma 41.1 we can identify \( \overline{B}^n \) with \([0, 1]^n\). Since \( B \) is by hypothesis covered by small open subsets and since any subset of a small set is again small we obtain from
Corollary 2.76 that there exists a \( k \in \mathbb{N} \) such that each
\[
F\left( \left[ \frac{a_1}{k}, \frac{a_1+1}{k} \right] \times \ldots \times \left[ \frac{a_n}{k}, \frac{a_n+1}{k} \right] \times \left[ \frac{a_{n+1}}{k}, \frac{a_{n+1}+1}{k} \right] \right)_{c=0,1}^{c=B^n}
\]
is small for all \( a_1, \ldots, a_{n+1} \in \{0, \ldots, k-1\} \). We equip \([0,1]^n = B^n\) with the CW-structure defined on page 962 given by the “subcubes” of side length \( \frac{1}{k} \). Furthermore we set \( s_i = \frac{i}{k}, i = 0, \ldots, k \). By design this CW-structure and this choice of \( s_i \) has the desired properties.

We continue with the following claim.

Claim. Let \( i \in \{0, \ldots, k - 1\} \). Given a map \( \tilde{F}_i : B^n \times \{s_i\} \to Y \) with \( p \circ \tilde{F}_i = F|_{B^n \times \{s_i\}} \) there exists a map \( \tilde{F}_{i+1} : B^n \times [s_i, s_{i+1}] \to Y \) such that the following diagram commutes:

\[
\begin{array}{ccc}
B^n \times \{s_i\} & \xrightarrow{\tilde{F}_i} & Y \\
\downarrow & & \downarrow p \\
B^n \times [s_i, s_{i+1}] & \xrightarrow{\tilde{F}_{i+1}} & B.
\end{array}
\]

In fact the claim follows immediately from the argument of the proof of Proposition 112.8 applied to the CW-complex \( K := X = B^n \) and the subcomplex \( L = \emptyset \). Indeed, in the proof of Proposition 112.8 we did not need to assume that \( p : Y \to B \) is a Serre fibration, all we ever used is that for every cell \( e \) of \( B \) the image \( F(e) \) is small in the above sense. But in our present setting this is guaranteed by our choice of the CW-structure on \( B^n \).

We set \( \tilde{F}_0 = \tilde{f}_0 : B^n \times \{0\} \to Y \). Iteratively applying the previous claim we obtain maps \( \tilde{F}_i : B^n \times [s_i, s_{i+1}] \to Y \) that agree on the overlaps of the domains. By Lemma 14.3 all these maps together define a continuous map \( \tilde{F} : B^n \times [0,1] \to Y \) which by construction has the desired properties.

As we saw on page 2643 every projection \( p : B \times F \to B \) is a (Serre) fibration. This observation, together with Proposition 113.1 leads us naturally to the following definition.

**Definition.** Let \( F \) be a topological space.

1. A map \( p : Y \to B \) between two topological spaces is called an \( F \)-bundle over \( B \) if given any \( b \in B \) there exists an open neighborhood \( U \) of \( b \) and a homeomorphism \( \Phi : p^{-1}(U) \to U \times F \) such that the following diagram commutes:

\[
\begin{array}{ccc}
p^{-1}(U) & \xrightarrow{\Phi} & U \times F \\
p \downarrow & & \downarrow (x,f) \mapsto x \\
U.
\end{array}
\]

Alternatively we call such a map \( p : Y \to B \) a bundle projection with fiber \( F \). As for fibrations we sometimes refer to \( B \) as the base space and to \( Y \) as the total space. Furthermore we refer to the map \( p : Y \to B \) as the projection.
We say that two $F$-bundles $p: Y \to B$ and $q: Z \to B$ are equivalent if there exists a homeomorphism $f: Y \to Z$ such that the following diagram commutes:

$$
\begin{array}{ccc}
Y & \xrightarrow{f} & Z \\
p \downarrow & & \downarrow q \\
B & & B
\end{array}
$$

The following proposition will be the incarnation of Theorem 112.7 that we will use most often.

**Proposition 113.2.** Let $p: Y \to B$ be a fiber bundle with fiber $F$.

1. The map $p: Y \to B$ is a Serre fibration.
2. We pick $y_0 \in Y$ and we write $b_0 = p(y_0)$. We pick an identification $F \cong p^{-1}(b_0)$. We denote by $i: F = p^{-1}(b_0) \to Y$ the inclusion. We use the fact from (1) that $p: Y \to B$ is a Serre fibration to define maps $\partial_n: \pi_n(B,b_0) \to \pi_{n-1}(F,y_0)$, $n \in \mathbb{N}$, as in Theorem 112.7. The following sequence is exact:

$$
\cdots \xrightarrow{\partial_{n+1}} \pi_n(F,y_0) \xrightarrow{i_*} \pi_n(Y,y_0) \xrightarrow{p_*} \pi_n(B,b_0) \xrightarrow{\partial_n} \pi_{n-1}(Y,y_0) \xrightarrow{\partial_{n-1}} \cdots \xrightarrow{p_*} \pi_1(B,b_0) \xrightarrow{\partial_1} \pi_0(F,y_0) \xrightarrow{i_*} \pi_0(Y,y_0) \xrightarrow{p_*} \pi_0(B,b_0).
$$

3. If we are given a commutative diagram

$$
\begin{array}{ccc}
Y' & \xrightarrow{g} & Y \\
p' \downarrow & & \downarrow p \\
B' & \xrightarrow{f} & B
\end{array}
$$

where $p': Y' \to B'$ is a fiber bundle with fiber $F'$, then given any base point $y_0' \in Y'$ the obvious diagram of the long exact sequences of homotopy groups corresponding to the fiber bundles $p: Y \to B$ and $p': Y' \to B'$ is commutative.

4. If the fiber $F$ and the base space $B$ are path-connected, then the total space $Y$ is also path-connected.

**Proof.**

1. This part of the proposition is an immediate consequence of the definitions, Proposition 113.1 and the discussion on page 2643.
2. The second statement follows immediately from (1) and Theorem 112.7 (2).
3. This statement follows easily from Theorem 112.7 (1b).
4. This statement follows immediately from (2). 

Proposition 113.2 sparks our interest in fiber bundles. Fortunately, in the following discussion we will see that fiber bundles are ubiquitous and can be found throughout the notes.

**Examples.**
(1) For any two topological spaces $B$ and $F$ the projection map $p: B \times F \to B$ onto the first factor is evidently a fiber bundle with fiber $F$. Any $F$-bundle that is equivalent to such a bundle is called trivial, otherwise it is called non-trivial.

(2) The “obvious projection map” from the Möbius band to the circle $S^1$, i.e. the map
\[ Y = ([0, 1] \times [-1, 1])/(0, y) \sim (1, -y) \to S^1 (x, y) \mapsto e^{2\pi ix} \]
is easily seen to be a fiber bundle with fiber $[-1, 1]$. Since the Möbius band is not homeomorphic to the trivial bundle $S^1 \times [-1, 1]$ we see that the bundle is non-trivial.

(3) The same argument as in (2) shows that the Klein bottle is a non-trivial $S^1$-bundle over $S^1$. In Lemma 8.33 (1) we saw that the connected sum $\mathbb{R}P^2 \# \mathbb{R}P^2$ is homeomorphic to the Klein bottle. We have thus shown that $\mathbb{R}P^2 \# \mathbb{R}P^2$ is a non-trivial $S^1$-bundle over $S^1$. Amusingly an analogous statement holds in dimension four, namely the connected sum $\mathbb{C}P^2 \# \mathbb{C}P^2$ is a non-trivial $S^2$-bundle over $S^2$. It is a challenging exercise to prove this fact by hand, alternatively a proof can be found in [GoS99, p. 107] or [Scor05, p. 124]. Similarly, one can show that the connected sum $\mathbb{H}P^2 \# \mathbb{H}P^2$ is a non-trivial $S^4$-bundle over $S^4$.

(4) An $n$-dimensional vector bundle $p: W \to B$, in the sense of the definition on page ??, is by definition an $\mathbb{R}^n$-bundle over $B$.

We consider the next example in greater detail.

**Lemma 113.3.**

(1) Let $X$ be a topological space and let $f: X \to X$ be a homeomorphism. The natural projection
\[ \text{Tor}(X, f) = ([0, 1] \times X)/(0, x) \sim (1, f(x)) \quad [\{t\} \times V] \mapsto \{t\} = e^{2\pi i t} \]
is an $X$-bundle over $S^1$.

(2) Let $X$ be a topological space and let $f_0, f_1: X \to X$ be two homeomorphisms. If $f_0$ and $f_1$ are isotopic, then the two $X$-bundles $\text{Tor}(X, f_0) \to S^1$ and $\text{Tor}(X, f_1) \to S^1$ are equivalent.

(3) Let $V$ be an $n$-dimensional real vector space and let $\varphi: V \to V$ be an isomorphism of vector spaces. We equip $V$ with the topology given on page 116. For each $t \in [0, 1)$ we equip $\{t\} \times V \subset M(V, \varphi)$ with the obvious vector space structure. This turns the projection map $M(V, \varphi) \to S^1$ into an $n$-dimensional vector bundle.

**Proof.**

(1) We denote by $\pi: [0, 1] \to [0, 1]/0 \sim 1$ the obvious projection map. We consider the two open sets $U_1 := \pi((1/4, 2/3))$ and $U_2 := \pi([0, 1/3] \cup (2/3, 1])$ in $[0, 1]/0 \sim 1$. Furthermore
Examples.

More precisely, the question arises whether every self-homeomorphism of the trefoil and the complement of the figure-8 knot is a fiber bundle over $S^1$. Of course, there are many other knots, for example consider the stevedore knot shown in Figure 1586.

The following question arises:

**Question 113.4.** Is the complement of the stevedore knot a fiber bundle over $S^1$?

We continue with more examples of fiber bundles.
Lemma 113.5. Let \( g: C \to B \) be a map between topological spaces and let \( p: Y \to B \) be a fiber bundle with fiber \( F \). As in Lemma 25.16 (1) we consider the pullback

\[
g^*Y := \{(c, f) \mid c \in C \text{ and } f \in p^{-1}(g(c))\} \subset C \times Y,
\]

which is equipped with the subspace topology. Then the map

\[
g: g^*Y \to Y: (c, f) \mapsto g(c)
\]

is also an \( F \)-bundle.
Proof. The proof is, not surprisingly, also almost identical to the proof of Lemma 113.5.

Remark. The pullback of bundles satisfies basically the same statements as the pullback of vector bundles, see Lemma 113.5. There is surely no need to spell out these properties again.

The following lemma classifies bundles over compact intervals \([a,b]\) and also over the circle \(S^1\).

**Lemma 113.6.**

1. Every bundle over a compact interval \([a,b]\) is trivial.
2. If \(p : Y \to S^1\) is a fiber bundle with fiber \(X\), then there exists a homeomorphism \(f : X \to X\) such that \(p\) is equivalent to the above fiber bundle \(\text{Tor}(X,f) \to S^1\).

**Sketch of proof.**

1. This statement will be proved in Exercise 113.2.
2. Suppose we are given a fiber bundle \(p : Y \to S^1\) with fiber \(X\). Let \(\varphi : [0,2\pi] \to S^1\) be the map that is given by \(\varphi(t) = e^{it}\). It follows from (1) that the pullback bundle

\[
q : \varphi^*Y = \{(t,v) \in [0,2\pi] \times Y \mid v \in p^{-1}(\varphi(t))\} \to [0,2\pi]
\]

is trivial, i.e. there exists a homeomorphism \(\Phi : [0,2\pi] \times X \to \varphi^*Y\) such that the following diagram commutes

\[
\begin{array}{ccc}
[0,2\pi] \times X & \xrightarrow{\Phi} & \varphi^*Y \\
\downarrow{(t,x) \mapsto t} & & \downarrow{q} \\
[0,2\pi] & & \\
\end{array}
\]

We define \(f : X \to X\) to be the homeomorphism that is given by

\[
\varphi(0) = 1 = \varphi(2\pi)
\]

\[
X \xrightarrow{x \mapsto (0,x)} \{0\} \times X \xrightarrow{\Phi} q^{-1}(0) \xrightarrow{p^{-1}(1)} \leftarrow q^{-1}(2\pi) \xleftarrow{\Phi} \{2\pi\} \times X \xrightarrow{(2\pi,x) \mapsto x} X.
\]

We leave it as a mildly interesting exercise to the reader to verify that \(p : Y \to S^1\) is equivalent to the fiber bundle \(\text{Tor}(X,f) \to S^1\).

For the record we mention the following generalization of Lemma 113.6 (1).

**Proposition 113.7.** Let \(X\) be a topological space. If \(X\) is paracompact and contractible, then every bundle over \(X\) is trivial.

**Proof.** The statement of the proposition is almost the same as the statement of Proposition 113.5 (3) for vector bundles. The reference we gave for vector bundles, namely [Hat2, Theorem 1.6], also applies to general bundles.
We conclude this section with an example that shows how the above results can be used in practice. Thus let \( n \in \mathbb{N} \) and \( K \) be a closed \( k \)-dimensional submanifold of the smooth manifold \( S^n \). We calculate that for \( i = 1, \ldots, n-k-2 \) we have

\[
H_i(S^n \setminus K; \mathbb{Z}) \cong H^{n-i-1}(K; \mathbb{Z}) = 0.
\]

The following proposition shows that not only do the first \( n-k-2 \) homology vanish, but the first \( n-k-2 \) homotopy groups also vanish.

**Proposition 113.8.** (*) Let \( n \in \mathbb{N} \) and let \( K \) be a closed \( k \)-dimensional submanifold of the smooth manifold \( S^n \). For \( i = 1, \ldots, n-k-2 \) we have \( \pi_i(S^n \setminus K) = 0 \).

**Example.** Let \( K \) be the trefoil in \( \mathbb{R}^3 \) and let \( \mu \subset \mathbb{R}^3 \) be a meridian as defined on page 390. (See also Figure 1588 to the left.) In Lemma 46.14 we saw that \( \mu \) represents a non-zero element in \( H_1(S^3 \setminus K) \). It follows from the naturality of the Hurewicz homomorphism, see Proposition 52.2 (4), that \( \mu \) also represents a non-trivial element in \( \pi_1(S^3 \setminus K) \). The usual smooth embedding \( \mathbb{R}^3 \to \mathbb{R}^3 \times \{0\} \to \mathbb{R}^4 \) we can view \( K \) and \( \mu \) as submanifolds of \( S^4 = \mathbb{R}^4 \cup \{\infty\} \). By Proposition 113.8 we have \( \pi_1(S^4 \setminus K) = 0 \). In particular we obtain that \( \mu \) is trivial in \( \pi_1(S^4 \setminus K) \). In fact in Figure 1588 we show an embedded disk \( D \) in \( \mathbb{R}^4 \subset S^4 \) whose boundary is given by \( \mu \) and that does not intersect \( K \). Here we use the convention from page 437 i.e. “pinkness” of a point measures how large is the fourth coordinate.

![Figure 1588](image-url)

**Proof (⋆).** Let \( n \in \mathbb{N} \) and \( K \) be a closed \( k \)-dimensional submanifold of the smooth manifold \( S^n \). If \( n-k-2 \leq 0 \), then there is nothing to prove. Thus we assume that \( n-k-2 \geq 1 \), i.e. we assume that \( n \geq k+3 \).

We want to show that \( \pi_i(S^n \setminus K) = 0 \) for \( i = 1, \ldots, n-k-2 \). We already know that the corresponding homology groups vanish. Thus by Corollary 53.7 it suffices to show that \( \pi_1(S^n \setminus K) = 0 \). That is precisely what we will do in the remainder of this proof.

In the following we consider the case that \( K \) is connected. We leave it to the reader to modify the proof to deal with the case that \( K \) is disconnected. By the General Tubular Neighborhood Theorem 10.5 the closed submanifold \( K \) admits a tubular neighborhood \( p: \hat{W} \to K \). Recall that \( \hat{W} \) is a compact \( n \)-dimensional submanifold of \( S^n \) and that \( p \) is in particular a \( \overline{B}^{n-k} \)-bundle over \( K \). As we pointed out on page 2684 the projection \( p: \partial\hat{W} \to K \) is an \( S^{n-k-1} \)-bundle.

We write \( X = S^n \setminus \hat{W} \). By Proposition 10.11 and Lemma 10.1 we know that \( \pi_1(S^n \setminus K) \) is isomorphic to \( \pi_1(X) \). Thus it suffices to show that \( X \) is simply connected.
By Proposition 6.30 we know that $X$ is a compact $n$-dimensional submanifold of $S^n$ with $W \cap X = \partial W = \partial X$. From Proposition 113.2 (4) we know that $\partial W$ is connected. We pick a base point $x_0 \in \partial W$. By the Seifert–van Kampen Theorem 22.2 for smooth manifolds we know that the inclusion induced map 

$$\pi_1(X, x_0) \ast_{\pi_1(\partial W, x_0)} \pi_1(W, x_0) \to \pi_1(S^n, x_0)$$

is an isomorphism. We recall that Lemma 21.22 says that $A * G \cong A$. Thus, if we want to show that $\pi_1(X, x_0) = 0$ it follows from Lemma 21.22 that it suffices to prove the following claim.

Claim. The inclusion induced map $\pi_1(\partial W, x_0) \to \pi_1(W, x_0)$ is an isomorphism.

We denote both of the inclusions $\partial W \to W$ and $S^{n-k-1} \to \overline{B}^{n-k}$ by $i$. We have a commutative diagram

$$\begin{array}{ccc}
\partial W & \xrightarrow{i} & W \\
\downarrow & & \downarrow \\
K & \xrightarrow{i} & K
\end{array}$$

of fiber bundles with fibers $S^{n-k-1}$ and $\overline{B}^{n-k}$. From Proposition 113.2 (3) we obtain the following commutative diagram of long exact sequences of morphisms between pointed sets:

$$\begin{array}{ccc}
\ldots & \xrightarrow{\partial} & \pi_2(K) \xrightarrow{i_*} \pi_1(S^{n-k-1}) \xrightarrow{\partial} \pi_1(\partial W) \xrightarrow{i_*} \pi_1(K) \xrightarrow{\partial} \pi_0(S^{n-k-1}) \xrightarrow{i_*} \ldots \\
\downarrow & = & \downarrow \\
\ldots & \xrightarrow{\partial} & \pi_2(K) \xrightarrow{i_*} \pi_1(\overline{B}^{n-k}) \xrightarrow{i_*} \pi_1(W) \xrightarrow{\partial} \pi_1(K) \xrightarrow{\partial} \pi_0(\overline{B}^{n-k}) \xrightarrow{i_*} \ldots
\end{array}$$

Since $n - k \geq 3$ we have $n - k - 1 \geq 2$, thus $\pi_1(S^{n-k-1}) = 0$ by Proposition 14.14. It follows from a slight generalization of the Five Lemma 43.12 that the middle vertical map $i_*: \pi_1(\partial W) \to \pi_1(W)$ is an isomorphism. 

Remark. We want to sketch an alternative approach to proving Proposition 113.8. Thus let $n \in \mathbb{N}$, let $K$ be a closed $k$-dimensional submanifold of the smooth manifold $S^n$ and finally let $i \in \{1, \ldots, n-k-2\}$. We want to show that $\pi_i(S^n \setminus K, x_0) = 0$ for some base point $x_0 \in S^n \setminus K$. Let $[\varphi: (S^i, *) \to (S^n \setminus K, x_0)] \in \pi_i(S^n \setminus K, x_0)$ be a random element. We make the following observations:

1. By the Whitney Approximation Theorem 9.3 we can assume that $\varphi$ is smooth.
2. Since $i \neq n$ we know that $\pi_i(S^n, x_0) = 0$. It follows from Lemma 40.4 that there exists a map $\psi: \overline{B}^{i+1} \to S^n$ with $\psi|_{S^i} = \varphi$.
3. Once again, by the Whitney Approximation Theorem 9.3 we can assume that $\psi$ is also smooth.

More precisely, if one goes through the proof of the Five Lemma 43.12, then one realizes that it suffices that the right most vertical map is an injective morphism of pointed sets, i.e. the right most vertical map does not need to be a homomorphism of groups.
Since \( k+i+1 < n \) one would like to argue, similar to the Transversality Theorem 9.10 that we can homotop \( \psi \) rel \( S^i \) to a map that does not intersect \( K \), i.e., we would like to homotop \( \psi \) rel \( S^i \) to a map \( B^{i+1} \rightarrow S^n \setminus K \). By Lemma 40.4 this would then imply that \([\varphi] = 0 \in \pi_i(S^n \setminus K, x_0)\).

This approach can be turned into a proper proof, but we will not do so.

113.2. Hopf fibrations arising from complex and quaternionic projective spaces.

In this section we will see that the complex projective spaces \( \mathbb{C}P^n \) and the quaternionic projective spaces \( \mathbb{H}P^n \) give rise to interesting fiber bundles. In particular we will see that the Hopf map \( S^3 \rightarrow S^2 \) that we introduced on page 1071 is in fact an \( S^1 \) bundle.

In the following we introduce two straightforward higher-dimensional analogues of the original Hopf map.

**Definition.** Let \( n \in \mathbb{N} \). We refer to the maps
\[
p: S^{2n+1} = \{(z_0, \ldots, z_n) \in \mathbb{C}^{n+1} \mid |z_0|^2 + \cdots + |z_n|^2 = 1\} \rightarrow \mathbb{C}P^n
\]
and
\[
q: S^{4n+3} = \{(h_0, \ldots, h_n) \in \mathbb{H}^{n+1} \mid |h_0|^2 + \cdots + |h_n|^2 = 1\} \rightarrow \mathbb{H}P^n
\]
as **Hopf maps**.

The following proposition, together with Proposition 113.2, explains our interest in the Hopf maps.

**Proposition 113.9.** Let \( n \in \mathbb{N} \).

1. The Hopf map \( p: S^{2n+1} \rightarrow \mathbb{C}P^n \) is an \( S^1 \)-bundle.
2. The Hopf map \( q: S^{4n+3} \rightarrow \mathbb{H}P^n \) is an \( S^3 \)-bundle.

**Proof.** We only provide the proof of (2). The proof of (1) is a straightforward modification of the proof of (2). Given \( j \in \{0, \ldots, n\} \) we define
\[
V_j := \{[h_0 : \cdots : h_n] \in \mathbb{H}P^n \mid h_j \neq 0\}.
\]
The same argument as in the proof of Lemma 12.5 shows that \( V_j \) is an open subset of \( \mathbb{H}P^n \).

**Claim.** The map
\[
\Phi_j: q^{-1}(V_j) = \{(h_0, \ldots, h_n) \in \mathbb{H}^{n+1} \mid \sum_{i=0}^{n} |h_i|^2 = 1 \text{ and } h_j \neq 0\} \rightarrow V_j \times S^3
\]
\[
(h_0, \ldots, h_n) \mapsto ([h_0 : \cdots : h_n], |h_j|^{-1}h_j)
\]
is a homeomorphism.
We consider the map
\[
\Psi_j : V_j \times S^3 \to q^{-1}(V_j)
\]
\[
([h_0 : \cdots : h_j : \cdots : h_n], u) \mapsto \text{the normalization to length one of the non-zero vector (} u \cdot h_j^{-1} : h_0, \ldots, u \cdot h_j^{-1} \cdot h_j, \ldots, u \cdot h_j^{-1} \cdot h_n) \in \mathbb{H}^{n+1}.
\]

This map \(\Psi_j\) is well-defined. Indeed, a short calculation shows that if we pick a different representative for \([h_0 : \cdots : h_n]\), i.e., if we plug in \([\lambda : h_0 : \cdots : n]\) for some \(\lambda \in \mathbb{H} \setminus \{0\}\) then we obtain the same result. Using Lemma 3.22 one can show that the map \(\Psi_j\) is continuous. One easily verifies that \(\Psi_j\) and \(\Phi_j\) are inverses of one another.

It is clear that the open sets \(V_j\) cover all of \(\mathbb{H}P^n\) and that the triangles
\[
\begin{array}{ccc}
q^{-1}(V_j) & \xrightarrow{\Phi_j} & V_j \times S^3 \\
\downarrow q & & \downarrow \text{(v,h)→h} \\
S^3 & \xrightarrow{\pi} & S^3\end{array}
\]
commute. This shows, according to the definition on page 2680, that \(q : S^{4n+3} \to \mathbb{H}P^n\) is an \(S^3\)-bundle.

Proposition 113.9 combined with Proposition 113.2 gives us two interesting theorems.

**Theorem 113.10.**

(1) For all \(n \geq 3\) we have \(\pi_n(S^3) \cong \pi_n(S^2)\).

(2) We have \(\pi_3(S^2) \cong \mathbb{Z}\) and \(\pi_3(S^3)\) is generated by the Hopf map \(S^3 \to S^2\).

The second statement gives in particular an answer to Question 91.15 (1).

**Proof.**

(1) On page 197 we gave an identification of \(\mathbb{C}P^1\) with \(S^2\). Thus Proposition 113.9 (1), applied to \(n = 1\), tells us that the Hopf map \(p : S^3 \to S^2 = \mathbb{C}P^1\) defines an \(S^1\)-bundle. Proposition 113.2 gives us the long exact sequence
\[
\cdots \to \pi_n(S^1) \to \pi_n(S^3) \xrightarrow{p_\ast} \pi_n(S^2) \xrightarrow{\partial} \pi_{n-1}(S^1) \to \pi_{n-1}(S^3) \to \cdots
\]

The desired statement now follows from the example on page 1068 where we saw that \(\pi_k(S^1) = 0\) for \(k \geq 2\).

(2) In Corollary 53.6 (1) we saw that \(\pi_3(S^3) = \mathbb{Z} \cdot [\text{id}_{S^3}]\). By (1) the Hopf map \(p : S^3 \to S^2 = \mathbb{C}P^1\) induces an isomorphism \(p_\ast : \pi_3(S^3) \xrightarrow{\cong} \pi_3(S^2)\). The image of \([\text{id}_{S^3}]\) under \(p_\ast\) is the generator of \(\pi_3(S^2)\).

\textit{Note though that the order of the factors in the definition of \(\Psi_j\) is important since \(\mathbb{H}\) is not commutative.}

\textit{It is actually worth having a glance at the lower end of this sequence. We have the exact sequence}
\[
\pi_2(S^3) \xrightarrow{p_\ast} \pi_2(S^2) \xrightarrow{\partial} \pi_1(S^1) \to \pi_1(S^3).
\]

From Proposition 10.10 we know that \(\pi_1(S^3) = \pi_2(S^3) = 0\) and Proposition 16.17 we know that \(\pi_1(S^1) \cong \mathbb{Z}\). Thus we obtain that \(\pi_2(S^2) \cong \mathbb{Z}\). In Exercise 113.12 we will see that using this exact sequence we can obtain a new proof that \(\text{id}_{S^2}\) is a generator of \(\pi_2(S^2)\).
\begin{proof}
(1) By Lemma 60.9 (2) we can identify the quaternionic projective space $\mathbb{H}P^1$ with $S^4$. Therefore if we apply Proposition 113.9 (2) with $n = 1$ we obtain an $S^3$-bundle $q: S^7 \to \mathbb{H}P^1 = S^4$. We pick $y_0 \in S^7$ and we write $b_0 = q(y_0)$. We pick an identification $S^3 = q^{-1}(b_0)$ and we denote by $i: S^3 \to S^7$ the map that is given by the inclusion of the fiber $F = S^3$ into $S^7$. From Proposition 113.2 we obtain the following long exact sequence

\[ \cdots \to \pi_n(S^3, y_0) \xrightarrow{i_*} \pi_n(S^7, y_0) \xrightarrow{q_*} \pi_n(S^4, b_0) \xrightarrow{\partial} \pi_{n-1}(S^3, y_0) \xrightarrow{i_*} \pi_{n-1}(S^7, y_0) \to \cdots. \]

By Proposition 40.10 we know that $\pi_3(S^7, y_0) = 0$. By definition this implies that the map $i: S^3 \to S^7$ is homotopic rel $y_0$ to the constant map $c_{y_0}: S^3 \to \{y_0\}$. By Theorem 112.7 (3) this implies that the above long exact sequence splits into short exact sequences

\[ 0 \to \pi_n(S^7, y_0) \xrightarrow{i_*} \pi_n(S^4, b_0) \xrightarrow{\partial} \pi_{n-1}(S^3, y_0) \to 0. \]

Furthermore Theorem 112.7 (3) says that these short exact sequences split, therefore we obtain the promised isomorphisms $\pi_n(S^4, b_0) \cong \pi_n(S^7, y_0) \oplus \pi_{n-1}(S^3, y_0)$.

(2) The statement holds trivially Proposition 40.10 for $n = 1$. For $n \geq 2$ this statement follows from (1) and Proposition 40.10 which says in this context that $\pi_n(S^7) = 0$ for $n = 1, \ldots, 6$.

As we will see, Proposition 113.2 is a goose that just cannot stop laying golden eggs. For example we have the following theorem.

**Theorem 113.12.** We use the homeomorphism from page 197 to make the identification $\mathbb{C}P^1 = S^2$ and as on page 194 we view $\mathbb{C}P^1$ as a subset of each $\mathbb{C}P^n$ and of $\mathbb{C}P^\infty$.

(1) Let $n \in \mathbb{N}$. We denote by $p: S^{2n+1} \to \mathbb{C}P^n$ the Hopf map from page 2688. We have

\[ \pi_k(\mathbb{C}P^n) = \begin{cases} 
\mathbb{Z} \cdot [\text{id}_{\mathbb{C}P^n}], & \text{if } k = 2, \\
0, & \text{if } k = 1, 3, 4, 5, \ldots, 2n, \\
\mathbb{Z} \cdot [p], & \text{if } k = 2n + 1.
\end{cases} \]

(2) We have

\[ \pi_k(\mathbb{C}P^\infty) = \begin{cases} 
\mathbb{Z} \cdot [\text{id}_{\mathbb{C}P^\infty}], & \text{if } k = 2, \\
0, & \text{if } k = 1, 3, 4, 5, 6, \ldots.
\end{cases} \]
Remark. Let $k < l$. In Question 53.4 we had asked whether the complex projective space $\mathbb{C}P^k$ is a retract of $\mathbb{C}P^l$. In Proposition 90.14 we used the calculation of the cup product to give a negative answer. Now we can also use homotopy groups for the same purpose. More precisely, from Theorem 113.12, we obtain that $\pi_{2k+1}(\mathbb{C}P^k) \cong \mathbb{Z}$ but that $\pi_{2k+1}(\mathbb{C}P^l) = 0$. The usual argument, see Lemma 15.7 implies that once again we obtain a negative answer to Question 53.4, i.e. $\mathbb{C}P^k$ is not a retract of $\mathbb{C}P^l$.

Proof.

(1) By Proposition 113.9 (1) we know that for every $n \in \mathbb{N}$ the Hopf map $p : S^{2n+1} \to \mathbb{C}P^n$ is an $S^1$-bundle. Thus we obtain from Proposition 113.2 the following long exact sequence of homotopy groups:

$$
\ldots \to \pi_k(S^1) \to \pi_k(S^{2n+1}) \xrightarrow{p_*} \pi_k(\mathbb{C}P^n) \xrightarrow{\partial} \pi_{k-1}(S^1) \to \ldots
$$

We recall that $\pi_k(S^{2n+1}) = 0$ for $k = 1, \ldots, 2n$, that $\pi_{2n+1}(S^{2n+1}) \cong \mathbb{Z} \cdot [\text{id}_{S^{2n+1}}]$ and that $\pi_k(S^1) = 0$ for $k \geq 2$. Putting everything together implies immediately that $\pi_k(\mathbb{C}P^n) = 0$ for $k = 3, \ldots, 2n$ and that $\pi_{2n+1}(\mathbb{C}P^n) \cong \mathbb{Z} \cdot [p]$ Only the lower end of the long exact sequence requires slightly more thought. More precisely, we have the exact sequence

$$
\pi_2(S^{2n+1}) \to \pi_2(\mathbb{C}P^n) \xrightarrow{\partial} \pi_1(S^1) \to \pi_1(S^{2n+1}) \xrightarrow{\partial} \pi_1(\mathbb{C}P^n) \to \pi_0(S^1) \to \pi_0(S^{2n+1}).
$$

Since $S^1$ and $S^{2n+1}$ are path-connected we see that the map on the right is an isomorphism of pointed sets. It follows that $\pi_2(\mathbb{C}P^n) \cong \pi_1(S^1) \cong \mathbb{Z}$ and that $\pi_1(\mathbb{C}P^n) = 0$. (We had of course known the latter statement for a long time, see e.g. page 997.) The only thing which is not entirely clear from this argument is why $\text{id}_{\mathbb{C}P^1}$ represents a generator of $\pi_2(\mathbb{C}P^n)$. One could either heroically fight one’s way through the above isomorphism, in the same vein as in Exercise 113.12 and use that we know explicitly the generator of $\pi_1(S^1)$.

But fortunately we do not have to go down that route since in Corollary 53.6 (2) we already saw that $\text{id}_{\mathbb{C}P^1}$ represents a generator of $\pi_2(\mathbb{C}P^n)$.

(2) We calculate that

$$
\pi_k(\mathbb{C}P^\infty) = \pi_k\left( \bigcup_{n \in \mathbb{N}} \mathbb{C}P^n \right) = \lim_{\longrightarrow} \pi_k(\mathbb{C}P^n) = \left\{ \begin{array}{ll} \mathbb{Z} \cdot [\text{id}_{\mathbb{C}P^1}], & \text{if } k = 2, \\ 0, & \text{if } k = 1, 3, 4, 5, \ldots \end{array} \right.
$$

by Proposition 40.11 since, see Lemma 36.6 by (1)

we can view $\mathbb{C}P^\infty$ as a CW-complex where each $k$-skeleton is given by $\mathbb{C}P^n \subset \mathbb{C}P^\infty$.

113.3. The Hopf fibration arising from the octonions ($\ast$). In Proposition 113.9 we had in particular seen that the Hopf map $p : S^3 \to \mathbb{C}P^1 = S^2$ is an $S^1$-bundle and that the Hopf map $q : S^7 \to \mathbb{H}P^1 = S^4$ is an $S^3$-bundle. We exploited these fiber bundles in Theorems 113.10 and 113.11 to obtain non-trivial information on higher homotopy groups of spheres.

\footnote{Here we use the trivial, but useful observation that $p_*([\text{id}_{S^n}]) = [p]$.}
In our discussion of division algebras in Section 60.1, we gave the quaternions as a first example of a non-commutative division algebra. The algebra structure on the quaternions is still nonetheless quite reasonable, in particular the algebra structure is associative which was enough to define the quaternionic projective spaces on page 1472.

Next on the list of ever weirder division algebras were the octonions \( \mathbb{O} \) that we introduced on page 1465. Recall that the underlying vector space of the octonions is \( \mathbb{R}^8 \) but that this time the algebra structure is neither commutative nor associative. The only redeeming feature is that \( \mathbb{O} \) is still a division algebra.

Since the octonions are no longer associative one cannot just copy-paste the definition of the quaternionic projective spaces on page 1472 to define octonionic projective spaces in any obvious way. But we can make a prediction: if there was a first octonionic projective space, then it would presumably give rise to a Hopf fibration \( r: S^{15} \to \mathbb{O}P^1 = S^8 \) with fiber \( S^7 \). Alas, octonionic projective spaces do not exist. But as we will see, we can still use octonions to produce such a fiber bundle. More precisely, our goal in this section is to prove the following proposition.

**Proposition 113.13.** There exists a fiber bundle \( p: S^{15} \to S^8 \) with fiber \( S^7 \).

The proof of Proposition 113.13 is rather longish, thus we will first point out that it allows us to prove the following theorem.

**Theorem 113.14.**

1. For all \( n \geq 2 \) we have \( \pi_n(S^8) \cong \pi_n(S^{15}) \oplus \pi_{n-1}(S^7) \).
2. For \( n \in \{1,\ldots,14\} \) we have \( \pi_n(S^8) \cong \pi_{n-1}(S^7) \).

**Proof.** The proof is basically the same as the proof of Theorem 113.11. We just need to replace Proposition 113.9 (2) by Proposition 113.13. \( \blacksquare \)

We can copy-paste the remark after Theorem 113.11:

**Remark.** From Corollary 53.6 (1) we know that \( \pi_{15}(S^{15}) \cong \mathbb{Z} \). Thus it follows from Theorem 113.11 (1) that \( \pi_{15}(S^8) \) admits an epimorphism onto \( \mathbb{Z} \). In fact in Corollary 91.8 we already saw that the Hopf invariant is an epimorphism \( \pi_{15}(S^8) \to \mathbb{Z} \).

The remainder of this chapter is occupied with providing a proof of Proposition 113.13. We will need the notion of the join of two topological spaces that we introduced on page 207:

**Definition.** Let \( X \) and \( Y \) be two non-empty topological spaces. We define the join \( X \ast Y \) to be the topological space obtained from \( X \times [0,1] \times Y \), equipped with the product topology, by performing the following two types of identifications:

1. For every \( x \in X \) we identify all points in \( \{x\} \times \{0\} \times Y \) to a single point and
2. For every \( y \in Y \) we identify all points in \( X \times \{1\} \times \{y\} \) to a single point.

Furthermore, if one of \( X \) or \( Y \) is the empty topological space, then we define \( X \ast Y \) to be the other topological space.

We remind the reader of the following lemma.
Lemma 3.50. Given any \( m, n \in \mathbb{N}_0 \) the map
\[
S^m \ast S^n \to S^{m+n+1}
\]
\[
[(x, t, y)] \mapsto \left( x \cdot \cos \left( \frac{\pi t}{2} \right), y \cdot \sin \left( \frac{\pi t}{2} \right) \right)
\]
is a homeomorphism.

The following proposition explains our sudden interest in the join of two topological spaces.

**Proposition 113.15.** Let \( X \) be a topological space that is compact and Hausdorff. Furthermore let \( \varphi: X \times X \to X \) be a map. Given \( x \in X \) we consider the maps
\[
L_x: X \to X \quad \text{and} \quad R_x: X \to X
\]
\[
a \mapsto \varphi(x, a) \quad \text{and} \quad a \mapsto \varphi(a, x).
\]
If each map \( L_x: X \to X \) and each map \( R_x: X \to X \) is a homeomorphism, then the map
\[
h_\varphi: X \ast X \to \Sigma(X)
\]
\[
[(x, t, y)] \mapsto [(\varphi(x, y), 2t - 1)]
\]
is a fiber bundle with fiber \( X \).

**Example.** We write \( S^3 = \{ z \in \mathbb{H} | |z| = 1 \} \). By Lemma 60.1 (7) we know that for any \( w, z \in \mathbb{H} \) we have \( |w \cdot z| = |w| \cdot |z| \). Thus multiplication of quaternions defines a map \( \varphi: S^3 \times S^3 \to S^3 \). Given any \( z \in S^3 \) the map \( L_z \) is a homeomorphism. In fact an inverse is given by \( L_z^{-1} \) since for any \( x \in S^3 \) we have
\[
(L_z^{-1} \circ L_z)(x) = z^{-1} \cdot (z \cdot x) = (z^{-1} \cdot z) \cdot x = x,
\]
since \( \mathbb{H} \) is associative

and similarly we have \( L_z \circ L_z^{-1} = \text{id}_{S^3} \). The same argument shows that \( R_z \) is also a homeomorphism. Thus we obtain from Proposition 113.15 and Lemma 3.50 a fiber bundle \( p: S^7 \to S^4 \) with fiber \( S^3 \). We leave it to the heroically inclined reader to verify that this \( S^3 \)-bundle is equivalent to the \( S^3 \)-bundle \( q: S^7 \to \mathbb{HP}^1 = S^4 \) that we had constructed in the proof of Proposition 113.9.

**Proof.** We consider the following two subsets of \( \Sigma(X) \):
\[
C := \left( [-1, \frac{1}{2}] \times X \right) / \{-1\} \times X \quad \text{and} \quad D := \left( [-\frac{1}{2}, 1] \times X \right) / \{1\} \times X.
\]
We refer to Figure 1589 for an illustration. Since the interiors of these two sets cover \( \Sigma(X) \) it suffices to find trivializations of the map \( h_\varphi: X \ast X \to \Sigma(X) \) with fiber \( X \) over \( C \) and over \( D \).

We start out with finding a trivialization over \( C \).

**Claim.** The map
\[
\Psi: X \times C \to X \ast X
\]
\[
(x, [(y, t)]) \mapsto [(x, \frac{2}{3}(t + 1), L^{-1}_x(y))]
\]
Here the mnemonic device is that “L” should suggest “left-multiplication” and “R” should suggest “right-multiplication”.

It is a good exercise to first verify that the map is actually well-defined.
is continuous and it restricts to a homeomorphism onto $h^{-1}_\varphi(C)$.

By now the reader is surely aware of the fact that whenever we mix quotients with products we need to tread carefully. Thus let us first consider the maps

$$
\alpha: X \times X \to X \times X \\
(x, y) \mapsto (x, \varphi(x, y)) = (x, L_x(y))
$$

and

$$
\beta: X \times X \to X \times X \\
(x, y) \mapsto (x, L_x^{-1}(y)).
$$

Note that these two maps are inverses of one another. Also note that $\alpha$ is continuous by Lemma 3.8 (2b). Furthermore note that $\alpha$ is a bijection, in fact the inverse is given by $\beta$. Since $X$ is compact and Hausdorff we obtain from Proposition 3.12 and Proposition 2.43 (3) that $\alpha$ is a homeomorphism. In particular $\beta = \alpha^{-1}$ is also continuous.

Next we consider the map

$$
\psi: X \times ([-1, \frac{1}{2}] \times X) \to X \times [0, 1] \times X \\
(x, t, y) \mapsto (x, \frac{2}{3}(t+1), L_x^{-1}(y)).
$$

Since $\beta(x, y) = (x, L_x^{-1}(y))$ and since $\beta$ is continuous we see that $\psi$ is also continuous. Finally we consider the following commutative diagram

$$
\begin{array}{c}
X \times [-1, \frac{1}{2}] \times X \\
\downarrow \psi \\
X \times [0, 1] \times X \\
\end{array}
\xrightarrow{(x, t, y) \mapsto (x, 3(t+1), L_x^{-1}(y))}
\xrightarrow{f := p \circ \psi}
X \times X.
$$

Claim. The map $\Psi$ is continuous.

We had just seen that $f = p \circ \psi$ is continuous. Note that by Lemma 5.15 (1) the projection map $q: [-1, \frac{1}{2}] \times X \to ([-1, \frac{1}{2}] \times X) / \{-1\} \times X$ is a quotient map. Since $X$ is compact and Hausdorff we know by Lemma 2.73 that $X$ is regionally compact. Thus it follows from Theorem 5.16 that the top horizontal map $id_X \times q$ is a quotient map. Thus it follows from Lemma 5.17 (2) that $\psi$ is continuous.

One easily verifies that $\Psi$ defines a bijection

$$
\Psi: X \times C \to h^{-1}_\varphi(C).
$$

\[1570\] If the reader is unhappy about using Lemma 2.73 we point out that in our application of the proposition the topological space will be $X = S^n$ and thus obviously regionally compact.
Since $X$ is compact we know by Lemma 3.48 (1) that the left-hand side is compact. By Lemma 24.2 (2) and our hypothesis that $X$ is Hausdorff we know that the right-hand side is Hausdorff. Therefore it follows from Proposition 2.43 (3) that the continuous bijection $\Psi: X \times C \to h^{-1}_\varphi(C)$ is indeed a homeomorphism.

We consider the following diagram

$$
\begin{array}{ccc}
X \times C & \xrightarrow{\Psi} & h^{-1}_\varphi(C) \\
\downarrow{(x,c)\mapsto c} & & \downarrow{h_\varphi} \\
C.
\end{array}
$$

It is straightforward to verify that this diagram commutes. Since the top map is homeomorphism by the previous claim we have found a trivialization of $h_\varphi$ over $C$. We leave it to the reader to make the minor modifications needed to find a trivialization of $h_\varphi$ over $D$. □

Evidently the idea now is to replace the quaternions in the example on page 2693 by the octonions. In the following we recall the most salient bits from the discussion of octonions on page 1465. The octonions $O$ are $\mathbb{R}^8$ together with an algebra structure over $\mathbb{R}$ that has the following properties:

1. The octonions $O$ are a division algebra, i.e. for all $a \neq 0$ and $b \in O$ there exists an $x \in O$ with $a \cdot x = b$ and an $y \in O$ with $y \cdot a = b$.
2. The algebra structure is neither commutative nor associative.
3. Multiplication on $O$ respects the euclidean norm, more precisely, given $a, b \in O$ we have $\|a \cdot b\| = \|a\| \cdot \|b\|$.

It follows from (3) that the algebra multiplication induces a map $\varphi: S^7 \times S^7 \to S^7$.

**Lemma 113.16.** Given any $z \in S^7$ the maps $L_z: S^7 \to S^7$ and $R_z: S^7 \to S^7$, as defined in Proposition 113.13, are homeomorphisms.

**Proof.** First note that we can not recycle the argument from page 2693 since there we used that the quaternions are associative.

By Corollary 50.8 (2) it suffices to show that the maps $L_z$ and $R_z$ are injective. First we show that given any $z \in S^7$ the map $L_z: S^7 \to S^7$ is injective. So suppose that we have $a, b \in S^7$ with $L_z(a) = L_z(b)$. We obtain that

$$
\|a - b\| = \|z\| \cdot \|a - b\| = \|z \cdot (a - b)\| = \|z \cdot a - z \cdot b\| = \|L_z(a) - L_z(b)\| = 0.
$$

since $z \in S^7$ by (3) since $O$ is an algebra by definition of $L_z$ since $L_z(a) = L_z(b)$

Thus we see that $a = b$. Almost the same argument shows that $R_z$ is injective. □

Now we are basically done with the proof of Proposition 113.13.

---

1571 Note that in this second part we will need to use that the maps $R_x: X \to X$ are homeomorphisms.
1572 At first glance it might appear odd that we never used that the octonions are a division algebra, we only used the innocuous looking third property. But it is clear that (3) already implies that $O$ has no zero-divisors. By Lemma 60.5 this forces $O$ to be a division algebra.
Proof of Proposition 113.13. It follows immediately from Lemma 113.16, Proposition 113.15 and Lemma 3.50 that there exists a fiber bundle $p : S^15 \to S^8$ with fiber $S^7$. ■

Exercises for Chapter 113.

Exercise 113.1. Let $F$ be a topological space and let $p : Y \to B$ be an $F$-bundle. Suppose that the fiber $F$ and the base space $B$ are path-connected. Show directly, without making use of Proposition 113.2 (2), that the total space $Y$ is also path-connected.

Exercise 113.2. Let $p : Y \to [0, 1]$ be a bundle with fiber $F$. Show with your bare hands (i.e. without using Proposition 113.7) that $p$ is trivial, i.e. show that $p$ is equivalent to the trivial bundle $F \times [0, 1] \to [0, 1]$.

Exercise 113.3. Let $X$ be a topological space and let $f_0, f_1 : X \to X$ be homeomorphisms. Suppose that $f_0$ and $f_1$ are isotopic. Show that the two $X$-bundles $\text{Tor}(X, f_0) \to S^1$ and $\text{Tor}(X, f_1) \to S^1$ are equivalent.

Exercise 113.4. Let $f : \mathbb{R}^n \to \mathbb{R}^n$ be a diffeomorphism. Show that the corresponding $\mathbb{R}^n$-bundle $\text{Tor}(\mathbb{R}^n, f) \to S^1$ is equivalent to an $n$-dimensional vector bundle. 

Hint. Use Lemma 45.17 and Lemma 113.3 (2), the latter is a. k. a. Exercise 113.3.

Exercise 113.5. The Ehresmann Fibration Theorem says the following:
Let $f : M \to N$ be a smooth map between two closed smooth manifolds. We suppose that $N$ is connected. If $f$ is a submersion, i.e. if given any $P \in M$ the map $Df_P : T_PM \to T_{f(P)} N$ is an epimorphism, then $f$ is a fiber bundle.

Provide a proof of the Ehresmann Fibration Theorem using the Submersion Theorem 6.56.

Exercise 113.6. Use the Ehresmann Fibration Theorem, see Exercise 113.5, to give an alternative proof of the fact that the Hopf map $S^3 \to \mathbb{C}P^1$ defines an $S^1$-bundle over $\mathbb{C}P^1 = S^2$.

Exercise 113.7. As on page 1071 we consider the Hopf map:

\[ H : S^3 = \{(z_1, z_2) \in \mathbb{C}^2 \mid |z_1|^2 + |z_2|^2 = 1\} \to S^2 = \mathbb{C}P^1 \]

\[ (z_1, z_2) \mapsto [z_1 : z_2]. \]

(a) Let $P, Q \in S^2$ be two distinct points. Show that $H^{-1}\{P\} \cup H^{-1}\{Q\}$ is isotopic to a Hopf link, that we defined in Figure 1405.

(b) Let $P, Q, R \in S^2$ be two distinct points. Sketch the link $H^{-1}\{P\} \cup H^{-1}\{Q\} \cup H^{-1}\{R\}$.

Exercise 113.8. Let $n \in \mathbb{N}$. We consider the map

\[ \varphi : U(n) = \{A \in M(n \times n, \mathbb{C}) \mid A \cdot A^T = \text{id}\} \to \mathbb{C} \setminus \{0\} \]

\[ A \mapsto \det(A). \]

(a) Show that $\varphi$ takes values in $S^1$.

(b) Show that the map $\varphi : U(n) \to S^1$ is a fiber bundle.

Hint. You can use the Ehresmann Fibration Theorem from Exercise 113.5.
Exercise 113.9. Let $X$ be a topological space and let $f : X \to X$ be a homeomorphism. By the discussion on page 2682 and Proposition 113.2 we know that the map
\[
\text{Tor}(X, f) = \frac{(X \times [0, 1])}{(x, 0) \sim (f(x), 1)} \to S^1
\]
is a fibration. We make the obvious identification $X = X \times \{0\} \subset \text{Tor}(X, f)$. Let $k \in \mathbb{N}_0$ and let $\alpha : [0, 1] \to S^1$ be the usual loop given by $\alpha(t) = e^{2\pi it}$. By Proposition 112.5 and Lemma 42.2 we get a well-defined map
\[
\Theta(\alpha)_* : H_k(X; \mathbb{Z}) \to H_k(X; \mathbb{Z}).
\]
Show that $\Theta(\alpha)_* = (f_*)^{-1}$.

Exercise 113.10. Let $W$ be an $n$-dimensional smooth manifold and let $K$ be a compact proper connected $k$-dimensional submanifold with $k \leq n - 3$. Show that the inclusion induced map $\pi_1(W \setminus K) \to \pi_1(W)$ is an isomorphism.

Hint. Use Lemma 21.22 (3).

Exercise 113.11. The same way that we defined the infinite complex projective space $\mathbb{C}P^\infty$, see page 942, we define the infinite quaternionic projective space $\mathbb{H}P^\infty$ as the direct limit of the finite-dimensional quaternionic projective spaces $\mathbb{H}P^k$. Show that for any $i \in \mathbb{N}_{\geq 2}$ we have an isomorphism $\pi_i(\mathbb{H}P^\infty) \cong \pi_{i-1}(S^3)$.

Exercise 113.12. Let $p : S^3 \to S^2$ the Hopf fibration. In Proposition 113.9 we saw that it is an $S^1$-fiber bundle. We consider the connecting homomorphism $\partial : \pi_2(S^2) \to \pi_1(S^1)$ of the long exact sequence of homotopy groups from Proposition 113.2 (2). Show, just using the definition of the connecting homomorphism, that $\partial([\text{id}_{S^2}]) = [\text{id}_{S^1}]$.

Exercise 113.13. Show that the homotopy groups of $S^2$ and $S^3 \times \mathbb{C}P^\infty$ are isomorphic.

Exercise 113.14. Let $m, k \in \mathbb{N}$ and let $p : M \to S^k$ be a fiber bundle with fiber $S^m$. We denote by $i : S^m \to M$ the homeomorphism to any of the fibers.

(a) Show that $M$ is a closed $(m + k)$-dimensional topological manifold.

(b) We suppose that $m < k$ and we suppose that $M$ is orientable. Show that the maps $p_* : H_k(M) \to H_k(S^k)$ and $i_* : H_m(S^m) \to H_m(M)$ are isomorphisms and show that $H_i(M) = 0$ for $i \neq 0, k, m, m + n$.

Hint. Use Theorems 112.7 and 111.14 and use Poincaré Duality.

(c) We suppose again that $M$ is orientable. Show that the conclusion in (b) does not necessarily hold if we drop the hypothesis that $m < k$. 

114. Homotopy groups of Lie groups

In this chapter our focus will lie on the study of the homotopy groups of the matrix groups \( O(n) \) and \( U(n) \). Later on in the section we will see that we should also define a third type of groups, namely the groups \( \text{Sp}(n) \) which can be viewed as the quaternionic analogue of \( O(n) \) and \( U(n) \).

Since these groups are Lie groups and since this structure is helpful in our study of \( O(n) \) and \( U(n) \) we first give a short introduction to Lie groups.

114.1. Topological groups and Lie groups. First we recall the following definition from page 210.

**Definition.** A topological group is a topological space \( X \) together with a group structure such that the two maps

\[
X \times X \to X \quad \text{and} \quad X \to X
\]

\[
(x, y) \mapsto x \cdot y \quad \text{and} \quad x \mapsto x^{-1}
\]

are continuous. A morphism between topological groups \( X \) and \( Y \) is a homomorphism \( f: X \to Y \) that is furthermore continuous.

**Examples.**

(1) On page 211 we already saw that for any \( n \in \mathbb{N} \) the matrix groups \( \text{SL}(n, \mathbb{R}) \), \( O(n) \), \( \text{SO}(n) \), \( \text{GL}(n, \mathbb{C}) \), \( U(n) \) and \( \text{SU}(n) \) are topological groups.

(2) Let \( X \) be a topological space and let \( x_0 \in X \) be a base point. We consider the loop space \( \Omega(X, x_0) \), i.e. the set

\[
\Omega(X, x_0) = \{ \gamma: [0, 1] \to X \mid \gamma(0) = \gamma(1) = x_0 \}/\text{homotopy}
\]

equipped with the compact-open topology. As in Exercise 112.7 we equip the set \( \pi_1(X, x_0) = \Omega(X, x_0)/\sim \) with the quotient topology, i.e. we view \( \pi_1(X, x_0) \) as a topological space. Evidently \( \pi_1(X, x_0) \) admits a group structure, but somewhat surprisingly, the multiplication map \( \pi_1(X, x_0) \times \pi_1(X, x_0) \to \pi_1(X, x_0) \) is in general not continuous. In fact such an example is given by the Hawaiian Earrings, introduced in Exercise 25.1. We refer to [Fab11] for details.

We leave the elementary proof of the following lemma to the reader.

**Lemma 114.1.** Let \( G \) be a topological group and let \( H \) be a subgroup of \( G \). The map

\[
G \times H \to G
\]

\[
(g, h) \mapsto g \cdot h
\]

defines a right-action of \( H \) on \( G \) that is free and continuous.

To avoid any misunderstanding we introduce the following convention.

\[\text{[Fab11]}^{1573}\]

In fact, as is pointed out in [Fab11], the failure of \( \pi_1(X, x_0) \) to be a topological group is another instance of the phenomenon, discussed in Section 5.2, that in general product and quotient topologies do not mix well.
Convention. Let $G$ be a topological group and let $H$ be a subgroup. We denote by $G/H$ the topological space that is given by the equivalence relation
\[ g_1 \sim g_2 \iff \text{there exists an } h \in H \text{ with } g_1 \cdot h = g_2. \]

The following definition of a Lie group is quite similar to the above definition of a topological group.

Definition. A Lie group is a smooth manifold $X$ with empty boundary together with a group structure such that the two maps
\[ X \times X \to X \quad \text{and} \quad X \to X \quad (x, y) \mapsto x \cdot y \quad \text{and} \quad x \mapsto x^{-1} \]
are smooth.

Remark.

(1) It follows immediately from Lemma 6.23 (2) that a Lie group is also a topological group.

(2) As we will see in Exercise 114.2, strictly speaking one does not need to demand that the map $x \mapsto x^{-1}$ is smooth, since it follows already from the other properties.

Examples.

(1) It is straightforward to see that the smooth manifold $\mathbb{R}$ with the group structure given by addition and the smooth manifold $S^1$ with the group structure given by multiplication are Lie groups.

(2) The product $G_1 \times G_2$ of two Lie groups $G_1$ and $G_2$ admits a canonical smooth manifold structure by Proposition 6.51 and the group structures on $G_1$ and $G_2$ define a group structure on $G_1 \times G_2$. One can easily verify that $G_1 \times G_2$ is again a Lie group. In particular the torus $S^1 \times S^1$ is a Lie group.

As mentioned in the beginning of this chapter, we are now interested in the homotopy groups of the groups
\[ O(n) = \{ A \in M(n \times n, \mathbb{R}) \mid A^T A = \text{id} \} \]
\[ U(n) = \{ A \in M(n \times n, \mathbb{C}) \mid \overline{A}^T A = \text{id} \}. \]

As we will see later on, even if we are only interested in these groups it makes sense to extend our gaze and to consider the quaternionic analogue of $O(n)$ and $U(n)$:

Definition. Let $n \in \mathbb{N}$. We define
\[ \text{Sp}(n) = \{ A \in M(n \times n, \mathbb{H}) \mid \overline{A}^T A = \text{id} \}. \]

We will first discuss $\text{Sp}(n)$ a little bit before we settle on a name for it:

\[ \overline{A} = (\overline{a}_{ij}). \]
Lemma 114.2.

(1) We have $\text{Sp}(1) = S^3$.
(2) Let $n \in \mathbb{N}$. Matrix multiplication turns $\text{Sp}(n)$ into a group.
(3) Let $n \in \mathbb{N}$. We write $J = \begin{pmatrix} 0 & \text{id}_n \\ -\text{id}_n & 0 \end{pmatrix}$. The map

$$\Phi: \text{Sp}(n) \rightarrow \{ X \in \text{U}(2n) \mid JXJ^{-1} = X \}$$

$$P \mapsto \begin{pmatrix} A & B \\ -B & A \end{pmatrix}$$

where $A, B \in M(n \times n, \mathbb{C})$ and $P = A + Bj$ is a group isomorphism.

Proof.

(1) In Lemma [60.1] (5) we saw that for any quaternion $h \in \mathbb{H}$ we have $h \cdot \overline{h} = \|h\|^2$. It follows immediately that $\text{Sp}(1) = S^3$.

(2) We start out with the following observation: A straightforward calculation\footnote{It follows from $i \cdot j = k$ that any quaternion $a \cdot 1 + b \cdot i + c \cdot j + d \cdot k$ can be uniquely written as $(a \cdot 1 + b \cdot i) + (c \cdot 1 + d \cdot i) \cdot j$ where $a \cdot 1 + b \cdot i$ and $c \cdot 1 + d \cdot i$ are complex numbers. The same statement applies to matrices.} shows that for any two matrices $A, B \in M(n \times n, \mathbb{H})$ we have $(AB)^T = B^T A^T$. Now we turn to the proof that $\text{Sp}(n)$ is a group:

(a) The fact that $\mathbb{H}$ is associative implies immediately that the multiplication of matrices in $M(n \times n, \mathbb{H})$ is associative.

(b) The identity matrix is as usual a neutral element.

(c) Given $A \in \text{Sp}(n)$ we have by definition that $\overline{A}^T A = \text{id}$, i.e. $\overline{A}^T$ is a left-inverse.

The above observation implies that $\overline{A}^T$ is also a right-inverse.

(d) It follows from the above observation that $\text{Sp}(n)$ is closed under matrix multiplication and taking inverses.

We have thus shown that $\text{Sp}(n)$ is indeed a group.

(3) We will only use this isomorphism to justify the name for $\text{Sp}(n)$, otherwise it will not play a role. Therefore we will not provide the fairly elementary proof of this statement, instead we refer to [Bre93, p. 103] for the proof. \hfill $\blacksquare$

Not surprisingly we will now see that $\text{O}(n)$, $\text{U}(n)$ and $\text{Sp}(n)$ are Lie groups.

Lemma 114.3.

(1) Let $n \in \mathbb{N}$.

(a) The set $\text{O}(n)$ is a submanifold of $M(n \times n, \mathbb{R}) = \mathbb{R}^{n^2}$ of dimension $\frac{1}{2}n(n - 1)$.

(b) The set $\text{U}(n)$ is a submanifold of $M(n \times n, \mathbb{C}) = \mathbb{C}^{n^2} = \mathbb{R}^{2n^2}$ of dimension $n^2$.

(c) The set $\text{Sp}(n)$ is a submanifold of $M(n \times n, \mathbb{H}) = \mathbb{H}^{n^2} = \mathbb{R}^{4n^2}$ of dimension $2n^2 + n$.

\footnote{In the calculation we need to use the fact, mentioned in Lemma [60.1] (3), that for quaternions $w, z \in \mathbb{H}$ we have $\overline{w \cdot z} = w \cdot \overline{z}$.}
Furthermore, if we view $O(n)$ as a subspace of $O(n+1)$ in the obvious way, then $O(n)$ is a submanifold of $O(n+1)$. The same statements apply to $U(n)$ and $Sp(n)$.

(2) $O(n)$, $U(n)$ and $Sp(n)$, viewed as smooth manifolds in their own right, are closed, in particular they are compact.

(3) The usual matrix multiplication turns $O(n)$, $U(n)$ and $Sp(n)$ into Lie groups.

**Remark.**

(1) Recall that on page ?? we defined the symplectic group $Sp(2g, \mathbb{Z})$ as follows:

$$Sp(2g, \mathbb{Z}) = \{ A \in GL(2g, \mathbb{Z}) \mid A^T J A = A \} \quad \text{where} \quad J = \begin{pmatrix} 0 & \text{id}_g \\ -\text{id}_g & 0 \end{pmatrix}.$$ 

This definition, together with Lemmas 114.2 and 114.3, leads us to calling $Sp(n)$ the $n$-th compact symplectic group.

(2) The statements regarding the groups $O(n)$ and $U(n)$ are mostly already contained in Lemma 6.55.

**Proof.** In Lemma 6.55 we had basically proved statements (1) and (2) for the groups $O(n)$ and $U(n)$. The only aspect that we did not mention explicitly so far is that $O(n)$ is a submanifold of $O(n+1)$. We leave it to the reader to verify that this statement holds. The proof of (1) and (2) for $Sp(n)$ is basically the same.

In Lemma 3.53 we showed that $O(n)$ and $U(n)$ are topological groups. Almost the same argument given in that proof shows that matrix multiplication and taking inverses are smooth maps. This implies that $O(n)$ and $U(n)$ are Lie groups. Furthermore it is clear that multiplication in $Sp(n)$ is smooth. It remains to show that the map

$$Sp(n) \to Sp(n)$$

$$A \mapsto A^{-1}$$

is smooth. We will show this fact in Exercise 114.4. ■

Basically by definition we have $O(1) = S^0$ and $U(1) = S^1$, furthermore by Lemma 114.2 (1) we have $Sp(1) = S^3$. Thus it follows from Lemma 114.3 that these three spheres can be viewed as Lie groups. The question arises, whether perhaps other (all?) spheres can be equipped with the structure of a Lie group. The following lemma gives an easy way to rule out the existence of Lie group structures on some smooth manifolds.

**Lemma 114.4.** Every Lie group is parallelizable.\[1579\]

**Examples.** Recall that on page ?? we saw that $2n$-dimensional spheres with $n \geq 1$ are not parallelizable. Furthermore on page ?? we showed that for $g \neq 1$ the surface of genus $g$ is not parallelizable. Thus it follows from Lemma 114.4 that these spheres and surfaces cannot be equipped with a Lie group structure.

**Sketch of proof.** Let $G$ be an $n$-dimensional Lie group with trivial element $e$. We denote by $R_g : G \to G$ the map that is given by right-multiplication by $g$. Since $G$ is a Lie

\[1579\]Recall that according to the definition on page ?? a smooth manifold is called parallelizable if its tangent bundle is trivial.
group this map is in fact a diffeomorphism. The map
\[ G \times T_e G \to TG = \{(g, h) \mid g \in G \text{ and } w \in T_h G\} \]
\[ (g, v) \mapsto (g, (R_g)_*(v)) \]
is an isomorphism of vector bundles. (This statement is basically obvious, except that perhaps it is not completely clear why the map is continuous, we refer to [Lee02, Corollary 8.39] for more details.) But this shows that \( G \) is parallelizable. \( \square \)

The following lemma gives us more examples of Lie groups.

**Lemma 114.5.** Let \( G \) be a Lie group and let \( K \) be a finite normal subgroup. The quotient \( G/K \) admits a unique smooth manifold structure such that the projection \( G \to G/K \) is a local diffeomorphism. Furthermore the group structure on the quotient group \( G/K \) defines a Lie group structure on \( G/K \).

**Example.** It follows from Lemma [114.5] that for any \( n \in \mathbb{N} \) the quotients \( SU(n)/\{\pm \text{id}\} \) and \( (SU(n) \times SU(n))/\{\pm (\text{id}, \text{id})\} \) are Lie groups.

**Proof.** In Lemma [114.4] we already saw that the action of \( K \) on \( G \) is free and continuous. Since \( G \) is a Lie group one also sees that the action is smooth. Finally, since \( G \) is finite we get for free that the action is proper. Thus we obtain from Proposition [6.32] that \( G/K \) admits a unique smooth manifold structure (without boundary) such that the projection \( G \to G/K \) is a local diffeomorphism. We leave it to the reader to verify that the induced multiplication map \( G/K \times G/K \to G/K \) is again smooth. \( \square \)

Above we have seen that subgroups of matrix groups often give rise to Lie groups. Perhaps somewhat surprisingly, in a sense, all compact Lie groups arise that way. More precisely, the following theorem holds:

**Theorem 114.6.** Any compact Lie group is isomorphic (in the obvious sense) to a Lie subgroup of \( GL(n, \mathbb{R}) \) for some \( n \in \mathbb{N} \).

The theorem is a consequence of the so-called Peter-Weyl Theorem. We only stated the theorem for “general culture”. We will not make use of it and thus we refer to [BtD95, Theorem III.4.1] or alternatively to [Sep07, Theorem 3.28] for a proof.

**114.2. The homotopy groups of \( O(n) \), \( U(n) \) and \( Sp(n) \).** In this chapter we want to see what we can say about the homotopy groups of \( O(n) \), \( U(n) \) and \( Sp(n) \).

**Convention.**

(1) Given \( n \in \mathbb{N} \) we have the obvious monomorphism
\[ O(n) \to O(n+1) \]
\[ A \mapsto \begin{pmatrix} A & 0 \\ 0 & 1 \end{pmatrix} \]

Often we will use it to identify \( O(n) \) with its image in \( O(n+1) \). Similarly we view \( U(n) \) as a subgroup of \( U(n+1) \) and we view \( Sp(n) \) as a subgroup of \( Sp(n+1) \).

\[ \text{One could view Theorem [114.6] as an analogue of Proposition [9.1] or the Whitney Embedding Theorem [11.14]} \]
(2) We will view any subgroup of $GL(n, \mathbb{R})$, $GL(n, \mathbb{C})$ or $GL(n, \mathbb{H})$ as a topological space that is equipped with the base point given by the identity matrix. Thus in the remainder of this chapter we will suppress the base point in the discussion of fundamental groups.

The following lemma evidently uses the convention from page 2699.

**Lemma 114.7.** Let $n \in \mathbb{N}$. The maps

\[ \begin{align*}
O(n+1)/O(n) & \xrightarrow{p} S^n \\
U(n+1)/U(n) & \xrightarrow{q} S^{2n+1} \\
\text{and} & \\
Sp(n+1)/Sp(n) & \xrightarrow{r} S^{4n+3}
\end{align*} \]

are well-defined and they are homeomorphisms.

**Proof.**

(1) First we show that the given map $p : O(n+1)/O(n) \to S^n$ is well-defined. To do so we consider the map

\[ O(n+1) \to S^n, \quad V := (v_1 \ldots v_{n+1}) \mapsto v_{n+1} = V \cdot e_{n+1}. \]

Note that if we multiply $V$ on the right by a matrix of the form \( \left( \begin{array}{cc} A & 0 \\ 0 & 1 \end{array} \right) \), then the multiplication with $e_{n+1}$ is not affected. Therefore the above map $O(n+1) \to S^n$ descends to a map $O(n+1)/O(n) \to S^n$ which is exactly the map $p$ we consider in the lemma. This shows that $p$ is well-defined.

Also note that basic linear algebra tells us that given any point $v_{n+1} \in S^n$ there exist vectors $v_1, \ldots, v_n \in \mathbb{R}^n$ such that $v_1, \ldots, v_n, v_{n+1}$ form an orthonormal basis $\mathbb{R}^{n+1}$. This shows that the given map $p$ is a surjection. Similarly, elementary linear algebra shows that $p$ is injective. Finally note that $S^n$ is Hausdorff and note that Lemmas 114.3 and 2.40 imply that $O(n+1)/O(n)$ is compact. Therefore it follows from Proposition 2.43 (3) that the map $p$ is indeed a homeomorphism.

(2),(3) The proof for (2) and (3) is basically identical to the proof in (1), except that the linear algebra aspects require slightly more thought. \[ \square \]

The following proposition gives us new interesting examples of fiber bundles.

**Proposition 114.8.** Let $n \in \mathbb{N}$. The maps

\[ \begin{align*}
O(n+1) & \to S^n \\
U(n+1) & \to S^{2n+1} \\
\text{and} & \\
Sp(n+1) & \to S^{4n+3}
\end{align*} \]

are bundle projections with fibers given by $O(n)$, $U(n)$ and $Sp(n)$ respectively.

**Remark.** Without too much effort one can show that the bundle projections $O(n+1) \to S^n$ with fiber $O(n)$ and $U(n+1) \to S^{2n+1}$ with fiber $U(n)$ from the proposition restrict to bundle projections $SO(n+1) \to S^n$ with fiber $SO(n)$ and $SU(n+1) \to S^{2n+1}$ with fiber $SU(n)$.

---

\[ \text{It follows easily from } A^T A = \text{id} \text{ that every column } v \text{ of } A \text{ satisfies } \|v\| = 1, \text{i.e. every column lies in } S^n. \]
We will outline two approaches to proving Proposition 114.8. The first approach relies on the following proposition that shows more generally that Lie groups (and sometimes topological groups) give rise to fiber bundles.

**Proposition 114.9.** (*)

1. Let $G$ be a Lie group. If $H$ is a closed subgroup of $G$, then the projection $G \rightarrow G/H$ is a bundle projection with fiber $H$.
2. Let $G$ be a topological group and $H$ be a closed subgroup of $G$. If $H$ admits the structure of a Lie group, then the projection $G \rightarrow G/H$ is a bundle projection with fiber $H$.

**Remark.** One might hope that Proposition 114.9 (1) generalizes to all topological groups and subgroups. But as shown in [Karu58, p. 347], there exists a topological group $G$ and a closed subgroup $H$ such that the projection $G \rightarrow G/H$ is not a bundle projection.

**Proof of Proposition 114.9.**

1. This statement is proved in [Kiri08, Theorem 2.11]. Alternatively, if $G$ is a closed subgroup of some $GL(n, \mathbb{C})$, then the proposition is proved in [Bre93, p. 110].
2. This statement is proved in [Pal61, Corollary 4.1].

**First proof of Proposition 114.8.** These three statements are an immediate consequence of Lemma 114.7 and Proposition 114.9 (1).

**Second proof of Proposition 114.8.** In the following we give an outline of a “bare hands only” proof that the first projection map $p: O(n + 1) \rightarrow S^n$ is indeed a bundle projection with fiber $O(n)$. We leave it to the reader to modify the proof to deal with the two other cases.

Thus let $n \in \mathbb{N}$. As usual we equip $\mathbb{R}^{n+1}$ with the euclidean inner product $\langle \cdot, \cdot \rangle$. In this proof we identify $O(n + 1)$ with the group of isometries of $(\mathbb{R}^{n+1}, \langle \cdot, \cdot \rangle)$. More precisely, we do not distinguish in the notation between an isometry of $(\mathbb{R}^{n+1}, \langle \cdot, \cdot \rangle)$ and the matrix it represents with respect to the standard basis of $\mathbb{R}^{n+1}$.

We consider the two compact subsets

$$V = \{(x_1, \ldots, x_{n+1}) \in S^n \mid x_{n+1} \leq \frac{1}{2}\} \quad \text{and} \quad W = \{(x_1, \ldots, x_{n+1}) \in S^n \mid x_{n+1} \geq -\frac{1}{2}\}.$$ 

We continue with the following claim.

**Claim.** Let $P \in V$. We write $W(P) := \text{span}\{e_{n+1}, P\}$. There exists a unique orientation-preserving isometry $\alpha(P)$ of $\mathbb{R}^{n+1} = W(P) \oplus W(P)^\perp$ that satisfies the following two conditions:

1. the restriction of $\alpha(P)$ to $W(P)$ is an orientation-preserving isometry of $W(P)$ that sends $e_{n+1}$ to $P$,
2. it equals the identity on $W(P)^\perp$.

We illustrate the definition of $\alpha(P)$ in Figure 1590. In the 3-dimensional setting the isometry $\alpha(P)$ is the unique rotation around “the $W(P)^\perp$-axis” that sends $e_{n+1}$ to $P$.

[1582] Alternatively the reader can look up the proof of Proposition 114.9 (1).
Note that \((W(P), \langle \cdot, \cdot \rangle)\) and \((\mathbb{R}^2, \langle \cdot, \cdot \rangle)\) are both positive-definite and symmetric forms. Thus it follows from Exercise \([101.1]\) that both forms are also non-singular. Therefore we obtain from Sylvester’s Theorem \([101.10]\) that the two forms \((W(P), \langle \cdot, \cdot \rangle)\) and \((\mathbb{R}^2, \langle \cdot, \cdot \rangle)\) are isometric. In the latter case the orientation-preserving isometries are given by \(\text{SO}(2)\). Since \(\text{SO}(2) = S^1\) acts freely and transitively on \(S^1\) we see that given any two points \(X, Y \in \mathbb{R}^2\) with \(\|X\| = \|Y\|\) there exists a unique orientation-preserving isometry \(\beta\) of \((\mathbb{R}^2, \langle \cdot, \cdot \rangle)\) with \(\beta(X) = Y\). Since \((W(P), \langle \cdot, \cdot \rangle)\) is isometric to \((\mathbb{R}^2, \langle \cdot, \cdot \rangle)\) the same uniqueness statement applies to \(W(P)\) and the two points \(e_{n+1}, P \in W(P)\). The claim immediately follows from this observation.

We leave it to the reader to verify that the map \(\alpha: V \to O(n + 1)\) that we had just defined is indeed continuous. Next we consider the map

\[
f: V \times O(n) \to O(n+1) \quad (P, A) \mapsto \alpha(P) \circ \begin{pmatrix} A & 0 \\ 0 & 1 \end{pmatrix}.
\]

An entertaining exercise in linear algebra shows that the map \(f\) restricts to a bijection \(V \times O(n) \to p^{-1}(V)\). Since \(V\) and \(O(n)\) are compact we obtain from Proposition \([2.43]\) (3) that \(f\) defines a homeomorphism \(V \times O(n) \to p^{-1}(V)\).

Now recall that for any \(P \in V\) we have, by design, that \(\alpha(P)(e_{n+1}) = P\). Using this observation we see almost immediately that the following diagram commutes:

\[
\begin{array}{c}
V \times O(n) \xrightarrow{f} p^{-1}(V) \\
\downarrow (P,A) \mapsto P \quad \quad \quad \downarrow p \quad \quad \quad \quad \quad \downarrow B \mapsto B e_{n+1}
\end{array}
\]

This shows that we have found a trivialization of \(p\) over \(V\). With very minor modifications one can also find a trivialization of \(p\) over \(W\). Since the interiors of \(V\) and \(W\) cover all of \(S^n\) we see that these two trivializations show that \(p: O(n+1) \to S^n\) is indeed a fiber bundle with fiber \(O(n)\).

Now we can continue with the actual study of the homotopy groups of \(O(n)\), \(U(n)\) and \(\text{Sp}(n)\).
**Proposition 114.10.** Let \( n \in \mathbb{N} \).

1. The inclusion induced map\(^{1583}\)
   \[
   \pi_k(O(n)) \to \pi_k(O(n+1)) \quad \text{is an} \quad \begin{cases} 
   \text{isomorphism for } k < n-1, \\
   \text{epimorphism for } k = n-1. 
\end{cases}
   \]

2. The inclusion induced map
   \[
   \pi_k(U(n)) \to \pi_k(U(n+1)) \quad \text{is an} \quad \begin{cases} 
   \text{isomorphism for } k < 2n, \\
   \text{epimorphism for } k = 2n. 
\end{cases}
   \]

3. The inclusion induced map
   \[
   \pi_k(Sp(n)) \to \pi_k(Sp(n+1)) \quad \text{is an} \quad \begin{cases} 
   \text{isomorphism for } k < 4n+2, \\
   \text{epimorphism for } k = 4n+2. 
\end{cases}
   \]

**Example.**

1. We know that \( U(1) = S^1 \). Thus we obtain from Proposition 114.10 (2) that all unitary groups \( U(n) \) are path-connected.

2. Recall that in Lemma 114.2 (1) we pointed out that \( Sp(1) = S^3 \). Thus we obtain from Proposition 114.10 (3) that all compact symplectic groups \( Sp(n) \) are simply connected.

**Proof.** We prove the first statement. The proofs of the remaining two statements are almost identical\(^{1584}\). By Proposition 114.8 we have a bundle projection \( p: O(n+1) \to S^n \) with fiber \( O(n) \). From Proposition 113.2 we obtain a long exact sequence of the form
   \[
   \cdots \to \pi_{k+1}(S^n) \xrightarrow{\partial} \pi_k(O(n)) \to \pi_k(O(n+1)) \to \pi_k(S^n) \xrightarrow{\partial} \cdots
   \]
The desired statement now follows from the familiar fact that by Proposition 40.10 we have \( \pi_i(S^k) = 0 \) for \( i < k \).

As a corollary to Proposition 114.10 (1) we can now finally answer Question 51.5. More precisely, we have the following proposition.

**Proposition 114.11.**

1. For any \( n \in \mathbb{N} \) the inclusions \( i: SO(n) \to SL(n, \mathbb{R}) \) and \( j: SL(n, \mathbb{R}) \to GL_+(n, \mathbb{R}) \) are homotopy equivalences.

2. Let \( n \in \mathbb{N}_{\geq 2} \). We have isomorphisms
   \[
   \pi_1(SO(n)) \xrightarrow{i_*} \pi_1(SL(n, \mathbb{R})) \xrightarrow{j_*} \pi_1(GL_+(n, \mathbb{R})) \cong \begin{cases} 
   \mathbb{Z}, & \text{if } n = 2, \\
   \mathbb{Z}, & \text{if } n \geq 3.
\end{cases}
   \]

---

\(^{1583}\) Recall that in Lemma 2.65 (1) we saw that \( O(n) \) is disconnected. Thus in principle it is not completely clear what we mean by \( \pi_k(O(n)) \). But, as we pointed out on page 2703, we always consider \( O(n) \) as equipped with the base point that is given by the identity. Also note that it follows easily from Lemma 3.55 that for a topological group the isomorphism type of the homotopy groups does not depend on the choice of a base point.

\(^{1584}\) The only catch is that one needs to be careful about the degrees involved.
(3) In each of the three fundamental groups of (2) a generator of the group is represented by the loop

\[
S^1 \to \text{SO}(n)
\]

\[
e^{i\varphi} \mapsto \begin{pmatrix}
\cos(\varphi) & -\sin(\varphi) & 0 \\
\sin(\varphi) & \cos(\varphi) & 0 \\
0 & 0 & \text{id}_{n-2}
\end{pmatrix}.
\]

**Proof.**

(1) We proved this statement in Lemma 8.8.

(2) First we consider the case \(n = 2\). We have isomorphisms

\[
\mathbb{Z} \cong \pi_1(S^1, \text{id}) = \pi_1(\text{SO}(2), \text{id}) \xrightarrow{\cong} \pi_1(\text{SL}(2, \mathbb{R}), \text{id}) \xrightarrow{\cong} \pi_1(\text{GL}_+(2, \mathbb{R}), \text{id}).
\]

Now we consider the case \(n \geq 3\). We have isomorphisms

\[
\mathbb{Z}_2 \cong \pi_1(\text{SO}(3), \text{id}) \cong \pi_1(\text{SO}(n), \text{id}) \xrightarrow{\cong} \pi_1(\text{SL}(n, \mathbb{R}), \text{id}) \xrightarrow{\cong} \pi_1(\text{GL}_+(n, \mathbb{R}), \text{id}).
\]

(3) We consider the loop

\[
\gamma : S^1 \to \text{SO}(2)
\]

\[
e^{i\varphi} \mapsto \begin{pmatrix}
\cos(\varphi) & -\sin(\varphi) \\
\sin(\varphi) & \cos(\varphi)
\end{pmatrix}.
\]

Since \(\text{SO}(2) = S^1\) we know by Proposition 16.17 that \(\gamma\) represents a generator of \(\pi_1(\text{SO}(2))\). By Proposition 114.10 we know that the inclusion \(\text{SO}(2) \to \text{SO}(n)\) induces an epimorphism of fundamental groups. It follows immediately that the loop given in (3) is indeed a generator of \(\pi_1(\text{SO}(n))\). Since the inclusions \(i\) and \(j\) induce isomorphisms of fundamental groups we see that the given loop also represents a generator of \(\pi_1(\text{SL}(n, \mathbb{R}))\) and \(\pi_1(\text{GL}(n, \mathbb{R}))\).

114.3. **Spin groups.** Let \(n \geq 3\). Recall that in Lemma 2.65 (1) we showed that \(\text{SO}(n)\) is path-connected and in Corollary 114.11 (2) we had just seen that \(\pi_1(\text{SO}(n)) \cong \mathbb{Z}_2\). By Lemma 16.15 this implies that the universal covering, as defined on page 835, of \(\text{SO}(n)\) is a 2-fold covering of \(\text{SO}(n)\). For example in Theorem 51.2 we showed that the 2-fold covering of \(\text{SO}(3)\) is diffeomorphic to \(\text{SU}(2)\).

Thus the following question arises:
Question 114.12. Let \( n \geq 3 \).

1. Is the universal covering of \( SO(n) \) a group?
2. If yes, is it a group “we already know”?

It turns out that the answer to Question 114.12 (1) is yes. In fact, the following, initially perhaps somewhat surprising proposition holds. The proof turns out to be almost disappointingly easy.

Proposition 114.13. Let \( G \) be a connected Lie group and let \( p: \tilde{G} \to G \) be some covering (e.g. it could be the universal covering). We denote by \( 1_G \) the neutral element in \( G \). We pick a point \( 1_{\tilde{G}} \in p^{-1}(1_G) \). Then \( \tilde{G} \) admits a unique Lie group structure such that \( p: \tilde{G} \to G \) is a smooth map and a homomorphism and such that \( 1_{\tilde{G}} \) is the neutral element in \( \tilde{G} \).

Remark.

1. Let \( G \) be a topological group that is connected and locally path-connected. The proof of Proposition 114.13 also shows that given any covering \( p: \tilde{G} \to G \) of \( G \) together with a choice of \( \tilde{e} \in G \) with \( p(\tilde{e}) = e \) there exists a unique topological group structure on \( \tilde{G} \) with trivial element \( \tilde{e} \) which turns \( p \) into a group homomorphism.
2. Let \( k \in \mathbb{N}_{\geq 2} \). By Proposition 114.13 the universal covering \( \tilde{\text{SL}}(k, \mathbb{R}) \) of the Lie group \( \text{SL}(k, \mathbb{R}) \) is again Lie group. In [HallB15, Theorem C.12] it is shown that \( \tilde{\text{SL}}(k, \mathbb{R}) \) is not isomorphic to any subgroup of \( \text{GL}(n, \mathbb{R}) \) for any \( n \in \mathbb{N} \). This shows that Theorem 114.6 does not extend to non-compact Lie groups.

Sketch of the Proof. First note that we saw in Proposition 17.1 that \( \tilde{G} \) is a topological manifold that admits a unique smooth structure such that \( p: \tilde{G} \to G \) is a smooth map. Now we turn towards defining the Lie group structure on the smooth manifold \( \tilde{G} \). In fact we will give two equivalent definitions of the group structure on \( \tilde{G} \):

1. First note that by Proposition 16.20 we know that \( \tilde{G} \times \tilde{G} \) is also simply connected. We consider the maps

\[
\begin{align*}
\tilde{G} \times \tilde{G} &\xrightarrow{(x,y) \mapsto p(x) \cdot p(y)} G, \\
\tilde{G} &\xrightarrow{p} G.
\end{align*}
\]

It follows from Proposition 29.2 that there exists a unique lift \( \tilde{G} \times \tilde{G} \) to \( \tilde{G} \times \tilde{G} \), and

\[
\begin{align*}
(1_{\tilde{G}},1_{\tilde{G}}) &\mapsto 1_{\tilde{G}}, \\
\tilde{G} \times \tilde{G} &\xrightarrow{(x,y) \mapsto p(x) \cdot p(y)} G.
\end{align*}
\]

2. By Proposition 29.5 and Corollary 29.9 we can assume that \( \tilde{G} \) equals the canonical universal covering, i.e. we can assume that

\[
\tilde{G} = \{ \text{paths in } G \text{ starting at } 1_G \}/ \text{homotopies that fix the starting point and the endpoint}
\]
With that explicit description we define
\[
\widetilde{G} \times \widetilde{G} \to \widetilde{G}
\]
\[
([a(t)], [b(t)]) \mapsto [0, 1] \to G \quad t \mapsto a(t) \cdot b(t).
\]

Using the fact that the multiplication map \(\widetilde{G} \times \widetilde{G} \to \widetilde{G}\) is continuous one can show fairly easily that this map is well-defined.

We leave it as a charming exercise to show that the two given definitions of the group structure agree and that in both cases we defined a Lie group structure on \(\widetilde{G}\).

It remains to show that the group structure on \(\widetilde{G}\) is the unique Lie group structure on the smooth manifold \(\widetilde{G}\) for which \(1_{\widetilde{G}}\) is the neutral element and that turns \(p\) into a homomorphism. Suppose we are given a smooth map \(\varphi: \widetilde{G} \times \widetilde{G} \to \widetilde{G}\) that has the same properties. We obtain the following commutative diagram:

\[
\begin{array}{ccc}
\widetilde{G} \times \widetilde{G} & \xrightarrow{\varphi} & \widetilde{G} \\
p \times p \downarrow & & \downarrow p \\
G \times G & \xrightarrow{(x,y) \mapsto x \cdot y} & G.
\end{array}
\]

Since the diagram commutes we see that \(\varphi: \widetilde{G} \times \widetilde{G} \to \widetilde{G}\) is precisely a lift of the blue map \(\widetilde{G} \times \widetilde{G} \to G\) that sends \((1_{\widetilde{G}}, 1_{\widetilde{G}})\) to \(1_{\widetilde{G}}\). Thus by the uniqueness of the lift we see that the Lie group structure on \(\widetilde{G}\) is uniquely determined by our wish list.

This proposition leads us to the following definition.

**Definition.** Let \(n \geq 3\). We refer to the canonical universal covering of the pointed topological space \((\text{SO}(n), \text{id})\) as the spin group \(\text{Spin}(n)\). By Proposition 114.13 there exists a unique Lie group structure on \(\text{Spin}(n)\) for which the canonical base point is the neutral element and which has the property that the projection \(p: \text{Spin}(n) \to \text{SO}(n)\) is a smooth map and a group homomorphism.

The combination of Propositions 114.11 (2) and 114.13 and Corollary 29.9 shows that \(\text{Spin}(n)\) is indeed a Lie group and that \(p: \text{Spin}(n) \to \text{SO}(n)\) is a 2-fold covering that is a group homomorphism.

**Remark.** By Corollary 29.9 the universal covering of a smooth manifold, even if it is equipped with a base point, is only well-defined up to “equivalence”. This slightly awkward issue can be circumvented in two different ways:

1. either we use the explicit model of the universal covering of a based smooth manifold in terms of equivalence classes of paths, or

---

1587 The smoothness of the group multiplication is perhaps easier to prove with the first point of view, the fact that it is a group structure is possibly less confusing to verify with the second point of view.

1588 We refer to page 835 for the definition of the canonical universal covering of a suitable pointed topological space and to the definition of the corresponding canonical base point.
(2) in this particular situation there is a more elegant solution, one can give a purely algebraic explicit description of \( \text{Spin}(n) \). We refer to [Mein13, Chapter 3.1] for details.

It is harder to give an answer to Question \([114.12 (2)\). For reasonably low dimensions the following proposition gives a positive answer.

**Proposition 114.14.**

1. There exist Lie group isomorphisms:
   
   (a) \( \text{SO}(3) \cong \text{SU}(2)/\{\pm \text{id}\} \)
   
   (b) \( \text{SO}(4) \cong (\text{SU}(2) \times \text{SU}(2))/\{\pm (\text{id}, \text{id})\} \)
   
   (c) \( \text{SO}(5) \cong \text{Sp}(2)/\{\pm \text{id}\} \).

2. There exist Lie group isomorphisms

   (a) \( \text{Spin}(3) \cong \text{SU}(2) \)
   
   (b) \( \text{Spin}(4) \cong \text{SU}(2) \times \text{SU}(2) \)
   
   (c) \( \text{Spin}(5) \cong \text{Sp}(2) \)
   
   (d) \( \text{Spin}(6) \cong \text{SU}(4) \).

Proposition \([114.14 (b)\) thus says that for \( n = 3, 4, 5, 6 \) the spin group \( \text{Spin}(n) \) is isomorphic to Lie groups that we are already familiar with. But according to [Mein13, p. 53] “for \( n \geq 7 \), there are no further accidental isomorphisms of this type.” In other words, in general the answer to Question \([114.12 (2)\) is negative.

**Proof.**

1. (a) This statement follows immediately from Lemma \([51.1\) and Theorem \([51.2\).

   (b) In Proposition \([60.2\) we saw that the quaternion multiplication defines a group structure on \( S^3 = \{h \in \mathbb{H} \mid |h| = 1\} \) where the trivial element is given by \( 1 \in \mathbb{H} \). Furthermore in Proposition \([60.2\) we had also seen that the Lie groups \( \text{SU}(2) \) and \( S^3 \) are isomorphic. Thus it suffices to show that the Lie groups \( (S^3 \times S^3)/\{\pm (1, 1)\} \) and \( \text{SO}(4) \) are diffeomorphic. We consider the following map:

   \[
   \Phi: S^3 \times S^3 \to \text{SO}(4)
   \]

   \[
   (q_1, q_2) \mapsto \left( \mathbb{R}^4 = \mathbb{H} \to \mathbb{R}^4 = \mathbb{H}, \quad z \mapsto q_1 z q_2^{-1} \right).
   \]

   We make the following observations:

   (i) In Exercise \([60.1\) we showed that the map \( z \mapsto q_1 z q_2^{-1} \) does indeed define an element in \( \text{SO}(4) \).

   (ii) One can easily verify that the map \( \Phi \) is smooth and that it is a homomorphism.

   (iii) We leave it to the energetic reader to verify that the differential of \( \Phi \) at each point is invertible.

\[\text{Note that it follows from Lemma } [114.5] \text{ that the groups on the right-hand side are indeed Lie groups.}\]
(iv) We note that the kernel of this homomorphism is given by \{±(1, 1)\}. Indeed, the kernel of this homomorphism is given by the set of all \((q_1, q_2) \in S^3 \times S^3\) such that \(q_1 q_2^{-1} = z\) for all \(z \in \mathbb{H}\). By setting \(z = 1\) we obtain that \(q_1 = q_2\). Furthermore, since \(q_1 q_1^{-1} = 1\) for all \(z \in S^3\) we see that \(q_1 = q_2\) lies in the center of the group \(S^3\). An elementary calculation shows that the center of \(S^3\) is given by \(±1\). Thus the kernel of \(\Phi\) contains precisely the two elements \((1, 1)\) and \((-1, -1)\).

It follows from the above, Lemmas \[3.22\] and \[114.5\] and elementary group theory\[1590\] that the above map \(\Phi\) descends to a smooth and injective map

\[\Phi: (S^3 \times S^3)/\{±(1, 1)\} \to SO(4)\]

such that the differential at each point is invertible. By Lemmas \[114.3\] and \[114.5\] both sides are closed connected 6-dimensional smooth manifolds. Thus it follows from Corollary \[50.8\] (2) that the map \(\Phi\) is also surjective. It follows from the above results and the Inverse Mapping Theorem \[6.40\] (2) that \(\Phi\) is in fact a diffeomorphism.

(c) Let \(V\) be the real vector space of quaternionic Hermitian \(2 \times 2\)-matrices with trace 0. In other words we consider

\[V = \left\{ \left( \begin{array}{cc} a & b \\ c & d \end{array} \right) \in M(2 \times 2, \mathbb{H}) \right\} \bigg| a + d = 0, a, d \in \mathbb{R} \text{ and } b = \overline{c} \} \]  

Note that \(V\) is a 5-dimensional real vector space. The group \(Sp(2)\) acts by conjugation on \(V\).\[1591\] One easily verifies that the kernel is given by \(\{±id\}\). Furthermore by \[Pro07\] Chapter 4.5.3 there exists a positive-definite symmetric form on \(V\) that is preserved by this action. Thus, by Sylvester’s Theorem \[101.10\] this action defines a homomorphism \(Sp(2) \to SO(5)\). Similar to (b) we obtain a diffeomorphism \(Sp(2)/\{±id\} \cong SO(5)\).

(2) (a) By (2a) we can make the identification \(SO(3) = SU(2)/\{±id\}\) of Lie groups. By Theorem \[51.2\] we know that \(SU(2)\) is homeomorphic to \(S^3\), in particular we see that \(SU(2)\) is simply connected. By Lemma \[114.5\] the quotient map \(SU(2) \to SU(2)/\{±1\}\) is a covering map, it is smooth and it is a homomorphism. Thus we see that \(SU(2)\) is in fact the universal covering of \(SU(2)/\{±id\} = SO(3)\) and we deduce from Proposition \[114.13\] that \(Spin(3) \cong SU(2)\).

(b) By the same argument as in (2a) this statement can be deduced from (1b).

(c) By the same argument as in (2a) this statement can be deduced from (1c).

(d) We will not make use of this results, hence we will not provide a proof, instead we refer to \[Mein13\] p. 84 for details.

---

\[1590\] More precisely, we use the elementary fact that if \(\alpha: G \to H\) is a group homomorphism, then the induced map \(G/\ker(\alpha) \to H\) is injective.

\[1591\] The group \(Sp(2)\) acts evidently by conjugation on all quaternionic \(2 \times 2\)-matrices, in principle one now needs to verify that this action restricts to an action on \(V\).
Remark. Initially the spin groups might appear as amusing curiosities. In fact they arise naturally in many parts of mathematics and physics. We refer to [LaM89, Morg96, Mein13] for more details.

114.4. The Bott Periodicity Theorem. We continue with the following definition.

Definition. We define

\[ O = \lim_{\to} O(n) = \left\{ A = (a_{ij})_{i,j \in \mathbb{N}} \mid \text{there exists an } n \in \mathbb{N} \text{ and a } B \in O(n) \text{ with } A = \begin{pmatrix} B & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & \ddots \end{pmatrix} \right\} \]

where \( O \) has the obvious group structure and where \( O \) has the topology that is defined by the condition that subset \( U \subset O \) is open if and only if for each \( n \) the intersection \( U \cap O(n) \) is open. Similarly we define

\[ U = \lim_{\to} U(n), \quad \text{Sp} = \lim_{\to} \text{Sp}(n) \]

In Proposition 25.1 we saw that every direct system \( \{G_i\}_{i \in I} \) of groups admits a direct limit \( \lim_{\to} G_i \). In fact for the above direct limit \( O = \lim_{\to} O(n) \) the group structure is the “obvious” one given above. The following shows that these group structure are continuous, i.e. \( O, U \) and \( \text{Sp} \) are topological groups.

Lemma 114.15. The above group structures on \( O, U \) and \( \text{Sp} \) are continuous.

Remark. Initially one might be tempted to dismiss Lemma 114.15 as obvious. But in general there is a subtle issue. If \( \{G_i\}_{i \in I} \) is a direct system of topological groups, then the above multiplication on the direct limit \( \lim_{\to} G_i \) might not be continuous. Such examples are for example provided in [TSH98]. If one thinks about it for a while one realizes that this failure for the multiplication map to be continuous is another instance of the observation made in Section 5.2, that mixing product and quotient topologies is fraught with dangers.

Proof. This lemma can surely be proved, with a little effort, “by hand”. Alternatively one can use [TSH98, Theorem 2.7] which shows that for a direct system \( \{X_i\}_{i \in \mathbb{N}} \) of compact topological groups the above multiplication on \( \lim_{\to} X_i \) is indeed continuous. \( \square \)

For later usages of \( O, U \) and \( \text{Sp} \) we have to get the following technical lemma out of the way.

Lemma 114.16. (⋆) The topological spaces \( O, U \) and \( \text{Sp} \) admit CW-structures such that each \( O(n) \subset O, U(n) \subset U \) and \( \text{Sp}(n) \subset \text{Sp} \) is a subcomplex.

Proof. In [WhdJ44] it is shown that we can equip the \( O(n) \) with CW-structures such that for each \( n \) the subset \( O(n) \subset O(n+1) \) is actually a subcomplex. Analogous statements for \( U(n) \) and \( \text{Sp}(n) \) are proved in [Yok55, Theorem 5.3 and 5.5] or alternatively in [Stro11, Chapter 9.3.3]. It follows from Lemma 36.34 that \( O \) is a CW-complex. \( \square \)

Footnote: When we talk about the direct limit we have to say what category we consider. Here we want to consider the category of groups and of topological spaces at the same time. Since we have obvious inclusions maps \( O(n) \to O(n+1) \) we obtain from Lemma 25.3 that in both settings we obtain the same underlying set, which we can then equip with a group structure and a topology.
Now we turn to the study of the homotopy groups of $O$, $U$ and $Sp$.

**Lemma 114.17.** Given any $k \in \mathbb{N}$ we have

1. $\pi_k(O) = \lim_{\longrightarrow} \pi_k(O(n))$ \xrightarrow{\sim} \pi_k(O(N))$ for any $N \in \mathbb{N}$ with $N > k + 1$,
2. $\pi_k(U) = \lim_{\longrightarrow} \pi_k(U(n))$ \xrightarrow{\sim} \pi_k(U(N))$ for any $N \in \mathbb{N}$ with $2N > k$,
3. $\pi_k(Sp) = \lim_{\longrightarrow} \pi_k(Sp(n))$ \xrightarrow{\sim} \pi_k(Sp(N))$ for any $N \in \mathbb{N}$ with $4N > k - 2$.

**Proof.** We prove (1). The proofs of (2) and (3) are almost identical. We start out with the following claim.

**Claim.** Given any compact subset $K$ of $O$ there exists an $n \in \mathbb{N}$ with $K \subset O(n)$.

Let $K$ be a compact subset of $O$. Given $n \in \mathbb{N}$ we write $X_n := \{1, \ldots, n\} \times \{1, \ldots, n\}$. First recall that $O(n)$ is equipped with the subspace topology coming from the inclusion map $g_n : O(n) \subset M(n \times n, \mathbb{R}) = \mathbb{R}^{X_n} = \mathbb{R}^{n^2}$. Given $n \in \mathbb{N}$ we denote by $f_n : \mathbb{R}^{X_n} \rightarrow \mathbb{R}^{X_{n+1}}$ the obvious inclusion map. These have the property that for any $n \in \mathbb{N}$ the following diagram commutes:

\[
\begin{array}{ccc}
O(n) & \xrightarrow{g_n} & \mathbb{R}^{X_n} \\
\downarrow & & \downarrow f_n \\
O(n + 1) & \xrightarrow{g_{n+1}} & \mathbb{R}^{X_{n+1}}
\end{array}
\]

The above inclusion maps $g_n : O(n) \rightarrow \mathbb{R}^{X_n}$ induce a map $g : O = \lim_{\longrightarrow} O(n) \leftrightarrow \lim_{\longrightarrow} \mathbb{R}^{X_n}$. By our hypothesis that $K$ is compact and Lemma 2.40 we know that $g(K) \subset \lim_{\longrightarrow} \mathbb{R}^{X_n}$ is also compact. Basically the same argument as in the proof of Lemma 36.3 shows that there exists an $n \in \mathbb{N}$ with $g(K) \subset \mathbb{R}^{X_n}$. But this implies that $K \subset O(n)$. \(\blacklozenge\)

Now let $N \in \mathbb{N}$ with $N > k + 1$. We have

\[
\pi_k(O) = \lim_{\longrightarrow} \pi_k(O(n)) = \pi_k(O(N)).
\]

by Proposition 40.11 and the claim, Proposition 114.10 (1) and Lemma 2.42 \(\blacksquare\)

We will now state two versions of the Bott Periodicity Theorem which implies in particular that the homotopy groups of $O$, $U$ and $Sp$ are periodic.

The first theorem requires just a little bit of preparation.

(1) As above we equip $U$, $Sp$ and $O$ with the base point given by the infinite identity matrix. We use these base points to form the loop spaces $\Omega U$, $\Omega Sp$ and $\Omega O$.

(2) Given a point $x$ in a topological space $X$ we denote by $c_x$ the corresponding constant path.

(3) We use notation (2) to equip each loop space $\Omega(X, x_0)$ with the base $c_{x_0}$ and we can thus iterate the loop space construction.

(4) The obvious isomorphism $\mathbb{H} \cong \mathbb{R}^4$ of real vector spaces defines inclusion maps $Sp(n) \rightarrow O(4n)$ and $Sp \rightarrow O$.

(5) The inclusion $\mathbb{R} \rightarrow \mathbb{H}$ defines inclusions $O(n) \rightarrow Sp(n)$ and thus $O \rightarrow Sp$. 
**Theorem 114.18. (Bott Periodicity Theorem)** There exist homotopy equivalences

\[
\begin{align*}
(1) & \quad U \to \Omega^2 U \\
(2) & \quad \text{Sp} \to \Omega^4 \text{O} \\
(3) & \quad \text{O} \to \Omega^4 \text{Sp}.
\end{align*}
\]

Before we talk about the proof of the Bott Periodicity Theorem 114.18 let us move on to the following direct consequence.

**Theorem 114.19. (Bott Periodicity Theorem)** For any \(i \in \mathbb{N}_0\) we have

\[
\begin{align*}
(1) & \quad \pi_{i+2}(U) \cong \pi_i(U), \\
(2) & \quad \pi_{i+4}(\text{Sp}) \cong \pi_i(\text{O}), \\
(3) & \quad \pi_{i+4}(\text{O}) \cong \pi_i(\text{Sp}).
\end{align*}
\]

In particular, combining (2) and (3) we have for any \(i \in \mathbb{N}_0\) that

\[
\begin{align*}
(4) & \quad \pi_{i+8}(\text{O}) \cong \pi_i(\text{O}), \\
(5) & \quad \pi_{i+8}(\text{Sp}) \cong \pi_i(\text{Sp}).
\end{align*}
\]

**Proof of the Bott Periodicity Theorems** 114.18 and 114.19 First note that Theorem 114.19 follows immediately from Theorem 114.18 together with Corollary 112.15. All the known proofs are non-trivial and go well-beyond what we can do in these modest notes.

Theorem 114.18 was first proved by Raoul Bott [Bot57, Bot59, Bot70] in 1957. Another proof, using Morse theory, is given in [Miln63a, p. 129, 142]. There explicit maps that give these homotopy equivalences, they are described well in [DL61]. Nonetheless the description is too long for us to write down at this point.

There are many proofs of Theorem 114.19 which use a slightly different language, in particular it is at first glance not entirely clear whether they also imply Theorem 114.18. We refer to [Stro11, Chapter 32.6], [AGP02, Chapter 9.5], [APr99] and [Hat2, Theorem 2.16] for a discussions and proofs of Theorem 114.19.

Using the Bott Periodicity Theorem 114.19 we can completely determine the homotopy groups of O, U and Sp.

**Proposition 114.20.** The homotopy groups of O, U and Sp are as follows:

<table>
<thead>
<tr>
<th>(i \mod 8)</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
</tr>
</thead>
<tbody>
<tr>
<td>(\pi_i(U))</td>
<td>0</td>
<td>(\mathbb{Z})</td>
<td>0</td>
<td>(\mathbb{Z})</td>
<td>0</td>
<td>(\mathbb{Z})</td>
<td>0</td>
<td>(\mathbb{Z})</td>
</tr>
<tr>
<td>(\pi_i(O))</td>
<td>(\mathbb{Z}_2)</td>
<td>(\mathbb{Z}_2)</td>
<td>0</td>
<td>(\mathbb{Z})</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>(\mathbb{Z})</td>
</tr>
<tr>
<td>(\pi_i(Sp))</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>(\mathbb{Z})</td>
<td>(\mathbb{Z}_2)</td>
<td>(\mathbb{Z}_2)</td>
<td>0</td>
<td>(\mathbb{Z}).</td>
</tr>
</tbody>
</table>

**Proof.** The homotopy groups of U are straightforward to determine. More precisely, let \(i \in \mathbb{N}_0\). We have

\[
\pi_i(U) = \pi_{i \mod 2}(U) \xleftarrow{\cong} \pi_{i \mod 2}(U(1)) = \pi_{i \mod 2}(S^1) \xrightarrow{\cong} \begin{cases} 0, & \text{if } i = 0 \mod 2, \\ \mathbb{Z}, & \text{if } i = 1 \mod 2. \end{cases}
\]

Bott Periodicity Theorem 114.19 Lemma 114.17 (2) since \(U(1) = S^1\) see Lemma 2.03 and Proposition 16.17.

---

\[\text{For } i = 0 \text{ we actually have an isomorphism of pointed sets.}\]
Now we consider the homotopy groups of $O$ and $Sp$. By the Bott Periodicity Theorem 114.19 it suffices to compute the homotopy groups $\pi_i(O)$ and $\pi_i(Sp)$ for $i = 0, 1, 2, 3$. So let $i \in \{0, 1, 2, 3\}$. We have

$$
\pi_i(Sp) \cong \pi_i(Sp(1)) \cong \pi_i(S^3) \cong \begin{cases} 
0, & \text{if } i = 0, 1, 2, \\
\mathbb{Z}, & \text{if } i = 3.
\end{cases}
$$

Lemma 114.17 (3) since $Sp(1) = S^3$ Proposition 40.10 and Corollary 33.6 (1)

We turn to the calculation of the homotopy groups of $O$. First we note that for any $i \geq 1$ we have

$$
\pi_i(O) \cong \pi_i(O(i + 2)) \cong \pi_i(SO(i + 2)).
$$

Lemma 114.17 (3) Lemmas 2.65 and 3.55

Thus it remains to prove the following claim.

Claim.

(a) $\pi_0(O(2)) \cong \mathbb{Z}_2$
(b) $\pi_1(SO(3)) \cong \mathbb{Z}_2$
(c) $\pi_2(SO(4)) \cong 0$
(d) $\pi_3(SO(5)) \cong \mathbb{Z}$.

We turn to the proof of these four separate claims.

(a) By Lemma 2.65 (1) we know that $O(2)$ consists of two path components, thus $\pi_0(O(2))$ is by definition a pointed set with two elements.

(b) By Proposition 114.11 we know that $\pi_1(SO(3)) \cong \mathbb{Z}_2$.

(c) We have the following isomorphisms:

$$
\pi_2(SO(4)) \cong \pi_2((S^3 \times S^3)/\mathbb{Z}_2) \cong \pi_2(S^3 \times S^3) \cong \pi_2(S^3) \oplus \pi_2(S^3) = 0.
$$

Proposition 114.14 (1b) and 40.2 by Lemma 114.5 Proposition 40.8 Proposition 40.10

(d) We have the following isomorphisms:

$$
\pi_3(SO(5)) \cong \pi_3(Sp(2)/\{\pm \text{id}\}) \cong \pi_3(Sp(2)) \cong \pi_3(Sp) \cong \mathbb{Z}.
$$

Proposition 114.14 (1c) and 40.13 by Lemma 114.5 and Proposition 40.10 see above

114.5. H-spaces (*). In this final section of this chapter we want to state two general statements about homotopy groups of Lie groups. In fact these statements hold for a much wider class of topological spaces that we introduce now:

**Definition.** We say a topological space $X$ is an H-space if there exists a map $\mu: X \times X \to X$.
and an element \( e \in X \) such that \( \mu(e, e) = e \) and such that the maps
\[
(X, e) \mapsto (X, e) \quad \text{and} \quad (X, e) \mapsto (X, e)
\]
of pairs of topological spaces are homotopic to the identity.

**Examples.**

1. Evidently Lie groups and more generally, topological groups are H-spaces, where \( \mu \) is given by the group structure and \( e \) is the trivial element of the group. In particular we see that the Lie groups \( S^1 \) and \( S^3 \) are H-spaces.

2. The topological space \( S^7 \) together with the multiplication given by the octonion structure on \( O = \mathbb{R}^8 \) and with \( e = 1 = (1, 0, \ldots, 0) \in S^7 \) is an H-space. Since octonion multiplication is not associative we see that, at least with this multiplication, \( S^7 \) is not a topological group.

We have just seen that the spheres \( S^1, S^3 \) and \( S^7 \) are H-space. Before we continue with more examples we point out that we have all the tools to show that no other spheres have H-space structures.

**Theorem 114.21.** Let \( n \in \mathbb{N} \). If \( S^n \) admits the structure of an H-space, then \( n \in \{1, 3, 7\} \).

**Proof.** Let \( \mu: S^n \times S^n \to S^n \) be the multiplication map of an H-space structure and let \( e \in X \) be the “neutral” element. It follows immediately from the definition of the bidegree, see page 2223 together with Proposition 42.5 and the existence of \( e \), that the map \( \mu \) has bidegree \((1, 1)\). From Proposition 91.12 we obtain a map \( S^{2n+1} \to S^{n+1} \) with Hopf invariant \( \pm 1 \). By the Adams Theorem 110.11 we know that \( n + 1 \in \{2, 4, 8\} \).

We continue with one more amusing example of an H-space.

**Example.** Given a non-zero polynomial \( p(t) = \sum_{i=0}^{n} a_i t^i \in \mathbb{C}[t] \) we define
\[
[p(t)] := [a_0 : a_1 : \cdots : a_n : 0 : \ldots] \in \mathbb{C}\mathbb{P}^\infty.
\]
Evidently every element in \( \mathbb{C}\mathbb{P}^\infty \) is of that form. We consider the “multiplication” map
\[
\mu: \mathbb{C}\mathbb{P}^\infty \times \mathbb{C}\mathbb{P}^\infty \to \mathbb{C}\mathbb{P}^\infty
\]
\[
([p(t)], [q(t)]) \mapsto [p(t) \cdot q(t)],
\]
every \( e \in \mathbb{C}[t] \)

We leave it to the reader to verify that \( \mu \) is continuous. It is clear that left and right “multiplication” by \( e = [1] = [1 : 0 : \ldots] \) is the identity. This shows that \( \mathbb{C}\mathbb{P}^\infty \) together

---

1505 According to [Hub99, p. 747] the term H-space was coined by Jean-Pierre Serre to honor the work of Heinz Hopf.

1506 As usual, whenever we deal with topological spaces, all maps are understood to be continuous.

1507 Recall that by the discussion on page 1465 we know that for octonions \( w, z \in O = \mathbb{R}^8 \) we have \( \|w \cdot z\| = \|w\| \cdot \|z\| \), in particular the multiplication restricts to a map on \( S^7 \). Also note that multiplication by \( e = 1 \) is the identity.

1508 We partially proved the somewhat weaker Theorem 110.10.
with \(\mu\) and \(e\) is an H-space. Note that this multiplication \(\mu\) is commutative and associative, but it does not have inverses; thus \(\mu\) does not define a group structure on \(\mathbb{C}P^\infty\).

We formulate the last example as a lemma.

**Lemma 114.22.** Let \((X,x_0)\) be a pointed topological space. We denote by \(\Omega(X,x_0)\) the loop space as defined on page 2661.

1. The map
   \[
   \mu: \Omega(X,x_0) \times \Omega(X,x_0) \to \Omega(X,x_0)
   \]
   \[
   (f: [0,1] \to X, g: [0,1] \to X) \mapsto (f \ast g : [0,1] \to X)
   \]
   is continuous.

2. The map \(\mu: \Omega(X,x_0) \times \Omega(X,x_0) \to \Omega(X,x_0)\) from (1) together with the constant loop given by \(e(t) \equiv x_0\), turns \(\Omega(X,x_0)\) into an H-space.

**Remark.**

1. Note that for the H-space \(\Omega(X,x_0)\) “multiplication” by \(e\) is not the identity, it is only homotopy equivalent to the identity.

2. We had hinted at the existence of a multiplication map on \(\Omega(X,x_0)\) in Exercise 112.5.

**Proof.** Let \((X,x_0)\) be a pointed topological space. To simplify the notation we write \(\Omega X\) instead of \(\Omega(X,x_0)\).

1. We need to show that the map \(\mu: \Omega X \times \Omega X \to \Omega X\) is in fact continuous. By the “⇒”-direction of Proposition 5.6, applied to \(T = \Omega X \times \Omega X\) and the regionally compact topological space \(Y = [0,1]\), it suffices to show that the following map is continuous:
   \[
   \Phi: (\Omega X \times \Omega X) \times [0,1] \xrightarrow{\mu \times \text{id}} \Omega X \times [0,1] \xrightarrow{(f,t) \mapsto f(t)} X.
   \]
   On the subset \((\Omega X \times \Omega X) \times [0,\frac{1}{2}]\) this map is equal to
   \[
   (\Omega X \times \Omega X) \times [0,\frac{1}{2}] \xrightarrow{((f,g) \mapsto f) \times (t \mapsto 2t)} \Omega X \times [0,1] \xrightarrow{(f,t) \mapsto f(t)} X.
   \]
   The first map is evidently continuous. Furthermore, the second map is continuous by Proposition 5.4. Thus we have shown that the restriction of \(\Phi\) to the subset \((\Omega X \times \Omega X) \times [0,\frac{1}{2}]\) is continuous. Basically the same argument shows that the restriction of \(\Phi\) to \((\Omega X \times \Omega X) \times [\frac{1}{2},1]\) is continuous. It follows from Lemma 14.3 that \(\Phi\) itself is continuous.

2. Let \(e \in \Omega(X,x_0)\) be the constant loop given by \(e(t) \equiv x_0\). It is clear that \(\mu(e,e) = e\).

   Thus it remains to show that the maps
   \[
   (\Omega(X,x_0), e) \mapsto (\Omega(X,x_0), e) \quad \text{and} \quad (\Omega(X,x_0), e) \mapsto (\Omega(X,x_0), e)
   \]
   \[
   f \mapsto \mu(f,e) \quad \text{and} \quad f \mapsto \mu(e,f)
   \]

\[\text{Why are there elements in } \mathbb{C}P^\infty \text{ which do not have multiplicative inverses?}\]
of pairs of topological spaces are homotopic to the identity. We consider the map

\[ H: \Omega(X, x_0) \times [0, 1] \to \Omega(X, x_0) \]

\[ ((f: [0, 1] \to X), t) \mapsto \begin{cases} [0, 1] \to X & s \mapsto \begin{cases} f(\frac{2s}{t+1}), & \text{if } s \in [0, \frac{t+1}{2}], \\ x_0, & \text{otherwise.} \end{cases} \end{cases} \]

We leave it to the underchallenged reader to show, using the \( \Rightarrow \)-direction of Proposition 5.6, that this map \( H \) is in fact continuous. Note that we have \( H(e, t) = e \) for all \( t \in [0, 1] \). With these observations it is basically clear that it is the desired homotopy between the map \( f \mapsto \mu(f, e) \) and the identity.

Almost exactly the same way we deal with the second map \( f \mapsto \mu(e, f) \). 

The following lemma is the only statement on H-spaces that we can prove with our limited space resources.

**Lemma 114.23.** If \( X \) is a path-connected H-space, then \( \pi_1(X) \) is abelian.

**Remark.** Let \((Y, y_0)\) be a pointed topological space. We recall the following two facts:

(a) Recall that in Corollary 112.15 we saw that given any \( k \in \mathbb{N} \) there exists an isomorphism \( \pi_{k+1}(Y, y_0) \cong \pi_k(\Omega(Y, y_0)) \).

(b) We pointed out above that the loop space \( \Omega(Y, y_0) \) is an H-space.

The combination of (a), (b) and Lemma 114.23 implies that given any \( k \in \mathbb{N}_{\geq 2} \) we have

\[ \pi_k(Y, y_0) \cong \pi_{k-1}(\Omega(Y, y_0)) \cong \cdots \cong \pi_1(\Omega(\Omega \cdots \Omega(Y, y_0))) = \pi_1(\text{H-space}) = \text{abelian.} \]

We have thus shown that \( \pi_k(Y, y_0) \) is abelian for every \( k \geq 2 \). In other words, we have obtained a new proof for Proposition 40.3.

Just for kicks we provide two different proofs for Lemma 114.23. The first proof, which we provide here is “down to earth”. The second proof, which we will provide in the next section, is more structural.

**First proof of Lemma 114.23 (•).** We denote by \( \mu: X \times X \to X \) and \( e \in X \) the objects in the definition of an H-space. Let \( f, g: [0, 1] \to X \) be loops in \( e \). We need to show that the path \( f \ast g \) is path-homotopic to the path \( g \ast f \).

We denote by \( \mu(f, e) \) the path \( t \mapsto \mu(f(t), e) \) and similarly we define \( \mu(e, g) \). We consider the map

\[ F: [0, 1] \times [0, 1] \to X \]

\[ (s, t) \mapsto \mu(f(s), g(t)). \]
Note that this map is continuous by Lemma 3.8 (2b) and the fact that $\mu$ is continuous. Furthermore we consider the following path-homotopy:

$$H: [0, 1] \times [0, 1] \to X$$

$$(s, t) \mapsto \begin{cases} F(2s \cdot (1 - t), t), & \text{if } s \leq \frac{1}{2} \\ F((2 - 2s) \cdot (1 - t), t) + (2s - 1) \cdot (1, 1), & \text{if } s > \frac{1}{2}. \end{cases}$$

By carefully plugging in $t = 0$ and $t = 1$ we see that $H$ is a path-homotopy from the loop $\mu(f, e) \ast \mu(e, g)$ to the loop $\mu(e, g) \ast \mu(f, e)$.

By definition of an $H$-space there exists a homotopy $A: X \times [0, 1] \to X$ rel $\{e\}$ with $A_0 = \text{id}$ and $A_1 = \mu(-, e)$ and there exists a homotopy $B: X \times [0, 1] \to X$ rel $\{e\}$ with $B_0 = \text{id}$ and $B_1 = \mu(e, -)$. We consider the maps

$$A_f: [0, 1] \times [0, 1] \to X$$

$$(s, t) \mapsto A(f(s), t)$$

and

$$B_g: [0, 1] \times [0, 1] \to X$$

$$(s, t) \mapsto B(g(s), t).$$

Note that $A_f$ is a path-homotopy from the loop $f$ to the loop $\mu(f, e)$ and $B_g$ is a path-homotopy from the loop $g$ to the loop $\mu(e, g)$. The path-homotopy between the loops $f \ast g$ and $g \ast f$ is given by combining $H$ with $A_f$ and $B_g$ as indicated in Figure 1591. We leave it to the reader to conscientiously write down the precise homotopy.

![Figure 1591. Illustration for the proof of Lemma 114.23](image)

The following theorem was proved by William Browder [Browd60, Theorem 2] [Browd61, Theorem 6.11] in 1961.

**Theorem 114.24.** Let $X$ be a path-connected $H$-space. If the group $\bigoplus_{i=0}^{\infty} H_i(X; \mathbb{Z})$ is finitely generated, then

$$\min\{m \in \mathbb{N}_{\geq 2} \mid \pi_m(X) \neq 0\}$$

is odd. In particular we have $\pi_2(X) = 0$.

**Examples.**

1. On page 2716 we saw that $\mathbb{C}P^\infty$ is an $H$-space. Furthermore in Corollary 53.6 (2) we saw that $\pi_2(\mathbb{C}P^\infty) \neq 0$. Thus we see that in the statement of Theorem 114.24 we cannot drop the hypothesis that $\bigoplus_{i=0}^{\infty} H_i(X; \mathbb{Z})$ is a finitely generated group.

It follows easily from Lemma 2.35 (2') that this map is continuous.
Let \( k \in \mathbb{N} \). It follows from Theorem \[114.24\] together with Theorem \[113.12\] and the discussion on page \[1262\] that the finite complex projective space \( \mathbb{C}P^k \) does not admit an H-space structure.

We conclude this chapter with a corresponding theorem for Lie groups.

**Theorem 114.25.** If \( G \) is a path-connected Lie group, then
\[
\min\{m \in \mathbb{N}_\geq 2 \mid \pi_m(G) \neq 0\}
\]
is odd. In particular \( \pi_2(G) = 0 \).

**Remark.** There are many direct proofs in the literature for the statement that given a path-connected Lie group \( G \) the second homotopy group \( \pi_2(G) \) vanishes, see e.g. [Carta36] or [Miln63a, Theorem 21.7] or [BtD95, Proposition V.7.5].

Note that Theorem \[114.25\] has no conditions on the Lie group except that it needs to be path-connected. The reason why we can get away with so few conditions is given by the following proposition.

**Proposition 114.26.** Let \( G \) be a Lie group. There exists a compact Lie subgroup \( K \) such that \( G \) is homeomorphic to \( K \times \mathbb{R}^n \) for some \( n \in \mathbb{N}_0 \).

**Proof of Proposition 114.26.** Like many other foundational results on Lie groups this proposition has its origins in the work of Henri Cartan [Carta36]. A full proof is given in [Ma45, Theorem 11] or [Mos49, Theorem 2]. A sketch of the proof is provided in [Sam52, Chapter 7].

**Example.** We consider the group \( \text{Isom}(\mathbb{R}^n) \) of isometries of the vector space \( \mathbb{R}^n \) equipped with the usual inner product. It is an elementary, but not totally trivial fact, see [Rees83, p. 11], that
\[
\text{Isom}(\mathbb{R}^n) = \{ \text{all maps of the form } x \mapsto Ax + v \text{ where } A \in \text{O}(n) \text{ and } v \in \mathbb{R}^n \}.
\]
The maps
\[
\begin{align*}
\text{O}(n) \times \mathbb{R}^n & \to \text{Isom}(\mathbb{R}^n) \\
(A, v) & \mapsto (x \mapsto Ax + v)
\end{align*}
\]
and
\[
\begin{align*}
\text{Isom}(\mathbb{R}^n) & \to \text{O}(n) \times \mathbb{R}^n \\
f & \mapsto ((x \mapsto (f(x) - f(0)), f(0))
\end{align*}
\]
are inverses of one another. Thus we can use the smooth manifold structure on \( \text{O}(n) \times \mathbb{R}^n \) to turn \( \text{Isom}(\mathbb{R}^n) \) into a smooth manifold and it is quasi-obvious to see that this turns \( \text{Isom}(\mathbb{R}^n) \) into a Lie group. We can view \( \mathbb{R}^n \) and \( \text{O}(n) \) as subgroups of \( \text{Isom}(\mathbb{R}^n) \) in an obvious way. But one easily verifies that the map \( \text{O}(n) \times \mathbb{R}^n \to \text{Isom}(\mathbb{R}^n) \) is not an isomorphism. In other words, as predicted by Proposition \[114.26\] the Lie group \( \text{Isom}(\mathbb{R}^n) \) splits topologically into a product. But the Lie group does not split as a Lie group.

**Proof of Theorem 114.25.** Let \( G \) be a path-connected Lie group. By Proposition \[114.26\] we know that \( G \) is homotopy equivalent to a compact path-connected Lie group \( K \). By \[1601\] in fact a Lie group contains a maximal compact Lie subgroup which is furthermore unique up to conjugation. We will not make use of this fact.
Proposition 40.7 (2) it suffices to prove the desired statement for $K$. Since $K$ is in particular a compact smooth manifold we obtain from Proposition 64.6 that $\bigoplus_{i=0}^{\infty} H_i(X;\mathbb{Z})$ is a finitely generated abelian group. Thus we can conclude the proof by appealing to Theorem 114.24.

\[\square\]

114.6. **The Eckmann-Hilton Theorem** (⋆). In this section we will state and prove a theorem that was provided by Bruno Eckmann and Peter Hilton [Ech62] in 1962. The theorem is totally elementary, but at the same time it is surprisingly useful. In particular it will be the key to giving the second proof of Lemma 114.23.

The formulation of the Eckmann-Hilton Theorem requires the following harmless definition.

**Definition.** Let $X$ be a set.

1. A binary operation is nothing but a map $X \times X \rightarrow X$.
2. A binary operation $\mu : X \times X \rightarrow X$ is called unital if there exists an element $1 \in X$ such that $\mu(1, x) = \mu(x, 1) = x$ for all $x \in X$.

**Example.** The multiplication map on a group is evidently a unital binary operation.

The following theorem is in some sense quite elementary, but the cleverness lies in its formulation.

**Theorem 114.27. (Eckmann-Hilton Theorem)** Let $X$ be a set equipped with two binary operations “$\circ$” and “$\otimes$”. Suppose the following two conditions are satisfied:

(a) “$\circ$” and “$\otimes$” are both unital.
(b) For every $a, b, c, d \in X$ we have the equality

\[(a \otimes b) \circ (c \otimes d) = (a \circ c) \otimes (b \circ d).\]

Then “$\circ$” and “$\otimes$” are the same and they are commutative and associative.

**Proof.** First we show that the units of the two operations “$\circ$” and “$\otimes$” coincide:

\[1_{\circ} = 1_{\circ} \circ 1_{\circ} = (1_{\otimes} \circ 1_{\circ}) \circ (1_{\circ} \otimes 1_{\otimes}) = (1_{\otimes} \circ 1_{\circ}) \otimes (1_{\circ} \circ 1_{\otimes}) = 1_{\otimes} \otimes 1_{\circ} = 1_{\otimes}.\]

by (b)

Next we show that the two operations “$\circ$” and “$\otimes$” are the same and that they are commutative. Thus let $x, y \in X$. Then

\[x \circ y = (1 \otimes x) \circ (y \otimes 1) = (1 \circ y) \otimes (x \circ 1) = y \otimes x = (y \circ 1) \otimes (1 \circ x) = (y \otimes 1) \circ (1 \otimes x) = y \circ x.\]

by (b) again by (b)

Finally we show that the operations are associative. Thus let $x, y, z \in X$. We have the following equality:

\[(x \otimes y) \otimes z = (x \otimes y) \otimes (1 \otimes z) = (x \otimes 1) \otimes (y \otimes z) = x \otimes (y \otimes z).\]

one last time by (b)

Now we can prove the following lemma, which in particular gives the promised second, more structural proof of Lemma 114.23.
Lemma 114.28. Let $X$ be a path-connected $H$-space and let $x_0 \in X$. In the following we denote by $\mu: X \times X \to X$ the multiplication map of the $H$-space. We consider the following two binary operations on $\pi_1(X, x_0)$:

$$\pi_1(X, x_0) \times \pi_1(X, x_0) \to \pi_1(X, x_0) \quad \text{and} \quad \pi_1(X, x_0) \times \pi_1(X, x_0) \to \pi_1(X, x_0)$$

where

$$(f, [g]) \mapsto [f \ast g] \quad \text{and} \quad ([f], [g]) \mapsto \left[ [0, 1] \to X, t \mapsto \mu(f(t), g(t)) \right].$$

The following two statements hold:

1. The two binary operations agree.
2. The group $\pi_1(X, x_0)$ is abelian.

Proof. Let $X$ be a path-connected $H$-space and let $x_0 \in X$. We denote by $\mu: X \times X \to X$ the multiplication map of the $H$-space. Since $\mu$ is an $H$-space structure one sees easily that “$\otimes$” is a unital binary operation. Furthermore we have known ever since Proposition 14.7 that “$\circ$” is a unital binary operation. In Exercise 114.9 we will show that Condition (b) of the Eckmann-Hilton Theorem 114.27 is satisfied. Thus we obtain from the Eckmann-Hilton Theorem 114.27 the amusing fact that the two operations agree and we obtain that both operations are commutative. In particular this means that $\pi_1(X, x_0)$ is abelian. ■

Exercises for Chapter 114.

Exercise 114.1. Let $X$ be the torus minus one open disk. Does $X$ admit the structure of a topological group?

Exercise 114.2. Let $M$ be smooth manifold without boundary and let $g: M \times M \to M$ be a map that is smooth and that defines a group structure on $M$. Show that $(M, g)$ is a Lie group. In other words, show that the map $M \to M$ given by $x \mapsto x^{-1}$ is smooth. Hint. Use the Implicit Function Theorem, see e.g. [Lee02] p. 661.

Exercise 114.3. Let $n \in \mathbb{N}$. We define

$$GL(n, \mathbb{H}) = \left\{ A \in M(n \times n, \mathbb{H}) \mid \begin{array}{c} \text{there exist matrices } X, Y \in M(n \times n, \mathbb{H}) \text{ such that } AX = YA = \text{id} \end{array} \right\}.$$ 

Is $GL(n, \mathbb{H})$ an open subset of $M(n \times n, \mathbb{H})$?

Exercise 114.4. Let $n \in \mathbb{N}$. In the proof of Lemma 114.3 we already saw that $\text{Sp}(n)$ is a smooth manifold and that matrix multiplication turns $\text{Sp}(n)$ into a group. Show that the map

$$\text{Sp}(n) \to \text{Sp}(n), \quad A \mapsto A^{-1}$$

is a smooth map.

Note: The argument in the proof of Lemma 3.53 can be used to show that taking inverses in $GL(n, \mathbb{R})$ and $GL(n, \mathbb{C})$ is smooth. Does this help us in any way?

Remark. In principle one could use Exercise 114.2. But what do readers do who are still traumatized by the Implicit Function Theorem?
Exercise 114.5. Use the Ehresmann Fibration Theorem that we had stated in Exercise 113.5 to give a third proof that the map \( p: O(n + 1) \to S^n \) from Proposition 114.8 is a fiber bundle.

Exercise 114.6. Determine all closed non-orientable 2-dimensional smooth manifolds that admit a Lie group structure.

Exercise 114.7. We define \( SU = \lim_{\to} SU(n) \) the same way as we defined \( U \). Determine the homotopy groups of \( SU \).

Remark. You might want to use Exercise 113.8.

Exercise 114.8. (a) Let \( X \) be a CW-complex and let \( e \in X^0 \) be a point in the 0-skeleton. Suppose we are given a map \( \mu: X \times X \to X \) such that the two maps

\[
\begin{align*}
X & \to X \\
x & \mapsto \mu(x, e)
\end{align*}
\]

and

\[
\begin{align*}
X & \to X \\
x & \mapsto \mu(e, x)
\end{align*}
\]

are homotopic to the identity. Show that \( \mu \) is homotopic to a map \( \nu: X \times X \to X \) such that \( \nu(x, e) = \nu(e, x) = x \) for all \( x \in X \).

(b) Show that \( \nu \) in (a) defines an H-space structure on \( X \).

(c) Let \( X \) be a CW-complex. Suppose there exists a homotopy equivalence \( f: X \to Y \) to an H-space \( Y \). Show that \( X \) itself admits an H-space structure.

Exercise 114.9. Let \( (X, x_0) \) be a pointed path-connected H-space. Let \( \mu: X \times X \to X \) be the multiplication of the H-space structure. We consider the following two binary operations on \( \pi_1(X, x_0) \):

\[
\pi_1(X, x_0) \times \pi_1(X, x_0) \to \pi_1(X, x_0)
\]

\[
([f], [g]) \mapsto [f * g]
\]

and

\[
\pi_1(X, x_0) \times \pi_1(X, x_0) \to \pi_1(X, x_0)
\]

\[
([f], [g]) \mapsto ([0, 1] \to X, t \mapsto \mu(f(t), g(t)))
\]

Show that “\( \circ \)” and “\( \otimes \)” satisfy Condition (b) of the Eckmann-Hilton Theorem.

Exercise 114.10. Let \( (X, x_0) \) be a pointed topological space and let \( k \in \mathbb{N}_{\geq 2} \). Define the multiplication \( *: \pi_k(X, x_0) \times \pi_k(X, x_0) \to \pi_k(X, x_0) \) as on page 1055. Provide a different multiplication \( \otimes: \pi_k(X, x_0) \times \pi_k(X, x_0) \to \pi_k(X, x_0) \) such that “\( * \)” and “\( \otimes \)” satisfy the conditions of the Eckmann-Hilton Theorem. Conclude, once again, that \( \pi_k(X, x_0) \) is abelian.
115. THOM-PONTRYAGIN THEORY I: THE BASICS

In this chapter we will introduce the Thom-Pontryagin approach to calculating homotopy groups of spheres. Furthermore we will see that it allows us to reprove several earlier results. In Chapters 116 and 117 we will use the Thom-Pontryagin approach to obtain new results.

Before we start with discussing the Thom-Pontryagin theory we fix some notations and conventions.

Notation and Convention. Let \( n \in \mathbb{N}_0 \).

1. We denote by * the point in \( \overline{B}^n / S^{n-1} \) that is given by \([S^{n-1}]\).
2. We denote by * the “North Pole” \((0, \ldots, 0, 1) \in S^n\).

We make the following identifications:

a. We use the homeomorphism \( S^n \to \mathbb{R}^n \cup \{\infty\} \) from Lemma 2.44 which is given by stereographic projection, that sends the North Pole * to \( \infty \) to make the identification \( S^n = \mathbb{R}^n \cup \{\infty\} \).

b. On page 182 we wrote down an explicit homeomorphism \( \overline{B}^n / S^{n-1} \to S^n \). This homeomorphism sends * to \((0, \ldots, 0, 1), (x_1, \ldots, x_{n+1}) \mapsto (x_{n+1}, x_2, \ldots, x_n, -x_1) \). This way we obtain a homeomorphism \( \overline{B}^n / S^{n-1} \to S^n \) that sends * to \((0, \ldots, 0, 1) \).

c. Putting the two homeomorphisms from (a) and (b) together we obtain a homeomorphism

\[
\varphi : \overline{B}^n / S^{n-1} \to \mathbb{R}^n \cup \{\infty\}.
\]

It follows fairly easily from the definitions of the two maps in (a) and (b) that \( \varphi \) restricts to a diffeomorphism \( B^n \to \mathbb{R}^n \) and that \( \varphi \) is of the form

\[
x \mapsto \begin{cases} 
\eta(\|x\|) \cdot x, & \text{if } x \in B^n, \\
\infty, & \text{if } x = *,
\end{cases}
\]

where \( \eta : [0, 1) \to [0, \infty) \) is a strictly monotonically increasing function with \( \eta(0) = 0 \) and \( \lim_{t \to 1} \eta(t) = \infty \).

Summarizing we have the identifications \( S^n = \mathbb{R}^n \cup \{\infty\} = \overline{B}^n / S^{n-1} \) and under these identifications the points * \( \in S^n \), \( \infty \) and * \( \in \overline{B}^n / S^{n-1} \) get identified. We refer to Figure 1592 for an illustration.
115.1. The generalized Thom-Pontryagin construction. On page 2369 we saw that a proper oriented codimension-one submanifold of a compact oriented smooth manifold $M$ gives rise, via the Thom-Pontryagin construction, to a map $M \to S^1$. In this section we will generalize this construction.

The key objects in the more general construction of Thom-Pontryagin maps are “thickened” submanifolds:

**Definition.** Let $M$ be an orientable $n$-dimensional smooth manifold.

1. Let $N$ be a compact orientable proper $k$-dimensional submanifold of $M$. A *thickening* of $N$ is an injective map $g: B^{n-k} \times N \to M$ with the following properties:
   a. for all $P \in N$ we have $g(0,P) = P$,
   b. the image $g(B^{n-k} \times N)$ is a submanifold with corner of $M$,
   c. we have $g(B^{n-k} \times N) \cap \partial M = g(B^{n-k} \times \partial N)$.

We refer to Figure 1593 for an illustration.

2. A *thickened submanifold* of $M$ is a pair $(N,g)$ where $N$ is a compact orientable proper submanifold of $M$ and $g$ is a thickening for $N$.

3. Let $\varphi: M \to W$ be a smooth embedding of $M$ into a smooth manifold $W$ of the same dimension. Given a thickened $k$-dimensional submanifold $(N,g: B^{n-k} \times N)$ of $M \setminus \partial M$ we equip $\varphi(N)$ with the “obvious thickening”, namely with the thickening that is given by

$$\varphi_*(g): B^{n-k} \times \varphi(N) \to W$$

$$(v,P) \mapsto g(v,\varphi^{-1}(P)).$$

Evidently $(\varphi(N), \varphi_*(g))$ is a thickened submanifold of $W$.

---

Here one really would like to say that $g: B^{n-k} \times N \to M$ is an “smooth embedding”, but if $N$ has boundary, then it is not entirely clear in what sense $B^{n-k} \times N$ is a smooth manifold and what “smooth embedding” is supposed to mean.

The definition looks very similar to the definition of a tubular neighborhood. In fact a thickening is the same data as a trivial tubular neighborhood, it is just phrased in slightly different words.

On page 2384 we introduced the thickening of an *oriented* knot. For knots the present definition is the same as before, except that we no longer demand that the knot is oriented.

Note that here, in the definition of a thickened submanifold, we sneaked in the adjectives “compact”, “orientable” and “proper”, so that we will not have to carry them around all the time.
**Definition.** Let $M$ be an orientable $n$-dimensional smooth manifold. Given a thickened $k$-dimensional submanifold $(N, g: \overline{B}^{n-k} \times N \to M)$ we refer to the map $\rho_{(N, g)}: M \to S^{n-k} = \overline{B}^{n-k}/S^{n-k-1}$

\[
P \mapsto \begin{cases} [x], & \text{if } P = g(x, y) \text{ with } (x, y) \in \overline{B}^{n-k} \times N, \\ *, & \text{otherwise} \end{cases}
\]

as the Thom-Pontryagin map. (We refer to Figure 1594 for an illustration.) Sometimes we refer to this approach of assigning to a thickened $k$-dimensional submanifold a map $M \to S^{n-k}$ as the Thom-Pontryagin construction.

**Remark.**

1. Let $N$ be a compact oriented proper codimension-one submanifold of an oriented smooth manifold $M$. It follows immediately from Proposition 10.9 that $N$ admits a thickening $[-1, 1] \times N$ such that the inclusion $(-1, 1) \times N \to M$ is orientation-preserving. The map $\rho_N: M \to S^1$ that we defined on page 2360 is basically the same as the above map $\rho_{(N, g)}: M \to S^1$. The only difference is that the two maps differ by multiplication by $i \in S^1$.

2. We saw in Proposition 94.14 that the submanifold $\mathbb{C}P^1$ of $\mathbb{C}P^2$ does not admit a trivial tubular neighborhood, in particular it does not admit a thickening.

**Example.** Let $n \in \mathbb{N}$ and let $M$ be a closed orientable $n$-dimensional smooth manifold together with a 0-dimensional submanifold $N = \{P_1, \ldots, P_m\}$. Suppose $N$ is equipped with a thickening

$$g = g_1 \sqcup \cdots \sqcup g_m: (\overline{B}^n \times \{P_1\}) \sqcup \cdots \sqcup (\overline{B}^n \times \{P_m\}) \to M.$$ 

From the Thom-Pontryagin construction we obtain a map $\rho_{(N, g)}: M \to S^n$. It might not be clear what this is good for, but it is kind of fun. This example is illustrated in Figure 1595.

---

1606 It follows easily from Lemma 89.1 and Lemma 2.35 (2) that this map is indeed continuous.

1607 Furthermore we saw in Proposition 10.7 that this thickening is essentially unique.
The following lemma gives us a first interesting example of a Thom-Pontryagin map.

**Lemma 115.1.** Let \( n \in \mathbb{N} \) and let \( P \subseteq B^n \). We equip the \( 0 \)-dimensional smooth manifold \( \{P\} \) with any thickening \( g : \overline{B}^n \times \{P\} \to B^n \) that is orientation-preserving. The corresponding map

\[ \rho_{\{P\}g} : \overline{B}^n / S^{n-1} \to \overline{B}^n / S^{n-1} \]

is homotopic rel \( * \) to the identity map of \( \overline{B}^n / S^{n-1} \).

The proof of Lemma 115.1 relies on the following lemma which we will use on several occasions.

**Lemma 115.2.** Let \( m \in \mathbb{N} \). Given any real number \( r \in (0, 1) \) there exists a homotopy \( F : \overline{B}^m / S^{m-1} \times [0, 1] \to \overline{B}^m / S^{m-1} \) rel \( * \) with the following three properties:

1. \( F_0 = \text{id} \),
2. the restriction of \( F_1 \) to \( B^m_r \) is given by multiplication by \( \frac{1}{r} \),
3. for any point \( x \not\in B^m_r \) we have \( F_1(x) = * \).

**Proof.** Let \( r \in (0, 1) \). We consider the map

\[
(\overline{B}^m / S^{m-1}) \times [0, 1] \to \overline{B}^m / S^{m-1} \\
([x], t) \mapsto \begin{cases} 
[x \cdot (1 - t + t \cdot \frac{1}{r})], & \text{if } x \in B^m \text{ and } t < \frac{1 - \|x\|}{(\frac{1}{r} - 1) \cdot \|x\|} \\
* & \text{otherwise.}
\end{cases}
\]

We leave as to the engaged reader to verify that this map is indeed continuous. It is clear that \( F \) has the desired properties.

**Sketch of proof of Lemma 115.1.** It follows quite easily\(^{1608}\) from Theorem 8.36 that we can assume without loss of generality that \( P = 0 \) and that we can assume that \( g \) is the thickening \( g : \overline{B}^n \times \{0\} \to B^n \) given by \( g(v, 0) = \frac{1}{2} v \). By Lemma 115.2 there exists a homotopy \( F : (\overline{B}^n / S^{n-1}) \times [0, 1] \to \overline{B}^n / S^{n-1} \) rel \( * \) with the following three properties:

1. \( F_0 = \text{id} \),
2. \( F_1 \) is orientation-preserving,
3. \( F \) is compact.

\(^{1608}\) We equip \( \overline{B}^m \) and \( B^n \) with the usual orientation.

\(^{1609}\) The slightly hesitant “quite easily” refers to the fact that, if one thinks about it, we need that the diffeotopy of \( \mathbb{R}^{m+k} \) given by Theorem 8.36 has compact support.
(2) the restriction of $F_1$ to $B_{\frac{n}{2}}^n$ is given by the map $x \mapsto 2 \cdot x$.

(3) for any point $x \notin B_{\frac{n}{2}}^n$ we have $F_1(x) = \ast$.

If one thinks about it for a second, then one realizes that $F_1$ equals $\rho_{(0,\ast)}$ "on the nose". Thus we have found the desired homotopy. ■

115.2. The Thom-Pontryagin construction and homotopy groups. The following is the key observation which justifies our renewed interest in the Thom-Pontryagin construction.

**Observation.** Let $n, k \in \mathbb{N}_0$ and let $(N, g: \overline{B}^n \times N \to \mathbb{R}^{n+k})$ be a thickened $k$-dimensional submanifold of $\mathbb{R}^{n+k}$. We can view $(N, g: \overline{B}^n \times N \to \mathbb{R}^{n+k})$ also as a thickened submanifold of $\mathbb{R}^{n+k} \cup \{\infty\}$.

Note that the corresponding Thom-Pontryagin map $\rho_{(N, g)}: S^{n+k} = \mathbb{R}^{n+k} \cup \{\infty\} \to \overline{B}^n / S^{n-1} = S^n$

$P \mapsto \begin{cases} [x], & \text{if } P = g(x, y) \text{ with } (x, y) \in \overline{B}^n \times N, \\ \ast, & \text{otherwise}, \end{cases}$

sends $\infty$ to $\ast$. In particular $\rho_{(N, g)}$ defines an element in $\pi_{n+k}(S^n, \ast)$. It is worth repeating this observation:

**thickened** $k$-dimensional submanifolds of $\mathbb{R}^{n+k}$ give rise to elements in $\pi_{n+k}(S^n, \ast)$.

The following questions immediately arise:

**Question 115.3.** Let $n, k \in \mathbb{N}_0$.

(1) Which elements in $\pi_{n+k}(S^n, \ast)$ can be realized by Thom-Pontryagin maps?

(2) When do two thickened $k$-dimensional submanifolds of $\mathbb{R}^{n+k}$ give rise to the same element in $\pi_{n+k}(S^n, \ast)$.

Before we address this question we intend to discuss two examples in greater detail:

(1) the case of thickened 0-dimensional submanifolds of some $\mathbb{R}^n$, and

(2) the case of thickened 1-dimensional submanifolds of $\mathbb{R}^3$.

We start out with the first case. Dealing with this case requires one definition.

**Definition.** Let $P \in \mathbb{R}^n$ be a point and let $g: \{P\} \times \overline{B}^n \to \mathbb{R}^n$ be a thickening of $P$. We equip $\{P\} \times \overline{B}^n = \overline{B}^n$ and $\mathbb{R}^n$ with the standard orientations. We define

$$\text{sign}(g) := \begin{cases} +1, & \text{if } g \text{ is orientation-preserving}, \\ -1, & \text{if } g \text{ is orientation-reversing}. \end{cases}$$

Now we can discuss the case of thickened 0-dimensional submanifolds.

**Example.** Let $N = \{P_1, \ldots, P_m\}$ be a 0-dimensional submanifold of some $\mathbb{R}^n$ and suppose $N$ is equipped with a thickening $g = g_1 \sqcup \cdots \sqcup g_m: (\overline{B}^n \times P_1) \sqcup \cdots \sqcup (\overline{B}^n \times P_m) \to \mathbb{R}^n$.

---

1610 Why can we do so?
It follows almost immediately from Proposition 53.11 that

\[ [\rho_{(N,g)}] = \sum_{i=1}^{m} \text{sign}(g_i) \cdot \left[ \text{id}_{S^n} \right] \in \pi_n(S^n, *) \]

We continue our discussion of examples of the Thom-Pontryagin construction with knots and links. By the above discussion every thickened knot or link in \( \mathbb{R}^3 \), i.e. every thickened 1-dimensional submanifold of \( \mathbb{R}^3 \), gives rise to an element in \( \pi_3(S^2, *) \). For the trefoil together with some thickening we illustrate the corresponding map \( S^3 \to S^2 \) in Figure 1597.

Before we continue we need to introduce the following slight variation on a definition from page 2384.

**Definition.** Let \( K \) be a knot and let \( g: \overline{B}^2 \times K \to S^3 \) be a thickening. We pick an orientation for \( K \) and we equip \( g(\{1\} \times K) \) with the corresponding definition. We define \( \rho(K,g) \cdot \left[ \text{id}_{S^n} \right] \) to be the self-linking number of \( g := \text{lk}(K, g(\{1\} \times K)) \).

It follows from Proposition 99.10 (2) that this definition does not depend on the choice of the orientation of \( K \).

The following lemma deals with two basic, but important examples. Later on both examples will follow (at least up to sign) from a more general result, but for the geometrically inclined person it can be fun to consider the more direct arguments provided in the proof of the lemma.

**Lemma 115.4.** Let \( K \) be the trivial knot and let \( g: \overline{B}^2 \times K \to \mathbb{R}^3 \) be a thickening.

1. If \( g \) is a thickening with self-linking number zero, then \( [\rho_{(K,g)}] = 0 \in \pi_3(S^2, *) \).
2. If \( g \) is a thickening with self-linking number one, then \( [\rho_{(K,g)}] = [H] \in \pi_3(S^2, *) \) where \( H: (S^3, *) \to (S^2, *) \) denotes the Hopf map, that we defined on page 1071.

**Sketch of proof (\(*\)).** It follows easily from Lemma 99.1 that any two thickenings with the same self-linking number give rise to the same element in \( \pi_3(S^2, *) \). Furthermore it follows almost immediately from Lemma 27.1 that we can make the identification

\[ S^3 = (S^1 \times \overline{B}^2) \cup_{S^1 \times S^1} (\overline{B}^2 \times S^1) \]

---

\( ^{1611} \) We refer to page 2396 for the definition of the linking number \( \text{lk}(K, J) \) of two disjoint oriented knots \( K \) and \( J \).

\( ^{1612} \) The sign should be correct. Hopefully. Perhaps.

\( ^{1613} \) Note that here we need that in the statement of Lemma 99.1 for \( \mathbb{R}^3 \) we stated that there exists a diffeotopy of \( \mathbb{R}^3 \) with compact support.
such that $K = \{0\} \times S^1$. Furthermore it follows from Lemma 27.2 that the obvious inclusion of $B^2 \times S^1$ into the above decomposition of $S^3$ is a thickening of the trivial knot $K = S^1$ with self-linking number zero.

(1) Let $g$ be the thickening of the trivial knot $K$ with self-linking number zero. We want to show that $[\rho_{(K,g)}] = 0 \in \pi_3(S^2, \ast)$. By Proposition 54.9 it suffices to show that the map $\rho_{(K,g)}: S^3 \to S^2$ is homotopic to a constant map. (More precisely, Proposition 54.9 (7) says that in this context we do not need to worry about base points since $S^2$ is path-connected.) Using the above preparations we will prove in Exercise 15.1 that the map $\rho_{(K,g)}: S^3 \to S^2$ is indeed homotopic to a constant map.

(2) First we note that under the above identification of $S^3$ the Hopf map is given as follows:

$$H: (S^1 \times B^2) \cup_{S^1 \times S^1} (\overline{B^2} \times S^1) \to \mathbb{CP}^1$$

$$([(z,w)]) \mapsto \begin{cases} \left(\frac{w}{z}:1\right), & \text{if } z \in S^1 \text{ and } w \in \overline{B^2}, \\ \left[1: \frac{z}{w}\right], & \text{if } z \in \overline{B^2} \text{ and } w \in S^1. \end{cases}$$

Now note that it follows from Lemma 99.1 (1) that the map

$$g: \overline{B^2} \times S^1 \to \overline{B^2} \times S^1 \subset S^3 = (S^1 \times \overline{B^2}) \cup_{S^1 \times S^1} (\overline{B^2} \times S^1)$$

$$(z, w) \mapsto (z \cdot w, w)$$

is a thickening of the trivial knot of self-linking number one. Furthermore by definition the corresponding map $\rho_{(K,g)}$ is easily seen to be the map

$$\rho_{(K,g)}: (S^1 \times \overline{B^2}) \cup_{S^1 \times S^1} (\overline{B^2} \times S^1) \to \overline{B^2}/S^1$$

$$([(z,w)]) \mapsto \begin{cases} \infty = [S^1], & \text{if } z \in S^1 \text{ and } w \in \overline{B^2}, \\ \left[\frac{z}{w}\right], & \text{if } z \in \overline{B^2} \text{ and } w \in S^1. \end{cases}$$

Comparing the definitions of the Hopf map $H$ and the map $\rho_{(K,g)}$ on $\overline{B^2} \times S^1$ we see that we are perhaps not that far off.

Next we need to relate the targets $\mathbb{CP}^1$ and $\overline{B^2}/S^1$. To do so we consider the map $\Theta: \mathbb{CP}^1 \to \overline{B^2}/S^1$ that is given by $\Theta([1:z]) = \left(\frac{z}{1+|z|^2}\right)$ for $z \in \mathbb{C}$ and that is given by $\Theta([0:1]) = [S^1] = \ast \in \overline{B^2}/S^1$. It follows easily from Proposition 2.43 (3) that $\Theta$ is a homeomorphism. The particularly audacious reader can verify that this map is homotopic to the “official” identification $\mathbb{CP}^1 = \overline{B^2}/S^1$ which is given by the identification $\mathbb{CP}^1 = S^2$ from page 197 and the above identification $S^2 = \overline{B^2}/S^1$. Note that the image of the first solid torus $\overline{B^2} \times S^1$ under the map $\Theta \circ H$ equals the disk of radius $\frac{1}{2}$, i.e. it equals $\overline{B^2}_\frac{1}{2} \subset \overline{B^2}/S^1$.

1614 As a reality check one can verify that the map is well-defined, i.e. for $[(z,w)]$ with $(z,w) \in S^1 \times S^1$ we get consistent answers.

1615 Why does it say $[\frac{z}{w}]$ instead of $[z \cdot w]$, which might look more natural?
We apply Lemma 115.2 to obtain a homotopy \( F \) of \( B^2/S^1 \) with the following properties:
(a) \( F_0 = \text{id} \),
(b) the restriction of \( F_1 \) to \( B_1^2 \) is given by multiplication by 2,
(c) for any point \( x \not\in B_2^2 \) we have \( F_1(x) = * \).

The map \( F_0 \circ \Theta \circ H = \Theta \circ H \) is homotopic rel \( * \) to \( F_1 \circ \Theta \circ H \). It is now straightforward to show that \( F_1 \circ \Theta \circ H \) is homotopic rel \( * \) to \( \rho(K,g) \). We leave it to the reader to fill in the details.

We conclude this list of basic examples of the Thom-Pontryagin construction with the following lemma.

**Lemma 115.5.** Let \( n, k \in \mathbb{N}_0 \) with \( n + k \geq 2 \). Let \( (N_i, g_i), i = 1, \ldots, m \) be thickened \( k \)-dimensional submanifolds of \( \mathbb{R}^{n+k} \). If the images \( g_i(B^n \times N_i) \) are contained in \( m \) disjoint closed smooth \((n+k)\)-dimensional balls\(^{16,17} \), then
\[
\rho(N_1 \sqcup \cdots \sqcup N_m, g_1 \sqcup \cdots \sqcup g_m) = \rho(N_1, g_1) + \cdots + \rho(N_m, g_m) \in \pi_{n+k}(S^n, *) .
\]

**Proof.** This lemma follows easily from Proposition 53.11. We leave it to the reader to fill in the details.

The following proposition gives an affirmative answer to Question 115.3.

**Proposition 115.6.** Let \( k, n \in \mathbb{N}_0 \). Given any \( \varphi \in \pi_{n+k}(S^n, *) \) there exists a thickened \( k \)-dimensional submanifold \((N, g)\) of \( \mathbb{R}^{n+k} \) with \( \rho(N,g) = \varphi \).

**Proof.** Throughout this proof we find it convenient to view each \( m \)-dimensional sphere as the quotient \( \overline{B}^m/S^{m-1} \). So suppose we are given a map \( \varphi : \overline{B}^{n+k}/S^{n+k-1} \rightarrow \overline{B}^n/S^{n-1} \) with \( \varphi(*) = * \). As we pointed out in Corollary 9.4, it is a consequence of the Whitney Approximation Theorem 9.3 that we can arrange that \( \varphi \) is in fact a smooth map. It follows immediately from Sard’s Theorem 6.63 and Proposition 6.62 (2) that there exists a regular value \( z \in \overline{B}^n/S^{n-1} \) such that \( \varphi^{-1}(z) \) does not contain the point \(* \). By Proposition 8.29 (2) we can without loss of generality assume that the origin 0 is a regular value. By the Regular Value Theorem 11.1 we know that the preimage \( N : = \varphi^{-1}(0) \) is a closed orientable \( k \)-dimensional submanifold of \( B^{n+k} \). Furthermore by statement (4) of the Regular Value

\(^{16,17}\) Here a “closed smooth \((n+k)\)-dimensional ball” is shorthand for the image of a smooth embedding of \( B^{n+k} \) in \( \mathbb{R}^{n+k} \).

\(^{16,17}\) To be more precise, we apply Proposition 8.29 to the smooth manifold \( \overline{B}^n/S^{n-1} = \mathbb{R}^n \cup \{ \infty \} \) with \( P_1 = z, \ P_2 = \infty \) and \( Q_1 = 0 \) and \( Q_2 = \infty \).
Theorem 11.1 we know that there exists an $\epsilon > 0$ and a thickening $g: B^n \times N \to B^{n+k}$ such that $\varphi^{-1}(B^g\epsilon) = g(B^n \times N)$ and such that the following diagram commutes:

\[
\begin{array}{ccc}
B^n \times N & \xrightarrow{g} & B^{n+k} \\
\downarrow (p,x) \mapsto \varphi & & \downarrow \varphi \\
B^g\epsilon & \xrightarrow{} & B^n/S^{n-1}.
\end{array}
\]

This thickening $g$ allows us to consider the map $\rho_{(N,g)}: B^{n+k}/S^{n+k-1} \to B^n/S^{n-1}$. Note that in general $\varphi$ and $\rho_{(N,g)}$ are quite different maps. (We refer to Figure 1599 for an illustration of the two maps $\varphi$ and $\rho_{(N,g)}$.) But that does not bother us too much, since it suffices to prove the following claim.

**Claim.** The maps $\varphi$ and $\rho_{(N,g)}$ from $B^{n+k}/S^{n+k-1}$ to $B^n/S^{n-1}$ are homotopic rel $\ast$.

\[
\begin{array}{c}
\begin{array}{c}
B^{n+k}/S^{n+k-1} \\
\varphi
\end{array}
\end{array}
\quad \xrightarrow{\varphi} \quad
\begin{array}{c}
\begin{array}{c}
B^n/S^{n-1} \\
\ast
\end{array}
\end{array}
\quad \xleftarrow{\rho(N,g)}
\begin{array}{c}
\begin{array}{c}
B^{n+k}/S^{n+k-1} \\
N
\end{array}
\end{array}
\]

**Figure 1599**

First we remind the reader that in Lemma 115.2 (1) we showed that there exists a homotopy $F: (B^n/S^{n-1}) \times [0,1] \to B^n/S^{n-1}$ rel $\ast$ with the following properties:

1. $F_0 = \text{id}$,
2. the restriction of $F_1$ to $B^n$ is given by multiplication by $\frac{1}{s}$,
3. for any point $x \notin B^n_\epsilon$ we have $F_1(x) = \ast$.

We define $\psi = F_1 \circ \varphi$. It follows from (1) that $\psi$ is homotopic rel $\ast$ to $\varphi$. Therefore we are done once we have shown that $\psi$ in fact equals $\rho_{(N,g)}$. As a reminder, see the definition on page 2726 the map $\rho_{(N,g)}$ is given as follows:

\[
\rho_{(N,g)}: B^{n+k}/S^{n+k-1} \to S^n = B^n/S^{n-1}
\]

with $P \mapsto \begin{cases} x, & \text{if } P = g(x, y) \text{ with } (x, y) \in B^n \times N, \\ \ast, & \text{otherwise.} \end{cases}$

---

\[11618\] Note the discretely hidden multiplication by $\epsilon$ in the left-vertical map.\[11619\] Note that the above information implies in particular that $\varphi^{-1}(B^n\epsilon) = g(B^n \times N)$.\[11620\] But with either description of the map the points $P = g(x, y)$ with $x \in S^{n-1}$ and $y \in N$ get sent to $\ast$. So we really do consider the same map as before.
Now we verify that $\psi$ does indeed agree with $\rho_{(N,g)}$. Thus first suppose we are given a point $P = g(x,y)$ with $(x,y) \in B^n \times N$. We have
\[
\psi(P) = F_1(\varphi(g(x,y))) = F_1(\epsilon \cdot x) = \frac{1}{\epsilon} \epsilon \cdot x = x = \rho_{(N,g)}(g(x,y)) = \rho_{(N,g)}(P).
\]
Finally suppose that we are given a point $P \in B^{n+k} / S^{n+k-1}$ that does not lie in the subset $g(B^n \times N)$. In this case we calculate that
\[
\psi(P) = F_1(\varphi(P)) = F_1(\text{point that does not lie in } B^n_v) = * = \rho_{(N,g)}(P).
\]

115.3. The thickened cobordism groups and the Thom–Pontryagin Theorem. Recall that the Thom–Pontryagin construction from page 2726 makes the assignment
\[
\text{thickened } k\text{-dimensional submanifold of } \mathbb{R}^{n+k} \rightsquigarrow \text{map } (S^{n+k},*) \rightarrow (S^n,*)).
\]
Now we would like to answer Question 115.3 (2), i.e. we would like to determine when do two thickened $k$-dimensional submanifolds give rise to the same homotopy class of maps $(S^{n+k},*) \rightarrow (S^n,*)$. Loosely speaking we would like to fill in the left-hand side of
\[
?? \rightsquigarrow \text{map } (S^{n+k} \times [0,1],*,[0,1]) \rightarrow (S^n,*)
\]
A quick look at the Thom–Pontryagin construction suggests that the left-hand side should be filled in with a suitable thickened $(k+1)$-dimensional submanifold of $\mathbb{R}^{n+k} \times [0,1]$.

This makes sense, except that in Proposition 6.51 we saw that for products of two smooth manifolds it is advisable to have the smooth manifold with boundary as a first factor. Thus we will consider submanifolds of $[0,1] \times \mathbb{R}^{n+k}$.

Before we continue we introduce the following straightforward convention.

Convention. Given a topological space $X$ and an interval $I$ and some $t \in I$ we make at times the identification $X = \{t\} \times X$ via the obvious bijection.

The above observation leads us to the following definition which looks awfully similar to the definition of the notion of a cobordism of smooth manifolds that we introduced on page ??.

Definition. Let $k, m \in \mathbb{N}_0$.

1. Let $N_0$ and $N_1$ be two closed orientable $k$-dimensional submanifolds of $\mathbb{R}^m$. A **cobordism between $N_0$ and $N_1$** is a compact orientable proper $(k+1)$-dimensional submanifold $W$ of $[0,1] \times \mathbb{R}^m$ with $\partial W = \{0\} \times N_0 \cup \{1\} \times N_1$.

2. Let $(N_0, g_0)$ and $(N_1, g_1)$ be two thickened $k$-dimensional submanifolds of $\mathbb{R}^m$. A **thickened cobordism between $(N_0, g_0)$ and $(N_1, g_1)$** is a thickened $(k+1)$-dimensional

---

1621Perhaps in hindsight we should have defined homotopies as maps $[0,1] \times X \rightarrow Y$ instead of defining them as maps $X \times [0,1] \rightarrow Y$?
A submanifold \((W, G)\) of \([0, 1] \times \mathbb{R}^m\) where \(W\) is a cobordism between \(N_0\) and \(N_1\) and \(G\) is a thickening of \(W\) with the following two properties:

1. \(G|_{\{0\} \times \mathbb{R}^m} = g_0\) under the identification \(\{0\} \times \mathbb{B}^m = \mathbb{B}^m\),
2. \(G|_{\{1\} \times \mathbb{R}^m} = g_1\) under the identification \(\{1\} \times \mathbb{B}^m = \overline{\mathbb{B}}^m\).

If such a thickened cobordism exists, then we say that \((N_0, g_0)\) and \((N_1, g_1)\) are cobordant. If \((N, g)\) is cobordant to the empty submanifold, then we say \(N\) is a thickened null-cobordism and we say that \((N, g)\) is null-cobordant. The definition of a thickened cobordism is illustrated in Figure 1600.

![Thickened Cobordism Diagram](image)

**Figure 1600**

The following lemma shows that diffeotopies give rise to thickened cobordisms.

**Lemma 115.7.** Let \((M, g)\) be a thickened submanifold of \(\mathbb{R}^m\) and let \(\varphi\) be a diffeomorphism of \(\mathbb{R}^m\). If \(\varphi\) is diffeotopic to the identity, then \((\varphi(M), \varphi_*(g))\) is cobordant to \((M, g)\).

**Example.** Let \(m \in \mathbb{N}\). Any map \(\mathbb{R}^m \to \mathbb{R}^m\) of the form \(x \mapsto r \cdot x + P\) for some \(r > 0\) and \(P \in \mathbb{R}^m\) is clearly diffeotopic to the identity. Thus Lemma 115.7 says that given a thickened submanifold \((M, g)\) we can translate and shrink it without changing the thickened cobordism class.

**Proof.** Let \((M, g: \overline{B}^{m-k} \times M \to \mathbb{R}^m)\) be a thickened \(k\)-dimensional submanifold of \(\mathbb{R}^m\) and furthermore let \(F: \mathbb{R}^m \times [0, 1] \to \mathbb{R}^m\) be a diffeotopy from the identity to a diffeomorphism \(\varphi\). It is straightforward to verify that the map

\[
[0, 1] \times M \to [0, 1] \times \mathbb{R}^m,
(t, P) \mapsto (t, F(P, t))
\]

is a smooth embedding. We write \(W := F([0, 1] \times M)\). It is straightforward to verify that \(W\) together with the thickening given by

\[
\overline{B}^{m-k} \times W \to [0, 1] \times \mathbb{R}^m,
(v, (t, F(P, t))) \mapsto (t, F(g(v, P), t))
\]

is a thickened cobordism between \((M, g)\) and \((\varphi(M), \varphi_*(g))\).

---

Note that we work with submanifolds that are orientable, but we do not assume that they are equipped with an orientation.

Note that it follows from property (d) of a thickened submanifold, see page 2725 that we know that in fact \(G|_{\{0\} \times \mathbb{R}^m} \subseteq \{0\} \times \mathbb{R}^m\) and \(G|_{\{1\} \times \mathbb{R}^m} \subseteq \{1\} \times \mathbb{R}^m\).

We spare the reader the even more logical name “thickened cobordant”.

---
Lemma 115.8. “Being cobordant” is an equivalence relation on the set of thickened $k$-dimensional submanifolds of $\mathbb{R}^m$.

Sketch of proof. To simplify the discussion we ignore throughout the proof the thickenings. The reader should have no major troubles modifying the proof to also include the thickenings.

It is straightforward to see that “being cobordant” is reflexive and symmetric: Indeed, given a closed $k$-dimensional submanifold $N$ a cobordism from $N$ to itself is given by $[0, 1] \times N \subset [0, 1] \times \mathbb{R}^m$. Furthermore, suppose there exists a cobordism $W$ between $N_0$ and $N_1$. “Flipping” $W$ along $\mathbb{R}^m \times \{\frac{1}{2}\}$ we obtain a cobordism between $N_1$ and $N_0$.

The proof of transitivity takes more efforts. Initially the idea is quite simple. Given a cobordism $V$ from $N_0$ to $N_1$ and another cobordism $W$ from $N_1$ to $N_2$ one would like to stick them together to obtain a cobordism from $N_0$ to $N_2$. Unfortunately, as we had discussed on page 363 the resulting object is in general not a (smooth) submanifold of the smooth manifold $\mathbb{R}^m$.

Fortunately we had already developed all the tools to deal with the situation. More precisely, in Proposition 8.21 we saw that we can modify the cobordisms $V$ and $W$ to obtain cobordisms $V'$ and $W'$ that are products on $[0, \varepsilon] \times \mathbb{R}^m$ and $[1 - \varepsilon, 1] \times \mathbb{R}^m$ for a suitable $\varepsilon \in (0, \frac{1}{2})$. Now we can stick $V'$ and $W'$ together to obtain the desired cobordism $X$. We refer to Figure 1601 for an illustration.

![Figure 1601. Illustration for the proof of Lemma 1601](image)

The previous lemma allows us to make the following definition.

Definition. We denote by $\Omega^\text{th}_k(\mathbb{R}^m)$ the set of thickened cobordism classes of thickened $k$-dimensional submanifolds of $\mathbb{R}^m$. In light of the subsequent Proposition 115.9 we refer to $\Omega^\text{th}_k(\mathbb{R}^m)$ as a thickened cobordism group.

The definition of $\Omega^\text{th}_k(\mathbb{R}^m)$ is reminiscent of the definition of the cobordism group $\Omega_k$ that we gave on page 71. The group structure on $\Omega_k$ that we had introduced in Lemma ?? is given by “disjoint union”. We will now see that $\Omega^\text{th}_k(\mathbb{R}^m)$ also admits a group structure that is defined quite similarly.

Proposition 115.9. Let $k \in \mathbb{N}_0$ and let $m \in \mathbb{N}_{\geq 2}$. Let $(M, g)$ and $(N, h)$ be two thickened $k$-dimensional submanifolds of $\mathbb{R}^m$. Since $M$ and $N$ are compact we can pick $r, s \in \mathbb{R}_{>0}$...
with \( g(\overline{B}^{m-k} \times M) \subset B_r^m(0) \) and \( h(\overline{B}^{m-k} \times N) \subset B_s^m(0) \). Furthermore we pick two orientation-preserving smooth embeddings \( \varphi : \overline{B}_r^m(0) \to \mathbb{R}^m \) and \( \psi : \overline{B}_s^m(0) \to \mathbb{R}^m \) with disjoint images. We define

\[
[(M, g)] + [(N, h)] := [(\varphi(M) \sqcup \psi(N), \varphi_*(g) \sqcup \psi_*(h))] \quad \in \Omega_k^1(\mathbb{R}^m).
\]

(The definition of the operation “+” is illustrated in Figure 1602)

(1) The definition of “+” on \( \Omega_k^1(\mathbb{R}^m) \) is well-defined and commutative.

(2) The operation “+” defines a group structure on \( \Omega_k^1(\mathbb{R}^m) \). Here the following two statements hold:

(a) The neutral element is represented by the empty submanifold.

(b) Let \( \rho : \mathbb{R}^m \to \mathbb{R}^m \) be the reflection in a hyperplane. The inverse of \([[(M, g)]\] is given by \( [(\rho(M), \rho_*(g))]. \)

---

**Proof.**

(1) It follows from Theorem 8.36 and Lemma 115.7 that “+” is well-defined and commutative. Note that here we use that \( m \geq 2 \).

(2) It is basically obvious that “+” is associative and that the empty submanifold is a neutral element. Thus it remains to prove the statement regarding the inverse. It follows from Lemmas 115.7 and 18.5 that without loss of generality we can assume that the reflection \( \rho : \mathbb{R}^m \to \mathbb{R}^m \) is the reflection in the \((x_m = 0)\)-hyperplane. So let \((M, g: \overline{B}^{m-k} \times M \to \mathbb{R}^m)\) be a thickened \( k \)-dimensional submanifold of \( \mathbb{R}^m \). We set \( \epsilon = \frac{1}{4} \). It follows immediately from the discussion on page 2734 that we can assume that \( g(\overline{B}^{m-k} \times M) \) is contained in the ball \( \overline{B}_\epsilon^m((0, \ldots, 0, 2\epsilon)) \). We consider the map

\[
\varphi : \overline{B}^{m-k} \times (M \times [0, \pi]) \to [0, 1] \times \mathbb{R}^m
\]

\[
(v, (P, \gamma)) \mapsto \begin{pmatrix}
\cos(\gamma) & \sin(\gamma) & 0 \\
-\sin(\gamma) & \cos(\gamma) & 0 \\
0 & 0 & \text{id}_{m-1}
\end{pmatrix} \cdot \begin{pmatrix}
0 \\
(g(v, P)) \\
\epsilon_{\mathbb{R}^{m+1}}
\end{pmatrix}
\]

Using that \( g(\overline{B}^{m-k} \times M) \) is contained \( \overline{B}_\epsilon^m((0, \ldots, 0, 2\epsilon)) \) we can make the following three observations:

(a) The image of \( \varphi \) does indeed lie in \([0, 1] \times \mathbb{R}^m \).

---

\[1625\] It is worth remembering that the empty set is a submanifold of any dimension.
(b) The restriction to \( \{0\} \times M \times [0, \pi] \) is a proper smooth embedding. Therefore we can now consider the compact orientable proper \((k+1)\)-dimensional submanifold 
\( W = \varphi(\{0\} \times M \times [0, \pi]) \) of \([0, 1] \times \mathbb{R}^m\).

(c) The map \( \varphi \) gives rise to a thickening for \( W \).

It is now basically clear that we have constructed a thickened cobordism from the thickened submanifold \((M \sqcup \rho(M), g \sqcup \rho_*(g))\) to the empty submanifold. (We refer to Figure 1603 for an illustration.) But by the definition of “+” this implies that \((\rho(M), \rho_*(g))\) represents the inverse of \((M, g)\). ■

\[
\begin{tikzpicture}
  \node (M) at (0,0) {\(M\)};
  \node (rhoM) at (1,-1) {\(\rho(M)\)};
  \node (0timesRm) at (-1,0) {\(\{0\} \times \mathbb{R}^m\)};
  \node (1timesRm) at (2,0) {\(\{1\} \times \mathbb{R}^m\)};
  \draw[->] (M) -- (M) node[above] {W is a cobordism from the oriented manifold \(M \sqcup \rho(M)\) to the empty submanifold};
\end{tikzpicture}
\]

**Figure 1603**

Evidently our challenge now is to compute the groups \(\Omega^k_0(\mathbb{R}^m)\) for suitable values of \(m\) and \(k\). In general this might be quite difficult, but the following proposition gives a reasonably amusing calculation.

**Proposition 115.10.** Let \(m \geq 2\). The map \(\varphi\)\(^{1626}\)
\[
\varphi: \Omega^k_0(\mathbb{R}^m) \to \mathbb{Z}
\]
\[
[\{P_1\}, g_1] \sqcup \cdots \sqcup [\{P_k\}, g_k] \mapsto \sum_{i=1}^k \text{sign}(g_i)
\]
is well-defined and it is an isomorphism.

**Sketch of proof.** First we need to show that \(\varphi: \Omega^k_0(\mathbb{R}^m) \to \mathbb{Z}\) is well-defined. It suffices to show that for any connected thickened 1-dimensional cobordism \((Z, V) \subset [0, 1] \times \mathbb{R}^m\) between two 0-dimensional thickened submanifolds \((N_0, g_0)\) and \((N_1, g_1)\) we have the equality \(\varphi([\{N_0, g_0\}]) = \varphi([\{N_1, g_1\}])\). This statement follows from the classification of compact 1-dimensional smooth manifolds, see Theorem 7.5 and some orienation considerations. Since writing down the precise arguments regarding the orientations will only obfuscate the argument we refer to Figure 1604 for convincing pictures, and we leave it to the reader to fill in the details.

Next note that the map \(\varphi: \Omega^k_0(\mathbb{R}^m) \to \mathbb{Z}\) is, basically by definition, a homomorphism. Finally note that it is clear that \(\varphi\) is an epimorphism. Thus it remains to show that \(\varphi\) is a monomorphism. A straightforward induction argument shows that it suffices to prove the following claim.

**Claim.** For points \(P, Q \in \mathbb{R}^m\) and thickenings \(g\) and \(h\) of \(P\) and \(Q\) with \(\text{sign}(g) = -\text{sign}(h)\) we have \([\{P, g\}] + [\{Q, h\}] = 0 \in \Omega^k_0(\mathbb{R}^m)\).

\(^{1626}\)We refer to page 2728 for the definition of the sign of a thickening of a point.
In the following let ρ: ℝ^n → ℝ^n be the reflection in a hyperplane. By the discussion on page 2734 we can assume, after possibly applying a translation, that Q = ρ(P). Since ρ is orientation-reversing we see that sign(ρ∗(g)) = −sign(g) = sign(h). Now we calculate that

\[ [(P, g)] + [(Q, h)] = [(P, g)] + [(ρ(P), h)] = [(P, g)] + [(ρ(P), ρ∗(g))] = 0 \in \Omega^h_0(ℝ^n). \]

by sign(h) = sign(ρ∗(g)), Theorem 8.36 and Lemma 115.7 by Proposition 115.9 (2a)

Considering the discussion on page 2733 the following theorem does not come as a big surprise. It justifies our interest in the groups \( \Omega^h_k(ℝ^n) \).

**Theorem 115.11. (Thom-Pontryagin Theorem)** Let \( n, k \in \mathbb{N}_0 \) with \( n + k \geq 2 \). The map

\[ \Psi: \Omega^h_k(ℝ^{n+k}) \to \pi_{n+k}(S^n, \ast) \]

\[ [(N, g)] \mapsto [\rho(N, g)] \]

is well-defined and it is an isomorphism.

**Sketch of proof.** Fortunately we have already done basically all the work:

1. First we argue that \( \Psi \) is well-defined. Thus suppose that we are given thickened \( k \)-dimensional submanifolds \( (M, g) \) and \( (N, h) \) of \( ℝ^{n+k} \) that are cobordant. We pick a thickened cobordism \( (W, F): \mathcal{B}^n \times W \to [0, 1] \times ℝ^{n+k} \) in \( [0, 1] \times ℝ^{n+k} \). The corresponding map

\[ \rho_{(W,F)}: [0, 1] \times ℝ^{n+k} \to S^n \]

has the property that it sends a neighborhood of \([0, 1] \times \{ \infty \} \) to \( \ast \). Therefore it follows easily from Lemma 3.10 that the following map is continuous:

\[ S^{n+k} \times [0, 1] = (ℝ^{n+k} \cup \{ \infty \}) \times [0, 1] \to S^n \]

\[ (P, t) \mapsto \begin{cases} \rho_{(W,F)}(t, P), & \text{if } P \in ℝ^{n+k}, \\ \ast, & \text{if } P = \infty. \end{cases} \]

It follows from the above that this map is in fact a homotopy rel \( \ast \) between the map \( \rho_{(M,g)}: (S^{n+k}, \ast) \to (S^n, \ast) \) and the map \( \rho_{(N,h)}: (S^{n+k}, \ast) \to (S^n, \ast) \). In particular we have \( [\rho_{(M,g)}] = [\rho_{(N,h)}] \in \pi_{n+k}(S^n, \ast) \).

2. It follows immediately from Lemma 115.5 that \( \Psi \) is a homomorphism.

3. The statement of Proposition 115.6 is equivalent to saying that \( \Psi \) is an epimorphism.
(4) Finally it remains to show that $\Psi$ is in fact a monomorphism. So suppose that we are given two thickened $k$-dimensional submanifolds $(M, g)$ and $(N, h)$ of $\mathbb{R}^{n+k}$ such that $[\rho(M, g)] = [\rho(N, h)] \in \pi_{n+k}(S^n, *)$, i.e. such that there exists a homotopy $F: S^{n+k} \times [0,1] \to S^n$ rel $*$ from $\rho(M, g)$ to $\rho(N, h)$.

The proof of Proposition 115.6 can be modified without too many problems to show that the homotopy $F$ gives rise to a thickened cobordism between $(M, g)$ and $(N, h)$. We leave it to the reader to fill in the details. See also [Kos93 Theorem 9.5.5] or [Bre93 Chapter 16] for similar claims stated with more authority. 

From our above results we obtain the following corollary. Of course we proved this result earlier in Corollary 53.6 using very different methods.

**Corollary 115.12.** For any $m \geq 2$ the map

\[
\begin{align*}
\mathbb{Z} & \to \pi_m(S^m, *) \\
n & \mapsto n \cdot [\text{id}_{S^m}] 
\end{align*}
\]

is an isomorphism.

**Proof.** Let $P \in \mathbb{R}^m$ and let $g$ be a thickening for the submanifold $\{P\}$. We consider the two maps

\[
\begin{align*}
\mathbb{Z} & \to \Omega^0_{0}(\mathbb{R}^m) \\
n & \mapsto n \cdot [(\{0\}, g \text{ with sign}(g) = 1)] 
\end{align*}
\]

and

\[
\begin{align*}
\Omega^0_{0}(\mathbb{R}^m) & \to \pi_m(S^m, *) \\
[(N, g)] & \mapsto [\rho(N, g)].
\end{align*}
\]

The first map is an isomorphism by Proposition 115.10 and the second map is an isomorphism by the Thom-Pontryagin Theorem 115.11 applied to $k = 0$ and $m \geq 2$. Thus the composition of the two maps is an isomorphism. Finally it follows from Lemma 115.1 that the composition of these two maps sends $n$ to $n \cdot [\text{id}_{S^m}]$.

115.4. The calculation of the thickened cobordism group $\Omega^1_1(\mathbb{R}^3)$. Surely the most interesting calculation of a higher homotopy group that we have performed so far is that in Theorem 113.10 (2) we saw $\pi_3(S^2) \cong \mathbb{Z}$. Our goal now is to give a new proof of this fact using the Thom-Pontryagin Theorem 115.11 Thus we need to show that $\Omega^1_1(\mathbb{R}^3) \cong \mathbb{Z}$.

We start out with the following slightly subtle definition.

**Definition.** Let $m \in \mathbb{N}$.

1. Let $(M, v: \overline{B}^{m-k} \times \mathbb{R}^m)$ be a thickened $(m-k)$-dimensional submanifold of $\mathbb{R}^m$. The natural orientation of $M$ is the unique orientation that turns $v$ into an orientation-preserving map.

2. Similarly we define the natural orientation of a thickened cobordism.

This definition leads us to the following convention.

**Convention.** In this section we equip any thickened submanifold and any thickened cobordism with the natural orientation.

---

\[\text{Recall that } M \text{ is assumed to be orientable, but a priori it does not come with an orientation. It is not difficult to see that there exists a unique orientation on } M \text{ such that, if we equip } \overline{B}^{m-k} \times M \text{ with the product orientation, } v \text{ becomes orientation-preserving.}\]
Before we write down an explicit isomorphism we introduce the following definition which generalizes the definition of the self-linking number of a thickened knot that we introduced on page 2384.

**Definition.**

(1) Let \( K = K_1 \sqcup \cdots \sqcup K_m \) and \( L = L_1 \sqcup \cdots \sqcup L_n \) be two disjoint oriented links. We define the **linking number of \( K \) and \( L \)** as

\[
\text{lk}(K, L) = \sum_{i=1}^{m} \sum_{j=1}^{n} \text{lk}(K_i, L_j).
\]

(2) Let \((L, g)\) be a thickened link. We write \( L' = g(\{1\} \times L) \). We define the **self-linking number of \((L, g)\)** as \( \text{slk}(L, g) := \text{lk}(L, L') \).\(^{1628}\)

The following elementary lemma is at times useful for determining self-linking numbers of thickened links.

**Lemma 115.13.** If \((L, g) = (L_1 \sqcup \cdots \sqcup L_m, g_1 \sqcup \cdots \sqcup g_m)\) is a thickened link, then

\[
\text{slk}(L, g) := \sum_{i \neq j} \text{lk}(L_i, L_j) + \sum_{i=1}^{m} \text{slk}(L_i, g_i).
\]

**Proof.** We will prove the lemma in Exercise 115.2. \(\blacksquare\)

Now we can give the promised isomorphism.

**Theorem 115.14.** The map

\[
\Psi : \Omega^1_h(\mathbb{R}^3) \to \mathbb{Z}
\]

\[
[(L, g)] \mapsto \text{self-linking number} \ \text{slk}(L, g)
\]

is well-defined and it is an isomorphism. In particular we have \( \pi_3(S^2) \cong \mathbb{Z} \).

**Examples.**

(1) We consider the trivial knot \( K \) with a thickening \( g \) of self-linking number \(+1\). By Theorem 115.14 the thickened knot \((K, g)\) defines a generator of \( \Omega^1_h(\mathbb{R}^3) \). It follows from the isomorphism provided by the Thom-Pontryagin Theorem 115.11 that \( \rho(K, g) : S^3 \to S^2 \) represents a generator of \( \pi_3(S^2, *) \). In Lemma 115.4 we saw that \( \rho(K, g) \) represents the same element of \( \pi_3(S^2, *) \) as the Hopf map \( H : S^3 \to S^2 \). Thus we see once again that the Hopf map represents a generator of \( \pi_3(S^2) \).

\(^{1628}\)Here we use the above convention to view \( L \) as an oriented submanifold of \( \mathbb{R}^3 \), and we equip \( L' = g(\{1\} \times L) \) with the obvious corresponding orientation.
We consider the Hopf link \( L = L_1 \sqcup L_2 \) with the orientations shown in Figure 1606. We equip \( L = L_1 \sqcup L_2 \) with a “trivial thickening” \( g_1 \sqcup g_2 \), i.e. where the thickening \( g_i \) of each component \( L_i \) has self-linking number 0. We see that

\[
\text{slk}(L_1 \sqcup L_2, g_1 \sqcup g_2) = \text{lk}(L_1, L_2) + \text{lk}(L_2, L_1) + \text{slk}(L_1, g_1) + \text{slk}(L_2, g_2) = 1 + 1 = 2.
\]

This shows that the Hopf link, perhaps slightly counter-intuitively, gives rise to twice the generator of \( \pi_3(S^2, \ast) \).

Figure 1606

Since we already have an independent proof of Theorem 115.14 we will take the liberty to cut a few corners in the new proof of the theorem. The new proof of Theorem 115.14 will build on the following four lemmas. The first two lemmas generalize Proposition 99.6 and Lemma 99.14 from knots to links. They are perhaps interesting in their own right.

**Lemma 115.15.** Given any oriented link \( L \subset S^3 \) there exists a compact oriented connected surface \( F \subset S^3 \) such that \( \partial F = L \).

**Proof of Lemma 115.15.** Let \( L \subset S^3 \) be an oriented link. A modest generalization of Proposition 99.6 shows that there exists a compact oriented surface \( G \subset S^3 \) with \( \partial G = L \). In Exercise 115.5 we will show that we can turn \( G \) into a compact oriented connected surface \( F \) with \( \partial F = L \).

**Lemma 115.16.** If \( K = K_1 \sqcup \cdots \sqcup K_m \) and \( L = L_1 \sqcup \cdots \sqcup L_n \) are two oriented links, then the following statements hold:

1. There exist compact oriented proper 2-dimensional submanifolds \( S \) and \( T \) of \( \overline{B}^4 \) with \( \partial S = K \) and \( \partial T = L \) such that \( S \) and \( T \) are transverse.
2. Let \( S, T \) be two oriented proper 2-dimensional submanifolds of \( \overline{B}^4 \) with \( \partial S = K \) and \( \partial T = L \). If \( S \) and \( T \) are transverse, then

\[
\text{lk}(K, L) = S \cdot_{\overline{B}^4} T.
\]

---

1629 Here the equality \( \partial F = L \) is understood to be an equality of oriented submanifolds.

1630 Frankly it can be slightly annoying to give a completely rigorous proof that such a surface \( F \) exists. This is one of the main reasons why we made the caveat above that we are going to cut a few corners in the argument.

1631 Here \( S \cdot_{\overline{B}^4} T \) denotes the algebraic intersection number of the oriented transverse surfaces \( S \) and \( T \) in the oriented smooth manifold \( \overline{B}^4 \). We refer to page 2271 for the definition of the algebraic intersection number.
Example. As on page 1734 we consider the Hopf link that is illustrated in Figure 1607 on the left. On the right of Figure 1607 we show a compact oriented connected surface whose boundary equals the Hopf link.

![Hopf link and surface with two sides](image)

**Figure 1607**

**Proof of Lemma 115.16.**

1. The proof of this statement is virtually the same as the proof of Lemma 99.14, we just need to replace Proposition 99.6 by Lemma 115.15.

2. We leave it to the reader to verify that the proof of Lemma 99.14 (2) can be modified to deal not only with knots but also with links. ■

The following two lemmas that we need for the proof of Theorem 115.14 are arguably more technical.

**Lemma 115.17.** Let $K$ be an oriented knot in $\mathbb{R}^3$ and let $g$ and $h$ be two thickenings for $K$ in $\mathbb{R}^3$. If $\text{slk}(K, g) = \text{slk}(K, h)$, then $[(K, g)] = [(K, h)] \in \Omega_{th}^3(\mathbb{R}^3)$.

**Proof of Lemma 115.17(**). Since $\text{slk}(K, g) = \text{slk}(K, h)$ it follows from Lemma 99.1 that there exists a smooth isotopy $F: (\overline{B}^2 \times K) \times [0, 1] \to \mathbb{R}^3$ between $g$ and $h$ which has compact support and which has the property that $F(0, k, t) = k$ for all $k \in K$ and all $t \in [0, 1]$. We consider $W = [0, 1] \times K$ with the thickening given by

$$j: B^2 \times ([0, 1] \times K) \to [0, 1] \times \mathbb{R}^3$$

$$(v, (t, x)) \to (t, F((v, x), t)).$$

The thickened smooth manifold $(W, j)$ is a thickened cobordism between $(K, g)$ and $(K, h)$. ■

**Lemma 115.18.** Let $W$ be a compact oriented proper connected 2-dimensional submanifold of $\mathbb{R}^3 \times [0, 1)$ with boundary components $L_1, \ldots, L_m$. Given $s_1, \ldots, s_{m-1} \in \mathbb{Z}$ there exists a thickening $h$ for $W$ such that for $i = 1, \ldots, m-1$ we have $\text{slk}(L_i, h|_{L_i}) = s_i$.

![Thickened manifold](image)

**Figure 1608**

**Proof.** Evidently we can assume that $m \geq 1$. In this case $W$ is a compact oriented proper connected 2-dimensional submanifold with non-empty boundary. Thus by Proposition 10.6...
(3) there exists a thickening $f: \mathcal{B}^2 \times W \to \mathbb{R}^3 \times [0, 1]$ for $W$. For $i = 1, \ldots, m - 1$ we write $r_i := \text{slk}(L_i, g|L_i)$.

By Lemma 23.12 there exists a map $\varphi: W \to L_1 \vee \cdots \vee L_{m-1}$ that is the identity on each $L_i$. We pick a map $\psi: L_1 \vee \cdots \vee L_{m-1} \to \text{SO}(2) = S^1$ with the following property: under an orientation-preserving identification $L_i \cong S^1$ the restriction of $\psi$ to $L_i$ is given by $z \mapsto z^{s_i - r_i}$. Now we consider the thickening

$$h: \mathcal{B}^2 \times W \to W$$

$$\quad (v, P) \mapsto f\left(\left(\psi \circ \varphi(P)\right) \cdot \left[\begin{array}{c} v \\ \pm \text{SO}(2) \end{array}\right] \cdot \left[\begin{array}{c} v \\ P \end{array}\right] \right).$$

By Lemma 99.1 (1) we know that for any $i \in \{1, \ldots, m - 1\}$ we added $s_i - r_i$ to the self-linking number of $L_i$. Thus the thickening $h$ has all the desired properties.

Now we are in a position to provide the proof of Theorem 115.14. Sketch of proof of Theorem 115.14

(1) First we need to show that $\Psi: \Omega^{1b}_1(\mathbb{R}^3) \to \mathbb{Z}$ is well-defined. In the proof of this fact we borrow some ideas from the proof of Lemma 99.14 (2). So let $(W, F)$ be a thickened cobordism between $(K, g)$ and $(L, h)$. We write $W' = F(\{1\} \times W)$, $K' = g(\{1\} \times K)$ and $L' = h(\{1\} \times L)$. By Lemma 115.16 (1) there exist oriented proper 2-dimensional submanifolds $S$ and $S'$ of $\mathcal{B}^4$ with $\partial S = K$ and $\partial S' = K'$ such that $S$ and $S'$ are transverse. Similarly there exist $T, T'$ for $L$ and $L'$.

We can make the identification $S^4 = (-\mathcal{B}^4) \cup [0, 1] \times S^3 \cup \mathcal{B}^4$ (See Figure 1609 for an illustration.) Using Proposition 8.22 we can arrange that both $(-S) \cup W \cup T$ and $(-S') \cup W' \cup T'$ are oriented submanifolds of the smooth manifold $S^4$. We calculate that

$$\text{by definition of slk} \quad \text{Lemma 115.16 (2)}$$

$$- \text{slk}(K, g) + \text{slk}(L, h) \quad \downarrow$$

$$= - \text{lk}(K, K') + \text{lk}(L, L') \quad \downarrow$$

$$= (-S) \cdot \mathcal{B}^4 \quad (-S) + T \cdot \mathcal{B}^4 \quad T' \quad = (-S \cup W \cup T) \cdot \mathcal{B}^4 \quad (-S' \cup W' \cup T') \quad = 0.$$ 

since the only intersections appear between $S, S'$ and $T, T'$, here we use that $W$ and $W'$ are disjoint by Theorem 99.1 and $H_2(S^4, \mathbb{Z}) = 0$. We have thus shown that the self-linking numbers of $(K, g)$ and $(L, h)$ agree. This shows that the map $\Psi: \Omega^{1b}_1(\mathbb{R}^3) \to \mathbb{Z}$ is indeed well-defined.

(2) It follows easily from Exercise 99.6 that $\Psi$ is a homomorphism.

(3) By Lemma 99.1 there exists a knot in $\mathbb{R}^3$ with a thickening in $\mathbb{R}^3$ with self-linking number one, thus $\Psi$ is an epimorphism.

---

1632 Here, as a reminder, $L_1 \vee \cdots \vee L_{m-1}$ denotes the wedge of the topological spaces $L_1, \ldots, L_{m-1}$.

1633 If the reader does not feel like making this identification, then we point out that we only need that the right-hand side is a smooth manifold and that the second homology vanishes.
(4) It remains to show that $\Psi : \Omega^\text{th}_1(\mathbb{R}^3) \to \mathbb{Z}$ is a monomorphism. So suppose we are given a thickened $m$-component link $(L, g) = \bigsqcup_{i=1}^m (L_i, g_i)$ with $\Psi([(L, g)]) = 0$.

Note that by Lemma 115.15 there exists a compact oriented connected surface $W$ in $\mathbb{R}^3 \times [0, 1)$ whose boundary equals $L \subset \mathbb{R}^3 = \mathbb{R}^3 \times \{0\}$. Next note that by Lemma 115.18 we can equip $W$ with a thickening $h$ such that for $i = 1, \ldots, m - 1$ we have $\slk(L_i, h|_{L_i}) = \slk(L_i, g_i)$.

Claim. We also have $\slk(L_m, h|_{L_m}) = \slk(L_m, g_m)$.

Note that $(W, h)$ is a thickened cobordism between $(L, h|_L)$ and the empty link. In particular we obtain from (1) that $\slk(L, h|_L) = 0$. By our hypothesis on $(L, g)$ we also have $\slk(L, g) = 0$. We had already arranged that for $i = 1, \ldots, m - 1$ we have $\slk(L_i, h|_{L_i}) = \slk(L_i, g_i)$. It now follows immediately from Lemma 115.13 that $\slk(L_m, h|_{L_m}) = \slk(L_m, g_m)$.

Now we are done, since

$$[(L, g)] = [(L, h|_g)] = 0 \in \Omega^\text{th}_1(\mathbb{R}^3).$$

Lemma 115.17 since $(W, h)$ is a null-cobordism for $(L, h|_g)$. ■

115.5. The thickened cobordism group $\Omega^\text{th}_{2n-1}(\mathbb{R}^{4n-1})$. In Corollary 91.14 we had sketched a proof that given any $n \in \mathbb{N}$ there exists an epimorphism $\pi_{4n-1}(S^{2n}) \to \mathbb{Z}$. By the Thom-Pontryagin Theorem 115.11 this statement is equivalent to saying that there exists an epimorphism $\Omega^\text{th}_{2n-1}(\mathbb{R}^{4n-1}) \to \mathbb{Z}$. In this section we will give an alternative proof that such an epimorphism exists. Since we already have a proof for this statement we will only prove the most salient statements. In other words, this section is stuffed with entertaining exercises for the reader.

First of all we work with the same convention as in the last section.

Convention. In this section we equip any thickened submanifold and any thickened cobordism with the natural orientation that we introduced on page 2739.

We continue with the following notation that is germane to this section.
Notation. Let \( n \in \mathbb{N} \).

1. Given a closed oriented \( m \)-dimensional submanifold \( K \) of \( S^{2m+1} \) we denote by
   \[
   \beta_K: H_m(K; \mathbb{Z}) \to H^m(S^{2m+1} \setminus K; \mathbb{Z})
   \]
   the inverse of the isomorphism given by the Alexander Duality Theorem 92.5.

2. Given a compact oriented proper \((m+1)\)-dimensional submanifold \( W \) of \([0,1] \times S^{2m+1}\) we denote by
   \[
   \beta_W: H_{m+1}(W, \partial W; \mathbb{Z}) \to H^m([0,1] \times S^{2m+1}) \setminus W; \mathbb{Z})
   \]
   the inverse of the isomorphism given by the Alexander Duality Theorem 92.5.

With this notation we can introduce the following definition.

Definition. Let \( m \in \mathbb{N} \) and let \( K \) and \( L \) be two disjoint closed oriented \( m \)-dimensional submanifolds of \( S^{2m+1} \). We define the \textit{linking number} of \( K \) and \( L \) as
   \[
   \text{lk}(K, L) = \langle \beta_K([K]), [L] \rangle \in \mathbb{Z}
   \]
   where we view the fundamental class \([L]\) of \( L \) as a homology class in \( H_m(S^{2m+1} \setminus K; \mathbb{Z}) \).

Remark. The vigilant reader will not have failed to notice that in the 3-dimensional setting it is a priori not clear that the above definition of the linking number agrees with the definition given on page 2396. In Exercise 115.6 we will prove that in the 3-dimensional setting the two competing notions of linking numbers agree.

Proposition 115.19. Let \( n \in \mathbb{N} \) and let \( * \in \overline{B}^{2n} \). The map
   \[
   \Psi: \Omega_{2n-1}^\mathbb{B}(\mathbb{R}^{4n-1}) \to \mathbb{Z}
   \]
   
   \[
   [(N, g: \overline{B}^{2n} \times N \to \mathbb{R}^{4n-1})] \mapsto \text{lk}(N, g(* \times N))
   \]
   is a well-defined homomorphism.

Remark. Let \( n \in \mathbb{N} \). We recall that on page 2217 we used the cup product to define the Hopf invariant
   \[
   \text{Hopf}: \pi_{4n-1}(S^{2n}, *) \to \mathbb{Z}
   \]
   which is, as shown in Proposition 91.7, in fact a homomorphism. The audacious reader can attempt to show that, under the above isomorphism \( \Omega_{2n-1}^\mathbb{B}(\mathbb{R}^{4n-1}) \cong \pi_{4n-1}(S^{2n}, *) \), the Hopf invariant and the homomorphism \( \Psi: \Omega_{2n-1}^\mathbb{B}(\mathbb{R}^{4n-1}) \to \mathbb{Z} \) from Proposition 115.19 agree up to sign.\footnote{Attempting to determine the correct sign with confidence might have negative effects on one’s mental health.}

Proof. In Exercise 115.7 we will verify that \( \Psi \) is a homomorphism. Now let us actually show that \( \Psi \) is well-defined. Thus suppose that we are given thickened \((2n-1)\)-dimensional submanifolds \((N_0, g_0)\) and \((N_1, g_1)\) of \( \mathbb{R}^{4n-1} \) that are cobordant via a thickened cobordism \((W, G)\). We denote by \( i_0: \{0\} \times S^{4n-1} \to [0,1] \times S^{4n-1} \) the inclusion. Similarly we define \( i_1 \). We also use \( i_0, i_1 \) in a rather obvious way for restrictions of the above inclusion maps to suitable subsets. It follows immediately from the Alexander Duality Theorem 92.5 that...
we have the following commutative diagram

$$
\begin{array}{ccc}
H_{2n}(W, \partial W; \mathbb{Z}) & \xrightarrow{\approx} & H^{2n-1}(([0, 1] \times S^{4n-1}) \setminus W; \mathbb{Z}) \\
\downarrow \partial & & \downarrow \beta_W \\
H_{2n-1}([0] \times N_0; \mathbb{Z}) & \xrightarrow{\beta_{N_0}} & H^{2n-1}([0] \times (S^{4n-1} \setminus N_0); \mathbb{Z}) \\
H_{2n-1}([1] \times N_1; \mathbb{Z}) & \xrightarrow{\approx} & H^{2n-1}([1] \times (S^{4n-1} \setminus N_1); \mathbb{Z})
\end{array}
$$

where all horizontal maps are isomorphisms and where the left-hand vertical map is the connecting homomorphism of the long exact sequence in homology of the pair $(W, \partial W)$.

It follows that

follows from the above diagram and the fact that $[\partial W] = ([0] \times N_0) + ([1] \times N_1)$, see Proposition 87.27

$$
lk(N_0, g_0(* \times N_0)) = \langle \beta_{N_0}([N_0]), [g_0(* \times N_0)] \rangle = \langle \beta_W([W]), (i_0)_*([g_0(* \times N_0)]) \rangle
$$

Lemma 74.6 (3) it follows from $\partial(G(* \times W)) = g_0(* \times N_0) \cup g_1(* \times N_1)$ together with Corollary 87.28 (2) that $(i_0)_*([g_0(* \times N_0)]) = (i_1)_*([g_1(* \times N_1)])$

same argument backwards

We have thus shown that $\Psi$ is indeed well-defined.

Of course an invariant is only interesting if we can show that it assumes non-trivial values. If $n = 1$, then we already know\footnote{Here we assume for convenience that we already know that the two different definitions of the linking pairing in the 3-dimensional setting agree.} that the trivial knot $K$ together with the thickening $g$ of self-linking number one satisfies $\Psi([(N, g)]) = 1$. In particular we see that $\Psi: \Omega_1^\text{th}(\mathbb{R}^3) \to \mathbb{Z}$ is an epimorphism.

Recall that the combination of Propositions 91.7 and 91.13 shows that given any $n \in \mathbb{N}$ there exists a map $f: S^{4n-1} \to S^{2n}$ such that the Hopf invariant equals 2. The following proposition that can be viewed as an analogue of this fact.

**Proposition 115.20.** For any $n \in \mathbb{N}$ there exists a thickened $(2n - 1)$-dimensional submanifold $(N, g)$ in $\mathbb{R}^{4n-1}$ with $\Psi([(N, g)]) = 2$.

**Sketch of Proof.** We consider the “trivial $(2n - 1)$-dimensional knot”

$$
K = S^{2n-1} \times \{0\} = \{(z_1, \ldots, z_2n, 0, \ldots, 0) \in \mathbb{R}^{4n-1} \mid z_1^2 + \cdots + z_{2n}^2 = 1\}
$$

together with the map\footnote{This map $g$ is basically just the “obvious” thickening of $S^{2n-1} \subset \mathbb{R}^{2n}$ extended to higher dimensions.}

$$
g: \overline{B}^{2n} \times K \to \mathbb{R}^{4n-1} \\
((x, (y_1, \ldots, y_{2n-1})), (z, 0)) \mapsto (z + \frac{1}{4}x \cdot z, y).
$$
One can easily verify that, with a suitable orientation for \( K \), the pair \((K, g)\) is a thickened \((2n - 1)\)-dimensional submanifold of \( \mathbb{R}^{4n-1} \). It is not particularly difficult to show that \([g(* \times K)] = 0 \in H_{2n-1}(\mathbb{R}^{4n-1} \setminus K)\). Unfortunately this implies that \( \text{lk}(K, g(* \times K)) = 0 \).

The first idea would be to modify the thickening \( g \) in a similar vein as in Lemma 99.1. Instead we will recycle the example from page 2741 where we saw that the Hopf link gives rise to a non-trivial element in \( \Omega^1_{th}(\mathbb{R}^3) \). More precisely, we consider the diffeomorphism

\[
\Theta: \mathbb{R}^{4n-1} \to \mathbb{R}^{4n-1} \quad \left( x_1, \ldots, x_{2n}, y_1, \ldots, y_{2n-1} \right) \mapsto (y, x) + (0, \ldots, 0, 1, 0, \ldots, 0).
\]

Similar to the discussion on page 2741 one can now fairly easily show (voluntary exercise!) that \( \Psi([K \sqcup \Theta(K), g \sqcup \Theta_*(g)]) = \pm 2 \). Since \( \Psi \) is a homomorphism we see that there exists a thickened \((2n - 1)\)-dimensional submanifold \((N, g)\) in \( \mathbb{R}^{4n-1} \) with \( \Psi([N, g]) = 2 \). □

**Figure 1610**

**Remark.** In Theorem 110.11 we saw that, unless \( n = 2, 4, 8 \), there does not exist a map \( f: S^{2n-1} \to S^n \) with \( \text{Hopf}(f) = 1 \). If we believe for a second that the Hopf invariant corresponds to the above homomorphisms \( \Psi \), then this shows that Proposition 115.20 is optimal for \( n \not\in \{1, 2, 4\} \).

In summary, the Thom-Pontryagin Theorem 115.11 together with Propositions 115.19 and 115.20 give us the following result, which is precisely the content of Corollary 91.14.

**Proposition 115.21.** Given any even \( n \in \mathbb{N} \) there exists an epimorphism \( \pi_{2n-1}(S^n) \to \mathbb{Z} \).

---

**Exercises for Chapter 115.**

**Exercise 115.1.** We consider the map

\[
f: (S^1 \times \overline{B}^2) \cup_{S^1 \times S^1} (\overline{B}^2 \times S^1) \to \overline{B}^2/S^1
\]

\[
P \mapsto \begin{cases} [Q], & \text{if } P = [(Q, z)] \text{ with } Q \in \overline{B}^2 \text{ and } z \in S^1, \\ [S^1], & \text{if } P = [(z, Q)] \text{ with } z \in S^1 \text{ and } Q \in \overline{B}^2. \end{cases}
\]

Show that \( f \) is null-homotopic.

\[1637\] Also the remark after the proof might temper one’s optimism.
Exercise 115.2. Let \((L = L_1 \sqcup \cdots \sqcup L_m, g = g_1 \sqcup \cdots \sqcup g_m)\) be a thickened link. Show that
\[
\text{slk}(L, g) := \sum_{i \neq j} \text{lk}(L_i, L_j) + \sum_{i=1}^{m} \text{slk}(L_i, g_i).
\]

Exercise 115.3. Let \(m \geq 2\). The Thom-Pontryagin Theorem \[115.11\] implies in particular that \(\Omega_{m-1}^\text{th}(\mathbb{R}^m) \cong \pi_1(S^m) = 0\). This implies that every thickened submanifold of \(\mathbb{R}^m\) of codimension-one is null-cobordant. Prove this statement without making use of the Thom-Pontryagin Theorem \[115.11\].

Hint. Use Lemma \[98.3\].

Exercise 115.4. We consider the Hopf link \(H\) as shown in Figure \[1611\]. Draw an explicit oriented connected compact surface whose boundary equals the oriented link \(H\).

Remark. Note that the orientation of one of the components is different from the Hopf link that we had considered above in Figure \[1607\].

Exercise 115.5. Let \(L \subset S^3\) be an oriented link and let \(G \subset S^3\) be a compact oriented surface with \(\partial G = L\). We assume that \(G\) has no closed components.

(a) Show that \(S^3 \setminus G\) is path-connected.

(b) Give an outline of an argument why there exists a compact oriented connected surface \(F\) with \(\partial F = L\).

Exercise 115.6. Let \(K\) and \(J\) be two oriented disjoint knots in \(S^3\). Show that the two definitions of the linking number \(\text{lk}(K, J)\) given on pages \[2396\] and \[2745\] agree.

Exercise 115.7. Show that the map
\[
\Psi : \Omega_{2n-1}^\text{th}(\mathbb{R}^{4n-1}) \to \mathbb{Z}
\]
\[
[(N, g: \overline{B}^{2n} \times N \to \mathbb{R}^{4n-1})] \mapsto \text{lk}(N, g(* \times N))
\]
considered in Proposition \[115.19\] is a homomorphism.

Exercise 115.8. In Section \[115.5\] we had just seen that given any even \(n \in \mathbb{N}\) there exists an epimorphism \(\Omega_{n-1}^\text{th}(\mathbb{R}^{2n-1}) \to \mathbb{Z}\). What about the group \(\Omega_{n-1}^\text{th}(\mathbb{R}^{2n-1})\) if \(n\) is odd? Can we use linking numbers to define a homomorphism to \(\mathbb{Z}\)? Can we use them to find an epimorphism from \(\Omega_{n-1}^\text{th}(\mathbb{R}^{2n-1})\) to \(\mathbb{Z}\)?
116. Thom-Pontryagin Theory II: The Freudenthal Suspension Theorem

116.1. The framed cobordism group. In Chapter 115 we introduced the thickened cobordism groups $\Omega^k(R^{n+k})$ and we showed that they are isomorphic to $\pi_{n+k}(S^n,\ast)$. Furthermore we computed that $\Omega^{0k}(R^n) \cong Z$ and $\Omega^{1k}(R^3) \cong Z$. Finally we showed that given any $n \in \mathbb{N}$ there exists an epimorphism $\Omega^{2k}_{m-1}(R^{4n-1}) \to Z$. These calculations gave us new proofs for Corollary 53.6, Theorem 113.10 (2) and Corollary 91.14.

Even though these new proofs were very pleasant, it is now time for some new results. In this section we will prove the Freudenthal Suspension Theorem and we will calculate the homotopy groups $\pi_{n+1}(S^n)$ for $n \geq 3$. For the subsequent calculations it is better though to work with the “framed cobordism groups” $\Omega^k(R^n)$ that we introduce in this section. As we will see, the framed cobordism groups are isomorphic to the thickened cobordism group, but at times they are easier to calculate since they allow us to reduce many issues to linear algebra.

First we introduce the following definitions in linear algebra.

**Definition.** Given $m, k \in \mathbb{N}_0$ we write

- $GL(m, k) :=$ set of $k$-tuples of linearly independent vectors of $\mathbb{R}^m$
- $O(m, k) :=$ set of $k$-tuples of orthonormal vectors of $\mathbb{R}^m$.

We adopt the following conventions:

1. Given $v \in GL(m, k)$ we denote by $v_1, \ldots, v_k$ the corresponding column vectors.
2. Throughout we view both $GL(m, k)$ and $O(m, k)$ as subsets of the smooth manifold $M(m \times k, \mathbb{R}) = \mathbb{R}^{mk}$.

Now we can give the topological definition we are really interested in.

**Definition.** Let $m \in \mathbb{N}_0$ and let $N$ be an $m$-dimensional submanifold of $\mathbb{R}^m$. (Later on we will only be interested in $N = \mathbb{R}^m$, $N = [0,1] \times \mathbb{R}^{m-1}$ and the case that $N = \mathbb{B}_r^m(P)$ is a closed $m$-dimensional ball.)

1. Let $M$ be a compact orientable proper $k$-dimensional submanifold of $N$.
   - (a) Let $P \in M$. We say $v = (v_1, \ldots, v_{m-k}) \in GL(m, m-k)$ is a frame of $M$ at $P$ if the vectors $v_1, \ldots, v_{m-k}$, together with $T_PM \mathbb{R}^{mk}$, spans $\mathbb{R}^m$.
   - (b) A framing for $M$ is a smooth map $v: M \to GL(m, m-k)$ such that for each $P \in M$ the vectors $v_1(P), \ldots, v_{m-k}(P)$ are a frame of $M$ at $P$.
   - (c) We say that a framing $v = (v_1, \ldots, v_{m-k})$ is perpendicular if for each $P \in M$ the vectors $v_1(P), \ldots, v_{m-k}(P)$ lie in the orthogonal complement of $T_PM$, i.e. if they lie in the vector space
     \[(T_PM)^\perp = \{v \in \mathbb{R}^m \mid \langle v, w \rangle = 0 \text{ for all } w \in T_PM\} \]
     If the framing is perpendicular and if all the vectors are orthonormal, then we that the framing is orthonormal.
   - (d) A framed $k$-dimensional submanifold of $N$ is a pair $(M, v)$ where $M$ is a compact orientable proper $k$-dimensional submanifold of $N$ and $v$ is a framing for $M$. 
Let \((M, v)\) be a framed \(k\)-dimensional submanifold of \(N\) and let \(\varphi: N \rightarrow W\) be a smooth embedding of \(N\) into a smooth manifold of the same dimension. We consider the map

\[
\varphi_*(v): \varphi(M) \rightarrow \text{GL}(m, m-k) \quad P \mapsto (\varphi_*((v_1(\varphi^{-1}(P))), \ldots, \varphi_*((v_{m-k}(\varphi^{-1}(P)))).
\]

The pair \((\varphi(M), \varphi_*(v))\) is a framed submanifold of \(W\).

Some of the above definitions are illustrated in Figure 1612.

**Figure 1612**

Definition. Let \(k, m \in \mathbb{N}_0\) and let \((N_0, v_0)\) and \((N_1, v_1)\) be two framed \(k\)-dimensional submanifolds of \(\mathbb{R}^m\). A **framed cobordism between** \((N_0, v_0)\) and \((N_1, v_1)\) is a framed \((k+1)\)-dimensional submanifold \((W, V)\) of \([0, 1] \times \mathbb{R}^m\) such that the following three conditions are satisfied:

1. \(\partial W = \{(0) \times N_0\} \cup \{(1) \times N_1\},\)
2. \(V|_{\{0\} \times N_0} = v_0\) under the identification \(\{0\} \times \mathbb{R}^m = \mathbb{R}^m,\)
3. \(V|_{\{1\} \times N_1} = v_1\) under the identification \(\{1\} \times \mathbb{R}^m = \mathbb{R}^m,\)

If such a framed cobordism exists, then we say that \((N_0, v_0)\) and \((N_1, v_1)\) are **cobordant**.

The definition of a framed cobordism is illustrated in Figure 1613.

**Figure 1613**

Basically the same proof as in Lemma 115.8 gives us the following lemma.

**Lemma 116.1.** The property of “being cobordant” is an equivalence relation on the set of framed \(k\)-dimensional submanifolds of \(\mathbb{R}^m\).

This lemma leads us, not surprisingly, to the following definition.

---

1638 Here we use the isomorphism from Proposition 6.39 to identify \(T_P M\) with the vector subspace \(V_P M\) of \(\mathbb{R}^m\).

1639 Since we view \(\text{GL}(m, m-k)\) as a subset of the smooth manifold \(M(m \times (m-k), \mathbb{R}) = \mathbb{R}^{m(m-k)}\), it makes sense to say that a map \(M \rightarrow \text{GL}(m, m-k)\) is smooth.
**Definition.** We denote by $\Omega^k_\text{fr}(\mathbb{R}^m)$ the set of cobordism classes of framed $k$-dimensional submanifolds of $\mathbb{R}^m$. We refer to $\Omega^k_\text{fr}(\mathbb{R}^m)$ as a framed cobordism group.

The following proposition, which is the analogue of Proposition [115.9], justifies the name “framed cobordism group”.

**Proposition 116.2.** Let $k \in \mathbb{N}$ and let $m \in \mathbb{N}_{\geq 2}$. Let $(M, v)$ and $(N, w)$ be two framed $k$-dimensional submanifolds of $\mathbb{R}^m$. Since $M$ and $N$ are compact, we can pick $r, s \in \mathbb{R}_{>0}$ with $M \subset B^m_r(0)$ and $N \subset B^m_s(0)$. Furthermore, we pick two orientation-preserving smooth embeddings $\varphi: \overline{B}^m_r(0) \to \mathbb{R}^m$ and $\psi: \overline{B}^m_s(0) \to \mathbb{R}^m$ with disjoint images. We define

$$[(M, v)] + [(N, w)] := [(\varphi(M) \cup \psi(N), \varphi_*(v) \sqcup \psi_*(w))] \in \Omega^k_\text{fr}(\mathbb{R}^m).$$

This operation “$+”$ has the following properties:

1. The definition of “$+$” on $\Omega^k_\text{fr}(\mathbb{R}^m)$ is well-defined and commutative.
2. The operation “$+$” defines a group structure on $\Omega^k_\text{fr}(\mathbb{R}^m)$. The following statements hold:
   a. The neutral element is represented by the empty submanifold.
   b. Let $\rho: \mathbb{R}^m \to \mathbb{R}^m$ be the reflection in a hyperplane. The inverse of $[(M, v)]$ is given by $[(\rho(M), \rho_*(v))]$.

**Proof.** The proof is basically identical to the proof of Proposition [115.9]. We leave it to the reader to carry out the minor adjustments that are necessary to make the transition from thickened cobordisms groups to framed cobordism groups.

**Lemma 116.3.** Let $m \in \mathbb{N}_{\geq 2}$ and $k \in \{0, \ldots, m\}$.

1. Every framed $k$-dimensional submanifold $(M, v)$ of $\mathbb{R}^m$ is cobordant to $(M, w)$ where $w$ is an orthonormal framing.
2. Let $(W, V)$ be a framed cobordism between two framed $k$-dimensional submanifolds $(M_0, v_0)$ and $(M_1, v_1)$ of $\mathbb{R}^m$. If $v_0$ and $v_1$ are orthonormal, then there exist an orthonormal framing $V'$ for $W$ such that $(W, V')$ is a framed cobordism between $(M_0, v_0)$ and $(M_1, v_1)$.

**Proof (a).** We prove statement (1) of the lemma. The proof of statement (2) is a mild variation on the proof of statement (1). Thus, let $(M, v)$ be a framed $k$-dimensional submanifold of $\mathbb{R}^m$. Using the fact that being cobordant is transitive, the proof of the lemma can be broken into two stages:

1. First we show that there exists a perpendicular framing $v$ such that $(M, v)$ is cobordant to $(M, v)$.
2. Then we show that there exists an orthonormal framing $w$ such that $(M, v)$ is cobordant to $(M, w)$.

We carry out the two steps:

1. Let $(M, u: M \to \text{GL}(m, m-k))$ be a framed $k$-dimensional submanifold of $\mathbb{R}^m$.
   Given $P \in M$ we write $U_PM := \text{span}\{u_1(P), \ldots, u_k(P)\}$ and furthermore, we write $Z_PM := (T_PM)^\perp$. For each $P \in M$ the decomposition $\mathbb{R}^m = T_PM \oplus Z_PM$ defines a projection of $\mathbb{R}^m$ onto $Z_PM$. We denote the restriction of this projection to $U_PM$. 

by $\rho_P: U_PM \to Z_PM$. By definition of a framing this map is an isomorphism. We consider the product cobordism $W = [0,1] \times M$ equipped with the framing $V: W = [0,1] \times M \to \text{GL}(m,m-k)$

$$V(t,P) \mapsto (u(P) \cdot (1-t) + \rho_P(u(P)) \cdot t).$$

Basically by definition this is a framed cobordism from $(M,u)$ to $(M,v)$ where $v = V_1$ is a perpendicular framing.

(2) In Lemma [8.8](1) we showed that there exists a smooth deformation retraction $R: \text{GL}(m,m-k) \times [0,1] \to O(m,m-k)$ from $\text{GL}(m,m-k)$ to $O(m,m-k)$ which has the following extra property:

(*) For any $v = (v_1,\ldots,v_{m-k}) \in \text{GL}(m,m-k)$ and any $t \in [0,1]$ we have

$$\text{span of } R_t(v_1),\ldots,R_t(v_{m-k}) = \text{span of } v_1,\ldots,v_{m-k}.$$

Now let $(M,v)$ be a framed $k$-dimensional submanifold. We consider the product cobordism $W = [0,1] \times M$ equipped with the framing

$$V: W = [0,1] \times M \to \text{GL}(m,m-k)$$

$$(t,P) \mapsto R_t(v(P)).$$

It follows from the fact that $R$ is smooth and that (*) holds that this is a framed cobordism from $(M,v)$ to $(M,w)$ where $w = V_1$ is an orthonormal framing. □

The following proposition shows that the two types of cobordism groups that we introduced in this and the last chapter are in fact isomorphic.

**Proposition 116.4.** Let $m \in \mathbb{N}_{\geq 2}$ and let $k \in \{0,\ldots,m\}$. The map

$$\Phi: \Omega_{th}^k(\mathbb{R}^m) \to \Omega_{fr}^k(\mathbb{R}^m)$$

$$[(N,g: \overline{B}^{m-k} \times N)] \mapsto \left[N \text{ equipped with the framing that associates to } P \in N \text{ the frame } Df_{(0,P)}(e_1),\ldots,Df_{(0,P)}(e_{m-k})\right]$$

is well-defined and it is an isomorphism.

**Convention.** Let $n,k \in \mathbb{N}_0$ with $n + k \geq 2$. We use the isomorphisms from the Thom-Pontryagin Theorem [115.11] and Proposition [116.4] to make the identifications

$$\pi_{n+k}(S^n,*) = \Omega_{th}^k(\mathbb{R}^{n+k}) = \Omega_{fr}^k(\mathbb{R}^{n+k}).$$

**Sketch of proof.**

(1) It follows basically from the definitions that the framing associated to a thickened submanifold is indeed a framing. Applying the same procedure to a thickened cobordism between thickened submanifolds we obtain a framed cobordism between framed submanifolds. This shows that $\Phi$ is well-defined.

(2) It follows immediately from the definitions of the group structures that $\Phi$ is a homomorphism.

\[\text{It takes a little bit of thought to show that this is indeed a smooth map.}\]
(3) We sketch the construction of the inverse to $\Phi$. Let $(N, \{v_1, \ldots, v_{m-k}\})$ be a framed $k$-dimensional submanifold of $\mathbb{R}^m$. We consider the map
\[ g(v): \mathbb{R}^{m-k} \times N \to \mathbb{R}^m \]
\[ ((t_1, \ldots, t_{m-k}), P) \mapsto P + t_1 \cdot v_1(P) + \cdots + t_{m-k} \cdot v_{m-k}(P). \]

The same argument as in the proof of Theorem 8.24 shows that there exists an $\epsilon > 0$ such that $g(v)$ restricts to a smooth embedding $B^k(0) \times N \to \mathbb{R}^m$. After rescaling the ball we thus get a thickening $B^k \times N \to \mathbb{R}^m$ of $N$. It is straightforward to see that the class $[(N, g(v))] \in \Omega_k^{th}(\mathbb{R}^m)$ does not depend on the choice of $\epsilon > 0$. Since the same approach also works for cobordisms we obtain a well-defined map
\[ \Psi: \Omega_k^{fr}(\mathbb{R}^m) \to \Omega_k^{th}(\mathbb{R}^m). \]

It remains to show that $\Phi$ and $\Psi$ are inverses of one another. It follows basically immediately from the definitions and Lemma 116.3 (1) that $\Phi \circ \Psi$ is the identity on $\Omega_k^{fr}(\mathbb{R}^m)$. The fact that $\Psi \circ \Phi$ is the identity on $\Omega_k^{th}(\mathbb{R}^m)$ follows fairly immediately from the uniqueness of tubular neighborhoods, see Proposition 10.7, together with Lemma 10.4. 

**Definition.** Let $N$ be an orientable $k$-dimensional submanifold of $\mathbb{R}^m$ and let $n \geq m$.

1. We write $N_n := N \times \{0\} \subset \mathbb{R}^n$.

Now suppose we are given a framing $v: N \to \text{GL}(m, m-k)$ for $N$.

2. We define
\[ v_n: N_n \to \text{GL}(n, n-k) \]
\[ (P, 0) \mapsto \begin{pmatrix} v(P) & 0 \\ 0 & \text{id}_{n-m} \end{pmatrix}. \]

It is clear that $v_n$ is a framing for $N_n$. Note that $N_m = N$ and $v_m = v$.

3. We refer to $(N_n, v_n)$ as the $(n-m)$-fold suspension of $(N, v)$. In particular we refer to $(N_{m+1}, v_{m+1})$ as the suspension of $(N, v)$.

The same notation applies in an obvious way to (framed) submanifolds of $[0, 1] \times \mathbb{R}^m$.

The following lemma justifies the name “suspension” that we had used in the above definition.

**Lemma 116.5.** Let $m \in \mathbb{N}_{\geq 2}$ and let $k \in \{0, \ldots, m\}$.

1. The map
\[ \Omega_k^{fr}(\mathbb{R}^m) \to \Omega_k^{fr}(\mathbb{R}^{m+1}) \]
\[ [(N, v)] \mapsto [\text{the suspension of } (N, v)] \]

is well-defined and it is a homomorphism. We refer to it as the suspension homomorphism.

2. Under the identification from the convention on page 2752 the suspension homomorphisms on $\pi_{n+k}(S^n, *)$ and $\Omega_k^{fr}(\mathbb{R}^{n+k})$ agree up to sign in other words, the
The Freudenthal Suspension Theorem. In this section we will prove the following theorem that was first proved in 1937 by Hans Freudenthal [Freu37, p. 300].

**Theorem 116.6. (Freudenthal Suspension Theorem)** Let \( n, k \in \mathbb{N}_0 \). We suppose that \( n+k \geq 2 \). The suspension homomorphism \( \pi_{n+k}(S^n) \to \pi_{n+k+1}(S^{n+1}) \) from Lemma 40.19 is an isomorphism if \( n > k + 1 \) and it is an epimorphism if \( n = k + 1 \).

**Remark.**

1. The Freudenthal Suspension Theorem [116.6] can be reformulated as follows: given \( n \in \mathbb{N} \) the suspension homomorphism \( \pi_m(S^n) \to \pi_{m+1}(S^{n+1}) \) is an isomorphism if \( m < 2n-1 \) and that it is an epimorphism if \( m = 2n-1 \). We consider two situations in slightly more detail:
   (a) The Freudenthal Suspension Theorem [116.6] says that the suspension homomorphism \( \pi_3(S^2) \to \pi_4(S^3) \) is an epimorphism and it says that for any \( n \geq 3 \) the suspension homomorphism \( \pi_{n+1}(S^n) \to \pi_{n+2}(S^{n+1}) \) is an isomorphism. This special case will play an important role shortly.
   (b) The Freudenthal Suspension Theorem [116.6] almost recovers Theorems 113.11 (2) and 113.14 (2). Recall that these theorems stated that for \( m \in \{0, \ldots, 5\} \) we have \( \pi_m(S^2) \cong \pi_{m+1}(S^3) \) and that for \( m \in \{0, \ldots, 13\} \) we have \( \pi_m(S^7) \cong \pi_{m+1}(S^8) \).
2. Let \( n \in \mathbb{N}_0 \). Recall that on page 695 we saw that the suspension \( \Sigma(S^n) \) is homeomorphic to \( S^{n+1} \). Thus we see that the Freudenthal Suspension Theorem [116.6] is a consequence of the following stronger statement: Let \( X \) be an \((n-1)\)-connected topological space and let \(* \in X\) be a good base point.\(^{1642}\) Then the suspension homomorphism \( \pi_{n+k}(X, *) \to \pi_{n+k+1}(\Sigma(X), *) \) is an isomorphism for all \( n > k + 1 \) and it is an epimorphism for \( n = k + 1 \). This statement is proved in most textbooks on homotopy theory, see e.g. [Gra75, Theorem 16.34], [WhdG78, Theorem VII.7.13] or [DaK01, Theorem 8.7 and Chapter 10.3]. If \( X \) is a CW-complex, then the statement is also proved in [Hat02, Corollary 4.24]. The proof of [Hat02, Corollary 4.24] is actually a corollary to the Blakers-Massey Theorem [111.17] that we had stated but not proved.

\(^{1641}\) To be more precise, they might agree on the nose, but we will not spend valuable time on figuring out the sign.

\(^{1642}\) We refer to page 604 for the definition of a good point.
It follows from Lemma 116.5 that the Freudenthal Suspension Theorem 116.6 is equivalent to the following theorem.

**Theorem 116.7.** Let \( n, k \in \mathbb{N} \).

1. The suspension homomorphism \( \Omega_k^f(\mathbb{R}^{n+k}) \to \Omega_k^f(\mathbb{R}^{n+k+1}) \) is an epimorphism whenever \( n \geq k + 1 \).
2. The suspension homomorphism \( \Omega_k^f(\mathbb{R}^{n+k}) \to \Omega_k^f(\mathbb{R}^{n+k+1}) \) is a monomorphism whenever \( n > k + 1 \).

The basic behind the proof of Theorem 116.7 (1) is quite simple: given a framed \( k \)-dimensional submanifold of \( \mathbb{R}^{n+k+1} \) we want to use the “room provided by a large enough \( n \)” to show that it is cobordant to a framed submanifold coming from \( \mathbb{R}^{n+k} = \mathbb{R}^{n+k} \times \{0\} \). This idea is for the most part carried out in the following two lemmas.

**Lemma 116.8.** Let \( (M, v) \) be a framed \( k \)-dimensional submanifold of \( \mathbb{R}^{n+k+1} \). If \( n \geq k + 1 \), then there exists a framed cobordism from \( (M, v) \) to a framed \( k \)-dimensional submanifold \( (N, w) \) of \( \mathbb{R}^{n+k+1} \) with \( N \subset \mathbb{R}^{n+k} \times \{0\} \).

**Proof.** Let \( (M, v : M \to \text{GL}(n + k + 1, n + 1)) \) be a framed \( k \)-dimensional submanifold of \( \mathbb{R}^{n+k+1} \). We point out that by Lemma 116.3 (1) we can assume that \( v \) is an orthonormal framing.

It follows from \( n \geq k + 1 \) and Lemma 11.7 that there exists a vector \( \nu \in \mathbb{R}^{n+k+1} \) which satisfies the following condition:

(*) the vector \( \nu \) does not lie in any tangent space \( T_p M \) and \( \nu \) is not secant to \( M \), i.e., for any two distinct points \( x, y \in M \) the difference \( x - y \) is not parallel to \( \nu \).

By Lemma 3.32 (4) there exists a matrix \( A \in \text{SO}(n + k + 1) \) with \( A\nu = e_{n+k+1} \). By Lemma 8.5 there exists a diffeotopy of \( \mathbb{R}^{n+k+1} \) from \( \text{id}_{\mathbb{R}^{n+k+1}} \) to the diffeomorphism given by multiplying by \( A \). Therefore, by the obvious analogue of Lemma 115.7 for the framed cobordism group, we can assume without loss of generality that \( \nu = e_{n+k+1} \).

**Claim.** The map

\[
\Psi : [0, 1] \times M \to [0, 1] \times \mathbb{R}^{n+k+1} \\
(t, (x_1, \ldots, x_{n+k+1})) \mapsto (t, x_1, \ldots, x_{n+k}, (1 - t) \cdot x_{n+k+1})
\]

is a proper smooth embedding. The definition of \( \Psi \) is illustrated in Figure 1614.

It follows from the fact that for any two distinct points \( x, y \in M \) the difference \( x - y \) is not parallel to \( \nu = e_{n+k+1} \) that the map is injective. Furthermore note that the map \( \Psi \) is the composition of the inclusion \( i : [0, 1] \times M \to [0, 1] \times \mathbb{R}^{n+k+1} \) with the map

\[
\Theta : [0, 1] \times \mathbb{R}^{n+k+1} \to [0, 1] \times \mathbb{R}^{n+k+1} \\
(t, (x_1, \ldots, x_{n+k+1})) \mapsto (t, x_1, \ldots, x_{n+k}, (1 - t) \cdot x_{n+k+1})
\]

Here and throughout this proof we use Proposition 6.39 to view the tangent spaces of submanifolds of some \( \mathbb{R}^{m} \) as vector subspaces of \( \mathbb{R}^{m} \).
A straightforward calculation shows that

$$D\Theta(t,x_1,\ldots,x_{n+k+1}) = \begin{pmatrix} 1 & 0 & \cdots & 0 \\ 0 & \text{id}_{n+k} & 0 & 0 \\ -x_{n+k+1} & 0 & \cdots & 1-t \end{pmatrix}. $$

It follows immediately from this calculation and the fact that $e_{n+k+1}$ is not contained in any tangent space $T_PM$ that $\Psi = \Theta \circ i$ is an immersion. Together with the injectivity of $\Theta$, the fact that $M$ is compact and the ever-popular Proposition 2.43 (2) we obtain that $\Psi = \Theta \circ i$ is in fact a smooth embedding. It is also clear that the smooth embedding is proper.

We set $W := \Psi([0, 1] \times M)$. By the claim together with Proposition 8.1 (2) we know that $W$ is a proper $(k + 1)$-dimensional submanifold of $[0, 1] \times \mathbb{R}^{n+k+1}$. Basically by definition $W$ is a cobordism between $M \subset \mathbb{R}^{n+k+1}$ and some submanifold $N \subset \mathbb{R}^{n+k} \times \{0\}$.

It remains to extend the orthonormal framing $v : M \to \text{GL}(n+k+1, n+1)$ of $M$ to a framing of $W$. In fact, we obtain a framing of $W = \Psi([0, 1] \times M)$ by using the “same vectors” as for $M$. More precisely, we consider the map

$$V : W = \Psi([0, 1] \times M) \to \text{GL}(n+k+2, n+1)$$

$$\Psi(t, P) \mapsto \begin{pmatrix} 0 \\ v(P) \end{pmatrix}. $$

Evidently under the identification $\{0\} \times \mathbb{R}^{n+k+1} = \mathbb{R}^{n+k+1}$ we have $V|_M = v$. Thus it remains to show that $V$ is indeed a framing. A short moment’s thought shows that $V$ is smooth. The definition of $W$ and $V$ are illustrated in Figure 1614. Therefore it suffices to prove the following claim.

**Claim.** For any $t \in [0, 1]$ and any $P \in M$ the matrix $V(\Psi(t, P)) \in \text{GL}(n+k+2, n+1)$ is a frame for $W = \Psi([0, 1] \times M)$ at $\Psi(t, P)$.

Let $t \in [0, 1]$ and let $P \in M$. We point out that the columns of $V(\Psi(t, P))$ span an $(n+1)$-dimensional vector subspace of $\mathbb{R}^{n+k+2}$. Since $T_{\Phi(t,P)}(W)$ is a vector subspace of the complementary dimension $k+1$ it suffices to show that the intersection of these two vector subspaces is trivial.

![Illustration for the proof of Lemma 116.8](image)
We note that

\[
\begin{align*}
\text{by definition of } W &= \Psi([0, 1] \times M) = (\Theta \circ i)([0, 1] \times M) \text{ and the calculation of } D\Theta \\
T_{\Psi(t, P)}(W) \cap \text{span of the columns of } V(\Psi(t, P)) &= \begin{pmatrix} 1 & 0 & 0 & 0 \\
-x_{n+k+1} & 0 & 1 & t \\
\end{pmatrix} \cdot \begin{pmatrix} \mathbb{R} \\
\otimes \\
\end{pmatrix} \cap \text{span of the columns of } V(\Psi(t, P))
\end{align*}
\]

\[
\cong \left( \begin{pmatrix} \text{id} & 0 \\
0 & 1 - t \\
\end{pmatrix} \cdot T_P(M) \cap \text{span of the columns of } v(P) \right)
\]

since the first row of \( V \) is zero, we can ignore the first coordinate.  

Now let \( u \in T_P M \) be a non-zero vector. We write \( u = \begin{pmatrix} u' \\
u_{n+k+1} \end{pmatrix} \) with \( u' \in \mathbb{R}^{n+k} \) and \( u_{n+k+1} \in \mathbb{R} \). Note that \( u' \) is non-zero since we had arranged that \( e_{n+k+1} \notin T_P M \). Now we calculate that

\[
\left( \begin{pmatrix} \text{id} & 0 \\
0 & 1 - t \\
\end{pmatrix} \cdot T_P(M) \cdot u \right) \cdot u' = \left\langle \begin{pmatrix} u' \\
u_{n+k+1} \end{pmatrix} \right\rangle = \langle u', u' \rangle + (1 - t) \cdot u_{n+k+1}^2 > 0.
\]

But this shows that \( \begin{pmatrix} \text{id} \\
0 & 1 - t \\
\end{pmatrix} \cdot u \) is not orthogonal to \( T_P M \), in other words, this vector does not lie in \( (T_P M)^\perp \).

\[\blacksquare\]

**Lemma 116.9.** Let \((M, v)\) be a framed \( k \)-dimensional submanifold in \( \mathbb{R}^{n+k} \times \{0\} \subset \mathbb{R}^{n+k+1} \). If \( n \geq k + 1 \), then there exists a framed cobordism to \((M, w = (w_1, ..., w_{n+1}))\) where we have \( w_{n+1}(P) = e_{n+k+1} \) for all \( P \in M \).

**Proof.** Let \((M, u = (u_1, ..., u_{n+1}) : M \to \text{GL}(n+k+1, n+1))\) be a framed \( k \)-dimensional submanifold that is contained in \( \mathbb{R}^{n+k} \times \{0\} \subset \mathbb{R}^{n+k+1} \). By Lemma 116.3 (1) and Lemma 116.1 we can assume that \( u \) is orthonormal. We write \( e := e_{n+k+1} \).

**Claim.** There exists an orthonormal framing \( v = (v_1, ..., v_{n+1}) \) for \( M \) such that \((M, v)\) is cobordant to \((M, v)\) and such that for every \( P \in M \) we have \( v_{n+1}(P) \neq -e \).

Let \( x \in M \). Since \( M \) is contained in \( \mathbb{R}^{n+k} \times \{0\} \) we know that \( e \) is orthogonal to \( T_x M \). Therefore we can uniquely write \( e = \sum_{i=1}^{n+1} \lambda_i(x) \cdot u_i(P) \). Since \( \|e\| = 1 \) and since \( u \) is an orthonormal framing we actually have \( \sum_{i=1}^{n+1} \lambda_i^2(P) = 1 \). Thus we obtain a map

\[
\lambda : M \to S^n \\
x \mapsto (\lambda_1(x), ..., \lambda_{n+1}(x))
\]
which is fairly easily seen to be smooth. If \((0, \ldots, 0, -1) \not\in \lambda(M)\), then we can just take 
\(u = v\) and we are done. If not we proceed as follows. Since \(\dim(M) = k < n\) it follows from Proposition \[6.62\] that there exists a \(u \in S^n\) with \(u \not\in \lambda(M)\). By Lemma \[3.32\] \(4\) there exists a matrix 
\(A \in \text{SO}(n+1)\) with 
\(u = A \cdot (-e) \in S^n\). By Lemma \[2.65\] and Exercise \[18.7\] there exists a smooth path 
\(\gamma: [0, 1] \to \text{SO}(n+1)\) from \(\text{id}\) to \(A\). The desired framed cobordism is now given by the smooth manifold 
\([0, 1] \times M \to \text{GL}(n+k+2, n+1)\) together with the framing\[1615\]
\[
(t, x) \mapsto \begin{pmatrix} 0 \\ u(x) \end{pmatrix} \cdot \gamma(t).
\]
\(\in \text{GL}(n+k+2, n+1)\)

As a final step we want to “rotate \(v_{n+1}\) into \(e\).” To do this smoothly for every point we need to introduce two maps. Given 
\(u \in \mathbb{R}^{n+1} \setminus \{0\}\) we write
\[
\begin{align*}
T_u: \mathbb{R}^{n+k+1} &\to \mathbb{R}^{n+k+1} \\
y &\mapsto \begin{cases} 2 \cdot \langle y, u \rangle \cdot u - y & \text{reflection in the line } \mathbb{R} \cdot u \\
\text{orientation-preserving diffeomorphism} & \end{cases}
\end{align*}
\]

We will need the following elementary observation from linear algebra.

**Claim.** Let \(w \in \mathbb{R}^{n+k+1}\) with \(\|w\| = 1\). Let 
\(u = \frac{w + e}{\|w + e\|}\) be the normalized midpoint between \(w\) and \(e\). Then 
\(R_u(w) = e\).

We have
\[
R_u(w) = T_e(T_u(w)) = T_e \left(2 \cdot \left\langle w, \frac{w + e}{\|w + e\|} \right\rangle \cdot \frac{w + e}{\|w + e\|} - w \right) = T_e(e) = e.
\]

(short calculation using \(\langle w, w \rangle = \langle e, e \rangle\) \[1645\]

The above claim now allows us to come to the denouement of the argument. More precisely, given 
\(t \in [0, 1]\) and \(x \in M\) we write
\[
z(x) := \frac{v_{n+1}(x) + e}{\|v_{n+1}(x) + e\|} \quad \text{and} \quad z_t(x) = \frac{(1-t) \cdot e + t \cdot z(x)}{\| (1-t) \cdot e + t \cdot z(x) \|}.
\]

Note that \(z_0 = e\) and \(R_{z_0} = \text{id}\). Furthermore note that \(z_1 = z(x)\). Thus we obtain from the above claim that \(R_{z_1}(v_{n+1}(x)) = e\). Finally we consider the framed cobordism that is given by the submanifold 
\(Z = [0, 1] \times M\) of \([0, 1] \times \mathbb{R}^{n+k+1}\) together with the framing
\[
W: Z = [0, 1] \times M \to \text{GL}(n+k+2, n+1) \\
(t, x) \mapsto \begin{pmatrix} 0 \\ R_{z_t(x)} \circ v(x) \end{pmatrix}.
\]

\[1644\]Indeed, if \(v_{n+1}(x) = -e\), then \(e = -v_{n+1}(x)\), i.e. \(\lambda(x) = (0, \ldots, 0, -1)\).

\[1645\]That this framing has the correct properties can be seen as follows. Let \(v\) be the new framing at 
\(\{1\} \times M\). If we denote by \(\lambda_u, \lambda_v: M \to S^n\) the corresponding maps, then one easily sees that for each 
\(x \in M\) we have 
\(\lambda_u(x) = A^{-1} \cdot \lambda_v(x)\). Thus the fact that \(v\) does not lie in the image of \(\lambda_u\) implies that 
\(-e = A^{-1} \cdot v\) does not lie in the image of \(\lambda_v\).
We leave it to the reader to verify that the map $W$ is indeed a framing for the cobordism $Z = [0, 1] \times M \subset [0, 1] \times \mathbb{R}^{n+k+1}$. The discussion above shows that $(Z = [0, 1] \times M, W)$ is a framed cobordism from $(M, v)$ to a framed smooth manifold $(M, w = w_1, \ldots, w_n, e)$. ■

Exercise for Chapter 116

Exercise 116.1. In the proof of Proposition 117.4 we used the Freudenthal Suspension Theorem 116.6 to show that the map

$$
\mathbb{Z} \to \Omega^fr_k(\mathbb{R}^4)
$$

$[k] \mapsto k \cdot [(C_4, h_4)]$

is an epimorphism. Use Exercise 11.5 to give an alternative argument, which does not rely on the Freudenthal Suspension Theorem 116.6.

---

**Figure 1615. Illustration for the proof of Lemma 116.9.**

Now we turn to the actual proof of Theorem 116.7 and thus of the Freudenthal Suspension Theorem 116.6.

**Proof.** Let $n, k \in \mathbb{N}_0$ with $n + k \geq 2$.

1. Suppose that $n \geq k + 1$. We want to show that the suspension homomorphism $\Omega^fr_k(\mathbb{R}^{n+k}) \to \Omega^fr_k(\mathbb{R}^{n+k+1})$ is an epimorphism. Thus let $(M, v)$ be a framed $k$-dimensional submanifold of $\mathbb{R}^{n+k+1}$. It follows immediately from Lemmas 116.8 and 116.9 that $(M, v)$ is cobordant to a $k$-dimensional framed submanifold $(N, w)$ such that $N \subset \mathbb{R}^{n+k} \times \{0\}$ and such that $w_{n+1}(P) = e_{n+k+1}$ for all $P \in N$. But this means that $[(M, v)] = [(N, w)]$ lies in the image of the suspension homomorphism. Thus the suspension homomorphism $\Omega^fr_k(\mathbb{R}^{n+k}) \to \Omega^fr_k(\mathbb{R}^{n+k+1})$ is an epimorphism.

2. Suppose that $n > k + 1$. We want to show that the suspension homomorphism $\Omega^fr_k(\mathbb{R}^{n+k}) \to \Omega^fr_k(\mathbb{R}^{n+k+1})$ is a monomorphism. Therefore let $(M, v)$ and $(N, w)$ be two framed $k$-dimensional submanifolds of $\mathbb{R}^{n+k}$. Suppose there exists a framed cobordism $(W, V)$ in $[0, 1] \times \mathbb{R}^{n+k+1}$ between the suspensions of $(M, v)$ and $(N, w)$. Since $n > k + 1$, an argument as in Lemmas 116.8 and 116.9 shows that we can turn $(W, V)$ into a cobordism $(W', V')$ with $W' \subset [0, 1] \times \mathbb{R}^{n+k} \times \{0\}$ and such that $V'(P) = e_{n+k+1}$ for all $P \in W'$. But this shows that $(M, v)$ and $(N, w)$ are already cobordant. Thus we have shown that for $n > k + 1$ the suspension homomorphism $\Omega^fr_k(\mathbb{R}^{n+k}) \to \Omega^fr_k(\mathbb{R}^{n+k+1})$ is a monomorphism. ■
117. Thom-Pontryagin Theory III: The groups $\Omega^f_1(\mathbb{R}^{n+1})$ and $\Omega^f_2(\mathbb{R}^{n+2})$

In this chapter we will calculate the framed cobordism groups $\Omega^f_1(\mathbb{R}^{n+1})$ and $\Omega^f_2(\mathbb{R}^{n+2})$ “by hand” for $n \geq 3$. By the Thom-Pontryagin Theorem [115.11] and Proposition [116.4] this means that we calculate the homotopy groups $\pi_{n+1}(S^n)$ and $\pi_{n+2}(S^n)$ for $n \geq 3$. By now there might be more modern and efficient ways for computing these homotopy groups. But the geometric approach using Thom-Pontryagin theorem is still very charming, in particular it lets us use many techniques we have developed so far, and it gives us an opportunity to introduce a few new tricks. In particular we will get to introduce quadratic forms and the Arf invariant, which are purely algebraic objects, and are of great interest in the own right.

117.1. The calculation of the framed cobordism groups $\Omega^f_1(\mathbb{R}^{n+1})$ for $n \geq 3$. In Theorem [113.10] (2) (and alternatively in Theorem [115.14]) we saw that $\pi_3(S^2) \cong \mathbb{Z}$ and we saw that the Hopf map represents a generator of $\pi_3(S^2)$. Furthermore, by the Freudenthal Suspension Theorem [116.6] we know that for every $n \geq 3$ the suspension homomorphism $\pi_3(S^2) \to \pi_{n+1}(S^n)$ is an epimorphism. Thus we know that $\pi_{n+1}(S^n)$ is isomorphic to a quotient of $\mathbb{Z}$ and that $\pi_{n+1}(S^n)$ is generated by the $(n - 2)$-fold suspension of the Hopf map. The goal of this section is to prove the following theorem which determines this quotient.

**Theorem 117.1.** For every $n \geq 3$ there exists an isomorphism $\pi_{n+1}(S^n) \cong \mathbb{Z}_2$.

**Remark.**

1. In Theorem [109.13] we already saw that for every $n \geq 3$ we have $\pi_{n+1}(S^n) \neq 0$. The proof of Theorem [117.1] below is independent of Theorem [109.13]. In particular we will not make use of Steenrod operations.

2. By the Thom-Pontryagin Theorem [115.11] and Proposition [116.4] the theorem is equivalent to showing that for every $n \geq 3$ we have an isomorphism $\Omega^f_1(\mathbb{R}^{n+1}) \cong \mathbb{Z}_2$. This is exactly what we will do below. The approach that we take below to calculate $\Omega^f_1(\mathbb{R}^{n+1})$ differs, to the best of my knowledge, from the other proofs in the literature. We refer to [Pon59, Chapter 14] for Pontryagin’s original proof, which makes for challenging reading for the modern reader. A third, quite readable approach is presented in [Put].

3. There are various alternative proofs of Theorem [117.1]. The first proof was given by Hans Freudenthal [Freu37, p. 301] in 1937. Another proof is given in [Hat, p. 549] using “spectral sequences”.

4. The discussion preceding the theorem shows that the suspension of the Hopf map defines a non-trivial element in $\pi_4(S^3)$. This gives in particular an affirmative answer to Question [40.20].

As we had just mentioned above, proving Theorem [117.1] is equivalent to showing that for every $n \geq 3$ there exists an isomorphism $\Omega^f_1(\mathbb{R}^{n+1}) \cong \mathbb{Z}_2$. We will perform this calculation in the remainder of this section.

We start out our calculation of $\Omega^f_1(\mathbb{R}^{n+1})$ for $n \geq 3$ with the following definition.
Definition.

(1) We refer to $C := S^1$ as the standard circle in $\mathbb{R}^2$.
(2) We refer to the framing of $C \subset \mathbb{R}^2$ that is given by

$$t : C \to \mathbb{R}^2$$

$$\begin{pmatrix} x \\ y \end{pmatrix} \mapsto \begin{pmatrix} x \\ y \end{pmatrix}$$

as the trivial framing $t$ of $C$.
(3) Let $n \in \mathbb{N}_{\geq 2}$. We adopt the convention from page 2753 to define the standard circle $C_n$ in $\mathbb{R}^n$. Furthermore, using the definition from page 2753 we define the trivial framing $t_n$ for $C_n$.
(4) We refer to the framing of $C_3 \subset \mathbb{R}^3$ that is given by the map

$$h : C_3 \to \mathbb{R}^3$$

$$\begin{pmatrix} \cos(\varphi) \\ \sin(\varphi) \\ 0 \end{pmatrix} \mapsto t_3 \begin{pmatrix} \cos(\varphi) \\ \sin(\varphi) \\ 0 \end{pmatrix} \cdot \begin{pmatrix} \cos(\varphi) & -\sin(\varphi) \\ \sin(\varphi) & \cos(\varphi) \\ 0 & 0 \end{pmatrix} = \begin{pmatrix} \cos(\varphi) \\ \sin(\varphi) \\ 0 \end{pmatrix} \cdot \begin{pmatrix} \cos(\varphi) & -\sin(\varphi) \\ \sin(\varphi) & \cos(\varphi) \\ 0 & 1 \end{pmatrix}$$

$$\uparrow$$

don’t overlook the $t_3$

as the Hopf framing $h$ of $C_3$.
(5) Let $n \in \mathbb{N}_{\geq 3}$. As in (3) we use the convention from page 2753 to define the Hopf framing $h_n$ of $C_n$. These definitions are illustrated in Figure 1616.

Throughout this section we also use the following notation:

Notation.

(1) Given $g \in \mathbb{N}_0$ we denote by $\Sigma_{g,1}$ the surface of genus $g$ minus one open disk. We pick once and for all an orientation for $\Sigma_{g,1}$.
(2) For any $n \in \mathbb{N}_{\geq 2}$ we denote by

$$\rho : \mathbb{R}^n \to \mathbb{R}^n$$

$$(x_1, x_2, x_3, \ldots, x_n) \mapsto (x_1, -x_2, x_3, \ldots, x_n)$$

the reflection in the $(x_2 = 0)$-hyperplane.
(3) Given $n \in \mathbb{N}_0$ we make the identification $\mathbb{R}^n = \{0\} \times \mathbb{R}^n \subset [0,1] \times \mathbb{R}^n$.

The following two lemmas justify the names “trivial framing” and “Hopf framing”.

---

We leave the task of showing that this map is smooth to the every-ready reader.
Lemma 117.2.

1. Given any \( g \in N_0 \) there exists a proper smooth embedding \( \psi: \Sigma_{g,1} \to [0,1] \times \mathbb{R}^2 \) and a framing \( w \) for \( \psi(\Sigma_{g,1}) \) such that \( \partial \psi(\Sigma_{g,1}) = C_2 \) and such that the restriction of \( w \) to \( C_2 \) equals \( t \).

2. For every \( n \geq 2 \) we have \( [(C_n, t_n)] = 0 \in \Omega^f_1(\mathbb{R}^n) \).

Sketch of proof.

1. By now the seasoned reader should be fairly convinced that there exists a proper smooth embedding \( \psi: \Sigma_{g,1} \to [0,1] \times \mathbb{R}^2 \) with \( \psi(\partial \Sigma_{g,1}) = C_2 \) and such that the smooth embedding is a “product near the boundary”. More precisely, such that for some \( \epsilon \in (0,1) \) we have the equality \( \psi(\Sigma_{g,1}) \cap ([0,\epsilon] \times \mathbb{R}^2) = [0,\epsilon] \times C_2 \). Since \( \psi(\Sigma_{g,1}) \) is an oriented connected submanifold of \( [0,1] \times \mathbb{R}^2 \) of codimension two we see that \( \psi(\Sigma_{g,1}) \) has precisely two normal vector fields of length one. We refer to Figure 1617 for an illustration.

It follows almost immediately from the fact that \( \psi(\Sigma_{g,1}) \) is a product near \( \{0\} \times \mathbb{R}^2 \) that one of the above two normal vectors fields agrees with \( t \) on \( \{0\} \times S^1 \).

2. It follows from (1) that \( [(C_2, t_2)] = 0 \in \Omega^f_1(\mathbb{R}^2) \). From Lemma 116.5 we obtain that \( [(C_n, t_n)] = 0 \in \Omega^f_1(\mathbb{R}^n) \) for any \( n \in N_{\geq 2} \).

Lemma 117.3.

1. Under the isomorphism \( \Omega^f(\mathbb{R}^3) \cong \pi_3(S^2,\ast) \) the element \( [(C_3, h_3)] \) corresponds, up to a sign, to the element represented by the Hopf map \( S^3 \to S^2 \).

2. Let \( n \geq 4 \). Under the isomorphism \( \Omega^f_1(\mathbb{R}^n) \cong \pi_n(S^{n-1},\ast) \) the element \( [(C_n, h_n)] \) corresponds, up to a sign, to the element represented by the \((n-3)\)-fold suspension of the Hopf map \( S^3 \to S^2 \).

Proof. The first statement follows easily from Lemma 115.4. The second statement is a straightforward consequence of Lemma 116.5 (2). □

The following proposition is the first key ingredient in the calculation of \( \Omega^f_1(\mathbb{R}^n) \) for \( n \geq 4 \).

Proposition 117.4. Let \( n \in N_{\geq 4} \). The map

\[
\mathbb{Z}_2 \to \Omega^f_1(\mathbb{R}^n) \\
[k] \mapsto k \cdot [(C_n, h_n)]
\]

is well-defined and it is an epimorphism.
Our proof of Proposition 117.4 requires one definition and two lemmas.

**Definition.** Let \( n \in \mathbb{N} \geq 2 \) and let \( \gamma: S^1 \to \mathbb{R}^n \) be a smooth embedding. Furthermore let \( f: \gamma(S^1) \to \text{GL}(n, n-1) \) be a framing for \( \gamma(S^1) \) and let \( \alpha: S^1 \to \text{GL}_+(n-1, \mathbb{R}) \) be a smooth map. We define

\[
f(\alpha): \gamma(S^1) \to \text{GL}(n, n-1) \quad \gamma(z) \mapsto f(\gamma(z)) \cdot \alpha(z) \in \text{GL}(n, n-1) \in \text{GL}(n-1, \mathbb{R}).
\]

It follows easily from the fact that \( \alpha \) takes values in \( \text{GL}_+(n-1, \mathbb{R}) \) that \( f(\alpha) \) is again a framing of \( \gamma(S^1) \).

The first lemma that goes into the proof of Proposition 117.4 is really just a crucial example masquerading as a lemma.

**Lemma 117.5.** Let \( n \in \mathbb{N} \geq 3 \) and let \( \gamma: S^1 \to C_n \) be the obvious diffeomorphism. We consider the loop

\[
\alpha: S^1 \to \text{GL}_+(n-1, \mathbb{R}) \quad z = e^{i\varphi} \mapsto \begin{pmatrix}
\cos(\varphi) & -\sin(\varphi) & 0 \\
\sin(\varphi) & \cos(\varphi) & 0 \\
0 & 0 & \text{id}_{n-3}
\end{pmatrix}.
\]

As above let \( t_n \) be the trivial framing for \( C_n \) and let \( h_n \) be the Hopf framing for \( C_n \). We have the following two equalities of framings of \( C_n \):

1. We have \( t_n(\alpha) = h_n \).
2. We have \( t_n(\overline{\alpha}) = \rho_*(h_n) \).

**Proof (\(*\)).** The first statement follows immediately from the definitions. We turn to the proof of the second statement. As we will see, the proof of the second statement is given by a slightly tedious calculation. To simplify the notation we only deal with the case \( n = 3 \).

\[\text{[1647]}\]

\[\text{[2750]}\]

\[\text{[2750]}\]

\[\text{[1647]}\]

\[\text{[1647]}\]
At a given point $P = \gamma(e^{i\varphi}) = \begin{pmatrix} \cos(\varphi) \\ \sin(\varphi) \\ 0 \end{pmatrix} \in C_3$ we have

$$t_n(\pi) \begin{pmatrix} \cos(\varphi) \\ \sin(\varphi) \\ 0 \end{pmatrix} = t_n \begin{pmatrix} \cos(\varphi) \\ \sin(\varphi) \\ 0 \end{pmatrix} \cdot \alpha(e^{-i\varphi}) = \begin{pmatrix} \cos(\varphi) \\ \sin(\varphi) \\ 0 \end{pmatrix} \begin{pmatrix} \cos(-\varphi) - \sin(-\varphi) \\ \sin(-\varphi) \\ \cos(-\varphi) \end{pmatrix}$$

$$= \rho \begin{pmatrix} \cos(-\varphi) \\ \sin(-\varphi) \\ 0 \end{pmatrix} \cdot \begin{pmatrix} \cos(-\varphi) - \sin(-\varphi) \\ \sin(-\varphi) \\ \cos(-\varphi) \end{pmatrix}$$

$$= \rho \left( h_n \begin{pmatrix} \cos(-\varphi) \\ \sin(-\varphi) \\ 0 \end{pmatrix} \right)$$

This concludes the mind-numbing verification of the second statement.

\begin{lemma}
Let $n \in \mathbb{N}_{\geq 2}$ and let $\gamma: S^1 \to \mathbb{R}^n$ be a smooth embedding. Furthermore let $f: \gamma(S^1) \to \text{GL}(n, n-1)$ be a framing for $\gamma(S^1)$. Finally let $\alpha, \beta: S^1 \to \text{GL}_+(n-1, \mathbb{R})$ be two smooth maps. If $\alpha$ and $\beta$ are smoothly homotopic, then

$$[[\gamma(S^1), f(\alpha)] = [[\gamma(S^1), f(\beta)]] \in \Omega^{fr}_1(\mathbb{R}^n).$$

\end{lemma}

**Proof of Lemma 117.6**: We write $M = \gamma(S^1)$. Since $\alpha, \beta: S^1 \to \text{GL}_+(n-1, \mathbb{R})$ are smoothly homotopic we can pick a smooth homotopy $H: S^1 \times [0, 1] \to \text{GL}_+(n-1, \mathbb{R})$ with $H_0 = \alpha$ and $H_1 = \beta$. We consider the product cobordism $[0, 1] \times M$ equipped with the framing

$$V: [0, 1] \times M \to \text{GL}(n+1, n)$$

$$(t, \gamma(z)) \mapsto \begin{pmatrix} 1 & 0 \\ 0 & f(\gamma(z)) \cdot H(z, t) \end{pmatrix}$$

It is clear that $([0, 1] \times M, V)$ is a framed cobordism between $(\gamma(S^1), f(\alpha))$ and $(\gamma(S^1), f(\beta))$.

Now we can provide the proof of Proposition 117.4.

**Proof of Proposition 117.4**: Let $n \in \mathbb{N}_{\geq 4}$. We consider the following diagram
We make the following observations:

1. It follows quite easily from Theorem 115.14, Lemma 117.3 and Proposition 116.4 that the top horizontal map is an isomorphism.

2. The right vertical map is given by the \((n-3)\)-fold application of the suspension homomorphism defined on page 2753. Note that the right vertical map is an epimorphism by the FreudenthalSuspensionTheorem 116.7.

3. The top right triangle commutes by definition of the suspension homomorphism and by definition of \((C_n, h_n)\).

The above diagram and the above discussion show that it remains to prove the following claim.

**Claim.** The element \(2 \cdot [(C_n, h_n)]\) is trivial in \(\Omega^\fr_1(\mathbb{R}^n)\).

We consider the loop

\[
\alpha: S^1 \to GL_+(n-1, \mathbb{R})
\]

\[
z = e^{i\varphi} \mapsto \begin{pmatrix}
\cos(\varphi) & -\sin(\varphi) & 0 \\
\sin(\varphi) & \cos(\varphi) & 0 \\
0 & 0 & \text{id}_{n-3}
\end{pmatrix}.
\]

We have the following equalities in \(\Omega^\fr_1(\mathbb{R}^n)\):

\[
2 \cdot [(C_n, h_n)] = [(C_n, h_n)] + [(C_n, t_n(\alpha))] = [(C_n, h_n)] + [(C_n, t_n(\overline{\alpha})] = (\rho_\ast(C_n), \rho_\ast(h_n)) = [(C_n, h_n)] + (-[(C_n, h_n)]) = 0.
\]

Let \(n \geq 4\). Note that by Proposition 117.4 we now know that there exists an epimorphism \(\mathbb{Z}_2 \to \Omega^\fr_1(\mathbb{R}^n) \cong \pi_n(S^{n-1})\). In Theorem 109.13 we showed that \(\pi_{n+1}(S^n)\) is non-trivial. Therefore it follows that \(\pi_{n+1}(S^n) \cong \mathbb{Z}_2\), which means we have proved Theorem 117.1. The readers who studied Steenrod operations and who happen to be tired of Thom-Pontryagin theory can thus move on to next section.

For all others we provide a proof of Theorem 117.1 that does not rely on Theorem 109.13. More precisely, we prove the following proposition which is the main technical result of this section.

**Proposition 117.7.** For any \(n \in \mathbb{N}_{\geq 4}\) the map

\[
\mathbb{Z}_2 \to \Omega^\fr_1(\mathbb{R}^n)
\]

\[
[k] \mapsto k \cdot [(C_n, h_n)]
\]

is an isomorphism.
As we had mentioned many times, Theorem [117.1] is an immediate consequence of the Thom-Pontryagin Theorem [115.11] and Proposition [116.4] together with Proposition [117.7].

Proof. Let \( n \in \mathbb{N}_{\geq 4} \). By Proposition [117.4] it remains to show that \((C_n,h_n)\) represents a non-trivial element in \( \Omega^n_i(\mathbb{R}^n) \).

We start out with a more general discussion. Given any \( m \in \mathbb{N}_{\geq 2} \) we make the identification \( C_m = \{0\} \times C_m \subset [0,1] \times \mathbb{R}^m \). The following claim applies to all dimensions.

Claim. Let \( m \in \mathbb{N}_{\geq 2} \). Let \( F \) be a compact orientable connected proper 2-dimensional smooth manifold in \([0,1] \times \mathbb{R}^m\) with \( \partial F = C_m \). At most one of the two framings \( t_m \) and \( h_m \) can be extended to a framing of \( F \).

Suppose there exist framings \( T \) and \( H \) on \( F \) with \( T|_{C_m} = t_m \) and \( H|_{C_m} = h_m \). It follows from Lemma [116.3] that we can assume that \( T \) and \( H \) are orthonormal. We consider the map

\[
\Psi : F \to \GL(m - 1, \mathbb{R})
\]

\[
P \mapsto \text{the unique matrix } \Psi(P) \in \GL(m - 1, \mathbb{R}) \text{ with } T(P) \cdot \Psi(P) = H(P).
\]

We denote by \( i : C_m \to F \) the inclusion map and we denote by \( \gamma : S^1 \to C_m \) the usual diffeomorphism given by \( \gamma(e^{i\varphi}) = (\cos(\varphi), \sin(\varphi), 0, \ldots, 0) \). We make the following key observation: it follows immediately from the definitions and Lemma [117.5] that the map \( \Psi \circ i \circ \gamma : S^1 \to \GL(m - 1, \mathbb{R}) \) is precisely, on the nose, given by the map \( \alpha : S^1 \to \GL(m - 1, \mathbb{R}) \)

\[
e^{i\varphi} \mapsto \begin{pmatrix}
\cos(\varphi) & -\sin(\varphi) & 0 \\
\sin(\varphi) & \cos(\varphi) & 0 \\
0 & 0 & \text{id}_{m-3}
\end{pmatrix}.
\]

Now we consider the following diagram

\[
\begin{array}{c}
\xymatrix{
H_1(\partial F; \mathbb{Z}) \ar[r]^{\gamma_*} \ar[d]_{i_*} & H_1(S^1; \mathbb{Z}) \ar[r]^{\cong} \ar[d]_{\alpha_*} & \pi_1(S^1, 1) \\
H_1(F; \mathbb{Z}) \ar[r]_{\Psi_*} & H_1(\GL(m - 1, \mathbb{R})) \ar[r]^{\cong} & \pi_1(\GL(m - 1, \mathbb{R}), \text{id}).
}\end{array}
\]

We make the following observations:

1. The left-hand square commutes by the above equality \( \alpha = \Psi \circ i \circ \gamma \).
2. The two horizontal maps to the right are the Hurewicz homomorphisms that we introduced on page [1314]. The Hurewicz homomorphisms are isomorphisms by the Hurewicz Theorem [52.5] together with the fact that the fundamental groups on the right are both abelian.
3. The right-hand square commutes by the naturality of the Hurewicz homomorphisms, see Proposition [52.2] (4).

Let \( P \in F \). The fact that \( T \) and \( H \) are orthonormal means that the columns of \( T(P) \) and \( H(P) \) are bases for the same vector space, namely \((T_P F)^\perp\). Therefore there exists a matrix \( \Psi(P) \in \GL(m - 1, \mathbb{R}) \) such that \( T(P) \cdot \Psi(P) = H(P) \). We leave it to the reader to verify that the map \( P \mapsto \Psi(P) \) is continuous.
(4) By Proposition 114.11 (2) and (3) we know that the loop \( \alpha : S^1 \to \text{GL}(m-1, \mathbb{R}) \) represents a non-trivial element in \( \pi_1(\text{GL}(m-1, \mathbb{R}), \text{id}) \). This implies that the right vertical map \( \alpha_x : \pi_1(S^1, 1) \to \pi_1(\text{GL}(m-1, \mathbb{R}), \text{id}) \) is non-trivial.

(5) It follows from (1) – (4) that the left vertical map is also non-trivial. But this contradicts Lemma 148.8 (1).

Now we start out with the actual proof of the theorem. Thus let \( n \in \mathbb{N}_{\geq 4} \). As we pointed out above, we need to show that \((C_n, h_n)\) represents a non-trivial element in \( \Omega^F_n(\mathbb{R}^n) \). Suppose that \((C_n, h_n)\) represents in fact the trivial element in \( \Omega^F_n(\mathbb{R}^n) \). This means that there exists a framed cobordism \((F, v) = (F_n, v_n)\) in \([0,1] \times \mathbb{R}^n\) from \((C_n, h_n)\) to the empty smooth manifold. In other words, \( F = F_n \) is a compact orientable proper 2-dimensional submanifold of \([0,1] \times \mathbb{R}^n\) with \( \partial F_n = C_n \) and \( v = v_n \) is a framing with \( v|_{C_n} = h_n \). By throwing away all closed components of \( F_n \) we can assume that \( F_n \) is connected.

By the Surface Classification Theorem 23.4 we know that there exists a \( g \in \mathbb{N}_0 \) such that \( F \) is diffeomorphic to \( \Sigma := \Sigma_{g,1} \). In other words, there exists a proper smooth embedding \( \varphi : \Sigma \to [0,1] \times \mathbb{R}^n \) with \( \varphi(\Sigma) = F_n \). Given any \( m \geq n \) we denote by \( \varphi_m : \Sigma \to [0,1] \times \mathbb{R}^m \) the smooth embedding that is given by the composition of the smooth embedding \( \varphi \) with the obvious smooth embedding \([0,1] \times \mathbb{R}^n \to [0,1] \times \mathbb{R}^m \).

By Lemma 117.2 (1) there exists a proper smooth embedding \( \psi : \Sigma \to [0,1] \times \mathbb{R}^2 \) and a framing \( w_2 = w \) for \( G_2 = G := \psi(\Sigma) \) such that \( \partial \psi(\Sigma) = C_2 \) and such that the restriction of \( w_2 = w \) to \( C_2 \) equals \( t_2 \). Given \( m \geq 2 \) we denote by \( \psi_m : \Sigma \to [0,1] \times \mathbb{R}^m \) the smooth embedding that is given by the composition of the smooth embedding \( \psi \) with the obvious smooth embedding \([0,1] \times \mathbb{R}^2 \to [0,1] \times \mathbb{R}^n \).

Now we consider the two proper smooth embeddings \( \psi_n, \varphi_n : \Sigma \to [0,1] \times \mathbb{R}^n \). We can arrange\(^ {1649} \) that \( \psi_n|_{\partial \Sigma} = \varphi_n|_{\partial \Sigma} \).

It follows from Proposition 11.12 (2) and the Isotopy Extension Theorem 8.27 that there exists an \( m \geq n \) and a diffeomorphism \( \Psi \) of the smooth manifold \([0,1] \times \mathbb{R}^m \) such that \( \Psi(F_m) = G_m \) and such that the restriction of \( \Psi \) to \([0] \times \mathbb{R}^m \) is the identity. We refer to Figure 1618 for an illustration.

Since \((F_m, v_m)\) is an extension of \((C_m, h_m)\) and since the restriction of \( \Psi \) to \([0] \times \mathbb{R}^m \) is the identity we see that \( (\Psi(F_m), \Psi_*(v_m)) = (G_m, \Psi_*(v_m)) \) is an extension of \((C_m, h_m)\). On the other hand we saw \((G_m, w_m)\) is an extension of \((C_m, t_m)\). Thus both \( h_m \) and \( t_m \) can be extended over \( G_m \). But this contradicts the above claim. \( \blacksquare \)

In summary we have the following proposition.

**Proposition 117.8.**

\(^ {1649} \)This sentence contains a slight technical nuisance which we cleverly hide in a footnote. First of all, it should be pretty clear by now that \( \Sigma \) admits an orientation-reversing self-diffeomorphism. Thus, after possibly precomposing \( \varphi_n \) with such a diffeomorphism we can assume that \( \psi^{-1} \circ \varphi_n \) is orientation-preserving. Using Corollary 30.2 and using the Collar Neighborhood Theorem 8.12 we can then arrange, after possibly precomposing \( \varphi_n \) by another diffeomorphism, that \( \psi_n|_{\partial \Sigma} = \varphi_n|_{\partial \Sigma} \).
117.2. The calculation of the framed cobordism groups $\tilde{\Omega}_1^f(\mathbb{R}^{n+1})$ for $n \geq 3$. In this section we will introduce and calculate a slight variation on the framed cobordism group $\tilde{\Omega}_1^f(\mathbb{R}^{n+1})$. On its own this result is perhaps not all the interesting, but it will be a crucial ingredient in our calculation of $\tilde{\Omega}_2^f(\mathbb{R}^{n+2})$ in the coming sections.

117.3. The calculation of the framed cobordism groups $\Omega_2^f(\mathbb{R}^{n+2})$ for $n \geq 3$ I. Can we also do $\pi_4(S^2)$? Let $n \in \mathbb{N}_{\geq 3}$. Let $(F, v: GL(n+2, n))$ be a closed oriented framed 2-dimensional submanifold of $\mathbb{R}^{n+2}$. Now let $C$ be a closed oriented 1-dimensional submanifold of $F$. Given $P \in C$ we write

$$u_1(P) := \text{the unique positive tangent vector of } V_P C \text{ of length 1},$$

$$u_2(P) := \text{the unique vector in } (V_P C)^\perp \subset V_P F \text{ of length 1 that has the property that } (u_1(P), u_2(P)) \text{ form a positive basis for } V_P F.$$
We equip \( C \) with the framing \( v_C \) that at each point \( P \) is given by \( v_C(P) := (u_2(P), v(P)) \). Note that \( (C, v_C) \) defines an element in \( \Omega^\text{fr}_1(\mathbb{R}^{n+2}) \). By Proposition \[117.7\] we know that we have an isomorphism \( \chi : \Omega^\text{fr}_1(\mathbb{R}^{n+2}) \cong \mathbb{Z}_2 \). Note that for knot in \( S^3 \) can be compute this explicitly as \( \frac{1}{2} \) linking number if framing does indeed give a well-defined homomorphism in the previous section, then should say explicitly

**Lemma 117.9.** Let \( C \) and \( D \) be two closed oriented 1-dimensional submanifolds of a closed oriented framed 2-dimensional submanifold \( (F, v) \) of \( \mathbb{R}^{n+2} \). If \( [C] = [D] \in H_1(F; \mathbb{Z}) \), then \( \chi([(C, v_C)]) = \chi([(D, v_D)]) \).

**Proof.** Note that it follows from our hypothesis that \([C] = [D] \in H_1(F; \mathbb{Z})\) together with Corollary \[98.7\] that there exists a compact oriented proper 2-dimensional submanifold \( W \subset [0, 1] \times F \) such that \( \partial W = (\{0\} \times C) \cup (\{1\} \times -D) \). Similar to the above we consider for a point \( P \in C \) the vector

\[
u_2(P) := \text{the unique vector in } (V P W)^\perp \subset V P([0, 1] \times F) \text{ of length 1 that has the property that the orientation of } W \text{ at } P \text{ together with } u_2(M) \text{ form a positive basis for } V P F.
\]

We equip \( W \) with the framing \( v_W \) that at each point \( P \) is given by \( v_W(P) := (u_2(P), v(P)) \). One can now easily verify that \( (W, v_W) \), viewed as a submanifold of \([0, 1] \times \mathbb{R}^{n+2}\) is a framed cobordism between \((C, v_C)\) and \((D, v_D)\). This implies that \( \chi([(C, v_C)]) = \chi([(D, v_D)]) \). \( \blacksquare \)

It follows from Lemma \[117.9\] that we obtain a well-defined map

\[
q_{(F, v)} : H_1(F; \mathbb{Z}_2) \to \mathbb{Z}_2 \\
\sigma \mapsto \chi([(C, v_C)])
\]

closed oriented 1-dimensional submanifold with \([C] = \sigma\), this always exists by Corollary \[70.14\].

One might hope that \( q_{(F, v)} : H_1(F; \mathbb{Z}_2) \to \mathbb{Z}_2 \) is a homomorphism. In fact Pontryagin \[Pon38\] initially thought so. But it turns out that the situation is more complicated, namely it turns out that the following proposition holds.

**Proposition 117.10.** The map \( q_{(F, v)} : H_1(F; \mathbb{Z}_2) \to \mathbb{Z}_2 \) has the property, that for any \( x, y \in H_1(F; \mathbb{Z}_2) \) we have

\[
q(x + y) = q(x) + q(y) + Q_F(x, y)
\]

where \( Q_F : H_1(F; \mathbb{Z}_2) \times H_1(F; \mathbb{Z}_2) \to \mathbb{Z}_2 \) denotes the intersection form that we introduced on page \[2456\].

**Proof.** This requires some thought. Note that it suffices to deal with the case that \( F \) is standard in \( \mathbb{R}^3 \). \( \blacksquare \)
Proposition 117.10 shows that the map \( q : H_1(F; \mathbb{Z}_2) \rightarrow \mathbb{Z}_2 \) has a peculiar behavior that we had not yet encountered. In the next, purely algebraic section, we will see that \( q \) is a non-degenerate quadratic form over \( \mathbb{Z}_2 = \mathbb{F}_2 \) and we will give a complete classification of non-degenerate quadratic forms over \( \mathbb{Z}_2 = \mathbb{F}_2 \). This will allow us to proceed with our actual topological problem.

117.4. Interlude: Quadratic forms and the Arf invariant.

**Definition.** Let \( \mathbb{F} \) be a field.

(1) A quadratic form over \( \mathbb{F} \) is a pair \( (V, q) \) where \( V \) is a finite dimensional \( \mathbb{F} \)-vector space and \( q : V \rightarrow \mathbb{F} \) is a map which satisfies the following two conditions:

(a) For any \( x \in V \) and any \( \lambda \in \mathbb{F} \) we have \( q(\lambda \cdot x) = \lambda^2 \cdot q(x) \).

(b) The map

\[
V \times V \rightarrow \mathbb{F} \\
(x, y) \mapsto q(x + y) - q(x) - q(y)
\]

is a symmetric form over \( \mathbb{F} \) in the sense of the definition on page 2410. We refer to the symmetric form in (b) as the symmetric form associated to \( q \).

(2) We say that two quadratic forms \( (V, p) \) and \( (W, q) \) over \( \mathbb{F} \) are isometric if there exists an isomorphism \( \varphi : V \rightarrow W \) such that for all \( v \in V \) we have \( p(v) = q(\varphi(v)) \).

**Examples.**

(1) Let \( \mathbb{F} \) be a field, let \( V \) be a finite-dimensional vector space and let \( \langle , \rangle : V \times V \rightarrow \mathbb{F} \) be a form. A straightforward calculation shows that \( q(v) := \langle v, v \rangle \) defines a quadratic form. Indeed, it is clear, that (a) is satisfied, and for (b) we calculate that for any \( x, y \in V \) we have

\[
q(x + y) - q(x) - q(y) = \langle x + y, x + y \rangle - \langle x, x \rangle - \langle y, y \rangle = 2 \langle x, y \rangle.
\]

We refer to \( q \) as the quadratic form associated to \( \langle , \rangle \).

(2) If \( \mathbb{F} \) is a field of characteristic \( \neq 2 \), then basically the same calculation as in (1) shows that \( q \) is the quadratic form associated to the form \( (x, y) \mapsto \frac{1}{2}(q(x + y) - q(x) - q(y)) \).

(3) Let \( (F, v) \) be a closed oriented framed 2-dimensional submanifold of \( \mathbb{R}^n \). It follows from Propositions 117.10 and 101.21 that the map \( q(F,v) : H_1(F; \mathbb{F}_2) \rightarrow \mathbb{F}_2 \) that we introduced on page 2769 is a quadratic form over \( \mathbb{F}_2 \).

The above discussion shows that for fields of characteristic \( \neq 2 \) the classification of quadratic forms is essentially the same as the classification of forms. In the following we only consider the field \( \mathbb{F}_2 \).

**Definition.** Let \( (V, q) \) be a quadratic form over \( \mathbb{F}_2 \). We say \( q \) is non-degenerate if the associated symmetric form is non-singular in the sense of the definition on page 2411.

**Example.** We write \( \mathcal{W} := \mathbb{F}_2^2 \) and \( x := (1, 0) \) and \( y := (0, 1) \). One can easily verify that

\[
\langle , \rangle : \mathcal{W} \times \mathcal{W} \rightarrow \mathbb{F}_2 \\
(v, w) \mapsto \langle v, w \rangle = v^t \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} w
\]
is the unique non-singular symmetric form on $W$. Next we consider the following two maps:

$\sigma_0: W \rightarrow \mathbb{F}_2$

$0, x, y \mapsto 0$

$x + y \mapsto 1$

$\sigma_1: W \rightarrow \mathbb{F}_2$

$0 \mapsto 0$

$x, y, x + y \mapsto 1$.

One can easily verify by hand that both maps define a quadratic form on $W$ such that the associated symmetric form is the above form $\langle ., . \rangle$. In particular both quadratic forms are non-degenerate. It is also straightforward to verify that these two maps are in fact the only two non-degenerate quadratic forms on $W$. Finally note that $\sigma_0$ and $\sigma_1$ are not isometric for the rather silly reason that $\sigma_0$ sends three elements of $W$ to 0, whereas $\sigma_1$ only sends one element of $W$ to 0.

In the following our goal is to classify non-singular symmetric forms and non-degenerate quadratic forms over $\mathbb{F}_2$. It turns out that symmetric forms of $\mathbb{F}_2$ are not very interesting.

In fact the following proposition holds:

**Proposition 117.11.** Let $V$ be a finite-dimensional vector space over $\mathbb{F}_2$.

(1) Every non-singular even symmetric form $\langle ., . \rangle: V \times V \rightarrow \mathbb{F}_2$ admits a symplectic basis, i.e. there exists a basis $a_1, \ldots, a_k, b_1, \ldots, b_k$ for $V$ such that the following conditions are satisfied:

(a) For every $i, j \in \{1, \ldots, k\}$ we have $\langle a_i, a_j \rangle = \langle b_i, b_j \rangle = 0$.

(b) For every $i, j \in \{1, \ldots, k\}$ we have $\langle a_i, b_j \rangle = \delta_{ij}$.

(2) Any two non-singular symmetric forms over $V$ are isometric.

**Proof.**

(1) The proposition follows immediately from Proposition 101.22.

Now let us turn to the study of non-degenerate quadratic forms over $\mathbb{F}_2$. We already encountered the non-isometric quadratic forms $\sigma_0, \sigma_1: V \rightarrow \mathbb{F}_2$. We obtain more quadratic forms by taking direct sums. But the following lemma says that this way we will produce some isometric quadratic forms.

**Lemma 117.12.**

(1) The quadratic forms $\sigma_0 \oplus \sigma_0$ and $\sigma_1 \oplus \sigma_1$ on $W \oplus W$ are isometric.

(2) Let $m, n \in \mathbb{N}_0$. The quadratic form $m \cdot \sigma_0 \oplus n \cdot \sigma_1$ is isometric to $(m + n) \cdot \sigma_0$ if $n$ is even, and it is isometric to $(m + n - 1) \cdot \sigma_0 \oplus \sigma_1$ if $n$ is odd.

(3) Any non-degenerate quadratic form $(V, q)$ over $\mathbb{F}_2$ is isometric to a quadratic form $k \cdot \sigma_0$ or to a quadratic form $k \cdot \sigma_0 \oplus \sigma_1$. (Note that we do not claim that this is an exclusive “or”.

**Proof.**

(1) Let $x_1, y_1, x_2, y_2$ be the obvious basis of $W \oplus W = \mathbb{F}_2^2 \oplus \mathbb{F}_2^2$. We consider the isomorphism $\varphi: W \oplus W \rightarrow W \oplus W$ that is determined by

$x_1 \mapsto x_1 + x_2$

$y_1 \mapsto y_1 + x_2$

$x_2 \mapsto x_2 + y_2 + x_1 + y_1$

$y_2 \mapsto y_2 + x_1 + y_1$. 
It is straightforward, albeit not particularly entertaining, to verify that \( \varphi \) defines an isometry from \( (W \oplus W, \sigma_0 \oplus \sigma_0) \) to \( (W \oplus W, \sigma_1 \oplus \sigma_1) \).

(2) This statement follows immediately from (1).

(3) Let \( (V, q) \) be a quadratic form. We denote by \( \langle , \rangle \) the associated symmetric form. By Proposition 117.11 we know that there exists a symplectic basis \( a_1, \ldots, a_m, b_1, \ldots, b_m \) for \( (U, \langle , \rangle) \). Given \( i = 1, \ldots, m \) we denote by \( V_i \) the span of \( \{a_i, b_i\} \) and write \( q_i := q|_{V_i} \). It follows immediately from the fact that the \( V_i \) are orthogonal with respect to \( \langle , \rangle \) that \( (V, q) \) is isometric to \( (V_i, q_i) \oplus \cdots \oplus (V_m, q_m) \). Note that each \( (V_i, q_i) \) is a non-degenerate quadratic form over a 2-dimensional vector space. It follows from the above discussion that each \( (V_i, q_i) \) is isometric to either \( (W, \sigma_0) \) or \( (W, \sigma_1) \). The desired statement now follows from (2).

\[ \mathbf{Lemma\ 117.13.} \]Given any \( m \in \mathbb{N} \) we have

\[ \#N(m \cdot \sigma_0) > \#P(m \cdot \sigma_0) \quad \text{and} \quad \#N((m - 1) \cdot \sigma_0 \oplus \sigma_1) < \#P((m - 1) \cdot \sigma_0 \oplus \sigma_1). \]

\[ \text{Proof.} \] Given a quadratic form \( (V, q) \) over \( \mathbb{F}_2 \) we set

\[ r(q) := \#\{v \in V \mid q(v) = 0\} - \#\{v \in V \mid q(v) = 1\}. \]

The following claim contains the key calculation that we need to complete the proof of the lemma.

\[ \text{Claim.} \ Let \ (V, q) \ be a quadratic form. \]

(1) We have \( \#N(\sigma_0 \oplus q) = 3 \cdot \#N(q) + \#P(q) \) and \( \#P(\sigma_0 \oplus q) = 3 \cdot \#P(q) + \#N(q) \).

(2) We have \( r(\sigma_0 \oplus q) = 2 \cdot r(q) \).

Note that (2) is an immediate consequence of (1) and the simple observation that \( r(q) = \#N(q) - \#P(q) \). Thus it remains to prove (1). Note that given \( v \oplus w \in V \oplus W \) we see that

\[ (\sigma_0 \oplus q)(v \oplus w) = \sigma_0(v) + q(w) = \begin{cases} 0, & \text{if } v \in N(\sigma_0) \text{ and } w \in N(q) \text{ or } v \in P(\sigma_0) \text{ and } w \in P(q) \\ 0, & \text{if } v \in N(\sigma_0) \text{ and } u \in P(q) \text{ or } v \in P(\sigma_0) \text{ and } w \in N(q). \end{cases} \]

It follows immediately that \( P(q \oplus \sigma_0) = 3 \cdot P(q) + N(q) \) and that \( N(q \oplus \sigma_0) = 3 \cdot N(q) + P(q) \). \( \blacksquare \)
Now iteratively applying the claim we see that
\[
\begin{align*}
r(m \cdot \sigma_0) &= 2 \cdot r((m - 1) \cdot \sigma_0) = \ldots = 2^{m-1} \cdot r(\sigma_0) = 2^{m-1} \cdot 2 > 0 \quad \text{and} \\
r((m - 1) \cdot \sigma_0 \oplus \sigma_1) &= 2 \cdot r((m - 1) \cdot \sigma_0 \oplus \sigma_1) = \ldots = 2^{m-1} \cdot r(\sigma_1) = 2^{m-1} \cdot (-2) < 0.
\end{align*}
\]
This calculation immediately implies the desired result. ■

This leads us to the following definition.

**Definition.** Let \((V, q)\) be a quadratic form over \(\mathbb{F}_2\). We define its **Arf invariant** \(\text{Arf}(q) \in \mathbb{F}_2\) as follows:

\[
\text{Arf}(q) := \begin{cases} 
0, & \text{if } \#N(q) > \#P(q), \\
1, & \text{if } \#P(q) > \#N(q).
\end{cases}
\]

**Remark.**

(1) The Arf invariant was introduced in 1941 in a slightly different form, which we will explain below, by Cahit Arf \[\text{Arf41}\].

(2) The Arf invariant is sometimes jokingly referred to as the **democratic invariant**: every element \(u \in V\) gets to vote, and the majority decides that the value of the Arf invariant should be.

The following theorem now gives us the complete classification of non-degenerate quadratic forms over \(\mathbb{F}_2\).

**Theorem 117.14.**

(1) Let \((V, q)\) be a non-degenerate quadratic form. We set \(m := \text{dim}(V)\).

(a) \((V, q)\) is isometric to \(m \cdot \sigma_0\) if and only if \(\text{Arf}(q) = 0\).

(b) \((V, q)\) is isometric to \((m - 1) \cdot \sigma_0 \oplus \sigma_1\) if and only if \(\text{Arf}(q) = 1\).

(2) Two non-degenerate quadratic forms \((V_1, q_1)\) and \((V_2, q_2)\) over \(\mathbb{F}_2\) are isometric if and only if \(\text{dim}(V_1) = \text{dim}(V_2)\) and \(\text{Arf}(q_1) = \text{Arf}(q_2)\).

(3) For any two non-degenerate quadratic forms \((V_1, q_1)\) and \((V_2, q_2)\) we have

\[
\text{Arf}(q_1 \oplus q_2) = \text{Arf}(q_1) + \text{Arf}(q_2).
\]

**Proof.**

(1) This statement follows immediately from Lemmas \[117.12\] and \[117.13\].

(2) This statement follows immediately from (1).

(3) This statement follows easily from (1) and Lemma \[117.12\] (1). ■

The following proposition gives a neat calculation of the Arf invariant. In the next section we will use this proposition in our calculation of the Arf invariant.

**Proposition 117.15.** Let \((V, q)\) be a non-degenerate quadratic form over \(\mathbb{F}_2\). Given any symplectic basis \(a_1, \ldots, a_n, b_1, \ldots, b_n\) of the associated symmetric form we have the following equality:

\[
\text{Arf}(q) = \sum_{i=1}^{n} q(a_i) \cdot q(b_i) \in \mathbb{F}_2.
\]

\[1650\] To the best of my knowledge Cahit Arf and Alan Turing are the only two mathematicians of the 20th century who made it on a banknote.
Remark.

(1) The reinterpretation of the Arf invariant given in Proposition \([117.15]\) is actually the original definition given by Cahit Arf, see also Figure \(1620\).

(2) This reinterpretation of the Arf invariant has the great advantage that it also makes sense for quadratic forms over any field of characteristic 2. In this more general setting it is not entirely trivial to see that one actually obtains a well-defined invariant. We refer to [Dye78], [Kapy09, Theorem 27] and [Cohn03, Theorem 8.11.2] for details.

Proof. Let \((V, q)\) be a non-degenerate quadratic form over \(\mathbb{F}_2\) and let \(a_1, \ldots, a_n, b_1, \ldots, b_n\) be a symplectic basis of the associated symmetric form. As in the proof of Lemma \([117.12]\) we denote by \(V_i\) the span of \(\{a_i, b_i\}\), we write \(q_i := q|_{V_i}\) and we point out that \((V, q)\) is isometric to \((V_1, q_1) \oplus \cdots \oplus (V_n, q_n)\).

Note that each \((V_i, q_i)\) is a non-degenerate quadratic form over a 2-dimensional vector space. It follows from the above discussion that each \((V_i, q_i)\) is isometric to either \((W, \sigma_0)\) or \((W, \sigma_1)\). Now we perform the following calculation:

\[
\sum_{i=1}^{n} q(a_i) \cdot q(b_i) = \sum_{i=1}^{n} q_i(a_i) \cdot q(b_i) = \sum_{i=1}^{n} \left\{ \begin{array}{ll}
0, & \text{if } q_i \text{ is isometric to } \sigma_0 \\
1, & \text{if } q_i \text{ is isometric to } \sigma_1
\end{array} \right.
= \sum_{i=1}^{n} \text{Arf}(q_i)
\]

by inspection of the \(\sigma_i\) by inspection of the \(\sigma_i\)

\[
= \text{Arf}(q_1 \oplus \cdots \oplus q_n) = \text{Arf}(q).
\]

by Theorem \([117.14]\) (3)

This concludes our quick introduction to the Arf invariant. In the next section we will use the Arf invariant to calculate the framed cobordism groups \(\Omega^fr_2(\mathbb{R}^{n+2})\) for \(n \geq 3\). Note though that the Arf invariant appears in many other settings of topology, e.g. in knot theory [Pra07, Chapter 6.2] and surgery theory [Browd72].

117.5. The calculation of the framed cobordism groups \(\Omega^fr_2(\mathbb{R}^{n+2})\) for \(n \geq 3\) II. After this amusing purely algebraic section we now return to our actual goal, namely we still want to calculate the framed cobordism groups \(\Omega^fr_2(\mathbb{R}^{n+2})\) for \(n \geq 3\).

Let \((F, v)\) be a closed oriented framed 2-dimensional submanifold of \(\mathbb{R}^n\). Recall that it follows from Propositions \([117.10]\) and \([101.21]\) that the map \(q_{(F, v)} : H_1(F; \mathbb{F}_2) \to \mathbb{F}_2\) that we introduced on page \(2769\) is a quadratic form over \(\mathbb{F}_2\). We can now consider the corresponding Arf invariant \(\text{Arf}(F, v) := \text{Arf}(q_{(F, v)})\).
117. THOM-PONTRYAGIN THEORY III: THE GROUPS $\Omega^f_1(\mathbb{R}^{n+1})$ AND $\Omega^f_2(\mathbb{R}^{n+2})$ 2775

**Example.** We consider the torus $F := S^1 \times S^1$ as a submanifold of $\mathbb{C} \times \mathbb{C} = \mathbb{R}^4$. We equip $F$ with the framing

$$v: S^1 \times S^1 \mapsto GL(4,2) \quad (w, z) = (e^{is}, e^{it}) \mapsto \begin{pmatrix}
\sin(s) & 0 & -
\cos(s) & 0 & 0
\cos(t) & -\sin(t) & \cos(t)
\sin(s) & \cos(s) & \sin(t)
\end{pmatrix},$$

the columns get rotated by $e^{is}$ and $e^{it}$

We equip $H_1(S^1 \times S^1; \mathbb{F}_2)$ with the “obvious basis” $x$ and $y$ given by the two submanifolds $C_1 := S^1 \times \{1\}$ and $C_2 := \{1\} \times S^1$. One calculates by hand that $q(F,v)(x) = 1$ and $q(F,v)(y) = 1$. It follows from Proposition 117.10 that $q(F,v)(x + y) = 1$. Thus we see that $Arf(S^1 \times S^1, v)) = 1$.

why does this correspond to the composition of the Hopf map with suspension of the Hopf map?

**Proposition 117.16.** Let $(F, v)$ be a closed oriented framed 2-dimensional submanifold of $\mathbb{R}^n$. If $[(F, v)] = 0 \in \Omega^f_2(\mathbb{R}^{n+2})$, then $Arf([(F, v)]) = 0$.

**Proof.** Let $(F, v)$ be a closed oriented framed 2-dimensional submanifold of $\mathbb{R}^{n+2}$ which represents the trivial element in $\Omega^f_2(\mathbb{R}^{n+2})$. By definition this means that there exists a compact oriented proper framed 3-dimensional submanifold $(M, w)$ of $\mathbb{R}^{n+2} \times [0,1]$ such that $\partial M = \{0\} \times F$ and such that $w|_{\{1\} \times F} = v$. By Lemma ??, Lemma ?? and Exercise ?? we know that there exists a symplectic basis $a_1, \ldots, a_k, b_1, \ldots, b_k$ of $H_1(F; \mathbb{F}_2)$ such that $a_1, \ldots, a_k \in \ker(H_1(F; \mathbb{F}_2) \to H_1(M; \mathbb{F}_2))$. By the long exact sequence we know that there exist $c_1, \ldots, c_k \in H_2(M, F; \mathbb{F}_2)$ with $\partial c_i = a_i$. By Proposition ?? there exist compact properly embedded submanifolds $G_1, \ldots, G_k$ such that $[G_i]_{\mathbb{F}_2} = c_i$. But by +++++ these surfaces imply that $\chi(a_i) = 0$. Thus we see by Proposition 117.15 that $Arf(F, v) = 0$. $

**Proposition 117.17.**

(1) Let $n \geq 2$. The map

$$Arf: \Omega^f_2(\mathbb{R}^{n+2}) \to \mathbb{Z}_2 \quad [(F, v)] \mapsto Arf(F, v)$$

is a well-defined homomorphism.

(2) Given any $n \geq 2$ the following diagram commutes:

$$\Omega^f_2(\mathbb{R}^{n+2}) \xrightarrow{Arf} \mathbb{Z}_2.$$  

(3) For $n \geq 3$ the map $Arf: \Omega^f_2(\mathbb{R}^{n+2}) \to \mathbb{Z}_2$ is an isomorphism.

$^{1651}$Note that we do not claim that the $G_i$ are necessarily orientable.
Proof.

(1) By Proposition 117.16 we know that the map \([(F, v)] \mapsto \text{Arf}(F, v)\) is well-defined. It follows easily from Theorem 117.14 that the map is actually a homomorphism.

(2) This statement follows easily from the definitions together with Proposition 117.8.

(3) We just saw that there exists a framing \(v\) of \(S^1 \times S^1 \subset \mathbb{C} \times \mathbb{C} = \mathbb{R}^4\) such that \(\text{Arf}(S^1 \times S^1, v) = 1\). This shows that \(\text{Arf} : \Omega^2_2(\mathbb{R}^4) \to \mathbb{Z}_2\) is an epimorphism. Together with (2) we now see that for any \(n \geq 2\) the map \(\text{Arf} : \Omega^2_2(\mathbb{R}^{n+2}) \to \mathbb{Z}_2\) is an epimorphism.

+++++ could define \(\text{Arf}\) invariant of a knot, as \(\text{Arf}\) invariant of any Seifert surface, arguments we give should show that zero for slice knot ++++

117.6. Further results obtained using the Thom-Pontryagin approach. In this final section we summarize a few more results that have been proved using the Thom-Pontryagin approach. First of all, using the Thom-Pontryagin method Pontryagin [Pon50b] proved in 1950 the following theorem.

**Theorem 117.18.** For any \(n \geq 2\) we have \(\pi_{n+2}(S^n) \cong \mathbb{Z}_2\).

**Remark.**

(1) Recall that by Theorem 113.10 (1) we have for every \(n \geq 3\) we have an isomorphism \(\pi_n(S^n) \cong \pi_n(S^2)\). Furthermore we know by Theorem 117.1 that for every \(n \geq 3\) we have \(\pi_{n+1}(S^n) \cong \mathbb{Z}_2\). Putting these two results together shows that \(\pi_4(S^2) \cong \mathbb{Z}_2\).

(2) In Theorem 110.2 we used Steenrod operations to show that \(\pi_{n+2}(S^n) \neq 0\) for all \(n \geq 2\).

(3) By the Freudenthal Suspension Theorem 116.6 we know that the suspension homomorphism \(\pi_5(S^3) \to \pi_6(S^4)\) is an epimorphism and we know that for \(n > k + 1\) the suspension homomorphism \(\pi_{n+2}(S^n) \to \pi_{n+3}(S^{n+1})\) if an isomorphism for \(n \geq 5\).

(4) Unfortunately (1), (2) and (3) are not strong enough to give an alternative proof of Theorem 117.18.

**Proof.**

(1) As mentioned before, the theorem was proved by Lev Pontryagin [Pon50b, Pon59]. See also [Scor05] p. 233 and [WX10] Chapter 2.5 for outlines of the proof. The most readable account of the Thom-Pontryagin approach to proving the theorem is surely [Put].

(2) At the same time as Pontryagin two very different proofs that \(\pi_{n+2}(S^n) \cong \mathbb{Z}_2\) for \(n \geq 2\) were given by George W. Whitehead [WhdG50] and Jean-Pierre Serre [Ser53 Proposition 10]. We also refer to [Hat] Theorem 1.40 (a) for a proof using spectral sequences and Steenrod operations. Alternatively see also [Hu59] Theorem XI.15.2.

Finally Rokhlin [Rok52, Rok86a] used the Thom-Pontryagin approach to prove the following theorem.
Theorem 117.19.

1. We have $\pi_5(S^3) \cong \mathbb{Z}_2$, $\pi_6(S^3) \cong \mathbb{Z}_{12}$, $\pi_7(S^4) \cong \mathbb{Z} \oplus \mathbb{Z}_{12}$.

2. For any $n \geq 5$ we have $\pi_{n+3}(S^n) \cong \mathbb{Z}_{24}$.

Remark.

1. In Theorem 109.13 we used Steenrod operations to show the weaker statement that $\pi_{n+3}(S^n) \neq 0$ for all $n \geq 2$.

2. Note that Theorem 117.19 (1) gives a negative answer to Question 91.15 (2).

Proof.

(a) The theorem was proved by Vladimir Rokhlin [Rok52, p. 21] in 1952, using the above Thom-Pontryagin approach.

(b) A somewhat different proof is sketched in [WX10, Chapter 2.6]. Some of the results can also be found in [Ser53, Proposition 10]. Other proofs are given in [Hat, Theorem 1.40 (b)] and [Hu59, Chapter XI.16].

The results of the last two chapters summarize most (or all?) of the calculations of homotopy groups of spheres that have been obtained using the Thom-Pontryagin approach.

Exercises for Chapter 117

Exercise 117.1. Let $n \in \mathbb{N}_{\geq 2}$. We consider the loops

\[ \alpha: S^1 \to \text{GL}_+(n, \mathbb{R}) \]

\[ z = e^{i \varphi} \mapsto \begin{pmatrix} \cos(\varphi) & -\sin(\varphi) & 0 \\ \sin(\varphi) & \cos(\varphi) & 0 \\ 0 & 0 & \text{id}_{n-2} \end{pmatrix} \]

and

\[ \bar{\alpha}: S^1 \to \text{GL}_+(n, \mathbb{R}) \]

\[ z = e^{i \varphi} \mapsto \begin{pmatrix} \cos(\varphi) & \sin(\varphi) & 0 \\ -\sin(\varphi) & \cos(\varphi) & 0 \\ 0 & 0 & \text{id}_{n-2} \end{pmatrix} \].

Recall that in the proof of Lemma 117.6 we used the fact, proved in Proposition 114.11 (2), that $\pi_1(\text{GL}_+(n-1, \mathbb{R})) \cong \mathbb{Z}_2$, to show that $\alpha$ is path-homotopic to $\bar{\alpha}$. Give a direct proof that the loop $\alpha$ is path-homotopic to the loop $\bar{\alpha}$.

1652 In fact the first isomorphism $\pi_5(S^3) \cong \mathbb{Z}_2$ is a consequence of Theorem 113.10 and Theorem 117.18.

1653 In fact Rokhlin [Rok86b] initially thought that for $n \geq 5$ the groups $\pi_{n+3}(S^n)$ are isomorphic to $\mathbb{Z}_{12}$. The key to fixing the mistake is Rokhlin’s Theorem [102.5] regarding signatures of certain 4-dimensional smooth manifolds.
118. Summary of homotopy groups of spheres

The results from last chapter conclude our calculations of homotopy groups of spheres. Throughout the course we employed a long and varied list of tools to compute homotopy groups of spheres:

1. Covering theory, see page 1068.
2. The Cellular Approximation Theorem 38.13, see Proposition 40.10.
3. The Simplicial Approximation Theorem 62.8, see Corollary 62.10 and Exercise 62.6.
4. Homology theory and the Hurewicz Theorem 53.5, see Corollary 53.6.
5. The cup product, see Corollary 91.14.
6. Steenrod operations, see Theorems 109.13 and 110.2.
7. The long exact sequence of a fibration, see Theorem 113.10.
8. The Thom-Pontryagin Theory, see the Freudenthal Suspension Theorem 116.6 and Theorem 117.1.

In the following we summarize the results we have obtained on homotopy groups of spheres:

1. On page 1068 we saw that \( \pi_n(S^1) = 0 \) for \( n \geq 2 \).
2. Proposition 40.10 or alternatively Exercise 62.6 says that for any \( n \in \mathbb{N} \) we have \( \pi_1(S^n) = \ldots = \pi_{n-1}(S^n) = 0 \).
3. In Corollary 62.10 we showed that the homotopy groups of spheres are countable.
4. Corollary 53.6 (or alternatively by Corollary 115.12) we know that for any \( n \in \mathbb{N} \) we have \( \pi_n(S^n) \cong \mathbb{Z} \).
5. By Theorem 113.10 (1) we know that for every \( n \geq 3 \) we have an isomorphism \( \pi_n(S^2) \cong \pi_n(S^2) \). In particular, together with (4) we know that \( \pi_3(S^2) \cong \mathbb{Z} \). An alternative proof of the fact that \( \pi_3(S^2) \cong \mathbb{Z} \) is given by the combination of the Thom-Pontryagin Theorem 115.11 and Theorem 115.14.
6. In Corollary 91.14, and alternatively in Proposition 115.21 we saw that given any even \( n \in \mathbb{N} \) there exists an epimorphism \( \pi_{2n-1}(S^n) \twoheadrightarrow \mathbb{Z} \).
7. By Theorem 113.11 (1) we know that for every \( n \geq 2 \) we have an isomorphism \( \pi_n(S^4) \cong \pi_3(S^3) \oplus \pi_{n-1}(S^3) \). Furthermore, by Theorem 113.11 (1) we know that for every \( n \geq 2 \) we have an isomorphism \( \pi_n(S^8) \cong \pi_n(S^15) \oplus \pi_{n-1}(S^7) \).
8. By the Freudenthal Suspension Theorem 116.6 we know that for \( n = k + 1 \) we have an epimorphism \( \pi_{n+k}(S^n) \twoheadrightarrow \pi_{n+k+1}(S^{n+1}) \) and we know that for \( n > k + 1 \) we have an isomorphism \( \pi_{n+k}(S^n) \cong \pi_{n+k+1}(S^{n+1}) \).
9. By Theorem 113.11 (2) we know that \( \pi_6(S^4) \cong \pi_6(S^3) \) and by Theorem 113.14 (3) we know that \( \pi_{14}(S^8) \cong \pi_{13}(S^7) \).
10. In Theorem 109.13 we proved the following three statements:
(a) for any \( n \geq 2 \) the group \( \pi_{n+1}(S^n) \) is non-trivial,
(b) for any \( n \geq 4 \) the group \( \pi_{n+3}(S^n) \) is non-trivial,
(c) for any \( n \geq 8 \) the group \( \pi_{n+7}(S^n) \) is non-trivial.
11. By Theorem 117.1 we know that for every \( n \geq 3 \) we have \( \pi_{n+1}(S^n) \cong \mathbb{Z}_2 \). This is a refinement of statement (10a). Note that it follows from this fact together with (5) that \( \pi_4(S^2) \cong \mathbb{Z}_2 \).
In these lecture notes, the homotopy groups of low-dimensional spheres are discussed. The entries colored in blue have been proved. The theorem was first proved by Serre using “spectral sequences”. Expositions of the proof are also given in [Hat Theorem 1.21] and [Spa95 p. 515f].

The following theorem can be summarized as saying that we have picked up all elements of infinite order. In particular the theorem gives a complete answer to Question 91.16. This theorem can also be viewed as a strengthening of Serre’s Theorem 54.17. In fact, the strengthening is also due to Jean-Pierre Serre.

**Theorem 118.1.**

1. If $n$ is odd, then $\pi_k(S^n)$ is finite for $k \geq n+1$.
2. If $n$ is even, then the following two statements hold:
   a. The group $\pi_k(S^n)$ is finite for $k \geq n+1$ and $k \neq 2n-1$.
   b. The group $\pi_{2n-1}(S^n)$ is isomorphic to the direct sum of $\mathbb{Z}$ with a finite group.

**Proof.** The theorem was first proved by Serre [Ser53] using “spectral sequences”. Expositions of the proof are also given in [Hat Theorem 1.21] and [Spa95 p. 515f].

The following table, obtained from [Tod62, Chapter XIV], shows the low-dimensional homotopy groups of low-dimensional spheres. The entries colored in blue have been proved in these lecture notes.

Note that we showed in Theorem 113.10 (1) that the second and the third row, starting with $\pi_3$, are the same.

Recall that the Freudenthal Suspension Theorem 116.6 says that for any $n, k \in \mathbb{N}_0$ with $n > k + 1$ the suspension homomorphism $\pi_{n+k}(S^n) \to \pi_{n+k+1}(S^{n+1})$ is an isomorphism. Thus we see that the groups $\pi_{n+k}(S^n)$ “stabilize” as $n \to \infty$. It is therefore perhaps more instructive to shift in the above diagram the $i$-th row leftward by $i - 1$ terms. This way the diagonal lines become vertical. In other words we consider the following diagram where
\( \pi_{n+k} \) is short for \( \pi_{n+k}(S^n) \).

</table>

Here for convenience we colored the "diagonal" \( \pi_n(S^{2n}) \) in red, since the Freudenthal Suspension Theorem \( \text{[116.6]} \) implies that below the diagonal the groups on each column are the same.

We conclude this discussion of the precise homotopy groups of spheres with the following sobering fact:

**Fact 118.2.** There is no sphere \( S^n \) with \( n \geq 2 \) for which we know the isomorphism types of all homotopy groups.

"Here "we" is defined as members of our species.

As we had mentioned above, the Freudenthal Suspension Theorem \( \text{[116.6]} \) says that homotopy groups of spheres "stabilize". This leads us to the following definition.

**Definition.** Let \( k \in \mathbb{N}_0 \). We refer to\(^{1654}\)

\[
\pi_k^s := \lim_{n \to \infty} \pi_{n+k}(S^n)
\]

as the \( k \)-th stable homotopy group of spheres\(^{1654}\).

Note that it follows from Theorem \( \text{[118.1]} \) that for any \( k \geq 1 \) the \( k \)-th stable homotopy group \( \pi_k^s \) is finite. The following table obtained from \[Wiki\] gives the stable homotopy groups up to \( k = 63 \). It seems like 64 is the first dimension for which we do not know the

\(^{1654}\)Given \( k \in \mathbb{N}_0 \) the groups \( \{ \pi_{n+k}(S^n) \}_{n \in \mathbb{N}} \) together with the suspension homomorphisms form a direct system. Thus it makes sense to consider the direct limit.

\(^{1655}\)Note that for any \( n, k \) with \( n > k + 1 \) the Freudenthal Suspension Theorem \( \text{[116.6]} \) together with Lemma \( \text{[76.2]}(4) \) and Lemma \( \text{[76.3]} \) says that the natural map \( \pi_{n+k}(S^n) \to \pi_k^s \) is an isomorphism.
corresponding stable homotopy groups.

This concludes our discussion of the homotopy groups of spheres. We refer to [May99b, WX10, IWX01, Wiki] and [Hat02, Chapter 4] for a more detailed discussion.

Exercises for Chapter 118.

Exercise 118.1.

(a) Show that $\pi_4(\mathbb{H}\mathbb{P}^\infty) \cong \mathbb{Z}$.
(b) Show that $\pi_n(\mathbb{H}\mathbb{P}^\infty)$ is finite for $n \neq 4$.
(c) Show that $\pi_5(\mathbb{H}\mathbb{P}^\infty) \cong \mathbb{Z}_2$.

Remark. Use Proposition 113.9 together with the results of this chapter.
119. The CW-Approximation Theorem and the Whitehead Theorem

In the following chapters we will work a lot with CW-complexes. In this chapter we will first prove a hotchpotch of results on CW-complexes. Afterwards we will use these results to prove the CW-Approximation Theorem which often allows us to replace a topological space $X$ by a CW-complex that is homotopy equivalent to $X$. Furthermore we will prove the Whitehead theorem which says that if a map $f : X \to Y$ between CW-complexes induces an isomorphism of all homotopy groups, then $f$ is in fact a homotopy equivalence.

119.1. Modifying CW-complexes. As mentioned in the beginning of the chapter, CW-complexes will play a major role in this and the subsequent chapters. Thus, before we start out with proving the enticing theorems mentioned above, we intend to improve our understanding of CW-complexes.

The following, fairly self-evident convention will be in use in the coming chapters.

Convention.

(1) Given $n \in \mathbb{N}_0$ we write $\ast = (0, \ldots, 0, 1) \in S^n$. We view $S^n$ as a CW-complex with one 0-cell $\{\ast\}$ and one $n$-cell.

(2) We always form any wedge of spheres $\bigvee_{i \in I} S_i^{n_i}$ by identifying the points $\ast$. By Lemma 36.32 we can view the wedge $\bigvee_{i \in I} S_i^{n_i}$ as a CW-complex in the obvious way, i.e. we have one 0-cell $\{\ast\}$ and for each $i \in I$ we have one $n_i$-cell.

Before we do anything else we will introduce the following definition which will accompany us in the near future.

Definition. Let $f : X \to Y$ be a map between topological spaces.

(1) We say the map $f : X \to Y$ is 0-connected if $f_* : \pi_0(X) \to \pi_0(Y)$ is a surjection, in other words, each path-component of $Y$ contains a point in $f(X)$.

(2) Let $k \in \mathbb{N}$. We say the map $f : X \to Y$ is $k$-connected if the following two conditions are satisfied:

(a) the map $f_* : \pi_0(X) \to \pi_0(Y)$ is a bijection,

(b) for every $x_0 \in X$ the induced map $f_* : \pi_i(X, x_0) \to \pi_i(Y, f(x_0))$ is an isomorphism for $i = 1, \ldots, k - 1$, epimorphism for $i = k$.

Remark. Let $f : X \to Y$ be a map between path-connected topological spaces and let $k \in \mathbb{N}$. It follows from Proposition 40.5 that to verify that $f$ is $k$-connected it suffices to check the Condition (2b) for a single base point $x_0 \in X$.

Examples.

(1) The map $f : S^1 \vee S^1 \to S^1 \times S^1$ that is illustrated in Figure 1621 is easily seen to be 1-connected, but it is not 2-connected.
2783

(2) Let $X$ be a CW-complex and let $k \in \mathbb{N}_0$. Corollary 111.10 says that the inclusion $X^k \to X$ of the $k$-skeleton is a $k$-connected map. In fact, the previous example is of such type if we consider $X = S^1 \times S^1$ with the usual CW-structure, where the 1-skeleton is precisely $S^1 \vee S^1$.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{fig1621.png}
\caption{Figure 1621}
\end{figure}

The following is the main technical result which underpins many of the later results.

**Proposition 119.1.** Let $k \in \mathbb{N}_0$, let $A$ be a CW-complex and let $f: A \to X$ be a map to a topological space. If the map $f: A \to X$ is $k$-connected, then there exists CW-complex $B$ and a map $g: B \to X$ such that the following statements hold:

1. $A$ is a subcomplex of $B$,
2. the only extra cells of $B$ are $(k+1)$-dimensional, in particular the $k$-skeleton of $B$ equals the $k$-skeleton of $A$,
3. the restriction of $g$ to $A$ equals $f$,
4. the map $g: B \to X$ is $(k+1)$-connected.

**Remark.** In most applications of Proposition 119.1 we start out with a $k$-dimensional CW-complex. In this case we obtain a $(k+1)$-dimensional CW-complex such that $k$-skeleton equals $A$ and such that we can complete the map $f: A \to X$ to the following diagram:

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{fig1622.png}
\caption{Illustration of Proposition 119.1}
\end{figure}

Before we turn to the proof of Proposition 119.1 let us first formulate and prove the following corollary.

1656 Since we did not work with CW-complexes for a while we remind the reader that for a CW-complex $X$ and $l \in \mathbb{N}_0$ we denote by $X^l$ the $l$-skeleton i.e. the union of all cells of dimension $\leq l$. 
Corollary 119.2. (*) Let $A$ be a CW-complex and let $f: A \to X$ be a map to a topological space. There exists a CW-complex $B$ and a map $g: B \to X$ such that the following statements hold:

1. $A$ is a subcomplex of $B$,
2. the restriction of $g$ to $A$ equals $f$,
3. the map $g: B \to X$ is $k$-connected for every $k \in \mathbb{N}_0$.

Proof of Corollary 119.2 (*). Let $A$ be a CW-complex and let $f: A \to X$ be a map to a topological space. Without loss of generality we can and will assume that $A$ and $X$ are 0-connected. We set $B_0 := A$ and $g_0 := f$. We apply Proposition 119.1 to $B_0$ and $g_0$ and iterate this procedure to obtain a sequence of CW-complexes $\{B_n\}_{n \in \mathbb{N}_0}$ and maps $\{g_n: B_n \to X\}_{n \in \mathbb{N}_0}$ such that for each $n \in \mathbb{N}$ the following statements hold:

(a) $A$ is a subcomplex of $B_n$ and $B_{n-1}$ is a subcomplex of $B_n$,
(b) the only cells of $B_n$ that do not lie in $B_{n-1}$ are $n$-dimensional,
(c) the restriction of $g_n$ to $A$ equals $f$,
(d) the map $g_n: B_n \to X$ is $(n+1)$-connected.

We set $B := \lim_{\longrightarrow} B_n$ and we equip with the CW-structure given by Lemma 36.34. Furthermore we denote by $g: B \to X$ the map that is uniquely determined by the property that for each $n \in \mathbb{N}_0$ we have $g|_{B_n} = g_n$. We claim that $(B, g)$ have the desired properties. In fact (1) and (2) are clear by construction. Now let $k \in \mathbb{N}_0$. For a fixed base point in $B_{k+1}$ we consider the following commutative diagram

\[
\begin{array}{ccc}
\pi_k(B) & \xrightarrow{g_*} & \pi_k((k+1)\text{-skeleton of } B) \\
\pi_k((k+1)\text{-skeleton of } B) & \xrightarrow{g_*} & \pi_k((k+1)\text{-skeleton of } B_{k+1}) \\
\pi_k(B_{k+1}) & \xrightarrow{g_*} & \pi_k(X)
\end{array}
\]

Note that by construction the $(k+1)$-skeleton of $B$ equals the $(k+1)$-skeleton of $B_{k+1}$, thus the middle map is indeed the identity. It follows from Proposition 40.9 (1) that the outer horizontal maps are isomorphisms. Finally note that $g|_{B_{k+1}} = g_{k+1}$, which induces an isomorphism on $\pi_k$. Thus the left diagonal map is, as promised, an isomorphism. Keeping in mind the remark on page 2782 we see that the map $g: B \to X$ is $k$-connected for every $k \in \mathbb{N}_0$.

Now we turn to the proof of Proposition 119.1

Proof of Proposition 119.1. To simplify the discussion we only deal with the case that $A$ and $X$ are 0-connected. We leave it to the reader to handle the case that at least one of $A$ and $Y$ is not 0-connected. In particular we will not deal with the case $k = 0$.

So in the following, let $k \in \mathbb{N}$, let $A$ be a 0-connected CW-complex and let $f: A \to X$ be a $k$-connected map to a path-connected topological space. We pick a base point $a_0$ in
the 0-skeleton of $A$. We write $x_0 = f(a_0)$. We note that in general the map $f: A \to X$ fails to be $(k+1)$-connected for the following two reasons:

(a) the map $\pi_k(A, a_0) \to \pi_k(X, x_0)$ is not a monomorphism,
(b) the map $\pi_{k+1}(A, a_0) \to \pi_{k+1}(X, x_0)$ is not an epimorphism.

Both issues will be fixed by attaching $(k+1)$-cells to $A$ and extending $f$ to the $(k+1)$-cells in a suitable way. More precisely, we construct the CW-complex $B$ and a map $g: B \to X$ as follows:

(a) As usual we denote by $A^k$ the $k$-skeleton of $A$. Note that by Proposition 40.9 the map $\pi_k(A^k, x_0) \to \pi_k(A, a_0)$ is an epimorphism. This implies that we can pick a family $\{\varphi_i: (S^k, \ast) \to (A^k, a_0)\}_{i \in I}$ of maps that go into the $k$-skeleton of $A$, and that represent a generating set for $\ker(f_\ast: \pi_k(A, a_0) \to \pi_k(X, x_0))$. Note that by definition each map $f \circ \varphi_i: (S^k, \ast) \to (X, x_0)$ represents the trivial element in $\pi_k(X, x_0)$. Thus it follows from Lemma 40.4 that for each $i \in I$ where exists a map $F_i: \overline{B}_i^{k+1} \to X$ such that $F_i|S_i^k = f \circ \varphi_i$.
(b) Next we pick a family $\{\psi_j: (S^{k+1}, \ast) \to (X, x_0)\}_{j \in J}$ of maps that represent a generating set for $\pi_{k+1}(X, x_0)$.
(c) We set

$$B = \left( A \sqcup \bigsqcup_{i \in I} \overline{B}_i^{k+1} \right) / \sim \lor \bigvee_{j \in J} S_j^{k+1} \quad \text{with } \varphi_i(s) \sim s \text{ for } s \in S_i^k = \partial B_i^{k+1}.$$ 

Note that $B$ is a CW-complex in the following sense:

(i) We start out with the CW-complex that is given by the $k$-skeleton of $A$.
(ii) We attach one $(k+1)$-cell for each $i \in I$ with attaching map given by $\varphi_i$.
(iii) Afterwards we form the wedge with $\bigvee_{j \in J} S_j^{k+1}$. In other words, we attach one

$(k+1)$-cell for each $j \in J$ where the attaching map is given by sending all points in $S_j^k = \partial B_j^{k+1}$ to $a_0$.
(iv) Finally we attach the cells of $A$ of dimension $\geq k+1$ as usual to the above.
(d) We extend the original map $f: A \to X$ to a map $g: B \to X$ by defining it to be $F_i$ on each $\overline{B}_i^{k+1}$ and by defining it to be $\psi_j$ on each $S_j^{k+1}$. It follows easily from Lemma 36.20 that this map $g: B \to X$ is indeed continuous.

By construction $A$ is a subcomplex of $B$ and the only extra cells of $B$ are $(k+1)$-dimensional. Furthermore, by construction the restriction of $g$ to $A$ equals $f$. Thus it remains to show

---

1657 Here and throughout the proof we will implicitly use the remark on page 2782 regarding $k$-connected maps.
1658 A generating set for the kernel is for example given by taking all elements in the kernel.
1659 Here we implicitly use the convention from page 2782 to view the wedge of spheres, and thus also $B$, as a CW-complex.
that the map \( g : B \to X \) is \((k + 1)\)-connected. We denote by \( K := A^k = B^k \) the \(k\)-skeleton of \( A \) which equals by construction the \(k\)-skeleton of \( B \).

(a) First we show that the map \( g : B \to X \) is \(k\)-connected. To do so we note that for any \( r \in \mathbb{N}_0 \) we have the following commutative diagram

\[
\begin{array}{ccc}
\pi_r(A, a_0) & \xrightarrow{i_*} & \pi_r(B, a_0) \\
\downarrow{f_*} & & \downarrow{g_*} \\
\pi_r(K, x_0) & \xrightarrow{i_*} & \pi_r(X, x_0)
\end{array}
\]

where \( i \) always denotes an inclusion map. Since \( K \) is the \(k\)-skeleton of \( A \) and \( B \) we obtain from Corollary 111.10 that the maps \( K \to A \) and \( K \to B \) are \(k\)-connected. By hypothesis the map \( f : A \to X \) is \(k\)-connected. It follows almost immediately from this discussion and the commutative diagram that \( g : B \to X \) is also \(k\)-connected. Note that this discussion also implies that the inclusion \( A \to B \) is \(k\)-connected.

(b) Next we show that \( g_* : \pi_k(B, a_0) \to \pi_k(X, x_0) \) is a monomorphism. Similar to (a) we consider the following commutative diagram:

\[
\begin{array}{ccc}
\pi_k(A, a_0) & \xrightarrow{i_*} & \pi_k(B, a_0) \\
\downarrow{f_*} & & \downarrow{g_*} \\
\pi_k(X, x_0)
\end{array}
\]

As we pointed out in (a), we know that the top map \( i_* : \pi_k(A, a_0) \to \pi_k(B, a_0) \) is an epimorphism. Thus it suffices to show that

\[ \ker(f_* : \pi_k(A, a_0) \to \pi_k(X, x_0)) \subset \ker(i_* : \pi_k(A, a_0) \to \pi_k(B, a_0)). \]

But this inclusion holds basically by definition of \( B \). More precisely, it follows from the definition of \( B \) that for each \( i \in I \) the map \( \varphi_i : (S^k, *) \to (A, a_0) \) extends to a map \( (B^{k+1}, *) \to (B, a_0) \). By Lemma 40.4 we know that this implies that the maps \( \varphi_i : (S^k, *) \to (A, a_0) \) represent elements in the kernel of \( i_* \). On other hand, by definition, these maps represent a generating set for \( \ker(f_* : \pi_k(A, a_0) \to \pi_k(X, x_0)) \).

The desired inclusion of kernels is now a consequence of Lemma 19.3.

(c) It remains to show that the map \( g_* : \pi_{k+1}(B, a_0) \to \pi_{k+1}(X, x_0) \) is an epimorphism. In fact this is true almost by definition of \( B \). More precisely, given \( j \in J \) we have...
Lemma 3.22 that the map is continuous. This shows that the classes \([\{[\psi_j]\}]_{j \in J}\) lie in the image of \(g_*\). But since these classes generate \(\pi_{k+1}(X, x_0)\) we obtain from Lemma 19.3 that \(g_*\) is an epimorphism.

The following lemma gives a simple but useful criterion for extending maps from a subcomplex to the whole CW-complex.

**Lemma 119.3.** Let \((X, A)\) be a pair of CW-complexes and let \(f: A \to Y\) be a map to a path-connected topological space. Suppose the following condition holds:

1. For every \(n \in \mathbb{N}\) such that \(X \setminus A\) contains an \(n\)-cell we have the equality \(\pi_{n-1}(Y) = 0\).

Then \(f\) can be extended to a map \(\tilde{f}: X \to Y\). This statement is illustrated in Figure 1624.

![Figure 1624. Illustration of Lemma 119.3](image)

**Proof.** We start out with the following claim.

**Claim.** Given any \(n \in \mathbb{Z}_{\geq -1}\) we can extend \(f: A \to Y\) to a map \(A \cup X^n \to Y\).

We prove the claim by induction on \(n \in \mathbb{Z}_{\geq -1}\). For \(n = -1\) there is nothing to prove. So suppose the statement holds for some \(n \in \mathbb{Z}_{n \geq -1}\). By the slightest of all abuses we denote the given extension \(A \cup X^n \to Z\) again by \(f\). We denote by \(\{\phi_i: S^n \to X^n\}_{i \in I}\) the family of the attaching maps of all \((n + 1)\)-dimensional cells of \(X\) that are not contained in \(A\). If \(I = \emptyset\), then there is nothing to do. On the other hand if \(I \neq \emptyset\), then we know by the hypothesis (1) that \(\pi_n(Y) = 0\). It follows from Lemma 40.4 that for each \(i \in I\) there exists a map \(g_i: B_i^{n+1} \to Y\) with \(g_i|_{S^n} = f \circ \phi_i: S^n \to Y\). We consider the following map:

\[
A \cup X^{n+1} = \left( (A \cup X^n) \cup \bigcup_{i \in I} B_i^{n+1}\right) / \sim \to Y
\]

\[
[P] \mapsto \begin{cases} f(P), & \text{if } P \in A \cup X^n, \\ g_i(P), & \text{if } P \in B_i^{n+1}. \end{cases}
\]

It follows from \(g_i|_{S^n} = f \circ \phi_i\) that this map is well-defined. Furthermore we obtain from Lemma 3.22 that the map is continuous.

The sequence of maps from the claim defines a map \(\tilde{f}: X = A \cup X = \bigcup_{n \in \mathbb{N}_0} (A \cup X^n) \to Y\). Since the map is continuous on each \(A \cup X^n\) we obtain from Lemma 36.20 that \(\tilde{f}\) is also continuous. It now clear that this map \(\tilde{f}\) is the desired extension.

We conclude this section with the formulation of a special case Lemma 119.3.

**Definition.** We say a topological space \(Y\) is weakly contractible if \(\pi_n(Y) = 0\) for all \(n \in \mathbb{N}_0\).

\[\text{Since } Y \text{ is path-connected we know by Proposition 40.5 that we do not need to worry about base points.}\]
Example. By Corollary 40.12 we know that the infinite-dimensional sphere $S^\infty$ is weakly contractible.

The following corollary is an immediate consequence of Lemma 119.3.

**Corollary 119.4.** Let $(X, A)$ be a pair of CW-complexes and let $f: A \to Y$ be a map to a topological space. If $Y$ is weakly contractible, then $f$ can be extended to a map $\tilde{f}: X \to Y$. In other words, we have the following situation

$$
\begin{array}{ccc}
A & \xrightarrow{f} & Y \\
\downarrow & & \downarrow \\
X & \xleftarrow{\tilde{f}} & \text{if } Y \text{ is weakly contractible}
\end{array}
$$

119.2. **Weak homotopy equivalences and the CW-Approximation Theorem.** The definition of a $k$-connected map between topological spaces naturally leads to the following definition which we had encountered once before on page 1569.

**Definition.** We say that a map $f: X \to Y$ between topological spaces is a **weak homotopy equivalence** if $f$ is $k$-connected for all $k \in \mathbb{N}_0$.

The following lemma gives in particular a practical approach to showing that a given map is a weak homotopy equivalence.

**Lemma 119.5.** Let $f: X \to Y$ be a map between topological spaces.

1. If $f$ is a homotopy equivalence, then it is also a weak homotopy equivalence.
2. If $g: X \to Y$ is a map that is homotopic to $f$, then $f$ is a weak homotopy equivalence $\iff$ $g$ is a weak homotopy equivalence
3. If $X$ and $Y$ are path-connected, then the following holds:

$$
\text{if } f \text{ is a weak homotopy equivalence } \iff \text{there exists an } x_0 \in X \text{ such that for every } k \in \mathbb{N} \text{ the induced map } f_*: \pi_k(X, x_0) \to \pi_k(Y, f(x_0)) \text{ is an isomorphism}.
$$

**Proof.**

1. This statement is an immediate consequence of Proposition 10.7 (2).
2. This statement follows immediately from Proposition 10.7 (1).
3. This statement follows easily from the definitions, the fact that $X$ and $Y$ are path-connected and Proposition 54.9 (3).  

As we just saw in Lemma 119.5, a homotopy equivalence is also a weak homotopy equivalence. But the following example shows that in general the converse does not hold.

\footnote{Recall that by the definition on page 135 the statement $\pi_0(Y) = 0$ means that $Y$ is non-empty and path-connected.}
Example. We turn the “topologist’s sine curve” from page 131 into the so-called “quasi-circle” \( X \) by connecting the vertical interval with the right-hand endpoint. This topological space is illustrated in Figure 1625. We make the following observations:

1. One can easily show that the quasi-circle is path-connected, i.e. \( \pi_0(X) = 0 \).
2. In Exercise 2.52 we showed that the topologist’s sine curve is not path-connected. A similar argument, see Exercise 119.3(a), shows that the image of every map \( S^n \to X \) lies in a contractible subset of \( X \). By Propositions 18.16(2) and 40.7(2) this implies that all homotopy groups \( \pi_n(X), n \geq 1 \) of \( X \) are zero.
3. Pick \( x_0 \in X \). It follows from (1) and (2) that the inclusion \( i : \{x_0\} \to X \) is a weak homotopy equivalence.
4. In Exercise 119.3(b) we will see, in contrast, that the inclusion \( i \) is not a homotopy equivalence.

![The graph of the function \( \sin(\frac{x}{2}) \) with \( x \in (0, \pi] \) and the interval from \( (0, -1) \) to \( (0, 1) \) on the \( y \)-axis](image)

**Figure 1625**

We conclude this discussion of weak homotopies with the following proposition which relates weak homotopy equivalences to induced maps on homology groups.

**Proposition 119.6.** Let \( f : X \to Y \) be a map between topological spaces.

1. If \( f \) is a weak homotopy equivalence, then for any abelian group \( G \) and any \( n \in \mathbb{N}_0 \) the induced maps \( f_* : H_n(X; G) \to H_n(Y; G) \) and \( f^* : H^n(Y; G) \to H^n(X; G) \) are isomorphisms.
2. If \( X \) and \( Y \) are simply connected and if \( f_* : H_n(X) \to H_n(Y) \) is an isomorphism for every \( n \geq 2 \), then \( f \) is a weak homotopy equivalence.

In fact we can basically generalize (2) to the following less readable statement:

2'. Suppose the following conditions are satisfied:
   1. \( X \) and \( Y \) are both path-connected, both are locally path-connected and both are semi-locally simply connected. (As discussed in Corollary 29.9 this means that both topological spaces admit universal coverings.)
   2. For some \( x \in X \) the induced map \( f_* : \pi_1(X, x) \to \pi_1(Y, f(x)) \) is an isomorphism.

We write \( y = f(x) \) and we denote by \( p : (\tilde{X}, \tilde{x}) \to (X, x) \) and \( q : (\tilde{Y}, \tilde{y}) \to (Y, y) \) the universal covers of \((X, x)\) and \((Y, y)\). By (a) and Proposition 29.2 we know that the map \( f \) lifts to a map \( \tilde{f} : (\tilde{X}, \tilde{x}) \to (\tilde{Y}, \tilde{y}) \). We also demand the following:
   1. The map \( \tilde{f}_* : H_n(\tilde{X}) \to H_n(\tilde{Y}) \) is an isomorphism for every \( n \geq 2 \).

Then \( f \) is a weak homotopy equivalence.
Proof.

(1) Let $f: X \to Y$ be a weak homotopy equivalence. It follows easily from Lemmas 41.14 and Lemmas 73.14 that we can assume, without loss of generality, that $X$ and $Y$ are path-connected. Let $x_0 \in X$. By our hypothesis we know that the map $f_*: \pi_n(X, x_0) \to \pi_n(Y, f(x_0))$ is an isomorphism for all $n \in \mathbb{N}_0$. It follows from Theorem 111.14 (1), which in turn is a consequence of the Relative Hurewicz Theorem 111.13, that the induced maps $f_*: H_n(X; Z) \to H_n(Y; Z)$ are isomorphisms for all $n \in \mathbb{N}_0$. The desired statement is now a consequence of Corollary 73.20.

(2) This statement is just a reformulation of Theorem 111.14 (2).

(3) By (b) together with Lemma 119.5 it remains to show that $f_*: \pi_n(X, x) \to \pi_n(Y, y)$ is an isomorphism for every $n \geq 2$. Now let $n \geq 2$. We consider the following diagram:

$$
\begin{array}{ccc}
\pi_n(\widetilde{X}, \widetilde{x}) & \xrightarrow{\tilde{f}_*} & \pi_n(\widetilde{Y}, \widetilde{y}) \\
\downarrow p_* & & \downarrow q_* \\
\pi_n(X, x) & \xrightarrow{f_*} & \pi_n(Y, y).
\end{array}
$$

We make the following observations:

(a) The diagram commutes by definition of $\tilde{f}$.

(b) It follows from Proposition 40.13 that the vertical maps are isomorphisms.

(c) By (2) and by our hypothesis (c) we know that $\tilde{f}: \widetilde{X} \to \widetilde{Y}$ is a weak homotopy equivalence. This implies that the top horizontal map is an isomorphism.

It follows from the above that the bottom horizontal map is indeed an isomorphism.

In the remainder of this section we will study CW-approximations of topological spaces.

Definition. Let $X$ be a topological space. A CW-approximation is a CW-complex $Z$ together with a weak homotopy equivalence $f: Z \to X$.

Example. Let $X$ be the quasi-circle. As we had just discussed, the inclusion of the CW-complex $\{x_0\}$, consisting of a single 0-cell, into the quasi-circle $X$ is a CW-approximation of the quasi-circle $X$.

Before we state a general theorem we turn to the delicate topic of products of CW-complexes. More precisely, if $X$ and $Y$ are CW-complex with only countably many cells, then it follows from Proposition 36.23 that the product $X \times Y$ has a product CW-structure. But, as we pointed out in Lemma 36.24, in general this is not true for arbitrary CW-complexes. This leads us to the following lemma.

Lemma 119.7. (⋆) Let $X$ and $Y$ be two CW-complexes. We define the topological space $X \otimes Y$, whose underlying set is $X \times Y$, as on page 963. The identity map $\text{id}: X \otimes Y \to X \times Y$ is a CW-approximation.

Proof (⋆). By Proposition 36.23 we know that $X \otimes Y$ is a CW-complex and we know that the identity map $\text{id}: X \otimes Y \to X \times Y$ is continuous. In Proposition 36.26 we showed that the induced maps on fundamental groups are isomorphisms. Basically the same argument,
with the obvious extension of Lemma 36.27 to higher dimensions, shows that the map \( \text{id}: X \otimes Y \to X \times Y \) is a weak homotopy equivalence.

The following theorem says that CW-approximations always exist.

**Theorem 119.8. (CW-Approximation Theorem)**

1. Every topological space \( X \) admits a CW-approximation \( f: Z \to X \).
2. Let \( k \in \mathbb{N}_0 \). If \( X \) is a \( k \)-connected topological space, then there exists a CW-approximation \( f: Z \to X \) such that \( Z \) has a single \( 0 \)-cell and such that \( Z \) has no cells in dimensions \( 1, \ldots, k \).

In both cases, given a point \( x_0 \in X \) we can find \( f \) and \( z_0 \in Z^0 \) such that \( f(z_0) = x_0 \).

**Proof of the CW-Approximation Theorem 119.8** Let \( X \) be a topological space.

1. We need to show that \( X \) admits a CW-approximation. By considering each path-component of \( X \) separately we can assume that \( X \) is path-connected.

   Thus let \( X \) be a path-connected topological space. We pick a point \( x_0 \in X \). We set \( Z_0 = \{ x_0 \} \) and we define \( f_0: Z_0 \to X \) as the inclusion map. By iteratively appealing to Proposition 119.1 we obtain the following commutative diagram

\[
\begin{array}{ccc}
Z_0 \xrightarrow{f_0} & X \\
\downarrow & \Rightarrow \\
Z_1 \xrightarrow{f_1} & X \\
\downarrow & \Rightarrow \\
Z_2 \xrightarrow{f_2} & X \\
\vdots & \Rightarrow \\
\end{array}
\]

such that the \((k-1)\)-skeleton of each \( Z_k \) equals \( Z_{k-1} \). We set \( Z = \bigcup_{k \in \mathbb{N}_0} Z_k \) and we define \( f: Z \to X \) in the obvious way. Note that by construction \( Z \) is a CW-complex such that for each \( k \in \mathbb{N}_0 \) the \( k \)-skeleton is given by \( Z_k \). Furthermore it follows from Lemma 36.20 that \( f \) is continuous.

It remains to show that \( f: Z \to X \) is indeed a weak homotopy equivalence. So let \( k \in \mathbb{N}_0 \). We consider the following commutative diagram

\[
\begin{array}{ccc}
\pi_k(Z_{k+1}, x_0) & \xrightarrow{\iota^*} & \pi_k(Z, x_0) \\
\downarrow f_{k+1} \circ & & \downarrow f_* \\
\pi_k(X, x_0) & \xleftarrow{\pi_k(x_0)} & \pi_k(X, x_0)
\end{array}
\]

where \( \iota: Z_{k+1} \to Z \) denotes the inclusion map. The left-hand diagonal map is an isomorphism by construction of \( f_{k+1}: Z_{k+1} \to X \). Furthermore the top horizontal
map is an isomorphism by Proposition 40.9 and the fact that $Z_{k+1}$ is the $(k+1)$-skeleton of $Z$. We deduce from the commutative diagram that the right-hand diagonal map is also an isomorphism.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{fig1626.png}
\caption{Illustration for the proof of Theorem 119.8}
\end{figure}

(2) Let $k \in \mathbb{N}_0$. If $X$ is $k$-connected, then in the proof given in (1) we can start out with the CW-complexes $\{x_0\} = Z_0 = Z_1 = \cdots = Z_k$ and where $f_0 = f_1 = \cdots = f_k$ are the inclusion maps. Only beginning with $f_{k+1}$ do we appeal to Proposition 119.1 to provide the further CW-complexes $Z_j$ and maps $f_j: Z_j \to X$. For the remainder of the proof of (2) we now proceed as in (1). Since the $k$-skeleton of $Z = \bigcup_{k \in \mathbb{N}_0} Z_k$ equals $Z_k = \{x_0\}$ we see that $Z$ has the desired properties.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{fig1627.png}
\caption{Figure 1627}
\end{figure}

\section*{Examples.}

(1) We consider the topological space $X = \{0\} \cup \{\frac{1}{n} \mid n \in \mathbb{N}\} \subset \mathbb{R}$ equipped with the subspace topology coming from $\mathbb{R}$. Note that $X$ is not a CW-complex. Furthermore we consider $Z = \mathbb{N}_0 \subset \mathbb{R}$ with the discrete topology. This is a 0-dimensional CW-complex and the map

\begin{equation}
\begin{array}{ccc}
f: Z = \mathbb{N}_0 & \to & X = \{0\} \cup \{\frac{1}{n} \mid n \in \mathbb{N}\} \\
\quad n & \mapsto & \begin{cases} 
0, & \text{if } n = 0, \\
\frac{1}{n}, & \text{otherwise}
\end{cases}
\end{array}
\end{equation}

is easily seen to be a weak homotopy equivalence. Thus $f: Z \to X$ is a CW-approximation. We refer to Figure 1627 for an illustration.

(2) We consider the pseudocircle that we introduced on page 107. Recall that the pseudocircle is the set $X = \{a, b, c, d\}$ where the topology is given by the set

\[ \mathcal{T} := \{\emptyset, \{a\}, \{c\}, \{a, c\}, \{a, b, c\}, \{a, c, d\}, X\}. \]

On page 107 we gave an explicit map $f: S^1 \to X$ that is also illustrated in Figure 1628. In Exercise 16.13 we showed that $f_*: \pi_1(S^1, 1) \to \pi_1(X, a)$ is an isomorphism. A slight variation on the definition of $f$ also shows that $X$ is path-connected. Furthermore, by the discussion on page 1068 and by Exercise 40.5 we know that $\pi_n(S^1, 1) = \pi_n(X, a) = 0$ for $n \geq 2$. Thus we obtain from Lemma 119.5 that $f$...
is a weak homotopy equivalence. Since $S^1$ is a CW-complex we see that the map $f: S^1 \to X$ is a CW-approximation for the pseudocircle $X$.

\end{tikzpicture}
\end{figure}\]

119.3. **The Whitehead Theorem.** Usually, in algebraic topology one goes from topological situations to algebra using various functors. For example, any map between (pointed) topological spaces gives rise to a map between homology groups and homotopy groups. Unfortunately almost invariably in the passage from topology to algebra some information gets lost.

In Proposition 40.7 (2) we saw that a homotopy equivalence between topological spaces gives rise to isomorphisms of higher homotopy groups. The following theorem shows that, rather amazingly, in this particular case the converse holds, at least if we restrict ourselves to maps between CW-complexes.

**Theorem 119.9. (Whitehead Theorem)**\(^{1664}\) Let $f: X \to Y$ be a map between two connected CW-complexes.\(^{1665}\)

1. If $f: X \to Y$ is a weak homotopy equivalence, then $f$ is a homotopy equivalence.

In fact, there is a more refined version dealing with base points:

2. Let $x_0 \in X^0$ and $y_0 \in Y^0$ be base points in the 0-skeleta of $X$ respectively $Y$. If $f: X \to Y$ is a weak homotopy equivalence with $f(x_0) = y_0$, then there exists a homotopy equivalence between the pointed topological spaces $(X, x_0)$ and $(Y, y_0)$.

For inclusion maps we have the following very useful variation on the Whitehead Theorem 119.9.

**Proposition 119.10.** Let $Y$ be a connected CW-complex, let $X$ be a connected subcomplex and let $x_0 \in X$ be a point. We denote by $i: X \to Y$ the inclusion map. If the induced maps $i_*: \pi_n(X, x_0) \to \pi_n(Y, x_0)$ are isomorphisms for all $n \in \mathbb{N}$, then $X$ is a deformation retract of $Y$.

**Examples.**

1. Let $Y$ be a simply connected 1-dimensional CW-complex and let $x_0$ be a point in the 0-skeleton of $Y$. By Lemma 40.15 (or alternatively Lemma 33.8) we know that $\pi_n(Y, x_0) = 0$ for all $n \in \mathbb{N}$. In other words, the inclusion map $\{x_0\} \to Y$ is a weak homotopy equivalence. Thus it follows from Proposition 119.10 that $Y$ admits a deformation retraction to $\{x_0\}$, in particular $Y$ is contractible.

\(^{1661}\)As we pointed out on page 337, the name “Whitehead Theorem” is sometimes also used for Theorem 111.14. Our naming convention agrees with [Hat02, Theorem 4.5] and [Rot88, p. 370].

\(^{1665}\)Note that we do not assume that the map $f$ is cellular.
For example, let $Y$ be the universal covering of $S^1 \vee S^1$. We view $S^1 \vee S^1$ as a CW-complex in the obvious way. By Proposition 36.37 we can equip $Y$ with the structure of a 1-dimensional CW-complex. By definition of a universal covering we know that $Y$ is simply connected. It follows from the above discussion that any point $x_0$ in the 0-skeleton of $Y$ is a deformation retract. We refer to Figure 1629 for an illustration.

![Diagram](image)

\( Y \) is the universal covering of \( S^1 \vee S^1 \)

\( S^1 \vee S^1 \)

\( p \)

\( x_0 \)

**Figure 1629**

(2) On page 2788 we pointed out that Corollary 10.12 says that $S^\infty$ is weakly contractible. Thus it follows from the Whitehead Theorem 119.9 that $S^\infty$ is contractible.\(^{1666}\)

(3) We consider the knotted curve $X$ in the solid torus $Y = \overline{B^2} \times S^1$ that is shown in Figure 1630. It follows from Theorem 64.2 (3) together with Lemma 61.24 that we can equip $Y$ with a CW-structure such that $X$ is a subcomplex. It should be pretty clear that the inclusion induced map $\pi_1(X, x_0) \to \pi_1(Y, x_0)$ is an isomorphism. Furthermore, since $X$ and $Y$ are homotopy equivalent to $S^1$ we see that the higher homotopy groups of $X$ and $Y$ vanish. In particular for every $n \in \mathbb{N}_{\geq 2}$ the induced maps $i_* : \pi_n(X, x_0) \to \pi_n(Y, y_0)$ are isomorphisms. In other words we see that all the hypotheses of Proposition 119.10 are satisfied. This shows that $X$ is a retract of $Y$. This answers the question that we had posed on page 484.

![Diagram](image)

**Figure 1630**

**Remark.** One might be tempted to interpret the Whitehead Theorem 119.9 as saying that if two CW-complexes have isomorphic homotopy groups, then they are homotopy equivalent. But this statement is false.

(1) For example let us consider the lens spaces $L(5,1)$ and $L(5,2)$. Recall that both are quotients of $S^3$ by some action of $\mathbb{Z}_5$ and both are closed 3-dimensional smooth

\(^{1666}\)In fact in Lemma 36.4 we gave an explicit homotopy from the identity of $S^\infty$ to a constant map. By Lemma 18.12 this implies that $S^\infty$ is contractible.
manifolds. In particular both are CW-complexes by Theorem 64.5. On page 1069 we saw that the homotopy groups of these two lens spaces are isomorphic. On the other hand we see on page ?? that \( L(5, 1) \) and \( L(5, 2) \) are not homotopy equivalent.

(2) We consider the topological spaces \( S^2 \) and \( S^3 \times \mathbb{CP}^\infty \). Evidently \( S^2 \) and \( S^3 \) are CW-complexes. It follows from Lemma 36.6 and Proposition 36.23 that \( S^3 \times \mathbb{CP}^\infty \) is also a CW-complex. In Exercise 113.13 we saw that \( S^2 \) and \( S^3 \times \mathbb{CP}^\infty \) have isomorphic homotopic groups. On the other hand it follows immediately from the discussion on page 1263 and the Künneth Theorem 58.8 that the homology groups of \( S^2 \) and \( S^3 \times \mathbb{CP}^\infty \) are (dramatically) different. Thus the two CW-complexes are not homotopy equivalent.

**Remark.** The analogous statement of the Whitehead Theorem 119.9 does not hold if we drop the hypothesis that \( X \) and \( Y \) are CW-complexes, in other words, the statement does not hold for general topological spaces. We can provide two examples:

(1) On page 2789 we already discussed the fact that the quasi-circle is weakly contractible but not contractible. In other words, the quasi-circle is weakly homotopy equivalent to a point, but it is not homotopy equivalent to a point.

(2) Since weird topological spaces are so much fun, let us consider another example. More precisely, let us consider the following subset of \( \mathbb{R}^2 \) which is also illustrated in Figure 1631:

\[
Y := \text{line segment from } (0, 1) \text{ to } (0, -1) \cup \bigcup_{n \in \mathbb{N}} \text{line segment from } (0, 1) \text{ to } \left( \frac{1}{n}, 0 \right) \\
\quad \quad \quad \quad \cup \bigcup_{n \in \mathbb{N}} \text{line segment from } (0, -1) \text{ to } \left( -\frac{1}{n}, 0 \right).
\]

We equip \( Y \) with the subspace topology. In Exercise 119.4 (a) we will see that the homotopy groups of \( Y \) are trivial. This implies that any inclusion \( X = \{ * \} \to Y \) is a weak homotopy equivalence. On the other hand we show in Exercise 119.4 (b) that \( Y \) is not contractible. The readers who are less inclined towards doing the exercises are referred to [Mau80, p. 301] instead.

---

\footnote{1667}{It is also a moderately amusing exercise to find an explicit CW-structure on lens spaces. One could start either from the definition of a lens space or the reinterpretation given by Lemma ???.}

\footnote{1668}{In fact this follows easily from the fact that \( \pi_k(S^2) = \pi_k(S^3) \) for \( k \geq 3 \) (see Theorem 113.10) and the fact that \( \pi_k(\mathbb{CP}^\infty) = \mathbb{Z} \) for \( k = 2 \) and \( \pi_k(\mathbb{CP}^\infty) = 0 \) for \( k \neq 2 \) (see Theorem 113.12 (2)).}

\footnote{1669}{This shows in particular that \( Y \) is not a CW-complex. Is there a more direct way for showing that \( Y \) is not a CW-complex?}
The proof of the Whitehead Theorem relies on the following lemma.

**Lemma 119.11.** Let \((X, A)\) be a pair of CW-complexes and let \((Y, B)\) be a pair of topological spaces with \(B \neq \emptyset\). We make the following assumption: For every \(n \in \mathbb{N}_0\) such that \(X \setminus A\) has at least one \(n\)-dimensional cell we assume that \(\pi_n(Y, B, y_0) = 0\) for all \(y_0 \in B\). Then every map \(f: (X, A) \to (Y, B)\) is homotopic rel \(A\) to a map \(X \to B\).

**Proof.** We start out with the following claim.

**Claim.** Let \(k \in \mathbb{N}\). Let \(f: (X, A) \to (Y, B)\) be a map. If \(f(X^{k-1}) \subset B\), then there exists a homotopy rel \(A \cup X^{k-1}\) from \(f\) to a map \(g\) with \(g(X^k) \subset B\).

If there are no \(k\)-cells in \(X \setminus A\), then we have \(X^k \subset X^{k-1} \cup A\), in particular we already have \(f(X^k) \subset B\), and we are thus done. Now suppose that there exists at least one \(k\)-cell in \(X \setminus A\). By our hypothesis this implies that \(\pi_k(Y, B, y_0) = 0\) for every \(y_0 \in B\). Let \(\{\Phi_i: B^k \to X\}_{i \in I}\) be the characteristic maps of the \(k\)-cells in \(X \setminus A\). Given \(i \in I\) we denote by \(\phi_i: S^{k-1} \to X\) the corresponding attaching map. It follows from \(f(X^{k-1}) \subset B\), from \(\pi_k(Y, B, y_0) = 0\) and Proposition 111.8 (2) ⇒ (1) that there exists a homotopy \(F_i\) rel \(S^{k-1}\) from the map \(f \circ \Phi_i: B^k \to Y\) to a map whose image is contained in \(B\). It follows from Lemma 18.23 applied to \(A \cup X^k = (A \cup X^{k-1}) \cup \bigcup_{i \in I} \phi_i \left( \bigcup B_i^k \right)\) that these homotopies on all such cells, together with the constant homotopy on \(A \cup X^{k-1}\), give rise to a homotopy \(H\) on \(A \cup X^k\) rel \(A \cup X^{k-1}\) with \(H_0|_{A \cup X^{k-1}} = f\) and with \(H_1(X^k) \subset B\). By the Homotopy Extension Theorem we can extend this homotopy \(H\) to a homotopy \(\tilde{H}: X \times [0, 1] \to Y\) with \(\tilde{H}_0 = f\). This homotopy has all the desired properties.

First suppose that \(X\) is a finite-dimensional CW-complex. It is clear that the hypothesis of the claim holds for \(k = -1\) since, by definition, \(X^{-1} = \emptyset\). Now we can apply the claim iteratively finitely many times. Combining these finitely many homotopies together as in Lemma 18.3 we obtain the desired homotopy.

In the case that \(X\) is infinite-dimensional we obtain an infinite sequence of homotopies. We can combine these homotopies using the rather tricky Lemma and we obtain again the desired homotopy.

Now we are already in a position to provide the proof of Proposition 119.10.

**Proof of Proposition 119.10.** Let \(Y\) be a connected CW-complex, let \(X\) be a connected subcomplex and let \(x_0 \in X\). We denote by \(i: X \to Y\) the inclusion map. We suppose that the induced maps \(i_*: \pi_n(X, x_0) \to \pi_n(Y, x_0)\) are isomorphisms for all \(n \in \mathbb{N}\). We need to show that \(X\) is a deformation retract of \(Y\).

Recall that by our hypothesis \(Y\) is connected, in particular it is path-connected by Proposition 36.10 (7). Thus it follows from Proposition 54.9 that the induced maps
\( i_* : \pi_n(X, x_0) \to \pi_n(Y, x_0) \) are in fact isomorphisms for all \( x_0 \in X \). Next we note that it follows from our hypothesis and the long exact sequence of homotopy groups given by Proposition 111.4 that all relative homotopy groups \( \pi_n(Y, X, x_0) \) are trivial for all \( x_0 \in X \). This observation allows us apply Lemma 119.11 to the identity map \( (Y, X) \to (Y, X) \). From Lemma 119.11 we obtain a homotopy \( H \) rel \( X \) from \( \text{id}_Y \) to a map whose image lies in \( X \). But this means, by definition, that \( H \) is a deformation retraction from \( Y \) to \( X \). \( \blacksquare \)

**Figure 1633. Illustration for the proof of Proposition 119.10.**

We will reduce the proof of the Whitehead Theorem 119.9 to Proposition 119.10. The trick hereby is to use the notion of a mapping cylinder that we introduced on page 697. For the reader’s convenience we recall the definition.

**Definition.** Given a map \( f : X \to Y \) between topological spaces we define the corresponding **mapping cylinder** to be the topological space \( \text{Cyl}(f) := \text{Cyl}(f : X \to Y) := ((X \times [0, 1]) \sqcup Y) / \sim \) where \( (x, 1) \sim f(x) \) for all \( x \in X \). We illustrate the definition in Figure 1634.

**Figure 1634. Illustration for the proof of the Whitehead Theorem 119.9.**

Now we can provide the actual proof of the Whitehead Theorem 119.9.

**Proof of the Whitehead Theorem 119.9.** Let \( X \) and \( Y \) be two connected CW-complexes. Let \( x_0 \in X \) be a base point. Furthermore let \( f : X \to Y \) be a map such that the induced maps \( f_* : \pi_n(X, x_0) \to \pi_n(Y, f(x_0)) \) are isomorphisms for all \( n \in \mathbb{N} \).

1. By the Cellular Approximation Theorem 38.13 the map \( f \) is homotopic to a cellular map \( f' \). We make the following two observations:
   (i) By Lemma 18.11 (3) the map \( f \) is a homotopy equivalence if and only if \( f' \) is a homotopy equivalence.
   (ii) By Lemma 119.3 (2) the map \( f \) is a weak homotopy equivalence if and only if \( f' \) is a weak homotopy equivalence.
As usual we denote by $\text{Cyl}(f')$ the mapping cylinder of $f': X \to Y$. We consider the following diagram of maps:

\[
\begin{array}{c}
X \\
\downarrow^i \\
\text{Cyl}(f') \\
\uparrow_r \\
Y \\
\end{array}
\]

\[f' \quad \text{weak homotopy equivalence} \]

We make the following comments and observations:

(a) The map $r: \text{Cyl}(f') \to Y$ is the obvious map given by the identity on $Y$ and given by sending $[(x, t)]$ to $f'(x)$.

(b) The map $i: X \to \text{Cyl}(f')$ is the obvious inclusion given by $x \mapsto [(x, 0)]$.

(c) It is clear that the above diagram commutes.

(d) By (ii) and our hypothesis the map $f': X \to Y$ is a weak homotopy equivalence.

(e) By Lemma 24.8 (2) we know that the map $r: \text{Cyl}(f) \to Y$ is a homotopy equivalence. In particular we obtain from Lemma 119.5 (1) that $r$ is a weak homotopy equivalence.

(f) It follows from (c), (d) and (e) that $i$ is a weak homotopy equivalence.

(g) Since $f': X \to Y$ is cellular we use Corollary 36.35 (3) to equip $\text{Cyl}(f': X \to Y)$ with a natural CW-structure such that $X \times \{0\} = i(X)$ is a subcomplex.

(h) It follows immediately from (f) and (g) together with Proposition 119.10 that the map $i: X \to \text{Cyl}(f')$ is homotopy equivalence.

(i) We obtain from (e) and (h) and Lemma 18.11 (1) that $f$ is indeed a homotopy equivalence.

(2) Now suppose we are given $x_0 \in X^0$ and $y_0 \in Y^0$ such that $f(x_0) = y_0$. Since $f$ is cellular on the subcomplex $\{x_0\}$ we obtain from the Cellular Approximation Theorem 38.13 that the map $f$ is homotopic rel $x_0$ to a cellular map $f'$. Note that we still have $f'(x_0) = y_0$. Using this input it is not difficult to convince oneself that the argument in (1) can be modified to give the desired homotopy rel $\{x_0\}$. We leave it to the punctilious reader to go through the details.

119.4. Application of the Whitehead Theorem: Topological spaces dominated by CW-complexes. We recall the following definition from page 2077.

**Definition.** We say that a topological space $X$ is **dominated by a topological space** $Y$ if there exist maps $i: X \to Y$ and $r: Y \to X$ such that $r \circ i$ is homotopic to the identity $\text{id}_X$.

The goal of this section is to prove the following result which we already mentioned in Section 85.5.

**Proposition 119.12.** Let $X$ be a topological space. If $X$ is dominated by a CW-complex, then $X$ is homotopy equivalent to a CW-complex.

---

Some of the arguments below overlap with the proof of Lemma 24.8 (2). The reason for not appealing to Lemma 24.8 (2) is that in statement (2) of the Whitehead Theorem 119.9 we also want to do the case rel a fixed point.
Remark.

(1) An alternative proof for Proposition 119.12 that does not use the Whitehead Theorem 119.9 but that uses a mapping telescope construction similar to the telescope construction from page 1010 is given in [Hat02, Proposition A.11].

(2) In Section 85.5 we stated, without proofs but with detailed references, several generalizations of refinements of Proposition 119.12.

The following simply definition will prove convenient in the proof of Proposition 119.12.

**Definition.** Let \( f: X \to Y \) be a map between topological spaces. A map \( g: Y \to X \) is called a homotopy left inverse of \( f \) if \( g \circ f \) is homotopic to \( \text{id}_X \). Furthermore, a map \( h: Y \to X \) is called a homotopy right inverse of \( f \) if \( f \circ h \) is homotopic to \( \text{id}_Y \).

In Exercise 18.18 we proved the following elementary lemma.

**Lemma 119.13.** Let \( f: X \to Y \) be a map between topological spaces. If \( f \) admits a homotopy left inverse \( g \) and a homotopy right inverse \( h \), then \( f \) is in fact a homotopy equivalence and both \( g \) and \( h \) are homotopy inverses.

Now it is fairly straightforward to provide a proof of Proposition 119.12.

**Proof of Proposition 119.12.** Let \( X \) be a topological space that is dominated by a CW-complex \( Y \). Recall that this means that there exist maps \( i: X \to Y \) and \( r: Y \to X \) such that \( r \circ i \) is homotopic to the identity \( \text{id}_X \). Without loss of generality we can and will assume that \( X \) and \( Y \) are path-connected. We pick a base point \( y_0 \in Y \) and we write \( x_0 := r(x_0) \). Since \( r \circ i \) is homotopic to the identity we obtain from Proposition 40.7 (1) that the map \( r_\ast \circ i_\ast = (r \circ i)_\ast: \pi_j(X,x_0) \to \pi_j(X,x_0) \) is an isomorphism for all \( j \in \mathbb{N}_0 \). In particular we see that \( r_\ast: \pi_j(Y,y_0) \to \pi_j(X,x_0) \) is an epimorphism for all \( j \in \mathbb{N}_0 \).

By Corollary 119.2 there exists a CW-complex \( Z \) which contains \( Y \) as a subcomplex and a map \( R: Z \to X \) that extends \( r \) and that is a weak homotopy equivalence. Thus we are now in the following setting:

\[
\begin{array}{ccc}
X & \xrightarrow{i} & Y \\
\downarrow{r} & & \downarrow{t} \\
& \text{subcomplex} & \text{weak homotopy equivalence} \\
& Z & \downarrow{R}
\end{array}
\]

Here denote by \( t: X \to Z \) the inclusion map. (Note though that we do not claim that the diagram commutes.) It remains to prove the following claim.

**Claim.** The map \( t \circ i: X \to Z \) is a homotopy equivalence.

Since \( R \circ (t \circ i) = (R \circ t) \circ i = r \circ i \) is homotopic to \( \text{id}_X \) we know that \( R \) is homotopy left inverse of \( t \circ i \). Furthermore, we obtain from Proposition 40.7 (1) that \( R \circ (t \circ i) \) is a weak homotopy equivalence. Since \( R \) is a weak homotopy equivalence we see that \( t \circ i \) is also a weak homotopy equivalence. Thus we see that \( (t \circ i) \circ R: Z \to Z \) is a weak homotopy equivalence. Since \( Z \) is a CW-complex it follows from the Whitehead Theorem 119.9 that throughout the proof we use the characterization of weak homotopy equivalences given by Lemma 119.5 (3).
the map \((t \circ i) \circ R\) is a homotopy equivalence. This implies that there exists a map \(k: Z \to Z\) such that \((t \circ i) \circ R \circ k\) is homotopic to \(\text{id}_Z\). We have thus shown that \(R \circ k\) is a homotopy right inverse for \(t \circ i\). Since we already pointed out above that \(t \circ i\) admits a homotopy left inverse we obtain from Lemma 119.13 that \(t \circ i\) is a homotopy equivalence.

119.5. Application of the Whitehead Theorem: Highly connected CW-complexes.

In this section we want to discuss the following natural question.

**Question 119.14.** Let \(X\) be a CW-complex which is \(n\)-connected for some \(n \in \mathbb{N}_0\). Is \(X\) homotopy equivalent to a CW-complex \(Y\) which has one 0-cell and no cells in dimensions 1, \ldots, \(n\)?

It turns out that we already dealt with the not entirely trivial case, that \(n = 0\). For the convenience of the reader we recall Proposition 39.11. Its precise statement gives us one possible approach to answering Question 119.14.

**Proposition 39.11.** Let \(X\) be a 0-connected CW-complex.

1. There exists a contractible 1-dimensional subcomplex \(T\) which contains all 0-cells.
2. Given any \(T\) as in (1) the quotient \(X/T\) is a CW-complex with precisely one 0-cell. Furthermore the projection \(X \to X/T\) is a homotopy equivalence.

\(^9\)Such a subcomplex is basically what we called a spanning tree on page 229.

![Illustration of Proposition 39.11](image)

**Figure 1635.** Illustration of Proposition 39.11.

Proposition 39.11 suggests the following approach to answering Question 119.14: Given an \(n\)-connected CW-complex \(X\) we need to find a contractible subcomplex \(S\) that contains the \(n\)-skeleton \(X^n\). The catch is, as the following example shows, in general such a subcomplex just does not exist.

**Example.** Let \(X\) be the 2-dimensional CW-complex corresponding to the presentation \(\langle x \mid x^2 = e, x^3 = e \rangle\). This CW-complex is constructed by attaching two 2-cells to \(S^1\) via the attaching maps \(z \mapsto z^2\) and \(z \mapsto z^3\). We refer to Figure 1636 for an illustration. We have

\[\pi_1(X) \cong \langle x \mid x^2 = e, x^3 = e \rangle \cong \mathbb{Z}/\text{subgroup generated by } 2 \text{ and } 3 \cong 0.\]

We have thus shown that \(X\) is 1-connected. In Exercise 119.9 we will see that \(X\) does not admit a contractible subcomplex \(S\) which contains the 1-skeleton of \(X\) and which has the property that \(X/S\) is homotopy equivalent to \(X\).

In light of the example it comes perhaps as a surprise that Question 119.14 actually does have an affirmative answer:

\(^{1672}\)Recall that on page 995 we showed that any finite presentation \(\langle g_1, \ldots, r_k \mid r_1, \ldots, r_l \rangle\) naturally gives rise to a CW-complex with one 0-cell, \(k\) 1-cells and \(l\) 2-cells.
Let $X$ be a CW-complex, let $x_0 \in X$ and let $n \in \mathbb{N}_0$. If $X$ is $n$-connected, then there exists a CW-complex $Y$ which has a single 0-cell $y_0$ and no cells in dimensions $1, \ldots, n$ such that the pair $(X, x_0)$ is homotopy equivalent to the pair $(Y, y_0)$.

**Proof.** Let $X$ be an $n$-connected CW-complex and let $x_0 \in X$. By the CW-Approximation Theorem 119.8 (2) there exists a CW-complex $Y$ which has a single 0-cell $\{y_0\}$ and no cells in dimensions $1, \ldots, n$ and a map $f: (Y, y_0) \rightarrow (X, x_0)$ which is a weak homotopy equivalence. Thus we can apply the Whitehead Theorem 119.9 (2) to the map $f$ and we see that $f$ is in fact a homotopy equivalence of pointed topological spaces. Well, that was quick. $lacktriangle$

**Remark.** The construction of the CW-complex $Y$ in the proof of Proposition 119.15 is quite wasteful. In particular, without any refinement of the construction, it will almost invariably provide an infinite-dimensional CW-complex $Y$. It turns out that often one can do better. More precisely, in [Hat02 Proposition 4.C.1] the following statement is shown: given a finite $n$-connected CW-complex $X$ there exists a CW-approximation $f: Y \rightarrow X$ where $Y$ is a finite CW-complex with a single 0-cell and such that $Y$ has no cells in dimensions $1, \ldots, n$.

### 119.6. Application of the Whitehead Theorem: Elementary collapses

It is not always easy to determine whether two topological spaces are homotopy equivalent. The following definition is useful for systematizing the search for homotopy equivalences between CW-complexes.

**Definition.** Let $X$ be a CW-complex. We say that a CW-complex $Y$ is an *elementary expansion of $X$* if the following holds:

1. $Y = X \cup e^{n-1} \cup e^n$ where $e^{n-1}$ is an $(n-1)$-cell that is not contained in $X$ and $e^n$ is an $n$-cell that is not contained in $X$.
2. There exists a map $\varphi: \overline{B}^n \rightarrow Y$ with the following properties:
   (a) The map $\varphi$ is the characteristic map for the $n$-cell $e^n$.
   (b) The map $\overline{B}^{n-1} \xrightarrow{\cong} S_{\geq 0}^{n-1} \xrightarrow{\varphi} Y$ is the characteristic map for the $(n-1)$-cell $e^{n-1}$.
   (c) We have $\varphi(S_{\geq 0}^{n-1}) \subset X^{n-1}$.

Conversely we also say that the CW-complex $X$ is an *elementary collapse of $Y$*. We refer to Figure 1637 for an illustration.

We continue with another definition.

---

1673 Here we use the explicit homeomorphism $\overline{B}^{n-1} \xrightarrow{\cong} S_{\geq 0}^{n-1}$ from page 116.
**Definition.** Let $X$ and $Y$ be CW-complexes. We say $X$ and $Y$ are *simple homotopy equivalent* if there exists a sequence $X = X_0, X_1, \ldots, X_k = Y$ such that for $i = 1, \ldots, k$ one of the following three statements holds:

1. $X_i$ is an elementary expansion of $X_{i-1}$, or
2. $X_i$ is an elementary collapse of $X_{i-1}$, or
3. $X_i$ is isomorphic, as a CW-complex, to $X_{i-1}$.

The following lemma justifies the name “simple homotopy equivalent”.

**Lemma 119.16.** Let $X$ and $Y$ be CW-complexes. If $X$ and $Y$ are simple homotopy equivalent, then they are homotopy equivalent.

**Proof (†).** By Lemma 18.11 the notion of being homotopy equivalent is an equivalence relation. Thus it suffices to show that if a CW-complex $X$ is an elementary collapse of a CW-complex $Y$, then $X$ is homotopy equivalent to $Y$. In fact, by Lemma 18.14 it suffices to show that $X$ is a deformation retract of $Y$. We saw on page 549 that there exists a deformation retraction from $B^n$ to $S^{n-1}_{\leq 0}$. It follows from Lemma 18.23 that this deformation retraction, together with the constant homotopy on $X$, defines a deformation retraction from $Y$ to $X$. $lacksquare$
It is also interesting to consider an interesting special case.

**Definition.** A finite CW-complex is called *collapsible* if there exists a sequence of elementary collapses that abuts in a CW-complex consisting of a single point.

![Collapsible CW-complex](image)

**Figure 1640**

The following lemma is an immediate consequence of Lemma 119.16.

**Lemma 119.17.** Let $X$ be a CW-complex. If $X$ is collapsible, then $X$ is contractible.

It is natural to ask whether the converses of Lemmas 119.16 and 119.17 hold. More precisely, we have the following questions.

**Question 119.18.**

1. Let $X$ be a finite CW-complex. If $X$ is homotopy equivalent to a point, does it follow that $X$ is collapsible?
2. Let $X$ and $Y$ be finite CW-complexes.
   a. If $X$ and $Y$ are homeomorphic, does it follow that $X$ and $Y$ are simple homotopy equivalent?
   b. If $X$ and $Y$ are homotopy equivalent, does it follow that $X$ and $Y$ are simple homotopy equivalent?

In the remainder of this chapter we will discuss Question 119.18 (1). We will answer Question 119.18 (2) when we discuss Chapman’s Theorem and Theorem 119.9. To address Question 119.18 (1) it is useful to formulate the following corollary to the Whitehead Theorem 119.9.

**Corollary 119.19.** Let $X$ be a CW-complex. If $X$ is simply connected and if we have $H_n(X; \mathbb{Z}) = 0$ for all $n \geq 2$, then $X$ is contractible, i.e. $X$ is homotopy equivalent to a point.

**Proof.** We let $Y = \{\ast\}$ be the topological space that consists of a single point and let $f : X \to Y = \{\ast\}$ be the only map there is. It follows immediately from Proposition 119.6 that $f$ is a weak homotopy equivalence. Thus the desired statement follows from the Whitehead Theorem 119.9 (1).

In the following we will use Corollary 119.19 to give not one, but two examples of CW-complexes that give a negative answer to Question 119.18 (1).

**Examples.**

1. We equip $S^1$ with the usual CW-structure with one 0-cell $1 \in S^1$ and one 1-cell. Let $\gamma = \text{id}: S^1 \to S^1$ be the identity map. The *dunce cap* is defined as the CW-complex $X$ that is given by attaching one 2-cell to $S^1$ where the attaching map $S^1 \to S^1$ is given...
by the loop $\gamma \ast \gamma \ast \gamma$, i.e., by the loop that is given by the composition of $\gamma$, $\gamma$ and $\gamma$. Using Proposition 37.11 (2) it is straightforward to show that $X$ is simply connected. Furthermore it follows almost from Proposition 48.7 that the cellular homology, and thus by Proposition 48.4 also the singular homology, vanishes in dimensions $\geq 2$. It follows from Corollary 119.19 that the dunce cap is contractible. On the other hand it is clear that the dunce cap is not collapsible since there is only one cell in dimensions 0, 1 and 2 and no two of them can be matched to allow for an elementary collapse.

Figure 1641

(2) It is also possible to give an example of a CW-complex that can be visualized as a subset of $\mathbb{R}^3$. More precisely, consider the topological space $X$ that is shown in Figure 1642 and in Figure 1643. It is commonly referred to as Bing’s house with two rooms. We equip $X$ with the fairly obvious CW-structure. In Exercise 119.11 we will see that $X$ is simply connected and that $H_n(X; \mathbb{Z}) = 0$ for $n \geq 2$. Thus, as in the previous example we can appeal to Corollary 119.19 to conclude that the house with two rooms is contractible. We leave the arduous task of showing that $X$ is not collapsible to the reader.

Figure 1642

Let $X$ be the dunce cap. In 1963 Christopher Zeeman [Ze63a, Theorem 1] showed that $X \times [0, 1]$, equipped with the product CW-structure, is in fact collapsible. This result prompted Zeeman in 1963 to propose the following conjecture [Ze63a, Conjecture 1].

---

1674 The conscientious reader will notice that we had encountered this topological space in Exercise 38.2.

1675 One could of course also prove this “by hand”, but I am pretty sure that few people will enjoy doing this exercise. In fact I have not yet found a book which gives a down-to-earth proof that the dunce cap is contractible.

1676 This example was given by R. H. Bing [Bin64, p. 109] in 1964. In fact the picture we show in Figure 1642 is a slightly modified version of Bing’s original drawing.

1677 A more direct argument for showing that Bing’s house with two rooms is contractible is given on [Hat02, p. 4].
Conjecture 119.20. (Zeeman Conjecture) If $X$ is a finite contractible 2-dimensional CW-complex, then $X \times [0, 1]$ is collapsible.

Like many other conjectures on CW-complexes, this conjecture sounds deceptively simple and elementary. In fact Zeeman was fully aware of the fact that the conjecture is almost certainly very difficult since he showed [Ze63a, Theorem 2] that a proof of the Zeeman Conjecture [119.20] would lead to a new proof of the Poincaré Conjecture in dimension three, which was finally proved in 2003 by Perelman using a heavy dose of analysis, see Theorem ??.

Furthermore, Sergey Matveev [Matv87] (see also [Kupe17a, Proposition 4.2] and [Barm11, Chapter 11]) showed that the Andrews-Curtis Conjecture [21.18] is a special case of the Zeeman Conjecture [119.20]. We refer to [MR93, Matv07, Kupe17a] for more information on the Zeeman Conjecture.

Exercises for Chapter 119.

Exercise 119.1. Let $X = \mathbb{R}$. We equip $X$ with the CW-structure where the 0-skeleton is given by $Z$. The proof of Proposition [119.10] provides a fairly explicit deformation retraction from $X = \mathbb{R}$ to $\{0\}$. What does this deformation retraction look like?

Exercise 119.2. Let $X$ be the universal covering of $S^1 \vee S^1$. On page 2794 we saw that $X$ admits a deformation retraction to $x_0 \in X$. What does an explicit deformation retraction of $X$ to the point $x_0$ look like? We refer to Figure 1644 for an illustration.

Exercise 119.3. Let $X$ be the quasi-circle that we introduced on page 2789.

(a) Show that the image of every map $S^n \to X$ lies in a contractible subset of $X$. 

\[

\text{Illustration of Exercise 119.2} \\
\end{array}
\]

\[
\begin{array}{c}
\text{What does a deformation retraction to the point $x_0$ look like?} \\
\end{array}
\]

*Figure 1644. Illustration of Exercise 119.2*
(b) Let $x_0$ be a point on $X$. Show that the inclusion $\{x_0\} \rightarrow X$ is not a homotopy equivalence.

*Remark.* By Lemma 18.12 this statement is equivalent to the statement that the inclusion $\{x_0\} \rightarrow X$ is not homotopic to the identity.

**Exercise 119.4.** We consider the following subset of $\mathbb{R}^2$:

$$X := \text{line segment from } (0, 1) \text{ to } (0, -1) \cup \bigcup_{n \in \mathbb{N}} \text{line segment from } (0, 1) \text{ to } \left(\frac{1}{n}, 0\right) \cup \bigcup_{n \in \mathbb{N}} \text{line segment from } (0, -1) \text{ to } \left(-\frac{1}{n}, 0\right).$$

We equip $X$ with the subspace topology coming from $\mathbb{R}^2$. We refer to Figure 1631 for an illustration.

(a) Show that all of the homotopy groups of $X$ are trivial.
(b) Show that $X$ is not contractible.

You might want to make use of Lemma 18.12 and Exercise 18.20.

**Exercise 119.5.** Let $X$ and $Y$ be two CW-complexes of dimension at most $n$. Furthermore let $f : X \rightarrow Y$ be a map that is $(n+1)$-connected. Show that $f$ is a homotopy equivalence.

**Exercise 119.6.** Let $f : X \rightarrow Y$ be a map between path-connected CW-complexes. Let $x_0 \in X$. We assume that $f_* : \pi_k(X, x_0) \rightarrow \pi_k(Y, f(x_0))$ is the trivial map for every $k \in \mathbb{N}$. Does it follow that $f$ is homotopic to a constant map?

**Exercise 119.7.**

(a) Give an explicit CW-approximation for the Cantor set, as defined on page 100.
(b) Give an explicit CW-approximation for the topologist’s sine curve, as defined on page 131.

**Exercise 119.8.** Let $X$ be a connected CW-complex and let $k \leq l$ be natural numbers. We suppose that $\pi_i(X) = H_i(X; \mathbb{Z}) = 0$ for $i = k, \ldots, l$. Does it follow that $X$ is homotopy equivalent to a CW-complex which has no cells in dimensions $k, \ldots, l$?

*Remark.* If $k = 1$, then this question is precisely Question 119.14.

**Exercise 119.9.** Let $X$ be the 2-dimensional CW-complex corresponding to the presentation $\langle x \mid x^2 = e, x^3 = e \rangle$. We refer to Figure 1636 for an illustration. Show that $X$ does not admit a contractible subcomplex $S$ which contains the 1-skeleton of $X$ and which has the property that $X/S$ is homotopy equivalent to $X$.

*Hint.* Use the long exact sequence coming from Theorem 43.3.

**Exercise 119.10.** Show that the three CW-complexes shown in Figure 1645 are simple homotopy equivalent.

*Remark.* It is possibly less confusing to first consider $Y$ and $Z$.

![Figure 1645. Illustration of Exercise 119.10](image_url)
Exercise 119.11. Let $X$ be Bing’s house with two rooms, i.e. $X$ is the CW-complex that we defined in Figure 1642.

(a) Show that $X$ is simply connected.
(b) Show that $H_n(X; \mathbb{Z}) = 0$ for $n \geq 2$.

*Hint.* Using Proposition 16.5 and using Euler characteristics will cut down the work considerably.

(c) Show that $X$ is not collapsible.

Exercise 119.12. Let $n \in \mathbb{N}$ and furthermore let $f, g : S^n \to S^n$ be two maps. Show that if $f_* = g_* : H_n(S^n) \to H_n(S^n)$, then $f$ and $g$ are homotopic.

Exercise 119.13.

(1) Let $M$ be a non-empty connected $n$-dimensional smooth manifold. Furthermore let $\varphi : \overline{B^n} \to M$ be a smooth embedding. Show that there exists a homeomorphism $\varphi : M/\varphi(S^{n-1}) \to M \vee S^n$ such that the map $M \to M/\varphi(S^{n-1}) \xrightarrow{\varphi} M \vee S^n \to M$ is homotopic to the identity.

(2) We consider the map

$$
\Theta : S^1 \times S^2 \xrightarrow{\text{projection}} (S^1 \times S^2) \vee S^3 \xrightarrow{\text{as in (1)}} (S^1 \times S^2) \vee S^3 \to S^1 \times S^2.
$$

given by id on $S^1 \times S^2$ and by the Hopf map $S^3 \to S^2$ on $S^3$.

Show the following statements:
(a) $\Theta$ induces the identity on all homology groups.
(b) $\Theta$ induces the identity on $\pi_1$ and $\pi_2$.
(c) $\Theta$ does not induce the identity on $\pi_3$.

![Figure 1646. Illustration for Exercise 119.13](image-url)
120. Eilenberg-Maclane Spaces

In this chapter we introduce Eilenberg-Maclane spaces. Even though the definition is quite straightforward, these topological spaces will henceforth play an essential role.

120.1. The definition and basic examples of Eilenberg-Maclane Spaces. We recall the following definition from page 1251.

Definition. Let $\pi$ be an abelian group and let $n \in \mathbb{N}$. We say that a non-empty topological space $X$ is a Moore space of type $M(\pi, n)$ if the following conditions are satisfied:

1. $X$ admits a CW-structure,
2. for any $i \neq n$ we have $\tilde{H}_i(X; \mathbb{Z}) = 0$,
3. $H_n(X) \cong \pi$.
4. If $n \geq 2$, then we demand that $X$ is simply connected.

For the reader’s convenience we recall the main result that we proved regarding Moore spaces.

Proposition 47.11. Given any $n \in \mathbb{N}$ and given any abelian group $\pi$ there exists an $(n + 1)$-dimensional CW-complex that has no cells in dimensions $1, \ldots, n - 1$ and that is a Moore space of type $M(\pi, n)$.

In light of the topics discussed in this chapter it is perhaps helpful to give a quick recap of the proof of Proposition 47.11.

Sketch of proof. Since $\pi$ is abelian it follows immediately from Lemma 57.16(1) that there exists a free resolution of $\pi$ of the following form:

$$0 \rightarrow \mathbb{Z}(A) \xrightarrow{\varphi} \mathbb{Z}(B) \xrightarrow{\rho} \pi \rightarrow 0.$$

We let $X := \bigvee_{a \in A} S^n_a$ and we let $Y := \bigvee_{b \in B} S^n_b$. We equip $X$ and $Y$ with the obvious CW-structures and we can make the identifications $H_n(X; \mathbb{Z}) = \mathbb{Z}(A)$ and $H_n(Y; \mathbb{Z}) = \mathbb{Z}(B)$. We construct a cellular map $h: X \rightarrow Y$ such that the induced map $H_n(X; \mathbb{Z}) \rightarrow H_n(Y; \mathbb{Z})$ agrees with $\varphi$ under the above identifications. The mapping cone $\text{Cone}(h: X \rightarrow Y)$ then has the desired properties.

The definition of an Eilenberg-Maclane space is almost identical to the definition of a Moore space, we just swap homology groups for homotopy groups:

Definition. Let $\pi$ be a group and let $n \in \mathbb{N}$. Let $X$ be a topological space.

1. We say that $X$ is an Eilenberg-Maclane space of type $K(\pi, n)$ if the following conditions hold:
   a. $X$ admits a CW-structure,
   b. for any $i \neq n$ we have $\pi_i(X) = 0$,
   c. $\pi_n(X) \cong \pi$.

2. Let $x_0 \in X$. We say $(X, x_0)$ is a pointed Eilenberg-Maclane space of type $K(\pi, n)$ if $X$ is an Eilenberg-Maclane space of type $K(\pi, n)$ and if $X$ admits a CW-structure such that $x_0$ lies in the 0-skeleton of $X$. 
Remark.

(1) Our definition of an Eilenberg-Maclane space agrees with the definition in [DaK01, p. 177]. Conversely in [WhdG78, p. 239], [Spa95, p. 424], [Bre93, p. 488] and [Hat02, p. 365] it does not say (at least explicitly) that an Eilenberg-Maclane space needs to admit a CW-structure.

(2) If a topological space $X$ is an Eilenberg-Maclane space of type $K(\pi, n)$, then often in the literature one just says that $X$ is a $K(\pi, n)$. We will refrain from using this language.

It is perhaps initially not clear why the concept of an Eilenberg-Maclane space is useful, but at the very least it is a fun exercise to go through our long list of topological spaces that we have studied and to determine which ones are Eilenberg-Maclane spaces:

(1) We start with the trivial group $\{e\}$. Let $n \in \mathbb{N}$. In this case it is easy to find Eilenberg-Maclane spaces of type $K(\{e\}, n)$. In fact it follows from Proposition 10.7 (2) that any contractible CW-complex is an Eilenberg-Maclane space of type $K(\{e\}, n)$. Thus we see in particular that for any $k \in \mathbb{N}_0$ the open ball $B^k$ and the closed ball $\overline{B}^k$ are Eilenberg-Maclane spaces of type $K(\{e\}, n)$.

(2) Let $k \in \mathbb{N}$. It follows from Corollary 16.18 and the discussion on page 1068 that the $k$-dimensional torus $(S^1)^k$ is an Eilenberg-Maclane space of type $K(\mathbb{Z}^k, 1)$.

(3) Let $g \in \mathbb{N}_{\geq 2}$ and let $\Sigma_g$ be a surface of genus $g$. On page 1070 we saw that $\pi_i(\Sigma_g) = 0$ for $i \geq 2$. Thus we see that $\Sigma_g$ is an Eilenberg-Maclane space of type $K(\pi_1(\Sigma_g), 1)$.

(4) Let $k \in \mathbb{N}$ and let $F = \langle x_1, \ldots, x_k \rangle$ be the free group on $k$ generators. It follows from the discussion on page 1066 and Lemma 40.15 that the wedge $\bigvee_{i=1}^k S^1$ of $k$ circles is an Eilenberg-Maclane space of type $K(F, 1)$.

(5) It follows from Lemma 36.5 (3) together with Proposition 40.13 and Corollary 40.12 that the infinite real projective space $\lim \mathbb{R}P^k =: \mathbb{R}P^\infty \cong S^\infty / x \sim -x$ is an Eilenberg-Maclane space of type $K(\mathbb{Z}_2, 1)$.

\[\text{Figure 1647}\]

---

\[\text{1678}^6\text{It is perhaps worth recalling that } \pi_0(X) = 0 \text{ means, by the definition on page 135, that } X \text{ is non-empty and path-connected. In particular, by Proposition 54.9 (2) the isomorphism type of the homotopy groups } \pi_n(X), n \in \mathbb{N}, \text{ does not depend on the choice of the base point.}\]

\[\text{1679}^6\text{In Lemma 36.5 (4c) we showed that there exists a homeomorphism } \mathbb{R}P^\infty \cong S^\infty / x \sim -x.\]
We have now obtained a short but pleasant list of Eilenberg-Maclane spaces of type $K(\pi, 1)$. It is harder to find examples of Eilenberg-Maclane spaces of type $K(\pi, n)$ with $n \geq 2$ for a non-trivial group $\pi$. It turns out that we had found one interesting example of that type:

(6) Recall that by Lemma 36.6 we know that $\mathbb{C}P^\infty$ admits a CW-structure. It follows from Theorem 113.12(2) that the infinite complex projective space $\mathbb{C}P^\infty$ is an Eilenberg-Maclane space of type $K(\mathbb{Z}, 2)$.

Remark.

(1) One might initially hope that perhaps $\mathbb{H}P^\infty$ could be an Eilenberg-Maclane space of type $K(\pi, 4)$. First note that by Lemma 60.9(7) we know that $\mathbb{H}P^\infty$ is indeed a CW-complex. Furthermore, in in Exercise 118.1 we obtained the following results:
   (a) There exists an isomorphism $\pi_4(\mathbb{H}P^\infty) \cong \mathbb{Z}$.
   (b) The group $\pi_n(\mathbb{H}P^\infty)$ is finite for $n \neq 4$, in particular $\pi_n(\mathbb{H}P^\infty) \otimes \mathbb{Q} = 0$ for $n \neq 4$.
   (c) There exists an isomorphism $\pi_5(\mathbb{H}P^\infty) \cong \mathbb{Z}_2$.

So we see that “rationally” $\mathbb{H}P^\infty$ looks like an Eilenberg-Maclane space, but it is just not an Eilenberg-Maclane space.

(2) In the following chapters we will give many examples of “perfectly reasonable” topological spaces that are Eilenberg-Maclane spaces of type $K(\pi, 1)$. For $n \geq 2$ it seems that $\mathbb{C}P^\infty$ is basically the only Eilenberg-Maclane space of type $K(\pi, n)$ for some non-trivial group $\pi$ which appears “in nature”.

Our next goal is to find Eilenberg-Maclane spaces of type $K(\mathbb{Z}_m, 1)$ for arbitrary $m$. For $m = 2$ we had just seen that $\mathbb{R}P^\infty$ is such an Eilenberg-Maclane space. We recall that in Lemma 36.5(3) we saw that we can make the identification $\mathbb{R}P^\infty = S^\infty/\{\pm 1\}$ where the group $\{\pm 1\} \cong \mathbb{Z}_2$ acts in the obvious way on $S^\infty$. The idea is to generalize this example. More precisely we want to find appropriate actions of any finite cyclic group on $S^\infty$.

At this point it is convenient to recall that given coprime $p, q \in \mathbb{N}$ we defined on page 502 the lens spaces $L(p, q) = S^3/\mathbb{Z}_p$ as the quotient of $S^3$ by a suitable action of $\mathbb{Z}_p$ on $S^3$. If one ponders for a while about the definition of lens spaces one is led to the following lemma.

**Lemma 120.1.** Let $m \in \mathbb{N}$ and let $r_1, r_2, \ldots \in \mathbb{N}$ be natural numbers that are coprime to $m$.

(1) The map

\[ (\mathbb{Z}_m \times S^\infty, ([k], (z_1, z_2, z_3, \ldots))) \mapsto (e^{2\pi i k r_1/m} z_1, e^{2\pi i k r_2/m} z_2, \ldots) \]

defines a continuous and discrete action of $\mathbb{Z}_m$ on $S^\infty$.

(2) The quotient space $L(m, r_1, r_2, \ldots) := S^\infty/\mathbb{Z}_m$ admits a CW-structure.

(3) The quotient space $L(m, r_1, r_2, \ldots) := S^\infty/\mathbb{Z}_m$ is an Eilenberg-Maclane space of type $K(\mathbb{Z}_m, 1)$.

---

The slightly hesitant “basically” refers to the fact that out of $\mathbb{C}P^\infty$ one can build a few other examples of Eilenberg-Maclane spaces, e.g. one can consider $\mathbb{C}P^\infty \times B^k$ or, as we will see shortly, the product $\mathbb{C}P^\infty \times \mathbb{C}P^\infty$ is an Eilenberg-Maclane space of type $K(\mathbb{Z}^2, 2)$. 
On page ?? we saw, using the linking pairing, that lens spaces with isomorphic fundamental groups are not necessarily homotopy equivalent. We can not define a linking pairing on the topological spaces $L(m, r_1, r_2, \ldots)$. Thus the following question arises:

**Question 120.2.** How can one show that given $m \in \mathbb{N}$ the homotopy type of the topological spaces $L(m, r_1, r_2, \ldots)$ depends on the choice of the parameters $r_i$?

**Proof.**

(1) The proof of this statement is quite similar to the task performed in Exercise 36.4. We leave it to the motivated reader to prove the desired statement. As always it takes a little effort to work rigorously with the topology of $S^\infty = \lim_{\to} S^n$.

(2) Given $n \in \mathbb{N}$ the action of $\mathbb{Z}_m$ on $S^\infty$ restricts to an action on $S^{2n-1} \subset S^\infty$. In [Hat02, p. 144] or alternatively [Shas14, p. 196] an explicit CW-structure for $S^{2n-1}/\mathbb{Z}_m$ is constructed. These CW-structures have the property that for $k < l$ the $(2k - 1)$-skeleton of $S^{2l-1}/\mathbb{Z}_m$ is precisely the CW-complex $S^{2k-1}/\mathbb{Z}_m$. It follows quite easily from Lemma 25.5 that the CW-structures on the $S^{2n-1}/\mathbb{Z}_m$ give rise to a CW-structure on $S^\infty/\mathbb{Z}_m$.

(3) (a) Let $n \geq 2$. We calculate that

$$\pi_n(L(m, r_1, r_2, \ldots)) \cong \pi_n(S^\infty/\mathbb{Z}_m) \cong \pi_n(S^\infty) = 0.$$

↑

follows from from (1), Proposition 40.13 and from the fact that $n \geq 2$

Proposition 40.13 and Corollary 40.12

(b) It follows immediately from (1), Theorem 16.16 and Corollary 40.12 that we have isomorphisms $\pi_1(L(m, r_1, r_2, \ldots)) = \pi_1(S^\infty/\mathbb{Z}_m) \cong \mathbb{Z}_m$. ■

The following proposition allows us to construct more Eilenberg-Maclane spaces out of given ones.

**Proposition 120.3.**

(1) Let $X$ be an Eilenberg-Maclane space of type $K(A, n)$ and let $Y$ be an Eilenberg-Maclane space of type $K(B, n)$.

(a) The CW-complex $X \otimes Y$, that is defined on page 963, is an Eilenberg-Maclane space of type $K(A \times B, n)$.

(b) If at least one of $X$ or $Y$ has only countably many cells, then the product $X \times Y$ is an Eilenberg-Maclane space of type $K(A \times B, n)$.

The remaining two statements only apply to the case $n = 1$.

(2) Let $X$ be an Eilenberg-Maclane space of type $K(\pi, n)$. We pick a base point $x_0 \in X$ and we pick an isomorphism $\varphi: \pi_1(X, x_0) \to \pi$. Let $\Gamma$ be a subgroup of $\pi$. We denote by $\tilde{X}$ the covering space of $X$ corresponding to the subgroup $\varphi^{-1}(\Gamma) \subset \pi_1(X, x_0)$. Then $\tilde{X}$ is an Eilenberg-Maclane space of type $K(\Gamma, n)$.

---

\[\text{Here we view } S^\infty \text{ as a subset of } C^\infty \text{ via the identification } C^\infty = R^\infty \text{ from page 339.}\]
(3) Let \( X \) be an Eilenberg-Maclane space of type \( K(A,1) \) and let \( Y \) be an Eilenberg-Maclane space of type \( K(B,1) \). We pick CW-structures for \( X \) and \( Y \). Then any wedge \( X \vee Y \) is an Eilenberg-Maclane space of type \( K(A \ast B,1) \).

Remark. The restriction in Proposition 120.3 (1) on the CW-complexes \( X \) and \( Y \) is a major nuisance. Even though this condition on the number of cells is not an issue for the Eilenberg-Maclane spaces that we have considered above, the “canonical” Eilenberg-Maclane spaces that we will construct shortly do not satisfy this condition. Thus one should apply Proposition 120.3 (1) with great caution.

Proof.

1. Recall that by construction and by Proposition 36.23 we know \( X \otimes Y \) is a CW-complex whose underlying set is \( X \times Y \). Let \( \text{id} : X \otimes Y \to X \times Y \) be the identity map. We pick \( x \in X \) and \( y \in Y \). Given any \( k \in \mathbb{N}_0 \) we have the following isomorphisms

\[
\pi_k(X \otimes Y, (x,y)) \cong \pi_k(X \times Y, (x,y)) \cong \pi_k(X,x) \times \pi_k(Y,y) \cong \begin{cases} A \times B, & \text{if } k = n, \\ 0, & \text{otherwise.} \end{cases}
\]

Lemma 19.7  Propositions 16.20 and 40.8

Since \( X \otimes Y \) is a CW-complex we obtain from this discussion that \( X \otimes Y \) is an Eilenberg-Maclane space of type \( K(A \times B, n) \).

If at least one of \( X \) or \( Y \) has only countably many cells, then we know by Proposition 36.23 that \( X \otimes Y = X \times Y \), i.e. \( X \times Y \) itself is an Eilenberg-Maclane space of type \( K(A \times B, n) \).

2. First note that we know by Proposition 36.37 that \( \tilde{X} \) is a CW-complex. It now follows immediately from Proposition 40.13 that \( \tilde{X} \) is an Eilenberg-Maclane space of type \( K(\Gamma, n) \).

3. Let \( x \in X^0 \) and \( y \in Y^0 \) be points in the 0-skeleta of \( X \) and \( Y \). By Proposition 36.10 (5) we know that the points \( x \) and \( y \) are good. Thus it follows from Proposition 20.3 that we have isomorphisms \( \pi_1(X \vee Y) \cong \pi_1(X) \ast \pi_1(Y) \cong A \ast B \). Furthermore we obtain basically immediately from Exercise 53.3 that all higher homotopy groups of \( X \vee Y \) vanish. Finally we know by Lemma 36.32 (4) that \( X \vee Y \) is a CW-complex.  

The following lemma summarizes a few basic facts about Eilenberg-Maclane spaces.

Lemma 120.4. Let \( n \in \mathbb{N} \) and let \( \pi \) be a group. If \( X \) is an Eilenberg-Maclane space of type \( K(\pi, n) \), then given any abelian group \( G \) the following statements hold:

1. We have \( H_0(X;G) \cong G \) and \( H^0(X;G) \cong G \).
2. For \( i = 1, \ldots, n-1 \) we have \( H_i(X;G) = 0 \) and \( H^i(X;G) = 0 \).

---

Since \( X \) is a CW-complex we know from Proposition 36.10 (6) that \( X \) is locally simply connected. Therefore it follows from Proposition 29.3 that the covering exists and it follows from Proposition 29.8 that the covering corresponding to the subgroup \( \varphi^{-1}(\Gamma) \subset \pi_1(X,x_0) \) is essentially unique.

Recall our convention from page 970 whenever we take the wedge of CW-complexes, we only use points in the 0-skeleton. The “any” now refers to the fact that, under this restriction, any wedge is in fact an Eilenberg-Maclane space.
(3) Given any \( x_0 \in X \) the Hurewicz homomorphism \( \pi_n(X, x_0)_{ab} \to H_n(X; \mathbb{Z}) \) is an isomorphism. In particular \( H_n(X; \mathbb{Z}) \cong \pi_{ab} \).

(4) The evaluation map \( H^n(X; G) \to \operatorname{Hom}(H_n(X; \mathbb{Z}), G) \) is an isomorphism.

**Proof.** The statements follow easily from the Hurewicz Theorems 52.5 and 53.5 and from the Universal Coefficient Theorems 57.19 and 75.13. The experienced reader will have no troubles with filling in the details. ■

120.2. **Killing higher homotopy groups.** In the subsequent section we will give a general construction of Eilenberg-Maclane spaces. To streamline the discussion we outsource a few preparations to the present section.

First we point out that the following, fairly self-evident convention will be in effect in the coming chapters.

**Convention.**

(1) Given \( n \in \mathbb{N}_0 \) we write \( * = (0, \ldots, 0, 1) \in S^n \). We equip \( S^n \) with the canonical CW-structure from page 935, i.e. we view \( S^n \) as a CW-complex with one 0-cell \( \{*\} \) and one \( n \)-cell.

(2) We always form any wedge of spheres \( \bigvee_{i \in I} S^m_i \) by identifying the points \( * \in S^m_i \). By Lemma 36.32 (4) we can and will view the wedge \( \bigvee_{i \in I} S^m_i \) as a CW-complex in the obvious way, i.e. we have one 0-cell \( \{*\} \) and for each \( i \in I \) we have one \( n_i \)-cell.

(3) By a slight abuse of notation we sometimes say \( X \) is a \( k \)-dimensional CW-complex if the highest dimension of a cell is \( \leq k \).

We start out with the following calculation.

**Proposition 120.5.** Let \( I \) be a set, let \( n \in \mathbb{N} \) and for each \( i \in I \) let \( S^n_i \) be a copy of \( S^n \). For each \( i \in I \) we denote by \( \varphi_i: S^n \to S^n_i \) the obvious homeomorphism. By a slight abuse of notation we denote by \( \varphi_i \) also the composition of \( \varphi_i \) with the canonical inclusion map \( S^n_i \to \bigvee_{i \in I} S^n_i \).

(1) For any \( i \in \{1, \ldots, n - 1\} \) we have \( \pi_i \left( \bigvee_{i \in I} S^n_i, * \right) = 0 \).

(2) If \( n = 1 \), then the homomorphism

\[
\langle \{x_i\}_{i \in I} \rangle \to \pi_1 \left( \bigvee_{i \in I} S^1_i, * \right)
\]

\( x_i \mapsto [\varphi_i] \)

is an isomorphism.

(3) If \( n \geq 2 \), then the homomorphism

\[
\mathbb{Z}^{(I)} = \bigoplus_{i \in I} \mathbb{Z} \cdot i \to \pi_n \left( \bigvee_{i \in I} S^n_i, * \right)
\]

\( i \mapsto [\varphi_i] \)

is an isomorphism.
Proof.

(1) As we pointed out above, we can view $\bigvee S^n_i$ as a CW-complex with one 0-cell and no other cells outside of dimension $n$. It follows from Proposition 40.9 that all homotopy groups in dimension $1, \ldots, n-1$ vanish.

(2) In the case that $I$ is a finite set, then, as we saw in the proof of Lemma 20.4, the statement follows easily from applying Proposition 20.3 altogether $k-1$ times. The general case is proved in Proposition 20.7.

(3) Let $n \in \mathbb{N} \geq 2$. We consider the maps

$$Z^{(I)} = \bigoplus_{i \in I} \mathbb{Z} \cdot i \xrightarrow{\varphi} \bigoplus_{i \in I} H_n(S^n_i, \mathbb{Z}) \xrightarrow{\pi} H_n\left(\bigvee_{i \in I} S^n_i, \mathbb{Z}\right) \xrightarrow{\pi} \pi_n\left(\bigvee_{i \in I} S^n_i, \ast\right).$$

given by $i \mapsto [S^n_i]$ Proposition 47.9 by the Hurewicz Theorem 53.5 which we can apply by (1).

It is straightforward to verify that this composition of isomorphisms is precisely the isomorphism under consideration. ■

We continue with the following two propositions which basically says that for a given CW-complex one can “kill” all homotopy groups beyond a chosen degree.

**Proposition 120.6.** Let $k \in \mathbb{N}$, let $X$ be a connected $(k+1)$-dimensional CW-complex and let $x_0 \in X$ be a base point.

1. There exists a $(k+2)$-dimensional CW-complex $Y$ with the following properties:
   (a) the $(k+1)$-skeleton of $Y$ agrees with $X$,
   (b) for $i = 1, \ldots, k$ the inclusion induced map $\pi_i(X, x_0) \to \pi_i(Y, x_0)$ is an isomorphism, and
   (c) we have $\pi_{k+1}(Y, x_0) = 0$.
2. The CW-complex $Y$ in (1) can be chosen canonically.
3. If $X$ has countably many cells, then $Y$ as in (1) can be chosen to have countably many cells.

**Proof.**

(1) We pick a set $\{\varphi_j : (S^{k+1}_j, \ast) \to (X, x_0)\}_{j \in J}$ of maps that represent a generating set for the group $\pi_{k+1}(X, x_0)$. We set

$$Y = \left( X \sqcup \bigcup_{j \in J} \overline{B}_j^{k+2} \right) / \sim$$

with $\varphi_j(s) \sim s$ for $s \in S^{k+1}_j = \partial \overline{B}_j^{k+2}$.

---

\[\text{[1684]}\] By Lemma 19.14 the given data does indeed determine a unique homomorphism.

\[\text{[1685]}\] Since $n \geq 2$ we know by Proposition 40.3 that the right-hand side is an abelian group. Thus it follows from Lemma 19.1 that the given data does indeed determine a unique homomorphism.

\[\text{[1686]}\] We follow the convention established on pages 2813 and 2814, i.e. when we say “$n$-dimensional CW-complex” we allow for the possibility that the highest dimension of a cell is $< n$.

\[\text{[1687]}\] Here “canonical” is shorthand for saying that in the proof of the proposition we provide an explicit construction of $Y$ does not depend on any choices.

\[\text{[1688]}\] Note though that we do not claim that we can find a canonical $Y$ with countably many cells.
Put differently, $Y$ is the $(k + 2)$-dimensional CW-complex that is obtained from $X$
by attaching one $(k + 2)$-cell for each $j \in J$ with attaching map given by $\varphi_j$. We
denote by $i : X \to Y$ the inclusion map. Now we verify that $Y$ has all the desired
qualities.

(a) By construction $Y$ is a $(k + 2)$-dimensional CW-complex such that the $(k + 1)$-
skeleton equals $X$.

(b) It follows immediately from Proposition 40.9 and (a) that the inclusion induced
map $i_\ast : \pi_s(X, x_0) \to \pi_s(Y, x_0)$ is an isomorphism for $s = 1, \ldots, k$ and that the
map $i_\ast : \pi_{k+1}(X, x_0) \to \pi_{k+1}(Y, x_0)$ is an epimorphism.

(c) Let $j \in J$. We have the following simple but useful commutative diagram:

\[
\begin{array}{ccc}
S^{k+1} & \xrightarrow{\varphi_j} & X \\
\downarrow & & \downarrow \\
\overline{B^{k+2}} & \xrightarrow{\bigcup_{j \in J} B^{k+2}} & X \sqcup \bigcup_{j \in J} \overline{B^{k+2}} & \to Y.
\end{array}
\]

In other words, the map $i \circ \varphi_j : S^{k+1} \to Y$ extends to a map $\overline{B^{k+2}} \to Y$. By
Lemma 40.4 this implies that $i_\ast([\varphi_j]) = [i \circ \varphi_j] = 0 \in \pi_{k+1}(Y, x_0)$.

(d) Since $\{[\varphi_j] : j \in J\}$ is by choice a generating set for $\pi_{k+1}(X, x_0)$ we obtain from (c)
that $i_\ast : \pi_{k+1}(X, x_0) \to \pi_{k+1}(Y, x_0)$ has trivial image.

(e) It follows from (b) and (d) that $\pi_{k+1}(Y, x_0) = 0$.

We have thus verified that $Y$ has all the desired properties.

(2) It is easy to come up with a canonical $Y$: in the construction provided in (1) we
just need to consider the set of all maps $(S^{k+1}, \ast) \to (X, x_0)$. Evidently this set is
canonical and evidently it represents a generating set for $\pi_{k+1}(X, x_0)$. The resulting
CW-complex $Y$ is the canonical CW-complex we desired.

(3) Finally suppose that $X$ has countably many cells. It follows from the rather non-
trivial Proposition 85.19 that $\pi_{k+1}(X, x_0)$ is countable. Therefore we can pick a
countable family $\{\varphi_j : (S^{k+1}, \ast) \to (X, x_0)\}_{j \in J}$ of maps that represent a generating
set for the group $\pi_{k+1}(X, x_0)$. The resulting CW-complex $Y$ evidently has only
countably many cells.

We conclude this technical section with the following proposition that is mostly just an
iterated application of Proposition 120.6.
**Proposition 120.7.** Let \( k \in \mathbb{N} \), let \( Y \) be a connected \((k + 1)\)-dimensional CW-complex and let \( y_0 \in Y \).

1. There exists a CW-complex \( Z \) with the following three properties:
   (a) the \((k + 1)\)-skeleton of \( Z \) equals \( Y \),
   (b) we have \( \pi_i(Z) = 0 \) for \( i \geq k + 1 \),
   (c) for any \( i \in \{1, \ldots, k\} \) the inclusion induced map \( \pi_i(Y, y_0) \xrightarrow{\cong} \pi_i(Z, y_0) \) is an isomorphism.
2. The CW-complex \( Z \) in (1) can be chosen canonically.
3. If \( Y \) has countably many cells, then \( Z \) as in (1) can be chosen to have countably many cells.

**Proof.** Let \( k \in \mathbb{N} \) and let \( Y \) be a connected \((k + 1)\)-dimensional CW-complex. Let \( y_0 \in Y \).

1. We define \( Z_{k+1} = Y \). For \( i = k + 1, k + 2, \ldots \) we iteratively apply Proposition 120.6 to \( Z_i \) to obtain a sequence of CW-complexes \( Z_{k+1}, Z_{k+2}, \ldots \) with the following properties:
   (i) each \( Z_{i} \) is an \( i \)-dimensional CW-complex,
   (ii) for each \( i \geq k + 1 \) the \( i \)-skeleton of \( Z_{i+1} \) is given by \( Z_{i} \),
   (iii) for each \( i \geq k + 1 \) we have \( \pi_i(Z_{i+1}, y_0) = 0 \).

   We set \( Z := \lim_{\longrightarrow} Z_i = \bigcup_{i=k+1}^{\infty} Z_i \) and we equip it with the obvious CW-structure such that for each \( i \geq k + 1 \) the \( i \)-skeleton of \( Z \) is given by \( Z_i \). We claim that \( Z \) has the desired three properties:
   (a) It follows from (ii) that the \((k + 1)\)-skeleton of \( Z \) equals \( Y \).
   (b) Let \( i \geq k + 1 \). We have
      \[
      \pi_i(Z, y_0) \xrightarrow{\cong} \pi_i((i + 1)\text{-skeleton } Z^{i+1} \text{ of } Z, y_0) = \pi_i(Z_{i+1}, y_0) = 0.
      \]
      
   (c) This statement follows immediately from (a) and Proposition 40.9.

2. This statement follows immediately from Proposition 120.6 (2).

3. This statement follows immediately from Proposition 120.6 (3). \( \square \)

**120.3. Existence of Eilenberg-Maclane Spaces.** Using the examples from the first section and using Proposition 120.3 we can “by hand” construct Eilenberg-Maclane spaces of type \( K(\pi, 1) \) for many groups \( \pi \). One can ask for which pairs \((\pi, n)\) there exist corresponding Eilenberg-Maclane spaces. There is one obvious restriction: since homotopy groups \( \pi_n(X) \) with \( n \geq 2 \) are abelian, see Proposition 40.3 we see that for \( n \geq 2 \) we can only hope to find an Eilenberg-Maclane space of type \( K(\pi, n) \) if \( \pi \) is abelian. Perhaps somewhat surprisingly this is the only restriction on the existence of Eilenberg-Maclane spaces.

**Theorem 120.8.** Let \( n \in \mathbb{N} \) and let \( \pi \) be a group. If \( n \geq 2 \), then we demand that \( \pi \) is abelian. There exists a canonical triple \((X, x_0, \varphi : \pi_n(X, x_0) \to \pi)\) with the following properties:

1. \( X \) is an Eilenberg-Maclane space of type \( K(\pi, n) \).
Definition. We refer to the canonical CW-complex from Theorem 120.8 as the canonical Eilenberg-Maclane space $K(\pi, n)$.

Remark. As we will see shortly, the canonical Eilenberg-Maclane spaces that we construct in the proof of Theorem 120.8 are monstrously large. More precisely, the CW-complex of type $K(\pi, n)$ has uncountably many cells in each dimension $\geq n + 1$. The cautionary remark from page 2812 about taking products of Eilenberg-Maclane spaces thus applies to the canonical Eilenberg-Maclane spaces.

After the discussion of the previous section the approach to producing an Eilenberg-Maclane space of type $K(\pi, n)$ is presumably pretty clear:

1. Start out with a CW-complex with one 0-cell, no cells in dimension $1, \ldots, n-1$ and “sufficiently” many $n$-cells to be able to “generate” the group $\pi$.
2. Attach $(n+1)$-cells to chop down the $n$-th homotopy group to obtain the desired group $\pi$.
3. Attach cells of dimension $\geq n+2$ to kill all homotopy groups in dimensions $\geq n+1$.

We basically know how to perform (1) and (3), so it remains to do (2) carefully. The combination of steps (1) and (2) is performed in the following proposition.

Proposition 120.9.

1. Let $\pi$ be any group. There exists a canonical triple $(Y, x_0, \varphi: \pi_1(Y, x_0) \to \pi)$ with the following properties:
   a. $Y$ is a 2-dimensional CW-complex with one 0-cell $\{x_0\}$,
   b. $\varphi: \pi_1(Y, x_0) \to \pi$ is an isomorphism.
2. Let $\pi$ be an abelian group $\pi$ and let $n \in \mathbb{N}_{\geq 2}$. There exists a canonical triple $(Y, x_0, \varphi: \pi_n(Y, x_0) \to \pi)$ with the following properties:
   a. $Y$ is an $(n+1)$-dimensional CW-complex with one 0-cell $\{x_0\}$ and no cells in dimensions $1, \ldots, n-1$,
   b. $\varphi: \pi_n(Y, x_0) \to \pi$ is an isomorphism.

Remark. The first result is related to Corollary 37.12 which says that given any finitely presented group $\pi$ there exists a finite connected 2-dimensional CW-complex $Y$ with $\pi_1(Y) \cong \pi$.

Before we provide the proof of Proposition 120.9 we convince ourselves of the fact that this proposition, together with Proposition 120.7 does indeed imply Theorem 120.8.

Proof of Theorem 120.8. In the following we discuss the case $n \geq 2$. The proof for $n = 1$ is almost identical. Thus let $n \in \mathbb{N}_{\geq 2}$ and let $\pi$ be an abelian group. By Proposition 120.9 (2) there exists a canonical triple $(Y, x_0, \varphi: \pi_n(Y, x_0) \to \pi)$ with the following properties:

1. $Y$ is an $(n+1)$-dimensional CW-complex with one 0-cell $\{0\}$ and no cells in dimensions $1, \ldots, n-1$,
2. $\varphi: \pi_n(Y, x_0) \to \pi$ is an isomorphism.
We plug this data into Proposition 120.7 and we obtain a canonical CW-complex $Z$ with the following three properties:

3. the $(n+1)$-skeleton of $Z$ equals $Y$ (here we use that $Y$ equals its own $(n+1)$-skeleton),
4. we have $\pi_j(Z) = 0$ for $j \geq n + 1$,
5. the inclusion $i: Y \to Z$ induces an isomorphism $\pi_n(Y, x_0) \xrightarrow{\approx} \pi_n(Z, x_0)$.

Note that it follows from (1) and (3) together with Proposition 40.9 that the following holds:

6. We have $\pi_j(Z, x_0) = 0$ for $j = 1, \ldots, n - 1$.

It follows immediately from all of the above statements that the canonical triple

$$(Z, x_0, \varphi \circ i^{-1}: \pi_n(Z, x_0) \xleftarrow{i_*} \pi_1(Y, x_0) \xrightarrow{\varphi} \pi)$$

has all the desired properties.

Now we turn to the proof of Proposition 120.9. The proof naturally splits into the two cases $n = 1$ and $n \geq 2$.

**Proof of Proposition 120.9** (1). Let $\pi$ be a group. Given $g \in \pi$ we write $S^1_g := S^1 \times \{g\}$, i.e. $S^1_g$ is a copy of $S^1$. Let $\ast = (0, 1) \in S^1$ be the usual base point of $S^1$. We consider the wedge $X := \bigvee_{g \in \pi} S^1_g$ which is given by identifying all the points $(*, g) \in S^1_g$. We denote by $x_0 \in X$ the wedge point. We apply the convention from page 2813 to view $X$ as a CW-complex in the obvious way.

By Proposition 120.5 (2) we have a canonical identification $\langle \{x_g\}_{g \in \pi} \rangle = \pi_1(X, x_0)$. Thus, by Lemma 19.14 there exists a unique homomorphism $\psi: \pi_1(X, x_0) = \langle \{x_g\}_{g \in \pi} \rangle \to \pi$ such that $\psi(x_g) = g$ for every $g \in \pi$. This homomorphism is, by construction, an epimorphism. We set $\Gamma = \ker(\psi)$.

Next let $\{\alpha_j: (S^1, \ast) \to (X, x_0)\}_{j \in J}$ be the family of all loops that represent an element in $\Gamma = \ker(\psi): \pi_1(X, x_0) \to \pi$. We set

$$Y = \left( X \cup \bigcup_{j \in J} B^2_j \right) / \sim \quad \text{with } \alpha_j(s) \sim s \text{ for } s \in S^1_j = \partial B^2_j.$$ 

Put differently, $Y$ is the 2-dimensional CW-complex that is obtained from $X$ by attaching one 2-cell for each $j \in J$ with attaching map given by $\alpha_j$. By construction $Y$ is a 2-dimensional CW-complex such that the 1-skeleton equals $X$. We denote by $i: X \to Y$ the inclusion map.

**Claim.** The map $i_*: \pi_1(X, x_0) \to \pi_1(Y, x_0)$ descends to a map

$$\varphi: \pi_1(X, x_0)/\Gamma \to \pi_1(Y, x_0)$$

and this map is an isomorphism.

The proof of the claim naturally breaks into several parts.

1. Let $j \in J$. The same elementary argument as in the proof of Proposition 120.6 shows that the map $i \circ \alpha_j: S^1 \to Y$ extends to a map $B^2_j \to Y$. By Lemma 14.1 this
observation implies that $i_+([\alpha_j]) = [i \circ \alpha_j] = 0 \in \pi_1(X, x_0)$. Since $\{[\alpha_j]\}_{j \in J}$ contains every single element of $\Gamma$ we see that $i_+: \pi_1(X, x_0) \to \pi_1(Y, y_0)$ descends to a map

$$\varphi: \pi_1(X, x_0)/\Gamma \to \pi_1(Y, y_0).$$

(2) It follows from $X = Y^1$ and Proposition [40.9] that the map $i_+: \pi_1(X, x_0) \to \pi_1(Y, y_0)$ is an epimorphism. This implies that $\varphi$ is also an epimorphism.

(3) We still need to show that the map $\varphi: \pi_1(X, x_0)/\Gamma \to \pi_1(Y, y_0)$ is a monomorphism.

At this stage this is equivalent to showing that $\ker(i_+: \pi_1(X, x_0) \to \pi_1(Y, y_0)) = \Gamma$. Thus let $g \in \ker(i_+: \pi_1(X, x_0) \to \pi_1(Y, y_0))$. We start out with the following claim.

Claim. There exists a finite subset $\{i_1, \ldots, i_m\} \subset I$ such that $g$ lies in the kernel of the inclusion induced map $\pi_1(X, x_0) \to \pi_1((X \sqcup (B^2_{i_1} \cup \cdots \cup B^2_{i_m}))/\sim, x_0)$.

By Lemma [25.9] there exists a compact subset $K$ of $Y$ such that $g$ lies in the kernel of the inclusion induced map $\pi_1(X, x_0) \to \pi_1(X \cup K, x_0)$. The claim now follows easily from Lemma [36.16] (2).

Let $I = \{i_1, \ldots, i_m\}$ be such a finite subset. It follows from Proposition [37.11] (2), applied altogether $m$ times, together with Exercise [21.1] that we have the following commutative diagram

$$
\begin{array}{ccc}
\pi_1(X, x_0) & \longrightarrow & \pi_1((X \sqcup (B^2_{i_1} \cup \cdots \cup B^2_{i_m}))/\sim, x_0) \\
\downarrow & & \downarrow \\
\pi_1(X, x_0)/\langle [\alpha_{i_1}], \ldots, [\alpha_{i_m}] \rangle.
\end{array}
$$

Thus we see that $g \in \langle [\alpha_{i_1}], \ldots, [\alpha_{i_m}] \rangle$. Since $[\alpha_{i_1}], \ldots, [\alpha_{i_m}]$ lie by definition in $\Gamma$ we see that $g \in \Gamma$.

We are now basically done. Indeed, the CW-complex $Y$ is 2-dimensional, it has a single 0-cell $x_0$ and it is canonical. Furthermore the map $\psi: \pi_1(X, x_0) \to \pi$ induces an isomorphism $\tilde{\psi}: \pi_1(X, x_0)/\Gamma \to \pi$. Thus we see that the canonical triple

$$\langle Y, x_0, \pi_1(Y, x_0) \rangle \xleftarrow{\varphi} \pi_1(X, x_0)/\Gamma \xrightarrow{\psi} \pi$$

has all the desired properties.

Now we turn to the proof of Proposition 120.9 (2).

**Proof of Proposition 120.9 (2).** Let $\pi$ be an abelian group and let $n \geq 2$. If we do not care about a canonical construction, then we could just use Proposition 47.11 to obtain an $(n + 1)$-dimensional CW-complex $Y$ with one 0-cell and no cells in dimensions $1, \ldots, n - 1$ and with $H_n(Y; \mathbb{Z}) \cong \pi$. By the Hurewicz Theorem 53.5 this implies that $\pi_n(Y) \cong \pi$. Unfortunately this construction is not canonical.

Since we are really eager to have canonical constructions we need to provide a different argument. Evidently, in the following discussion, we will try for as long as possible to roll over ideas from the proof of Proposition 120.9 (1).
We make the following clarifications and observations:

1. For each \( g \in \pi \) we write \( S^n_g := S^n \times \{g\} \). We consider \( * = (0, \ldots, 0, 1) \in S^n \). As in (1) we consider the wedge \( X := \underset{g \in \pi}{\bigvee} S^n_g \) and we view \( X \) canonically as a CW-complex. We denote by \( x_0 \in X \) the wedge point.

By Proposition [120,3] (3) we have a canonical identification \( \pi_n(X, *) = \mathbb{Z}^{(\pi)} \). Since \( \pi \) is an abelian group we know from Lemma [19,1] that there exists a unique homomorphism \( \psi: \pi_n(X, *) = \mathbb{Z}^{(\pi)} \to \pi \) with \( \psi(g) = g \) for every \( g \in \pi \). This homomorphism is, by construction, an epimorphism. We set \( \Gamma = \ker(\psi) \).

Next let \( \{\alpha_j: (S^n, *) \to (X, x_0)\}_{j \in J} \) be the family of all maps that represent an element in \( \Gamma = \ker(\psi: \pi_n(X, *) \to \pi) \). As in the proof of (1) we set

\[
Y = \left( X \sqcup \bigsqcup_{j \in J} \overline{B^n_j} \right) / \sim \quad \text{with} \quad \alpha_j(s) \sim s \quad \text{for} \quad s \in S^n_j = \partial B^n_j.
\]

By construction \( Y \) is an \((n + 1)\)-dimensional CW-complex such that the \( n \)-skeleton equals \( X \). We denote by \( i: X \to Y \) the inclusion map.

Claim. The map \( i_*: \pi_n(X, x_0) \to \pi_n(Y, x_0) \) descends to a map

\[
\varphi: \pi_n(X, x_0) / \Gamma \to \pi_n(Y, x_0)
\]

and this map is an isomorphism.

We consider the following diagram

\[
\begin{array}{cccc}
\Gamma & \to & \pi_n(X, x_0) & \xrightarrow{i_*} & \pi_n(Y, x_0) & \to & 0 \\
\downarrow_{a_j \mapsto [\alpha_j]} & & \downarrow & & \downarrow & & \\
\bigoplus_{j \in J} \mathbb{Z} \cdot a_j & \xrightarrow{a_j \mapsto [\alpha_j]} & \pi_n(X, x_0) & \xrightarrow{i_*} & \pi_n(Y, x_0) & \to & 0 \\
\downarrow & & \downarrow_{\cong} & & \downarrow_{\cong} & & \\
\bigoplus_{j \in J} \mathbb{Z} \cdot a_j & \xrightarrow{a_j \mapsto [\alpha_j, (S^n)]} & \text{H}_n(X; \mathbb{Z}) & \xrightarrow{i_*} & \text{H}_n(Y; \mathbb{Z}) & \to & 0.
\end{array}
\]

We make the following clarifications and observations:

1. The squares at the top commute basically by definition. Note that the vertical map to the top left is an epimorphism by definition of the family \( \{\alpha_j\}_{j \in J} \).
2. The vertical maps between the second and the third row, which are located in the middle and to the right, are the Hurewicz homomorphisms from page 1324.
3. It follows from the naturality of the Hurewicz homomorphism, see Lemma [53,1] (3), that the square to the bottom right commutes.
4. It follows basically immediately from the definition of the Hurewicz homomorphism that the square to the bottom left commutes.
5. By construction we know that \( X \) and \( Y \) have precisely one 0-cell and no cells in dimension \( 1, \ldots, n - 1 \). This implies by Proposition [40,9] that \( X \) and \( Y \) are \((n - 1)\)-connected. Now we obtain from the Hurewicz Theorem [53,5] that the vertical maps in the middle and to the right are both isomorphisms.
It follows from a modest generalization of Lemma 46.19 that the bottom horizontal sequence is exact.\footnote{Lemma 46.19 was formulated for attaching a single \((n+1)\)-cell, but basically the same argument also works for attaching an arbitrary family of \((n+1)\)-cells.}

It follows from all the information assembled above that the top horizontal sequence is also exact. But this fact is just a reformulation of the statement that we are supposed to prove in the claim.

As in the proof of (1) we are now basically done. Indeed, the CW-complex \(Y\) is \((n+1)\)-dimensional, it has a single 0-cell \(x_0\), it has no cells in dimensions \(1, \ldots, n\) and it is canonical. Furthermore the map \(\psi: \pi_n(X, x_0) \to \pi\) induces an isomorphism \(\overline{\psi}: \pi_n(X, x_0)/\Gamma \to \pi\). Thus we see that the canonical triple

\[
\left( Y, x_0, \pi_n(Y, x_0) \right) \left\langle \overline{\psi} \right\rangle \pi_n(X, x_0)/\Gamma \overline{\psi} \pi
\]

has all the desired properties.\[\square\]

We have now seen that given any group there exists a CW-complex that is an Eilenberg-Maclane space. But it is pretty clear that the construction provided by the proof of Theorem 120.8 is pretty wasteful, except for the trivial group the construction provides an infinite-dimensional CW-complex. In many cases, e.g. for the groups \(\pi = \mathbb{Z}^m\), there are, as we have seen on page 2809, much simpler, finite-dimensional Eilenberg-Maclane spaces of type \(K(\pi, 1)\). This point towards a common tension:

1. On the one hand it is nice to have “small constructions” with few cells. For example it is much easier to visualize finite CW-complexes and it is usually much easier to calculate invariants for finite CW-complexes.
2. On the other hand it is nice to have canonical constructions which do not depend on any choices. But such constructions are almost invariably humongous.

This situation is comparable to the discussion of free resolutions of abelian groups. On the one hand, for actual calculations one prefers “small” free resolutions. On the hand, say to give unambiguous definitions of Tor-groups and Ext-groups one needs to work with the canonical free resolution from page 1408 which is outrageously wasteful.

It is natural to ask whether “small” groups also admit “small” Eilenberg-Maclane spaces. For example the following question arises:

\textbf{Question 120.10.} Let \(m \in \mathbb{N}_{\geq 2}\). Can we find a finite-dimensional Eilenberg-Maclane space of type \(K(\mathbb{Z}_m, 1)\)?

In some instances one can also attempt to perform the three-step-process from page 2817 with more care to provide “smaller” Eilenberg-Maclane spaces. In the remainder of this section we want to discuss the construction of the Eilenberg-Maclane spaces \(K(\mathbb{Z}, n)\). For \(n = 1\) everything that can be said had been said on page 2809.

We will now construct an explicit Eilenberg-Maclane space of type \(K(\mathbb{Z}, 2)\) using the above procedure:

1. We start with \(X_2 := \mathbb{C}P^1 = S^2\). We have \(\pi_1(X_2 = \mathbb{C}P^1) = 0\) and \(\pi_2(X_2 = \mathbb{C}P^1) \cong \mathbb{Z}\).
(2) By Theorem \[113.12\] we know that \( \pi_3(\mathbb{C}P^1) = [p] \) where \( p: S^3 \rightarrow \mathbb{C}P^1 \) denotes the Hopf map from page 2688.

(3) We set \( X_4 := B^3 \cup_{p: S^3 \rightarrow \mathbb{C}P^1} \mathbb{C}P^1 \).

(4) By Lemma \[91.2\] (1) we know that \( X_4 \) is homeomorphic to \( \mathbb{C}P^2 \).

(5) By Theorem \[113.12\] we know that \( \pi_3(\mathbb{C}P^2) = 0 \) and \( \pi_4(\mathbb{C}P^2) = 0 \). Furthermore it tells us that \( \pi_5(\mathbb{C}P^2) = [p] \) where \( p: S^5 \rightarrow \mathbb{C}P^2 \) denotes the Hopf map from page 2688.

(6) Similar to (3) we consider \( X_6 := B^3 \cup_{p: S^3 \rightarrow \mathbb{C}P^1} \mathbb{C}P^1 \).

(7) As in (4), using Footnote \[1690\] we see that \( X_6 \) is homeomorphic to \( \mathbb{C}P^3 \).

Iterating this process we obtain the sequence \( \mathbb{C}P^2, \mathbb{C}P^4, \ldots \) and we end up with the infinite complex projective space \( \mathbb{C}P^\infty \). This shows, once again, that \( \mathbb{C}P^\infty \) is an Eilenberg-Maclane space of type \( K(\mathbb{Z}, 2) \). A similar discussion, shows how to construct an Eilenberg-Maclane space of type \( K(\mathbb{Z}_2, 1) \) starting with \( X_2 = \mathbb{R}P^2 \), by imitating the above approach one once again ends up with \( \mathbb{R}P^\infty \).

For \( n \geq 3 \) there seem to be no straightforward models for \( K(\mathbb{Z}, n) \). But the following lemma gives us at least a little bit of extra control, which will play a crucial role at a later point.

**Lemma 120.11.** Given any \( n \in \mathbb{N} \) there exists an Eilenberg-Maclane space of type \( K(\mathbb{Z}, n) \) with precisely one 0-cell, precisely one \( n \)-cell, no cell of dimension \( n + 1 \) and only countably many cells in dimensions \( \geq n + 2 \).

**Remark.** Let \( n \in \mathbb{N} \). Note that the canonical Eilenberg-Maclane space of type \( K(\mathbb{Z}, n) \) that we constructed in the proof of Theorem \[120.8\] is not of the form as described in Lemma \[120.11\]. We will discuss this in more detail in Exercise \[120.4\].

**Proof.** Let \( n \in \mathbb{N} \). We consider \( Y = S^n \). Recall that by Corollary \[53.6\] we know that \( \pi_n(S^n) \cong \mathbb{Z} \). By Proposition \[120.7\] (3) there exists a CW-complex \( Z \) with the following four properties:

1. the \((n + 1)\)-skeleton of \( Z \) equals \( Y = S^n \), in particular \( Z \) has only one 0-cell, no cells in dimension 1, \ldots, \( n - 1 \), one cell in dimension \( n \) and no cell in dimension \( n + 1 \),
2. we have \( \pi_i(Z) = 0 \) for \( i \geq n + 1 \),

\[\text{Footnote 1690:}\] For the convenience of the reader we repeat the argument. For the convenience of the author we prove a slight generalization of Lemma \[91.2\] (1). Thus let \( n \in \mathbb{N} \). We consider the maps

\[
f: \text{Cone}(S^{2n+1}) \rightarrow \mathbb{C}P^{n+1} \quad ([z_0, \ldots, z_n, r]) \mapsto [(r \cdot z_0, \ldots, r \cdot z_n, 1 - r)] \quad \text{and} \quad g: \mathbb{C}P^n \rightarrow \mathbb{C}P^{n+1} \quad [z_0 : \ldots : z_n] \mapsto [z_0 : \ldots : z_n : 0].
\]

These maps are continuous by Lemma \[3.22\] and Lemma \[3.21\] (3). It follows immediately from the definitions that these two maps define a map

\[
\text{Cone}(p: S^{2n+1} \rightarrow \mathbb{C}P^n) \rightarrow \mathbb{C}P^{n+1} \quad = (\text{Cone}(S^{2n+1}) \cup \mathbb{C}P^n)/\sim
\]

which is easily seen to be a bijection. It follows from Lemma \[3.22\] that this map is continuous. Furthermore, using Proposition \[2.43\] (3) and Proposition \[3.40\] one sees that the map is in fact a homeomorphism.

\[\text{Footnote 1691:}\] Here we are lucky, we did everything to kill \( \pi_3(\mathbb{C}P^2) \), but without any effort on our side we also managed to dispose of \( \pi_4(\mathbb{C}P^2) \).
(3) for any $i \in \{1, \ldots, n\}$ and any base point $x_0 \in S^n$ the inclusion induced map
\[ \pi_i(Y, x_0) \xrightarrow{\cong} \pi_i(Z, x_0) \]
is an isomorphism.
(4) the CW-complex $Z$ has only countably many cells.

By Proposition 40.10 we know that $\pi_i(Y, x_0) = 0$ for $i = 1, \ldots, n - 1$. Thus $Z$ is the desired Eilenberg-Maclane space of type $K(Z, n)$. ■

120.4. Uniqueness of Eilenberg-Maclane Spaces. Next we turn to the question to what degree Eilenberg-Maclane spaces of a given type are unique. Evidently the homeomorphism type is not unique, since given an Eilenberg-Maclane space $X$ we obtain Eilenberg-Maclane spaces of the same type by considering say the products $X \times B^m$. Nonetheless the following theorem says that the homotopy type of Eilenberg-Maclane spaces of a given type are in fact unique:

**Theorem 120.12.** Let $n \in \mathbb{N}$ and let $\pi$ be an (abelian) group. The following two statements hold:

1. Any two Eilenberg-Maclane spaces of type $K(\pi, n)$ are homotopy equivalent.
2. If $(X, x_0)$ and $(Y, y_0)$ are two pointed Eilenberg-Maclane spaces of type $K(\pi, n)$ with $x_0 \in X^0$ and $y_0 \in Y^0$ and if $\varphi : \pi_n(X, x_0) \rightarrow \pi_n(Y, y_0)$ is an isomorphism, then there exists a homotopy equivalence $f : (X, x_0) \rightarrow (Y, y_0)$ of pointed topological spaces with $f_* = \varphi : \pi_n(X, x_0) \rightarrow \pi_n(Y, y_0)$.

Before we turn to the proof of Theorem 120.12 it is worth, and fun, to discuss several immediate consequences thereof. For example, Theorem 120.12 settles Question 120.2 in a perhaps unexpected way: Given $m \in \mathbb{N}$ the homotopy type of the topological spaces $L(m, r_1, r_2, \ldots)$ does not depend on the choice of the parameters $r_i$, since all of these topological spaces are Eilenberg-Maclane spaces of type $K(Z_m, 1)$, but these are therefore homotopy equivalent by Theorem 120.12.

For convenience we record the following corollary which is an immediate consequence of Theorem 120.12, Corollary 42.8 and the discussion on page 1401.

**Corollary 120.13.** Let $\pi$ be a group and let $n \in \mathbb{N}$. If $X$ and $Y$ are two Eilenberg-Maclane spaces of the type $K(\pi, n)$, then for any $i \in \mathbb{N}$ and any abelian group $G$ we have an isomorphism $H_i(X; G) \cong H_i(Y; G)$.

Perhaps somewhat surprisingly we can use Corollary 120.13 to give a negative answer to Question 120.10 for $m = 2$.

**Corollary 120.14.** There is no finite-dimensional Eilenberg-Maclane space of type $K(\mathbb{Z}_2, 1)$.

**Proof.** Let $K$ be an Eilenberg-Maclane space of type $K(\mathbb{Z}_2, 1)$. Given any $i \in \mathbb{N}$ we calculate that
\[ H_i(K; \mathbb{Z}_2) \cong H_i(\text{any Eilenberg-Maclane space of type } K(\mathbb{Z}_2, 1); \mathbb{Z}_2) \cong H_i(\mathbb{R}P^\infty; \mathbb{Z}_2) \cong \mathbb{Z}_2. \]

\[ \uparrow \text{ by Corollary 120.13} \]

\[ \uparrow \text{ see page 2809} \]

Whenever we deal with Eilenberg-Maclane spaces of type $K(\pi, n)$ with $n \geq 2$ it is understood throughout these lecture notes that $\pi$ is abelian.
It follows from the discussion on page 1402 that $K$ is of dimension $> i$ for all $i \in \mathbb{N}$, in other words, $K$ is infinite-dimensional.

Evidently this suggests that the answer to Question 120.10 is negative. But right now we lack the tools to calculate the homology groups of the quotients $S^\infty/\mathbb{Z}_m$ that we constructed in Lemma 120.1. We will return to this question on page ??.

The following proposition basically says that it is easy to construct maps from CW-complexes to Eilenberg-Maclane spaces. This statement is the key to proving Theorem 120.12. As we will see shortly, the proposition is of interest in its own right.

**Proposition 120.15.** Let $n \in \mathbb{N}$ and let $\pi$ be an (abelian) group. Furthermore let $Y$ be an Eilenberg-Maclane space of type $K(\pi, n)$ and let $y_0 \in Y$. Finally let $X$ be a CW-complex and let $x_0 \in X$ be a point in the 0-skeleton $X^0$. If $X$ is $(n-1)$-connected, then the following two statements hold:

1. Let $\varphi: \pi_n(X, x_0) \to \pi_n(Y, y_0)$ be a homomorphism. There exists a map $f: X \to Y$ with $f(x_0) = y_0$ such that $f_* = \varphi: \pi_n(X, x_0) \to \pi_n(Y, y_0)$.

2. Suppose we are given two maps $f_0, f_1: X \to Y$ such that $f_0(x_0) = f_1(x_0) = y_0$. If $f_0* = f_1* : \pi_n(X, x_0) \to \pi_n(Y, y_0)$, then there exists a homotopy relative to $x_0$ from $f_0$ to $f_1$.

**Remark.** In Proposition 79.10 with $n = 1$ and $Y = S^1$, we proved a “smooth manifold version” of Proposition 120.15.

**Figure 1649.** Illustration for Proposition 120.15

**Proof of Theorem 120.12 assuming Proposition 120.15.** Let $n \in \mathbb{N}$ and let $\pi$ be an (abelian) group. Statement (1) is basically an immediate consequence of Statement (2). Therefore it now remains to prove Statement (2). Thus let $(X, x_0)$ and $(Y, y_0)$ be two pointed Eilenberg-Maclane spaces of type $K(\pi, n)$ where $x_0 \in X^0$ and $y_0 \in Y^0$. Furthermore let $\varphi: \pi_n(X, x_0) \to \pi_n(Y, y_0)$ be an isomorphism. Since $X$ is, as an Eilenberg-Maclane space of type $K(\pi, n)$, $(n-1)$-connected, we can appeal to Proposition 120.13 (1) to obtain a map $f: X \to Y$ with $f(x_0) = y_0$ such that $f_* = \varphi: \pi_n(X, x_0) \to \pi_n(Y, y_0)$. It suffices to prove the following claim.

**Claim.** The map $f$ is a homotopy equivalence $(X, x_0) \to (Y, y_0)$ of pointed topological spaces.

As above we obtain from Proposition 120.15 (1) the existence of a map $g: Y \to X$ with $g(y_0) = x_0$ such that $g_* = \varphi^{-1}: \pi_n(Y, y_0) \to \pi_n(X, x_0)$. Note that

$$(g \circ f)_* = \varphi^{-1} \circ \varphi = \text{id}_{\pi_n(X, x_0)} = (\text{id}_X)_*$$
and note that \((g \circ f)(x_0) = x_0 = (\text{id}_X)(x_0)\). Thus it follows from Proposition 120.15 (2) that \(g \circ f\) is homotopic rel \(x_0\) to \(\text{id}_X\). Basically the same argument shows that \(f \circ g\) is homotopic rel \(y_0\) to \(\text{id}_Y\). But this means that \(g\) is indeed the desired homotopy inverse. ■

At this point it remains to prove Proposition 120.15. The proof of the proposition relies on the following two lemmas. The following lemma is the key ingredient in the proof of Proposition 120.15.

**Lemma 120.16.** Let \(n \in \mathbb{N}\). Let \(X\) be a CW-complex that consists of a single 0-cell \(x_0\) and that otherwise contains only cells in dimensions \(n\) and \(n + 1\). Furthermore let \((Y, y_0)\) be a pointed topological space and let \(\gamma: \pi_n(X, x_0) \rightarrow \pi_n(Y, y_0)\) be a homomorphism. There exists a map \(h: (X, x_0) \rightarrow (Y, y_0)\) such that \(h_* = \gamma\).

CW-complex \(X\) with one 0-cell \(x_0\) and otherwise cells in dimension \(n, n + 1\)

\[
\xymatrix{ B_j^{n+1} \ar@{<->}[rr]^{\gamma: \pi_n(X, x_0) \rightarrow \pi_n(Y, y_0)} & & Y \ar@{<->}[ll]_{Y, y_0} \ar@{<->}[ll]_{g \circ \psi_j |_{S^n}} \ar@{<->}[ll]_{\varphi_i} \ar@{<->}[ll]_{X, x_0} \ar@{<->}[ll]_{g_i \text{ with } \gamma([\varphi_i]) = [g_i]} \ar@{<->}[ll]_{B_i^n / S^{n-1}} \ar@{<->}[ll]_{\psi_j} }
\]

**Figure 1650.** Illustration for the proof of Lemma 120.16

**Proof.** We proceed in the following steps.

1. We note that by our hypothesis we have \(X^{n-1} = \{x_0\}\).
2. Let \(\{\varphi_i: (B_i^n, S^{n-1}) \rightarrow (X^n, X^{n-1} = \{x_0\})\}_{i \in I}\) be the characteristic maps of the \(n\)-cells of the CW-complex \(X\). Note that since \(X^{n-1} = \{x_0\}\) each map \(\varphi_i\) descends to a map \(\varphi_i: B_i^n / S^{n-1} \rightarrow X^n\).
3. By Lemma 36.33 (2) the maps \(\varphi_i\) induce a homeomorphism \(\Phi: \bigvee_{i \in I} B_i^n / S^{n-1} \rightarrow X^n\).
   By a slight abuse of notation we denote by \(x_0\) the wedge point of the wedge.
4. Let \(i \in I\). Note that the map \(\varphi_i\) defines an element in \(\pi_n(X, x_0)\). We pick a map \(g_i: B_i^n / S^{n-1} \rightarrow (Y, y_0)\) with \(\gamma([\varphi_i]) = [g_i]\).
5. We consider the map

\[
g: \bigvee_{i \in I} B_i^n / S^{n-1} \rightarrow Y \\
[\cdot] \mapsto g_i([\cdot]) \quad \text{if} \ x \in B_i^n.
\]
(6) We consider the following diagram:

\[
\begin{array}{cccccc}
\pi_n(X^n, x_0) & \xleftarrow{\Phi_*} & \pi_n(\bigvee_{i \in I} B_i^n / S_i^{n-1}, x_0) & \xrightarrow{g_*} & \pi_n(Y, y_0). \\
& \text{\text{\scriptsize $i_*$}} & \downarrow \gamma & & \\
& & \pi_n(X, x_0) & & \\
\end{array}
\]

where the left diagonal map is induced by the inclusion \(i : X^n \to X\).

(7) It follows immediately from the construction of \(g\) that if we send any of the classes \([id : B^n \to B_i^n] \in \pi_n(X^n, x)\) on a journey through the diagram, then we obtain the same result. But by Proposition 120.5 (3) the classes \([id : B^n \to B_i^n], i \in I\), form a generating set for \(\pi_n(\bigvee_{i \in I} B_i^n / S_i^{n-1}, x_0)\). Thus it follows that the diagram commutes.

(8) Let \(* = (0, \ldots, 0, 1) \in S^n \subset B^{n+1}\) the usual base point. Let \(\{\psi_j : B^{n+1} \to X^{n+1}\}_{j \in J}\) be the characteristic maps of the \((n + 1)\)-cells of \(X\). It follows from Lemma 3.32 that we can arrange that for every \(j \in J\) we have \(\psi_j(*) = x_0\).

(9) Let \(j \in J\). Note that

\[
[g \circ \Phi^{-1} \circ \psi_j|_{S^n}] = (g_* \circ \Phi^{-1}_*)([\psi_j|_{S^n}]) = \gamma([\psi_j|_{S^n}]) = \gamma([0]) = 0 \in \pi_n(Y, y_0).
\]

Thus we obtain from Lemma 40.4 that there exists a map \(h_j : B^{n+1} \to Y\) such that \(h_j|_{S^n} = g \circ \Phi^{-1} \circ (\psi_j|_{S^n})\).

(10) Since for each \(j \in J\) we have \(h_j|_{S^n} = g \circ \Phi^{-1} \circ (\psi_j|_{S^n})\) we can use the maps \(h_j\) to extend \(g \circ \Phi^{-1}\) to a map

\(h : X = (X^n \cup \bigcup_{j \in J} B_j^{n+1}) / \sim \to Y\) where \(\psi_j(x) \sim x\) for any \(x \in S^n\).

(11) We obtain the following diagram

\[
\begin{array}{cccccc}
\pi_n(X^n, x_0) & \xleftarrow{(g \circ \Phi^{-1})_*} & \pi_n(Y, y_0) \\
& \text{\text{\scriptsize $i_*$}} & \downarrow \gamma & & \\
& & \pi_n(X, x_0) & & \\
& & \xrightarrow{h_*} & & \\
\end{array}
\]

(12) We already saw that the diagram commutes for \(\gamma\). Since \(h|_{X^n} = g \circ \Phi^{-1}\) we see that the diagram commutes also for the map \(h_*\).

(13) The left diagonal map \(i_* : \pi_n(X^n, x_0) \to \pi_n(X, x_0)\) is an epimorphism by Proposition 40.9.

(14) It follows from (12) and (13) that the maps \(\gamma\) and \(h_*\) from \(\pi_n(X, x_0)\) to \(\pi_n(Y, y_0)\) agree.

The second lemma is just a convenient special case of Lemma 119.3.
Lemma 120.17. Let $X$ be a CW-complex, let $n \in \mathbb{N}$ and let $f: A \to Y$ be a map from a subcomplex $A \subset X$ to a path-connected topological space with $X^n \subset A$.

(1) If $\pi_n(Y) = 0$, then we can extend $f$ to a map $f: A \cup X^{n+1} \to Y$.
(2) If $\pi_i(Y) = 0$ for every $i \geq n$, then we can extend $f$ to a map $f: X \to Y$.

![Diagram](image)

**Figure 1651.** Illustration of Lemma 120.17

We break the proof of Proposition 120.15 into two parts. In the first part we deal with the situation that the $(n-1)$-skeleton consists just of a point. Afterwards we will discuss how the general case can be reduced to this special case.

**Proof of Proposition 120.15.** If $X^{n-1} = \{x_0\}$. Let $n \in \mathbb{N}$ and let $\pi$ be an (abelian) group. Furthermore let $Y$ be an Eilenberg-Maclane space of type $K(\pi, n)$ and let $y_0 \in Y$. Finally let $X$ be a CW-complex and let $n \in \mathbb{N}$. We assume that $X^{n-1} = \{x_0\}$.

(1) Let $\varphi: \pi_n(X, x_0) \to \pi_n(Y, y_0)$ be a homomorphism. We need to show that there exists a map $f: X \to Y$ with $f(x_0) = y_0$ such that $f_* = \varphi: \pi_n(X, x_0) \to \pi_n(Y, y_0)$.

We denote by $i: X^{n+1} \to X$ the inclusion map. By Proposition 40.9 we know that $i_*: \pi_n(X^{n+1}, x_0) \to \pi_n(X, x_0)$ is an isomorphism. The following diagram contains all the maps of interest to us:

$$
\begin{array}{ccc}
\pi_n(X^{n+1}, x_0) & \xrightarrow{h_*} & \pi_n(Y, y_0) \\
i_* & \cong & \\
\pi_n(X, x_0) & \xrightarrow{f_*} & \pi_n(Y, y_0).
\end{array}
$$

Since $X^{n-1} = \{x_0\}$ we can apply Lemma 120.16 to the CW-complex $X^{n+1}$. We obtain from Lemma 120.16 that there exists a map $h: X^{n+1} \to Y$ with $h(x_0) = y_0$ such that $h_* = \varphi \circ i_*: \pi_n(X^{n+1}, x_0) \to \pi_n(Y, y_0)$. Since $Y$ is an Eilenberg-Maclane space of type $K(\pi, n)$ we know that $\pi_j(Y) = 0$ for $j \geq n + 1$. Thus we obtain from Lemma 120.17 (2) that we can extend $h: X^{n+1} \to Y$ to a map $f: X \to Y$. It remains to show that $f_* = \varphi: \pi_n(X, x_0) \to \pi_n(Y, y_0)$. This is indeed the case since

$$
f_* = f_* \circ i_* \circ i_*^{-1} = (f \circ i)_* \circ i_*^{-1} = h_* \circ i_*^{-1} = (\varphi \circ i_*) \circ i_*^{-1} = \varphi.
$$

since $i_*$ is an isomorphism since $h$ extends $f$ since $h_* = \varphi \circ i_*$. 

(2) Suppose we are given two maps $f_0, f_1: X \to Y$ such that $f_0(x_0) = f_1(x_0) = y_0$ and such that $f_0_* = f_1_*: \pi_n(X, x_0) \to \pi_n(Y, y_0)$. We need to show that there exists a homotopy rel $x_0$ from $f_0$ to $f_1$. We consider the product $X \times [0, 1]$ and we equip it with the product CW-structure coming from Proposition 36.23. Given $k \in \mathbb{N}_0$ we
write
\[ Z^k = (X \times \{0\}) \cup \left( X^{k-1} \times [0,1] \right) \cup (X \times \{1\}) \subset X \times [0,1]. \]

The idea is to define the homotopy on \( X \times [0,1] = \bigcup_{n \in \mathbb{N}_0} Z^n \) by breaking the task into three steps.

(a) First we note that the fact that \( X^0 = \cdots = X^{n-1} \) implies that \( Z^1 = \cdots = Z^n \).

Now let \( h: Z^1 = Z^n \to Y \) be the map that is given by \( f_0 \) on \( X \times \{0\} \), \( f_1 \) on \( X \times \{1\} \) and the constant map \( c_{x_0} \) on \( \{x_0\} \times [0,1] \).

(b) We denote by \( \{ \varphi_i: \overline{B}^n_i \to X \}_{i \in I} \) the characteristic maps of the \( n \)-cells of \( X \).

Since \( X^{n-1} = \{x_0\} \) we see that each \( \varphi_i \) descends to a map \( \psi_i: \overline{B}^n_i/S_i^{n-1} \to X \).

We denote by \( * = [S_i^{n-1}] \) the obvious base point of the sphere \( \overline{B}^n_i/S_i^{n-1} \).

Now recall that by hypothesis we have \( f_{0*} = f_{1*}: \pi_n(X, x_0) \to \pi_n(Y, y_0) \). This implies that for every \( i \in I \) we have \( [f_0 \circ \psi_i] = [f_1 \circ \psi_i] \in \pi_n(Y, y_0) \).

In other words, for every \( i \in I \) there exists a map \( F_i: \overline{B}^n_i/S_i^{n-1} \times [0,1] \to Y \) with \( F_{i0} = f_0 \circ \psi_i \), \( F_{i1} = f_1 \circ \psi_i \) and \( F_i(*, t) = y_0 \) for all \( t \in [0,1] \). We define

\[ h_{n+1}: Z^{n+1} \to Y \quad P \mapsto \begin{cases} h_0(P), & \text{if } P \in Z^1 = Z^n, \\ F_i(Q, t), & \text{if } P = (\varphi_i(Q), t) \text{ with } Q \in \overline{B}^n_i. \end{cases} \]

It follows immediately from the properties of the \( F_i \) that this map is well-defined. Furthermore, it follows almost immediately from Lemma \[36.7\] \( (4) \) that \( h_{n+1} \) is continuous.

(c) Finally we are in the following situation:

\[ \begin{array}{ccc} Z^{n+1} & \xrightarrow{h_{n+1}} & Y \\ \downarrow & & \downarrow h \\ X \times [0,1] & & \end{array} \]

By definition of the CW-structure on \( X \times [0,1] \) we know that the \((n+1)\)-skeleton of \( X \times [0,1] \) is contained in \( Z^{n+1} \). In other words, any cell of \( X \times [0,1] \) that is not contained in \( Z^{n+1} \) is of dimension \( \geq n + 2 \). Since \( Y \) is an Eilenberg-Maclane space of type \( K(\pi, n) \) we know that \( \pi_k(Y, y_0) = 0 \) for \( k \geq n + 1 \). Thus we obtain from Lemma \[120.17\] \( (2) \) that there exists a map \( H: X \times [0,1] \to Y \) which makes the above diagram commute. Evidently this is the desired homotopy between \( f_0 \) and \( f_1 \). \[\square\]

Proof of Proposition \[120.15\] for the general case. Let \( X \) be a CW-complex and let \( x_0 \in X \) be a point in the 0-skeleton \( X^0 \). We suppose that \( X \) is \((n-1)\)-connected. By Proposition \[119.15\] we know that there exists a homotopy equivalence \( f: (X, x_0) \to (\tilde{X}, \tilde{x}_0) \) where \( \tilde{X} \) is a CW-complex that has one 0-cell \( \{\tilde{x}_0\} \) and no cells in dimensions 1, \ldots, \( n \).

By Proposition \[40.7\] we know that \( f_*: \pi_n(X, x_0) \to \pi_n(\tilde{X}, \tilde{x}_0) \) is an isomorphism. By the
above argument we know that the desired conclusions hold for \((\bar{X}, \bar{x}_0)\). It is now fairly elementary to see that the statements of Proposition \ref{120.15} also hold for \((X, x_0)\). \hfill \Box

Before we move on we prove an important addendum to Proposition \ref{18.16}. To motivate its relevance we recall an earlier result: If \(f_0, f_1 : (X, x_0) \rightarrow (Y, y_0)\) are two maps between pointed topological spaces, then by Proposition \ref{18.16} (1) the following two statements hold:

1. If \(f_0\) and \(f_1\) are homotopic rel \(x_0\), then \(f_0 \sim f_1\).
2. If \(f_0\) and \(f_1\) are homotopic (with no constraints on the base point), then there exists an \(\alpha \in \pi_1(Y, y_0)\) such that \(f_0(z) = \alpha \cdot f_1(z) \cdot \alpha^{-1}\) for all \(z \in \pi_1(Y, y_0)\).

One can view Proposition \ref{120.15} (2) as a partial converse to (1). The following proposition is the analogous partial converse to (2).

**Proposition 120.18.** (*) Let \(\pi\) be a group, let \(Y\) be an Eilenberg-Maclane space of type \(K(\pi, 1)\) and let \(y_0 \in Y\). Furthermore let \(X\) be a 0-connected CW-complex and let \(x_0 \in X\) be a point in the 0-skeleton \(X^0\). Suppose we are given two maps \(f_0, f_1 : X \rightarrow Y\) such that \(f_0(x_0) = f_1(x_0) = y_0\). If there exists an \(\alpha \in \pi_1(Y, y_0)\) such that \(f_0(z) = \alpha \cdot f_1(z) \cdot \alpha^{-1}\) for all \(z \in \pi_1(Y, y_0)\), then there exists a homotopy \(\tilde{h}_n\) from \(f_0\) to \(f_1\).

**Proof.** (*) The proof of the proposition is similar to the proof of Proposition \ref{120.15} (2). In the following provide a sketch of the argument. We leave it to the reader to fill in the details. First of all we point out that by Proposition \ref{119.15} we can assume that \(X\) has a single 0-cell \(\{x_0\}\). Now we consider the product \(X \times [0, 1]\) and we equip it with the product CW-structure coming from Proposition \ref{36.23}. Given \(k \in \mathbb{N}_0\) we write

\[
Z^k = (X \times \{0\}) \cup (X^{k-1} \times [0, 1]) \cup (X \times \{1\}) \subset X \times [0, 1].
\]

As above we define the homotopy on \(X \times [0, 1] = \bigcup_{n \in \mathbb{N}_0} Z^n\) by breaking the task into three friendly steps.

1. We pick a map \(\beta : [0, 1] \rightarrow Y\) that represents \(\alpha \in \pi_1(Y, y_0)\). Let \(h : Z^1 = Z^n \rightarrow Y\) be the map that is given by \(f_0\) on \(X \times \{0\}\), \(f_1\) on \(X \times \{1\}\) and the map \(\beta\) on \(\{x_0\} \times [0, 1] = [0, 1]\).

\[\text{Note that in contrast to Proposition 120.15 (2) it does not say \"rel \(x_0\)\".}\]
(2) Given a 1-cell $\gamma$ of $X$ we denote by $\phi_\gamma: S^1 = \partial([0, 1]^2) \to Z^1$ the attaching map of the product cell $\gamma \times [0, 1]$. We have

$$h_\ast([\phi_\gamma]) = \frac{[h|_{[\gamma \times 0]}]}{[h|_{\{x_0\} \times [0, 1]}]} \cdot \frac{[\partial_\ast]}{[\partial|_{\{x_0\} \times [0, 1]}]} = \alpha \cdot [f_\ast(\gamma)] \cdot \frac{1}{\alpha^{-1} \cdot \alpha \cdot [f_\ast(\gamma)]^{-1}} \cdot \frac{1}{\alpha^{-1}} = e \in \pi_1(Y, y_0).$$

It follows from Lemma 14.1 that the map $h \circ \phi_\gamma: \partial([0, 1]^2) \to Y$ extends to a map $\psi_\gamma: [0, 1]^2 \to Y$. We use this map to extend $h$ over the 2-cell $\gamma \times [0, 1]$. If we do this for all 1-cells of $X$ we obtain the desired extension of $h$ to a map $Z^2 \to Y$.

(3) We use Lemma 120.17 (2) and the fact that $Y$ is an Eilenberg-Maclane space of type $K(\pi, 1)$ to extend the map $h$ to a homotopy $F: X \times [0, 1] \to Y$.

We conclude this section with a discussion of the statement of Proposition 120.15. It is not unreasonable to ask whether one really needs in Proposition 120.15 the hypothesis that $X$ is $(n - 1)$-connected. But we will now see that in neither of the two parts can we drop this condition.

(1) By Theorem 113.10 we know that there exists an isomorphism $\varphi: \pi_3(S^2, *) \simeq \mathbb{Z}$. Now let $(Y, y_0)$ be any pointed Eilenberg-Maclane space of type $K(\mathbb{Z}, 3)$. At a very first glance one might hope that there exists a map $f: (S^2, *) \to (Y, y_0)$ such that $f_\ast = \varphi: \pi_3(S^2, *) \to \pi_3(Y, y_0) = \mathbb{Z}$. But this is not the case. Indeed, since $Y$ is an Eilenberg-Maclane space of type $K(\mathbb{Z}, 2)$ we know that $\pi_2(Y, y_0) = 0$. This means that any map $f: (S^2, *) \to (Y, y_0)$ is homotopic to the constant map. In particular any such map induces the zero map on $\pi_3$. Thus we cannot realize $\varphi$ by a map $(S^2, *) \to (Y, y_0)$.

(2) On page 2810 we pointed out that the infinite complex projective space $\mathbb{C}P^\infty$ is an Eilenberg-Maclane space of type $K(\mathbb{Z}, 2)$. By the discussion on page 197 we can view $S^2 = \mathbb{C}P^1$ as a subset of $\mathbb{C}P^\infty$. We denote by $y_0 \in S^2$ the North Pole. We pick some point $x_0$ on the torus $S^1 \times S^1$. We consider the following two maps from the torus $S^1 \times S^1 \to S^2 \subset \mathbb{C}P^\infty$:

(a) The map $f_0$ is the constant map that sends all points to $y_0$. 

\[ \text{Figure 1653. Illustration for the proof of Proposition 120.18} \]
(b) The map \( f_1 : S^1 \times S^1 \to B^2 / S^1 = S^2 \) is a map that sends the points of a given embedded disk to \( B^2 \) and sends all other points to the single point \([S^1] = y_0\). (These two maps \( f_0 \) and \( f_1 \) are illustrated in Figure 1654.) Now we claim that we have \( f_{0*} = f_{1*} : \pi_2(S^1 \times S^1, *) \to \pi_2(\mathbb{C}P^\infty, *) \), but that \( f_0 \) and \( f_1 \) are, contrary to what one might expect, \textit{not} homotopic. To prove this claim we recall that on page 1068 we saw that \( \pi_2(S^1 \times S^1) = 0 \). In particular both maps induce the same map on \( \pi_2 \). Nonetheless the two maps are not homotopic. This can be seen by studying the induced map on \( H_2 \). It is clear that \( f_0 \) induces the trivial map on \( H_2 \). On the other hand we saw in the proof of Proposition 69.3 that \( f_1 \) induces an isomorphism \( H_2(S^1 \times S^1; \mathbb{Z}) \to H_2(\mathbb{C}P^\infty; \mathbb{Z}) \). By the discussion on page 1263 we know that the inclusion induced map \( H_2(S^2; \mathbb{Z}) \to H_2(\mathbb{C}P^\infty; \mathbb{Z}) \) is an isomorphism. Therefore we see that the map \( f_{1*} : H_2(S^1 \times S^1; \mathbb{Z}) \to H_2(\mathbb{C}P^\infty) \) is non-trivial. Thus we obtain from Proposition 12.5 that the maps \( f_0 \) and \( f_1 \) are in fact not homotopic.

![Figure 1654](image)

At least in terms of invariants any Eilenberg-Maclane space \( K(\pi, n) \) is a particularly simple topological space. Therefore it seems not totally unreasonable to hope that given a CW-complex \( X \) one can perhaps classify the maps from \( X \) to \( K(\pi, n) \), say up to homotopy. The above examples show that the maps are \textit{not} classified by \( \text{Hom}(\pi_n(X), \pi) \). But perhaps there is some other way? Let us record this as a question:

**Question 120.19.** Let \( n \in \mathbb{N} \) and let \( \pi \) be an (abelian) group. Let \( X \) be a CW-complex. Can we classify the maps \( X \to K(\pi, n) \) up to homotopy?

### 120.5. First applications of Eilenberg-Maclane spaces.

We recall the following definition from page 1944.

**Definition.** Let \( G \) be a group, let \( Y \) be a topological space and let \( y_0 \in Y \) be a point with an identification \( \pi_1(Y, y_0) \cong G \). Given another topological space \( X \) and \( x_0 \in X \) we say that a homomorphism \( \varphi : \pi_1(X, x_0) \to G = \pi_1(Y, y_0) \) is realized by a map \( g : X \to Y \) if \( g(x_0) = y_0 \) and if \( g_* = \varphi \). If there is no danger of confusion we will drop the base points from the notation.

Next we recall the following question that we had formulated a while ago.
Questions 79.9 and 79.11. Let $X$ be a connected CW-complex.

(0) Can every homomorphism $\pi_1(X) \to \mathbb{Z} = \pi_1(S^1)$ be realized by a map $X \to S^1$?

(1) Let $g \geq 1$ and let $\Sigma_g$ be the surface of genus $g \geq 1$. Can every homomorphism $\pi_1(X) \to \pi_1(\Sigma_g)$ be realized by a map $X \to \Sigma_g$?

(2) Can every homomorphism $\pi_1(X) \to \pi_1\left(\bigvee_{i=1}^k S^1\right) = \langle x_1, \ldots, x_k \rangle$ be realized by a map $X \to \bigvee_{i=1}^k S^1$?

(3) Can every homomorphism $\pi_1(X) \to \mathbb{Z}_2 = \pi_1(\mathbb{R}P^2)$ be realized by a map $X \to \mathbb{R}P^2$?

In Proposition 79.10 we had used de Rham cohomology to give an affirmative answer to (0) if $X$ is a smooth manifold. Furthermore in Exercise 90.7 we gave, by considering the isomorphism $\pi_1(\mathbb{R}P^2) \cong \mathbb{Z}_2$, a negative answer to (3). Fortunately we can now give a complete answer to (0), (1) and (2).

**Proposition 120.20.**

(a) The answer to (0), (1) and (2) is “yes”. Furthermore, if in the formulation of (3) we replace $\mathbb{R}P^2$ by $\mathbb{R}P^\infty$, then the answer to (3) is also yes.

(b) If $X$ is a smooth manifold, then the following two statements hold:

(i) In (0) and (1) we can find smooth realizations.

(ii) In (2) we can find a realization $f : X \to \bigvee_{i=1}^k S^1$ which has the property that the restriction of $f$ to the complement of $f^{-1}$ (wedge point) is smooth.

**Proof.**

(a) The desired statement follows immediately from Proposition 120.15 and the fact that on page 2809 we saw that $S^1$, $\bigvee_{i=1}^k S^1$, $\Sigma_g$ and $\mathbb{R}P^\infty$ are Eilenberg-Maclane spaces.

(b) (i) This statement follows from the Whitney Approximation Theorem 9.3.

(ii) As we pointed out on page 404, this statement is a consequence of Proposition 9.7.

Using Proposition 120.20 we obtain the following pleasant proposition.

**Proposition 120.21.** If $M$ is a compact orientable connected $n$-dimensional smooth manifold, then the following two statements are equivalent:

1. there exists an epimorphism $\pi_1(M) \to \langle x_1, \ldots, x_k \rangle$,
2. there exist disjoint connected non-empty $(n-1)$-dimensional submanifolds $F_1, \ldots, F_k$ of $M$ such that $M \setminus (F_1 \cup \cdots \cup F_k)$ is connected.

**Sketch of a proof.** First note that the “(2) $\Rightarrow$ (1)” implication is precisely the content of Proposition 98.8. Thus it remains to prove the “(1) $\Rightarrow$ (2)” implication. Therefore suppose that there exists an epimorphism $\pi_1(M) \to \langle x_1, \ldots, x_k \rangle$. We consider the wedge
We denote by $*$ the wedge point and for $i = 1, \ldots, k$ we write $J_i := S^1_i \setminus \{*\}$. By Proposition 120.20 (b) we can realize this epimorphism by a map $f : M \to \bigvee_{i=1}^k S^1_i$ which is smooth on $M \setminus \{f^{-1}\{*\}\}$. Let $i \in \{1, \ldots, k\}$. It follows from Sard’s Theorem 6.63 that there exists a regular value $z_i \in J_i$. We obtain from Lemma 9.8 that the preimage $G_i := f^{-1}(z_i)$ is an orientable proper $(n - 1)$-dimensional submanifold of $M$. In Exercise 120.3 we will prove the following two statements:

1. each $G_i$ is non-empty,
2. for each $i \in \{1, \ldots, k\}$ we can find a component $F_i$ of $G_i$ such that $M \setminus (F_1 \cup \cdots \cup F_k)$ is connected.

\[ \begin{array}{ccc}
M & \xrightarrow{f} & \bigvee_{i=1}^k S^1_i \\
\bigvee_{i=1}^k S^1_i & \xrightarrow{f^{-1}} & J_1 \cup \cdots \cup J_k
\end{array} \]

\textbf{Figure 1655. Illustration for the proof of Proposition 120.21.}

Now is a good time to recall the following question.

\textbf{Question 98.9. Let $g \in \mathbb{N}$ and let $\Sigma_g$ be the surface of genus $g$.}

1. \textit{What is the maximal number $k = k(g) \in \mathbb{N}_0$ for which we can find $k$ disjoint curves $F_1, \ldots, F_k$ on $\Sigma_g$ such that $\Sigma_g \setminus (F_1 \cup \cdots \cup F_k)$ is connected?}
2. \textit{What is the maximal $l = l(g) \in \mathbb{N}_0$ for which there exists an epimorphism from $\pi_1(\Sigma_g)$ onto a free group of $l$ generators?}

We make the following easy observations:

1. As we already observed on page 2373 it follows immediately from peeking at Figure 1656 that $k(g) \geq g$.

\[ \begin{array}{ccc}
\Sigma_3 & \rightarrow & \Sigma_3
\end{array} \]

\textbf{Figure 1656}

(2) It follows from Lemma 21.13 that we have an epimorphism

\[ \begin{array}{rrr}
\pi_1(\Sigma_g) & \cong \pi_1(\Sigma_g) \text{ by Proposition 22.3} & \cong \pi_1(\Sigma_g) \\
\langle x_1, y_1, \ldots, x_g, y_g \mid x_1 y_1 x_1^{-1} y_1^{-1} \cdots x_g y_g x_g^{-1} y_g^{-1} \rangle & \rightarrow & \langle x_1, \ldots, x_g \rangle \\
x_i & \rightarrow & x_i \\
y_i & \rightarrow & e
\end{array} \]

from $\pi_1(\Sigma_g)$ onto a free group on $g$ generators.

More interestingly, by Proposition 120.21 we now know that the two questions actually give the same answer. Even better, we can now give a complete answer:

\textbf{Proposition 120.22. Let $g \in \mathbb{N}$ and let $\Sigma_g$ be the surface of genus $g$. If there exists an epimorphism $\Sigma_g$ onto a free group on $k$ generators, then $k \leq g$.}
Proof. Let \( g \in \mathbb{N} \), let \( \Sigma_g \) be the surface of genus \( g \) and let \(* \in \Sigma_g\) be a base point. Let \( \varphi: \pi_1(\Sigma_g,*) \to F_k \) be an epimorphism onto a free group on \( k \) generators. We start out with the following preparations:

1. By the discussion on page 2809 we know that \( X := \bigvee_{i=1}^k S^1 \) is an Eilenberg-Maclane space of type \( K(F_k,1) \). We pick \( x_0 \in X \) and as usual we make the identification \( \pi_1(X,x_0) = F_k \).

2. It follows from Proposition 120.15 that there exists a map \( f: (\Sigma_g,*) \to (X,x_0) \) with \( f_* = \varphi: \pi_1(\Sigma_g,*) \to \pi_1(X,x_0) = F_k \). Note that the map \( f_*: \pi_1(\Sigma_g,*) \to \pi_1(X,x_0) \) is an epimorphism.

3. The Hurewicz Theorem 52.5 together with Proposition 21.20 (9), implies that the induced map \( f_*: H^1(\Sigma_g;\mathbb{Z}) \to H^1(X;\mathbb{Z}) \) is an epimorphism.

4. In general, if \( \alpha: A \to B \) is an epimorphism between two groups, then elementary algebra tells us that the induced map \( \text{Hom}(B,\mathbb{Z}) \to \text{Hom}(A,\mathbb{Z}) \) is a monomorphism. From this elementary observation, together with (3), we obtain that the induced map \( f^*: \text{Hom}(H^1(X;\mathbb{Z}),\mathbb{Z}) \to \text{Hom}(H^1(\Sigma_g;\mathbb{Z}),\mathbb{Z}) \) is a monomorphism.

5. It follows immediately from (4) together with Proposition 75.18 that the induced map \( f^*: H^2(X;\mathbb{Z}) \to H^2(\Sigma_g;\mathbb{Z}) \) is also a monomorphism.

6. Since \( X \) is a 1-dimensional CW-complex we obtain almost immediately from Proposition 74.4 that \( H^2(X;\mathbb{Z}) = 0 \). In particular the cup product on \( H^1(X;\mathbb{Z}) \) vanishes.

Now we consider the form

\[
\varphi: H^1(\Sigma_g;\mathbb{Z}) \times H^1(\Sigma_g;\mathbb{Z}) \to \mathbb{Z} \\
(\alpha,\beta) \mapsto (\alpha \cup \beta, [\Sigma_g]).
\]

Given \( U \subset H^1(\Sigma_g;\mathbb{Z}) \) we write as usual

\[
U^\perp = \{ v \in H^1(\Sigma_g;\mathbb{Z}) \mid \varphi(u,v) = 0 \text{ for all } u \in U \}.
\]

Now we see that

\[
\text{since } X = \bigvee_{i=1}^k S^1 \text{ is a monomorphism and by Proposition 00.2 we know that } \varphi \text{ is non-singular, hence we obtain the equality from Exercise 00.2}
\]

\[
k = \text{rank}(H^1(X;\mathbb{Z})) \quad \downarrow \quad \text{rank}(i^* H^1(X;\mathbb{Z})) \quad \downarrow \quad \text{rank}(H^1(\Sigma_g;\mathbb{Z})) - \text{rank}((i^* H^1(X;\mathbb{Z}))^\perp)
\]

\[
\leq \text{rank}(H^1(\Sigma_g;\mathbb{Z})) - \text{rank}(i^* H^1(X;\mathbb{Z})) = 2g - k.
\]

it follows from (6) and Lemma 81.10 as above we have \( \text{rank}(i^* H^1(X;\mathbb{Z})) = k \) and by the discussion on page 1844 we know that \( \text{rank}(H^1(\Sigma_g;\mathbb{Z})) = 2g \)

Thus we see that \( k \leq 2g - k \), i.e. we see that \( k \leq g \).

120.6. Eilenberg–MacLane spaces and the social choice problem ♦. In this section we give a fun, but perhaps not entirely serious application of Eilenberg-Maclane spaces. Let us recall the following definition from page 1347.
**Definition.** Let $X$ be a topological space and let $n \in \mathbb{N}$. A *social choice of type $n$* is a map 

$$f : X^n = \underbrace{X \times \cdots \times X}_{n \text{ times}} \to X$$

such that the following three axioms are satisfied:

(a) The map $f$ is continuous.
(b) For every $x \in X$ we have $f(x, \ldots, x) = x$.
(c) For every permutation $\sigma \in S_n$ and any $(x_1, \ldots, x_n) \in X^n$ we have

$$f(x_{\sigma(1)}, \ldots, x_{\sigma(n)}) = f(x_1, \ldots, x_n).$$

We say that a topological space is *social*, if for every $n \in \mathbb{N}$ it admits a social choice of type $n$.

We refer to Section 54.1 for a discussion why social topological spaces are interesting. Now let $X$ be a topological space. The combination of Lemmas 54.4 and 54.5 shows that if $X$ is social, then for every $k \in \mathbb{N}$ the homotopy group $\pi_k(X)$ is abelian and it is strongly divisible, i.e. given any $n \in \mathbb{N}$ the map $g \mapsto n \cdot g$ is an isomorphism. Furthermore, Proposition 54.2 together with the Whitehead Theorem 119.9 show that if $X$ is in fact a CW-complex, with the property that in any dimension it has only finitely many cells, then $X$ is contractible. Back in Section 54.1 this discussion lead us to the following question.

**Question 54.7.** Does there exist a non-empty CW-complex that is social but that is not contractible?

It turns out that we can now formulate a positive answer to Question 54.7.

**Theorem 120.23.**

(1) Any CW-complex that is homotopy equivalent to the product of a family of Eilenberg-Maclane spaces of type $K(Q, k_i)$, $i \in I$ is social.

(2) Conversely, if $X$ is a connected social CW-complex, then it is is homotopy equivalent to the product of a family of Eilenberg-Maclane spaces of type $K(Q, k_i)$, $i \in I$.

**Proof.** This theorem is proved in [EGH62, p. 90] and [Weinb04, Theorem 1.3], see also [Eckm04, Theorems 4 and 7]. For the most part the proofs do not go much beyond what we have covered so far, except that they build on a result of Alexander Grothendieck [Groth57, Chapter V], see also [HZ74, p. 32] and [Hirz69, p. 254].

**Remark.** As always there are various variations and generalizations of Theorem 120.23. For example by [Weinb04, Example 1.4] any Eilenberg-Maclane space of type $K(\mathbb{Z}_2, 1)$, e.g. according to the discussion on page 2809 we could take $\mathbb{R}P^\infty$, has the property that given any odd $n \in \mathbb{N}$ it admits a social choice of type $n$.

**120.7. An extension of the Hurewicz Theorem 53.5** In this last section we will use Eilenberg-Maclane spaces in a surprising way to obtain an addendum to the Hurewicz Theorem 53.5. To formulate the theorem it is convenient to introduce the following definition.

**Definition.** Given a group $\pi$ and $n \in \mathbb{N}_0$ we define $H_n(\pi) := H_n(K(\pi, 1), \mathbb{Z})$ where $K(\pi, 1)$ denotes the canonical Eilenberg-Maclane space introduced in Theorem 120.8. We refer to $H_n(\pi)$ as the *$n$-th homology group of the group $\pi$*. 
Remark. The concept of the homology groups $H_n(\pi)$ of a group $\pi$ will play an important role in this section. Afterwards it takes a well-earned rest before it will take center stage in Chapter ??.

The following lemma is an immediate consequence of Corollary 120.13.

**Lemma 120.24.** Let $\pi$ be a group and let $n \in \mathbb{N}_0$. For any Eilenberg-Maclane space $X$ of type $K(\pi, 1)$ we have $H_0(\pi) \cong H_0(X; \mathbb{Z})$.

**Example.** Let $m \in \mathbb{N}$ and let $n \in \mathbb{N}_0$. We calculate that

$$H_n(\text{the group } \mathbb{Z}^m) \cong H_n(\text{any Eilenberg-Maclane space } K(\mathbb{Z}^m, 1)) \cong H_n((S^1)^m) \cong \mathbb{Z}^\left(\begin{array}{c} m \\ n \end{array}\right).$$

by Lemma 120.24 by the discussion on page 2809 we know that $(S^1)^m$ is an Eilenberg-Maclane space of type $K(\mathbb{Z}^m, 1)$

We continue with the following lemma.

**Lemma 120.25.** (*)& Let $(X, x_0)$ be a pointed 0-connected topological space. There exists a natural map

$$\eta: H_2(X; \mathbb{Z}) \to H_2(\pi_1(X, x_0))$$

which has the following property: whenever $(Y, y_0)$ is a pointed Eilenberg-Maclane space of type $K(\pi_1(X, x_0), 1)$ and $f: (X, x_0) \to (Y, y_0)$ is a map of pointed topological spaces that induces an isomorphism of fundamental groups, then there exists an isomorphism $\mu: H_2(Y; \mathbb{Z}) \to H_2(\pi_1(X, x_0))$ such that the following diagram commutes:

$$\begin{array}{ccc}
H_2(X; \mathbb{Z}) & \xrightarrow{\eta} & H_2(\pi_1(X, x_0)) \\
\downarrow f_* & & \downarrow \approx \\
H_2(Y; \mathbb{Z}) & & H_2(\pi_1(X, x_0))
\end{array}$$

**Proof.** (*). Let $(X, x_0)$ be a pointed 0-connected topological space. We write $\pi = \pi_1(X, x_0)$. Let $(Z, z_0, \varphi: \pi_1(Z, z_0) \to \pi)$ be the canonical triple introduced in Theorem 120.8. By the CW-Approximation Theorem 119.8 there exists a CW-approximation $f: (Y, y_0) \to (X, x_0)$. Note that by Proposition 119.6 we know that $f$ induces isomorphisms on all homology groups.

By Proposition 120.15 (1) we know that there exists a map $g: (Y, y_0) \to (Z, z_0)$ such that $g_* = \varphi^{-1} \circ f_*: \pi_1(Y, y_0) \to \pi_1(Z, z_0)$. We set

$$\eta := g_* \circ (f_*)^{-1}: H_2(X; \mathbb{Z}) \to H_2(Z; \mathbb{Z}) =: H_2(\pi_1(X, x_0)).$$

Using Proposition 120.15 (1) it is not difficult to verify that $\eta$ has the desired properties. ■

Now we can formulate the following theorem.
**Theorem 120.26. (Hurewicz Theorem)** Let \( n \in \mathbb{N} \) and let \( X \) be an \((n - 1)\)-connected topological space and let \( x_0 \in X \).

1. If \( n = 1 \), then the sequence

\[
\pi_2(X, x_0) \xrightarrow{\Phi(x, x_0)} H_2(X; \mathbb{Z}) \xrightarrow{\eta} H_2(\pi_1(X, x_0)) \rightarrow 0
\]

is exact. This implies in particular that the cokernel of the Hurewicz homomorphism \( \Phi(x, x_0) : \pi_2(X, x_0) \rightarrow H_2(X; \mathbb{Z}) \) is isomorphic to \( H_2(\pi_1(X)) \).

2. If \( n > 1 \), then the Hurewicz homomorphism \( \Phi(x, x_0) : \pi_{n+1}(X, x_0) \rightarrow H_{n+1}(X; \mathbb{Z}) \) is an epimorphism.

**Remark.**

1. We refer to [WhdG78, Theorem V.7.9] for a generalization of the above theorem.
2. Let \( n > 1 \). Furthermore let \( X \) be an \((n - 1)\)-connected topological space. By the above Hurewicz Theorem [120.26] (2) we now know that the Hurewicz homomorphism \( \Phi(x, x_0) : \pi_{n+1}(X, x_0) \rightarrow H_{n+1}(X; \mathbb{Z}) \) is an epimorphism. For \( n \geq 3 \) the kernel of the Hurewicz homomorphism is discussed in [Hilt53, p.105] and [WhdJ50, p. 72]. Furthermore, for the more tricky case \( n = 2 \) the kernel of the Hurewicz homomorphism is determined in [WhdJ50, pages 72, 76 and Theorem 20].

**Example.** Let \( X \) be a simply connected topological space and let \( x_0 \in X \). By Theorem [120.26] applied to the case \( n = 2 \), the Hurewicz homomorphism \( \pi_3(X, x_0) \rightarrow H_3(X; \mathbb{Z}) \) is in fact an epimorphism. It is natural to wonder whether Theorem [120.26] can be improved upon. For example it is a priori not unreasonable to ask whether the Hurewicz homomorphism \( \pi_k(X, x_0) \rightarrow H_k(X; \mathbb{Z}) \) is an epimorphism for every \( k \in \mathbb{Z} \). It turns out, we have a counterexample at hand, namely \( X = \mathbb{C}P^\infty \). By Theorem [113.12] we know that \( \mathbb{C}P^\infty \) is simply connected and that \( \pi_k(\mathbb{C}P^\infty) = 0 \) for \( k \geq 3 \). But by the discussion on page [1263] we know that \( H_k(\mathbb{C}P^\infty; \mathbb{Z}) \cong \mathbb{Z} \) for every even \( k \). In particular the Hurewicz homomorphism \( \pi_k(\mathbb{C}P^\infty) \rightarrow H_k(\mathbb{C}P^\infty; \mathbb{Z}) \) is not an epimorphism.

The proof of Theorem [120.26] crucially relies on the following lemma.

**Lemma 120.27.** Let \( \pi \) be an abelian group and let \( n \in \mathbb{N}_{\geq 2} \). If \( Y \) is an Eilenberg-Maclane space of type \( K(\pi, n) \), then \( H_{n+1}(Y; \mathbb{Z}) = 0 \).

**Examples.**

1. The statement of Lemma [120.27] is somewhat surprising since it is emphatically wrong for \( n = 1 \). For example by the discussion on page [2809] we know that \( S^1 \times S^1 \) is an Eilenberg-Maclane space of type \( K(\mathbb{Z}^2, 1) \) and we have \( H_2(S^1 \times S^1; \mathbb{Z}) = 0 \).

2. As a reality check, let us consider the only Eilenberg-Maclane space for \( n \geq 2 \) that we understand, namely \( \mathbb{C}P^\infty \) which is by the discussion on page [2810], an Eilenberg-Maclane space of type \( K(\mathbb{Z}, 2) \). By the calculation on page [1263] we do know that \( H_3(\mathbb{C}P^\infty; \mathbb{Z}) \) is indeed trivial.

**Proof of Lemma 120.27.** Let \( n \in \mathbb{N}_{\geq 2} \) and let \( \pi \) be an abelian group. It follows from Corollary [120.13] that it suffices to show that there exists a single Eilenberg-Maclane space \( Z \) of type \( K(\pi, n) \) with \( H_{n+1}(Z; \mathbb{Z}) = 0 \).
By Proposition [47.11] we know that there exists an \((n + 1)\)-dimensional CW-complex that is a Moore space \(Y\) of type \(K(\pi, n)\). Recall that this means that

1. \(Y\) is simply connected,
2. \(H_n(Y; \mathbb{Z}) \cong \pi\),
3. for any \(i \neq n\) we have \(\tilde{H}_i(Y; \mathbb{Z}) = 0\).

We pick a base point \(y_0 \in Y\). By Corollary [53.7] we know that (1), (2) and (3) imply that

4. \(\pi_i(Y, y_0) = 0\) for \(i = 1, \ldots, n - 1\) and that \(\pi_n(Y, y_0) \cong \pi\).

By Proposition [120.7] there exists a CW-complex \(Z\) with the following properties:

5. \((n + 1)\)-skeleton of \(Z\) equals \(Y\).
6. We have \(\pi_i(Z) = 0\) for \(i \geq n + 1\).
7. For \(i = 1, \ldots, n\) the inclusion \(Y \to Z\) induces an isomorphism \(\pi_i(Y, y_0) \cong \pi_i(Z, y_0)\).

It follows from (4), (6) and (7) that \(Z\) is an Eilenberg-Maclane space of type \(K(\pi, n)\).

Since \(Y\) is the \((n + 1)\)-skeleton of the CW-complex \(Z\) we obtain from Lemma [48.1] (4) that the map \(H_{n+1}(Y; \mathbb{Z}) \to H_{n+1}(Z; \mathbb{Z})\) is an epimorphism. Together with (3) this implies that \(H_{n+1}(Z; \mathbb{Z}) = 0\). We have thus found the desired Eilenberg-Maclane space \(Z\). \(\blacksquare\)

Now we turn to the actual proof of Theorem [120.26] For convenience we break the proof into three parts:

1. First we prove Theorem [120.26] (1) for 2-dimensional CW-complexes.
2. Then we prove Theorem [120.26] (2) for \((n + 1)\)-dimensional CW-complexes.
3. Finally we deal with the general case of Theorem [120.26]

**Proof of Theorem [120.26] (1) for 2-dimensional CW-complexes.** Let \(X\) be a 2-dimensional CW-complex that is 0-connected. Let \(x_0 \in X\). By Proposition [120.7] there exists a CW-complex \(Y\) with the following properties:

1. The 2-skeleton of \(Y\) equals \(X\).
2. We have \(\pi_i(Y, x_0) = 0\) for \(i \geq 2\).
3. The inclusion map \(i: X \to Y\) induces an isomorphism \(i_*: \pi_1(X, x_0) \cong \pi_1(Y, x_0)\).

It follows from (1), (2) and (3) that \(Y\) is an Eilenberg-Maclane space of type \(K(\pi_1(X, x_0), 1)\).

Next we consider the following diagram:

\[
\begin{align*}
\pi_3(Y, X, x_0) & \xrightarrow{\partial} \pi_2(X, x_0) \xrightarrow{\Phi(Y, x_0)} \pi_2(Y, x_0) \xrightarrow{\Phi(Y, x_0)} \pi_2(Y, X, x_0) \xrightarrow{\partial} \pi_1(X, x_0) \xrightarrow{i_*} \pi_1(Y, x_0) \\
H_3(Y, X; \mathbb{Z}) & \xrightarrow{\partial} H_2(X; \mathbb{Z}) \xrightarrow{\Phi(Y, x_0)} H_2(Y; \mathbb{Z}) \xrightarrow{\Phi(Y, x_0)} H_2(Y, X; \mathbb{Z}) \xrightarrow{\partial} H_2(\pi_1(X, x_0)) \\
\end{align*}
\]

Here we use that \(Y\) is its own \((n + 1)\)-skeleton.

The reader will not have failed to notice that this proof shares some ideas with the proof of Lemma [120.11]
We make the following clarifications and observations:

(a) The horizontal sequences are the long exact sequences of homology and homotopy groups of the pair \((Y, X)\), given by Corollary 43.16 and by Proposition 111.4.

(b) The vertical maps are the (relative) Hurewicz homomorphisms that we introduced on pages 1324 and 2633.

(c) The diagram commutes by Lemma 111.11 (3).

(d) It follows from (2), (3) and the lower end of the upper long exact sequence that \(\pi_j(Y, X) = 0\) for \(j = 0, 1\). In other words, the pair \((Y, X)\) is 2-connected.

(e) It follows from (d) and the Relative Hurewicz Theorem 111.13 that the left-hand vertical map is an epimorphism.

(f) The map \(\eta\) and the isomorphism \(\mu\) are given by Lemma 120.25. In particular these maps turn the lower triangle into a commutative triangle.

(g) Since \(X\) is the 2-skeleton of \(Y\) we obtain from Lemma 48.1 that \(H_2(Y, X; \mathbb{Z}) = 0\).

From this data one can easily deduce that the sequence

\[
\pi_2(X, x_0) \xrightarrow{\Phi(X,x_0)} \mathbb{H}_2(X; \mathbb{Z}) \xrightarrow{\eta} \mathbb{H}_2(\pi_1(X,x_0)) \rightarrow 0
\]

is exact.

\[\square\]

Proof of Theorem 120.26 (2) for \((n + 1)\)-dimensional CW-complexes. Let \(n \in \mathbb{N}_{\geq 2}\) and let \(X\) be an \((n + 1)\)-dimensional CW-complex that is \((n - 1)\)-connected. Let \(x_0 \in X\). By Proposition 120.7 there exists a CW-complex \(Y\) with the following properties:

1. The \((n + 1)\)-skeleton of \(Y\) equals \(X\).
2. We have \(\pi_i(Y, x_0) = 0\) for \(i \geq n + 1\).
3. For every \(j \in \{1, \ldots, n\}\) the inclusion map \(i: X \rightarrow Y\) induces an isomorphism \(i_*: \pi_j(X, x_0) \xrightarrow{\cong} \pi_j(Y, x_0)\).

It follows from (1), (2) and (3) that \(Y\) is an Eilenberg-Maclane space of type \(K(\pi_n(X, x_0), n)\).

Next we consider the following diagram:

\[
\begin{array}{ccccccccc}
\pi_{n+2}(Y, X) & \xrightarrow{\beta} & \pi_{n+1}(X) & \xrightarrow{=} & \mathbb{H}_{n+1}(Y) & \xrightarrow{\Phi_{X}} & \pi_{n+1}(Y, X) & \xrightarrow{\beta} & \pi_n(X) & \xrightarrow{i_*} & \pi_n(Y) & \rightarrow & \ldots \\
\cong \Phi(x,Y) & & \downarrow \Phi_X & & & & \downarrow \Phi_Y & & & & & & \\
H_{n+2}(Y, X) & \xrightarrow{\beta} & H_{n+1}(X) & \rightarrow & H_{n+1}(Y). & \cong 0 & \text{by Prop. 120.27}
\end{array}
\]

---

1697 People with shaky memories, like your author, might be surprised that it does not say that the map is an isomorphism. The point is that the Relative Hurewicz Theorem 111.13 shows that the Hurewicz homomorphism \(\pi_3(Y, X, x_0)^r \rightarrow H_3(Y, X; \mathbb{Z})\) is an isomorphism where \(\pi_3(Y, X, x_0)^r\) is the quotient of \(\pi_3(Y, X, x_0)\) by a suitable action of \(\pi_1(x, x_0)\). Thus the Hurewicz homomorphism \(\pi_3(Y, X, x_0) \rightarrow H_3(Y, X; \mathbb{Z})\) is an epimorphism, but in general it is not an isomorphism.

1698 For evident space reasons we drop the base points from the discussion.
We make the following clarifications and observations:

(a) As in the previous proof the horizontal sequences are long exact sequences of the pair 
\((Y, X)\). Furthermore the vertical maps are the (relative) Hurewicz homomorphisms 
and the diagram commutes by Lemma 111.1 (3).

(b) It follows from (2), (3) and the lower end of the upper long exact sequence that
\(\pi_j(Y, X) = 0\) for \(j = 0, \ldots, n+1\). In other words, the pair \((Y, X)\) is \((n+1)\)-connected.

(c) It follows immediately from (a) and the Relative Hurewicz Theorem 111.13, together 
with the fact that \(\pi_1(X, x_0) = 0\), that the left-hand vertical map is an isomorphism.

(d) Since \(Y\) is an Eilenberg-Maclane space of type \(K(\pi_n(X, x_0), n)\) 
and since \(n \geq 2\) we obtain from Lemma 120.27 that \(H_{n+1}(Y) = 0\).

It follows from the above that the second vertical map \(\pi_{n+1}(X) \to H_{n+1}(X)\) is, as promised, 
an epimorphism.

\[\begin{array}{ccc}
\pi_{n+1}(Y^{n+1}, y_1) & \xrightarrow{i_*} & \pi_{n+1}(Y, y_1) \\
\Phi_{(Y^{n+1}, y_1)} & \searrow & \Phi_{(Y, y_1)} \\
H_{n+1}(Y^{n+1}; Z) & \xrightarrow{i_*} & H_{n+1}(Y; Z) \\
\end{array} \]

\[\begin{array}{ccc}
f_* & \cong & f_* \\
\Phi_{(X, x_1)} & \searrow & \Phi_{(X, x_0)} \\
\pi_{n+1}(X, x_1) & \xrightarrow{\gamma_*} & \pi_{n+1}(X, x_0) \\
\end{array} \]

\[\begin{array}{ccc}
H_{n+1}(Y; Z) & \xrightarrow{\text{id}} & H_{n+1}(X; Z) \\
\end{array} \]

We make the following clarifications and observations:

(1) The vertical maps are the Hurewicz homomorphisms.

(2) The horizontal map to the top right is the isomorphism that is induced by the path
\(\gamma_*\), see Proposition 10.5.

(3) The two squares to the left commute by Proposition 52.2.

(4) The square to the right commutes by Lemma 53.1 (2).

(5) We know from the above proof of Theorem 120.26 for \((n+1)\)-dimensional CW-
complexes, and the fact that \(Y^{n+1}\) is \((n-1)\)-connected, that the left vertical map is 
an epimorphism.

(6) By Lemma 48.1 (4) we know that the bottom left horizontal map is an epimorphism.

(7) Since \(f\) is a weak homotopy equivalence we know that the top middle horizontal map 
is an isomorphism. Furthermore we obtain from Proposition 119.6 that the bottom 
middle horizontal map is also an isomorphism.

(8) It follows from all the information assembled above that the right vertical map is an 
epimorphism.

The proof for \(n = 1\) is quite similar, with a few minor extra complications. We leave it to 
the reader to fill in the details.
Theorem 120.26 (2) says that given a pointed 0-connected topological space \((X, x_0)\) there is a curious interplay between \(\pi_2(X, x_0), \) \(H_2(X)\) and the second homology of \(\pi_1(X, x_0)\). We want to get a better intuition for what is happening by considering two corollaries to Theorem 120.26 (2).

**Corollary 120.28.** Let \((X, x_0)\) be some pointed 0-connected topological space. If \(\pi_1(X, x_0) \cong \mathbb{Z}\), then the Hurewicz homomorphism \(\Phi_{(X, x_0)} : \pi_2(X, x_0) \to H_2(X; \mathbb{Z})\) is an epimorphism.

**Proof.** In the discussion on page 2836 we saw that \(H_2(\pi_1(X, x_0)) \cong H_2(\mathbb{Z}) \cong H_2(S^1) = 0\). Thus it follows immediately from Theorem 120.26 (2) that the Hurewicz homomorphism \(\pi_2(X, x_0) \to H_2(X; \mathbb{Z})\) is an epimorphism.

The proof of Corollary 120.28 is in many ways beyond reproach, it is clear and rigorous. The only catch is that it is not very geometric and we do not really get a good understanding why the statement is true. To rectify this we will sketch an alternative, quite geometric, proof for Corollary 120.28 in Exercise 120.10.

We move on to the second corollary to Theorem 120.26 (2).

**Corollary 120.29.** If \(X\) is a 0-connected topological space such that \(\pi_1(X) \cong \mathbb{Z}^m\) for some \(m \in \mathbb{N}_{\geq 2}\), then for any \(x_0 \in X\) we have

\[
\text{coker} \left( \Phi_{(X, x_0)} : \pi_2(X, x_0) \to H_2(X; \mathbb{Z}) \right) \cong H_2(\pi_1(X)) \cong H_2(\mathbb{Z}^m) \cong \mathbb{Z} \left( \begin{array}{c} m \\ 2 \end{array} \right).
\]

In particular we see that \(H_2(X; \mathbb{Z})\) is non-trivial.

In the following we want to get a better understanding how this “extra” homology in \(H_2(X; \mathbb{Z})\) arises. To simplify the discussion let us consider the case \(m = 2\). Thus let \((X, x_0)\) be a pointed 0-connected topological space with \(\pi_1(X, x_0) \cong \mathbb{Z}^2\). We proceed as follows:

1. We pick two loops \(\alpha, \beta : (S^1, *) \to (X, x_0)\) that represent a generating set for the group \(\pi_1(X, x_0) \cong \mathbb{Z}^2\).

   We consider the loop \(\varphi = \alpha * \beta * \overline{\alpha} * \overline{\beta} : (S^1, *) \to (X, x_0)\). Since \(\pi_1(X, x_0)\) is abelian we see that the loop \(\varphi\) represents the trivial element in \(\pi_1(X, x_0)\). By Lemma 14.1 this means that we can extend the loop to a map \(\Phi : \mathbb{B}^2 \to X\).

2. We make the “obvious” identification \(\mathbb{B}^2 = [0, 1]^2\) which identifies the “quarter-circles” on \(S^1\) with the four sides of the square.

3. Let \(\sim\) be the usual equivalence relation on \([0, 1]^2\) given by \((x, 0) \sim (x, 1)\) and \((y, 0) \sim (y, 1)\). The quotient \(T := [0, 1]^2/\sim\) is the 2-dimensional torus. We equip \(T\) with the base point \(*\) that is represented by any of the vertices.

4. The map \(\Phi : \mathbb{B}^2 = [0, 1]^2 \to X\) descends to a map \(\overline{\Phi} : T := [0, 1]^2/\sim \to X\).

This approach feels like we are creating surfaces ex nihilo. But the following lemma shows that miraculously this approach works.

\[\text{Exercise 120.10...}\]
Lemma 120.30. We continue with the above notation. The map
\[ \mu: \mathbb{H}_2(T; \mathbb{Z}) \rightarrow \text{coker}(\pi_2(X, x_0) \rightarrow \mathbb{H}_2(X; \mathbb{Z})) \]
\[ \sigma \mapsto [\Phi_*(\sigma)] \]
is an isomorphism.

Sketch of proof. As in the proof of Theorem 120.26 (2) we can assume that \( X \) is a 3-dimensional CW-complex. Furthermore, by the proof of Theorem 120.26 (2) we know that there exists an inclusion \( i: X \rightarrow Y \) of \( X \) into an Eilenberg-Maclane space \( Y \) of type \( K(\mathbb{Z}^2, 1) \) such that the inclusion induced map \( i_*: \pi_1(X, x_0) \rightarrow \pi_1(Y, x_0) \) is an isomorphism. We consider the following simple minded diagram

\[ \Phi \quad X \quad i \quad \Phi \]
\[ T \quad i_0 \Phi \quad Y \]

and we consider the induced diagram

\[ \pi_1(T, *) \quad i_* \quad \pi_1(Y, y_0). \]

We make the following observations:

1. The map \( \Phi_*: \pi_1(T, *) \rightarrow \pi_1(X, x_0) \) is by design an epimorphism. Since both groups are isomorphic to \( \mathbb{Z}^2 \) we obtain from Lemma 19.8 (5) that \( \Phi_* \) is in fact an isomorphism.

2. As we mentioned above, the map \( i_*: \pi_1(X, x_0) \rightarrow \pi_1(Y, x_0) \) is an isomorphism.

3. By (1) and (2) we know that \( (i \circ \Phi)_* = i_* \circ \Phi_*: \pi_1(T, *) \rightarrow \pi_1(Y, x_0) \) is an isomorphism.

4. By the discussion on page 2809 and by the above we know that both \( T \) and \( Y \) are Eilenberg-Maclane spaces of type \( K(\mathbb{Z}^2, 1) \). Thus we obtain from the Whitehead Theorem 119.9 that \( i \circ \Phi: T \rightarrow Y \) is in fact a homotopy equivalence.

5. Since \( i \circ \Phi \) is a homotopy equivalence we obtain from Corollary 42.8 that the induced map \( (i \circ \Phi)_* = i_* \circ \Phi_*: \mathbb{H}_2(T; \mathbb{Z}) \rightarrow \mathbb{H}_2(Y; \mathbb{Z}) \) is an isomorphism.
It remains to consider the following diagram

\[
\begin{array}{ccc}
H_2(T;\mathbb{Z}) & \xrightarrow{\cong} & H_2(X;\mathbb{Z}) \\
\xrightarrow{\varphi_*} & & \xrightarrow{i_*} \\
\text{coker}(\pi_2(X, x_0) \to H_2(X;\mathbb{Z})). & & \cong \\
\end{array}
\]

By the above discussion we know that the composition of the top two horizontal maps is an isomorphism and by Theorem 120.26 together with Lemma 120.25, we know that the diagonal map to the right is an isomorphism. It follows that the diagonal map to the left is also an isomorphism.

Exercises for Chapter 120.

**Exercise 120.1.** We consider the real projective plane \(\mathbb{R}P^2 = \mathbb{B}^2 / \sim\) where for \(x \in S^1\) we have \(x \sim -x\). Let \(\varphi: \mathbb{B}^2 \to \mathbb{R}P^2\) be a smooth embedding. We consider the map

\[
f: \mathbb{R}P^2 \to \mathbb{B}^2 / S^1 = S^2 = \mathbb{C}P^1 \subset \mathbb{C}P^\infty
\]

\[
P \mapsto \begin{cases} [Q], & \text{if } P = \varphi(Q) \text{ for some } Q \in \mathbb{B}^2, \\ [S^1], & \text{otherwise.} \end{cases}
\]

Is the map \(f\) homotopic to the constant map?

**Exercise 120.2.** Let \(X\) be a connected \(k\)-dimensional CW-complex and let \(k \in \mathbb{N}\).

(a) Does there exist a CW-complex \(Y\) with \(Y^k = X\) and \(\pi_k(Y) = 0\)?
(b) Does there exist a CW-complex \(Y\) with \(Y^k = X\) and \(\pi_k(Y;\mathbb{Z}) = 0\)?

**Exercise 120.3.** Finish the proof of Proposition 120.21.

*Hint.* Use Lemma 98.3.

**Exercise 120.4.** Let \(n \in \mathbb{N}\). In Lemma 120.1 we showed that there exists an Eilenberg-Maclane space \(X\) of type \(K(Z, n)\) with precisely one 0-cell, precisely one \(n\)-cell and no cell of dimension \(n + 1\). What is the minimal dimension in which the canonical Eilenberg-Maclane space of type \(K(Z, n)\) has more cells than \(X\)?

**Exercise 120.5.** Let \(n \in \mathbb{N}\). We consider \(n \cdot \mathbb{R}P^2\), i.e. we consider the connected sum of \(n\) copies of \(\mathbb{R}P^2\).

(a) What is the maximal number \(k \in \mathbb{N}_0\) for which we can find \(k\) disjoint curves \(F_1, \ldots, F_k\) on \(n \cdot \mathbb{R}P^2\) such that \(n \cdot \mathbb{R}P^2 \setminus (F_1 \cup \cdots \cup F_k)\) is connected?
(b) What is the maximal \( l \in \mathbb{N}_0 \) for which there exists an epimorphism from \( \pi_1(n \cdot \mathbb{R}P^2) \)
onto a free group of \( l \) generators?

**Remark.** By Proposition \( \text{22.7} \) we know that there exists an isomorphism
\[
\pi_1(n \cdot \mathbb{R}P^2) \cong \langle x_1, \ldots, x_n \mid x_1^2 \cdots x_n^2 \rangle.
\]

**Remark.** This exercise is basically a variation on Question \( \text{98.9} \).

**Exercise 120.6.** In Lemma \( \text{81.9} \) we proved the following statement:

\( (*) \) Let \( X \) be a topological space. For any \( \phi \in \text{H}^1(X; \mathbb{Z}) \) we have \( \phi \circ \phi = 0 \).

Our goal is to give an alternative proof of this statement:

(a) Show that \( (*) \) holds for \( X = S^1 \).
(b) Let \( X \) be a CW-complex. Use (a) and Proposition \( \text{120.15} \) to provide a proof of \( (*) \) for CW-complexes.
(c) Use the CW-Approximation Theorem \( \text{119.8} \) and Proposition \( \text{119.6} \) to show, using (b), that \( (*) \) holds for all topological spaces.

**Exercise 120.7.** Show that there exists an abelian group \( \pi \) and Moore spaces \( X \) and \( Y \) of type \( \text{K}(\pi, 1) \) that are not homotopy equivalent.

**Hint.** You could use the fundamental group to distinguish \( X \) and \( Y \).

**Remark.** In Exercise \( \text{120.8} \) we will deal with Moore spaces of type \( \text{K}(\pi, n) \) with \( n \geq 2 \).

**Exercise 120.8.** Let \( \pi \) be an abelian group and let \( n \in \mathbb{N}_{\geq 2} \). In this exercise we will show that any two Moore spaces of type \( \text{M}(\pi, n) \) are in fact homotopy equivalent. First note that by Proposition \( \text{47.11} \) there exists an \( (n + 1) \)-dimensional CW-complex \( X \) that has no cells in dimensions \( 1, \ldots, n - 1 \) and that is a Moore space of type \( \text{M}(\pi, n) \). It suffices to show that \( X \) is homotopy equivalent to any other Moore space \( Y \) of type \( \text{M}(\pi, n) \).

This task is broken up into two steps:

(a) Use Lemma \( \text{120.16} \) to show that there exists a map \( f : X \to Y \) that induces an isomorphism \( f_* : \pi_n(X) \to \pi_n(Y) \).
(b) Use Lemma \( \text{53.1} \) Proposition \( \text{119.6} \) and the Whitehead Theorem \( \text{119.9} \)(1) to show that \( f \) is a homotopy equivalence.

**Remark.** Together with Exercise \( \text{120.7} \) this gives a complete answer to Question \( \text{47.14} \).

**Exercise 120.9.** Let \( n \in \mathbb{N} \). We set \( M = (S^1)^n \). Let \( \varphi : \pi_1(M) \to \mathbb{Z}^n \) be an isomorphism. Show that it is not possible to extend \( \varphi \) over a bounding \( (n + 1) \)-dimensional smooth manifold. More precisely, show that there is no pair \( (W, \psi : \pi_1(W) \to \mathbb{Z}^n) \) where \( W \) is a compact orientable connected smooth manifold with \( \partial W = M \) and where \( \psi \) is a homomorphism that satisfies \( \varphi = \psi \circ i_* \) where \( i : M \to W \) denotes the inclusion.

**Remark.** By Theorem \( \text{64.5} \) we know that any compact smooth manifold \( W \) admits a CW-structure.

**Exercise 120.10.** Let \( X \) be a 1-connected topological space with \( \pi_1(X) \cong \mathbb{Z} \). By Corollary \( \text{120.28} \) we know that the Hurewicz homomorphism \( \pi_2(X) \to \text{H}_2(X; \mathbb{Z}) \) is an epimorphism. The goal of this exercise is to sketch an alternative geometric proof. Thus let \( \varphi \in \text{H}_2(X; \mathbb{Z}) \). By Proposition \( \text{70.3} \) there exists a surface \( \Sigma_g \) of some genus \( g \in \mathbb{N}_0 \) and
a map \( f: \Sigma_g \to X \) such that \( f_*([\Sigma_g]) = \varphi \in H_2(X; \mathbb{Z}) \). If \( g = 0 \), then we are done. So suppose that \( g \geq 1 \). We proceed with the following steps:

(a) Show that there exists a curve \( C \subset \Sigma_g \) with \([C] \neq 0 \in H_1(\Sigma_g; \mathbb{Z})\) but such that \( f_*([C]) = \pi_1(X) \).

Remark. You might want to use Corollary \ref{cor:corollary} at some point.

(b) Get inspired by Figure \ref{fig:figure}.

(c) Complete the proof of the statement.

**Exercise 120.11.** Let \( \pi \) be a group, let \( \varphi: \pi \to \pi \) be an endomorphism and let \( K \) be an Eilenberg-Maclane space of type \( K(\pi, 1) \). By Proposition \ref{prop:proposition} we know that there exists a map \( f: (K(\pi, 1), *) \to (K(\pi, 1)) \) such that \( f_* = \varphi \). Now suppose that \( \varphi \) is an isomorphism. Can always find such a map \( f \) which is furthermore a homeomorphism?

**Exercise 120.12.** Let \( F_n := \langle x_1, \ldots, x_n \rangle \) the free group on \( n \) generators \( x_1, \ldots, x_n \) and let \( \varphi: F_n \to F_n \) be an isomorphism. We consider the semidirect product \( \pi := F_n \rtimes \mathbb{Z} \) as defined on page \ref{page}. Show that there exists a 2-dimensional Eilenberg-Maclane space of type \( K(\pi, 1) \).

**Hint.** Note that \( X := \bigvee_{i=1}^n S^1_i \) is an Eilenberg-Maclane space of type \( K(F_n, 1) \). By Proposition \ref{prop:proposition} there exists a map \( f: (X, *) \to (X, *) \) with \( f_* = \varphi \). Now consider the mapping torus \( \text{Tor}(X, f) \). Use Proposition \ref{prop:proposition}. It might also be useful to consider Lemma \ref{lemma}. 
121. Invariants obtained through Eilenberg-Maclane spaces

In this chapter we will see how one can use Eilenberg-Maclane spaces to define contravariant functors from the category of CW-complexes to the category of abelian groups. In this chapter and in Chapter ?? we will relate these functors to the cohomology functors.

Before we jump into the chapter we remind the reader that given topological spaces $X$ and $Y$ we denote by $Y^X$ the set of all continuous maps from $X$ to $Y$. Throughout this and the coming chapters we always equip $Y^X$ with the compact-open topology that we introduced on page 234.

121.1. The homotopy category of topological spaces. In this short section we recall some definitions and results regarding topological spaces and the homotopy category of topological spaces. This section partly serves as a warm-up for the discussion of pointed topological spaces in the following sections.

First we recall the following definition from page 543.

**Definition.** Given two topological spaces $X$ and $Y$ we define

$$[X,Y] := \{\text{continuous maps } X \to Y\} / \sim$$

where $f \sim g$ if there exists a homotopy between $f$ and $g$.

We also recall the following definition from page 544.

**Definition.** The homotopy category $\mathcal{H}$ is defined to be the category where the objects are topological spaces and where the set of morphisms between two topological spaces $X$ and $Y$ is given by the set $[X,Y]$.\footnote{The composition of $[f: X \to Y]$ and $[g: Y \to Z]$ is evidently defined to be $[g \circ f: X \to Z]$, by Lemma \ref{lem:homotopy-categories}, this definition does not depend on the choice of representatives.}

The following lemma is basically an immediate consequence of the definitions.

**Lemma 121.1.** Let $f: X \to Y$ be a map between topological spaces. The corresponding morphism $[f] \in \text{Mor}_\mathcal{H}(X,Y)$ is invertible in the sense of the definition on page 478 if and only if $f$ is a homotopy equivalence.

**Proof.** Note that by definition $[f] \in \text{Mor}_\mathcal{H}(X,Y)$ is invertible if and only if there exists $[g] \in \text{Mor}_\mathcal{H}(Y,X)$ with $[f \circ g] = [\text{id}_Y]$ and $[g \circ f] = [\text{id}_X]$. Now the statement of the lemma is indeed clear. \hfill \blacksquare

In the following we show how some constructions of topological spaces interact with the homotopy category $\mathcal{H}$. First we have following rather dull lemma.

**Lemma 121.2.** Let $X$, $Y$ and $Z$ be topological spaces. The map

$$\chi: [X,Y] \times [X,Z] \to [X,Y \times Z]$$

$$([f: X \to Y], [g: X \to Z]) \mapsto [f \times g: X \to Y \times Z]$$

is well-defined.

**Proof.** Nothing can possibly go wrong in any attempt to prove this lemma. \hfill \blacksquare
Lemma 121.3. The maps

\[ X \mapsto \text{free loop space } \Omega(X) := \{ \varphi \in X^{[0,1]} \mid \varphi(0) = \varphi(1) \} \]

\[ [f : X \to Y] \mapsto \left[ \Omega(f) : \Omega(X) \to \Omega(Y) \right. \]

\[ \left. (\varphi : [0,1] \to X) \mapsto (f \circ \varphi : [0,1] \to Y) \right] \]

and

\[ X \mapsto \text{suspension } \Sigma(X) := (X \times [-1,1]) / \sim \]

\[ [f : X \to Y] \mapsto \left[ \Sigma(f) : \Sigma(X) \to \Sigma(Y) \right. \]

\[ \left. [(x,t)] \mapsto [(f(x),t)] \right] \]

both define covariant functors from \( \mathcal{H} \) to itself.

Proof. There are only two statements one needs to think about: given a map \( f : X \to Y \) one needs to show that \( \Omega(f) \) and \( \Sigma(f) \) are continuous, and given homotopic maps \( f, g : X \to Y \) one needs to show that the corresponding maps on the right hand side are also homotopic. For the free loop spaces the statements follow from Lemma 5.5 (1) and (3). For suspensions these two statements follow immediately from Lemma 24.4 (1) and (4).

Just for kicks we also mention the following definition, which is reminiscent of the definition that we gave on page 1060. We will make use of this definition, with a slight twist, in the near future.

Definition. Let \( X \) be a topological space. We consider the wedge \( \Sigma(X) \vee \Sigma(X) \) that is given by identifying the \text{“South Pole } [X \times \{-1\}] \text{”} on the left with the \text{“North Pole } [X \times \{1\}] \text{”} on the right. We refer to the map

\[ \Sigma(X) \to \Sigma(X) \vee \Sigma(X) \]

\[ [(x,t)] \mapsto \begin{cases} [(x,2t+1)] \text{ in the first term,} & \text{if } t \in [-1,0], \\ [(x,2t-1)] \text{ in the second term,} & \text{if } t \in [0,1]. \end{cases} \]

as the \text{pinching map}\textsuperscript{1701}

\[ \xymatrix{ X \ar@/^/[rr] \ar@/_/[rr] \ar@/^/[rrr] \ar@/_/[rrr] & \ar@{..}[r] & \Sigma(X) \ar@/^/[rr] \ar@/_/[rr] & \ar@{..}[r] & \Sigma(X) \vee \Sigma(X) \ar@/^/[rr] \ar@/_/[rr] & \ar@{..}[r] & \Sigma(X) \ar@/^/[rr] \ar@/_/[rr] & \ar@{..}[r] & \Sigma(X) \ar@/^/[rr] \ar@/_/[rr] \ar@{..}[r] & \Sigma(X) \vee \Sigma(X) \ar@/^/[rr] \ar@/_/[rr] } \]

\[ \text{Figure 1660} \]

In some instances the sets \([X,Y]\) have some extra structure. For example we have the following elementary but cute lemma.

\textsuperscript{1701}It follows easily from Lemma 3.22 and Lemma 2.35 (2) that the pinching map is continuous.
Lemma 121.4. Let $X$ be a topological space and let $G$ be an (abelian) topological group, e.g. we could take $G = S^1$. The set $[X, G]$ together with the multiplication map

$$\nu: [X, G] \times [X, G] \to [X, G]$$

$$[f], [g] \mapsto \left[ \begin{array}{c} X \to G \\ x \mapsto f(x) \cdot g(x) \end{array} \right]$$

is an (abelian) group.

Remark. Let $X$ be a topological space and let $G$ be a topological group. In Lemma 5.12 we showed, under the extra hypothesis that $G$ is regionally compact, that the set $G^X$ with the obvious multiplication map $G^X \times G^X \to G^X$ is in fact a topological group. We could equip $[X, G] = G^X/\sim$ with the quotient topology, but the discussion on page 2698 shows that in general the resulting multiplication map $\nu: [X, G] \times [X, G] \to [X, G]$ is no longer continuous. Thus in general we cannot view $[X, G]$ as a topological group.

Proof. In fact the only thing one needs to verify is that the map $\nu$ is actually well-defined. But this follows easily from the fact that the group multiplication $G \times G \to G$ is continuous. We leave it to the reader to fill in the details. □

There are several drawbacks to considering topological spaces which are not equipped with base points.

1) Without a base point the homotopy groups $\pi_n(X)$ are at best defined up to isomorphism, but they are not defined “on the nose”.

2) The operation of taking wedges is not well-defined.

In the following section we will introduce the analogue of the homotopy category for pointed topological spaces. This will take care of the above issues, but it will require some adjustments at other places.

121.2. The homotopy category of pointed topological spaces. In the latter part of this chapter it will be essential that we always work with pointed topological spaces. To prepare for this discussion we need to rephrase all the concepts and results from the previous section in the language of pointed topological spaces.

We start out with a few definitions. Some of them we have encountered before on page 1005.

Definition.

1) A pointed topological space is a pair $(X, x_0)$ where $X$ is a topological space and $x_0 \in X$ is a point. We refer to $x_0$ as the base point of the pointed topological space.

2) A map $f: (X, x_0) \to (Y, y_0)$ between pointed topological spaces is a map $f: X \to Y$ with $f(x_0) = y_0$.

3) We say that two maps $f, g: (X, x_0) \to (Y, y_0)$ between pointed topological spaces are homotopic if there exists a homotopy $F: X \times [0,1] \to Y \text{ rel } \{x_0\}$ from $f$ to $g$. We use this notion of “homotopic” to define the notion of a homotopy equivalence between pointed topological spaces.
(4) A pointed CW-complex is a pair \((X, x_0)\) where \(X\) is a CW-complex and \(x_0\) is a point in the 0-skeleton \(X^0\) of \(X\).

(5) Given two pointed topological spaces \((X, x_0)\) and \((Y, y_0)\) we write
\[
\langle (X, x_0), (Y, y_0) \rangle := \{ \text{maps } (X, x_0) \to (Y, y_0) \}/\sim
\]
where \(f \sim g\) if there exists a homotopy in the above sense between \(f\) and \(g\).

Given a map \(f: (X, x_0) \to (Y, y_0)\) we denote its equivalence class by \([f]\) as usual.

(6) Let \((X, x_0)\) and \((Y, y_0)\) be two topological spaces. Let \(0 \in \langle (X, x_0), (Y, y_0) \rangle\) be the element that is represented by constant map \(X \to Y\) given by \(x \mapsto y_0\). We refer to 0 as the trivial element.

The following lemma is the analogue of Lemma [18.7]

**Lemma 121.5.** Let \((X, x_0)\), \((Y, y_0)\) and \((Z, z_0)\) be pointed topological spaces. The map
\[
\langle (X, x_0), (Y, y_0) \rangle \times \langle (Y, y_0), (Z, z_0) \rangle \to \langle (X, x_0), (Z, z_0) \rangle
\]
\([(f], [g]) \mapsto [g \circ f]

is well-defined.

**Proof.** The proof of this lemma is almost identical to the proof of Lemma [18.7] and it is left to the insomniac reader.

Lemma [121.5] shows that the following definition makes sense.

**Definition.** The pointed homotopy category \(\mathcal{P}\text{HomTop}\) is the category where the objects are pointed topological spaces and where the set of morphisms between two pointed topological spaces \((X, x_0)\) and \((Y, y_0)\) is given by the set \(\langle (X, x_0), (Y, y_0) \rangle\).

The following lemma is the analogue of Lemma [121.1]

**Lemma 121.6.** Let \((X, x_0)\) and \((Y, y_0)\) be pointed topological spaces.

1. Let \(f: (X, x_0) \to (Y, y_0)\) be a map. The corresponding morphism
\[
[f] \in \text{Mor}_{\mathcal{P}\text{HomTop}}((X, x_0), (Y, y_0)) = \langle (X, x_0), (Y, y_0) \rangle
\]
is invertible if and only if \(f\) is a homotopy equivalence.

2. In the category \(\mathcal{P}\text{HomTop}\) we have
\[
\langle (X, x_0), (Y, y_0) \rangle_{\text{inv}} = \text{all elements of } \langle (X, x_0), (Y, y_0) \rangle \text{ that are represented by a homotopy equivalence.}
\]

**Proof.** The first statement is, as in the case of Lemma [121.1] an immediate consequence of the definitions. The second statement is a reformulation of the first statement.

---

1702 The notation \((X, Y)\) goes back to [Hat02, p. 357], where it says “the notation \(\langle \ldots \rangle\) is intended to suggest pointed homotopy classes”.

1703 At the moment this notation might sound a little risqué. But it will turn out to be a useful notation.

1704 We refer to page 478 for the definition of an invertible morphism.

1705 On page 478 we defined \(\text{Mor}_C(X, Y)_{\text{inv}}\) to be the set of all invertible morphisms.
In the following we discuss the operations of taking products, wedges, loop spaces and suspensions in the context of the pointed homotopy category. We start out with the following convention.

**Convention.** Given pointed topological spaces \((X, x_0)\) and \((Y, y_0)\) we equip the product \(X \times Y\) with the point \((x_0, y_0)\).

For completeness we mention the following uninspiring analogue to Lemma 121.2.

**Lemma 121.7.** Let \((X, x_0)\), \((Y, y_0)\) and \((Z, z_0)\) be pointed topological spaces. The map

\[
\chi: \langle (X, x_0), (Y, y_0) \rangle \times \langle (X, x_0), (Z, z_0) \rangle \to \langle (X, x_0), (Y \times Z, (y_0, z_0)) \rangle
\]

\[
([f : X \to Y], [g : X \to Z]) \mapsto [f \times g : X \to Y \times Z]
\]

is well-defined and it is natural.

**Proof.** Conveniently enough the proof is identical to the proof of Lemma 121.2. 

As discussed on page 559, one advantage of working with pointed topological spaces is that we have an unambiguous wedge operation.

**Definition.** Given a family \(\{(X_i, x_i)\}_{i \in I}\) of pointed topological spaces we define the wedge

\[
\bigvee_{i \in I} (X_i, x_i) := \left( \bigcup_{i \in I} X_i \right) / \sim \quad \text{where } x_i \sim x_j \text{ for any } i, j \in I.
\]

We equip this wedge with the base point given by the wedge point.

**Lemma 121.8.** Let \((X, x_0)\), \((Y, y_0)\) and \((Z, z_0)\) be pointed topological spaces. The map

\[
\nu: \langle (X, x_0), (Z, z_0) \rangle \times \langle (Y, y_0), (Z, z_0) \rangle \to \langle (X, x_0) \vee (Y, y_0), (Z, z_0) \rangle
\]

\[
([f : X \to Z], [g : Y \to Z]) \mapsto [f \vee g]
\]

is well-defined.

**Proof.** The statement of the lemma is, in contrast to Lemma 121.5 and 121.7 non-trivial. It is a reformulation of Lemma 18.27 which traces its ancestry to the formidable Theorem 5.16.

Now we would like to generalize the free loop space \(\Omega(X)\) and the suspension \(\Sigma(X)\) to pointed topological spaces. It is pretty clear what we do about loop spaces:

**Definition.** Given a pointed topological space \((X, x_0)\) we consider the loop space \(\Omega(X, x_0) := \{ f \in X^{[0,1]} \mid f(0) = f(1) = x_0 \}\)

and we equip the loop space \(\Omega(X, x_0)\) with the base point \(c_{x_0}\) which is just the constant path \([0, 1] \to X, t \mapsto x_0\). Often we will suppress the base point from the notation, but throughout the subsequent chapters we will always view \(\Omega(X, x_0)\) as a pointed topological space.

For completeness we write down explicitly the following fairly obvious lemma which is the analogue of the first statement of Lemma 121.3.
Lemma 121.9. The maps

\[(X, x_0) \mapsto (\Omega(X, x_0), c_{x_0})\]

\[\{f : (X, x_0) \to (Y, y_0)\} \mapsto \begin{cases} \Omega(X, x_0) \to \Omega(Y, y_0) \\ (\gamma : [0, 1] \to X) \mapsto (f \circ \gamma : [0, 1] \to Y) \end{cases}\]

define a covariant functor from the category $\mathbf{PHomTop}$ to itself.

Proof. The lemma follows easily basically from Lemma 5.5 (1) and (3), one just needs to make a few minute modifications to factor in the base points. We leave this elementary task to the inexhaustible reader. \[\square\]

The loop spaces $\Omega(X, x_0)$ have one big advantage over the free loop spaces $\Omega(X)$. Given two loops in $(X, x_0)$ we can form the product, as defined on page 465. As we had already hinted at in Lemma 114.22 this multiplication turns $\Omega(X, x_0)$ into a group “up to homotopy”. More precisely we have the following definition and lemma which hark back to the happy days when our biggest worry was to define the fundamental group of a pointed topological space.

Definition. Let $(X, x_0)$ be a pointed topological space. We consider the map

\[\mu : \Omega(X, x_0) \times \Omega(X, x_0) \to \Omega(X, x_0)\]

\[(f, g) \mapsto f \ast g = \begin{cases} [0, 1] \to X \\ t \mapsto \begin{cases} f(2t), & \text{if } t \in [0, \frac{1}{2}] \\ g(2t - 1), & \text{if } t \in \left(\frac{1}{2}, 1\right] \end{cases} \end{cases} \]

For entertainment the definition of this map is illustrated in Figure 1661.

![Figure 1661](image)

The following lemma summarizes many important properties of $\mu$.

Lemma 121.10. Let $(X, x_0)$ be a pointed topological space. The multiplication map

\[\mu : \Omega(X, x_0) \times \Omega(X, x_0) \to \Omega(X, x_0)\]

has the following properties.

(1) The map $\mu : \Omega(X, x_0) \times \Omega(X, x_0) \to \Omega(X, x_0)$ is continuous\[\uparrow\text{it is base-point preserving and it is natural in $(X, x_0)$}\]

(2) The two maps

\[\lambda : \Omega(X, x_0) \to \Omega(X, x_0) \quad \text{and} \quad \rho : \Omega(X, x_0) \to \Omega(X, x_0)\]

\[f \mapsto \mu(c_{x_0}, f) \quad \text{and} \quad f \mapsto \mu(f, c_{x_0})\]

between pointed topological spaces are both homotopic to the identity.
(3) The map
\[ \eta : \Omega(X, x_0) \to \Omega(X, x_0) \]
\[ f \mapsto \bar{f} := \left( t \mapsto f(1-t) \right) \]
is a homeomorphism and base point preserving.

(4) The map
\[ \Omega(X, x_0) \to \Omega(X, x_0) \]
\[ f \mapsto \mu(f, \bar{f}) \]
between pointed topological spaces is homotopic to the constant map \( f \mapsto c_{x_0} \).

(5) The two maps
\[ \Omega(X, x_0) \times \Omega(X, x_0) \times \Omega(X, x_0) \to \Omega(X, x_0) \]
\[ (f, g, h) \mapsto \mu(\mu(f, g), h) \]
and
\[ (f, g, h) \mapsto \mu(f, \mu(g, h)) \]
between pointed topological spaces are homotopic.

Remark.

(1) In many ways Lemma 121.10 is quite similar to Proposition 14.6. In fact it is not difficult to formulate and prove a result which combines both. As it is, the two results are stated at the appropriate level of generality for what they are aimed for.

(2) Let \((X, x_0)\) be a pointed topological space. In Lemma 121.10 (2) we just showed that the multiplication map \( \Omega(X, x_0) \times \Omega(X, x_0) \to \Omega(X, x_0) \) is continuous. The fundamental group \( \pi_1(X, x_0) := \Omega(X, x_0)/\sim \) is a quotient of \( \Omega(X, x_0) \), hence it can be equipped with the quotient topology. It turns out, see the discussion on page 2698 that the induced multiplication map \( \pi_1(X, x_0) \times \pi_1(X, x_0) \to \pi_1(X, x_0) \) is in general not continuous.

Proof (**). Let \((X, x_0)\) be a pointed topological space.

(1) The statement that \( \mu \) is continuous is precisely the content of Lemma 114.22 (1). The statements that \( \mu \) is base-point preserving and natural follows basically immediately from the definitions.

(2) This statement is a reformulation of Lemma 114.22 (2).

(3) Evidently the map \( \eta : \Omega(X, x_0) \to \Omega(X, x_0) \) is base point preserving. It follows immediately from Lemma 5.5 (5), applied to the homeomorphism \([0, 1] \to [0, 1]\) that

\[ \Omega(X, x_0) \] is equipped with the compact-open topology and \( \Omega(X, x_0) \times \Omega(X, x_0) \) is correspondingly equipped with the product topology. Furthermore we view \( \Omega(X, x_0) \) and \( \Omega(X, x_0) \times \Omega(X, x_0) \) as pointed topological spaces.

\textsuperscript{1706}Recall that \( \Omega(X, x_0) \) is equipped with the compact-open topology and \( \Omega(X, x_0) \times \Omega(X, x_0) \) is correspondingly equipped with the product topology. Furthermore we view \( \Omega(X, x_0) \) and \( \Omega(X, x_0) \times \Omega(X, x_0) \) as pointed topological spaces.

\textsuperscript{1707}Here “natural” means that if \( f : (X, x_0) \to (Y, y_0) \) is a map between pointed topological spaces, then the following diagram commutes:

\[ \begin{array}{ccc}
\Omega(X, x_0) \times \Omega(X, x_0) & \xrightarrow{\mu} & \Omega(X, x_0) \\
\downarrow f \times f & & \downarrow f_* \\
\Omega(Y, y_0) \times \Omega(Y, y_0) & \xrightarrow{\mu} & \Omega(Y, y_0)
\end{array} \]
is given by $t \mapsto 1 - t$, that the map $\eta: \Omega(X, x_0) \to \Omega(X, x_0)$ is continuous. Since $\eta \circ \eta = \text{id}$ we see that $\eta$ is in fact a homeomorphism.

(4) We consider the map

$$H: \Omega(X, x_0) \times [0, 1] \to \Omega(X, x_0)$$

$$(f, t) \mapsto \begin{cases} [0, 1] \to X \\ s \mapsto \begin{cases} f(2s \cdot t), & \text{if } s \in [0, \frac{1}{2}], \\ f(2t - 2s \cdot t), & \text{if } s \in \left(\frac{1}{2}, 1\right] \end{cases} \end{cases}.$$

Again, using the argument in the proof of Lemma 114.22 (1) we see that $H$ is continuous. It is now clear that $H$ is a homotopy between the constant map $f \mapsto c_{x_0}$ and the map $f \mapsto \mu(f, \tilde{f})$. We refer to Figure 1662 for an illustration.

(5) To simplify the notation we write $\Omega(X)$ instead of $\Omega(X, x_0)$. We consider the map

$$H: \Omega(X) \times \Omega(X) \times \Omega(X) \times [0, 1] \to \Omega(X)$$

$$(f, g, h, t) \mapsto \begin{cases} [0, 1] \to X \\ s \mapsto \begin{cases} f(\frac{4s}{t+1}), & \text{if } s \in [0, \frac{t+1}{4}], \\ g(4s - t - 1), & \text{if } s \in \left[\frac{t+1}{4}, \frac{t+2}{4}\right), \\ h\left(\frac{4s - 2 - t}{t+1}\right), & \text{if } s \in \left[\frac{t+2}{4}, 1\right] \end{cases} \end{cases}.$$

The same argument as in the proof of Lemma 114.22 (1) shows that the map $H$ is continuous. One can now easily verify that the map $H$ defines a homotopy between $(f, g, h) \mapsto \mu(f, g, h)$ and $(f, g) \mapsto \mu(f, \mu(g, h))$. We refer to Figure 1662 for an illustration.

\[\text{Figure 1662. Illustrations for the proofs of Lemma 121.10 (4) and (5).}\]

The loop space construction is so much fun that one might as well apply it several times. This leads us to the following notation:

**Notation.** Let $(X, x_0)$ be a pointed topological space. We define

$$\Omega^k(X, x_0) := \Omega \cdots \Omega\left( \Omega(X, x_0) \right)$$

where we apply the $\Omega$-functor $k$ times.

In Figure 1663, we do our best at illustrating a loop in the pointed topological space $(\Omega(X, x_0), c_{x_0})$. What should become apparent is that such a loop is basically the same as a map $([0, 1]^2, \partial[0, 1]^2) \to (X, x_0)$. The following proposition makes this idea precise.
Proposition 121.11. Let \((X, x_0)\) be a pointed topological space and let \(k \in \mathbb{N}\). The map

\[
\{ F \in X^{[0,1]^k} \mid F(\partial[0,1]^k) = \{x_0\} \} \rightarrow \Omega^k(X, x_0)
\]

is a homeomorphism.

Proof (*). To simplify the notation we only discuss the case \(k = 2\). The general case is treated the same way. We write \(I = J = [0,1]\). We start out with the following subtle observation:

(*) The inclusion \(\Omega(X, x_0) \rightarrow X^I\) induces a map \(\Omega(X, x_0)^J \rightarrow (X^I)^J\). By Lemma 5.5 (2) this map is an embedding. This means that it is legitimate to view the topological space \(\Omega(\Omega(X, x_0), c_{x_0})\) as a subspace of \((X^I)^J\).

This preamble implies that it suffices to show that the map

\[
\Phi: \{ F \in X^I \times J \mid F(\partial(I \times J)) = \{x_0\} \} \rightarrow \Omega(\Omega(X, x_0), c_{x_0}) \subset (X^I)^J
\]

\[
F \mapsto \left( \begin{array}{c}
J \rightarrow \Omega(X, x_0) \subset X^I \\
t \mapsto \left( \begin{array}{c}
I \rightarrow X \\
s \mapsto F(s,t) \end{array} \right) \end{array} \right)
\]

is a homeomorphism. First note that the map \(\Phi\) is, basically by definition, a bijection. Next note that \(\Phi\) is a restriction of the map

\[
\Psi: X^I \times J \rightarrow (X^I)^J
\]

\[
(F: I \times J \rightarrow X) \mapsto \left( \begin{array}{c}
J \rightarrow X^I \\
t \mapsto \left( \begin{array}{c}
I \rightarrow F(s,t) \end{array} \right) \end{array} \right)
\]

But it follows from the intricate Proposition 5.7 and the fact that \(I = J = [0,1]\) are regionally compact and Hausdorff, that the map \(\Psi\) is a homeomorphism. Thus we have shown that our original map \(\Phi\) is also a homeomorphism. 

Now let us turn towards the suspension operation. Given a pointed topological space \((X, x_0)\) ideally we would like to equip the suspension \(\Sigma(X)\) with a base point in a “systematic” way. The obvious idea is to fix some \(t \in [-1,1]\) once and for all and to equip every suspension \(\Sigma(X)\) with the base point represented by \([x_0, t]\). As we will see later on, we really really want the pinching map to be a map of pointed topological spaces. But if one thinks about it, and if one keeps an eye on Figure 1664, one see that for every single choice
of fixed \( t \) the pinching map (and note that for the wedge operation we also have to use our specified base points) will fail to be base point preserving.

![Diagram](image)

**Figure 1664**

There is a rather “brutal” solution to the dilemma: We solve the conundrum of which \([ (x_0, t) ] \) to choose by declaring all these points to be the same. More precisely, we consider the following modified version of the suspension.

*Definition.* Given a pointed topological space \((X, x_0)\) we defined the *reduced suspension* of \((X, x_0)\) to be the topological space \(S(X, x_0) := \Sigma(X)/\{x_0\} \times [-1, 1]\) \(\uparrow\) strictly speaking we are using Lemma 3.28 (1)

\[S(X, x_0) := \Sigma(X)/\{x_0\} \times [-1, 1] = (X \times [-1, 1])/(X \times \{1\} \cup \{x_0\} \times [-1, 1]).\]

We always equip \(S(X, x_0)\) with the base point \(s_{x_0} := [\{x_0\} \times [-1, 1]]\). We refer to Figure 1665 for an illustration.

![Diagram](image)

**Figure 1665**

The following lemma summarizes the key properties of the reduced suspension. The lemma can partly be viewed as the “pointed” version of the second part of Lemma 121.3.

**Lemma 121.12.**

\[^{1708}\text{Note that given a topological space } X \text{ we denote the usual suspension by } \Sigma(X) \text{ and given a pointed topological space we denote its reduced suspension by } S(X, x_0). \text{ Rather confusingly this notation is the opposite of the notation used in } \text{[Hat02].} \]
The maps

\[(X, x_0) \mapsto (S(X, x_0), s_{x_0})\]

\[f: (X, x_0) \rightarrow (Y, y_0) \mapsto \left( S(f): S(X, x_0) \rightarrow S(Y, y_0) \middle| [(x, t)] \mapsto [(f(x), t)] \right)\]

define a covariant functor from the category \(\mathcal{P}Hom_{\text{Top}}\) to itself.

The obvious projection map \(\Sigma(X) \rightarrow S(X, x_0)\) defines a natural transformation between the functors \((X, x_0) \mapsto \Sigma(X)\) and \((X, x_0) \mapsto S(X, x_0)\). In other words, in plain English, given a map \(f: (X, x_0) \rightarrow (Y, y_0)\) between pointed topological spaces the following diagram commutes:

\[
\begin{array}{ccc}
\Sigma(X) & \xrightarrow{\Sigma(f)} & \Sigma(Y) \\
\downarrow & & \downarrow \\
S(X, x_0) & \xrightarrow{S(f)} & S(Y, y_0).
\end{array}
\]

Given any pointed topological space \((X, x_0)\) the pinching map

\[\omega: S(X, x_0) \rightarrow S(X, x_0) \lor S(X, x_0)\]

\[[(x, t)] \mapsto \begin{cases} 
[(x, 2t + 1)] \text{ in the first term,} & \text{if } t \in [-1, 0], \\
[(x, 2t - 1)] \text{ in the second term,} & \text{if } t \in [0, 1].
\end{cases}\]

is continuous and base point preserving.

If \((X, x_0)\) is a pointed CW-complex, then the following two statements hold:

(a) The reduced suspension \(S(X, x_0)\) has a natural CW-structure such that the obvious projection map \(\Sigma(X) \rightarrow S(X, x_0)\) is a cellular map and such that \(\{s_{x_0}\}\) is a 0-cell. In particular \((S(X, x_0), s_{x_0})\) is a pointed CW-complex.

(b) Given any \(t \in [-1, 1]\) the projection map \(\Sigma(X) \rightarrow S(X, x_0)\) is a homotopy equivalence of the pointed topological spaces \((\Sigma(X), [(x_0, t)]) \rightarrow (S(X, x_0), s_{x_0})\).

Convention. Given a pointed CW-complex \((X, x_0)\) we always equip the reduced suspension \(S(X, x_0)\) with the CW-structure coming from Lemma 121.12 (4a).

Proof.

(1) The first statement is proved basically the same way as we proved Lemma 24.4. Note that the proof of the statement that if \(f, g: (X, x_0) \rightarrow (Y, y_0)\) are homotopic implies that \(S(f), S(g)\) are homotopic is somewhat delicate, see the proof of Lemma 24.4 (4).

(2) This statement follows almost immediately from the definitions.

(3) This statement follows easily from Lemma 3.22.

(4) The last statement is slightly more subtle. We proceed as follows:

(a) By Proposition 36.23 (3b) we can equip \(X \times [-1, 1]\) with the product CW-structure.

(b) As Corollary 36.35 we equip the suspension \(\Sigma(X) = (X \times [-1, 1])/\sim\) with the quotient CW-structure.

\footnote{It follows from Lemma 3.22 that the map \(S(f)\) is actually continuous.}
(c) This CW-structure has the property that the image of \( \{x_0\} \times [-1, 1] \) in \( \Sigma(X) \) is a subcomplex which we now denote by \( A \).

(d) It follows from Lemma [36.32] that the quotient \( \Sigma(X)/A = S(X, x_0) \) admits a natural CW-structure which has the convenient property that the projection map \( \Sigma(X) \to \Sigma(X)/A = S(X, x_0) \) is cellular and which has the property that \( s_{x_0} \) is a 0-cell.

By Theorem [39.1] we know that the inclusion map \( i: A \to X \) is a cofibration. Since \( [(x_0, t)] \) is a deformation retract of \( A \) we obtain from Lemma [39.9] (3) that the obvious projection map \( \Sigma(X) \to S(X, x_0) \) is a homotopy equivalence of the pointed topological spaces \( (\Sigma(X), [(x_0, t)]) \to (S(X, x_0), s_{x_0}) \).

The following innocuous looking proposition is one of the main building stones for the subsequent discussion.

**Proposition 121.13.** Let \((X, x_0)\) and \((Y, y_0)\) be pointed topological spaces. The map

\[
\mathfrak{T}: \langle (S(X, x_0), s_{x_0}), (Y, y_0) \rangle \to \langle (X, x_0), (\Omega(Y), y_0), c_{y_0} \rangle
\]

\[
\begin{bmatrix}
S(X, x_0) & \to & Y \\
([x, t]) & \mapsto & f([(x, t)])
\end{bmatrix}
\]

is a bijection. Furthermore this bijection is natural in \((X, x_0)\) and \((Y, y_0)\).\(^{1710}\)

**Remark.** Recall that we denote by \( \mathcal{PHomTop} \) the pointed homotopy category that we introduced on page 2849. In the language of the definition on page 2673 the proposition says that the functors

\[
F: \mathcal{PHomTop} \to \mathcal{PHomTop}
\]

which are defined by

\[
(X, x_0) \mapsto S(X, x_0)
\]

\[
[f] \mapsto [S(f)]
\]

and

\[
G: \mathcal{PHomTop} \to \mathcal{PHomTop}
\]

\[
(X, x_0) \mapsto \Omega(X, x_0)
\]

\[
[f] \mapsto [\Omega(f)]
\]

are adjoint.

\(^{1710}\)Put somewhat more precisely: if we are given a pointed topological space \((Y, y_0)\), then the two maps

\[
(X, x_0) \mapsto \langle (S(X, x_0), s_{x_0}), (Y, y_0) \rangle \quad \text{and} \quad (X, x_0) \mapsto \langle (X, x_0), (\Omega(Y), y_0), c_{y_0} \rangle
\]

define contravariant functors from the category of pointed topological spaces to the category of sets. The map \( \mathfrak{T} \) defines a natural isomorphism between these two functors. The analogous statement holds with the roles of \((X, x_0)\) and \((Y, y_0)\) reversed.
Proof. Let \((X, x_0)\) and \((Y, y_0)\) be pointed topological spaces. First we consider the map

\[
\begin{align*}
\{\text{set of maps } X \times [-1, 1] \to Y\} & \to \{\text{set of maps } X \to Y^{[0,1]}\} \\
(f: X \times [-1, 1] \to Y) & \mapsto \left( \begin{array}{c}
X \to Y^{[0,1]} \\
x \mapsto \left( [0,1] \to Y \\
t \mapsto f(x, 2t - 1) \right) \end{array} \right).
\end{align*}
\]

It follows from Proposition 5.6 and the fact that \([0, 1] \cong [-1, 1]\) is regionally compact that this map is well-defined\(^{1711}\) and that it is a bijection. Using Lemma 3.24 it is not hard to see that the given map induces a bijection

\[
\{\text{set of maps } (S(X, x_0), s_{x_0}) \to (Y, y_0)\} \to \{\text{set of maps } (X, x_0) \to (\Omega(Y, y_0), c_{y_0})\}.
\]

Basically the same approach also deals with homotopies. More precisely, it follows from Proposition 5.6 and the fact that \([0, 1] \cong [-1, 1]\) is regionally compact that the obvious map

\[
Y([-1,1] \times (X \times [0,1])) \to (Y^{[0,1]} \times [0,1])
\]

is a bijection. Using Proposition 18.20 one can now show that this bijection induces a bijection between homotopies of maps \((S(X, x_0), s_{x_0}) \to (Y, y_0)\) and homotopies of maps \((X, x_0) \to (\Omega(Y, y_0), c_{y_0})\). In summary this shows that the map

\[
\Upsilon: \langle (S(X, x_0), s_{x_0}), (Y, y_0) \rangle \to \langle (X, x_0), (\Omega(Y, y_0), c_{y_0}) \rangle
\]

is indeed a bijection. We leave it to the reader to fill in the details.

Finally we point out that it follows immediately from the definitions that \(\Upsilon\) is natural in \((X, x_0)\) and \((Y, y_0)\). \(\blacksquare\)

121.3. Eilenberg-Maclane spaces give rise to invariants of topological spaces.

Ideally we prefer to work, for as long as possible, with CW-complexes. Alas not all interesting constructions of new topological spaces necessarily turn CW-complexes into CW-complexes. For example, if \((X, x_0)\) is a pointed CW-complex it is not clear whether the loop space \(\Omega(X, x_0)\) is again a CW-complex\(^{1712}\).

This leads us to the following definition.

**Definition.** We denote by \(\mathcal{W}\) the class of all pointed topological spaces \((X, x_0)\) such that there exists a pointed CW-complex \((Y, y_0)\) which is homotopy equivalent to \((Y, y_0)\).

The following theorem was first proved by Milnor in 1958.

**Theorem 121.14.** If \((X, x_0) \in \mathcal{W}\), then for any \(k \in \mathbb{N}\) the iterated loop space \(\Omega^k(X, x_0)\) also lies in \(\mathcal{W}\).

\(^{1711}\)Here “well-defined” means that the map \(X \to Y^{[0,1]}\) that we associate to \(f: X \times [-1, 1] \to Y\) is indeed continuous.

\(^{1712}\)I could not find an example where \(\Omega(X, x_0)\) does not admit a CW-structure and I could not find a theorem that says that \(\Omega(X, x_0)\) always admits a CW-structure.
If \((X, x_0)\) is a pointed CW-complex, then \cite[Corollary 3]{Mil59} implies that the pointed topological space \((\Omega(X, x_0), c_{x_0})\) lies in \(\mathcal{W}\). (Alternatively we refer to \cite[Corollary 5.3.7]{FrPi90a} for a proof of a very similar statement.) More generally, if \((X, x_0)\) is an Eilenberg-Maclane space, then it follows from Lemma 5.5 (5) and the above that \((\Omega(X, x_0), c_{x_0})\) again lies in \(\mathcal{W}\). Iterating this argument we also obtain the statement for every \(k \geq 2\).

This leads us to the following definition:

**Definition.** Let \(n \in \mathbb{N}\) and let \(G\) be an (abelian) group\footnote{As explained in Footnote \ref{footnote1692}, whenever we deal with Eilenberg-Maclane spaces of type \(K(\pi, n)\) with \(n \geq 2\) it is understood that \(\pi\) is abelian.}.

1. A weak pointed Eilenberg-Maclane space of type \(K(G, n)\) is a pair \((X, x_0)\) such that for any \(i \neq n\) we have \(\pi_i(X, x_0) = 0\) and such that \(\pi_n(X, x_0) \cong G\).
2. A polarized Eilenberg-Maclane space\footnote{Our language now allows for the slightly awkward possibility that a polarized Eilenberg-Maclane space is not an Eilenberg-Maclane space since the underlying topological space might not be a CW-complex. We are confident though that this will not become an issue.} of type \(K(G, n)\) is a triple \((X, x_0, \alpha)\) where \((X, x_0)\) is a weak pointed Eilenberg-Maclane space of type \(K(G, n)\) and \(\alpha\) is an isomorphism \(\pi_n(X, x_0) \xrightarrow{\cong} G\).

**Examples.**

1. We equip \(S^1\) with the base point \(* = (1, 0)\). Let \(\varphi : \pi_1(S^1, *) \xrightarrow{\cong} \mathbb{Z}\) be the standard isomorphism from page \ref{page1068}. We see that \((S^1, *, \varphi)\) is a polarized Eilenberg-Maclane space of type \(K(\mathbb{Z}, 1)\).
2. We equip \(\mathbb{C}P^\infty\) with the base point \(* = [1 : 0 : 0 : \ldots]\). Let \(\psi : \pi_2(\mathbb{C}P^\infty, *) \xrightarrow{\cong} \mathbb{Z}\) be the usual isomorphism from Theorem \ref{thm113.12} (2). We see that \((\mathbb{C}P^\infty, *, \psi)\) is a polarized Eilenberg-Maclane space of type \(K(\mathbb{Z}, 2)\).

Now we turn to more general constructions of polarized Eilenberg-Maclane spaces.
The discussion above shows that given any \( k \in \mathbb{N}_0 \) we can and will view \( \Omega^k(K(G, n + k)) \) as a polarized Eilenberg-Maclane of type \( K(G, n) \).

The following lemma shows that in the based homotopy category all polarized Eilenberg-Maclane spaces of a given type are essentially the same.

**Lemma 121.15.** Let \((K, k_0, \varphi)\) and \((L, l_0, \psi)\) be two polarized Eilenberg-Maclane spaces of the same type. There exists a unique class \( \Xi = (K, k_0, (L, l_0)) \in \langle (K, k_0), (L, l_0) \rangle_{\text{inv}} \) such that the induced map \( \Xi_*: \pi_n(K, k_0) \to \pi_n(L, l_0) \) agrees with \( \psi^{-1} \circ \varphi. \) When there is no danger of confusion we just write \( \Xi = \Xi_{(K, k_0), (L, l_0)} \).

**Proof.** Let \( n \in \mathbb{N} \), let \( G \) be an (abelian) group and let \((K, k_0, \varphi)\) and \((L, l_0, \psi)\) be two polarized Eilenberg-Maclane spaces of type \( K(G, n) \). Since \((K, k_0)\) and \((L, l_0)\) lie in \( \mathcal{W} \) we know that there exist pointed CW-complexes \((X, x_0)\) and \((Y, y_0)\) together with homotopy equivalences \( \kappa: (X, x_0) \to (K, k_0) \) and \( \lambda: (Y, y_0) \to (L, l_0) \) of pointed topological spaces. We consider the following diagram

\[
\begin{array}{c}
\langle (K, k_0), (L, l_0) \rangle_{\text{inv}} \\
\downarrow \kappa^* \\
\langle (X, x_0), (L, l_0) \rangle_{\text{inv}} \\
\downarrow \lambda_* \\
\langle (X, x_0), (Y, y_0) \rangle_{\text{inv}} \\
\end{array}
\]

\[
\xrightarrow{[f] \to f_*} \xrightarrow{[f] \to f_*} \xrightarrow{[f] \to f_*} \xrightarrow{[f] \to f_*}
\]

\[
\begin{array}{c}
\Hom(\pi_n(K, k_0), \pi_n(L, l_0)) \\
\downarrow \kappa^* \\
\Hom(\pi_n(X, x_0), \pi_n(L, l_0)) \\
\downarrow \lambda_* \\
\Hom(\pi_n(X, x_0), \pi_n(Y, y_0)).
\end{array}
\]

It follows almost immediately from the definitions that this diagram commutes. We obtain from Lemmas [121.6 and [15.1] that the vertical maps to the left are bijections. Furthermore we obtain from Proposition [40.7] that the vertical maps to the right are bijections. It follows from Theorem [120.12] and Proposition [120.13] that any isomorphism in \( \Hom(\pi_n(X, x_0), \pi_n(Y, y_0)) \) is realized by a unique element in \( \langle (X, x_0), (Y, y_0) \rangle_{\text{inv}} \). By the diagram this information propagates to the top. \hfill \blacksquare

**Notation.** Let \( n \in \mathbb{N} \), let \( G \) be an abelian group and let \( k \in \mathbb{N}_0 \). From the discussion on page 2859 and Lemma 121.15 we obtain a canonical element \( \Xi = (K(G, n), \Omega^k K(G, n + k)) \) viewed as a pointed topological space. By Lemma 15.1 we know that the map

\[
\Xi_*: \langle (X, x_0), K(G, n) \rangle \to \langle (X, x_0), \Omega^k K(G, n + k) \rangle \quad [g] \mapsto \Xi \circ [g]
\]

is a bijection. Sometimes we use the bijection \( \Xi_* \) to identify the left-hand side with the right-hand side. We make the analogous identification if \((X, x_0)\) is the target instead of the domain.

We formulate the next example as a lemma. Since we will not directly make use of it we take a few liberties in its formulation.

\footnote{To lessen the burden on the reader’s eyes we do not include \( \varphi \) and \( \psi \) in the notation.}
Lemma 121.16. We equip \( S^1 \) with the base point \( * = (1, 0) \) and we equip \( \mathbb{C}P^\infty \) with the base point \([1: 0: 0: \ldots]\). As on page 2859 we consider the polarized Eilenberg-Maclane spaces \((S^1, *, \varphi)\) of type \( K(\mathbb{Z}, 1) \) and we consider the polarized Eilenberg-Maclane space \((\mathbb{C}P^\infty, *, \psi)\) of type \( K(\mathbb{Z}, 2) \). We have the following homeomorphisms and inclusions maps

\[
[0, 1]^2 / \partial[0, 1]^2 \xrightarrow{\cong} B^2 / S^1 \xrightarrow{\cong} S^2 \xrightarrow{\cong} \mathbb{C}P^1 \hookrightarrow \mathbb{C}P^\infty.
\]

We use these maps to view \([0, 1]^2 / \partial([0, 1]^2)\) as a subset of \( \mathbb{C}P^\infty \). The map

\[
\Xi: S^1 \rightarrow \Omega(\mathbb{C}P^\infty, *)
\]

\[
e^{is} \mapsto \left( [0, 1] \mapsto \frac{[0, 1]^2 / \partial([0, 1]^2) \subset \mathbb{C}P^\infty}{((s, t)}
\]

represents the class \( \Xi \in \langle (S^1, *), \Omega(\mathbb{C}P^\infty, *) \rangle \) given by Lemma 121.15.

**Figure 1667.** Illustration of Lemma 121.16.

**Proof.** Let \( i: [0, 1]^2 / \partial([0, 1]^2) \rightarrow \mathbb{C}P^\infty \) be the above inclusion map. It follows immediately from the definition of \( \Xi: S^1 \rightarrow \Omega(\mathbb{C}P^\infty, *) \) that the map \( \Xi \) factors through a map \( \eta: S^1 \rightarrow \Omega([0, 1]^2 / \partial([0, 1]^2), *) \). We consider the following diagram:

\[
\begin{array}{ccc}
\pi_2([0, 1]^2 / \partial([0, 1]^2), *) & \xrightarrow{\partial_2} & \pi_1(\Omega([0, 1]^2 / \partial([0, 1]^2), *)) \\
\downarrow{\cong} \quad \downarrow{\cong} \\
\pi_2(\mathbb{C}P^\infty, *) & \xrightarrow{\partial_2} & \pi_1(\Omega(\mathbb{C}P^\infty, *)) \\
\end{array}
\]

We make the following observations:

1. The horizontal maps are defined in Corollary 112.15. Furthermore note that Corollary 112.15 tells us that the horizontal maps are isomorphisms and that the square commutes.

2. The triangle commutes since \( \Xi = \Omega(i) \circ \eta \).

3. The left-hand vertical map is an isomorphism by Corollary 53.6.

4. By Corollary 53.6 we know that \( \pi_2([0, 1]^2 / \partial([0, 1]^2), *) = \mathbb{Z} \cdot \text{id}_{[0, 1]^2} \) and by Proposition 16.17 (1) we know that \( \pi_1(S^1, *) = \mathbb{Z} \cdot \text{id}_{[0, 1]} \).

5. It follows easily from the definition of \( \partial_2 \), see Corollary 112.15, that \( \partial_2 \) and \( \eta_* \) send their respective generators to the same element in \( \pi_1(\Omega([0, 1]^2 / \partial([0, 1]^2), *)) \). Since

\[\text{Note that by the definition of the above maps the point } \partial([0, 1]^2) \text{ corresponds to the point } * = [1: 0: 0: \ldots] \in \mathbb{C}P^\infty.\]
all groups are isomorphic to $\mathbb{Z}$ and since $\partial_2$ is an isomorphism we see that $\eta_*$ is an isomorphism.

(6) We obtain from the above data that $\Xi_*$ is an isomorphism. It is now basically clear that $\Xi$ represents the desired element in $\langle (S^1, \ast), \Omega(\mathbb{C}P^\infty, \ast) \rangle$. \hfill $\blacksquare$

So far it seems like we have been rambling. But the following amazing definition puts us finally on an interesting track.

Definition. Let $n \in \mathbb{N}$ and let $G$ be an abelian group. Furthermore let $X = (X, x_0)$ be a pointed topological space. To simplify the notation we suppress the base point $x_0$ throughout the subsequent discussion. We refer to the following map as the multiplication map on $\langle X, K(G, n) \rangle$:

$$\langle X, K(G, n) \rangle \times \langle X, K(G, n) \rangle \xrightarrow{\downarrow \chi \text{ from Lemma 121.7}} \langle X, \Omega K(G, n+1) \rangle \times \langle X, \Omega K(G, n+1) \rangle \xrightarrow{\downarrow \mu_* \text{ defined on page 2851}} \langle X, \Omega K(G, n+1) \rangle = \langle X, K(G, n) \rangle.$$ \uparrow

since $G$ is abelian the Eilenberg-Maclane space $\Omega K(G, n+1)$ exists for every $n$ thus we can use the identification $\Xi_*$, from page 2860

Remark.

(1) It is worth stressing what we just did. In the definition of the multiplication on $\langle (X, x_0), K(G, n) \rangle$ we used two essential facts:

(a) We could replace $K(G, n)$ by the loop space $\Omega K(G, n+1)$.

(b) The loop space $\Omega K(G, n+1)$ comes with a multiplication.

Later on we will use these two ideas in a more general context.

(2) It is perhaps worth pointing out that in general topological spaces are not even homotopy equivalent to loop spaces. For example we know by Lemma 114.22 together with Theorem 114.21, the discussion on page 2720 and Exercise 114.8 that $S^n$ with $n \neq 1, 3, 7$ and $\mathbb{C}P^n$ with $n \in \mathbb{N}$ are not homotopy equivalent to loop spaces.

The following proposition says that the above definition is actually meaningful.

Proposition 121.17. Let $n \in \mathbb{N}$, let $G$ be an abelian group and let $(X, x_0)$ be a pointed topological space. The above multiplication turns the set $\langle (X, x_0), K(G, n) \rangle$ into a group. Furthermore the neutral element of the group $\langle (X, x_0), K(G, n) \rangle$ is given, not surprisingly, by $0$.

---

1717 It is though essential that all maps we consider are in fact base point preserving. In particular, recall that $K(G, n)$ and $\Omega K(G, n)$ are pointed topological spaces.

1718 Recall that on page 2849 we defined $0 \in \langle (X, x_0), (Y, y_0) \rangle$ to be the class that is represented by the constant map $X \to Y$, $x \mapsto y_0$. 
Proof. Let \( n \in \mathbb{N} \), let \( G \) be an abelian group and let \((X, x_0)\) be a pointed topological space. Recall that we have the identification

\[
\Xi_* : \langle (X, x_0), K(G, n) \rangle = \langle (X, x_0), \Omega K(G, n + 1) \rangle
\]

from page 2860. Note that \( \Xi_*(0) = 0 \). Thus the proposition follows from the next lemma. ■

Lemma 121.18. Let \((K, k_0)\) be a pointed topological space. The map

\[
\langle (X, x_0), \Omega(K, k_0) \rangle \times \langle (X, x_0), \Omega(K, k_0) \rangle \quad \mu_\ast \\
\langle (X, x_0), \Omega(K, k_0) \rangle
\]

defines a group structure. The group structure has the following properties:

1. The neutral element is given by 0.
2. We consider the map \( \eta : \Omega(K, k_0) \to \Omega(K, k_0) \)

\[
f \mapsto \overline{f}.
\]

The inverse of \([f] \in \langle (X, x_0), \Omega(K, k_0) \rangle\) is given by \( \eta_*([f]) \).

Proof. As we will see shortly, this statement follows fairly easily from Lemma 121.10. In particular we will see that the statements have precisely little to do with \((X, x_0)\). In an effort to lighten the notation we henceforth write \( X \) instead of the more accurate \((X, x_0)\) and similarly we write \( K \) instead of \((K, k_0)\). This time we denote by \( c \in \Omega K \) the constant path at \( k_0 \in K \). We consider the maps

\[
\rho : \Omega K \to \Omega K \times \Omega K, \quad \lambda : \Omega K \to \Omega K \times \Omega K, \quad \sigma : \Omega K \to \Omega K \times \Omega K
\]

\[
f \mapsto (f, c), \quad f \mapsto (c, f), \quad f \mapsto (f, \overline{f}).
\]

Now we turn to the actual proofs of the various statements.

1. Let us first show that \( 0 = [c] \) is a neutral element in \( \langle X, \Omega K \rangle \). We consider the following diagram

\[
\begin{array}{ccc}
\langle X, \Omega K \rangle & \xrightarrow{[f] \mapsto ([f], [c])} & \langle X, \Omega K \rangle \times \langle X, \Omega K \rangle \\
\rho_* & \downarrow \chi & \downarrow \mu_* \\
\langle X, \Omega K \times \Omega K \rangle & \xrightarrow{\text{multiplication}} & \langle X, \Omega K \rangle
\end{array}
\]

\[\text{In Lemma 121.10 (3) we showed that } \eta \text{ is continuous.}\]
The upper triangle commutes basically by definition of the maps. Now let us turn to the lower triangle. It follows from Lemma 121.10 (2) that the map $\mu \circ \rho : \Omega K \to \Omega K$ is homotopic to the identity rel the base point. In other words, we have the equality $[\mu \circ \rho] = [\operatorname{id}] \in (\Omega K, \Omega K)$. Thus it follows, if you want from Lemma 15.3 that the triangle does indeed commute.

Now we start out with $[f] \in \langle X, \Omega K \rangle$ at the top left. Since going right-down is precisely right-multiplication by $[c] = 0$ we see that 0 is indeed a right-neutral element with respect to the product structure. Basically the same argument, with $\rho$ replaced by $\lambda$ shows that 0 is also a left-neutral element.

(2) We consider the following diagram:

$$
\begin{array}{ccc}
\langle X, \Omega K \rangle & \xrightarrow{[f] \to ([f], \eta_*([f]))} & \langle X, \Omega K \rangle \times \langle X, \Omega K \rangle \\
& \sigma_* \downarrow & \downarrow \chi \\
& \langle X, \Omega K \times \Omega K \rangle & \mu_* \\
& \downarrow & \downarrow \\
& \langle X, \Omega K \rangle.
\end{array}
$$

As in (1) we obtain from Lemma 121.10 (4) that the diagram commutes. It follows that $\eta_*([f])$ is a right-inverse to $[f]$. The same argument shows that it is also a left-inverse to $[f]$.

(3) Using Lemma 121.10 (5) one can show, with the same approach as above, that the product structure on $\langle X, \Omega K \rangle$ is associative. Filling in the details is the content of Exercise 121.3.

The reader of the previous proof might ask the following question:

**Question 121.19.** Why do we actually consider the sets $\langle (X, x_0), K(G, n) \rangle$ instead of the sets $\langle (X, x_0), \Omega K(G, n+1) \rangle$? After all, we just showed that the group structure is really defined on the latter set.

The group structure on $\langle (X, x_0), K(G, n) \rangle$ is certainly rather mysterious. The following lemma hopefully elucidates the group structure in the case $K(Z, 1)$.

**Lemma 121.20.** Let $\Xi : S^1 \to \Omega(\mathbb{C}P^\infty, \ast)$ be the homotopy equivalence defined in Lemma 121.16. Given any topological space $X$ we have the following commutative diagram where the horizontal maps are bijections:

$$
\begin{array}{ccc}
[X, S^1] \times [X, S^1] & \xrightarrow{\Xi_* \times \Xi_*} & [X, \Omega \mathbb{C}P^\infty] \times [X, \Omega \mathbb{C}P^\infty] \\
\downarrow \nu & & \downarrow \mu_* \\
[X, S^1] & \xrightarrow{\Xi_*} & [X, \Omega \mathbb{C}P^\infty].
\end{array}
$$

Here the left vertical map is given by Lemma 121.4.
Proof. The statement of the lemma has nothing to do with $X$. In fact, it suffices to show that the following map agrees up to homotopy:

$$
\begin{array}{ccc}
S^1 \times S^1 & \xrightarrow{\Xi \times \Xi} & (\Omega \mathbb{C}P^\infty, \ast) \times (\Omega \mathbb{C}P^\infty, \ast) \\
\downarrow (z,w) \mapsto z \cdot w & & \downarrow \mu \\
S^1 & \xrightarrow{\Xi} & \Omega(\mathbb{C}P^\infty, \ast).
\end{array}
$$

We outsource this verification to Exercise [121.1].

Perhaps the first question that arises when we introduce a group is whether the group abelian. It turns out that in this case we can answer this question in the affirmative.

**Proposition 121.21.** Let $n \in \mathbb{N}$ and let $G$ be an abelian group. For every pointed topological space $(X, x_0)$ the group $\langle (X, x_0), K(G, n) \rangle$ is abelian.

**Proof.** Let $n \in \mathbb{N}$ and let $G$ be an abelian group. We write $L = K(G, n + 1)$ and we write $M = K(G, n + 2)$. Finally let $(X, x_0)$ be a pointed topological space. We make the following preparations.

(1) By the discussion on page 2859 we know that $K(G, n), \Omega L$ and $\Omega(\Omega M)$ are polarized Eilenberg-Maclane spaces of type $K(G, n)$. Thus we obtain from Lemma 121.15 homotopy equivalences $f: (K(G, n), \ast) \to (\Omega L, \ast)$ and $g: (\Omega L, \ast) \to (\Omega(\Omega M), \ast)$.

(2) We define

$$
\square M := \{ f: [0, 1]^2 \to M \mid f(\partial[0, 1]^2) = \{\ast\}\}.
$$

As always we equip $\square M$ with the compact-open topology. Furthermore let

$$
\Theta: \square M \to \Omega(\Omega M) \\
(f: [0, 1]^2 \to M) \mapsto (t \mapsto (s \mapsto f(s, t)))
$$

be the homeomorphism from Proposition 121.11.

(3) We consider the map

$$
\alpha: \square M \times \square M \to \square M \\
(f, g) \mapsto \begin{cases}
[0, 1]^2 & \to M \\
(s, t) & \mapsto \begin{cases}
f(s, 2t), & \text{if } t \in [0, \frac{1}{2}], \\
g(s, 2t - 1), & \text{if } t \in (\frac{1}{2}, 1]
\end{cases}
\end{cases}.
$$

The same argument as in the proof of Lemma 114.22 (1) shows that $\alpha$ is continuous.

(4) Since the pointed topological space $(X, x_0)$ is really just a bystander we will abbreviate it to $X$.

Some of the above objects are illustrated in Figure 1668.

**Claim.** The following diagram commutes:

$$
\begin{array}{ccc}
\langle X, K(G, n) \rangle \times \langle X, K(G, n) \rangle & \xrightarrow{\text{group multiplication}} & \langle X, K(G, n) \rangle \\
\downarrow (\Theta^{-1} \circ g)_{\ast} \times (\Theta^{-1} \circ g)_{\ast} & & \downarrow (\Theta^{-1} \circ g)_{\ast} \\
\langle X, \square M \rangle \times \langle X, \square M \rangle & \xrightarrow{\chi} & \langle X, \square M \times \square M \rangle \\
\downarrow \alpha_{\ast} & & \downarrow \alpha_{\ast} \\
\langle X, \square M \rangle & & \langle X, \square M \rangle.
\end{array}
$$
Furthermore the vertical maps are bijections.

To show that the above diagram commutes we expand it into an even larger diagram. More precisely, we consider the following diagram:

\[
\begin{array}{ccc}
\langle X, K(G, n) \rangle \times \langle X, K(G, n) \rangle & \xrightarrow{\text{group multiplication}} & \langle X, K(G, n) \rangle \\
\downarrow f \times f & & \downarrow f \\
\langle X, \Omega L \rangle \times \langle X, \Omega L \rangle & \xrightarrow{\chi} & \langle X, \Omega L \times \Omega L \rangle \\
\downarrow g \times g & & \downarrow (g \times g) \\
\langle X, \Omega(\Omega M) \rangle \times \langle X, \Omega(\Omega M) \rangle & \xrightarrow{\chi} & \langle X, \Omega(\Omega M) \times \Omega(\Omega M) \rangle \\
\downarrow \theta^{-1} \times \theta^{-1} & & \downarrow (\theta^{-1} \times \theta^{-1}) \\
\langle X, \Box M \rangle \times \langle X, \Box M \rangle & \xrightarrow{\chi} & \langle X, \Box M \times \Box M \rangle \\
\downarrow \alpha & & \downarrow \alpha \\
\end{array}
\]

We make the following observations:

1. By Lemma 15.1 we know that the vertical maps between the first and second and between the second and the third row are bijections.
2. Since $\Theta$ is a homeomorphism we see that the bottom vertical maps are also bijections.
3. By definition of the group multiplication on $\langle X, K(G, n) \rangle$ the top rectangle commutes.
4. It follows immediately from the definition of $\chi$ that the two smaller rectangles on the left commute.
5. It follows from Lemma 121.10 (1) that the middle right rectangle commutes.
6. It follows immediately from the definition of the maps $\mu$, $\alpha$ and $\Theta$ that

\[\alpha \circ (\Theta \times \Theta) = \Theta \circ \mu : \Omega(\Omega M) \times \Omega(\Omega M) \to \Box M.\]

This equality implies that the lower right rectangle commutes. \qed

The claim can be summarized as saying that it suffices to show that the bottom multiplication map on $\langle X, \Box M \rangle$ is commutative. Next we consider the swap map

\[\sigma : \Box M \times \Box M \to \Box M \times \Box M \quad (f, g) \mapsto (g, f).\]
We obtain the following diagram:

\[
\begin{array}{ccc}
\langle X, \square M \rangle \times \langle X, \square M \rangle & \xrightarrow{\chi} & \langle X, \square M \times \square M \rangle \\
\downarrow (a,b) \mapsto (b,a) & \quad & \downarrow \sigma_* \\
\langle X, \square M \rangle \times \langle X, \square M \rangle & \xrightarrow{\alpha_*} & \langle X, \square M \rangle
\end{array}
\]

We make the following observations:

1. The statement that the multiplication on \(\langle X, \square M \rangle\) is commutative is, by definition, equivalent to the statement that the large rectangle commutes.

2. It follows immediately from the definitions of the various maps that the smaller rectangle on the left commutes. Thus it suffices to show that the smaller rectangle on the right commutes.

In particular, since \(\alpha_* \circ \sigma_* = (\alpha \circ \sigma)_*\) it suffices to prove the following claim.\(^{1721}\)

**Claim.** The maps \(\alpha\) and \(\alpha \circ \sigma\) from the pointed topological space \(\square M \times \square M\) to the pointed topological space \(\square M\) are homotopic.

In Figure 1669 we indicate how one can define a homotopy from \(\alpha\) to \(\alpha \circ \sigma\). We leave it to the punctilious reader to write down a precise formula for a homotopy from \(\square M \times \square M\) to \(\square M\).

As in the proof of Lemma 121.10 one can use the “\(\Rightarrow\)”-direction of Proposition 5.6 to show that the map provided by the reader is actually continuous. \(\blacksquare\)

**Remark.** As the reader with a well-developed long-term memory will have noticed, the proof of Proposition 121.21 eventually is very similar to the proof of Proposition 40.3. In particular Figure 1669 looks almost the same as Figure 684.

121.4. **Alternative description of the group structure.** Once again let \(n \in \mathbb{N}\), let \(G\) be an abelian group and let \((X, x_0)\) be a pointed topological space. In this section we give an alternative description of the group structure on

\[
\langle (X, x_0), K(G, n) \rangle \xrightarrow{\xi} \langle (X, x_0), \Omega K(G, n + 1) \rangle \xrightarrow{\xi_*} \langle S(X, x_0), K(G, n + 1) \rangle.
\]

\(^{1720}\)Thus once again \(X\) plays no role in the argument.

\(^{1721}\)For example this could be done using the maps introduced in the proof of Lemma 40.2
Before we state the relevant proposition we recall some of the objects that we have introduced recently:

1. On page 2856 we introduced the pinching map

\[ \omega : S(X, x_0) \to S(X, x_0) \cup S(X, x_0) \]

where \( S(X, x_0) \) denotes the reduced suspension.

2. In Lemmas 121.7 and 121.8 we introduced the maps

\[ \chi : \langle (X, x_0), (Y, y_0) \rangle \times \langle (X, x_0), (Z, z_0) \rangle \to \langle (X, x_0), (Y \times Z, (y_0, z_0)) \rangle \]

\[ ([f : X \to Y], [g : X \to Z]) \mapsto [f \times g : X \to Y \times Z] \]

and

\[ \nu : \langle (X, x_0), (Z, z_0) \rangle \times \langle (Y, y_0), (Z, z_0) \rangle \to \langle (X, x_0) \cup (Y, y_0), (Z, z_0) \rangle \]

\[ ([f : X \to Z], [g : Y \to Z]) \mapsto [f \lor g] \]

The following proposition shows that instead of the map \( \mu \) on the loop space we can also use the pinching map on the reduced suspension to define the group structure.

**Proposition 121.22.** Let \((X, x_0)\) and \((K, k_0)\) be pointed topological spaces. The following diagram commutes:

\[
\begin{array}{ccc}
\langle (X, x_0), \Omega(K, k_0) \rangle \times \langle (X, x_0), \Omega(K, k_0) \rangle & \xrightarrow{\times \times} & \langle S(X, x_0), (K, k_0) \rangle \times \langle S(X, x_0), (K, k_0) \rangle \\
\downarrow{\chi} & & \downarrow{\nu} \\
\langle (X, x_0), \Omega(K, k_0) \times \Omega(K, k_0) \rangle & \xrightarrow{\mu \times} & \langle S(X, x_0) \cup S(X, x_0), (K, k_0) \rangle \\
\downarrow{\mu^*} & & \downarrow{\omega^*} \\
\langle (X, x_0), \Omega(K, k_0) \rangle & \xrightarrow{\gamma} & \langle S(X, x_0), (K, k_0) \rangle.
\end{array}
\]

**Remark.** The multiplication map on \( \langle S(X, x_0), (K, k_0) \rangle \) is arguably more geometric surely more appealing to some readers. Nonetheless, any attempt to prove that this multiplication map defines an (abelian) group structure promises to be notationally somewhat messy.

**Proof.** Let \( f, g : (X, x_0) \to \Omega(K, k_0) \) be two maps. One can easily verify that

\[
(\gamma \circ \mu^* \circ \chi)([f], [g]) = \begin{cases} 
S(X, x_0) \to (K, k_0) \\
([x, t]) \mapsto \begin{cases} 
f(t + 1), & \text{if } t \in [-1, 0], \\
g(t), & \text{if } t \in [0, 1]
\end{cases}
\end{cases} = (\omega^* \circ \nu)(\gamma([f]), \gamma([g])).
\]

This shows that the diagram does indeed commute.\[\blacksquare\]
121.5. **Functoriality.** Let \( n \in \mathbb{N} \). In this section we will see, perhaps not surprisingly, that the abelian groups \( \langle (X,x_0), K(G,n) \rangle \) are functorial in \( (X,x_0) \) and \( G \). To make this precise we need to introduce the following piece of notation.

**Definition.** Let \( n \in \mathbb{N} \) and let \( \varphi : G \to H \) be a homomorphism between two (abelian) groups. We denote by \([\varphi] \in \langle K(G,n), K(H,n) \rangle\) the canonical homotopy class of maps defined in Proposition 120.15.

We have the following lemma.

**Lemma 121.23.** Let \( n \in \mathbb{N} \). The maps

\[
G \mapsto K(G,n) \\
(\varphi : G \to H) \mapsto [\varphi] \in \langle K(G,n), K(H,n) \rangle
\]

define a covariant functor from the category of (abelian) groups to the pointed homotopy category.

**Proof.** The fact that the maps define a covariant functor is an immediate consequence of the uniqueness statement in Proposition 120.15.

If one thinks about this lemma for a second, then one realizes that this lemma is actually quite astounding. So far we spent almost all our time trying to define functors from topological spaces to (abelian) groups in the hope of being able to use algebra to understand topological spaces. But now we have functors which go the other way around. In principle this will allow us to use tools from topology to gain a better understanding of groups. In fact we already saw a glimpse of this phenomenon in Proposition 120.22. Unfortunately at this very moment we cannot develop this theme. But in Chapter ?? this idea will come back with a vengeance.

After this short digression we can formulate the following proposition.

**Proposition 121.24.** Let \( n \in \mathbb{N} \).

1. Let \( G \) be an abelian group. The maps

\[
(X,x_0) \mapsto \langle (X,x_0), K(G,n) \rangle \\
(f : (X,x_0) \to (Y,y_0)) \mapsto \left( \langle (Y,y_0), K(G,n) \rangle \mapsto \langle (X,x_0), K(G,n) \rangle \right)
\]

define a contravariant functor from the category of pointed topological spaces to the category of abelian groups.

2. Let \( (X,x_0) \) be a pointed topological space. The maps

\[
G \mapsto \langle (X,x_0), K(G,n) \rangle \\
(\varphi : G \to H) \mapsto \left( \langle (X,x_0), K(G,n) \rangle \mapsto \langle (X,x_0), K(H,n) \rangle \right)
\]

More precisely, by Proposition 120.15 there exists a unique \([f] \in \langle K(G,n), K(H,n) \rangle\) such that the map \( f_* : G = \pi_n(K(G,n)) \to \pi_n(K(H,n)) = H \) agrees with \( \varphi \). Here we used that the canonical Eilenberg-Maclane spaces \( K(J,n) \) are pointed and that they come with an identification \( \pi_n(K(J,n)) = J \).
define a covariant functor from the category of abelian groups to the category of abelian groups.

**Proof.** Let \( n \in \mathbb{N} \).

(1) We fix an abelian group \( G \). First note that it follows from Lemma 15.4 that the assignment \( (X, x_0) \mapsto \langle (X, x_0), K(G, n) \rangle \) is a contravariant functor from the category of pointed topological spaces to the category of sets. Thus it remains to show that this assignment defines actually a functor to the category of abelian groups. More precisely, it remains to show that for any map \( f \in \langle (X, x_0), (Y, y_0) \rangle \) the induced map \( \langle (Y, y_0), K(G, n) \rangle \to \langle (X, x_0), K(G, n) \rangle \) is actually a group homomorphism. But that is basically obvious since the above definition of the group structure on \( \langle (X, x_0), K(G, n) \rangle \) has nothing to do with \( X \). We leave it to the sceptical reader to fill in the details.

(2) Let \((X, x_0)\) be a pointed topological space. By Lemmas 15.3 and Lemma 121.23 we know that the assignment \( G \mapsto \langle (X, x_0), K(G, n) \rangle \) defines a covariant functor from the category of abelian groups to the category of sets. As in (1) it remains to show that the assignment actually defines a functor to the category of abelian groups. This requires a little more effort than (1). The argument breaks up into two parts, namely we have to deal with the “horizontal” and the “vertical” aspects of the definition on page 2862.

(a) Recall that in Corollary 112.15 we gave an explicit natural isomorphism

\[ \alpha_k: \pi_k(K, k_0) \cong \pi_{k-1}(\Omega(K, k_0), c_{x_0}) \quad \text{for every } k \in \mathbb{N}. \]

It follows from the naturality of these isomorphisms, and the precise definition of the maps \( \Xi \) on page 2860 that for a given homomorphism \( \varphi: G \to H \) of (abelian) groups we obtain a commutative diagram

\[ \begin{array}{ccc}
\langle (X, x_0), K(G, n) \rangle & \xrightarrow{\Xi_*} & \langle (X, x_0), \Omega K(G, n + 1) \rangle \\
\downarrow{\varphi_*} & & \downarrow{\varphi_*} \\
\langle (X, x_0), K(H, n) \rangle & \xrightarrow{\Xi_*} & \langle (X, x_0), \Omega K(H, n + 1) \rangle.
\end{array} \]

This takes care of the ‘horizontal’ part.

(b) It follows from Lemma 121.7, Lemma 121.10 (1) and Lemma 121.23 that the “vertical” part of the definition on page 2862 is functorial in \( \varphi \).

As the reader will know by now, base points are something of a nuisance. Fortunately in Proposition 38.7 we already saw that on many occasions we can stop worrying about base points, the following proposition nicely complements Proposition 38.7

**Proposition 121.25.** Let \((X, x_0)\) and \((Y, y_0)\) be two pointed CW-complexes. If \( Y \) is path-connected, if \( \pi_1(Y, y_0) \) is abelian and if \( \pi_i(Y, y_0) = 0 \) for \( i \geq 2 \), then the natural map \( \langle (X, x_0), (Y, y_0) \rangle \to [X, Y] \) is also a bijection.

\[ ^{1723} \text{In other words, } (Y, y_0) \text{ is a pointed Eilenberg-Maclane space of type } K(\pi, 1) \text{ where } \pi \cong \pi_1(Y, y_0) \text{ is an abelian group.} \]
Remark. We equip $S^1$, $S^2$ and $S^1 \vee S^2$ with the usual base point \(*\). In Exercise 121.2 we will show that the map $[(S^2, \ast), (S^1 \vee S^2, \ast)] \to [S^2, S^1 \vee S^2]$ is not an injection. This shows that in Proposition 121.25 we cannot just drop the hypothesis that $\pi_i(Y, y_0) = 0$ for $i \geq 2$.

Proof. Let $(Y, y_0)$ be a pointed path-connected CW-complex such that the fundamental group $\pi_1(Y, y_0)$ is abelian and such that $\pi_i(Y, y_0) = 0$ for $i \geq 2$. By Proposition 38.7 (1) it remains to show that the map $\langle (X, x_0), (Y, y_0) \rangle \to [X, Y]$ is injective. Despite initial appearances, the argument will be quite different from the argument provided in the proof of Proposition 38.7 (1) (2). So let $f_0, f_1: (X, x_0) \to (Y, y_0)$ be two maps that are homotopic as maps $X \to Y$. By Proposition 18.16 (1) we know that there exists a $\gamma \in \pi_1(Y, y_0)$ such that $f_0 \ast (g) = \gamma \cdot f_1 \ast (g) \cdot \gamma^{-1} \in \pi_1(Y, y_0)$ for every $g \in \pi_1(X, x_0)$. But since $\pi_1(Y, y_0)$ is abelian we see that $f_0 \ast = f_1 \ast$. Since by hypothesis we have $\pi_i(Y, y_0) = 0$ for $i \geq 2$ we can appeal to Proposition 120.15 (2) which now shows that there exists a homotopy from $f_0$ to $f_1$ rel $x_0$.

In the following discussion we will use Proposition 121.24 (1) to dispose of the base points.

Definition. Let $n \in \mathbb{N}$ and let $G$ be an abelian group.

1. Let $X$ be a connected CW-complex. We pick a point $x_0 \in X^0$. By Propositions 38.7 and 121.25 the natural map
$$
\Psi_{(X, x_0)}: \langle (X, x_0), (K(G, n), \ast) \rangle \to [X, K(G, n)]
$$

is a bijection. We use this bijection, together with the group structure on the left-hand side defined in Proposition 121.17 to turn the right-hand side $[X, K(G, n)]$ into a group. In Corollary 121.26 below we will see that this definition does not depend on the choice of $x_0$.

2. Now let $X$ be any CW-complex. Let $\{X_i\}_{i \in I}$ be the set of its components. We have
$$
[X, K(G, n)] \overset{\uparrow}{=} \prod_{i \in I} [X_i, K(G, n)]
$$

by Lemma 3.3 (2)

We define the group structure on each $[X_i, K(G, n)]$ as in (1) and for $i \neq j$ we define the multiplication on $[X_i, K(G, n)] \times [X_j, K(G, n)]$ to be the trivial map. One easily verifies that this defines an abelian group structure on $[X, K(G, n)]$.

The following corollary to Proposition 121.24 (1) shows that this definition of the group structure on $[X, K(G, n)]$ does not depend on the choice of the base point $x_0 \in X^0$.

Corollary 121.26. Let $n \in \mathbb{N}$, let $G$ be an abelian group and let $X$ be a connected CW-complex. The definition of the group structure on $[X, K(G, n)]$ does not depend on the choice of $x_0 \in X^0$.

\footnote{Note that here we use that $G$ is an abelian group, even for $n = 1.$}
Proof (**). Let \( n \in \mathbb{N} \), let \( G \) be an abelian group and let \( X \) be a connected CW-complex. Now let \( x_0, x_1 \in X \) be two points in the 0-skeleton of \( X \). Since \( X \) is connected we know by Proposition \[38.10\] that there exists a map \( f \colon X \to X \) with the following properties:

(a) The map \( f \) is homotopic to the identity.
(b) We have \( f(x_0) = x_1 \).
(c) The map \( f \) defines a homotopy equivalence \((X, x_0) \to (X, x_1)\) of pointed topological spaces.

We consider the following diagram

\[
\begin{array}{ccc}
\langle (X, x_1), (K(G, n), *) \rangle & \xrightarrow{f^*} & \langle (X, x_0), (K(G, n), *) \rangle \\
\Psi_{(X,x_1)} \downarrow \Psi_{(X,x_0)} & & \downarrow \\
[X, K(G, n)] & \xrightarrow{f^*} & [X, K(G, n)].
\end{array}
\]

We make the following observations:

(1) It follows basically immediately from the definitions that the diagram commutes.
(2) It follows from (c) and Lemmas \[15.4\] and \[15.5\] that the top horizontal map is a bijection.
(3) By Proposition \[121.24\] we know that top horizontal map is in fact an isomorphism.
(4) By (a) we know that the bottom map is in fact the identity.

It follows immediately from the above that it does not matter whether we use \( \Psi_{(X,x_1)} \) or \( \Psi_{(X,x_0)} \) to define the group structure on \([X, K(G, n)]\).

121.6. Basic calculations. In this section we want to do a few bare-hands calculation of our new invariant \( \langle (X, x_0), K(G, n) \rangle \). Before we start with the calculations it is useful to introduce the following notation.

**Notation.** Let \( n \in \mathbb{N} \) and let \( G \) be an abelian group. Furthermore let \((X, x_0)\) be a pointed topological space. For the purpose of this section we write

\[
h^n((X, x_0); G) := \langle (X, x_0), K(G, n) \rangle.
\]

Before we state the second main calculation it is helpful to introduce the following convention.

**Convention.** Let \( G \) be an abelian group. We make the identifications

\[
H_1(K(G, 1); \mathbb{Z}) = \pi_1(K(G, 1), *)_{\text{ab}} = G_{\text{ab}} = G.
\]

\[
\uparrow \quad \text{Hurewicz Theorem 52.5} \quad \uparrow \quad \text{from Theorem 120.8} \quad \uparrow \quad \text{since } G \text{ is abelian}
\]

**Lemma 121.27.** Let \( G \) be an abelian group. Let \( X \) be a connected CW-complex and let \( x_0 \in X^0 \) be a point. The map

\[
h^1((X, x_0); G) \to \text{Hom}(H_1(X; \mathbb{Z}), G)
\]

\[
[f \colon (X, x_0) \to (K(G, 1), *)] \to (f_* 
\text{H}_1(X; \mathbb{Z}) \to H_1(K(G, 1); \mathbb{Z}) = G)
\]

is a natural isomorphism.
Proof.

(1) It follows from Proposition \ref{inv120.15} and the Hurewicz Theorem \ref{hurewicz52.5} that the given map is a bijection.

(2) It follows immediately from the definitions that the map is natural in \( X \).

(3) It remains to show that the given map is a homomorphism. We write \( Y = K(G, 2) \).

We make the usual identification \( \langle X, K(G, 1) \rangle = \langle X, \Omega Y \rangle \). Furthermore we use the natural isomorphism

\[
\text{Hom}(H_1(X; \mathbb{Z}), G) \to \text{Hom}(\pi_1(X, x_0), \pi_1(\Omega Y))
\]

\[
\varphi \mapsto (\pi_1(X, x_0) \to \pi_1(X, x_0)_{\text{ab}} = H_1(X; \mathbb{Z}) \xrightarrow{\varphi} G = \pi_1(\Omega Y))
\]

to identify the group on the left with the group on the right. Next we consider the following diagram

\[
\begin{array}{ccc}
\langle X, \Omega Y \rangle \times \langle X, \Omega Y \rangle & \xrightarrow{\langle [f], [g] \rangle \mapsto (f_*, g_*)} & \text{Hom}(\pi_1(X), \pi_1(\Omega Y)) \times \text{Hom}(\pi_1(X), \pi_1(\Omega Y)) \\
\langle f, g \rangle \mapsto [f \times g] & & \downarrow \text{Hom}(\pi_1(X), \pi_1(\Omega Y) \times \pi_1(\Omega Y)) \\
\langle X, \Omega Y \rangle \times \langle X, \Omega Y \rangle & \xrightarrow{\mu_*} & \text{Hom}(\pi_1(X), \pi_1(\Omega Y))
\end{array}
\]

We make the following clarifications and observations:

(a) The upper rectangle commutes basically by definition.

(b) The lower square also commutes basically by definition. Slightly more precisely, let \([f] \in \langle X, \Omega Y \times \Omega Y \rangle\). We consider the maps \( X \xrightarrow{f} \Omega Y \times \Omega Y \xrightarrow{\varphi} \Omega Y \). By functoriality we have \((\mu \circ f)_* = \mu_* \circ f_*\). But this equality just means that in the lower square it does not matter whether we take the down-right route or the right-down route.

(c) It follows from Lemma \ref{inv114.28} that the right vertical maps give precisely the group multiplication on \( \text{Hom}(\pi_1(X), \pi_1(\Omega Y)) \).

This shows that the given map is indeed a group homomorphism. \( \blacksquare \)

121.7. **Product structures \((*)\)**. Let \((X, x_0)\) be a pointed CW-complex and let \( m, n \in \mathbb{N} \).

Our goal in this section is to define a potentially interesting map

\[
\langle (X, x_0), K(\mathbb{Z}, m) \rangle \times \langle (X, x_0), K(\mathbb{Z}, n) \rangle \to \langle (X, x_0), K(\mathbb{Z}, m + n) \rangle.
\]

The key to defining such a map is the following humble construction.

**Definition.** Given two pointed topological spaces \((X, x_0)\) and \((Y, y_0)\) the *smash product* is defined as

\[
X \wedge Y = \left( X \times Y \right) / \left( \left. X \times Y \right\} \right)
\]

where we use Exercise \ref{smash18.30} to make the identification \( X \vee Y := \left( X \times \{ y_0 \} \right) \times \left( \{ x_0 \} \times Y \right) \).
We equip $X \wedge Y$ with the base point given by $[X \vee Y]$.

Remark. As we discussed in Exercise 36.12 and on page 965 in the category of pointed topological spaces the smash product is actually the categorical product.

In Exercise 18.30 we already showed that $S^m \wedge S^n$ is homeomorphic to $S^{m+n}$. For our purpose it is useful to have a canonical homeomorphism that we can all agree upon. This is given in the following lemma.

**Lemma 121.28.** Given $m, n \in \mathbb{N}$ there exists a canonical homeomorphism

$$S^m \wedge S^n \cong S^{m+n}.$$ 

**Convention.** We will use the canonical homeomorphism from Lemma 121.28 to make the identification $S^m \wedge S^n = S^{m+n}$.

**Proof.** We write $I = [0,1]$. Given any $k \in \mathbb{N}_0$ we have the following identifications of pointed topological spaces:

$$\left( I^k / \partial I^k, [\partial I^k] \right) \xrightarrow{\cong} \left( B^k / S^{k-1}, [S^{k-1}] \right) \xrightarrow{\cong} \left( S^k, \ast \right).$$

Let $m, n \in \mathbb{N}_0$. Using the above identification we obtain the following homeomorphism by Lemma 3.28 (1)

$$S^m \wedge S^n \cong I^m / \partial I^m \wedge I^n / \partial I^n \xrightarrow{\cong} (I^m / \partial I^m \cup \partial I^n \times I^n) = I^m+n / \partial I^m+n \xrightarrow{\cong} S^{m+n}.$$

We have thus given an explicit homeomorphism between $S^m \wedge S^n$ and $S^{m+n}$. □

The following lemma is basically just a mild reformulation of Lemma 120.11.

**Lemma 121.29.** Let $k \in \mathbb{N}$. There exists a polarized Eilenberg-Maclane space $(Y_k, \ast, \varphi)$ of type $K(Z, k)$ with the following properties:

1. The $k$-skeleton of $Y_k$ equals $S^k$ with the usual CW-structure defined on page 2813.
2. The CW-complex $Y_k$ has no cell of dimension $k+1$.
3. The CW-complex $Y_k$ has only countably many cells in dimensions $\geq k+2$.

Now we turn to the actual definition of the product structure.

**Definition.** Let $m, n \in \mathbb{N}$. In the following discussion all topological spaces are viewed as pointed objects.

1. We consider the polarized Eilenberg-Maclane spaces $Y_m$ and $Y_n$ that we introduced in Lemma 121.29. Recall that from Lemma 121.15 we obtain canonical elements $\Xi_m \in \langle K(Z, m), Y_m \rangle_{inv}$ and $\Xi_n \in \langle K(Z, n), Y_n \rangle_{inv}$.
2. Since $Y_m$ and $Y_n$ are CW-complexes with countably many cells we can equip the product $Y_m \times Y_n$ with the CW-structure defined in Lemma 36.32.
3. We denote by $p: Y_m \times Y_n \to Y_m \wedge Y_n = (Y_m \times Y_n) / \sim$ the obvious projection.
4. It follows from the explicit description of the CW-structure defined in Lemma 36.32 that $Y_m \wedge Y_n = (Y_m \times Y_n) / \sim$ has precisely one cell in dimension 0, no cells in
dimension 1, . . . , m + n − 1, one cell in dimension m + n and no cell in dimension m + n + 1. Furthermore it follows immediately from the definitions that the map

\[ S^{m+n} = S^m \land S^n \to Y_m \land Y_n \]

defines a homeomorphism onto the (m + n + 1)-skeleton of Y_m \land Y_n. In particular we obtain from Proposition 40.9 that Y_{m+n} is (m + n − 1)-connected and we obtain that the map \( \varphi : \mathbb{Z} = \pi_{m+n}(S^{m+n}) \to \pi_{m+n}(Y_m \land Y_n) \) is an isomorphism.

(5) Since \( Y_m \times Y_n \) is an (m + n − 1)-connected CW-complex we obtain from Proposition 120.15 a unique class \( \mu \in \langle Y_m \land Y_n, K(Z, m + n) \rangle \) that induces the preferred isomorphism \( \varphi^{-1} : \pi_{m+n}(Y_m \land Y_n, *) \xrightarrow{\cong} \mathbb{Z} \).

After these preparations we consider the following diagram

\[
\begin{array}{ccc}
\langle X, Y_m \rangle \times \langle X, Y_n \rangle & \xrightarrow{\chi} & \langle X, Y_m \times Y_n \rangle \\
\cong \langle X, K(Z, m) \rangle \times \langle X, K(Z, n) \rangle & \xrightarrow{\mu_\ast} & \langle X, K(Z, m + n) \rangle.
\end{array}
\]

We refer to the bottom horizontal map, which we defined through the upper path of maps, as the cup product.

**Theorem 121.30.** Let \( X = (X, x_0) \) be a pointed CW-complex and let \( m, n \in \mathbb{N} \). The cup product

\[
\cup : \langle X, K(Z, m) \rangle \times \langle X, K(Z, n) \rangle \to \langle X, K(Z, m + n) \rangle
\]

is bilinear. Furthermore the cup product is associative and graded commutative in the sense that for \( \varphi \in \langle X, K(Z, m) \rangle \) and \( \psi \in \langle X, K(Z, n) \rangle \) we have

\[
\varphi \cup \psi = (-1)^{m \cdot n} \cdot \psi \cup \varphi.
\]

**Proof.** We will not make use of this theorem, thus we will also not provide a proof. Instead we refer to [Stro11, Theorem 21.61] for the proof. Note that [Stro11, Theorem 21.61] does not explicitly say that \( X \) needs to be a CW-complex, but implicitly the discussion on [Stro11, Chapter 21] seems to assume that the setting is a convenient category in the sense of Theorems 36.28 and 36.30. We will discuss this issue in more detail right after this proof.

The above definition of the cup product is in a way rather awkward, it is esthetically wrong to introduce the CW-complexes \( Y_m \) and \( Y_n \). We conclude this section with a longish but hopefully quite interesting discussion which explains why we introduced the CW-complexes \( Y_m \) and \( Y_n \) and how we can get around introducing them.

**Definition.**

1. Let \( A \) and \( B \) be CW-complexes. We denote by \( A \otimes B \) the product CW-complex that we defined on page 963. Recall that the underlying set is just \( A \times B \).
2. Let \( (A, a_0) \) and \( (B, b_0) \) be pointed CW-complexes. We write

\[
A \otimes B := (A \otimes B)/(A \times \{b_0\} \cup \{a_0\} \times B).
\]
We consider the following notation:

We make the following observations:

1. Let $r \in \mathbb{N}$. We write $K_r = K(\mathbb{Z}, r)$. We consider the polarized Eilenberg-MacLane spaces $Y_r$ that we introduced in Lemma \[121.29\] and we denote by $\Xi_r \in \langle K_r, Y_r \rangle_{\text{inv}}$ the canonical element given by Lemma \[121.15\].

2. Given topological spaces $A$ and $B$ we denote by $p: A \times B \to A \wedge B$ the obvious projection. Similarly, given CW-complexes $A$ and $B$ we denote by $p: A \otimes B \to A \otimes B$ the obvious projection.

We consider the following diagram

$$
\begin{array}{cccc}
\langle X, Y_m \rangle \times \langle X, Y_n \rangle & \xrightarrow{\chi} & \langle X, Y_m \times Y_n \rangle & \xrightarrow{p_*} & \langle X, Y_m \wedge Y_n \rangle \\
\langle X, K_m \rangle \times \langle X, K_n \rangle & \xrightarrow{(f,g) \mapsto f \times g} & \langle X, K_m \times K_n \rangle & \xrightarrow{p_*} & \langle X, K_m \wedge K_n \rangle & \xrightarrow{???} & \langle X, K_{m+n} \rangle.
\end{array}
$$

We make the following observations:

1. Since $K_m$ and $K_n$ have uncountably many cells the product $K_m \times K_n$ is not a CW-complex.

2. It follows from (1) that $K_m \wedge K_n$ has no obvious CW-structure. Thus there is no clear path to constructing a map $K_m \wedge K_n \to K_{m+n}$.

3. It follows from (2) that the “direttissima” approach to defining the cup product by going straight from left to right runs into a major obstacle.

4. Since $Y_m$ and $Y_n$ have countably many cells we know, by Lemmas \[36.32\] and \[36.32\] that $Y_m \times Y_n$ and $Y_m \wedge Y_n$ are CW-complexes. As discussed above, we obtain from Proposition \[120.15\] a canonical class $\mu \in \langle Y_m \wedge Y_n, K(\mathbb{Z}, m+n) \rangle$.

5. One way of getting around (3) is to use (4), i.e. we take the “upper route” in the diagram. This is how in the above we defined the cup product.

6. As for $Y_m \wedge Y_n$ one sees that $K_m \otimes K_n$ is $(m+n-1)$-connected and that we have a canonical map $\pi_{m+n}(K_m \otimes K_n) \to \mathbb{Z}$. Since $K_m \otimes K_n$ is a CW-complex we obtain from Proposition \[120.15\] a canonical element $\nu \in \langle K_m \otimes K_n, K_{m+n+1} \rangle$.

7. Unfortunately the issue in (1) also means that the map $\eta: K_m \otimes K_n \to K_m \times K_n$ is not a homeomorphism. Thus there is no obvious way how we can take the lower route in the diagram.

\[\text{In fact it is also not immediately clear whether } K_m \wedge K_n \text{ is say } (m+n-1)\text{-connected.}\]
Now we switch to the category of CGWH-spaces that we introduced on page \textbf{967}. In particular we now assume that \( X \) is a CGWH-space. Recall that by Theorem \textbf{36.30}(2) we know that every CW-complex is a CGWH-space.

(8) Given two CGWH-spaces \( A \) and \( B \) we know by Theorem \textbf{36.30} that there exists a product \textit{in the category of CGWH-spaces}. As on page \textbf{968} we denote this categorical product by \( A \times B \) and we denote by \( p: A \times B \to A \) and \( q: A \times B \to B \) the two projections maps.

(9) Let \( f: X \to K_m \) and \( g: X \to K_n \) be maps. Since \( X, K_m \) and \( K_n \) are CGWH-spaces we know, by definition of the product in a category, that there exists a unique map \( f \times g: X \to K_m \times K_n \) such that \( f = p \circ (f \times g) \) and \( g = q \circ (f \times g) \).

(10) Since \( K_m \) and \( K_n \) are CW-complexes we know by Theorem \textbf{36.30}(5) that the identity map \( \Theta: K_m \times K_n \to K_m \otimes K_n \) is actually a homeomorphism.\footnote{1726}{For our purpose we only need the weaker result that \( \Theta: K_m \times K_n \to K_m \otimes K_n \) is continuous.}

(11) It follows from (9) and (10) that we have a “lower route” from \( \langle X, K_m \rangle \times \langle X, K_n \rangle \) to \( \langle X, K_{m+n} \rangle \). This gives us an approach to defining the cup product without introducing the slightly artificial \( Y_m \) and \( Y_n \).

(12) It follows easily from the definitions that in the diagram the square to the lower left commutes. One can now see reasonably easily that the two definitions of the cup product agree.

The second approach to defining the cup product is much more natural than the initial approach. In particular, using a similar circle of ideas one can define a cup product

\[
\langle X, K(R, m) \rangle \times \langle X, K(R, n) \rangle \to \langle X, K(R, m + n) \rangle
\]

for any commutative ring \( R \). We refer to [\textbf{Stro11}, Chapter 21.4] for details.

---

**Exercises for Chapter 121.**

**Exercise 121.1.** We consider the following diagram:

\[
\begin{array}{ccc}
S^1 \times S^1 & \xrightarrow{\Xi \times \Xi} & (\Omega \mathbb{CP}^\infty, *) \times (\Omega \mathbb{CP}^\infty, *) \\
\downarrow & & \downarrow \mu \\
S^1 & \xrightarrow{\Xi} & \Omega(\mathbb{CP}^\infty, *)
\end{array}
\]

The map \( \Xi: S^1 \to \Omega(\mathbb{CP}^\infty, *) \) is defined in Lemma \textbf{121.16} and the map \( \mu \) is defined on page \textbf{2851}. Show that the diagram commutes up to homotopy.

**Exercise 121.2.** We equip \( S^1 \), \( S^2 \) and \( S^1 \lor S^2 \) with the usual base points which in each case we call \(*\). Show that the map \( ((S^2, *), (S^1 \lor S^2, *)) \to [S^2, S^1 \lor S^2] \) is not an injection.

**Exercise 121.3.** Let \( (X, x_0) \) and \( (K, k_0) \) be pointed topological spaces. Show that the multiplication on \( \langle (X, x_0), (K, k_0) \rangle \) defined in Lemma \textbf{121.18} is actually associative.
Exercise 121.4. Let \((X, x_0)\) and \((K, \ast)\) be pointed topological spaces. We consider the double loop space \(\Omega^2(K, \ast) = \Omega(\Omega(K, \ast))\). By the construction on page 2862 we have a binary operation
\[
\circ : \langle (X, x_0), \Omega(\Omega(K, \ast)) \rangle \times \langle (X, x_0), \Omega(\Omega(K, \ast)) \rangle \to \langle (X, x_0), \Omega(\Omega(K, \ast)) \rangle.
\]
In Proposition 121.17 we showed in particular that this binary operation is unital. Provide another binary unital operation \(\otimes\) on \(\langle (X, x_0), \Omega(\Omega(K, \ast)) \rangle\) such that the conditions of the Eckmann-Hilton Theorem 114.27 are satisfied.

Remark. Once we have shown that we can apply the Eckmann-Hilton Theorem 114.27 we see that \(\circ\) defines a group structure on \(\langle (X, x_0), \Omega(\Omega(K, \ast)) \rangle\) and we obtain that this group is abelian. Thus this provides an alternative approach to proving Proposition 121.21 and to proving some of the statements of Proposition 121.17.

Remark. Coming up with an idea for defining \(\otimes\) is not difficult. Providing a complete proof that Condition (b) of the Eckmann-Hilton Theorem 114.27 is satisfied might be more painful. Especially once one starts wondering why certain maps are actually continuous.

Exercise 121.5. Let \(n \in \mathbb{N}\) and let \(G\) be an abelian group. Let \(k \in \mathbb{N}\). We denote by \(\ast\) the usual base point of \(S^k\). Compute the groups \(\langle (S^k, \ast), K(G, n) \rangle\).

Remark. Once one unravels the definitions one can fairly easily write down bijections to familiar groups. The only catch is that one really needs to show that these bijections are in fact group isomorphisms. The Eckmann-Hilton Theorem 114.27 might once again ride to the rescue.

Exercise 121.6. Let \((X, x_0)\) be a pointed topological space. We equip \(S^1\) with the base point \(\ast = (0, 1)\). Show that the smash product \(X \wedge S^1\) is homeomorphic to the reduced suspension \(S(X, x_0)\).

Remark. Personally I like Lemma 3.28 (1).

Exercise 121.7. To simplify the notation, given a pointed topological space \((Y, y_0)\) we now write \(SY = S(Y, y_0)\) and \(\Omega Y = \Omega(Y, y_0)\).

(a) Let \((Y, y_0)\) be a point topological space. Show that the set \(\pi_0(\Omega Y)\) has a natural group structure.

(b) Let \((X, x_0)\) be a point topological space.

(1) Show that there exists a natural isomorphism from \(\pi_0(\Omega(SX))\) to the free group on the set \(\pi_0(X)\).

(2) Let \((X, x_0)\) be a point topological space. Show that there exists a natural isomorphism from \(\pi_0(\Omega^2(S^2X))\) to the free abelian group on the set \(\pi_0(X)\).

(3) How does the sequence continue?

Nomenclature

\((M \# N, K \# L)\) connected sum of pairs \((M, K)\) and \((N, L)\)

\(*\mathbb{C}P^2\) fake \(\mathbb{C}P^2\) with non-trivial Kirby-Siebenmann invariant

\(-M\) smooth manifold equipped with the opposite orientation

\(1_K\) multiplicatively neutral element in \(H^*_{\text{simp}}(K; R)\)

\(1_X\) multiplicatively neutral element in \(H^*(X; R)\)

\([K]\) fundamental class of a closed oriented pseudomanifold

\([K]_{\mathbb{F}_2}\) \(\mathbb{F}_2\)-fundamental class of a closed pseudomanifold

\([M]\) fundamental class of a compact oriented smooth manifold

\([M]_{\mathbb{F}_2}\) \(\mathbb{F}_2\)-fundamental class of a compact smooth manifold

\([M]_{\mathbb{R}}\) real fundamental class of a compact oriented smooth manifold

\([M]_{\mathbb{F}_2}\) \(\mathbb{F}_2\)-fundamental class of a compact oriented smooth manifold

\([S^n]\) standard generator of \(H_n(S^n)\)

\([X, Y]\) maps \(X \rightarrow Y\) up to homotopy

\([X, Y]\) set of homotopy classes of maps \(X \rightarrow Y\)

\([x, y]\) commutator \(xyx^{-1}y^{-1}\)

\([z_0, \ldots, z_k]\) map \(\Delta^k \rightarrow \mathbb{R}^n\) defined by \(z_0, \ldots, z_k \in \mathbb{R}^n\)

\(#S\) cardinality of a set

\(\alpha \ast \beta\) product of paths

\(\int_M \omega\) integral of a differential form \(\omega\)

\(\text{AbGr}\) category of abelian groups

\(\text{AbsGraph}\) category of abstract graphs

\(\text{CGWH}\) category of CGWH-spaces

\(\text{ChCplx}\) category of chain complexes

\(\text{CRing}\) category of commutative rings

\(\text{CW}\) category of CW-complexes

\(\text{FullCW}\) full category of CW-complexes

\(\text{FullPCW}\) full category of pointed CW-complexes

\(\text{GradAb}\) category of \(S\)-graded abelian groups

\(\text{GradMod}_R\) category of \(S\)-graded \(R\)-modules
| **GrRing** | category of graded rings |
| **HomTop** | homotopy category of topological spaces |
| **MapTop** | category of maps between topological spaces |
| **PairTop** | category of pairs of topological spaces |
| **PSmMfd** | category of pointed smooth manifolds |
| **PTop** | category of pointed topological spaces |
| **Ring** | category of rings |
| **Set** | category of sets |
| **SimpCplx** | category of abstract simplicial complexes |
| **SimpCplx** | category of simplicial complexes |
| **SmMfd** | category of smooth manifolds |
| **Top** | category of topological spaces |
| **TopGr** | category of topological groups |
| **UndirAbsGraph** | category of undirected abstract graphs |
| **Vec\K** | category of \(\K\)-vector spaces |
| \(\chi(X)\) | Euler characteristic of a CW-complex |
| \(\chi(X)\) | Euler characteristic of a topological space |
| \(C^*(X,A;G)\) | relative cochain complex |
| \(C_n^b(X;\R)\) | bounded cochain complex |
| \(C^\text{smooth}_n(M;G)\) | smooth singular cochain complex |
| \(\Delta^n\) | standard \(n\)-simplex |
| \(\emptyset\) | the empty set |
| \(\epsilon_X\) | augmentation map \(C_0(X) \rightarrow \Z\) |
| \(\Gamma^A_n(M)\) | set of all \(R\)-sections along \(A\) |
| \(\Delta^s\) | \(\Delta^n \setminus \partial\Delta^n\) |
| \(\text{St}(\hat{K},s)\) | open star of the simplex \(s\) |
| \(\mathbb{L}\) | long line |
| \(\mathbb{L}^+\) | open long ray |
| \(\Lambda(\varphi)\) | Lefschetz number of a map \(\varphi\) |
| \(\Lambda(\varphi,\F)\) | \(\F\)-Lefschetz number of a map \(\varphi\) |
| \(\langle X, x_0 \rangle, \langle Y, y_0 \rangle\) | maps \((X,x_0) \rightarrow (Y,y_0)\) up to homotopy |
| \(\langle X, x_0 \rangle, \langle Y, y_0 \rangle\) | maps \((X,x_0) \rightarrow (Y,y_0)\) up to homotopy |
| \(\langle X \mid R \rangle\) | presentation with generating set \(X\) and relator set \(R\) |
| \(\langle x_1, \ldots, x_k \mid r_1, \ldots, r_l \rangle\) | presentation with generators \(x_1, \ldots, x_k\) and relators \(r_1, \ldots, r_l\) |
| \(\langle , \rangle\) | Kronecker pairing |
| \(\langle , \rangle\) | Kronecker pairing with \(R\)-coefficients |
| \(\Delta\) | planar \(n\)-simplex |
| \(\mapsto\) | map from ordinary to relative homology |
| \(\mapsto\) | map from reduced to ordinary homology |
| \(\mapsto\) | map from reduced to relative homology |
| \(\mapsto\) | map from relative homology to homology of the quotient |
| \(\mathbb{R}P^n\) | real projective space |
| \(\mathbb{C}P^\infty\) | infinite-dimensional complex projective space |
NOMENCLATURE

\( \mathbb{C}P^n \) complex projective space

\( \mathbb{H}P^\infty \) infinite-dimensional quaternionic projective space

\( \mathbb{H}P^n \) quaternionic projective space

\( \mathbb{N} \) the natural numbers 1, 2, …

\( \mathbb{N}_0 \) the natural numbers 0, 1, 2, …

\( \mathbb{O}P^1 \) octonionic projective line

\( \mathbb{O}P^2 \) octonionic projective plane

\( \mathbb{R}P^\infty \) infinite-dimensional real projective space

\( \mathbb{Z}(S) \) free abelian group generated by the set \( S \)

\( \mathbb{Z}_n \) \( \mathbb{Z}/n\mathbb{Z} \)

\( \mathcal{N}_n \) unoriented cobordism group

\( \mathcal{P}(X) \) power set of the set \( X \)

\( \Omega(X) \) free path space

\( \Omega(x, x_0) \) loop space

\( \Omega^k(\mathbb{R}^m) \) framed cobordism group

\( \Omega^k_0(\mathbb{R}^m) \) thickened cobordism group

\( \Omega_n \) \( n \)-th cobordism group

\( \text{Sp}(2g, \mathbb{Z}) \) symplectic group

\( \text{Aut}(\pi) \) automorphism group of a group \( \pi \)

\( \text{cat}(X) \) Lusternik-Schnirelmann category of a topological space \( X \)

\( \text{cl}(X) \) cup length of a topological space \( X \)

\( \text{Cone}(K) \) simplicial cone on an abstract simplicial complex \( K \)

\( \text{Cone}(X) \) cone of a topological space \( X \)

\( \text{C}_c^*(X; G) \) chain complex with compact support

\( \text{C}_{\text{simp}, \leq}^*(K; G) \) simplicial cochain complex

\( \text{C}_c^*(K; G) \) simplicial cochain complex

\( \text{C}^\text{CW}_*(X) \) cellular chain complex

\( \text{C}^\text{CW}_*(X) \) cellular cochain complex

\( \text{C}^\text{han}_*(M) \) handle chain complex

\( \text{C}_{\text{simp}, \leq}^*(K) \) simplicial chain complex of an ordered abstract simplicial complex

\( \text{C}_{\text{simp}}^*(K) \) simplicial chain complex of an abstract simplicial complex

\( \text{C}_n(X) \) \( n \)-th singular chain group of \( X \)

\( \text{C}_n(X, A) \) relative singular chain group

\( \text{C}_{\text{simp}, \leq}^n(K) \) \( n \)-th simplicial chain group of an ordered abstract simplicial complex \( K \)

\( \text{C}_{\text{simp}}^n(K) \) \( n \)-th simplicial chain group of the abstract simplicial complex \( K \)

\( \text{C}^\text{dR}_*(M) \) de Rham cochain complex

\( \text{deg}(\Phi) \) degree of an automorphism of a group isomorphic to \( \mathbb{Z} \)

\( \text{deg}(f) \) degree of a map \( f : S^n \to S^n \)

\( \text{deg}(f, x) \) local degree of a map \( f \) at a point \( x \)

\( \text{diam}(A) \) diameter of a subset \( A \) of a metric space

\( D_W M \) double of a topological (smooth) manifold \( M \) along \( W \)

\( D_{f_P} \) differential of a smooth map \( f : M \to N \) at \( P \in M \)

\( D M \) double of a topological (smooth) manifold \( M \)
ev: $H^n(C; G) \to \text{Hom}(H_n(C), G)$ evaluation map

$\text{ev}: H^n(X; F) \to \text{Hom}_F(H_n(X; F), F)$ evaluation map with $F$-coefficients

$\text{Ext}(H, G)$ $G$-Ext-group of $H$

$F H$ maximal torsion-free quotient of $H$

$F H$ maximal torsion-free quotient of an abelian group

$\text{genus}(M)$ genus of a surface $M$

$\text{GL}_+(n, \mathbb{R})$ real matrices of positive determinant

$\text{Homeo}(X)$ group of self-homeomorphism of $X$

$H^k_{\text{simp}}(K; G)$ $k$-th simplicial cohomology group

$H^k_{\text{simp}}(K; G)$ $k$-th simplicial cohomology group

$H^n(X; A; G)$ $n$-th relative singular cohomology

$H^n_{\text{CW}}(X)$ $n$-th cellular cohomology group

$H^n_{\text{smooth}}(M; G)$ $n$-th smooth singular cohomology group

$H^n_{\text{H}}(M)$ $n$-th handle homology group

$H_n(\pi)$ $n$-th homology group of a group $\pi$

$H_n(X)$ $n$-th singular homology group

$H_n(X; G)$ singular homology with $G$-coefficients

$H^n_{\text{CW}}(X)$ $n$-th cellular homology group

$H^n_{\text{fr}}(X; G)$ locally finite homology

$H^n_{\text{simp}}(K)$ $n$-th simplicial homology group of an abstract simplicial complex

$H^n_{\text{simp}}(K)$ $n$-th simplicial homology group of an ordered abstract simplicial complex

$H^n_{\text{simp}}(K; G)$ simplicial homology with $G$-coefficients

$H_{\text{fr}}$ quaternionic Hopf map

$H_{\text{O}}$ octonionic Hopf map

$H^n_b(X; \mathbb{R})$ $n$-th bounded cohomology group

$H^n_{\text{fr}}(X; G)$ cohomology with compact support

$H^n_{\text{dr}}(M, A)$ relative de Rham cohomology groups

$H^n_{\text{fr}}(M)$ $n$-th de Rham cohomology group

$\text{index}(f, g, P)$ index of an intersection point of two maps $f$ and $g$

$\text{index}(f, z)$ index of a map $f$ at a fixed point $z$

$\text{index}(v, x)$ index of a vector field $v$ at a zero $x$

$\text{Inn}(\pi)$ inner automorphism group of a group $\pi$

$\text{Isom}(M, g)$ group of isometries of the Riemannian manifold $(M, g)$

$\text{Isom}^+(M, g)$ group of orientation-preserving isometries of the Riemannian manifold $(M, g)$

$K(\pi, n)$ canonical Eilenberg-Maclane space of type $K(\pi, n)$

$\text{lim}^1$ lim one of an inverse system of abelian groups

$\text{link}(K, s)$ link of the simplex $s$

$\text{link}(K, J)$ linking number of oriented knots $K$ and $J$

$\text{MCG}(M)$ mapping class group of a smooth manifold

$\text{MCG}(M)$ orientation-preserving mapping class group of a smooth manifold

$\text{mesh}(Y)$ the largest diameter of a simplex

$\text{Mor}_c(X, Y)_{\text{inv}}$ set of invertible morphisms

$M(\pi, n)$ Moore space of type $M(\pi, n)$
NOMENCLATURE

\[ M(\varphi) \quad \text{algebraic mapping cone of } \varphi : C_* \to D_* \]
\[ \text{Out}(\pi) \quad \text{outer automorphism group of a group } \pi \]
\[ O \quad \text{infinite orthogonal group} \]
\[ \text{PD}_M \quad \text{Poincaré duality isomorphism} \]
\[ \text{rank}(A) \quad \text{rank of an abelian group } A \]
\[ \text{rank}(M) \quad \text{rank of a module over a commutative domain } R. \]
\[ \text{sd}(K) \quad \text{barycentric subdivision of the simplicial complex } K \]
\[ \text{sign}(M) \quad \text{signature of a } 4n\text{-dimensional topological manifold} \]
\[ \text{Spin}(n) \quad \text{spin group} \]
\[ \text{Sp} \quad \text{infinite symplectic group} \]
\[ \text{Sp}(n) \quad \text{compact symplectic group} \]
\[ \text{St}(K,s) \quad \text{star of the simplex } s \]
\[ \text{Tor}(A) \quad \text{torsion subgroup of an abelian group } A \]
\[ \text{Tor}(H,G) \quad G\text{-torsion of } H \]
\[ \text{Tor}(X,f) \quad \text{mapping torus of } f : X \to X \]
\[ \text{tr}(\varphi) \quad \text{trace of the endomorphism } \varphi \]
\[ T_P M \quad \text{tangent space of a smooth manifold } M \text{ at } P \]
\[ U \quad \text{infinite unitary group} \]
\[ \text{Vect}^n_\mathbb{C}(X) \quad \text{set of isomorphism classes of } n\text{-dimensional } \mathbb{C}\text{-vector bundles over } X \]
\[ \text{Vect}^n_\mathbb{R}(X) \quad \text{set of isomorphism classes of } n\text{-dimensional } \mathbb{R}\text{-vector bundles over } X \]
\[ \text{Vect}^n_{\mathbb{R}^+}(X) \quad \text{set of isomorphism classes of oriented } n\text{-dimensional } \mathbb{R}\text{-vector bundles over } X \]
\[ V_P M \quad \text{visual tangent space of a submanifold of some } \mathbb{R}^n \]
\[ \text{sign}(\sigma) \quad \text{sign of the permutation } \sigma \]
\[ \mathbb{L}_{>0} \quad \text{closed long ray} \]
\[ \mathbb{L}^n \quad \text{n-dimensional closed ball in } \mathbb{R}^n \]
\[ \mathbb{B}^n(y) \quad \text{closed } r\text{-ball around } y \in \mathbb{R}^n \]
\[ \partial \Delta^n \quad \text{all points on } \Delta^n \text{ where at least one coordinate is zero} \]
\[ \partial_0X \quad \partial_0X = \partial X \setminus \partial M \text{ of a submanifold } X \text{ of a manifold } M \]
\[ \partial_0 \quad \partial_0 \text{ of a submanifold with corner} \]
\[ \partial_1X \quad \partial_1X = \partial X \cap \partial M \text{ of a submanifold } X \text{ of a manifold } M \]
\[ \partial_1 \quad \partial_1 \text{ of a submanifold with corner} \]
\[ \partial_c M \quad \text{corner set of a submanifold } M \text{ with corner} \]
\[ \Phi_s \quad \text{characteristic map in a totally ordered simplicial complex} \]
\[ \pi_0(X) \quad \text{the set of path-components of a topological space } X \]
\[ \pi_1(X,x_0) \quad \text{fundamental group of } (X,x_0) \]
\[ \pi_k^s \quad \text{stable homotopy group} \]
\[ \pi_n(X,A,x_0) \quad \text{relative homotopy group} \]
\[ \pi_n(X,x_0) \quad n\text{-th homotopy group of } (X,x_0) \]
\[ \Sigma(K) \quad \text{simplicial suspension of an abstract simplicial complex } K \]
\[ \Sigma(X) \quad \text{Suspension of } X \]
\[ \Sigma(X) \] suspension of a topological space \( X \)
\[ \Sigma_g \] surface of genus \( g \)
\[ \Sigma_{g,n} \] surface of genus \( g \) minus \( n \) open disks
\[ \theta_{\mathbb{R}} \] the canonical singular cochain in \( C^1(\mathbb{R}) \)
\[ \theta_{\mathbb{R}} \] the canonical singular cochain in \( C^1(\mathbb{Z}) \)
\[ \lim \] inverse limit of an inverse system
\[ \lim \] direct limit of a direct system
\[ \varphi \cup \psi \] cup product
\[ \varphi \cap \sigma \] cap product on (co-) homology
\[ \varphi \cup \psi \] relative cup product on cohomology
\[ \varphi \cup \psi \] relative cup product
\[ \varphi \times \psi \] cross product on cohomology
\[ \wedge^k V^* \] vector space of alternating \( k \)-forms on \( V \)
\[ \tilde{C}_*(X) \] reduced chain complex
\[ \tilde{p}_I(M) \] \( I \)-Pontryagin number of a smooth manifold \( M \)
\[ \tilde{X}_{x_0} \] canonical universal covering corresponding of \( (X, x_0) \)
\[ \tilde{X}_{x_0} \] universal covering with respect to \( x_0 \in X \)
\[ \tilde{X}_{x_0}^\Gamma \] canonical covering corresponding to \( \Gamma \subset \pi_1(X, x_0) \)
\[ \tilde{H}_n(X) \] \( n \)-th reduced homology group
\[ A \otimes B \] tensor product of two abelian groups \( A \) and \( B \)
\[ A \otimes_K B \] tensor product of two real vector spaces \( A \) and \( B \)
\[ B^n \] \( n \)-dimensional open ball in \( \mathbb{R}^n \)
\[ B^n_r(y) \] open \( r \)-ball around \( y \in \mathbb{R}^n \)
\[ b_n(X) \] the \( n \)-th Betti number of a topological space
\[ b_n(X, A) \] the \( n \)-th Betti number of a pair of topological space
\[ C(X, x_0) \] reduced cone of \( (X, x_0) \)
\[ C_* \otimes D_* \] tensor product of chain complexes
\[ c_y \] the constant map that sends all points to \( y \)
\[ d(A, B) \] distance between two subsets of a metric space
\[ E_8 \] the \( 8 \times 8 \)-matrix \( E_8 \)
\[ f \cdot g \] algebraic intersection of two maps that intersect nicely
\[ H \] Hopf map
\[ H_n \] upper half-space in \( \mathbb{R}^n \)
\[ i^j_n \] the \( j \)-th face map \( \Delta^{n-1} \to \Delta^n \)
\[ K^{inv} \] inverse of a knot
\[ K^{mir} \] mirror image of a knot \( K \)
\[ K^{mir} \] mirror of a knot
\[ K^{rev} \] reverse of a knot
\[ K_1 \ast \cdots \ast K_m \] simplicial join of abstract simplicial complexes
\[ L(p, q) \] lens space
\[ M \# N \] connected sum of smooth manifolds \( M \) and \( N \)
\[ M \# N \] connected sum of topological manifolds \( M \) and \( N \)
$M \#_b M'$ boundary connected sum of two smooth manifolds $M$ and $N$

$M \setminus F$ the smooth manifold $M$ cut along a codimension-one submanifold $F$

$M/\partial F$ the smooth manifold $M$ cut along a codimension-one submanifold $F$

$M^b(\varphi)$ handle attachment to $M$ along $\varphi$

$M^s(\varphi)$ handle attachment to $M$ along $\varphi$

$surgery on $M along $\varphi$

$N \rtimes_{\varphi} \mathbb{Z}_k$ semidirect product of groups $N$ and $\mathbb{Z}_k$

$N(U)$ nerve complex of a cover $U$

$N_g$ non-orientable surface of genus $g$

$N_{g,n}$ non-orientable surface of genus $g$ minus $n$ open disks

$p(E)$ total Pontryagin class of a vector bundle $E$

$P(x, x_0)$ path space

$p_i(E)$ $i$-th Pontryagin class of a vector bundle $E$

$p_i(M)$ $i$-Pontryagin class of a smooth manifold $M$

$p_i(M, \mathbb{Q})$ $i$-th rational Pontryagin class of a smooth manifold

$Q^{as}(M)$ asymmetric intersection pairing

$Q^{as}_{M, A, B}$ asymmetric intersection pairing

$Q^{red}(M)$ reduced intersection form

$Q_M$ intersection form of an even dimensional topological manifold

$Q^{\mathbb{F}_2}_M$ $\mathbb{F}_2$-value intersection form of an even dimensional topological manifold

$S(X, x_0)$ reduced suspension

$S^3(L)$ Dehn surgery along the framed link $(L, r)$

$S^3(K)$ Dehn surgery along $K$

$S^\infty$ infinite-dimensional sphere

$S^n$ $n$-dimensional sphere in $\mathbb{R}^{n+1}$

$S^n_r(y)$ $n$-dimensional sphere of radius $r$ around $y$

$S^n_{\geq 0}$ upper hemisphere of $S^n$

$S^n_{\leq 0}$ lower hemisphere of $S^n$

$s^\perp$ dual chain of a simplex $s$

$X \ast X$ join of topological spaces $X$ and $Y$

$X \ast Y \ast Z$ join of topological spaces $X$, $Y$ and $Z$

$X/A$ quotient of topological space $X$ by subset $A$

$X \otimes Y$ product of two CW-complexes

$X \vee Y$ wedge of the topological spaces $X$ and $Y$

$X \wedge Y$ smash product of $X$ and $Y$

$X \times Y$ product in the category of CGWH-spaces

$X^Y$ set of continuous maps $Y \to X$

$Y \cup_{\varphi} Z$ $Y$ glued to $Z$ via $\varphi$

$Y \cup_Z X$ pushout of $Y \leftarrow Z \to X$

Results and statements about topological spaces:
- Criteria for maps to be homeomorphisms, see 2.43 (3), 2.45
- Product of quotient map with identity is quotient map, see 5.16
- Cones are contractible, see 24.1

Results and statements about smooth manifolds:
- Smooth map is homotopic to its linearization, see 45.17
- Smooth embeddings of smooth manifolds into some $\mathbb{R}^n$, see 9.1 (1), 11.6, 11.8
  - Existence of partitions of unity, see 6.57
  - Existence of a locally finite atlas, see 6.60
  - Continuous maps are homotopic to smooth maps, see 18.7, 9.3
  - Smooth orientation-preserving embeddings of collection of balls are unique up to smooth isotopy, see 8.36
- For $n \geq 4$ every finitely presented group is the fundamental group of an $n$-dimensional smooth manifold, see 22.10 and page 2550
- Smooth manifolds admit simplicial structures, see 63.37 and 64.2
- The Hauptvermutung holds for smooth simplicial structures, see 64.4
- Compact smooth manifolds admit Morse functions, see Proposition 104.6
- Compact smooth manifold admit handle decompositions, see 104.11
- Handle decompositions give rise to CW-complex, see 103.18
- CW-structures on smooth manifolds, see 63.37, 64.3, 66.14, 66.16, 85.18, 104.12
- There exist only countably many diffeomorphism types of compact $n$-dimensional smooth manifolds, see 28.3
- The diffeomorphism problem is unsolvable in dimension $\geq 4$, see 28.4
- Continuous maps between smooth manifolds are homotopic to smooth maps, see 9.3
- Maps from manifolds to topological spaces can be smoothed on preimages of open balls, see 9.6
- Homology classes that can be represented by (embeddings) of smooth manifolds, see 70.4, 70.14, 70.17, 98.4, 98.6, ??, 70.18 and ??.
- Explicit construction of cyclic coverings of topological spaces, see 98.11
- Submanifolds can be made transverse, see 9.10
- The signature of closed smooth manifolds is multiplicative under finite coverings, see ??.
- Classification of 1-dimensional smooth manifolds, see 7.5 and 108.1
- Classification of compact 2-dimensional smooth manifolds, see 23.4
- Results on $\text{Diff}(S^n)$, see page ??.
- Closed smooth manifolds of Euler characteristic zero admit nowhere vanishing vector field, see 97.4
- Homology groups and fundamental group of compact topological manifold are finitely generated, see 64.6
Results and statements about submanifolds of smooth manifolds:
- Submanifolds admit unique tubular neighborhoods, see 8.24, 8.26, 10.5 and 10.7.
- Isotopies of submanifolds can be extended, see 8.27.
- The Lefshetz Fixed Point Theorem for smooth manifolds, see 63.10.

Results and statements about topological manifolds:
- Topological manifolds can be embedded in some $\mathbb{R}^n$, see 9.1 (2).
- Existence of partitions of unity, see 6.57.
- Topological manifolds are metrizable, see 9.2.
- Existence of a locally finite atlas, see 6.60.
- There exist only countably many homeomorphism types of compact $n$-dimensional topological manifolds, see 28.3.
- Every compact topological manifold is a retract of a finite simplicial complex, see 85.12.
- Every compact topological manifold is homotopy equivalent to a CW-complex, see 85.18, 85.24 and 85.25.
- CW-structures on topological manifolds, see 85.27, 85.28 and 85.30.
- Homology groups and fundamental group of compact topological manifold are finitely generated, see 85.13.
- The homeomorphism problem is unsolvable in dimension $\geq 4$, see 28.4.
- The Lefshetz Fixed Point Theorem for topological manifolds, see 85.11.
- Result on homology groups and homotopy groups of topological manifolds, see 85.13, 85.17, 87.3 and 66.6.
- Classification of 1-dimensional topological manifolds, see 7.1 and 7.12.
- Classification of compact 2-dimensional topological manifolds, see 23.4.
- The self-homeomorphism group of a topological manifold is locally contractible, see ??.

Results and statements about simplicial complexes:
- Simplicial complexes are Hausdorff, 61.5.
- Maps are homotopic to simplicial maps, see 62.8.
- Simplicial structures give rise to CW-structures, see 61.24.
- Simplicial (co-)homology is naturally isomorphic to singular (co-)homology, see 63.22, 63.25, 63.27, 63.30, 67.6, 67.11 and 67.17.
- Simplicial complexes are PL-homeomorphic if and only if they are stellar equivalent, see 64.21.
- The Lefshetz Fixed Point Theorem for simplicial complexes, see 65.9.

Results and statements about topological graphs and CW-complexes:
- CW-complexes are Hausdorff, normal, locally contractible and locally path-connected, see 36.10.
- Every point on a CW-complex is good, see 36.10.
- CW-complexes have the homotopy extension property, see 38.1.
- Maps are homotopic to cellular maps, see 38.13.
- Products of CW-complexes, see 36.23, Theorem 37.9, 37.11, 36.25.
− Every finite CW-complex can be embedded in some $\mathbb{R}^n$, see 85.9.
− Fundamental groups of CW-complexes, see 20.5
− Homotopy groups of countable CW-complexes are countable, see 85.19
− Every CW-complex is homotopy equivalent to a simplicial complex, see 62.12
− Singular and cellular (co-) homology are naturally isomorphic, see 48.4, 49.10 and 74.4
− The singular and cellular chain complexes are chain homotopy equivalent, see 49.10
− A topological space that is dominated by a CW-complex is homotopy equivalent to a CW-complex, see 119.12.
− The higher homotopy groups of any countable 0-connected CW-complex are countable, see 85.19
− Every $k$-connected CW-complex is homotopy equivalent to a CW-complex with a single 0-cell and no cells in dimension $1, \ldots, k$, see 39.11 and 119.15
− Taking the quotient by a contractible subcomplex is a homotopy equivalence, see 37.8 and 39.10
− The Lefschetz Fixed Point Theorem for CW-complexes, see 85.11.
− Every finite CW-complex admits a thickening, i.e. it is homotopy equivalent to a compact smooth manifold, see 107.7.

Results and statements about knots and links:
− Calculation of the fundamental group of the complement of the trefoil, see 27.5
− Every knot, after a rotation, admits a projection that is a knot diagram, see 27.19
− Two knot diagrams for a given knot are related by Reidemeister moves, 27.21
− Characterization of the meridian of a knot, see 8.50
− Definition of the connected sum of two oriented knots, see 1
− Knots of genus zero are trivial, see 8.47
− Calculation of the fundamental group of any knot complement, see 27.23
− Abelianization of the fundamental group of a knot complement, see 27.25
− Homology groups of a knot complement, see 68.16
− Knots admit Seifert surfaces, see 99.6
− Knots of genus zero are trivial, see 8.47
− Linking numbers are symmetric, see 99.11
− Linking numbers can be calculated from Seifert surfaces, see 99.12
− Linking numbers can be calculated from link diagrams, see 99.13
− 4-dimensional interpretation of linking numbers, see 99.14
− Any two knots in $\mathbb{R}^3$ become smoothly isotopic in $\mathbb{R}^4$, see 11.11
− The trefoil is chiral, see 99.5 and ??
− Existence of a knot that is neither amphichiral, nor reversible nor invertible, see 99.4
− Existence of non-trivial high-dimensional knots, see 27.38

Results and statements about groups:
− Classification of finitely generated abelian groups, see 19.4
− Retract of a finitely presented group is again finitely presented, see 21.16
– Maps in amalgamated products and HNN-extensions are monomorphisms, see 21.24 and 26.2.
– The word problem, the conjugacy problem and the isomorphism problem are unsolvable for finitely presented groups, see 28.2.
– Subgroups of free groups are free groups, see 31.4 and 37.10.
– The Ping-Pong Lemma, see 19.12.
– Any two finite presentations are related by Tietze transformations, see 21.7.
– Surface groups are linear and residually finite, see 34.10.
– Surface groups are not free, see 31.17.
– Finite-index subgroups of finitely presented groups are finitely presented, see 37.15.

Results and statements about (co-) homology groups:
– Isomorphisms between homology groups are induced by chain maps, see 49.1.
– Maps that induce isomorphisms on homology are chain homotopy equivalences, see 49.2 and 49.3.
– Singular and cellular (co-) homology are naturally isomorphic, see 48.4, 49.10 and 74.4.
– Singular and cellular chain complexes are chain homotopy equivalent, see 49.10 and 67.1.
– Singular and simplicial (co-) homology are naturally isomorphic, see 63.22, 63.25, 63.27 and 67.6.
– Singular and simplicial chain complexes are chain homotopy equivalent, see 63.25.
– Singular and handle homology are isomorphic, see 106.3.
– Relationship between relative homology and homology of quotient space, see 43.22 and 46.17.
– Explicit representatives of homology classes, see 45.2, 45.3 and page 1561.
– Linking pairing is (anti-) symmetric, see ??.

CW-structure on \( \mathbb{R}P^k \), \[ 935, 2514 \]
cap product on \( \mathbb{R}P^2 \), \[ 2024 \]
cap product on the torus, \[ 2023 \]
cap product of \( (S^1)^n \), \[ 2057 \]
cap product of \( \mathbb{C}P^n \), \[ 2198 \]
cap product of \( \mathbb{C}P^\infty \), \[ 2200 \]
cap product of \( \mathbb{C}P^n \), \[ 2290 \]
cap product of \( \mathbb{H}P^n \), \[ 2205 \]
cap product of \( \mathbb{O}P^2 \), \[ 2205 \]
cap product of \( \mathbb{R}P^2 \), \[ 1998 \]
cap product of \( \mathbb{R}P^\infty \), \[ 2202, 2326 \]
cap product of \( \mathbb{R}P^n \), \[ 2202 \]
cap product of \( S^m \times S^n \), \[ 2036 \]
cap product of \( X \times Y \), \[ 2056 \]
cap product of a suspension, \[ 2009 \]
cap product of a wedge \( X \vee Y \), \[ 2010 \]
cap product of non-orientable surfaces, \[ 2001 \]
cap product of the surface of genus \( g \), \[ 1995 \]
cap product of the torus, \[ 1698, 1993 \]
cap product of wedge of spheres, \[ 1991 \]
intersection form of \( M \# N \), \[ 2423 \]
intersection form of \( K3 \)-surface, \[ 2461 \]
intersection form of surface of genus \( g \), \[ 2413 \]
local homology groups of a simplicial complex, \[ 1647 \]
local homology groups of a topological manifold, \[ 1151 \]
